Investigation of thermochromism in a series of side-chain, liquid-crystalline, azobenzene-containing polymers

Stephan Freiberg, François Lagugné-Labarthet, Paul Rochon, and Almeria Natansohn

Abstract: The thermochromic properties of a series of liquid crystalline polymethacrylates, containing azobenzene side-chains with variable spacer lengths, were investigated. Annealing the amorphous polymer thin films above the glass transition temperature results in a rearrangement of the azobenzene moieties, causing a hypsochromic shift in the electronic absorption spectra. A detailed investigation of the spectral shift was performed by in situ UV–vis spectroscopy and indicated the formation of H-type aggregates by the side-chain chromophores above the glass transition temperature. The rate at which the hypsochromic shift occurs is faster for polymers with shorter spacers since their high glass transition temperature results in a higher thermal energy during the thermochromic effect. Experimentally determined activation energies show that the aggregation occurs primarily due to side-chain relaxation (β-relaxation) and main-chain relaxation (α-relaxation). Further annealing above the isotropization temperature resulted in the onset of deaggregation and in most cases showed that the chromophores were freed from the ordered state.

Key words: liquid-crystalline polymer, thermochromic properties, chain relaxation, aggregation, thin films, azobenzene mesogens.

Résumé : Les propriétés thermochromes d'une série de films minces de polymères liquide-cristallins contenant des mésogènes azobenzène sont présentées. Des mesures in situ en spectroscopie UV–vis mettent en évidence la formation d'agrégats de type H lorsque de tels films minces sont chauffés proche de leur température de transition vitreuse. L'analyse des spectres UV–vis permet d'identifier les différentes étapes mises en jeu pendant la formation des agrégats. L'étude dynamique de la formation d'agrégats montre que la relaxation des groupes mésogènes (relaxation de type β) prédomine indépendamment de la longueur des espaceurs tandis que la relaxation de la chaine principale (relaxation de type α) joue un rôle moindre tout en étant dépendant de la taille des espaceurs.

Mots clés : polymères liquide-cristallins, propriétés thermochromes, relaxation de chaîne, agrégation, films minces, mésogènes azobenzènes.

Introduction

In the past decade, the optical properties of azobenzene-containing, side-chain liquid crystal polymers (SCLCPs) have drawn considerable attention from both fundamental and applied aspects. Similar to amorphous azopolymers, the optical properties of azo-containing SCLCPs, such as birefringence and dichroism, can be modulated through *trans-cis-trans* photoisomerization. Molecular photoinduced orientation — created by an angular redistribution of the azobenzene moieties in a direction perpendicular to the polarization direction of the actinic light — is stable, can be triggered rapidly, and can be completely erased. This property is of great interest for photonic applications, making these materials appropriate for all-optical data storage purposes, optical switching, and other photonic devices (1–6).

In a previous work (7), we have shown that a high degree of remnant molecular orientation could be achieved in SCLCPs but that the stability of the photoinduced orientation was strongly influenced by the formation of aggregation. The formation of aggregates in the azobenzene SCLCP thin films is dictated by various parameters such as the molecular weight of the polymer, the length of the spacer that decouples the chromophore from the main chain, and, subsequently, its glass transition temperature (T_g). The formation of aggregates under annealing conditions induces large wavelength shifts that vary from $\Delta\lambda$ = 10 to 60 nm, depending on the spacer length, and that can be accompanied by the

Chart 1.

formation of a smectic mesophase (7, 8). The shift in absorption wavelength is caused by the interaction of chromophores as they self-organize in an anti-parallel fashion during the formation of smectic domains.

The backbone flexibility and the side-chain relaxation are the two dominant factors responsible for the formation and stability of organized domains. Their effect has been extensively investigated on Langmuir–Blodgett films of polyglutamates containing azobenzene moieties, using UV–vis polarized spectroscopy and X-ray reflectivity (9). The results obtained by Menzel et al. (9) have led to a deeper insight into the various possible types of aggregation at different photoisomerization and annealing steps.

There are, however, no in-depth reports of temperature-dependent aggregation studies for a series of SCLCP films with variable spacer lengths. In the present study we have systematically investigated the thermochromic properties of a series of azobenzene SCLCPs; we emphasize the role of main-chain and side-chain relaxation on the nature of the aggregate formation. This concludes our work on a series of manuscripts on SCLCPs as examined by the Natansohn group (7, 8, 10).

Experimental

The synthesis and the spectroscopic and optical characterization of this series of polymers (pXMAN) are described elsewhere (8). Their general structure is shown in Chart 1, where X is the number of methylene units and varies from 2 to 12. The physical data of pDR1M and the pXMAN series are summarized in Table 1.

Table 1. Physical data of the pXMAN series and pDR1M.

Material	T_g (°C)	Mn	Amorphous state λ_{max} (nm)
PDR1M	129	2000 – 10 000	466
P2MAN	110	5000	455
P3MAN	80	4400	436
P4MAN	85	4400	431
P5MAN	68	3500	428
P6MAN	70	4000	455
P7MAN	57	8600	431
P8MAN	45	4600	428
P9MAN	31	3500	412
P10MAN	25	3200	410
P11MAN	30	4000	411
P12MAN	25	4800	410

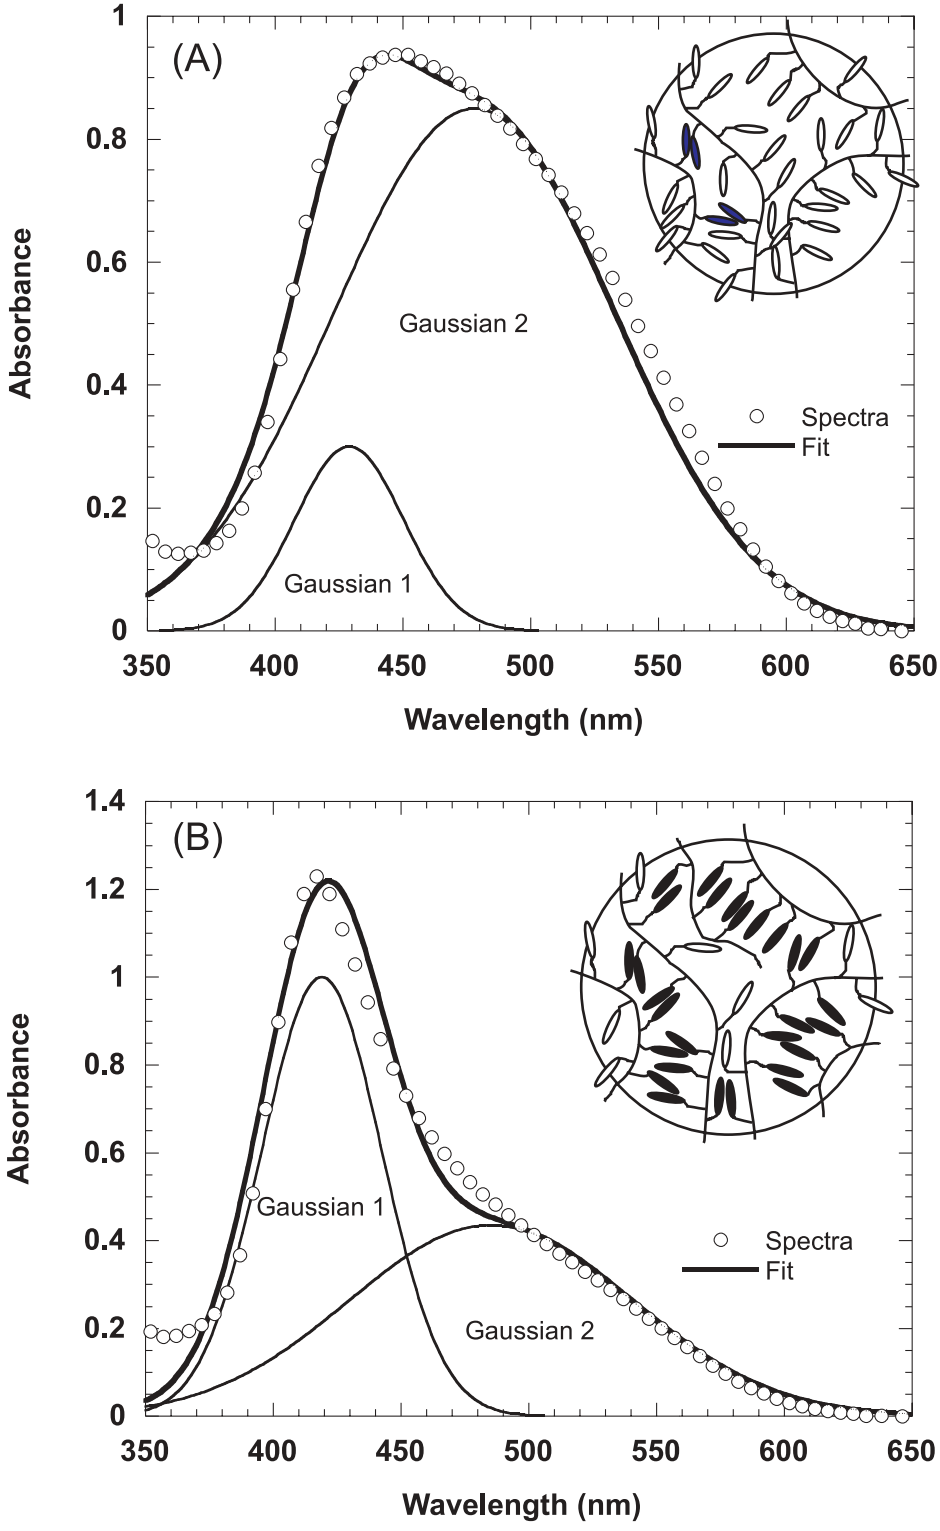
All of the films were spin-cast, from solutions containing 15–20 mg of polymer per 1 mL of dichloromethane, onto clean glass substrates at about 1500 rpm, to obtain an absorbance in the visible range of about 1 and a thickness between 200 and 400 nm. Heat treatment was performed using an Instec HS 400 thermal hot stage, and the data were collected on a Beckman DU 7400 series photo-diode array spectrophotometer.

Fitting the UV spectra

The UV spectra can be described using two Gaussian functions, as shown in Fig. 1. The Gaussian function G1 is assigned to H-aggregated azobenzene while the Gaussian function G2 is assigned to free, unaggregated azobenzene, as reported previously (7). Whatever the considered state — unaggregated mesogens of the amorphous state (Fig. 1A) or H-aggregated mesogens (Fig. 1B) — the fitted curves are very close to the experimental spectra. The parameters of G1 (height, width, and λ_{max}) were allowed to vary freely throughout the entire fitting process. The wavelength of maximum absorption (λ_{max}) and the full width at half maximum (width) of G2 were determined from the UV spectra of isotropic samples and were held constant throughout the fitting for all spectra, but the height was allowed to vary.

The areas of G1 and G2 were plotted against time for isothermal experiments (variation of absorbance at a fixed temperature) and could be fitted using a bi-exponential function. For the hypsochromic shift induced by annealing the thin film, the time-dependent variation of G1 is fit to a bi-exponential rise

$$[1] \qquad Y = Y_0 + A(1 - e^{-k_a t}) + B(1 - e^{-k_b t})$$



The variation of G2 is fit to a bi-exponential decay process as described by

$$[2] \qquad Y = Y_0 + Ae^{-k_a t} + Be^{-k_b t}$$

The amplitude A and the rate constant k_a are defined as the fast contribution to the process while the amplitude B and the rate constant k_b are defined as the slow contribution of the process.

Fig. 1. Illustrative example for the fitting procedure. Gaussian 1 (G1) is the fitting function related to the H-aggregated azobenzene moieties. Gaussian 2 (G2) is the fitting function related to the free unaggregated azobenzene contribution. After spin-coating (A), the spectrum shows a dominant contribution of the free azobenzene moieties. After annealing at 120 °C for 20 min (B), a clear hypsochromic shift is observed, and the contribution of the aggregated chromophores is dominant. The agreement between the experimental spectrum (○) and the resulting fitting curve G1 + G2 (full line) is quite good.

Results and discussion

The thermochromic effects are mainly observed through the intense absorption band in the visible range, which is assigned to a vibronic coupling between n–π^* and π–π^* electronic transitions; this spectral absorption is due to the strong charge transfer between the electron-donor group (amino) and the electron-withdrawing (nitro) acceptor group. As previously reported, the thermochromism exhibited by the polymers of the pXMAN series varies with the spacer length (8).

(*i*) For the polymer with the shortest spacer, p2MAN, no thermochromic effect is observed. The polymer is amorphous and has properties similar to homopolymers or copolymers with similar structures, such as pDR1M, which differs only by an N-ethyl group in the place of the N-methyl group (Chart 1). The presence of a short spacer does not provide the mesogen with enough mobility to allow rearrangement of the chromophores.

(*ii*) The thin films of the polymers with the shorter spacers, p3MAN to p8MAN, undergo a hypsochromic shift after heating to the glass transition temperature. Annealing these films at temperatures within the isotropization range results in the destruction of the ordered phase and a bathochromic shift.

(*iii*) For the polymers with longer spacers, p9MAN to p12MAN, the hypsochromic shift occurs readily at room temperature, owing to their low T_g (25–31 °C). A recovery of the isotropic state can be observed when annealing in the isotropization range.

To investigate the thermochromic properties, two sets of experiments were conducted. First, variable temperature (ramping) experiments were performed by recording UV–vis spectra between room temperature and the isotropization or decomposition temperature at a ramp rate of 2 degrees per minute (dpm) and by collecting spectra every minute. Each spectrum was deconvolved into two Gaussian curves, allowing the aggregation process to be followed as a function of the annealing temperature. In a second set of experiments, the spectra were collected during isothermal runs where UV spectra were recorded at a given annealing temperature as a function of time. Isothermal experiments were performed primarily on p3MAN–p8MAN, to examine the first color change (hypsochromic shift). The second color change (bathochromic shift) was examined by experimenting with the thin films of selected polymers; namely, p4MAN, p5MAN, p8MAN, p9MAN, p11MAN, and p12MAN.

Ramping experiments

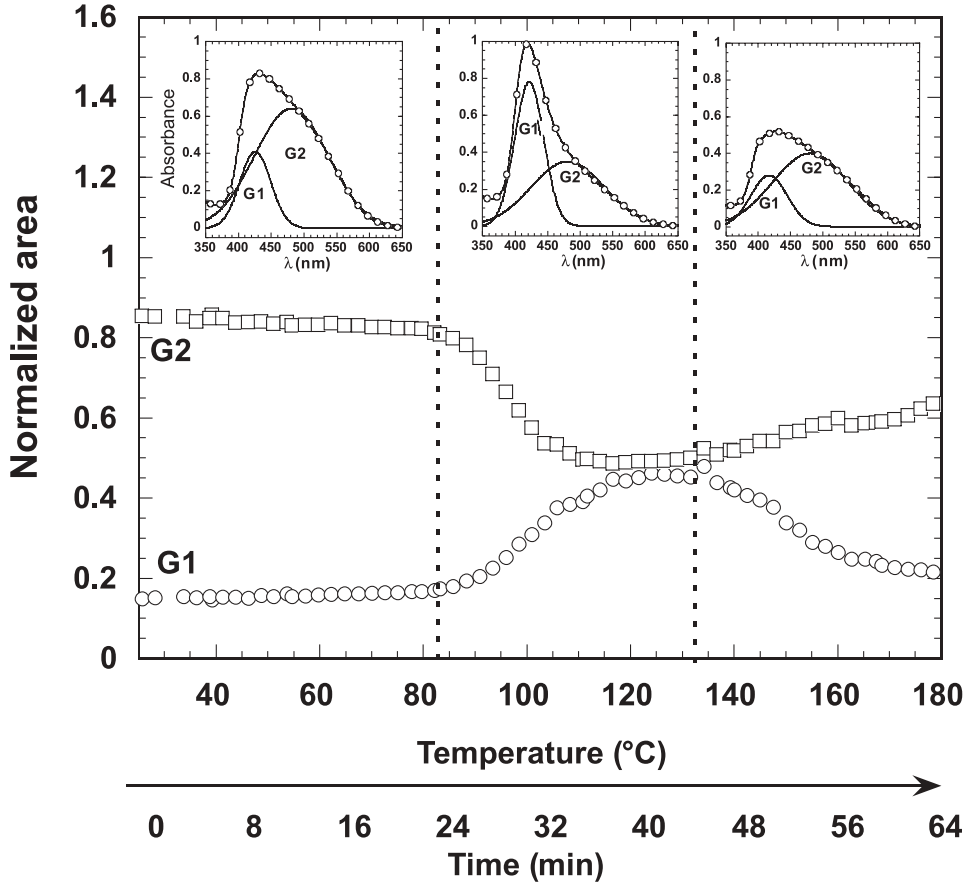
As an illustrative example, Fig. 2 shows the results of a ramping experiment performed on p4MAN (T_g = 74 °C), and it is representative of all pXMAN ramping experiments with X = 3–8. It can be seen that a first color change (blue shift) starts to occur at about the glass transition temperature (about 80 °C), where the area of G1 increases and, conversely, the area of G2 decreases. At a temperature of 116 °C, G1 reaches a maximum and G2 reaches a minimum. At about 130 °C, G1 starts to decrease and G2 starts to increase, suggesting the onset of the second color change (red shift). At this point, the amount of free azobenzenes starts to increase while the amount of aggregates starts to decrease, owing to the onset of isotropization.

The increase in G1 at a temperature close to T_g is assigned to the formation of H-aggregates, in agreement with the classification made by Kunitake and co-workers (11). The fact that the electronic transition undergoes a blue shift and becomes narrower suggests that the chromophore moities are interdigitated with their dipolar moments opposite to the adjacent chromophores. Such organization produces a weaker charge transfer between the donor amino group and the withdrawing nitro group. Subsequently, if the charge transfer decreases, the electronic transition has a π–π character rather than an n–π^* character, and a blue shift is observed. The second color change (red shift) occurs during the isotropization range where aggregation is destroyed during melting.

The results of ramping experiments for polymers p9MAN to p12MAN exhibit a different trend, since their glass transition temperature is lower. Shown in Fig. 3, the ramping experiment for p11MAN (T_g = 40 °C) exhibits additional features. Immediately, after spin coating, the absorption spectrum shows two contributions related to free and H-aggregated azobenzene moieties. The contribution of aggregated azobenzene increases when annealing, until 80 °C. Above this temperature, the aggregates are disappearing and the absorption band can be fitted with a single Gaussian function, as seen in the inset of Fig. 3. Its normalized absorbance reaches 1.2, indicating that the absorption coefficient depends strongly on the environment around the chromophores, in particular the inhomogeneous intermolecular chromophore interactions.

Isothermal experiments

The dynamic measurements performed at fixed temperatures allow us to obtain greater insight into the dynamic rates involved in the formation of aggregates. For a given annealing temperature, the changes in absorption of the electronic transition can be correlated to the activation energy of both the backbone chain and the side-chain chromophores. Both hypsochromic and bathochromic shifts are discussed for the pXMAN series.



Hypsochromic shift

The plots shown in Figs. 4A and 4B for p7MAN are representative of the evolution of G1 and G2, respectively, during a typical isothermal experiment. Both curve sequences show that the rate at which the thermochromism occurs increases significantly with temperature.

Fitting the curves to a bi-exponential process results in two amplitude constants, A and B, and two rate constants, k_a and k_b. The fast amplitude constant, A, tends to increase with temperature while the slow contribution, B, decreases. The rate constants k_a and k_b represent the fast and slow processes, respectively, and also increase with temperature. In general, it is also observed that the rates at which thermochromism occurs (at $T - T_g$) are larger for polymers with shorter spacers. This is illustrated in Fig. 5, which shows that p3MAN and p4MAN have higher k_a and k_b values (at $T - T_g$) than p7MAN; this trend is observed for p3MAN to p8MAN. It is also noteworthy that thermochromism occurs

Fig. 2. Temperature-dependent variation of the area of fitting functions G1 and G2 for p4MAN. Two transitions can be clearly observed with an initial hypsochromic shift followed by a bathochromic shift at higher temperature, as shown in the inset. At a temperature of 135 °C, the bathochromic shift is accompanied by the formation of a smectic mesophase. This variation is typical for the series from p3MAN to p8MAN.

at T_g for p3MAN and p4MAN but occurs at T_g + 20 °C for the polymers p5MAN to p8MAN. Intuitively, these results are unexpected, since polymers containing longer spacers (lower T_gs) should have more freedom of motion to undergo aggregation. The results show that the aggregation process occurs more readily at T_g for p3MAN and p4MAN than for the polymers with longer spacers. A rigorous explanation of these results will be discussed in the "activation energies" section.

For the longer side-chains polymers, p9MAN–p12MAN, the dynamics of the first color change is less readily observable since it appears to be, in part, complete after spin-casting. Likely, the low T_g associated with these materials support immediate aggregation during the spin-casting procedure.

Activation energies

Activation energies (E_as) were estimated for the fast and slow processes, using the k_a and k_b constants obtained from the isothermal experiments. The validity of the Arrhenius law has been widely demonstrated for the study of liquid-crystalline polymers. The activation energy related to the fast and slow contributions obtained at different temperatures was determined using the Arrhenius equation

$$[3] \qquad \ln(k_i) = A - \frac{E_a}{R}\frac{1}{T}$$

where k_i is the considered rate constant (s^{-1}), A is a constant, R is the molar gas constant (R = 8.31 $J \cdot mol^{-1} \cdot K^{-1}$), and T is the temperature in Kelvin. From eq. [3], the activation energy is proportional to the slope of the natural logarithm of k_i (s^{-1}) vs. reciprocal temperature (Kelvin). The activation energies for the fast and slow processes are deduced from the slopes of the $k_i = f(T - T_g)$ plots (Fig. 5) and are reported in Table 2.

In general, the activation energy required to induce polymer backbone motion (α-relaxation) is typically in the range of 70–150 $kJ \cdot mol^{-1}$, depending on the spacer length, and occurs at the glass transition temperature (12–15). Activation energies for the mesogen relaxation (β-relaxation) are, rather, in the range of 50–100 $kJ \cdot mol^{-1}$ and are observable at temperatures lower than T_g (T_g – 20 °C). (12, 13, 15–19). In addition the β-relaxation is generally independent of the spacer length (20, 21). As reported in Table 2, the activation energy values associated with the slow rate, k_b, tend to decrease with spacer length. Polymers with short spacers have a larger E_a value (80–100 $kJ \cdot mol^{-1}$) while the LCPs with longer spacers have smaller activation energies (30–

Fig. 3. Temperature-dependent variation of the area of fitting functions G1 and G2 for p11MAN. Two transitions can be clearly observed with an initial hypsochromic shift following by a bathochromic shift at higher temperature, as shown in the inset.

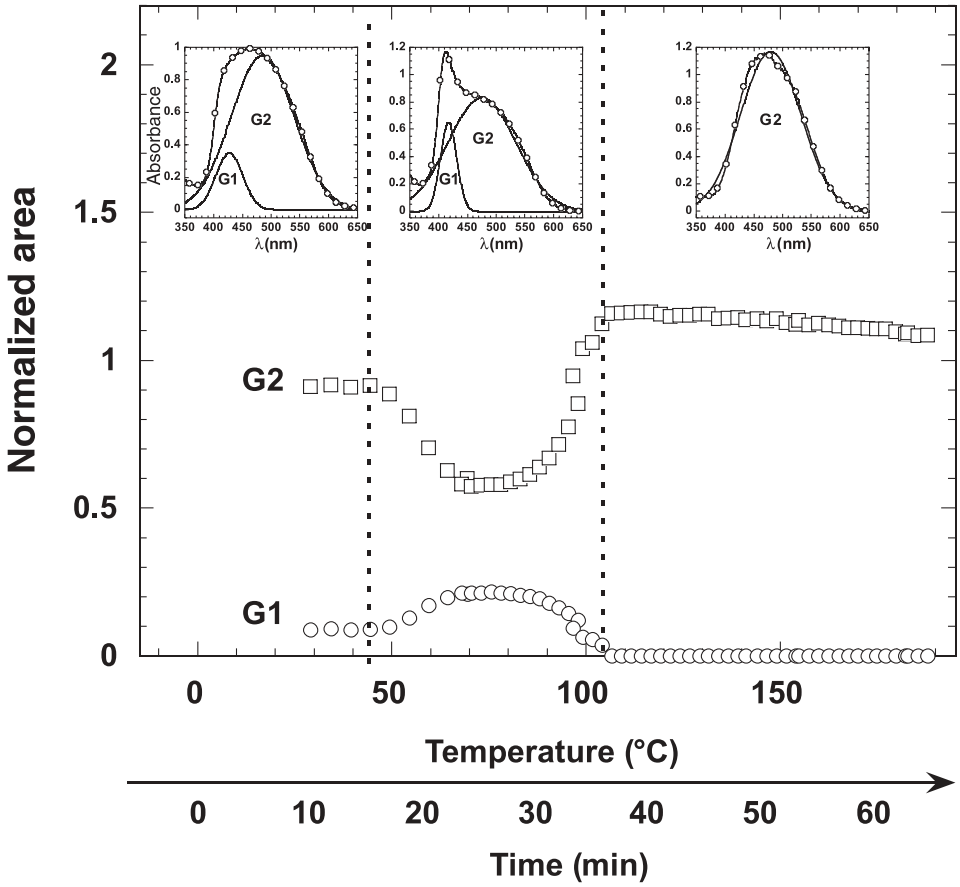

Table 2. Activation energies (E_a) extracted from ramping experiments during the hypsochromic shift for the polymers from p3MAN to p8MAN.

		Aggregated chromophores G1		Non-aggregated chromophores G2	
	T_g (°C)	E_a (kJ·mol^{-1}) (from k_a)	E_a (kJ·mol^{-1}) (from k_b)	E_a (kJ·mol^{-1}) (from k_a)	E_a (kJ·mol^{-1}) (from k_b)
P3MAN	80	62	116	51	108
P4MAN	85	66	82	73	87
P5MAN	68	50	69	41	92
P6MAN	70	66	26	62	50
P7MAN	57	66	66	75	75
P8MAN	45	50	55	33	60

50 kJ·mol^{-1}). The activation energies associated with the fast rate constants appear to remain stable within experimental uncertainty (30–70 kJ·mol^{-1}) and are independent of the spacer length. By analogy with previous studies (12, 13, 15–19), the values of the activation energies determined experimentally suggest that the fast process is, presumably, associated with mesogen relaxation, and the slow process is due to main-chain relaxation.

Earlier, when discussing Fig. 5, we mentioned that polymers with longer spacers tend to undergo the first color change at temperatures of about T_g + 20 °C, while p3MAN and p4MAN undergo the first color change at about T_g. In addition, the rate constants k_a and k_b, associated with the thermochromic process, are greater at $T - T_g$ for the polymers with shorter spacers, as shown in Fig. 5. These results are unexpected since polymers with longer spacers are expected to be more mobile than the polymers with shorter spacers. However, when annealed at about their respective glass transition temperature, the polymers with shorter chains (p3MAN, p4MAN) are supplied with more energy than their counterparts with longer chains. Since the mesogen relaxation activation energy is independent of the spacer length, it is the same for all polymers. However, the glass transition temperature increases with decreasing spacer

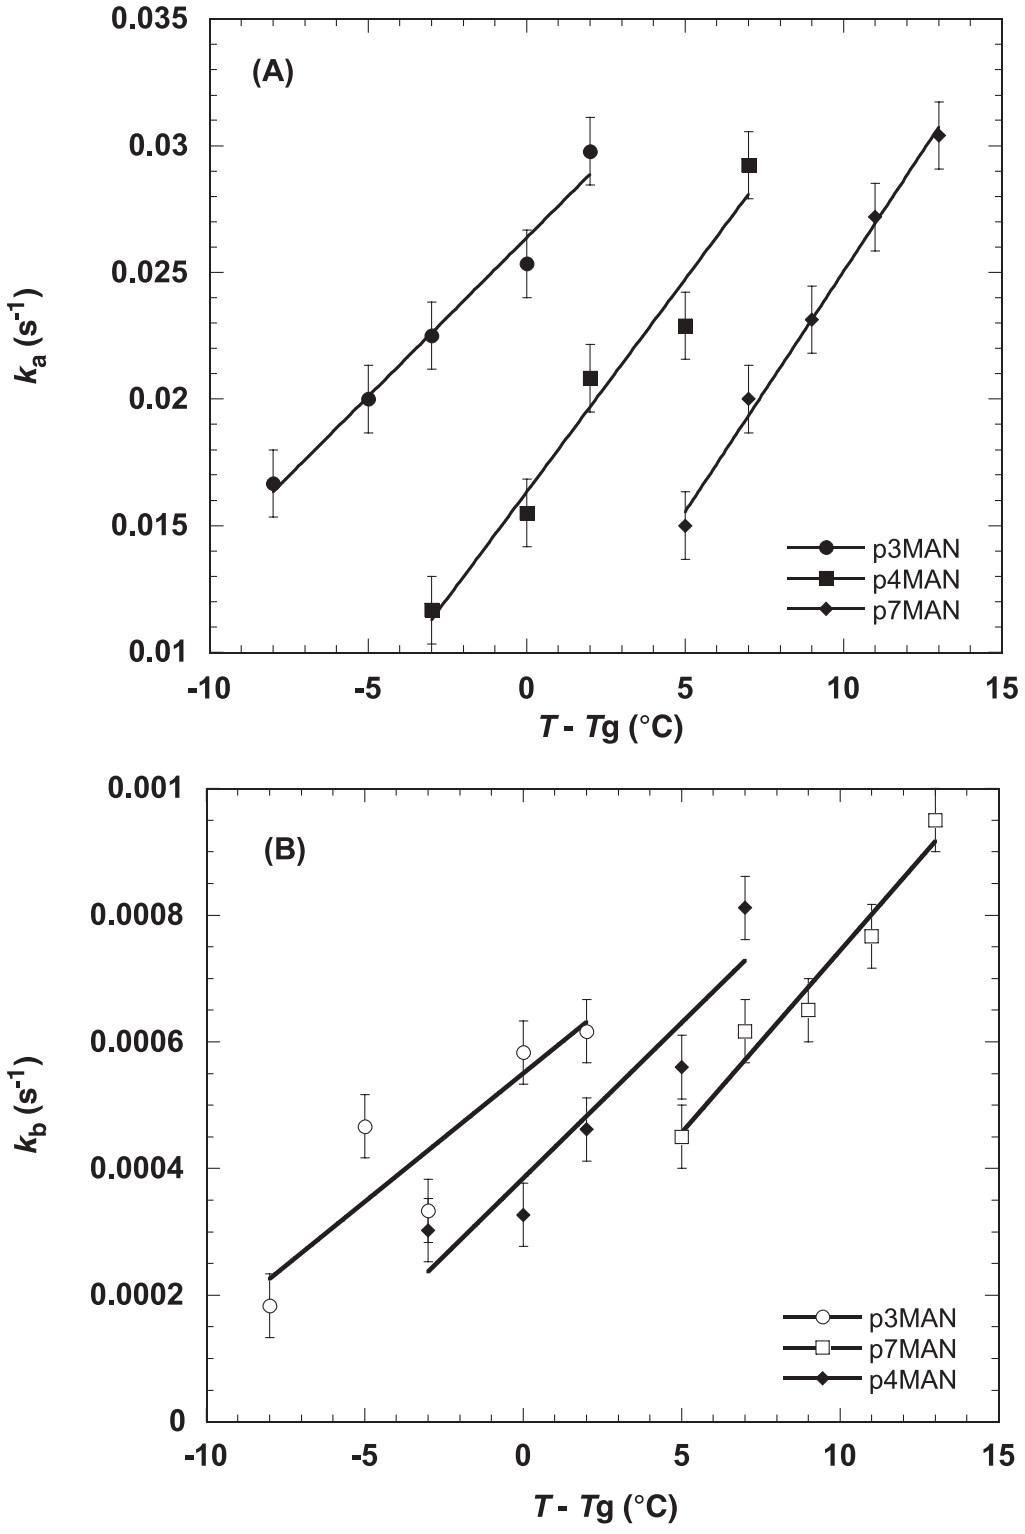
Fig. 4. Isothermal experiments performed during the hypsochromic shift for p7MAN. The measurements were done at different annealing temperatures and were fitted with a bi-exponential function for both G1 (A) and G2 (B).



length, and excess of thermal energy is supplied at T_g for polymers with the shortest spacers. The excess thermal energy supplied for the same process in different polymers implies that the color change will occur more readily for polymers with shorter spacers, as observed in Fig. 5.

Bathochromic shift

The evolution of G1 for p4MAN, p5MAN, and p8MAN experiments shows a decrease in curve area at temperatures inside the isotropization range with a concurrent increase in the area of G2 (shown for p4MAN in Figs. 6A and 6B). Al-

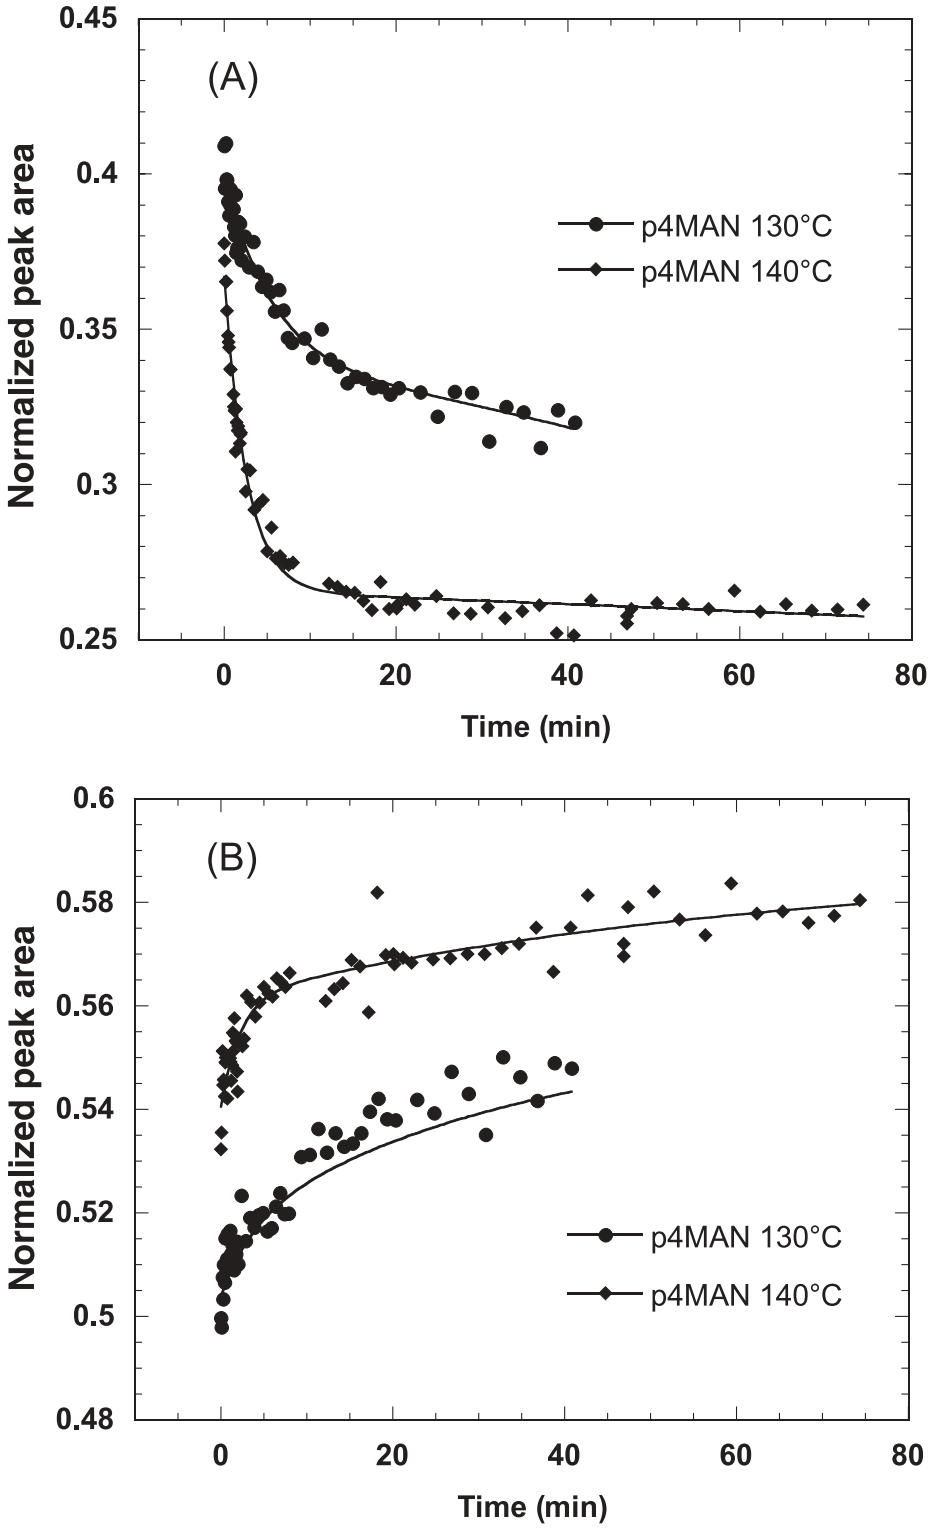

Fig. 5. (A) Fast constant rates, k_a, for p3MAN, p4MAN, and p7MAN vs. $T - T_g$ for G1; the rates are larger near T_g for the polymers with shorter spacers; (B) Slow constant rates, k_b, for p3MAN, p4MAN, and p7MAN vs. $T - T_g$ for G1; the rates are larger near T_g for the polymers with shorter spacers.

though quantitative information is not gathered from these experiments, qualitative observation shows that the aggregates generally undergo destruction at temperatures inside the isotropization range. Similarly, the second color change for p9MAN–p12MAN inside the isotropization range results in a disappearance of the aggregation peak (G1), while the

Fig. 6. Isothermal experiments performed during the bathochromic shift for p4MAN. The decrease of G1 (A) and concomitant increase of G2 (B) were measured at 130 and 140 °C, but the erratic behavior does not allow a quantitative analysis of the activation energies.

peak relative to free chromophores becomes almost symmetric, as shown in Fig. 3 for temperature above 100 °C. Therefore, the bathochromic shift observed above the isotropization temperature confirms destruction of the smectic phase. However, isotropization is not complete in the cases of the polymers with the shortest spacers (p3MAN and p4MAN) since they are prone to decomposition before they reach an isotropization temperature.

© 2003 NRC Canada

Conclusion

The thermochromic properties of a series of azobenzene-containing, liquid-crystalline polymers were investigated. A hypsochromic shift in the absorption spectra at the glass transition temperature is attributed to H-aggregation of the chromophores during smectic phase formation. A bathochromic shift during isotropization is attributed to deaggregation of the chromophores during melting.

Isothermal experiments were of particular interest in estimating the contribution of backbone relaxation and side-chain relaxation. The activation energies for the fast process were found to be similar for all of the polymers in the series and were assigned to the mesogen relaxation. On the other hand, E_as associated with the slow process decreased with increasing spacer length, which is characteristic of the main-chain relaxation.

The results of experiments within the isotropization range confirmed that the bathochromic shift is due to deaggregation of the side-chain chromophores.

Theoretical studies of model compounds of lathyrane-type diterpenes

Yukimasa Terada, Tomoo Matsuura, Yukari Mori, and Shosuke Yamamura

Abstract: The conformation of the 11-membered ring of the lathyrane skeleton has been investigated using NMR spectra and theoretical calculations. Some other skeletons, such as jatrophane, jatrapholane, and tigliane, seem to be derived from this framework, and the conformation is important in connection with the configuration of the resultant diterpenes. The conformation of lathyrane is principally defined by the orientation of the two methyl groups; namely, the methyl groups on C_1 and C_6 directed above or below the ring plane. Theoretical calculations revealed that the predominant conformation is altered depending on the oxygen functional groups on the ring. As far as the bond lengths, bond angles, and dihedral angles are concerned, all calculation methods afforded reasonable results. In contrast, as regards conformational stability, only the ab initio molecular orbital method (RHF/6-31G*) predicted the most stable conformation, consistent with NOE experiments. On the other hand, the stable conformations predicted by the ab initio method (RHF/STO-3G), the semi-empirical molecular orbital method (MOPAC(PM3)), and the molecular mechanics calculations (MM3) did not necessarily agree with the conformers suggested by the NOE experiments.

Key words: ab initio MO, semi-empirical MO, molecular mechanics, 11-membered ring conformation, NOE.

Résumé : On a étudié la conformation du cycle à onze chaînons du squelette lathyrane en faisant appel à la spectroscopie RMN et à des calculs théoriques. Il semble que d'autres squelettes, tels ceux du jatrophane, du jatrapholane et du tigliane, sont dérivés de celui-ci et sa conformation est importante en relation avec la configuration des diterpènes qui en résultent. La conformation du lathyrane est définie principalement par l'orientation des deux groupes méthyles, à savoir les groupes méthyles en C_1 et en C_6 orientés vers le dessus ou le dessous du plan du cycle. Les calculs théoriques révèlent que la conformation privilégiée varie avec la nature des groupes fonctionnels oxygénés présents sur le cycle. En ce qui concerne les longueurs des liaisons, des angles des liaisons et des angles dièdres, toutes les méthodes de calcul conduisent à des résultats raisonnables. Ce n'est toutefois pas le cas pour la stabilité conformationnelle; en effet, seule la méthode ab initio d'orbitales moléculaires (RHF/6-31G*) permet de prédire la conformation la plus stable, telle qu'observée par des expériences d'effet Overhauser nucléaire (eOn). Toutefois les conformations les plus stables prédites par la méthode ab initio (RHF/STO-3G), la méthode d'orbitales moléculaires semi-expérimentale (MOPAC(PM3)) et les calculs de mécanique moléculaire (MM3) ne correspondent pas nécessairement avec les conformères suggérés par les expériences d'eOn.

Mots clés : OM ab initio, OM semi-empirique, mécanique moléculaire, conformation d'un cycle à onze chaînons, eOn.

Introduction

A variety of diterpenes with a unique structure have been isolated from the plant species *Euphorbiacea* and *Thymeleacea*. A number of these compounds have remarkable bioactivities, such as skin-irritant, tumor-promotion, and proinflammatory properties. It is noteworthy that some macro- and polycyclic diterpenes have exhibited anti-tumor activities (1). Therefore, discovery of a synthetic route to these diterpenes will contribute to the development of a new class of medicines.

Diterpenes are divided into several groups by their molecular framework. One key intermediate of these skeletons is the lathyrane type (2). Some other skeletons, such as jatrophane, jatrapholane, and tigliane, seem to be derived from this framework, as shown in Scheme 1. For example, we reported transformation of the lathyrane skeleton to jatrapholane and daphnane types (3). Recently, we also reported the transannular cyclization of the lathyrane type to the jatrapholane type (4). Moreover, in the course of these cyclization reactions, we synthesized several lathyrane derivatives that have some oxygen functional groups, as shown in Fig. 1. We studied the conformation of these lathyrane derivatives based on the NMR spectra. NOE experiments suggested that the predominant conformation is affected by the type and location of the oxygen functional groups. The conformation of the 11-membered ring of lathyrane can be roughly classified into four groups by the orientation of the two methyl groups on the double bonds. However, the re-

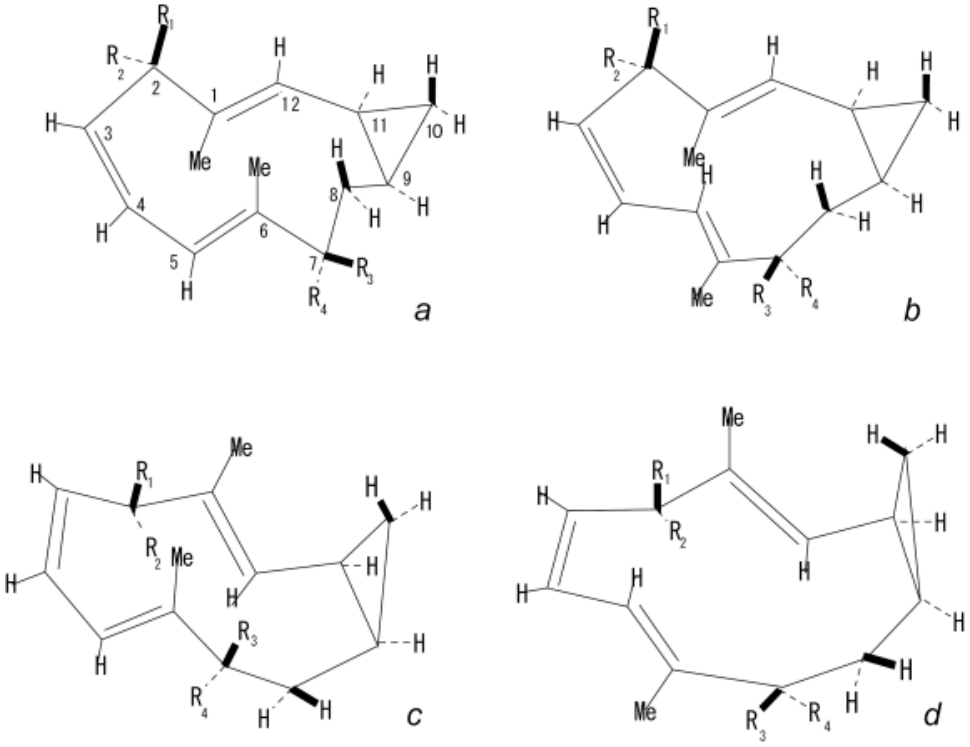
sults of NOE experiments could not specify one of the four conformational groups. Therefore, we started conformational analysis of the 11-membered ring by several theoretical methods, because the conformation is important in determining the configuration of the transannular reaction product (4, 5).

To simplify the calculation and to save time, a truncated lathyrane model was postulated, as shown in Fig. 2. Namely, the cyclopentene ring was simplified to a double bond and the dimethyl group on the cyclopropane ring was replaced by hydrogen atoms. The letter m represents these postulated model structures.

We sought the minimum energy conformer within each conformational group of 5 lathyrane model structures. The "stochastic search for conformers" option in the MM3(96) program was used to generate a number of conformers in a group. Subsequently, the obtained, unique conformers were optimized by MM3(96), MOPAC(PM3), or ab initio (RHF/STO-3G and RHF/6-31G*) MO programs. The conformational stability predicted by these theoretical methods were compared with the NOE results.



In addition, the transition state for conformational interchange was identified by the RHF/6-31G* optimization and subsequent one-point calculation at the B3LYP/6-31G* level of theory. The activation energy estimated for the model compound **m2** suggested free interchange between the **m2a** and **m2b** conformations.

Results

Structure optimization of the truncated lathyrane model was performed by the ab initio and semi-empirical molecular orbital (MO) methods, as well as the molecular mechanics (MM) method. The conformation of the 11-membered ring of the lathyrane skeleton can be classified into four groups by the orientation of the C_1 and C_6 methyl groups; that is: $\alpha - \beta$ (**a**), $\alpha - \alpha$ (**b**), $\beta - \beta$ (**c**), and $\beta - \alpha$ (**d**), respectively, as shown in Fig. 2. The relative conformational energies of **a**, **b**, **c**, and **d** of the model compounds (**m1**~**m5**) and the relative population calculated at 25 °C under the assumption of the Boltzmann distribution are shown in Table 1. The stable conformers of the model compounds optimized by RHF/6-31G* calculations are shown in Fig. 3. Except for the model compound **m4**, the conformers with the β-oriented C_1 methyl group were distinctly less stable than the conformers with the α-oriented C_1 methyl group. The observed NOE enhancements (%), together with the calculated nonbonding hydrogen—hydrogen interatomic distances, are shown in Table 2.

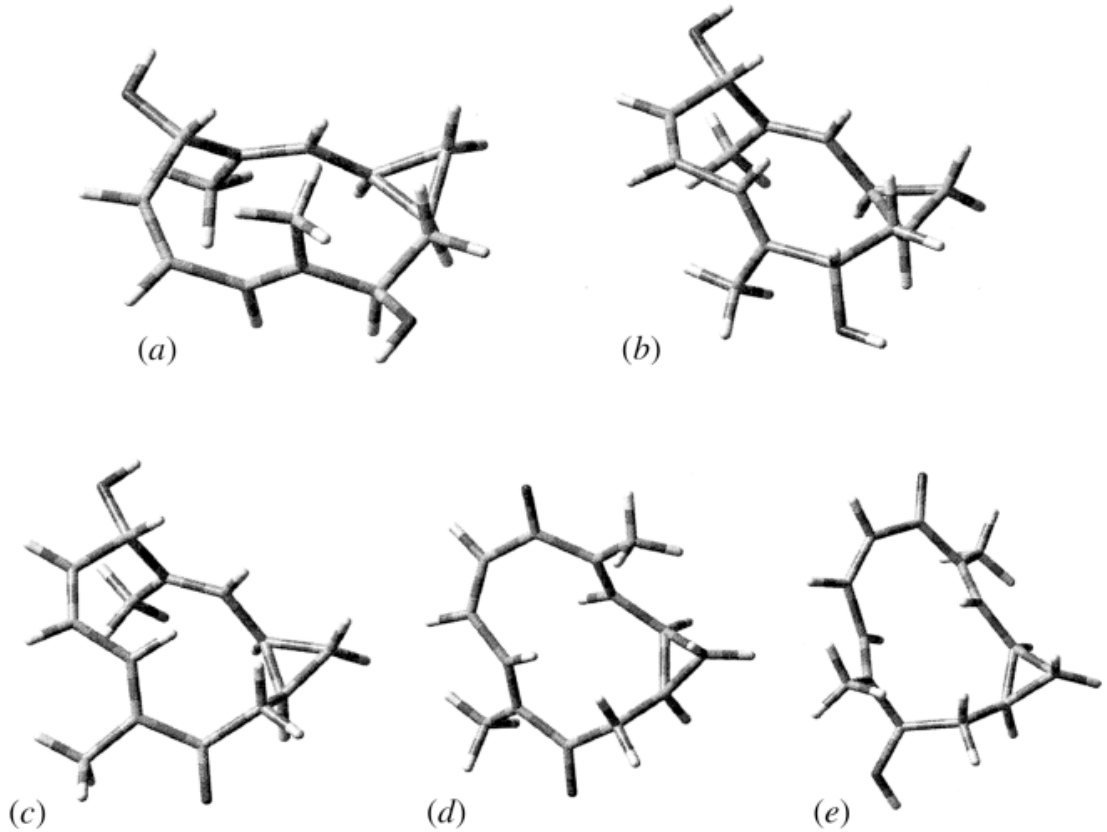
In Table 3, the resultant bond lengths, bond angles, and dihedral angles of the 11-membered ring of the model compound **m2a** are shown and compared with the result of the X-ray crystallographic analysis of 3,8,14,20-tetraacetyl-7-(2-methyl-butanoyl)-synadenol (6). The model compound **m2** was selected, since the configuration of the oxygen functional groups on C_2 and C_7 were comparable to that of the compound analyzed by X-ray analysis. For comparison of the predictability of the theoretical methods, standard errors were calculated by the following equation:

$$\mathrm{SE} = \sqrt{\frac{\sum_{i=1}^{n}(P_{x_i} - P_{c_i})^2}{n}}$$

where P_{x_i} and P_{c_i} indicate geometric parameters obtained by the X-ray analysis and the theoretical calculation; these are shown in Table 3.

We also investigated the transition state for conformational interconversion between **m2a** and **m2b**. The transition structure with a single imaginary frequency (65.6 *i* cm^{-1}) was identified at the RHF/6-31G* level. The stable conformers and the transition structure are shown in Fig. 4. The C_5=C_6 double bond seems to turn around with almost no effect on other parts of the 11-membered ring. The C_3-C_4-C_5-C_6 dihedral angle of **m2a**, **m2b**, and the transition state were 69.9°, –101.7°, and 147.7°, respectively. Furthermore, the activation free energies of the conformational interconversion, starting from **m2a** and **m2b**, were estimated at 31.02 kJ mol^{-1} and 37.18 kJ mol^{-1}, respectively.

Discussion



In solution, a molecule exists in an equilibrium mixture of various conformational isomers. The best way to find the global minimum conformation must be to optimize all such possible conformers. Actually, Saunders et al. (7) calculated the conformational energy of cycloheptadecane and discussed the method to find the global minimum conformation of a flexible molecule. Since the 11-membered ring of the lathyrane model compounds includes 3 double bonds and condenses with a cyclopropane ring, the conformational flexibility is considerably restricted. Therefore, paying attention to the C_7-C_8 torsion angle, the conformation of the 11-membered ring can be classified into four groups by the relative orientation of the two methyl groups on C_1 and C_6, as

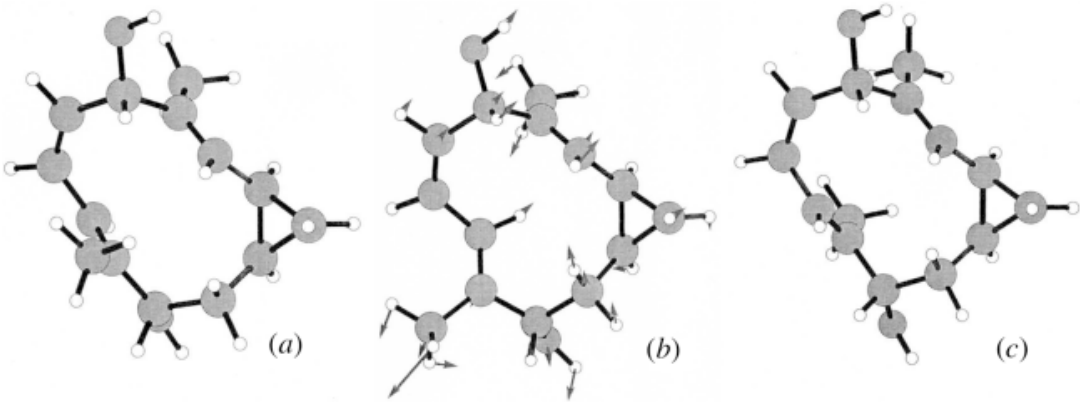
shown in Fig. 2. By inspection of the Dreiding model, we generated initial coordinates of each group and evolved 200 conformers using the "stochastic search for conformers" option of the MM3(96) program. Subsequently, unique conformers (having a dihedral angle differing by more than 15° from other conformers) were selected and optimized using the above-mentioned theoretical methods.



The accuracy of the calculation methods was confirmed by comparison with the experimental result. In Table 3, the calculation results of the model compound **m2a** and, as

a standard of comparison, the reported results of an X-ray crystallographic analysis of 3,8,14,20-tetraacetyl-7-(2-methylbutanoyl)-synadenol (6) are shown. Regardless of the difference in the molecular structure, all calculation methods afforded bond lengths, bond angles, and dihedral angles in good agreement with the X-ray results. In addition, all standard errors by different calculation methods were comparable. Therefore, as far as the geometrical accuracy is concerned, there is little difference in these theoretical methods.

Moreover, no distinct difference was detected between the geometrical parameters of the diterpene structure (**2**) in Fig. 1 and the truncated model structure (**m2**) in Fig. 2 (the data are not shown). Thus, the removal of the 5-membered ring or the cyclopropane dimethyl group did not seriously influence the conformation of the 11-membered ring. Since all atoms bonding to the C_3=C_4 double bond were fixed in a plane and the cyclopropane dimethyl group did not contact the 11-membered ring, they must have little steric influence on the 11-membered ring. Accordingly, the calculations on the truncated models caused no inconsistency in the 11-membered ring conformation.

The resultant relative values of the minimum energy of each group are listed in Table 1. Excluding the exceptional result of the model compound **m4**, conformers with the β-oriented C_1 methyl group were considerably less stable than the conformers with the α-oriented C_1 methyl group. Actually, the reported conformation of the lathyrane derivatives with a C_1=C_{12} double bond had the α-oriented C_1 Me group (3, 6, 8). To direct the C_1 methyl group upward, two single bonds (namely, C_1—C_2 and C_{11}—C_{12}) must be rotated. As a result of this rotation, the cyclopropane ring becomes almost perpendicular to the 11-membered ring; moreover, this rotation also affects the relative position of C_7 and C_8. Because of these conformational requirements, the conformations with the β-oriented C_1 methyl group must be more destabilized than the α-oriented C_1 methyl conformers. In fact, the effect of flipping the C_1 methyl group is much larger than that of the C_6 methyl group (see Table 1). Moreover, since the cyclopropane ring of the β-oriented C_1 methyl conformation is approximately perpendicular to the 11-membered ring, one of the cyclopropane methyl groups causes steric hindrance with the 11-membered ring. Therefore, conformations with the β-oriented C_1 methyl group must be further destabilized in the lathyrane skeleton when compared with the truncated model compounds. On the assumption of a Boltzmann distribution, the 11 kJ mol^{-1} difference in stability corresponds to the overwhelming existence (99%) of the stable conformer; therefore, the less stable conformer must have no effect on the NMR spectra.

In the case of the dicarbonyl compound (**m4**), the **d** con-

[a]Reference 6.

former was stabilized — especially the RHF/6-31G* optimized conformation — and the one-point calculation by B3LYP/6-31G* demonstrated that **m4d** was the most stable.[2] This is exceptional, because other compounds in this work and in previous results (3, 6, 8) exhibited a predominance of the α-oriented C_1 methyl conformation. All unsaturated bonds of **m4** (namely, C_{12}—C_1, C_2—O_{19}, C_3—C_4, C_5—C_6, and C_7—O_{20}) are conjugated; moreover, C_{12}—C_1 and C_2—O_{19}, as well as C_5—C_6 and C_7—O_{20} of the calculated **m4d**, were nearly co-planar. The *s-trans* arrangement of this conformation seems to be strainless; therefore, the disadvantage of the β-oriented C_1-methyl conformation may be overcome by the conjugation effect of these nearly planar unsaturated systems. While **m5** also has the C_2—O_{19} carbonyl group, the conformational change caused by the saturation of the C_7 carbon must force the C_{12}=C_1—C_2=O_{19} system to deviate from planarity. Because of this conformational change, **m5a** was the most stable conformation of this compound.

The relative energies of the minimum conformations of the individual conformational groups and their proportion at 25 °C under the assumption of Boltzmann distribution are shown in Table 1. From this relative population, the predominant conformation of the model compounds (**m1**~**m5**) and the possibility of conformational equilibrium are indicated. The NOE enhancement (%) and the calculated nonbonding hydrogen—hydrogen distance are also shown in Table 2. Since NOE is observed at the inverse sixth power of the interatomic distance (9), it is favorably observed between hydrogens located as close as possible. Except for the 6-31G* calculation, the calculated relative stability was not necessarily consistent with the NOE observation as shown in Table 2. The stable conformations predicted by both the RHF/6-31G* minimization and single-point DFT calculation based on the RHF/6-31G* optimized structure were always consistent with the NOE observation. For example, RHF/6-31G* calculations predicted that **m1a** is the most stable, and all hydrogen—hydrogen distances in **m1a** were short enough, whereas other conformers of **m1** had at least one distant H–H pair for NOE observation. Since both α-oriented C—H bonds on C_5 and C_7 of **m1a** were almost perpendicular to the average ring plane, these protons were close to each other. In contrast, the corresponding protons of **m1c** were not so close, because the quasi-equatorial C_7 proton was extended to the outside of the 11-membered ring. Similarly, the 6-31G* prediction of other compounds agreed well with the NOE observation. In contrast, the STO-3G, PM3, and MM3 calculations did not necessarily agree with the NOE observation. Namely, the STO-3G and PM3 calculations incorrectly predicted that **m1b** was the most stable. For the model compound **m2**, the MM3 method incorrectly predicted that the predominant conformation is **m2a**, and this disagrees with the NOE observation between H_5 and $H_{7\beta}$. As regards the model compound **m3**, all calculations except for PM3 suggested that **m3b** is the overwhelmingly predominant conformation.

Based on the energy difference between the conformers of the DFT single-point calculation in Table 1, the populations were estimated, for **m2a** and **m2b**, as 38% and 62%, respectively. Therefore, if the interchange is possible at room temperature, this compound may be a conformational mixture. However, all NMR spectra consist of only one set of signals, indicating that each compound adopts one conformation or exists in a conformational mixture by rapid interchange. The estimated, relatively low activation energy of the inversion of the C_5=C_6 double bond suggests free inversion of the dou-

[2]The 6-31G* optimized conformation of **m4d** was consistent with the NOE observation (see Table 2).

© 2003 NRC Canada

ble bond. When the flipping of the double bond is faster than the NMR time scale, the observed NOE is the average of all the conformations present in the solution. In such a case, we cannot rule out the co-existence of **m2a**, though there was no NOE observation suggesting **m2a**. Differing from **m2**, the calculated large energy difference revealed that compounds **m1**, **m3**, **m4**, and **m5** adopt, exclusively, a single conformation regardless of the activation energy.

Conclusion

All calculation methods used in this work afforded comparable bond lengths, bond angles, and dihedral angles, as shown in Table 2. In contrast, the predominant conformations predicted by the different methods differed. Only the 6-31G* calculations always predicted the predominant conformations that agreed with the NOE results. Thus, the conformational stability predicted by the MM3, PM3, and STO-3G methods is not necessarily correct. Therefore, ab initio calculations using a larger basis set are desirable for such peculiar ring systems as the lathyrane type.

Methods

The structure of lathyrane derivatives, together with the type and location of the oxygen functional groups, are shown in Fig. 1.[3] ^{1}H NMR spectra were obtained at 400 MHz on a JEOL JNM-GX400 spectrometer using $CDCl_3$ solutions, as follows: **1**: δ: 5.66 (1H, br s), 4.93 (1H, d, *J* = 11.6 Hz), 4.63 (1H, br s), 4.02 (1H, d, *J* = 8.5 Hz), 2.54 (1H, m), 2.37 (2H, m), 2.29 (1H, m), 1.94 (1H, dd, *J* = 4.3, 12.1 Hz), 1.75 (3H, complex), 1.45 (3H, d, *J* = 1.5 Hz), 1.42 (3H, d, *J* = 1.5 Hz), 1.19 (1H, dd, *J* = 8.5, 11.6 Hz), 1.03 (3H, s), 1.00 (3H, s), 0.74 (1H, ddd, *J* = 3.9, 8.5, 11.2 Hz); **2**: δ: 5.54 (1H, br s), 4.83 (1H, d, *J* = 11.4 Hz), 4.65 (1H, br s), 4.30 (1H, br s), 2.58 (2H, m), 2.40 (1H, m), 2.19 (1H, m), 2.16 (1H, ddd, *J* = 3.6, 5.3, 14.8 Hz), 1.80 (2H, m), 1.58 (1H, m), 1.54 (3H, s), 1.42 (3H, s), 1.25 (1H, dd, *J* = 9.3, 11.8 Hz), 1.11 (3H, s), 1.04 (3H, s), 0.99 (1H, ddd, *J* = 3.6, 9.3, 11.8 Hz); **4**: δ: 7.02 (1H, br s), 5.71 (1H, dd, *J* = 1.5, 9.8 Hz), 3.03 (1H, dd, *J* = 11.7, 12.1 Hz), 2.80–2.65 (3H, complex), 2.59 (1H, m), 2.46 (1H, dd, *J* = 4.4, 12.1 Hz), 1.93 (2H, m), 1.67 (3H, d, *J* = 1.5 Hz), 1.66 (3H, d, *J* = 2.0 Hz), 1.31 (1H, dd, *J* = 9.3, 9.8 Hz), 1.11 (6H, s), 1.06 (1H, ddd, *J* = 4.4, 9.3, 11.7 Hz); **5**: δ: 5.98 (1H, br s), 5.60 (1H, dd, *J* = 1.0, 11.6 Hz), 4.20 (1H, d, *J* = 9.2 Hz), 2.76 (1H, m), 2.64–2.51 (3H, complex), 2.01 (1H, dd, *J* = 6.4, 13.6 Hz), 1.90–1.81 (2H, complex), 1.77 (3H, d, *J* = 1.0 Hz), 1.74 (1H, m), 1.51 (3H, s), 1.38 (1H, dd, *J* = 8.8, 11.6 Hz), 1.12 (3H, s), 1.08 (1H, overlapped), 1.07 (3H, s).

The calculations were performed on the truncated model structures, as shown in Fig. 2. The starting coordinates of each conformation of the truncated model structures (**m1**~**m5**) were generated by inspection of the Dreiding molecular model using standard bond lengths and bond angles. Then, 200 conformers were evolved using the stochastic search option of the MM3(96) program (10). Similar conformers whose dihedral angles were within ±15° from the corresponding angles of an already selected conformation and unsuitable conformers having a sterically isomerized double bond or a cyclopropane ring were removed. Intramolecular flexibility of the surviving conformers was optimized by the following theoretical methods: namely, the ab initio MO, semi-empirical MO, and MM methods.

Ab initio calculations of MO were carried out using the Gaussian 98 program package (11). The structure was optimized at the RHF/STO-3G or RHF/6-31G* level. To introduce more correlation effects, a single-point calculation was performed on the 6-31G* optimized structure, employing the B3LYP/6-31G* level of theory (12). All ab initio MO calculations were performed on a FACOM VPP5000/56 super computer at Nagoya University Computation Center.

Semi-empirical MO calculations were done by employing the PM3 method in MOPAC Ver. 6.01 (13). All the geometric variables were completely optimized for each conformer in order to locate the minimum energy conformation. The calculations were carried out on a FACOM GP7000F at Nagoya University Computation Center.

Molecular mechanics calculations were performed using the MM3(96) program package downloaded from QCPE (10). Force constants not parameterized in the program were estimated using the parameter estimation routine. All the geometric variables were completely optimized by block-diagonal, then full-matrix, minimization methods. Calculations were performed on an IBM RS/6000 UNIX work station.

Barrier height for the flipping of the 11-membered ring of the model compound (**m2**) was estimated by RHF/6-31G* level calculations of Gaussian 98 (11). The transition structure of the pseudo-rotation of the C_5=C_6 double bond was searched using the QST3 key word; then, the resultant conformation was optimized under the TS key word. Furthermore, the frequency analysis was performed on the transition state and the two stable conformers (**m2a** and **m2b**); then they were confirmed by existence or absence of a single imaginary mode. The activation energy was the difference in the Gibbs free energy between the transition state and either stable conformation.

Theoretical studies on the one- and two-photon absorption of tetrabenzoporphyrins and phthalocyanines

Xin Zhou, Ai-Min Ren, Ji-Kang Feng, and Xiao-Juan Liu

Abstract: The one-photon absorption (OPA) properties of tetrabenzoporphyrins (TBPs) and phthalocyanines (Pcs) were studied using the semiempirical ZINDO method and time-dependent density functional theory (TDDFT), respectively. The compared results confirmed that the semiempirical ZINDO method was reasonably reliable when calculating the OPA of tetrabenzoporphyrins and phthalocyanines. On the basis of the OPA properties obtained from the ZINDO method, two-photon absorption (TPA) properties of two series of molecules were investigated, using ZINDO and sum-over-states (SOS) methods. The results showed that the TPA cross-sections of all molecules were in the range of $220.6 \times 10^{-50} - 345.9 \times 10^{-50}$ $cm^4 \cdot s \cdot photon^{-1}$, which were in the same order of magnitude as the values reported in the literature. The relatively larger $\delta(\omega)$ value for Pcs with respect to that for corresponding TBPs originates from larger intramolecular charge transfer, which can be characterized by the difference of dipole moment between S_0 and S_1 and the transition dipole moment between S_1 and S_5.

Key words: two-photon absorption, ZINDO, sum-over-states, tetrabenzoporphyrin, phthalocyanines.

Résumé : On a étudié les propriétés d'absorption monophotoniques (« OPA ») de tétrabenzoporphyrines (TBPs) et de phtalocyanines (Pcs) à l'aide de la méthode semi-empirique ZINDO et de la théorie fonctionnelle de la densité dépendante du temps (« TDDFT »). Une comparaison des résultats confirme que pour le calcul des « OPA » des tétrabenzoporphyrines et des phtalocyanines, la méthode semi-empirique ZINDO donne des valeurs raisonnablement fiables. Sur la base des « OPA » obtenus par la méthode ZINDO, on a étudié les propriétés d'absorption biphotoniques (« TPA ») de deux séries de molécules ont été étudiées à l'aide des méthodes ZINDO et de la somme de tous les états (« SOS »). Les résultats montrent que les sections droites des « TPA » de toutes les molécules se situent dans la fourchette $220{,}6 \times 10^{-50}$ à $345{,}9 \times 10^{-50}$ $cm^4 \cdot s \cdot photon^{-1}$, valeurs qui sont du même ordre de grandeur que celles rapportées dans la littérature. La valeur de $\delta(\omega)$ relativement plus élevée pour les Pcs par rapport aux THBs résulte d'un plus grand transfert de charge qui peut être caractérisé par la différence entre les moments dipolaires S_0 et S_1 et le moment dipolaire de transition entre S_1 et S_5.

Mots clés : absorption biphotonique, ZINDO, somme de tous les états, tétrabenzoporphyrine, phtalocyanine.

[Traduit par la Rédaction]

Introduction

The phthalocyanines (Pcs) and tetrabenzoporphyrins (TBPs) have attracted considerable attention because of their applications in a wide variety of important chemical, physical, and biological processes, including electrophotographic systems (1), photonvoltaic cells for energy conversion (2), optical power limiting (3, 4), photosensitizers (5), and photodynamic therapy (6–9). Much theoretical and experimental effort has been exerted in attempts to elucidate the electronic, spectroscopic, and optical properties of these molecules (10–17). Experimentally, the spectroscopic properties of Pcs in the vapor phase and in solvents were measures by Edwards and Goutermans (14). The spectroscopic studies of TBPs were carried out by Ehrenberg and Johnson (15). They examined the basic absorption and fluorescence properties of TBPs in a variety of solvents and mixtures and pointed out the potential applications of these dyes as either ultrasensitive probes or photosensitizers. Ortí et al. (16) used the valence effective Hamiltonian quantum-chemical method to theoretically determine the molecular and solid-state electronic structures of metal-free phthalocyanine. Nguyen and Pachter (17) investigated and compared the ground-state electronic structures and spectra of ZnTBP and ZnPc using density functional theory.

Previous experimental observations and theoretical investigations of TBPs and Pcs have focused on the study of one-photon absorption (OPA) properties, although the potential significance of two-photon absorption (TPA) properties has also been paid attention (10, 18, 19). In recent years, the TPA of molecules has become a more and more exciting nonlinear optical phenomenon that possesses great potential for application in photonic and biological areas, such as

three-dimensional optical storage (20, 21), two-photon fluorescence excitation microscopy (22, 23), and two-photon upconverted lasing (24, 25). To find organic molecules with large TPA cross-sections, many efforts were devoted to experimentally developing chromophores with novel structures and conjugation patterns (26, 27). Meanwhile, theoretical calculations were also employed, to establish the structure–property relationships for a large number of TPA dyes and to understand the underlying mechanisms for increasing the TPA cross-section (28–30).

Recently, Karotki et al. (10) investigated the increase of TPA in a series of porphyrins and tetraazaporphyrins by measuring the absolute TPA cross-section with 100-fs-duration pulses in two ranges of laser wavelengths, from 1100 to 1500 nm and from 700 to 800 nm. The cross-section in the Q transition region was $1 \times 10^{-50} - 10 \times 10^{-50}$ cm^4·s·photon^{-1}, and in the Soret transition region they found an enhancement of the TPA cross-section by one order of magnitude. In symmetrically substituted tetraazaporphyrins with strong electron acceptors, further enhancement of the TPA cross-section — up to 1600×10^{-50} cm^4·s·photon^{-1} — was found.

In this paper, we have first investigated the OPA properties of tetrabenzoporphyrin (H_2TBP), metallo-TBPs (MgTBP, ZnTBP), phthalocyanine (H_2Pc), and metallo-Pcs (MgPc, ZnPc) by means of time-dependent density functional theory (TDDFT) and ZINDO and then compared the results obtained from the two methods. Then, ZINDO and sum-over-states (SOS) were employed to calculate the second hyperpolarizability and TPA properties of six molecules on the basis of geometries optimized by B3LYP/6-31G and the OPA properties obtained from the ZINDO method.

Theoretical methodology

The TPA process corresponds to simultaneous absorption of two photons. The TPA efficiency of an organic molecule at optical frequency $\omega/2\pi$ can be characterized by the TPA cross-section $\delta(\omega)$. It can be directly related to the imaginary part of the second hyperpolarizability $\gamma(-\omega;\omega,\omega,-\omega)$ by the following equation (31):

$$[1] \qquad \delta(\omega) = \frac{8\pi^2\hbar\omega^2}{n^2c^2} L^4 \operatorname{Im}\gamma(-\omega;\omega,\omega,-\omega)$$

where $\hbar$ is Planck's constant divided by 2π; n is the refractive index of medium; c is the speed of light; and L is a local field factor (equal to 1 for vacuum).

The SOS expression to evaluate the components of the second hyperpolarizability γ_{ijkl} can be induced using perturbation theory and the density matrix method. By considering a power expansion of the energy with respect to the applied field, the γ_{ijkl} Cartesian components are given by the following equation (32, 33):

$$[2] \qquad \gamma_{ijkl}(-\omega_\sigma;\omega_1,\omega_2,\omega_3) = \frac{4\pi^3}{3h^3} \mathrm{P}(i,j,k,l;-\omega_\sigma;\omega_1,\omega_2,\omega_3) \times \left[\sum_{m\neq o}\sum_{n\neq o}\sum_{p\neq o} \frac{\langle o|\mu_i|m\rangle\langle m|\bar{\mu}_j|n\rangle\langle n|\bar{\mu}_k|p\rangle\langle p|\mu_l|o\rangle}{(\omega_{mo}-\omega_\sigma-i\Gamma_{mo})(\omega_{no}-\omega_2-\omega_3-i\Gamma_{no})(\omega_{po}-\omega_3-i\Gamma_{po})} - \sum_{m\neq o}\sum_{n\neq o} \frac{\langle o|\mu_i|m\rangle\langle m|\mu_j|o\rangle\langle o|\mu_k|n\rangle\langle n|\mu_l|o\rangle}{(\omega_{mo}-\omega_\sigma-i\Gamma_{mo})(\omega_{no}-\omega_3-i\Gamma_{no})(\omega_{no}+\omega_2-i\Gamma_{no})} \right]$$

where P(i, j, k, l;$-\omega_\sigma$; ω_1, ω_2, ω_3) is a permutation operator defined in such a way that for any permutation of (i, j, k, l), an equivalent permutation of ($-\omega_\sigma$; ω_1, ω_2, ω_3) is made simultaneously; $\omega_\sigma = \omega_1 + \omega_2 + \omega_3$ is the polarization response frequency; ω_1, ω_2, ω_3 indicate the frequencies of the perturbing radiation fields (considering the degenerate TPA, $\omega_1 = \omega_2 = \omega$ and $\omega_3 = -\omega$); i, j, k, and l correspond to the molecular axes x, y, and z; m, n, and p denote excited states and o, the ground state; μ_j is the j (= x, y, z)th component of the dipole operator; ($\langle m|\bar{\mu}_j|n\rangle = \langle m|\mu_j|n\rangle - \langle o|\mu_j|o\rangle$); $(h/2\pi)\omega_{mo}$ is the transition energy between the m and o states; and Γ_{mo} is the damping factor of the excited state m. Considering that the higher the excited state, the shorter is its lifetime, the Γ_{mo} is expressed as follows (34):

$$[3] \qquad \Gamma_{mo} = 0.08 \times \frac{\omega_{mo}}{\omega_{1o}}$$

To compare the calculated δ value with the experimental value measured in solution, the orientationally averaged (isotropic) value of γ is evaluated, which is defined as

$$[4] \qquad \langle\gamma\rangle = \frac{1}{15}\sum_{i,j}(\gamma_{iijj} + \gamma_{ijij} + \gamma_{ijji}); \qquad i,j = x,y,z$$

Generally, the position and relative strength of the two-photon resonance for centrosymmetric molecules are to be predicted using the following simplified form of the SOS expression (28, 32):

$$[5] \qquad \delta \propto \frac{M_{0k}{}^2 M_{kn}{}^2}{(E_{0k} - E_{0n}/2)^2\Gamma}$$

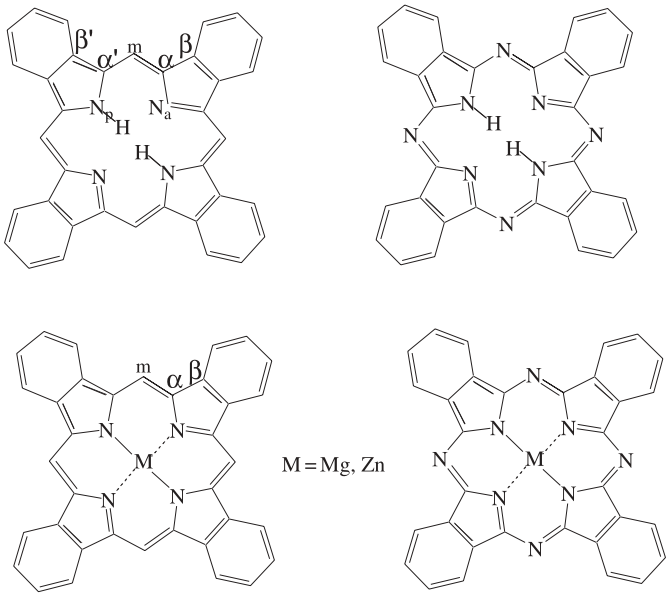
where M_{ij} is the transition dipole moment from the state i to the state j; E_{ij} is the corresponding excitation energy; the subscripts 0, k, and n refer to the ground state S_0, the intermediate state S_k, and the TPA final state S_n, respectively;

© 2003 NRC Canada

and the damping factor Γ has been calculated according to eq. [3].

In principle, any kind of self-consistent field molecular orbital (SCFMO) procedure combined with configuration interaction (CI) can be used to calculate the physical values in the above expression. In the present paper, the B3LYP/6-31G method was first used to calculate molecular equilibrium geometry. Then, the property of the electronic excited state was obtained by single and double electron excitation configuration interaction (SDCI), using the ZINDO program and TDDFT, respectively. Furthermore, on the basis of the OPA parameters obtained from the ZINDO method, TPA properties of the molecules are provided. Then, according to eqs. [1]–[4], the second hyperpolarizability γ and the TPA cross-section δ(ω) were calculated.

Results and discussion



Molecular structures

The compounds studied in this paper are shown in Fig. 1. Since the molecular structures used in the calculations have an important effect on the accuracy of the computed spectra, it is necessary to compare the calculated structural parameters with theoretical and experimental results. In this paper, the molecular geometries were optimized by the B3LYP method in the Gaussian 98 program package, using the 6-31G basis set under the following symmetry constraints: D_{4h} for bivalent metallic derivatives and D_{2h} for metal-free phthalocyanine or tetrabenzoporphyrin (35). Figure 1 and Table 1 display the molecular labels and structural parameters. For H_2Pc, the parameters obtained by the B3LYP/6-31G method are consistent with the PM3-optimized parameters (15). Although, for the C_α—N_m and C_α—N_m bonds, the lengths of 1.324 and 1.340 Å are smaller than the PM3-optimized values of 1.344 and 1.349 Å, they are in line with the X-ray value of 1.330 Å reported for α-H_2Pc (38). Compared with the literature value (15), the N_p—C_α distance of H_2Pc (1.388 Å) is overestimated by 0.023 Å, which is comparable with the value reported in ref. 38 (1.36–1.38 Å). As far as ZnPc is concerned, the geometric parameters are in good agreement with the previous DFT calculation (17). The predicted Zn—N bond distance is slightly longer than those obtained from experimental observation. The C—C and C—N distances are well within 0.02 Å of the experimental values. The calculated bond angles are almost within 2° of the experimental values.

One-photon absorption

On the basis of the geometries optimized by B3LYP/6-31G, we have studied the OPA properties for all molecules. For comparison, the semi-empirical ZINDO and TDDFT are, respectively, used to obtain the OPA wavelength $\lambda^{(1)}$ and the corresponding oscillator strength, which are included in Tables 2 and 3, along with the experimental results. As shown in Table 2, in comparison with the results of the TDDFT calculations, the Q-band absorption peaks of all six compounds predicted by the ZINDO method are in better agreement with the experimental observations. For example, for ZnTBP, the result is 602.8 nm, which is longer than the TDDFT result (561.3 nm) and almost equal to the datum (601.8 nm) taken from the gas-phase supersonic jet (32). As

Fig. 1. Molecular structures and labels for the compounds studied.

can be seen in Table 3, the Q-band absorption peak of ZnPc calculated by ZINDO is at 609.9 nm, which is close to the value obtained from the gas-phase supersonic jet (635.8 nm) (37), while the TDDFT result is 584.2 nm. The results calculated by ZINDO suggest, for either TBPs or Pcs, that the presence of the metal ion makes the Q-band absorption peak exhibit blue-shifts to a certain extent (from 638.0 nm of H_2TBP to 603.4 nm of MgTBP and to 602.8 nm of ZnTBP; from 642.0 nm of H_2Pc to 611.3 nm of MgPc and to 609.9 nm of ZnPc). It is known that the Q-bands of TBPs and Pcs arise from π-electron transitions from occupied to unoccupied orbitals. From the HOMO–LUMO gaps of all compounds in Table 4 we see that, since there are coordination bonds between metals (Mg, Zn) and pyrrole nitrogens, the HOMO–LUMO gaps of metal phthalocyanines and tetrabenzoporphyrins (MPcs and MTBPs) are larger than those of metal-free phthalocyanine and tetrabenzoporphyrin (H_2Pc and H_2TBP), and so maximum absorption wavelengths of MPcs and MTBPs are shorter than those of H_2TBP and H_2Pc. The difference in the central metal has little effect on the Q-band absorption of TBPs and Pcs, which is in good agreement with the conclusion found in the literature (35).

The B-band absorption is dominated by transitions from the HOMO-1 to the two degenerate LUMOs. For the B-bands of the Pcs, the semi-empirical ZINDO results are in line with the TDDFT calculations, and they are consistent with the experimental data. For H_2Pc, the ZINDO result is 351.5 nm with an oscillator strength of 0.28, and TDDFT predicts an absorption peak at 343.5 nm with an oscillator strength of 0.26. These values are in agreement with the experimental values (340 nm) obtained in vapor-phase absorption spectra (14). As far as MgPc is concerned, the B-band gained by ZINDO is predicted to appear at 328.1 nm (oscillator strength f = 0.04), and TDDFT indicates that it is located at 335.2 nm with a stronger oscillator strength of 0.68. The result in the literature (14) is 332 nm, which accords

with our calculations. For ZnPc, the ZINDO result of 327.9 nm (*f* = 0.04) and the TDDFT value of 325.3 nm (*f* = 0.34) are almost equal to the value found in the experiment (14) (326.5 nm) and the result (326 nm) found in the literature (42). In the terms of TBPs, the B-bands obtained from TDDFT exhibit more reasonable values to the experimental results than those of ZINDO. The B-band of H_2TBP, predicted by TDDFT, is 396.9 nm (*f* = 1.10); the ZNIDO result is 363.2 nm with a stronger oscillator strength of 1.55, and the corresponding experimental value is 429.3 nm (16). As to MgTBP and ZnTBP, the differences between TDDFT and ZINDO in the B-band are about 30 nm. The results suggest that for predicting the B-band absorptions of TBPs, the TDDFT method can give better results than the ZINDO

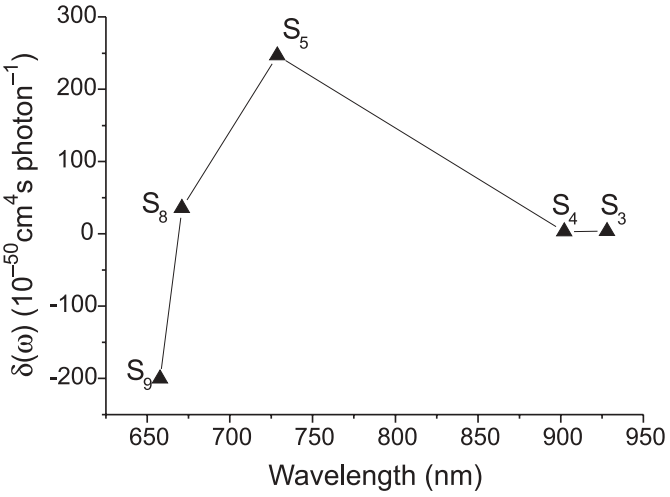
method. In general, compared with the calculated TDDFT and the experimental results, the OPA spectra predicted by the semi-empirical ZINDO method are reasonably reliable.

Two-photon absorption property

According to eqs. [1]–[4], we compiled a program that calculated the average second hyperpolarizability <γ> and TPA cross-section δ(ω) by ourselves. By using the program combined with the ZINDO method, we calculated the real and imaginary parts of <γ>, as well as the δ(ω) value (ω = $2\pi/\lambda^{(2)}$ is the speed of light) and the corresponding two-photon absorption wavelength $\lambda^{(2)}_{max}$ and transition nature (configurations and weight) for the maximum TPA (shown in Table 5). To verify the accuracy of the method used, we chose stilbene (molecule A in Table 5) and 4,4′-bis(dimethylamino)stilbene (molecule B in Table 5) as comparison samples, and the corresponding experimental values are given in parentheses. We can see from Table 5 that the results we calculated are in good agreement with experimental values. It was observed that, from H_2TBP to MTBP (M = Mg, Zn), $\lambda^{(2)}_{max}$ is slightly blue-shifted. From H_2Pc to MPc, $\lambda^{(2)}_{max}$ is blue-shifted by 24~25 nm. Compared with $\lambda^{(2)}_{max}$ of H_2TBP (729 nm), the TPA wavelength of H_2Pc (817.2 nm) is red-shifted by 88 nm. The $\lambda^{(2)}_{max}$ of MPc are about 55 nm longer than that of the corresponding MTBP (M = Mg, Zn). However, the difference of the metal ion has little effect on the TPA wavelength.

From Table 5, one can obtain the information that the TPA final state of the six compounds is S_5, which is described mainly by mixing the two-electron promotion from the (HOMO, HOMO) to the (LUMO, LUMO) and from the (HOMO, HOMO) to the (LUMO+1, LUMO+1). It can be seen that for TBPs and Pcs, the two-electron promotion plays an important role in the TPA of the investigated molecules. So, to analyze the TPA properties of TBPs and Pcs, it is very necessary to add the double configuration interaction to the calculations. The results show that because of the similar structure between TBPs and Pcs from the metal-free system to the metallo-system, the changes of the TPA wavelengths exhibit a similar trend.

To verify whether we have gained $\lambda^{(2)}_{max}$ when δ(ω) is maximized by our method, we selected molecule ZnTBP as an example and considered the 5 lowest two-photon allowed excited states as the TPA final state. It is known that the selection rule for TPA is different from that of OPA (44). One change of parity is required for a one-photon transition, while two-photon transitions must have initial and final states with the same parity. For molecules that, like all molecules studied in this paper, have central symmetry, a change in parity between the initial and final states (wave functions) is required for every photon involved in the transition for electric dipole transitions. So, for ZnTBP, the 5 lowest two-photon allowed excited states are S_3, S_4, S_5, S_8, and S_9, respectively. In term of eqs. [1] and [2], we have calculated δ(ω) (shown in Fig. 2). The results listed in Fig. 2 indicates that at S_5, $\lambda^{(2)}$ surely corresponds to the maximum δ(ω), 274.9×10^{-50} $cm^4 \cdot s \cdot photon^{-1}$, at 728.6 nm. Both theoretical and experimental results indicate that there is no evident one-photon absorption in the range of 700–950 nm, and TPA can be expected in this range. Our calculated TPA wavelength of ZnTBP is just in this range.



Now, we pay attention to the TPA cross-sections of these compounds. As can be seen in Table 5, we first compared the TPA cross-section of H_2TBP and MTBP. The magnitude of δ(ω) for H_2TBP is 220.6×10^{-50} $cm^4 \cdot s \cdot photon^{-1}$, while for MgTBP, it is 278.3×10^{-50} $cm^4 \cdot s \cdot photon^{-1}$, and for ZnTBP, it is 274.9×10^{-50} $cm^4 \cdot s \cdot photon^{-1}$. It was found that since the addition of metal ions in the molecule forms coordination

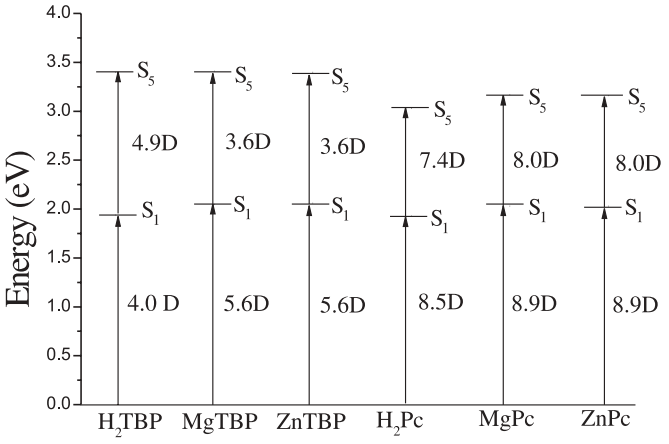
Fig. 2. The TPA spectrum of ZnTBP.

bonds, the conjugation range of molecule enlargers and the TPA cross-section of the molecule drastically increases. But the effect of the difference of the metal atom on the TPA cross-section is very small, which is similar to the trend of the OPA parameters in the same molecules, as well as the results obtained from ref. 35. The same trend can be obtained when one studies the TPA cross-sections of the Pcs.

From Table 4, one can find that the TPA cross-sections of Pcs are bigger than those of corresponding TBPs. For example, the TPA cross-section maximum of MgPc is 345.9 × 10^{-50} $cm^4\cdot s\cdot photon^{-1}$, while that of MgTBP is equal to 278.3 × 10^{-50} $cm^4\cdot s\cdot photon^{-1}$. The maximum TPA cross-section of H_2Pc is 292.6 × 10^{-50} $cm^4\cdot s\cdot photon^{-1}$, while that of H_2TBP is equal to 220.4 × 10^{-50} $cm^4\cdot s\cdot photon^{-1}$. In the literature (10, 19), the TPA properties of porphyrins have been experimentally measured. For H_2TBP, the $\delta(\omega)$ is equal to 57 × 10^{-50} $cm^4\cdot s\cdot photon^{-1}$ when the incident laser frequency reaches 13 800 cm^{-1} (λ = 724 nm). The experimental value of H_2TBP is about one fourth of our calculation (220.4 × 10^{-50} $cm^4\cdot s\cdot photon^{-1}$). However, experimentally there is no TPA peak in the TPA spectrum of H_2TBP. In other words, it is possible to reach a larger TPA cross-section value if one changes the incident laser frequency. Moreover, the authors in ref. 19 also pointed out that the gained results only provide a qualitative explanation of the TPA spectra, and a quantitative description of the absolute TPA cross-section values is not readily available. In addition, a theoretical investigation of the one- and two-photon properties of porphyrins is presented by Masthay et al. (18). The results in this reference suggest that if both photons are linearly polarized, the TPA cross-section of free-base porphyrin (FBP) — the analogue of TBPs — is 585.715 × 10^{-50} $cm^4\cdot s\cdot photon^{-1}$. In contrast, the TPA cross-section value of FBP reaches a maximum of 143.886 × 10^{-50} $cm^4\cdot s$ $photon^{-1}$ if both photons are circularly polarized.

The above reports suggest that because of the differences in calculation methods and experimental conditions, the TPA cross-section for the same compound differs a lot. As a whole, the maximum TPA cross-sections of all compounds calculated in this paper are the same order of magnitude as the values reported in the literature, which suggests that the above discussions about the TPA properties can give some useful information in the understanding of the structure–property relationships of porphyrins, phthalocyanines, and their analogs.



On the basis of the results of the calculations, as shown in Fig. 3, we can rationalize the increase in the TPA cross-section on going from TBPs to Pcs on the basis of (*i*) an increase in the S_0 to S_1 transition dipole moment (M_{01}) from 4.0 to 8.5 D (from H_2TBP to H_2Pc) and from 5.6 to 8.9 D (from MTBP to MPc, M = Mg, Zn); (*ii*) an increase in the S_1 to S_5 transition dipole moment (M_{15}) from 4.9 to 7.4 D (from H_2TBP to H_2Pc) and from 3.6 to 8.0 D (from MTBP to MPc, M = Mg, Zn). According to eq. [5], we find that the major contributors to the enhanced $\delta(\omega)$ value of Pcs with respect to that of TBPs are the increase in the S_0 to S_1 transi-

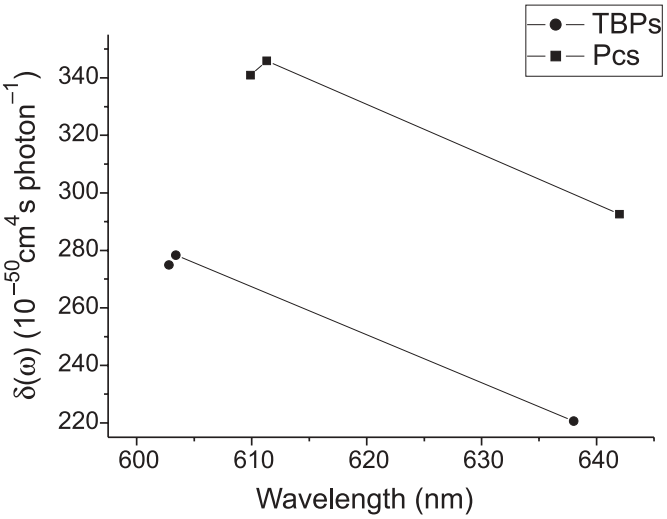
tion dipole moment and the increase in the S_1 to S_5 transition dipole moment.

To further understand the micromechanism of the difference in the TPA cross-sections of TBPs and Pcs, we also analyzed the changed value of the charge ΔQ, from the ground state Q_0 to the excited state Q_1 of the molecules. Here, we take H_2TBP and H_2Pc as comparison examples and analyze the charge distribution of the moiety, including pyrrole N atoms (N_p, N_a), C_α, and meso N or C (N_m, C_m) in the two compounds. The detailed data are collected in Table 6, and the relative labels of atoms are shown in Fig. 1. As can be seen from Table 6 and Fig. 1, the ΔQ of H_2Pc (0.079548) is larger than that of H_2TBP (0.047994). The results illustrate that the relatively larger $\delta(\omega)$ value for Pcs, in comparison with that for TBPs, originates from a larger intramolecular charge transfer, which can be characterized by the transition dipole moment between the S_0 and S_1 and the transition dipole moment between S_1 and S_5.

Analyzing the above results, one can find that, whether looking at the OPA properties or the TPA properties, TBPs and Pcs have many similar points. Figure 4 depicts the relationship between the one-photon Q-band absorptions obtained by the ZINDO method and TPA cross-sections of the two series. The two similarly shaped lines appear in Fig. 4. It is obvious that from the changing tendency in the two quantities of TBPs we can obtain similar information about Pcs. In other words, when one examines the one- and two-photon absorption properties of Pcs, they can gain some enlightenment about the absorption property rules of TBPs.

Fig. 4. The relationship between the Q-band wavelength and TPA cross-section of TBPs and Pcs.



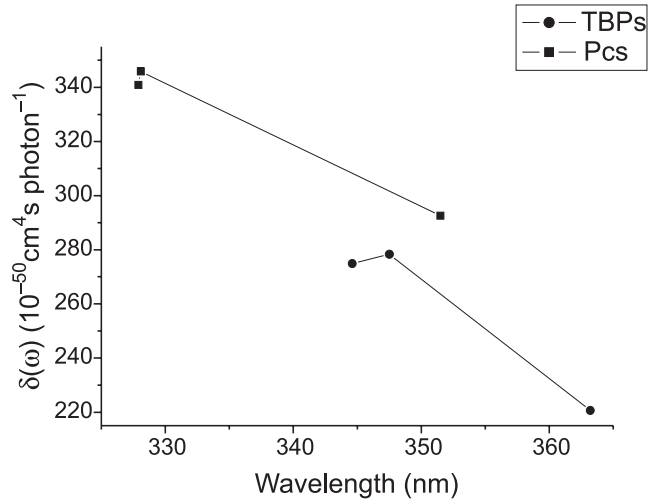


Fig. 5. The relationship between the B-band wavelength and TPA cross-section of TBPs and Pcs.

The relationships between the B-band absorption and the TPA cross-section of all molecules are shown in Fig. 5. The results, as exhibited, are similar.

Summary

We have studied the theoretical one- and two-photon absorption properties of tetrabenzoporphyrins and phthalo-

© 2003 NRC Canada

cyanines. The calculated results are in good agreement with the experimental values. The results suggest for the two series of molecules that there are some similarities in both one-photon absorption and two-photon absorption properties. From the changing trend in one- and two-photon absorption properties of TBPs (or Pcs), one can gain some enlightenment on the nonlinear optical properties of Pcs (or TBPs). The increase in the S_0 to S_1 transition dipole moment and the increase in the S_1 to S_5 transition dipole moment are the major contributors to the enhanced $\delta(\omega)$ value of Pcs with respect to those of the corresponding TBPs.

Phosphorus magnetic shielding tensors for transition-metal compounds containing phosphine, phosphido, and phosphinidene ligands: Insights from computational chemistry

Kirk W. Feindel and Roderick E. Wasylishen

Abstract: The present study examines the quality of the restricted Hartree–Fock (RHF) ab initio, B3LYP hybrid density functional theory (DFT), and relativistic zeroth-order regular approximation (ZORA) DFT methods for the calculation of phosphorus chemical shift (CS) tensors in phosphine, phosphido, and phosphinidene transition-metal complexes. A detailed comparison of calculated and experimental ^{31}P CS tensors allows us to identify the characteristic advantages of each computational method. The results from B3LYP and ZORA-DFT calculations indicate that a double-ζ quality basis set reproduces experimental values of the principal components of the ^{31}P CS tensor in many of the phosphorus-containing transition-metal complexes investigated, whereas the RHF method requires a triple-ζ doubly polarized basis set, yet fails in the case of the terminal phosphido group. Inclusion of the spin-orbit relativistic correction with the ZORA-DFT formalism requires a triple-ζ quality basis set to reproduce the experimental data. We demonstrate the merit of modern computational methods for investigating theoretically the effect of geometric variations upon the phosphorus CS tensor by systematically altering the W—P bond length and the W-P-C_{Me} bond angle in $W(CO)_5(PMe_3)$. Additionally, a previously reported correlation, determined experimentally, relating the ^{31}P CS tensor to the Fe-P-Fe bond angle in a series of iron phosphido-bridging compounds, has been reproduced with calculations using the model compound $Fe_2(CO)_6(\mu_2\text{-}PPh_2)(\mu_2\text{-}Cl)$. The results presented demonstrate the value of modern computational techniques for obtaining a greater understanding of the relationship between phosphorus chemical shifts and molecular structure.

Key words: ^{31}P chemical shift, phosphine, phosphido, phosphinidene, RHF, B3LYP, relativistic, ZORA-DFT.

Résumé : Dans le présent travail, on examine la qualité de la théorie de densité fonctionnelle hybride B3LYP (« DFT »), une méthode ab initio de Hartree–Fock restreinte (« RHF »), ainsi que les méthodes « DFT » relativistes d'approximation régulière d'ordre zéro (« ZORA ») pour le calcul des tenseurs des déplacements chimiques (DC) du phosphore dans les complexes de métaux de transition contenant des groupes phosphine, phosphido et phosphinidène. Une comparaison détaillée des tenseurs calculés et expérimentaux des DC du ^{31}P a permis d'identifier les avantages caractéristiques de chacune de ces méthodes de calcul. Les résultats obtenus par les calculs B3YLP et « ZORA-DFT » indiquent qu'un ensemble de base de qualité double-ζ permet de reproduire les valeurs expérimentales des principaux composants du tenseur du DC du ^{31}P de plusieurs des complexes étudiés de métaux de transition contenant du phosphore; par ailleurs, la méthode RHF qui nécessite un ensemble de base doublement polarisé triple-ζ ne donne même pas de bons résultats avec le groupe phosphido terminal. Pour pouvoir reproduire les résultats expérimentaux en incluant la correction relativiste spin-orbite dans le formalisme « ZORA-DFT », il est nécessaire d'utiliser un ensemble de base de qualité triple-ζ. On démontre les mérites des méthodes modernes de calcul pour étudier d'une façon théorique l'effet des variations géométriques sur le tenseur du DC du ^{31}P en faisant varier d'une façon systématique la longueur de la liaison W—P et l'angle de liaison W-P-C_{Me} dans $W(CO)_5(PMe_3)$. De plus, des calculs sur le composé modèle $Fe_2(CO)_6(\mu_2\text{-}PPh_2)(\mu_2\text{-}Cl)$ ont permis de reproduire une corrélation rapportée antérieurement, déterminée de façon expérimentale et qui permet de relier le tenseur du DC du ^{31}P à l'angle de la liaison Fe-P-Fe dans une série de composés du fer contenant un pont phosphido. Les résultats présentés démontrent la valeur des techniques modernes de calculs théoriques pour arriver à une meilleure compréhension de la relation entre les déplacements chimiques du phosphore et la structure moléculaire.

Mots clés : déplacement chimique du ^{31}P, phosphine, phosphido, phosphinidène, « RHF », B3LYP, relativiste, « ZORA-DFT ».

Introduction

Phosphorus compounds containing one or more formal localized electron lone pairs are important ligands in transition-metal chemistry. Phosphorus ligands possess the ability to act as σ-donors and π-acceptors simultaneously, allowing the ligand to adapt to the electronic characteristics of a metallic centre (1). Transition-metal-containing phosphorus compounds have found use in numerous applications, ranging from catalysis (2–7) to medicine (8–10). Phosphorus-31 nuclear magnetic resonance (NMR) spectroscopy is one of the most important techniques for characterizing such compounds (11), and therefore, understanding the origin of phosphorus chemical shifts and their relationship with molecular structure is essential.

Phosphorus-31 NMR spectroscopic studies are very common in both the liquid (solution) and solid states, and there are several reviews that deal specifically with solution ^{31}P NMR of phosphorus ligands in transition-metal complexes (12, 13). Despite this, phosphorus chemical shifts are generally not well understood (13–15). Considerable effort has been devoted to identifying empirical correlations between isotropic ^{31}P chemical shifts and molecular structure, such as in the presence or absence of metal–metal bonds in phosphido-bridging complexes (16), or correlations between chemical shifts and electronic transitions (17) or electron density (18), with little attempt to understand the theoretical origin of these observed empirical trends. More than ten years ago, Randall and Carty (19) recognized the importance of attempting to characterize phosphorus chemical shift (CS) tensors to rationalize chemical shift – structure relationships in transition-metal complexes. The magnetic shielding experienced by a particular nucleus in a molecule is generally characterized by a symmetric, second-rank tensor that can be described by three principal components and three Euler angles, which relate the principal axis system (PAS) of the tensor to the molecular framework of the molecule (20).

The last decade has yielded prodigious advances in the efficiency and affordability of desktop computers, thereby allowing many aspects of computational chemistry to become more accessible. The development of user-friendly software such as Gaussian 98W (21) enables experimentalists to readily calculate molecular properties such as nuclear magnetic shielding tensors (σ) based on first principles (ab initio) or density functional theory (DFT). For relatively small molecules containing first-row elements, the agreement between ab initio calculated magnetic shielding tensors and experiment is almost quantitative (22, 23). The success of theoretical methods for calculating magnetic shielding tensors at heavier nuclei continues to improve (24). Quantum chemical calculations of magnetic shielding tensors can provide the missing link that relates experimentally measured chemical shifts and structural parameters (25). Computational results may serve to complement experimental data and can provide information that may be difficult to obtain experimentally, such as the orientation of the PAS of the CS tensor (26). Single-crystal NMR or dipolar chemical shift NMR experiments often yield, at best, a twofold ambiguity in the orientation of CS tensors (27–29), whereas calculations yield a single orientation. Using an ab initio calculated orientation to interpret experimental results is often invaluable; it allows a confident assignment of the CS tensor orientation in the molecular frame of reference, as we recently demonstrated for the ^{31}P CS tensor in several phosphido-bridging complexes (27). However, one must take a cautious approach to the assignment of the tensor orientation if two of the components are quantitatively similar either experimentally or theoretically (i.e., tensors approaching axial symmetry); in these cases the calculated data may be as ambiguous as the experimental data one is trying to interpret. Of course, for a CS tensor that is truly axially symmetric, the question of the orientation of the two degenerate components becomes irrelevant.

Establishing the reliability of quantum chemical methods for the calculation of CS tensors in a variety of systems is important. In the past many computational papers have focussed on isotropic phosphorus chemical shifts (30–33). From an experimentalist's perspective, computational methods should ideally reproduce not only the isotropic value but also the three principal components of the tensor and their orientation. One needs to recognize that although the calculated isotropic value and span of the CS tensor (see Definitions and background theory) may be well reproduced, the agreement could be the result of a fortuitous cancellation of errors in the values of the tensor principal components (vide infra) (34).

Theoretical studies of phosphorus CS tensors have shown that ab initio and DFT methods are capable of reproducing experimental data for small phosphorus-containing compounds (30–33, 35–47) and for transition-metal-containing phosphorus compounds (27, 48–50). These calculations *qualitatively* reproduce experimental isotropic CS data and have enabled easy investigation of the effects of geometric structural variations on phosphorus magnetic shielding (27, 30, 32, 40, 42, 44, 46, 51–54). Several studies have indicated that in many cases inclusion of electron correlation generally improves agreement with experiment (30, 33, 35, 44). However, *quantitative* reproduction of experimental CS tensors for light nuclei such as ^{13}C, ^{15}N, ^{17}O, and ^{19}F in small molecules remains a challenge (25, 55). For example, Auer, Gauss, and Stanton (55) have shown that quantitative reproduction of gas-phase ^{13}C CS tensors requires large (quadrupule-ζ) uncontracted basis set CCSD(T) (coupled-cluster singles and doubles augmented by perturbation corrections for triple excitations) calculations with consideration of vibrational effects. In small molecules (e.g., C_3H_4, CF_4) a standard deviation of 1–2 ppm can be achieved. For a recent review on electron-correlated methods and quantitative reproduction of experimental chemical shifts, see ref. 25.

A number of studies have been published that explicitly compare experimental and theoretical phosphorus CS tensors (27, 35, 38, 40–43, 46, 47, 49, 53–56). Only a few investigations involve complexes containing nuclei heavier than sulfur (27, 33, 45, 48–50, 57), and although limited, the quantum chemical studies involving transition-metal-containing phosphorus compounds (predominantly phosphines) have provided a basis for the interpretation of phosphorus chemical shifts. Kaupp (48) was the first to investigate theoretically ^{31}P chemical shifts in a series of transition-metal phosphines, using sum-over-states density-functional perturbation theory (SOS-DFPT) with individual gauges for localized orbitals (IGLO). Later, Ruiz-Morales and Ziegler (49) employed a gauge-including atomic orbitals (GIAO) DFT

© 2003 NRC Canada

method for a similar series of complexes, analyzing specific paramagnetic couplings between occupied and virtual orbitals. Bühl et al. (50), also using the SOS-DFPT-IGLO method, have demonstrated that calculations on larger systems containing multiple metal centres are feasible, and in the case of $Ru_4(CO)_{13}(\mu_3\text{-PPh})$ they accurately reproduce the experimental ^{31}P CS tensor. More recently, van Wüllen (33) explored various DFT approaches and the ab initio Hartree–Fock (HF) and second-order Møller–Plesset perturbation theory (MP2) methods, using both IGLO and GIAO variants, as well as the method proposed by Wilson, Amos, and Handy (58). Eichele et al. (27) employed the restricted Hartree–Fock (RHF) method to calculate the phosphorus CS tensor of phosphido ligands in several ruthenium carbonyl compounds, reproducing the orientations found experimentally. However, a more comprehensive investigation, involving a greater number of phosphorus-containing transition-metal compounds, is still lacking.

The purpose of the present investigation is twofold. First, to provide the experimentalist with an indication of the reliability of ab initio (RHF), hybrid DFT (B3LYP), and pure DFT (ZORA-DFT) methods for the reproduction of experimental ^{31}P CS tensors in transition-metal-containing complexes. Second, to demonstrate the value of quantum chemical calculations as a method to examine the effect of molecular geometry on phosphorus magnetic shielding tensors in model compounds. Relativistic effects on phosphorus magnetic shielding tensors are also investigated for select compounds, using the ZORA-DFT method.

Definitions and background theory

Experimental NMR spectroscopists measure chemical shifts and CS tensors, while first-principles calculations provide magnetic shielding constants and magnetic shielding tensors. The relationship between chemical shift (δ) and magnetic shielding (σ) is described by

$$[1] \qquad \delta_{ii} = \frac{\sigma_{ref} - \sigma_{ii}}{1 - \sigma_{ref}}$$

where i = 1, 2, 3 represents the principal components of the CS and magnetic shielding tensors and σ_{ref} is the isotropic magnetic shielding of some reference compound. For comparison of experimental with calculated data, experimental ^{31}P chemical shifts have been converted to magnetic shielding (or vice versa) using the ^{31}P absolute magnetic shielding scale established by Jameson et al. (59), σ_{ref} = 328.35 ppm (85% aq H_3PO_4). Since σ_{ref} is small relative to one, eq. [1] can be simplified to

$$[2] \qquad \sigma_{ii} \approx 328.35 - \delta_{ii}$$

The principal components of the magnetic shielding tensor are defined such that $\sigma_{11} \leq \sigma_{22} \leq \sigma_{33}$; thus, σ_{33} represents the most shielded principal component. The isotropic shielding, σ_{iso}, is equal to one third the trace of the tensor

$$[3] \qquad \sigma_{iso} = \frac{\sigma_{11} + \sigma_{22} + \sigma_{33}}{3}$$

The span, Ω (60), describes the maximum orientation dependence of the magnetic shielding interaction and is defined as

$$[4] \qquad \Omega = \sigma_{33} - \sigma_{11} = \frac{(\delta_{11} - \delta_{33})}{1 - \sigma_{ref}} \approx \delta_{11} - \delta_{33}$$

Computational methods

The RHF ab initio non-relativistic method imposes doubly occupied (degenerate) spatial orbitals (61), and in practice the computational requirement for HF methods scale between N^2 and N^3, where N is the number of basis functions (62). The HF method does not include electron correlation effects; it treats electron–electron interactions as an average effect, and thus is not expected to give quantitatively accurate results, particularly if the nucleus in question bears a lone pair (23) (vide infra).

In the DFT formalism (63), electron correlation effects are accounted for implicitly through the use of an exchange-correlation (XC) functional. Current DFT methods do not yield exact results, since the functional form of the exact XC energy is unknown. Calculations converge toward a certain value as the basis set size is increased, but theory does not allow an evaluation of the errors inherent in this limit. The quality of the result can only be determined through comparison with experiment (64). For the purposes of our hybrid-DFT studies, Becke's B3LYP functional (65, 66), which mixes the Kohn–Sham orbital exchange energy functional, E_x, with gradient-corrected E_x and E_c (correlation contribution to the functional), has been employed. B3LYP is acknowledged as one of the most successful and widely used hybrid XC functionals (67, 68).

For heavy nuclei, relativistic effects become important as the core electrons move with speeds approaching that of light. Scalar relativistic effects include the mass–velocity correction, which results from the dependence of the electron mass on the velocity, and the Darwin correction, which accounts for the high-frequency oscillation of the electron around its mean position. These two contributors to scalar relativistic effects have opposite sign and, in practice, often essentially cancel each other. The spin-orbit relativistic term arises from the interaction of the nuclear magnetic moment with the magnetic field that is generated by the movement of an electron (69).

Relativistic effects should be considered if elements with $Z > 36$ are present in the molecule of interest (70). For very heavy elements (i.e., Au, Hg, Pt, etc.), relativistic effects also perturb valence orbitals, resulting in significant changes in fundamental properties such as magnetic shielding (71). The inclusion of relativistic effects is most important when calculating absolute values of magnetic shielding. In the case of chemical shift calculations, relativistic effects tend to cancel (72, 73); thus, to a first approximation, they are often ignored. Both the RHF and B3LYP-DFT methods, although non-relativistic, can employ quasi-relativistic effective core potentials (RECPs) on heavy atoms to correct for scalar, and in some cases spin-orbit, relativistic effects. While RECPs are not recommended for the calculation of magnetic shielding involving the heavy nuclei, they have been successful for neighbouring nuclei (72, 74). The ZORA-DFT method (75, 76) provides the benefits of the efficient DFT procedure with the ability to account for scalar and spin-orbit relativistic effects without the use of RECPs.

Computational details: Methods and molecular structures

Calculations of magnetic shielding tensors were performed using the gauge-including atomic orbital (GIAO) (77) method with Gaussian 98W (revision A.7) (21), Gaussian 98 (revision A.4) (78) (RHF and B3LYP), and the NMR module (79) of the Amsterdam density functional (ADF 2000.02, 2002.01, 2002.02) package (80) (ZORA-DFT). Gaussian 98 calculations were performed on an IBM RS/6000 workstation or a Windows-based PC. ADF calculations were performed on an IBM RS/6000 workstation or an AMD-based Linux PC or 8 processor cluster. RHF and B3LYP calculations employed locally dense Gaussian-type basis sets, which are part of the standard Gaussian 98 package. The full potential Slater-type ZORA basis sets used are available in the standard ADF package (see Table 1 for a description of ZORA basis sets). For all ADF calculations, the XC functional employed the local density approximation (LDA) given by Vosko, Wilk, and Nusair (VWN) (81) and the generalized gradient approximation (GGA) of Becke 88 (82) and Perdew 86 (83). All ZORA-DFT calculations include scalar relativistic corrections.

Atomic coordinates were calculated from X-ray structures (Table 2). Phenyl and cyclopentadienyl rings were assumed planar with hydrogens added at a fixed C—H bond length of 1.08 Å (104). Hydrogens were added to methyl and ethyl groups with an assumed tetrahedral geometry and a fixed bond length of 1.09 Å. To reduce computational time, one of the two similar phosphorus sites in compounds **3**, **13**, and **15** was modified by replacing the existing phenyl groups with methyl groups. The P—CH_3 bond length was fixed to the P—C_{ipso} bond length. The geometry of the hydrogen nuclei added to **15** was optimized at the HF/3-21G level of theory.

Unless noted otherwise, RHF and B3LYP calculations were performed for compounds **1**–**17** by employing the 6-31G(d) or 6-311+G(2d) diffuse basis set for phosphorus and directly bonded atoms, the LANL2DZ RECP for metallic centres, and 3-21G on the remainder of the molecule. ZORA-DFT calculations, including only scalar relativistic corrections, were performed using the ZORA (II) basis set on all nuclei.

Results and discussion

Phosphorus nuclear magnetic shielding tensors were calculated for the transition-metal-containing phosphine, phosphido, and phosphinidine compounds (**1**–**17**), shown in Fig. 1, using the RHF, B3LYP, and relativistic ZORA-DFT methods in an effort to determine the minimum basis set required to qualitatively reproduce experimental ^{31}P CS tensors. Many of the compounds investigated contain relatively heavy metal nuclei, for which the viability of these methods has not been tested previously. Phosphorus CS tensors for all compounds chosen have been formerly characterized by solid-state ^{31}P NMR techniques. For example, the calculated orientation of the phosphorus CS tensor principal components for compounds **6**, **7**, **9**, and **17** are compared with previously obtained data from single-crystal ^{31}P NMR experiments (28, 29, 92, 103).

Practical considerations

Chemical shift range

The CS range of ^{31}P is approximately 2000 ppm, extending from δ_{iso} = 1362 ppm for *t*-BuP[$(Cr(CO)_5]_2$ to δ_{iso} = –552 ppm for gaseous P_4 (105) with respect to 85% aq H_3PO_4. Differences between observed and calculated shifts should be considered relative to the CS range of phosphorus. For comparison of calculated with experimental values, agreement within 10% of the average of the experimentally measured spans for the compounds studied herein is considered excellent.

Errors owing to molecular geometry

The most reliable experimental structures have been employed for the shielding calculations herein; however, phosphorus CS tensors are known to be dependent on bond lengths and bond angles (27, 30, 32, 40, 44, 54). For example, in the case of phosphine, PH_3, Jameson et al. (51) have estimated $\partial\sigma(^{31}P)/\partial r \cong -150$ ppm/Å. Thus, any errors in the assumed structure make a *quantitative* comparison of calculated phosphorus magnetic shielding tensors with experiment difficult.

Intermolecular effects

The experimental data discussed herein, as well as the structural data used, are for compounds in the solid state. The experimental solid-state data intrinsically include intermolecular effects, which will affect the observed chemical shift to some extent. The calculations are performed on a single isolated molecule without consideration of intermolecular effects. Intermolecular effects are known to be predominantly *deshielding* for the isotropic value (106, 107); thus, one might expect systematic deviations in our gas-phase model from experimental values. Using phosphine as an example, the ^{31}P gas-to-liquid chemical shift is approximately 20 ppm (note, the phosphorus nucleus is more shielded in the gas phase) (59). In general, intermolecular ef-

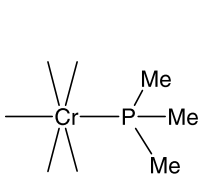
Note: For computational efficiency, one of the two similar phosphorus sites in compounds **3**, **13**, and **15** was modified by replacing the phenyl groups with methyl groups. Reported magnetic shielding tensors are for the phosphorus bearing the phenyl group.

fects, rovibrational averaging, and differences between assumed and actual molecular structure are expected to have a minor effect on chemical shifts compared with the experimental trends we are attempting to reproduce with the calculations (vide infra). In the discussion that follows, experimental and calculated chemical shifts will be compared without further explicit discussion of the gas-to-solid shifts.

Spin-orbit relativistic correction



The effect of the spin-orbit relativistic correction with the ZORA-DFT method on the phosphorus magnetic shielding has been investigated for phosphines **1**, **5**, and **8** using the ZORA (V) basis set and for **13** using the ZORA (II) and locally dense ZORA (I/V) (i.e., ZORA (V) for metallic centres, phosphorus, and directly bonded nuclei and ZORA (I) for the remainder of the molecule) basis sets. Compounds **1**, **5**, and **8** are isostructural, each with a different group VI transition metal. Previous calculations for this series did not include spin-orbit corrections, and Kaupp (48) postulated this as the reason for the observed deviation of the SOS-DFPT-IGLO calculation of the $W(CO)_5(PMe_3)$ phosphorus CS tensor from experimental values. Herein, both scalar-only and scalar + spin-orbit relativistic calculations have been performed. Table 3 provides a comparison of experimental and calculated values. Although the results for the tungsten compound (**8**) are poorest in both calculations, the spin-orbit calculation yields significant improvement over the scalar-only calculation (Fig. 2). Relative to experimental values, the scalar-only ZORA-DFT calculation underestimates all three phosphorus magnetic shielding tensor principal components and yields a larger span. The effect of including the spin-orbit correction increases when progressing down group VI from Cr to W. In all three cases, including the spin-orbit correction improves agreement with experiment, and as expected, the most noticeable effect is for **8**. For this complex, the agreement with experiment improves by over 10% for the tensor principal components and reduces the span from 72 to 32 ppm (relative to 12 ppm experimentally). The deviation of the calculated values from experiment (Δ = calcd – expt), averaged for the three complexes, are as follows: $\Delta\sigma_{iso} = -1$, $\Delta\sigma_{11} = -7$, $\Delta\sigma_{22} = -1$, $\Delta\sigma_{33} = 3$, and $\Delta\Omega = 10$ ppm. Inclusion of spin-orbit relativistic effects increased the computational time by approximately four, relative to the scalar-only calculation for **1**, **5**, and **8**.

For **13**, the ZORA (IV) and (V) scalar-only calculations yield isotropic values (inclusive of locally dense combinations) deshielded relative to experimental data by approximately 65 ppm (σ_{11} is affected predominantly).[2] The scalar-only ZORA (II) calculation provides values in excellent agreement with experiment. Inclusion of spin-orbit relativis-

tic effects for **13** with the ZORA (II) and locally dense ZORA (I/V) basis sets leads to an increase in shielding for all three principal components, with the greatest effect observed for σ_{33}, and an increased isotropic shielding of 33 ppm for both calculations. Thus, the effective deshielding observed when employing larger triple-ζ basis sets with the scalar-ZORA-DFT method may be due to the exclusion of the spin-orbit relativistic correction. The scalar-only ZORA (II) calculation is in best agreement with experiment and requires much less computational time.

Choice of basis sets

A series of calculations was performed on $Ru_2(CO)_6(\mu_2\text{-}PPh_2)_2$ (**13**), for which high-quality experimental X-ray (97) and solid-state NMR (27) data are available, to investigate the basis set dependence for the RHF, B3LYP, and ZORA-DFT methods (see Appendix A for discussion). Results are summarized in Fig. 3.[3] After examining these results, with consideration of computational time, as well as results obtained from investigation of the spin-orbit relativistic correction (vide supra), basis sets for calculations on the remaining compounds were chosen. RHF and B3LYP calculations were performed for compounds **1**–**17**, employing the 6-31G(d) or 6-311+G(2d) diffuse basis set for phosphorus and directly bonded atoms, the LANL2DZ RECP for metallic centres, and 3-21G on the remainder of the molecule. ZORA-DFT calculations, including only scalar relativistic corrections, were performed using the ZORA (II) basis set on all nuclei.

Comparison of calculated and experimental chemical shift tensors

The following discussion will deal with results obtained for both the 6-31G(d) and the 6-311+G(2d) locally dense basis sets (RHF and B3LYP) and the ZORA (II) basis set.[4] Discussion of observed trends for each of the computational methods will be divided into the following three general sections: (*i*) transition-metal phosphines (**1**–**8**), (*ii*) phosphido-bridging clusters (**10**–**15**), and (*iii*) terminal phosphido and phosphinidene (**16** and **17**). Compound **9** is treated separately from the other phosphines, as the metal centre is in a distorted square-planar bonding arrangement, not pseudo-octahedral as are **1**–**8**. The phosphorus nuclei in these compounds exhibit the following characteristic isotropic chemical shifts and spans: for the phosphines (**1**–**8**), δ_{iso} = –36 to 52 ppm and Ω = 11 to 158 ppm; for the three phosphorus sites in Wilkinson's catalyst (**9**), δ_{iso} = –50 to 76 ppm and Ω = 150 to 271 ppm; for the phosphido-bridging clusters (**10**–**15**), δ_{iso} = 114 to 185 ppm and Ω = 179 to 308 ppm; for the terminal phosphido (**16**), δ_{iso} = 1208 ppm and Ω = 2308 ppm; and for the phosphinidene (**17**), δ_{iso} = 414 ppm and Ω = 829 ppm. Figure 4 compares the RHF/6-311+G(2d), B3LYP/6-31(d), and ZORA (II) results with experimental values. Average deviations of calculated from experimental (Δ = calcd – exptl) ^{31}P magnetic shielding values for the phosphines (**1**–**8**) and phosphido-bridging compounds (**10**–**15**) are provided in Table 4.

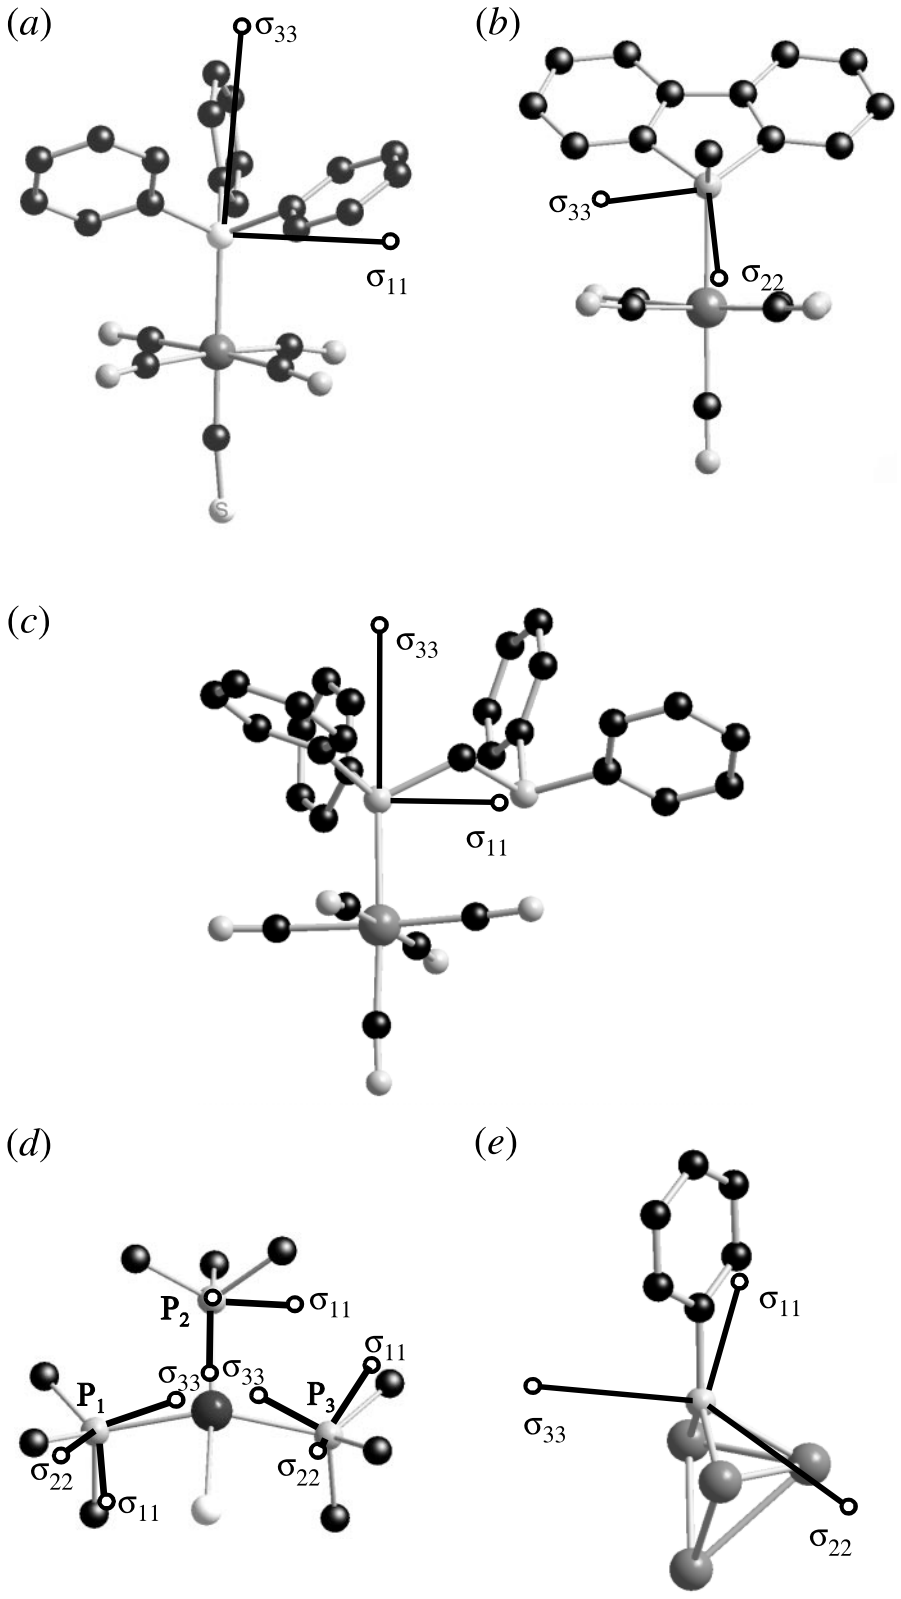
	ZORA (II)	22	21	28	16	–4

[a]RHF and B3LYP calculations employed locally dense basis sets; the indicated basis set was used for P and directly bonded nuclei, the LANL2DZ ECP was used for metallic centres, and 3-21G on all remaining nuclei. The ZORA-DFT calculation includes only scalar relativistic corrections.

Transition-metal phosphines

Transition-metal phosphine complexes exhibit ^{31}P isotropic magnetic *shieldings*, ranging from approximately 200 to 350 ppm (i.e., $\delta_{iso} \cong 130$ to –20 ppm) with spans less than 200 ppm. As already mentioned, previous theoretical investigations of the ^{31}P CS tensor in phosphines containing transition metals have been made by Kaupp (48), Ruiz-Morales and Ziegler (49), and van Wüllen (33). Kaupp concluded that proper interpretation of ^{31}P chemical shifts of substituted phosphine ligands in transition-metal complexes requires a detailed analysis of the electronic structure of the ligand; the increase in ^{31}P magnetic shielding observed when moving down the periodic table in the $M(CO)_5(PX_3)$ (M = Cr, Mo, W; X = H, Me, F, Cl) systems is the result of contributions from the perpendicular components of the shielding tensor ($\sigma_\perp$) (48). A subsequent study by Ruiz-Morales and Ziegler (49) (excluding M = W, including X = Ph) identified both positive and, in the case of X = F, Cl, negative contributions to the ^{31}P chemical shift from paramagnetic couplings between specific ligand and complex orbitals. In the present study we report calculated phosphorus magnetic shielding tensors for large phosphine ligands (e.g., PPh_3, DBP (5-phenyldibenzophosphole)) and the group VI $M(CO)_5(PMe_3)$ systems, including spin-orbit relativistic effects. In addition, we investigate the influence of varying the W—P bond length, as well as the W-P-C_{Me} bond angle in **8**, and examine the phosphorus CS tensors for the three unique phosphorus nuclei in Wilkinson's catalyst (**9**).



Comparison of the calculated and experimental values of the phosphorus magnetic shielding tensor principal components yields several insights. For **1**–**8**, the RHF/6-311+G(2d) calculations provide the most accurate results for the isotropic shielding and the three principal components of the magnetic shielding tensor; however, the span is consistently overestimated, as follows: $\Delta\sigma_{iso} = -1$, $\Delta\sigma_{11} = -33$, $\Delta\sigma_{22} = -2$, $\Delta\sigma_{33} = 32$, and $\Delta\Omega = 66$ ppm. In most cases σ_{11} (except **5**) is deshielded and σ_{33} is shielded relative to experimental values. Both the B3LYP and ZORA-DFT calculations with only a double-ζ quality basis set provide results that are surprisingly accurate. For the B3LYP/6-31G(d) calculations, the average deviations from experiment are $\Delta\sigma_{iso} = 35$, $\Delta\sigma_{11} = 19$, $\Delta\sigma_{22} = 41$, $\Delta\sigma_{33} = 46$, and $\Delta\Omega = 27$ ppm. The ZORA (II) calculation overestimates the isotropic shielding, σ_{22}, and σ_{33} in most cases (except σ_{33} for **7**), as follows: $\Delta\sigma_{iso} = 37$, $\Delta\sigma_{11} = 13$, $\Delta\sigma_{22} = 48$, $\Delta\sigma_{33} = 49$, and $\Delta\Omega = 36$ ppm. The RHF/6-31G(d) calculations do not give qualitatively accurate results relative to experiment (except for the span that is fortuitously reproduced with $\Delta\Omega = 36$ ppm). The RHF and B3LYP results with the 6-31G(d) basis set display similar trends, and apart from σ_{11} for **3**, the calculated tensor principal components, and thus the isotropic values, are shielded relative to experiment. Consistently, the calculated span is greater than the experimental span. In principle, one should expect an improvement in calculated values upon increasing the basis set to 6-311+G(2d) (vide supra); in practice, however, with the B3LYP method, calculated results worsened relative to experiment. For all compounds, the tensor principal components and the isotropic values are deshielded relative to the experimental values, and the calculated spans exceed those measured.

In an experimental ^{31}P NMR study of compound **4** the direction of greatest shielding at the phosphorus site was assumed to be along the P—Cr bond axis (88). Since the approximate local mirror plane of the PPh_3 ligand is preserved, the principal component of least shielding is either in the local mirror plane or perpendicular to it (88). Experimentally the two perpendicular components are reported to exhibit the same chemical shift, even though the local mirror plane is only approximate. The RHF and B3LYP methods indicate that σ_{33} is 8.5 ± 1.5° off the Cr—P bond axis (supporting the assumption made in the experimental study) and that σ_{11} is perpendicular to the local mirror plane (Fig. 5*a*). The ZORA (II) calculation predicts σ_{33} at an angle of 15° with the Cr—P bond axis.

The phosphorus CS tensor orientation for **6** has been determined experimentally via a single-crystal ^{31}P NMR study (28). This compound provides an important example as to why one should not always assume that the most shielded component of the phosphorus CS tensor in these systems would be approximately along the metal–phosphorus bond.

Orientation of the ^{31}P CS tensor in its PAS for (*a*) *trans*-$Cr(CO)_4CS(PPh_3)$ (**4**), (*b*) $Mo(CO)_5$(MeDBP) (**6**), (*c*) $Mo(CO)_5(\eta^1$-dppm) (**7**), (*d*) $RhCl(PPh_3)_3$ (**9**), and (*e*) $Ru_4(CO)_{13}(\mu_3$-PPh) (**17**). For clarity, hydrogen nuclei have been omitted; (*d*) only *ipso*-carbons of the phenyl rings are shown; and (*e*) carbonyl groups are omitted.

© 2003 NRC Canada

In this case, the electronic environment about phosphorus was found to deviate considerably from axial symmetry; σ_{33} is not along the Mo—P bond axis. In fact, both σ_{11} and σ_{33} are perpendicular to the Mo—P axis, with σ_{33} approximately perpendicular to the local mirror plane. Experimentally the Mo-P-σ_{ii} angles are 87°, 8°, and 83° for i = 1, 2, and 3, respectively. The RHF and B3LYP calculations with the 6-31G(d) basis set and the ZORA (II) calculation provide qualitatively accurate orientations (Fig. 5*b*), whereas the RHF and B3LYP calculations with the triple-ζ basis set switch the placement of σ_{22} and σ_{33}. Experimentally these two components differ by only 18 ppm. The difference between σ_{22} and σ_{33} in the calculations ranges from 6 ppm for the ZORA (II) calculation to 15 ppm for the RHF/6-311+G(2d) calculation. When the CS tensor for a particular nucleus nears axial symmetry, one must take care to accurately determine the proper orientation of the two components that are close in chemical shift. The RHF and B3LYP methods indicate an Mo-P-σ_{11} angle of 92.5 ± 2.5° (ZORA (II) 101°). Excluding orientations obtained from the 6-311+G(2d) calculations, the Mo-P-σ_{22} angle ranges from 10° (B3LYP) to 17° (RHF) and the Mo-P-σ_{33} angle ranges from 73° (RHF) to 89° (ZORA (II)).

For **7**, all three computational methods are in agreement with the experimental phosphorus CS tensor orientation determined via a single-crystal ^{31}P NMR study (29); σ_{33} is 11.2° off the Mo—P bond axis and σ_{11} is approximately perpendicular to one of the Mo-P-C_{ipso} planes (Fig. 5*c*). The RHF and B3LYP results indicate that the Mo-P-σ_{33} angle is 14 ± 2° and σ_{11} is 19 ± 1° off the normal to the plane. The ZORA (II) calculation indicates an Mo-P-σ_{33} angle of 36° and that σ_{11} is 13° off the normal to the plane.

Wilkinson's catalyst, $RhCl(PPh_3)_3$ (**9**), contains three crystallographically and magnetically non-equivalent phosphorus nuclei. The orientations of the phosphorus CS tensors in their PAS have been proposed from a single-crystal ^{31}P NMR study (92), and thus **9** is a suitable system for investigating the reliability of quantum chemical calculations for the reproduction of the tensor orientations. This compound proved challenging for all computational methods employed. The calculations employing double-ζ quality basis sets provided results closest to the experimental values. The RHF/6-31G(d) calculation performed best; average deviations for the three phosphorus nuclei are $\Delta\sigma_{iso}$ = –28, $\Delta\sigma_{11}$ = –10, $\Delta\sigma_{22}$ = –80, $\Delta\sigma_{33}$ = 9, and $\Delta\Omega$ = 19 ppm. Both the RHF and B3LYP methods with the 6-311+G(2d) basis set yield values deshielded on the order of 100 ppm. The values of the phosphorus magnetic shielding tensor principal components were calculated to be deshielded relative to experiment, except in the case of the RHF/6-31G(d) calculations. These trends are different from those observed for the other phosphines investigated. As noted, the other eight phosphines studied are in a pseudo-octahedral bonding arrangement, whereas $RhCl(PPh_3)_3$ is in a slightly distorted square planar arrangement. Intermolecular effects are expected to be more significant for this structure, and ligands are expected to display magnetic shielding trends characteristic of the structural environment of the metal. However, because of the large triphenylphosphine ligands, distances from the metal to nuclei of neighbouring molecules are greater than 4.4 Å. Although we cannot conclude that the difference in magnetic shielding trends observed here is solely a result of the structural environment of the metal, a study investigating observed trends in calculated shieldings for various structural systems could be conducted. Experimentally, the orientation of the three phosphorus CS tensors was assigned by assuming that σ_{33} lies approximately along the P—Rh bond in each case. All methods employed herein qualitatively reproduce the experimental CS tensor orientation for each of the three phosphorus sites, indicating the same general orientation (Fig. 5*d*). Numerical values are presented in Table 5.

Table 5. Calculated[a] orientation of the three ^{31}P magnetic shielding tensors in Wilkinson's catalyst, $RhCl(PPh_3)_3$ (**9**).

Site	Rh-P-σ_{ii}	Angle (°)	
P_1	i = 1	85	(ZORA (II) = 92)
	i = 2	90±1	
	i = 3	176.5±1.5	
P_2	i = 1	89.5±2.5	
	i = 2	90.5±2.5	
	i = 3	177±1	
P_3	i = 1	96±1	
	i = 2	78.5±1.5	(ZORA (II) = 63)
	i = 3	166.5±1.5	(ZORA (II) = 153)

[a]Unless otherwise stated, the angle given is the average of the angles obtained from the RHF, B3LYP, and ZORA (II) calculations. RHF and B3LYP calculations employed locally dense basis sets; 6-31G(d) or 6-311+G(2d) was used for P and directly bonded nuclei, the LANL2DZ ECP for metallic centres, and 3-21G on all remaining nuclei.

Phosphido-bridging clusters

Phosphido-bridging groups in transition-metal complexes normally exhibit ^{31}P isotropic shieldings between 100 and 600 ppm (i.e., $\delta_{iso} \cong$ 230 to –270 ppm) with spans of less than 500 ppm. Recently, Eichele et al. (27) reported an in-depth experimental and theoretical study of phosphorus CS tensors in ruthenium phosphido-bridging complexes. In the present study we investigate the ability of various theoretical methods to reproduce the available experimental data for phosphido-bridging compounds containing first- and second-row transition metals. The data discussed below includes only the phosphido-bridging compounds (**10**–**15**).

As with the phosphines, the B3LYP/6-31G(d), ZORA (II), and RHF/6-311+G(2d) calculations yield the most accurate results relative to experiment. For the phosphido-bridging compounds, the B3LYP/6-31G(d) method provides excellent results, as follows: $\Delta\sigma_{iso}$ = 15, $\Delta\sigma_{11}$ = 21, $\Delta\sigma_{22}$ = 26, $\Delta\sigma_{33}$ = –3, and $\Delta\Omega$ = –24 ppm. With the double-ζ ZORA (II) basis set, the ZORA-DFT method yields results comparable to the B3LYP/6-31G(d) calculations but reproduces the span more accurately; $\Delta\Omega$ = –4 ppm. The RHF/6-311+G(2d) calculations provide results in good agreement with experiment, although the calculated isotropic shielding and σ_{11} are consistently overestimated. The average deviations are $\Delta\sigma_{iso}$ = 36, $\Delta\sigma_{11}$ = 76, $\Delta\sigma_{22}$ = 22, $\Delta\sigma_{33}$ = 11, and $\Delta\Omega$ = –65 ppm. Since σ_{11} is not well reproduced, the accuracy of σ_{iso} is clearly the result of the superb values calculated for σ_{22} and σ_{33}. This illustrates the importance of studying the tensor principal components obtained from a calculation rather than relying solely on the isotropic value. Similar to results ob-

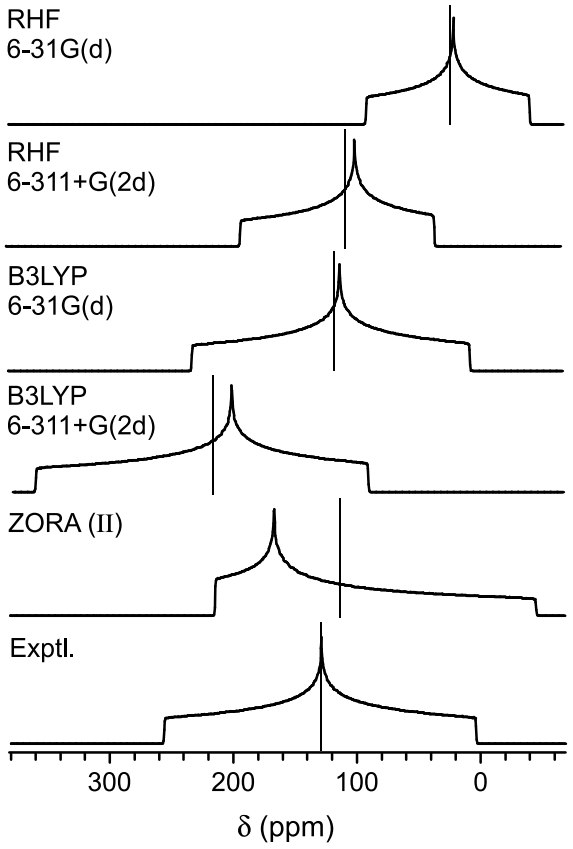
© 2003 NRC Canada

tained for the phosphine complexes, employing the 6-311+G(2d) basis set with the B3LYP functional for the phosphido-bridging complexes provides values in poor agreement with experiment relative to the double-ζ calculation. The average deviations from experiment with the larger basis set are $\Delta\sigma_{iso} = -66$, $\Delta\sigma_{11} = -78$, $\Delta\sigma_{22} = -52$, and $\Delta\sigma_{33} = -67$ ppm; σ_{11} and σ_{33} are always underestimated relative to experimental values. Despite the deviations exhibited for the tensor principal components, the span is fortuitously reproduced with $\Delta\Omega = 12$ ppm. Disappointing results are realized with the RHF/6-31G(d) calculations. In all cases, the calculated principal components and isotropic values are greatly overestimated with $\Delta\sigma_{iso} = 121$, $\Delta\sigma_{11} = 170$, $\Delta\sigma_{22} = 106$, $\Delta\sigma_{33} = 89$, and $\Delta\Omega = -81$ ppm.

The importance of considering the three principal components of the magnetic shielding tensor is illustrated in Fig. 6. The ^{31}P NMR powder pattern simulated from experimental data is compared with results from the three computational methods employed for **12**, a phosphido-bridging ruthenium cluster. There is obviously great variation in the calculation of the ^{31}P CS tensor, depending on the computational method and basis set employed. The RHF/6-311+G(2d), B3LYP/6-31G(d), and ZORA (II) calculations all yield excellent values of the isotropic shielding. The RHF/6-311+G(2d) method underestimates the span by 96 ppm, as σ_{11} is shielded by 66 ppm and σ_{33} is deshielded by 30 ppm relative to experiment. The ZORA (II) method reproduces the span very well, but σ_{11} and σ_{33} are shielded by 42 and 49 ppm, respectively, and σ_{22} is deshielded by 38 ppm relative to experiment. These observations bring a key point to the forefront: calculations may reproduce the isotropic shift (and (or) span) regardless of the agreement between experimental and calculated values of the CS tensor principal components.

Although the orientation of the phosphorus CS tensor in the molecular framework of the iron phosphido-bridging complex (**10**) has not been investigated experimentally, Eichele et al. (27) have recently proposed the orientation of the phosphorus CS tensor in ruthenium phosphido-bridging compounds. Their single-crystal ^{31}P NMR study of **13** (denoted compound **4** in ref. 27) yielded two possible orientations of the phosphorus CS tensor, placing σ_{11} either 25° above or below the phosphorus–phosphorus internuclear vector as depicted in Fig. 7. Using RHF GIAO calculations, σ_{11} was predicted to be oriented above the internuclear vector. In the present study, the B3LYP and ZORA (II) methods indicate the same orientation for **10** and **13** as was proposed in ref. 27, placing the least-shielded component (σ_{11}) approximately 25° above the bridging ligand internuclear vector. Curiously, the RHF calculations provide a different orientation for **10**, placing σ_{11} approximately 25° below and σ_{33} 65° above the bridging ligand internuclear vector. In this study we have not otherwise encountered orientations from the RHF, B3LYP, and ZORA methods that are in disagreement, except for **6**, where two of the tensor principal components exhibit similar chemical shifts (vide supra). Perhaps proper treatment of electron correlation is necessary to obtain the correct orientation of the phosphorus CS tensor in compound **10**, which contains a μ_2-Cl ligand, and thus, in this case the RHF method is inadequate.

Fig. 6. Simulated ^{31}P powder patterns for compound **12**. Experimental values (ref. 27). The RHF and B3LYP calculations employed locally dense basis sets. Solid vertical line indicates δ_{iso}. Note: the scale is chemical shift, δ, not magnetic shielding, σ.



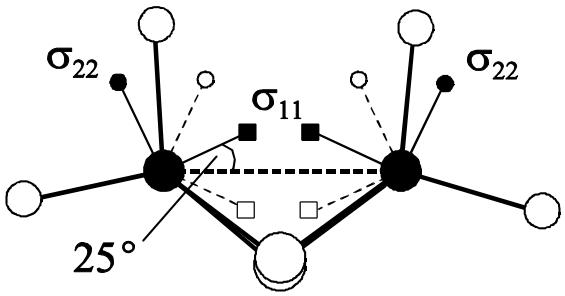


Fig. 7. Two possible orientations of the ^{31}P CS tensor for $Ru_2(CO)_6(\mu_2\text{-}PPh_2)_2$ (**13**) obtained from a single-crystal NMR study (adapted from ref. 27). For clarity, only the metallic centres, phosphorus nuclei (shaded), and *ipso*-carbons of the phenyl groups are shown. B3LYP and ZORA-DFT calculations for $Fe_2(CO)_6(\mu_2\text{-}Cl)(\mu_2\text{-}PPh_2)$ (**10**) and **13** reproduce the orientation, placing σ_{11} 25° above the bridging ligand internuclear vector.

Terminal phosphido and phosphinidene

Terminal phosphido complexes represent a class of compounds that exhibit the largest observed ^{31}P chemical shifts (101). For example, compound **16** has an isotropic chemical shift of 1208 ppm and a span of over 2300 ppm. Both the B3LYP and ZORA-DFT methods produce results in agreement with experiment. Experimentally, the values of σ_{11} and

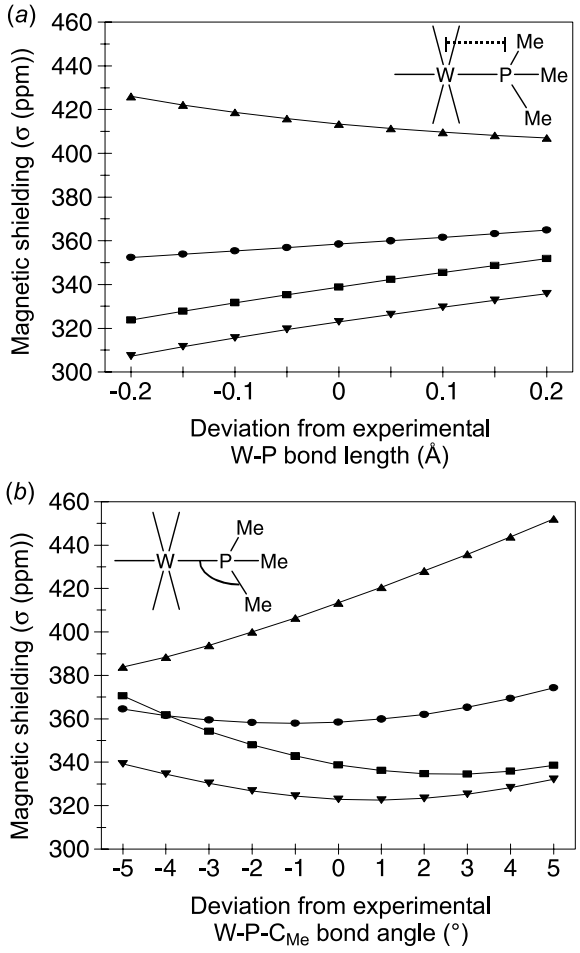
© 2003 NRC Canada

σ_{22} are identical, –1650 ppm. The B3LYP/6-311+G(2d) method performs well, reproducing values of σ_{11} and σ_{22} that are closest to each other and experimental values, and the span is within 35 ppm. The ZORA (II) method most accurately calculates the isotropic shielding and the span, differing from experiment by –14 and 27 ppm, respectively. Although the σ_{11} and σ_{22} values obtained with the ZORA-DFT method are not similar, their average, –1626 ppm, is only 24 ppm greater than the experimental value. The RHF calculations fail completely, likely due to the combination of the demands of representing the bonding arrangement and the formally localized lone pair of electrons on the phosphorus (vide supra). The advantage of DFT methods is clearly demonstrated by this example; despite the difficulty of this calculation, the performance of both the B3LYP and ZORA (II) methods is outstanding.

Phosphorus CS tensors have been investigated experimentally for several phosphinidenes. Transition-metal phosphinidenes generally exhibit phosphorus CS tensor spans greater than 500 ppm and isotropic shieldings for μ_3 and μ_4 complexes, including those containing second- and third-row transition metals, ranging from –200 to 300 ppm (108). However, many contain four or more transition metals and large ligands with complex bonding arrangements, thus hindering computational studies. At this time we limit our study to $Ru_4(CO)_{13}(\mu_3\text{-PPh})$ (**17**), for which the phosphorus CS tensor orientation was determined in a single-crystal ^{31}P NMR study (compound **2**, ref. 103). Experimentally, σ_{11} is highly deshielded, resulting in a large span of 829 ppm. Bühl et al. (50) have previously calculated the phosphorus CS tensor for **17** employing the SOS-DFPT-IGLO formalism, reporting values for the tensor principal components and their orientation in the PAS. Relative to experiment, the values reported are $\Delta\sigma_{iso}$ = 16, $\Delta\sigma_{11}$ = 41, $\Delta\sigma_{22}$ = 12, $\Delta\sigma_{33}$ = –5, and $\Delta\Omega$ = –46 ppm.

Herein, the RHF/6-311+G(2d), B3LYP/6-31G(d), and ZORA (II) methods outperform the RHF/6-31G(d) and B3LYP/6-311+G(2d) calculations. RHF/6-311+G(2d) provides the most impressive agreement with experiment. The isotropic shielding and σ_{33} are deshielded by 9 and 35 ppm; σ_{11} and σ_{22} are shielded by only 1 and 8 ppm, respectively; and the span is underestimated by 37 ppm relative to experiment. The B3LYP/6-31G(d) and ZORA (II) results are also excellent, considering the span of the CS tensor. The experimental ^{31}P CS tensor orientation for **17** was rationalized via frontier molecular orbital calculations, which determined that σ_{33} is perpendicular to the open face formed by the cluster of Ru nuclei and that σ_{11} forms an angle of 8° with the C—P bond axis. Calculations of Bühl et al. (50) reproduce the experimental orientation, predicting σ_{11} to be 9° off the C—P bond. The angle reported herein for σ_{33} relative to the open face of the cluster is the average of the three angles obtained by considering the three different planes that may be formed by the phosphorus nucleus and any two of the three ruthenium nuclei. The RHF and B3LYP methods indicate that σ_{33} forms an angle of 107.5 ± 2° with the open face and σ_{11} an angle of approximately 14° with the C—P bond axis (Fig. 5*e*). From the ZORA (II) calculation, σ_{33} forms an angle of 103° with the open face and σ_{11} is at an angle of 9° with respect to the C—P bond axis.

Effect of systematic geometric variation on nuclear magnetic shielding



Quantum chemical calculations are able to provide direct information regarding the effects of systematic geometric variations on magnetic shielding tensors (109). However, experimentally, different ligands must be used to alter the system geometry, resulting in uncertainty as to what portion of the observed change in the CS tensor is actually due to the geometric variation and not the ligand change. Numerous quantum chemical studies have investigated the effects of geometric variations on the ^{31}P magnetic shielding tensor in smaller phosphorus-containing compounds (30, 32, 40, 42, 44, 46, 51–54). Recently, Avalle et al. (110) performed B3LYP-DFT calculations of ^{119}Sn chemical shifts for a series of organometallic compounds and found that the Sn-N-C bond angle strongly influences the calculated chemical shift. As well, we have previously studied the effect of varying the Ru-P-Ru bond angle in **13** via alteration of the Ru—P bond length (27), supporting an experimental correlation established by Carty et al. (94). As expected, a general ^{31}P deshielding trend was observed upon decrease of the Ru-P-Ru angle (increase of the Ru—P bond lengths).

The impact of systematic geometric variation on the phosphorus magnetic shielding tensor of the transition-metal phosphine $W(CO)_5(PMe_3)$ (**8**) was investigated using the RHF/6-311+G(2d) method. The W—P bond length was varied by ±0.2 Å in 0.05 Å increments. The W-P-C_{Me} angles were varied by ±4° in increments of 1°. The phosphorus magnetic shielding tensor for phosphine ligands bound to transition metals is often oriented such that σ_{33} lies approximately along the M—P bond, as is the case with **8**. As such, one would expect that a change in the bond length will have the least impact on the shielding component along this direction, while the perpendicular components will be more influenced. As evident in Fig. 8*a*, σ_{33}, which lies along the W—P bond axis, is more shielded for shorter W—P bond lengths (47 ppm/Å), while the perpendicular tensor components display more prominent deshielding trends (–70 ppm/Å). As expected, the isotropic shielding exhibits a less dramatic dependence; for shorter W—P bond lengths a moderate decrease in shielding is observed (–31 ppm/Å). Varying the W-P-C_{Me} bond angles produces some interesting trends in the values of the tensor principal components (Fig. 8*b*). For W-P-C_{Me} bond angles smaller than experimental values, σ_{33} exhibits an almost linear decrease in shielding while σ_{22} becomes more shielded. Bond angles up to 3° from experimental geometry result in deshielding of σ_{22}, while larger angles cause σ_{22} to increase. Any change in the W-P-C_{Me} bond angles leads to an increase in shielding for σ_{11}.

We have employed the iron phosphido-bridging complex (**10**) as a model system to investigate theoretically an experimentally determined correlation between the ligand bond angle (Fe-P-Fe) and the observed ^{31}P isotropic chemical shift in iron phosphido-bridging compounds. Compound **10** was included in the experimental study by Carty et al. (94). Herein, the Fe-P-Fe bond angle in **10** was varied from 69° to 76° in 1° increments by proportionally changing the Fe—P bond lengths. The B3LYP/6-311+G(2d) locally dense method was employed for this study. Similar trends in the phosphorus magnetic shielding tensor isotropic and principal

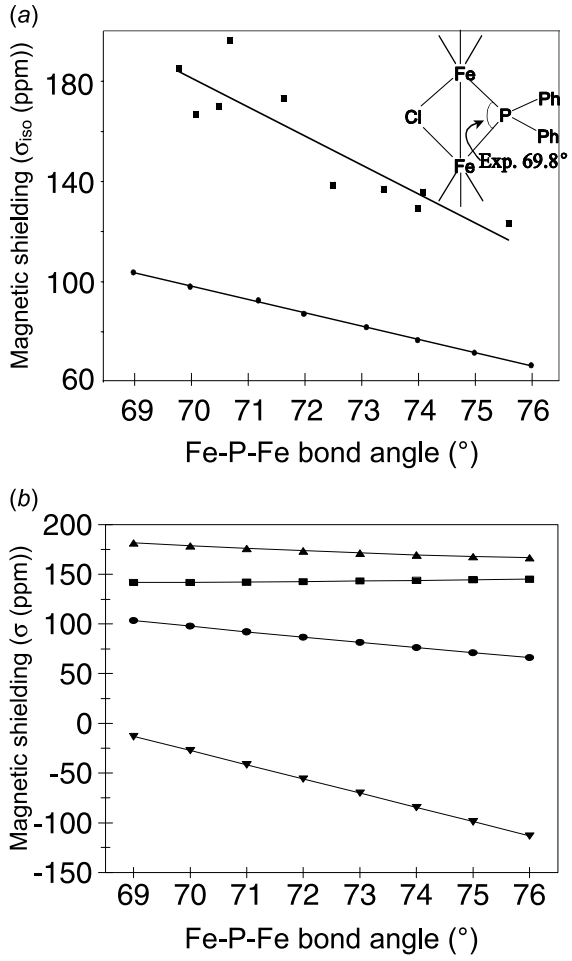
Fig. 8. Effect of systematic geometric variation of the W—P bond length (*a*) or the W-P-C_{Me} bond angle (*b*), relative to experimental values, on the calculated ^{31}P magnetic shielding for $W(CO)_5(PMe_3)$ (**8**). σ_{iso} = ●, σ_{11} = ▼, σ_{22} = ■, σ_{33} = ▲. Calculated values obtained with the RHF/6-311+G(2d) locally dense basis set method.



component values were observed for both **10** and the ruthenium analogue, **13** (27). As the M-P-M bond angle increases, a general deshielding of σ_{iso} is observed, with the trend being dictated by σ_{11}, in agreement with experimental results (94) (Fig. 9). Interestingly, when employing the RHF method in this study of **10**, the deshielding trend is dominated by σ_{33}. In all cases the trend is controlled by the phosphorus CS tensor principal component that is above the internuclear vector between the bridging ligands (vide supra). By fixing the ligand—metal bond length and varying the metal—metal bond length in a model phosphido compound, correlations between the degree of metal—metal interaction and ^{31}P chemical shift could also be investigated.

Conclusions

Experimental ^{31}P CS tensor data for a range of transition-metal-containing phosphine, phosphido, and phosphinidene complexes have been compared with results obtained from quantum chemical calculations employing GIAO RHF, B3LYP, and relativistic ZORA-DFT methods. The results

Fig. 9. Relationship between the Fe-P-Fe angle in $Fe_2(CO)_6(\mu_2\text{-}Cl)(\mu_2\text{-}PPh_2)$ (**10**) and the calculated ^{31}P magnetic shielding tensor. (*a*) The calculations confirm the experimentally observed (ref. 94) general deshielding trend as the Fe-P-Fe bond angle increases in a series of $Fe_2(CO)_6(\mu_2\text{-}PPh_2)(\mu_2\text{-}X)$ (X = ligand) complexes. Illustrated in (*b*) is the dependence of the calculated principal components on the Fe-P-Fe angle. σ_{iso} = ●, σ_{11} = ▼, σ_{22} = ■, σ_{33} = ▲. Calculated values obtained with the B3LYP/6-311+G(2d) locally dense basis set method.

presented are indicative of the viability and dependability of these methods for the computation of phosphorus magnetic shielding tensors in transition-metal-containing compounds. Numerous trends are observed in the deviation of calculated from experimental values of the magnetic shielding tensors. As well, the usefulness of employing computational methods for the investigation of geometric dependencies of the nuclear magnetic shielding tensor has been demonstrated. The present work indicates that a double-ζ quality basis set with either the B3LYP functional or the scalar-ZORA-DFT method *qualitatively* reproduce experimental ^{31}P CS tensors in phosphorus compounds containing first-, second-, or third-row transition metals. Use of larger, triple-ζ basis sets with these methods yields values that deviated farther from experiment. The RHF method requires a triple-ζ doubly polarized diffuse basis set to approach experimental values of the ^{31}P CS tensor principal components, yet completely fails

© 2003 NRC Canada

for the terminal phosphido group in compound **16**. Inclusion of the spin-orbit relativistic correction with the ZORA-DFT method requires use of the triple-ζ basis set to reproduce experimental data. These methods will, in most cases, qualitatively reproduce the experimental orientation of the ^{31}P CS tensor in its PAS, although the RHF method should be avoided in systems where electron-correlation may be very important.

Systematic trends in the deviation of calculated from experimental phosphorus magnetic shielding tensors for the phosphines investigated herein have been observed, as follows: RHF and B3LYP calculations at the 6-31G(d) level always overestimate the tensor principal components (i.e., more shielded than experiment) and the span; the RHF/6-311+G(2d) method usually underestimates σ_{11} and always overestimates σ_{33} and Ω; the B3LYP/6-311+G(2d) calculations provide values that are always deshielded and a span greater than experiment; and in most cases, the ZORA (II) method overestimates σ_{iso}, σ_{22}, and σ_{33}. For the phosphido-bridging compounds investigated herein, all values from the RHF/6-31G(d) calculations are more shielded and provide larger spans than experiment; the RHF/6-311+G(2d) values for σ_{iso} and σ_{11} are overestimated; the B3LYP/6-311+G(2d) results for σ_{11} and σ_{33} are deshielded relative to experiment; and σ_{iso} from the ZORA (II) method is too large. In general, with the same basis sets, the RHF calculations converged more rapidly than those with the B3LYP functional. Although, in most cases, the B3LYP/6-31G(d) and ZORA (II) calculations yield values in excellent agreement with experiment, one should note that the ZORA (II) method requires more computational time. Clearly, for more quantitative agreement with experiment, much larger basis sets, medium effects, and rovibrational averaging would need to be considered. At this time such computations on molecules as large as those considered here are not feasible.

With continual improvements in technology and the development of new computational techniques, the outlook for the calculation of magnetic shielding tensors in systems containing heavy nuclei is very bright. Recent developments correcting for self-interaction in approximate DFT methods (111) and the introduction and success of magnetically corrected basis sets for magnetic shielding tensor calculations (112) is extremely promising. The results presented here clearly demonstrate that modern computational techniques are a valuable resource to experimentalists interested in a greater understanding of the relationship between phosphorus chemical shifts and molecular structure.

Acknowledgments

The authors thank all members of the solid-state NMR group at the University of Alberta and Prof. Cynthia Jameson for helpful comments and discussions. Dr. David Bryce is thanked for assistance with the ZORA-DFT calculations and several useful suggestions. Prof. P.-N. Roy is thanked for allowing use of his AMD-based cluster, *Plethora*, sponsored by the Canadian Foundation for Innovation (CFI). R.E.W. is a Canada Research Chair in Physical Chemistry at the University of Alberta and thanks the Natural Sciences and Engineering Research Council of Canada (NSERC) and the University of Alberta for research grants. K.W.F. thanks NSERC, the Alberta Ingenuity Fund, and the University of Alberta for post-graduate scholarships.

Appendix A: Investigation of basis set performance.

To investigate the effectiveness and efficiency of various locally dense (A1) basis set combinations with the RHF and B3LYP methods, a series of calculations was performed on $Ru_2(CO)_6(u_2\text{-}PPh_2)_2$ (**13**). Results are summarized in Fig. 3.[5] This compound is a typical phosphido-bridging, transition-metal carbonyl complex with $\delta_{iso}(^{31}P)$ = 114 ppm (σ_{iso} = 214 ppm) and Ω = 308 ppm (A2). The basis sets for the phosphorus and directly bonded nuclei were varied in each calculation, while the LANL2DZ RECP (A3) was used for transition metals, and 3-21G was employed for the remainder of the molecule. The RHF method, with the small 3-21G basis set, does not reproduce experimental isotropic values (Fig. 3*a*). A significant improvement is noted upon use of a double-ζ quality basis set (cc-pVDZ or 6-31G(d)), but inclusion of diffuse functions yields no greater accuracy for the increased computational requirement. The RHF results appear to converge to the experimental values of the ^{31}P CS tensor principal components upon addition of a third outer valence function and the inclusion of diffuse functions and a single polarization function (6-311+G(d)). The addition of a second polarization function yields calculated values that effectively reproduce experimental data. As depicted in Fig. 3*b*, the B3LYP functional reproduces experimental values of the principal components of the ^{31}P magnetic shielding tensor in **13** with only a singly polarized double-ζ quality basis set. The basis set dependence is similar to that of the RHF method, except that the values obtained with the B3LYP method are deshielded; use of a triple-ζ basis set with the B3LYP functional provides results that are deshielded on the order of 100 ppm relative to experiment and RHF results. However, calculations employing the quadruple-ζ basis set cc-pVQZ begin to approach the experimental values. In general, the addition of polarization functions had a deshielding effect with both the RHF and B3LYP methods. Based on these results, RHF and B3LYP calculations were performed for **1**–**17**, employing the 6-31G(d) or 6-311+G(2d) diffuse basis set for phosphorus and directly bonded atoms.

ZORA-DFT calculations were performed for compound **13**, employing the full potential Slater-type ZORA (II), (IV), and (V) relativistic basis sets, as well as numerous locally dense combinations. The notation used for indication of locally dense basis sets is as follows: ZORA (I/V) signifies the ZORA (V) basis set for metallic centres, phosphorus, and directly bonded atoms and the ZORA (I) basis set for the remainder of the molecule. Calculations for **13** indicate that the use of locally dense basis sets for relativistic ZORA-DFT calculations yield similar data to those obtained through the use of uniform basis sets (Fig. 3*c*).[6] The largest discrepancy for the isotropic magnetic shielding was observed for the ZORA (I/IV) combination relative to the ZORA (IV) results (+9 ppm). In most cases, σ_{11} (except for ZORA (I/V)) is deshielded, while σ_{22} and σ_{33} (except for ZORA (III/IV)) are shielded relative to the results obtained from use of the larger basis set only. Upon use of a locally dense basis set the span increased 9 ppm on average. The use of locally dense basis sets substantially reduces the required computational time; the ZORA (I/V) calculation required approximately one fifth the time of the ZORA (V) calculation. For efficiency, when a triple-ζ level of theory with the ZORA-DFT method is desired, with little compromise to the results of the calculation, the use of locally dense basis sets is highly recommended for magnetic shielding calculations.

Inclusion complexation involving sugar-containing species: β-cyclodextrin and sugar surfactants

Vincent C. Reinsborough and Vanessa C. Stephenson

Abstract: Surface tension, proton NMR, and computer modeling studies were undertaken in nonionic alkylpolyglycoside (APG) solutions containing β-cyclodextrin (β-CD) with a view to characterize the inclusion complexes formed and to determine if the sugar entities of the host and guest molecules played a significant role in the process. The APGs investigated were four glucopyranosides (octyl G8, decyl G10, dodecyl G12, tetradecyl G14) and two maltosides (decyl M10, dodecyl M12). Critical micelle concentrations (CMC) were obtained in the surfactant–β-CD systems, which in all cases increased with increasing β-CD concentration. The 1:1 APG–β-CD inclusion complex was principally formed with binding constants of 425 (mol $L^{-1})^{-1}$ for the G12 complex, 340 (mol $L^{-1})^{-1}$ for the G10 complex, and 125 (mol $L^{-1})^{-1}$ for the M12 complex. The preferred configuration of the G-12–β-CD complex has the surfactant tail coiled in the CD cavity with the surfactant sugar moiety sealing off the narrower opening of the CD torus.

Key words: alkylpolyglycoside, β-cyclodextrin, NMR, critical micelle concentration, surface tension.

Résumé : Afin de caractériser les complexes d'inclusion qui se forment et pour déterminer si les sucres des molécules hôtes et invitées jouent un rôle significatif dans le processus, on a entrepris des études de tension superficielle, de RMN du proton et de modélisation moléculaire de solutions de polyglucosides d'alkyle non ioniques (PGA) contenant de la β-cyclodextrine (β-CD). Les PGA étudiés sont quatre glucopyranosides (d'octyle G8, de décyle G10, de dodécyle G12 et de tétradécyle G14) et deux maltosides (de décyle M10 et de dodécyle M12). On a déterminé les concentrations micellaires critiques (CMC) dans les systèmes agent de surface–β-CD qui augmentent dans tous les cas avec une augmentation de la concentration de β-CD. Le complexe d'inclusion principal est le PGA–β-CD 1:1 avec le G12 (constante de fixation = 425 (mol $L^{-1})^{-1}$), le G10 (constante de fixation = 340 (mol $L^{-1})^{-1}$) et le M12 (constante de fixation = 125 (mol $L^{-1})^{-1}$). Dans la configuration privilégiée par le complexe G1–β-CD, la queue de la chaîne de l'agent de surface est repliée dans la cavité de la CD alors que la portion sucrée de l'agent de surface ferme l'ouverture moins large du tore de la CD.

Mots clés : polyglycoside d'alkyle, β-cyclodextrine, RMN, concentration micellaire critique, tension superficielle. .

[Traduit par la Rédaction]

Introduction

Cyclodextrins are cyclical sugars composed of α-D-glucopyranose units bound end-on-end, which can incorporate within their cavities molecules of the correct fit and hydrophobicity in solution or in solid form (1, 2). The complexes thus formed find a wide range of uses in pharmaceutical (3), industrial (4), and reaction chemistry (5, 6). Because of its relatively low cost, high purity, and snug accommodation of a large number of common guest molecular moieties — notably the phenyl group — in primarily 1:1 complexes, the most common cyclodextrin investigated has been β-cyclodextrin (β-CD), which consists of seven end-on-end, interconnected glucose residues.

Surfactants are particularly strongly complexed by β-cyclodextrin, with the hydrophobic hydrocarbon chain tail usually enfolded within the cavity. A particular group of surfactants that is of current interest is the nonionic alkylpolyglycosides (APGs), which consist of hydrocarbon chains attached to sugar groups (Fig. 1). APGs are often termed "green" detergents because they environmentally degrade relatively innocuously (7). When β-CD and an APG form complexes, it is of some interest what influence the sugar–sugar interaction has upon the inclusion process and structure. The usual surfactant–CD situation finds the surfactant head situated in the mouth of the cyclodextrin torus, with the principal interaction in the complex being that between the included surfactant tail and the inside of the β-CD torus (Fig. 2). Binding constants determined through proton NMR and critical micelle concentrations (CMC) determined through surface tension can provide valuable insights into this situation. In this report, computer modelling has been coupled with the results of the foregoing investigations to obtain a more detailed picture of the positioning of the surfactant within the CD torus.

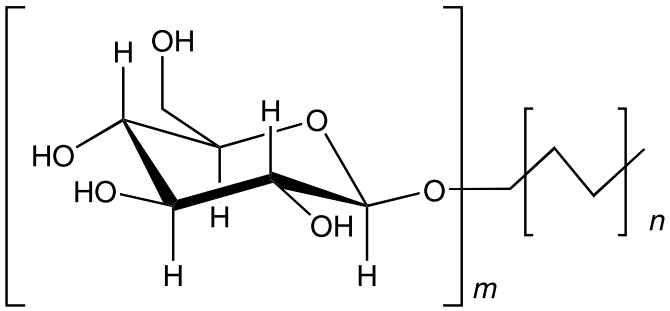
Fig. 1. Alkylpolyglycoside (APG), where m = 1 (glucopyranoside) or 2 (maltoside) and n = 6–12.



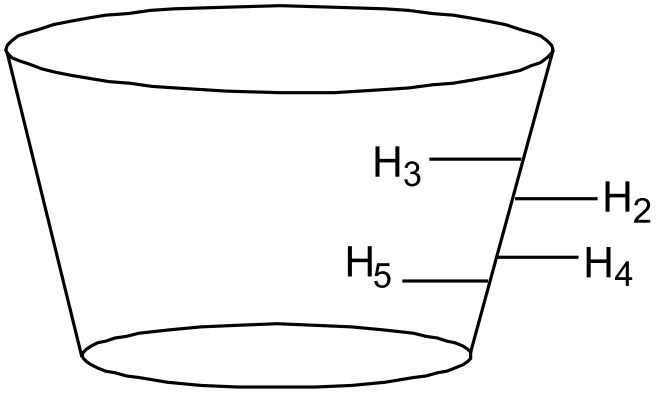


Fig. 2. Cyclodextrin (CD) torus with locations of particular H atoms important to NMR.

deionized water, using the value of 72.6 dyne cm^{-1} (1 dyne = 10 μN) as the surface tension of pure water. In each surfactant system, β-CD concentrations of 0.25, 0.50, 0.75, 1.0, 1.5, and 2.0 mmol L^{-1} were used to obtain the surface tension data. The critical micelle concentration (CMC) for each system was determined in the normal manner, as the intersection of the surface tension vs. log[surfactant] plot (Fig. 3).

Proton NMR data for the surfactant–β-CD systems were collected on a JEOL 270 MHz spectrometer. Of particular interest were the peak shifts of the H_3 and H_5 protons located on the interior wall of the β-CD torus (Fig. 2). Surfactant addition resulted in these peaks being shifted upfield while the exterior H_2 and H_4 peaks were unaffected. With surfactants G8 and M10 (see below), interference from surfactant peaks rendered the assignment of the β-CD H_3 and H_5 peaks problematic, a situation commonly encountered with β-CD inclusion complexes (8). Association constants for complex formation between β-CD and surfactant (K_a) were obtained by the NMR titration technique (9, 10), whereby surfactant was added incrementally to β-CD solutions and the peak shifts of either the β-CD H_3 or H_5 protons were noted until no further change occurred (Fig. 4).

Molecular mechanics studies were undertaken to decide the most favourable orientation of the sugar surfactant G12 within the CD torus upon complexation. Systems were modeled using the PC Spartan Pro Computational Program via the MMFF94 force field while employing solvation parameters available in the program. Initial attempts to model the β-CD molecule foundered because the torus folded in on itself on energy minimization, owing, in part, to the solvation model. Crystallographic data were obtained from K.B. Lipkowitz (Indiana University, Purdue University, U.S.A.), and dihedral angles of the core structure were fixed so as to allow the bond lengths and angles of the core to vary while keeping its cyclic shape during geometry optimizations. This approach proved very successful.

Table 1. CMC values for pure alkylpolyglycosides in water at 25 °C.

Sugar surfactant	CMC (mM) – this work	CMC (mM) – literature values
G12	0.16	0.12 (11), 0.13 (12), 0.14 (13)
G10	2.0	1.99 (11), 2.0 (14), 2–3 (15), 4.2 (13)
G8	17	17.4 (16), 20–25 (15), 25 (17), 25.4 (13)
M14	0.012	—
M12	0.15	0.14 (13), 0.15 (18), 0.16 (11, 16, 17, 19), 0.1–0.6 (15), 0.2 (14)
M10	1.8	1.4 (13), 1.6 (14), 3.23 (11).

The sugar surfactants used were octyl-β-D-glucopyranoside (G8), decyl-β-D-glucopyranoside (G10), dodecyl-β-D-glucopyranoside (G12), tetradecyl-β-D-glucopyranoside (G14), decyl-β-D-maltoside (M10), and dodecyl-β-D-maltoside (M12). All were purchased from Fluka, except for G8 (Sigma) and G14 (Sigma). β-CD was obtained from Aldrich and dried in vacuo at room temperature before use. All chemicals were supplied as 98%–99% purity and were not further treated.

Results and discussion

The CMC values for the pure alkylpolyglycosides, as determined by surface tension at 25 °C, are shown in Table 1, together with the corresponding literature values. The usual observation with surfactants that possess hydrocarbon tails — that a decrease of two carbons in the tail results in an increase of an order of magnitude in the CMC value — appears to hold with the alkylpolyglycosides. Adding β-CD to sugar surfactant solutions always brought about an increase in the CMC, which is not unexpected because of the competing β-CD–surfactant complexation equilibrium (Figs. 5 and 6) thus introduced. Determination of the CMC of short-chained surfactants such as G8 is fraught with more error because of the greater instability of the micelle, viz. Fig. 5. It is of interest that, in all the systems investigated, subtracting the surfactant concentration from the CMC value reproduced approximately the CMC value of the pure surfactant. This argues for a 1:1 complexation as the principal interaction that occurs between the surfactant and the non-surface-active cyclodextrin.

Association constants, determined by NMR analysis, for the binding of β-CD and G12 (undertaken in 2.0 and 1.0 mmol L^{-1} β-CD) were in reasonable agreement at 440 ± 40 (mol $L^{-1})^{-1}$ and 410 ± 40 (mol $L^{-1})^{-1}$, respectively, when the ring interior H_5 proton peak shift was followed. For G10 and M12, when the chemical shifts for the same peak were used, association constants of 340 ± 30 (mol $L^{-1})^{-1}$ and

125 ± 10 (mol L^{-1})$^{-1}$, respectively, were obtained in 1.0 mmol L^{-1} β-CD. The ring interior H_3 proton peak shifts gave inconsistent results, possibly due to signal interference from surfactant protons. Lengthening the surfactant hydrocarbon chain increases the binding strength, as is generally found with cyclodextrin–surfactant complexations. This is consistent with the surfactant tail residing in the hydrophobic CD cavity in the complex formed. A comparison of the binding constants for G12 and M12 indicates that the extra sugar moiety in the M12 surfactant head decreases the strength of the β-CD complex. The negative effect on the binding generated by the second sugar molecule points to no significant sugar–sugar interaction being involved in the binding; therefore, the surfactant head is not in the CD cavity in the complex but is likely in the mouth of the cavity where water–sugar interactions predominate. Also, the observation that the NMR peak shifts reached a plateau at 1 and 2 mmol L^{-1} surfactant in the 1.0 and 2.0 mmol L^{-1} β-CD systems, respectively, supported the CMC results that allowed us to assign a 1:1 stoichiometry to the principal com-

plex being formed. The magnitudes of the binding constants are consistent with binding constants of other β-CD complexes with surfactants with 10–12 carbon atoms in the hydrocarbon tail (8).

Having the surfactant head located in the narrower rather than the wider opening of the β-CD torus led to a more stable structure by roughly 196 kJ mol^{-1} when computational calculations were performed on 10 various conformers of the 1:1 β-CD–G12 complex. In each of the optimized conformers, the sugar head-group remained in its boat conformation and oriented itself in such a fashion as to maximize the number of hydrogen bonds to the hydroxyl groups lining the rim of the CD cavity. The advantage of the narrower CD opening is that it possesses freely rotating primary hydroxyl groups, which leads to extra hydrogen bonding possibilities. Hydrophobic forces also play a significant role, as the surfactant tail bends and folds into the wider opening of the CD cavity. In the lowest energy conformer found, the coiled tail resides in the cavity with the sugar moiety of the surfactant, blocking completely the narrower CD entrance (Fig. 7). Even though the calculations were conducted only for the β-CD–G12 complex, the situation with G10 and G8 is expected to be similar. Modeling the maltosyl surfactants, M14, M12, and M10, even at an elementary level, is more

Fig. 7. Space-filled model showing (*a*) the G12 sugar head-group in its snug conformation within the narrow β-CD opening and, in a view from the opposite side of the complex, (*b*) the coiled hydrocarbon tail of G12 tucked into the wider β-CD opening. The hydrogen atoms have been omitted to assist in viewing. The carbon atoms are shown in grey while the oxygen atoms are in red.

difficult and was not attempted. However, simple steric considerations suggest that the structure of the 1:1 complexes of these sugar surfactants with β-CD would be similarly disposed. With the narrower cavity of the α-CD molecule and the wider cavity of the γ-CD molecule, as compared with the β-CD molecule, the stereochemical fit of the sugar moiety in both these complexes would likely be less snug, giving rise to lower binding constants, unless a compensatory shift in the insertion position were to occur within the cavity. It would be of interest to pursue these studies, to delineate further the CD inclusion process.

Conclusion

Sugar surfactants form stable 1:1 complexes with β-CD in which the coiled surfactant occupies the CD cavity with the sugar head-group occupying, snugly, the narrower CD opening.

Azabenzenes (azines) — The nitrogen derivatives of benzene with one to six N atoms: Stability, homodesmotic stabilization energy, electron distribution, and magnetic ring current; a computational study

Jürgen Fabian and E. Lewars

Abstract: The twelve azabenzenes — the species formed by replacing CH groups of benzene by N — were examined computationally (with emphasis on the six contiguous-nitrogen species). MP2(fc)/6-31G*, B3LYP/6-31G*, CCSD(T)/6-31G*//MP2(fc)/6-31G*, and G3(MP2) calculations were used to probe kinetic and thermodynamic stabilities, homodesmotic ring-opening energies, electron distribution (bond orders and lengths, Bird index), and NICS values, primarily to discern where the transition occurs from reasonably stable to highly fragile species. Some azabenzenes with three and those with four or more nitrogens are thermodynamically unstable, but kinetic stabilities indicated that, with the possible exception of hexaazabenzene, all the azabenzenes should be isolable, although some with four nitrogens might decompose at room temperature, and pentaazabenzene would require matrix isolation techniques. Although homodesmotic ring-opening reactions showed an almost monotonic decrease in the stability of the cyclic relative to the open-chain species (in appropriate ring-opening reactions) on going from benzene to hexaazabenzene, bond-order variation and NICS suggested this may be because of increasing destabilization by nitrogen lone pairs rather than because of a decrease in electron delocalization (in aromaticity).

Key words: azines, azabenzenes, pentazine, hexazine, ab initio, DFT, aromaticity.

Résumé : On a fait des calculs théoriques sur douze azabenzènes, les espèces qui se forment en remplaçant des groupes CH du benzène par un N, en portant une attention spéciale aux espèces comportant des azotes contigus. On utilisé les calculs MP2(fc)6-31G*, B3LYP/6-31G*, CCSD(T)/6-31G*//MP2(fc)/6-31G* et G3(MP2) pour étudier les stabilités cinétiques et thermodynamiques, les énergies d'ouvertures de cycles homodesmotiques, les distributions d'électrons (ordres et longueurs des liaisons et indice de Bird) ainsi que les valeurs NICS, principalement pour déceler l'endroit où se produit la transition d'une espèce raisonnablement stable vers une qui est extrêmement fragile. Quelques azabenzènes comportant trois azotes et tous ceux qui en contiennent quatre ou plus sont thermodynamiquement instables; toutefois, les stabilités cinétiques indiquent que, à l'exception de l'hexaazabenzène, on devrait pouvoir isoler tous les azabenzènes même si quelques-uns de ceux qui contiennent quatre azotes pourraient se décomposer à la température ambiante et que pour le pentaazabenzène il faudrait probablement faire appel à des techniques d'isolation dans une matrice. Même si les réactions d'ouverture de cycle homodesmotiques présentent toutes une diminution monotone de la stabilité du cycle par rapport aux espèces en chaînes ouvertes (dans des réactions appropriées d'ouverture de cycle) lorsqu'on passe du benzène à l'hexaazabenzène, la variation dans l'ordre de liaison et dans les valeurs de NICS suggèrent que cette tendance pourrait être due à une augmentation de la déstabilisation par des doublets non appariés de l'azote plutôt qu'à une diminution dans la délocalisation électronique (dans l'aromaticité).

Mots clés : azines, azabenzènes, pentazine, hexazine, ab initio, DFT, aromaticité.

Introduction

General

This paper describes our computational study of the nitrogen analogues of benzene: the molecules formally derived from benzene (with which we compare them) by replacing CH groups by nitrogen atoms. Figures 1 and 2 show these molecules and the designations (**N0**, **N1**, etc.) that will be

used here for brevity, along with parameters that are discussed below. The species are conveniently divided into those with contiguous (1,2-, 1,2,3-, etc.) and noncontiguous (1,3-, 1,4-, etc.) nitrogens. It is convenient to take benzene as the first (**N0**) member of the contiguous-N class. The heterocycles can be named by replacement nomenclature as azabenzene, 1,2-diazabenzene, …, hexaazabenzene or by the less elegant Hantsch–Widman system as azines (i.e., azine, 1,2-diazene, …, hexazine) (1). The properties examined are (*i*) activation energies and reaction energies (i.e., kinetic and thermodynamic stabilities) for decomposition to stable two-heavy-atom triply bonded fragments, e.g., $N_6 \rightarrow 3N_2$; (*ii*) homodesmotic ring-opening, e.g., N_6 + 2 HN=NH $\rightarrow$ hexaazahexatriene + tetraazabutadiene; (*iii*) electron distribution, as indicated by bond order – bond length variation; (*iv*) ring-current effects, as indicated by calculated nucleus-independent chemical shifts (NICS).

There are at least four reasons why these compounds are interesting, namely: (*a*) any chemist with imagination must be intrigued by the possibility of obtaining an oligomeric version of a widespread element known so far only as a diatomic molecule. This would be realized in the molecule at the end of the replacement series, N_6; (*b*) benzene and pyridine (the **N0** and **N1** replacement members) are well-known, very stable substances, but hexaazabenzene is (as indicated so far only by computations) exceedingly unstable. One wonders where and why the transition to extreme instability occurs; (*c*) benzene and pyridine are unequivocally "aromatic" (2). It would be interesting to see if continued replacement of CH by N suppresses this (admittedly elusive) characteristic; (*d*) nitrogen oligomers have been considered as possible high-energy-density materials; their kinetic and thermodynamic stabilities are relevant to this (and to *a*, *b*, and, to some extent, *c*).

Our main objective was to examine the trends in properties as CH is replaced by N and to locate the point or region between highly stable molecules like benzene and pyridine and the unstable hexaazabenzene. For this reason, we concentrate on the N-contiguous species and discuss the noncontiguous ones somewhat peripherally.

Literature

All these heterocycles have been reviewed up to 1995 in the latest edition of the encyclopedia edited by Katritzky et al. (3). First, we briefly describe what is known *experimentally* about azabenzenes, then consider the computational literature.

Experimental literature

N0, N1

Benzene and pyridine are commercially important compounds known for almost two centuries (4).

N2

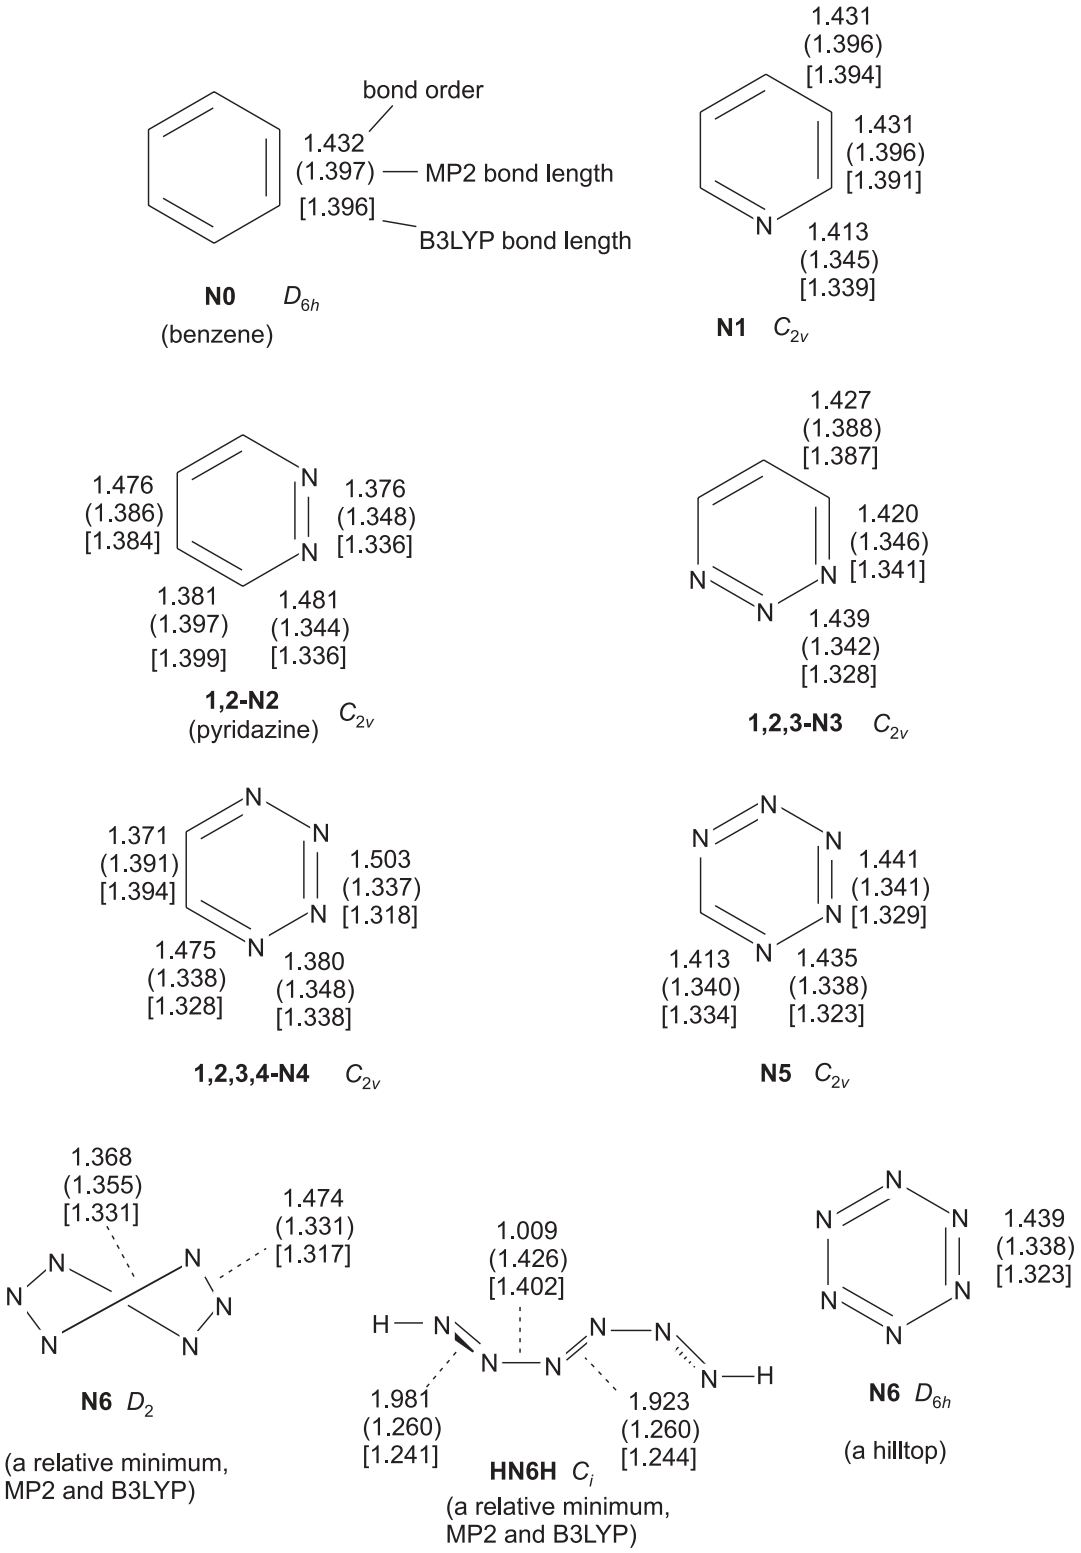
1,2-Diazabenzene (pyridazine) (5), 1,3-diazabenzene (pyrimidine) (6), and 1,4-diazabenzene (pyrazine) (7) are well-known, stable compounds, regarded as normal aromatic heterocycles. The 1,3-system is the motif of nucleic acid pyrimidine bases and, fused to a five-membered ring, of purine bases. The 1,4-system has long been well known (8) and is even found in natural products of potential utility (9).

N3

1,2,3-Triazabenzene was first made in 1981 and is, as expected from the known fragility of chains and rings with contiguous nitrogen atoms (10), the least stable triazabenzene, but it is still readily handled at room temperature (11). A colorless crystalline solid, it melts at 71 °C and decomposes at 130 °C to form mainly tar. The molecule is readily attacked by nucleophiles and undergoes Diels–Alder reactions with alkynes. 1,2,4-Triazabenzene has been known since 1966 (12). 1,3,5-Triazabenzene (cyanuric acid) was isolated in 1895, although the correct structure was not assigned till 1954 (13).

N4–N6

The systems with four to six nitrogens atoms are of more interest to theorists. 1,2,4,5-Tetraazabenzene is well known, having been made in 1900 (14). 1,2,3,4-Tetraazabenzene and 1,2,3,5-tetraazabenzene are unknown (15).



Pentaazabenzene (15) and hexaazabenzene (15) are unknown; there have been tentative speculations on the possible experimental generation of N_6 species by azide dimerization under electron pulse radiolysis (16), polarographic conditions (17), and the low-temperature photolysis of an azide-platinum complex (18).

Computational literature

Most of the computational literature on the azabenzenes is somewhat eclectic, in that few papers are devoted to just one compound or to a narrow group of compounds like, say, the N_2 or N_3 species. Therefore, we cannot review this literature in a strict nitrogen-sequential (i.e., N_1, N_2, …) order. There have been a few theoretical papers in which benzene and some or all of the azabenzenes were examined for one particular property (some of these papers are discussed below in connection with our investigation of the property; for example, aromaticity). Maksić et al. (19) investigated π-electron correlation energy and NICS in pyridine, **1,2-N2**, **1,2,3-N3**, and **1,2,4,5-N4**. Rauhut (20) reviewed computations on various heterocycles, mentioning, among the azabenzenes, the diaza- and triazabenzenes and the tetraazabenzenes **1,2,4,5-N4** and **1,2,3,4-N4**. Gambiagi et al. (21) investigated the aromaticity of the azabenzenes, subjecting AM1 geometries to PM3 calculations of a bond index that reflects electronic charge in bonds. Williams and Whitehead (22) used MNDO, AM1, PM3, and noncorrelated ab initio methods to calculate their heats of formation, while Doerksen and Thakkar (23) studied the polarizabilities of the N_3–N_6 members. Politzer and co-workers (24, 25) studied the electrostatic potentials and local ionization energies of some azabenzenes. Katritzky and Barczynski (26), in a study of the aromaticity of five- and six-membered heterocycles with the AM1 method and geometric, energetic, and magnetic criteria, examined **1,2,3-N3**, **1,2,4,5-N4**, and **1,2,3,4-N4** and concluded that the evidence was "that pyridine-like nitrogen atoms have relatively little effect on "classical" aromaticity". Sanz et al. (27) calculated the basicities of pyridine, the diazabenzenes, the triazabenzenes, and the tetraazabenzenes at the MNDO, AM1, and Hartree–Fock levels. A study by Wiberg et al.

triazabenzenes, and the tetraazabenzenes were investigated with the help of Hartree–Fock 6-31G* single-point calculations on lower-level geometries by Mó et al. (29). Fos et al. (30) compared the accuracy of MNDO and HF/4-31G calculations for the heats of formation of the N_2–N_4 azabenzenes.

In a pioneering study of hexaazabenzene, Saxe and Schaefer (31) briefly reviewed the experimental status of the entire azabenzene series and the computational work thus far on hexaazabenzene and reported their Hartree–Fock and preliminary correlated (configuration interaction) work, which predicted that planar (D_{6h}) hexaazabenzene is "a dimple on top of a mountain". They wisely qualified this whimsical but apt characterization with the caveat that the prediction "carries with it not a trace of infallibility". Early work by Engelke (32, 33) on hexaazabenzene and other nitrogen-rich species established that the planar (D_{6h}) species, although a relative minimum on the potential energy surface (PES) at the Hartree–Fock level, is a hilltop with correlated (MP2) calculations. Using correlated ab initio calculations, Glukhovtsev and Schleyer (34) compared hexaazabenzene to open-chain isomers and showed that the cyclic structure adopts a twisted (D_2) shape, and they used isodesmic-type reactions (below) to show that this is destabilized, rather than stabilized like benzene, with regard to ring-opening; these workers also commented on reports of the preparation of N_6 species and clarified some results for N_6 species reported by Engelke (33), Nguyen and co-workers (35–37), and Ramek (38). Simkin et al. (39), in a review of aroma-

© 2003 NRC Canada

ticity in connection with heterocycles, summarized work comparing the resonance energies of benzene, pyridine, the diazabenzenes, **1,3,5-N3**, **1,2,4,5-N4**, and **N6** and reviewed the role of σ-to-σ* electron transfer in **N6**.

Computational methods

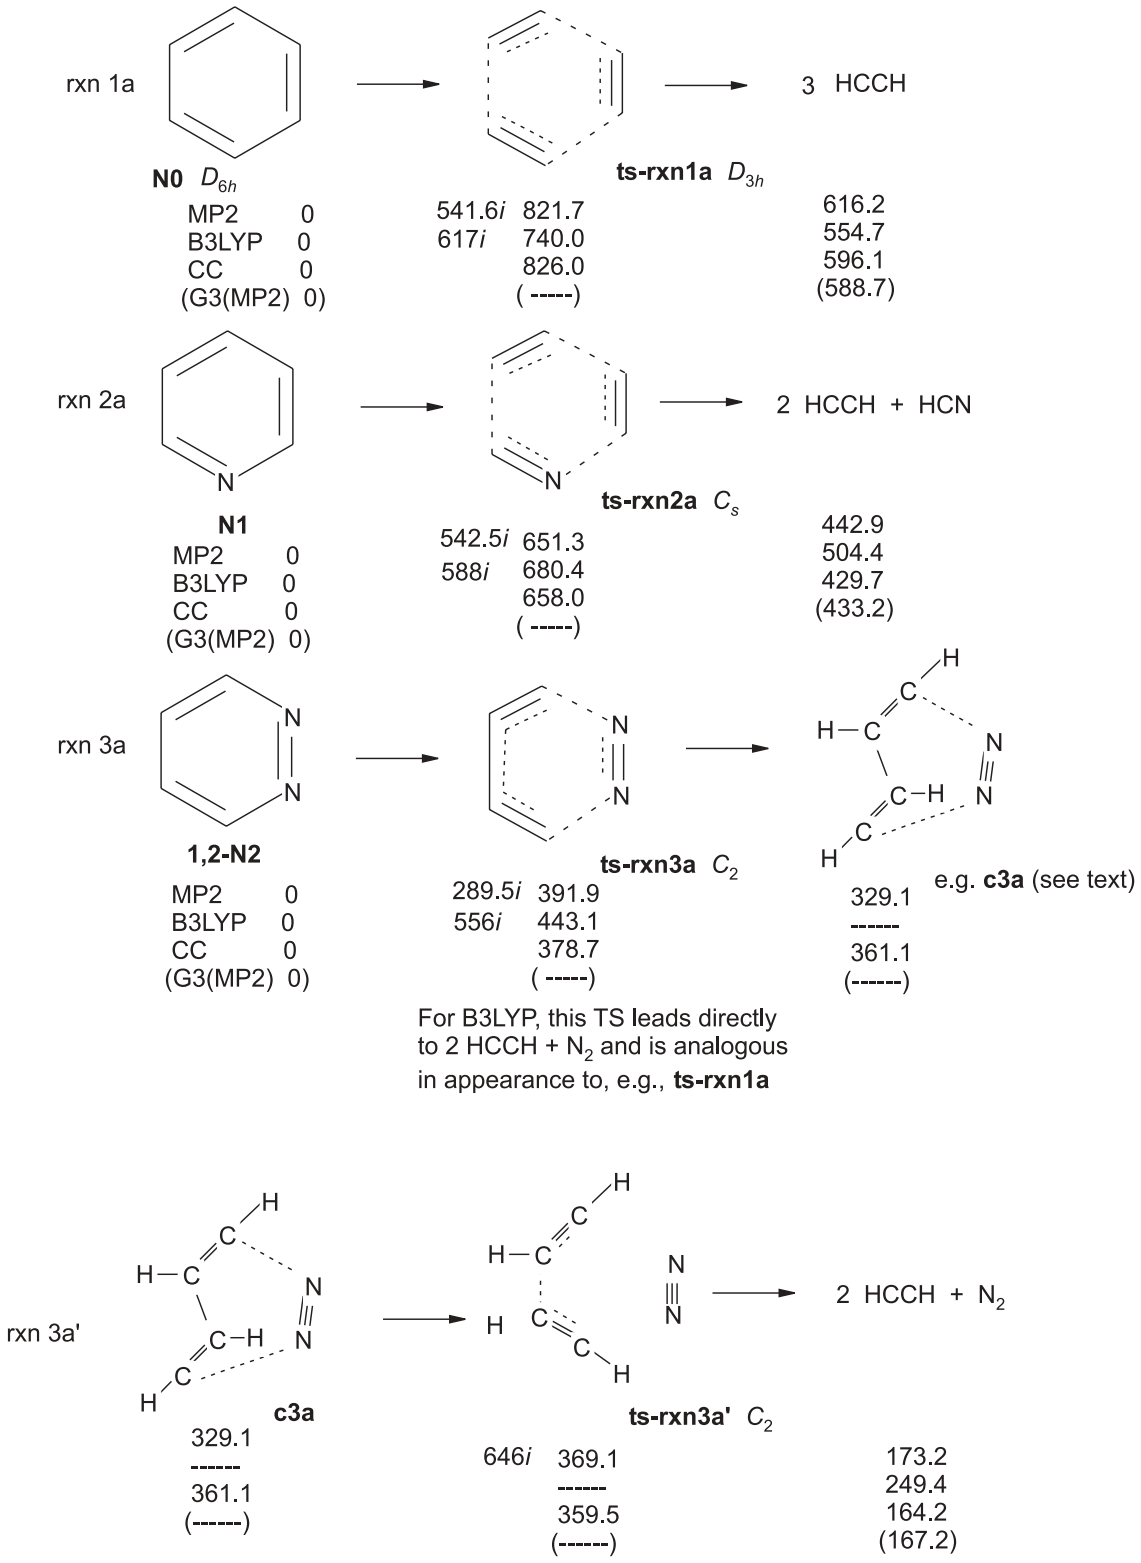
Calculations were done with Gaussian 98 for Windows (G98W) (40) and visualized with GaussView 2.1 for Windows (41) on a 933 Pentium 3 or a 1.5 GHz Pentium 4 computer equipped with Microsoft Windows NT 4.00, 1 GB of memory, and 15 360 MB of scratch space. Ab initio (42) MP2 (frozen-core, MP2(fc)) and DFT (43) B3LYP calculations were full geometry optimizations followed by frequency calculations (44). Zero-point energies (ZPEs) from the frequency jobs were multiplied by the appropriate correction factors (0.9670 for MP2(fc)/6-31G* and 0.9806 for B3LYP/6-31G*) recommended by Scott and Radom (45) and added to the raw energies to give the ZPE-corrected energies. Coupled-cluster calculations were CCSD(T) (46) single-point calculations on MP2 geometries, and the basis set was 6-31G*. The coupled-cluster energies were corrected with the MP2/6-31G* ZPEs. G3(MP2) energies (47), which are almost as accurate as G3 values (48) but considerably faster, refer to G3MP2 (0 K) values. Absolute total energies, ZPEs, and ZPE-corrected energies are given in the supplementary material.[3] All transition states were checked by intrinsic reaction coordinate (IRC) calculations (49), which showed that they connect the cyclic molecule with its fragmentation products in a concerted reaction, except for anomalies connected with reactions 3a and (or) 3a′ and possibly 4a (Fig. 3) for the MP2 PES.

For reaction 3a, we were unable to find an MP2 transition state linking **1,2-N2** and 2 HCCH + N_2, but we located instead **ts-rxn3a** (rxn = reaction) (Fig. 3), which connects **1,2-N2** with a van der Waals complex of a species CHCHCHCH and N_2. There appears to be a series of these loosely bound complexes, and **c3a** (Fig. 3) may not be exactly the one to which **ts-rxn3a** leads (the IRC was unable to travel downhill all the way to the complex). The complex **c3a** decomposes via a transition state **ts-rxn3a′** to 2HCCH + N_2. The relative energies of **1,2-N2**, **ts-rxn3a**, **c3a**, and **ts-rxn3a′** indicate that **c3a** decomposes readily to 2 HCCH + N_2. Indeed, the CC energies of **c3a** and **ts-rxn3a′**, 361.1 and 359.5 kJ mol^{-1}, place the latter marginally below its precursor, but this is not unusual when single-point calculations are performed on a minimum and a transition state representing a very low barrier — this is seen also for reaction 9a, discussed below. Because of the fragility of complexes of the type **c3a**, in the following discussion we regard the first step, reaction 3a, as the critical one in the two-step (rxn 3a, rxn 3a′) fragmentation of **1,2-N2** to 2HCCH + N_2. For reaction 4a we found an MP2 transition state, **ts-rxn4a**, which led from **1,2-N2** to what appeared to be a complex, CHCHCHN + HCN; however, when the IRC run was allowed to proceed well toward this supposed complex and the resulting non-stationary point was optimized, it dissociated to HCCH + 2HCN. Attempts to find an MP2 transition state unambiguously linking **1,2-N2** with HCCH + 2HCN failed, and we consider **ts-rxn4a** to lead directly to the products or to pass through a complex resembling only a dimple on the MP2 PES.

Discussion

Activation energies and reaction energies

We calculated the activation and reaction energies for fragmentation of the azabenzenes into two-heavy-atom fragments, e.g., $N_6 \rightarrow 3N_2$. That the energies of this particular reaction mode should be a good indication of the kinetic (from activation energy) and thermodynamic (from reaction energy) stabilities of the cyclic systems is intuitively apparent for hexaazabenzene (it is hard to imagine any other reasonable decomposition mode for N_6) at one end of the substitution continuum and is demonstrated for benzene, at the other end, by its formation from ethyne thermally or under catalysis (50). Kinetic and thermodynamic stabilities are very important probes of the properties of exotic molecules because they address directly the question of their possible existence, their stability, and their ease of experimental manipulation. Because of the importance of activation and reaction energies, we examined the results of calculations at the four levels shown in Figs. 3 and 4 (see computational methods section for details). For simplicity we use relative energies (activation and reaction energies) from the differences in the ZPE-corrected "absolute" energies; these represent 0 K enthalpy differences (51). These relative energies should show the same trends as, and not differ greatly from, relative energies that take into account the increase in translational, rotational, and vibrational energy of a molecule on going to room temperature (51).



Inspection of Figs. 3 and 4 shows that the MP2, B3LYP, and CCSD(T) calculations all agree on the trends in activation and reaction energies as the number of nitrogens increases: the activation and reaction energies are predicted to fall, as one would expect to actually be the case. The reaction energies become negative when we reach molecules with three contiguous or four noncontiguous nitrogens (actually, **1,2,4-N3** is predicted by MP2 and CC to have slightly negative reaction energies). Comparing MP2, B3LYP, and CC, we see that MP2 and CC agree to within 20 kJ mol^{-1} for activation and reaction energies (for reaction 1a, the CC reaction energy is 20 kJ mol^{-1} lower and for reaction 3b, the CC activation energy is 19 kJ mol^{-1} higher than for the MP2 values, and the other deviations are less), except for reaction 6a, for which the activation energy from the CC method is 35 kJ mol^{-1} higher than that from the MP2 method, and reaction 9a, for which the CC reaction energy is 24 kJ mol^{-1} higher than the MP2.

In contrast to the fair consonance of MP2 and CC energies, the B3LYP activation and reaction energies usually differ considerably from the MP2 and CC values and are almost always higher. For the nine contiguous-N species activation energies (reactions 1a–9a), only for reactions 2a, 7a, and 8a is the B3LYP energy within 30 kJ mol^{-1} of the MP2 and the CC values; for 6a it is 6 kJ mol^{-1} higher than the CC but 40 kJ mol^{-1} higher than the MP2. For reactions 1a, 3a,

[3] Supplementary data may be purchased from the Depository of Unpublished Data, Document Delivery, CISTI, National Research Council Canada, Ottawa, ON K1A 0S2, Canada (http://www.nrc.ca/cisti/irm/unpub_e.shtml for information on ordering electronically).

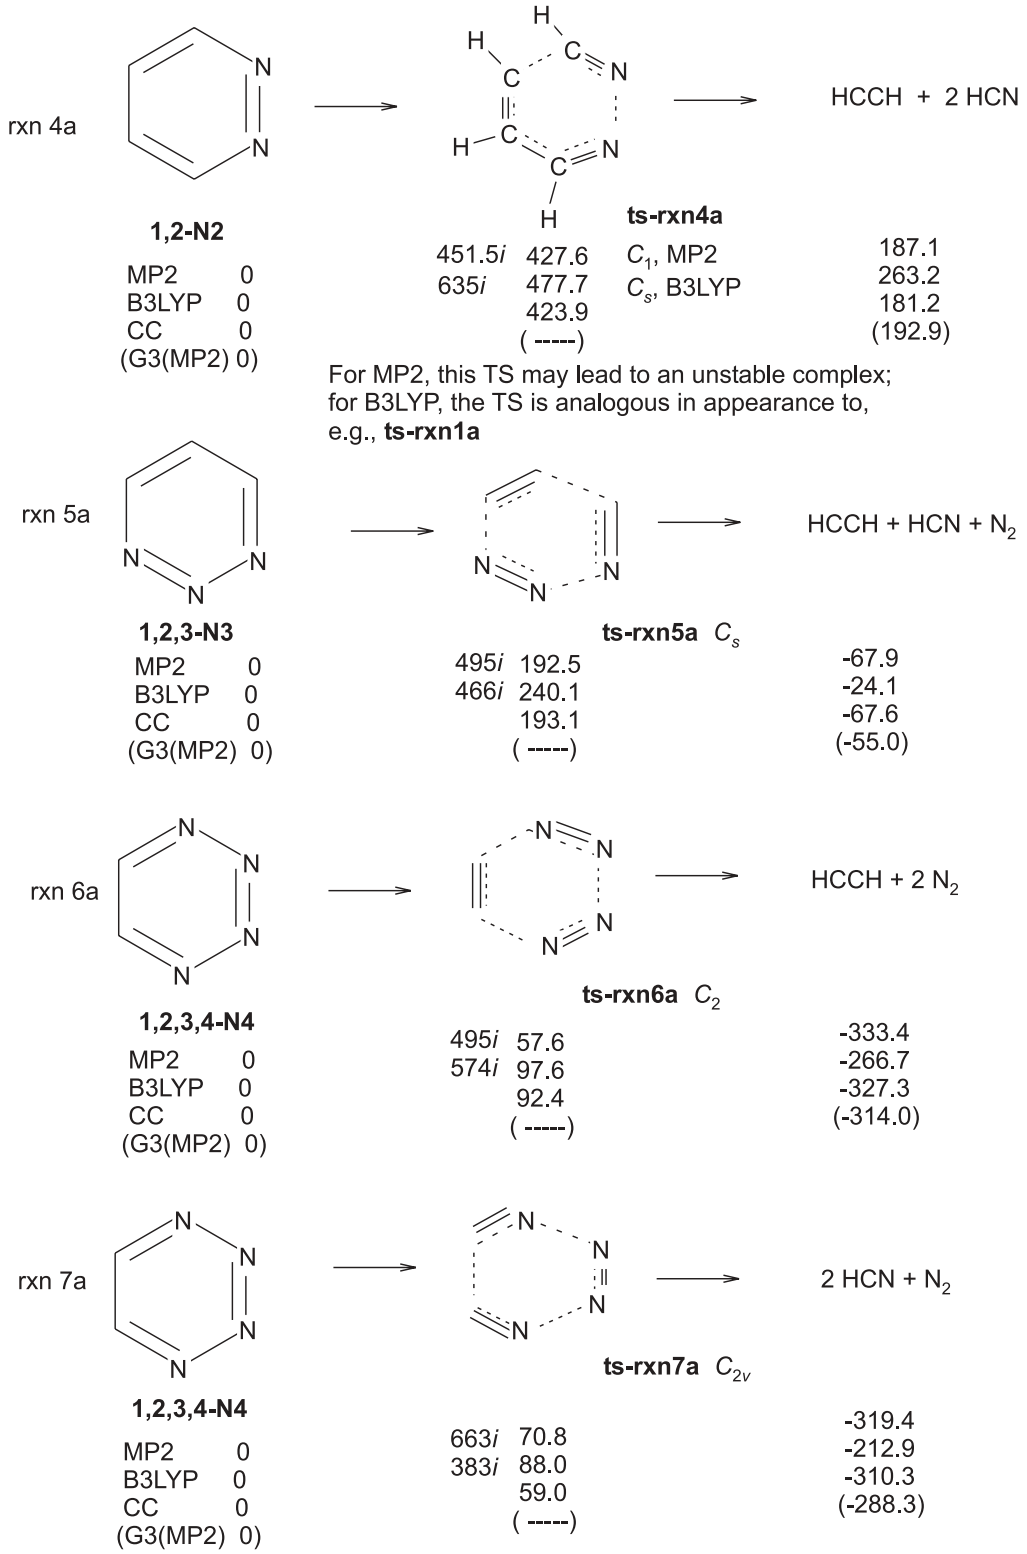

Fig. 3. Activation and reaction energies for fragmentation of contiguous-N azabenzenes into stable two-heavy-atom triply bonded fragments. See text for computational details.

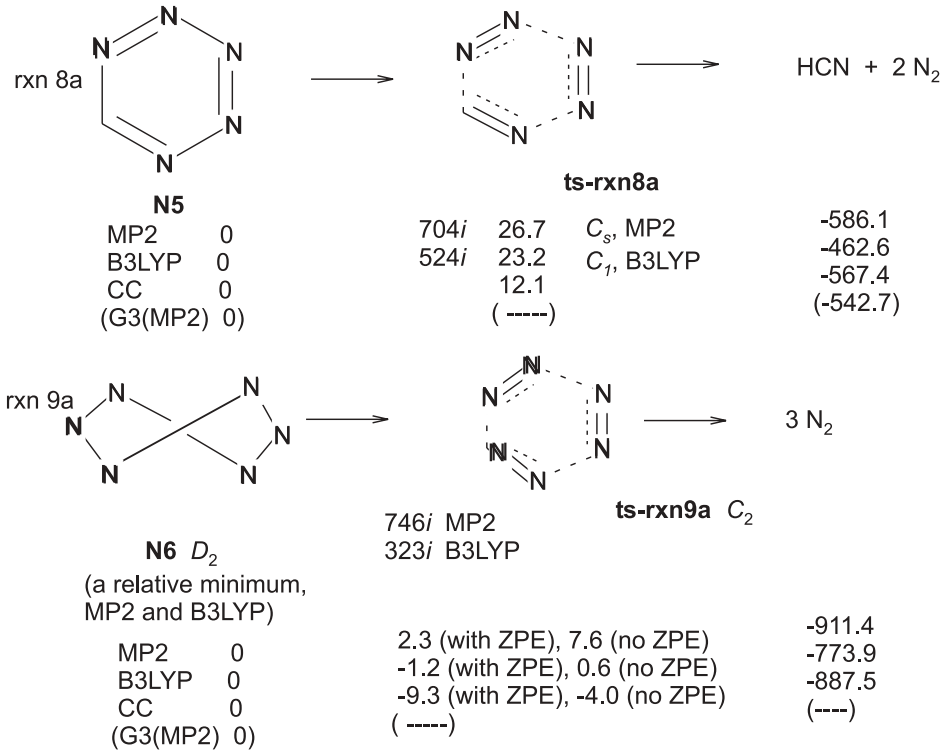
4a, and 5a, the B3LYP deviations are from 47 to 86 kJ mol^{-1}. For the nine contiguous-N species reaction energies, the B3LYP values exceed the MP2 and CC ones from 60 (6a) to 137 kJ mol^{-1} (9a), except for reaction 1a (61 and 41 kJ mol^{-1} smaller than the MP2 and CC values). For the seven non-contiguous-N species (reactions 1b–7b) activation energies, the B3LYP deviations (all positive) are less than for the contiguous-N set. For reactions 1b, 5b, 6b, and 7b, the B3LYP

© 2003 NRC Canada

Fig. 3 (*continued*).

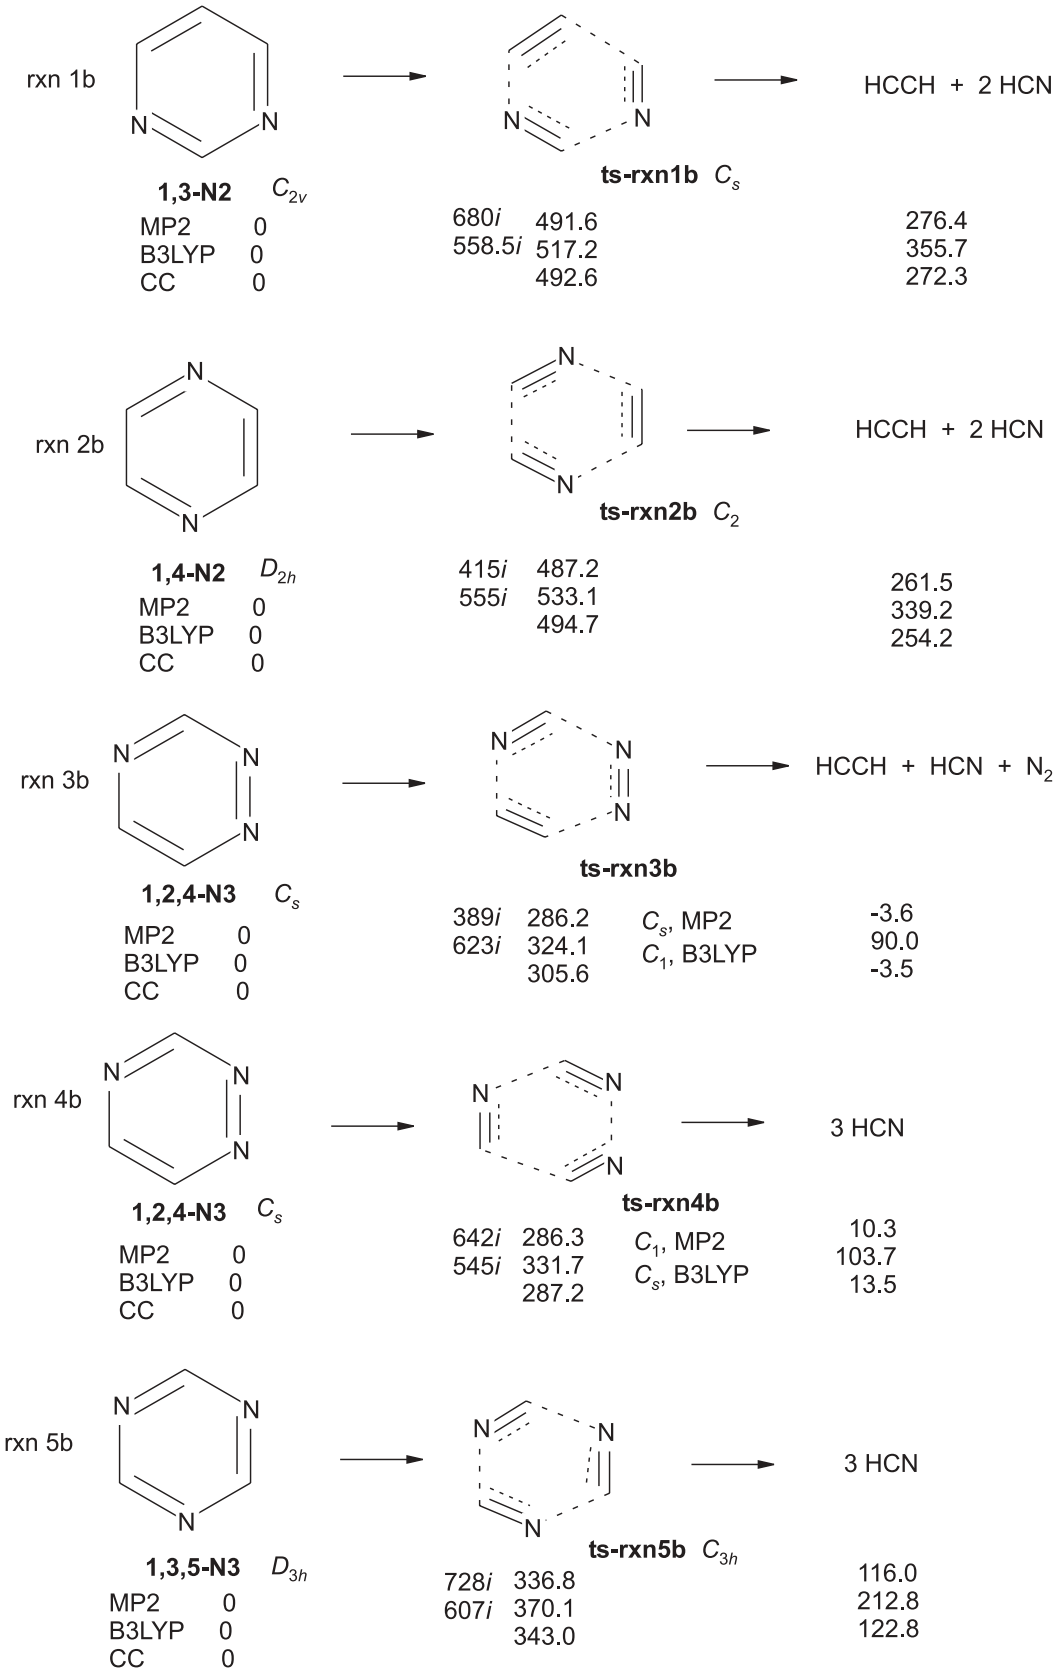


values are within about 30 kJ mol^{-1} of the MP2 and CC ones; for 2b, 3b, and 4b, we find deviations of 38–46 kJ mol^{-1}, except for 3b, where the B3LYP value lies only 18 kJ mol^{-1} above the CC one. For the seven noncontiguous-N species reaction energies, the B3LYP values exceed the MP2 and CC ones from 77 (2b) to 111 kJ mol^{-1} (6b).

To obtain an independent indication of which set of energies, the B3LYP or the MP2 and CC ones (these two latter being quite similar to each other), were the more reliable, we obtained the G3(MP2) reaction energies for reactions 1a–8a (Fig. 3). G3(MP2) activation energies and the reaction energy for reaction 9a are not reported because the Hartree–

© 2003 NRC Canada

Fig. 3 (*concluded*).



Fock (HF) level geometry optimization step in the G3(MP2) procedure does not always lead to a reasonable approximation of the transition-state geometry found on the correlated (B3LYP or MP2) potential energy surface and because, for reaction 9a, calculations at the HF and correlated (46, 52) levels give qualitatively different results. For a process like the fragmentation of a closed-shell molecule into closed-shell products, G3(MP2) calculations should reliably give relative energies to within 10 kJ mol^{-1} (47, 48) (reactions involving uncoupling of paired electrons are problematic (53)). Table 1 shows that the G3(MP2) reaction energies agree quite well with the CC values (average of absolute deviations 12 kJ mol^{-1}; maximum deviation 25 kJ mol^{-1}) and fairly well with the MP2 values (average of absolute deviations 19 kJ mol^{-1}) but deviate significantly more from the B3LYP relative energies (average of absolute deviations 62 kJ mol^{-1}). The MP2 and CC activation energies agree to within 20 kJ mol^{-1} (reaction 3b) but deviate by up to 86 kJ mol^{-1} from the B3LYP values (reaction 1a) (except for the case of reaction 6a, which is anomalous in that here it is the CC and B3LYP activation energies that are similar and lie 35–40 kJ mol^{-1} above the MP2 energy; careful checking of the calculations left this anomaly unexplained). As a further check on the accuracy of the CC relative energies for our reactions, we compared the calculated and experimental activation energies for two well-studied six-electron pericyclic reactions, namely the Diels–Alder reaction of 1,3-butadiene with ethene and the Cope rearrangement of 1,5-hexadiene. Our CCSD(T)/6-31G*//MP2(fc)/6-31G* values for the Diels–Alder reaction were 114 kJ mol^{-1}, cf. 105 kJ mol^{-1} from experiment (54), and for the Cope rearrangement, they were 161 kJ mol^{-1}, cf. 140 kJ mol^{-1} from experiment (55), approximating the Cope transition state as a bis(allyl radical) species à la Houk et al. (56). For these reasons, we regard the CC relative energies, activation and reaction, as reliable and will refer to these in evaluating the kinetic and thermodynamic stabilities of these species. These results suggest that these CC energies (0 K enthalpy differences) are accurate to within ca. 30 kJ mol^{-1} and that they thus reflect fairly well the relative and even the absolute stabilities (kinetic and thermodynamic) of these molecules. Some discrepancies between our MP2 reaction energies and those of Wiberg et al. may be because of their use, in some cases, of estimated ZPEs (28).

We briefly address the considerable differences in MP2 and B3LYP activation and reaction energies. It has very recently been claimed that diffuse (plus) functions are "vital" for calculating relative energies (57). We examined the effect of diffuse functions (6-31+G* basis) on some of these reactions; the activation and reaction energies do indeed move closer to the MP2 values, but only modestly (ca. 10–20 kJ mol^{-1} in most cases; for reaction 1a, however, the reaction energy increases from 554.7 to 629.4 kJ mol^{-1}, cf. the MP2 value of 616.2 kJ mol^{-1}). Much improvement for B3LYP beyond the 6-31G* basis set would be somewhat unexpected, as it is now well established that DFT is much less responsive to large basis sets than is ab initio (43*a*, 58). We are inclined to attribute the moderately inferior showing of DFT here to the fact that current functionals are semiempirical — there is no purely theoretical DFT way to improve DFT functionals (59) — and so may prove inadequate outside their sphere of parameterization. There are even cases in which ab initio works but DFT simply fails (60).

The MP2 and B3LYP geometries of benzene and the azabenzenes (Figs. 1 and 2) agree well, the biggest difference being ca. 0.02 Å (found in **1,2,3,4-N4**, **N5**, and **N6**),

with the MP2 lengths almost always being the longer (exceptions are found in **1,2-N2**, **1,2,3,4-N4**, **1,4-N2**, and **1,2,4-N3**).

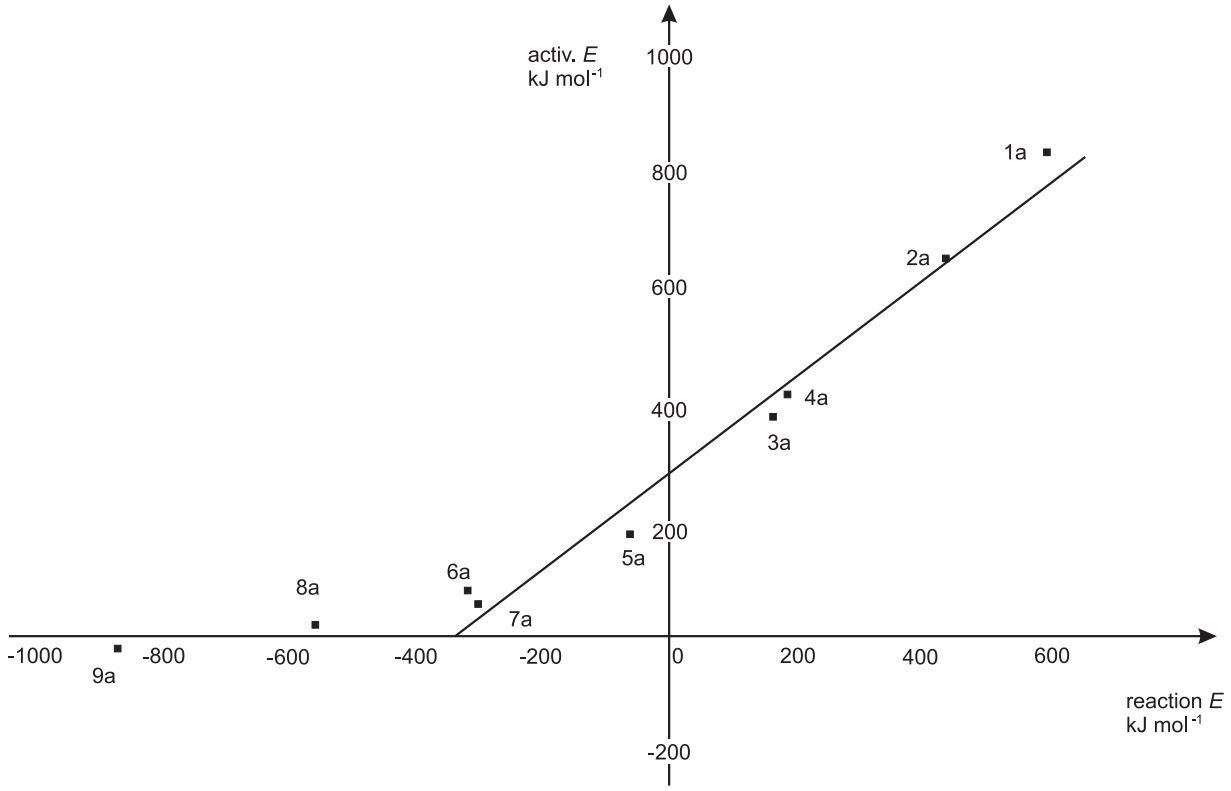

Figure 5 shows a plot of the CCSD(T)/6-31G*//MP2(fc)/6-31G* (Fig. 3) activation energies against reaction energies for reactions 1a–9a (the significance of this graph is discussed below). Focusing first on the (CC) reaction energies, we see that among the seven contiguous-N (including benzene here, **N0**–**N6**) species (Fig. 3) only three, those with 0, 1, and 2 nitrogens (reactions 1a–4a), are predicted to be thermodynamically stable with respect to fragmentation to their two-heavy-atom "components". Among the six noncontiguous-N species (Fig. 4; not included in Fig. 5), three, **1,3-N2**, **1,4-N2**, and **1,3,5-N3** (reactions 1b, 2b, and 5b), are predicted to be thermodynamically stable, and **1,2,4-N3** (reactions 3b and 4b) is a borderline "neutral" case, in that one fragmentation mode (3b) is very slightly exothermic and the other (4b) is only slightly endothermic (–3.5 and 13.5 kJ mol^{-1}, respectively). Where more than one fragmentation mode is possible (reactions 3a–4a, 6a–7a, and 3b–4b), there is little difference (less than 20 kJ mol^{-1}) between their reaction energies (this is true too for the activation energies — discussed below — except for 6a–7a, which differ by 33 kJ mol^{-1}). Note that the azabenzenes are predicted to be *thermodynamically* either robustly stable (reaction energies over 167 kJ mol^{-1}, 3a), or distinctly unstable (reaction energies less than –229 kJ mol^{-1}, 6b), except possibly for **1,2,3-N3** (reaction 5a is calculated to be mildly exothermic, –67.6 kJ mol^{-1}) and **1,2,4-N3** (the borderline reactions 3b and 4b, above).

Let us now examine the CCSD(T)/6-31G*//MP2(fc)/6-31G* activation energies and their relationship to the reaction energies. We point out that from experience a barrier to decomposition of ca. 100 kJ mol^{-1} represents the threshold for isolating a compound at room temperature. For example, pentazole, HN_5, and its conjugate base, N_5^-, have been estimated by extrapolation from data for derivatives to have room temperature activation energies and half-lives of 75 kJ mol^{-1} and 10 min and 106 kJ mol^{-1} and 2 days, respectively (61), while (*E*)-cycloheptene, with an (*E*)-to-(*Z*) activation energy of 71 kJ mol^{-1}, has an extrapolated room temperature half-life of tens of seconds (62). It is clear that in accord with the facts, benzene, pyridine, **1,2-N2**, **1,3-N2**, **1,4-N2**, and **1,3,5-N3** (reactions 1a, 2a, 3a/4a, 1b, 2b, and 5b, respectively) are predicted to be unambiguously stable: the thermodynamic and kinetic obstacles (over 100 and over 300 kJ mol^{-1}, respectively) to their fragmentation are substantial. For **1,2,4-N3** (reactions 3b and 4b), the activation energy (ca. 300 kJ mol^{-1}) is expected to ensure that this compound is isolable at room temperature, whatever may be the uncertainty (above) about its thermodynamic stability; the compound is known and "stable" (12). Similarly, for **1,2,3-N3**, for which the reaction energy (reaction 5a, –67.6 kJ mol^{-1}) appears to be but is not quite unequivocally negative, the fairly high calculated activation energy (193.1 kJ mol^{-1}) indicates that this compound should be fairly stable at room temperature, and indeed, 1,2,3-triazabenzene can be handled at room temperature but decomposes at 130 °C (11).

The tetraazabenzenes form an interesting mix of stable and unstable species. **1,2,3,5-N4** is likely to be kinetically stable at or somewhat below room temperature (reaction 6b, activation energy 115.7 kJ mol^{-1}) but should decompose on heating to give HCN and N_2. Interestingly, this molecule was calculated (55) by CISD to be 33 kJ mol^{-1} lower in energy than the well-known (14) **1,2,4,5-N4**. Our CCSD(T)/6-31G*//MP2(fc)/6-31G* (with MP2(fc)/6-31G* ZPE correc-

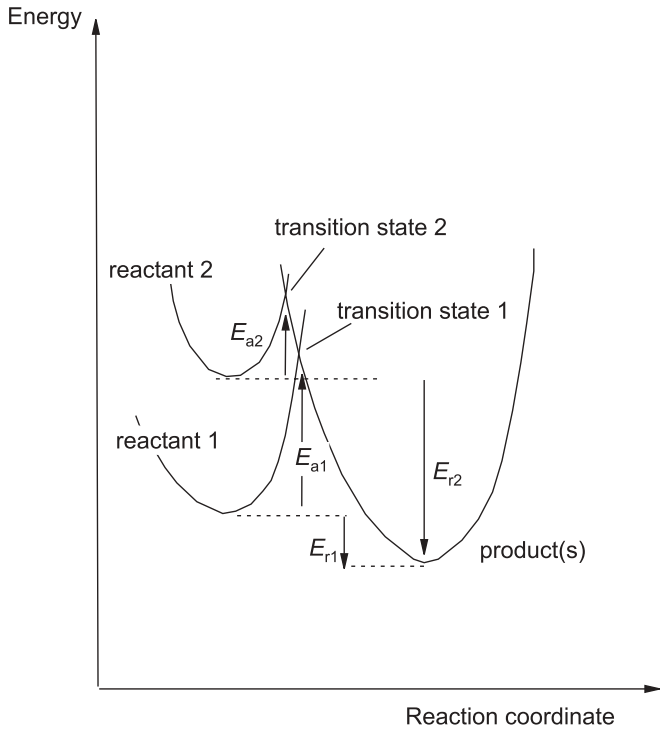
Fig. 5. Activation energy vs. reaction energy for the fragmentation reactions 1a, etc., of the contiguous-N azabenzenes at the CCSD(T)/6-31G*//MP2(fc)/6-31G* level (Fig. 3 shows the reactions and energies). The least-squares linear fit to points 1a–7a corresponds to activation E = 0.816 reaction E + 297, with r^2 = 0.979.

tions) energies were as follows: **1,2,3,5-N4**, –295.50198 au; **1,2,4,5-N4**, –295.49044 au. This indeed places the unknown **1,2,3,5-N4** below **1,2,4,5-N4**, by 0.01154 au or 30.3 kJ mol^{-1}.

1,2,4,5-N4 is predicted, correctly, to have substantial kinetic stability (reaction 7b, activation energy 151.4 kJ mol^{-1}) against decomposition to HCN and N_2. This tetraazabenzene has been known for over a century (14). It indeed undergoes thermal decomposition to HCN and N_2 but is stable enough to participate in Diels–Alder reactions (14), and derivatives of it are well known and have been used as reagents, e.g., as oxidants (63). **1,2,3,4-N4** is expected to decompose at about room temperature to HCN and N_2 (reaction 7a), possibly in competition with decomposition to HCCH and N_2 (reaction 6a), the calculated activation energies being 59.0 and 92.4 kJ mol^{-1}, respectively. Early calculations (semiempirical AM1) by Kaihoh et al. (64) suggested that this molecule would decompose to 2HCN and N_2 in a concerted reaction with an activation energy of 298 kJ mol^{-1} and to HCCH and $2N_2$ by a stepwise path with an activation energy of 145 kJ mol^{-1} for the rate-determining step.

We now come to systems of particular interest: those with five and six nitrogens. The fair linear correlation between calculated reaction energy and calculated activation energy (Fig. 5 plots the data for the contiguous-N molecules) that holds for benzene and all the **N1** to **N4** molecules (i.e., for reactions 1a–7a and 1b–7b) breaks down for pentaazabenzene and hexaazabenzene; their activation energies, being perforce positive, "should" correspond to reaction energies of ca. –400 kJ mol^{-1}, but in fact the calculated reaction energies are –567.4 and –887.5 kJ mol^{-1}, respectively. These molecules are thus more energy-rich than would be suggested by comparison of their activation energies with those of other azabenzenes; alternatively, one might say that they are in a sense stabler than they have a right to be, since their reaction energies are those "expected" for quite negative (!) activation energies. Pentaazabenzene, with a calculated fragmentation activation energy of 12.1 kJ mol^{-1} (the MP2 and B3LYP calculations essentially concur with the single-point CC in this, their values being only ca. 13 kJ mol^{-1} higher) is expected to require matrix isolation techniques (65) for its spectroscopic study but should be observable.

Hexaazabenzene surely is a holy grail of the synthetic chemist seeking nitrogen allotropes N_x. Both MP2(fc)/6-31G* and B3LYP/6-31G* optimizations yield a twisted, D_2 geometry as the potential energy surface *relative* minimum for cyclic N_6 (in agreement with the MP2(full) optimizations with a bigger basis set by Glukhovtsev and Schleyer (34)). Unfortunately, our calculations strongly indicate that it has, at best, an exceedingly low barrier for decomposition to dinitrogen. The three methods (MP2, B3LYP, CC) give activation energies without ZPE of 7.6, 0.6, and –4.0 kJ mol^{-1}; adding ZPE alters the values to 2.3, –1.2, and –9.3 kJ mol^{-1}. The negative energy without ZPE is probably simply because of the error inherent in calculating a small energy difference with single-point calculations (CC on MP2 geometries), and the negative values with ZPE are presumably just the result of errors in the ZPE, possibly combined with (for the CC value) the aforementioned single-point-method error (that **ts-rxn9a** is indeed the desired transition



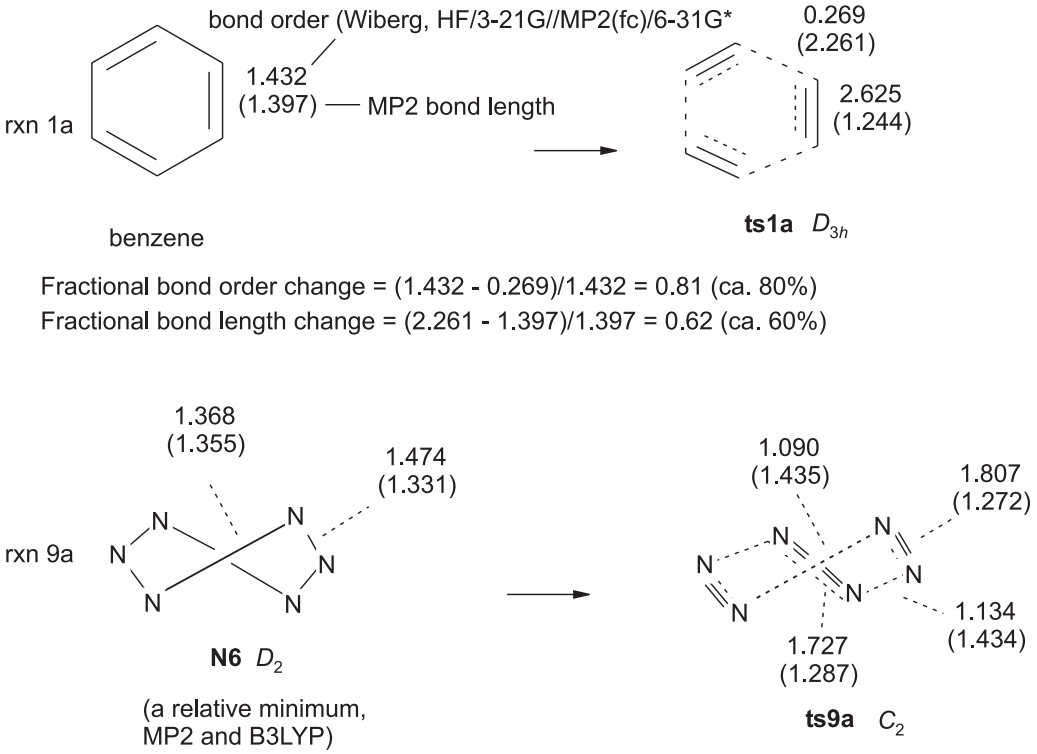
© 2003 NRC Canada

state was shown the B3LYP and MP2 IRC calculations). In any case, the barrier is so small that it is swamped by the errors in all three calculational levels; a barrier of less than 20, and perhaps less than 10 kJ mol^{-1}, is indicated. In fact, the calculated barrier is so close to zero that it is even possible that cyclic N_6 is not really a potential energy surface relative minimum (the acyclic C_2 symmetry N_6 species calculated (34) to be 109 kJ mol^{-1} stabler than hexaazabenzene, is perhaps a more viable synthetic objective, although we have not calculated its kinetic stability).

We now briefly comment further on the relationship between activation and reaction energies for the azabenzenes, as depicted in Fig. 5 for the contiguous-N molecules. For the nine reactions 1a–9a, the plot of activation energy vs. reaction energy is reasonably linear, with the exception of the points corresponding to reactions 8a (pentaazabenzene fragmentation) and 9a (hexaazabenzene fragmentation). This correlation of activation energy with reaction energy (the noncontiguous-N molecules also show a rough linear relationship) is in accord with the Bell–Evans–Polanyi principle (66, 67), which asserts that in a series of related reactions, as the reactions grow more exothermic, the barriers should decrease proportionately. Although apparently not resting on a rigorous theoretical basis, the principle has been manifested as a linear activation vs. reaction energy plot in another series of unimolecular organic reactions involving bond breaking, namely the cleavage of three-, four-, and five-membered rings fused to a cyclohexane ring (68). The concept behind the principle is that in an energy–reaction coordinate plot, the transition state can be regarded as the point where the curves for the reactant and the product cross. Factors that raise the energy of the reactant relative to that of the product then decrease the activation energy and also make the reaction more exergonic, or less endergonic (Fig. 6). The anomalous energetic situation of pentaaza- and hexaazabenzene has been noted above. Reactions with such a low barrier should have transition states resembling the reactants rather than the products, in accord with the Hammond (Hammond–Leffler) principle (66, 69, 70), and this is clearly seen in Fig. 7, which compares reactants with fragmentation transition states for benzene and hexaazabenzene. For benzene, the bonds that break are ca. 80% (according to the bond order change) or ca. 60% (according to the bond length change) broken in the transition state. Thus this transition state is quite product-like. For hexaazabenzene, bond breaking (the lower symmetry cf. benzene presents us with two kinds of breaking bonds) has progressed by only ca. 20% using bond-order changes and only ca. 6%–8% using bond-length changes, making for a reactant-like transition state; the geometry needs to distort but little for the molecule to start falling apart.

The benzene fragmentation transition state has been studied by Wagenseller et al. (71) at several levels; their best (MP4SDTQ/6-31+G*//MP2/6-31G* + ZPE) activation energy was 215 kJ mol^{-1} for the trimerization reaction, the reverse reaction from our viewpoint, cf. our CC single-point value of 826.0 – 596.1 (Fig. 3) = 230 kJ mol^{-1}. Jiao and Schleyer (72) investigated the transition state with emphasis on the question of its aromaticity and obtained, with DFT (B3LYP) and ab initio (MP4SDTQ//MP2), using the 6-311+G** basis set, activation and reaction energies of ca. 790 and 584 kJ mol^{-1}, respectively. In connection with a sophisticated NICS analysis, Morao and Cossío (73) obtained (B3LYP/6-31+G*) activation and reaction energies of 830 and 628 kJ mol^{-1}, respectively. These compare quite well with our CC values of 826 and 591 kJ mol^{-1}, particularly in view of our reservations about the accuracy of DFT here.

Fig. 6. The Bell–Evans–Polanyi principle. Here, reactant 2 is of higher energy than reactant 1 relative to the product(s) in a series of related reactions. See text.



Homodesmotic ring-opening

These calculations were performed on the reactions shown in Fig. 8 and were limited to the contiguous-N azabenzenes. They were designed to assess the stabilization of these molecules relative to their open-chain analogues (e.g., benzene, cf. 1,3,5-hexatriene). With a caveat (below), this is a measure of cyclic conjugation energies or resonance energies, i.e., of aromaticity. Isodesmic reactions are reactions, usually hypothetical, which conserve the numbers of each kind of bond (74). They have the desirable feature that errors, owing to inaccuracies in the non-evenhanded way (mainly because of the imperfect treatment of electron correlation) that energy is calculated for different kinds of molecules, tend to cancel. Several kinds of isodesmic reactions have been developed in an attempt to improve the similarity of the bonds on the two sides of the equation. Williams and Whitehead (22) used an "isolabal" scheme, involving only aromatic rings, to calculate the heats of formation of all twelve (**N1**–**N6**) azabenzenes, employing semiempirical and noncorrelated ab initio (HF/4-31G and 6-31G**) methods. Chesnut (75) found that bond separation isodesmic reactions with ab initio and DFT methods (MP2 and BLYP) gave reasonably good resonance energies, and Chesnut and Davis (76) later reviewed the proliferating varieties of isodesmic reactions and introduced their "homomolecular differential bond separa-

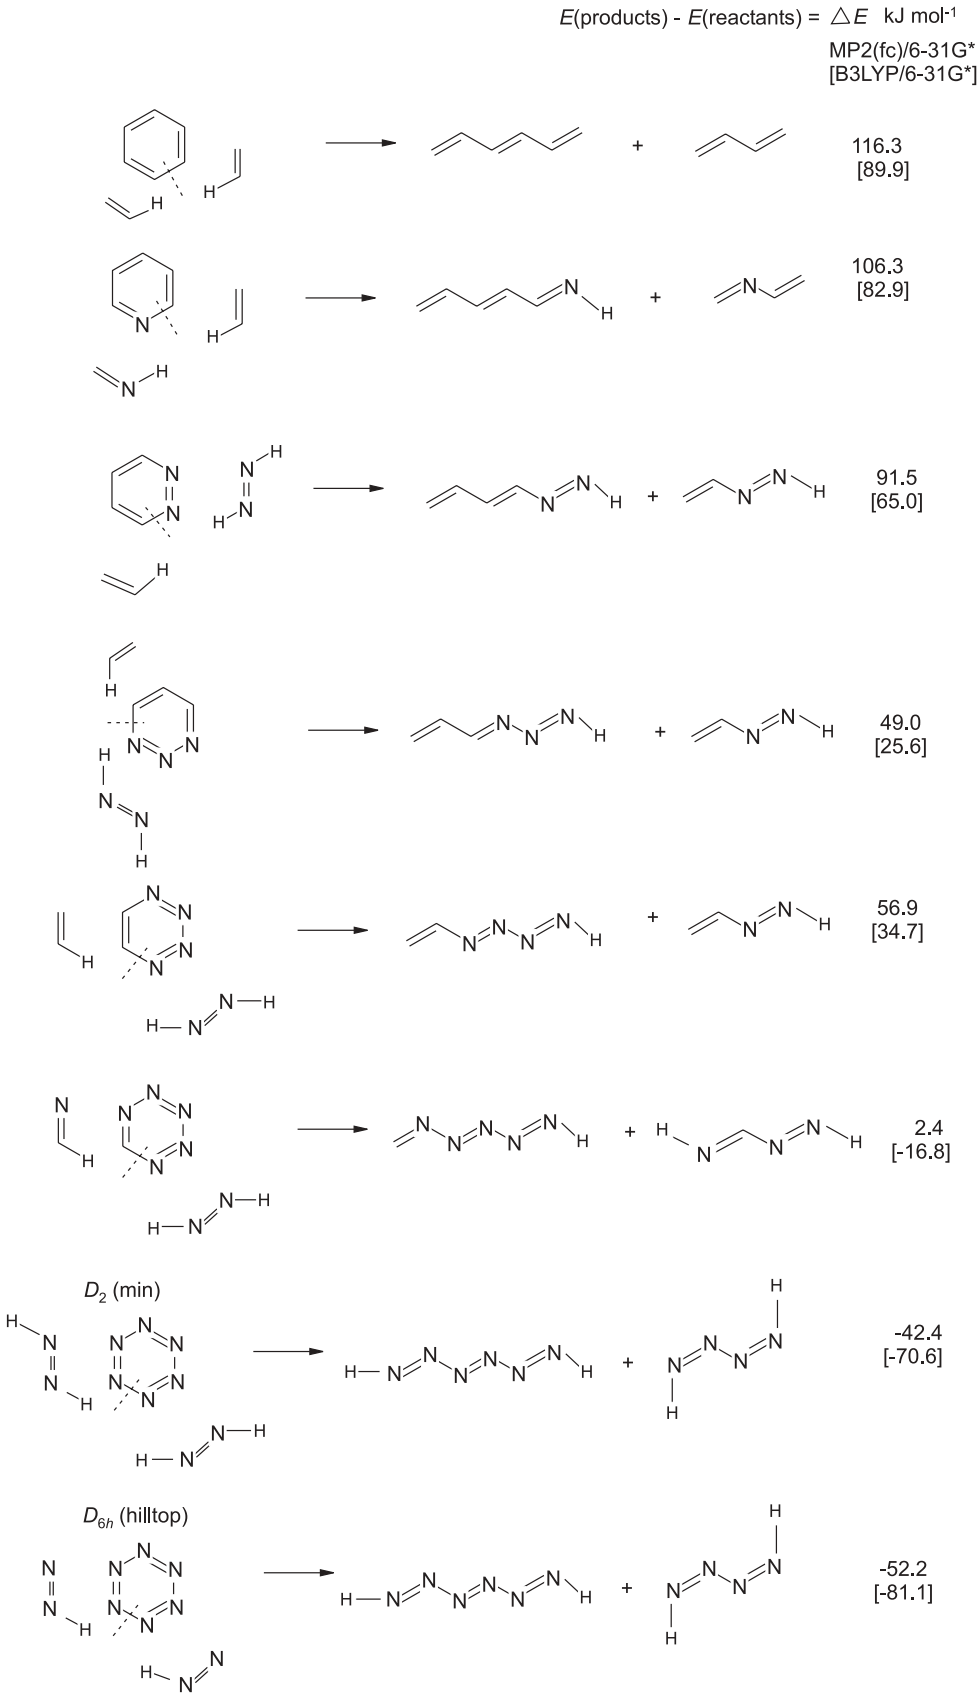
Fig. 7. Comparison of changes in bond order and length on going to the transition state for benzene and hexaazabenzene.



tion" reactions. Glukhovtsev et al. (77) showed that homodesmotic isodesmic reactions (e.g., breaking benzene into three 1,3-butadiene molecules using three ethene molecules, thus conserving the number of sp^2–sp^2 bonds (Fig. 9*a*)) give good values of resonance energies. Delamere et al. (78) used a simple version of homodesmotic reactions to probe the aromaticity of the pentalenoquinones; the molecules were unzipped to acyclic trienediones, preserving the number of sp^2–sp^2 bonds. This unzipping method gives virtually the same results as the more conventional "fragmentation" homodesmic reactions; reactions (*a*) and (*b*) in Fig. 9 are endothermic by 97.0 and 94.0 kJ mol^{-1}, respectively, using the pBP* DFT method (78). We use this homodesmic approach (Fig. 8) here for its simplicity and concur that "the (homodesmotic energy) scheme…has become the most dependable tool for obtaining numerical values of RE" (79). This "resonance energy" (RE) is, essentially, the widely used aromatic stabilization energy, ASE (80).

Figure 8 shows that homodesmic ring-opening is endothermic (the products contain more energy than the reactants) for benzene and the **N1**–**N4** molecules, essentially thermoneutral or slightly exothermic for pentaazabenzene (MP2: 2.4, B3LYP: –16.8 kJ mol^{-1}), and exothermic for hexaazabenzene, with the D_{6h} hilltop being more energy-rich than the D_2 relative minimum by 10 kJ mol^{-1}, according to both MP2 and B3LYP. The decrease in ΔE (Fig. 8) from **N1**–**N5** is qualitatively almost monotonic (ΔE is ca. 10 kJ mol^{-1} bigger for **N4** than for **N3**). Good isodesmic-type reactions essentially eliminate energy differences between reactants and products due to bond energy differences, so ΔE for such reactions is usually due to differences in electron delocalization energy (differences in resonance energy) and (or) differences in strain energy. The resonance energy of the cyclic species is obtained by adding its strain energy to ΔE. This is illustrated by calculations of the resonance energies of benzene, cyclobutadiene, and planar cyclooctatetraene (77). The strain energy (a concept associated with distortion of σ bonds from their normal angles) of benzene is taken as being small or zero and that of smaller rings as being positive (77, 78). The ΔE values in Fig. 8 show that benzene and the **N1**–**N4** molecules are distinctly stabilized with respect to bond-energy-compensated ring opening to acyclic analogues; **N5** is about neutral in this regard; and **N6** is distinctly unstable in this sense. Our values of ΔE for benzene (MP2: 116.3, B3LYP: 89.9 kJ mol^{-1}) and D_2 hexaazabenzene (MP2: –42.4, B3LYP: –70.6 kJ mol^{-1}) using reactions of Fig. 9, type *b*, lead to the same conclusions as those obtained by Glukhovtsev and Schleyer (34) from MP4SDTQ/6-31G(d,p)//MP2(full)/6-31G(d,p) calculations on reactions of Fig. 9, type *a* (benzene 100.0; D_2 hexaazabenzene –73.6 kJ mol^{-1}). The ca. 100 kJ mol^{-1} stabilization of benzene can be ascribed to cyclic electron dissociation — its resonance energy (77). Does the nearly monotonic decrease in ΔE with increasing numbers of nitrogens result

Fig. 9. Homodesmotic fragmentation (*a*) and unzipping (*b*) reactions (both of which conserve sp^2–sp^2 bonds) give essentially the same results (DFT pBP/DN* calculations (71)).

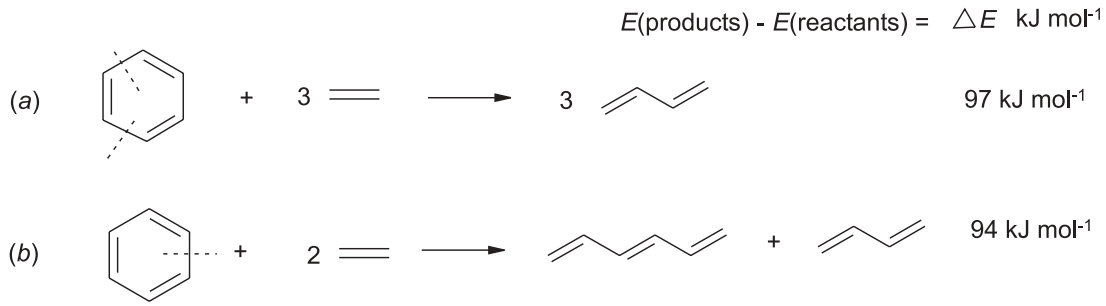

Table 1. Deviation of G3(MP2) reaction energies (kJ mol^{-1}) from those calculated at the CCSD(T)/6-31G*//MP2(fc)/6-31G*, MP2(fc)/6-31G*, and B3LYP/6-31G* levels, for reactions 1a–8a (Fig. 3).

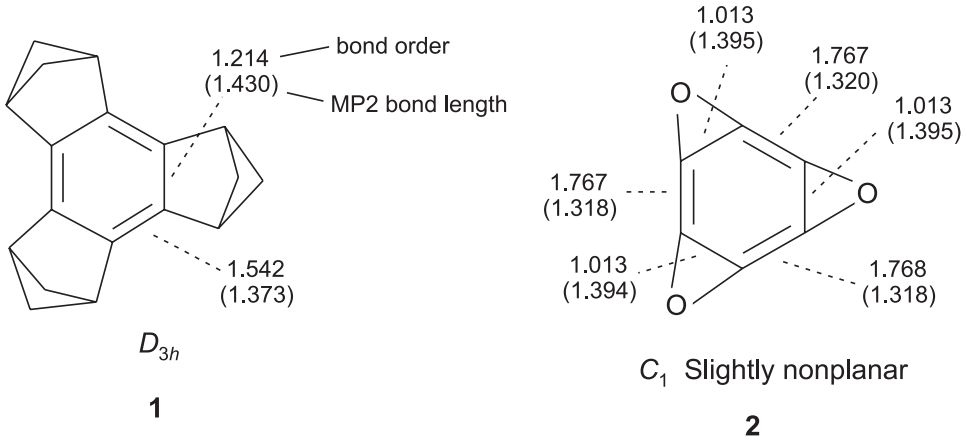
Reaction	Deviation from CC	Deviation from MP2[a]	Deviation from B3LYP[a]
1a	–3	–27	34
2a	4	–10	29
3a	3	–6	–82
4a	12	6	–70
5a	13	13	–79
6a	13	19	–47
7a	22	31	–75
8a	25	43	–80
Average	12	19	62

[a]Deviation = G3(MP2) reaction energy — coupled cluster, etc., reaction energy. The averages are the arithmetic means of the absolute values of the deviations.

from a progressive decrease in resonance energy? This would be the case if there were no factors other than resonance at work in the series. In fact, however, replacing CH groups with nitrogens introduces electron lone pairs, and an obvious way that these may destabilize these molecules is by simple electrostatic repulsion, a possibility considered by Glukhovtsev and Schleyer (77). A subtler way in which lone pairs might effect destabilization is by weakening C—N or N—N bonds, by donating nonbonding electrons into σ* orbitals (81). In any case it seems likely that some destabilizing effect associated with nitrogen lone pairs is operating and, thus, that the homodesmotic Δ*E* values beyond the **N2** or **N3** molecules would have to be somehow corrected for this destabilizing effect, to extract the resonance energy of the heterocycle; cf. the correction of Δ*E* for strain for some molecules (77, 78). The effect of lone-pair interactions on the proton affinities of the azabenzenes has been noted by Sanz et al. (27) and by Mó et al. (29), the latter finding no correlation with lone-pair energies. Katritzky and Barczynski (26) concluded from an AM1 probe of aromaticity using geometric, energetic, and magnetic criteria that the azabenzene nitrogens have little effect on "classical" aromaticity, but they studied only **1,2,3-N3**, **1,2,4,5-N4**, and **1,2,3,4-N4** among the azabenzenes. Wiberg et al. (28) performed at the HF, MP2, and MP3 levels isodesmic-type hydrogen transfer reaction calculations (e.g., cyclohexadiene plus pyridine giving dihydropyridine plus benzene), as well as hydrogenation energy calculations (a kind of isodesmic calculation), and concluded that the resonance energies of benzene, pyridine, **1,3-N2**, and **1,4-N2** are essentially the same.



Electron distribution as indicated by bond order – bond length variation

These were calculated for benzene and the six contiguous-N azabenzenes (Fig. 1) and for the six noncontiguous-N azabenzenes (Fig. 2). The idea here is that an aromatic, cyclically delocalized ring should show less variation in bond order than one with localized single and double bonds. For example, for the cyclopentadienyl cation, the relative minimum on the potential energy surface is a C_{2v} species with three kinds of bonds (82), but for the anion the minimum is a D_{5h} species with only one kind of bond and, thus, with an even electron distribution (83). Several, somewhat complex, indexes based essentially on deviations from uniformity of bond length or bond order have been suggested as probes of aromaticity (84); simple indexes that are essentially deviations from an average bond length have also been used (85). We are skeptical of the usefulness of such indexes in probing aromaticity in the series pyridine–pentaazabenzene, because unlike the case of carbocycles like benzene, cyclopropenyl species, cyclopentadienyl species, etc. — and even azulene and benzocyclobutene (85) — one expects (and finds) an uneven electron distribution due to the presence of C—C, C—N, and N—N bonds, which makes it uncertain what the electron distribution "should" be in the absence of aromatic delocalization. This makes it hard to draw reliable conclusions beyond that given simply by the symmetry (e.g., that **1,3,5-N3**, being D_{3h}, has only one kind of C—N bond and so is cyclically delocalized like benzene, rather than possessing single and double bonds like the hypothetical cyclohexatriene). Nevertheless, we document calculated bond orders and lengths for benzene and all the azabenzenes (Figs. 1 and 2) and use these bond orders to calculate the Bird aromaticity index (86). This is essentially the standard deviation (more precisely, a somewhat biased version of the variance) of the bond orders, adjusted (for six-membered potentially aromatic rings) so that benzene gets an index of 100 (*V*, below, = 0) and Kekulé benzene (cyclohexatriene, with bond orders 1,2,1,2,1,2; V_K, below, = 33.3) an index of zero.

$$[1] \qquad V = \frac{100}{\bar{N}}\sqrt{\frac{\sum (N_i - \bar{N})^2}{n}}$$

© 2003 NRC Canada

Fig. 10. Tris(bicyclo[2.2.1]hexeno)benzene (**1**) and tris(oxireno)benzene (**2**); HF/3-21G Wiberg bond indexes on MP2(fc)/6-31G* geometries.

$$[2] \qquad I = 100\left(1 - \frac{V}{V_K}\right)$$

where V_K = 33.3, using Kekulé bond orders 1,2,1,2,1,2.

For six-membered rings, the summation in eq. [1] is over the six bond orders N_i; $\bar{N}$ is the arithmetic mean of the bond orders; and n = 6. V is commonly denoted σ_n. V_K in eq. [2] is V for Kekulé benzene (cyclohexatriene). The Bird index (I, eq. [2]) was chosen because, unlike some other indexes, it can be calculated for any cyclic species for which bond orders are available; because it is straightforward; and because it is probably as good as any other index based on deviations from bond order or bond length. Obviously the value of I depends on the bond orders used, and since there is no single, correct bond order (87), there is no uniquely correct Bird index for any molecule. Bird used bond orders estimated from experimental or from estimated bond lengths, presumably because, at the time, good fully optimized molecular geometries were not available for sizable molecules. We use here Wiberg bond orders (88) calculated at the HF/3-21G level on MP2(fc)/6-31G* geometries (the algorithm that implements bond order and related calculations in Gaussian 98 is by Glendening et al. (89)); all these geometries were checked by frequency calculations at the same (MP2) level to ensure they were potential energy surface relative minima.

Table 2 shows the results of our Bird index calculations for the azabenzenes; to put these values in perspective we also show our values for some five-membered-ring aromatics and for two potentially cyclohexatriene-like benzene rings: **1**, tris(bicyclo[2.1.1]hexeno)benzene, and **2**, tris(oxireno)benzene (Fig. 10), which we briefly discuss below. Values obtained by Bird (Table 2) often differ considerably from ours, showing the effect of using different bond order values. If bond-order variation were the only criterion for aromaticity, the Bird index could be regarded as a measure of how aromatic a molecule is, percentage-wise, compared with benzene. For example, pyridine could be said to be 98.2% (Wiberg bond orders) as aromatic as benzene. The index probably does reflect to some extent the amount of cyclic delocalization in a potentially aromatic ring; the five-membered heterocycles in the table have considerably smaller I values than benzene, with furan having the smallest value, in accord with the conventionally accepted order of their aromaticity. Particularly interesting are the I values for **1** and **2**, molecules designed to impose bond alternation on benzene by diverting electron density from formal double bonds: the former to avoid strain in the bicyclic moieties, the latter to avoid, in the oxirene moieties, strain and antiaromaticity. The aromaticity of **1** has been evaluated from magnetic properties and isodesmic reactions, with the conclusion that, in accord with previous work on the molecule, it "retains a substantial degree of aromaticity" (90), which accords with I = 64.3. Molecule **2** has the astonishingly small Bird index of 18.5, suggesting it is essentially a cyclohexatriene; bond fixation in benzooxirenes has been exam-

Table 2. Bird indexes (79) for benzene, the azabenzenes, thiophene, pyrrole, furan, and the bond-localized benzenes **1** and **2**.

	Bird index, I	
Molecule	From Wiberg BOs	From estimated BOs (Bird (86*a* and 86*b*))
Benzene	100	100 (86*b*)
N1 (pyridine)	98.2	85.7 (86*b*)
1,2-N2	89.5	78.9 (86*b*)
1,2,3-N3	98.4	76.9 (86*b*)
1,2,3,4-N4	88.5	
N5	97.5	
N6 (D_2)	89.6	
N6 (D_{6h}) (a hilltop)	100	
1,3-N2	97.7	
1,4-N2	98.8	
1,2,4-N3	89.1	86.1 (86*b*)
1,3,5-N3	100	100 (86*b*)
1,2,3,4-N4	96.9	
1,2,4,5-N4	99.5	97.8 (86*b*)
Thiophene	52.1	66 (86*a*)
Pyrrole	58.4	59 (86*a*)
Furan	23.2	43 (86*a*)
1 (Fig. 10)	64.3	
2 (Fig. 10)	18.5	

Note: Bond orders: HF/3-21G Wiberg bond orders on MP2(fc)/6-31G* geometries. Where available, values calculated by Bird (79*a*, 79*b*) from estimated bond orders are given.

ined computationally, and the pronounced bond length fixation in **2** was noted (91). Like oxirenes in general, **2** is unknown (92). Bond-order variation indicates that all twelve azabenzenes are about as delocalized (as "aromatic") as benzene, with Bird indexes of 89–100.

Ring-current effects as indicated by calculated nucleus-independent chemical shifts (NICS)

The calculated magnetic shielding of a ring on a probe nucleus without charge — the nucleus-independent chemical shift or NICS — has become a popular method of testing cyclic molecules for the ring-current effects believed to be associated with aromaticity or antiaromaticity. Since its introduction by Schleyer et al. in 1996 (93), the NICS method has been applied widely, e.g., to the putative homoaromatic compound triquinacene (94); to the correlation of magnetic with other criteria for aromaticity (95); to novel sulfur-containing compounds (96); to inorganic rings (97); to pentafulvene and silicon, germanium, and tin derivatives thereof (98); and to transition states (99). There are variations of the method in which the probe nucleus is placed above the ring to avoid local σ-bond effects (100), and the variation of shielding with distance above the ring has been analyzed theoretically (73).

Our NICS results for the contiguous-N azabenzenes are shown in Fig. 11. These are from GIAO HF/6-31G* calculations on MP2(fc)/6-31G* geometries; in our experience, this level generally gives essentially the same results as HF/6-31+G*//B3LYP/6-31G* calculations, one level that was used in the original NICS work (93). The shielding was calculated at 0, 0.5, 1, 1.5, 2, and 2.5 Å above the ring center, and Fig. 11 actually shows, for convenience, –NICS (= BQ isotropic (93); BQ, for Banquo, is Gaussian's designation of a ghost atom) rather than NICS values, since the NICS values are all negative except for NICS 0 of D_{6h} **N6**. In work on the quinones of pentalene, Delamere et al. (78) showed that plots of –NICS against distance above the ring center ("NICS curves") could be useful in examining related molecules for aromatic, nonaromatic, or antiaromatic character. Although we have not plotted actual curves here, the data in Fig. 11 show that by this magnetic test all eight species are aromatic: the –NICS 1 values are all ca. 12–13, and the –NICS 2 values are all ca. 5–6, cf. the benzene values of 12.81 and 5.46, respectively (for convenience we omit the NICS units of NMR ppm). This inclusiveness comfortably accommodates the suggestion that a molecule be considered nonaromatic if it has "less than half the magnitude of property in comparison to benzene" (101). The only considerable divergence from the values for benzene is in the –NICS 0 values, which, for all six planar molecules, benzene to **N5** (D_2 **N6** is twisted and D_{6h} **N6** is not a "real" molecule but rather a hilltop), fall monotonically and dramatically from 11.54 to 1.67. We attribute this to an effect involving the in-plane σ electrons and (or) lone pairs (97) and draw attention to the importance of calculating shielding above the ring plane, as has been recognized by others (100).

Integrating the results

Despite the nearly monotonic decrease in kinetic and thermodynamic stabilities for all the azabenzenes (e.g., Fig. 5) and in "resistance" to homodesmotic ring opening for the contiguous-N species (Fig. 8), the indication from bond-order variation (Table 2) and, more strongly, from NICS (Fig. 11) is that all the azabenzenes are delocalized much like benzene, i.e., are "aromatic" (2). The question of correlation between "classical" energetic criteria on the one hand and magnetic and other criteria on the other has been discussed at length in the literature, with conclusions ranging from significant correlation (95, 102) to little correlation (103) and even to the view that different magnetic criteria can diverge strongly as probes of aromaticity (101).

Fig. 11. NICS values (ppm) for the contiguous-N azabenzenes, at 0, 0.5, 1, 1.5, 2, and 2.5 Å above the ring center. From HF/6-31G* GIAO calculations on MP2(fc)/6-31G* geometries.

Conclusions

These calculations indicate that all the azabenzenes are probably "aromatic" in the sense of resembling benzene in sustaining a diatropic ring current (as measured by NICS values) and in evenness of electron distribution around the ring (as measured by the Bird bond order uniformity index). However, increasing nitrogen substitution causes a steady (in the contiguous-N series, a nearly monotonic) decrease in kinetic and thermodynamic stability (as measured by comparison of the energies of reactants with the energies of

© 2003 NRC Canada

transition states for fragmentation and with the energies of fragmentation products). A study of the stability of the contiguous-N series toward ring opening (as measured by homodesmotic ring-opening energies) also showed a steady decrease in stability with increasing nitrogen substitution. We ascribe these decreases in stability to the lone pairs on nitrogen, which may act by simple electrostatic repulsion and (or) by weakening C—N and N—N bonds by donation of *n* electrons into σ* orbitals. The still-unknown azabenzenes (1,2,3,4-, 1,2,3,5-, pentaaza-, and hexaazabenzene) are relative minima on the MP2/6-31G* and B3LYP/6-31G* potential energy surfaces, but for hexaazabenzene, the barrier to fragmentation is so low (e.g., 2.3 kJ mol^{-1} with MP2/6-31G*) that this species may in reality not be able to exist.

Bismuth-mediated reductive dehalogenation of α-halocarbonyl compounds[1]

Yoon Joo Lee and Tak Hang Chan

Abstract: Bismuth metal, activated by ammonium hydrogen fluoride, was found to reduce various α-halocarbonyl compounds efficiently and chemoselectively in aqueous media to give the dehalogenated reduction products in excellent yields.

Key words: bismuth, reduction, α-halocarbonyl compounds, fluoride salts, aqueous media, bismuth enolates, aldol reaction.

Résumé : On a observé que le bismuth métallique activé par du fluorure d'ammonium permet de réduire en milieu aqueux divers composés α-halocarbonylés de façon efficace et chimiosélective pour conduire avec de bons rendements à la formation des produits de réduction déshalogénés.

Mots clés : bismuth, réduction, composés α-halocarbonylés, fluorures, milieu aqueux, énolates de bismuth, réaction aldolique.

[Traduit par la Rédaction]

Introduction

The reductive dehalogenation of α-halocarbonyl compounds (without affecting the carbonyl group) has received considerable attention in organic chemistry. A number of reagents have been developed for this selective reduction, including: (*i*) reducing agents, such as zinc in acetic acid (1), sodium dithionate (2), organotin hydrides (3), borohydride (4), and low-valent transition metal salts (e.g., titanium(III) (5), vanadium(II) (6), and chromium(II) (7)); (*ii*) strong nucleophiles that may act as reducing agents, such as iodide ions (8), phosphines (9), iodophosphines (10), iodotrimethylsilane (11), thiols (12), selenols (13), tellurolates (14), and amines (15); (*iii*) stoichiometric amounts of zero-valent transition metal carbonyls of iron (16), cobalt (17), and molybdenum (18); (*iv*) heterogeneous hydrogenation catalysts involving transition metal surfaces (19); and (*v*) composite reducing systems of tin or silicon hydrides with transition metal catalysts, such as palladium (20) and molybdenum (21). The choice of a reducing agent usually depends on what other functional groups are present. Typically, these methods have to be carried out with organic solvents as the reaction media. Recently, Ranu et al. (22) reported an efficient and general methodology for the chemoselective reduction of α-halocarbonyl compounds in aqueous media. They discovered that indium metal could reduce α-halocarbonyl compounds to the corresponding dehalogenated carbonyl compounds in water under sonication. A wide range of structurally diverse α-bromo and α-iodoketones and esters was found to undergo the reductive dehalogenation by this procedure, to provide the corresponding reduction products in excellent yields. More recently, a useful employment of indium metal for the reductive dehalogenation reaction in aqueous media was reported by Chae et al. (23). One very important aspect of these reduction systems involving indium metal is the use of water as a reaction medium, which has attracted considerable interest in recent years in the context of green chemistry (24). We are interested in seeking an alternative to indium for aqueous reactions because of the high cost of indium and its potential toxicity. In this connection, among the heavy metals such as indium, antimony, mercury, and lead, bismuth metal is relatively inexpensive and nontoxic (25). In 1995, Ren et al. (26) reported the selective reduction of carbon–carbon double bonds in α,β-unsaturated esters by sodium borohydride in combination with bismuth chloride in ethanol. Subsequently, they also found the $NaBH_4$–$BiCl_3$ system to be very effective for the reduction of nitroarenes to primary amines (27). More recently, $BiCl_3$–Al and $BiCl_3$–Sm have been used to mediate the coupling of α-bromocarbonyl compounds with aldehydes (28). In all these cases, it was presumed that activated bismuth was generated by the reduction of the bismuth chloride, even though bismuth metal by itself was not active. Recently, we found that many metals can be rendered reactive in aqueous media by the activation of fluoride salts (29). We have therefore examined the possibility of activating bismuth metal by fluoride salts in aqueous media for various reactions.

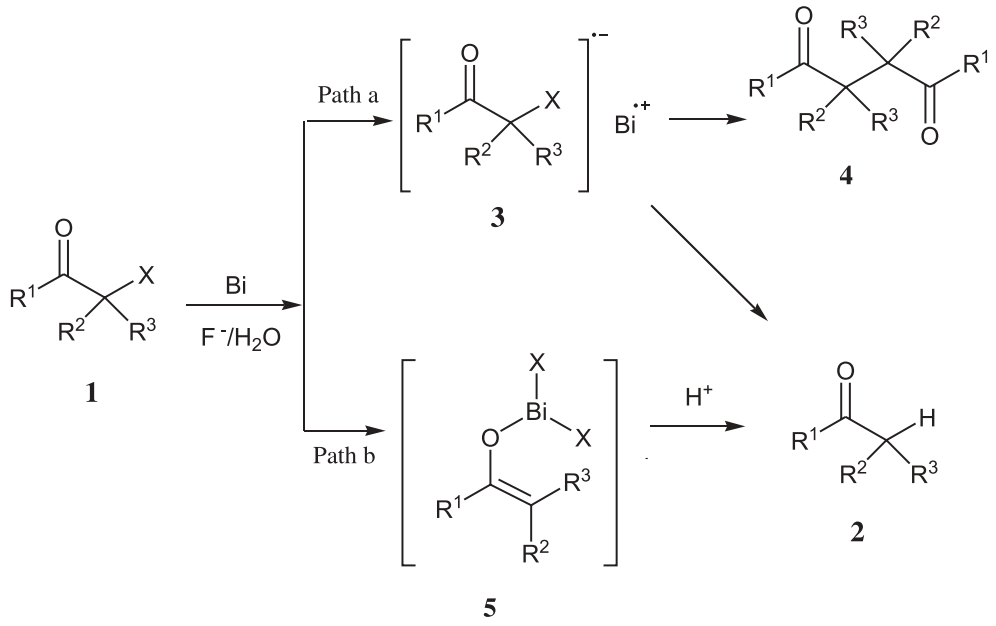
ous media (30). This prompted us to initiate a systematic investigation into the reduction of α-halocarbonyl compounds (**1**) by bismuth metal with ammonium hydrogen fluoride in aqueous media (Scheme 1). The results are summarized in Table 1.

As can be seen in Table 1, bismuth metal activated by ammonium hydrogen fluoride could effectively reduce various α-halocarbonyl compounds in aqueous media at room temperature, to provide the corresponding dehalogenated reduction products in fairly high yields. It should be emphasized that in the absence of the fluoride salt, the reduction with bismuth did not proceed to any significant extent. The reduction of the chloro compound (entry 3) was found to be much slower in comparison with those of the bromo compounds. It is important to note that this reduction system is highly chemoselective. Usually, the nitro group is very sensitive to reduction by metals. However, under these reduction conditions, *p*-nitroacetophenone could be obtained successfully without reducing the nitro group (entry 11). This should be compared with the $BiCl_3$–$NaBH_4$ system, which reduces nitro function as well (27). Furthermore, in the case of 2,4′-dibromoacetophenone, the bromo group on the aromatic ring also remained unaffected (entry 12). These results indicate that the present reaction conditions for the reduction of α-halocarbonyl compounds to dehalogenated carbonyl compounds are compatible with the nitro groups and the haloaryl, as well as the carbonyl, groups (ketone, acid, and ester). Finally, no reductive pinacol coupling products, derived from the carbonyl function, were observed (29*a*).

The exact role of the fluoride salt in the activation of metal in aqueous media is not known. Many metals may be unreactive in water because of the formation of water-insoluble metal oxide on the metal surface. Previously, it was suggested that the fluoride anion may render the metal oxide water soluble through formation of complex fluoride salts and allow further reaction at the metal surface to take place (29*a*). Metal-mediated reactions in aqueous media may proceed by different mechanisms, depending on the metal used. In many cases, it is considered that metal-mediated aqueous reactions go through a single electron transfer (SET) process on the metal surface, generating a radical anion intermediate **3** (31). While the precise mechanism for the bismuth-mediated reductive dehalogenation of α-halocarbonyl compounds is not known at this point, the fact that the radical self-coupling product **4** was not observed as a side product under the reaction condition suggests that the reduction did not undergo the SET process (Scheme 2, path a). It is more likely that the reduction by bismuth metal in the presence of ammonium hydrogen fluoride in aqueous media proceeds through the formation of a bismuth enolate intermediate **5** (Scheme 2, path b), which, on protonation, gives the reduction product **2**. Similar bismuth enolates have been invoked for the $BiCl_3$–Al mediated aldol condensation (28).

Scheme 1.



1 **2**

Supporting evidence for the intermediacy of bismuth enolate was obtained by carrying out an aldol condensation under the same reaction conditions. 3-Bromoisobutyrophenone (**1e**) and benzaldehyde in the presence of bismuth and NH_4HF_2 were stirred in water at room temperature overnight. The reaction proceeded cleanly, and the starting **1e** was completely consumed. In addition to the reduction product **2e** in 63% yield, the aldol product **6** was obtained in 37% yield (Scheme 3). It appeared that, in the competition between protonation and aldol reaction, the protonation process was favoured. One should be able to increase the yield of the aldol product **6** by increasing the rate of aldol condensation or suppressing the protonation reaction. This can be achieved by decreasing the amount of water (Table 2, entry 2), since the rate of the aldol reaction is dependant on the concentration of aldehyde. Alternatively, one can also reduce the rate of protonation by replacing water with D_2O, taking advantage of the kinetic isotope effect (32). This was indeed found to be the case (Table 2, entries 3 and 4). These results suggest that bismuth metal, under fluoride activation, may

be a viable method to mediate crossed aldol type reactions, and its scope should be further explored (33).

Conclusion

The bismuth-mediated reductive dehalogenation of α-halocarbonyl compounds in aqueous media was investigated. Bismuth metal, activated by ammonium hydrogen fluoride, was found to reduce various α-halocarbonyl compounds efficiently under mild conditions, to afford the corresponding dehalogenated reduction products in excellent yields. The results showed that the reduction was highly chemoselective and suggested that the reduction products were presumably formed from the bismuth enolate intermediate.

Experimental

General information

Chemicals were purchased from Aldrich or Alfa Aesar Chemical Company. Thin layer chromatography was performed on plastic plates precoated with silica gel (60 F_{254}), which were developed using a mixture of hexane and ethyl acetate as the eluent. Analytes were visualized by UV light or by dipping the plate into a developing agent (a solution of ammonium molybdate and ceric sulfate in dilute sulfuric acid) and heating with a heat gun. Column chromatography was performed on 230–400 mesh silica gel. Melting points were determined using a Gallenkamp apparatus and were uncorrected. ^{1}H NMR spectra and ^{13}C NMR spectra were recorded on a Varian Mercury 300 MHz spectrometer at ambient temperature. Chemical shifts (δ) were reported in parts per million (ppm) and referenced to $CDCl_3$ at δ 7.25 ppm for ^{1}H and δ 77.00 ppm for ^{13}C. The multiplicity of each signal was indicated by s (singlet), d (doublet), t (triplet), q (quartet), quint (quintet), sept (septet), and m (multiplet). Coupling constants (*J*) were reported in Hertz (Hz).

General procedure for bismuth-mediated reductive dehalogenation

To a mixture of an α-halocarbonyl compound (1 mmol), bismuth powder (1.5 mmol), and NH_4HF_2 (1.5 mmol) was added distilled water (1 mL). The reaction mixture was vigorously stirred at room temperature until the reaction was

© 2003 NRC Canada

completed (1–24 h). Additional distilled water (10 mL) was added to the reaction mixture, and the product was extracted with diethyl ether (3 × 30 mL). The combined organic layer was dried over anhydrous Na_2SO_4 and filtered. After the evaporation of solvent under reduced pressure, the crude product was purified by flash column chromatography on silica gel, using 2% ethyl acetate in hexane as the eluent, to give the corresponding pure reduction product. Their identities were confirmed by comparison with authentic samples.

Bismuth-mediated aldol type reaction

To a mixture of 2-bromoisobutyrophenone (1 mmol), benzaldehyde (1.1 mmol), bismuth powder (1.5 mmol), and NH_4HF_2 (1.5 mmol) was added water or D_2O (1 or 5 mL). The reaction mixture was vigorously stirred at room temperature for 12 h. Additional distilled water (10 mL) was added to the reaction mixture, and the product was extracted with diethyl ether (3 × 30 mL). The combined organic layer was dried over anhydrous Na_2SO_4 and filtered. After the evaporation of solvent under reduced pressure, the crude product was analyzed by ^{1}H NMR for product distribution. The mixture was purified by flash column chromatography on silica gel, using 5% ethyl acetate in hexane as the eluent, to give the reduction product **2e** and the aldol product **6** (34) as a white solid. mp 105–107 °C. The β-(acyloxy)alkyl radical rearrangement revisited[1]

David Crich and Dae-Hwan Suk

Abstract: A β-(acyloxy)alkyl radical precursor, containing a carboxylate residue suitably placed for the trapping of any intermediate alkene radical cations, has been constructed. In nonpolar solutions the probe, in the form of either the free acid or its tetrabutylammonium salt, undergoes the typical rearrangement reaction with no evidence of trapping, leading to the conclusion that the reaction is either concerted or that collapse of any intermediate contact ion pair is so rapid as to preclude the possibility of trapping.

Key words: radical, rearrangement, contact ion pair.

Résumé : Un précurseur de transposition d'un radical β-(acyloxy)alkyle, equippé d'un résidu carboxylate convenablement placé pour piéger des intermediares alcene cation radicalaire, a été construit. En milieu apolaire la sonde, sous forme d'acide carboxylique ou sel de tetrabutylammonium quaternaire, subit la transposition typique et ne manifest aucune évidence de piègage, ce qui mène à la conclusion que la réaction est soit concertée, soit a lieu par l'intermédiaire d'une paire d'ions intime qui se réunit trop rapidement pour admettere la possibilité de piègage.

Mots clés : transposition radicalaire, paire d'ions intime.

Introduction

Initially thought to be concerted (1), the β-(phosphatoxy)alkyl radical rearrangement has recently been shown to involve a rate-determining radical ionic fragmentation to a contact radical ion pair with subsequent collapse to the product radical (Scheme 1, X = $P(OR)_2$) (2, 3). The jury is still out, however, in the case of the closely related β-(acyloxy)alkyl radical rearrangement (1), otherwise known as the Surzur–Tanner rearrangement (4). In this paper we describe attempts at trapping any intermediate contact ion pair, which attest, at the least, to the rapidity of its collapse to the product radical.

The evidence for the fragmentation mechanism in the rearrangement of β-(phosphatoxy)alkyl radicals is spectroscopic and kinetic (2, 3, 5) and is well supported by a range of trapping experiments (6–10). Thus, in more polar solvents, β-phenyl-β-(phosphatoxy)ethyl radicals fragment to give the styryl radical cation, which is readily detected in time-resolved laser flash photolytic experiments, and the phosphate anion. Kinetic experiments reveal the Arrhenius parameters for the fragmentation, with log(A) values typically in the vicinity of 10–12 (2, 3, 11). When the same experiments are conducted in nonpolar solvents only the rearranged radical is observed, but the Arrhenius parameters for these rearrangements closely resemble those for the fragmentations in more polar solvents (2, 3, 12, 13). The congruence between the two sets of Arrhenius parameters leads to the conclusion that both involve rate-determining fragmentation to a contact radical ionic pair, but that in nonpolar solvents rapid collapse to the product radical precludes the possibility of cage escape and spectroscopic detection of the radical cation. Note that, owing to the nanosecond timescale of the instrument used in the LFP experiments and the expected sub-nanosecond times anticipated for the escape of ions from contact ion pairs (14), only those radical cations that live long enough to escape the initial contact pair can be observed spectroscopically. Numerous trapping studies (6–10) have pointed to the ability of nucleophiles to intervene in this mechanism by trapping the alkene radical cation, and the stereochemical information retained in some of them (9) indicates that, with appropriate nucleophiles, trapping can take place at the level of the contact radical ion pair.

Significant effort has also been focused on the mechanism of the β-(acyloxy)alkyl radical rearrangement (15). A variety of stereochemical and isotopic labeling studies point to a reaction that is the formal equivalent of a 2,3-sigmatropic shift (Scheme 2) (1, 15). However, kinetic studies conducted by classical competition and (or) ESR spectroscopic methods (1, 15) and by time-resolved laser flash photolysis methods (13) have revealed Arrhenius parameters, especially typical log(A) values of 11.0–14.0, which closely parallel those of the β-(phosphatoxy)alkyl radical rearrangements, thereby strongly suggesting an analogous rate-determining fragmentation followed by an extremely rapid collapse to the product

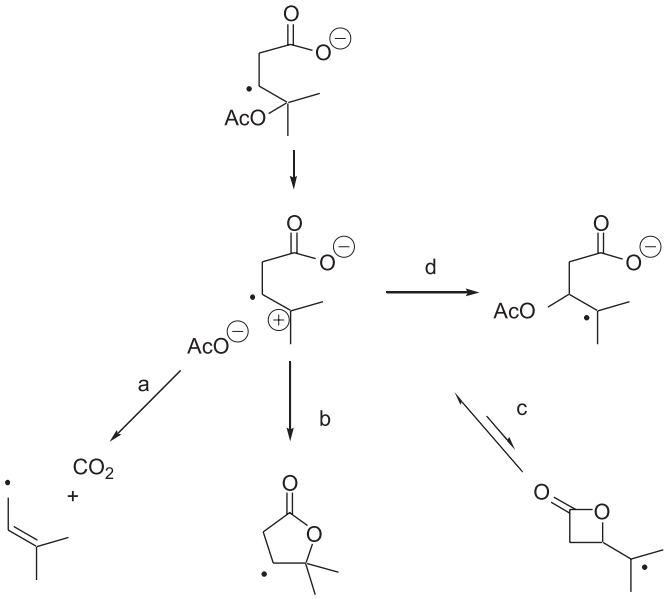
Scheme 1. The fragmentation–recombination mechanism for the rearrangement of ester-substituted radicals.

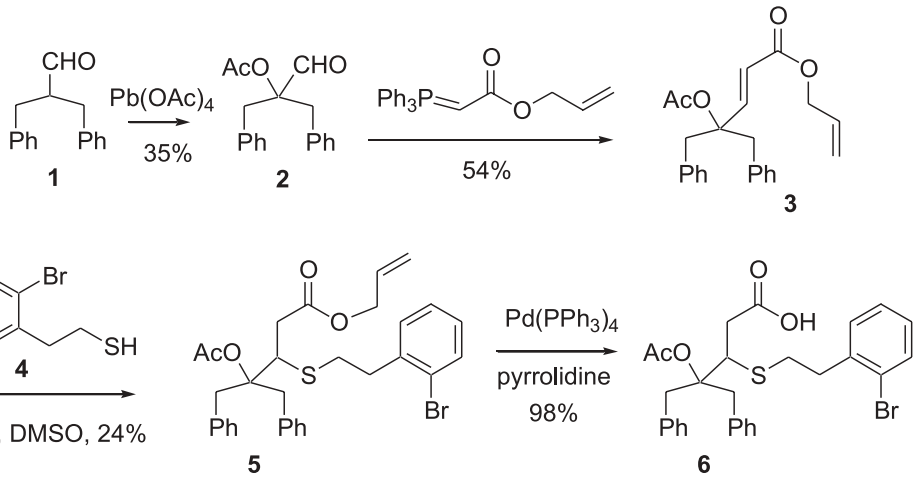


Scheme 2. A concerted mechanism for the [2,3]-rearrangement of β-(acyloxy)alkyl radicals.

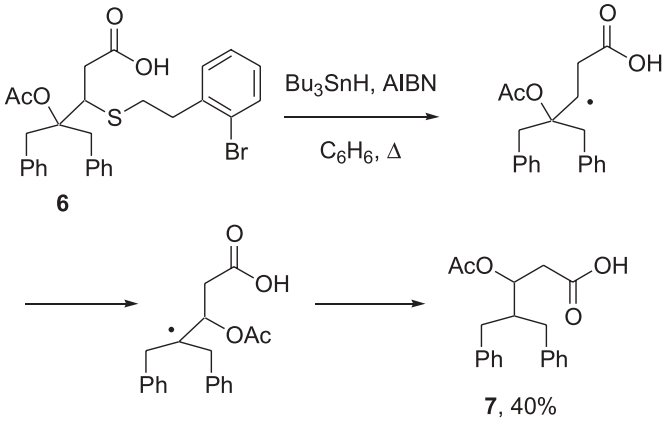
radical (Scheme 1, X = CR). In contrast to the phosphates, though, is the failure of several trapping studies to subvert the rearrangement reaction and the lack of any direct observation of the intermediate alkene radical cation in such a mechanism. These apparent inconsistencies may be reconciled with the fragmentation mechanism if it is supposed that the carboxylate anion is much more basic than the diphenylphosphate anion, which leads to an even more rapid collapse of the contact ion pair, with which neither trapping nor cage escape can compete (16–18).[3]

The investigations reported in this paper were spurred by the possibility that carboxylates homoallylic to alkene radical cations might undergo facile decarboxylation (Scheme 3, path a) (19), analogous to the way in which glycine-based aminium radical cations suffer rapid decarboxylation (20, 21). Alternatively, it was considered possible that the radical cation might be trapped in a 5-endo-trig manner to yield γ-lactone-based products (Scheme 3, path b). There also exists the possibility that the alkene radical cation takes part in a 4-exo-cyclization to afford an azetidinone-substituted methyl radical (Scheme 3, path c), but, as these are known to fragment with rate constants of 10^5–10^6 s^{-1} at 80 °C (19), any equilibrium of this kind was expected to favor the open-chain product. Any or all of these processes could possibly divert the initial contact ion pair from collapse to the rearranged radical (Scheme 3, path d) and so potentially provide evidence for the intervention of alkene radical cations in the β-(acyloxy)alkyl radical rearrangement.

Scheme 3. Possible reaction pathways for carboxy-substituted β-(acyloxy)alkyl radicals.



A suitable radical precursor was synthesized, as outlined in Scheme 4, with the main design feature being the use of the 2-(2-bromophenyl)ethanesulfenyl group (22) as a stable radical precursor β to the potentially enolizable carboxylate function. Thus, oxidation of 2-benzyl dihydrocinnamaldehyde **1** with lead tetraacetate afforded the acetoxyaldehyde **2**, which was immediately converted to the allyl ester **3** by Wittig olefination. Conjugate addition of 2-(2-bromophenyl)ethanethiol **4** (23) gave adduct **5** in poor but sufficient yield. Finally, removal of the allyl ester to give the product **6** was achieved with palladium(0) catalysis in the presence of pyrrolidine as nucleophile, the choice of ester and cleavage conditions being dictated by the desire to minimize elimination of the sulfide group.



[3] Against this background of experimental evidence it must be recognized that a series of computational investigations have supported the concerted mechanisms for rearrangement, although the more recent versions admit the possibility of a dissociative mechanism (16–18).

© 2003 NRC Canada

Scheme 4. Synthesis of the radical precursor **6**.

Scheme 5. Rearrangement of **6** to **7**.

Exposure of **6** to tributyltin hydride and benzene at reflux, with initiation by AIBN, afforded the rearrangement product **7** in 40% isolated yield, thereby establishing the viability of the rearrangement in question (Scheme 5, Table 1).

Similar results were obtained (Table 1) when **6** was first converted to its tetrabutylammonium salt before exposure to tributyltin hydride and AIBN in both benzene and THF at reflux. Careful inspection of the ^{1}H NMR spectra of the reaction mixtures in each case did not provide any evidence for the formation of products that may have been anticipated as arising from pathways a, b, and c of Scheme 3. In each case the only discernible products were **7**, arising from the rearrangement and the unreacted substrate **6**. Finally, neutralization of a methanolic solution of **6** with potassium hydroxide followed by azeotroping to dryness, then treatment with tributyltin hydride and AIBN in benzene at reflux also resulted only in the formation of the rearranged product **7** (Table 1). The relatively poor mass balances in some of these reactions are attributed to decomposition on silica gel chromatography, particularly the elimination of acetate from **7**. Under most conditions significant amounts of unreacted substrate **6** remained after prolonged treatment with tributyltin hydride and AIBN. While other explanations are possible, this is most likely symptomatic of the difficulty of sustaining good chain propagation under the dilute conditions employed to minimize the possibility of premature radical trapping by the hydride.

Table 1. Rearrangement of acid **6** and its salts.

Substrate	Solvent	Recovered **6** (%)[a]	Yield **7** (%)[a]
6	Benzene	9	40
6 Bu_4N^+ salt	Benzene	45	35
6 Bu_4N^+ salt	Tetrahydrofuran	49	20
6 K^+ salt	Benzene	0	63

[a]Yields refer to isolated material.

Overall we are driven to the conclusion that in nonpolar solvents the β-acyloxyalkyl rearrangement is either concerted or proceeds via a contact ion pair in which the rate of recombination to give the rearranged radical significantly exceeds that of trapping by intramolecular carboxylates. Given that the rate constant for intermolecular attack of acetate anion on the resonance-stabilized, photochemically generated 4-methoxystyrene radical cation in acetonitrile solution is 4×10^{10} (mol $L^{-1})^{-1}$ s^{-1} (24), it is perhaps not surprising that collapse of the acetate onto the alkene radical cation, within the confines of the putative contact ion pair, out-competes other modes of trapping, even intramolecular.

Experimental part

2-Acetoxy-2-benzyldihydrocinnamaldehyde (2)

To a solution of 2-benzyldihydrocinnamaldehyde **1** (27.1 g, 0.12 mol) and $Pb(OAc)_4$ (58.9 g, 0.13 mol) in benzene (250 mL) was added BF_3OEt_2 (15.3 mL, 0.12 mol) (25). After stirring overnight at room temperature, the reaction mixture was washed with Na_2CO_3 solution and the washings back extracted with Et_2O (100 mL). The combined organic layer was washed with brine and then dried over $MgSO_4$. Evaporation of the solvent under reduced pressure followed by column chromatography on silica gel (eluent: hexane → hexane–EtOAc, 20:1) gave the title product (11.9 g, 35%), which was used immediately in the next step. ^{1}H NMR ($CDCl_3$) δ: 2.11 (s, 3H), 3.16 (d, 2H, J = 8.6 Hz), 3.23 (d, 2H, J = 8.6 Hz), 7.13–7.31 (m, 10H), 9.26 (s, 1H).

© 2003 NRC Canada

^{13}C NMR ($CDCl_3$) δ: 21.5, 40.3, 86.4, 127.5, 128.8, 131.0, 134.8, 171.3, 201.6.

Allyl 4-acetoxy-4-benzyl-5-phenyl-2*E*-pentenoate (3)

To a solution of **2** (12.9 g, 45.7 mmol) in benzene (200 mL) was added (allyloxycarbonylmethylidene)triphenylphosphorane (16.5 g, 45.7 mmol) (26). The mixture was heated to reflux overnight, then cooled to room temperature, diluted with EtOAc, and washed with water and brine, then dried over $MgSO_4$. Evaporation of the solvent under reduced pressure followed by column chromatography on silica gel (eluent: hexane) gave the target product **3** (9.1 g, 54%). ^{1}H NMR ($CDCl_3$) δ: 1.95 (s, 3H), 3.20 (d, 2H, J = 8.3 Hz), 3.63 (d, 2H, J = 8.3 Hz), 4.62–4.64 (m, 2H), 5.23–5.31 (m, 2H), 5.64 (d, 1H, J = 9.5 Hz), 5.86–5.94 (m, 1H), 6.90 (d, 1H, J = 9.5 Hz), 7.10–7.27 (m, 10H). ^{13}C NMR ($CDCl_3$) δ: 22.5, 43.4, 65.4, 84.8, 118.4, 120.9, 127.3, 128.5, 131.0, 132.5, 135.7, 150.1, 165.9, 170.7. Anal. calcd. for $C_{23}H_{24}O_4$: C 75.80, H 6.64; found: C 75.96, H 6.69.

Allyl 4-acetoxy-4-benzyl-3-[2-(2-bromophenyl)ethylsulfanyl]-5-phenylpentanoate (5)

To an ice-cooled solution of **3** (4.5 g, 12.3 mmol) and 2-(2-bromophenyl)ethylthiol **4** (23) (2.7 g, 12.3 mmol) in DMSO (20 mL) was added NaH (50 mg, 1.2 mmol). The reaction mixture was stirred overnight at room temperature before it was diluted with CH_2Cl_2, then washed with water and brine, and dried over $MgSO_4$. Evaporation of the solvent under reduced pressure followed by column chromatography on silica gel (eluent: hexane → hexane–EtOAc, 10:1) gave the thioether **5** (1.7 g, 24% based on 0.52 g recovered starting material). ^{1}H NMR ($CDCl_3$) δ: 1.81–1.87 (m, 1H), 2.05 (s, 3H), 2.21–2.25 (m, 1H), 2.92–3.07 (m, 4H), 3.22 (s, 2H), 3.57(d, 1H, J = 8.5 Hz), 3.71 (d, 1H J = 8.5 Hz), 4.08–4.10 (m, 1H), 4.44–4.49 (m, 2H), 5.14–5.23 (m, 2H), 5.77–5.83 (m, 1H), 7.05–7.54 (m, 14H). ^{13}C NMR ($CDCl_3$) δ: 22.9, 35.3, 37.0, 38.4, 41.1, 41.7, 49.8, 65.6, 89.0, 118.5, 124.8, 127.2, 127.3, 127.9, 128.55, 128.61, 128.67, 131.2 131.4, 132.5, 133.3, 136.9, 137.2, 140.0 171.1, 171.8. Anal. calcd. for $C_{31}H_{33}BrO_4S$: C 64.02, H 5.72; found: C 64.44, H 5.69.

4-Acetoxy-4-benzyl-3-[2-(2-bromophenyl)ethylsulfanyl]-5-phenylpentanoic acid (6)

To an ice-cooled solution of **5** (1.1 g, 1.9 mmol), $Pd(PPh_3)_4$ (55 mg, 0.05 mmol), and PPh_3 (25 mg, 0.1 mmol) in CH_2Cl_2 (50 mL) was added pyrrolidine (1.6 mL). After stirring for 1.5 h at room temperature, the reaction mixture was washed with 1 N HCl, water, and brine, then dried over $MgSO_4$. Evaporation of the solvent under reduced pressure followed by column chromatography on silica gel (eluent: hexane–EtOAc, 5:1 → 1:3) gave the title acid **6** (1.0 g, 98%). ^{1}H NMR ($CDCl_3$) δ: 1.72–1.78 (m, 1H), 2.04 (s, 3H), 2.15–2.20 (m, 1H), 2.96–3.01 (m, 4H), 3.18 (s, 2H), 3.54 (d, 1H, J = 8.5Hz), 3.69 (d, 1H, J = 8.5Hz), 4.01–4.04 (m, 1H), 7.05–7.51 (m, 14H). ^{13}C NMR ($CDCl_3$) δ: 22.9, 35.5, 36.9, 37.9, 41.1, 41.7, 49.5, 89.1, 124.8, 127.3, 127.4, 127.9, 128.6, 128.7, 131.1, 131.4, 133.3, 136.8, 137.1, 139.9, 171.2, 176.7. Anal. calcd. for $C_{28}H_{29}BrO_4S$: C 62.11, H 5.40; found: C 62.33, H 5.40.

3-Acetoxy-4-benzyl-5-phenylpentanoic acid (7)

A solution of Bu_3SnH (59.6 μL, 0.22 mmol) and AIBN (1.5 mg, 9.2 μmol) in benzene (3.1 mL) was added dropwise over 3 h with the aid of a syringe pump to a solution of **6** (100 mg, 0.18 mmol) in benzene (3.1 mL) at reflux under Ar. After heating to reflux for a further 1 h, the reaction mixture was cooled to room temperature and concentrated under reduced pressure. The residue was dissolved in MeCN (1 mL) and extracted with hexanes (3 × 3 mL). The acetonitrile layer was concentrated under reduced pressure and purified by column chromatography on silica gel (eluent: hexane–EtOAc, 2:1) to afford **7** (24.1 mg, 40%) ^{1}H NMR ($CDCl_3$) δ: 1.96 (s, 3H), 2.42–2.46 (m, 1H), 2.55–2.71 (m, 6H), 5.23–5.26 (m, 1H), 7.07–7.30 (m, 10H). ^{13}C NMR ($CDCl_3$) δ: 21.3, 36.3, 36.6, 45.4, 71.8, 126.6, 126.7, 128.8, 128.9, 129.33, 129.39, 140.1, 140.3, 170.8, 175.6: ESI-HR-MS calcd. for $C_{20}H_{22}NaO_4$: 349.1416; found: 349.1428 ($[M + Na]^+$).

Vacuum pyrolysis of *N*,*N*-dimethylbicyclo-[3.2.0]hepta-3,6-dien-1-amine — He I ultraviolet photoelectron spectroscopic and computational studies[1]

Tom Bajorek and Nick H. Werstiuk

Abstract: The photoelectron spectra of *N*,*N*-dimethylbicyclo[3.2.0]hepta-3,6-dien-1-amine (**1**) and its pyrolysate were obtained using an unique ultraviolet (UV) photoelectron (PE) spectrometer interfaced with a CW CO_2 laser. Pyrolysis of **1** in the source chamber of the PE spectrometer initially generates the transient *N*,*N*-dimethylcyclohepta-1*E*,3*Z*,5*Z*-trien-1-amine (**2**) — the computed barrier is 21.5 kcal mol^{-1} — that isomerizes to the all-cis isomer with a barrier of only 5.0 kcal mol^{-1}. There is no evidence for the formation of *N*,*N*-dimethycyclohepta-1*Z*,3*E*,5*Z*-trien-1-amine (**4**), formation of which has an zero-point-energy corrected barrier of 28.4 kcal mol^{-1}. A PE spectrum of an authentic sample of *N*,*N*-dimethylcyclohepta-1*Z*,3*Z*,5*Z*-trien-1-amine (**3**) correlated well with the pyrolysis spectrum. Molecular orbitals and their energies were obtained with Becke3LYP calculations.

Key words: vacuum pyrolysis, *N*,*N*-dimethylbicyclo[3.2.0]hepta-3,6-dien-1-amine, photoelectron spectroscopy, DFT calculations.

Résumé : Faisant appel à un spectrophotomètre photoélectronique (PE) ultraviolet (UV) unique lié à un laser à CO_2 « CW », on a déterminé les spectres photoélectroniques de la *N*,*N*-diméthylbicyclo[3.20]hepta-3,6-dién-1-amine (**1**) et de son produit de pyrolyse. La pyrolyse du composé **1** dans la source du spectrophotomètre PE conduit initialement à la formation d'une espèce transitoire, la *N*,*N*-diméthylcyclohepta-1*E*,3*Z*,5*Z*-trién-1-amine (**2**) avec une barrière calculée de 21,5 kcal mol^{-1}; celle-ci s'isomérise en isomère complètement cis avec une barrière de 5,0 kcal mol^{-1}. On n'a observé aucune indication pour suggérer la formation de la *N*,*N*-diméthylcyclohepta-1*Z*,3*E*,5*Z*-trién-1-amine (**4**) pour laquelle la barrière corrigée à l'énergie au point zéro est de 28,4 kcal mol^{-1}. Un spectre PE d'un échantillon authentique de *N*,*N*-diméthylcyclohepta-1*Z*,3*Z*,5*Z*-trién-1-amine (**3**) présente une bonne corrélation avec celui du spectre du produit de la pyrolyse. On a aussi obtenu les orbitales moléculaires et leurs énergies à l'aide de calculs Becke3LYP.

Mots clés : pyrolyse sous vide, *N*,*N*-diméthylbicyclo[3.20]hepta-3,6-dién-1-amine, spectroscopie photoélectronique, calculs « DTF ».

Introduction

Combining ab initio calculations with UV-PE spectroscopy yields information about the bonding and electronic structure of stable molecules and transient species that is provided by no other technique. We have recently shown through the pyrolysis of bicyclo[3.2.0]hept-6-en-2-one that *E*,*Z* isomers of cyclohepta-2,4-dien-1-one may be differentiated and identified with the combination of PE spectroscopy and MO calculations (1). The cyclobutene moiety of bicyclo[3.2.0]hept-6-en-2-one undergoes a thermal conrotatory electrocyclic reaction in accord with the Woodward–Hoffmann rules with two products being possible, one with the trans double bond at the C1-C2 position and one with the trans double bond at the C3-C4 position. It was observed experimentally that only the product with the trans double bond between C4 and C5 was generated. This was also confirmed by DFT calculations. Houk and co-workers (2) have computationally investigated the preferential direction of twisting of the breaking σ bond in thermal electrocyclic reactions of substituted cyclobutenes and found a computational way of predicting the stereoselectivity of the thermal cyclobutene ring opening. The term "torquoselectivity" was introduced to describe this type of stereoselective process (2*c*). Based on their finding the authors have concluded that electron-donating substituents preferentially rotate outward while electron-withdrawing substituents preferentially rotate inward. It has been shown that electronic control dominates over the steric influence in the conrotatory ring opening both computationally and experimentally (2, 3). The results we obtained on bicyclo[3.2.0]hept-6-en-2-one are in accord with the proposal by Houk.

Previous studies on bicyclo[3.2.0]hepta-3,6-diene established the product to be *Z*,*Z*,*Z*-1,3,5-cycloheptatriene, sug-

Fig. 1. Experimental and simulated partial PE spectra of: (*a*) **1**; (*b*) pyrolysate of **1**; (*c*) **3**; (*d*) simulated partial PE spectrum of **1**; (*e*) simulated partial PE spectrum of **2**; and (*f*) simulated partial PE spectrum of **3**.

gesting that the thermal ring opening occurs via the thermally forbidden disrotatory path (4, 5). We undertook the photoelectron spectroscopic and computational investigation of the pyrolysis of *N*,*N*-dimethylbicyclo[3.2.0]hepta-3,6-dien-1-amine (**1**) to study the electrocyclic ring opening of the cyclobutene moiety of a fused ring system substituted with an electron-donating group. This work was aimed at the determinating whether this bicyclic system substituted with a strong electron-donating group undergoes the thermally allowed conrotatory ring expansion or follows the thermally forbidden disrotatory path. This study also allowed us to establish whether the theory of torquoselectivity applies to a bicyclic system. The results of our computational and experimental studies are reported in this paper.

Experimental

The PE spectra in this investigation were recorded using a locally build PE spectrometer interfaced with a CW CO_2 laser and calibrated using the IP band of N_2, which is seen at 15.6 eV in the experimental spectra (6). The linearity of the spectral scale was established by using the two lowest IP bands of methyl iodide at 9.54 and 10.16 eV, as well, prior to the experiments. Pyrolysis of the starting material was accomplished using the CW CO_2 laser focused on a tip of a quartz nozzle of the probe directly in the source chamber of the PE spectrometer. In this way, the laser is used as a directed heat source that produces a 2 to 3 mm hot zone 10 mm away from the ionization zone. Laser settings and temperatures at the nozzle were calibrated by measuring the temperature with a thermocouple inserted into a closed tip quartz probe positioned in the source of the PE spectrometer. The temperature of approximately 600 °C used in these experiments was obtained with a laser power setting of approximately 55 W.

Becke3LYP/6-31+G(*d*) DFT (7) calculations predict ionization potentials (IPs) with good accuracy (8) and simulated PE spectra calculated from MO energies with a FORTRAN program PESPEC (9) can be used for assigning the bands of experimental PE spectra and for identifying products of pyrolysis reactions. DFT calculations were performed with Gaussian 98 (10). Initial molecular geometries were generated using HyperChem (11). Displays of molecular orbitals and molecular geometries were obtained with Molekel (12).

Results and discussion

The photoelectron spectrum of **1** shows two distinct, broad IPs with vertical ionization potentials (IP_vs) at 8.0 and 9.1 eV as shown in Fig. 1*a*. The first IP corresponds to the highest occupied molecular orbital (HOMO) which is mainly the lone pair of nitrogen with a contribution from the bridging σ bond that is illustrated as $n_N(\sigma)$ in Fig. 2. The experimental and calculated IP_vs are listed in Table 1. The predicted first IP is lower than the experimentally observed IP_v by 0.29 eV. A similar difference between the predicted and experimental IP_vs is observed for the second band that results from the overlap of two IPs. The predicted IP_vs at 8.65 and 8.97 eV correspond to HOMO-1 and HOMO-2, both of which have π character (Fig. 2). Taking the average between these two calculated IP_vs and comparing the value to the observed IP yields a difference of 0.29 eV. Overall, the simulated PE spectrum of **1** (Fig. 1*d*) correlates well with the experimental spectrum. The simulation shows two broad bands that are similar in shape and intensity to the IPs observed experimentally.

Upon pyrolysis, **1** yields a new PE spectrum (Fig. 1*b*). A new band appears at 7.3 eV and broad second and third bands are found at 8.7 and 9.7 eV, respectively. A fourth IP at approximately 10.4 eV appears as a shoulder on the very broad feature beginning at 11 eV. While the calculated first IP_v of the *E*,*Z*,*Z* isomer **2** is at 6.52 eV, a band is not seen below 7 eV in the pyrolysis spectrum when the spectrum was scanned between 6–16 eV. The simulated spectrum of **2**

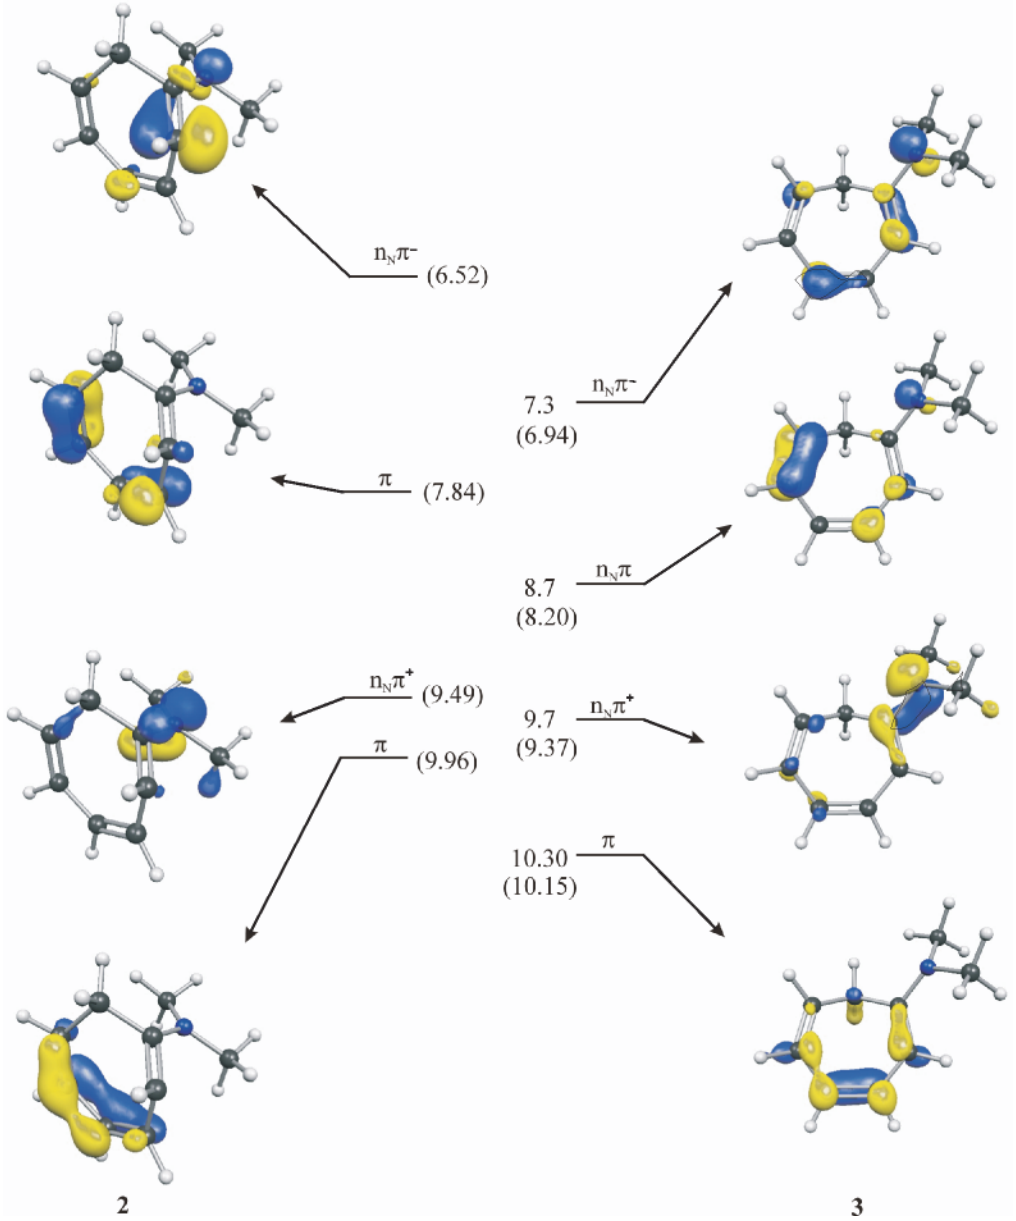
[a]The pyrolysate of **1**.

is displayed as Fig. 1*e*. The difference between the first calculated IP_v of **2** and the first experimentally observed IP_v of the pyrolysate is 0.78 eV. Similarly, the difference between the second computed IP_v and the second experimental IP_v is 0.86 eV. These differences between the theoretical and experimental ionization potential are too large to allow for the assignment of the pyrolysis spectrum to **2**.



We also synthesized an authentic sample of *N*,*N*-dimethylcyclohepta-1*Z*,3*Z*,5*Z*-trien-1-amine (**3**) (13) and recorded its spectrum (Fig. 1*c*) as it is a potential product of the forbidden disrotatory ring opening of **1**. The PE spectrum of **3** shows four distinct bands at 7.3, 8.7, 9.7, and 10.4 eV. The differences between the experimental and calculated IP_vs are 0.36, 0.50, 0.33, and 0.25 eV. The simulated spectrum of **3** (Fig. 1*f*) correlates very well with the experimentally observed one showing four distinct IPs. These IPs of **3** correlate with the four Becke MOs HOMO to HOMO-3 shown in Fig. 3. The HOMO has antibonding character between the nitrogen lone pair and the π system of the adjacent C1-C2 double bond and is denoted as $n_N\pi^-$. HOMO-1, which is denoted as $n_N\pi$, also exhibits mixing between the nitrogen lone pair and the π system of the cycloheptatrienyl group. In HOMO-2 the nitrogen lone pair and the π system of the adjacent double bond mix with bonding character and are shown as $n_N\pi^+$ in Fig. 3. The fourth MO (HOMO-3) has π-bonding character that includes the three double bonds of the cycloheptatriene ring and no contribution from the nitrogen lone pair. Figure 3 displays the first four MOs of **2** and **3** and their ionization potentials. The HOMO of **2** is also a $n_N\pi^-$ MO but it exhibits a larger p coefficient on the strained trans double bond than is observed in the HOMO of **3**. HOMO-1 of **2** is π rather than $n_N\pi$ type as observed in **3** and exhibits mixing with the nitrogen lone pair. HOMO-2 of **2** also has a $n_N\pi^+$ character as seen in **3**. In this case, the bonding interaction is predominantly localized at the C1—N bond because the double bond is twisted, unlike the case for **3** where the bonding interaction in HOMO-2 includes N, C1, and C2. HOMO-3 of **2** has π-bonding character between C3-C4-C5-C6 and there is no contribution from the trans double bond, unlike HOMO-3 of **3** that includes all three double bonds.

It is known that *N*,*N*-dimethylcyclohepta-1,3,5-trien-7-amine (**9**) yields **3** via a 1,5-hydrogen shift (13) upon pyrolysis. Consequently we prepared **9** — its PE spectrum is displayed as Fig. 4*a* — and studied its pyrolysis. In fact, the spectrum obtained from the pyrolysis of **9** (Fig. 4*b*) also exhibits broadened second and third bands and the PE spectra obtained upon pyrolysis of **1** (Fig. 1*b*) and **9** show common features. The broadening of the bands observed in the pyrolysis spectra of **1** and **9** at 8.7 and 9.4 eV undoubtedly results from the free rotation of the dimethylamino group and there is a change in the conformation populations at the elevated temperatures of the pyrolysis experiments. Calculations show that *N*,*N*-dimethylcyclohepta-1,3,5-trien-1-amine (**3**) can exist in two conformations. One where the lone pair of the nitrogen of the dimethylamino group points in a direction opposite to the C7 methylene group (Fig. 5, **3a**), and one where the dimethylamino lone pair points in the same direction as the C7 methylene group (Fig. 5, **3b**). The energy barrier for the rotation of the dimethylamino group was found to be 8.3 kcal mol^{-1}. The calculated first four IP_vs of **3a** are: 6.94, 8.21, 9.38, and 10.16 eV. The predicted first four IP_vs of **3b** are: 6.87, 8.31, 9.47, and 10.21 eV; the rotation of the dimethylamino group has the largest impact on the second and third IPs. We also found that heating **3** under the pyrolysis conditions yields a spectrum (Fig. 4*c*) with broadened second and third bands. The calculations predict that the second and third IP bands should be affected most by the free rotation of the dimethylamino group and this appears to be in accord with experiment. It is apparent that **3** is the product of the pyrolysis of **1**.

That **1** yields **3** suggests that the thermal electrocyclic reaction follows the forbidden disrotatory path. Yet a transition state calculation — the zero-point-energy corrected barrier being 21.5 kcal mol^{-1} — for the ring opening of **1** located transition state **TS1** that leads to **2**. The computed, zero-point-energy corrected barrier — the transition state is **TS3** — for the ring opening of **1** to **4**, which is the *E*,*Z*,*E* isomer is 28.4 kcal mol^{-1}. The transition state for the forbidden disrotatory process that would link **1** and **3** could not be located. Exhaustive attempts to locate this transition state

resulted in the generation of **TS1**. Since **2** is not observed upon the pyrolysis of **1**, we located the transition state for the isomerization of the *E*,*Z*,*Z* isomer **2** to the *Z*,*Z*,*Z* isomer **3**. The transition state **TS2** for this process lies only 5.0 kcal mol^{-1} above **2**. The rearrangement of **1** is illustrated in Scheme 1. In the case of **1**, the dimethylamino group is pyramidalized with the dihedral angle between C1-C8-C9-N being 28.2°. In the case of **2**, this dihedral angle is only 9.3°. This planarization facilitates the n-π interaction of the lone pair with the adjacent trans double bond and may lower the barrier for isomerization with the driving force being the release of strain and the formation of a conjugated cyclic π system. Comparing HOMO-3 of **3** and **2** (Fig. 3), triene **3** is 29.7 kcal mol^{-1} lower in energy than **1** and 22.3 kcal mol^{-1} lower in energy than **2**. According to our calculations, **1** initially undergoes a thermal conrotatory ring opening to yield **2** that isomerizes to **3**. The total and relative energies of the four compounds and the transition states are listed in Table 2.

That barrier for ring opening of **1** is relatively low was confirmed by ^{1}H NMR spectroscopy. A spectrum of **1** was recorded and the sample was allowed to stand at room temperature in the dark. A spectrum obtained after 24 h showed signals due to **3** as determined from the ^{1}H NMR spectrum of an authentic sample of **3**. After 5 days, **1** and **3** were present in a 1:1 ratio.

According to the theory of torquoselectivity, electron donors preferentially favor the formation of a trans double bond to which the electron-donating group is attached, while electron acceptors yield a cis double bond when both substituents are in the cis position on the starting cyclobutene. Thus, an electron-donating group rotates outward upon

breaking of the σ bond in the cyclobutene moiety, while an electron acceptor substituent rotates inward (2). In the case of the cyclobutene conrotatory ring opening of **1**, we have found that the inward–outward rotation terminology does not apply in the way described by Houk. The constrained geometry of the bicyclic system does not allow for the rotation of the substituents at the bridgehead carbons of the

breaking σ bond. The bridgehead carbons C1 and C4 move away from each other in the transition state as shown by the displacement vectors displayed in Fig. 6*c*, while the substituent undergoes planarization through the movement of the C1—N bond. Fig. 6*a* shows the front view of the transition-state geometry and Fig. 6*b* shows the view along the C1—C2 bond. The dimethylamino group shows marginal movement inward rather that outward, which is contrary to the theoretical predictions that donors preferentially rotate outward. The hydrogen at the C4 position in **1** rotates outward while C5 shows no apparent movement. Nevertheless, the stereochemical outcome is in accord with the theory of torquoselectivity; the electron-donating dimethylamino group leads to the formation of a trans double bond in the final

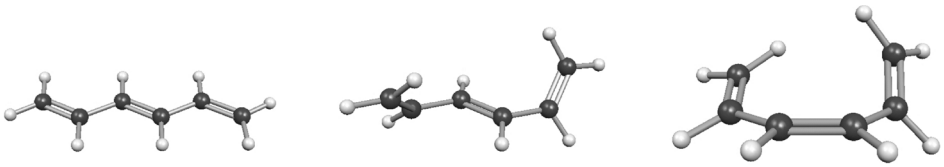
[a]The dihedral angle between C1, the carbons of the methyls of the dimethyamino group, and the nitrogen atom.

product. In going from **1** to **2**, the N—C1 bond becomes shorter by 0.09 Å and the C1—C2 distance decreases by 0.136 Å as the single bond is converted into the strained trans double bond of **2** that is 0.015 Å longer than the corresponding C1-C2 cis double bond of **3** (Table 3). Since there is a break in the conjugation of the π system introduced by the trans double bond between C3-C4 of **4**, all three double bonds are shorter that those in **2** and **3** (Table 3). A calculation on *N*,*N*-dimethyl-*N*-vinylamine (**5**) showed that the amine is pyramidalized with a dihedral angle of 19.7° among C1, the two methyl groups of the amine, and the nitrogen. The C1—N bond of **5** is slightly shorter than in **3** and the C1-C2 double bond is also shorter than in **3** and **2** by 0.026 and 0.041 Å, respectively, but it is only slightly longer than in **4**. Not unexpectedly, conjugation plays a significant role in determining the bond lengths in these molecules.

The thermal conrotatory ring opening of **1** yields **2** and not **4** most likely because **2** has two coplanar double bonds that extend the conjugation. In **4** this conjugation is broken by the trans double bond between C3-C4. Our calculations on unsubstituted cycloheptatriene indicate a difference in energy of 7.5 kcal mol^{-1} between cyclohepta-1(E),3(Z),5(Z)-triene (**6**) and cyclohepta-1*Z*,3*E*,5*Z*-triene (**7**), **6** being lower in energy than **7** (Fig. 7).

A calculation on hexa-1,3,5-triene (**8**) also shows a considerable difference in energy between two hexatrienes that

Fig. 7. Schematic representation of **6** and **7**



6 **7**

have constrained dihedral angles to resemble those of **6** and **7** (Fig. 8). In hexatriene **8a** the dihedral angles between C1-C2-C3-C4 and C3-C4-C5-C6 have been constrained to 57° to resemble **7**. Similarly in hexatriene **8b**, the dihedral angle between C1-C2-C3-C4 has also been constrained to 57° to resemble **6**. The difference in energy between the two hexatrienes was found to be 2.9 kcal mol^{-1}. The total and relative energies are listed in Table 2. The conjugation of the double bonds in **8b** is reduced, thus increasing the energy. The energy of the system is higher in a case where none of the double bonds are coplanar as in **7** and **4** and it is lower in a case where at least two of the double bonds are conjugated and coplanar as in **6** and **2**. Therefore, the formation of **2** is favored over **4** since in **2** the conjugation is preserved between two double bonds where as in **4** there is a complete break in the conjugation of the π system.

Conclusions

Our computational and PES study of the pyrolysis of *N*,*N*-dimethylbicyclo[3.2.0]hepta-3,6-dien-1-amine (**1**) has shown that the initial product of this reaction is *N*,*N*-dimethylcyclohepta-1*E*,3*Z*,5*Z*-trien-1-amine (**2**) which then isomerizes to *N*,*N*-dimethylcyclohepta-1*Z*,3*Z*,5*Z*-trien-1-amine (**3**) with an energy barrier of 5.9 kcal mol^{-1}. Transition-state calculations at B3LYP/6-31+G(*d*) have shown that the ring opening of the cyclobutene moiety of **1** follows the conrotatory path to give **2** with an energy barrier of 22.8 kcal mol^{-1}. The energy barrier for the ring opening to yield **4** was found to be 30.5 kcal mol^{-1}. Therefore, the PE spectrum of **4** was not observed. The PE spectrum of **2** was also not observed because of the low-energy barrier for the isomerization of the trans double bond in **2** to a cis double bond, which yielded **3** as the product of the pyrolysis. Thus, the thermal reaction of **1** still follows the Woodward–Hoffmann rules. The driving force of this reaction is the release of ring strain and the formation of a thermodynamically more stable **3**, which preserves the coplanarity and resonance of the three conjugated double bonds of the cycloheptatriene ring with the contribution of the resonance from the dimethylamino group.[3]

Diastereoselective reduction of α-aminoketones: Synthesis of *anti*- and *syn*-β-aminoalcohols[1]

David S. Fraser, Sheldon B. Park, and J. Michael Chong

Abstract: Reduction of *N*-*t*-BOC-protected-*N*-alkyl α-aminoketones with $LiEt_3BH$ or Li(*s*-Bu)$_3$BH furnishes protected *syn*-β-aminoalcohols with high selectivities. In contrast, removal of the BOC group followed by reduction of the aminoketone gives *anti*-β-aminoalcohols with variable selectivities. With aromatic ketones, selectivities are typically high while aliphatic ketones show mediocre to high selectivities depending on steric considerations.

Key words: β-aminoalcohol, diastereoselective reduction.

Résumé : La réduction, à l'aide de $LiEt_3BH$ ou de Li(*s*-Bu)$_3$BH, de *N*-alkyl-α-aminocétones portant un groupe protecteur *N*-*t*-BOC conduit à la formation de *syn*-β-aminoalcools protégés avec des sélectivités élevées. Par ailleurs, si on enlève le groupe BOC, la réduction de l'aminocétone conduit à la formation de β-aminoalcools anti avec des sélectivités variables. Avec les cétones aromatiques, les sélectivités sont généralement élevées alors que les sélectivités obtenues avec les cétones aliphatiques varient de médiocres à élevées suivant l'encombrement stérique.

Mots clés : β-aminoalcool, réduction diastéréosélective.

[Traduit par la Rédaction]

Introduction

The β-aminoalcohol moiety is found in many natural products, pharmaceuticals, and ligands used for asymmetric synthesis (1). Stereoselective approaches to this important class of compounds include nucleophilic additions to α-aminoaldehydes (2) or chiral imine derivatives (3), manipulations of chiral cyanohydrins (4), and reductions of α-aminoketones (5–7).

The stereoselective reduction of α-aminoketones has been a common route to specific diastereomers of β-aminoalcohols and much of the early work in this area has been reviewed by Tramontini (5). This early work consisted only of reductions of arylketones and only a very few good selectivities were achieved. Since then, considerably more research has been carried out and a reasonable understanding of factors affecting syn- and anti-diastereoselectivity is beginning to emerge (6).

As part of our work with α-aminoorganostannanes, we showed that *N*-BOC-*N*-alkyl-aminostannanes can be transmetalated with alkyllithiums and the resulting α-aminoorganolithiums can be trapped with aldehydes to provide β-amino alcohols with complete retention of stereochemistry at the amino centre (8). However, a 1:1 mixture of diastereomers is usually produced (Scheme 1).

Thus, we decided to examine the diastereoselective reduction of α-aminoketones (Scheme 2). We anticipated that the *N*-BOC-amino group would act as the large group in Cram–Felkin-Ahn type reductions such that the syn products **4** would be favoured. Removal of the BOC group would then provide *syn*-aminoalcohols **5**. Conversely, initial removal of the BOC group would give ketones **6** wherein the amino group would be expected to act as a coordinating group in chelation–Cram type reductions so that *anti*-aminoalcohols **7** would predominate. Since either enantiomer of stannane **1** could be prepared from the corresponding acylstannane, this approach would allow for the preparation of any of the four possible diastereomers of β-aminoalcohols from the same acylstannane (9).

Results and discussions

Synthesis of aminoketones

In some cases, aminoketones could be prepared in good yields directly from the corresponding organolithium by reaction with dimethylamides. However, this route gave low yields with hindered organolithiums. Thus, trapping with aldehydes followed by oxidation was usually used. For aromatic aldehydes, yields of trapped products were typically 80%–95% while aliphatic aldehydes usually gave lower (65%–78%) yields, consistent with the expectation that enolization may be a competing side-reaction. Oxidation of alcohols under Swern conditions yielded no identifiable products while the chromium reagents PDC and PCC gave only modest yields. Eventually it was found that TPAP oxidation (10) gave excellent (80%–95%) yields of ketones **3** (Table 1).

Cram-selective reduction of *t*-BOC-protected aminoketones

Reductions of ketone **3a** with DIBAL-H (toluene, –78 °C) or $Zn(BH_4)_2$ proceeded with poor selectivities to give mixtures of diastereomeric alcohols in ratios of 60:40 and 65:35, respectively. In contrast, reduction of **3a** with L-selectride® ($Li(s\text{-}Bu)_3BH$) gave a near quantitative yield of a single alcohol (Table 2, entry 1). L-Selectride® also reduced the more hindered ketone **3b** with essentially complete diastereoselectivity; however, complete reduction of ketone **3b** could not be achieved, even with a large excess (10 equiv.) of reagent. Fortunately, the related but less-bulky reagent Super-hydride® (lithium triethylborohydride) reduced ketone **3b** to afford alcohol **4b** in near quantitative yield, albeit with slightly diminished stereoselectivity (Table 2, entry 3).

Other ketones were also reduced with Super-hydride®. In general, arylketones (Table 2, entries 4–8) provided the syn-isomer as the only one detectable by ^{1}H NMR spectroscopy. For the arylketones examined, only the isopropyl=substituted ketone **3b** gave some of the anti-isomer. This is consistent with expectations based on a Felkin-Anh model where the BOC-amino group acts as the large group; with R = *n*-alkyl, essentially complete diastereoselectivity is observed

but with R = *i*-Pr, the larger isopropyl group offers a small amount of competition. With alkyl ketones, selectivities were not perfect but still very good (Table 2, entires 9–16). There is a general trend in which the selectivity increases as the steric bulk of R″ increases (Table 2, compare entries 11–13). The lowest selectivity was observed with the isopropyl-substituted ketone **3m**, which gave a 91:9 mixture of diastereomers. Reduction of **3m** with L-Selectride® gave only the syn-isomer but the reaction was sluggish and only low conversion was observed (Table 2, entry 15), a result comparable to that previously noted for isopropyl-substituted ketone **3b** (Table 2, entries 2, 3). In contrast, the relatively unhindered ketone **3i** was efficiently reduced with L-Selectride® to provide **4i** in high yield (Table 2, entry 10). Thus, it is apparent that the very bulky L-Selectride® can give very high selectivities but is subject to steric constraints while Super-hydride® consistently gives good to excellent selectivities, even for hindered systems. High syn selectivity could be achieved for all of the compounds studied.

Preparation of aminoalcohols 5 and analysis of their ^{1}H NMR spectra

Analysis of the ^{1}H NMR spectra of the alcohols **4** was complicated by the presence of carbamate rotamers which often led to broad lines. Deprotection with TFA gave the products **5**. The yields for these deprotections were lower than would normally be expected for this sort of procedure,

possibly because the β-aminoalcohols are somewhat soluble in water, and complete extraction from the basic aqueous phase is not easily achieved.

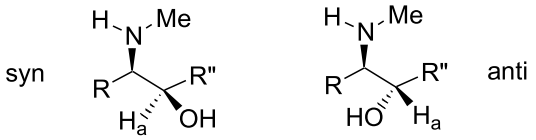
With the aminoalcohols in hand, they could be converted to their corresponding oxazolidinones, a method previously used to determine the relative configuration of β-aminoalcohols (11). Thus, it is known that cyclization of a *syn*-β-aminoalcohol leads to a *trans*-oxazolidinone, which has a smaller J_{ab} than the corresponding *cis*-oxazolidinone derived from an *anti*-β-aminoalcohol, consistent with expectations based on Karplus relationships. For example, cyclization of **5a** using Wuts and Pruitt's method (12) gave oxazolidinone **8a** which exhibited J_{ab} = 6.0 Hz, confirming trans stereochemistry for **8a** and hence syn stereochemistry for **5a** (Scheme 3).

Rather than convert all of the aminoalcohols to oxazolidinones, we determined the stereoselectivity of the reductions based on the observation that the carbinol protons (H_a) of all of the *N*-methyl-β-aminoalcohols prepared have significantly different chemical shifts for the syn- and anti-diastereomers (Table 3).

There is a signal separation of at least 0.15 ppm and usually 0.3–0.5 ppm in each case that allows a positive identification of each diastereomer. In addition, the important trend is that H_a of the anti-diastereomer always appears downfield of the syn-isomer. This allows the assignment of stereochemistry without the need to prepare oxazolidinone derivatives if spectral data for both isomers is available.

Scheme 3.

5a J_{ab} = 6.0 Hz **8a**



Chelation-controlled reduction with $Zn(BH_4)_2$

Removal of the BOC protecting group from ketones **3** with TFA gave quantitative yields of the aminoketones **6**. These ketones were not very stable and were used immediately. Subsequent reduction with $Zn(BH_4)_2$ gave predominantly the anti-aminoalcohols in the yields and selectivities shown in Table 4. Reductions with $NaBH_4$ generally gave lower selectivities (e.g., **6a** afforded a syn:anti ratio of 10:90) and were not explored further.

For the phenylketones examined (Table 4, entries 1–7), selectivities were generally excellent. In many cases, only the anti-diastereomer was detected. The lowest selectivity was observed with ketone **6c** (R = Me), where 7% of the syn-diastereomer was formed. The lower selectivity can be attributed to the relatively small size of the CH_3 group, which would be less effective at blocking the disfavoured side of the carbonyl in the Cram chelation model.

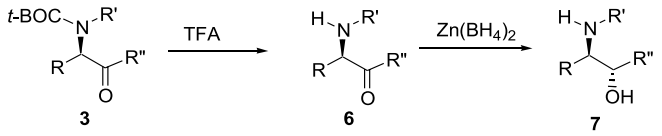
5n/7n	CH_3	*n*-C_5H_{11}	3.09	3.59

[a]Spectra were recorded in dilute $CDCl_3$ solution.

The yields for these reductions were moderate. As no starting material was recovered from these reductions, it seems likely that the relatively high degree of water solubility of the β-aminoalcohols is at least partially responsible.



With aliphatic ketones (Table 4, entries 8–14), reductions were generally not very selective. In some cases (Table 4, entries 9–11), essentially no selectivity was observed. These results can be explained by invoking the Felkin–Anh model. For example, ketone **6i** has no obviously larger group so little selectivity is expected. If we consider ketone **6m**, the isopropyl side chain becomes the large group, so the predominant diastereomer is actually the Cram control product. The reduction of **6l** can be explained via this same model, but in this case the bulky *tert*-butyl group in the R′′ position provides the Cram control, as observed by Cherest et al. (13) Thus, the aliphatic α-aminoketones do not seem to be reduced by $Zn(BH_4)_2$ in a true chelation-controlled fashion. The desired anti stereochemistry is obtained only when the side chains are sterically bulky enough to direct the reduction via a Felkin-Anh type transition state.

Enantiomerically enriched β-aminoalcohols

It was of interest to apply the oxidation–reduction protocol established to compounds of high enantiomeric purity. If the amino centre is epimerized in any of the steps, then the value of this route would be greatly lessened.

To investigate whether the stereochemistry at the amino centre was preserved, the sequence shown in Scheme 4 was followed. Trans-metalation and trapping of stannane (*S*)-**1b** yielded (*R*)-**2b** as a mixture of diastereomers. HPLC analysis (ChiralCel OD) indicated that (*R*)-**2b** had an ee of 96%. TPAP oxidation of the mixture and subsequent reduction with Super-hydride® yielded (*R*)-**4b** (Scheme 4). HPLC analysis of the product showed that (*R*)-**4b** had 94% ee. This established that the TPAP oxidation and Super-hydride® reduction occur with only a small amount (2%) of racemization. Similarly, a sample of (*R*)-**2b** was prepared in 94% ee, and oxidized to (*R*)-**3b** with TPAP. (*R*)-**3b** was subjected to the procedure for chelation-controlled reduction with zinc borohydride, and the BOC group was then reinstated to allow HPLC analysis. HPLC subsequently showed that (*R*)-**7b** had an ee of 92%. Thus, the extent of epimerization is relatively minor for the overall conversion to either syn or anti aminoalcohols.

Conclusions

Tributylstannylalkylcarbamates **1** may be converted to either *syn*- or *anti*-β-aminoalcohols as shown in Scheme 1. The tributylstannylalkylcarbamates are easily transmetalated and trapped to yield a diastereomeric mixture of β-aminoalcohols. Trapping with non-enolizable aldehydes results in 80%–95% yields of alcohol; enolizable aldehydes result in 50%–75% yields of alcohol. Oxidation of the diastereomeric mixture of β-aminoalcohols to α-aminoketones with TPAP– NMO proceeds in 80%–95% yield. These α-aminoketones may be directly reduced with $LiEt_3BH$ to give the *syn*-β-aminoalcohol in 82% – >99% de. Removal of the BOC group followed by chelation-controlled reduction with $Zn(BH_4)_2$ gives the *anti*-β-aminoalcohol in 86% – >98% de for arylketones and certain alkylketones. Chelation-controlled reduction proceeds with low selectivity for unbranched alkylketones. The reaction sequence proceeds with only 2% racemization of the amino centre for enantiomerically enriched examples.

Experimental section

All reactions were carried out in dry glassware under an atmosphere of argon unless otherwise noted. Low-temperature baths were prepared as follows: –60 °C, dry ice – $CHCl_3$; –78 °C, dry ice – acetone; –95 °C, liquid N_2 – MeOH. Diethyl ether and THF were distilled from Na – benzophenone ketyl. CH_2Cl_2 was distilled from CaH_2. DMF was distilled from CaH_2 and stored over 3 Å molecular sieves. Aldehydes were distilled or purified by chromatography on basic alumina. Carbamates **1a**–**1e** were prepared as previously described (8). Zinc borohydride solution was prepared according to the method of Gensler et al. (14) Other reagents were used as purchased (Aldrich). Thin layer chromatography was performed with silica gel 60 F_{254} aluminum sheets (Merck 5554). Developed plates were visualized with 4% phosphomolybdic acid in EtOH. Flash chromatography was performed using Merck 9385 silica gel (230–400 mesh). Melting points were determined on a Mel-Temp melting point apparatus and are uncorrected. Optical rotations were measured on a PerkinElmer 241 digital polarimeter. Infrared spectra were obtained as thin films between NaCl plates or as KBr pellets on an MB-100 FT IR spectrometer. NMR spectra were obtained on Bruker AM-250 or AC-200 spectrometers using $CDCl_3$ or C_6D_6 as solvent. Internal references were TMS (δ 0.0) in ^{1}H spectra and $CDCl_3$ (δ 77.0) or C_6D_6 (δ 128.0) in ^{13}C spectra. NMR data is presented in the following order: (multiplicity, integration, coupling constants in Hz, assignment). An asterisk (*) denotes the major rotamer or diastereomer where a positive distinction could be made. Mass spectrometry was done by electrospray ionization on a VG Quattro II mass spectrometer using CH_3CN or CH_2C_2 as solvent. Elemental analyses were done by M-H-W Laboratories, Phoenix, Ariz.

tert-Butyl *N*-benzyl-*N*-(1-tributylstannylethyl)carbamate (1f)

This compound was prepared from *tert*-butyl *N*-(1-tributylstannylethyl)carbamate (8) and benzyl bromide. It was obtained in 92% yield as a clear colourless oil. IR (neat) (cm^{-1}): 2922, 1675, 1457, 1166. ^{1}H NMR (250 MHz, $CDCl_3$) δ: 7.4–7.2 (m, 5H, ArH), 4.41 (ABq, 2H, J = 15.3 Hz, Δδ = 0.43, $ArCH_2N$), 2.80 (q, 1H, J = 7.3 Hz, CHN), 1.7–1.1 (m, 15H, $SnCH_2CH_2CH_2CH_3$ and CH_3CHN), 1.43 (s, 9H, $C(CH_3)_3$), 1.0–0.6 (m, 15H, $SnCH_2CH_2CH_2CH_3$). ^{13}C NMR (63 MHz, $CDCl_3$) δ: 155.51, 139.05, 128.79, 128.19, 127.58, 126.96, 79.03, 51.96, 42.80 (^1J = 383, 365 Hz), 29.09 (^2J = 17 Hz), 28.36, 27.51 (^3J = 56 Hz), 17.44, 13.65, 10.44 (^1J = 326, 313 Hz). ES-MS *m/e*: 524 [M + 1 (^{118}Sn), 65], 526 [M + 1 (^{120}Sn), 100]. Anal. calcd. for $C_{25}H_{47}NO_2Sn$: C 58.61, H 9.25, N 2.73; found: C 58.76, H 9.02, N 2.68.

tert-Butyl *N*-benzyl-*N*-(1-tributylstannylhexyl)carbamate (1g)

This compound was prepared from *tert*-butyl *N*-(1-tributylstannylhexyl)carbamate (8) and benzyl bromide. It was obtained in 94% yield as a clear colourless oil. IR (neat) (cm^{-1}): 2917, 1676, 1457, 1167. ^{1}H NMR (250 MHz, $CDCl_3$) δ: 7.4–7.1 (m, 5H, ArH), 4.39 (ABq, 2H, J = 15.1 Hz, Δδ = 0.57, $ArCH_2N$), 2.77 (m, 1H, CHN), 1.8–1.0 (m, 20H, $SnCH_2CH_2CH_2CH_3$ and $CH_3(CH_2)_4CHN$), 1.44 (s, 9H, $C(CH_3)_3$), 1.0–0.75 (m, 12H, $SnCH_2CH_2CH_2CH_3$ and $CH_3(CH_2)_4CHN$), 0.75–0.50 (m, 6H, $SnCH_2CH_2CH_2CH_3$). ^{13}C NMR (63 MHz, $CDCl_3$) δ: 156.15, *155.45, 138.90, 128.20, 127.08, *78.99, 72.10, 53.28, 49.22 (^1J = 380, 360 Hz), 32.36, 31.77, 29.11 (^2J = 18 Hz), 28.44, 27.76, 27.51 (^3J = 56 Hz), 22.56, 13.95, 13.64, 10.62 (^1J = 321, 310 Hz). ES-MS *m/e*: 580 [M + 1 (^{118}Sn), 85], 582 [M + 1 (^{120}Sn), 100]. Anal. calcd. for $C_{29}H_{55}NO_2Sn$: C 61.28, H 9.75, N 2.46; found: C 61.30, H 9.78, N 2.43.

2-(*N*-*tert*-Butoxycarbonyl-*N*-methylamino)-1-phenyl-1-butanone (3a)

To a cooled (–78 °C) stirred solution of stannane **1a** (2.00 g, 4.33 mmol) in THF (20 mL) was added BuLi (1.6 mol/L in hexanes, 3.25 mL, 5.20 mmol) dropwise and the resulting solution was stirred for 10 min. A solution of *N*,*N*-dimethylbenzamide (0.839 g, 5.97 mmol) in THF (2 mL) was added and stirring was continued for 5 min. The reaction was quenched with sa. NH_4Cl and diluted with ether. Standard aqueous workup followed by flash chromatography on silica gel (80 g, hexanes:ether (12:1)) afforded ketone **3a** as a colourless oil. IR (neat) (cm^{-1}): 1689, 1388, 1150. ^{1}H NMR (200 MHz, $CDCl_3$) δ: 8.1–7.9 (m, 2H, ArH), 7.6–7.4 (m, 3H, ArH), 5.54 (dd, 0.6H, J = 5.8, 9.2 Hz, CHN), 5.20 (dd, 0.4H, J = 5.7, 9.1 Hz, CHN), 2.69 (s, 1.2H, NCH_3), 2.61 (s, 1.8H, NCH_3), 1.9 (m, 2H, CH_3CH_2), 1.52 (s, 3.6H, $C(CH_3)_3$), 1.46 (s, 5.4H, $C(CH_3)_3$), 0.95 (m, 3H, CH_3CH_2). ^{13}C NMR (50 MHz, $CDCl_3$) δ: *199.23, 198.55, *155.87, 154.96, *135.76, 133.01, 128.42, 128.08, 80.41, *79.94, 61.60, *59.56, 29.61, *29.27, 28.23, 20.94, *20.60, 10.35, *10.11. EI-MS *m/e*: 278 [M + 1, 3], 222 (21), 204 (19), 172 (76), 116 (100), 105 (71), 72 (96). Anal. calcd. for $C_{16}H_{23}NO_3$: C 69.29, H 8.36, N 5.05; found: C 69.40, H 8.12, N 4.91.

General procedure A: Preparation of racemic 2-(*N*-*tert*-butoxycarbonyl-*N*-alkylamino)-1-aryl-1-alkanols and 1-alkyl-1-alkanols 2 and TPAP–NMO oxidations to ketones 3

To a cooled (–78 °C) solution of the appropriate *tert*-butyl-*N*-methyl-*N*-(1-tributylstannylalkyl)carbamate in THF (0.25 mol/L) was added dropwise BuLi (1.6 mol/L in hex-

© 2003 NRC Canada

anes, 1.1 equiv.) and the resulting solution was stirred for 15 min. The appropriate aldehyde (1.1 equiv.) was then syringed into the flask and the solution was stirred for a further 15 min. The reaction was quenched with sat. NH_4Cl solution and Et_2O was added. The solution was washed 3 times with H_2O, dried on $MgSO_4$, filtered, and concentrated in vacuo. Flash chromatography (30 g silica/g substrate, hexanes–Et_2O (4:1)) furnished the desired alcohol **2**.

To a 0.5 mol/L solution of the appropriate alcohol in CH_2Cl_2 was added *N*-methylmorpholine-*N*-oxide (1.5 equiv.) and powdered 4 Å mol sieves (500 mg/mmol). Tetrapropylammonium perruthenate (0.05 equiv.) was then added in one portion. The solution was stirred for 1 h, then filtered through a short pad of silica. Concentration of the filtrate in vacuo yielded the crude ketone. Flash chromatography (20 g silica/g substrate, hexane–Et_2O (3:1)) afforded the pure ketone **3** as a colourless oil (10).

*2-(*N-tert-*Butoxycarbonyl*-N-*methylamino)-3-methyl-1-phenyl-1-butanone (3b)*

Stannane **1b** and benzaldehyde were allowed to react according to *General procedure A* to give alcohol **2b** in 94% yield as a mixture of diastereomers. Oxidation of **2b** then gave **3b** in 83% yield as a clear colourless oil. IR (neat) (cm^{-1}): 2955, 1690, 1598, 1459, 1380. ^{1}H NMR (250 MHz, $CDCl_3$) δ: 8.12 (m, 1.3H, ArH), 8.02 (m, 0.7H, ArH), 7.6–7.4 (m, 3H, ArH), 5.31 (d, 0.7H, *J* = 10.6 Hz, CHN), 5.05 (d, 0.3H, *J* = 10.6 Hz, CHN), 2.66 (s, 1H, NCH_3), 2.62 (s, 2H, NCH_3), 2.41 (m, 1H, C*H*$(CH_3)_2$), 1.54 (s, 3H, $C(CH_3)_3$), 1.44 (s, 6H, $C(CH_3)_3$), 0.93 (m, 6H, $CH(CH_3)_2$). ^{13}C NMR (63 MHz, $CDCl_3$) δ: *197.67, 196.64, *155.71, 154.75, 136.39, *136.08, 133.07, 128.50, 128.35, 128.25, 80.29, *79.79, 63.86, *62.41, *29.00, 28.87, 28.25, *28.08, 25.86, *25.59, 19.84, *19.65, 18.34, *17.99. ES-MS *m/e*: 292 [M + 1, 100]. Anal. calcd. for $C_{17}H_{25}NO_3$: C 70.07, H 8.65, N 4.81; found: C 70.09, H 8.54, N 4.82.

*2-(*N-tert-*Butoxycarbonyl*-N-*methylamino)-1-phenyl-1-propanone (3c)*

Stannane **1c** and benzaldehyde were allowed to react according to *General procedure A* to give alcohol **2c** in 91% yield as a mixture of diastereomers. Oxidation of **2c** then gave **3c** in 92% yield as a clear colourless oil. IR (neat) (cm^{-1}): 2963, 1691, 1597, 1449, 1389. ^{1}H NMR (250 MHz, $CDCl_3$) δ: 8.1–7.9 (m, 2H, ArH), 7.6–7.4 (m, 3H, ArH), 5.69 (q, 0.6H, *J* = 6.8 Hz, CHN), 5.17 (q, 0.4H, *J* = 6.6 Hz, CHN), 2.80 (s, 1.1H, NCH_3), 2.63 (s, 1.9H, NCH_3), 1.45 (s, 6.9H, $C(CH_3)_3$), 1.42 (s, 2.1H, $C(CH_3)_3$), 1.37 (d, 3H, *J* = 7.0 Hz, CHC*H*$_3$). ^{13}C NMR (63 MHz, $CDCl_3$) δ: *198.98, 198.15, *154.92, 154.09, 135.20, *132.58, 128.06, 127.89, 127.71, 79.99, *79.57, 56.64, *54.30, 30.37, *29.17, 27.83, 13.33, *12.80. *2-(*N-tert-*Butoxycarbonyl*-N-*methylamino)-3-octanone (3n)*

Aminoalcohol **2n** was prepared according to *General procedure A* from stannane **1c** and hexanal in 77% yield as a mixture of diastereomers. The title compound was prepared from alcohol **2n** in 87% yield as a clear colourless oil. IR (neat) (cm^{-1}): 2930, 1702, 1460, 1382, 1315, 1252, 1154. ^1H NMR (250 MHz, $CDCl_3$) δ: 4.75–4.55 (br, 0.5H, CHN), 4.30–4.05 (br, 0.5H, CHN), 2.84 (br s, 1.5H, CH_3N), 2.73 (br s, 1.5H, CH_3N), 2.43 (t, 2H, *J* = 7.2 Hz, CH_2CO), 1.65–1.45 (m, 2H, CH_2CH_2CO), 1.47 (br s, 9H, $C(CH_3)_3$), 1.40–1.15 (m, 7H, CH_3CHN and $CH_3CH_2CH_2$), 0.89 (t, 3H, *J* = 6.8 Hz, $CH_3(CH_2)_4$). ^{13}C NMR (63 MHz, $CDCl_3$) δ: 208.87, 208.50, 155.35, 154.20, 79.90, 79.52, 61.04, 58.98, *38.38, 38.09, 31.49, 31.00, 30.28, 27.84, 22.89, 21.98, 13.41, 12.79, 12.27. ES-MS *m/e*: 258 [M + 1, 100].

General procedure B: Reduction of ketones with Super-hydride®

To a –78 °C solution of the appropriate ketone in THF (0.25 mol/L) was slowly added Super-hydride® (1.0 mol/L in THF, 3.0 equiv.). The reaction mixture was stirred for 15 min and then quenched with 4 N NaOH solution. While the reaction mixture was still cold, 30% H_2O_2 solution was added dropwise (*vigorous reaction*). The reaction mixture was taken up in Et_2O, washed twice with water, and then brine. The organic layer was dried on $MgSO_4$, filtered through Celite, and concentrated in vacuo to yield the alcohol, which did not require purification.

syn-*2-(*N-tert-*Butoxycarbonyl*-N-*methylamino)-3-methyl-1-phenyl-1-butanol (4b)*

This compound was prepared from aminoketone **3b** according to *General procedure B* as a 98:2 mixture of diastereomers. **4b** was obtained in 97% yield as a white, oily solid, mp 106–110.5 °C. IR (melt) (cm^{-1}): 3409, 2955, 1672, 1463, 1356, 1162. ^1H NMR (250 MHz, $CDCl_3$) δ: 7.4–7.1 (m, 4.5H, ArH), 6.8–6.4 (br, 0.5H, ArH), 5.02 (d, 0.5H, *J* = 8.5 Hz, C*H*OH), 5.01 (d, 0.5H, *J* = 8.5 Hz, C*H*OH), 3.8–3.6 (br d, 0.3H, CHN), 3.0–2.0 (m, 4.7H, NCH_3, CHN, and $(CH_3)_2CH$), 1.7–1.2 (br s, 7.5H, $C(CH_3)_3$), 1.2–1.0 (m, 5H, $C(CH_3)_3$ and $(CH_3)_2CH$), 1.0–0.7 (m, 3.5H, $(CH_3)CH$). ^{13}C NMR (63 MHz, $CDCl_3$) δ: 157.50 (br), *155.89, 143.46, *143.26, 127.68, 126.73, 126.46, *125.96, 125.31, 79.94, *78.39, *73.79, 73.53, 66.07, 40.48, 30.44, *28.13, 27.79, *26.69, 26.56, *20.13, 19.97. ES-MS *m/e*: 294 [M + 1, 100]. Anal. calcd. for $C_{17}H_{27}NO_3$: C 69.59, H 9.28, N 4.77; found: C 69.76, H 9.03, N 4.59.

syn-*2-(*N-tert-*Butoxycarbonyl*-N-*methylamino)-1-phenyl-1-propanol (4c)*

This compound was prepared from aminoketone **3c** according to *General procedure B* as a >99:<1 mixture of diastereomers in 98% yield as a clear oil. IR (neat) (cm^{-1}): 3416, 2949, 1675, 1448, 1349, 1155. ^1H NMR (250 MHz, $CDCl_3$) δ: 7.4–7.25 (m, 5H, ArH), 4.56 (d, 1H, *J* = 8.3 Hz, C*H*OH), 4.16 (br, 1H, CHN), 2.75 (br, 3H, NCH_3), 1.47 (s, 9H, $C(CH_3)_3$), 1.03 (br d, 3H, CH_3CHN). ^{13}C NMR (63 MHz, $CDCl_3$) δ: *156.47 (br), 155.63 (br), 142.08, 127.58, 126.85, 126.16, 78.94 (br), 75.48, 67.14, *57.03 (br), 56.20 (br), 30.22 (br), 27.77, 24.93, 13.95. ES-MS *m/e*: 266 [M + 1, 100]. Anal. calcd. for $C_{15}H_{23}NO_3$: C 67.90, H 8.74, N 5.28; found: C 67.84, H 8.59, N 5.10. This is a previously reported compound (15).

syn-*2-(*N-tert-*Butoxycarbonyl*-N-*methylamino)-1-phenyl-1-heptanol (4d)*

This compound was prepared from aminoketone **3d** according to *General procedure B* as a >99:<1 mixture of diastereomers in 100% yield as a clear, colourless oil. IR (neat) (cm^{-1}): 3418, 2924, 1676, 1455, 1357, 1160. ^1H NMR (250 MHz, $CDCl_3$) δ: 7.5–7.1 (m, 5H, ArH), 4.8–4.4 (br m, 1H, C*H*OH), 4.4–3.6 (br m, 1H, CHN), 2.84 (br s, 1.5H, NCH_3), 2.61 (br s, 1.5H, NCH_3), 1.45 (s, 7H, $C(CH_3)_3$), 1.41 (s, 2H, $C(CH_3)_3$), 1.23 (m, 8H, $(CH_2)_4CH_3$), 0.84 (br, 3H, $(CH_2)_4CH_3$). ^{13}C NMR (63 MHz, $CDCl_3$) δ: *157.52, 156.59, *142.58, 142.18, 128.16, *128.05, 127.55, *127.20, 126.68, *126.31, *79.68, 79.34, 75.58, 60.52 (br), *31.30, 31.13, 28.19, *25.81, 25.47, 22.32, 13.77. ES-MS *m/e*: 322 [M + 1, 100]. Anal. calcd. for $C_{19}H_{31}NO_3$: C 70.99, H 9.72, N 4.36; found: C 71.20, H 9.73, N 4.20.

syn-*2-Cyclohexyl-2-(*N-tert-*butoxycarbonyl*-N-*methylamino)-1-phenylethanol (4e)*

This compound was prepared from aminoketone **3e** according to *General procedure B* as a >99:<1 mixture of diastereomers except that 2.0 equiv. of Super-hydride® were used and flash chromatography (30g silica/g substrate, hex–Et_2O (2:1)) was required to remove a small amount (~6%) of starting material. Alcohol **4e** was obtained in 93% yield as a clear viscous oil (99% based on recovered starting material). IR (neat) (cm^{-1}): 3403, 2918, 1670, 1461, 1397, 1163. ^1H NMR (200 MHz, $CDCl_3$) δ: 7.5–7.1 (m, 5H, ArH), 5.01 (d, 1H, *J* = 3.5 Hz, C*H*OH), 3.79 (br d, 1H, CHN), 3.0–2.4 (br m, 3H, NCH_3), 2.4–0.8 (br m, 11H, *c*-C_6H_{11}), 1.5–1.3 (br s, 9H, $C(CH_3)_3$). ^{13}C NMR (50 MHz, $CDCl_3$) δ: 157.60, *155.87, 143.34, 127.58, 126.52, 126.34, *125.93, 125.22, 80.01, 78.22, 75.48, 73.03, *72.87, 64.39, 40.52, 35.48, *35.25, 30.59, 30.45, 30.27, 30.04, 28.07, 27.69, 26.27, 25.80, 25.68. ES-MS *m/e*: 334 [M + 1, 100]. Anal. calcd. for $C_{20}H_{31}NO_3$: C 72.04, H 9.37, N 4.20; found: C 71.95, H 9.20, N 4.12.

syn-*2-(*N-*Benzyl*-N-tert-*butoxycarbonylamino)-1-phenyl-1-propanol (4f)*

This compound was prepared from ketone **3f** according to *General procedure B* as a >99:<1 mixture of diastereomers. The diastereomeric ratio was determined by integration of the carbinol H signals in the ^1H NMR spectrum of the deprotected aminoalcohol **5f**. **4f** was obtained in 100% yield as a clear viscous oil. IR (neat) (cm^{-1}): 3401, 3063, 2959, 1675, 1604, 1450, 1262. ^1H NMR (250 MHz, $CDCl_3$) δ: 7.7–6.9 (m, 10H, ArH), 4.67 (d, 1H, *J* = 7.0 Hz, $ArCH_2N$), 4.5–4.2 (m, 1H, $ArCH_2N$), 4.0–3.6 (m, 2H, C*H*OH and CHN),

© 2003 NRC Canada

1.45 (br s, 9H, $C(CH_3)_3$), 1.14 (m, 3H, CH_3CHN). ^{13}C NMR (63 MHz, $CDCl_3$) δ: 156.82, 142.52, 138.69, 128.03, 127.91, 127.07, 126.90, 126.61, 126.07, 80.06, 76.52, 59.66, 51.02, 28.05, 15.25. ES-MS *m/e*: 342 [M + 1, 100]. Anal. calcd. for $C_{21}H_{27}NO_3$: C 73.87, H 7.97, N 4.10; found: C 73.69, H 8.18, N 3.98.

syn-*2-(*N-*Benzyl*-N-tert-*butoxycarbonylamino)-1-phenyl-1-heptanol (4g)

This compound was prepared from ketone **3g** according to *General procedure B* as a >99:<1 mixture of diastereomers. The diastereomeric ratio was determined by integration of the carbinol H signals in the ^1H NMR spectrum of the deprotected aminoalcohol **5g**. **4g** was obtained in 94% yield as a clear viscous oil. IR (neat) (cm^{-1}): 3399, 3029, 2942, 1675, 1459, 1365, 1248, 1167. ^1H NMR (250 MHz, $CDCl_3$) δ: 7.5–6.9 (m, 10H, ArH), 4.75 (m, 1H, $ArCH_2N$), 4.30 (m, 1H, $ArCH_2N$), 3.45 (m, 2H, C*H*OH and CHN), 1.7–1.4 (m, 2H, CH_2CHN), 1.44 (br s, 9H, $C(CH_3)_3$), 1.2–0.9 (m, 6H, $CH_3(CH_2)_3CH_2$), 0.78 (m, 3H, $CH_3(CH_2)_4$). ^{13}C NMR (63 MHz, $CDCl_3$) δ: 157.67, 143.00, 138.30, 128.23, 127.80, 127.12, 126.09, 125.85, 80.65, 75.53, 74.55, 38.82, 31.40, *29.09, 28.34, 27.93, 26.23, 22.35, 13.85. ES-MS *m/e*: 398 [M + 1, 100]. Anal. calcd. for $C_{25}H_{35}NO_3$: C 75.53, H 8.87, N 3.52; found: C 75.64, H 8.66, N 3.52. The ^1H NMR (200 MHz, DMSO-d_6) signal for $C(CH_3)_3$ coalesced at or below 352 K. The barrier to rotation ($\Delta G_c^{\ddagger}$) was estimated to be 17.8 kcal/mol.

syn-*4-(*N-tert-*Butoxycarbonyl*-N-*methylamino)-3-nonanol (4i)

This compound was prepared according to *General procedure B* from ketone **3i** in 81% yield as a syn–anti (96:4) mixture of diastereomers. The diastereomeric ratio was determined by integration of the carbinol H signals in the ^1H NMR spectrum of the deprotected aminoalcohol **5i**. **4i** was obtained as a clear colourless oil. IR (neat) (cm^{-1}): 3438, 2925, 1675, 1458, 1355, 1157. ^1H NMR (250 MHz, $CDCl_3$) δ: 3.47 (m, 2H, C*H*OH and CHN), 2.78 (s, 3H, CH_3N), 1.70–1.15 (m, 10H, $CH_3(CH_2)_4CHN$ and CH_2CHOH), 1.46 (s, 9H, $C(CH_3)_3$), 1.00 (app. t, 3H, J = 7.4 Hz, CH_3CH_2CHOH), 0.89 (m, 3H, $CH_3(CH_2)_4CHN$). ^{13}C NMR (63 MHz, $CDCl_3$) δ: *157.20, 156.64, 79.24, 73.92, 31.39, 28.13, 27.23, 26.73, *25.65, 25.48, 22.32, 13.71, *9.83, 9.61. ES-MS *m/e*: 274 [M + 1, 100]. Anal. calcd. for $C_{15}H_{31}NO_3$: C 65.89, H 11.43, N 5.12; found: C 66.01, H 11.18, N 5.05.

syn-*7-(*N-tert-*Butoxycarbonyl*-N-*methylamino)-6-dodecanol (4j)

This compound was prepared according to *General procedure B* from ketone **3j** in 86% yield as a syn–anti (96:4) mixture of diastereomers. The diastereomeric ratio was determined by integration of the carbinol H signals in the ^1H NMR spectrum of the deprotected aminoalcohol **5j**. **4j** was obtained as a clear colourless oil. IR (neat) (cm^{-1}): 3433, 2921, 1674, 1457, 1366, 1157. ^1H NMR (250 MHz, $CDCl_3$) δ: 3.52 (m, 2H, C*H*OH and CHN), 2.78 (s, 3H, CH_3N), 1.7–1.1 (m, 16H, $CH_3(CH_2)_4CHN$ and $CH_3(CH_2)_4CHOH$), 1.45 (s, 9H, $C(CH_3)_3$), 1.0–0.8 (m, 6H, $CH_3(CH_2)_4CHN$ and $CH_3(CH_2)_4CHOH$). ^{13}C NMR (63 MHz, $CDCl_3$) δ: *157.31, 156.70, 79.41, 72.66, *34.58, 34.13, *31.83, 31.50, 28.24, *25.79, 25.61, 25.20, 22.47, 13.86. ES-MS *m/e*: 316 [M + 1, 100]. Anal. calcd. for $C_{18}H_{37}NO_3$: C 68.53, H 11.82, N 4.44; found: C 68.76, H 11.68, N 4.35.

syn-*4-(*N-tert-*Butoxycarbonyl*-N-*methylamino)-2-methyl-3-nonanol (4k)

This compound was prepared according to *General procedure B* from ketone **3k** in 81% yield as a syn–anti (97:3) mixture of diastereomers. The diastereomeric ratio was determined by integration of the carbinol H signals in the ^1H NMR spectrum of the deprotected aminoalcohol **5k**. **4k** was obtained as a clear colourless oil. IR (neat) (cm^{-1}): 3449, 2925, 1743, 1676, 1458, 1360, 1157. ^1H NMR (250 MHz, $CDCl_3$) δ: 4.1–3.8 (m, 1H, C*H*OH), 3.29 (m, 1H, CHN), 2.83 (s, 0.5 H, CH_3N), 2.77 (s, 2.5H, CH_3N), 1.9–1.6 (m, 1H, CH_3CHCH_3), 1.46 (s, 9H, $C(CH_3)_3$), 1.4–1.1 (m, 8H, $CH_3(CH_2)_4CHN$), 1.1–0.8 (m, 9H, CH_3CHCH_3 and $CH_3(CH_2)_4$). ^{13}C NMR (63 MHz, $CDCl_3$) δ: *157.64, 156.87, 82.70, 79.53, *76.87, 76.34, 59.62, 57.05, *32.28, 32.01, 31.49, 30.35, *29.68, 28.67, 28.25, 28.13, *25.67, 25.49, 22.45, 20.07, 17.45, *16.45, 15.23, 13.84. ES-MS *m/e*: 288 [M + 1, 100]. Anal. calcd. for $C_{16}H_{33}NO_3$: C 66.86, H 11.57, N 4.87; found: C 66.86, H 11.72, N 4.95.

syn-*4-(*N-tert-*Butoxycarbonyl*-N-*methylamino)-2,2-dimethyl-3-nonanol (4l)

This compound was prepared according to *General procedure B* from ketone **3l** in 99% yield as a clear colourless oil. IR (neat) (cm^{-1}): 3461, 2926, 1675, 1463, 1396, 1364, 1159. ^1H NMR (250 MHz, $CDCl_3$) δ: 4.18 (m, 0.6H, C*H*OH), 3.75 (m, 0.25H, C*H*OH), 3.45 (m, 0.15H, C*H*OH), 3.18 (m, 1H, CHN), 3.0–2.7 (m, 3H, CH_3N), 2.3–1.6 (m, 2H,CH_2CHN), 1.45 (s, 9H, $OC(CH_3)_3$), 1.40–1.15 (m, 6H, $CH_3(CH_2)_3CH_2CHN$), 0.95 (s, 9H,$CHOHC(CH_3)_3$), 0.95–0.80 (m, 3H, $CH_3(CH_2)_4$). ^{13}C NMR (63 MHz, $CDCl_3$) δ: 157 (br), *156.06, 85.01, *81.46, 81 (br), *79.10, 78.5 (br), 65 (br), 57.40, *54.29, 53.5 (br), 40 (br), 35.37, *35.09, 31.46, 31.27, 31.02, 30.35 (br), 29.75 (br), 28.14, 26.17, 26.06, 25.39, 24.05, 22.40, 22.30, 13.71. ES-MS *m/e*: 302 [M + 1, 100]. Anal. calcd. for $C_{17}H_{35}NO_3$: C 67.73, H 11.70, N 4.65; found: C 67.93, H 11.59, N 4.66.

syn-*3-(*N-tert-*Butoxycarbonyl*-N-*methylamino)-2-methyl-4-nonanol (4m)

This compound was prepared according to the *General procedure B* from ketone **3m** in 82% yield as a syn–anti (91:9) mixture of diastereomers. The diastereomeric ratio was determined by integration of the carbinol H signals in the ^1H NMR spectrum of the deprotected aminoalcohol **5m**. **4m** was obtained as a clear colourless oil. IR (neat) (cm^{-1}): 3445, 2928, 1675, 1462, 1362, 1158. ^1H NMR (250 MHz, $CDCl_3$) δ: 3.95–3.70 (m, 1H, CHN), 3.50 (m, 1H, C*H*OH), 2.88 (s, 3H, CH_3N), 1.7–1.2 (m, 9H, CH_3CHCH_3 and $CH_3(CH_2)_4CHOH$), 1.46 (s, 9H, $C(CH_3)_3$), 1.01 (d, 3H, J = 6.4 Hz, CH_3CHCH_3), 0.95–0.8 (m, 6H, CH_3CHCH_3 and $CH_3(CH_2)_4$). ^{13}C NMR (63 MHz, $CDCl_3$) δ: *157.11, 156.63, *79.54, 79.08, 71.36, *71.20, 64.17, *35.09, 34.67, 31.90, 28.27, *26.41, 26.22, *25.81, 25.62, 22.51, 19.96, 13.90. ES-MS *m/e*: 288 [M + 1, 100]. Anal. calcd. for

© 2003 NRC Canada

$C_{16}H_{33}NO_3$: C 66.86, H 11.57, N 4.87; found: C 66.93, H 11.42, N 4.73.

syn-*2-(*N-tert-*Butoxycarbonyl-*N-*methylamino)-3-octanol (4n)

This compound was prepared according to *General procedure B* from ketone **3n** in 87% yield as a syn–anti (96:4) mixture of diastereomers. The diastereomeric ratio was determined by integration of the carbinol H signals in the ^{1}H NMR spectrum of the deprotected aminoalcohol **5n**. It was obtained as a clear colourless oil. IR (neat) (cm^{-1}): 3433, 2925, 1676, 1460, 1348, 1156. ^{1}H NMR (250 MHz, $CDCl_3$) δ: 3.89 (app. quintet, 1H, *J* = 7.1 Hz, CHN), 3.51 (m, 1H, C*H*OH), 2.79 (s, 3H, CH_3N), 1.60–1.25 (m, 8H, $CH_3(CH_2)_4CHOH$), 1.46 (s, 9H, $C(CH_3)_3$), 1.15 (d, 3H, *J* = 6.9, CH_3CHN), 0.89 (m, 3H, $CH_3(CH_2)_4$). ^{13}C NMR (63 MHz, $CDCl_3$) δ: 157.18 (br), 79.73, 73.24, 56.29, 34.36, 31.94, 28.41, 25.14, 22.61, 14.69, 14.01. ES-MS *m/e*: 260 [M + 1, 100].

General procedure C: Conversion of BOC-protected amines to aminoalcohols 5

To a 6.4 mol/L (50% v/v, 15 mmol) solution of trifluoroacetic acid in CH_2Cl_2 was added anisole (1.5 mmol). A solution of **4** (1 mmol) in CH_2Cl_2 (1.2 mL) was slowly added to the acid solution. The mixture was stirred for 45 min, taken up in Et_2O (40 mL), extracted with 1 N HCl (3 × 25 mL), and basified with 30% w/v NaOH in brine. NaCl was added to make a sat. solution, which was extracted with CH_2Cl_2 (5 × 15 mL). The organic layer was then dried on $MgSO_4$, filtered through a cotton plug, and concentrated in vacuo to yield amino alcohol **5**.

syn-*2-(*N-*Methylamino)-1-phenyl-1-butanol (5a)

To a cooled (–78 °C) solution of ketone **3a** (100 mg, 0.36 mmol) in THF (2 mL) was added L-Selectride® (1.0 mol/L in THF, 0.72 mL. 0.72 mmol) and the resulting mixture was stirred for 10 min. Water (2 mL) was added dropwise followed by 4 mol/L HCl (2 mL). The mixture was heated at reflux overnight. The mixture was diluted with ether (10 mL) and extracted with 1 mol/L HCl (3 × 10 mL). The acid extracts were basified with 4 mol/L NaOH and extracted with ether (30, 20, 20 mL). The ethereal extracts were dried ($MgSO_4$) and concentrated in vacuo to provide 65 mg (100%) of the known (16) **5a** as a white solid, mp 112–114 °C. ^{1}H NMR (250 MHz, $CDCl_3$) δ: 7.35–7.20 (m, 5H, ArH), 4.30 (d, 1H, *J* = 7.8 Hz, CHOH), 2.90 (br s, 2H, NH and OH), 2.48 (m, 1H, CHN), 2.39 (s, 3H, NCH_3), 1.40 (m, 2H, CH_2CH_3), 0.83 (t, 3H, *J* = 7.4 Hz, CH_2CH_3).

syn-*2-(*N-*Methylamino)-3-methyl-1-phenyl-1-butanol (5b)

Following *General procedure C*, 0.296 g (1.0 mmol) of **4b** was converted to **5b** (0.147 g, 75%) as a pale yellow oil. IR (neat) (cm^{-1}): 3344, 2929, 1603, 1460, 1390. ^{1}H NMR (200 MHz, C_6D_6) δ: 7.4 (m, 2H, ArH), 7.2 (m, 3H, ArH), 4.43 (d, 1H, *J* = 5.1 Hz, C*H*OH), 2.24 (dd, 1H, *J* = 4.4, 5.0 Hz, CHN), 2.03 (s, 3H, NCH_3), 1.57 (d of sept., 1H, *J* = 4.3, 6.9 Hz, CH_3CHCH_3), 0.76 (d, 3H, *J* = 6.9 Hz, CH_3CH), 0.69 (d, 3H, *J* = 6.9 Hz, CH_3CH). ^{13}C NMR (50 MHz, C_6D_6) δ: 145.65, 128.35, 127.10, 126.72, 72.54, 72.14, 37.38, 30.21, 20.42, 17.88. ES-MS *m/e*: 194 [M + 1, 100]. Anal. calcd. for $C_{12}H_{19}NO$: C 74.57, H 9.91, N 7.25; found: C 74.68, H 9.84, N 6.96. The ^{1}H NMR spectrum showed a signal for the carbinol proton of the anti-diastereomer (δ 4.77), which integrated to 2%.

syn-*2-(*N-*Methylamino)-1-phenyl-1-propanol (5c)

This compound was prepared according to *General procedure C* from **4c** in 63% yield as a white solid, mp 116 to 117 °C (lit. (17) value, 118 °C). IR (KBr pellet) (cm^{-1}): 3071, 2981, 2789, 1476, 1384, 1060. ^{1}H NMR (250 MHz, C_6D_6) δ: 7.4 (m, 2H, ArH), 7.2 (m, 3H, ArH), 4.06 (d, 1H, *J* = 8.0 Hz, C*H*OH), 2.35 (dq, 1H, *J* = 8.0, 6.4 Hz, CHN), 2.00 (s, 3H, NCH_3), 0.64 (d, 3H, *J* = 6.4 Hz, CH_3CHN). ^{13}C NMR (63 MHz, C_6D_6) δ: 143.68, 127.67, 126.85, 77.61, 61.79, 33.23, 15.39. ES-MS *m/e*: 166 [M + 1, 100]. Anal. calcd. for $C_{10}H_{15}NO$: C 72.69, H 9.15, N 8.48; found: C 72.47, H 8.99, N, 8.49. There was only a small signal for the carbinol H (δ 4.70) of the anti-diastereomer in the ^{1}H NMR spectrum, which integrated to <1%. This compound has been previously reported.

syn-*2-(*N-*Methylamino)-1-phenyl-1-heptanol (5d)

This compound was prepared according to *General procedure C* from **4d** in 74% yield as a clear yellow oil. IR (neat) (cm^{-1}): 3320, 3030, 2937, 1603, 1457, 1340. ^{1}H NMR (250 MHz, C_6D_6) δ: 7.4 (m, 2H, ArH), 7.2 (m, 3H, ArH), 4.32 (d, 1H, *J* = 7.3 Hz, C*H*OH), 2.42 (dt, 1H, *J* = 4.9, 7.1 Hz, CHN), 2.03 (s, 3H, NCH_3), 1.4–0.9 (m, 8H, $CH_3CH_2CH_2CH_2CH_2CH$), 0.82 (t, 3H, *J* = 7.0 Hz, CH_3CH_2). ^{13}C NMR (63 MHz, C_6D_6) δ: 144.26, 128.35, 127.44, 127.32, 74.74, 65.80, 33.08, 32.27, 29.83, 25.72, 22.85, 14.19. ES-MS *m/e*: 222 [M + 1, 100]. Anal. calcd. for $C_{14}H_{23}NO$: C 75.97, H 10.47, N 6.33; found: C 75.76, H 10.56, N 6.13. There was only a small signal for the carbinol H (δ 4.89) of the anti-diastereomer in the ^{1}H NMR spectrum, which integrated to <1%.

syn-*2-Cyclohexyl-2-(*N-*methylamino)-1-phenylethanol (5e)

This compound was prepared according *General procedure C* from **4e** in 71% yield as a clear yellow oil that crystallized on standing, mp 37 to 38 °C. IR (neat) (cm^{-1}): 3136, 2920, 1446, 1351. ^{1}H NMR (250 MHz, C_6D_6) δ: 7.4 (m, 2H, ArH), 7.2 (m, 3H, ArH), 4.51 (d, 1H, *J* = 4.6 Hz, C*H*OH), 2.24 (t, 1H, *J* = 4.5 Hz, CHN), 2.03 (s, 3H, NCH_3), 1.8–1.4 (br, 5H, *c*-C_6H_{11}), 1.4–1.2 (br, 1H, *c*-C_6H_{11}), 1.2–0.9 (br, 4H, *c*-C_6H_{11}), 0.9–0.7 (br, 1H, *c*-C_6H_{11}). ^{13}C NMR (63 MHz, C_6D_6) δ: 146.17, 128.39, 126.97, 126.57, 72.03, 71.45, 41.15, 37.44, 30.85, 29.00, 26.86, 26.80. ES-MS *m/e*: 234 [M + 1, 100]. Anal. calcd. for $C_{15}H_{23}NO$: C 77.21, H 9.93, N 6.00; found: C 77.39, H 9.71, N 5.91. There was only a small signal for the carbinol H (δ 4.81) of the anti-diastereomer in the ^{1}H NMR spectrum, which integrated to <1%.

syn-*2-(*N-*Benzylamino)-1-phenyl-1-propanol (5f)

This compound was prepared from alcohol **4f** according to *General procedure C* except that the final extraction was performed with Et_2O. It was obtained in 90% yield as a white solid, mp 93.0–94.5 °C. IR (KBr pellet) (cm^{-1}): 3091, 2829, 1434, 1384, 1052. ^{1}H NMR (250 MHz, C_6D_6) δ: 7.5–7.0 (m, 10H, ArH), 4.14 (d, 1H, *J* = 8.0 Hz, C*H*OH), 3.37

© 2003 NRC Canada

(ABq, 2H, J = 13.0 Hz, $\Delta\delta$ = 0.19, $ArCH_2N$), 2.62 (m, 1H, CHN), 0.72 (d, 3H, J = 6.3 Hz, CH_3CHN). ^{13}C NMR (63 MHz, C_6D_6) δ: 143.47, 140.64, 128.63, 128.41, 128.34, 127.61, 127.47, 127.21, 77.79, 59.68, 51.34, 16.22. ES-MS *m/e*: 242 [M + 1, 100]. Anal. calcd. for $C_{16}H_{19}NO$: C 79.63, H 7.94. N 5.80; found: C 79.50, H 7.79, N 5.71. The ^1H NMR spectrum showed a signal for the carbinol proton of the anti-diastereomer (δ 4.72), which integrated to <1%.

syn-*2-(*N-*Benzylamino)-1-phenyl-1-heptanol (5g)*

This compound was prepared from alcohol **4g** according to *General procedure C*, except that the final extraction was performed with Et_2O. It was obtained in 89% yield as a white solid, mp 48.5–51.5 °C. IR (KBr pellet) (cm^{-1}): 3122, 2938, 2862, 1449, 1384, 1046. ^1H NMR (250 MHz, C_6D_6) δ: 7.5–7.0 (m, 10H, ArH), 4.38 (d, 1H, J = 6.7 Hz, C*H*OH), 3.47 (ABq, 2H, J = 12.9 Hz, $\Delta\delta$ = 0.08, $ArCH_2N$), 2.64 (m, 1H, CHN), 1.45–0.90 (m, 8H, $CH_3(CH_2)_4$), 0.82 (m, 3H, $CH_3(CH_2)_4$). ^{13}C NMR (63 MHz, C_6D_6) δ: 144.59, 141.10, 129.00, 128.87, 128.74, 127.82, 127.57, 75.32, 64.17, 51.91, 32.59, 31.32, 26.08, 23.22, 14.58. ES-MS *m/e*: 298 [M + 1, 100]. Anal. calcd. for $C_{20}H_{27}NO$: C 80.76, H 9.15, N 4.71; found: C 80.86, H 8.98, N 4.69. The ^1H NMR spectrum showed a signal for the carbinol proton of the anti-diastereomer (δ 4.89), which integrated to <1%.

syn-*4-(*N-*Methylamino)-3-nonanol (5i)*

Following *General procedure C*, (0.179 g, 0.65 mmol) of *syn*-4-(*N*-tert-butoxycarbonyl-*N*-methylamino)-3-nonanol (**4i**) was converted to 0.097 g (86%) of **5i** as a clear oil. IR (neat) (cm^{-1}): 3337, 2921, 1421, 1106. ^1H NMR (250 MHz, C_6D_6) δ: 3.24 (dt, 1H, J = 3.4, 7.8 Hz, C*H*OH), 2.14 (s, 3H, CH_3N), 2.11 (m, 1H, CHN), 1.65–1.10 (m, 10H, CH_2CHOH and $CH_3(CH_2)_4CHN$), 1.12 (app. t, 3H, J = 7.3 Hz, CH_3CH_2CHOH), 0.90 (app. t, 3H, J = 6.9 Hz, $CH_3(CH_2)_4CHN$). ^{13}C NMR (63 MHz, C_6D_6) δ: 73.11, 63.62, 33.55, 32.53, 30.23, 27.66, 25.71, 22.95, 14.23, 10.61. ES-MS *m/e*: 174 [M + 1, 100]. Anal. calcd. for $C_{10}H_{23}NO$: C 70.12, H 13.53, N 8.18; found: C 70.00, H 13.66, N 8.12. The ^1H NMR spectrum showed a signal for the carbinol proton of the anti-diastereomer (δ 3.55), which integrated to 4%.

syn-*7-(*N-*Methylamino)-6-dodecanol (5j)*

This compound was prepared according to *General procedure C* from **4j** in 79% yield as a clear colourless oil. IR (neat) (cm^{-1}): 3345, 2910, 2798, 1460, 1378, 1089. ^1H NMR (250 MHz, C_6D_6) δ: 3.31 (app. td, 1H, J = 7.4, 3.4 Hz, C*H*OH), 2.14 (m, 1H, CHN), 2.12 (s, 3H, CH_3N), 1.8–1.0 (m, 16H, $CH_3(CH_2)_4CHN$ and $CH_3(CH_2)_4CHOH$), 1.0–0.8 (m, 6H, $CH_3(CH_2)_4CHN$ and $CH_3(CH_2)_4CHOH$). ^{13}C NMR (63 MHz, C_6D_6) δ: 71.78, 64.04, 35.08, 33.56, 32.53, 30.28, 26.212, 25.74, 23.15, 22.96, 14.31, 14.25. ES-MS *m/e*: 216 [M + 1, 100]. Anal. calcd. for $C_{13}H_{29}NO$: C 72.50, H 13.57, N 6.50; found: C 72.38, H 13.50, N 6.34. The ^1H NMR spectrum showed a signal for the carbinol proton of the anti-diastereomer (δ 3.70), which integrated to 4%.

syn-*4-(*N-*Methylamino)-2-methyl-3-nonanol (5k)*

This compound was prepared according to *General procedure C* from **4k** in 38% yield as a clear colourless oil. IR (neat) (cm^{-1}): 3380, 2920, 1459. ^1H NMR (250 MHz, C_6D_6) δ: 3.10 (dd, 1H, J = 4.2, 7.1 Hz, C*H*OH), 2.26 (m, 1H, CHN), 2.10 (s, 3H, CH_3N), 1.68 (d of sept., 1H, J = 4.1, 6.8 Hz, CH_3CHCH_3) 1.45–1.10 (m, 8H, $CH_3(CH_2)_4$), 1.12 (d, 3H, J = 6.8 Hz, CH_3CHCH_3), 1.04 (d, 3H, J = 6.8 Hz, CH_3CHCH_3), 0.89 (app. t, 3H, $CH_3(CH_2)_4$). ^{13}C NMR (63 MHz, C_6D_6) δ: 75.93, 60.83, 33.23, 32.46, 30.59, 30.29, 25.47, 22.94, 20.78, 16.25, 14.24. ES-MS *m/e*: 188 [M + 1, 100]. Anal. calcd. for $C_{11}H_{25}NO$: C 70.53, H 13.45, N 7.48; found: C 70.60, H 13.33, N 7.50. The ^1H NMR spectrum showed a signal for the carbinol proton of the anti-diastereomer (δ 3.25), which integrated to 3%.

syn-*4-(*N-*Methylamino)-2,2-dimethyl-3-nonanol (5l)*

This compound was prepared according *General procedure C* from **4l** in 85% yield as a clear colourless oil. IR (neat) (cm^{-1}): 3326, 2921, 1460, 1089. ^1H NMR (250 MHz, C_6D_6) δ: 2.94 (d, 1H, J = 3.9 Hz, C*H*OH), 2.17 (m, 1H, CHN), 2.12 (s, 3H, CH_3N), 1.45–1.05 (m, 8H, $CH_3(CH_2)_4$), 1.00 (s, 9H, $C(CH_3)_3$), 0.89 (t, 3H, J = 6.9 Hz, $CH_3(CH_2)_4$). ^{13}C NMR (63 MHz, C_6D_6) δ: 78.90, 59.11, 36.37, 35.64, 35.14, 32.33, 26.26, 26.00, 22.98, 14.23. ES-MS *m/e*: 202 [M + 1, 100]. The ^1H NMR spectrum showed no detectable signal for the carbinol proton of the anti-diastereomer (δ 3.38).

syn-*3-(*N-*Methylamino)-2-methyl-4-nonanol (5m)*

This compound was prepared according to *General procedure C* from **4m** in 77% yield as a clear colourless oil. IR (neat) (cm^{-1}): 3340, 2927, 1462, 1120. ^1H NMR (250 MHz, C_6D_6) δ: 3.40 (m, 1H, C*H*OH), 2.22 (s, 3H, CH_3N), 1.85 (app. t, 1H, J = 4.7 Hz, CHN), 1.8–1.2 (m, 9H, CH_3CHCH_3 and $CH_3(CH_2)_4$), 0.92 (m, 3H, $CH_3(CH_2)_4$), 0.82 (d, 3H, J = 6.9 Hz, CH_3CHCH_3), 0.71 (d, 3H, J = 6.9 Hz, CH_3CHCH_3). ^{13}C NMR (63 MHz, C_6D_6) δ: 70.34, 69.71, 37.61, 37.02, 32.45, 30.56, 26.29, 23.12, 20.16, 17.98, 14.31. ES-MS *m/e*: 188 [M + 1, 100]. The ^1H NMR spectrum showed a signal for the carbinol proton of the anti-diastereomer (δ 3.65), which integrated to 9%.

syn-*2-(*N-*Methylamino)-3-octanol (5n)*

This compound was prepared according to *General procedure C* from **4n** in 75% yield as a clear colourless oil. IR (neat) (cm^{-1}): 3328, 2920, 1454, 1112. ^1H NMR (250 MHz, C_6D_6) δ: 3.09 (app. td, 1H, J = 8.2, 3.0 Hz, C*H*OH), 2.09 (m, 1H, CHN), 2.06 (s, 3H, CH_3N), 1.60–1.15 (m, 8H, $CH_3(CH_2)_4$), 0.92 (m, 3H, $CH_3(CH_2)_4$), 0.74 (d, 3H, J = 6.3 Hz, CH_3CHN). ^{13}C NMR (63 MHz, C_6D_6) δ: 74.25, 60.19, 34.39, 33.29, 32.48, 25.90, 23.11, 15.39, 14.31. ES-MS *m/e*: 160 [M + 1, 100]. The ^1H NMR spectrum showed a signal for the carbinol proton of the anti-diastereomer (δ 3.59), which integrated to 4%.

General procedure D: Preparation of ketones 6 and reduction with $Zn(BH_4)_2$ to alcohols 7

To a solution of trifluoroacetic acid (6.4 mol/L in CH_2Cl_2, 4.5 mL, 28 mmol) was added anisole (0.310 g, 2.8 mmol). A solution of ketone **3** (0.498 g, 1.9 mmol) in CH_2Cl_2 (4.5 mL) was added dropwise. Gas evolution was evident and the reaction mixture turned pale yellow. The mixture was stirred for 45 min, taken up in Et_2O (50 mL), and extracted with

© 2003 NRC Canada

1 N HCl (3 × 40 mL). The acid extract was basified with 30% w/v NaOH in brine and extracted with CH_2Cl_2 (3 × 40 mL). The CH_2Cl_2 extracts were dried on $MgSO_4$, filtered through Celite, and concentrated in vacuo to yield the crude deprotected ketone **6**.

Ketone **6** was dissolved in Et_2O (3 mL) and syringed into a –78 °C solution of $Zn(BH_4)_2$ (0.15 mol/L in Et_2O, 2 equiv.). The mixture was stirred for 1 h and then quenched with 2 N HCl (15 mL). The mixture was diluted with 1 N HCl (40 mL) and extracted with Et_2O (40 mL). The acid layer was basified with 30% w/v NaOH in brine and then extracted with CH_2Cl_2 (3 × 40 mL). The CH_2Cl_2 extracts were dried on $MgSO_4$, filtered through Celite, and concentrated in vacuo to yield alcohol **7**.

*Preparation of 2-(*N*-methylamino)-1-phenyl-1-butanone (6a) and reduction with $Zn(BH_4)_2$*

Ketone **6a** was obtained from ketone **3a** according to *General procedure D* as a colourless oil in 97% yield. ^{1}H NMR (250 MHz, $CDCl_3$) δ: 7.96 (m, 2H, ArH), 7.6–7.4(m, 3H, ArH), 4.12 (dd, 1H, *J* = 5.0, 6.0 Hz, CHN), 2.80 (s, 1H, NH), 2.37 (s, 3H, NCH_3), 1.82–1.60 (m, 2H, CH_2CH_3), 0.93 (t, 3H, *J* = 7.3 Hz, CH_2CH_3).

anti-2-(*N*-Methylamino)-1-phenyl-1-butanol (**7a**) was prepared in 65% yield as a white solid, mp 87.5–88.0 °C. ^{1}H NMR (250 MHz, $CDCl_3$) δ: 7.3 (m, 5H, ArH), 4.83 (d, 1H, *J* = 4.0 Hz, C*H*OH), 2.52 (m, 1H, CHN), 2.50 (s, 3H, NCH_3), 1.20 (m, 2H, CH_2CH_3), 0.82 (t, 3H, *J* = 7.4 Hz, CH_2CH_3). This compound has been previously reported (18).

*Preparation of 2-(*N*-methylamino)-3-methyl-1-phenyl-1-butanone (6b) and reduction with $Zn(BH_4)_2$*

Ketone **6b** was obtained from ketone **3b** according to *General procedure D* as yellow oil. IR (neat) (cm^{-1}): 3337, 2927, 2796, 1679, 1598, 1460. ^{1}H NMR (250 MHz, C_6D_6) δ: 7.87 (m, 2H, ArH), 7.1–7.0 (m, 3H, ArH), 3.71 (d, 1H, *J* = 4.5 Hz, CHN), 2.24 (s, 3H, NCH_3), 1.91 (d sept, 1H, *J* = 4.5, 6.8 Hz, C*H*CHN), 1.15 (d, 3H, *J* = 6.8 Hz, CH_3CHCH_3), 0.81 (d, 3H, *J* = 6.8 Hz, CH_3CHCH_3). ^{13}C NMR (63 MHz, C_6D_6) δ: 203.25, 137.58, 132.96, 128.85, 128.37, 69.84, 35.87, 31.60, 20.56, 17.03.

anti-2-(*N*-Methylamino)-3-methyl-1-phenyl-1-butanol (**7b**) was prepared in 56% yield (for two steps) as a clear yellow oil. IR (neat) (cm^{-1}): 3355, 2923, 1603, 1465, 1390. ^{1}H NMR (250 MHz, C_6D_6) δ: 7.4 (m, 2H, ArH), 7.15 (m, 3H, ArH), 4.77 (d, 1H, *J* = 5.0 Hz, C*H*OH), 2.30 (dd, 1H, *J* = 3.6, 5.0 Hz, C*H*NHCH$_3$), 2.12 (s, 3H, NCH_3), 1.6 (d sept., 1H, *J* = 3.6, 6.9 Hz, CH_3CHCH_3), 0.82 (d, 3H, *J* = 6.9 Hz, CH_3CH), 0.66 (d, 3H, *J* = 6.9 Hz, CH_3CH). ^{13}C NMR (63 MHz, C_6D_6) δ: 143.48, 128.27, 127.03, 126.69, 73.00, 70.50, 35.97, 28.22, 21.47, 17.53. ES-MS *m*/*e*: 194 [M + 1, 100]. Anal. calcd. for $C_{12}H_{19}NO$: C 74.57, H 9.91, N 7.25; found: C 74.52, H 10.00, N 7.42. There was only a small signal for the carbinol H (δ 4.43) of the syn-diastereomer in the ^{1}H NMR spectrum, which integrated to <1%.

*2-(*N*-Methylamino)-1-phenyl-1-propanone (6c) and reduction with $Zn(BH_4)_2$*

Ketone **6c** was prepared according to *General procedure D*. From 0.498 g (1.9 mmol) of **3c** there was obtained 0.327 g of **6c** as a yellow oil. IR (neat) (cm^{-1}): 3331, 2939, 2797, 1684, 1597, 1449. ^{1}H NMR (250 MHz, C_6D_6) δ: 7.85 (m, 2H, ArH), 7.15–6.95 (m, 3H, ArH), 3.85 (q, 1H, *J* = 7.0 Hz, CHN), 2.21 (s, 3H, NCH_3), 1.11 (d, 3H, *J* = 7.0 Hz, CH_3CHN). ^{13}C NMR (63 MHz, C_6D_6) δ: 202.81, 136.40, 133.04, 128.82, 128.51, 59.76, 34.51, 19.34. This crude material was reduced to give a pale yellow solid (0.198 g). The carbinol H signals (δ 4.06 (syn), 4.70 (anti)) in the ^{1}H NMR spectrum of this material indicated that there was a 93:7 anti:syn mixture of diastereomers present. Flash chromatography (3 g SiO_2, ethyl acetate/0.5% Et_3N) afforded 0.098 g (31%) of *anti*-2-(*N*-methylamino)-1-phenyl-1-propanol (**7c**) as a white solid, mp 73.5–74.5 °C (lit (17) mp value 79 °C). IR (KBr pellet) (cm^{-1}): 3080, 2967, 2816, 1452, 1384, 1042. ^{1}H NMR (250 MHz, C_6D_6) δ: 7.4 (m, 2H, ArH), 7.2 (m, 3H, ArH), 4.70 (d, 1H, *J* = 5.7 Hz, C*H*OH), 2.48 (m, 1H, CHN), 2.05 (s, 3H, NCH_3), 0.63 (d, 3H, *J* = 6.5 Hz, CH_3CHN). ^{13}C NMR (63 MHz, C_6D_6) δ: 143.03, 128.24, 127.00, 126.52, 73.14, 60.95, 33.73, 13.65. ES-MS *m*/*e*: 166 [M + 1, 100]. Anal. calcd. for $C_{10}H_{15}NO$: C 72.69, H 9.15, N 8.48; found: C 72.72, H 8.97, N 8.50.

*Preparation of 2-(*N*-methylamino)-1-phenyl-1-heptanone (6d) and reduction with $Zn(BH_4)_2$*

This compound was prepared from ketone **3d** according to *General procedure D* except that the final extraction was performed with Et_2O instead of CH_2Cl_2 and the flash chromatography was omitted. The crude deprotected ketone **6d** was obtained as a yellow oil. IR (neat) (cm^{-1}): 3350, 2913, 1682, 1597, 1457, 1232. ^{1}H NMR (250 MHz, C_6D_6) δ: 7.93 (m, 2H, ArH), 7.15–7.0 (m, 3H, ArH), 4.40 (dd, 1H, *J* = 7.3, 4.3 Hz, CHN), 2.26 (s, 3H, NCH_3), 1.65–1.55 (m, 2H, $(CH_2)_4CH_3$), 1.55–1.30 (m, 3H, $(CH_2)_4CH_3$), 1.30–1.00 (m, 3H, $(CH_2)_4CH_3$), 0.81 (t, 3H, *J* = 6.8 Hz, $(CH_2)_4CH_3$). ^{13}C NMR (63 MHz, C_6D_6) δ: 202.90, 137.00, 133.00, 128.84, 128.42, 64.68, 35.11, 33.97, 32.11, 25.98, 22.82, 14.15.

anti-2-(*N*-Methylamino)-1-phenyl-1-heptanol (**7d**) was prepared in 61% yield as a white solid, mp 56–57.5 °C. IR (KBr pellet) (cm^{-1}): 3309, 3120, 2931, 2854, 1561, 1466, 1384, 1049. ^{1}H NMR (250 MHz, C_6D_6) δ: 7.4 (m, 2H, ArH), 7.2 (m, 3H, ArH), 4.89 (d, 1H, *J* = 3.3 Hz, C*H*OH), 2.46, (m, 1H, CHN), 2.19 (s, 3H, NCH_3), 1.25–0.85 (m, 8H, $CH_3CH_2CH_2CH_2CH_2$), 0.77 (t, 3H, *J* = 7.0 Hz, $CH_3CH_2CH_2CH_2CH_2$). ^{13}C NMR (63 MHz, C_6D_6) δ: 146.76, 128.24, 126.97, 126.55, 71.90, 66.04, 34.40, 32.18, 28.41, 26.52, 22.85, 14.16. ES-MS *m*/*e*: 222 [M + 1, 100]. Anal. calcd. for $C_{14}H_{23}NO$: C 75.97, H 10.47, N 6.33; found: C 76.10, H 10.38, N 6.32. There was only a small signal for the carbinol H (δ 4.32) of the syn-diastereomer in the ^{1}H NMR spectrum, which integrated to <1%.

*Preparation of 2-cyclohexyl-2-(*N*-methylamino)-1-phenylethanone (6e) and reduction with $Zn(BH_4)_2$*

This compound was prepared from ketone **3e** according to the procedure described in *General procedure D* except that the final extraction was performed with Et_2O instead of CH_2Cl_2 and flash chromatography was omitted. The crude deprotected ketone **6e** was obtained as a yellow oil. IR (neat) (cm^{-1}): 3350, 2904, 1679, 1597, 1449, 1217. ^{1}H NMR (250 MHz, C_6D_6) δ: 7.93 (m, 2H, ArH), 7.1–7.0 (m, 3H, ArH), 3.78 (d, 1H, *J* = 4.5 Hz, CHN), 2.25 (s, 3H, NCH_3), 2.0–1.4 (m, 7H, *c*-C_6H_{11}), 1.3–0.8 (m, 4H, *c*-C_6H_{11}). ^{13}C NMR (63 MHz, C_6D_6) δ: 203.42, 137.84, 133.01, 128.90,

© 2003 NRC Canada

128.40, 69.62, 41.88, 35.90, 31.11, 28.11, 26.80, 26.62, 26.56.

anti-2-Cyclohexyl-2-(*N*-methylamino)-1-phenylethanol (**7e**) was prepared in 63% yield (for both steps) as a white solid, mp 94.5–96 °C. IR (KBr pellet) (cm^{-1}): 3316, 3076, 2918, 2851, 1561, 1452, 1385, 1056. ^{1}H NMR (250 MHz, C_6D_6) δ: 7.4 (m, 2H, ArH), 7.2 (m, 3H, ArH), 4.81 (d, 1H, *J* = 5.0 Hz, C*H*OH), 2.30 (dd, 1H, *J* = 4.9, 4.6 Hz, CHN), 2.16 (s, 3H, NCH_3), 1.85 (m, 1H, C*H*CHN), 1.7–1.2 (m, 5H, *c*-C_6H_{11}), 1.1–0.8 (m, 5H, *c*-C_6H_{11}). ^{13}C NMR (63 MHz, C_6D_6) δ: 143.37, 128.25, 127.06, 126.72, 72.75, 70.62, 38.98, 36.14, 31.84, 28.35, 26.86, 26.74. ES-MS *m*/*e*: 234 [M + 1, 100]. Anal. calcd. for $C_{15}H_{23}NO$: C 77.21, H 9.93, N 6.00; found: C 76.96, H 9.79, N 5.90. There was only a small signal for the carbinol H (δ 4.51) of the syn-diastereomer in the ^{1}H NMR spectrum, which integrated to <1%.

*Preparation of 2-(*N*-Benzylamino)-1-phenyl-1-propanone (6f) and Reduction with $Zn(BH_4)_2$*

This compound was prepared from ketone **3f** according to *General procedure D*. It was obtained in 92% yield as a pale yellow oil. IR (neat) (cm^{-1}): 3330, 3029, 2975, 1683, 1597, 1449, 1217, 1152. ^{1}H NMR (250 MHz, C_6D_6) δ: 7.78 (m, 2H, ArH), 7.4–6.95 (m, 8H, ArH), 4.06 (q, 1H, *J* = 7.0 Hz, CHN), 3.62 (ABq, 2H, *J* = 13.1 Hz, Δδ = 0.21, $ArCH_2N$), 1.11 (d, 3H, *J* = 7.0 Hz, CH_3CHN). ^{13}C NMR (63 MHz, C_6D_6) δ: 202.48, 140.62, 135.89, 132.60, 128.15, 128.10, 127.22, 126.73, 56.84, 51.66, 19.44.

anti-2-(*N*-Benzylamino)-1-phenyl-1-propanol (**7f**) was obtained in 77% yield (for both steps) as a clear oil. IR (neat) (cm^{-1}): 3355, 2880, 1603, 1494, 1454, 1199, 1065. ^{1}H NMR (250 MHz, C_6D_6) δ: 7.5–7.0 (m, 10H, ArH), 4.72 (d, 1H, *J* = 3.5 Hz, C*H*OH), 3.52 (ABq, 2H, *J* = 13.3 Hz, Δδ = 0.04, $ArCH_2N$), 2.74 (dq, 1H, *J* = 3.5, 6.5 Hz, CHN), 0.70 (d, 3H, *J* = 6.5 Hz, CH_3CHN). ^{13}C NMR (63 MHz, C_6D_6) δ: 142.83, 140.54, 128.61, 128.36, 128.22, 127.18, 127.01, 126.51, 73.59, 58.17, 51.15, 14.09. ES-MS *m*/*e*: 242 [M + 1, 100]. Anal. calcd. for $C_{16}H_{19}NO$: C 79.63, H 7.94, N 5.80; found: C 79.83, H 7.85, N 5.80. The ^{1}H NMR spectrum showed a signal for the carbinol proton of the syn-diastereomer (δ 4.14), which integrated to 1%. This is a previously reported compound (4).

*Preparation of 2-(*N*-benzylamino)-1-phenyl-1-heptanone (6g) and reduction with $Zn(BH_4)_2$*

This compound was prepared from ketone **3g** according to *General procedure D*. It was obtained in 65% yield as a pale yellow oil. IR (neat) (cm^{-1}): 3331, 2909, 1685, 1592, 1455. ^{1}H NMR (250 MHz, C_6D_6) δ: 7.88 (m, 2H, ArH), 7.36 (m, 2H, ArH), 7.3–6.9 (m, 6H, ArH), 4.12 (m, 1H, CHN), 3.66 (ABq, 2H, *J* = 13.1 Hz, Δδ = 0.24, $ArCH_2N$), 1.85–0.85 (m, 8H, $CH_3(CH_2)_4$), 0.81 (m, 3H, $CH_3(CH_2)_4$). ^{13}C NMR (63 MHz, C_6D_6) δ: 203.00, 141.01, 136.90, 132.99, 128.83, 128.70, 128.54, 127.19, 61.80, 52.46, 34.22, 31.99, 25.87, 22.80, 14.16.

anti-2-(*N*-Benzylamino)-1-phenyl-1-heptanol (**7g**) was obtained in 61% yield (for both steps) as a clear viscous oil. IR (neat) (cm^{-1}): 3402, 2915, 1455, 1051. ^{1}H NMR (250 MHz, C_6D_6) δ: 7.5–6.9 (m, 10H, ArH), 4.89 (d, 1H, *J* = 3.5 Hz, C*H*OH), 3.64 (ABq, 2H, *J* = 13.2 Hz, Δδ = 0.12, $ArCH_2N$), 2.66 (m, 1H, CHN), 1.4–0.8 (m, 8H, $CH_3(CH_2)_4$), 0.75 (m, 3H, $CH_3(CH_2)_4$). ^{13}C NMR (63 MHz, C_6D_6) δ: 142.50, 140.64, 128.69, 128.52, 128.27, 127.34, 127.03, 126.48, 72.33, 62.86, 51.77, 31.99, 28.49, 26.32, 22.80, 14.13. ES-MS *m*/*e*: 298 [M + 1, 100]. Anal. calcd. for $C_{20}H_{27}NO$: C 80.76, H 9.15, N 4.71; found: C 81.00, H 9.20, N 4.71. The ^{1}H NMR spectrum showed a signal for the carbinol proton of the syn-diastereomer (δ 4.38), which integrated to <1%.

*Preparation of 2-(*N*-benzylamino)-3-octanone (6h) and reduction with $Zn(BH_4)_2$*

This compound was prepared from ketone **3h** according to *General procedure D*. It was obtained in 88% yield as a pale yellow oil. IR (neat) (cm^{-1}): 3333, 3028, 2923, 1712, 1457, 1128. ^{1}H NMR (250 MHz, C_6D_6) δ: 7.4–7.0 (m, 5H, ArH), 3.56 (ABq, 2H, *J* = 13.2 Hz, Δδ = 0.10, $ArCH_2N$), 3.08 (q, 1H, *J* = 7.0 Hz, CHN), 2.08 (AB of app. ABX_2, 2H, *J* = 17.1, 7.4 Hz, Δδ = 0.11, $CH_2C(O)$), 1.53 (app. p, 2H, *J* = 7.4 Hz, $CH_2CH_2C(O)$), 1.4–1.05 (m, 4H, $CH_3CH_2CH_2CH_2CH_2C(O)$), 0.96 (d, 3H, *J* = 7.0 Hz, CH_3CHN], 0.85 (m, 3H, $CH_3(CH_2)_4C(O)$). ^{13}C NMR (63 MHz, C_6D_6) δ: 212.40, 140.93, 128.54, 128.40, 127.15, 61.89, 52.06, 39.18, 31.75, 23.59, 22.81, 18.07, 14.10.

anti-2-(*N*-Benzylamino)-3-octanol (7h) was obtained in 75% yield (for both steps) as an ~80:20 mixture of anti- and syn-diastereomers, respectively. Spectral data for **7h** are as follows: IR (neat) (cm^{-1}): 3378, 2934, 1456, 1108. ^{1}H NMR (250 MHz, C_6D_6) δ: 7.4–7.0 (m, 5H, ArH), 3.58 (app. dt, 0.8H, *J* = 3.0, 6.3 Hz, C*H*OH (anti)), 3.56 (s, 1.6H, $ArCH_2N$ (anti)), 3.53 (ABq, 0.4H, *J* = 13.0 Hz, Δδ = 0.21, $ArCH_2N$ (syn)), 3.16 (dt, 0.2H, *J* = 2.8, 8.3 Hz, C*H*OH (syn)), 2.48, (dq, 1H, *J* = 3.0, 6.5 Hz, CHN), 1.8–1.1 (m, 8H, $CH_3(CH_2)_4$), 1.0–0.8 (m, 6H, $CH_3(CH_2)_4$ and CH_3CHN). ^{13}C NMR (63 MHz, C_6D_6) δ: 141.38, 129.00, 128.75, 75.11 (syn), 71.86 (anti), 58.25 (syn), 57.12 (anti), 51.85, 34.66 (syn), 33.59, 32.81, 27.02, 26.32 (syn), 23.47, 16.76 (syn), 14.70, 14.43. ES-MS *m*/*e*: 236 [M + 1, 100]. Anal. calcd. for $C_{15}H_{25}NO$: C 76.55, H 10.71, N 5.95; found: C 76.48, H 10.52, N 6.07.

*Preparation of 4-(*N*-methylamino)-3-nonanone (6i) and reduction with $Zn(BH_4)_2$*

Ketone **3i** was deprotected according to *General procedure D* in quantitative yield as a pale yellow oil. IR (neat) (cm^{-1}): 3362, 2919, 2797, 1712, 1460, 1378, 1124. ^{1}H NMR (250 MHz, C_6D_6) δ: 2.88 (m, 1H, CHN), 2.10 (AB of ABX_3, 2H, Δδ = 0.18, *J* = 17.7, 7.4 Hz, CH_2CO), 2.14 (s, 3H, CH_3N), 1.50–1.05 (m, 8H, $CH_3(CH_2)_4CHN$), 0.99 (t, 3H, *J* = 7.3 Hz, CH_3CH_2CO), 0.86 (t, 3H, *J* = 7.6 Hz, $CH_3(CH_2)_4CHN$). ^{13}C NMR (63 MHz, C_6D_6) δ: 213.00, 69.44, 34.96, 32.66, 32.54, 32.17, 25.81, 22.83, 14.16, 7.77.

The deprotected ketone **6i** was reduced according to *General procedure D* except that the final extraction was done with Et_2O and the chromatography was omitted. A 69% yield (for both steps) of alcohols **5i** and **7i** in a 55:45 syn:anti ratio was obtained. ^{1}H NMR (250 MHz, C_6D_6) δ: 3.55 (dt, 0.45H, *J* = 9.1, 3.6 Hz, C*H*OH (anti)), 3.23 (dt, 0.55H, *J* = 3.4, 7.2, C*H*OH (syn)), 2.18 (s, 1.35H, CH_3N (anti)), 2.15 (m, 1H, CHN), 2.12 (s, 1.65H, CH_3N (syn)), 1.6–1.0 (m, 10H, $CH_3(CH_2)_4CHN$ and CH_2CHOH), 1.0–0.85 (m, 6H, $CH_3(CH_2)_4CHN$ and CH_3CH_2CHOH). ^{13}C

© 2003 NRC Canada

NMR (63 MHz, C_6D_6) δ: 73.14 (syn), 71.84 (anti), 64.26 (anti), 63.59 (syn), 34.56 (anti), 33.63 (syn), 32.53, 30.29 (syn), 28.89 (anti), 27.70, 26.65 (anti), 25.71, 22.97 (syn), 14.25, 11.31 (anti), 10.63 (syn).

*Preparation of 7-(*N*-methylamino)-6-dodecanone (6j) and reduction with $Zn(BH_4)_2$*

Ketone **3j** was deprotected according to *General procedure D* in ~77% yield as a pale yellow oil. IR (neat) (cm^{-1}): 3341, 2913, 2797, 1711, 1460, 1371, 1133. ^1H NMR (250 MHz, C_6D_6) δ: 2.92 (m, 1H, CHN), 2.20 (AB of app. ABX_2, 2H, Δδ = 0.14, *J* = 17.0, 7.3 Hz, CH_2CO), 2.18 (s, 3H, CH_3N), 1.60 (p, 2H, *J* = 7.3 Hz, CH_2CH_2CO), 1.50–1.05 (m, 12H, $CH_3(CH_2)_4CHN$ and $CH_3CH_2CH_2CH_2CH_2CO$), 1.0–0.75 (overlapping t, 6H, $CH_3(CH_2)_4CHN$ and $CH_3(CH_2)_4CO$). ^{13}C NMR (63 MHz, C_6D_6) δ: 212.41, 69.66, 39.57, 35.05, 32.50, 31.85, 25.86, 23.62, 22.86, 14.18, 14.10.

The ketone **6j** was reduced according to *General procedure D* except that the final extraction was done with Et_2O and the chromatography was omitted. The alcohols **5j/7j** was obtained in 65% yield (for both steps) as a white solid, which was a 50:50 mixture of diastereomers. ^1H NMR (250 MHz, C_6D_6) δ: 3.72 (br m, 0.5H, C*H*OH (anti)), 3.39 (br m, 0.5H, C*H*OH (syn)), 2.4–2.0 (br m, 4H, CH_3N and CHN), 1.65–1.1 (m, 16H, $CH_3(CH_2)_4CHN$ and $CH_3(CH_2)_4CHOH$), 1.1–0.7 (m, 6H, $CH_3(CH_2)_4CHN$ and $CH_3(CH_2)_4CHOH$).

*Preparation of 4-(*N*-methylamino)-2-methyl-3-nonanone (6k) and reduction with $Zn(BH_4)_2$*

Ketone **3k** was deprotected according to *General procedure D* in quantitative yield as a pale yellow oil. IR (neat) (cm^{-1}): 3338, 2919, 2797, 1711, 1462, 1381, 1135, 1039. ^1H NMR (250 MHz, C_6D_6) δ: 3.03 (dd, 1H, *J* = 4.5, 7.4 Hz, CHN), 2.45 (sept., 1H, *J* = 6.8 Hz, CH_3CHCH_3), 2.16 (s, 3H, CH_3N), 1.55–1.05 (m, 8H, $CH_3(CH_2)_4CHN$), 1.01 (d, 3H, *J* = 6.7 Hz, CH_3CHCH_3), 0.91 (d, 3H, *J* = 6.7 Hz, CH_3CHCH_3), 0.87 (t, 3H, *J* = 7.0 Hz, $CH_3(CH_2)_4CHN$]. ^{13}C NMR (63 MHz, C_6D_6) δ: 215.91, 67.90, 37.84, 35.08, 32.53, 32.22, 26.07, 22.89, 18.84, 17.93, 14.19.

The ketone **6k** was reduced according to *General procedure D* except that the final extraction was performed with Et_2O and the chromatography was omitted. A 69% yield of alcohols **5k/7k** (for both steps) was obtained as a clear oil, which was a 59:41 syn:anti mixture of diastereomers. ^1H NMR (250 MHz, C_6D_6) δ: 3.25 (dd, 0.4H, *J* = 3.1, 8.9 Hz, C*H*OH (anti)], 3.09 (dd, 0.6H, *J* = 4.4, 7.1 Hz, C*H*OH (syn)), 2.4–2.2 (m, 1H, CHN), 2.14 (s, 1.2H, CH_3N (anti)), 2.10 (s, 1.8H, CH_3N (syn)), 1.9–1.6 (m, 1H, CH_3CHCH_3), 1.5–1.0 (m, 8H, $CH_3(CH_2)_4CHN$), 1.24 (d, 1.2H, *J* = 6.5 Hz, CH_3CHCH_3 (anti)), 1.12 (d, 1.8H, *J* = 6.8 Hz, CH_3CHCH_3 (syn)), 1.05 (d, 1.8H, *J* = 6.7 Hz, CH_3CHCH_3 (syn)), 1.0–0.8 (m, 3H, $CH_3(CH_2)_4CHN$), 0.78 (d, 1.2H, *J* = 6.7 Hz, CH_3CHCH_3 (anti)). ^{13}C NMR (63 MHz, C_6D_6) δ: 75.93 (syn), 75.11 (anti), 62.00 (anti), 60.95 (syn), 34.12 (anti), 33.26 (syn), 32.50, 30.54 (syn), 30.39 (anti), 30.22 (syn), 27.77 (anti), 26.60 (anti), 25.50 (syn), 23.01 (anti), 22.96 (syn), 20.78 (syn), 20.67 (anti), 18.67 (anti), 16.28 (syn), 14.26.

*Preparation of 4-(*N*-methylamino)-2,2-dimethyl-3-nonanone (6l) and reduction with $Zn(BH_4)_2$*

Ketone **3l** was deprotected according to *General procedure D* in 91% yield as a clear oil. IR (neat) (cm^{-1}): 3331, 2920, 2795, 1703, 1468, 1365, 1133, 1057. ^1H NMR (250 MHz, C_6D_6) δ: 3.34 (dd, 1H, *J* = 3.2, 8.4 Hz, CHN), 2.12 (s, 3H, CH_3N), 1.65–1.10 (m, 8H, $CH_3(CH_2)_4CHN$), 1.02 (s, 9H, $C(CH_3)_3$), 0.88 (t, 3H, *J* = 6.8 Hz, $CH_3(CH_2)_4CHN$). ^{13}C NMR (63 MHz, C_6D_6) δ: 217.38, 63.16, 43.15, 35.04, 35.57, 32.16, 26.39, 22.94, 14.22.

The ketone **6l** was reduced according to *General procedure D* except that the last extraction was performed with Et_2O and the chromatography was omitted. The alcohol was obtained in 63% yield (for both steps) as a clear oil, which was a 96:4 anti:syn mixture of diastereomers. *anti*-4-(*N*-methylamino)-2,2-dimethyl-3-nonanol (**7l**) exhibited the following spectral characteristics: IR (neat) (cm^{-1}): 3319, 2916, 1467, 1361, 1089, 1014. ^1H NMR (250 MHz, C_6D_6) δ: 3.38 (d, 1H, *J* = 1.9, C*H*OH), 2.37 (dt, 1H, *J* = 2.2, 8.8 Hz, CHN), 2.19 (s, 3H, CH_3N), 1.45–1.10 (m, 8H, $CH_3(CH_2)_4$), 1.07 (s, 9H, $C(CH_3)_3$), 0.89 [t, 3H, *J* = 6.7 Hz, $CH_3(CH2)_4$). ^{13}C NMR (63 MHz, C_6D_6) δ: 77.82, 62.40, 34.63, 32.64, 30.07, 27.41, 27.13, 26.26, 23.08, 14.29. ES-MS *m/e*: 202 [M + 1, 100].

*Preparation of 3-(*N*-methylamino)-2-methyl-4-nonanone (6m) and reduction with $Zn(BH_4)_2$*

Ketone **3m** was deprotected according to *General procedure D* in quantitative yield as a pale yellow oil. IR (neat) (cm^{-1}): 3362, 2929, 2797, 1708, 1463, 1373, 1135. ^1H NMR (250 MHz, C_6D_6) δ: 2.69 (d, 1H, *J* = 5.2 Hz, CHN), 2.13 (AB of app. ABX2, 2H, Δδ = 0.18, *J* = 17.0, 7.5 Hz, CH_2CO), 2.17 (s, 3H, CH_3N), 1.74 (d of sept., 1H, *J* = 5.2, 6.8 Hz, CH_3CHCH_3), 1.57 (p, 2H, *J* = 7.4 Hz, CH_2CH_2CO), 1.35–1.05 (m, 4H, $CH_3CH_2CH_2CH_2CH_2CO$), 0.95 (d, 3H, *J* = 6.8 Hz, CH_3CHCH_3), 0.86 (t, 3H, *J* = 8.8 Hz, $CH_3(CH_2)_4CO$), 0.77 (d, 3H, *J* = 6.8 Hz, CH_3CHCH_3). ^{13}C NMR (63 MHz, C_6D_6) δ: 212.55, 75.20, 40.82, 35.91, 31.83, 30.54, 23.57, 22.86, 20.39, 17.49. 14.07.

The ketone **6m** was reduced according to *General procedure D* except that the final extraction was performed with Et_2O and the chromatography was omitted. The alcohol was obtained in 81% yield (for both steps) as a clear oil, which was a 96:4 anti:syn mixture of diastereomers. *anti*-3-(*N*-Methylamino)-2-methyl-4-nonanol (**7m**) exhibited the following spectral characteristics: IR (neat) (cm^{-1}): 3380, 2916, 1462, 1103. ^1H NMR (250 MHz, C_6D_6) δ: 3.65 (m, 1H, C*H*OH), 2.24 (s, 3H, CH_3N), 1.98 (dd, 1H, *J* = 5.2, 4.8 Hz, CHN), 1.72 (d of sept., 1H, *J* = 5.2, 6.9 Hz, CH_3CHCH_3), 1.50–1.25 (m, 8H, $CH_3(CH_2)_4CHOH$), 0.93 (t, 3H, *J* = 6.7 Hz, $CH_3(CH_2)_4$), 0.91 (d, 3H, *J* = 6.9 Hz, CH_3CHCH_3), 0.79 (d, 3H, *J* = 6.9 Hz, CH_3CHCH_3). ^{13}C NMR (63 MHz, C_6D_6) δ: 70.65, 69.42, 36.48, 32.84, 32.52, 29.08, 26.74, 23.14, 21.11, 18.65, 14.31. ES-MS *m/e*: 188 [M + 1, 100].

*Preparation of 2-(*N*-methylamino)-3-octanone (6n) and reduction with $Zn(BH_4)_2$*

Ketone **3n** was deprotected according to *General procedure D* in ~87% yield as a pale yellow oil. IR (neat) (cm^{-1}): 3341, 2916, 2797, 1712, 1457, 1371, 1135. ^1H NMR (250 MHz, C_6D_6) δ: 2.91 (q, 1H, *J* = 7.0 Hz, CHN), 2.15

(AB of ABX_3, 2H, $\Delta\delta$ = 0.09, J = 17.0, 7.4 Hz, CH_2CO), 2.14 (s, 3H, CH_3N), 1.55 (p, 2H, J = 7.4 Hz, CH_2CH_2CO), 1.45–1.05 (m, 4H, $CH_3CH_2CH_2CH_2CH2CO$), 0.96 (d, 3H, J = 7.0 Hz, CH_3CHN), 0.85 (t, 3H, J = 6.9 Hz, $CH_3(CH_2)_4CO$). ^{13}C NMR (63 MHz, C_6D_6) δ: 212.34, 64.55, 38.99, 34.51, 31.78, 23.56, 22.82, 17.65, 14.07.

The ketone **6n** was reduced according to *General procedure D* except that the final extraction was performed with Et_2O and the chromatography was omitted. The alcohols **5n/7n** were obtained in 66% yield (for both steps) as a yellow oil, which was a 37:63 syn:anti mixture of diastereomers. ^{1}H NMR (250 MHz, C_6D_6) δ: 3.58 (dt, 0.4H, J = 8.8, 3.4 Hz, C*H*OH (anti)), 3.15 (dt, 0.6H, J = 2.9, 8.3 Hz, C*H*OH (syn)), 2.3–2.1 (m, 1H, CHN), 2.12 (s, 1.2H, CH_3N (anti)), 2.11 (s, 1.8H, CH_3N (syn)), 1.8–1.1 (m, 8H, $CH_3(CH_2)_4CHOH$), 0.93 (m, 3H, $CH_3(CH_2)_4CHOH$), 0.85 (d, 1.2H, J = 6.5 Hz, CH_3CHN (anti)), 0.79 (d, 1.8H, CH_3CHN (syn)). ^{13}C NMR (63 MHz, C_6D_6) δ: 74.32 (syn), 71.32 (anti), 60.23 (syn), 59.40 (anti), 34.39 (syn), 33.64 (anti), 33.40, 32.50, 26.64 (anti), 25.91 (syn), 23.12, 15.45 (syn), 14.31, 13.14 (anti).

Experimental for the preparation of enantiomerically enriched β-aminoalcohols

(2*R*)-2-(*N-tert*-Butoxycarbonyl-*N*-methylamino)-3-methyl-1-phenyl-1-butanol ((***R***)-**2b**). This compound was prepared from (***S***)-**1b** and benzaldehyde according to *General procedure A* except that the reaction was run at –95 °C and was stirred for 10 min. Aminoalcohol (***R***)-**2b** was obtained in 71% yield as a mixture of diastereomers. HPLC (Chiralcel OD, 4.6 mm × 150 mm, 98:2 hex./*i*-PrOH, 0.25 mL/min) indicated that the product was 94% ee. Another sample of this compound was prepared that had an ee of 96%.

*(*R*)-2-(*N-tert-*Butoxycarbonyl-*N-*methylamino)-3-methyl-1-phenyl-1-butanone ((R)-3b)*

This compound was prepared according to *General procedure A* from (***R***)-**2b** (94% ee) in 95% yield. It exhibited spectral data as for racemic **3b** and optical rotation $[\alpha]_D$ = +254.9 (*c* 1.10, THF).

*(1*R*,2*R*)-2-(*N-tert-*Butoxycarbonyl-*N-*methylamino)-3-methyl-1-phenyl-1-butanol ((R)-4b)*

This compound was prepared from ketone (***R***)-**3b** (made from (***R***)-**2b** of 96% ee) according to *General procedure B* in 88% yield. It exhibited spectral data as described for compound **4b**. HPLC (Chiralcel OD, 4.6 mm × 150 mm, 98:2 hex./*i*-PrOH, 0.25 mL/min) indicated that it had an ee of 94%.

Pachymoside A — A novel glycolipid isolated from the marine sponge *Pachymatisma johnstonia*[1]

Kaoru Warabi, William T. Zimmerman, Jingkai Shen, Annick Gauthier, Marilyn Robertson, B. Brett Finlay, Rob van Soest, and Raymond J. Andersen

Abstract: Crude extracts of the North Sea marine sponge *Pachymatisma johnstonia* showed promising activity in a new assay for inhibitors of bacterial type III secretion. Bioassay-guided fractionation resulted in the isolation of the pachymosides, a new family of sponge glycolipids. A major part of the structural diversity in this family of glycolipids involves increasing degrees of acetylation and differing positions of acetylation on a common pachymoside glycolipid template. All of the metabolites with these variations in acetylation pattern were converted into the same peracetylpachymoside methyl ester (**2**) for purification and spectroscopic analysis. Pachymoside A (**1**) is the component of the mixture that has natural acetylation at the eight galactose hydroxyls and at the C-6 hydroxyls of glucose-B and glucose-D. Chemical degradation and transformation in conjunction with extensive analysis of 800 MHz NMR data was used to elucidate the structure of pachymoside A (**1**).

Key words: Pachymatisma johnstonia, marine sponge, pachymoside, glycolipid.

Résumé : Les produits bruts extraits de l'éponge marine de la mer du Nord *Pachymatisma Johnstonia* présentent une activité intéressante dans un nouvel essai pour les inhibiteurs de la sécrétion bactérienne de type III. Des fractionnements orientés par des bioessais ont permis d'isoler les pachymosides, une nouvelle famille de glycolipides des éponges. Une partie importante de la diversité structurelle de cette famille de glycolipides implique des degrés croissants d'acétylation et des différences dans les positions de l'acétylation sur un gabarit commun du glycolipide pachymoside. Tous les métabolites comportant ces variations dans le patron d'acétylation ont été transformés dans le même ester méthylique du peracétylpachymoside (**2**) aux fins de purification et d'analyse spectroscopique. Le pachymoside A (**1**) est le composant du mélange qui correspond à l'acétylation naturelle au niveau des huit hydroxyles du galactose et aux hydroxyles en C-6 du glucose-B et du glucose-D. Afin d'élucider la structure du pachymoside A (**1**), on a utilisé une dégradation et une transformation chimique de concert avec une analyse extensive des données RMN à 800 MHz.

Mots clés : Pachymatisma johnstonia, éponge marine, pachymoside, glycolipide.

[Traduit par la Rédaction]

Introduction

Several important gram-negative pathogenic bacteria deliver virulence factors directly into host cells via a "type III secretion system" (TTSS) (1–4). These include *Bordetella pertussis*, the cause of whooping cough, *Chlamydia trachomatis*, the cause of a sexually transmitted disease that leads to blindness, enterohemorrhagic *Escherichia coli* (EHEC), the cause of "hamburger" disease, and *Salmonella typhi*, the cause of typhoid fever. EHEC (5) and the closely related enteropathogenic *E. coli* (EPEC) (6), the major cause of infantile diaherria that kills several thousand children worldwide each year, have served as important models for studying TTSSs and their role in pathogenicity. While many bacterial pathogens attach themselves to host cell proteins, these pathogenic *E. coli* are remarkable because they use a TTSS to deliver their own receptors into the host cells to which they attach. The bacterial protein receptor delivered into the host cell by the *E. coli* TTSS is called Tir for "translocated intimin receptor". Once inside the host cell, Tir binds to an *E. coli* protein "intimin" on the surface of the bacterium to give intimate attachment, a required prelude to

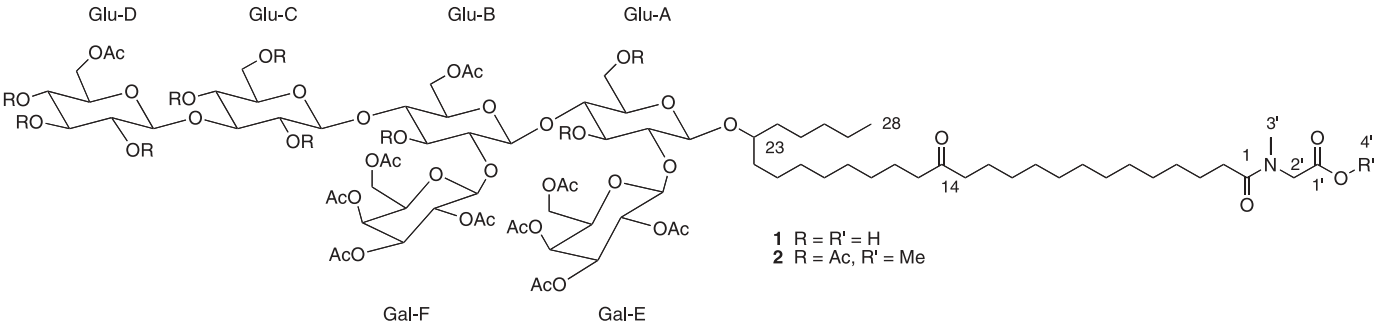
virulence. The TTSS, which forms a syringe-like pore that spans both bacterial and host cell membranes, consists of more than 20 proteins. Deleting or mutating any part of the TTSS significantly reduces the virulence of the affected *E. coli*. Non-pathogenic intestinal *E. coli* do not have TTSSs.

The TTSS is considered an attractive target for the development of new antibiotics that would selectively target pathogenic gram negative bacteria but would not harm the ordinary microflora that do not possess this virulence mechanism (1, 7–9). An added benefit of this type of hypothetical antibacterial agent is that by targeting a virulence mechanism, there would be little or no selective pressure for viability, potentially reducing the development of resistance. No TTSS inhibitors were known at the outset of our research. Consequently, there was a significant need to discover TTSS inhibitors that could be used to provide proof principle demonstrations and drug leads for this novel approach to treating important infectious diseases.

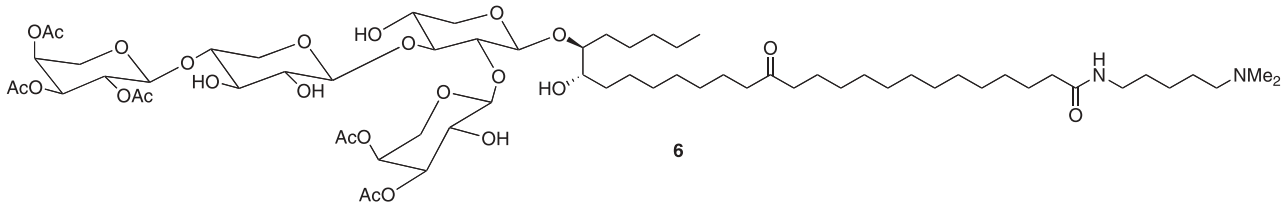
Marine sponges, which are the richest source of bioactive marine natural products (10, 11), are constantly exposed to bacteria in seawater and it has frequently been proposed that they contain chemical agents that have evolved to prevent pathogenic bacteria from infecting them (12, 13). We have screened a library of crude extracts from marine sponges for their ability to inhibit type III secretion of *E. coli* secreted proteins (Esps) by EPEC without affecting the growth or general secretion of the bacterium (1). Two extracts showed promising activity in the screen. Recently, we reported the structure of caminoside A, an antimicrobial glycolipid isolated from the Caribbean sponge *Caminus sphaeroconia* that was the first compound active in the TTSS inhibition screen (14, 15).[4] The second active extract came from the sponge *Pachymatisma johnstonia* (Bowerbank, 1842) collected along the coast of the Isle of Mann. Bioassay-guided fractionation of the *P. johnstonia* extract yielded a complex family of glycolipids that were active in the TTSS assay. The structure elucidation of pachymoside A (**1**), a novel glycolipid that is a representative member of this family, is described below.

Results and discussion

The TTSS inhibitory fraction obtained from an initial Sephadex LH20 chromatographic separation (eluent: MeOH) of the crude *P. johnstonia* extract gave spectroscopic data that was indicative of a complex mixture of closely related glycolipids. LR-FAB-MS analysis of the mixture revealed a series of clusters of molecular ions with centres at *m/z* 1918, 1932, 1944, 1961, 1973, 1988, 2003, 2015, and 2046. The ^{1}H and ^{13}C NMR spectra of the mixture showed evidence for the presence of a number of monosaccharide anomeric carbons, a large number of carbinol methines and methylenes, extensive acetylation, and a long aliphatic chain. All chromatographic attempts to resolve the complex mixture of natural products into individual components failed. To facilitate purification of the mixture, it was first methylated with (trimethylsilyl)diazomethane and then acetylated with Ac_2O–pyridine in the presence of DMAP. Reversed-phase HPLC separation of the mixture of derivatized natural products gave a pure peracetylpachymoside A methyl ester (**2**) as a colourless glass.



Peracetylpachymoside A methyl ester (**2**) gave a $[M + Na]^+$ ion at *m/z* 2333.9639 in the ESI-HR-MS consistent with a molecular formula of $C_{106}H_{159}NO_{54}$ (calcd. for $^{12}C_{105}{}^{13}CH_{159}NO_{54}Na$, 2333.9658), requiring 28 sites of unsaturation. The ^{13}C NMR spectrum of **2** (100 MHz) recorded in C_6D_6 showed the same general features of a glycolipid observed in the spectrum of the natural product mixture. Thus, it was possible to attribute clusters of peaks to ester or amide carbonyls (δ 168–170), monosaccharide anomeric carbons (δ 100–102), carbinol methines and methylenes (δ 67–81), methyl groups attached to O or N (δ 49–52), acetate methyl carbons (δ 29–31), and a significant saturated aliphatic fragment (δ 14–43). The ^{1}H NMR spectrum of **2** was very congested at 500 MHz so all of the ^{1}H 1D and 2D data used in the structure elucidation was recorded at 800 MHz in C_6D_6, which gave excellent dispersion.



The first step in the structure elucidation of **2** involved chemical degradation of the mixture of natural pachymosides to liberate the individual monosaccharides. Treatment of the pachymoside mixture with acetyl chloride in dry MeOH cleaved the glycosidic linkages and converted the individual monosaccharides into mixtures of α- and β-methylglycopyranosides. After removal of the reagents in vacuo, the resulting residue was acetylated with Ac_2O in pyridine and a catalytic amount of DMAP to give the peracetylated methylglycosides of the individual monosaccharides. Fractionation of the peracetylated methylglycosides via reversed-phase HPLC gave an inseparable mixture of methyl 2,3,4,6-tetra-*O*-acetyl-α-glucopyranoside (**3**) and methyl 2,3,4,6-tetra-*O*-acetyl-α-galactopyranoside (**4**) in a ratio of ≈2:1, respectively. The difference in intensities of the resonances for each of **3** and **4** made it possible to identify each of the component compounds by analysis of the 1D and 2D NMR data obtained for the mixture. To confirm the assigned structures of **3** and **4**, authentic samples of D-glucose and D-galactose were converted into their peractylated methyl α-glycopyranosides and the NMR chemical shifts of the authentic compounds were compared with the degradation products. Chiral GC analysis of the alditol acetates prepared from authentic L- and D-glucose and D-galactose and the alditol acetates prepared from the monosaccharides obtained by aqueous hydrolysis of the pachymoside mixture showed that the glucose and galactose residues in the pachymosides had the D configuration.

A very non-polar fraction, which contained a mixture of the aglycon portions of the pachymosides, was also obtained

[4] While the current study was underway, another group reported screening a chemical library for inhibition of YopE transcription with a luciferase reporter assay, yielding three compounds that inhibited the reporter signal expressed from the *yopE* promoter and effector protein secretion with little effect on bacterial growth (15). One compound appears to be affecting type III regulation, and this and one other compound are specific to the virulence-associated TTSS, and do not affect flagellum assembly and motility. Overall, these results are evidence in support of TTSS-specific inhibitors, although the bacterial target(s) and ability to inhibit TTSS in infected host cells awaits further study.

© 2003 NRC Canada

from the methanolysis reaction on the pachymoside mixture described above. HPLC fractionation of the mixture of aglycons yielded a number of closely related compounds. Methanolysis of pure peracetylpachymoside A methyl ester (**2**), followed by analysis of the non-polar product by HPLC, ^{1}H NMR, and EI-MS, revealed that the methyl ester **5** obtained from the large-scale methanolysis of the mixture of pachymosides corresponded to the aglycon fragment of **2**. The ester **5** gave a M^+ ion at *m/z* 539.4567 in the EI-HR-MS appropriate for a molecular formula of $C_{32}H_{61}NO_5$ (calcd. 539.4550), requiring three sites of unsaturation.

Three associated pairs of singlets were apparent in the ^{1}H NMR spectrum of **5**, each of which exhibited an intensity ratio of ca. 4:1. A singlet at δ 3.71 in the ^{1}H NMR spectrum (associated peak at δ 3.77), which showed a HMQC correlation to a carbon at δ 52.5 and a HMBC correlation to a carbon at δ 170.0, was assigned to a methyl ester. A second singlet at δ 3.05 (associated peak at δ 2.95), which showed an HMQC correlation to a carbon at δ 36.5 and HMBC correlations to carbons at δ 172.0 and 49.0, was assigned to a *N*-methyl amide. The third singlet at δ 4.11 (associated peak at δ 4.03), integrated for only two protons relative to the other singlets. It showed a HMQC correlation to a carbon at δ 49.0 and HMBC correlations to the ester carbonyl at δ 170.0, the amide carbonyl at δ 172.0, and the *N*-methyl carbon at δ 36.5, and was assigned to the α carbon of an *N*-acyl-*N*-methylglycine methyl ester fragment. As is typical for tertiary amides, slow rotation about the *N*-acyl-*N*-methylglycine amide bond is presumed to be responsible for the presence of associated pairs of peaks observed in the ^{1}H NMR spectrum for the *N*-methyl, methyl ester, and glycine α-methylene resonances.

Additional features in the ^{1}H NMR spectrum of **5** included a six proton multiplet at δ 2.36, a deshielded one proton multiplet at δ 3.55, and a three proton triplet at δ 0.87. The six proton multiplet (δ 2.36) showed HMQC correlations into carbon resonances at δ 38.1 and 42.8, and HMBC correlations into the amide carbonyl resonance at δ 172.0 and into a deshielded carbon resonance at δ 211.0, assigned to a saturated ketone. These correlations indicated that the six proton multiplet was comprised of three separate but coincidentally chemical shift-equivalent methylene resonances that were assigned to a methylene α to the amide carbonyl and two methylenes α to a saturated ketone. Consistent with these assignments, there was a small triplet at δ 2.20 in the ^{1}H NMR spectrum that was assigned to the methylene α to the amide carbonyl in the minor rotamer of **5**. The methine resonance at δ 3.55 showed a HMQC correlation to the carbon resonance at δ 72.5 consistent with the presence of a secondary alcohol in **5**, and the triplet at δ 0.87 was assigned to a methyl at the end of a linear aliphatic chain. Since the methyl ester, *N*-methylamide, and ketone carbonyls accounted for the three sites of unsaturation in **5**, and the only terminal residues identified in the NMR data were the methyl ester and aliphatic methyl groups, the aglycon had to have a 27-carbon linear chain extending from the *N*-acyl amide carbonyl to the terminal methyl group, and there had to be saturated ketone and secondary alcohol functionalities situated along the chain.

The positions of the ketone and secondary alcohol functionalities in **5** were determined by analysis of the EI-HR-MS data obtained for the compound as shown in Fig. 1. A major peak at *m/z* 145.0739 ($C_6H_{11}NO_3$) was attributed to a McLafferty rearrangement involving the C-4 amide carbonyl that results in cleavage of the C-5—C-6 bond, confirming the presence of the *N*-acyl-*N*-methylglycine methyl ester fragment at one terminus of the aglycon. A pair of peaks at *m/z* 284.2232 ($C_{16}H_{30}NO_3$) and 341.2557 ($C_{19}H_{35}NO_4$) were attributed to McLafferty rearrangements occurring on both sides of the ketone functionality, which located the ketone at C-14. Finally, a peak at *m/z* 468.3697 ($C_{27}H_{50}NO_5$) was assigned to an α cleavage adjacent to the secondary alcohol, which had to be at C-23. The base peak in the mass spectrum of **5** resulted from a cleavage of the amide bond to

give a fragment ion at *m/z* 104.0709 ($C_4H_{10}NO_2$), which had the molecular formula of protonated *N*-methylglycine methyl ester.

Subtracting the atoms present in the aglycon ($C_{32}H_{60}NO_5$) from the molecular formula of peracetylpachymoside A methyl ester (**2**) ($C_{106}H_{159}NO_{54}$) left $C_{74}H_{99}O_{49}$ and 25 sites of unsaturation unaccounted for. Preliminary analysis of the NMR data obtained for **2**, in conjunction with the degradation studies, indicated the remaining atoms had to be part of glucose, galactose, or acetate residues. Six anomeric carbons and their attached protons (δ ^{13}C: ^{1}H; 100.7:4.67; 101.4:4.21; 101.4:4.56; 101.4:4.78; 101.5:4.61; 102.1:4.31) could be readily identified in the HSQC spectrum of **2** (Fig. 2). Subtracting the 36 carbons of six hexose monosaccharides (glucose and galactose) from the 74 carbons remaining to be accounted for, left 38 carbons, which corresponded to 19 acetate residues. The six sites of unsaturation accounted for by the putative monosaccharide rings, along with the 19 sites of unsaturation associated with the acetate residues and the three sites of unsaturation in the aglycon, accounted for all of the unsaturation required by the molecular formula of **2**. Therefore, what remained was to determine the connectivity among the aglycon, the six monosaccharide residues, and the 19 acetates, as well as determining the relative stereochemistry of the polysaccharide portion of the molecule. These features of **2** were elucidated by detailed analysis of its 800 MHz NMR data (Figs. 3 and 4).

Starting with the six well-resolved anomeric proton resonances, it was possible by careful analysis of the COSY, 1D-TOCSY, 2D-TOCSY, HSQC, and HMBC data to assign resonances to all of the hydrogen and carbon atoms in each of the six monosaccharide residues as listed in Table 1. Degradation had shown that the pachymosides contained only D-glucose and D-galactose monomers. Analysis of the ^{1}H vicinal NMR coupling constants for each of the monosaccharide residues A to F confirmed that there were four glucose units (A–D) and two galactose units (F and E) in **2**. In addition, all six of the anomeric proton resonances appeared as doublets with coupling constants between 7.0 and 8.2 Hz, indi-

Fig. 3. Expansion of gHMBC of peracetylpachymoside A methyl ester (**2**), (natural abundance) acquired at 800 MHz in C_6D_6. Assignments for carbinol methine and methylene HMBC correlations to acetate carbonyls are indicated. No coupling for C-4 to its attached acetate carbonyl is observed for the unlabeled sample.

cating that all of the glycosidic linkages were β. Examination of the proton chemical shifts (Table 1) in each of the monosaccharide residues for acyl shifts predicted that glucose-A was acetylated at C-3 and C-6, glucose-B was acetylated at C-3 and C-6, glucose-C was acetylated at C-2, C-4, and C-6, glucose-D was acetylated at C-2, C-3, C-4, and C-6, galactose-E was acetylated at C-2, C-3, C-4, and C-6, and galactose-F was also acetylated at C-2, C-3, C-4, and C-6. This acetylation pattern, which was confirmed by HMBC correlations from the corresponding monosaccharide protons to the acetate carbonyls (Fig. 3), was consistent with the presence of 19 acetate residues in **2**. Finally, HMBC and ROESY correlations (Table 1 and Fig. 4) provided the information required to identify the linkages between the six monosaccharide residues A–F and the aglycon as shown in Fig. 4.

NMR analysis of the crude mixture of pachymosides showed that the natural products are partially acetylated. Information about the natural acetylation pattern was lost during the peracetylation step required for isolation of pure peracetylpachymoside A methyl ester (**2**). To locate the sites of introduced acetylation in **2**, a second portion of the crude pachymoside mixture was methylated with (trimethylsilyl)diazomethane and then acetylated with $(CH_3{}^{13}CO)_2O$, pyridine, and DMAP as before. The crude reaction mixture was fractionated to give peracetylpachymoside A methyl ester (**2**) labelled at the sites of synthetic acetylation with $CH_3{}^{13}CO$. The ESI-LR-MS of the unlabeled peracetylpachymoside A methyl ester (**2**) gave a $[M + Na]^+$ at *m*/*z* 2335, while the corresponding ESI-LR-MS of the ^{13}C-acetate labelled compound gave two $[M + Na]^+$ major peaks at *m*/*z* 2343/2344, indicating the addition of eight and nine ^{13}C-acetyl groups. An HMBC spectrum collected on the ^{13}C-labelled sample of **2** showed intense peaks for the monosaccharide proton to acetyl carbonyl correlations involving ^{13}C-labelled acetate residues and essentially no correlations for the natural abundance acetates (Fig. 5). Using this intensity difference as a marker of introduced acetate, it was possible to show that ^{13}C-acetate had been introduced at 10 sites in the molecule (A-3, A-6, B-3, B-6, C-2, C-6, D-2, D-3, D-4, D-6; see Fig. 5). Evidence for labelled acetate introduction at C-4 came from the observation of additional scalar coupling in the glucose-C H-4 resonance observed at 400 MHz, which was attributed to three bond ^{1}H/^{13}C coupling. The absence of a corresponding HMBC cross peak in the 800 MHz spectrum is an anomaly produced by the line broadening of the C residue H-4 resonance at high field (vide infra). There was no evidence for introduction of ^{13}C-labelled acetate at any of the hydroxyl positions of the galactose-E and galactose-F residues, indicating that they are fully acetylated in all of the natural pachymosides. Since there is evidence for introduction of labelled acetate at 11 hydroxyls in **2** and the MS data indicates that only eight or nine labelled acetates have been introduced in individual molecules, the natural pachymoside mixture must consist in part of a major group of compounds that have the same aglycon **5**, are peracetylated on the galactose residues E and F, and have either two or three acetates distributed among

the 11 hydroxyl functionalities of the four glucose residues A–D.

The mass of a pachymoside having the aglycon **5** and acetylation at 10 sites is 1918, a mass found in the FAB-MS of the crude mixture of natural pachymosides prior to derivatization. Adding an additional acetate to the sugar alcohols generates a natural pachymoside with a mass of 1960, which was also represented in the FAB-MS of the crude mixture. Therefore, it appears that a major part of the structural diversity in this family of glycolipids involves increasing degrees of acetylation and differing positions of acetylation on the pachymoside template. All of these variations in acetylation pattern would have been converted into the same peracetylpachymoside A methyl ester (**2**) upon derivatization for purification. We have arbitrarily chosen to define pachymoside A (**1**) as the component that has natural acetylation at the eight galactose hydroxyls and at B-6 and D-6, since the HMBC correlation intensities in the ^{13}C-labelled compound indicate that these latter two positions have the greatest degree of natural acetylation.

It was clear from the NMR data obtained for the mixture of natural pachymosides and the aglycons liberated by methanolysis that there are also natural variations in the aglycon. There was evidence for aliphatic methyl doublets in the ^{1}H NMR spectrum of both the mixture of aglycon methyl esters and the natural pachymoside mixture indicating the presence of internal methyl branches on the aglycon fatty acyl chain. The detailed structures of the various aglycons other than **5** have not been determined due to the difficulties of locating branching methyls in a long aliphatic chain.

During the course of analyzing the NMR data for peracetylpachymoside A methyl ester (**2**), an unexpected difference in the data obtained at 400, 500, and 800 MHz in

[5] Supplementary data may be purchased from the Directory of Unpublished Data, Document Delivery, CISTI, National Research Council Canada, Ottawa, ON K1A 0S2, Canada (http://www.nrc.ca/cisti/irm/unpub_e.shtml for information on ordering electronically).

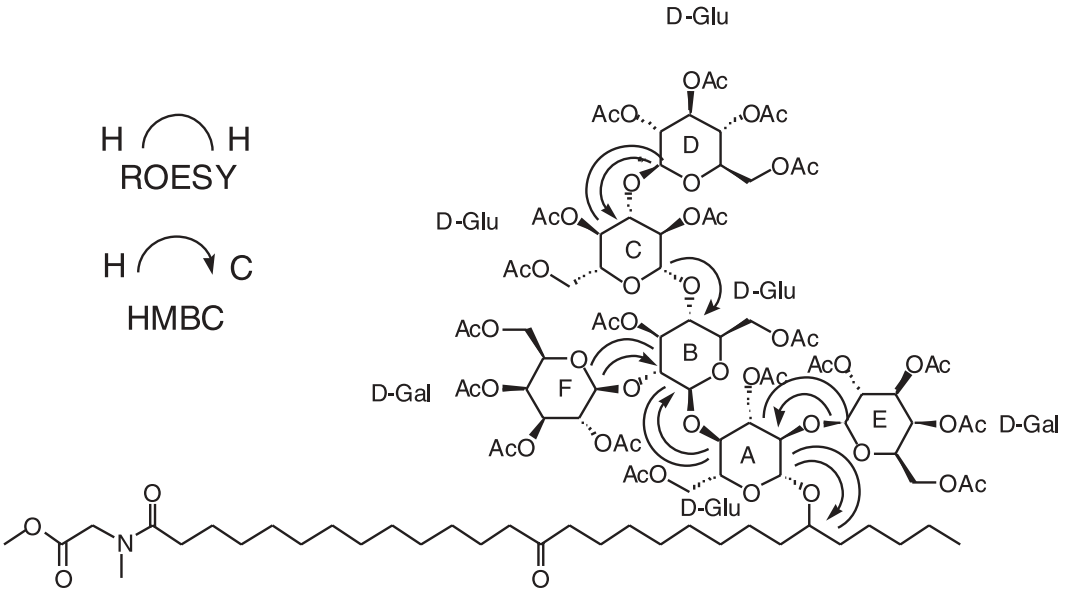
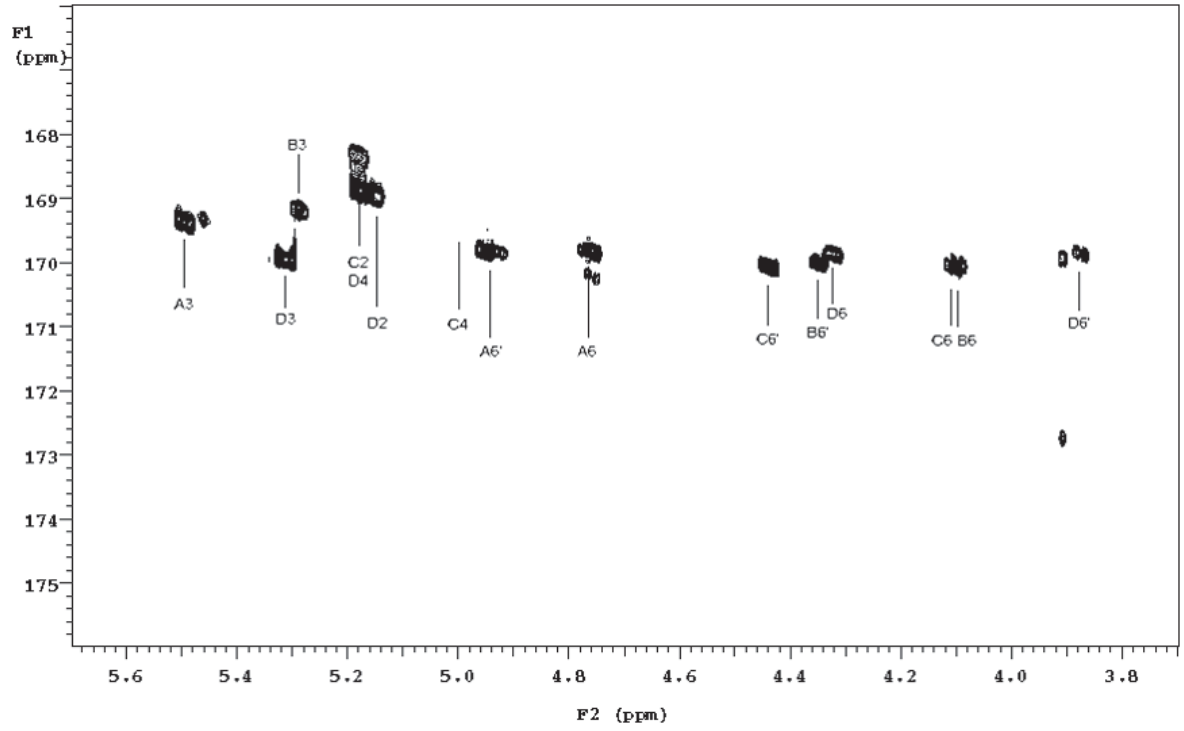
Fig. 4. A minimal set of unambiguous ROESY and HMBC correlations linking the substructures of **2**.





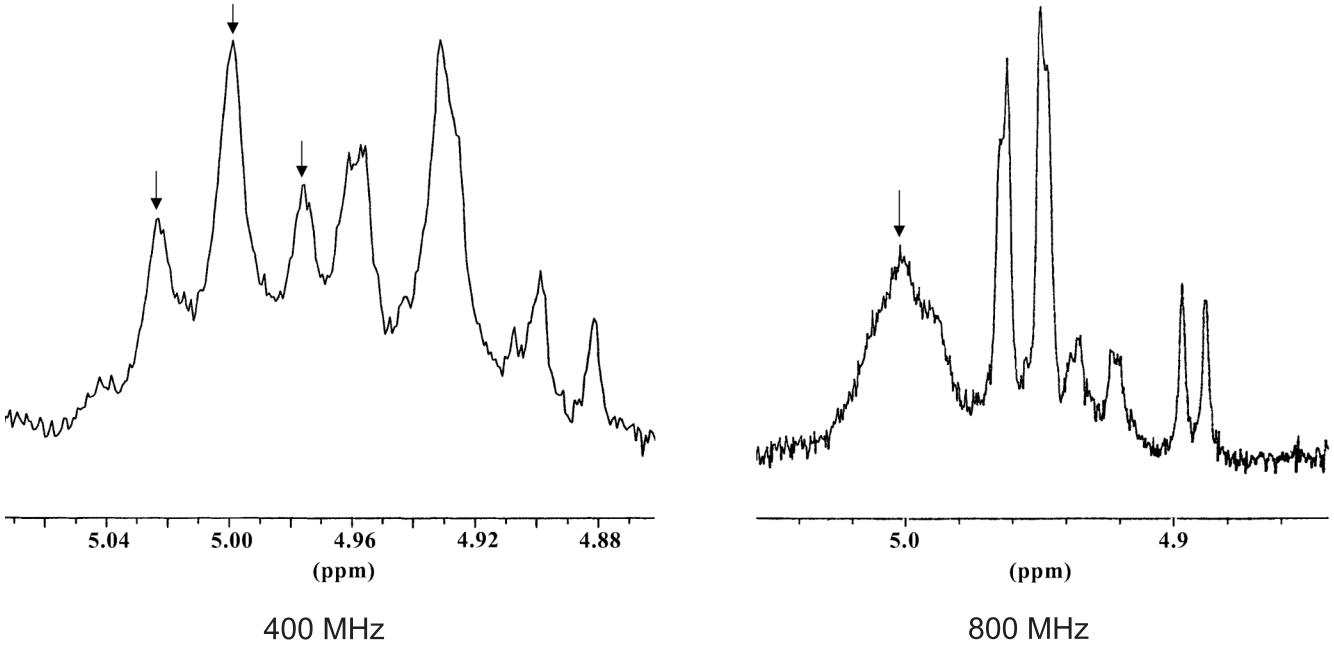


Fig. 5. Expansion of gHMBC spectrum of peracetylpachymoside A methyl ester (**2**) ($CH_3{}^{13}CO$-labeled) acquired at 800 MHz in C_6D_6. Assignments of methines and methylenes coupled to ^{13}C-labeled acetates are indicated. The methine at C-4 exhibits weak coupling at 500 MHz (2D data), while none is observed at 800 MHz. 1D proton data (400 MHz) for this methine exhibits additional splitting (unlabeled appears as triplet, ^{13}C-labeled appears as triplet of doublets). Cross peaks for the methylene to carbonyl coupling are of generally weaker intensity than the methines and vary in order of decreasing intensity as follows: C6 > A6 > B6 > D6.

C_6D_6 was encountered. As shown in Fig. 6, the resonance assigned to the glucose-C H-4 resonance appeared as a clear dd (J = 9.9, 9.6 Hz) at 400 and 500 MHz as expected, but appeared as a broad unresolved multiplet at 800 MHz. Normally the increased dispersion at 800 MHz simplifies multiplets by removing many second-order effects and signal overlap. Therefore, the deterioration of the multiplet structure on going from 400 to 800 MHz was contrary to our usual experience with 800 MHz data. One possible explanation for the observation is restricted conformational mobility at C-4 of glucose-C that is fast on the NMR timescale at 400 MHz leading to a single sharp resonance, but slow on

Fig. 6. NMR spectra (400 and 800 MHz) (C_6D_6) of the glucose-C residue H-4 resonance.

the NMR timescale at 800 MHz leading to a broadening of the resonance. Since the H-1, H-2, and H-6/H-6′ resonances in residue C are sharp at 800 MHz, the conformational equilibrium probably does not involve a change in the pyranose conformation. The existence of at least two conformers for rotation about the C-4 oxygen to acetate carbonyl bond that interconvert slowly on the 800 MHz NMR timescale, is a probable explanation for the observed field-dependent NMR behaviour of H-4 on glucose-C. We are not aware of any literature reports of similar observations of peak shape change as a function of increasing field strength.

Glycolipids are emerging as an important class of structurally diverse sponge metabolites that frequently have interesting biological activities (14, 16–21). The pachymosides represent a novel family of sponge glycolipids that have unprecedented glycon and aglycon fragments. The fatty acyl component of their aglycon has the same number of carbons and identical positioning of ketone and glycon attachments as the fatty acyl component of erylusamine E (**6**), one of a family of IL-6 receptor antagonists isolated from sponges in the genus *Erylus* (19, 20). However, the sugar residues in **1** (D-glucose and D-galactose) and **6** (D-arabinose and L-xylose) are different, the number and connectivity of the sugars are different, and the amino components of the aglycon amides are different. The pachymosides have an acidic aglycon while the erylusamines all have basic aglycons. One interesting structural feature of the pachymosides is the complete acetylation of the galactose residues and only partial acetylation of the glucose residues. Further investigation of the biological activity of the pachymosides revealed that although they showed promising activity in the TTSS inhibition assay, they are not true TTSS inhibitors. Rather, their observed activity appears to stem from their ability to effectively activate extracellular bacterial proteases that rapidly degrade the excreted Esps, resulting in a false indication of TTSS inhibition in the assay (1).

Experimental

General experimental procedures

^{1}H, COSY-gr, HMBC-gr (optimized for $^{2,3}J$ = 8 Hz), and HMQC-gr for (peracetyl pachymoside A methyl ester) were initially recorded on a Bruker AMX500 NMR spectrometer. These experiments plus 1D- and 2D-TOCSY, ROESY, HSQC, eCOSY, and *J*-resolved experiments were repeated on a Varian INOVA 800 MHz spectrometer at the NANUC facility at the University of Alberta. ^{13}C NMR data were recorded on a Bruker AM400 NMR spectrometer. Chemical shifts were referenced to solvent peaks (δ_H 7.15 ppm, δ_C 128.0 ppm for C_6D_6). Low-resolution electrospray (ES) mass spectra were recorded on a Bruker Esquire LC mass spectrometer, operated by direct infusion. High-resolution ES mass spectra were recorded on a Micromass LCT mass spectrometer. Both low- and high-resolution EI mass spectra were recorded on an AEI MS-50 mass spectrometer. Flash silica gel column chromatography was performed using 230–400 mesh silica gel 60 (Silicycle). Preparative HPLC separations were performed using a Waters 515 pump and a Waters 2487 dual tunable absorbance detector. Solvents were all HPLC grade (Fisher) and filtered prior to use. Thin layer chromatography (TLC) was performed with Merck silica gel 60 F_{254} aluminum sheets, and visualized with vanillin – sulfuric acid spray reagent. Pyridine, methanol, benzene, acetic anhydride, 4-(dimethylamino)pyridine (DMAP), and (trimethylsilyl)diazomethane (solution in hexanes) used in derivatization reactions were anhydrous and (or) reagent grade (Aldrich) and used without further purification. Acetic anhydride (1,1′-$^{13}C_2$, 99%) was purchased from Cambridge Isotope Laboratories, Inc.

Biological material and isolation of pachymosides

Specimens of *P. johnstonia* (650 g wet weight) were collected by hand using SCUBA from rocky subtidal marine

© 2003 NRC Canada

habitats along the coast of the Isle of Mann. A voucher sample (ZMA 17065) has been deposited at the Zoologisch Museum, University of Amsterdam. Freshly collected sponge material was frozen immediately and stored at –15 °C until workup. A portion of the frozen sponge (wet wt 111 g) was cut into pieces and extracted twice with MeOH over a six day period. The combined MeOH extracts were filtered and concentrated by rotary evaporation to an amber semisolid. This residue was partitioned between water (50 mL) and ethyl acetate (ea) (100 mL), and the aqueous layer extracted twice more with ethyl acetate (100 mL ea). The yellow-colored ethyl acetate solution was evaporated to dryness in vacuo to afford 1.60 g of a greenish amber amorphous solid. A portion of this material (0.16 g) was purified by Sephadex™ LH-20 size exclusion chromatography (28 mm ID × 100 cm bed length) eluting with 100% MeOH. Early eluting like fractions (as detected by TLC developed with 15% MeOH–CH_2Cl_2) were combined and concentrated in vacuo to give a mixture of pachymosides as a white amorphous solid (0.106 g). This material exhibited a distribution of molecular ion clusters centred at *m/z* 1973/1974 in the LR-FAB-MS.

Methanolysis of the pachymoside mixture

Pachymosides (60 mg) were dissolved in 10 mL of anhydrous methanol and 0.2 mL of CH_3COCl was slowly added. The reaction mixture was stirred at 70 °C with refluxing for 2 h. MeOH was removed from the reaction mixture in vacuo and the resulting residue was partitioned between H_2O and Et_2O. The aglycon methyl esters (25 mg) went into the organic phase and the methyl glycosides (30mg) went into the aqueous phase.

Acetylation of monosaccharide methylglycosides

The mixture of monosaccharide methyl glycosides (20 mg) obtained from methanolysis of the pachymosides was added to 9 mL of anhydrous pyridine, 3 mL of acetic anhydride, and ~1 mg of DMAP as catalyst. The reaction mixture was stirred overnight at room temperature. After removal of the pyridine and acetic anhydride under high vacuum, the crude product was partitioned between H_2O and Et_2O. The organic extract soluble materials were purified by isocratic normal phase HPLC (eluent: 31% EtOAc:69% hexanes) monitored with a RI detector to give one fraction containing peracetylated glucose/galactose α-methyl glycopyranosides and a second fraction containing peracetylated glucose/galactose β-methyl glycopyranosides.

Preparation of monosaccharide standards

Commercial D-glucose or D-galactose (20 mg, 0.11 mmol) were dissolved in 10 mL MeOH with 0.2 mL of CH_3COCl (2 mmol) and stirred with refluxing at 70 °C for 2 h. The solvent was then removed in vacuo to give a residue that was partitioned between H_2O and Et_2O. The aqueous fraction was dried and added to 9 mL (100 mmol) of anhydrous pyridine and 3 mL of acetic anhydride (30 mmol) with ~1 mg of DMAP as a catalyst. The acetylation mixture was stirred at room temperature overnight. After removal of the pyridine and acetic anhydride under high vacuum, the crude product was partitioned between H_2O and Et_2O and the organic extract was purified by normal-phase HPLC as described above to give pure samples of methyl 2,3,4,6-tetra-*O*-acetyl-α-D-glucopyranoside (**3**) and methyl 2,3,4,6-tetra-*O*-acetyl-α-D-galactopyranoside (**4**).

Chiral GC analysis of alditol acetates

The pachymoside mixture was hydrolyzed for 1 h at reflux in H_2O (20 mL) and 0.25 mL of 6 N HCl. The reaction was worked up by evaporating the H_2O to dryness under high vacuum and the residue was partitioned between H_2O and Et_2O. The water soluble materials were concentrated to dryness via lyophilization and reduced with $NaBH_4$ in MeOH at rt. After removing the MeOH in vacuo, the residue was treated with acetic anhydride and pyridine and a catalytic amount of DMAP to give a mixture of alditol acetates. Normal-phase flash chromatography separated the mixture into glucitol peracetate and galactitol peracetate. Commercial samples of D-glucose, L-glucose, and D-galactose were also converted to their alditol peracetates using the same reaction conditions. The alditol peracetates were analyzed by GC on a Chrial Select 1000 β-Dex-390 column using flame ionization detection. The GC analysis showed that the glucose and galactose obtained from hydrolysis of the pachymoside mixture both had the D configuration.

Aglycon (5)

The Et_2O soluble fraction (25mg) from methanolysis of the pachymoside mixture was loaded on a normal phase silica gel flash column and eluted with a gradient of hexanes–EtOAc (5% EtOAc:95% hexanes – 100%EtOAc). The fractions eluting with 20% EtOAc:80% hexanes contained one major component and one minor component by TLC analysis. The more polar major component was fractionated further by isocratic reversed-phase HPLC (eluent: 88% MeOH:12% H_2O (monitored at 206.0 nm)) to give pure methyl ester **5** (see *Results and discussion* for spectroscopic data).

Esterification of the pachymoside mixture

A 45 mg (ca. 0.024 mmol) sample of the pachymoside mixture was dissolved in a mixture of 0.5 mL each of MeOH and benzene and treated with 0.080 mL of (trimethylsilyl)diazomethane (2.0 mol L^{-1} solution in hexanes) and stirred at ambient temperature for 24 min. The reaction mixture was diluted with 5 mL EtOAc, evaporated to dryness (aspirator), then redissolved in EtOAc (6 mL), washed with sat. NaCl solution, dried (Na_2 SO_4) and again evaporated in vacuo to a film (38 mg). A short reaction time was found to be critical in this step. If left to react overnight, most of the acetate groups appeared to be lost, as determined by NMR. Mass spectroscopy (ES) on this sample again exhibited a distribution of molecular ion clusters centered at 2012 (Na^+ adducts) with a nearly identical pattern to that found for the underivatized material. This represents a shift in molecular weight of plus 14 amu, which is correct for the methyl ester derivative, and confirms that the acetate groups of the pachymosides remained fully intact in this step.

LR-ESI-MS data[a]: (Na^+ adducts) *1956* (55), 1969 (75), *1998* (70), 2012 (100), *2040* (65), 2053 (80); exchanged with CD_3OD: *1965* (50), 1979 (75), *2006* (55), 2018 (100), *2046* (50), 2060 (70). (Italic indicates homolog ions that

© 2003 NRC Canada

would afford pachymoside A peracetate upon full acetylation).

Acetylation of the pachymoside methyl ester mixture

The sample of mixed pachymoside methyl esters (38 mg) was dissolved in anhydrous pyridine (3.0 mL) under argon and treated with 1.3 mg DMAP, then with 1 g of acetic anhydride (or 1,1′-$^{13}C_2$ acetic anhydride) and stirred for 15 h at ambient temperature. After evaporation under high vacuum, the residue was taken up in EtOAc–hexanes (1:1) and subjected to flash column chromatography (12 × 210 mm) eluting with EtOAc–hexanes (4:1) to afford 35 mg of a white solid. TLC in this solvent system showed a spot at 0.18 R_f for the desired derivative. This was taken up in MeOH (2.0 mL) and fractionated by reverse-phase HPLC (Inertsil C_{18} 9.4 × 250 mm, eluting with H_2O–1-PrOH (7:4). UV detection at 202 and 280 nm, up to 3 mg per injection) to give pachymoside A methyl ester (**2**), peracetate (4.0 mg) (or its corresponding 1-^{13}C-acetylated analog).

Data for unlabeled analog

HR-ESI-MS: *m*/*z* 2333.9639 (calcd. for $^{12}C_{105}{}^{13}CH_{159}NO_{54}Na$ 2333.9658); ^{1}H and ^{13}C NMR (800 and 100 MHz, respectively) see Table 1.

LR-ESI-MS: Unlabeled acetate derivative: 2335 (100, Na^+), 1178 ($2Na^+$). ^{13}C-acetate derivative: 2343/2344 (100, Na^+), 1183 (10, $2Na^+$), indicating the presence of eight to nine ^{13}C-acetyl groups.

(Note: LR-ESI-MS data *m*/*z* absolute values estimated at ±1 amu at these values; relative values of the weighted cluster center are reported. Each molecular ion cluster generally shows three or more sequential peaks owing to naturally abundant ^{13}C).

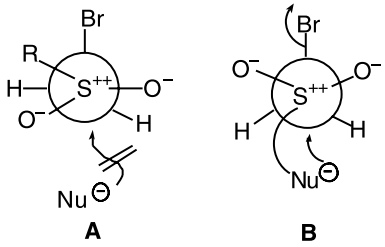
Generic synthesis of β-sultams via domino alkylation of bromomethanesulfonamides[1]

William R.S. Barton and Leo A. Paquette

Abstract: Reaction of *N*-substituted bromomethanesulfonamides with 2 equiv of potassium carbonate and an α-halo ketone, ester, or nitrile leads directly to 3-substituted β-sultams. The first step is intermolecular and is followed by an intramolecular alkylation. The process is particularly efficient when diethyl bromomalonate and 3-chloro-2-butanone are involved. In the latter example, no competitive cyclization to form a six-membered ring is seen. The functional groups in certain of the β-sultam products can be subsequently manipulated to give bicyclic products.

Key words: β-sultams, intramolecular S_N2 displacement, sulfonamides, ring closing metathesis, four-membered heterocycles.

Résumé : La réaction de bromométhanesulfonamides *N*-substitués avec deux équivalents de carbonate de potassium et des cétones, des esters ou des nitriles α-halogénés conduit directement à des β-sultames substitués en position 3. La première étape est intermoléculaire et elle est suivie par une alkylation intramoléculaire. La méthode est particulièrement efficace avec le bromomalonate de diéthyle et la 3-chlorobutan-2-one. Dans ce dernier cas, on n'a pas observé de cyclisation compétitive conduisant à la formation d'un cycle à six chaînons. Les groupes fonctionnels dans certains β-sultames formés comme produits peuvent être manipulés subséquemment pour conduire à des produits bicycliques.



Mots clés : β-sultames, déplacement S_N2 intramoléculaire, sulfonamides, métathèse avec fermeture de cycle, hétérocycles à quatre chaînons.

[Traduit par la Rédaction]

Introduction

As a result of their close structural similarity to β-lactams, β-sultams have been rather extensively investigated for their antibacterial properties. Despite the significantly heightened reactivity (ca. 10^3-fold) toward hydrolysis resident in these strained sulfur analogues (1), none have exhibited truly remarkable antibiotic features. However, other biological activities have surfaced. For example, the irreversible inhibition of human neutrophile elastase has recently been documented for a member of this class (2). In part, the quest for more structurally varied β-sultams has been limited by existing synthetic methodology (3). Since the hydrogen atoms at C-3 are not activated by any neighboring group, the direct introduction of substituents at this site has often proven troublesome.

Reported herein is a direct, flexible approach to C-3 functionalized β-sultams. This new methodology is based on the inertness of α-bromomethanesulfonamides to intermolecular S_N2 displacement and the contrasting ease of intramolecular ejection of bromide ion (4). The dramatically different transition-state characteristics for these allied reactions are depicted in **A** and **B**.

In the intermolecular process **A**, the field effect exerted by the two sulfonyl oxygens requires close approach of the nucleophile to at least one atom of high electron density, thus strongly decelerating backside attack (5). When intramolecularity is involved, as in **B**, geometric factors conspire to require orientation of the sulfonyl oxygens as remote as possible from the attacking nucleophile. As a consequence, cyclization reactions are facilitated, in line with a cooperative inductive effect (6).

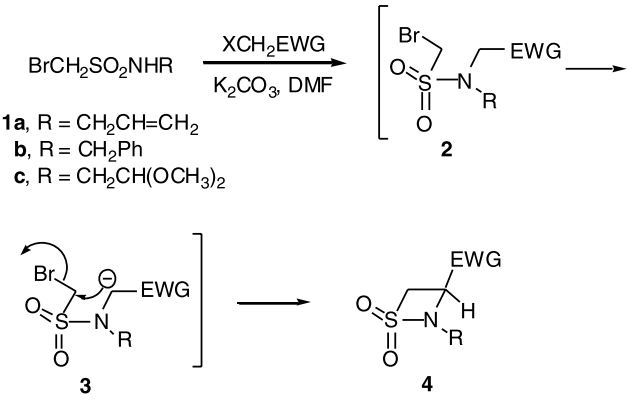
Results and discussion

The sulfonamides **1a**–**1c** were conveniently prepared by the reaction of readily available bromomethanesulfonyl chloride (7) with the relevant primary amine in CH_2Cl_2, containing both DMAP and Hünig's base, at –10 °C (8). Treatment of these sulfonamides with 2 equiv of potassium carbonate and an α-halo ketone, ester, or nitrile in DMF at various nonoptimized temperatures generated the β-sultams **4** (Scheme 1). The simple alkylation products **2** can be isolated in high yield if the reaction is performed instead at room temperature (rt) in the same solvent and quenched after approximately 3 h. Presumably, further deprotonation ensues upon continued reaction to give **3**, the nucleophilic site in which gives indication of being well disposed to cyclization.



The overall process is not limited to activated primary halides and proceeds with notably high efficiency when diethyl bromomalonate and 3-chloro-2-butanone are involved (Scheme 2). The latter example holds considerable mechanistic significance. In this case, the closure of **7** with elaboration of β-sultam **9** can a priori be viewed as competitive, with the formation and cyclization of enolate **8**. Were **8** to experience intramolecular displacement, the six-membered isomer **10** would result. While no information is available regarding the possible intervention of **8**, it is patently clear that no **10** is formed. This outcome is regarded to be a reflection of the fact that the relatively elongated C—S and N—S bonds of acyclic α-bromosulfonamides (9) are more ideally suited to the reaction trajectory defined by **7** than that prevailing in **8** (10). An impressively regioselective one-pot, two-step domino (11) alkylative sequence is the result.

The direct availability of the functionalized β-sultams **4** provides an unrivaled opportunity to synthesize bicyclic derivatives in a straightforward manner. Several preparative options that can deliver these targets are illustrated below. As shown in Scheme 3, the controlled addition of methylmagnesium bromide to ester **4f** gave rise to a chromatographically separable mixture of **4d** and **11**, thereby setting the stage for their independent conversion to diene **12** (Scheme 3). For this purpose, **4d** was subjected to a Wittig olefination with methylenetriphenylphosphorane, and **11** was dehydrated with phosphorus oxychloride in pyridine. Ring-closing metathesis (RCM) of **12** in the presence of tricyclohexylphosphine[1,3-bis(2,4,6-trimethylphenyl)-4,5-dihydroimidazole-2-ylidene][benzylidene]ruthenium(IV) dichloride (**14**) (12) was then exploited to generate **13** in near quantitative yield.

Compound **15** was produced by a related route that involved the condensation of **4f** with an equivalent of allylmagnesium bromide. The coupling step was followed by migration of the double bond into conjugation with the ketone carbonyl. In this way, the stage was set for application of RCM technology for the conversion of **15** to **16** (Scheme 4).

When esters **4f** and **4h** were subjected to the action of sodium borohydride in wet THF, alcohols **17a** and **17b** were obtained. As shown in Scheme 5, the first of these was conveniently transformed via mesylate **18** into primary iodide **19**. In the *N*-benzyl series, bromide **20** was prepared more directly by reaction of **17b** with triphenylphosphine

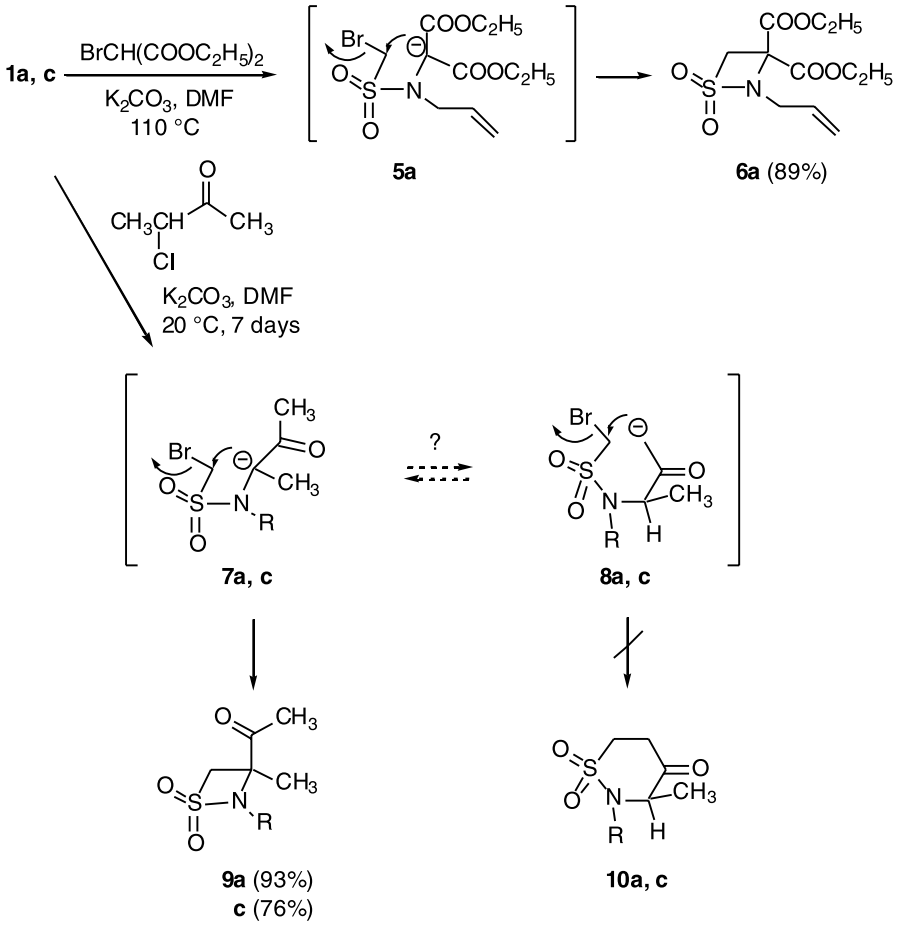
Scheme 1.

	R	X	EWG	Yield of 4, %
4d	$-CH_2CH=CH_2$	Cl	$-COCH_3$	59
4e	$-CH_2CH=CH_2$	Br	–COPh	81
4f	$-CH_2CH=CH_2$	Br	$-COOC_2H_5$	56
4g	$-CH_2CH=CH_2$	Br	–CN	61
4h	$-CH_2Ph$	Br	$-COOC_2H_5$	70

dibromide. When **19** was heated with tributyltin hydride in benzene, 5-exo cyclization (13) operated predominantly, to deliver bicyclic sultam **28** as a 3:1 mixture of diastereomers in nonoptimized 47% yield. In contrast, the primary radical did not enter into homolytic aromatic substitution (14). Instead, the kinetically preferred reaction involved fragmentation of the strained heterocyclic ring with formation of **22**.

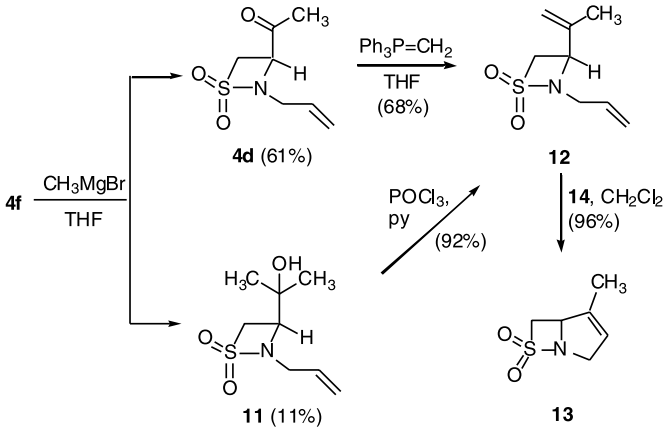
Conclusion

N-Substituted bromomethanesulfonamides are amenable to base-promoted condensation with α-halo ketones, esters, and nitriles under conditions where a second S_N2 displacement, now intramolecular, can operate in tandem fashion. This domino alkylation sequence exhibits a reactivity order where ketone > nitrile > ester. Evidence has been obtained that the formation of four-membered β-sultam products is kinetically favored over cyclization to give the six-membered analogs. Although β-lactams have previously been generated by the stepwise closure of α-haloacetamides (15), in only one report has azetidinone construction been described from cyclic precursors in a single operation (16). The protocol described herein is tailored to the ready introduction of useful functional groups at C-3, such that arrival at bicyclic β-sultams of varied type is conveniently feasible. In this connection, the preferred cyclization of **19** to **21** under free-radical conditions without competitive homolytic fragmentation is noteworthy.



Experimental

β-Sultam 4d



A solution of **1a** (100 mg, 0.467 mmol) in DMF (1.5 mL) was stirred with potassium carbonate (129 mg, 0.934 mmol) for 20 min, treated with a solution of chloroacetone (48 mg, 0.51 mmol) in DMF (1.5 mL), and allowed to react for 48 h.

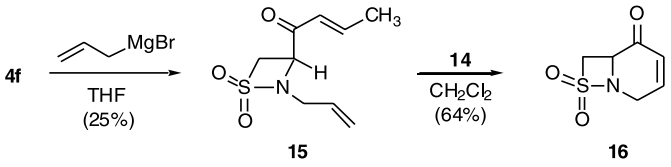
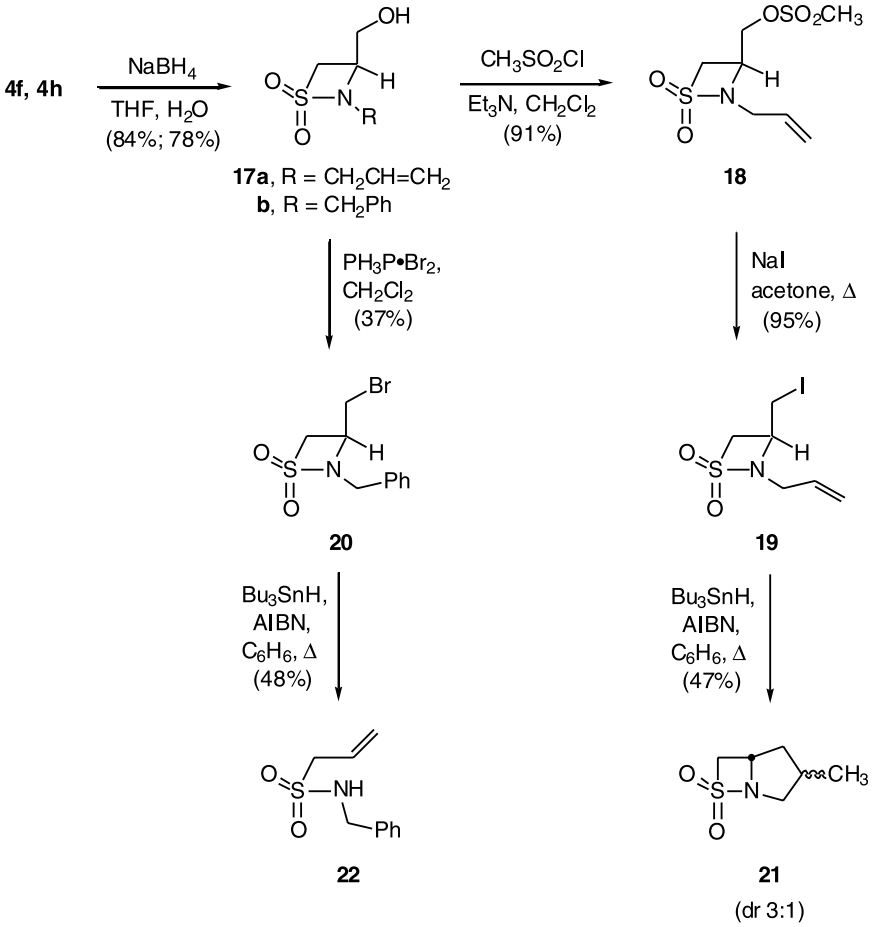


Scheme 2.

Scheme 3.

Scheme 4.



The reaction mixture was quenched with water and extracted with ethyl acetate (3×). The combined organic layers were washed with water and brine (2×), dried, and evaporated. The residue was chromatographed on silica gel (elution with hexanes – ethyl acetate 3:2) to give **4d** as a colorless oil (53 mg, 59%). ^{1}H NMR (300 MHz, $CDCl_3$) δ: 5.89–5.78 (m, 1 H), 5.40–5.25 (m, 2 H), 4.26 (dd, *J* = 8.8, 12.7 Hz, 1 H), 4.09 (dd, *J* = 6.4, 12.7 Hz, 1 H), 3.92–3.84 (m, 1 H), 3.69–3.57 (m, 2 H), 2.29 (s, 3 H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 203.3, 130.4, 121.0, 60.1, 52.1, 49.5, 25.5. ES-HR-MS (*m*/*z*) ([M+Na]$^+$) calcd: 212.0352; obsd: 212.0357.

β-Sultam 4e

Analogous reaction of **1a** (100 mg, 0.467 mmol) with potassium carbonate (130 mg, 0.934 mmol) and phenacyl bromide (93 mg, 0.467 mmol) in DMF (3 mL total) at rt for 6 days furnished 95 mg (81%) of **4e** as a colorless oil. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 7.93–7.88 (m, 2 H), 7.66–7.60 (m, 1 H), 7.53–7.47 (m, 2 H), 5.80 (m, 1 H), 5.34–5.26 (m, 1 H), 5.20–5.16 (m, 1 H), 4.68 (dd, *J* = 6.5, 8.3 Hz, 1 H), 4.40 (dd, *J* = 8.3, 12.2 Hz, 1 H), 4.19 (dd, *J* = 6.5, 12.2 Hz, 1 H), 3.88–3.81 (m, 1 H), 3.75–3.70 (m, 1 H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 192.5, 134.5, 134.2, 131.1, 129.2, 128.5, 120.6, 60.9, 48.9, 48.7. Scheme 5.

β-Sultam 4f

Compound **1a** (2.00 g, 9.34 mmol), ethyl bromoacetate (1.04 mL, 9.34 mmol), and potassium carbonate (2.84 g, 20.6 mmol) in DMF (80 mL) was stirred overnight at rt and heated to 105 °C for 3.5 h. Following the predescribed workup, there was isolated 1.14 g (56%) of **4f** as a colorless oil. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 5.95–5.82 (m, 1 H), 5.40–5.24 (m, 2 H), 4.33–4.18 (m, 4 H), 3.88–3.71 (m, 3 H), 1.30 (t, J = 7.1 Hz, 3 H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 168.0, 130.7, 120.5, 62.4, 60.5, 49.0, 46.5, 14.0. ES-HR-MS m/z ([M+Na]$^+$) calcd: 242.0457; obsd: 242.0458.

β-Sultam 4g

A mixture of **1a** (200 mg, 0.934 mmol), bromoacetonitrile (123 mg, 0.934 mmol), and potassium carbonate (260 mg, 1.87 mmol) was stirred at rt for 72 h and processed as detailed above. There was isolated 98 mg (61%) of **4g** as a colorless oil. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 5.88–5.80 (m, 1 H), 5.52–5.37 (m, 2 H), 4.46 (dd, J = 7.9, 12.7 Hz, 1 H), 4.37 (dd, J = 4.5, 12.7 Hz, 1 H), 4.18 (dd, J = 4.5, 7.9 Hz, 1 H), 3.94–3.79 (m, 2 H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 129.2, 122.0, 114.8, 62.1, 48.3, 35.7. ES-HR-MS m/z ([M+Na]$^+$) calcd: 195.0199; obsd: 195.0237.

β-Sultam 4h

Comparable reaction of **1b** (2.08 g, 7.87 mmol) with ethyl bromoacetate (0.87 mL, 7.87 mmol) and potassium carbonate (2.18 g, 15.7 mmol) in DMF (40 mL) for 18 h at rt and 4 h at 110 °C afforded 1.48 g (70%) of **4h** as a colorless oil. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 7.40–7.30 (m, 5 H), 4.46 (d, J = 14.2 Hz, 1 H), 4.35–4.18 (m, 3 H), 4.17–4.05 (m, 2 H), 3.78 (dd, J = 6.1, 8.1 Hz, 1 H), 1.19 (t, J = 7.1 Hz, 3 H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 167.9, 133.8, 129.0, 128.7, 128.2, 60.5, 49.9, 46.7, 13.9. ES-HR-MS m/z ([M+Na]$^+$) calcd: 292.0614; obsd: 292.0604.

β-Sultam 6a

A mixture of **1a** (500 mg, 234 mmol) and potassium carbonate (650 mg, 4.68 mmol) in DMF (2.5 mL) was treated with diethyl bromomalonate (0.38 mL, 2.34 mmol) and stirred overnight at rt and at 110 °C for 3 h. The reaction mixture was quenched with water and extracted with ethyl acetate (3×). The usual workup yielded 0.61 g (89%) of **6a** as a colorless oil. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 6.00–5.87 (m, 1 H), 5.43–5.21 (m, 2 H), 4.50 (s, 2 H), 4.32 (q, J = 7.1 Hz, 4 H), 3.99–3.96 (m, 2 H), 1.32 (t, J = 7.1 Hz, 6 H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 165.9, 131.7, 119.4, 64.7, 63.3, 57.7, 46.8, 14.0. ES-HR-MS m/z ([M+Na]$^+$) calcd: 314.0667; obsd: 314.0678.

β-Sultam 9a

Analogous reaction of **1a** (100 mg, 0.467 mmol) with 3-chloro-2-butanone (55 mg, 0.467 mmol) and potassium carbonate (129 mg, 0.93 mmol) in DMF (2.5 mL) at rt for 7 days provided 94 mg (93%) of **9a** as a colorless oil. ^{1}H

β-Sultam 9c

Bromomethanesulfonyl chloride (from 20.00 g (0.107 mmol) of sodium bromomethanesulfonate and 22.20 g (0.102 mmol) of phosphorus pentachloride) dissolved in CH_2Cl_2 (100 mL) was added to aminoacetaldehyde dimethyl acetal (12.29 mL, 0.112 mmol), DMAP (20 mg), and triethylamine (15.60 mL, 0.112 mmol) in CH_2Cl_2 (100 mL) at 0 °C over 30 min. Stirring was maintained at this cold temperature for 4 h, at which point the reaction mixture was allowed to warm to rt, stirred overnight, quenched with saturated $NaHSO_4$ solution, and extracted with CH_2Cl_2 (3×). The combined organic phases were washed with brine, dried, and evaporated to yield 12.97 g (50% over two steps) of **1c** as a colorless oil. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 5.05 (t, *J* = 6.0 Hz, 1 H), 4.47 (s, 2 H), 4.42 (t, *J* = 5.0 Hz, 1 H), 3.42 (s, 6 H), 3.31 (dd, *J* = 6.0, 5.0 Hz, 2 H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 102.9, 54.7, 45.3, 41.9. ES-HR-MS *m/z* ($[M+Na]^+$) calcd: 283.9563; obsd: 283.9548.

To a solution of **1c** (123 mg, 0.467 mmol) and 3-chloro-2-butanone (55 mg, 0.467 mmol) in DMF (25 mL) was added potassium carbonate (129 mg, 0.734 mmol). The mixture was stirred at rt for 6 days and processed as described above to give 89 mg (76%) of **9c** as a colorless oil. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 4.43 (dd, *J* = 4.1, 6.1 Hz, 1 H), 4.23 (d, *J* = 12.8 Hz, 1 H), 3.82 (d, *J* = 12.8 Hz, 1 H), 3.45–3.39 (m, 4 H), 3.35 (s, 3 H), 2.93 (dd, *J* = 6.1, 14.3 Hz, 1 H), 2.39 (s, 3 H), 1.57 (s, 3 H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 205.2, 107.8, 66.7, 57.2, 54.7, 54.6, 43.4, 23.5, 16.8.

Addition of methylmagnesium bromide to 4f

A solution of methylmagnesium bromide in THF (7.28 mL of 3.0 mol L^{-1}, 21.9 mmol) was added over a 20 min period to a solution of **4f** (1.20 g, 5.46 mmol) in the same solvent (100 mL) previously cooled to –78 °C. The mixture was stirred in the cold for 5 h, quenched with saturated NH_4Cl solution, warmed to rt, and extracted with CH_2Cl_2 (2×). The combined organic layers were washed with brine, dried, and evaporated. The residue was chromatographed on silica gel (elution with hexanes – ethyl acetate 3:2) and afforded 630 mg (61%) of **4d** (identical to the sample prepared above) and 126 mg (11%) of **11** as a colorless oil. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 5.98–5.87 (m, 1 H), 5.42–5.26 (m, 2 H), 4.15 (dd, *J* = 6.1, 12.4 Hz, 1 H), 4.02 (dd, *J* = 8.3, 12.4 Hz, 1 H), 3.92 (dd, *J* = 6.1, 15.5 Hz, 1 H), 3.66–3.58 (m, 1 H), 3.16 (dd, *J* = 6.1, 8.3 Hz, 1 H), 2.32–2.30 (m, 1 H), 1.26 (s, 3 H) 1.16 (s, 3 H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 132.0, 119.7, 70.3, 58.6, 54.6, 50.7, 27.4, 24.8. ES-HR-MS *m/z* ($[M+Na]^+$) calcd: 228.0665; obsd: 228.0667.

Dienyl sultam 12

Olefination of 4d

A solution of *n*-butyllithium in hexanes (0.94 mL of 1.6 mol L^{-1}, 1.50 mmol) was added dropwise to a stirred solution of methyltriphenylphosphonium bromide (536 mg, 1.5 mmol) in THF (10 mL) at 0 °C. After being stirred for 20 min in the cold, the reaction mixture was brought to –42 °C and a solution of **4d** (189 mg, 1.0 mmol) in THF (10 mL) was introduced over 20 min, prior to warming to rt 30 min later. After overnight stirring, saturated NH_4Cl solution was added, and the product was extracted into ether (3×). The combined organic phases were dried and evaporated to leave a residue that was purified by chromatography on silica gel. Elution with 5:1 hexanes – ethyl acetate gave 127 mg (68%) of **12** as a colorless oil. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 5.95–5.81 (m, 1 H), 5.43 (dd, *J* = 1.1, 17.1 Hz, 1 H), 5.23 (dd, *J* = 1.1, 10.2 Hz, 1 H), 5.16 (s, 1 H), 5.04 (d, *J* = 1.1 Hz, 1 H), 4.11 (dd, *J* = 7.9, 12.2 Hz, 1 H), 3.90 (dd, *J* = 6.5, 12.2 Hz, 1 H), 3.77–3.70 (m, 2 H), 3.52 (dd, *J* = 5.6, 14.8 Hz, 1 H), 1.81 (s, 3 H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 139.9, 131.3, 119.7, 116.1, 61.7, 52.0, 48.3, 30.3. ES-HR-MS *m/z* ($[M+Na]^+$) calcd: 210.0559; obsd: 210.0562.

Dehydration of 11

A solution of **11** (131 mg, 0.64 mmol) in pyridine (10 mL) was treated dropwise with phosphorus oxychloride (0.59 mL, 6.40 mmol) over 5 min. The reaction mixture was stirred overnight at rt, cooled in an ice bath, and cautiously quenched with warm water. After 30 min, the aqueous layer was extracted with ether (2×), and the combined organic layers were washed with 0.5 mol L^{-1} hydrochloric acid, followed by water; dried; and freed of solvent. There was isolated 110 mg (92%) of **12**, identical in all respects to the material generated in the above section (Olefination of 4d).

Ring closing metathesis of 12

β-Sultam **12** (118 mg, 0.63 mmol) dissolved in CH_2Cl_2 (10 mL) was added to a deoxygenated solution of **14** (27 mg, 0.032 mmol) in the same solvent (40 mL). The reaction mixture was heated to a gentle reflux, periodically evacuated to remove ethylene, cooled to rt, and evaporated to dryness. Chromatography of the residue on silica gel provided 96 mg (96%) of **13** as a white solid, mp 85–86 °C. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 5.61 (m, 1 H), 4.49–4.41 (m, 2 H), 4.38–4.36 (m, 1 H), 4.09 (ddd, *J* = 0.7, 3.7, 12.4 Hz, 1 H), 3.76–3.71 (m, 1 H), 1.79–1.77 (m, 3 H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 135.8, 125.7, 65.0, 55.7, 54.3, 12.0. ES-HR-MS *m/z* ($[M+Na]^+$) calcd: 182.0246; obsd: 182.0253.

Addition of allylmagnesium bromide to 4f

Allylmagnesium bromide (273 mL of 1.0 mol L^{-1} in THF) was added over 10 min to **4f** (0.20 g, 0.91 mmol) in THF (20 mL) at –78 °C. The reaction mixture was stirred in the cold for 3.5 h, quenched carefully with concentrated NH_4Cl solution at –78 °C, warmed to rt, stirred for 3.5 h, and extracted with ethyl acetate (3×). The customary workup (elution with 3:1 hexane – ethyl acetate) gave 48 mg (25%) of **15**. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 7.17–7.07 (m, 1 H), 6.63–6.56 (m, 1 H), 5.88–5.77 (m, 1 H), 5.39–5.24 (m, 2 H), 4.25 (dd, *J* = 8.6, 12.5 Hz, 1 H), 4.08 (dd, *J* = 6.5, 12.5 Hz, 1 H), 3.90–3.80 (m, 2 H), 3.67–3.60 (m, 1 H), 1.98 (dd, *J* = 1.7, 7.0 Hz, 3 H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 193.1, 148.0, 130.4, 125.3, 121.1, 60.6, 51.1, 49.4, 18.8. ES-HR-MS *m/z* ($[M+Na]^+$) calcd: 238.0508; obsd: 238.0507.

Ring closing metathesis of 15

To a solution of **15** (43 mg, 0.20 mmol) dissolved in CH_2Cl_2 (60 mL) was added a deoxygenated solution of **14** (8.5 mg, 0.001 mmol) in the same solvent (2 mL); this was gently refluxed during 2.5 h, with periodic evacuation of the vessel to remove ethylene, and evaporated to dryness. Chromatographic purification of the residue on silica gel furnished 22 mg (64%) of **16** as a colorless oil. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 6.99 (ddd, *J* = 2.3, 4.0, 10.8 Hz, 1 H), 6.25 (ddd, *J* = 2.3, 2.4, 10.8 Hz, 1 H), 4.61 (dd, *J* = 8.3, 12.8 Hz, 1 H), 4.33 (dd, *J* = 2.8, 12.8 Hz, 1 H), 4.26–4.16 (m, 2 H), 3.93–3.84 (m, 1 H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 190.8, 146.4, 127.0, 64.6, 45.9, 38.8. ES-HR-MS *m/z* ($[M+Na]^+$) calcd: 196.0039; obsd: 196.0039.

Hydride reduction of 4f

β-Sultam **4f** (0.60 g, 2.73 mmol) dissolved in THF (5 mL) was introduced into a cold (0 °C), vigorously stirred suspension of sodium borohydride (0.52 g, 13.7 mmol) in THF (25 mL), followed by the slow addition of water (10 mL), also at 0 °C. The reaction mixture was stirred at rt for 10 min, treated successively with ethyl acetate and 1.0 mol L^{-1} hydrochloric acid (20 mL), and agitated for a further 20 min. The separated aqueous layer was extracted with ethyl acetate, and the combined organic layers were washed with saturated $NaHCO_3$ solution and brine, dried, and evaporated to give 405 mg (84%) of **17a** as a colorless oil. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 5.96–5.83 (m, 1 H), 5.42–5.35 (m, 1 H), 5.27 (dd, *J* = 1.1, 10.0 Hz, 1H), 4.16 (dd, *J* = 6.3, 12.4 Hz, 1 H), 4.06 (dd, *J* = 7.8, 12.4 Hz, 1 H), 3.90–3.77 (m, 2 H), 3.65 (dd, *J* = 3.1, 12.1 Hz, 1 H), 3.56 (dd, *J* = 6.4, 14.6 Hz, 1 H), 3.42–3.37 (m, 1 H), 2.42 (s, 1 H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 131.7, 120.0, 61.4, 58.9, 48.9, 48.4. ES-HR-MS *m/z* ($[M+Na]^+$) calcd: 200.0358; obsd: 200.0353.

Hydride reduction of 4h

A 0.50 g (1.86 mmol) sample of **4h** was reduced with sodium borohydride (0.70 g, 18.6 mmol) in the predescribed manner. After chromatography, there was isolated 335 mg (78%) of **17b** as a colorless oil. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 7.40–7.30 (m, 5 H), 4.49 (d, *J* = 13.2 Hz, 1 H), 4.18–4.01 (m, 3 H), 3.49–3.36 (m, 3 H), 2.05 (dd, *J* = 4.2, 8.0 Hz, 1 H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 134.8, 129.0, 128.7, 128.4, 61.3, 59.0, 50.1, 49.0. ES-HR-MS *m/z* ($[M+Na]^+$) calcd: 250.0508; obsd: 250.0500.

Mesylation of 17a

Samples of **17a** (0.38 g, 2.14 mmol) and Et_3N (0.75 mL, 5.35 mmol) were dissolved in CH_2Cl_2 (40 mL) and treated dropwise with a solution of methanesulfonyl chloride (0.20 mL, 2.57 mmol) in CH_2Cl_2 (5 mL). The reaction mixture was stirred for 3 h, quenched with water, and extracted with CH_2Cl_2 (2×). The combined organic layers were washed with brine, dried, and freed of solvent to provide 0.50 g (91%) of **18** as a colorless oil. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 5.93–5.82 (m, 1 H), 5.43–5.37 (m, 1 H), 5.32–5.27 (m, 1 H), 4.40 (dd, *J* = 4.7, 11.3 Hz, 1 H), 4.30 (dd, *J* = 4.5, 11.3 Hz, 1 H), 4.20 (dd, *J* = 8.1, 12.7 Hz, 1 H), 4.04 (m, *J* = 5.9, 12.7 Hz, 1 H), 3.90–3.83 (m, 1 H), 3.66–3.54 (m, 2 H), 3.11 (s, 3 H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 131.2, 120.6, 67.9, 60.1, 49.0, 45.6, 35.0. ES-HR-MS *m/z* ($[M+Na]^+$) calcd: 278.0127; obsd: 278.0125.

Formation of iodide 19

A solution of **18** (200 mg, 0.78 mmol) in acetone (15 mL) was treated with sodium iodide (1.17 g, 780 mmol), heated to reflux for 24 h in the absence of light, cooled to rt, and evaporated to dryness. The residue was slurried with ether (3×) and filtered. The dark oily residue resulting from evaporation of the ether was chromatographed on silica gel. Elution with 10:1 to 6:1 hexane – ethyl acetate afforded **19** (212 mg, 95%) as a colorless oil. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 5.93–5.82 (m, 1 H), 5.44–5.37 (m, 1 H), 5.30–5.27 (m, 1 H, 4.21 (dd, *J* = 12.7, 7.5 Hz, 1 H), 3.91–3.83 (m, 2 H), 3.61 (dd, *J* = 14.6, 6.4 Hz, 1 H), 3.45–3.39 (m, 2 H), 3.23–3.17 (m, 1 H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 131.4, 120.4, 64.5, 48.6, 48.5, 5.5. ES-HR-MS *m/z* ($[M+Na]^+$) calcd: 309.9369; obsd: 309.9374.

Generation of bromide 20

Alcohol **17b** (1.29 g, 5.58 mmol) in CH_2Cl_2 (10 mL) was added dropwise to a stirred suspension of triphenylphosphine dibromide (2.59 g, 6.14 mmol) in CH_2Cl_2 (15 mL) at 0 °C. The mixture was stirred for 30 min, warmed to rt, stirred for 3 h, quenched with saturated $NaHCO_3$ solution, and extracted with CH_2Cl_2 (2×). The combined organic phases were dried and evaporated. The resulting residue was purified by chromatography on silica gel to give 605 mg (37%) of **20** as a colorless oil. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 7.40–7.32 (m, 5 H), 4.45 (d, *J* = 14.1 Hz, 1 H), 4.21 (dd, *J* = 17.7, 7.8 Hz, 1 H), 4.11 (d, *J* = 14.1 Hz, 1 H), 3.96 (dd, *J* = 12.7, 5.7 Hz, 1 H), 3.56–3.49 (m, 1 H), 3.23–3.15 (m, 2 H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 134.3, 129.0 (2 C), 128.8 (2 C), 128.5, 63.0, 49.9, 48.1, 32.7. ES-HR-MS *m/z* ($[M+Na]^+$) calcd: 311.9664; obsd: 311.9677.

Radical cyclization of 19

A solution of tributylstannane (0.16 mL, 0.60 mmol) and AIBN (17 mg, 0.10 mmol) in benzene (10 mL) was added to a solution of **19** (144 mg, 0.503 mmol) in benzene (50 mL) at the reflux temperature over a period of 12 h. The cooled reaction mixture was evaporated to dryess and the residue was chromatographed on silica gel to give **21** as a colorless oily 3:1 mixture of diastereomers. ^{1}H NMR (300 MHz, C_6D_6) δ: 3.65 (dd, *J* = 12.7, 7.0 Hz, 1 H), 3.56 (dd, *J* = 12.8, 7.0 Hz, 1 H), 3.23–3.15 (m, 1 H), 3.10 (dd, *J* = 12.7, 4.9 Hz, 1 H), 3.00–2.96 (m, 1 H), 2.77 (dd, *J* = 10.2, 7.5 Hz, 1 H), 2.25–2.08 (m, 2 H), 1.77–1.71 (m, 1 H), 1.42–1.23 (m, 2 H), 1.17–1.07 (m, 1 H), 1.00–0.82 (m, 4 H), 0.71 (d, *J* = 6.5 Hz, 3 H), 0.55 (d, *J* = 6.4 Hz, 3 H). ^{13}C NMR (75 MHz, C_6D_6) δ: (major isomer) 66.0, 55.0, 46.5, 38.6, 34.0, 16.4. ES-HR-MS *m/z* ($[M+Na]^+$) calcd: 184.0403; obsd: 184.0411.

Radical fragmentation of 20

A solution of tributylstannane (123 mg, 0.424 mmol) and AIBN (67 mg, 0.41 mmol) in benzene (2.5 mL) was added to a solution of **20** (107 mg, 0.369 mmol) in benzene (20 mL) at the reflux temperature over a period of 9 h. Workup in the predescribed manner afforded 37 mg (48%) of **22** as a colorless oil contaminated with a very minor

© 2003 NRC Canada

amount of the uncleaved reduction product. ^{1}H NMR (300 MHz, C_6D_6) δ: 7.40–7.23 (m, 5 H), 5.90–5.76 (m, 1 H), 5.38–5.35 (m, 1 H), 5.28–5.21 (m, 1 H), 5.00–4.96 (m, 1 H), 4.27 (d, J = 6.2 Hz, 2 H), 3.64 (dd, J = 8.1, 0.8 Hz, 2 H). ^{13}C NMR (75 MHz, C_6D_6) δ: 137.7, 128.6, 128.1 (2 C), 128.0 (2 C), 126.4, 122.8, 57.2, 47.1. Diastereoselectivity in asymmetric allylations: The role of vicinal chirality in the allyl nucleophile for S_E2' reactions with aldehydes[1]

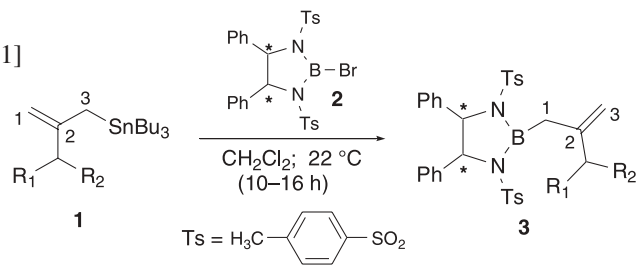
David R. Williams, Kevin G. Meyer, Khalida Shamim, and Samarjit Patnaik

Abstract: A series of nonracemic homoallylic alcohols have been prepared by asymmetric allylation using the (*R*,*R*)- and (*S*,*S*)-1,2-diamino-1,2-diphenylethane bis-sulfonamide controller ligands for in situ formation of chiral B-allyl-1,3,2-diazaborolidines. Diastereofacial selectivity is influenced by adjacent stereochemistry incorporated into the allyl moiety at C-2, in addition to the expected role of the chiral auxiliary. Additional asymmetry in the aldehyde reactant introduces threefold stereodifferentiation. A model is developed to identify reinforcing stereochemical relationships, and examples have ascertained the relative significance of these factors. The methodology supports the construction of complex homoallylic alcohols in a highly convergent fashion.

Key words: asymmetric allylation, diastereofacial selectivity, 1,4-stereocontrol, homoallylic alcohols.

Résumé : On a préparé une série d'alcools homoallyliques non racémiques en procédant à l'allylation asymétrique à l'aide des ligands de contrôle (*R*,*R*)- et (*S*,*S*)-1,2-diamino-1,2-diphényléthane bis-sulfonamide pour la formation in situ de B-allyl-1,3,2-diazaborolidines chirales. La sélectivité diastéréofaciale est influencée par la stéréochimie adjacente qui est incorporée dans la portion allyle au niveau C-2, en plus du rôle attendu de l'auxiliaire chiral. Une asymétrie additionnelle dans l'aldéhyde utilisé comme réactif introduit une triple stéréodifférenciation. On a développé un modèle pour identifier les relations stéréochimiques qui se renforcent et divers exemples ont permis de confirmer la signification relative de ces facteurs. La méthodologie se prête à la construction d'alcools homoallyliques complexes d'une façon extrêmement convergente.

Mots clés : allylation asymétrique, sélectivité diastéréofaciale, stéréocontrôle 1,4, alcools homoallyliques.



[Traduit par la Rédaction]

Introduction

Asymmetric allylation processes are generally recognized as important tools for stereocontrolled synthesis (1). Impressive levels of stereoselectivity have been achieved for the reactions of allyl and crotyl nucleophiles with aldehydes, leading to the formation of nonracemic homoallylic alcohols (2). Iterations of this scheme are propagated by oxidative cleavage of the terminal olefin and the generation of an aldehyde for sequentially increasing complexity. As often utilized in combination with aldol reactions, asymmetric allylation has provided, in large measure, a significant advance for syntheses of natural products of polyacetate and polypropionate origin (3).

In 1989, Corey and co-workers (4, 5) reported (*R*,*R*)- and (*S*,*S*)-1,2-diamino-1,2-diphenylethane *N*,*N*-sulfonamides as effective chiral auxiliaries to enable enantioselective Diels–Alder, aldol, and allylation reactions. We recognized that the mild conditions needed for transmetalation (eq. [1]) of allylstannanes **1** to nonracemic B-allyl-1,3,2-diazaborolidines **3** with bromoborane **2** would support molecular complexity and functionalization in the allyl segment with substitution at C-2. Thus, asymmetric allylation could prove widely useful for strategic bond formation in a convergent synthesis approach. Recent successes along these lines in our programs, towards hennoxazole A (6), amphidinolide K (7), and phorboxazole A (8), have been encouraging. This study will examine, in detail, the role of vicinal chirality in the allyl component as a result of substitution at the adjacent methylene ($R_1 \neq R_2$ in **1**) of the nascent nucleophile. We will explore the impact of this additional element of asymmetry for stereochemically reinforcing and nonreinforcing relationships with the auxiliary of **3** in the production of diastereomeric alcohols.

Results and discussion

Our preliminary studies (9) have shown that a range of functionality is tolerated under the ambient conditions of transmetalation of **1** to borane **2**. Examples of compatible functional groups include isolated alkenes, dithioacetals, *para*-methoxybenzyl, and benzyl ethers, esters, vinylstannanes, and most silyl ethers. The presence of Lewis-acid-sensitive protecting groups, such as methoxymethyl (MOM), β-methoxyethoxymethyl (MEM), and tetrahydropyranyl (THP) ethers, as well as other ketals and acetals, are incompatible with bromoborane **2**. Additionally, most allylsilanes do not undergo a productive transmetalation with bromoborane **2**. Upon the in situ formation of allylborane **3** at room temperature, reactions are cooled to –78 °C for the introduction of stoichiometric aldehyde, leading to complete condensations within 2 to 3 h. A variety of functionality may also be incorporated in the aldehyde component. As demonstrated by the reactions of enantiomeric stannanes **4** and **5**, the introduction of a stereogenic center that is separated by at least one methylene unit from the reactive allyl moiety plays little or no role in determining the diastereoselectivity of the condensation. The chiral auxiliary is the major factor to consider in the production of the new chiral alcohols **7** and **8**.

In previous studies by Nishigaichi et al. (10), moderate stereocontrol in the addition of racemic allylstannanes **9ab** to simple aldehydes was observed. Thus, the placement of methoxy or acetoxy substituents directly adjacent to the reactive allyl component resulted in a diastereofacial preference, which was strongly influenced by the choice of Lewis acid. Related chromium- and indium-mediated allylations (11) have produced 1,4-syn-diol derivatives with diastereomeric excesses of 60–90%.

[3]

9a R = CH_3
9b R = Ac

10 [1, 4-*syn*] **11** [1, 4-*anti*]

With these observations in mind, we have examined the role of adjacent stereogenicity as a control factor for our asymmetric allylations (eq. [1]; $R_1 \neq R_2$). Two general pathways were deployed for the preparation of starting stannanes bearing a chiral carbon at the C-2 allylic position by the introduction of a methyl or hydroxyl substituent.

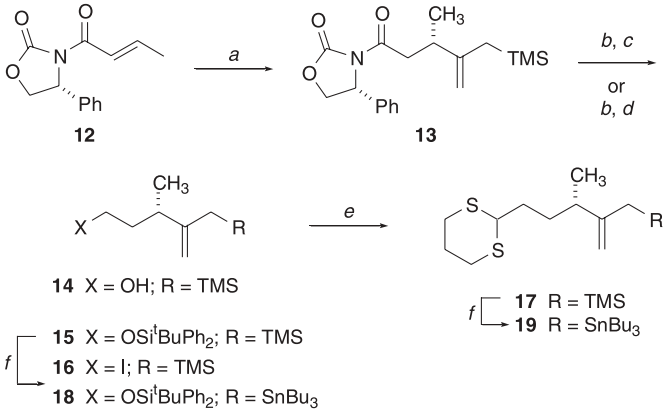
In the former case, we have utilized our asymmetric conjugate addition methodology (12) for reactions of the alkenylcopper species derived from the Grignard reagent of 2-bromo-3-trimethylsilyl-1-propene (13) with *N*-enoyl-4-phenyl-1,3-oxazolidinone **12**. The imide **13** (diastereomeric ratio (dr) 25:1) was purified by flash chromatography and reduced to yield alcohol **14**, which was subsequently O-protected as the corresponding *tert*-butyldiphenylsilyl ether **15**. Additional complexity was introduced by direct conversion of **14** to the primary iodide **16** for alkylation with 2-lithio-1,3-dithiane, providing the allylsilane **17**. The allylic silanes **15** and **17** were transformed into the desired stannanes **18** and **19** via quantitative, low-temperature reactions to yield the intermediate bromides (R = Br) with subsequent displacement with tri-*n*-butylstannylcopper dimethylsulfide complex (14). In analogous fashion, we also prepared *ent*-**18**.[3] While other routes have been devised and reduced to practice, Scheme 1 offers simplicity and generality.[4]

For the preparation of stannanes bearing an allylic hydroxyl substituent, the aliphatic aldehydes **20** (R = H and R = $CH_2CH{=}CHCH_3$) were converted into the chiral epoxy-alcohols **21** via Wittig olefination, reduction, and Sharpless asymmetric epoxidation (15), as illustrated in Scheme 2.

Mesylation and immediate reduction of crude epoxy sulfonate with zinc dust in the presence of sodium iodide (16) gave optically active **22** in excellent yield. The secondary alcohol in **22** was then used to direct allylic lithiation (17) for C-alkylation with tri-*n*-butylstannyl iodide. Acylation with benzoic anhydride led to pure **23a** (R = H) or **23b** (R = $CH_2CH{=}CH{-}CH_3$) for our allylation experiments.[5]

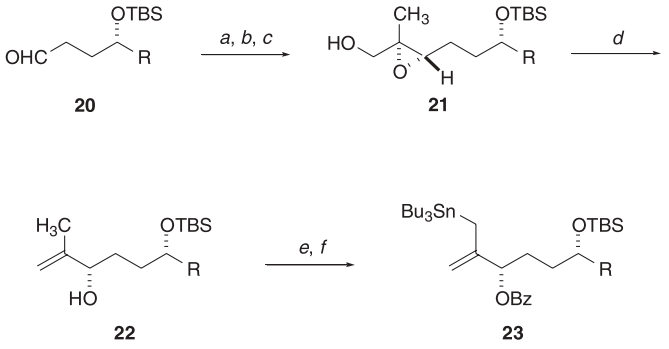
Results of our allylation studies are assembled in Table 1.[6] Data regarding the stereoselectivity of each condensation reaction was obtained by an initial flash silica-gel column to separate product diastereomers from other organic components, including the chiral auxiliary, which can be recovered and recycled. Thus, overall yields of these attempts were readily assessed, and the ratios of diastereomeric products

[3] Experimental details for the preparation of allylstannanes **18**, **19**, and *ent*-**18** will be published in the full account of the synthesis of leucascandrolide A.



[4] An alternative method for general introduction of the allylic silane uses methyl ketones for kinetic deprotonation, and transformation to their corresponding vinyl triflates. Cross-coupling with (trimethylsilyl)methyl magnesium chloride in the presence of $Ni(acac)_2$ (THF at 22 °C) yields the C-2-substituted allylic silanes.

[5] Experimental details for the preparation of stannanes **23a**, **23b**, and (*R*)-**23b** will be published in the full account of our total synthesis of amphidinolide K (see also ref. 7).



[6] We have used a standard set of conditions for these examples of asymmetric allylation, and further attempts to optimize yields or product ratios have not been made in most cases.

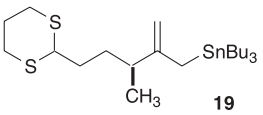
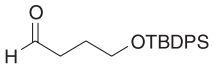
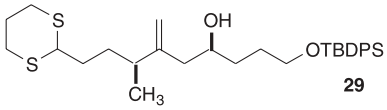
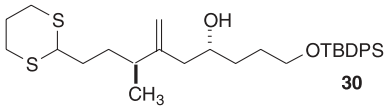
were obtained by the integration of selected proton signals in the NMR (400 MHz) spectra. Further confirmations of product ratios in most examples were available via analytical HPLC. In cases that provided a reasonable level of stereoselectivity, the major products were isolated and purified by silica-gel flash chromatography or preparative thin-layer chromatography for complete spectroscopic characterizations. Trace amounts of minor diastereomers or challenging separations from reactions that afforded little selectivity hampered our efforts for full characterization of these materials. However, the stereochemical redundance of our study provided fully characterized major products, which were then compared and identified as minor components in related examples. The assignment of absolute stereochemistry of each purified homoallylic alcohol of Table 1 was determined by Kakisawa analysis of the corresponding Mosher esters (18). Initially, these studies examined reactions with simple aldehydes, as summarized in entries 1 and 2 of Table 1. Reactions were evaluated using bromoborane **2**, bearing the (*R*,*R*)- and the (*S*,*S*)-sulfonamides. The presence of α-stereogenicity in the stannanes **19** and **23a** produced reactions consistent with stereochemically-reinforcing and nonreinforcing relationships with the auxiliaries (19).[7] Best results were obtained using the (*R*,*R*)-**2**, which yielded the 1,4-*syn*-diastereoisomers as major products. The benzoate substituent of **23a** in entry 2 was more effective in reinforcing, as well as countering, the bias of the auxiliary compared with the methyl substitution of **19** in entry 1.

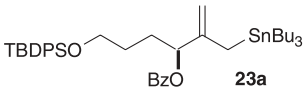
Fig. 1. Diastereofacial selection in allylation reactions.

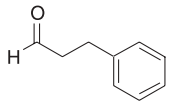


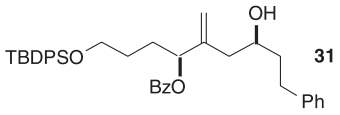


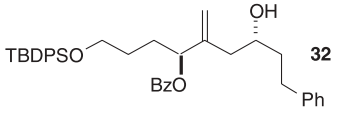


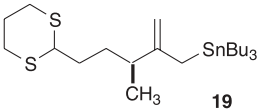


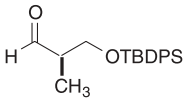


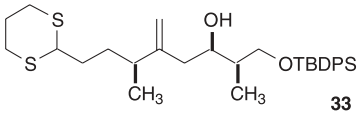


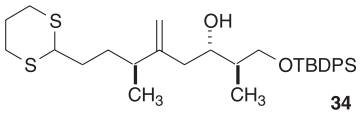


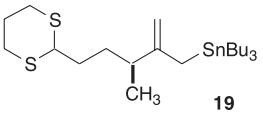


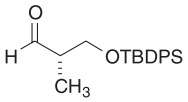


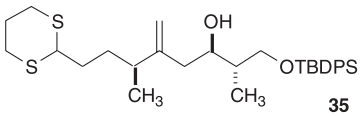


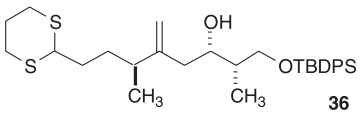


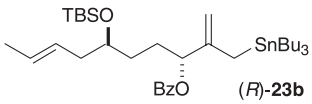


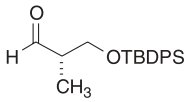


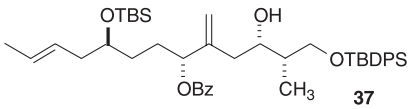


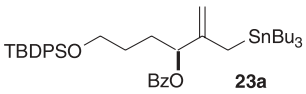


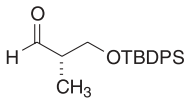


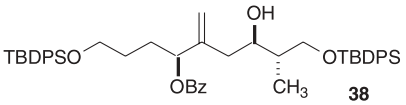


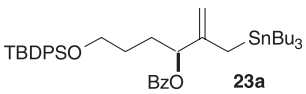


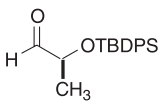


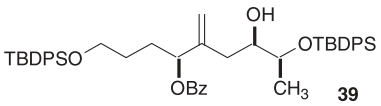












Our rationale for the stereoselectivity of these reactions is illustrated in the diagrams of Fig. 1. Transmetalation gives the sp^2 hybridized borane **3**, which reversibly binds the aldehyde in the axial orientation **24** and provides a synclinal disposition of the Lewis acid with respect to the aldehydic hydrogen. This complexation serves to activate the electrophilic carbonyl, as well as to trigger nucleophilicity of the allyl moiety. Structure **24** also presents a rehybridization of boron to a tetrahedral geometry, and the five-membered heterocyclic ring assumes a conformation that minimizes the nonbonded interactions of sulfonyl and phenyl substituents. Facial selectivity in **24** is determined by the relative energies of diastereomeric transition states as the reactive C_1 and C_3 carbons approach bonding proximity. Thus, our arguments consider bonding via the closed, chair-like arrangements of **25** and **26** as useful models to depict interactions that may contribute to a difference in transition-state energies. Since facial selectivity is not determined by the initial complexation, we offer the following contrivance to aid the visualization of **24** to **25** and **26** (Fig. 1): This process can be visualized from **24** by a rotation (arrow a) of the carbonyl (approximately 90°) and subsequent attack at the *re* face, as depicted in the favored situation in **25** wherein the illustration of **24** is reoriented by a 90° rotation (allyl is projected forward). On the other hand, rotation of the aldehyde in the clockwise direction in **24** (arrow b) results in the unfavorable nonbonded interactions of the aldehydic hydrogen with the

[7] We have utilized the terms "reinforcing" and "nonreinforcing", as introduced by Evans et al. (19), to describe the relationships of stereochemical elements within a reactant.

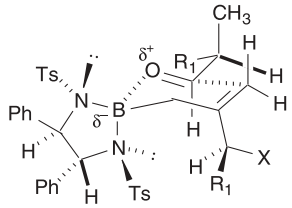
[d]Ratios were determined by HPLC separations on a Chiralpak AD column via elution with 1% isopropanol in hexanes.
[e]Unreacted aldehyde (15%–25%) was recovered in these reactions.



equatorial toluenesulfonyl group of the auxiliary, as shown in **26** (a 90° rotation of **24** with aldehyde projected forward). Thus, our modeling suggests that this nonbonded interaction raises the transition-state energy for *si* face reactions in the case of the (*R*,*R*)-chiral controller (20).

The consequences of steric interactions resulting from allylic branching of the C-2 substituent of **3** introduce an additional level of complexity. As illustrated in Fig. 1, the stereogenic center derived from stannanes such as **19** and **23ab** provides a stereochemically reinforcing scenario in **25** (X = CH_3 or OBz) by a minimization of the A(1,3)-strain, which also directs the methine hydrogen into the region near the sulfonyl group of the auxiliary (21, 22).[8,9] This becomes problematic in the nonreinforcing case, **26**. Aside from steric arguments, the allylic oxygen in the benzoate conformer of **25** (X = OBz) is also anticipated to have electronic effects, which favor the nucleophilic character of the olefin. The composite picture for these allylations suggests that the consequences of isopropyl substitution at C-2 in **25** (X and R_1 = CH_3) is less significant than the interaction of the aldehydic hydrogen and toluenesulfonyl moiety in **26**. This aspect is addressed with greater clarity in Fig. 2, where the proximity of reactive centers at C-1 and C-3 in **27** directs the C-2-branched substituent away from the developing chair. Alternatively, the situation in **26** (Fig. 1) projects the aldehydic hydrogen directly under the six-membered transition state and into the neighboring sulfonyl group. Finally, our models have also incorporated the role of α-chirality in the aldehyde. Diagram **28** in Fig. 2 describes a model for Felkin–Anh addition to the carbonyl while maintaining the favorable relationships of asymmetry, as previously described in **25** (23).[10]

Fig. 2. Preferred transition-state arrangements for asymmetric allylation using (*R*,*R*)-**2**.

27 (Ph's of the (*R*,*R*)-auxiliary have been removed for clarity.)

28

Since the feature of chirality in the aldehyde component multiplies the complexity of the reaction twofold, this aspect was first evaluated with the enantiomerically pure (*R*)- and (*S*)-2-methyl-3-hydroxypropanal derivatives, as shown in entries 3 and 4. The influence of α-stereochemistry in the aldehyde accentuated the reinforcing characteristics of the stannane and the (*R*,*R*)-auxiliary through the expected mode of Felkin–Anh addition (entry 3), yielding predominantly the all-*syn* adduct **33**. On the other hand, it was not sufficient to merely coordinate the chirality of the aldehyde with the (*S*,*S*)-auxiliary **2** in entry 4. This example led to a 1.7:1 mixture of diastereomers; and this points out the importance of allylic stereochemistry in the starting stannane. As observed in reactions with achiral aldehydes, the allylic benzoates **23a** and **23b** led to excellent diastereoselectivity in the matched

[8]The energy requirements for the A(1,3)-strain in **25** (X = CH_3) are estimated to be in the range of 0.4–0.7 kcal/mol, compared with the 1,3-H/H interaction. See ref. 21.
[9]Interestingly, the preferred transition state **25** (X = OBz) may present characteristics that resemble the "inside alkoxy effect" proposed by Stork, Houk, and Jäger for allylic ethers and alcohols. See ref. 22.
[10]Factors for the diastereoselectivity of the aldol reaction using boron enolates derived from chiral ethyl ketones pose some related concerns. Some examples include those found in ref. 23.

© 2004 NRC Canada

cases for Felkin–Anh addition (entries 5 and 7). However, it seems sufficient to coordinate the stereochemically reinforcing asymmetry of the allylic benzoate **23a** with **2** (*R*,*R*) for stereocontrolled condensations via the anti-Felkin mode (entry 6).

Our experiments have also evaluated the effect of β-chirality in the aldehyde, as precipitated by our studies toward leucascandrolide A (24). Tabulated by the results of entries 8, 9, and 10, threefold stereodifferentiation was observed. As documented in previous cases, the cooperation of allylic chirality in the stannane with the auxiliary **2** was a dominant feature. However, the resulting stereochemistry of the major adduct does not conform to the expected result of the Evans polar model for reactions of β-alkoxy aldehydes (19). A challenging situation was also presented by the nonracemic β,γ-unsaturated aldehyde (25)[11] used in entries 11, 12, and 13. Epimerization of this sensitive substrate was avoided, and good yields of condensation products were obtained in spite of considerable steric hindrance. Thus, while the anticipated cooperation of the asymmetry of the stannane and **2** remained intact, the nature of the α-substitution in the aldehyde failed to deliver a clear preference for Felkin or anti-Felkin arrangements. More extensive studies will be needed to probe the issues raised by these entries.

Finally, the versatility of this approach is displayed by the functional complexity of the aldehydes used for entries 14, 15, and 16.[12] Our plans recognized the reinforcing characteristics of stannane **23b** and (*R*,*R*)-**2**, as well as the inherent Felkin–Anh face selectivity for the nonracemic epoxy–aldehyde, as shown in entry 14. This situation is remarkably predictable, as demonstrated by the use of the diastereomeric stannane (*R*)-**23b** in entry 15, which yielded a productive reaction with the (*S*,*S*)-sulfonamide auxiliary and provided for Felkin–Anh addition to give the homoallylic alcohol **50**. The presence of the additional stereocenter at C-4 in the aldehyde (OTIPS of entries 15 and 16) did not impact the stereoselectivity in a major way and demonstrates the flexibility of this methodology for the synthesis of a family of complex diastereoisomers.

Experimental section

General

Infrared spectra were recorded on a Mattson Galaxy 4020 FT-IR instrument with use of an internal standard. Proton and carbon spectra were recorded on a 400 MHz spectrometer in FT mode. Proton chemical shifts are reported in δ, using as a reference the appropriate signal for residual solvent protons, as follows: 7.26 for *d*-chloroform and 7.20 for d_6-benzene. Carbon chemical shifts are reported in δ, using the center peak of the solvent signal as a reference, as follows: 77.0 for $CDCl_3$. Mass spectra were obtained on a Kratos MS80 RFAQQ instrument. Optical rotations were measured using a PerkinElmer 241 polarimeter. Concentration (*c*) is reported as g/100 mL, and temperature is room temperature. Tetrahydrofuran (THF) and diethyl ether (Et_2O) were freshly distilled from sodium benzophenone ketyl. Dimethylformamide (DMF), methylene chloride (CH_2Cl_2), pyridine, oxalyl chloride, triethylamine (Et_3N), benzene, and toluene were distilled from calcium hydride. Ethyl acetate (EtOAc) and hexanes for chromatography were distilled from glass prior to use. Column chromatography was conducted using silica gel 60 (230–400 mesh) from E.M. Science. Precoated glass plates 60F-254 (E. Merck, 0.25 mm and 0.50 mm thickness) were used for analytical and preparative thin layer chromatography (TLC). Reactions were carried out in flame-dried glassware under an inert atmosphere. Elemental analyses were performed by Galbraith Laboratories, Tenn., U.S.A.

General allylation procedure

A 35 mL Schlenk flask was charged with (*S*,*S*) or (*R*,*R*)-*N*,*N*′-bis-*para*-toluenesulfonyl-1,2-diamino-1,2-diphenylethane (0.22 g, 0.42 mmol) and heated to ~90 °C under vacuum (30 Pa). After 12 h, the resulting white solid was cooled to room temperature and CH_2Cl_2 (4 mL) was added under an argon atmosphere. The resultant solution was cooled to 0 °C and treated with fresh boron tribromide (0.42 mL of a 1.0 mol L^{-1} solution in CH_2Cl_2 (Aldrich®), 0.42 mmol). The resulting orange solution was stirred at 0 °C for 10 min, warmed to room temperature, and stirred for 1 h. The solvent and HBr were removed carefully under reduced pressure (0.2 mmHg). The resulting solid was dissolved in CH_2Cl_2 (4 mL), stirred for 10 min, and concentrated under high vacuum. The yellow solid was diluted again with CH_2Cl_2 (4 mL) and cooled to 0 °C, and a solution of the allylstannane (0.47 mmol) in CH_2Cl_2 (~1 mL) was added. The yellow solution was stirred for 16 h at room temperature. After this time the reaction was cooled to –78 °C, and a solution of aldehyde (0.31 mmol) in CH_2Cl_2 (~1 mL) was added. The reaction mixture was stirred at –78 °C for 2 h and then quenched with pH 7 buffer (1 mL). The mixture was allowed to warm to room temperature and diluted with CH_2Cl_2 (15 mL). The organic phase was washed with saturated aqueous $NaHCO_3$ (15 mL). The aqueous phase was extracted with CH_2Cl_2 (15 mL). The combined organic phases were dried ($MgSO_4$), filtered, and concentrated in vacuo. The resulting solid was dissolved in Et_2O and filtered to recover the sparingly soluble bis-sulfonamide chiral auxiliary. The filtrate was concentrated in vacuo, and the residue was purified by flash silica-gel chromatography to yield the mixture of secondary homoallylic alcohols. Diastereomeric ratios were initially determined by the integration of selected proton signals in NMR (400 MHz) spectra. Product ratios were also obtained by analytical HPLC (see notes of Table 1 for conditions). Major diastereomers were purified by flash column chromatography or preparative TLC (silica gel) for full characterization. Solvents for chromatography and data for full characterization of major adducts are included below.

(4*S*,7*S*)-1-(*tert*-Butyldiphenylsilanyloxy)-9-([1,3]dithian-2-yl)-7-methyl-6-methylene-nonan-4-ol (29)

Application of the allylation procedure above led to the

[11]The route for preparation of the nonracemic β,γ-unsaturated aldehyde (entries 11, 12, and 13 of Table 1) has been previously described; see ref. 25 and also ref. 8.

[12]The preparation of optically active aldehydes for entries 14, 15, and 16 has been described in the course of our total synthesis of amphidinolide K. Experimental details are found in the supporting information of ref. 7.

Conclusion

In summary, a powerfully convergent strategy for the diastereoselective synthesis of homoallylic alcohols has been described. Our asymmetric allylation reaction incorporates three elements of stereodifferentiation. Optimal results are provided when adjacent asymmetry in the starting stannane

© 2004 NRC Canada

is stereochemically reinforcing with respect to chirality of the bis-sulfonamide auxiliary. Products featuring 1,4-*syn*-stereochemistry are favored. The incorporation of α- or β-stereogenecity in the starting aldehyde has been documented. The diastereofacial selectivity of reactions with α-substituted aldehydes is predicted by the Felkin–Anh model. Overall, this methodology permits the construction of complex arrangements of stereochemistry and functionality as a useful tool for the synthesis of complex natural products.

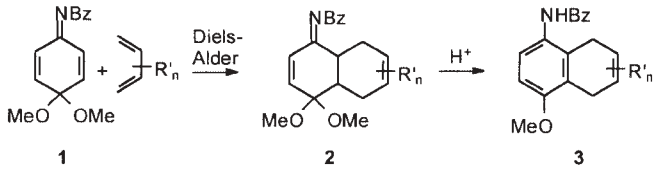
The Diels–Alder reactions of quinone imine ketals[1]

Scott C. Banfield and Michael A. Kerr

Abstract: *N*-Benzoyl- and *N*-arylsulfonyl-*p*-benzoquinone-mono-imine ketals (QIKs) undergo smooth Diels–Alder cycloadditions with typical 1,3-butadienes to yield the expected *endo* adducts. Treatment with catalytic acid rapidly converts the adducts to dihydronaphthalenes. The *N*-benzoyl derivatives require high pressures for cycloadditions while the *N*-tosyl and *N*-nosyl derivatives proceed under thermal (ambient pressure) conditions. In all cases the cycloadditions are completely regioselective.

Key words: Diels–Alder, quinone imine ketal, hyperbaric chemistry.



Résumé : Les cétals des *N*-benzoyl- et *N*-arylsulfonyl-*p*-benzoquinonemonoimines donnent facilement des réactions de cycloaddition de Diels–Alder avec les buta-1,3-dienes typiques et ils conduisent à la formation des adduits *endo* attendus. Le traitement avec une quantité catalytique d'acide provoque une transposition des adduits en dihydronaphtalènes. Les dérivés *N*-benzoylés nécessitent de hautes pressions pour donner les réactions de cycloaddition alors que les dérivés *N*-tosyl- et *N*-nosyl- se produisent à des conditions de température et de pression ambiantes. Dans tous les cas, les réactions de cycloadditions sont complètement diastéréosélectives.

Mots clés : Diels–Alder, cétal de la quinoneimine, chimie hyperbarique.

Introduction

The synthetic utility of the Diels–Alder reaction is questioned by no one. Its versatile ability to form a cyclohexene ring (with up to four new stereocenters) with exquisite control is well documented (1). So much work has been done to expand our understanding of this process over the years that one may now plan a complex synthesis involving a Diels–Alder reaction with a high degree of confidence for success. Even though the Diels–Alder reaction is a "mature reaction" in terms of its development, many opportunities exist to expand its utility. These include new dienophiles, dienes, and catalysts. Such developments allow the synthetic chemist the opportunity to tackle new and exciting challenges. Several years ago, we reported the participation of a benzoylated quinone imine ketal **1** in [4+2]-cycloadditions at ultra-high pressures (Scheme 1) (2). Prior to that work, the only report of such reactivity was made by Coutts et al. (3), in which several examples of sulphonylated quinone imine ketals as dienophiles were reported, although Swenton and coworkers (4) have explored the otherwise rich chemistry of benzoylated quinone imine ketals. The stable cycloadducts **2** could be isolated and purified or treated with acid to yield a dihydronaphthalene **3**. Subsequent to our initial report, we disclosed the synthesis of the tricyclic ergot skeleton using this reaction (5). This in turn inspired us to explore a general strategy for the synthesis of 5-methoxy indoles, which we recently reported in preliminary form (6). In the present paper we report the full details and an expanded scope of the hyperbaric Diels–Alder reactions of *N*-benzoyl quinone imine ketals, as well as a more generally usable and scalable thermal variant involving the *N*-arylsulphonyl counterparts.

Scheme 1.

Results and discussion

Synthesis of quinone imine ketals

The *N*-benzoyl quinone imine ketals **5a–d** were prepared by a simplification of the anodic oxidation method reported by Swenton et al. (4*a*) (Table 1). The oxidation is technically simple and is carried out in an open beaker on a stir plate with a platinum mesh electrode at a constant current of 0.3 A. Although other *N*-acyl derivatives (pivaloyl, acetyl, *tert*-butoxycarbonyl) were considered, the low reactivity of these compounds in a Diels–Alder sense, compared with the *N*-arylsulphonyl compounds (vide infra), led us to pursue the *N*-tosyl and *N*-nosyl derivatives instead.

While anodic oxidation yielded the desired products in the preparation of the *N*-arylsulphonyl QIKs, the yields were less than optimal and the reactions somewhat messy. We turned to oxidation with phenyliodo bis acetate (PIBA) (7). The preparation of QIKs by oxidation with this reagent has

The Diels–Alder reactivity of QIKs

As expected, the removal of one carbonyl from conjugation with the dienophilic double bond greatly attenuates the dienophilicity of QIKs with respect to the parent *p*-benzoquinones. In fact, when QIKs **5** were subjected to reaction with a variety of 1,3-butadienes at elevated temperatures (150 °C), only decomposition was observed after 3 days. At this stage, high pressures were examined for several reasons, as follows: (*i*) The thermal activation ($\Delta H^{\ddagger}$) can be replaced by entropic activation ($\Delta V^{\ddagger}$) without the problem of thermal decomposition, and (*ii*) it is suspected that much of the low reactivity of these systems stems from the steric encumbrance imposed by the quaternary center adjacent to the reacting π-system, an encumbrance that can be overcome by the use of high pressures (8). In the case of the arylsulfonyl QIKs **7**, the increased electron-withdrawing ability of the tosyl or nosyl groups may overcome the inherent lack of reactivity, and a thermal process may be viable.

A key positive attribute of QIKs as dienophiles resides in the very properties that cause problems with reactivity. The presence of only one LUMO – lowering group on the reacting dienophilic π-bond imparts a degree of regioselectivity often missing in the parent quinones. In addition, the ketal moiety, which is restricted to be essentially orthogonal to the reacting π-systems, all but precludes the transition state A′ leading to the pseudo-*meta* regioisomer B′ (Fig. 1).

High pressure Diels–Alder reactions

The *N*-benzoyl QIK **5a** was subjected to reaction with a series of 5 dienes at 13 kbar (1 bar = 10^5 Pa) at ambient temperature[3] (Table 3). Typically, the reactions took about 7 days to proceed to completion and generally led to clean conversion to the *endo* cycloadducts.[4] These adducts are surprisingly stable to isolation and chromatography, although prolonged exposure to silica gel leads to small conversions to the aromatized species (vide infra). A consideration when using 2,3-dimethylbutadiene (entry d) is competitive polymerization of the diene. Use of a large excess of the diene often resulted in the solidification of the entire reaction mixture. This result is typical of our experiences using dienes that are unsubstituted at both termini of the diene moiety at elevated pressures. The fact that 1-*tert*-butyldimethylsilyloxy-1,3-butadiene (entry e) underwent reaction in higher

[3] This excludes the heating of the sample, which undoubtedly occurs upon compression of the high-pressure apparatus.
[4] The fact that these are *endo* adducts has been confirmed by NOESY experiments and has been published (ref. 2).

yield and in less time is not surprising, since it is highly activated by the electron-donating silyloxy substituent.

Of interest to us for the synthesis of alkaloids was the fact that treatment of the adducts with a trace of acid effected the smooth aromatization to a dihydronaphthalene (i.e., **2**→**3** in Scheme 1). Table 4 shows the results of a series of reactions in which the initially formed adduct was isolated and the crude material treated with a drop of concentrated HCl in

© 2004 NRC Canada

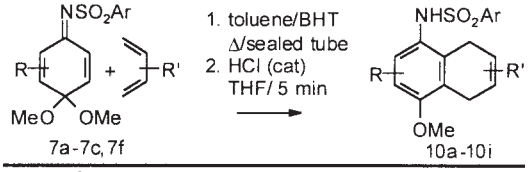
to 50 °C. This relatively minor increase in temperature reduced the reaction times from 7 days to 12 h.

The method of aromatization was also investigated. Mild acid sources such as silica gel were ineffective in promoting the transformation, while a mild Lewis acid such as ytterbium triflate resulted in decomposition. Use of *p*-toluenesulfonic acid resulted in the formation of desired product but also produced the free phenol, possibly because of hydrolysis by the water of hydration in the tosic acid.

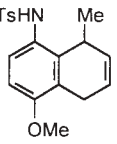
Ambient pressure Diels–Alder reactions

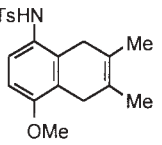
In an attempt to make this reaction more widely applicable, we examined the Diels–Alder cycloadditions of *N*-tosyl and *N*-nosyl QIKs in the cycloadditions process. Replacement of the benzoyl moiety with the more electron-withdrawing aryl sulfonyl group should serve to enhance the dienophilicity of the QIK. To this end, **7a–c** and **7f** were heated in toluene with a series of 1,3-butadienes (Table 5). The *N*-tosyl QIKs underwent cycloadditions smoothly at 140 °C (sealed tube), while the more reactive nosyl derivatives required 100 °C as the reaction temperature. In most cases, a substantial amount of conversion to the dihydronaphthalene was observed. The aromatization was driven to completion by treatment with acid, as before, to yield the dihydronaphthalenes **10** in excellent yields. Other than the milder reaction temperatures, an advantage of using a nosyl group is the ease of removal of such a group from the adduct (9). On a larger scale, the reaction was performed in refluxing xylenes, using a standard reflux apparatus, and the aromatization was performed by addition of HCl directly to the xylenes solution. The dihydronaphthalene precipitated from the reaction mixture upon cooling with no significant reduction in chemical yield.

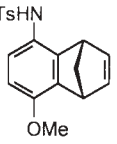
The cycloadducts themselves are suitable substrates for further oxidation and cycloadditions (Scheme 2). Adduct **10c** was hydrogenated to yield **11**, which could be oxidized as before in excellent yield to the QIK **12**. Cycloaddition of **12** with 3-methyl-1,3-pentadiene proceeded to give, after aromatization with catalytic HCl, the linear tricycle **13**.

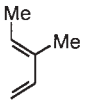


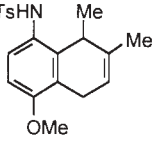
In summary, we have shown that quinone imine ketals bearing an electron-withdrawing group on the nitrogen atom are willing participants in hyperbaric or thermal Diels–Alder reactions. The adducts are readily aromatized with loss of methanol to produce dihydronaphthalenes in excellent yields. The synthetic utility of this process, including the conversion to 5-methoxyindoles, will be the subject of upcoming reports from our lab.

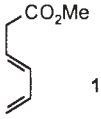


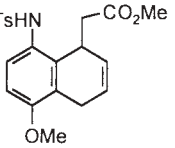


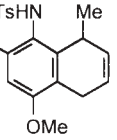


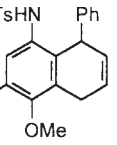


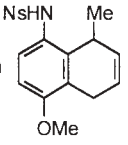


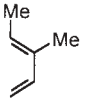


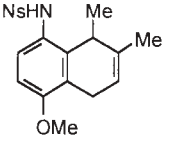












Experimental section

General considerations

Infrared spectra were obtained as thin films on NaCl plates. NMR spectra were obtained at 600 or 400 MHz (^{1}H) and 150 or 100 MHz (^{13}C). Spectra were obtained in $CDCl_3$ (referenced at 7.26 ppm for ^{1}H and 77.0 ppm for ^{13}C) or DMSO-d_6 (referenced at 2.49 ppm for ^{1}H and 39.5 ppm for ^{13}C). Coupling values (J) are in Hz. EI Mass spectra were obtained at an ionizing voltage of 70 eV. Hyperbaric conditions were achieved using a LECO^{TM} Tempres high-pressure chemical reactor. Dichloromethane, toluene, and THF were distilled prior to use, according to the standard procedures

(10). All other reagents were used as purchased from Aldrich or Lancaster and without purification. Reactions were checked for completion by TLC (EM Science, silica gel 60 F_{254}) and (or) ^{1}H NMR. Flash chromatography was performed using silica gel purchased from Silicycle Chemical Division Inc. (230–400 mesh). The synthesis of the *N*-benzoyl quinone imine ketals was carried out in the manner described by Swenton et al. (4*a*) with the only change being that the reaction was performed in an open beaker using a simple power source capable of producing a constant current of 0.3 A. The anode was a 2.5 cm × 5 cm Pt mesh cylinder, and the cathode was a 1 cm diameter Pt wire hoop. A simple laboratory power source was employed in the anodic oxidations. The Diels–Alder chemistry of the *N*-benzoyl quinone imine ketals has been described by us (2, 5, 6); however, a representative example for the preparation and Diels–Alder reaction of **5a** is given below.

General procedure for the preparation of *N*-benzoyl quinone imine ketals via anodic oxidation

Preparation of 5a

N-(4-Methoxyphenyl)benzamide (3.00 g, 13.2 mmol) was dissolved in 300 mL of a 2% solution of $LiClO_4$–CH_3OH. The mixture was cooled to 0 °C, and $NaHCO_3$ (6.00 g) was added. The mixture was rapidly stirred and anodically oxidized at a constant current (0.3 A) until consumption of the starting material was complete by TLC (approximately 140 min). The oxidation was stopped, and additional benzamide (2.62 g, 11.5 mmol) was added and allowed to dissolve, and the oxidation resumed until complete by TLC, approximately 140 min. The mixture was then poured into water and extracted several times with CH_2Cl_2. The combined organic layers were then washed with brine, dried (Na_2SO_4), filtered, and concentrated. The crude dienophile was then purified via flash chromatography (30%EtOAc–hexane) to yield 5.79 g (22.5 mmol, 91% yield) of the desired quinone imine ketal **5a**. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 7.91 (d, *J* = 8.2 Hz, 2H), 7.60–7.56 (m, 1H), 7.48–7.44 (m, 2H), 6.57 (d, *J* = 9.0 Hz, 2H), 6.46 (d, *J* = 8.6 Hz, 2H), 3.34 (s, 6H). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 180.3, 155.3, 139.6, 133.8, 132.9, 129.7, 128.9, 127.1, 93.2, 50.4. HR-MS (EI 70 eV) calcd. for $C_{15}H_{15}NO_3$: 257.1052; found: 257.1047.

General procedure for the high-pressure Diels–Alder reactions of *N*-benzoyl quinone imine ketals

Preparation of 8a and 9a

The quinone imine ketal **5a** (0.257 g, 1 mmol) was placed in a length (7″ (1″ = 25.4 mm)) of heat-shrinkable Teflon tubing. Dry CH_2Cl_2 (2 mL) was added, followed by an excess (0.5 mL) of technical grade piperylene. The tube was closed with a brass clamp and placed in the LECO^{TM} Tempres high-pressure chemical reactor. The pressure was raised to 13 kbar for a period of 7 days. The reaction mixture was poured directly onto a flash column of silica gel and eluted with 20% EtOAc in hexanes to produce 290 mg (90% yield) of a pure product, **8a**. ^{1}H NMR (250 MHz, $CDCl_3$) δ: 7.89 (d, *J* = 7.5 Hz, 2H), 7.52 (t, *J* = 7.5 Hz, 1H), 7.40 (t, *J* = 7.5, Hz, 2H), 6.09 (dd, *J* = 10.2, 2.1 Hz, 1H), 6.01 (d, *J* = 10.4 Hz, 1H), 5.71–5.68 (m, 2H), 3.28 (s, 3H), 3.25 (s, 3H), 3.27–3.22 (m, 1H), 2.72–2.64 (m, 2H), 2.20–1.88 (m, 2H), 1.48 (d, *J* = 7.6 Hz, 3H). ^{13}C NMR (63 MHz, $CDCl_3$) δ: 179.5, 164.7, 138.8, 133.4, 133.0, 132.9, 129.4, 128.5, 125.0, 123.8, 99.5, 49.7, 47.7, 43.7 (two signals), 35.0, 24.3, 18.7. IR (thin film) (cm^{-1}) ν: 3050, 3010, 2950, 2920, 2815, 1655, 1640, 1440, 1255. MS *m*/*z* (relative intensity): 326 (12, [M + 1]), 325 (48, $[M]^+$), 294 (15), 293 (21), 258 (43), 237 (20), 105 (100). HR-MS (EI 70 eV) calcd. for $C_{20}H_{23}NO_3$: 325.1678; found: 325.1687.

Preparation of 9a

The reaction performed, as for the preparation of **8a**, using **5a** (0.776 g, 3.0 mmol) and piperylene (0.613 g, 9.0 mmol) resulted in the formation of crude **8a**, which was taken up in 20 mL THF. Concentrated HCl (1 drop) was added, and the mixture was stirred for 30 min, after which time solid $NaHCO_3$ was added. The mixture was then stirred for an additional 10 min, and anhyd $MgSO_4$ was then added; stirring continued for 10 min further. The mixture was filtered, washed with THF, and concentrated. The crude residue was purified via trituration with cold hexanes; the solid was filtered and dried. The yield was 0.857 g (97%). ^{1}H NMR (400 MHz, DMSO) δ: 9.79 (s, 1H), 7.97 (app d, *J* = 6.8 Hz, 2H), 7.59–7.49 (m, 3H), 7.12 (d, *J* = 8.6 Hz, 1H), 6.85 (d, *J* = 8.6 Hz, 1Hz), 5.91–5.84 (m, 2H), 3.80 (s, 3H), 3.63–3.56 (m, 1H), 3.28–3.24 (m, 1H), 3.09–3.02 (m, 1H), 1.05 (d, *J* = 7.0 Hz, 3H). ^{13}C NMR (100 MHz, DMSO) δ: 165.9, 154.8, 137.7, 134.6, 131.4, 130.6, 128.4, 127.7, 127.5, 127.0, 122.8, 122.7, 107.5, 55.4, 29.9, 24.0, 22.4. IR (thin films) ν: 3276, 1643. MS *m*/*z* (relative intensity): 294 (14, [M + 1]), 293 (66, $[M]^+$), 188 (21), 105 (100), 77 (43). HR-MS (EI 70 eV) calcd. for $C_{19}H_{19}NO_2$: 293.1416; found: 293.1409.

Typical procedure for the synthesis of *N*-arylsulfonyl quinone imine ketals

Preparation of 7a

In a 250 mL round-bottom flask, containing 125 mL of methanol, was dissolved 10.00 g (36 mmol) of **6a**. The solution was cooled to 0 °C; then 11.70 g (36 mmol) of diacetoxyiodobenzene was added portion-wise over 5 min. The flask was purged with argon and stirred until complete by TLC (approximately 30 min). The reaction mixture was then poured into water and extracted with EtOAc, then washed

© 2004 NRC Canada

successively with water, saturated $NaHCO_3$ (aq), and brine; then it was dried with $MgSO_4$, filtered, and concentrated. The crude product was then purified via recrystalization from CH_2Cl_2 to yield 9.87 g (32 mmol, 89% yield) of the product **7a** as a white solid. mp 109–111 °C. ^{1}H NMR (600 MHz, DMSO-d_6) δ: 7.81 (d, J = 8.2 Hz, 2H), 7.45 (d, J = 8.2 Hz, 2H), 7.36 (dd, J = 10.5, 2.2 Hz, 1H), 7.12 (dd, J = 10.5, 2.9 Hz, 1H), 7.01 (dd, J = 10.2, 2.9 Hz, 1H), 6.36 (dd, J = 10.2, 2.2 Hz, 1H), 3.28 (s, 6H), 2.40 (s, 3H). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 162.8, 143.9, 143.2, 141.9, 137.4, 130.4, 129.4, 127.1, 123.0, 91.9, 50.3, 21.7. IR (thin film) (cm^{-1}) ν: 2835, 1555, 1321, 1156. MS *m/z* (relative intensity): 308 (3, [M + 1]), 307 (19, [M]$^+$), 276 (27), 152 (100), 139 (13), 121 (14), 91 (33). HR-MS (EI 70 eV) calcd. for $C_{15}H_{17}NO_4S$: 307.0878; found: 307.0879.

Quinone imine ketal (7b)

Oxidation of 11.10 g (36 mmol) of the nosylated *p*-anisidine **6b** with 11.62 g (36 mmol) of diacetoxyiodobenzene in 125 mL of methanol was performed in a similar manner to the preparation of compound **7a**, method A. The crude product was purified via a mixed recrystalization from EtOAc–MeOH to yield 9.00 g (26.6 mmol, 74% yield) of the product **7b** as an off-white solid. mp 132–135 °C. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 8.39 and 8.18 (AA′BB′ system, 4H), 7.52 (dd, J = 10.5, 2.0 Hz, 1H), 6.87 (dd, J = 10.5, 2.7 Hz, 1H), 6.80 (dd, J = 10.2, 2.7 Hz, 1H), 6.34 (dd, J = 10.2, 2.0 Hz, 1H), 3.38 (s, 6H). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 164.3, 150.2, 146.1, 144.7, 143.4, 129.9, 128.5, 124.1, 123.1, 91.7, 50.3. IR (thin film) (cm^{-1}) ν: 1532, 1326, 1154. MS *m/z* (relative intensity): 338 (5, [M]$^+$), 307 (46), 170 (14), 152 (100), 121 (28), 106 (17). HR-MS (EI 70 eV) calcd. for $C_{14}H_{14}N_2O_6S$: 338.0573; found: 338.0568.

Quinone imine ketal (7c)

Oxidation of 3.85 g (12.5 mmol) of the tosylated *p*-anisidine **6c** with 4.03 g (12.5 mmol) of diacetoxyiodobenzene in 50 mL of methanol was performed in a similar manner to the preparation of compound **7a**, method A. The crude product was purified via a recrystalization from CH_2Cl_2 to yield 3.05 g (9.0 mmol, 72% yield) of the product **7c** as a yellow solid. mp 137–140 °C. ^{1}H NMR (400 MHz, DMSO-d_6) δ: 7.80 (d, J = 8.4 Hz, 2H), 7.45 (d, J = 8.4 Hz, 2H), 7.30 (d, J = 10.5 Hz, 1H), 7.05 (dd, J = 10.5, 2.5 Hz, 1H), 5.98 (d, J = 2.5 Hz, 1H), 3.60 (s, 3H), 3.27 (s, 6H), 2.41 (s, 3H). ^{13}C NMR (100 MHz, DMSO-d_6) δ: 159.1, 150.2, 144.7, 144.0, 137.3, 129.7, 126.7, 120.9, 111.6, 94.3, 55.3, 49.9, 21.1. IR (thin film) (cm^{-1}) ν: 2938, 1313, 1147. MS *m/z* (relative intensity): 338 (2, [M + 1]), 337 (10, [M]$^+$), 306 (100), 182 (51), 151 (43), 91 (35). HR-MS (EI 70 eV) calcd. for $C_{16}H_{19}NO_5S$: 337.0984; found: 337.0992.

Quinone imine ketal (7d)

Oxidation of 5.00 g (16.3 mmol) of the tosylated *p*-anisidine **6d** with 5.25 g (16.3 mmol) of diacetoxyiodobenzene in 50 mL of methanol was performed in a similar manner to the preparation of compound **7a**, method A. The crude product was purified via recrystalization from CH_2Cl_2 to yield 4.74 g (14.1 mmol, 87% yield) of the product **7d** as a yellow solid and as a (1.8:1) mixture of *trans*- and *cis*-isomers, respectively. mp 110–112 °C. ^{1}H NMR (400 MHz, DMSO-d_6, *trans*-isomer) δ: 7.79 (d, J = 8.3 Hz, 2H), 7.42 (d, J = 8.3 Hz, 2H), 6.79 (d, J = 10.2 Hz, 1H), 6.62 (d, J = 1.6 Hz, 1H), 6.36 (dd, J = 10.2, 1.6 Hz, 1H), 3.85 (s, 3H), 3.20 (s, 6H), 2.39 (s, 3H). ^{1}H NMR (400 MHz, DMSO-d_6, *cis*-isomer) δ: 7.79 (obscured by aryl sulfonyl, 2H), 7.42 (d, J = 8.3 Hz, 2H), 7.42 (obscured by aryl sulfonyl, 1H), 6.89 (d, J = 10.2 Hz, 1H), 5.77 (m, 1H), 3.79 (s, 3H), 3.20 (s, 6H), 2.39 (s, 3H). ^{13}C NMR (100 MHz, DMSO-d_6, both isomers) δ: 170.7, 169.4, 166.3, 165.5, 143.7, 143.6, 142.8, 141.1, 138.4, 138.1, 130.7, 129.7 (two overlapping signals), 126.7, 126.6, 122.8, 102.7, 96.4, 92.7, 92.6, 56.6, 56.5, 50.8 (two overlapping signals), 21.0 (two overlapping signals). IR (thin film) (cm^{-1}) ν: 2835, 1596, 1302, 1146. MS *m/z* (relative intensity): 338 (2, [M + 1]), 337 (9, [M]$^+$), 306 (36), 182 (100), 151 (8), 91 (24). HR-MS (EI 70 eV) calcd. for $C_{16}H_{19}NO_5S$: 337.0984; found: 337.0989.

Quinone imine ketal (7f)

Oxidation of 2.00 g (6.4 mmol) of the tosylated *p*-anisidine **6f** with 2.07 g (6.4 mmol) of diacetoxyiodobenzene in 20 mL of methanol was performed in a similar manner to the preparation of compound **7a**, method B. Filtration and washing with hexanes yielded 1.78 g (5.2 mmol, 81% yield) of the product **7f** as a yellow solid and as a (1.1:1) mixture of *cis*- and *trans*-isomers, respectively. No further purification was required. mp 100–102 °C. ^{1}H NMR (400 MHz, DMSO-d_6, *trans*-isomer) δ: 7.82 (d, J = 8.4 Hz, 2H), 7.57 (dd, J = 10.4, 2.0 Hz, 1H), 7.47–7.45 (m, 2H), 7.18 (d, J = 10.4 Hz, 1H), 6.86 (d, J = 2.0 Hz, 1H), 3.20 (s, 6H), 2.41 (s, 3H). ^{1}H NMR (400 MHz, DMSO-d_6, *cis*-isomer) δ: 7.83 (d, J = 8.4 Hz, 2H), 7.72 (d, J = 2.1 Hz, 1H), 7.47–7.45 (m, 2H), 7.10 (d, J = 10.3 Hz, 1H), 6.60 (dd, J = 10.3, 2.1 Hz, 1H), 3.20 (s, 6H), 2.41 (s, 3H). ^{13}C NMR (100 MHz, DMSO-d_6, both isomers) δ: 161.8, 160.9, 152.8, 149.7, 144.2, 144.1, 143.5, 142.2, 137.1, 137.0, 132.6, 131.6, 129.5 (two overlapping signals), 127.2, 127.1, 125.1, 124.7, 94.34, 94.31, 51.61, 51.58, 21.7 (two overlapping signals). IR (thin film) (cm^{-1}) ν: 2924, 2837, 1320, 1156. MS *m/z* (relative intensity): 343 (9, [M + 2]), 342 (6, [M + 1]), 341 (23, [M]$^+$), 310 (45), 306 (32), 186 (100), 139 (23), 91 (92). HR-MS (EI 70 eV) calcd. for $C_{15}H_{16}ClNO_4S$: 341.0489; found: 341.0494.

Typical procedure for the thermal Diels–Alder–aromatization reactions of quinone imine ketals

Preparation of dihydronaphthalene (10a)

The quinone imine ketal **7a** (0.503 g, 1.6 mmol) and piperylene (0.393 g, 5.8 mmol) were taken up in dry toluene (2.3 mL) in an oven-dried sealed tube. One crystal of the radical inhibitor BHT was added, and the tube was flushed with argon before sealing. The reaction mixture was heated at 140 °C for a period of 24 h, after which time the reaction mixture was concentrated and taken up in dry THF (20 mL). Concentrated HCl (2 drops) was added, and the mixture was stirred under argon for 30 min, after which time solid $NaHCO_3$ was added. The mixture was then stirred for an additional 10 min, and anhyd $MgSO_4$ was then added; stirring continued for 10 min further. The mixture was filtered, washed with THF, and concentrated. The crude residue was purified via trituration with cold hexane; the solid was fil-

tered and dried to yield 0.509 g (1.48 mmol, 90% yield) of the product **10a** as a white solid. mp 152–156 °C. ^{1}H NMR (400 MHz, DMSO-d_6) δ: 9.23 (s, 1H), 7.58 (d, J = 8.3 Hz, 2H), 7.37 (d, J = 8.3 Hz, 2H), 6.60 (d, J = 8.7 Hz, 1H), 6.36 (d, J = 8.7 Hz, 1H), 5.90–5.79 (m, 2H), 3.81–3.71 (m, 1H), 3.69 (s, 3H), 3.27–3.20 (m, 1H), 2.99–2.93 (m, 1H), 2.38 (s, 3H), 1.06 (d, J = 6.8 Hz, 3H). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 155.4, 143.5, 137.7, 136.7, 130.2, 129.5, 127.2, 125.4, 124.9, 124.3, 123.0, 107.2, 55.3, 29.7, 24.2, 22.5, 21.5. IR (thin film) (cm^{-1}) ν: 3244, 1484, 1160. MS *m/z* (relative intensity): 344 (17, [M + 1]), 343 (73, [M]$^+$), 277 (7), 188 (100), 92 (6), 91 (24). HR-MS (EI 70 eV) calcd. for $C_{19}H_{21}NO_3S$: 343.1242; found: 343.1245.

Dihydronaphthalene (10b)

The reaction between quinone imine ketal **7a** (0.504 g, 1.6 mmol) and 2,3-dimethyl-1,3-butadiene (0.509 g, 5.7 mmol) was performed in a similar manner to the preparation of compound **10a**. The crude residue was purified via trituration with cold hexane; the solid was filtered and dried to yield 0.506 g (1.41 mmol, 88% yield) of the product **10b** as a white solid. mp 172–175 °C. ^{1}H NMR (400 MHz, DMSO-d_6) δ: 9.21 (s, 1H), 7.54 (d, J = 8.3 Hz, 2H), 7.34 (d, J = 8.3 Hz, 2H), 6.67–6.61 (m, 2H), 3.71 (s, 3H), 3.02–2.97 (m, 4H), 2.36 (s, 3H), 1.66 (s, 3H), 1.57 (s, 3H). ^{13}C NMR (100 MHz, DMSO-d_6) δ: 154.7, 142.7, 138.1, 133.3, 129.5, 126.7, 126.0, 125.5, 123.4, 122.0, 121.8, 107.2, 55.2, 32.1, 30.8, 20.9, 18.2 (two overlapping signals). IR (thin film) (cm^{-1}) ν: 3274, 1486, 1161. MS *m/z* (relative intensity): 358 (16, [M + 1]), 357 (66, [M]$^+$), 202 (3), 186 (100), 171 (23), 91 (18). HR-MS (EI 70 eV) calcd. for $C_{20}H_{23}NO_3S$: 357.1399; found: 357.1406.

Dihydronaphthalene (10c)

The reaction between quinone imine ketal **7a** (1.00 g, 3.25 mmol) and cyclopentadiene (0.98 mL, 11.8 mmol) was performed in a similar manner to the preparation of compound **10a**. The crude residue was purified via trituration with cold hexane; the solid was filtered and dried to yield 1.082 g (3.17 mmol, 98% yield) of the product **10c** as an off-white solid. mp 137–140 °C. ^{1}H NMR (400 MHz, DMSO-d_6) δ: 9.51 (s, 1H), 7.45 (d, J = 8.1 Hz, 2H), 7.31 (d, J = 8.1 Hz, 2H), 6.65 (dd, J = 5.2, 3.0 Hz, 1H), 6.58 (d, J = 8.8 Hz, 1H), 6.51 (d, J = 8.8 Hz, 1H), 6.26 (dd, J = 5.2, 3.0 Hz, 1H), 3.94 (br s, 1H), 3.76 (br s, 1H), 3.68 (s, 3H), 2.33 (s, 3H), 1.90 (d, J = 7.0 Hz, 1H), 1.67 (d, J = 7.0 Hz, 1H). ^{13}C NMR (150 MHz, DMSO-d_6) δ: 151.6, 149.4, 142.8, 142.7, 142.2, 138.1, 137.1, 129.4, 126.8, 124.1, 123.8, 109.3, 68.8, 55.3, 48.0, 46.2, 20.9. IR (thin film) (cm^{-1}) ν: 3260, 1490, 1161. MS *m/z* (relative intensity): 342 (11, [M + 1]), 341 (43, [M]$^+$), 186 (100), 160 (13), 91 (25). HR-MS (EI 70 eV) calcd. for $C_{19}H_{19}NO_3S$: 341.1086; found: 341.1081.

Dihydronaphthalene (10d)

The reaction between quinone imine ketal **7a** (0.508 g, 1.65 mmol) and 3-methyl-1,3-pentadiene (0.471 g, 5.7 mmol) was performed in a similar manner to the preparation of compound **10a**. The crude residue was purified via trituration with cold hexane; the solid was filtered and dried to yield 0.563 g (1.58 mmol, 96% yield) of the product **10d** as a white solid. mp 160–162 °C. ^{1}H NMR (400 MHz, DMSO) δ: 9.24 (s, 1H), 7.55 (app d, J = 8.3 Hz, 2H), 7.35 (app d, J = 8.3 Hz, 2H), 6.62 (d, J = 8.7 Hz, 1H), 6.50 (d, J = 8.7 Hz, 1H), 5.51–5.50 (m, 1H), 3.70 (s, 3H), 3.45–3.41 (m, 1H), 3.24 (dd, J = 21.6, 5.4 Hz, 1H), 2.89 (dd, J = 21.6, 2.3 Hz, 1H), 2.37 (s, 3H), 1.67 (s, 3H), 1.00 (d, J = 6.8 Hz, 3H). ^{13}C NMR (100 MHz, DMSO) δ: 154.7, 142.5, 140.3, 137.9, 137.1, 129.3, 126.5, 126.0, 125.3, 123.3, 117.8, 107.1, 55.3, 34.1, 24.3, 21.2, 21.0, 20.4. IR (thin film) (cm^{-1}) ν: 3279, 1486, 1161. MS *m/z* (relative intensity): 358 (15, [M + 1]), 357 (62, [M]$^+$), 202 (100), 187 (45), 172 (18), 91 (12). HR-MS (EI 70 eV) calcd. for $C_{20}H_{23}NO_3S$: 357.1399; found: 357.1402.

Dihydronaphthalene (10e)

The reaction between quinone imine ketal **7a** (0.304 g, 0.99 mmol) and methyl (*E*)-3,5-hexadienoate (0.442 g, 3.5 mmol) was performed in a similar manner to the preparation of compound **10a**. The crude residue was purified via flash chromatography (40% EtOAc–hexane) to yield 0.303 g (0.75 mmol, 76% yield) of the product **10e** as a white solid. mp 124–127 °C. ^{1}H NMR (400 MHz, DMSO-d_6) δ: 9.31 (s, 1H), 7.57 (d, J = 8.2 Hz, 2H), 7.37 (d, J = 8.2 Hz, 2H), 6.65 (d, J = 8.7 Hz, 1H), 6.42 (d, J = 8.7 Hz, 1H), 5.95–5.87 (m, 2H), 4.18–4.14 (m, 1H), 3.70 (s, 3H), 3.59 (s, 3H), 3.29–3.22 (m, 1H), 3.00–2.94 (m, 1H), 2.65 (dd, J = 15.4, 3.8 Hz, 1H), 2.38 (s, 3H), 2.14 (dd, J = 15.4, 10.5 Hz, 1H). ^{13}C NMR (100 MHz, DMSO-d_6) δ: 171.5, 155.1, 142.8, 137.9, 137.2, 129.6, 127.8, 126.8, 126.3, 125.8, 125.4, 124.5, 107.8, 55.4, 51.3, 40.5, 31.2, 24.1, 21.0. IR (thin film) (cm^{-1}) ν: 3255, 1735, 1485, 1161. MS *m/z* (relative intensity): 402 (8, [M + 1]), 401 (30, [M]$^+$), 327 (31), 246 (18), 186 (84), 172 (100), 91 (28). HR-MS (EI 70 eV) calcd. for $C_{21}H_{23}NO_5S$: 401.1297; found: 401.1292.

Dihydronaphthalene (10f)

The reaction between quinone imine ketal **7c** (0.501 g, 1.49 mmol) and piperylene (0.357 g, 5.2 mmol) was performed in a similar manner to the preparation of compound **10a**. The crude residue was purified via trituration with cold hexane; the solid was filtered and dried to yield 0.472 g (1.26 mmol, 85% yield) of the product **10f** as an off-white solid. mp 210–213 °C. ^{1}H NMR (400 MHz, DMSO-d_6) δ: 8.90 (s, 1H), 7.50 (d, J = 8.2 Hz, 2H), 7.31 (d, J = 8.2 Hz, 2H), 6.30 (s, 3H), 5.89–5.80 (m, 2H), 3.96–3.95 (m, 1H), 3.75 (s, 3H), 3.23–3.10 (m, 1H), 3.05 (s, 3H), 2.96–2.93 (m, 1H), 2.37 (s, 3H), 1.07 (d, J = 7.0 Hz, 3H). ^{13}C NMR (100 MHz, DMSO-d_6) δ: 156.1, 155.2, 141.9, 141.8, 139.4, 130.8, 128.7, 126.7, 122.6, 114.1, 113.7, 92.9, 55.4, 54.5, 29.8, 23.7, 22.5, 20.9. IR (thin film) (cm^{-1}) ν: 3239, 1591, 1160. MS *m/z* (relative intensity): 374 (6, [M + 1]), 373 (15, [M]$^+$), 218 (100), 186 (18), 91 (16). HR-MS (EI 70 eV) calcd. for $C_{20}H_{23}NO_4S$: 373.1348; found: 373.1352.

Dihydronaphthalene (10g)

The reaction between quinone imine ketal **7f** (0.500 g, 1.46 mmol) and 1-phenyl-1,3-butadiene (0.686 g, 5.27 mmol) was performed in a similar manner to the preparation of compound **10a**. The crude residue was purified via trituration with cold hexane; the solid was filtered and dried to yield 0.631 g (1.43 mmol, 98% yield) of the product **10g**

© 2004 NRC Canada

as a white solid. mp 152–155 °C. ^{1}H NMR (400 MHz, DMSO-d_6) δ: 9.17 (s, 1H), 7.43 (d, J = 8.1 Hz, 2H), 7.31 (d, J = 8.1 Hz, 2H), 7.23 (dd, J = 7.4, 7.2 Hz, 2H), 7.15 (t, J = 7.4 Hz, 1H), 7.06 (d, J = 7.2 Hz, 2H), 6.37 (s, 1H), 5.96–5.88 (m, 2H), 5.19–5.18 (m, 1H), 3.77 (s, 3H), 3.45–3.44 (m, 2H), 2.36 (s, 3H). ^{13}C NMR (100 MHz, DMSO-d_6) δ: 151.4, 144.5, 143.2, 136.5, 135.9, 131.5, 131.1, 129.5, 129.3, 128.4, 127.9, 127.0, 126.0, 124.9, 123.7, 121.8, 60.0, 40.9, 24.9, 21.0. IR (thin film) (cm^{-1}) ν: 3329, 1161. MS *m*/*z* (relative intensity): 440 (12, [M + 1]), 439 (40, [M]$^+$), 311 (16), 284 (100), 249 (45), 234 (30), 130 (42), 91 (78). HR-MS (EI 70 eV) calcd. for $C_{24}H_{22}ClNO_3S$: 439.1009; found: 439.1005.

Dihydronaphthalene (10h)

The quinone imine ketal **7b** (0.511 g, 1.51 mmol) and piperylene were taken up in dry toluene (2.3 mL) in an oven-dried sealed tube. One crystal of the radical inhibitor BHT was added, and the tube was flushed with argon before sealing. The reaction mixture was heated at 100 °C for a period of 7 h, after which time the reaction mixture was concentrated and taken up in dry THF (20 mL). Concentrated HCl (2 drops) was added, and the mixture was stirred under argon for 30 min, after which time solid $NaHCO_3$ was added. The mixture was then stirred for an additional 10 min, and anhyd $MgSO_4$ was then added, stirring for 10 min further. The mixture was then filtered, washed with reagent grade THF, and concentrated. The crude residue was purified via trituration with cold hexane; the solid was filtered and dried to yield 0.564 g (1.50 mmol, 99% yield) of the product **10h** as a white solid. mp 193–195 °C. ^{1}H NMR (400 MHz, DMSO-d_6) δ: 9.74 (s, 1H), 8.41 (d, J = 8.8 Hz, 2H), 7.94 (d, J = 8.8 Hz, 2H), 6.61 (d, J = 8.7 Hz, 1H), 6.35 (d, J = 8.7 Hz, 1H), 5.90–5.75 (m, 2H), 3.78–3.76 (m, 1H), 3.70 (s, 3H), 3.27–3.22 (m, 1H), 3.00–2.94 (m, 1H), 1.07 (d, J = 7.0 Hz, 3H). ^{13}C NMR (100 MHz, DMSO-d_6) δ: 155.5, 149.6, 146.4, 140.1, 130.7, 128.4, 126.3, 125.2, 124.6, 123.8, 122.8, 107.4, 55.3, 29.6, 24.0, 22.4. IR (thin film) (cm^{-1}) ν: 3275, 1588, 1532, 1349, 1167. MS *m*/*z* (relative intensity): 375 (11, [M + 1]), 374 (49, [M]$^+$), 188 (100), 173 (32), 122 (10). HR-MS (EI 70 eV) calcd. for $C_{18}H_{18}N_2O_5S$: 374.0936; found: 374.0940.

Dihydronaphthalene (10i)

The quinone imine ketal **7b** (0.500 g, 1.48 mmol) and 3-methyl-1,3-pentadiene (0.447 g, 5.44 mmol) were taken up in dry toluene (2.3 mL) in an oven-dried sealed tube. One crystal of the radical inhibitor BHT was added, and the tube was flushed with argon before sealing. The reaction mixture was heated at 100 °C for a period of 8 h, at which point NMR analysis revealed 100% conversion to the desired dihydronaphthalene **10i**. The reaction mixture was concentrated, and the crude residue was purified via trituration with cold hexane to yield 0.487 g (1.25 mmol, 85% yield) of the product **10i** as a yellow solid. mp 166–169 °C. ^{1}H NMR (400 MHz, DMSO-d_6) δ: 9.75 (s, 1H), 8.41 (d, J = 8.9 Hz, 2H), 7.92 (d, J = 8.9 Hz, 2H), 6.63 (d, J = 8.8 Hz, 1H), 6.46 (d, J = 8.8 Hz, 1H), 5.53–5.52 (m, 1H), 3.70 (s, 3H), 3.44–3.43 (m, 1H), 3.28–3.21 (m, 1H), 2.94–2.88 (m, 1H), 1.67 (s, 3H), 1.02 (d, J = 6.8 Hz, 3H).^{13}C NMR (100 MHz, DMSO-d_6) δ: 155.3, 149.6, 146.4, 140.7, 137.1, 128.4, 126.4, 124.7, 124.6, 123.8, 118.1, 107.5, 55.3, 34.2, 24.8, 21.1, 20.3. Nucleophilic additions of lactam-derived enol triflates to aldehydes mediated by nickel(II) and chromium(II) salts[1]

Leah P. Easton and Gregory R. Dake

Abstract: Enol trifluoromethanesulfonates (triflates) derived from *N*-protected lactams undergo nickel(II)-chloride- and chromium(II)-chloride-promoted carbonyl additions to aldehydes. The yields of this process range from 42%–84%.

Key words: nickel(II) chloride, chromium(II) chloride, carbonyl addition, lactam-derived enol triflate.

Résumé : Sous l'influence du chlorure de nickel(II) ou du chlorure de chrome(II), les trifluorométhanesulfonates (triflates) d'énol obtenus à partir de lactames *N*-protégés donnent lieu à des réactions d'addition de carbonyles avec formation d'aldéhydes avec des rendements qui vont de 42% à 84%.

Mots clés : chlorure de nickel(II), chlorure de chrome(II), addition de carbonyle, triflate d'énol dérivé de lactames.

[Traduit par la Rédaction]

Introduction

To investigate the use of semipinacol reactions for the construction of alkaloid natural products (1), our group became interested in the preparation of compounds such as **A** (Scheme 1). Functionalized lactams appeared to be reasonable starting materials for the preparation of compounds like **A**. Currently we use a synthetic protocol that involves the following: (*a*) conversion of the *N*-protected lactam to its enol trifluoromethanesulfonate (triflate); (*b*) formation of a vinylstannane from the enol triflate using a palladium(0)-catalyzed coupling reaction; and (*c*) transmetalation of the stannane to a more nucleophilic lithium or magnesium species, which is reacted with a carbonyl compound. Although this procedure works well and can be scaled up, it does have drawbacks. Specifically, the requirement of hexamethyldistannane in the sequence is a liability because of its expense and toxicity (2).[3] Because of the known facility of mixtures of nickel(II) and chromium(II) salts in promoting additions of vinyl halides or triflates to carbonyl compounds (3), we were intrigued by the possibility of using such a process on a triflate derived from a lactam, thus possibly removing the need for hexamethyldistannane. A precedent for this proposed transformation is the use of a lactone-derived enol triflate in a nickel(II)–chromium(II) salt promoted aldehyde addition reaction, reported by Nicolaou and co-workers (4). Despite the growing use of lactam-derived enol triflates as substrates for metal-promoted (or catalyzed) reactions (5), we were unsure of the plausibility of our hypothesis. We are aware, to the best of our knowledge, of no examples of nickel(II)–chromium(II)-promoted carbonyl addition reactions using lactam-derived enol triflates. Our successful investigations on the feasibility of this process are disclosed in this report.

Results and discussion

The known enol triflate **1**[4] was selected to probe the viability of the nickel(II)–chromium(II)-promoted carbonyl addition. Enol triflate **1** was easily formed by deprotonating *N*-*tert*-butoxycarbonyl-2-piperidone with lithium hexamethyldisilazide followed by enolate quenching with *N*-(5-chloro-2-pyridyl)-triflimide. Unlike enol triflates derived from 5- and 7-membered ring lactams, which can be difficult to store and handle,[5] **1** can be purified by column chromatography on silica gel and can be stored for weeks in the freezer. The reaction between **1** and benzaldehyde, using a variety of different conditions, was initially explored (Scheme 2 and Table 1).

A typical set of reaction conditions suitable for the nickel(II)–chromium(II) carbonyl addition process were

used. Treatment of **1** with excess benzaldehyde (6 equiv), in the presence of 6 equiv of chromium(II) chloride and nickel(II) chloride (2 mol%), in a 1:1 mixture of degassed DMF–THF mixture at room temperature for 15 h produced the desired adduct **2** in 60% isolated yield (entry 1). The structure of **2** was established by spectroscopic methods. The IR spectrum of **2** contained absorptions typical of both alcohol (3404 cm^{-1}) and carbonyl (1682 cm^{-1}) functional groups. Key signals in the ^1H NMR spectrum of **2** at δ 5.35 ppm (d, J = 9.2 Hz, 1H) and δ 1.29 ppm (s, 9H) could be attributed to the allylic methine proton and the protons on the *tert*-butyl group. It is noteworthy that the alkoxide that is presumably generated after the carbonyl addition does not cyclize into the *tert*-butyl carbamate protecting group to form an oxazolidinone (6).

The choice of solvent had a substantial effect on the course of this reaction. For example, no reaction was observed to take place when using THF as the sole solvent, and using a 1:1 mixture of degassed THF and DMSO produced **2** in only 10% yield (entry 2). Omitting the ether solvent and running the reaction in DMSO alone improved the process somewhat (26% yield of **2**, entry 3). An amide solvent was clearly superior, as running the reaction in DMF alone restored the yield to acceptable levels, 66% (entry 4). Sonication probably better disperses the chromium(II) chloride during the reaction, compared with simple stirring (4). Using stirring to agitate the reaction mixture in DMF resulted in a lowered yield of **2** of 50% (entry 5). Unfortunately, the use of a smaller amount of chromium(II) chloride (4 equiv) drastically reduced the amount of adduct **2** that was isolated after reaction (27%, entry 6). In contrast, the use of a substantial excess of benzaldehyde is not necessary. Adduct **2** was isolated in 63% yield when 2 equiv of benzaldehyde was used with DMF as solvent (entry 7). These conditions (using either 6 or 2 equiv of electrophile) were adapted as our "standard protocol" for this process.

The effect of the different protecting groups on the nitrogen of the enol triflate nucleophile was then examined (Scheme 3). Although the *N*-toluenesulfonyl derivative **3** did react as a nucleophile using these reaction conditions, the efficiency of the reaction was much lower in comparison with the reactions of **1**. For example, the reaction of **3** with benzaldehyde produced allylic alcohol **4** in 46% yield. Hexanal could also be employed as an electrophile. Allylic alcohol **5** was isolated from the reaction of **3** and hexanal in 42% yield. Attempts to use other common protecting groups for

nitrogen, such as benzyloxycarbonyl (Cbz), trifluoromethansulfonyl (Tf), or benzoyl, were complicated by either the instability of the enol triflates or the formation of several byproducts during the chromium(II)–nickel(II)-promoted carbonyl addition process.

Using the standard conditions, a variety of aldehydes were then reacted with **1** to probe the scope and limitations of the electrophilic partner (Scheme 4 and Table 2). Electron-rich aromatic aldehydes such as *p*-anisaldehyde (entry 1) or furfural (entry 2) could be used in this reaction, although the yields of the products **6** and **7** were modest: 42% and 49%, respectively. Interestingly, aliphatic aldehydes react more effectively, and the carbonyl addition products could be isolated in much higher yields. As examples, the reactions of **1** with hexanal and isopropanal, using the standard conditions, resulted in the formation of allylic alcohols **8** and **9** in 84% and 76% isolated yields, respectively (entries 3 and 4). Considering the previous use of the chromium(II)–nickel(II)-promoted addition reaction in complex total synthesis (7), it was not surprising that common organic functional groups are compatible with these conditions. Functionalities such as acetals (entry 5, **10**, 62% yield), ethers (entry 6, **11**, 71% yield), and alkynes (entry 7, **12**, 51% yield) were well tolerated in the reaction of **1** under these conditions. Interestingly, attempts to react **1** with cinnamaldehyde were unsuccessful because of problems with decomposition.

Although the desired transformation does occur, this process has its own drawbacks. The first is the large amount of chromium(II) chloride that is required for reaction. Reducing the number of equivalents of chromium(II) salts would substantially improve this process. The lack of reactivity in ethereal solvents is a second handicap that we have uncovered. Although nitrogen-based ligand scaffolds have been used to generate catalytic versions of this carbonyl-addition reaction, those processes typically use THF as a solvent or co-solvent (8). Our preliminary investigations have found that no reaction occurs in THF, despite the presence of external ligands. Finally, the sonication of reaction mixtures is much more easily performed on a small scale. An alternative method for agitation would be required for large-scale reactions. The convenient resolution of all of these issues would generate a generally useful synthetic protocol.

Conclusion

Lactam-derived enol triflates have been demonstrated to undergo nickel(II)–chromium(II) salt mediated carbonyl addition reactions with aldehydes to produce functionalized allylic alcohols. Interestingly, reactions involving aliphatic aldehydes are typically higher yielding compared with aromatic aldehydes. With the feasibility of this protocol established, efforts to render this process *catalytic* in nickel and chromium (9) and to apply this reaction in the construction of nitrogen-containing natural products are underway in our laboratories.

Experimental

General information

All reactions were carried out under a nitrogen atmosphere in flame-dried glassware. Tetrahydrofuran was distilled from sodium, using benzophenone as an indicator. Dimethyl sulfoxide was distilled from calcium hydride under reduced pressure. Dimethyl formamide was dried over molecular sieves (4 Å) and degassed by sparging with nitrogen gas. Commercially available aldehydes (Aldrich) were distilled over sodium sulfate under reduced pressure prior to use. Nickel chloride (98%) was purchased from Aldrich and chromium chloride (99.9%) was purchased from Strem.

Thin-layer chromatography (TLC) was performed on DC-Fertigplatten SIL G-25 UV_{254} pre-coated TLC plates. Sonication was carried out using a Branson 3200 sonicator. Melting points were performed using a Mel-Temp II apparatus (lab devices U.S.A.) and are uncorrected. Infrared (IR) spectra were obtained using a PerkinElmer 1710 FT-IR spectrometer. Proton nuclear magnetic resonance (^{1}H NMR) spectra were recorded in deuterated chloroform, using a Bruker WH-400 spectrometer. Carbon nuclear magnetic resonance (^{13}C NMR) spectra were recorded in deuterated chloroform, using a Bruker AV-300 spectrometer. Chemical shifts (δ) are reported in parts per million (ppm) and are referenced to deuterated chloroform (δ 7.24 ppm ^{1}H NMR; δ 77.0 ppm ^{13}C NMR). Low-resolution mass spectra (LR-MS) were recorded using either a Kratos-AEI model MS 50 or an Aligent 6890 series GC with a 5973 MS. Microanalyses were performed on either a Carlo Erba Elemental Analyzer Model 1106 or a CHN-O Elemental Analyzer Model 1108.

tert-Butyl 6-{[(trifluoromethyl)sulfonyl]oxy}-3,4-dihydropyridine-1(2*H*)-carboxylate (1)

To a solution of 367 mg of 1,1,1,3,3,3-hexamethyldisilazane (2.27 mmol) in 3 mL of THF at –78 °C was added 1.57 mL of *n*-butyllithium in hexane (2.26 mmol, 1.44 mol L^{-1}). After stirring for 20 min, the mixture was transferred via cannula to a solution of 300 mg of 1-(*tert*-butoxycarbonyl)piperidin-2-one (1.50 mmol) in 5 mL of THF at –78 °C. After stirring for 2 h, 1.18 g of *N*-(5-chloro-2-pyridyl)triflimide (3.00 mmol) in 5 mL of THF was added. The cold bath was removed, and the mixture was allowed to warm to 25 °C. After 1 h the reaction was quenched with 8 mL of a 10% aqueous solution of sodium hydroxide. The aqueous phase was extracted with three 5 mL portions of diethyl ether. The combined ethereal extracts were dried over sodium sulfate, filtered, and concentrated using rotary evaporation. Purification via flash chromatography (1:19 ethyl acetate – hexanes, containing 1% triethylamine) on silica gel gave 415 mg (84%) of a clear colourless oil. IR (film) (cm^{-1}): 1726, 1684, 1422, 1211, 1141. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 5.26 (t, *J* = 3.97 Hz, 1H), 3.60–3.56 (m, 2H), 2.24 (td, *J* = 6.71, 3.97 Hz, 2H), 1.77–1.70 (m, 2H), 1.47 (s, H).

Representative procedure for the coupling of lactam-derived enol triflates with aldehydes: _tert_-butyl 6-[hydroxy(phenyl)methyl]-3,4-dihydropyridine-1(2*H*)-carboxylate (2)

A round-bottom flask was charged with 111 mg of chromium(II) chloride (0.91 mmol) and 0.4 mg of nickel(II) chloride (0.003 mmol) and a stirbar. After capping the flask with a septum, DMF (1 mL) was added, and the thick green suspension was stirred for 10 min. Benzaldehyde (96 mg, 0.91 mmol) and a solution of **1** (50 mg, 0.15 mmol) in 1 mL of DMF were added sequentially. The flask containing the reaction mixture was placed in a sonication bath and sonicated for 15 h. Diethyl ether (5 mL) and water (2 mL, containing 1% of triethylamine) was added. The aqueous phase was extracted with three 3 mL portions of diethyl ether. The combined organic extracts were dried over sodium sulfate, filtered, and concentrated in vacuo. Purification via flash chromatography (1:19 ethyl acetate – hexanes, containing 1% triethylamine) on silica gel gave 29 mg (66%) of clear colourless oil. IR (film) (cm^{-1}): 3404, 1682, 1394, 1368, 1256, 1160. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 7.34–7.15 (m, 5H), 5.85 (bs, 1H), 5.45 (t, *J* = 3.66 Hz, 1H), 5.35 (d, *J* = 9.16 Hz, 1H), 3.73 (dt, *J* = 12.51, 4.27 Hz, 1H), 3.03 (t, *J* = 10.99 Hz, 1H), 2.19–2.13 (m, 2H), 1.83–1.68 (m, 2H), 1.29 (s, 9H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 155.6, 143.7, 142.9, 129.1, 127.9, 127.2, 119.7, 82.6, 67.2, 46.9, 29.4, 24.5, 24.4. LR-MS (EI) *m*/*z* (relative intensity): 289 ([M^+ + 1], 3), 233 (17), 215 (17), 189 (60), 187 (12), 172 (12), 171 (38), 170 (84), 156 (16), 143 (18), 130 (21), 115 (12), 105 (15), 82 (13), 77 (24), 59 (19), 57 (100), 55 (18).

1-[(4-Methylphenyl)sulfonyl]-1,4,5,6-tetrahydropyridin-2-yl trifluoromethanesulfonate (3)

To 1-(*p*-toluenesulfonyl)-piperidin-2-one (200 mg, 0.79 mmol) in THF (6 mL) at –78 °C was added a solution of potassium bis(trimethylsilyl)amide (189 mg, 0.947 mmol) in 2 mL of THF. After stirring for 45 min at –78 °C, a solution of 338 mg of *N*-phenyltriflimide (0.37 mmol) in 3 mL of THF was added. The mixture was allowed to warm to 25 °C. After 1 h the reaction was quenched with 5 mL of a saturated aqueous ammonium chloride solution. The aqueous phase was extracted with three 4 mL portions of dichloromethane. The combined extracts were dried over sodium sulfate, filtered, and concentrated via rotary evaporation. Purification via flash chromatography (1:3 ethyl acetate – hexanes, containing 1% triethylamine) on silica gel gave 195 mg (64%) of white crystals, mp 47 to 48 °C. IR (KBr) (cm^{-1}): 3436, 1674, 1425, 1362, 1213, 1173. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 7.75 (d, *J* = 8.24 Hz, 2H), 7.32 (d, *J* = 8.24 Hz, 2H), 5.43 (t, *J* = 3.97 Hz, 1H), 3.60–3.64 (m, 2H), 2.42 (s, 3H), 2.09–2.14 (m, 2H), 1.53–1.45 (m, 2H).

Synthesis, resolution, and application of 2,2′-bis(diphenylphosphino)-3,3′-binaphtho[*b*]furan (BINAPFu)[1]

Neil G. Andersen, Masood Parvez, Robert McDonald, and Brian A. Keay

Abstract: (±)-2,2′-Bis(diphenylphosphino)-3,3′-binaphtho[2,1-*b*]furan (BINAPFu) was synthesized from 2-naphthoxyacetic acid in a five-step sequence in 62% overall yield. A variety of reported resolution procedures for biaryl bisphosphines did not work with (±)-BINAPFu; thus, a new resolution method was developed, involving the Staudinger reaction of the aforementioned racemate of BINAPFu with an enantiopure camphor sulfonyl azide derivative. The resulting diastereomeric phosphinimines were separated by flash chromatography. Subsequent hydrolysis to the corresponding bis-phosphine oxide and trichlorosilane reduction provided enantiopure BINAPFu. The absolute stereochemical configuration of BINAPFu was established by X-ray crystallography. BINAPFu was compared with commercially available 2,2′-bis(diphenylphosphino)-1,1′-binaphthalene (BINAP) in Pd(0)-catalyzed intermolecular Heck reactions. Investigation of the Heck arylation of 2,3-dihydrofuran showed BINAPFu to be more efficacious than BINAP in dioxane at 30 °C. A variety of phosphorus selenides were prepared, and the $^1J_{P\text{-}Se}$ coupling constants measured, to obtain a comparative scale of parent phosphine basicity. The phosphorus atoms in BINAPFu were found to be electron deficient when compared with BINAP but slightly more electron rich than trifurylphosphine.

Key words: naphthofurans, atropisomers, electron-deficient phosphines, asymmetric Heck reactions, Staudinger reaction.

Résumé : Utilisant l'acide 2-naphtoxyacétique comme produit de départ, on a réalisé la synthèse en cinq étapes du (±)-2,2′-bis(diphénylphosphino)-3,3′-binaphto[2,1-*b*]furane (BINAPFu), avec un rendement global de 62 %. Plusieurs méthodes connues de résolutions ont été tentées sans succès sur le (±)-BINAPFu; on a donc développé une nouvelle méthode de résolution impliquant la réaction du (±)-BINAPFu avec un dérivé énantiopur de l'azoture de camphresulfonyle. On a séparé les phosphinimines diastéréomères résultantes par chromatographie éclair. L'hydrolyse subséquente de l'oxyde de bis-phosphine correspondante et une réduction à l'aide de trichlorosilane ont conduit au BINAPFu énantiopur. La configuration stéréochimique absolue du BINAPFu a été établie par diffraction des rayons X. On a comparé le BINAPFu au 2,2′-bis(diphénylphosphino)-1,1′-binaphtalène (BINAP) dans les réactions intermoléculaires de Heck catalysées par le Pd(0). Une étude de l'arylation de Heck du 2,3-dihydrofurane a montré que le BINAPFu est plus efficace que le BINAP, dans le dioxane, à 30 °C. On a préparé une variété de séléniures de phosphore et on a mesuré les constantes de couplage $^1J_{P\text{-}Se}$ afin d'obtenir une échelle comparative de la basicité de la phosphine de base. On a trouvé que les atomes de phosphore du BINAPFu sont déficients en électron par comparaison avec le BINAP, mais qu'ils sont plus riches en électrons que la trifurylphosphine.

Mots clés : naphtofuranes, atropisomères, phosphine déficiente en électron, réaction de Heck asymétriques, réaction de Staudinger.

Introduction

Since Noyori and co-workers' (1) introduction of 2,2′-bis(diphenylphosphino)-1,1′-binaphthyl (BINAP) as a chiral ligand for asymmetric catalysis, numerous workers have shown that remarkably high degrees of enantioselectivity can be obtained using this phosphine in a wide variety of transition-metal-mediated organic reactions (2). Based on the superior results often realized using BINAP in asymmetric transformations, coupled with the recent interest in 2-furyl phosphine ligands (3), a project was undertaken to develop an axially stereogenic diphosphine ligand that incorporates the 2-furyl group. At the onset of this endeavor, a literature search revealed that no such structure had ever been reported. Moreover, it was clear that very little was known about how phosphine σ-donor ability affected the

course of enantioselective reactions. However, many workers have now sought to develop chiral 2-furyl phosphine ligands for asymmetric synthesis, and several reports of asymmetric reactions using these ligands have recently been disclosed (4, 5). These investigations have been prompted, in part, by recent evidence that suggests that less electron-rich ligands are or should be advantageous in some metal-mediated organic processes. For example, Shibasaki and co-workers (6) have recently developed 2,2′-bis(diphenylarsino)-1,1′-binaphthyl (**1**, BINAs) and have shown this poorly donating ligand to be more effective than BINAP **2** for an intramolecular asymmetric Heck reaction (Scheme 1) (7). In addition, Amatore and co-workers (8) have studied the oxidative addition of phenyl iodide with in situ generated palladium(0) complexes of triphenylphosphine and TFP, showing that in DMF, $\{Pd(dba)_2 + n(trifurylphosphine)\}$ is always more reactive than $\{Pd(dba)_2 + nPPh_3\}$, for $n \geq 2$ (7). These reports, in conjunction with our interests in the asymmetric polyene cyclization (9), led to the development of a novel 3,3′-bifuryl-derived diphosphine analogue of BINAP (Scheme 1), namely, BINAPFu **3** (10).

To develop a C_2-symmetric furyl phosphine analogue of BINAP, it was conceived that a prudent design would retain the bis(diphenylphosphino) moieties and incorporate the furyl functionality into the biaryl framework. In this way, it was felt that the electronic properties of the phosphine ligand could be altered with minimal perturbation of the chiral pocket structure. Since Benincori and co-workers (5*i*, 11) have concluded that the BIBENFu **4** ligand is not configurationally stable at room temperature, it was decided to prepare the more sterically bulky bisnaphtho[*b*]furan skeleton, as PM3 semi-empirical calculations on **3** indicated that the rotational energy of the bifuryl bond in **3** would be quite high. This paper describes the design aspects, synthesis, resolution, and application of the BINAPFu **3** ligand.

Synthesis of (±)-BINAPFu 3

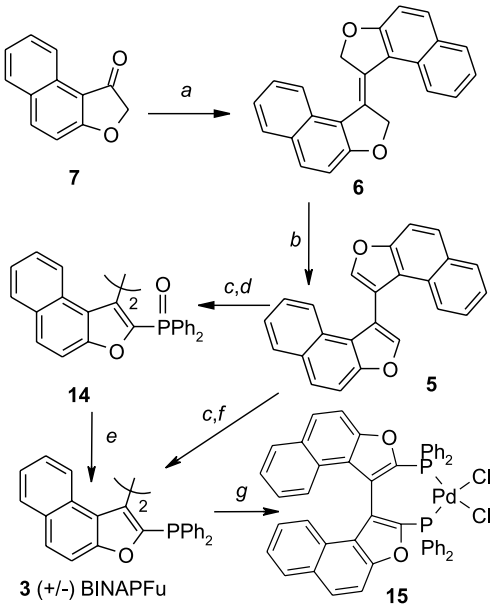
Two initial routes to the synthesis of **3** were unsuccessful (12) and led to a design in which the key reaction involved a McMurry coupling. The low-valent titanium homocoupling of aldehydes and ketones, developed independently by Mukaiyama et al. (13), Tyrlik et al. (14), and McMurry et al. (15), has been applied in a wide variety of contexts to prepare symmetrical olefins (16). It was thought that the BINAPFu bifuryl bond could be constructed via a McMurry coupling of ketone **7** followed by DDQ oxidation of the resultant olefin **6** (Scheme 2). Finally, introduction of the diphenylphosphino groups into **5** would give (±)-BINAPFu **3**.

Although ketone **7** has been previously reported (17), the syntheses were characterized by low product yields (<35%) and difficult isolation procedures. It was therefore decided that a new, efficient synthesis of the required ketone **7** should be developed. Since 1-acetyl-2-hydroxynaphthalene (**8**) was readily available, it was reasoned that α-chlorination of the ketone function to give **9**, followed by 5-*exo-trig* ring closure, would provide an expedient route to the desired ketone **7** (Scheme 3). Unfortunately, several chlorination reagents, including sulfuryl chloride (18) and hexachloro-2,4-cyclohexadienone (19), failed to provide α-chloroketone **9** in good yields. Recourse was sought in the three-step α-bromination of ketone **10** via TMS enol ether **11** (Scheme 3). Treatment of hydroxy-ketone **8** with 1.1 equiv of *tert*-butyldimethylsilyl chloride in CH_2Cl_2 and Et_3N furnished TBS ether **10** in 89% yield. Although the TMS enol ether **11** could be formed using LHMDS and TMSCl in an ethereal solvent, much more consistent results were obtained when ketone **10** was treated with TMSOTf in a mixture of CH_2Cl_2 and triethylamine. Bromination of enol silyl ether **11** with

© 2004 NRC Canada

1 equiv of Br_2 in CCl_4 proceeded with loss of TMSBr to furnish α-bromo ketone **12** in modest yield. Cleavage of the TBS ether under standard conditions occurred with concomitant ring closure, to provide the desired naphthoketone **7** in 61% overall yield. Although this four-step synthetic sequence provided the desired ketone **7** in moderate yield, without the need for costly purification routines, the use of expensive protecting groups and reagents rendered this method somewhat infeasible for large-scale preparation.

To address these concerns, an alternative synthesis of compound **7** was conceived whereby readily available 2-naphthoxyacetic acid (**13**) could be subjected to Friedel–Crafts acylation conditions to provide the desired compound directly (Scheme 3). Treatment of acid **13** with Eaton's reagent (20) at ambient temperature for 18 h afforded the desired ketone **7** in 68% yield. Alternatively, preparation of the corresponding acyl chloride, under standard conditions, and subsequent reaction with $AlCl_3$ gave naphthoketone **7** in 95% yield. Interestingly, in both cases, acylation occurred regiospecifically in the 1-position to give the desired product **7** with remarkable purity. This procedure, which does not require any purification steps, can easily be performed on a 50 g scale to provide ketone **7** in excellent yield.



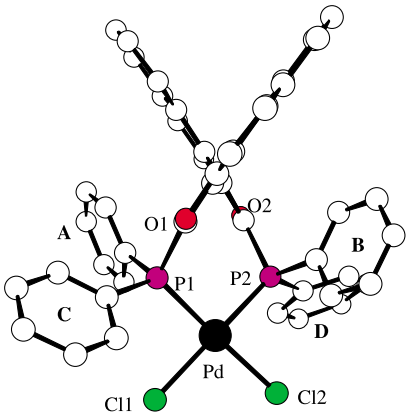
Reductive coupling of compound **7** with $TiCl_4$ and zinc–copper couple (21) in refluxing DME smoothly provided olefin **6** in good yield (Scheme 4). Activated zinc dust (22) worked equally as well for this purpose, giving biaryl **5** in 78% isolated yield after DDQ oxidation (23). ^{1}H NMR analysis of compound **6** showed that the product had been formed essentially as a single isomer (>95%), which was assigned the *E* configuration on the basis of steric arguments. Owing to facile carbon-carbon double bond migration, olefin **6** could not be fully characterized. Upon oxidation with DDQ, the broad singlet (δ: 5.25 ppm) that integrated as four protons in the ^{1}H NMR spectrum of **6** was replaced by a sharp singlet (δ: 7.87 ppm) that represented the two furan α-protons in biaryl **5**.

Installation of the bis(diphenylphosphino) moieties was accomplished by lithiation of the biaryl scaffold **5** with 2.5 equiv of *t*-BuLi and subsequent treatment of the resulting dianion with freshly distilled diphenylphosphinic chloride. This provided phosphine oxide **14** in 88% yield (Scheme 4). Reduction of the oxide **14** with trichlorosilane in a mixture of xylenes and triethylamine furnished (±)-BINAPFu (**3**) in >95% yield. Alternatively, lithiation of biaryl **5** followed by treatment of the resultant dianion with 2.0 equiv of chlorodiphenylphosphine gave (±)-BINAPFu **3** directly in 91% yield.

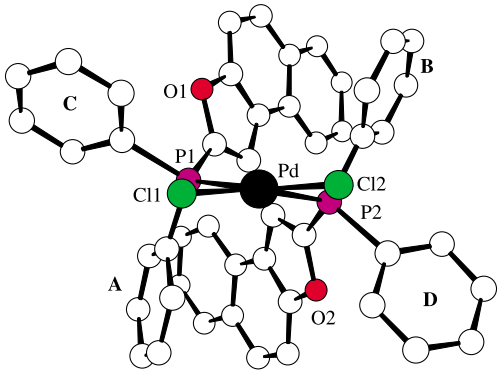
Structural characterization of (±)-BINAPFu 3

As stated previously, a fundamental aspect of the ligand design required that the 2-furyl groups be incorporated in such a way that the electronic properties of the phosphorus atoms may be altered with as little perturbation of the chiral pocket structure as possible. To investigate the success of the ligand design with respect to this requirement, the palladium(II) chloride complex of BINAPFu **15** was prepared (5*i*) and analyzed by single crystal X-ray diffraction (Fig. 1). Crystals of compound **15** were obtained by slow diffusion of

Scheme 4. 8.2 equiv Zn dust, 2.0 equiv $TiCl_4$, DME, reflux, 18 h; (*b*) 1.0 equiv DDQ, benzene, reflux, 4 h, 78% (2 steps); (*c*) 2.5 equiv *t*-BuLi, Et_2O, rt, 2 h; (*d*) 2.0 equiv $PPh_2(O)Cl$, rt, 12 h, 88%; (*e*) 20 equiv $SiCl_3H$, 24 equiv Et_3N, xylenes, 150 °C, 3 h, >95%; (*f*) 2.0 equiv PPh_2Cl, rt, 12 h, 91%; (*g*) 1.0 equiv $(CH_3CN)_2PdCl_2$, DCM, rt, 28 h, 93%.



Et_2O into an acetone-saturated solution of the complex under an argon atmosphere.



Comparing the projections of [(±)-BINAPFu]$PdCl_2$ (**15**) with Hayashi's [(*R*)-BINAP]$PdCl_2$ structure **16** (24), a few structural differences are immediately apparent. Whereas two of the phenyl rings (A and B) in the [(*R*)-BINAP]$PdCl_2$ complex **16** π-stack with the binaphthalene framework, the corresponding phenyl groups in compound **15** (A and B) do not show perpendicular relationships with the binaphtho[*b*]furan system. Also noteworthy in the [(±)-BINAPFu]$PdCl_2$ structure **15** is that the square planar geometry about the palladium atom seems to be less distorted than in the corresponding (*R*)-BINAP complex **16**. These observations suggest that the chiral pocket formed in the [BINAPFu]$PdCl_2$ complex **15** is somewhat less rigid than that obtained with the BINAP ligand **16**. However, several similarities are also observed upon comparing [BINAP]$PdCl_2$ **16** and [BINAPFu]$PdCl_2$ **15**. In both structures, two of the phenyl rings (C and D) project outward toward the coordination sites occupied by the chloride ligands. The [BINAP]$PdCl_2$ **16** bite angle (25), defined by the P1-Pd-P2 vertex, of 92.7° compares well with that measured for the [BINAPFu]$PdCl_2$ **15** (93.4°). Values for the Pd—P (**16**: 2.245 Å; **15**: 2.264 Å) and Pd—Cl (**16**: 2.350 Å; **15**: 2.333 Å) bond lengths compare quite favorably, although slight differences can be seen because of the reduced electron-donor ability of the BINAPFu ligand. As expected, the mean Pd—P bond length is slightly longer in the [BINAPFu]$PdCl_2$ complex, owing to the reduced σ-donor ability of the phosphorus atoms relative to BINAP. As a result, the Pd—Cl bond lengths are slightly shorter in compound **15**. Given the structural changes that had to be made to incorporate the 2-furyl moieties, it was felt that the struc-

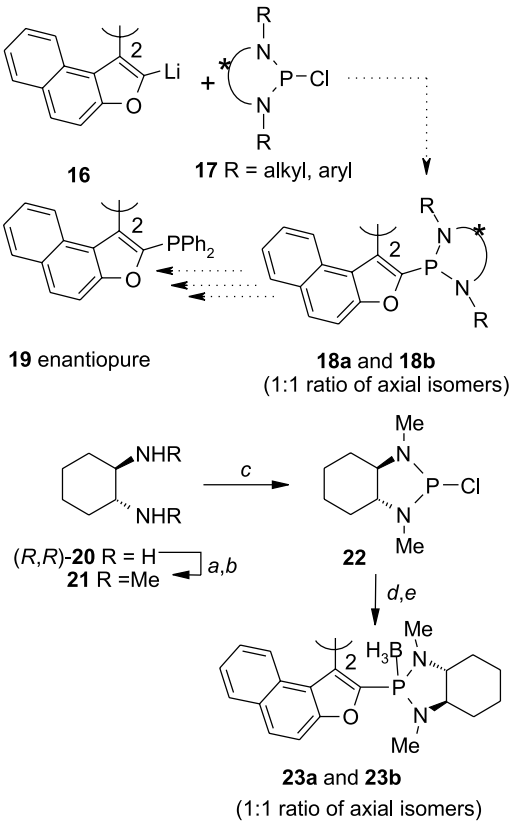
tural homology between the two organometallic complexes was great enough to warrant further investigation with the BINAPFu ligand.

Resolution of (±)-BINAPFu 3

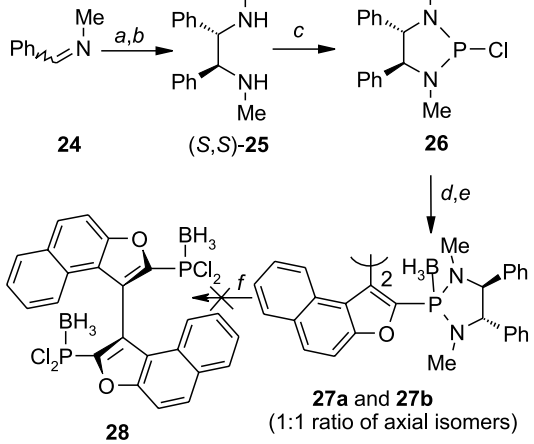
Subsequent to developing a simple, highly efficient synthesis of (±)-BINAPFu **3**, attention focused on finding a method for obtaining the two pure optical antipodes. To achieve this goal, it was first necessary to find a convenient method for determining the enantiopurity of diphosphine **3**. Fortunately, (±)-BINAPFu **3** could be readily separated by analytical HPLC using a Chiralcel® OJ column (25 °C; 95:5 MeOH:EtOH; 0.5 mL min^{-1}; 270 nm UV detection), indicating that the rotational barrier of the biaryl axis was of sufficient magnitude to impart optical activity at room temperature. Although preparative HPLC columns employing similar chiral stationary phases are commercially available (26), optical resolution of the BINAPFu ligand in large quantities using this method was deemed to be infeasible.

Although several methods for achieving optical resolution of stereogenic organophosphorus compounds are known (27), efforts were initially focused on procedures that have been applied to BINAP and related C_2-symmetric diphosphines. Unfortunately, the following reported procedures did not afford a suitable resolution method for (±)-BINAPFu **3**: (*a*) co-crystallization of phosphine oxide **14** with (–)-DBTA or (1*S*)-(+)-10-camphorsulfonic acid (28); (*b*) using enantiopure palladium(II) complexes with (*S*)-*N*,*N*-dimethyl-α-phenylethylamine or (*S*)-*N*,*N*-dimethyl-α-(2-naphthyl)ethylamine (29–31); (*c*) via formation of phosphonium salts with enantiopure organohalides like (*S*)-(+)-citronellyl bromide, (*S*)-(+)-citronellyl iodide (32), or (*S*)-(+)-1-iodo-2-methylbutane; and (*d*) attempts to resolve the bis-phosphonium salt



© 2004 NRC Canada

of **3** (generated with 2 equiv of iodomethane) by reaction with silver hydrogen dibenzoyl-L-tartrate (Ag-DBHT) (33) or silver (1*S*)-(+)-10-camphorsulfonate (34).



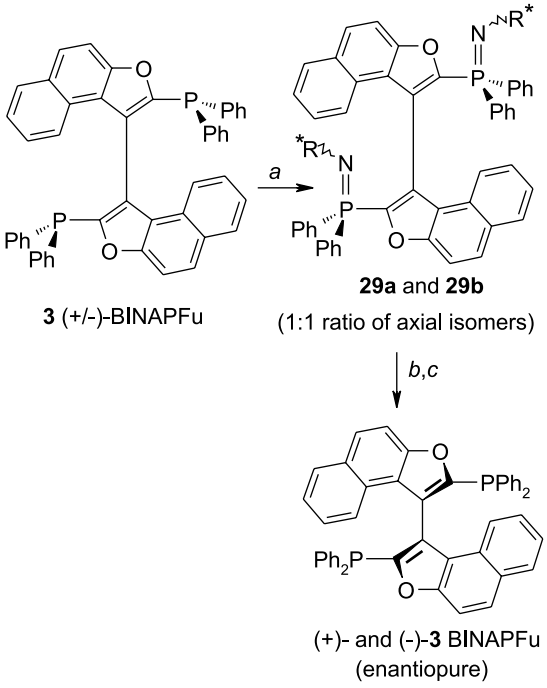
Although the synthesis developed for the BINAPFu ligand (vide supra) is short and efficient, failure to identify a suitable method for obtaining the optically pure material via known resolution methods led to the consideration of alternative synthetic routes. It was postulated that an enantiopure electrophile of type **17** could potentially be reacted with lithiated biaryl **16** to give bis-phosphonamide **18** as a 1:1 mixture of diastereomers (35) (Scheme 5). Such an approach would thus install the required 2,2′-phosphorus atoms while appending a chiral auxiliary for optical resolution. Separation of the resulting diastereomer mixture and subsequent synthetic manipulation of each pure isomer, **18a** and **18b**, would then provide routes to the optically pure BINAPFu antipodes. Following this general scheme, commercially available *trans*-1,2-cyclohexane diamine was resolved (36), and the (*R*,*R*)-isomer (37) **20** was converted to the corresponding *N*,*N*′-dimethyl derivative **21** according to a literature procedure (38) (Scheme 5). Diamine **21**, thus obtained, was treated with 1 molar equivalent of phosphorus trichloride, according to a standard procedure (39), to furnish chlorophosphine **22** in 72% isolated yield. This highly moisture- and oxygen-sensitive (39) compound was prepared using Schlenk techniques under an atmosphere of argon and was used without purification. Trapping dianion **16**, prepared as previously described, with 1,3-diazaphopholidine derivative **22** and subsequent reaction with BH_3·DMS provided a 1:1 mixture of diastereomers **23a** and **23b**, respectively (Scheme 5). Bis-borane complex **23** was prepared in situ to prevent potential complications due to air oxidation of the phosphine precursor (39). Although separation of compounds **23a** and **23b** could not be achieved using standard recrystallization or flash chromatographic techniques, a small sample (~3 mg) of each pure diastereomer was obtained by preparative HPLC, using a reversed-phase C_{18} column. While this labor-intensive and costly separation technique clearly did not provide large quantities of resolved material, the obtainment of diastereomerically pure borane adducts **23a** and **23b** was highly encouraging. Moreover, it was postulated that by simply changing the diamine used to prepare phosphoramidous chloride **17** (Scheme 5), it may be possible to prepare a more readily separable mixture of axial diastereomers.

Diamine **25** was prepared from **24** (40) and resolved (41) according to standard literature procedures (Scheme 6). Diazaphospholidine **26** (42) was subsequently prepared upon treatment of (*S*,*S*)-(–)-diamine **25** with 1 equiv of phosphorus trichloride in Et_3N–Et_2O solution. Further reaction with 2,2′-dilithiated binaphthofuran **16** and BH_3·DMS furnished a 1:1 mixture of axially isomeric borane adducts **27a** and **27b** in 71% yield. Fortunately, separation of stereoisomers **27a** and **27b** was facile by fractional crystallization from a $CHCl_3$–hexanes solvent system. Under these conditions, compound **27a** selectively crystallized, leaving highly enriched (>95%) isomer **27b** in the mother liquor. The latter compound could be further purified by flash chromatography. With pure borane adducts **27a** and **27b** in hand, attention was focused on removing the diamine moiety and installing the required phenyl substituents.

Scheme 5. (*a*) 2.1 equiv ethyl chloroacetate, 4.6 equiv NaOH, H_2O, 0 °C, 2 h, 82%; (*b*) 8.5 equiv $LiAlH_4$, THF, rt, 1 h, 92%; (*c*) 1.0 equiv PCl_3, 2 equiv NEt_3, Et_2O, –40 °C, 72%; (*d*) 0.5 equiv compound **16**, Et_2O, rt, 1.5 h; (*e*) 2 equiv BH_3·DMS, rt, 24 h, 74% (2 steps).

Scheme 6. (*a*) 1.5 equiv Mg, 1.5 equiv $TiCl_4$, 4 mol% $HgCl_2$, THF, 0 °C, 12 h, 61%; (*b*) optical resolution with L-(+)-tartaric acid; (*c*) 1.0 equiv PCl_3, 2 equiv NEt_3, Et_2O, –40 °C, 81%; (*d*) 0.5 equiv compound **16**, Et_2O, rt, 1.5 h; (*e*) 2 equiv BH_3·DMS, rt, 24 h, 71% (2 steps); (*f*) 8 equiv anhyd HCl, Et_2O.

Supported by literature precedent (35, 43), it was envisioned that the diamine chiral auxiliary could be cleaved from borane adduct **27a** upon treatment with anhyd HCl, providing enantiopure chloride **28** (Scheme 6). Subsequent



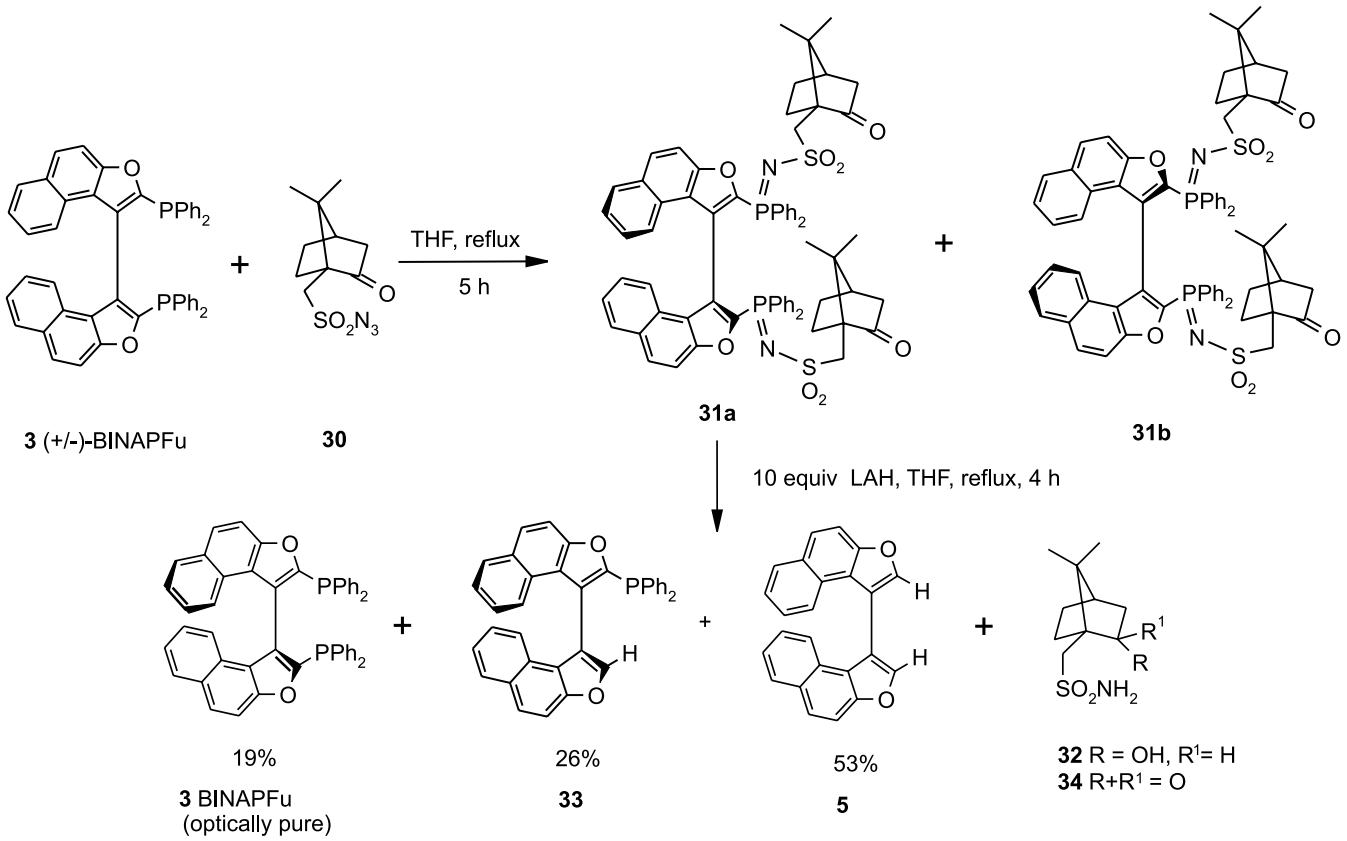
© 2004 NRC Canada

reaction of **28** with 4 equiv of phenyllithium or phenyl Grignard and removal of the BH_3 protecting group would then furnish the desired BINAPFu **3** in optically pure form. Following this approach, isomerically pure compound **27a** was treated with 8 molar equivalents of HCl (1.0 mol L^{-1} solution in Et_2O) at 0 °C for 1 h. The mixture thus obtained was filtered under argon to remove (1*S*,2*S*)-*N*,*N*′-dimethyl-1,2-diphenylethylenediamine dihydrochloride, and the filtrate was treated with 5 equiv of phenyllithium at –40 °C. Under these conditions, a complex mixture of products was obtained, as evidenced by ^{31}P NMR analysis. Lowering the reaction temperature to –40 °C for the acid addition or using phenyl Grignard in place of phenyllithium failed to improve this result. Employing anhyd HCl(g) instead of the 1.0 mol L^{-1} ethereal solution also afforded a complex mixture of products. In all cases, isolation of the unwanted amine hydrochloride salt confirmed that cleavage of the P—N bonds was occurring under the reaction conditions. Low temperature ^{31}P NMR analysis indicated that complex mixture formation was occurring previous to the addition of the organometallic reagent. Other Brönsted acids, including MsOH and TFA in methanolic solution, afforded similar results. The failure to identify suitable conditions for cleaving the diamine chiral auxiliary from borane adduct **27a** led to the development of a new resolution procedure for phosphines.

As several of the known methods for phosphine resolution were unsuccessful, we decided to develop a new resolution to obtain enantiopure BINAPFu **3**. Consideration of the resolution methods already attempted (vide supra) suggested that a newly developed procedure should ideally act directly on BINAPFu **3** or the corresponding bis-phosphine oxide **14** to minimize the number of synthetic steps. Moreover, owing to the difficulties experienced in the CSA and DBTA resolution techniques, it was concluded that a successful route would likely involve appending the resolving agent via a covalent linkage, thus providing two discrete diastereomeric compounds. Based on unsuccessful attempts with the *ortho*-palladated resolving agents (29–31), the diastereomeric compounds obtained by appending a resolving agent to the phosphine ligand should be neutral intermediates, to allow for possible chromatographic separation. Finally, considering the impasse reached with diazaphospholidine compound **27a**, cleavage of the chiral auxiliary to furnish the desired optically pure phosphine **3** or phosphine oxide **14** should not require strongly acidic reaction conditions. With these parameters in mind, it was conceived that a Staudinger reaction (44) between (±)-BINAPFu **3** and 2 equiv of an enantiopure organoazide could potentially give a 1:1 mixture of diastereomeric phosinimines **29a** and **29b** (Scheme 7) if the P=N bond rotational barrier was low enough to prevent geometrical isomerism. A literature survey revealed that the P=N rotational barrier for simple phosphinimines has been calculated to be ca. 2.54 kcal mol^{-1} (45). Hence it was rationalized that P=N geometrical isomerism would likely not complicate the proposed resolution technique. Separation of the phosphinimine mixture and subsequent reductive cleavage of the resolving agent from each pure isomer with $LiAlH_4$ would then furnish the desired, enantiomerically pure antipodes.

To develop a resolution procedure for (±)-BINAPFu based on phosphinimine formation, a readily available and optically pure organoazide needed to be identified (46). (1*S*)-10-camphorsulfonyl azide was chosen as a possible resolving agent; it can be prepared in a single step from commercially available (1*S*)-(+)-10-camphorsulfonyl chloride (47). Treatment of (±)-BINAPFu **3** with 2 molar equivalent of enantiopure sulfonyl azide **30** smoothly provided a 1:1 mixture of diastereomeric phosphinimines **31a** and **32b** in near quantitative yield (Scheme 8). Fortunately, phosphinimines **31a** and **31b** could be readily separated by flash chromatography on silica gel using a 9:1 $CHCl_3$–CH_3CN eluent mixture. With isomerically pure phosphinimines **31a** and **32b** in hand, attention was now focused on identifying a method for removing the chiral auxiliary to give optically pure BINAPFu **3** or the corresponding phosphine oxide **14**.

Scheme 7. (*a*) 2 equiv enantiopure azide ($*RN_3$); (*b*) separate axial stereoisomers; (*c*) H^- reduction, Et_2O.



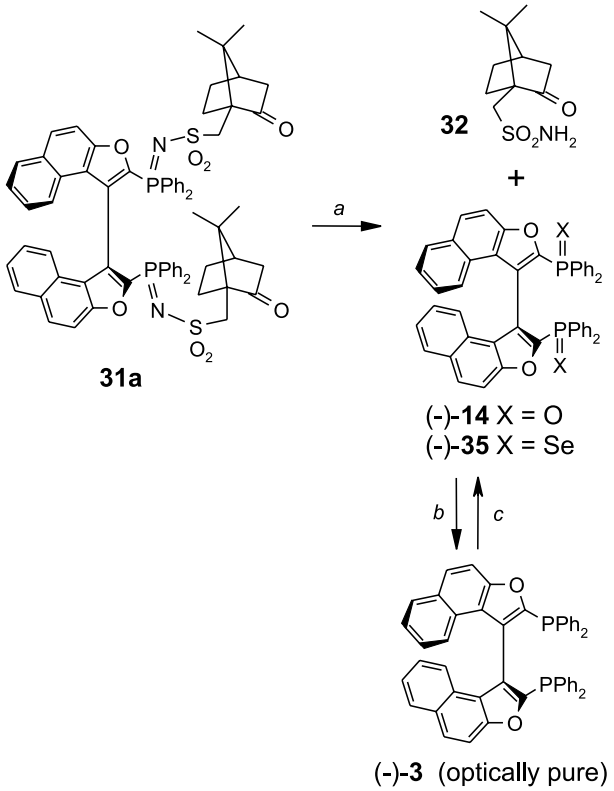
It was postulated that treatment of isomerically pure phosphinimine **31a** with excess $LiAlH_4$ would provide optically pure BINAPFu **3** along with isobornyl-10-sulfonamide **32** (Scheme 8) (48). Interestingly, heating compound **31a** with 10 equiv of LAH in THF resulted in the unexpected formation of 3,3′-binaphtho[*b*]furan (**5**) and monophosphine **33**. Although a small amount of the desired product was obtained and shown to be optically pure by HPLC analysis (Chiralcel® OJ column; 25 °C; 95:5 MeOH:EtOH; 0.5 mL min^{-1}; 270 nm UV detection), conditions to attenuate the formation of byproducts **5** and **33** could not be found. Performing this reaction at ambient temperature resulted in a similar product mixture, while employing weaker reducing agents, such as DIBAL or $NaBH_4$, failed to cleave the P=N bond.

Faced with the failure to prepare optically pure BINAPFu **3** in good yield via direct reduction of phosphinimine **31a**, it was postulated that the P=N bond could be cleaved using an aza-Wittig process (49). Hence, reaction of either compound **31a** or **31b** with CO_2 would afford optically pure phosphine

© 2004 NRC Canada

Scheme 8.

oxide **14** along with (1*S*)-10-camphorsulfonamide **34** (Scheme 8). Subsequent trichlorosilane reduction of phosphine oxide **14** thus obtained would then furnish the desired enantiopure BINAPFu ligand **3**. Surprisingly, bubbling CO_2 gas through a solution of isomerically pure phosphinimine **31a** in THF for a period of 4 h failed to cause any detectable cleavage of the P=N bond. Changing the solvent to acetone and lengthening the exposure time did not improve this result. Moreover, no reaction was observed upon refluxing compound **31a** in carbon disulfide for 24 h, suggesting that an aza-Wittig approach toward cleaving the phosphinimine moiety was not going to be feasible.

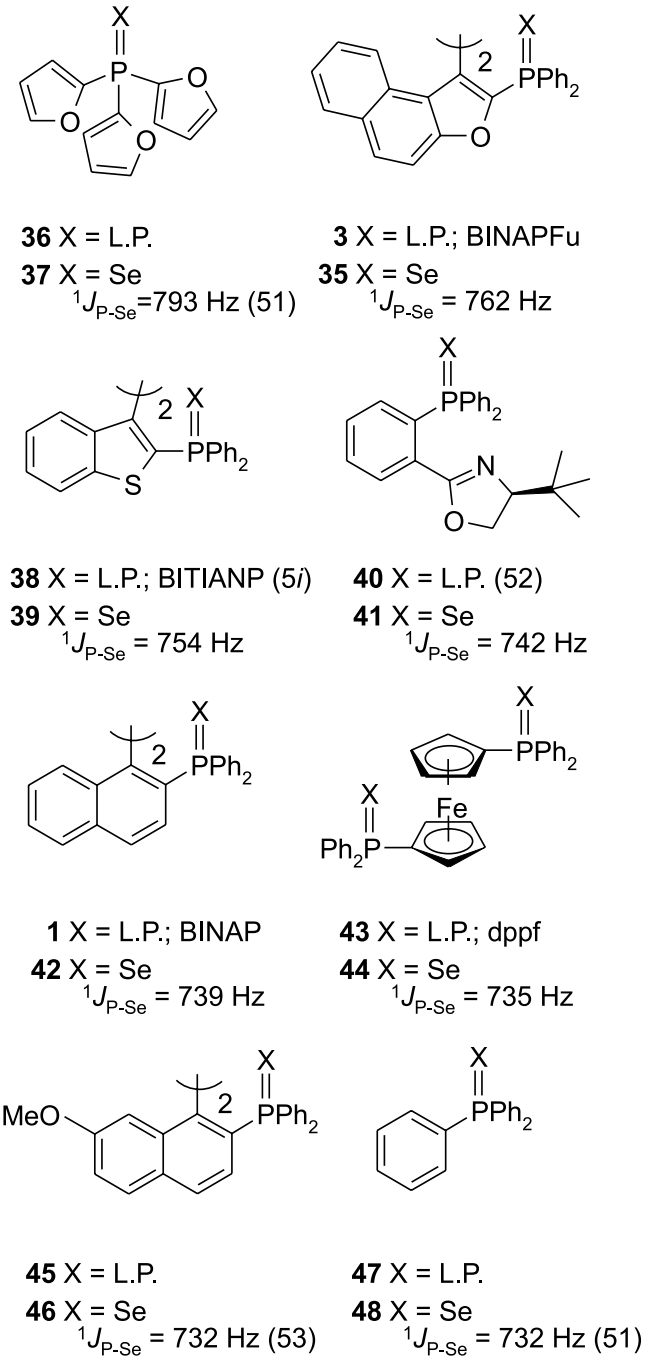


Since phosphinimine **31a** was inert towards aza-Wittig conditions, recourse was sought in the hydrolytic cleavage of the P=N bond using mineral acids (50). Stirring a solution of compound **31a** in THF and 1.5 mol L^{-1} H_2SO_4 at ambient temperature for 24 h failed to give any reaction, as evidenced by ^{31}P NMR analysis. Although this experiment did not result in the cleavage of the P=N bond, it is noteworthy that the binaphtho[*b*]furan system withstood the reaction conditions and was therefore more stable to acid than previously anticipated. Performing the reaction in refluxing THF, under otherwise identical conditions, cleanly provided the desired phosphine oxide, albeit in poor conversion (~15%). Subsequent experimentation revealed phosphine oxide **14** could be obtained in near quantitative yield by refluxing compound **31a** in a 3:2 mixture of 1,4-dioxane and 3 mol L^{-1} H_2SO_4 for 24 h (Scheme 9). Subsequent chromatographic removal of sulfonamide **32** and trichlorosilane reduction of the resulting phosphine oxide **14** provided BINAPFu **3** in excellent yield. HPLC analysis (vide supra) of the bisphosphine thus obtained showed a single peak at R_T = 23.7 min. Finally, optical rotation data revealed that phosphinimine **31a** yielded (–)-BINAPFu ($[\alpha]_D^{19}$ –203.0 (*c* 1.09, $CHCl_3$)). Performing the same hydrolysis–reduction sequence on phosphinimine **31b** provided (+)-BINAPFu **3** in near quantitative yield ($[\alpha]_D^{20}$ +201.8 (*c* 1.28, $CHCl_3$)). Heating the enantiopure (–)-BINAPFu ligand in *p*-xylenes at 150 °C for 7 days did not result in any racemization of the chiral axis, as evidenced by optical rotation and HPLC analysis.

Physical characterization of the BINAPFu ligand: Investigation of the σ-donor ability and absolute configuration assignment

Allen and Taylor (51) have reported that the $^1J(^{31}P\text{-}^{77}Se)$ coupling constant of phosphorus selenides may be used as a measure of parent phosphine basicity. A large coupling constant indicates high *s*-character of the phosphorus lone-pair orbital. In other words, poorly donating phosphine ligands exhibit large $^1J(^{31}P\text{-}^{77}Se)$ coupling constants. To gauge the donor ability of the BINAPFu ligand, a solution of optically pure (–)-**3** in $CHCl_3$ was heated with 10 molar equivalent of selenium powder for 5 h to afford bis-selenide **35** (Scheme 8). ^{31}P NMR analysis of selenide **35** clearly showed a strong singlet at +19.4 ppm with a satellite doublet ($^1J_{P\text{-}Se}$ = 762 Hz) due to $^{31}P\text{-}^{77}Se$ coupling. Performing the same reaction and ^{31}P NMR analysis on a variety of other commonly used phosphine ligands yielded the $^1J_{P\text{-}Se}$ coupling constants shown in Fig. 2. As the data clearly indi-

© 2004 NRC Canada



Scheme 9. (*a*) 3 mol L^{-1} H_2SO_4, 1,4-dioxane, 100 °C, 24 h, >95%; (*b*) 20 equiv $SiCl_3H$, 24 equiv Et_3N, xylenes, 150 °C, 3 h, >95%; (*c*) 10 equiv Se powder (100 mesh), $CHCl_3$, 60 °C, 5 h, 97%.

cates, the BINAPFu ligand **3** is far less basic than both triphenylphosphine (**47**) and BINAP (**1**). Moreover, BINAPFu **3** is significantly less basic that Benincori's benzothiophene-derived ligand BITIANP (**38**) (5*i*). Phosphinoaryl oxazoline ligand **40**, which has gained much attention in enantioselective allylic alkylation reactions (52), is also less basic than triphenylphosphine but significantly more basic than either BINAPFu or BITIANP. The small difference observed between the coupling constants for bis-selenides **42** and **46** suggest that this measure of σ-donor ability can be quite a sensitive technique. The latter selenide, derived from 7,7′-dimethoxy-2,2′-bis(diphenylphosphino)-1,1′-binaphthalene (**45**) (53), is slightly more basic than BINAP, owing to the electron-donating capacity of the remote 7,7′-methoxy substituents.

Having demonstrated that the electronic properties of BINAPFu **3** and BINAP **1** are dissimilar, with the former ligand resembling those of tri-2-furylphosphine (**36**), attention was focused on the final task of characterization. The absolute configuration of the biaryl axis needed to be elucidated. With phosphine selenide **35** in hand, prepared from optically pure (–)-BINAPFu (vide supra), it was rationalized that X-ray diffraction using the Bijvoet method (54) could determine the stereochemical assignment. Single crystal analysis of compound **35** furnished the structure depicted in Fig. 3. By refining the inverted structure and evaluating the Flack parameter, it was shown that the *S*-configuration was present in the crystal. Hence, phosphinimine **31a** corresponds to (*S*)-(–)-BINAPFu, while phosphinimine **31b** corresponds to (*R*)-(+)-BINAPFu. This relationship was verified via single crystal X-ray diffraction analysis of phosphinimine **31a** (Fig. 3). In this case, Bijvoet analysis was not required since the absolute stereochemistry of the biaryl axis could be ascertained by simple comparison with the known configurations of the camphor residues. Since (1*S*)-(+)-10-camphorsulfonyl chloride was used to prepare resolving agent **30**, it follows from Fig. 3 that phosphinimine **31a** is the *S*-axial diastereomer.

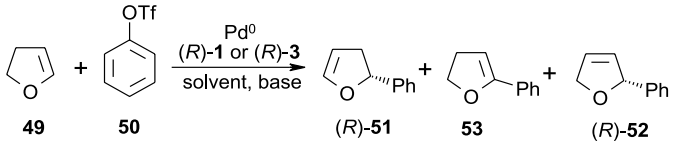
evaluating the performance of this ligand in metal-mediated asymmetric transformations remained.

Application of BINAPFu in the Heck arylation of 2,3-dihydrofuran using (*R*)-BINAP and (*R*)-BINAPFu

The asymmetric Heck arylation of 2,3-dihydrofuran (**49**), first reported by Hayashi and co-workers (24, 55), has been studied extensively and was therefore chosen as a suitable reaction to study using the BINAPFu ligand (Scheme 10). The Heck arylation of 2,3-dihydrofuran (**49**) was performed under a variety of reaction conditions (Table 1) on a 1.0 mmol scale (based on PhOTf) in sealed, screw-cap sample vials. In all cases, the Pd-catalysts (3 mol%) were formed in situ at 60 °C in the presence of an amine base under argon for 30 min. In general, catalysts formed using (*R*)-BINAP were bright orange in color, while catalysts derived from (*R*)-BINAPFu were bright yellow in color. After formation of the catalyst, PhOTf and 2,3-dihydrofuran

Scheme 10. (*a*) 3.0 equiv DIPEA, 3 mol% $Pd(OAc)_2$, 6 mol% (*R*)-BINAP, C_6H_6, 30 °C, 66 h.



(5.1 mmol) were carefully added by microlitre-syringe. The argon-purged vessels were subsequently sealed and placed in a thermostatically controlled oil bath for a specified period. In light of our inability to repeat Hayashi's experimental results, coupled with the fact that the reported ee values were ascertained using the chiral shift NMR analysis method, it was deemed prudent to perform control experiments using commercially supplied (*R*)-BINAP. To this end, all experiments were performed in parallel, using both the (*R*)-BINAP and (*R*)-BINAPFu catalyst systems, and were analyzed using chiral GC analysis conditions.

Employing Hayashi's original Heck arylation conditions with the (*R*)-BINAP ligand afforded 2,3-dihydrofuran product **51** in 27% yield and 86% ee (entry 1b). However, the reaction was only 30% complete after a 9 day period at 30 °C. In our hands, neither Hayashi's reported yield (78%) (55*a*) nor the enantiomeric excess of the 2,3-dihydrofuran product **51** (93%) (55*a*) were attainable under these reaction conditions. Utilizing (*R*)-BINAPFu under otherwise identical conditions afforded a 21% yield of product **51**, favoring the *R*-configuration in >97% ee. Extraordinarily, the enantiomeric purity of the minor isomer **52** was also greater than when (*R*)-BINAP was employed, and the sense of enantioselection was reversed. In other words, both products **51** and **52** were enriched in the *R*-configuration, suggesting that the reaction with BINAPFu may not follow Hayashi's proposed kinetic resolution mechanism. Repeating this experiment using Proton Sponge® (3.0 equiv) as the base provided much lower product conversion factors (entries 2a and 2b). Since the conditions reported in the literature for this reaction failed to give useful product conversions, alternative palladium sources, solvents, bases, and reaction temperatures were investigated.

A significant increase in product conversion was observed upon using a polar solvent such as 1,4-dioxane with DIPEA as the base (entry 3). The effect was more pronounced for the (*R*)-BINAPFu catalyst, giving a 61% yield of the 2,3-dihydrofuran product **51** (97% ee, entry 3a). Under identical conditions, the (*R*)-BINAP catalyst afforded only 43% yield of **51** (73% ee, entry 3b), albeit with higher regioselectivity. Again, the 2,5-dihydrofuran product **52** was formed with *S*-configuration selectivity using the (*R*)-BINAP catalyst, while the *R*-configuration was preferred with the (*R*)-BINAPFu catalyst. Since NMP has been used successfully in the Stille reaction with trifurylphosphine-derived catalysts (56), it was conceived that this polar solvent may also work well in the present case. Employing NMP as the solvent also afforded

[a]3 mol% $Pd(OAc)_2$ for 9 days.
[b](i-Pr)$_2$NEt used as base.
[c]*S*-configuration was favoured.
[d]Proton sponge used as base.
[e]1.5 mol% Pd_2dba_3 for 7 days.
[f]PMP used as base.

higher conversion factors (entries 4a and 4b) than those observed using benzene (entries 1a and 1b), but the ee of the major product **51** was diminished (79%) relative to the result obtained with dioxane (97%). The same general trend in enantioselection was observed, wherein the absolute configuration of the 2,5-dihydrofuran product **52** differed between the two catalyst systems studied. The use of $Pd(OAc)_2$ as the pre-catalyst was not required to achieve good enantioselectivity. Utilizing the $Pd_2(dba)_3$–(*R*)-BINAPFu catalyst system in dioxane at 50 °C with DIPEA as the base afforded a 25% yield of compound **51** in 76% ee (entry 5a). The same conditions in conjunction with a $Pd_2(dba)_3$–(*R*)-BINAP catalyst system furnished compounds **51** and **52** in higher conversion and isomeric selectivity but with reduced enantioselectivity (entry 5b). Using these conditions, both catalysts provided 2,5-dihydrofuran product **52**, favoring the *R*-configuration. Virtually the same product conversion, regioselectivity, and ee were obtained using the (*R*)-BINAPFu ligand in benzene at 70 °C (entry 6a). However, a significant increase in conversion and decrease in isomer selectivity was observed using (*R*)-BINAP in benzene at 70 °C (entry 6b). Although the conversion was certainly poorer with the (*R*)-BINAPFu catalyst, it was encouraging to note that respectable enantioselectivities could also be achieved at higher temperatures. In other words, this result suggested that it may be possible to get this reaction to go to completion while still obtaining reasonable levels of enantioselection.

A study of various ethereal solvents at elevated temperature (entries 7–9) revealed that full conversion was attainable, without a significant loss in enantioselectivity, using 1,4-dioxane as the solvent at 100 °C (entries 9a and 9b). Moreover, at high temperatures, the (*R*)-BINAPFu catalyst

© 2004 NRC Canada

afforded less of the unwanted conjugated isomer **53** and afforded higher selectivity in favor of the 2,3-dihydrofuran product **51**. In all cases, utilization of high-temperature conditions (>50 °C) provided the 2,5-dihydrofuran product **52** enriched in the *R*-isomer, regardless of whether (*R*)-BINAP or (*R*)-BINAPFu was used as the ligand. Conducting the reaction in DMF at 90 °C with DIPEA as the base and an (*R*)-BINAPFu-derived catalyst afforded excellent isomer selectivity with a slight reduction in enantioselectivity (entry 10a). At elevated temperatures, the conditions that employed dioxane as the solvent and PMP as the tertiary amine base yielded the 2,3-dihydrofuran product **51** in 80% ee with only modest regioselectivity (entry 11a). Ozawa, Kubo, and Hayashi have reported (55*b*) higher degrees of enantioselection, at the expense of regioselectivity, using Proton Sponge® as the base. Using this base in dioxane at 100 °C with the (*R*)-BINAPFu catalyst did not result in increased enantioselectivity (entry 12a). However, in accordance with Hayashi's findings, a significant decrease in isomer selectivity was observed. Finally, changing back to the $Pd(OAc)_2$ catalyst and using dioxane as the solvent at 100 °C with DIPEA as the base gave a slight increase in product regioselectivity (entry 13a, cf. entry 9a).

Examining the results listed in Table 1 as a whole, a few general trends immediately emerge. Firstly, the enantiomeric purity of the 2,3-dihydrofuran isomer **51** was always higher when the (*R*)-BINAPFu-derived catalyst system was used. At low temperatures (<50 °C), employing dioxane as the solvent with DIPEA as the base afforded the best balance between conversion (71%) and enantioselectivity of the 2,3-dihydrofuran product **51** (97%). However, in this temperature domain, the (*R*)-BINAP catalyst generally affords a much higher isomer selectivity. The (*R*)-BINAPFu catalyst consistently provides products **51** and **52**, both enriched in the *R*-configuration. In contrast, the (*R*)-BINAP catalyst gives compounds **51** and **52** of opposite configuration only at low temperature (30 °C). At higher temperatures (>70 °C), full conversion of the phenyl triflate can be realized with either catalyst system. Under such conditions, the (*R*)-BINAPFu catalyst typically gives the major product in 71%–80% ee, while the (*R*)-BINAP catalyst produces product **51** in 35%–57% ee. High-temperature conditions, in conjunction with the (*R*)-BINAPFu catalyst system, give rise to higher isomeric ratios in favor of the 2,3-dihydrofuran product **51** and attenuated formation of the conjugated isomer **53**, relative to the corresponding reactions employing the (*R*)-BINAP-derived catalyst. Perhaps of greatest significance is the observation that high enantioselectivity for the 2,3-dihydrofuran isomer **51** does not seem to correlate with poor isomeric selectivity. Recall that Hayashi, Ozawa, and coworkers used this argument as strong evidence supporting a kinetic resolution mechanism (24). Notwithstanding our inability to repeat these workers' findings (vide supra), the experimental results obtained using the BINAPFu ligand suggest that this assertion may indeed be incorrect.

Conclusions

We have designed, synthesized, and resolved a new binaphthofuran ligand (BINAPFu) for use in asymmetric metal-catalyzed reactions. The ligand is easily prepared in 5 steps from readily available starting material. A new resolution procedure was designed for phosphines, involving the Staudinger reaction with a camphor sulfonyl azide derivative. BINAPFu outperformed BINAP in the Heck reaction between phenyl triflate and 2,3-dihydrofuran. Further structural modifications of BINAPFu are currently underway to improve the enantioselectivity of high-temperature Heck arylation reactions.

Experimental section

General comments

Melting points were determined using either an Electrothermal® melting point apparatus in sealed capillary tubes or an A.H. Thomas hot-stage and are uncorrected. Boiling points are uncorrected and refer to measured air-bath temperatures using a Kugelrohr short-path distillation apparatus. Optical rotation data was obtained on a Rudolph Autopol III polarimeter using a quartz cell with a 10 cm path length. Infrared spectra were recorded on a Mattson Galaxy Series 4030 FT-IR spectrometer. ^{1}H and ^{13}C NMR spectra were obtained on a Bruker ACE 200 (^{1}H, 200 MHz; ^{13}C, 50 MHz), a Bruker AM 400 (^{1}H, 400 MHz; ^{13}C, 100 MHz), or a Bruker DRX 400 (^{1}H, 400 MHz; ^{13}C, 100 MHz) spectrometer. Unless otherwise noted, deuteriochloroform was used as the NMR solvent. ^{31}P NMR spectra were obtained on a Varian XL 200 (^{31}P, 81 MHz), a Bruker AMX 300 (^{31}P, 121.5 MHz), or a Bruker DRX 400 (^{31}P, 162 MHz) spectrometer using an external reference of 30% H_3PO_4 in D_2O set to 0 ppm. Unless specified otherwise, ^{31}P NMR samples were prepared using deuteriochloroform as the solvent. GC–MS analysis was performed on a Hewlett-Packard 5890 Series II gas chromatograph equipped with a Hewlett-Packard OV 101, low polarity, 12 m × 0.2 mm column, in conjunction with a Hewlett-Packard 5971A mass selective detector. Low-resolution mass spectra on nonvolatile samples were obtained on a VG 7070 or a Kratos MS80 mass spectrometer using 70 eV ionization with direct probe sample introduction. HR-MS and FAB-MS analyses were obtained using a Kratos MS80 spectrometer. Elemental analyses were obtained from the University of Calgary's Control Equipment Corporation 440 Elemental Analyzer. X-ray structure determination[3] was performed by Dr. M. Parvez (University of Calgary), using a Rigaku AFC6S diffractometer with graphite monochromated Mo Kα radiation, or by Dr. R. McDonald (University of Alberta), using a Bruker P4 diffractometer equipped with a SMART 1000 CCD area detector and 18 kW rotating anode X-ray generator. Column chromatography was performed using silica gel 60 (E. Merck, 0.04–0.063 mm, 230–400 mesh), using the flash method (57). Sol-

vent systems refer to mixtures, by volume, of hexanes and ethyl acetate unless specified otherwise. Analytical HPLC analyses were performed on an ICI LC 1440 instrument equipped with an ICI LC 1150 HPLC Pump (C_{18} column or Chiralcel OJ column with an ICI LC 12010 UV–vis detector) or a Waters 4886 instrument (Nova-Pak C_{18} reverse-phase column or Chiralcel OB column with a Waters 486 UV detector). Preparative HPLC was done on the latter instrument equipped with a 25 mm × 100 mm Water Nova-Pak C_{18} reversed-phase column. Chiral gas chromatography was performed on either a Shimadzu GC-9A gas chromatograph (25 m × 0.33 mm (i.d.) Cydex-B fused silica column with a flame ionization detector) or a Varian Star 3400 CX instrument (30 m × 0.32 mm (i.d.) Cyclodex-B fused silica column with a flame ionization detector).

Chlorination of 1-acetyl-2-hydroxynaphthalene (8)

Method 1

To a solution of 1-acetyl-2-hydroxynaphthalene **8** (100 mg, 0.537 mmol) in CH_2Cl_2 (2 mL), H_2O (11 μL, 0.59 mmol), and MeOH (23 μL, 0.59 mmol), was added SO_2Cl_2 (53 μL, 0.65 mmol). The mixture was refluxed under an N_2 atmosphere for 1 h and subsequently quenched with H_2O (20 mL). The solution was extracted with ether (20 mL), washed with H_2O (2 × 20 mL), and dried ($MgSO_4$). Concentration of the organic phase afforded a greenish yellow oil. Only a trace amount of the desired product **9** was evident in the crude ^{1}H NMR spectrum.

Method 2

Hexachloro-2,4-cyclohexadienone (19) (111 mg, 0.371 mmol) was added to a solution of 1-acetyl-2-hydroxynaphthalene (69 mg, 0.37 mmol) in absolute ethanol (3 mL), and the mixture was refluxed under a nitrogen atmosphere for 15 h. The solvent was removed in vacuo to give a brown residue. ^{1}H NMR analysis showed that the major component of the mixture was unreacted starting material **8**, as well as a minor amount (<30%) of the desired α-chloroketone **9**, as evidenced by a singlet at 4.8 ppm corresponding to H-12. The product was not stable to column chromatography.

1-Acetyl-2-[(*tert*-butyldimethylsilyl)oxy]naphthalene (10)

To a solution of 1-acetyl-2-hydroxynaphthalene (**8**) (21.9 g, 0.117 mol) in Et_3N (75 mL, 0.538 mol) and CH_2Cl_2 (500 mL) was added TBSCl (19.4 g, 0.129 mmol). The mixture was stirred at room temperature (rt) for 18 h before it was quenched with H_2O (500 mL). The mixture was then stirred for 1 h and extracted with ether (3 × 500 mL), and the pooled organic extracts were washed with a 10% HCl solution (2 × 500 mL) and H_2O (2 × 500 mL). The organic layer was dried ($MgSO_4$) and concentrated under reduced pressure to give 31.4 g (89%) of the TBS ether **10** as a light yellow oil. ^{1}H NMR (200 MHz) δ: 0.28 (s, 6H), 1.02 (s, 9H), 2.68 (s, 3H), 7.10 (d, J = 12 Hz, 1H), 7.47 (m, 2H), 7.76 (m, 2H), 7.78 (d, J = 12 Hz, 1H). This material was used in the next step without further purification.

1-[(1-Trimethylsilyl)oxy]ethenyl-2-[(*tert*-butyldimethylsilyl)oxy]naphthalene (11)

To a solution of silyl ether **10** (31.4 g, 0.105 mol) in CH_2Cl_2 (600 mL) and Et_3N (73 mL, 0.52 mol) at 0 °C was added TMSOTf (24 mL, 0.13 mol). The mixture was warmed to rt and stirring was continued for 1 h under an N_2 atmosphere. The mixture was diluted with $CHCl_3$ (100 mL), washed with brine (2 × 300 mL), dried (Na_2SO_4), and evaporated to dryness under reduced pressure to give crude enol ether **11** in quantitative yield. ^{1}H NMR (200 MHz) δ: 0.18 (s, 9H), 0.27 (s, 6H), 1.09 (s, 9H), 4.39 (s, 1H), 4.74 (s, 1H), 7.07 (d, J = 11 Hz, 1H), 7.45 (m, 2H), 7.71 (m, 2H), 8.08 (d, J = 11 Hz, 1H). Trimethylsilyl enol ether **11** was used directly in the subsequent step.

1-(2-Bromoacetyl)-2-[(*tert*-butyldimethylsilyl)oxy]naphthalene (12)

In a flask equipped with a dropping funnel, TMS enol ether **11** (38.9 g, 0.105 mol) was dissolved in CCl_4 (450 mL) and cooled to 0 °C. A solution of bromine (5.66 mL, 0.119 mol) in CCl_4 (100 mL) was placed in the dropping funnel, and 20 mL of this solution was added to the reaction mixture; after warming to rt, the remaining 80 mL of the bromine solution was added over a 30 min period. The mixture was stirred for a further 30 min and diluted with H_2O (200 mL), and the layers were separated. The aqueous layer was extracted with $CHCl_3$ (2 × 100 mL), and the combined organic layers were washed with an $Na_2S_2O_3$ solution (200 mL) and H_2O (2 × 200 mL). The organic fraction was dried (Na_2SO_4) and concentrated in vacuo to furnish 39.5 g of compound **12** as a light orange oil. ^{1}H NMR (200 MHz) δ: 0.29 (s, 6H), 1.05 (s, 9H), 4.58 (s, 2H), 7.08 (d, J = 11 Hz, 1H), 7.50 (m, 2H), 7.78 (m, 2H), 7.85 (d, J = 11 Hz, 1H).

Naphtho[2,1-*b*]furan-3(2H)-one (7) from bromide 12

To a solution of compound **12** (39.7 g, 0.105 mol) in THF (400 mL) at 0 °C was slowly added TBAF (1.0 mol L^{-1} solution in THF, 110 mL, 0.110 mol) under an N_2 atmosphere. The mixture was allowed to stir at 0 °C for 10 min and at rt for 15 min. The dark purple solution was then quenched with NH_4Cl solution (100 mL), and the THF was removed in vacuo. The remaining residue was extracted with ether (3 × 100 mL), and the combined ether layers were washed with brine (100 mL) and H_2O (3 × 150 mL), dried ($MgSO_4$), and evaporated under reduced pressure. The crude product was purified by column chromatography (20:1, hexanes – ethyl acetate) to give 15.1 g (72% from compound **11**) of cyclized ketone **7** as a light yellow solid: mp 133 °C (lit (58) 133 °C). IR (KBr) (cm^{-1}): 1688. ^{1}H NMR (200 MHz, $CDCl_3$) δ: 8.75 (d, J = 8.2 Hz, 1H), 8.05 (d, J = 9.0 Hz, 1H), 7.82 (d, J = 8.0 Hz, 1H), 7.66 (dt, J = 7.6, 0.9 Hz, 1H), 7.47 (dt, J = 7.6, 1.0 Hz, 1H), 7.24 (dd, J = 7.8, 2.4 Hz, 1H), 4.77 (s, 2H). ^{13}C NMR (50 MHz, $CDCl_3$) δ: 199.9 (C), 176.6 (C), 139.7 (CH), 129.8 (CH), 129.2 (C), 129.1 (C), 126.4 (CH), 125.4 (CH), 123.1 (CH), 113.9 (CH), 113.5 (C), 75.5 (CH_2). MS, m/z (relative intensity, %): 184 ($[M]^+$, 74), 155 (87), 126 (100). Exact mass calcd for $C_{12}H_8O$: 184.0524; found: 184.0520.

Naphtho[2,1-*b*]furan-3(2H)-one (7) from 2-naphthoxyacetic acid (13)

2-Naphthoxyacetic acid (20.1 g, 99.3 mmol) in dry benzene (1000 mL) was treated with a catalytic amount of pyridine and 2 equiv $SOCl_2$ (14.4 mL, 198.6 mmol) at reflux under an N_2 atmosphere for 2 h. The cooled solution was

© 2004 NRC Canada

then concentrated in vacuo, and the resulting residue was taken up into C_6H_6 (500 mL) and cooled to 0 °C. To the solution was then added $AlCl_3$ (19.8 g, 148.9 mmol), and the resulting solution was stirred for 12 h at ambient temperature. The mixture was then quenched with brine and extracted with benzene (2 × 100 mL). The combined organic extracts were then washed with water (2 × 100 mL) and filtered through neutral alumina. The filtrate was then concentrated under reduced pressure to afford the desired product **7** (17.2 g, 95%), which was found to be clean by ^{1}H NMR analysis. Spectra were identical to compound **7** made from bromide **12**.

3,3′-Binaphtho[2,1-*b*]furan (5)

Into a 1 L, 3-neck round-bottom flask equipped with an addition funnel was weighed activated zinc dust (29.3 g, 0.448 mol) and DME (300 mL). The mixture was cooled to –78 °C, and to it was carefully added $TiCl_4$ dropwise via syringe over a 30 min period. The resulting blue mixture was warmed to reflux, and the starting naphthoketone **7** (10.0 g, 54.4 mmol in 100 mL DME) was added dropwise over a 20 min period. The resulting mixture was heated to reflux under an N_2 atmosphere for 18 h. The cooled mixture was then filtered through a coarse sintered glass funnel, and the filtrate was concentrated under reduced pressure to give **6** as an orange, gummy residue. This residue was immediately dissolved in C_6H_6 (300 mL) and treated with DDQ (6.17 g, 27.2 mmol) at reflux under an N_2 atmosphere for 4 h. The cooled mixture was then quenched with saturated $Na_2S_2O_3$ and extracted with ether (3 × 100 mL). The combined organic extracts were dried ($MgSO_4$) and concentrated to afford the crude title compound. The product **5** was readily purified by flash chromatography (100:1 hexanes – ethyl acetate) to afford the analytically pure biaryl (7.13 g, 78%). mp 292–294 °C. IR (KBr) (cm^{-1}): 2850, 1436. ^{1}H NMR (200 MHz, $CDCl_3$) δ: 7.94 (d, *J* = 8.2 Hz, 1H), 7.86 (s, 1 H), 7.84 (m, 2H), 7.75 (d, *J* = 8.5 Hz, 1H), 7.35 (dt, *J* = 7.5, 1.0 Hz, 1H), 7.09 (dt, *J* = 7.7, 1.3 Hz, 1H). ^{13}C NMR (50 MHz, $CDCl_3$) δ: 153.5 (C), 142.8 (CH), 130.8 (C), 128.6 (CH), 128.4 (C), 126.4 (CH), 126.3 (CH), 124.5 (CH), 123.3 (CH), 112.1 (C), 113.9 (C), 112.6 (CH). MS, *m*/*z* (relative intensity, %): 334 ([M]$^+$, 100), 305 (31), 276 (32), 138 (18). Exact mass calcd for $C_{24}H_{14}O_2$: 334.0994; found: 334.0970. Anal calcd for $C_{24}H_{14}O_2$: C 86.20, H 4.22; found: C 85.96, H 4.04.

2,2′-Bis(diphenylphosphonyl)-3,3′-binaphtho[2,1-*b*]furan (14)

3,3′-Binaphtho[2,1-*b*]furan **5** (0.593 g, 1.776 mmol) in dry Et_2O (30 mL) was lithiated with *t*-BuLi (2.61 mL, 4.440 mmol, 1.7 mol L^{-1} solution in hexanes) at 0 °C. After 1 h at 0 °C, the vessel was warmed to rt and stirred for a further 2 h under an N_2 atmosphere. To the mixture was then added freshly distilled diphenylphosphinic chloride (0.85 mL, 4.440 mmol), and the resulting white slurry was stirred overnight at room temperature. The reaction mixture was then quenched with water and extracted with $CHCl_3$ (3 × 50 mL). The combined organic extracts were washed with 10% $NaHCO_3$, water, and brine. The organic phase was then dried ($MgSO_4$) and concentrated in vacuo to afford a light yellow solid residue. The crude material **14** was purified by column chromatography (3:1 CH_2Cl_2–EtOAc → 19:1 CH_2Cl_2–MeOH) to afford the title compound (1.150 g, 88%). mp 289–290 °C. IR (KBr) (cm^{-1}): 2924, 1437, 1120. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 7.87 (d, *J* = 8.1 Hz, 1H), 7.83 (d, *J* = 9.1 Hz, 1H), 7.72 (m, 2H), 7.64 (d, *J* = 9.0 Hz, 1H), 7.56 (d, *J* = 7.3 Hz, 1H), 7.53 (d, *J* = 7.3 Hz, 1H), 7.46 (d, *J* = 8.3 Hz, 1H), 7.36 (m, 2H), 7.23 (m, 3H), 7.06 (t, *J* = 7.6 Hz, 1H), 6.96 (dt, *J* = 7.7, 3.1 Hz, 2H). ^{13}C NMR (50 MHz, $CDCl_3$) δ: 155.5 (d, *J* = 8 Hz, C), 145.8 (d, *J* = 128 Hz, C), 132.1 (CH), 132.1 (d, *J* = 35 Hz, C), 132.0 (CH), 131.9 (d, *J* = 3 Hz, CH), 130.8 (C), 129.9 (d, *J* = 31 Hz, C), 128.7 (CH), 128.1 (d, *J* = 13 Hz, CH), 127.6 (d, *J* = 13 Hz, CH), 126.9 (CH), 124.8 (CH), 124.6 (C), 122.7 (CH), 121.5 (d, *J* = 8 Hz, C), 112.6 (CH). ^{31}P NMR (81 MHz, $CDCl_3$) δ: 16.5. MS, *m*/*z* (relative intensity, %): 533 ([M$^+$ – P(O)Ph_2], 100), 201 (54). Exact mass calcd for $C_{48}H_{32}P_2O_4$: 734.1778; found: 734.1731.

(±)-2,2′-Bis(diphenylphosphino)-3,3′-binaphtho[2,1-*b*]furan (3)

3,3′-Binaphtho[2,1-*b*]furan **5** (3.4 g, 10.2 mmol) in dry Et_2O (130 mL) was lithiated with *t*-BuLi (11.2 mL, 22.4 mmol, 2.0 mol L^{-1} solution in hexanes) at 0 °C. After 1 h at 0 °C, the vessel was warmed to rt and stirred for a further 2 h under an N_2 atmosphere. To the mixture was then added freshly distilled chlorodiphenylphosphine (4.0 mL, 22.4 mmol), and the resulting white slurry was stirred overnight at room temperature. The reaction mixture was quenched with water and extracted with $CHCl_3$ (3 × 125 mL). The combined organic extracts were washed with 10% $NaHCO_3$, water, and brine. The organic phase was dried ($MgSO_4$) and concentrated in vacuo to afford a light brown solid residue. The crude material (±)-**3** was purified by crystallization ($CHCl_3$–MeOH) to afford the title compound (6.49 g, 91%). mp 228–229 °C. IR (KBr) (cm^{-1}): 3052, 1433. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 7.90 (d, *J* = 8.1 Hz, 1H), 7.84 (d, *J* = 9.0 Hz, 1H), 7.76 (d, *J* = 9.1 Hz, 1H), 7.62 (d, *J* = 8.3 Hz, 1H), 7.37 (m, 2H), 7.35–7.30 (m, 4H), 7.24–7.14 (m, 5H), 7.04 (td, *J* = 7.4, 1.0 Hz, 1H). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 156.3 (C), 152.9 (d, *J* = 34 Hz, C), 135.4 (d, *J* = 71 Hz, C), 133.7 (CH), 133.6 (CH), 133.5 (CH), 130.7 (C), 128.6 (d, *J* = 4 Hz, CH), 128.5 (CH), 128.3 (C), 128.1 (d, *J* = 2 Hz, CH), 127.4 (CH), 126.5 (d, *J* = 35 Hz, C), 126.7 (CH), 124.5 (CH), 123.0 (CH), 122.5 (C), 112.9 (CH). ^{31}P NMR (81 MHz, $CDCl_3$) δ: –32.3. MS, *m*/*z* (relative intensity, %): 625 ([M$^+$ – Ph], 1), 517 (37), 408 (79), 183 (100). Exact mass calcd for $C_{48}H_{32}P_2O_2$: 702.1878; found: 702.1841.

Preparation of bis-*P*-borane-(R^*_{ax})-2,2′-bis[(8*R*,9*R*)-*N*,*N*′-dimethyl-1,3-diazahexahydro-2-phosphinoindan-2-yl]-3,3′-binaphtho[2,1-*b*]furan complex (23a) and bis-*P*-borane-(S^*_{ax})-2,2′-bis[(8*R*,9*R*)-*N*,*N*′-dimethyl-1,3-diazahexahydro-2-phosphinoindan-2-yl]-3,3′-binaphtho[2,1-*b*]furan complex (23b)

To a solution of naphtho[*b*]furan **5** (0.173 g, 0.518 mmol) in Et_2O (5.0 mL) at –78 °C was added 2.05 equiv of *t*-BuLi (1.7 mol L^{-1} in hexanes, 0.62 mL, 1.1 mmol). The resulting mixture was warmed to 0 °C and stirred under an atmosphere of nitrogen for 1.5 h. To the vessel was then added enantiopure 2-chloro-2,2′-bis[8*R*,9*R*]-*N*,*N*′-dimethyl-1,3-diazahexahydro-2-phosphinoindane (**22**) (38, 39) (0.219 g,

1.06 mmol). The reaction contents were allowed to warm to rt over a 1 h period and subsequently left to stir for 24 h. To the vessel was then added borane – dimethyl sulfide complex (2.0 mol L^{-1} solution in THF, 0.531 mL, 1.06 mmol), and the resulting mixture was left to react for a further 24 h. The reaction contents were then quenched with brine (50 mL) and extracted with $CHCl_3$ (3 × 50 mL). The combined organic extracts were dried ($MgSO_4$) and concentrated under reduced pressure to afford a light yellow oil. The crude material was purified by column chromatography (15:1) to afford a 1:1 mixture of the title compounds (0.270 g, 74%). A small sample (~3 mg) of each pure diastereomer was obtained by exhaustive preparative high performance liquid phase chromatography (Nova-Pak C_{18}, 93:7 $CH_3CN:H_2O$, 1.0 mL min^{-1}, 320 nm detection). The first isomer to elute, compound **23a**, was obtained as a colorless film exhibiting the following analytical data: IR (KBr) (cm^{-1}): 2937, 2387 (BH_3), 1462, 1025. ^{1}H NMR (400 MHz) δ: –0.50 to 0.63 (bq, 3H), 1.10–1.62 (m, 4H), 1.89 (t, *J* = 12.9 Hz, 2H), 2.00–2.13 (m, 2H), 2.19 (d, *J* = 14.5 Hz, 3H), 2.48 (td, *J* = 10.4, 3.0 Hz, 1H), 2.74 (d, *J* = 12.8 Hz, 3H), 3.18 (t, *J* = 9.6 Hz, 1H), 7.02 (t, *J* = 7.0 Hz, 1H), 7.32 (t, *J* = 7.0 Hz, 1H), 7.58 (d, *J* = 7.8 Hz, 1H), 7.82 (d, *J* = 9.1 Hz, 1H), 7.90 (d, *J* = 9.1 Hz, 1H), 7.91 (d, *J* = 7.8 Hz, 1H). ^{13}C NMR (100 MHz) (ppm): 24.7 (CH_2), 24.8 (CH_2), 29.0 (d, *J* = 8 Hz, CH_2), 29.3 (d, *J* = 5 Hz, CH_2), 30.4 (d, *J* = 3 Hz, CH_3), 32.6 (d, *J* = 10 Hz, CH_3), 65.8 (d, *J* = 3 Hz, CH), 68.4 (CH), 113.4 (CH), 122.8 (C), 122.9 (C), 123.5 (CH), 125.1 (CH), 126.4 (d, *J* = 19 Hz, C), 126.8 (CH), 128.9 (CH), 129.3 (CH), 131.3 (C), 150.4 (d, *J* = 30 Hz, C), 155.5 (d, *J* = 4 Hz, C). ^{31}P NMR (162 MHz) (ppm): +94.1 (q, *J* = 71 Hz). FAB-MS, *m/z* (relative intensity, %): 725 (48, $[M + Na]^+$). Compound **23b**, also obtained as a colorless film, had the following properties: IR (KBr) (cm^{-1}): 2935, 2390 (BH_3), 1461, 1003. ^{1}H NMR (400 MHz) δ: –0.48 (qd, *J* = 12.3, 3.6 Hz, 1H), 0.08 (m, 1H), 0.20–1.20 (bq, 3H), 0.78–0.97 (m, 2H), 1.28 (d, *J* = 8.6 Hz, 1H), 1.39 (d, *J* = 9.8 Hz, 2H), 1.65 (d, *J* = 8.9 Hz, 1H), 2.10 (td, *J* = 12.0, 3.2 Hz, 1H), 2.26 (m, 1H), 2.36 (d, *J* = 13.1 Hz, 3H), 2.62 (d, *J* = 14.2 Hz, 3H), 7.13 (t, *J* = 8.0 Hz, 1H), 7.36 (t, *J* = 7.1 Hz, 1H), 7.55 (d, *J* = 8.3 Hz, 1H), 7.88 (ABq, *J* = 9.2 Hz, 2H), 7.94 (d, *J* = 8.1 Hz, 1H). ^{13}C NMR (100 MHz) (ppm): 23.7 (CH_2), 24.1 (CH_2), 27.3 (d, *J* = 5 Hz, CH_2), 28.2 (d, *J* = 8 Hz, CH_2), 30.3 (d, *J* = 2 Hz, CH_3), 32.8 (d, *J* = 10 Hz, CH_3), 64.1 (d, *J* = 3 Hz, CH), 68.2 (CH), 113.5 (CH), 123.1 (d, *J* = 5 Hz, C), 123.2 (d, *J* = 9 Hz, C), 123.7 (CH), 125.3 (CH), 127.1 (CH), 128.7 (CH), 129.0 (C), 129.5 (CH), 131.5 (C), 150.3 (d, *J* = 40 Hz, C), 155.5 (d, *J* = 6 Hz, C). ^{31}P NMR (162 MHz) (ppm): +98.7 (q, *J* = 74 Hz). FAB-MS, *m/z* (relative intensity, %): 725 (7, $[M + Na]^+$).

2-Chloro-1,3-dimethyl-4,5-diphenyl-1,3,2-diazaphospholidine (26)

Under an argon atmosphere, (1*S*,2*S*)-*N*,*N*-dimethyl-1,2-diphenylethylenediamine (**25**) (40, 41) (1.59 g, 6.63 mmol) was dissolved in freshly distilled Et_2O (40 mL) and Et_3N (1.85 mL, 13.3 mmol). The reaction mixture was then cooled to –40 °C; phosphorus trichloride (0.578 mL, 6.63 mmol) was added; and the resultant thick white slurry was stirred for 30 min at –40 °C, for 1 h at 0 °C, and for 24 h at room temperature. The slurry was filtered under an atmosphere of argon, and the filtrate was concentrated under reduced pressure in an inert atmosphere to give a bright yellow solid residue. Crude phosphoramidous chloride **26**: ^{1}H NMR (200 MHz) δ: 2.55 (d, *J* = 19.5 Hz, 3H), 4.28 (d, *J* = 7.4 Hz, 1H), 7.11–7.40 (m, 5H). ^{13}C NMR (50 MHz) (ppm): 31.8 (d, *J* = 21 Hz, CH_3), 78.1 (d, *J* = 11 Hz, CH), 128.2 (CH), 128.7 (CH), 128.8 (CH), 137.1 (d, *J* = 2 Hz, C). ^{31}P NMR (62 MHz) (ppm): +173.6. Compound **26** was used in the subsequent step without further purification.

Bis-*P*-borane-(R^*_{ax})-2,2′-bis[(4*R*,5*R*)-1,3-dimethyl-4,5-diphenyl-1,3,2-diazaphospholidin-2-yl]-3,3′-binaphtho-[2,1-*b*]furan complex (27a) and bis-*P*-borane-(S^*_{ax})-2,2′-bis[(4*R*,5*R*)-1,3-dimethyl-4,5-diphenyl-1,3,2-diazaphospholidin-2-yl]-3,3′-binaphtho[2,1-*b*]furan complex (27b)

To a solution of naphtho[*b*]furan (**5**) (0.245 g, 0.734 mmol) in Et_2O (8.0 mL) at –78 °C was added 2.2 equiv of *t*-BuLi (1.7 mol L^{-1} in hexanes, 0.949 mL, 1.61 mmol). The resulting mixture was warmed to 0 °C and stirred under an atmosphere of nitrogen for 1.5 h. To the vessel was then added enantiopure diazaphospholidine reagent **26** (0.491 g, 1.61 mmol). The reaction contents were allowed to warm to rt over a 1 h period and subsequently left to stir for 3 h. To the vessel was then added borane – dimethyl sulfide complex (2.0 mol L^{-1} solution in THF, 1.10 mL, 2.20 mmol), and the resulting mixture was left to react for a further 4 h. The reaction contents were then quenched with brine (50 mL) and extracted with $CHCl_3$ (3 × 75 mL). The combined organic extracts were dried ($MgSO_4$) and concentrated in vacuo to afford a light yellow solid residue. The crude material was purified by column chromatography (15:1) to afford a 1:1 mixture of the title compounds. Separation of the mixture was achieved by recrystallization from a binary mixture of $CHCl_3$ and hexanes. Under these conditions, compound **27a** crystallized, diastereomerically pure, as long white needles (0.304 g, 46%) characterized by the following analytical data: mp 123–124 °C. IR (KBr) (cm^{-1}): 2869, 2392 (BH_3), 1455, 1147. ^{1}H NMR (300 MHz) δ: –0.32 to 0.84 (bs, 3H), 2.02 (d, *J* = 11.3 Hz, 3H), 2.71 (d, *J* = 13.3 Hz, 3H), 4.00 (d, *J* = 8.7 Hz, 1H), 4.80 (d, *J* = 8.7 Hz, 1H), 7.02–7.45 (m, 12H), 7.74 (d, *J* = 7.9 Hz, 1H), 7.84–8.10 (m, 3H). ^{13}C NMR (75 MHz) (ppm): 31.8 (d, *J* = 3 Hz, CH_3), 32.7 (d, *J* = 11 Hz, CH_3), 75.1 (d, *J* = 3 Hz, CH), 76.3 (CH), 112.7 (CH), 122.4 (C), 122.5 (C), 122.8 (CH), 124.8 (CH), 126.2 (C), 126.9 (CH), 127.7 (CH), 128.0 (CH), 128.5 (CH), 128.6 (CH), 128.8 (CH), 129.1 (CH), 131.1 (C), 137.6 (d, *J* = 9 Hz, C), 138.5 (d, *J* = 4 Hz, C), 151.6 (d, *J* = 26 Hz, C), 155.0 (d, *J* = 3 Hz, C). ^{31}P NMR (81 MHz) (ppm): +98.7 (bs). FAB-MS, *m/z* (relative intensity, %): 899 (1, $[M + H]^+$). Borane adduct **27b** was obtained isomerically pure after flash chromatographic (15:1) purification of the mother liquor. The following analytical data were recorded for this compound: mp 138–140 °C ($CHCl_3$–hexanes). IR (KBr) (cm^{-1}): 2869, 2390 (BH_3), 1455, 1146. ^{1}H NMR (400 MHz) δ: –0.32–1.00 (bs, 3H), 2.11 (d, *J* = 13.7 Hz, 3H), 2.86 (d, *J* = 11.1 Hz, 3H), 4.15 (d, *J* = 8.7 Hz, 1H), 4.61 (d, *J* = 8.7 Hz, 1H), 6.99 (t, *J* = 7.2 Hz, 1H), 7.12–7.23 (m, 2H), 7.25–7.34 (m, 4H), 7.35–7.50 (m, 5H), 7.70 (d, *J* = 8.2 Hz, 1H), 7.91–8.03 (m, 3H). ^{13}C NMR (100 MHz) (ppm): 31.8 (d, *J* = 5 Hz, CH_3), 33.4 (d, *J* = 11 Hz, CH_3), 75.1 (d, *J* = 2 Hz, CH), 76.4 (CH), 113.3

MS, *m/z* (relative intensity, %): 531 ([$M^+ - C_{32}H_{40}NO_6PS_2$], 1). FAB MS, *m/z* (relative intensity, %): 1161 ([M]$^+$, 38), 531 (72). Anal calcd for $C_{68}H_{62}P_2S_2O_8N_2$ + $CHCl_3$: C 64.61, H 5.11, N 2.18; found: C 64.75, H 4.98, N 2.37.

X-ray crystallographic analysis on **31a** was performed at the University of Alberta on a Bruker P4 diffractometer equipped with a SMART 1000 CCD area detector, using graphite-monochromated Mo Kα radiation. The following crystal parameters were obtained: monoclinic, $P2_1$ (No. 4); a = 16.248(2) Å; b = 11.0208(16) Å; c = 35.643(5) Å; V = 6372.8(15) Å^3; Z = 4; R = 0.0696; Rw = 0.2355.

(–)-2,2′-Bis(diphenylphosphonyl)-3,3′-binaphtho[2,1-*b*]furan (14)

Phosphinimine **31a** (1.44 g, 1.24 mmol) in dioxane (50 mL) was treated with 3 mol L^{-1} aqueous H_2SO_4 (35 mL), and the resulting mixture was heated to reflux for 12 h. The cooled mixture was then quenched with 10% NaOH and extracted with $CHCl_3$ (3 × 100 mL). The combined organic extracts were dried ($MgSO_4$) and concentrated in vacuo to afford the crude phosphine oxide. The product was purified by flash chromatography on basic alumina (1:1 hexanes – ethyl acetate → 9:1 $CHCl_3$–MeOH) to afford the desired phosphine oxide (–)-**14** in quantitative yield. $[\alpha]_D^{19}$ –166.6 (*c* 1.01, $CHCl_3$). ^{1}H and ^{13}C spectra were indentical to those of (±)-**14**.

(–)-2,2′-Bis(diphenylphosphino)-3,3′-binaphtho[2,1-*b*]furan (3)

Phosphine oxide (–)-**14** (821 mg, 1.12 mmol) was dissolved in a mixture of xylenes (25 mL) and Et_3N (3.75 mL, 26.8 mmol). To the solution was added $SiCl_3H$ (2.26 mL, 22.4 mmol), and the resulting mixture was heated to 100 °C under argon for 1 h. The mixture was then heated to 150 °C for 3 h and subsequently cooled to 65 °C. To the vessel was then added dropwise 30% NaOH (60 mL). The resulting mixture was vigorously stirred for 1 h at 65 °C. The cooled reaction mixture was extracted with $CHCl_3$ (3 × 100 mL), and the combined organic phases were dried ($MgSO_4$) and concentrated in vacuo. The product (–)-**3** was purified by flash chromatography (20:1 hexanes – ethyl acetate) to afford the optically pure (*S*)-BINAPFu (785 mg, 100%). $[\alpha]_D^{19}$ –203.0 (*c* 1.09, $CHCl_3$). Heating the enantiopure ligand in *p*-xylenes at 150 °C for 7 days did not result in any racemization of the chiral axis, as evidenced by optical rotation and HPLC analysis (Chiralcel® OJ, 95:5 MeOH:EtOH, 0.5 mL min^{-1}, 270 nm detection). ^{1}H and ^{13}C spectra were identical to those of (±)-**3**.

(±)-Dichloro[2,2′-bis(diphenylphosphino)-3,3′-binaphtho[2,1-*b*]furan]-palladium (II) (15)

(±)-2,2′-Bis(diphenylphosphino)-3,3′-binaphtho[2,1-*b*]furan (**3**) (300 mg, 0.427 mmol) and bis(acetonitrile)dichloropalladium(II) (111 mg, 0.427 mmol) were stirred in CH_2Cl_2 (20 mL) at rt for 15 h. The solution was concentrated in vacuo, and the residue was purified by recrystallization from acetone–ether to give 349 mg (93%) of palladium adduct **15** as orange crystals: mp 312–314 °C. IR (KBr) (cm^{-1}): 3056, 1095, 999, 690. ^{1}H NMR (400 MHz) δ: 6.59 (m, J = 6.9 Hz, 2H), 6.82 (t, J = 7.3 Hz, 1H), 7.08 (t, J = 7.6 Hz, 1H), 7.27–7.52 (m, 6H), 7.65 (d, J = 7.5 Hz, 1H), 7.67 (d, J = 8.4 Hz, 1H), 7.77 (d, J = 9.1 Hz, 1H), 7.91 (d, J = 8.1 Hz, 1H), 8.11 (d, J = 7.6 Hz, 1H), 8.15 (d, J = 7.6 Hz, 1H). ^{13}C NMR (100 MHz) (ppm): 112.6 (CH), 122.0 (d, J = 2 Hz, C), 123.8 (dd, J = 7, 6 Hz, C), 124.3 (dd, J = 62, 4 Hz, C), 125.8 (CH), 126.8 (dd, J = 68, 5 Hz, C), 127.8 (CH), 128.1 (C), 128.3 (t, J = 6 Hz, CH), 128.5 (t, J = 6 Hz, CH), 128.9 (CH), 129.2 (CH), 131.2 (d, J = 2 Hz, C), 131.6 (CH), 132.0 (CH), 134.3 (t, J = 5 Hz, CH), 136.3 (t, J = 7 Hz, CH), 147.4 (d, J = 73 Hz, C), 158.1 (dd, J = 4, 3 Hz, C). ^{31}P

NMR (162 MHz) (ppm): +11.3. FAB-MS, *m/z* (relative intensity, %): 901 (9, $[M(^{35}Cl_2) + Na]^+$), 878 (9, $[M^+(^{35}Cl_2)]$).

X-ray crystallographic analysis on **15** was performed at the University of Calgary on an Enraf-Nonius CAD-4 diffractometer with graphite monochromated Cu Kα radiation. The following crystal parameters were obtained: monoclinic, $P2_1/n$ (No. 14); a = 16.673(5) Å, b = 18.478(7) Å, c = 13.702(3) Å; V = 4134(2) Å^3; Z = 4; R = 0.053; Rw = 0.041.

(–)-(S_{ax})-2,2′-Bis(selenodiphenylphosphinyl)-3,3′-binaphtho[2,1-*b*]furan (35)

The following procedure is based on a method reported by Allen and Taylor (51). To a 0.02 mol L^{-1} solution of the BINAPFu (–)-**3** (0.119 g, 0.170 mmol) in $CHCl_3$ was added 10 molar equivalents of Se dust (100 mesh). The resulting mixture was heated to reflux under an atmosphere of argon gas for a 5 h period. The cooled mixture was filtered through a pad of Celite®, and the filterings were washed with a small volume of $CHCl_3$. Concentration of the filtrate under reduced pressure furnished the crude phosphine selenide (–)-**35**. The crude product was recrystallized from CH_3CN to furnish the analytically pure product (0.142 g, 97%). X-ray diffraction analysis of a single crystal thus obtained, using the Bijvoet method, showed the *S*-configuration for the biaryl axis. Phosphine selenide (–)-**35** gave the following analytical data: mp 176–178 °C (CH_3CN). IR (KBr) (cm^{-1}): 2923, 1435, 1095, 1003. ^{1}H NMR (400 MHz) δ: 7.04–7.15 (m, 6H), 7.19–7.26 (m, 1H), 7.35 (t, J = 8.0 Hz, 1H), 7.49 (d, J = 8.2 Hz, 1H), 7.61 (d, J = 9.1 Hz, 1H), 7.67–7.79 (m, 4H), 7.82 (d, J = 9.1 Hz, 1H), 7.87 (d, J = 8.1 Hz, 1H). ^{13}C NMR (50 MHz) δ: 112.9 (CH), 122.5 (C), 122.6 (C), 123.2 (CH), 124.9 (d, J = 16 Hz, C), 125.4 (CH), 127.3 (CH), 128.1 (d, J = 3 Hz, CH), 128.2 (CH), 128.3 (CH), 129.2 (d, J = 3 Hz, CH), 129.2 (d, J = 21 Hz, C), 130.3 (d, J = 30 Hz, C), 131.2 (d, J = 3 Hz, C), 131.8 (d, J = 3 Hz, CH), 132.0 (d, J = 3 Hz, CH), 133.1 (d, J = 12 Hz, CH), 133.7 (d, J = 12 Hz, CH), 142.1 (d, J = 99 Hz, C), 155.2 (d, J = 7 Hz, C). ^{31}P NMR (162 MHz) (ppm): +19.4 ($^1J_{P\text{-}Se}$ = 762 Hz). MS, *m/z* (relative intensity, %): 597 (47, $[M^+ - PPh_2Se]$), 517 (100, $[M^+ - PPh_2Se_2]$). Exact mass calcd for $[M^+ - PPh_2{}^{80}Se]$: 597.0523; found: 597.0520. Anal calcd for $C_{48}H_{32}O_2P_2Se_2 + CH_3CN$: C 66.60, H 3.91, N 1.55; found: C 66.41, H 3.91, N 1.70.

X-ray crystallographic analysis on **35** was performed at the University of Calgary on a Rigaku AFC6S diffractometer with graphite-monochromated Mo Kα radiation. The following crystal parameters were obtained: monoclinic, $P2_1$ (No. 4); a = 9.842(4) Å; b = 21.045(5) Å; c = 10.347(3) Å; V = 2031(1) Å^3; Z = 2; R = 0.0406; Rw = 0.0915; Flack parameter (60) = 0.006(19). Bijvoet analysis was performed. A refinement of the inverted structure was carried out and converged with R = 0.0465 (Rw = 0.1043 with Flack parameter = 0.20(2)) and was therefore rejected as the absolute configuration present in the crystal.

General procedure for the Heck arylation of 2,3-dihydrofuran

Into a 2 dram (1 dram = 1.771845 g) screw-cap vial was measured $Pd(OAc)_2$ (2.2 mg, 9.97 μmol), (*S*)-BINAPFu (21.0 mg, 29.9 μmol), Hunig's base (255 μL, 1.46 mmol), and 1,4-dioxane (2.5 mL). The resulting mixture was heated to 60 °C under an argon atmosphere for 30 min. To the vessel was then added 2,3-dihydrofuran (189 μL, 2.50 mmol) and phenyl triflate (79 μL, 0.488 mmol). The mixture was thermostatically heated to 100 °C for a 7 day period. The crude mixture was filtered through a pad of celite and analyzed by chiral GC (Cyclodex B column, 80 °C start temperature, 2 min initial hold time, 1 °C min^{-1} ramp rate, 220 °C final temperature). The reaction products eluted in the following order: (*S*)-2-phenyl-2,3-dihydrofuran T_r = 26.1 min; (*R*)-5-phenyl-2,3-dihydrofuran T_r = 26.7 min; 2-phenyl-4,5-dihydrofuran T_r = 28.9 min; (*R*)-2-phenyl-2,5-dihydrofuran T_r = 31.2 min; (*S*)-2-phenyl-2,5-dihydrofuran T_r = 31.6 min.

A new family of monocyclopentadienyl organoscandium *bis*-alkyls supported by a bulky trialkylphosphine oxide ancillary[1]

Lee D. Henderson, Glen D. MacInnis, Warren E. Piers, and Masood Parvez

Abstract: Treatment of the oligomeric compound $[Cp^*ScCl_2]_n$ ($Cp^* = C_5Me_5$) with tri-*tert*-butylphosphine oxide in THF leads to the monocyclopentadienyl scandium dichloride $[Cp^*(t\text{-}Bu_3P{=}O)ScCl_2]$ as a monomeric, THF-free solid in 72% yield. This compound can be alkylated with MeLi to give the corresponding dimethyl derivative, $[Cp^*(t\text{-}Bu_3P{=}O)ScMe_2]$, **1**. The crystal structures of these two compounds have been done and reveal a three-legged piano stool geometry about the scandium center. The coordinated phosphine oxide ligand exchanges with free donor in both compounds via an associative mechanism, as indicated by the activation parameters ($\Delta H^{\ddagger}$ = 6.4–8.4 kcal mol^{-1}; $\Delta S^{\ddagger}$ = –22.5 to –26.6 eu). Thus, the $Cp^*(t\text{-}Bu_3P{=}O)$ ligand set provides a stable platform for organoscandium chemistry. This was demonstrated by the activation of **1** by treatment with $B(C_6F_5)_3$ to form the fully characterized contact ion pair $[Cp^*(t\text{-}Bu_3P{=}O)ScMe]^+[MeB(C_6F_5)_3]^-$, **2**, which is an active ethylene polymerization catalyst.

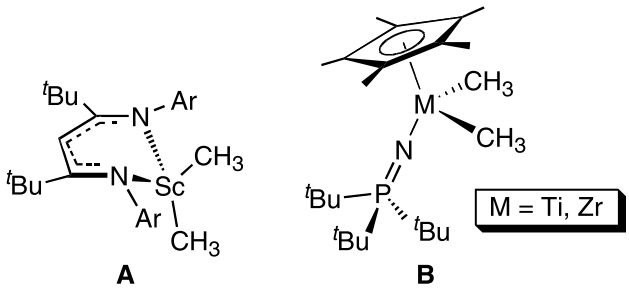
Key words: organoscandium compounds, olefin polymerization, cationic complexes.

Résumé : Le traitement du produit oligomère $[Cp^*ScCl_2]_n$ ($Cp^* = C_5Me_5$) avec de l'oxyde de tri-*tert*-butylphosphine, dans le THF, conduit à la formation du dichlorure de monocyclopentadiénylscandium, $[Cp^*(t\text{-}Bu_3P{=}O)ScCl_2]$, isolé avec un rendement de 72 %, sous la forme monomère et exempt de THF. Ce composé peut être alkylé avec du MeLi pour donner le dérivé diméthylé correspondant, $[Cp^*(t\text{-}Bu_3P{=}O)ScMe_2]$, **1**. On a déterminé les structures cristallines de ces deux composés qui comportent une géométrie en banc de piano à trois pattes autour du centre scandium. Le ligand oxyde de phosphine qui est coordiné s'échange avec un donneur libre dans les deux composés, par le biais d'un mécanisme associatif suggéré par les paramètres d'activation ($\Delta H^{\ddagger}$ = 6,4 à 8,4 kcal mol^{-1}; $\Delta S^{\ddagger}$ = –22,5 à –26,6 ue). Ainsi, l'ensemble de ligand $Cp^*t\text{-}Bu_3P{=}O$ fournit une plate-forme stable pour la chimie de composés organiques du scandium. Ceci a été démontré par l'activation de **1** par traitement avec du $B(C_6F_5)_3$ qui conduit à la formation de la paire d'ions de contact complètement caractérisé, $[Cp^*(t\text{-}Bu_3P{=}O)ScMe]^+[MeB(C_6F_5)_3]^-$ (**2**), qui est un catalyseur actif pour la polymérisation de l'éthylène.

Mots clés : composés organiques du scandium, polymérisation des oléfines, complexes cationiques.

[Traduit par la Rédaction]

Introduction



Suitable ligand environments for group 3 metal bis-alkyl functions free from occluded salts or coordinating solvent molecules are rare; this lack of abundance has prevented development of the chemistry of organo group 3 dialkyls to the same degree as the extensively explored group 4 dialkyls (1). A notable exception is the bulky β-diketiminato (nacnac) ligand framework (**A**) and related structures (2), which supports the chemistry of base-free scandium dialkyls (3) and cationic scandium alkyls (4) but cannot eliminate the need for THF ligation in analogous organoyttrium chemistry (5). Despite the success of this ligand ancillary and its derivatives (6), new environments are of interest in the continued expansion of this area of early transition-metal organometallic chemistry.

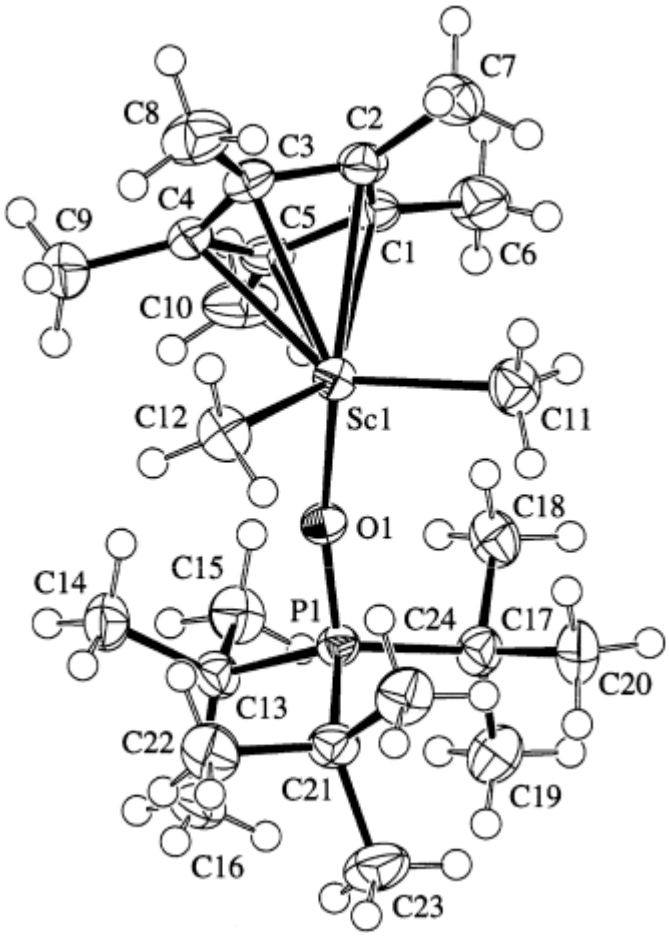
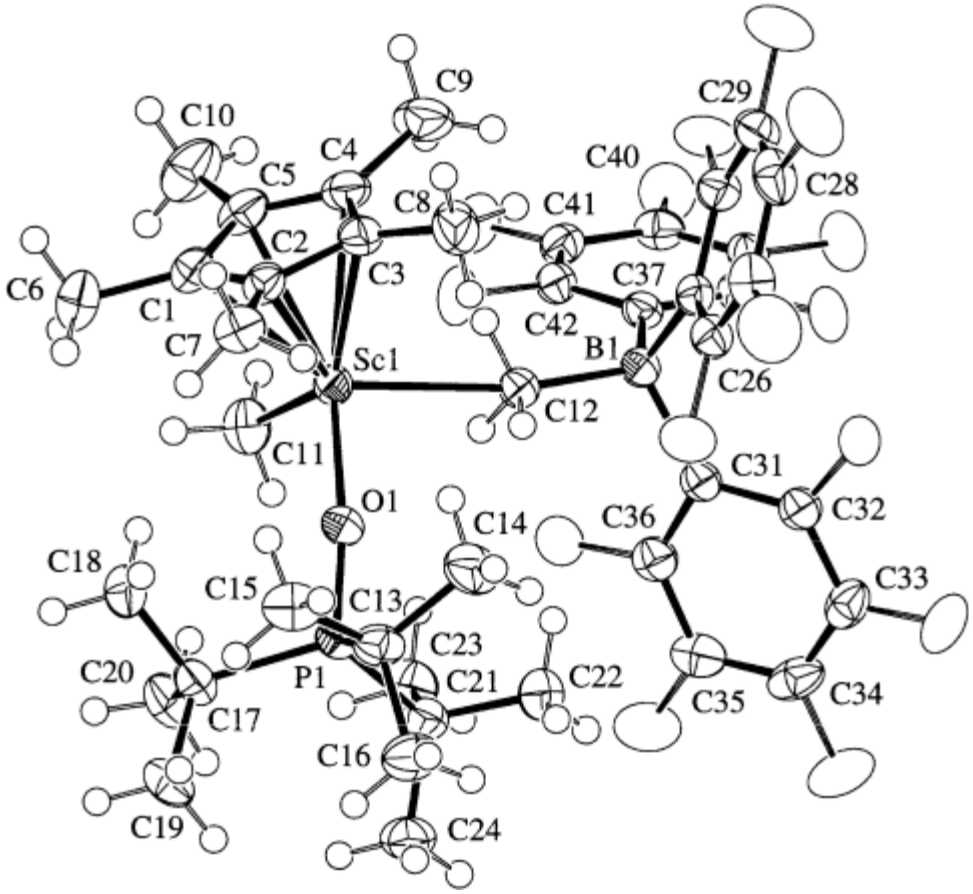


Scheme 1.

Inspiration for possible organo group 3 ligand environments can be found in successful areas of group 4 metal chemistry. Stephan and co-workers (7) and others (8) have demonstrated the efficacy of the bulky phosphinimide ligand t-$Bu_3P{=}N^-$ as a steric replacement for the Cp* ligand ($C_5Me_5^-$), following a strategy originally tendered by Wolczanski and co-workers (9) and embodied in the tri-*tert*-butylmethoxide "tritox" ligand system. Thus, the organotitanium and zirconium compounds **B** are sterically analogous to the more well-known permethylmetallocenes but with a somewhat more open environment in the immediate vicinity of the metal center, which confers high reactivity. Since dialkyl group 3 chemistry requires a monoanionic ancillary ligand set, either the Cp* or the phosphinimide ligand must be neutralized to transfer this general ligand environment to scandium or yttrium. Herein we describe the preparation and some preliminary chemistry of [Cp*(t-$Bu_3P{=}O$)$ScMe_2$], **1**, a new THF-free organoscandium dimethyl complex incorporating a bulky phosphine oxide ligand as a Cp* equivalent.

The synthesis of **1** is straightforward and shown in Scheme 1.[4] Treatment of $[Cp^*ScCl_2]_n$ (10), which possesses an ill-defined oligomeric structure, with t-$Bu_3P{=}O$ (11) leads to deoligomerization and formation of [Cp*(t-$Bu_3P{=}O$)$ScCl_2$] in good yield on a multigram scale. Downfield shifts in the ^1H and ^{31}P NMR spectra (by 0.18 ppm and 24.5 ppm, respectively) are observed for the coordinated t-$Bu_3P{=}O$ relative to the free ligand, mirroring trends observed in other $R_3P{=}O$ coordination compounds of scandium (12). Notably, the material is isolated free of THF even though the reaction is performed in this normally persistent solvent, attesting to the steric satisfaction provided by the Cp* – phosphine oxide combination to the Lewis-acidic scandium center. The dichloride is readily methylated when treated with MeLi in toluene, giving **1** in 45% isolated yield

Fig. 1. Molecular structure of [Cp*(t-$Bu_3P{=}O$)$ScMe_2$], **1**, with hydrogen atoms omitted for clarity. Selected metrical parameters are given below; numbers in parentheses are analogous distances and angles for [Cp*(t-$Bu_3P{=}O$)$ScCl_2$]. Distances (Å): Sc(1)—$Cp^*_{centroid}$, 2.21(1) (2.159(4)); Sc(1)—O(1), 2.072(1) (2.0373(1)); Sc(1)—C(11), 2.251(2) (Sc(1)—Cl(1), 2.3906(6)); Sc(1)—C(12), 2.252(2) (Sc(1)—Cl(2), 2.3995(5)); O(1)—P(1), 1.5225(13) (1.5336(10)). Angles (°): Sc(1)-O(1)-P(1), 162.09(8) (161.12(6)); O(1)-Sc(1)-C(11), 103.22(7) (101.01(3)); O(1)-Sc(1)-C(12), 100.16(7) (100.02(3)); C(11)-Sc(1)-C(12), 104.48(8) (105.54(2)).



(^1H NMR (Sc—Me) = –0.36 ppm; ^{31}P NMR = 82.2 ppm). Care must be taken not to expose this compound to excess MeLi, to avoid the formation of a side product that we believe to be the scandate complex $[Cp^*ScMe_3]^-[Li]^+$.

Both **1** and its dichloride precursor are monomeric in the solid state as determined by X-ray crystallography; the structure of **1** is shown in Fig. 1, along with selected metrical parameters for both compounds for comparative purposes. The structures are grossly similar to that reported for [Cp*(t-$Bu_3P{=}N$)$TiCl_2$] (7*a*), with the phosphine oxide ligand occupying a roughly equivalent region of coordination space to that of the Cp* ligand in a tetrahedral environment. Fig. 2. Molecular structure of $[Cp^*(t\text{-}Bu_3P{=}O)ScMe]^+[MeB(C_6F_5)_3]^-$, **2**, with hydrogen atoms omitted for clarity. Selected bond distances (Å): Sc(1)—$Cp^*_{centroid}$, 2.155(1); Sc(1)—O(1), 2.0370(13); Sc(1)—C(11), 2.201(2); Sc(1)—C(12), 2.529(11); O(1)—P(1), 1.536(13); B(1)—C(12), 1.658(7). Selected bond angles (°): Sc(1)-O(1)-P(1), 167.49(8); Sc(1)-C(12)-B(1), 170.00(11); O(1)-Sc(1)-C(11), 102.10(7); O(1)-Sc(1)-C(12), 95.06(5).

Scheme 2.

Sc(1)-O(1)-P(1) angles are about the same for both compounds and are bent slightly away from the Cp* ligand. The Sc(1)—O(1) distances are comparable with those of other phosphine oxide complexes of scandium (12) and intermediate between the typical distances for scandium alkoxides (≈1.90 Å (13)) and scandium ethers (≈2.20 Å (14)). In **1**, the Sc(1)—O(1) distance is elongated relative to the dichloride, reflecting the lower Lewis acidity of the Cp^*ScMe_2 fragment.

Despite the accessibility of these new organoscandium compounds, the dative nature of the phosphine oxide – scandium linkage raises concerns about the kinetic stability of this ligand and its suitability as an ancillary. Indeed, for both the dichloride and **1**, the coordinated $t\text{-}Bu_3P{=}O$ ligand exchanges with free ligand on the NMR timescale. The barriers to exchange, as measured by the coalescence method (15) using variable temperature ^1H NMR spectra, was 11.9(5) kcal mol^{-1} (253 K) for $[Cp^*(t\text{-}Bu_3P{=}O)ScCl_2]$ and 17.7(5) kcal mol^{-1} (363 K) for the less Lewis-acidic dimethyl derivative **1**. The activation parameters were determined by analysis of the rate constants at various temperatures using EXSY methods (16) and the $\Delta S^{\ddagger}$ values are –22.4(8) and –26.6(6) eu for the dichloride and **1**, respectively. These values are consistent with an associative mechanism for ligand exchange and indicate that the compounds are stable towards dissociation of the ligand under ambient conditions. It should be noted, however, that compound **1** decomposes to unknown products when heated to temperatures above 80 °C in toluene, a process that is accelerated in the donor solvent THF.

Treatment of **1** with 1 equiv of $B(C_6F_5)_3$ in toluene leads to a soluble contact ion pair, $[Cp^*(t\text{-}Bu_3P{=}O)ScMe]^+[MeB(C_6F_5)_3]^-$, **2** (Scheme 2), demonstrating that the Cp^*–$t\text{-}Bu_3P{=}O$ ligand set can deliver a stable platform for organometallic chemistry. Although phosphine oxide adducts of $B(C_6F_5)_3$ are known (17), the ^{11}B NMR chemical shift for **2** (–15.2 ppm) and the small difference between the *meta* and *para* fluorine signals in the ^{19}F NMR spectrum ($\Delta_{m,p}$ = 4.1 ppm (18)) clearly establishes **2** as a contact ion pair deriving from methide abstraction (19). Separate, nonexchanging signals for Sc-Me (–0.07 ppm) and B-Me (1.09 ppm, br) in-

© 2004 NRC Canada

dicate that this abstraction is irreversible, at least on the NMR timescale; a similar lack of Sc-Me–B-Me exchange is observed in the organoscandium methyl cation of complex **A** (4*b*). The structure was confirmed by X-ray analysis of colourless crystals of **2** grown from toluene; an ORTEP diagram is shown in Fig. 2, along with selected distances and angles. The carbon-boron distance in the anion is 1.658(7) Å, comparable with that observed in the contact ion pair formed from the β-diketiminato complex **A** (4*b*). In contrast to the nacnac system, however, there are no close Sc···F contacts, and the Sc(1)···C(12) contact of 2.529(11) Å is much closer than the 2.703(6) Å observed in the ion pair formed from **A**. In addition, the B(1)-C(12)-Sc(1) angle of 170.00(11)° is more characteristic of a metallocenium ion pair (19). The decreased steric congestion about scandium relative to **1** allows for a slightly more linearly coordinated phosphine oxide ligand (Sc(1)-O(1)-P(1) = 167.49(8)°).

Compound **2** is relatively thermally stable in solution, and preliminary experiments indicate that **2** is a highly active ethylene polymerization catalyst at room temperature and 1 atm (1 atm = 101.325 kPa) of ethylene (1.3×10^5 g mol^{-1} h^{-1} of polyethylene). However, polymerizations carried out at higher temperatures indicated a decline in activity presumably due to catalyst decomposition, either thermally or via catalyst interaction with the solvent and with monomer feed scrubbers present in the medium.

In summary, we have prepared a new dimethyl scandium derivative with a ligand environment that mimics the metallocene set (20) but provides two reactive hydrocarbyl ligands with which to develop new organoscandium chemistry. The facile preparation of these novel compounds offers an opportunity to open new areas of organoscandium chemistry.

New 1,3-dihydroazepin-2-one derivatives by [3,3]-sigmatropic rearrangement of suitably substituted 2-alkenylcyclopropyl isocyanates[1]

Hans-Ulrich Reissig, Gesine Böttcher, and Reinhold Zimmer

Abstract: The 2-siloxysubstituted 2-alkenylcyclopropanecarboxylic acids **10**–**14** were converted into the corresponding carbonyl azides by treatment with DPPA (diphenyl phosphorazidate) and triethylamine. On heating to 80 °C these intermediates smoothly furnished azepinone derivatives **19**–**25** in moderate to good overall yields, which are the result of a sequence of Curtius reaction to cyclopropylisocyanates, [3,3]-sigmatropic rearrangement, and a final proton shift. The primary products may undergo desilylation (to afford azepin-2,5-diones such as **23**) or double bond migration (to compound **25**). Cyclopropanecarboxylic acids *cis*-**32**, *cis*-**34**, and *cis*-**35**, which bear no 2-siloxy group, similarly provided azepinone derivatives **36**–**38** in good yields. No influence of the 2-siloxy substituent on the reaction course and rates could be observed in these qualitative studies, which was confirmed by DFT calculations with model compounds **39**–**42** showing similar reaction barriers for rearrangements of cyclopropylisocyanates with or without a 2-hydroxy group.

Key words: vinyl cyclopropanes, carbonylazides, [3.3]-sigmatropic rearrangements, azepinones.

Résumé : Les acides carboxyliques 2-alcénylcyclopropanecarboxyliques portant un substituant 2-siloxy (**10**–**14**) peuvent être transformés en azotures de carbonyle correspondants par traitement avec du phosphorazidate de diphényle (« DPPA ») et de la triéthylamine. Par chauffage à 80 °C, ces intermédiaires peuvent facilement se transformer en dérivés de l'azépinone (**19**–**25**) avec des rendements allant de moyens à bons; cette transformation est le résultat d'une séquence impliquant une réaction de Curtius conduisant aux isocyanates de cyclopropyle, d'un réarrangement sigmatropique [3,3] et d'un déplacement final de proton. Les produits primaires peuvent aussi subir une désilylation (qui conduisent à des azépine-2,5-diones, tel le produit **23**) ou une migration de double liaison (conduisant au composé **25**). Les acides cyclopropanecarboxyliques *cis*-**32**, *cis*-**34** et *cis*-**35** qui ne portent pas de groupe siloxy en position 2 conduisent aussi à des dérivés de l'azépinone (**36**–**38**) avec de bons rendements. Dans ces études qualitatives, on n'a pas observé d'influence du substituant siloxy en position 2 sur l'orientation ou la vitesse des réactions; cette observation a été confirmée par des calculs DFT sur les composés modèles **39**–**42** qui ont montré que les barrières aux réactions de réarrangement sont semblables pour les isocyanates de cyclopropyle avec ou sans groupe hydroxy en position 2.

Mots clés : vinylcyclopropanes, azoture de carbonyle, réarrangements sigmatropiques [3,3], azépinones.

[Traduit par la Rédaction]

Introduction

The Cope rearrangement of divinylcyclopropanes to cycloheptadienes establishes a valuable and stereoselective pathway to seven-membered ring systems often applied in natural product synthesis (1). Seminal contributions are due to the efforts of the Piers group (2). One method to generate functionalized divinylcyclopropane derivatives able to undergo the crucial 3,3-sigmatropic rearrangement employed vinylcyclopropyl ketones **A** that by *O*-silylation provided the corresponding silyl enol ethers **B**. Their thermolysis furnished cycloheptadiene derivatives **C**, and desilylation gave a series of 4-cyclohepten-1-ones **D** (3). Inspired by these results we anticipated that 2-siloxycyclopropanecarboxaldehydes **E** should be convertible into divinylcyclopropane derivatives **F** with an alternative substitution pattern that would finally provide 3-cyclohepten-1-ones via cycloheptadiene derivatives **G**. However, we had to learn that donor–acceptor substituted cyclopropanes (4) such as **E** can not be isolated since they immediately undergo the related [3,3]-

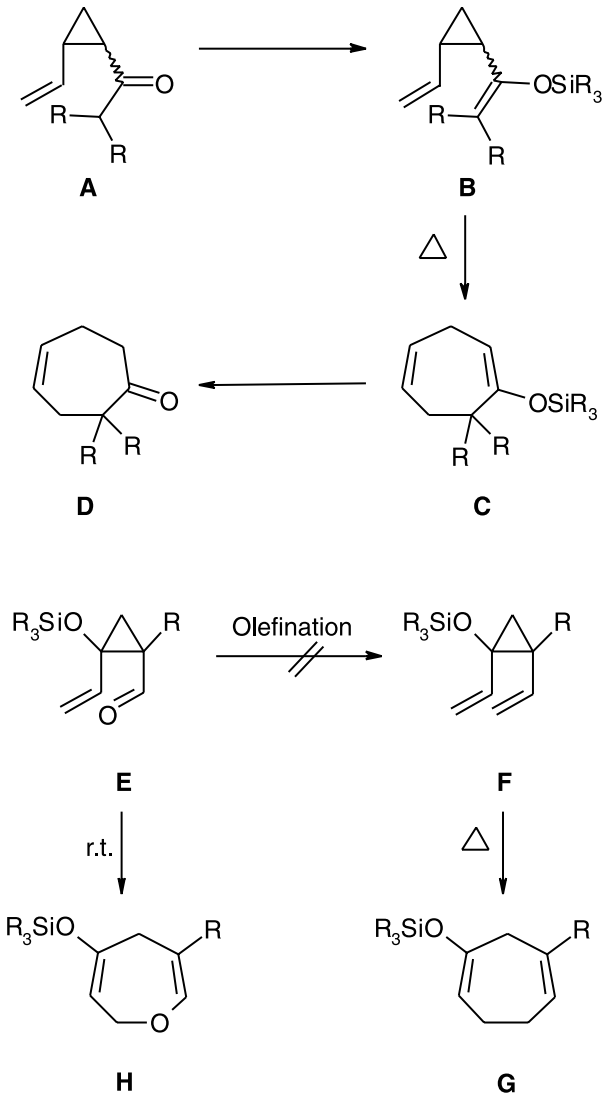
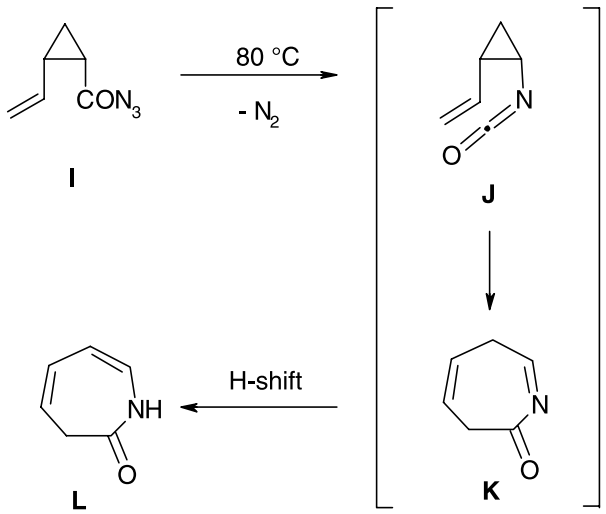
sigmatropic rearrangement involving the CO double bond, smoothly affording functionalized 2,5-dihydrooxepines **H** (5, 6) (Scheme 1).



This surprising entry to seven-membered heterocycles prompted us to investigate the rearrangements of other compounds derived from easily available methyl 2-alkenyl-2-siloxycyclopropanecarboxylates. Among several systems examined (7) cyclopropyl isocyanates turned out to be the most interesting compounds. Although early examples of their rearrangement have been known since the pioneer study of Vogel et al. (8) in 1965, this pathway to azepinone derivatives was an almost forgotten reaction. Vogel found that heating of cis-substituted carbonyl azide **I** to 80 °C smoothly provided the 1,3-dihydroazepin-2-one **L**. Logical intermediates are isocyanate **J**, formed by Curtius reaction, which rearranged to 3,6-dihydroazepin-2-one **K** and a hydrogen shift finally furnished lactam L. Only heating to 350 °C caused rearrangement of the corresponding trans-substituted carbonyl azide. Meanwhile, just a few additional examples have been reported (9), although this approach to seven-membered heterocycles seems to be fairly flexible. In this report we want to disclose full details of our experiments, which involved siloxysubstituted cyclopropyl isocyanates and provided the corresponding functionalized 1,3-dihydroazepin-2-ones. For comparison, a few examples without siloxy group were included in this study (Scheme 2).

Results



Although donor–acceptor substituted cyclopropanes are extremely versatile building blocks in organic synthesis (4), those with an additional 2-alkenyl group are even more useful. They open further pathways such as (formal) pericyclic processes involving the double bond or — after ring cleavage — Michael-type additions or Diels–Alder reactions of the intermediately generated enones. For the purpose of this study methyl 2-alkenyl-2-siloxycyclopropanecarboxylates **1**–**4** (10) with the less base labile *tert*-butyldimethylsilyl group were employed as starting materials. Compounds **1**–**4** are mixtures of cis/trans isomers, however, treatment with lithium diisopropylamide (LDA) followed by addition of an appropriate electrophile afforded C-1 substituted derivatives **5**–**9** in good yields and — most importantly — with the required cis arrangement of the alkenyl groups and the methoxycarbonyl group (11). We found many years ago that enolates derived from methyl siloxycyclopropanecarboxylates accept electrophiles with a surprising diastereoselectivity, which was interpreted as a stereoelectronic effect of the siloxy group (12) (Scheme 3).

Methyl esters **5**–**9** were easily converted into carboxylic acids **10**–**14** by treatment with potassium trimethylsilanolate — a mild method that has considerable advantages over standard saponification procedures (13). With carboxylic acid **13** we examined known literature methods for the conversion to the carbonyl azide. The Weinstock procedure (method A) (14), which employs ethyl chloroformate, triethylamine, and finally sodium azide in water, provided the desired cyclopropylcarbonyl azide **15** in 54% yield, whereas application of the commercially available diphenyl phosphorazidate (DPPA) in toluene at 0 °C (method B) (15) afforded **15** in 22% yield. Despite the lower yield in this example we gen-

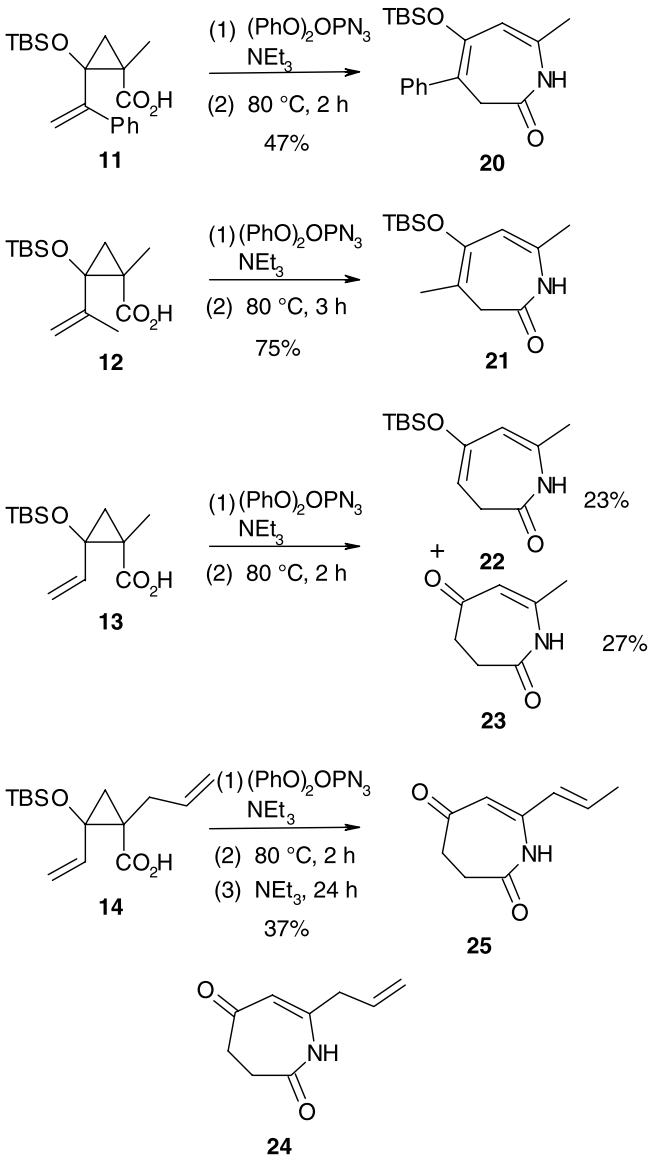
3	7	Me	Me	H	12	84
4	8	Me	H	H	13	70
4	9	Allyl	H	H	14	49

erally employed the latter method because it is easy to perform in organic solvents and the generated carbonyl azide can therefore be directly converted into the 1,3-dihydroazepin-2-ones by heating to 80 °C. To demonstrate this option carboxylic acid **10** was treated with DPPA at room temperature to furnish carbonyl azide **16** in 76% yield. Heating of this product to 80 °C for 3 h induced the Curtius rearrangement to cyclopropyl isocyanate **17**, which directly suffered the 3,3-sigmatropic ring-enlargement process, thus affording the expected bicyclic azepin-2-one derivative **19** in 68% yield via intermediate **18**. This sequence may be performed as a one-pot procedure without isolation of azide **16**; compound **19** was isolated in 48% yield, which is comparable to the two step procedure, but more convenient to perform (Scheme 4).

Having established the proper reaction conditions, we employed carboxylic acids **11**–**14** as starting materials. As expected, compounds **11** and **12** furnished seven-membered heterocycles **20** and **21** in good overall yield. The less-substituted carboxylic acid **13** led to rearranged product **22**, which is apparently more sensitive with respect to desilylation. Hydrolysis of the silyl enol ether unit of azepin-2-one **22** occurred probably during purification and produced 1*H*-

Scheme 4.



azepin-2,5-dione **23**. The rearrangement product obtained from carboxylic acid **14** seems to be even more labile. Here only 1*H*-azepin-2,5-dione derivatives **24** and **25** were isolated, primarily as a mixture with 7-(2-propenyl) and 7-(1-propenyl) substituents, but after treatment with triethylamine, compound **25** with conjugated double bonds was obtained exclusively in moderate yield. All reactions collected in Scheme 5 were not optimized, which should leave room for improvement of yields.

With carboxylic acid **13** we tried to trap the intermediate cyclopropyl isocyanate by performing the reaction sequence in *tert*-butanol instead of toluene. Surprisingly, only 1*H*-azepin-2,5-dione **23** was isolated in low yield (7). The expected urethane **26** could not be detected indicating that the rearrangement of the cyclopropyl isocycanate is considerably faster than the intermolecular reaction with *tert*-butanol. To gain additional insight into the reactivity of siloxy-substituted cyclopropyl azides we also studied phenyl-substituted derivative **28**, which was efficiently prepared from carboxylic acid **27** by the DPPA method. Curtius rearrangement of azide **28** occurred at 80 °C affording isocyanate **29** in excellent yield. Product **29** is the first siloxy-substituted cyclopropyl isocyanate that could be isolated. Unfortunately, this compound could not successfully be rearranged into a benzannulated azepine derivate. Finally, after a BF_3 etherate treatment of **29**, we isolated a little amount of a crystalline compound to which we assign structure **30** (16) (Scheme 6).

For comparison, we included *cis*-alkenylcyclopropanecarboxylic acids *without* a siloxy group into this study. The sequence to obtain the required cis-compounds is demonstrated for diphenyl-substituted compound **32**. Standard

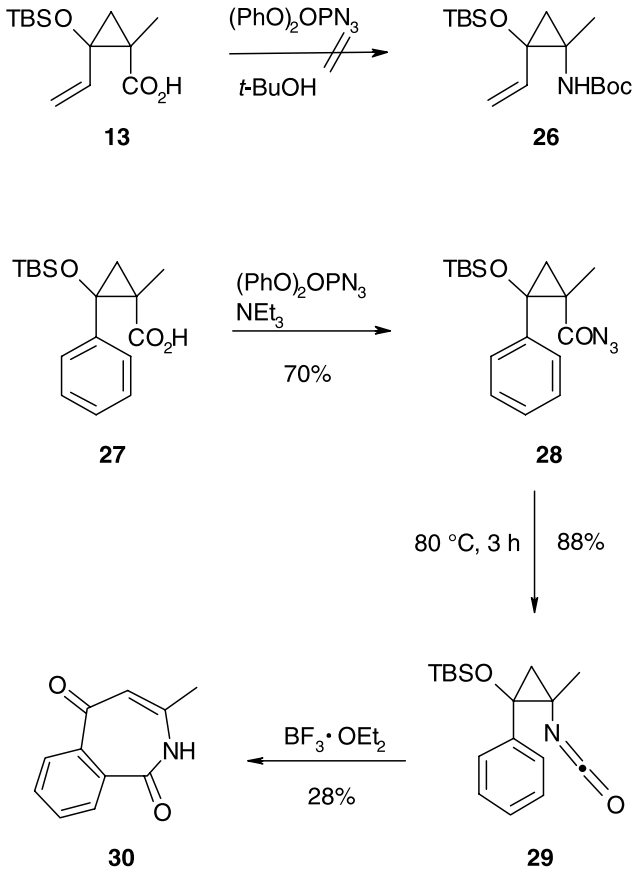
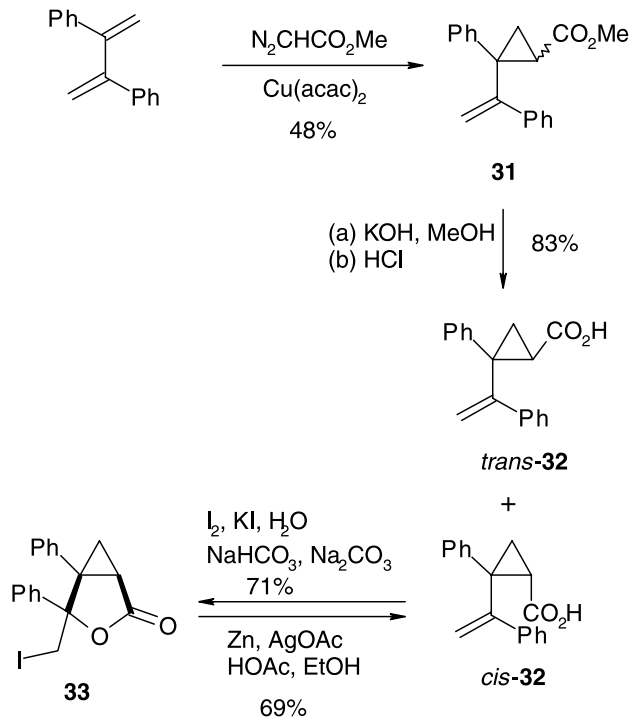


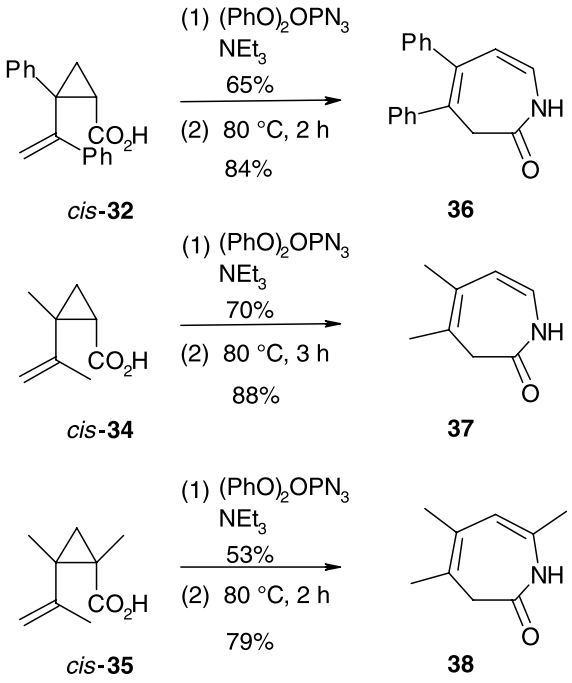
Scheme 5.



cyclopropanation of 2,3-diphenyl-1,3-butadiene with methyl diazoacetate provided the expected vinylcyclopropane derivative **31** in good yield and as a 57:43 mixture of diastereomers. The ester was saponified and the *cis*/*trans*-carboxylic acids **32** were subjected to iodolactonization (17), which provided a mixture of the iodolactone **33** (two diastereomers) derived from the cis-isomer and of unconsumed *trans*-**32**. Since the latter could easily be separated by extraction, the remaining iodolactone **33** was finally converted back to diastereomerically pure carboxylic acid *cis*-**32** by reduction with a zinc–silver couple in acetic acid (18). This chemical separation of diastereomers is fairly convenient and allowed the use of diastereomerically pure *cis*-cyclopropanecarboxylic acid **32**. Analogously, cis-compounds **34** and **35** were prepared from the corresponding alkenylcyclopropanes (Scheme 7).

Conversions of these three *cis*-alkenylcyclopropanecarboxylic acids **32**, **34**, and **35** into the corresponding azides by the DPPA method proceeded in good yields and subsequent thermal rearrangement of the purified azides smoothly

Scheme 6.



Scheme 7.

afforded the expected 1,3-dihydroazepin-2-ones **36**, **37**, and **38**, respectively, in moderate to good overall yields. No apparent difference in the reaction rates of the carbonyl azide

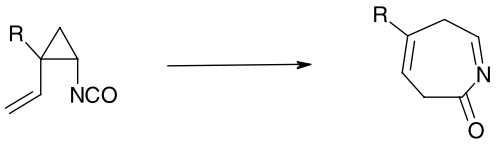
Scheme 8.



conversion or the rearrangement steps compared with siloxy-substituted compounds could be observed (Scheme 8).

Discussion

We found efficient methods to generate *cis*-alkenylcyclopropanecarboxylic acids (with or without a 2-siloxy group) and to convert these intermediates into the corresponding carbonyl azides. Individual examples of these azides were isolated. Their thermolysis at 80 °C afforded the desired 1,3-dihydroazepin-2-ones via alkenylcyclopropyl isocyanates. The Curtius rearrangement seems to be the rate-determining step of the sequence, since the isocyanate could only be isolated when a cis-located alkenyl group was absent (see compound **29**). For suitably cis-substituted compounds the subsequent [3,3]-sigmatropic ring-enlargement to the 3,6-dihydroazepin-2-one and the hydrogen shift to the final product are apparently much faster reactions (see Scheme 2).

For an estimation of the influence of the substitution pattern on the rate of the 3,3-sigmatropic rearrangement, Sperling (19)[4] performed DFT calculations (B3LYP/6-31G*) with two model systems **39** and **40**. The transformation of these compounds into 3,6-dihydroazepin-2-ones **41** and **42**, respectively, have to surpass only slightly different barriers that are in the order of 70 kJ/mol indicating that these rearrangements can occur at relatively low temperature — probably considerably lower than the applied 80 °C. In contrast, the reaction enthalpies are much more influenced by the substitution pattern: the cyclopropanol derivative **40** undergoes a much more exothermic reaction, which is likely due to the destabilization of the cyclopropane stage by this substituent and (or) the gain of conjugation in the product. These calculated energies suggest that the transition structures of the

Scheme 9.

	R	$\Delta H_o^{\ddagger}$(kJ/mol)	ΔH_o (kJ/mol)

40	OH	71.7	-61.7	**42**

Cope rearrangements are located early at the reaction coordinate, thus strongly resembling the starting materials and not the seven-membered products (Scheme 9).

Finally, we want to stress that the almost unexplored route to azepin-2-one derivatives via cyclopropyl isocyanates offers an interesting possibility for generating this type of heterocycle (20). The functionalized compounds presented in this report should be of interest for further synthetic use and can probably be employed in combinatorial chemistry.

Experimental section

All reactions were carried out under an argon atmosphere in flame-dried flasks, and the components were added by using syringes. All solvents were dried by standard methods. IR spectra were measured with a PerkinElmer FT-IR spectrometer Nicolet 5 SXC. ^{1}H and ^{13}C NMR spectra were recorded on Bruker instruments (AC 300, AC 500) in $CDCl_3$ solution. The chemical shifts are given relative to the TMS or to the $CDCl_3$ signal (δ_H = 7.27, δ_C = 77.0). The splitting patterns are designated as singulet (s), doublet (d), triplet (t), and multiplet (m). Higher order NMR spectra were approximately interpreted as first-order spectra if possible. CO_2H protons could not be identified for all carboxylic acids. Neutral alumina (activity III, Fa. Merck) was used for column chromatography. Melting points (uncorrected) were measured with an apparatus from Rapido.

Starting materials **1**–**4** and compounds **7**–**9** were prepared by literature procedures (21). Detailed procedures for synthesis of *cis*-**34** and *cis*-**35** are given in ref. 7. All other chemicals were commercially available and were used as received.

Methyl *t*-2-*tert*-butyldimethylsiloxy-*c*-2-(1-cyclohexenyl)-1-methyl-*r*-1-cyclopropanecarboxylate (5)

According to the general procedure described in ref. 21, 2-siloxycyclopropanecarboxylate **1** (2.68 g, 9.60 mmol) was deprotonated with LDA (14.4 mmol) and alkylated with methyliodide (7.04 g, 49.6 mmol) in THF (100 mL) at −78 °C for 17 h. Purification of the crude product (0.915 g) by Kugelrohr distillation (125 °C, 0.015 mbar (1 bar = 10^5 Pa) yielded 1.90 g (60%) of **6** as a colorless oil that slowly crystallized at room temperature (rt) (mp 38–42 °C). IR (cm^{-1}): 2935, 2855 (C-H), 1725 (C=O), 1250 (Si-C), 1305, 1150 (C-O). ^{1}H NMR ($CDCl_3$, 300 MHz) δ: 5.66 (m_c, 1H, 2′-H), 3.57 (s, 3H, CO_2Me), 2.25–1.99, 1.68–1.42 (2m, 8H, 3′-H to 6′-H), 1.88 (d, J = 5.8 Hz, 1H, 3-H_{trans}), 1.40 (s, 3H, 1-Me), 0.86 (s, 9H, *t*-Bu), 0.73 (d, J = 5.8 Hz, 1H, 3-H_{cis}),

Methyl *t*-2-*tert*-butyldimethylsiloxy-*c*-2-(1-phenylethenyl)-1-methyl-*r*-1-cyclopropanecarboxylate (6)

According to the general procedure described in ref. 21, 2-siloxycyclopropanecarboxylate **2** (0.922 g, 2.77 mmol) was deprotonated with LDA (4.00 mmol) and alkylated with methyliodide (1.09 g, 7.68 mmol) in THF (50 mL) at –78 °C for 19 h. Purification of the crude product (0.915 g) by column chromatography (heptane/EtOAc, 10:1) yielded 0.559 g (60%) of **6** as a colorless oil. ^1H NMR ($CDCl_3$, 300 MHz) δ: 7.40–7.07 (m, 5H, Ph), 5.55, 5.19 (2s, 1H each, 2′-H), 3.17 (s, 3H, CO_2Me), 1.96 (d, J = 5.9 Hz, 1H, 3-H_{trans}), 1.45 (s, 3H, 1-Me), 0.84 (d, J = 5.9 Hz, 1H, 3-H_{cis}), 0.64 (s, 9H, *t*-Bu), 0.00, –0.24 (2s, 6H, $SiMe_2$). ^{13}C NMR ($CDCl_3$, 75.5 MHz) δ: 172.6, 51.5 (s, q, CO_2Me), 145.5 (s, C-1′), 137.6, 127.8, 127.4, 126.9 (s, 3d, Ph), 115.0 (t, C-2′), 67.3 (s, C-2), 31.8 (s, C-1), 25.4, 18.0 (q, s, *t*-Bu), 24.3 (t, C-3), 15.0 (q, 1-Me), –4.0, –4.3 (2q, $SiMe_2$).

Saponification with $KOSiMe_3$ (general procedure 1)

To a solution of methyl cyclopropanecarboxylate (1 equiv.) in toluene (5 mL/mmol ester) was added $KOSiMe_3$ (3 equiv.) and the solution was heated (time and temperature are indicated in individual experiments). The mixture was cooled to room temperature, quenched with saturated aqueous ammonium chloride solution and the product was extracted with diethyl ether. The combined organic layers were dried over $MgSO_4$ and concentrated.

t-2-tert-*Butyldimethylsiloxy*-c-*2-(1-cyclohexenyl)-1-methyl*-r-*1-cyclopropanecarboxylic acid (10)*

According to *general procedure 1*, methyl cyclopropanecarboxylate **5** (1.86 g, 5.74 mmol) and $KOSiMe_3$ (2.21 g, 17.2 mmol) in toluene (60 mL) were heated for 3 h at 100 °C and yielded **10** (1.70 g, 96%) as a colorless solid, mp 115–120 °C. IR (cm^{-1}): 3400 (CO_2H), 2930, 2860 (C-H), 1690 (C=O), 1305, 1245 (Si-C). ^1H NMR ($CDCl_3$, 300 MHz) δ: 5.76 (m_c, 1H, 2′-H), 2.25–2.11 (m, 1H, 3′-H), 2.00 (br. s, 2H, 6′-H), 1.89 (d, J = 5.8 Hz, 1H, 3-H_{trans}), 1.72–1.60 (m, 1H, 3′-H), 1.53 (m_c, 4H, 4′-H, 5′-H), 1.40 (s, 3H, 1-Me), 0.87 (s, 9H, *t*-Bu), 0.79 (d, J = 5.8 Hz, 1H, 3-H_{cis}), 0.07, 0.06 (2s, 6H, $SiMe_2$). ^{13}C NMR ($CDCl_3$, 75.5 MHz) δ: 179.7 (s, CO_2H), 134.5 (s, C-1′), 126.5 (d, C-2′), 69.9 (s, C-2), 30.1 (s, C-1), 25.7, 18.1 (q, s, *t*-Bu), 25.2, 25.0, 22.6*,[5] 22.3 (4 t, C-3, C-3′ to C-6′), 14.8 (q, 1-Me), –3.8, –4.3 (2 q, $SiMe_2$). Preparation of cyclopropanecarbonyl azide (general procedure 2)

To a solution of the cyclopropanecarboxylic acid (1 equiv.) in toluene (3–5 mL/mmol acid) was added NEt_3 (1.3–1.7 equiv.) and DPPA (1.1–1.7 equiv.). After stirring at 0 °C for 1–3 h the solvent was removed in vacuo and the residue was filtered (silica gel, diethyl ether/pentane).

One-pot procedure for synthesis of 1,3-dihydroazepin-2-ones (general procedure 3)

The corresponding cyclopropanecarboxylic acid (1 equiv.) was dissolved in toluene (10–30 mL/mmol acid) and cooled to 0 °C. After addition of NEt_3 (5.2–6 equiv.) and DPPA (1.8–3 equiv.) the mixture was allowed to warm up to room temperature. The solution was stirred for 2 to 3 h at this temperature and then heated to 80 °C for 2 to 3 h. Removal of the solvent in vacuo gave the crude product that was purified by column chromatography (silica gel, heptane/EtOAc, 2:1 to 0:1) or by recrystallization (heptane/EtOAc).

t-*2*-tert-*Butyldimethylsiloxy-1-methyl*-c-*2-vinyl*-r-*1-cyclopropanecarbonyl azide (15)*

Method A

To a solution of cyclopropanecarboxylic acid **13** (0.120 g, 0.503 mmol) in acetone (5 mL) NEt_3 (0.074 g, 0.73 mmol) and ethyl chloroformiate (0.084 g, 0.77 mmol) were slowly added at 0 °C. After 20 min at 0 °C, NaN_3 (0.060 g, 0.90 mmol) dissolved in water (5 mL) was added dropwise to the solution and stirred at this temperature for a further 2 h. The reaction mixture was poured into a mixture of ice/water and extracted with chloroform. The combined organic layers were washed with water and dried over Na_2SO_4. Removal of the solvent in vacuo gave 0.076 g (54%) of **15** as colorless oil.

Method B

According to *general procedure 2*, cyclopropanecarboxylic acid **13** (0.100 g, 0.39 mmol), NEt_3 (0.190 g, 1.88 mmol) and DPPA (0.266 g, 0.966 mmol) in toluene (5 mL) were stirred for 1.5 h at 0 °C. The resulting mixture was diluted with diethyl ether (25 mL) and water (5 mL) and the aqueous phase was extracted with diethyl ether (2 × 20 mL). The combined organic phases were washed with satd. aq. $NaHCO_3$ solution and brine (5 mL each) and dried over $MgSO_4$. Purification by flash chromatography (heptane/EtOAc, 2:1) gave 0.024 g (22%) of **15** as a yellow oil and 0.116 g (43%) of DPPA. Compound **15**: ^1H NMR ($CDCl_3$, 300 MHz) δ: 5.73 (dd, J = 17.0, 10.7 Hz, 1H, 1′-H), 5.17 (dd J = 17.0, 1.5 Hz, 1H, 2′-H), 5.04 (dd, J = 10.7, 1.5 Hz, 1H, 2′-H), 1.85 (d, J = 6.2 Hz, 1H, 3-H_{trans}), 1.29 (s, 3H, 1-Me), 0.95 (d, J = 6.2 Hz, 1H, 3-H_{cis}), 0.79 (s, H, *t*-Bu), 0.01, –0.03 (2s, 6H, $SiMe_2$). ^{13}C NMR ($CDCl_3$, 75.5 MHz) δ: 179.3 (s, C=O), 135.7 (d, C-1′), 116.0 (t, C-2′), 67.0 (s, C-2), 35.4 (s, C-1), 26.7 (t, C-3), 25.8, 18.2 (q, s, *t*-Bu), 14.9 (q, 1-Me), –3.5, –3.6 (2q, $SiMe_2$).

t-*2*-tert-*Butyldimethylsiloxy*-c-*2-(1-cyclohexenyl)-1-methyl*-r-*1-cyclopropanecarbonyl azide (16)*

According to *general procedure 2*, cyclopropanecarboxylic acid **10** (0.304 g, 0.979 mmol), NEt_3 (0.124 g, 1.22 mmol) and DPPA (0.299 g, 1.09 mmol) in toluene (3 mL) were stirred for 1 h at 0 °C. Filtration (diethyl ether/pentane, 10:1) of the crude product yielded 0.248 g (76%) **16** as colorless crystals, mp 37–39 °C. IR (cm^{-1}): 2950 (CH), 2135 (N_3), 1695 (C=O), 1640 (C=C), 1250 (Si-C). ^1H NMR ($CDCl_3$, 300 MHz) δ: 5.62 (m_c, 1H, 2′-H), 2.26–2.09 (m, 1H, 3′-H), 2.00 (m_c, 2H, 6′-H), 1.93 (d, J = 5.7 Hz, 1H, 3-H_{trans}), 1.59–1.47 (m, 5H, 3′-H, 4′-H, 5′-H), 1.37 (s, 3H, 1-Me), 0.79 (s, 9H, *t*Bu), 0.77 (d, J = 5.7 Hz, 1H, 3-H_{cis}), 0.07, 0.06 (2s, 6H, $SiMe_2$). ^{13}C NMR ($CDCl_3$, 75.5 MHz) δ: 179.3 (s, C=O), 134.1 (s, C-1′), 127.0 (d, C-2′), 71.3 (s, C-2), 33.4 (s, C-1), 25.6, 18.1 (q, s, *t*-Bu), 25.8, 25.0, 22.6, 22.3 (4t, C-3′ to C-6′), 14.9 (q, 1-Me), –3.9, –4.3 (2q, $SiMe_2$). Anal. calcd. for $C_{17}H_{29}N_3O_2Si$ (284.5): C 60.86, H 8.71, N 12.52; found: C 61.64, H 9.25, N 12.27. No better elemental analysis could be obtained.

2-Aza-1-oxo-3-methyl-5-tert-butyldimethylsiloxy-4,5-dihydrobicyclo[4.5.0]decane (19)

Carbonyl azide **16** (0.206 g, 0.614 mmol) was heated in toluene (5 mL) for 3 h to 80 °C under an argon atmosphere. Removal of the solvent in vacuo and purification of the resulting residue by recrystallization (heptane) gave 0.128 g (68%) of azepinone **19** as colorless crystals, mp 125–129 °C. IR (cm^{-1}): 3420 (NH), 2940–2850 (CH), 1670 (C=O), 1640 (C=C), 1260 (Si-C). ^1H NMR ($CDCl_3$, 300 MHz) δ: 7.88 (br. s, 1H, NH), 5.49 (s, 1H, 4-H), 2.82–2.78 (m, 1H, 9-H), 2.39 (d, J = 6.8 Hz, 1H, 9a-H), 2.24 (m_c, 1H, 8-H), 1.96 (s, 3H, 3-Me), 1.84 (m_c, 1H, 9-H), 1.71–1.61 (m, 3H, 7-H, 6-H), 1.51–1.44 (m, 1H, 8-H), 1.35–1.28 (m, 1H, 7-H), 0.92 (s, 9H, *t*-Bu), 0.07, 0.00 (2s, 6H, $SiMe_2$). ^{13}C NMR ($CDCl_3$, 75.5 MHz) δ: 172.8 (s, C=O), 143.8 (s, C-5), 133.6 (s, C-3), 112.5 (s, C-5a), 111.4 (d, C-4), 39.2 (d, C-9a), 25.8, 18.1 (q, s, *t*-Bu), 23.7 (t, C-9), 23.2 (t, C-8), 22.9 (t, C-7), 22.1 (t, C-6), 21.8 (q, 3-Me), –3.9, -4.3 (2q, $SiMe_2$). Anal. calcd. for $C_{17}H_{29}NO_2Si$ (307.5): C 66.41, H 9.51, N 4.56: found: C 66.84, H 9.73, N 4.51.

One-pot procedure

According to *general procedure 3*, cyclopropanecarboxylic acid **10** (0.312 g, 1.00 mmol), NEt_3 (0.526 g, 5.20 mmol) and DPPA (0.523 g, 1.90 mmol) in toluene (10 mL) were stirred for 1 h at 0 °C and then heated for 2.5 h to 80 °C. Purification by column chromatography (heptane/EtOAc, 2:1) yielded 0.147 g (48%) azepinone **19** as colorless crystals, mp 126–130 °C.

5-tert-*Butyldimethylsiloxy-7-methyl-4-phenyl-1,3-dihydroazepin-2-one (20)*

According to *general procedure 3*, cyclopropanecarboxylic acid **11** (0.064 g, 0.192 mmol), NEt_3 (0.112 g,

© 2004 NRC Canada

1.11 mmol), and DPPA (0.161 g, 0.585 mmol) in toluene (5 mL) were stirred for 1 h at 0 °C and then heated for 2 h to 80 °C. Purification by column chromatography (heptane/EtOAc, 2:1 to 0:1) yielded 0.030 g (47%) of azepinone **20** as a colorless solid. ^{1}H NMR ($CDCl_3$, 300 MHz) δ: 7.90 (br. s, 1H, NH), 7.68–7.28 (m, 5H, Ph), 5.78 (s, 1H, 6-H), 3.24 (s, 2H, 3-H), 2.21 (s, 3H, 7-Me), 0.93 (s, 9H, *t*-Bu), 0.15 (s, 6H, $SiMe_2$). ^{13}C NMR ($CDCl_3$, 75.5 MHz) δ: 169.8 (s, C=O), 145.2 (s, C-5), 139.5 (s, C-7), 134.7, 128.5, 127.7, 126.2 (s, 3d, Ph), 112.7 (d, C-6), 111.3 (s, C-4), 39.7 (t, C-3), 25.6, 18.0 (q, s, *t*-Bu), 22.2 (q, 7-Me), -4.3 (q, $SiMe_2$). Anal. calcd. for $C_{19}H_{27}NO_2Si$ (329.5): C 69.26, H 8.26, N 4.25; found: C 68.68, H 7.89, N 4.40.

5-tert-*Butyldimethylsiloxy-4,7-dimethyl-1,3-dihydroazepin-2-one (21)*

According to *general procedure 3*, cyclopropanecarboxylic acid **12** (0.600 g, 2.22 mmol), NEt_3 (1.35 g, 13.3 mmol), and DPPA (1.16 g, 4.13 mmol) in toluene (20 mL) were stirred for 1 h at 0 °C and then heated for 3 h to 80 °C. Purification by column chromatography (hexane/EtOAc, 4:1 to 1.1) yielded 0.445 g (75%) of azepinone **21** as colorless needles, mp 141–143 °C. IR (cm^{-1}): 3500 (NH), 1685 (C=O), 1650 (C=C), 1250 (Si-C), 1200 (C-O). ^{1}H NMR ($CDCl_3$, 300 MHz) δ: 7.45 (br. s, 1H, NH), 5.39 (s, 1H, 6-H), 2.61 (s, 2H, 3-H), 1.90, 1.75 (2 s, 3H each, 4-Me, 7-Me), 0.86 (s, 9H, *t*-Bu), 0.00 (s, 6H, $SiMe_2$). ^{13}C NMR ($CDCl_3$, 75.5 MHz) δ: 169.0 (s, C=O), 144.1 (s, C-5), 133.3 (s, C-7), 111.9 (d, C-6), 108.6 (s, C-4), 39.9 (t, C-3), 25.7, 18.1 (q, s, *t*-Bu), 21.9, 17.5 (2q, 4-Me, 7-Me), –4.1 (q, $SiMe_2$). Anal. calcd. for $C_{14}H_{25}NO_2Si$ (267.4): C 62.87, H 9.42, N 5.24; found: C 62.73, H 9.18, N 5.20.

5-tert-*Butyldimethylsiloxy-7-methyl-1,3-dihydroazepin-2-one (22) and 7-methyl-3,4-dihydro-1*H-*azepin-2,5-dione (23)*

According to *general procedure 3*, cyclopropanecarboxylic acid **13** (0.261 g, 1.02 mmol), NEt_3 (0.543 g, 5.47 mmol), and DPPA (0.502 g, 1.82 mmol) in toluene (30 mL) were stirred for 1 h at 0 °C and then heated for 2 h to 80 °C. Purification by column chromatography (heptane/EtOAc, 4:1 to 1:3) yielded 0.056 g (23%) of azepinone **22** as a colorless solid and 0.037 g (27%) of azepindione **23** as colorless crystals, mp 179–184 °C. Compound **22**: IR (cm^{-1}): 3400 (NH), 2950–2800 (CH), 1690 (C=O), 1640 (C=C), 1430 (C-O), 1235 (Si-C). ^{1}H NMR ($CDCl_3$, 300 MHz) δ: 8.26 (br. s, 1H, NH), 5.33 (s, 1H, 6-H), 4.66 (t, *J* = 7 Hz, 1H, 4-H), 2.59 (d, *J* = 7 Hz, 2H, 3-H), 1.87 (s, 3H, 7-Me), 0.79 (s, 9H, *t*-Bu), 0.00 (s, 6H, $SiMe_2$). ^{13}C NMR ($CDCl_3$, 75.5 MHz) δ: 170.0 (s, C=O), 151.3 (s, C-5), 135.5 (s, C-7), 111.0 (d, C-6), 97.8 (d, C-4), 33.1 (t, C-3), 25.7, 18.2 (q, s, *t*-Bu), 22.2 (q, 7-Me), –4.7, –4.9 (2q, $SiMe_2$). Anal. calcd. for $C_{13}H_{23}NO_2Si$ (253.4): C 61.61, H 9.15, N 5.53; found: C 59.13, H 9.00, N 9.88. No better elemental analysis could be obtained. Compound **23**: IR (cm^{-1}): 3400 (NH), 2950 (CH), 1700 (C=O), 1650, 1615 (C=C). ^{1}H NMR ($CDCl_3$, 300 MHz) δ: 8.23 (br. s, 1H, NH), 5.47 (s, 1H, 6-H), 2.72 (m_c, 4H, 3-H, 4-H), 2.07 (s, 3H, 7-Me). ^{13}C NMR ($CDCl_3$, 75.5 MHz) δ: 196.9 (s, C-5), 174.8 (s, C-2), 145.9 (s, C-7), 111.7 (d, C-6), 35.5, 30.3 (2t, C-3, C-4), 24.3 (q, 7-Me). Anal. calcd. for $C_7H_9NO_2$ (139.1): C 60.42, H 6.52, N 10.07; found: C 60.34, H 6.76, N 10.03.

*7-Allyl-3,4-dihydro-1*H-*azepin-2,5-dione (24) and 7-(*E*)-(1-propenyl)-3,4-dihydro-1*H-*azepin-2,5-dione (25)*

According to *general procedure 3*, cyclopropanecarboxylic acid **14** (22) (0.074 g, 0.262 mmol), NEt_3 (0.144 g, 1.42 mmol), and DPPA (0.161 g, 0.585 mmol) in toluene (5 mL) were stirred for 1 h at 0 °C and then heated for 2 h to 80 °C. Purification by by column chromatography (heptane/EtOAc, 1:1) yielded 0.018 g (42%) of a mixture of azepindiones **24** and **25** as a colorless solid (ratio of **24**:**25**, ca. 1:1.2). Signals assigned to compound **24**: ^{1}H NMR ($CDCl_3$, 500 MHz) δ: 7.80 (br. s, 1H, NH), 5.79 (m_c, 1H, 2′-H), 5.50 (s, 1H, 6-H), 5.26 (dd, *J* = 7.8, 1.3 Hz, 1H, 3′-H), 2.84–2.63 (m, 4H, 3-H, 4-H).

Isomerization of 24 to 25

The mixture of **24**/**25** (0.016 g, 0.097 mmol) was stirred with NEt_3 (5 drops) in dichloromethane (2 mL) at room temperature for 24 h. Removal of the solvent in vacuo and purification of the residue by column chromatography (heptane/EtOAc, 1:2) yielded 0.016 g (37% from **14**) of azepindione **25** as colorless crystals, mp 122–130 °C. ^{1}H NMR ($CDCl_3$, 500 MHz) δ: 7.64 (br. s, 1H, NH), 6.31 (dq, *J* = 15.7, 6.8 Hz, 1H, 2′-H), 5.94 (dd, *J* = 15.7, 1.6 Hz, H, 1′-H), 5.53 (s, 1H, 6-H), 2.73 (m_c, 2H, 3-H), 2.32 (m_c, 2H, 4-H), 1.89 (dd, *J* = 6.8, 1.6 Hz, 3H, 3′-H). ^{13}C NMR ($CDCl_3$, 126 MHz) δ: 197.7 (s, C-5), 174.1 (s, C-2), 142.8 (s, C-7), 133.9 (d, C-1′), 128.7 (d, C-2′), 112.0 (d, C-6), 36.3 (t, C-3), 30.6 (t, C-4), 18.5 (q, C-3′). Due to the small amount of **25** no further characterization was possible.

t-*2*-tert-*Butyldimethylsiloxy-1-methyl*-c-*2-phenyl*-r-*1-cyclopropanecarboxylic acid (27)*

According to *general procedure 1*, the corresponding methyl cyclopropanecarboxylate (0.173 g, 0.540 mmol) and $KOSiMe_3$ (0.209 g, 1.62 mmol) in toluene (5 mL) were heated for 2.5 h to 100 °C and yielded **27** (0.144 g, 83%) as light yellow crystals, mp 140–145 °C (recrystallization from heptane/EtOAc). IR (cm^{-1}): 3450 (CO_2H), 2960 (CH), 1690 (C=O), 1255 (SiC). ^{1}H NMR ($CDCl_3$, 300 MHz) δ: 7.32–7.21 (m, 5H, Ph), 2.16 (d, *J* = 6.0 Hz, 1H, 3-H_{trans}), 1.51 (s, 3H, 1-Me), 1.01 (d, *J* = 6.0 Hz, 1H, 3-H_{cis}), 0.83 (s, 9H, *t*-Bu), 0.00, –0.37 (2s, 6H, $SiMe_2$). ^{13}C NMR ($CDCl_3$, 75.5 MHz) δ: 178.4 (s, CO_2H), 138.8, 128.7, 127.7, 127.6 (s, 3d, Ph), 67.7 (s, C-2), 31.8 (s, C-1), 25.6, 18.0 (q, s, *t*-Bu), 24.8 (t, C-3), 14.8 (q, 1-Me), –4.2*[5] (q, $SiMe_2$). Anal. calcd. for $C_{17}H_{26}O_3Si$ (306.5): C 66.62, H 8.55; found: C 67.06, H 8.67.

t-*2*-tert-*Butyldimethylsiloxy-1-methyl*-c-*2-phenyl*-r-*1-cyclopropanecarbonyl azide (28)*

According to *general procedure 2*, cyclopropanecarboxylic acid **27** (0.301 g, 0.982 mmol), NEt_3 (0.158 g, 1.56 mmol), and DPPA (0.300 g, 1.09 mmol) in toluene (5 mL) were stirred for 1 h at 0 °C. Filtration (pentane/diethyl ether, 10:1) of the crude product yielded 0.226 g (70%) of **28** as colorless crystals, mp 40–42 °C. IR (cm^{-1}): 2900 (CH), 2145 (N_3), 1695 (C=O), 1255 (SiC). ^{1}H NMR ($CDCl_3$, 300 MHz) δ: 7.32–7.23 (m, 5H, Ph), 2.35 (d, *J* = 6.1 Hz, 1H, 3-H_{trans}), 1.56 (s, 3H, 1-Me), 1.11 (d, *J* = 6.1 Hz, 1H, 3-H_{cis}), 0.84 (s, 9H, *t*-Bu), 0.01, –0.36 (2 s, 6H, $SiMe_2$). ^{13}C NMR ($CDCl_3$, 75.5 MHz) δ: 179.2 (s, C=O), 138.3, 128.8, 128.0, 127.8 (s, 3d, Ph), 68.9 (s, C-2), 34.8 (s,

© 2004 NRC Canada

C-1), 25.5, 17.9 (q, s, *t*-Bu), 25.4 (t, C-3), 14.9 (q, 1-Me), –4.2 (q, $SiMe_2$). Anal. calcd. for $C_{17}H_{25}N_3O_2Si$ (331.5): C 61.60, H 7.60, N 12.68; found: C 62.08, H 7.54, N 12.40.

t-*2*-tert-*Butyldimethylsiloxy-1-methyl*-c-*2-phenyl*-r-*1-cyclopropylisocyanate (29)*

Carbonyl azide **28** (0.126 g, 0.380 mmol) was heated in toluene (3 mL) for 2 h at 80 °C under an argon atmosphere. Removal of the solvent in vacuo and purification of the resulting crude product by filtration (silica gel, diethyl ether/pentane) gave 0.102 g (88%) of isocyanate **29** as a reddish oil. IR (cm^{-1}): 3080–2880 (CH), 2235 (NCO). ^{1}H NMR ($CDCl_3$, 300 MHz) δ: 7.43–7.25 (m, 5H, Ph), 1.64 (s, 3H, 1-Me), 1.62 (d, J = 7.2 Hz, 1H, 3-H_{trans}), 1.03 (d, J = 7.2 Hz, 1H, 3-H_{cis}), 0.84 (s, 9H, *t*-Bu), 0.00, –0.31 (2s, 6H, $SiMe_2$). ^{13}C NMR ($CDCl_3$, 75.5 MHz) δ: 138.7, 128.6, 128.4, 128.3 (s, 3d, Ph), 120.4 (br. s, NCO), 65.1 (s, C-2), 41.6 (s, C-1), 25.4 (t, C-3), 25.6, 17.9 (q, s, *t*Bu), 19.8 (q, 1-Me), –3.7, –4.0 (2q, $SiMe_2$). Anal. calcd. for $C_{17}H_{25}NO_2Si$ (303.5): C 67.29, H 8.30, N 4.68; found: C 67.26, H 8.25, N 4.56.

*3-Methyl-2*H-*benzo[c]azepin-2,5-dione (30)*

Analogously to ref. 23, isocyanate **29** (0.058 g, 0.185 mmol) was treated with boron trifluoride etherate (1 mL, ≈0.8 mmol) at 0 °C for 2.5 h. The reaction mixture was allowed to warm to room temperature and was then quenched with water (2 mL). The aqueous phase was extracted several times with diethyl ether and the combined organic phases were dried over $MgSO_4$. Purification of the resulting crude product by column chromatography (chloroform/methanol, 60:1) yielded 10 mg (28%) of azepindione **30** as colorless needles, mp 150–155 °C (lit. (16) mp 120–122 °C). ^{1}H NMR ($CDCl_3$, 500 MHz) δ: 8.10–8.04 (m, 2H, Ar), 7.74–7.66 (m, 1H, Ar), 7.58–7.50 (m, 1H, Ar), 7.50 (br. s, 1H, NH), 6.57 (s, 1H, 6-H), 2.41 (s, 3H, 7-Me). ^{13}C NMR ($CDCl_3$, 126 MHz) δ: 192.5 (s, C-5), 182.9 (s, C-2), 135.4, 131.2, 129.2, 129.0, 128.9, 128.6, 128.3 (3s, 4d, Ar, C-7), 97.4 (d, C-6), 24.8 (q, 7-Me). Due to the low amount of **30** no further characterization could be performed.

Methyl t/c-*2-phenyl*-c/t-*2-(1-phenylethenyl)*-r-*1-cyclopropanecarboxylate (31)*

Cyclopropane **31** was prepared according to the general procedure described in the literature (21) by slow addition of methyl diazoacetate (2.88 g, 28.0 mmol) to a refluxing suspension of $Cu(acac)_2$ (0.131 g, 0.500 mmol) and 2,3-diphenyl-1,3-butadiene (5.15 g, 25.0 mmol) in EtOAc (80 mL) (reaction time: 19 h). Purification was achieved by column chromatography (silica gel, heptane/EtOAc (6:1)). Fraction 1: 1.98 g (39%) starting material; fraction 2: 3.38 g (48%) of **31** (ratio of isomers = 57:43) as a colorless oil. IR (cm^{-1}): 3090 (CH), 1735 (C=O), 1380, 1170 (C-O). ^{1}H NMR ($CDCl_3$, 300 MHz) major isomer δ: 7.42–7.14 (m, 10H, Ph), 5.46 (s, 2H, 2′-H), 3.41 (s, 3H, CO_2Me), 2.52 (dd, J = 8.2, 5.8 Hz, 1H, 1-H), 2.17 (dd, J = 6.1, 5.8 Hz, 1H, 3-H_{trans}), 1.46 (dd, J = 8.2, 6.1 Hz, 1H, 3-H_{cis}); minor isomer δ: 7.42–7.14 (m, 10H, Ph), 5.89, 5.49 (2s, 1H each, 2′-H), 3.37 (s, 3H, CO_2Me), 2.60 (dd, J = 8.1, 6.2 Hz, 1H, 1-H), 2.00 (dd, J = 6.2, 4.9 Hz, 1H, 3-H_{trans}), 1.54 (dd, J = 8.1, 4.9 Hz, 1H, 3-H_{cis}). ^{13}C NMR ($CDCl_3$, 75.5 MHz) major isomer, δ: 170.8, 51.5 (s, q, CO_2Me), 139.1 (s, C-1′), 145.5, 138.1, 128.3, 127.9, 127.8, 127.1, 126.5, 126.3 (2s, 6d, Ph), 114.9 (t, C-2′), 40.0 (s, C-2), 27.6 (d, C-1), 17.8 (t, C-3); minor isomer δ: 170.7, 51.5 (s, q, CO_2Me), 150.7, 143.1 (2s, Ph), 139.3 (s, C-1′), 129.4, 128.0, 127.7, 127.5, 127.3, 126.7 (6d, Ph), 118.0 (t, C-2′), 38.7 (s, C-2), 29.8 (d, C-1), 23.1 (t, C-3). Anal. calcd. for $C_{19}H_{18}O_2$ (278.4): C 81.98, H 6.52; found: C 81.68, H 6.66.

t/c-*2-Phenyl*-c/t-*2-(1-phenylethenyl)*-r-*1-cyclopropanecarboxylic acid (32)*

Methyl cyclopropanecarboxylate **31** (1.94 g, 6.95 mmol, ratio of isomers = 47:53) was added to a solution of KOH (1.52 g, 25.0 mmol) in methanol (30 mL) and heated for 5 h under reflux. After removal of the solvent in vacuo, water was added to the residue and extracted several times with diethyl ether. The aqueous layer was acidified with a 2 N HCl solution under ice cooling to pH 2 to 3, extracted with diethyl ether (5 times), and the combined organic layers were dried over Na_2SO_4. Purification of the crude product by recrystallization (methanol) gave **32** (1.52 g, 83%, cis:trans = 45:55) as a colorless solid, mp 154–156 °C. For analytical data of *cis*- and *trans*-**32** see the next section.

Iodolactonization of carboxylic acid cis-*32*

According to a procedure described in the literature (17) cyclopropanecarboxylic acid **32** (1.61 g, 6.09 mmol, cis:trans = 48:52) was dissolved in a 1:1 mixture of 1.6 mol/L $NaHCO_3$ and satd. aq. Na_2CO_3 solution (6 mL each) and cooled to 0 °C. To this mixture a 0.7 mol/L solution of I_2 in 2.5 mol/L KI solution (5.6 mL, 3.92 mmol) was added dropwise over a period of 3 h. After stirring for 30 min at this temperature the precipitate (iodolactone **33**) was filtered off and washed with water. The resulting filtrate was extracted twice with chloroform, acidified with a 2 N HCl solution, and finally extracted with diethyl ether. Both organic phases were combined and dried over $MgSO_4$ and the solvent was removed to provide *trans*-**32**. Yield: 0.798 g (34%, with respect to *cis*-**32**: 71%) of iodolactone **33** as a solid, mp 59–64 °C, and 0.466 g (29%, with respect to *trans*-**32**: 56%) of *trans*-**32** as a colorless oil.

4-Iodomethyl-4,5-diphenyl-3-oxa-bicyclo[3.1.0]hexan-2-one (33)

A 1:1 mixture of two diastereomers. IR (cm^{-1}): 1765 (C=O), 1445, 1185, 990, 965, 760. ^{1}H NMR ($CDCl_3$, 300 MHz) δ: 7.45–7.08 (m, 20H, Ph), 3.96, 3.86, 3.72, 3.53 (4 d, J = 11.4 Hz, 1H each, 4-CH_2), 2.53 (dd, J = 8.4, 4.2 Hz, 1H, 1-H*[6]), 2.47 (dd, J = 9.0, 3.1 Hz, 1H, 1-H*[6]), 1.75 (dd, J = 4.9, 3.1 Hz, 1H, 6-H*[6]), 1.37–1.30 (m, 3H, 6-H*[6]). ^{13}C NMR ($CDCl_3$, 75.5 MHz) δ: 174.3, 174.2 (2 s, C=O), 139.5, 139.4, 134.4, 134.2, 131.5, 130.7, 129.0, 128.7, 128.5, 128.4, 128.3, 128.3, 128.1, 127.9, 125.7, 125.0 (4s, 12d, Ph), 88.1, 86.5 (2s, C-5), 42.3, 40.4 (2s, C-4), 25.9*[5] (d, C-1), 19.2, 19.0 (2t, C-6), 14.3, 7.9 (2t, C-1′) HR-MS (80 eV) calcd. for $C_{18}H_{25}O_2I$: 390.0117; found: 390.0132.

***c-2-Phenyl-t-2-(1-phenylethenyl)-r-1-cyclopropanecarboxylic acid* (trans-*32*)**

^{1}H NMR ($CDCl_3$, 300 MHz) δ: 7.44–7.09 (m, 10H, Ph), 6.90 (br. s, 1H, CO_2H), 5.44 (s, 2H, 2′-H), 2.47 (dd, J = 8.1, 5.8 Hz, 1H, 1-H), 2.11 (t, J = 5.5 Hz, 1H, 3-H_{trans}), 1.50 (dd, J = 8.1, 4.9 Hz, 1H, 3-H_{cis}). Anal. calcd. for $C_{18}H_{16}O_2$ (264.3): C 81.79, H 6.10; found: C 81.61, H 6.10.

***t-2-Phenyl-c-2-(1-phenylethenyl)-r-1-cyclopropanecarboxylic acid* (cis-*32*)**

According to a procedure described in the literature (18) zinc dust (0.395 g, 6.23 mmol) was added to a hot solution of AgOAc (0.0039 g, 0.0234 mmol) and glacial acid (15 drops) and stirred for 30 min. After removal of the glacial acid the residue was washed with diethyl ether (5 times). To the resulting Ag/Zn couple were added the iodolactone **33** (0.700 g, 1.79 mmol) dissolved in diethyl ether (15 mL), ethanol (4.25 mL), and few drops of glacial acid and the suspension was heated under reflux for 7 h. The cooled suspension was filtered and the filtrate was successively washed with satd. aq. $NaHCO_3$ solution and brine. Drying of the organic layer with $MgSO_4$ and removal of the solvent gave 0.146 g of the crude product, which was purified by column chromatography (heptane/EtOAc, 4:1). Yield: 0.327 g (69%) of *cis*-**32** as a colorless oil. IR (cm^{-1}): 3400 (CO_2H), 2925 (CH), 1700 (C=O), 1440, 1225. ^{1}H NMR ($CDCl_3$, 300 MHz) δ: 10.21 (br. s, 1H, CO_2H), 7.36–7.13 (m, 10H, Ph), 5.76, 5.42 (2s, 1H each, 2′-H), 2.52 (dd, J = 8.1, 6.1 Hz, 1H, 1-H), 1.90 (dd, J = 6.1, 5.0 Hz, 1H, 3-H_{trans}), 1.56 (dd, J = 8.1, 5.0 Hz, 1H, 3-H_{cis}). ^{13}C NMR ($CDCl_3$, 75.5 MHz) δ: 176.9 (s, C=O), 145.2 (s, C-1′), 142.9, 139.5, 128.4, 128.0, 127.6, 127.4, 126.7, 126.5 (2s, 6d, Ph), 118.1 (t, C-2′), 39.8 (s, C-2), 36.1 (d, C-1), 23.1 (t, C-3). HR-MS (80 eV) calcd.: 264.1150; found: 264.1163. Anal. calcd. for $C_{18}H_{16}O_2$ (264.3): C 81.79, H 6.10; found: C 80.93, H 6.17.

4,5-Diphenyl-1,3-dihydroazepin-2-one (36)

According to *general procedure 2*, cyclopropanecarboxylic acid *cis*-**32** (0.258 g, 0.976 mmol), NEt_3 (0.335 g, 3.32 mmol), and DPPA (0.170 g, 1.68 mmol) in toluene (20 mL) were stirred for 2 h at 0 °C. Filtration (diethyl ether/pentane, 20:1) of the crude product yielded 0.184 g (65%) of *t*-2-phenyl-*c*-2-(1-phenylethenyl)-*r*-1-cyclopropanecarbonyl azide as a colorless oil. IR (cm^{-1}): 3060, 2950 (CH), 2135 (N_3), 1710 (C=O), 1495 (CH). ^{1}H NMR ($CDCl_3$, 300 MHz) δ: 7.39–7.16 (m, 10H, Ph), 5.92, 5.50 (2 s, 1H each, 2′-H), 2.58 (dd, J = 8.0, 6.1 Hz, 1H, 1-H), 2.08 (dd, J = 6.1, 5.0 Hz, 1H, 3-H_{trans}), 1.64 (dd, J = 8.0, 5.0 Hz, 1H, 3-H_{cis}). ^{13}C NMR ($CDCl_3$, 75.5 MHz) δ: 176.5 (C=O), 144.6 (s, C-1′), 142.2, 139.0, 128.4, 128.0, 127.5, 126.7, 126.6, 126.3 (2s, 6d, Ph), 118.6 (t, C-2′), 41.5 (s, C-2), 32.3 (d, C-1), 24.4 (t, C-3). Anal. calcd. for $C_{18}H_{15}N_3O$ (298.3): C 74.72, H 5.22, N 14.52; found: C 74.46, H 5.13, N 13.86.

The azide (0.192 g, 0.446 mmol) was heated in toluene (10 mL) for 2 h to 100 °C under an argon atmosphere. Removal of the solvent in vacuo and purification of the resulting product by recrystallization (heptane/EtOAc) gave 0.098 g (84%) of azepinone **36** as colorless crystals, mp 181–183 °C. IR (cm^{-1}): 3205 (NH), 3080 (CH), 1675 (C=O), 1625 (C=C). ^{1}H NMR ($CDCl_3$, 300 MHz) δ: 9.18 (br. s, 1H, NH), 7.43–6.93 (m, 10H, 2 Ph), 6.36 (dd, J = 8.9, 4.7 Hz, 1H, 7-H), 5.96 (d, J = 8.9 Hz, 1H, 6-H), 3.38 (s, 2H, 3-H). ^{13}C NMR ($CDCl_3$, 75.5 MHz) δ: 168.1 (s, C-2), 140.8, 140.0, 135.8, 128.2 (4s, Ph, C-4, C-5), 130.1, 120.0, 127.9, 127.8, 127.0, 126.8, 125.6 (7d, Ph, C-7), 118.3 (d, C-6), 44.2 (t, C-3). Anal. calcd. for $C_{18}H_{15}NO$ (261.3): C 82.37, H 5.78, N 5.36; found: C 82.01, H 5.70, N 5.26.

4,5-Dimethyl-1,3-dihydro-azepin-2-one (37)

According to *general procedure 2*, cyclopropanecarboxylic acid *cis*-**34** (0.240 g, 1.71 mmol), NEt_3 (0.288 g, 2.85 mmol), and DPPA (0.554 g, 2.01 mmol) in toluene (5 mL) were stirred for 3 h at 0 °C. Filtration (diethyl ether/pentane 20:1) of the crude product yielded 0.194 g (70%) of *c*-2-isopropenyl-*t*-2-methyl-*r*-1-cyclopropanecarbonyl azide as a colorless oil. IR (cm^{-1}): 2975 (CH), 2160 (N_3), 1705 (C=O), 1650 (C=C), 1375, 1195. ^{1}H NMR ($CDCl_3$, 300 MHz) δ: 4.96 (q, J = 1.5 Hz, 1H, 2′-H), 4.91 (s, 1H, 2′-H), 1.73 (br. s, 3H, 1′-Me), 1.70–1.64 (m, 2H, 1-H, 3-H), 1.29 (s, 3H, 2-Me), 1.11–1.07 (m, 1H, 3-H). ^{13}C NMR ($CDCl_3$, 75.5 MHz) δ: 177.4 (s, C=O), 143.3 (s, C-1′), 114.3 (t, C-2′), 37.0 (s, C-2), 30.4, 25.1, 20.8 (d, 2q, C-1, 1′-Me, 2-Me), 22.3 (t, C-3). Anal. calcd. for $C_8H_{11}N_3O$ (165.2): C 58.17, H 6.71, N 25.44; found: C 57.39, H 6.61, N 23.42.

The crude product (0.042 g, 0.274 mmol) was heated in toluene (2 mL) for 2 h to 100 °C under an argon atmosphere. Removal of the solvent gave 0.033 g (88%) of azepinone **37** as a colorless solid. ^{1}H NMR ($CDCl_3$, 300 MHz) δ: 8.26 (br. s, 1H, NH), 6.09 (dd, J = 8.8, 4.4 Hz, 1H, 7-H), 5.73 (d, J = 8.8 Hz, 1H, 6-H), 2.78 (s, 2H, 3-H), 1.91, 1.80 (2s, 3H each, 4-Me, 5-Me). ^{13}C NMR ($CDCl_3$, 75.5 MHz) δ: 168.3 (s, C-2), 127.9, 124.4 (2d, C-6, C-7), 122.7, 111.9 (2s, C-4, C-5), 43.7 (t, C-3), 20.7, 17.9 (2q, 4-Me, 5-Me). Due to the low amount of **37** no elemental analysis could be performed.

4,5,7-Trimethyl-1,3-dihydroazepin-2-one (38)

According to *general procedure 2*, cyclopropanecarboxylic acid *cis*-**35** (0.254 g, 1.65 mmol), NEt_3 (0.231 g, 2.28 mmol), and DPPA (0.488 g, 1.77 mmol) in toluene (5 mL) were stirred for 1 h at 0 °C. Filtration (diethyl ether/pentane, 20:1) of the crude product yielded 0.159 g (53%) of *c*-2-isopropenyl-*t*-1,2-dimethyl-*r*-1-cyclopropanecarbonyl azide as a colorless oil. IR (cm^{-1}): 2970 (CH), 2135 (N_3), 1705 (C=O), 1680 (C=C). ^{1}H NMR ($CDCl_3$, 300 MHz) δ: 4.84, 4.01 (2m, 1H each, 2′-H), 1.90 (d, J = 4.8 Hz, 1H, 3-H_{trans}), 1.73 (br. s, 3H, 1′-Me), 1.40, 1.32 (2s, 3H each, 2-Me, 1-Me), 0.68 (d, J = 4.8 Hz, 1H, 3-H_{cis}). ^{13}C NMR ($CDCl_3$, 75.5 MHz) δ: 180.3 (s, C=O), 145.3 (s, C-1′), 113.3 (t, C-2′), 38.2 (s, C-2), 32.4 (s, C-1), 27.0 (t, C-3), 20.8, 20.7, 16.0 (3q, 2-Me, 1′-Me, 1-Me). Anal. calcd. for $C_9H_{13}N_3O$ (179.2): C 60.32, H 7.31, N 23.45; found: C 60.53, H 7.89, N 21.70.

The azide (0.068 g, 0.379 mmol) was heated in toluene (3 mL) for 2 h to 80 °C under an argon atmosphere. Removal of the solvent in vacuo and recrystallization (heptane/EtOAc) gave 0.045 g (79%) of azepinone **38** as colorless crystals, mp 130–132 °C. IR (cm^{-1}): 3500–3400 (NH) 3080, 2950–2850 (CH), 1650 (C=O), 1610 (C=C), 1380 (CH). ^{1}H NMR ($CDCl_3$, 300 MHz) δ: 8.36 (br. s, 1H, NH), 5.56 (s, 1H, 6-H), 2.76 (s, 2H, 3-H), 1.99, 1.87, 1.75 (3s, 3H each, 4-Me, 5-Me, 7-Me). ^{13}C NMR ($CDCl_3$, 75.5 MHz) δ: 167.7 (s, C-2), 131.7, 127.9, 122.2 (3s, C-4, C-5, C-7), 117.3 (d, C-6), 43.4 (t, C-3), 22.1, 20.4, 18.0 (3q, 4-Me, 5-Me, 7-

An iterative approach to three fragments of ionomycin[1]

Claude Spino and Martin Allan

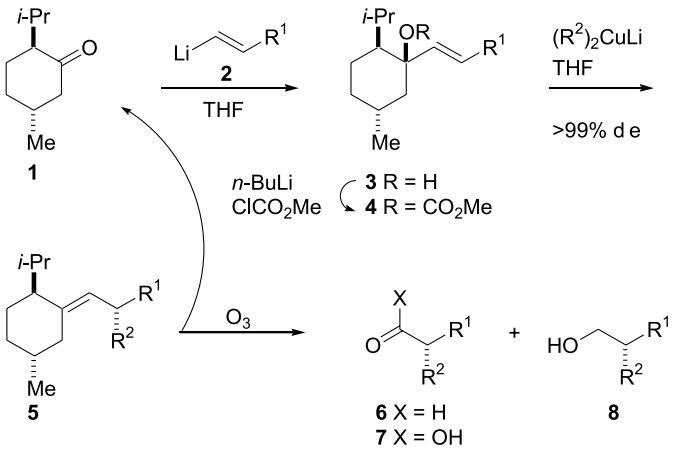
Abstract: The S_N2' displacement of menthone-derived allylic carbonates with cuprate reagents occurs with high diastereoselectivity. This method can be used in an iterative fashion to construct stereocenters bearing a 1,3-relationship in a carbon chain. Each iteration provides the adduct in greater than 99% de. The synthesis of three fragments of the polyether ionophore ionomycin is disclosed.

Key words: menthone, chiral auxiliary, S_N2' displacement, cuprate, iteration, ionomycin.

Résumé : La substitution S_N2' de carbonates allyliques dérivés de la menthone avec des cuprates se produit avec une grande diastéréosélectivité. On peut utiliser cette méthode de façon itérative pour construire des stéréocentres ayant une relation 1,3 dans une chaîne carbonée. Chaque itération fournit l'adduit avec un excès diastéréomérique plus grand que 99 %. On a réalisé la synthèse de trois fragments du polyéther ionophore de l'ionomycine.

Mots clés : menthone, auxiliaire chiral, substitution S_N2', cuprate, itération, ionomycine.

[Traduit par la Rédaction]



Introduction

We have developed in recent years a methodology equivalent to the alkylation of chiral enolates (1, 2). The key step in the strategy is the S_N2' displacement by cuprate reagents of a chiral allylic carbonate derived from (+)- or (–)-menthone **1** (Scheme 1). The transfer of chirality from carbonate **4** is generally high. Among the advantages of this strategy over the alkylation of chiral enolates is the higher diastereoselectivity generally achieved and the possible introduction of aryl and 2° or 3° alkyl groups.

Conceptually, the iterative alkylation of chiral enolates to form polyalkyl chains with a 1,3-relationship between the stereocenters is appealing. However, the relatively low reactivity of chiral enolates sometimes prohibits their reaction with β-branched alkyl halides or often requires that the electrophile be used in large excess. In addition, to be useful, any method used iteratively must provide products of high stereochemical purity at each iteration. For these reasons, examples of the use of enolates in an iterative approach to synthesis are scarce (3). The high diastereoselectivities and increased reactivity provided by our system prompted us to verify it's usefulness in an iterative approach to three fragments of the polyether ionophore ionomycin (Fig. 1) (4, 5).

We prepared a large quantity of **3** (R^1 = Me), the addition product of *trans*-propenyllithium to (–)-menthone (Scheme 1). The alcohol was isolated as a single diastereomer (1). We also prepared *ent*-**3** (R^1 = Me) starting from (+)-menthone. The corresponding carbonate **4** (R^1 = Me) was prepared immediately before its reaction with the cyanocuprate derived from *tert*-butyl methyl ether (6). Compound **9a** was then isolated in 92% yield (Scheme 2). Analysis by GC revealed the presence of essentially one diastereomer. For analysis purposes, the diastereomer **9b** was prepared from the same menthone, by addition of the cuprate derived from methyllithium on the carbonate of **13**, bearing the $CH_2O(t\text{-Bu})$ moiety (Scheme 3).

Scheme 1.

Ozonolysis of **9a** with a reductive work-up ($NaBH_4$) and conversion of the resulting alcohol **10** to the iodide **11** was achieved in high yield. In addition, some quantity of **10** was

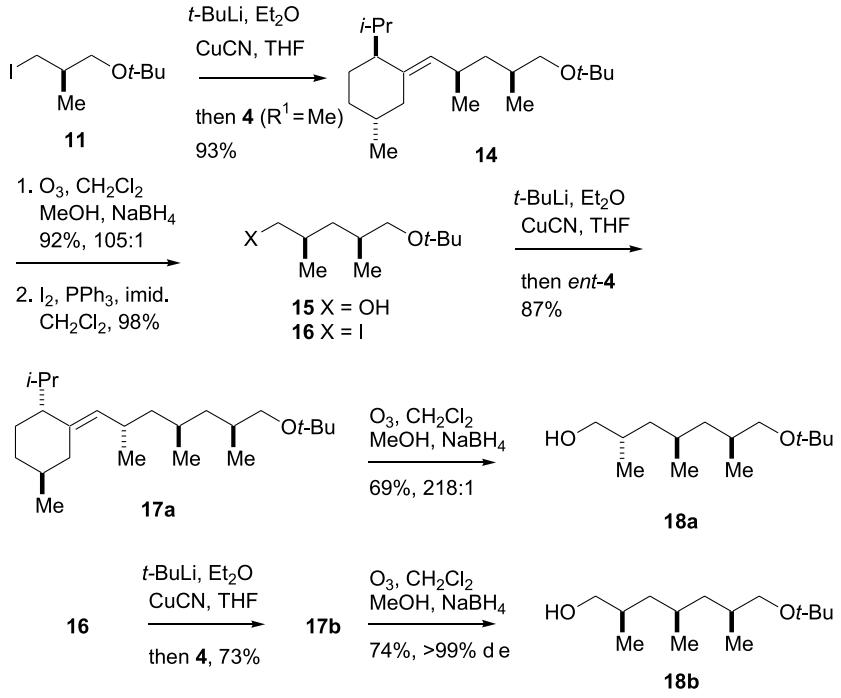
oxidized to the aldehyde **12**, which is an intermediate to fragment C of ionomycin. This two-steps procedure for **12** was more efficient than the direct ozonolysis of **9a** in terms of yield and purity of the aldehyde, which was then used crude in the next step (vide infra).

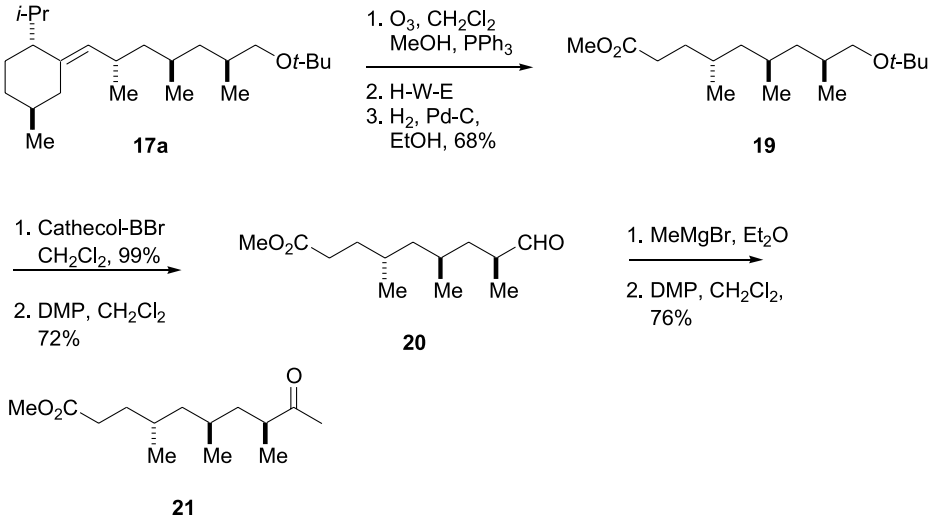
The first iteration was tested with iodide **11**. Exchange of the iodine for lithium was accomplished with *t*-BuLi in diethyl ether and the monoalkylcyanocuprate derived from the resulting alkyllithium was added to carbonate **4** (R^1 = Me) with high diastereoselectivity to give **14** in 93% isolated yield (Scheme 4). Ozonolysis of **14** furnished syn alcohol **15**, which was shown to be >99% diastereomerically pure by comparison with an authentic sample of the diastereomeric *anti*-**15**, obtained by the same series of reaction starting from racemic **11**. A sufficient amount of **15** (precursor to fragment B of ionomycin) was set aside for its eventual coupling with fragments A and C. For that purpose, the free alcohol will be oxidized while the protected one will be converted to a primary iodide. The remainder of alcohol **15** was converted to iodide **16**, uneventfully. The latter suffered a lithium–iodine exchange under the same conditions as per **11** and further reaction with copper cyanide afforded the corresponding monoalkylcyanocuprate. Adding *ent*-**4** (R^1 = Me) to this mixture gave adduct **17a** in 87% yield. Ozonolysis gave alcohol **18a** as a 218:1 ratio of diastereomers, as shown by comparison with an authentic sample of its diastereomer **18b** (GC analysis). Alcohol **18b** was obtained by adding the same cyanocuprate made from **16** to carbonate **4** (R^1 = Me) followed by oxidative cleavage. Alcohol **18b** was also formed in >99% de. Any of the diastereomers of **18** can be prepared simply by choosing the appropriate carbonate (**4** or *ent*-**4** (R^1 = Me)) during the synthesis.

Fragment A of ionomycin was completed by a series of straightforward steps (Scheme 5). The auxiliary in **17a** was cleaved by ozonolysis and reductive work-up with triphenylphosphine gave an aldehyde. The latter was converted to the α,β-unsaturated methyl ester by a Wadsworth–Emmons reaction, which was further hydrogenated to give **19** in good overall yield. Deprotection of the *tert*-butyl ether with bromocatecholborane (7) gave the alcohol quantitatively, which was oxidized to aldehyde **20**. Conversion to fragment A (**21**) was performed using standard steps (4*a*).



With fragments A and a precursor to fragment B in hand, we set out to prepare fragment C. Unpurified aldehyde **12** was reacted with Roush's (*E*)-crotyl boronate (8) to give alcohol **22** in 71% yield as a 82:18 ratio of diastereomers as determined by GC analysis (Scheme 6). The mixture was easily separated by column chromatography to yield 57% of pure alcohol **22**. Although the ratio was slightly lower than that obtained using the Brown protocol (9), the Roush method proved easier to use and provided a higher yield of pure **22**. After protection of the alcohol as it's triethylsilyl ether, the terminal double bond was cleaved to fragment C (**24**).

Conclusion



We have demonstrated the power of cyanoalkylcuprate displacement on menthone-derived carbonates as a synthetic

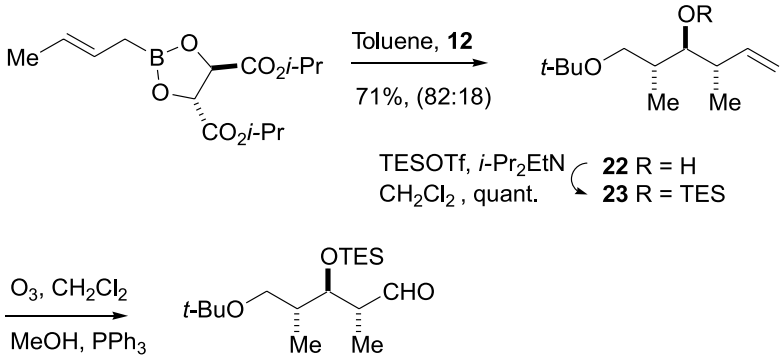
Scheme 5.

technology for the iterative preparation of 1,3-polymethyl-substituted carbon chains. Each iteration proceeded with >100:1 selectivity. A single intermediate **9** served to make fragments A, B, and C in 13, five, and five steps, respectively. It was itself prepared in three steps from (–)-menthone. This highly efficient strategy allowed us to make large quantities of each of these three fragments of ionomycin. The synthesis of fragment D is underway and the total synthesis of ionomycin will be reported in due course.



Experimental section

All reactions were carried out under an atmosphere of argon. Ethyl ether, toluene, and benzene were dried over metallic sodium using benzophenone as an indicator, while tetrahydrofuran was dried over both sodium and potassium using the same indicator. Methanol was distilled from magnesium. Dichloromethane, triethylamine, imidazole, diisopropylethylamine, and diisopropylamine were distilled over calcium hydride. Hexanes was purchased anhydrous from Aldrich. Copper cyanide was purchased from Aldrich and used as is. Thin layer chromatography was performed using 0.25 mm Silica Gel 60 F254 (EM Science-Merck) and flash chromatography using silica gel Kieselgel 60 (230–400 mesh ASTM).

All NMR spectra were taken in deuterated chloroform on a Brüker AC-300 (^{1}H (300 MHz), ^{13}C (75 MHz)). Chemical shifts are reported in parts per million (PPM) (δ) downfield from tetramethylsilane. The splitting patterns are designated as s (singlet), d (doublet), t (triplet), q (quartet), qi (quintet),

sx (sextet), sp (septet), oc (octuplet), m (multiplet). The IR spectra were determined on a PerkinElmer 1600 Fourier transform spectrometer. The IR spectra were determined neat, unless otherwise stated. The melting points were performed on a Mettler Toledo model 62. High- and low-resolution mass spectra (HR-MS and LR-MS) were obtained with a micromass spectrometer ZAB-1F model VG. GC analysis was performed using an Agilent series 6890 on a HP5 column (5% phenyl methyl siloxane) 30 m × 0.25 μM. All compounds were separated using a 100 °C for 2 min and 10 °C/min to 200 °C temperature program.

Alkene 9a

A solution of *tert*-butyl methyl ether (600 mL) and potassium *tert*-butoxide (18.33 g, 163 mmol) was cooled to –78 °C, then *s*-BuLi (117 mL of a 1.4 mol L^{-1} solution in hexanes, 163 mmol) was added dropwise. The resulting mixture was stirred for 2.5 h. In another flask, a solution of CuCN (14.63 g, 327 mmol) and LiBr (28.36g, 327 mmol) in THF (130 mL) was cooled to –78 °C. This solution was added dropwise to the first one by cannula, and stirring was continued for 1 h. The carbonate was dissolved in a minimum amount of THF, then added to the mixture dropwise. The mixture was allowed to warm gradually to room temperature while stirring for 18 h. The reaction was quenched by adding a satd. aq. NH_4Cl and NH_4OH (9:1) solution. The aqueous layer was separated and extracted with Et_2O three times. The combined organic extracts were washed with brine, then dried over anhyd $MgSO_4$, filtered, and concentrated in vacuo. Purification by flash chromatography on silica gel (hexanes) afforded the cuprate adduct (10.61 g, 92%) as a colourless oil. GC analysis showed a (426:1) diastereoisomer ratio. $[\alpha]_D$ = –2.82° ($CHCl_3$, *c* = 1.44). IR (cm^{-1}): 2970, 1461. ^1H NMR ($CDCl_3$) δ: 4.85 (d, 1H, *J* = 9.4 Hz), 3.23 (dd, 1H, *J* = 8.3 and 5.5 Hz), 3.03 (t, 1H, *J* = 8.5 Hz), 2.65–2.31 (m, 1H), 2.35 (dm, 1H, *J* = 16.5 Hz), 1.90 (sx, 1H, *J* = 6.8 Hz), 1.81–1.65 (m, 4H), 1.58–1.51 (m, 1H), 1.33-1.04 (m, 2H), 1.17 (s, 9H), 0.95–0.83 (m, 12H). ^{13}C NMR ($CDCl_3$) δ: 139.8 (s), 125.0 (d), 72.3 (s), 67.0 (t), 51.1 (d), 35.6 (t), 32.8 (d), 32.4 (d), 31.9 (t), 27.6 (q), 26.9 (t), 26.5 (d), 22.1 (q), 20.6 (q), 19.8 (q), 18.6 (q). Alkene 9b

A solution of alcohol **13** (451 mg, 1.68 mmol) in THF (17 mL) was cooled to –78 °C. *n*-BuLi (1.26 mL of a 1.87 mol L^{-1} solution in hexanes, 2.36 mmol) was added dropwise, then stirring continued for 2 h. $ClCO_2Me$ (0.20 mL, 2.53 mmol) was added. The mixture was stirred for 2 h at –78 °C, then for 1 h while letting the reaction warm to 0 °C, and 1 h at 0 °C. The reaction was quenched by adding a satd. aq. NH_4Cl solution. The aqueous layer was separated and extracted with Et_2O three times. The combined organic extracts were washed with brine, then dried over anhyd $MgSO_4$, filtered, and concentrated in vacuo. The crude carbonate was used in the next step without further purification.

To a solution of CuCN (603 mg, 6.73 mmol) in THF (28 mL) cooled to –78 °C, MeLi (4.21 mL of a 1.6 mol L^{-1} solution in Et_2O, 6.73 mmol) was added slowly. This mixture was stirred for 1.5 h. The carbonate was dissolved in a minimum of THF, then added to the reaction mixture at –60 °C. Stirring was continued for 17 h, while the reaction was allowed to reach room temperature. The reaction was quenched by adding a satd. aq. NH_4Cl and NH_4OH (9:1) solution. The aqueous layer was separated and extracted with Et_2O three times. The combined organic extracts were washed with brine, then dried over anhyd $MgSO_4$, filtered, and concentrated in vacuo. Purification by flash chromatography on silica gel (hexanes) afforded cuprate adduct **9b** (256 mg, 57%) as a colourless oil. $[\alpha]_D$ = –48.9° ($CHCl_3$, *c* = 1.34). ^1H NMR ($CDCl_3$) δ: 4.83 (d, 1H, *J* = 9.4 Hz), 3.15 (dd, 1H, *J* = 8.8 and 6.1 Hz), 3.03 (t, 1H, *J* = 8.3 Hz), 2.66–2.54 (m, 1H), 2.35–2.29 (m, 1H), 1.91 (sx, 1H, *J* = 7.1 Hz), 1.81–1.64 (m, 4H), 1.58–1.52 (m, 1H), 1.33-1.24 (m, 1H), 1.16 (s, 9H), 1.14–1.06 (m, 1H), 0.95 (d, 3H, *J* = 6.6 Hz), 0.90 (d, 3H, *J* = 6.1 Hz), 0.87 (d, 3H, *J* = 6.6 Hz), 0.84 (d, 3H, *J* = 6.9 Hz). LR-MS (*m*/*z* (relative intensity)): 266 (M^+, 5), 210 (35), 123 (100). HR-MS calcd. for $C_{18}H_{34}O$: 266.2610; found: 266.2614.

General procedure for the ozonolysis of cuprate adducts to the corresponding alcohols

O_3 was bubbled through a stirred solution of cuprate adduct in CH_2Cl_2 and MeOH (4:1, 0.1 mol L^{-1}) at –78 °C until the appearance of a blue colour. Then argon was bubbled through this solution until the blue colour disappeared. $NaBH_4$ (5.0 equiv.) was added portion-wise. The mixture was allowed to warm to room temperature slowly while stirring for 16 h. The reaction was quenched by adding a satd. aq. NH_4Cl solution. The aqueous layer was separated and extracted with CH_2Cl_2 three times. The combined organic

extracts were washed with brine, then dried over anhyd $MgSO_4$, filtered, and concentrated in vacuo.

Alcohol 10

Prepared from **9a** (1.0 g, 3.75 mmol) according to the general procedure for the ozonolysis of cuprate adducts. Purified by flash chromatography on silica gel (hexanes–AcOEt, 30%) gave 467 mg of **10** (85%) as a colourless oil. $[\alpha]_D = -16.8°$ ($CHCl_3$, $c = 1.84$). IR (cm^{-1}): 3384. ^1H NMR ($CDCl_3$) δ: 3.66–3.50 (m, 3H), 3.28 (t, 1H, $J = 8.8$ Hz), 2.00 (m, 1H), 1.21 (s, 9H), 0.85 (d, 3H, $J = 7.15$ Hz). LR-MS (*m/z* (relative intensity)): 131 (M^+ – Me, 80), 89 (100), 87 (10). HR-MS calcd. for $C_7H_{14}O_2$: 131.1072; found: 131.1076.

Iodide 11

(A higher overall yield of iodide **11** from **9a** was obtained using crude alcohol **10**). To a solution of alcohol **10** (1.21 g, 8.30 mmol) in CH_2Cl_2 (165 mL) was added imidazole (3.39 g, 50.0 mmol), then Ph_3P (8.71 g, 33.3 mmol). After complete dissolution of PPh_3, the solution was protected from light, cooled to 0 °C, and I_2 (8.45 g, 33.3 mmol) was added. The mixture was warmed to room temperature and stirring was continued for 16 h. The reaction was quenched by adding a satd. aq. $Na_2S_2O_3$ solution. The aqueous layer was separated and extracted with EtOAc three times. The combined organic extracts were dried over anhyd $MgSO_4$, filtered, and concentrated in vacuo. The crude extract was triturated twice with hexanes to remove the remaining PPh_3. Purification by flash chromatography on silica gel (hexanes–EtOAc, 2%) afforded iodide **11** (1.71 g, 81% for two steps) as a slightly yellow oil. $[\alpha]_D = -12.4°$ ($CHCl_3$, $c = 1.46$). IR (cm^{-1}): 2973, 1479. ^1H NMR ($CDCl_3$) δ: 3.31 (d, 2H, J = 4.4 Hz), 3.23 (dd, 1H, J = 9.4, 5.5 Hz), 3.13 (t, 1H, J = 8.0 Hz), 1.66–1.55 (m, 1H), 1.18 (s, 9H), 0.96 (d, 3H, J = 6.6 Hz). ^{13}C NMR ($CDCl_3$) δ: 72.6 (s), 65.4 (t), 35.3 (t), 27.6 (s), 17.8 (q), 15.1 (q). LR-MS (*m/z* (relative intensity)): 256 (M^+, 10), 241 (25), 87 (100). HR-MS calcd. for $C_8H_{17}OI$: 256.0324; found: 256.0318.

Aldehyde 12

To a solution of alcohol (467 mg, 3.20 mmol) in wet CH_2Cl_2 (8.5 mL) was added Dess–Martin periodinane (1.628 g, 3.84 mmol). The mixture was stirred for 30 min. The reaction solution was evaporated in vacuo, then diluted with Et_2O, washed with a solution of satd. aq. $Na_2S_2O_3$, washed with a solution of satd. aq. $NaHCO_3$, and washed with brine. The combined aqueous extracts were extracted with Et_2O three times. The combined organic extracts were dried over anhyd $MgSO_4$, filtered, and concentrated in vacuo to afforded crude aldehyde, which was used without further purification in the next step.

Alcohol 13

A solution of 3-*tert*-butyloxy-1-iodo-1-propene (914 mg, 3,78 mmol) in Et_2O (11 mL) was cooled to –78 °C, then *t*-BuLi (6.05 mL of a 1.25 mol L^{-1} solution in Et_2O, 7.56 mmol) was added dropwise. The mixture was stirred for 1.6 h at –78 °C and 1.5 h at 0 °C, then cooled again at –78 °C. (–)-Menthone (0.44 mL, 2.52 mmol) was dissolved in a minimum of Et_2O, then added to the reaction. Stirring was continued for 21 h and the reaction was allowed to reach room temperature slowly during this time. The reaction was quenched by adding a satd. aq. NH_4Cl solution. The aqueous layer was separated and extracted with Et_2O three times. The combined organic extracts were washed with brine, then dried over anhyd $MgSO_4$, filtered, and concentrated in vacuo. Purification by flash chromatography on silica gel (10% EtOAc in hexanes) afforded alcohol **13** (472 mg, 70%) as a colourless oil. $[\alpha]_D = -19.1°$ ($CHCl_3$, $c = 1.98$). IR (cm^{-1}): 3466, 1468. ^1H NMR ($CDCl_3$) δ: 5.77 (dt, 1H, J = 15.9 and 5.0 Hz), 5.68 (d, 1H, J = 15.9 Hz), 3.95 (dd, 2H, J = 5.0 and 2.2 Hz), 2.02–1.90 (m, 1H), 1.80–1.67 (m, 2H), 1.54–1.43 (m, 4H), 1.21 (s, 9H), 1.23–1.11 (m, 2H), 0.94–0.83 (m, 10H). LR-MS (*m/z* (relative intensity)): 268 (M^+, 5), 212 (55), 127 (100). HR-MS calcd. for $C_{18}H_{34}O$: 268.2402; found: 268.2393.

General procedure for the addition of cuprates to allylic carbonates

A solution of the iodide (1.5 equiv.) in Et_2O (0.1 mol L^{-1}) was cooled to –78 °C. *t*-BuLi (3.0 equiv. of a solution in Et_2O) was added dropwise. The mixture was stirred for 30 min, then warmed to 0 °C for 1 h, and cooled again to –78 °C. In a different round-bottomed flask, CuCN (1.5 equiv.) in THF (0.2 mol L^{-1}) was degassed and purged with argon twice before being cooled to –78 °C. The organolithium solution was cannulated dropwise into the CuCN solution. The reaction was stirred for 2 h. The carbonate was dissolved in a minimum of THF, then added to the cuprate reaction mixture at –50 °C. While stirring, the temperature was allowed to reach 0 °C slowly over a 1 h period, then room temperature over a 16 h period. The reaction was quenched by adding a satd. aq. NH_4Cl and NH_4OH (9:1) solution. The aqueous layer was separated and extracted with Et_2O three times. The combined organic extracts were washed with brine, then dried over anhyd $MgSO_4$, filtered, and concentrated in vacuo.

Alkene 14

Prepared from **11** (6.40 g, 25.0 mmol) following the general procedure for the addition of cuprates to allylic carbonates. Flash column chromatography (hexanes) gave 4.77 g (93%) of **14** as a colourless oil. $[\alpha]_D = -30.8°$ ($CHCl_3$, c = 2.37). IR (cm^{-1}): 2864, 1478. ^1H NMR ($CDCl_3$) δ: 4.81 (d, 1H, J = 9.4 Hz), 3.19 (dd, 1H, J = 8.3 and 5.5 Hz), 3.02 (t, 2H, J = 7.7 Hz), 2.59–2.47 (m, 1H), 2.39–2.31 (m, 1H), 1.91 (sx, 1H, J = 7.1 Hz), 1.80–1.50 (m, 6H), 1.37–1.19 (m, 2H), 1.17 (s, 9H), 1.13–0.95 (m, 2H), 0.92–0.83 (m, 15H). ^{13}C NMR ($CDCl_3$) δ: 138.2 (s), 128.4 (d), 72.1 (s), 67.7 (q), 50.7 (t), 42.3 (t), 35.7 (t), 32.6 (d), 32.2 (t), 31.9 (d), 29.0 (d), 27.6 (q), 26.8 (t), 26.5 (d), 22.7 (q), 22.1 (q), 20.9 (q), 19.7 (q), 17.3 (q). LR-MS (*m/z* (relative intensity)): 173 (M^+ – Me, 10), 143 (20), 97 (100). HR-MS calcd. for $C_{10}H_{21}O_2$: 173.1541; found: 173.1535. Minor isomer of alcohol **15** (made from the ozonolysis of the minor isomer of alkene **14**): $[\alpha]_D$ = +10.1° ($CHCl_3$, *c* = 1.43). IR (cm^{-1}): 3318, 1479. ^1H NMR ($CDCl_3$) δ: 3.45 (d, 2H, *J* = 6.6 Hz), 3.18–3.09 (m, 2H), 1.79 (oc, 2H, *J* = 6.6 Hz), 1.34–1.25 (m, 1H), 1.18 (s, 9H), 1.20–1.10 (m, 1H), 0.88 (d, 6H, *J* = 7.2 Hz). LR-MS (*m/z* (relative intensity)): 173 (M^+ – Me, 10), 143 (25), 83 (100). HR-MS calcd. for $C_{10}H_{21}O_2$: 173.1541; found: 173.1546.

Iodide 16

Prepared from **15** (2.68 g, 14.2 mmol) according to the same procedure as per iodide **11**. Flash chromatography on silica gel (hexanes–EtOAc, 10%) afforded iodide **16** (4.17 g, 98%) as a colourless oil. $[\alpha]_D$ = –1.4° ($CHCl_3$, *c* = 1.28). IR (cm^{-1}): 2974, 1479. ^1H NMR ($CDCl_3$) δ: 3.26 (dd, 1H, *J* = 9.9 and 4.4 Hz), 3.20 (dd, 1H, *J* = 8.3 and 5.0 Hz), 3.12 (dd, 1H, *J* = 9.4 and 6.0 Hz), 3.05 (dd, 1H, *J* = 8.3 and 6.6 Hz), 1.74–1.51 (m, 2H), 1.44–1.35 (m, 1H), 1.17 (s, 9H), 1.05–0.95 (m, 1H), 0.99 (d, 3H, *J* = 6.6 Hz), 0.90 (d, 3H, *J* = 6.6 Hz). ^{13}C NMR ($CDCl_3$) δ: 72.3 (s), 67.0 (t), 41.0 (t), 32.0 (d), 31.5 (d), 27.5 (t), 21.5 (q), 18.1 (q), 17.7 (q). LR-MS (*m/z* (relative intensity)): 283 (M^+ – Me, 20), 225 (30), 115 (100). HR-MS calcd. for $C_{10}H_{21}O_2$: 283.0559; found: 283.0563.

Alkene 17a

Prepared from **16** (1.12 g, 3.75 mmol) and carbonate *ent*-**8** following the general procedure for the addition of cuprates to allyl carbonates. Flash column chromatography (hexanes) gave 762 mg (87%) of **17a** as a colourless oil. $[\alpha]_D$ = +18.9° ($CHCl_3$, *c* = 2.07). IR (cm^{-1}): 2955, 1478. ^1H NMR ($CDCl_3$) δ: 4.85 (d, 1H, *J* = 9.1 Hz), 3.22 (dd, 1H, *J* = 8.7 and 4.7 Hz), 2.92 (t, 1H, *J* = 8.5 Hz), 2.53–2.43 (m, 1H), 2.39–2.31 (m, 1H), 1.91 (sx, 1H, *J* = 6.7 Hz), 1.80–1.47 (m, 6H), 1.28–1.17 (m, 2H), 1.16 (s, 9H), 1.15–0.96 (m, 3H), 0.92 (d, 3H, *J* = 6.3 Hz), 0.89 (d, 3H, *J* = 5.6 Hz), 0.87 (d, 6H, *J* = 5.8 Hz), 0.85 (d, 6H, *J* = 5.9 Hz). ^{13}C NMR ($CDCl_3$) δ: 137.4 (s), 129.0 (d), 72.1 (s), 67.2 (t), 50.9 (d), 45.4 (t), 42.1 (t), 35.9 (t), 32.7 (d), 32.3 (t), 31.3 (d), 28.9 (d), 27.9 (d), 27.6 (q), 27.1 (t), 26.5 (d), 22.1 (q), 21.3 (q), 21.0 (q), 20.7 (q), 19.7 (q), 18.3 (q). LR-MS (*m/z* (relative intensity)): 350 (M^+, 5), 294 (40), 99 (100). HR-MS calcd. for $C_{24}H_{36}O$: 350.3548; found: 350.3557.

Alkene 17b

Prepared from **16** (447 mg, 1.50 mmol) and carbonate **8** following the general procedure for the addition of cuprates to allyl carbonates. Flash column chromatography (hexanes) gave 255 mg (73%) of **17b** as a colourless oil. $[\alpha]_D$ = –28.8° ($CHCl_3$, *c* = 1.57). ^1H NMR ($CDCl_3$) δ: 4.77 (d, 1H, *J* = 9.4 Hz), 3.20 (dd, 1H, *J* = 8.8 and 5.5 Hz), 3.00 (t, 1H, *J* = 7.7 Hz), 2.56-2.46 (m, 1H), 2.40–2.32 (m, 1H), 1.89 (sx, 1H, *J* = 7.2 Hz), 1.80–1.61 (m, 5H), 1.54–1.43 (m, 1H), 1.31–1.06 (m, 4H), 1.16 (s, 9H), 0.99–0.88 (m, 3H), 0.92 (d, 3H, *J* = 6.1 Hz), 0.87 (d, 6H, *J* = 6.6 Hz), 0.85 (d, 6H, *J* = 6.1 Hz), 0.82 (d, 3H, *J* = 6.6 Hz). LR-MS (*m/z* (relative intensity)): 350 (M^+, 5), 293 (50), 141 (100). HR-MS calcd. for $C_{24}H_{46}O$: 350.3548; found: 350.3553.

Alcohol 18a

Prepared from **17a** (150 mg, 0.43 mmol) according to the general procedure for the ozonolysis of cuprate adducts. Flash chromatography on silica gel (hexanes–AcOEt, 20%) afforded 67 mg (69%) of alcohol **18a** as a colourless oil. GC analysis showed a (218:1) diastereoisomer ratio. $[\alpha]_D$ = –22.5° ($CHCl_3$, *c* = 1.13). IR (cm^{-1}): 3334, 1462. ^1H NMR ($CDCl_3$) δ: 3.48 (dd, 1H, *J* = 10.7 and 6.2 Hz), 3.40 (dd, 1H, *J* = 10.7 and 6.4 Hz), 3.18 (dd, 1H, *J* = 8.3 and 5.3 Hz), 3.04 (t, 1H, *J* = 8.4 Hz), 1.78–1.58 (m, 2H), 1.33–1.24 (m, 2H), 1.17 (s, 9H), 1.11–1.06 (m, 2H), 0.99–0.92 (m, 1H), 0.88 (d, 6H, *J* = 6.5 Hz), 0.86 (d, 3H, *J* = 6.4 Hz). LR-MS (*m/z* (relative intensity)): 230 (M^+, 5), 215 (10), 83 (100). HR-MS calcd. for $C_{13}H_{27}O_2$: 215.2011; found: 215.2003.

Alcohol 18b

Prepared from **17b** (234 mg, 0.67 mmol) according to the general procedure for the ozonolysis of cuprate adducts. The alcohol was purified by flash chromatography on silica gel (hexanes–AcOEt, 20%) to afford 113 mg (74%) of **18b** as a colourless oil. $[\alpha]_D$ = +8.7° ($CHCl_3$, *c* = 1.33). IR (cm^{-1}): 3351, 1480. ^1H NMR ($CDCl_3$) δ: 3.54 (dd, 1H, *J* = 11.0 and 5.5 Hz), 3.36 (dd, 1H *J* = 10.5 and 6.6 Hz), 3.21 (dd, 1H *J* = 8.8 and 5.0 Hz), 3.02 (t, 1H, *J* = 7.2 Hz), 1.79–1.54 (m, 2H), 1.31 (m, 2H) 1.16 (s, 9H), 0.93 (d, 3H, *J* = 6.6 Hz), 0.90–0.81 (m, 3H), 0.89 (d, 6H, *J* = 6.6 Hz). LR-MS (*m/z* (relative intensity)): 215 (M^+ – Me, 10), 173 (30), 83 (100). HR-MS calcd. for $C_{13}H_{27}O_2$: 215.2011; found: 215.2007.

Ester 19

Through a stirred solution of **17a** (800 mg, 2.28 mmol) in CH_2Cl_2 (19 mL) and MeOH (4 mL) at –78 °C was bubbled O_3 until the appearance of a blue colour. Then, argon gas was bubbled through the solution until the blue colour disappeared and Ph_3P (720 mg, 2.74 mmol) was added. The mixture was warmed to room temperature and stirred for 4 h. The reaction was concentrated in vacuo, then triturated twice with hexanes. The crude aldehyde was used in the next step without further purification. The crude aldehyde was dissolved in CH_2Cl_2 (27 mL), then $MeO_2CCH{=}PPh_3$ (1.723 g, 5.154 mmol) was added. The mixture was stirred and heated to reflux for 17.5 h. The reaction was cooled to room temperature, then concentrated in vacuo. Two triturations, first with Et_2O then with hexanes, were performed. Purification by flash chromatography on silica gel (5% EtOAc in hexanes) afforded only the trans alkene (490 mg, 76%) as a

© 2004 NRC Canada

colourless oil. $[\alpha]_D$ = +22.0° ($CHCl_3$, *c* = 1.82). IR (cm^{-1}): 1725, 1658. ^1H NMR ($CDCl_3$) δ: 6.88 (dd, 1H, *J* = 15.4 and 8.3 Hz), 5.78 (d, 1H *J* = 15.4 Hz), 3.72 (s, 3H), 3.18 (dd, 1H, *J* = 8.3 and 5.0 Hz), 2.99 (t, 1H, *J* = 8.0 Hz), 2.40 (sp, 1H, *J* = 7.2 Hz), 1.68 (oc, 1H, *J* = 5.5 Hz), 1.56 (oc, 1H, *J* = 6.6 Hz), 1.36–1.25 (m, 2H), 1.22–1.10 (m, 1H) 1.15 (s, 9H), 1.00 (d, 3H, *J* = 6.6 Hz), 0.94–0.85 (m, 1H), 0.88 (d, 3H, *J* = 6.6 Hz), 0.86 (d, 3H, *J* = 6.1 Hz). ^{13}C NMR ($CDCl_3$) δ: 167.1 (s), 155.2 (d), 118.7 (d), 72.0 (s), 66.7 (t), 51.1 (q), 43.3 (t), 41.6 (t), 33.8 (d), 31.1 (d), 27.6 (d), 27.3 (q), 20.3 (q), 19.0 (q), 18.2 (q). LR-MS (*m/z* (relative intensity)): 269 (M^+ – Me, 10), 227 (15), 127 (100). HR-MS calcd. for $C_{16}H_{29}O_3$: 269.2117; found: 269.2119.

To the α,β-unsaturated ester (426 mg, 1.50 mmol) dissolved in EtOH (15 mL) was added 5% Pd/C (75 mg). The reaction was degassed and flushed with argon 3 times, before being stirred for 2 h under 1 atm of H_2 (1 atm = 101.325 kPa). The mixture was filtered over a pad of Celite, then concentrated in vacuo. Purification by flash chromatography on silica gel (5% EtOAc in hexanes) afforded ester **19** (388 mg, 90%) as a colourless oil. $[\alpha]_D$ = –17.9° ($CHCl_3$, *c* = 0.88). IR (cm^{-1}): 1744, 1462. ^1H NMR ($CDCl_3$) δ: 3.66 (s, 3H), 3.19 (dd, 1H *J* = 8.8 and 5.5 Hz), 3.02 (t, 1H, *J* = 7.7 Hz), 2.37–2.25 (m, 2H), 1.69 (oc, 1H, *J* = 6.1 Hz), 1.62–1.42 (m, 4H), 1.37–1.18 (m, 1H), 1.17 (s, 9H), 1.16–1.06 (m, 1H), 1.02–0.90 (m, 2H), 0.87 (d, 3H, *J* = 6.6 Hz), 0.83 (d, 3H, *J* = 6.1 Hz), 0.82 (d, 3H, *J* = 6.6 Hz). LR-MS (*m/z* (relative intensity)): 271 (M^+ – Me, 5), 229 (20), 87 (100). HR-MS calcd. for $C_{16}H_{31}O_3$: 271.2273; found: 271.2265.

Aldehyde 20

To a solution of ester **19** (120 mg, 0.42 mmol) in CH_2Cl_2 (1.7 mL) was added slowly a solution of *B*-bromocatecholborane (167 mg, 0.84 mmol) in CH_2Cl_2 (2.0 mL). The reaction was stirred for 15 min, then H_2O (5 mL) was added. Stirring continued for 30 min. The aqueous layer was separated and extracted with CH_2Cl_2 3 times. The combined organic extracts were washed 3 times with a solution of satd. aq. Na_2CO_3, then dried over anhyd $MgSO_4$, filtered, and concentrated in vacuo. Purification by flash chromatography on silica gel (20% EtOAc in hexanes) afforded a primary alcohol (95 mg, 99%) as a colourless oil. $[\alpha]_D$ = –22.6° ($CHCl_3$, *c* = 1.46). IR (cm^{-1}): 3347, 1744, 1462. ^1H NMR ($CDCl_3$) δ: 3.66 (s, 3H), 3.50–3.39 (m, 2H), 2.38–2.24 (m, 2H), 1.77–1.36 (m, 6H), 1.34–1.25 (m, 1H), 1.15–0.87 (m, 3H), 0.92 (d, 3H, *J* = 6.6 Hz), 0.84 (d, 6H, *J* = 6.1 Hz). LR-MS (*m/z* (relative intensity)): 200 (M^+ – CH_2O, 20), 157 (20), 83 (100). HR-MS calcd. for $C_{12}H_{24}O_2$: 200.1776; found: 200.1782.

To a solution of this alcohol (157 mg, 0.69 mmol) in wet CH_2Cl_2 (3 mL) was added Dess–Martin's periodinane (349 mg, 0.82 mmol). The mixture was stirred for 30 min. The solution was then concentrated in vacuo, diluted with Et_2O, washed with a solution of satd. aq. $Na_2S_2O_3$, satd. aq. $NaHCO_3$, and with brine. The combined aqueous extracts were extracted with Et_2O 3 times. The combined organic extracts were dried over anhyd $MgSO_4$, filtered, and concentrated in vacuo. Purification by flash chromatography on silica gel (10% EtOAc in hexanes) afforded aldehyde **20** (113 mg, 72%) as a colourless oil. ^1H NMR ($CDCl_3$) δ: 9.59 (d, 1H, *J* = 2.2. Hz), 3.67 (s, 3H), 2.44 (dq, 1H, *J* = 7.2 and 2.8 Hz), 2.38–2.24 (m, 2H), 1.71–1.40 (m, 6H), 1.20–1.10 (m, 2H), 1.08 (d, 3H, *J* = 6.6 Hz), 0.86 (d, 3H, *J* = 6.0 Hz), 0.84 (d, 3H, *J* = 6.1 Hz). LR-MS (*m/z* (relative intensity)): 200 (M^+ – CO, 5), 197 (5), 87 (100). HR-MS calcd. for $C_{12}H_{24}O_2$: 200.1776; found: 200.1784.

Ketone 21

$[\alpha]_D$ = –14.1° ($CHCl_3$, *c* = 1.74) (lit. (4*b*) value –14.5°, CH_2Cl_2, *c* = 1.22). ^1H NMR ($CDCl_3$) δ: 3.66 (s, 3H), 2.61 (sx, 1H, *J* = 7.1 Hz), 2.40–2.23 (m, 2H), 2.13 (s, 3H), 1.66–1.39 (m, 5H), 1.15–1.02 (m, 5H), 1.07 (d, 3H, *J* = 6.6 Hz), 0.83 (d, 6H, *J* = 6.6 Hz). ^{13}C NMR ($CDCl_3$) δ: 212.9 (s), 174.4 (s), 51.4 (q), 44.7 (d), 44.1 (t), 41.1 (t), 32.7 (t), 31.8 (t), 29.6 (d), 27.9 (d), 19.5 (q), 18.8 (q), 16.9 (q). LR-MS (*m/z* (relative intensity)): 243 (MH^+, 5), 211 (20), 97 (100). HR-MS calcd. for $C_{14}H_{27}O_3$: 243.1960; found: 243.1953.

Alcohol 22

To a solution of Roush's crotyl borane (9.5 mL of a 0.51 mol L^{-1} solution in toluene, 4.81 mmol) was added 4 Å molecular sieves (60 mg). This mixture was stirred for 10 min, then cooled to –78 °C. Crude aldehyde **12** in toluene (2.5 mL) was added dropwise, then stirred for 4 h. $NaBH_4$ (40 mg, 1.05 mmol) in EtOH (1 mL) was added dropwise, then the reaction was warmed to 0 °C. NaOH (4 mL of a 2 N aqueous solution) was added and stirred for 1.5 h. The aqueous layer was separated and extracted with Et_2O 3 times. The combined organic extracts were dried over anhyd $MgSO_4$, filtered, and concentrated in vacuo. GC analysis of the crude product gave a (82:18) diastereoisomer ratio. Purification by flash chromatography on silica gel (2% EtOAc in hexanes) afforded the desired pure alcohol **22** (363 mg, 57%) as a colourless oil, and its diastereomer (88 mg, 14%) as a colourless oil. **22**: $[\alpha]_D$ = –29.3° ($CHCl_3$, *c* = 2.09). ^1H NMR ($CDCl_3$) δ: 6.01–5.89 (m, 1H), 5.07–5.02 (m, 2H), 4.37 (s, 1H), 3.49 (dd, 1H, *J* = 8.8 and 3.9 Hz), 3.37–3.31 (m, 2H), 2.37–2.31 (m, 1H), 1.89–1.77 (m, 1H), 1.20 (s, 9H), 1.10 (d, 3H, *J* = 6.6. Hz), 0.82 (d, 6H, *J* = 7.2 Hz). ^{13}C NMR ($CDCl_3$) δ: 139.9 (d), 114.7 (t), 80.8 (d), 76.5 (s), 67.7 (t), 41.1 (d), 36.2 (d), 27.2 (q), 17.8 (q), 13.5 (q). LR-MS (*m/z* (relative intensity)): 185 (M^+ – Me, 5), 145 (30), 84 (100). HR-MS calcd. for $C_{11}H_{21}O_2$: 185.1541; found: 185.1546. Minor isomer of alcohol **22**: $[\alpha]_D$ = +6.6° ($CHCl_3$, *c* = 3.72). ^1H NMR ($CDCl_3$) δ: 5.89-5.77 (m, 1H), 5.13–5.05 (m, 2H), 3.52–3.44 (m, 3H), 3.21 (d, 1H, *J* = 1.7 Hz), 2.26 (sx, 1H, *J* = 6.6 Hz), 1.90–1.80 (m, 1H), 1.18 (s, 9H), 0.97 (d, 3H, *J* = 7.2. Hz), 0.94 (d, 3H, *J* = 6.6 Hz). LR-MS (*m/z* (relative intensity)): 201 (MH^+, 100), 145 (50). HR-MS calcd. for $C_{12}H_{25}O_2$: 201.1854; found: 201.1858.

Silyl ether 23

To a solution of alcohol **22** (500 mg, 2.5 mmol) in CH_2Cl_2 (50 mL) at 0 °C was added *i*-Pr_2EtN (0.61 mL, 3.5 mmol) and TESOTf (0.68 mL, 3.0 mmol). The reaction was stirred for 30 min. The reaction was quenched by adding a satd. aq. $NaHCO_3$ solution. The aqueous layer was separated and extracted with Et_2O 3 times. The combined organic extracts were dried over anhyd $MgSO_4$, filtered, and concentrated in vacuo. Purification by flash chromatography on silica gel (2% EtOAc in hexanes) afforded the silyl ether **23** (784 mg, quantitative) as a colourless oil. $[\alpha]_D$ = +16.8° ($CHCl_3$, *c* =

© 2004 NRC Canada

1.98). ^{1}H NMR ($CDCl_3$) δ: 5.88 (ddd, 1H, *J* = 17.6, 10.4, and 8.2 Hz), 5.00–4.94 (m, 2H), 3.49–3.44 (m, 2H), 3.09 (t, 1H, *J* = 8.3. Hz), 2.43–2.31 (m, 1H), 1.84–1.71 (m, 1H), 1.16 (s, 9H), 1.02 (d, 3H, *J* = 7.2 Hz), 0.97 (t, 9H, *J* = 8.3 Hz), 0.89 (d, 3H, *J* = 6.6 Hz), 0.62 (q, 6H, *J* = 8.3 Hz). LR-MS (*m*/*z* (relative intensity)): 259 ($M^+ - C_4H_7$, 40), 229 (45), 173 (100). HR-MS calcd. for $C_{14}H_{31}O_2Si$: 259.2093; found: 259.2097.

Aldehyde 24

Through a stirred solution of silyl ether **23** (784 mg, 2.5 mmol) in CH_2Cl_2 (20 mL) and MeOH (5 mL) at –78 °C was bubbled O_3 until the appearance of a blue colour. Then argon was bubbled through the solution until the blue colour disappeared. Ph_3P (981 mg, 3.75 mmol) was added. The mixture was warmed to room temperature and stirred for 4 h. The reaction was concentrated in vacuo, then triturated twice with hexanes. The crude aldehyde was not purified further. ^{1}H NMR ($CDCl_3$) δ: 9.78 (d, 1H, *J* = 2.2 Hz), 3.95 (dd, 1H, *J* = 5.0 and 3.9 Hz), 3.38 (dd, 1H, *J* = 8.8 and 6.1 Hz), 3.17 (dd, 1H, *J* = 8.8 and 6.6 Hz), 2.63–.54 (m, 1H), 1.93 (sp, 1H, *J* = 6.1 Hz), 1.16 (s, 9H), 1.11 (d, 1H, *J* = 7.2 Hz), 0.96 (t, 9H, *J* = 7.7 Hz), 0.90 (d, 3H, *J* = 6.6 Hz), 0.62 (q, 6H, *J* = 7.7 Hz).[3]

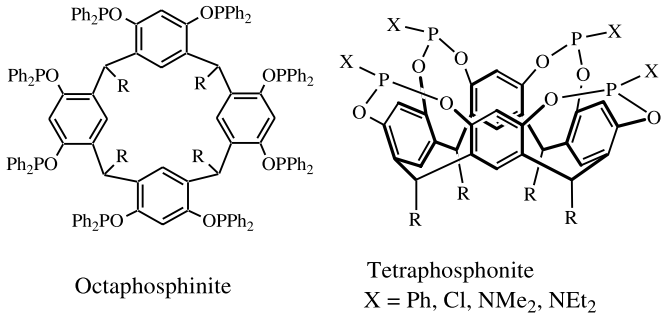
Synthesis and conformations of phosphine- and phosphinite-derivatized resorcinarenes[1]

Dana J. Eisler and Richard J. Puddephatt

Abstract: The synthesis of resorcinarene derivatives with four or eight alkynyldiphenylphosphine or diphenylphosphinite functional groups is reported. The tetraphosphinite derivatives have effective C_{2v} symmetry and have the potential to adopt two different boat conformations in which the arene groups with phosphinite substituents are horizontal or vertical. A method for the determination of the solution-state conformation of the resorcinarene skeleton using correlated ^{1}H and ^{13}C NMR data is reported, and the boat conformation of one tetraphosphinite compound in the solid state has been determined crystallographically.

Key words: phosphine, phosphinite, resorcinarene, conformation.

Résumé : On a réalisé la synthèse de dérivés du résorcinarène portant quatre ou huit groupes fonctionnels alkynyldiphénylphosphine ou diphénylphosphinite. Les dérivés tétraphosphinites sont de symétrie effective C_{2v} et ils peuvent adopter deux conformations en bateau différentes dans lesquelles les groupes arènes portant les substituants phosphinites sont soit en position horizontale soit en position verticale. Faisant appel aux données de la RMN du ^{1}H et du ^{13}C, on a mis au point une méthode de déterminer la conformation en solution du squelette résorcinarène et on a fait appel à la diffraction des rayons X pour déterminer la conformation bateau d'un composé tétraphosphinite à l'état solide.



Mots clés : phosphine, phosphinite, résorcinarène, conformation.

[Traduit par la Rédaction]

Introduction

Resorcinarenes are macrocyclic octanols that provide a platform upon which multiple ligating groups can be arranged in an organized fashion (1–3). Thus, resorcinarenes can be used to arrange several metal centers in close proximity at the rim of the macrocyclic cavity, and there is then the potential for achieving size- and shape-selective catalysis and for establishing cooperativity between two or more metal centers in bond activation processes (3–5). While it is possible to bind early transition metals directly to the oxygen atoms of the resorcinol arene rings, it is better to incorporate soft donors, such as phosphorus donors, to develop the chemistry with the late transition metals (6). There are octaphosphinite and tetraphosphonite derivatives of resorcinarenes, as illustrated in Chart 1, but no octaphosphine or tetraphosphinite derivative appears to be known (7). This article reports the first examples of such compounds. They are derived from recently reported resorcinarenes in which two opposite arene rings are protected by acylation of the phenol groups (8, 9).

Results and discussion

Synthesis of octa(alkynyldiphenylphosphine) derivatives

The resorcinarene **1** (10) was converted to the octapropargyl resorcinarene (**2**) (11), and the new octa(propargyl carbonate) resorcinarene (**3**) as outlined in Scheme 1. Two new octa(alkynyldiphenylphosphine) resorcinarenes **4** and **5** were then synthesized by treatment of **2** or **3** with *n*-butyllithium followed by the addition of chlorodiphenylphosphine, as shown in Scheme 2. The alkynyldiphenylphosphine derivatives **4** and **5** are isolated as colourless solids. They are moderately air-sensitive, the decomposition being complete in hours in solution or weeks in the solid state.

Synthesis of tetra(diphenylphosphinite) derivatives

The tetraester resorcinarenes **6a**–**6e** were prepared as shown in Scheme 3, by a procedure similar to that described

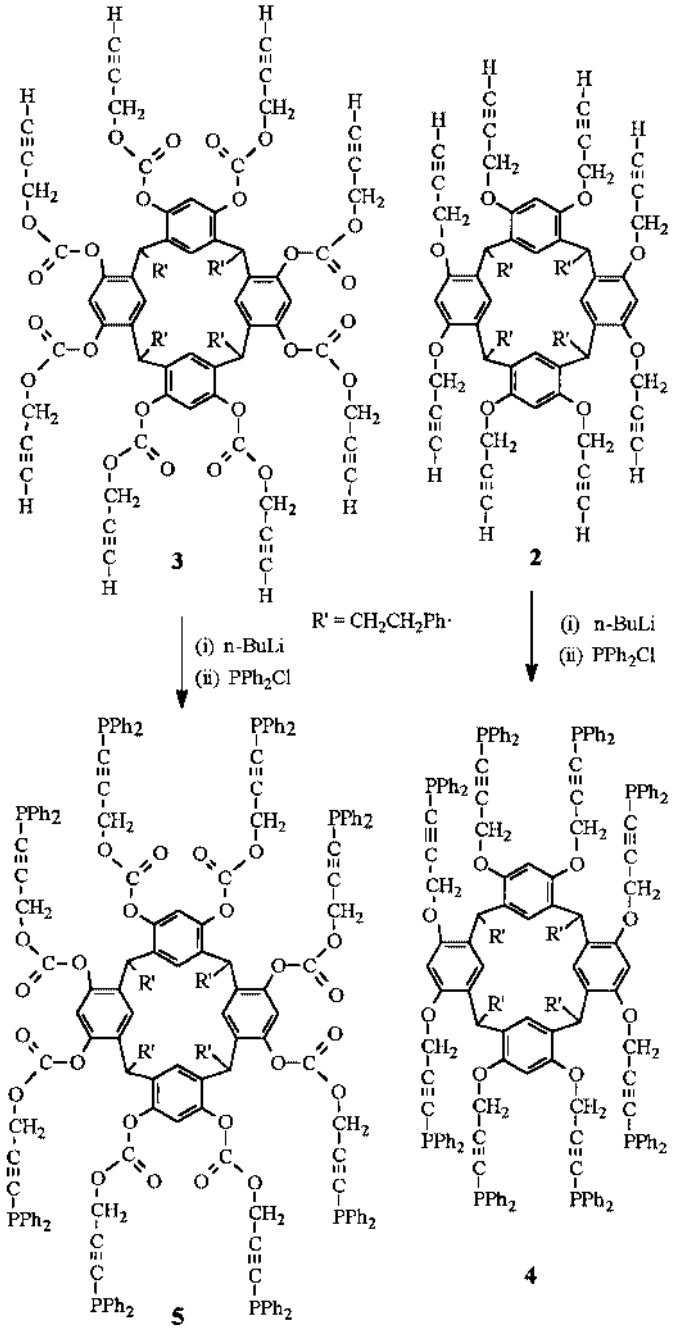
earlier for **6a** (8). The compounds **6a**–**6e** precipitate from the reaction solution with 2 equiv. of triethylammonium chloride incorporated, but pure samples, without triethylammonium chloride, were obtained by recrystallization. Further reaction of compounds **6a**–**6e** with chlorodiphenylphosphine, in the presence of triethylamine as base, gave the resorcinarenes **7a**–**7e** as outlined in Scheme 3. The new compounds **7a**–**7e** are colourless solids, which are air stable in the solid state but which decompose easily in solution on exposure to oxygen or moisture.

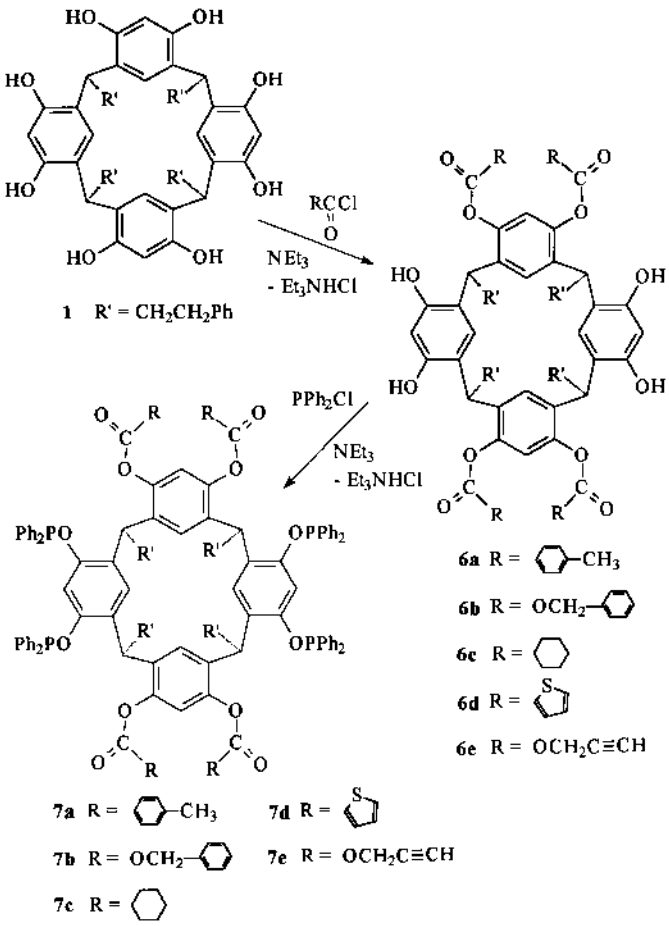
Characterization of the octa(alkyne) and octa(alkynyldiphenylphosphine) derivatives

The ^{1}H and ^{13}C NMR spectra of **2** and **3** at room temperature are indicative of effective C_{4v} symmetry. Thus, all propargyl groups and arene groups in resorcinarene **3** were equivalent by NMR. The methylene protons of the propargyl groups of **3** are diastereotopic, and so appeared as an AB multiplet ($J(H^aH^b)$ = 16 Hz in **3**), with further splitting by the acetylenic proton. The apparent symmetry of the NMR spectra could indicate a symmetrical bowl structure, but it is likely, based on several precedents (1, 6) that the compounds exist in a boat conformation with C_{2v} symmetry. Easy interconversion between equivalent boat conformations, each having C_{2v} symmetry, then leads to the apparent C_{4v} symmetry (eq. [1]). The NMR spectra of **3** were essentially unchanged down to –80 °C, indicating a low energy barrier to the fluxionality of eq. [1].

The ^{1}H, ^{13}C, and ^{31}P NMR spectra of the octa(diphenylphosphine) resorcinarene compounds **4** and **5** at room temperature were also consistent with C_{4v} symmetry. For example, only a single resonance was observed for each compound in the ^{31}P NMR spectrum, indicating effective equivalence of all diphenylphosphine groups. For compound **4** at –80 °C, the ^{1}H NMR spectrum resolved giving the spectrum expected for the boat conformation, with effective C_{2v} symmetry. For example, two sets of resonances were ob-



[1]



served for the methylene protons of the propargyl groups in the ^{1}H NMR spectrum at –80 °C, corresponding to substituents of the upright and flattened arene rings of the boat conformation. The resonances for each CH_2 group of the phenethyl substituents also split at –80 °C as these protons are diastereotopic in the boat conformation. The ^{31}P NMR spectrum of **4** at –80 °C resolved into two broad singlets (Fig. 1). The coalescence temperature was –50 °C for the methylene protons of the propargyl groups, giving through the Eyring equation the activation energy ΔG^* = 41(1) kJ mol^{-1} for the fluxionality according to eq. [1]. Thus, the addition of the bulky diphenylphosphine groups increases the energy barrier to the fluxionality of eq. [1] in **4** relative to the parent **2**, for which no fluxional behavior was observed (11). The ^{1}H and ^{31}P NMR spectra of compound **5** were broad at –80 °C but no splitting was observed, suggest-

Scheme 3.

ing a lower energy barrier to the fluxionality of eq. [1] in **5** compared to **4**.

Characterization of the tetra(diphenylphosphinite) derivatives

The tetra(diphenylphosphinite) derivatives **7** could exist in either boat conformation **A** or **B** (Chart 2), with the arene groups carrying the diphenylphosphinite groups in the upright or flattened positions, respectively. The structure of the tetra(benzyl carbonate) tetra(diphenylphosphinite) resorcinarene derivative **7b** in the solid state was determined crystallographically. The structure is shown in Fig. 1 and provides a benchmark for characterization of the series of tetraphosphinite derivatives. The resorcinarene skeleton of **7b** adopts a boat conformation, with the phosphinite-derivatized rings in a flattened position and the acylated rings in an upright position (conformation **B**, Chart 2). The upright resorcinol arene rings are near parallel, with the angle between the planes of the upright rings (fold angle) being 1°, while the flattened rings have a fold angle of 153°. There is little twisting distortion of the resorcinarene skeleton, as seen by the dihedral angles between opposing resorcinol arene rings of only 5° in each case. The molecule has crystallographically imposed C_2 symmetry. The boat conformation does not yield a large cavity between the upright arene rings of the resorcinarene but the four benzyl carbonate groups of **7b** extend the bowl structure, and there are two tetrahydrofuran molecules present as guest molecules in this region, as shown in Fig. 2.

The solution structures of **7** and of the precursor molecules **6** were probed by NMR spectroscopy. The ^{1}H and ^{13}C NMR spectra of the tetraester compounds **6a**–**6e** were consistent with effective C_{2v} symmetry, as described previously for **6a** (8), and the spectra remained essentially unchanged down to –80 °C. Hence, no information could be obtained about conformational switching between boat conformations (acylated rings up vs. acylated rings flattened, each having C_{2v} symmetry).

The ^{1}H, ^{13}C, and ^{31}P NMR spectra of compound **7b** will be described as an example of the series of compounds **7**.

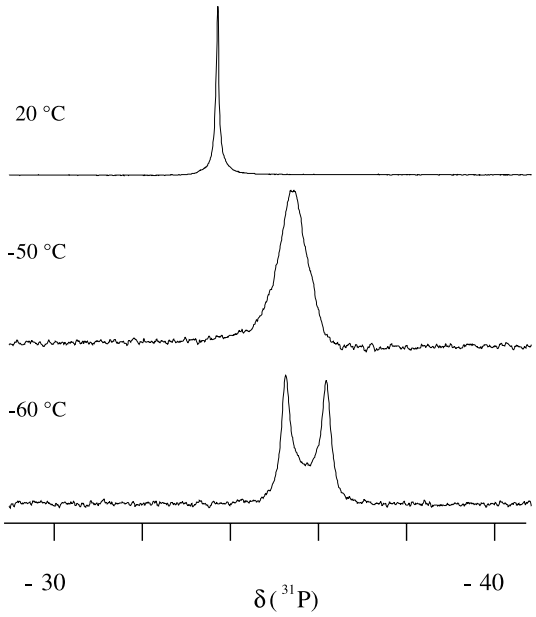

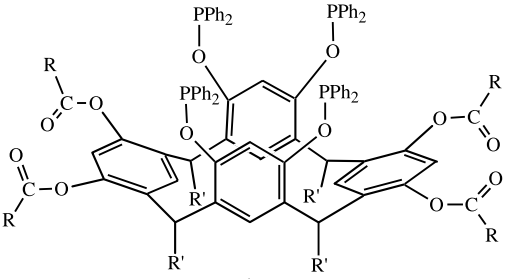

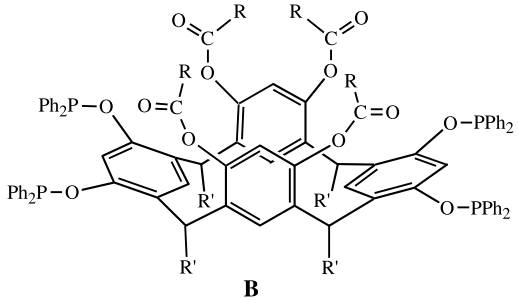

Chart 2.

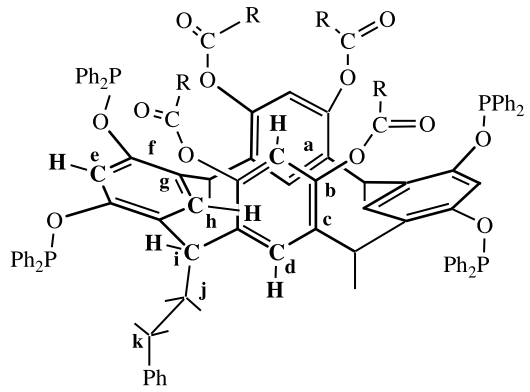
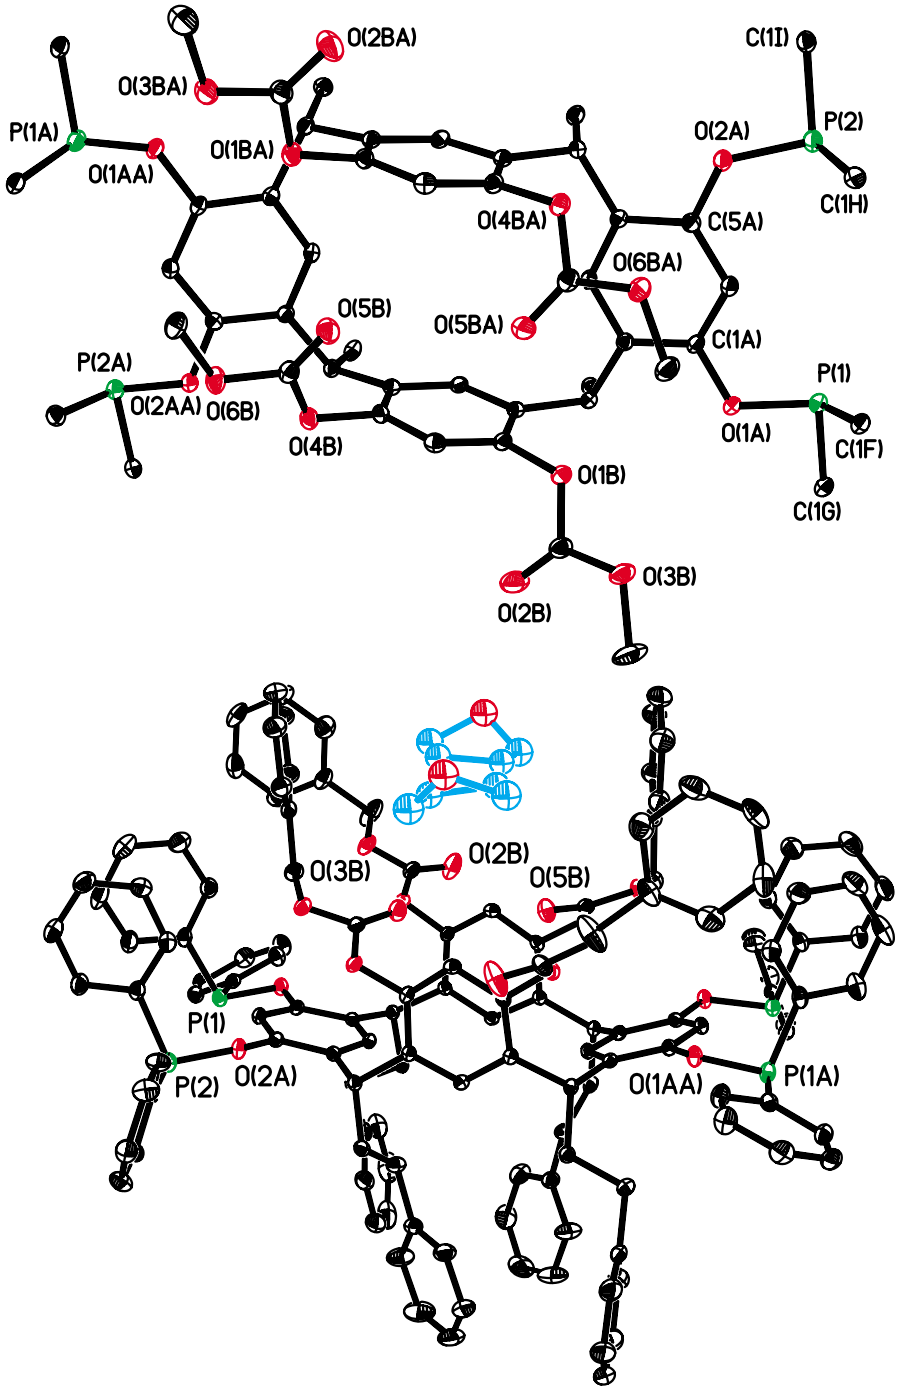


A

B

The NMR spectra at room temperature indicated effective C_{2v} symmetry. There were separate resonances for the aryl protons or carbon atoms of the acylated and phosphinite-derivatized resorcinol arene rings in the ^{1}H or ^{13}C NMR spectrum of **7b**, as expected for a single conformer with C_{2v} symmetry. A single resonance was observed in the ^{31}P NMR spectrum, as expected for C_{2v} symmetry. The low-temperature ^{1}H and ^{31}P NMR spectra of compounds **7a**–**7e** remained essentially unchanged, and so there was no evidence for fluxionality between the conformers of Chart 2. Relatively small motions are needed to convert the solid-state structure of **7b**, with C_2 symmetry, to a boat conformer with C_{2v} symmetry. However, a simple analysis of the spectra do not indicate if the same boat conformer, with the arene rings bearing the diphenylphosphinite substituents in the flattened position, is present in solution or if it can interconvert easily to the other conformer. A more detailed analysis of the 2D ^{1}H–^{13}C correlated NMR spectra (gHSQC and gHMBC) for compounds **6a**–**7e** makes it possible to establish which conformation is present in the solution state. For simplicity, the conformations will be assigned as **A**, acylated rings flattened, and **B**, acylated rings upright (Chart 2), and the assignment of conformation in solution is described below.

Chart 3.



It has been established that the magnitude of the chemical shift separation of the resonances for H^{h} and H^{d} (Chart 3) can be taken as a measure of the distortion of the resorcinarene skeleton towards a boat conformation (8). Chemical shift differences of 0.3–0.6 ppm have recently been reported for a series of C_{2v} symmetrical tetraesters, which exist in a boat conformation in solution (8*b*). Furthermore, the resonance for the proton H^{h} on the flattened ring appears at higher field since it lies in the shielding zone of the upright rings (8, 12). Thus, if the resonances for H^{d} and H^{h} can be unambiguously assigned, it is possible to identify the conformation of the resorcinarene skeleton in solution.

For the series of tetraester resorcinarene compounds **6a**–**6e**, compound **6e** will serve as an example for how the skeletal atoms are assigned. The bridging methine carbon (C^{i} (Chart 3)) can be assigned from the gHSQC experiment, since the directly bonded proton H^{i} ($\delta = 4.58$) has a characteristic triplet appearance due to coupling with the two H^{j} protons. Further confirmation of the identification of this carbon atom comes from the observation of long-range couplings with H^{j} and H^{k} in the gHMBC experiment (Fig. 3). With the unambiguous assignment of C^{i} and H^{i} established, it is possible to assign the carbon atoms C^{b}, C^{c}, C^{d}, C^{f}, C^{g}, and C^{h} from the gHMBC data, as these all show long-range coupling to H^{i}. The protons H^{d} and H^{h} can be identified readily from the gHMBC experiment from the correlation with C^{i}, and the directly bonded carbon atoms C^{d} and C^{h} are then assigned from the gHSQC data. The two pairs of carbon atoms C^{b}, C^{c} and C^{f}, C^{g} were identified from their long-range couplings to H^{d} and H^{h}, respectively. The carbon atom C^{c} can be distinguished from C^{b} (and likewise, C^{g} from C^{f}) from the gHMBC data, since only C^{c} is correlated to the H^{j} protons. With the assignment of C^{b}, C^{c}, C^{f}, and C^{g} estab-

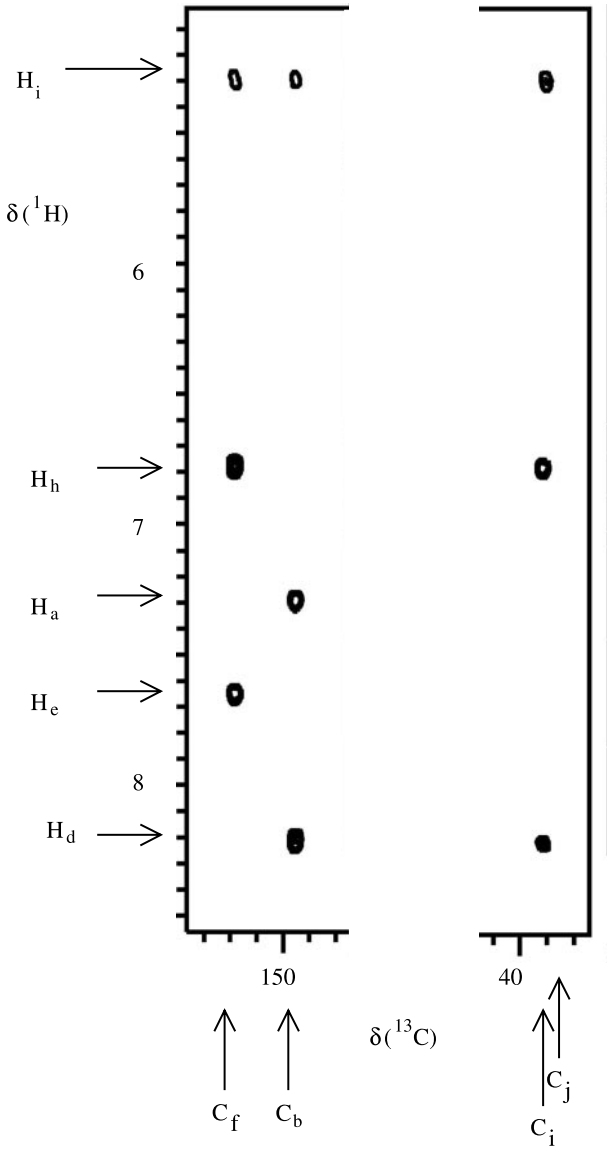
Fig. 2. Views of the structure of compound **7b**. Above: A top view, with only the ipso carbon atoms of the phenyl groups and α-carbon atoms of the phenethyl groups shown, for clarity. Below: A side view with all heavy atoms included, illustrating the position of the guest molecules of THF in the extended bowl defined by the benzyl carbonate substituents. Selected bond distances and angles: P1—O1A (1.659(1) Å), P2—O2A (1.665(2) Å), P1-O1A-C (119.6(1)°), P2-O2A-C (122.5(1)°).



lished, it is possible to identify H^a and H^e, from long-range coupling in the gHMBC experiment. The gHSQC data then allows the assignment of C^a and C^e by correlation with H^a and H^e, thus, completing the full assignment of the resorcinarene skeletal atoms.

To determine which conformation is present in solution, it is necessary to be able to identify which ring is unsubstituted, and which ring contains the acyl substituents. This can be achieved from the observation that the addition of the acyl substituents results in a significant shift of the resonance for C^a in the ^{13}C NMR spectrum (8). In compound **1**, the resonance for C^a appears at δ = 103.44, which is slightly shifted with the addition of the propargyl groups in **3** to δ = 100.78. The addition of eight propargyl carbonate substituents in **2** however results in a shift to δ = 115.46. Final confirmation of the effect of the acyl substituents is obtained from compound **6e**, where the resonance for C^a (acylated rings) appears at δ = 115.76, whereas the resonance for C^e

© 2004 NRC Canada

Fig. 3. A section of the gHMBC ^{1}H–^{13}C correlated spectrum of compound **7c**, illustrating how the conformation is assigned. Similar spectra were obtained for all compounds **6** and **7**.

(unsubstituted) appears at δ = 103.42. Similar shifts are observed for the other tetra-acylated resorcinarene compounds **6a**–**6d**. Thus, with the identity of the rings established, comparison of the chemical shifts for the protons H^{d} and H^{h} allows the assignment of the conformation in solution. For compound **6e**, the resonance for H^{d} appears at δ = 6.94, while that for H^{h} is located at δ = 7.27 (Table 1). Hence, since H^{d} is the most shielded, this indicates that **6e** is present as conformation **A** (acylated rings in the flattened position) in solution. Similar treatment of the data for compounds **6a**–**6d** established that in each case, conformation **A** is present in solution. Conformation **A** has been established for compounds **6d** and **6e**, as the triethylammonium chloride and pyridinium chloride inclusion compounds, respectively, by preliminary X-ray structure determinations, so the preferred conformer is the same in both solution and solid states.

Table 1. ^{1}H NMR chemical shifts[a] (ppm) of skeletal ring hydrogen atoms.

Compound	a	d	e	h	Δδ (d,h)
6a	7.01	7.05	6.61	7.37	0.32
6b	6.94	7.00	6.06	7.28	0.28
6c	6.54	6.94	5.83	7.21	0.26
6d	6.88	7.17	6.11	7.30	0.13
6e	7.01	6.94	5.81	7.27	0.31
7a	7.00	7.71	6.78	6.25	1.46
7b	6.77	7.63	6.96	6.16	1.47
7c	6.63	7.52	6.99	6.11	1.41
7d	7.04	7.69	6.81	6.20	1.49
7e	6.87	7.51	6.90	6.05	1.46

[a]Not all resonances were directly observed in the ^{1}H NMR spectra, thus some chemical shifts were obtained from the 2D NMR data.

Assignment of the skeletal atoms for the tetraphosphinite compounds **7a**–**7e** is accomplished from the solution NMR data using the same technique outlined for compound **6e**. However, for the phosphinite derivatives, an additional confirmation is possible. In the carbon spectra of **7a**–**7e**, the phosphorus atoms of the diphenylphosphinite groups couple both to C^{f} and C^{e}. Hence, the resonance for C^{f} appears as a doublet, while the resonance for C^{e} appears as a multiplet, as it couples to both nearby diphenylphosphinite substituents. The skeletal carbon and hydrogen atom assignments are for **7a**–**7e** are summarized in Tables 1 and 2. In each case, it was established that, in solution, the phosphinite resorcinarene compounds adopt conformation **B** (phosphinite rings flattened), which is in accordance with the structure obtained for **7b**. The chemical shift separation of the resonances for H^{d} and H^{h} in the phosphinite derivatives is far greater than that observed for the parent tetraesters, ranging from 1.41 to 1.49 for the former compared with 0.13–0.31 in the latter (Table 1). The larger separation indicates a greater deformation towards a boat conformation in solution for the phosphinite derivatives compared to the parent tetraesters.

Conclusions

The resorcinarene compound **1** has been derivatized to give several new organophosphorus compounds. The octopus-like octa(alkynyldiphenylphosphine) compounds **4** and **5** have effective C_{4v} symmetry and have the potential to form highly metalated resorcinarene complexes. The tetra(diphenylphosphinite) derivatives **7a**–**7e** can potentially adopt two different boat conformations. If the boat conformation in which the phosphinite derivatized rings are in the upright position is adopted (**A**, Chart 1), the resorcinarene offers a platform of four coplanar phosphorus donors in relatively close proximity, suitable for forming cluster complexes. On the other hand, if the boat conformation in which the phosphinite-derivatized rings are in the flattened position is adopted (**B**, Chart 1), the overall resorcinarene architecture can be viewed as a bis(diphosphinite) ligand, with well-separated pairs of phosphorus donors. To develop this chemistry, a method for determining the preferred conformation of the tetraphosphinite compounds **7a**–**7e** in solution was needed and has been established by use of ^{1}H, ^{13}C, and ^{31}P NMR spectroscopic data.

Experimental

The reactions, except for the preparation of the tetraester and octaester compounds, were carried out under a nitrogen atmosphere using standard Schlenk techniques. NMR and IR spectra were recorded using a Varian Inova 400 NMR or a Varian Mercury 400 NMR and a Perkin-Elmer FT-IR 2000 spectrometer, respectively. The resorcinarene compounds **1** (10), **2** (11), and **6a** (8) were prepared by literature methods. In the NMR assignments for compounds **6a**–**7e**, the skeletal carbon resonances are grouped according to the substituents on the resorcinol arene rings as follows: (Unsub.) = unsubstituted ring, (Acyl) = acylated ring, and (Phos.) = phosphinite-derivatized ring. The corresponding aryl protons are treated in a similar fashion.

Resorcinarene(OC(O)OCH$_2$C≡CH)$_8$ (3)

A solution of **1** (4.5 g, 4.97 mmol) in CH_2Cl_2 (20 mL) was treated with triethylamine (6.2 mL, 44.5 mmol) resulting in the immediate formation of a pink slurry. The mixture was stirred for 10 min and propargyl chloroformate (5.0 mL, 49.2 mmol) was added in 1.0 mL portions at 3 min intervals. The solution was stirred for 10 min, extracted with two 30 mL portions of water, and dried over $MgSO_4$. The solution was filtered and the product recrystallized from CH_2Cl_2–MeOH. White solid, mp 146–148 °C. Yield: 3.05 g, 39%. FT-IR (cm^{-1}): 2133 ν(C≡C). ^1H NMR ($CDCl_3$) δ: 2.19 (m, 8H, CHC*H*$_2$CH$_2$Ph), 2.53 (t, 8H, $^4J_{HH}$ = 2 Hz, OC(O)OCH$_2$C≡C*H*), 2.60 (m, 8H, CHCH$_2$C*H*$_2$Ph), 4.49 (t, 4H, $^3J_{HH}$ = 8 Hz, C*H*CH$_2$CH$_2$Ph), 4.74 (m, 16H, $^2J_{HH}$ = 16 Hz, $^4J_{HH}$ = 2 Hz, OC(O)OC*H*$_2$C≡CH), 6.85 (s, 4H, Ar-*H*, meta to O), 7.21 (s, 4H, Ar-*H*, ortho to O), 7.03, 7.15 (m, 20H, Ar-*H*, *Ph*). ^{13}C NMR δ: 33.96 (CHCH$_2$*C*H$_2$Ph), 36.05 (*C*HCH$_2$CH$_2$Ph), 36.80 (CH*C*H$_2$CH$_2$Ph), 56.04 (OC(O)O*C*H$_2$C≡CH), 76.10, 76.73 (OC(O)OCH$_2$*C*≡*C*H), 115.46 (Ar-*C*H, ortho to O), 125.69 (Ar-*C*H, meta to O), 125.79, 128.16, 128.30 (Ar-*C*, *Ph*), 132.23 (Ar-*C*C), 141.10 (ipso-*C*, *Ph*), 146.93 (Ar-*C*O), 151.81 (O*C*(O)OCH$_2$C≡CH). Resorcinarene(OC(O)OCH$_2$C≡CPPh$_2$)$_8$ (5)

A solution of **3** (2.0 g, 1.28 mmol) in ether (140 mL) was cooled to –40 °C. To this was added a cold (–40 °C) solution of *n*-butyllithium (6.6 mL, 10.6 mmol) in ether (10 mL) via cannula over several min. The mixture was stirred for 1 h and a cold solution (–40 °C) of PPh_2Cl (2.0 mL, 10.6 mmol) in THF (15 mL) was added via cannula over 10 min. The mixture was then slowly warmed to room temperature and allowed to stir for 1.5 h. The solvent was removed under vacuum and the residue dissolved in CH_2Cl_2 (30 mL). The solution was filtered and a dark brown oil was precipitated

© 2004 NRC Canada

with pentane. The oil was washed with pentane (50 mL), redissolved in CH_2Cl_2, and precipitated with pentane followed by several washings with pentane (3 × 20 mL). The oil was dried under vacuum and a light brown solid was obtained: mp 71–73 °C. Yield: 2.38 g, 61%. FT-IR (cm^{-1}): 2194 ν(C≡C). ^{1}H NMR (CD_2Cl_2) δ: 2.26 (m, 8H, CHCH_2CH$_2$Ph), 2.58 (m, 8H, CHCH$_2$CH_2Ph), 4.49 (t, 4H, $^3J_{HH}$ = 8 Hz, CHCH$_2$CH$_2$Ph), 4.90 (m, 16H, $^2J_{HH}$ = 16 Hz, OC(O)OCH_2C≡CPPh$_2$), 6.97–7.59 (m, 108H, Ar-*H*, meta to O, *Ph*). ^{13}C NMR δ: 34.13 (CHCH$_2$*C*H$_2$Ph), 36.19 (*C*HCH$_2$CH$_2$Ph), 37.30 (CH*C*H$_2$CH$_2$Ph), 57.42 (O*C*H$_2$C≡CPPh$_2$), 85.84 (d, $^2J_{PC}$ = 13 Hz, OC(O)OCH$_2$*C*≡CPPh$_2$), 101.40 (OC(O)OCH$_2$C≡*C*PPh$_2$), 115.73 (Ar-*C*H ortho to O), 126.17 (Ar-*C*H meta to O), 125.91, 128.33–132.69 (Ar-*C*, *Ph*), 132.80 (Ar-*C*C), 135.26 (m, ipso-*C*, P*Ph*$_2$), 141.42 (ipso-*C*, *Ph*), 147.21 (Ar-*C*O), 152.10 (O*C*(O)OCH$_2$C≡CPPh$_2$).^{31}P NMR δ: –33.70 (s). Resorcinarene(OC(O)C$_4$H$_3$S)$_4$(OPPh$_2$)$_4$ (7d)

This was prepared similarly from **6d** (1.0 g, 0.743 mmol), triethylamine (0.52 mL, 3.72 mmol), and chlorodiphenylphosphine (0.70 mL, 3.72 mmol). White solid, mp 249–251 °C. Yield: 1.25 g, 81%. ^{1}H NMR (CD_2Cl_2) δ: 2.10 (m, 4H, CHC*H*$_2$CH$_2$Ph), 2.34 (m, 8H, CHC*H*$_2$C*H*$_2$Ph), 2.68 (m, 4H, CHCH$_2$C*H*$_2$Ph), 4.77 (t, 4H, $^3J_{HH}$ = 8 Hz C*H*CH$_2$CH$_2$Ph), 6.20 (s, 2H, Ar-*H*), 6.80–7.61 (m, 76H, *Ph*, Ar-*H*, C$_4$*H*$_3$S); Phos.: 6.20 (s, 2H, Ar-*H*, meta to O); Acyl: 7.69 (s, 2H, Ar-*H*, meta to O). ^{13}C NMR δ: 34.79 (CHCH$_2$*C*H$_2$Ph), 37.20 (CH*C*H$_2$CH$_2$Ph), 37.86 (*C*HCH$_2$CH$_2$Ph), 125.81, 128.29–130.11, 130.81, 131.04, 133.07, 135.01 (Ar-*C*, *Ph*, *C*$_4$H$_3$S), 141.29 (m, ipso-*C*, P*Ph*$_2$), 142.42 (ipso-*C*, *Ph*), 159.92 (*C*=O); Phos.: 106.86 (m, Ar-*C*H, ortho to O), 126.89 (Ar-*C*H, meta to O), 130.29 (Ar-*C*C), 153.15 (d, $^2J_{PC}$ = 9 Hz, Ar-*C*O); Acyl: 117.76 (Ar-*C*H, ortho to O), 126.62 (Ar-*C*H, meta to O), 131.85 (Ar-*C*C), 148.02 (Ar-*C*O). ^{31}P NMR δ: 109.50 (s). Anal. calcd. for $C_{128}H_{100}O_{12}S_4P_4$ (%): C 73.83, H 4.84; found: C 74.41, H 5.07.

Resorcinarene(OC(O)OCH$_2$C≡CH)$_4$(OPPh$_2$)$_4$ (7e)

This was prepared similarly from **6e** (1.0 g, 0.811 mmol), triethylamine (0.57 mL, 4.05 mmol), and chlorodiphenylphosphine (0.77 mL, 4.07 mmol). White solid, mp 146–148 °C. Yield: 1.25 g, 78%. ^{1}H NMR (CD_2Cl_2) δ: 2.02, 2.23 (m, 8H, CHC*H*$_2$CH$_2$Ph), 2.37, 2.55 (m, 8H, CHCH$_2$C*H*$_2$Ph), 2.52 (t, 4H, $^4J_{HH}$ = 2 Hz, OC(O)OCH$_2$C≡C*H*), 4.36 (s, br, 8H, OC(O)OC*H*$_2$C≡CH), 4.72 (t, 4H, $^3J_{HH}$ = 8 Hz, C*H*CH$_2$CH$_2$Ph), 6.98–7.65 (m, 64H, Ar-*H*, *Ph*); Phos.: 6.05 (s, 2H, Ar-*H*, meta to O); Acyl: 7.51 (s, 2H, Ar-*H*, meta to O). ^{13}C NMR δ: 34.54 (CHCH$_2$*C*H$_2$Ph), 36.70 (*C*HCH$_2$CH$_2$Ph), 37.89 (CH*C*H$_2$CH$_2$Ph), 55.92 (OC(O)O*C*H$_2$C≡CH), 75.88, 77.35 (OC(O)OCH$_2$*C*≡*C*H), 125.75, 128.25–131.13 (Ar-*C*, *Ph*), 141.25 (m, ipso-*C*, P*Ph*$_2$), 142.35 (ipso-*C*, *Ph*), 152.15 (O*C*(O)OCH$_2$C≡CH); Phos.: 105.78 (m, Ar-*C*H, ortho to O), 127.33 (Ar-*C*H, meta to O), 128.81 (Ar-*C*C), 153.10 (d, $^2J_{PC}$ = 10 Hz, Ar-*C*O); Acyl: 117.05 (Ar-*C*H, ortho to O), 125.20 (Ar-*C*H, meta to O), 132.20 (Ar-*C*C), 147.86 (Ar-*C*O). ^{31}P NMR δ: 110.73 (s). Anal. calcd. for $C_{124}H_{100}O_{16}P_4$ (%): C 75.60, H 5.12; found: C 75.17, H 5.41.

X-ray structure determination

A crystal of **7b**·2THF, grown from a THF–pentane solution, was mounted on a glass fibre. Data were collected using a Nonius-Kappa CCD diffractometer using COLLECT

© 2004 NRC Canada

(13) software. The unit cell parameters were calculated and refined from the full data set. Crystal cell refinement and data reduction was carried out using the Nonius DENZO package. The data were scaled using SCALEPACK (14). The SHELXTL V5.1 (15) program package was used to solve and refine the structure. The centrosymmetric space group *C*2/*c* was chosen based on E-statistics and resulted in successful refinement of the data. The hydrogen atoms were calculated geometrically and were riding on their respective carbon atoms. The solvent of crystallization was disordered and was modeled as an isotropic 40:40:20 disordered mixture, with the carbon–carbon and carbon–oxygen distances fixed. Except as mentioned above, all non-hydrogen atoms were refined with anisotropic thermal parameters. Crystal data are summarized in Table 3.[3]

Regiospecific synthesis of alkylphenanthrenes using a combined directed *ortho* and remote metalation – Suzuki–Miyaura cross coupling strategy[1]

Xiongwei Cai, Stephen Brown, Peter Hodson, and Victor Snieckus

Abstract: Using a combined directed *ortho* metalation (DoM) – Suzuki–Miyaura cross coupling – directed remote metalation (DreM) approach, the alkylphenanthrenes (APs) 1-methyl- (**5a**), 1,7-dimethyl- (**5b**), 2,7-dimethyl- (**5c**), 7-ethyl-1-methyl- (**15**), and 7-*tert*-butyl-1-methylphenanthrenes (**27**) have been synthesized in four to seven steps and 21%–36% overall yields. In contrast to classical protocols, this method, which may be scaled to gram quantities, provides single isomers of APs in high purity of value as analytical standards for environmental studies. Aminocarbonylation of triflates to *N*,*N*-diethylbenzamides (**9** → **10**) and anionic Fries rearrangement (**23** → **24**) provide other potential links to DoM chemistry.

Key words: phenanthrene, directed *ortho* metalation, Suzuki–Miyaura cross coupling, synthesis, polycyclic aromatic hydrocarbon, carbonylation.

Résumé : Faisant appel à une approche combinant une métallation orientée en ortho (MOo), un couplage croisé de Suzuki et Miyaura et une métallation orientée à distance (MOdi), on a réalisé des synthèses d'alkylphénanthrènes (AP), les 1-méthyl- (**5a**), 1,7-diméthyl- (**5b**), 2,7-diméthyl- (**5c**), 7-éthyl-1-méthyl- (**15**) et 7-*tert*-butyl-1-méthylphénanthrènes (**27**), qui impliquaient de quatre à sept étapes avec des rendements globaux allant de 21 % à 36 %. Par opposition avec les protocoles classiques, cette méthode être réalisée à des échelles du gramme et elle conduit à des isomères uniques d'AP, de grande pureté qui peuvent être utilisés comme références pour des études environnementales. L'aminocarbonylation de triflates de *N*,*N*-diéthylbenzamides (**9** → **10**) et le réarrangement anionique de Fries (**23** → **24**) fournissent d'autres liens vers la chimie de la MOo.

Mots clés : phénanthrène, métallation orienté en *ortho*, couplage croisé de Suzuki et Miyaura, hydrocarbure aromatique polycyclique, carbonylation.

[Traduit par la Rédaction]

Introduction

Alkylphenanthrenes (APs) represent a significant class of polycyclic aromatic hydrocarbons (PAHs) found in soil, sediment, and other aquatic sites, which constitute environmental pollutants with substantial levels of toxicity towards marine diatoms, gastropods, mussels, crustaceans, and especially fish (1–3). The key biological marker for toxicity, retene (7-isopropyl-1-methylphenanthrene) causes reductions in recruitment and growth and an increased prevalence of morphological abnormalities of laval pink salmon and Pacific herring (3, 4), effects which were observed in the 1989 Exxon Valdez oil spill in Alaska (1). Among the various PAH classes, the APs have been sparsely evaluated for toxicity effects, arguably because of lack of commercial sources of analytically pure compounds in sufficient quantity. Only a few APs are available, e.g., 1-methyl-, 1,7-dimethylphenanthrene, and retene at times of uncertain and insufficient isomer purity and inadequate quantity.[3] Among the few methods of phenanthrene synthesis, classical electrophilic substitution (5), Pschorr reaction (6), ring expansion (7), Mallory photocyclization (8), and recently, palladium-catalyzed trimerization (9) and radical cyclization (10), tactics have, to various degrees, been applied to AP preparation but suffer in length or produce mixtures of isomers. We report a combined metalation – Suzuki–Miyaura cross cou-

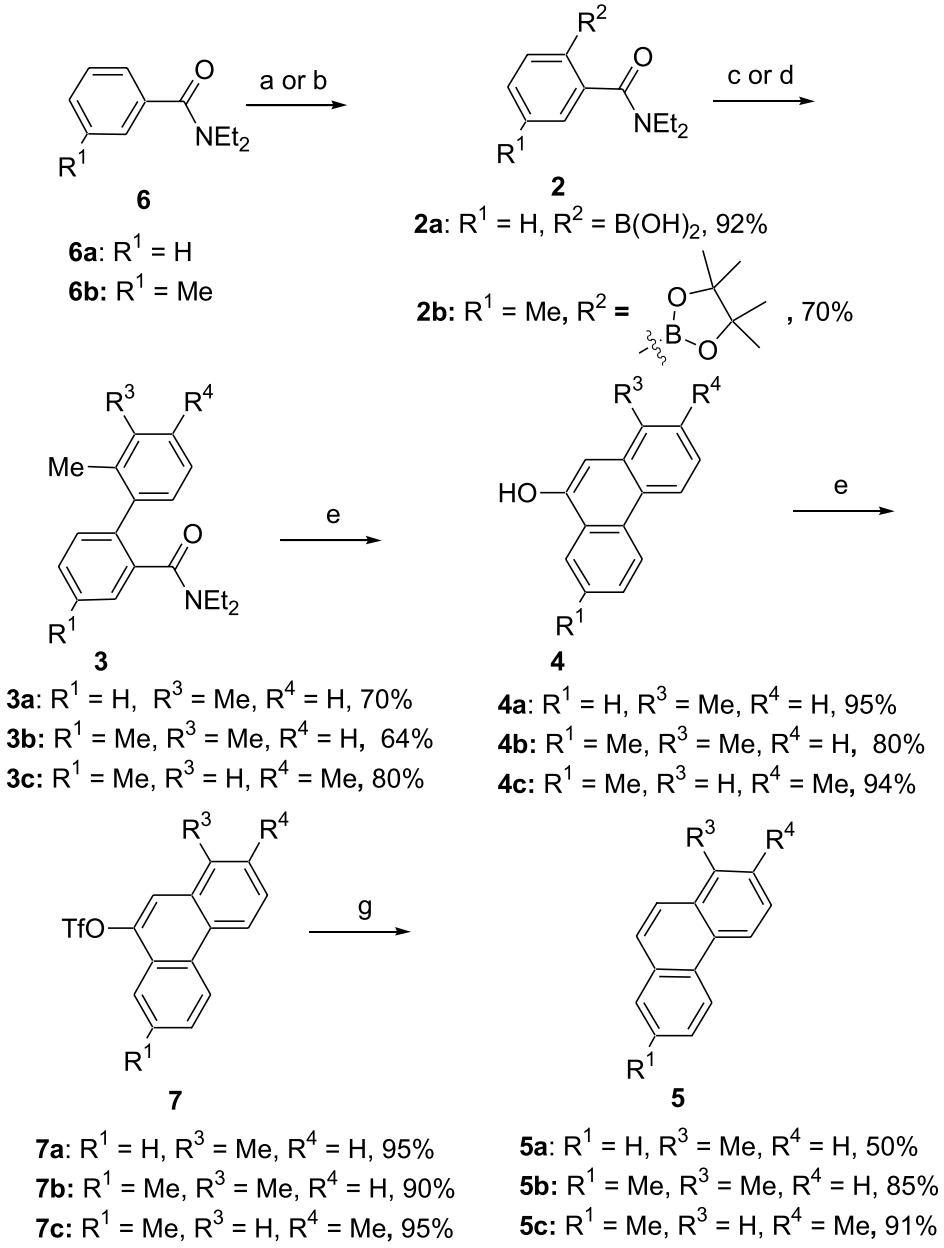
Scheme 1.

pling methodology involving both directed *ortho* (DoM) and remote metalation (DreM) reactions, **1** + **2** → **3** → **4** → **5** (Scheme 1) that provides short, efficient, and regioselective routes to APs **5a**, **5c**, **15**, and **27**. This general strategy provides the phenanthrene class of PAHs as single isomers in preparative quantities and contrasts with classical methods, which invariably involve harsh conditions, lack of regioselectivity, and considerable handling of potentially toxic materials (11). Recently, de Koning et al. has reported a general phenanthrene synthesis using *t*-BuOK-mediated cyclization of esters corresponding to **3** (12).

Synthesis of 1-methyl- (5a), 1,7-dimethyl- (5b), and 2,7-dimethyl- (5c) phenanthrenes

The synthesis of 1-methylphenanthrene (**5a**) (Scheme 2) was initiated from *N*,*N*-diethylbenzamide (**6a**) that upon metalation under standard conditions (*s*-BuLi / TMEDA / –78 °C / THF / 1 h) followed by quenching with trimethyl borate and acidic workup afforded the boronic acid **2a**. Without purification, **2a** was subjected, as the reactant in excess (1.4 equiv.), to the Suzuki–Miyaura cross coupling reaction with the commercially available 3-bromo-*o*-xylene to give the biaryl amide **3a** in good yield. Metalation–boronation of **6b**, the insecticide DEET® (13), at –98 °C proceeded smoothly to give the corresponding boronic acid, which was isolated and purified as the pinacol boronate **2b**. NMR analysis provided structural confirmation that DoM of **6b** occurred exclusively on C-6, a result differing with Beak and Brown's observation that metalation of **6b** under similar conditions but using MeOD quench yields C-6 and C-2 deuterated products in the ratio of 2:1 (Scheme 2) (14). The observed difference in regioselectivity using trimethyl borate as the electrophile may be due to its greater size. Boronate **2b** was subjected to Suzuki–Miyaura cross coupling with 3-bromo-*o*-xylene and 4-bromo-*m*-xylene to give biaryls **3b** and **3c**, respectively, in satisfactory yields.

Application of the standard DreM conditions (11*a*) to the biaryl amides **3a**–**3c** (2.5 equiv. of LDA / THF / 0 °C) resulted in smooth cyclization to the 9-phenanthrols **4a**–**4c**, which underwent oxidation slowly and changed colors in the air but were stable in sealed vials at –30 °C. The 9-phenanthrols **4a**–**4c** were then converted into their triflates **7a**–**7c** (15), which upon Pd-catalyzed hydrogenolysis in the presence of formic acid, afforded 1-methyl-phenanthrene (**5a**), 1,7-dimethylphenanthrene (**5b**), and 2,7-dimethylphenanthrene (**5c**) in modest to excellent yields. Overall yields (**5a** (29%), **5b** (27%), **5c** (45%), in four to six steps from commercial materials) cannot be compared with previous routes for lack of data with the exception of **6a**, which was obtained by Pschorr synthesis in 21% overall yield and four steps (16).



Synthesis of 7-ethyl-1-methylphenanthrene (15)

The synthesis of the homologous 7-ethyl-1-methylphanthrene (**15**) commenced from 3-ethylbenzamide (**10**), which was obtained by a aminocarbonylation protocol (Scheme 3). Thus, commercial 3-ethylphenol (**8**) was converted into the corresponding triflate **9** (15), which was subjected to aminocarbonylation conditions (17) using a number of phosphine ligands that included PPh_3, dppf, and dppp. In the case of PPh_3, rapid black precipitation was observed and the product **10** was obtained in low yield with the material balance being recovered starting material (72%). In contrast, the bidentate ligands dppp and dppf behaved well, leading to similar yields of **10** and completion of reactions with only trace amounts of starting material being detected by GC at the conclusion of the reaction. In this two-phase reaction, it is imperative to ensure good mixing, especially when the reaction is carried out on a large scale. Thus, using a balloon of CO led to poorer yields and longer completion times compared to bubbling CO into the solution for the duration of the reaction.

Metalation of 3-ethylbenzamide **10** (Scheme 4) under the low-temperature conditions used previously for **6b** (Scheme 2) followed by boronation and treatment with pinacol paralleled the reaction of **6b** in that it led to the formation of boronate **11**, the product of exclusive C-6 deprotonation. The isolated and purified boronate **11** was subjected to Suzuki–Miyaura cross coupling with 3-bromo-*o*-xylene under the previously defined conditions to afford the biaryl amide **12**, which, upon treatment with LDA, led cleanly to the 9-phenanthrol **13**. Analogous to the **4** → **7** reactions,

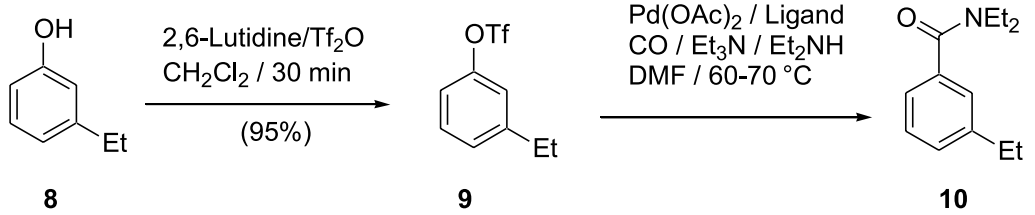
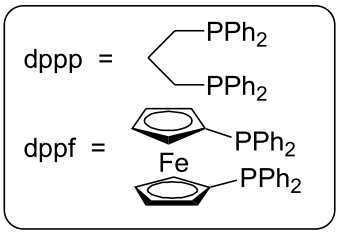
conversion of **13** into its triflate **14** followed by Pd-catalyzed hydrogenolysis by the agency of formic acid furnished **15** in high yield and >98% purity (HPLC analysis). This concluded the synthesis of 7-ethyl-1-methylphenthrene (**15**) in six steps in an overall yield of 36%.



Synthesis of 7-*tert*-butyl-1-methylphenanthrene (27)

In pursuit of the same strategy (Scheme 3) for the synthesis of 7-*tert*-butyl-1-methyl-phenanthrene (**27**, Scheme 5), we envisaged the preparation of the requisite benzamide **18** by the amidocarbonylation of **17**, which, in turn, was available in high yield from the commercial phenol **16** (Scheme 6). However, modest exploration of conditions and bidentate phosphine ligands for the reaction **17** → **18**, as indicated in tabular form, gave unsatisfactory results.



Therefore, a strategy involving the inversion of coupling partners in the Suzuki–Miyaura reaction **20** + **21** → **19** was pursued (Scheme 7). Thus, 4-*tert*-butylphenol **22** (Scheme 5) was quantitatively converted into the *O*-carbamate **23** that was subjected to conditions (*s*-BuLi / TMEDA / –78 °C) for the anionic Fries rearrangement (18) to give the salicylamide **24** in good yield. Conversion of **24** into triflate **20** using 2,6-lutidine proceeded in low yield (20%) compared to that achieved for previously prepared triflates. However, using pyridine as catalyst, **20** was obtained in good yield. In the key step, triflate **20** underwent Suzuki–Miyaura cross cou-

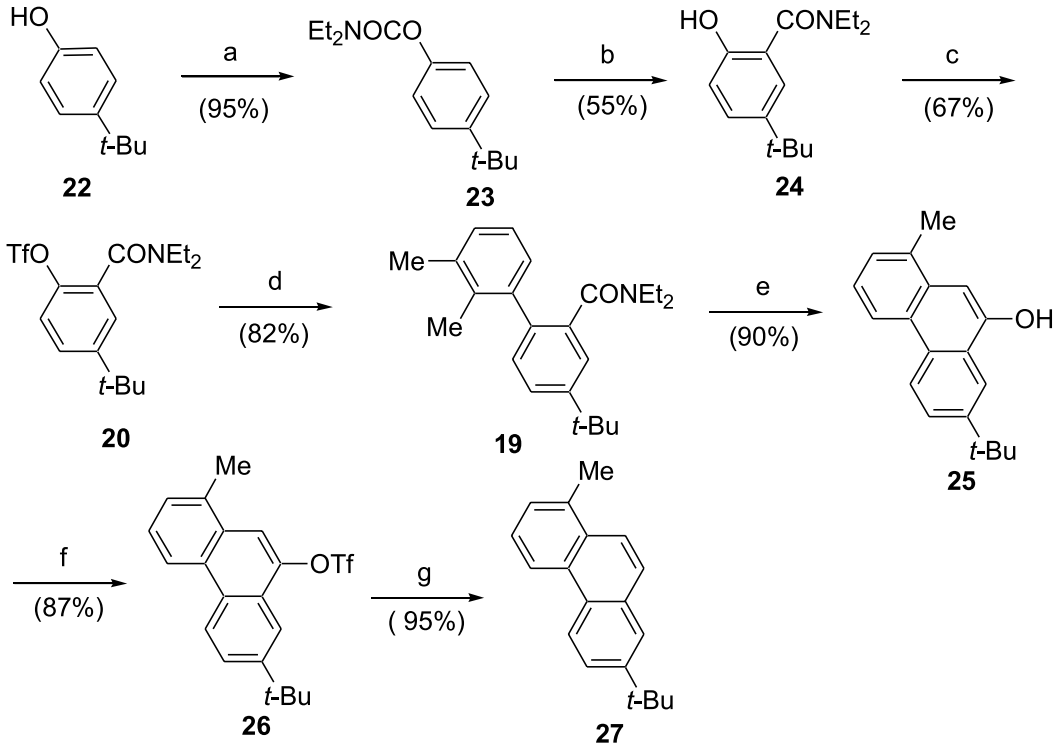
pling with the commercial boronic acid **21**, to form the biaryl amide **19** in very good yield. As before, LDA-mediated cyclization furnished, in excellent yield, the 9-phenanthrol **25** that was converted into its triflate **26** and thence into the target 7-*tert*-butyl-1-methylphenanthrene **27**. Thus, the synthesis of **27** was accomplished in seven steps in an overall yield of 21%.

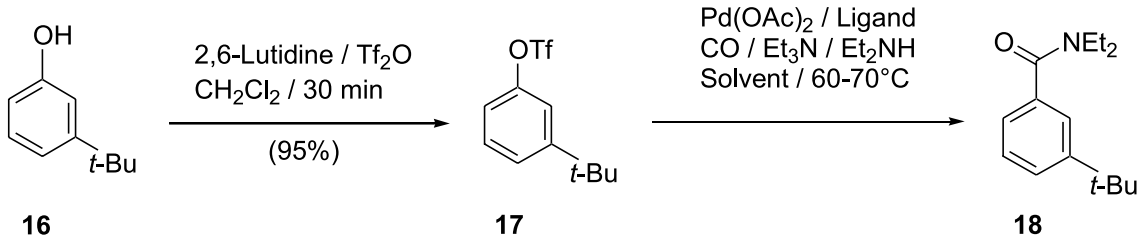
Conclusion

This work constitutes a contribution for the convenient and efficient preparation of the phenanthrene class of PAHs that contrasts with classical methods in terms of regioselectivity, brevity, mildness of conditions, and necessity for considerable handling of potentially toxic materials. Thus, the alkylphenanthrenes (APs) 1-methyl- (**5a**), 1,7-dimethyl- (**5b**), 2,7-dimethyl- (**5c**), 7-ethyl-1-methyl- (**15**), and 7-*tert*-butyl-1-methyl (**27**) phenanthrenes have been synthesized by a combined D*o*M – Suzuki–Miyaura cross coupling – DreM methodology in overall yields of 29% (five steps), 27% (five steps), 45% (five steps), 36% (six steps), and 21% (seven steps), respectively. A general and effective methodology has been thereby provided that allows anticipated application for the synthesis of various APs as single isomers in high purity and in scales ranging from 1 to 4 g. As an adjunct, a representative aminocarbonylation method of readily available aryl triflates to *N*,*N*-diethylbenzamides has been briefly investigated (Scheme 3) based on which a further general link to D*o*M chemistry may be anticipated.



Experimental section

General methods



Melting points are uncorrected. IR spectra were recorded neat or as KBr discs using a BOMEM FT-IR spectrometer.

^{1}H (300 MHz) and ^{13}C (75.43 MHz) NMR spectra were obtained in $CDCl_3$ using either TMS (for ^{1}H) or $CDCl_3$ (for ^{13}C) as the internal standard on a Bruker Avance-300 spectrometer. THF was freshly distilled from sodium benzophenone ketyl under nitrogen and CH_2Cl_2 and HN-*i*-Pr_2 were freshly distilled from CaH_2 under nitrogen. *n*-Butyllithium and *s*-butyllithium were purchased from Aldrich as solutions in hexanes, stored in resealable containers, and titrated periodically against *s*-butanol using 1,10-phenanthroline as the indicator (19). *N*,*N*-Diethyl benzamide (**6a**) was prepared from benzoyl chloride (20). *N*,*N*-Diethyl toluamide (DEET®) (**6b**), 6-bromo-*o*-xylene, 6-bromo-*m*-xylene, and 2,3-dimethylphenylboronic acid (**21**) were purchased from Aldrich Chemical Co. All experiments were carried out under argon in dried glassware, using syringe-septum cap techniques. The –78 °C and 0 °C external bath temperatures designated are approximate as achieved by a dry ice–acetone or ice–salt baths, respectively. Flash column chromatography was carried out using Merck Kieselgel 60 silica gel (particle size 32–63) with different ratios of EtOAc–hexane as eluents.

General procedures

A. Lithiation of benzamides

A solution of the benzamide (1.00 mmol) in anhyd THF (2 mL) was added dropwise to a stirred solution of *s*-BuLi–TMEDA (1:1, 1.20 mmol) complex in anhyd THF (3 mL) at –78 °C. The resulting mixture was stirred at –78 °C for 1 h, treated with an excess of $B(OMe)_3$ (2.40 mmol), and the mixture was warmed to ambient temperature over 8–12 h and quenched with a satd. aq. NH_4Cl solution (5 mL). The aqueous portion was extracted with Et_2O (3 × 5 mL), and the extract was dried (Na_2SO_4) and concentrated in vacuo. The residue was purified by flash column chromatography (EtOAc–hexanes) to afford the product.

B. Cross coupling reaction of arylboronic acids with aryl halides and aryl triflates

A mixture of $Pd(PPh_3)_4$ (0.04 mmol) and aryl halide or aryl triflate (1 mmol) in DME (3 mL) was stirred at room temperature (rt) for 10 min. The solution of aryl boronic acid (1.4 mmol) in a minimum amount of ethanol (1 mL) and DME (2 mL) mixture was added, followed by the addition of 2 mol L^{-1} aq. Na_2CO_3 solution (3 mL). The resulting mixture was heated at reflux for 12 h, cooled to rt, and extracted with Et_2O (3 × 5 mL). The organic extract was dried (Na_2SO_4) and concentrated in vacuo. The residue was purified by flash column chromatography (EtOAc–hexanes) to afford the product.

C. Synthesis of 9-phenanthrols

To a solution of LDA (2.50 mmol) in THF (8 mL) was added a solution of 2′-methyldiphenyl-2-carboxamide (1.00 mmol) in THF (2 mL) at 0 °C. The resulting mixture was stirred at rt for 30 min and quenched with a satd. aq. NH_4Cl solution (5 mL). The aqueous portion was extracted with Et_2O (3 × 5 mL) and the extract was dried (Na_2SO_4) and concentrated in vacuo. The residue was purified by flash column chromatography (EtOAc–hexanes) to afford the product.

D. Synthesis of triflates

A solution of the phenanthrol (1.00 mmol) and 2,6-lutidine or pyridine (1.2 mmol) in CH_2Cl_2 (10 mL) was stirred for 5 min at 0 °C followed by the addition of triflic anhydride (1.20 mmol). The resulting mixture was stirred at rt for 30 min and water was added (5 mL). The aqueous layer was separated and extracted with CH_2Cl_2 (3 × 10 mL). The combined extract was dried (Na_2SO_4) and concentrated in vacuo. The residue was purified by flash column chromatography (EtOAc–hexane) to afford the product.

2-(N,N-Diethylcarboxamido)phenylboronic acid (2a)

According to general procedure A, a solution of *N*,*N*-diethylbenzamide (1.77 g, 10.0 mmol), *s*-BuLi (9.60 mL of a 1.25 mol L^{-1} solution, 12.0 mmol), and TMEDA (1.07 mL, 1.39 g, 12.0 mmol) was treated with $B(OMe)_3$ (2.73 mL, 2.50 g, 24.0 mmol). Normal workup afforded 2.03 g (92%) of product as a viscous oil that was used in the cross coupling reactions without further purification.

N,N-*Diethyl 2′,3′-dimethyldiphenyl-2-carboxamide (3a)*

According to general procedure B, 1-bromo-2,3-dimethylbenzene (1.36 mL, 1.85 g, 10.0 mmol) was subjected to reaction with 2-(*N*,*N*-diethylcarboxamido)phenylboronic acid (3.09 g, 14 mmol) in the presence of $Pd(PPh_3)_4$ (0.185 g, 0.16 mmol). Normal workup followed by flash chromatography (EtOAc–hexanes, 1:5) afforded 2.30 g (82%) of **3a** as colorless crystals, mp 68 to 69 °C (EtOAc). IR (KBr) (cm^{-1}): 1632. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 0.59 (br s, 3H), 0.80 (br s, 3H), 2.01 (s, 3H), 2.19 (s, 3H), 2.40–3.30 (br m, 3H), 3.65 (br s, 1H), 6.90–7.15 (m, 4H), 7.25 (s, 3H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 12.1, 14.0, 17.5, 20.9, 38.2, 42.8, 117.3, 118.9, 124.9, 127.5, 127.9, 128.6, 129.5, 130.1, 131.2, 135.0, 137.1, 137.6, 170.3. EI-MS *m*/*z* (rel. int.): 281 (M^+, 100), 209 (20), 181 (13), 165 (47), 74 (30). HR-MS *m*/*z* calcd. for $C_{19}H_{23}NO$: 281.1780; found: 281.1776.

1-Methyl-9-phenanthrol (4a)

According to general procedure C, treatment of a solution of *N*,*N*-diethyl 2′,3′-dimethylbiphenyl-2-carboxamide (2.81 g, 10 mmol) in THF (20 mL) with a solution of LDA (25.0 mmol) in THF (80 mL) followed by acidification, normal workup, and flash chromatography (hexane) afforded 1.98 g (95%) of **4a** as colorless crystals, mp 194–197 °C (CH_2Cl_2) (lit. (21) mp 199.5–200.5 °C (benzene)). IR (KBr) (cm^{-1}): 3307. ^{1}H NMR (300 MHz, DMSO-d_6) δ: 2.61 (s, 3H), 7.34 (t, *J* = 7.8 Hz, 1H), 7.39 (t, *J* = 6.8 Hz, 1H), 7.61–7.72 (m, 2H), 8.31 (d, *J* = 7.4 Hz, 1H), 8.53 (d, *J* = 7.8 Hz, 1H), 8.77 (d, *J* = 7.6 Hz, 1H), 10.39 (s, 1H). ^{13}C NMR (75 MHz, DMSO-d_6) δ: 20.5, 102.3, 121.7, 123.3, 123.9, 126.1, 128.0, 128.7, 132.2, 132.6, 132.9, 151.9. EI-MS *m*/*z* (rel. int.): 208 (M^+, 100), 178 (17), 165 (38), 152 (5), 89 (5), 76 (5).

1-Methylphenanthryl-9 trifluoromethanesulfonate (7a)

According to general procedure D, to a solution of 1-methyl-9-phenanthrol (**4a**) (1.04 g, 5.00 mmol) and 2,6-lutidine (0.69 mL, 0.64 g, 6.00 mmol) in CH_2Cl_2 was added triflic anhydride (1.01 mL, 1.69 g, 6.00 mmol). Normal workup followed by flash chromatography (hexane) afforded 1.62 g (95%) of **7a** as colorless crystals, mp 60 to 61 °C

(EtOAc). IR (KBr) (cm^{-1}): 1416, 1206, 1139. ^1H NMR (300 MHz, $CDCl_3$) δ: 2.72 (s, 3H), 7.49 (s, 1H), 7.57 (t, *J* = 7.2 Hz, 1H), 7.71–7.77 (m, 2H), 7.91 (s, 1H), 8.15–8.21 (m, 1H), 8.47 (d, *J* = 6.9 Hz, 1H), 8.63–8.68 (m, 1H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 20.0, 114.8, 119.5 (q, *J* = 323 Hz), 121.2, 121.9, 123.7, 125.4, 127.8, 128.0, 129.1, 129.8, 130.1, 132.6, 135.8, 144.7. EI-MS *m/z* (rel. int.): 340 (M^+, 55), 207 (49), 179 (100), 152 (5), 69 (8). HR-MS *m*/z calcd. for $C_{16}H_{11}F_3O_3S$: 340.0381; found: 340.0387.

1-Methylphenanthrene (5a)

A stirred mixture of 1-methylphenanthryl-9 trifluoromethanesulfonate (**7a**) (0.340 g, 1.00 mmol), $Pd(OAc)_2$ (4.5 mg, 0.02 mmol), PPh3, (10.5 mg, 0.04 mmol), Et_3N (0.303 g, 3.00 mmol), and HCO_2H (0.08 mL, 92 mg, 2.00 mmol) in DMF (10 mL) was heated at 60–70 °C for 30 min. The reaction mixture was cooled to rt, water was added, and the mixture was extracted with Et_2O. The combined organic layer was dried (Na_2SO_4), concentrated to dryness, and the residue was subjected to flash chromatography (hexane) to afford 96 mg (50%) of **6a** as colorless crystals, mp 118 to119 °C (hexane) (lit. (22) mp 120 to 121 °C (ethanol)). IR (KBr) (cm^{-1}): 1598. ^1H NMR (300 MHz, $CDCl_3$) δ: 2.87 (s, 3H), 7.56 (d, *J* = 7.2 Hz, 1H), 7.63–7.69 (m, 3H), 7.88 (d, *J* = 9.2 Hz, 1H), 8.01 (d, *J* = 9.2 Hz, 1H), 8.04 (t, *J* = 9.2 Hz, 1H), 8.69 (d, *J* = 8.1 Hz, 1H), 8.81 (d, *J* = 8.1 Hz, 1H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 20.5, 121.4, 123.4, 123.5, 126.7, 127.1, 127.2, 128.3, 129.0, 130.9, 131.3, 132.2, 135.4. EI-MS *m/z* (rel. int.): 192 (M^+, 100), 165 (23), 150 (4), 139 (4), 95 (28), 83 (24).

Pinacolo[2-(*N,N*-diethylcarboxamido)-4-methylphenyl]boronate (2b)

According to general procedure A, a solution of *N*,*N*-diethyl-3-methylbenzamide (1.91 g, 10.0 mmol), *s*-BuLi (9.60 mL of a 1.25 mol L^{-1} solution,12.0 mmol), and TMEDA (1.07 mL, 1.39 g, 12.0 mmol) was treated with $B(OMe)_3$ (2.73 mL, 2.50 g, 24.0 mmol). Normal workup afforded a thick oil that was stirred with pinacol (2.83 g, 24.0 mmol) and $MgSO_4$ in dry CH_2Cl_2 for 12 h. Filtration and concentration of the filtrate gave a residue that was purified by flash chromatography (EtOAc–hexanes, 1:3) to afford 2.21 g (70%) of **2b** as a colorless oil. IR (neat) (cm^{-1}): 1633, 1432, 1350. ^1H NMR (300 MHz, $CDCl_3$) δ: 0.88 (t, *J* = 7.2 Hz, 3H), 1.15 (s, 12H), 1.20 (t, *J* = 7.2 Hz, 3H), 2.20 (s, 3H), 3.02 (q, *J* = 7.2 Hz, 2H), 3.41 (q, *J* = 7.2 Hz, 2H), 6.90 (s, 1H), 7.02 (d, *J* = 8.1 Hz, 1H), 7.56 (d, *J* = 8.1 Hz, 1H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 14.2, 14.4, 22.3, 25.5, 38.8, 43.6, 84.2, 123.1, 126.8, 129.2, 136.2, 141.7, 144.1, 172.5. EI-MS *m/z* (rel. int.): 316 (M^+ – H, 25), 302 (13), 259 (100), 218 (18), 174 (18), 144 (18), 177 (18), 83 (7), 55 (4). HR-MS *m/z* calcd. for $C_{18}H_{27}BNO_3$ (M^+ – H): 316.2084; found: 316.2093.

N,N-*Diethyl 3,2′,3′-trimethyldiphenyl-2-carboxamide (3b)*

According to general procedure B, 1-bromo-2,3-dimethylbenzene (1.36 mL, 1.85 g, 10.0 mmol) was subjected to reaction with **2b** (3.16 g, 10 mmol) in the presence of $Pd(PPh_3)_4$ (0.185 g, 0.16 mmol). Normal workup followed by flash chromatography (EtOAc–hexane, 1:5) afforded 1.89 g (64%) of **3b** as colorless crystals, mp 66–68 °C (EtOAc). IR (KBr) (cm^{-1}): 1630. ^1H NMR (300 MHz, $CDCl_3$) δ: 0.65 (br, 3H), 0.75–1.00 (br, 3H), 2.28 (s, 3H), 2.48 (s, 3H), 2.50–3.30 (br, 4H), 3.65–3.85 (s, 1H), 6.98–7.23 (m, 6H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 12.0, 13.9, 17.4, 20.8, 21.3, 38.0, 42.7, 124.7, 127.4, 129.2, 130.0, 130.9, 131.6, 136.9, 137.1, 170.4. EI-MS *m/z* (rel. int.): 295 (M^+, 35), 222 (100), 177 (48), 180 (57), 165 (65), 74 (47). HR-MS *m/z* calcd. for $C_{20}H_{25}NO$: 295.1936; found: 295.1932.

1,7-Dimethyl-9-phenanthrol (4b)

According to general procedure C, treatment of a solution of **3b** (2.95 g, 10 mmol) in THF (20 mL) with a solution of LDA (25.0 mmol) in THF (80 mL) for 30 min followed by acidification, normal workup, and flash chromatography (hexane) afforded 1.78 g (80%) of **4b** as colorless crystals, mp 203–205 °C (CH_2Cl_2). IR (KBr) (cm^{-1}): 3351. ^1H NMR (300 MHz, $CDCl_3$) δ: 2.54 (s, 3H), 2.59 (s, 3H), 7.20 (s, 1H), 7.30–7.39 (m, 2H), 7.51 (d, *J* = 9.0 Hz, 1H), 8.07 (s, 1H), 8.49 (d, *J* = 9.0 Hz, 1H), 8.65 (d, *J* = 9.0 Hz, 1H), 10.30 (s, 1H). ^{13}C NMR (75 MHz, DMSO-d_6) δ: 20.9, 22.4, 102.5, 121.8, 123.1, 124.0, 124.2, 126.4, 126.8, 128.6, 129.9, 130.4, 132.4, 133.0, 136.6, 151.9. EI-MS *m/z* (rel. int.): 222 (M^+, 100), 207 (7), 194 (13), 179 (41), 110 (3), 89 (3). HR-MS *m/z* calcd. for $C_{16}H_{14}O$: 222.1045; found: 222.1040.

1,7-Dimethylphenanthryl-9-trifluoromethanesulfonate (7b)

According to general procedure D, a solution of **4b** (1.11 g, 5.00 mmol) and 2,6-lutidine (0.69 mL, 0.64 g, 6.00 mmol) in CH_2Cl_2 was treated with triflic anhydride (1.01 mL, 1.69 g, 6.00 mmol). Normal workup followed by flash chromatography (hexane) afforded 1.42 (90%) g of **7b** as colorless crystals, mp 74 to 75 °C (EtOAc). IR (KBr) (cm^{-1}): 1421, 1215, 1140. ^1H NMR (300 MHz, $CDCl_3$) δ: 2.64 (s, 3H), 2.75 (s, 3H), 7.49 (d, *J* = 7.2 Hz, 1H), 7.57–7.64 (m, 2H), 7.72 (s, 1H), 7.74 (s, 1H), 8.53 (d, *J* = 8.4 Hz, 1H), 8.63 (d, *J* = 8.4 Hz, 1H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 20.4, 22.5, 115.0, 119.5 (q, *J* = 315 Hz), 121.4, 121.7, 123.9, 125.8, 128.0, 128.9, 129.8, 130.6, 130.8, 136.0, 138.4, 144.9. EI-MS *m/z* (rel. int.): 354 (M^+, 38), 221 (39), 193 (100), 178 (20), 69 (7). H-MS *m/z* calcd. for $C_{17}H_{13}O_3F_3S$: 354.0538; found: 354.0545.

1,7-Dimethylphenanthrene (5b)

A stirred mixture of **7b** (0.354 g, 1.00 mmol), $Pd(OAc)_2$ (4.5 mg, 0.02 mmol), PPh_3 (10.5 mg, 0.04 mmol), Et_3N (0.303 g, 3.00 mmol), and HCO_2H (0.08 mL, 92 mg, 2.00 mmol) in DMF (10 mL) was heated at 60–70 °C for 30 min, cooled to rt, and treated with water (10 mL). The resulting aqueous solution was extracted with Et_2O (3 × 10 mL), the combined organic extract was dried (Na_2SO_4) and concentrated in vacuo, and the residue was subjected to flash chromatography (hexane) to afford 175 mg (85%) of **5b** as colorless crystals, mp 83 to 84 °C (hexane) (lit. (23) mp 86 °C (ethanol)). ^1H NMR (300 MHz, $CDCl_3$) δ: 2.59 (s, 3H), 2.78 (s, 3H), 7.43–7.58 (m, 3H), 7.71 (s, 1H), 7.75 (d, *J* = 9.1 Hz, 2H), 7.90 (d, *J* = 9.1 Hz, 1H), 8.70 (d, *J* = 8.4 Hz, 1H), 8.62 (d, *J* = 8.4 Hz, 1H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 20.4, 21.9, 121.2, 123.4, 126.5, 126.9, 127.8, 128.8, 129.0, 130.9, 131.0, 132.3, 135.3, 136.6. EI-MS *m/z* (rel. int.): 206 (M^+, 100), 192 (18), 179 96), 166 (6), 152 (5), 102 (6), 88 (5). HR-MS *m/z* calcd. for $C_{16}H_{14}$: 206.1096; found: 206.1090.

N,N-*Diethyl 4,2′,4′-trimethyldiphenyl-2-carboxamide (3c)*

According to general procedure B, 1-bromo-2,4-dimethylbenzene (0.27 mL, 0.37 g, 2.0 mmol) was subjected to reaction with pinacolo[2-(*N*,*N*-diethylcarboxamido)-4-methylphenyl]boronate (**2b**) (0.63 g, 2.0 mmol) in the presence of $Pd(PPh_3)_4$ (37 mg, 0.032 mmol). Normal workup followed by flash chromatography (EtOAc–hexane, 1:5) afforded 0.38 g (80%) of **3c** as a colorless oil. IR (neat) (cm^{-1}) 1633. ^1H NMR (300 MHz, $CDCl_3$) δ: 0.60–0.90 (m, 6H), 2.20 (s, 3H), 2.32 (s, 3H), 2.40 (s, 3H), 2.50–3.90 (br, 4H), 6.90–7.30 (m, 6H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 20.6, 21.5, 21.5, 126.2, 128.1, 128.6, 129.3, 130.1, 130.7, 131.2, 135.0, 135.1, 137.3, 137.4, 137.6, 170.8. EI-MS *m*/*z* (rel. int.): 294 (18), 265 (64), 74 (70). HR-MS *m*/*z* calcd. for $C_{20}H_{25}NO$: 295.1936; found: 295.1930.

2,7-Dimethyl-9-phenanthrol (4c)

According to general procedure C, treatment of a solution of (**3c**) (0.30 g, 1.0 mmol) in THF (10 mL) with a solution of LDA (2.5 mmol) in THF (10 mL) for 30 min followed by acidification, normal workup, and flash chromatography (hexane) afforded 0.21 g (94%) of **4c** as colorless crystals, mp 154 to 155 °C (CH_2Cl_2). IR (KBr) (cm^{-1}): 3545. ^1H NMR (500 MHz, $CDCl_3$) δ: 2.46 (s, 3H), 2.53 (s, 3H), 7.00 (s, 1H), 7.25 (dd, *J* = 8.5, 1.5 Hz, 1H), 7.49 (dd, *J* = 8.5, 1.5 Hz, 1H), 7.50 (s, 1H), 8.05 (s, 1H), 8.48 (d, *J* = 8.5 Hz, 1H), 8.58 (d, *J* = 8.5 Hz, 1H), 10.21 (s, 1H). ^{13}C NMR (125 MHz, DMSO-d_6) δ: 22.0, 22.1, 105.5, 122.9, 123.2, 124.2, 126.0, 126.7, 126.8, 129.5, 129.8, 133.6, 135.9, 136.5, 151.5. EI-MS *m*/*z* (rel. int.): 223 (100), 208 (30). HR-MS *m*/*z* calcd. for $C_{16}H_{14}O$: 222.1045; found: 222.1039.

2,7-Dimethylphenanthryl-9 trifluoromethanesulfonate (7c)

According to general procedure D, a solution of **4c** (0.11 g, 0.50 mmol) and 2,6-lutidine (0.07 mL, 0.064 g, 0.60 mmol) in CH_2Cl_2 was treated with triflic anhydride (0.10 mL, 0.17 g, 0.60 mmol). Normal workup followed by flash chromatography (hexane) afforded 0.17 g (95%) of **7c** as colorless crystals, mp 138 to 139 °C (hexane). IR (KBr) (cm^{-1}): 1430. ^1H NMR (500 MHz, $CDCl_3$) δ: 2.58 (s, 3H), 2.63 (s, 3H), 7.53 (dd, *J* = 8.5, 1.0 Hz, 1H), 7.58 (dd, *J* = 8.5, 1.0 Hz, 1H), 7.66 (s, 1H), 7.68 (s, 1H), 7.92 (s, 1H), 8.51 (*J* = 8.0 Hz, 1H), 8.56 (d, *J* = 8.0 Hz, 1H). ^{13}C NMR (125 MHz, $CDCl_3$) δ: 21.8, 22.2, 118.0, 119.2 (q, *J* = 318 Hz), 121.5, 122.9, 123.2, 125.5, 127.9, 128.9, 130.0, 130.3, 130.6, 137.6, 137.8, 144.71. EI-MS *m*/*z* (rel. int.): 354 (5), 221 (22), 193 (100), 178 (25), 69 (24). HR-MS *m*/*z* calcd. for $C_{17}H_{13}O_3F_3S$: 354.0538; found: 354.0540.

2,7-Dimethylphenanthrene (5c)

A stirred mixture of **7c** (0.035 g, 0.10 mmol), $Pd(OAc)_2$ (0.5 mg, 0.02 mmol), PPh_3 (1.0 mg, 0.004 mmol), Et_3N (0.030 g, 0.30 mmol), and HCO_2H (0.01 mL, 9 mg, 0.20 mmol) in DMF (2 mL) was heated at 60–70 °C for 30 min, cooled to rt, and treated with water (2 mL). The resulting aqueous solution was extracted with Et_2O (3 × 2 mL), the combined organic layer was dried (Na_2SO_4) and concentrated in vacuo, and the residue was subjected to flash chromatography (hexane) to afford 18 mg (91%) of **5c** as colorless crystals, mp 100 to 101 °C (hexane) (lit. (24*a*) mp 101 to 102 °C (ethanol); lit. (24*b*) mp 101 to 102 °C (methanol)). ^1H NMR (25) (500 MHz, $CDCl_3$) δ: 2.60 (s, 6H), 7.50 (dd, *J* = 8.5, 1.5 Hz, 2H), 7.69 (s, 2H), 7.70 (s, 2H), 8.58 (d, *J* = 8.5 Hz, 2H). ^{13}C NMR (125 MHz, $CDCl_3$) δ: 21.9, 122.8, 127.1, 128.5, 128.6, 128.7, 132.3, 136.2. EI-MS *m*/*z* (rel. int.): 206 (100), 191 (46), 189 (47), 178 (19), 69 (20).

3-Ethylphenyltrifluoromethanesulfonate (9)

According to method D, a solution of 3-ethylphenol (**8**) (1.22 g, 10.00 mmol) and 2,6-lutidine (1.40 mL, 1.28 g, 12.00 mmol) in CH_2Cl_2 (100 mL) was treated with triflic anhydride (2.01 mL, 3.38 g, 12.00 mmol). Normal workup followed by flash chromatography (hexane) afforded 2.28 g (90%) of **9** as a colorless oil. IR (neat) (cm^{-1}): 1424, 1214, 1143. ^1H NMR (300 MHz, $CDCl_3$) δ: 1.29 (t, *J* = 8.4 Hz, 3H), 2.73 (q, *J* = 8.4 Hz, 2H), 7.14 (s, 1H), 7.19–7.34 (m, 2H), 7.38 (t, *J* = 15.0 Hz, 1H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 15.4, 28.9, 118.8, 119.2 (q, *J* = 315 Hz), 121.0, 129.4, 130.4, 147.6, 150.1. EI-MS *m*/*z* (rel. int.): 254 (M^+, 100), 174 (75), 121 (47), 91 (90), 77 (22), 65 (8), which showed identical ^1H NMR, ^{13}C NMR, and MS spectra to those reported for authentic material (26).

N,N-*Diethyl 3-ethylbenzamide (10)*

A stirred mixture of **9** (0.254 g, 1.00 mmol), $Pd(OAc)_2$ (6.7 mg, 0.03 mmol), dppf (33 mg, 0.06 mmol), Et_3N (0.42 mL, 0.303 g, 2.00 mmol), and Et_2NH (2.06 mL, 1.46 g, 20.0 mmol) in DMF (10 mL) was heated at 60–70 °C for 12 h, cooled to rt, and treated with water (10 mL). The aqueous portion was extracted with Et_2O (3 × 10 mL) and the extract was dried (Na_2SO_4) and concentrated in vacuo. The residue was purified by flash column chromatography (EtOAc–hexane, 1:5) to afford 0.140 g (70%) of **10** as a yellow oil. IR (neat) (cm^{-1}): 1633. ^1H NMR (300 MHz, $CDCl_3$) δ: 1.00–1.20 (br, 6H), 1.17 (t, *J* = 7.2 Hz, 3H), 2.60 (q, *J* = 7.2 Hz, 2H), 3.17 (br s, 2H), 3.48 (br s, 2H), 7.08–7.27 (m, 4H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 13.2, 14.6, 15.7, 29.1, 39.5, 43.6, 123.7, 126.7, 128.9, 137.6, 144.7, 171.8. EI-MS *m*/*z* (rel. int.): 205 (M^+, 58), 176 (7), 133 (100), 105 (28), 77 (17). HR-MS *m*/*z* calcd. for $C_{13}H_{19}NO$: 205.1467; found: 205.1469.

Pinacolo[2-(*N,N*-diethylcarboxamido)-3-ethylphenyl]boronate (11)

According to general procedure A, a solution of **10** (2.05 g, 10.0 mmol), *s*-BuLi (9.60 mL of a 1.25 mol L^{-1} solution, 12.0 mmol), and TMEDA (1.07 mL, 1.39 g, 12.0 mmol) was treated with $B(OMe)_3$ (2.73 mL, 2.50 g, 24.0 mmol). Normal workup afforded a thick oil that was stirred with a solution of pinacol (2.83 g, 24.0 mmol) and anhyd $MgSO_4$ (5 g) in dry CH_2Cl_2 (20 mL). Filtration followed by concentration gave a residue that was purified by flash chromatography (EtOAc–hexane, 1:3) to afford 2.51 g (76%) of **11** as a colorless oil. IR (neat) (cm^{-1}): 1635, 1432, 1354. ^1H NMR (300 MHz, $CDCl_3$) δ: 1.01 (t, *J* = 7.5 Hz, 3H), 1.20 (t, *J* = 8.1 Hz, 3H), 1.25–1.30 (m, 15H), 2.63 (q, *J* = 7.5 Hz, 2H), 3.14 (q, *J* = 8.1 Hz, 2H), 3.55 (q, *J* = 8.1 Hz, 2H), 7.06 (s, 1H), 7.17 (d, *J* = 7.5 Hz, 1H), 7.72 (d, *J* = 7.5 Hz, 1H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 12.9, 14.1, 15.6, 25.2, 38.5, 43.3, 83.9, 125.4, 127.7, 135.9, 143.9, 149.9, 171.0. EI-MS *m*/*z* (rel. int.): 331 (M^+, 21), 273 (100), 232 (16), 188 (6), 158 (7), 105 (8), 55 (4). HR-MS *m*/*z* calcd. for $C_{19}H_{30}BNO_3$: 331.2319; found: 331.2321.

N,N-*Diethyl 3-ethyl-2′,3′-dimethylbiphenyl-2-carboxamide (12)*

According to general procedure B, 1-bromo-2,3-dimethylbenzene (1.36 mL, 1.85 g, 10.0 mmol) was subjected to reaction with **11** (3.31 g, 10 mmol) in the presence of $Pd(PPh_3)_4$ (0.185 g, 0.16 mmol). Normal workup followed by flash chromatography (EtOAc–hexane, 1:5) afforded 1.85 g (60%) of **12** as a viscous oil. IR (neat) (cm^{-1}): 1634. ^1H NMR (300 MHz, $CDCl_3$) δ: 0.68 (s, 3H), 0.75–1.04 (br, 3H), 1.28 (t, *J* = 7.8 Hz, 3H), 2.08 (s, 3H), 2.27 (s, 3H), 2.72 (q, *J* = 7.8 Hz, 2H), 2.75–3.30 (br, 4H), 3.73 (s, 1H), 6.96–7.25 (m, 6H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 12.1, 14.1, 15.6, 17.6, 20.9, 28.8, 38.2, 42.8, 125.4, 126.8, 128.0, 129.4, 130.1, 135.1, 137.2, 143.5, 170.8. EI-MS *m/z* (rel. int.): 309 (M^+, 100), 280 (13), 237 (15), 209 (8), 178 (18), 165 (15), 74 (35). HR-MS *m/z* calcd. for $C_{21}H_{27}NO$: 309.2093; found: 309.2086.

7-Ethyl-1-methyl-9-phenanthrol (13)

According to general procedure C, treatment of a solution of **12** (3.09 g, 10 mmol) in THL (20 mL) with a solution of LDA (25.0 mmol) in THF (80 mL) for 30 min followed by acidification, normal workup, and flash chromatography (hexane) afforded 2.24 g (95%) of **13** as colorless crystals, mp 192–195 °C (CH_2Cl_2). IR (KBr) (cm^{-1}): 3306. ^1H NMR (300 MHz, $CDCl_3$) δ: 1.28 (t, *J* = 8.1 Hz, 3H), 2.60 (s, 3H), 2.84 (q, *J* = 8.1 Hz, 2H), 7.25 (s, 1H), 7.28–7.38 (m, 2H), 7.51 (d, *J* = 8.4 Hz, 1H), 8.12 (s, 1H), 8.47 (d, *J* = 8.1 Hz, 1H), 8.63 (d, *J* = 8.1 Hz, 1H), 10.36 (s, 1H). ^{13}C NMR (75M Hz, $CDCl_3$) δ: 16.4, 20.5, 29.2, 102.1, 121.5, 123.7, 124.0, 126.1, 126.6, 127.4, 128.2, 128.4, 130.4, 132.2, 132.7, 142.5, 151.8. EI-MS *m/z* (rel. int.): 236 (M^+, 100), 221 (65), 207 (10), 193 (15), 179 (10), 165 (4), 89 (3). HR-MS *m/z* calcd. for $C_{17}H_{16}O$: 236.1201; found: 236.1206.

7-Ethyl-1-methylphenanthryl-9-trifluoromethanesulfonate (14)

According to general procedure D, a solution of **13** (1.18 g, 5.00 mmol) and 2,6-lutidine (0.69 mL, 0.64 g, 6.00 mmol) in CH_2Cl_2 (100 mL) was treated with triflic anhydride (1.01 mL, 1.69 g, 6.00 mmol). Normal workup followed by flash chromatography (hexane) afforded 1.20 g (95%) of **14** as colorless crystals, mp 61 to 62 °C (EtOAc). IR (KBr) (cm^{-1}): 1421, 1208, 1135. ^1H NMR (300 MHz, $CDCl_3$) δ: 1.41 (t, *J* = 7.5 Hz, 3H), 2.74 (s, 3H), 2.95 (q, *J* = 7.5 Hz, 2H), 7.48 (d, *J* = 7.2 Hz, 1H), 7.57–7.66 (m, 2H), 7.91 (s, 1H), 7.97 (s, 1H), 8.52 (d, *J* = 9.0 Hz, 1H), 8.64 (d, *J* = 9.0 Hz, 1H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 15.7, 20.1, 29.4, 114.7, 119.3 (q, *J* = 323 Hz), 120.1, 121.1, 123.7, 129.3, 129.5, 130.2, 130.7, 135.7, 144.3, 144.7. EI-MS *m/z* (rel. int.): 368 (M^+, 35), 235 (45), 207 (100), 192 (18), 165 (3), 69 (7). HR-MS *m/z* calcd. for $C_{18}H_{15}F_3O_3S$: 368.0684; found: 368.0689.

7-Ethyl-1-methylphenanthrene (15)

A stirred mixture of **14** (0.368 g, 1.00 mmol), $Pd(OAc)_2$ (4.5 mg, 0.02 mmol), PPh_3 (10.5 mg, 0.04 mmol), Et_3N (0.42 mL, 0.303 g, 3.00 mmol), and HCO_2H (0.08 mL, 92 mg, 2.00 mmol) in DMF (10 mL) was heated at 60–70 °C for 30 min. The reaction mixture was cooled to rt and water was added (10 mL). The aqueous layer was separated and extracted with Et_2O (3 × 10 mL), and the extract was dried (Na_2SO_4) and concentrated in vacuo. The residue was purified by flash column chromatography (hexane) to afford 202 mg (92%) of **15** as colorless crystals, mp 92 to 93 °C (hexane) (lit. (27) mp 87.5 °C (MeOH)). ^1H NMR (300 MHz, $CDCl_3$) δ: 1.47 (t, *J* = 7.5 Hz, 3H), 2.84 (s, 3H), 2.96 (q, *J* = 7.5 Hz, 2H), 7.48–7.65 (m, 3H), 7.78 (s, 1H), 7.81 (d, *J* = 9.0 Hz, 1H), 8.01 (d, *J* = 9.0 Hz, 1H), 8.63 (d, *J* = 9.0 Hz, 1H), 8.69 (d, *J* = 9.0 Hz, 1H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 16.1, 20.4, 29.2, 121.2, 123.2, 123.4, 126.5, 127.0, 127.2, 127.7, 127.8, 129.2, 130.8, 130.9, 132.3, 135.2, 142.9. EI-MS *m/z* (rel. int.): 220 (M^+, 100), 205 (73), 189 (15), 178 (3), 165 (3), 101 (4). HR-MS *m/z* calcd. for $C_{17}H_{16}$: 220.1252; found: 220.1255.

N,N-*Diethyl 4-*tert*-butylphenyl carbamate (23)*

To a suspension of sodium hydride (0.48 g, 60% in mineral oil, 12 mmol) in anhyd THF (20 mL) was added 4-*tert*-butylphenol (1.50 g, 10 mmol). After hydrogen evolution ceased (1 h), diethylcarbamoyl chloride (1.51 mL, 1.62 g, 12 mmol) was added and the reaction mixture was stirred at rt for 2 h, and treated with water (10 mL). The aqueous layer was separated and extracted with Et_2O (3 × 20 mL). The combined extract was dried (Na_2SO_4) and concentrated in vacuo to give a residue that was purified by flash column chromatography (EtOAc–hexane, 1:3) to afford 1.49 g (60%) of **23** as colorless crystals, mp 77 to 78 °C (CH_2Cl_2) (lit. (28) mp 86 °C (pentene)). IR (KBr) (cm^{-1}): 1706, 1480, 1402, 1277, 1211. ^1H NMR (300 MHz, $CDCl_3$) δ: 1.25 (s, 6H), 1.34 (s, 9H), 3.43 (s, 4H), 7.04–7.10 (m, 2H), 7.36–7.42 (m, 2H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 13.8, 14.6, 31.8, 34.7, 42.2, 42.6, 121.4, 126.4, 148.1, 149.6, 154.8. EI-MS *m/z* (rel. int.): 249 (M^+, 35), 163 (2), 146 (2), 135 (3), 100 (100), 72 (7). HR-MS *m/z* calcd. for $C_{15}H_{23}NO_2$: 249.1729; found: 249.1736.

N,N-*Diethyl 4-tert-butyl-2-hydroxybenzamide (24)*

A solution of **23** (2.49 g, 10.0 mmol) in anhyd THF (20 mL) was added dropwise to a solution of *s*-BuLi (9.6 mL of 1.25 mol L^{-1} solution, 12.0 mmol) and TMEDA (1.07 mL, 1.39 g, 12.0 mmol) in anhyd THF (30 mL) at –78 °C. The reaction mixture was stirred at –78 °C for 1 h, allowed to warm to rt over 12 h, and quenched with a satd. aq. NH_4Cl solution (10 mL). The aqueous layer was separated and extracted with Et_2O (3 × 20 mL), and the combined extract was dried (Na_2SO_4) and concentrated in vacuo. The resulting residue was purified by flash column chromatography (EtOAc–hexanes, 1:5) to afford 1.37 g (55%) of **24** as colorless crystals, mp 133 – 135 °C (CH_2Cl_2). IR (KBr) (cm^{-1}): 3142, 1595, 1268. ^1H NMR (300 MHz, $CDCl_3$) δ: 1.27–1.33 (m, 15H), 3.51 (q, *J* = 7.2 Hz, 4H), 6.92 (d, *J* = 17.1 Hz, 1H), 7.27 (d, *J* = 5.0 Hz, 1H) 7.34 (dd, *J* = 17.1, 5.0 Hz, 1H), 9.50 (s, 1H). $^{13}CNMR$ (75 MHz, $CDCl_3$) δ:13.8, 31.8, 34.4, 42.5, 117.6, 118.1, 124.3, 129.6, 141.4, 156.4, 172.2. EI-MS *m/z* (rel. int.): 249 (M^+, 31), 234 (72), 177 (76), 161 (100), 133 (16), 105 (20), 72 (38). HR-MS *m/z* calcd. for $C_{15}H_{23}NO_2$: 249.1729; found: 249.1719.

4*-tert-*Butyl-2-(*N,N-*diethylcarboxamido)phenyl trifluoromethanesulfonate (20)

According to general procedure D, a solution of **24** (2.49 g, 10.0 mmol) and pyridine (0.97 mL, 0.95 g, 12.0 mmol) in CH_2Cl_2 (100 mL) was treated with triflic an-

© 2004 NRC Canada

hydride (2.01 mL, 3.38 g, 12.0 mmol). Normal workup followed by flash chromatography (EtOAc–hexane, 1:5) afforded 2.48 g (65%) of **20** as a colorless oil. IR (neat) (cm^{-1}): 1645, 1426, 1215. ^1H NMR ($CDCl_3$) δ: 1.08 (t, J = 7.2 Hz, 3H), 1.17 (t, J = 7.2 Hz, 3H), 1.30 (s, 9H), 3.16 (q, J = 7.2 Hz, 2H), 3.40–3.70 (br, 2H), 7.23 (d, J = 8.6 Hz, 1H), 7.37 (d, J = 2.1 Hz, 1H), 7.40 (dd, J = 8.6, 2.1 Hz, 1H). ^{13}C NMR ($CDCl_3$) δ: 12.7, 14.2, 31.4, 35.1, 39.5, 43.3, 118.8 (q, J = 323 Hz), 121.5, 125.8, 128.0, 130.7, 143.3, 152.1, 166.2. EI-MS m/z (rel. int.): 382 (M^+, 71), 309 (100), 233 (38), 161 (73), 72 (69). HR-MS m/z calcd. for $C_{16}H_{22}F_3NO_4S$: 381.1222; found: 381.1234.

N,N-*Diethyl 3*-tert-*butyl-2′,3′-trimethyldiphenyl-2-carboxamide (19)*

According to general procedure B, 2,3-dimethylphenylboronic acid (1.50 g, 10.0 mmol) was subjected to reaction with **20** (3.82 g, 10 mmol) in the presence of $Pd(PPh_3)_4$ (0.185 g, 0.16 mmol). Normal workup followed by flash chromatography (EtOAc–hexane, 1:5) afforded 2.76 g (82%) of **19** as a viscous oil. IR (cm^{-1}): 1634. ^1H NMR ($CDCl_3$) δ: 0.69 (t, J = 7.2 Hz, 3H), 0.70–1.0 (br, 3H), 1.35 (s, 9H), 2.10 (s, 3H), 2.27 (s, 3H), 2.50–3.90 (br m, 4H), 6.80–7.43 (m, 6H). ^{13}C NMR ($CDCl_3$) δ: 12.2, 13.8, 24.1, 31.6, 34.9, 38.3, 124.4, 125.4, 126.5, 127.6, 128.4, 129.3, 134.7, 137.1, 142.6, 150.3, 151.6, 155.5, 171.1. EI-MS m/z (rel. int.): 337 (M^+, 97), 322 (7), 264 (100), 250 (37), 209 (40), 181 (12), 165 (17), 74 (32). HR-MS m/z calcd. for $C_{23}H_{31}NO$: 337.2406; found: 337.2398.

7*-tert-*Butyl-1-methyl-9-phenanthrol (25)

According to general procedure C, treatment of a solution of **19** (3.37 g, 10 mmol) in THF (20 mL) with a solution of LDA (25.0 mmol) in THF (80 mL) for 30 min followed by acidification, normal workup, and flash chromatography (hexane) afforded 2.38 g (90%) of **25** as a powder that gave colorless crystals, mp 165–168 °C (CH_2Cl_2). IR (KBr) (cm^{-1}): 3466. ^1H NMR ($CDCl_3$) δ: 1.53 (s, 9H), 2.63 (s, 3H), 5.81 (s, 1H), 7.20 (s, 1H), 7.38–7.45 (m, 2H), 7.81 (dd, J = 8.1, 2.1 Hz, 1H), 8.36 (d, J = 2.1 Hz, 1H), 8.49 (d, J = 8.1 Hz, 1H), 8.64 (d, J = 9.0 Hz, 1H). ^{13}C NMR ($CDCl_3$) δ 20.6, 31.1, 35.7, 103.4, 118.4, 121.3, 123.6, 124.3, 125.5, 126.2, 127.3, 128.2, 130.5, 131.9, 133.4, 149.9, 150.3. EI-MS m/z (rel. int.): 264 (M^+, 100), 250 (50), 232 (13), 221 (22), 194 (13), 179 (12), 165 (9), 11 (8). HR-MS m/z calcd. for $C_{19}H_{20}O$: 264.1514 (accurate data could not be obtained due to oxidation of the sample).

7*-tert-*Butyl-1-methylphenanthryl-9-trifluoromethanesulfonate (26)

According to general procedure D, to a solution of **25** (1.32 g, 5.00 mmol) and 2,6-lutidine (0.69 mL, 0.64 g, 6.00 mmol) in CH_2Cl_2 (100 mL) was added triflic anhydride (1.01 mL, 1.69 g, 6.00 mmol). Normal workup followed by flash chromatography (hexane) afforded 1.72 g (87%) of **26** as colorless crystals, mp 103 to 104 °C (EtOAc). IR (KBr) (cm^{-1}): 1423, 1207, 1139. ^1H NMR ($CDCl_3$) δ: 1.61 (s, 9H), 2.73 (s, 3H), 7.45 (d, J = 7.2 Hz, 1H), 7.56 (t, J = 8.4 Hz, 1H), 7.88 (dd, J = 9.0, 1.8 Hz, 1H), 7.93 (s, 1H), 8.27 (d, J = 1.8 Hz, 1H), 8.44 (d, J = 8.1 Hz, 1H), 8.66 (d, J = 9.0 Hz, 1H). ^{13}C NMR ($CDCl_3$) δ: 20.0, 31.6, 35.5, 114.7, 117.6, 119.4 (q, J = 323 Hz), 121.1, 123.6, 125.1, 126.9, 127.7, 128.7, 129.6, 130.1, 130.6, 135.6, 144.9, 151.2. EI-MS m/z (rel. int.): 396 (M^+, 68), 381 (14), 263 (100), 236 (75), 220 (32), 205 (16), 179 (8), 69 (11). HR-MS m/z calcd. for $C_{20}H_{19}F_3O_3S$: 396.1007; found: 396.1008.

7*-tert-*Butyl-1-methylphenanthrene (27)

A stirred mixture of **26** (0.396 g, 1.00 mmol), $Pd(OAc)_2$ (4.5 mg, 0.02 mmol), PPh_3 (10.5 mg, 0.04 mmol), Et_3N (0.42 mL, 0.303 g, 3.00 mmol), and HCO_2H (0.08 mL, 92 mg, 2.00 mmol) in DMF (10 mL) was heated at 60–70 °C for 30 min. The reaction mixture was cooled to rt, water (0 mL) was added, and the mixture was extracted with Et_2O (3 × 10 mL). The combined organic extract was dried (Na_2SO_4), concentrated to dryness, and the residue was subjected to flash chromatography (hexane) to afford 248 mg (95%) of **27** as colorless crystals, mp 126 to 127 °C (hexane). ^1H NMR ($CDCl_3$) δ: 1.74 (s, 9H), 2.96 (s, 3H), 7.64 (d, J = 7.4 Hz, 1H), 7.74 (t, J = 7.5 Hz, 1H), 7.93 (dd, J = 8.6, 1.8 Hz, 1H), 7.98 (d, J = 9.3 Hz, 1H), 8.12 (s, 1H), 8.14 (d, J = 9.2 Hz, 1H), 8.77 (d, J = 8.6 Hz, 1H), 8.82 (d, J = 8.8 Hz, 1H). ^{13}C NMR ($CDCl_3$) δ: 20.5, 32.0, 35.3, 121.7, 123.7, 125.8, 126.9, 127.9, 128.2, 129.4, 131.2, 131.5, 132.6, 135.6, 150.0. EI-MS m/z (rel. int.): 248 (M^+, 100), 234 (95), 218 (10), 205 (13), 189 (7), 178 (3). HR-MS m/z calcd. for $C_{19}H_{20}$: 248.1565; found: 248.1564.

Comparison of the Suzuki cross-coupling reactions of 4,7-dichloroquinoline and 7-chloro-4-iodoquinoline with arylboronic acids using phosphine-free palladium catalysis in water[1]

Richard W. Friesen and Laird A. Trimble

Abstract: 4,7-Dichloroquinoline (**1a**) and 7-chloro-4-iodoquinoline (**1b**) undergo Suzuki cross-coupling reactions with arylboronic acids catalyzed by phosphine-free palladium acetate in boiling water. Using phenylboronic acid (**2**), the reaction of **1a** provides 7-chloro-4-phenylquinoline (**3**) (78%) together with diphenylquinoline (**4**) (12%), while **1b** reacts in a much more regioselective fashion and provides **3** in 98% isolated yield. Although **1b** undergoes a more regioselective Suzuki reaction than **1a**, additional important observations are that the overall reaction of **1b** with **2** is three times slower than **1a** and that the reaction occurs in the absence of tetrabutylammonium bromide. Using optimized reaction conditions, a variety of aryl and vinylboronic acids undergo regioselective Suzuki cross-coupling with **1b** to provide the products **7**, **10**, and **11** in good to excellent yield.

Key words: palladium, cross-coupling, regioselectivity, quinolines, boronic acids.

Résumé : La 4,7-dichloroquinoléine (**1a**) et la 7-chloro-4-iodoquinoléine (**1b**) subissent des réactions de couplage de Suzuki avec les acides arylboroniques qui sont catalysées par de l'acétate de palladium sans phosphine dans de l'eau bouillante. Avec l'acide phénylboronique (**2**), la réaction du composé **1a** fournit la 7-chloro-4-phénylquinoléine (**3**) (78%) aux côtés de diphénylquinoléine (**4**) (12%) alors que le composé **1b** réagit d'une façon beaucoup plus régiosélective et fournit le composé **3** avec un rendement de 98% en produit isolé. Même si le composé **1b** donne lieu à une réaction de Suzuki plus régiosélective que celle du composé **1a**, des observations importantes additionnelles sont que la vitesse globale du composé **1b** avec **2** est trois fois plus lente que celle du composé **1a** et que la réaction se produit en l'absence de bromure de tétrabutylammonium. Utilisant des conditions réactionnelles optimisées, une variété d'acides aryl- et vinylboroniques donnent lieu à des réactions régiosélectives de couplage croisé de Suzuki avec le composé **1b** et elles fournissent les produits **7**, **10** et **11** avec des rendements allant de bons à excellents.

Mots clés : palladium, couplage croisé, régiosélectivité, quinoléines, acides boroniques.

[Traduit par la Rédaction]

Introduction

The palladium-catalyzed cross-coupling of aryl halides with boronic acids, commonly referred to as the Suzuki reaction (1–5), is an exceptionally versatile and highly utilized reaction for the construction of carbon-carbon bonds and, in particular, for the preparation of heterobiaryls. The use of heteroaryl chlorides as one of the coupling partners has seen increasing utility (6–11) and is attractive since the starting materials are often more readily available than the corresponding bromides or iodides. We have recently described (12) the synthesis of 2,4,7-trisubstituted quinoline 5-lipoxygenase inhibitors using, as one of the key steps, the regioselective Suzuki cross-coupling reaction of 4,7-dichloroquinoline (**1a**) with arylboronic acids. As originally described by Mitchell and co-workers (6), the reaction of **1a** with 1.1 equiv. of phenylboronic acid (**2**) catalyzed by $Pd(Ph_3P)_4$ (3%) in refluxing aqueous ethanol – benzene and in the presence of Na_2CO_3 provided, after 48 h, 7-chloro-4-phenylquinoline (**3**) in 82% isolated yield (Scheme 1). It was not mentioned whether the bis-addition product 4,7-diphenylquinoline (**4**) or the regioisomeric mono-addition product 4-chloro-7-phenylquinoline (**5**) were observed in this reaction.

We have repeated this Suzuki cross-coupling reaction between **1a** and **2** in connection with our medicinal chemistry program. Dichloride **1a** was consumed in 6 h, and in addition to **3** (81%), a significant amount of bis-addition product **4** (10%) was obtained. Previous reports have demonstrated that 4,7-dichloroquinoline (**1a**) undergoes regioselective palladium-catalyzed Stille (13) and alkoxycarbonylation (14)

reactions at the C4 position. However, in the latter reaction, alkoxycarbonylation at both C4 and C7 produces varying amounts of diester, depending on the reaction conditions used. Therefore, the observation of **4** in the reaction of **1a** and **2** was not completely unexpected. Since we required an efficient cross-coupling procedure that would bring about regioselective monofunctionalization of a quinoline (6, 7, 13–17), such as **1a**, without consuming more elaborate boronic acids by the production of bis-addition products, we undertook a more detailed study of the reactions of **1a** and the corresponding iodide **1b** to optimize the formation of **3**. The results of this study are presented here.

Results and discussion

Structural assignment

In their initial publication (6), Mitchell and co-workers assigned regioisomer **3** as the product of the Suzuki cross-coupling reaction between **1a** and **2**. This assignment was made without any structural verification, although one might reasonably expect **3** to be produced as the major regioisomer based on precedence with other reactions of **1a** (13, 14, 18). However, we felt that a rigorous structural assignment was warranted since the production of the bis-addition adduct **4** reveals that reactivity at both C4 and C7 is possible. ^{1}H NMR experiments ($CDCl_3$, 600 MHz) indicated that **3** is indeed the predominant mono-substituted regioisomer formed. Thus, proton resonance assignments (see Table 1) were made using a 2D-COSY experiment.[3] In a subsequent series of nuclear Overhauser enhancement (nOe) experiments, clear enhancements in resonance intensity were observed for H9 upon irradiation of H3 and H5, while irradiation of H8 did not result in nOe of any other resonance.

3

Reaction optimization studies

To optimize the reaction of **1a** for mono-substitution at C4, we rapidly surveyed many of the reaction conditions that are typically modified in the Suzuki cross-coupling reaction (1–5), including, for example, the palladium catalyst ($PdCl_2(Ph_3P)_2$, $Pd_2(dba)_3$ (with and without P(*t*-Bu)$_3$), Pd(dppf)Cl_2), solvents (DMF, THF, EtOH), aqueous base (Na_2CO_3, Cs_2CO_3), temperature, and the use of additives (KF). None of these changes substantially altered the yields of **3** and **4** that were observed upon reaction of **1a** with **2**. Several reports over the last decade have described the successful cross-coupling of arylboronic acids and aryl bromides, iodides, or triflates using phosphine-free palladium, such as $Pd(OAc)_2$, in aqueous–organic co-solvents (19, 20) or in water alone (21, 22). Employing reaction conditions optimized by Leadbeater and Marco (22), the reaction of **1a** with 1.1 equiv. of **2** in the presence of 1% $Pd(OAc)_2$ and 0.25 equiv. of nBu$_4$NBr in refluxing water (oil bath at 150 °C) under nitrogen atmosphere provided **3** (78%) and **4** (12%) upon consumption of **1a**. Although this reaction differed little from all the others we had surveyed in terms of the yields of the two products, it was complete within 30 min (Table 2, entry 1), while the majority of the others, including the original reaction described by Mitchell, required extended reaction times (6 h to 2 days). Since the rapidity of the reaction under these conditions was perceived as an advantage, we chose to further characterize the cross-coupling reaction of **1a** using phosphine-free palladium in water.

The results of the two experiments are informative. First, when the reaction between **1a** and **2** was stopped prior to consumption of **1a** (at 15 min), we observed the presence

Table 1. 7-Chloro-4-phenylquinoline (**3**): ^{1}H NMR spectrum and nOe experiments.

Proton[a]	Assignment[b]	nOe observed[c]

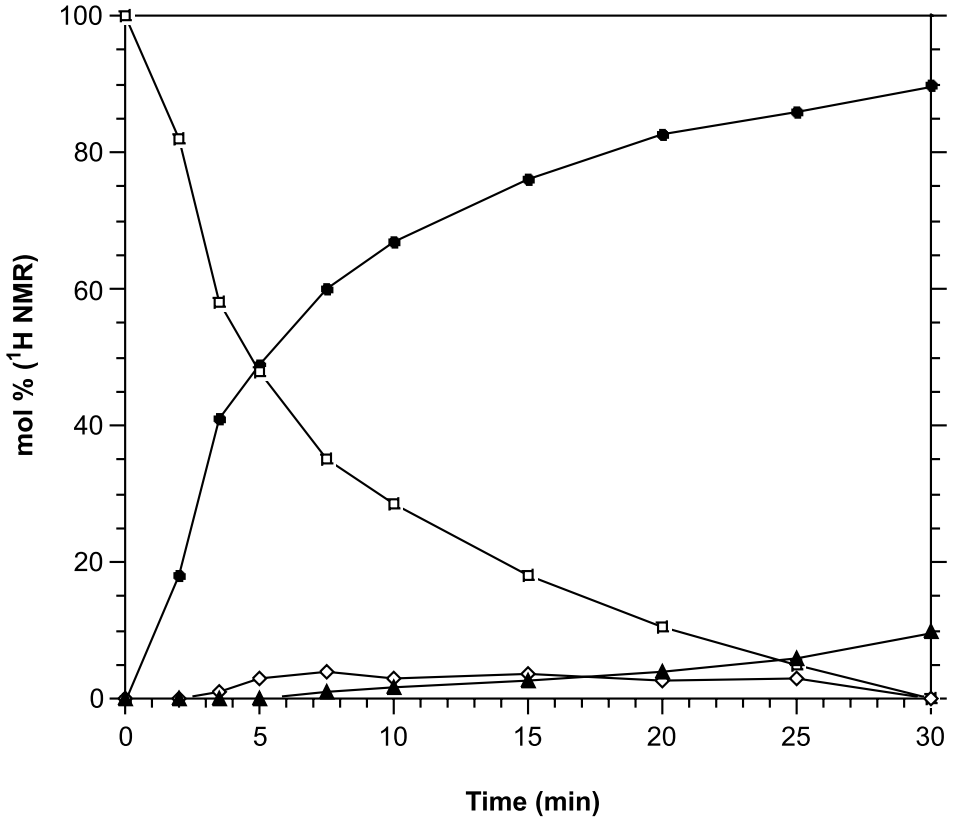
of minor amounts of the regioisomeric mono-addition product 4-chloro-7-phenylquinoline **5** (isolated as an inseparable mixture with **3** and identified by ^{1}H NMR spectroscopy). Second, using excess phenylboronic acid (2.2 equiv.), the yield of **4** could be increased to 24% (Table 2, entry 2). These observations suggest that although the aryl chloride at C4 is more reactive than the C7 aryl chloride, the latter is sufficiently reactive that the bis-addition product **4** can be derived from the initial reaction at either C4 or C7, followed by a second coupling, which is competitive with the first. Owing to the inherent reactivity of the two chlorides, it was expected that it would be difficult to identify reaction conditions for **1a** that would eliminate cross-coupling at C7 and provide **3** exclusively.

Thus, we turned our attention to the reactions of 7-chloro-4-iodoquinoline (**1b**) (15, 18). Since the order of reactivity of aryl halides in the Suzuki cross-coupling reaction is generally accepted to be I > Br >> Cl (1–5), it was thought that introduction of a C4-iodide might enhance the inherent C4 regioselectivity by virtue of the additional chemoselectivity that would be imparted by the more reactive iodide.

The difference in the reactivity of the two dihaloquinolines **1a** and **1b** was clearly seen upon monitoring the time course of their reactions with **2** (1.1 equiv. **2**, 0.25 equiv. nBu$_4$NBr, 1% $Pd(OAc)_2$, 1 equiv. Na_2CO_3, H_2O, reflux) by ^{1}H NMR spectroscopy. At suitable time points, aliquots of each reaction mixture were removed and analyzed for **1a** or **1b**, **3**, **4**, and **5** by the integration of characteristic and well-separated proton resonances (see Experimental section). The data are plotted in Figs. 1 and 2 for the reactions of **1a** and **1b**, respectively. In Fig. 1, it is clearly seen that **3**, **4**, and **5** were formed throughout the time-course of the reaction. When the starting material **1a** was consumed at 30 min, the reaction mixture was composed of **3** and **4** in a ratio of approximately 9:1. In contrast, the reaction of **1b** with **2** (Fig. 2) revealed that **3** was the only product formed until starting material was consumed (at 1.5 h), after which time the bis-addition product **4** was produced at the expense of **3**. The regioisomeric mono-adduct **5** was not observed in this latter reaction. Of note, and somewhat surprising, is the fact that the dramatic improvement in regioselectivity observed with **1b** (compared with **1a**) occurs at an overall reaction rate that is three times slower than that of **1a** (1.5 h vs. 30 min).

A subsequent reaction of **1b** with 1.1 equiv. of **2** under the conditions described above provided **3** (98%) and **4** (0.2%) upon consumption of **1b** at 1.5 h (Table 2, entry 3). However, if the reaction was allowed to progress for 3 h, the yield of **4** increased to 12% at the expense of **3** (85%) (Table 2, entry 4). These observations are consistent with the results shown in Fig. 2.



Subjection of **1b** and **2** to the reaction conditions originally described by Mitchell also provided **3** (93%) as the sole product upon consumption of **1b** (24 h), suggesting that the regioselectivity observed in the Suzuki reactions of **1b** is not limited to reactions catalyzed by phosphine-free palladium in water but is inherent to the reactivity of **1b**. Similarly, the overall rate of reaction of **1b** is approximately three times slower than that of **1a** under the Mitchell conditions (see introduction), suggesting that the solely aqueous conditions do not significantly impact the relative overall rates of reaction of **1a** and **1b**.

Thus, the cross-coupling reaction of the chloro-iodide **1b** catalyzed by phosphine-free $Pd(OAc)_2$ in water is slower but more regioselective than the dichloride **1a**. The difference in reactivity was further exemplified by the results obtained from conducting a competition experiment between **1a** and **1b** for phenylboronic acid (**2**) (1.0 equiv. of each of the quinolines and 1.02 equiv. of phenylboronic acid) using 1% $Pd(OAc)_2$ (Scheme 2). After 2 h, only the chloro-iodide **1b** was consumed to afford **3** (97%), and the dichloride **1a** was recovered in good yield (93%).

The differences that are observed in the reaction regioselectivity and overall reaction rate of **1a** and **1b** are readily rationalized. First, the regioselectivity of each reaction is reflective of the rate of irreversible oxidative addition of Pd(0) (generated from Pd(2+) and phenylboronic acid (19, 23)) to the C4 and C7 aryl halide bonds. In the case of dichloride **1a**, although the reactivity of the two chlorides is in the order C4—Cl > C7—Cl, the C7—Cl is of sufficient reactivity that the bis-addition product **4** derives from the initial reaction at either site, followed by a second coupling

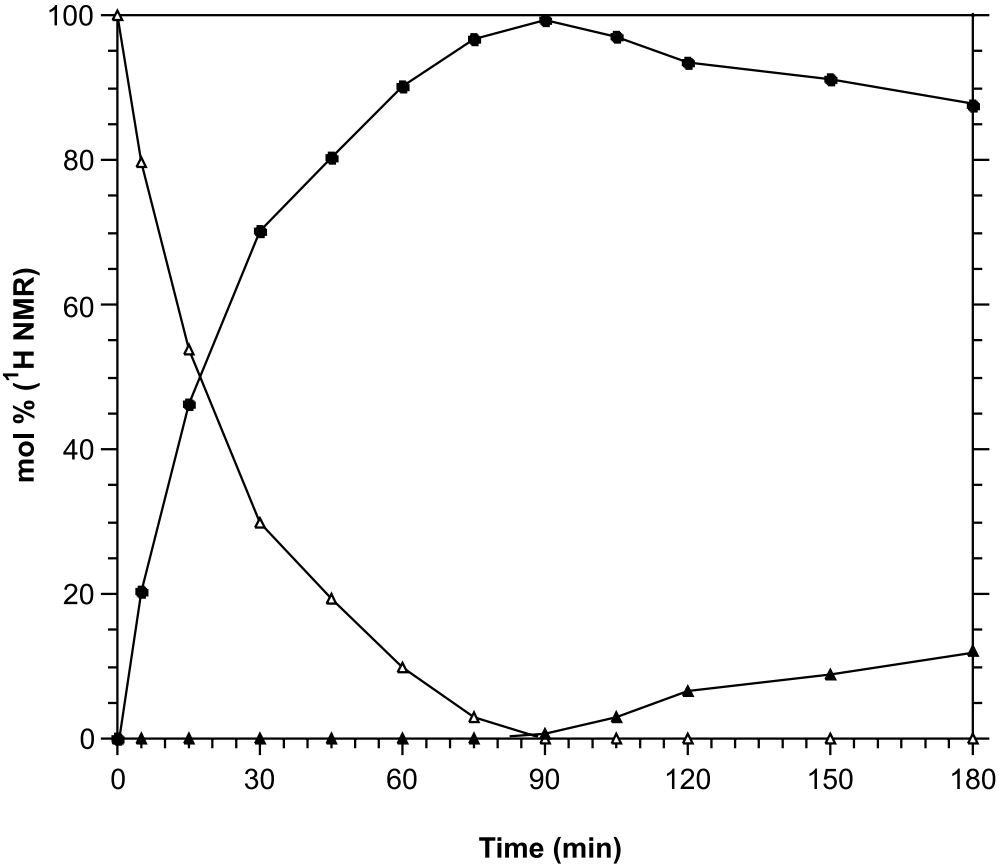
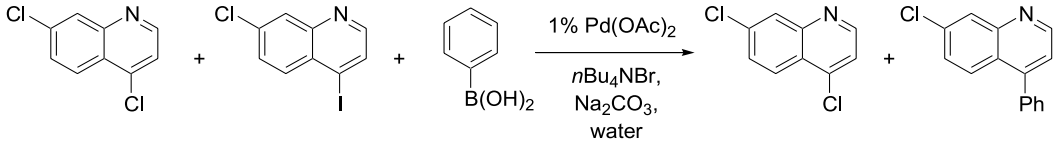
Fig. 1. Time course of the $Pd(OAc)_2$-catalyzed coupling reaction of **1a** and **2**. The mol% of **1a** (□), **3** (●), **4** (▲), and **5** (◇), as measured by ^1H NMR spectroscopy (see Experimental section), are represented as a function of time.



that is competitive with the first. For chloro-iodide **1b**, the difference in reactivity between C4—I and C7—Cl is > 100:1 (Table 2, entry 3). This chemoselectivity dictates that the bis-addition product **4** is produced only when the starting material is essentially completely consumed (see Fig. 2). Second, the more rapid overall reaction of **1a** compared with **1b** suggests that the oxidative addition step is not rate limiting in the overall catalytic cycle of **1b**. In contrast to those Suzuki reactions, in which the oxidative addition step is rate determining (leading to the typical ordering of overall reactivity I > Br >> Cl (1–5)), here transmetalation of the aryl-Pd-I species that is derived from **1b** appears to be rate determining. There are previous reports suggesting that transmetalation, rather than oxidative addition, can be rate determining in Suzuki cross-coupling reactions using both phosphine-free (21) and phosphine-ligated palladium catalysts (24, 25). Subtle differences in reaction conditions also have a dramatic impact on the mechanism since both oxidative addition (19) and transmetalation (21) steps have been found to be rate determining when using ligandless palladium catalysts. Thus, even though **1b** undergoes a rapid, irreversible, and chemoselective oxidative addition of Pd(0) to the aryl iodide bond at C4 (which results in very high regioselectivity compared with **1a**), the decreased rate of transmetalation results in the overall rate of reaction of chloro-iodide **1b** becoming slower than that of dichloride **1a** (note that the rate-determining step in the overall catalytic cycle of **1a** may be the oxidative addition or transmetalation steps). In addition, in spite of the fact that the overall rate of cross-coupling of **1a** is more rapid than **1b**, the highly chemoselective, rapid, and irreversible oxidative addition of Pd(0) to **1b** rationalizes the selective consumption of **1b** over that of **1a** in the competition experiment outlined in Scheme 2. Similar observations were made by Fu and co-workers (25) in their study of the Suzuki cross-coupling reactions catalyzed by $Pd_2(dba)_3$–$P(t\text{-}Bu)_3$. In these examples, the cross-couplings of aryl bromides with phenylboronic acid proceeded more rapidly than the corresponding aryl iodides, and in competition experiments analogous to those outlined in Scheme 2, only the aryl iodides underwent cross-coupling.



Another interesting observation was made when the cross-coupling reaction of **1a** and **2** was conducted in the presence of 0.25 equiv. $n\text{Bu}_4\text{NI}$ rather than $n\text{Bu}_4\text{NBr}$ (compare Table 2, entries 1 and 5). This modification had little effect on the isolated yield of **3** (73%) and **4** (13%), but the reaction now required 1.5 h to reach completion, similar to the rate that was observed using **1b** and $n\text{Bu}_4\text{NBr}$ (Table 2, entry 3). The presence of ammonium salts (21, 26) and the variation of halides (27–29) have been shown to have profound effects on the rate and mechanism of palladium-catalyzed processes in general. Although the reason behind this rate change is not completely understood, one can simplistically speculate that the aryl-Pd-Cl intermediate (formed upon reaction of **1a** with Pd(0)) is converted to aryl-Pd-I in the presence of $n\text{Bu}_4\text{NI}$ (the bond strength for palladium halides is Pd—Cl < Pd—Br < Pd—I (30, 31)). The reaction regioselectivity would still be governed by the relative rate of oxidative addi-

Scheme 2.

1a (1.0 equiv.) **1b** (1.0 equiv.) **2** (1.02 equiv.) **1a** (93%) **3** (97%)

tion of Pd(0) to the aryl chlorides at C4 and (or) C7, but the overall rate would depend on the transmetalation of phenylboronic acid (**2**) to the aryl-Pd-I intermediate.

Since **1b** displays superb C4-regioselectivity and provides **3** in excellent yield upon reaction with **2**, we set out to further characterize the cross-coupling reactions of **1b** using **2** as substrate (Table 2, entries 6–10). Surprisingly, when the nBu$_4$NBr additive was removed (Table 2, entry 6), **1b** was consumed within 30 min, a threefold increase in overall rate. The yield of **3** (97%) was not affected. A similar observation of threefold rate enhancement in the absence of nBu$_4$NBr was made, using **1a** as substrate (Table 2, entry 7). These observations are surprising since they are in contrast to literature data (21), which suggest that nBu$_4$NBr is required for successful Suzuki cross-couplings using phosphine-free $Pd(OAc)_2$ in water. It may further imply a possible change in mechanism between the two reaction conditions (27, 28). The yield of **3** (96%) was not affected by decreasing the amount of phenylboronic acid (**2**) from 1.1 to 1.02 equiv. (Table 2, entry 8). This seemingly minor modification is important, since the reaction of **1b** still proceeds to completion, but monitoring for the disappearance of starting material **1b** becomes unnecessary. Recall that monitoring for the disappearance of starting material **1b** is necessary when using 1.1 equiv. of **2** since prolongation of the reaction after consumption of starting material (from 1.5 to 3 h) results in a significant increase in the formation of **4** (Table 2, entries 3 and 4). Finally, although the amount of $Pd(OAc)_2$ used can be decreased from 1% to 0.01%, this reduction in catalyst loading occurs with a corresponding increase in the time required for the reaction to reach completion (Table 2, entries 9 and 10).

Reaction scope

As illustrated in Scheme 3 and Table 3 (entries 1–14), reaction of **1b** using the optimized reaction conditions (A: 1.0 equiv. **1b**, 1.02 equiv. **6** or **8** or **9**, 1% $Pd(OAc)_2$, 1.0 equiv. Na_2CO_3, H_2O (1 mL/mmol **1b**), bath temperature 150 °C) with a variety of boronic acids afforded the expected products **7**, **10**, and **11** in good to excellent yields (84%–97%) without observation of the corresponding bis-addition prod-

Scheme 3.

ucts analogous to **4**. Degassing of the water (19, 21) is not required for a successful cross-coupling reaction.

The range of arylboronic acids **6** that serve as suitable coupling partners include those bearing electron donating and withdrawing substituents at the *ortho*-, *meta*-, and *para*-positions. 3-Thienylboronic acid **8** (Table 3, entry 13) and (*E*)-1-hexenylboronic acid **9** (Table 3, entry 14) are also suitable substrates. Typically, these reactions are complete within 1 h, but there are some exceptions. No reaction is observed after 2 h when using the sterically encumbered 2,6-dimethylphenylboronic acid (**6k**) (Table 3, entry 12). In several other examples, the reactions do not proceed to completion even after 2.5 h, as evidenced by the observation (TLC) or isolation of starting material **1b**. In each of these examples, the black precipitate that signals the completion of the reaction (and which is typically seen with those substrates that do consume all of **1b**) is not produced even if additional arylboronic acid or palladium catalyst is added. For several cases, the quantity of residual **1b** is minor (not isolated), and products **7** are obtained in yields over 88% (Table 3, entries 3, 7, 10, 13). In two cases (Table 3, entries 4 and 6), significant amounts of **1b** remain, although yields of **7** based on recovered starting material are still good. There does not appear to be any correlation between the steric or electronic nature of the substituent on the arylboronic acid and the extent of consumption of **1b**. Since these reactions are heterogeneous and take place in the absence of organic co-solvent, it is possible that the aqueous solubility or some other physical property of the boronic acid substrates may be responsible for these observed differences. However, this cannot be the sole explanation. Reactions of two representative arylboronic acids (**6c** and **6g**) with **1b** were conducted under the biphasic Mitchell reaction conditions ($Pd(Ph_3P)_4$, aqueous ethanol – toluene) for comparison purposes, and the reactivity patterns observed are similar to those observed under the phosphine-free palladium conditions in water (compare Table 3, entries 4 and 15, and 8 and 16, respectively). In the case of **6g**, **7g** was obtained in good yield (94%), but the reaction was complete after only 24 h. In the case of **6c**, a significant amount of starting material remained after an extended reaction time (2 days).

We have demonstrated that 7-chloro-4-iodoquinoline (**1b**) undergoes highly regioselective Suzuki cross-coupling reactions at C4 with a variety of boronic acids (aryl and vinyl), catalyzed by phosphine-free palladium in water solvent in the absence of nBu$_4$NBr. The regioselectivity that is observed is superior to that observed with the dichloride **1a**, but the overall reaction rate of **1b** is three times slower than **1a** (using phenylboronic acid). These results can be inter-

preted by considering that transmetalation of the intermediate aryl-Pd-I species, rather than the formation of this species by the rapid and chemoselective oxidative addition of Pd(0) to **1b**, is the rate-determining step in the overall catalytic cycle of **1b**.

Experimental section

All reagents were obtained from commercial suppliers except **1b**, which was prepared from **1a** and aqueous HI (57%) as described (15, 18). Melting points are uncorrected. FT-IR spectra were recorded as solutions in chloroform unless stated otherwise, and wavenumbers (ν) are reported in cm^{-1}. ^1H and ^{13}C NMR spectra were recorded as solutions in acetone-d_6, unless stated otherwise, at field strengths of 400 MHz (^1H) or 100 MHz (^{13}C). Chemical shifts are reported in parts per million (ppm) relative to the signals of residual protonated solvent as internal standard. ^{13}C NMR spectra were acquired with proton decoupling, and peak multiplicities refer to J_{CF}. Elemental analyses were performed at the Laboratoire d'Analyse Élémentaire in the Department of Chemistry, Université de Montréal, Montréal.

Reactions for Figs. 1 and 2

A mixture of **1a** (1.00 g, 5.04 mmol) (Fig. 1) or **1b** (1.46 g, 5.04 mmol) (Fig. 2), phenylboronic acid (**2**) (97%, 647 mg, 1.02 equiv.), nBu$_4$NBr (406 mg, 0.25 equiv.), $Pd(OAc)_2$ (11 mg, 0.01 equiv.), Na_2CO_3 (2.5 mL of a 2 mol/L solution, 1.0 equiv.), and water (2.5 mL) was placed in a 50 mL round-bottom flask under a nitrogen atmosphere and immersed in an oil bath at 150 °C. After the time intervals indicated in the figures, a small aliquot of the reaction mixture was removed and dissolved in ethyl acetate. The mixture was dried ($MgSO_4$), filtered, and concentrated. The crude residue was analyzed by ^1H NMR spectroscopy. One or more of the following characteristic resonances were integrated, and for each compound present, the mol% composition of the sample was calculated. **1a**: 7.74 (d, 1H), 7.78 (dd, 1H), 8.30 (d, 1H), 8.89 (d, 1H); **1b**: 7.75 (dd, 1H), 8.20 (d, 1H), 8.53 (d, 1H); **3**: 7.37 (d, 1H), 7.86 (d, 1H), 8.11 (d, 1H), 8.92 (d, 1H); **4**: 8.02 (d, 1H, J = 8.8 Hz), 8.39 (d, 1H), 8.99 (d, 1H); **5**: 8.34 (d, 1H), 8.36 (d, 1H), 8.87 (d, 1H). The resulting data were used to generate Figs. 1 and 2.

Competition experiment (Scheme 2)

A mixture of **1a** (1.00 g, 5.04 mmol), **1b** (1.46 g, 5.04 mmol), phenylboronic acid (**2**) (97%, 647 mg, 1.02 equiv.), nBu$_4$NBr (406 mg, 0.25 equiv.), $Pd(OAc)_2$ (11 mg, 0.01 equiv.), Na_2CO_3 (2.5 mL of a 2 mol/L solution, 1.0 equiv.), and water (2.5 mL) was placed in a 50 mL round-bottom flask under a nitrogen atmosphere and immersed in an oil bath at 150 °C. After stirring for 2 h, the mixture was cooled to room temperature; water (50 mL) was added, and the mixture was extracted twice with ethyl acetate (50 mL). The combined organics were washed with water (50 mL) and brine (50 mL), dried ($MgSO_4$), filtered, and concentrated. The residue was subjected to flash column chromatography (SiO_2, eluting with hexane–ether 4:1 volume fraction) to provide **1a** (927 mg, 93%) as a white solid and **3** (1.17 g, 97%) as a white solid.

Typical procedure (Table 3)

A mixture of **1b** (1.46 g, 5.04 mmol), phenylboronic acid **2** (97%, 647 mg, 1.02 equiv.), $Pd(OAc)_2$ (11 mg, 0.01 equiv.), Na_2CO_3 (2.5 mL of a 2 mol/L solution, 1.0 equiv.), and water (2.5 mL) was placed in a 50 mL round-bottom flask under a nitrogen atmosphere and immersed in an oil bath at 150 °C. After stirring for 45 min, the mixture was cooled to room temperature; water (50 mL) was added, and the mixture was extracted twice with ethyl acetate (50 mL). The combined organics were washed with water (50 mL) and brine (50 mL), dried ($MgSO_4$), filtered, and concentrated. The residue was subjected to flash column chromatography (SiO_2, eluting with hexane–ether 3:1 volume fraction) to provide **3** (1.16 g, 96%) as a white solid and **4** (9 mg, 0.7%) as a white solid (Table 2, entry 8 and Table 3, entry 1).

7-Chloro-4-phenylquinoline (3)

mp 73 to 74 °C (lit. (6) value mp 73.5–74.5 °C). ^1H NMR δ: 7.37 (d, 1H, J = 4.4 Hz), 7.47–7.58 (m, 6H), 7.86 (d, 1H, J = 9.0 Hz), 8.11 (d, 1H, J = 2.1 Hz), 8.92 (d, 1H, J = 4.4 Hz). ^{13}C NMR δ: 122.1, 125.4, 127.7, 127.9, 129.0, 129.1, 129.2, 129.9, 134.9, 137.8, 148.5, 149.6, 151.7.

4,7-Diphenylquinoline (4)

mp 128 to 129 °C. IR: 3023. ^1H NMR δ: 7.44 (d, 1H, J = 4.3 Hz), 7.48 (m, 1H), 7.54–7.63 (m, 7H), 7.88 (m, 2H), 7.93 (dd, 1H, J = 1.9, 8.8 Hz), 8.02 (d, 1H, J = 8.8 Hz), 8.39 (d, 1H, J = 1.8 Hz), 8.99 (d, 1H, J = 4.4 Hz). ^{13}C NMR δ: 122.1, 126.4, 126.8, 127.1, 128.1, 128.8, 129.3, 129.5, 129.9, 130.3, 138.8, 140.7, 142.4, 148.8, 150.1, 151.5. Anal. calcd. for $C_{21}H_{15}N$: C 89.65, H 5.37, N 4.98; found: C 89.47, H 5.38, N 4.99.

The remainder of the examples cited in Table 3 were prepared on the same scale in a manner similar to **3**, with reaction times as listed in the table. The eluting solvents used for column chromatography are indicated below.

7-Chloro-4-(2-methylphenyl)quinoline (7a)

Chromatography (hexane–ether 4:1 volume fraction) provided **7a** as a white solid (1.19 g, 93%), mp 86 to 87 °C. IR: 3017. ^1H NMR δ: 2.07 (s, 3H), 7.26 (d, 1H, J = 7.5 Hz), 7.36–7.49 (m, 5H), 7.55 (dd, 1H, J = 2.1, 9.0 Hz), 8.15 (d, 1H, J = 2.1 Hz), 9.00 (d, 1H, J = 4.3 Hz). ^{13}C NMR δ: 19.6, 122.4, 126.1, 126.4, 127.8, 128.1, 129.0, 129.1, 129.8, 130.7, 135.0, 136.1, 137.3, 148.5, 149.4, 151.9. 7-Chloro-4-(2-chlorophenyl)quinoline (7c)

Chromatography (hexane – ethyl acetate 6:1 volume fraction) provided **1b** (466 mg, 32%) and **7c** as a white solid (803 mg, 58%), mp 89 to 90 °C. IR: 2976. ^{1}H NMR δ: 7.43 (d, 1H, J = 4.4 Hz), 7.44 (dd, 1H, J = 1.8, 7.3 Hz), 7.49–7.59 (m, 4H), 7.64 (dd, 1H, J = 1.4, 7.8 Hz), 8.16 (d, 1H, J = 1.8 Hz), 9.02 (d, 1H, J = 4.4 Hz). ^{13}C NMR δ: 122.7, 125.6, 127.8, 128.0, 129.0, 130.2, 130.8, 131.9, 133.1, 135.1, 136.5, 146.0, 149.3, 151.8. Anal. calcd. for $C_{15}H_9Cl_2N$: C 65.72, H 3.31, N 5.11; found: C 65.67, H 3.24, N 5.08.

7-Chloro-4-(3-fluorophenyl)quinoline (7d)

Chromatography (hexane–ether 4:1 volume fraction) provided **7d** as a white solid (1.26 g, 97%), mp 88 to 89 °C. IR: 2979. ^{1}H NMR δ: 7.32–7.41 (m, 3H), 7.49 (d, 1H, J = 4.4 Hz), 7.59 (dd, 1H, J = 2.2, 9.0 Hz), 7.65 (br q, 1H, J = 7.8 Hz), 7.92 (d, 1H, J = 9.0 Hz), 8.13 (d, 1H, J = 2.1 Hz), 8.98 (d, 1H, J = 4.4 Hz). ^{13}C NMR δ: 115.9 (d, J_{CF} = 21.1 Hz), 116.8 (d, J_{CF} = 22.5 Hz), 122.2, 125.2, 126.0 (d, J_{CF} = 2.7 Hz), 127.8, 128.0, 129.0, 131.2 (d, J_{CF} = 8.5 Hz), 135.1, 140.1 (d, J_{CF} = 7.9 Hz), 147.1, 149.6, 151.8, 163.2 (d, J_{CF} = 245.6 Hz). Anal. calcd. for $C_{15}H_9ClFN$: C 69.91, H 3.52, N 5.44; found: C 69.70, H 3.50, N 5.45.

4-(3-Acetamidophenyl)-7-chloroquinoline (7e)

Chromatography (hexane – ethyl acetate 1:2 volume fraction) provided **1b** (142 mg, 10%) and **7e** as a white solid (1.14 g, 76%), mp 184 to 185 °C. IR: 3435, 3015, 1692. ^{1}H NMR ($CDCl_3$) δ: 2.23 (s, 3H), 7.22 (br d, 1H, J = 7.6 Hz), 7.33 (d, 1H, J = 4.4 Hz), 7.44–7.50 (m, 2H), 7.63–7.69 (m, 3H), 7.89 (d, 1H, J = 9.0 Hz), 8.17 (d, 1H, J = 2.0 Hz), 8.94 (d, 1H, J = 4.4 Hz). ^{13}C NMR ($CDCl_3$) δ: 24.6, 120.1, 120.8, 121.4, 125.1, 125.2, 127.3, 127.9, 128.1, 129.4, 135.7, 138.0, 138.5, 148.4, 148.7, 150.4, 168.7. Anal. calcd. for $C_{17}H_{13}ClN_2O$: C 68.81, H 4.42, N 9.44; found: C 68.86, H 4.49, N 9.12.

7-Chloro-4-(3-cyanophenyl)quinoline (7f)

Chromatography (hexane – ethyl acetate 3:1 volume fraction) provided **7f** as a white solid (1.18 g, 88%), mp 160 to 161 °C. IR: 2982, 2234. ^{1}H NMR ($CDCl_3$) δ: 7.26 (d, 1H, J = 4.4 Hz), 7.43 (dd, 1H, J = 2.1, 9.0 Hz), 7.62–7.78 (m, 5H), 8.11 (d, 1H, J = 2.1 Hz), 8.91 (d, 1H, J = 4.4 Hz). ^{13}C NMR ($CDCl_3$) δ: 113.1, 118.1, 121.3, 124.4, 126.3, 128.1, 128.8, 129.6, 132.1, 132.6, 133.6, 135.6, 138.6, 145.8, 148.9, 150.8. Anal. calcd. for $C_{16}H_9ClN_2$: C 72.60, H 3.43, N 10.58; found: C 72.50, H 3.39, N 10.55.

7-Chloro-4-(4-fluorophenyl)quinoline (7g)

Chromatography (hexane – ethyl acetate 4:1 volume fraction) provided **7g** as a white solid (1.25 g, 96%), mp 105 to 106 °C. IR: 2978. ^{1}H NMR δ: 7.39 (br t, 2H, J = 8.8 Hz), 7.47 (d, 1H, J = 4.4 Hz), 7.59 (dd, 1H, J = 2.2, 9.0 Hz), 7.61–7.66 (m, 2H), 7.92 (d, 1H, J = 9.0 Hz), 8.14 (d, 1H, J = 2.2 Hz), 8.98 (d, 1H, J = 4.4 Hz). ^{13}C NMR δ: 116.1 (d, $J_{C\text{-}F}$ = 21.8 Hz), 122.3, 125.4, 127.81, 127.85, 129.0, 132.0 (d, $J_{C\text{-}F}$ = 8.5 Hz), 134.0, 135.0, 147.5, 149.6, 151.8, 163.4 (d, $J_{C\text{-}F}$ = 246.5 Hz). Anal. calcd. for $C_{15}H_9ClFN$: C 69.91, H 3.52, N 5.44; found: C 69.73, H 3.40, N 5.44.

7-Chloro-4-(4-methoxyphenyl)quinoline (7h)

Chromatography (hexane – ethyl acetate 3:1 volume fraction) provided **7h** as a white solid (1.32 g, 97%), mp 90 to 91 °C. IR: 2963. ^{1}H NMR δ: 3.92 (s, 3H), 7.15 (br d, 2H, J = 8.7 Hz), 7.42 (d, 1H, J = 4.4 Hz), 7.50 (br d, 2H, J = 8.7 Hz), 7.56 (dd, 1H, J = 2.2, 9.0 Hz), 7.98 (d, 1H, J = 9.0 Hz), 8.11 (d, 1H, J = 2.2 Hz), 8.93 (d, 1H, J = 4.4 Hz). ^{13}C NMR δ: 55.3, 114.6, 122.0, 125.6, 127.5, 128.1, 128.9, 129.9, 131.2, 134.8, 148.3, 149.8, 151.8, 160.7. Anal. calcd. for $C_{16}H_{12}ClNO$: C 71.25, H 4.48, N 5.19; found: C 71.16, H 4.47, N 5.13.

4-(4-Acetylphenyl)-7-chloroquinoline (7i)

Chromatography (hexane – ethyl acetate 3:2 volume fraction) provided **7i** as a white solid (1.27 g, 89%), mp 143 to 144 °C. IR: 3015, 1688. ^{1}H NMR δ: 2.70 (s, 3H), 7.52 (d, 1H, J = 4.4 Hz), 7.61 (dd, 1H, J = 2.2, 9.0 Hz), 7.73 (d, 2H, J = 8.4 Hz), 7.91 (d, 1H, J = 9.0 Hz), 8.16 (d, 1H, J = 2.2 Hz), 8.21 (d, 2H, J = 8.4 Hz), 9.02 (d, 1H, J = 4.4 Hz). ^{13}C NMR δ: 26.4, 122.1, 125.1, 127.8, 128.0, 128.98, 129.01, 130.2, 135.1, 137.7, 142.2, 147.5, 149.6, 151.8, 197.1. Anal. calcd. for $C_{17}H_{12}ClNO$: C 72.47, H 4.29, N 4.97; found: C 72.36, H 4.34, N 4.90.

4-(4-Benzyloxy-3-fluorophenyl)-7-chloroquinoline (7j)

Chromatography (hexane – ethyl acetate 3:1 volume fraction) provided **7j** as a white solid (1.70 g, 93%), mp 150 to 151 °C. IR: 3014. ^{1}H NMR ($CDCl_3$) δ: 5.26 (s, 2H), 7.18 (m, 2H), 7.27 (br d, 1H, J = 11.5 Hz), 7.30 (d, 1H, J = 4.4 Hz), 7.39 (m, 1H), 7.43–7.53 (m, 5H), 7.89 (d, 1H, J = 9.0 Hz), 8.19 (d, 1H, J = 1.9 Hz), 8.93 (d, 1H, J = 4.4 Hz). ^{13}C NMR ($CDCl_3$) δ: 71.3, 115.5, 117.4, 117.6, 121.3, 125.0, 125.41, 125.45, 127.0, 127.4, 127.7, 128.3, 128.7, 130.5, 130.6, 135.4, 136.1, 147.0, 147.1, 147.3, 149.0, 150.8, 151.3, 153.8. Anal. calcd. for $C_{22}H_{15}ClFNO$: C 72.63, H 4.16, N 3.85; found: C 72.21, H 4.12, N 3.83.

7-Chloro-4-(3-thienyl)quinoline (10)

Chromatography (hexane – ethyl acetate 4:1 volume fraction) provided **10** as a white solid (1.10 g, 89%), mp 74 to 75 °C. IR: 2975. ^{1}H NMR δ: 7.43 (dd, 1H, J = 1.2, 4.9 Hz), 7.49 (d, 1H, J = 4.4 Hz), 7.56 (dd, 1H, J = 2.2, 9.1 Hz), 7.74 (dd, 1H, J = 3.0, 4.9 Hz), 7.80 (m, 1H), 8.10 (m, 2H), 8.92 (d, 1H, J = 4.4 Hz). ^{13}C NMR δ: 121.9, 125.4, 126.2, 127.3, 127.7, 128.0, 129.0, 129.2, 134.9, 138.2, 143.2, 149.7, 151.8. Anal. calcd. for $C_{13}H_8ClNS$: C 63.54, H 3.28, N 5.70; found: C 63.53, H 3.20, N 5.66.

(E)-7-Chloro-4-(1-hexenyl)quinoline (11)

Chromatography (hexane–ether 4:1 volume fraction) provided **11** as a colorless oil (1.05 g, 95%). IR (film): 2957, 2928, 1579. ^{1}H NMR δ: 0.95 (t, 3H, J = 7.3 Hz), 1.42 (m, 2H), 1.53 (m, 2H), 2.36 (br q, 2H, J = 7.0 Hz), 6.59 (dt, 1H, J = 15.6, 7.0 Hz), 7.15 (d, 1H, J = 15.6 Hz), 7.54 (m, 2H), 8.03 (d, 1H, J = 2.2 Hz), 8.21 (d, 1H, J = 9.0 Hz), 8.81 (d, 1H, J = 4.6 Hz). ^{13}C NMR δ: 13.8, 22.5, 31.4, 33.3, 117.7, 124.3, 125.0, 126.1, 127.1, 128.9, 134.7, 139.3, 143.7, 149.6, 151.8. Anal. calcd. for $C_{15}H_{16}ClN$: C 73.31, H 6.56, N 5.70; found: C 73.15, H 6.66, N 5.64.

Part 1: Efficient strategies for the construction of variably substituted bicyclo[5.3.1]undecenones (AB taxane ring systems)[1]

Alain Laurent, Nidia P. Villalva-Servín, Pat Forgione, Peter D. Wilson, David V. Smil, and Alex G. Fallis

Abstract: Strategies for the construction of cyclic molecules containing variably substituted bicyclo[5.3.1]undecenones (AB taxane ring systems) are described. These routes employ a multi-component coupling protocol that utilizes sequential magnesium-mediated carbometallation of propargyl alcohols and intramolecular Diels–Alder reactions (IMDA). The cycloaddition generates the key eight-membered taxane ring as a single diastereomer, induced by preferential Lewis acid (diethylaluminum chloride or boron trifluoride etherate) complexation with the cross-ring oxygens. Both the electronic nature of the dienophile and the neighbouring group non-bonded interactions contribute to the success of these cycloadditions.

Key words: magnesium chelate, Lewis acid, intramolecular Diels–Alder, cycloaddition.

Résumé : On décrit des stratégies permettant de construire des molécules cycliques contenant des bicyclo[5.3.1]undécénones (cycles AB du taxane). Ces routes font appel à un protocole de couplage à plusieurs composants qui utilise en séquence des réactions de carbométallation d'alcools propargyliques catalysées par le magnésium et des réactions de Diels–Alder intramoléculaires. La cycloaddition génère le cycle à huit chaînons du taxane sous la forme d'une seul diastéréomère en raison de la complexation préférentielle de l'acide de Lewis (chlorure de diéthylaluminium ou éthérate du trifluorure de bore) avec les atomes d'oxygène dans la partie opposée du cycle. La nature électronique du diénophile ainsi que les interactions non liées du groupe voisin jouent toutes les deux en faveur du succès de ces cycloadditions.

Mots clés : chélate magnésien, acide de Lewis, Diels–Alder intramoléculaire, cycloaddition.

Introduction

Taxol® (paclitaxel) and Taxotere® (docetaxel) are now established chemotherapeutic agents (selling more than $1 billion US each annually) for the treatment of ovarian and breast cancer. These drugs operate by a novel mechanism of action that differs from other spindle poisons such as vincristine. Based on a long tradition of natural products isolation and discovery, nature has provided a novel structure that represents a new chemotherapeutic lead. Thus, as previously demonstrated for penicillins and tetracyclines, modified taxoid structures have provided new understanding of the mode of action. Eventually novel compounds with improved water solubility and better therapeutic properties will be developed. We hope that eventually our own research will be able to contribute to this area with new, improved drugs. Paclitaxel **1** (Taxol®) and docetaxel **2** (Taxotere®) (Fig. 1) continue to receive increased medicinal attention because of their increased utility, particularly for mixed chemotherapy. These diterpenoids, classified as alkaloids (!), have elicited considerable interest over the last two decades, principally as a result of their proven chemotherapeutic utility and their attraction as highly challenging synthetic targets (1). The total synthesis of Taxol® has been surmounted by six different groups (2). However, new, efficient strategies for construction of the unique taxane tricyclo[9.3.1.$0^{3,8}$]pentadecane nu-

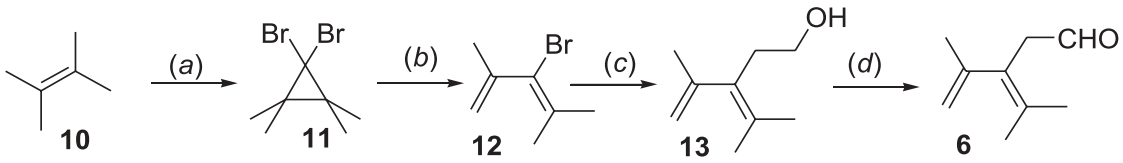
cleus are still required if we are to make new, improved analogues.

Carbometallation – intramolecular cycloaddition strategy

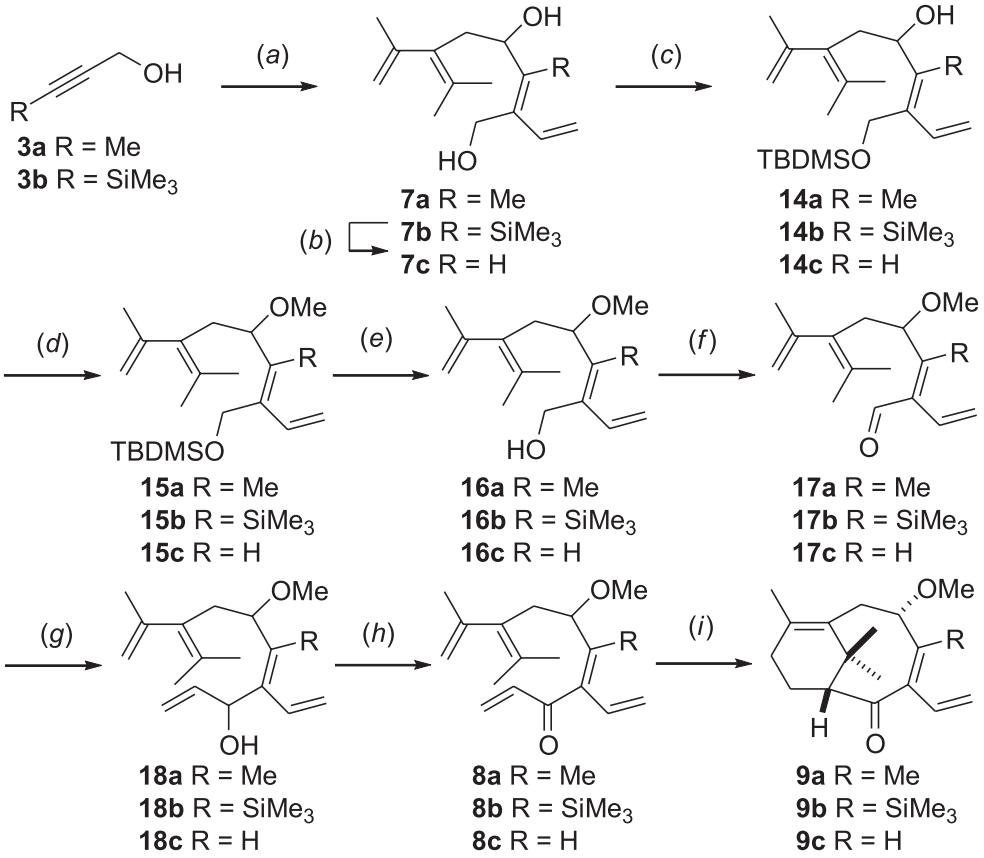
We have a long-standing interest in the area of taxane synthesis. We have examined different protocols, but particularly those that involve diverse strategies and that encompass intramolecular Diels–Alder sequences (3). We continue to develop more efficient and convergent routes for the preparation of the carbocyclic taxane skeleton via versatile approaches to the AB ring system. We wish to report the details of our recent progress, involving combinations of carbometallation reactions of propargyl alcohols and type II intramolecular Diels–Alder (IMDA) reactions (4) to generate eight-membered rings, induced by the presence of an endocyclic *cis*-akene (5). The following paper (6) describes further studies with related building blocks and their conversion to the tricyclic ABC taxane nucleus.

We have previously described the versatility of the magnesium-mediated carbometallation of propargyl alcohols for the assembly of several diverse structures generated in a single reaction. This three-component coupling strategy allows the direct regio- and stereocontrolled synthesis of halodienes, diene-diols, enediynes, tetraenes, tetrasubstituted alkenes, substituted furans, and 2(5*H*)-furanones (butenolides) with vinyl and related Grignard reagents (7).



We have also established the beneficial influence of "planar" double bonds and aromatic rings in the side chain, to control the stereochemistry of IMDA reactions (8). For oxygenated targets, isopropylidene acetal tether control groups direct the enantioselectivity of the adducts, especially for *cis*-decalins (9). A related concept, namely the possibility of controlling the geometry of the side chain with a *cis* double bond, appeared attractive for the construction of the eight-membered ring embedded in the bicyclo[5.3.1]undecene AB skeleton of taxoids. We envisaged that a carbometallation strategy would allow efficient access to suitable cycloaddition precursors, which in turn would lead to the rapid assembly of variably functionalized taxane AB-ring systems.

This general strategy, via the magnesium chelate **5** and the cycloaddition precursor **8**, is outlined in Scheme 1 (5). We anticipated that the synthesis of key intermediate diols of type **7** could be conducted in one pot via the addition of Grignard reagents **4** to terminally substituted propargylic alcohols **3** and subsequent trapping of the putative magnesium chelate **5** with diene aldehyde **6**. Further elaboration would allow access to Diels–Alder precursors such as **8**. These cross-conjugated dienones were expected to readily undergo intramolecular cyclization to afford the desired bicyclo[5.3.1]undecenone skeletons **9** in the presence of a Lewis acid. Molecular modeling suggested that modest stereoselection might be achieved during the cycloaddition created by the preferential complexation between the cross-ring oxygens. In view of the flexibility available for the carbometallation partners, these cores could be constructed with sufficient functionality for the eventual attachment of the C-ring by annulation, cycloaddition, or ring-closing metathesis procedures.



Current structure activity relationships (SAR) data for Taxol® have established that the C2 benzoate, the C4 acetate, and the oxetane or hydrogen bond acceptor on the "southern" perimeter of the molecule are crucial for activity. In contrast, the "northern" perimeter C7 hydroxyl and C10 acetate substituents can be omitted without compromising efficacy (1). Although not essential, the C9 hydroxyl increases activity slightly and acts as a useful handle for the formation of resolvable derivatives (10) or the introduction of solubilizing groups (11). We elected to employ diene aldehyde **6** as a source of the future C9 oxygen to take advantage of the rapid AB-ring assembly afforded by an IMDA

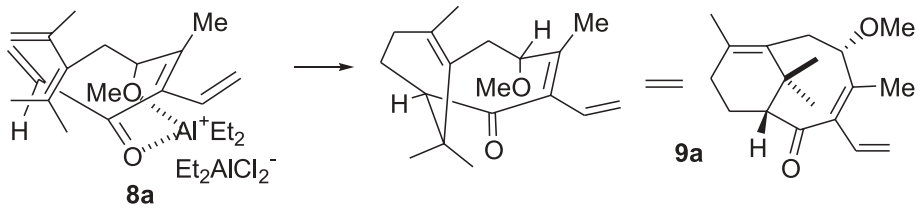
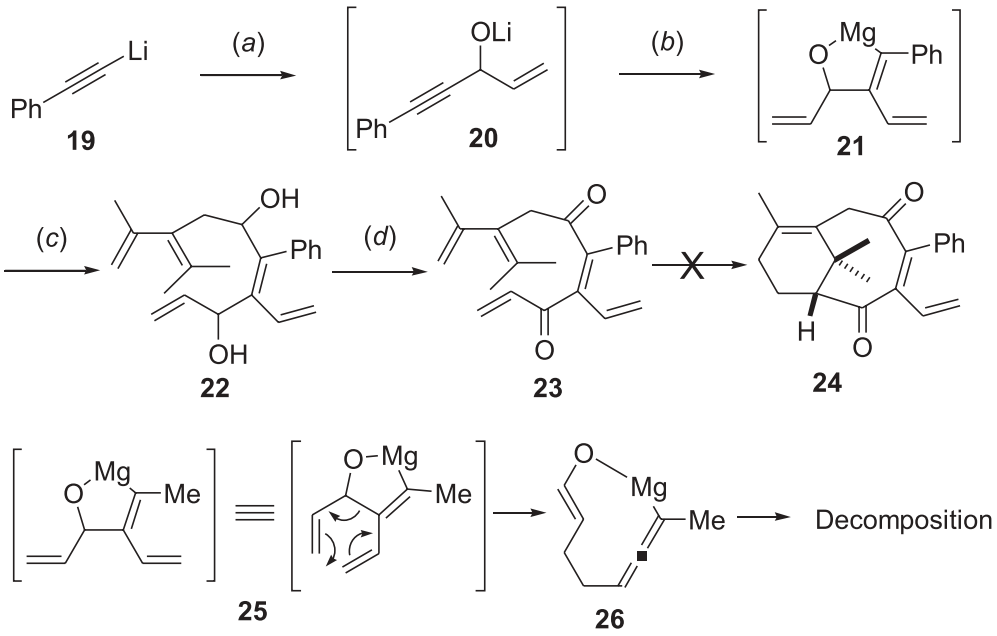
strategy for **9**, while the propargylic alcohol **3** would contribute the requisite C2 oxygen.

Magnesium-mediated carbometallation – intramolecular Diels–Alder studies



Diene aldehyde **6** was readily prepared in multigram quantities and 45% overall yield via our reported four-step sequence from 2,3-dimethyl-2-butene **10** (Scheme 2) (3*d*). Subsequent thermal rearrangement of the initially formed 1,1-dibromo-2,2,3,3-tetramethylcyclopropane **11** gave bromodiene **12**, and lithium–halogen exchange followed by alkylation with ethylene oxide afforded diene alcohol **13**. Diene aldehyde **6** was somewhat sensitive to prolonged storage, so it was prepared immediately prior to use by oxidation of diene alcohol **13** with Dess–Martin periodinane (12).

Our route for the preparation of the keto-pentaene **8a** began with the addition of vinylmagnesium chloride to 2-butynol (**3a**) and followed by quenching of the intermediate magnesium anion with diene aldehyde **6** (Scheme 3). Selective protection of the primary allylic alcohol, as silyl ether **14a**, permitted methylation of the secondary allylic alcohol in diol **7a** and subsequent fluoride-mediated desilylation of the methylated intermediate **15a** to afford alcohol **16a**. Swern, *o*-iodoxybenzoic acid (IBX), or Dess–Martin oxidation to aldehyde **17a** was followed by the addition of vinylmagnesium chloride and a second IBX or Dess–Martin oxidation of alcohol **18a** to give the Diels–Alder precursor **8a**.



The Diels–Alder cycloaddition of substrate **8a** proceeded smoothly in the presence of Et_2AlCl to afford the taxane AB-ring building block **9a** as a single diastereomer (Scheme 3). The observed stereoselectivity, confirmed by X-

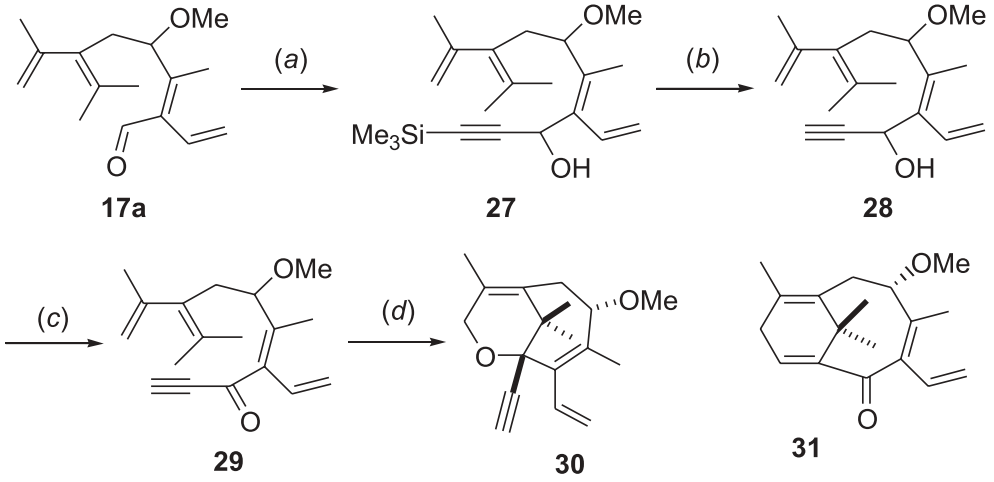
Fig. 2. Diastereoselective Lewis-acid complexation of **8a**.

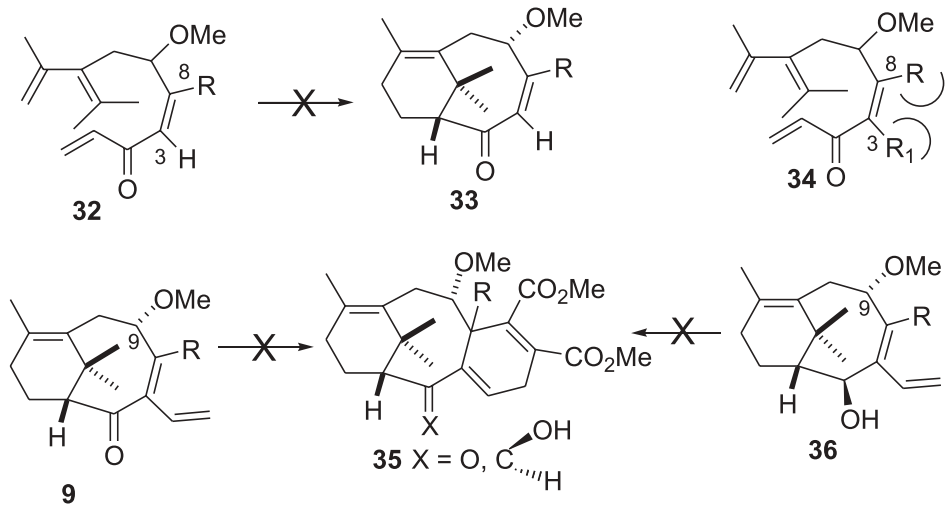
Scheme 4. Reagents and conditions: (*a*) CH_2=CHCHO; (*b*) CH_2=CHMgCl; (*c*) **6**; (*d*) Dess–Martin periodinane, CH_2Cl_2, rt, 1 h, 80%.

ray crystallographic analysis (5), arose from chelation control provided by complexation of the Lewis acid between the C2 carbonyl and C9 methoxy substituents (Fig. 2). The geometry appears particularly favourable, created by the chair-like arrangement of the atoms involved. Related chelation effects have been shown to control the selectivity of both intermolecular (13) and intramolecular cycloadditions (14) mediated by Lewis acids.



This direct route to the bicyclo[5.3.1]undecenone **9a** was also utilized to construct compounds **9b** and **9c** in a parallel fashion. Trimethylsilyl acetylene propargyl alcohol provided access to intermediate **7b**, from which the silyl group could be readily removed to afford the corresponding carbometallation product **7c**. This ultimately provided access to the bicyclo[5.3.1]undecenone **9c**, or alternatively, the silyl group could be retained until the adduct **9b**, to afford a second source of **9c**, as illustrated in Scheme 3.

An attempt to shorten this sequence, as we had done for our furan syntheses (7) with an acetylenic anion, gave variable results. The in situ generation of a secondary alkoxide by carbometallation to install the dienophilic olefin worked well with a phenyl substituent (Scheme 4). Thus the lithium salt of phenyl acetylene **19** was condensed with acrolein, treated with excess vinylmagnesium chloride, and quenched with diene aldehyde **6** to afford the phenyl pentadiene diol **22** directly. Subsequent oxidation of the allylic alcohols provided the diketone **23**. Unfortunately, this cross-conjugated diketone readily decomposed in the presence of Lewis acids. In addition, attempted thermal cycloadditions of **23** failed to give **24**. This appears to be a consequence of the reduced dienophilic character of **23** due to its extended conjugation, combined with the bulky phenyl group and the presence of a single methylene unit in the tether. This excessive planarity precluded the formation of the required Diels–Alder transition-state conformation. The phenyl acetylide was replaced with propynyllithium, and the sequence was repeated; however, a second complication was discovered. The modified electronic environment and reduced size of the methyl substituent in the chelate resulted in a rapid oxy-Cope rearrangement of the intermediate magnesium alkoxide **25**. The resulting allene aldehyde enolate **26** decomposed under the reaction conditions and necessitated the abandonment of this procedure.



Another variation was investigated, based on related studies by Shea and co-workers (4) who incorporated an oxygen in the tether, to prepare an A-ring cycloheaxadiene. Ring systems of type **31** are desirable because of the increased potency of C14-substituted taxoids (1). The addition of trimethylsilylethynyl lithium to the unsaturated aldehyde **17a** was converted to the alternative Diels–Alder precursor **29**

Scheme 5. Reagents and conditions: (*a*) (*i*) TMS–acetylene, BuLi, THF, –78 °C, 30 min; (*ii*) **17a**, –78 °C, 1 h, 89%; (*b*) TBAF, THF, rt, 1 h, 85%; (*c*) Dess–Martin periodinane, CH_2Cl_2, rt, 1 h, 86%; (*d*) Et_2AlCl, CH_2Cl_2, –78 °C to 0 °C, 5 min, 62%.

Scheme 6.

with the intention of preparing **31**. Experimentally, the heterocyclic cycloaddition adduct **30**, containing a seven-membered ring, was formed exclusively (Scheme 5).

In the course of these investigations, several additional subtleties of these Diels–Alder precursors were uncovered. It was anticipated, in view of the success of the cyclization of **8** to **9**, that the cyclization of **32** under Lewis-acid conditions should also be straightforward. This would permit a "Robinson annulation"-type approach for the attachment of the C ring (Scheme 6). However, when members of the family represented by **32** in which the C3 substituent is hydrogen were investigated, they were completely inert under the cycloaddition reaction conditions above. These experiments revealed that an important nonbonded interaction played a key role in the success of these cycloadditions. A substituent at the C3 position (taxane numbering, **34**) is required to ensure the dienophile attains the required conformation. This interaction causes the enone to fold under the diene, to ensure the requisite transition state for the cycloaddition. The examples in Scheme 3 confirm this effect.

Additional examples with C3 allyl substituents are discussed in the following paper. Thus the vinyl methyl at C8 may be replaced by hydrogen (**8c**), but the group at C3 is more important than the substituent at C8.

It will be obvious that we intended to attach the C ring to the diene adducts **9** by a second Diels–Alder reaction of either an intermolecular or intramolecular variety, the latter via attachment of an ester dienophile to the C9 centre. However, a number of attempts to elaborate the ABC-ring core from **9** with a suitable C-ring dienophile via Diels–Alder protocols were unsuccessful (Scheme 6). Several activated dienophiles (maleic anhydride, *N*-phenylmaleimide) and even "relatively flat" diethyl acetylenedicarboxylate were investigated, but these reactions failed to yield significant amounts of the desired adducts. The stereochemical control available from an allylic hydroxyl or ether group in cycloadditions is well established (15). Reduction of the carbonyl in **9a** gave **36**, and protection afforded the *p*-methoxybenzyl ether (not illustrated). These compounds also failed to react with the same three dienophiles, although in these cases,

© 2004 NRC Canada

only the starting materials were recovered. Consequently, other variations were examined. These alternative protocols initially included modification of the vinyl silyl group present in **8b** (Scheme 3). Halodesilylation to afford the vinyl bromide in place of the C8 methyl substituent would have permitted subsequent palladium couplings for ring C appendages. Unfortunately, the desired transformation failed. However, an efficient method for attaching the C ring is described in the following paper.

Experimental section

Reagents, unless otherwise noted, were purchased from the Aldrich Chemical Company and used as received. Reaction solvents were distilled under a nitrogen atmosphere prior to use unless otherwise stated. Diethyl ether (Et_2O) and tetrahydrofuran (THF) were distilled from Na metal and benzophenone ketyl, while dichloromethane (CH_2Cl_2) was distilled from calcium hydride (CaH_2). All other solvents used were reagent grade.

All manipulations were carried out under a nitrogen atmosphere in flame-dried glassware. Analytical thin-layer chromatography (TLC) was performed on commercial aluminum sheets precoated (0.2 mm layer thickness) with silica gel 60 F_{254} (E. Merck), visualized with a UV_{254} lamp (Spectroline Longlife filter), and stained with 20% phosphomolybdic acid in ethanol (Aldrich Chemical Company). Column chromatography on silica gel (60 Å, 230–400 mesh, E. Merck) was performed with hexanes and ethyl acetate (EtOAc).

Melting points were determined in capillary tubes with a Thomas-Hoover unit-melt apparatus and are uncorrected. FT-IR spectra were recorded on a Bomem Michelson 100 FT-IR spectrometer, with samples loaded as neat films on NaCl plates. All ^{1}H and ^{13}C NMR spectra were obtained on a 500 MHz Brüker AMX500 or a 300 MHz Brüker AMX300 in $CDCl_3$ (referenced to the residual solvent signals at δ 7.24 and 77.00 ppm for ^{1}H and ^{13}C, respectively) or C_6D_6 (referenced to the residual solvent signals at δ 7.15 and 127.00 ppm for ^{1}H and ^{13}C, respectively). Features of peaks in the ^{1}H NMR spectra are labeled in brackets after each chemical shift in the following order: multiplicity (s = singlet, d = doublet, t = triplet, q = quartet, m = multiplet), coupling constant, and integration. Mass spectra (MS) were determined on a V.G. micromass 7070 HS instrument, using an ionization energy of 70 eV. Elemental analyses were conducted by M-H-W Laboratories (Phoenix, Arizona, U.S.A.). The purity of the title compounds were judged to be >95% pure, as determined by a combination of GC–MS, ^{1}H NMR, and ^{13}C NMR analysis.

1,1-Dibromo-2,2,3,3-tetramethyl-cyclopropane (11)

Bromoform (80.0 mL, 916 mmol) was added dropwise by means of an addition funnel to a stirred suspension of 2,3-dimethyl-2-butene **10** (50.0 mL, 421 mmol) and potassium *tert*-butoxide (86.4 g, 770 mmol) in pentane (150 mL) at 0 °C over a period of 1 h. After warming to 21 °C, stirring was continued for another 2 h prior to the addition of water (200 mL). The layers were separated, and the aqueous layer was extracted with hexanes (2 × 150 mL). The combined organic extracts were washed with brine (4 × 80 mL), dried ($MgSO_4$), filtered, and concentrated under reduced pressure. Cold methanol (100 mL) was added to the residue, and the solution was cooled to 0 °C. The resulting precipitate was then collected by filtration, washed with cold methanol (20 mL), and allowed to dry in air. The mother liquor was concentrated under reduced pressure, and the precipitation cycle was repeated to yield more of the white crystalline solid (75 g, 71%). mp = 77 to 78 °C. ^{1}H NMR ($CDCl_3$, 300 MHz) δ: 1.25 (s, 12H). ^{13}C NMR ($CDCl_3$, 75 MHz) δ: 18.4, 35.5, 58.7.

3-Bromo-2,4-dimethyl-penta-1,3-diene (12)

1,1-Dibromo-2,2,3,3-tetramethyl-cyclopropane **11** (28.7 g, 118 mmol) was slowly heated with a propane torch, and the resulting liquid was collected by distillation between 120–140 °C. The distillate was further purified by two additional distillations. The product was treated with NaOH pellets for 0.5 h and then filtered through glass wool to afford a colorless liquid (15.7 g, 80%). The product was stored at –20 °C over grains of NaOH. ^{1}H NMR ($CDCl_3$, 300 MHz) δ: 1.73 (s, 3H), 1.75 (s, 3H), 1.82 (s, 3H), 4.73–4.75 (m, 1H), 4.89–4.91 (m, 1H). ^{13}C NMR ($CDCl_3$, 75 MHz) δ: 17.0, 17.2, 19.8, 107.8, 111.9, 133.4, 145.7.

3-Isopropenyl-4-methyl-pent-3-en-1-ol (13)

A solution of 3-bromo-2,4-dimethylpenta-1,3-diene **12** (13.5 g, 77.0 mmol) in THF (235 mL) at –78 °C was added to a stirred solution of *tert*-butyllithium (100.0 mL, 170.0 mmol, 1.7 mol L^{-1} in pentane) cooled to –78 °C. After 0.5 h, ethylene oxide (39 mL) was added via a cannula. The resulting solution was subsequently stirred for 1 h at –78 °C and then for 1 h at 21 °C. Water (200 mL) was then added; the layers were separated, and the aqueous layer was extracted with ether (4 × 100 mL). The combined organic extracts were dried ($MgSO_4$), filtered, and concentrated under reduced pressure. Purification by flash chromatography (silica gel, ethyl acetate – hexanes) provided the title compound as a colorless liquid (9.0 g, 83%). IR (neat) (cm^{-1}) ν: 3357, 2923, 1623. ^{1}H NMR ($CDCl_3$, 300 MHz) δ: 0.90 (s, 1H), 1.67 (s, 3H), 1.69 (s, 3H), 1.75 (s, 3H), 2.37 (t, J = 6.7 Hz, 2H), 3.60 (t, J = 6.7 Hz, 2H), 4.54–4.56 (m, 1H), 4.93–4.95 (m, 1H). ^{13}C NMR ($CDCl_3$, 75 MHz) δ: 20.3, 22.2, 22.9, 34.2, 61.6, 113.9, 128.9, 132.9, 146.7. HR-MS (EI) *m*/*z* calcd. for $C_9H_{16}O$: 140.1201; found: 140.1213.

4-Methyl-3-vinyl-pent-3-enal (6)

Dess–Martin periodinane (8.30 g, 19.6 mmol) was added to a solution of 3-isopropenyl-4-methyl-pent-3-en-1-ol **13** (2.50 g, 17.8 mmol) in dichloromethane (30 mL) at 21 °C. The resulting solution was stirred for 0.5 h prior to dilution with a 10% aq. solution of NaOH (30 mL). The layers were separated, and the organic layer was extracted with dichloromethane (3 × 30 mL). The combined organic extracts were dried ($MgSO_4$), filtered, and concentrated under reduced pressure to afford the title compound as a colorless liquid (2.34 g, 95%). IR (neat) (cm^{-1}) ν: 2923, 1706, 1630. ^{1}H NMR ($CDCl_3$, 300 MHz) δ: 1.66 (s, 3H), 1.73 (s, 6H), 3.12 (d, J = 2.6 Hz, 2H), 4.62–4.64 (m, 1H), 4.93–4.96 (m, 1H), 9.52 (t, J = 2.6 Hz, 1H). ^{13}C NMR ($CDCl_3$, 75 MHz) δ: 20.5, 22.2, 22.5, 47.1, 114.6, 127.4, 131.9, 146.3, 200.3. HR-MS (EI) *m*/*z* calcd. for $C_9H_{14}O$: 138.1045; found: 138.1049.

3-Trimethylsilanyl-prop-2-yn-1-ol (3b)

Butyl lithium (189 mL, 434 mmol, 2.3 mol L^{-1} in hexane) was added to a solution of propargyl alcohol (11.0 mL, 189 mmol) in THF (300 mL) cooled to –78 °C. After 45 min, chlorotrimethylsilane (57.6 mL, 453 mmol) was added, and the solution was warmed to 21 °C for 3 h. After cooling to 0 °C, 10% aq. sulfuric acid (250 mL) was added; the layers were separated after 15 min, and the aqueous layer was extracted with ether (2 × 150 mL). The combined organic extracts were washed with brine (2 × 100 mL), dried ($MgSO_4$), filtered, and concentrated under reduced pressure. Purification by flash chromatography (silica gel, ether – petroleum ether) provided the title compound as a colorless oil (15.1 g, 62%). IR (neat) (cm^{-1}) ν: 3324, 2961, 2901, 2177. ^1H NMR ($CDCl_3$, 300 MHz) δ: 0.15 (s, 9H), 1.8 (s, 1H), 4.24 (s, 2H). ^{13}C NMR ($CDCl_3$, 75 MHz) δ: 0.13, 51.9, 91.0, 104.2. HR-MS (EI) *m/z* calcd. for $C_6H_{12}OSi$ ($[M]^+$): 128.0657; found: 128.0686.

General procedure for the carbometallation of the propargylic alcohols

Vinylmagnesium chloride (2.5 equiv.) was added to a solution of the propargylic alcohol (1.0 equiv.) in cyclohexane ([alcohol] = 1.0 mol L^{-1}) at 21 °C. The solution was heated at reflux for 20 h and cooled to –78 °C, and 4-methyl-3-vinyl-pent-3-enal **6** (0.5 equiv.) in ether ([aldehyde] = 0.3 mol L^{-1}) was added. The solution was stirred for 30 min at –78 °C, for 1 h at 0 °C, and for 1 h at 21 °C. The reaction was subsequently cooled to 0 °C, and a saturated aqueous solution of NH_4Cl added. The layers were separated, and the aqueous layer was extracted with dichloromethane. The combined organic extracts were washed with brine, dried ($MgSO_4$), filtered, and concentrated under reduced pressure. The crude material was purified by flash chromatography (silica gel, ether – petroleum ether).

6-Isopropenyl-3,7-dimethyl-2-vinyl-octa-2,6-diene-1,4-diol (7a)

71% from **3a**. IR (neat) (cm^{-1}) ν: 3355, 2964, 2917, 1630, 1442, 1374, 998, 900. ^1H NMR ($CDCl_3$, 500 MHz) δ: 1.65 (s, 3H), 1.66 (s, 3H), 1.73 (s, 3H), 1.82 (s, 3H), 2.19 (dd, *J* = 14.0, 5.2 Hz, 1H), 2.54 (s, 1H), 2.63 (dd, *J* = 14.0, 8.5 Hz, 1H), 4.24 (d, *J* = 11.9 Hz, 1H), 4.36 (d, *J* = 11.9 Hz, 1H), 4.67 (s, 1H), 4.85 (dd, *J* = 8.5, 5.2 Hz, 1H), 4.98 (s, 1H), 5.09 (dd, *J* = 11.1, 1.2 Hz, 1H), 5.42 (dd, *J* = 17.5, 1.2 Hz, 1H), 6.62 (dd, *J* = 17.5, 11.1 Hz, 1H). ^{13}C NMR ($CDCl_3$, 125 MHz) δ: 13.0, 20.2, 22.0, 22.6, 36.9, 57.5, 70.1, 114.1, 114.2, 129.0, 132.5, 133.4, 134.8, 141.0, 146.7. HR-MS (EI) *m/z* calcd. for $C_{15}H_{24}O_2$ ($[M]^+$): 236.1777; found: 236.1791.

6-Isopropenyl-7-methyl-3-trimethylsilanyl-2-vinyl-octa-2,6-diene-1,4-diol (7b)

56% from **3b**. IR (neat) (cm^{-1}) ν: 3408, 3075, 2958, 2913, 1631. ^1H NMR ($CDCl_3$, 500 MHz) δ: 0.21 (s, 9H), 1.72 (s, 3H), 1.76 (s, 3H), 1.79 (s, 3H), 2.06 (dd, *J* = 14.4, 2.8 Hz, 1H), 2.69 (dd, *J* = 14.4, 10.8 Hz, 1H), 4.25 (d, *J* = 11.7 Hz, 1H), 4.54 (d, *J* = 11.7 Hz, 1H), 4.62 (s, 1H), 4.67 (dd, *J* = 10.8, 2.8 Hz, 1H), 5.03 (s, 1H), 5.17 (dd, *J* = 11.0, 0.9 Hz, 1H), 5.47 (dd, *J* = 17.3, 0.9 Hz, 1H), 6.69 (dd, *J* = 17.3, 11.0 Hz, 1H). ^{13}C NMR ($CDCl_3$, 125 MHz) δ: 1.3, 20.2, 21.9, 23.3, 38.1, 58.6, 72.1, 114.3, 114.6, 130.2, 133.1, 138.0, 146.0, 146.6, 147.5. HR-MS (EI) *m/z* calcd. for $C_{17}H_{28}OSi$ ($[M^+ – H_2O]$): 276.1909; found: 276.1932.

6-Isopropenyl-7-methyl-2-vinyl-octa-2,6-diene-1,4-diol (7c)

Sodium methoxide (1.93 g, 34.0 mmol) was added to a solution of diol **7b** (2.50 g, 8.50 mmol) in methanol (40 mL) at 21 °C. The solution was heated at reflux for 2 h and then concentrated. A saturated aqueous solution of NH_4Cl (50 mL) was added; the layers were separated, and the aqueous layer was extracted with ether (2 × 40 mL). The combined organic extracts were washed with brine (2 × 50 mL), dried ($MgSO_4$), filtered, and concentrated under reduced pressure. Purification by flash chromatography (silica gel, ether – petroleum ether) provided the title compound as a colorless oil (1.64 g, 87%). IR (neat) (cm^{-1}) ν: 3308, 2908, 2859, 1630, 1606. ^1H NMR ($CDCl_3$, 500 MHz) δ: 1.69 (s, 3H), 1.70 (s, 3H), 1.76 (s, 3H), 2.27 (dd, *J* = 13.9, 5.1 Hz, 1H), 2.50 (dd, *J* = 13.9, 8.5 Hz, 1H), 4.27 (d, *J* = 12.1 Hz, 1H), 4.32 (d, *J* = 12.1 Hz, 1H), 4.35 (ddd, *J* = 8.5, 7.8, 5.1 Hz, 1H), 4.58 (s, 1H), 4.98 (s, 1H), 5.10 (d, *J* = 10.9 Hz, 1H), 5.38 (d, *J* = 17.6 Hz, 1H), 5.61 (d, *J* = 7.8 Hz, 1H), 6.25 (dd, *J* = 17.6, 10.9 Hz, 1H). ^{13}C NMR ($CDCl_3$, 125 MHz) δ: 20.2, 21.9, 22.4, 38.6, 57.2, 66.9, 114.0, 114.2, 129.8, 132.2, 136.3, 138.1, 139.5, 146.2. HR-MS (EI) *m/z* calcd. for $C_{14}H_{20}O$ ($[M^+ – H_2O]$): 204.1514; found: 204.1503.

General procedure for silylation of the primary alcohols

tert-Butyldimethylsilyl chloride (1.1 equiv.) and DMAP (1.1 equiv.) were sequentially added to a solution of the diol (1.0 equiv.) in dichloromethane ([diol] = 1.0 mol L^{-1}) at 0 °C, and the solution was stirred for 18 h at 21 °C. A saturated aqueous solution of $NaHCO_3$ was then added; the layers were separated, and the aqueous layer was extracted with ether. The combined organic extracts were washed with brine, dried ($MgSO_4$), filtered, and concentrated under reduced pressure. The crude material was purified by flash chromatography (silica gel, ether – petroleum ether).

3-(*tert*-Butyl-dimethyl-silanyloxymethyl)-7-isopropenyl-4,8-dimethyl-nona-1,3,7-trien-5-ol (14a)

92% from **7a**. General procedure for methylation of the secondary alcohols

Sodium hydride (3.0 equiv., 60% dispersion in mineral oil) was added to a solution of the alcohol (1.0 equiv.) in THF ([alcohol] = 1.0 mol L^{-1}) at 0 °C. After 30 min, iodomethane (20.0 equiv.) was added, and the solution was stirred for 18 h at 21 °C. A saturated aqueous solution of NH_4Cl was subsequently added; the layers were separated, and the aqueous layer was extracted with dichloromethane. The combined organic extracts were washed with brine, dried ($MgSO_4$), filtered, and concentrated under reduced pressure. The crude material was purified by flash chromatography (silica gel, ether – petroleum ether).

General procedures for oxidation of the secondary alcohols

Oxalyl chloride (1.5 equiv.) was added to a solution of DMSO (3.0 equiv.) in dichloromethane ([oxalyl chloride] = 1.0 mol L^{-1}) at –78 °C. After 5 min, the alcohol (1.0 equiv.) was added, and the solution was stirred for 1 h at –78 °C. Triethylamine (7.0 equiv.) was added, and the solution was warmed to 0 °C for 1 h. A saturated aqueous solution of NH_4Cl was added; the layers were separated, and the aqueous layer was extracted with ether. The combined organic extracts were washed with brine, dried ($MgSO_4$), filtered, and concentrated under reduced pressure. The crude material was purified by flash chromatography (silica gel, ether – petroleum ether).

The alcohol (1.0 equiv.) in THF was added to a solution of IBX (1.5 equiv.) in DMSO ([alcohol] = 1.0 mol L^{-1}) at 0 °C. The resulting solution was stirred for 3 h at 21 °C prior to the addition of water. Following filtration, the solution was extracted with ether. The combined organic extracts were washed with brine, dried ($MgSO_4$), filtered, and concentrated. The crude material was purified by flash chromatography (silica gel, ether – petroleum ether).

General procedures for Diels–Alder cyclizations

Diethylaluminum chloride (1.1 equiv., 1.0 mol L^{-1} in hexane) was added to a solution of ketone (1.0 equiv.) in dichloromethane ([ketone] = 1.0 mol L^{-1}) at –78 °C. The solution was slowly warmed to 0 °C and, after 5 min, cooled to –78 °C. A saturated aqueous solution of $NaHCO_3$ was added; the layers were separated, and the aqueous layer was extracted with ether. The combined organic extracts were washed with brine, dried ($MgSO_4$), filtered, and concentrated under reduced pressure. The crude material was purified by flash chromatography (silica gel, ether – petroleum ether).

Borontrifluoride etherate (1.0 equiv.) was added to a solution of ketone (1.0 equiv.) in dichloromethane (such that [ketone] = 1.0 mol L^{-1}) at –78 °C, and the solution was stirred for 2 h. A saturated aqueous solution of $NaHCO_3$ was then added; the layers were separated, and the aqueous layer was extracted with ether. The combined organic extracts were washed with brine, dried ($MgSO_4$), filtered, and concentrated under reduced pressure. The crude material was purified by flash chromatography (silica gel, ether – petroleum ether).

HR-MS (EI) *m/z* calcd. for $C_{18}H_{24}O$ ([M$^+$ – H_2O]): 256.1827; found: 256.1840.

6-Ethynyl-3-methoxy-4,9,10,10-tetramethyl-5-vinyl-7-oxa-bicyclo[4.3.1]deca-1(9),4-diene (30)

Diethylaluminium chloride (1.10 mL, 1.10 mmol, 1.0 mol L^{-1} in hexane) was added to a solution of ketone **29** (0.272 g, 1.00 mmol) in dichloromethane (20 mL) at –78 °C. The solution was slowly warmed to 0 °C and, after 5 min, cooled to –78 °C. A saturated aqueous solution of $NaHCO_3$ (20 mL) was added; the layers were separated, and the aqueous layer was extracted with ether (2 × 30 mL). The combined organic extracts were washed with brine (2 × 30 mL), dried ($MgSO_4$), filtered, and concentrated under reduced pressure. Purification by flash chromatography (silica gel, ether – petroleum ether) provided the title compound as a colorless oil (0.167 g, 62%). IR (neat) (cm^{-1}) ν: 3285, 2974, 2931, 2821, 1608, 1561. ^{1}H NMR (C_6D_6, 500 MHz) δ: 1.18 (d, *J* = 13.5 Hz, 1H), 1.36 (s, 3H), 1.37 (s, 3H), 1.44 (s, 3H), 1.51 (dd, *J* = 13.8, 10.2 Hz, 1H), 1.92 (d, *J* = 13.5 Hz, 1H), 2.01 (s, 3H), 2.72 (s, 1H), 2.85 (dd, *J* = 13.8, 7.0 Hz, 1H), 3.14 (s, 3H), 3.53 (dd, *J* = 10.2, 7.0 Hz, 1H), 5.10 (dd, *J* = 11.9, 1.5 Hz, 1H), 5.38 (dd, *J* = 18.0, 1.5 Hz, 1H), 6.89 (dd, *J* = 18.0, 11.9 Hz, 1H). ^{13}C NMR (C_6D_6, 75 MHz) δ: 21.5, 22.0, 22.2, 24.8, 30.7, 37.6, 44.2, 57.0, 77.6, 78.9, 79.7, 81.3, 113.9, 127.3, 129.2, 131.3, 133.0, 136.3. HR-MS (EI) *m/z* calcd. for $C_{18}H_{24}O_2$ ([M]$^+$): 272.1776; found: 272.1743.

Conclusion

We have successfully extended the magnesium-mediated carbometallation protocol developed in our laboratories to more complex systems and studied various aspects in more depth. In addition, the nuances of the *cis*-alkene tether controlled intramolecular Diels–Alder reactions to bicyclo-

[5.3.1]undecenones have been delineated. A key feature is the diastereoselectivity derived from Lewis acid complexation, which implies that enantioselective cycloaddition may eventually be feasible. A direct route to these taxane AB-ring building blocks has been established for future elaboration into the complete nucleus by different procedures. In total, these procedures provide direct access to functionalized molecules that may be employed for a variety of synthetic objectives.

Part 2: Efficient strategies for the construction of variably substituted bicyclo[5.3.1]undecenones (AB-taxane ring systems) and their conversion to tricyclo[9.3.1.0^{3,8}]pentadecenones (ABC taxane ring systems) and bicyclo[2.2.2]octanones[1]

Nidia P. Villalva-Servín, Alain Laurent, and Alex G. Fallis

Abstract: The extension of our strategies for the construction of cyclic molecules containing variably substituted bicyclo[5.3.1]undecenones (AB taxane ring systems) for the synthesis of the tricyclo[9.3.1.0^{3,8}]pentadecenone (ABC taxane ring system) and bicyclo[2.2.2]octanones are described. These routes employ a multi-component coupling protocol that employs sequential magnesium-mediated carbometallation of allyl-substituted propargyl alcohols followed by diastereoselective Lewis acid catalyzed intramolecular Diels–Alder reactions (IMDA). Subsequent ring-closing metathesis (RCM) afforded the ABC taxane core structure. Enone accelerated [3,3] sigmatropic rearrangements (Cope rearrangements) generated the bicyclo[2.2.2]octanone nucleus. In the presence of a Lewis acid, the dienophile precursor underwent a tandem reaction via the adduct directly to the bicyclo[2.2.2]octanones. This is the first example of a novel enone accelerated carbocycle Cope rearrangement and provides direct access to bicyclo[2.2.2]octanones by a new route that compliments the traditional cyclohexadiene cycloaddition approach.

Key words: magnesium chelate, Lewis acid, taxanes, Diels–Alder, sigmatropic rearrangement, oxy-Cope, ring-closing metathesis, bicyclo[2.2.2]octanone.

Résumé : On décrit une extension de nos stratégies développées pour la construction de molécules cycliques contenant des bicyclo[5.3.1]undécénones (noyaux AB du taxane) portant divers substituants à la synthèse d'un tricyclo[9.3.1.0^{3,8}]pentadécénone (noyaux ABC du taxane) et de bicyclo[2.2.2]octanones. Ces voies impliquent un protocole de couplage à plusieurs composants qui fait appel à des réactions séquentielles de carbométallation catalysée par le magnésium d'alcools propargyliques portant un substituant allyle et de réactions diastéréosélectives de Diels–Alder intramoléculaires catalysées par un acide de Lewis. La réaction subséquente de métathèse de fermeture de cycle conduit au noyau fondamental ABC du taxane. Des réarrangements sigmatropiques [3,3] accélérés de l'énone (réarrangements de Cope) génèrent le noyau bicyclo[2.2.2]octanone. En présence d'un acide de Lewis, le précurseur diénophile donne lieu à une réaction en tandem, par le biais de l'adduit, qui conduit directement à la bicyclo[2.2.2]octanone. Cette réaction correspond au premier exemple d'un nouveau réarrangement de carbocycle de Cope accéléré par une énone et elle permet d'accéder directement aux bicyclo[2.2.2]octanones par une nouvelle voie qui est un complément à l'approche traditionnelle des cycloadditions au cyclohexadiène.

Mots clés : chélate magnésien, acide de Lewis, taxanes, Diels–Alder, réarrangement sigmatropique, oxy-Cope, métathèse avec cyclisation, bicyclo[2.2.2]octanone.

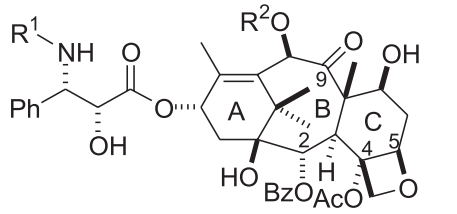
bicyclo[5.3.1]undecenone skeleton. These investigations have been expanded to a synthesis of the carbocyclic ABC taxane core via a carbometallation–cycloaddition-ring-closing metathesis strategy. In addition, the Diels–Alder dienophile precursors may be converted in a tandem reaction to bicyclo[2.2.2]octanones (Fig. 1).

Carbometallation – intramolecular cycloaddition strategy



We have described our magnesium-mediated carbometallation of propargyl alcohols followed by diastereoselective Lewis acid catalyzed intramolecular Diels–Alder reactions for the preparation of bicyclo[5.3.1]undecenones (AB-taxane ring systems), as illustrated in Scheme 1. Unfortunately, as discussed in the preceding paper, the proposed [4 + 2] combinations with the family represented by **9** or **11** failed to give the desired adduct(s) **10**.

Cope rearrangements towards ring C taxanes and bicyclo[2.2.2]octanones

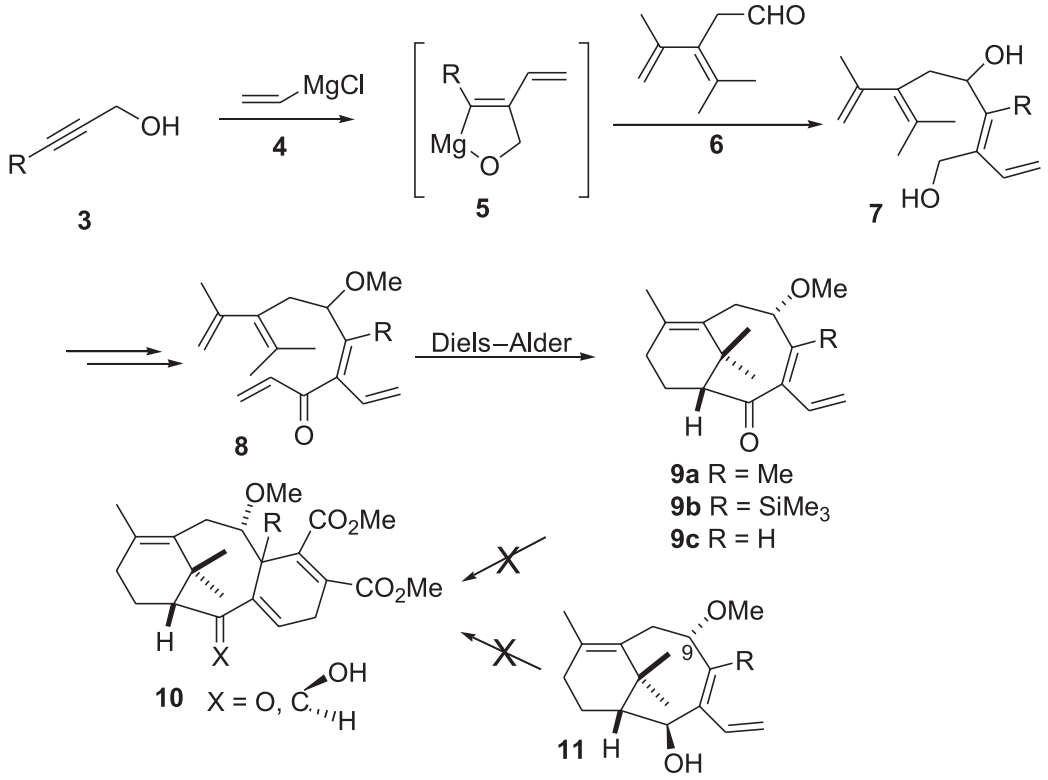
Clearly, a new approach was required to extend and build on this knowledge and capitalize on our ring assembly protocol. An efficient method was required to attach the C ring and assemble the complete ABC taxane nucleus. Two additional options appeared attractive, but both required repeating the synthesis from the beginning. Our initial plan was to prepare **14** from **9d**, as illustrated in Scheme 2. Based on previous studies, we have established that nucleophilic attack at the C2 carbonyl occurred from the underside of **9a**. Thus, it was anticipated that an anion-based [3,3] sigmatropic rearrangement would deliver the allyl group from the concave side of the molecule and thus establish, after protonation, the correct *trans* ring stereochemistry of the taxane natural products. Addition of allyl Grignard to **9d** should generate the bis-allyl secondary alcohol **12**. A subsequent oxy-Cope rearrangement could then be employed to install the allyl functionality in **13** for ring-closing metathesis to the tricyclic skeleton **14** (Scheme 2). However, this sequence had an inherent risk, owing to the very reactive nature of the ring A and ring B olefins. This complication affected our plans but also provided an unexpected, synthetically useful transformation, discovered earlier (1) and summarized below.

The existence of atropisomerism in taxane ring systems is well established (2, 3). Variable temperature ^{1}H NMR was investigated to determine the conformational bias in the bicyclo[5.3.1]undecene type synthon **9a**. It was anticipated that the details of the carbonyl-*exo* and carbonyl-*endo* conformers could be examined for their synthetic potential and stereochemical bias. However, rather than the conformational isomerization expected, the enone **9a** underwent a facile Cope rearrangement (commencing at ~60 °C), to give the bicyclo[2.2.2]octanone product **15a** (Scheme 3). Experimentally, this [3,3]-sigmatropic rearrangement afforded the same bicyclic ketone **15a** directly in 71% yield after 3 h in refluxing toluene (Scheme 3). The temperature required (110 °C) to effect this transformation is significantly lower than most carbocyclic rearrangements of this type (4). Consequently, this rearrangement provides an attractive method

Fig. 1. Current taxoid drugs.

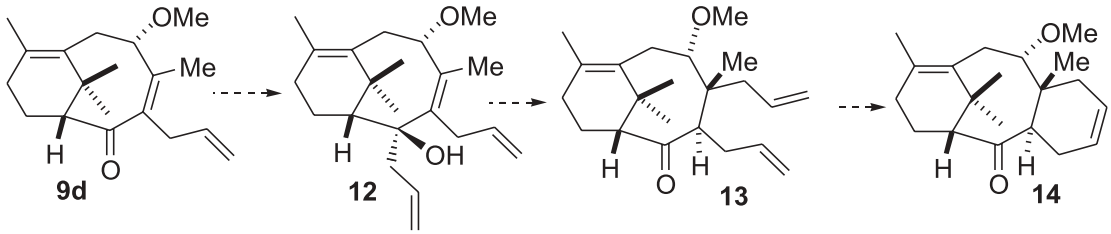
Paclitaxel **1** (Taxol®) R^1 = Bz, R^2 = Ac

Docetaxel **2** (Taxotere®) R^1 = Boc, R^2 = H



for the preparation of densely substituted bicyclooctenones **15**. The reverse transformation from an oxy-Cope bicyclo[2.2.2]octene precursor was employed in previous approaches to the taxane AB ring system (5). The ease of the rearrangement in **9a** is a consequence of the excellent alignment of the reactive diene units in a pre-organized chair-like conformation that mimics the required transition state. Our published X-ray analysis of **9a** (1) revealed that the C3—C8 separation is 3.13 Å, a separation less than the 3.2–3.3 Å c-d separation required for enediynes to undergo spontaneous cycloaromatization at room temperature (6, 7). However, an additional, beneficial influence from the carbonyl group is also implicated. Reduction of the carbonyl in **9a** to provide alcohol **11** (Scheme 1) and subsequent protection as the *p*-methoxybenzyl ether produced compound **16**, which was stable to prolonged reflux (20 h) in toluene, and none of **17** was observed (Scheme 3). Additional evidence for the importance of the conjugated carbonyl and its electronic influence was illustrated by the ease with which the tandem rearrangement **8** to **9** to **15** occurred at 0–22 °C in the presence of a catalytic amount of Lewis acid (Et_2AlCl, 70%–92%).

For subsequent synthetic applications this tandem conversion provides an attractive entry to highly functionalized bicyclo[2.2.2]octanones, which will complement the traditional route from cycloaddition of cyclohexadienes. These substitution patterns are difficult to achieve by traditional routes (for example, sorbiquinol, Fig. 2, (8)). This accelerating influence exerted by a conjugated carbonyl group in a carbocyclic [3,3] sigmatropic rearrangement does not appear to have been observed prior to our discovery. We are currently investigating the potential and generality of this interesting transformation.



Based on the data above, it seemed reasonable to conclude that the anionic oxy-Cope rearrangement of a potassium salt should proceed at approximately 40–50 °C (9), and thus, the carbocyclic [3,3] rearrangement would not be competitive, as a consequence of the higher energy required. The adduct **9d** was synthesized in a parallel fashion to examine the validity of this assumption, as outlined in Scheme 4. Allylation of the ketone **9d** provided the allyl alcohol **13**. However, at room temperature the potassium salt derived from treatment with potassium *tert*-butoxide did not rearrange to the desired bis-allyl ketone **18** (Scheme 5) but followed a different pathway. Instead, the loss of the allyl substituent followed by double bond migration to **19** was observed. The use of potassium hydride provided no improvement and generated the isomeric ketone **20**. The failure of these mild conditions prompted a single experiment under more forcing conditions

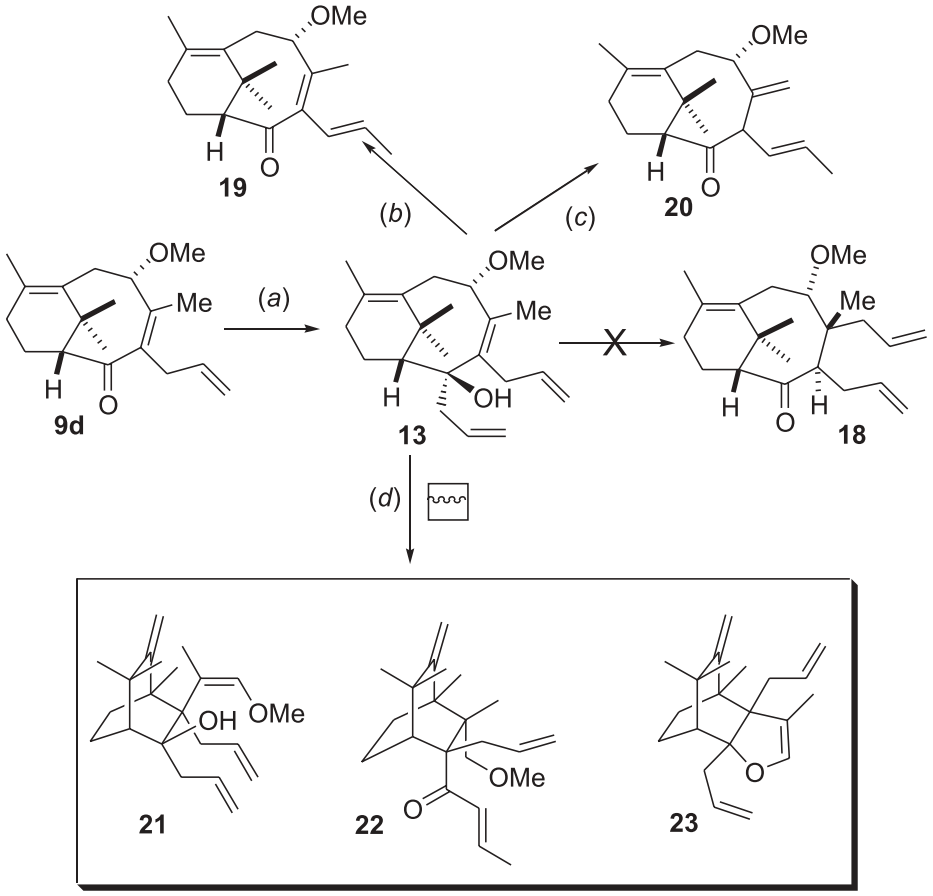
in which treatment of **13** with 1,8-diazobiocyclo[5.4.0]undec-7-ene (DBU) under microwave irradiation also failed to produce the desired ring C precursor but gave instead the mixture of bicyclo[2.2.2]octenes **21** (7%), **22** (16%), and **23** (19%).

Ring-closing metathesis (RCM) for ring C

Despite the failure of the previous approach, the idea of installing the C ring by ring-closing metathesis was attractive. This variation for ring C is represented by the transformation **9f** to **24** in Scheme 6. One option was the introduction of a C3 allyl group by modification of the vinyl silyl group present in **9e** (Scheme 4). However, bromodesilylation failed and thus eliminated the possibility of direct palladium coupling from an advanced intermediate.

Consequently the strategy was modified (Scheme 6) to commence with an allyl-substituted propargyl alcohol **3c** followed by exposure to an allyl Grignard reagent for conversion to **8f**. Cycloaddition would generate the bicyclic ketone **9f** for conversion to the tricyclic compound **24**. The preparation of the desired Diels–Alder adduct **9f** and the precursor compounds is outlined in Scheme 4.



There appear to be two reports in which RCM approaches have been employed for the assembly of taxane AB (10) and BC (11) ring systems. However, the route in Scheme 6 for the construction of taxane ABC ring systems has not been explored. With the synthesis of the bicyclo[5.3.1]undecene **9f** completed it was anticipated that generation of the requisite cyclohexadiene **24** could be easily achieved. Indeed, treatment of **9f** with the second generation Grubbs' catalyst **30** ((4,5-dihydroIMES)(PCy_3)Cl_2Ru=CHPh) (12) gave rise to the desired tricyclo[$9.3.1.0^{3,8}$]pentadecane nucleus **24** in high yield (93%) (Scheme 7).

3-Trimethylsilanyl-prop-2-yn-1-ol (3b)

Butyl lithium (189 mL, 434 mmol, 2.3 mol L^{-1} in hexane) was added to a solution of propargyl alcohol (11.0 mL, 189 mmol) in THF (300 mL) cooled to –78 °C. After 45 min, chlorotrimethylsilane (57.6 mL, 453 mmol) was added, and the solution was warmed to 21 °C for 3 h. After cooling to 0 °C, 10% aqueous sulfuric acid (250 mL) was added, and the layers were separated after 15 min, and the aqueous layer was extracted with ether (2 × 150 mL). The combined organic extracts were washed with brine (2 × 100 mL), dried ($MgSO_4$), filtered, and concentrated under reduced pressure. Purification by flash chromatography (silica gel, ether – petroleum ether) provided the title compound as a colorless oil (15.1 g, 62%). IR (neat) (cm^{-1}) ν: 3324, 2961, 2901, 2177. ^1H NMR ($CDCl_3$, 300 MHz) δ: 0.15 (s, 9H), 1.8 (s, 1H), 4.24 (s, 2H). ^{13}C NMR ($CDCl_3$, 75 MHz) δ: 0.13, 51.9, 91.0, 104.2. HR-MS (EI) *m/z* calcd. for $C_6H_{12}OSi$ ($[M]^+$): 128.0657; found: 128.0686.

3-Allyl-prop-2-yn-1-ol (3c) (14)

Propargyl alcohol (5.8 mL, 0.10 mol) was added to a stirred solution of acetone (400 mL), followed by allyl bromide (10.4 mL, 0.120 mol), potassium carbonate (27.6 g, 0.200 mol), sodium iodide (30 g, 0.20 mol), and copper iodide (19.0 g, 0.100 mol). The reaction was stirred under nitrogen at 21 °C for 5 h, quenched with 1 N HCl (120 mL), diluted with water (500 mL), and stirred for 10 min. The reaction mixture was subsequently filtered and extracted with diethyl ether (5 × 100 mL). The combined organic extracts were dried ($MgSO_4$), filtered, and concentrated under reduced pressure. The title compound was isolated as a colourless oil and purified by distillation (80–82 °C at 3 mmHg (1 mmHg = 133.322 Pa), 92%). IR (neat) (cm^{-1}) ν: 3351, 3086–2983, 2918–2872, 1420, 918, 780. ^1H NMR (C_6D_6, 300 MHz) δ: 2.33 (s, 1H), 2.94–2.98 (m, 2H), 4.24 (t, *J* = 2.2 Hz, 2H), 5.07 (ddd, *J* = 10.0, 3.3, 1.6 Hz, 1H), 5.27 (ddd, *J* = 17.0, 3.5, 1.7 Hz, 1H), 5.80 (dddd, *J* = 16.6, 10.6, 6.0, 5.6 Hz, 1H). ^{13}C NMR (C_6D_6, 75 MHz) δ: 23.2, 51.1, 81.9, 82.3, 116.1, 132.8. HR-MS (EI) *m/z* calcd. for C_6H_8O ($[M]^+$): 96.05752; found: 96.05597.

General procedure for the carbometallation of the propargylic alcohols

Vinyl- or allylmagnesium chloride (2.5 equiv.) was added to a solution of the propargylic alcohol (1.0 equiv.) in cyclohexane ([alcohol] = 1.0 mol L^{-1}) at 21 °C. The solution was heated at reflux for 20 h and cooled to –78 °C, and 4-methyl-3-vinyl-pent-3-enal **6** (0.5 equiv.) in ether ([aldehyde] = 0.3 mol L^{-1}) was added. The solution was stirred for 30 min at –78 °C, for 1 h at 0 °C, and for 1 h at 21 °C. The reaction was subsequently cooled to 0 °C, and a saturated aqueous solution of NH_4Cl added. The layers were separated, and the aqueous layer was extracted with dichloromethane. The combined organic extracts were washed with brine, dried ($MgSO_4$), filtered, and concentrated under reduced pressure. The crude material was purified by flash chromatography (silica gel, ether – petroleum ether).

2-Allyl-6-isopropenyl-3,7-dimethyl-octa-2,6-diene-1,4-diol (7d)

79% from **3a**. IR (neat) (cm^{-1}) ν: 3361, 3076, 2976, 2915, 1635, 1010, 996, 902. ^1H NMR (C_6D_6, 300 MHz) δ: 1.67 (s, 3H), 1.74 (s, 3H), 1.75 (s, 3H), 1.77 (s, 3H), 2.25 (dd, *J* = 13.9, 5.6 Hz, 1H), 2.6 (dd, *J* = 13.9, 8.1 Hz, 1H), 2.95 (d, *J* = 6.2 Hz, 2H), 3.00 (s, br, 2H), 3.93 (d, *J* = 11.6 Hz, 1H), 4.31 (d, *J* = 11.6 Hz, 1H), 4.69 (dd, *J* = 2.6, 0.8 Hz, 1H), 4.83 (dd, *J* = 8.1, 5.7 Hz, 1H), 4.99 (dd, *J* = 10.0, 2.0 Hz, 1H), 5.00 (d, 1H), 5.05 (dd, *J* = 17.1, 2.0 Hz, 1H), 5.78 (dddd, *J* = 16.9, 10.2, 6.4, 6.4 Hz, 1H). ^{13}C NMR (C_6D_6, 75 MHz) δ: 13.0, 20.3, 22.1, 22.6, 36.3, 37.2, 60.8, 69.6, 114.3, 115.2, 128.9, 132.5, 133.6, 136.1, 137.3, 146.7. General procedures for oxidation of the primary alcohols

Oxalyl chloride (1.5 equiv.) was added to a solution of DMSO (3.0 equiv.) in dichloromethane ([oxalyl chloride] = 1.0 mol L^{-1}) at –78 °C. After 5 min, the alcohol (1.0 equiv.) was added, and the solution was stirred for 1 h at –78 °C. Triethylamine (7.0 equiv.) was added, and the solution was warmed to 0 °C for 1 h. A saturated aqueous solution of NH_4Cl was added; the layers were separated, and the aqueous layer was extracted with ether. The combined organic extracts were washed with brine, dried ($MgSO_4$), filtered, and concentrated under reduced pressure. The crude material was purified by flash chromatography (silica gel, ether – petroleum ether).

The alcohol (1.0 equiv.) in THF was added to a solution of *o*-iodoxybenzoic acid (IBX) (1.5 equiv.) in DMSO (such that [alcohol] = 1.0 mol L^{-1}) at 0 °C. The resulting solution was stirred for 3 h at 21 °C prior to the addition of water. Following filtration, the solution was extracted with ether. The combined organic extracts were washed with brine, dried ($MgSO_4$), filtered, and concentrated. The crude material was purified by flash chromatography (silica gel, ether – petroleum ether).

General procedures for Diels–Alder cyclizations

Diethylaluminum chloride (1.1 equiv., 1.0 mol L^{-1} in hexane) was added to a solution of ketone (1.0 equiv.) in dichloromethane ([ketone] = 1.0 mol L^{-1}) at –78 °C. The solution was slowly warmed to 0 °C and, after 5 min, cooled to –78 °C. A saturated aqueous solution of $NaHCO_3$ was added; the layers were separated, and the aqueous layer was extracted with ether. The combined organic extracts were washed with brine, dried ($MgSO_4$), filtered, and concentrated under reduced pressure. The crude material was purified by flash chromatography (silica gel, ether – petroleum ether).

Borontrifluoride etherate (1.0 equiv.) was added to a solution of ketone (1.0 equiv.) in dichloromethane (such that [ketone] = 1.0 mol L^{-1}) at –78 °C, and the solution was stirred for 2 h. A saturated aqueous solution of $NaHCO_3$ was then added; the layers were separated, and the aqueous layer was extracted with ether. The combined organic extracts were washed with brine, dried ($MgSO_4$), filtered, and concentrated under reduced pressure. The crude material was purified by flash chromatography (silica gel, ether – petroleum ether).

2,3-Diallyl-5-methoxy-4,8,11,11-tetramethyl-bicyclo[5.3.1]undeca-3,7-dien-2-ol (13)

Allylmagnesium chloride (1.3 mL, 2.6 mmol, 1.6 mol L^{-1} in THF) was added to a solution of ketone **9d** (0.376 g, 1.3 mmol) in ether (20 mL) at –78 °C. The solution was stirred for 1 h at –78 °C and for 30 min at 0 °C. A saturated aqueous solution of NH_4Cl (30 mL) was then added; the layers were separated, and the aqueous layer was extracted with ether (2 × 30 mL). The combined organic extracts were washed with brine (2 × 30 mL), dried ($MgSO_4$), filtered, and concentrated under reduced pressure. Purification by flash chromatography (silica gel, ether – petroleum ether) provided the title compound as a viscous oil (0.253 g, 59%). IR (neat) (cm^{-1}) ν: 3458, 3052–2814, 1640, 1463, 1093, 911. ^1H NMR (C_6D_6, 300 MHz) δ: 0.99 (s, 1H), 1.04 (s, 3H), 1.27–1.35 (m, 1H), 1.43 (s, 3H), 1.64 (s, 3H), 1.67–1.69 (m, 2H), 1.76 (s, 3H), 1.79–1.84 (m, 1H), 2.18 (dd, br, 1H), 2.33 (dd, *J* = 14.0, 6.2 Hz, 1H), 2.51 (dd, *J* = 17.3, 5.7 Hz, 1H), 2.58–2.70 (m, 2H), 2.74–2.90 (m, 2H), 3.30 (s, 3H), 4.99 (dd, *J* = 17.3 Hz, 2H), 5.05 (dd, *J* = 9.6 Hz, 2H), 5.73 (dddd, *J* = 16.7, 10.4, 6.1, 4.8 Hz, 1H), 5.87 (dddd, *J* = 17.2, 10.2, 7.6, 5.8 Hz, 1H), 5.93 (dd, *J* = 11.0, 6.3 Hz, 1H). ^{13}C NMR (C_6D_6, 75 MHz) δ: 15.0, 20.8, 21.3, 28.3, 29.3, 32.8, 36.5, 38.0, 39.9, 45.8, 52.3, 57.3, 81.1, 82.4, 115.1, 119.1, 131.2, 133.2, 135.6, 135.8, 137.7, 138.5. HR-MS (EI) *m/z* calcd. for $C_{22}H_{34}O_2$ ($[M]^+$): 330.2559; found: 330.2559.

Attempted oxy-Cope rearrangement

A solution of alcohol **13** (0.119 g, 0.360 mmol) and DBU (0.110 g, 0.720 mmol) in dry, deoxygenated toluene (10 mL) was heated in a quartz tube for 1 h at 220 °C. The solution

© 2004 NRC Canada

was then cooled to 21 °C, transferred to a round-bottom flask, and concentrated under reduced pressure. The residue was purified by flash chromatography (silica gel, ether – petroleum ether) to afford the compounds **21** (7%), **22** (16%), and **23** (19%) as a mixture of white solids.

Conclusion

We have demonstrated the utility of bis-allylpropargyl alcohol in our magnesium-mediated carbometallation protocol for the synthesis of the AB taxane ring by a *cis*-alkene tether controlled intramolecular Diels–Alder reaction, followed by closing metathesis (RCM), to generate a substituted tricyclo[9.3.1.0^{3,8}]pentadecenone (ABC taxane) ring system. We have discovered the first example of an enone accelerated Cope rearrangement. This isomerization of conjugated bicyclo[5.3.1]undecadienes provides a rapid entry into bicyclo[2.2.2]octanone skeletons that complements the more traditional [4 + 2] cyclizations from cyclohexadienes. We are examining the generality of this conjugative effect. In total, the procedures described above provide direct access to a number of useful unsaturated compounds and bicyclic ring systems, which may be employed for a variety of synthetic objectives.

Photogeneration of 1,5-naphthoquinone methides via excited-state (formal) intramolecular proton transfer (ESIPT) and photodehydration of 1-naphthol derivatives in aqueous solution[1]

Matthew Lukeman, Duane Veale, Peter Wan, V. Ranjit N. Munasinghe, and John E.T. Corrie

Abstract: The photochemistry of naphthols **1**, **2**, **4**, **5** and **9**, and phenol **10** has been studied in aqueous solution with the primary aim of exploring the viability of such compounds for naphthoquinone and quinone methide photogeneration, along the lines already demonstrated by our group for phenol derivatives. 1-Naphthol (**1**) is known to be substantially more acidic than 2-naphthol (**2**) in the singlet excited state (pK_a^* = 0.4 and 2.8, respectively) and it was expected that this difference in excited-state acidity might be manifested in higher reactivity of 1-naphthol derivatives for photochemical reactions requiring excited-state naphtholate ions, such as quinone methide formation. Our results show that three types of naphthoquinone methides (**26a**, **26b**, and **27**) are readily photogenerated in aqueous solution by irradiation of 1-naphthols. Photolysis of the parent 1-naphthol (**1**) in neutral aqueous solution gave 1,5-naphthoquinone methide **26a** as well as the non-Kekulé 1,8-naphthoquinone methide **26b**, both via the process of excited-state (formal) intramolecular proton transfer (ESIPT), based on the observation of deuterium exchange at the 5- and 8-positions, respectively, on photolysis in D_2O–CH_3CN. A transient assignable to the 1,5-naphthoquinone methide **26a** was observed in laser flash photolysis experiments. The isomeric 2-naphthol (**2**) was unreactive under similar conditions. The more conjugated 1,5-naphthoquinone methide **27** was formed efficiently via photodehydroxylation of **4**; isomeric **5** was unreactive. The efficient photosolvolytic reaction observed for **4** opens the way to design related naphthol systems for application as photoreleasable protecting groups by virtue of the long-wavelength absorption of the naphthalene chromophore.

Key words: photosolvolysis, excited-state intramolecular proton transfer, quinone methide, photorelease, photoprotonation.

Résumé : Opérant en solution aqueuse, on a étudié la photochimie des naphtols **1**, **2**, **4**, **5** et **9** et du phénol **10** afin de déterminer la viabilité de tels composés pour la photogénération de méthides de naphtoquinone et de quinone suivant les voies déjà mises de l'avant par notre groupe pour les dérivés du phénol. Il est bien connu que, dans l'état excité singulet, le 1-naphtol (**1**) est beaucoup plus acide que le 2-naphtol (**2**) (pK_a^* de 0,4 et 2,8, respectivement) et on s'attendait à ce que cette différence d'acidité dans l'état excité pourrait se manifester par une plus grande réactivité des dérivés du 1-naphtol pour les réactions photochimiques impliquant des ions naphtanolates dans l'état excité, tel que la formation de méthide. Nos résultats démontrent que l'irradiation des 1-naphtols en solutions aqueuses conduit facilement à la formation de trois types de méthides de naphtoquinones (**26a**, **26b** et **27**). L'irradiation du 1-naphtol fondamental (**1**), en solutions aqueuses neutres, conduit au méthide de 1,5-naphtoquinone (**26a**) ainsi qu'au méthide de 1,8-naphtoquinone (**26b**), une structure qui ne répond pas aux normes de Kekulé; sur la base d'expériences de photolyse dans un mélange de D_2O–CH_3CN qui conduisent à un échange de deutérium dans les positions respectivement 5 et 8, ces deux méthides se produisent par un processus de transfert intramoléculaire de proton dans l'état excité (formel). Lors d'expériences de photolyse éclair au laser, on a observé une entité transitoire attribuable au méthide de la 1,5-naphtoquinone. Dans des conditions semblables, le 2-naphtol (**2**) isomère n'est pas réactif. Le méthide de la 1,5-naphtoquinone (**27**) qui est plus conjuguée se forme facilement par photodéhydroxylation du composé **4**; son isomère **5** n'est pas réactif. La réaction efficace de photosolvolyse du composé **4** ouvre la voie au développement de systèmes de naphtols qui pourraient être utilisés comme groupes protecteurs qui pourraient être éliminés photochimiquement en

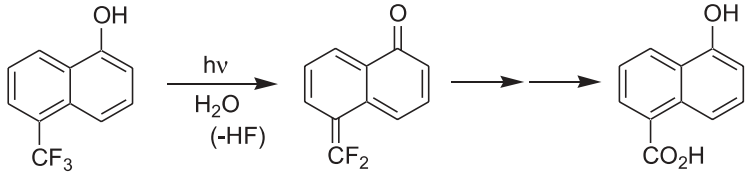
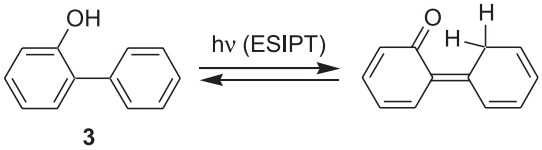
Introduction



Quinone methides are reactive intermediates of general interest in organic chemistry (1–3). Recent studies from our laboratory (1, 2, 4, 5) have demonstrated that suitably designed simple phenol derivatives give rise to quinone methide-type intermediates efficiently on photolysis in aqueous solution. The substrates that we have investigated so far all possess a phenol and a benzylic-type alcohol or styryl moiety. The enhanced acidity of the phenol moiety in S_1 in these systems is essential for reaction, as previously described (1, 2, 4, 5). We have not investigated simple naphthol derivatives extensively except in some biaryl systems containing a 2-naphthol chromophore, where the quinone methides photogenerated are of the biaryl type (6).

Some time ago, Seiler and Wirz (7) reported the photohydrolysis (to the corresponding carboxylic acids) of a variety of trifluoromethyl-substituted 1-and 2-naphthols (as well as several phenols) and invoked the initial formation of naphthoquinone and quinone methides in their photohydrolysis mechanism (e.g., eq. [1]). Webb et al. (8) have reported a detailed study of the excited-state proton transfer dynamics of 1-naphthol (**1**) and have shown that it is a much stronger acid (in S_1) than 2-naphthol (**2**) (pK_a* values of 0.4 and 2.8, respectively). Moreover, it was shown that the 5- and 8-positions of **1** are much more basic in S_1, as evidenced by deuterium incorporation at these positions when **1** was irradiated in *acidic* D_2O. The formation of two isomeric naphthoquinone methide intermediates was proposed to account for the photoexchange but whether such intermediates were formed via a water-mediated excited-state (formal) intramolecular proton transfer (ESIPT) (from the naphthol OH to the carbon 5- or 8-position) was not explicitly addressed. We have recently reported (9) the first explicit example of an ESIPT from a phenolic OH to an aromatic ring carbon (on the ring not containing the phenolic OH) in 2-phenylphenol (**3**) (eq. [2]). This result led us to investigate whether such a process could operate in the naphthols (**1** and **2**), since naphthols are formally made up of two benzene rings, one of them containing a phenol moiety. Also addressed is whether suitably designed 1-naphthol derivatives **4** and **5** will react in an analogous manner as reported by us (1) for the parent hydroxy-substituted benzyl alcohols with respect to naphthoquinone methide formation. Seiler and Wirz's earlier results (7) suggest that this would indeed be possible.



The photochemistry of phenols is also involved in the *p*-hydroxyphenacyl photodeprotection system reported by Givens and co-workers (10). An example designed to photorelease acetic acid from **6** is shown in eq. [3] (11). The essentials of the mechanism involve formation of a spiroketone intermediate **7** from photolysis of *p*-hydroxyphenacyl derivatives bearing good leaving groups, such as *p*-hydroxyphenacyl acetate **6**. Ring opening of **7** by water gives the observed product **8**. Release of the protected moiety (e.g., acetic acid from **6**) is believed to occur in the pri-

mary photochemical step. Although the question of triplet vs. singlet state reactivity (which might be dependent on the nature of the leaving group at the α-position) has been a topic of debate (10*c*, 11), the involvement of excited-state (singlet or triplet) deprotonation of the phenol moiety in the reaction sequence for formation of intermediate **7** seems likely. We felt that related substrates **9** and **10** might react similarly. The results of investigations of a variety of naphthols **1**,**2**,**4**, **5** and **9** (and phenol **10**) aimed at providing further insights to all of the above related photochemical reactions are reported herein.

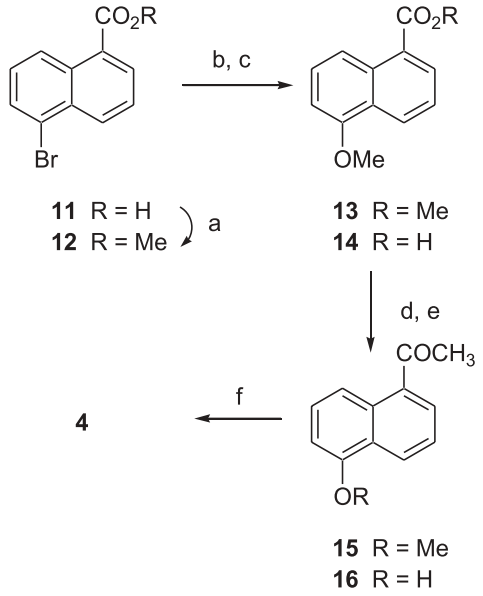
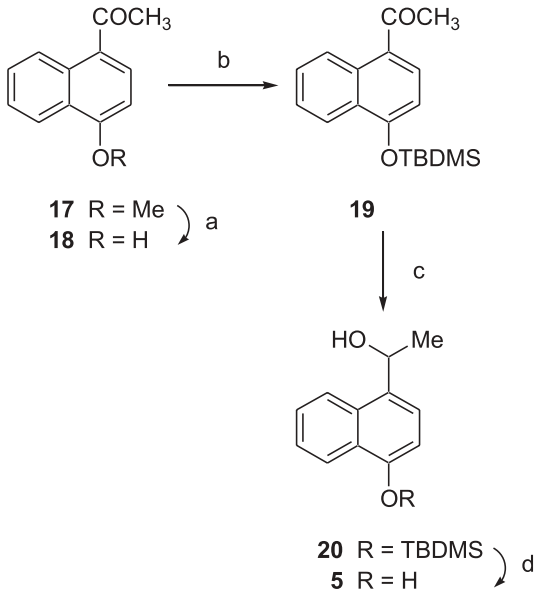
Results and discussion



Materials

1- and 2-Naphthols (**1** and **2**) were purchased from Aldrich and were sublimed and recrystallized from hexanes prior to use. The hydroxyethylnaphthols **4** and **5** were synthesized as shown in Schemes 1 and 2. Although the corresponding hydroxyketones are both known compounds, the synthetic routes previously described were not particularly convenient or led to mixtures of regioisomers. The routes shown in the schemes were straightforward but, particularly for the 5-isomer, were only reached after some exploration of other published methods. For synthesis of the 5-isomer **4** (Scheme 1), the readily prepared 5-bromo-1-naphthoic acid **11** (12) was esterified and the 5-bromo group was displaced with methoxide in a copper(I)-catalyzed procedure (13). Further steps to the phenolic ketone **16** and its subsequent reduction readily gave the alcohol **4**. Note however that the work up procedure for the thiophenoxide-mediated demethylation of the methyl ether **15** (and of **17** in the route to the 4-hydroxy compound **5**), which used a literature procedure (14), was modified by addition of hydrogen peroxide to oxidize excess thiophenol, thereby minimizing the odour associated with the procedure. The route to the 4-isomer **5** (Scheme 2) requires no further comment, except to note that direct borohydride reduction of the phenolic ketone **18** gave only dark, uncharacterized material and it was found necessary to protect the phenol as its TBDMS ether **19** during this step. No attempts were made in this study at synthesizing derivatives of **1** with substituents at the 8-position, although these compounds would indeed be worthwhile to investigate in the future. The naphthacyl acetate **9** was prepared as shown in Scheme 3 and the 3-hydroxyphenacyl acetate **10** was made by a route similar to those for the corresponding 4-hydroxy esters previously described (11).



Deuterium exchange studies of 1 and 2

As noted in the *Introduction*, Webb et al. (8) have shown that 1-naphthol (**1**) is considerably more acidic than 2-naphthol (**2**) in S_1, due to the enhanced (localized) charge transfer character available for **1** but not for **2**, the latter

compound having a more diffuse excited state electronic distribution. Moreover, charge transfer from the oxygen to the ring is localized at the 5- and 8-positions of **1**. To demonstrate the enhancement of basicity at these positions of **1**, they irradiated **1** in *acidic* D_2O–CH_3CN and showed that positions 5 and 8 were efficiently exchanged ($\Phi = 0.11$ in 99% D_2O, pD 3; Table 1) while similar irradiation of **2** resulted in no exchange. Photolysis in acidic solution raises the possibility that the exchange may be due to photoprotonation of **1** by hydronium ion, a process that is well known for 1-

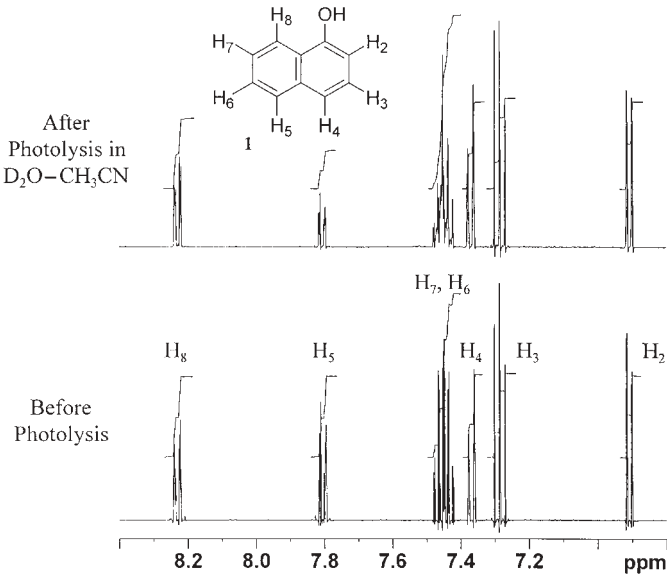
[a]Fluorescence emission quantum yield in neat CH_3CN. Measured relative to the reported fluorescence quantum yield for 1-naphthol in cyclohexane (Φ_f = 0.174) (15) with correction to account for differences in the indices of refraction of the different solvents. Estimated error of ±10% of quoted value. Values in brackets are the fluorescence quantum yields in cyclohexane, from ref 15.

[b]Fluorescence lifetime in neat CH_3CN measured by single photon counting. Lifetimes measured in this way have an estimated error of ±0.2 ns. Values in brackets are the fluorescence lifetimes in cyclohexane from ref. 15.



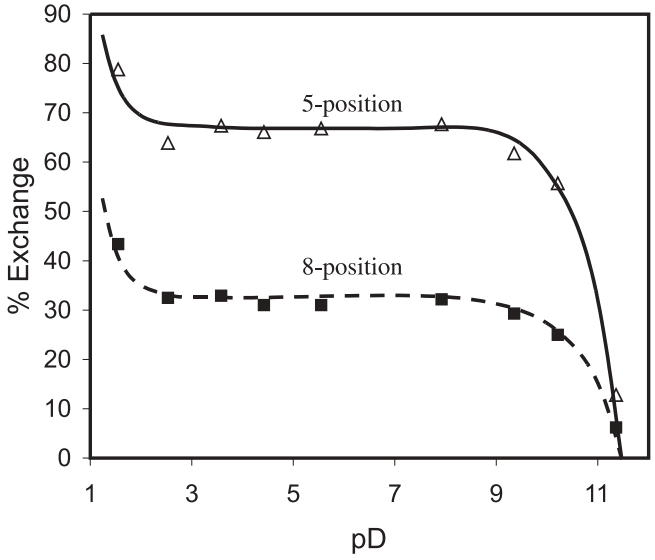
[c]Quantum yield of total deuterium exchange (of all ring positions) in 99% D_2O (pD 3) from ref. 8.

[d]Quantum yield of photomethanolysis in H_2O–CH_3OH (1:1). Estimated error ±10% of quoted value. Measured relative to the quantum yield for photomethanolysis of *o*-hydroxybenzhydrol in the same solvent (5).

methoxynaphthalene (16) and other aromatic compounds (17–19), but does not occur for 2-methoxynaphthalene (16). Therefore, we decided to study photochemical deuterium incorporation of **1** and **2** in aqueous solution, initially under neutral conditions and then over a wide pH range and as a function of water content. To our knowledge, this kind of study has not been previously reported for the naphthols. A similar study for **3** (eq. [2]) (9) resulted in the discovery of a new type of ESIPT (vide infra).

Irradiations of **1** and **2** were carried out in 1:1 D_2O–CH_3CN (~10^{-3} mol L^{-1}, pD 7, Rayonet photochemical reactor, 300 nm lamps, <30 min). Irradiation of **1** for 20 min resulted in efficient incorporation of deuterium at positions 5 (55%) and 8 (20%) to give **1-5D** and **1-8D**, respectively (eq. [4]). This was readily evident by examination of

Fig. 1. 500 MHz ^{1}H NMR spectra of **1** before (bottom), and after (top) 20 min irradiation at 300 nm in D_2O–CH_3CN (1:1), showing decreases in the integrated area of the peaks at 7.80 and 8.22 ppm assigned to ring protons at the 5- and 8-positions, respectively.



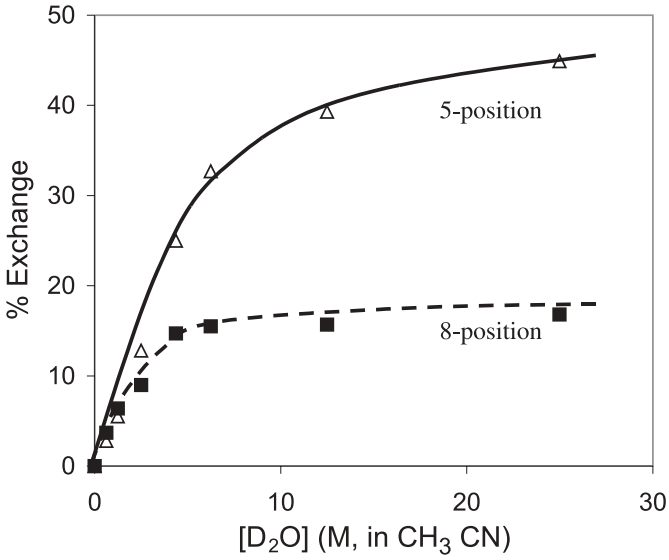
[4] **1** $\xrightarrow[D_2O-CH_3CN]{h\nu}$ **1-5D** + **1-8D**

500 MHz ^{1}H NMR spectra (Fig. 1); the areas of the peaks assigned to protons at the 5- and 8-positions (7.81 and 8.23 ppm, respectively) decreased smoothly with irradiation. The two overlapping triplets at 7.47 and 7.45 ppm assigned to the protons at the 6- and 7- ring positions exhibited changes consistent with diminished coupling to the adjacent protons at the 5- and 8-positions as they are replaced with deuterium. MS analysis of the photolyzed sample indicated an isotope distribution of 37% nondeuterated, 52% monodeuterated, and 11% dideuterated 1-naphthol, consistent with the overall deuterium incorporation measured by NMR. The observation of deuterium incorporation in neutral solution suggests that protonation by acid (D_3O^+) is not responsible for the observed reaction, and that the exchange might be due to an ESIPT process. Formation of **1-5D** and **1-8D** from an ESIPT to the 5- and 8-positions would necessarily proceed via quinone methides **26a-D** and **26b-D**, which have been previously proposed by Webb et al. (8). 2-Naphthol (**2**) did not undergo any observable exchange, even on prolonged irradiation, and the compound was completely recovered.

To better our understanding of the effect of acid on the deuterium incorporation reaction of **1**, photolyses were carried out in which the pD of the aqueous portion was varied over the pD range 1.5–11.4 (Fig. 2). While acid catalysis is observed at pD < 2.5, exchange efficiency was essentially constant from pD 2.5 through to pD 9. Since the hydronium ion concentration varies by many orders of magnitude over

© 2004 NRC Canada

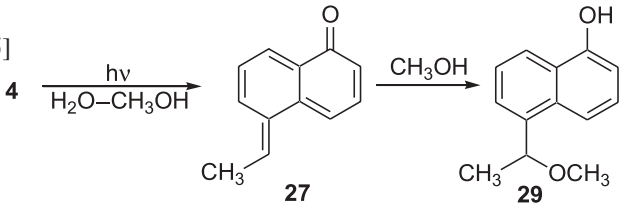
Fig. 2. Plot of % deuterium exchange at the 5- (triangles) and 8- (squares) positions vs. pD (in D_2O–CH_3CN (1:1)) for **1**. Solutions (20 mg substrate in 40 mL solution) were irradiated at 254 nm (16 lamps) for 15 min.



this pH range, it is very unlikely that the deuterium incorporation observed within this range results from protonation by D_3O^+ present in solution. The exchange efficiency decreases above pD 9, which corresponds with the ground state pK_a of **1** (pK_a = 9.2 (8)), indicating that the deprotonated form $\mathbf{1}^-$ does not undergo exchange. Consistent with this, no exchange was observed at high pD. This result rules out a stepwise mechanism in which **1** first undergoes excited-state proton transfer (ESPT) to give excited phenolate ($\mathbf{1}^-$*) that is protonated by D_2O in a subsequent step, since every excitation of $\mathbf{1}^-$ would necessarily lead to an excited phenolate. It is apparent that the naphthol OH is required for reaction, suggesting that an ESIPT might be taking place.

To investigate the role of solvent water in the ESIPT reaction of **1**, photolyses were performed in which the concentration of D_2O (in CH_3CN cosolvent) was varied (Fig. 3). The deuterium exchange efficiency for **1** was negligible at low D_2O concentrations, but increased dramatically as more D_2O was added. The enhancement of reaction efficiency appeared to reach saturation at about 1:1 D_2O–CH_3CN. The need for water to mediate the proton transfer indicates that the ESIPT is not intrinsic, in contrast to the ESIPT observed for **3**. This is probably because the distance between the acidic proton and both basic carbons is too large to allow ground state hydrogen bonding interactions, which are thought to be a prerequisite for intrinsic ESIPTs (9*b*). The efficiency for exchange at the 8-position plateaus at lower water concentrations than does exchange at the 5-position. This could be because the OH functionality is much closer to the 8-position, so less water is required to mediate the proton transfer.

Photodehydroxylation and photodehydration of 4 and 5



We have previously shown that the photolysis of phenols containing benzylic alcohol groups gives rise to *ortho*-, *meta*-, and *para*-quinone methides in high yield (1). In an attempt

Fig. 3. Plot of % deuterium exchange at 5- (triangles) and 8- (squares) positions vs. D_2O content (pD 7).

to apply this strategy to naphthoquinone methide generation, derivatives **4** and **5** were studied. The naphthoquinone methides produced by net photodehydration of **4** or **5** (**27** and **28**, respectively) were not expected to be sufficiently stable to isolate, so we instead sought to obtain indirect evidence of their presence by isolating their photosubstitution products arising from nucleophilic attack. For example, in methanol–water solutions, the expected photoproduct from **4** is methyl ether **29** (eq. [5]). Although formation of **29** is

[5]

consistent with the presence of **27** as an intermediate, reaction through a cationic intermediate would give the same product and cannot be excluded on the basis of product studies alone.

Irradiation of **4** in 1:1 H_2O–CH_3OH (~10^{-3} mol L^{-1}, Rayonet photochemical reactor, 300 nm lamps, 1 min) did indeed give **29** in 48% yield (eq. [5]), while solutions kept in the dark did not react. The photosubstitution is clean and has a remarkably high quantum yield for production of **29** from **4**, measured to be 0.84 ± 0.04 (Table 1). This value represents the highest reported quantum yield to date for photomethanolysis of benzyl alcohol derivatives. The high quantum yield for formation of **29** implies that attack by water on **27** to regenerate starting material must be very inefficient. This is in line with the known high nucleophilicity of methanol relative to that of water (20). Pure samples of **29** were obtained by chromatographic separation of the photolysate, and photolysis of these samples in 1:1 aqueous acetonitrile regenerated **4**. The methyl ether product can therefore also undergo photosubstitution, presumably through formal

© 2004 NRC Canada

loss of methanol to regenerate **27**. This result shows that ether and ester derivatives of **4** might prove useful as protecting groups for photorelease of alcohols and acids.

Results from the deuterium incorporation studies of **1** show that electron density in singlet excited 1-naphthols is primarily localized at the 5-position, and to a lesser extent at the 8-position. Naphthols **4** and **29** both react through the substituent located at the 5-position. In contrast to these examples, the substituent in **5** is located at the 4-position. No deuterium was incorporated at this position on irradiation of **1**, indicating that minimal charge is transferred to this position on excitation. When **5** was irradiated under similar conditions as **4**, no reaction was observed, showing that photodehydroxylation requires excited state charge transfer from the naphthol OH.

Photochemical studies of 9 and 10

The proposed mechanism for the photosolvolytic rearrangement of **6** (11) that leads to the release of acetic acid appears to require either ESPT to solvent water or an ESIPT from the phenol to the carbonyl oxygen mediated by water, to generate a reactive excited phenolate or a related enol species, respectively, prior to formation of spiroketone **7**. It was of interest to determine whether derivatives such as naphthol **9** and phenol **10** would show similar photosolvolysis. Since the parent 1-naphthol (**1**) has already been shown to undergo a water-mediated ESIPT to the 5- and 8-positions, it seemed reasonable to expect that a similar process could operate in **9**, with the difference that the proton transfer would end up at the carbonyl oxygen. This could activate the compound for release of acetic acid in a manner similar to the reactivity observed for **6**. In the case of phenol **10**, it is well known that there is substantial charge transfer through meta-positions on the benzene ring in S_1 that allows efficient formation of *m*-quinone methides (1, 2, 5). Such charge transfer would be expected to enhance ESIPT from the phenol to the carbonyl moiety of **10**, resulting in a reaction similar to that observed for **6**. To our surprise, both **9** and **10** were found to be completely unreactive in 1:1 H_2O–CH_3CN even on extended irradiation. Complete recovery of the substrates was achieved in all cases. What was surprising was the lack of photodecomposition even on extended photolysis, which leads us to suggest that ESPT or ESIPT processes are occurring for these compounds, but lead to no net chemistry. In the case of **10**, subsequent formation of the non-Kekulé spiroketone intermediate seems to be prohibitive as it would be a ground-state species. For **9**, formation of the requisite spiroketone would seem possible but on closer examination, such a reaction would result in loss of two aromatic rings *and* formation of a strained spiroketone. Moreover, the excited singlet or triplet energy of **9** (a 5-hydroxy-1-acetylnaphthalene) is expected to be substantially lower than that of **6** (a 4-hydroxyacetophenone). One of these factors probably explains the lack of reaction of **9**. No further studies of **9** and **10** were pursued due to their photoinertness in aqueous solution.

Fluorescence measurements

As the ESIPT reaction of **1** is strongly mediated by water, the fluorescence behaviour with respect to water concentration was studied to provide mechanistic insights. If the ESIPT reaction occurs from S_1, as do most ESPTs from phenols, addition of water to the solvent mixture should lead to quenching of the fluorescence intensity by enhancing the proton transfer pathways. Indeed, the fluorescence emission of **1** (in CH_3CN), after an initial red shift from λ_{max} 340 nm to λ_{max} 355 nm on addition of small amounts of water, was progressively quenched by added water, concomitant with a growth in fluorescence intensity at 460 nm. In pure water, the 355 nm band was completely quenched and only emission from the 460 nm band was observed. The band at 460 nm results from emission from the excited 1-naphtholate ion (**1**$^-$), which arises from ESPT from the OH proton of **1** to solvent (water), and is consistent with the previous assignment (8). Relatively large amounts of water were required for efficient formation of **1**$^-$, just as the ESIPT of **1** to give **1-5D** and **1-8D** required large amounts of D_2O. This correlation is not surprising as the two processes are closely related. Thus, quenching of the fluorescence emission of **1** in the presence of water arises from a combination of two competing pathways from S_1, namely ESPT to solvent water and water-mediated ESIPT to the 5- and 8-positions.

The fluorescence behaviour of **5** closely resembled that of **1**. Small amounts of water led to an initial red shift of the fluorescence emission band from λ_{max} 358 nm in neat CH_3CN to λ_{max} 375 nm (Fig. 4). Larger amounts of water led to quenching of this fluorescence band and to a growth in emission at 465 nm (from naphtholate ion **5**$^-$). This information suggests that there are no major pathways that deactivate the singlet excited state of **5** other than those available for **1**.

The fluorescence behaviour of **4** is quite different from that observed for **1** and **5**. Small amounts of water led to a red shift of the fluorescence emission band from λ_{max} 345 nm in neat CH_3CN to λ_{max} 360 nm, though significant quenching of this band was achieved with less water than required for **1** or **5** (Fig. 5). Naphtholate (**4**$^-$) emission (λ_{max} 460 nm) was observed only at high water concentrations and was much weaker than the observed emission of **1**$^-$ or **5**$^-$. Modified Stern–Volmer quenching plots of the emission intensity of **4** and **5** with added water are shown in Fig. 6. The enhanced quenching by water for **4** relative to **5** can be clearly seen. Since the pK_a values for **1**, **4**, and **5** are expected to be approximately equivalent, an additional water-dependent deactivation pathway must be operating for **4**. The net dehydration reaction to give **27** that is available for **4** but not for **1** or **5** can explain this additional quenching if deprotonation of the naphthol and dehydroxylation of the benzylic alcohol are concerted from S_1. This pathway would also compete with ESPT to solvent, explaining the weaker phenolate emission observed. Both Stern–Volmer plots exhibit a squared dependence on water concentration. Our group has previously reported nonlinear fluorescence quenching by water for related phenols, an effect attributable to involvement of water clusters in the ESPT (4).

Fluorescence quantum yields and lifetimes were measured for **4** and **5** in CH_3CN and are listed in Table 1, along with literature values for **1** and **2**. Both **4** and **5** exhibit similar photophysical behaviour to **1** in CH_3CN, indicating that no

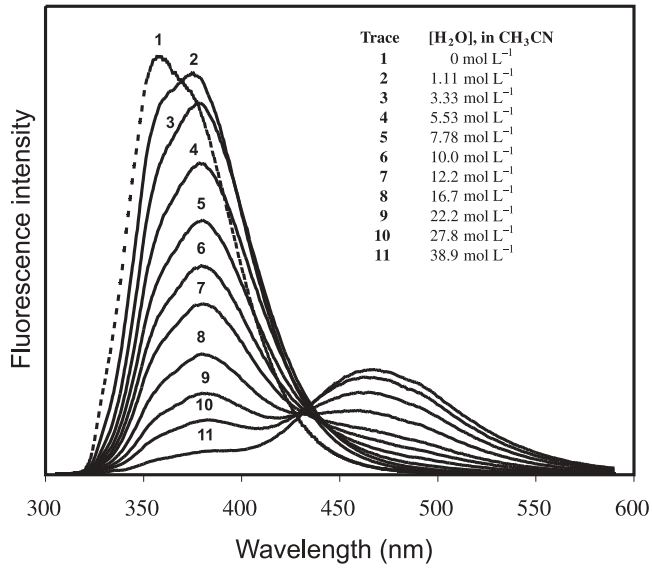
Fig. 4. Representative fluorescence quenching traces of **5** by added water in CH_3CN (λ_{ex} 300 nm). Water concentrations are given in the legend. Naphtholate (**5**$^-$) emission grows in at λ_{em} 460 nm with increasing water content.



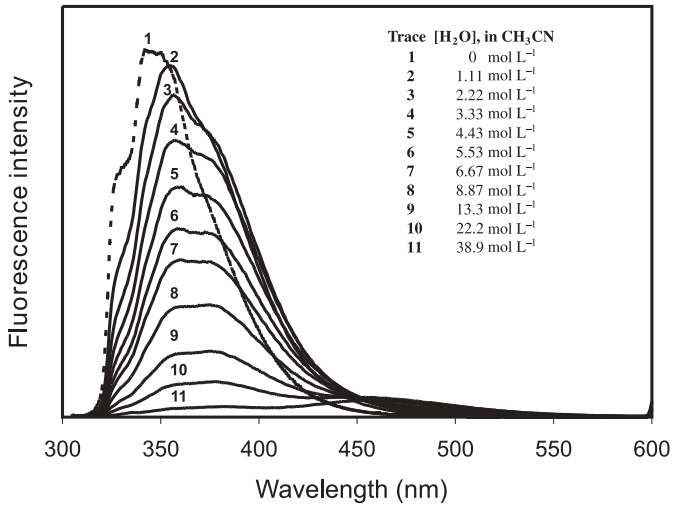


Fig. 5. Representative fluorescence quenching traces of **4** by added water in CH_3CN (λ_{ex} 300 nm). Water concentrations are given in the legend. Naphtholate (**4**$^-$) emission grows in at λ_{em} 465 nm with increasing water content.

major deactivation pathways open up on addition of the hydroxyethyl substituent to the 1-naphthol chromophore except when water is present.

Laser flash photolysis (LFP)

LFP experiments were performed for **1**, **4**, and **5** to gain direct evidence of the suspected naphthoquinone methide intermediates. The resulting data are summarized in Table 2. Mathivanan et al. (19*b*) previously studied 1-methoxynaphthalene by LFP in hexafluoroisopropyl alcohol (HFIP) and observed a transient with a broad absorption band at λ_{max} 550 nm and a second, more narrow band at

Fig. 6. Stern–Volmer plots for steady-state fluorescence quenching of **4** (triangles) and **5** (diamonds) by H_2O (in CH_3CN). The lines drawn are fits to $I_0/I = 1 + K_{SV}[H_2O]^2$.

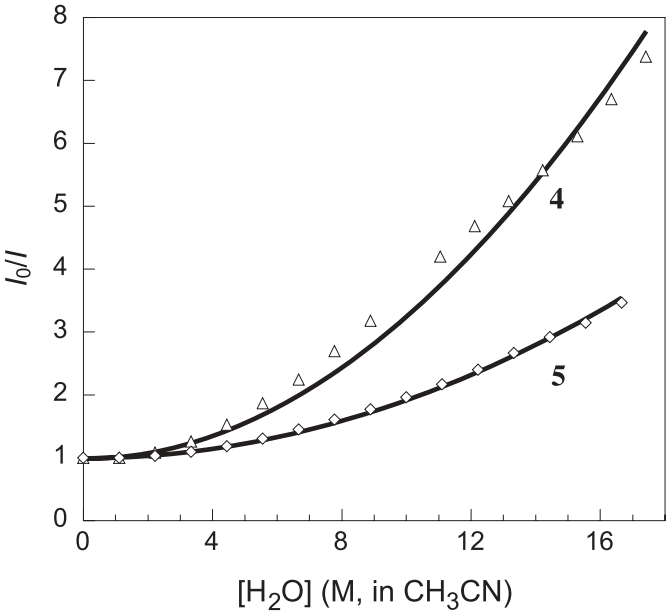

Table 2. Summary of laser flash photolysis transient data.[a]

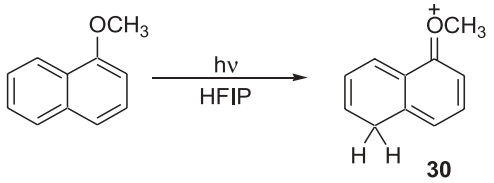
Transient	λ_{max}[b] (nm)	τ[c] (μs)	k_q[d] (10^6 M^{-1} s^{-1})
26a	350, 530	17	0.90±0.10
27	410, 700	33	1.0±0.1
32	410, 700	1.7	>>50[e]
33	350, 530	45	Not determined

[a]LFP was performed on flowing solutions that were ~10^{-5} mol L^{-1} in the appropriate substrate. Excitation was achieved with an excimer laser (308 nm, ~ 10 ns, <30 mJ/pulse).

[b]Absorption maxima in H_2O–CH_3CN (1:1) solution.



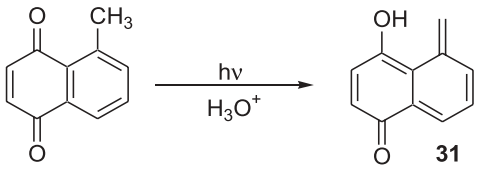
[c]Transient lifetime in H_2O–CH_3CN (1:1) solution, oxygen purged. The estimated error is ±10% of the reported value.

[d]Bimolecular quenching rate constant with added ethanolamine in H_2O–CH_3CN (1:1) solution, according to the following equation: $k_{obs} = k_0 + k_q[Q]$.

[e]Complete quenching was observed with 5.5 mol L^{-1} ethanolamine. Transients with lifetimes as short as 20 ns are readily detectable on the system used, so for complete quenching to be realized with 5.5 mol L^{-1} quencher, k_q must be at least 5×10^7 M^{-1} s^{-1}, and is probably at least an order of magnitude higher.

λ_{max} 360 nm, both of which were assigned to cation **30** obtained via photoprotonation (from HFIP) of 1-methoxynaphthalene at the 5-position (eq. [6]). This tran-

[6]



30

sient could not be detected in aqueous acid, which the authors proposed was because rapid reaction with water reduced the lifetime of the cation to a value shorter than their system could detect. This intermediate bears structural

© 2004 NRC Canada

resemblance to suspected naphthoquinone methide **26a** resulting from ESIPT to the 5-position in **1**. Chiang et al. (21) observed naphthoquinone methide **31** by LFP in dilute aqueous acid solution (generated by γ-hydrogen abstraction in 5-methyl-1,4-naphthoquinone (eq. [7])). This transient had a broad visible absorption band at λ_{max} 600 nm with a lifetime

[7] 

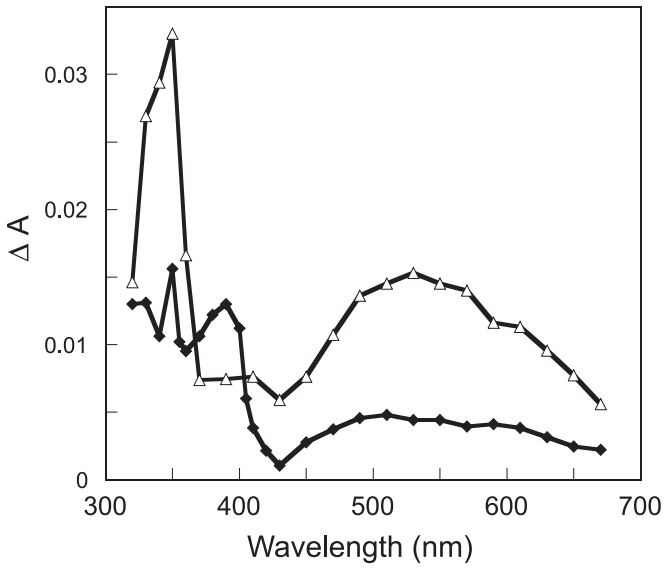
of ≈1 μs (lifetime shortened as pH was decreased), and is structurally related to **27** produced on photodehydration of **4**.

Nanosecond LFP of **1** in 1:1 H_2O–CH_3CN (O_2 saturated) resulted in the formation of a transient with a broad absorption band at 530 nm and a second, more narrow band at 340 nm (Fig. 7). Both peaks appeared immediately after the laser pulse (≈10 ns) and decayed to baseline. The decay kinetics of both peaks fit a monoexponential curve, giving a lifetime of 16 ± 2 μs. This transient spectrum is very similar to that assigned to **30** (19*b*), though blue-shifted by about 20 nm. We assign this absorption to be **26a** formed on ESIPT of **1**. The observed lifetime of 16 ± 2 μs in aqueous solution indicates that this transient is much less reactive with water than **30**, which is expected because of the greater electrophilic nature of **30**. Naphthoquinone methide **26b** is non-Kekulé and is expected to decay within the time of the laser pulse (10 ns). LFP of **1** in neat CH_3CN (O_2 purged) led to formation of a weaker transient (Fig. 7) with a broad visible band (λ_{max} 510 nm) and narrower bands with λ_{max} 390 and 350 nm. We assign this transient to the 1-naphthoxy radical based on the similarity of the observed absorption spectrum to that known for this species (22).

Nanosecond LFP of **4** in 1:1 H_2O-CH_3CN (O_2 saturated) resulted in the formation of a strongly absorbing transient immediately after the laser pulse, with peaks at 410 and 700 nm (Fig. 8). The decay kinetics gave a biexponential fit with a short-lived minor component (τ = 1.5 ± 0.5 μs) and a longer lived major component (τ = 34 ± 2 μs) that both decayed cleanly to baseline. This biphasic decay was observed at all wavelengths, demonstrating that the two decaying species have similar absorbance profiles. The position of the bands is consistent with what is expected for **27**: the red shift relative to **26a** results from the extra unit of conjugation and the extra methyl substituent. The long-wavelength band is similar to that reported for related naphthoquinone methide **31** by Chiang et al. (21). The major (long-lived) component of the observed absorption is assigned to **27** on this basis and on the results of the product studies. The shorter lived species can be assigned to cation **32** that would result from dehydroxylation without prior deprotonation of the phenol, a process well known for methoxy-substituted benzyl alcohols. This cation possesses a similar degree of conjugation as **27**, which would explain its similar absorbance characteristics. Its much shorter lifetime is consistent with the expected enhanced reactivity of a charged species relative to a neutral and closed-shell naphthoquinone methide. No strong transients were observed on LFP of **4** in neat CH_3CN (O_2 purged) in the absence of water. Instead, a weak transient was observed with a broad band at 580 nm, and with narrower bands at 400 and 350 nm (Fig. 8). This species closely resembles the transient observed for **1** in neat CH_3CN in the position, structure, and intensity of the absorption bands. This transient is therefore assigned to the 1-naphthoxy radical of **4**.

A strong transient was also observed on LFP of **5** (in H_2O–CH_3CN (1:1)), which exhibited a broad absorption

Fig. 7. Transient absorption observed on LFP of **1** in H_2O–CH_3CN (1:1) (triangles) and in neat CH_3CN (diamonds) (λ_{ex} 308 nm, O_2 purged for both). For both spectra, the decay trace was taken immediately after the laser pulse (~10 ns).



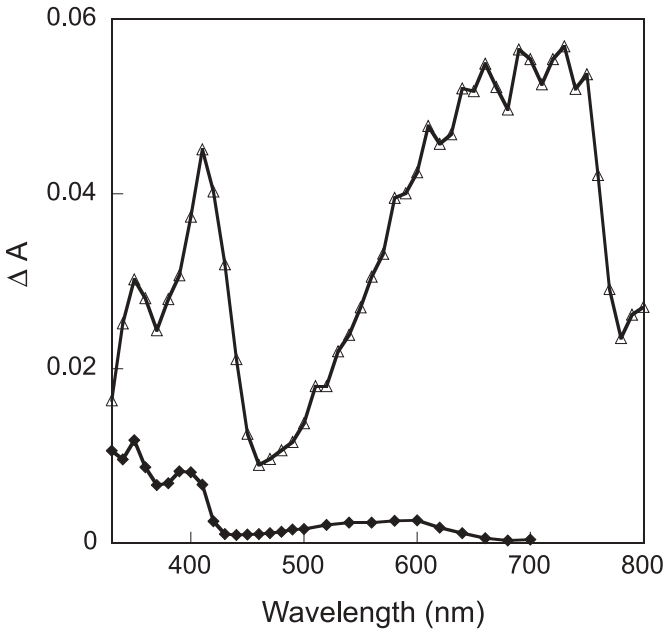


Fig. 8. Transient absorption observed on LFP of **5** in H_2O–CH_3CN (1:1) (triangles) and in neat CH_3CN (diamonds) (λ_{ex} = 308 nm, O_2 purged for both). The decay traces were taken immediately after the laser pulse (~10 ns).

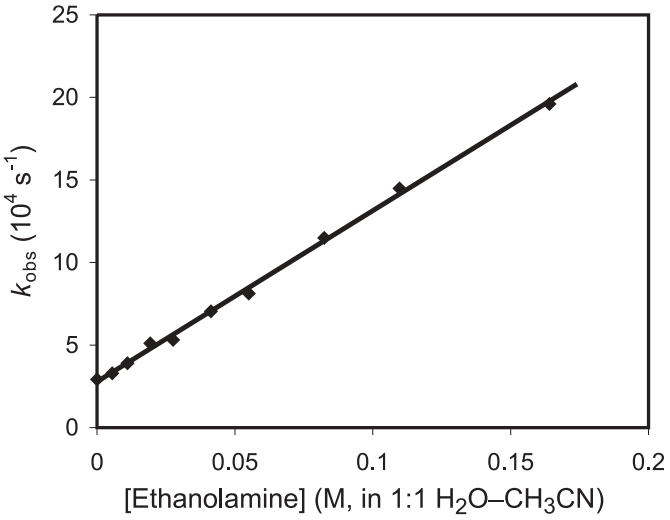
© 2004 NRC Canada

band at 520 nm, a small band at 410 nm, and a strong narrow band at 350 nm. Again, all peaks displayed first-order decay kinetics, each with the same lifetime of 45 ± 2 μs. Product studies showed that **5** does not undergo photosubstitution; therefore, this transient is unlikely to be **28**. Nevertheless, the spectrum closely resembles that assigned to **26a**. Indeed, **5** should be able to form a similar naphthoquinone methide resulting from ESIPT to the 5-position of the naphthol ring. On this basis, we assign this absorption to naphthoquinone methide **33**. The enhanced lifetime of **33** relative to **26a** is probably due to steric shielding of the 5-position by the hydroxyethyl substituent that retards deprotonation at this site. LFP of **5** in neat CH_3CN shows formation of small amounts of the corresponding 1-naphthoxy radical.

Additional support for our assignment of the major transients observed for **1** and **4** as naphthoquinone methides was sought through quenching studies. We have recently shown (23) that ethanolamine can efficiently quench quinone methide intermediates. For **27** (or cation **32**), the expected quenching mechanism is nucleophilic attack at the benzylic position to furnish the ethanolamine adduct, while for quinone methide **26a**, the expected quenching mechanism is base-catalyzed tautomerization. Quenching analyses were first performed for the transients arising from LFP of **4** (Fig. 9). At the smallest ethanolamine concentration used (5.5 mM in H_2O–CH_3CN (1:1)), the short-lived component of the decay (assigned to **32**) was completely quenched, leaving only the longer lived component (assigned to **27**). As carbocations are known to react very rapidly with added nucleophiles, this observation supports our assignment of the short-lived component to **32**. The dynamic quenching of quinone methide **27** with added ethanolamine is plotted in Fig. 9 and a linear correlation was observed, giving a bimolecular quenching rate constant of $1.0 \pm 0.1 \times 10^6$ M^{-1} s^{-1}. A similar quenching analysis was performed for the transient formed on LFP of **1** (assigned to **26a**), and results are presented in Fig. 10. The decay of this transient was also accelerated with added ethanolamine, giving a good linear fit with k_q at $9.0 \pm 1.0 \times 10^5$ M^{-1} s^{-1}.

Fig. 9. Quenching plot showing the increase in the decay rate of **27** at 680 nm with added ethanolamine in H_2O–CH_3CN (1:1). Line is the least-squares fit to the data and gives $k_q = 1.0 \times 10^6$ M^{-1} s^{-1}. Estimated error is ±10%.



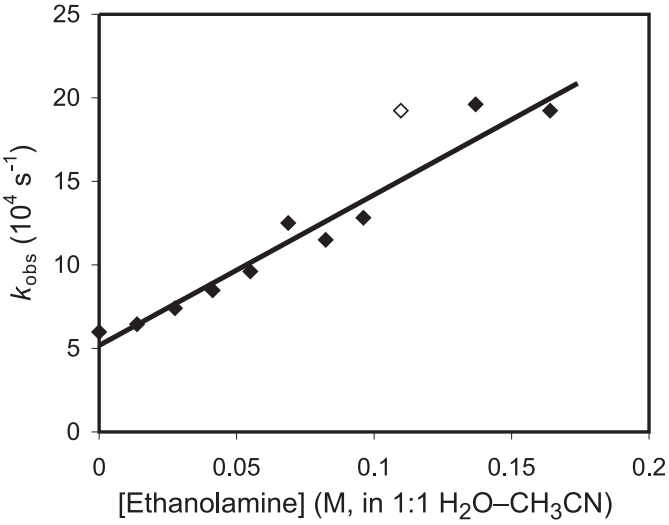


Fig. 10. Quenching plot showing the increase in the decay rate of **26a** at 530 nm with added ethanolamine in H_2O–CH_3CN (1:1). Line is the least-squares fit to the data and gives $k_q = 9.0 \times 10^5$ M^{-1} s^{-1}. Estimated error is ±15%. Outlined point was not included in the least-squares analysis.

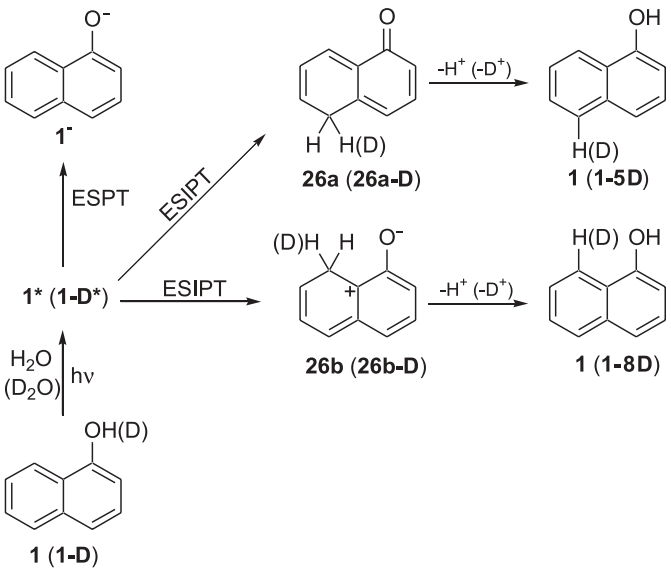
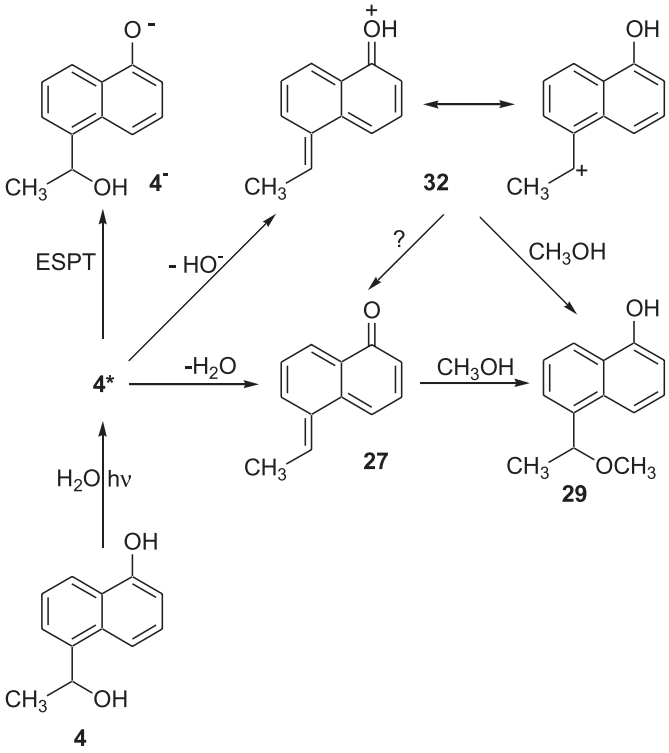


Mechanisms of reaction

The deuterium incorporation reaction of **1** on photolysis in D_2O–CH_3CN (1:1) is proposed to occur via a water-mediated ESIPT from the naphthol OH to the aromatic ring carbons at the 5- and 8-positions, to give naphthoquinone methide intermediates **26a** and **26b**, respectively, (Scheme 4). The enhanced acidity of the naphthol OH in the excited state ($pK_a^* = 0.4$) and the enhanced excited-state basicity of the 5- and 8-positions of 1-alkoxy- and 1-hydroxy-substituted naphthalenes suggest that an intramolecular acid–base reaction might be possible. The propensity of **1** to undergo excited-state proton transfer reactions in aqueous conditions is further demonstrated in fluorescence studies, with emission from (**1**$^-$)* observed on photolysis of **1** in aqueous conditions. The protonation of the 5- and 8-positions in the pH range 2.5–9 does not result from electrophilic attack by H_3O^+ (or D_3O^+) since the exchange efficiency is independent of pH (pD) throughout this large pH range. Solvent water alone cannot be acting as the acid, since no exchange was observed for irradiated (basic) solutions of **1**$^-$. Under basic conditions, the naphthalene still has a powerful electron-donating group at the 1-position, and the concentration of water is still very high. It is thus evident that the reaction requires the OH functionality, suggesting that the reaction proceeds through ESIPT from the OH to the ring carbons. The need for water to mediate the proton transfer was clearly borne out by the product studies, with efficient reaction only being observed at fairly high water concentrations. This is because the OH group is too far from the basic sites to allow any direct spatial interaction, so water is needed to "solvate" the proton as it is transferred. We have previously implicated water as mediating ESIPTs between remote sites in other phenols (4). Direct evidence for

© 2004 NRC Canada

Scheme 4.

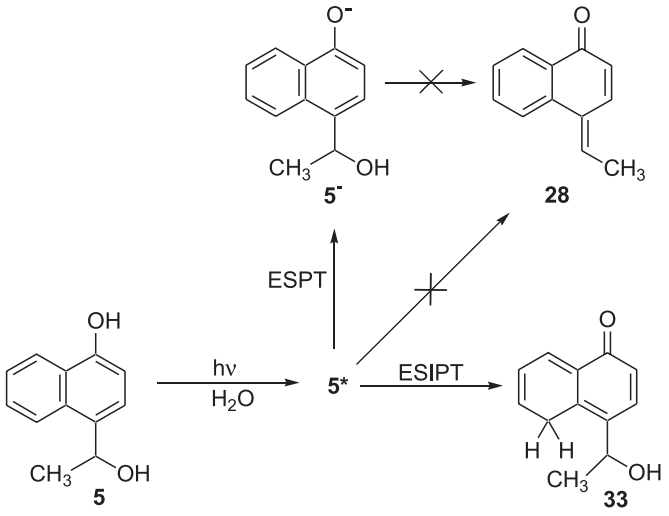


naphthoquinone methide intermediate **26a** that would arise from ESIPT to the 5-position was provided by LFP studies, lending further support to our mechanistic proposal.

An additional consideration of interest in the ESIPT of **1** is the possible presence of other intermediates prior to naphthoquinone methide formation. We recently reported an example of a simple hydroxybiaryl for which ESIPT to two aromatic carbon positions was observed (24). ESIPT to both positions was strongly water dependent, as is the ESIPT of **1** in the present work. Furthermore, the efficiency of exchange of the two positions had almost identical dependencies on water content, which is unlikely if the two routes are wholly independent. To account for this, we suggested that ESIPT first leads to a "proton – π complex", which can rearrange to either of the two possible quinone methides (24). The ESIPT in **1** appears not to occur through this route. Deuterium exchange efficiencies at the 5- and 8-positions appear to have different dependencies on water concentration, with exchange at the 8-position reaching saturation with less water than exchange at the 5-position. This observation favours a mechanistic picture where two separate ESIPTs are occuring that do not share a common intermediate prior to QM formation.

The photosubstitution reaction of **4** is mechanistically related to the ESIPT reaction of **1** in that it relies on excited-state charge transfer from the naphthol OH to the 5-position. The photochemical reactivity of **4** in aqueous solution can be explained as occuring through three different pathways (Scheme 5): (*i*) ESPT of the naphthol proton to solvent water to give $\mathbf{4}^{-}$; (*ii*) dehydroxylation of the benzylic alcohol moiety to give **32**; and (*iii*) photodehydration to form **27**. Evidence for the first pathway comes from the fluorescence studies: emission from $\mathbf{4}^{-*}$ was observed on excitation of **4** at high water concentrations, indicating that an adiabatic ESPT is occuring. As for the second pathway, a short-lived transient observed in LFP studies was assignable to the cation **32** that would result from simple dehydroxylation. Cation **32** might also undergo deprotonation to give **27**. The

Scheme 5.



third and major pathway involves deprotonation of the naphthol OH concerted with dehydroxylation of the benzylic site to give **27** directly. The formation of the naphthoquinone methide intermediate **27** was inferred from the results of the product studies and the observation of a transient on LFP of **4** that was assignable to **27**. That the reaction to give **27** is concerted was inferred primarily from the fluorescence studies. The enhanced quenching of the fluoresence emission of **4** in aqueous solution by water over 1-naphthol derivatives **1** and **5** shows that an additional deactivation pathway is available for **4** that is not available for **1** or **5**, with this pathway being photodehydration to form **27**. If the ESPT to solvent preceded dehydroxylation of the benzylic alcohol, no enhanced quenching would be observed, since **1**, **4**, and **5** would be expected to have similar ESPT rates. The LFP quenching studies for **4** demonstrated that very small amounts of ethanolamine rapidly quenched the cation. If the cation was a precursor to **27**, the presence of ethanolamine would substantially reduce the amount of **27** that is observed, and that was not the case. Therefore, the only remaining option to explain the reactivity is via a concerted mechanism.

The reactivity of **5** (Scheme 6) is different from that of **4** in that no photosubstitution was observed in the product studies. Photodehydration to form naphthoquinone methide **28** therefore does not occur. The ESIPT in **1** and the photosubstitution reaction of **4** are both interpreted as arising from enhanced localized charge transfer from the naphtholic OH to the 5- and 8- ring positions. The failure of **5** to react through the 4-position confirms that this charge transfer is crucial for photodehydration. A strong transient was observed on LFP of **5** and was assigned to **33**, indicating that **5** reacts though an ESIPT pathway similar to that observed for

© 2004 NRC Canada

Scheme 6.

1. Despite containing a potentially reactive substituent at the 4-position, the chemistry is still dominated by the localized charge transfer to the 5- and 8-positions.

Experimental

General

^{1}H NMR spectra were obtained on Bruker AC300 (300 MHz), AM360 (360 MHz), AVANCE 500 (500 MHz), Varian AM400 (400 MHz), or JEOL FX90Q (90 MHz) instruments in $CDCl_3$ unless otherwise specified. Low-resolution mass spectra were obtained on a Finnigan 3300 (CI) and HR-MS were obtained on a Kratos Concept H (EI) instrument. UV–vis spectra were recorded on a Varian Cary 5 instrument. Acetonitrile (HPLC or spectral grade) used for fluorescence and LFP experiments was dried by distillation from calcium hydride. Organic extracts were dried over anhydrous magnesium sulfate and filtered. pD values were measured for the aqueous portion (prior to mixing with CH_3CN cosolvent) using a Fisher Accumet 915 pH meter and were not corrected for the deuterium isotope effect. Solutions were unbuffered with pD values adjusted with either NaOD (pD > 7) or D_2SO_4 (pD < 7).

Materials

5-(1-Hydroxyethyl)-1-naphthol (4)

A solution of 5-bromo-1-naphthoic acid **11** (12) (4.5 g, 17.9 mmol) and concentrated sulfuric acid (1.35 mL) in methanol (65 mL) was heated at reflux for 8 h, cooled, diluted with diethyl ether and washed with aqueous sodium hydrogen carbonate, water and brine, dried and evaporated under reduced pressure. The residue was crystallized from methanol to give methyl 5-bromo-1-naphthoate **12**. Yield: 3.5 g (74%); mp 66 to 67 °C (lit. (12) mp 66 to 67 °C).

A mixture of **12** (6.0 g, 22.6 mmol), CuBr (0.93 g, 6.5 mmol), ethyl acetate (1.77 mL, 18.1 mmol) and 25% sodium methoxide in methanol (Aldrich; 30.8 mL, 142.6 mmol) was heated under reflux for 3.5 h under nitrogen. The copper salts were filtered and the solid was washed with methanol. The combined filtrate was concentrated to about 5 mL, diluted with water and extracted with dichloromethane. The extracts were washed with brine, dried and evaporated, and crystallized from hexanes to give methyl 5-methoxy-1-naphthoate **13**. Yield 3.43 g (70%); mp 76–76.5 °C (lit. (25) mp 74.5–75.5 °C). This material (7.7 g) was saponified in aqueous methanolic sodium hydroxide to give 5-methoxy-1-naphthoic acid **14**. Yield: 6.1 g (85%); mp 225–227 °C (from ethanol) (lit. (26) mp 227–229 °C).

A solution of **14** (2.02 g, 10 mmol) stirred under nitrogen in anhyd THF (40 mL) was diluted with anhydrous diethyl ether (110 mL) and a 1.5 mol L^{-1} solution of methyl lithium in diethyl ether (16.7 mL, 25 mmol) was added over 20 min at room temperature. The mixture was stirred for 1.5 h and acetone (17 mL) was added. After 5 min, the solution was diluted with 2 mol L^{-1} aqueous hydrochloric acid and extracted with diethyl ether. The organic phase was washed with water, aqueous sodium hydrogen carbonate, water and brine, dried and evaporated under reduced pressure. The residue was crystallized from petroleum ether (bp 60–80 °C) to give 1-acetyl-5-methoxynaphthalene **15**. Yield: 1.56 g (78%), mp 85–87 °C (lit. (27) mp 88 to 89 °C).

Dry *N*-methyl-2-pyrrolidinone (10.5 mL) was added under nitrogen to a mixture of **15** (4.2 g, 21.0 mmol) and anhydrous potassium carbonate (0.145 g, 1.05 mmol) and the mixture was stirred for 5 min at room temperature. Thiophenol (3.23 mL, 31.5 mmol) was added and the mixture was heated at 190 °C for 45 min and cooled. Methanol (105 mL) and triethylamine (4.2 mL) were added, followed by 30% hydrogen peroxide (4.2 mL) in four equal portions over ~5 min. The solution was stirred for 10 min, then concentrated under vacuum to ~10 mL, diluted with 5% aqueous sodium hydroxide and extracted with diethyl ether. The aqueous layer was acidified to pH 2 with 6 mol L^{-1} hydrochloric acid and extracted with diethyl ether and the organic extract was washed with brine, dried and evaporated under reduced pressure. The residue was crystallized from EtOAc–hexanes to give 1-acetyl-5-hydroxynaphthalene **16** as pale yellow crystals. Yield: 2.82 g (72%); mp 173–174.5 °C (lit. (28) mp 172.5–173.5 °C). ^{1}H NMR (400 MHz, $CDCl_3$ – 10% CD_3OD) δ: 2.74 (s, 3H, CH_3), 6.90 (d, J = 7.6 Hz, 1H, Ar-H), 7.40 (m, 1H, Ar-H), 7.47 (m, 1H, Ar-H), 7.92 (d, J = 7.1 Hz, 1H, Ar-H), 8.14 (d, J = 8.6 Hz, 1H, Ar-H), 8.49 (d, J = 8.6 Hz, 1H, Ar-H).

A solution of **16** (1.60 g, 8.60 mmol) in EtOH (59 mL) was stirred at 0 °C and sodium borohydride (0.57 g, 15.1 mmol) was added. After 10 min, the solution was allowed to warm to room temperature and stirred for 1.5 h, then concentrated to ~10 mL. Unreacted borohydride was destroyed by dropwise addition of glacial acetic acid and the solution was diluted with water and extracted with ethyl acetate. The organic phase was washed with brine, dried and evaporated under reduced pressure. The residue was purified by flash chromatography (EtOAc–hexanes (3:7)) to give the title alcohol **4** as beige crystals. Yield: 0.89 g (55%); mp 167.5–169 °C (from EtOAc–hexanes). ^{1}H NMR (500 MHz, $CDCl_3$ – 10% CD_3OD) δ: 1.63 (d, J = 6.0 Hz, 3H, Me), 5.62 (q, J = 6.0 Hz, 1H, C*H*OH), 6.85 (d, J = 7.7 Hz, 1H, Ar-H), 7.33 (m, 1H, Ar-H), 7.45 (t, J = 7.7 Hz, 1H, Ar-H), 7.58 (d, J = 8.5 Hz, 1H, Ar-H), 7.68 (d, J = 6.8 Hz, 1H, Ar-H), 8.20 (d, J = 8.6 Hz, 1H, Ar-H). HR-MS calcd. for $C_{12}H_{12}O_2$: 188.0837; observed: 188.0838.

4-(1-Hydroxyethyl)-1-naphthol (5)

1-Acetyl-4-methoxynaphthalene **17** (29) was demethylated as described above for the 5-isomer **15** to give 1-acetyl-4-hydroxynaphthalene **18** as yellow crystals (from aqueous methanol), mp 198–199.5 °C (lit. (30) mp 197 °C).

A solution of **18** (2.0 g, 10.75 mmol) and TBDMS chloride (2.89 g, 19.2 mmol) in anhyd DMF (9.3 mL) was treated with imidazole (2.72 g, 40.0 mmol) and the mixture was stirred at room temperature for 2 h, then diluted with diethyl ether. The diluted solution was washed with 0.1 mol L^{-1} aqueous sodium carbonate and brine, dried and evaporated under reduced pressure to give crude 4-*tert*-butyldimethylsilyloxy-1-acetylnaphthalene **19** as a beige solid. Yield: 2.58 g (80%). This material was used without further purification. Thus, a solution of **19** (3.33 g, 11.1 mmol) in methanol (86 mL) was stirred at 10 °C and treated with sodium borohydride (0.42 g, 11.1 mmol) in three portions. The solution was stirred for 10 min at 10 °C and for 45 min at room temperature, then concentrated to ~30 mL and treated dropwise with glacial acetic acid (1.5 mL). The solution was diluted with water and extracted with ethyl acetate. The organic phase was washed with brine, dried and evaporated under reduced pressure to give crude 1-(4-*tert*-butyldimethylsilyloxy-1-naphthalenyl)ethanol **20** as a reddish brown viscous gum. Yield: 3.0 g (89%). This material was dissolved in THF (30.5 mL) and treated with 1 mol L^{-1} tetrabutylammonium fluoride in THF (10.93 mL). After 20 min at room temperature the solution was diluted with diethyl ether and washed with water and brine, dried and evaporated under reduced pressure. The residue was flash chromatographed (EtOAc-hexanes (3:7)) to give the title alcohol **5** as a brown solid. Yield: 1.64 g (88%). Crystallization from EtOAc–hexanes was accompanied by some decomposition in the mother liquor but gave the pure alcohol, mp 126–127.5 °C. ^{1}H NMR (500 MHz, $CDCl_3$ – 10% CD_3OD) δ: 1.63 (d, J = 6.5 Hz, 3H, CH_3), 5.57 (q, J = 6.5 Hz, 1H, C*H*OH), 6.83 (d, J = 7.7 Hz, 1H, Ar-H), 7.44–7.47 (m, 2H, Ar-H), 7.49–7.53 (m, 1H, Ar-H), 8.07 (d, J = 8.4 Hz, 1H, Ar-H), 8.27–8.29 (m, 1H, Ar-H). HR-MS calcd. for $C_{12}H_{12}O_2$: 188.0837; observed: 188.0837.

2-(5-Hydroxy-1-naphthalenyl)-2-oxoethyl acetate (9)

A stirred solution of 5-acetoxy-1-naphthoic acid **21** (31) (1.75 g, 7.6 mmol) in dry dichloromethane (30 mL) was treated at room temperature with oxalyl chloride (1.3 mL, 14.9 mmol) and dry DMF (65 μL). After 1 h, the solution was evaporated under reduced pressure and kept overnight under vacuum to leave the crude acid chloride **22**. Yield: 1.95 g (100%). This material (1.89 g, 7.6 mmol) was dissolved in a mixture of anhyd THF and acetonitrile (1:1; 15 mL) and treated with triethylamine (2.11 mL, 15.1 mmol). The solution was cooled in an ice bath and a 2 mol L^{-1} solution of trimethylsilyldiazomethane in hexane (Aldrich; 7.6 mL, 15.2 mmol) was added over 15 min. After 0.5 h, the solution was allowed to warm to room temperature and stirred overnight, then diluted with diethyl ether and washed with sat $NaHCO_3$, water, and brine, dried and evaporated under reduced pressure. The residue was triturated with diethyl ether to give crude diazoketone **23** as a brown solid. Yield: 1.43g (74%). ^{1}H NMR (90 MHz, $CDCl_3$ – 5% CD_3OD) δ: 2.42 (s, 3H, CH_3), 5.66 (s, 1H, CHN_2), 7.23–8.40 (m, 6H, Ar-H).

A solution of **23** (1.43 g, 5.36 mmol) in a mixture of THF and methanol (1:1; 28.6 mL) was treated with concentrated aqueous ammonia (4.77 mL). After 2 h at room temperature, the solution was diluted with ice water and adjusted to pH 8.0 with saturated aqueous oxalic acid. The aqueous layer was extracted with ethyl acetate and the organic extract was washed with water, dried and evaporated under reduced pressure. The residue was flash chromatographed (ethyl acetate – hexanes (3:7)) to give 2-diazo-1-(5-hydroxy-1-naphthalenyl)ethanone **24** as a yellow solid. Yield: 0.56 g (47%). ^{1}H NMR (90 MHz, $CDCl_3$ – 10% CD_3OD) δ: 5.73 (s, 1H, CHN_2), 6.80–8.44 (m, 6H, Ar-H). This material (0.47 g, 2.17 mmol) was added in portions over ~3 min to a stirred mixture of concentrated hydrochloric acid (0.44 mL) and glacial acetic acid (4.4 mL). After 0.5 h, the solution was diluted with water (22 mL) and stirred for 10 min. The precipitated solid was filtered, washed with cold water (3 mL), and dried under vacuum to give crude 1-chloroacetyl-5-hydroxynaphthalene **25** as a yellow powder. Yield: 0.39 g (82%). ^{1}H NMR (90 MHz, $CDCl_3$ – 5% CD_3OD) δ: 4.76 (s, 2H, CH_2Cl), 6.82–8.55 (m, 6H, Ar-H).

A stirred solution of **25** (0.39 g, 1.77 mmol) and glacial acetic acid (0.132 mL, 2.3 mmol) in dry toluene (23 mL) was cooled in ice and treated with DBU (0.344 mL, 2.3 mmol). The solution was stirred in the ice bath for 1 h, then at room temperature overnight. The solution was diluted with water, the aqueous layer was adjusted to pH 2 with 1 mol L^{-1} hydrochloric acid, and the mixture was extracted with diethyl ether. The organic layer was washed with water and brine, dried and evaporated under reduced pressure. The residue was dissolved in ethanol (7 mL), thiourea (0.15 g) was added and the solution was heated at reflux for 0.5 h to remove residual **25**, then concentrated under reduced pressure and partitioned between ethyl acetate and water. The organic phase was washed with water and brine, dried and evaporated and the residue was flash chromatographed (ethyl acetate – hexanes (3:7)). The recovered material was crystallized from toluene to give the title compound **9** as yellow plates. Yield: 0.29 g (50%); mp 99.5–101 °C. ^{1}H NMR (400 MHz) δ: 2.25 (s, 3H, CH_3), 5.31 (s, 2H, CH_2), 6.86 (d, J = 7.5 Hz, 1H, Ar-H), 7.39 (dd, J = 7.8 and 8.4 Hz, Ar-H), 7.48 (dd, J = 7.4 and 8.3 Hz, Ar-H), 7.83 (d, J = 7.0 Hz, Ar-H), 8.14 (d, J = 8.6 Hz, Ar-H), 8.44 (d, J = 8.4 Hz, Ar-H). Anal. calcd. for $C_{14}H_{12}O_4$: C 68.85, H 4.95; found: C 68.57, H 4.89.

2-(3-Hydroxyphenyl)-2-oxoethyl acetate (10)

A stirred solution of 3-hydroxyphenacyl bromide (32) (4.0 g, 18.6 mmol) and glacial acetic acid (2.45 mL, 42.8 mmol) in acetonitrile (63 mL) was cooled in an ice bath and treated dropwise with triethylamine (5.44 mL, 39.1 mmol). The solution was allowed to warm to room temperature and stirred for 2 h, then diluted with brine and extracted with diethyl ether. The extract was washed with 1 mol L^{-1} aq. HCl and brine, dried and evaporated under reduced pressure to give a brown gum (3.3 g) that was dissolved in boiling water, decolorized with charcoal, and extracted with diethyl ether. The extract was dried and evaporated and the residue was crystallized from ethyl acetate –

© 2004 NRC Canada

hexanes to give the title compound **10**. Yield: 0.9 g (25%); mp 94 °C. ^{1}H NMR (400 MHz, $CDCl_3$ – 10% CD_3OD) δ: 2.21 (s, 3H, CH_3), 5.30 (s, 2H, CH_2), 6.94–7.46 (m, 4H, Ar-H). Anal. calcd. for $C_{10}H_{10}O_4$: C 61.85, H 5.19; found: C 61.56, H 5.16.

Product studies

Preparative photolyses for **1**, **2**, **4**, and **5** were carried out with samples (10–20 mg) dissolved in the appropriate solvent (40–100 mL) and transferred to a quartz tube. The solution was irradiated in a RPR-100 photochemical reactor fitted with 254 or 300 nm lamps with continuous cooling (by a cold finger) and purging by a stream of argon for approximately 10 min before and continuously during irradiation (via a long stainless steel needle). Photolysis times ranged from 3 to 30 min, depending on the conversion desired, the efficiency of the reaction, and the size of the sample. After photolysis, aqueous samples were worked up by extraction with CH_2Cl_2 after addition of aq. NaCl. Direct evaporation of the organic solvent was used when samples were irradiated in wholly organic solvents. Typical experiments are described below. Analytical scale photolyses were employed for **9** and **10**, using NMR tubes, as described below.

Photolysis of 1

Photolysis of **1** (20 mg) in 1:1 D_2O–CH_3CN (v/v) (40 mL) with eight lamps (300 nm) for 20 min followed by standard workup gave starting material with deuterium incorporation at the 5-position (55%) and 8-position (19%) with no side products, as determined by 500 MHz ^{1}H NMR. MS analysis of the same sample indicated that it consisted of 37% non-deuterated, 52% monodeuterated, and 11% dideuterated substrate, giving the equivalent overall deuterium incorporation as measured by NMR.

Photolysis of 2

Photolysis of **2** (20 mg) in 1:1 D_2O–CH_3CN (v/v) (40 mL) with 16 lamps (300 nm) for 1 h followed by standard workup gave only starting material with no deuterium incorporation at any position, as determined by 500 MHz ^{1}H NMR. MS analysis of the same sample also indicated that no additional deuterium was incorporated in the sample following photolysis.

Photolysis of 4

Photolysis of **4** (50 mg) in 1:1 H_2O–CH_3OH (v/v) (100 mL) with four lamps (300 nm) for 1 min followed by standard workup gave methyl ether **29** in 48% conversion. Photolysis product **29** was chromatographically isolated on silica gel (10% EtOAc in CH_2Cl_2). ^{1}H NMR (300 MHz, $CDCl_3$) δ: 1.58 (d, 3H, CH_3), 3.30 (br s, 3H, OCH_3), 5.04 (q, 1H, ArC-H), 5.80 (br s, 1H, OH), 6.82 (d, 1H, Ar-H), 7.33 (t, 1H, Ar-H), 7.48 (t, 1H, Ar-H), 7.59 (d, 1H, Ar-H), 7.70 (d, 1H, Ar-H) 8.16 (d, 1H, Ar-H). HR-MS calcd. for $C_{13}H_{14}O_2$: 202.0994; observed: 202.0993.

Photolysis of 5

Photolysis of **5** (20 mg) in 1:1 H_2O–CH_3OH (v/v) (100 mL) containing $NaHCO_3$ (25 mg) with 16 lamps (300 nm) for 3 min followed by standard workup cleanly regenerated starting material with no reaction observable by 300 MHz ^{1}H NMR. A small amount of thermal decomposition was observed when $NaHCO_3$ was not added to the solution.

Photolysis of 9 and 10

In a typical procedure, 2–5 mg of substrate was dissolved in ~2 mL of D_2O–CD_3CN (1:1). The solution was transferred to an NMR tube and deoxygenated by purging with argon for 10 min. The tube was then placed in the middle of the Rayonet reactor (16 × 300 nm lamps) and irradiated for up to 30 min. ^{1}H NMR spectra were taken before and after photolysis without workup. Both **9** and **10** were found to be photochemically inert for up to 30 min photolysis. Under these conditions, **6** would have resulted in quantitative conversion to **8** in about 10 min of photolysis.

Quantum yields

The quantum yield for total deuterium incorporation in **1** has been previously reported (8) to be $\Phi_{H\text{-}D}$ = 0.11 in 99% D_2O, pD 3. Our results demonstrate that the exchange efficiency is the same at pD 7 and pD 3, and that the exchange efficiency appears to plateau around 1:1 H_2O–CH_3CN. Given these data, it is reasonable to assume that $\Phi_{H\text{-}D}$ in neutral 1:1 D_2O–CH_3CN solution should be approximately equal to 0.11 as previously measured. The quantum yield for the photosubstitution reaction of **4** was measured relative to the photomethanolysis reaction of *o*-hydroxybenzhydrol in H_2O–CH_3OH (1:1) (Φ = 0.46) (5). Preparative scale photoreactions (10^{-3} mol L^{-1}, 50 mL H_2O–CH_3OH (1:1), Ar purged, 2 × 254 nm lamps, 1–3 min) were performed for **4** and the reference compound, and the extent of reaction was measured by 300 MHz ^{1}H NMR. The reported value of Φ = 0.84 ± 0.04 is the average of three such runs.

Fluorescence measurements

Steady-state fluorescence measurements were conducted on a Photon Technology International A-1010 (PTI) QuantaMaster luminescence spectrometer. All solutions (absorbance ≈ 0.1 at λ_{ex} 300 nm) were purged with argon prior to excitation. Fluorescence lifetimes were measured on a PTI LS-1 instrument using time-correlated single-photon-counting techniques (10 000 counts, λ_{ex} 300 nm, λ_{em} 350 nm).

Laser flash photolysis (LFP)

A Spectra-Physics excimer laser (308 nm, ~10 ns, <30 mJ/pulse) was used for excitation and signals were digitized with a Tektronix TDS 520 recorder. Samples of OD ~ 0.3 at 308 nm were prepared and irradiated in quartz cells. Static cells were used for the kinetic studies of samples, otherwise flow cells were used for all other studies. Samples in flow cells were continuously purged with a stream of N_2 or O_2. Samples in static cells were purged with N_2 or O_2 then sealed prior to photolysis.

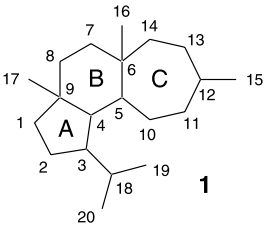
Synthetic studies on cyathin diterpenes — Total synthesis of (±)-allocyathin B_3[1]

Dale E. Ward, Yuanzhu Gai, Qi Qiao, and Jianheng Shen

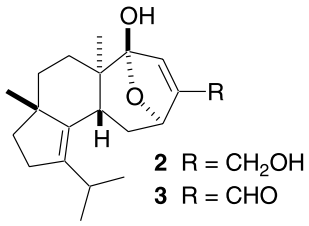
Abstract: The synthesis of racemic allocyathin B_3 from an advanced intermediate possessing the ring system and relative stereochemistry but lacking the isopropyl and hydroxymethyl groups is reported. The isopropyl group was introduced by radical cyclization of a methyl propargyl acetal of an α-bromoketone and the hydroxymethyl group was generated by Pd-catalyzed carbonylation of a vinyl triflate. The route provides functionalized intermediates that could allow access to more complex members of the cyathin family of diterpenes. Several modifications and improvements to the procedures previously described for the synthesis of the advanced intermediate have been achieved.

Key words: cyathin diterpenes, cyathanes, allocyathin B_3.



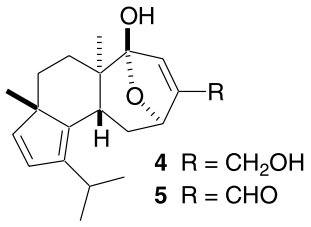
Résumé : On a complété la synthèse de l'allocyathine B_3 à partir d'un intermédiaire avancé comportant le système cyclique et la stéréochimie relative dans lequel il manquait les groupes isopropyle et hydroxyméthyle. Le groupe isopropyle a été introduit par une cyclisation radicalaire d'un cétal méthylique et propargylique d'une α-bromocétone et le groupe hydroxyméthyle a été généré par une carbonylation catalysée par le Pd d'un triflate de vinyle. Cette voie fournit des intermédiaires fonctionnalisés qui permettent d'accéder aux membres plus complexes de la famille de la cyathine des diterpènes. On a développé plusieurs modifications et améliorations aux méthodes décrites pour la synthèse de l'intermédiaire avancé.

Mots clés : diterpènes de la famille de la cyathine, cyathanes, allocyanthine B_3.



[Traduit par la Rédaction]

Introduction



In the1970s, Ayer and co-workers described (1) a family of ca. 20 structurally related diterpenes, isolated from the culture broths of several species of bird's nest fungi of the genus *Cyathus*.[3] These so-called cyathins have the unique cyathane (**1**) (1*b*) carbon skeleton and were the first members of a then new diterpene family. All cyathins have an unfunctionalized B ring bearing trans methyl groups at C-6 and C-9 and, with the exception of allocyathin B_2 (**6**), possess a trans 6–7 ring fusion (cf. **2**–**5**); differences occur in the degree of oxidation and unsaturation around the five-membered and seven-membered rings. More recently, several cyathane diterpenoids with structures closely related to the cyathins have been isolated from a variety of fungi. For example, the striatins (from *C. striatus*) (2) and the erinacines (from *Hericium erinaceum*) (3) are carbohydrate conjugates of cyathins (e.g., **7**), the sarcodonins (from *Sarcodon scabrosus*) (4) are cyathins with a C-19 alcohol (e.g., **8**), and the scabronines (also from *S. scabrosus*) (5) are cyathins with a C-17 carboxylic acid.

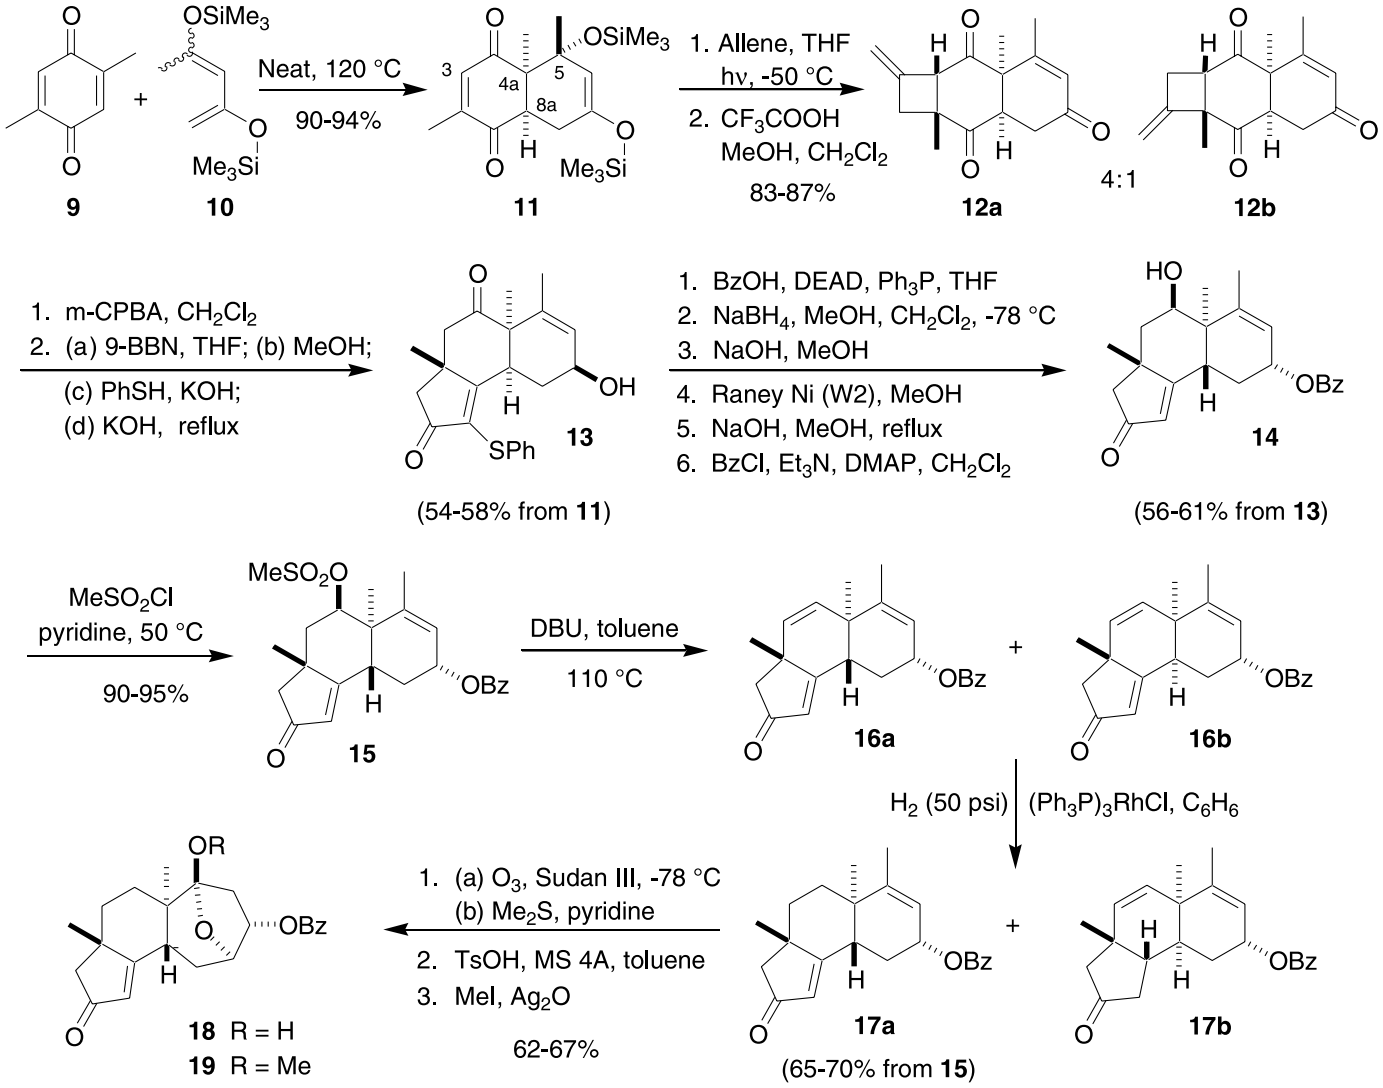
Many of the cyathins show strong antimicrobial activity (1*b*, 6) particularly the unsaturated aldehydes cyathin B_3 (**3**) and cyathin C_3 (**5**). The recent discovery that certain erinacines (3) and scarborines (5, 7) can stimulate the production of nerve growth factor (NGF) and thereby have potential therapeutic value in the treatment of neurodegenerative diseases has generated substantial interest in the synthesis of cyathane diterpenes (8). Although several strategies have successfully produced 5-6-7 tricyclic intermediates (9, 10), only four groups have achieved the total syntheses of a naturally occurring cyathane diterpene. Both Snider et al. (11) and Tori et al. (12) have reported syntheses of racemic allocyathin B_2 (**6**); Snider et al. also obtained (+)-erinacine A (**7**) by separation of the diastereomers resulting from glycosidation of (±)-**6** with D-xylose. The elegant synthesis of sarcodonin G (**8**) by Piers et al. (13) was the first of a cyathane with the characteristic trans 6–7 ring fusion. In this paper we report a full account of our work culminating in the total synthesis of racemic allocyathin B_3 (**4**) by a general route that should be applicable to many of the cyathane diterpenes (14).

Results and discussion

The biological activity and novel structure of the cyathins prompted Ayer et al. to initiate synthetic studies. Cyathin A_3 (**2**), the major metabolite isolated from *C. helenae*, can be easily transformed into several of the other members including **3**–**6** (1*d*, 1*f*) and was a logical synthetic target. The initial objective was a 5-6-6 tricyclic intermediate (15) and the feasibility of obtaining the desired seven-membered C ring by expansion of a six-membered cyclic ketone was demonstrated in a model study (15*c*). Approaches based on A + C → AC → ABC (15*b*) and on C → BC → ABC (15*c*) strategies failed to produce a tricyclic intermediate (15*a*).[4] In a conceptually different approach, the C ring of **2** was envisaged to arise from intramolecular aldol reaction of a 6-oxoheptanal derived by oxidative fragmentation of a 1-methylcyclohexene and a suitable 5-6-6 tricyclic intermediate (i.e., **13**) was efficiently prepared using a B → BC → ABC strategy (Scheme 1) (15*c*, 16).

Ward (9) successfully converted **13** into **19** (Scheme 1), an intermediate possessing the ring system and relative stereochemistry present in cyathin diterpenes (cf. **2**–**5**). In considering the conversion of **19** into a cyathin diterpene (e.g., **2**), strategies for introduction of an isopropyl group at C-3 (cyathane numbering) were not obvious. After considerable experimentation, a method was established to introduce a 3-carbon side chain based on radical cyclization of a propargyl α-bromoacetal (cf. **21** and **22** in Scheme 2); however, all attempts to unravel the resulting 3-methylenetetrahydrofuran in **22** to reveal the A ring present in one of the cyathins failed (17). Several years later, the significant interest in cyathane diterpenes as inducers of NGF production prompted us to reexamine this synthetic route (18).

Several modifications and improvements to the procedures previously described (9, 16) for the synthesis of the tricyclic intermediate **19** from **9** (Scheme 1) have been achieved resulting in an improved overall yield (10% → 12%). We found that the Diels–Alder reaction of **9** and **10** (a 1:1 mixture of *E*- and *Z*-isomers) was conveniently conducted in the absence of solvent at 120 °C to give the adduct **11** as a single stereoisomer in excellent yield after distillation. The relative configuration of **11** was assigned based on the observation of positive NOEs at HC-8a on irradiation of H_3CC-4a and at HC-3 on irradiation of H_3CC-5. The formation of **11** is consistent with an endo reaction of **9** and (*Z*)-**10** and the preferential reaction of (*Z*)-**10** was confirmed by the isolation of **10** enriched in the (*E*)-isomer from the Diels–Alder reaction mixture. Photochemical [2 + 2] addition of allene to **11** proceeded as reported (15*c*, 16) with the exception that trifluoroacetic acid (in place of Amberlyst-15) was used to hydrolyze the photoadducts to give a 4:1 mixture of **12a** and **12b**, respectively, in 85% yield after chromatography. Contrary to the previous report (16), pure **12a** could be obtained by fractional crystallization of this mixture, albeit in modest yield. More conveniently, the crude mixture of **12a** and **12b** (i.e., before chromatography) was subjected to the previously described protocol (9) to give **13** in 55% overall yield from **11**. It is noteworthy that crystalline **13** is obtained directly from the crude reaction mixture after this sequence and in only five operations from **9** in 50% yield without the need for chromatography.



The reported (9) transformation of **13** into **14** (Scheme 1) required a tedious chromatographic purification step after Mitsunobu benzoylation to remove a large amount of by products. We found that this purification could be avoided because the subsequent chemoselective $NaBH_4$ reduction (19) of the C-5 ketone was tolerant of these contaminants and after base hydrolysis of this crude reaction mixture, aqueous work up removed most of the impurities other than Ph_3PO. The presence of Ph_3PO did not interfere with the ensuing Raney Ni desulfurization, base-catalyzed epimerization of the ring junction, and benzoylation thereby allowing the six-stage conversion of **13** into **14** to be carried out with unpurified intermediates in an overall yield comparable to that reported previously. Using the published (9) protocol, we were unable to reproduce the conversion of **14** into **16a**, the major difficulty being the formation of up to 25% of the inseparable epimerized isomer **16b** along with **16a**. Reduction of this mixture of **16a** and **16b** with H_2 and Wilkinson's catalyst gave a separable mixture of the desired **17a** and **17b**. Because **16b** was much less susceptible to reduction than **16a** under these conditions, pure **16b** could be isolated from incomplete reductions of the mixture. After much experimentation it was determined that the formation of **16b** was greatly attenuated (**16a**:**16b** > 20:1) if freshly distilled DBU was used to effect elimination of **15** and if the reaction time was strictly monitored. Although the reaction under these conditions could successfully be conducted with crude **15** (as reported) reproducible results were obtained only using purified materials. Reduction of **16a** as before (9) gave **17a** in 67% overall yield from **14**.

Considerable effort was directed at optimizing the conversion of **17a** to **19** (Scheme 1). Chemoselective ozonolysis of the cyclohexene-type olefin in **17a** was achieved in the pres-

[4] A, B, and C refer to the rings in **1** and the various synthetic strategies can be characterized by the sequence in which the rings are introduced.

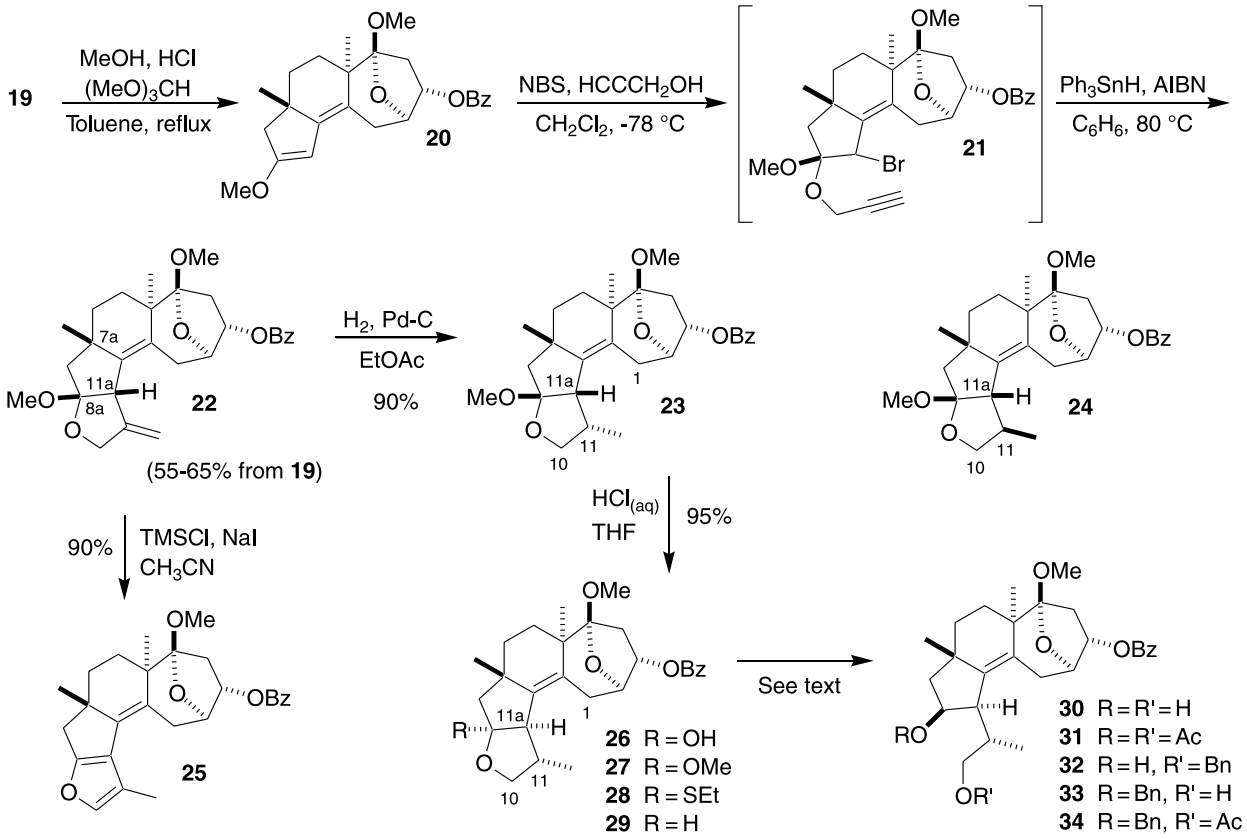
Scheme 1.



ence of Sudan III (20) to give the corresponding ketoaldehyde (9) (Scheme 1). In the presence of TsOH, the ketoaldehyde underwent aldol cyclization with concomitant 1,2-migration of the benzoyl group to give **18** along with significant quantities (3:1) of a side product derived from simple hydrolysis of the benzoate group in the ketoaldehyde (9). The cyclization reaction was very sensitive to the presence of water and various conditions (different acids, solvents, drying protocols) were attempted to improve the yield of **18**. Optimal results were obtained with the use of dry TsOH in dry toluene in the presence of 5 Å molecular sieves at 50 °C, which gave **18** in 80% yield and with very little of the hydrolysis side product (<5%). All of the above work was conducted using a rather old jar (>30 years) of $TsOH{\cdot}H_2O$ (slightly off-white flakes, Eastman); we were surprised to find that cyclization could not be effected using $TsOH{\cdot}H_2O$ from a "new" bottle (white crystals, Aldrich). Although the source of this discrepancy is uncertain, after much experimentation we were able to reproduce the cyclization using new $TsOH{\cdot}H_2O$ with 5% of H_2SO_4. We found that methylation of **18** with MeI to give **19** proceeded in higher yield and with fewer side products using freshly prepared Ag_2O rather than NaH (9) as the base.

Numerous attempts to introduce an isopropyl or other suitable functional group at the α-position of the cyclopentenone in **19** failed. It was noted that a product tentatively identified as the methyl dienol ether of **18** was isolated from an unsuccessful attempt to produce **19** from **18** by treatment with acidic MeOH and $(MeO)_3CH$ in refluxing toluene. Subjecting **19** to similar conditions gave **20** in near quantitative yield (Scheme 2). Our interest in the formation of a dienol ether such as **19** was inspired by the possibility of forming the desired C—C bond by radical cyclization of a derived α-bromoacetal as reported by the Ueno (21) and Stork (22) groups. For our purposes, cyclization of an allylic radical (23) would be required, which at that time (17) had not been demonstrated in the literature. Cohalogenation (24) of **20** with *N*-bromosuccinimide (NBS) and propargyl alcohol gave the somewhat unstable **21** as a single diastereomer (^1H NMR) which cyclized to **22** (60% overall yield from **19**) on treatment with Ph_3SnH and AIBN in refluxing benzene (25). Under the same conditions but replacing propargyl al-

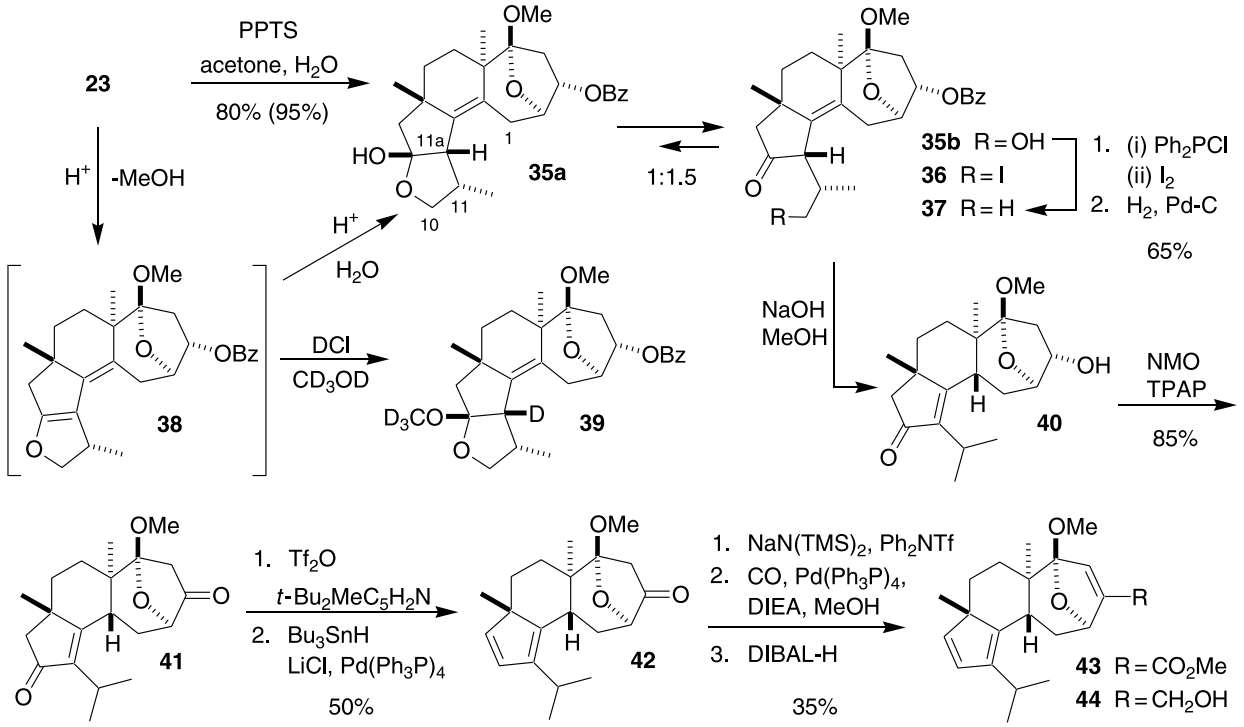
Scheme 2.

cohol with allyl alcohol, **20** was converted into a 1:1 mixture of **23** and **24** in 45% yield.[5] Hydrogenation of **22** gave **23** as a single diastereomer in good yield. The relative configuration of **22** was established by NOE experiments; HC-11a and H_3CC-7a were enhanced on irradiation of the C-8a methoxy protons and the C-8a methoxy group was enhanced on irradiation of the C-7a methyl protons establishing the cis relationship among these three groups. The relative configuration of **23** was assigned based on the $^3J_{HH}$ coupling constants between HC-11 and H_2C-10 (4, <1 Hz) and HC-11a (6.5 Hz), which are consistent with the corresponding H-H dihedral angles (44°, –81°, and –28°, respectively) calculated for **23** by molecular mechanics;[6] the endo orientation of the C-11 methyl group accounts for its significant shielding by the alkene (δ_H 0.83) and is the expected result of hydrogenation from the sterically less-encumbered convex face of the fused ring system. It is noteworthy that the relative configuration at C-11 in **23** is the same as that in the sarcodonins A and G (4) and possibly in the cyathins A_4 and C_5 (1*d*). It was assumed that the relative configuration at C-7a and C-11a in **24** was the same as that in **22** and **23**. The exo orientation of the C-11 methyl group in **24** (δ_H 1.23) is consistent with the observed $^3J_{HH}$ coupling constants between HC-11 and H_2C-10 (6, 7 Hz) and HC-11a (3.5 Hz) as expected from the corresponding H-H dihedral angles (157°, 32°, and –137°, respectively) calculated for **24** by molecular mechanics.[6]



Unmasking the isopropyl group present in **22** proved to be difficult. Treatment with protic or Lewis acids led to loss of methanol and formation of the corresponding furan derivative as observed in related systems (26). For example, treatment of **22** with TMSI (prepared in situ) gave **25** in 90% yield (Scheme 2). Because of the facile formation of **25** from **22**, efforts were directed at unraveling the reduced derivative **23**. Exposure of **23** to 10% aq. HCl in THF slowly (ca. 14 h) produced the isomerized hemiacetal **26** without evidence of an intermediate (by TLC monitoring). The relative configuration of **26** was assigned based on the large changes in the $^3J_{HH}$ coupling constants between H_2C-10 and HC-11 (8, 10.5 Hz) and in the chemical shift of the C-11 methyl group (δ 1.32) compared to **23** (and **35a**, vide infra). These coupling constants are consistent with the corresponding H-H dihedral angles (–36°, –161°) for **26** calculated by molecular mechanics,[6] which also indicated that **26** was 1.3 kcal/mol more stable than **35a**.

Attempts to trap the hydroxy ketone tautomer of hemiacetal **26** by formation of acetate (Ac_2O, DMAP), xanthate ((*i*) CS_2, DBU; (*ii*) MeI), or dithioacetal (EtSH, H^+)[7] derivatives failed. Alternatively, reduction of **26** with $NaBH_4$ in ethanol gave the diol **30** in 70% yield (Scheme 2).

[5] This reaction was not optimized.
[6] CaChe, version 3.9.
[7] The cyclic thioacetal **28** was obtained under these conditions.

© 2004 NRC Canada

Scheme 3.

Deoxygenation of one or both hydroxy groups in **30** via a Barton-type process (27) was envisaged; however, attempted formation of a xanthate ((*i*) NaH, CS_2; (*ii*) MeI), thionocarbonate ($C_6F_5OC(S)Cl$, DMAP, pyridine) (28) or cyclic thionocarbonate (29) derivative surprisingly resulted in the formation of **29**. Similar cyclization of a sterically congested 1,4-diol on attempted derivatization has been observed previously (30). Acetylation of **30** (Ac_2O, DMAP, Et_3N) smoothly gave the diacetate **31** but benzylation of **30** (NaH, BnBr, Bu_4NI) gave a 1:1 mixture of the monobenzyl ethers **32** and **33** in 65% yield. Unfortunately, all efforts to deoxygenate the alcohol group in **32** or **33** were unsuccessful. For example, although acetylation of **33** (Ac_2O, Et_3N, DMAP) to give **34** was uneventful, attempted formation of a thionocarbonate ($C_6F_5OC(S)Cl$, DMAP, pyridine) from **33** unfortunately gave **29**.

A serendipitous observation was crucial to the eventual endgame (Scheme 3). On one occasion (31),[8] hydrogenation of **22** under the usual conditions unexpectedly gave **35** (25%) along with **23**. Importantly and in sharp contrast to **26**, **35** was a 1.5:1 mixture (by NMR in $CDCl_3$ solution) of the hydroxy ketone (**35b**) and hemiacetal (**35a**) tautomers, respectively, and esters of the hydroxy ketone tautomer **35b** could be prepared in good yield. A more detailed investigation of the hydrolysis of **23** was undertaken. On standing in $CDCl_3$ solution, **23** quantitatively isomerized into **27** within 3 days (presumably catalyzed by adventitious HCl); molecular mechanics[6] indicated that **27** was 2.1 kcal/mol more stable than **23** largely due to the decreased steric interaction between the C-11 methyl group with H_2C-1 in the former. Hydrolysis of **27** (10% aq. HCl in THF, 14 days) also gave **26** but much more slowly than hydrolysis of **23** (14 h) under the same conditions. Exposure of **23** to DCl in CD_3OD solution gave **39** at the same rate as the loss of **23** suggesting the formation of **38** as an intermediate. The formation of **39** indicated that hydrolysis of **23** without isomerization to **26** might be possible. After considerable experimentation, we found that reaction of **23** with pyridinium 4-methylbenzenesulfonate (PPTS) in aqueous acetone for 12 days gave **35** (80%) along with recovered **23** (15%) (Scheme 3).

Several methods for deoxygenation of the alcohol group in **35b** were attempted with varying success. The desired transformation was best accomplished by reaction of **35** with Ph_2PCl followed by I_2 (32) and reduction of the resulting iodide **36** with H_2 over Pd–C to give **37** (65% overall from **35**). At this stage, the amount of available material necessitated a direct route to the target with little opportunity for optimization. Treatment of **37** with NaOH in MeOH resulted in hydrolysis of the benzoate ester with concomitant isomerization of the double bond into the required position to give **40**. This isomerization reestablishes the desired trans 6–7 ring fusion, as expected; the presence of the transannular acetal within the seven-membered ring makes the cis-fused diastereomer impossibly strained. To avoid schemes requiring protection and deprotection steps, **40** was directly oxidized to diketone **41** with tetrapropylammonium perruthenate (TPAP) and *N*-methylmorpholine (NMO) (33). Selective deoxygenation of the cyclopentenone carbonyl was achieved by reaction of **40** with triflic anhydride (Tf_2O) in the presence of the hindered base 2,6-di-*tert*-butyl-4-methylpyridine (34) to chemoselectively give the dienol triflate, which was reduced to cyclopentadiene **41** by Pd-catalyzed reaction with Bu_3SnH (35, 36). Finally, introduction of the vinyl hydroxymethyl group was achieved by Pd-

[8] This outcome was presumably due to the presence of adventitious acid (31) but could not be reproduced despite numerous attempts.

© 2004 NRC Canada

catalyzed carbonylation (37) of the vinyl triflate derived from **42** followed by DIBAL-H reduction of the resulting methyl ester **43** to give (±)-**44**. Spectral data (^{1}H and ^{13}C NMR, UV, MS) for (±)-**44** closely matched that previously reported (1*b*, 38) for (–)-**44**. Hydrolysis of **44** to allocyathin B_3 (**4**; a mixture of hydroxy ketone and hemiacetal tautomers) proceeds readily in THF solution on exposure to aq. $HClO_4$ (1*d*).

In conclusion, the synthesis of racemic allocyathin B_3 (**4**) was achieved by introduction of the required isopropyl and vinyl hydroxymethyl groups onto an advanced intermediate (**19**) already possessing the correct ring system and relative stereochemistry. This is the first synthesis of a cyathin diterpene incorporating the trans 6–7 ring fusion and a fully functionalized seven–membered ring. The reported solution for introduction the isopropyl group (i.e., **19** → **40**; seven steps, 35% yield) provides intermediates with potentially useful functionality. For example, intermediate **35** has functionality that potentially can provide access to any of the various oxidation patterns present on the A (i.e., five-membered) ring of cyathin and related diterpenes. Indeed, simple modifications of the general route reported herein can be contemplated that might lead to *any* of the known cyathin diterpenes and several related natural products. Finally, this approach should be adaptable to asymmetric synthesis via an enantioselective Diels–Alder reaction of **9** and **10**. Our progress towards these objectives will be reported in due course.

Experimental

General methods

All solvents were distilled prior to use. Et_3N was distilled from CaH_2 and stored over KOH pellets. Anhydrous solvents were distilled under argon as follows: ether and tetrahydrofuran (THF) from benzophenone potassium ketyl; benzene, toluene, and CH_2Cl_2 from CaH_2 and stored over 4 Å molecular sieves; MeOH from $Mg(OMe)_2$. Unless otherwise noted, reactions were carried out under an atmosphere of argon and reaction temperatures refer to the bath. Concentration refers to removal of volatiles at water aspirator pressure on a rotary evaporator with final traces of solvent removed at high vacuum (ca. 1 mbar).

Preparative TLC (PTLC) was carried out on glass plates (20 × 20 cm) precoated (0.25 mm) with silica gel 60 F_{254}. Materials were detected by visualization under an ultraviolet lamp (254 nm) and (or) by treating a 1 cm vertical strip removed from the plate with a solution of phosphomolybdic acid (5%) containing a trace of ceric sulfate in aqueous sulfuric acid (5% v/v), followed by charring on a hot plate. Flash column chromatography (FCC) was performed according to Still et al. (39) with Merck Silica Gel 60 (40–63 μm). Dry FCC was performed according to Harwood (40). Medium pressure chromatography (MPC) was performed as described by Taber (41) using Silica Gel 60 (10–40 μm, type H). All mixed solvent eluents are reported as v/v solutions.

Spectral data

High resolution mass spectra (HR-MS) and low resolution mass spectra (LR-MS) were obtained on a VG 70E double focussing high resolution spectrometer; only partial data are reported. EI ionization was accomplished at 70 eV and CI at 50 eV with ammonia as the reagent gas; only partial data are reported. IR spectra were recorded on a Fourier transform interferometer using a diffuse reflectance cell (DRIFT); only diagnostic and (or) intense peaks are reported. Unless otherwise noted, NMR spectra were measured in $CDCl_3$ solution at 300 or 500 MHz for ^{1}H and 75 or 125 MHz for ^{13}C. For ^{1}H NMR, residual $CHCl_3$ in $CDCl_3$ was employed as the internal standard (δ 7.26); for ^{13}C NMR, $CDCl_3$ was employed (δ 77.2). The ^{1}H NMR chemical shifts and coupling constants were determined assuming first-order behavior. Multiplicity is indicated by one or more of the following: s (singlet), d (doublet), t (triplet), q (quartet), m (multiplet), br (broad), ap (apparent); the list of coupling constants (*J*) corresponds to the order of the multiplicity assignment. ^{1}H NMR spectra were normally obtained with a digital resolution of 0.2–0.3 Hz/pt and coupling constants are reported to the nearest 0.5 Hz. The ^{1}H NMR assignments were made on the basis of chemical shift and multiplicity and were confirmed, where necessary, by homonuclear decoupling and (or) NOE experiments. The multiplicity of ^{13}C NMR signals refers to the number of attached Hs (i.e., s = C, d = CH, t = CH_2, q = CH_3) and was determined by *J*-modulation (42).

Materials

Quinone **9** (43) and diene **10** (44) were prepared by known procedures. All other reagents were commercially available and, unless otherwise noted, were used as received.

*(4a*R*,5*R*,8a*R*)-rel-4a,5,8,8a-Tetrahydro-2,4a,5-trimethyl-5,7-bistrimethylsilyloxy-*p*-naphthoquinone (11)*

A suspension of **9** (10 g, 74 mmol) in **10** (85 g, 0.35 mol) was heated at 120 °C. After 42 h, excess **10** was removed by distillation (74–67 °C/1.7 mbar) and the residue was purified by bulb-to-bulb distillation (160–180 °C/0.2 mbar) to give **11** (16) as a viscous yellow oil (26 g, 93%).

*(2a*R*,3a*R*,7a*R*,8a*S*)-rel-1,2,2a,3,3a,4,5,7a,8,8a-Decahydro-2a,7,7a-trimethyl-1-methylenecyclobuta[b]naphthalen-3,5,8-trione (12a) and (2a*S*,3a*R*,7a*R*,8a*S*)-rel-1,2,2a,3,3a,4,5,7a,8,8a-decahydro-2a,7,7a-trimethyl-2-methylenecyclobuta[b]naphthalen-3,5,8-trione (12b)*

A solution of **11** (20 g, 53 mmol) and excess allene (150 mL) in dry THF (180 mL) was irradiated with a 1200 W mercury vapor lamp in a Pyrex vacuum-jacketed water-cooled immersion well while argon was bubbled through the solution. The entire apparatus was fitted with a dry ice condenser and was immersed in a dry ice – acetone bath that maintained an internal temperature of ca. –50 °C. After 12 h, the bath was removed and the excess allene was recovered (and could be reused) by passing the argon effluent through a dry ice condenser and the remaining reaction mixture was concentrated to afford the crude photoadducts as an oil (22 g). Trifluoroacetic acid (1 mL) was added to a stirred solution of the crude photoadducts (10 g) and MeOH (20 mL) in CH_2Cl_2 (180 mL). After 2 h, toluene (5 mL) was added and the mixture was concentrated to give crude **12** (6.8 g; **12a**:**12b** was 4:1 by ^{1}H NMR) that was purified by FCC (50% ethyl acetate in hexane) to give **12** as a 4:1 mixture of **12a** and **12b**, respectively, (5.3 g, 85% from **11**). Fractional crystallization of the mixture from ether–hexane gave pure **12a** (2.3 g; mp 120–124 °C, 136–138 °C (CCl_4)) and a second crop of highly enriched **12a** (0.4 g). Spectral data for

© 2004 NRC Canada

12a closely matched that reported previously (16). The mother liquor from the above crystallization (2.6 g) was a 1.1:1 mixture of **12a** and **12b**, respectively. NMR spectral data for **12b** was readily extracted from the spectra of the mixture. ^{1}H NMR (500 MHz, $CDCl_3$) δ: 5.90 (1H, q, J = 1.5 Hz, HC-6), 5.00 (1H, br s) and 5.00 (1H, br s) (exocyclic methylene Hs), 3.31 (1H, dddd, J = 2.5, 3, 10, 16 Hz, HC-1), 3.20 (1H, dd, J = 3.5, 4.5 Hz, HC-3a), 3.16 (1H, dd, J = 3.5, 17.5 Hz, HC-4), 3.04 (1H, dd, J = 5.5, 10 Hz, HC-8a), 2.99 (1H, dddd, J = 2, 2.5, 5.5, 16 Hz, HC-1), 2.54 (1H, dd, J = 4.5, 17.5 Hz, HC-4), 1.85 (3H, d, J = 1.5 Hz, H_3CC-7), 1.52 (3H, s, H_3C), 1.44 (3H, s, H_3C). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 210.3 (s), 206.2 (s), 195.2 (s), 158.6 (s), 147.5 (s), 129.4 (d), 109.6 (t), 58.8 (s), 54,5 (s), 52.7 (d), 48.2 (d), 35.0, (t), 34.2 (t), 24.0 (q), 22.0 (q), 20.9 (q).

(3aS,5aR,8S,9aS)-rel-3a,4,5a,8,9,9a-Hexahydro-8-hydroxy-3a,5a,6-trimethyl-1-(phenylthio)-2H-benz[e]indene-2,5(3H)-dione (13)

Using the previously described procedure (9), a solution of crude **12** (1.78 g) (obtained as described above) and mCPBA (50%, 3.39 g, 9.92 mmol) in CH_2Cl_2 (200 mL) was stirred at room temperature for 48 h. $(CH_3)_2S$ (2 mL) was added and after 1 h, the reaction mixture was washed with satd. $NaHCO_3$, dried over Na_2SO_4, and concentrated to give the crude epoxides (1.85 g). 9-BBN (0.5 mol L^{-1} in THF, 24 mL, 12 mmol) was added to a stirred solution of the above crude epoxides (1.85 g) in THF (80 mL) at 0 °C under argon. The cooling bath was removed and after 5 h, MeOH (100 mL) was added. The solution was cooled to 0 °C and thiophenol (0.83 mL, 0.89 g, 8.1 mmol) and 2 N aq. KOH (0.31 mL, 0.62 mmol) were added. The solution was allowed to warm to room temperature and after 14 h, 2 N aq. KOH (8.5 mL, 1.2 mmol) was added and the resulting solution was heated under reflux for 2 h. The reaction mixture was concentrated, diluted with water, and extracted with CH_2Cl_2 (×3). The combined CH_2Cl_2 layers were washed with dilute aq. NaOH and with water, dried over Na_2SO_4, and concentrated to give an oil that on trituration with ether provided crystalline **13** (1.25 g, 54% from **11**; mp 209–211 °C). Spectral data for **13** closely matched that reported previously (16).

(3aS,5R,5aR,8R,9aR)-rel-8-(Benzoyloxy)-3,3a,4,5,5a,8,9,9a-octahydro-5-hydroxy-3a,5a,6-trimethyl-2H-benz[e]inden-2-one (14)

Using the previously described procedure (9), diethyl azodicarboxylate (0.23 mL, 0.25 mg, 1.5 mmol) was added dropwise over 5 min to a stirred solution of **13** (308 mg, 0.837 mmol), Ph_3P (309 mg, 1.18 mmol), and $PhCO_2H$ (155 mg, 1.27 mmol) in dry THF (36 mL) at 15–20 °C under argon. After 1 h, MeOH (5 mL) was added and the mixture was concentrated to give the crude benzoate **80** (1.09 g). $NaBH_4$ (128 mg, 3.38 mmol) was added to a solution of the above crude benzoate (1.09 g) in 1:1 CH_2Cl_2–MeOH (50 mL) at –78 °C. After standing at –78 °C for 14 h, acetic acid (2 mL) was added with stirring and the reaction mixture was allowed to warm to room temperature. Concentration from toluene (×2) provided the crude alcohol that was taken up in MeOH (100 mL) and 1 N NaOH (15 mL) was added and the reaction mixture was heated to 50 °C. After 16 h, the mixture was concentrated, diluted with water, and extracted with CH_2Cl_2 (×3). The combined CH_2Cl_2 layers were dried over Na_2SO_4, and concentrated to give the crude diol (650 mg; the major contaminant was Ph_3PO). W2 Raney Ni (1.6 mL) was added to a stirred solution of the above crude diol (650 mg) in MeOH (35 mL). After 2 h, the mixture was filtered through Celite and the combined filtrate and washings were concentrated to provide the crude desulfurized diol **82** (566 mg) that was taken up in MeOH (35 mL) and NaOH (545 mg, 13.6 mmol) was added and the resulting solution was heated under reflux for 5 days to effect epimerization of the ring junction. The reaction mixture was made slightly acidic (pH 6) by addition of 6 N HCl(aq) and $NaHCO_3$ (0.4 g) was added. The mixture was concentrated to dryness and the resulting solid was extracted with 30% MeOH in CH_2Cl_2 (×3). Concentration of the combined extracts provided a residue that was dissolved in CH_2Cl_2 (40 mL) and PhCOCl (0.28 mL, 0.34 g, 2.4 mmol), Et_3N (0.56 mL, 0.41 g, 4.0 mmol), and DMAP (20 mg, 0.16 mmol) were added. The reaction mixture was kept at 4 °C for 16 h and then MeOH (2 mL) was added. After 30 min, the solution was concentrated and the resulting oil was fractionated by MPC (eluting first with CH_2Cl_2 then with 75% ethyl acetate in hexane) to give **14** (171 mg, 56% overall yield from **13**). Spectral data for **14** closely matched that reported previously (9).

(3aS,5R,5aR,8R,9aR)-rel-8-(Benzoyloxy)-3,3a,4,5,5a,8,9,9a-octahydro-5-methanesulfonyloxy-3a,5a,6-trimethyl-2H-benz[e]inden-2-one (15)

Using the previously described procedure (9), methanesulfonyl chloride (0.90 mL, 1.3 g, 11 mmol) was added over 15 h using a syringe pump to a stirred solution of **14** (526 mg, 1.44 mmol) in dry pyridine (50 mL) at 50 °C under argon. The mixture was concentrated from toluene and then diluted with ethyl acetate, washed with dilute aq. HCl, satd. $NaHCO_3$ and brine, dried over Na_2SO_4, concentrated, and fractionated by FCC (25% ethyl acetate in hexane) to give **15** (580 mg, 91%). IR (KBr) ν_{max} (cm^{-1}): 2956, 1712, 1270, 1174, 918. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 8.56 (2H, m, Ph), 7.59 (1H, m, Ph), 7.54 (2H, m, Ph), 5.85 (1H, d, J = 1.5 Hz, HC-1), 5.73 (1H, m, HC-8), 5.52 (1H, br s, HC-7), 5.07 (1H, dd, J = 2.5, 2.5 Hz, HC-5), 3.22 (1H, br d, J = 13 Hz, HC-9a), 3.08 (3H, s, H_3CSO_3), 2.59 (1H, dd, J = 2.5, 15.5 Hz, HC-4), 2.39 (1H, d, J = 18 Hz, HC-3), 2.35 (1H, m, HC-9), 2.26 (1H, d, J = 18 Hz, HC-3), 1.93 (1H, dd, J = 11, 13 Hz, HC-9), 1.91 (1H, dd, J = 2.5, 15.5 Hz, HC-4), 1.83 (3H, dd, J = 1.5, 1.5 Hz, H_3CC-6), 1.47 (3H, s, H_3C), 1.02 (3H, s, H_3C). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 206.5 (s, C-4), 185.5 (s, C-2), 166.2 (s), 142.2 (s), 133.1 (d), 130.1 (s), 129.6 (d × 2), 128.3 (d × 2), 126.7 (d), 124.1 (d), 80.2 (d), 69.9 (d), 53.5 (t), 45.5 (s), 42.4 (s), 39.6 (q), 39.5 (t), 35.7 (d), 29.2 (q), 26.3 (t), 18.9 (q), 17.6 (q). LR-MS (EI), *m/z* (relative intensity): 348 ($[M - CH_3SO_3H]^+$, 11), 269 (16), 226 (22), 211 (28), 183 (12), 149 (36), 122 (20), 105 (100).

(3aR,5aR,8R,9aR)-rel-8-(Benzoyloxy)-3,3a,5a,8,9,9a-hexahydro-3a,5a,6-trimethyl-2H-benz[e]inden-2-one (16a)

Freshly distilled DBU (0.75 mL, 760 mg, 5.0 mmol) was added to a stirred solution of **15** (460 mg, 1.04 mmol) in toluene (30 mL) under argon and the mixture was heated under reflux. Reaction progress was monitored by TLC (50% ethyl acetate in hexane) and after 30–40 h, **15** was no longer

© 2004 NRC Canada

present. The mixture was diluted with ethyl acetate and washed with dilute aq. HCl, satd. $NaHCO_3$ and brine, dried over Na_2SO_4, concentrated, and fractionated by FCC (30% ethyl acetate in hexane) to give **16a** as a colorless oil (301 mg, 83%). Spectral data for **16a** closely matched that reported previously (9). Similar reactions using the DBU "as received" or with extended reaction times gave inseparable mixtures of **16a** with up to 25% of **16b** in lower yields (50%–75%).

(3aR,5aR,8R,9aS)-rel-8-(Benzoyloxy)-3,3a,5a,8,9,9a-hexahydro-3a,5a,6-trimethyl-2H-benz[e]inden-2-one (16b), (3aR,5aS,8S,9aR)-rel-8-(benzoyloxy)-3,3a,4,5,5a,8,9,9a-octahydro-3a,5a,6-trimethyl-2H-benz[e]inden-2-one (17a), and (3aR,5aR,8R,9aS,9bS)-rel-8-(benzoyloxy)-1,3,3a,5a,8,9,9a,9b-octahydro-3a,5a,6-trimethyl-2H-benz[e]inden-2-one (17b)

A solution of a 3:1 mixture of **16a** and **16b**, respectively (99 mg, 0.28 mmol), and $(Ph_3P)_3RhCl$ (25 mg, 0.027 mmol) in degassed benzene (12 mL) was stirred under a H_2 atmosphere (ca. 3 bar) for 72 h. The mixture was concentrated and fractionated by FCC (30% ethyl acetate in hexane) to give **17a** (68 mg, 68%), **17b** (23 mg, 23%), and **16b** (4.5 mg, 5%). Spectral data for **17a** closely matched that reported previously (9). Spectral data for **17b**: IR (KBr) ν_{max} (cm^{-1}): 2958, 2920, 1742, 1711, 1601, 1271, 1112. ^1H NMR (300 MHz, $CDCl_3$) δ: 8.06 (2H, m, Ph), 7.54 (1H, m, Ph), 7.44 (2H, m, Ph), 5.66 (2H, ap s, HC-4, HC-5), 5.44 (1H, m, HC-8), 5.38 (1H, br s, HC-7), 2.71 (1H, dd, J = 8.5, 19 Hz, HC-1), 2.43 (1H, d, J = 19 Hz, HC-1), 2.21 (1H, d, J = 18.5, HC-3), 2.10 (1H, d, J = 18.5 Hz, HC-3), 2.20–2.06 (3H, m, HC-9b, H_2C-9), 1.75 (3H, br s, H_3C), 1.60 (1H, ddd, J = 3.5, 3.5, 13 Hz, HC-9a), 1.31 (3H, s, H_3C), 1.06 (3H, s, H_3C). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 218.1 (s), 166.5 (s), 144.3 (s), 133.2 (d), 132.9 (d, Ph), 132.5 (d), 130.6 (s), 129.6 (d × 2), 128.3 (d × 2), 119.7 (d), 68.9 (d), 49.9 (t), 42.1 (d), 41.4 (t), 40.7 (d), 39.6 (s), 38.8 (s), 28.4 (q), 28.3 (q), 26.3 (t), 19.6 (q). Spectral data for **16b**: IR (KBr) ν_{max} (cm^{-1}): 2965, 2927, 1712, 1616, 1267. ^1H NMR (300 MHz, $CDCl_3$) δ: 8.05 (2H, m, Ph), 7.58 (1H, m, Ph), 7.46 (2H, m, Ph), 6.03 (1H, s, HC-1), 5.82 (1H, d, J = 5.5 Hz, HC-7), 5.69 (1H, d, J = 10 Hz, HC-4 or HC-5), 5.62 (1H, d, J = 10 Hz, HC-4 or HC-5), 5.42 (1H, br s, HC-8), 3.17 (1H, br d, J = 13.5 Hz, HC-9a), 2.39 (2H, ap s, H_2C-3), 2.30 (1H, ddd, J = 3.5, 13.5, 13.5 Hz, HC-9), 2.08 (1H, br d, J = 13.5 Hz, HC-9), 1.87 (3H, s, H_3C), 1.38 (3H, s, H_3C), 1.09 (3H, s, H_3C). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 218.1 (s), 166.5 (s), 144.3 (s), 133.2 (d), 132.9 (d, Ph), 132.5 (d), 130.5 (s), 129.6 (d × 2), 129.3 (d, C-3), 128.4 (d × 2), 119.7 (d), 68.9 (d), 49.9 (t), 40.6 (d), 39.6 (s), 38.7 (s), 28.4 (q), 28.3 (q), 26.3 (t), 19.6 (q). LR-MS (EI), *m/z* (relative intensity): 348 ($[M]^+$, 14), 243 (29), 226 (14), 211 (25), 183 (15), 149 (21), 105 (83), 84 (100). A similar reduction of pure **16a** (200 mg) under the above conditions gave **17a** (179 mg, 88%).

(3aR,5aS,6S,8R,9S,10aS)-rel-8-(Benzoyloxy)-3a,4,5,5a,6,7,8,9,10,10a-decahydro-6-methoxy-3a,5a-dimethyl-6,9-epoxycyclohept[e]inden-2(3H)-one (18)

A stream of ozone in air was bubbled through a solution of **17a** (295 mg, 0.84 mmol) and a small amount (1 to 2 mg) of Sudan III in 10% methanolic dichloromethane (40 mL) at –78 °C until the red color was discharged. Argon was bubbled through the solution for 20 min (to remove excess O_3) and then pyridine (0.1 mL) and dimethyl sulfide (0.5 mL) were added and the solution kept at 4 °C (refrigerator) for 16 h. The mixture was concentrated from xylene (to remove pyridine and dimethyl sulfoxide) to provide essentially homogeneous ketoaldehyde (320 mg, 99%). A solution of the ketaoaldehyde (320 mg, 0.84 mmol) in benzene (150 mL) was dried by concentration to a volume of ca. 100 mL via distillation under argon. Activated molecular sieves 5 Å (4.5 g; ca. 70 pellets) was added to this solution. A suspension of *p*-toluenesulfonic acid monohydrate (320 mg, 1.86 mmol) in toluene (80 mL) was heated under reflux in a modified Dean–Stark trap containing activated 5 Å molecular sieves. After 45 min, the resulting dry TsOH solution was allowed to cool to room temperature and then was added to the above solution of ketoaldehyde and the reaction mixture was heated to 50 °C. After 48 h, the mixture was allowed to cool to room temperature and $NaHCO_3$ (3 g) was added. After stirring for 20 min, the mixture was diluted with ethyl acetate (100 mL) and filtered. The combined filtrate and washings (20% MeOH in CH_2Cl_2) were concentrated and fractionated by FCC (30%–50% ethyl acetate in hexane) to give **18** (260 mg, 81%). Spectral data for **18** closely matched that reported previously (9).

(3aR,5aS,6S,8R,9S,10aS)-rel-8-(Benzoyloxy)-3a,4,5,5a,6,7,8,9,10,10a-decahydro-6-methoxy-3a,5a-dimethyl-6,9-epoxycyclohept[e]inden-2(3H)-one (19)

The acetal (166 mg, 0.434 mmol) was dissolved in MeI (5 mL); freshly prepared Ag_2O (100 mg, 0.43 mmol) was added in portions every 2 to 3 h for 24 h to a stirred solution of **18** (166 mg, 0.434 mmol) in MeI (5 mL). The reaction mixture was diluted with ethyl acetate and filtered through Celite. The combined filtrate and washings were concentrated and fractionated by FCC (20% ethyl acetate in hexane) to give **19** (138 mg, 83%). Spectral data for **19** closely matched that reported previously (9).

(3aS,5aR,6R,8S,9R)-rel-3,3a,4,5,5a,6,7,8,9,10-Decahydro-2,6-dimethoxy-3a,5a-dimethyl-6,9-epoxycyclohept[e]inden-8-yl benzoate (20)

A solution of 3% HCl in MeOH (0.45 mL) was added to a solution of **19** (18 mg, 0.045 mmol) and trimethyl orthoformate (0.6 mL) in toluene (3 mL). After 1 h, toluene (1 mL) was added and the reaction mixture was concentrated to a volume of ca. 1 mL by distillation of the solvent at atmospheric pressure. The reaction mixture was concentrated under reduced pressure to give **20** (19 mg) that was essentially homogeneous by TLC and was used in the next step without further purification. A sample purified by FCC (20% ethyl acetate in hexane) gave the following spectral characteristics: IR (cm^{-1}): 1716, 1608. ^1H NMR (300 MHz, C_6D_6) δ: 8.24 (2H, m, Ar-H), 7.10 (3H, m, Ar-H), 5.23 (1H, dd, J = 2, 7.5 Hz, HC-8), 5.01 (1H, br s, HC-1), 4.60 (1H, d, J = 4.5 Hz, HC-9), 3.48 (3H, s, H_3COC-6), 3.28 (3H, s, H_3COC-2), 2.54 (1H, dd, J = 4.5, 14 Hz, HC-10), 2.51 (1H, dd, J = 7.5, 14.5 Hz, HC-7), 2.38 (1H, d, J = 14.5 Hz, HC-3), 2.15 (1H, d, J = 14 Hz, HC-10), 2.14 (1H, dd, J = 2, 14.5 Hz, HC-7), 2.13 (1H, d, J = 14.5 Hz, HC-3), 1.55

(2*R*,3*S*,5*R*,5a*R*,7a*S*,8a*R*,11a*R*)-rel-1,2,3,4,5,5a,6,7,7a,8,8a,10,11,11a-Tetradecahydro-5,8a-dimethoxy-5a,7a-dimethyl-11-methylene-2,5-epoxycyclohept[6,7]indeno[2,1-b]furan-3-yl benzoate (22)

A solution of *N*-bromosuccinimide (recrystallized; 12 mg, 0.068 mmol) in CH_2Cl_2 (1.2 mL) was added to a stirred solution of the above crude **20** (19 mg) and distilled propargyl alcohol (0.12 mL, 115 mg, 2.0 mmol) in CH_2Cl_2 (0.8 mL) at –78 °C under argon. After 20 min, the reaction mixture was quenched by addition of 10% aq. $Na_2S_2O_3$ and the cooling bath was removed. The mixture was diluted with CH_2Cl_2 and washed with aq. $NaHCO_3$ and water, dried over Na_2SO_4, and concentrated to give the crude α-bromoacetal **21** (28 mg) that was somewhat unstable and was used immediately without further purification. Attempted fractionation of the crude by FCC (35% ethyl acetate in hexane) gave a sample (ca. 85% purity) with the following spectral characteristics: ^1H NMR (300 MHz, C_6D_6) δ: 8.22 (2H, m, Ph), 7.14 (3H, m, Ph), 5.43 (1H, dd, *J* = 2, 7 Hz, HC-8), 4.85 (1H, s, HC-1), 4.53 (1H, br d, *J* = 5 Hz, HC-9), 3.99 (2H, ap d, *J* = 2 Hz, H_2CO), 3.40 (3H, s, H_3COC-6), 3.11 (3H, s, H_3COC-2), 2.41 (1H, br d, *J* = 14 Hz, HC-10), 2.32 (1H, dd, *J* = 7, 15 Hz, HC-7), 2.19 (1H, dd, *J* = 5, 14 Hz, HC-10), 2.15–2.05 (2H, m, HC-3, HC-7), 2.04 (1H, t, *J* = 2 Hz, HC≡C), 1.70–1.30 (5H, m), 1.44 (3H, s, H_3C), 1.42 (3H, d, H_3C). Ph_3SnH (27 mg, 0.077 mmol) and AIBN, (1.6 mg, 0.01 mmol) were added to a solution of the above crude **21** (28 mg) in freshly distilled, degassed benzene (3 mL) under argon and the reaction mixture was immersed in an oil bath preheated to 80 °C. After 2 h, the mixture was concentrated and fractionated by MPC (10%–60% ethyl acetate in hexane) to give **22** (14 mg, 67% yield from **19**): IR (cm^{-1}): 1717. ^1H NMR (300 MHz, $CDCl_3$) δ: 8.03 (2H, m, Ph), 7.57 (1H, m, Ph), 7.45 (2H, m, Ph), 5.27 (1H, br s, HC=C), 5.20 (1H, br s, HC=C), 5.05 (1H, dd, *J* = 2, 7.5 Hz, HC-3), 4.37 (1H, br d, *J* = 5 Hz, HC-2), 4.34 (1H, br d, *J* = 11.5 Hz, HC-10), 4.28 (1H, br d, *J* = 11.5 Hz, HC-10), 3.76 (1H, br s, HC-11a), 3.40 (3H, s, H_3COC-5), 3.29 (3H, s, H_3COC-8a), 2.90 (1H, dd, *J* = 1, 15 Hz, HC-1), 2.36 (2H, m, HC-1, HC-4), 2.03 (2H, m, HC-8, HC-4), 1.83 (1H, d, *J* = 13.5 Hz, HC-8), 1.67–1.47 (4H, m, H_2C-6, H_2C-7), 1.18 (3H, s, H_3C), 1.15 (3H, s, H_3C). ^{13}C NMR (75 MHz, C_6D_6) δ: 166.5 (s), 148.9 (s), 140.5 (s), 132.8 (d), 130.9 (s), 130.6 (s), 129.6 (d × 2), 128.3 (d × 2), 117.6 (s), 111.0 (s), 110.3 (t), 78.9 (d), 78.3 (d), 71.0 (t), 56.0 (d), 50.4 (q), 49.6 (q), 49.0 (t), 45.9 (s), 43.0 (s), 33.0 (t), 32.6 (t), 29.4 (t), 28.3 (t), 27.8 (q), 20.1 (q). (2*R*,3*S*,5*R*,5a*R*,7a*S*,8a*R*,11*S*,11a*S*)-rel-11a-Deuterio-8a-trideuteriomethoxy-1,2,3,4,5,5a,6,7,7a,8,8a,10,11,11a-tetradecahydro-5-methoxy-5a,7a,11-trimethyl-2,5-epoxycyclohept[6,7]indeno[2,1-b]furan-3-yl benzoate (39)

A solution of **23** (1.2 mg, 0.0026 mmol) in CD_3OD containing 1% DCl was allowed to stand for 27 h. The mixture was concentrated and fractionated by MPC (20% ethyl acetate in hexane) to give **39** (1.2 mg, quantitative). ^1H NMR (300 MHz, $CDCl_3$) δ: 8.04 (2H, m, Ph), 7.58 (1H, m, Ph), 7.46 (2H, m, Ph), 4.96 (1H, dd, *J* = 2, 7.5 Hz, HC-3), 4.42 (1H, d, *J* = 4.5 Hz, HC-2), 4.11 (1H, dd, *J* = 4, 8.5 Hz, HC-10), 3.73 (1H, d, *J* = 8.5 Hz, HC-10), 3.43 (3H, s, H_3CO), 2.56 (1H, dd, *J* = 4.5, 14 Hz, HC-1), 2.40 (1H, m, HC-11), 2.38 (1H, dd, *J* = 7.5, 14.5 Hz, HC-4), 2.24 (1H, d, *J* = 13 Hz, HC-8), 2.06 (2H, m, HC-1, HC-4), 1.23 (3H, s, H_3C) and 1.22 (3H, s, H_3C) (H_3C-16), 0.83 (3H, d, *J* = 7 Hz, H_3C). LR-MS (EI), *m*/*z* (relative intensity): 472 ($[M]^+$, 11), 438 (69), 332 (20), 315 (88), 275 (17), 217 (21), 157 (19), 105 (100).

(1*S*,3a*S*,5a*R*,6*R*,8*S*,9*R*)-rel-3,3a,4,5,5a,6,7,8,9,10-Decahydro-8-(hydroxy)-6-methoxy-3a,5a-dimethyl-1-(1-methylethyl)-6,9-epoxycyclohept[e]inden-2(1*H*)-one (40)

Aqueous NaOH (1 mol L^{-1}, ca. 0.2 mL) was added to a solution of **37** (4.6 mg, 0.010 mmol) in MeOH (1.5 mL) and the mixture was heated under reflux. After 10 h, the mixture was diluted with CH_2Cl_2, washed with satd. $NaHCO_3$, dried over Na_2SO_4, concentrated to give **40** (3.5 mg), which was homogeneous by ^1H NMR and was used in the next step without further purification. ^1H NMR (300 MHz, $CDCl_3$) δ: 4.25 (1H, m, HC-9), 4.20 (1H, m, HC-8), 3.36 (3H, s, H_3CO), 2.94 (1H, sept, *J* = 7 Hz, HCC-1), 2.57 (1H, dd, *J* = 3, 13 Hz, HC-10a), 2.46 (1H, dd, *J* = 7.5, 15 Hz, HC-7),

2.31 (1H, ddd, *J* = 4, 13, 14 Hz, HC-10), 2.19 (1H, d, *J* = 18.5, HC-3), 2.11 (1H, d, *J* = 18.5, HC-3), 1.87 (1H, br d, *J* = 14 Hz, HC-10), 1.78–1.47 (5H, m, HC-7, H_2C-4, H_2C-5), 1.21 (3H, s, H_3C), 1.19 (3H, d, *J* = 7 Hz, H_3C), 1.18 (3H, d *J* = 7 Hz, H_3C), 0.96 (3H, s, H_3C).

(3aS,5aR,6R,9R,10aR)-rel-3,3a,4,5,5a,6,7,9,10,10a-Decahydro-6-methoxy-3a,5a-dimethyl-1-(1-methylethyl)-6,9-epoxycyclohept[e]indene-2,8-dione (41)

TPAP (5.3 mg, 0.015 mmol) was added to a stirred suspension of powdered 4 Å molecular sieves (20 mg), *N*-methylmorpholine oxide (3.8 mg, 0.032 mmol), and alcohol **40** (3.5 mg) in dry CH_3CN (0.8 mL). After 2 h, the mixture was concentrated and fractionated by FCC (20% ethyl acetate in hexane) to give **41** (3 mg, 85% from **37**). ^{1}H NMR (300 MHz, $CDCl_3$) δ: 4.32 (1H, br s, HC-9), 3.39 (3H, s, H_3CO), 2.91 (1H, sept, *J* = 7 Hz, HCC-1), 2.79–2.72 (2H, m, HC-7, HC-10a), 2.53 (1H, d, *J* = 18.5 Hz, HC-7), 2.44 (1H, ddd, *J* = 4, 13, 13 Hz, HC-10), 2.20 (1H, d, *J* = 18.5 Hz, HC-3), 2.12 (1H, d, *J* = 18.5 Hz, HC-3), 1.94 (1H, ddd, *J* = 2.5, 4, 13 Hz, HC-10), 1.78 (1H, m, HC-4 or HC-5), 1.55 (3H, m, HC-4, HC-5), 1.20 (3H, d, *J* = 7 Hz, H_3C), 1.17 (3H, s, H_3C), 1.16 (3H, d, *J* = 7 Hz, H_3C), 1.06 (3H, s, H_3C).

(3aS,5aR,6R,9R,10aR)-rel-4,5,5a,6,7,9,10,10a-Octahydro-6-methoxy-3a,5a-dimethyl-1-(1-methylethyl)-6,9-epoxycyclohept[e]inden-8(3aH)-one (42)

A solution of Tf_2O in CH_2Cl_2 (0.5 mol L^{-1}, 34 μL, 0.017 mmol) was added to a stirred solution of 2,6-di(*tert*-butyl)-4-methylpyridine (4.6 mg, 0.023 mmol) and **41** (3 mg, 9 μmol) in CH_2Cl_2 (0.8 mL) under argon and the mixture was heated under reflux. After 2 h, the mixture was concentrated and the residue taken up in pentane and filtered. The combined filtrate and washings were concentrated and fractionated by FCC (10% ethyl acetate in hexane) to give the enol triflate (3 mg). ^{1}H NMR (300 MHz, $CDCl_3$) δ: 6.09 (1H, s, HC=COTf). A solution of the above triflate (3 mg) in THF (0.3 mL) and a solution of Bu_3SnH in THF (0.4 mol L^{-1}, 40 μL) were sequentially added to a stirred solution of $Pd(Ph_3P)_4$ (3.8 mg, 0.0033 mmol) and dry LiCl (4 mg, 0.094 mmol) in dry THF (0.4 mL) under argon and the mixture was heated under reflux. After 1.5 h, the mixture was diluted with hexane and washed with 5% NH_4OH and brine, dried, concentrated, and fractionated by FCC (5% ethyl acetate in hexane) to give **42** (1.4 mg, 50%). ^{1}H NMR (300 MHz, $CDCl_3$) δ: 6.29 (1H, d, *J* = 5.5 Hz, HC-3 or HC-2), 6.23 (1H, d, *J* = 5.5 Hz, HC-3 or HC-2), 4.30 (1H, br s, HC-9), 3.38 (1H, s, H_3CO), 2.89 (1H, sept, *J* = 7 Hz, HCC-1), 2.72 (1H, d, *J* = 18.5 Hz, HC-7), 2.57 (1H, d, *J* = 18.5 Hz, HC-7), 2.49 (1H, dd, *J* = 2.5, 13.5 Hz, HC-10a), 2.39 (1H, ddd, *J* = 3.5, 12, 13.5 Hz, HC-10), 1.93 (1H, ddd, *J* = 2.5, 2.5, 12 Hz, HC-10), 1.68 (1H, ddd, *J* = 3, 3, 13 Hz, HC-4 or HC-5), 1.50–1.17 (3H, m, HC-4, HC-5), 1.09 (3H, d, *J* = 7 Hz, H_3C), 1.03 (3H, d, *J* = 7 Hz, H_3C), 0.95 (3H, s, H_3C-17), 0.88 (3H, s, H_3C-16).

Methyl (3aS,5aR,6R,9R,10aR)-rel-3a,4,5,5a,6,9,10,10a-Octahydro-6-methoxy-3a,5a-dimethyl-1-(1-methylethyl)-6,9-epoxycyclohept[e]indene-8-carboxylate (43)

$NaN(TMS)_2$ (1 mol L^{-1} in THF, 35 μL, 35 μmol) was added to a stirred solution of ketone **42** (1.4 mg, 4.4 μmol) and $PhN(Tf)_2$ (5.1 mg, 14 μmol) in THF (0.5 mL) at –78 °C under argon. After 30 min, the reaction was quenched by addition of water. The mixture was diluted with ethyl acetate, washed with brine, dried over Na_2SO_4, and concentrated to give a residue that contained a 3:1 mixture of the desired enol triflate and **42**, respectively. The residue was resubjected to triflation under the above conditions and the resulting crude product was fractionated by MPC (5% ethyl acetate in hexane) to give the enol triflate (1.3 mg). ^{1}H NMR (300 MHz, $CDCl_3$) δ: 6.08 (1H, s, HC=COTf). $Pd(Ph_3P)_4$ (3.1 mg, 2.7 μmol) and MeOH (50 μL) were sequentially added to a stirred solution of the above triflate (1.3 mg, 2.9 μmol) and *i*-Pr_2EtN (0.9 mg, 7 μmol) in CO-saturated THF (0.4 mL) at room temperature. The mixture was stirred under CO (1 atm, 1 std atm = 101.325 kPa) for 1 h and then was concentrated and fractionated by MPC (5% ethyl acetate in hexane) to give the ester **43** (0.9 mg, 50% from **42**). ^{1}H NMR (300 MHz, $CDCl_3$) δ: 7.13 (1H, s, HC-7), 6.30 (1H, d, *J* = 5.5 Hz, HC-3), 6.21 (1H, d, *J* = 5.5 Hz, HC-2), 5.08 (1H, dd, *J* = 2, 3 Hz, HC-9), 3.81 (3H, s, H_3COCO), 3.34 (3H, s, H_3COC-6), 2.96 (1H, sept, *J* = 7 Hz, HCC-1), 2.45–2.35 (2H, m, HC-10a, HC-10), 1.70–1.20 (5H, m, HC-10, H_2C-4, H_2C-5), 1.10 (3H, d, *J* = 7 Hz, H_3C), 1.03 (3H, d, *J* = 7 Hz, H_3C), 0.92 (3H, s, H_3C), 0.81 (3H, s, H_3C).

(±)-Allocyathin B_3 methyl acetal (44)

DIBAL-H (1.5 mol L^{-1} in toluene, 20 μL, 30 μmol) was added to a stirred solution of **43** (0.9 mg, 2.5 μmol) in dry ether (0.4 mL) under argon at –20 °C. After 30 min, the reaction was quenched by addition of MeOH (0.2 mL). After 1 h, the mixture was diluted with ether, washed with brine, dried over Na_2SO_4, concentrated, and fractionated by FCC (60% ethyl acetate in hexane) to give **44** (0.6 mg, 70%). UV λ_{max} (nm): 255 (CH_3CN–H_2O). ^{1}H NMR (500 MHz, $CDCl_3$) δ: 6.29 (1H, d, *J* = 5.5 Hz, HC-1), 6.20 (1H, d, *J* = 5.5 Hz, HC-2), 6.10 (1H, dd, *J* = 1.5, 2 Hz, HC-13), 4.80 (1H, dd, *J* = 2, 3 Hz, HC-11), 4.37 (1H, br d, *J* = 15 Hz, HC-15), 4.32 (1H, br d, *J* = 15 Hz, HC-15), 3.31 (3H, s, H_3CO), 2.95 (1H, sept, *J* = 7 Hz, HC-18), 2.52 (1H, dd, *J* = 4, 13 Hz, HC-5), 2.38 (1H, ddd, *J* = 3, 13, 13 Hz, HC-10), 1.70–1.40 (5H, m, HC-10, H_2C-8, H_2C-7), 1.09 (3H, d, *J* = 7 Hz, H_3CC-18), 1.03 (3H, d, *J* = 7 Hz, H_3CC-18), 0.92 (3H, s, H_3C-16 or -17), 0.79 (3H, s, H_3C-17 or -16). ^{13}C NMR (125 MHz, $CDCl_3$) δ: 148.3 (s, C-12), 144.5 (d, C-1), 142.7 (s, C-3), 141.1 (s, C-4), 128.0 (d, C-2), 124.3 (d, C-13), 114.6 (s, C-14), 78.5 (s, C-11), 59.3 (t, C-15), 54.3 (s, C-9), 51.1 (q, OCH_3), 44.7 (s, C-6), 39.5 (d, C-5), 31.5 (t, C-8), 29.2 (t, C-7), 26.0 (t, C-10), 25.9 (d, C-18), 22.9 (q, C-19), 22.8 (q, C-20), 20.9 (q, C-17), 12.0 (q, C-16). LR-MS (EI), *m/z* (relative intensity): 330 ($[M]^+$, 35), 312 (29), 299 (12), 297 (22), 187 (49), 173 (28), 141 (100). HR-MS *m/z* calcd. for $C_{21}H_{30}O_3$: 330.2195; found: 330.2195 (EI).

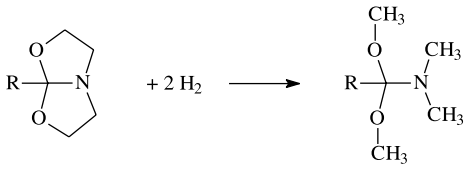
Preparation and characterization of bicyclic amide acetals and monothioacetals[1]

J. Peter Guthrie, Roger T. Gallant, and Michael C. Jennings

Abstract: We have prepared and characterized new examples of 5-substituted-1-aza-4,6-dioxabicyclo[3.3.0]octanes (bicyclic amide acetals) and examples of the new heterocyclic system, 5-substituted-1-aza-4-oxa-6-thiabicyclo[3.3.0]octanes (bicyclic amide monothioacetals). Detailed analysis of NMR coupling constants and X-ray structure determination for an example of each class of compound established the stereochemistry and conformation of these ring systems.

Key words: bicyclic amide acetals, preparation, coupling constants, X-ray structure.

Résumé : On a préparé et caractérisé de nouveaux exemples de 1-aza-4,6-dioxabicyclo[3.3.0]octanes substitués en position 5 (amide acétals bicycliques) et des exemples du nouveau système hétérocyclique 1-aza-4-oxa-6-thiabicyclo[3.3.0]octanes substitués en position 5 (amide monothioacétals bicycliques). Une étude détaillée des constantes de couplage de la RMN et la détermination de la structure, par diffraction des rayons X, d'un exemple de chacune de ces classes de composés permet d'établir la stéréochimie et la conformation de ces composés cycliques.



Mots clés : amide acétals bicycliques, préparation, constantes de couplage, structure par diffraction des rayons X.

[Traduit par la Rédaction]

Introduction

We have been interested in determining the energies of tetrahedral intermediates in acyl transfer reactions by an indirect thermochemical approach (1–7). Attempts to extend this approach from simple amides (2) to amides with various substituents on the α-carbon ran into frustrating problems of purification. Amide acetals could be made but could not be purified. In an attempt to overcome this problem we have turned to bicyclic versions of these compounds. Our plan is to determine the heats of hydrolysis and, thus, the heats of formation of the bicyclic acetals and monothioacetals and proceed from these to, first, the heats of formation of the acyclic acetals and monothioacetals, using computational methods to determine the heats of reaction for the hypothetical hydrogenations shown in reactions [1] and [2], and thence, to the free energies of formation of the analogous tetrahedral intermediates.

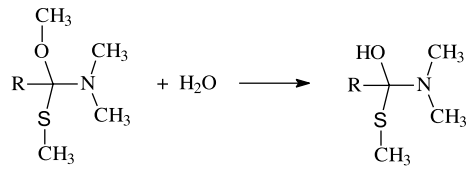
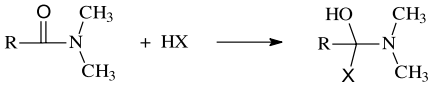
[2]



By methods that we have reported (8) and that involve a hypothetical hydrolysis, free energies of the acyclic amide acetals can be used to calculate the free energies of the corresponding amide hemiacetals and amide hydrates.

[3]



Similarly, the free energies of the acyclic amide monothioacetals can be used to calculate the free energies of the corresponding amide hemithioacetals.

[4]

The energies of these adducts can be combined with free energies of the amides to permit calculation of the free energy changes for addition reactions of amides, reactions that are quite unfavorable and difficult to determine experimentally.

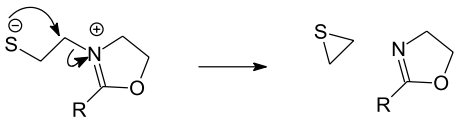
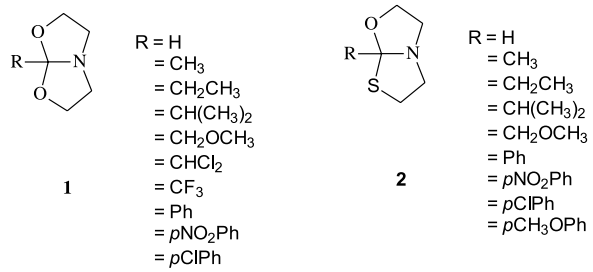
X = OH, OCH_3, SCH_3.



The first stage in this project was to prepare and characterize the bicyclic compounds, only a few of which were known. Calorimetric studies of these compounds are complete and computational studies to complement and in some cases to supplement them are nearly complete. The rest of our studies on these compounds will be reported in due course.

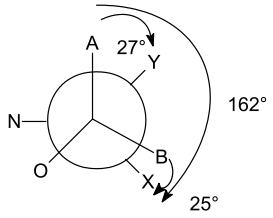
Results

The compounds examined in this work are shown in Scheme 1. The original plan had been to prepare compounds with a range of electron-withdrawing substituents, but difficulties were encountered in some of these attempted preparations, and then it became clear that the rate of hydrolysis was very sensitive to electron withdrawal, such that strong electron-withdrawing groups made hydrolysis too slow for the calorimetric measurements we planned to carry out.



Although some of the bicyclic amide acetals are known compounds, most are novel, and preparations range from very easy to quite difficult.

The standard methods for preparation of compounds **1**, substituted 1-aza-4,6-dioxabicyclo[3.3.0]octanes, involve either reaction of diethanolamine with the corresponding nitrile, using a small amount of sodium as catalyst, or reaction of diethanolamine with the corresponding acyclic amide acetal. Similar methods allowed preparation of the novel compounds **2**, substituted 1-aza-4-oxa-6-thiabicyclo[3.3.0]octanes, by using 2-(2-mercaptoethyl)aminoethanol. The compounds **2** were thermally sensitive and could not be obtained by the standard reaction of a nitrile with 2-(2-mercaptoethyl)aminoethanol at 80 °C; such conditions led only to the oxazoline corresponding to the nitrile. Reaction at room temperature, though slow, led to the desired compounds. Attempted distillation of the crude 5-substituted-1-aza-4-oxa-6-thiabicyclo[3.3.0]octane at temperatures over 110 °C also led to breakdown to the corresponding oxazoline. A reasonable explanation is relatively facile cleavage of ethylene sulfide, e.g., by



The 5-substituted-1-aza-4-oxa-6-thiabicyclo[3.3.0]octanes were higher boiling than the corresponding oxazolines and so purification by fractional distillation was possible if the temperature could be kept low enough to avoid thermal fragmentation. For the aryl-substituted compounds this was not possible, and pure product could be obtained only when the 5-substituted-1-aza-4-oxa-6-thiabicyclo[3.3.0]octane could be crystallized, as for **2** with R = phenyl and 4-nitrophenyl. In the case of **2** with R = 4-chlorophenyl and 4-methoxyphenyl, crystallization was not achieved, and the best samples were only 94% and 90% pure, with the remainder being the corresponding oxazoline. Details of these preparations and of the preparations of other compounds used in this work are found in the experimental section.

Scheme 1.

The oxazolidinooxazolidine system in the bicyclic amide acetals has two identical five-membered rings — each with four distinctive proton environments — leading to an ABXY pattern, with complicated splitting. The assignment of the methylene signals was based on the ^{1}H, ^{13}C, gCOSY, and gHSQC spectra. The proton NMR spectra of the 5-*R*-1-aza-4,6-dioxabicyclo[3.3.0]octanes are resolved well enough to allow a direct graphical calculation of the true chemical shifts and coupling constants. These calculated values were verified with the use of ACD Labs H NMR spin simulation software (9), as shown in Fig. 1. The worst deviation in chemical shift between the simulated and experimental spectra was approximately 0.002 parts per million (ppm). The chemical shifts and coupling constants resulting from this analysis are summarized in Tables 1 and 2. Analysis of the coupling constants by means of the Karplus–Conroy equation (10–12), using generic values of J° = 8.5 Hz and J^{180} = 9.5 Hz (as recommended when no better estimates are available (13)) led to the conclusion that the geometry of the ring systems for 5-(4-nitrophenyl)- 1-aza-4,6-dioxabicyclo[3.3.0]octane is as shown in

The logic of this assignment is as follows: (*i*) If the AB and XY protons were eclipsed (whether A with X and B with Y or A with Y and B with X), then $^3J_{AX} + {}^3J_{AY} = {}^3J_{BX} + {}^3J_{BY}$, but this is not the case; (*ii*) If the protons are staggered, then one of A and B will be *anti* to one of X and Y and gauche to the other, and the other of A and B will be gauche to both X and Y. Since *J* is largest for protons that are *anti*, the largest of the ^3J coupling constants must be for the pair of protons that are most nearly *anti*. This is $^3J_{AX}$; (*iii*) If A is approximately *anti* to X, then $^3J_{AY} \approx {}^3J_{BX}$, as is found; if instead A and Y were approximately *anti*, then $^3J_{AX} \approx {}^3J_{BY}$, which is not the case.

An X-ray structure was obtained for 5-(4-nitrophenyl)-1-

aza-4,6-dioxabicyclo[3.3.0]octane. This structure, Fig. 2, confirms that the bicyclic amide acetals have the five-membered rings *cis*-fused, as Anteunis et al. had concluded (14) based on analysis of the ^{1}H NMR spectra. The dihedral angles were close to, though not identical with, those deduced from the Karplus–Conroy analysis; the worst deviation was for the A–X dihedral, 146° rather than 162°. Examination of bond lengths in the X-ray structure showed no sign of an anomeric effect, which would be expected to cause a shortening of the quaternary carbon–nitrogen bond and a lengthening of at least one of the quaternary carbon–oxygen bonds.

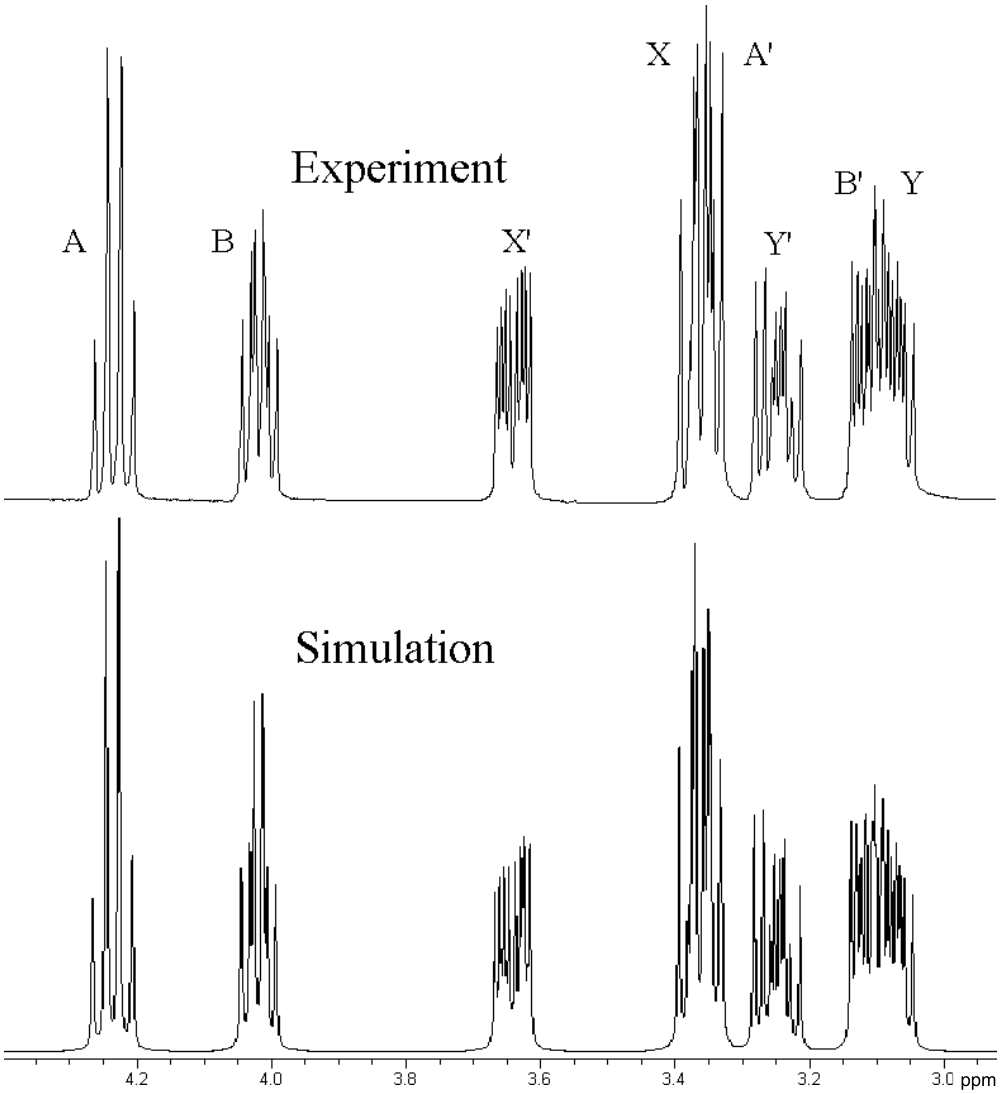
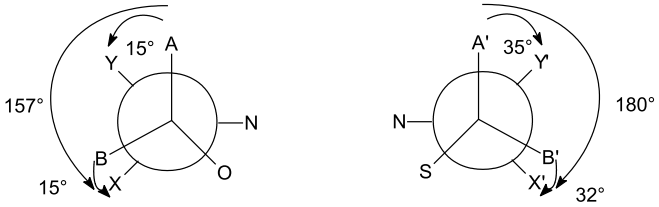
Fig. 2. Crystal structure of 5-(4-nitrophenyl)-1-aza-4,6-dioxabicyclo[3.3.0]octane.



The mass spectra of these compounds were analyzed for characteristic fragmentation patterns. There were differences in fragmentation pattern for 5-aryl- vs. 5-alkyl-substituted 1-aza-4,6-dioxabicyclo[3.3.0]octanes. These results are collected in Table 3. The molecular ion peak for each bicyclic amide acetal was present with low relative intensity. Two primary fragmentation routes appear to be important based on the electron impact studies of these compounds, as follows: cleavage of the ring and elimination of the substituent. In the alkyl-substituted bicyclic amide acetals, the substituent elimination route appears to become more prevalent as R becomes larger. When the substituent was an aryl group, cleavage of the ring was favored, yielding dominant $[M - CH_2O]^+$ and acyl cation fragments.

The thiazolidinooxazolidine ring system has a more complicated ^{1}H NMR splitting pattern, with two overlapping ABXY patterns. The pattern for the thiazolidine ring will be labeled A′B′X′Y′; the primes are used to indicate the analogy with the unprimed peak in the oxazolidine ring. This is not the usual convention, where single primes are used to indicate protons that are chemically but not magnetically equivalent, which is not the case here. All the protons are different, and the pattern, though complicated, can be analyzed as in the oxazolidinooxazolidine case. The assignment of the methylene signals was based on the ^{1}H, ^{13}C, gCOSY, and gHSQC spectra. The ^{13}C signal for the methylene at lowest field was assigned to CH_2-O; the ^{13}C signal for the methylene at highest field was assigned to CH_2S. The combination of gCOSY and gHSQC spectra allowed the remaining assignments. Simulated spectra were in good agreement with the observed spectra, as shown in Fig. 3. The chemical shifts and coupling constants are found in Tables 4 and 5.



For most of the 5-substituted-1-aza-4-oxa-6-thiabicyclo-[3.3.0]octanes, the same logic as for the dioxa case can be used to deduce the dihedral angles for the oxazolidino ring from the Karplus–Conroy curve, but for three compounds (R = H, ethyl, and methoxymethyl), all four ^3J values are approximately equal, which leads to a contradiction. If $^3J_{AX} + {}^3J_{AY} \approx {}^3J_{BX} + {}^3J_{BY}$, then one might conclude that the hydrogens were eclipsed, but if so the dihedral angles would be 0° and 120°, leading to distinctly different coupling constants. We are forced to conclude that in fact the structure is partly staggered, and that the Karplus–Conroy curve, especially with generic parameter values, is only an approximate guide. The structures are, in all cases, likely to be staggered but closer to eclipsed than to fully staggered geometry. The approximate nature of the dihedral angles deduced from the Karplus–Conroy curve is shown by comparison with the X-ray structure for R = 4-nitrophenyl, where the AY and BX dihedrals are found to be 27.45° and 26.62°, respectively, and not 15° and 15°, as deduced from the coupling constants. Likewise the AX dihedral is 144.5°, according to the X-ray analysis, rather than 157°, as deduced from coupling constants. The Karplus–Conroy curve is a useful guide but is not exact. The coupling constants for the thiazolidino ring

Fig. 3. Experimental and simulated ^{1}H NMR spectra for 5-(4-nitrophenyl)-1-aza-4-oxa-6-thiabicyclo[3.3.0]octane.

were not all the same, and the logic used for the dioxa case led to a simpler analysis. Analysis of the coupling constants for 6-(4-nitrophenyl)-1-aza-6-thia-4-oxabicyclo[3.3.0]octane by the Karplus–Conroy equation leads to the geometries shown:

An X-ray structure was determined for 6-(4-nitrophenyl)-1-aza-6-thia-4-oxabicyclo[3.3.0]octane; see Fig. 4. Again, the five-membered rings are *cis*-fused, and the dihedral angles are in approximate, though not exact, agreement with the values from the Karplus–Conroy analysis.

The X-ray structure revealed an N-C-S anomeric effect; the quaternary carbon–nitrogen bond is shorter relative to the CH_2—N bonds (1.43 Å vs. 1.46 Å or 1.50 Å), and the quaternary carbon–sulfur bond is longer than the CH_2—S bond (1.93 Å vs. 1.80 Å). The X-ray crystal structure data are found in Tables S-1 to S-10.[3]

The mass spectra of the 5-substituted 1-aza-6-thia-4-oxabicyclo[3.3.0]octanes showed more complex fragmentation patterns, as one might expect for the less-symmetrical structures. Once again there were differences in preferred fragmentation pattern for 5-aryl- vs. 5-alkyl-substituted compounds. These results are found in Table 6. The molecular ion is present in greater amount in the sulfur-containing bicyclic acetals. As for the dioxa series, elimination of the

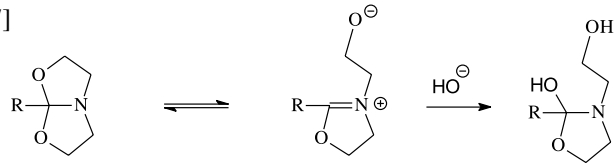
substituent R on C_5 becomes more important as R becomes larger, and ring cleavage is favored when R is an aryl group.



Discussion

As we had hoped, the bicyclic amide acetals and monothioacetals were much easier to purify than the acyclic amide dimethyl acetals and the amide dialkyl monothioacetals, although the bicyclic compounds are still rather sensitive. A range of these compounds has now been prepared, though it proved difficult to prepare even the bicyclic acetals of amides with electron-withdrawing substituents. Although no kinetics were carried out, it is clear that the rate of hydrolysis of these compounds is very sensitive to the nature of the substituent on the 5-carbon, as would be expected, given that this carbon becomes the carbon of an iminium ion during the hydrolysis. It is interesting that the hydrolysis is facile in basic solution, while the corresponding cations (from protonation or alkylation on nitrogen) can be studied in solution (14) or even recrystallized (15). We presume that this is a consequence of the facile reclosure of the cation, resulting from C–N cleavage and the more effective competition by hydroxide to trap the cation from C–O cleavage.

We have demonstrated by NMR and X-ray structure determination that both the 5-substituted 1-aza-4,6-dioxabicyclo[3.3.0]octanes and the 5-substituted 1-aza-6-thia-4-oxabicyclo[3.3.0]octanes are *cis* fused, with the ring methylene groups approximately staggered. Examination of the structure of 5-(4-nitrophenyl)-1-aza-4,6-dioxabicyclo[3.3.0]-octane showed no sign of changes in bond lengths attributable to an anomeric effect. All four C—O bonds were essentially the same length, 1.41, 1.41, 1.41, and 1.40 Å, as were all three C—N bonds, 1.47, 1.46, and 1.46 Å. Thus, the bonds that cannot be part of an anomeric effect are the same length as those that, in principle, might be. Consideration of the expected position of the nitrogen lone pair showed that this was not lined up to overlap with the σ* orbital of the C_5—O bond. Since the anomeric effect is attributed to this kind of overlap, the absence of bond length changes becomes reasonable. By contrast, the structure of 5-(4-nitrophenyl)-substituted 1-aza-6-thia-4-oxabicyclo[3.3.0]octane shows definite changes in bond length in the directions expected for an anomeric effect, namely, shortening of the C_5—N bond (1.43 Å vs. 1.46 Å or 1.50 Å) and lengthening of the C_5—S bond (1.80 Å vs. 1.93 Å). There is even a shortening of the C_5—O bond (1.40 Å vs. 1.44 Å). Examination of the structure suggests a dihedral angle between the N lone pair and the C—S bond of 140°. Apparently, this angle, though well short of 180°, is enough to allow for overlap of the lone pair and σ* antibonding orbitals. The longer C—S bonds, relative to C—O bonds, force a loss of symmetry in the bicyclic monothioacetal, and this allows partial overlap of the sort leading to an anomeric effect.

Experimental

General methods

Nuclear magnetic resonance spectra were recorded on a Varian Gemini 200 (^{1}H at 200.1 MHz, ^{13}C at 50.3 MHz), a Varian Gemini 300 (^{1}H at 299.9 MHz, ^{13}C at 75.4 MHz), a Varian Mercury 400 (^{1}H at 400.1 MHz, ^{13}C at 100.6 MHz), a Varian Inova 600 (^{1}H at 599.7 MHz), or a Bruker AMX-500 (University of Ottawa, Ont.) spectrometer (^{1}H at 500.1 MHz, ^{13}C at 125.8 MHz). Mass spectra were recorded on a Finnigan MAT 8200 high-resolution spectrometer. Melting points were recorded on a Gallenkamp melting point apparatus.

Data were collected on a Nonius Kappa-CCD diffractometer (either at the University of Western Ontario or the University of Toronto) using COLLECT software (16). For both compounds, the unit cell parameters were calculated and refined from the full data set. Crystal cell refinement and data reduction were carried out using the Nonius DENZO package (17). The data were scaled using SCALEPACK (18). The SHELXTL 5.1 (19) program package was used to solve the structure by direct methods, followed by successive difference Fouriers. The molecule was very well behaved. All non-hydrogen atoms were refined with anisotropic thermal parameters. The hydrogen atoms were calculated geometrically and were riding on their respective carbon atoms.

Crystals of 5-(*p*-nitrophenyl)-1-aza-4,6-dioxabicyclo-[3.3.0]octane were grown from diethyl ether. A colourless, thin plate was mounted on a glass fibre. Data were collected at low temperature (–73 °C). The crystal data and refinement parameters for $C_{11}H_{12}N_2O_4$ are listed in Table S-1.[3] Interatomic distances and angles are listed in Table S-3. The reflection data and systematic absences were consistent with the monoclinic space group $P2_1/c$. The largest residual electron density peak (0.155 e/A^3) was not associated with anything of significance. Full-matrix least-squares refinement on F^2 gave R_1 = 4.39 and wR_2 = 10.43 at convergence.

Crystals of 5-(*p*-nitrophenyl)-1-aza-4-oxa-6-thiabicyclo-[3.3.0]octane were grown from hexanes. A colourless, thin plate was mounted on a glass fibre and sent to the University

of Toronto. Data were collected at low temperature (–123 °C). The crystal data and refinement parameters for $C_{11}H_{12}N_2O_3S$ are listed in Table S-6. Interatomic distances and angles are listed in Table S-8. The reflection data were consistent with the triclinic space group $P\bar{1}$. The largest residual electron density peak (0.724 e/A^3) was not associated with anything of significance. Full-matrix least-squares refinement on F^2 gave R_1 = 7.94 and wR_2 = 16.88 at convergence.

Materials

1-Aza-4,6-dioxabicyclo [3.3.0] octane

1-Aza-4,6-dioxabicyclo [3.3.0] octane was prepared from diethanolamine (Caledon) and *N*,*N*-dimethylformamide dimethyl acetal (Aldrich) following Arnold and Kornilov (20) in 80.9% yield; bp 68 °C (7.0 torr (1 torr = 133.322 Pa)) (lit. (20) value bp 65 to 66 °C (5 torr)). ^{1}H NMR (400 MHz, $CDCl_3$)[4] δ: 2.90–2.96 (2H, m), 3.16–3.25 (2H, m), 3.77–3.87 (4H, m), 5.80 (1H, s). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 52.53, 64.39, 114.91. Exact mass calcd. for $C_5H_9NO_2$: 115.0633; found: 115.0633.

In the same way were prepared the following two compounds.

1-Aza-4-oxa-6-thiabicyclo[3.3.0]octane

75.8% yield; bp 64 °C (0.050 torr). ^{1}H NMR (400 MHz, $CDCl_3$) δ: 2.78–2.85 (2H, m), 3.03–3.08 (1H, m), 3.10–3.14 (1H, m), 3.15–3.20 (1H, m), 3.48–3.52 (1H, m),.3.92–3.97 (1H,q), 4.08–4.13 (1H,q). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 31.08, 49.59, 55.46, 65.37, 106.96. Exact mass calcd. for C_5H_9NOS: 131.0405; found: 131.0398.

5-Methyl-1-aza-4-oxa-6-thiabicyclo[3.3.0]octane

Prepared from from *N*,*N*-dimethylamide dimethyl acetal (21); 90.2% yield; bp 58 °C (0.025 torr). ^{1}H NMR (400 MHz, $CDCl_3$) δ: 1.81 (3H, s), 2.78–2.85 (1H, m), 2.90–2.95 (1H, m), 3.02–3.12 (1H, m), 3.20–3.35 (2H, m), 3.50–3.58 (1H, m), 3.92–4.02 (1H, q), 4.03–4.12 (1H, q). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 31.0, 33.8, 50.5, 55.8, 65.7, 119.2. Exact mass calcd. for $C_6H_{11}NOS$: 145.0561; found: 145.0557.

General preparation of 5-substituted-1-aza-4,6-dioxabicyclo[3.3.0]octanes

Diethanolamine (Caledon) (25.0 g, 0.238 mol) and a sliver of sodium metal were placed in a two-necked, round-bottomed flask fitted with a condenser. The system was sealed with the use of septa. An exhaust needle was placed in the septum at the top of the condenser, while a stream of nitrogen was fed through the septum on the neck of the round-bottomed flask. A positive pressure of nitrogen was maintained throughout the remainder of the reaction. A magnetic stirrer and gentle heating with an oil bath (~50 °C) helped dissolve the sodium metal. Once the sodium had completely dissolved, the appropriate nitrile (0.239 mol) was added to the reaction flask with a syringe. The temperature of the oil bath was raised to 100 °C, and the reaction proceeded for 40 h at that temperature. Upon cooling, the reaction mixture was placed in a separatory funnel, and the product was extracted with multiple portions of hexanes. The hexanes were removed by rotary evaporation. The residue was doubly distilled at reduced pressure to give a clear colourless liquid.

In this way were prepared the following five compounds.

5-Methyl-1-aza-4,6-dioxabicyclo[3.3.0]octane

25.5% yield; bp 52 °C (5.0 torr) (lit. (15) value bp 65° (11 torr)). ^{1}H NMR (400 MHz, $CDCl_3$) δ: 1.49 (3H, s), 2.88–2.96 (2H, m), 3.18–3.26 (2H, m), 3.76–3.83 (2H, m), 3.83–3.90 (2H, m). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 24.0, 53.0, 64.8, 123.1. Exact mass calcd. for $C_6H_{11}NO_2$: 129.0790; found: 129.0791.

5-Ethyl-1-aza-4,6-dioxabicyclo[3.3.0] octane

17.4% yield; bp 81 °C (9.5 torr) (lit. (15) value bp 72 °C (12 torr)). ^{1}H NMR (400 MHz, $CDCl_3$) δ: 0.96 (3H, t), 1.78 (2H, q), 2.92–3.00 (2H, m), 3.18–3.27 (2H, m), 3.78–3.85 (2H, m), 3.87–3.95 (2H, m). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 8.7, 30.6, 53.6, 65.0, 125.1. Exact mass calcd. for $C_7H_{13}NO_2$: 143.0946; found: 143.0944.

5-Isopropyl-1-aza-4,6-dioxabicyclo[3.3.0] octane

31.2% yield; bp 86 °C (10 torr). ^{1}H NMR (400 MHz, $CDCl_3$) δ: 0.97 (3H, s), 0.98 (3H, s), 1.96 (1H, sept), 2.92–2.98 (2H, m), 3.17–3.25 (2H, m), 3.77–3.83 (2H, m), 3.85–3.92 (2H, m). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 17.4, 35.8, 54.3, 65.2, 126.8. Exact mass calcd. for $C_8H_{15}NO_2$: 157.1103; found: 157.1098.

5-Methoxymethyl-1-aza-4,6-dioxabicyclo[3.3.0] octane

10.1% yield; bp 105 °C (8 torr). ^{1}H NMR (400 MHz, $CDCl_3$) δ: 2.94–3.00 (2H, m), 3.24–3.31 (2H, m), 3.41 (3H, s), 3.47 (2H, s), 3.84–3.90 (2H, m), 3.92–3.98 (2H, m). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 53.0, 59.6, 65.2, 73.9, 122.1. Exact mass calcd. for $C_7H_{13}NO_3$: 159.0895; found: 159.0890.

5-Phenyl-1-aza-4,6-dioxabicyclo[3.3.0] octane

17.3% yield; bp 150 °C (5.0 torr) (lit. (15) value bp 79 to 80 °C (0.03 torr)). ^{1}H NMR (400 MHz, $CDCl_3$) δ: 3.05–3.13 (2H, m), 3.30–3.40 (2H, m), 3.96–4.03 (2H, m), 4.09–4.16 (2H, m), 7.32 (3H, t), 7.61 (2H, d). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 53.0, 65.7, 123.2, 125.9, 128.1, 128.4, 140.1. Exact mass calcd. for $C_{11}H_{13}NO_2$: 191.0946; found: 191.0943.

5-(*p*-Nitrophenyl)-1-aza-4,6-dioxabicyclo[3.3.0]octane

The experimental procedure followed that of the synthesis of 5-methyl-1-aza-4,6-dioxabicyclo[3.3.0]octane with some modifications. A sliver of sodium metal was dissolved in warm diethanolamine (Caledon) (25.1 g, 0.238 mol), as usual. However, solid *p*-nitrobenzonitrile (Aldrich) (35.0 g, 0.236 mol) was dissolved in 1,4-dioxane (Caledon) prior to addition to the reaction flask. The reaction proceeded for 48 h at 80 °C. Upon removal of the 1,4-dioxane by rotary evaporation, a yellow solid precipitated. The solid was recrystallized from diethyl ether, giving shiny, pale yellow crystals (15.8 g, 28.3% yield); mp 90 to 91 °C. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 3.08–3.14 (2H, m), 3.28–3.38 (2H, m), 3.95–4.00 (2H, m), 4.05–4.14 (2H, m), 7.77 (2H, d), 8.19 (2H, d). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 53.8, 66.5, 122.4,

[4] Abbreviations used: m, multiplet; s, singlet, d, doublet; t, triplet; q, quartet.

123.9, 127.7, 147.5, 148.1. Exact mass calcd. for $C_{11}H_{12}N_2O_4$: 236.0797; found: 236.0807.

5-(*p*-Chlorophenyl)-1-aza-4,6-dioxabicyclo[3.3.0]octane

Solid *p*-chlorobenzonitrile (Aldrich) (20.0 g, 0.145 mol) was placed in a round-bottomed flask. Enough diethanolamine (Caledon) was added to the reaction flask to completely cover the nitrile. This excess of diethanolamine helped reduce the amount of *p*-chlorobenzonitrile that sublimed onto the upper walls of the reaction flask during the reaction. The round-bottorned flask was fitted with a condenser and kept under an N_2 atmosphere. The oil bath was heated to 50 °C and the reaction proceeded for 4 days. The reaction flask was allowed to cool before addition of hexanes to extract the title compound. Removal of hexanes by rotary evaporation resulted in a white solid that contained the target compound and unreacted nitrile. Recrystallization could not remove all of the nitrile. The white solid was placed in a sublimation apparatus, to take advantage of the willingness of the nitrile to sublime. Reduced pressure (0.025 torr) and very gentle heating removed the nitrile exclusively. The remaining solid was recrystallized in hexanes to give white crystals (2.9 g, 8.9% yield); mp 43–45 °C. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 3.05–3.12 (2H, m), 3.29–3.37 (2H, m), 3.94–4.00 (2H, m), 4.06–4.13 (2H, m), 7.30 (2H, d), 7.53 (2H, d). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 53.0, 65.8, 122.8, 127.6, 128.1, 134.3, 138.8. Exact mass calcd. for $C_{11}H_{12}NO_2Cl$: 225.0557; found: 225.0557.

5-Trifluoromethyl-1-aza-4,6-dioxabicyclo[3.3.0]octane

A sliver of sodium metal was dissolved in diethanolamine (Caledon) (28.7 g, 0.273 mol) and placed in a 300 cc Parr Instruments bomb. The bomb was placed into a dry ice – acetone bath to lower the temperature of the bomb and its contents to –78 °C. At that temperature, the contents of the bomb solidified. Freshly prepared, condensed trifluoroacetonitrile (prepared from trifluoroacetamide (22)) (~30 mL, ~0.316 mol) was poured into the chilled bomb. The bomb was then immediately sealed. Undoubtedly some trifluoroacetonitrile was lost during this crude transfer. The bomb was placed into its temperature controller and set to 70 °C. The temperature inside the bomb rose dramatically, requiring cooling of the bomb. Once the temperature was brought under control, the bomb was adjusted to 70 °C where it remained for 48 h. At the end of the reaction period, the bomb was flushed with nitrogen before opening to ensure removal of any remaining trifluoroacetonitrile. Inside the bomb was an orange viscous liquid that was mainly unreacted diethanolamine. Extraction with hexanes resulted in pure 5-trifluoromethyl-1-aza-4,6-dioxabicyclo[3.3.0]octane. The liquid crystallized on its own after sitting on the bench for 2 weeks. Recrystallization from hexanes resulted in translucent crystals (0.25 g, 0.5% yield). ^{1}H NMR (400 MHz, $CDCl_3$) δ: 3.01–3.09 (2H, m), 3.31–3.40 (2H, m), 3.99–4.06 (2H, m), 4.07–4.15 (2H, m). ^{19}F NMR (300 MHz, $CFCl_3$) δ: 83.0. ^{13}C NMR (100 MHz, $CDCl_3$) δ: 52.5, 66.7, 120.5, 123.3. Exact mass calcd. for $C_6H_8NO_2F_3$: 183.0505; found: 183.0503.

5-Dichloromethyl-1-aza-4,6-dioxabicyclo[3.3.0] octane

The experimental procedure followed that of the synthesis of 5-methyl-1-aza-4,6-dioxabicyclo[3.3.0]octane, with some modifications. Diethanolamine (Caledon) (12.5 g, 0.119 mol) and 75 mL of 1,4-dioxane (Caledon) were placed in the reaction flask with *no catalyst*. Caution: The standard reaction of 1:1 amine:nitrile with sodium catalyst in the absence of solvent resulted in an explosion. Dichloroacetonitrile (Aldrich) (10.0 mL, 0.125 mol) was added slowly to the reaction flask with a syringe. Once the nitrile was completely added, the oil bath was heated gently until it reached 50 °C. The evolution of ammonia appeared to be very rapid, so heating was stopped. The reaction continued at room temperature for 48 h. The 1,4-dioxane solvent was removed by rotary evaporation, leaving a thick residue. It was placed in a separatory funnel for extraction with hexanes. A white solid precipitated in the separatory funnel when hexanes were added. Recrystallization with hexanes resulted in white shiny flakes (5.65 g, 24.0% yield); mp 62 to 63 °C. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 3.02–3.10 (2H, m), 3.42–3.51 (2H, m), 4.02–4.14 (4H, m), 5.75 (1H, s). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 54.3, 67.2, 74.0, 123.4. Exact mass calcd. for $C_6H_9NO_2Cl_2$: 197.0009; found:. 197.0007.

5-Ethyl-1-aza-4-oxa-6-thiabicyclo[3.3.0]octane

With some heating, a sliver of sodium metal (Aldrich) was dissolved in freshly prepared 2-(2-mercaptoethyl)-aminoethanol (20.0 g, 0.165 mol) in a round-bottomed flask. Propionitrile (Aldrich) (25 mL, 0.328 mol) was added to the reaction flask and allowed to stir for 2 weeks at room temperature under an N_2 atmosphere. It was found that an excess of nitrile made the consistency of the final reaction mixture easier to handle. An extraction with diethyl ether removed the title compound and its corresponding oxazoline. The mixture was doubly distilled at reduced pressure to give a clear colorless fraction (3.5 g, 13.3% yield); bp 50 °C (0.025 torr). ^{1}H NMR (400 MHz, $CDCl_3$) δ: 1.05 (3H, t), 1.99 (2H, m), 2.80–2.88 (2H, m), 2.99–3.09 (1H, m), 3.19–3.29 (2H, m), 3.48–3.57 (1H, m), 3.92 (1H, q), 4.05 (1H, q). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 9.9, 33.0, 37.0, 51.0, 56.0, 65.5, 123.3. Exact mass calcd. for $C_7H_{13}NOS$: 159.0718; found: 159.0717.

In the same way were prepared the following three compounds.

5-Isopropyl-1-aza-4-oxa-6-thiabicyclo[3.3.0]octane

14.3% yield; bp 53 °C (0.025 torr). ^{1}H NMR (400 MHz, $CDCl_3$) δ: 1.00 (3H, d), 1.10 (3H, d), 2.06 (1H, sept), 2.78–2.88 (2H, m), 2.98–3.08 (1H, m), 3.14–3.25 (2H, m), 3.47–3.55 (1H, m), 3.90 (1H, q), 4.03 (1H, q). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 18.1, 18.5, 32.8, 40.2, 52.0, 56.9, 65.8, 126.4. Exact mass calcd. for $C_8H_{15}NOS$: 173.0874; found: 173.0878.

5-Methoxymethyl-1-aza-4-oxa-6-thiabicyclo[3.3.0]octane

19.0% yield; bp 73 °C (0.025 torr). ^{1}H NMR (400 MHz, $CDCl_3$) δ: 2.75–2.86 (2H, m), 3.00–3.12 (1H, m), 3.15–3.27 (2H, m), 3.40 (3H, s), 3.48–3.55 (1H, m), 3.58 (2H, s), 3.98 (1H, q), 4.08 (1H, q). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 32.0, 51.0, 56.0, 60.0, 66.0, 76.5, 120.0. Exact mass calcd. for $C_7H_{13}NO_2S$: 175.0667; found: 175.0671.

5-Phenyl-1-aza-4-oxa-6-thiabicyclo[3.3.0]octane

The product mixture, after extraction, was distilled at reduced pressure only to remove the by-product, 2-phenyl-

oxazoline (~80 °C at 0.25 torr), leaving relatively pure bicyclic amide acetal in the still-pot. The contents of the still-pot were dissolved in diethyl ether and placed in a freezer. After 5 days, a solid had precipitated and was recrystallized, giving white shiny flakes (12.6% yield); mp 46–48 °C. ^{1}H NMR (500 MHz, $CDCl_3$) δ: 2.96–3.05 (2H, m), 3.14–3.20 (1H, m), 3.28–3.34 (2H, m), 3.53–3.57 (1H, m), 4.00 (1H, q), 4.19 (1H, q), 7.27 (1H, t), 7.32 (2H, t), 7.63 (2H, d). ^{13}C NMR (125 MHz, $CDCl_3$) δ: 33.74, 50.77, 56.37, 65.16, 120.00, 127.86, 142.92. Exact mass calcd. for $C_{11}H_{13}NOS$: 207.0718; found: 207.0723.

5-(*p*-Nitrophenyl)-1-aza-4-oxa-6-thiabicyclo[3.3.0]octane

With some heating, a sliver of sodium metal was dissolved in freshly prepared 2-(2-mercaptoethyl)-aminoethanol (20.0 g, 0.165 mol) in a round-bottomed flask. In a separate flask, solid *p*-nitrobenzonitrile (Aldrich) (24.5 g, 0.165 mol) was dissolved in 1,4-dioxane (Caledon). The nitrile solution was then added to the reaction flask. The reaction mixture was allowed to stir for 2 weeks at room temperature under an N_2 atmosphere. At the end of the reaction period, rotary evaporation was used to remove the 1,4-dioxane solvent. Diethyl ether was used to extract the title compound from the residue. The ethereal solution was placed in the freezer to facilitate crystallization. Within a short period of time, a yellow solid formed, which was collected and recrystallized from ether to give shiny, pale yellow flakes (5.4 g, 13.0% yield); mp 75 to 76 °C. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 3.05–3.15 (2H, m), 3.20–3.29 (1H, m), 3.33–3.40 (2H, m), 3.61–3.68 (1H, m), 4.02 (1H, q), 4.23 (1H, q), 7.75 (2H, d), 8.18 (2H, d). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 34.8, 51.8, 57.8, 65.8, 119.0, 124.0, 127.0, 147.9, 150.2. Exact mass calcd. for $C_{11}H_{12}N_2O_3S$: 252.0569; found: 252.0565.

5-(*p*-Chlorophenyl)-1-aza-4-oxa-6-thiabicyclo[3.3.0]octane

The experimental procedure followed that of the synthesis of 5-(*p*-nitrophenyl)-1-aza-4-oxa-6-thiabicyclo[3.3.0]octane, using freshly prepared 2-(2-mercaptoethyl)-aminoethanol (20.0 g, 0.165 mol) and *p*-chlorobenzonitrile (Aldrich) (25.1 g, 0.183 mol) dissolved in 1,4-dioxane. When the ethereal solution from the extraction was placed in the freezer, white needle-like crystals formed. These were later confirmed to be *p*-chlorophenyl-oxazoline. Several attempts at recrystallization successively removed less and less oxazoline. The product mixture still contained oxazoline. Since the oxazoline had a lower boiling point than the bicyclic amide monothioacetal, sublimation was used in a final attempt to remove the oxazoline. The sublimation was carried out under reduced pressure (0.025 torr) with very gentle heating. Before long, the cold finger of the sublimation apparatus was coated with a white solid. The remaining colorless liquid in the sublimation apparatus was determined to be 94% pure by NMR (4.2 g, 10.5% yield). Repeated attempts at sublimation provided no improvement in the purity of the title compound. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 2.98–3.11 (2H, m), 3.14–3.22 (1H, m), 3.28–3.38 (2H, m), 3.54–3.61 (1H, m), 4.02 (1H, q), 4.21 (1H, q), 7.28 (2H, d), 7.55 (2H, d). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 34.01, 51.0, 56.6, 65.5, 119.4, 127.2, 128.3, 133.8, 141.7. Exact mass calcd. for $C_{11}H_{12}ClNOS$: 241.0328; found: 241.0326.

5-(*p*-Methoxyphenyl)-1-aza-4-oxa-6-thiabicyclo[3.3.0]octane

The experimental procedure followed that of the synthesis of 5-(*p*-chlorophenyl)-1-aza-4-oxa-6-thiabicyclo[3.3.0]octane, using freshly prepared 2-(2-mercaptoethyl)-aminoethanol (22.5 g, 0.186 mol) and *p*-methoxybenzonitrile (Aldrich) (25.7 g, 0.193 mol). After sublimation of the product mixture, the remaining colorless liquid was determined to be 90% title compound and 10% *p*-methoxyphenyl-oxazoline (3.4 g, 7.7% yield). ^{1}H NMR (400 MHz, $CDCl_3$) δ: 2.96–3.07 (2H, m), 3.07–3.20 (1H, m), 3.27–3.37 (2H, m), 3.50–3.60 (1H, m), 3.78 (3H, s), 4.02 (1H, q), 4.20 (1H, q), 6.82 (2H, d), 7.55 (2H, d). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 34.0, 51.5, 55.5, 56.5, 66.0, 120.4, 127.5, 130.0. Exact mass calcd. for $C_{12}H_{15}NO_2S$: 237.0824; found: 237.0825.

2-(2-Mercaptoethyl)aminoethanol

This procedure was based on a preparation of *N*-(2-methoxyethyl)-*N*-(2-mercaptoethyl)amine (23). Ethanolamine (Aldrich) (25.0 g, 0.409 mol) and 200 mL of 1,4-dioxane (Caledon) were added to a two-necked, round-bottomed flask. A condenser and a dropping funnel, containing roughly 25 mL of 1,4-dioxane, were connected to the round-bottomed flask. Septa were used to seal the system. An exhaust needle was placed in one septum, while nitrogen was introduced through the other. The contents were warmed to a temperature just below that at which refluxing occurred. At this point, ethylene sulfide (Aldrich) (25.0 g, 0.416 mol) was transferred with the use of a cannula to the dropping funnel that contained dioxane. Once transfer was completed, the dropping funnel was opened to allow the dioxane solution containing ethylene sulfide to be added dropwise. On completion of the addition, the reaction mixture was allowed to reflux for 6 h. The reaction mixture was allowed to cool before removal of the dioxane by rotary evaporation. The residue was immediately distilled under reduced pressure. If the residue was not distilled immediately (for instance, if it were distilled the following day), a noticeable reduction in yield was observed. The distillate collected was a clear, colorless liquid and, on occasion, a white solid when returned to atmospheric pressure (23.7 g, 47.8% yield); bp 50 °C (0.050 torr) (lit. (24) value bp 66–69 °C (0.03 torr)). ^{1}H NMR (400 MHz, $CDCl_3$) δ: 1.97 (3H, br s), 2.66 (2H, t), 2.76 (2H, t), 2.81 (2H, t), 3.63 (2H, t). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 25.0, 50.4, 51.6, 60.9. Exact mass calcd. for $C_4H_{11}NOS$: 121.0561; found: 121.0558.

RZnI vs. R_2Zn in Pd(0)-catalyzed cross-coupling reactions with thioimidates[1]

William P. Roberts, Indranath Ghosh, and Peter A. Jacobi

Abstract: Thioimidates **1**-*Z* undergo facile cross-coupling with Pd(0)–RZnI but are inert to Pd(0)–R_2Zn. This difference is due to the lower Lewis acidity of R_2Zn, as opposed to lower nucleophilicity. Various sources of RZnI (R = Me, Et) and Pd(0) were evaluated for their convenience and reactivity.

Key words: thioimidates, cross-coupling, dialkylzincs, alkylzinc iodides.

Résumé : Les thioimidates (**1**-*Z*) donnent facilement des réactions de couplages croisés avec le Pd(0)–RZnI, mais ils sont inertes vis-à-vis du Pd(0)–R_2Zn. Cette différence est attribuée à l'acidité de Lewis plus faible du R_2Zn plutôt que d'un caractère nucléophile plus faible. On a évalué diverses sources de RZnI (R = Me, Et) pour leur facilité d'accès et leur réactivité.

Mots clés : thioimidates, couplage croisé, dialkylzinc, iodures d'alkylzinc.

[Traduit par la Rédaction]

Introduction

Recently we described an unusual reactivity pattern of *E*- and *Z*-thioimidates **1**-*E,Z*, which undergo Pd(0)-catalyzed cross-coupling with alkyl zinc iodides at markedly different rates (Scheme 1) (1). Thioimidates **1**-*Z* were cleanly converted to imines **3**-*Z* using Pd(0)–RZnI, while the geometric isomers **1**-*E* were inert (R = Me, Et). This difference was traced to a previously unrecognized activating effect of RZnI and other Lewis acids, which serve to polarize the thioimidate C—S bond by complexing with the imidate nitrogen. NMR studies showed that the reactive *Z*-isomers readily coordinate Zn(II), most likely as η^1- or η^5-chelates (cf. **2**-*Z*) (2*a*, 2*b*). In either geometry, oxidative addition to Pd(0) is facilitated by the increased electrophilicity of the C—S bond. In contrast, Zn(II) chelation is not possible with **1**-*E*, and simple imine complexes of type **2**-*E* are sterically disfavored.[3] In the absence of such activation, oxidative addition does not occur, even with stoichiometric Pd(0). Cross-coupling to afford **3**-*E* therefore fails. Interestingly, however, addition of the smaller (and harder) Lewis acid BF_3 efficiently catalyzed the conversion of **1**-*E* to **3**-*E* when B = H. These conditions were also effective with other systems previously regarded as unreactive (2*c*).

In ongoing studies we have evaluated a number of procedures for preparing RZnI (R = Me, Et) (3). One of the most widely employed methods involves transmetallation of Grignard reagents with ZnI_2 (eq. [1], R = Me, Et) (4).

$$[1] \qquad RMgBr + ZnI_2 \longrightarrow RZnI + MgBrI$$

However, in our hands this reaction gave RZnI of relatively low reactivity. For example, MeZnI prepared by this route reacted sluggishly with **1**-*Z* when E = CO_2t-Bu and not at all when E = CHO (in general, the formyl derivatives of **1**-*Z* are slightly less reactive toward cross-coupling).[4] More satisfactory results were obtained following eq. [2] (R = Me, Et), involving oxidative addition of RI to activated Zn (5).

$$[2] \qquad RI + Zn \longrightarrow RZnI$$

Both MeZnI and EtZnI prepared in this manner were consistently more reactive, regardless of the substitution pattern of **1**-*Z* (E = CO_2t-Bu, CHO; B = H, Me, Ph). However, we also experienced a number of drawbacks to this procedure, which requires activation of Zn with 1,2-dibromoethane and trimethylsilyl chloride (5*b*–5*d*). In addition, one has to guard against competitive Wurtz coupling, and the RZnI must be prepared fresh before every reaction. Equation [3] (R = Me, Et) takes advantage of the Schlenk equilibrium between

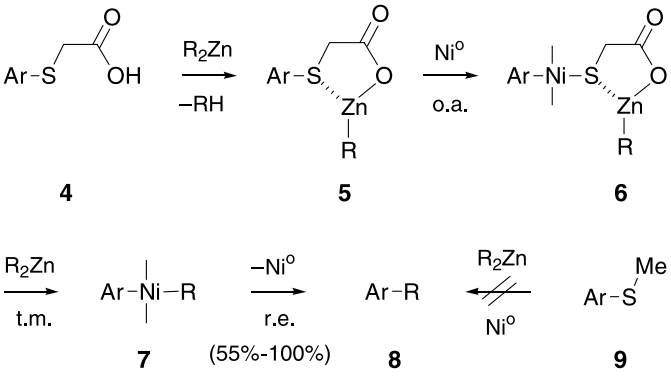
Scheme 1.

R_2Zn and ZnI_2, which Abraham and Rolfe (6) showed lies far to the right in polar solvents such as THF.

[3] $R_2Zn + ZnI_2 \rightleftharpoons 2RZnI$



In general, this procedure worked well, but for reproducible results the ZnI_2 had to be freshly sublimed. By far the most convenient procedure for generating RZnI of uniform reactivity was the method of Charette and co-workers (eq. [4], R = Me, Et) (7).

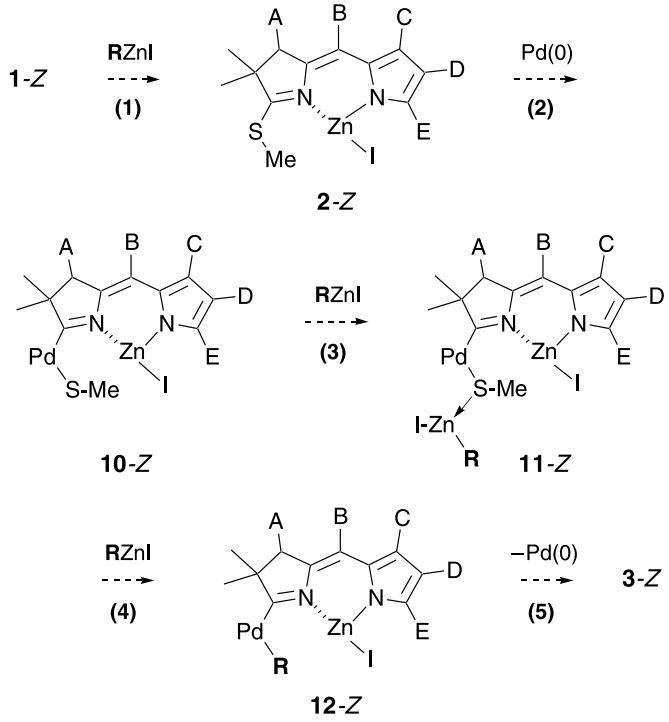
[4] $R_2Zn + I_2 \longrightarrow RZnI + RI$

This method takes advantage of the nucleophilic character of R_2Zn and its ability to effect substitution on I_2. Among other advantages, displacement is carried out at –40 °C and is complete within minutes. Furthermore, both Me_2Zn and Et_2Zn are commercially available and relatively stable.

With a reliable means of preparing RZnI, we explored the effect of various Pd catalysts on converting **1**-*Z* to **3**-*Z* (cf. Scheme 1). Hayashi et al. (8) reported that dichloro[1.1′-bis-(diphenylphosphino)ferrocene]palladium(II) [($PdCl_2$(dppf)] was particularly effective in coupling *n*- and *sec*-BuZnCl with bromobenzene. The efficacy of $PdCl_2$(dppf) was ascribed to its large P-Pd-P bond angle, which presumably accelerates reductive elimination. In our case, however, we observed no significant advantage of $PdCl_2$(dppf) over a number of simpler homogeneous catalysts.[5] Perhaps the most convenient catalyst system tested was heterogeneous Pd–C, which has recently been employed in a number of related cross-coupling reactions (9). Although not quite as reactive as homogeneous PdL_4, Pd–C gave yields of imines **3**-*Z* in the range of 70%.

Scheme 2.

Given the ready availability of Me_2Zn and Et_2Zn (vide supra), it was of interest to examine the cross-coupling of these species with thioimidates **1**-*Z*. In contrast to the case with RZnI (5*c*), there are only scattered reports of transition-metal-catalyzed coupling of dialkylzincs R_2Zn with thioorganics. The most notable of these stem from the elegant studies of Liebeskind and co-workers (10),[6] who showed that thioglycolic acids **4** are excellent substrates for coupling with both RZnI and R_2Zn (Scheme 2). However, these examples represent a special case, since strong Zn-chelation assists both oxidative addition (o.a.) and subsequent transmetalation (t.m.). Under identical conditions, thiomethyl derivatives **9** are essentially inert.



In the present work we observed a dramatic difference in reactivity between RZnI and R_2Zn (R = Me, Et). As noted above, Pd(0)-catalyzed cross-coupling of thioimidates **1**-*Z* with RZnI occurred readily to give high yields of the corresponding imines **3**-*Z* (Scheme 1). In contrast, salt-free Me_2Zn and Et_2Zn failed to react under Pd(0) catalysis[7] and gave only trace amounts of **3**-*Z* when more reactive Ni catalysts were used (10).[6] The reasons for this difference were unclear. Previously we showed that the conversion of thioimidate **1**-*Z* to imine **3**-*Z* using Pd(0)–RZnI requires five steps, involving a minimum of 3 equiv. of RZnI for complete cross-coupling (Fig. 1) (1). Two equivalents are taken up in complexation (steps **1** and **3**), while the third is the source of RZnI for intermolecular transmetalation (step **4**) (10*a*). It seemed unlikely that the rate of reductive elimination (step **5**) would be greatly effected by a change from EtZnI to Et_2Zn. Therefore, we focused our attention on steps **1**–**4**, substituting R_2Zn for RZnI.

It was tempting to attribute this failure to a difference in nucleophilicity between RZnI and R_2Zn, which could have a significant impact on transmetallation (step **4**). However, there is some indication that dialkylzincs are at least as reactive as alkylzinc halides toward simple electrophiles (4). In one experiment we compared the relative rates of addition of

[5] Including, among others, $PdCl_2(PPh_3)_4$, $Pd(PPh_3)_4$, and $Pd_2(dba)_3$–*tris*(2-furylphosphine).

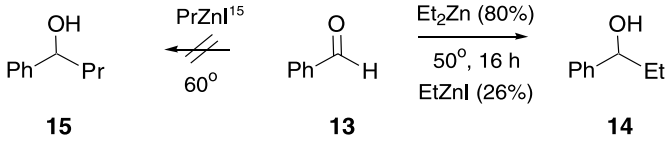
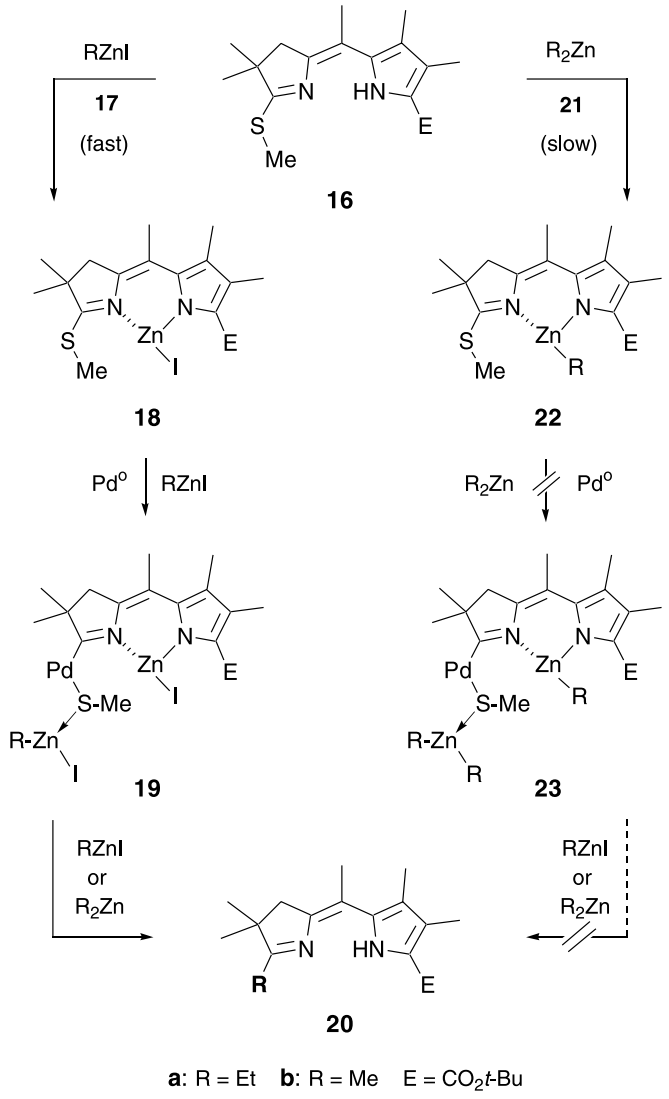
Fig. 1. Steps involved in conversion of thioimidates **1**-*Z* to imines **3**-*Z* using RZnI–Pd(0): (**1**) N-complexation with Zn; (**2**) oxidative addition; (**3**) S-complexation with Zn; (**4**) transmetalation; (**5**) reductive elimination.



Et_2Zn and EtZnI to benzaldehyde. With Et_2Zn, GC analysis shows that the reaction is 80% complete after 16 h at 50 °C in THF–$PhCH_3$ (Scheme 3; see also Experimental section) (11).[8] During this same period, EtZnI reacts to the extent of 26%. Similar results have been found for PrZnI, which is reported to be unreactive at temperatures up to 60 °C (12).[9] In any event, both species are only weakly nucleophilic in the absence of added Lewis acids or bases (4).



A more likely possibility was that dialkylzincs are less effective activators for oxidative addition (step **2**) and (or) transmetalation (step **4**). Both processes require strong complexation with Zn (1, 10*a*). This argument finds support in the fact that dialkylzincs are generally poorer acceptors than alkylzinc iodides (i.e., weaker Lewis acids) (4, 13, 14). In both species, Zn has a low-lying, filled 3*d* shell, and its coordination chemistry is influenced mainly by electrostatic effects (14*b*). In alkylzinc iodides, the metal center is covalently bonded to an electronegative iodine atom, which renders Zn more electron deficient (13). Consequently, there is a strong driving force for coordination between alkylzinc iodides and Lewis bases (EtZnI exists as a coordination polymer in the solid state) (13). In contrast, dialkylzincs are bonded to two R groups, and Zn is less electron deficient. This is reflected in the fact that dialkylzincs are less prone to undergo association or complexation and always occur as monomers (14).

NMR studies demonstrated the difference in the complexing abilities of RZnI and R_2Zn with thioimidates of type **1**-*Z*. With thioimidate **16**, for example, addition of ex-

Scheme 3.

Scheme 4.

cess EtZnI (**17a**) effects immediate loss of the N-H proton and concomitant liberation of ethane (Scheme 4). The resulting Zn complex **18** readily undergoes oxidative addition to Pd(0) to afford **19a** and, ultimately, imine **20a** following transmetallation and reductive elimination. Under identical conditions, but employing Et_2Zn (**21a**), deprotonation and complexation of **16** requires several hours. At the end of this period, the resultant complex **22a** was treated with Pd(0), but little or no oxidative addition could be detected. These experiments were carried out with 6 equiv. of **21a** and stoichiometric Pd(0), which returned only unchanged **16**

[8] See also ref. 4, p. 109.

© 2004 NRC Canada

upon quenching. It is worth noting that Zn complexes **18** and **22a** differ only in one ligand on Zn (I vs. Et). We believe it is the greater electron deficiency of Zn in **18** that provides the driving force for oxidative addition.

We performed a number of experiments to test this idea. Thioimidate **16** was first combined with 2 equiv. of Et_2Zn (**21a**) in THF–$PhCH_3$, and the resulting solution was allowed to stand at room temperature (RT) until complexation to give **22a** was complete. The reaction was then treated with catalytic Pd(0), and 1 equiv. of EtZnI (**17a**) was slowly added in the dark.[10] As expected based upon the pathway outlined in Scheme 4, we observed no formation of imine **20a**, since under these conditions oxidative addition to give **23a** does not occur. However, when this sequence was reversed the results were markedly different. Treatment of **16** with 2 equiv. of EtZnI (**17a**) and catalytic Pd(0), followed by 1 equiv. of *either* EtZnI (**17a**) *or* Et_2Zn (**21a**) led to formation of imine **20a** at approximately the same rate. This demonstrates that once oxidative addition *and S*-complexation with RZnI to give **19a** occurs, transmetalation and reductive elimination are equally facile with RZnI or R_2Zn. Next, we carried out a crossover experiment using MeZnI (**17b**) and Et_2Zn (**21a**). In this case, treatment of **16** with 2 equiv. of MeZnI – catalytic Pd(0), followed by slow addition of Et_2Zn, gave almost exclusively imine **20a** (R = Et). Interestingly, it was necessary to carry out this experiment with strict exclusion of light. Roughly equal amounts of **20a** and **20b** were obtained if this precaution was not taken.[11]

These experiments left unanswered the question of whether the lower complexing ability of R_2Zn also impacted on transmetallation. That is, do **19** and **23** undergo transmetallation at different rates? As shown by Liebeskind and co-workers (10*a*), this step requires considerable weakening of the Pd—S bond. Some indication that this was a problem could be inferred from our early experiments with Ni catalysts and R_2Zn (vide supra), which also produced little or no cross-coupling product **3**-*Z*. In these examples, however, oxidative addition to Ni almost certainly occurred (10).[6] To explore this issue further, we treated **16** with 0.9 equiv. of EtZnI, followed by catalytic Pd(0) and 2 equiv. of Et_2Zn. Our reasoning was that there should be sufficient EtZnI to produce complex **18**, which in turn is activated toward oxidative addition. At this point, however, there would be insufficient EtZnI to further activate the Pd—S bond to transmetalation.[12] Any such activation would have to come from Et_2Zn. Under these conditions we saw only very slow formation of imine **20a** (much slower than when employing 3 equiv. of EtZnI under otherwise identical conditions).

Finally, we briefly explored the possibility of in situ activation of both Et_2Zn and Me_2Zn toward Pd(0)-catalyzed cross-coupling. In this regard we were particularly drawn to the studies of Chastrette and Amouroux (15), who showed that the nucleophilic properties of linear dialkylzincs are markedly increased by tetra-*n*-butylammonium halides (Bu_4NX), while still maintaining the strong acceptor character of Zn (14*b*). Properties of this type might facilitate oxidative addition and (or) transmetallation. However, these modifications were only marginally successful in our case. Inclusion of either Bu_4NI or Bu_4NCl with Me_2Zn–Pd(0) had a modest effect in cross-coupling experiments with thioimidate **16**, raising the yield of imine **20b** from 0% to ~30% (cf. Scheme 4). It is possible, however, that more powerful donors might have a greater impact on accelerating these reactions, and this merits further investigation.

Experimental section

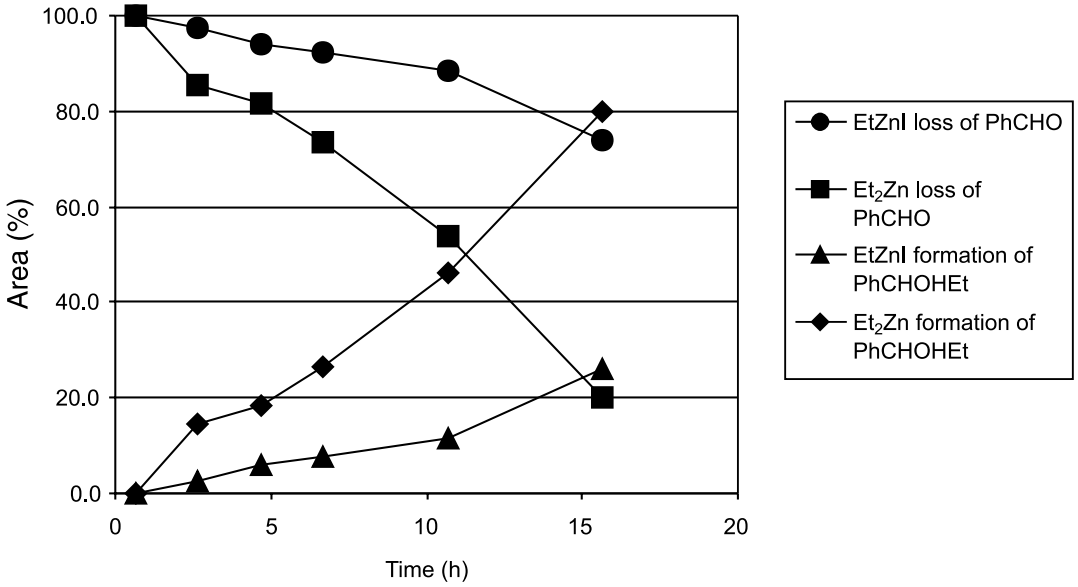
Melting points were determined in open capillaries and are uncorrected. ^{1}H NMR spectra were recorded at 300, 400, or 500 MHz and are expressed as parts per million (ppm) downfield from tetramethylsilane. All reactions were carried out in oven-dried glassware under an inert atmosphere of nitrogen or argon.

Formation of EtZnI

A flask containing 0.634 g (2.5 mmol) of iodine and 2.5 mL of THF was stirred at room temperature for 15 min to ensure that the iodine had completely dissolved. The solution was then cooled to –40 °C, and 2.5 mL (2.5 mmol, 1 equiv.) of 1 mol L^{-1} Et_2Zn in toluene was added in one portion. After an additional 5 min at –40 °C, the cold bath was removed, and the flask was allowed to warm to room temperature. This solution was then titrated against a freshly prepared 1 mol L^{-1} iodine-in-THF solution.

5-[1-(5-Ethyl-4,4-dimethyl-3,4-dihydro-pyrrol-2-ylidene)-ethyl]-3,4-dimethyl-1*H*-pyrrole-2-carboxylic acid *tert*-butyl ester (20a)

A solution of 25.0 mg (0.069 mmol) of thioimidate **16** and 4.8 mg (6.9 μmol, 0.1 equiv.) of $PdCl_2(PPh_3)_2$ in 1 mL of toluene was treated with 1.2 mL (0.414 mmol, 6 equiv.) of 0.4 mol L^{-1} EtZnI in THF–toluene (1:1) under argon. After stirring for 60 min at room temperature, the mixture was taken up in 5 mL of Et_2O, stirred for 10 min, and filtered through celite. To the filtrate was added 5 mL of saturated (sat'd) NH_4Cl, and the aqueous layer was extracted with Et_2O. The combined organic layers were washed with sat'd $NaHCO_3$, dried over Na_2SO_4, filtered, and concentrated to dryness under reduced pressure. The residue was purified by flash chromatography (silica gel, EtOAc:hexanes = 1:9 to 1:5) to give 16 mg (70%) of the imine **20a** as an off-white solid. R_f (1:4 EtOAc:hexanes) 0.54. ^{1}H NMR (500 MHz, $CDCl_3$): 1.18 (s, 6H), 1.33 (t, J = 7.32, 3H), 1.57 (s, 9H), 2.11 (s, 2H), 2.18 (s, 3H), 2.29 (s, 3H), 2.42 (q, J = 7.32, 2H), 2.58 (s, 2H), 11.69 (br s, 1H). ^{13}C NMR (500 MHz, $CDCl_3$): 189.5, 161.36, 149.10, 132.16, 127.36, 119.06, 118.38, 114.26, 79.86, 47.83, 44.44, 28.87, 26.40, 22.19, 18.47, 11.73, 11.67, 10.54. HR-MS (FAB) calcd. for $C_{21}H_{32}N_2O_2$: 344.2464; found: 344.2543 ([M + H]). Anal. calcd. for $C_{21}H_{32}N_2O_2$: C 73.22, H 9.36, N 8.13; found: C 73.20, H 9.44, N 8.08.



[10]Unless otherwise noted, the source of Pd(0) is $PdCl_2(PPh_3)_2$.

[11]The mechanism for this alkyl group exchange is unknown at present but may be related to the facile photoinduced synthesis of organozinc reagents recently described by Charette et al. (cf. ref. 7*b*).

[12]An alternative explanation is that oxidative addition to **18** requires activation by complexation of EtZnI at *both* the imidate N- and S-atoms. However, such a species would suffer prohibitive steric strain from the adjacent geminal dimethyl groups.

Fig. 2. The ratio of benzaldehyde to 1-phenyl-propan-1-ol.

Crossover experiment, 2 EtZnI + 1 Et_2Zn

A total of 10 mg (27.6 μmol) of thioimidate **16** was dissolved in 0.4 mL of toluene. To this was added 110 μL (55.2 μmol, 2 equiv.) of 0.5 mol L^{-1} EtZnI–THF, and the reaction was stirred at room temperature under argon. After stirring for 5 min, 2 mg (2.7 μmol, 0.1 equiv.) of $PdCl_2(PPh_3)_2$ was added, and the flask was purged with argon and wrapped in foil. After stirring for an additional 30 min, the reaction was checked by TLC, and no product was observed. At this time 28 μL (27.6 μmol, 1 equiv.) of 1 mol L^{-1} Et_2Zn in toluene was added dropwise over a period of 30 min. Monitoring of the reaction by TLC (1:9 EtOAc:hexanes) showed formation of **20a** after 30 min.

Crossover experiment, 2Et_2Zn + 1 EtZnI

A total of 10 mg (27.6 μmol) of thioimidate **16** was dissolved in 0.4 mL of toluene. To this was added 55 μL (55.2 μmol, 2 equiv.) of 1 mol L^{-1} Et_2Zn–THF, and the reaction was stirred at room temperature under argon. After stirring for 6 h to ensure complexation, 2 mg (2.7 μmol, 0.1 equiv.) of $PdCl_2(PPh_3)_2$ was added, and the flask was purged with argon and wrapped in foil. After an additional 30 min passed, the reaction was checked by TLC, and no products were observed. At this time, 55 μL (27.6 μmol, 1 equiv.) of 0.5 mol L^{-1} EtZnI in THF was added dropwise over 1 h. Monitoring of the reaction by TLC (1:9 EtOAc:hexanes) showed no formation of **20a**.

Crossover experiment, 2 MeZnI + 6Et_2Zn

A solution of 10 mg (27.6 μmol) of thioimidate **16** in 0.4 mL of toluene was treated with 110 μL (55.2 μmol, 2 equiv.) of 0.5 mol L^{-1} MeZnI–THF, and the resultant solution was stirred at room temperature under argon. After stirring for 5 min, 2 mg (2.7 μmol, 0.1 equiv.) of $PdCl_2(PPh_3)_2$ was added, and the flask was purged with argon and wrapped in foil. After stirring an additional 30 min, the reaction was checked by TLC, and no products were observed. At this time, 10 μL (10 μmol, 0.4 equiv.) of 1 mol L^{-1} Et_2Zn in toluene was added dropwise every 10 min for 2.5 h. Monitoring of the reaction by TLC (1:9 EtOAc:hexanes) showed formation of **20a** after 30 min, and at no point was **20b** observed. Upon completion of the addition of Et_2Zn, the reaction was allowed to stir for an additional 3 h and then worked up as in the synthesis of **20a** (vide supra). ^1H NMR confirmed that no **20b** was formed. If no foil was employed and (or) addition of Et_2Zn was completed too quickly, both **20a** and **20b** were observed.

Crossover experiment, 0.9 EtZnI + 2Et_2Zn

A solution of 10 mg (27.6 μmol) of thioimidate **16** in 0.4 mL of toluene was treated with 49 μL (25 μmol, 0.9 equiv.) of 0.5 mol L^{-1} EtZnI–THF, and the resultant solution was stirred at room temperature under argon. After stirring for 5 min, 2 mg (2.7 μmol, 0.1 equiv.) of $PdCl_2(PPh_3)_2$ was added, and the flask was purged with argon and wrapped in foil. After stirring an additional 30 min, the reaction was checked by TLC, and no products were observed. At this time, 55 μL (55 μmol, 2 equiv.) of 1 mol L^{-1} Et_2Zn in toluene was added dropwise over a period of 60 min. Monitoring of the reaction by TLC (1:9 EtOAc:hexanes) showed formation of **20a** after 50 min. The identical procedure employing 3 equiv. of EtZnI showed immediate formation of **20a**.

Addition of Et_2Zn to benzaldehyde

To 30 μL (3.3 mmol) benzaldehyde was added 1.2 mL of THF under argon. This solution was then treated with 1.0 mL (9.9 mmol, 3 equiv.) of 1 mol L^{-1} Et_2Zn–toluene, and the flask was immersed into an oil bath maintained at 50 °C. Using a 100 μL syringe, 50 μL aliquots were taken and quenched into 300 μL of MeOH. A 25 μL portion of each quenched aliquot was injected onto an HP 6890 GC, employing an HP-35 column (30 m × 0.25 mm × 0.25 μm film thickness). The temperature profile for the GC was as follows: 10 min at 60 °C, then an increase of 15 °C min^{-1} up to 220 °C, followed by 10 min at 220 °C. The ratio of benzaldehyde to 1-phenyl-propan-1-ol is plotted in Fig. 2 using Microsoft Excel 98®.

© 2004 NRC Canada

Addition of EtZnI to benzaldehyde

A solution consisting of 30 μL (3.3 mmol) of benzaldehyde and 2.2 mL (9.9 mmol, 3 equiv.) of 1 mol L^{-1} EtZnI in 1:1 THF:toluene was stirred in an oil bath maintained at 50 °C. The reaction progress was monitored and analyzed, as in the reaction employing Et_2Zn and benzaldehyde (see Fig. 2).

The solid-state molecular structure of $W(NO)_3Cl_3$ and the nature of its W—NO bonding[1]

Trevor W. Hayton, Brian O. Patrick, Peter Legzdins, and W. Stephen McNeil

Abstract: The monomeric trinitrosyl complex, $W(NO)_3Cl_3$, can be prepared by the treatment of WCl_6 in CH_2Cl_2 with NO gas, and its identity has been unambiguously confirmed by a single-crystal X-ray diffraction analysis. The complex crystallizes in the space group $Pmn2_1$ as a three-component twin (a = 10.4280(4) Å, b = 6.3289(2) Å, c = 5.6854(2) Å, Z = 2, R_1 = 0.065, wR_2 = 0.176). Its solid-state molecular structure consists of a tungsten centre bound to three chloride ligands and three linear nitrosyl ligands in a *fac*-octahedral stereochemistry. In addition, the structure contains a crystallographically imposed mirror plane. The two independent W—N linkages are 1.88(2) and 1.92(1) Å long, while the two corresponding N—O bond lengths are 1.13(2) and 1.16(2) Å. DFT calculations on *fac*-$W(NO)_3Cl_3$ at the B3LYP/LANL2DZ level of theory afford optimized intramolecular metrical parameters that match the X-ray crystallographically determined bond lengths and bond angles quite well. In addition, they provide a rationale for the nearly linear W-N-O linkages extant in the complex. Solutions of *fac*-$W(NO)_3Cl_3$ in CH_2Cl_2 lose ClNO under ambient conditions and deposit the well-known $[W(NO)_2Cl_2]_n$ polymer, and this conversion is fully reversible.

Key words: nitrosyl, tungsten, structure, bonding.

Résumé : On peut préparer le complexe trinitrosyle monomère, $W(NO)_3Cl_3$, en traitant du WCl_6 dans le CH_2Cl_2 avec du NO à l'état gazeux et on a confirmé d'une façon non ambigüe son identité par diffraction des rayons X. Le complexe cristallise dans le groupe d'espace $Pmn2_1$, sous la forme de jumeau à trois composant, avec a = 10,4280(4) Å, b = 6,3289(2) Å et c = 5,6854(2) Å, Z = 2, R_1 = 0,065 et wR_2 = 0,176. Sa structure moléculaire à l'état solide consiste en un atome de tungstène central lié à trois ligands chlorures et à trois ligands linéaires nitrosyles dans une stéréochimie *fac*-octaédrique. De plus, la structure comporte un plan miroir imposé par la cristallographie. Les deux liaisons W—N indépendantes sont égales à 1,88(2) et 1,92(1) Å respectivement alors que les longueurs des deux liaisons N—O correspondantes sont égales à 1,13(2) et 1,16(2) Å. Des calculs DFT sur le *fac*-$W(NO)_3Cl_3$ au niveau B3LYP/LANL2DZ de la théorie permettent d'obtenir des paramètres métriques intramoléculaires optimisés qui correspondent à ceux obtenus par diffraction des rayons X pour les longueurs et des angles de liaison. De plus, ils fournissent une explication pour l'arrangement pratiquement linéaire des liaisons W-N-O observés dans le complexe. En solution dans le CH_2Cl_2 dans les conditions ambiantes, le *fac*-$W(NO)_3Cl_3$ perd du ClNO, le polymère bien connu $[W(NO)_2Cl_2]_n$ se dépose et cette transformation est complètement réversible.

Mots clés : nitrosyle, tungstène, structure, liaison.

Introduction

The characteristic properties of metal–nitrosyl complexes are of fundamental importance and practical significance (1). An intriguing feature of metal nitrosyls is that, unlike their isoelectronic carbonyl analogues, polynitrosyl complexes (i.e., those containing three or more NO ligands per metal centre) are relatively rare (2). Thus, among the known coordination and organometallic metal–NO complexes, the only examples of species containing $M(NO)_3$ fragments are $[(\eta^5\text{-}C_5H_5)V(NO)_3][PF_6]$ (3), $[V(NO)_3Cl_2]_n$ (4, 5), $W(NO)_3Cl_3$ (6, 7), $[W(NO)_3Br_2]_2$ (8), $Mn(NO)_3L$ (L = neutral 2-electron donor) (9–18), $Fe(NO)_3X$ (X = halide or pseudohalide) (19–22), and $Co(NO)_3$ (23). Until recently, the only one of these complexes to have been characterized by X-ray crystallography was $Mn(NO)_3(PPh_3)$ (10). Given the rarity of metal–trinitrosyl complexes and the paucity of information currently available about them, we have begun to reinvestigate these systems. The first observations from our laboratory in this regard involved the $Fe(NO)_3X$ systems, which we found to exhibit a striking feature in their solid-state molecular structures (24). Specifically, the four such iron complexes that have now been structurally characterized possess Fe-N-O angles that are bent inward by about 15° in the so-called "*attracto*" conformation (2), in which the O-Fe-O angles are

less than the N-Fe-N angles. This feature led us to wonder if other trinitrosyl complexes might also exhibit similar structural features. Consequently, for our next target in this class of compounds we decided to determine the solid-state molecular structure of $W(NO)_3Cl_3$.

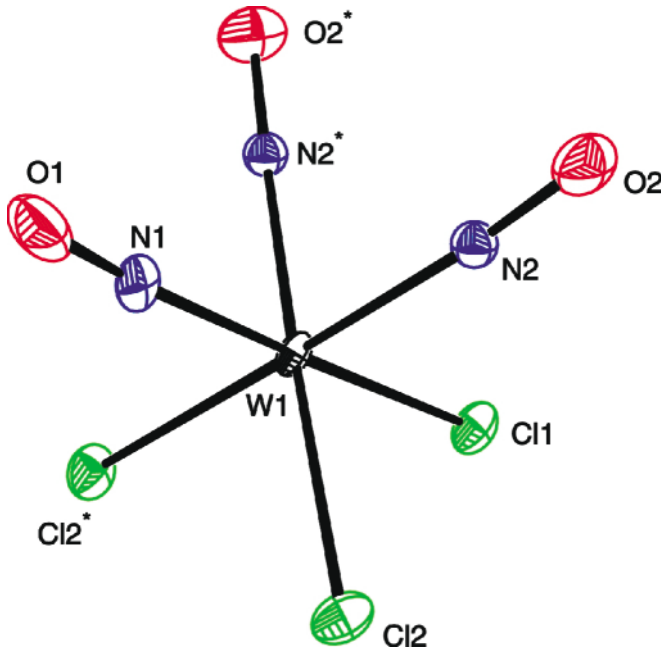
Our interest in $W(NO)_3Cl_3$ dates back to 1984 when we reported its synthesis by the treatment of WCl_6 in CH_2Cl_2 with NO (7). Our original formulation of this material was based solely on elemental analyses and IR spectroscopic data, since we could not establish its solid-state molecular structure by X-ray crystallography at that time. However, other investigators, using similar preparative and characterization methods, had formulated this material at various times as a nitrosyl chloride adduct of $W(NO)_2Cl_2$, i.e., $W(NO)_2Cl_2{\cdot}ClNO$ (25), or as the seven-coordinate tetranitrosyl complex, $W(NO)_4Cl_3$ (26, 27). In other words, uncertainty about the true nature of this nitrosyl complex has existed for the past 19 years. We now wish to report that we have definitively determined the molecular structure of $W(NO)_3Cl_3$ in the solid state and in the process have established that it loses ClNO reversibly in CH_2Cl_2 solutions at room temperature. In this report we also present the results of DFT calculations that provide a rationale for the nearly linear W-N-O linkages extant in this molecule.

Results and discussion

Synthesis and structural characterization of $W(NO)_3Cl_3$

As we have described previously (7), $W(NO)_3Cl_3$ is conveniently synthesized by bubbling NO gas through a CH_2Cl_2 solution of WCl_6 (eq. [1]).

$$[1] \qquad WCl_6 + 6\ NO \rightarrow W(NO)_3Cl_3 + 3\ ClNO$$



Prepared in this manner, the trinitrosyl complex is obtained as a bright green powder. The formation of single crystals of this complex requires the very slow addition of NO to the WCl_6 solution. This requirement can be met by connecting a glass-walled bomb filled with NO (1 atm (1 atm = 101.325 kPa)) via a bridge to a Schlenk tube containing a CH_2Cl_2 solution of WCl_6 and allowing the NO to diffuse slowly into the solution over the course of several weeks. In this manner, $W(NO)_3Cl_3$ can be obtained as small green crystals. As outlined in the Experimental section, the X-ray crystallographic analysis of these crystals has not been a straightforward matter, but eventual utilization of the TwinSolve software (28) to examine the raw diffraction data revealed that $W(NO)_3Cl_3$ crystallizes in the orthorhombic space group $Pmn2_1$ as a three-component twin. The intramolecular metrical parameters for $W(NO)_3Cl_3$ are collected in Table 1, and a plot of its solid-state molecular structure is shown in Fig. 1.

Although the extensive twinning does result in a structure of somewhat diminished quality, it is clear nevertheless that in the solid state $W(NO)_3Cl_3$ is monomeric, consisting of a tungsten centre bound to three chloride ligands and three nitrosyl ligands in a *fac*-octahedral stereochemistry. Furthermore, the structure contains a crystallographically imposed mirror plane. The two W—N bond lengths are 1.88(2) and 1.92(1) Å, while the corresponding N—O distances are 1.13(2) and 1.16(2) Å. The W—N bond lengths are comparable to those extant in related dinitrosyl species; for in-

stance, $(\eta^5\text{-}C_5H_5)W(NO)_2Cl$ exhibits W—N distances of 1.832(9) and 1.819(8) Å (29), while the dimer $[WCl_3(NO)_2]_2^{2-}$ contains a W—N link of 1.85(1) Å (30). Most importantly, the two independent W-N-O linkages in $W(NO)_3Cl_3$ are essentially linear (W-N-O = 177(2)° and 175.7(9)°), unlike the Fe-N-O links in the recently characterized iron trinitrosyl complexes (24). The two W—Cl distances are 2.369(3) and 2.395(5) Å, and each interligand angle in *fac*-$W(NO)_3Cl_3$ is essentially 90° or 180° (Table 1).

Theoretical investigations of the W—NO bonding in *fac*-$W(NO)_3Cl_3$

In an effort to understand the differences between the solid-state structures of the $Fe(NO)_3X$ complexes and *fac*-$W(NO)_3Cl_3$, DFT calculations have been performed on *fac*-$W(NO)_3Cl_3$ using the B3LYP method and a LANL2DZ basis set. The resulting optimized geometry reproduces the key features of the experimentally determined structure remarkably well, including the approximate C_{3v} symmetry and the nearly linear nitrosyl ligands (Fig. 2). The optimized structure has W-N-O angles of 176.9°, 176.9°, and 176.6° in an "*attracto*" conformation, which is very similar to the experimental structure (W-N-O angles of 175.7(9)° and 177(2)°) (Table 1). Other metrical parameters also agree within experimental error, with the exception of the W—Cl bond lengths, which are calculated to be slightly longer (2.435, 2.435, and 2.436 Å) than those seen in the experimental structure (2.369(3) and 2.395(5) Å).

Lowest-energy structures have been determined with all three W-N-O angles contracted inward at identical values of 165°, 170°, 175°, and 179° and the NO groups bent outward at W-N-O angles of 181°, 185°, and 190°. The results are shown as solid circles in Fig. 3, which depicts the variation of the relative energy of *fac*-$W(NO)_3Cl_3$ as a function of the W-N-O angles. Variation of the W-N-O angle represents a fairly shallow energy well, with the calculated global energy minimum (open circle on Fig. 3, at an average W-N-O angle of 176.8°) being less than 1 kJ/mol below a structure with

Fig. 3. Relative energy of *fac*-$W(NO)_3Cl_3$ with changing W-N-O angles. In this representation, W-N-O angles less than 180° correspond to inward bending of the nitrosyl ligands to achieve the "*attracto*" configuration, and W-N-O angles greater than 180° correspond to outward bending of the nitrosyl ligands to achieve the "*repulso*" configuration. The open circle represents the energy of the fully optimized structure.

three perfectly linear nitrosyl linkages and less than 2 kJ/mol below a structure with the NO groups bent outward by an equivalent amount (i.e., W-N-O = 183.2°). Further bending of the NO ligands, either inward or outward, results in a much greater increase of energy, with an inward W-N-O angle of 165° representing an energy increase of over 8 kJ/mol. Two depictions of the calculated HOMO of the complex are shown in Fig. 4. Taking the molecular symmetry as C_{3v}, this orbital is best viewed as the symmetric a_1 π-backbonding combination of a tungsten d_{z^2} orbital with three NO π* orbitals. This is the highest-energy member of the three occupied orbitals that form the M-N-O backbonding interactions in *fac*-$W(NO)_3Cl_3$. The other two are of *e* symmetry and correspond roughly to the overlap of symmetric combinations of NO π* orbitals orthogonal to the *z* axis with appropriate metal-orbital combinations.

The linear W-N-O linkages of *fac*-$W(NO)_3Cl_3$ contrast to those exhibited by the series of structurally characterized iron–trinitrosyl complexes, $[(NO)_3FeX]^{n+}$ (n = 0, X = Cl, BF_4; n = 1, X = EtCN) (24). Like the tungsten compound, these iron complexes effectively possess C_{3v} symmetry, but unlike the tungsten complex, each iron species exhibits a distinctly "*attracto*" conformation of the three nitrosyl groups, with Fe-N-O angles ranging between 160° and 170°. At first glance, therefore, both the iron and tungsten complexes represent 18-electron C_{3v} symmetric trinitrosyl species, affording no immediately obvious electronic explanation for the difference in their M-N-O bond angles. However, the critical distinction between these systems lies in the

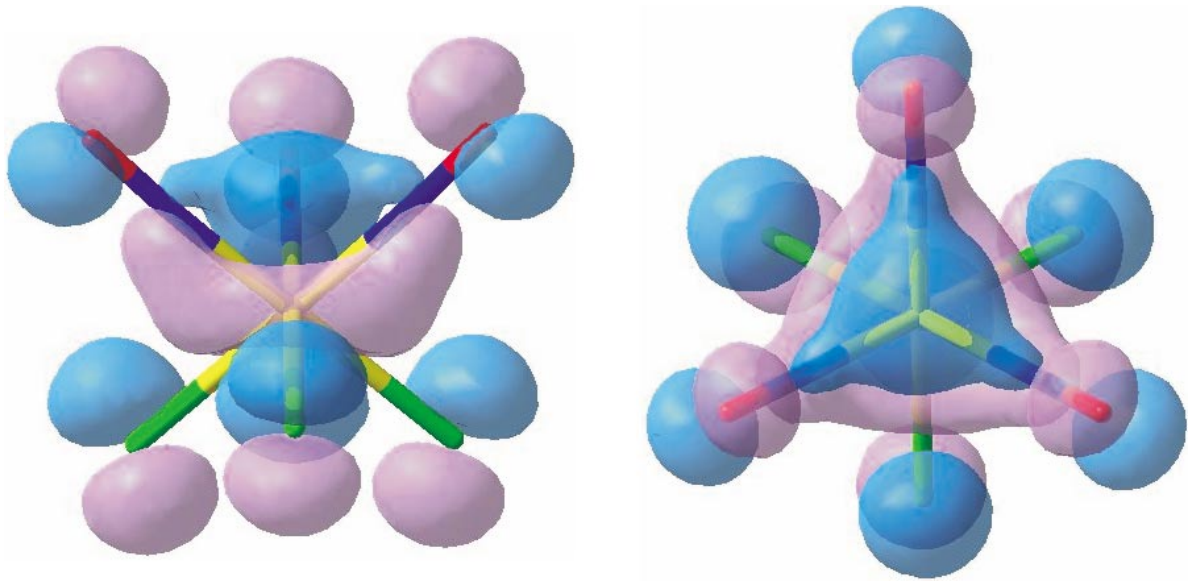
Fig. 4. Two pictorial representations of the HOMO in *fac*-$W(NO)_3Cl_3$.



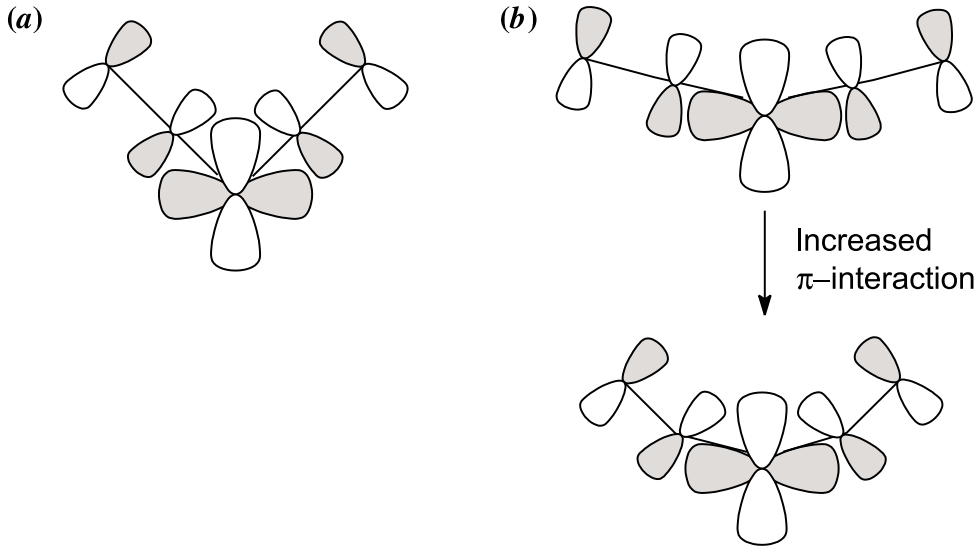


Fig. 5. (*a*) Qualitative pictorial representation of the π interaction between the metal and two orthogonal NO ligands; (*b*) Qualitative pictorial representation of the increased π interaction upon NO bending when the nitrosyl ligands are not orthogonal.

fact that the degree of bending observed in the metal–nitrosyl linkages is related to the N-M-N angles of the complex. Essentially, nonorthogonal nitrosyl groups, which share interactions with the same metal orbital(s) but are not perfectly oriented in the nodal planes of those orbitals, can enhance back-bonding from the metal by symmetrically adjusting the M-N-O angles (31, 32). This phenomenon is depicted pictorially in Fig. 5. In the tungsten complex, which exhibits orthogonal and effectively linear W-N-O groups, each nitrosyl ligand lies in the nodal plane of the metal-based orbital with which it forms a π interaction and does not need to bend to maximize this interaction (Fig. 5*a*). In contrast, the iron complexes exhibit N-Fe-N angles as great as 112°. Thus, each nitrosyl ligand does not lie in a nodal plane of the metal-based orbital with which it forms a π bond, and consequently, the nitrosyl ligand bends to maximize its π interaction (Fig. 5*b*).

These results are also consistent with previous theoretical considerations. In 1965 Kettle suggested (33) that any molecule of C_{3v} symmetry containing an $M(CO)_3$ or $M(NO)_3$ fragment must *necessarily* have bent M-E-O groups (E = C or N) resulting from inequivalent overlaps in the two sets of π-orbitals on each ligand, namely those parallel and perpendicular to the principal axis. Of course, the symmetry constraint does not guarantee that such bending will be large, or even detectable, and the observed angles of *fac*-$W(NO)_3Cl_3$ are sufficiently bent at 176° to satisfy this hypothesis. In any case, the restriction is relaxed somewhat if strict C_{3v} symmetry is lowered, and the experimentally determined structure of *fac*-$W(NO)_3Cl_3$ has a single crystallographic mirror plane that renders one NO and one Cl group very slightly inequivalent from the other two. Thus, the three NO ligands in *fac*-$W(NO)_3Cl_3$ remain essentially linear. A strong bending of the NO groups is neither favoured because of nonorthogonal

© 2004 NRC Canada

NO groups, as it is with the $Fe(NO)_3X$ compounds; nor enforced by a high electron count at the tungsten centre (31); nor dictated by strong symmetry constraints.

Solution and spectroscopic properties of *fac*-$W(NO)_3Cl_3$

As a solid, pure *fac*-$W(NO)_3Cl_3$ is thermally stable under ambient conditions. However, in CH_2Cl_2 solutions it readily loses ClNO, resulting in the precipitation of the well-known $[W(NO)_2Cl_2]_n$ polymer (eq. [2]) (7). We have now established that this conversion is fully reversible, since monitoring by IR spectroscopy confirms that the addition of excess ClNO to a CH_2Cl_2 suspension of independently prepared $[W(NO)_2Cl_2]_n$ (7) results in the formation of *fac*-$W(NO)_3Cl_3$.

$$[2] \qquad n\ fac\text{-}W(NO)_3Cl_3 \rightleftharpoons [W(NO)_2Cl_2]_n\downarrow + n\ ClNO$$

This reaction of ClNO with $[W(NO)_2Cl_2]_n$ (i.e., conversion 2 proceeding to the left) is similar to its reactions with other ML_n species to give $ML_{n-2}(NO)Cl$ (2). During these latter conversions, two ligands (L) contributing four electrons to the metal are displaced by a chloride and a nitrosyl group, while in $[W(NO)_2Cl_2]_n$ two bridging Cl→W dative interactions are broken to generate the trinitrosyl complex. To the best of our knowledge, though, the transformation summarized in eq. [2] is the first reported case in which its reversibility has been established.

Our determination of the solid-state molecular structure of *fac*-$W(NO)_3Cl_3$ establishes it as a trinitrosyl complex and not as the ClNO adduct of $W(NO)_2Cl_2$, i.e., $W(NO)_2Cl_2{\cdot}ClNO$, as had been proposed by some investigators (25). In addition, the IR spectra of *fac*-$W(NO)_3Cl_3$ indicate that it is probably a principal constituent of the material previously described in two reports (26, 27) as $W(NO)_4Cl_3$. Authentic *fac*-$W(NO)_3Cl_3$ as a Nujol mull exhibits three ν(NO) bands at 1773, 1794, and 1933 cm^{-1} in its IR spectrum. As a KBr pellet, it displays these IR bands at 1608, 1762, and 1934 cm^{-1}, similar to those attributed to the putative tetranitrosyl (27).[3] Furthermore, the material formulated as $W(NO)_4Cl_3$, like authentic *fac*-$W(NO)_3Cl_3$ (7), reacts with Lewis bases, L, to form either $W(NO)Cl_3L_2$ or $W(NO)_2Cl_2L_2$-type complexes. Hence, it is our view that the putative tetranitrosyl complex, $W(NO)_4Cl_3$, is really impure *fac*-$W(NO)_3Cl_3$.

Summary

In summary, we have confirmed the identity of *fac*-$W(NO)_3Cl_3$ and have established the intramolecular metrical parameters of this complex by a single-crystal X-ray diffraction analysis. DFT calculations on this complex have also allowed us to rationalize why this compound possesses essentially linear W-N-O linkages. Finally, we have demonstrated that the trinitrosyl complex reversibly eliminates ClNO when dissolved in CH_2Cl_2, the only chloronitrosyl complex yet known to exhibit this behaviour.

Experimental

General methods

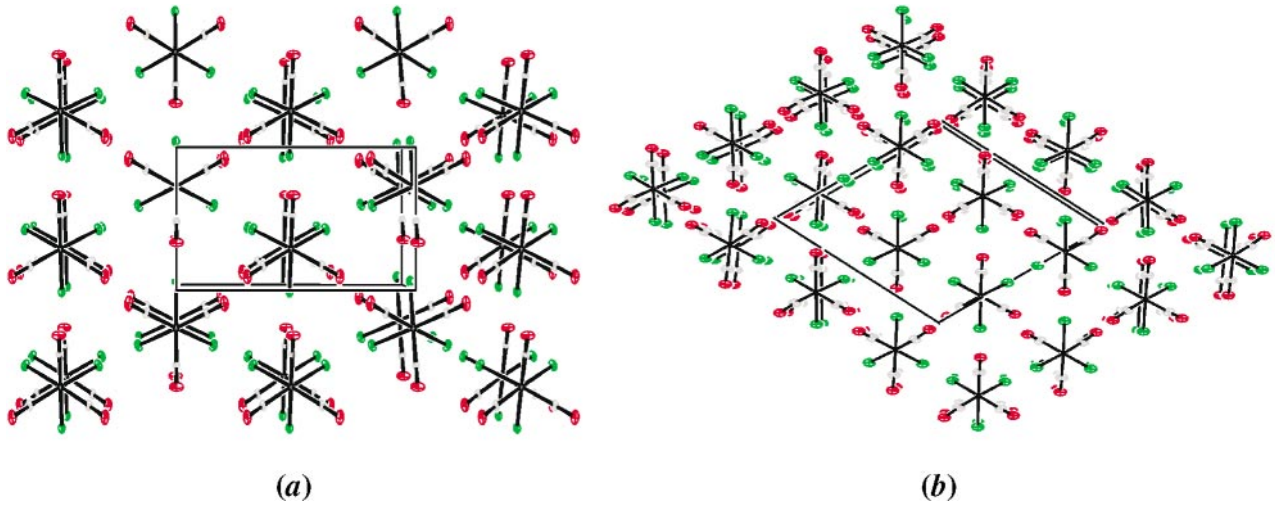
All manipulations were performed under anaerobic and anhydrous conditions either under high vacuum or in an atmosphere of prepurified dinitrogen or argon. General procedures routinely employed in these laboratories have been described in detail previously (34). Dichloromethane was distilled from calcium hydride. WCl_6 was purchased from Strem chemicals; $W(CO)_6$ was purchased from Aldrich; and NO was purchased from Linde. All chemicals were used as received. $[W(NO)_2Cl_2]_n$ (7) and ClNO (35) were prepared by the published procedures.

Crystal growth of *fac*-$W(NO)_3Cl_3$

The preparation of powder samples of *fac*-$W(NO)_3Cl_3$ has been described previously (7). The preparation of crystalline samples of this complex was accomplished in the following manner: A deep-red CH_2Cl_2 (60 mL) solution of WCl_6 (0.331 g, 0.83 mmol) in a 100 mL Schlenk tube was connected via a glass bridge to a glass-walled bomb (500 mL) filled with NO (1 atm). The bridge and headspace above the CH_2Cl_2 solution were filled with Ar (1 atm), and the Kontes Rotoflo valve of the bomb was slowly opened. The apparatus was allowed to stand undisturbed at ambient temperatures for 1 month, after which time a mass of small green crystals (0.126 g, 40% yield) was isolated by removal of the supernatant solution by cannulation. IR (Nujol) (cm^{-1}): 1773 (s), 1794 (w), 1933 (w) IR (KBr) (cm^{-1}): 1608 (s br), 1762 (s br), 1934 (m). MS (EI, 100 °C) *m/z*: 351 ($[P^+ - NO]$).

Preparation of *fac*-$W(NO)_3Cl_3$ from $[W(NO)_2Cl_2]_n$

To a Schlenk tube charged with a powder sample of $[W(NO)_2Cl_2]_n$ (0.397 g, 1.26 mmol) at room temperature was added a solution of ClNO (0.26 mol/L solution in CH_2Cl_2, 15 mL, 3.9 mmol). The suspension was stirred for 30 min, during which time the olive-green powder characteristic of $[W(NO)_2Cl_2]_n$ was replaced by a bright green microcrystalline material. The supernatant solution was removed by filter cannula and discarded, and a further aliquot of ClNO (0.26 mol/L solution in CH_2Cl_2, 15 mL, 3.9 mmol) was added to the Schlenk tube. The mixture was stirred for a further 30 min, and the supernatant solution was then removed from the bright green powder by filter cannulation and discarded. The bright green powder was dried in vacuo (0.214 g, 47% yield). Infrared spectroscopy confirmed its identity as authentic *fac*-$W(NO)_3Cl_3$.



X-ray crystallography

Data collection for $W(NO)_3Cl_3$ was originally attempted in 1984 using an Enraf-Nonius CAD4-F diffractometer. However, attempts to index the unit cell were unsuccessful, and no data were ever collected. During the current investigation, data collection was carried out on a Rigaku/ADSC CCD diffractometer, where prior knowledge of the unit cell and its orientation was not required for data collection. The data were collected using graphite-monochromated Mo Kα radiation in 0.50° oscillations with 35 s exposures at

[3] The striking differences in the IR spectra of *fac*-$W(NO)_3Cl_3$ as a Nujol mull and as a KBr pellet suggest that it reacts in the solid state with KBr, possibly forming some $[WCl_2Br_2(NO)_2]^{2-}$. Thus, our KBr IR spectrum and that recorded by Taube and co-workers (ref. 27) is probably due to a mixture of nitrosyl compounds.

Fig. 6. ORTEP packing diagrams of (*a*) the correct orthorhombic cell viewed down the 5.69 Å *c*-axis and (*b*) the incorrect monoclinic cell viewed down the 5.68 Å *b*-axis.

–100 ± 1 °C. Preliminary treatment of the data using d*TREK (36) revealed a monoclinic unit cell with dimensions a = 12.174 Å, b = 5.676 Å, c = 12.177 Å, β = 117.49°, and V = 746.43 Å^3 (Fig. 6*b*). Integration was carried out to a maximum 2θ value of 59.5°. The internal consistency of the equivalent reflections was poor (R_{int} = 0.099); nevertheless, a reasonable preliminary solution was found in space group $P2_1/n$. Subsequent structure expansion and refinement revealed a significantly disordered structure, with three partially occupied nitrosyls interspersed between the three facial chlorides and three partially occupied chlorides interspersed between the three facial nitrosyls. Final residuals after anisotropic refinement were unsatisfactorily high (R_1 ~ 15%). An analysis of the crystal packing revealed several unreasonably short intermolecular contacts, including oxygen–oxygen contacts as short as 1.55 Å, chlorine–oxygen contacts as short as 1.88 Å, and chlorine–chlorine contacts as short as 2.18 Å. A re-examination of the raw data using TwinSolve (28) revealed an orthorhombic unit cell with dimensions a = 10.4280 Å, b = 6.3289 Å, and c = 5.6854 Å and with one-half the volume of the original cell (Fig. 6*a*). The internal consistency of the data was much better, with R_{int} = 0.04. This crystal formed with three twin components, where components 1 and 2 are related by a rotation of 180° around the axis normal to (–1, –1, 0), components 1 and 3 are related by a 180° rotation around the axis normal to (–1, 1, 0), and components 2 and 3 are related by a 123° rotation around the axis normal to (0, 0, 1). Data were integrated measuring all reflections, including those overlapped by reflections from other twin components. A Patterson (37) solution, using nonoverlapped data, was found in space group $Pmn2_1$, with the molecule residing on the mirror plane perpendicular to the *a*-axis. Figure 6 shows both the correct orthorhombic unit cell and the incorrect monoclinic unit cell and the evident similarities among their packing arrangements. Subsequent anisotropic refinement revealed no disorder and reasonable displacement parameters for all but one atom (N2). Refinement using all data (including overlapped reflections from the two minor components in HKLF5 format) gave final residuals of R_1 = 0.065 ($I > 2\sigma(I)$) and wR_2 = 0.176 (all data). Refinement of the batch scale factors associated with each twin component gave relative populations of 0.708, 0.217(1), and 0.075(1) for twin components 1, 2, and 3, respectively. N2 was refined isotropically while all other atoms were refined anisotropically. The absorption correction was performed along with batch scaling in a single step. The resulting transmission factors include contributions from absorption, detectable variations in beam intensity, and inhomogeneity of the detector surface. The final cycle of full-matrix, least-squares refinement was based on 2395 observed reflections and 49 parameters.

Neutral atom scattering factors were taken from Cromer and Waber (38). Anomalous dispersion effects were included in F_{calcd} (39); the values for $\Delta f'$ and $\Delta f''$ were those of Creagh and McAuley (40). The values for mass attenuation coefficients were those of Creagh and Hubbell (41). All calculations were performed using the CrystalClear software package of Rigaku/MSC, Inc. (42), which includes TwinSolve, or SHELXL-97 (43). X-ray crystallographic data are collected in Table 2, and full details of the crystallographic analysis are provided in the supplementary material.[4]

Theoretical DFT calculations

All theoretical calculations were performed using Gaussian03W (44). All calculations utilized a DFT method, using the three-parameter exchange functional of Becke (45) and the correlation functional of Lee, Yang, and Parr

[4] Supplementary material consists of full details of the crystallographic (CIF) and theoretical (PDF) analyses of *fac*-$W(NO)_3Cl_3$. Supplementary data may be purchased from the Depository of Unpublished Data, Document Delivery, CISTI, National Research Council Canada, Ottawa, ON K1A 0S2, Canada (http://www.nrc.ca/cisti/irm/unpub_e.shtml for information on ordering electronically). CSD 413576 contains the crystallographic data for this paper. These data can be obtained, free of charge, from the ICSD-Team/Crystal Structure Depot, Fachinformationszentrum (FIZ) Karlsruhe, Germany via CRYSDATA@FIZ-Karlsruhe.DE.

Radio labelling of the gibberellin plant growth inhibitor 16,17-dihydro-GA_5[1]

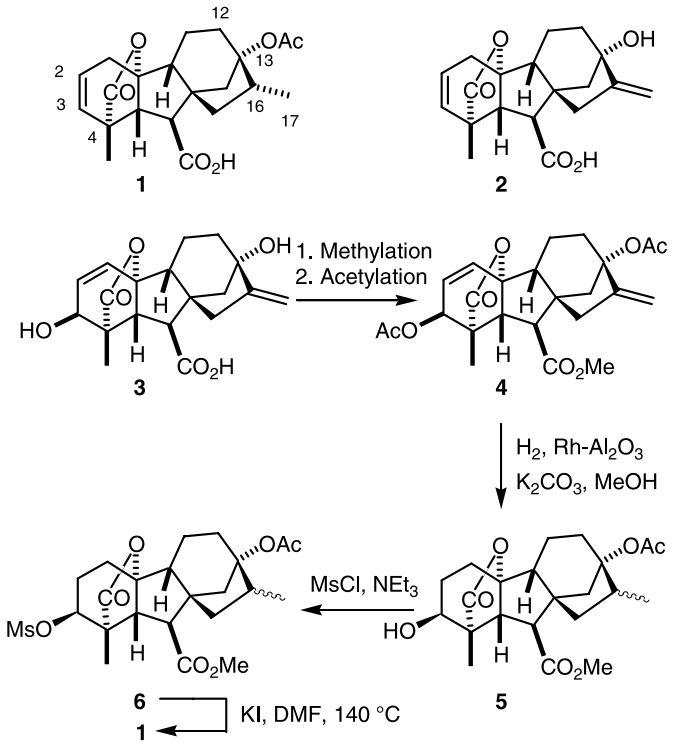
Ellen J. Beck, Bruce Twitchin, and Lewis N. Mander

Abstract: An improved five-step procedure has been developed for the synthesis of the gibberellin plant growth inhibitor 16,17-dihydro-GA_5 from gibberellic acid. The 3-^{13}C and 3-^{14}C derivatives of this material have also been prepared by excising C-3 from the carbon skeleton (ozonolysis of a Δ^2-alkene derivative and subsequent retro-Claisen reaction) and then reassembling the A-ring by means of an intramolecular aldol reaction.

Key words: gibberellin, growth inhibitor, degradation, Radio labelling, Wittig reaction.

Résumé : On a développé une méthode améliorée en cinq étapes pour la synthèse, à partir de l'acide gibbérellique, du 16,17-dihydro-GA_5, un inhibiteur de la gibbérelline, une hormone de croissance des plantes. On a aussi préparé les dérivés 3-^{13}C et 3-^{14}C de ce produit en procédant à l'enlèvement du C-3 du squelette carboné (ozonolyse du dérivé Δ^2-alcène suivie d'une réaction subséquente de rétro-Claisen) et un réassemblage du noyau A par le biais d'une réaction intramoléculaire aldolique.

Mots clés : gibbérelline, inhibiteur de croissance, dégradation, marquage radioactif, réaction de Wittig.



[Traduit par la Rédaction]

Introduction

The modified gibberellin *exo*-16,17-dihydro-GA_5-13-acetate (**1**) and related compounds are some of the most potent plant growth retardants presently known (1). Under greenhouse conditions, dosages of **1**, equivalent to 500 mg ha^{-1}, give distinct effects in wheat, barley, and many other graminaceous species. This substance has shown considerable promise for reducing the risk of lodging in cereal crops and, in field trials on wheat and barley, has been shown to be effective at application rates of ca. 25 g ha^{-1}. In contrast, rates of 200 or 1000 g ha^{-1} of prohexadione-Ca or chlormequat chloride, respectively, are required to produce an equivalent effect (2). Gibberellic acid (GA_3) (**3**) is readily available in tonne quantities from the fermentation of the fungus *Gibberella fujikuroi* and is relatively cheap, so there appeared to be reasonable prospects of producing **1** using **3** as a starting material. Several procedures for converting **3** into GA_5 (**2**) or its 16,17-dihydro derivatives have been reported (3), but none appeared sufficiently practical to produce **1** on a commercial basis. Of particular concern were the challenges of achieving a high overall yield, a minimization of steps, the use of cheap reagents, and the avoidance of chromatography. Assuming that these requirements could be addressed satisfactorily, the next phase of any commercialization and registration process would require isotopic labelling of **1** (desirably in a location that would not be lost through metabolism), to allow tracking and subsequent testing of metabolites for toxicity. In this paper we describe a high-yielding, five-step synthesis of **1** that meets the stated criteria, as well as derivatives of **1** that have been labelled with ^{13}C and ^{14}C at C-3.

Our first approach to the synthesis of **1** is outlined in Scheme 1 and involves simple hydrogenation of GA_3 deriva-

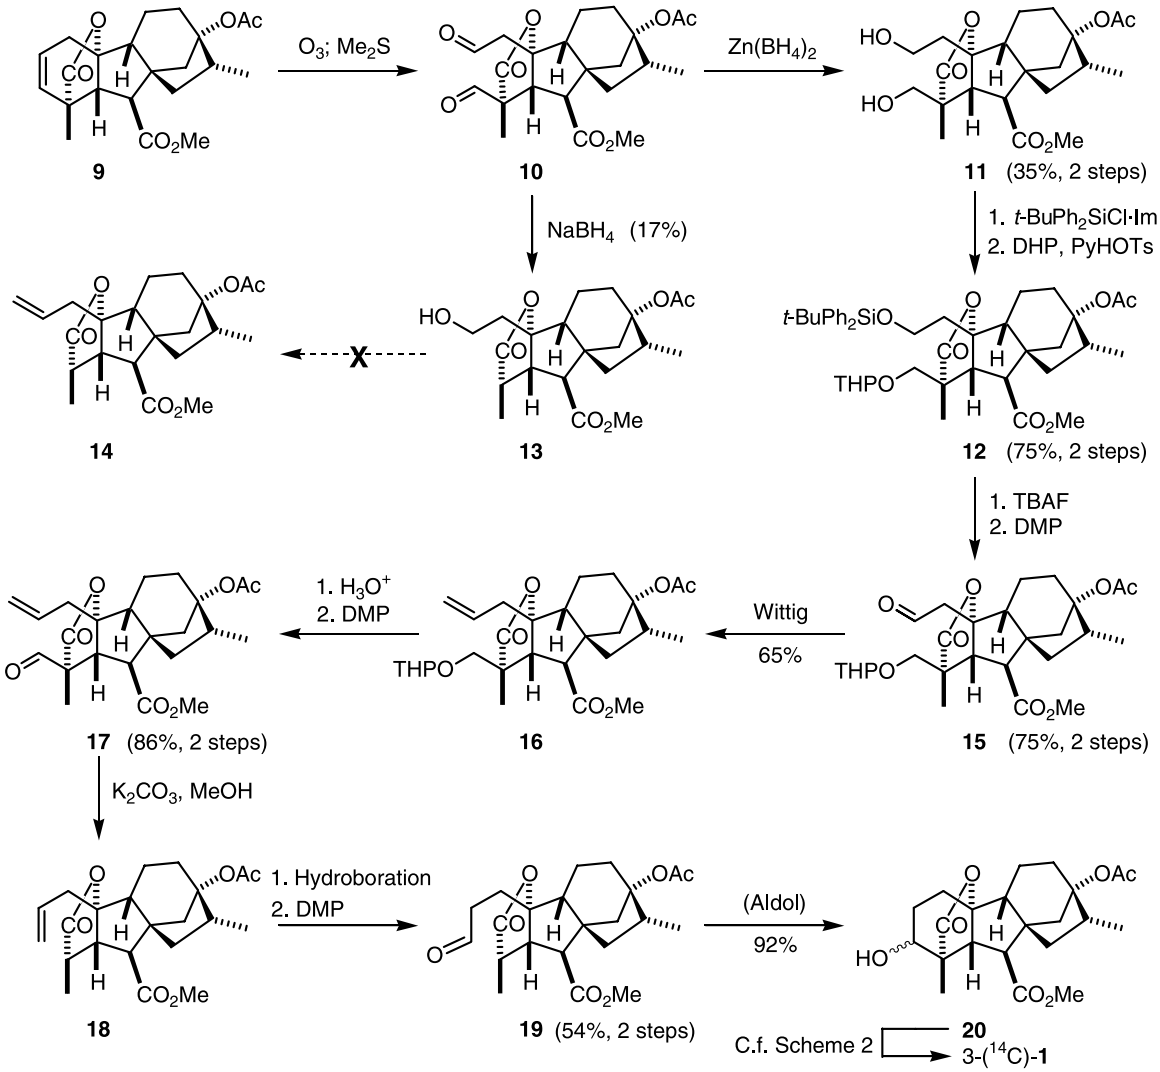
Scheme 2.

tives followed by dehydration of the 3-hydroxyl. Hydrogenation of GA_3 methyl ester over Pd- and Pt-based catalysts has been reported (4) to afford poor yields of a ca. 1:1 mixture of tetrahydro derivatives epimeric at C-16, since hydrogenolysis of the lactone function in the A-ring to give acidic products also occurs (ca. 30% with Pd–charcoal and 70% with PtO_2). Although hydrogenolysis is minimal with Rh–Al_2O_3, provided that the reduction is carried out in a non-polar solvent (acetone and ethyl acetate are suitable), a 2:1 mixture (*exo–endo*) of the 16-epimers is still obtained. The stereochemistry at C-16 (5) is established from the observation of mutual upfield shifts of the resonances from C-12 and C-17 in ^{13}C NMR spectra for the *endo* epimer (6), owing to the γ-gauche effect (7). Acylation of the 13-hydroxyl in the substrate, however, results in a minor degree of steric shielding of the *exo* face of the D-ring, favouring approach of the catalyst to the *endo* face of the 17-methylene group, such that the *exo*:*endo* ratio of 16-epimers from hydrogenation is improved. Thus, the diacetate **4** was reduced to give a 4:1 mixture of epimers in favor of the *exo*-isomer. Then, in preparation for the introduction of the Δ^2 alkene bond, the 3-acetate function was selectively hydrolyzed to give **5**. Although direct dehydration with, for example, $POCl_3$ (8) was feasible, our preferred procedure was based on preparation of the 3-mesylate **6** followed by DBU (1,8-diazabicyclo-[5.4.0]undec-7ene) induced elimination. Loss of the 13-acetate function could not be avoided during alkaline hydrolysis of the methyl ester, but treatment of **6** with KI in DMF at 140 °C effected both alkene formation and demethylation, with preservation of the acetate function to afford **1**.

Although this sequence was reasonably efficient, there appeared to be several opportunities for streamlining, including the elimination of the unnecessary "loop" of methylation (expensive) and demethylation of the carboxy function (modest yield). The changes are outlined in Scheme 2. Thus, GA_3 (**3**) was acetylated (acetic anhydride – $ZnCl_2$), and the resulting mixed anhydride **7** was hydrogenated in situ (after replacement of solvent with ethyl acetate), following which the solvent was removed, and the mixture was hydrolyzed in KOH–methanol to afford **8**. In this way, not only were the first three reactions carried out in "one pot", but the proportion of *exo* epimer was elevated to ca. 90%. Mesylation followed by elimination then led to the target compound **1** in 56% overall yield, with the amount of *endo* epimer being progressively reduced by successive recrystallizations.



Next, we addressed the question of isotopic labelling. While the introduction of ^{14}C at C-17 in **1** would have been relatively straightforward, loss of this carbon by metabolic degradation was considered to be a possibility. Therefore, it was required that the label be located within the main skeleton. To achieve this aim, we elected to base our approach on the excision and restoration of C-3, the latter step being carried out by means of a Wittig methylenation, for which labelled reagents could be readily obtained. After a number of false starts we arrived at the sequence outlined in Scheme 3, in which the key steps are the removal of C-3 by a retrograde Claisen reaction (**17**→**18**) and the subsequent reconstitution of the gibberellin skeleton by means of an intramolecular aldol reaction (**19**→**20**) (for which there were several precedents) (9).

The dialdehyde **10** proved to be extremely labile and was therefore immediately reduced to diol **11** with zinc borohydride, as the more obvious reagent, sodium borohydride, afforded complex mixtures. We had originally planned to remove C-3 by means of a retrograde aldol process, given that an equivalent process is known to lead very readily to the inversion of stereochemistry in 3β-hydroxy gibberellins (10), but were surprised to find that **11** was stable to an extensive range of bases. Fortuitously, we had identified **13** as a minor component of the mixture obtained from the sodium borohydride treatment of dialdehyde **10** and, in a trial investigation, had oxidized it to the corresponding aldehyde and submitted it to a Wittig reaction. When we discovered that the desired alkene product **14** could not be obtained, possibly because of a competing aldol reaction between the lactone and aldehyde functions, we decided to postpone cleavage of the C-4 residue so that it could serve as a blocking group during the Wittig reaction. Thus, the C-2 carbinol function was selectively protected with *tert*-butyldiphenylsilyl chloride; then the C-3 hydroxyl was masked as a tetrahydropyranyl ether to furnish **12**. The silyl group was removed from C-2; the resulting alcohol was oxidized with the Dess–Martin periodinane (DMP) (11), and then the aldehyde product **15** was subjected to a series of Wittig reactions with a view to optimizing the yield of alkene while minimizing the amount of reagent used. The optimal stoichiometry proved to be 1.5 equiv. of ylide (generated from methyltriphenyl phosphonium iodide and potassium *tert*-butoxide), which afforded a 67% yield of **16** (based on substrate).

Following the hydrolysis of the THP function and oxidation, the resulting aldehyde **17** smoothly underwent a retro-Claisen reaction to give **18**, which was submitted to a number of hydroborating reagents, the most satisfactory of which proved to be disiamylborane. After oxidation to aldehyde **19**, the gibberellin skeleton was reassembled by an intramolecular aldol reaction to produce **20** as a 1:2 mixture of 3β:3α epimers. The mixture was then converted to **1**, using a similar protocol to the one employed in the latter part of Scheme 1. After repeating each of the eight steps from **15** to **1** at least three times and obtaining reproducible yields, aldehyde **15** was treated with ^{13}C- and ^{14}C-labelled phosphorane, and the sequence leading to 3-(^{14}C)–**1** was carried through in three batches, with a total yield of 40 mCi (1 Ci = 37 GBq) being obtained with the latter reagent.

Scheme 3.

Experimental

Melting points (°C) were recorded on a Reichert hot-stage apparatus and are uncorrected. Infrared spectra (ν_{max}, cm^{-1}) were recorded on a PerkinElmer 1800 Fourier Transform Infrared spectrometer. NMR spectra were recorded on a Varian Gemini 300 MHz instrument. For proton spectra recorded in chloroform, the residual peak of $CHCl_3$ was used as the internal reference (7.26 parts per million (ppm)), while the central peak of $CDCl_3$ (77.0 ppm) was used as the reference for ^{13}C spectra. Low- and high-resolution EI mass spectra (EI-MS, 70 eV) were recorded on a Fisons Autospec double focussing mass spectrometer. C, H, and N microanalyses were measured on a Carlo Erba EA 1106 CHN-O instrument and were carried out by the Australian National University Analytical Services Unit, Canberra. ^{14}C-methyltriphenylphosphonium iodide was supplied by Amersham Australia Pty Ltd., and the ^{13}C reagent was supplied by the Aldrich Chemical Co.

13-Acetoxy-3β-hydroxy-20-nor-16-*epi*-gibberellan-7-oic acid 19,10-lactone 8

To a suspension of GA_3 (10.8 g, 0.03 mol) in acetic anhydride (40 mL, 0.635 mol) was added zinc chloride (8.0 mg), and the mixture was left to stir overnight at room temperature (room temp) (15 h), by which time complete solution had occurred. The solvent was removed in vacuo and warmed to 60 °C. The residue was then redissolved in ethyl acetate, and the solution was reduced to a viscous oil. It is important to remove most of the solvent, since acetic acid promotes the opening of the A-ring lactone and slows the rate of reaction. This material was dissolved in ethyl acetate (100 mL); 5% rhodium on alumina (1 g) was added, and stirring was maintained under an atmosphere of hydrogen for 48 h. After purging with nitrogen, the solution was filtered through Celite (note that the catalyst may be reused several times), and the solvent was removed in vacuo to afford the crude product as a gum (17.4 g). IR (cm^{-1}): 1816, 1777, 1737. ^1H NMR δ: 0.87 (d, J = 6.9 Hz, 3H, H-17), 1.05 (s, 3H, H-18), 1.56–2.36 (m, 14H), 1.98 (s, 3H, OAc), 2.08 (s, 3H, OAc), 2.21 (s, 3H, OAc), 2.65 (d, J = 10.7 Hz, 1H, H-6), 3.11 (d, J = 10.9 Hz, 1H, H-5), 3.72, 4.92 (br s, 1H, H-3). ^{13}C NMR δ: 14.7, 17.2, 18.8, 21.0, 21.1, 22.3, 25.3, 27.5, 37.4, 38.8, 41.2, 44.8, 49.1, 49.1, 51.9, 52.2, 53.1, 54.9, 71.1, 84.8, 92.7 165.4, 167.8, 170.1, 170.3, 176.4.

The material prepared above was dissolved in methanol

(50 mL) and cooled to 5 °C initially; then 4 mol L^{-1} aq KOH (65 mL) was added slowly over 2 h, and the progress of the reaction was monitored by TLC. The pH of the reaction was then adjusted to pH 8 using 2 N HCl, and a volume of solvent equal to the amount of methanol (50 mL) was removed in vacuo. The reaction mixture was then diluted with water (60 mL), and any neutral material was extracted with ethyl acetate (2 × 50 mL). After the aqueous solution was cooled to 5 °C and the pH was adjusted to pH 3 with 4 mol L^{-1} HCl, the resulting precipitate was filtered and washed with water (2 × 50 mL). The crystalline product was dried under high vacuum at 60 °C to give the crude 16,17-dihydro-GA_1-13-acetate (**8**) (8.2 g, 76% yield). A sample was crystallized from ethyl acetate – petroleum ether, mp 179–181 °C. IR (cm^{-1}): 3506, 2951, 2877, 1772, 1734, 1438, 1370, 1272, 1243, 1198, 1173, 1101, 1059, 1038, 1020, 997, 972, 952, 928, 735. ^{1}H NMR δ: 0.88 (d, *J* = 6.9 Hz, 3H, H-17), 1.13 (s, 3H, H-18), 1.56–2.36 (m, 14H), 2.01 (s, 3H, OAc), 2.68 (d, *J* = 10.7 Hz, 1H, H-6), 3.19 (d, *J* = 10.9 Hz, 1H, H-5), 3.72 (s, 3H, CO_2CH_3), 3.83 (m, 1H, H-3). ^{13}C NMR δ: 14.9, 17.6, 19.1, 21.8, 27.6, 28.2, 37.8, 39.3, 41.3, 45.5, 49.2, 51.4, 52.0, 52.2, 54.6, 54.8, 70.3, 85.6, 93.8, 170.7, 173.1, 178.3. LR-MS *m/z* (relative intensity): 406 ([M^+], 7), 388 (16), 364 (100), 346 (65), 321 (85), 289 (47), 243 (26) 225 (20). HR-MS calcd. for $C_{22}H_{30}O_7$ ([M^+]): 406.1992; found: 406.1995. Anal. calcd. for $C_{22}H_{30}O_7$ (%): C 65.01, H 7.44; found: C 64.76, H 7.30.

13-Acetoxy-20-nor-16-*epi*-gibberell-2-en-7-oic acid 19,10-lactone 7-methyl ester 9

After 16,17-dihydro-GA_1 13-acetate (**8**) (406 mg, 1 mmol) was treated with diazomethane, excess reagent and solvent were removed; the residue was dissolved in dry pyridine (2.35 mL) at 0 °C under nitrogen, and methanesulfonyl chloride (194 μL, 2.5 mmol) was added with stirring. The reaction was allowed to warm to room temp, and stirring continued for 24 h. Ice chips were added to quench the reaction, and the product was extracted into ethyl acetate. After washing with dilute HCl and brine, the solution was dried and reduced to dryness. The crude product was dissolved in dry toluene (20 mL); DBU (0.5 mL) was added, and the mixture was heated under reflux for 20 h. The solution was decanted from a tarry residue, diluted with ether (50 mL), washed with dilute HCl and brine, and dried ($MgSO_4$). After removal of solvent, chromatography on silica gel (1:2 ethyl acetate : hexane) afforded the title compound as a colourless solid (298 mg, 77%). A sample was crystallized from ethyl acetate – petroleum ether, mp 110–112 °C. IR (cm^{-1}): 3033, 2954, 2875, 1775, 1734, 1437, 1368, 1242, 1198, 1168, 1100, 1030 939, 893, 735, 704. ^{1}H NMR δ: 0.88 (d, *J* = 6.9 Hz, 3H, H-17), 0.94 (dd, *J* = 6.0, 12.6 Hz, 1H), 1.21 (s, 3H, H-18), 1.60–2.40 (m, 11H), 2.01 (s, 3H, OAc), 2.56 (dq, *J* = 18.7, 1.8 Hz, 1H, H-1), 2.62 (dq, *J* = 18.7, 1.8 Hz, 1H, H-1), 2.65, 2.78 (2 × Abd, *J* = 9.3 Hz, 2 × 1H, H-5, H-6), 3.73 (s, 3H, OMe), 5.66 (d, *J* = 9.3 Hz, H-3), 5.80 (dt, *J* = 9.2, 3.2 Hz, H-2). ^{13}C NMR δ: 15.5, 17.7, 19.1, 21.8, 35.6, 37.5, 39.6, 41.0, 45.5, 48.3, 50.2, 52.0, 55.1, 52.3, 55.1, 55.3, 85.6, 91.9, 128.0, 132.4, 173.1, 177.9. LR-MS *m/z* (relative intensity): 388 ([M^+], 4), 357 (9), 344 (37), 284 (100), 259 (18), 241 (36), 225 (65). HR-MS calcd. for $C_{22}H_{28}O_6$ ([M^+]): 388.1885; found: 388.1879. Anal. calcd. for $C_{22}H_{28}O_6$ (%): C 68.02, H 7.26; found: C 68.22, H 7.35.

13-Acetoxy-20-nor-16-*epi*-gibberell-2-en-7-oic acid 19,10-lactone 1

To a solution of 16,17-dihydro-GA_1 13-acetate (**5**) (392 mg, 1 mmol) in dry pyridine (2.35 mL) at 0 °C under nitrogen was added mesyl chloride (194 μL, 2.5 mmol), with stirring. The reaction was allowed to warm to room temp, and stirring was continued for 24 h. To the residue was added DMF (5 mL) and KI (1.25 g), and the mixture was heated to 130 °C for 48 h and then cooled to room temp. The reaction was diluted with water (20 mL) and then acidified with 1 mol L^{-1} HCl (10 mL). The mixture was then extracted with dichloromethane (×5). The organic phase was washed with water, $Na_2S_2O_3$, and brine and dried ($MgSO_4$), and the solvent was evaporated in vacuo. The residue was crystallized from ethyl acetate – petroleum ether to give **1** (288 mg, 73%), mp 222–224 °C. When the methyl ester of **8** was used in place of the parent acid, purification was carried out by silica gel chromatography (3:1 hexane : ethyl acetate → 1:1 hexane : ethyl acetate with acetic acid (2 mL L^{-1})), furnishing the alkene acid **1** in 74% yield and its methyl ester in 14% yield. Similar results were obtained when the mixture of 3-epimers (obtained from the aldol reaction of aldehyde **19**) was employed. IR (cm^{-1}): 3532, 3180, 2959, 2925, 2853, 1772, 1732, 1455, 1370, 1246, 1226, 1172, 1143, 1101, 1029, 939, 736, 702. ^{1}H NMR δ: 0.89 (d, *J* = 6.9 Hz, 3H, H-17), 1.16 (dd, *J* = 6.0, 12.6 Hz, 1H), 1.27 (s, 3H, H-18), 1.60–2.40 (m, 11H), 2.02 (s, 3H, OAc), 2.18 (dq, *J* = 18.7, 1.8 Hz, 1H, H-1) 2.60 (dq, *J* = 18.7, 1.8 Hz, 1H, H′-1) 2.68, 2.74 (2 × Abd, *J* = 9.3 Hz, 2 × 1H, H-5, H-6), 5.68 (d, *J* = 9.3 Hz, H-3), 5.82 (dt, *J* = 9.2, 3.2 Hz, H-2). ^{13}C NMR δ: 15.6, 17.7, 19.1, 21.8, 35.6, 37.4, 39.7, 40.9, 45.2, 48.4, 50.2, 51.8, 55.1, 55.3, 85.6, 91.8, 128.0, 132.4, 170.8, 177.6, 177.8. LR-MS *m/z* (relative intensity): 374 ([M^+], 6), 332 (57), 330 (58), 314 (9), 289 (28), 270 (100), 241 (21), 225 (44). HR-MS calcd. for $C_{21}H_{26}O_6$ ([M^+]): 374.1729; found: 374.1724. Anal. calcd. for $C_{21}H_{26}O_6$ (%): C 67.36, H 7.00; found: C 67.39, H 7.36.

13-Acetoxy-2,3-dioxo-2,3-seco-20-nor-16-*epi*-gibberellan-7-oic acid 19,10-lactone 7-methyl ester 10

Ozone was bubbled through a solution of 13-acetoxy-16,17-dihydro-GA_5 methyl ester (**9**) (3.4 g, 8.8 mmol) in dichloromethane (150 mL) cooled to –78 °C, until a faint blue color appeared. Nitrogen was then bubbled through the solution for 15 min to remove the excess ozone. Methyl sulfide (3.2 mL, 43 mmol, 5 equiv.) was added, and the reaction was allowed to warm slowly in the cold bath for 1 h. The reaction was stirred at room temp overnight. The reaction mixture was then washed with water and brine and dried ($MgSO_4$), and the solvent was removed in vacuo. No further purification was attempted, owing to the instability of the dialdehyde. IR (cm^{-1}): 3439, 2949, 2872, 1770, 1730, 1436, 1369, 1241, 1205, 1173, 1112, 1039, 961, 734, 701. ^{1}H NMR δ: 0.91 (d, 3H, H-17), 1.0–2.0 (m), 1.4 (s, 3H, H-18), 2.00 (s, 3H, OAc), 2.2–2.6 (m), 2.73 (d, 1H, *J* = 1.1 Hz, H-6), 3.59 (s, 1H, H-5), 3.70 (s, 3H, CO_2CH_3), 9.62 (s, 1H, H-2), 9.69 (d, 1H, *J* = 0.7 Hz, H-3).

13-Acetoxy-2,3-dihydroxy-2,3-seco-20-nor-16-*epi*-gibberellan-7-oic acid 19,10-lactone 7-methyl ester 11

A solution of $Zn(BH_4)_2$ in DME (0.5 mol L^{-1} solution, 33 mL, 2 equiv.) was added to a solution of crude dialdehyde **10** (3.46 g, 8.2 mmol) in DME (60 mL) cooled to 0 °C, and the reaction was stirred for 1.5 h. The reaction was then quenched with acetone, and most of the DME was removed in vacuo. The residue was taken up in ethyl acetate and 10% HCl. The aqueous layer was extracted with ethyl acetate (×3). The combined organic extracts were washed with water and brine and dried ($MgSO_4$), and the solvent was removed in vacuo. Purification by silica gel chromatography (ethyl acetate) furnished the diol (1.25 g) in 35% over the two steps. IR (cm^{-1}): 3440, 2947, 2872, 1731, 1436, 1370, 1334, 1240, 1173, 1113, 1038, 957, 735. ^{1}H NMR δ: 0.92 (d, *J* = 6.9 Hz, 3H, H-17), 1.21 (s, 3H, H-18), 1.48–2.0 (m, 7H), 2.0 (s, 3H, OAc), 2.11–2.2 (m, 3H), 2.51 (m, 2H), 2.78 (d, *J* = 0.96 Hz, 1H, H-6), 3.17 (br, 2H, OH), 3.29 (d, *J* = 1.4 Hz, 1H, H-5), 3.63, 3.73 (2 × Abd, *J* = 10.9 Hz, 2H, H-3), 3.70 (s, 3H, CO_2CH_3), 3.88 (m, 2H, H-2). ^{13}C NMR δ: 18.1, 18.2, 19.2, 22.0, 33.1, 34.5, 39.6, 42.8, 43.3, 47.3, 50.4, 51.0, 51.5, 52.3, 52.9, 58.7, 69.8, 87.1, 95.6, 170.6, 176.0, 180.7. LR-MS *m/z* (relative intensity): 424 ([M^+], 7), 394 (10), 381 (50), 364 (52), 339 (100), 319 (30), 307 (34), 291 (36), 277 (28), 261 (55), 231 (50) 201 (35). HR-MS calcd. for $C_{22}H_{32}O_8$: 424.2097; found: 424.2089.

When this reaction was performed on a 235 mg scale with sodium borohydride in ethanol, a gross mixture was obtained, from which diol **11** (27 mg) and alcohol **13** (40 mg) were obtained. For the latter product: ^{1}H NMR δ: 0.91 (d, *J* = 6.9 Hz, 3H, H-17), 1.23 (d, 3H, *J* = 6.0 Hz H-18), 1.48–2.0 (m, 7H), 1.99 (s, 3H, OAc), 2.11–2.2 (m, 3H), 2.48 (m, 2H), 2.72 (d, *J* = 0.9 Hz, 1H, H-6), 3.15 (m, 1H, H-4), 3.29 (dd, *J* = 0.9, 10.7 Hz, 1H, H-5), 3.70 (s, 3H, CO_2CH_3), 3.81 (m, 4H, H-2 + H-3).

13-Acetoxy-2-*tert*-butyldiphenylsilyloxy-3-hydroxy-2,3-seco-20-nor-16-*epi*-gibberellan-7-oic acid 19,10-lactone 7-methyl ester

Triethylamine (0.51 mL, 3.7 mmol, 1.1 equiv.) and then TBDPS-Cl (0.95 mL, 3.7 mmol, 1.1 equiv.) were added to a cooled solution of the diol **11** (1.41 g, 3.3 mmol, 1 equiv.) and imidazole (0.05 g, 0.66 mmol, 0.2 equiv.) in DMF (75 mL), and the reaction was stirred overnight at room temp. The reaction was then poured into ethyl acetate and water, and the aqueous layer was extracted with ethyl acetate (×4). The combined organic extracts were washed with water and brine and dried ($MgSO_4$), and the solvent was removed in vacuo. Purification by silica gel chromatography (5:1 hexane : ethyl acetate → ethyl acetate) furnished the mono-protected diol in 86% yield. IR (cm^{-1}): 3454, 3071, 3050, 2934, 2859, 1760, 1732, 1589, 1471, 1461, 1428, 1369, 1334, 1239, 1169, 1112, 1086, 1038, 972, 958, 823, 738, 703. ^{1}H NMR δ: 0.89 (d, *J* = 6.8 Hz, 3H, H-17), 1.04 (s, 9H, $SiCCH_3$), 1.21 (s, 3H, H-18), 1.47 (dd, *J* = 5.9, 12.7 Hz, 1H), 1.58–1.73 (m, 5H), 1.87 (m, 1H), 1.98 (s, 3H, OAc), 2.12–2.24 (m, 3H), 2.44 (m, 2H), 2.73 (d, *J* = 1.5 Hz, 1H, H-6), 2.96 (d, *J* = 1.5 Hz, 1H, H-5), 3.56 (s, 2H, H-3), 3.62 (s, 3H, CO_2CH_3), 3.84–3.93 (m, 2H, H-2), 7.38–7.46 (m, 6H, Ar), 7.66–7.70 (m, 4H, Ar). ^{13}C NMR δ: 18.1, 18.4, 19.25, 19.3, 22.1, 27.1, 33.2. 34.5, 41.0, 42.9, 43.5, 47.9, 49.9, 51.0, 51.9, 52.6, 52.9, 60.2, 70.1, 87.2, 95.4, 127.99, 128.0, 130.02, 130.04, 133.55, 133.6, 135.8, 135.9, 170.6, 174.6, 180.5. Anal. calcd. for $C_{37}H_{47}O_7Si$ (%): C 68.85, H 7.60; found: C 68.67, H 7.51.

13-Acetoxy-2-*tert*-butyldiphenylsilyloxy-3-tetrahydropyranyloxy-2,3-seco-20-nor-16-*epi*-gibberellan-7-oic acid 19,10-lactone 7-methyl ester 12

Dihydropyran (0.03 mL, 0.38 mmol, 2 equiv.) and pyridinium *p*-toluenesulfonate (0.002 g, 0.006 mmol, 0.05 equiv.) were added to the silyl ether prepared above (0.127 g, 0.19 mmol, 1 equiv.) in dichloromethane (5 mL), and the reaction was stirred at room temp overnight. The reaction mixture was then washed with water and brine and dried ($MgSO_4$), and the solvent was removed in vacuo. Purification by silica gel chromatography (5:1 hexane : ethyl acetate → 3:1 hexane : ethyl acetate) furnished the protected compound **12** as a colorless gum in 87% yield. IR (cm^{-1}): 2942, 2859, 1764, 1732, 1453, 1428, 1367, 1254, 1238, 1167, 1112, 1077, 1036, 969, 904, 822, 740, 703. ^{1}H NMR δ: 0.88 (d, *J* = 7.0 Hz, 3H, H-17), 1.02 (s, 9H, CCH_3), 1.03 (s, 9H, CCH_3), 1.18 (s, 3H, H-18), 1.19 (s, 3H, H-18), 1.26–1.82 (m, 13H), 1.97 (s, 3H, OAc), 1.98 (s, 3H, OAc), 2.04 (d, *J* = 7.8 Hz, 0.5H), 2.09 (d, *J* = 7.8 Hz, 0.5H), 2.33–2.46 (m, 4H), 2.72 (br s, 1H), 3.04 (d, *J* = 9.2 Hz, 1H, H-5), 3.19 (d, *J* = 9.1 Hz, 1H), 3.47 (d, *J* = 9.3 Hz, 1H), 3.51 (m, 2H), 3.59 (s, 3H, CO_2CH_3), 3.60 (s, 3H, CO_2CH_3), 3.67–3.89 (m, 4H), 4.54 (m, 1H, THP H), 4.64 (m, 1H, THP H), 7.40 (m, 6H, phenyl), 7.67 (m, 4H, phenyl). Anal. calcd. for $C_{43}H_{58}O_9Si$ (%): C 69.14, H 7.83; found: C 69.40, H 7.95.

13-Acetoxy-2-hydroxy-3-tetrahydropyranyloxy-2,3-seco-20-nor-16-*epi*-gibberellan-7-oic acid 19,10-lactone 7-methyl ester

Tetrabutylammonium fluoride (2.0 mL, 2.0 mmol, 3 equiv.) was added to a solution of silyl ether **12** (0.501 g, 0.67 mmol, 1 equiv.) in THF (20 mL) and stirred at room temp for 4 to 5 h until reaction was complete. The reaction mixture was then poured into ethyl acetate and water. The aqueous phase was extracted with ethyl acetate (×3). The combined organic phases were washed with water and brine and dried ($MgSO_4$), and the solvent was removed in vacuo. Purification by silica gel chromatography (1:1 ethyl acetate : hexane → 2:1 ethyl acetate : hexane) furnished the deprotected compound as a colorless gum in 94% yield. IR (cm^{-1}): 3480, 2944, 2871, 1760, 1731, 1453, 1370, 1239, 1125, 1068, 1035, 958, 904. ^{1}H NMR δ: 0.93 (d, *J* = 7.0 Hz, 3H, H-17), 1.21 (s, 3H, H-18), 1.48–1.99 (m, 2H), 2.00 (s, 3H, OAc), 2.15–2.40 (m, 4H), 2.50 (m, 2H), 2.80 (m 1H), 3.24 (d, *J* = 9.1 Hz, 1H), 3.30 (d, *J* = 12.6 Hz, 1H), 3.52 (m, 2H), 3.71 (s, 3H, CO_2CH_3), 3.71–3.94 (m, 5H), 4.58 (m, 1H, THP), 4.67 (m, 1H, THP). Anal. calcd. for $C_{27}H_{40}O_9$ (%): C 63.76, H 7.93; found: C 63.47, H 7.47.

13-Acetoxy-2-oxo-3-tetrahydropyranyloxy-2,3-seco-20-nor-16-*epi*-gibberellan-7-oic acid 19,10-lactone 7-methyl ester 15

Dess–Martin periodinane (0.077 g, 0.20 mmol, 1.5 equiv.) was added to a solution of the alcohol prepared above (0.069 g, 0.14 mmol, 1 equiv.) in dichloromethane (2 mL) at room temp. The reaction was stirred for 1 h; then 1 mol L^{-1}

© 2004 NRC Canada

$Na_2S_2O_3$ (1 mL) and saturated $NaHCO_3$ (1 mL) solutions were added, and the mixture was stirred vigorously until both layers were clear. The aqueous phase was then extracted with dichloromethane (×3). The combined organic phases were washed with water and brine and dried ($MgSO_4$), and the solvent was removed in vacuo. Purification by silica gel chromatography (1:1 ethyl acetate : hexane) furnished aldehyde **15** as a colorless gum in 80% yield. IR (cm^{-1}): 2945, 2870, 1768, 1728, 1436, 1368, 1253, 1238, 1125, 1067, 1036, 962, 904. ^{1}H NMR δ: 0.91 (d, J = 7.0 Hz, 3H, H-17), 1.22 (s, 3H, H-18), 1.48–1.99 (m, 15H), 2.00 (s, 3H, OAc), 2.11 (m, 1H), 2.49 (m, 2H), 2.81 (m, 1H), 3.05 (m, 1H), 3.20 (m, 2H), 3.55 (m, 1H), 3.69 (s, 3H, CO_2CH_3), 3.68–3.82 (m, 1H), 3.97 (d, J = 8.9 Hz, 1H), 4.56 (m, 1H, THP), 4.68 (m, 1H, THP), 9.97 (m, 1H, CHO). Anal. calcd. for $C_{27}H_{38}O_9$ (%): C 64.02, H 7.56; found: C 63.73, H 7.60.

13-Acetoxy-4-tetrahydropyranyloxymethyl-3,4-seco-20-nor-16-*epi*-gibberell-2-en-7-oic acid 19,10-lactone 7-methyl ester 16

Potassium *tert*-butoxide (1.0 mol L^{-1} solution in THF, 3.4 mL, 3.4 mmol, 1.4 equiv.) was added to a suspension of methyl triphenylphosphine iodide (1.5 g, 3.7 mmol, 1.5 equiv.) in THF (30 mL) and stirred at room temp for 30 min. The stirring was then stopped, and the precipitate in the ylide solution was allowed to settle for at least 30 min. Aldehyde **14** (1.24 g, 2.4 mmol, 1 equiv.) was dissolved in THF (20 mL), and the supernatant ylide solution was cannulated into the aldehyde solution. The reaction was stirred for 1 h and then poured into ethyl acetate and water. The aqueous layer was extracted with ethyl acetate (×3). The combined organic layers were washed with water (×1) and brine and dried ($MgSO_4$), and the solvent was removed in vacuo. Purification by silica gel chromatography (2:1 hexane : ethyl acetate) furnished the olefin in 65% yield. IR (cm^{-1}): 2945, 2870, 1764, 1731, 1436, 1369, 1238, 1125, 1067, 1036, 970, 904. ^{1}H NMR δ: 0.91 (d, J = 6.9 Hz, 3H, H-17), 1.23 (s, 3H, H-18), 1.46–1.84 (m, 14H), 1.99 (s, 3H, OAc), 1.96–2.14 (m, 2H), 2.47 (m, 2H), 2.76 (m, 3H), 3.09 (d, J = 9.6 Hz, 1H), 3.23 (d, J = 9.1 Hz, 0.5H), 3.53 (d, part obscured, J = 9.5 Hz, 1.5H), 3.68 (s, 3H, CO_2Me), 3.68–3.86 (m, 1H), 3.93 (d, J = 9.1 Hz, 1H), 4.58, 4.66 (m, 1H, THP), 5.13 (m, 2H, H-3), 5.97 (m, 1H, H-2). Anal. calcd. for $C_{28}H_{40}O_8$ (%): C 66.65, H 7.99; found: C 66.31, H 7.96.

13-Acetoxy-4-hydroxymethyl-3,4-seco-20-nor-16-*epi*-gibberell-2-en-7-oic acid 19,10-lactone 7-methyl ester

A catalytic amount (10 mg) of *p*-toluenesulfonic acid was added to the THP-protected gibberellin **16** (0.151 g, 0.30 mmol) in methanol (10 mL) and stirred at room temp overnight. The methanol was then removed in vacuo, and the residue was taken up in ethyl acetate. The solution was washed with $NaHCO_3$, water, and brine and then dried ($MgSO_4$), and the solvent was removed in vacuo. The crude mixture was chromatographed (1:1 hexane : ethyl acetate) to furnish the alcohol (0.119 g) as a colorless gum in 94% yield. IR (cm^{-1}): 3455, 3076, 2946, 2871, 1760, 1732, 1435, 1369, 1238, 1169, 1037, 972. ^{1}H NMR δ: 0.93 (d, J = 6.9 Hz, 3H, H-17), 1.26 (s, 3H, H-18), 1.49 (dd, J = 6.3, 12.8 Hz, 1H), 1.56–1.84 (m, 7H), 1.96–2.1 (m, 3H), 1.99 (s, 3H, OAc), 2.46 (m, 2H), 2.68 (m, 2H), 2.76 (s, 1H, H-6), 2.89 (s, 1H, H-5), 3.68 (s, 3H, CO_2Me), 3.68 (s, 2H, H-3), 5.18 (m, 2H, H-3), 5.93 (m, 1H, H-2). ^{13}C NMR δ: 18.1, 18.3, 19.2, 22.1, 33.2, 34.6, 42.8, 43.5, 43.6, 47.8, 49.7, 51.0, 52.0, 52.3, 52.9, 69.6, 87.2, 95.9, 119.3, 133.1, 170.6, 174.8, 180.6. LR-MS *m*/*z* (relative intensity): 420, ([M^+], 5), 379 (97), 319 (100), 291 (60), 273 (43), 259 (64), 231 (55). HR-MS calcd. for $C_{23}H_{32}O_7$ ([M^+]): 420.2148; found: 420.2128.

13-Acetoxy-4-formyl-3,4-seco-20-nor-16-*epi*-gibberell-2-en-7-oic acid 19,10-lactone 7-methyl ester 17

Dess–Martin periodinane (0.16 g, 0.42 mmol, 1.5 equiv.) was added to a solution of the alcohol prepared above (0.119 g, 0.28 mmol, 1 equiv.) in dichloromethane (10 mL) and stirred at room temp for 1.5 h. The reaction was stirred for 1 h; then 1 mol L^{-1} $Na_2S_2O_3$ (5 mL) and saturated $NaHCO_3$ (5 mL) solutions were added, and the mixture was stirred vigorously until both layers were clear. The aqueous phase was then extracted with dichloromethane (×3). The combined organic phases were washed with water and brine and dried ($MgSO_4$), and the solvent was removed in vacuo. Purification by silica gel chromatography (2:1 hexane : ethyl acetate) furnished the aldehyde **17** (0.109 g) in 92% yield. IR (cm^{-1}): 2944, 2870, 1766, 1731, 1435, 1369, 1239, 1168, 1109, 1036, 917. ^{1}H NMR δ: 0.92 (d, J = 6.9 Hz, 3H, H-17), 1.40 (s, 3H, H-18), 1.49 (dd, J = 6.2, 12.9 Hz, 1H), 1.60–1.90 (m, 6H), 1.95 (d, J = 6.7 Hz, 1H), 2.00 (s, 3H, OAc), 2.11 (d, J = 8.7 Hz, 1H), 2.42–2.55 (m, 4H), 2.66 (d, J = 1.5 Hz, 1H, H-6), 3.56 (d, J = 1.7 Hz, 1H, H-5), 3.70 (s, 3H, CO_2Me), 5.16 (m, 2H, H-3), 5.72 (m, 1H, H-2), 9.47 (s, 1H, CHO). ^{13}C NMR δ: 17.1, 18.1, 19.2, 22.0, 33.1, 34.7, 42.3, 42.7, 43.3, 47.9, 48.1, 51.2, 52.2, 52.3, 60.9, 87.0, 96.5, 121.1, 131.9, 170.5, 174.4, 175.1, 195.2. LR-MS *m*/*z* (relative intensity): 418 ([M^+], 3), 377 (100), 359 (27), 349 (30), 333 (34), 317 (60), 289 (18), 257 (16), 231 (23). HR-MS calcd. for $C_{23}H_{30}O_7$ ([M^+]): 418.1992; found: 418.2000. Anal. calcd. for $C_{23}H_{30}O_7$ (%): C 66.01, H 7.23; found: C 65.57, H 6.63.

13-Acetoxy-3,4-seco-20-nor-16-*epi*-gibberell-2-en-7-oic acid 19,10-lactone 7-methyl ester 18

An aqueous solution of potassium carbonate (1 mol L^{-1}, 12.5 mL) was added to aldehyde **16** (0.714 g, 1.7 mmol, 1 equiv.) in methanol (50 mL) and stirred at room temp for 3 min. The reaction was then quenched with 1 mol L^{-1} HCl (10 mL) and poured into ethyl acetate and water. The aqueous phase was then extracted with ethyl acetate (×4). The combined organic phase was washed with water and brine and dried ($MgSO_4$), and the solvent was removed in vacuo. Purification by silica gel chromatography (2:1 hexane : ethyl acetate) furnished the deformylation product **18** (0.641 g) in 96% yield. IR (cm^{-1}): 2953, 2871, 1768, 1731, 1435, 1368, 1245, 1165, 1033, 960. ^{1}H NMR δ: 0.904 (d, J = 7.0 Hz, 3H, H-17), 1.20 (d, J = 7.4 Hz, 3H, H-18), 1.38 (dt, J = 13.1, 6.3 Hz 1H), 1.60–2.05 (m, 7H), 1.99 (s, 3H, OAc), 2.34 (dd, J = 8.2, 13.9 Hz, 1H), 2.45 (m, 2H), 2.67 (dd, J = 6.3, 14.0 Hz, 1H), 2.72 (d, J = 2.6 Hz, 1H, H-6), 2.91 (dq, J = 7.4, 10.9 Hz, 1H, H-4), 3.07 (dd, J = 2.6, 10.7 Hz, 1H, H-5), 3.69 (s, 3H, CO_2Me), 5.24 (m, 2H, H-3), 5.91 (m, J = 1H, H-2). ^{13}C NMR δ: 12.0, 18.3, 19.2, 22.0, 33.4, 35.2, 38.4, 42.0, 42.9, 43.1, 49.3, 49.9, 50.8, 51.0, 52.0, 87.0, 95.5,

120.6, 131.9, 170.6, 174.9, 179.6. LR-MS *m/z* (relative intensity): 390 ([M$^+$], 10), 349 (100), 330 (30), 305 (45), 289 (55), 275 (27), 261 (36), 233 (32), 201 (24), 173 (32). HR-MS calcd. for $C_{22}H_{30}O_6$ ([M$^+$]): 390.2042; found: 390.2044. Anal. calcd. for $C_{22}H_{30}O_6$ (%): C 67.67, H 7.74; found: C 67.52, H 7.82.

13-Acetoxy-3-hydroxy-3,4-seco-20-nor-16-*epi*-gibberellan-7-oic acid 19,10-lactone 7-methyl ester

2,3-Dimethyl-2-butene (0.36 mL, 3.0 mmol, 1.5 equiv.) was added to borane – dimethyl sulfide (2.0 mol L^{-1} solution in THF, 1.5 mL, 3.0 mmol, 1.5 equiv.) in THF (3 mL) at 0 °C. The reaction was stirred at 0 °C for 10 min and then at room temp for 1 h. The reaction was then cooled to 0 °C and alkene **18** (0.78 g, 2.0 mmol, 1 equiv.) was added in THF (10 mL). After stirring for 1.5 h, the reaction was quenched with ethanol (1 mL). Na_2HPO_4 (2 mol L^{-1} aqueous solution, 4 mL) and H_2O_2 (30%, 4 mL) were added simultaneously, and the reaction was stirred overnight at room temp. The reaction was poured into ethyl acetate and water. The aqueous phase was then extracted with ethyl acetate (×3). The combined organic phase was washed with water (×2) and brine and dried ($MgSO_4$), and the solvent was removed in vacuo. Purification by silica gel chromatography (2:1 hexane : ethyl acetate → ethyl acetate) furnished the primary alcohol (0.529 g) in 65% yield and the epimeric secondary alcohols (0.053 g) in 6% yield. IR (cm^{-1}): 3450, 2946, 2871, 1764, 1730, 1453, 1435, 1369, 1334, 1311, 1245, 1172, 1037, 960. ^{1}H NMR δ: 0.90 (d, *J* = 6.9 Hz, 3H, H-17), 1.22 (d, *J* = 7.0 Hz, 3H, H-18), 1.41 (m, 1H), 1.50–2.02 (m, 12H), 1.99 (s, 3H, OAc), 2.52 (m, 2H), 2.73 (d, *J* = 2.3 Hz, 1H, H-6), 3.01 (m, 2H, H-4), (dd, *J* = 2.3, 10.7 Hz, 1H, H-5), 3.67 (t, *J* = 6.0 Hz, 2H, H-3), 3.68 (s, 3H, CO_2Me). ^{13}C NMR δ: 12.1, 18.5, 19.2, 22.0, 27.3, 33.5, 34.2, 35.2, 38.4, 42.9, 43.2, 49.7, 49.9, 50.8, 51.1, 52.1, 62.8, 87.0, 96.0, 170.6, 174.9, 179.5. HR-MS calcd. for $C_{22}H_{32}O_7$: 408.2148; found: 408.2146.

13-Acetoxy-3-oxo-3,4-seco-20-nor-16-*epi*-gibberellan-7-oic acid 19,10-lactone 7-methyl ester 19

Dess–Martin periodinane (0.21 g, 0.55 mmol, 1.5 equiv.) was added to a solution of the alcohol prepared above (0.15 g, 0.37 mmol, 1 equiv.) in dichloromethane (15 mL). The reaction was stirred for 1 h; then 1 mol L^{-1} $Na_2S_2O_3$ (10 mL) and saturated $NaHCO_3$ (10 mL) solutions were added, and the mixture was stirred vigorously until both layers were clear. The aqueous phase was then extracted with dichloromethane (×3). The combined organic phases were washed with water and brine and dried ($MgSO_4$), and the solvent was removed in vacuo. Purification by silica gel chromatography (2:1 ethyl acetate : hexane) furnished the aldehyde **19** (0.124 g) in 83% yield. IR (cm^{-1}): 2945, 2870, 2728, 1766, 1727, 1453, 1436, 1368, 1245, 1191, 1174, 1036, 959. ^{1}H NMR δ: 0.91 (d, *J* = 6.9 Hz, 3H, H-17), 1.23 (d, *J* = 6.0 Hz, 3H, H-18), 1.43 (dd, *J* = 6.0, 13.1 Hz, 1H), 1.60–2.11 (m, 8H), 1.99 (s, 3H, OAc), 2.23 (m, 1H), 2.40–2.66 (m, 4H), 2.72 (d, *J* = 1.8 Hz, 1H, H-6), 2.98 (m, 2H, H-4, H-5), 3.69 (s, 3H, CO_2CH_3), 9.80 (t, *J* = 1.1 Hz, 1H, CHO). ^{13}C NMR δ: 12.0, 18.4, 19.2, 22.0, 29.6, 33.4, 35.1, 38.1, 38.9, 42.8, 43.1, 49.5, 49.6, 50.9, 51.0, 52.1, 86.8, 95.0, 170.5, 174.9, 179.0, 200.7. LR-MS *m/z* (relative intensity): 406 ([M$^+$], 27), 364 (81), 346 (65), 321 (100), 303 (35), 289 (89). HR-MS calcd. for $C_{22}H_{30}O_7$ ([M$^+$]): 406.1992; found: 406.1993.

13-Acetoxy-3α/3β-hydroxy-20-nor-16-*epi*-gibberellan-7-oic acid 19,10-lactone 7-methyl ester 20

Aqueous potassium carbonate (1 mol L^{-1}, 2.6 mL, 2.6 mmol, 5 equiv.) was added to aldehyde **18** (0.213 g, 0.52 mmol, 1 equiv.) in methanol (10.4 mL) and stirred at room temp for 3 h. The reaction was then quenched with excess 1 mol L^{-1} HCl (5 mL) and poured into ethyl acetate and water. The aqueous phase was then extracted with ethyl acetate (×4). The combined organic phase was washed with water and brine and dried ($MgSO_4$), and the solvent was removed in vacuo. Purification by silica gel chromatography (1:1 hexane : ethyl acetate → 2:1 ethyl acetate : hexane) furnished the epimeric alcohols **20** (0.195 g) in 92% yield. Data for the 3α-epimer have been provided above. 3α-OH epimer: mp 190 to 191 °C. IR (cm^{-1}): 3474, 2952, 2874, 1770, 1732, 1439, 1370, 1246, 1195, 1173, 1130, 1058, 1041, 1023, 950, 900, 735. ^{1}H NMR δ: 0.88 (d, *J* = 6.9 Hz, 3H, H 17), 1.16 (s, 3H, H-18), 1.40–2.36 (m, 14H), 2.01 (s, 3H, OAc), 2.54 (d, *J* = 10.3 Hz, 1H, H-6), 2.75 (d, *J* = 10.3 Hz, 1H, H-5), 3.68 (dd, 1H, *J* = 10.6, 5.9 Hz, 1H, H-3), 3.73 (s, 3H, CO_2CH_3). ^{13}C NMR δ: 13.1, 17.6, 19.1, 21.8, 29.7, 30.3, 37.6, 39.4, 41.1, 45.5, 50.3, 52.0, 52.3, 54.3, 54.7, 56.9, 73.0, 85.4, 92.6, 170.6, 173.0, 177.5. LR-MS *m/z* (relative intensity): 406 ([M$^+$], 7), 388 (16), 364 (100), 346 (65), 321 (85), 289 (47), 243 (26) 225 (20). HR-MS calcd. for $C_{22}H_{30}O_7$ ([M$^+$]): 406.1992; found: 406.1988. Anal. calcd. for $C_{22}H_{30}O_7$ (%): C 65.01, H 7.44; found: C 64.95, H 7.41.

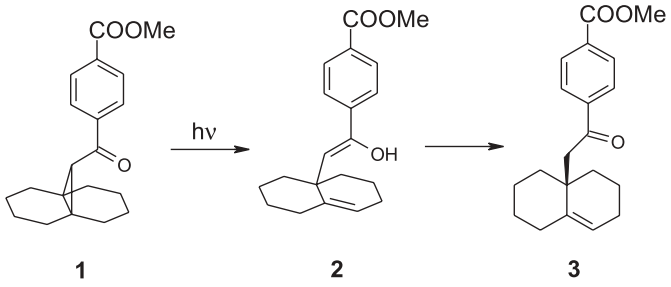
The crystal structure of a simple enol formed in a single-crystal-to-single-crystal enolene rearrangement[1]

Kenneth C.W. Chong, Brian O. Patrick, and John R. Scheffer

Abstract: When crystals of 9-tricyclo[4.4.1.0]undecalyl-4-(carbomethoxy)phenyl ketone (**1**) were allowed to stand in the dark for extended periods of time at room temperature, the compound underwent a thermal reaction — the enolene rearrangement — to afford enol **2**. The crystals remained transparent and appeared unchanged in shape as the reaction proceeded. X-ray diffraction data were collected on single crystals containing 17%, 25%, 66%, and 100% of the enol. The crystal structure of a simple enol was obtained via this novel single-crystal-to-single-crystal enolene rearrangement.

Key words: single crystal, thermal, rearrangement, enol, enolene.

Résumé : Laissés à la température ambiante et à l'abri de la lumière pour des périodes prolongées, la 9-tricyclo-[4.4.1.0]undécalyl-4-(carbométhoxy)phényl cétone (**1**) subit une réaction thermique, le réarrangement énolène, qui conduit à la formation de l'énol **2**. Alors que la réaction se produit, les cristaux demeurent transparents et leur forme ne semble pas avoir changé. On a obtenu des données de diffraction des rayons X sur des échantillons contenant 17 %, 25 %, 66 % et 100 % d'énol. On a déterminé la structure cristalline d'un énol simple par le biais de ce nouveau réarrangement énolène d'un cristal unique à un cristal unique.



Mots clés : cristal unique, thermique, réarrangement, énol, énolène.

Introduction

The work reported in this paper is an outgrowth of our investigation into the photochemistry of ketones possessing the tricyclo[4.4.1.0]undecane ring system, e.g., **1** (Scheme 1) (1). Compounds of this type undergo photochemical Norrish type II cleavage in solution to afford chiral products (e.g., **3**), and the purpose of our original study was to explore methods of carrying out such transformations enantioselectively (2). During the course of this work, we had occasion to determine the X-ray crystal structure of ketone **1**, and the present paper reports the interesting results that were obtained in the process.

Scheme 1.

Results and discussion

The electron density maps obtained from single crystals of ketone **1** invariably contained residual peaks from a second component, and try as we might, we were never able to prepare a sample of ketone **1** completely free of this substance. The highest purity we were able to achieve was approximately 83%. After a series of control experiments ruled out the possibility that the impurity was ketone **3** formed by ambient light irradiation of ketone **1** during its preparation and storage, it became apparent that the unknown was being produced *thermally*. Thus, by simply allowing crystals of ketone **1** to stand in the dark for extended periods of time at room temperature, it was possible to prepare samples in which the unknown "impurity" was actually the major component. For example, after 5 days at room temperature, the extent of conversion to the unknown was 68%; after 12 days the conversion was 100%. Crystals that had been treated in this manner retained their integrity; that is, they remained transparent and appeared unchanged to the naked eye, suggesting the occurrence of a single-crystal-to-single-crystal reaction (3). Accordingly, X-ray diffraction data were col-

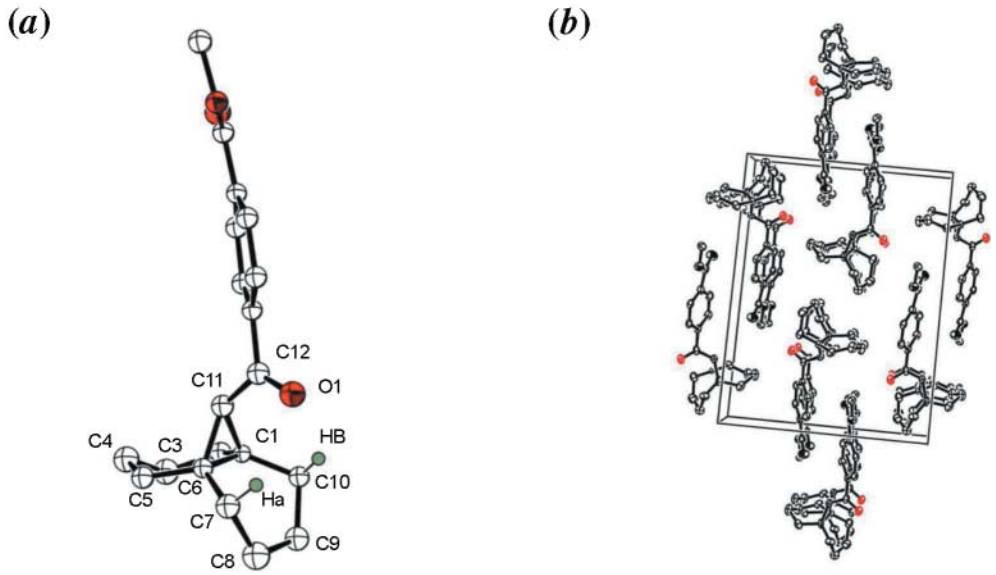
lected on single crystals containing 17%, 25%, 68%, and 100% of the unknown substance.

Solving the structure of these mixed crystals revealed that the unknown component was enol **2**, the tautomer of ketone **3** (Scheme 1). In agreement with this, conventional solution-phase workup of the mixed crystals gave mixtures of ketone **3** and unreacted **1**. By working quickly in anhydrous benzene-d_6, it was possible to measure the ^{1}H NMR spectrum of enol **2**, which showed three distinct signals at 4.81, 5.44, and 7.05 parts per million (ppm), corresponding to H11, H7, and the enolic hydrogen of enol **2**, respectively (Fig. 1*a*).

The thermal rearrangement of cyclopropyl ketone **1** to enol **2** is an example of the so-called enolene rearrangement, which interconverts γ-hydrogen-containing cyclopropyl ketones and enolizable γ,δ-unsaturated ketones (4). In the present instance the enol intermediate is isolable, since it is generated in the crystalline state, where the acid or base required for conversion to the keto form is lacking. Crystalline samples of enol **2** were stable for weeks at ambient temperatures under anhydrous conditions. As outlined in our original communication, enol **2** is also generated by irradiation of cyclopropyl ketone **1** in the crystalline state, a process that could be followed by solid-state infrared spectroscopy (1). In this case the reaction is not a single-crystal-to-single-crystal transformation. Photolysis of single crystals of ketone **1** caused them to become brittle and opaque, perhaps as a result of the reaction being less homogeneously distributed throughout the bulk of the crystal.

Table 1 shows the change in unit cell dimensions as a function of conversion for the thermal reaction. The data indicate a smooth transformation of ketone **1** into enol **2**. The space group remains $P2_1/n$, and the number of molecules in the unit cell is constant at $Z = 4$. There is a gradual increase in the length of the *a* and *c* axes, while there is a decrease in *b* in going from reactant to product. Overall, the unit cell volume increased by approximately 1.5%. Even though the increase in *c* (5.3%) seems rather large for a single-crystal-to-single-crystal reaction, other single-crystal-to-single-crystal reactions involving cell dimension changes of up to 5% have been reported (5).

Figure 2 provides ORTEP drawings of the molecular and crystal structures of cyclopropyl ketone **1**, and Fig. 1 does the same for enol **2**. Figure 3 depicts the superposition of these two structures in the mixed crystal containing 68% of enol **2** and 32% of ketone **1**. It is apparent from Fig. 3 that the correspondence between reactant **1** and product **2** is rather poor, indicating that significant motions take place during the rearrangement. This is not surprising when one considers the large relief of strain accompanying opening of the 3-membered ring. Based on the structure of the enol, the mechanism of the reaction is seen to involve transfer of hydrogen atom H_a to O1, accompanied by cleavage of the C6—C11 bond of the cyclopropane ring. The O1 to H_a distance is 2.23 Å, much shorter than the sum of the van der Waals radii for oxygen and hydrogen (2.72 Å) (6).[3] Interestingly, the distance between O1 and the other γ-hydrogen atom (H_b) is 2.37 Å, only 0.15 Å greater than the distance to H_a; yet, no H_b transfer occurs. A similar situation was encountered recently in a photochemical hydrogen atom abstraction reaction, where a difference in C=O···H distance of 0.27 Å (2.72 Å vs. 2.99 Å) led to exclusive abstraction of the nearer hydrogen (7).



[3] Angular relationships are also important in γ-hydrogen transfer reactions. The value of the angle ω, defined as the degree to which the γ-hydrogen lies outside the mean plane of the carbonyl group, is 20° for H_a and 43° for H_b. The value of the angle Δ (the C=O···H angle) is 99° for H_a and 89° for H_b. The value of the angle θ (the C-H···O angle) is 136° for both H_a and H_b. Values of these parameters for a large number of photochemical hydrogen atom abstraction reactions have been reported and discussed. The present paper is the first instance in which such parameters have been determined for a thermal reaction involving γ-hydrogen transfer.

Fig. 2. (*a*) ORTEP drawing and (*b*) crystal packing diagram of ketone **1**. The oxygen atoms of the keto groups are in red.

The structural changes involved in the transformation of ketone **1** to enol **2** are evidenced by the changes in bond angles and bond lengths given in Table 2. As the reaction proceeds, cleavage of the C6—C11 bond occurs, leading to an increase of the C6-C1-C11 bond angle from 60.1° in **1** to 110.7° in **2**. This causes a significant shift in the position of C11, C12, O1, and the aryl group. At the same time, the C11—C12 bond length decreases as it is transformed from a single to a double bond, and the C12—O1 bond length increases as it changes from a double to a single bond. While these motions are significantly greater than those accompanying other unimolecular single-crystal-to-single-crystal reactions (8), the overall packing arrangement remains constant, and as a result, the process can still occur in a topochemical fashion.

Attempts to recrystallize enol **2** to obtain a thermodynamically more stable crystal modification were unsuccessful, as tautomerization led exclusively to ketone **3**. However, molecular mechanics calculations showed that the minimum energy conformation of enol **2** is very similar to that determined by X-ray crystallography, a factor that might have facilitated the single-crystal-to-single-crystal transformation. Attempts were made to determine if the enol would undergo topochemical ketonization. However, tautomerization occurred only when crystals of enol **2** were heated above their melting point (82–84 °C).

			O1—H1	N/A	0.85(2)

[a]H7 is the "equatorial" hydrogen on C7. The axial hydrogen on this carbon is H_a, which is transferred in the reaction.

In summary, we have successfully obtained the crystal structure of a simple enol formed via a novel single-crystal-to-single-crystal enolene rearrangement. Simple enols are defined as species derived from the tautomerization of monofunctional aldehydes and ketones in which the enol is the only functional group present (9). In solution, simple enols ketonize rapidly unless kinetically stabilized by the presence of nearby bulky substituents. As a result, very few simple enols have been characterized crystallographically, since they tend to ketonize before they crystallize out (10). In the present instance, the enol is generated *in the crystalline state*, where it is protected from reagents that catalyze its ketonization. Under these conditions, the enol is stable over a period of weeks and can be fully characterized by a variety of techniques, including X-ray crystallography.

Experimental

General procedures

General procedures have been described in detail elsewhere (1).

Synthesis of ketone 1

The procedure for the preparation of this compound has been discussed in detail in the supporting information of ref. 1. X-ray quality crystals were grown by cooling a saturated hexanes solution at 4 °C; mp 68 to 69 °C. IR (KBr pellet) (cm^{-1}): 2927, 1720, 1666, 1445, 1278, 1224, 1109, 742. ^{1}H (400 MHz, $CDCl_3$) δ: 1.28–1.49 (10H, m), 1.97 (4H, m), 2.11 (1H, s), 3.93 (3H, s), 7.92 (2H, d, J = 8.9 Hz), 8.10 (2H, d, J = 8.9 Hz). ^{13}C (75 MHz, $CDCl_3$) δ: 199.95, 166.41, 143.00, 133.08, 129.73, 127.68, 52.36, 37.22, 33.60, 31.60, 28.16, 21.53, 20.82. HR-MS (ESI) calcd. mass for $C_{20}H_{25}O_3$: 313.25085; found: 313.25115. Anal calcd.: C 76.89, H 7.74; found: C 76.97, H 7.60.

Enol 2

mp 82–84 °C. ^{1}H (400 MHz, C_6D_6) δ: 1.12–2.22 (14H, m), 3.49 (3H, s), 4.81 (1H, s), 5.44 (1H, m), 7.05 (1H, s), 7.74 (2H, d, J = 8.2 Hz), 8.20 (2H, d, J = 8.2 Hz).

Ketone 3

mp 79 to 80 °C (ether – petroleum ether). IR (KBr pellet) (cm^{-1}): 2925, 1718, 1685, 1438, 1281, 1109, 957, 761, 666. ^{1}H (400 MHz, $CDCl_3$) δ: 8.08 (2H, d, J = 7.0 Hz), 7.95 (2H, d, J = 7.0 Hz), 5.40 (1H, m), 3.90 (3H, s), 3.23 (1H, d, J = 15.0 Hz), 3.13 (1H, d, J = 15.0 Hz), 2.23 (1H, m), 1.98–2.05 (1H, m), 1.87–1.92 (3 H, m), 1.76 (1H, m) 1.43–1.65 (4H, m), 1.14–1.31 (3H, m). ^{13}C (APT, 75 MHz, $CDCl_3$) δ: 200.50 (+), 166.28 (+), 142.39 (+), 142.26 (+), 133.43 (+),

129.76 (–), 127.81 (–), 121.40 (–), 52.40 (–), 41.67 (+), 39.07 (+), 38.23 (+), 35.71 (+), 32.67 (+), 28.24 (+), 25.55 (+), 22.34 (+), 18.92 (+). HR-MS (CI, NH_3) calcd. mass for $C_{20}H_{25}O_3$: 313.25085; found: 313.25115. Anal. calcd.: C 76.89, H 7.74; found: C 76.75, H 7.68.

Single-crystal-to-single-crystal reaction

X-ray diffraction data were collected for three different single crystals of ketone **1**. The first one showed the presence of 25% of enol **2**. The second showed a similar composition of the enol to the first, and the structure was not refined. This sample was allowed to stand at room temperature, and X-ray diffraction data were collected after 5 and 12 days, leading to the crystal structures containing 68% and 100% of enol **2**, respectively. The X-ray data of the third sample showed the presence of about 17% of the rearranged product.

X-ray crystallography

X-ray analyses were performed on a Rigaku/ADSC CCD diffractomer using Mo Kα irradiation at –100 °C. The structures were solved using the direct methods program SIR-97 (11), and full-matrix least-square refinement on F^2 were completed using the program SHELXL-97 (12).[4]

Bifunctional bis(oxazolines) as potential ligands in catalytic asymmetric reactions[1]

Stephen Hanessian, Eric Jnoff, Noemy Bernstein, and Michel Simard

Abstract: C_2-symmetrical bis(oxazoline) ligands bearing pendant alkylthio ether groups were synthesized, and the structures of Cu complexes were determined by single crystal X-ray diffraction. The potential utility in catalysis was shown in the asymmetric addition of methyllithium to an aromatic aldimine, which resulted in a mixture of products with an enantiomeric excess of 68%.

Key words: two-center catalysis, bis(oxazoline), aldimine, imine alkylation.

Résumé : On a effectué la synthèse de ligands bis(oxazoline) à symétrie C_2 portant des groupes alkylthioéthers pendants et on a déterminé les structures de complexes de cuivre par diffraction des rayons X de cristaux uniques. Leur utilité potentielle en catalyse a été mise en évidence par l'addition asymétrique du méthyllithium sur une aldimine aromatique qui a conduit à la formation d'un mélange de produits avec un excès énantiomérique de 68%.

Mots clés : catalyse à deux centres, bis(oxazoline), aldimine, alkylation d'imine.

[Traduit par la Rédaction]

Introduction

Catalytic asymmetric reactions have assumed great importance in the realm of organic synthesis (1). In practice, a ligand possessing one or more elements of chirality is used in sub-stoichiometric amounts, with or without the presence of a metal (2). Among the more popular and synthetically useful ligands are the so-called C_2-symmetric bis(oxazolines) (3), which are easily prepared from naturally available amino acids by well-precedented chemical transformations (4). Fig. 1 depicts the structure of a typical 2,2′-bis(oxazolino)methane with appropriate stereodifferentiating appendages (*t*-Bu Box, **1**) (4). This ligand has been extensively used in conjunction with divalent metals as chiral Lewis acids in a number of catalytic reactions (3).

The use of bis(oxazoline) ligands that possess additional coordination sites leading to bifunctional catalysis has been less studied (5). Aggarwal et al. (6) prepared C_2-symmetric bis(oxazoline) ligands from cysteine and methionine and studied a catalytic version of an asymmetric sulfur ylide epoxidation of aldehydes mediated by Cu(II).

Recently, we described the catalytic asymmetric reduction of ketones by borane in the presence of thiazolidines derived from penicillamine (7). We report herein the synthesis and X-ray crystal structures of several novel C_2-symmetrical bis(oxazolino)methanes **2**–**5** and related structures with pendant ether and thioether appendages (Fig. 1). These ligands could have potentially interesting applications in catalysis. In this regard, we show an example of a catalytic asymmetric addition of MeLi to an aromatic aldimine (8).

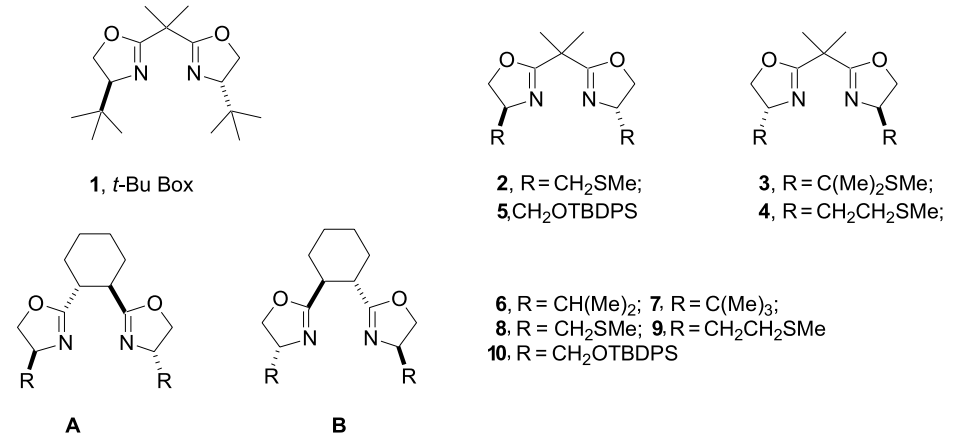
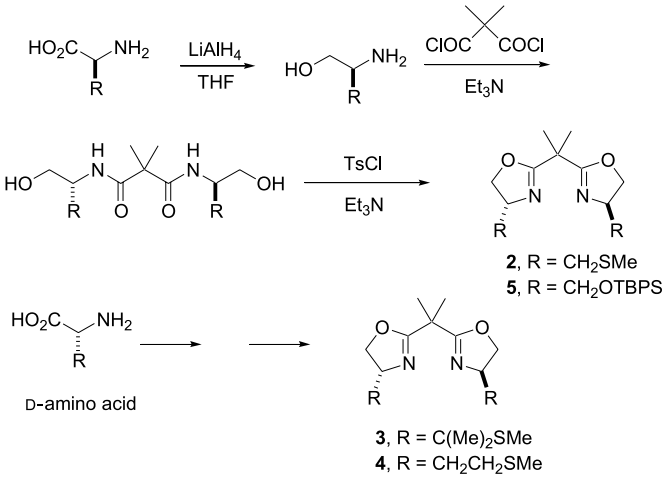
Synthesis

The synthesis of bis(oxazoline) ligands **2**–**5** is shown in Scheme 1 and follows an established protocol for other alkyl-substituted analogues (4). Thus, the amino acids L-cysteine, D-penicillamine, and D-methionine were individually reduced to the corresponding amino alcohols, *S*-methylated in the case of L-cysteine and D-penicillamine, and then reacted with 2,2-dimethylmalonyl dichloride to afford the corresponding bis-amides. Treatment with TsCl and Et_3N effected cyclization to the respective ligands **2**–**4**. The L-serine analogue **5** was similarly prepared from the O-TBDPS ether.



Another set of ligands representing a constrained scaffold (9) was prepared from 1,2-*trans*-cyclohexane dicarboxylic acid using the same protocol. Thus, treatment of the racemic diacid with *S*-methyl L-cysteine-ol, D-methionine-ol, L-valinol, O-TBDPS L-serinol, and L-*tert*-butylglycinol afforded mixtures of diastereomeric diamides that could be separated by chromatography. These were individually cyclized to the diastereomeric bis-(oxazoline) derivatives **6**–**10**. The identity of the major diastereomer was ascertained from the X-ray structure of the *tert*-butylglycinol product **7**, prepared from the resolved diacid as the quinine salt and inferred in the others.

X-ray structures of ligands and Cu(II) complexes



The ORTEP diagrams of selected ligands and their Cu(II) complexes are shown in Fig. 2, with corresponding bond

Scheme 1.

lengths and angles shown in Table 1.[3] Bis-(oxazoline)ditriflate **3a** formed monoclinic crystals in which Cu was pentacoordinated with the oxazoline nitrogens and the penicillamine methylthio groups, forming a trigonal bipyramid with N12 and S11 in the axial positions (164°–171°) (Fig. 2B). It is of interest that the two *S*-methyl groups occupy an *anti*-relationship in the complex. Only one triflate group was coordinated to copper.

Complex **4a** formed orthorhombic crystals with an unusual coordination around Cu (Fig. 3A, Table 2). The two oxazoline nitrogens and only one of the methionine sulfur atoms were coordinated to Cu in an axial orientation (N1-Cu-S2 angle = 172.3°), and two chlorines were in equatorial positions, forming a trigonal bipyramidal geometry. Curiously, the *S*-methyl group of the other methionine side-chain remained uncoordinated, thus adding an element of structural dissymmetry.

Ligand **4** also gave a crystalline complex **4b** with Cu(II)bis-triflate (Fig. 3B, Table 3). In this case an octahedral geometry was observed in which the two methionine sulfur atoms were engaged as equatorial coordination sites in two seven-membered rings. In contrast to complex **3a**, both axial sites were occupied by triflates. A strong Jahn–Teller effect was observed in this neutral complex, as evidenced by the shorter C4—N and Cu—S distances compared with Cu—OTf. The Cu atom was moved out of plane, by 0.2 Å, toward O31.

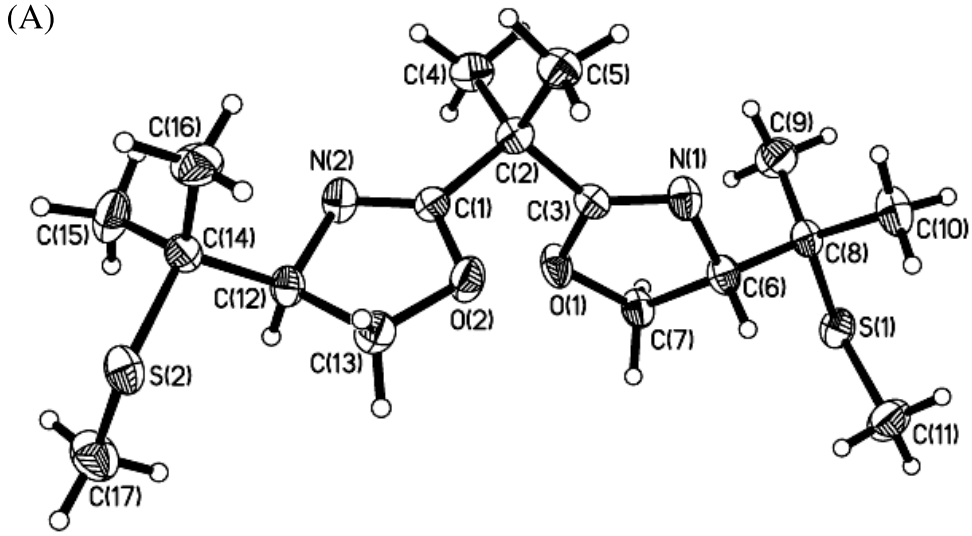
N(12)-Cu(1)-S(11)	170.0(2)

Ligand **7** crystallized with a molecule of water that was internally hydrogen-bonded in a bidentate fashion with the two oxazoline nitrogens (Fig. 4A, Table 4). The corresponding Cu(II) dichloride complex **7a** afforded monoclinic crystals with quasi-equidistant coordination sites, forming a distorted seven-membered ring (Fig. 4B).



Catalytic asymmetric addition to an aldimine

The addition of organometallic reagents to aldimines is a method of synthesis of secondary amines (8). Although there are examples for the asymmetric synthesis of amines using stoichiometric amounts of external ligands (8, 10), by comparison there are fewer catalytic versions (11).

$Cu(OTf)_2$ complex **3a**

The groups of Tomioka and co-workers (12) and Denmark et al. (13) have reported on catalytic additions of alkyllithium reagents to *N*-arylaldimines in the presence of external ligands such as β-amino ethers, chiral amino alcohols, (–)-sparteine, and bis(oxazolines). The most promising ligands were (–)-sparteine and bis(oxazolines), giving ee values as high as 80% in some instances (13).

Initially, Denmark et al. (13) reported that *N*-arylaldimines were practically unreactive to MeLi at low temperature, unless ligands such as (–)-sparteine or *t*-Bu Box (**1**) were present in stoichiometric amounts. Catalytic versions with aryl *N*-*p*-methoxyphenylaldimines and arylalkyl analogues (possessing an enolizable α-hydrogen) with MeLi were reported with 0.1–0.2 equiv. of (–)-sparteine or *t*-Bu

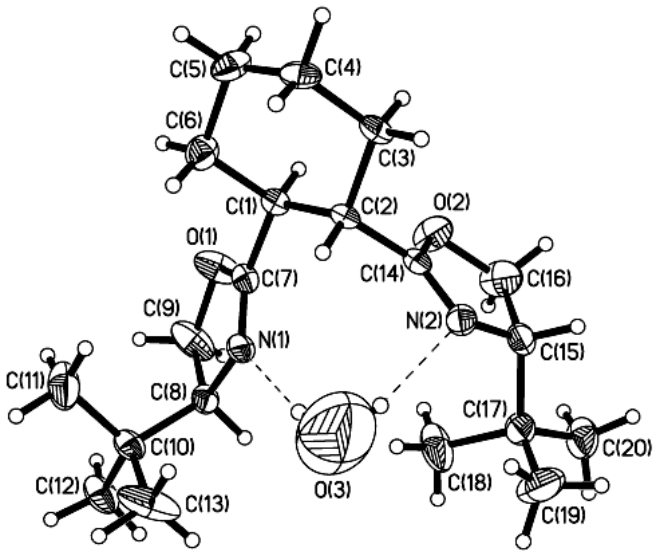
Box **1**, affording the corresponding secondary amines (Scheme 2) in excellent yields and enantiomeric excesses of 82% (for BuLi) and 68% (for MeLi), respectively. Denmark and Stiff (14) also studied the effect of ligand structure of the bis-(oxazoline) in the reaction of aryl *N*-*p*-methoxyphenyl aldimines with MeLi. They concluded that the ligand bite angle ϕ played a minor role and that the nature of the stereodifferentiating oxazoline substituents (e.g. *t*-Bu) had a dramatic effect on selectivity.



The catalytic asymmetric alkylation of *N*-*p*-methoxyphenyl benzaldehyde imine with MeLi was tried with ligands **2**–**4**, using the *t*-Bu Box catalyst **1** as a control (Scheme 2). The best ligand proved to be the one derived from D-penicillamine **3**, which gave an ee equal to **1**. In the presence of $Cu(OTf)_2$ or $Yb(OTf)_3$ in toluene, the ees for **1** and **4** were 48% and 33%, respectively, with either additive.

Structurally, the thioether appendage in ligand **3** is very similar to a *tert*-butyl group, except for the replacement of a *C*-methyl by an *S*-methyl group. While it can be assumed that the Li cation may be coordinated by the oxazoline nitrogens, there is no direct evidence that the thioether groups are

$CuCl_2$ complex **7a**

also involved in a bidentate manner. Thus, it is not surprising that in the absence of such a tetracoordination (as observed for the Cu complexes), the extent of asymmetric induction was equal to the *t*-Bu Box ligand **1** (13).

The lower enantioselectivities shown in the case of **2** and **4** may be because of the smaller size of the thioether appendage compared with **3** and **1**, as observed by Denmark and Stiff for bis-(oxazolines) with different side-chains (14).

In spite of the interesting structural data available from the X-ray structures of the Cu complexes, especially **4a** with a tricoordinated geometry, we were not able to effectively utilize them as catalysts in a variety of representative model reactions.

Table 4. Bond lengths and bond angles for ligand **7** monohydrate and Cu(II) complex **7a**.

Bond lengths (Å)	
Cu—N(1)	1.993(3)
Cu—N(2)	2.003(3)
Cu—Cl(1)	2.221(13)

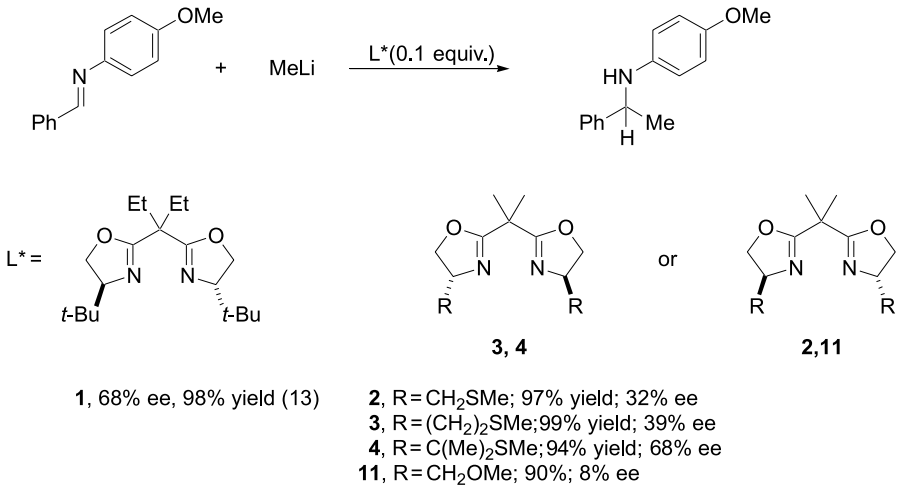
Thus, treatment of styrene with ethyl diazoacetate in the presence of **4** and CuOTf gave the corresponding cyclopropane in 40% ee for the *trans*-isomer (*cis*:*trans*, 1:2 by NMR) (15). Addition of methylmagnesium bromide to *p*-methoxybenzaldehyde in the presence of ligand **3** (10 mol%) gave the secondary alcohol in 10% ee. Using stoichiometric ligand raised the ee to 55% (HPLC). Applications to asymmetric reduction with BH_3·THF of acetophenone, allylation of benzaldehyde with allyltributylstannane, Michael addition to cyclohexenone, and Diels–Alder reaction with cyclopentadiene and *N*-acryloyloxazolidinone gave racemic products.

Future work will focus on exploiting other ligands with bidentate character in catalytic asymmetric reactions.

Experimental

General procedure



Flash chromatography was carried out using 230–400 mesh silica gel. Mixtures of ethyl acetate – hexanes were used as the eluents, unless otherwise specified. Analytical thin layer chromatography (TLC) was performed on glass plates coated with a 0.02 mm layer of silica gel 60 F-254. Melting points were uncorrected. IR spectra were recorded as films. ^{1}H and ^{13}C NMR spectra were recorded at 300 and 75 MHz, respectively, and the chemical shifts are reported in parts per million on the δ scale, with $CDCl_3$ as reference, unless otherwise specified. MS and HR-MS spectra were recorded using electron ionization or by the FAB technique. Optical rotations were measured in $CHCl_3$ at 23 °C. All reactions were carried out under nitrogen or argon unless otherwise specified. The –78 °C temperature is approximate, as achieved by a dry ice – acetone bath. The term "normal workup" means the addition of saturated aqueous NH_4Cl solution to the reaction mixture, followed by extraction with ethyl acetate, drying over Na_2SO_4, filtration, and evaporation of the filtrate in vacuo to afford the crude product.

Representative procedure for the bis-amide formation

To a solution of D-penicillaminol (0.20 g, 1.40 mmol) in dry CH_2Cl_2 (3 mL) was added Et_3N (0.5 mL, 3.6 mmol) at room temperature (r.t.), followed by dropwise addition of dimethylmalonyl chloride (0.10 g, 0.59 mmol) in dry CH_2Cl_2 (0.5 mL). A white precipitate began to form, and the mixture was stirred overnight, then concentrated in vacuo al-

Viscous oil (140 mg, 54%). $[\alpha]_D$ +53° (c 0.5 $CHCl_3$). ^1H NMR (400 MHz) ($CDCl_3$): 4.21 (2H, dd, J = 9.5, 8.5, 2 × OC*H*HCHN), 4.09 (2H, m, 2 × NC*H*), 3.77 (2H, t, J = 7.9, 2 × OCH*H*CHN), 2.59–2.47 (6H, m, 2 × CH_2SMe and $CH_2CHCHCH_2$), 2.06 and 2.0595 (each 3H, s, SCH_3), 1.93 (2H, m, CHC*H*H$(CH_2)_2$C*H*HCH), 1.83–1.65 (6H, m, CHCH*H*$(CH_2)_2$CH*H*CH and 2 × CH_2CH_2SMe), 1.47–1.41 and 1.28–1.23 (each 2H, m, $CH_2CH_2CH_2CH_2$). ^{13}C NMR (100 MHz) ($CDCl_3$): 169.05, 71.87, 64.87, 39.80, 35.30, 30.42, 29.61, 24.84, 15.39. HR-MS calcd. for $C_{18}H_{31}O_2N_2S_2$: 371.1827; found: 371.1821.

Ligand 10

Diastereomers A and B could be separated after cyclization (59% total).

Diastereomer A

White solid (26 mg). $[\alpha]_D$ –58 (c 1.33, $CHCl_3$). ^1H NMR (400 MHz) ($CDCl_3$): 7.67–7.62 (8H, m, ArH), 7.43–7.31 (12H, m, ArH), 4.21–4.07 (6H, m, 2 × OCH_2CHN), 3.79 (2H, dd, J = 10.07, 3.51, 2 × C*H*HOTBDPS), 3.51 (2H, dd, J = 10.03, 6.68, 2 × CH*H*OTBDPS), 2.59 (2H, m, $CH(CH_2)_4CH$), 1.91, 1.73, 1.49 & 1.27 (each 2H, m, $CH_2CH_2CH_2CH_2$), 1.04 (18H, s, 2 × $C(CH_3)_3$). ^{13}C NMR (100 MHz) ($CDCl_3$): 170.16, 135.44, 133.27, 129.60, 129.55, 127.59, 69.97, 67.20, 65.58, 40.08, 29.29, 26.73, 24.79, 19.15. LR-MS: ([M + 1]) 740.

Diastereomer B

White solid (30 mg). $[\alpha]_D$ –21.9 (c 1.65, $CHCl_3$). ^1H NMR (400 MHz) ($CDCl_3$): 7.67–7.62 (8H, m, ArH), 7.44–7.35 (12H, m, ArH), 4.20–4.12 (6H, m, 2 × OCH_2CHN), 3.80–3.77 (2H, m, 2 × C*H*HOTBDPS), 3.56–3.52 (2H, m, 2 × CH*H*OTBDPS), 2.53 (2H, m, $CH(CH_2)_4CH$), 1.97, 1.72, 1.48 & 1.26 (each 2H, m, $CH_2CH_2CH_2CH_2$), 1.04 (18H, s, 2 × $C(CH_3)_3$). ^{13}C NMR (100 MHz) ($CDCl_3$): 170.62, 135.47, 133.27, 129.60, 129.54, 127.59, 127.55, 69.77, 67.29, 65.53, 39.82, 29.75, 26.69, 24.85, 19.14.

General procedure for ligand–Cu complexes

To a solution of the ligand (0.067 mmol) in anhydrous CH_2Cl_2 was added the copper salt (0.06 mmol). The mixture was stirred until it became homogeneous. Hexanes (0.3–0.5 mL) were added, and the solution was allowed to stand 2 days at room temperature and several days at 0 °C to afford the crystalline complexes.

Catalytic asymmetric addition of MeLi to an aldimine (13)

A solution of MeLi (2 equiv., 1.6 mol L^{-1} Et_2O) and ligand (0.1 equiv.) in toluene was stirred for 30 min at −41 °C. A solution of *N*-*p*-methoxyphenyl benzaldehyde imine in toluene was added over 10 min. After 60 min stirring at −41 °C, the mixture was quenched with 2 mL methanol. After dilution with water, the organic phase was extracted with ether and dried over Na_2SO_4. The product was purified by flash chromatography (hexanes:EtOAc 85:15). The enantiomeric excesses were measured by chiral HPLC analysis; OD, l: 210 nm; flow: 0.5 mL min^{-1}; hexanes:isopropanol 95:5; with elution times of 18.70 and 20.59 min for a racemic mixture.

C_{19} quassinoid model studies: Preparation of *trans*-perhydroindans via a vinylogous Mukaiyama aldol – free-radical cyclization route[1]

Matthew G. Donahue and David J. Hart

Abstract: Aldehyde **9** was prepared in 5 steps from 3,5-dimethylbenzoic acid. Treatment of **9** with ketene acetals **10** and **19** and titanium tetrachloride gave free-radical cyclization substrates **11** and **20** in 67% and 51% yields, respectively. Tri-*n*-butylstannane-mediated cyclization of **11** and **20** gave *trans*-perhydroindans **14** and **21** in 60% and 63% yields, respectively. The relationship of these studies to an approach to C_{19} quassinoids is discussed.

Key words: vinylogous Mukaiyama aldol reaction, free-radical cyclization, *trans*-perhydroindans, C_{19} quassinoids, 1,2-asymmetric induction.

Résumé : L'aldéhyde **9** est préparé en 5 étapes à partir de l'acide 3,5-diméthylbenzoique. Le traitement de **9** avec les acetals de kétène **10** et **19** et le tetrachlorure de titane donne les substrats de cyclisation par radicaux libres **11** et **20** avec des rendements respectifs de 67% et 51%. La cyclisation de **11** et **20** par le tri-*n*-butylstanne donne les *trans*-perhydroindanes **14** et **21** avec des rendements respectifs de 60% et 63%. On discute la relation de ces études avec une approche vers les quassinoides en C_{19}.

Mots clés : réaction d'aldol vinylogue de Mukaiyama, cyclisation par radicaux libres, *trans*-perhydroindanes, quassinoides en C_{19}, induction asymétrique-1,2.

Introduction

The C_{19} quassinoids are a small family of terpenoids that have received less attention from the synthetic community than the corresponding C_{20} quassinoids (1). Indeed only the second synthesis of a C_{19} quassinoid was reported in 1999, when Grieco described a synthesis of (5*R*)-polyandrane (**1**) (2). We have been investigating a unified approach to selected C_{19} and C_{20} quassinoids that involves an extension of free-radical cyclization chemistry previously developed in our laboratories (3). The plan for the polyandranes (Fig. 1) involves preparation of *trans*-perhydroindans of type **2** via free-radical cyclization of substrates of type **3**. This communication reports preliminary results of this study.

Results and discussion

Our first objective was to prepare a substrate of type **3** where the incipient C_{11} hydroxyl group of the polyandranes is replaced with a methyl group and R_1 and R_2 are electron-withdrawing and methyl groups, respectively. The specific substrate selected for synthesis (**11**) was prepared as described in Schemes 1 and 2. 3,5-Dimethylbenzoic acid (**4**) was subjected to Birch reduction, according to an established procedure, to provide **5** (mp 113–115 °C) in 95% yield (4). Aldol condensation of the dianion derived from **5** with formaldehyde provided hydroxy acid **6** in 93% yield (5). Reduction of **6** using lithium aluminum hydride provided diol **7** (mp 99 to 100 °C) in 57% yield. Treatment of **7** with NBS in tetrahydrofuran gave cycloetherification product **8** (99%), and oxidation of the primary alcohol using Swern's conditions provided aldehyde **9** in 96% yield (6).

Reaction of **9** with dienol ether **10** (7) in the presence of titanium tetrachloride gave a 6:1 mixture of vinylogous Mukaiyama aldol products **11** (67%) and **12** (11%) (8).[3] We note that promotion of the vinylogous Mukaiyama aldol with boron trifluoride etherate provided **11** (mp 134 to 135 °C) and **12** (mp 83–85 °C) in 11% and 42% yields, respectively.

[3]The stereochemical assignments at C_7 for **11** and **12** were based on NMR correlations with related compounds, including one for which an X-ray crystal structure was obtained. NMR studies on the cyclization products derived from **11** and **12** also clearly defined C_7 stereochemistry.

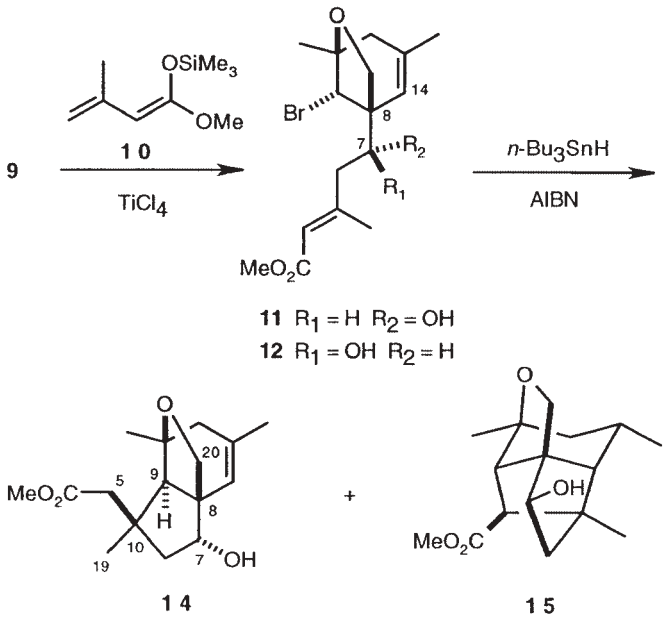
Fig. 1. Synthetic plan.

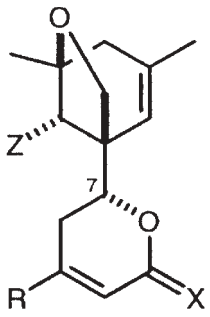


Scheme 1. Synthesis of aldehyde **9**.

In addition, titanium tetrachloride mediated reaction of *des*-bromo compound **13** with **10** gave a complex mixture of products that contained very little material resulting from a vinylogous aldol. Thus, the nature of the Lewis acid and the presence of a bromine atom in **9** play a central role in the observed diastereoselectivity. We speculate that the stereoselectivity observed with titanium tetrachloride is due to a combination of a chelation effect and principles for 1,2-asymmetric induction introduced by Felkin and co-workers

Scheme 2. Vinylogous Mukaiyama aldol – free-radical cyclization.

(9*a*) and Ahn and Eisenstein (9*b*). Thus, a complex between the Lewis acid and **9**, which involves bridging of the bromine and carbonyl oxygen with titanium, is conformationally constrained such that attack *anti* to the C_8—C_{14} bond should be stereoelectronically preferred, giving rise to **11** in a conformation in which substituents are staggered along the C_7—C_8 bond.



Treatment of **11** with tri-*n*-butylstannane in the presence of 2,2′-azobisisobutyronitrile (AIBN) provided cyclization products **14** (60%) and small amounts (less than 6%) of material suspected to be the C_{10} epimer of **14**. We note that a less than 1% yield of **15**, an interesting product derived from an initial 6-endo cyclization, was also isolated. The stereochemistry of **14** was established by difference NOE experiments, which confirmed a *cis*-relationship between the C_7 hydrogen and C_{20} methylene group, a *cis*-relationship between the C_{20} and C_5 methylene groups, and a *cis*-relationship between the C_9 hydrogen and C_{19} methyl group. This result established the viability of the proposed preparation of compounds of type **2** by free-radical cyclization of compounds of type **3**. It also demonstrated that this approach was unlikely to directly afford the required C_9–C_{10} stereochemical relationship.[4]

Two attempts to address the C_9–C_{10} stereochemical problem are described in Fig. 2 and Scheme 3. An examination of molecular models suggested that lactone **17** was constrained such that cyclization would provide the desired C_9–C_{10} stereochemistry. Treatment of **9** with 3-methyl-1-trimethylsiloxy-1,3-butadiene in the presence of potassium *tert*-butoxide followed by Jones oxidation of the resulting lactols **16** provided **17** in 33% overall yield (Fig. 2) (10). We were disappointed to find that attempts to cyclize **17** under a variety of conditions failed (11). For example, typical tri-*n*-

[4] Similar cyclization of **12** provided a 76% yield of the C_7 epimer. We note that derivatives of **11** and **12** lacking the impending C_{10} methyl group were prepared and cyclized with comparable results. In these cases compounds of type **14** (53%–72%) and the corresponding C_{10} epimer (15%–18%) were isolated, and the structures of all products were rigorously established.

Scheme 3. Synthesis and cyclization of **20**.

butylstannane conditions gave only reduction product **18** (mp 135 to 136 °C). Apparently, conformational constraints present in **17** severely retard radical cyclization rates relative to **11**. A potentially useful modification of the chemistry involved cyclization of **20**. This substrate was prepared in 51% yield by reaction of ketene acetal **19** with aldehyde **9** (12).[5,6] Free-radical cyclization of **20** provided **21** in 63% yield. We imagine the reductive decarboxylation of **21** will afford the required C_{10} methyl group.

Ketene acetal 19

IR (neat) (cm^{-1}): 3078, 1650, 1605. ^1H NMR (C_6D_6, 500 MHz) δ: 0.17 (s, 9H), 3.04 (s, 3H), 3.14 (dd, J = 6.5, 1.2 Hz, 2H), 4.21 (s, 1H), 4.95 (d, J = 2.4 Hz, 1H), 5.05 (dd, J = 10.1, 2.1 Hz, 1H), 5.16 (dd, J = 17.1, 2.0 Hz, 1H), 5.31 (d, J = 2.5 Hz, 1H), 6.05 (dddd, J = 17.1, 10.2, 6.8, 6.6 Hz, 1H). ^{13}C NMR (C_6D_6, 125 MHz) δ: 0.47 (q), 42.4 (t), 54.6

[5] Ketene acetal **19** was prepared by deprotonation and silylation of methyl (*E*)-3-methylhexa-2,5-dienoate (12). The reaction of **9** with **19** also provided 6% of the C_7 diastereomer of **20** and several minor products (perhaps lactones) whose structures have yet to be determined.
[6] We note that reaction of **9** with a 1:1 mixture of **19** and its geometrical isomer provided lactones (stereochemistry at C_7 unknown) as the major products (Fig. 1). Thus, ketene acetal geometry influences the stereochemistry of this vinylogous Mukaiyama aldol.

Conclusions

In summary, a seven-step synthesis of **21** from 3,5-dimethylbenzoic acid has been developed. The chemistry extends the scope of a free-radical cyclization route to perhydroindans and reveals some interesting stereochemical features of the vinylogous Mukaiyama aldol condensation. Compound **21** is functionalized appropriately for the pursuit of the polyandranes at all positions except C_{11}. Modifications of this chemistry, incorporating more appropriate functionality at C_{11}, are being developed.

Diversity-oriented synthesis of enantiopure *N*-protected β,β-dialkylserines[1]

James E. Dettwiler and William D. Lubell

Abstract: A series of enantiomerically pure *N*-Boc-protected β,β-dialkylserines was synthesized by addition of the appropriate Grignard reagent to *N*-(Boc)serine methyl ester, followed by TEMPO-catalysed oxidation of the primary alcohol with sodium chlorite and sodium hypochlorite.

Key words: amino acid, serine, β,β-dialkylserines, ring-closing metathesis.

Résumé : Une série énantiomériquement pure de β,β-dialkylserines *N*-Boc protégées est synthétisée par addition du réactif de Grignard correspondant sur l'ester méthylique de la *N*-(Boc)serine suivie d'une oxydation catalysée de l'alcool primaire avec TEMPO, du chlorite de sodium et de l'hypochlorite de sodium.

Mots clés : acide aminé, sérine, β,β-dialkylserines, cyclisation par métathèse.

Introduction

β-Alkylserines are constituents of biologically active peptides, as well as starting materials for the synthesis of unusual amino acids and heterocycles (1–14). In peptides, the alkyl groups of β-substituted amino acids may exhibit steric interactions that can restrain χ-dihedral angle geometry and orient side-chains in particular conformations (1). They may also play roles that influence the interactions of the peptide with its environment and with its biological receptor. Alcohol activation and displacement may be used to convert β-alkylserines into aziridine-2-carboxylates (2–8), β-alkylcysteines (2, 3), and β-alkyltryptophans (4, 5), as well as amino acids possessing unnatural β-substituents like fluorine (6–8). Although many methods have been developed for the preparation of β-alkylserines, few approaches have been explored for the synthesis of the related, more substituted β,β-dialkylserines (10–14). The protection of serine as its OBO (2,6,7-trioxabicyclo[2.2.2]octyl) ester, followed by oxidation and addition of nucleophiles, such as Grignard reagents, at the β-carbon represents a notable means for stereoselectively synthesizing β,β-dialkylserines (10). Although diastereoselective condensations of aldehydes onto chiral glycine enolates have furnished a series of β-alkylserine analogs, the lower reactivity of ketones in this aldol approach limits its application for making β,β-dialkylserines (11–13). Recently, we have reported a two-step approach for synthesizing *N*-protected β-hydroxyvaline (β,β-dimethylserine), which involved treatment of *N*-protected serine methyl ester with methyl Grignard reagent followed by a selective oxidation of the resulting diol (14). When *N*-Boc-D-serine methyl ester was employed in this sequence, the corresponding *N*-Boc-L-β-hydroxyvaline (97% enantiomeric purity) was produced in 80% overall yield on a multi-gram scale. In light of this efficiency, we have investigated alternative Grignard reagents in this process and have now developed an effective diversity oriented synthesis of enantiopure *N*-Boc-β,β-dialkyl serines.

Results and discussion

For our investigation, a series of Grignard reagents were chosen, possessing primary and secondary alkyl, allyl, vinyl, benzyl, and aryl substitution. All of the Grignard reagents were obtained from commercial sources and used without further purification. Using conditions optimized with methyl magnesium bromide (14), the Grignard reagent was added to a solution of *N*-Boc-D-serine methyl ester at –78 °C in diethyl ether (THF in the case of vinyl magnesium bromide, Scheme 1). The desired diol **2** was typically obtained as the major product, contaminated with minor amounts of the corresponding ketone **3**. For example, diols **2a**–**2e** were isolated in 68%–83% yields after purification by silica gel column chromatography (Table 1). On the other hand, *iso*-propyl magnesium chloride reacted on *N*-Boc-D-serine methyl ester to provide diol **2g** in 38% yield along with the less substituted diol **4** (4:1 diastereomeric mixture) from reduction of the ketone intermediate **3g** (15). Reversing the addition of *N*-Boc-D-serine methyl ester by adding it to a solution of the *iso*-propyl Grignard reagent afforded the same result. Vinylmagnesium bromide reacted with the *N*-Boc-D-serine methyl ester to provide a 1:1 mixture of diol **2f** and homoallylic ketone **3h**, as measured by integration of the vinyl protons at 6.01 and 5.80 parts per million (ppm), respectively, in the ^{1}H NMR spectrum of the crude product in $CDCl_3$. Silica gel column chromatography was used to isolate diol **2f** and ketone **3h** in 25% and 35% respective yields, as well as a

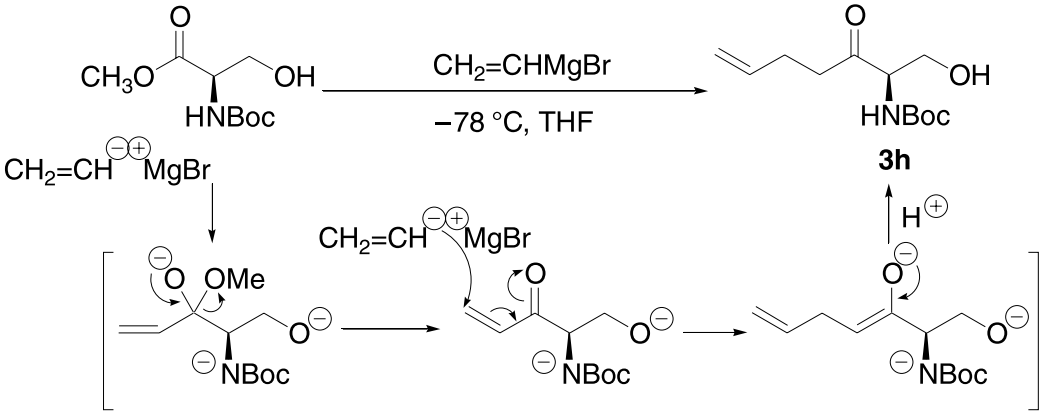
[a]Results obtained from inverse addition of *N*-Boc-L-serine methyl ester to *iso*-propyl Grignard reagent are reported in parentheses.

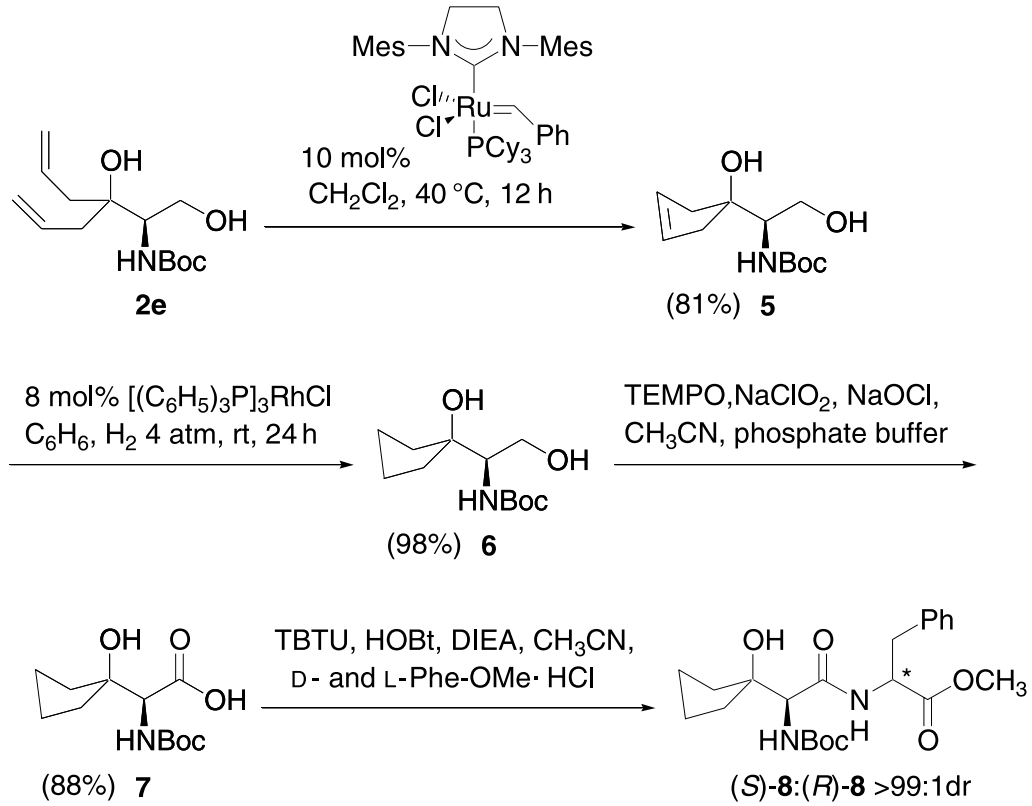
[b]*trans*-α,β-Unsaturated enone (2*R*)-2-[*N*-(Boc)amino]-1-hydroxy-hex-4-en-3-one **3i**.

[c](2*R*)-2-[*N*-(Boc)Amino]-1-hydroxy-hept-6-en-3-one **3h**; in addition, a 1:4 mixture of **3h** and (2*R*)-2-[*N*-(Boc)amino]-3-vinyl-pent-4-en-1,3-diol **2f** was isolated in 22% yield.



[d](2*R*)-2-[*N*-(Boc)Amino]-4-methyl-pentane-1,3-diol **4**, resulting from ketone reduction, was also isolated as a 4:1 diastereomeric mixture in 32% (41%) yield.

22% yield of a mixed fraction containing a 1:4 ratio of **3h** and **2f**. Addition of *N*-Boc-D-serine methyl ester to vinylmagnesium bromide gave a similar result. Homoallylic ketone **3h** was identified based on the presence of its carbonyl carbon at 207 ppm, as well as its COSY spectrum in $CDCl_3$, in which the vinyl protons (5.01 and 5.79 ppm) were shown to be coupled to allylic protons at 2.37 ppm. Apparently, attack of the ester followed by loss of methoxide ion provided the α,β-unsaturated ketone **3f**, which underwent conjugate addition to furnish the corresponding enolate and delivered **3h** after work-up (Scheme 2). Homoallylic ketone has been previously reported as the side product from addition of vinylmagnesium bromide to β-hydroxy ester derivatives in ether (16, 17). The addition of allyl magnesium chloride on *N*-Boc-D-serine methyl ester provided diol **2e** in 68% yield, as well as *trans*-α,β-unsaturated enone **3i** in 16% yield. Enone **3i** was likely formed from β,γ-unsubstituted ketone during quenching of the reaction with aqueous saturated NH_4Cl, which has previously been reported to effect conjugation (18).



Cycloalkyl β-hydroxy α-amino acids, such as **7** in racemic form, have served as intermediates for preparation of novel β-lactam antibiotics (19–21). (*S*)-Cleonin, a component of the antitumor antibiotic cleorycin, is a cyclopropyl β-hydroxy α-amino acid that has recently been made by a route featuring the titanium(VI)-isopropoxide-catalysed addition of ethyl magnesium bromide to a fully protected serine methyl ester (22, 23). Cyclopentyl β-hydroxy α-amino acid has been introduced into the antimicrobial agent R-106 aureobasidin (24) by a route featuring a retro-aldol–aldol reaction, in which the β-hydroxy-*N*-methyl valine residue loses acetone and incorporates cyclopentanone into the native peptide (25, 26). The new aureobasidin analogue showed activity comparable with the native peptide R-106 (26). In light of such interest in cycloalkyl β-hydroxy α-amino acids, cyclopentenyl amino diol **5** was synthesized by ring-closure metathesis on bis-allyl amino diol **2e** (27–29). Exposure of amino diol **2e** to benzylidene[1,3-bis(mesitylene)-2-imidazolidinylidene]tricyclohexylphosphine ruthenium(IV) dichloride (10 mol%) in CH_2Cl_2 for 24 h at

© 2004 NRC Canada

Scheme 2. Mechanism for the formation of (2*R*)-2-[*N*-(Boc)amino]-1-hydroxy-hept-6-en-3-one **3h**.

Scheme 3. Synthesis and enantiomeric purity of cyclopentane amino acid **7**.

40 °C provided a dark brown, crude reaction product that was first passed through a silica gel column and then treated with activated carbon for 12 h at room temperature to yield **5** as a colorless oil in 81% yield (30). Reduction of the double bond in the five-membered ring of **5** was accomplished using Wilkinson's catalyst, which provided, after a similar chromatography – activated carbon purification, saturated product **6** in 98% yield (31, 32).

As in our synthesis of β-hydroxyvaline (14), selective primary alcohol oxidation was accomplished by treating diols **2a**–**2g** and **6** with TEMPO (2,2,6,6-tetramethyl-1-piperidinyloxy) free radical, sodium chlorite, and sodium hypochlorite in a sodium-phosphate-buffered acetonitrile solution (Scheme 1) (33). *N*-Boc-β,β-Dialkylserines **1a**–**1g** and **7** were obtained in 72%–96% yields after purification by silica gel column chromatography (Table 1).

To ascertain if racemization had occured during the synthesis of the various β,β-dialkylserines **1a**–**1f** and **7** from *N*-Boc-D-serine methyl ester, the enantiomeric purity of cyclopentane amino acid **7** was evaluated after conversion to diastereomeric dipeptide **8** (Scheme 3). Both (*S*)- and (*R*)-phenylalanine methyl ester hydrochloride were independently coupled with acid **7**, using benzotriazol-1-yl-1,1,3,3-tetramethyluronium tetrafluoroborate (TBTU) and 1-hydroxybenzotriazole (HOBt) in acetonitrile. Observation of the signals for the diastereotopic α-protons at 3.91 and 3.84 ppm in the 400 MHz ^{1}H NMR spectra of **8** (obtained after aqueous workup) during incremental additions of (*S*)-**8** in (*R*)-**8** in

© 2004 NRC Canada

$CDCl_3$, demonstrated dipeptide (*R*)-**8** to be of >98% diastereomeric purity. Protected diastereomer (*S*)-**8** and *N*-Boc-β,β-dialkylserines **1a**–**1g** and **7** are thus all presumed to be of similarly high enantiomeric purity.

Conclusion

The diversity oriented synthesis of enantiopure L-*N*-Boc-β,β-dialkylserines has been achieved in two practical steps from *N*-(Boc)-D-serine methyl ester as chiral educt. In light of applications of alkyl-branched serines in the study of biologically active peptides and the synthesis of other amino acids and heterocycles, this route provides a useful set of tools for peptide science and novel building blocks for diversity oriented synthesis.

Experimental section

General

Reagent and solvent purification, spectroscopic and spectrometric analyses, and chromatography — all were performed as described in the general section of the experimental that was presented in a previous work (14). The spectra for **1b**, **1f**, and **1g** were measured in D_2O with added NaOD, using dioxane (3.75 ppm, 67.19 ppm) as internal reference; in $CDCl_3$, the compounds were observed as conformational isomers. The synthesis and the analysis of (*S*)-β-hydroxy-*N*-(Boc)valine **1a** was performed as described previously (14). Minor reaction components were characterized by LC-MS using total ion chromatography (TIC).

General procedure for preparation of diol derivatives

A solution of *N*-(Boc)-L-serine methyl ester (548 mg, 2.5 mmol) in Et_2O at –78 °C was treated dropwise with a solution of the Grignard reagent (600 mol%, 15 mmol). The initial volume of Et_2O was adjusted to afford a 0.1 mol L^{-1} concentration of *N*-(Boc)-L-serine methyl ester after Grignard reagent addition. The dry ice bath was removed, and the reaction mixture was stirred for 2 h at room temperature, cooled to 0 °C, and treated dropwise with a solution of aqueous saturated NH_4Cl (20 mL). The phases were separated, and the aqueous layer was extracted with EtOAc (3 × 20 mL). The organic phases were combined, washed with brine, dried with $MgSO_4$, filtered, and evaporated to an oily residue, which was purified on silica gel.

(2*R*)-2-[*N*-(Boc)Amino]-3-ethyl-pentane-1,3-diol (2b)

Product from addition of ethyl magnesium bromide (3.0 mol L^{-1} in Et_2O) was purified on a silica gel column using a gradient of 5%–10% EtOAc in hexanes as eluant. First to elute was diol **2b,** a white solid (501 mg, 81%). TLC R_f = 0.30 (50% EtOAc in hexanes); mp 97 to 98 °C. $[\alpha]_D^{20}$ –29.0° (*c* 1.0, $CHCl_3$). ^{1}H NMR (400 MHz, $CDCl_3$) δ: 0.84 (t, 3H, *J* = 7.31), 0.90 (t, 3H, *J* = 7.38), 1.45 (s, 9H), 1.50–1.61 (m, 3H), 1.66–1.75 (m, 1H), 3.05 (s, 1H), 3.32 (s, 1H), 3.57 (d, 1H, *J* = 9.0), 3.78 (d, 1H, *J* = 4.7), 4.00 (d, 1H, *J* = 11.2), 5.50 (d, 1H, *J* = 8.9). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 7.6, 7.9, 27.2, 28.2, 28.5, 54.4, 63.6, 78.2, 79.6, 156.5. HR-MS calcd. for $C_{12}H_{26}NO_4$ ($[MH]^+$): 248.1862; found: 248.1871. Anal. calcd. for $C_{12}H_{25}NO_4$: C 58.27, H 10.19, N 5.66; found: C 58.44, H 10.50, N 5.65.

Second to elute was (2*R*)-2-[*N*-(Boc)amino]-1-hydroxy-pentan-3-one (**3b**), an oil (22 mg, 4%): TLC R_f = 0.14 (50% EtOAc in hexanes). ^{1}H NMR (400 MHz, $CDCl_3$) δ: 0.97 (q, 3H, *J* = 7.6), 1.44 (s, 9H), 3.48–3.68 (m, 4H). MS (TIC) *m*/*z*: 219.8 ($[M + 2H]^+$).

(2*R*)-2-[*N*-(Boc)Amino]-1,1-diphenyl-propane-1,3-diol (2c)

Product from addition of phenyl magnesium bromide (3.0 mol L^{-1} in Et_2O) was purified on a silica gel column using a gradient of 10%–15% EtOAc in hexanes as eluant. First to elute was diol **2c**, a white solid (678 mg, 79%): TLC R_f = 0.48 (50% EtOAc in hexanes); mp 68 to 69 °C. $[\alpha]_D^{20}$ 65.6° (*c* 1.0, $CHCl_3$). ^{1}H NMR (400 MHz, $CDCl_3$) δ: 1.32 (s, 9H), 2.91 (s, 1H), 3.67 (d, 1H, *J* = 11.0), 3.77 (d, 1H, *J* = 10.7), 4.65 (d, 1H, *J* = 7.7), 4.86 (s, 1H), 5.53 (d, 1H, *J* = 8.4), 7.13–7.31 (m, 6H), 7.45–7.51 (m, 4H). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 28.4, 55.5, 63.9, 79.9, 81.8, 125.2 (2C), 125.5 (2C), 126.9, 127.0, 128.3 (2C), 128.6 (2C), 144.7, 145.5, 156.2. HR-MS calcd. for $C_{20}H_{26}NO_4$ ($[MH]^+$): 344.1862; found: 344.1851.

Second to elute was (2*R*)-2-[*N*-(Boc)amino]-3-hydroxy-1-phenyl-propan-1-one (**3c**), an oil (27 mg, 4%): TLC R_f = 0.37 (50% EtOAc in hexanes). ^{1}H NMR (400 MHz, CD_3OD) δ: 1.45 (s, 9H), 3.80 (dd, 1H, *J* = 5.0, *J* = 11.4), 3.91 (dd, 1H, J_1 = 4.7, J_2 = 11.4), 5.23 (s, 1H), 7.00–7.53 (m, 2H), 7.54–7.66 (m, 1H), 8.01 (m, 2H). MS (TIC) *m*/*z*: 266.8 ($[MH]^+$).

(2*R*)-2-[*N*-(Boc)Amino]-3-benzyl-4-phenyl-butane-1,3-diol (2d)

Product from addition of benzyl magnesium bromide (3.0 mol L^{-1} in Et_2O) was purified on a silica gel column using a gradient of 10%–15% EtOAc in hexanes as eluant. First to elute was diol **2d**, a white solid (687 mg, 74%): TLC R_f = 0.49 (50% EtOAc in hexanes); mp 86 to 87 °C. $[\alpha]_D^{20}$ –13.6° (*c* 1.0, $CHCl_3$). ^{1}H NMR (400 MHz, $CDCl_3$) δ: 1.44 (s, 9H), 2.68–3.00 (m, 6H), 3.64 (br s, 1H), 3.92 (br s, 2H), 5.19 (br s, 1H), 7.19–7.33 (m, 10H). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 28.1, 28.5, 42.6, 42.8, 57.0, 63.6, 80.0, 126.9 (2C), 128.5 (4C), 130.9 (4C), 136.4 136.6, 156.7. HR-MS calcd. for $C_{22}H_{30}NO_4$ (TOF EI): 372.2175; found: 372.2174. Anal. calcd. for $C_{22}H_{29}NO_4$+H_2O: C 67.84, H 8.02, N 3.60; found: C 67.91, H 8.11, N 3.65.

Second to elute was (2*R*)-3-[*N*-(Boc)amino]-4-hydroxy-1-phenyl-butan-2-one (**3d**), an oil (77 mg, 11%): TLC R_f = 0.39 (50% EtOAc in hexanes). ^{1}H NMR (400 MHz, CD_3OD) δ: 1.45 (s, 9H), 3.79 (d, 1H, *J* = 10.9), 3.89 (s, 2H), 3.90 (d, 1H, *J* = 10.9), 4.29 (s, 1H), 7.20–7.19 (m, 5H). MS (TIC) *m*/*z*: 280.8 ($[MH]^+$).

(2*R*)-2-[*N*-(Boc)Amino])-3-allyl-hex-5-ene-1,3-diol (2e)

Product from addition of allyl magnesium bromide (1.0 mol L^{-1} in Et_2O) was purified on a silica gel column using a gradient of 20%–25% EtOAc in hexanes as eluant. First to elute was diol **2e**, a white solid (485 mg, 68%): TLC R_f = 0.48 (50% EtOAc in hexanes); mp 69 to 70 °C. $[\alpha]_D^{20}$ –21.0° (*c* 1.0, $CHCl_3$). ^{1}H NMR (400 MHz, $CDCl_3$) δ: 1.45 (s, 9H), 2.30–2.36 (m, 3H), 2.45 (dd, 1H, J_1 = 6.4, J_2 = 14.0), 3.30–3.37 (m, 2H), 3.59 (d, 1H, *J* = 8.9), 3.80 (d, 1H, *J* = 10.5), 4.00 (d, 1H, *J* = 10.8), 5.10–5.18 (m, 4H), 5.51 (d,

1H, J = 9.0), 5.78–5.90 (m, 2H). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 28.5, 40.47, 41.3, 54.9, 63.3, 77.0, 79.8, 119.2, 119,3, 132.8, 132.9, 156.3. HR-MS calcd. for $C_{14}H_{26}NO_4$ ($[MH]^+$): 272.1862; found: 272.1874. Anal. calcd. for $C_{14}H_{25}NO_4$: C 61.97, H 9.29, N 5.16; found: C 61.71, H 9.52, N 5.08.

Second to elute was (2*R*)-2-[*N*-(Boc)amino]-1-hydroxy-hex-4-en-3-one (**3i**), an oil (109 mg, 16%): TLC R_f = 0.44 (50% EtOAc in hexanes). ^{1}H NMR (400 MHz, $CDCl_3$) δ: 1.44 (s, 9H), 1.94 (d, 3H, J = 6.3), 3.76 (s, 1H), 3.88 (m, 2H), 6.31 (d, 1H, J = 15.6), 7.07 (m, 1H). MS (TIC) *m/z*: 230.8 ($[MH]^+$).

(2*R*)-2-[*N*-(Boc)Amino]-3-vinyl-pent-4-en-1,3-diol (2f)

A solution of *N*-Boc-L-serine methyl ester (1.1 g, 5.0 mmol) in THF (20 mL) at –78 °C was treated with a solution of vinyl magnesium bromide in THF (1.0 mol L^{-1}, 600 mol%, 30 mmol, 30 mL), and the reaction mixture was stirred, quenched, and purified as described in the general procedure. Chromatography was performed using a gradient of 25%–30% EtOAc in hexanes as eluant. First to elute was homoallylic ketone (2*R*)-2-[*N*-(Boc)amino]-1-hydroxy-hept-6-en-3-one **3h**, a white solid (429 mg), TLC R_f = 0.53 (50% EtOAc in hexanes); mp 57 to 58 °C. $[\alpha]_D^{20}$ –30.0° (*c* 1.0, $CHCl_3$). ^{1}H NMR (400 MHz, $CDCl_3$) δ: 1.45 (s, 9H), 2.36–2.39 (m, 2H), 2.65–2.75 (m, 3H), 3.90 (m, 1H), 3.96 (m, 1H), 4.33 (s, 1H), 5.01 (m, 2H), 5.76–5.81 (s, 1H), 5.79 (m, 1H). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 28.1, 29.0, 39.8, 62.4, 63.8, 81.1, 116.3, 137.4, 158.0, 207.9. HR-MS calcd. for $C_{12}H_{22}NO_4$ ($[MH]^+$): 244.1549; found: 244.1551. Anal. calcd. for $C_{12}H_{21}NO_4$: C 59.24, H 8.70, N 5.76; found: C 59.29, H 8.80, N 5.59.

Then a 1:4 mixture of **3h** and diol **2f** was recovered (264 mg, 22%).

Last to elute was diol **2f**, a white solid (306 mg, 25%): TLC R_f = 0.48 (50% EtOAc in hexanes); mp 68 to 69 °C. $[\alpha]_D^{20}$ 35.7° (*c* 1.0, $CHCl_3$). ^{1}H NMR (400 MHz, $CDCl_3$) δ: 1.44 (s, 9H), 3.66 (br s, 1H), 3.75 (d, 1H, J = 3.1), 3.78 (d, 1H, J = 3.2), 3.96 (d, 1H, J = 16.9), 5.17 (d, 1H, J = 10.7), 5.25–5.34 (br m, 3H), 5.44 (d, 1H, J = 17.2), 5.89–6.02 (br m, 2H). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 28.5, 56.1, 63.2, 79.7, 79.8, 114.2, 114.4, 139.9, 140.2, 156.5. HR-MS calcd. for $C_{12}H_{22}NO_4$ ($[MH]^+$): 244.1549; found: 244.1551. Anal. calcd. for $C_{12}H_{21}NO_4$: C 59.24, H 8.70, N 5.76; found: C 59.20, H 9.06, N 5.70.

(2*R*)-2-[*N*-(Boc)Amino]-3-isopropyl-4-methyl-pentane-1,3-diol (2g)

Product from addition of *iso*-propyl magnesium chloride (2.0 mol L^{-1} in Et_2O) was purified on a silica gel column using a gradient of 10%–15% EtOAc in hexanes as eluant. First to elute was diol **2g**, a white solid (262 mg, 38%): TLC R_f = 0.55 (50% EtOAc in hexanes); mp 84 to 85 °C. $[\alpha]_D^{20}$ –24.4° (*c* 1.0, $CHCl_3$). ^{1}H NMR (400 MHz, $CDCl_3$) δ: 1.01 (m, 12H), 1.45 (s, 9H), 2.06 (br s, 2H), 2.94 (s, 1H), 3.26 (br s, 1H), 3.83 (br s, 1H), 3.94 (br d, 2H, J = 7.7), 5.41 (br s, 1H). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 17.9, 18.6, 18.7, 19.1, 28.5, 32.4, 34.9, 53.5, 64.8, 79.7, 80.0, 156.1. HR-MS calcd. for $C_{14}H_{30}NO_4$ ($[MH]^+$) 276.2175; found: 276.2179. Anal. calcd. for $C_{14}H_{29}NO_4$: C 61.06, H 10.61, N 5.09; found: C 61.48, H 10.78, N 5.08.

Second to elute was (2*R*)-2-[*N*-(Boc)amino]-1-hydroxy-4-methyl-pentan-3-one (**3g**), an oil (110 mg, 19%): R_f = 0.38 (50% EtOAc in hexanes). ^{1}H NMR (400 MHz, CD_3OD) δ: 1.07 (d, 3H, J = 6.8), 1.11 (d, 3H, J = 6.8), 1.45 (s, 9H), 2.96 (sept, 1H, J = 6.9), 3.75–3.86 (m, 2H), 1.45 (s, 9H), 4.79 (s, 1H). MS (TIC) *m/z*: 232.8 ($[MH]^+$).

Third to elute was (2*R*)-2-[*N*-(Boc)amino]-4-methyl-pentane-1,3-diol (**4**), a white solid (186 mg, 32%) containing a 4:1 diastereomeric mixture, as ascertained on measurement of the diastereotopic multiplets for the C_4 proton at 1.80 and 1.68 ppm. TLC R_f = 0.15 (50% EtOAc in hexanes). Signals for the major diastereomer: ^{1}H NMR (400 MHz, CD_3OD) δ: 0.92 (d, 3H, J = 6.6), 0.97 (d, 3H, J = 6.9), 1.78 (s, 9H), 1.80 (m, 1H), 3.31–3.53 (m, 1H), 3.53- 3.76 (m, 3H), 6.26 (d, 1H, J = 8.4).

Distinct signals for the minor isomer: ^{1}H NMR (400 MHz, CD_3OD) δ: 1.68 (m, 1H), 5.82 (d, 1H, J = 8.4). MS (TIC) *m/z*: 234.9 ($[MH]^+$).

General procedure for preparation of *N*-protected β,β-dialkyl-L-serines (1a–1g) and (7)

A mixture of diol **2b**–**2g** (1.5 mmol), sodium phosphate buffer (6.0 mL, 0.67 mol L^{-1}, pH = 6.7), and TEMPO (10 mol%, 0.15 mmol, 24 mg) in acetonitrile (7.5 mL) was heated to 35 °C and treated simultaneneously over 2 h (Caution! Do not mix bleach and sodium chlorite before adding to the reaction mixture) (33) with sodium chlorite (200 mol%, 3 mmol, 1.5 mL of solution: 5.71 g 80% mass fraction, 50.5 mmol in 25 mL of water) and diluted sodium hypochlorite (2 mol%, 0.03 mmol, 790 μL of solution: 0.66 mL commercial bleach 10.8% mass fraction in 25 mL of water). The mixture was stirred at 35 °C overnight, cooled to room temperature, treated with solid citric acid (pH = 3), and extracted with EtOAc (3 × 10 mL). The organic phases were combined, dried with $MgSO_4$, filtered, and evaporated. The solid residue, containing **1b**–**1g** and **7**, was purified by filtration through a pad of silica gel using, initially, 5% EtOAc in hexanes, followed by a solution of 1% AcOH in AcOEt. Evaporation of the collected filtrate gave *N*-protected β,β-dialkyl-L-serines **1b**–**1g** and **7**.

(2*R*)-2-[*N*-(Boc)Amino]-3-ethyl-3-hydroxy-pentanoic acid (1b)

Product was isolated as a white solid (361 mg, 92%): TLC R_f = 0.35 (89% $CHCl_3$, 10% MeOH, 1% CH_3CO_2H); mp 113 to 114 °C. $[\alpha]_D^{20}$ –9.5° (*c* 1.0, $CHCl_3$). ^{1}H NMR (300 MHz, D_2O, NaOD) δ: 0.80–0.91 (m, 6H), 1.43 (s, 9H), 1.46–1.66 (m, 4H), 3.98 (s, 1H). ^{13}C NMR (75 MHz, D_2O, NaOD) δ: 7.5, 7.7, 27.5, 28.3, 28.5, 60.6, 76.6, 81.8, 158.2, 178.9. HR-MS calcd. for $C_{12}H_{24}NO_5$ ($[MH]^+$): 262.1654; found: 262.1659. Anal. calcd. for $C_{12}H_{23}NO_5$: C 55.16, H 8.87, N 5.36; found: C 55.31, H 9.09, N 5.36.

(2*R*)-2-[*N*-(Boc)Amino]-3-hydroxy-3,3-diphenyl-propionic acid (1c)

Product was isolated as a white solid (407 mg, 76%): TLC R_f = 0.55 (89% $CHCl_3$, 10% MeOH, 1% CH_3CO_2H); mp 175 to 176 °C. $[\alpha]_D^{20}$ 29.9° (*c* 1.0, $CHCl_3$). ^{1}H NMR (400 MHz, CD_3OD) δ: 1.32 (s, 9H), 5.27 (s, 1H), 7.17 (m, 2H), 7.28 (m, 4H), 7.53 (m, 4H). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 28.6, 60.6, 80.5, 80.8, 126.9 (2C), 127.2 (2C),

© 2004 NRC Canada

127.9, 128.0, 129.0 (4C), 145.7, 146.0, 157.5, 174.6. HR-MS calcd. for $C_{20}H_{24}NO_5$ ([MH]$^+$): 358.1654; found: 358.1645. Anal. calcd. for $C_{20}H_{23}NO_5$: C 67.21, H 6.49, N 3.92; found: C 67.05, H 6.66, N 4.00.

(2*R*)-2-[*N*-(Boc)Amino]-3-benzyl-3-hydroxy-4-phenyl-butyric acid (1d)

Product was isolated as a white solid (428 mg, 74%): TLC R_f = 0.48 (89% $CHCl_3$, 10% MeOH, 1% CH_3CO_2H); mp 76 to 77 °C. $[\alpha]_D^{20}$ –20.0° (*c* 1.0, MeOH). ^{1}H NMR (400 MHz, CD_3OD) δ: 1.46 (s, 9H), 2.66 (d, 1H, *J* = 14.1), 2.85–2.92 (m, 3H), 4.0 (s, 1H), 7.19–7.32 (m, 10H). ^{13}C NMR (100 MHz, CD_3OD) δ: 28.7, 43.2, 43.3, 60.4, 76.7, 80.8, 127.4, 127.5, 128.9, 129.0, 132.1 (2C), 138.0 (2C), 157.8, 175.4. HR-MS calcd. for $C_{22}H_{27}NO_5$ (TOF EI): 385.1877; found: 385.1889. Anal. calcd. for $C_{22}H_{27}NO_5$: C 68.55, H 7.06, N 3.63; found: C 68.10, H 7.17, N 3.68.

(2*R*)-2-[*N*-(Boc)Amino]-3-allyl-3-hydroxy-hex-5-enoic acid (1e)

Product was isolated as a yellow oil (334 mg, 78%): TLC R_f = 0.45 (89% $CHCl_3$, 10% MeOH, 1% CH_3COOH). $[\alpha]_D^{20}$ 14.4° (*c* 1.0, CH_3OH). ^{1}H NMR (400 MHz, CD_3OD) δ: 1.45 (s, 9H), 2.27–2.39 (m, 4H), 4.84 (s, 1H), 5.08–5.16 (m, 4H), 5.80–5.96 (m, 2H). ^{13}C NMR (100 MHz, CD_3OD) δ: 28.7, 41.4, 41.7, 60.4, 75.9, 80.8, 119.1, 119.3, 134.2, 134.4, 157.8, 174.3. HR-MS calcd. for $C_{14}H_{24}NO_5$ (TOF EI): 286.1654; found: 286.1660.

(2*R*)-2-[*N*-(Boc)Amino]-3-hydroxy-3-vinyl-pent-4-enoic acid (1f)

Product was isolated as yellow oil **1f** (313 mg, 81%): TLC R_f = 0.40 (89% $CHCl_3$, 10% MeOH, 1% CH_3CO_2H). $[\alpha]_D^{20}$ 17.9° (*c* 1.0, $CHCl_3$). ^{1}H NMR (300 MHz, D_2O, NaOD) δ: 1.42 (s, 9H), 4.02 (s, 1H), 5.23–5.36 (m, 4H), 5.96–6.08 (m, 2H). ^{13}C NMR (75 MHz, D_2O, NaOD) δ: 28.3, 62.8, 77.3, 81.9, 115.9, 116.0, 138.7, 139.2, 158.1, 177.0. HR-MS calcd. for $C_{12}H_{20}NO_5$ ([MH]$^+$): 258.1342; found: 258.1344.

(2*R*)-2-[*N*-(Boc)Amino]-3-hydroxy-3-isopropyl-4-methyl-pentanoic acid (1g)

Product was isolated as a white solid **1g** (313 mg, 72%): TLC R_f = 0.57 (89% $CHCl_3$, 10% MeOH, 1% CH_3CO_2H); mp 55 to 56 °C. $[\alpha]_D^{20}$ 18.0° (*c* 1.0, $CHCl_3$). ^{1}H NMR (300 MHz, D_2O, NaOD) δ: 0.84–1.01 (m, 12H), 1.44 (s, 9H), 1.88–1.98 (m, 1H), 2.03–2.14 (m, 1H), 4.19 (s, 1H). ^{13}C NMR (75 MHz, D_2O, NaOD) δ: 16.8, 17.6, 17.8, 31.5, 35.1, 55.1, 67.2, 79.5, 81.7, 158.1, 180.8. HR-MS calcd. for $C_{14}H_{28}NO_5$ (TOF EI): 290.1967; found: 290.1966.

(2*R*)-2-[1-*N*-(Boc)Amino-2-(1′-hydroxy-cyclopentyl]-acetic acid (7)

Product was isolated from TEMPO oxidation of diol **6** (39.6 mg, 0.161 mmol) as a yellow oil **7** (37 mg, 88%): TLC R_f = 0.40 (89% $CHCl_3$, 10% MeOH, 1% CH_3COOH). $[\alpha]_D^{20}$ –86.5° (*c* 1.5, $CHCl_3$). ^{1}H NMR (400 MHz, $CDCl_3$) δ: 1.45 (s, 9H), 1.61–1.85 (m, 8H), 4.25 (d, 1H, *J* = 8.5), 5.74 (d, 1H, *J* = 8.1). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 23.3, 24.1, 28.4, 37.4, 38.0, 60.5, 80.7, 83.6, 156.5, 174.8. HR-MS calcd. for $C_{12}H_{22}NO_5$ ([MH]$^+$): 260.1498; found: 260.1510.

(1′*R*)-1-[1′-*N*-(Boc)Amino-2′-hydroxy-ethyl]-cyclopent-3-enol (5)

A solution of amino diol **2e** (68 mg, 0.25 mmol) in degassed CH_2Cl_2 (1 mL) was treated with benzylidene[1,3-bis(mesitylene)-2-imidazolidinylidene]tricyclohexylphosphine ruthenium(IV) dichloride (21 mg, 0.025 mmol) under an argon atmosphere, stirred overnight at 40 °C, and evaporated to a dark brown, oily residue, which was passed through a silica gel column using a 1:1 mixture of EtOAc in $CHCl_3$ as eluant. The colored product was stirred overnight with activated charcoal (50 mass equiv., 3.4 g) in CH_2Cl_2 (25 mL) to give, after filtration, cyclopentene **5** as a colorless oil (49 mg, 81%): TLC R_f = 0.39 (70% EtOAc in hexanes). $[\alpha]_D^{20}$ –10.5° (*c* 1.0, $CHCl_3$). ^{1}H NMR (300 MHz, $CDCl_3$) δ: 1.46 (s, 9H), 2.34–2.68 (m, 6H), 3.67 (m, 1H), 3.84 (dd, 1H, J_1 = 3.2, J_2 = 11.4), 3.99 (dd, 1H, J_1 = 3.0, J_2 = 11.4), 5.49 (d, 1H, *J* = 8.5), 5.73 (s, 2H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 28.5, 45.4, 46.1, 57.4, 64.4, 79.8, 84.8, 128.1, 128.8, 156.4. HR-MS calcd. for $C_{12}H_{22}NO_4$ ([MH]$^+$): 244.1549; found: 244.1552.

(1′*R*)-1-[1′-*N*-(Boc)Amino-2′-hydroxy-ethyl]-cyclopentanol (6)

A solution of cyclopentene **5** (60 mg, 0.25 mmol) in degassed benzene (3.1 mL) was treated with tris(triphenylphosphine)chlororhodium(I) (9.34 mol%, 0.01 mmol, 9.3 mg), heated at 60 °C under a hydrogen atmosphere (4 atm (1 atm = 101.325 kPa)) for 24 h, and evaporated to a dark brown residue, which was passed through a pad of silica gel using a 1:1 mixture of EtOAc in $CHCl_3$ as eluant. The colored product was stirred overnight with activated charcoal (50 mass equiv., 3.0 g) in $CHCl_3$ (25 mL) and filtered to give cyclopentane **6** as a white solid (59 mg, 98%): TLC R_f = 0.39 (70% EtOAc in hexanes); mp 88 to 89 °C. $[\alpha]_D^{20}$ –14.1° (*c* 1.0, $CHCl_3$). ^{1}H NMR (300 MHz, $CDCl_3$) δ: 1.45 (s, 9H), 1.52–1.95 (m, 8H), 3.27 (br s, 1H), 3.37 (br s, 1H), 3.49 (d, 1H, *J* = 8.9), 3.83 (d, 1H, *J* = 10.1), 3.97 (dd, 1H, J_1 = 2.8, J_2 = 11.2), 5.61 (d, 1H, *J* = 8.8). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 23.5, 24.1, 28.5, 38.4, 38.5, 57.6, 64.5, 79.6, 85.6, 156.4. HR-MS calcd. for $C_{12}H_{24}NO_4$ ([MH]$^+$): 246.1705; found: 246.1712.

Enantiomeric purity of (2*R*)-2-[1-*N*-(Boc)amino-2-(1′-hydroxy-cyclopentyl)]-acetic acid (7)

A solution of **7** (15 mg, 0.058 mmol) in CH_3CN (0.5 mL) at 0 °C was treated with HOBt (100 mol%, 11 mg, 0.058 mmol) and TBTU (150 mol%, 28 mg, 0.087 mmol), stirred for 30 min, and treated with a premixed solution of (*S*)- or (*R*)-phenylalanine methyl ester hydrochloride (300 mol%, 37.5 mg, 0.174 mmol) and diisopropylethylamine (DIEA) (400 mol%, 30 mg, 0.232 mmol, 41 μL) in CH_3CN (0.5 mL) at 0 °C. The reaction mixture was stirred for 48 h at room temperature when TLC (EtOAc) showed complete disappearance of the starting acid **7**. The solvent was evaporated, and the solid residue was resuspended in CH_2Cl_2 (10 mL). The organic phase was washed with an aqueous saturated solution of $NaHCO_3$ (2 × 3 mL), 1 N NaH_2PO_4 (2 × 3 mL), and brine (3 mL); dried with $MgSO_4$; filtered; and evaporated to give a residue that was directly examined by 400 MHz ^{1}H NMR spectroscopy in $CDCl_3$. Reactions of phenyldimethylsilyllithium with β-*N*,*N*-dimethylaminoenones: A convenient synthesis of β-dimethyl(phenyl)silylacrylic acid and its derivatives[1]

Ian Fleming, Elena Marangon, Chiara Roni, Matthew G. Russell, and Sandra Taliansky Chamudis

Abstract: Phenyldimethylsilyllithium reacted with 5,5-dimethyl-3-(*N*,*N*-dimethylamino)cyclohex-2-enone (**7**), 3-(*E*)-*N*,*N*-dimethylaminopropenal (**11**), and 4-*N*,*N*-dimethylaminobut-3-en-2-one (**13**) to give the corresponding β-silyl-α,β-unsaturated carbonyl compounds **8**, **12**, and **14**, in which the dimethylamino group has been displaced by the phenyldimethylsilyl group. Phenyldimethylsilyllithium reacted with ethyl β-*N*,*N*-dimethylaminopropenoate (**15**) by conjugate addition, but, in contrast to the ketones **7** and **13** and the aldehyde **11**, the intermediate enolate **16** was *C*-protonated in the aqueous work-up to give ethyl 3-*N*,*N*-dimethylamino-3-dimethyl(phenyl)silylpropanoate (**17**). When the enolate **16** was instead given a mysteriously brief treatment with methyl iodide before work-up, the product was ethyl 3-(*E*)-dimethy(phenyl)silylpropenoate (**18**). Phenyllithium and methyllithium also added conjugatively to ethyl β-*N*,*N*-dimethylaminoacrylate (**15**) but, in contrast to the silyl case, the intermediate enolate **22** reacted unexceptionally with methyl iodide to give the products **25** and **26** of stereoselective *C*-methylation. This synthesis of the ester **18** was used to synthesize the Oppolzer sultam derivative **30**.

Key words: conjugate addition, elimination, substitution, silyllithium, silylenone.

Résumé : Le phényldiméthylsilyllithium réagit avec la 5,5-diméthyl-3-(*N*,*N*-diméthylamino)cyclohex-2-énone (**7**), le 3-(*E*)-*N*,*N*-diméthylaminopropénal (**11**) et la 4-*N*,*N*-diméthylaminobut-3-én-2-one (**13**) pour conduire à la formation des composés carbonylés β-silyl-α,β-insaturés correspondants, **8**, **12** et **14** dans lesquels le groupe diméthylamino a été remplacé par un groupe phényldiméthylsilyle. Avec le β-*N*,*N*-diméthylaminopropénoate d'éthyle (**15**), le phényldiméthylsilyllithium donne une réaction d'addition conjuguée, mais, par opposition avec ce qui a été observé avec les cétones **7** et **13** et l'aldéhyde **11**, l'intermédiaire énolique **16** la récupération aqueuse des produits provoque une *C*-alkylation qui conduit au 3-*N*,*N*-diméthylamino-3-diméthyl(phényl)silylpropénoate (**17**). Toutefois, lorsque l'énolate **16** est soumis à un mystérieusement court traitement par de l'iodure de méthyle avant la récupération des produits, le produit obtenu est alors le 3-(*E*)-diméthyl(phényl)silylpropénoate d'éthyle (**18**). Le phényllithium et le méthyllithium s'ajoutent aussi de façon conjugue au β-*N*,*N*-diméthylaminopropénoate d'éthyle (**15**) mais, par opposition à ce qui a été observé dans le cas silylé, l'intermédiaire énolique **22** réagit sans surprise avec l'iodure de méthyle pour conduire aux produits **25** et **26** de *C*-méthylation stéréosélective. Cette synthèse de l'ester **18** a été utilisée pour réaliser la synthèse du dérivé sultame d'Oppolzer **30**.

Mots clés : addition conjugue, élimination, substitution, silyllithium, silylénone.

[Traduit par la Rédaction]

Introduction

The phenyldimethylsilyllithium reagent (1) was first made and, along with its triphenylsilyl analogue, quite extensively studied by Gilman in the 1950s and 1960s (2), but it has been relatively little used except as a source of the corresponding cuprate reagent (3), which we introduced in 1978 (4). More recently, we have been engaged in further studies of the silyllithium reagent itself (5), and of its reactions with a number of substrates, including aromatic esters (6), α-silyloxy esters (7), saturated esters (8), amides (9, 10), thioamides (11), nitriles (12), sulfonamides (13), and acid chlorides (14). Most notably, tertiary amides have been a source of several remarkable reactions, which we have to a large

extent unravelled (9, 10). Most strikingly, the simple *N*,*N*-dimethylamide **1** could be induced to give in good yield any one of three distinct products (**2**, **3**, or **4**), depending upon the reaction conditions and (or) the stoichiometry (Scheme 1) (8, 9).

Almost every change we made to the structure of the starting amide led to other surprises, an experience Gilman was not immune to either. Thus, the reaction of the acetylenic amide **5** proved to be different from the saturated amide, not only because conjugate addition was now both possible and what occurred, but also because reduction took place as well, at least in the products **6** that we could recognise (Scheme 2). Conjugate addition is hardly surprising, since silyllithium and stannyllithium reagents can easily react in this way with unsaturated carbonyl compounds in THF (15), although the cuprates are usually rather better, but reduction to an aldehyde had not been a common outcome in our earlier work. The yield, however, was unimpressive, and we did not pursue this unpromising line. More interesting were the results of reactions with vinylogous amide systems, which we reported in a preliminary communication (16), and which we report in full here.

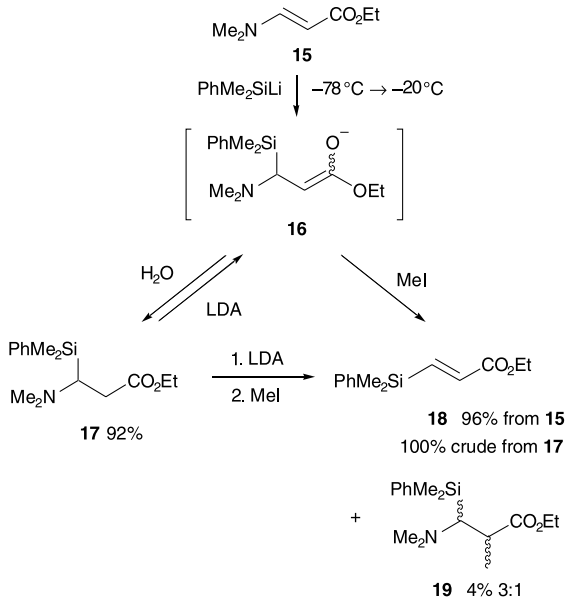
Scheme 3.

Results and discussion

The reaction of phenyldimethylsilyllithium with the enone **7** was unexceptional in giving the β-silylenone **8** in which the dimethylamino group has been replaced by the silyl group (Scheme 3). Two pathways might have been followed. In one, the silyllithium reagent attacked the carbonyl group directly to give the enamine **9**, hydrolysis of which, followed by elimination of water, would give the enone **8**. Alternatively, conjugate attack took place to give the enolate **10**, which underwent elimination of the dimethylamino group. A similar outcome was found for the enal **11** giving the enal **12**, in a less clean reaction with the same two possible pathways. The conjugate addition–elimination pathway is certainly followed in the reaction between the silyllithium reagent and the enone **13**, which gave the β-silylenone **14** in good yield. Furthermore, it is known that a β-amino group encourages conjugate addition by organolithium reagents (17), and trimethylsilyllithium is also known to give conjugate addition, rather than direct attack at the carbonyl group, with cyclohexenones in THF (15). Finally, it is not obvious why the pathway involving direct attack at the carbonyl group should not enter the carbene-forming sequence that we have seen is so accessible in the reactions described earlier, and involved, for example, in the formation of the enediamine **3** and the α-aminosilane **4** (9, 10). It seems likely that the conjugate addition–elimination pathway is followed in all of these reactions.



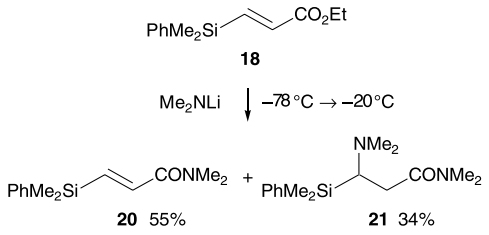
The products **8**, **12**, and **14** are easily made by other methods (18–20), and so we have not taken this investigation any further. Instead, we investigated the corresponding reaction with the vinylogous carbamate **15**, which gave us a curious result, and, incidentally, a better synthesis of the ester **18** than the one we had been using quite extensively hitherto in our synthetic work.

When we added the silyllithium reagent to the ester **15**, the only product after an aqueous quench was that of conjugate addition **17** (Scheme 4). While this is unsurprising in itself, it raised the first question: why was the dimethylamino group eliminated in the experiments in Scheme 3, and not here? One possibility is that the ketone and aldehyde enolates are kinetically protonated on oxygen. The resultant enols might then live long enough to expel the dimethylamino group in the aqueous medium before they underwent tautomerism to the ketones or the aldehyde. In contrast, it is possible that the ester enolate is protonated directly on carbon, and the dimethylamino group would not then be so easily lost.

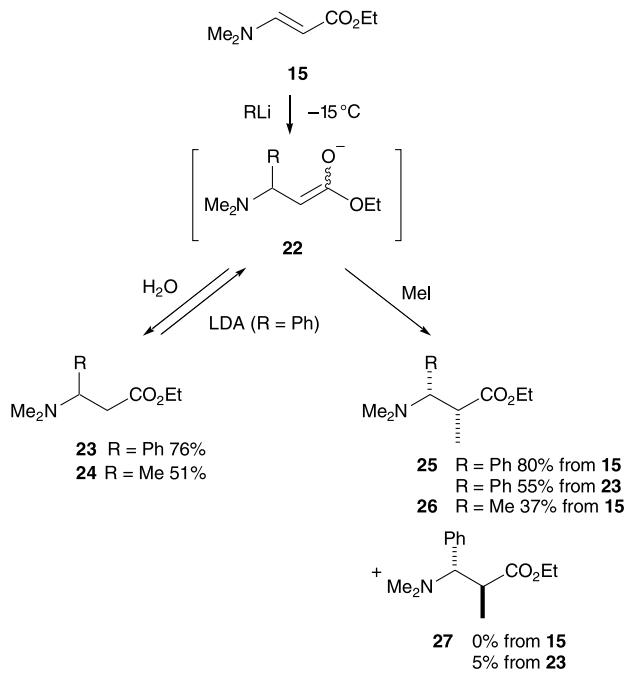
However, this was not the most puzzling observation. If, instead of the aqueous quench, we added methyl iodide, and then worked up in the usual way, the major product was the β-silylester **18**. This was not the result that we expected, because the carbon atom of the enolate ion **16** ought to have

© 2004 NRC Canada

Scheme 4.



been more nucleophilic towards methyl iodide than the dimethylamino group. The product of enolate methylation **19** was detectable on one occasion, and then only in a small amount. Similarly, when we regenerated the enolate **16** from the ester **17** using LDA, and treated that enolate with methyl iodide, the same unsaturated ester **18** was formed.

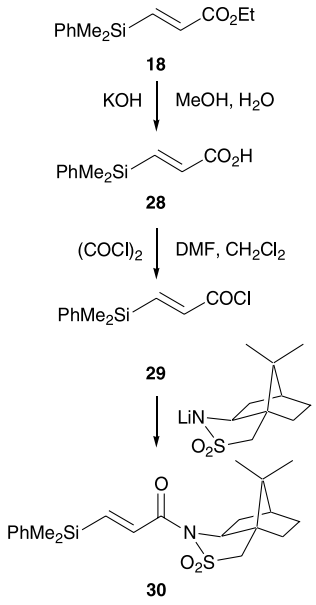


Additionally remarkable is that the elimination of dimethylamine **16** → **18** achieved by the treatment with methyl iodide took only a few minutes at –20 °C. In contrast, if we treated the amine **17** with methyl iodide in THF, little *N*-methylation took place over 18 h at room temperature — we recovered the amine **17** in 86% yield. Evidently, the α-silyl group does not on its own increase the nucleophilicity of the nitrogen lone pair (21) enough to suggest an exceptionally easy *N*-methylation. It seems improbable that coordination by the enolate oxygen to the silyl group could make the nitrogen lone pair more nucleophilic than the carbon atom of the enolate ion, and we have no convincing explanation for the ease with which the elimination took place. It is not specific to using methyl iodide, since benzyl bromide and allyl bromide had the same effect, although not in such good yield. The most obvious explanation would have been that the dimethylamide ion had already been expelled from the enolate **16** before the aqueous quench, and had added back during the aqueous quench giving the saturated ester **17**. The role of the methyl iodide in this scenario would have been to quench the dimethylamide ion, and prevent it from adding back. This is not the explanation, because the unsaturated ester **18**, which would have been the product of that elimination, reacted with lithium dimethylamide to give the amides **20** and **21** (Scheme 5). These products were not present in the reaction mixtures from Scheme 3. Furthermore, quenching the reaction mixture from the conjugate addition by injecting it directly into aqueous hydrochloric acid, which can be expected to protonate the amide ion rapidly, gave largely the ester **17** (67%) and only a little (9%) of the product of elimination **18**.

The easy elimination induced by methyl iodide has something to do with the presence of the silyl group. We repeated

Scheme 5.

Scheme 6.



the reaction with the ester **15** using phenyllithium instead of phenyldimethylsilyllithium (Scheme 6). Conjugate addition took place to give the enolate **22** (R = Ph); quenching with ammonium chloride solution gave the amino ester **23**, but quenching with methyl iodide gave the expected enolate methylation, with the expected (22) high degree of diastereoselectivity in favour of the known (23) isomer **25**. Regeneration of the enolate **22** (R = Ph) from the ester **23** using LDA, followed by methylation with methyl iodide, gave the same result: *C*-methylation, this time with a detectable but small amount of the diastereoisomer **27** formed as well. In some rather lower yielding, but otherwise similar reactions, methyllithium also added in a conjugate manner, and the enolate **22** (R = Me) could be trapped with either protons or methyl iodide to give the esters **24** and **26**, respectively.

The ester **18** has usually been prepared most economically by hydrosilylation–dehydrogenation of ethyl acrylate (24), but in that otherwise excellent method it is always contaminated with the saturated analogue, no matter how much of an excess of ethyl acrylate is used to limit the amount of hydrosilylation. In our experience, the saturated analogue, although harmless to what we were doing, has frequently been difficult to remove, and we have found ourselves carrying it through the next few steps of our synthetic work until we found a stage at which it could be removed relatively easily.

Schcme 7.

The synthesis reported here is free of this problem. For further development, it was helpful to saponify the crude ester **18**, to separate acidic products from the inevitable silicon-containing by-products. The carboxylic acid was occasionally crystalline, but recrystallization, either of the acid or of various salts was not practical. Since we needed it attached to Oppolzer's sultam, as did he (25), we converted the acid into its acid chloride and joined it onto the auxiliary (Scheme 7), at which point we had a crystalline derivative **30** that could be purified by recrystallization. The overall yield of this useful compound from the amino ester **15** was 41%.

Experimental

^{13}C NMR data from attached proton tests (APT) are given in the form 133.6– when the C atom has an odd number of H atoms attached, and 167.2+ when it has an even number of H atoms attached.

(*E*)- and (*Z*)-3-Dimethyl(phenyl)silybut-2-enal (6)

But-2-ynoic acid *N*,*N*-dimethylamide (26) (0.22 g, 2.00 mmol) in THF (2 mL) was added dropwise to dimethyl-(phenyl)silyllithium (1, 7) (4.8 mL, 1 mol dm^{-3} in THF, 4.8 mmol) at –78 °C, and the mixture was kept at –20 °C for 1 h. Saturated aqueous sodium bicarbonate (5 mL) and diethylether (5 mL) were added. The aqueous portion was removed and the basic products extracted from the organic fraction with dilute hydrochloric acid (3 N). The aqueous layers were basified (10% NaOH) to pH 12 and then extracted with ether (3 × 20 mL), dried ($MgSO_4$) and evaporated under reduced pressure to give the crude products (0.24 g). Chromatography (SiO_2, CH_2Cl_2) gave the *aldehydes* (0.09 g, 22%) as an inseparable mixture (*E*:*Z*, 5:1). (*E*)-isomer: ^{1}H NMR (250 MHz, $CDCl_3$) δ: 10.1 (1H, d, *J* = 7.8, CHO), 7.5–7.4 (2H, m, Ph), 7.4–7.2 (3H, m, Ph), 6.3 (1H, dq, *J* = 7.8 and 1.7, C=CH), 2.2 (3H, d, *J* = 1.7, CMe), and 0.4 (6H, s, $SiMe_2$). ^{13}C NMR ($CDCl_3$) δ: 192.9–, 167.2+, 142.9–, 137.5+, 133.6–, 128.3–, 15.9– and –0.9– (1 signal missing). (*Z*)-isomer: ^{1}H NMR (250 MHz, $CDCl_3$) δ: 9.7 (1H, d, *J* = 8.5, CHO), 7.5–7.4 (2H, m, Ph), 7.4–7.2 (3H, m, Ph), 6.5 (1H, dq, *J* = 8.5 and 1.4, C=CH), 2.1 (3H, d, *J* = 1.4, CMe), and 0.5 (6H, s, $SiMe_2$). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 190.2–, 163.9+, 137.8–, 135.4+, 134.0–, 129.7–, 128.1–, 26.8– and –0.4–.

5,5-Dimethyl-3-(dimethylphenylsilyl)cyclohex-2-enone (8)

Dimethyl(phenyl)silyllithium (2.4 mL, 1 mol dm^{-3} in THF, 2.4 mmol) was added dropwise to 5,5-dimethyl-3-(dimethylamino)cyclohex-2-enone (0.37 g, 2.20 mmol) in THF (2 mL) at –78 °C, the mixture stirred at –78 °C for 1 h, and then kept at –20 °C for 1 h. Saturated aqueous sodium bicarbonate solution (5 mL) and diethyl ether (5 mL) were added. The aqueous portion was removed and the basic products removed from the organic fraction with dilute hydrochloric acid. The organic layers were dried ($MgSO_4$) and evaporated under reduced pressure to give the crude neutral products (0.65 g) as a yellow oil. Chromatography (SiO_2, CH_2Cl_2) gave the ketone (18) (0.51 g, 90%) as an oil. R_f(CH_2Cl_2) 0.44. IR ν_{max} (film, cm^{-1}): 1675 (C=O), 1589 (C=C), 1249 (SiC), and 1112 (SiC). ^{1}H NMR (250 MHz, $CDCl_3$) δ: 7.5–7.45 (2H, m, Ph), 7.4–7.35 (3H, m, Ph), 6.30 (1H, t, *J* = 1.8, C=CH), 2.24 (2H, s, CH_2CO), 2.19 (2H, d, *J* = 1.8, CH_2C=C), 0.95 (6H, s, CMe_2), and 0.43 (6H, s, $SiMe_2$). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 199.0+, 163.4+, 136.0–, 135.4–, 133.9–, 129.6–, 128.1–, 51.5+, 42.1+, 34.3+, 28.1– and –4.4–. MS *m*/*z* (EI): 259.1 (50%, MH$^+$), 243.1 (90, M – Me), and 137.0 (100) (found: M$^+$, 258.14402; $C_{16}H_{22}OSi$ requires M, 258.14398).

3-(*E*)-Dimethyl(phenyl)silylpropenal (12)

3-(*E*)-*N*,*N*-Dimethylaminopropenal (90%, 0.5 mL, 4.5 mmol) in THF (4.5 mL) was added dropwise to a solution of dimethyl(phenyl)silyllithium (0.9 mol dm^{-3} in THF, 5.5 mL, 4.95 mmol) under argon at –78 °C. The mixture was stirred for 1 h at this temperature and then at –15 °C for 1 h. Saturated aqueous sodium bicarbonate solution (5 mL) was added. The organic layer was washed with water (2 mL). The combined aqueous layers were extracted with ether (3 × 2 mL). The combined organic layers were washed with aqueous hydrochloric acid (3 N, 2 mL), brine (2 mL), dried ($MgSO_4$), and the solvent evaporated under reduced pressure. The residue was distilled to give the aldehyde (19) (0.342 g, 40%), bp 91 °C at 0.9 mmHg (1 mmHg = 133.322 Pa). R_f(CH_2Cl_2) 0.84. IR ν_{max} (film, cm^{-1}): 1693 (C=O), 1428 (C=C), 1251 (SiC), and 1117 (SiC). ^{1}H NMR (400 MHz, $CDCl_3$) δ: 9.53 (1H, d, *J* = 7.6, CHO) 7.52–7.50 (2H, m, Ph), 7.40–7.30 (4H, m, Ph and CHSi), 6.54 (1H, dd, *J* = 18.7 and 7.6, CHCO), and 0.47 (6H, s, Si*Me*$_2$). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 194.5–, 156.4–, 145.1–, 135.7+, 133.7–, 129.8–, 128.1– and –3.4–. MS *m*/*z* (EI): found: M$^+$, 190.08271; $C_{11}H_{14}OSi$ requires M, 190.08132.

4-(*E*)-[Dimethyl(phenyl)silyl]but-3-en-2-one (14)

Dimethyl(phenyl)silyllithium (0.9 mol dm^{-3} in THF, 5.25 mL, 4.7 mmol) was added dropwise to a solution of 4-*N*,*N*-dimethylaminobut-3-en-2-one (0.5 mL, 4.3 mmol) in THF (5 mL) at –78 °C under argon. The mixture was stirred at this temperature for 1 h, and then at –10 °C for 1 h. Aque-

© 2004 NRC Canada

ous sodium bicarbonate (saturated, 5 mL) and ether (5 mL) were added and the layers separated. The aqueous layer was extracted with ether (2 × 3 mL). The combined organic layers were washed with dilute hydrochloric acid (3 N, 2 × 3 mL), brine (2 mL), dried ($MgSO_4$), and the solvent evaporated off under reduced pressure. The residue was chromatographed (SiO_2, light petroleum (bp 40–60 °C)) to give the ketone (20) (0.66 g, 76%). R_f(Et_2O) 0.87. IR ν_{max} (Nujol, cm^{-1}): 1678 (C=O), 1217 ($SiMe_2$), 1115 (SiPh), 735 (Ph), and 700 (Ph). ^1H NMR (400 MHz, $CDCl_3$) δ: 7.52–7.49 (2H, m, Ph), 7.40–7.36 (3H, m, Ph), 7.11 (1H, d, *J* = 19.2, SiCH), 6.48 (1H, d, *J* = 19.2, CHCO), 2.28 (3H, s, COMe), and 0.43 (6H, s, $SiMe_2$). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 198.6+, 145.6–, 144.0–, 136.3+, 133.8–, 129.6–, 127.9–, 26.3–, –3.2–. MS *m*/*z* (ESI): 227 (100%, M^+Na) (found: MNa^+, 227.0871; $C_{12}H_{16}OSi$ requires M + Na, 227.0868).

Ethyl 3-*N*,*N*-dimethylamino-3-dimethyl(phenyl)silylpropanoate (17)

Dimethyl(phenyl)silyllithium (4.1 mL, 1 mol dm^{-3} in THF, 4.1 mmol) was added dropwise to (*E*)-ethyl 3-(dimethylamino)propenoate (0.53 g, 3.72 mmol) in THF (5 mL) at –78 °C. The mixture was stirred at –78 °C for 1 h then kept at –20 °C for 1 h. Saturated aqueous sodium bicarbonate (5 mL) and ether (5 mL) were added. The aqueous portion was removed and the basic products extracted from the organic fraction with dilute hydrochloric acid (3 N). The aqueous extract was basified (10% NaOH) to pH 12 and then extracted with ether (3 × 20 mL), dried ($MgSO_4$) and evaporated under reduced pressure to give the *ester* (1.17 g, 92%) as an oil. R_f(Et_2O) 0.95. IR ν_{max} (film, cm^{-1}): 1732 (C=O), 1249 (SiC), and 1111 (SiC), 836 (SiC), 734 (Ph), and 701 (Ph). ^1H NMR (250 MHz, $CDCl_3$) δ: 7.57–7.53 (2H, m, Ph), 7.36–7.26 (3H, m, Ph), 4.03 (2H, q, *J* = 7.2, OCH_2Me), 2.92 (1H, dd, *J* = 8.7 and 5.2, CHSiN), 2.56 (1H, dd, *J* = 15.2 and 8.8, CH_AH_BCO), 2.29 (6H, s, NMe_2), 2.26 (1H, dd, *J* = 14.7 and 5.1, CH_AH_BCO), 1.20 (3H, t, *J* 7.2, OCH_2Me), 0.42 (3H, s, $SiMe_AMe_B$), and 0.37 (3H, s, $SiMe_AMe_B$). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 174.2+, 138.2+, 134.5–, 129.1–, 127.8–, 60.3+, 53.6–, 43.9–, 30.8+, 14.1–, 2.4– and –3.32–. LSI-MS m/*z*: found: MH^+, 280.1750; $C_{15}H_{25}NO_2Si$ requires M + H, 280.1727. In various runs, the neutral fraction gave small amounts of the conjugated ester **18** (typically 9%), identical (^1H NMR, ^{13}C NMR) with the sample described below.

A sample of the ester **17** was stirred overnight in iodomethane at room temperature. This gave, on work-up, recovered starting material (86%) and ethyl (*E*)-3-(dimethylphenylsilyl)-propenoate (14%).

Ethyl 3-(*E*)-dimethy(phenyl)silylpropenoate (18)

Method A

Ethyl 3-(*E*)-*N*,*N*-dimethylaminopropenoate (3 mL, 21 mmol) was added dropwise to a solution of dimethyl(phenyl)silyllithium (0.52 mol dm^{-3} in THF, 48 mL, 25 mmol) and toluene (25 mL) under argon at –15 °C keeping the temperature below –10 °C, and then kept at –15 °C for 15 min. Methyl iodide (3.9 mL, 63 mmol) was added dropwise keeping the temperature below –5 °C. The mixture was stirred at room temperature for 20 min and quenched with water (10 mL). The organic layer was washed with water (2 × 10 mL) and the combined aqueous layers extracted with ether (4 × 5 mL). The combined organic layers were washed with aqueous hydrochloric acid (3 N, 7 mL). The aqueous layer was then extracted with ether (4 × 2 mL). The combined organic layers were washed with brine (10 mL), dried ($MgSO_4$), filtered and the solvent evaporated under reduced pressure to give the crude ester (27) (9.9 g, 96%). Chromatography of an earlier run, with some losses, gave pure ester (67%). R_f(Et_2O:light petroleum (bp 40–60 °C), 50:50) 0.85. IR ν_{max} (film, cm^{-1}): 1727 (C=O), 732 (Ph), and 700 (Ph). ^1H NMR (400 MHz, $CDCl_3$) δ: 7.60–7.50 (2H, m, Ph), 7.40–7.32 (3H, m, Ph), 7.28 (1H, d, *J* = 19, CH=), 6.28 (1H, d, *J* = 19, CH=), 4.21 (2H, q, *J* = 7.1, OCH_2), 1.29 (3H, t, *J* = 7.1, CH_2Me), and 0.43 (6H, s, $SiMe_2$). ^1H NMR (100 MHz, $CDCl_3$) δ: 165.7+, 147.3–, 136.4+, 135.4–, 133.8–, 129.5–, 128.0–, 60.6+, 14.2– and –3.2–. MS *m*/*z* (EI): found: M^+, 234.1083; $C_{13}H_{18}O_2Si$ requires 234.1076). MS *m*/*z* (ESI): 257 (100%, Mna^+) (found: MNa^+, 257.0971; $C_{13}H_{18}O_2Si$ requires M + Na, 257.0974). In one run, the basic fraction gave ethyl 2-methyl-3-dimethylamino-3-dimethyl(phenyl)silylpropanoate (**19**) (4%) as an inseparable mixture of isomers (~3:1) characterized only by the definitive ^1H NMR spectrum: (250 MHz, $CDCl_3$) δ major isomer: 7.60–7.55 (2H, m, Ph), 7.35–7.30 (3H, m, Ph), 4.08 (2H, q, *J* = 7.4, CO_2CH_2Me), 2.90–2.70 (2H, m, CHN and C*H*Me), 2.40 (6H, s, NMe_2), 1.23 (3H, t, *J* = 7.1, CO_2CH_2Me), 0.97 (3H, d, *J* = 6.8, CH*Me*), and 0.42 (6H, s, $SiMe_2$); minor isomer: 7.60–7.55 (2H, m, Ph), 7.35–7.30 (3H, m, Ph), 3.91 (1H, q, *J* = 7.1, $CO_2CH_AH_BMe$), 3.91 (1H, q, *J* = 7.1, $CO_2CH_AH_BMe$), 2.90–2.70 (2H, m, CHN and C*H*Me), 2.37 (6H, s, NMe_2), 1.20 (3H, t, *J* = 7.1, CO_2CH_2Me), 0.97 (3H, d, *J* = 6.8, CH*Me*), and 0.41 (6H, s, $SiMe_2$).

Method B

n-Butyllithium (1.45 mol dm^{-3} in hexanes, 5.4 mL, 7.9 mmol) was added slowly to a stirred solution of distilled diisopropylamine (1.1 mL, 7.9 mmol) in dry THF (3.6 mL) at 0 °C under nitrogen. After 15 min, the solution was cooled to –78 °C and ethyl (*E*)-3-(*N*,*N*-dimethylamino)-3-dimethyl(phenyl)silylpropanoate (1.0 g, 3.6 mmol) in dry THF (4.5 mL) added by cannula, and the mixture was stirred for 1 h. Methyl iodide (1.5 mL, 25 mmol) was added slowly, and the mixture stirred for 1 h at –78 °C and warmed over 20 min to 0 °C. Saturated ammonium chloride solution was added, the layers separated, and the aqueous layers extracted with ether. The combined organic layers were washed with brine, dried ($MgSO_4$), and evaporated to give ethyl (*E*)-3-dimethyl(phenyl)silylpropenoate (0.88 g, >100%), identical (TLC, ^1H NMR) with the earlier sample. Basification of the aqueous layers (10% NaOH), and extraction with ether gave the basic products (25 mg), which were a complex mixture of several compounds (^1H NMR).

Method C

The procedure of Method A was followed, but benzyl bromide was used in place of methyl iodide. The products were the unsaturated ester **18** (43%) and the conjugate addition product **17** (38%). There was no sign of the product of *C*-benzylation.

© 2004 NRC Canada

Method D

The procedure of Method A was followed, but allyl bromide was used in place of methyl iodide. The products were the unsaturated ester **18** (67%) and the conjugate addition product **17** (3%). There was no sign of the product of *C*-allylation.

(*E*)-*N*,*N*-Dimethyl-3-dimethyl(phenyl)silylpropenamide (20) and *N*,*N*-dimethyl-3-dimethylamino-3-dimethyl(phenyl)silylpropionamide (21)

n-Butyllithium (1.5 mL of a 1.7 mol dm^{-3} solution in hexanes, 2.55 mmol) was added to dimethylamine (2.2 mL of a 1.7 mol dm^{-3} solution in THF, 3.7 mmol) at –78 °C and stirred at this temperature for 1 h to give a solution of lithium dimethylamide. (*E*)-Ethyl 3-dimethyl(phenyl)silylpropenoate (0.39 g, 1.68 mmol) in THF (2.0 mL) was added dropwise at –78 °C and stirred at this temperature for 30 min and then kept at –20 °C for 30 min. Saturated aqueous sodium bicarbonate (5 mL) and ether (5 mL) were added. The aqueous portion was removed and the basic products extracted from the organic fraction with hydrochloric acid (3 N). The organic layer was dried ($MgSO_4$) and evaporated under reduced pressure to give (E)-N,N- *dimethyl*-3-*dimethyl*(*phenyl*)*silylpropenamide* (0.215 g, 55%). R_f(Et_2O) 0.25. ^{1}H NMR (250 MHz, $CDCl_3$) δ: 7.55–7.52 (2H, m, Ph), 7.39–7.29 (3H, m, Ph), 7.25 (1H, d, *J* = 18.4, SiCH=C*H*), 6.29 (1H, d, *J* = 18.4, C*H*=CH), 3.04 (6H, br s, $CONMe_2$), and 0.39 (6H, s, $SiMe_2$). The aqueous extract was basified (10% NaOH) to pH 12, and then extracted with ether (3 × 20 mL), dried ($MgSO_4$), and evaporated under reduced pressure to give N,N-*dimethyl*-3-(*dimethylamino*)-3-*dimethyl*(*phenyl*)*silylpropionamide* (0.16 g, 34%). R_f(Et_2O) 0.36. ^{1}H NMR (250 MHz, $CDCl_3$) δ: 7.62–7.54 (2H, m, Ph), 7.36–7.32 (3H, m, Ph), 2.88 (3H, s, $CONMe_AMe_B$), 2.82 (3H, s, $CONMe_AMe_B$), 2.60 (1H, dd, *J* = 13.2 and 5.4, CHNSi), 2.35 (6H, s, $CHNMe_2$), 2.28–1.95 (2H, m, $COCH_2$), 0.40 (3H, s, $SiMe_AMe_B$), and 0.38 (3H, s, $SiMe_AMe_B$).

Ethyl 3-*N*,*N*-dimethylamino-3-phenylpropionate (23)

Phenyllithium (1.8 mol dm^{-3}, 12.5 mL, 22.4 mmol) was added slowly to a solution of ethyl (*E*)-3-*N*,*N*-dimethylaminopropenoate (1.84 g, 2 mL, 14 mmol) in dry ether (17 mL) under argon at –15 °C, keeping the temperature below –5 °C. The mixture was stirred at –10 °C for 0.5 h and at room temperature for 2.5 h. The mixture was quenched with aqueous ammonium chloride solution (25 mL, saturated). The aqueous layer was extracted with ether (3 × 10 mL). The combined organic layers were washed with aqueous hydrochloric acid (3 N, 65 mL). The aqueous layer was extracted with ether (3 × 10 mL), and then basified to pH 11 with sodium hydroxide solution (10%) using universal indicator paper, and the aqueous layer was extracted with ether (3 × 50 mL). The combined organic layers were washed with brine (1 × 30 mL), dried ($MgSO_4$), and evaporated under reduced pressure to give the amine (28) as an oil (2.4 g, 76%). IR ν_{max}(film, cm^{-1}): 1735 (C=O), 1371 (CHCO) and 700 (Ph). ^{1}H NMR (400 MHz, $CDCl_3$) δ: 7.33 (2H, m, Ph), 7.27–7.23 (3H, m, Ph), 4.06 (2H, q, *J* = 7.1, OCH_2), 3.86 (1H, dd, *J* = 6.9 and 8.2, C*H*Ph), 2.95 (1H, dd, *J* = 14.8 and 6.9, CH_ACH_B), 2.69 (1H, dd, *J* = 14.8 and 8.2, $CH_AC H_B$), 2.18 (6H, s, NMe_2), and 1.11 (3H, t, *J* = 7.1, CH_2Me). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 171.7+, 138.8+, 128.4–, 128–, 127.4–, 68.7–, 66.4+, 42.2–, 38.6+, 14.0–. MS *m*/*z* (EI): 222 (100%, MH^+) (found: MH^+, 222.1493; $C_{13}H_{19}O_2N$ requires M + H, 222.1494); hydrochloride, mp 190 °C (from Me_2CO) (lit. (29) mp 192 °C).

Ethyl (2*SR*,3*RS*)-3-dimethylamino-2-methyl-3- phenylpropionate (25)

Method A

Phenyllithium (12.5 mL, 1.8 mol dm^{-3}, 22.4 mmol) was added slowly to a solution of ethyl (*E*)-*N*,*N*-dimethylaminopropenoate (2 g, 2 mL, 14 mmol) in dry ether (17 mL) under Ar at –15 °C, keeping the temperature below 0 °C. The mixture was stirred at –10 °C for 0.5 h and then kept at room temperature for 1 h. Methyl iodide (2.2 mL, 35 mmol) was added at –15 °C, and the solution kept at room temperature for 15 h. The reaction was quenched with ammonium chloride solution (40 mL). The aqueous layer was extracted with ether (3 × 10 mL). The combined organic layers were acidified with hydrochloric acid (3 N, 65 mL). The aqueous layer was washed with ether (2 × 15 mL), basified with sodium hydroxide solution (10%), and the basic product extracted with ether (4 × 40 mL). The organic layer was washed with brine, dried ($MgSO_4$), and the solvent evaporated under reduced pressure to give the amine (23) (2.52 g, 80%). R_f(Et_2O–light petroleum (bp 40–60 °C), 1:1) 0.55. IR ν_{max} (film, cm^{-1}): 1735 (C=O), 756 (Ph), and 705 (Ph). ^{13}C NMR (400 MHz, $CDCl_3$) δ: 7.36–7.26 (3H, m, Ph), 7.13–7.12 (2H, m, Ph), 4.20 (2H, qd, *J* = 1.9 and 7.1, OCH_2), 3.68 (1H, d, *J* 11.0, PhC*H*), 3.15 (1H, dq, *J* = 11.0 and 6.8, C*H*Me), 2.10 (6H, s, NMe_2), 1.28 (3H, t, *J* 7.1, CH_2Me), and 0.93 (3H, d, *J* 6.8, $CHMe$). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 175.6+, 134.0–, 129.3–, 127.9–, 127.3–, 72.3–, 60.0+, 42.1–, 41.2–, 14.6– and 14.2–. MS *m*/*z* (EI): 236 (2%, MH^+), 191 (8, MH – OEt), and 160 (100, M – Ph) (found: M^+, 236.1649; $C_{14}H_{22}NO_2$ requires M, 236.1645).

Method B

Butyllithium (1.47 mol dm^{-3} in hexane, 50 mL, 1.44 mmol) was added to a solution of diisopropylamine (0.22 mL, 1.58 mmol) in dry THF (7.20 mL) under nitrogen at –78 °C and stirred for 15 min. Ethyl 3-dimethylamino-3-phenylpropionate (0.159 g, 0.718 mmol) was added at –78 °C, and the temperature maintained for 1 h. Methyl iodide (0.11 mL, 1.8 mmol) was added, the mixture stirred at –78 °C for 30 min and then allowed to come to room temperature and kept for 1 h. The reaction was quenched with ammonium chloride solution (10 mL). The aqueous layer was extracted with ether (3 × 3 mL). The combined organic layers were washed with brine, dried ($MgSO_4$), and the solvent was evaporated off under reduced pressure. The residue was dissolved in ether (20 mL) and washed with hydrochloric acid (3 N, 20 mL). The aqueous layer was washed with ether (3 × 6 mL) and basified with sodium hydroxide solution (10%), extracted with ether (4 × 10 mL), and the combined organic layers washed with brine, dried ($MgSO_4$), and evaporated under reduced pressure to give a mixture of the esters (0.117 g, 60%) in a ratio of 10:1. R_f(Et_2O–light petroleum (bp 40–60 °C), 1:1) 0.55. ^{1}H NMR (400 MHz, $CDCl_3$) δ (signals from the major isomer, identical to those reported

© 2004 NRC Canada

above, together with signals from the minor isomer **27**): 7.36–7.26 (3H, m, Ph), 7.13–7.12 (2H, m, Ph), 3.85 (2H, q, J = 7.1, OCH_2), 3.74 (1H, d, J = 11.0, PhC*H*), 3.10 (1H, dq, J = 11.0 and 6.85, C*H*Me), 2.10 (6H, s, NMe_2), 1.35 (3H, d, J = 6.85, CH*Me*), and 0.91 (3H, t, J = 7.1, OCH_2*Me*).

Ethyl 3-*N*,*N*-dimethylaminobutanoate (24)

Methyllithium (1.54 mol dm^{-3} in Et_2O, 18.5 mL, 28.5 mmol) was added to 3-(*E*)-*N*,*N*-dimethylaminopropenoate (2 g, 14 mmol) in dry ether (17 mL) at –15 °C under nitrogen, maintaining the temperature below 0 °C. The reaction was stirred at 0 °C for 30 min and then kept at room temperature for 1 h. The reaction was quenched with ammonium chloride solution (40 mL). The aqueous layer was extracted with ether (3 × 10 mL). The combined organic layers were washed with brine, dried ($MgSO_4$), and the solvent evaporated under reduced pressure to give the amine (30) (1.14g, 51%). IR ν_{max} (film, cm^{-1}): 1732 (C=O). ^{1}H NMR (400 MHz, $CDCl_3$) δ: 4.13 (2H, q, J = 7.1, OCH_2), 3.10 (1H, ddq, J = 8.5, 5.7, and 6.6, C*H*Me), 2.53 (1H, dd, J = 14.4 and 5.7, CH_ACH_BCO), 2.23 (6H, s, NMe_2), 2.18 (1H, dd, J = 14.4 and 8.5, CH_ACH_BCO), 1.24 (3H, t, J 7.1, OCH_2*Me*), and 1.03 (3H, d, J = 6.6, CH*Me*).

Ethyl 3-*N*,*N*-dimethylamino-2-methylbutanoate (26)

Methyllithium (1.54 mol dm^{-3} in Et_2O, 37 mL, 28.5 mmol)) was added to 3-(*E*)-*N*,*N*-dimethylaminopropenoate (4 g, 28 mmol) in dry ether (34 mL) at –15 °C under nitrogen, maintaining the temperature below 0 °C. The reaction was stirred at –15 °C for 30 min and then kept at room temperature for 16 h. The mixture was cooled to –15 °C, methyl iodide (2.2 mL, 35 mmol) was added, and the mixture kept at room temperature for 16 h. The reaction was quenched with ammonium chloride solution (15 mL) and water (10 mL). The aqueous layer was extracted with ether (3 × 10 mL). The combined organic layers were washed with brine and part of the solvent evaporated under reduced pressure. The organic layer was washed with hydrochloric acid solution (3 N), and the aqueous layer was washed with ether (3 × 8 mL). The aqueous layer was basified with sodium hydroxide solution (10%), and extracted with ether (5 × 17 mL). The organic layer was washed with brine, dried ($MgSO_4$), and the solvent evaporated off to give the *amine* (1.80 g, 37%) with only one diastereoisomer detectable, presumably the 2*RS*,3*RS* isomer by analogy with the formation of the known compound **25**. IR ν_{max} (film, cm^{-1}): 1735 (C=O) and 1155 (OC). ^{1}H NMR (400 MHz, $CDCl_3$) δ: 4.15 (2H, m, OCH_2), 2.75 (1H, dq, J = 9.6 and 6.6, NC*H*Me), 2.51 (1H, dq, J = 9.6 and 6.9, COC*H*Me), 2.19 (6H, s, NMe_2), 1.09 (3H, d, J = 6.9, COCH*Me*), and 0.89 (3H, d, J = 6.6, NCH*Me*). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 176.1+, 61.8–, 59.8–, 44.6–, 40.6–, 14.2– and 8.5–. MS *m*/*z* (EI): 173 (30%, M^+), 158 (20, M – Me), 128 (13, M – EtO), 73 (39, CO_2Et), and 72 (100, Me_2N=CHMe) (found: M^+, 173.1411; $C_9H_{19}NO_2$ requires M, 173.1416).

3-(*E*)-Dimethyl(phenyl)silylpropenoic acid (28)

The crude ethyl 3-(*E*)-dimethy(phenyl)silylpropenoate (**15**) (9.9 g) in methanol (40 mL) and potassium hydroxide (10 g) in distilled water (9 mL) were stirred at room temperature for 1.5 h. The methanol and ethanol were evaporated off under reduced pressure, and the residue was taken up in distilled water (30 mL), washed with ether (4 × 10 mL), acidified to pH 1 with aqueous hydrochloric acid (3 N, ~50 mL), and extracted with ether (4 × 15 mL). The combined organic layers were washed with brine (15 mL), dried ($MgSO_4$), and the solvent evaporated off under reduced pressure to give the acid (19) (3.2 g, 75% over two steps) as an indeterminately low-melting solid. R_f(Et_2O:light petroleum (bp 40–60 °C), 50:50) 0.43. IR ν_{max} (film, cm^{-1}): 1694 (C=O), 1593 (C=C), 840 ($SiMe_2$), 732 (Ph), and 700 (Ph). ^{1}H NMR (400 MHz, $CDCl_3$) δ: 7.53–7.48 (2H, m, Ph), 7.51 (1H, d, J = 19, SiCH), 7.42–7.36 (3H, m, Ph), 6.29 (1H, d, J = 19, CHCO), and 0.45 (6H, s, $SiMe_2$). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 170.9+, 150.8–, 136.0+, 134.5–, 133.8–, 130.4–, 128.0–, and –3.6–. MS *m*/*z* (ESI): 229 (10%, MNa^+). Anal. calcd. for $C_{11}H_{14}O_2Si$ (%): C 64.0, H 6.8; found: C 64.0 H 6.9. Benzylamine salt, mp 130 to 131 °C (from MeOH). N.B. Upon addition of ether to the basic aqueous solution, the formation of three layers was often observed. The dark-coloured middle layer, presumably the carboxylate salt, not completely soluble in the aqueous layer, was combined with the lower aqueous layer, and carried through in the acidification step. This problem was worse when sodium hydroxide was used to hydrolyze the ester, and largely avoided by using potassium hydroxide.

***N*-{*E*-3-[Dimethyl(phenyl)silyl]propenoyl-(7*R*)-2,10-camphorsultam (30)**

Oxalyl chloride (2 mL, 23 mmol), was added to 3-(*E*)-dimethyl(phenyl)silylpropenoic acid (3.2 g, 16 mmol) in dichloromethane (11 mL) under nitrogen at room temperature, followed by *N*,*N*-dimethylformamide (0.55 mL), and the mixture was stirred at this temperature until the bubbling ceased (~1 h). The solvent and the excess oxalyl chloride were evaporated off under reduced pressure at 50 °C and then at 2 mmHg (1 mmHg = 133.322 Pa) for 2 h to give the acid chloride **29**. Meanwhile, *n*-butyllithium (1.6 mol L^{-1}, ~10 mL) was added to (1*R*)-(+)-2,10-camphorsultam (31) (3.23 g, 15 mmol) in THF (15 mL) under nitrogen at –78 °C, using 1-pyreneacetic acid as the indicator. This solution was added by cannula to the solution of the acid chloride **29** in THF (20 mL) at –78 °C, and the mixture stirred at room temperature for 1 h. The mixture was filtered through a silica pad, washing through with ether (50 mL). This filtrate was washed with sodium bicarbonate (30 mL), dried ($MgSO_4$), filtered and the solvent evaporated off under reduced pressure to give the crude product (5.694 g, 90%), which was crystallized from ethanol (3.5 mL) to give a first crop of the *imide* (2.23 g, 35% from the acid) as pale yellow needles, mp 90 to 91 °C (from EtOH). The mother liquors were then evaporated to give a second crop (0.14 g, 2%), mp 88.5–89.5 °C. The mother liquors were chromatographed (SiO_2, light petroleum (bp 40–60 °C) – Et_2O, 9:1) to give a third crop (0.765 g, 12%), mp 89.5–90 °C, making the total yield (3.13 g, 49%). $[\alpha]_D^{20}$ +63.1 (*c* 1.04 in $CHCl_3$). R_f(Et_2O–light petroleum (bp 40–60 °C), 50:50) 0.47. IR ν_{max}(Nujol, cm^{-1}): 1672 (C=O), 1598 (C=C), 1166 (SO_2N), and 1117 (SiPh). ^{1}H NMR (250 MHz, $CDCl_3$) δ: 7.52–7.50 (2H, m, Ph), 7.48 (1H, d, J = 18.2, SiCH), 7.36–7.35 (3H, m, Ph), 7.01 (1H, d, J = 18.2, CHCO), 3.93 (1H, dd, J = 7.0 and 5.7, NCH), 3.50 (1H, d, J = 13.8, $SO_2CH_AH_B$),

Studies directed toward the synthesis of reiswigin A: Total synthesis of (±)-*epi*-reiswigin A[1]

David I. MaGee and Dean E. Shannon

Abstract: As a testing ground for the practical application of asymmetric synthesis, (–)-reiswigin A, a potent antiviral agent, was chosen as a target for total synthesis. Initial studies were undertaken to prove the viability of the key asymmetric step, enantioselective deprotonation of an intermediate *meso*-bicyclic ketone, using a chiral lithium amide base. Enantiomeric excesses in the range of 90%–94% were routinely obtained, even on runs as large as 10 g. Unfortunately, conversion of this key enantio-enriched intermediate to the natural product proved unsuccessful. While these studies were enroute, a parallel synthesis using the racemic compound was transformed into (±)-*epi*-reiswigin A.

Key words: asymmetric deprotonation, synthesis, (±)-*epi*-reiswigin A.

Résumé : Comme méthode d'application pratique de synthèse asymétrique, la cible choisie a été la (–)-reiswigine A, un agent antiviral puissant. Les études initiales ont été entreprises pour montrer la viabilité de l'étape asymétrique clé, la déprotonation énantiosélective cétone *méso*-bicyclique intermédiaire à l'aide d'une base chirale, un amide de lithium. On a régulièrement obtenu des excès énantiomériques de l'ordre de 90 % à 94 %, même avec des lots allant jusqu'à 10 g. Malheureusement, de cet intermédiaire clé énantiomériquement enrichi en produit naturel n'a pu être réalisée. Alors que ces travaux progressaient, dans une synthèse parallèle il a été possible de transformer le produit racémique en (±)-*épi*-reiswigine A.

Mot clés : déprotonation asymétrique, synthèse, (±)-*épi*-reiswigine A.

[Traduit par la Rédaction]

Introduction

The development of methods for the preparation of carbocylic natural products with control of relative and absolute stereochemistries has been a longstanding challenge in organic synthesis. The problem of controlling the configuration of a stereogenic centre on a pendant side chain relative to the ring to which it is attached has been particularly troublesome. We report that enantioselective deprotonation can be used to help address this problem. As a testing ground for the practical application of this strategy, a biologically and structurally interesting natural product, (–)-reiswigin A (**1**) (Fig. 1), was chosen as a target for total synthesis.

Reiswigin A is a hydroazulenoid diterpene that was obtained from the deepwater marine sponge organism *Epipolasis reiswigi* collected by submersible at 330 m. Its isolation and characterization using mass spectrometry, IR, UV, and one- and two-dimensional NMR techniques was first reported by Koehn et al. (1). It was found to have intriguing biological properties, with complete inhibitory in vitro activity against herpes simplex type 1 virus (IC_{50} 2 mg) and vesicular stomatitis virus (IC_{50} 2 mg) and partial inhibition at 20 mg against murine A59 hepatitis virus. The absolute stereochemistry was not established until Snider et al. (2) developed an asymmetric synthesis of (–)-reiswigin A in 1990. A second synthesis by Kim et al. (3) in 1994 confirmed the assignments.

Retrosynthetically (Fig. 1), it was envisaged that reiswigin A could be generated from an intermediate such as **2** via some type of intramolecular condensation reaction, i.e., dithiane alkylation of **3** with a suitable electrophile derived from **2** and methylation of the thermodynamic enolate to install the angular ring methyl (C-11). Compound **2** could be conveniently generated by oxidative cleavage of the [3.2.1]-silyl enol ether produced by desymmetrization of the *meso* ketone **4** via enantioselective deprotonation (4). Bicyclic ketones like **4** are known and can be easily accessed by [4+3]-cycloaddition (5) between compounds like **5** and **6** (6).

Results and discussions

Construction of the [3.2.1]-bicyclic ketone became the first targeted intermediate. Starting with the known ketoaldehyde **8** (6), obtained as an inseparable 5:1 mixture of stereoisomers by acid catalyzed hydrolysis of [4+3]-cycloadduct **7**, Wittig reaction with acetonyltriphenylphosphorane (7) afforded, after separation of the *endo* and *exo* isomers, *E*- and *Z*-unsaturated diketone **9** in 73% combined yield (Scheme 1). The *E*- and *Z*-isomers of diketone **9** were then hydrogenated over 10% Pd–C to yield **4** in 95% yield. Selective ketalization provided ketone **10** in 81% yield. Complete

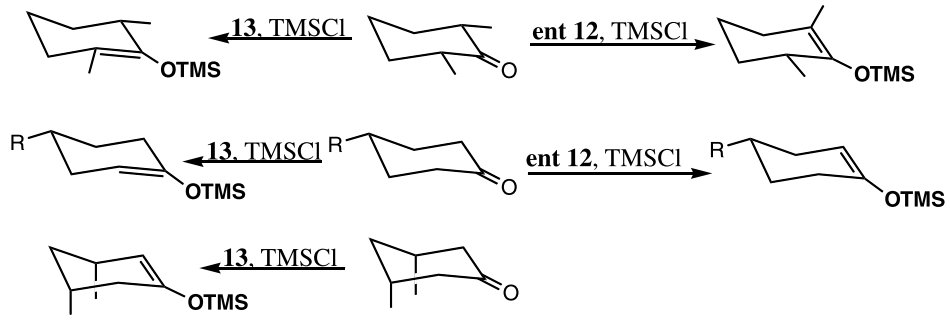
Fig. 1. Retrosynthetic analysis of (–)-reiswigin A.

Scheme 1. (*a*) 10% H_2SO_4, 1,4-dioxane, Δ; (*b*) acetonyltriphenylphosphorylidene, THF, Δ; (*c*) H_2, Pd–C, EtOAc; (*d*) ethylene glycol, $HC(OMe)_3$, pTSA, CH_2Cl_2; (*e*) (–)-**12**·hydrochloride salt, *n*-BuLi, TMSCl, THF, –30 °C to –100 °C.

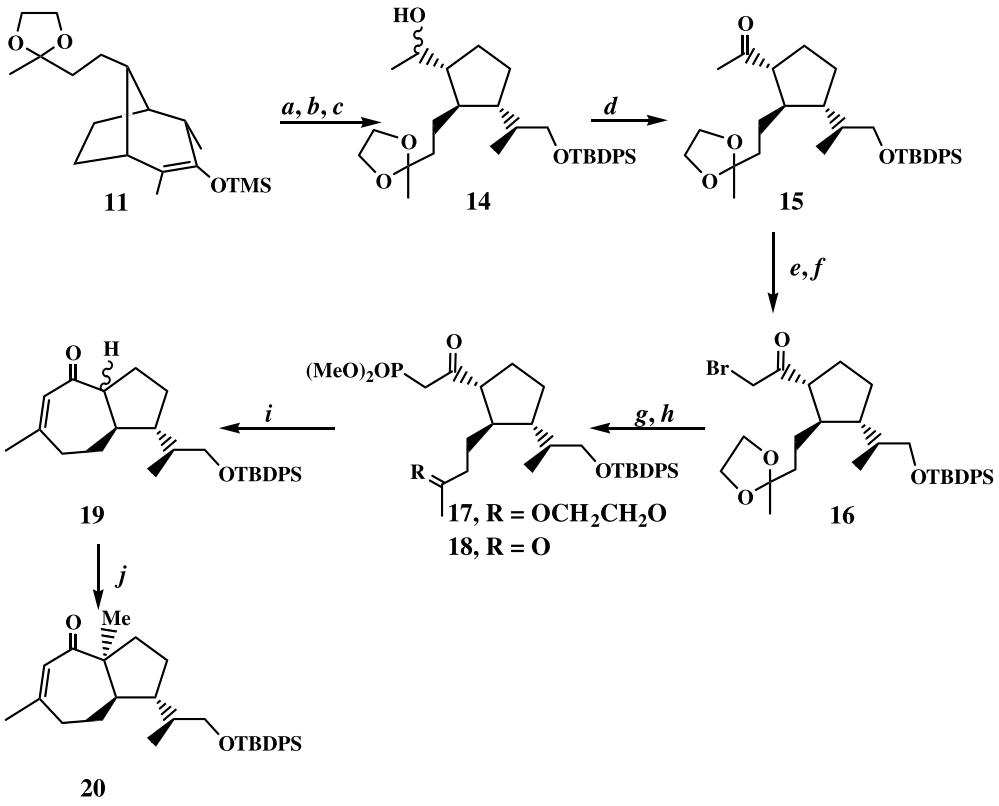
and facile control of all the relative stereochemistries made this route very appealing.

Ketone **10** was deprotonated using chiral lithium amide base (CLAMB) **12** (8) and Corey's internal quench procedure to produce silyl enol ether **11** in 91% yield and 94% ee.[3]



At this time the absolute stereochemistry and choice of base are worthy of comment. Although many studies had been undertaken on the desymmetrization of *meso* cyclic ketones, there had not been any previous studies on compounds that had substitution at all positions. However, examination of the studies on 2,6-dimethyl- (9), 3,5-dimethyl- (10), and 4-alkyl-cyclohexanones (11) suggested that Simpkins' base **12** (11)[4] and Koga's base **13** (12) give enantio-complimentary results, Fig. 2. Thus, it was believed that CLAMB **13** or CLAMB **12** would be the chiral base of choice, depending on which one was found to give the highest ee. Another consideration, however, was the fact that the synthesis of Simpkins' amine was considerably shorter and its recovery after reaction with the ketone much easier.

When CLAMBs **12** and **13** were used to deprotonate *meso*-ketone **10**, they were found to favour removal of the same enantiotopic proton (i.e., optical rotation of the resulting silyl enol ethers had the same sign). This supported the



[3] The ee was determined via oxidation of the TMS – enol ether with DMDO, followed by use of chiral shift reagents. Complete separation of the methyl doublets was observed; integration of the ^{1}H NMR signals gave the enantiomeric ratio. This value was corroborated by conversion of another intermediate into its Mosher's ester, followed by integration of the ^{19}F and ^{1}H NMR signals of the diastereoisomers.
[4] Examples found in the literature used the enantiomer of **12**.

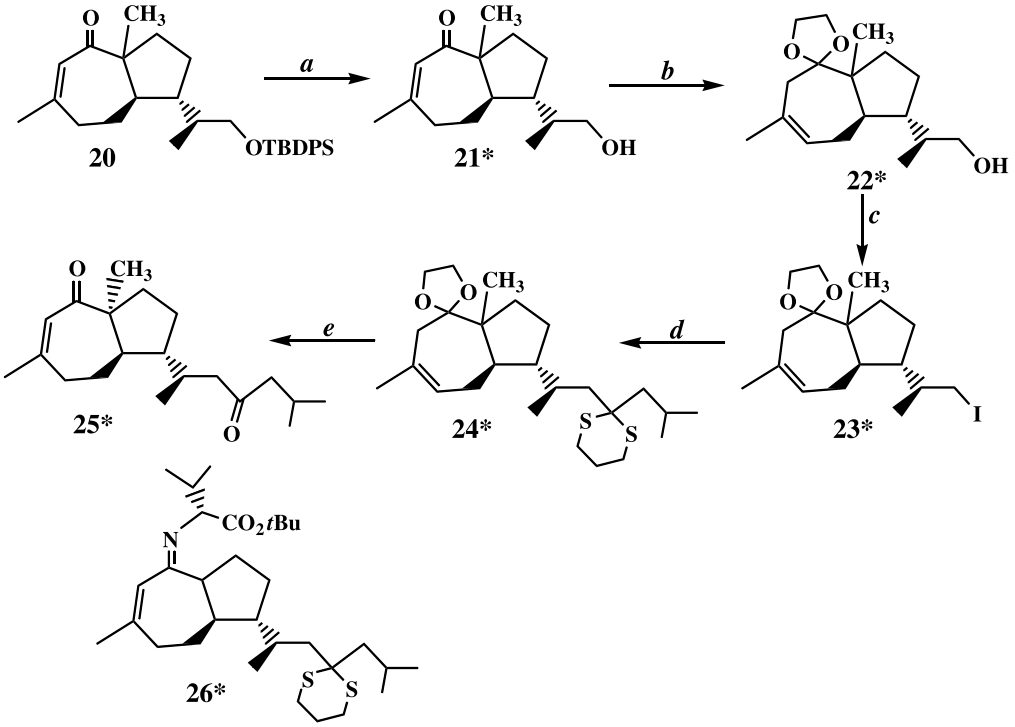
Fig. 2. Previous studies on asymmetric deprotonation of various substituted *meso*-cyclohexanones.

Scheme 2. (*a*) $NaIO_4$, $RuCl_3$, CCl_4, CH_3CN, H_2O, 15 °C; (*b*) $BH_3{\cdot}SMe_2$, THF, 0 °C; (*c*) TBDPSCI, DMAP, TEA, CH_2Cl_2; (*d*) $(COCl)_2$, DMSO, TEA, CH_2Cl_2, –60 °C; (*e*) LDA, TMSCl, THF, –78 °C; (*f*) NBS, THF, 0 °C; (*g*) $P(OMe)_3$, toluene, Δ; (*h*) PPTS, CH_3CN, Δ; (*i*) benzyltrimethylammonium methoxide, CH_3CN, 0 °C; (*j*) LDA, MeI, HMPA, THF, –78 °C to 0 °C.



above conclusion and suggested that these chiral bases act on ketone **10** in a manner similar to the above-noted substituted cyclohexanones. The degree of stereoinduction and isolated yield were found to be higher using CLAMB **12** (90%–94% ee, 91% yield) than **13** (72%–75% ee, 84% yield). The high ees demonstrated the first known successful enantioselective deprotonation of a fully substituted *meso*-cyclohexanone and verified our earlier assumption that this technique would be useful for this substrate.[5]

With enantioenriched enol ether **11** in hand, the synthesis was continued (Scheme 2). Oxidative cleavage using Sharpless (13) conditions produced a highly unstable keto-acid, which was immediately reduced to the diol with $BH_3{\cdot}SMe_2$ (14) in 64% yield over the two steps. Several attempts at selective reduction of the acid functionality gave either only the starting acid or diol. Following standard conditions, the very polar diastereomeric alcohols were transformed to their *tert*-butyldiphenylsilyl ethers **14** via selective protection of the primary alcohol (15) followed by oxidation to ketone **15** using Swern conditions (16). It was hoped that protection of the primary alcohol with a very bulky group would help direct methylation at C-1; however, it was real-

[5] As a means of determining the absolute stereochemistry, attempts were made to obtain crystals that were suitable for X-ray analysis. Unfortunately all derivatives were found to be oils or failed to deliver suitable crystals. Therefore, all structures are shown with the stereochemistry inferred from the above analysis.

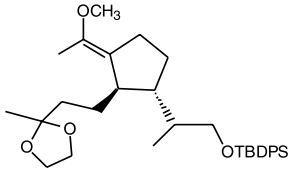
Scheme 3. (*a*) TBAF, THF; (*b*) ethylene glycol, $HC(OMe)_3$, pTSA, CH_2Cl_2; (*c*) PPh_3, I_2, imidazole, Et_2O, CH_3CN; (*d*) 2-isobutyl-1,3-dithiane, *n*-BuLi, THF, 0 °C to –90 °C; (*e*) $HgCl_2$, aq. CH_3CN, Δ.

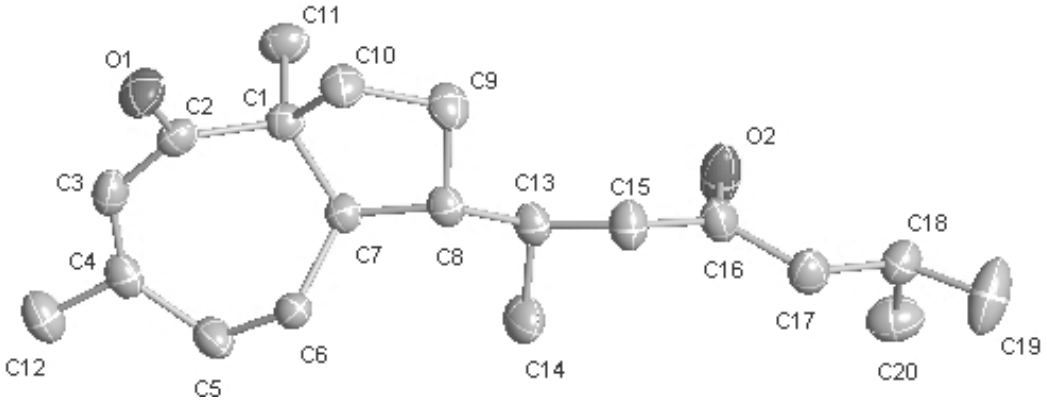


ized that 1,3-stereoinduction must override 1,2-stereoinduction in order for this to happen. Simple molecular modeling (MMFF92) on an analogue of **15** supported this speculation.[6] The six most stable conformers were found to be within 1.5 kcal of one another; of these, the four lowest energy conformations all had at least one phenyl group blocking the α-face. In fact, the first conformer that did not have this arrangement was 1.7 kcal higher in energy than the global minimum. To this end, valiant efforts were undertaken to methylate the thermodynamic enolate of ketone **15**; however, they were to no avail. The ineffectiveness of alkylation was primarily attributed to an inability to effect quantitative thermodynamic enolate formation.

To alleviate this difficulty, **15** was transformed into cycloheptenone **19** by the following sequence (Scheme 2): (*a*) bromination of the kinetic enolate with NBS (17) to give α-bromo-ketone **16**; (*b*) Arbuzov (18) reaction with trimethylphosphite to generate β-keto phosphonate **17**; (*c*) acid-catalyzed deprotection (19) of the dioxolane; and (*d*) intramolecular Horner–Emmons reaction. The intramolecular cyclization proved more difficult than expected. Following the traditional protocol of using DBU (20), very little desired product was obtained. Extended reaction times at room temperature or higher led to no improvement, while use of sodium hydride gave an unacceptable 34% yield. Fortunately, the use of benzyltrimethylammonium (BTMA) methoxide (21) led to the desired cycloheptenone in 75% yield, as an approximate 1:1 mixture of C-1 epimers, presumably because of the use of excess base. The epimeric mixture was of no concern, since the fate of that stereocenter was to be determined in the next step

Treatment of the epimeric cycloheptenones with LDA, followed by addition of MeI, gave a single alkylated product in 65% yield (Scheme 2). Extensive NMR investigation proved inconclusive in determining the structure of this alkylated product. Preliminary evidence,[7] however, suggested that C-11 was *trans* to C-5 and therefore the undesired product. It was reasoned that if the methylation were done before cyclization then perhaps the substrate would adopt a conformation that would allow for the desired stereochemical addition. Previous studies (22) on a ketone similar to compound **15** were unsuccessful in obtaining the thermodynamic methylation product. Ketophosphonate **17** (Scheme 2), on the other hand, had the potential to undergo a Weiler-type reaction (23). Treatment of **17** with NaH, followed by *n*-BuLi and then MeI gave no reaction. Furthermore, the use of lithium diethylamide as base yielded no improvement.

Although the nOe studies on compound **19** were disappointing, they were not conclusive. It was therefore decided



[6] The calculations were performed on the following structure:

[7] A small enhancement was seen in the nOesy experiment between H-11 and H-13, while no cross-peak was observed between H-11 and H-5.

Fig. 3. X-ray crystal structure of *epi*-reiswigin A.

that this compound should be carried on in an effort to finish the synthesis, thus allowing for the details of the isovaleraldehyde side-chain addition to be established. The spectra obtained from the final compound could then be compared to that of the natural product for definitive identification. This would unequivocally show whether or not the proper relative stereochemistry had been secured. In addition, owing to the lack of enantio-enriched material at this time, the synthesis was continued with racemic material.

To promote the desired substitution reaction, it was decided to protect the cyclic ketone as its ketal (Scheme 3). First, exposure of racemic ketone **19***[8] to TBAF (15) generated the primary alcohol **21***. When this alcohol was subjected to standard ketalization conditions, ketal-alcohol **22*** was obtained in only 58% yield with complete double-bond migration (24). Unexpectedly, however, a significant amount of ketal formate (30%) was produced. However, this was easily converted to the desired alcohol by exposure to aqueous base, therefore giving an overall yield of 88% for the ketalization. The alcohol was then converted to iodide **23*** in 62% yield, using conditions developed by Garegg and Samuelsson (25). When the iodide was treated with the anion of isobutyldithiane (26), dithioketal **24*** was produced in 81% yield. To achieve this yield, it was imperative to use HMPA and low temperatures; failure to do so resulted in significant elimination. Completion of the synthesis was accomplished by subjecting **24*** to $HgCl_2$ (27) in refluxing, aqueous CH_3CN to furnish **25*** in 67% yield (Scheme 3). Close examination of the ^1H and ^{13}C NMR data clearly indicated that our synthetic compound was not identical to the natural product reiswigin A. Furthermore, suitable crystals of **25** were obtained, and X-ray diffraction studies[9] unequivocally verified the earlier hypothesis; that is, the C-11 methyl group had unfortunately added incorrectly (Fig. 3), and this in fact meant that we had synthesized *epi*-reiswigin A.

Given that the configuration at C-1 was incorrect, efforts were directed towards finding a solution. It was felt that perhaps conversion of the cyclic ketone functionality into a chiral imine (2), similar to Snider's synthesis of (–)-reiswigin A, would force methylation from the desired face; see **26*** in Scheme 3. Unfortunately, when cycloheptenone **17*** was treated with *tert*-butyl L-valine ester (28) in refluxing toluene, only recovered starting material was obtained. Efforts to produce the imine using a variety of methods failed. Attempts to alter the stereochemical outcome of alkylation by using bulky chiral Lewis acids (29) also proved futile.

Given these results, it appears that it is unlikely that any nucleophilic-, electrophilic-, or radical-type additions to introduce the angular methyl group this late in the synthesis has any chance of success. Therefore, a revision of the synthetic route will have to be undertaken to account for this problem.

Summary

In conclusion, *epi*-reiswigin A was synthesized in 19 steps from the known keto-aldehyde **8** with an overall yield of 2.2%, with an average 82% yield per step. Efforts are currently underway to alter the strategy to allow for incorporation of the C-1 methyl group with the correct configuration. Although it was unfortunate that all endeavors to introduce the methyl group with the correct stereochemistry in the final stages of the synthesis failed, it was gratifying to see that the asymmetric deprotonation strategy worked as designed. Given the ease at which controlling the configuration of a stereogenic centre on a pendant side chain relative to the ring to which it is attached was accomplished, this approach should find use in the synthesis of similar cyclopentanoid compounds such as cereoplastol II (30) and albolic acid (31).

Experimental

All nonaqueous reactions were carried out in flame-dried round bottom flasks under an inert atmosphere (nitrogen or argon), unless stated otherwise. Temperatures indicated refer

[8] Racemic **19*** was generated as outlined in Schemes 1 and 2, except that deprotonation of **10** was performed with LDA.

[9] The crystallographic data for this compound has been deposited as supplementary data. Supplementary data may be purchased from the Depository of Unpublished Data, Document Delivery, CISTI, National Research Council Canada, Ottawa, ON K1A 0S2, Canada (http://www.nrc.ca/cisti/irm/unpub_e.shtml for information on ordering electronically). to an external bath. All reactions were magnetically stirred. All organic solvents were distilled and dried following known procedures (32). Reagents were purchased from various commercial suppliers and used without further purification. Analytical thin layer chromatography (TLC) was performed using Merck 60 F-254 silica gel precoated glass plates (0.25 mm). Visualization was effected by short wave UV illumination and (or) $KMnO_4$ or PMA dip, followed by development on a hot plate. Flash column chromatography was performed using Fisher silica gel (32–63 particle size). Melting points were measured on a Gallenkamp melting point apparatus with uncorrected temperatures. Infrared spectra were recorded on either a PerkinElmer 598 IR spectrometer using NaCl cells and $CHCl_3$ as solvent or on a Bruker IFS 25 IR spectrometer using KBr discs and neat sample. Peaks are reported in wavenumbers (cm^{-1}). Nuclear magnetic resonance spectra[10] were recorded on a Varian Unity-400 (400 MHz) NMR spectrometer with $CDCl_3$ as solvent (unless stated otherwise). Chemical shifts were reported in parts per million (ppm) relative to $SiMe_4$ as internal standard, and coupling constants were reported in Hz. Low-and high-resolution electron impact mass spectra were recorded on a Kratos MS50TC mass spectrometer, with fragments reported as their m^+/z ratio. Optical rotations were measured on a PerkinElmer 241 polarimeter.

Synthesis of [3.2.1]-bicycloheptanone 7

To activated (33) copper powder (14.5 g, 228 mmol) and oven-dried sodium iodide (51.3 g, 342 mmol) was added 240 mL of CH_3CN. To the stirring mixture was slowly added 2,4-dibromo-3-pentanone **6** (41.7 g, 171 mmol) in 20 mL of CH_3CN and 6-acetoxyfulvene **5** (7.8 g, 57 mmol) in 20 mL of CH_3CN, simultaneously. The reaction mixture was stirred at room temperature for 16 h and then poured into 900 mL of a 1:1:1 mixture of ether, 30% NH_4OH, and H_2O. The layers were separated, and the aqueous layer was extracted with ether (3 × 180 mL). The combined organic layers were washed with H_2O (until the aqueous layer was neutral) and brine and then dried over $MgSO_4$, filtered, and concentrated in vacuo. The crude residue was first flash filtered through a pad of silica gel (8:1 hexanes (Hex) : EtOAc as eluant) and then more rigorously purified via SiO_2 column chromatography (14:1 Hex:EtOAc as eluant) to give 9.3 g (74% yield) of enol acetate **7** (4) as a colorless oil. IR (cm^{-1}): 2920, 1740, 1705, 1375, 1080. ^{1}H NMR δ: 1.07 (3H, d, J = 7.0), 1.11 (3H, d, J = 6.8), 2.18 (3H, s), 2.53–2.64 (2H, m), 3.16 (1H, br.s), 3.57 (1H, br.s), 6.16 (1H, dd, J = 2.6, 6.0), 6.22 (1H, dd, J = 2.67 6.1), 7.02 (1H, s). ^{13}C NMR δ: 13.8, 13.9, 20.7, 45.5, 47.8, 51.3, 52.9, 121.8, 134.4, 135.2, 135.3, 168.2, 211.2. HR-EI-MS: $C_{11}H_{14}O_2$ = 178.09909 ([$M^+ - C_2H_2O$]), $C_{11}H_{14}O_2$ = 178.09938 (calcd.).

Synthesis of ketoaldehyde 8

To enol acetate **7** (9.3 g, 42 mmol) was added 180 mL of 1,4-dioxane and 180 mL of 10% H_2SO_4. The reaction mixture was stirred at reflux for 6 h; the heat source was removed, and ice-cold saturated K_2CO_3 was immediately but carefully added until the mixture was neutral. It was then extracted with ether (5×), and the combined organic extracts were washed with H_2O and brine, dried over $MgSO_4$, and filtered. Concentration under reduced pressure gave crude ketoaldehyde **8** in a 5:1 ratio as a brown oil. All spectral data were identical to that reported by Hoffmann (6). This crude mixture was used directly in the next step.

Synthesis of unsaturated diketone 9

A crude mixture of aldehyde **8** (5.9 g, 33 mmol) in 15 mL of THF was added to a mixture of acetonyltriphenylphosphorane (12.7 g, 40 mmol) and 115 mL of THF. The reaction mixture was stirred at reflux for 2 days, cooled to room temperature, diluted with ether, and filtered through a pad of Celite, and the solvent was removed under reduced pressure. Purification by SiO_2 column chromatography (5:1 Hex:EtOAc as eluant) afforded 6.1 g of the *trans*-isomer and 0.61 g of the *cis*-isomer (73% combined yield over the two steps) as colorless oils.

trans-*Isomer*

IR (cm^{-1}): 2925, 1710, 1670, 1625, 1440, 1360. ^{1}H NMR δ: 1.06 (6H, d, J = 7.0), 2.23 (3H, s), 2.57 (2H, dq, J = 2.8, 6.9), 2.72 (2H, br. s), 3.02 (1H, d, J = 7.9), 6.07 (2H, dd, J = 0.9, 0.9), 6.13 (1H, dd, J = 16.0, 0.9), 6.78 (1H, dd, J = 16.1, 7.9). ^{13}C NMR δ: 13.9 (2C), 27.0, 50.3 (2C), 51.2 (2C), 57.9, 131.3, 133.9 (2C), 147.8, 198.5, 211.3. HR-EI-MS: $C_{14}H_{18}O_2$ = 218.13026 ([$M]^+$), $C_{14}H_{18}O_2$ = 218.13068 (calcd.).

cis-*Isomer*

IR (cm^{-1}): 2930, 1710, 1695, 1610, 1450, 1350, 1170. ^{1}H NMR δ: 1.03 (6H, d, J = 6.8), 2.24 (3H, s), 2.63 (2H, d, J = 0.9), 2.65–2.69 (2H, m), 4.00 (1H, d, J = 7.7), 6.06 (2H, dd, J = 1.5, 0.9), 6.07–6.18 (2H, m). ^{13}C NMR δ: 13.8 (2C), 31.7, 50.4 (2C), 52.2 (2C), 54.6, 126.9, 134.6 (2C), 150.1, 199.0, 212.2. HR-EI-MS: $C_{14}H_{18}O_2$ = 218.13002 ([$M]^+$), $C_{14}H_{18}O_2$ = 218.13068 (calcd.).

Synthesis of diketone 4

The unsaturated *E*- and *Z*-mixture of diketone **9** (10.0 g, 45.8 mmol) in 150 mL of EtOAc was placed in a Parr bottle, followed by a catalytic amount of 10% palladium on activated carbon (~1 g). The mixture was then shaken at room temperature on a Parr hydrogenation apparatus under H_2 atmosphere (~40 psi (1 psi = 6.894 kPa)) for 30 min. Celite was then added, and the reaction mixture was filtered, and the solvent was removed in vacuo. Purification by SiO_2 column chromatography (5:1 Hex:EtOAc as eluant) afforded 9.70 g (95% yield) of diketone **4** as a colorless oil. IR (cm^{-1}): 2930, 1710, 1360. ^{1}H NMR δ: 0.96 (6H, d, J = 6.7), 1.38 (2H, d, J = 8.9), 1.52–1.62 (4H, m), 2.02 (2H, br. d, J = 4.1), 2.17–2.21 (1H, m), 2.19 (3H, s), 2.47 (2H, m), 2.54 (2H, t, J = 7.5). ^{13}C NMR δ: 12.5 (2C), 21.9 (2C), 25.1, 29.9, 42.0, 47.0 (2C), 50.5 (2C), 52.3, 208.6, 213.3. HR-EI-MS: $C_{14}H_{28}O_2$ = 222.16047 ([$M]^+$), $C_{14}H_{28}O_2$ = 222.16199 (calcd.).

Synthesis of ketoketal 10

To a catalytic amount of pTSA in 70 mL of CH_2Cl_2 was added diketone **4** (5.7 g, 25.6 mmol) in 15 mL of CH_2Cl_2. To this stirring solution was added ethylene glycol (1.7 mL,

[10]Copies of ^{1}H and ^{13}C NMR spectra of all compounds are provided as supplemental material (see footnote 9).

© 2004 NRC Canada

30.7 mmol) and 98% trimethylorthoformate (3.4 mL, 30.7 mmol). The reaction mixture was stirred at room temperature for 5 h, diluted with saturated $NaHCO_3$, and extracted with CH_2Cl_2 (2×). The combined organics were washed with H_2O and brine and dried over $MgSO_4$. The solvent was removed under reduced pressure, and the residue was purified by SiO_2 column chromatography (5:1 Hex:EtOAc as eluant) to give 5.5 g (81% yield) of ketoketal **10** as a low-melting white solid. Further purification could be accomplished by recrystallization from hexane; mp 45.0–46.1 °C. IR (cm^{-1}): 2960, 1705, 1380, 1055. ^1H NMR δ: 0.96 (6H, d, J = 6.7), 1.33 (3H, s), 1.34–1.40 (4H, m), 1.58–1.62 (2H, m), 1.71–1.78 (2H, m), 2.04 (2H, br.d, J = 4.1), 2.18 (1H, t, J = 7.4), 2.47 (2H, dq, J = 1.6, 6.6), 3.91–3.99 (4H, m). ^{13}C NMR δ: 12.6 (2C), 22.0 (2C), 23.7, 25.6, 37.7, 47.2 (2C), 50.7 (2C), 53.3, 64.6 (2C), 109.9, 213.7. HR-EI-MS: $C_{16}H_{26}O_3$ = 266.18874 ($[M]^+$), $C_{16}H_{26}O_3$ = 266.18820 (calcd.).

Synthesis of silyl enol ether 11

To a mixture of Simpkins' (+) chiral amine HCl salt **12** (4.97 g, 18.7 mmol) and 90 mL of THF cooled to –30 °C was added a 2.5 mol L^{-1} solution of *n*-BuLi in hexane (14.5 mL, 36.3 mmol), dropwise. After complete addition, the mixture was stirred for an additional 20 min at –30 °C and then for 2 h at room temperature. It was cooled to –100 °C, and 98% chlorotrimethylsilane (5.7 mL, 44.0 mmol) was added quickly, followed immediately by slow dropwise addition of ketone **10** (2.93 g, 11.0 mmol) in 20 mL of THF. The reaction mixture was stirred at –100 °C for 1 h, and then triethylamine (9.2 mL, 66.0 mmol) was added, and stirring continued at –100 °C for 10 min. Ethyl acetate was added, and the mixture was concentrated under reduced pressure. The residue was diluted with ether and filtered through a pad of Celite, and the solvent was removed in vacuo. Purification by SiO_2 column chromatography (hexane followed by 20:1 Hex:EtOAc as eluant) afforded 3.39 g (91% yield) of silyl enol ether **11** as a colorless oil in 94% enantiomeric excess. $[\alpha]_D$ –20.5 (c = 1.27, CH_2Cl_2). IR (cm^{-1}): 2965, 1670, 1380, 1110, 1060, 885. ^1H NMR δ: 0.15 (9H, s), 0.97 (3H, d, J = 7.0), 1.20–1.26 (2H, m), 1.32 (3H, s), 1.47–1.56 (1H, m), 1.53, (3H, d, J = 2.2), 1.58–1.78 (6H, m), 1.88–1.91 (2H, m), 2.48–2.52 (1H, m), 3.90–3.98 (4H, m). ^{13}C NMR δ: 0.4 (3C), 15.2, 15.9, 20.7, 23.7, 26.2, 30.1, 37.5, 42.3, 44.2, 45.4, 49.4, 64.6 (2C), 110.1, 120.3, 144.7. HR-EI-MS: $C_{19}H_{34}SiO_3$ = 338.22751 ($[M]^+$), $C_{19}H_{34}SiO_3$ = 338.22772 (calcd.).

Synthesis of racemic silyl enol ether 11*

To a mixture of diisopropylamine (2.82 mL, 20 mmol) and 50 mL of THF cooled to –78 °C was added a 2.5 mol L^{-1} solution of *n*-BuLi in hexane (8.0 mL, 20 mmol), dropwise. After complete addition, the mixture was stirred for 5 min; then 98% chlorotrimethylsilane (2.85 mL, 22.0 mmol) was added, followed immediately by dropwise addition of ketone **10** (4.79 g, 18.0 mmol) in 20 mL of THF. The reaction mixture was stirred at –78 °C for 1 h, and then triethylamine (4.6 mL, 33.0 mmol) was added. After stirring for 10 min, the mixture was concentrated under reduced pressure. The residue was diluted with ether and filtered through a pad of Celite, and the solvent was removed in vacuo. Purification by SiO_2 column chromatography (hexane followed by 20:1 Hex:EtOAc as eluant) afforded 5.89 g (97% yield) of silyl enol ether **11*** as a colorless oil.

Synthesis of diastereomeric alcohols 14

A mixture of silyl enol ether **11** (2.49 g, 7.36 mmol), sodium metaperiodate (6.30 g, 29.44 mmol), a catalytic amount of ruthenium trichloride, and 52.5 mL of CCl_4:CH_3CN:H_2O (2:2:3) was vigorously stirred at ~5 °C for 10 min. It was then diluted with CH_2Cl_2 and just enough H_2O to dissolve the precipitate. The layers were separated, and the aqueous phase was extracted with CH_2Cl_2 (3×) and dried over Na_2SO_4. The combined organics were concentrated under reduced pressure, diluted with ether, and filtered through a pad of Celite. Concentration in vacuo afforded crude ketoacid as a black oil, which was unstable and therefore was used immediately for the subsequent reaction.

To a 2.0 mol L^{-1} THF solution of borane – dimethyl sulfide complex (19.9 mL, 39.72 mmol) was added 23 mL of THF. The solution was cooled to 0 °C, followed by dropwise addition of the crude ketoacid (1.98 g, 6.62 mmol) in 12 mL of THF. After complete addition, the ice-water bath was removed, and the reaction mixture was allowed to stir at room temperature for 2 h. Excess borane was then destroyed at 0 °C by slow dropwise addition of H_2O, followed by a few drops of 5% NaOH, and then stirring at room temperature for 15 min. The cloudy mixture was concentrated in vacuo, diluted with EtOAc, dried over $MgSO_4$, and filtered, and the solvent was removed under reduced pressure. The residue was taken up in ethyl acetate and filtered through a pad of SiO_2 (EtOAc as eluant) to afford 1.35 g of a 1:1 diastereomeric mixture of diols **14** as colorless oils. The diastereoisomeric diols **14** (1.80 g, 6.28 mmol) in 10 mL of CH_2Cl_2 were added quickly to a solution of 4-dimethylaminopyridine (100 mg), triethylamine (3.5 mL, 25.1 mmol), and 98% *tert*-butylchlorodiphenylsilane (1.83 mL, 6.91 mmol) in 20 mL of CH_2Cl_2. The reaction mixture was stirred at room temperature overnight, diluted with saturated $NaHCO_3$, and extracted with CH_2Cl_2 (2×). The combined organics were washed with H_2O and brine and dried over $MgSO_4$. It was then filtered, and the solvent was removed in vacuo. The product was purified by SiO_2 chromatography (2:1 Hex:EtOAc as eluant) to give 2.63 g of the diasteromeric silyl ethers as colorless oils.

Less polar diastereoisomer

$[\alpha]_D$ +6.4 (c = 1.02, CH_2Cl_2). HR-EI-MS: $C_{28}H_{41}SiO_2$ = 437.28546 ([M^+ – $C_4H_8O_2$]), $C_{28}H_{41}SiO_2$ = 437.28760 (calcd.).

Synthesis of ketone 15

To a stirring solution of 98% oxalyl chloride (0.51 mL, 5.68 mmol) in 8 mL of CH_2Cl_2 cooled to –60 °C was added dimethyl sulfoxide (0.84 mL, 11.82 mmol) in 8 mL of CH_2Cl_2, dropwise. This mixture was stirred at –60 °C for 15 min; then the alcohol (2.48 g, 4.73 mmol) in 14 mL of CH_2Cl_2 was slowly added. After stirring at –60 °C for 30 min, triethylamine (3.3 mL, 23.6 mmol) was added; the cold bath was removed, and stirring continued at room temperature for 10 min. The cloudy solution was diluted with saturated $NaHCO_3$ and extracted with CH_2Cl_2 (2×). The combined organics were washed with H_2O and brine and dried over $MgSO_4$ and filtered, and the solvent was evaporated in vacuo. Purification by SiO_2 column chromatography (3:1 Hex:EtOAc as eluant) afforded 2.25 g (91% yield) of ketone **15** as a colorless oil. $[\alpha]_D$ +5.6 (c = 1.10, CH_2Cl_2). IR (cm^{-1}): 3070, 2920, 1960, 1890, 1820, 1700, 1465, 1370, 1235. ^{1}H NMR δ: 1.03 (3H, d, J = 6.7), 1.05 (9H, s), 1.27–1.36 (2H, m), 1.29 (3H, s), 1.54–1.70 (7H, m), 1.72–1.76 (1H, m), 2.04–2.08 (1H, m), 2.11 (3H, s), 2.55 (1H, ddd, J = 5.9, 5.9, 8.3), 3.45 (1H, dd, J = 6.6, 10.0), 3.63 (1H, dd, J = 4.4, 9.9), 3.86–3.95 (4H, m), 7.35–7.43 (6H, m), 7.65–7.67 (4H, m). ^{13}C NMR δ: 16.4, 19.3, 23.8, 26.9 (3C), 28.8, 29.1, 29.3, 30.2, 37.4, 39.0, 43.7, 48.2, 58.5, 64.6 (2C), 67.1, 109.8, 127.5 (4C), 129.5 (2C), 133.9 (2C), 135.6 (4C), 210.9. HR-EI-MS: $C_{28}H_{37}SiO_4$ = 465.24595 ([M^+ – C_4H_9]), $C_{28}H_{37}SiO_4$ = 465.24612 (calcd.).

Synthesis of bromoketone 16

To a solution of diisopropylamine (0.84 mL, 6.38 mmol) in 14 mL of THF cooled to –78 °C was added a 2.5 mol L^{-1} solution of *n*-BuLi in hexane (2.4 mL, 6.06 mmol), dropwise. The mixture was stirred at –78 °C for 15 min; then 98% TMSCl (0.83 mL, 6.38 mmol) was added quickly, followed immediately by slow addition of a solution of ketone **15** (1.67 g, 3.19 mmol) in 14 mL of THF. The reaction mixture was stirred at –78 °C for 45 min and then at room temperature for 10 min. Triethylamine (1.3 mL, 9.57 mmol) was then added; the solution was stirred for 10 min, concentrated in vacuo, diluted with ether, and filtered through a pad of Celite. Solvent removal under reduced pressure afforded crude silyl enol ether as a pale yellow oil, which was used directly for the subsequent reaction.

To a mixture of *N*-bromosuccinimide (568 mg, 3.19 mmol) in 13 mL of THF cooled to 0 °C was added the silyl enol ether (1.90 g, 3.19 mmol) in 12 mL of THF. The reaction mixture was stirred for 2 h at 0 °C, diluted with ether, washed with saturated $NaHCO_3$ and brine, and dried over $MgSO_4$. The solvent was removed in vacuo, and purification via SiO_2 column chromatography (5:1 Hex:EtOAc as eluant) afforded 1.65 g (86% yield over the two steps) of α-bromoketone **16** as a colorless oil. $[\alpha]_D$ +6.4 (c = 1.3, CH_2Cl_2). IR (cm^{-1}): 3060, 2910, 1960, 1890, 1825, 1710, 1470, 1375, 1250, 1070, 945, 705. ^{1}H NMR δ: 1.02 (3H, d, J = 6.8), 1.05 (9H, s), 1.27–1.41 (3H, m), 1.28 (3H, s), 1.55–1.72 (6H, m), 1.79–1.85 (1H, m), 2.08–2.14 (1H, m), 2.91 (1H, ddd, J = 5.8, 5.8, 8.8), 3.46 (1H, dd, J = 6.4, 10.0), 3.62 (1H, dd, J = 4.5, 10.0), 3.86–3.94 (4H, m), 3.94 (2H, d, J = 0.9), 7.35–7.43 (6H, m), 7.65–7.67 (4H, m). ^{13}C NMR δ: 16.4, 19.3, 23.8, 26.9 (3C), 29.3, 29.9, 34.2, 37.2, 38.8, 44.4, 48.2, 54.6, 64.6 (3C), 67.0, 109.8, 127.6 (4C), 129.5 (2C), 133.8, 133.9, 135.6 (4C), 203.9. HR-EI-MS: $C_{16}H_{26}O_3{}^{79}Br$ = 345.10657 ([M^+ – $C_{16}H_{19}SiO$]), $C_{16}H_{26}O_3{}^{79}Br$ = 345.10654 (calcd.).

Synthesis of ketophosphonate 17

A mixture of α-bromoketone **16** (1.73 g, 2.88 mmol) and trimethylphosphite (1.4 mL, 11.5 mmol) in 29 mL of toluene was stirred at reflux overnight. After cooling to room temperature and concentration in vacuo, the residue was purified by SiO_2 column chromatography (1:3 Hex:EtOAc to EtOAc as eluant) to give 1.60 g (88% yield) of ketophosphonate **17** as a colorless oil. $[\alpha]_D$ +11.5 (c = 1.5, CH_2Cl_2). IR (cm^{-1}): 3060, 2910, 1960, 1895, 1835, 1710, 1460, 1375, 1265, 1050. ^{1}H NMR δ: 1.02 (3H, d, J = 6.7), 1.04 (9H, s), 1.27–1.36 (2H, m), 1.29 (3H, s), 1.55–1.73 (7H, m), 1.78–1.84 (1H, m), 2.08–2.14 (1H, m), 2.82 (1H, ddd, J = 5.4, 5.4, 8.6), 3.07 (1H, dd, J = 14.0, 22.6), 3.15 (1H, dd, J = 14.0, 22.6), 3.44 (1H, dd, J = 6.5, 9.9), 3.62 (1H, dd, J = 4.4, 10.0), 3.77 (6H, d, J = 11.3), 3.86–3.95 (4H, m), 7.35–7.43 (6H, m), 7.64–7.67 (4H, m). ^{13}C NMR δ: 16.3, 19.2, 23.7, 26.8 (3C), 28.9, 29.2, 30.0, 37.1, 39.0, 40.0 (d, J = 513.2), 43.3, 48.2, 52.9 (2C, d, J = 41.4), 58.5 (d, J = 6.4), 64.5 (2C), 67.1, 109.8, 127.5 (4C), 129.4 (2C), 133.9 (2C), 135.5 (4C), 203.8 (d, J = 25.6). HR-EI-MS: $C_{30}H_{42}PSiO_7$ = 573.24459 ([M^+ – C_4H_9]), $C_{30}H_{42}PSiO_7$ = 573.24377 (calcd.).

Synthesis of diketophosphonate 18

To ketophosphonate **17** (1.00 g, 1.59 mmol) in 10 mL of 20% aqueous acetonitrile was added a catalytic amount of pyridinium *p*-toluenesulfonate. The reaction mixture was stirred at reflux for 1 h, cooled to room temperature, and concentrated in vacuo. The residue was taken up in CH_2Cl_2 and washed with a small amount of H_2O. The aqueous phase was extracted with CH_2Cl_2 (2×), and the combined organics were washed with brine, dried over $MgSO_4$, and filtered, and the solvent was removed in vacuo. Purification via SiO_2 column chromatography (EtOAc as eluant) afforded 846 mg (91% yield) of diketophosphonate **18** as a colorless oil. $[\alpha]_D$ +10.4 (c = 1.3, CH_2Cl_2). IR (cm^{-1}): 3060, 2910, 1970, 1890, 1825, 1720, 1695, 1460, 1375, 1260, 1050. ^{1}H NMR δ: 1.03 (3H, d, J = 6.7), 1.05 (9H, s), 1.29–1.36 (1H, m), 1.40–1.50 (1H, m), 1.56–1.73 (4H, m), 1.74–1.88 (2H, m), 2.11 (3H, s), 2.11–2.17 (1H, m), 2.41 (2H, t, J = 7.7), 2.81 (1H, ddd, J = 5.8, 5.8, 9.1), 3.05 (1H, dd, J = 13.9, 22.5), 3.18 (1H, dd, J = 13.9, 22.6), 3.46 (1H, dd, J = 6.3, 10.1), 3.62 (1H, dd, J = 4.5, 10.0), 3.77 (3H, d, J = 11.3), 3.78 (3H, d, J = 11.3), 7.34–7.43 (6H, m), 7.64–7.67 (4H, m). ^{13}C NMR δ: 16.2, 19.1, 26.8 (3C), 28.9 (2C), 29.4, 29.8, 38.7, 39.9 (d, J = 513.2), 41.7, 42.1, 48.1, 52.8 (d, J = 38.2), 52.9 (d, J = 38.2), 58.6 (d, J = 6.4), 66.8, 127.5 (4C), 129.4 (2C), 133.7,

133.8, 135.4 (2C), 135.5 (2C), 203.5 (d, J = 25.6), 208.6. HR-EI-MS: $C_{28}H_{38}PSiO_6$ = 529.21589 ([$M^+ - C_4H_9$]), $C_{28}H_{38}PSiO_6$ = 529.21753 (calcd.).

Synthesis of heptenone 19

To a solution of diketophosphonate **18** (820 mg, 1.40 mmol) in 14 mL of CH_3CN cooled to 0 °C was added a solution of 40% by weight benzyltrimethylammonium methoxide in MeOH (1.2 mL, 2.80 mmol). The reaction mixture was stirred at 0 °C for 15 min and then at room temperature for 1.5 h. After neutralization with saturated NH_4Cl and extraction with ether (3×), the combined organics were washed with brine, dried over $MgSO_4$, and filtered, and the solvent was removed in vacuo. Purification via SiO_2 column chromatography (29:1 Hex:EtOAc as eluant) gave 482 mg (75% yield) of cycloheptenone **19** as a separable epimeric mixture (approximately 1:1) of colorless oils.

Less polar epimer

IR (cm^{-1}): 3060, 2910, 1960, 1890, 1825, 1660, 1640, 1465, 1375, 1200, 1100. ^1H NMR δ: 0.98 (3H, d, J = 6.8), 1.05 (9H, s), 1.16–1.23 (1H, m), 1.27–1.37 (1H, m), 1.45–1.53 (1H, m), 1.59–1.67 (1H, m), 1.69–1.79 (2H, m), 1.85–1.92 (1H, m), 1.87 (3H, s), 1.94–2.03 (1H, m), 2.12 (1H, dq, J = 3.9, 10.0), 2.26–2.30 (2H, m), 3.02 (1H, dt, J = 9.9, 7.2), 3.46 (1H, dd, J = 6.9, 10.0), 3.62 (1H, dd, J = 5.4, 10.0), 5.84 (1H, s), 7.35–7.44 (6H, m), 7.65–7.67 (4H, m). ^{13}C NMR δ: 16.3, 19.2, 25.9, 26.4, 26.8 (3C), 28.1, 31.9, 35.6, 38.1, 44.4, 48.6, 57.3, 66.7, 127.6 (4C), 128.6, 129.5 (2C), 133.8 (2C), 135.5 (2C), 135.6 (2C), 155.7, 204.4. Synthesis of methylated cycloheptenone 20

To a solution of diisopropylamine (0.157 mL, 1.20 mmol) in 3 mL of THF at –50 °C was added a 2.5 mol L^{-1} solution of *n*-BuLi in hexane (0.44 mL, 1.10 mmol), dropwise. The solution was stirred at –50 °C for 15 min and then cooled to –78 °C. A solution of cycloheptenone **19** (461 mg, 1.00 mmol, mixture of epimers) in 2 mL of THF was then added slowly, and stirring continued at –78 °C for 40 min. HMPA (0.5 mL) was then added, and the reaction mixture was warmed to 0 °C, followed by addition of iodomethane (0.189 mL, 3.00 mmol). The reaction mixture was allowed to warm gradually to room temperature and to stir for 6 h; it was diluted with ether; washed with saturated NH_4Cl, H_2O (2×), and brine; dried over $MgSO_4$; and filtered, and the solvent was removed in vacuo. Purification by SiO_2 column chromatography (29:1 Hex:EtOAc as eluant) afforded 308 mg (65% yield) of **20** as a colorless oil. $[\alpha]_D$ +9.2 (c = 0.25, CH_2Cl_2). IR (cm^{-1}): 3080, 2905, 1960, 1890, 1825, 1660, 1450, 1375, 1100. ^1H NMR δ: 1.02 (3H, d, J = 6.7), 1.06 (9H, s), 1.10 (3H, s), 1.17–1.26 (1H, m), 1.36–1.56 (4H, m), 1.61–1.67 (2H, m), 1.71–1.77 (1H, m), 1.83 (3H, d, J = 0.5), 2.04 (1H, dt, J = 6.5, 12.8), 2.15–2.33 (2H, m), 3.45 (1H, dd, J = 6.7, 9.9), 3.63 (1H, dd, J = 4.7, 10.0), 5.79 (1H, s), 7.35–7.45 (6H, m), 7.65–7.67 (4H, m). ^{13}C NMR δ: 16.5, 19.3, 25.6, 26.9 (3C), 27.3, 28.0, 32.7, 34.8, 36.6, 40.1, 50.4, 51.6, 61.4, 67.1, 126.6, 127.6 (4C), 129.6 (2C), 133.9 (2C), 135.6 (4C), 151.5, 208.5. HR-EI-MS: $C_{27}H_{33}SiO_2$ = 417.22515 ([$M^+ - C_4H_9$]), $C_{27}H_{33}SiO_2$ = 417.22498 (calcd.).

Synthesis of keto-alcohol 21*

To a solution of silyl ether **20***[11] (175 mg, 0.37 mmol) in 2.5 mL of THF was added a 1 mol L^{-1} solution of tetrabutylammonium fluoride in THF (0.56 mL, 0.56 mmol). The reaction mixture was stirred at room temperature for 2 h, diluted with EtOAc, and concentrated in vacuo. The residue was filtered quickly through a pad of silica gel using 1:1 Hex:EtOAc and concentrated in vacuo. A more rigorous purification via SiO_2 column chromatography (2:1 Hex:EtOAc as eluant) gave 82 mg (94% yield) of alcohol **21** as a colorless oil. IR (cm^{-1}): 3435, 2915, 1660, 1635, 1440, 1380, 1030. ^1H NMR δ: 1.03 (3H, d, J = 6.7), 1.17 (3H, s), 1.23–1.69 (7H, m), 1.73–1.81 (2H, m), 1.85 (3H, d, J = 0.5), 2.08 (1H, dt, J = 6.5, 12.8), 2.23–2.38 (2H, m), 3.45 (1H, dd, J = 7.2, 10.4), 3.68 (1H, dd, J = 4.4, 10.5), 5.81 (1H, s). ^{13}C NMR δ: 16.2, 25.5, 27.4, 28.0, 32.9, 34.8, 36.7, 40.3, 50.5, 51.7, 61.5, 66.4, 126.6, 151.5, 208.5. HR-EI-MS: $C_{15}H_{24}O_2$ = 236.17802 ([M^+]), $C_{15}H_{24}O_2$ = 236.17763 (calcd.).

Synthesis of ketal alcohol 22*

To a solution of cycloheptenone **21** (80 mg, 0.34 mmol) in 1.7 mL of CH_2Cl_2 was added pTSA (5 mg), ethylene glycol (38 mL, 0.68 mmol), and trimethylorthoformate (76 mL, 0.68 mmol). The reaction mixture was stirred at room temperature for 5 h, then diluted with NH_4OH, and stirred for an additional 30 min. After separation of the two layers, the aqueous phase was extracted with CH_2Cl_2 (2×). The combined organics were washed with H_2O and brine, dried over $MgSO_4$, and filtered. The solvent was removed in vacuo, and the residue was purified via SiO_2 column chromatography (5:1 Hex:EtOAc as eluant) to give 83 mg (88% yield) of ketal **22*** as a colorless oil. IR (cm^{-1}): 3380, 2925, 1720, 1690, 1450, 1370, 1285. ^1H NMR δ: 1.00 (3H, d, J = 6.8), 1.08 (3H, s), 1.22–1.38 (3H, m), 1.49–1.58 (2H, m), 1.59–1.71 (2H, m), 1.66 (3H, s), 1.82–1.90 (1H, m), 1.95–2.05 (1H, m), 2.22 (1H, AB quartet, J = 18.3), 2.37–2.47 (1H, m), 2.54 (1H, AB quartet, J = 17.9), 3.40 (1H, dd, J = 7.6, 10.5), 3.66 (1H, dd, J = 4.4, 10.5), 3.87–4.06 (4H, m), 5.45–5.49 (1H, m). ^{13}C NMR δ: 16.2, 25.8, 25.9, 27.1, 30.6, 33.1, 39.7, 40.8, 49.2, 51.6, 52.6, 64.0, 65.7, 66.4, 113.6,

[11]The synthesis was continued using racemic material. Racemic keto-alcohol **21*** was synthesized following the same steps as for optically pure **21**, with the exception that the deprotonation of **10** was done with LDA and not chiral lithium amide base **12**.

© 2004 NRC Canada

123.5, 132.6. HR-EI-MS: $C_{17}H_{28}O_3$ = 280.20383 ([M]$^+$), $C_{17}H_{28}O_3$ = 280.20386 (calcd.).

Synthesis of iodoketal 23*

To a solution of triphenylphosphine (37 mg, 0.14 mmol), imidazole (15 mg, 0.22 mmol), 2 mL of Et_2O, and 1 mL of CH_3CN was added iodine (33 mg, 0.13 mmol). After stirring for 10 min at room temperature, alcohol **22*** (30 mg, 0.11 mmol) in 1 mL of Et_2O was added. The reaction mixture was stirred at room temperature for 1 h, diluted with ether, and filtered through a pad of Celite, and then the solvent was removed under reduced pressure. Purification via SiO_2 column chromatography (29:1 Hex:EtOAc as eluant) afforded 27 mg (62% yield) of iodoketal **23*** as a colorless oil. IR (cm^{-1}): 2910, 1440, 1370, 1110, 835, 670. ^{1}H NMR δ: 1.06 (3H, d, *J* = 6.5), 1.08, (3H, s), 1.19–1.25 (1H, m), 1.26–1.34 (1H, m), 1.40–1.55 (3H, m), 1.66 (3H, s), 1.73 (1H, ddd, *J* = 6.5, 6.5, 11.9), 1.86–1.94 (2H, m), 2.18 (1H, AB quartet, *J* = 18.0), 2.39–2.48 (1H, m), 2.57 (1H, AB quartet, *J* = 18.1), 3.08 (1H, dd, *J* = 7.6, 9.5), 3.34 (1H, dd, *J* = 2.8, 9.5), 3.87–4.07 (4H, m), 5.46–5.48 (1H, m). ^{13}C NMR δ: 16.2, 20.1, 25.8, 25.9, 26.9, 31.0, 32.6, 40.0, 40.8, 51.8 (2C), 52.9, 63.9, 65.8, 113.3, 123.5, 132.6. HR-EI-MS: $C_{17}H_{27}IO_2$ = 390.10505 ([M]$^+$), $C_{17}H_{27}IO_2$ = 390.10559 (calcd.).

Synthesis of dithioketal 24*

To a solution of isobutyldithiane (32 mg, 0.18 mmol) in 0.5 mL of THF at 0 °C was added a 2.5 mol L^{-1} solution of *n*-BuLi in hexane (56 mL, 0.14 mmol), dropwise. The mixture was stirred at 0 °C for 1 h; then 100 µL of HMPA was added, and the solution was cooled to –90 °C. Iodoketal **23*** (14 mg, 0.036 mmol), cooled in a separate cooling bath to –50 °C, in 0.5 mL of THF was added via cannula to the reaction mixture. After stirring at –90 °C for 30 min, 2 mL of 0.3% oxalic acid was added, and the organic product was extracted with ether (2×). The combined organics were washed with H_2O (2×) and brine, dried over $MgSO_4$, and filtered, and the solvent was removed in vacuo. Purification via SiO_2 column chromatography (hexane to 29:1 Hex:EtOAc as eluant) gave 12.6 mg (81% yield) of dithioketal **24*** as a colorless oil. IR (cm^{-1}): 2920, 1465, 1370, 1100. ^{1}H NMR δ: 1.02 (3H, d, *J* = 6.7), 1.03 (3H, d, *J* = 6.7), 1.09 (3H, s), 1.10 (3H, d, *J* = 5.6), 1.20–1.32 (2H, m), 1.44–1.49 (1H, m), 1.53–1.65 (3H, m), 1.65 (3H, s), 1.79–1.98 (8H, m), 2.12–2.19 (1H, m), 2.29 (1H, AB quartet, *J* = 18.1), 2.30–2.41 (1H, m), 2.45 (1H, AB quartet, *J* = 18.0), 2.74–2.89 (4H, m), 3.86–4.06 (4H, m), 5.48 (1H, m). ^{13}C NMR δ: 22.1, 25.1, 25.2 (2C), 25.3, 25.6, 25.9, 26.3, 26.6 (2C), 28.8, 30.5, 33.7, 40.9, 43.3, 48.4, 50.7, 52.4, 53.6, 55.1, 64.3, 65.4, 114.0, 123.4, 132.4. HR-EI-MS: $C_{25}H_{42}S_2O_2$ = 438.26058 ([M]$^+$), $C_{25}H_{42}S_2O_2$ = 438.26263 (calcd.).

Synthesis of *epi*-reiswigin A 25*

To dithioketal **24*** (4.5 mg, 0.010 mmol) in 0.5 mL of 20% aqueous CH_3CN was added mercuric chloride (6.0 mg, 0.022 mmol), and the mixture was stirred at reflux for 2.5 h. It was then allowed to cool, diluted with ether, and filtered through a pad of Celite. The filtrate was washed with saturated $NaHCO_3$, H_2O, and brine and dried over $MgSO_4$ and filtered, and the solvent was removed in vacuo. Purification by SiO_2 preparative thin layer chromatography (8:1 Hex:EtOAc as eluant) afforded 2.0 mg (67% yield) of *epi*-reiswigin A **25***, as a low-melting white solid. Recrystallization from hexane provided crystals that were suitable for X-ray analysis; mp 35.9–36.8 °C. IR (cm^{-1}): 2915, 1710, 1660, 1450, 1370. ^{1}H NMR δ: 0.92 (3H, d, *J* = 6.7), 0.93 (6H, d, *J* = 6.7), 1.17 (3H, s), 1.20–1.29 (1H, m), 1.41–1.53 (4H, m), 1.67–1.73 (1H, m), 1.77–1.82 (1H, m), 1.85 (3H, s), 2.04–2.23 (5H, m), 2.26–2.33 (3H, m), 2.41 (1H, dd, *J* = 3.3, 16.1), 5.81 (1H, s). ^{13}C NMR δ: 19.7, 22.6, 22.7, 24.5, 25.6, 26.6, 28.3, 32.3, 32.4, 34.6, 36.6, 47.3, 52.0, 52.6, 53.5, 61.3, 126.6, 151.7, 208.2, 210.7. HR-EI-MS: $C_{20}H_{32}O_2$ = 304.24017 ([M]$^+$), $C_{20}H_{32}O_2$ = 304.24023 (calcd.).

Acknowledgments

Financial support from the Natural Sciences and Engineering Research Council of Canada (NSERC) and the University of New Brunswick (UNB) is gratefully acknowledged. We also wish to thank Gilles Vautour for recording all mass spectra, Dr. Andreas Decken for solving the X-ray crystal structure, and Dr. Larry Calhoun for helpful discussions on the interpretation of some of the NMR spectra. We thank the Harbor Branch Oceanographic Institute, Ft. Pierce, Fla., U.S.A., for kindly providing us with copies of ^{1}H and ^{13}C NMR spectra for (–)-reiswigin A.

Biobleaching chemistry of laccase-mediator systems on high-lignin-content kraft pulps[1]

Fadi S. Chakar and Arthur J. Ragauskas

Abstract: A high-lignin-content softwood kraft pulp was reacted with laccase in the presence of 1-hydroxybenzotriazole (HBT), *N*-acetyl-*N*-phenylhydroxylamine (NHA), and violuric acid (VA). The biodelignification response with violuric acid was superior to both 1-hydroxybenzotriazole and *N*-acetyl-*N*-phenylhydroxylamine. NMR analysis of residual lignins isolated before and after the biobleaching treatments revealed that the latter material was highly oxidized and that the magnitude of structural changes was most pronounced with the laccase – violuric acid biobleaching system. An increase in the content of carboxylic acid groups and a decrease in methoxyl groups were noted with all three laccase-mediator systems. The oxidation biobleaching pathway is directed primarily towards noncondensed C5 phenolic lignin functional structures for all three laccase-mediated systems. The laccase – violuric acid system was also reactive towards C5-condensed phenolic lignin structures.

Key words: laccase, mediator, lignin, pulp, biobleaching, phenolics.

Résumé : On a soumis de la pulpe de papier kraft ayant un degré élevé de lignine à une réaction avec de la laccase en présence de 1-hydroxybenzotriazole (HBT), de *N*-acétyl-*N*-phénylhydroxylamine (NHA) et d'acide violurique (AV). La réponse de biodélignification avec de l'acide violurique est supérieure celle observée avec le 1-hydroxybenzotriazole ou la *N*-acétyl-*N*-phénylhydroxylamine. L'analyse RMN des lignines résiduelles isolées avant et après les traitements de bioblanchiment révèle que ces derniers matériaux sont fortement oxydés et que l'amplitude des changements structuraux est maximale avec le système de bioblanchiment avec de la laccase et de l'acide violurique. Avec chacun des systèmes utilisés, on a noté une augmentation de la teneur en groupes acides carboxyliques et une diminution en groupes méthoxyles. Pour les trois systèmes catalysés par la laccase, la voie d'oxydation de bioblanchiment est orientée principalement vers les structures fonctionnelles de la lignine phénolique en C5 non condensée. Le système de laccase – acide violurique est aussi réactif vis-à-vis des structures fonctionnelles de la lignine phénolique en C5 condensée.

Mots clés : laccase, médiateur, lignine, pulpe, bioblanchiment, phénoliques.

[Traduit par la Rédaction]

Introduction

The bleaching of kraft pulps is an integral component of manufacturing high-value products in the pulp and paper industry. Historically, removal of lignin from kraft pulps was accomplished primarily using chlorine or hypochlorous acid. However, because of environmental concerns, these chemical agents have been replaced with the use of chlorine dioxide, hydrogen peroxide, and oxygen (1). Nonetheless, each of these chemical agents has certain limitations, and research is ongoing for improved lignin removal treatments. One promising future strategy for bleaching kraft pulps involves the use of biological systems (2). Currently, several enzymatic technologies are being developed for pulp-bleaching operations, including manganese peroxidase, lignin peroxidase, and laccase (3, 4). Although all of these biobleaching technologies have advanced over the past decade, laccase biobleaching treatments have achieved some of the most notable results, yielding +50% delignification of low-lignin content kraft pulps with little oxidative degradation towards pulp carbohydrates (5–7). The high oxidative selectivity of a laccase biobleaching system towards lignin has been shown to provide distinct pulp-yield benefits when high-lignin-content kraft pulps are biodelignified (8–10).

It is now well established that laccase delignification of kraft pulps can only occur in the presence of a low-molecular-weight chemical mediator. This is commonly attributed to pulp fiber dimensions, which prevent the diffusion of laccase into the fiber to allow for lignin oxidation (11). Hence, laccase biobleaching of pulp fibers involves the oxidation of laccase by O_2, laccase oxidation of a mediator, and the diffusion of oxidized mediator into the fiber, which then oxidizes the lignin. The majority of the oxidized lignin is removed in a subsequent alkaline extraction stage.

The efficacy of a laccase-mediator system (LMS) for delignification is critically dependent on the type of mediator employed. The first reported mediator for LMS delignification was 2,2′-azinobis(3-ethylbenzothiazoline-6-sulfonate); its bleaching chemistry has been extensively Hexplored (12–14). Additional mediators have since been discovered that significantly improve the overall delignification effect of an LMS-stage (15). Many of these media-

tors contain an *N*-hydroxy functionality, and the active delignification species is believed to be the nitroxyl radical (16). The first of these *N*-hydroxy mediators was 1-hydroxybenzotriazole (HBT). It was shown that with a laccase-HBT treatment delignification could be extended by 20%–30% over a laccase-2,2′-azinobis(3-ethylbenzothiazoline-6-sulfonate) treatment (17). LMS delignification chemistry using HBT with low-lignin-content kraft pulps or lignin model compounds has been extensively studied (18–22). Essential observations with respect to residual lignin structural changes after an LMS_{HBT} treatment are that the overall phenolic component of lignin is oxidatively decreased and carboxylic acid groups are introduced. Recently, *N*-acetyl-*N*-phenylhydroxylamine (NHA) and violuric acid (23) were introduced as improved *N*-hydroxy mediators (see Fig. 1) for LMS biobleaching treatments.

The delignification chemistry of LMS, employing violuric acid, vis-a-vis lignin structural changes remains largely unknown. To provide a fundamental basis from which new LMS bleaching technologies can be further advanced, this study examines the changes in lignin structure before and after an LMS treatment using violuric acid and compares these results against NHA and HBT.

Fig. 1. Chemical structure of NHA, HBT, and VA.

Experimental

Materials and methods

1-Hydroxybenzotriazole, violuric acid, and all other reagents and solvents were purchased from Aldrich, Milwaukee, Wis., and used as received, except for *p*-dioxane and *N*-acetyl-*N*-phenylhydroxylamine. *p*-Dioxane was freshly distilled over $NaBH_4$ before use. *N*-Acetyl-*N*-phenylhydroxylamine was synthesized in accordance with the Oxley et al. procedure (23). Laccase from *Trametes villosa* was donated by Novo Nordisk Biochem. A high-lignin-content southern softwood kraft pulp was prepared from *Pinus taeda* chips at Potlatch Corporation facilities in Cloquet, Minn. The pulp was thoroughly washed, screened, centrifuged, and stored at 4 °C. Prior to an LMS treatment the pulps were Soxhlet extracted with acetone and air dried.

Pulp characterization

The lignin content of the kraft pulps in this study was determined by a $KMnO_4$ titration of the pulp in accordance with TAPPI Standard Methods T236-cm85 (24). This procedure yields a value known as the kappa number, which is an indirect measurement of the lignin content in pulp: % mass lignin = 0.15 × kappa number. The kappa number of the Soxhlet-extracted starting kraft pulp was 71.4.

Enzyme assay

Laccase activity was measured by monitoring the rate of oxidation of syringaldazine (17). One unit of activity (U) was defined as the change in absorbance at 530 nm of 0.001 min^{-1} mL^{-1} of enzyme solution in a 100 mmol/L potassium phosphate buffer (2.20 mL) and 0.216 mmol/L syringaldazine in methanol (0.30 mL, pH 6.7). The procedure was carried out at 23 °C. The activity of the laccase was 1.87×10^6 U/mL of enzyme solution.

Laccase-mediator system (LMS) general procedure

A 2000 mL capacity 316 Parr reactor equipped with a stirrer, a pressure gauge, and a heating mantle and connected to a Parr 4842 temperature controller was charged with 60.00 g of pulp and distilled water (1137 mL). The pulp slurry was heated to 45.0 °C and was maintained at this temperature throughout the duration of the treatment. VA, NHA, or HBT (0.0206 mol) was then added to the heated slurry. (Note: (% mass mediator)/(mass pulp) was 5.4% VA; 4.6% HBT; 5.2% NHA) Subsequent to mixing the pulp slurry (approx. 5 min), the pH was adjusted to 4.5 with glacial acetic acid or saturated sodium bicarbonate solution. Laccase (93 500 U, 3 mL of enzyme solution) was added, and the reactor was sealed and pressurized with oxygen to 145 psi (1 psi = 6.894 757 kPa). After a reaction time of 2 h, stirring was halted, the reactor was depressurized, and the reacted pulp was removed from the reactor and thoroughly washed with distilled water (4800 mL). The treated pulp was then subjected to either an acidic dioxane extraction (see Isolation of residual lignins section below) or an alkaline extraction followed by an acidic dioxane extraction.

Alkaline extraction

Pulp fibers (60 g) were extracted with an aqueous 0.5 mol/L NaOH (75.00 mL) solution for 1 h at 80.0 °C with mixing. The fibers were then filtered and extensively washed until the filtrate was colorless and pH neutral. Prior studies with this pulp have shown that only 4% of the lignin present in the fiber is alkaline extractable without an LMS pretreatment (25).

Control bleaching experiments (MS)

The softwood kraft pulp was treated in accordance with the laccase-mediator delignification procedure described above, except no laccase was employed. Kappa number analysis of the pulp after a mediator system (MS), employing VA, HBT, or NHA, indicated no change in lignin content of the pulp.

Isolation of residual lignins

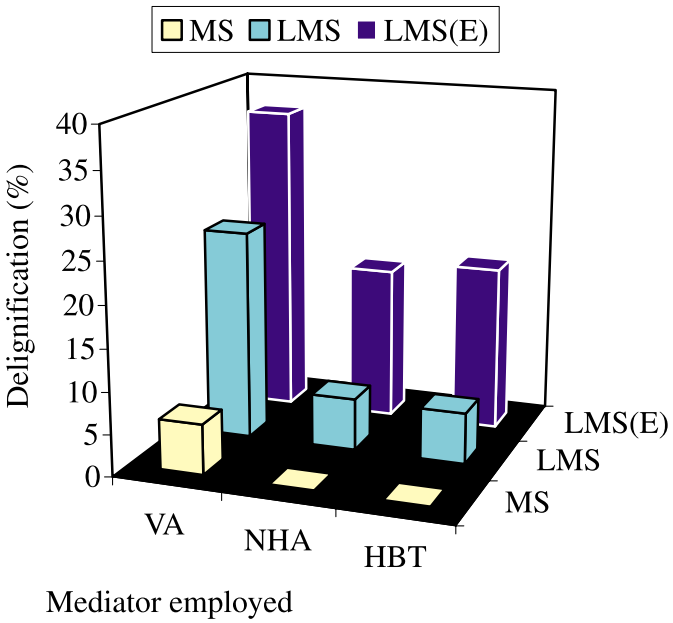
The isolation of residual lignins was carried out following standard literature methods (26, 27). In summary, a 5 L, three-necked round-bottom flask containing boiling chips

© 2004 NRC Canada

and fitted with a Friedrichs condenser was charged with 50 g of air-dried pulp. A solution of 0.10 mol/L HCl of 9:1 *p*-dioxane:water (1440 mL) was added to the pulp. The reaction mixture was refluxed for 2 h under an argon atmosphere before it was cooled and filtered through a 4 L capacity coarse fritted-glass Buchner funnel covered with filter paper. The resulting filtrate was passed through a fritted-glass Buchner funnel packed with celite to remove any pulp fines that may have been present. The lignin–water–dioxane mixture was then neutralized with an aqueous saturated solution of sodium bicarbonate to an apparent pH value of 5.0–5.5 and concentrated under reduced pressure to approximately 10% of the initial volume. Deionized water (approx. 400 mL) was added, and the mixture was concentrated again under reduced pressure to remove the last traces of *p*-dioxane. The resulting lignin–water mixture was transferred to a 1 L beaker, diluted with deionized water to a volume of approximately 800 mL, acidified to a pH of 2.0–2.5 with an aqueous 1 mol/L HCl solution, and centrifuged. The supernatant was siphoned and acidified with the addition of pH 2 aqueous HCl (200 mL). This step was repeated three times, each time reducing the volume of wash water by 30%. The lignin was then freeze dried and characterized by NMR. Lignin yields were calculated as follows: % lignin yield = ((mass of lignin isolated)/(initial kappa of brownstock) × 0.15) × 100. Lignin yields ranged from 45.4%–49.0%.

NMR characterization of residual lignins

The residual lignins isolated from the brownstock, MS, LMS, and LMS(E) were analyzed using a 400 MHz Bruker DMX spectrometer. Quantitative ^{13}C NMR spectra were acquired and analyzed in accordance with established literature methods (28). In brief, lignin (160–168 mg) was dissolved in 450 μL of DMSO-d_6, and the spectral data were acquired using an inverse gated decoupling sequence, 90° pulse angle, 14 s pulse delay, 23 000 Hz sweep, 10 000 – 12 000 transients, at 50.0 °C. The Fourier transformed spectra were integrated in accordance with reported chemical shifts for lignin functional groups. The integrals were normalized to the aromatic signals, which were assigned a value of six.



Lignin samples were also derivatized with 2-chloro-4,4,5,5-tetramethyl-1,3,2-dioxaphospholane and analyzed by ^{31}P NMR following literature methods (29). ^{31}P NMR spectra were recorded using an inverse gated decoupling sequence, 90° pulse angle, 25 s pulse delay, 13 000 Hz sweep, and 150 transients, at room temperature. NMR spectral acquisition and analysis were accomplished using Bruker's XWINNMR 2.1 software.

The lignin functional groups characterized by ^{13}C and ^{31}P NMR had standard errors of 2.0% and 1.2%, respectively. This was experimentally determined by three separate NMR measurements on three separately isolated lignin samples.

Results and discussion

Until recently, most LMS research activities have focused primarily on determining the delignification chemistry of low-lignin-content kraft pulps. Studies by Chakar and Ragauskas (25) have demonstrated that LMS delignification of high-lignin-content kraft pulps provides several distinct benefits, including improved pulp yields and simplification

Fig. 2. Extent of pulp delignification for MS, LMS, and LMS(E) treated kraft pulps using VA, NHA, and HBT as mediators, employing an SW kraft pulp with an initial kappa number 71.4.

of the overall bleaching process. This report examines the delignification chemistry of the newest generation of *N*-hydroxy mediators VA and NHA and compares these results against HBT employing a high-lignin-content softwood kraft pulp.

LMS delignification

The delignification response of LMS treatments employing NHA, HBT, and VA as mediators was established using an acetone-extracted softwood kraft pulp with an initial lignin content of 10.7% by mass. Furthermore, control experiments (MS) were carried out in accordance with the LMS procedure, except laccase was not used. The results shown in Fig. 2 clearly indicate that a treatment in the presence of a mediator and no laccase led to no delignification. This lack of activity has been reported on pulps treated solely with laccase and no mediator (4).

Based on the results summarized in Fig. 2, the delignification response of the LMS_{NHA} and LMS_{HBT} system was similar. The effectiveness of LMS_{VA} vis-à-vis delignification is evident as the LMS_{VA} system outperformed both the LMS_{HBT} and LMS_{NHA} treatments. Alkaline extraction of the LMS-treated pulps resulted in a further reduction in the lignin content of the pulp, to be expected since the alkaline conditions enhance the dissolution of oxidized lignin fragments.

Overall, the LMS treatment followed by an alkaline extraction removed 20%, 19%, and 37% lignin from the starting pulp, employing HBT, NHA, and VA as mediators, respectively. The improved efficiency of VA as a mediator for LMS is not limited to high-lignin-content pulps, as comparable results have been reported for low-lignin-content pulps (30). The biodelignification properties of LMS_{VA} have been shown to be accompanied by a darkening of the pulp due to the formation of quinoidal lignin structures (31), which can be oxidatively removed in subsequent bleaching

treatments. Several studies have attempted to correlate the biodelignification efficiency of mediators with isolated key parameters such as dissociation energies (19), radical half-lives (16), steric effects (32), and redox potentials (33). However, global correlations have been difficult to establish, although undoubtedly these parameters must be important

factors. To further define the fundamentals of LMS delignification on the kraft pulp used in this study, the structure of residual lignins before and after the biobleaching treatments was examined.

NMR analysis

Residual lignins were isolated from the starting pulp, as well as the MS, LMS, and LMS(E) treated pulps, following literature methods (20). Figure 3 summarizes the lignin functional groups examined in this study. Quantification of these functional groups in lignin was determined using ^{13}C NMR and ^{31}P NMR after lignin phosphitylation.

NMR analysis of the residual lignin isolated from the MS_{VA}, MS_{HBT}, and MS_{NHA} treated pulps (i.e., pulps treated with mediator and no laccase) indicated no changes in the content of lignin functional groups with regards to the lignin isolated from starting pulp. This result was consistent with the results of the lignin content determinations of the MS treated pulps and supports the conclusion that laccase is a critical component in the overall LMS delignification process. Figures 4 and 5 summarize the ^{13}C and ^{31}P NMR spectral data acquired for the residual lignin isolated from starting softwood kraft pulp.

Of the various structural features of lignin, changes in carboxylic acid group content are often a strong indicative sign of oxidative degradation of lignin during pulp bleaching. The acid groups content of the residual lignin from the starting pulp, LMS, and LMS(E) treated pulps is summarized in Fig. 6. These results indicate the residual lignin after an LMS stage is enriched with acid groups. The increase in acid group content of the LMS_{HBT} and LMS_{NHA} treated pulps were comparable (26%), whereas the LMS_{VA} treated pulp had a 57% greater increase in acid groups. These results mirror the observed changes in delignification of the pulps after the LMS treatments. Interestingly, the acid group content for all LMS treated pulps increased slightly after the alkaline extraction stage. Since the extraction process removes oxidized lignin fractions, it seems unlikely that this effect is due solely to an enrichment process. Previous studies by our group have shown that LMS treated pulps are enriched with quinones, and these units are known to undergo a benzylic acid rearrangement upon exposure to base, as shown in Scheme 1.

These and other reactions presumably contribute to the increase in acid groups after an LMS(E) treatment. The oxidative formation of carboxyl groups in lignin during pulp bleaching is most frequently accompanied with oxidative degradation of phenoxy groups. The phenoxy content of the starting, LMS, and LMS(E) treated pulps is presented in Figs. 7 and 8. The results in Fig. 7 clearly demonstrate that all the residual lignins isolated after LMS treatments were depleted of C5-noncondensed phenolic hydroxyls. The LMS_{NHA} treatment removed 22% of noncondensed phenoxy, LMS_{HBT} removed 16%, and LMS_{VA} removed 44% with respect to the starting pulp. The improved delignification properties of LMS_{VA} were reflected in the increased degradation of C5-noncondensed phenolics. The minor increase in

phenolics after the LMS(E) stage suggests that the alkaline extraction is not causing further oxidative damage to phenolic lignin and is perhaps enriching the remaining lignin with phenolic units.

Figure 8 summarizes the changes in C5-condensed phenoxy groups after LMS and LMS(E) treatments. In general, bleaching chemistry of kraft pulps has shown that C5-noncondensed phenolics are resistant to assorted oxidative bleaching agents, including chlorine dioxide (34) and alkaline–oxygen conditions (35).

The biobleaching chemistry of an LMS_{VA} treatment was the only LMS process capable of significantly degrading C5-condensed phenolics in the pulp. These results suggest that this mediator exhibits an enhanced oxidative capability towards phenolic units in lignin. These data also clearly demonstrate that the LMS_{HBT} or LMS_{NHA} treatments do not oxidatively degrade C5-condensed phenolics in this high-kappa kraft pulp. This result differs from our previous studies employing low-lignin-content kraft pulps (i.e., pulps having <5% lignin content) in which we observed that an $LMS_{NHA\ or\ HBT}$ treatment would degrade both C5-condensed and noncondensed phenolic units with only a slight preference for C5-noncondensed lignin phenolic units (17). On this basis, the ^{31}P NMR results suggest that the oxidative

Table 1. Ratio of substituted to unsubstituted aromatic carbons in residual lignin samples, as determined by quantitative ^{13}C NMR.

Residual lignin isolated from	Ratio of substituted to unsubstituted aromatic carbons
Brownstock	1.67:1.00
LMS_{NHA}	2.07:1.00
LMS_{HBT}	1.92:1.00
LMS_{VA}	1.97:1.00
LMS_{NHA}(E)	1.96:1.00
LMS_{HBT}(E)	1.85:1.00
LMS_{VA}(E)	1.87:1.00

Note: Chemical shift distribution for substituted aromatic lignin is δ 154–123 parts per million (ppm), and for unsubstituted aromatic carbons, the frequency range is δ 123–106 ppm.

selectivity of the LMS_{VA} system is different than that of LMS_{HBT} and LMS_{NHA}. Nonetheless, the overall trend of these LMS systems indicates that the preferred site of phenolic oxidation is directed toward C5-noncondensed units in lignin.

Along with the oxidative degradation of phenolic units in lignin, side-chain oxidation of lignin has been proposed to occur to lignin during an LMS treatment. Figure 9 reveals that the content of aliphatic hydroxyl groups in residual lignins isolated after treatment with LMS_{NHA}, LMS_{HBT}, and LMS_{VA} is decreased by 11%–28% with respect to the brownstock lignin, with the greatest change occurring when VA and NHA were employed as mediators.

The lack of reactivity of C5-condensed phenolic structures suggests that the residual lignin after the LMS treatment on the high-lignin-content kraft pulps is of a condensed character. This claim was evaluated by measuring the ratio of substituted to unsubstituted aromatic carbon groups in the ^{13}C NMR spectra of the starting, LMS, and LMS(E) treated pulps. Table 1 summarizes the results of this investigation, and the data clearly support the hypothesis that after an LMS(E) treatment of a high-kappa kraft pulp, the lignin is further enriched in condensed lignin structures.

Figure 10 summarizes the changes in β-O-4 aryl ether content of the lignin structures before and after the LMS treatment, as determined by ^{13}C NMR. The results indicate that such structures are resistant to LMS treatments. Similar trends have been reported in previous LMS studies, using HBT as the mediator, on low-lignin-content kraft pulps (17). In contrast, reports on lignin model compound studies have indicated that such structures are reactive towards LMS (14). The factors contributing to this inactivity in kraft pulps remain unknown. However, it may be possible that this behavior is related to a selectivity phenomenon. Although a dimeric β-O-aryl ether lignin model compound may respond to an LMS treatment, a different scenario may be envisioned when dealing with the actual lignin macropolymer that contains an array of functional groups. On this basis, an LMS treatment may have a higher affinity towards other functional groups than β-O-aryl ether, and in turn, this may explain the resistance observed in this study and in the literature.

The results shown in Fig. 11 reveal a decrease in the content of methoxy groups. These results are consistent with previous LMS studies on low-lignin-content kraft pulps employing ABTS and HBT as mediators (36).

Conclusions

In summary, these results established that LMS_{VA} outperforms LMS_{HBT} and LMS_{NHA} with respect to delignification

of high-lignin-content kraft pulps. The mediator effectiveness of VA was further supported by the magnitude of lignin structural changes with respect to NHA and HBT used as mediators for an LMS treatment. Spectral analyses of residual lignins isolated before and after LMS treatments, employing VA, NHA, and HBT as mediators, revealed that these mediators preferentially react with C5-noncondensed phenolic lignin structures, whereas C5-condensed phenolic lignin structures were to a large extent inactive. Nonetheless, in the presence of laccase and VA, our results indicate a decrease in the latter type of lignin functional groups, suggesting that the selectivity between these mediators may be different. These results are consistent with the studies reported by Pfaller et al. (37), which had reported that LMS_{VA} generally exhibited improved delignification over the use of either NHA or HBT.

It is now well established that HBT, VA, and NHA undergo degradation reactions during an LMS reaction (38). The results in this report further emphasis the sensitivity of an LMS stage to the structure of the mediator. The improved

© 2004 NRC Canada

delignification properties of LMS_{VA} are likely to be due, in part, to the unique properties of nitroxyl radical derived from the oxime, as opposed to a dialkyl *N*-hydroxy derivative. Further studies directed at exploring these issues are ongoing.

Acknowledgments

The authors would like to express their gratitude to Union Camp (now International Paper), Savannah, Georgia, for supplying the wood source; Potlatch Corporation for pulping the chips; and Novozyme, Inc. for furnishing the laccase needed for these studies. Portions of this work were used by F.S.C. as partial fulfillment of the requirements for the Ph.D. degree at the Institute of Paper Science and Technology. The authors also wish to acknowledge the financial assistance of the U.S. Department of Energy (DOE) (Cooperative Agreement No. DE-FC36-99GO10374) and USDA grant 98-35501-6911. However, any opinions, findings, conclusions, or recommendations expressed herein are those of the author(s) and do not necessarily reflect the views of the DOE or USDA. Finally, A.J.R. wishes to thank J.B. Stothers for his guidance, friendship, and help throughout his research career.

Total synthesis of (–)-pateamine A, a novel immunosuppressive agent from *Mycale* sp[1]

Gerald Pattenden, Douglas J. Critcher, and Modesto Remuiñán

Abstract: A convergent synthesis of the unique thiazole-containing polyene bis-lactone pateamine A (**1**) isolated from the marine sponge *Mycale* sp is described. The synthesis features the ubiquitous Stille sp^2–sp^2 coupling reaction to elaborate the *E*,*Z*-diene macrolide core **23** and the all-*E* polyenamine side chain in the natural product. It also highlights the scope for enantiopure sulfinimine intermediates in the synthesis of chiral β-amino ester moieties in complex structures.

Key words: pateamine A, immunosuppressive agent from marine sponge *Mycale* sp, total synthesis, novel 19-membered bis-lactone, thiazole metabolite, polyenamine, Stille reaction, sulfinimines, chiral β-amino esters.

Résumé : On décrit une synthèse convergente de la patéamine A (**1**), une bis-lactone polyénique unique contenant un noyau thiazole isolée de l'éponge marine de l'espèce *Mycale*. La synthèse comprend une réaction omniprésente de couplage sp^2–sp^2 de Stille pour élaborer le macrolide *E*,*Z*-diénique fondamental **23** et la chaîne latérale polyénamine complètement *E* du produit naturel. Elle comporte aussi le moyen d'obtenir des intermédiaires sulfinimines énantiopurs dans la synthèse des portions esters β-aminés chiraux des structures complexes.

Mots clés : patéamine A, agent immunosuppressant de l'éponge marine de l'espèce *Mycale*, synthèse totale, nouvelle bis-lactone à 19 chaînons, métabolite thiazole, polyénamine, réaction de Stille, sulfinimines, esters β-aminés chiraux.

[Traduit par la Rédaction]

Introduction

Pateamine A (**1**) is a novel thiazole-containing 19-membered bis-lactone isolated by Munro and co-workers (1) from the marine sponge *Mycale* sp located off the coast of New Zealand. The natural product exhibits antifungal activity and also shows potent immunosuppresant properties with low cytotoxicity.[3] The bis-lactone core in pateamine accommodates an *E*,*Z*-1,3-diene unit together with a β-amino ester residue, and is substituted by an unusual polyenamine side chain. The absolute stereochemistry for pateamine A followed from degradation studies, in concert with synthetic work and NMR experiments (2). This stereochemical assignment was corroborated by a total synthesis of (–)-pateamine A presented by Romo et al. in 1998 (3). In an earlier publication from our laboratory (4) we layed the foundation for a total synthesis of pateamine A by describing a synthesis of the bis-lactone portion **2**, corresponding to deammoniated pateamine, based on an intramolecuar sp^2–sp^2 Stille coupling reaction (5, 6) to install the *E*,*Z*-1,3-diene unit as a key stratagem (7). To develop this strategy to pateamine A itself, we required a procedure for introducing the chiral β-amino ester moiety into the macrolide core, and methodology to elaborate the all-*E*-trienamine side chain in the natural product. In this paper we describe solutions to these issues, which have culminated in a new total synthesis of (–)- pateamine A (8).

Received 9 September 2003. Published on the NRC Research Press Web site at http://canjchem.nrc.ca on 20 February 2004.

This paper is dedicated to Professor E. Piers, who pioneered the development and application of the intramolecular Stille reaction in small ring synthesis, and made seminal contributions in target natural product synthesis.

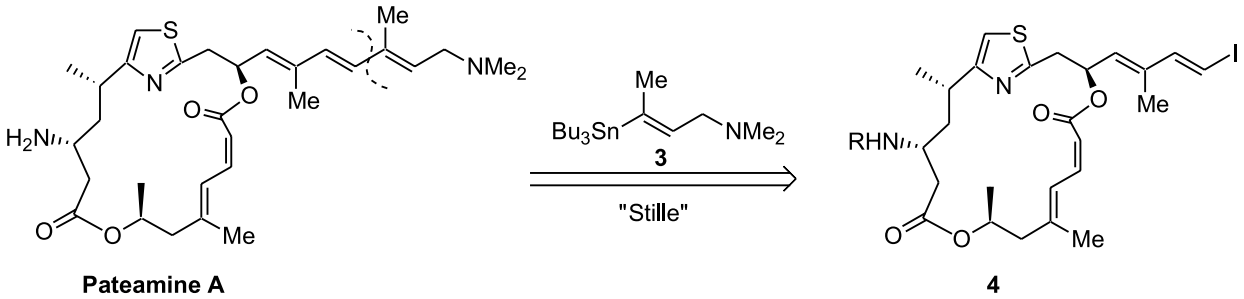
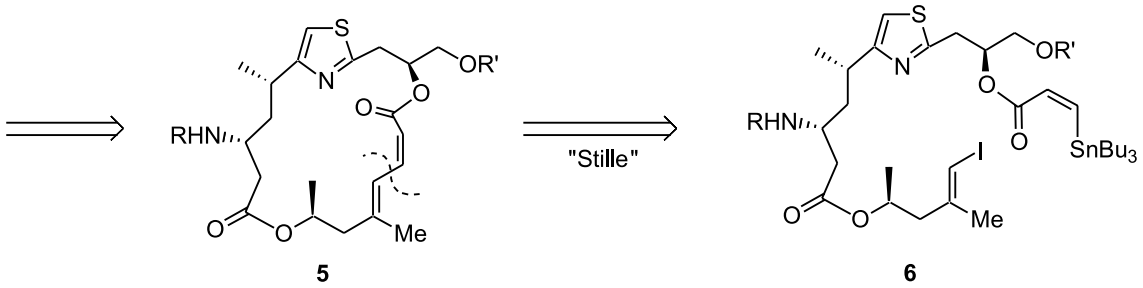
Synthetic strategy

Our overall synthetic strategy to pateamine A (**1**) was based on utilization of the ubiquitous Stille sp^2–sp^2 coupling reaction, firstly in an *intramolecular* manner to elaborate the *E*,*Z*-diene macrolide core **5** from the vinyl stannane-vinyl iodide precursor **6**, and secondly to produce the all-*E* polyene side chain using an *intermolecular* reaction between the vinyl iodide **4** and the dimethylaminostannane **3**. In turn, we planned to synthesize the stannane-iodide **6** from the 2,4-disubstituted thiazolepropanal **7** using nucleophilic addition of an appropriate carbanion to the corresponding chiral sulfinimine, as a key step (Scheme 1).



Synthesis of the thiazolepropanal 7



The thiazolepropanal intermediate **7** was smoothly synthesized starting from the chiral pool compounds dimethyl *L*-malate **8** and *S*-methyl 3-hydroxy-2-methylpropionate **13a**, and utilizing a modified Hantzch reaction between the thioamide **12** and the α-bromoketone **15b** as a key step. Thus, starting with commercially available dimethyl *L*-malate, the thioamide **12** was first elaborated in six straightforward steps

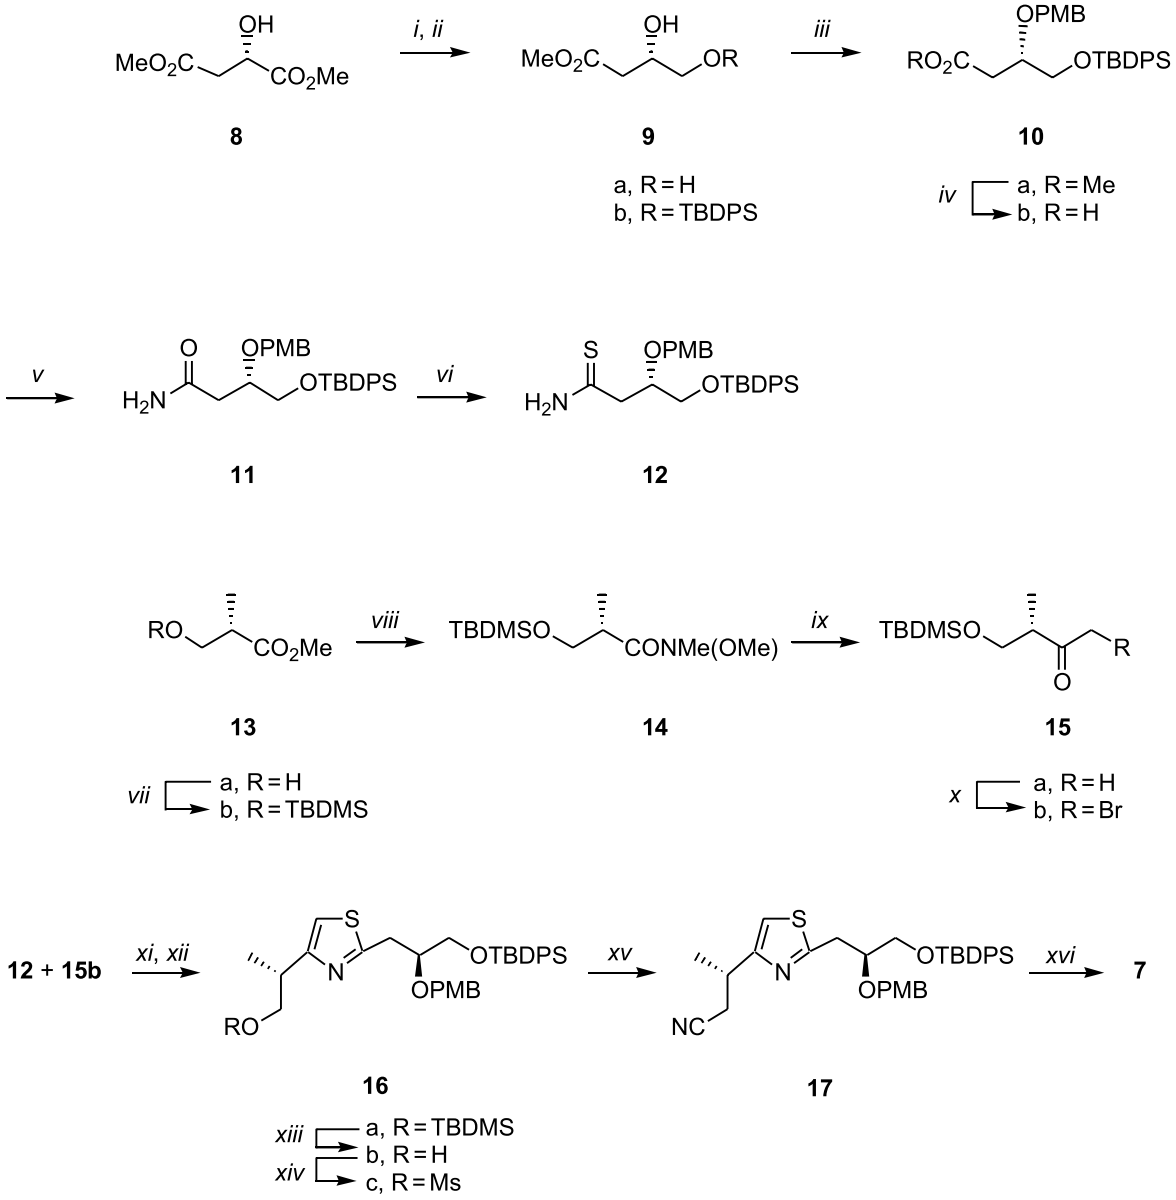
Scheme 1. Retrosynthesis.



involving: (*i*) reduction using BH_3SMe_2–$NaBH_4$ and protection of the resulting primary alcohol **9a** as its TBDPS ether **9b**; (*ii*) protection of the secondary alcohol group in **9b** as its PMB ether **10a** followed by saponification of the resulting methyl ester to the corresponding carboxylic acid **10b**; and (*iii*) conversion of the acid **10b** into the thioamide **12** via the amide **11**. In a similar straightforward manner, commercially available *S*-methyl 3-hydroxy-2-methylpropionate **13a** was elaborated to the α-bromoketone **15b** following: (*i*) protection as the TBDMS ether **13b** followed by conversion into the Weinreb amide **14**; and (*ii*) addition of methylmagnesium bromide to **14**, and bromination of the resulting methyl ketone **15a** via its TMS enol ether using bromine at –78 °C. A modified Hantzsch reaction (9) between **12** and **15b** in the presence of 2,6-lutidine, followed by dehydration of the thiazoline intermediate using TFAA, then gave the 2,4-disubstituted thiazole **16a** in 64% overall yield. The thiazolepropanal intermediate **7** was then elaborated from the TBDMS ether **16a** in four straightforward steps using a one-carbon homologation and proceding via the alcohol **16b**, the mesylate **16c** and the nitrile **17** (Scheme 2).

Synthesis of the vinyl stannane – vinyl iodide 22 and elaboration to the macrolide 23

Our next objective was to elaborate the substituted vinyl iodide intermediate **22** from the thiazolepropanal **7**, by addition of the enolate produced from the chiral acetate **19** to the enantiopure sulfinimine **18** derived from **7** as a key and cru-

Scheme 2. Reagents and conditions: (*i*) $BH_3{\cdot}SMe_2$, $NaBH_4$, THF, 92%; (*ii*) TBDPSCl, Et_3N, DMAP, DCM, rt, 12 h, 93%; (*iii*) $PMBOC(=NH)CCl_3$, CSA, DCM, rt, 3 days, 76%; (*iv*) LiOH, H_2O–THF, rt, 12 h, 90%; (*v*) $ClCO_2Et$, Et_3N, NH_4OH, rt, 30 min, 93%; (*vi*) Lawesson's reagent, THF, rt, 30 min, 99%; (*vii*) TBDMSCl, Et_3N, DMAP, DCM, rt, 24 h, 95%; (*viii*) HNMeOMe·HCl, $AlMe_3$, DCM, Δ, 5 h, 61%; (*ix*) 1.5 equiv. MeMgBr, THF, 0 °C, 1 h, 94%; (*x*) LiHMDS, –78 °C, TMSCl, Br_2, 86%; (*xi*) 2,6-lutidine, DCM, rt, 12 h; (*xii*) $(CF_3CO)_2O$, Py, DCM, –30 °C, 30 min, 64% (two steps); (*xiii*) AcOH–THF–H_2O, rt, 12 h, 92%; (*xiv*) MsCl, Et_3N, DCM, 0 °C, 1 h; (*xv*) NaCN, DMSO, 60 °C, 6 h, 77% (two steps); (*xvi*) DIBAL, toluene, 0 °C, 2 h, 85%.

cial step. Thus, following a procedure described by Davis et al. (10), treatment of the thiazolepropanal **7** with (*R*)-*p*-toluenesulfinamide in the presence of titanium(IV) ethoxide at 50 °C first led to the chiral sulfinimine **18** in 64% yield. Much to our pleasure deprotonation of the ester **19** derived from the known corresponding chiral alcohol (11), using LiHMDS at –78 °C, followed by addition of the sulfinimine **18** to the resulting enolate, gave the substituted β-amino ester **20a** in 63% yield and approximately 90% diastereselectivity. The ρ-toluenesulfinyl group in **20a** was cleaved by treatment with TFA–methanol to provide the (3*R*)-amine **20b** whose configuration was established unambiguously using the NMR spectroscopic procedure reported by Riguera and co-workers (12), in concert with comparison of data with the corresponding (3*S*)-amine synthesized contemporaneously. We commend highly this straightforward and reproducible procedure for synthesizing reasonably complex chiral β-amino esters via sulfinimines, such as **18**. Hitherto, we had examined the scope for adding chiral amine nucleophiles to Michael acceptors, similar to **2**, and for chiral alcohol and azide precursors in preparing chiral β-amino ester precursors similar to **20**, but neither of these procedures gave encouraging results (Scheme 3). In their total synthesis of (–)-pateamine A, Romo et al. (3) used the ring open-

© 2004 NRC Canada

ing of a chiral β-lactam intermediate by an hydroxyl nucleophile, as a stratagem to elaborate the β-amino macrolide portion in the natural product.

With the chiral amine **20b** in hand, we were now poised to elaborate the key vinyl iodide – vinyl stannane intermediate **22** and study the critical intramolecular Stille reaction leading to the macrolide core **23** in pateamine A. Thus, the amine **20b** was first protected as the corresponding trichloro-*tert*-butoxycarbamate (TcBOC) **21a** and the PMB ether group was then cleaved leading to the secondary alcohol **21b**. Esterification of *Z*-3-tri-*n*-butylstannylpropenoic acid (13) with the alcohol **21b**, under Yamaguchi conditions (14), then led to the Stille reaction precursor **22**. Gratifyingly, when the stannane–iodide **22** was treated under Farina's conditions (15) with Ph_3As–Pd(O) dibenzylideneacetone in DMF at 55 °C for 1 h, it underwent smooth intramolecular sp^2–sp^2 coupling with complete preservation of the *E*- and *Z*-stereochemistries of the reacting partners and produced the *Z*,*E*-diene macrolide **23** in 65% yield (7, 16) (Scheme 4).

Introduction of the all-*E*-trienamine side chain and completion of (–)-pateamine A

We examined a range of olefination and coupling methods starting from the substituted bis-lactone **23** to install the all-*E* trienamine side chain in pateamine A, and ultimately elected to use a second (intermolecular) Stille reaction between the vinyl stannane **3** and the vinyl iododiene **26** derived from **23** as the key step. Thus, deprotection of the silyl ether group in **23**, followed by oxidation of the resulting alcohol **24a**, using a pyridine-buffered Dess–Martin periodinane procedure first gave the aldehyde **24b**. A Wittig reaction between **24b** and 2-(triphenylphosphoranylidene) propionaldehyde next gave the homologated *E*-unsaturated aldehyde **25**, which was then converted into the vinyl iodide **26** using a Takai reaction (17). A Stille coupling reaction between the vinyl iododiene **26** and the dimethylamino-substituted vinyl stannane **3**, using $Pd(CH_3CN)_2Cl_2$ in DMF at room temperature (18) then led to TcBOC-protected pateamine A (**27**) in an unoptimized yield of 36%. Finally, deprotection of **27** using a Cd–Pb couple in aq. NH_4OAc (19) gave (–)-pateamine A (**1**), which showed NMR spectroscopic and chiroptical data that were identical to those reported for the natural product isolated from *Mycale* sp.

In conclusion, a convergent total synthesis of the novel immunosuppressive agent, pateamine A, from the sponge *Mycale* sp has been achieved. The synthesis is concise, and features the Stille sp^2–sp^2 coupling reaction to elaborate key stereodefined polyene units in this novel structure.

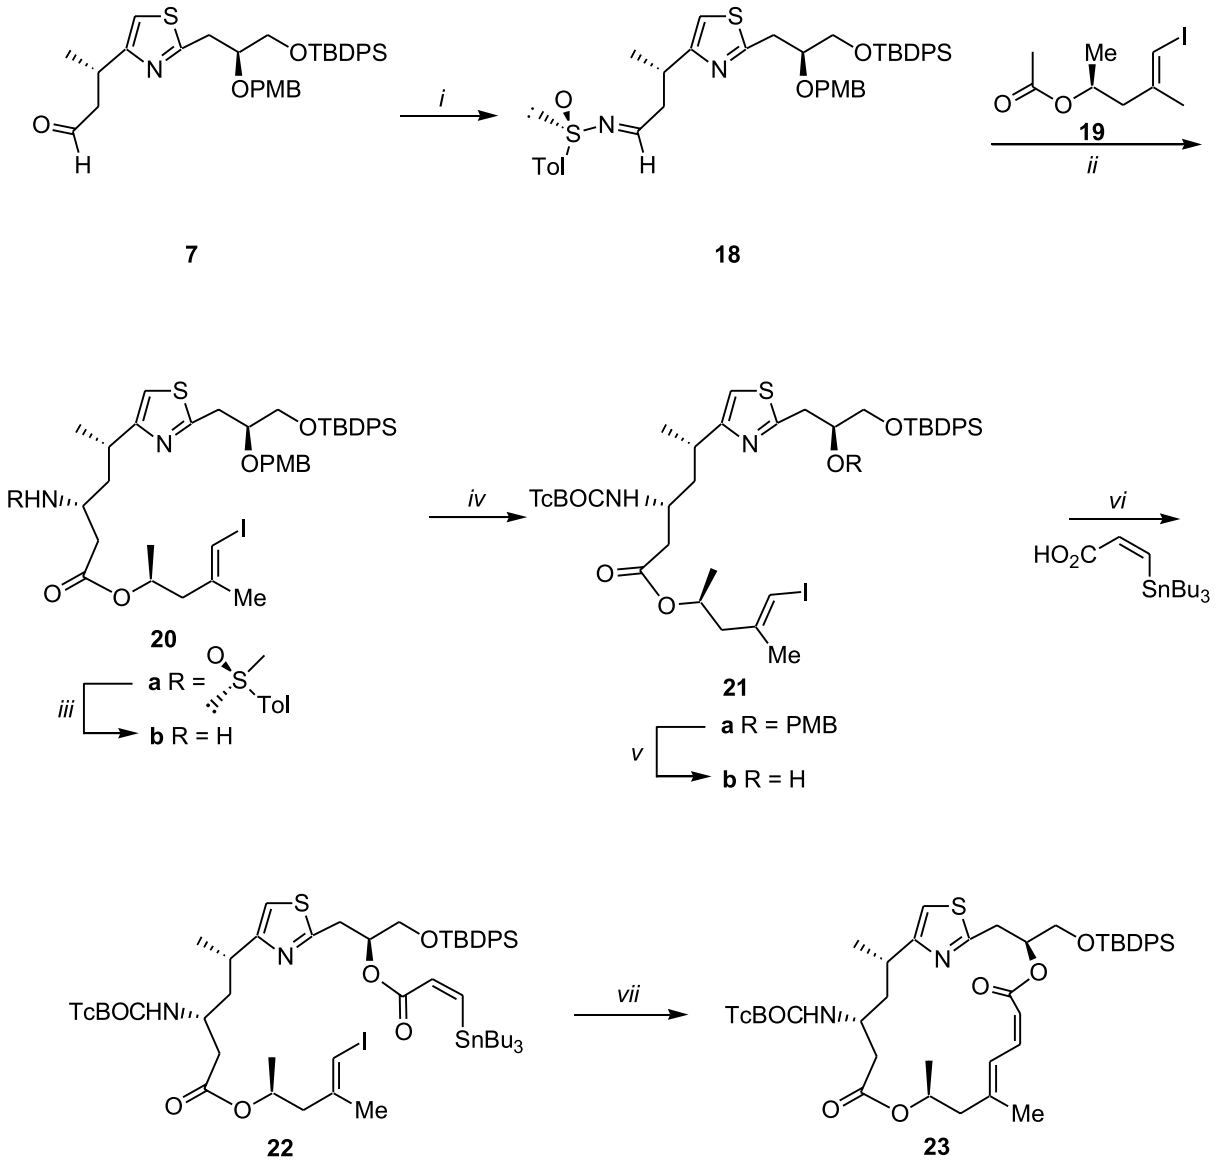
For general experimental details see ref. 20.

(*S*)-4-(*tert*-Butyldiphenylsilanyloxy)-3-(4-methoxybenzyloxy)butyric acid methyl ester (10a)



Camphorsulfonic acid (1.75 g, 7.5 mmol) was added in one portion to a stirred solution of the alcohol **9b** (21) (28 g, 75.26 mmol) and *p*-methoxybenzyltrichloroacetimidate (42.5 g, 150 mmol) in CH_2Cl_2 (250 mL) at 0 °C. The mixture was allowed to warm to room temperature, and stirred at this temperature for 3 days. The solvent was removed in vacuo, and the residue was dissolved in a mixture of CH_2Cl_2 (100 mL) and petroleum ether (bp 40–60 °C) (200 mL). The precipitated solids were filtered off and the filtrate was then concentrated in vacuo. The residue was purified by flash chromatography eluting with ethyl acetate:petroleum ether (bp 40–60 °C, 1:9 → 1:7) to give the *protected alcohol* (28.1 g, 76%) as a colourless oil. $[\alpha]_D^{24}$ –15.7 (*c* 1.35 in $CHCl_3$). IR ν_{max} (cm^{-1}, film): 2931, 1738, 1513, 1248, 1112, 703. ^1H NMR (360 MHz, $CDCl_3$) δ: 7.69–7.65 (4H, m, ArH), 7.46–7.36 (6H, m, ArH), 7.19 (2H, d, *J* = 8.7, MeOArH), 6.84 (2H, d, *J* = 8.7, MeOArH), 4.53 (1H, d, *J* = 11.1, CH_2Ar), 4.47 (1 H, d, *J* = 11.1, CH_2Ar), 4.04–4.00 (1H, m, CHOPMB), 3.80 (3H, s, OCH_3), 3.74 (1H, dd, *J* 5.2 and 10.5, CH_2OTPS), 3.67 (3H, s, OCH_3), 3.63 (1H, dd, *J* = 5.7 and 10.5, CH_2OTPS), 2.70 (1H, dd, *J* = 4.6 and 15.6, CH_2CO_2Me), 2.57 (1H, dd, *J* = 8.3 and 15.6, CH_2CO_2Me), 1.06 (9H, s, $((CH_3)_3CSi$). ^{13}C NMR (90.6 MHz, $CDCl_3$) δ: 171.8, 158.8, 135.2, 132.9, 132.8, 131.5, 130.2, 129.3, 129.0, 127.4, 113.4, 113.3, 75.9, 71.8, 64.8, 54.8, 51.2, 37.1, 26.4, 18.8. MS *m/z* (ES): 515.2203 (M + Na, $C_{29}H_{36}O_5SiNa$ requires 515.2230).

(*S*)-4-(*tert*-Butyldiphenylsilanyloxy)-3-(4-methoxybenzyloxy)butyramide (11)

A solution of lithium hydroxide (1.5 mol L^{-1}) in water (113 mL) was added to a solution of the ester **10a** (28 g, 56.9 mmol) in THF (250 mL) and MeOH (2 mL). The biphasic mixture was stirred at room temperature for 48 h and then acidified carefully with 2 N HCl (aq). The separated aqueous layer was extracted with ethyl acetate (3 × 200 mL) and the combined organic extracts were then dried ($MgSO_4$) and concentrated in vacuo. The residue was purified by flash chromatography, eluting with ethyl acetate:petroleum ether (bp 40–60 °C, 1:1) to give the corresponding carboxylic acid **10b** (25 g, 90%) as a colourless oil. Ethyl chloroformate (5.5 mL, 57.5 mmol) was added dropwise to a solution of the carboxylic acid (25 g, 52.3 mmol) and triethylamine (10.2 mL, 75.2 mmol) in THF (250 mL) at 0 °C. The mixture was allowed to warm to room temperature and stirred at this temperature for 30 min. Concentrated aqueous ammonia (75 mL) was added rapidly at 0 °C and the mixture was warmed to room temperature and then concentrated in vacuo. 2 N HCl was added until the mixture was acidic, and the aqueous layer was then extracted with ethyl acetate (3 × 150 mL). The combined organic extracts were dried ($MgSO_4$) and evaporated to dryness in vacuo. The residue was purified by flash chromatography, eluting with ethyl acetate:petroleum ether (bp 40–60 °C, 1:1 → 2:1) to give the *amide* (23 g, 93%) as a colourless oil. $[\alpha]_D^{24}$ –16.8 (*c* 0.19 in $CHCl_3$). IR ν_{max} (cm^{-1}, film): 3346, 3193, 2930, 1681, 1513, 1248, 1112, 703. ^1H NMR (360 MHz, $CDCl_3$) δ: 7.69–7.66 (4H, m, ArH), 7.47–7.36 (6H, m, ArH), 7.20 (2H, d, *J* = 8.7, MeOArH), 6.85 (2H, d, *J* = 8.7, MeOArH), 6.07 (1H, br s, NH), 5.26 (1H, br s, NH), 4.59 (1H, d, *J* = 11.0, CH_2Ar), 4.44 (1H, d, *J* = 11.0, CH_2Ar), 3.97–3.91 (1H, m, CHOPMB), 3.81 (3H, s, CH_3O), 3.76 (1H, dd, *J* = 5.1 and 10.7, CH_2OTPS), 3.70 (1H, dd, *J* = 5.2 and 10.7, CH_2OTPS), 2.58 (1H, dd, *J* = 3.8 and 15.1, CH_2CONH_2), 2.47 (1H, dd, *J* = 8.1 and 15.6, CH_2CONH_2), 1.07 (9H, s, $((CH_3)_3CSi$). ^{13} C NMR (90.6 MHz, $CDCl_3$) δ: 173.4, 159.2,

tion of *N*,*O*-dimethylhydroxylamine hydrochloride (8.8 g, 90.2 mmol) in CH_2Cl_2 (100 mL) at 0 °C. Once the gas evolution had ceased, the mixture was allowed to warm to room temperature and stirred at this temperature for 1 h. The solution was added dropwise via cannula to a stirred solution of the ester **13b** (10.44g, 45.1 mmol) in CH_2Cl_2 (30 mL) at room temperature. The mixture was heated under reflux for 5 h and then stirred at room temperature for 12 h. The mixture was poured cautiously into ice cold 2 N HCl, and the separated aqueous layer was then extracted with CH_2Cl_2 (4 × 60 mL). The combined organic extracts were washed with a saturated solution of $NaHCO_3$ and then dried ($MgSO_4$). The solvent was removed at reduced pressure, and the residue was purified by flash chromatography, eluting with ethyl acetate:petroleum ether (bp 40–60 °C, 1:3 → 1:1) to give the *amide* (7.1 g, 61%) as a colourless oil. $[\alpha]_D^{26}$ 21.1 (*c* 0.38 in $CHCl_3$). IR ν_{max} (cm^{-1}, film): 2930, 1667, 1103, 837. ^1H NMR (360 MHz, $CDCl_3$) δ: 3.84 (1H, dd, *J* = 8.2 and 9.4), 3.72 (3H, br s, OCH_3), 3.54 (1H, dd, *J* = 6.1 and 9.5), 3.20 (3H, br s, CH_3), 3.22–3.16 (1H, m, *CH*CH_3), 1.07 (3H, d, *J* = 6.9, C*H*$_3$CH), 0.88 (9H, s, $((CH_3)_3CSi)$, 0.05 (3H, s, CH_3Si), 0.04 (3H, s, CH_3Si). ^{13}C NMR (90.6 MHz, $CDCl_3$) δ: 176.1, 65.7, 65.1, 38.1, 29.7, 25.8, 18.2, 13.7, –5.45. (*S*)-4-(*tert*-Butyldimethylsilanyloxy)-3-methylbutan-2-one (15a)

A solution of methylmagnesium bromide (3.0 mol L^{-1}) in ether (15 mL) was added dropwise via syringe to a stirred solution of the Weinreb amide **14** (6.8 g, 26.0 mmol) in diethyl ether at 0 °C. The mixture was stirred at 0 °C for 30 min, and then allowed to warm to room temperature. An ice cold saturated solution of NH_4Cl was added and the separated aqueous layer was then extracted with diethyl ether (3 × 50 mL). The combined organic extracts were washed with a saturated solution of $NaHCO_3$ and then dried ($MgSO_4$). The solvent was removed in vacuo and the crude methyl ketone (5.56 g, 94%) was used directly in the next step. $[\alpha]_D^{24}$ 23.9 (*c* 0.20 in $CHCl_3$). IR ν_{max} (cm^{-1}, film): 2930, 1717, 1092, 836. ^1H NMR (360 MHz, $CDCl_3$) δ: 3.73 (1H, dd, *J* = 7.2 and 9.8, CH_2O), 3.65 (1H, dd, *J* = 5.5 and 9.5, CH_2O), 2.77–2.71 (1H, m, C*H*CH_3), 2.18 (3H, s, CH_3CO), 1.05 (3H, d, *J* = 6.9, C*H*$_3$CH), 0.88 (9H, s, $((CH_3)_3CSi)$, 0.05 (3H, s, CH_3Si), 0.04 (3H, s, CH_3Si). ^{13}C NMR (90.6 MHz, $CDCl_3$) δ: 211.5, 65.1, 48.9, 29.1, 25.4, 17.8, 12.5, –5.9.

(*S*)-1-Bromo-4-(*tert*-butyldimethylsilanyloxy)-3-methylbutan-2-one (15b)

A solution of LiHMDS (1.0 mol L^{-1}) in THF (23 mL) was added dropwise over 30 min to a stirred solution of the ketone **15a** (4.7 g, 21.75 mmol) in THF (75 mL) at –78 °C under an atmosphere of nitrogen. The mixture was stirred at –78° for 1 h, then chlorotrimethylsilane (3.0 mL, 23.9 mmol) was added, and the solution was allowed to warm to 0 °C where it was stirred for 20 min. The solution was again cooled to –78 °C, and bromine (1.12 mL, 20.5 mmol) was

then injected rapidly. The orange solution was allowed to warm to room temperature and then poured cautiously into a mixture of a saturated solution of NH_4Cl and a solution of sodium thiosulfate. The mixture was shaken vigorously and the separated aqueous layer was extracted with ethyl acetate (3 × 30 mL). The combined organic extracts were dried ($MgSO_4$) and evaporated to dryness in vacuo. The residue was purified by flash chromatography, eluting with ethyl acetate:petroleum ether (bp 40–60 °C, 1:20 → 1:10) to give the *bromide* (5.5 g, 86%) as a colourless oil. $[\alpha]_D^{27}$ 99.9 (*c* 1.36 in $CHCl_3$). IR ν_{max} (cm^{-1}, film): 2930, 1718, 1095, 837. ^1H NMR (360 MHz, $CDCl_3$) δ: 4.11 (1H, d, *J* = 13.2, CH_2Br), 4.06 (1H, d, *J* = 13.2, CH_2Br), 3.73–3.70 (2H, m, CH_2O), 3.20–3.11 (1H, m, C*H*CH_3), 1.11 (3H, d, *J* = 6.9, C*H*$_3$CH), 0.91 (9H, s, $((CH_3)_3CSi)$, 0.08 (3H, s, CH_3Si), 0.06 (3H, s, CH_3Si). ^{13}C NMR(90.6 MHz, $CDCl_3$) δ: 204.4, 66.0, 45.9, 35.7, 25.7, 18.0, 12.9, –5.7.

4-[(*R*)-2-(*tert*-Butyldimethylsilanyloxy)-1-methylethyl]-2-[(*S*)-3-(*tert*-butyldiphenylsilanyloxy)-2-(4-methoxybenzyloxy)propyl]thiazole (16a)

A solution of the bromoketone **15b** (7.73 g, 26.2 mmol) in CH_2Cl_2 (60 mL) was added via cannula over 0.5 h to a stirred solution of thioamide **12** (11.75 g, 23.8 mmol) and 2,6-lutidine (4.16 mL, 35.7 mmol) in CH_2Cl_2 (150 mL) at 0 °C. The mixture was stirred at room temperature for 14 h and then the solvent was removed in vacuo. The residue was purified by flash chromatography, eluting with ethyl acetate:petroleum ether (bp 40–60 °C, 1:6 → 1:4) to give the corresponding thiazoline (12.25 g, 73%) as a colourless oil, which was used immediately in the next step.

Trifluoroacetic anhydride (7.43 mL, 52.6 mmol) was added dropwise over 20 min to a stirred solution of the thiazoline (9.3 g, 13.15 mmol) in CH_2Cl_2 (150 mL) at –30 °C. After 5 min, pyridine (7.43 mL, 52.7 mmol) was added and the mixture was stirred at –30 °C for 20 min. The mixture was quenched with brine (150 mL) and extracted with CH_2Cl_2 (2 × 150 mL). The combined organic extracts were dried ($MgSO_4$) and concentrated in vacuo. The residue was purified by flash chromatography, eluting with ethyl acetate:petroleum ether (bp 40–60 °C, 1:20 → 1:10) to give the *thiazole* (7.9 g, 87%) as a colourless oil. $[\alpha]_D^{24}$ –28.2 (*c* 0.88 in $CHCl_3$). IR ν_{max} (cm^{-1}, film): 2928, 1514, 1248, 1112, 836, 702. ^1H NMR (360 MHz, $CDCl_3$) δ: 7.70–7.67 (4H, m, ArH), 7.47–7.33 (6H, m, ArH), 7.16 (2H, d, *J* = 8.7, MeOArH), 6.83 (1H, s, ThzH), 6.81 (2H, d, *J* = 8.6, MeOArH), 4.54 (1H, d, *J* = 10.9, CH_2Ar), 4.43 (1H, d, *J* = 11.0, CH_2Ar), 3.95–3.88 (1H, m, CHOPMB), 3.87 (1H, dd, *J* = 5.6 and 9.7, CH_2OTPS), 3.80 (3H, s, CH_3O), 3.79–3.76 (2H, m, CH_2OTBS), 3.67 (1H, dd, *J* = 6.8 and 9.7, CH_2OTPS), 3.35 (1H, dd, *J* = 4.3 and 15.0, CH_2Thz), 3.20 (1H, dd, *J* = 8.1 and 15.1, CH_2Thz), 3.13–3.07 (1H, m, CHThz), 1.31 (3H, d, *J* = 7.0, C*H*$_3$CH), 1.07 (9H, s, $((CH_3)_3CSi)$, 0.86 (9H, s, $((CH_3)_3CSi)$, –0.02 (3H, s, CH_3Si), –0.03 (3H, s, CH_3Si). ^{13}C NMR (90.6 MHz, $CDCl_3$) δ: 166.5(s), 159.1(s), 158.9(s), 135.7(d), 135.6(d), 133.4(s), 133.3(s), 130.6(s), 129.7(d), 129.4(d), 127.7(d), 127.6(d), 113.7(d), 112.9(d), 79.5(d), 72.1(t), 67.5(t), 65.4(t), 55.3(t), 39.1(d), 36.0(t), 26.9(q), 25.9(q), 19.3(s), 18.3(s), 16.6(q), –5.3(q), –5.4(q). MS *m*/*z* (ES): 690.3519 (M + H, $C_{39}H_{56}NO_4SSi_2$ requires 690.3486).

(*R*)-2-{2-[(*S*)-3-(*tert*-Butyldiphenylsilanyloxy)-2-(4-methoxybenzyloxy)propyl]thiazol-4-yl}propan-1-ol (16b)

Acetic acid (120 mL) was added, in one portion to a biphasic solution of the thiazole **16a** (8 g, 10.6 mmol) in THF:H_2O (1:1, 120 mL), and the mixture was stirred at room temperature for 14 h and then evaporated to dryness in vacuo. The residue was dissolved in CH_2Cl_2 (200 mL), and the solution was washed with a saturated solution of $NaHCO_3$, then dried ($MgSO_4$) and evaporated in vacuo. The residue was filtered through a short pad of silica gel eluting with ethyl acetate:petroleum ether (bp 40–60 °C, 1:1) to give the *alcohol* (6.1 g, 92%) as a colourless oil. $[\alpha]_D^{24}$ –18.5 (*c* 0.26 in $CHCl_3$). IR ν_{max} (cm^{-1}, film): 3412, 2930, 1514, 1112, 823, 702. ^1H NMR (360 MHz, $CDCl_3$) δ: 7.69–7.66 (4H, m, ArH), 7.46–7.35 (6H, m, ArH), 7.13 (2H, d, *J* = 8.8, MeOArH), 6.84 (1H, s, ThzH), 6.81 (2H, d, *J* = 8.7, MeOArH), 4.52 (1H, d, *J* = 11.1, CH_2Ar), 4.39 (1H, d, *J* = 11.1, CH_2Ar), 3.92–3.86 (1H, m, CHOPMB), 3.80–3.67 (4H, m, CH_2OTPS and CH_2OH), 3.79 (3H, s, CH_3O), 3.36 (1H, dd, *J* = 4.1 and 15.0, CH_2Thz), 3.20 (1H, dd, *J* = 8.2 and 15.0, CH_2Thz), 3.13–3.08 (1H, m, CHThz), 1.30 (3H, d, *J* = 7.0, C*H*$_3$CH), 1.07 (9H, s, $((CH_3)_3CSi)$. ^{13}C NMR (90.6 MHz, $CDCl_3$) δ: 167.6, 159.3, 159.1, 135.6, 135.5, 133.3, 133.2, 130.3, 129.7, 129.6, 127.7, 113.6, 112.5, 78.9, 72.0, 67.7, 65.1, 55.2, 37.7, 35.9, 26.8, 19.2, 16.1. MS *m*/*z* (ES): 598.2403 (M + Na, $C_{33}H_{41}NO_4SSiNa$ requires 598.2423).

Methanesulfonic acid (*R*)-2-{2-[(*S*)-3-(*tert*-butyldiphenylsilanyloxy)-2-(4-methoxybenzyloxy)propyl]thiazol-4-yl}propyl ester (16c)

Methanesulfonyl chloride (0.98 mL, 12.7 mmol) was added to a solution of the alcohol **16b** (6.1 g, 10.6 mmol) and triethylamine (2.1 mL, 4.52 mmol) in CH_2Cl_2 (80 mL) at 0 °C and the resulting mixture was then stirred at 0 °C for 1 h. The solution was washed successively with brine (70 mL) and a saturated solution of $NaHCO_3$ (70 mL), and then evaporated to dryness in vacuo to leave the crude *mesylate* (96%), which was used directly in the next step. $[\alpha]_D^{24}$ –20.6 (*c* 0.63 in $CHCl_3$). Trifluoroacetic acid (1.4 mL, 18.3 mmol) was added to a solution of the sulfinamine **20a** (0.91 g, 0.92 mmol) in dry methanol (20 mL) al 0 °C and the mixture was stirred at room temperature for 4 h and then concentrated at reduced pressure below 35 °C. The residue was dissolved in CH_2Cl_2 (25 mL), and the solution was washed with a saturated solution of $NaHCO_3$ (20 mL), and brine (20 mL), and then evaporated to dryness in vacuo. The residue was purified by flash chromatography on silica gel, eluting with ethyl acetate:petroleum ether (bp 40–60 °C, 1:3 → 1:0) to give the *amine* (0.74 g, 95%) as a colourless oil. $[\alpha]_D^{24}$ –3.9 (*c* 0.31 in $CHCl_3$). IR ν_{max} (cm^{-1}, film): 3340, 2929, 1728, 1112, 702. ^{1}H NMR (360 MHz, $CDCl_3$) δ: 7.70–7.67 (4H, m, ArH), 7.45–7.34 (6H, m, ArH), 7.16 (2H, d, J = 8.7, MeOArH), 6.82 (2H, d, J = 8.7, MeOArH), 6.81 (1H, s, ThzH), 5.94 (1H, s, C=CH), 5.07–5.04 (1H, m, CHOCO), 4.54 (1H, d, J = 11.0, CH_2Ar), 4.42 (1H, d, J = 11.2, CH_2Ar), 3.95–3.88 (1H, m, CHOPMB), 3.81–3.76 (2H, m, CH_2OTPS), 3.80 (3H, s, CH_3O), 3.36 (1H, dd, J = 4.2 and 15.1, CH_2Thz), 3.21 (1H, dd, J = 8.2 and 15.0, CH_2Thz), 3.17–3.11 (1H, m, CH), 3.07–3.02 (1H, m, CH), 2.48–2.21 (4H, m, CH_2CO_2 and CH_2C=C), 1.89–1.83 (1H, m, CH_2CHN), 1.82 (3H, s, CH_3C=C), 1.64–1.56 (1H, m, CH_2CHN), 1.31 (3H, d, J = 6.9, CH_3CH), 1.18 (3H, d, J = 6.7, CH_3CH), 1.08 (9H, s, ($(CH_3)_3$CSi). ^{13}C NMR (90.6 MHz, $CDCl_3$) δ: 171.7, 166.9, 160.6, 158.9, 143.9, 135.5, 135.5, 133.3, 133.2, 130.4, 129.6, 129.2, 127.9, 127.6, 117.8, 113.6, 111.9, 79.1, 77.7, 72.0, 68.1, 65.3, 55.2, 46.2, 45.7, 44.7, 42.9, 35.9, 33.0, 26.7, 25.0, 21.5, 19.8, 19.1. MS *m/z* (ES): 855.2663 (M + H, $C_{43}H_{56}N_2O_5SSiI$ requires 855.2724).

The amine was reacted with chiral α-methoxyphenylacetic acid (MPA), and the NMR spectrum of the resulting MPA amide, complexed with $Ba(ClO_4)_2$ was studied using the procedure developed by Riguera and co-workers (12). A similar NMR study was made with the enantiopure (3*S*)-amine prepared from the ester **19** and the enantiomeric sulfinimine corresponding to **18**. Inspection and comparison of relevant chemical shift data with the $Ba(ClO_4)_2$-complexed MPA amides confirmed the 3*R*-amine configuration in **20b**, and hence in **20a**.

(3*R*,5*S*)-5-{2-[(*S*)-3-(*tert*-Butyldiphenylsilanyloxy)-2-(4-methoxybenzyloxy)propyl]thiazol-4-yl}-3-(2,2,2-trichloro-1,1-dimethylethoxycarbonylamino)hexanoic acid (*E*)-(*S*)-4-iodo-1,3-dimethylbut-3-enyl ester (21a)

A solution of the amine **20b** (870 mg, 1 mmol) in CH_2Cl_2 (16 mL) was added dropwise over 30 min to a slurry of 1,1-dimethyl-2,2,2-trichloroethyl chloroformate (1.22 g, 5.1 mmol) in pyridine (12 mL) at 0 °C and the yellow suspension was stirred at 0 °C for 1.5 h and then evaporated to dryness in vacuo. The orange residue was purified by flash chromatography on silica gel, eluting with ethyl acetate:petroleum ether (bp 40–60 °C, 1:5 → 1:4) to give *the TcBOC-protected*

(3*R*,5*S*)-5-{2-[(*S*)-3-(*tert*-Butyldiphenylsilanyloxy)-2-((*Z*)-3-tributylstannanylacryloyloxy)propyl]thiazol-4-yl}-3-(2,2,2-trichloro-1,1-dimethylethoxycarbonylamino)hexanoic acid (*E*)-(*S*)-4-iodo-1,3-dimethylbut-3-enyl ester (22)

Lithium hydroxide monohydrate (65.0 mg, 1.55 mmol) was added to a solution of (*Z*)-3-(tributylstannyl)propenoate (0.5 g, 1.29 mmol) (13) in a mixture of THF:H_2O (4:1) and MeOH (1.5 mL) at room temperature. The mixture was stirred at 60 °C for 48 h and then concentrated at reduced pressure. The residue was acidified carefully with 1 mol L^{-1} HCl and the aqueous solution was then extracted with ethyl acetate (3 × 15 mL). The combined organic extracts were dried ($MgSO_4$) and evaporated in vacuo to leave the *Z*-3-tributylstannane propenoic acid as a colourless oil. ^1H NMR (360 MHz, $CDCl_3$) δ: 7.40 (1H, d, *J* = 13.0, C=CH), 6.78 (1H, d, *J* = 13.0, C=CH), 1.52–1.46 (6H, m), 1.32–1.23 (6H, m), 1.00–0.96 (6H, m), 0.89 (9H, t, *J* = 7.3, CH_3CH_2). ^{13}C NMR (90.6 MHz, $CDCl_3$) δ: 171.5, 161.5, 134.1, 29.1, 27.2, 13.6, 11.0, which was used straightaway.

2,4,6-Trichlorobenzoyl chloride (0.24 mL, 1.57 mmol) was added to a solution of the stannylpropenoic acid (570 mg, 1.57 mmol) and triethylamine in THF (6 mL) at room temperature and the mixture was stirred at room temperature for 1 h. The volume of THF was reduced by evaporation in vacuo and then replaced by toluene (3 mL). The solution was cooled to –30 °C and then a solution of the alcohol **21b** (690 mg, 0.75 mmol) in toluene (4 mL) was added via cannula followed by DMAP (450 mg, 3.7 mmol). The mixture was stirred at –30 °C for 40 min and then quenched with 1 N HCl (10 mL). The separated aqueous extract was extracted with ethyl acetate (3 × 15 mL), and the combined organic extracts were then dried ($MgSO_4$) and evaporated to dryness in vacuo. The residue was purified by flash chromatography on silica gel, eluting with ethyl acetate:petroleum ether (bp 40–60 °C, 1:12 → 1:8) to give the *ester* (640 mg, 67%) as a colourless oil. $[\alpha]_D^{24}$ 1.21 (*c* 0.66 in $CHCl_3$). Dess–Martin periodinane (237 mg, 0.56 mmol) was added in one portion to a mixture of the alcohol **24a** (139 mg, 0.22 mmol) and pyridine (0.14 mL, 1.79 mmol) in CH_2Cl_2 (8 mL) at 0 °C. The white suspension was stirred at 0 °C for 30 min and then at room temperature for 3 h. The mixture was poured into ethyl acetate (8 mL) and a saturated solution of $NaHCO_3$ (8 mL), and the separated organic extract was then washed with 1 mol L^{-1} Na_2SO_3. The combined aqueous extracts were extracted with ethyl acetate (10 mL) and the combined organic extracts were dried ($MgSO_4$) and concentrated at reduced pressure. The residue was purified by flash chromatography, eluting with ethyl acetate:petroleum ether (bp 40–60 °C, 1:2 → 1:1) to give the *aldehyde* (88 mg, 70%) as a colourless oil. $[\alpha]_D^{26}$ –178.4 (*c* 0.56 in $CHCl_3$). Mono- and disubstitutions of (hepta-2,5-diyne-1,7-diol) bis(dicobalt) derivatives — Selectivity in Nicholas reactions[1]

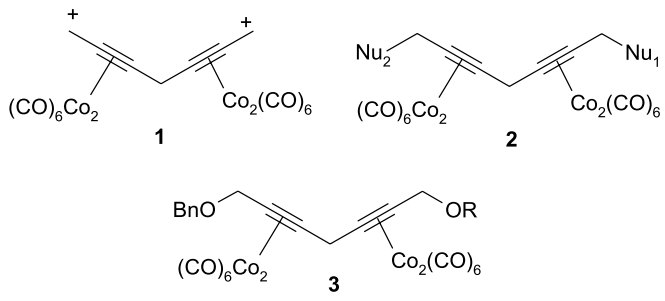
Richard Guo, Romelo Gibe, and James R. Green

Abstract: Bis(hexacarbonyldicobalt) complexes of benzyl ether – methyl ether or benzyl ether – acetate derivatives of hepta-2,5-diyne-1,7-diols undergo selective Lewis-acid-mediated Nicholas reactions with enol silanes, silyl ketene acetals, and allylstannanes, preferentially replacing the methyl ether or acetate function. Hydride nucleophiles are similarly incorporated selectively using a benzyl ether – alcohol derivative. Subsequent Nicholas reaction at the benzyloxy-bearing site may be accomplished with an identical or a different nucleophile, affording skipped 1,4-diyne-$Co_4(CO)_{12}$ complexes. In instances of lower selectivity for monosubstitution reactions with benzyl ethers, reverting to the use of a menthyl ether – methyl ether complex gives much improved selectivity for methyl ether substitution.

Key words: cobalt alkyne complexes, Nicholas reaction, Lewis acids, 1,4-diynes.



Résumé : Le bis(hexacarbonyldicobalt) forme des complexes avec des dérivés de l'hepta-2,5-diyne-1,7-diol portant un éther benzylique à une extrémité et un éther méthylique ou un acétate à l'autre extrémité qui donnent des réactions de Nicholas, catalysées par un acide de Lewis, avec des silanes énoliques, des acétals de cétènes silylés et des allylstannanes au cours desquelles il se produit un remplacement sélectif de l'éther méthylique ou de la fonction acétate. Les hydrures nucléophiles sont aussi incorporés d'une façon sélective en utilisant un dérivé portant à chaque extrémité un éther benzylique et un alcool. Une réaction de Nicholas subséquente au niveau du site portant le groupe benzyloxy-, réalisée avec un nucléophile identique ou différent, conduit des complexes 1,4-diyne-$Co_4(CO)_{12}$. Dans les cas où la sélectivité est plus faible lors des réactions de monosubstitution avec les éthers benzyliques, l'utilisation d'un complexe avec un dérivé portant un éther menthylique et un éther méthylique à chaque extrémité donne lieu à une sélectivité améliorée pour la substitution de l'éther méthylique.

Mots clés : complexes d'alcynes avec le cobalt, réaction de Nicholas, acides de Lewis, 1,4-diynes.

[Traduit par la Rédaction]

The chemistry of propargylhexacarbonyldicobalt cations, or the Nicholas reaction, has seen extensive use in organic synthesis (1). This interest stems from the predictable regiochemical and stereochemical aspects of the Nicholas reaction, and from the ability of cobalt alkyne complexes to protect the alkyne unit (2), to allow nonconventional alkyne geometries, to participate in synthetically useful cycloaddition reactions (3–5), and to alter the steric size of the formal alkyne function (6).

We have been interested in the use of tandem Nicholas reactions, both of derivatives of butyne-1,4-diol cobalt complexes, and of derivatives of bis(propargyl alcohol) complexes, for a number of synthetic purposes (7). The matter of selectivity where two sites for Nicholas reaction chemistry exist is an important issue, but this has been addressed only on rare occasion in butyne-1,4-diol-$Co_2(CO)_6$ derivatives (7*b*, 8), and not at all in the case of bis(propargyl alcohol)-$Co_4(CO)_{12}$ derivatives (9). Furthermore, substrates that would serve as synthons for skipped bis(propargyl) cations **1** selectively would give rise to 1,4-diyne complexes **2**, which are promising intermediates in the synthesis of compounds with skipped diene, diyne, or enyne functions, such as petrocortynes, petroformynes, and petrosiacetylenes (10), eicosanoids and oxoeicosanoids (11), including several of the leukotrienes (12). Consequently, we deemed the study of the selectivity in Nicholas reactions of **3** to be of importance; we have reported in preliminary form the substitution reactions of **3** and wish to more fully describe our efforts in this area (13).

Scheme 1.

Scheme 2.

The requisite heptyne-1,7-diol derivatives were prepared from benzyl propargyl ether (Scheme 1). Copper(I)-catalyzed coupling of the corresponding bromomagnesium acetylide with propargyl bromide afforded diyne **4** (78% yield), which was functionalized in two ways. Deprotonation of **4** with MeLi and exposure of the resultant acetylide to chloromethyl methyl ether gave benzyl methyl diether **5a** (59% yield). Alternatively, treatment of the same lithium acetylide with paraformaldehyde gave ether alcohol **6** (55% yield), and subsequent acetylation with acetic anhydride – BF_3-OEt_2 afforded the benzyl ether acetate **5b** (69% yield). The bis(hexacarbonyldicobalt) complexes of the diynediol derivatives were then prepared in a straightforward manner by subjecting **5a** and **5b** to excess $Co_2(CO)_8$, to give **3a** (77% yield) and **3b** (78% yield), respectively.

With two related substrates in hand, we investigated reactions of **3a** and **3b** with a series of representative nucleophiles, including the allylmetals allyltributylstannane (**7a**) and allyltrimethylsilane (**7b**), propiophenone trimethylsilyl enol ether (**7c**), ethyl cyclohexanecarboxylate trimethylsilyl ketene acetal (**7d**), and cyclohexanone trimethylsilyl enol ether (**7e**), all mediated by BF_3-OEt_2 (Scheme 2).

Allylation of **3a** or **3b** could be accomplished by either allyltributylstannane or allyltrimethylsilane; allyltributyltin, however, proved to be the significantly superior nucleophile for monosubstitution reactions. In the case of methyl ether **3a**, for example, reaction of 1.0 equiv. of BF_3-OEt_2 at 0 °C with 2.0 equiv. allyltrimethylsilane gave **8a** in a 39% yield (80% yield based on recovered starting material), and considerable recovered **3a**. Additional amounts of BF_3-OEt_2 caused greater conversion, but afforded significant amounts of diallylated **9a**. Conversely, allyltributyltin afforded a 63% yield of **8a** (82% based on recovered starting material (brsm) **3a**) in the presence of 2.0 equiv. of BF_3-OEt_2 (0 °C, 2 equiv. allyltributyltin) with more manageable amounts of unreacted **3a** (24%) and **9a** (7.5% yield). With acetate **3b**, reasonable results could be obtained with 1.5 equiv. BF_3-OEt_2 (0 °C, 1.5 equiv. allyltributyltin), giving **8a** (62% yield, 75% yield based on recovered starting **3b**), with 17% recovered **3b** (Table 1).

This necessity to optimize nucleophile – electrophile – Lewis acid stoichiometries in each case proved to be a general requirement with **3a** and **3b** and all nucleophiles, but allowed for satisfactory amounts of monosubstitution products in most cases, normally by stopping at the 80%–90% conversion range. The substitution of silyl enol ether **7c** with **3b** was found to be able to give **8b** in a 64% yield (70% brsm), while silyl ketene acetal **7d** with **3b** gave a 63% yield (70% brsm) of **8c**. Silyl enol ether **7e** proved somewhat less selective, and reactions were terminated at lower conversion levels (60%–70%) to minimize disubstitution. Under these circumstances, acetate **3b** afforded **8d** in 41% (70% brsm), while with methyl ether **3a**, **8d** could be obtained in 43% yield (76% brsm).

Intentional disubstitution reactions were attempted in two cases, using excess BF_3-OEt_2–nucleophile combinations (4 equiv. each). In the case of diallylation of **3a**, allyltributylstannane proved satisfactory, giving **9a** (73% yield) along with 12% of **8a**. Nevertheless, allyltrimethylsilane was superior in this regard, as complete consumption of **3a** occurred to give **9a** in 90% yield. Propiophenone trimethylsilyl enol ether **7c** also was amenable to giving disubstitution,

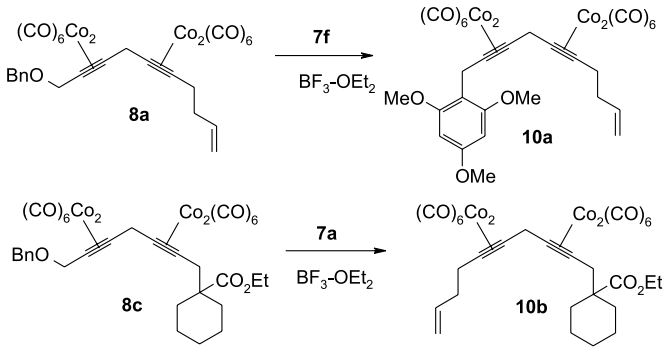
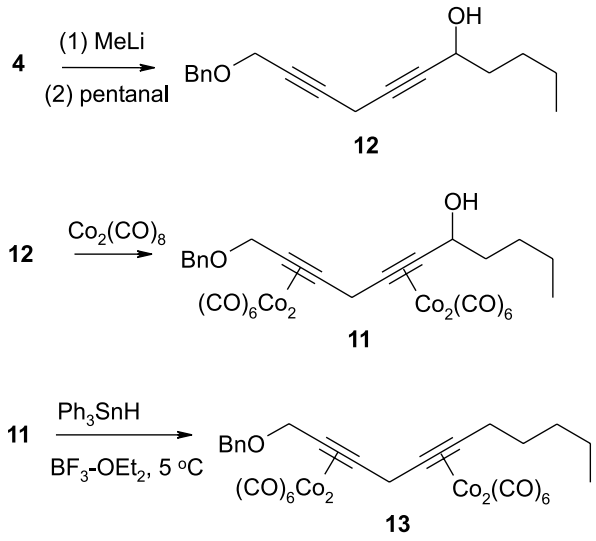
[b]Yields in parentheses are based on recovered starting material (brsm).

transforming **3b** to **9b** as a 1:1 diastereomeric mixture (70% yield).



In addition to the persubstitution reactions described above, we wished to determine whether this framework possessed the ability to incorporate two different nucleophiles in disubstitution reactions. For this purpose, we chose allylation product **8a**, by virtue of the low reactivity of the isolated alkene function to many Lewis acid – nucleophile combinations. In the event, **8a** was subjected to reaction with BF_3-OEt_2 and 1,3,5-trimethoxybenzene (**7f**) (2 equiv. each, 0 °C). The benzyloxy function was replaced cleanly, and **10a** could be isolated in 95% yield. Ester-substituted **8c** also was successful in substitution by a second nucleophile, as allyltrimethylsilane and BF_3-OEt_2 (2.0 equiv. each, 0 °C) gave **10b** in 76% yield (Scheme 3).

As a final choice of nucleophile for Nicholas substitution reactions, we also chose to look at a stannane to induce an overall reduction. In this case, we selected substrate **11**, due to the *n*-pentyl group often being present as a (*Z*)-alkene substituent in leukotriene systems, and due to the fact that an alcohol function should be ionizable without destruction of the stannane nucleophile. This compound was prepared from **4**, by trapping of the lithium acetylide with pentanal, and reaction of unpurified alcohol **12** with $Co_2(CO)_8$ to form **11** (44% yield from **4**) (Scheme 4).



Reduction of **11** with BF_3-OEt_2 and a reactive stannane such as Bu_3SnH and Me_3SnH tended to be unselective, tending to give complete reduction of the alcohol and ether functions. Using the less reactive Ph_3SnH and BF_3-OEt_2 under carefully controlled conditions gave greater selectivity, however. At 5 °C, with 1.5 equiv. Ph_3SnH with 1.0 equiv. BF_3-OEt_2, total selectivity for reduction of the alcohol could be realized, and **13** (84% yield) was isolated as the sole product.

The results in Table 1 demonstrate that, in most cases, the benzyloxy function served as an acceptable potential leaving group which would be retained in monosubstitution reactions in deference to alcohol, methyl ether, or acetate functions. In the cases of allyltrimethylsilane (**7a**) and cyclohexanone silyl enol ether (**7e**) as the nucleophile, the reactions had to be terminated at relatively low levels of conversion and as a result the isolated yields of monosubstitution products **8a** and **8d** were limited. We deemed the selectivity in these cases insufficient, and chose to investigate alternatives that would give greater discrimination between oxygen functions, and hence, greater monosubstitution selectivity. We have observed selectivity in Nicholas reaction-based 4 + 3 cycloaddition chemistry by employing an isopropyl ether as the more slowly ionizing oxygen func-

Scheme 3.

Scheme 4.

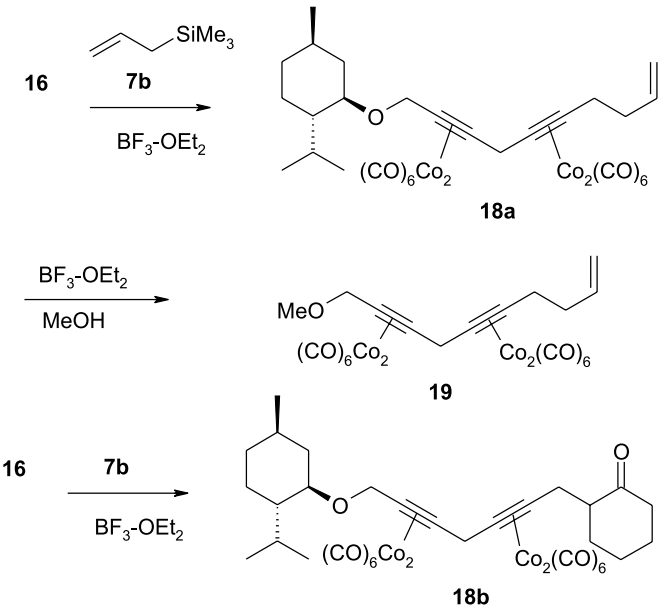
tion (7*b*). Due to its straightforward preparation relative to isopropyl propargyl ether (14), we chose instead menthyloxy containing **14** (15) as a starting point. The bromomagnesium acetylide of this propargylic ether was coupled with propargyl bromide to afford diyne **15** (75% yield), which in turn was converted to the menthyl methyl diynyl diether bis(dicobalt) complex **16** by deprotonation and subsequent trapping with chloromethyl methyl ether, and exposure of unpurified intermediate **17** to $Co_2(CO)_8$ (72% yield overall from **15**) (Scheme 1).

With complex **16** in hand, we investigated its reactivity towards allyltrimethylsilane (**7a**) and cyclohexanone trimethylsilyl enol ether (**7e**). With allyltrimethylsilane, the use of near stoichiometric amounts of Lewis acid BF_3-OEt_2 resulted in the recovery of substantial amounts of starting **16**. For example, with even 2 equiv. of BF_3-OEt_2, allyltrimethylsilane (1.5 equiv., 12 h, –10 °C), 31% recovery of **16** was found in addition to **18a** (31%, 54% based on recovered **16**). The amount of conversion increased with further excess amounts of BF_3-OEt_2, and at 4 equiv., **16** was consumed completely and a 71% yield of **18a** was obtained (Scheme 5). Further increased amounts of Lewis acid gave a gradual degradation of product yield.



In the case of cyclohexanone trimethylsilyl enol ether (**7e**), an analogous trend was found with increasing amounts of BF_3-OEt_2, but modest amounts of starting material remained even at 4 equiv. (6% **16** recovery, 52% yield of **18b**, 60% yield brsm). In this case, switching the Lewis acid to Bu_2BOTf (1.2 equiv.), in addition to an excess (3 equiv.) of nucleophile gave an improved yield (71%) of **18b**, while greater excesses of this Lewis acid gave near-complete destruction of the product. In the case of **18b**, a new chiral centre was generated. An apparent doubling of the several of signals was apparent in both the ^1H and ^{13}C NMR spectra of **18b**, and integration of the signals showed that **18b** existed as a 1:1 diastereomeric mixture. This was most clearly apparent for ^1H NMR resonances for the diastereotopic propargyl methylene group α- to the ether oxygen, which resonated at 4.851 and 4.847 ppm, and 4.53 and 4.52 ppm for the two diastereomers. Due to the distance between the reacting centre and the nearest centre of chirality, this lack of asymmetric induction was not surprising.

We chose **18a** for study to determine whether the removal of the menthyloxy group was facile. Again, the substrate proved to be relatively sluggish in terms of reaction, but in the presence of 3 equiv. each of BF_3-OEt_2 and MeOH (0 °C, CH_2Cl_2), methoxy-substitution product **19** could be obtained in 65% yield (75% brsm).

A combination of these results with those of ref. 7*b* suggests the following approximate order in the kinetic ionization of oxygen-based functions in Nicholas reactions: OH > OMe, OAc > OBn > O-*i*-Pr, O-menthyl, OTBDMS. The dominant factor in this ordering is most likely steric accessibility to the oxygen atom, although it is likely that inductive effects in the benzyl ether plays some role in reducing its basicity. A lower basicity of the acetate function is also known (16, 17), but is offset by its innately better leaving group ability.

With respect to the nucleophiles concerned, no clear pattern of nucleophile reactivity vs. selectivity has emerged. For example, in the case of allylation, the more reactive allylstannane gives greater selectivity for monosubstitution; by contrast, a less reactive tin hydride (Ph_3SnH vs. Bu_3SnH or Me_3SnH) (18) is more productive in reductions. Nevertheless, by careful choice of conditions and nucleophile, synthetically useful amounts of selective monosubstitution products can be obtained in most cases using the benzyl substrates **3a** and **3b**. Disubstitution reactions of with either two identical or two different nucleophiles can also be accomplished in good to excellent yields. With the poorer cases for **3a** or **3b**, the menthyl ether complex **16** gives very good selectivity for monosubstitution; in fact, the menthoxy group is removed at all only sluggishly.

Scheme 5.

Experimental section

General methods

All solvents were used after distillation from the appropriate drying agent. Diethyl ether and THF were distilled from benzophenone ketyl immediately prior to use. Dichloromethane was distilled from CaH_2 immediately prior to use. Commercial BF_3-OEt_2 was distilled and stored under nitrogen. All reactions were performed under nitrogen unless otherwise noted. Flash chromatography was performed as described by Still et al. (19) using (230–240 mesh) silica gel 60.

NMR spectra were run at 500 MHz or 300 MHz for ^1H, and 125 MHz or 75 MHz for ^{13}C in $CDCl_3$; chemical shifts are given in ppm and coupling constants (*J*) are given in Hz. Mass spectra were run at the Chemistry and Biochemistry Mass Spectrometry Facility, University of Windsor, and the Mass Spectrometry Facility, Wayne State University.

6-Benzyloxy-1,4-hexadiyne (4)

To the freshly prepared EtMgBr (25 mmol) in dry THF (20 mL) was added 3-benzyloxy-1-propyne (3.000 g, 20.00 mmol) over 10 min. After several minutes, the THF began to reflux. When the exothermic reaction had subsided, the flask was warmed for 30 min at 55 °C. The solution was

© 2004 NRC Canada

then cooled to 30 °C and powdered CuCl (60 mg) was added. After 15 min, propargyl bromide (2.2 mL, 20 mmol) was added over 30 min. The mixture was warmed for 1 h to 60 °C. After cooling to room temperature, the reaction mixture was poured into a solution of NH_4Cl (3.0 g) and KCN (100 mg) in water (10 mL). After vigorous shaking, the reaction was subjected to a conventional workup. Flash chromatography (petroleum ether:diethyl ether, 10:1) followed by distillation afforded **4** (1.160 g, 78%); bp 116–120 °C/0.5 torr (1 torr = 133.322 Pa). IR (neat, NaCl) (cm^{-1}) ν_{max}: 3292, 3030, 2856, 1496. ^{1}H NMR δ: 7.35 (m, 5H), 4.62 (s, 2H), 4.20 (t, *J* = 3.4, 2H), 3.26 (m, 2H), 2.13 (t, *J* = 4.5, 1 H). ^{13}C NMR δ: 137.9, 128.8, 128.5, 128.3, 80.4, 78.2, 77.9, 72.0, 69.5, 57.9, 10.1. MS *m/e*: 184 (M^+). HR-MS *m/e* for $C_{13}H_{12}O$ calcd. (M^+): 184.0888; found: 184.0886.

7-Benzyloxy-2,5-heptadiyn-1-ol (6)

To **4** (1.000 g, 5.4 mmol) in dry Et_2O (10 mL) was added MeLi (1.5 mol L^{-1} in Et_2O, 3.6 mL, 5.4 mmol) at –78 °C over 20 min. Thereafter, the solution was warmed to –30 °C and paraformaldehyde (300 mg) was added. After 45 min, the mixture was heated under reflux for 3 h. After cooling to room temperature, the mixture was poured into ice water (10 mL), and a conventional workup performed. Flash chromatography (petroleum ether – diethyl ether, 1:1) followed by distillation afforded **6** (640 mg, 55%); bp 125–129 °C/0.5 torr (1 torr = 133.322 Pa). IR (neat, NaCl) (cm^{-1}) ν_{max}: 3402, 3030, 2914, 2282. ^{1}H NMR δ: 7.27–7.35 (m, 5H), 4.60 (s, 2H), 4.28 (s, 2H), 4.18 (t, *J* = 2.1, 2H), 3.29 (m, 2H), 1.62 (s, 1 H). ^{13}C NMR δ: 137.7, 128.8, 128.5, 128.3, 80.9, 79.8, 79.5, 77.1, 72.1, 57.9, 51.4, 10.4. MS *m/e*: 214 (M^+). HR-MS *m/e* for $C_{14}H_{14}O_2$ calcd. (M^+): 214.0994; found: 214.0990.

1-Acetoxy-7-benzyloxy-2,5-heptadiyne (5b)

To a mixture of compound **6** (1.200 g, 5.60 mmol) and Ac_2O (0.75 mL, 8.4 mmol) in THF (10 mL) was added an excess of BF_3-Et_2O at –78 °C over a period of 20 min. The reaction was warmed to 0 °C, and monitored by TLC. After 1.5 h, when the starting material had disappeared, the reaction mixture was poured into satd. $NaHCO_3$(aq). After a conventional workup, flash chromatography (petroleum ether:diethyl ether, 1:1) afforded product **5b** (985 mg, 69%); bp 108–110 °C/0.5 torr (1 torr = 133.322 Pa). IR (neat, NaCl) (cm^{-1}) ν_{max}: 3030, 2929, 2280, 1722, 1604, 1495. ^{1}H NMR δ: 7.27–7.40 (m, 5H), 4.68 (t, *J* = 2.1, 2H), 4.59 (s, 2H), 4.17 (t, *J* = 2.1, 2H), 3.29 (pentet, *J* = 2.1, 2H), 2.09 (s, 3H). ^{13}C NMR δ:170.0, 137.3, 128.3, 128.0, 127.8, 80.6, 79.8, 76.8, 74.6, 71.6, 57.4, 52.3, 20.6, 9.9. MS *m/e*: 256 (M^+). HR-MS *m/e* for $C_{16}H_{16}O_3$ calcd. (M^+): 256.1099; found: 256.1100.

Dodecacarbonyl[μ^4-(η,η,η,η)(1-acetoxy-7-benzyloxy-2,5-heptadiyne)]tetracobalt (2 Co-Co) (3b)

General procedure for complexation

To a solution of **5b** (1.000 g, 3.90 mmol) in anhyd. Et_2O (20 mL) at 0 °C was added an excess of dicobalt octacarbonyl. After 4 h, the reaction mixture was allowed to warm to room temperature. The resulting mixture was filtered through Celite® and the solvent was removed in vacuo. Flash chromatography (petroleum ether:diethyl ether, 15:1) afforded product **3b** (2.580 g, 78%). IR (neat, NaCl) (cm^{-1}) ν_{max}: 3031, 2922, 2860, 2087, 2034, 1742, 1626. ^{1}H NMR δ: 7.27–7.39 (m, 5H), 5.30 (s, 2H), 4.69 (s 2H), 4.66 (s, 2H), 4.61 (s, 2H), 2.09 (s, 3H). ^{13}C NMR δ: 199.4, 170.5, 137.7, 128.4, 127.7, 127.6, 92.8, 91.5, 91.1, 90.3, 73.1, 69.9, 64.3, 41.0, 20.3. MS (LSI-MS) *m/e*: 827 (M – 1)$^+$, 744 (M – 3CO)$^+$, 688 (M – 5CO)$^+$, 660 (M – 6CO)$^+$. Anal. calcd. for $C_{28}H_{16}Co_4O_{15}$ (%): C 40.61, H 1.95; found: C 40.49, H 1.88.

1-Benzyloxy-7-methoxy-2,5-heptadiyne (5a)

To a solution of compound **4** (480 mg, 2.60 mmol) in dry Et_2O (10 mL) was added MeLi (1.48 mol L^{-1} in Et_2O, 2.2 mL, 3.3 mmol) at –78 °C over 20 min. The mixture was stirred for 30 min at –78 °C. Chloromethyl methyl ether (0.20 mL, 2.60 mmol) was added dropwise over 20 min, and the temperature was then allowed to rise to room temperature. The reaction was kept at room temperature for 2 h. Thereafter, cold water was added and the mixture subjected to a conventional workup. Flash chromatography (petroleum ether:diethyl ether, 10:1) afforded product **5a** (330 mg, 59%); bp: 112–114 °C/0.5 torr (1 torr = 133.322 Pa). IR (neat, NaCl) (cm^{-1}) ν_{max}: 3031, 2929, 2280, 1604, 1495. ^{1}H NMR δ: 7.27–7.37 (m, 5H), 4.60 (s 2H), 4.18 (t, *J* = 2.0, 2H), 4.10 (t, *J* = 2.0, 2H), 3.38 (s, 3H), 3.30 (t, *J* = 2.0, 2H). ^{13}C NMR δ: 137.2, 128.1, 127.7, 127.5, 80.1, 80.0, 76.4, 76.3, 71.2, 59.6, 57.2, 57.1, 9.6. MS *m/e*: 228 (M^+). HR-MS *m/e* for $C_{15}H_{16}O$ calcd. (M^+): 228.1150; found: 228.1155.

Dodecacarbonyl[μ^4-(η,η,η,η)(1-benzyloxy-7-methoxy-2,5-heptadiyne)]tetracobalt (2 Co-Co) (3a)

Compound **5a** (300 mg, 1.32 mmol) was subjected to reaction with $Co_2(CO)_8$ via the general procedure. Flash chromatography (petroleum ether:diethyl ether, 20:1) afforded product **3a** (810 mg, 77%). IR (neat, NaCl) (cm^{-1}) ν_{max}: 3033, 2926, 2087, 2049, 2021. ^{1}H NMR δ: 7.27–7.39 (m, 5H), 4.73 (s, 2H), 4.69 (s, 2H), 4.65 (s, 2H), 4.57 (s, 2H), 3.44 (s, 3H). ^{13}C NMR δ: 199.6, 137.9, 128.4, 127.7, 127.5, 93.1, 92.7, 91.5, 91.2, 73.1, 72.6, 69.8, 58.8, 41.1. MS (EI) *m/e*: 744 (M – 2CO)$^+$, 716 (M – 3CO)$^+$. (LSI-MS) *m/e*: 799 (M – 1)$^+$, 716 (M – 3CO)$^+$, 632 (M – 6CO)$^+$.

Dodecacarbonyl[μ^4-(η,η,η,η)(1-benzyloxy-9-ene-2,5-decadiyne)]tetracobalt (2 Co-Co) (8a)

General procedure for substitution reactions

To a solution of compound **3b** (300 mg, 0.36 mmol) and nucleophile **7b** (179 mg, 0.54 mmol) in CH_2Cl_2 (15 mL) at 0 °C was added freshly distilled BF_3-Et_2O (77 mg, 0.54 mmol) dissolved in CH_2Cl_2 (5 mL) over 30 min. After 5 h, $NaHCO_3$(aq) was added. After a conventional workup, flash chromatography (petroleum ether:diethyl ether, 20:1) afforded product **8a** (183 mg, 62%); a subsequent fraction contained **3b** (50 mg, 16.7%). **8a**: IR (neat, NaCl) (cm^{-1}) ν_{max}: 3033, 2928, 2087, 2040, 1642. ^{1}H NMR δ: 7.27–7.39 (m, 5H), 5.89 (m, 1H), 5.14 (dd, *J* = 1.5, 15.6, 1H), 5.08 (dd, *J* = 1.5, 10.2, 1H), 4.72 (s, 2H), 4.68 (s, 2H), 4.64 (s, 2H), 2.95 (t, *J* = 8.0, 2H), 2.40 (m, 2H). ^{13}C NMR δ: 199.6, 137.8, 136.8, 128.4, 127.8, 127.5, 116.0, 93.8, 93.6, 93.5, 92.6, 73.1, 69.8, 41.2, 35.6, 32.8. 3CO)$^+$, 586 (M – 8CO)$^+$. MS (LSI-MS) *m/e*: 726 (M – 3CO)$^+$, 642 (M – 6CO)$^+$.

From **3a**: To a solution of complex **3a** (200 mg, 0.25 mmol) in CH_2C1_2 (15 mL) was condensed with nucleophile **7b** (166 mg, 0.50 mmol) in the presence of BF_3-Et_2O (71 mg, 0.50 mmol, 2 equiv.) according to the general procedure. After flash chromatography (petroleum ether:diethyl ether, 20:1), **8a** (127 mg, 63%) was obtained, followed by **3a** (47 mg, 23.5%).

From **3a** and **7a**: The reaction of the complex **3a** (200 mg, 0.25 mmol) with **7a** (79 µL, 57 mg, 0.50 mmol) in the presence of BF_3-Et_2O (36 mg, 0.25 mmol, 1 equiv.) according to the general procedure. After flash chromatography (petroleum ether:diethyl ether, 20:1), **8a** (79 mg, 39%) was obtained, followed by **3a** (102 mg, 51%).

Dodecacarbonyl[μ^4-(η,η,η,η)(1-benzyloxy-8-methyl-9-oxo-9-phenyl-2,5-nonadiyne)]tetracobalt (2 Co-Co) (8b)

Complex **3b** (300 mg, 0.36 mmol) was reacted with the nucleophile **7c** (150 mg, 0.72 mmol) in the presence of BF_3-Et_2O (51 mg, 0.36 mmol) via the general procedure. Flash chromatography (petroleum ether:diethyl ether, 10:1) afforded **8b** (208 mg, 64%). IR (neat, NaCl) (cm^{-1}) ν_{max}: 3033, 2934, 2085, 2063, 1990, 1683. ^{1}H NMR δ: 8.04 (d, *J* = 7.7, 2H), 7.27–7.59 (m, 8H), 4.76 (s, 2H), 4.75 (s, 2H), 4.58 (d, *J* = 4.8, 2H), 3.74 (m, 1H), 3.71 (1/2AB, *J* = 11.7, 1H), 2.93 (1/2AB, *J* = 11.7, 1H), 1.37 (d, *J* = 6.7, 3H). ^{13}C NMR δ: 201.7, 199.6, 137.9, 135.5, 133.3, 128.7, 128.3, 127.6, 127.5, 127.4, 97.3, 93.9, 93.0, 91.0, 73.0, 69.8, 43.1, 41.0, 36.1, 19.4. MS (EI) *m/e*: 818 (M – 3CO)$^+$, 762 (M –5CO)$^+$. (LSI-MS) *m/e*: 819 (M + 1 – 3CO)$^+$, 763 (M + 1 – 5CO)$^+$, 735 (M + 1 – 6CO)$^+$. A subsequent fraction contained **3b** (27 mg, 9%).

Dodecacarbonyl[μ^4-(η,η,η,η)(1-benzyloxy-7-(1-ethoxycarbonylcyclohexyl)-2,5-heptadiyne)]tetracobalt (2 Co-Co) (8c)

Compound **3b** was (300 mg, 0.36 mmol) reacted with nucleophile **7d** (150 mg, 0.72 mmol) in the presence of BF_3-Et_2O (51 mg, 0.36 mmol) according to the general procedure. Flash chromatography (petroleum ether:diethyl ether, 15:1) afforded product **8c** (210 mg, 63%). IR (neat, NaCl) (cm^{-1}) ν_{max}: 3033, 2935, 2094, 2086, 2022, 1730. ^{1}H NMR δ: 7.27–7.39 (m, 5H), 4.73 (s, 2H), 4.70 (s, 2H), 4.60 (s, 2H), 4.20 (q, *J* = 7.0, 2H), 3.23 (s, 2H), 1.25–2.17 (m, 13H). ^{13}C NMR δ: 199.7, 175.4, 137.8, 128.4, 127.7, 127.5, 95.2, 93.0, 92.9, 90.9, 73.0, 69.7, 60.6, 48.1, 41.0, 34.6, 25.5, 22.8, 14.0. MS (EI) *m/e*: 840 (M – 3CO)$^+$, 700 (M – 7CO)$^+$. (LSI-MS) *m/e*: 840 (M – 3CO)$^+$, 728 (M – 6CO)$^+$. A subsequent fraction contained **3b** (28 mg, 9%).

Dodecacarbonyl[μ^4-(η,η,η,η)(1-benzyloxy-7-(2-oxocyclohexyl)-2,5-heptadiyne)]tetracobalt (2 Co-Co) (8d)

Complex **3b** (200 mg, 0.24 mmol) was condensed with the nucleophile **7e** (86 mg, 0.29 mmol) in the presence of BF_3-Et_2O (51 mg, 0.36 mmol) via the general procedure. Flash chromatography (petroleum ether:diethyl ether, 10:1) afforded **8d** (85 mg, 41%). IR (neat, NaCl) (cm^{-1}) ν_{max}: 3033, 2933, 2085, 2022, 1716. ^{1}H NMR δ: 7.27–7.39 (m, 5H), 4.75 (s, 2H), 4.72 (s, 2H), 4.64 (s, 2H), 3.58 (m, 1 H), 1.49–2.60 (m, 10H). ^{13}C NMR δ: 210.9, 199.6, 137.9, 128.3, 127.6, 127.5, 98.1, 93.6, 92.9, 91.1, 73.0, 69.8, 53.4, 42.0, 41.2, 35.4, 32.8, 28.2, 25.3. MS (EI) *m/e*: 782 (M – 3CO)$^+$, 642 (M – 8CO)$^+$. (LSI-MS) *m/e*: 782 (M – 3CO)$^+$, 698 (M – 6CO)$^+$. A subsequent fraction contained **3b** (54 mg, 27%).

From **3a**: The complex **3a** (300 mg, 0.37 mmol) also reacted with the nucleophile **7e** (78 mg, 0.44 mmol) in the presence of BF_3-Et_2O (54 mg, 0.38 mmol) via the general procedure. Flash chromatography afforded **8d** (141 mg, 43%), followed by **3a** (130 mg, 43%).

Dodecacarbonyl[μ^4-(η,η,η,η)(trideca-1,12-diene-5,8-diyne)]tetracobalt (2 Co-Co) (9a)

Complex **3a** (200 mg, 0.25 mmol) was condensed with nucleophile **7b** (331 mg, 1.00 mmol) in the presence of BF_3-Et_2O (142 mg, 1.00 mmol) via the general procedure. Flash chromatography (petroleum ether:diethyl ether, 10:1) afforded **9a** (127 mg, 73%). IR (neat, NaCl) (cm^{-1}) ν_{max}: 3085, 2941, 2093, 2022, 1643. ^{1}H NMR δ: 5.94 (m, 2H), 5.17 (dd, *J* = 1.4 Hz, 17.2, 2H), 5.10 (dd, *J* = 1.4, 10.0, 2H), 4.65 (s, 4H), 2.99 (t, *J* = 7.9, 4H), 2.40 (m, 2H). ^{13}C NMR δ: 199.9, 136.8, 116.0, 98.5, 92.6, 41.4, 35.6, 32.8. MS (EI): 716 (M – 1CO)$^+$, 688 (M – 2CO)$^+$. (LSI-MS) *m/e*: 716 (M – 1CO)$^+$, 604 (M – 5CO)$^+$. A subsequent fraction contained **8b** (27.0 mg, 12%)

Under directly analogous conditions, the reaction of complex **3a** (200 mg, 0.25 mmol) with **7a** (0.16 mL, 1.0 mmol) and BF_3-OEt_2 (142 mg, 1.00 mmol) afforded product **9a** (170 mg, 90%).

Dodecacarbonyl[μ^4-(η,η,η,η)(2,10-dimethyl-1,11-diphenylundeca-4,7-diyne-1,11-dione)]tetracobalt (2 Co-Co) (9b)

Complex **3b** (75.1mg, 0.0907 mmol) was condensed with **7c** (74.9mg, 0.363 mmol) in the presence of BF_3-OEt_2 (46 µL, 0.36 mmol) via the general procedure. Flash chromatography (petroleum ether:diethyl ether, 10:1) gave **9b** (59.0 mg, 70%) as a 1:1 diastereomeric mixture. IR (neat, NaCl) (cm^{-1}) ν_{max}: 2093, 2084, 2051, 2017, 1683. ^{1}H NMR δ: 8.03 (d, *J* = 8.0, 4H), 7.57 (t, *J* = 7.6, 2H), 7.48 (apparent t, *J* = 7.7, 4H), 4.56 + 4.46 (AB, *J* = 18.1) and 4.52 (s) (2H), 3.73–3.81 (m, 4H), 2.91–3.03 (m, 2H), 1.41 (d, *J* = 6.5) and 1.39 (d, *J* = 6.5) (6H). ^{13}C NMR δ: 201.7, 199.9 and 199.5, 135.5, 133.29 and 133.28, 128.8, 128.4, 97.4 and 97.3, 93.9 and 93.8, 43.1, 41.0 and 40.9 36.0, 19.6 and 19.4. MS (EI) *m/e*: 844 (M – 3CO)$^+$, 648 (M – 10CO)$^+$. (LSI-MS) *m/e*: 929 (M + 1)$^+$, 844 (M – 3CO)$^+$.

Dodecacarbonyl[μ^4-(η,η,η,η)(1-(2,4,6-trimethoxyphenyl)dec-9-ene-2,5-diyne)]tetracobalt (2 Co-Co) (10a)

Compound **8a** (240 mg, 0.30 mmol) was condensed with 1,3,5-trimethoxybenzene (**7f**) (101 mg, 0.60 mmol) in the presence of BF_3-Et_2O (85 mg, 0.60 mmol) via the general procedure. Flash chromatography (petroleum ether:diethyl ether, 20:1) afforded **10a** (245 mg, 95%). IR (neat, NaCl) (cm^{-1}) ν_{max}: 3007, 2942, 2082, 2045, 2022, 1615. ^{1}H NMR δ: 6.14 (s, 2H), 5.95 (m, 1H), 5.18 (dd, *J* = 1.5, 17.0, 1H), 5.08 (dd, *J* = 1.5, 10.0, 1H), 4.59 (s, 2H), 4.17 (s, 2H), 3.81 (s, 3H), 3.77 (s, 6H), 3.06 (t, *J* = 8.1, 2H), 2.45 (m, 2H). ^{13}C NMR δ: 199.9, 160.5, 158.7, 136.9, 115.8, 108.2, 100.2, 98.4, 93.5, 92.8, 89.9, 55.3, 54.7, 41.2, 35.6, 32.8, 26.0. Synthesis of dodecacarbonyl[μ^4-(η,η,η,η)(1-benzyloxy-7-hydroxy-2,5-undecadiyne)]tetracobalt (2 Co-Co) (11)

To a solution of freshly prepared 6-benzyloxy-1,4-hexadiyne (**4**) (56.4 mg, 3.06 mmol) in THF at –78 °C was added methyllithium (3.06 mL, 1.5 mol L^{-1}, 4.59 mmol). The mixture was stirred for 20 min and freshly distilled pentanal (651 μL, 6.12 mmol) was added dropwise. After stirring for 3 h, the reaction mixture diluted with cold water at 0 °C. Following a conventional workup, the crude product was diluted with diethyl ether and placed in an ice bath. An excess amount of cobalt carbonyl was added and the mixture stirred for 3.5 h. Following removal of the volatiles under reduced pressure, flash chromatography (petroleum ether:diethyl ether, 20:1) gave (**11**) (90.2 mg, 44%) as a red-brown oil. IR (neat) (cm^{-1}) ν_{max}: 3386, 2919, 2012. ^{1}H NMR δ: 7.32 (m, 5H), 4.68 (m, 7H), 2.79 (d, *J* = 5.2, 1H), 1.64 (m, 3H), 1.36 (m, 3H), 0.92 (t, *J* = 7.1, 3H). ^{13}C NMR δ: 199.6, 199.3, 137.0, 128.5, 128.1, 128.0, 102.4, 92.0, 91.3, 91.0, 73.4, 71.5, 70.1, 41.2, 39.2, 28.5, 22.4, 13.9. Efficient construction of benzohydrindenones from aryltrienones via domino Nazarov electrocyclization – electrophilic aromatic substitution[1]

Cindy C. Browder, Fredrik P. Marmsäter, and F.G. West

Abstract: 1,4-Dien-3-ones substituted with pendant arylethyl side chains attached at C-1 were readily prepared from substituted dihydrocinnamaldehydes. Treatment with $TiCl_4$ at low temperature effected domino Nazarov electrocyclization – arene trapping within 5 min to give racemic benzohydrindenones in near-quantitative yield and with complete diastereoselectivity.

Key words: domino process, electrophilic aromatic substitution, Lewis acid, Nazarov cyclization.

Résumé : Utilisant des dihydrocinnamaldéhydes substitués comme produits de départ, on a facilement préparé des 1,4-dién-3-ones substituées portant des chaînes latérales aryléthyles attachées en position C-1. Leur traitement par du $TiCl_4$ à basse température provoque en cinq minutes des réactions en chaîne d'électrocyclisation de Nazarov et de piégeage d'arène qui conduisent à la formation de benzohydrindénones avec un rendement pratiquement quantitatif et une diastéréosélectivité complète.

Mots clés : procédé domino, substitution aromatique électrophile, acide de Lewis, cyclisation de Nazarov.

[Traduit par la Rédaction]

Introduction

Domino processes have become important tools for organic synthesis, since they permit the one-stage construction of complex products from comparatively simple reactants (1). We have examined the use of the Nazarov reaction (2) of cross-conjugated dienones as a versatile initiating step for a variety of domino processes (3). The intermediate resulting from Lewis or Brønsted acid-catalyzed electrocyclic ring closure is a 2-oxido- or 2-hydroxycyclopentenyl cation (Scheme 1), which can potentially react as either a 2π partner in a [4 + 3]-cycloaddition (3*c*) or as an electrophile in a variety of intra- or intermolecular cation trapping processes (3*a*, 3*b*, 3*d*–3*f*).

In the latter category, we are particularly interested in developing routes to the hydrindan skeleton and benzannulated derivatives. These substructures are found within many natural and unnatural targets (4), including steroids (5), alkaloids (6) and the interesting hamigeran sponge metabolites, which have shown promising activity against polio and herpes viruses (7). Previous studies indicated that a suitably substituted butenyl group at C-1 of the dienone reactants **1** could participate in efficient 6-endo cation–olefin cyclization to furnish hydrindenyl cations **2** (Scheme 1) (3*d*). However, in most cases a mixture of products **3**–**5** ensued, resulting from the several available termination pathways available to this intermediate following 6-endo cyclization. In contrast, aryltrienones **6** underwent clean conversion to **7** in high yield via a cascade polycyclization process that began with a similar 6-endo cation–olefin cyclization (3*e*). We surmised that under the Nazarov conditions, cyclization via intermolecular electrophilic aromatic substitution could be an efficient and highly selective termination process. We therefore sought to explore the *direct* trapping of the Nazarov intermediate with pendant aryl groups (8). In this full account, we describe the convenient preparation of the necessary aryldienone substrates, and their high-yield and stereoselective conversion into benzohydrindenones.

Results and discussion

Substrate synthesis

Several possible approaches to the aryldienone substrates needed to investigate the desired process were considered. The most flexible strategy involved addition of alkenyl anions **8** into enals **9** (prepared by Horner–Wadsworth–Emmons (HWE) olefination of readily available hydro-

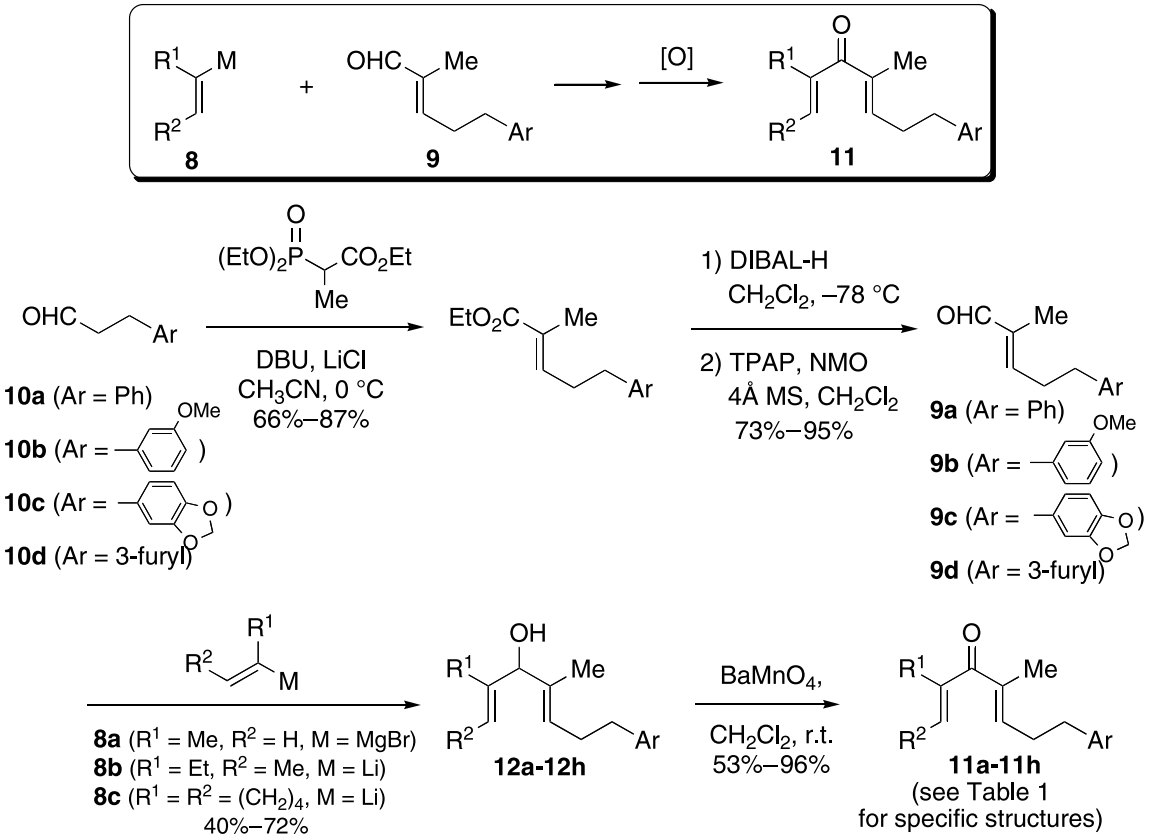
 doi: 10.1139/V03-203 © 2004 NRC Canada

Scheme 1.

cinnamaldehydes **10**), followed by oxidation of the resulting dienols to dienones **11** (Scheme 2). Aldehydes **10b** and **10c** were prepared from the corresponding cinnamic acids, and together with the commercially available **10a** were subjected to olefination with triethyl phosphonopropionate under the modified Roush–Masamune conditions (9). Half-reduction to the enals **9a**–9**c** was most easily accomplished using a two-step reduction–oxidation sequence (excess DIBAL-H, then TPAP/NMO). Furan-containing enal **9d** was also prepared from (*E*)-3-furanacrylic acid using a similar sequence. This naturally occurring compound, perillenal, is a pheromone of the pine saw fly (10). Although it has been synthesized by a variety of methods, we have found that this route is quite convenient for the preparation of this compound in quantity (11).

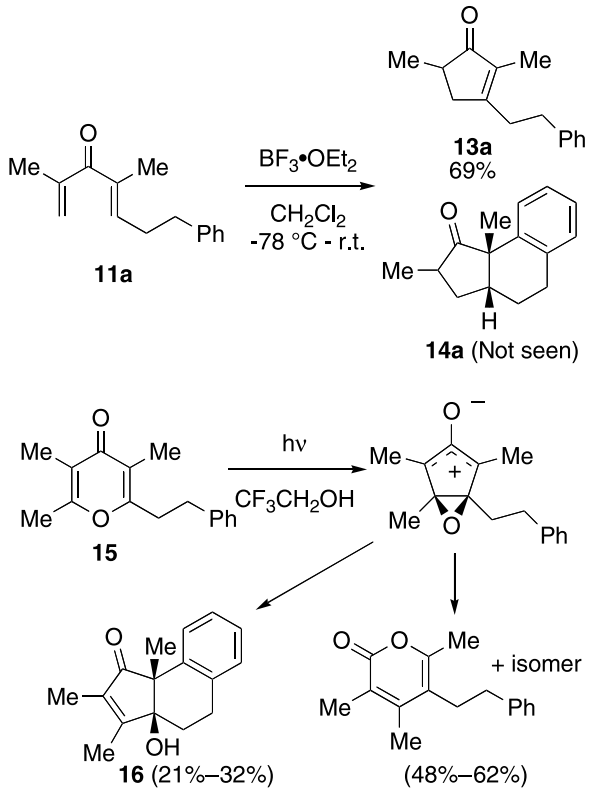
With enals **9a**–**9d** in hand, conversion to the dienone substrates was readily effected by addition of 2-propenylmagnesium bromide, (*Z*)-3-lithio-3-hexene, or 1-lithiocyclohexene. The latter two were generated in situ from the trisylhydrazones of 3-hexanone and cyclohexanone under modified Shapiro conditions (12). Oxidation of the resulting dienols **12** was best accomplished using $BaMnO_4$ (13), providing dienones **11a**–**11h** in moderate to good yield.

Cyclization studies



Initial attempts to effect the desired domino cyclization used the simplest substrate, **11a** (Scheme 3). In the event, we found that, although **11a** underwent the Nazarov electrocyclization upon treatment with $BF_3{\cdot}OEt_2$, subsequent electrophilic aromatic substitution did not occur. Instead, cyclopentenone **13a** was isolated in 69% yield. In the prior cascade polycyclization study, which also involved termination by cyclization onto a monosubstituted phenyl ring, $TiCl_4$ had been found to be superior to $BF_3{\cdot}OEt_2$, which furnished various quantities of truncated products resulting from incomplete cyclization of the polyene array (3*e*). However, in the case of **11a**, $TiCl_4$ gave a complex mixture of products containing neither **13a** nor any of the desired domino cyclization product **14a**. While disappointing, this result was not entirely unexpected. In earlier work involving attempted arene capture of photochemically generated 2-oxidocyclopentenyl cations, simple phenyl groups were found to be insufficiently nucleophilic to effectively trap the intermediate (e.g., **15** → **16**) in competition with other pathways (14). However, more electron-rich aryl groups had been effective, suggesting that substrates **11b**–**11h** would have a greater likelihood of undergoing the second cyclization event.

As with **11a**, treatment of **11b**–**11g** with $BF_3{\cdot}OEt_2$ gave cyclopentenone products derived from initial Nazarov cyclization and elimination rather than arene trapping. However, these products were admixed with cyclopentanone-containing products containing one fewer aryl protons in the ^{1}H NMR spectra than the starting dienones. These new compounds proved to be the desired benzohydrindenones derived from domino cyclization. In an effort to enhance this process at the expense of the monocyclization, we examined the use of the stronger Lewis acid, $TiCl_4$. The choice of Lewis acid indeed proved to be critical, as the desired products **14b**–**14g** were cleanly obtained in high yield within 5 min at –78 °C (Table 1). The arene substitution reaction occurred at the sterically less demanding position in all cases (para to the methoxy substituent rather than ortho for **11b**–**11d** and meta/para to the methylenedioxy group for **11e**–**11g**).[4] Furan-containing substrate **11h** was of interest, given the substantial precedent for the ability of pendant furans to participate in cationic cyclization processes (15), as well as the synthetic versatility of the furan nucleus in the resulting annulated products (16). In the event (entry 7), we found that this example proceeded in only 55% yield, and required warming to room temperature to fully consume the starting material. The remainder of the material appeared to be oligomeric by-products, presumably because of the higher temperature needed in this case. It is notable that simple Nazarov cyclization products analogous to **13a** were not isolated in any of these examples. The high efficiency of the electrophilic aromatic substitution process by **11b**–**11h** as compared with other possible termination pathways is striking. Examples of simple acyclic oxyallyl cations reacting with arenes to give a mixture of simple substitution products



[4] Arene substitution patterns were readily discernable from the coupling patterns of the remaining aromatic protons in the ^{1}H NMR spectra of products **14b**–**4g**.

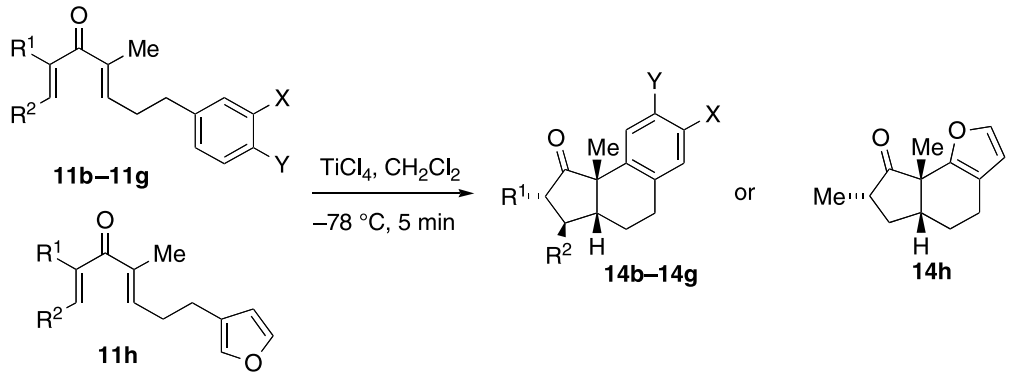
Scheme 2.

Scheme 3.

and [4 + 3]-adducts are known (17). A similar process in these intramolecular cases is unlikely, due to the substantial strain that would be encountered in the cycloaddition transition state; however, it is possible that products **14b**–**14h** may form through an abortive cycloaddition pathway in analogy to the intermolecular examples noted above.



There are several important stereochemical considerations in these domino cyclizations. First, in cases employing tetrasubstituted dienones (i.e., $R^2 \neq H$; entries 2, 3, 5, and 6), orbital symmetry considerations demand a conrotatory electrocyclization (18), which ensures that R^2 will be cis to the neighbouring bridgehead proton (Scheme 4). Subsequent arene trapping of the racemic oxyallyl cation intermediate is presumed to proceed with approach of the aromatic ring from the same face as the side chain to which it is attached to give a *cis*-hydrindan ring fusion, in analogy to other Nazarov-initiated domino processes that involve 6-endo cyclizations (4*a*, 4*d*, 4*e*). Finally, the relative configuration at C-2 was assigned with R^1 trans to the hydrindan bridgehead substituents based on presumed protonation of the enolate precursor from the convex face, and following previous observations of this selectivity in related systems (4). These assignments were confirmed in the case of **14f** by single crystal X-ray diffraction analysis[5] and other examples were assigned by analogy.

We found that 1,4-dien-3-ones with pendant electron-rich aryl groups attached through C-1 can undergo efficient domino cyclization to give arene-fused hydrindenones with

[5] X-ray diffraction data for **14f** were previously published. See the *Supporting Information* for ref. 8.

complete stereoselectively. Studies aimed at applying this methodology and related chemistry to targets containing this skeleton will be reported elsewhere in due course.

Experimental

General information

Reactions were conducted in oven-dried (120 °C) or flame-dried glassware under a positive nitrogen atmosphere unless otherwise stated. Transfer of anhydrous solvents or mixtures was accomplished with oven-dried syringes or cannulae. Solvents were distilled before use: dichloromethane from calcium hydride; diethyl ether and tetrahydrofuran from sodium benzophenone ketyl. Thin layer chromatography (TLC) was performed on plates of silica precoated with 0.25 mm Kieselgel 60 F_{254}. Flash chromatography columns were packed with 230–400 mesh silica gel. Where given, column dimensions include outer diameters. Radial chromatography was performed on plates of silica precoated with 1, 2, or 4 mm silica gel 60 PF_{254} containing gypsum. Barium manganate was purchased from Aldrich and was used without any prior activation or purification.

Proton nuclear magnetic resonance spectra (^1H NMR) were recorded on a 500 MHz Varian VXR NMR unless otherwise stated, and the chemical shifts are reported on the δ scale (ppm) downfield from tetramethylsilane. Coupling constants (*J*) are reported in Hz. Splitting patterns are designated as s (singlet), d (doublet), t (triplet), q (quartet), m (multiplet), br (broad), dd (doublet of doublets), etc. Carbon nuclear magnetic resonance spectra (^{13}C NMR) were obtained at 125 MHz and are reported (ppm) relative to the center line of a triplet at 77.23 ppm for deuterochloroform. Infrared (IR) spectra were measured with a Mattson Galaxy 3000 FT-IR or a Mattson Polaris FT-IR spectrophotometer.

© 2004 NRC Canada

Mass spectra were determined on a VG Micromass 7050E mass spectrometer equipped with a VG 2000 Data system. Elemental analyses were obtained from Altantic Microlabs Inc., Norcross, Ga.

Representative synthesis of hydrocinnamaldehydes 10

3-(3-Methoxyphenyl)propanal (10b)

General procedure for the LAH reduction

In a dry 50 mL round-bottomed flask fitted with a rubber septum and nitrogen inlet, a solution was made of 3-methoxycinnamic acid (5.139 g, 28.84 mmol) in THF (40 mL). A slurry of lithium aluminum hydride (LAH) (1.574 g, 41.47 mmol) in THF (250 mL) was prepared similarly in a dry 500 mL round-bottomed flask fitted with rubber septum, nitrogen inlet, and magnetic stirbar. The cinnamic acid solution was added slowly (1 to 2 h) via cannula to the LAH slurry at room temperature (rt). The mixture was stirred for 1 h after the end of the addition, then quenched by dropwise addition of MeOH (10 mL). 15 g of Celite/$NaSO_4$·$10H_2O$ (1:1) was added and the slurry was stirred for 15 h. Vacuum filtration and concentration provided 4.042 g (84%) 3-(3-methoxyphenyl)propanol as a pale yellow oil. ^{1}H NMR was in agreement with previously published data (19): R_f 0.36 (EtOAc/Hex, 1:1). IR (thin film, cm^{-1}): 3355 (br), 2939, 2863, 2835. ^{1}H NMR ($CDCl_3$) δ: 7.20 (t, J = 7.7 Hz, 1H), 6.90 (d, J = 7.6 Hz, 1H), 6.76–6.72 (m, 2H), 3.79 (s, 3H), 3.68 (t, J = 6.4 Hz, 2H), 2.69 (t, J = 7.7 Hz, 2H), 1.92–1.86 (m, 2H), 1.44 (br s, 1H). ^{13}C NMR ($CDCl_3$) δ: 129.6, 121.1, 114.5, 111.4, 111.1, 107.0, 62.5, 55.4, 34.3, 32.3.

3-(3-Methoxyphenyl)propanol 3.9a (1.037 g, 6.237 mmol) was treated with TPAP (0.076 g, 0.217 mmol, 3.5 mol %), NMO (0.887 g, 7.70 mmol), and crushed 4 Å molecular sieves (1.250 g) in CH_2Cl_2 (65 mL) as per the general procedure described for **9a** below. TLC showed the reaction was complete after 40 min. Column chromatography (silica gel, 235 mm × 35 mm, EtOAc/Hex, 1:1) provided 0.610 g (60%) 3-(3-methoxyphenyl)propanal 3.10a as a pale yellow oil: R_f 0.59 (EtOAc/Hex, 1:1). IR (thin film, cm^{-1}): 2955, 2921, 2849, 1709. ^{1}H NMR ($CDCl_3$) δ: 9.83 (t, J = 1.4 Hz, 1H), 7.22 (t, J = 7.9 Hz, 1H), 6.81–6.74 (m, 3H), 3.80 (s, 3H), 2.94 (t, J = 7.6 Hz, 2H), 2.79 (td, J = 7.6, 1.4 Hz, 2H). ^{13}C NMR ($CDCl_3$) δ: 201.8, 160.0, 142.2, 129.9, 120.8, 114.4, 111.8, 55.4, 45.4, 28.3.

3-(3,4-Methylenedioxyphenyl)propanol (10c)

(3,4-Methylenedioxy)cinnamic acid was treated with LAH in THF as per the procedure described for **10b**. The crude product provided 3-(3,4-methylenedioxyphenyl)propanol with a ^{1}H NMR spectrum in accordance with previously published data (20): R_f 0.29 (EtOAc/Hex, 1:1). ^{1}H NMR ($CDCl_3$) δ: 6.75–6.61 (m, 3H), 5.93 (s, 2H), 3.67 (t, J = 7.6 Hz, 2H), 2.64 (t, J = 7.6 Hz, 2H), 1.85 (tt, J = 7.6, 7.6 Hz, 2H), 1.26 (br s, 1H).

3-(3,4-Methylenedioxyphenyl)propanol (2.453 g, 13.61 mmol) was treated with TPAP (0.127 g, 0.362 mmol), NMO (1.882 g, 16.07 mmol), and crushed 4 Å sieves (2.883 g) in CH_2Cl_2 (150 mL) as per the general procedure described for **9a** below. Column chromatography (silica gel, 214 mm × 40 mm, EtOAc/Hex (1:4)) provided 3-(3,4-methylenedioxyphenyl)propanal (**10c**) (1.713 g, 71%) as a clear, colorless oil. ^{1}H NMR data were in accordance with previously published data (21): R_f 0.22 (EtOAc/Hex, 1:4). ^{1}H NMR ($CDCl_3$) δ: 9.80 (t, J = 1.4 Hz, 1H), 6.73 (d, J = 7.9 Hz, 1H), 6.68 (d, J = 2.2 Hz, 1H), 6.64 (dd, J = 7.9, 2.2 Hz, 1H), 5.92 (s, 2H), 2.88 (t, J = 7.4 Hz, 2H), 2.74 (td, J = 7.4, 1.2 Hz, 2H).

3-(3-Furyl)propanal (10d)

(*E*)-3-Furan acrylic acid (0.993 g, 7.19 mmol) was treated with LAH (0.571 g, 15.0 mmol) in THF (74 mL) as per the procedure described for **10b**. The crude product was redissolved in methanol (75 mL). Pd/C (0.268 g, 0.126 mmol) was introduced into the flask; the flask was evacuated and purged with nitrogen five times. The flask was evacuated again and then opened to a hydrogen balloon. After 30 min, the flask was evacuated and flushed with nitrogen. The slurry was then concentrated by rotary evaporation and filtered through a Celite plug. The crude product was concentrated and subjected to column chromatography (silica gel, 195 mm × 35 mm, EtOAc/Hex (0:1) and increased concentration to EtOAc/Hex (1:1)) to provide 3-(3-furyl)propanol (0.832 g, 60%) as a clear, pale yellow oil. ^{1}H and ^{13}C NMR and IR were consistent with previously published data (22): R_f 0.39 (EtOAc/Hex, 1:1). IR (thin film, cm^{-1}): 3333 (br), 2937, 2862. ^{1}H NMR ($CDCl_3$) δ: 7.36–7.35 (m, 1H), 7.24–7.23 (m, 1H), 6.28–6.27 (m, 1H), 3.68 (t, J = 6.4 Hz, 2H), 2.52 (t, J = 7.5 Hz, 2H), 1.83 (tt, J = 6.5, 6.5 Hz, 2H), 1.51 (br s, 1H). ^{13}C NMR ($CDCl_3$) δ: 143.1, 139.1, 124.6, 111.2, 62.5, 33.0, 21.2.

In a dry 25 mL round-bottomed flask fitted with a magnetic stirbar, a rubber septum, and a nitrogen inlet, oxalyl chloride (0.51 mL, 5.8 mmol) was dissolved in CH_2Cl_2 (9 mL) and cooled to –78 °C. A solution of DMSO (0.79 mL, 11 mmol) in CH_2Cl_2 (5 mL) was added dropwise via cannula. The mixture was stirred for 5 min before a solution of 3-(3-furyl)propanol (0.613 g, 4.86 mmol) in CH_2Cl_2 (2 mL) was added dropwise via cannula. After 15 min of additional stirring, triethylamine (3.4 mL, 24 mmol) was added dropwise via syringe. The reaction mixture was then allowed to warm slowly to rt, at which point it was quenched with water (15 mL). The layers were separated and the aqueous layer extracted with CH_2Cl_2 (3 × 5 mL). The combined organic portions were dried ($MgSO_4$) and concentrated to provide crude 3-(3-furyl)propanal as a brown oil, whose ^{1}H NMR spectrum was consistent with previously published data (23): R_f 0.56 (EtOAc/Hex, 1:1). ^{1}H NMR ($CDCl_3$) δ: 9.80 (t, J = 1.4 Hz, 1H), 7.37 (t, J = 1.7 Hz, 1H), 7.24–7.22 (m, 1H), 6.27–6.26 (m, 1H), 2.76 (br d, J = 6.7 Hz, 2H), 2.71 (td, J = 6.7, 1.2 Hz, 2H). ^{13}C NMR ($CDCl_3$) δ: 201.8, 143.3, 139.3, 123.5, 110.9, 44.2, 17.7.

Representative synthesis of aldehydes 9

(E)-2-Methyl-5-phenyl-2-pentenal (9a)

General procedure for the HWE olefination

In a dry 250 mL round-bottomed flask equipped with a rubber septum, a nitrogen inlet, and a magnetic stir bar, triethylphosphopropionate (2.097 g, 8.801 mmol), CH_3CN (60 mL), and LiCl (0.377 g, 8.90 mmol) were combined. 1,8-Diaza-bicyclo[5.4.0]undec-7-ene (DBU) (1.32 mL,

© 2004 NRC Canada

8.79 mmol) was added via syringe. The reaction mixture was allowed to stir at rt for 15 min, then cooled to 0 °C. Dihydrocinnamaldehyde **10a** (Aldrich; 0.77 mL, 5.9 mmol) in CH_3CN (5 mL) was then added dropwise via cannula and the reaction mixture was monitored by TLC. The reaction was complete within 30 min and was then quenched with satd. NH_4Cl (50 mL) and extracted with Et_2O (3 × 20 mL). Radial chromatography (silica gel, 4 mm plate, EtOAc/Hex (1:9)) provided ethyl (*E*)-2-methyl-5-phenyl-2-pentenoate (1.132 g, 89%) as a clear, colorless oil. ^1H and ^{13}C NMR and IR were in accordance with previously published data (24): R_f 0.53 (EtOAc/Hex, 1:4). IR (thin film, cm^{-1}): 3087, 3061, 3035, 3016, 1709. ^1H NMR ($CDCl_3$) δ: 7.37–7.27 (m, 2H), 7.23–7.18 (m, 3H), 6.80 (tq, *J* = 7.4, 1.5 Hz, 1H), 4.18 (q, *J* = 7.1 Hz, 2H), 2.75 (t, *J* = 7.8 Hz, 2H), 2.49 (dt, *J* = 7.8, 7.8 Hz, 2H), 1.78 (s, 3H), 1.29 (t, *J* = 7.1 Hz, 3H). ^{13}C NMR ($CDCl_3$) δ: 168.4, 141.5, 141.1, 128.6, 128.5, 126.3, 60.7, 35.0, 30.8, 14.5, 12.5 (two sp^2 carbon resonances overlapping).

General procedure for the DIBAL-H reduction

Ethyl (*E*)-2-methyl-5-phenyl-2-pentenoate (1.049 g, 4.803 mmol) was dissolved in CH_2Cl_2 (48 mL) in a dry 100 mL round-bottomed flask fitted with a rubber septum, a nitrogen inlet, and a magnetic stirbar. The solution was cooled to –78 °C and diisobutylaluminum hydride (DIBAL-H) (6.5 mL of a 1.5 mo L^{-1} solution, 9.8 mmol) was added dropwise via syringe. TLC indicated that the reaction was complete after 15 min. The reaction was quenched with saturated aqueous potassium sodium tartrate (10 mL) and stirred 5 h. The layers were separated and the aqueous layer extracted with CH_2Cl_2 (3 × 10 mL). The combined organic layers were dried ($MgSO_4$) and concentrated. Column chromatography (silica gel, 185 mm × 35 mm, EtOAc/Hex (1:4) and increased concentration to EtOAc/Hex (1:1)) provided (*E*)-2-methyl-5-phenyl-2-pentenol (0.792 g, 94%) as a clear, colorless oil. ^1H and ^{13}C NMR and IR are consistent with previously published data (25). R_f 0.42 (EtOAc/Hex, 1:1). IR (thin film, cm^{-1}): 3336 (br), 2923, 2855. ^1H NMR ($CDCl_3$) δ: 7.30–7.27 (m, 2H), 7.2–7.15 (m, 3H), 5.47 (tq, *J* = 7.1, 1.4 Hz, 1H), 4.00 (d, *J* = 5.2 Hz, 2H), 2.68 (t, *J* = 7.9 Hz, 2H), 2.37 (dt, *J* = 7.9, 7.9 Hz, 2H) overlapping with 2.36 (br s, 1H), 1.62 (s, 3H). ^{13}C NMR ($CDCl_3$) δ: 142.2, 135.6, 128.6, 128.5, 126.0, 125.4, 69.0, 35.9, 29.7, 13.8.

General procedure for the TPAP oxidation

(*E*)-2-Methyl-5-phenyl-2-pentenol (0.761 g, 4.32 mmol) was dissolved in CH_2Cl_2 (33 mL) in a dry 100 mL round-bottomed flask fitted with a rubber septum, a nitrogen inlet, and a magnetic stirbar. Crushed 4 Å molecular sieves (0.984 g) and 4-methylmorpholine-*N*-oxide (NMO) (0.597 g, 5.18 mmol) were added and stirred 5 min. Tetrapropylammonium perruthenate (TPAP) (0.074 g, 0.21 mmol, 3.5 mol %) was added slowly. TLC showed the reaction was complete after 30 min. The slurry was concentrated and eluted over silica with CH_2Cl_2 and EtOAc. The filtrate was concentrated under reduced pressure to yield crude (*E*)-2-methyl-5-phenyl-2-pentenal (**9a**) (0.652 g, 87%) as a brown oil, which was used without further purification. R_f 0.40 (EtOAc/Hex, 1:4). IR (thin film, cm^{-1}): 2915, 2857, 2823, 2760, 2713, 1683, 1646. ^1H NMR ($CDCl_3$) δ: 9.39 (s, 1H), 7.33–7.28 (m, 2H), 7.25–7.18 (m, 3H), 6.51 (dq, *J* = 7.3, 1.4 Hz, 1H), 2.83 (t, *J* = 7.7 Hz, 2H), 2.69 (dt, *J* = 7.7, 7.7 Hz, 2H), 1.69 (s, 3H). ^{13}C NMR ($CDCl_3$) δ: 195.4, 153.4, 140.8, 140.1, 128.8, 128.6, 126.5, 34.6, 30.9, 9.4.

(E)- 5-(3-Methoxyphenyl)-2-methyl-2-pentenal (9b)

The procedures described for **9a** were carried out using 3-methoxydihydrocinnamaldehyde (**10b**) in the initial HWE step.

Ethyl (*E*)-5-(3-methoxyphenyl)-2-methyl-2-pentenoate: colorless oil. R_f 0.65 (EtOAc/Hex, 1:1). IR (thin film, cm^{-1}): 2980, 2936, 1706. ^1H NMR ($CDCl_3$) δ: 7.21 (t, *J* = 7.6 Hz, 1H), 6.83–6.74 (m, 4H), 4.18 (q, *J* = 7.1 Hz, 2H), 3.80 (s, 3H), 2.73 (t, *J* = 7.8 Hz, 2H), 2.48 (dt, *J* = 7.8, 7.8 Hz, 2H), 1.80–1.79 (d, *J* = 1.3 Hz, 3H), 1.29 (t, *J* = 7.1 Hz, 3H). ^{13}C NMR ($CDCl_3$) δ: 168.4, 159.9, 143.1, 141.1, 129.7, 128.7, 121.0, 114.4, 111.6, 60.7, 55.4, 35.0, 30.7, 14.5, 12.5. Anal. calcd. for $C_{15}H_{20}O_3$: C 72.55, H 8.12; found: C 72.42, H 8.12.

(*E*)-5-(3-Methoxyphenyl)-2-methyl-2-pentenol: pale yellow oil. R_f 0.74 (EtOAc/Hex, 1:1). IR (thin film, cm^{-1}): 3358 (br), 2935, 2922, 2857, 2835. ^1H NMR ($CDCl_3$) δ: 7.23–7.19 (m, 1H), 6.81–6.78 (m, 1H), 6.76–6.73 (m, 2H), 5.47 (tq, *J* = 7.1, 1.3 Hz, 1H), 4.00 (s, 2H), 3.81 (s, 3H), 2.66 (t, *J* = 7.6 Hz, 2H), 2.36 (dt, *J* = 7.6, 7.6 Hz, 2H), 1.64 (s, 3H), 1.39 (br s, 1H). ^{13}C NMR ($CDCl_3$) δ: 159.8, 143.9, 135.7, 129.5, 125.5, 121.1, 114.5, 111.2, 69.1, 55.3, 35.9, 29.6, 13.9.

(*E*)-5-(3-Methoxyphenyl)-2-methyl-2-pentenal (**9b:**) pale yellow oil. R_f 0.67 (EtOAc/Hex, 1:1). IR (thin film, cm^{-1}): 2927, 2835, 2763, 2713, 1684. ^1H NMR ($CDCl_3$) δ: 9.39 (s, 1H), 7.23 (t, *J* = 7.8 Hz, 1H), 6.81–6.74 (m, 3H), 6.51 (tq, *J* = 7.2, 1.4 Hz, 1H), 3.81 (s, 3H), 2.81 (t, *J* = 7.6 Hz, 2H), 2.68 (dt, *J* = 7.6, 7.6 Hz, 2H), 1.71 (d, *J* = 1.3 Hz, 3H). ^{13}C NMR ($CDCl_3$) δ: 195.4, 160.0, 153.4, 142.4, 140.1, 129.8, 120.9, 114.5, 111.6, 55.4, 34.6, 30.7, 9.4.

(E)- 5-(3,4-Methylenedioxyphenyl)-2-methyl-2-pentenal (9c)

The procedures described above for **9a** were carried out using 3,4-methylenedioxydihydrocinnamaldehyde (**10c**) in the initial HWE step.

(*E*)-5-(3,4-Methylenedioxyphenyl)-2-methyl-2-pentenoate: pale yellow oil. R_f 0.69 (EtOAc/Hex, 1:1). IR (thin film, cm^{-1}): 2978, 2924, 2900, 1706. ^1H NMR ($CDCl_3$) δ: 6.77 (tq, *J* = 7.4, 1.4 Hz, 1H), 6.73 (d, *J* = 7.8 Hz, 1H), 6.68 (d, *J* = 1.7 Hz, 1H), 6.63 (dd, *J* = 7.9, 1.7 Hz, 1H), 5.92 (s, 2H), 4.18 (q, *J* = 7.1 Hz, 2H), 2.67 (t, *J* = 7.5 Hz, 2H), 2.44 (dt, *J* = 7.5, 7.5 Hz, 2H), 1.79 (d, *J* = 1.3 Hz, 3H), 1.29 (t, *J* = 7.1 Hz, 3H). ^{13}C NMR ($CDCl_3$) δ: 168.4, 147.8, 146.0, 141.0, 135.3, 128.7, 121.3, 109.0, 108.4, 101.0, 60.7, 34.7, 31.1, 14.5, 12.6. Anal. calcd. for $C_{15}H_{18}O_2$: C 68.68, H 6.92; found: C 68.85, H 6.86.

(*E*)-5-(3,4-Methylenedioxyphenyl)-2-methyl-2-pentenol: pale yellow oil. R_f 0.45 (EtOAc/Hex, 1:1). IR (thin film, cm^{-1}): 3226 (br), 2937, 2922. ^1H NMR ($CDCl_3$) δ: 6.72 (d, *J* = 7.9 Hz, 1H), 6.68 (d, *J* = 1.7 Hz, 1H), 6.63 (dd, *J* = 7.9, 1.7 Hz, 1H), 5.92 (s, 2H), 5.44 (tq, *J* = 7.0, 1.4 Hz, 1H), 3.99 (s, 2H), 2.59 (t, *J* = 7.5 Hz, 2H), 2.31 (dt, *J* = 7.5, 7.5 Hz, 2H), 1.63 (s, 3H). ^{13}C NMR ($CDCl_3$) δ: 147.7, 145.8, 136.1, 135.7, 125.3, 121.3, 109.1, 108.3, 101.0, 69.1, 35.6, 30.0, 13.9.

© 2004 NRC Canada

(*E*)-5-(3,4-methylenedioxyphenyl)-2-methyl-2-pentenal (**9c**): pale yellow oil. R_f 0.67 (EtOAc/Hex, 1:1). IR (thin film, cm^{-1}): 2924, 2857, 2777, 2715, 1683. ^1H NMR ($CDCl_3$) δ: 9.38 (s, 1H), 6.74 (d, *J* = 7.9 Hz, 1H), 6.68 (d, *J* = 1.8 Hz, 1H), 6.63 (dd, *J* = 7.8, 1.7 Hz, 1H)), 6.48 (tq, *J* = 7.2, 1.3 Hz, 1H), 5.94 (s, 2H), 2.74 (t, *J* = 7.6 Hz, 2H), 2.63 (dt, *J* = 7.6, 7.6 Hz, 2H), 1.69 (s, 3H). ^{13}C NMR ($CDCl_3$) δ: 195.4, 153.3, 147.9, 146.2, 140.1, 134.6, 121.4, 108.9, 108.5, 101.1, 34.4, 31.1, 9.4.

(E)-5-(3′-Furyl)-2-methyl-2-pentenal (perillenal) (9d)

The HWE – reduction – oxidation procedure described for **9a** was followed using 3-(3′-furyl)propanal (24).

Ethyl (*E*)-5-(3′-furyl)-2-methyl-2-pentenoate: pale yellow oil. R_f 0.67 (EtOAc/Hex, 1:1). IR (thin film, cm^{-1}): 2984, 2930, 2860, 1705. ^1H NMR ($CDCl_3$) δ: 7.36–7.34 (m, 1H), 7.26–7.24 (m, 1H), 6.77 (tq, *J* = 7.2, 1.4 Hz, 1H), 6.29–6.27 (m, 1H), 4.19 (q, *J* = 7.1 Hz, 2H), 2.57 (t, *J* = 7.4 Hz, 2H), 2.43 (dt, *J* = 7.4, 7.4 Hz, 2H), 1.81 (d, *J* = 1.3 Hz, 3H), 1.29 (t, *J* = 7.1 Hz, 3H). ^{13}C NMR ($CDCl_3$) δ: 168.3, 143.1, 141.1, 139.2, 128.7, 124.3, 111.1, 60.7, 29.4, 24.1, 14.5, 12.6.

(*E*)-5-(3′-Furyl)-2-methyl-2-pentenol: yellow oil. ^1H NMR consistent with previously published data (11*d*); R_f 0.43 (EtOAc/Hex, 1:1). ^1H NMR ($CDCl_3$) δ: 7.36–7.34 (m, 1H), 7.23–7.21 (m, 1H), 6.28–6.26 (m, 1H), 5.45 (tq, *J* = 7.0, 1.3 Hz, 1H), 4.00 (s, 2H), 2.49 (t, *J* = 7.6 Hz, 2H), 2.30 (dt, *J* = 7.6, 7.6 Hz, 2H), 1.66 (br s, 3H), 1.58 (br s, 1H). ^{13}C NMR ($CDCl_3$) δ: 142.9, 139.1, 135.7, 125.5, 124.9, 111.2, 69.1, 28.3, 24.9, 13.9.

(*E*)-5-(3-Furyl)-2-methyl-2-pentenal (**9d**): yellow oil. ^1H NMR consistent with previously published data (5, 11*c*); R_f 0.60 (EtOAc/Hex, 1:1). ^1H NMR ($CDCl_3$) δ: 9.39 (s, 1H), 7.36–7.37 (m, 1H), 7.25–7.24 (m, 1H), 6.49 (tq, *J* = 7.1, 1.3 Hz, 1H), 6.29–6.28 (m, 1H), 2.67–2.60 (m, 4H), 1.72 (br s, 3H). ^{13}C NMR ($CDCl_3$) δ: 195.3, 153.4, 143.3, 140.1, 139.3, 123.8, 110.9, 29.5, 23.8, 9.5.

Representative synthesis of dienones 11

(E)-2,4-Dimethyl-7-phenyl-1,4-heptadien-3-one (11a)

General procedure for the Grignard reaction

In a dry 10 mL round-bottomed flask equipped with a magnetic stir bar, a nitrogen inlet, a reflux condenser, and a rubber septum, magnesium powder (0.031 g, 1.3 mmol) was stirred with THF (2.0 mL). 2-Bromopropene (0.088 mL, 0.99 mmol) was added dropwise until exothermic reaction began, and then one drop at a time allowing the flask to cool between drops. When all of the bromide had been added, the Grignard reagent was cooled to 0 °C. (*E*)-2-Methyl-5-phenyl-2-pentenal **9a** (0.132 g, 0.760 mmol) was added to the Grignard reagent via cannula, and the reaction was monitored by TLC. The reaction was complete within 5 min and was quenched with satd. NH_4Cl (5 mL) and extracted with Et_2O (3 × 5 mL). The combined Et_2O layers were then dried ($MgSO_4$) and concentrated. Radial chromatography (silica gel, 2 mm plate, EtOAc/Hex (1:4)) provided (*E*)-2,4-dimethyl-7-phenyl-1,4-heptadien-3-ol **12a** (0.116 g, 71%) as a clear, pale yellow oil. R_f 0.32 (EtOAc/Hex, 1:4). IR (thin film, cm^{-1}): 3406 (br), 3027, 2856. ^1H NMR ($CDCl_3$) δ: 7.30–7.26 (m, 2H), 7.21–7.17 (m, 3H), 5.55 (tdq, *J* = 7.1, 1.1, 1.1 Hz, 1H), 5.05 (br s, 1H), 4.91 (dq, *J* = 1.5, 1.1 Hz, 1H), 4.19 (s, 1H), 2.70 (t, *J* = 7.7 Hz, 2H), 2.39 (dt, *J* = 7.7, 7.7 Hz, 2H), 1.57 (br s, 3H), 1.47 (br s, 3H). ^{13}C NMR ($CDCl_3$) δ: 145.5, 142.2, 135.8, 128.6, 128.5, 127.0, 126.0, 110.9, 80.9, 35.9, 29.8, 18.9, 11.6. Anal. calcd. for $C_{15}H_{20}O$: C 83.22, H 9.32; found: C 83.29, H 9.34.

General procedure for the barium manganate oxidation

In a dry 10 mL round-bottomed flask equipped with a magnetic stir bar, a nitrogen inlet, and a rubber septum, **12a** (0.111 g, 0.514 mmol) was dissolved in CH_2Cl_2 (5 mL) and combined with barium manganate (0.647 g, 2.69 mmol). After 5 days, TLC indicated that the dienol was consumed. The reaction mixture was concentrated, and the slurry was filtered over a pad of Celite on silica in CH_2Cl_2, followed by washing with EtOAc. The eluent was concentrated and radial chromatography (silica gel, 2 mm plate, EtOAc/Hex (1:9)) provided (*E*)-2,4-dimethyl-7-phenyl-1,4-heptadien-3-one **11a** (0.075 g, 68%) as a clear, pale yellow oil. R_f 0.50 (EtOAc/Hex, 1:4). IR (thin film, cm^{-1}): 2924, 2857, 1650. ^1H NMR ($CDCl_3$) δ: 7.32–7.28 (m, 2H), 7.23–7.18 (m, 3H), 6.39 (tq, *J* = 7.2, 1.3 Hz, 1H), 5.54 (dq, *J* = 1.6, 1.0 Hz, 1H), 5.33–5.32 (m, 1H), 2.78 (t, *J* = 7.6 Hz, 2H), 2.56 (dt, *J* = 7.6, 7.6 Hz, 2H), 1.92 (br s, 3H), 1.79 (br s, 3H). ^{13}C NMR ($CDCl_3$) δ: 200.8, 144.0, 143.2, 141.3, 136.6, 128.7, 128.6, 126.4, 123.1, 35.0, 30.9, 19.4, 12.5.

(E)-2,4-Dimethyl-7-(3-methoxyphenyl)-1,4-heptadien-3-one (11b)

The general procedures described for **11a** were followed using **9b** in place of **9a**.

(*E*)-7-(3-Methoxyphenyl)-2,4-dimethyl-1,4-heptadiene-3-ol (**12b**): colorless oil. R_f 0.66 (EtOAc/Hex, 1:1). IR (thin film, cm^{-1}): 3451 (br), 2937, 2921, 2856, 2830. ^1H NMR ($CDCl_3$) δ: 7.20 (td, *J* = 7.7, 1.3 Hz, 1H), 6.79 (d, *J* = 7.7 Hz, 1H), 6.75–6.72 (m, 2H), 5.54 (tdd, *J* = 7.1, 1.2, 1.2 Hz, 1H), 5.05 (s, 1H), 4.92–4.90 (m, 1H), 4.39 (s, 1H), 3.80 (s, 3H), 2.68 (t, *J* = 7.4, Hz, 2H), 2.38 (dt, *J* = 7.4, 7.4 Hz, 2H), 1.57 (s, 3H), 1.48 (s, 3H). ^{13}C NMR ($CDCl_3$) δ: 159.8, 145.5, 143.8, 135.8, 129.5, 127.0, 121.1, 114.5, 111.2, 110.9, 80.8, 55.4, 35.9, 29.7, 18.9, 11.6.

(*E*)-7-(3-Methoxyphenyl)-2,4-dimethyl-1,4-heptadiene-3-one (**11b**): pale yellow oil. R_f 0.47 (EtOAc/Hex, 1:4). IR (thin film, cm^{-1}): 2924, 2836, 1643. ^1H NMR ($CDCl_3$) δ: 7.21 (t, *J* = 7.8 Hz, 1H), 6.80–6.73 (m, 3H), 6.39 (tq, *J* = 7.2, 1.3 Hz, 1H), 5.54 (dq, *J* = 1.5, 1.5 Hz, 1H), 5.33 (s, 1H), 3.80 (s, 3H), 2.75 (t, *J* = 7.6 Hz, 2H), 2.56 (dt, *J* = 7.6, 7.6 Hz, 2H), 1.92 (br s, 3H), 1.80 (br s, 3H). ^{13}C NMR ($CDCl_3$) δ: 200.8, 159.9, 144.0, 143.2, 142.9, 136.6, 129.7, 123.1, 120.9, 114.4, 111.5, 55.4, 35.0, 30.8, 19.4, 12.5. Anal. calcd. for $C_{16}H_{20}O_2$: C 78.65, H 8.25; found: C 78.60, H 8.23.

(E,E′)-8-(3-Methoxyphenyl)-3-ethyl-5-methyl-2,5-octadien-4-one (11c)

General procedure for the Shapiro reaction

3-Pentanone trisyl hydrazone (0.489 g, 1.34 mmol) was dissolved in THF (13 mL) and cooled to –78 °C in a dry 50 mL round-bottomed flask fitted with arubber septum, a nitrogen inlet, and a magnetic stir bar. *sec*-BuLi (1.23 mol L^{-1} in hexane, 2.2 mL, 2.7 mmol) was added

© 2004 NRC Canada

dropwise by syringe and the mixture was allowed to stir at −78 °C for 1.5 h. Following this period, the reaction was placed in a 0 °C bath for 30 min or until nitrogen evolution ceased. After recooling to –78 °C, (*E*)-5-(3-methoxyphenyl)-2-methyl-2-pentenal (**9b**) (0.245 g, 1.28 mmol) was added via cannula in a solution with THF (2 mL). The reaction was monitored by TLC and quenched with satd. NH_4Cl (10 mL) upon consumption of aldehyde. The crude product was extracted with Et_2O (3 × 10 mL), dried ($MgSO_4$), concentrated, and purified by radial chromatography (silica gel, 2 mm plate, EtOAc/Hex (1:10 to 1:4)) to yield 0.165 g (47%) (*E*,*E*′)-8-(3-methoxyphenyl)-3-ethyl-5-methyl-2,5-octadien-4-ol (**12c**) as a clear, pale yellow oil. R_f 0.64 (EtOAc/Hex, 1:1). IR (thin film, cm^{-1}): 3453 (br), 2961, 2929, 2871, 2857. ^1H NMR ($CDCl_3$) δ: 7.20 (t, *J* = 8.0 Hz, 1H), 6.80 (d, *J* = 8.0 Hz, 1H), 6.76–6.73 (m, 2H), 5.57 (tdq, *J* = 7.1, 1.2, 1.2 Hz, 1H), 5.53 (q, *J* = 6.8 Hz, 1H), 4.40 (s, 1H), 3.81 (s, 3H), 2.68 (t, *J* = 7.6 Hz, 2H), 2.38 (dt, *J* = 7.6, 7.6 Hz, 2H), 2.04–1.97 (m, 1H), 1.91–1.83 (m, 1H), 1.65 (d, *J* = 6.8 Hz, 3H), 1.57 (br s, 1H), 1.46 (s, 3H), 0.92 (t, *J* = 7.6 Hz, 3H). ^{13}C NMR ($CDCl_3$) δ: 159.8, 144.0, 142.0, 136.4, 129.5, 125.8, 121.1, 120.3, 114.5, 111.2, 80.6, 55.4, 36.0, 29.8, 20.5, 13.7, 13.1, 12.4.

Dienol **12c** was oxidized with barium manganate per the procedure described for **11a** to give (*E*,*E*′)-8-(3-methoxyphenyl)-3-ethyl-5-methyl-2,5-octadien-4-one (**11c**) as a pale yellow oil. R_f 0.69 (EtOAc/Hex, 1:1). IR (thin film, cm^{-1}): 2962, 2931, 2836, 1634. ^1H NMR ($CDCl_3$) δ: 7.22 (t, *J* = 7.8 Hz, 1H), 6.79–6.73 (m, 3H), 6.12 (tq, *J* = 7.2, 1.5 Hz, 1H), 6.00 (q, *J* = 7.0 Hz, 1H), 3.80 (s, 3H), 2.74 (t, *J* = 7.6 Hz, 2H), 2.53 (dt, *J* = 7.6, 7.6 Hz, 2H), 2.34 (q, *J* = 7.6 Hz, 2H), 1.79 (br s, 3H), 1.76 (d, *J* = 7.0 Hz, 3H), 0.93 (t, *J* = 7.6 Hz, 3H). ^{13}C NMR ($CDCl_3$) δ: 201.5, 159.9, 143.4, 143.1, 140.8, 137.6, 135.8, 129.6, 121.0, 114.6, 111.4, 55.4, 35.1, 30.4, 20.2, 14.1, 13.2, 13.1.

*(*E*)-1-Cyclohexenyl-5-(3-methoxyphenyl)-2-methyl-2-penten-1-one (11d)*

The general procedures described for **11c** were followed using cyclohexanone trisyl hydrazone in place of 3-pentanone trisyl hydrazone.

(*E*)-1-Cyclohexenyl-5-(3-methoxyphenyl)-2-methyl-2-penten-1-ol (**12d**): pale yellow oil. R_f 0.26 (EtOAc/Hex, 1:4). IR (thin film, cm^{-1}): 3418 (br), 2924, 2855, 2835. ^1H NMR ($CDCl_3$) δ: 7.19 (t, *J* = 7.6 Hz, 1H), 6.79 (d, *J* = 7.6 Hz, 1H), 6.76–6.72 (m, 2H), 5.73 (dddd, *J* = 3.4, 3.4, 1.8, 1.8 Hz, 1H), 5.51 (tqd, *J* = 7.1, 1.2, 1.2 Hz, 1H), 4.30 (s, 1H), 3.80 (s, 3H), 2.67 (t, *J* = 7.6 Hz, 2H), 2.38 (dt, *J* = 7.6, 7.6 Hz, 2H), 2.07–2.02 (m, 2H), 1.80–1.67 (m, 2H), 1.62–1.51 (m, 5H), 1.46 (s, 3H). ^{13}C NMR ($CDCl_3$) δ: 159.8, 143.9, 138.0, 136.2, 129.4, 125.7, 122.8, 121.1, 114.5, 111.2, 80.9, 55.3, 36.0, 29.7, 25.2, 24.6, 22.9, 22.8, 12.3. Anal. calcd. for $C_{19}H_{26}O_2$: C 79.68, H 9.15; found C 79.41, H 9.12.

(*E*)-1-Cyclohexenyl-5-(3-methoxyphenyl)-2-methyl-2-penten-1-one (**11d**): pale yellow oil. R_f 0.38 (EtOAc/Hex, 1:4). IR (thin film, cm^{-1}): 2933, 2858, 2836, 1632. ^1H NMR ($CDCl_3$) δ: 7.22 (ddd, *J* = 7.6, 7.6, 1.0 Hz, 1H), 6.81–6.74 (m, 3H), 6.31 (ddd, *J* = 3.9, 2.2, 1.7 Hz, 1H), 6.12 (tq, *J* = 7.2, 1.5 Hz, 1H), 3.81 (s, 3H), 2.75 (t, *J* = 7.6 Hz, 2H), 2.54 (dt, *J* = 7.6, 7.6 Hz, 2H), 2.27–2.23 (m, 2H), 2.19–2.14 (m, 2H), 1.80 (d, *J* = 1.4 Hz, 3H), 1.69–1.57 (m, 4H). ^{13}C NMR ($CDCl_3$) δ: 200.9, 159.9, 143.2, 140.2, 140.0, 138.4, 136.6, 129.6, 121.0, 114.5, 111.4, 55.4, 35.1, 30.4, 25.9, 24.5, 22.3, 21.9, 13.2.

*(*E*)-7-(3,4-Methylenedioxyphenyl)-2,4-dimethyl-1,4-heptadien-3-one (11e)*

The general procedures described for **11a** were followed using **9c** in place of **9a**.

(*E*)-1-Cyclohexenyl-5-(3,4-methylendioxyphenyl)-2-methyl-2-penten-1-one (**11g**): pale yellow oil. R_f 0.39 (EtOAc/Hex, 1:4). ^1H NMR ($CDCl_3$) δ: 6.73 (d, *J* = 7.8 Hz, 1H), 6.68 (d, *J* = 1.7 Hz, 1H), 6.63 (dd, *J* = 7.8, 1.7 Hz, 1H), 6.31 (dddd, *J* = 3.7, 3.7, 2.2, 1.6 Hz, 1H), 6.10 (tq, *J* = 7.2, 1.4 Hz, 1H), 5.92 (s, 2H), 2.68 (t, *J* = 7.5 Hz, 2H), 2.48 (dt, *J* = 7.5, 7.5 Hz, 2H), 2.26–2.22 (m, 2H), 2.19–2.15 (m, 2H), 1.78 (d, *J* = 0.8 Hz, 3H), 1.68–1.58 (m, 4H). ^{13}C NMR ($CDCl_3$) δ: 200.9, 147.9, 146.0, 140.1, 139.9, 138.5, 136.7, 135.5, 121.4, 109.0, 108.4, 101.1, 34.9, 30.8, 25.9, 24.5, 22.3, 21.9, 13.2.

(E)-7-(3′-Furyl)-2,4-dimethyl-1,4-heptadien-3-one (11h)

The general procedures described for **11a** were followed using **9d** in place of **9a**.

(*E*)-7-(3′-Furyl)-2,4-dimethyl-1,4-heptadien-3-ol (**12h**): colorless oil. R_f 0.70 (EtOAc/Hex, 1:1). ^1H NMR ($CDCl_3$) δ: 7.35 (t, *J* = 1.6 Hz, 1H), 7.23–7.22 (m, 1H), 6.30–6.28 (m, 1H), 5.54 (tdq, *J* = 7.1, 1.2, 1.2 Hz, 1H), 5.07 (br s, 1H), 4.93 (dq, *J* = 4.0, 1.5 Hz, 1H), 4.41 (br s, 1H), 2.51 (t, *J* = 7.6 Hz, 2H), 2.33 (dt, *J* = 7.6, 7.6 Hz, 2H), 1.59 (br s, 3H), 1.57 (br s, 1H), 1.52 (s, 3H). ^{13}C NMR ($CDCl_3$) δ: 145.6, 142.9, 139.1, 135.8, 127.0, 124.9, 111.2, 111.0, 80.8, 28.4, 24.9, 28.8, 11.7.

(*E*)-7-(3′-Furyl)-2,4-dimethyl-1,4-heptadien-3-one (**11h**): colorless oil. R_f 0.63 (EtOAc/Hex, 1:1). ^1H NMR ($CDCl_3$) δ: 7.36 (t, *J* = 1.5 Hz, 1H), 7.23–7.22 (m, 1H), 6.37 (tq, *J* = 7.0, 1.3 Hz, 1H), 6.28–6.27 (m, 1H), 5.56 (dq, *J* = 1.5, 1.5 Hz, 1H), 5.36–5.35 (m, 1H), 2.59 (t, *J* = 7.0 Hz, 2H), 2.50 (dt, *J* = 7.0, 7.0 Hz, 2H), 1.93 (dd, *J* = 1.5, 1.0 Hz, 3H), 1.84–1.82 (m, 3H). ^{13}C NMR ($CDCl_3$) δ 200.8, 144.1, 143.2, 143.1, 139.2, 136.7, 124.2, 123.1, 111.0, 29.5, 24.1, 19.4, 12.6. Anal. calcd. for $C_{13}H_{16}O_2$: C 76.44, H 7.90; found: C 76.15, H 7.92.

Cyclization of 11a

2,5-Dimethyl-3-(2-phenylethyl)cyclopent-2-en-1-one (13a)

A solution of **11a** (0.073 g, 0.34 mmol) in CH_2Cl_2 (35 mL) in a 100 mL round-bottomed flask fitted with a magnetic stir bar, a nitrogen inlet, and a rubber septum, was cooled to –78 °C. $BF_3{\cdot}OEt_2$ (0.180 mL, 1.42 mmol) was added dropwise. The reaction was then allowed to warm slowly to rt, after which TLC indicated **11a** was consumed. The reaction was quenched with H_2O (20 mL), the layers separated, and the aqueous layer extracted with CH_2Cl_2. The combined organic layers were dried ($MgSO_4$), concentrated, and subjected to radial chromatography (silica gel, 2 mm plate, EtOAc/Hex (1:4)) to provide **13a** (0.036 g, 69%) as a clear, colorless oil. R_f 0.55 (EtOAc/Hex, 1:1). IR (thin film, cm^{-1}): 2962, 2924, 2861, 1697, 1649. ^1H NMR ($CDCl_3$) δ: 7.30–7.26 (m, 2H), 7.23–7.15 (m, 3H), 2.83 (t, *J* = 7.4 Hz, 2H), 2.75–2.68 (m, 3H), 2.34 (qdd, *J* = 7.2, 7.2, 2.4 Hz, 1H), 2.06 (br d, *J* = 18.4 Hz, 1H), 1.57 (t, *J* = 2.0 Hz, 3H), 1.14 (d, *J* = 7.4 Hz, 3H). ^{13}C NMR ($CDCl_3$) δ: 212.7, 170.7, 140.9, 135.7, 128.7, 128.4, 126.5, 39.6, 38.8, 33.5, 33.1, 16.8, 8.2.

Representative procedure for domino Nazarov cyclization – arene trapping of 11

Benzohydrindenone (14f)

Dienone **11f** (51 mg, 0.18 mmol) was dissolved in CH_2Cl_2 (18 mL) and cooled to –78 °C. A solution of $TiCl_4$ in CH_2Cl_2 (0.050 mL of a 3.51 mol L^{-1} solution, 0.18 mmol) was added dropwise, and after 5 min TLC showed complete consumption of the starting material. The reaction was quenched with water (5 mL) and allowed to warm to rt, then the layers were separated and the aqueous layer extracted with CH_2Cl_2 (3 × 5 mL). The combined organic layers were dried ($MgSO_4$) and concentrated to give 51 mg (99%) of **14f** as colorless crystals, deemed pure by TLC and NMR analysis: mp 71 to 72 °C. R_f 0.48 (EtOAc/hexanes, 1:4). IR (thin film, cm^{-1}): 2959, 2923, 2867, 1731. ^1H NMR ($CDCl_3$, 500 MHz) δ: 6.97 (s, 1H), 6.49 (s, 1H), 5.86 (s, 2H), 2.76 (ddd, *J* = 17.2, 13.0, 6.0 Hz, 1H), 2.63 (ddd, *J* = 17.1, 6.2, 1.6 Hz, 1H), 2.02 (dddd, *J* = 13.9, 5.2, 3.3, 1.8 Hz, 1H), 1.87 (dddd, *J* = 13.5, 13.5, 6.1, 3.7 Hz, 1H), 1.82–1.75 (m, 2H), 1.71–1.66 (m, 1H), 1.54–1.45 (m, 2H), 1.34 (s, 3H), 1.12 (d, *J* = 6.1 Hz, 3H), 0.65 (t, *J* = 7.5 Hz, 3H). ^{13}C NMR ($CDCl_3$, 125 MHz) δ: 221.6, 146.3, 146.3, 129.1, 128.4, 108.8, 108.4, 100.9, 56.6, 51.9, 48.8, 33.3, 27.2, 25.1, 21.9, 18.4, 17.7, 11.2.

The representative procedure described for the formation of **14f** was followed to give **14b**–**14e** and **14g**.

Benzohydrindenone **14b**: pale yellow oil; single regio- and diastereoisomer by ^1H and ^{13}C NMR analysis. R_f 0.39 (EtOAc/Hex, 1:4). IR (thin film, cm^{-1}): 2958, 2926, 2870, 1732. ^1H NMR ($CDCl_3$) δ: 7.42 (d, *J* = 8.8 Hz, 1H), 6.71 (dd, *J* = 8.8, 2.8 Hz, 1H), 6.58 (d, *J* = 2.8 Hz, 1H), 3.76 (s, 3H), 2.88 (ddd, *J* = 17.4, 12.0, 6.0 Hz, 1H), 2.72 (ddd, *J* = 17.4, 6.0, 2.0 Hz, 1H), 2.28 (ddq, *J* = 11.3, 8.2, 7.1 Hz, 1H), 2.19 (ddt, *J* = 12.0, 6.0, 3.5 Hz, 1H), 2.07 (ddd, *J* = 12.5, 8.3, 6.1 Hz, 1H), 2.00 (dddd, *J* = 12.5, 9.8, 6.1, 3.8 Hz, 1H), 1.92–1.85 (m, 2H), 1.36 (s, 3H), 0.99 (d, *J* = 7.1 Hz, 3H). ^{13}C NMR ($CDCl_3$) δ 222.6, 158.1, 136.9, 130.3, 127.7, 113.9, 112.8, 55.3, 50.7, 42.9, 41.5, 31.7, 27.2, 25.4, 21.3, 16.0.

Benzohydrindenone **14c**: colorless oil; single regio- and stereoisomer by ^1H and ^{13}C NMR analysis. R_f 0.70 (EtOAc/Hex, 1:1). IR (thin film, cm^{-1}): 2958, 2923, 2865, 1730. ^1H NMR ($CDCl_3$) δ: 7.37 (d, *J* = 8.7 Hz, 1H), 6.70 (dd, *J* = 8.6, 2.8 Hz, 1H), 6.57 (d, *J* = 2.8 Hz, 1H), 3.75 (s, 3H), 2.84 (ddd, *J* = 17.7, 13.0, 6.5 Hz, 1H), 2.71 (dd, *J* = 17.5, 5.0 Hz, 1H), 2.04 (dddd, *J* = 14.0, 5.1, 3.3, 1.8 Hz, 1H), 1.91 (dqd, *J* = 13.5, 6.2, 3.5 Hz, 1H), 1.83–1.75 (m, 2H), 1.73–1.68 (m, 1H), 1.54–1.42 (m, 2H), 1.35 (s, 3H), 1.12 (d, *J* = 6.1 Hz, 3H), 0.61 (t, *J* = 7.5 Hz, 3H). ^{13}C NMR ($CDCl_3$) δ: 221.6, 158.0, 137.0, 130.1, 127.5, 113.9, 112.7, 56.6, 55.3, 51.4, 48.9, 33.2, 27.1, 25.1, 21.9, 18.3, 17.7, 11.1.

Benzohydrindenone **14d**: colorless solid; single regio- and stereoisomer by ^{1}H and ^{13}C NMR analysis; mp 86–88 °C. R_f 0.40 (EtOAc/Hex, 1:4). IR (thin film, cm^{-1}) 2924, 2855, 1734. ^{1}H NMR ($CDCl_3$) δ: 7.66 (d, J = 8.8 Hz, 1H), 6.76 (dd, J = 8.8, 2.4 Hz, 1H), 6.57 (d, J = 2.8 Hz, 1H), 3.77 (s, 3H), 2.79 (ddd, J = 17.5, 13.2, 5.8 Hz, 1H), 2.67 (ddd, J = 17.5, 5.9, 2.4 Hz, 1H), 2.10–2.00 (m, 3H), 1.92–1.80 (m, 4H), 1.76 (ddd, J = 13.1, 11.4, 3.4 Hz, 1H), 1.49–1.40 (m, 1H), 1.42 (s, 3H), 1.29–1.08 (m, 3H), 1.04–0.96 (m, 1H). ^{13}C NMR ($CDCl_3$) δ: 219.6, 157.9, 137.1, 130.7, 128.9, 113.6, 112.8, 55.3, 54.3, 50.7, 48.2, 41.0, 30.6, 28.5, 26.4, 26.1, 25.8, 25.7, 19.1.

Benzohydrindenone **14e**: pale yellow oil; single regio- and diastereoisomer by ^{1}H and ^{13}C NMR analysis. R_f 0.39 (EtOAc/Hex, 1:4). IR (thin film, cm^{-1}): 2959, 2925, 2872, 1732. ^{1}H NMR ($CDCl_3$) δ: 7.01 (s, 1H), 6.50 (s, 1H), 5.88 (d, J = 1.5 Hz, 1H), 5.86 (d, J = 1.5 Hz, 1H), 2.80 (ddd, J = 17.0, 12.3, 5.9 Hz, 1H), 2.64 (ddd, J = 17.0, 5.9, 2.2 Hz, 1H), 2.28 (ddq, J = 15.4, 11.2, 7.2 Hz, 1H), 2.20–2.14 (m, 1H), 2.06 (ddd, J = 12.5, 8.3, 6.0 Hz, 1H), 1.96 (dddd, J = 12.5, 12.5, 6.0, 3.8, Hz, 1H), 1.90 (dd, J = 1.4, 1.4 Hz, 1H), 1.89–1.83 (m, 1H), 1.35 (s, 3H), 1.01 (d, J = 7.2 Hz, 3H). ^{13}C NMR ($CDCl_3$) δ: 146.4, 129.0, 128.5, 108.7, 100.9, 51.1, 42.8, 41.4, 31.6, 27.2, 25.4, 21.4, 16.0.

Benzohydrindenone **14g**: pale yellow solid; single regio- and stereoisomer by ^{1}H and ^{13}C NMR analysis; mp 124–126 °C. R_f 0.32 (EtOAc/Hex, 1:4). IR (thin film, cm^{-1}): 2924, 2856, 1735. ^{1}H NMR ($CDCl_3$) δ: 7.25 (s, 1H), 6.48 (s, 1H), 5.88 (d, J = 1.5 Hz, 1H), 5.84 (d, J = 1.5 Hz, 1H), 2.75–2.66 (m, 1H), 2.62–2.54 (m, 1H), 2.09–2.03 (m, 2H), 2.03–1.97 (m, 1H), 1.85–1.78 (m, 4H), 1.74 (ddd, J = 13.1, 11.2, 3.4 Hz, 1H), 1.47–1.39 (m, 1H), 1.39 (s, 3H), 1.24–1.07 (m, 3H), 1.05–0.97 (m, 1H). ^{13}C NMR ($CDCl_3$) δ: 219.4, 146.4, 146.2, 129.7, 129.1, 109.2, 108.5, 100.9, 54.2, 51.2, 48.1, 41.0, 30.6, 28.5, 26.4, 26.1, 25.7, 25.7, 19.2.

Cyclization of 3h furohydrindenone (14h)

(*E*)-7-(3-Furyl)-2,4-dimethyl-1,4-heptadien-3-one (**11h**) (0.042 g, 0.21 mmol) was dissolved in CH_2Cl_2 (20 mL) and cooled to –78 °C. $TiCl_4$ (0.060 mL of a 3.51 mol L^{-1} solution in CH_2Cl_2, 0.21 mmol) was added, and the reaction was allowed to warm to rt; after 15 min at rt, the reaction was quenched with H_2O (10 mL), and stirred overnight. The layers were separated, the aqueous layer was extracted with CH_2Cl_2 (3 × 10 mL), dried ($MgSO_4$), and concentrated. Radial chromatography (silica gel, 1 mm plate, EtOAc/Hex (1:4)) provided 0.024 g (56%) of the tricyclic ketone **14h** as a colorless oil and a single regio- and stereoisomer by ^{1}H and ^{13}C NMR analysis. R_f 0.70 (EtOAc/Hex, 1:1). ^{1}H NMR ($CDCl_3$) δ: 7.30 (d, J = 1.9 Hz, 1H), 6.15 (d, J = 1.9 Hz, 1H), 2.51–2.48 (m, 2H), 2.35–2.25 (m, 3H), 2.07 (ddd, J = 8.5, 6.3, 6.3 Hz, 1H), 1.91–1.86 (m, 2H), 1.39 (s, 3H), 1.05 (d, J = 7.1 Hz, 3H). ^{13}C NMR ($CDCl_3$) δ: 218.8, 147.9, 142.8, 117.4, 110.3, 49.8, 43.1, 42.8, 31.7, 29.9, 22.4, 18.8, 15.2. IR (thin film, cm^{-1}): 2960, 2924, 2853, 1739, 1456.

Acknowledgments

We thank U.S. National Institutes of Health (GM 44720) for support of this work, Dr. Atta Arif for assistance in obtaining the X-ray crystal structure of **14f**, and Ben Jessie for preliminary experiments in this study.

Molecular tectonics — Use of urethanes and ureas derived from tetraphenylmethane and tetraphenylsilane to build porous chiral hydrogen-bonded networks[1]

Dominic Laliberté, Thierry Maris, and James D. Wuest

Abstract: Tetraphenylmethane, tetraphenylsilane, and simple derivatives with substituents that do not engage in hydrogen bonding typically crystallize as close-packed structures with essentially no space available for the inclusion of guests. In contrast, derivatives with hydrogen-bonding groups are known to favor the formation of open networks that include significant amounts of guests. To explore this phenomenon, we synthesized six new derivatives **5a**–**5e** and **6a** of tetraphenylmethane and tetraphenylsilane with urethane and urea groups at the para positions, crystallized the compounds, and determined their structures by X-ray crystallography. As expected, all six compounds crystallize to form porous three-dimensional hydrogen-bonded networks. In the case of tetraurea **5e**, 66% of the volume of the crystals is accessible to guests, and guests can be exchanged in single crystals without loss of crystallinity. Of special note are: (*i*) the use of tetrakis(4-isocyanatophenyl)methane (**1f**) as a precursor for making enantiomerically pure tetraurethanes and tetraureas, including compounds **5b**, **5c**; and (*ii*) their subsequent crystallization to give porous chiral hydrogen-bonded networks. Such materials promise to include chiral guests enantioselectively and to be useful in the separation of racemates, asymmetric catalysis, and other applications.

Key words: crystal engineering, molecular tectonics, hydrogen bonding, networks, porosity, urethanes, ureas, tetraphenylmethane, tetraphenylsilane.

Résumé : Le tétraphénylméthane, le tétraphénylsilane et leurs dérivés simples ne portant pas de substituants pouvant participer à des liaisons hydrogène cristallisent généralement sous la forme de structures compactes dans lesquelles il n'y a pas de place disponible pour l'inclusion de molécules invitées. Par contraste, il est bien connu que les dérivés comportant des groupes pouvant donner lieu à des liaisons hydrogène favorisent la formation de réseaux ouverts qui peuvent inclure des quantités importantes de molécules invitées. Dans le but d'étudier ce phénomène, on a réalisé la synthèse de six nouveaux dérivés, **5a**–**5e** et **6a**, du tétraphénylméthane et du tétraphénylsilane portant des groupes uréthane et urée en position para qui ont été cristallisés et dont on a déterminé la structure par diffraction des rayons X. Tel que prévu, les six composés cristallisent en formant des réseaux poreux tridimensionnels reliés par des ponts hydrogène. Dans le cas de la tétraurée **5e**, 66 % du volume des cristaux est disponible pour des molécules invitées et les invités peuvent être échangés dans les cristaux uniques sans perte de cristallinité. Il est particulièrement important de noter: (*i*) qu'il est possible d'utiliser le tétrakis(4-isocyanatophényl)-méthane (**1f**) comme précurseur dans la synthèse de tétrauréthanes et de tétraurées énantiomèrement pures, y compris les composés **5b**, **5c** et (*ii*) qu'il est possible de les cristalliser subséquemment pour donner des réseaux chiraux poreux reliés par des ponts hydrogène. Des tels produits pourraient inclure énantiosélectivement des molécules invitées chirales et ainsi être utilisés dans la séparation de racémates, en catalyse asymétrique ou dans d'autres applications.

Mots clés : ingénierie cristalline, tectonique moléculaire, liaison hydrogène, réseaux, porosité, uréthanes, urées, tétraphénylméthane, tétraphénylsilane.

Introduction

No reliable method yet exists for predicting the detailed structure of molecular crystals (1–4), and the relationship between the structure of crystals and their physical properties remains poorly understood. For these reasons, attempts to control molecular crystallization and to engineer crystals for specific applications remain largely empirical activities.

As a result, crystal engineering offers exceptional challenges and opportunities, and it has become one of the most exciting areas in contemporary science (5).

In a recent review (1), Dunitz identifies a strategy for directing molecular crystallization that has played a key role in bringing crystal engineering to the forefront of science: "…computational methods for predicting crystal structures of organic compounds cannot yet be regarded as reliable. From a more qualitative and descriptive viewpoint has come the notion that certain groupings in organic molecules exercise attractive intermolecular interactions and so guide the molecules into distinctive patterns in their crystal structures…This indeed has become one of the tenets of crystal engineering. The prime example of a structure directing interaction is, of course, the hydrogen bond."

This strategy can be used to design molecules to serve as subunits for the programmed construction of particular crystalline networks. This can be achieved by incorporating carefully oriented arrays of sticky sites that interact intermolecularly according to reliable motifs. Such molecules have been called tectons (6), a term derived from the Greek word for builder, and molecular tectonics refers to the strategy of building supramolecular structures from tectonic subunits (6, 7).

Tectons have arrays of sticky sites that direct intermolecular association, linked to cores that orient the sticky sites and introduce other desirable molecular features. In favorable cases, the oriented sticky sites play a dominant role in association and place each tecton in a predetermined position relative to its neighbors. Normally, tectons cannot form structures that pack efficiently and simultaneously obey the imperatives of strong directional interactions, so open molecular networks are favored, with significant space for the inclusion of guests. Many different sticky sites and cores can be used, giving molecular tectonics wide scope as a strategy for creating ordered materials with unique properties. In particular, we have recently made hydrogen-bonded molecular crystals that (*i*) can be engineered with sub-nanometric precision (8); (*ii*) use at least 75% of their volume to include guests, which can be exchanged without loss of crystallinity (9); (*iii*) can be deformed by at least 30% without loss of crystallinity (10); and (*iv*) react with external agents to give single crystals of new compounds with retention of the original crystalline architecture (11, 12).[3]

Invaluable basic information about molecular tectonics can be acquired through systematic comparison of structures built from tectons with a fixed core and variable sticky sites, or with fixed sticky sites and variable cores. In such studies, relatively rigid cores are beneficial because they facilitate comparison by minimizing polymorphism due to multiple conformations. The tetraphenylmethyl core (**1a**) and its tetraphenylsilyl analogue **2a** are particularly attractive choices, and various tectons with simple hydrogen-bonding sites attached to these cores have been used in crystal engineering (8, 13–16).

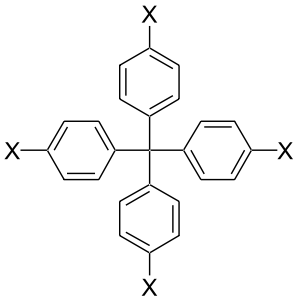
Tetraphenylmethane and tetraphenylsilane crystallize to form isomorphous close-packed structures held together by multiple phenyl–phenyl embraces (17, 18), and simple derivatives with substituents that do not engage in hydrogen bonding also typically form close-packed structures (19–29). In contrast, 4-substituted derivatives with simple hydrogen-bonding groups, including tetraphenols **1b** and **2b** (13), tetraboronic acids **1c** and **2c** (8), and other compounds (15, 16), are known to favor open networks that include significant amounts of guests. Even derivatives with substituents that form relatively weak C-H···O hydrogen bonds, such as tetrakis(4-nitrophenyl)methane (**1d**) (14), can form open networks.

To explore the scope of this phenomenon, help identify its origins, and test its potential for creating ordered materials with new properties, we have extended our study of tectons derived from tetraphenylmethane and tetraphenylsilane to include new 4-substituted derivatives bearing urethane and urea groups, which have been used previously in crystal engineering because they self-associate reliably in the solid state to form hydrogen-bonded chains **3** and **4** (30–37). In this paper, we show how such compounds can be made and used to generate networks that are both porous and chiral.

Results and discussion

Synthesis of urethanes and ureas derived from tetraphenylmethane and tetraphenylsilane

Tetrakis(4-nitrophenyl)methane (**1d**) (38) was reduced by an improved procedure (H_2/Pd/C, THF) to provide a 99% yield of the known tetrakis(4-aminophenyl)methane (**1e**) (16, 38, 39). Subsequent reaction of tetramine **1e** with triphosgene and triethylamine gave tetrakis(4-isocyanatophenyl)methane (**1f**) in 97% yield. The analogous isothiocyanate **1g** was obtained in 89% yield by the reaction of tetramine **1e** with thiophosgene and triethylamine. Heating tetra(isocyanate) **1f** with alcohols and amines then gave the corresponding urethanes and ureas. In this way, urethanes **5a**, **5b** and ureas **5c**, **5d** were prepared from ethanol, (*R*)-2-butanol, (*S*)-2-butylamine, and (*S*)-α-methylbenzylamine in yields of 83%, 78%, 99%, and 99%, respectively. Treatment of tetra(isocyanate) **1f** with aqueous ammonia at 25 °C gave simple urea **5e** in 92% yield. For comparison with tetraurethane **5a,** analogue **6a** with a tetraphenylsilyl core was prepared in 18% yield by Pd-catalyzed coupling of tetrakis(4-bromophenyl)silane (**2d**) (40) with ethyl carbamate (41).



Structure of tetrakis(4-isothiocyanatophenyl)methane (1g)

Tetra(isothiocyanate) **1g** was crystallized from $CHCl_3$–hexane, and its structure was determined by X-ray diffraction (Table 1, Fig. 1).[4] Like most other simple derivatives of tetraphenylmethane and tetraphenylsilane (17–29), compound **1g** forms a close-packed structure without included guests. This observation confirms that molecules with a

close structural relationship to tectons **5a**–**5e**, but without an ability to self-associate by hydrogen bonding, are not predisposed to form inclusion compounds.

Analysis of hydrogen-bonded networks formed by crystallization of tetraurethane 5a and the analogous silane 6a

Tecton **5a** crystallized from THF–pentane in the tetragonal space group *I*-4 as an inclusion compound of well-defined composition **5a**·2THF (Table 1).[4] The structure is shown in Figs. 2 and 3. The tectons can be divided into two equal populations (Fig. 2), one that donates single hydrogen bonds to four symmetrically oriented neighbors, and the other that accepts hydrogen bonds from four symmetrically oriented neighbors and simultaneously donates hydrogen bonds to four molecules of THF. Connecting the tetrahedral centers of hydrogen-bonded tectons defines a diamondoid network (42) with an alternating hydrogen bond donor–acceptor arrangement, in which each node is surrounded by four belonging to the other population. The network is held

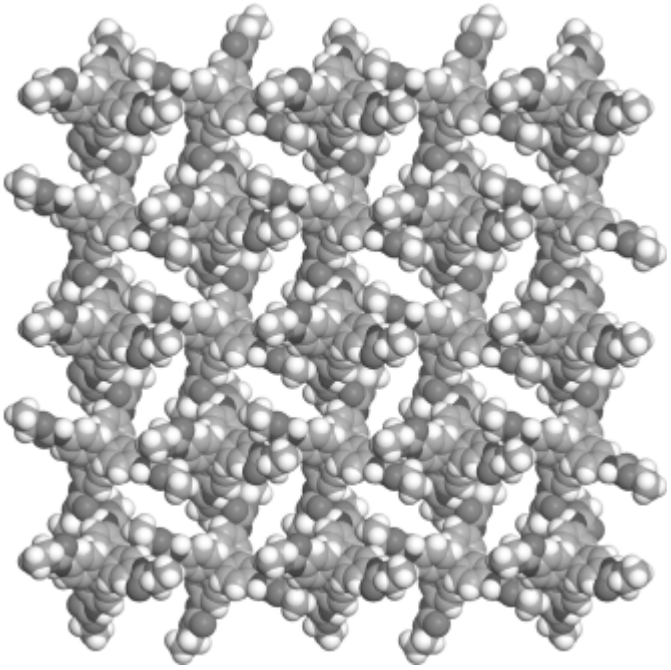
Fig. 3. View along the *c* axis of the network constructed from tetraurethane **5a** showing a 2 × 2 × 4 array of unit cells. Guests are omitted, and atoms are shown as spheres of van der Waals radii to reveal the cross sections of the channels. Atoms of hydrogen appear in white, atoms of carbon in light gray, atoms of oxygen in gray, and atoms of nitrogen in dark gray.



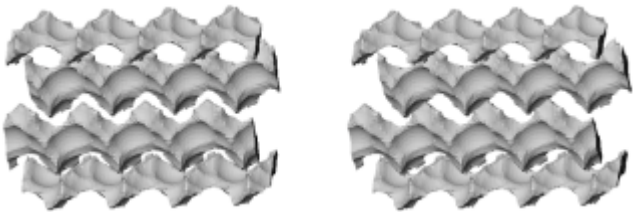


Fig. 4. Stereoscopic representation of the parallel helical channels defined by the network constructed from tetraurethane **5a**. The image shows a 1 × 1 × 4 array of unit cells viewed with the *c* axis horizontal. The outsides of the channels appear in light gray, and dark gray is used to show where the channels are cut by the boundaries of the array. The surface of the channels is defined by the possible loci of the centre of a sphere of diameter 3 Å as it rolls over the surface of the ordered network.[7]

together by only four hydrogen bonds per tecton. The average distance between the tetrahedral centers of hydrogen-bonded neighbors defines an intertectonic separation of 12.6 Å, which is too small to permit interpenetration (43, 44). Approximately 29% of the volume of crystals of tecton **5a** is available for including guests,[5] which occupy parallel channels that lie along the *c* axis and have cross sections measuring nearly 11 × 3 Å^2 (Fig. 3).[6] Close examination of the channels reveals that each is helical and chiral, with equal numbers of helices of opposite handedness (Fig. 4).[7]

Crystallization of tetraboronic acid **1c** and the analogous silane **2c** under similar conditions is known to produce isostructural hydrogen-bonded networks (8). Replacing the central C—C bonds in compound **1c** with longer Si—C bonds in analogue **2c** results in a rational expansion of the network, with predictable control of geometry on the sub-nanometric scale. To further test the ability of molecular tectonics to control crystallization with this degree of precision, we compared the structure of tetraurethane **5a** with that formed by the corresponding silane **6a**. Tecton **6a** crystallized from dioxane–pentane in the tetragonal space group $P4_2/n$ as an inclusion compound with the composition **6a**·2 dioxane (Table 1).[4] The structure is shown in Figs. 5 and 6. Each tecton donates four hydrogen bonds to four neighboring molecules of dioxane, and each molecule of dioxane accepts two hydrogen bonds from different tectons, thereby creating a diamondoid network (42) in which dioxane is an essential structural component (Fig. 5). The average Si···Si distance between closest pairs of tectons within the network is 16.6 Å, which is large enough to permit sixfold interpenetration (Fig. 6) (43, 44). This fills the available volume completely, giving a close-packed structure containing only tecton **6a** and molecules of dioxane that are an integral part of the network.

The observed structures of tectons **5a** and **6a** are largely consistent with the emerging principles of molecular tectonics. In particular, both compounds crystallize as expected to form open hydrogen-bonded diamondoid networks that incorporate solvent. Unexpectedly, the networks are not isostructural, but it is important to note that tecton **5a** was crystallized from THF–pentane and tecton **6a** from dioxane–hexane. We subsequently found that tecton **5a** can also be crystallized from dioxane and tecton **6a** from THF. However, we elected not to study these new structures further because those already solved did not show exceptional porosity.

Porous chiral hydrogen-bonded networks formed by crystallization of enantiomerically pure tetraurethane 5b and tetraurea 5c

Exciting opportunities for constructing new types of porous molecular networks are created by using enantiomerically pure tectons such as analogues **5b**–**5d** of tetraurethane **5a**. The principles of molecular tectonics suggest that crystallization of these analogues should produce porous hydrogen-bonded networks, as observed in the case of tecton **5a**. However, these new networks will be chiral and may therefore be able to include chiral guests enantio-

[5] The percentage of volume accessible to guests was estimated by the PLATON program (45, 46), using standard parameters (9, 13).

[6] The dimensions of a channel in a particular direction correspond to the cross section of an imaginary cylinder that could be passed through the hypothetical open network in the given direction in contact with the van der Waals surface. Such values are inherently conservative because (*i*) they measure the cross section at the most narrow constriction, and (*ii*) they systematically underestimate the sizes of channels that are not uniform and linear.

[7] Representations of channels were generated by the Cavities option in the programs ATOMS Version 5.1 (Shape Software, 521 Hidden Valley Road, Kingsport, TN 37663; www.shapesoftware.com). We are grateful to Eric Dowty of Shape Software for integrating this capacity in ATOMS at our suggestion.

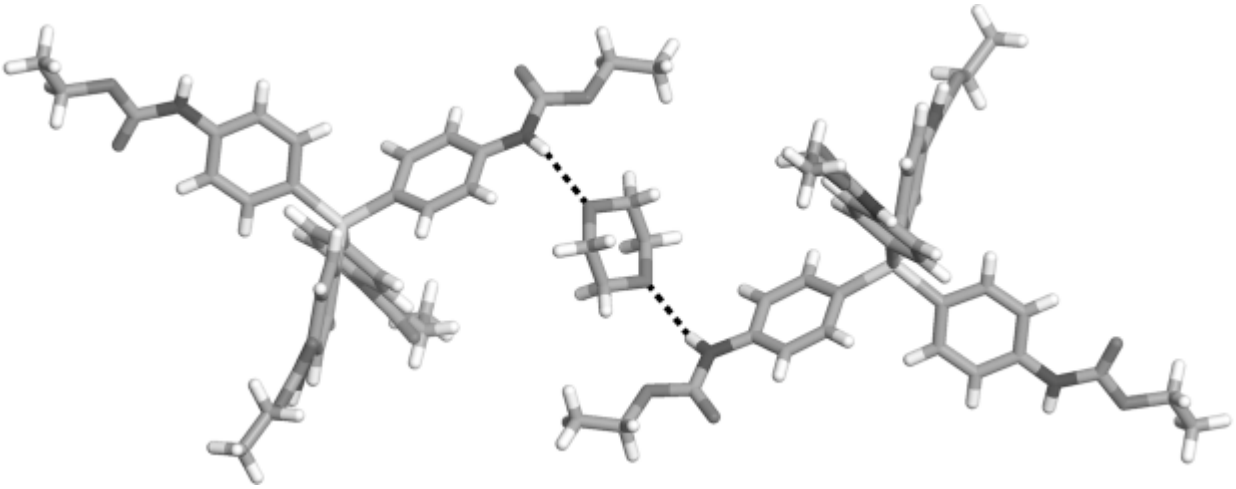
Fig. 5. View of part of the structure of crystals of tetraurethane **6a** grown from dioxane–pentane, showing two tectons linked by hydrogen bonds donated to an intervening molecule of dioxane. Hydrogen bonds appear as broken lines.



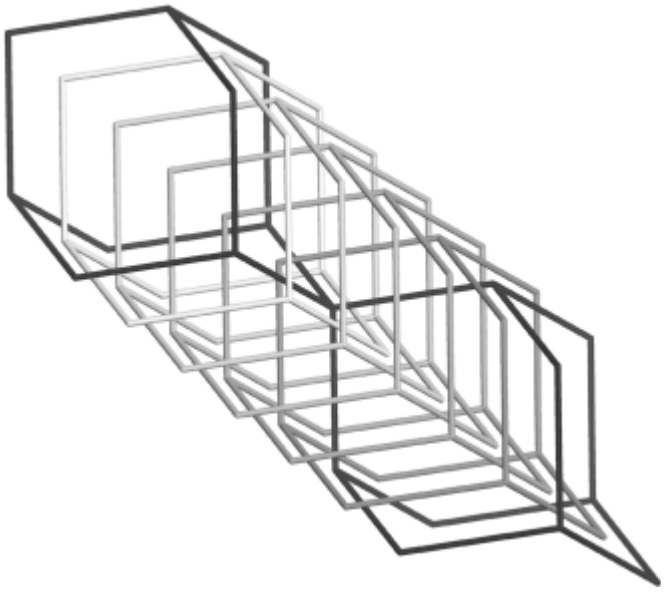


Fig. 6. Representation of the sixfold interpenetrated diamondoid networks generated by association of tetraurethane **6a** with dioxane. In this drawing, the central silicon atom of each tetraurethane lies at the intersection of solid lines that represent hydrogen bonding to four neighbors via intervening molecules of dioxane. Independent networks are shown in different shades of gray.

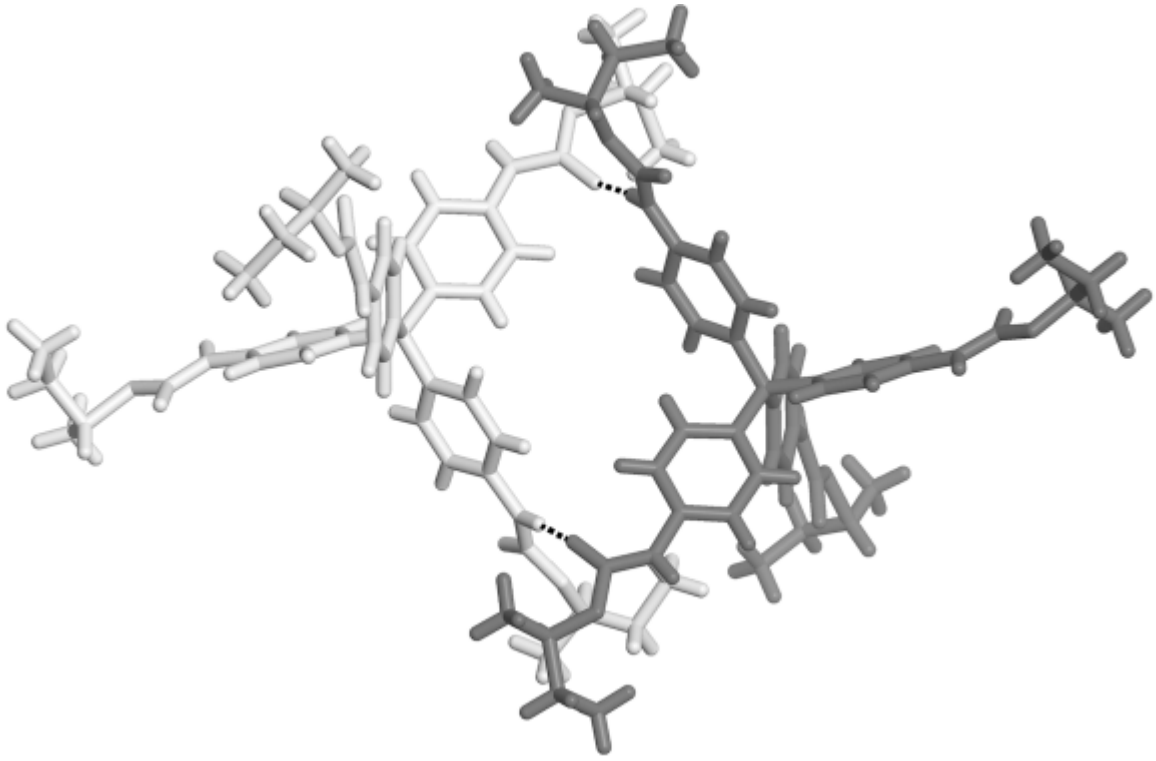
selectively. Such behavior would illustrate a key advantage of using molecules to make porous materials for applications in separation and catalysis, rather than using inorganic analogues such as zeolites. Specifically, creating asymmetric environments within supramolecular materials can be achieved by simple modifications of the individual molecular components, whereas very few zeolites are inherently chiral (47–49). As result, an important goal in crystal engineering is to devise molecules that form porous chiral hydrogen-bonded networks and then to use the resulting materials for the enantioselective inclusion and exchange of guests. However, few successes have been reported so far (50–58).

Enantiomerically pure tetraurethane **5b** crystallized from THF–pentane in the tetragonal space group $I4_1$ as an inclusion compound of approximate composition **5b**·2 pentane (Table 2).[4,8] As shown in Fig. 7, each tecton forms a total of eight hydrogen bonds with four symmetrically oriented neighbors, and each urethane group serves simultaneously as a donor and acceptor of hydrogen bonds. This defines a diamondoid network (42) in which the average intertectonic distance between the tetrahedral centers of neighbors is 9.73 Å. No interpenetration is observed (43, 44), and 16% of the volume remains available for including guests.[5] Despite intensive effort, we were unable to grow crystals of tecton **5b** suitable for X-ray diffraction when we used racemic solvents such as (±)-2-bromobutane, (±)-2-chloropentane, and (±)-2-methyltetrahydrofuran, so we were unable to examine the enantioselectivity of inclusion.

Crystals of the analogous enantiomerically pure tetraurea **5c** were obtained by allowing dioxane to diffuse into solutions in HCOOH. X-ray crystallography established that tecton **5c** crystallized under these conditions in the tetragonal space group $I4_1$ as an inclusion compound of well-defined composition **5c**·2HCOOH (Table 2).[4] Self-association of tetraurea **5c** produces a hydrogen-bonded diamondoid network (42) isostructural to the one generated by the analogous tetraurethane **5b** (Fig. 8). Each tecton forms a total of 16 hydrogen bonds with four symmetrically oriented neighbors, and each urea group serves simultaneously as a double donor and double acceptor of hydrogen bonds. No interpenetration is observed (43, 44), and 17% of the volume remains available for including guests.[5] Unfortunately, we were unable to grow crystals of tecton **5c** suitable for X-ray diffraction from racemic solvents, so we were not able to confirm that inclusion is enantioselective.



[8] The composition was estimated by X-ray crystallography and by ^{1}H NMR spectroscopy of dissolved samples. The amount of any H_2O included could not be determined accurately.

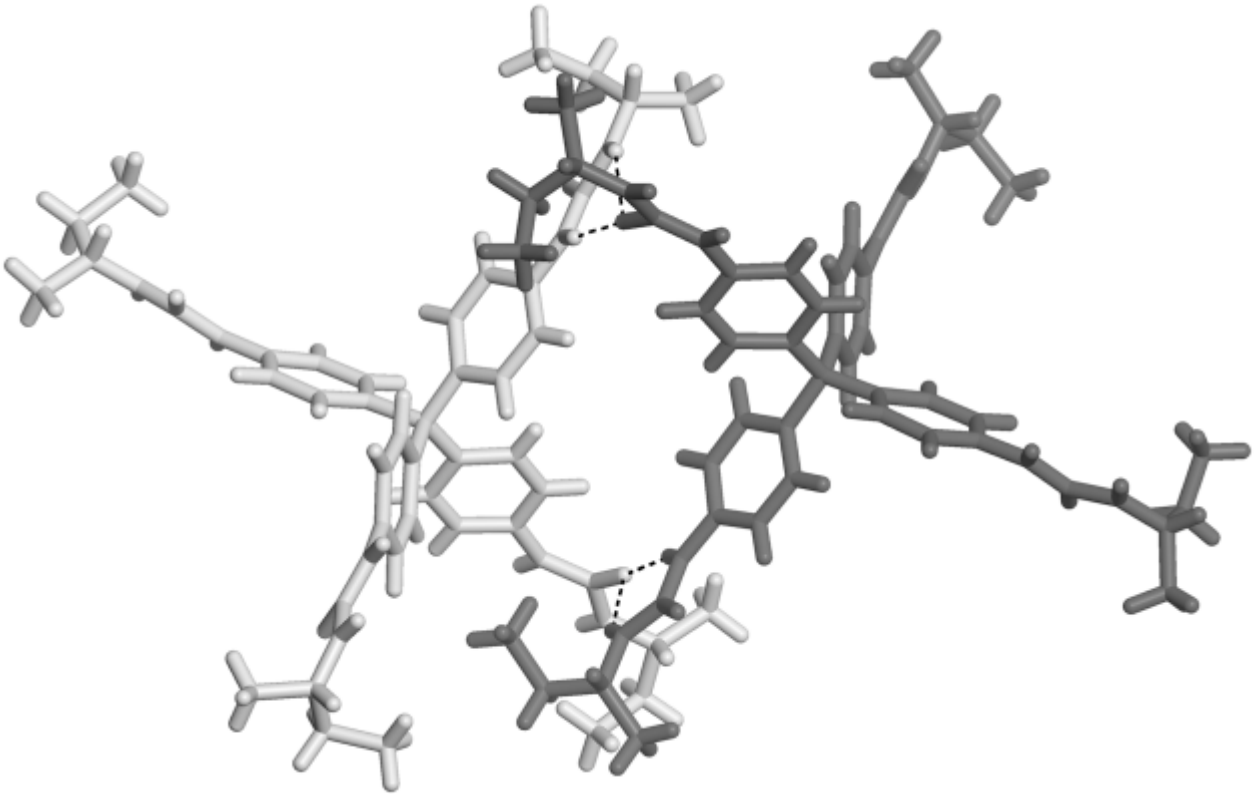
Fig. 7. Representation of the structure of crystals of tetraurethane **5b** grown from THF–pentane, showing a tecton (dark gray) hydrogen-bonded to one of four neighbors (light gray). The illustrated neighbor is equivalent by symmetry to three others, which are omitted for clarity. Hydrogen bonds appear as broken lines, and guests are omitted for clarity. Each urethane group serves simultaneously as a donor and acceptor of hydrogen bonds.



Porous hydrogen-bonded network formed by crystallization of tetraurea 5e

Tetraurea **5e** crystallized from DMSO–dioxane in the tetragonal space group $P\text{-}42_1c$ as an inclusion compound with the approximate composition **5e**·2DMSO·5dioxane (Table 2).[4,8] The composition of the crystals indicated immediately that a large fraction of the volume is accessible to guests. As shown in Fig. 9, each tecton forms hydrogen bonds with six neighboring tectons (Fig. 9*a*). Two neighbors that lie along the c axis on opposite sides of the central tecton are equivalent by symmetry, and each accepts four hydrogen bonds from the central tecton (Fig. 9*b*). The other four neighbors form a second symmetry-equivalent set, and each donates two hydrogen bonds to the central tecton

© 2004 NRC Canada

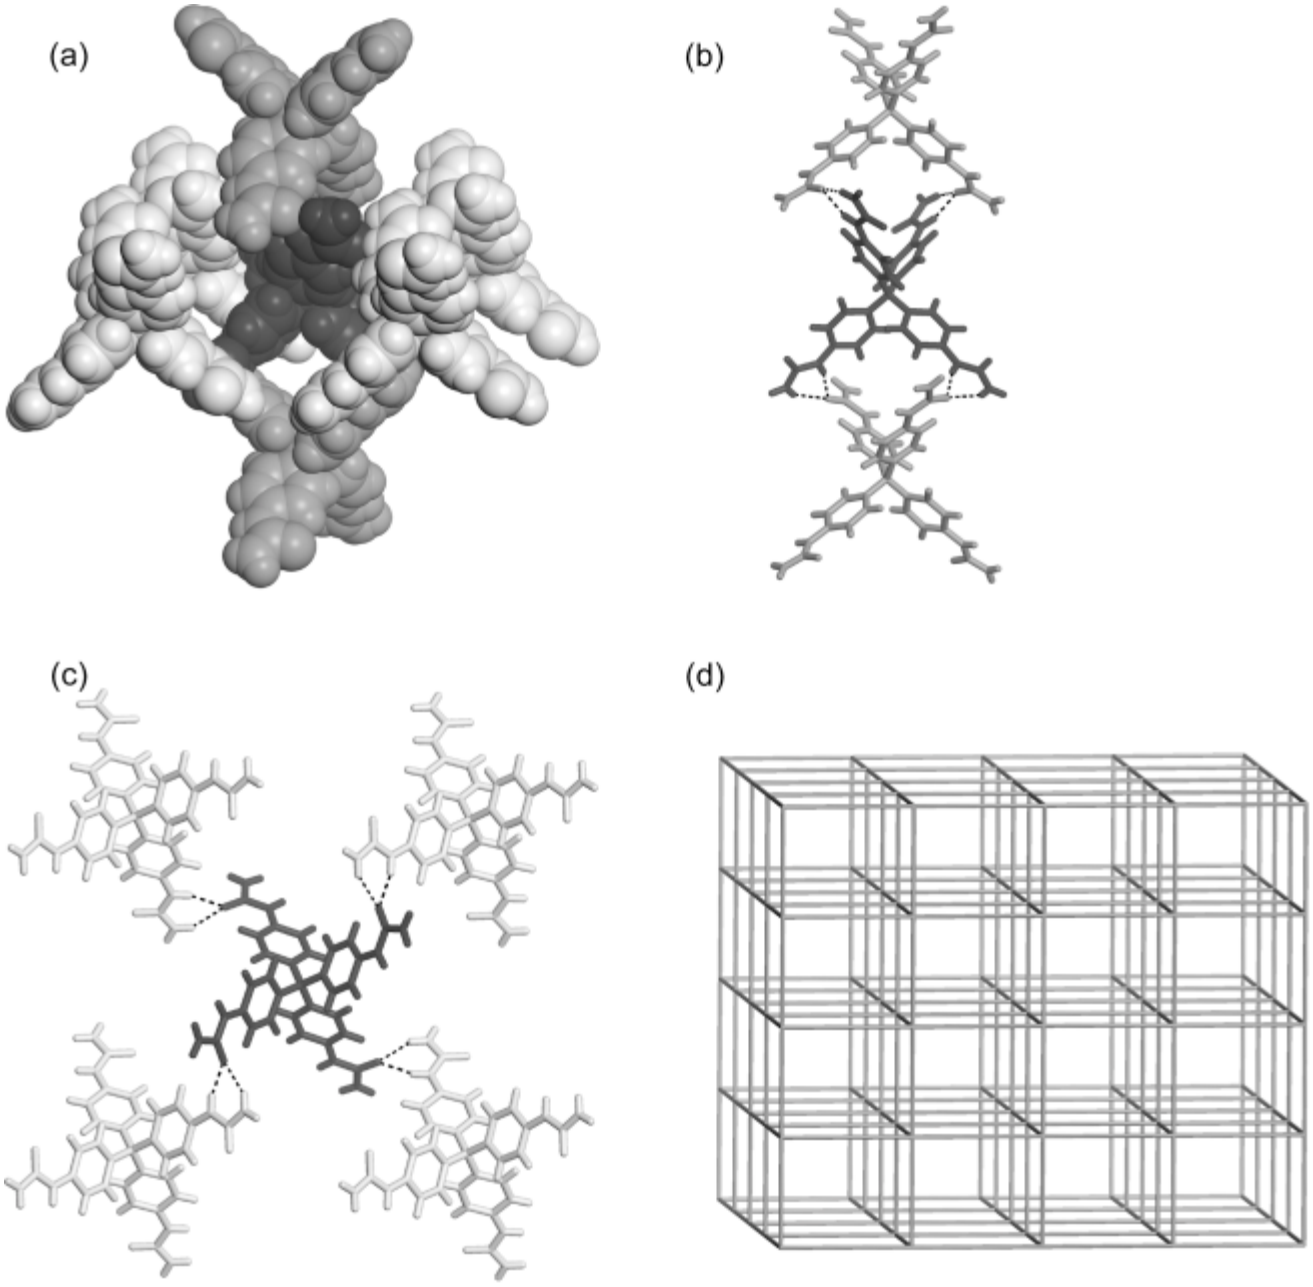
Fig. 8. Representation of the structure of crystals of tetraurea **5c** grown from HCOOH–dioxane, showing a tecton (dark gray) hydrogen-bonded to one of four neighbors (light gray). The illustrated neighbor is equivalent by symmetry to three others, which are not shown. Hydrogen bonds appear as broken lines, and guests are omitted for clarity. Each urea group serves simultaneously as a double donor and double acceptor of hydrogen bonds.

(Fig. 9*c*). In addition, part of the N—H bonds not used in intertectonic hydrogen bonding remain available for interacting with included DMSO. Each tecton therefore participates in a total of 16 hydrogen bonds with neighboring tectons. Joining the tetrahedral centers of the tectons defines the approximately octahedral 6-connected network shown in Fig. 9*d*. The average intertectonic distances are 10.30 Å in the *c* direction and 12.22 Å in the *a* and *b* directions.

No interpenetration is observed (43, 44), and approximately 66% of the volume of crystals of tecton **5e** remains available for the inclusion of guests,[5] which occupy interconnected channels. The porosity is unusually high, and it far exceeds the fraction of volume (normally about 30%) that is considered to remain unfilled in normal molecular crystals because of inefficient packing (59). The most significant channels are aligned with the *ab* diagonal and have cross sections measuring approximately 5.7 × 6.3 $Å^2$ at the narrowest points (Fig. 10).[6] The surface shown in Fig. 11 further defines the shape and complex interconnectivity of the channels.[7]

The network built from tecton **5e** is very porous, the interior of crystals is made accessible by significant interconnected channels, and high structural integrity is ensured by the formation of 16 hydrogen bonds per tecton. As a result, guests can be exchanged in single crystals without loss of crystallinity. For example, single crystals of estimated composition **5e**·2DMSO·5dioxane and approximate dimensions 1 mm × 1 mm × 5 mm were suspended in THF at 25 °C for 24 h. Subsequent analysis of recovered samples by ^{1}H NMR spectroscopy in solution showed complete replacement of dioxane by THF. The recovered samples remained transparent, showed no morphological changes visible by optical microscopy, and continued to diffract. Study of single exchanged crystals by X-ray diffraction showed little variation in the unit cell parameters (Table 2), suggesting that the network undergoes little distortion.

Conclusions



Our studies of tetraurethanes and tetraureas **5a**–**5e** and **6a** confirm that (*i*) tetraphenylmethane and tetraphenylsilane are effective cores for constructing molecules of value in crystal engineering, and (*ii*) substituting these cores with hydrogen-bonding groups produces tectons that crystallize predictably to give open three-dimensional networks that can include significant amounts of guests. Of special note is the observation that enantiomerically pure tectons such as tetraurethane **5b** and tetraurea **5c** can be made conveniently from tetra(isocyanate) **1f** and crystallize to give porous chiral networks. Such molecular materials have unique properties that promise to make them useful in enantioselective catalysis, the resolution of racemates, and other applications.

sodium ketyl of benzophenone. Xantphos (60) and tetrakis-(4-bromophenyl)silane (**2d**) (40) were synthesized according to known procedures. All other reagents were commercial products that were used without further purification.

Tetrakis(4-aminophenyl)methane (1e) (16, 38, 39)

A suspension of tetrakis(4-nitrophenyl)methane (**1d**, 4.10 g, 8.19 mmol) (38) and 10% Pd/C (410 mg) in THF (300 mL) was stirred for 70 h in a Parr reactor at 25 °C under H_2 (1200 kPa). The resulting mixture was filtered through Celite®, and volatiles were removed by evaporation under reduced pressure. The residue was triturated with $CHCl_3$ and washed with CH_3OH to afford tetrakis(4-aminophenyl)methane (**1e**, 3.09 g, 8.12 mmol, 99%) (16, 38, 39) as a colorless solid that was used without further purification. A sample of analytical purity was obtained by crystallization from ethanol–water to afford small colorless crystals; mp 319 °C (lit. (16) mp 331 °C, lit. (38) mp 319 to

Tetrakis(4-isocyanatophenyl)methane (1f)

A solution of triphosgene (1.39 g, 4.68 mmol) in dry THF (10 mL) was added dropwise to a stirred solution of tetrakis-(4-aminophenyl)methane (**1e**, 1.19 g, 3.13 mmol) and triethylamine (3.49 mL, 25.0 mmol) in dry THF (60 mL) at –78 °C under N_2. The mixture was then warmed to 0 °C during 2 h, and insoluble solids were removed by filtration through Celite®. Volatiles were removed by evaporation under reduced pressure to give tetrakis(4-isocyanatophenyl) methane (**1f**, 1.48 g, 3.05 mmol, 97%) as a colorless solid that was used without further purification. A sample of analytical purity was obtained by sublimation (130 °C/0.1 mm Hg (1 mm Hg = 133.322 Pa)), mp 53 to 54 °C (softening). Tetrakis(4-isothiocyanatophenyl)methane (1g)

Thiophosgene (0.264 mL, 3.46 mmol) was added dropwise to a stirred solution of tetrakis(4-aminophenyl) methane (**1e**, 300 mg, 0.788 mmol) and triethylamine (0.880 mL, 6.31 mmol) in dry THF (25 mL) at –10 °C under N_2. The resulting mixture was then warmed to 25 °C during 1 h. Water was added, and the mixture was extracted twice with CH_2Cl_2. The combined organic extracts were dried over Na_2SO_4, and volatiles were removed by evaporation under reduced pressure. The residual solid was purified by flash chromatography (silica, CH_2Cl_2 (30%) – hexane (70%), R_f 0.59) to provide tetrakis(4-isothiocyanatophenyl) methane (**1g**, 386 mg, 0.703 mmol, 89%) as a colorless solid, mp 203 to 204 °C. IR (KBr) (cm^{-1}): 2200–2000 (bs), 1496, 932, 817. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 7.15 (d, ^3J = 8.9 Hz, 8H), 7.10 (d, ^3J = 8.9 Hz, 8H). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 144.4, 136.4, 131.8, 130.1, 125.6, 64.2. Tetraurea 5d

A procedure similar to the one used to synthesize tetraurea **5c** converted tetrakis(4-isocyanatophenyl)methane (**1f**, 125 mg, 0.258 mmol) and (*S*)-α-methylbenzylamine (0.166 mL, 1.30 mmol) into tetraurea **5d** (248 mg, 0.256 mmol, 99%), which was isolated as a colorless solid. A sample of analytical purity was obtained by crystallization from CH_3OH, mp 262 to 263 °C. $[\alpha]_D$ = –116° (*c* 0.30 in ethanol). IR (KBr) (cm^{-1}): 3400, 1677, 1596, 1506, 1407, 1319, 1292, 1238, 1115, 821. ^{1}H NMR (400 MHz, DMSO-d_6) δ: 8.36 (s, 4H), 7.31 (m, 16H), 7.22 (m, 12H), 6.88 (d, ^3J = 8.7 Hz, 8H), 6.56 (d, ^3J = 7.6 Hz, 4H), 4.79 (dq, ^3J = 7.6, 6.9 Hz, 4H), 1.36 (d, ^3J = 6.9 Hz, 12H). ^{13}C NMR (75 MHz, DMSO-d_6) δ: 154.4, 145.2, 139.7, 137.9, 130.7, 128.3, 126.6, 125.8, 116.6, 62.1, 48.6, 23.1. FAB-MS (3-nitrobenzyl alcohol) *m/e*: 969. Anal. calcd. for $C_{61}H_{60}N_8O_4$: C 75.60, H 6.24, N 11.56; found: C 75.26, H 6.37, N 11.39.

Tetraurea 5e

Aqueous NH_3 (28%, 5 mL) was added to a stirred solution of tetrakis(4-isocyanatophenyl)methane (**1f**, 480 mg, 0.991 mmol) in dry THF (20 mL), and the resulting mixture was stirred for 1 h. Volatiles were then removed by evaporation under reduced pressure, and the residual solid was washed with water and crystallized from 2-methoxyethanol–THF to provide tetraurea **5e** (501 mg, 0.907 mmol, 92%) as a colorless solid, mp > 330 °C. IR (KBr) (cm^{-1}): 3500–3000 (bs), 1666, 1588, 1532, 1509, 1410, 1344, 816. ^{1}H NMR (400 MHz, DMSO-d_6) δ: 8.49 (s, 4H), 7.26 (d, ^3J = 8.7 Hz, 8H), 6.93 (d, ^3J = 8.7 Hz, 8H), 5.80 (s, 8H). ^{13}C NMR (100 MHz, DMSO-d_6) δ: 156.1, 139.9, 138.1, 130.6, 116.9, 62.2. FAB-HR-MS (3-nitrobenzyl alcohol) calcd. for $C_{29}H_{28}N_8O_4$ *m/e*: 552.223352; found: 552.225072. Anal. calcd. for $C_{29}H_{28}N_8O_4 \cdot 1.5H_2O$: C 60.09, H 5.39; found: C 59.91, H 5.96.

Tetraurethane 6a

Deoxygenated dioxane (10 mL) was added to a deoxygenated mixture of tetrakis(4-bromophenyl)silane (**2d**, 652 mg, 1.00 mmol) (40), $Pd(OOCCH_3)_2$ (45.0 mg, 0.200 mmol), Xantphos (180 mg, 0.311 mmol) (60), Cs_2CO_3 (1.70 g, 5.22 mmol), and ethyl carbamate (392 mg, 4.40 mmol). The resulting mixture was stirred at reflux for 48 h under N_2 and then filtered through Celite®. Volatiles were removed by evaporation under reduced pressure, and the residual solid was purified by flash chromatography (silica, $CH_3COOC_2H_5$ (40%) – hexane (60%), R_f 0.25) to give tetraurethane **6a** (125 mg, 0.183 mmol, 18%) as a colorless solid, mp 138 to 139 °C. IR (KBr) (cm^{-1}): 3500–3300, 2980, 2928, 1707, 1596, 1519, 1396, 1319, 1222, 1062, 824, 685, 536. ^{1}H NMR (300 MHz, DMSO-d_6) δ: 9.74 (s, 4H), 7.49 (d, ^3J = 8.3 Hz, 8H), 7.33 (d, ^3J = 8.3 Hz, 8H), 4.12 (q, ^3J = 7.1 Hz, 8H), 1.24 (t, ^3J = 7.1 Hz, 12H). ^{13}C NMR (75 MHz, DMSO-d_6) δ: 153.5, 140.6, 136.4, 127.2, 117.7, 60.2, 14.5.

FAB-HR-MS (3-nitrobenzyl alcohol) calcd. for $C_{36}H_{40}N_4O_8Si$ *m/e*: 684.261543; found: 684.260943.

X-ray crystallographic studies

The structures were solved by direct methods using SHELXS-97 (61) and refined with SHELXL-97 (62). All non-hydrogen atoms were refined anisotropically, whereas hydrogen atoms were placed in ideal positions and refined as riding atoms.

Crystallization of compounds 1g, 5a–5e, and 6a

Single crystals of tetra(isothiocyanate) **1g** suitable for analysis by X-ray diffraction were grown from $CHCl_3$–hexane. Crystals of tetraurethanes **5a** and **6a** were obtained by slow diffusion of pentane into solutions in THF or dioxane at 25 °C. Crystals of tetraurethane **5b** were grown by slow diffusion of pentane into a solution in dioxane at 25 °C. Crystals of tetraurea **5c** were obtained by slow diffusion of dioxane into a solution in HCOOH at 25 °C. Crystals of tetraurea **5e** were grown by slow diffusion of dioxane into a solution in DMSO at 25 °C.

Acknowledgments

We are grateful to the Natural Sciences and Engineering Research Council of Canada (NSERC), the Ministère de l'Éducation du Québec, the Canada Foundation for Innovation, the Canada Research Chairs Program, and Merck Frosst for financial support. In addition, acknowledgment is made to the donors of the Petroleum Research Fund, administered by the American Chemical Society, for support of this research. Dominic Laliberté is grateful to Boehringer Ingelheim for a fellowship.

Sequential olefin metathesis — Intramolecular asymmetric Heck reactions in the synthesis of polycycles[1]

Mark Lautens and Valentin Zunic

Abstract: Application of the intramolecular asymmetric Heck reaction in the desymmetrization of a novel class of symmetrical bicyclodienes, synthesized through a diastereoselective double ring-closing metathesis (DSRCM) reaction, was achieved with good yields (approximately 80%) and excellent enantioselectivities (up to 99% ee). Three contiguous stereocenters are established in a single desymmetrization reaction. The use of thallium carbonate as base in the asymmetric Heck reaction favours double bond migration in **13**. Cationic conditions delivered products with good to excellent enantioselectivities, surpassing the results under neutral conditions.

Key words: asymmetric, Heck, polycycles, metathesis, stereoselective, desymmetrization.

Résumé : L'application de la réaction asymétrique intramoléculaire de Heck pour la désymétrisation d'une nouvelle classe de bicyclodiènes symétriques, obtenus par une réaction de métathèse à double cyclisation diastéréosélective, a été réalisée avec de bons rendements (environ 80 %) et d'excellentes énantiosélectivités (jusqu'à 99 % ee). Les trois stéréocentres contigus ont été établis au cours d'une seule réaction de désymétrisation. L'utilization du carbonate de thallium comme base dans la réaction asymétrique de Heck favorise la migration de la double liaison dans le composé **13**. Les conditions cationiques ont permis de livrer des produits avec des énantiosélectivités allant de bonnes à excellentes qui étaient supérieures à celles obtenues dans des conditions neutres.

Mots clés : asymétrique, Heck, polycycles, métathèse, stéréosélective, désymétrisation.

[Traduit par la Rédaction]

Introduction

Heck reactions are among the most important and widely used carbopalladation reactions (1, 2). The effect of substrate, catalyst, ligand, and additives has been examined, resulting in highly selective Heck reactions. The enantioselective variant (3) of the Heck reaction has been successfully developed to the point where both tertiary and quaternary centers can be generated in excellent enantioselectivity and in good to excellent yields. The application of the asymmetric Heck reaction (AHR) has been most widely studied in its intermolecular variant, with ees >96% having been reported. For the intramolecular Heck reaction, the ee values are typically around 80%, with notable exceptions leading to >90% ee (3).

Since the initial reports in 1989 (4), many of the reported intramolecular AHRs involve the desymmetrization of prochiral alkene substrates (5).[3] This methodology has proven to be a powerful tool for the rapid construction of polycyclic compounds. The carbo- and heterocycles synthesized via the intramolecular AHR have been used as building blocks for complex natural products or as model compounds for pharmaceutically relevant substances (6).

We have reported the formation of *cis*- and *trans*-decalin systems, as well as *cis*-diquinanes, via a diastereoselective double ring-closing olefin metathesis reaction (DSRCM) (7) (see Fig. 1). These symmetrical bicyclodienes are ideal substrates in the area of alkene differentiation reactions. Desymmetrization of a symmetrical molecule to yield an enantiomerically enriched product is certainly a topic of great interest (8).

In this report we describe the intramolecular AHR on the bicyclodienes generated through the DSRCM methodology previously reported from our laboratories.

Results

Substrates used in our studies were conveniently prepared by appending appropriate aryl-halide tethers to the tertiary diallylic alcohol **1**. Thus, reaction of the tertiary alcohol **1**

Scheme 1. DSRCM in the synthesis of diquinane Heck reaction precursors.

with potassium hydride followed by 2-bromobenzyl bromide or 2-iodobenzyl bromide provided the coupled products **2** and **3** in >80% yield (Scheme 1).

Ring-closing metathesis of the haloaryl tetraenes **2** and **3** with Grubbs catalyst **4** provided the desired *cis*-fused bicyclo[3.3.0]octadienes **5** and **6** as the sole bicyclic products in good overall yields.

With a reliable and efficient route to the desired bicyclo[3.3.0]octadienes **5** and **6**, a detailed investigation into the AHR was then performed. Since oxidative addition with aryl iodides is much more facile than the analogous bromides (1), our initial investigations focused on the iodo-Heck precursors. Pd_2dba_3 was used as the palladium(0) source because of its ease of handling and its reported role in producing reproducible results (9) in asymmetric Heck reactions. The range of substrates that work well with BINAP (10) in asymmetric Heck reactions led us to initiate our studies using this ligand. The results from screening a variety of bases and solvents are shown in Table 1.

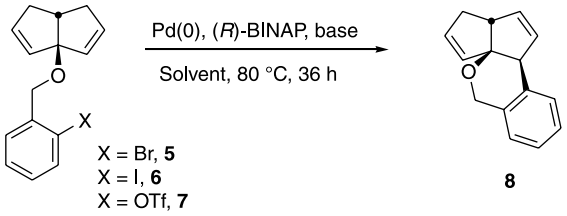
The results presented in Table 1 show that a variety of conditions are effective in promoting the asymmetric synthesis of **8**[4] It is generally accepted that cationic conditions, e.g., use of silver(I) salts to sequester a halide from palladium after the oxidative addition of the aryl halide, will generally lead to chiral products with higher enantiomeric ratios than those realized under neutral conditions (3, 9, 11).[5] However, under neutral conditions and in the presence of a tertiary amine base, similar levels of enantioselectivity to those seen under cationic conditions are obtained (Table 1, entry 2) (12).[6] The high enantiomeric excess obtained with the triflate substrate **7**[7] is the same as when an aryl iodide is used in the presence of a silver salt (cf. Table 1, entries 4 and 10). Triflate substrates can be used in lieu of the halide substrates with expensive silver salts.

Recent advances in the AHR have shown that a variety of other ligands mediate the reaction with equal levels of efficiency (3). A brief survey of other chiral ligands successfully used in the AHR is presented in Table 2.

Particularly noteworthy is the fact that the chiral phosphinooxazoline (PHOX) (13) ligand (*S*)-*t*-Bu-POX (14) does not efficiently mediate the asymmetric Heck reaction in this case (Table 2, entry 3). The use of *tol*-BINAP as ligand provides **8** with higher levels of enantioselectivity and yield than with BINAP. The use of cationic conditions with a more electron-rich bisphosphine will ensure a tighter binding of the bisphosphine throughout the catalytic cycle of the reaction.

Having explored the intramolecular AHR in the desymmetrization of bicyclo[3.3.0]octadienes, we focused our attention on applying the same transformation to the desymmetrization of bicyclo[4.4.0]decadienes. The synthesis of the required aryl-halide-tethered substrates was carried out in a similar manner to that discussed above for the preparation of diquinane substrates (Scheme 2). The DSRCM event

[4] The relative stereochemistry of **8** was proven by careful analysis of various 2D NMR experiments (COSY, ROESY, HMQC). The absolute stereochemistry of **8** has yet to be determined.



[5] Cationic conditions facilitate the binding of the chiral bidentate ligand, olefin, and aryl group in the square planar Pd(II) intermediate in the enantiodescriminating carbopalladation step.

[6] Overman (see ref. 12) in his studies in the use of asymmetric Heck reactions in the synthesis of chiral oxindoles noted a similar phenomenon. No conclusive argument was put forth in his studies, and results in our studies do not help to explain the highly effective role of tertiary amine bases in asymmetric Heck reactions. See ref. 9, as well as ref. 12.

[7] Substrate **7** was prepared in four steps, starting from **1** and 2-(*tert*-butyldimethylsilyloxy)benzylbromide. See experimental section for details.

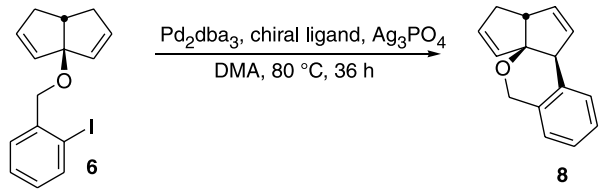
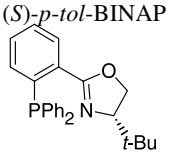
Table 1. Effects of solvents and bases on the asymmetric synthesis of **8**.

Entry	Substrate	Pd source	Solvent	Base (2 equiv.)	Yield (%)	Enantiomeric excess (%)
1	**5**	$Pd(OAc)_2$	CH_3CN	Et_3N	43	93
2	**6**	Pd_2dba_3-$CHCl_3$	CH_3CN	Et_3N	52	98
3	**6**	Pd_2dba_3-$CHCl_3$	CH_3CN	K_2CO_3	60	83
4	**6**	Pd_2dba_3-$CHCl_3$	CH_3CN	Ag_2CO_3	80	97
5	**6**	Pd_2dba_3-$CHCl_3$	CH_3CN	Ag_3PO_4	37	97
6	**6**	Pd_2dba_3-$CHCl_3$	THF	Ag_3PO_4	73	94
7	**6**	Pd_2dba_3-$CHCl_3$	Toluene	Ag_3PO_4	77	99
8	**6**	Pd_2dba_3-$CHCl_3$	DMA	Ag_3PO_4	57	91
9	**6**	Pd_2dba_3-$CHCl_3$	NMP	Ag_3PO_4	60	63
10	**7**	Pd_2dba_3-$CHCl_3$	CH_3CN	K_2CO_3	53	97



was carried out in a highly efficient process with the Grubbs second generation catalyst (4,5-dihydroIMES)$(PCy_3)Cl_2Ru$=CHPh (**9**). The reaction was efficient with catalyst loadings as low as 2 mol% (cf. 12 mol% of $[Cl_2(Cy_3P)_2Ru$=CHPh] (**4**)) (7) and was complete in 30 min in refluxing dichloromethane. A 4.5:1 mixture of diastereomeric bicyclo[4.4.0]decadienes was obtained, favouring the *cis*-fused decalin. The minor diastereomer was removed by stirring the reaction mixture with silica gel for ~15 min at room temperature followed by flash chromatography on silica gel.[8]



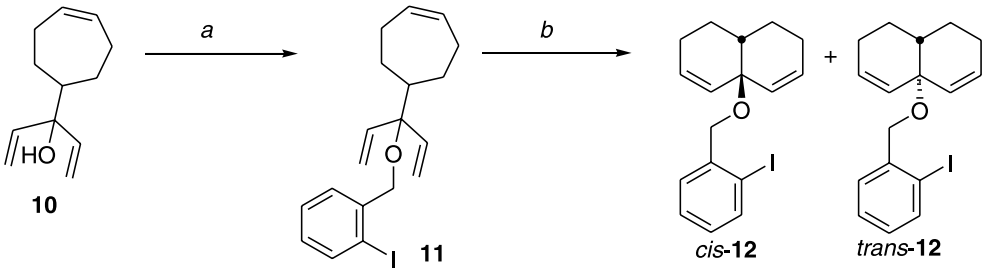
Application of the AHR to aryl iodide *cis*-**12** provided regioisomeric alkene products[9] in a 1:1 ratio and a combined 60% yield (Scheme 3). This system is more complex, since olefin isomerization is now a significant process. A β-hydride addition – elimination step involving **13** with a chiral hydridopalladium species, formed from the Heck reaction of *cis*-**12**, leads to the formation of **14**. Of note, the two regioisomeric products have different ee values (15).

Studies on the bicyclo[3.3.0]octadiene series revealed *p-tol*-BINAP to be the ligand that delivered products with the highest enantiomeric excess. Having obtained alkenes **13** and **14** in modest enantioselectivity, a brief study of chiral ligands was carried out to determine whether the alkene isomerization process could be controlled (Table 3).

Enantiomeric excesses in this series are lower, perhaps because of the elevated temperature used (100 °C versus 80 °C) for the desymmetrization of the bicyclo[4.4.0]decadiene **12**. The higher temperatures were required because of the sluggish nature of the Pd-PHOX catalysts with this substrate.[10] *p-tol*-BINAP is clearly the ligand that affords products with the highest enantiomeric ratios. Unlike palladium catalysts

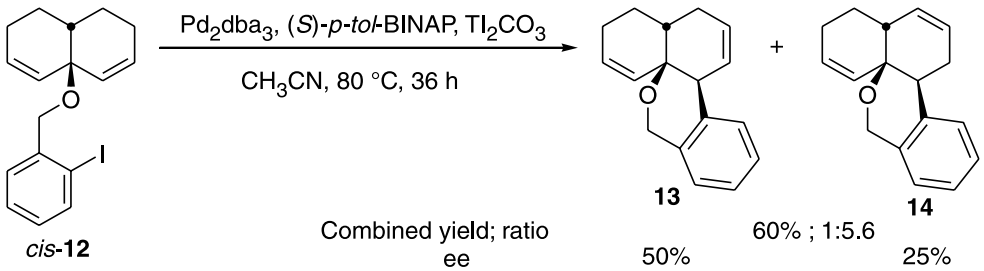
Table 2. Effect of ligand in the asymmetric synthesis of **8**.

Entry	Ligand	Yield (%)	ee (%)
1	(*S*)-BINAP	57	91
2	(*S*)-*p-tol*-BINAP	87	99
3	 (*S*)-*t*-Bu-Pox	18	29



derived from BINAP, virtually no C=C double bond migration has been reported for Pd-PHOX catalysts. Yet, in the present system, the use of the (*S*)-*t*-Bu-POX and (*S*)-*i*-Pr-(*S*)-DIPOF (16) ligands resulted in a 1:2 ratio of the regioisomers **13** and **14**, respectively, with lower levels of enantioselectivity than seen with the BINAP catalysts (Table 3, entries 3 and 4).

The use of silver salts in the reactions of **12** did not seem to lead to any bias in the formation of the regioisomeric alkene products. However, the utilization of Tl_2CO_3 as base provided a 1:5.6 ratio of **13**:**14** (Scheme 4) with similar yields and levels of enantiomeric excesses as those seen with silver salts.



[8] Generally, the isolation of the bicyclodienes mentioned in this report required triethylamine-neutralized silica gel in the purification step.
[9] The relative stereochemistry of **13** and **14** are assumed to be as depicted, since 2D-NMR experiments (ROESY, NOESY) were unsuccessful at elucidating the relative stereochemistry assignment of **13** and **14**. To our knowledge, the intramolecular Heck reaction is a facile means to access *cis*-fused bicycles (see refs. 1–3). The absolute stereochemistry of **13** and **14** have yet to be determined.
[10] For the sake of consistency, the same temperature was used throughout the series in this ligand survey.

Scheme 2. Synthesis of bicyclo[4.4.0]decadienes for intramolecular Heck reactions. Conditions: (*a*) KH, 2-iodobenzyl bromide, THF, 23 °C, 12 h, 85%; (*b*) (4,5-dihydroIMES) $(PCy_3)Cl_2Ru$=CHPh (**9**) (2 mol%), CH_2Cl_2, reflux, 30 min, 4.5:1 (*cis*-**12**:*trans*-**12**), 100%.

Scheme 3. Desymmetrization of bicyclo[4.4.0]decadienes.

The exploration of the analogous aryl triflate substrate tethered to the bicyclo[4.4.0]decadienes was also undertaken in attempts to increase the enantiomeric excesses of the polycyclic products.[11] Subjecting triflate *cis*-**15** under AHR conditions provided the polycyclic products **13** and **14** in ~1:1 ratio but with significantly higher levels of asymmetric induction (Scheme 5). Attempts are now being directed at expanding the scope of this sequential olefin metathesis – intramolecular AHR sequence and highlighting the usefulness of the polycycles through further chemical transformations.

Summary

The stereoselective synthesis of tetracycles is made possible using a DSRCM and asymmetric Heck strategy. Cationic conditions in the asymmetric Heck reaction gave high enantioselectivities in the desymmetrization process in which three contiguous chiral centers are established with high enantioselectivities in a single step.

Experimental

The following experimental details apply to all subsequent experiments.

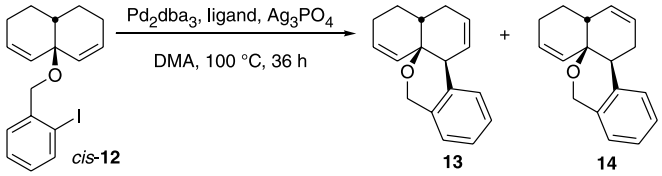
All reactions were carried out under an atmosphere of dry argon or nitrogen in oven- (overnight at 90 °C and then cooled under a stream of Ar or N_2) or flame-dried glassware. Solvents and solutions were transferred with syringes and cannulae, using standard inert atmosphere techniques.

^{1}H NMR spectra were recorded at 400 MHz, using a Varian XL400 spectrometer with $CDCl_3$ and TMS as reference standards (δ = 0.00 parts per million (ppm) or 7.26 ppm). ^{13}C NMR were recorded at 100 MHz using the same spectrometer with $CDCl_3$ as reference standard (δ = 77.16 ppm). IR spectra were obtained using a Nicolet DX FT-IR spectrometer as a neat film between KBr plates. High resolution mass spectra were obtained from a VG 70-250S (double focusing) mass spectrometer at 70 eV.

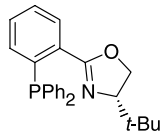
High performance liquid chromatography (HPLC) was performed on an Agilent 1100 Series HPLC using a CHIRACEL OD column. Column chromatography was performed as flash chromatography, as reported by Still et al. (17), using (200–400 mesh) Merck grade silica gel.

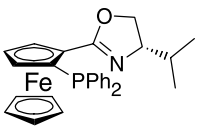
Toluene and THF were distilled from sodium–benzophenone. DMF was dried by prolonged standing over molecular sieves. CH_2Cl_2 was distilled from CaH_2.

Grubbs catalyst (**4**) was prepared according to the literature procedure (18) and triturated for 12–18 h in a 1:1 mixture of acetone and methanol. The absence of free tricyclohexyl phosphine and tricyclohexyl phosphine oxide was confirmed by ^{31}P NMR and was crucial for the double metathesis reactions to proceed. (DihydroIMES)(PCy_3)-Cl_2Ru=CHPh (**9**) was used as received from Strem. The following compounds were prepared as reported in the literature: 4-Allyl-3-vinyl-hepta-1,5-dien-3-ol (**1**) (7), 3-cyclohept-4-enyl-penta-1,4-dien-3-ol (**10**) (7), and 2-(*tert*-butyldimethylsilyloxy)benzyl bromide (19).



1-(2-Allyl-1,1-divinyl-pent-4-enyloxymethyl)-2-bromobenzene (2)





KH (35% dispersion in mineral oil, 1.0 g, 4 equiv.) was washed three times with pentane, dried under a stream of argon, and suspended in THF (10 mL). A solution of alcohol **1** in THF (5 mL) was added dropwise via cannula. After 15 min at room temperature, 2-bromobenzyl bromide was added all at once, and the resulting solution was stirred at

[11]Substrate *cis*-**15** was prepared in four steps, starting from **10** and 2-(*tert*-butyldimethylsilyloxy)benzylbromide. See experimental section for details.

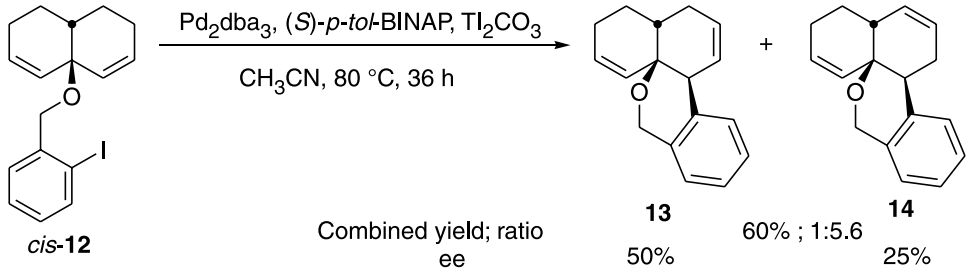
[a]Ratio was determined by integration of the singlet at 3.30 ppm (**13**) and the triplet at 2.83 ppm (**14**) in the ^{1}H NMR of the crude reaction mixture.
[b]Combined isolated yield.
[c]Undetermined.

room temperature for 2 h. The mixture was quenched by dropwise addition of water (25 mL) and then extracted with ether (3 × 30 mL). The organic layers were dried over Na_2SO_4, filtered, and concentrated. Flash chromatography (100% hexanes) on triethylamine-washed silica gel provided the product as a colourless oil (740 mg, 95%). IR (neat): 3074(m), 2978(m), 2922(m), 1914(w), 1869(w), 1831(w), 1638(m), 1439(m), 1269(w), 1091(s), 931(s), 910(s), 748(s), 667(w). ^{1}H NMR (400 MHz, $CDCl_3$) δ: 7.62 (1H, d, *J* = 8 Hz), 7.48 (1H, d, *J* = 8 Hz), 7.31 (1H, t, *J* = 7.6 Hz), 7.12–7.08 (1H, m), 5.93–5.86 (2H, m), 5.88–5.80 (2H, m), 5.38 (2H, dd, *J* = 11.2 Hz, 0.8 Hz), 5.31 (2H, dd, *J* = 17.6 Hz, 0.8 Hz), 5.01–4.93 (4H, m), 4.40 (2H, s), 2.48–2.42 (2H, m), 2.02–1.94 (2H, m), 1.84–1.90 (1H, m). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 139.22, 138.78, 137.67, 132.22, 128.44, 128.27, 127.39, 121.89, 118.04, 115.41, 83.98, 64.97, 48.28, 34.56. HR-MS calcd. for $C_{19}H_{23}OBr$ ([M]$^+$): 345.2788; found: 345.2791.

3a-(2-Bromobenzyloxy)-1,3a,6,6a-tetrahydropentalene (5)

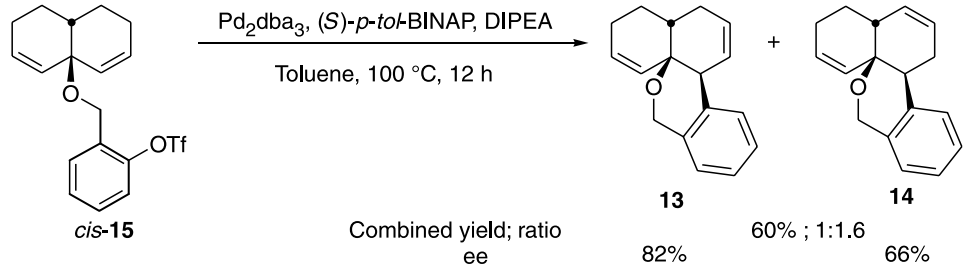
To a solution of **2** (930 mg, 2.67 mmol) in 50 mL of dichloromethane was added Grubbs catalyst **4** all at once. The reaction was stirred under a closed system for 20 h at room temperature. The solvent was removed in vacuo, and the residue was purified by flash chromatography (100% hexanes → 5% Et_2O–hexanes) on triethylamine-washed silica gel to provide the product (530 mg, 70%) as a colourless oil. IR (neat): 3047(s), 2918(s), 2851(s), 1619(w), 1467(m), 1350(s), 1218(m), 1097(m), 1070(m), 989(m), 750(s). ^{1}H NMR (400 MHz, $CDCl_3$) δ: 7.47–7.53 (2H, m), 7.30–7.24 (1H, m), 7.11–7.07 (1H, m), 5.94–5.91 (2H, m), 5.84–5.82 (2H, m), 4.46 (2H, s), 2.90–2.84 (3H, m), 2.14–2.08 (2H, m). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 138.97, 134.67, 132.38, 132.35, 129.28, 128.58, 127.43, 122.52, 106.00, 65.13, 43.10, 40.79. HR-MS calcd. for $C_{15}H_{15}OBr$ ([M]$^+$): 290.0306; found: 290.0301.

1-(2-Allyl-1,1-divinyl-pent-4-enyloxymethyl)-2-iodobenzene (3)



Following the the benzylation procedure to make **2**, alcohol **1** (1.15 g, 6.4 mmol) was reacted with 2-iodobenzylbromide (2.09 g, 7.06 mmol) to yield the product (2.08 g, 83%) as a colourless oil. IR (neat): 3073(m), 2911(m), 1952(w), 1908(w), 1864(w), 1627(s), 1440(s), 1085(s), 1012(s), 906(s), 752(s). ^{1}H NMR (400 MHz, $CDCl_3$) δ: 7.77 (1H, d, *J* = 7.6 Hz), 7.57 (1H, d, *J* = 7.6 Hz), 7.36 (1H, t, *J* = 8 Hz), 6.96 (1H, t, *J* = 8 Hz), 5.90 (2H, dd, *J* = 17.6 Hz, 10.8 Hz), 5.89–5.80 (2H, m), 5.39 (2H, dd, *J* = 11.2 Hz, 1.6 Hz), 5.31 (2H, dd, *J* = 17.6 Hz, 1.6 Hz), 5.02–4.94 (4H, m), 4.29 (2H, s), 2.49–2.43 (2H, m), 2.02–1.94 (2H, m), 1.90–1.84 (1H, m). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 141.95, 138.84, 138.78, 137.63, 128.61, 128.23, 118.08, 115.43, 96.91, 83.99, 69.69, 48.26, 34.56. HR-MS calcd. for $C_{19}H_{23}OI$ ([M]$^+$): 393.0715; found: 393.0703.

3a-(2-Iodobenzyloxy)-1,3a,6,6a-tetrahydro-pentalene (6)



Following the procedure for RCM of tetraene **2**, iodobenzyl ether **3** (2.00 g, 5.08 mmol) was reacted with Grubbs catalyst **4** (250 mg, 6 mol%) in CH_2Cl_2 (50 mL) to provide the product (1.18 g, 70%) as a colourless oil after flash chromatography (5% Et_2O–hexanes) on triethylamine-washed silica gel. IR (neat): 3060(s), 2912(s), 1444(m), 1350(s), 1215(m), 1097(m), 1077(s), 1009(s), 942(w), 747(s). ^{1}H NMR (400 MHz, $CDCl_3$) δ: 7.87–7.76 (1H, m), 7.49–7.47 (1H, m), 7.34–7.30 (1H, m), 6.96–6.92 (1H, m), 5.94–5.92 (2H, m), 5.84 (2H, dt, *J* = 6 Hz, 1.6 Hz), 4.38 (2H, s), 2.91–2.84 (3H, m), 2.07–2.15 (2H, m). ^{13}C NMR

Scheme 4. Regiocontrol in the asymmetric Heck reaction using Tl salts.

Scheme 5. Asymmetric synthesis of **13** and **14** under cationic conditions.

(100 MHz, $CDCl_3$) δ: 141.80, 139.01, 134.71, 132.41, 128.99, 128.90, 128.30, 106.00, 97.70, 69.81, 43.21, 40.80. HR-MS calcd. for $C_{15}H_{13}OI$ ($[M]^+$): 338.0149; found: 338.0167.

Preparation of trifluoromethanesulfonic acid 2-(6,6a-dihydro-1*H*-pentalen-3a-yloxymethyl)-phenyl ester (7)

KH (35% dispersion in mineral oil, 1.0 g, 3 equiv.) was washed three times with pentane, dried under a stream of argon, and suspended in 10 mL of THF. Alcohol **1** in 5 mL of THF was added via cannula. The solution was heated to reflux for 10 min, cooled to room temperature, and a solution of 2-(*tert*-butyldimethylsilyloxy)benzyl bromide (19) in 5 mL of THF was added via cannula. The solution was stirred at reflux for 3 h, cooled to room temperature, quenched by dropwise addition of water (25 mL), extracted with ether (3 × 30 mL), dried over Na_2SO_4, filtered, and concentrated. Flash chromatography (100% hexanes) on triethylamine-washed silica gel provided 1-(2-allyl-1,1-divinyl-pent-4-enyloxymethyl)-2-(*tert*-butyldimethylsiloxy)-benzene (939 mg, 85%) as a colourless oil. IR (neat): 3088(s), 2919(s), 2855(s), 1634(m), 1579(m), 1491(s), 1250(s), 1070(m), 913(s), 832(s), 730(m). ^{1}H NMR (400 MHz, $CDCl_3$) δ: 7.57–7.55 (1H, m), 7.11 (1H, td, *J* = 7.6 Hz, 0.8 Hz), 6.98 (1H, td, *J* = 7.6 Hz, 0.8 Hz), 6.74 (1H, dd, *J* = 8 Hz, 0.8 Hz), 5.92–5.82 (4H, m), 5.35 (2H, dd, *J* = 10.8 Hz, 1.6 Hz), 5.29 (2H, dd, *J* = 17.8 Hz, 1.6 Hz), 5.02–4.94 (4H, m), 4.40 (2H, s), 2.51–2.44 (2H, m), 2.01–1.93 (2H, m), 0.97 (9H, s), 0.18 (6H, s). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 152.21, 138.96, 137.91, 131.09, 131.46, 127.46, 127.25, 121.20, 118.03, 117.72, 115.28, 83.69, 61.07, 48.21, 34.57, 18.30, –4.11. HR-MS calcd. for $C_{21}H_{30}O_2Si$ ($[M - C_4H_9]^+$): 341.1936; found: 341.1934.

In a 10 mL round-bottom flask was added 1-(2-allyl-1,1-divinyl-pent-4-enyloxymethyl)-2-(*tert*-butyldimethylsiloxy)-benzene (300 mg, 0.75 mmol) and 3 mL of THF. To this solution was added TBAF (235 mg, 0.90 mmol) all at once at room temperature, and the reaction mixture was stirred at room temperature for 30 min. The reaction was diluted with water (10 mL) and extracted with ether (3 × 10 mL). The combined organic layers were dried over Na_2SO_4, filtered, and concentrated. The residue (2-(2-allyl-1,1-divinyl-pent-4-enyloxymethyl)-phenol) was then used in the next reaction without further purification. IR (neat): 3386(s), 3075(m), 2923(m), 1826(w), 1638(m), 1491(m), 1241(s), 1026(m), 912(s), 753(s). ^{1}H NMR (400 MHz, $CDCl_3$) δ: 7.75 (1H, br s), 7.18–7.14 (1H, m), 6.93–6.78 (3H, m), 5.91–5.75 (4H, m), 5.44–5.31 (4H, m), 5.02–4.95 (4H, m), 4.55 (2H, s), 2.39–2.32 (2H, m), 1.99–1.91 (2H, m), 1.87–1.82 (1H, m). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 156.33, 138.01, 136.83, 128.98, 127.70, 123.56, 119.82, 118.77, 116.68, 115.92, 85.33, 65.69, 47.79, 34.42. HR-MS calcd. for $C_{19}H_{24}O_2$ ($[M]^+$): 284.1776; found: 284.1780.

In a 10 mL round-bottom flask was added 2-(2-allyl-1,1-divinyl-pent-4-enyloxymethyl)-phenol (215 mg, 0.75 mmol), CH_2Cl_2 (5 mL), and Et_3N (440 μL, 4 equiv.). The solution was then cooled to –78 °C and Tf_2O (254 μL, 2 equiv.) was added dropwise via syringe. The reaction mixture was stirred at –78 °C for 15 min, at which point water (5 mL) was added. The flask was warmed to room temperature and extracted with ether (3 × 15 mL), and the organic extracts were dried over Na_2SO_4, filtered, and concentrated. Flash chromatography (2% Et_2O–hexanes) on triethylamine-washed silica gel provided trifluoromethanesulfonic acid 2-(2-allyl-1,1-divinyl-pent-4-enyloxy methyl)-phenyl ester as a colourless oil (240 mg, 81%). IR (neat): 3074(s), 2903(m), 1918(w), 1863(w), 1634(m), 1487(m), 1413(s), 1210(s), 1099(s), 1066(s), 996(s), 896(s), 764(s), 605(m). ^{1}H NMR (400 MHz, $CDCl_3$) δ: 7.68 (1H, dd, *J* = 7.6 Hz, 0.8 Hz), 7.38 (1H, td, *J* = 7.6 Hz, 1.2 Hz), 7.32 (1H, td, *J* = 8.2 Hz, 2 Hz), 7.25–7.23 (1H, m), 5.87 (2H, dd, *J* = 17.6 Hz, 11.2 Hz), 5.86–5.78 (2H, m), 5.40 (2H, dd, *J* = 11.2 Hz, 1.2 Hz), 5.30 (2H, dd, *J* = 17.6 Hz, 1.6 Hz), 5.00–4.93 (4H, m), 4.46 (2H, s), 2.45–2.39 (2H, m), 1.99–1.92 (2H, m), 1.89–183

4a-(2-Iodobenzyloxy)-1,2,4a,7,8,8a-hexahydro-napthalene (12)

In a 100 mL round-bottom flask was added 5-[1-(2-iodobenzyloxy)-1-vinyl-allyl]-cycloheptene (850 mg, 2.15 mmol) and 50 mL of CH_2Cl_2 under nitrogen. To this solution was added ruthenium catalyst **9** (35 mg, 0.04 mmol), and the solution was refluxed for 1 h, at which time all of the starting material had been consumed. ^{1}H NMR analysis showed a 4.5:1 mixture of diastereomers (integration of signals at 5.89 ppm (multiplet corresponding to all of the olefinic protons of the *trans* decalin plus half of the olefin protons of the *cis* decalin product) and 5.63 ppm (half of the olefin protons of the *cis* decalin)). Silica gel (~200 mg) was added, and the mixture was stirred at room temperature for 15 min. The solution was filtered, and the silica gel was washed with a copious amount of CH_2Cl_2. The solvent was removed in vacuo, and the residue was purified by flash chromatography (2% Et_2O–hexanes) to provide 520 mg (65%) of the *cis*-bicyclo[4.4.0]decadiene as a clear oil. IR (neat): 3011(m), 2922(s), 1952(w), 1911(w), 1826(w), 1871(w), 1650(w), 1562(m), 1434(s), 1371(m), 1265(m), 1202(m), 1110(m), 1066(s), 945(m), 747(s), 647(m). ^{1}H NMR (400 MHz, $CDCl_3$) δ: 7.76 (1H, d, J = 8 Hz), 7.52 (1H, d, J = 8 Hz), 7.32 (1H, t, J = 7.6 Hz), 6.93 (1H, t, J = 7.6 Hz), 5.89 (2H, dt, J = 9,9 Hz, 3.6 Hz), 5.63 (2H, dt, J = 9.9 Hz, 2.1 Hz), 4.42 (2H, s), 2.23–2.17 (1H, m), 2.14–2.01 (4H, m), 1.90–1.83 (2H, m), 1.51–1.59 (2H, m). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 142.09, 138.92, 130.29, 129.93, 129.07, 128.81, 128.31, 97.70, 74.68, 68.79, 34.58, 24.51, 23.46. HR-MS calcd. for $C_{17}H_{19}OI$ ([M]$^+$): 366.0480; found: 366.0483.

Preparation of triflouromethanesulfonic acid 2-(1,7,8,8a-tetrahydro-2*H*-naphthalen-4a-yloxymethyl)-phenol ester (15)

KH (35% dispersion in mineral oil, 1.0 g, 3 equiv.) was washed three times with pentane, dried under a stream of argon, and suspended in 10 mL of THF. Alcohol **10** in 5 mL of THF was added via cannula. The solution was heated to reflux for 10 min, cooled to room temperature, and a solution of 2-(*tert*-butyldimethylsilyloxy)benzyl bromide (19) in 5 mL of THF was added via cannula. The solution was stirred at reflux for 3 h, cooled to room temperature, quenched by dropwise addition of water (25 mL), extracted with ether (3 × 30 mL), dried over Na_2SO_4, filtered, and concentrated. Flash chromatography (100% hexanes) on triethylamine-washed silica gel provided *tert*-butyl[2-(1-cyclohept-4-enyl-1-vinyl-allyloxymethyl)-phenoxy]-dimethylsilane (939 mg, 85%) as a colourless oil. IR (neat): 2929(s), 1858(w), 1602(m), 1584(m), 1489(s), 1378(m), 1252(s), 1114(m), 924(s), 838(s), 758(m), 692(m). ^{1}H NMR (400 MHz, $CDCl_3$) δ: 7.56–7.54 (1H, m), 7.13–7.09 (1H, m), 7.00–6.96 (1H, m), 6.75–6.73 (1H, m), 5.84 (2H, dd, J = 17.6 Hz, 11.2 Hz), 5.79–5.77 (2H, m), 5.33 (2H, dd, J = 10.8 Hz, 1.6 Hz), 5.26 (2H, dd, J = 17.6 Hz, 1.6 Hz), 4.39 (2H, s), 2.32–2.27 (2H, m), 2.08–1.97 (4H, m), 1.80 (1H, tt, J = 10.8 Hz, 2.4 Hz), 1.12–1.04 (2H, m), 0.97 (9H, s), 0.18 (6H, s). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 152.29, 138.18, 132.12, 131.23, 127.48, 127.27, 121.23, 118.09, 117.41, 83.65, 60.92, 52.99, 28.19, 25.85, 18.31, –4.10. HR-MS calcd. for $C_{25}H_{38}O_2Si$ ([M]$^+$): 396.6448; found: 396.6451.

In a 10 mL round-bottom flask was added *tert*-butyl[2-(1-cyclohept-4-enyl-1-vinyl-allyloxymethyl)-phenoxy]-dimethylsilane (300 mg, 0.75 mmol) and 3 mL of THF. To this solution was added TBAF all at once at room temperature, and the reaction mixture was stirred at room temperature for 10 min. The reaction was diluted with water (10 mL) and extracted with ether (3 × 10 mL). The combined organic layers were dried over Na_2SO_4, filtered, and concentrated. The residue [2-(1-cyclohept-4-enyl-1-vinyl-allyloxymethyl)phenol] was then used in the next reaction without further purification. IR (neat): 3362(s), 3017(m), 2930(m), 1930(w), 1861(w), 1590(m), 1244(s), 1024(s), 845(w), 754(s), 692(w). ^{1}H NMR (400 MHz, $CDCl_3$) δ: 8.01 (1H, br s), 7.20–7.16 (1H, m), 6.95–6.80 (3H, m), 5.85 (2H, dd, J = 17.8 Hz, 11.2 Hz), 5.77–5.75 (2H, m), 5.42 (2H, d, J = 10.8 Hz), 5.32 (2H, d, J = 17.6 Hz), 4.59 (2H, s), 2.32–2.26 (2H, m), 2.03–1.92 (4H, m), 1.82 (1H, tt, J = 10.4 Hz, 2.4 Hz), 1.15–1.06 (2H, m). ^{13}C NMR (100 MHz, $CDCl_3$) δ:

HR-MS calcd. for $C_{20}H_{23}O_4SF_3$ ([M]$^+$): 416.1269; found: 416.1280.

In a 100 mL round-bottom flask was added triflouromethanesulfonic acid 2-(1-cyclohept-4-enyl-1-vinyl-allyloxymethyl)-phenyl ester (850 mg, 2.15 mmol) and 50 mL of CH_2Cl_2 under nitrogen. To this solution was added ruthenium catalyst **9** (35 mg, 0.04 mmol), and the solution was refluxed for 1 h, at which time all of the starting material had been consumed. ^{1}H NMR analysis showed a 4.5:1 mixture of diastereomers (integration of signals at 5.90 ppm (multiplet corresponding to all of the olefinic protons of the *trans* decalin plus half of the olefin protons of the *cis* decalin product) and 5.59 ppm (half of the olefin protons of the *cis* decalin)). Silica gel (~200 mg) was added, and the mixture was stirred at room temperature for 15 min. The solution was filtered, and the silica gel was washed with a copious amount of CH_2Cl_2. The solvent was removed in vacuo, and the residue was purified by flash chromatography (2% Et_2O–hexanes) to provide 520 mg (65%) of the *cis*-bicyclo-[4.4.0]decadiene (**15**) as a clear oil. IR (neat): 3029(m), 2941(s), 1487(m), 1454(m), 1418(s), 1330(w), 1209(s), 1143(s), 1056(m), 895(s), 763(m), 734(m), 602(m). ^{1}H NMR (400 MHz, $CDCl_3$) δ: 7.65–7.63 (1H, m), 7.37–7.22 (3H, m), 5.90 (2H, dt, J = 10.4 Hz, 3.6 Hz), 5.59 (2H, dt, J = 9.6 Hz, 2 Hz), 4.56 (2H, s), 2.20–2.00 (5H, m), 1.87–1.79 (2H, m), 1.50–1.59 (2H, m). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 147.13, 133.09, 130.60, 130.50, 129.59, 128.86, 128.48, 120.95, 118.72 (q, J = 319.2 Hz), 74.97, 58.62, 34.44, 24.39, 23.40. HR-MS calcd. for $C_{18}H_{19}O_4SF_3$ ([M]$^+$): 388.0956; found: 388.0962.

General procedure for the asymmetric Heck reaction using $Pd(OAc)_2$

In a 10 mL round-bottom flask equipped with a stir bar and reflux condenser was added $Pd(OAc)_2$ (11.5 mg, 0.0513 mmol), (*R*)-BINAP (63.88 mg, 0.1025 mmol), Et_3N (74 μL, 0.513 mmol), and 2 mL of CH_3CN under an argon flush. The mixture was heated to 70 °C for 3 h and then the aryl halide (0.342 mmol) in 1 mL of CH_3CN was added via cannula. The reaction was stirred at 70 °C for 16 h. The reaction was cooled to room temperature, diluted with water (5 mL), and extracted with ether (3 × 10 mL). The organic layers were combined, dried over Na_2SO_4, filtered, and concentrated. Flash chromatography (2.5% Et_2O–hexanes → 5% Et_2O–hexanes) provided the product as an oil.

General procedure for the asymmetric Heck reaction using Pd_2dba_3

In a 10 mL round-bottom flask equipped with a stir bar and reflux condenser was added Pd_2dba_3 (8.15 mg, 0.0089 mmol), (*R*)-*tol*-BINAP (12.19 mg, 0.01958 mmol), and base (0.356 mmol) in solvent (1 mL) under an argon atmosphere. The solution was stirred at room temperature for 40 min, and then a solution of the aryl halide (0.178 mmol) in 1.5 mL of solvent was added via cannula under argon. The reaction was heated to 80 °C and stirred at this temperature for 36 h. The flask was cooled to room temperature, diluted with ether (20 mL), and washed with saturated aqueous $NaHCO_3$ (7 mL). The aqueous layer was further extracted with Et_2O (2 × 10 mL), and the combined organic extracts were washed with brine (7 mL) and dried over Na_2SO_4. Removal of the organic solvent followed by flash chromatography (5%–10% Et_2O–hexanes) provided the product as a colourless oil.

4b,6a,7,11-Tetrahydro-10-oxa-pentaleno[1,6a-a]naphthalene (8)

Following the general procedure for the asymmetric Heck reaction, the title compound was obtained as a colorless oil, which darkens upon storage at room temperature for prolonged time. The enantiomeric excess of the cyclized product was determined by HPLC analysis, as follows: CHIRACEL OD, 10% *i*-PrOH–hexanes, retention times for the enantiomers = 10.9 min, 11.5 min. (V_O = 0.5 ml/min, 23 °C, UV monitor: 254 nm.) $[\alpha]_D^{25}$ = +124.7 (c = 1.0, $CHCl_3$) (99% ee). ^{1}H NMR (400 MHz, $CDCl_3$) δ: 7.23 (1H, d, J = 7.2 Hz), 7.18 (1H, d, J = 7.2 Hz), 7.13 (1H, d, J = 7.2 Hz), 7.08 (1H, d, J = 7.2 Hz), 5.96 (1H, dt, J = 5.6 Hz, 2 Hz), 5.83 (1H, dt, J = 5.6 Hz, 2.8 Hz), 5.72 (1H, dt, J = 6.4 Hz, 2 Hz), 5.66 (1H, dt, J = 6 Hz, 1.6 Hz), 4.70 (1H, d, J = 14 Hz), 4.60 (1H, d, J = 14 Hz), 3.83 (1H, d, J = 2 Hz), 3.48 (1H, dt, J = 8.8 Hz, 2 Hz), 2.83 (1H, ddt, J = 17.2 Hz, 8.8 Hz, 2 Hz), 2.16 (1H, dd, J = 17.2 Hz, 2 Hz). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 136.10, 135.13, 134.36, 134.14, 133.50, 132.65, 128.06, 127.58, 125.77, 125.13, 97.42, 64.18, 50.46, 50.31, 36.99. HR-MS calcd. for $C_{15}H_{13}O$ ([M]$^+$): 210.1042; found: 210.1044.

4b,7,7a,8,9,13-Hexahydrodibenzo[*c*,*i*]chromene (13) and 4b,5,7a,8,9,13-hexahydrodibenzo[*c*,*i*]chromene (14)

Following the general procedure for the asymmetric Heck reaction, the title compounds were obtained as colorless oils after flash chromatography (2% Et_2O–hexanes → 5% Et_2O–hexanes). Enantiomeric excesses of the cyclized products were determined by HPLC analysis, as follows: CHIRACEL OD, 10% *i*-PrOH–hexanes, retention times for the enantiomers: **13** = 4.02 min, 4.55 min; **14** = 4.43 min, 5.60 min.

© 2004 NRC Canada

(V_O = 1 ml/min, 23 °C, UV monitor: 220 nm.) **13** = $[\alpha]_D^{25}$ = –101.2 (c = 0.90, $CHCl_3$) (82% ee, using (*S*)-*tol*-BINAP); **14** = $[\alpha]_D^{25}$ = –88.9 (c = 0.85, $CHCl_3$) (66% ee, using (*S*)-*tol*-BINAP).

TRIBUTE / HOMMAGE

This Special Issue of the *Canadian Journal of Chemistry* is dedicated to Professor Ed Piers for not only his outstanding contributions to the field of organic synthesis but also for his positive influence on more than 95 graduate students and postdoctoral fellows and his exemplary leadership to the profession of chemistry across Canada.

Edward Piers was born in the Province of Alberta, Canada, in 1938. He acquired his B.Sc. and Ph.D. degrees from the University of Alberta in 1959 and 1963, respectively. Following his Ph.D. studies, which were carried out under the supervision of Professor R.K. Brown, he spent two years as a postdoctoral fellow in the laboratory of Professor J.P. Kutney at the University of British Columbia. In 1965, Ed became a faculty member at UBC, where he is currently Professor of Chemistry.

Ed's research program has resulted in over 190 publications and focused mainly on studies involving (*a*) the development of new reagents and methods for organic synthesis, and (*b*) the total synthesis of biologically active and structurally challenging natural products utilizing these reagents and methods. Earlier in his career his research group focused on the utilization of cuprates in conjugate addition reactions as a means for introducing stereocentres into molecules. In addition, his group spent some time investigating the use and rearrangements of divinylcycloproapne systems and ultimately applied these reactions to the synthesis of complex natural products. In recent years, Ed and his research group have prepared and developed a number of new bifunctional and trifunctional reagents derived from organostannane and organogermane precursors. The use of these reagents in synthetic transformations usually required the addition of copper and (or) palladium reagents. Interestingly, the use of copper-based species has proven extremely beneficial for Ed's group over his entire career. During the course of these studies, a number of effective annulation methods were developed and they have played key roles in the total syntheses of several structurally complex natural products including aristolone, fukinone, α-cubebene, copacamphene, ylangocamphor, *cis*- and *trans*-sativenediol, isolongifolene, β-himachalene, 9-pupukeanone, triophamine, sinularene, quadrone, stemodin, palauolide, amijitrienol, $\Delta^{9(12)}$-capnellene, ambiliol B, stephalic acid, 8-epi-oplopanone, chiloscyphone, homalomentol A and B, crinipellin B, sarcodonin G, dysidiolide, africanol, and kelsoene.

His outstanding contributions to not only the field of organic chemistry but also as a teacher has resulted in Ed being the recipient of a number of awards, including an Alfred P. Sloan Fellowship (1970), the Chemical Institute of Canada (CIC) Merck, Sharpe and Dohme Award (1979), Killam Senior Fellowship (1984), the UBC Killam Research Prize (1989), the CSC Alfred Bader Award in Organic Chemistry (1994), the CSC R.U. Lemieux Award for Organic Chemistry (1996), and the ICI Montreal Medal (1999). In 1989, Ed was elected a Fellow of the Royal Society of Canada.

Ed has inspired many a student to pursue a career in the field of organic synthesis. His exemplary teaching skills resulted in him being awarded twice the C.I.C. Departmental Master Teaching Award (1972 and 1985). Ed's enthusiasm for synthesis, solving problems, and working out mechanisms was addictive and had an infectious effect on those working with him. These traits were not only seen when discussing research results with him, but also during his weekly

Ce numéro spécial de la *Revue canadienne de chimie* est consacré au professeur Ed Piers en hommage à ses contributions exceptionnelles dans le domaine de la synthèse organique, ainsi qu'en reconnaissance de l'influence positive qu'il a exercée sur plus de 95 doctorants et boursiers de perfectionnement postdoctoral et de son leadership exemplaire pour la profession de chimiste dans tout le Canada.

Edward Piers est né dans la province d'Alberta, au Canada, en 1938. Il a décroché son baccalauréat ès sciences et son doctorat de l'Université de l'Alberta en 1959 et en 1963 respectivement. Après ses études de doctorat, pour lesquelles il avait le professeur R.K. Brown comme directeur de thèse, il a passé deux ans comme boursier de perfectionnement postdoctoral dans le laboratoire du professeur J.P. Kutney à l'Université de la Colombie-Britannique. En 1965, Ed est devenu membre du corps enseignant de l'UBC, où il est actuellement professeur de chimie.

Le programme de recherche d'Ed a produit plus de 190 publications; il était axé principalement sur des études portant sur (*a*) la mise au point de nouveaux agents réactifs et méthodes pour la synthèse organique et (*b*) la synthèse intégrale de produits naturels biologiquement actifs et structuralement complexes au moyen de ces agents réactifs et méthodes. Au début de sa carrière, son groupe de recherche se concentrait sur l'utilisation de cuprates dans des réactions d'addition conjuguée pour introduire des stéréocentres dans des molécules. Par ailleurs, son groupe a consacré un certain temps à étudier l'utilisation et le réaménagement de systèmes divinylcyclopropanes et a fini par appliquer ces réactions à la synthèse de produits naturels complexes. Au cours des dernières années, Ed et son groupe de recherche ont préparé et mis au point un certain nombre de nouveaux agents bifonctionnels et trifonctionnels dérivés de précurseurs de l'organostannane et de l'organogermane. L'utilisation de ces agents dans des transformations synthétiques exige habituellement l'addition d'agents réactifs au cuivre ou au palladium. Il est intéressant de noter que l'utilisation d'espèces basées sur le cuivre s'est révélée extrêmement profitable pour le groupe d'Ed au cours de toute sa carrière. Pendant ces études, plusieurs méthodes d'annulation efficaces ont été mises au point et elles ont joué un rôle clé dans la synthèse intégrale de plusieurs produits naturels structuraux complexes, parmi lesquels ont trouve les suivants : aristolone, fukinone, α-cubebène, copacamphène, ylangocamphre, *cis*- et *trans*-sativénédiol, isolongifolène, β-himachalène, 9-pupukéanone, triophamine, sinularène, quadrone, stémodin, palauolide, amijitriénol, $\Delta^{9(12)}$-capnellène, ambiliol B, acide stéphalique, 8-*epi*-oplopanone, chiloscyphone, homalomenthol A et B, crinipellin B, sarcodonin G, dysidiolide, africanol et kelsoène.

Ses contributions exceptionnelles, non seulement dans le secteur de la chimie organique, mais également comme enseignant, ont mérité à Ed de nombreux prix, parmi lesquels une bourse de recherche Alfred P. Sloan (1970), le prix Marck, Sharpe et Dohme de l'Institut de chimie du Canada (ICC), une bourse de travail libre pour universitaire Killam (1989), et le prix de la recherche Killam de l'ICC (1989), le prix Alfred Bader de chimie organique de la Société canadienne de chimie (SCC) (1994), le prix R.U. Lemieux de chimie organique de la SCC (1996) et la Médaille de Montréal de l'ICC (1999). En 1989, Ed a été élu membre de la Société royale du Canada.

group meetings that focused on solving problems. Ed's respect for his co-workers, patience and never-ending willingness to discuss chemistry led those who worked with him to achieve high standards. His superb mentoring skills have resulted in many of the 65 graduate students (listed at the end of this tribute) and 33 postdoctoral fellows (also listed at the end of this tribute) ending up with excellent positions at universities, in the pharmaceutical industry, or in the chemical industry.

Ed has made significant contributions to the profession of chemistry in Canada. From 1982–1985, he was a member of the Natural Sciences and Engineering Research Council (NSERC) Chemistry Grants Selection Committee and was Chair of the Committee during 1984 to 1985. He has also been active in the Canadian Society for Chemistry (CSC). From 1990–1993 he was a member of the executive of the CSC Board of Directors, and he served as President of the CSC from 1991 to 1992. While he was Vice-President of this organization from 1990 to 1991, he was very actively involved with increasing the graduate student membership in the CSC. Ed has served the CSC by organizing or co-organizing national and international symposia at a variety of conferences. Ed also served three years (1993–1996) as a member of the Rutherford Medal (Chemistry) Selection Committee of the Royal Society of Canada and was Chair of this committee during 1995 to 1996. He was also a member of the RSC Academy of Science Council Fellowship Review Committee for 3 years (1992–1995). Ed has served on some national and international editorial and advisory boards. He has twice (1981–1984; 1990–1993) been a member of the Editorial Board of the *Canadian Journal of Chemistry,* he has served on the International Advisory Board of the *Encyclopedia of Reagents for Organic Synthesis* (1992–1995), and he is currently a member of the Advisory Editorial Board of Chemical Communications and the International Advisory Board of *J. Chem. Soc. Perkin Trans. 1*. Ed has also held Visiting Professorships at a number of universities, including UC Irvine, Western Ontario, and Sao Paulo.

Ed was born and raised in a small town in northern Alberta called Neerlandia (pop. 80), which lies a few kilometers north of Barrhead. He is married to Shirley and they have two sons, Warren and Kevin, who have Ph.Ds in inorganic chemistry and genetics, respectively.

The authors of this issue and the editors are pleased to present this special issue to Edward Piers as a token of our appreciation for his relentless passion and enthusiasm for chemistry and for his exemplary mentoring skills.

Brian A. Keay

Ed a été une source d'inspiration pour de nombreux étudiants qui ont choisi de faire carrière dans le domaine de la synthèse organique. Ses compétences exemplaires d'enseignant lui ont valu deux fois le prix Departmental Master Teaching de l'ICC (1972 et 1985). L'enthousiasme d'Ed pour la synthèse, la résolution de problème et la compréhension de mécanismes était comme une drogue et contagieux pour tous ceux qui travaillaient avec lui. Ces traits de caractère n'étaient pas seulement évidents lorsqu'on parlait de résultats de recherche avec lui, mais également pendant les réunions de groupe hebdomadaires qui se concentraient sur la résolution de problèmes. Le respect d'Ed pour ses collaborateurs, sa patience et son éternelle disponibilité à parler de chimie ont inspiré ceux qui travaillaient avec lui à atteindre des normes élevées. Ses superbes compétences en mentorat ont eu pour résultat que bon nombre des 65 doctorants (dont les noms figurent à la fin de cet hommage) et 33 boursiers de perfectionnement postdoctoral (dont les noms figurent également à la fin de cet hommage) qu'il a guidés ont obtenu d'excellents postes dans des universités, dans l'industrie pharmaceutique ou dans l'industrie chimique.

Ed a apporté une importante contribution à la profession de chimiste au Canada. Entre 1982 et 1985, il était membre du Comité de sélection des bourses en chimie du Conseil de recherches en sciences naturelles et en génie (CRSNG) et président de ce Comité de 1984 à 1985. Il s'est également impliqué dans la Société canadienne de chimie (SCC). Entre 1990 et 1993, il était membre du bureau du Conseil d'administration de la SCC et il a fait office de président de cet organisme de 1991 à 1992. Pendant qu'il était vice-président de la SCC, de 1990 à 1991, il s'est consacré très énergiquement à faire augmenter le nombre de doctorants membres de la SCC. Ed a aidé la SCC en organisant ou en co-organisant des symposiums nationaux et internationaux lors de diverses conférences. Il a également été pendant trois ans (1993–1996) membre du comité de sélection pour la Médaille Rutherford (chimie) de la Société royale du Canada et il était président de ce comité de 1995 à 1996. Il était également membre du Comité du Conseil des candidatures de l'Académie des sciences de la SRC pendant trois ans (1992–1995). Ed a également siégé au sein de plusieurs comités éditoriaux et consultatifs nationaux et internationaux. Il a été deux fois (1981–1984; 1990–1993) membre du comité éditorial de la *Revue canadienne de chimie*, membre du comité consultatif international de la *Encyclopedia of Reagents for Organic Synthesis* (1992–1995), et il est actuellement membre du Comité consultatif éditorial de *Chemical Communications* et du Comité consultatif international de *J. Chem. Soc. Perkin Trans. 1*. Ed a également été titulaire d'une chaire de professeur invité à plusieurs universités, notamment UC Irvine, Western Ontario et Sao Paulo.

Ed est né et a grandi dans une petite ville du nord de l'Alberta appelée Neerlandia (80 habitants) située à 15 kilomètres au nord de Barrhead. Il est marié à Shirley avec laquelle il a eu deux fils, Warren et Kevin, qui sont titulaires de doctorats en chimie inorganique et en génétique respectivement.

Les auteurs de ce numéro et la rédaction sont ravis de présenter ce numéro spécial à Edward Piers en gage de leur appréciation pour sa passion et son enthousiasme inextinguibles pour la chimie et pour ses compétences exemplaires en mentorat.

Role of trinuclear Zn(II) complexes in promoting the hydrolysis of 4-nitrophenyl acetate

Qing-Chun Ge, Yan-He Guo, Hai Lin, Dong-Zhao Gao, Hua-Kuan Lin, and Shou-Rong Zhu

Abstract: Potentiometric determination shows that trinuclear Zn(II) complexes of the four tripods 1,3,5-tri(2′,5′-diazahexyl)benzene (L1), 1,3,5-tri(2′,5′-diazaheptyl)benzene (L2), 1,3,5-tri(2′,5′-diazaoctyl)benzene (L3), and 1,3,5-tri(2′,5′-diazanonyl)benzene (L4) could be potential hydrolytic catalysts. CH_3CN solutions containing $[3Zn:L]^T$ (0.5~2 × 10^{-3} mol·dm^{-3}) with I = 0.10 mol·dm^{-3} of KNO_3 and Good's buffer (10% volume fraction) were studied for the catalyzing hydrolysis of *p*-nitrophenyl acetate (NA, 0.5~2 × 10^{-3} mol·dm^{-3}), at 298 K, in the 6.5–8.2 pH range. The observed rate constants, k_{obs}, fit the equilibrium equation $k_{obs} = k_{com}[3Zn:L]^T + k_{OH}[OH^-] + k_0$. The sigmoid pH~$k_{com}$ profiles for NA hydrolysis suggest that either the Zn(II)-bound hydroxyl or the Zn(II)-bound water forms of the catalysts can be the active species. The observed second-order rate constants are 0.0082, 0.011, 0.0059, and 0.0019 mol^{-1}·dm^3·s^{-1} for the four $Zn_3L–H_2O$ complexes (k_A) and 0.342, 0.257, 0.382, and 0.091 mol^{-1}·dm^3·s^{-1} for the four $Zn_3L–OH^-$ groups (k_B), respectively. However, under the condition that [NA] = 0.5 × 10^{-3} mol·dm^{-3} and $[3Zn:L1]^T$ = 2~4 × 10^{-2} mol·dm^{-3} at pH 7.6, the observed rate constants, k_{obs}, obey the equilibrium $k_{obs} = k_{com}[3Zn:L]^T/(1/K' + [3Zn:L]^T)$. This indicates that the 3:1 complex (or its deprotonated hydroxide form) mediates NA hydrolysis by nucleophilic attack of the carboxyl center with the pre-formation of a coordination bond between the carboxyl oxygen atom and the Zn(II) ion. Comparison with other models was made, and the reasons for the high catalytic efficiency of the tripodal complexes were given.

Key words: tripod, Zn(II), catalysis, NA hydrolysis, polynuclear.

Résumé : Des mesures potentiométriques ont montré que les complexes trinucléaires du Zn(II) de quatre bases en trépieds, le 1,3,5-tri(2′,5′-diazahexyl)benzène (L1), le 1,3,5-tri(2′,5′-diazaheptyl)benzène (L2), le 1,3,5-tri(2′,5′-diazaoctyl)benzène (L3) et le 1,3,5-tri(2′,5′-diazanonyl)benzène (L4) pourraient agir comme catalyseurs d'hydrolyse. On a étudié l'utilité de solutions contenant de 0,5 à 2 × 10^{-3} mol·dm^{-3} de $[3Zn:L]^T$ dans du CH_3CN à I = 0,10 mol·dm^{-3} de KNO_3 avec un tampon de Good à 10% (v/v) comme catalyseurs pour l'hydrolyse de l'acétate de *p*-nitrophényle (AN), à des concentrations de 0,5 à 2 × 10^{-3} mol·dm^{-3}, à 298 K et à des pH allant de 6,5 à 8,2. Les constantes de vitesse observées (k_{obs}) peuvent être ajustées par une équation d'équilibre de la forme $k_{obs} = k_{com}[3Zn:L]^T + k_{OH}[OH^-] + k_0$. Les profiles sigmoïdes du pK~k_{com} pour l'hydrolyse de l'AN suggèrent que les formes du catalyseur dans lesquelles le Zn(II) est lié à un hydroxyle et Zn(II) est lié à une molécule d'eau peuvent agir comme espèces actives. Les constantes de vitesse du deuxième ordre sont respectivement 0,0082, 0,011, 0,0059 et 0,0019 mol^{-1}·dm^3·s^{-1} pour les quatre complexes $Zn_3L–H_2O$ (k_A) et de 0,342, 0,257, 0,382 et 0,091 mol^{-1}·dm^3·s^{-1} pour les quatre complexes $Zn_3L–OH^-$ (k_B). Toutefois, dans les conditions où [AN] = 0,5 × 10^{-3} mol·dm^{-3} et que $[3Zn:L1]^T$ = 2~4 × 10^{-2} mol·dm^{-3}, à un pH de 7,6, les constantes de vitesses observées (k_{obs}) peuvent être ajustées par une équation d'équilibre de la forme $k_{obs} = k_{com}[3Zn:L]^T/(1/K' + [3Zn:L]^T)$. Ceci suggère que le complexe 3:1 (ou sa forme hydroxyde déprotonée) agit comme médiateur de l'hydrolyse de l'AN par l'attaque du nucléophile sur le centre carboxylique, avec la préformation d'une liaison de coordination entre l'atome d'oxygène du carboxyle et l'ion Zn(II). On a fait une comparaison avec d'autres modèles et on donne les raisons qui peuvent expliquer l'efficacité catalytique élevée des complexes en trépieds.

Mots clés : trépieds, Zn(II), catalyse, AN hydrolyse, polynucléaire.

Introduction

Zinc ion is biologically important and has been found in the active site of more than 200 types of enzymes such as carbonic anhydrase (1), carboxypeptidase (2), and alkaline phosphatase (3). In a protein environment, tetrahedral or penta-coordinate Zn^{2+} is ideally suited to activate a bound water, typically forming Zn^{2+}–OH as a nucleophile, which attacks the carbonyl carbon of a peptide bond, the carbon of carbon dioxide, or the phosphorus of a phosphate ester.

Recently, there have been many research efforts to design and synthesize model complexes for zinc enzymes, and detailed structural and mechanistic data are available. There is

Chart 1.

considerable interest in this field in developing rate increases and specificities similar to those of natural enzymes (4–10). Therefore, a large number of ligands, such as those in Chart 1, have been developed, which generate water-soluble and catalytic hydroxyl complexes (4–8). For example, the tris(3-aminopropyl)amine **II** complex of Co(III) increases the rate of hydrolysis of BNPP, bis(*p*-nitrophenyl)phosphate, by 10 times, with its rate maximum at pH 7 (5).

We have initiated a research program for development of novel dephosphorylation catalysts based on Zn(II) complexes of polyaza tripods. However, the hydrolysis of phosphate esters is fairly slow in neutral solution, so the substrate was changed to 4-nitrophenyl acetate (NA). NA is a very convenient substrate because hydrolysis can be followed easily and interactions with the good leaving groups are probably unimportant. We used the benzene-spaced tripods (L) because of the following factors: firstly, to increase the hydrophobicity around Zn(II); secondly, to widen the size of the semi-cavity formed by the tripod; and thirdly, to help with binding of aromatic substrates by π–π stacking interaction.

Another advantage of the use of tripods is attributed to the potential of these flexible ligands to form polynuclear complexes rather than mononuclear ones (11, 12), since it is reported that the reactivity of the center of enzymes depends on both the structure and the number of metal ions. For example, the elegant trinuclear zinc (II) complex of **IV** has been shown to hydrolyze RNA more efficiently than its dinuclear analog, and the maximum reactivity of **IV** was obtained when the ligand-to-metal ratio was 1:3 (7). Our purpose is to examine the catalytic effect of the mono-and trinuclear models on the rates of hydrolysis of NA, although we do not get into the relevance of an enzyme such as carbonic anhydrase (CA), where only one Zn(II) is present (2).

Experimental

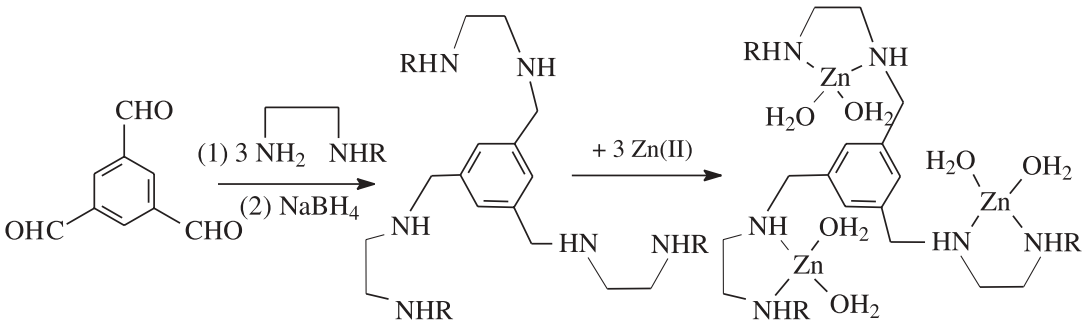
Materials

All reagents and solvents used were of analytical grade. Acetonitrile (CH_3CN) was distilled over calcium hydride and stored in a dark bottle. 4-Nitrophenyl acetate (NA) was recrystallized from dry diethyl ether. 4-Nitrophenol (pK_a = 7.1), MES (2-(*N*-morpholino)-enthanesulfonic acid, pK_a = 6.39), MOPS (3-(morpholino)-proanesulfonic acid, pK_a = 7.2), HEPES (*N*-1-hydroxyethylpiperazine-*N*′-2-ethanesulfonic, pK_a = 7.5), and EPPS (*N*-2-hydroxyethylpiperazine-*N*′-3-propanesulfonic acid, pK_a = 8.0) were obtained from Aldrich Co.

Synthesis

The synthesis of 1,3,5-tri(2′,5′-diazahexyl)benzene (L1), 1,3,5-tri(2′,5′-diazaheptyl)benzene (L2), 1,3,5-tri(2′,5′-diazaoctyl)benzene (L3), and 1,3,5-tri(2′,5′-diazanonyl)benzene (L4) was neatly performed by condensation of 1,3,5-benzene-tricarboxaldehyde (13) with 3 equiv of *N*-R-ethylenediamine (R = methyl, ethyl, *n*-propyl, and *n*-butyl) and subsequent reduction with $NaBH_4$ (14). The synthesis of the L compounds and the formation of their complexes into the 3:1 Zn(II):L ratio are shown in Scheme 1.

Potentiometric measurements



Potentiometric titrations were carried out with a Beckman auto-titrator of Model Φ71. The apparatus and procedure have been described before (14). The concentrations of the reagents are $[Zn^{2+}] = 3[L] = 3 \times 10^{-3}$ mol·dm^{-3}. Computation of equilibrium constants was made using the TITFIT (15) program.

Kinetics of 4-nitrophenyl acetate hydrolysis

A kinetic study was carried out by the UV spectral method using a Shimadzu UV-160A spectrophotometer equipped with a thermostated cell (298 K). The hydrolysis rate of 4-nitrophenyl acetate (NA) in aqueous solution was measured by an initial slope method, following the increase in 400 nm absorption of the released 4-nitrophenolate. The reaction solution was maintained at 298 K, and the ionic strength was adjusted to 0.10 mol·dm^{-3} with KNO_3. The concentrations of the 3:1 Zn(II):L complexes in the reaction solution, $[3Zn:L]^T$, were 0.5, 1.0, 1.5, and 2.0 × 10^{-3} mol·dm^{-3}, respectively (according to the concentration of L). The concentrations of NA were controlled at 0.5, 1.0, 1.5, and 2.0 × 10^{-3} mol·dm^{-3}, respectively. MES, MOPS, HEPES, and EPPS buffers (20 mmol·dm^{-3}) were used to maintain pH, and they do not coordinate with metal ions under these conditions (6). To increase the solubility of NA, 10% CH_3CN–H_2O solution was used. For the initial rate determination, the following typical procedure was employed: After 4-nitrophenyl acetate and the complexes (in 10% CH_3CN solution and at the appropriate pH) were mixed, the UV absorption increase was recorded immediately (the reference experiment did not contain the catalyst). The increase in concentration of nitrophenolate was measured every 5–60 s. The initial slope (<5% conversion) of a plot of measured absorbance vs. time was determined (correlation coefficient 0.99). All the experiments were run in triplicate, and the tabulated data represent the average of these experiments.

Results and discussion

Active nucleophile in 3:1 Zn:L systems

The stability constants of various complexes of the four tripods (1×10^{-3} mol·dm^{-3}) with Zn(II) (3×10^{-3} mol·dm^{-3}) have been determined at 25 °C (I = 0.10 mol·dm^{-3} KNO_3 (11)), and the data are listed in Table 1. When in a 3:1 metal:ligand ratio, the system does prefer polynuclear complexes. As is seen from Fig. 1, there are four major complexes in solution, i.e., $ZnLH_4$ (114 (these values in parentheses stand for the stoichiometries of metal ion, ligand, and proton, respectively)), Zn_2LH_2 (212), Zn_3L (310), and Zn_3LH_{-1} (31–1), forming in turn with the increase of pH. The negative value (–1) means the release of a proton of Zn(II)-bound water. In the 3:1 Zn(II):L2 system (Fig. 1), the mononuclear protonated species $ZnLH_4$ (the charge is omitted for clarity) forms in the wide 3–6 pH range and becomes a major species at the 3.5~5 pH range. The diprotonated dinuclear complex Zn_2LH_2 starts to form at pH 4.0 and reaches the maximum concentration (>85%) at pH ca. 5.5. Subsequently, the trinuclear complexes Zn_3L and Zn_3LH_{-1} (Zn_3L–OH) start to form at pH 5 and 5.5, respectively, but the neutral species Zn_3L never becomes a predominant species, with its maximum concentration (<50%) at pH ca. 6.5. The action of other systems are similar to that of Zn(II):L2.

In the complex Zn_3L (Scheme 1), each branch of L coordinates with metal ions using two secondary nitrogen atoms, and the Zn(II)-bound water is easy to deprotonate to give the monohydroxyl M_3LH_{-1} (or M_3L–OH, 31–1). Seen from Table 1, all the pK_a values for the process $M_3L \rightarrow M_3LH_{-1} + H^+$, according to eq. [1], are in the 7.25~7.52 range. This indicates that the coordinated water molecules in the Zn_3L–H_2O complexes have low pK_as, similar to values for the hydrolytic Zn(II)-enzymes (16), facilitating the production of the nucleophilic Zn(II)-bound hydroxide species at physiological pH.

$$[1] \qquad pK_a = \log\beta_{310} - \log\beta_{31-1}$$

Hydrolysis rates

To determine whether the hydrolysis of NA is promoted by [Zn_3L] or [Zn_3L–OH^-], hydrolysis of NA (0.5, 1.0, 1.5, and 2.0 mmol·dm^{-3}) in a 10% CH_3CN (volume fraction) aqueous solution of the Zn(II) complexes (0.5, 1.0, 1.5, and 2.0 mmol·dm^{-3}; refers to the concentration of L) in the pH range 6.5~8.2 (Good's buffer, 20 mmol·dm^{-3}) at 25 °C and with I = 0.10 mol·dm^{-3} KNO_3 was carried out using a UV–vis spectrometer. The hydrolysis rate of 4-nitrophenyl acetate (NA) in aqueous solution was measured by an "initial rate" method, following the increased absorption of the released 4-nitrophenolate (NP^-) at 400 nm (6). The use of a buffer during the analysis was required, since the pH of the solution would cause changes in the concentration of the 4-nitrophenolate anion. The concentration of the released 4-nitrophenolate was calculated from the extinction coefficient at 400 nm (ε = 17 900 (mol·L^{-1})$^{-1}$·cm^{-1}).

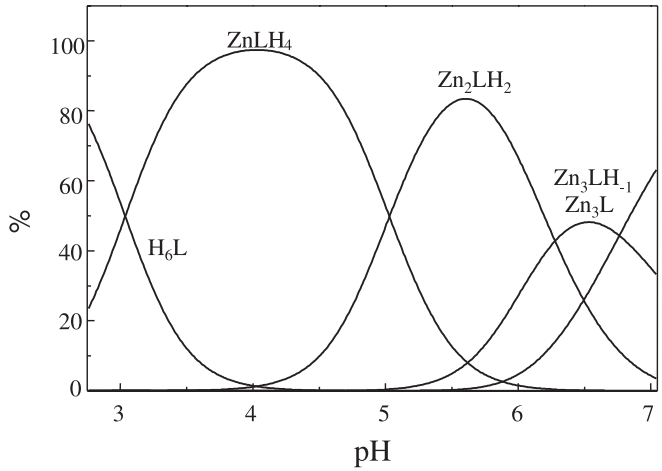

Table 1. The stability constants of complexes formed by L in the presence of Zn^{2+}.

Equilibria	L1	L2	L3	L4
$\log\beta_{114}$[a]	47.27±0.05	45.06±0.04	46.38±0.03	44.04±0.07
$\log\beta_{212}$	39.65±0.04	37.80±0.05	38.64±0.05	36.01±0.08
$\log\beta_{310}$	28.89±0.08	28.50±0.05	28.49±0.06	26.61±0.10
$\log\beta_{31-1}$	21.42±0.10	21.25±0.08	20.97±0.04	19.13±0.07

Note: Reaction conditions are 25 °C, I = 0.1 mol·dm^{-3} KNO_3, [L] = 1/3[Zn^{2+}] = 1×10^{-3} mol·dm^{-3} (14).

[a]The l, m, and n values of $\log\beta_{lmn}$ stand for the stoichiometries of metal ion, ligand, and proton, respectively. The negative value (–1) means the release of a proton of Zn(II)-bound water.

Fig. 1. Species distribution as a function of pH for the 3:1 Zn(II)–L2 complex; 25.0 ± 0.1 °C, I = 0.1 mol·dm^{-3} KNO_3, [L] = 1/3[Zn(II)] = 1×10^{-3} mol·dm^{-3}.

1.5	1.054	3.32	9.37	12.86	19.12	24.02	30.41
2.0	1.385	4.17	11.60	15.85	22.08	28.83	35.28

Note: $[3Zn:L]^T$ = 0.5, 1.0, 1.5, and 2.0 × 10^{-3} mol·L^{-1} (25.0 ± 0.1 °C, I = 0.1 mol·dm^{-3} KNO_3, 0.02 mol·dm^{-3} Good's buffer, 10% CH_3CN).

As shown in Fig. 2, the initial rate, v, can be obtained from the slope (<5% conversion) of a plot of the measured absorbance (A) vs. time (s). It is observed that the initial rate v increases linearly with the concentration of NA. Therefore, v is expressed as in the following (eq.[2]):

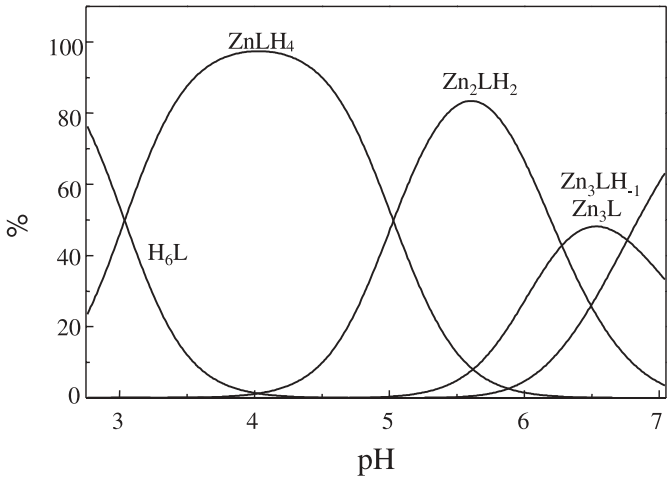
$$[2] \qquad v = d[NP]/dt = dA/\varepsilon b dt = k_{obs}[NA]$$

where b is the length of the cell, [NA] is the concentration of NA, and k_{obs} is the observed rate constant, respectively. The values of k_{obs}, obtained as the slopes of the plots of v vs. [NA] at different pH values, are listed in Table 2 for the different systems.

In solution, the following three factors are also involved: (*i*) k_{com}, the catalysis of metal complexes; (*ii*) k_{OH}, the catalysis of OH^-; and (*iii*) k_0, the effect of solution contribution to the hydrolysis rate of NA. Therefore, v should be represented by eq. [3].

$$[3] \qquad v = k_{obs}[NA] = (k_{com}[3Zn:L]^T + k_{OH}[OH^-] + k_0)[NA]$$

where $[3Zn:L]^T$ is the total concentration of the metal complexes.



Plots of k_{obs} vs. $[3Zn:L]^T$ (Fig. 3) show that the rate of NA hydrolysis catalyzed by the Zn(II) complexes increases linearly with the concentration of the complexes, and the magnitude of the slope gradually decreases with decreasing pH. The slopes of the lines at different pH are the values of k_{com}, which are listed in Table 3.

It is interesting that NA hydrolysis does take place in the absence of complexes (Fig. 4). This indicates that OH^- and (or) solvent can catalyze NA hydrolysis. In the absence of Zn(II) complex, eq. [3] can be written in the form of eq. [3.1].

$$[3.1] \qquad v = k_{obs}[NA] = (k_{OH}[OH^-] + k_0)[NA]$$

A least-squares fit from a plot of reaction rate v vs. [NA] gives the following: k_{OH} = 13.27 $mol^{-1}\cdot dm^3\cdot s^{-1}$, k_0 = 4.33 × 10^{-7} s^{-1}, and γ = 0.998. The reported values are k_{OH} = 19.41 $mol^{-1}\cdot dm^3\cdot s^{-1}$, k_0 = 8.16 × 10^{-7} s^{-1}, and γ = 0.997 in the literature (17). The small value of k_0 is probably due to the solvolysis of NA (i.e., water attack on the ester).

Fig. 2. Dependence of absorbance (A) on time (s) for the hydrolysis of NA catalyzed by [3Zn:L1]; pH = 7.42, [NA] = 1.0 × 10^{-3} mol·dm^{-3}, 1/3[Zn^{2+}] = [L1] = 1.0 × 10^{-3} mol·dm^{-3}, 25.0 ± 0.1 °C, I = 0.1 mol·dm^{-3} KNO_3, λ = 400 nm.

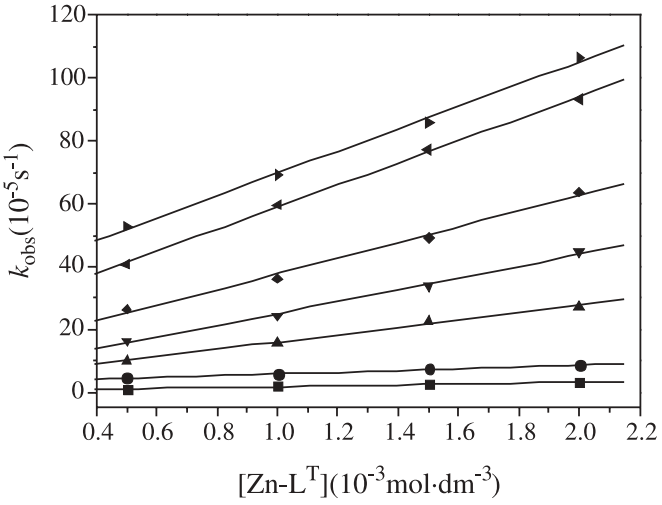
Fig. 3. Plots of k_{obs} vs. $[3Zn:L]^T$. The pH values from the bottom up are 6.54, 6.95, 7.23, 7.42, 7.61, 7.90, and 8.19, respectively.



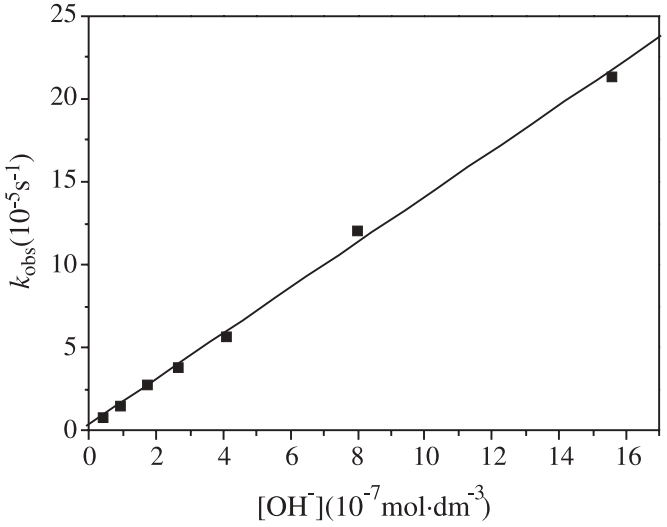


Fig. 4. The plot of k_{obs} vs. $[OH^-]$ in the absence of metal complexes (25.0 ± 0.1 °C, I = 0.1 mol·dm^{-3} KNO_3, 10% CH_3CN).

As discussed above, there is an equilibrium between the complexes Zn_3L and Zn_3LH_{-1} with a pK_a for the deprotonation of the Zn(II)-bound water in complex Zn_3L–H_2O (Scheme 1). The concentrations of Zn_3L and Zn_3LH_{-1} are expressed by eq. [4].

$$[4] \quad [Zn_3L] = [3Zn:L]^T[H^+]/(K_a + [H^+])$$

$$[Zn_3LH_{-1}] = [3Zn:L]^T\ K_a/(K_a + [H^+])$$

Since both the Zn(II) complexes with hydroxyl and water are the catalytic active species, eq. [5] is then obtained from the results of eqs. [3] and [4].

$$[5] \quad k_{com} = k_A[Zn_3L] + k_B[Zn_3LH_{-1}]$$

where k_A and k_B are the second-order rate constants of NA hydrolysis catalyzed by Zn_3L and Zn_3LH_{-1}, respectively.

Thus, when k_{com} is plotted vs. $[H^+]$, the values of k_A, k_B, and K_a can be obtained according to eq. [6].

$$[6] \quad k_{com} = (k_A[H^+] + k_BK_a)/([H^+] + K_a)$$

$$= k_A + (k_B - k_A)/(1 + [H^+]/K_a)$$

All reactions exhibited sigmoid pH–rate profiles when the observed rate constant k_{com} is plotted as a function of pH (Fig. 5), with inflection points at pH 7.46, 7.40, 7.44, and 7.38 for $[3Zn–L_x]$ (x = 1, 2, 3, 4), respectively. These results are in good agreement with pK_a values obtained from potentiometric pH-titrations. Such pH-profiles were observed in a number of phosphate or carboxyl ester hydrolyses promoted by Zn(II), Co(II), and Cu(II) complexes (6, 9, 18), and all presented with metal–hydroxyl species as the active catalysts. Analysis of k_{com} vs. $[H^+]$ (eq. [6]) gives the values of the second-order rate constants of NA hydrolysis catalyzed by complexes Zn_3L and Zn_3LH_{-1}, respectively; these are listed in Table 4.

Mechanisms

Based on the results mentioned above, referring to the catalytic mechanism of carbonic anhydrase, the catalytic mechanism for 3:1 Zn(II):L systems is proposed as shown in Scheme 2. The hydrolysis process involves the initial interaction of NA with the Zn(II)-coordinated water (**1**) or hydroxide group (**1′**) and then the slow dissociation of *p*-nitrophenolate and the binding of acetate by nucleophiles. The carboxylate oxygen of NA coordinates to the Zn(II) center, and the coordination conformation of the Zn(II) center changes to trigonal bipyramid, together with the nucleophilic attack of Zn(II)-water (**1**) or Zn(II)-hydroxide (**1′**) toward the carboxyl carbon. Subsequently, the acetate: nucleophile (**2** or **2′**) decomposes into acetate and Zn(II)-bound water or hydroxyl complex in aqueous solution at a fast rate, and thus, a catalytic cycle is completed. As shown in Table 1, poly-Zn(II) centers can activate a nucleophilic water molecule by decreasing its pK_a (nucleophilic catalysis) to form the stronger nucleophile Zn(II)-OH.

To determine the effect of free Zn(II) ion on the hydrolysis rate of NA (since the coordination of Zn(II) with the tripod is not 100% in the pH range studied), we also did control experiments, by replacing the Zn(II) complexes of L by equal molar Zn(II) ion alone. We found that Zn(II) has al-
