

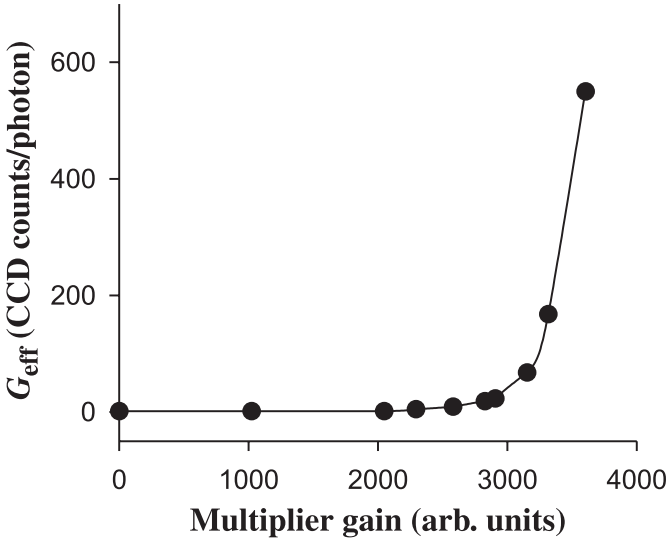

Fig. 5. A plot showing experimentally measured effective gain (see eq. [1] for the definition) as a function of applied multiplier gain. The experiment was carried out at an excitation power of 190 μW and wavelength of 514 nm.

Characterization and calibration of the CCD photodetector

While CCD photodetectors offer excellent sensitivity, the ability to monitor many molecules at a time, and good data acquisition rates, they suffer from a disadvantage to photon-counting modules in that they do not directly yield the number of photons emitted by a fluorophore. Since the ability to directly count numbers of emitted photons is often of great value in single-molecule fluorescence experiments, this limitation is somewhat problematic. The main challenge with correlating CCD counts to emitted photons is that the true gain factor for the detector is generally not well-known. In the Cascade 512F camera, for example, the gain factor is altered by changing the magnitude of the voltage between different pixels in the serial transfer register, which in turn affects the number of secondary electrons generated as charge is moved through the register. While the gain factor is, of course, correlated to the serial register voltages, the quantitative relationship between the two is not well-defined. A further complication is that CCD devices do not necessarily show fixed multiplicative gain; since the electron impact ionization process is, itself, a stochastic process, the gain factor itself can show statistical variations (so-called excess noise).

In an effort to quantify some of these effects for our photodetector, we have developed a simple procedure for calibrating our CCD detector against a well-defined source of photons such that CCD counts can be approximately converted into the number of incident photons. For the sake of simplicity, we will give an overall, working definition of effective gain as follows:

$$[1] \qquad \text{CCD counts} = N_{\text{photons}} \times G_{\text{eff}}$$

where CCD counts is the average number of analog-to-digital unit counts read from the CCD after subtracting dark counts, N_{photons} is the average number of photons hitting the detector chip in a known integration period, and G_{eff} is the overall effective gain of the system. We will include several operational factors in G_{eff}, including the quantum efficiency of the photodetector chip, the conversion gain that relates CCD electrons and CCD counts, and finally the on-chip multiplication gain. Our procedure for measuring G_{eff} is to align a heavily attenuated laser beam of known wavelength and power (the latter measured using a calibrated power meter) onto the chip, and record the average number of CCD counts over a known integration period. The value N_{photons} is then simply calculated from eq. [2]:

$$[2] \qquad N_{\text{photons}} = \frac{\lambda P_0 \Delta t}{hc}$$

where λ, P, Δt, h, and c are the laser wavelength, power, integration period, Planck's constant, and the speed of light, respectively. It should be noted that while using an attenuated laser beam for camera calibration can be very effective, great care must be taken to avoid causing photo damage to the chip; this procedure must be applied with particular care if applied to an intensified CCD camera, as it could easily lead to instrument damage.

Figure 5 shows a plot of G_{eff} as a function of the applied multiplier gain (λ = 514 nm, P_0 = 190 μW). At low values of applied multiplier gain, G_{eff} increases very slowly, but shows an exponential increase at higher values (2000–3000 arb. units). An exponential increase in gain with applied voltage is common in devices that make use of a series of elements to generate electron cascades (19). We found that at multiplier gains greater than 3500, dark counts begin to play a significant role in the overall signal, so the measurement range was restricted to below this value. For the single-molecule experiments described in the previous section, multiplication gains around 1000–2000 arb. units were sufficient to allow detection of only the brightest individual molecules; however, many molecules could be readily discerned in the range of 2000–3000 arb. units. We carried out the majority of our measurements at a setting of 2907 arb. units, which corresponds to a G_{eff} of 22.3 ± 0.2 CCD counts per

© 2005 NRC Canada

photon. At these settings, typical R6G molecules yield a photon count rate of around 250–400 counts per 100 ms time interval, which is in reasonable agreement with results collected using photon-counting modules (see for example, ref. 15).

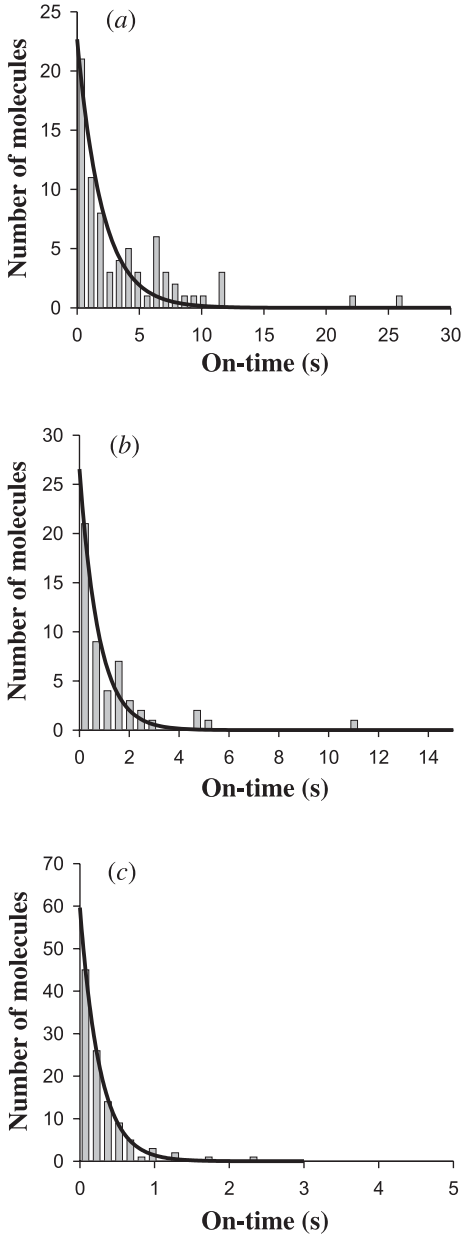
We note that there are several sources of experimental error in this calibration procedure that limit its accuracy. For the Cascade 512F, the quantum efficiency of the photodetector chip increases by approximately 25% over the spectral range of 500–650 nm (20). Because of this and the finite width of emission peaks of fluorescent molecules, order one corrections in G_{eff} are needed. One can estimate the amount of error this causes by weighting the emission intensities from a bulk spectrum by the quantum efficiency of the detector at that wavelength. For R6G, this effect leads to an underestimate in G_{eff} of ~10%. While significant, this problem with the calibration procedure can be corrected for in a reasonable way. It is also worth noting that the latest generation of on-chip multiplier gain CCD cameras from Photometrics have a moderately invariant quantum efficiency over the spectral range of 500–700 nm, and for these cameras, the inaccuracy in the calibration procedure caused by this effect will become negligible.

Another potential source of error in this calibration procedure is the excess noise that is intrinsic to devices that do not have fixed, multiplicative gain. The excess noise factor (F) can be defined as (19):

$$[3] \qquad F = 1 + \frac{\sigma_G^{\,2}}{\langle G \rangle^2}$$

where σ_G^2 and $\langle G \rangle$ are the variance and mean of the gain, respectively. For a detector with deterministic gain, F should be equal to unity (zero variance in gain); for devices that have random gain, the excess noise factor can be considerably larger. Intensified CCD cameras typically have F values in the range of 1.5–3.5, though under some conditions this can go as high as 60, making calibration problematic (19, 21). For the Cascade camera, the manufacturer reports experimentally measured F values of around 1.4 at the highest gain of the instrument. To measure an upper limit on the excess noise that is relevant for the gain levels used in our typical SM measurements, we estimated F using our experimentally measured mean effective gain and variance in effective gain. While not the most accurate method for measuring the excess noise factor (for a more rigorous method see ref. 21), this approach will provide a reasonable "order of magnitude" measure of F. From our measurements, the F value works out to be ~1.005, indicating that, at the settings we use in SM experiments, excess noise effects are minimal. Variations in quantum efficiency with wavelength for the detector will be the dominant factor in terms of limiting the overall accuracy of the calibration procedure. It is worth noting that the selection of a multiplier gain level for use in SM experiments must take into account several factors; one must carefully balance the enhancement in signal levels that can be attained with high gains against the overall increase in system noise caused by excess noise. Overall, the SNR of the measurement will be lowered by the excess noise factor, so it is important in SM experiments not to use a multiplier gain that is higher than absolutely necessary.

Comparison of different fluorophores (R6G, bodipy-FL, and EGFP)



To further explore the capabilities of our microscope system, we have carried out a comparative study of the photophysical properties of several different fluorophores that have significant utility in biological applications. In particular, we have focused on two fluorophores, EGFP and bodipy-FL, which have both found extensive use as fluorescent labels of biological molecules (22, 23). As SM fluorescence techniques are increasingly applied to studies of biological systems, characterizing the basic optical properties of fluorophores that are used in these applications is of increasing importance.

As noted in the first section, a particularly useful approach for characterizing fluorophores in SM systems is to generate frequency histograms of on-times for individual molecules. In Figs. 6*a*–6*c*, we compare on-time histograms for R6G, EGFP, and bodipy-FL, all taken under the same illumination intensity and with molecules immobilized in a matrix (PMMA for R6G and bodipy-FL, a water-filled agarose gel for EGFP). For each of these fluorophores, the on-time histograms follow simple, single-exponential decay curves (fitting constants shown in the figure captions). The decay constant for the exponential fits provides a direct measure of the photobleaching stability of the different fluorophores, with the general photostability of the molecules measured here following the order: R6G > bodipy-FL > EGFP. It is important to note that the photobleaching time of a fluorophore represents a fundamental limit on a SM measurement, because once a molecule photobleaches, the experiment is over. This is a particular problem for studies that involve imaging the movement of labeled molecules during the time course of a biological process (e.g., refs. 24–27).

Of particular importance in this regard is the on-time histogram for EGFP, shown in Fig. 6*c*. EGFP has revolutionized many aspects of in vivo molecular biology experiments, as it allows proteins to be fluorescently labeled exclusively through the use of a cell's genetic machinery (for a recent review, see ref. 23). However, as is clear from the on-time frequency histogram measurements shown here, EGFP has very poor photostability (τ_{ON} = 0.27 s, in excellent agreement with ref. 28), and if one were to use EGFP for SM imaging applications, the amount of information that could be gathered before photobleaching ends the experiment is minimal. R6G is significantly more photostable than EGFP (τ_{ON} = 2.00 s), though ideally, one would prefer mean photobleaching times that are on the order of many minutes to hours. This has been one of the major driving forces behind the development of semiconductor "quantum dots" for fluorescence imaging applications (29, 30). Quantum dots have many properties that are similar to individual fluorescent molecules, but in general have much greater photostability than organic dyes. An additional complication arising from the use of EGFP as a fluorescent label is that the molecule shows unusual blinking behaviour; that is, EGFP has been reported to undergo multiple transitions between an emissive and nonemissive state over several different timescales (28, 31). In our measurements, we have noted that a small, but significant population of EGFP molecules undergoes repeated on–off blinking, even after illumination for many tens of minutes (data not shown). Despite a great deal of in-depth

Fig. 6. The histograms and single exponential fits of on-time distribution of: (*a*) R6G; (*b*) BODIPY in PMMA coating; and (*c*) EGFP in agarose gel (pH 7.0). The corresponding photobleaching time constants are: (*a*) τ_{ON} = 2.00 s; (*b*) τ_{ON} = 0.78 s; and (*c*) τ_{ON} = 0.27 s. The excitation intensity in each case was 0.6 kW/cm^2.

study, the underlying cause of this photophysical behaviour is still poorly understood. What is clear, however, is that the poor photostability and complex photophysics of EGFP make it a far from ideal label for use in SM biological imaging experiments.

As a possible alternative to EGFP for SM imaging experiments, we have also characterized bodipy-FL, a member of the boron-based "bodipy" (4,4-difluoro-4-bora-3a,4a-diaza-*s*-indacene) class of dyes marketed by Molecular Probes. While bodipy-FL would have to be directly coupled to a biomolecule to be used in imaging applications, it has a number of properties that make it a strong potential candidate for use as a SM fluorophore in biological imaging. It has a high quantum yield and extinction coefficient (quantum yield ~ 0.8, extinction coefficient ~ 90 000 M^{-1} cm^{-1} in methanol (32) and confirmed independently in our lab), and can be readily coupled to proteins or nucleic acids through a reactive amine group. As shown in the histogram of fluorescent on-times for bodipy-FL (Fig. 6*b*), the fluorophore has a characteristic on-time decay constant that is approximately three times greater than that of EGFP. Bodipy-FL also shows no evidence of blinking even after many minutes of observation under constant illumination conditions. A further possible benefit of using bodipy-FL dyes for SM experiments is that, under appropriate conditions, the molecule can form several different types of aggregates, including a quenched H dimer (33, 34). This has a huge number of possible SM applications, including the high-resolution measurement of distances between labeled protein residues by means of fluorescence quenching. One can envision monitoring single-molecule enzyme kinetics by observing substrate molecules that have been heavily labeled with bodipy-FL; the sudden onset of fluorescence when one member of the quenched H dimer has been removed could be used as an indicator that an enzymatic event has occurred. A similar approach, based upon quenching of dimeric cyanine dyes (the BOBO, TOTO, and YOYO classes of dyes, for example), has found useful applications for both bulk and single-molecule labeling studies of DNA (22, 35, 36). In general, intermolecular dimerization has the potential to be of great impact in this important discipline.

Summary

In this work, we have described the design, construction, and characterization of a fluorescence microscope with single-molecule sensitivity and resolution. Our microscope makes use of a new type of CCD camera with on-chip multiplier gain. A test system, consisting of molecules of the laser dye R6G immobilized in a polymer matrix, was studied in terms of SNR, photobleaching statistics, and photophysical behaviour, to allow comparison of our apparatus' performance and capabilities with other SM microscope systems reported in the literature. The microscope system attained comparable sensitivity, collection efficiency, and resolution to that reported by others in the field, indicating that the apparatus and in particular the CCD photodetector, was well-suited for SM measurements. We characterized the CCD detector performance in greater detail through the development of a simple calibration procedure to extract photon counts from CCD detector counts. Finally, we have compared and contrasted the photophysical properties of several fluorescent molecules that are commonly used as labels in fluorescence imaging, and, for the fluorophore bodipy-FL, have suggested some research directions that will be pursued in future experiments.

Synthesis and spectra of aldehyde- and ketone-*O*-(2,5-dihydro-2-methoxy-5,5-dimethyl-1,3,4-oxadiazol-2-yl)oximes — Thermal sources of some methoxy(oximino)carbenes

Arkadiusz Klys, Malgorzata Dawid, and John Warkentin

Abstract: Ten new oxadiazoline sources of methoxy(oximino)carbenes were synthesized by exchanging the acetoxy group of 2-acetoxy-2-methoxy-Δ^3-1,3,4-oxadiazoline with an oximino group. The new compounds were characterized by means of spectroscopy and the formation of carbenes upon thermolysis of a few was demonstrated by means of interception with *tert*-butyl alcohol. The carbenes fragmented to form methoxycarbonyl and iminyl radicals.

Key words: 2,2-dioxyoxadiazoline, methoxy(oximino)carbene, oxadiazole, radical pair, rearrangement.

Résumé : On a effectué la synthèse de 10 nouvelles oxadiazolines sources de méthoxy(oximino)carbènes en procédant à l'échange du groupe acétoxy de la 2-acétoxy-2-méthoxy-Δ^3-1,3,4-oxadiazoline avec un groupe oximino. On a caractérisé les nouveaux composés par spectroscopie et la formation de carbènes par thermolyse de quelques-unes de ces sources a été mise en évidence par leur interception par l'alcool *tert*-butylique. Les carbènes se fragmentent avec formation des radicaux méthoxycarbonyle et iminyle.

Mots clés : 2,2-dioxyoxadiazoline, méthoxy(oximino)carbène, oxadiazole, paire de radicaux, réarrangement.

[Traduit par la Rédaction]

Introduction

Some 2,5-dihydro-5,5-dimethyl-2,2-dioxy-1,3,4-oxadiazoles (**1a**–**1d**) (also known as 5,5-dimethyl-2,2-dioxy-Δ^3-1,3,4-oxadiazolines) have been shown to be versatile reagents for the generation of carbenes including alkoxymethoxy-, acetoxymethoxy-, alkoxyaryloxy-, and diaryloxycarbenes. (1) Having shown that an alkyne functional group in the carbene from **1e** (2) and a carbonyl group in the carbene from **1f** (3) can intercept a dialkoxycarbene in an intramolecular reaction, leading to interesting products, and that thiocarbonyl groups are effective interceptors in intermolecular reactions (4), we decided to try the oxadiazoline approach to generate carbenes containing other functional groups (Scheme 1).

We now report the preparation of some aldehyde and ketone-*O*-(2,5-dihydro-2-methoxy-5,5-dimethyl-1,3,4-oxadiazol-2-yl)oximes (**2**) (also known as corresponding oxadiazolinyl oximes) that are precursors of carbenes of type **3** (Scheme 2), and show that carbenes **3d** and **3e** are indeed generated by thermolysis of **2d** and **2e**. Some potential intramolecular reactions of a generalized carbene **3** are shown in Scheme 3.

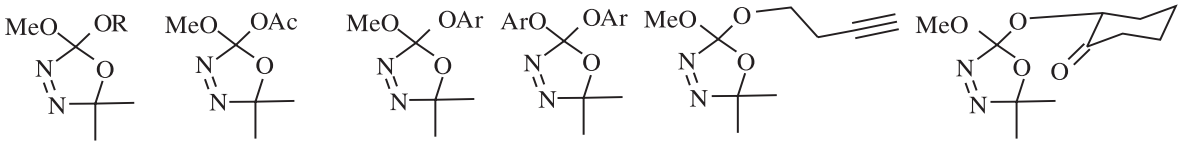
Methods, results, and discussion



Compounds **2** were prepared by the exchange method (5), from 2-acetoxy-2-methoxy-2,5-dihydro-5,5-dimethyl-1,3,4-oxadiazole (also known as 2-acetoxy-2-methoxy-5,5-dimethyl-Δ^3-1,3,4-oxadiazoline) (**4**) and the appropriate oxime (**5**) in the presence of catalytic *p*-toluenesulfonic or trifluoroacetic acid (Scheme 4). All of the oximes used in this work are known compounds and compounds **2**, with the exception of **2b**, were the (*E*)-isomers. In the case of **2b**, a mixture of (*E*)- and (*Z*)-isomers was obtained. They were not separated and the ^{13}C NMR spectrum of the major isomer was assigned on the basis of signal intensities.

The oximes **5** were prepared by standard methods, including the (*Z*)-oxime of benzaldehyde (6). Exchange with the latter gave the same product (**2c**) as that obtained with the (*E*)-oxime of benzaldehyde, indicating that the oxime isomerizes under the acidic exchange conditions or that the product isomerizes after exchange has occurred (or both). To date we have been unable to prepare analogues of **2** with a (*Z*)-aldoxime unit.

Structural assignments are based on ^{1}H and ^{13}C NMR spectra, as well as high-resolution mass spectra of more complex samples. In some cases, the connectivity was supported with gradient HSQC spectra, to correlate ^{1}H and ^{13}C NMR chemical shifts. The ^{13}C NMR spectra of 2,2-

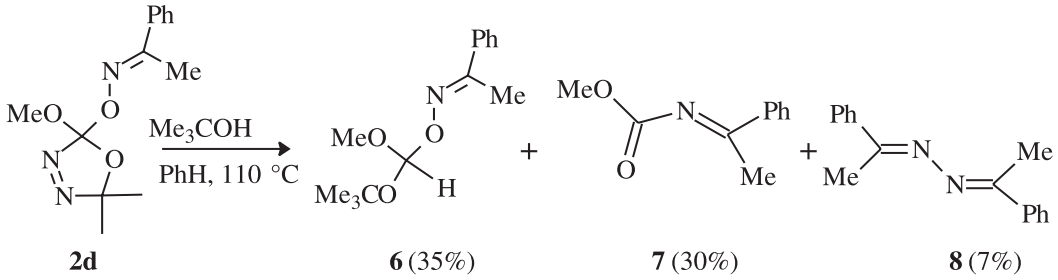
dialkoxy-5,5-dimethyl-Δ^3-1,3,4-oxadiazolines have the C-2 and C-5 signals near 137 and 119 δ, respectively (7). Values of the ^{13}C NMR chemical shift of iminyl carbons in 25 ketoximes fall between δ = 157.7 and 170.1 (8).



IR spectra were generally not informative enough to provide strong evidence of structure, with a weak band attributed to C=N stretching (9) near 1650 cm^{-1}. The carbonyl frequency of **2j**, as well as strong fingerprint bands for a few of the compounds **2** are included.

To test for the intermediacy of a carbene **3**, the potential precursor **2** was thermolysed in dry benzene, and in benzene containing *tert*-butyl alcohol (1.05 mol/L). Compounds chosen for initial study, namely **2d** and **2e**, are members of the family **2** with unsaturation in the group(s) attached to the iminyl carbon.

Thermolysis of **2d** in benzene containing *tert*-butyl alcohol (1.05 mol/L) gave **6** (35%) and **7** (30%) as major products. Acetophenone azine was also isolated. Capture of a carbene intermediate by the alcohol would afford **6**, while intramolecular rearrangment, by 1,2-migration of the iminyl function, or fragmentation to radicals and radical pair coupling, would lead to **7** (Scheme 5). There is precedent for the capture of carbenes by alcohols (10), and for rearrangement of acyloxycarbenes (1*f*, 11), which are models for **3**. Concerted rearrangement of carbene **3d** to **7** need not necessarily involve a large rate constant, even though rearrangement competed with bimolecular capture by *tert*-butyl alcohol. Capture of dimethoxycarbene by alcohols, in acetonitrile at room temperature, occurs with pseudo-first-order rate constants lying between about 10^4 s^{-1} (ethanol) and 10^5 s^{-1} (methanol) (10*a*). Capture occurs by protonation to form an ion pair, and would be slowed in benzene, accelerated by the higher temperature used in this work, and probably slowed for *tert*-butyl alcohol, given that ethanol reacts more slowly than methanol.

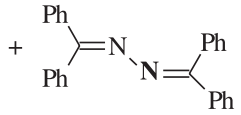
Scheme 5.



2d **6** (35%) **7** (30%) **8** (7%)

Scheme 6.

2e **9** (32%) **10** (12%) **11** (14%)

12 (5%)

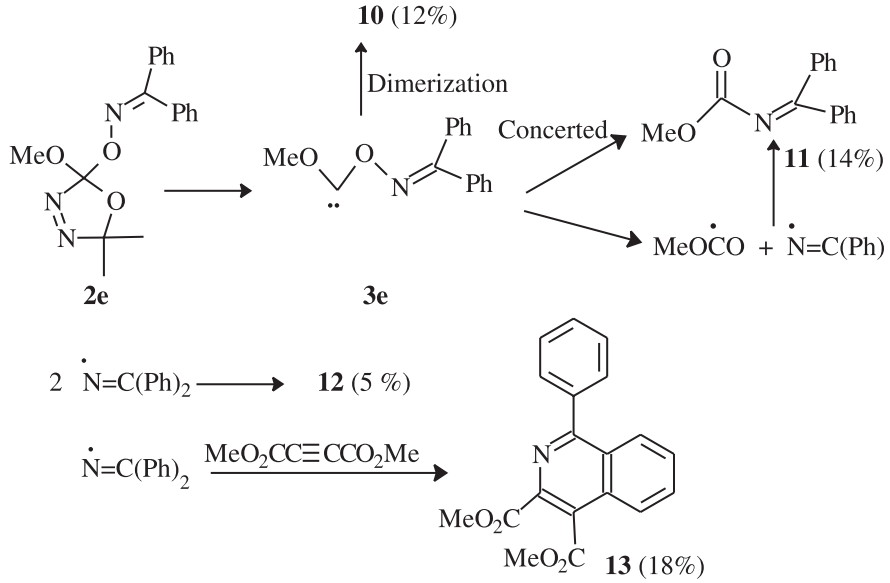
Alternatively, **7** could arise by coupling of the methoxycarbonyl- and methylphenyliminyl radical pair. Some dialkoxycarbenes have been shown to fragment to radical pairs at 110 °C (10*d*, 12). The fact that acetophenone azine was isolated means that the radical-pair mechanism plays some role because the azine is almost certainly derived from coupling of the appropriate iminyl radicals. The fraction of **7** that arises by that route, as opposed to intramolecular rearrangement of **3d**, is not known at this time.

Compound **2e** afforded four products (**9**–**12**) when thermolysed in benzene containing *tert*-butyl alcohol (1.05 mol/L). Orthoformate **9** (32%) is the product of capture of carbene **3e** with *tert*-butyl alcohol while compound **10** (12%) is the carbene dimer and **11** (14%) appears to be the product of a 1,2-migration of the diphenyliminyl group to the carbene site of **3e**, either in a concerted intramolecular rearrangement or by means of coupling of methoxycarbonyl radicals and diphenyliminyl radicals (Scheme 6).

Analogous rearrangements, which are known for some acyloxycarbenes (1*f*, 11), appear to be concerted, in general. In the present case, the formation of diphenyliminyl radicals is strongly implied by the finding of compound **12**, which is most likely the product of coupling of the latter radicals. This conclusion was reinforced when thermolysis of **2e** in the presence of dimethyl acetylenedicarboxylate (DMAD) gave a mixture of products from which **13** was isolated. Presumably, **13** arose from intramolecular, radical aromatic substitution following addition of the diphenyliminyl radical to DMAD. Thus, the rearrangement of **3e** occurred, at least in part, by the carbene homolysis – radical combination mechanism.

There isn't any evidence for or against intramolecular addition of carbenes **3** to the iminyl functional group to generate the bicyclic intermediate of Scheme 3. Survival of such materials at 110 °C is unlikely, and alternative methods for generating carbenes **3** at lower temperatures will need to be investigated.

Summary



Ten new oxadiazolines, with a methoxy and an oximino substituent at C-2, were prepared and characterized. All of them can be expected to afford methoxy(oximino)carbenes upon thermolysis in benzene, as demonstrated for two of them by means of trapping with *tert*-butyl alcohol. In the absence of the alcohol a carbene dimer, as well as products from carbene fragmentation to a radical pair, were isolated (Scheme 7).

Experimental

IR spectra were taken with a Bruker Tensor 27 FT-IR instrument equipped with a Harrick ATR accessory and a ZnSe crystal. Neat samples in the solid or liquid state were used. NMR spectra were obtained with Bruker AV 200 or AV 600 instruments and, in one case, with a Varian Geminii 200BB machine. ^{1}H NMR chemical shifts in $CDCl_3$ and in C_6D_6 were referenced to the signal from $CHCl_3$ at δ =

© 2005 NRC Canada

Scheme 7.

7.26 ppm and the C_6HD_5 signal at 7.16 ppm, respectively. ^{13}C NMR shifts for solutions in $CDCl_3$ were referenced to the center line of the $CDCl_3$ triplet at δ = 77.16 ppm. Mass spectra were taken with a Micromass (Waters) GCT, TOF mass spectrometer, with ammonia for CI spectra. Most of the oxadiazolines gave $(M + H)^+$ masses, as well as the base peak corresponding to the 2-methoxy-5,5-dimethyl-Δ^3-1,3,4-oxadiazolinyl species ($C_5H_9N_2O_2$). A few did not afford $(M + H)^+$ masses, but gave the base peak instead. The mass corresponding to loss of N_2 was not generally observed.

Synthesis

The standard procedure involved 20 mmol of the acetoxymethoxyoxadiazoline (**4**) in methylene chloride containing a catalytic amount of toluenesulfonic acid and 20 mmol of the relevant oxime, except in the case of the preparation of **2g**, where the oxime was used in fourfold excess. The solution was kept at room temperature for 2 days before aq. KOH (5 mL H_2O plus ca. 0.4 g of KOH) was added and the resulting two-phase mixture was left for 1 day, except in the case of **2d**, which is rapidly destroyed by strong base. In that case, the catalytic acid and acetic acid were removed by means of a quick extraction with aq. $NaHCO_3$. After separation of the phases, washing with water, and drying with Na_2SO_4, the solvent was evaporated and the residue was column chromatographed on SiO_2 with 10% EtOAc in hexane for elution. The first fraction to be eluted was always the oxadiazoline. Yields (unoptimized) were about 40% in all cases except for **2g**, which was obtained in 15%–25% yield.

Acetone-O-(2,5-dihydro-2-methoxy-5,5-dimethyl-1,3,4-oxadiazol-2-yl)oxime (2a)

Colourless oil. ^1H NMR (200.1 MHz, $CDCl_3$) δ: 1.56 (s, 3H), 1.61 (s, 3H), 1.87 (s, 3H), 1.95 (s, 3H), 3.60 (s, 3H). ^{13}C NMR (50.3 MHz, $CDCl_3$) δ: 15.58, 21.40, 22.55, 24.13, 52.26, 119.91, 137.69, 158.65. MS (CI, NH_3) *m/z*: calcd. for $C_8H_{16}N_3O_3$ $(M + H)^+$: 202.23; found: 202.2.

2-Butanone-O-(1,5-dihydro-2-methoxy-5,5-dimethyl-1,3,4-oxadiazol-2-yl)oximes (2b) (E/Z mixture, not separated except for ^{13}C NMR of the major isomer)

Colourless oil. IR (most intense peaks, cm^{-1}): 1165, 1112, 898. ^1H NMR (600 MHz, $CDCl_3$) (major : minor isomer ratio ca. 2.5:1, integrations separate for each isomer) δ: (major isomer) 1.028 (t, *J* = 7.6 Hz, 3H), 1.556 (s, 3H), 1.625 (s, 3H), 1.933 (s, 3H), 2.191 (q, *J* = 7.6 Hz, 2H), 3.629 (s, 3H); (minor isomer) 1.087 (t, 3H), 1.558 (s, 3H), 1.611 (s, 3H), 1.845 (s, 3H), 2.418 (m, 2H), 3.608 (s, 3H). ^{13}C NMR (200 MHz, $CDCl_3$) (major isomer) δ: 10.62, 14.67, 19.52, 23.21, 24.22, 29.46, 52.95, 120.50, 163.10. HR-MS (CI, NH_3) *m/z*: calcd. for $C_9H_{18}N_3O_3$ $(M + H)^+$: 216.1348; found: 216.1345.

Benzaldehyde-O-(1,5-dihydro-2-methoxy-5,5-dimethyl-1,3,4-oxadiazol-2-yl)(E)-oxime (2c)

White solid, mp 65 °C. ^1H NMR (200.1 MHz, $CDCl_3$) δ: 1.60 (s, 3H), 1.69 (s, 3H), 3.69 (s, 3H), 7.33-7.55 (m, 5H), 8.23 (s, 1H). ^{13}C NMR (50.3 MHz, $CDCl_3$) δ: 23.22, 24.87, 53.12, 121.22, 127.71, 128.88, 130.89, 131.09, 138.31, 152.51. HR-MS (CI, NH_3) *m/z* calcd. for $C_{12}H_{16}N_3O_3$ $(M + H)^+$: 250.1192; found: 250.1171.

Acetophenone-O-(1,5-dihydro-2-methoxy-5,5-dimethyl-1,3,4-oxadiazol-2-yl)oxime (2d)

Colourless oil. IR (most-intense peaks, cm^{-1}): 1166.0, 1109.3, 904.8, 762.3, 693.5. ^1H NMR (200.1 MHz, $CDCl_3$) δ: 1.59 (s, 3H), 1.65 (s, 3H), 2.36 (s, 3H), 3.71 (s, 3H), 7.33–7.36 (m, 3H), 7.53–7.58 (m, 2H). ^{13}C NMR (50.3 MHz, $CDCl_3$) δ: 13.53, 23.12, 24.89, 53.13, 120.97, 126.52, 128.50, 129.90, 135.62, 138.51, 158.68. In the *E*-oxime itself, the chemical shift of the iminyl carbon ($CDCl_3$) is 155.9 δ (8). HR-MS (CI, NH_3) *m/z* calcd. for $C_{13}H_{18}N_3O_3$ $(M + H)^+$: 264.1348; found: 264.1361.

Benzophenone-O-(1,5-dihydro-2-methoxy-5,5-dimethyl-1,3,4-oxadiazol-2-yl)oxime (2e)

Colourless solid, mp 63 to 64 °C. IR (strongest sig-

nals, cm^{-1}: 1028.26, 923.09, 700.03. ^1H NMR (200.1 MHz, $CDCl_3$) δ: 1.58 (s, 3H), 1.68 (s, 3H), 3.54 (s, 3H), 7.29–7.44 (m, 10H). ^{13}C NMR (50.3 MHz, $CDCl_3$) δ: 23.21, 24.96, 53.16, 121.02, 128.17, 128.34, 128.47, 129.26, 130.16, 132.60, 135.59, 160.73. HR-MS (CI, NH_3) *m/z* calcd. for $C_{18}H_{21}N_3O_3$ $(M + H)^+$: 326.1505; found: 326.1482.

Fluorenone*-O-*(1,5-dihydro-2-methoxy-5,5-dimethyl-1,3,4-oxadiazol-2-yl)oxime (2f)

Pale yellow solid, mp 105 to 106 °C. IR (most intense peaks, cm^{-1}): 1166.18, 1098.28, 899.09. ^1H NMR (600 MHz, $CDCl_3$) δ: 1.65 (s, 3H), 1.78 (s, 3H), 3.81 (s, 3H), 7.23 (t, *J* = 7.2 Hz, 1H), 7.36, 7.33 (t, *J* = 7.2 Hz, 1H), 7.38 (t, *J* = 7.2 Hz, 1H), 7.45 (t, *J* = 7.2 Hz, 1H), 7.58 (d, *J* = 7.2 Hz, 1H), 7.60 (d, *J* = 7.2 Hz, 1H), 7.63 (d, *J* = 7.2 Hz, 1H), 8.33 (d, *J* = 7.2 Hz, 1H). ^{13}C NMR (150 MHz, $CDCl_3$) δ: 23.27, 24.94, 53.47, 120.13, 120.17, 121.80, 122.41, 128.17, 128.59, 129.99, 130.35, 130.91, 132.01, 135.00, 138.80, 140.88, 142.13, 155.33. HR-MS (CI, NH_3) *m/z* calcd. for $C_{18}H_{18}N_3O_3$ $(M + H)^+$: 324.1348; found: 324.1331.

2,3,4,5-Tetraphenylcyclopentadienone*-O-*(1,5-dihydro-2-methoxy-5,5-dimethyl-1,3,4-oxadiazol-2-yl)oxime (2g)

Reddish foam. ^1H NMR (200 MHz, $CDCl_3$) δ: 1.05 (s, 3H), 1.38 (s, 3H), 3.03 (s, 3H), 6.73–6.85 (m, 4H), 6.99–7.27 (m, 16H). ^{13}C NMR (50.3 MHz, $CDCl_3$) δ: 21.99, 25.10, 53.30, 121.60, 124.69, 126.75, 126.98, 127.21, 127.47, 127.61, 127.76, 130.01, 130.08, 130.66, 131.32, 132.66, 132.51, 132.66, 133.60, 134.05, 136.30, 138.16, 145.61, 151.57, 160.88. HR-MS (CI, NH_3) *m/z* calcd. for $C_{34}H_{29}N_3O_3$: 527.2209; found: 527.2213.

Cyclopentanone*-O-*(1,5-dihydro-2-methoxy-5,5-dimethyl-1,3,4-oxadiazol-2-yl)oxime (2h)

Colourless oil. ^1H NMR (200 MHz, $CDCl_3$) δ: 1.57 and 1.62 (2s, superimposed on m, total 10H), 2.18 (m, 2H), 2.53 (m, 2H), 3.60 (s, 3H). ^{13}C NMR (150 MHz, $CDCl_3$) δ: 23.19, 24.77, 25.48, 25.70, 25.99, 26.82, 32.18, 52.86, 120.34, 138.46, 164.34. MS (CI, NH_3) *m/z* calcd. for $C_5H_9N_2O_2$ $(M - C_5H_8NO)^+$: 129.14; found: 129.1 (100%).

Cyclohexanone*-O-*(1,5-dihydro-2-methoxy-5,5-dimethyl-1,3,4-oxadiazol-2-yl)oxime (2i)

Colourless oil. IR (C=N and four most intense peaks, cm^{-1}): 1763.2, 1164.3, 1101.8, 897.8, 862.3. ^1H NMR (600 MHz, $CDCl_3$) δ: 1.57 (s, 3H), 1.61 (s, 3H), 1.70–1.80 (m, 6H), 2.36 (distorted t, 2H), 2.52 (distorted t, 2H), 3.59 (s, 3H). ^{13}C NMR (150 MHz, $CDCl_3$) δ: 23.33, 24.70, 25.23, 28.43, 31.31, 52.87, 120.49, 125.67, 138.29, 171.14. MS (CI, NH_3) *m/z* calcd. for $C_5H_9N_2O_2$ $(M - C_6H_{10}NO)^+$: 129.14; found: 129.1 (100%).

Biacetyl*-O-*(1,5-dihydro-2-methoxy-5,5-dimethyl-1,3,4-oxadiazol-2-yl)]monoxime (2j)

Colourless oil. IR (neat, cm^{-1}): 1702.4 (C=O), 913.3 (most intense fingerprint peak). ^1H NMR (200.2 MHz, $CDCl_3$) δ: 1.59 (s, 3H), 1.67 (s, 3H), 2.05 (s, 3H), 2.28 (s, 3H), 3.70 (s, 3H). ^1H NMR (200.2 MHz, C_6D_6) δ: 1.27 (s, 3H), 1.40 (s, 3H), 1.76 (s, 3H), 1.90 (s, 3H), 3.44 (s, 3H). ^{13}C NMR (50.3 MHz, $CDCl_3$) δ: 9.54, 23.30, 24.81, 25.59, 53.35, 99.78, 147.40, 188.23, 220.02. MS (CI, NH_3) *m/z* calcd. for $C_9H_{16}N_3O_4$ $(M + H)^+$: 230.24; found: 230.1.

Thermolysis procedure

The oxadiazoline (1.5 mmol) in 5 mL of benzene, added to 5.25 mmol of *tert*-butyl alcohol, was heated in a sealed vessel at 110 °C for 24 h. The tube was then opened, and the solvent and volatile products were evaporated with a rotary evaporator. The residue was column chromatographed on silica gel with petroleum ether – ethyl acetate as the eluent. Some fractions had to be rechromatographed on a 2 mm silica plate in a Chromatotron apparatus, with the same solvents for elution. Thermolysis of **2d** afforded products **6**–**8**. The carbene dimer was not found.

Acetophenone*-O-(tert-*butoxy)(methoxymethylene)oxime (6)

Colourless oil, yield 35%. ^1H NMR (600 MHz, $CDCl_3$) δ: 1.35 (s, 9H), 2.29 (s, 3H), 3.42 (s, 3H), 6.00 (s, 1H), 7.35–7.36 (m, 3H), 7.65–7.67 (m, 2H). ^{13}C NMR (150 MHz, $CDCl_3$) δ: 13.48, 14.27, 28.97, 31.74, 51.31, 113.90, 126.42, 128.51, 129.43, 156.07.

Methyl (phenylethylidene)carbamate (7)

Colourless oil, in 30% yield. ^1H NMR (600 MHz, $CDCl_3$) δ: 2.39 (s, 3H), 3.92 (s, 3H), 7.39–7.45 (m, 3H), 7.72–7.73 (m, 2H). ^{13}C NMR (150 MHz, $CDCl_3$) δ: 13.88, 54.81, 126.53, 128.12, 130.15, 134.09, 153.99 (C=N), 162.22 (C=O).

Acetophenone azine (8) (13)

Yield: 7%. ^1H NMR (200.2 MHz, $CDCl_3$) δ: 2.33 (s, 6H), 7.42–7.45 (m, 6H), 7.91–7.93 (m, 4H). ^{13}C NMR (150 MHz, $CDCl_3$) δ: 15.25, 126.82, 128.51, 129.83, 138.51, 158.15. HR-MS (CI, NH_3) *m/z* calcd. for $C_{16}H_{16}N_2$: 236.1313; found: 236.1313 and 237.1387 $(M + H)^+$.

Thermolysis of **2e** afforded benzophenone-*O*-(*tert*-butoxy)(methoxymethylene)oxime (**9**), the carbene dimer (**10**), methyl (diphenylmethylene)carbamate ($MeOCON{=}CPh_2$, **11**) (14), and benzophenone azine (**12**, 5%) (15).

Benzophenone*-O-(tert-*butoxy)(methoxymethylene)oxime (9)

Compound **9** was very susceptible to hydrolysis and was not obtained in a pure state. Yield: ca. 32%. ^1H NMR (200.2 MHz, $CDCl_3$) δ: 1.29 (s, 9H), 3.40 (s, 3H), 5.99 (s, 1H), 7.31–7.52 (m, 10H). ^{13}C NMR (50.3 MHz, $CDCl_3$) δ: 28.92, 51.38, 114.01, 128.02–129.58 (eight signals visible in this range, but not resolved). A meaningful mass spectrum could not be obtained.

1,2-Dimethoxy-1,2-(diphenyliminoxy)ethene (10)

Colourless oil, yield 12%. ^1H NMR (200.2 MHz, $CDCl_3$) δ: 3.66 (s, 6H), 7.33–7.27 (m, 10H). ^{13}C NMR (50.3 MHz, $CDCl_3$) δ: 55.40, 128.45, 128.55, 129.03, 129.17, 129.94, 131.08, 132.20, 134.70, 154.67, 164.63. A correlation between the ^1H and ^{13}C NMR signals was established by means of gradient HSQC spectra. The trans isomer was assumed.

© 2005 NRC Canada

Methyl (diphenylmethylene)carbamate (11) (14)

Pale yellow oil, yield 14%. ^{1}H NMR (200.2 MHz, $CDCl_3$) δ: 3.86 (s, 3H), 7.33–7.59 (m, 10H). ^{13}C NMR (50.3 MHz, $CDCl_3$) δ: 53.26, 128.46, 129.10, 131.30, 136.48, 163.31 (C=O), 171.55 (C=N). The signals at 128.46 and 129.10 are much more intense than the other ArH signals, and probably correspond to several coincident chemical shifts.

Dimethyl 1-phenylisoquinoline-3,4-dicarboxylate (13)

Oxadiazoline **2e** (488 mg, 1.5 mmol) in benzene, heated with DMAD (745 mg, 5.25 mmol) and worked up as described previously, gave 85 mg (2.7 mmol, 18%) of **13**.[4]

White solid, mp 126 to 127 °C. ^{1}H NMR (600 MHz, $CDCl_3$) δ: 4.03 (s, 3H), 4.12 (s, 3H), 7.52–7.56 (m, 3H), 7.68–7.71 (m, 3H), 7.83 (t, J = 7.5 Hz, 1H), 8.01 (d, J = 8.4 Hz, 1H), 8.17 (d, J = 8.4 Hz, 1H). ^{13}C NMR (150 MHz, $CDCl_3$) δ: 53.3, 53.4, 125.7, 127.6, 127.8, 128.3, 128.7, 129.5, 129.8, 130.3, 131.8, 132.2, 133.8, 138.5, 162.3, 166.1, 168.2. The structure of **13** was determined by means of X-ray crystallography.

Acknowledgements

The authors are grateful to the Natural Sciences and Engineering Research Council of Canada (NSERC) for generous financial support and to Dr. Patton Giles, Chemical Abstracts, Columbus Ohio, for assistance with some of the nomenclature. The work of Professor J. Britten, who determined the structure of **13** by means of X-ray crystallography, is greatly appreciated. Preliminary work on the synthesis of a few of the oxadiazolines by Dr. Paramashivappa Rangappa is also acknowledged.

Lanthanide complexes of an oxazoline-phenoxide hybrid chelate

David J. Berg, Chuanjian Zhou, Tosha Barclay, Xuening Fei, Shengyu Feng, Kevin A. Ogilvie, Robert A. Gossage, Brendan Twamley, and Mark Wood

Abstract: The synthesis of 2-(2′-hydroxy-3′-allylphenyl)-4,4-dimethyl-2-oxazoline, H-Allox (**3**), and lanthanide tris chelate complexes, *mer*-Ln(Allox)$_3$ (Ln = La (**4**), Ce (**5**), Sm (**6**), Er (**7**), and Y (**8**)), derived from it are reported. A six-coordinate mer geometry without alkene coordination was confirmed in the solid state by X-ray crystallography for **5** and **7**. Variable-temperature NMR experiments suggested that this is the most stable isomer in solution as well, although the inequivalent ligand environments undergo rapid averaging at room temperature for all five complexes. A mechanistic investigation indicated that this fluxional process is an intramolecular six-coordinate rearrangement, but it was not possible to distinguish between a Bailar (trigonal) or Rây–Dutt (rhombic) twist. Kinetic parameters for the fluxional process were determined by line shape analysis for **8** yielding $\Delta H^{\ddagger}$ = 24 ± 2 kJ mol^{-1} and $\Delta S^{\ddagger}$ = –99 ± 10 J mol^{-1} K^{-1}. The structural and dynamic features of **4**–**8** were compared with the related In, Ga, and Al tris(2-oxazolylphenoxides).

Key words: oxazoline, phenoxide, lanthanide, Group 3, Rây–Dutt twist, Bailar twist, Eyring plot, X-ray crystallography, mer isomer, variable-temperature NMR, line shape analysis, dynamic NMR, paramagnetic NMR, bidentate ligands.

Résumé : On rapporte la synthèse de la 2-(2′-hydroxy-3′-allylphényl)-4,4-diméthyl-2-oxazoline, H-Allox (**3**) et de complexes de lanthanide trischélates, *mer*-Ln(Allox)$_3$ (Ln = La (**4**), Ce (**5**), Sm (**6**), Er (**7**) et Y (**8**)) qui en dérivent. Pour les complexes **5** et **7**, les données cristallographiques ont permis de confirmer que, à l'état solide, ces complexes adoptent une géométrie mer six coordinnées sans coordination d'alcène. Les données d'expériences de RMN à température variable suggèrent que, en solution, cet isomère est aussi le plus stable même si les environnements inéquivalents des ligands de chacun de ces cinq complexes sous soumis à une moyenne rapide. Une investigation mécanistique indique que ce processus fluxionnel correspond à un réarrangement intramoléculaire à six coordonnées, mais il n'a pas été possible de faire une distinction entre une torsion de Bailar (trigonale) ou de Rây–Dutt (rhombique). On a déterminé les paramètres cinétiques du processus fluxionnel par une analyse de la forme des bandes du composé **8** et on en a déduit des valeurs de $\Delta H^{\ddagger}$ = 24 ± 2 kJ mol^{-1} et $\Delta S^{\ddagger}$ = –99 ± 10 J mol^{-1} K^{-1}. Les caractéristiques structurales et dynamiques des composés **4**–**8** avec celles des composés apparentés des tris(2-oxazolylphénolates) d'indium, de gallium et d'aluminium.

Mots clés : oxazoline, phénolate, lanthanide, Groupe 3, torsion de Rây–Dutt, torsion de Bailar, courbe de Eyring, cristallographie par diffraction des rayons X, isomère mer, RMN à température variable, analyse de la forme des bandes, RMN dynamique, RMN paramagnétique, ligands bidentates.

[Traduit par la Rédaction]

Introduction

The transition metal and Group 13 chemistry of chelating 2-(2′-hydroxyphenyl)-2-oxazoline ligands (H-**I**) has been extensively studied for two principal reasons. First, this chelate type is found in nature as part of microbial metal transport agents, especially the Fe(III) transporting siderophores (1, 2). Second, asymmetric ligands of this kind are easily prepared from readily available chiral β-aminoalcohols and the resulting chiral metal complexes have proven useful as

asymmetric oxidation catalysts (2). Despite the interest in 2-(2′-hydroxyphenyl)-2-oxazolines, and oxazolines in general, as ligands in transition metal chemistry, the Group 3 and lanthanide chemistry of such complexes has not been very well explored. To date, the limited oxazoline coordination chemistry that has been disclosed with these elements has been almost exclusively restricted to the neutral methylene-bis(oxazolines) (**II**, box) (3) or their close relatives containing additional donors: pyridine-bis(oxazolines) (**III**, *pybox*) (3, 4), 2,2′-bipyridine-bis(oxazolines) (**IV**) (3), and dibenzofuran-bis(oxazolines) (**V**) (3). This is remarkable considering the success of these ligands in catalytically active complexes of the *d*-block metals (2). Indeed, even though little work has been done so far, enantiomerically pure **II**–**V** have proven successful in Group 3 and lanthanide chemistry for asymmetric hetero-Diels–Alder (3), glyoxylate-ene (4*a*), Mukayama–Michael (4*b*), and annulation and addition reactions of allenylsilanes with aldehydes (4*c*).

Recently, examples of lanthanide complexes with anionic oxazoline-containing ligands (**I**, **VI**, and **VII**) have been reported (5–7). The tetrakis complex of 2-(2′-hydroxyphenyl)-4,4-dimethyl-2-oxazoline (**I**) with Ce^{4+} was prepared as a possible precursor to CeO_2 films by thermal decomposition. Lanthanide complexes of **VI** proved effective as asymmetric catalysts for the 1,3-dipolar cycloaddition of nitrones to alkenes, although the structure of the actual catalyst was not established (being formed in situ from $Yb(OTf)_3$ and **VI**) (6). The deprotonated box ligand **VII** has been used to prepare Ln[**VII**][NR_2]$_2$ (Ln = Y and R = $SiHMe_2$; Ln = La, Nd, Sm, Lu, and R = $SiMe_3$) and Ln[**VII**][$CH(SiMe_3)_2$]$_2$ (7) complexes that serve as hydroamination catalysts.

In this paper, we report the synthesis, solid-state structure, and solution behaviour of lanthanide complexes containing deprotonated 2-(2′-hydroxy-3′-allylphenyl)-4,4-dimethyl-2-oxazoline (Allox). The goal of this work is to understand the structural chemistry of tris(oxazoline-phenoxide) complexes of the lanthanides in solid state and solution. Although the present complexes are achiral, their solution behaviour should provide useful information about the suitability of enantiomerically pure variants as asymmetric Lewis acid catalysts. Besides providing some additional steric bulk, the allyl substituent was deliberately incorporated to assess whether coordination of the tethered alkene can occur. We have previously observed rare examples of alkene coordination with lanthanide centres for a phenoxide ligand bearing a tethered allyl group so it was of interest to see if this also occurred with Allox.[2]

Experimental

General procedures

All manipulations were carried out under an argon or nitrogen atmosphere, with the rigorous exclusion of oxygen and water, using standard glovebox (Braun MB150-GII) or Schlenk techniques. Tetrahydrofuran (THF), hexane, and toluene were dried by distillation from sodium benzophenone ketyl under argon immediately prior to use. The appropriate lanthanide tris(silylamides), Ln[$N(SiMe_3)_2$]$_3$, were prepared according to literature procedures (8). All NMR spectra (^{1}H, ^{13}C) including variable-temperature experiments were recorded on a Bruker AMX-360 MHz spectrometer and referenced to residual solvent resonances. All deuterated solvents were dried over activated 4 Å molecular sieves and spectra were recorded using 5 mm tubes fitted with a Teflon® valve (Brunfeldt). Variable-temperature NMR spectra and plots of δ vs. $1/T$ for paramagnetic complexes **5**–**7** are included in the Supplementary material,[3] while a representative high-temperature spectrum is included in the experimental data for each complex given below. Melting points were recorded using a Büchi melting point apparatus and are not corrected. Elemental analyses were performed by Canadian Microanalytical, Delta, British Columbia. Mass spectra were recorded on a Kratos Concept H spectrometer using electron impact (70 eV) ionization. The molecular ion simulation for complex **6** is shown in Fig. 1; simulations for **4**–**7** are included in the Supplementary material.[3]

Fig. 1. (*a*) Experimental and (*b*) calculated isotopic patterns for the molecular ion of $Sm(Allox)_3$ (**6**).

0.126 mol) were suspended in dry 1,2-dichlorochlorobenzene (150 mL) in a Kontes flask under argon. The flask was sealed and the reaction mixture was heated to 170 °C for 24 h; all solids dissolved upon heating. After cooling, the flask was opened and the contents were poured onto ice (200 g). Dichloromethane (200 mL) was added and the two-phase mixture was separated. The organic layer was washed repeatedly with water, dried over anhydr. $MgSO_4$, filtered, and the solvent removed from the filtrate under vacuum to afford 2-(2′-hydroxyphenyl)-4,4-dimethyl-2-oxazoline (9) as white crystals. Yield: 12.5 g (78%); mp 58–60 °C. ^{1}H NMR (*d*-chloroform) δ: 12.17 (br s, 1H, O*H*), 7.65 (d, 1H, 6′-aryl*H*, J = 7.5 Hz), 7.34 (t, 1H, 4′-aryl*H*, J = 7.5 Hz), 6.98 (d, 1H, 3′-aryl*H*, J = 8.0 Hz), 6.83 (t, 1H, 5′-aryl*H*, J = 7.8 Hz), 4.07 (s, 2H, CH_2), 1.37 (s, 6H, CH_3). ^{13}C NMR (*d*-chloroform) δ: 164.2 (*C*=N), 159.9 (2′-aryl*C*), 133.2, 127.9, 118.6, 116.7 (aryl*C*H), 112.4 (1′-aryl*C*), 78.4 (CMe_2CH_2O), 67.1 (CMe_2), 28.5 (CH_3).

2-(2′-Allyloxyphenyl)-4,4-dimethyl-2-oxazoline (2)

The crude 2-(2′-hydroxyphenyl)-4,4-dimethyloxazoline (4.0 g, 0.021 mol) was placed in a round bottomed flask and dissolved in 100 mL of acetone. Excess allylbromide (3.19 g, 0.0264 mol), K_2CO_3 (12.1 g, 0.0872 mol), and *n*-$Bu_4N^+Br^-$ (0.34 g, 0.0017 mol), as a phase-transfer catalyst, were added. The suspension was stirred vigorously at room temperature for 6 days. The salts were removed by filtration and the solvent was stripped under vacuum. The residue was redissolved in diethyl ether (100 mL), filtered to remove further solids, and again taken to dryness under vacuum. The residue was columned on silica gel (hexane) and the pure allyl ether was isolated as a yellow oil. Yield: 4.11 g (85%). ^{1}H NMR (*d*-chloroform) δ: 7.61 (d, 1H, 6′-aryl*H*, J = 7.8 Hz), 7.24 (t, 1H, 4′-aryl*H*, J = 7.6 Hz), 6.87 (d, 1H, 3′-aryl*H*, J = 7.9 Hz), 6.81 (t, 1H, 5′-aryl*H*, J = 7.8 Hz), 5.95 (m, 1H, C*H*=CH_2), 5.46 (d, 1H, CH=CH_{trans}, J = 16.9 Hz), 5.17 (d, 1H, CH=CH_{cis}, J = 11.1 Hz), 4.46 (d, 2H, OCH_2CH=CH_2, J = 6.6 Hz), 3.98 (s, 2H, CH_2), 1.32 (s, 6H, CH_3). HR-MS (EI) calcd.: M^+ 231.1259; found: 231.1271.

2-(2′-Hydroxy-3′-allylphenyl)-4,4-dimethyl-2-oxazoline (H-Allox, 3)

Neat allyl ether **2** (3.3 g, 0.014 mol) was placed in a Kontes flask and heated with rapid stirring at 160 °C for 36 h. The resulting brown oil was chromatographed on silica gel (hexane – diethyl ether, 30:1) to afford **3** as a straw-colored oil. Carrying out the Claissen rearrangement at higher temperatures decreases the time required, but results in considerable production of the 4′-allyl isomer that is difficult to remove chromatographically. Yield: 2.9 g (88%). ^{1}H NMR (*d*-chloroform) δ: 12.42 (br s, 1H, O*H*), 7.43 (d, 1H, 6′-aryl*H*, J = 7.7 Hz), 7.18 (d, 1H, 4′-aryl*H*, J = 7.8 Hz), 6.72 (t, 1H, 5′-aryl*H*, J = 7.7 Hz), 5.95 (m, 1H, C*H*=CH_2), 5.05 (d, 1H, CH=CH_{trans}, J = 16.5 Hz), 5.02 (d, 1H, CH=CH_{cis}, J = 10.1 Hz), 4.01 (s, 2H, CH_2), 3.39 (d, 2H, CH_2CH=CH_2, J = 6.7 Hz), 1.30 (s, 6H, CH_3). ^{13}C NMR (*d*-chloroform) δ: 164.1 (*C*=N), 158.0 (2′-aryl*C*), 136.9 (*C*H=CH_2), 133.6 (aryl*C*H), 127.8 (3′-aryl*C*), 126.2, 118.4 (aryl*C*H), 115.8 (CH=*C*H_2), 112.4 (1′-aryl*C*), 78.6 (CMe_2CH_2O), 67.3 (CMe_2), 34.3 ($CH_2CH=CH_2$), 28.8 (CH_3). HR-MS (EI) calcd.: M^+ 231.1259; found: 231.1265.

La(Allox)$_3$ (4)

A solution of **3** (0.069 g, 0.30 mmol) in 4 mL of toluene was added to a solution of $La[N(SiMe_3)_2]_3$ (0.062 g, 0.10 mmol) in 4 mL of toluene in the glovebox. The solution immediately turned pale yellow and all solids dissolved. The solution was stirred overnight at room temperature and the solvent was removed under reduced pressure to yield a granular white solid. The solid was redissolved in a minimum of hot hexane–toluene (80:20), filtered though a Celite® pad, and the filtrate was then allowed to slowly cool to room tem-

perature. The clear, colorless blocks of **4** that deposited from solution were collected by vacuum filtration and dried under vacuum. Yield: 0.061 g (73%); mp 180–182 °C. ^{1}H NMR (d_8-toluene) δ: 7.90 (dd, 1H, 6′-aryl*H*, *J* = 7.7, 1.8 Hz), 7.20 (dd, 1H, 4′-aryl*H*, *J* = 7.2, 1.8 Hz), 6.59 (t, 1H, 5′-aryl*H*, *J* = 7.5 Hz), 5.98 (m, 1H, C*H*=CH$_2$), 5.00 (d, 1H, CH=CH_{trans}, *J* = 17.1 Hz), 4.90 (d, 1H, CH=CH_{cis}, *J* = 10.3 Hz), 3.47 (s, 2H, OCH_2), 3.45 (d, 2H, CH_2CH=CH$_2$, *J* = 6.7 Hz), 1.27 (s, 6H, CMe_2). ^{13}C NMR (d_8-toluene) δ: 168.0 (*C*=N), 157.8 (2′-aryl*C*), 137.6 (*C*H=CH$_2$), 135.1 (aryl*C*H), 130.9 (aryl*C*), 115.3 (aryl*C*H), 115.0 (CH=*C*H$_2$), 112.0 (1′-aryl*C*), 78.0 (CMe$_2$*C*H$_2$O), 67.4 (*C*Me$_2$), 35.5 (*C*H$_2$CH=CH$_2$), 28.5 (*C*H$_3$). The remaining aryl C resonance was not discernible. MS (EI) *m*/*z* (amu): 829 (M$^+$ ^{139}La, 44%), 599 (M$^+$ – L, 10%), 527 (M$^+$ – L – (C$_4$H$_8$O), 7%), 455 (M$^+$ – L – 2(C$_4$H$_8$O), 100%). Anal. calcd. for C$_{42}$H$_{48}$N$_3$O$_6$La (%): C 60.80, H 5.83, N 5.06; found: C 61.22, H 5.52, N 5.00.

Ce(Allox)$_3$ (5)

Complex **5** was prepared using a procedure analogous to **4** from Ce[N(SiMe$_3$)$_2$]$_3$ (0.062 g, 0.10 mmol) and 3 equiv. of **3**. Small, bright yellow blocks of **5** were isolated by allowing a warm (60 °C) hexane–toluene solution to cool to room temperature. Yield: 0.072 g (87%); mp 196–199 °C. ^{1}H NMR (d_8-toluene, 323 K) δ: 11.86 (d, 3H, 6′-aryl*H*, *J* = 7.4 Hz), 10.63 (d, 3H, 4′-aryl*H*, *J* = 6.8 Hz), 9.37 (t, 3H, 5′-aryl*H*, *J* = 6.3 Hz), 8.06 (m, 3H, C*H*=CH$_2$), 5.65 (d, 3H, CH=CH_{trans}, *J* = 14 Hz), 5.39 (d, 3H, CH=CH_{cis}, *J* = 8 Hz), 4.27 (br s, $\upsilon_{1/2}$ = 18 Hz, 6H, CH_2CH=CH$_2$), 1.00 (s, $\upsilon_{1/2}$ = 8 Hz, 6H, CH_2), –9.48 (br s, $\upsilon_{1/2}$ = 34 Hz, 18H, CH_3). MS (EI) *m*/*z* (amu): 830 (M$^+$ ^{140}Ce, 43%), 516 (100%). Anal. calcd. for C$_{42}$H$_{48}$N$_3$O$_6$Ce (%): C 60.71, H 5.82, N 5.06; found: C 61.05, H 5.71, N 4.92.

Sm(Allox)$_3$ (6)

Complex **6** was isolated as colorless crystals in the same manner as **4** and **5** previously starting from Sm[N(SiMe$_3$)$_2$]$_3$ (0.063 g, 0.10 mmol) and 3 equiv. of **3**. Yield: 0.052 g (62%); mp 173–176 °C. IR (Nujol, NaCl, cm^{-1}): 1652 (vw), 1635 (sh w), 1597 (s), 1558 (w), 1345 (w), 1260 (s), 1226 (vw), 1190 (w), 1160 (w), 1132 (m), 1096 (m), 1065 (w), 1055 (w), 862 (w), 822 (w), 768 (m), 750 (w), 720 (w), 667 (m). The IR spectra of complexes **4**, **5**, **7**, and **8** were superimposable with that of **6**. ^{1}H NMR (d_8-toluene, 373 K) δ: 9.23 (d, 3H, 6′-aryl*H*, *J* = 8.7 Hz), 7.87 (d, 3H, 4′-aryl*H*, *J* = 6.5 Hz), 7.68 (t, 3H, 5′-aryl*H*, *J* = 8.5 Hz), 6.10 (m, 3H, C*H*=CH$_2$), 4.97 (d, 3H, CH=CH_{trans}, *J* = 16 Hz), 4.85 (d, 3H, CH=CH_{cis}, *J* = 11 Hz), 2.83 (d, 6H, CH_2CH=CH$_2$, *J* = 6.4 Hz), 2.73 (s, 6H, CH_2), –2.94 (br s, $\upsilon_{1/2}$ = 4 Hz, 18H, CH_3). MS (EI) *m*/*z* (amu): 842 (M$^+$ ^{152}Sm, 68%), 612 (M$^+$ – L, 10%), 540 (M$^+$ – L – (C$_4$H$_8$O), 16%), 468 (M$^+$ – L – 2(C$_4$H$_8$O), 100%). Anal. calcd. for C$_{42}$H$_{48}$N$_3$O$_6$Sm (%): C 59.97, H 5.75, N 5.00; found: C 60.30, H 5.58, N 5.01.

Er(Allox)$_3$ (7)

Complex **7** was obtained as well-formed, bright pink prisms using the procedure outlined for **4** previously starting from Er[N(SiMe$_3$)$_2$]$_3$ (0.065 g, 0.10 mmol) and 3 equiv. of **3**. Yield: 0.077 g (90%); mp 168–170 °C. ^{1}H NMR (d_8-toluene, 373 K, all resonances are broad singlets) δ: 80.1 ($\upsilon_{1/2}$ = 4400 Hz, 18H, CH_3), 37.8 ($\upsilon_{1/2}$ = 480 Hz, 6H, CH_2), –1.51 ($\upsilon_{1/2}$ = 68 Hz, 3H, alkene*H*), –7.0 ($\upsilon_{1/2}$ = 180 Hz, 3H, alkene*H*), –12.1 ($\upsilon_{1/2}$ = 50 Hz, 3H, aryl*H*), –15.3 ($\upsilon_{1/2}$ = 35 Hz, 3H, aryl*H*), –20.8 ($\upsilon_{1/2}$ = 80 Hz, 3H, aryl*H*). One CH$_2$ (6H) resonance was not observable. MS (EI) *m*/*z* (amu): 858 (M$^+$ ^{168}Er, 100%), 628 (M$^+$ – L, 7%), 554 (M$^+$ – L – (C$_4$H$_8$O), 12%), 482 (M$^+$ – L – 2(C$_4$H$_8$O), 43%). Anal. calcd. for C$_{42}$H$_{48}$N$_3$O$_6$Er (%): C 58.79, H 5.64, N 4.90; found: C 60.71, H 5.92, N 4.62.

Y(Allox)$_3$ (8)

Complex **8** was isolated as colorless crystals using the procedure described for **4** starting from Y[N(SiMe$_3$)$_2$]$_3$ (0.057 g, 0.10 mmol) and 3 equiv. of **3**. Yield: 0.036 g (63%); mp 185 to 186 °C. ^{1}H NMR (d_8-toluene) δ: 7.90 (dd, 3H, 6′-aryl*H*, *J* = 8.0, 1.9 Hz), 7.16 (dd, 3H, 4′-aryl*H*, *J* = 7.3, 1.9 Hz), 6.57 (t, 3H, 5′-aryl*H*, *J* = 7.7 Hz), 5.89 (m, 3H, C*H*=CH$_2$), 4.95 (d, 3H, CH=CH_{trans}, *J* = 17.0 Hz), 4.86 (d, 3H, CH=CH_{cis}, *J* = 10.0 Hz), 3.51 (s, 6H, CH_2), 3.40 (d, 6H, CH_2CH=CH$_2$, *J* = 6.7 Hz), 1.25 (s, 18H, CMe_2). ^{13}C NMR (d_8-toluene) δ: 138.1 (*C*H=CH$_2$), 134.8 (aryl*C*H), 132.2 (aryl*C*), 115.1 (aryl*C*H), 114.7 (CH=*C*H$_2$), 112.5 (1′-aryl*C*), 78.1 (CMe$_2$*C*H$_2$O), 67.8 (*C*Me$_2$), 35.4 (*C*H$_2$CH=CH$_2$), 28.4 (*C*H$_3$). The remaining aryl C resonances and the oxazoline C=N resonance were not discernible. MS (EI) *m*/*z* (amu): 779 (M$^+$ ^{89}Y, 100%), 405 (M$^+$ – L – 2(C$_4$H$_8$O), 26%). Anal. calcd. for C$_{42}$H$_{48}$N$_3$O$_6$Y (%): C 64.69, H 6.20, N 5.39; found: C 65.01, H 6.44, N 5.15.

X-ray crystallographic studies

Crystals of **5** and **7** suitable for X-ray crystallography were grown by allowing a hot, concentrated, toluene–hexane solution to slowly cool to room temperature. Typical crystallographic procedures are illustrated for compound **5** in the following section. Crystals of **5** suitable for X-ray diffraction were removed from the flask, covered with a layer of hydrocarbon oil, attached to a glass fiber, and placed in the low-temperature nitrogen stream (10). Data was collected at 83(2) K using a Bruker/Siemens SMART APEX instrument (Mo Kα radiation, λ = 0.710 73 Å) equipped with a Cryocool NeverIce low-temperature device. Data were measured using ω scans of 0.3° per frame for 30 s, and a full sphere of data was collected. A total of 2132 frames were collected with a final resolution of 0.77 Å. The first 50 frames were recollected at the end of data collection to monitor for decay. Cell parameters were retrieved using SMART (11) software and refined using SAINTPlus (12) on all observed reflections. Data reduction and correction for Lorentzian polarization and decay were performed using the SAINTPlus (12) software. Absorption corrections were applied using SADABS (13). The structure was solved by direct methods and refined by the least-squares method on F^2 using the SHELXTL program package (14). The structure was solved in the space group $P2_1/n$ (No. 14) by analysis of systematic absences. All atoms were refined anisotropically. One of the terminal vinyl groups was disordered. This was modeled with an occupancy of 66% for the major fraction. Soft restraints were applied to maintain the correct geometry. No decomposition was observed during data collection. Details of the data collection and refinement are given in Ta-

Results and discussion

Synthesis and characterization

The chelating neutral ligand 2-(2′-hydroxy-3′-allylphenyl)-4,4-dimethyl-2-oxazoline (HAllox, **3**) was prepared in three steps from 2-cyanophenol as illustrated in Scheme 1. The oxazoline ring was first introduced by the Lewis-acid-catalyzed cyclization of 2-cyanophenol and 2-amino-2-methylpropanol using ytterbium triflate as the catalyst. Although this reaction proceeds slowly at 170 °C in 1,2-dichlorobenzene, we prefer this route to the $ZnCl_2$-catalyzed cyclization (9) because the product is cleaner and yields are comparable. Introduction of the 3′-allyl group was achieved in two steps by the Claissen rearrangement of the allyl phenyl ether **2**.

Lanthanide complexes **4**–**8** of the new oxazoline-phenoxide ligand were most readily prepared by an acid–base reaction between the neutral ligand **3** and $Ln[N(SiMe_3)_2]_3$ in toluene (Scheme 1: Ln = La **4**, Ce **5**, Sm **6**, Er **7**, Y **8**). Metathesis reactions between the lithium salt LiAllox and YCl_3 or $LaCl_3$ in THF produced **4** or **8**, respectively, but the yields were much lower by this route (20%–30%). The complexes displayed the characteristic colour of each ion (Ce yellow, Er pink, La, Sm, Y colourless). Complexes **4**–**8** display similar melting points and their IR spectra as Nujol mulls are superimposable suggesting that these complexes are isostructural in the solid state. This observation was confirmed for **5** and **7** by X-ray crystallography (vide infra). All complexes gave an acceptable elemental analysis, but the carbon percentage was slightly high in all cases, possibly indicating retention of toluene solvent (from recrystallization).

All of the $Ln(Allox)_3$ complexes prepared gave well-behaved mass spectra with molecular ions as the base peaks for complexes of the smaller metals (Er **7** and Y **8**). Simulation of the molecular ion pattern provided unequivocal evidence for the formation of the tris chelate complexes, especially for **4**–**7**, since these metals have distinctive isotopic patterns. An example of the match between the experimental and calculated molecular ion pattern is shown in Fig. 1 for $Sm(Allox)_3$ (**6**). The dominant fragments in the mass spectra of **4**–**8** represent the loss of one or two ligands and the loss of C_4H_8O, presumably from cleavage of the oxazoline ring. The latter has been observed previously during the thermal decomposition of $Ce(Me_2\text{-phenox})_4$ (Me_2-phenox, ligand **I**) (5).

Solid-state structures

Crystallographic data for **5** and **7** are summarized in Table 1. Selected distances and angles are given in Table 2, and ORTEP3 (15) plots of the structures are shown in Figs. 2 (**5**, Ce) and 3 (**7**, Er). The structures of **5** and **7** are very similar to one another, showing a distorted octahedral coordination environment and a mer arrangement of the three chelating Allox ligands. The allyl groups clearly are not within bonding distance of the metal as the closest contacts between the internal or terminal alkene carbons and the metals are more than 4 Å.

More than 40 structures have been reported of metal complexes containing derivatives of the 2-oxazolylphenoxide chelate unit. These structures span all groups of the *d*-block and the Group 13 metals, but there are no examples contain-

ing Group 3, lanthanide, (or actinide) ions.[4] Of the published structures, the best comparisons to **5** and **7** are the six-coordinate, tris chelate complexes of Al, Ga, and In, all of which also adopt a mer geometry (16). In fact, the other known tris chelates of this ligand type, three for Mn (2*d*, 2*h*) and one for Fe (17), crystallize exclusively in the mer geometry. There appears to be a pronounced trans influence operative in **5** and **7** as the M—N distance trans to oxygen is ca. 0.12 Å longer than that trans to nitrogen in both cases. A similar, but much smaller, effect is observed in the tris che-

[4]A complete listing of these structures and a table summarizing important metrical parameters is given in the Supplementary material.[3]

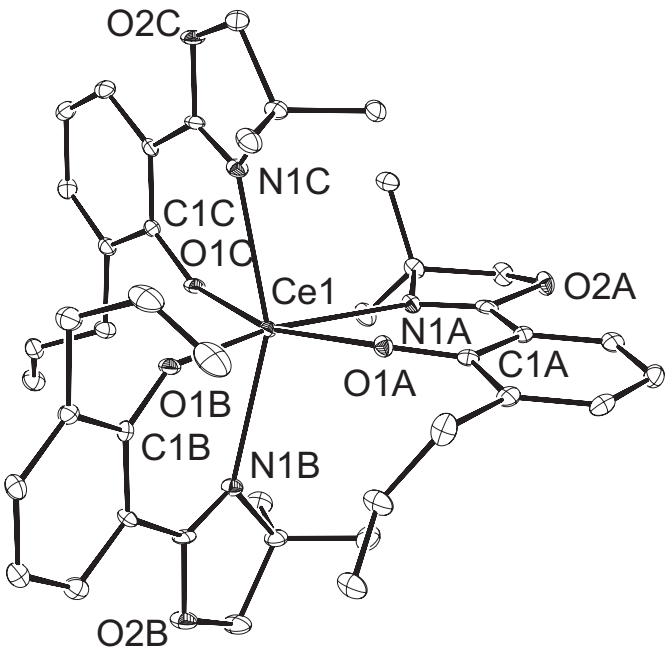
Fig. 2. ORTEP3 (16) plot (30% probability) of Ce(Allox)$_3$ (**5**).



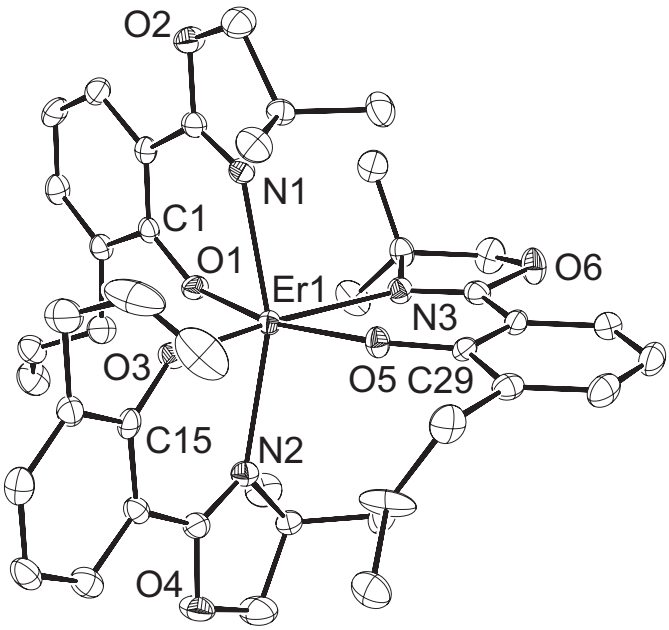


Fig. 3. ORTEP3 (16) plot (30% probability) of Er(Allox)$_3$ (**7**).

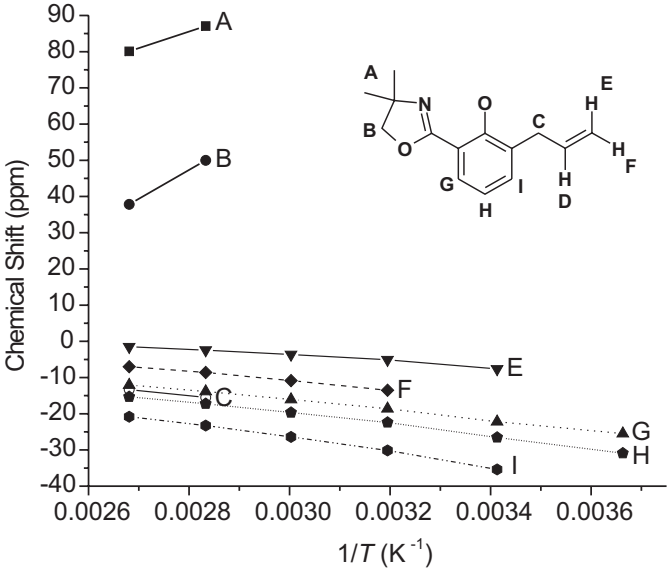
late complexes of Group 13 where the average difference is only ca. 0.03 Å (16). The Ln—O bond lengths in **5** and **7** are 0.07 Å *shorter* than predicted from In(Phox)$_3$ (PhoxH = 2-(2′-hydroxyphenyl)-2-oxazoline) (16*a*) after adjustment for differences in ionic radii[5] (18). In contrast, the Ln—N distances are 0.20 (**5**, Ce) and 0.17 (**7**, Er) Å *longer* than expected using this same comparison. All of these observations are consistent with a greater affinity for oxygen vs. nitrogen for the lanthanides.

There are only two structures reported of any type that contain a neutral oxazoline ring bonded to a Group 3 or lanthanide ion and both complexes contain the oxazoline ring as part of a chiral, tridentate "pybox" ligand (Sc(Ph-pybox)(OTf)$_3$(H$_2$O) (4*c*) and [La(Ph$_2$-pybox)(OTf)$_2$(H$_2$O)$_4$]$^+$-[OTf]$^-$ (4*b*)). The Sc—N(ox) distances in the seven-coordinate Sc complex predict Ce—N and Er—N distances of 2.56 and 2.44 Å, respectively, almost exactly matching those observed in **5** and **7** for the trans pair of oxazoline Ln—N bonds.[5] The La—N(ox) distances in the nine-coordinate La complex predict Ce—N and Er—N distances of 2.47 and 2.35 Å, respectively, far shorter than those actually observed. However, the La comparison is based on the nine-coordinate radius of La^{3+} and since the La centre is bound by four small water molecules, this radius is likely an overestimation of the size of the metal ion.

Subtle differences are detectable between the structures of **5** and **7**. In particular, although the difference in Ln—O bond lengths in the two structures (0.125 Å) matches the difference in ionic radii for the two metals (18), the difference in Ln—N bond distance (0.155 Å) is slightly larger than expected. Thus, the Er—N(oxazoline) distance in **7** is relatively short compared to that in **5**. Since Er is the smaller of the two metals, this runs counter to steric arguments; stronger oxazoline binding owing to the higher charge to size ratio of Er may explain this effect. In any case, it seems quite clear from the foregoing discussion that these complexes are not significantly crowded, as we might expect for a six-coordinate lanthanide center and relatively small ligand substituents.

The Ln-O-C angles of the phenoxide group are considerably less bent in **5** (146.2(3)°–148.9(3)°) and **7** (142.7(2)°–146.4(2)°) than those in the Group 13 tris chelates (122°–135°) (16), and only complexes of the Group 4 metals show M-O-C angles of more than 140° (19). Terminal Ln-O-C(aryl) angles are usually greater than 160° (20) so the observed angles are in fact more bent than usual because of the constraints of the chelate geometry.[6] The chelate bite itself (O-Ln-N (**5** (68.62(11)°–70.02(11)°), **7** (73.24(9)°–75.41(9)°)) is the smallest of any reported 2-oxazolylphenoxide structure (range (76°–96°), median (87°)),[4] but this is primarily a reflection of the fact that Ce and Er are the largest metals to which this ligand has been complexed.

Solution behaviour



The NMR spectra of **4**–**8** in d_8-toluene each show a single set of nine resonances for the Allox ligand consistent with average C_{3v} molecular symmetry. Since this symmetry is unlikely in a static structure, we investigated the variable-temperature ^{1}H NMR spectra of all complexes at both high and low temperature. In all cases, lowering the temperature resulted in decoalescence into at least 17, and usually more, resonances (vide infra). The resonances for paramagnetic complexes **5**–**7** showed good linear behaviour in δ vs. 1/*T*

[5] Ionic radii from ref. 18: coordination number (CN) = 6 for In^{3+} 0.800 Å, Ce^{3+} 1.01 Å, Y^{3+} 0.90 Å, Er^{3+} 0.89 Å; CN = 7, Sc^{3+} 0.81 Å; CN = 9, La^{3+} 1.22 Å.

[6] The mean Ln-O-C angle in terminal phenoxides bearing only H or Me groups in the ortho positions is 167° with a standard deviation of 8° and an overall range of 144°–180°. Some typical examples are given in ref. 20.

Fig. 4. ^{1}H NMR chemical shift (δ) vs. the inverse temperature ($1/T$) plot for Er(Allox)$_3$ (**7**) above coalescence (d_8-toluene, 360 MHz).

plots above and below coalescence, consistent with a single species in each temperature regime. A sample plot for **7** above coalescence is shown in Fig. 4; remaining plots are included in the Supplementary material.[3] The line widths below coalescence were quite broad for Er, but the wider chemical shift window made it possible to distinguish 30 peaks in the low-temperature spectra. This is consistent with the low symmetry environment found in the solid-state structure since 36 resonances are expected if the molecule possesses C_1 symmetry.

In the case of Ce and Sm, resonances clearly overlap with one another, but the observation of six methyl signals in the low-temperature spectra of **6** indicates that the low-temperature limiting structure of this complex also possesses C_1 symmetry (Fig. 5). Addition of d_8-THF to a d_8-toluene solution of **6** had a minor effect on the chemical shifts observed, but did not alter the coalescence behaviour. Changing the concentration of **6** over a fivefold range also caused no changes in dynamic behaviour. Taken together, the observation of linear δ vs. $1/T$ behaviour above or below coalescence and the lack of concentration or coordinating solvent effects strongly imply that an intramolecular fluxional process is operative.

The diamagnetic complexes **4** and **8** show similar behaviour to their paramagnetic counterparts except that the smaller spectral dispersion leads to a much lower coalescence temperature and more overlap in the low-temperature spectra. The full VT NMR spectra of **8** are shown in Fig. 6 and an expansion of the most downfield aryl resonance is shown in Fig. 7. Most of the resonances that have decoalesced in the 193 K spectrum (Fig. 6) appear to be in 2:1 intensity ratio (resonances near 6.0 and 8.2 ppm, for example). However, closer inspection reveals that this is most likely due to accidental overlap of resonances. This is clear in the expansion of the downfield aryl resonance (6′-aryl H) because this proton cannot give rise to a true triplet given the coupling constants involved for this aryl position. The observation of an

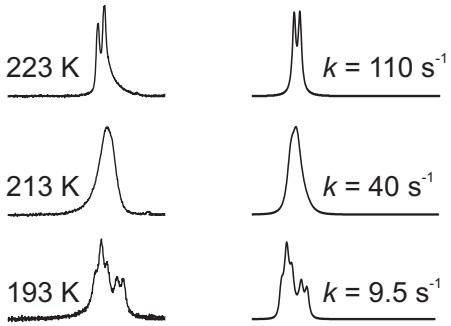

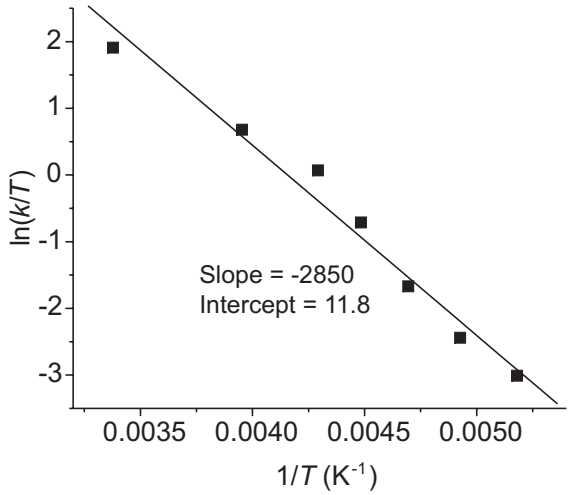

Fig. 9. Eyring plot for the exchange process of $Y(Allox)_3$ (**8**).

apparent triplet can only be explained by the overlap of two doublets (a doublet of doublets pattern is expected, but the smaller coupling is not resolvable given the line widths in this spectrum). The four methyl resonances between 1.0–1.8 ppm in the 193 K spectrum integrate as 3:3:3:9, which also can only be explained by accidental overlap of three (of the six) inequivalent methyl groups at 1.0 ppm.

The VT behaviour of the downfield aryl resonance was simulated by DNMR3 assuming that a single process exchanges all three inequivalent resonances; a subset of the simulated and observed spectra is shown in Fig. 8. The Eyring plot for this process (Fig. 9) gave $\Delta H^{\ddagger} = 24 \pm 2$ kJ mol^{-1} and $\Delta S^{\ddagger} = -99 \pm 15$ J mol^{-1} K^{-1}. While the errors in these parameters are admittedly quite large, the large negative entropy of activation is inconsistent with a dissociative mechanism (21). An associative process to produce a seven-coordinate complex is also highly unlikely given the lack of solvent and concentration dependence. A process involving a "hinged" five-coordinate intermediate cannot be entirely excluded, but most examples of rearrangements proceeding by partial dissociation of a chelate ligand show positive activation entropies (22). Conversely, a six-coordinate rearrangement of the anion in $K_3[Ga(catecholate)_3]$ has been established that shows a negative activation entropy of –20 to –47 J mol^{-1} K^{-1} depending on the solvent and conditions (23).

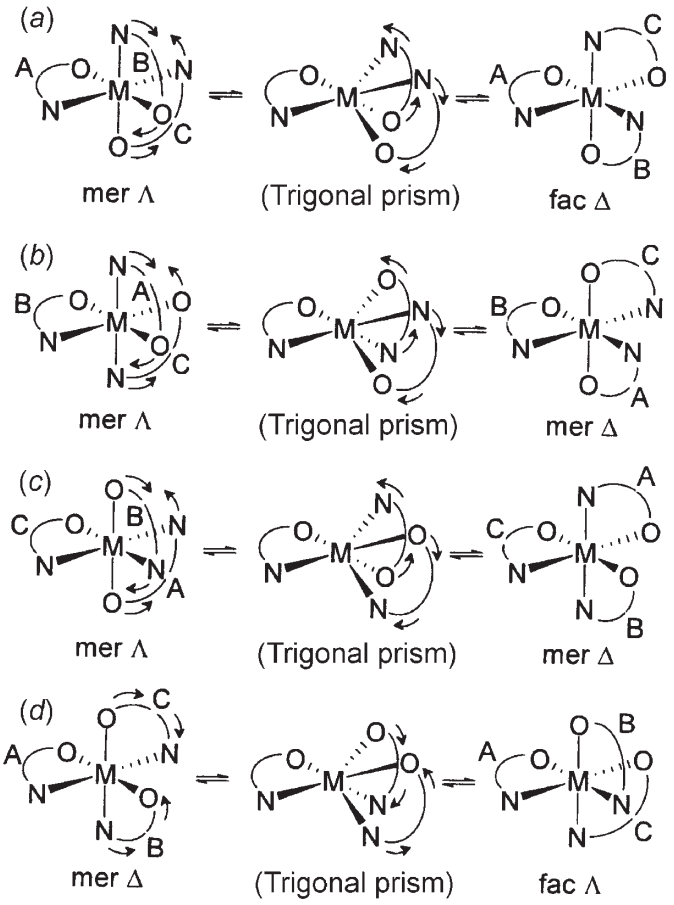
The foregoing discussion suggests that **4**–**8** undergo a six-coordinate fluxional process in solution. The options include the familiar Bailar (trigonal) or Rây–Dutt (rhombic) twists (Figs. 10 and 11) (24). Negative entropies of activation are often associated with both of these processes (23, 25).

The Bailar twist cannot interconvert mer and fac isomers, but it can scramble ligands between sites within the mer geometry and cause racemization (*mer*-Δ with *mer*-Λ). The Rây–Dutt twist can interconvert all four isomers (*mer*-Δ, *mer*-Λ, *fac*-Δ, *fac*-Λ) (26). We cannot distinguish between these two possibilities because we would need to observe fac and mer exchange to confirm a Rây–Dutt twist (26) and the fac isomer is not observed in the low-temperature NMR spectra of **4**–**8**.

Theoretically, it is also possible to distinguish between these two mechanisms kinetically since the Bailar twist exchanges ligand environments at different rates [$\mathbf{A} \rightarrow \mathbf{C}$, $\mathbf{B} \rightarrow \mathbf{B}$, $\mathbf{C} \rightarrow \mathbf{A}$] while a Rây–Dutt twist permutes ligand environments at an equal rate [$\mathbf{A} \rightarrow \mathbf{C}$, $\mathbf{B} \rightarrow \mathbf{A}$, $\mathbf{C} \rightarrow \mathbf{B}$] (Figs. 10*a*–10*c*) (26, 27). Unfortunately, the spectral dispersion in the VT NMR of diamagnetic complexes **4** and **8** is not sufficient to model exchange by anything more than a single process.

© 2005 NRC Canada

Fig. 10. Interconversion of geometric and optical isomers by the Rây–Dutt (rhombic) twist mechanism.



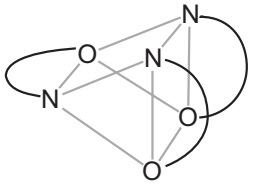


Fig. 11. The trigonal prismatic Rây–Dutt intermediate.

If the fac isomer is present and exchanging with the mer isomer, it must be in low concentration at all temperatures or we would not observe linear behaviour in plots of δ vs. $1/T$ for **5**–**7**.[7]

The relative energetics of the Rây–Dutt and Bailar twist mechanisms have been assessed theoretically by Rodger and Johnson (28). They suggest that the Bailar twist will generally be favoured if the ratio of chelate bite angle (b) to hard sphere contact distance (l) between adjacent ligand atoms (not part of the same chelate) is small ($b/l \approx 0.5$), and the Rây–Dutt twist will be favoured if this ratio is large ($b/l \approx 1.5$). According to these calculations, there is no energetic difference between the two mechanisms at $b/l = 0.914$. This ratio is 0.76 (Ce) and 0.82 (Er) in complexes **5** and **7**. It should also be pointed out that a recent experimental study on *mer*-Ga(fox)$_3$ (Hfox = 5-fluoro-8-hydroxyquinoline) using 2D EXSY NMR was able to kinetically distinguish between the two twist mechanisms and found that *both* contributed to the fluxional behaviour of this compound (27). Interestingly, the b/l ratio for *mer*-Ga(ox)$_3$ (Hox = 8-hydroxyquinoline) is 0.90 (29), almost exactly the value predicted by Rodger and Johnson to give equal energetics for either twist mechanism. Thus, while theoretical treatments suggest that **4**–**8** should undergo a Bailar rather than a Rây–Dutt twist, the mechanisms may be close enough in energy that both are operative.[8]

The fluxional Group 13 tris chelates (M(3′-MePhox)$_3$, M = Al, Ga, In) were previously investigated by VT NMR spectroscopy (16*a*). These complexes also undergo intramolecular rearrangement of inequivalent ligands within the mer geometry on the NMR timescale at, or just above, room temperature. In the case of In, there was some evidence for formation of the fac isomer as a distinct (nonexchanging) species at high temperature. The authors did not determine $\Delta S^{\ddagger}$ and were unable to rule out a bond rupture (five-coordinate Berry pseudorotation) mechanism. However, $\Delta G^{\ddagger}$ values were calculated at the coalescence temperatures and as might be expected, they decrease in the order Al (72 kJ mol^{-1}) > Ga (64 kJ mol^{-1}) > In (<42 kJ mol^{-1}). The value reported for In was based on the lowest temperature attained of 213 K; using the activation parameters for **8**, we calculate a value of $\Delta G^{\ddagger}$ = 45 kJ mol^{-1} at this temperature. While it might seem surprising that the much larger[4] Y complex has a larger $\Delta G^{\ddagger}$ value, the oxazoline rings in the In structure are unsubstituted while those in **8** bear two methyl groups in the 4 position. These methyl groups are relatively close to the metal centre (avg. 3.89 Å in **7**) and may well increase the barrier to a six-coordinate rearrangement.

Concluding remarks

Lanthanide complexes of the hybrid oxazoline-phenoxide chelating ligand Allox are readily accessible and adopt a six-coordinate mer geometry in the solid state without coordination of the pendant allyl substituents. NMR evidence suggests that this structure is maintained in solution over a wide temperature range, but exchange of inequivalent ligands within the mer geometry occurs rapidly on the NMR timescale at room temperature for all complexes studied. A more detailed study of the exchange process for Y complex **8** supports an intramolecular six-coordinate rearrangement, although it is not possible to distinguish between a Bailar (trigonal) or Rây–Dutt (rhombic) twist mechanism.

Oxo-rhenium(V) complexes with 8-hydroxyquinoline derivatives

Olivier Sigouin and André L. Beauchamp

Abstract: Compounds of the types $ReOCl_2(L)(PPh_3)$ and $ReOCl(L)_2$ were prepared by reacting $ReOCl_3(PPh_3)_2$ with 8-hydroxyquinoline (HL) and its 2-methyl, 2-chloro, 5-chloro, 5-nitro, 5,7-dichloro, 5,7-dibromo, and 5,7-diiodo derivatives. With the bulky 2-phenyl-8-hydroxyquinoline, only $ReOCl_2(L)(PPh_3)$ could be isolated, whereas the still bulkier 2-*tert*-butyl derivative did not react. For $ReOCl_2(L)(PPh_3)$, the coordination of the quinoline oxygen trans to the Re=O bond and the cis-dichloro arrangement in the equatorial plane were established from crystallographic studies on the 2-chloro and the 5,7-dibromo complexes. From the combined data for these various derivatives, the ^{1}H NMR signals could be fully assigned. With both series of compounds, a complex *d–d* absorption pattern is observed in the visible spectra, corresponding to the excitation of a *d* electron from the interaxial *d* orbital in the equatorial plane to the empty d_{xz} and d_{yz} orbitals, which are inequivalent in these low-symmetry systems. Deconvolution revealed the presence of two very weak low-energy components (~10 000 and ~12 000 cm^{-1}), which are assigned to the two expected singlet–triplet transitions, whereas two stronger bands at higher energy (~14 000 and ~17 000 cm^{-1}) originate from the two singlet–singlet transitions. These bands are not substantially displaced by substitution on the 8-hydroxyquinoline rings.

Key words: rhenium, quinoline, crystal structure, *d–d* electron transitions.

Résumé : Des composés de types $ReOCl_2(L)(PPh_3)$ et $ReOCl(L)_2$ ont été préparés par réaction de $ReOCl_3(PPh_3)_2$ avec la 8-hydroxyquinoline (HL) et ses dérivés 2-méthyl, 2-chloro, 5-chloro, 5-nitro, 5,7-dichloro, 5,7-dibromo et 5,7-diiodo. Avec le ligand encombré 2-phényl-8-hydroxyquinoline, seul $ReOCl_2(L)(PPh_3)$ a pu être isolé, alors que le dérivé 2-*tert*-butyl encore plus encombré n'a pas réagi. Pour $ReOCl_2(L)(PPh_3)$, la coordination de l'oxygène de la quinoline en trans de la liaison Re=O et l'arrangement cis-dichloro dans le plan équatorial ont été déterminés au moyen d'études cristallographiques sur les complexes des ligands 2-chloro et 5,7-dibromo. L'ensemble des données pour ces différents dérivés a permis de faire une attribution complète des signaux RMN ^{1}H. Pour les deux séries de composés, un motif d'absorption *d–d* compliqué est observé dans le spectre visible, qui correspond à l'excitation d'un électron *d* depuis l'orbitale *d* interaxiale dans le plan équatorial vers les orbitales vacantes d_{xz} et d_{yz}, qui ne sont pas équivalentes dans ces systèmes de basse symétrie. La déconvolution révèle la présence de deux composantes très faibles à basse énergie (~10 000 et ~12 000 cm^{-1}), qui sont attribuées aux deux transitions singulet–triplet attendues, tandis que les bandes plus fortes à énergie supérieure (~14 000 et ~17 000 cm^{-1}) proviennent de deux transitions singulet–singulet. Ces bandes ne sont pas déplacées appréciablement par substitution sur le cycle de la 8-hydroxyquinoline.

Mots clés : rhénium, quinoline, structure cristalline, transitions électroniques *d–d*.

Introduction

Systems giving rise to electronic transitions between low-spin and high-spin states at low energy cost present considerable interest, since they may provide a basis for developing molecular switches and devices for efficient information storage. The d^2 oxo-rhenium(V) core is a stable unit in which the ground state is low-spin and diamagnetic, since the strong π bonds formed via the oxygen p_x and p_y orbitals raise the d_{xz} and d_{yz} orbitals (LUMO) above the other interaxial *d* orbital (HOMO) in which the two *d* electrons are coupled. However, if the HOMO–LUMO gap could be reduced and become comparable with the pairing energy, the molecule could adopt a high-spin triplet ground state or possess a readily accessible high-spin excited state that could be involved in spin crossover processes.

In a previous study (1), the HOMO–LUMO gap was found to be relatively small in $ReOCl(P{\sim}O)_2$ compounds containing bidentate mixed $P{\sim}O^-$ ligands. To better understand the factors affecting the HOMO–LUMO gap, we recently examined various $ReOX_3$(dppe) and $ReO(OR)X_2$-(dppe) complexes, where the coordination sphere remained close to that of the $ReOCl(P{\sim}O)_2$ species and the equatorial *cis-P,P* arrangement was provided by bis(diphenylphosphino)-ethane(dppe) (2). The presence of a strong π-donor RO^- group trans to the Re=O bond in $ReO(OR)X_2$(dppe) was found to produce an energy gap greater than those of the $ReOX_3$(dppe) compounds, where the trans position is occu-

pied by a halogen. The present study was intended to determine to what extent the energy gap is sensitive to π interactions with donor atoms in the equatorial plane. To this end, we selected the 8-hydroxyquinoline ligand. Although little is known about the influence of this ligand on *d–d* transitions, it was hoped that the Re(V) complexes could provide information about the interaction of its aromatic π system with the interaxial *d* orbitals: when coordinated in the equatorial plane, the π system should interact with the d_{xz} and d_{yz} orbitals, whereas coordination parallel to the Re=O direction would generate interactions with the third interaxial orbital.

We are reporting here the preparation and characterization of $ReOCl_2(L)(PPh_3)$ and $ReOCl(L)_2$ compounds with a series of variously substituted deprotonated 8-hydroxyquinolines (L^-) (**I**). The low-energy UV–vis spectra were found to be rather insensitive to ring substitution, but in contrast with the dppe compounds studied earlier, all four expected low-energy *d–d* bands could be unraveled from the complicated spectral pattern observed.

I

Experimental section

Reactants and methods

8-Hydroxyquinoline (Hqn),[2] most of its derivatives (2-methyl, 5-monosubstituted and 5,7-disubstituted), $KReO_4$, and all other reactants were obtained from Aldrich and used without further purification. 2-Phenyl- and 2-*tert*-butyl-8-hydroxyquinoline were prepared as described by Delapierre et al. (3). The preparation of 2-chloro-8-hydroxyquinoline is described in the following. $ReOCl_3(PPh_3)_2$ (4) was prepared by the literature method.

IR spectra were recorded on PerkinElmer Spectrum One (4000–400 cm^{-1}, KBr pellets) or Bio-Rad Excalibur series FTS 3000FX (4000–200 cm^{-1}, CsI pellets). The NMR spectra were measured with Bruker AV-300, AMX-300, AV-400, or ARX-400 spectrometers. For the ^1H spectra, the residual solvent signal (DMSO-d_6 (2.50 ppm), acetone-d_6 (2.17 ppm), $CDCl_3$ (7.26 ppm), CD_3OD (3.31 ppm)) was used as internal reference. H_3PO_4 was used as an external reference (δ = 0) for the ^{31}P spectra. Electronic spectra were recorded as DMSO, chloroform, or dichloromethane solutions in quartz cells with a UV–vis–near-IR Cary 5E spectrometer. Elemental analyses were run at the Laboratoire d'Analyse Élémentaire de l'Université de Montréal.

Preparation of 2-chloro-8-hydroxyquinoline

This ligand was prepared by reacting $POCl_3$ with 2,8-dihydroxyquinoline obtained from Hqn via the *N*-oxide (5–7).

In glacial acetic acid (25 mL) and 30% H_2O_2 (10 mL) were dissolved 4.00 g (27.6 mmol) of Hqn. The mixture was heated at 70 °C for 16 h and after cooling to room temperature (RT), pH was adjusted to 12 with NH_4OH. The brown solid was collected by filtration and extracted with a hexane–acetone (10:1) mixture. Solvent evaporation yielded yellow crystals of Hqn-*N*-oxide (1.47 g, yield 33%); mp 138 °C (lit. value (5) mp 138–140 °C).

The Hqn-*N*-oxide (3.85 g, 23.9 mmol) was dissolved in acetic anhydride and heated at 140 °C for 5 h. The solvent was removed under reduced pressure and the dark-gray solid was washed with ethanol to give light-yellow 8-acetoxy-2-hydroxyquinoline (1.90 g, yield 39%). ^1H NMR ($CDCl_3$, ppm) δ: 10.17 (br s, 1H, OH), 7.80 (d, J = 9.5 Hz, H4), 7.44 (dd, J_1 = 7.9 Hz, J_2 = 1.2 Hz, H5), 7.37 (dd, J_1 = 7.9 Hz, J_2 = 1.2 Hz, H7), 7.21 (t, J = 7.9 Hz, H6), 6.68 (d, J = 9.6 Hz, H3), 2.51 (s, CH_3COO). Anal. calcd. for $C_{11}H_9NO_3$ (%): C 65.02, H 4.46, N 6.89; found: C 64.89, H 4.56, N 6.83.

The 8-acetoxy-2-hydroxy derivative was dissolved in methanol with 1 equiv. of K_2CO_3 and the reaction mixture was stirred at RT for 1 h. The solvent was evaporated, the brown product was dissolved in water, and a 10% HCl solution was slowly added. Colorless 2,8-dihydroxyquinoline was collected by filtration (1.40 g, yield 93%). ^1H NMR (CD_3OD, ppm) δ: 7.99 (d, J = 9.5 Hz, H4), 7.18 (dd, J_1 = 7.9 Hz, J_2 = 1.2 Hz, H5), 7.12 (t, J = 7.8 Hz, H6), 7.02 (dd, J_1 = 7.7 Hz, J_2 = 1.2 Hz, H7), 6.66 (d, J = 9.5 Hz, H3). Anal. calcd. for $C_9H_7NO_2$ (%): C 67.07, H 4.38, N 8.69; found: C 66.31, H 4.22, N 8.40.

The dihydroxy compound was dissolved in excess $POCl_3$ (10 mL) and heated on a steam bath for 1 h. The mixture was slowly transferred into a mixture of ice (75 g) and NH_4OH (37 mL). The white solid was filtered and dissolution in concd. HCl (75 mL) gave a clear yellow solution, which was heated on a steam bath for 1 h. A Na_2CO_3 solution (1.8 mol/L, 200 mL) was then added to precipitate the light-brown solid, which was collected by filtration and purified by chromatography on silica gel with hexane – ethyl acetate (80:20) as eluent. After solvent evaporation, the solid was dissolved in methanol, water was added to cloudiness, and the mixture was placed in the freezer for a few hours. The white crystalline solid (0.68 g, yield 41%) was filtered and dried in vacuo. ^1H NMR ($CDCl_3$): see Table 1. Anal. calcd. for C_9H_6ClNO (%): C 60.19, H 3.37, N 7.80; found: C 59.81, H 3.17, N 7.80.

Preparation of the $ReOCl_2(L)(PPh_3)$ compounds

These compounds were prepared following the method of Mazzi et al. (8), but benzene was replaced by THF as the solvent and reaction time was adjusted for each system.

In a typical run, $ReOCl_3(PPh_3)_2$ (0.12 mmol) was stirred in a refluxing solution of the ligand (0.12 mmol) in THF (10 mL). The colorless or yellow solution turned green first

[2] The neutral ligand is represented by Hqn and the coordinated deprotonated form by qn^-. The various derivatives are identified by an appropriate prefix showing the positions of the substituents: for instance, 2-Cl-qn^- for the 2-chloro-8-hydroxyquinoline anion.

[e]Not observed.

and then became very dark. When the reaction was stopped, the solvent was evaporated to dryness, the solid was redissolved in dichloromethane (acetone for the 2-Cl-qn compound), precipitated with diethyl ether, filtered, washed with acetone and diethylether, and dried in vacuo. For the less soluble Hqn complex, a precipitate was present at the end of the reaction and solvent evaporation was unnecessary.

Details for each compound are provided in the following. In all cases, the ^{1}H NMR spectra showed multiplets between 7.2 and 7.5 ppm for coordinated PPh_3. The remaining signals are listed in Table 1.

$ReOCl_2$(qn)(PPh_3)

The brown precipitate was filtered from the reaction mixture after 19 h. Yield: 87%. IR (CsI, cm^{-1}): 976 (s) ν(Re=O), 347 (w), 293 (w) ν(Re-Cl). ^{31}P NMR (DMSO-d_6) (ppm) δ: –12.5 (s). Anal. calcd. for $C_{27}H_{21}Cl_2NO_2PRe$ (%): C 47.72, H 3.11, N 2.06; found: C 47.57, H 3.02, N 2.13.

$ReOCl_2$(2-Me-qn)(PPh_3)

Reaction time: 24 h. Green-brown solid. Yield: 77%. IR (CsI, cm^{-1}): 972 (s) ν(Re=O), 314 (w), 284 (w) ν(Re-Cl). ^{31}P NMR (DMSO-d_6, ppm) δ: –17.4 (s). Anal. calcd. for $C_{28}H_{23}Cl_2NO_2PRe$ (%): C 48.49, H 3.34, N 2.02; found: C 48.37, H 3.42, N 2.01.

$ReOCl_2$(2-Cl-qn)(PPh_3)

Reaction time: 2 h. Recrystallization in acetone gave a green solid containing one lattice acetone molecule per formula. Yield: 63%. IR (CsI, cm^{-1}): 977 (s) ν(Re=O), 324 (w), 281 (w) ν(Re-Cl). ^{31}P NMR (DMSO-d_6, ppm) δ: –18.0 (s). Anal. calcd. for $C_{30}H_{26}Cl_3NO_3PRe$ (%): C 46.67, H 3.39, N 1.81; found: C 46.71, H 3.28, N 1.75.

$ReOCl_2$(2-Ph-qn)(PPh_3)

Reaction time: 23 h. Green-brown solid. Yield: 42%. IR (CsI, cm^{-1}): 974 (s) ν(Re=O), 328 (w), 279 (w) ν(Re-Cl). ^{31}P NMR (DMSO-d_6, ppm) δ: –16.7 (s). Anal. calcd. for $C_{33}H_{25}Cl_2NO_2PRe$ (%): C 50.03, H 3.27, N 1.74; found: C 49.82, H 3.31, N 1.79.

$ReOCl_2$(5-Cl-qn)(PPh_3)

Reaction time: 24 h. Brown solid. Yield: 91%. IR (CsI, cm^{-1}): 980 (s) ν(Re=O), 345 (w), 296 (w) ν(Re-Cl). ^{31}P NMR (DMSO-d_6, ppm) δ: –12.1 (s). Anal. calcd. for $C_{27}H_{20}Cl_3NO_2PRe$ (%): C 45.42, H 2.82, N 1.97; found: C 45.21, H 2.75, N 2.02.

$ReOCl_2$(5,7-Cl_2-qn)(PPh_3)

Reaction time: 21 h. Brown solid. Yield: 85%. IR (CsI, cm^{-1}): 980 (s) ν(Re=O), 311 (w), 282 (w) ν(Re-Cl). ^{31}P NMR (DMSO-d_6, ppm) δ: –12.4 (s). Anal. calcd. for $C_{27}H_{19}Cl_4NO_2PRe$ (%): C 43.33, H 2.56, N 1.87; found: C 43.03, H 2.57, N 1.78.

$ReOCl_2$(5,7-Br_2-qn)(PPh_3)

Reaction time: 21 h. Brown solid. Yield: 83%. IR (CsI, cm^{-1}): 984 (s) ν(Re=O), 324 (w), 279 (w) ν(Re-Cl). ^{31}P NMR (DMSO-d_6, ppm) δ: –10.8 (s). Anal. calcd. for $C_{27}H_{19}Br_2Cl_2NO_2PRe$ (%): C 38.73, H 2.29, N 1.67; found: C 37.43, H 2.07, N 1.66.

© 2005 NRC Canada

$ReOCl_2(5,7\text{-}I_2\text{-}qn)(PPh_3)$

Reaction time: 21 h. Brown solid. Yield: 93%. IR (CsI, cm^{-1}): 984 (s) ν(Re=O), 324 (w), 290 (w) ν(Re-Cl). ^{31}P NMR (DMSO-d_6, ppm) δ: –10.9 (s). Anal. calcd. for $C_{27}H_{19}Cl_2I_2NO_2PRe$ (%): C 34.82, H 2.06, N 1.50; found: C 34.87, H 1.75, N 1.49.

$ReOCl_2(5\text{-}NO_2\text{-}qn)(PPh_3)$

Prepared according to Chen et al. (9). Deep-green solid. Yield: 81%. IR (CsI, cm^{-1}): 977 (s) ν(Re=O), 324 (w), 285 (w) ν(Re-Cl). ^{31}P NMR (DMSO-d_6, ppm) δ: –9.3 (s). Anal. calcd. for $C_{27}H_{20}Cl_2N_2O_4PRe$ (%): C 44.76, H 2.78, N 3.87; found: C 44.71, H 2.78, N 3.87.

Preparation of the $ReOCl(L)_2$ compounds

These compounds were obtained according to Mazzi et al. (8), but the solvent used was THF instead of benzene. In a typical run, $ReOCl_3(PPh_3)_2$ (500 mg, 0.60 mmol) was added to a refluxing solution of the ligand (1.3 mmol) and Et_3N (0.2 mL, 1.44 mmol) in THF (50 mL). The mixture was stirred and the dark-brown or greenish-brown solid was filtered, washed with diethylether, rinsed with water to remove $(Et_3NH)Cl$, and finally dried in vacuo. Individual details are provided in the following and the ^1H NMR data are given in Table 1.

$ReOCl(qn)_2$

Reaction time: 20 h. Brown solid. Yield: 82%. IR (CsI, cm^{-1}): 968 (s) ν(Re=O), 312 (w) ν(Re-Cl). Anal. calcd. for $C_{18}H_{12}ClN_2O_3Re$ (%): C 41.11, H 2.30, N 5.33; found: C 40.49, H 2.20, N 5.26.

$ReOCl(2\text{-}Me\text{-}qn)_2$

Reaction time: 20 h. Brownish-green solid. Yield: 56%. IR (CsI, cm^{-1}): 970 (s) ν(Re=O), 320 (w), ν(Re-Cl). Anal. calcd. for $C_{20}H_{16}ClN_2O_3Re$ (%): C 43.36, H 2.91, N 5.06; found: C 42.72, H 2.88, N 4.97.

$ReOCl(2\text{-}Cl\text{-}qn)_2$

Reaction time: 3 h. Green solid. The compound recrystallized from CH_2Cl_2 contained 0.8 lattice solvent molecules per formula. Yield: 57%. IR (CsI, cm^{-1}): 968 (s) ν(Re=O), 324 (w), ν(Re-Cl). Anal. calcd. for $C_{18.8}H_{11.6}Cl_{4.6}N_2O_3Re$ (%): C 34.07, H 1.76, N 4.23; found: C 34.19, H 1.91, N 4.17.

$ReOCl(5\text{-}Cl\text{-}qn)_2$

Reaction time: 21 h. Dark-brown solid. Yield: 31%. IR (CsI, cm^{-1}): 976 (s) ν(Re=O), 324 (w) ν(Re-Cl). Anal. calcd. for $C_{18}H_{10}Cl_3N_2O_3Re$ (%): C 36.34, H 1.69, N 4.71; found: C 36.29, H 1.74, N 4.34.

$ReOCl(5\text{-}NO_2\text{-}qn)_2$ and $ReOCl(5,7\text{-}X_2\text{-}qn)_2$ for X = Cl, Br, I

The dark-brown raw solids contained a small amount of $ReOCl_2(L)(PPh_3)$ that could not be totally removed by chromatography on silica gel. The ^1H NMR data for these 2:1 species are included in Table 1.

Crystallographic measurements and structure determination

Dark-green crystals of $ReOCl_2(2\text{-Cl-qn})(PPh_3)$ were obtained by slow evaporation of an acetone solution. A crystal was mounted on a Bruker SMART CCD 2K diffractometer operating with graphite-monochromatized CuKα radiation and controlled by the SMART software (10). Sets of 30 oscillation frames of 0.3° over a range of 9° were recorded in four regions of the reciprocal space, from which the reduced cell was determined by least-squares refinement. For data collection, frames were recorded for different orientations of the crystal and detector so as to cover at least 95% of the reciprocal sphere. At the end, the first 101 frames were remeasured and the intensities of the 907 reflections did not show any decomposition of the crystal. The frames were analyzed with the SAINT software (11), which determined the intensity and the position of each spot. Accurate cell parameters were obtained by least-squares refinement over the positions of the whole data set. Irregular crystal shapes precluded the calculation of an analytical correction for absorption, but an empirical correction was applied using SADABS (12).

The SHELXTL system (13) was used for all calculations and drawings. The coordinates of the Re atoms were determined by direct methods and the positions of all other non-hydrogen atoms were found by the standard Fourier method. The structures were refined on F_o^2 using all reflections. The H atoms were fixed using a riding model with $U_{iso} = 1.2 \times U_{eq}$ of the atom to which they are bonded. Crystal data are listed in Table 2.[3]

Brown crystals of $ReOCl_2(5,7\text{-}Br_2\text{-qn})(PPh_3)$ were obtained by recrystallization in CH_2Cl_2–pentane. The crystallographic study was carried out with an Enraf-Nonius CAD-4 diffractometer operating with CuKα radiation under the control of the CAD-4 software (14). The reduced cell was initially determined from 20–25 spots located on a preliminary rotation photograph and centered in the detector aperture. Accurate cell parameters were then determined from the positions of 25 high-angle reflections centered with the SETANG and DETTH procedures. The intensities were recorded by ω/2θ scan. Possible crystal decomposition was monitored by measuring five standard reflections every hour. All data in the whole sphere were collected at room temperature. An absorption correction based on the crystal geometry was applied. The data were finally corrected for the effects of Lorentz and polarization, and averaged to provide the basic two-octant set.

The non-hydrogen atoms of the complex molecule were located and refined as stated previously. In the subsequent ΔF map, two regions centered on the inversion centers at (0, 0, 1/2) and (0, 0, 0), respectively, contained a number of small peaks owing to severely disordered solvent. No consis-

tent models for CH_2Cl_2 or pentane molecules could be assembled from these peaks. Therefore, this part of the structure was modeled by using the SQUEEZE procedure of the PLATON software (15), which indicated the presence of two cavities of 310 Å^3, each occupied by 95 electrons. Considering that CH_2Cl_2 and pentane both contain 42 electrons and that their volumes are 106 and 191 Å^3, respectively, each cavity should contain, on average, 0.8 pentane and 1.5 CH_2Cl_2 molecules. The contribution of the disordered solvent was calculated with the BYPASS procedure of van der Sluis and Spek (16) and a new hkl/F_o^2 list bypassing the solvent contribution was generated. The final model consisting of the ordered part only, without the disordered solvent contribution, was refined against this new data list, which is the one corresponding with the CIF file. Refinement converged normally to R = 0.0455. The solvent molecules were taken into account in the calculation of the derived quantities given in Table 2.

Results and discussion

The chemistry used by Mazzi et al. (8) to prepare $ReOCl_2$(qn)(PPh_3) and $ReOCl$(qn)$_2$ is applied here to obtain a series of complexes with various substituted 8-hydroxyquinolines. Refluxing equivalent amounts of the ligand and $ReOCl_3(PPh_3)_2$ leads to $ReOCl_2$(L)(PPh_3) compounds, in which one phosphine and the chlorine atom trans to the Re=O bond are displaced. By reacting 2 equiv. of ligand in the presence of 2 equiv. of Et_3N, the $ReOCl$(L)$_2$ products were obtained. No complexes could be prepared when a bulky *tert*-butyl substituent was present α to the N atom, whereas only the 1:1 complex was isolated with the phenyl-substituted ligand.

IR and NMR spectroscopies

Beside the large number of vibrations because of the quinolinate and PPh_3 ligands, all compounds show strong IR bands in the 968–984 cm^{-1} range for the Re=O stretching mode. Weaker features at ~325 and ~285 cm^{-1} are likely due to Re-Cl stretching, bands in this region being commonly found for similar systems (17).

The ^{1}H NMR signals of the free ligands are listed in Table 1 and identified following the numbering scheme **I**. Except for the 2-substituted compounds, a typical doublet of doublets is observed for H-3 at 7.4–7.9 ppm with couplings of 4 to 5 and 8 to 9 Hz, respectively. From the coupling constants and the COSY spectrum of Hqn, the adjacent protons are identified at 8.1–8.6 ppm (J = 8 to 9 Hz) and 8.8–9.0 ppm (J = 4 to 5 Hz). The latter signal must originate from H-2, since it disappears for the 2-substituted derivatives, whereas the remaining doublets for H-3 and H-4 show the larger coupling. Systematically, the H-2 and H-4 protons appear downfield from H-3, as expected from the mesomeric effect in the six-membered nitrogen heterocycle.

For the 5,7-disubstituted compounds, the remaining C-H signal is a singlet obviously due to H-6. When the phenol ring is not substituted, H-6 usually appears as a pseudo-triplet at ~7.4 ppm, resulting from roughly equal couplings (7–9 Hz) to two adjacent protons at ~7.1 and ~7.35 ppm, respectively. The latter signal is assigned to H-5, since it

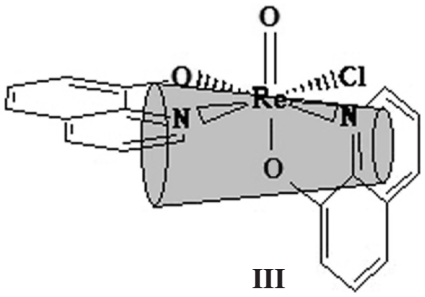
[d]For the $ReOCl(L)_2$ complexes, the signals in the first line are assigned to the axial ligand.

shows a proximity to H-4 in the NOESY spectrum. For the 5-substituted molecules, the doublet at 7.0–7.2 ppm is assigned to H-7, by comparison with the unsubstituted rings. As expected, the remaining H-6 resonance is found to be very sensitive to the presence of the adjacent electron-attracting substituents: for instance, introducing a 5-nitro group induces a large 1.8 ppm downfield shift. In the free molecules, small couplings of 1 to 2 Hz are generally observed between nonadjacent protons on either ring. Also, in most cases, a broad resonance appears at low field for the OH proton.

In the $ReOCl_2(L)(PPh_3)$ compounds, the phosphine gives rise to ^{1}H multiplets in the 7.2–7.5 ppm range and to a ^{31}P singlet lying between –9 and –12.5 ppm, except for the 2-substituted ligands, where this signal is shifted to ca. –17 ppm. The signals for the coordinated quinolinate are listed in Table 3. Assignments in the pyridine ring are straightforward, based on multiplicity and couplings. For the phenolate ring, the lowest-field signal, whose position is very substituent-sensitive, originates from H-6. When the ring is not substituted, two of the protons are masked by those of PPh_3, and the only resolved signal at 6.6–6.8 ppm is assigned to H-7 by comparison with the 5-substituted ligands.

The $ReOCl(L)_2$ compounds exhibit two sets of ^{1}H signals, showing that the two ligands are inequivalent, in agreement with the structure (**II**) observed by Chen et al. (9) for $ReOCl(NO_2\text{-qn})(NH_2\text{-qn})$. From the COSY spectrum of $ReOCl(qn)_2$, two sets of connected H-2/H-3/H-4 signals were defined, in which the H-2 and H-4 doublets could be identified individually from their respective coupling constants. Two H-5/H-6/H-7 sets could also be assembled, but the similar coupling constants made it impossible to identify H-5 and H-7 individually at this stage. This could be done, however, from a NOESY spectrum, where each H-4 proton showed a cross peak with a proton in the other ring, which identified the latter proton as H-5 and established the connection between the H-2/H-3/H-4 and the H-5/H-6/H-7 sets belonging to the same ligand.



II

There is no direct evidence to associate a given complete set to either the axial or the equatorial ligand. The tentative

© 2005 NRC Canada

identification proposed in Table 3 is based on the assumption that the phenol ring signals for the axial ligand in $ReOCl(L)_2$ should be similar to those of the equally axial ligand in $ReOCl_2(L)(PPh_3)$, since this ring should be similarly influenced by the very large electronic effect of the oxo ligand via the trans O=Re-O unit and it should not be greatly affected by the anisotropy or other features of the equatorial ligands. With the assignment proposed, the average δ[axial $ReOCl(L)_2$] – δ[$ReOCl_2(L)(PPh_3)$] difference is 0.13 ppm for H-6 and –0.18 ppm for H-7, whereas these values would be 0.56 and 0.85 ppm, respectively, for the alternate possibility. In contrast, the pyridine ring signals of these axial ligands show larger differences: 0.45 ppm for H-2, 0.29 ppm for H-3, and 0.12 ppm for H-4. Since these differences are systematically positive, they may reflect the anisotropy effect of the PPh_3 rings in $ReOCl_2(L)(PPh_3)$, which is no longer present in $ReOCl(L)_2$. Also consistent with this interpretation is the fact that the H-2 or 2-CH_3 protons of the equatorial ligand appear at a much higher field than those of the axial one. For instance, the chemical shifts of H-2 in $ReOCl(qn)_2$ are 8.27 ppm (equatorial) vs. 8.88 ppm (axial), whereas those of the 2-CH_3 groups in $ReOCl(2\text{-Me-qn})_2$ are 2.34 ppm (equatorial) vs. 3.56 ppm (axial). This could be ascribed to the fact that these protons lie in the cone of anisotropy of the axial pyridine ring (**III**). Thus, these various effects are consistent with the structure proposed for $ReOCl(L)_2$, which should be the one favored electronically, since two π-donor ligands lie trans to weakly π-accepting pyridine rings.

III

X-ray diffraction studies

The $ReOCl_2(5,7\text{-}Br_2\text{-qn})(PPh_3)$ and $ReOCl_2(2\text{-Cl-qn})(PPh_3)$ molecules are shown in Figs. 1 and 2, respectively. In both compounds, the rhenium atom has a distorted octahedral coordination, created by an oxo ligand, two chlorine atoms, a phosphine, and a *N*,*O*-coordinated quinolinate. In agreement with a general trend in mono-oxo Re(V) chemistry, the quinolinate oxygen donor lies trans to the Re=O bond, which results in the quinolinate plane being roughly parallel to the Re=O direction. The PPh_3 group is found to be cis to the nitrogen atom in the equatorial plane. This arrangement has also been reported for $ReOCl_2(5\text{-nitro-qn})(PPh_3)$ (9).

Selected distances and angles are presented in Table 4. The Re=O bond lengths (1.656(8) and 1.671(4) Å) are in good agreement with the value expected for Re(V) mono-oxo complexes (18). The trans influence of PPh_3 makes the opposite Re—Cl(1) bond 0.05 Å longer than the other in both complexes. The Re—O(2) distances (1.999(6) and 2.021(4) Å), which are ~0.1 Å longer than the typical value

for Re—OR bonds (2), reflect the constraint imposed by the five-membered chelate ring.

The oxo ligand tends to produce a general displacement of the adjacent bonds in the opposite direction, which results in the Re atom lying above the plane defined by the four equatorial donor atoms. The distances of rhenium to the $PNCl_2$ plane are 0.23 and 0.28 Å for the 5,7-Br-qn and 2-Cl-qn complexes, respectively. Additional distortion is introduced by the bidentate coordination of the quinolinate ligand, whose O(2)-Re-N bite angle is ~76°. This small angle af-

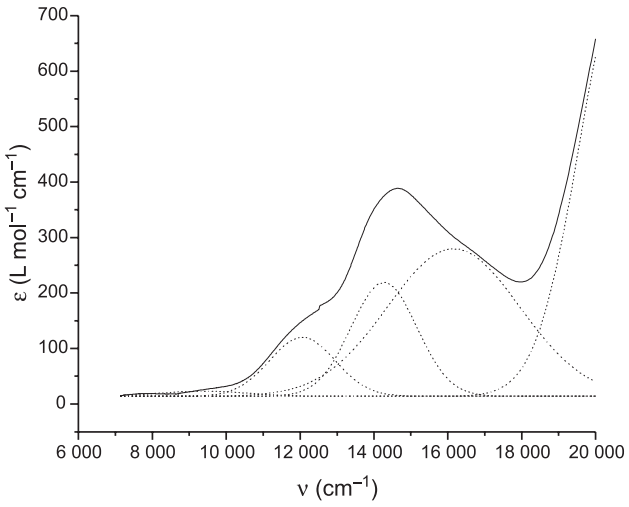
Bond angles (°)		
O(1)-Re-O(2)	163.2(3)	160.2(2)
O(1)-Re-N	93.2(3)	86.7(2)
O(2)-Re-N	76.2(3)	75.5(2)
O(1)-Re-Cl(1)	100.0(3)	99.8(2)
O(2)-Re-Cl(1)	92.5(2)	87.24(13)
N-Re-Cl(1)	87.1(2)	84.76(14)
O(1)-Re-Cl(2)	102.3(3)	105.67(17)
O(2)-Re-Cl(2)	89.5(2)	92.79(13)
N-Re-Cl(2)	164.0(2)	167.15(14)
Cl(1)-Re-Cl(2)	86.42(10)	89.59(7)
O(1)-Re-P	86.3(3)	91.18(16)
O(2)-Re-P	81.1(2)	81.86(13)
N-Re-P	91.3(2)	94.35(14)
Cl(1)-Re-P	173.58(8)	168.92(6)
Cl(2)-Re-P	93.49(8)	88.98(7)
Re-O(2)-C(6)	118.7(5)	119.4(4)
Re-N-C(1)	131.1(8)	127.2(5)
Re-N-C(5)	112.0(6)	115.4(4)

fects mainly the O(1)-Re-O(2) unit, which is definitely nonlinear: 163.2(3)° for 2-Cl-qn and 160.2(2)° for 5,7-Br_2-qn. The Re=O bond is displaced away from the chloro ligands, as evidenced from the Cl-Re=O angles (100°–106°) being systematically greater than the N-Re=O and P-Re=O angles (87°–94°).

The 2-chloro substituent enhances the distortion of the octahedron. This group further displaces the Re=O bond toward PPh_3, as evidenced from the O(1)-Re-P angle of 86.3(3)°, compared to 91.2(2)° in the 5,7-Br_2-qn complex. The angle between the Cl(2)-Re-O(1) plane and the mean plane through the quinolinate ligand increases from 10.5° for the dibromo complex to 22.2° here. The distortion is also illustrated by the sum of the deviations of the Cl, P, and N atoms from their least-squares plane: these atoms are virtually coplanar for the dibromo complex, but the mean deviation is 0.69 Å for $ReOCl_2$(2-Cl-qn)(PPh_3).



In both complexes, intramolecular π-stacking interactions exist between one of the phosphine phenyl rings (C(31)-C(36)) and the quinolinate ligand, which are roughly parallel (dihedral angles of 11.7° and 12.9° for the 5,7-Br_2-qn and 2-Cl-qn complexes, respectively) and separated by ~3.42 Å.

The molecules are packed individually in the unit cell, with normal van der Waals contacts, including some intermolecular π stacking.

UV–vis spectroscopy

The low-energy (8 000–20 000 cm^{-1}) region of the UV–vis absorption spectra was recorded for all complexes, generally in $CHCl_3$. For a few less soluble complexes, DMSO was used to improve the quality of the spectra. The DMSO solutions were stable and the spectral features were similar to those of the weaker spectra in $CHCl_3$, showing that the same species was present in both solvents. The spectra of $ReOCl_2(qn)(PPh_3)$ and $ReOCl(qn)_2$ are illustrated in Figs. 3 and 4, respectively. In each case, four individual compo-

Fig. 4. UV–vis spectra of $ReOCl(qn)_2$ in DMSO (full line). Dashed lines correspond to the four components obtained by deconvolution.

nents were obtained by deconvolution using ORIGIN (19). The data are listed in Table 5.

Since these complexes have no symmetry, the d_{yz} and d_{xz} orbitals, which are degenerate under D_{4h} symmetry, become inequivalent. For consistency with the recent study of Da Re and Hopkins (20) on the isoelectronic oxo-Mo(IV) core, d_{yz} will be assumed to lie at lower energy than d_{xz}. The five lowest-energy electronic states expected are depicted in Fig. 5, in increasing order of energy.

Both series of complexes show a strong maximum between 13 700 and 14 900 cm^{-1}. For the $ReOCl(L)_2$ compounds, another strong peak is visible at 17 000–18 300 cm^{-1}, whereas the related band is present as an unresolved component at slightly lower energy for the $ReOCl_2(L)(PPh_3)$ compounds. These absorptions are assigned to the spin-allowed [S → S*] and [S → S**] transitions, respectively. On the low-energy side, there is a distinct dissymmetry in the main peak and a rather long tail before intensity falls off to zero. Two weak features are revealed by deconvolution, which are assigned to the two anticipated singlet–triplet transitions. These transitions being spin-forbidden, their extinction coefficients are expected to be ~10, and this is indeed the case for the first transition $(d_{xy})^2 \rightarrow (d_{xy})^1(d_{yz})^1$ [S → T*] at ~10 000 cm^{-1}. The coefficient is much higher (~100) for the second transition $(d_{xy})^2 \rightarrow (d_{xy})^1(d_{xz})^1$ [S → T**] at ~12 000 cm^{-1}, but enhanced intensity could be due to mixing between the higher-energy triplet state and the lowest-energy singlet states (20), as a result of strong spin-orbit couplings commonly found for third-row transition metals. The separations (Table 6) between the two triplet states, the two singlet states, and the second triplet – first singlet states (roughly 2000 cm^{-1}) are in good agreement with the values calculated by Da Re and Hopkins (20).

Comparison of the data within each series reveals that ring substitution does not introduce dramatic effects on the spectra: the strongly electron-attracting 5-nitro substituent seems to slightly increase the [S → S**] transition energy in the $ReOCl_2(L)(PPh_3)$ series, but the effect is modest and no recognizable trend can be detected. Thus, the HOMO–LUMO gap is not substantially affected by ligand substitution in these systems.

The spin-allowed [S → S*] and [S → S**] bands in both series are observed at somewhat lower energy than for the $ReO(OR)X_2$(dppe) compounds studied earlier, where they were found at ~16 500 and 20 000 cm^{-1}, respectively (2). This can be explained by the lower electron-donating ability

of the quinolinate oxygen compared to alkoxo groups, considering that donation from the ligand trans to the Re=O bond was previously identified as a very sensitive factor. However, this reduction is not large enough to bring the energies below those of the $ReOX_3$(dppe) compounds (~12 000 and ~16 400 cm^{-1}).

Concluding remarks

Homologous series of $ReOCl_2(L)(PPh_3)$ and $ReOCl(L)_2$ compounds were prepared with various 8-hydroxyquinolines bearing substituents with different steric and electronic properties. Comparisons between these related compounds allowed us to fully interpret their ^{1}H NMR spectral features. The positions of the UV–vis bands used to estimate the HOMO–LUMO gap failed to reveal a large effect of ring substitution on electronic transitions, but it confirmed that the donor ability of the ligand trans to the Re=O band plays a major role. On the other hand, the fact that the spin-forbidden singlet–triplet bands were readily observed makes these systems attractive for future in-depth spectroscopic studies to improve our understanding of the low-lying excited states and the spin-crossover processes, whose control is crucial for the eventual development of optically or magnetically tunable materials (1, 21).

Triazene derivatives of (1,*x*)-diazacycloalkanes. Part III. Synthesis and characterization of a series of 1,4-di[2-aryl-1-diazenyl]piperazines

Vanessa Renée Little, Reid Tingley, and Keith Vaughan

Abstract: Reaction of a series of diazonium salts with piperazine in a 2:1 molar ratio affords excellent yields of the 1,4-di-[2-aryl-1-diazenyl]piperazines (**3**), which have been characterized by IR and NMR spectroscopy. Structural characterization is supported by elemental analysis or by mass spectrometry with accurate mass measurement of the molecular ion. The protons of the piperazine ring hydrogens give rise to a sharp singlet at ca. 4 ppm in the NMR spectra, indicating that the conformational equilibrium in the piperazine ring is rapid on the NMR timescale. The four equivalent carbon atoms of the piperazine ring resonate in the range 46–48 ppm. A variable temperature NMR experiment suggests that there is restricted rotation around the N2—N3 bond of the triazene moiety in **3**. The NMR data compares favorably with previous reported data for 1-aryldiazenyl-4-methylpiperazines (**1**) and 1,4-di-(2-aryldiazen-1-yl)homopiperazines (**2b**).

Key words: triazene, piperazine, diazonium coupling, NMR.

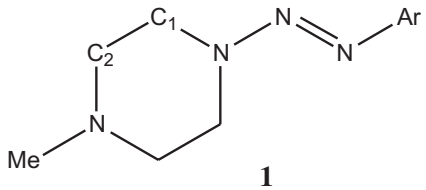
Résumé : La réaction d'une série de sels de diazonium avec de la pipérazine dans un rapport molaire de 2 : 1 conduit, avec d'excellents rendements, à des 1,4-di-[2-aryldiazén-1-yl]pipéprazines (**3**) qui ont été caractérisées par les spectres IR et RMN. Les caractérisations des structures sont supportées par des analyses élémentaires ou par spectrométrie de masse avec des mesures précises de la masse de l'ion moléculaire. Dans le spectre RMN, les protons du noyau pipérazine se présentent sous la forme d'un singulet effilé à environ 4 ppm, ce qui suggère que l'équilibre conformationnel du cycle pipérazine est rapide par rapport à l'échelle de temps de la RMN. La résonance des quatre atomes de carbone équivalents du noyau de la pipérazine se situe entre 46 et 48 ppm. Une expérience de RMN à température variable suggère l'existence d'une rotation empêchée autour de la liaison N2—N3 de la portion triazène du composé **3**. Les données de la RMN se comparent avantageusement avec celles rapportées antérieurement pour les 1-aryldiazényl-4-méthylpipérazines (**1**) et 1,4-di-(2-aryldiazén-1-yl)homopipérazines (**2b**).

Mots clés : triazène, pipérazine, couplage de diazonium, RMN.

[Traduit par la Rédaction]

Introduction

In previous studies (1, 2), a series of 4-methyl-1-(2-aryldiazen-1-yl-)piperazines (**1**), 4-methyl-1-[aryldiazenyl]-homopiperazines (**2a**), and 1,4-di-(2-aryldiazen-1-yl) diazepanes (**2b**) were synthesized and characterized by spectroscopic measurements. In the process of characterizing these triazenes by NMR spectroscopy, the chemical shift parameters of the protons and carbons in the piperazine ring were clearly established and verified by some classical 2D NMR work. The aim of the present work was to synthesize a series of the 1,4-di-[2-aryl-1-diazenyl]piperazines (**3**) with a similar range of aryl substituents as in the previous series and to establish the spectroscopic parameters of the new series of bistriazenopiperazines (**3**). This work is an essential part of our broad-ranging study of the synthesis of triazene derivatives of (1,*x*)-diazacycloalkanes and is an essential link between the previously reported data (1, 2) and further studies of triazenes derived from several ring-substituted piperazines.



Some compounds of type **3** have been reported previously (3), but the range of aryl substituents reported excludes many of the substituents used routinely in our work. In the previous work, the range of aryl substituents was limited to the nitro, carboxyl, methyl, and halogeno groups. We have expanded the range of substituents to include the cyano, acetyl, carboxamido, sulfonamido, and alkoxycarbonyl groups. Therefore, it was essential to undertake the synthesis of the new analogues in the series **3a**–**3f**, and **3j**–**3l** inclusive, and the previously reported analogues **3g**–**3i**, **3m**, and **3n** were synthesized as part of the present study to acquire ^{13}C NMR data for the full range of compounds. In the process of repeating the literature work, it was noted that some melting points were at variance from those reported (3). These melting points have been checked assiduously and the identity of the discrepant compounds has been confirmed by elemental analysis or high-resolution mass spectrometry. It should be noted here that Butkus and co-workers (4) reported the synthesis of an analogous bistriazene (**3**, X = *p*-SO_3K) as part of a study of the anti-inflammatory activity of triazenes.

Experimental

All reagents were reagent grade materials purchased from Sigma-Aldrich Canada Ltd. and were used without further purification. Melting points were determined on a Fisher-Johns melting point apparatus and are uncorrected. IR spectra were obtained using Nujol mulls or KBr discs on a Bruker Vector 22 spectrometer. ^{1}H and ^{13}C NMR spectra were obtained with either: (*i*) Bruker AC 250 MHz or 500 MHz spectrometers at the Atlantic Regional Magnetic Resonance Center at Dalhousie University; or (*ii*) the ANASAZI 60 MHz EFT spectrometer at SMU. Chemical shifts were recorded in $CDCl_3$ solutions at 20 °C (unless specified otherwise), and are relative to TMS as internal standard. Elemental analyses were performed by the Canadian Microanalytical Service Ltd., Delta, British Columbia.

© 2005 NRC Canada

Accurate mass measurements were made on a CEC 21-110B mass spectrometer operated at a mass resolution of 8000 (10% valley) by computer-controlled peak matching to appropriate PFK reference ions. Spectra were obtained using electron ionization at 70 V and a source temperature of 175 °C, with samples being introduced by means of a heatable quartz probe. The standard deviation of mass measurement was ±0.0008 amu, which is an average of 3.6 ppm over the mass range 100–300 amu.

1,4-Di-[2-aryl-1-diazenyl]-piperazines (3a–3n)

General procedure

The aromatic primary amine (0.01 mol) was dissolved in 10 mL of 3 mol/L hydrochloric acid, with the aid of heat if necessary, and the resulting solution was cooled in an ice–salt bath to 0 °C. The solution was diazotized with a solution of sodium nitrite (0.76 g, 0.011 mol) in water (10 mL) while maintaining the temperature below 5 °C, and then stirred for a further 0.5 h in the cold water. The solution was then neutralized with saturated sodium bicarbonate solution, after which the neat piperazine (0.005 mol) was added slowly to the mixture. After stirring for a further 0.5 h, the mixture was further neutralized to pH 7 with saturated sodium carbonate solution (total volume ca. 10 mL) and then left to stir until precipitation was deemed to be complete (1–3 h). The solid product was filtered under suction, dried and recrystal- from an appropriate solvent to give the following compounds.

*1,4-Di-[2-(*p*-cyanophenyl)-1-diazenyl]-piperazine (3a)*

Pale yellow needles, 91%; mp 275 to 276 °C (DMSO). IR ν_{max} (Nujol, cm^{-1}): 842, 2225. ^1H NMR (60 MHz, $CDCl_3$) δ: 4.12 (s, 8H), 7.51 (d, J = 2.4 Hz, 4H), 7.59 (d, J = 2.4 Hz, 4H). Anal. calcd. for $C_{18}H_{16}N_8$ (%): C 62.8, H 4.7, N 32.6; found: C 62.8, H 4.9, N 32.4.

p-*Methoxycarbonyl-(3b)*

Off-white needles, 100%; mp 203–206 °C (DMSO). IR ν_{max} (Nujol, cm^{-1}): 857, 1713. ^1H NMR (60 MHz, $CDCl_3$) δ: 3.90 (s, 6H, O-Me), 4.08 (s, 8H), 7.48 (d, J = 8.4 Hz, 4H), 8.04 (d, J = 8.4 Hz, 4H). HR-MS (EI) m/z calcd. for $C_{20}H_{22}N_6O_4$: 410.1702; found: 410.1692.

p-*Ethoxycarbonyl-(3c)*

Pale yellow needles, 87%; mp 172–174 °C (DMSO). IR ν_{max} (Nujol, cm^{-1}): 859, 1702. ^1H NMR (60 MHz, $CDCl_3$) δ: 1.38 (t, J = 7.0 Hz, 6H, C-Me), 4.06 (s, 8H, N-CH_2), 4.36 (q, J = 6.6 Hz, 4H, O-CH_2), 7.48 (d, J = 9 Hz, 4H), 8.05 (d, J = 9 Hz, 4H). ^{13}C NMR (15.1 MHz, $CDCl_3$) δ: 13.5 (CH_3), 45.9 (N-CH_2), 60.0 (O-CH_2), 119.8, 127.3, 129.8, 152.6 (arom.), 165.6 (C=O). HR-MS (EI) m/z calcd. for $C_{22}H_{26}N_6O_4$: 438.2015; found: 438.2019.

p-*Acetyl-(3d)*

Orange prisms, 89%; mp 239–241 °C (DMSO). IR ν_{max} (Nujol, cm^{-1}): 847, 1670. ^1H NMR (60 MHz, $CDCl_3$) δ: 2.59 (s, 6H, acetyl-Me), 4.10 (s, 8H, N-CH_2), 7.51 (d, J = 8.7 Hz, 4H), 8.0 (d, J = 8.7 Hz, 4H). ^{13}C NMR (15.1 MHz, $CDCl_3$) δ: 47.5, 121.3, 130.7. HR-MS (EI) m/z calcd. for $C_{20}H_{22}N_6O_2$: 378.1804; found: 378.1803.

p-*Carboxamido-(3e)*

Yellow solid, 100%; mp 285–287 °C (DMSO). IR ν_{max} (Nujol, cm^{-1}): 858, 1654, 3173, 3385. ^1H NMR (250 MHz, d_6-DMSO) δ: 4.09 (s, 8H), 6.77 (d, J = 9.6 Hz, 4H), 7.27 (d, J = 9.6 Hz, 4H). MS (EI) m/z (%): 77(32), 105(48), 121(100) [$C_6H_4CONH_3^+$], 148(23.5) [$NH_2COC_6H_4N_2^+$], 233(3) [$M^+ - N_2C_6H_4CONH$].

p-*Sulphonamido-(3f)*

Pale yellow solid, 60%; mp 217–223 °C (EtOH–DMSO). IR ν_{max} (Nujol, cm^{-1}): 836, 1160, 1377, 3183, 3341. ^1H NMR (60 MHz, d_6-DMSO) δ: 4.12 (s, 8H), 7.27 (d, J = 8.4 Hz, 4H), 7.82 (d, J = 8.4 Hz, 4H). MS (EI) m/z (%): 77(100), 156(25) [$C_6H_4NH_2^+$], 157(68) [$C_6H_4NH_3^+$], 170(21) [$NH_2SO_2C_6H_4N_2^+$].

p-*Tolyl-(3g)*

Short yellow needles, 89%; mp 172–174 °C (DMSO) (lit. value (3) mp 148 to 149 °C). IR ν_{max} (Nujol, cm^{-1}): 821. ^1H NMR (60 MHz, $CDCl_3$) δ: 2.33 (s, 6H, Ar-Me), 3.94 (s, 8H, N-CH_2), 7.1 (d, J = 8.7 Hz, 4H), 7.39 (d, J = 8.7 Hz, 4H). ^{13}C NMR (15.1 MHz, $CDCl_3$) δ: 20.6 (Ar-Me), 46.1 (N-CH_2), 120.7, 129.1, 135.9, 147.4 (arom.). HR-MS (EI) m/z calcd. for $C_{18}H_{22}N_6$: 322.1906; found: 322.1898.

p-*Bromo-(3h)*

Fine white needles, 91%; mp 199–203 °C (DMSO) (lit. value (3) mp 203 °C). IR ν_{max} (Nujol, cm^{-1}): 827. ^1H NMR (60 MHz, $CDCl_3$) δ: 4.00 (s, 8H), 7.32 (d, J = 7.2 Hz, 4H), 7.5 (d, J = 9 Hz, 4H). ^{13}C NMR (15.1 MHz, $CDCl_3$) δ: 46.5, 122.4, 131.9. Anal. calcd. for $C_{16}H_{16}Br_2N_6$ (%): C 42.5, H 3.5, N 18.6; found: C 42.3, H 3.6, N 18.1.

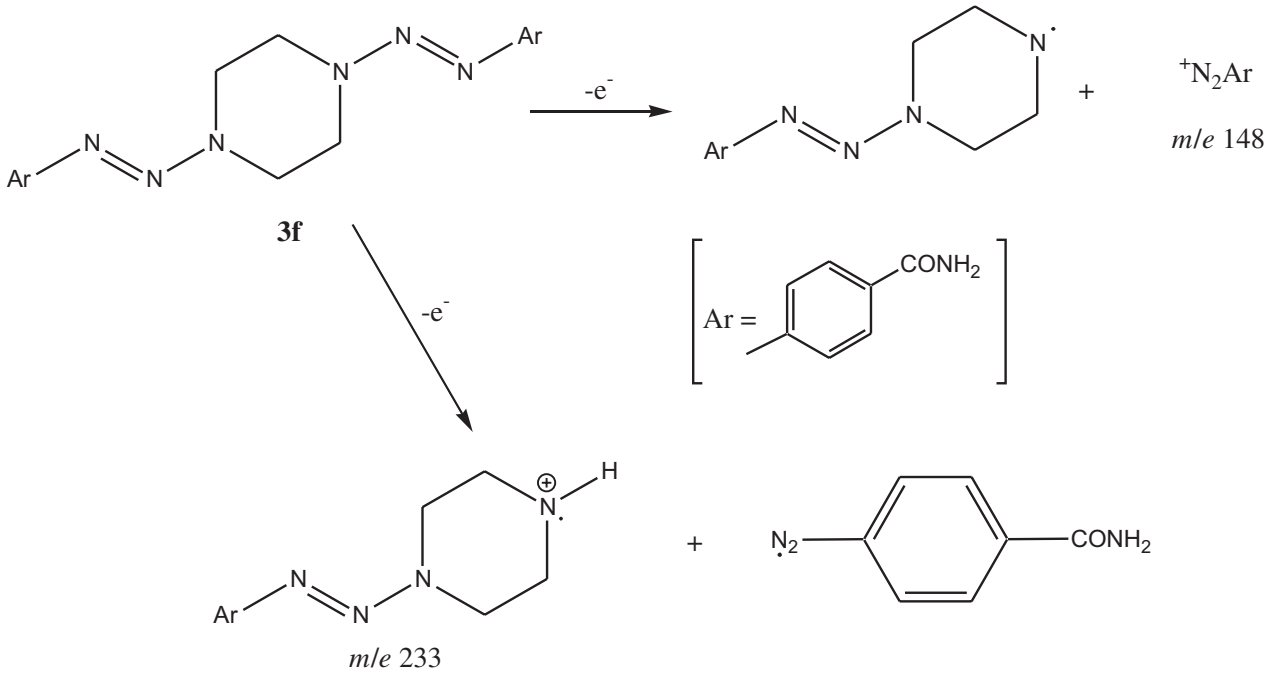
Phenyl-(3i, X = H)

Lustrous amber plates, 68%; mp 129 to 130 °C (ethanol) (lit. (3) mp 124 to 125 °C). IR ν_{max} (Nujol, cm^{-1}): 697. ^1H NMR (60 MHz, $CDCl_3$) δ: 3.97 (s, 8H), 7.1–7.5 (m, 10H). ^{13}C NMR (15.1 MHz, $CDCl_3$) δ: 47.7, 120.3, 126.0, 128.4, 137.3. Anal. calcd. for $C_{16}H_{18}N_6$ (%): C 65.3, H 6.1, N 28.6; found: C 65.3, H 6.2, N 28.6.

o-*Cyano-(3j)*

Pale yellow prisms, 94%; mp 190–192 °C (DMSO). IR ν_{max} (Nujol, cm^{-1}): 765, 2225. ^1H NMR (60 MHz, $CDCl_3$) δ: 4.19 (s, 8H), 7.08–7.73 (m, 8H). HR-MS (EI) m/z calcd. for $C_{18}H_{16}N_8$: 344.1498; found: 344.1492.

o-*Methoxycarbonyl-(3k)*



Golden oily prisms, 74%; mp 108–122 °C (ethanol). IR ν_{max} (Nujol, cm^{-1}): 765, 1715. ^1H NMR (60 MHz, $CDCl_3$) δ: 3.87 (s, 6H, O-Me), 4.03 (s, 8H, N-CH_2), 7.07–7.79 (m, 8H). ^{13}C NMR (15.1 MHz, $CDCl_3$) δ: 48.6 (N-CH_2), 53.9 (O-Me), 121.3, 127.7, 131.6, 133.7, 151.3 (aromatic), 170.0 (C=O). HR-MS (EI) m/z calcd. for $C_{20}H_{22}N_6O_4$: 410.1702; found: 410.1688.

o-*Ethoxycarbonyl-(3l)*

Golden prisms, 85%; mp 103–105 °C (ethanol). IR ν_{max} (Nujol, cm^{-1}): 764, 1703. ^1H NMR (60 MHz, $CDCl_3$) δ: 1.36 (t, J = 7.1 Hz, 6H, C-Me), 4.03 (s, 8H, N-CH_2), 4.35 (q, J = 7.1 Hz, 4H, O-CH_2), 7.07–7.79 (m, 8H). ^{13}C NMR (15.1 MHz, $CDCl_3$) δ: 15.8 (C-Me), 48.1 (N-CH_2), 62.5 (O-CH_2), 121.0, 127.5, 128.4, 131.3, 133.3, 150.7 (arom.). MS (EI) *m/z* calcd. for $C_{22}H_{26}N_6O_4$: 438.2015; found: 438.2010.

o-*Tolyl-(3m)*

Short off-white needles, 86%; mp 99 to 100 °C (DMSO) (lit. value (3) mp 104 to 105 °C). IR ν_{max} (Nujol, cm^{-1}): 750. ^1H NMR (60 MHz, $CDCl_3$) δ: 2.44 (s, 6H, Ar-Me), 3.99 (s, 8H, N-CH_2), 7.02–7.39 (m, 8H). ^{13}C NMR (15.1 MHz, $CDCl_3$) δ: 17.15, 46.2, 116.2, 125.9, 126.1, 130.2, 132.7, 147.5. Anal. calcd. for $C_{18}H_{22}N_6$ (%): C 67.1, H 6.8, N 26.1; found: C 66.8, H 6.8, N 26.1.

o-*Chloro-(3n)*

Off-white prisms, 76%; mp 88–90 °C (DMSO) (lit. value (3) mp 84–86 °C). IR ν_{max} (Nujol, cm^{-1}): 755. ^1H NMR (60 MHz, $CDCl_3$) δ: 4.04 (s, 8H), 7.03–7.54 (m, 8H). ^{13}C NMR (15.1 MHz, $CDCl_3$) δ: 46.25, 118.2, 126.3, 126.7, 129.4, 129.7, 146.0.

Results and discussion

Diazonium coupling with piperazine proceeded smoothly to afford the triazenes (**3a**–**3n**) in good yield ranging from 60%–100%. Percentage recovery after recrystallization ranged from 60%–89%. These bistriazenes proved to be somewhat intractable to the preferred recrystallization solvents, such as ethanol, ethyl acetate, toluene, etc., and in many cases purification was carried out by recrystallization from dimethyl sulfoxide. The melting point of the recrystallized bistriazene was sharp in most cases, but surprisingly, the melting point found in this study was in some cases different from that reported earlier by Yamarates et al. (3). These conflicting melting points have been doubly checked and the structures of the particular compounds in question have been confirmed by elemental analysis or accurate mass measurement of the molecular ions, in addition to NMR and IR spectroscopy. The IR spectra of the bistriazenes **3** have been recorded to confirm the identity of the aryl substituent (X-) and to assign the out-of-plane bending vibration as confirmation of the position of the substituent.

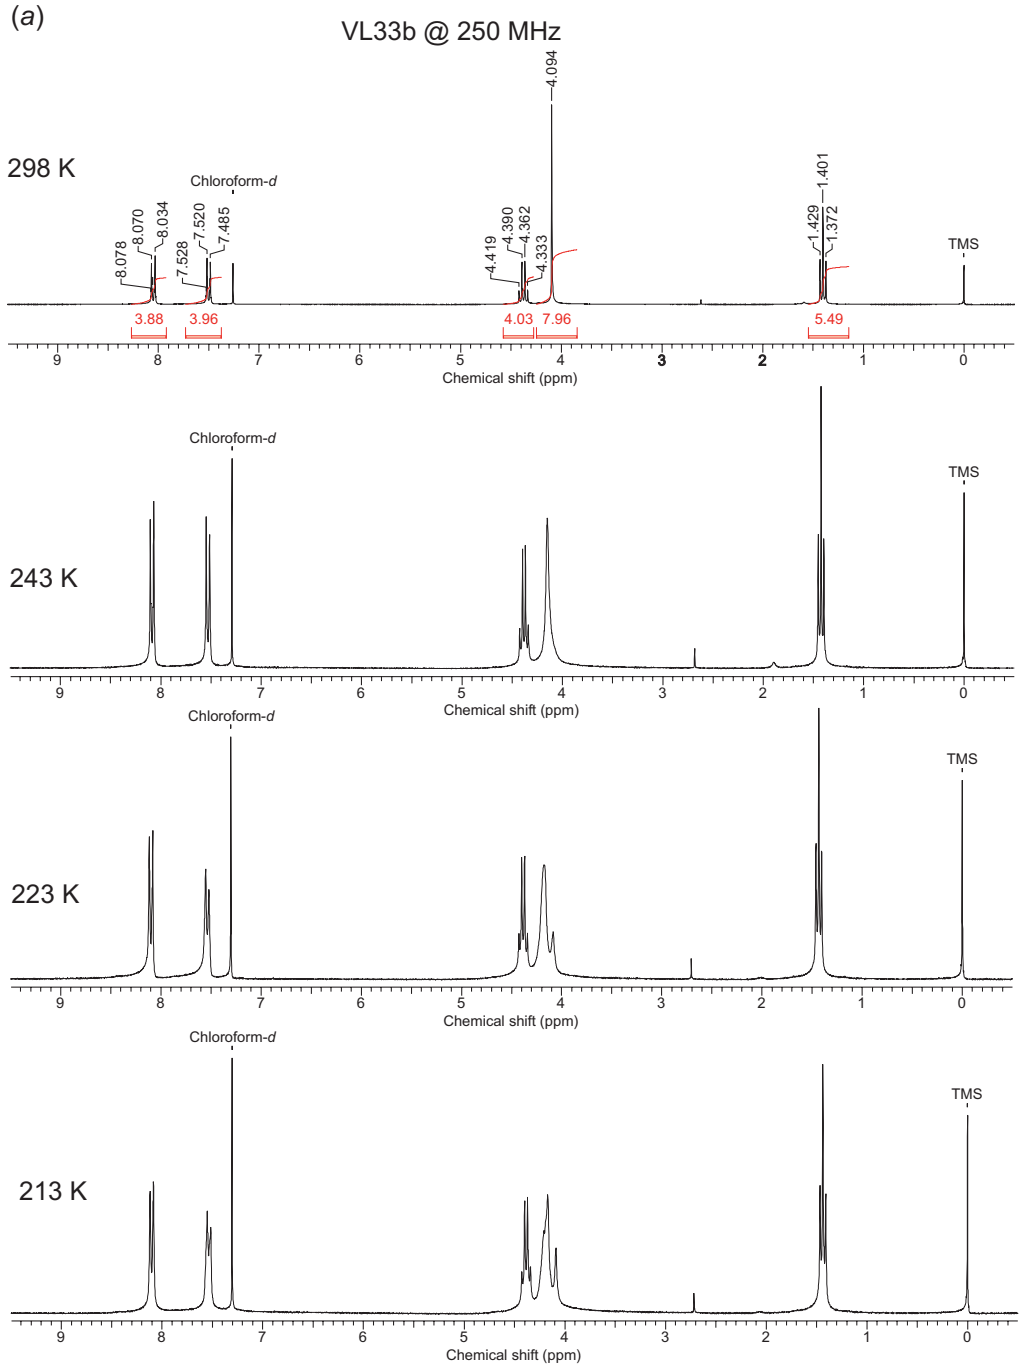

Table 1. Comparison of the ^1H and ^{13}C NMR chemical shifts in the spectra of the new bistriazenes **3** compared with the previously reported data for triazenes of type **1** (1) and the bistriazenes of type **2b** (2).

Series no.	Methylene protons of the piperazine ring (ppm)	Carbon signals of the piperazine ring carbons (ppm)
3	3.9–4.2	46–48
1	ca. 3.9	47 (C1)
2b	4.0 (Ha)	46 (C1)
	4.2 (Hb)	54 (C2)

All of the compounds in series **3** have been analyzed by ^1H NMR spectroscopy. The protons of the four equivalent methylene groups in the piperazine ring appear as a sharp singlet in the range 3.94–4.19 ppm; these spectra all show the predictable aromatic signals and the protons of the aryl substituent (if present). Although most of the new bistriazenes are only sparingly soluble in $CDCl_3$, the concentration in $CDCl_3$ was sufficient to allow recording of proton signals at 60 MHz, with the exception of the *p*-carboxamido-(**3e**) and *p*-sulfonamido-(**3f**) derivatives. These were recorded in d_6-DMSO solution. However, the low solubility of the bistriazenes limited the characterization by ^{13}C NMR to **3c**, **3d**, **3g**–**3i**, and **3k**–**3n**. Nevertheless, it is apparent that the four equivalent carbon atoms of the piperazine ring resonate in the range 46–48 ppm. The proton and carbon-13 chemical shifts in the spectra of the new bistriazenes **3** compare favorably with the previously reported data for triazenes of type **1** (1) and the bistriazenes of type **2b** (2) as shown in Table 1.

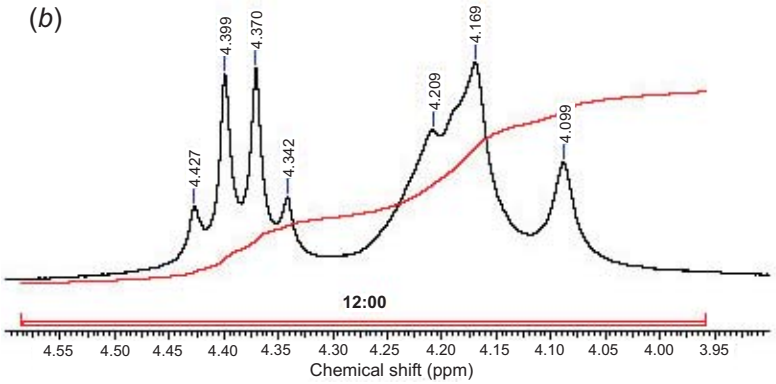
Fig. 2. (*a*) Stack plot of the variable-temperature ^{1}H NMR spectra of compound **3c** in deuteriochloroform.



All of the new compounds in series **3** have been characterized by either elemental analysis or high resolution mass spectrometry, with the exception of **3e** and **3f**, which did not display stable molecular ions. Evidence for the structures of **3e** and **3f** was apparent from the fragmentation patterns. Thus, the mass spectrum of **3e** shows fragments at *m*/*e* 233 and 148, which are the fragments arising from cleavage of one of the N—N bonds in a triazene moiety (Fig. 1).

The simplicity of the NMR spectra of these bistriazenes **3** is a little surprising if one considers the possible conformational and rotational options available to these molecules. The sharpness of the proton and carbon signals in the ambient temperature spectra indicates that the N2—N3 bonds in the triazene moieties are not subjected to restricted rotation because of resonance, as has been observed previously with 1-aryl-3,3-dialkyltriazenes (5) and recently with 1,3-diphenyltriazenes (6); furthermore, the observation of a single sharp peak arising from the eight equivalent piperazine ring hydrogens suggests that any conformational equilibria of the piperazine ring is rapid at ambient temperature.

The next logical step in this study was to explore the VT NMR behavior of some representative examples of series **3** in solution. Compounds **3c** and **3d** were chosen on the basis of their demonstrated solubility in $CDCl_3$ at low tempera-

Fig. 2. (*b*) Detail of the ^{1}H NMR spectrum of compound **3c** at 213 K.

tures. Figure 2*a* shows a stack plot of the ^{1}H NMR spectra of **3c** down to 213 K; Fig. 2*b* is a detail of the 213 K spectrum. Most of the signals in the 213 K spectrum are sharp and unchanged with the exception of the signal at ca. 4.1 ppm, which separates into three clear lines at 4.088, 4.169, and 4.209 ppm (with the extra feature of a fourth signal as an unresolved shoulder). Clearly, there is a dynamic equilibrium occurring to create the chemical shift variance in the piperazine ring protons of the different species. There are three possible options: (*a*) equilibrium between the chair conformations of the piperazine ring; (*b*) equilibrium between species in which the N-aryldiazenylgroups occupy axial or equatorial positions; (*c*) rotational equilibrium between the rotamers **4A** and **4B**.

In light of previous work and conclusions (5) with regard to restricted rotation about the N2—N3 bond in the triazene moiety because of resonance, the third option (*c*) is the preferred explanation for the observed NMR spectrum of **3c** at 213 K. An equilibrium mixture of **4A** and **4B** would theoretically show four different proton chemical shifts in the region of the piperazine ring protons, i.e., Ha and Hb in **4A** and Hc and Hd in **4B**. This is consistent with the observed spectrum of **3c** at 213 K, if one assumes the shoulder at ca. 4.2 ppm is a real signal. The VT NMR spectrum of compound **3d** shows a similar phenomenon; the signal at 4.112 ppm resolves at 213 K into three distinct lines with a shoulder, and the aromatic signal of the H-atoms ortho to the triazenido moiety at ca. 7.5 ppm is considerably broadened.

Conclusion

The results reported here are complementary to our previous reported studies of the *N*-aryldiazenyl-*N*-methylpiperazines (**1**) (1), the *N*-aryldiazenyl-*N*-methylhomopiperazines (**2a**) (2), and the *N*,*N*-bis(aryldiazenyl-)homopiperazines (**2b**) (2). We now have a clear picture of the methodology of synthesizing these compounds and we are assembling a detailed compendium of the spectroscopic characteristics of these *N*-aryldiazenylheterocycles for future reference. This is a central part of our wider goal, which is the synthesis of new triazene derivatives of (1,*x*)-diazacycloalkanes (1, 2). Further elaboration of this goal will require exploration of the synthesis of new analogues of the bistriazene **3** with substituents in the piperazine ring, to shed light on the conformational options available to the piperazine ring. Also, we will endeavor to exploit the application of our triazenidopiperazines as triazene linkers in solid phase synthesis, an area of triazene chemistry that has recently attracted much attention (7).

Transition metal complexes of a sterically demanding diimine ligand

Jason D. Masuda and Douglas W. Stephan

Abstract: The reaction of the metal halide with the sterically demanding ligand (i-$Pr_2C_6H_3N$)(C(Me)(NC_6H_3-i-Pr_2))$_2$ afforded the complexes (i-$Pr_2C_6H_3N$)(C(Me)(NC_6H_3-i-Pr_2))$_2MX_2$ (X = Cl, M = Fe (**2**), Co (**3**); X = Br, M = Ni (**4**), M = Cu (**5**), Zn (**6**)). The species of **2** reacts with $Li(OEt_2)B(C_6F_5)_4$ to form the yellow adduct [(i-$Pr_2C_6H_3N$)(C(Me)(NC_6H_3-i-Pr_2))$_2$Fe(μ-Cl)$_2$Li(OEt_2)$_2$][$B(C_6F_5)_4$] (**7**) while alkylation of **2** gave (i-$Pr_2C_6H_3N$)(C(Me)(NC_6H_3-i-Pr_2))$_2$FeClCH$_2$SiMe$_3$ (**8**). The species [(i-$Pr_2C_6H_3N$)(C(Me)(NC_6H_3-i-Pr_2))$_2$Ni(η^3-C_3H_5)][$B(3,5\text{-}CF_3C_6H_3)_4$] (**9**) was obtained from reaction of **1** with [(η^3-C_3H_5)NiBr]$_2$ and [Na][$B(3,5\text{-}(CF_3)_2C_6H_3)_4$] while reaction of **4** with Super-Hydride afforded (i-$Pr_2C_6H_3N$)-(C(Me)(NC_6H_3-i-Pr_2))$_2$NiH$_2$BEt_2 (**10**). X-ray data are reported for **2**–**10**. The sterically demanding nature of the ligand inhibits subsequent reactivity of these species.

Key words: sterically demanding ligands, chelate complexes, X-ray structure, diimine ligands.

Résumé : La réaction d'un halogénure métallique avec le ligand stériquement encombré (i-$Pr_2C_6H_3N$)(C(Me)(NC_6H_3-i-Pr_2))$_2$ conduit à la formation des complexes (i-$Pr_2C_6H_3N$)(C(Me)(NC_6H_3-i-Pr_2))$_2MX_2$ (X = Cl, M = Fe (**2**), Co (**3**); X = Br, M = Ni (**4**), M = Cu (**5**), Zn (**6**)). L'espèce **2** réagit avec le $Li(OEt_2)B(C_6F_5)_4$ pour former l'adduit jaune [(i-$Pr_2C_6H_3N$)(C(Me)(NC_6H_3-i-Pr_2))$_2$Fe(μ-Cl)$_2$Li(OEt_2)$_2$][$B(C_6F_5)_4$] (**7**) alors que l'alkylation du composé **2** conduit à la formation du complexe (i-$Pr_2C_6H_3N$)(C(Me)(NC_6H_3-i-Pr_2))$_2$FeClCH$_2$SiMe$_3$ (**8**). On a obtenu l'espèce (i-$Pr_2C_6H_3N$)-(C(Me)(NC_6H_3-i-Pr_2))$_2$Ni(η^3-C_3H_5)][$B(3,5\text{-}CF_3C_6H_3)_4$] (**9**) par réaction du composé **1** avec le [(η^3-C_3H_5)NiBr]$_2$ et le [Na][$B(3,5\text{-}(CF_3)_2C_6H_3)_4$] alors que la réaction du composé **4** avec le Super-Hydrure conduit à la formation du (i-$Pr_2C_6H_3N$)(C(Me)(NC_6H_3-i-Pr_2))$_2$NiH$_2$BEt_2 (**10**). On rapporte les données de diffraction des rayons X par les composés **2**–**10**. L'encombrement stérique du ligand inhibe toute réactivité subséquente de ces espèces.

[Traduit par la Rédaction]

Introduction

Recently, much attention has focused on sterically demanding chelating ligands such as the neutral, diimine-based ligand ((C(Me)NC_6H_3-i-Pr_2)$_2$) and [HC(C(Me)NC_6H_3-i-Pr_2)$_2$]$^-$ (Scheme 1). Such ligands have been utilized for late transition metal olefin polymerization catalysts, as well as for the isolation of novel low-valent Al and Ga derivatives (1–4). Mindiola and co-workers (5) have used the latter ligand to isolate the first Ti–phosphinidene complex. In our labs, we have recently been probing new bulky ligands in late transition metals (6–8) and main group chemistry (9). For example, we have recently reported the use of the bulky phosphinimine–imine ligand (i-$Pr_2C_6H_3N$)C(Me)CHPPh_2-(NC_6H_3-i-Pr_2) to prepare neutral and cationic Al complexes (9), while Welch et al. (10) reported related complexes based on the ligand (i-$Pr_2C_6H_3N$)$C_6H_4PPh_2$(NC_6H_3-i-Pr_2). In recent efforts, we have also reported the synthesis of the sterically demanding *N*-aryl-imidoyl amidine ligand i-$Pr_2C_6H_3N$(C(Me)NC_6H_3-i-Pr_2)$_2$ and its use in the synthesis of Al-based alkyl and hydride cations.[2] Several previous reports have described metal complexes involving the *N*-imidoyl amidine systems (R = H) (11–19) and the related 2,2′-dipyridylamino ligand (20–34). Cotton et al. (31) serendipitously obtained [PhNCHN(Ph)CHNPh]$CoCl_2$ while the related species [(4-MePh)NCHN(4-MePh)(4-MePh)-NC]Pd(C_6F_5)$_2$ was reported by Uson et al. (33). Finally, Wilkinson and co-workers (32) characterized the species (C_5Me_5)Ir[N(2,6-MeC_6H_3)CHNRCNC_6H_3(Me)CH_2] (R = *t*-Bu, 2,6-i-PrC_6H_3). In this manuscript, we report the use of this bulky ligand i-$Pr_2C_6H_3N$(C(Me)NC_6H_3-i-Pr_2)$_2$ in the synthesis of a series of transition metal complexes. Structural studies of these complexes are presented and discussed.

Experimental

General data

All preparations were done under an atmosphere of dry, O_2-free N_2 employing both Schlenk line techniques and a Vacuum Atmospheres inert atmosphere glovebox. Solvents were purified employing a Grubbs'-type solvent purification system manufactured by Innovative Technology. Deuterated

 doi: 10.1139/V05-057 © 2005 NRC Canada

Scheme 1. Bulking chelating ligand complexes.

solvents were purified using the appropriate techniques. All organic reagents were purified by conventional methods. ^{1}H, ^{31}P, ^{11}B, ^{19}F, and ^{13}C NMR spectra were recorded on Bruker Avance-300 and -500 spectrometers. All spectra were recorded in C_6D_6 at 25 °C unless otherwise noted. Trace amounts of protonated solvents were used as references and chemical shifts are reported relative to $SiMe_4$. ^{31}P, ^{11}B, and ^{19}F NMR spectra were referenced to external 85% H_3PO_4, $BF_3{\cdot}Et_2O$, and $CFCl_3$, respectively. Combustion analyses were done in-house employing a PerkinElmer CHN analyzer. [Na][B(3,5-$CF_3C_6H_3)_4$] was prepared as outlined (36). $LiCH_2SiMe_3$ and Super-Hydride were purchased from Aldrich Chemical Co. as solutions and crystallized. The ligand (*i*-$Pr_2C_6H_3N$)C(Me)(NC_6H_3-*i*-Pr_2)C(Me)(NC_6H_3*i*-Pr_2) (**1**) was prepared by published methods.[2]

Synthesis of (*i*-$Pr_2C_6H_3N$)(C(Me)(NC_6H_3-*i*-Pr_2))$_2MCl_2$ (M = Fe (2), Co (3))

These compounds were prepared in a similar fashion and thus one preparation is detailed. To a solution of **1** (200 mg, 0.345 mmol) in 5 mL toluene was added $FeCl_2$ (43 mg, 0.345 mmol). The mixture was heated to 110 °C for 3 days after which the insoluble, off-white $FeCl_2$ had been replaced with a yellow solid. The toluene was then removed in vacuo and the remaining solids dissolved in approximately 10 mL CH_2Cl_2. This solution was then filtered through Celite® and layered with 10 mL toluene. After several days, 213 mg of bright yellow – orange crystals were isolated. **2**: Yield: 79%; magnetic susceptibility 5.79 μ_B. Anal. calcd. for $C_{40}H_{57}N_3FeCl_2$: C 67.99, H 8.13, N 5.95; found: C 68.22, H 8.40, N 6.00. **3**: Blue crystals. Yield: 87%; magnetic susceptibility 3.35 μ_B. Anal. calcd. for $C_{40}H_{57}N_3CoCl_2$: C 67.69, H 8.09, N 5.92; found: C 67.55, H 7.84, N 5.87.

Synthesis of (*i*-$Pr_2C_6H_3N$)(C(Me)(NC_6H_3-*i*-Pr_2))$_2NiBr_2$ (4)

To a solution of **1** (1.000 g, 1.72 mmol) in 15 mL xylenes was added $NiBr_2$ (377 mg, 1.72 mmol). The mixture was heated to 140 °C for 3 days. This resulted in the formation of a purple solid suspended in a bright blue solution. The xylenes were then decanted, the solids washed with 2 × 10 mL pentane, and dried in vacuo to give 1.186 g of powder **4**. X-ray quality dark purple crystals were grown from a solution in CH_2Cl_2 layered with toluene. **4**: Yield: 86%; magnetic susceptibility 4.98 μ_B. Anal. calcd. for $C_{40}H_{57}N_3NiBr_2$: C 60.17, H 7.19, N 5.26; found: C 60.38, H 7.23, N 5.25. The decanted xylenes and pentane washings were combined and after a few weeks, a small amount of blue crystals formed. Crystallographic analysis proved this to be [CH_3C(*i*-$Pr_2C_6H_3N)_2HNiBr_3$][CH_3C(*i*-$Pr_2C_6H_3NH)_2$] resulting from a small amount of CH_3C(*i*-$Pr_2C_6H_3N)_2H$ impurity in the **1** starting material.

Synthesis of (*i*-$Pr_2C_6H_3N$)(C(Me)(NC_6H_3-*i*-Pr_2))$_2MBr_2$ (M = Cu (5), Zn (6))

These compounds were prepared in a similar fashion and thus one preparation is detailed. To a solution of **1** (100 mg, 0.172 mmol) in 5 mL THF was added 38 mg (0.172 mmol) $CuBr_2$ and the mixture was left to stir overnight, after which a copious amount of burgundy colored solids formed. The solids were filtered from the reaction mixture to give 83 mg of material. **5**: Yield: 60%; magnetic susceptibility 1.99 μ_B. X-ray quality burgundy colored crystals were grown from a hot MeCN solution slowly cooled to –35 °C. Anal. calcd. for $C_{40}H_{57}N_3CuBr_2$: C 59.81, H 7.15, N 5.23; found: C 59.43, H 7.30, N 5.15. **6**: Yield: 90%. X-ray quality colorless crystals were grown by cooling a $CHCl_3$ solution to –35 °C. ^{1}H NMR (CD_2Cl_2): 7.24–7.57 (m, 9H, *m*, *p*-Ar), 3.42 (sept, 4H, CH, $|J_{H\text{-}H}|$ = 6.9 Hz), 3.41 (sept, 2H, CH, $|J_{H\text{-}H}|$ = 6.9 Hz), 1.76 (s, 6H, Me), 1.37 (d, 12H, *i*-Pr, $|J_{H\text{-}H}|$ = 6.9 Hz), 1.30 (d, 12H, *i*-Pr, $|J_{H\text{-}H}|$ = 6.9 Hz), 1.13 (d, 12H, *i*-Pr, $|J_{H\text{-}H}|$ = 6.9 Hz). ^{13}C NMR (CD_2Cl_2): 167.8, 146.4, 141.3, 141.1, 137.2, 132.0, 127.9, 126.8, 125.5, 29.1, 28.8, 26.0, 24.8, 24.7, 24.0. Anal. calcd. for $C_{40}H_{57}N_3ZnBr_2$: C 59.67, H 7.14, N 5.22; found: C 59.26, H 7.12, N 5.12.

Synthesis of (*i*-$Pr_2C_6H_3N$)(C(Me)(NC_6H_3-*i*-Pr_2))$_2$Fe(μ-$Cl)_2Li(OEt_2)_2$][$B(C_6F_5)_4$] (7)

To a rapidly stirring suspension of **2** (100 mg, 0.142 mmol) in 5 mL toluene was added 107 mg (0.142 mmol) $Li(OEt_2)_2B(C_6F_5)_4$ in 5 mL of diethyl ether. The reaction was allowed to stir overnight after which the mixture turned from yellow-orange to a bright yellow color. Filtration of the mixture through Celite® and removal of the solvent gave a yellow oil, which crystallized upon addition of pentane. Yield: 41%; magnetic susceptibility 5.23 μ_B. X-ray quality crystals were grown by diffusion of pentane vapor into a diethyl ether – toluene solution of the material. Anal. calcd. for $C_{72}H_{77}N_3FeCl_2LiBF_{20}O$: C 56.12, H 5.03, N 2.73; found: C 56.30, H 4.73, N 2.50.

Synthesis of (*i*-$Pr_2C_6H_3N$)(C(Me)(NC_6H_3-*i*-Pr_2))$_2FeClCH_2SiMe_3$ (8)

To a rapidly stirring suspension of **2** (100 mg, 0.142 mmol) in 5 mL toluene cooled to –35 °C was added $LiCH_2SiMe_3$ (13 mg, 0.142 mmol) in 3 mL of cold toluene. The reaction was allowed to warm to 25 °C over several hours. The mixture became deep purple in color. Filtration of the mixture and cooling the filtrate to –35 °C overnight gave fine purple needles. The crystals were filtered off and washed with 2 ×

10 mL of cold pentane. Yield: 55%; magnetic susceptibility 5.61 μ_B. X-ray quality purple crystals were grown from a toluene solution layered with pentane. Anal. calcd. for $C_{44}H_{68}N_3FeSiCl$: C 69.68, H 9.03, N 5.54; found: C 70.18, H 8.56, N 6.20.

Synthesis of [(*i*-$Pr_2C_6H_3N$)(C(Me)(NC_6H_3-*i*-Pr_2))$_2$Ni(η^3-C_3H_5)][B(3,5-$(CF_3)_2C_6H_3)_4$] (9)

To a solution of **1** (100 mg, 0.174 mmol) in 8 mL CH_2Cl_2 was added $[(\eta^3\text{-}C_3H_5)NiBr]_2$ (32 mg, 0.174 mmol) and [Na][B(3,5-$(CF_3)_2C_6H_3)_4$] (155 mg, 0.174 mmol). The mixture was stirred overnight. The resulting brown solution was filtered to remove NaBr and the filtrate was cooled to –35 °C overnight to give brown crystals, which were separated from the solution by decantation and washed with 3 × 5 mL of cold pentane. Yield: 33%. ^{1}H NMR (CD_2Cl_2): 7.71 (br s, 8H, *o*-Ar_F), 7.56 (br s, 4H, *p*-Ar_F), 7.00–7.58 (m, 9H, *m*, *p*-Ar), 5.74 (dt, 1H, allyl CH, $|J_{H\text{-}H}|$ = 13.5 Hz, $|J_{H\text{-}H}|$ = 7.1 Hz), 3.69 (sept, 2H, CH, $|J_{H\text{-}H}|$ = 6.9 Hz), 3.01 (sept, 2H, CH, $|J_{H\text{-}H}|$ = 6.9 Hz), 2.87 (sept, 1H, CH, $|J_{H\text{-}H}|$ = 6.9 Hz), 2.72 (sept, 1H, CH, $|J_{H\text{-}H}|$ = 6.9 Hz), 2.16 and 2.11 (d, 2H, allyl-syn, $|J_{H\text{-}H}|$ = 13.5 Hz), 1.79 and 1.77 (d, 2H, allyl-anti, $|J_{H\text{-}H}|$ = 7.1 Hz), 1.66 (s, 6H, Me), 1.55 (d, 6H, *i*-Pr, $|J_{H\text{-}H}|$ = 6.9 Hz), 1.44 (d, 6H, *i*-Pr, $|J_{H\text{-}H}|$ = 6.9 Hz), 1.33 (d, 6H, *i*-Pr, $|J_{H\text{-}H}|$ = 6.9 Hz), 1.29 (d, 6H, *i*-Pr, $|J_{H\text{-}H}|$ = 6.9 Hz), 1.28 (d, 6H, *i*-Pr, $|J_{H\text{-}H}|$ = 6.9 Hz), 1.21 (d, 6H, *i*-Pr, $|J_{H\text{-}H}|$ = 6.9 Hz). ^{13}C NMR (CD_2Cl_2): 163.7, 162.4 (q, J_{CF} = 49 Hz), 149.4, 145.0, 149.9, 137.8, 136.9, 136.5, 135.4, 132.7, 130.6, 130.1 (br m), 129.7 (br m), 129.6, 129.3 (br m), 128.9 (br m), 128.7, 128.3, 127.3, 127.2, 127.0, 125.8, 125.5, 123.4, 119.8, 118.1 (br m), 65.6, 29.9, 29.4, 29.3, 29.1, 25.0, 24.9, 24.8, 24.2, 24.0, 23.7, 23.4, 21.7. ^{11}B NMR (CD_2Cl_2): –10.9. ^{19}F NMR (CD_2Cl_2): –63.2. Anal. calcd. for $C_{75}H_{74}N_3NiBF_{24}$: C 58.38, H 4.83, N 2.72; found: C 58.07, H 4.89, N 2.66.

Synthesis of (*i*-$Pr_2C_6H_3N$)(C(Me)(NC_6H_3-*i*-Pr_2))$_2$$NiH_2BEt_2$ (10)

To a rapidly stirring slurry of **4** (200 mg, 0.251 mmol) in 10 mL toluene was added Super-Hydride (0.551 mL, 1.0 mol/L in THF). An immediate evolution of gas was observed. The purple solution was allowed to stir for 4 h after which the solvent was removed in vacuo. The solid was dissolved in approx. 5 mL toluene, filtered through Celite®, layered with 5 mL pentane, and cooled to –35 °C overnight. The resulting brown-red crystals were separated from the solution and washed with 3 × 10 mL of cold pentane. Yield: 47%; magnetic susceptibility 1.11 μ_B. Anal. calcd. for $C_{44}H_{69}N_3NiB$: C 74.48, H 9.80, N 5.92; found: C 74.93, H 9.81, N 5.92.

X-ray data collection and reduction

Crystals were manipulated and mounted in capillaries in a glovebox, thus maintaining a dry, O_2-free environment for each crystal. Diffraction experiments were performed on a Siemens SMART System CCD diffractometer. The data were collected in a hemisphere of data in 1448 frames with 10 s exposure times. The observed extinctions were consistent with the space groups in each case. The data sets were collected ($4.5° < 2\theta < 45°$–$50.0°$). A measure of decay was obtained by recollecting the first 50 frames of each data set. The intensities of reflections within these frames showed no statistically significant change over the duration of the data collections. The data were processed using the SAINT and XPREP processing packages (37). An empirical absorption correction based on redundant data was applied to each data set. Subsequent solution and refinement was performed using the SHELXTL solution package (37).

Structure solution and refinement

Non-hydrogen atomic scattering factors were taken from the literature tabulations. The heavy atom positions were determined using direct methods employing the SHELXTL direct-methods routine. The remaining non-hydrogen atoms were located from successive difference Fourier map calculations. The refinements were carried out by using full-matrix least-squares techniques on *F*. In the final cycles of each refinement, all non-hydrogen atoms were assigned anisotropic temperature factors in the absence of disorder or insufficient data. In the latter cases, atoms were treated isotropically. C-H atom positions were calculated and allowed to ride on the carbon to which they are bonded assuming a C—H bond length of 0.95 Å. H-atom temperature factors were fixed at 1.10 times the isotropic temperature factor of the C atom to which they were bonded. The H-atom contributions were calculated, but not refined. The locations of the largest peaks in the final difference Fourier map calculation as well as the magnitude of the residual electron densities in each case were of no chemical significance. Addition details are provided in the Supplementary data.[3] See Table 1 for the crystallographic data for **2**–**10**.

Results and discussion

The reaction of the metal halide in toluene or xylenes with ligand **1** at elevated temperatures afforded the complexes (*i*-$Pr_2C_6H_3N$)(C(Me)(NC_6H_3-*i*-Pr_2))$_2$$MX_2$ (X = Cl, M = Fe (**2**), Co (**3**); X = Br, M = Ni (**4**)) in yields of 79%, 87%, and 86%, respectively (Scheme 2). In the latter case, formation of the Ni complex required the more forcing conditions of 4 days of heating in xylenes at 140 °C to form **4**. These vigorous conditions stand in stark contrast to those required for the formations of $H_2C(C(Me)NC_6H_3\text{-}i\text{-}Pr_2)_2NiBr_2$ (37) and $(C(Me)(NC_6H_3\text{-}i\text{-}Pr_2)_2)NiBr_2$ (38), which form readily at room temperature. Magnetic susceptibility measurements for **2**, **3**, and **4** gave a magnetic moment of 4.79, 3.35, and 4.98 μ_B, respectively, consistent with these formulations. In a similar fashion, the straightforward reaction of **1** with equimolar amounts of $CuBr_2$ or $ZnBr_2$ in THF at room temperature gave compounds (*i*-$Pr_2C_6H_3N$)(C(Me)(NC_6H_3*i*-Pr_2))$_2$$MBr_2$ (M = Cu (**5**), Zn (**6**)). The ^{1}H NMR spectrum of **5** gave se-

verely broadened lines, while the spectrum of **6** was similar to the free ligand. Magnetic susceptibility measurements of **5** gave a magnetic moment of 1.99 μ_B.

The overall geometries of the complexes **2**–**6** as determined by X-ray crystallographic studies are similar and thus only two representative ORTEP drawings are provided (Figs. 1 and 2). In all cases, the aryl rings are approximately orthogonal to the chelate plane and the metals adopt a pseudo-tetrahedral geometry. In the case of compounds **2** and **3**, the molecules crystallize such that they sit on a crystallographically imposed mirror plane bisecting the ligand and passing through the plane containing the metal atom – dichloride fragment. The key metric parameters are summarized in Table 2. The M—Cl distances in **2** and **3** and the M—Br distance in **4** increases for the Fe, Co, Ni series consistent with increasing atomic radius. The M—Br distances for **5** and **6** are longer, as expected, averaging 2.367 and 2.357 Å, respectively. The X-M-X angles found in **2**–**4** are slightly larger than the typical tetrahedral angle ranging from 116.79(8)° to 120.14(8)°. For **5** and **6**, the Br-M-Br angles were found to be 106.82(7)° and 117.80(5)°. The M—N distances fall in a narrow range between 1.959(6) and 2.096(3) Å. Similarly, the N—C distances of the imine fragments vary from 1.287(6) to 1.317(10) Å. These latter bond lengths are slightly longer than those found in the free ligand (1.272(3) and 1.269(3) Å). The ligand bite angles ranged from 84.61(15)° for the Fe species to 90.1(3)° for the Cu species. The N-M-X angles, in general, fall in the range from 101.54(12)° to 123.67(13)°; however, the largest range of thse angles was observed for **5** where the N-Cu-Br angles were found to be 132.9(2)° and 105.8(2)°. These large N-Cu-Br angles, the large bite angle, short M—N distances, and the small X-M-X angle in **5** are illustrative of the greater distortion from a tetrahedral geometry at Cu relative

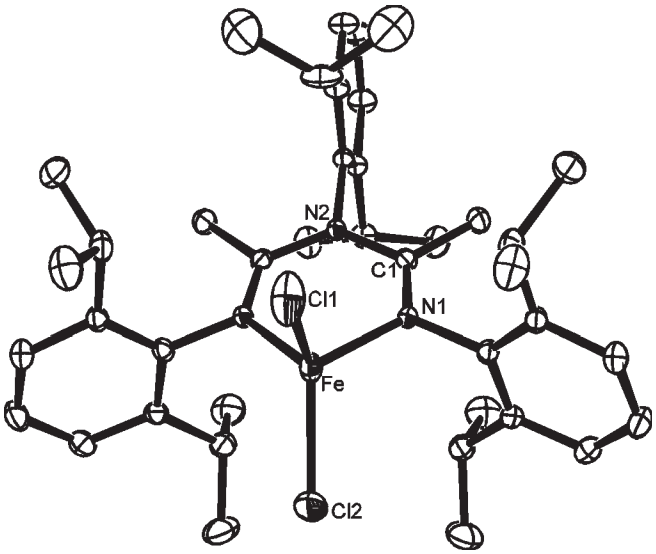
Fig. 1. ORTEP of **2** or **3** (30% thermal ellipsoids are shown). Hydrogen atoms are omitted for clarity. These compounds are isomorphous.



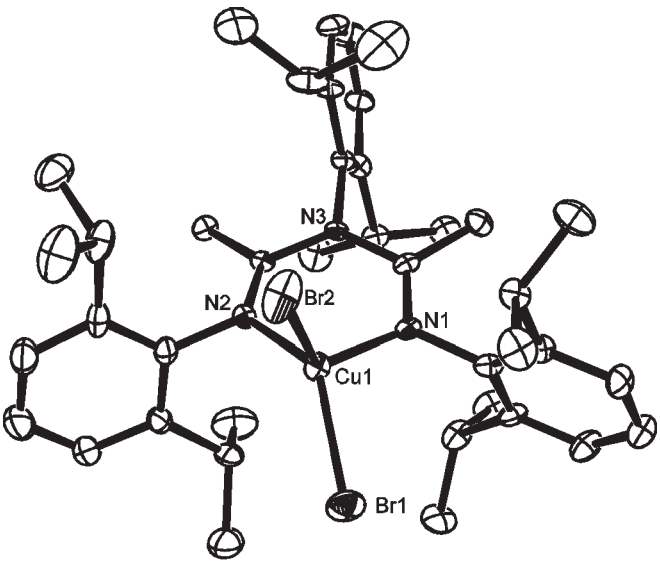


Fig. 2. ORTEP of **5** (30% thermal ellipsoids are shown). Hydrogen atoms are omitted for clarity.

to the other compounds (Fig. 2). In this case, it appears that steric crowding results in the displacement of the Cu atom out of the ligand plane, and a twisting of the $CuBr_2$ plane to minimize interactions with the bulky Ar groups.

The species **2** reacts with $Li(OEt_2)_2B(C_6F_5)_4$ to form the yellow adduct $[(i\text{-}Pr_2C_6H_3N)(C(Me)(NC_6H_3\text{-}i\text{-}Pr_2))_2Fe(\mu\text{-}Cl)_2Li(OEt_2)_2][B(C_6F_5)_4]$ (**7**) in 41% isolated yield (Scheme 2). Crystallographic characterization of **7** revealed a pseudo-tetrahedral geometry about Fe in which two chlorine atoms bridge the Fe and Li atoms (Fig. 3). The pseudo-tetrahedral coordination sphere of Li is completed by the coordination of two molecules of ether. The Fe—N distances average 2.034(4) Å, which is shorter than that observed for **2**. This is consistent with a more electron-deficient metal center as a result of the bridging of the Cl ligands to Li. This view is also consistent with the longer avg. Fe—Cl bond length of 2.2774(17) Å. A consequence of the bridging Cl atoms is also a small increase in the diimine ligand bite angle to 86.18(14)°. The Li—Cl bond lengths in **7** were found to be 2.474(10) and 2.352(11) Å, which gives rise to an Fe—Li separation of 3.163(9) Å.

Alkylation of **2** with 1 equiv. of $LiCH_2SiMe_3$ proceeds to give $(i\text{-}Pr_2C_6H_3N)(C(Me)(NC_6H_3\text{-}i\text{-}Pr_2))_2FeClCH_2SiMe_3$ (**8**) in 55% isolated yield (Scheme 2). The magnetic susceptibility of **8** was determined to be 5.61 μ_B, consistent with a high-spin Fe(II) species. X-ray structural study of **8** con-

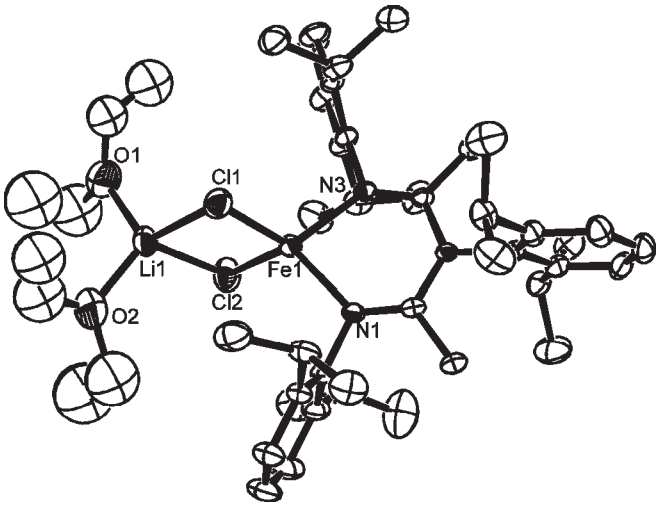
Fig. 3. ORTEP of the cation of **7** (30% thermal ellipsoids are shown). Hydrogen atoms are omitted for clarity. Bond lengths (Å): Fe(1)—N(3) 2.030(4), Fe(1)—N(1) 2.034(3), Fe(1)—Cl(2) 2.2706(17), Fe(1)—Cl(1) 2.2842(17), Fe(1)—Li(1) 3.163(9), Cl(1)—Li(1) 2.474(10), Cl(2)—Li(1) 2.352(11), N(1)—C(37) 1.291(5), N(1)—C(1) 1.451(5), N(2)—C(13) 1.466(5), Li(1)—O(2) 1.943(11), Li(1)—O(1) 1.968(10). Bond angles (°): N(3)-Fe(1)-N(1) 86.18(14), N(3)-Fe(1)-Cl(2) 123.86(11), N(1)-Fe(1)-Cl(2) 114.69(11), N(3)-Fe(1)-Cl(1) 113.49(10), N(1)-Fe(1)-Cl(1) 121.78(11), Cl(2)-Fe(1)-Cl(1) 98.82(7), O(2)-Li(1)-O(1) 114.8(5), O(2)-Li(1)-Cl(2) 113.6(5), O(1)-Li(1)-Cl(2) 106.8(5), O(2)-Li(1)-Cl(1) 111.3(5), O(1)-Li(1)-Cl(1) 116.5(5).



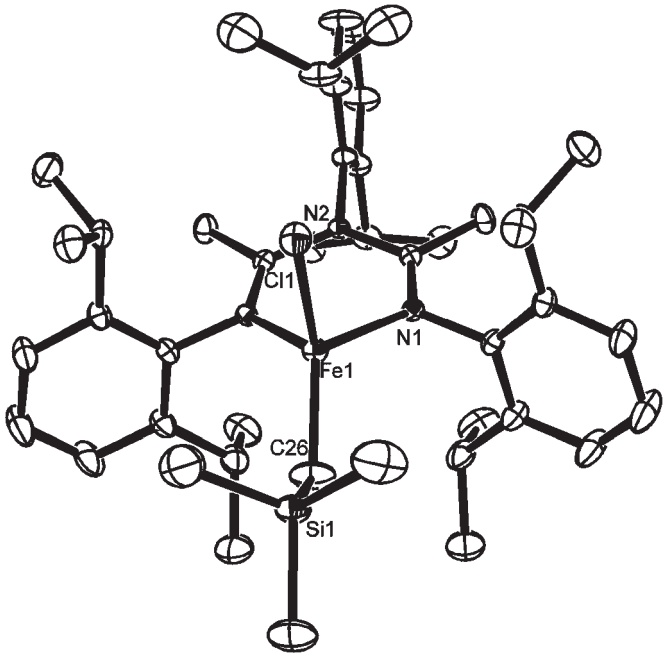


Fig. 4. ORTEP of **8** (30% thermal ellipsoids are shown). Hydrogen atoms are omitted for clarity. Bond lengths (Å): Fe(1)—C(26) 2.038(6), Fe(1)—N(1) 2.114(3), Fe(1)—Cl(1) 2.2762(15), N(1)—C(1) 1.281(4), N(1)—C(3) 1.454(4). Bond angles (°): C(26)-Fe(1)-N(1) 117.67(13), N(1)-Fe(1)-N(1) 82.99(13), C(26)-Fe(1)-Cl(1) 124.89(18), N(1)-Fe(1)-Cl(1) 102.50(7), C(1)-N(1)-Fe(1) 127.9(2).

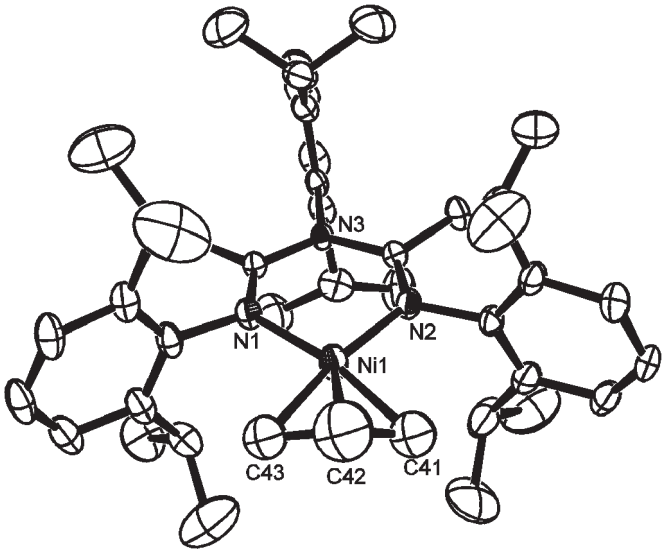
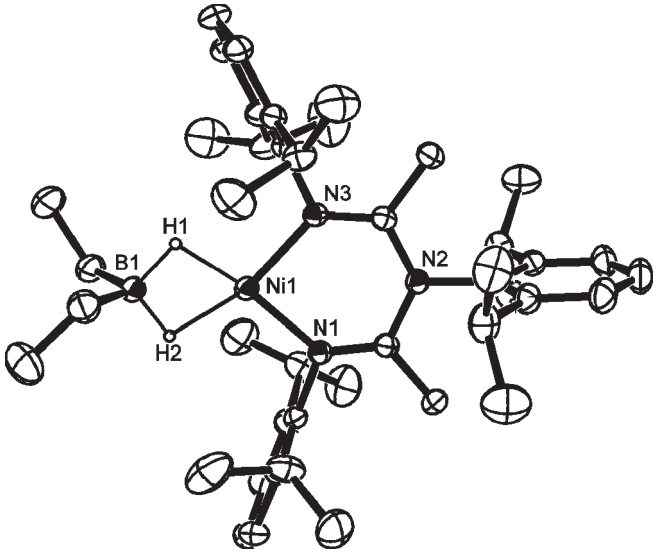


firmed the formulation, with the molecule residing on a crystallographically imposed mirror plane that bisects the ligand and passes through the pseudo-tetrahedral Fe center and the plane containing Cl and the (CH_2SiMe_3) fragment (Fig. 4). The incorporation of an electron-donating alkyl group results in the expected lengthening of the Fe—N bond length to 2.114(3) Å. Similarly the Fe—Cl distance of 2.2762(15) Å in **8** is longer than that found in **2**. The longer Fe—N distance also results in a slightly smaller ligand bite angle of 82.99(13)°. Attempts to further alkylate Fe were unsuccessful, presumably a reflection of the steric crowding about the Fe center of **8**. In addition, attempts to alkylate with MeLi or *t*-BuLi were also unsuccessful leading to apparent compound degradation.

Reactions of **1** with $[(\eta^3\text{-}C_3H_5)NiBr]_2$ and [Na][B(3,5-$(CF_3)_2C_6H_3)_4$] afforded the salt [(*i*-$Pr_2C_6H_3N$)(C(Me)-$(NC_6H_3\text{-}i\text{-}Pr_2)$)$_2$Ni($\eta^3$-$C_3H_5$)][B(3,5-$(CF_3)_2C_6H_3)_4$] (**9**) in 33% isolated yield. The ^{1}H NMR spectrum of **9** is consistent with this formulation and indicative of a η^3-bonding mode of the allyl fragment. Variable-temperature studies (–90 to 35 °C) show no change in the allyl signals, reflecting the absence of dynamic behavior. Attempts to react **9** with CO, ethylene, or $PhPH_2$ failed to show any reaction, even under forcing conditions (refluxing toluene), again reflecting the maintenance of the η^3-bonding mode of the allyl fragment. X-ray data also confirmed this binding mode (Fig. 5). The Ni—N distances in **9** were found to be 1.915(6) and 1.916(6) Å. These distances, which are shorter than those found in **4**, are con-

© 2005 NRC Canada

Fig. 5. ORTEP for the cation of **9** (30% thermal ellipsoids are shown). Hydrogen atoms are omitted for clarity. Bond lengths (Å): Ni(1)—N(1) 1.915(6), Ni(1)—N(2) 1.916(6), Ni(1)—C(42) 1.96(2), Ni(1)—C(41) 2.019(14), Ni(1)—C(43) 2.049(11), N(1)—C(3) 1.306(8), N(2)—C(1) 1.290(8). Bond angles (°): N(1)-Ni(1)-N(2) 92.1(2), N(1)-Ni(1)-C(42) 134.4(7), N(2)-Ni(1)-C(42) 131.9(7), N(1)-Ni(1)-C(41) 168.9(4), N(2)-Ni(1)-C(41) 98.1(4), C(42)-Ni(1)-C(41) 37.1(7), N(1)-Ni(1)-C(43) 97.6(4), N(2)-Ni(1)-C(43) 170.2(4), C(42)-Ni(1)-C(43) 38.5(7), C(41)-Ni(1)-C(43) 72.2(5), C(3)-N(1)-Ni(1) 127.7(4), C(41)-C(42)-C(43) 135(2).



sistent with the presence of the formal positive charge. The Ni–allyl interaction results in Ni—C bond lengths of 1.96(2), 2.019(14), and 2.049(11) Å, typical of the η^3-bonding mode (39, 40).

Finally, reactions of **4** with Super-Hydride afforded brown-red crystals of the species formulated as $(i\text{-Pr}_2C_6H_3N)(C(Me)(NC_6H_3\text{-}i\text{-Pr}_2))_2NiH_2BEt_2$ (**10**) in 45% yield (Scheme 2). The magnetic susceptibility of **10** was determined to be 2.87 μ_B. X-ray data confirmed the above formulation of **10** as a formally Ni(I) species and revealed the pseudo-tetrahedral geometry about Ni in which two hydride atoms bridge the Ni and B centers (Fig. 6). The Ni—N distances average 1.947(2) Å, while the Ni—B separation is 2.165(4) Å. Location and refinement of the hydride atoms revealed an avg. Ni—H distance of 1.70(1) Å and B—H distances of 1.20(1) Å. Attempts to remove borane from **10** via reaction with BuLi were unsuccessful. Similarly, **10** proved to be unreactive with primary phosphine or phenol.

Summary

This manuscript describes the synthesis and structure of a series of transition metal complexes of the bulky *N*-aryl-imidoyl amidine ligand $(i\text{-Pr}_2C_6H_3N)(C(Me)(NC_6H_3\text{-}i\text{-Pr}_2))_2$. While a variety of complexes are readily accessible, the resulting complexes are generally robust and unreactive, principally a result of the sterically demanding nature of the ligand. As a result, we are continuing efforts to utilize this ligand to stabilize and isolate reactive transition metal fragments.

Fig. 6. ORTEP of **10** (30% thermal ellipsoids are shown). All hydrogen atoms except the bridging hydrogen atoms are omitted for clarity. Bond lengths (Å): Ni(1)—N(1) 1.946(2), Ni(1)—N(3) 1.949(2), Ni(1)—B(1) 2.165(4), B(1)—C(41) 1.600(6), B(1)—C(43) 1.616(6), N(1)—C(5) 1.456(4), N(3)—C(3) 1.305(4), N(3)—C(29) 1.447(4). Bond angles (°): N(1)-Ni(1)-N(3) 89.48(10), N(1)-Ni(1)-B(1) 138.37(13), N(3)-Ni(1)-B(1) 132.15(13), C(41)-B(1)-C(43) 114.6(3), C(41)-B(1)-Ni(1) 119.8(3), C(43)-B(1)-Ni(1) 125.5(3), C(1)-N(1)-Ni(1) 130.1(2).

Theoretical study of the reaction of titanium ion with ethane — Structure, mechanism, and potential energy surface

Dongju Zhang, Xuebing Fu, Ruoxi Wang, and Chengbu Liu

Abstract: Density functional theory in its B3LYP variant has been used to study the reaction of Ti^+ (^4F) with ethane in the gas phase. The potential energy surface corresponding to [Ti, C_2, H_6]$^+$, has been examined in detail at the B3LYP/6-311++G(3df,3pd)//B3LYP/6-311+G(d,p) level of theory. The quality of this theoretical method has been calibrated against the available thermochemical data. Three activation branches, C—H, C—C, and synchronous C—H and C—C bond activations, were proposed along the reaction coordinates, and two new mechanisms, the sequential 1,1-H_2 elimination and the concerted elimination of CH_4, were found.

Key words: Ti^+, ethane, reaction mechanism, potential energy surface, density functional theory.

Résumé : Une variante B3LYP de la théorie de la densité fonctionnelle a été utilizée pour étudier la réaction du Ti^+ (^4F) avec l'éthane en phase gazeuse. Opérant au niveau B3LYP/6-311++G(3df,3pd)//B3LYP/6-311+G(d,p) de la théorie, on a examiné en détail la surface d'énergie potentielle qui correspond à [Ti, C_2, H_6]$^+$. La qualité de cette méthode théorique a été calibrée en fonction de données thermodynamiques disponibles. On propose trois branches d'activation, C—H, C—C et des activations synchrones de liaison C—H et C—C ainsi que des coordonnées réactionnelles et on propose deux nouveaux mécanismes, l'élimination séquentielle 1,1 de H_2 et une élimination concertée de CH_4.

Mots clés : Ti^+, éthane, mécanisme réactionnel, surface d'énergie potentielle, théorie de la densité fonctionnelle.

[Traduit par la Rédaction]

Introduction

C—H and C—C bond activations of hydrocarbons at metal centers are of fundamental importance in various areas of chemical research, such as biochemistry, organometallic chemistry, and homo- and heterogeneous catalysis (1, 2). Extensive experimental studies of the reactions of first-row transition-metal ions with simple alkanes in the gas phase have been made by various techniques (1–13) since Allison et al. (14) observed in 1979 that atomic transition metal ions can activate C—C and C—H bonds in alkanes. In these reactions, the oxidative additions of C—H and C—C bonds to the metal center are two fundamental steps, from which a series of products results, such as small neutral molecules (H_2, CH_4, C_2H_4, etc.) and fragmentation ions. The general mechanisms in these reactions are shown in Scheme 1, where metal ion M^+ first inserts into a C—H or C—C bond, forming intermediate **A** or **B**. The species **A** can further rearrange into **C**, a precursor for the elimination of H_2 via a β-H shift.

As to the reactions of Ti^+ with small alkanes, detailed experimental studies have been reported by several groups during the last 20 years (7–13). On the theoretical side, several outstanding works have also been conducted in the recent years by using ab initio and density function calculations (15–19), and the relevant results have provided some important information on the potential energy surfaces (PESs). The most detailed computational results for the reaction of Ti^+ with methane have been reported by Sililia and Russo (18). However, for the reaction of Ti^+ with ethane, the detailed examination of the PES is scarce, although great effort has been devoted to its experimental research. This work aims at this gap and presents a detailed theoretical study of this reaction, including the geometries and energies of various intermediates, transition states and products, reaction mechanisms, and interesting PES properties of the [Ti, C_2, H_6]$^+$ system.

It is known that the theoretical research for the systems involving transition metals is difficult to accurately deal with in ab initio molecular orbital theory, since there are many near-degenerate electronic states in these systems. As an alternative, density functional theory (DFT) (20, 21) has recently attracted considerable attention, which has recently been widely applied to electronic structure calculations for systems that contain transition metals. The electron correlation effect in these systems is expected to play an important role in determining the geometries, energetics, and electronic configurations. The DFT method has been shown to be particularly useful and computationally efficient for systems with a relatively large number of electrons that are difficult to deal with in ab initio molecular orbital theory (22). Furthermore, the spin contamination in the Kohn–Sham single determinant reference function proved to be relatively

minimal. In view of the computational effectiveness and reliability of DFT, it is desirable to utilize it throughout this work.

Computational details

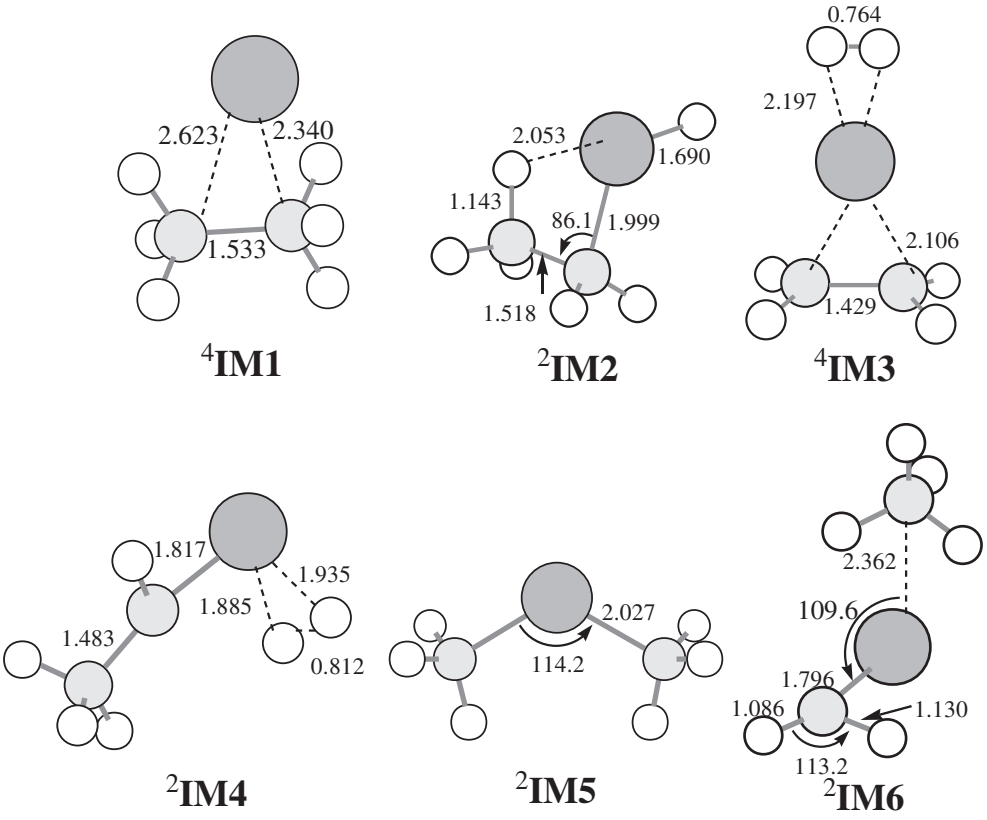
Density functional calculations were performed at the B3LYP/6-311+G(d,p) level (23, 24) as implemented in the GAUSSIAN 98 program (25). The stationary points on the PES of [Ti, C_2, H_6]$^+$ have been characterized as minima or first-order saddle points by evaluating their vibrational frequencies and normal modes. Intrinsic reaction coordinate (IRC) (26) calculations were performed in both directions from each transition state to further verify whether the located transition states connect the expected minima. To analyze the sensitivity of the stationary points to basis sets, the relative energies were also reevaluated using the large 6-311++G(3df,3pd) basis set based on the B3LYP/6-311+G(d,p) geometries. The stability of the wave function for symmetry breaking has been checked for each identified stationary point. The zero-point vibrational energies have been included in the reported energies.

Calibration of theoretical calculations

The B3LYP functional has shown a very promising performance for ion–ligand complexes (27–29), predicting properties such as bond dissociation energies, geometries, harmonic frequencies, and electronic details with accuracy comparable to those obtained from highly correlated wave functions based on ab initio methods. To clarify the general reliability expected from the present calculations, we compared the predicted chemical properties of several species involved in the title reaction with corresponding experimental data.

Atomic asymptote of titanium ion

We first tested the ability of the level of theory to describe low-lying states of Ti^+. Experimentally, the ground state of Ti^+ is $^4F(3d^24s^1)$, with the excited atomic state $^2F(3d^24s)$ lying just 13.2 kcal mol^{-1} higher in energy (30). In the present calculations, both the B3LYP/6-311+G(d,p) and B3LYP/6-311++G(3df,3pd)//B3LYP/6-311+G(d,p) methods predict the correct order of these two electronic states. The calculated separation values between ^4F and ^2F at the two levels of theory are almost the same, approximately 13 kcal mol^{-1}, and in good agreement with the experimental observation.



Bond dissociation energies

Table 1 compares theoretical bond dissociation energies (BDE) of several species involved in the title reaction to experimental values. To allow for a more direct comparison to the experimental values, the theoretical BDEs have been corrected to 0 K by including zero-point vibrational energy, noted as D_0. It is noted that the values obtained with the large basis set don't seem to improve the BDEs obviously, indicating that the 6-311+G(d,p) basis set is flexible enough to describe the electronic characters of the species involved in the reaction of Ti^+ with C_2H_6.

From Table 1, we found that the calculated D_0 values for the concerned species are in fairly good agreement with experimental observations. The errors introduced by the calculations are slightly more severe for the Ti^+-R species (R denotes an organic fragment) than for the simple hydrocarbon species. However, our main goals in the present work

Fig. 1. Optimized geometries (in Å and °) for the energetically most favorable intermediates on both the doublet and quartet surfaces of [Ti, C_2, H_6]$^+$ at the B3LYP/6-311+G(d,p) level. The superscripts denote the spin multiplicities.

are the examination of the detailed mechanism and the relative energies of the species involved, not the calculation of accurate bond energies. Thus, we consider that the discrepancies between the calculated results and measured values are acceptable. In addition, the reliability expected from the present theoretical level can be also estimated by comparing the expectation values of $\langle S^2 \rangle$ with the exact values of $\langle S^2 \rangle$ (0.75 for doublets, and 3.75 for quartets). We found that the spin contamination was small for all species involved.

To further clarify the general reliability of the chosen level of theory for the reactions of Ti^+ with an alkane, we first studied its reaction with methane. Table 2 compares the computed geometries and energies for the three structures involved in this reaction with early theoretical predications (18). Clearly, the present results are basically identical to the work previously published by Sicilia and Russo (18) in all essential details. This also makes us confident in using the chosen level of theory for describing the $Ti^+ + C_2H_6$ system.

The above results lead us to conclude that the level of theory used in this work is capable of describing the basic electronic characteristics of the species of interest.

Results and discussion

In terms of the mechanism proposed in Scheme 1, we designed various intermediates and transition states on the PES of [Ti, C_2, H_6]$^+$. After a careful search along both the doublet and quartet surfaces, we found two different reaction channels from those proposed in Scheme 1: one is 1,1-H_2 elimination and the other is the concerted activation of C—C and C—H bonds, which are in contrast to the general 1,2-H_2 elimination and the individual C—C and C—H bond activations, respectively.

In the present calculations, six intermediates (noted as **IM1**–**IM6**, respectively) and six first-order saddle points (noted as **TS1**–**TS6**, respectively) on each of the doublet and quartet PESs of [Ti, C_2, H_6]$^+$ have been located. We found that most of the intermediates and transition states on the doublet and quartet surfaces are geometrically very similar. Only their energetically most favorable geometries are shown in Figs. 1 and 2 for simplification, where the superscript on each species denotes the spin multiplicity. Table 3 summarizes the calculated total energies and relative ener-

Fig. 2. Optimized geometries (in Å and °) for the energetically most favorable first-order saddle points on both the doublet and quartet surfaces of [Ti, C_2, H_6]$^+$ at the B3LYP/6-311+G(d,p) level. The superscripts denote the spin multiplicities and the values in parentheses are the imaginary frequencies corresponding to the transition vectors.

gies for all species involved, including reactants, intermediates, transition states, and products at all spin states considered, at both the B3LYP/6-311+G(d,p) and B3LYP/6-311++G(3df,3pd)//B3LYP/6-311+G(d,p) levels. In the following discussion, the relative energy always involves those obtained at the latter, more accurate level.

Intermediate **IM1** is an encounter complex formed when Ti^+ (^4F) and C_2H_6 approach each other. Its ground state was located on the quartet PES and was found to more stable in energy by 26.9 kcal mol^{-1} than the isolated reactants. The corresponding doublet state is less stable by 12.3 kcal mol^{-1}. Our calculations indicate that the two Ti—C distances in ^{4}**IM1** are 2.340 and 2.623 Å, respectively, corresponding to a purely electrostatic interaction between two reactants, as is expected for a closed-shell ligand. This encounter complex is a common initial adduct to three subsequent activation branches: C—C bond activation, C—H bond activation, and synchronous C—C and C—H bond activations. In the following text, we will describe these reaction mechanisms in detail.

C—H bond activation branch

We first pay attention to the C—H bond activation branch on the PES of [Ti, C_2, H_6]$^+$. This branch starts from the initial ion–molecule complex (**IM1**). Along the reaction coordinate, it can be converted into a C—H bond inserted species **IM2**, via a C—H bond cleavage transition state (**TS1**). This C—H bond inserted species has a doublet ground state and its energy was calculated to be more stable by 17.7 kcal mol^{-1} than the reactants. This result is in good agreement with the experimental finding that the formation of this intermediate was estimated to be 18.45 ± 6.92 kcal mol^{-1} exothermic (12). Its quartet state counterpart, ^{4}**IM2** was calculated to be 27.9 kcal mol^{-1} less stable than the corresponding ground state. It should be noted that an intersystem crossing from the quartet surface over onto the doublet surface must occur to react along the ground-state surface, as the ground state of **IM1** is quartet state, while that of **IM2** is doublet. The ground state of **TS1** was also located on the doublet surface. It has C_1 symmetry and its energy was calculated to be 12.9 kcal mol^{-1} above ^{2}**IM1** with an imaginary frequency of 1098i. IRC calculations confirm that this TS is a correct, first-order saddle point for the C—H bond insertion reaction. As shown in Fig. 2, the breaking C—H bond in ^{2}**TS1** is elongated to 1.574 Å. We also attempted to optimize the quartet saddle points of the C—H bond activation, however, the initially guessed structures always collapsed into ^{4}**IM2**, indicating that the PES in this area is very flat. This may be attributed to the deficiency of the DFT method used for describing the transition states in very flat regions of PESs. To obtain more information on the quartet region, we also optimized this TS structure at the

MP2/6-311+G(d,p) level, and indeed found a first-order saddle with a single imaginary frequency of 633i. A single-point energy calculation for this TS at the B3LYP/6-311+G(d,p)//MP2/6-311+G(d,p) level reveals its energy is only 0.2 kcal mol^{-1} above ^{4}**IM2**, confirming the very flat potential energy surface at this region. However, the TS optimization using the B3LYP/6-311+G(d,p) method starting from the MP2 saddle point leads to a continuous decrease of the imaginary frequency and converge to the quartet state of ^{4}**IM2**.

Once **IM2** is formed, it can undergo various possible production channels by decomposition or isomerization. We found that four channels are available from this intermediate along both the doublet and quartet surfaces, as shown in panels **a** and **a′** of Fig. 3, respectively. The energetically most favorable reaction path involves a β-H migration to form a product-like intermediate (**IM3**) via saddle point **TS2**. It is should be noted that **IM3** is a complex between cationic titanium-ethylene and molecular hydrogen. The ground state of this intermediate was located on its quartet surface, where H—H bond length (0.764 Å) has resembled that of free H_2 (0.742 Å). The complex differs from the generally proposed dihydrido minimum, where the metal ion has already inserted into H_2 molecule, as shown in Scheme 1. We also tried to find such a dihydrido minimum on both the doublet and quartet PESs, however, the input structures all collapsed into **IM2** or **IM3** after optimization. This behavior has also been observed in previous studies by Holthausen and co-workers (33, 34) for reactions of Fe^+ and Co^+ with ethane. IRC calculations have confirmed that the two minima (**IM2** and **IM3**) are connected by **TS2**. This TS involves a five-membered ring structure, as shown in Fig. 2. In its doublet structure (^{2}**TS2**) the breaking C—H bond is elongated to 1.556 Å and the forming H—H distance is 1.067 Å. The direct dissociation of **IM3** leads to products H_2 + $Ti(C_2H_4)^+$. This reaction channel is referred as the 1,2-H_2 elimination pathway, endothermal by 1.9 kcal mol^{-1} on the doublet surface and exothermic by 5.5 kcal mol^{-1} on the quartet surface relative to the reactants, respectively. It is the energetically most favorable reaction channel. This result is

Fig. 3. Potential energy surfaces for the reaction of Ti^+ with C_2H_6 along the reaction coordinate calculated at the B3LYP/6-311++G(3df,3dp)//B3LYP/6-311+G(d,p) level of theory for: (**a**) C—H bond activation branches on the doublet surface; (**b**) C—C bond activation branch on the doublet surface; (**c**) C—H and C—C bond concerted activation branch on the doublet surface; and (**a′**), (**b′**), (**c′**) the corresponding values on the quartet surface.

in good agreement with earlier experimental findings: i.e., only the H_2 elimination products were observed at low energies (10–13).

The second pathway from **IM2** takes some similarity to the first one mentioned previously, only the β-H migration is replaced by a α-H migration. This process involves a four-membered ring TS (**TS3**). On the doublet surface, the barrier was calculated to be 18.8 kcal mol^{-1}, higher by 8.2 kcal mol^{-1} than that of the β-H migration. The forward product of **TS3** is the intermediate **IM4**, a complex of ethylidene titanium cation with molecule hydrogen, whose dissociation also leads to the loss of H_2. This H_2 loss channel is referred to as 1,1-H_2 elimination as contrasted with the 1,2-H_2 elimination mentioned previously, which is endothermic by 11.3 kcal mol^{-1} on the doublet surface and by 19.5 kcal mol^{-1} on the quartet surface. Although this 1,1-H_2 elimination channel is energetically less favorable compared to the 1,2-H_2 elimination channel, it could be an alternative path for H_2 loss from the reaction of Ti^+ with C_2H_6 at high energy. The other two channels from **IM2** are its direct fragmentation processes by rupturing the Ti—H bond to form $TiC_2H_5^+$ + H, endothermic by 39.5 kcal mol^{-1}, or by rupturing the Ti—C bond to form TiH^+ + C_2H_5, endothermic by 49.1 kcal mol^{-1}, which is consistent with the corresponding experimentally determined threshold for this reaction (50.4 kcal mol^{-1}) (12).

C—C bond activation branch

Along the C—C bond activation branch (panels **b** and **b′** of Fig. 3), the next minimum after the initial complex **IM1** is intermediate **IM5**, a dimethyl species, in which Ti^+ has been inserted into the C—C bond. This inserted species has C_s symmetry, and as expected, its ground state is a doublet state with an energy of 28.9 kcal mol^{-1} lower than the separated reactants. The counterpart of this intermediate on the quartet surface (^{4}**IM5**) is 33.0 kcal mol^{-1} less stable. Our calculations fairly reproduce the experimental finding that this intermediate lies 28.6 ± 6.0 kcal mol^{-1} lower in energy than the Ti^+ + C_2H_6 reactants (12). Similar to the C—H bond activation branch, an intersystem crossing from the quartet surface over onto the doublet surface is expected to occur around this region. As shown in the panel **b** of Fig. 3, ^{2}**IM5** is a global minimum on the doublet surface. **IM1** and **IM5** are connected by a first-order saddle point (**TS4**), which corresponds to C—C bond activation. On the doublet surface, the activation barrier was found to be 25.1 kcal mol^{-1}. ^{2}**TS4** has C_1 symmetry, where the C—C distance is enlarged

© 2005 NRC Canada

to 2.005 Å and the two Ti—C distances are shortened to 2.302 and 1.927 Å, respectively. It is clear from these geometry parameters that ^{2}**TS4** is a three-membered ring transition state. The imaginary frequency of this TS is 607i cm^{-1}, and the corresponding transition vector indicated by the vibration analysis corresponds to the breaking of the C—C bond and the reorientation of the methyl groups. Great efforts have also been made to locate such a TS on its quartet surface using the DFT method, however, the initially guessed structures at all times converge to ^{4}**IM5**. This situation is largely similar to that found previously in the C—H bond activation branch. To estimate the barrier of C—C bond activation on the quartet surface, we optimized the structure of ^{4}**TS4** using the same method as for locating ^{4}**TS1**. Its estimated relative energy is 4.5 kcal mol^{-1} above the reactants and only 0.5 kcal mol^{-1} less stable than the corresponding intermediate ^{4}**IM5**, confirming the very flat PES around this region.

Once **IM5** is formed, it can undergo two possible production channels immediately by isomerization or decomposition. One is the process directly cleaving the Ti—C bond in **IM5**, which led to $TiCH_3^+ + CH_3$ as proposed in Scheme 1. The process was calculated to be endothermic by 22.1 kcal mol^{-1}. The other is an energetically more favorable reaction path, which involves the isomerization of **IM5** into **IM6**, via a four-center transition state (**TS5**). As shown in Fig. 2, ^{2}**TS5** is an H-migration transition state on the PES in which a hydrogen atom is migrating from a carbon atom to another one and the breaking and forming C—H bond lengths are 1.528 and 1.451 Å, respectively. The corresponding imaginary frequency is 1329i cm^{-1}. The vibration analyses have also shown that the corresponding transition vectors are completely consistent with the notion of a 1,3-H shift. The forward product of **TS5** is **IM6**, a complex between CH_4 and $TiCH_2^+$. Both the methane moiety and the titanium–carbene unit in **IM6** are only slightly distorted compared to the geometric parameters of free CH_4 and $TiCH_2^+$. The methane unit in ^{2}**IM6** coordinates to the $TiCH_2^+$ species by η^3 shape with a value of 109.6° for the C-Ti-C angle. Its energy is calculated to be 10.8 kcal mol^{-1} more stable on the doublet surface and 0.83 kcal mol^{-1} more stable on the quartet surface than the separate reactants. After **IM6** is formed, the production channel dissociating into $TiCH_2^+ + CH_4$ would be open, which requires 15.2 and 14.4 kcal mol^{-1} on the doublet and quartet surfaces, respectively, and the overall reaction $Ti^+(^4F) + C_2H_6 \rightarrow TiCH_2^+ + CH_4$ is endothermic by 4.4 kcal mol^{-1} on the doublet surface and by 13.6 kcal mol^{-1} on the quartet surface.

As shown in Fig. 3*b*, along the ground-state PES, we note that the relative energy of C—C bond activation TS, ^{2}**TS4** is 10.5 kcal mol^{-1} above the entrance channel and 12.2 kcal mol^{-1} higher than the energy of **TS1**, the C—H bond activation TS. Thus, from a purely energetic point of view, the C—C bond activation pathway is less favorable than the C—H bond activation. This is the reason why only the H_2 elimination products were observed at low energies (10–13), whereas the CH_4 elimination products were not. Our calculated barrier height for the CH_4 elimination channel (10.5 kcal mol^{-1}) is considered accurate enough in view of the good performance of the calculation method selected, although it seems to be lower than the observed threshold for the appearance of Ti^+CH_2 (22.1 ± 2.3 kcal mol^{-1}) (12), which had been noted to be an unreasonably overestimated value (12).

Concerted activation branch of C—H and C—C bonds

As indicated above, both the C—C bond and C—H bond activation mechanisms of ethane by Ti^+ are addition–elimination reactions, involving two consecutive elementary steps: the oxidative addition of Ti^+ to C-C or C-H and the following reductive elimination of small molecules. In the present calculations, however, we also found another new reaction channel for C—C bond and C—H bond activations, which is a concerted process of the C—C and C—H bond activations. On each of the doublet and quartet surfaces, a three-membered ring TS (**TS6**) has been identified as a transition structure. The ground state of this TS is located on its quartet surface, and its relative energy is 32.6 kcal mol^{-1} above the entrance channel, and the corresponding doublet state is 11.6 kcal mol^{-1} less stable. The imaginary frequency of ^{4}**TS$_6$** is 690i cm^{-1}, and its transition vector corresponds to the expected components of the reaction coordinate: the breaking of the C—C bond and migration of a H atom from one C atom to another. To confirm two minima connected by ^{4}**TS6**, a careful IRC calculation started from this TS has been performed along both "forward" and "reverse" directions. The calculated results indicate that the forward direction leads to ^{4}**IM6**, while the reverse direction leads to ^{4}**IM1**. The activation energy from ^{4}**IM1** to ^{4}**TS6** is 59.5 kcal mol^{-1}. Although this energy barrier is much higher than those of the consecutive C—C bond and C—H bond activation processes discussed previously, it could be an alternative pathway for CH_4 loss from the reaction of Ti^+ with C_2H_6 at elevated energy. The reaction processes on the doublet and quartet surfaces along the concerted activation branches are shown in panels **c** and **c′** of Fig. 3.

Summary

The gas-phase reaction of Ti^+ with C_2H_6 has been studied by using density functional theory. The reaction of Ti^+ with C_2H_6 involves two mechanisms in nature: the consecutive activation mechanism of C—C or C—H bonds and the concerted activation mechanism of C—C and C—H bonds. The PES profiles of three activation branches (C—H and C—C bond activations and concerted C—H and C—C bond activation) along the reaction coordinate have been clearly revealed. The 1,1-H_2 elimination and concerted loss of CH_4 from the reaction of Ti^+ with C_2H_6 are possible alternative pathways at elevated energy compared to the general mechanism proposed earlier. However, the activation energies of these processes are higher than the corresponding ones proposed in the general mechanisms. Our calculations provide further insight into the elementary step mechanisms of the C—C and C—H bond activations in small alkanes by metal centers.

On the synthesis of new amphiphilic entities by the succinic coupling of β-cyclodextrins to calixarenes

Christopher K. Jankowski, Sébastien Arseneau, Jérome Blu, Laurent Mauclaire, and Nicolas Aychet

Abstract: Novel molecules, composed of a β-cyclodextrin coupled via a succinic diamide linker to di-*n*-octyl-calix[4]arene monocrown-6 or to biscrown-6-calix[4]arene, were synthesized by two independent routes: from mono-6′-deoxy-6′-amino-β-cyclodextrin, and from tetraaminocalix[4]arene derivatives.

Key words: β-cyclodextrin–calix[4]arene coupling, aminosuccinate-β-CD, aminosuccinate-calix[4]arene, octyloxy-calix[4]arene–monocrown-6, calix[4]arene–biscrown-6.

Résumé : La synthèse de nouvelles molécules, formées d'une β-cyclodextrine couplée à un éther di-*n*-octyl-calix[4]arène monocouronne-6 ou d'un biscouronne-6-calix[4]arène par le biais d'un diamide succinique, a été réalisée par deux voies indépendantes au départ de la mono-6′-désoxy-6′-amino-β-cyclodextrine et de dérivés du tétraaminocalix[4]arène.

Mots clés : couplage β-cyclodextrine–calix[4]arène, aminosuccinate-β-CD, aminosuccinate-calix[4]arène, octyloxy-calix[4]arène–monocouronne-6, calix[4]arène–biscouronne-6.

[Traduit par la Rédaction]

Introduction

Cyclodextrins (CD) (1, 2) and calixarenes (CAL), two important classes of compounds in inclusion chemistry, demonstrate different, but complementary affinities. Cyclodextrins are hydrophilic and amphiphilic, while calixarenes (and their crown ether derivatives) are insoluble in water (3, 4). In our search for new methods of construction of amphiphilic species from CDs, we considered the system of a CD and a CAL-crown coupled together (Fig. 1).

These new CAL-crown–CD species should demonstrate potential applications in the transport and vectorization of drugs (5–7), especially through the attachment of specific "arms"; still maintaining cage-inclusion properties (8–13), exploiting crown, calixarene, and cyclodextrin propensities to react with guest molecules, and a kind of self-organization. It is also expected that the final molecule obtained from the di-*n*-octyl-monocrown (**1**) should maintain its rigidity, in particular because of the space-oriented conformation of the calixarene crown. The second calixarene system (biscrown-6 calix[4]arene (**2**)) does in fact demonstrate greater rigidity, as well as an increased hosting capacity (two crown-6 ethers).

In our previous work (14), we reported on the successful nitration of both crown and biscrown calixarenes (Table 1). Di-*n*-octyl calix[4]arene–monocrown-6 (octMC-6) (**1**), and its biscrown analog, calix[4]arene–biscrown-6 (BC-6) (**2**), obtained by nitration with concd. HNO_3, giving up to 90% yield of crude $(NO_2)_4$octMC-6 (**4**) or $(NO_2)_4$BC-6 (**5**). In this paper, we would like to report on the synthesis of the CD–CAL-crown compounds, starting with these tetranitro derivatives **4** and **5**, and coupling them to β-CD **3** through a succinic diamide linker.

Results and discussion

In the first series, the tetranitro product **4** was reduced at high yield (>90%) with Raney nickel, giving the tetraamine $(NH_2)_4$octMC-6 (**6**). This in turn was reacted with succinic anhydride in DMF. The use of the succinyl coupling was justified by the need to create a spacer of desired length, enabling access to the amino-β-CD **8** for the coupling through an amide bond formation. This pathway has been successfully used for some hindered amines, peptides, and even small proteins (15); in the event that the coupling reaction fails, a longer linker can be used. In this case, the reaction was successful: the addition of the linker to the amino-calixarene produced (succ.-NH)$_4$octMC-6 (**9**, yield: 90%). This was then condensed with the NH_2-β-CD (**8**) prepared from β-CD by the following previously reported sequence: selective in situ supra-molecular 6-monotosylation by the inclusion method (16), conversion to its 6-azide with NaN_3, and reduction via triphenylphosphine to the amine **8** (17, 18).

Fig. 1. Overall scheme of the coupling reactions.

In the parallel series of the BC-6 calixarene, we produced a similar yield for the tetraamino derivative ($(NH_2)_4$BC-6, **7**) by Raney nickel reduction of the corresponding tetranitro derivative **5**, followed by obtaining the *N*-succinyl derivative **10** (yield: 87%–90%), which was condensed with NH_2-β-CD (8).

The identification of the relatively high molecular weight compounds involved in this synthetic pathway was first performed using ESI-MS then, after further purification, by NMR. The presence of crown-6 ether greatly facilitated the detection of the by-products via Cs^+ complexes, which are formed easily in the gas phase from crown-6-ether-containing compounds (19). In particular, we were able to follow the progress of the reactions by observing the presence of the stable crown–Cs^+ complex. For a second calixarene derivative (this one containing the biscrown moiety), the formation of doubly charged, two-Cs^+ cations was observed, along with the usual presence of protonation and of cationization by other alkali metal cations (20).

The NMR spectra of products recorded in solvents such as DMSO-d_6 or $CDCl_3$ displayed separate proton groups for the crown and sugar moieties, as well as for the aromatic and benzylic calixarene nuclei (21). The detailed analysis of the spectra of all molecules involved in this scheme is presented in the following sections (also see Experimental).

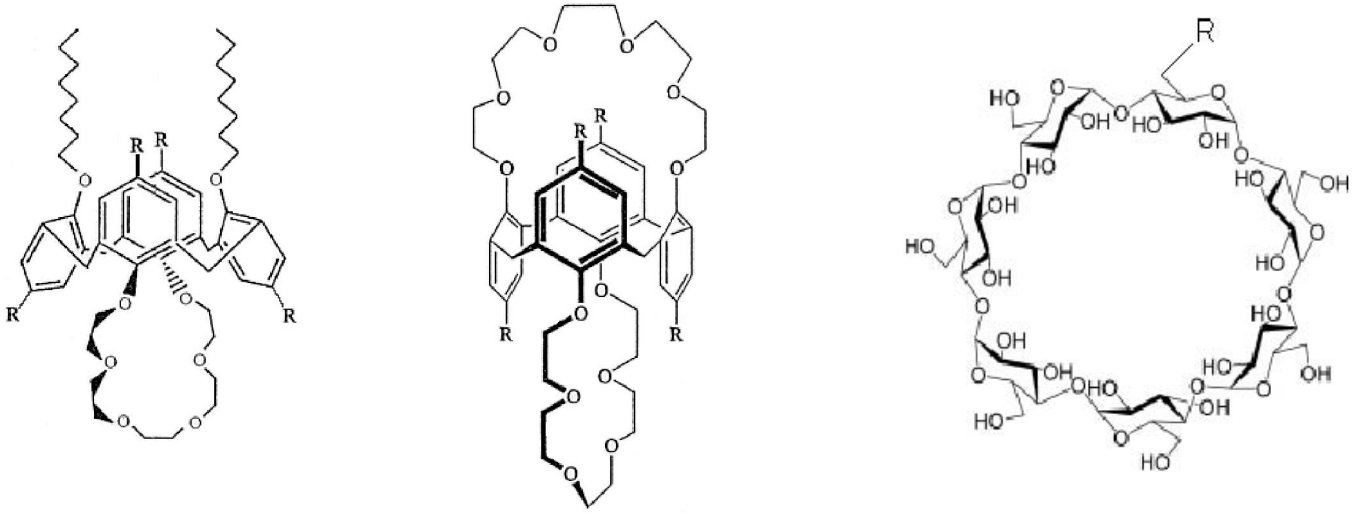
CD–CAL-crown coupling

Since both β-CD-amines and CAL-amines were available, as were their amino-succinates, we attempted to synthesize the (β-CD-NH-succ.-NH)$_n$-CAL via two separate methods (Fig. 1).

Condensation of amino-β-CD **8** with the tetra-*N*-succinyl derivative of octMC-6 **9** led to a mixture of products (yield: 30%). Two methods of coupling were attempted: firstly, by using the DCC or DIC coupling agents, according to the procedures developed in our laboratories (in particular with the modification of the DIC method by the addition of HOBt), and secondly, by the direct (but inefficient) coupling of the amine to the acid terminus of the mono-succinate (22).

For the octMC-6 series, analysis of the mixture of coupling products obtained via the DCC method revealed a small quantity (5%) of tetra-coupling product **12** (Table 1, n = 4, mass: 5775, detected by MALDI-TOF as MNa^+ and MK^+ ions), and a larger quantity (23%) of the diamide (n = 2, mass: 3543).

The diamides in this series were modelled: of the three isomers (cis-crown, cis-octyl, and trans), the lowest energy was calculated for the cis-crown isomer (219.87 kcal/mol), while both trans (241.90 kcal/mol) and cis-octyl (221.56 kcal/mol) isomers were more energetic. The cis-crown isomer is stabilized (relative to the trans isomer) by the hydrogen bonding between two neighboring cyclodextrin units. At this stage, we cannot confirm which of the cis (octyl and crown) or trans systems were formed.



The low solubility of these compounds as well as difficulty with both their crystallization and their purification through column chromatography led us to acetylate them prior to column chromatography separation. When acetylation of the final coupling mixture involving the octMC-6 was completed, the presence of two products, the first corresponding to acetylated dicyclodextrin calixarenes **18** (23) and the second to acetylated CD-dimer **19** resulting from the earlier-mentioned coupling of the amine **8** with the (succ.-NH)-β-CD **11** was confirmed. This compound had already been characterized as a methylated derivative of (β-CD-NH-CO-CH_2)$_2$ in the previous series. The MALDI-TOF for this compound revealed, however, its incomplete acetylation. The mass observed for (Ac-β-CD-NH-succ.-NH)$_n$octMC-6 (n = 4, **18**) (peracetylated twice with acetic anhydride) was closer to that of the total *O*-acetylation of 78 of 80 hydroxyls present, and it did allow the MALDI-TOF spectrum to be recorded (target mass of 9138.6). Purification through this route did not significantly improve the quality of products obtained.

For the BC-6 series, the only β-CD-coupled products obtained were from the coupling of **10** to **8** (yield: 26%). The major components of this mixture were (β-CD-NH-succ.-NH)$_2$(succ.-NH)$_2$BC-6 (**15**, mass: 3521) and, unexpectedly, the dimer compound (β-CD-NH-CO-CH_2)$_2$ (**16**) (complete

name: di-*N*,*N*′-[(mono-6′-deoxy-6′-amino-β-cyclomaltoheptaose)yl]succinamide), ratio 1:5. The coupling reaction (attempted via both the DCC and the DIC method) with **7** and **11** led only to the CD dimer resulting from the amino-β-CD and the residual succinic anhydride (total yield: 11%). To explain this result, the molecules of diamides **15** were modelled, revealing that the cis isomer was more stable (229.53 kcal/mol) than the trans isomer (256.98 kcal/mol). This is due to hydrogen bonding between the two cyclodextrin units in the cis isomer. Also, in this case, the crown-6 ring was flattened by this interaction.

A common feature of both coupling mixtures (for octMC-6 and BC-6) was (β-CD-NH-CO-CH_2)$_2$ (**16**) (24–27). Using ESI-MS, the presence of this product (mass: 2350, recorded as MNa^+ at *m*/*z* 2375) was then confirmed. The compound was compared to and characterized as its permethylated derivative **17** (mass: 2910, as MNa^+ at *m*/*z* 2933).

Initially, ESI-MS was used to identify these large molecules. In particular, the succinamides (from both sides of the synthetic scheme: amino-β-CD and amino-calixarene) showed the expected MH^+, MNa^+, and MCs^+ ions. For both series, the final coupling products were identified via MALDI-TOF.

The reversed coupling (of (succ.-NH)-β-CD (**11**) and (NH_2)$_4$octMC-6 (**6**)) produced a mixture of products with lesser yields (10%–15%). Even when the DCC method was used, the yield of cyclodextrin–calixarene coupled products was half as much.

Conclusion

The route from the amino-CAL coupled on (succ.-NH)-β-CD (**11**) gave smaller yields than the route from the tetrasuccinamido-CAL (where the linker is first fixed to the calixarene). This difference between the two coupling routes could be explained by the access to the coupling site on the bare tetraaminocalixarene being more hindered than for the equivalent site on the succinic-linked tetraaminocalixarene. The succinyl radical linked to the tetraaminocalixarene thus serves as a better spacer, which makes the coupling to NH_2-β-CD (**8**) slightly easier. This confirms the value of a longer linker for connecting with the NH_2-β-CD to realize the coupling with amino-CAL.

Another explanation for the lack of success in the formation of the coupling products in the BC-6 series is the hindrance within the BC-6 system, and (or) the stability of the tetrasuccinate (which demonstrated some hydrogen bonding between the NH and COOH groups of neighbouring systems). Molecular modelling of the succinates **9** and **10** showed that the presence of two long octyl chains disturbed the formation of this bonding relation for the octMC-6 series. In this way, the already-hindered access to the carboxylic group (even with the DCC coupling method) with the amine **8** gave lower yields because of this interaction.

The solubility of the final coupling products in most of the common organic solvents and the difficulty of separating them on a chromatographic column (because of their extreme polarity) remains a major experimental difficulty. In this respect, the use of permethylated or selectively methylated CD is a viable alternative to this route (28).

This successful assembling of calixarene to the β-CD ring, using the peptide-originated succinyl coupling via the DCC method, opens the way for further applications. For example, we can explore the connection of small peptides, and perhaps eventually use the calixarene platform with stereo-oriented amino groups to construct peptide helices (29, 30).

In particular, from the succ.-NH-calixarene in 1,3-alternate conformation we can build two double helix peptide chains, and from the cone conformation, the said self-supported quadruple helix. The certain originality of the method applied remains its versatility — if one failed to obtain the sequence from the succ.-NH-CAL route, the sequence from succ.-NH-CD could be more successful. Such an organization may afford solubilization and hosting sites affinities towards cations and neutral guests.

Experimental

Materials and methods

All chemicals used in this study were purchased from Aldrich Chemicals except the parent calixarenes bought from Acros Chemicals. The NH_2-β-CD was synthesized as described in ref. 16. The NMR spectra were recorded on Bruker 200, 300 (Chemagnetics), and 500 MHz spectrometers in DMSO-d_6, pyridine-d_5, D_2O, and $CDCl_3$ solutions as indicated. The ESI-MS spectra were recorded on a Quattro II Micromass apparatus (detailed as described in ref. 4). The MALDI-TOF spectra (UPMC, LCSOB, Paris, France) were recorded on a Voyager TM Elite, BioSpecRes Station (Applied Biosystems) with the 2550 Laser RDEHCCA method, pressure 2.71 e^{-7}, in positive ion mode, accelerating voltage 20 kV, on a DHB (dihydroxy benzoic alcohol) matrix. The molecular modelling was performed with the help of HyperChem (31).

General procedures

Nitration of octMC-6 1 and BC-6 (2)

500 mg of BC-6 (or octMC-6) were taken in 25 mL of CH_2Cl_2 in a three-necked 250 mL flask under nitrogen and continuous magnetic stirring and cooled to 0 °C. Then, 2 mL of fuming nitric acid were added and 2.5 mL of acetic anhydride with another 10 mL of CH_2Cl_2 that was added over a 15 min period. The temperature was slowly taken back to room temperature and the mixture was treated with triethylamine to alkaline pH then washed twice with 20 mL of satd. $NaHCO_3$ and NaCl. The organic layer was dried over anhydr. $MgSO_4$. After filtration and evaporation to dryness, the residue was purified on a silica gel (63–200 mesh) chromatographic column (for example with 5% MeOH in CH_2Cl_2) enabled to isolate the tetranitro compounds under constant TLC control. Yield (NMR pure compound): 75% (NO_2)$_4$octMC-6 (**4**), 55% (NO_2)$_4$BC-6 (**5**).

Tetra-p-*nitro-di*-n-*ocMC-6 (4)*

$C_{54}H_{70}N_4O_{16}$ (1031.2 g/mol), mp 184 °C. ^{1}H NMR (500 MHz, $CDCl_3$): 8.00–8.06 (8H, s, Ar*H* meta), 3.92, 4.00 (s, ArCH_2Ar), 3.73, 3.70, 3.66, 3.52, 3.50 (m, OCH_2 crown), 3.47 (octyl, H-1), 1.1–1.5 (octyl, H-2–H-7), 0.9 (octyl, H-8). ^{13}C NMR (125 MHz, $CDCl_3$): 161.5, 162.2 (Ar C-NO_2), 156.8, 156.3 (Ar C-OR), 142.1, 135.1, 122.4, 122.2 (Ar C-CH_2), 130.3, 130.0, 129.7, 125.5 (Ar C-H), 70.2–71.9 (OCH_2CH_2O crown 5C, octyl C1), 37.7, 37.2 (ArCH_2Ar),

14.0–37.0 (octyl C-2–C-8). ESI-MS *m/z* calcd.: 1054.2 (MNa^+), 1163.2 (MCs^+); found: 1053.4 (MNa^+), 1163.3 (MCs^+).

Tetra-p-*nitro-BC-6 (5)*

$C_{48}H_{56}N_4O_{20}$ (1009.0 g/mol). ^1H NMR (500 MHz, $CDCl_3$): 8.09 (s, 8H, ArH meta), 3.97 (s, 8H, ArCH_2Ar), 3.54, 3.50, 3.42, 3.41, 3.40 (m, ArCH_2Ar, OCH_2 crown). ^{13}C NMR (125 MHz, $CDCl_3$): 125.99, 134.21, 142.98, 161.52 (Ar), 69.39, 70.59, 70.66, 70.70, 70.84, 70.92, 71.03, 71.08, 71.65 (OCH_2 crown), 37.45 (ArCH_2Ar). ESI-MS *m/z* calcd.: 1032.0 (MNa^+), 1041.0 (MCs^+); found: 1031.3 (MNa^+), 1141.3 (Mcs^+).

Raney nickel reduction

300 mg of $(NO_2)_4$octMC-6 (**4**) (or $(NO_2)_4$BC-6, **5**) was taken in a three-necked 250 mL flask with 20 mL of anhydrous toluene and one spatula of Raney nickel (Aldrich 3800) and was put under nitrogen. The mixture was then connected to the hydrogen generator and put under an atmosphere of H_2 with vigorous magnetic stirring and heated to 70 °C for 3 h. The flask was transferred under nitrogen and the catalyst filtered (caution: Raney nickel with H_2 is a potential fire hazard in the lab on contact with atmospheric oxygen on dryness) on a VF4 Celite adsorbent. The toluene solution was evaporated to dryness under vacuum. Yield: 90% $(NH_2)_4$octMC-6 (**6**), 90% $(NH_2)_4$BC-6 (**7**).

Tetra-p-*amino-di*-n-*octMC-6 (6)*

$C_{54}H_{78}N_4O_8$ (911.2 g/mol), mp 160 °C. ^1H NMR (300 MHz, $CDCl_3$): 6.45 (4H, s, ArH octyl), 6.29 (4H, s, ArH crown), 3.61, 3.72, 3.80 (m, OCH_2CH_2O crown), 3.52 (2H, t, octyl H-1), 3.32 (8H, s, ArCH_2Ar), 3.30 (br, N*H*), 1.10–1.60 (m, octyl H-2–H-7), 0.8–0.9 (3H, t, octyl H-8). ^{13}C NMR (75 MHz, $CDCl_3$): 149.6 (Ar ipso octyl), 149.3 (Ar ipso crown), 140.8 (Ar para crown), 140.2 (Ar para octyl), 134.3 (Ar ortho octyl), 132.9 (Ar ortho crown), 118.4 (Ar meta crown), 117.6 (Ar meta octyl), 72.9 (C-1 octyl), 69.9–72.3 (OCH_2 crown), 36.4 (ArCH_2Ar), 22.0–32.0 (C-2–C-7 octyl), 14.3 (C-8 octyl). ESI-MS *m/z* calcd.: 1043.2 (MCs^+); found: 1043.3 (MCs^+).

Tetra-p-*amino-BC-6 (7)*

$C_{48}H_{64}N_4O_{12}$ (889.0 g/mol). ^1H NMR (300 MHz, $CDCl_3$): 6.50 (8H, s, ArH), 3.35 (8H, s, ArCH_2Ar), 3.67, 3.78, 3.86, 4.00 (m, OCH_2 crown), 3.75 (br, N*H*). ^{13}C NMR (75 MHz, $CDCl_3$): 149.2 (Ar ipso), 141.1 (Ar para), 132.9 (Ar ortho), 118.7 (Ar meta), 70.0–72.0 (OCH_2CH_2O crown), 36.3 (ArCH_2Ar). ESI-MS PI *m/z* calcd.: 1021.0 (MCs^+); found: 1021.4 (MCs^+).

Mono-6′-deoxy-6′-amino-cyclomaltoheptaose (8)

(Starting amino-CD for the reverse coupling). $C_{42}H_{71}NO_{34}$ (1133.9 g/mol), mp 190 °C. ^1H NMR (300 MHz, D_2O): 5.05–5.12 (7H, H-1 β-CD), 3.8–4.1 (H-3 β-CD amino, H-6 β-CD, H-5 β-CD, H-6 β-CD), 3.72 (dd, br, H-4 β-CD), 3.62 (t, br, H-2 β-CD), 3.53 (t), 3.22 (d, H-6′ β-CD), 2.98 (dd, H-6″ β-CD). ^{13}C NMR (75 MHz, D_2O): 102.5 (C-1), 83.5 (C-4 β-CD′), 82.0 (C-4, β-CD), 72–75 (C-2, C-3, C-5), 61.3 (C-6), 41.3 (C-NH_2). ESI-MS PI *m/z* calcd.: 1134.9 (MH^+); found: 1134.7 (MH^+).

N-*Succinylation of amines*

171 mg of (NH_2)BC-6 (or 252 mg of (NH_2)octMC-6 or 986.5 mg (NH_2)-β-CD) compound was reacted with 87 mg of succinic anhydride in 5 mL of DMF at room temperature for 12 h, then lyophilized to dryness and analyzed via ESI-MS or MALDI-TOF and NMR. Yield: 90% (succ.-NH)$_4$octMC-6 (**9**), 85% (succ.-NH)$_4$BC-6 (**10**), 90% (succ.-NH) β-CD (**11**).

(Succ.-NH)$_4$octMC-6 (9)

$C_{70}H_{94}N_4O_{20}$ (1311.5 g/mol). ^1H NMR (500 MHz, DMSO-d_6): 7.43, 7.45 (s, 8H, ArH meta), 3.0–4.0 (m, OCH_2 crown, ArCH_2Ar), 2.59, 2.62 (CH_2 succ.), 1.00–1.35 (m, octyl C-1–C-7), 0.95 (t, 3H, octyl C-8). ^{13}C NMR (125 MHz, DMSO-d_6): 174.0, 169.4, 169.0 (-CO-succ.), 152.3, 151.7, 133.9, 134.1, 133.8, 133.4, 119.6, 119.3 (Ar), 70.0, 69.9, 69.5, 68.9 (OCH_2 crown), 10.0–40.0 (ArCH_2Ar, octyl C-1–C-8), 29.38, 29.19 (CH_2 succ.), 14.20 (octyl C-8). ESI-MS *m/z* calcd.: 1443.5 (MCs^+); found: 1443.6 (MCs^+).

(Succ.-NH)$_4$BC-6 (10)

$C_{64}H_{80}N_4O_{24}$ (1289.3 g/mol). ^1H NMR (500 MHz, DMSO-d_6): 7.43 (s, 8H, ArH meta), 3.00–4.00 (m, OCH_2 crown, ArCH_2Ar), 2.50–2.60 (m, CH_2 succ.). ^{13}C NMR (125 MHz, DMSO-d_6): 173.94, 169.41 (-CO- succ.), 151.88, 133.99, 133.43, 119.41 (Ar), 69.98, 69.43, 68.95, 68.41 (OCH_2 crown), 37.88 (ArCH_2Ar), 29.07, 28.92 (CH_2 succ.). ESI-MS *m/z* calcd.: 1421.3 (MCs^+); found: 1421.4 (MCs^+).

Mono-6′-deoxy-6′-amidosuccinyl-cyclomaltoheptaose (11)

$C_{46}H_{75}NO_{37}$ (1234.1 g/mol), mp 155–159 °C. ^1H NMR (500 MHz, Pyr-d_5): 8.67 (t, 1H, NH_{CD}, $^3J_{NH\text{-}6^I}$ = 5.7 Hz), 7.4–7.9 (14 O*H*), 5.51–5.61 (6H, H-$1^{II\text{-}VII}{}_{CD}$), 5.45 (d, 1H, H-$1^I{}_{CD}$, $^3J_{1^I\text{-}2^I}$ = 3.5 Hz), 4.63–4.78 (H-$3^{II\text{-}VII}{}_{CD}$), 4.64 (H-$3^I{}_{CD}$), 4.62–4.69 (H-$6^{II\text{-}VII}{}_{CD}$), 4.31–4.57 (H-$5^{II\text{-}VII}{}_{CD}$/H-$6'^{II\text{-}VII}{}_{CD}$), 4.46 (H-$5^I{}_{CD}$), 4.04–4.27 (H-$4^{II\text{-}VII}{}_{CD}$), 4.19 (H-$6^I{}_{CD}$), 4.12 (H-$6'^I{}_{CD}$), 3.98–4.11 (H-$2^{II\text{-}VII}{}_{CD}$), 3.88 (H-$2^I{}_{CD}$), 3.87 (H-$4^I{}_{CD}$), 2.77–2.94 (4H, Hb/Hc, syst. AA′B). ^{13}C NMR (75 MHz, DMSO-d_6): 101.8 (C-1), 81.4 (C-4), 71–73 (C-2, C-3, C-5), 59.8 (C-6), 29.2–29.8 (CH_2CH_2 succ.). ESI-MS *m/z* calcd.: 1235.1 (MH^+); found: 1234.9 (MH^+).

Coupling reaction

181 mg of NH_2-β-CD (**8**) was put together with 46 mg of (succ. NH)$_4$octMC-6 (**9**) (or 45 mg of (succ. NH)$_4$BC-6 (**10**)) with the help of DCI (30 μL) and HOBt (30 mg) in 2.5 mL of DMF for over 24 h. The mixture was separated on silica gel (63–200 mesh) with 5% MeOH (in CH_2Cl_2) then with 10% MeOH (in CH_2Cl_2). Yield: 6% (β-CD-NH-succ.-NH)$_2$(succ.-NH)$_2$-BC-6 (**15**), 25% (β-CD-NH-succ-NH)$_4$octMC-6 (**12**), 5% (β-CD-NH-succ.-NH)$_2$(succ.-NH)$_2$-octMC-6 (**13**).

(β-CD-NH-succ.-NH)$_2$(succ.-NH)$_2$-octMC-6 (13)

$C_{154}H_{232}N_6O_{86}$ (3543.5 g/mol). ^1H NMR (200 MHz, DMSO-d_6): 5.10–5.30 (m, H-1, CD), 3.40–3.75 (OCH_2 crown, C-1 octyl, ArCH_2Ar, C*H* β-CD), 2.50–2.75 (CH_2, succ.), 0.85–1.50 (m, octyl). MALDI-TOF *m/z* calcd.: 3544.5 (MH^+), 3566.5 (MNa^+); found: 3543 (MH^+), 3566 (MNa^+).

(β-CD-NH-succ.-NH)$_4$-octMC-6 (12) (selected data)

$C_{238}H_{370}N_8O_{152}$ (5775.4 g/mol). Yield: total 30% (**12** and **13**). ^1H NMR (200 MHz, DMSO-d_6): 7.60 (m br, N*H*), 7.50 (m, Ar*H*), 5.10–5.30 (m, H-1, β-CD), 3.50–4.60 (m, OCH_2

Viscosities of some tetraalkylammonium bromides in 2-ethoxyethanol at 308.15, 313.15, 318.15, and 323.15 K

Purushottam Haldar and Bijan Das

Abstract: The viscosities of the solutions of tetraethylammonium bromide (Et_4NBr), tetrapropylammonium bromide (Pr_4NBr), tetrabutylammonium bromide (Bu_4NBr), tetrapentylammonium bromide (Pen_4NBr), and tetraheptylammonium bromide (Hep_4NBr) in 2-ethoxyethanol have been reported at 308.15, 313.15, 318.15, and 323.15 K. The viscosity data have been analyzed by the Jones–Dole equation for the associated electrolytes to evaluate the viscosity *B* coefficients of the electrolytes. These data have also been analyzed by the transition-state treatment to obtain the contribution of the solutes to the free energy of activation for viscous flow of the solution. The viscosity of the solvent is found to be greatly modified by the presence of all of the tetraalkylammonium ions investigated. Moreover, the tetraalkylammonium ions are found to be unsolvated in 2-ethoxyethanol solutions, they behave neither as structure-breaker nor as structure-maker and the formation of the transition state is made less favorable in their presence.

Key words: viscosity, electrolytes, tetraalkylammonium ion, 2-ethoxyethanol, ionic contribution, solvation, transition-state treatment.

Résumé : On a mesuré les viscosités de solutions du bromure de tétraéthylammonium (Et_4NBr), du bromure de tétrapropylammonium (Pr_4NBr), du bromure de tétrabutylammonium (Bu_4NBr), du bromure de tétrapentylammonium (Pen_4NBr), et du bromure de tétraheptylammonium (Hep_4NBr) dans le 2-éthoxyéthanol, à 308,15, 313,15, 318,15 et 323,15 K. Les données de viscosité ont été analysées à l'aide de l'équation de Jones–Dole pour les électrolytes associés afin d'évaluer leurs coefficients *B* de viscosité. On a aussi analysé ces données par le traitement de l'état de transition afin de pouvoir obtenir les contributions des solutés à l'énergie libre d'activation. On a trouvé que la viscosité du solvant est grandement modifiée par la présence de chacun des ions tétraalkylammonium étudiés. Des plus, on a trouvé que les ions tétraalkylammonium ne sont pas solvatés dans les solutions de 2-éthoxyéthanol, qu'ils n'agissent ni pour briser ni pour former des structures et que la formation de l'état de transition est rendue moins favorable en raison de leur présence.

Mots clés : viscosité, électrolytes, ion tétraalkylammonium, 2-éthoxyéthanol, contribution ionique, solvatation, traitement de l'état de transition.

[Traduit par la Rédaction]

Introduction

Recently, we initiated a comprehensive program to study the solvation and association behavior of several 1:1 electrolytes in different nonaqueous solvents from the measurements of various transport, thermodynamic, and spectroscopic properties (1–5). As a part of this series of investigations, we have, very recently, reported (6, 7) the results of conductance measurements on a number of tetraalkylammonium salts, e.g., tetraethylammonium bromide (Et_4NBr), tetrapropylammonium bromide (Pr_4NBr), tetrabutylammonium bromide (Bu_4NBr), tetrapentylammonium bromide (Pen_4NBr), and tetraheptylammonium bromide (Hep_4NBr) in 2-ethoxyethanol at 308.15, 313.15, 318.15, and 323.15 K. We have now extended this work to study the viscometric behavior of these electrolyte solutions since viscometry is well-suited to provide information concerning the solvation of the ions and their effects on the structure of the solvent in the near environment of the solute particles (8–10).

Experimental

2-Ethoxyethanol (G.R.E. Merck, India) was dried with potassium carbonate and distilled twice in an all-glass distillation set immediately before use and the middle fraction was collected. The densities and viscosities of 2-ethoxyethanol at 308.15, 313.15, 318.15, and 323.15 K are reported in Table 1. The physical properties of the purified solvent are found to be in good agreement with the literature values (11–15). Also included in this table are the relative permittivities (ε) of 2-ethoxyethanol at different temperatures obtained from the literature (7, 11).

Tetraalkylammonium bromides were of purum or puriss grade (Fluka, Switzerland) and were purified as described in the literature (16). These salts were purified by recry-

318.15	0.909 94		1.189 3		12.25
323.15	0.906 02		1.087 1		11.99

stallization and the higher homologues (tetrapentylammonium bromide and tetraheptylammonium bromide) were recrystallized twice to ensure maximum purity. The recrystallized salts were dried in vacuo at elevated temperatures for 12 h immediately prior to use.

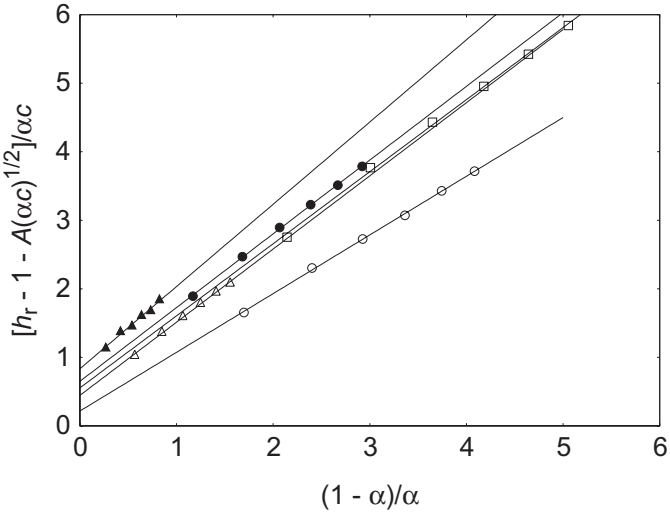
The kinematic viscosities (ν) were measured by means of a suspended level Ubbelohde viscometer. The viscometer was kept in a vertical position in a water thermostat controlled to ±0.01 K. The kinematic viscosity (ν) and the absolute viscosity (η) are given by the following equations:

$$[1] \qquad \nu = Ct - K/t$$

$$[2] \qquad \eta = \nu\rho$$

where t is the efflux time, ρ is the density, and C and K are the characteristic constants of the viscometer. The values of the constants C and K, determined by using the density and the viscosity values of water and 2-methoxyethanol (17), were found to be 1.646×10^{-5} cm^2 s^{-2} and –0.023 316 47 cm^2, respectively. The calibration constants were also checked with methanol (18). The estimated error of the viscosity measurements was ±0.05%. The required densities (ρ) were measured with an Ostwald–Sprengel type pycknometer having a bulb volume of 25 cm^3 and an internal diameter of the capillary of about 0.1 cm. The relative viscosity (η_r) was obtained as the ratio of the absolute viscosity of the solution (η) to that of the pure solvent (η_0).

The solutions were prepared by mass for the viscosity runs, the molalities being converted to molarities by the use of densities. To avoid moisture pick-up, all solutions were prepared in a dehumidified room with utmost care. In all cases, the experiments were performed at least in five replicates for each solution and the results were averaged. Several independent solutions were prepared and the runs were performed to ensure the reproducibility of the results.



Results and discussion

The measured relative viscosities (η_r) and densities (ρ) of electrolyte solutions as functions of molar concentrations (c) at 308.15, 313.15, 318.15, and 323.15 K are given in Table 2.

The relative viscosities of the electrolytes in solution are generally analyzed by the Jones–Dole equation (19):

$$[3] \qquad \eta_r = 1 + Ac^{1/2} + Bc$$

Fig. 1. Variation of $[\eta_r - 1 - A(\alpha c)^{1/2}]/\alpha c$ against $(1 - \alpha)/\alpha$ at 308.15 K in 2-ethoxyethanol for Et_4NBr (○), Pr_4NBr (△), Bu_4NBr (□), Pen_4NBr (●), and Hep_4NBr (▲).

where A and B, the characteristic parameters for salt and solvent, depend on ion–ion and ion–solvent interactions, respectively.

As the electrolytes investigated here are found to be somewhat associated from our earlier conductivity measurements (6, 7), the viscosity data have been analyzed by the following equation (9):

$$[4] \qquad \eta_r = 1 + A(\alpha c)^{1/2} + B\alpha c + B'(1 - \alpha)c$$

Here A, B, and B' are the characteristic constants and α is the degree of dissociation of the ion pair.
Equation [4] can be rearranged to give

$$[5] \qquad \frac{[\eta_r - 1 - A(\alpha c)^{1/2}]}{\alpha c} = B + B'\left(\frac{1-\alpha}{\alpha}\right)$$

For the evaluation of B coefficients from eq. [5], plots of $[\eta_r - 1 - A(\alpha c)^{1/2}]/\alpha c$ against $(1 - \alpha)/\alpha$ were constructed. These were found to be linear in all cases. A representative plot displays the variation of $[\eta_r - 1 - A(\alpha c)^{1/2}]/\alpha c$ against $(1 - \alpha)/\alpha$ at 308.15 K (Fig. 1). The values of α were calculated from the conductance data (6, 7) using the equations described in the literature (9). The A values were calculated theoretically from the physical parameters of the solvent and the limiting ionic equivalent conductances using the Falkenhagen and Vernon equation (20):

$$[6] \qquad A = \frac{0.2577\Lambda^0}{\eta_0(\varepsilon T)^{1/2}\lambda_+^0\lambda_-^0}\left[1 - 0.6863\left(\frac{\lambda_+^0 - \lambda_-^0}{\Lambda^0}\right)^2\right]$$

where η_0 is the coefficient of viscosity of the solvent, ε is its relative permittivity, T is the temperature in absolute scale, and Λ^0, λ_+^0, and λ_-^0 are the limiting equivalent conductivities of the electrolyte, cation, and anion, respectively. The values of the A coefficients thus obtained are recorded in Table 3. These have been used for the analysis of the viscosity data. The viscosity B coefficients have also been included in Table 3.

The viscosity data have also been analyzed on the basis of the transition-state treatment of the relative viscosity of electrolyte solutions, as suggested by Feakins et al. (21):

$$[7] \qquad B = \frac{\overline{V}_1^0 - \overline{V}_2^0}{1000} + \frac{\overline{V}_1^0}{1000}\left(\frac{\Delta\mu_2^{0\neq} - \Delta\mu_1^{0\neq}}{RT}\right)$$

In the above equation, $\overline{V}_1^0$ and $\overline{V}_2^0$ are the partial molar volumes of the solvent and solute, respectively. The contribution per mol of solute to the free energy of activation for viscous flow of the solution ($\Delta\mu_2^{0\neq}$) has been determined from the above relationship and is reported in Table 3. The free energy of activation per mol of the pure solvent ($\Delta\mu_1^{0\neq}$) is given by the equation:

$$[8] \qquad \Delta\mu_1^{0\neq} = \Delta G_1^{0\neq} = RT \ln\left(\frac{\eta_0 \overline{V}_1^0}{hN}\right)$$

where N is Avogadro's number and the other symbols have their usual significance.

The activation parameters for viscous flow for the electrolytes obtained from eq. [7] are given in Table 3.

The viscosity B coefficients shown in Table 3 are large and positive for all the electrolytes studied. The B values for the tetraalkylammonium bromides increase regularly as we go from tetraethylammonium bromide through tetraheptylammonium bromide. From this table, we see that $\Delta\mu_2^{0\neq}$ values for all the electrolytes are also large and positive, and they follow the same pattern as the B values.

To investigate the specific behavior of the individual ions comprising these electrolytes, it is necessary to split the viscosity B coefficients into their ionic components.

Krumgalz (22) proposed a method, to be applied for nonaqueous solvents, based on his contention that the larger tetraalkylammonium ions are essentially unsolvated in such solvents. Plots of the B coefficients of the iodides of these cations in several organic solvents against the cubes of the radii of the ions are indeed found to be linear for Bu_4N^+ and larger cations, values being known upto Hep_4N^+ (22). The intercepts of the straight lines then give the B coefficient of the counterion, iodide.

$$[9] \qquad B(R_4N^+) = B(I^-) + br^3_{R_4N^+}$$

The slope depends on the solvent and the temperature. The B coefficient of Pr_4NI may conform to the straight line ob-

tained using the larger cations in some solvents and not in others, whereas the values for Et_4NI and Me_4NI generally fall below the line. Possibly, the position of these tetraalkylammonium ions are caused by the shape of these ions during the viscous flow process in 2-ethoxyethanol making a relatively smaller contribution to B values. This would result from a more compact arrangement of the alkyl groups around the central nitrogen.

Since the tetraalkylammonium ions investigated in this work are found to be unsolvated in 2-ethoxyethanol from our earlier conductivity study (6, 7), the method of Krumgalz (22) described previously should, in principle, be applicable to the present viscosity data. In fact, we obtained very good straight lines (cf. Fig. 2) for tetraalkylammonium bromides with tetrapropylammonium and larger cations when $B(R_4NBr)$ values are plotted against the cubes of the radii of the cations (r) obtained from the literature (23–25) at all temperatures investigated (Et_4NBr being an exception, B coefficients of which always fall below the lines). The ionic viscosity B coefficients obtained following the Krumgalz method (22) are given in Table 4.

The observed order of the viscosity B values for the tetraalkylammonium ions (Table 3), $Hep_4N^+ > Pen_4N^+ > Bu_4N^+ > Pr_4N^+ > Et_4N^+$ (anion being common), shows that the obstruction of the solvent viscous flow increases with an increase in the size of these species in solution. This clearly

Fig. 2. Representative plot for the variation of the viscosity B coefficient of the tetraalkylammonium bromides against the cube of the cationic radius in 2-ethoxyethanol at 308.15 K (○), 313.15 K (△), 318.15 K (□), and 323.15 K (●).

indicates a lack of solvation of these ions in 2-ethoxyethanol solutions. Had these ions been solvated in 2-ethoxyethanol, the smaller ions with greater charge density would have been more solvated and the order of the ionic viscosity B coefficients would have been in the reverse order, which is, obviously, not the case here.

Figure 3 shows the temperature dependence of the viscosity B coefficients of the bromide and tetraalkylammonium ions in 2-ethoxyethanol. For all the ions studied, the B values are positive and their temperature coefficients are small; although positive coefficients are exhibited by the tetraalkylammonium ions, they are negligibly small. Bromide ion, however, shows a comparatively larger negative temperature coefficient. The temperature dependence of the B coefficients for the tetraalkylammonium ions in methanol, *N*-methyl-

Fig. 3. Temperature dependence of the ionic viscosity *B* coefficients in 2-ethoxyethanol for Br^- (△), Et_4N^+ (○), Pr_4N^+ (□), Bu_4N^+ (▲), Pen_4N^+ (●), and Hep_4N^+ (■).

formamide, *N*-methylpropionamide, and *N*-methylacetamide are also small (10, 26, 27), and we find the same behavior in the present solvent medium. This finding is in sharp contrast to the abnormally large temperature dependence of the *B* coefficients in water (10), and the remarkable difference can be ascribed to the extensive, hydrogen-bonded structure of water. The negligibly small d*B*/d*T* values of the tetraalkylammonium ions indicate that they behave neither as structure breaker nor as structure maker in 2-ethoxyethanol, whereas the negative d*B*/d*T* value for bromide ion in this medium demonstrates its structure-making behavior.

The ionic free energies of activation for viscous flow ($\Delta\mu_2^{0\neq}$, ion) based on a method similar to that used for the separation of the viscosity *B* coefficients have been presented in Table 4. The $\Delta\mu_2^{0\neq}$ values of the tetraalkylammonium ions are always found to be positive, thus indicating that the formation of the transition state is made less favorable in the presence of these ions. The ionic $\Delta\mu_2^{0\neq}$ values in the present series of tetraalkylammonium ions increase steadily with the formula weight of the cations (cf. Table 4); this behavior is reasonable when solvation effects are not overriding.

Solid lithium perchlorate as a powerful catalyst for the synthesis of β-aminoalcohols under solvent-free conditions

Najmodin Azizi and Mohammad R. Saidi

Abstract: Lithium perchlorate catalyzed the ring opening of epoxides with amines to provide the corresponding β-aminoalcohols in excellent yields with high regioselectivity. The reaction proceeds rapidly under mild and neutral conditions and worked well with primary, secondary, aliphatic, aromatic, and hindered amines in short times at room temperature, in the absence of solvent.

Key words: epoxide, lithium perchlorate, β-aminoalcohols, solvent-free.

Résumé : Le perchlorate de lithium catalyse l'ouverture de cycle des époxydes avec des amines qui conduit aux β-aminoalcools correspondants avec d'excellents rendements et une régiosélectivité élevée. La réaction se produit rapidement dans des conditions douces et neutres et elle se produit rapidement avec les amines primaires, secondaires, aliphatiques, aromatiques et empêchées, à la température ambiante et en l'absence de solvant.

Mots clés : époxyde, perchlorate de lithium, β-aminoalcools, sans solvant.

[Traduit par la Rédaction]

Introduction

β-Aminoalcohols are versatile intermediates in the synthesis of a vast variety of biologically active natural and synthetic products (1), unnatural amino acids (2), and chiral auxiliaries for asymmetric synthesis (3). The classical synthesis of β-aminoalcohols consists of heating an epoxide with an excess of amine at elevated temperatures (4). High temperatures may not be appropriate for certain functional groups. Also, a variety of air-sensitive or expensive catalysts had been reported in the literature to perform epoxide opening at room temperature. Many of these catalysts are either corrosive, or in some cases, they are being applied to aromatic amines with poor regioselectivity and with undesirable side reactions such as rearrangement and polymerization (5–7). However, there are still some limitations with the reported methods in the literature. For example, deactivated amines failed to open up the epoxides or require high temperatures. Furthermore, they require a high catalyst-to-substrate ratio, have a long reaction time, and they need volatile organic solvents that eventually results in the generation of a large amount of toxic waste. To overcome these limitations, the development of a better catalyst for the activation of epoxides, rendering them more susceptible to nucleophilic attack under a mild, efficient, and general method, is of great interest.

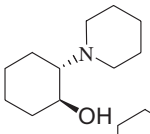
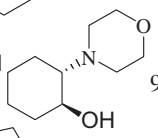
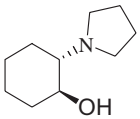
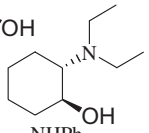
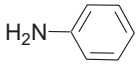
In recent years, to minimize the harmful organic solvents used in chemical processes, much attention has been devoted to the use of alternative media. Besides the use of supercritical fluid water and ionic liquids, the possibility of performing chemical reactions in the absence of solvent has been receiving more attention (8).

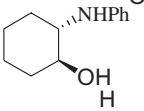


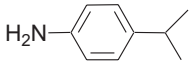


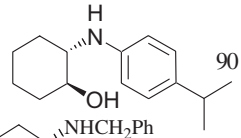


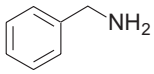


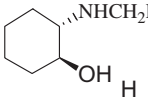


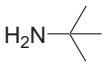


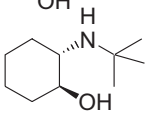












Results and discussion

Because of our interest for developing solvent-free and environmentally benign synthetic methods (9), herein, we report a more simple, general, and new catalytic route for the synthesis of β-aminoalcohols via opening of epoxides with amines under solvent-free conditions in the presence of a catalytic amount of $LiClO_4$. At first, we examined the reaction of cyclohexene oxide with aniline and 0.2 equiv. of solid $LiClO_4$ at room temperature. Complete conversion took place within 120 min, leading to quantitative yield of *trans*-2-phenyl amino cyclohexanol. This success encouraged us to exploit the generality and scope of this reaction for the opening of other epoxides with various aromatic and aliphatic amines under catalytic amounts of $LiClO_4$. The reaction proceeded well with aromatic, aliphatic, hindered, and unhindered amines. The role of $LiClO_4$ in catalyzing the opening of epoxide rings with amines maybe realized through the coordination of Li^+ with the epoxide oxygen and renders the epoxide more susceptible to nucleophilic attack by the amine, which after protonation forms the aminoalcohol (Table 1).

In the next step, we have examined various amines using styrene oxide as the unsymmetrical epoxide to investigate the regioselectivity outcome of the reaction. In all cases, the ring openings take place in highly regioselective fashion, affording the β-aminoalcohols in high yields. It should also be

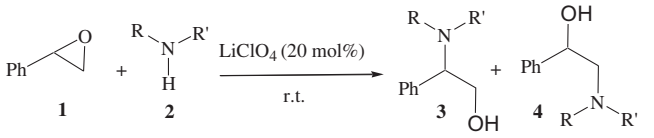
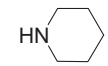
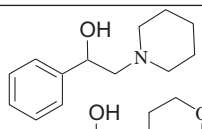
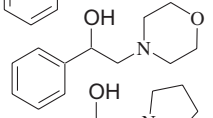
mentioned that without using solid $LiClO_4$, no reaction was observed among various amines and styrene oxide. On each occasion, the regioselectivity and the ratio of the two regioisomers were determined by ^1H NMR and by comparison with the reported value in the literature (6, 7).

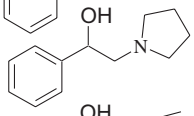


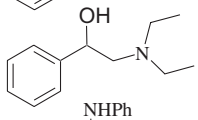
In conclusion, we have shown that $LiClO_4$ is a new, highly efficient catalyst for the opening of epoxides with amines leading to the synthesis of β-aminoalcohols. In fact, this reaction proceeds smoothly in solvent-free conditions, which is an important feature for the development of green chemistry.

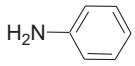


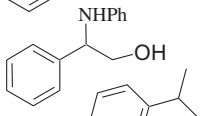


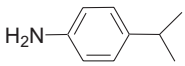


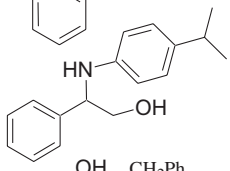


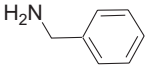


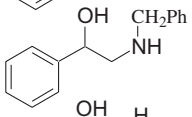


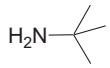


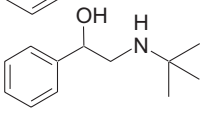












Experimental

General procedure for the preparation of β-aminoalcohols

To a mixture of epoxide (5 mmol) and amine (6 mmol) in the test tube, anhydr. $LiClO_4$ was added (0.1 g), and the mixture was stirred at room temperature for 30–180 min. When the reaction was completed, as indicated by TLC or GC, the reaction mixture was diluted with diethyl ether or ethyl acetate (15 mL) and washed with water; the organic phase was separated, dried with Na_2SO_4, and solvent was removed using a rotary evaporator. In all cases, almost pure compound was obtained. Further purification was carried out by short column chromatography on silica gel (ethyl acetate – petroleum ether). All compounds were characterized on the basis of their spectroscopic data (IR, NMR, and GC) and by comparison with those reported in the literature (Table 2).

^{29}Si NMR studies on the mechanism of dehydrocoupling of hydrosilanes with hydroxylic reagents in DMF — The role of DMF

Jerzy J. Chruściel

Abstract: Interactions of DMF with hydrosilanes were studied by ^{29}Si NMR. New resonance signals were observed in the ^{29}Si NMR spectra of $HMe_2SiOSiMe_2H$ and some (alkoxy)hydrosilanes for high ratios of concentrations [DMF]/[H-silane] at 25 °C. The intensities of new signals increased several times at –60 °C. It seems that these new resonances correspond to molecular complexes of DMF with hydrosilanes. The role of DMF in the mechanism of dehydrocoupling of hydrosilanes with hydroxylic reagents in the presence of Zn(II) and Cd(II) halides (X = Cl, Br, I) is discussed. Some common features of the reaction mechanism with the mechanism of hydride transfer from the Si—H bond to the carbenium ion are discussed.

Key words: hydrosilanes, hydroxylic reagents, reaction mechanism of dehydrocoupling in DMF, ^{29}Si NMR.

Résumé : Faisant appel à la RMN du ^{29}Si, on a étudié les interactions du DMF avec les hydrosilanes. À 25 °C et à des rapports élevés des concentrations [DMF]/[H-silane], on a observé de nouveaux signaux de résonance dans les spectres RMN du ^{29}Si du $HMe_2SiOSiMe_2H$ et de quelques (alkoxy)hydrosilanes. Les intensités des nouveaux signaux ont augmenté à quelques reprises à –60 °C. Il semble que ces nouvelles résonances correspondent à la formation de complexes moléculaires du DMF avec les hydrosilanes. On discute du rôle du DMF dans le mécanisme de déshydrocouplage des hydrosilanes avec les réactifs hydroxylés, en présence d'halogénures (X = Cl, Br, I) de Zn(II) et de Cd(II). On discute aussi de caractéristiques communes du mécanisme réactionnel avec le mécanisme de transfert d'hydrure de la liaison Si—H à l'ion carbénium.

Mots clés : hydrosilanes, réactifs hydroxylés, mécanisme de réaction du déshydrocouplage dans le DMF, RMN du ^{29}Si.

[Traduit par la Rédaction]

Introduction

A great number of publications have been devoted to the studies of the mechanism of the nucleophilic substitution of hydrogen at silicon (1–12). Dehydrocoupling reactions of hydrosilanes with nucleophilic reagents containing a hydroxyl group:

[1] $$\geq Si-H + HO-R \xrightarrow{Cat.} \geq Si-OR + H_2$$

find many practical applications, and especially in the synthesis of alkoxysilanes, acetoxysilanes, silanols, block siloxanes, and different derivatives of poly(methylsiloxanes) (13, 14). Precious contributions to acid-promoted solvolysis of hydrosilanes were made by Eaborn (2) and Nahlovský and Chvalovský (15, 16), and to the base-promoted solvolysis of hydrosilanes by Schowen and co-workers (17) and Eaborn and Jenkins (18). Reaction rates of the solvolysis of hydrosilanes strongly depend on their structure and medium effects (19–24). Usually, the reaction is catalyzed either by nucleophilic or electrophilic catalysts: bases, acids, metals, metal and tetralkylammonium salts, and metal complexes (13).

In dimethylformamide (DMF) medium, in the presence of zinc and cadmium halides as catalysts, *dehydrocoupling* of hydrosilanes with hydroxylic reagents *proceeds through a new mechanism of the nucleophilic substitution of the Si—H bond with reagents containing a hydroxyl group, because of zero order with respect to hydroxyl groups. It has been found to be first order in hydrosilanes and catalysts* (25–29). The driving force of the reaction is an electrophilic attack of active ionic forms of catalysts (Zn^{2+} or Cd^{2+}) on the hydrogen atom of the Si—H bond, as it was concluded from investigations of the effect of the common anion with the catalyst on reaction rates (29). The reaction is enthalpy-controlled. The high negative entropy of activation ($\Delta S^{\ddagger}$ = –30 to –35 eu) showed a highly complex and polar structure of the transition state (27). The low negative Hammett reaction constant (ρ = –0.12) and the low deuterium kinetic isotope effect (k_H/k_D = 1.4–1.5) suggested that the intermediate complex has an unsymmetrical nonlinear (bent) structure, and a high bond order for the Si—H (25).

Studies of DMF concentration on rates of reaction of triethylsilane with diphenylsilanediol and benzoic acid towards $ZnCl_2$ and $CdBr_2$, in solutions of DMF (n_{DMF}) with tetra-

hydrofuran (THF) and 1,4-dioxane, allowed us (30) to determine the reaction order with respect to DMF, which was dependent on the concentration of DMF. At lower concentrations of DMF, $n_{DMF} = 2$ was obtained. In less polar solvents (benzene, toluene, ether, THF), even at reflux, dehydrocoupling of tertiary hydrosilanes with hydroxylic reagents doesn't take place in the presence of Zn(II) and Cd(II) halides without cocatalysis by DMF molecules.

In this paper, results of the studies of interactions of hydrosilanes with DMF by means of ^{29}Si NMR spectroscopy are presented. The role of DMF in the mechanism of dehydrocoupling of hydrosilanes with hydroxylic reagents in the presence of Zn(II) and Cd(II) halides is discussed.

Experimental

Reagents

Syntheses and purification of some hydrosilanes, diphenylsilanediol, and the purification of DMF are described elsewhere (25, 27). All hydrosilanes were dried with $MgSO_4$ or molecular sieves (4 Å) and fractionally distilled. Their purity was controlled by GC (99.9%) and NMR. Ph_2MeSiH (Gelest, Inc., Tullytown, Penn.) was fractionally distilled at a bp of 138.5 °C / 11 torr (1 torr = 133.322 4 Pa). 1,1,3,3-Tetramethyldisiloxane was prepared by a hydrolytic condensation of HMe_2SiCl in ether at 0 °C (bp 70.5–71 °C, n_D^{20} = 1.3700). The physical data for the organosilicon compounds are available from ref. 31.

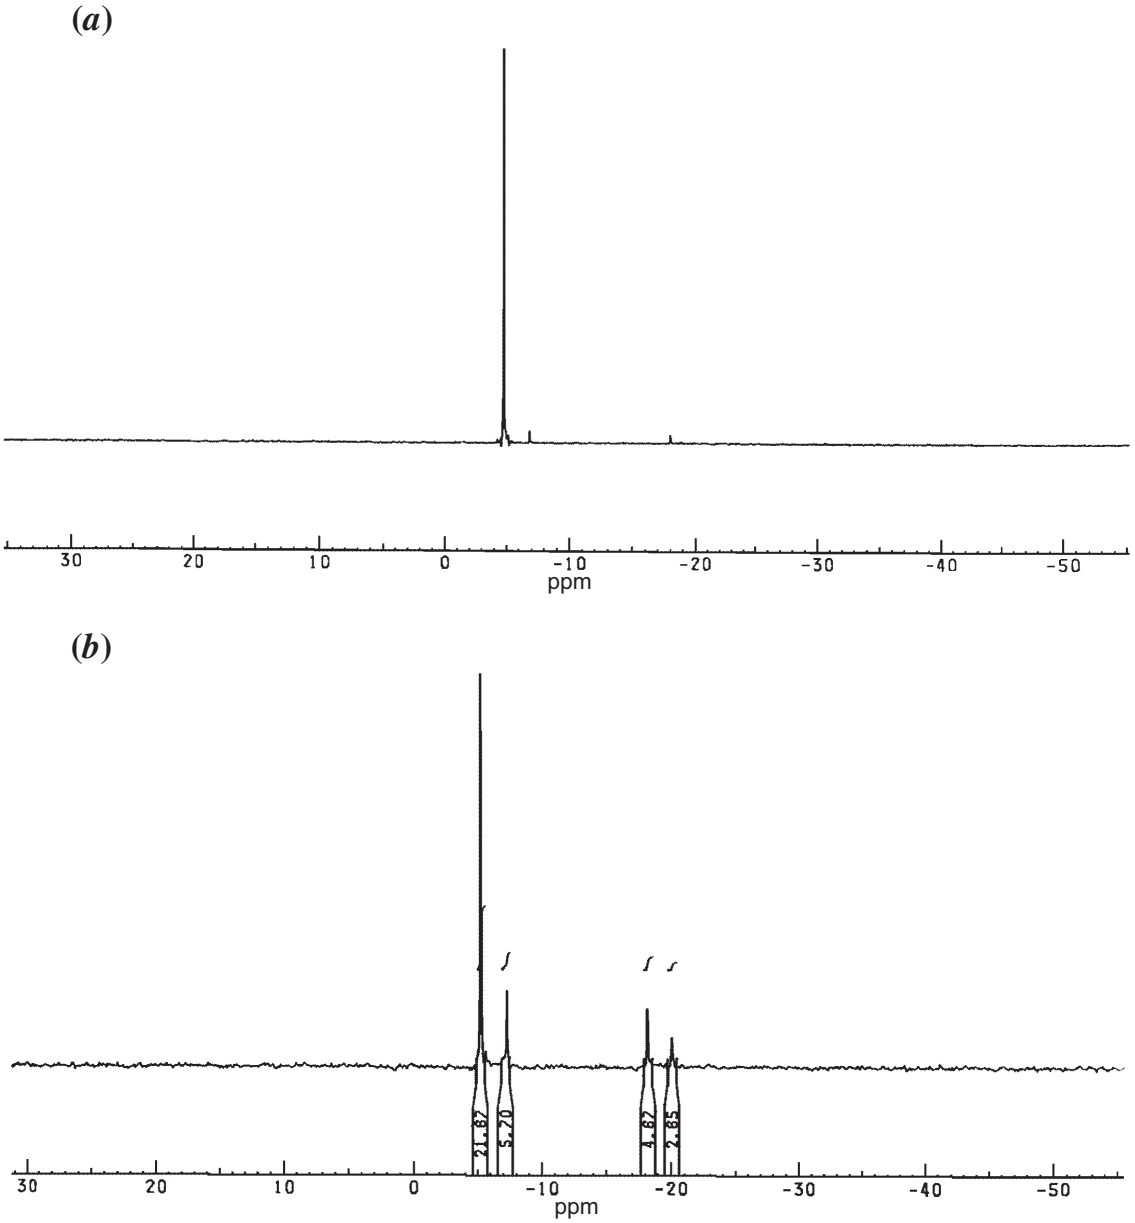
NMR

^{1}H, ^{29}Si, and ^{13}C NMR spectra were recorded on Bruker MSL 300 MHz instrument, operating in the FT mode at 59.627 MHz for ^{29}Si NMR, at 300.13 MHz for ^{1}H NMR, and at 75.47 MHz for ^{13}C NMR, using 10 mm OD sample tubes with a $CDCl_3$ internal (or external) lock. Hexamethyldisiloxane was used as the external ^{29}Si NMR standard (δ = 6.98 ppm, in $CDCl_3$). ^{29}Si NMR proton-decoupled measurements were made with use of the INEPT polarization transfer microprogram and the following parameters (for most spectra): TD (time domain - computer memory used for storage of data points of a spectrum) = 32 K, AQ (acquisition time) = 0.819 s, D0 (delay between pulses) = 4.0 s (or 3.0 s). The other delay values applied were D1 = 12.0 μs, D2 = 24.0 μs, D3 = 20.0 μs, D4 = 1.0 μs, D5 = 1000.0 μs, D6 = 20.0 ms (or 4.0 ms, or 16 ms), D7 = 46.0 ms, D8 = 5.0 ms (or 1.0 ms, or 8.0 ms), D9 = 1.0 μs, D10 = 8.9 μs, D11 = 28.0 μs (or 24.0 μs), D12 = 56.0 μs (or 48.0 μs), D13 = 1.0 μs, D14 = 1.0 μs, D15 = 100.0 μs.

NMR (in $CDCl_3$, δ ppm) for $HMe_2SiOSiMe_2H$: ^{1}H NMR (in C_6D_6): 0.13 (d, 12H, J = 3.01 Hz, CH_3-Si), 4.90 (h, 2H, J = 2.78 Hz, Si-H). ^{29}Si NMR: –4.61 (s). For $(MeO)_3SiH$: bp 83.5–84.0 °C / 744 torr (1 torr = 133.322 4 Pa). ^{29}Si NMR: –54.86 (s). For $(EtO)_3SiH$: bp 131.5 °C. ^{1}H NMR: 1.25 (t, 9H, J = 7.02 Hz, CH_3), 3.85 (q, 6H, J = 7.01 Hz, CH_2O). ^{13}C NMR: 18.06 (CH_3), 58.23 (CH_2O). ^{29}Si NMR: –58.44 (s). For $(EtO)_2MeSiH$: bp 98.0–98.5 °C / 742 torr (1 torr = 133.322 4 Pa). ^{1}H NMR: 0.21 (d, 3H, J = 1.77 Hz, CH_3-Si), 1.24 (t, 6H, J = 7.00 Hz, CH_3), 3.81 (q, 4H, J = 7.00 Hz, CH_2O), 4.58 (q, 1H, J = 1.72 Hz, Si-H. ^{13}C NMR: –3.50 (CH_3-Si), 18.17 (CH_3), 59.06 (CH_2O). ^{29}Si NMR: –16.13 (s). For $(EtO)Me_2SiH$: bp 57.5 °C / 752 torr (1 torr = 133.322 4 Pa). ^{1}H NMR: 0.21 (d, 6H, J = 2.85 Hz, CH_3-Si), 1.21 (t, 3H, J = 6.98 Hz, CH_3), 3.71 (q, 2H, J = 6.99 Hz, CH_2O), 4.62 (h, J = 2.81 Hz, Si-H). ^{13}C NMR: –1.61 (CH_3-Si), 18.14 (CH_3), 59.65 (CH_2O). ^{29}Si NMR: 4.67 (s).

The ^{29}Si-NMR data for the organosilicon compounds are also accessible from ref. 32.

Results and discussion



^{29}Si NMR studies

^{29}Si NMR is a very useful tool for studying the equilibria between four-coordinate silanes and higher-coordinate species in solution, as well as characterizing these compounds as penta- or hexa-coordinate silicon compounds (33, 34). According to Voronkov, such coordination of a solvent molecule to the silane takes place only when an electron-withdrawing substituent is present on the silicon atom (35–37). Five-, hexa-, and hypercoordinated silicon species were established as intermadiates in nucleophilic substitutions at silicon, in elegant and comprehensive studies, by Corriu and co-workers (6, 10, 11). Penta-coordinated silicon anions $MePhSiF_3^-$ and $Ph_3SiF_2^-$, prepared in a form of pure salts by Damrauer and Danahey (38) were found to be much more reactive toward strong nucleophiles than their tetravalent analogues (39). The temperature-dependent equilibria between tetra- and penta-coordinate forms in the compounds of the general formula o-$(Me_2NCH_2)C_6H_4SiXYZ$ were studied by West, Corriu, and co-workers (40). They concluded that the high reactivity of o-$(Me_2NCH_2)C_6H_4(C_{10}H_7)SiH_2$ with alcohols and acids was associated with intramolecular penta-coordination, which supported an earlier hypothesis that "the Si—H bond is activated toward substitution by coordinative expansion of the silicon atom". An activation of the Si—H bond by nucleophiles (e.g., in CsF-catalyzed reactions of hydrosilanes with alcohols and carbonyl compounds) is associated with coordination of the silicon atom, to give more reactive penta-coordinative species (11). The hydrogen atom has the lowest ability to penta-coordinate among functional groups at silicon (9). Five-coordinate hydrido- (41, 42) and dihydrido-silicates (43) were prepared and characterized by ^{29}Si NMR, e.g.: $HSi(OEt)_4^-K^+$, $[H_2Si(OEt)_3]^-K^+$. Five-coordinate silicon hydrides were postulated as intermediates of the reactions of trihydridosilanes with NaH, KH, and $LiAlH_4$ (44). The formation of penta-coordinated complexes of hydrosilanes containing electronegative ligands [$CF_3SO_2O^-$, 1-methylimidazole, hexamethylphosphoramid (HMPA), dimethylpropyleneurea (DMPU), EtO^-, PhO^-, and H^-) was studied by Bassindale and Jiang by means of ^{29}Si NMR spectroscopy (45). In some cases, cationic five-coordinated complexes $[Nu_2SiMe_2H]^+X^-$ (X = Cl, I, OSO_2CF_3) were isolated as pure compounds (46). Hypervalent silicon hydride compounds reacted with alcohols, water, and benzoic acid without added catalysts (47).

To confirm the presence of DMF molecules in the active complex of the reaction we have conducted studies of solutions of hydrosilanes with DMF by means of ^{29}Si NMR spectroscopy. We recorded ^{29}Si NMR spectra at different molar ratios of hydrosilanes to DMF at 25 °C and –60 °C. We did not find any evidence of a formation of molecular complexes by DMF with triorganohydrosilanes Et_3SiH, Et_2MeSiH, n-Pr_2MeSiH, t-$BuMe_2SiH$, $PhMe_2SiH$, and

Fig. 1. ^{29}Si NMR spectra of 1,1,3,3-tetramethyldisiloxane (M^H_2) and DMF in $CDCl_3$: (*a*) 0.46 cm^3 of M^H_2 and 1.60 cm^3 of DMF in 2.0 cm^3 of $CDCl_3$, at 25 °C; (*b*) 0.46 cm^3 of M^H_2 and 1.60 cm^3 of DMF in 2.0 cm^3 of $CDCl_3$, at –60 °C.

Ph_2MeSiH. No substantial changes in the chemical shifts were found in the ^{29}Si NMR spectra of their solutions in DMF, even for a large excess of DMF ([DMF]/[Si-H] ≈ 9–18) at room temperature and even at –60 °C. If such complexes are formed by alkyl(aryl)hydrosilanes in the reaction course, their concentration must be very low, but it seems to be sufficient for a promotion of their dehydrocoupling with hydroxylic reagents. According to the steady-state Bodenstein approximation (27), a concentration of the active complex doesn't need to be high. In our studies we have also used the most reactive hydrosilane towards silanols — 1,1,3,3-tetramethyldisiloxane (M^H_2, where: M^H denotes the $HMe_2SiO_{0.5}$ group). In the ^{29}Si NMR spectra of M^H_2 and DMF (in $CDCl_3$), recorded at room temperature, we have found two new singlets at about –7 ppm (δ_1) and –18 ppm (δ_2). The intensities of these new signals increased to 3.4% and 2.4%, respectively, when the molar ratio of DMF to M^H_2 increased from 1:1 to 8:1. At –60 °C, relative intensities of these signals reached 20.0% and 14.8%, respectively, for the molar ratio of DMF to M^H_2 of 8:1 (see Fig. 1 and Table 1). When the concentration of M^H_2 in the solution was doubled and the fraction of $CDCl_3$ was decreased twice, similar changes in ^{29}Si NMR spectra have been observed. In this case, high intensities of new signals at δ_1 = –7.59 ppm (20.7%) and δ_2 = –18.58 ppm (12.1%) were observed for the molar ratio 4:1 at –60 °C. At –60 °C and also at room temperature (Table 1), a third signal at δ_3 = –20.08 ppm (in expt. 6), or δ_3 = –20.70 ppm (in expt. 8), and δ_3 = –20.45 ppm (in expt. 10) was also observed in the spectra. At the lower temperature, the dielectric constant of DMF is much higher than at 25 °C (at –60 °C, ε_{DMF} = 58.3 (48)) and it can increase its ability to form complexes with hydrosilanes.

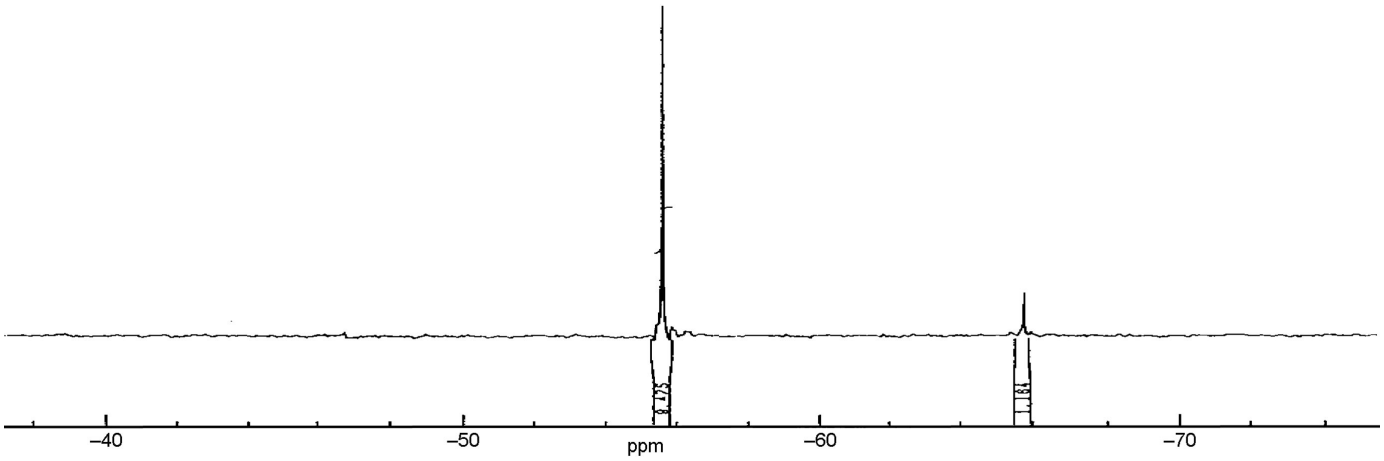
[a]The relative intensities of the signals (singlets) are given in brackets.

Scheme 1.



We presume that the singlets at –7 ppm (δ_1) correspond to a noncoordinated silicon atom, singlets at –18 ppm (δ_2) to the penta-coordinated silicon atom of M^H_2, and the singlets at –20 ppm (δ_3) belong to the complex of M^H_2 with two molecules of DMF (Scheme 1). The chemical shift of two magnetically equivalent silicon atoms in the molecule of $HMe_2SiOSiMe_2H$ always appears in the spectra (in $CDCl_3$) at δ_0 = –4.8 ppm.

We have also found new distinct NMR signals in the ^{29}Si NMR spectra of alkoxy-substituted hydrosilanes $(MeO)_3SiH$ (Fig. 2), $(EtO)_3SiH$, $(EtO)_2MeSiH$, and $(EtO)Me_2$-SiH, which may result from molecular complexes of the above silanes with DMF (see Table 2). (Alkoxyhydrosilanes have not been used in our kinetic studies, since ≡Si-OR groups can react with hydroxyl groups in the presence of Lewis acids (49)). For some of these silanes, we observed more than one new NMR signal. The maximum intensities of the most intensive new signals in their ^{29}Si NMR spectra recorded at –60 °C in $CDCl_3$ were as follows: 13.0% (δ_1 –65.8 ppm) for $(MeO)_3SiH$, 16.8% (δ_1 –69.1 ppm) for $(EtO)_3SiH$, 6.6% (δ_1 –26.9 ppm) for $(EtO)_2MeSiH$, and 12.7% (δ_1 –5.7 ppm) for $(EtO)Me_2SiH$. For the last three hydro(alkoxy)silanes, the intensities of these new signals were in the range 4.2%–7.6% at –60 °C when $CDCl_3$ was used as the external solvent. In the case of $(EtO)Me_2SiH$, two additional singlets at δ_2 –7.5 ppm (6.0%) and δ_2 –7.8 ppm (2.1%) were observed, and for $(EtO)_2MeSiH$ at δ_2 –43.3 ppm (1.3%) and δ_2 –50.7 ppm (1.0%). It seems that the oxygen atom of dimethyl formamide coordinates to the silicon atom of the hydrosilanes, since oxygen has a very high affinity to silicon because of (*p–d*) π conjugation. Apparently, oxygen atoms bound to silicon in M^H_2 and in hydro(alkoxy)silanes stabilize complexes of hydrosilanes with DMF. Saratov and Reikhsfeld (50) concluded that the nitrogen atom of DMF coordinates to the silicon in $PhSiH_3$, on the basis of the results of high-resolution ^{1}H NMR studies of $PhSiH_3$–DMF solutions in $CDCl_3$. The intermediacy of molecular complexes of (alkoxy)hydrosilanes with DMF and other solvents in pre-equilibriumm steps of reactions of the Si—H bond was proposed by Marciniec and Gulińska (51), on the basis of IR study of trialkoxysilane–solvent interactions.

As we can see from the NMR data, summarized in Tables 1 and 2, values of the differences ($\Delta\delta_I$) between the chemical shifts of noncomplexed hydrosilanes (δ_0) and those corresponding to the observed new signals (δ_1), $\Delta\delta_I = \delta_1 - \delta_0$, are pretty constant (~2.1 ppm for M^H_2, ~10 ppm for $(MeO)_3SiH$, ~9 ppm for $(EtO)_3SiH$ and $(EtO)_2MeSiH$, and ~8 ppm for $(EtO)Me_2SiH$), and they increased only very slightly with an increasing concentration of DMF and decreasing temperature. Also, values of $\Delta\delta_{II} = \delta_2 - \delta_0$ are constant within an experimental error (~13.3 ppm, for M^H_2; for

Fig. 2. ^{29}Si NMR spectrum of $HSi(OMe)_3$ (0.37 cm^3) and DMF (1.60 cm^3) in $CDCl_3$ (2.0 cm^3), recorded at –60 °C ([Si-H]/[DMF} = 1:8; δ (ppm): –55.60 (100%), –65.77 (13.0%)).

the (alkoxy)hydrosilanes used, more experimental data are needed).

The formation of anionic molecular complexes of $HSi(OR)_3$ (RO = EtO, PhO, *i*-PrO) with alkoxide anions (EtO^-, PhO^-, *i*-PrO^-) and H^- was proposed by Corriu and coworkers (44, 52) on the basis of their ^{29}Si NMR data (Δδ = –22 to –41 ppm). Hydrosilanes bearing strongly electronegative triflate groups at silicon form complexes with soft nucleophiles (TfO^-, NMI, HMPA, DMPU, and Et_3N). Their resonances appear at much lower frequences than those of the parent hydrosilanes (Δδ = –47 to –65 ppm). All of Corriu's and Bassindale's complexes were formed at a concentration ratio of nucleophiles to hydrosilanes of 1:1 or lower (45).

The role of DMF in the reaction mechanism

Presumably, DMF forms molecular complexes with hydrosilanes in fast reactions, prior to the formation (in the rate-determining step) of an active complex with catalysts (ZnX_2, CdX_2, X = Cl, Br, I). As a result of the interactions of DMF with the silicon atom in hydrosilanes, a polarization of the Si—H bond can be distinctly increased before it receives electrophilic assistance from the active forms of the catalysts (M^{2+}) (29), leading to the formation of the active complex.

The formation of hexa-coordinated species is consistent with the second order of dehydrocoupling with respect to DMF (30). Its molecules could neutralize a very slightly positive charge on the silicon atom in the transition state, which results from the studies of the Hammett free energy relationship (ρ = –0.12) (25). The intermediate product of the oxidative addition of the Si—H bond to M^{2+} may have a *three-centre, transition metal – hydrogen – silicon two-electron structure* (53), in which the hydride ion is replaced by the oxygen atom of the alcohol, silanol, carboxylic acid, or water in a fast consecutive step (29).

According to Baines and Eaborn (20), reactions involving the cleavage of Si—X bonds, under electrophilic conditions, consist of the electrophilic activation of a leaving group with *concerted or subsequent nucleophilic attack*. An assumption that the rate-determining step of the dehydrocoupling reaction has two stages: (1) *fast polarization of the Si—H bond, followed by* (2) *a rate-determining hydride transfer*, is also consistent with the observed formal kinetics.

It was proposed (29) that the first step of the reaction is the formation of a complex of ≡Si-H with active ionic forms of the catalysts (M^{2+}):

[2] $\equiv\overset{\delta+}{Si}-\overset{\delta-}{H} + \overset{\delta+}{M}X_2 \underset{k_{-1}}{\overset{k_1}{\rightleftharpoons}} \equiv\overset{\delta+}{Si}-\overset{\delta-}{H}\cdots\overset{\delta+}{M}X_2$

(Rate-determining step)

where M = Zn, Cd, and X = Cl, Br, I.

The slightly split silicon–hydrogen bond is completly broken in the next fast step, which might be quite complicated:

[3] $\equiv\overset{\delta+}{Si}-\overset{\delta-}{H}\cdots\overset{\delta+}{M}X_2 + HO-R \xrightarrow{k_2} \equiv Si-OR + MX_2 + H_2$

It also seems possible that the rate-determining stage (eq. [2]) could be composed of more than one step. A complexation of the Si—H bond by a catalyst could be a relatively fast process, while further rearrangement of such a complex to a three-centre transition state (A) might proceed as a rate-determining step (eq. [4]):

[4] $\equiv\overset{\delta+}{Si}-\overset{\delta-}{H}\cdots M^{2+} \underset{k_{-1}}{\overset{k_1}{\rightleftharpoons}} \left[\equiv Si\!-\!H\ (M^{2+})\right]$

(Rate-determining step) (A)

Thus, the Si—H bond may undergo a classic, fast, oxidative addition to the metal centre through the transition state (A) (eq. [5*a*]), causing a deep structural change of the hydrosilane substrate and a formation of adduct B:

[5*a*] $\left[\equiv Si\!-\!H\ (M^{2+})\right] \xrightarrow{\text{Fast}} \left[\equiv Si\ \ H\ (M^{2+})\right]$

(A) (B)

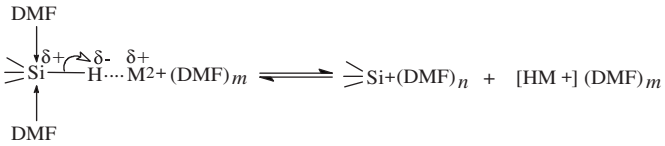
The adduct (B) may attach a nucleophile molecule (ROH), giving adduct C:

[5*b*] 

[5*c*] 

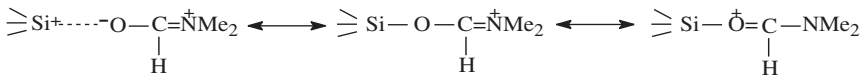


which may first undergo a reductive elimination of H_2, and subsequently, elimination of a catalyst active form (M^{2+}), through a structure (D), giving the main product of dehydrocoupling (≡Si-OR).

The participation of bishydrido complexes of Group VIII metals and other transition metals has very often been proposed in the mechanisms of reactions catalyzed by their derivatives.

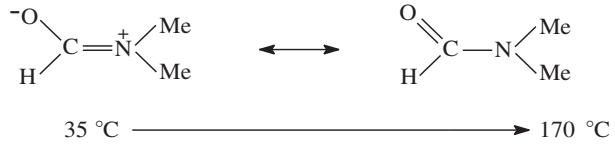
Comparison of the mechanisms of dehydrocoupling and the reaction of hydrosilanes with carbenium ions

We have observed several common features for *dehydrocoupling* and the reaction of hydrosilanes with carbenium ions, however, the latter reaction occurs in weakly nucleophilic medium (54–56) with: (1) the same formal kinetics, i.e., *first reaction order with respect both to the Si-H group and the electrophilic reagent,* i.e., MX_2 (M = Zn, Cd; X = Cl, Br, I) (27), or $\equiv C^+$ (54, 56)); (2) the same values of the deuterium kinetic isotope effect (1.4–1.5) (25, 54, 56); (3) very close values of $\Delta S^{\ddagger}$ (–30 to –35 eu (27) and –25 to –28 eu (54, 56)).



The formation of a silicocation ($\equiv Si^+$) in the rate-determining step cannot be excluded in the reaction course. We had observed an only slightly negative Hammett reaction constant (ρ = –0.12) for the dehydrocoupling process, not much different than for acid-catalyzed solvolysis of hydrosilanes (ρ = 0–0.5) (16), but still very low in comparison with ρ^* = –3.5, which was determined by Chojnowski and co-workers (54, 56) for the reaction of hydrosilanes with carbenium ions. A fast dissociation of the intermediate complex $\equiv Si\cdots H\cdots M^{2+}$ could proceed with *the formation of a silicenium cation (*$\equiv Si^+$*)*, which can be solvated by DMF:

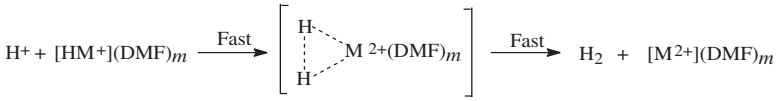
[6] 



where n = 1, 2; m = 3–5 (57, 58) (here, the hydrogen atom of the Si—H bond is considered as a ligand, replacing one molecule of DMF).

The structure of $ZnCl_2$ solutions in DMF, and appropriate ionic equilibria, were studied by Ishiguro et al. (57).

The positive charge on silicon can be stabilized by a resonance:



[7] 

In eq. [7], a second molecule of DMF (solvating silicenium cation), is omitted for simplicity — with two DMF molecules more resonance structures would be possible. A hindered rotation in DMF takes place at low and ambient temperature and two different ^1H NMR signals of CH_3 groups are observed, while at higher temperature both methyl protons are equivalent (59):

[8] 

Subsequently, the silicocation could be quickly attacked by the hydroxylic reagent:

[9] 

[10] 

The above mechanism is also consistent with formal kinetics. Silicenium cations are very unstable, but they can be stabilized by DMF (55), CH_2Cl_2 (57, 60), CH_3CN (61, 62), Et_2O (63), and other solvents (64). It seems that alternative to the concept of the intermediacy of the sovated $\equiv Si^+$, *the reaction could also proceed through the solvated, asymmetrical synchronous hydride transfer (SHT) transition state* because of the low value of the kinetic isotope effect (1.4–1.5). *A single electron transfer (SET) pathway* seems to be much less likely, when we consider all our eperimental results (25, 27, 29) (and especially the sensitivity of the reaction rate to steric effects (27)), and compare them with features of the SET process (54, 56).

© 2005 NRC Canada

Conclusions

1. Dehydrocoupling of tertiary hydrosilanes with hydroxylic reagents doesn't take place in the presence of Zn(II) and Cd(II) halides without cocatalysis by DMF molecules.
2. The reaction is second order with respect to DMF (30) for reactions of: (*a*) Et_3SiH with $Ph_2Si(OH)_2$, catalyzed by $ZnCl_2$, carried out at 25 °C in DMF–THF; (*b*) Et_3SiH with PhCOOH, catalyzed by $CdBr_2$, conducted at 25 °C in DMF-1,4-dioxane; and (*c*) in DMF–THF (in cases (*b*) and (*c*), only at lower concentrations of DMF.
3. New resonance signals were found in the ^{29}Si NMR spectra of solutions of $HMe_2SiOSiMe_2H$ (Fig. 1) and some (alkoxy)hydrosilanes ($(MeO)_3SiH$ (Fig. 2), $(EtO)_3SiH$, $(EtO)_2MeSiH$, and $(EtO)Me_2SiH$) in $CDCl_3$ at 25 °C and –60 °C. The intensities of these new signals were much higher at –60 °C. It seems that these new resonances correspond to molecular complexes of DMF with the hydrosilanes used. No evidence of the formation of such complexes by alkyl(aryl)-substituted tertiary hydrosilanes was found by means of ^{29}Si NMR spectroscopy. No new signals were detected in the spectra of their solutions with DMF in $CDCl_3$, neither at 25 °C nor at –60 °C.
4. Alternative mechanisms for the dehydrocoupling reaction of hydrosilanes with reagents containing hydroxyl group have been proposed. The rate-determining step of the reaction could also proceed through a three-centre transition state. Both a participation of a silicocation solvated by DMF molecules or a solvated, unsymmetrical synchronous hydride transfer (SHT) in the reaction mechanism seem to be possible as well. The single electron transfer pathway (SET) seems to be much less likely.

Acknowledgements

This paper is dedicated to the memory of Professor Zygmunt Lasocki (1921–1993), my very much respected teacher, in recognition of his precious contribution to organosilicon chemistry. The author is very grateful to Professor Julian Chojnowski (Centre of Molecular and Macromolecular Studies, Polish Academy of Sciences, Łódź) for helpful discussion. I also gratefully thank Professor Zofia M. Michalska and Dr. Krzysztof Strzelec for the gift of trimethoxysilane. This work was supported by the Polish State Committee for Scientific Research (KBN) under Research Project 1359/T09/95/08.

RAPID COMMUNICATION / COMMUNICATION RAPIDE

Palladium-catalyzed simple and efficient hydrogenative cleavage of azo compounds using recyclable polymer-supported formate

Keelara Abiraj, Gejjalagere R. Srinivasa, and D. Channe Gowda

Abstract: Palladium-catalyzed room temperature transfer hydrogenation of azo compounds using recyclable polymer-supported formate as the hydrogen donor produces corresponding amine(s) in excellent yields (88%–98%). This method was found to be highly facile with selectivity over a number of other functional groups such as halogen, alkene, nitrile, carbonyl, amide, methoxy, and hydroxyl.

Key words: azo compounds, catalytic transfer hydrogenation, polymer-supported formate, 10% Pd-C, amines.

Résumé : L'hydrogénation par transfert, catalysée par le palladium de composés azo, et réalisée à la température ambiante en faisant appel à du formiate déposé sur un polymère recyclable comme donneur d'hydrogène, conduit à la formation des amines correspondantes avec d'excellents rendements (88 %–98 %). On a trouvé que cette méthode d'une extrême facilité présente une sélectivité par rapport à d'autres groupes fonctionnels, tels les halogènes, alcènes, nitriles, carbonyles, amides et groupes méthoxy et hydroxyles.

Mots clés : composés azo, hydrogénation par transfert catalytique, formiate déposé sur un polymère, 10 % Pd-C, amines.

[Traduit par la Rédaction]

Polymer-supported reagents, catalysts, and scavengers are now ubiquitous throughout the fields of combinatorial chemistry, organic synthesis, and catalysis (1, 2). The use of polymer-supported reagents couples the advantages of solution phase chemistry (ease of monitoring the progress of the reaction by using chromatographic and spectroscopic techniques) with those of solid phase methods (use of excess reagents and easy isolation and purification of products). The utility and power of such reagents has been exquisitely demonstrated by the groups of Ley and others in synthesizing several complex natural products by multi-step sequences requiring many different kinds of heterogenized reagents, which can be removed by simple filtration (1–3). In view of the rapid development in the field of polymer-supported chemistry over the last few years, there is a pressing need for the proper exploitation of functionalized polymer-supported reagents in organic synthesis.

Reduction of azo compounds to the corresponding amine(s) is a synthetically important transformation, both in the laboratory and in industry. Although there are a good number of methods available for the reduction of azo compounds, limitations include the use of harsh conditions and (or) costly reagents (4). In comparison with all other reduction processes, catalytic transfer hydrogenation (CTH) employing hydrogen donors, e.g., ammonium formate, is safer, cost-effective, highly selective, rapid, and environmentally friendly (5). Various CTH systems such as cyclohexene – 5% Pd on asbestos (6*a*), ammonium formate – 10% Pd-C (6*b*), ammonium formate – zinc (6*c*), ammonium formate – magnesium (6*d*), hydrazinium monoformate – zinc (6*e*), and ammonium chloride – zinc (6*f*) have been developed for the reduction of azo compounds to the corresponding amine(s). However, ammonium-formate-aided CTH systems are the most versatile and widely employed. Though efficient, these ammonium formate CTH reactions are often troublesome since ammonium formate can sublime and block the reaction apparatus. Also, the reaction leads to the release of ammonia and could create significant problems when performed on a large scale. Moreover, the use of formate salts as hydrogen donors poses complications during isolation and purification of water-soluble products. Recently, potassium formate has been used as a hydrogen donor in various transfer hydrogenation reactions (7*a*–7*c*). However, alkali metal formate salts are not recommended for CTH reactions as these hydrogen donors reduce the catalyst activity.

Desai and Danks (8*a*) and Basu et al. (8*b*) performed the transfer hydrogenation of alkenes using polymer-supported formate as the hydrogen donor in the presence of Wilkinson's catalyst or $Pd(OAc)_2$. However, it has been observed that controlling the reduction rates is difficult with these active

homogeneous catalysts. On the other hand, the use of heterogeneous catalysts offers several advantages over homogeneous systems such as easy recovery and recycling of the catalyst, high selectivity, easy product isolation, and minimization of undesired toxic wastes. In this context, we probed the reduction of azo compounds employing polymer-supported formate as a hydrogen donor in the presence of 10% palladium on carbon as the heterogeneous catalyst. Our investigations revealed that the use of polymer-supported formate in conjunction with 10% Pd-C is highly efficient for the facile reduction of substituted azo compounds to the corresponding amine(s) (Scheme 1).

A wide range of structurally varied azo compounds, both symmetric and unsymmetric, underwent reduction by this procedure to furnish the corresponding amine(s). The results are summarized in Table 1. All the products were characterized by comparison of their TLC, melting points, IR and ^{1}H NMR spectra with authentic samples. The IR spectra of all the products showed a sharp doublet between 3500 and 3300 cm^{-1} ascribed for the NH_2 group and no absorption bands were noticed for the substrate azo compound (between 1630–1575 cm^{-1}) and intermediate hydrazo compound (2290–2440 cm^{-1}) clearly indicating the complete conversion of azo compounds to their corresponding amino derivate(s). Further, the appearance of a broad singlet between δ 4.5 and 6.5 owing to the NH_2 protons in the ^{1}H NMR spectra confirmed the products evidently. The reactions are, on the whole, reasonably fast and high yielding (88%–98%). It is worthwhile to note that our system selectively reduced azo compounds to the corresponding amines in the presence of other sensitive functional groups such as halogen (5*a*, 5*b*) (Table 1, entries 2–4), alkene (5*a*, 5*f*) (Table 1, entry 5), nitrile (5*a*, 5*b*) (Table 1, entry 6), and carbonyl (5*a*, 9) (Table 1, entries 7 and 8), which are susceptible to reduction under transfer hydrogenation conditions. In addition, many other functional groups such as amide, methoxy, acid, and hydroxyl are also compatible with the present system.

In the case of symmetrically substituted azo compounds,

8	4.0	92

the separation of products from the reaction mixture is simple and involves, in most of the cases, direct removal of the catalyst and resin by filtration and evaporation of the solvent under vacuum. The crude product, so isolated, was of excellent purity for most purposes. Hence, this procedure is highly advantageous to obtain water-soluble aromatic amines in high yields (Table 1, entries 2, 8, 11–13). Further, it is noteworthy here that the polymer-supported formate was regenerated and could be reused for further hydrogenolysis process. In total, 10 successive recycle runs were possible before there was an appreciable decrease in the reaction yield (Table 2).

To obtain optimum reduction conditions, a number of trails with a range of solvents, which are commonly employed for CTH reactions, were carried out. Methanol is found to be the best one as far as the solubility of substrate and rate of reaction is concerned. To examine the effects of catalyst loading, the reduction was attempted using different ratios of catalyst and substrate. We observed the optimal ratio of catalyst to substrate to be 1:4 by weight (approximately 0.05 mmol catalyst for 1 mmol of substrate). However, the rate of reduction was significantly slower when smaller amounts of catalyst were used. During the recycle runs, another 0.025 mmol of catalyst was added after the fifth cycle to increase the rate of reduction.

The reductive cleavage of azo compounds proceeds smoothly despite the dual heterogeneity of catalyst and polymer support. The initial step in the reduction would be the formation of palladium diformate by the reaction of palladium with the formate released from the polymeric support (10*a*, 10*b*). The palladium formate can then transfer two hydrogen atoms to the azo compound. In addition to this essential feature, the polymer-supported NH_3^+ may also provide H^+ to complete the reduction process (10*c*).

In conclusion, a highly facile polymer-supported formate – 10% Pd-C system was developed for the smooth reduction of azo compounds to the corresponding amine(s). The use of polymer-supported formate combines the advantages of polymer-supported chemistry with the flexibility of the CTH technique. The advantages include a safe reaction medium, high selectivity, rapidity, ease of operation, and simple recovery of the hydrogen donor. In addition, this approach is highly helpful for the reduction of symmetric azo compounds to obtain the corresponding amines in pure form with no work-up.

Experimental

Preparation of polymer-supported formate

The aminomethyl polystyrene (Advanced Chemtech, 1% DVB cross-linked, 100–200 mesh, 2 mmol/g) was washed with an excess of a 50% solution of formic acid in dichloromethane. The resulting polymer was washed thoroughly and successively with dichloromethane and ether, and dried under vacuum. The obtained resin was used as such for the reduction.

Determination of polymer-supported formate loading

The polymer-supported formate (1 g) was placed in a manually operated solid phase vessel and washed thoroughly with dil. HCl (0.05 N). The HCl washing containing formic acid (released from the resin) was collected and diluted to 50 mL in a volumetric flask. An aliquot (10 mL) of this solution was titrated potentiometrically against a standard NaOH solution. The formate loading was calculated to be 1.92 mmol/g.

General procedure for the reduction of azo compounds

To a solution of the azo compound (1 mmol) in methanol (15 mL) taken in a horizontal solid phase vessel, polymer-supported formate (1 g) and 10% Pd-C (50 mg, 0.05 mmol) were added. The suspension was shaken well[2] for the specified time at room temperature (Table 1). After consumption of the starting material, as monitored by TLC, the reaction mixture was filtered and washed thoroughly with methanol. The combined washings and filtrate were evaporated under reduced pressure. The crude product was found to be analytically pure in most cases. Where necessary, the crude product was taken into the organic layer and washed with saturated sodium chloride. For recycling purposes, the residue containing the polymer-supported formate and the catalyst was washed thoroughly and successively with DMF, dichloromethane, a 50% solution of formic acid in dichloromethane, dichloromethane, and ether. The activated resin along with the catalyst were dried under vacuum and used as obtained for further reduction reactions.

In the case of the reduction of unsymmetrically substituted azo compounds, the crude product was subjected either to preparative TLC or to column chromatography to separate two different constituent amines.

Acknowledgements

We gratefully acknowledge financial support from the University Grants Commission, New Delhi. We also acknowledge the Council of Scientific and Industrial Research, New Delhi for a research fellowship (to KA).

[2] The reaction mixture was subjected to shaking using a manual shaker as the shaking of the polymer-supported formate instead of stirring increases its life for recycling purposes.

Oxidation of anisoles to *p*-benzoquinone monoketals catalyzed by a ruthenium complex of 1,4,7-trimethyl-1,4,7-triazacyclononane with *tert*-butyl hydroperoxide[1]

Wai-Hung Cheung, Wing-Ping Yip, Wing-Yiu Yu, and Chi-Ming Che

Abstract: A protocol based on $[Ru^{III}(Me_3tacn)(CF_3CO_2)_2(H_2O)]CF_3CO_2$ (**1**, Me_3tacn = 1,4,7-trimethyl-1,4,7-triazacyclononane) as catalyst and *tert*-butyl hydroperoxide (TBHP) as oxidant was developed for oxidation of anisoles to *p*-benzoquinone monoketals. This reaction can be formally considered as regioselective aromatic C-H oxidation. With 2-methoxyanisole as substrate, 3,4-dimethoxy-4-*tert*-butoxy-2,5-cyclohexadienone can be obtained in up to 82% yield based on 84% substrate conversion.

Key words: oxidation, quinones, *tert*-butyl hydroperoxide, ruthenium catalyst.

Résumé : Un protocole basé sur l'utilisation du $[Ru^{III}(Me_3tacn)(CF_3CO_2)_2(H_2O)]CF_3CO_2$ (**1**, Me_3tacn = 1,4,7-trimethyl-1,4,7-triazacyclononane) comme catalyseur et de l'hydroperoxyde de *tert*-butyle comme oxydant a été élaboré pour l'oxydation des anisoles menant à la formation de monocétals de *p*-benzoquinone. On peut considérer formellement cette réaction comme une oxydation C-H aromatique régiosélective. Avec le 2-méthoxyanisole comme substrat, on obtient la 3,4-diméthoxy-4-*tert*-butoxycyclohexa-2,5-diénone avec un rendement pouvant atteindre 82 %, en se basant sur un taux de conversion du substrat de 84 %.

Mots clés : oxydation, quinones, hydroperoxyde de *tert*-butyle, catalyseur de ruthénium.

[Traduit par la Rédaction]

Introduction

p-Benzoquinones constitute a key structural element in many biologically interesting natural products such as neolignans and anthraquinone antibiotics (1, 2). Stoichiometric oxidation of substituted phenols by oxidants such as ammonium cerium(IV) nitrate (3) and thallium(III) nitrate (4) represents a common approach for quinone synthesis. Similarly, quinone monoketal, which is a valuable class of synthetic intermediates, can be readily obtained through oxidation of *para*-methoxy phenols by either electrochemical (5) or chemical oxidation using hypervalent iodine reagents (6). In view of growing environmental concern, there is an upsurge of interest in developing environmentally friendly and operationally safe catalytic protocols for hydrocarbon oxidations using more tractable oxidants such as molecular oxygen, aqueous hydrogen peroxide, and *tert*-butyl hydroperoxide (TBHP) (7). However, metal-catalyzed phenol oxidations by alkyl hydroperoxides are known to give poor product selectivity because of coupling of the phenoxy radicals (8). Recently, selective oxidation of phenols by TBHP has been achieved by Murahashi et al. (9) using $Ru(PPh_3)_3Cl_2$ as catalyst, and 4-(*tert*-butyldioxy)-4-alkyl-2,5-cyclohexadienones were produced in good yields.

It is well documented that ruthenium complexes are versatile catalysts for oxidative functionalization of C=C and C—H bonds (10). Extensive studies have shown that oxo-ruthenium complexes of chelating tertiary amines are powerful oxidants for alkenes, alkynes, and alkanes (11). We previously reported the preparation and X-ray structure characterization (12*c*) of $[Ru^{III}(Me_3tacn)(CF_3CO_2)_2(H_2O)]CF_3CO_2$ (**1**, Fig. 1), which is a robust catalyst (12) for homogeneous and heterogeneous oxidation of alcohols and alkenes using TBHP as the terminal oxidant; aldehydes and (or) ketones and epoxides can be obtained in excellent yields with product turnovers >6000. As part of our continuous effort to develop

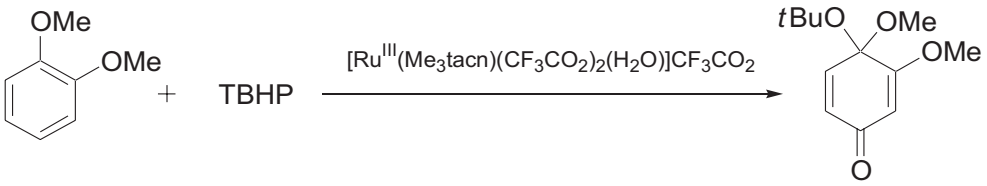
structurally characterized ruthenium complexes for organic catalysis, we are attracted to a recent work by Hirobe and co-workers (13), which states that $[Ru^{II}(Por)(CO)]$ (Por = porphyrinato) can effect catalytic oxidation of anisoles by 2,6-dichloropyridine *N*-oxide to give *p*-benzoquinones as the major product. The transformation was proposed to occur via oxidation of an aromatic C—H bond as a principal step (13). In this work we report that complex **1** can catalyze anisole to *p*-benzoquinone monoketals with up to 90% yield using TBHP as the oxidant. Results obtained under various reaction conditions (e.g., solvent systems, temperature) and with use of various substrates will be discussed.



Results and discussion

At the outset, treatment of 2-methoxyanisole (**2a**, 1 mmol) with TBHP (2.3 mmol) in the presence of $[Ru^{III}(Me_3tacn)(CF_3CO_2)_2(H_2O)]CF_3CO_2$ (**1**, 1 mol%) in CH_2Cl_2 at ambient temperature for 14 h produced 3,4-dimethoxy-4-*tert*-butoxy-2,5-cyclohexadienone (**3a**) in 48% isolated yield based on 46% anisole consumption (Table 1, entry1). Other oxidants such as *m*-chloroperoxybenzoic acid, hydrogen peroxide – urea adduct, Oxone®, chloramine-T, TEMPO, and 2,6-dichloropyridine *N*-oxide have been tested for their ability to oxidize **2a**. Under our reaction conditions (i.e., **1**:**2a**:oxidant = 1:100:230 in CH_2Cl_2), formation of **3a** was not detected, and the starting anisole (>90%) was recovered. According to Murahashi et al. (9), $Ru(PPh_3)_3Cl_2$ and $RuCl_3{\cdot}H_2O$ were reported to be effective catalysts for selective phenol oxidation by TBHP to give 4-(*tert*-butyldioxy)-4-alkyl-2,5-cyclohexanedienone. In this work, when $Ru(PPh_3)_3Cl_2$ and $RuCl_3{\cdot}H_2O$ were employed as catalysts for the oxidation of **2a** using THBP as oxidant, no effective consumption of the starting anisole was observed without product **3a** being detected.

The catalytic oxidation of other anisole derivatives has been examined by employing the following reaction condi-

[a]Isolated yield.
[b]The percentage of conversion was determined by GLC analysis.
[c]1,2-DCE = 1,2-dichloroethane.
[d]A dissolved mixture of complex **1** (1 mol%) in MeOH:*t*-BuOH with TBHP (3.5 mmol) was added slowly by a syringe pump (0.5 mL min^{-1}) to a solution of **2a** (1 mmol) with TBHP (3.5 mmol) in 1,2-DCE at 80 °C for 2 h. The reaction mixture was further stirred for 2 h, followed by a general work-up procedure.

tions (protocol I): **1** (1 mol%), TBHP (2.3 equiv.), and CH_2Cl_2 at room temperature. Unsubstituted anisole **2b** reacted with TBHP to afford quinone monoketal **3b** in 53% yield based on 84% conversion (Table 1, entry 2). Likewise, *ortho*- and *meta*-substituted methyl anisoles (**2c** and **2d**) were converted to their corresponding ketals in 57% and 41% yields, respectively (entries 3 and 4) under the Ru-catalyzed conditions. Yet the analogous reaction of 3,5-dimethylanisole gave quinone **3e** in 15% yield despite complete substrate conversion (entry 5). Analysis of the crude reaction mixture by ^{1}H NMR failed to identify any defined products other than **3e**. Interestingly, when 2,4-dimethylanisole (**2f**) was employed as substrate, the **1**-catalyzed TBHP reaction furnished benzoic acid **3f** as the only identifiable product in 89% yield (entry 6), presumably via benzylic C-H oxidation. Based on these findings, the **1**-catalyzed oxidation of anisoles to quinone monoketal could be regarded as a formal regioselective oxidation of the aromatic C—H bond *para* to the methoxy group.

Adopting protocol I, oxidaton of other functionalized anisoles was also explored. For example, the oxidation of 1,3,5-trimethoxybenzene was found to give dimethoxyquinone **3g** in 76% yield, without any ketal product (Table 1, entry 7). Notably, effective oxidation of 1,4-dimethoxybenzene, which does not bear any available aromatic C—H bonds, was observed under the "**1** + TBHP" conditions, and a mixture of monoketals **3b** (32%) and **3h** (19%) was obtained (entry 8).

Recently, Nicolaou et al. (14) reported a facile synthesis of aminoquinones by oxidation of anilides with hypervalent iodine reagents (Dess–Martin periodinane, DMP); aminoquinones have been shown to be valuable synthetic intermediates for polycycle constructions. In this work, we have studied the reactions of 2- and 3-methoxyanilides (**2i** and **2j**) with TBHP by employing protocol I, and the product *ortho*-aminoquinone **3i** was formed in merely 12%–20% yield (Table 1, entries 9–10). Oxidation of 2-bromoanisole also met with limited success, and the product **3k** was isolated in only 15% yield based on 29% substrate conversion (entry 11).

Having found a protocol for anisole oxidation by TBHP, we examined the effect of various experimental parameters on the efficiency of the transformation. Using **2a** as substrate, the **1**-catalyzed anisole oxidation was found to be sensitive to the solvent used. For instance, with hexane as solvent and under the reaction conditions **1**:**2a**:TBHP = 1:100:230 at room temperature for 14 h, a higher yield (68%) of **3a** was obtained, albeit with 9% conversion (Table 2, entry 2). Poor substrate conversion could be explained by the insolubility of the catalyst in hexane. Our previous results showed that **1** dissolves in alcoholic solvents such as MeOH and *t*-BuOH, leading to the formation of an alkoxyruthenium complex (12*c*). In this work, the ruthenium catalyst was found to be inactive when MeOH or *t*-BuOH was used as the solvent, and negligible substrate conversion was observed (entries 3 and 4). Compared to the case when CH_2Cl_2 was the solvent, other halogenated solvents, such as 1,2-dichloroethane, gave similar results (ca. 50% yield; 45% conversion) under identical experimental conditions (entry 5). Increasing the TBHP amount to 7.0 equiv. produced moderate improvement in product yields (60%) and substrate conversion (49%) for the **1**-catalyzed oxidation of **2a** (entry 6).

At higher catalyst loading (5.0 mol%), little improvement in the substrate conversion (57%) and product yield (49%) was observed for the **1**-catalyzed TBHP oxidation of **2a** (en-

Table 3. Catalytic oxidation of selected anisoles using protocol II.

Entry	Substrate	Product	Yield (%)[a]	Conversion (%)[b]
1	**2a**	**3a**	84	82
2	**2k**	**3k**	49	54
3	**2i**	**3i**	39	31
4	**2c**	**3c**	49	75
5	**2d**	**3d**	33	76

Note: Reaction conditions: a mixture of complex **1** (1.0 mol%) and TBHP (3.5 mmol) dissolved with MeOH-*t*-BuOH (1:1 by volume) was added slowly through a syringe pump (0.5 mL min^{-1}) over 2 h at 80 °C to a solution of the substrate (1 mmol) with TBHP (3.5 mmol). The reaction mixture was stirred for a further 2 h and quenched with sodium thiosulphate (100 mg).

[a]Isolated yield based on conversion.

[b]Conversions were determined by GLC analysis.

try 7, compare results in entry 1). However, reducing the catalyst loading to 0.5 mol% led to a higher product yield of 78% for the catalytic oxidation in spite of a 28% substrate conversion (entry 8). This finding suggests that higher catalyst loading may favor TBHP decomposition; however, the possibility of catalyst deactivation under the reaction conditions cannot be excluded.

Interestingly, when the catalytic oxidation was conducted at 80 °C (**1**:**2a**:TBHP = 1:100:700), the product ketal was obtained in 86% yield based on 62% anisole consumption (entry 9). At room temperature, the identical transformation resulted in only 45% substrate conversion and 66% yield for the formation of **3a**. Up to 93% yield of **3a** was attained when 14 equiv. TBHP was employed, though the substrate conversion remained at 62% (entry 11).

Based on the above studies, halogenated solvents are the solvents of choice for the **1**-catalyzed anisole oxidation, and an elevated temperature seems to produce high product yield and substrate conversion. While the amount of the TBHP has a moderate effect on the catalytic oxidation, low catalyst loading was found to favor high product yield. Taking these results into consideration, a modified catalytic procedure (protocol II) was developed (see experimental section for details). Complex **1** was first dissolved in an MeOH:*t*-BuOH mixture (1:1 by volume) and TBHP (3.5 equiv.). The homogenous mixture was added slowly through a syringe pump (0.5 mL min^{-1}) to a 1,2-dichloroethane solution containing **2a** (1 mmol) and TBHP (3.5 equiv.) at 80 °C. After 4 h of reaction, monoketal **3a** was obtained in 84% yield with 82% substrate conversion (entry 12). By employing protocol II and 2-bromoanisole (**2k**) as substrate, the Ru-catalyzed oxidation afforded **3k** in 49% yield based on 54% conversion (Table 3, entry 2). This result is a significant improvement when compared with the results using protocol I (yield 29%, conversion 15%; see Table 1, entry 11). As noted earlier, oxidation of 2-methoxyanilide **2i** using protocol I afforded quinone **3i** in 12% yield based on 32% conversion (Table 1, entry 9). However, when protocol II was adopted for the same reaction, a better yield of 39% for the formation of **3i** was observed, albeit with 31% conversion (Table 3, entry 3). Using protocol II, oxidation of methyl anisoles **2c** and **2d** by TBHP produced the corresponding ketals in 49% (**3c**) and 33% (**3d**) yields (Table 3, entries 4 and 5). These findings are comparable to those obtained by employing protocol I (Table 1, entries 3 and 4).

Reaction of peroxides with $[Ru^{III}(N_4)(H_2O)_2]^{3+}$ (N_4 = macrocyclic amine ligand) is known to generate oxo-ruthenium complexes (15, 16). To gain insight about the plausible reactive intermediates responsible for the **1**-catalyzed anisole oxidation by TBHP, we performed a stoichiometric reaction of a structurally defined oxo-ruthenium complex — $[Ru^{VI}(Me_3tacn)(CF_3CO_2)O_2](ClO_4)$ — with 2-methoxyanisole (**2a**). When **2a** (10 mmol) was treated with $[Ru^{VI}(Me_3tacn)(CF_3CO_2)O_2](ClO_4)$ (0.5 mmol) in degassed aqueous *tert*-butanol [*t*-BuOH:H_2O = 6:3 (by volume)] at room temperature for 16 h under an inert atmosphere, 2-methoxy-*p*-benzoquinone (**3l**) was isolated in 81% yield. The dioxoruthenium(VI) complex was reduced to $[Ru^{III}_2(Me_3tacn)(CF_3CO_2)_2(O)](ClO_4)$ in 76% yield. This finding appears to be consistent with the results reported by Hirobe and co-workers (13) that reactive oxo-ruthenium complex is an active intermediate for anisole oxidation.

Experimental section

Materials

All the solvents were distilled and dried before used. All the common laboratory reagents were used as received. $[Ru^{III}(Me_3tacn)(CF_3CO_2)_2(H_2O)]CF_3CO_2$ (**1**) was synthesized using a literature procedure (12*c*). *tert*-Butyl hydroperoxide was obtained commercially as a 70% aqueous solution, and the oxidant was pretreated according to a procedure described by Sharpless and Verhoeven (17) using 1,2-dichloroethane. The TBHP oxidant concentration was standardized by ^1H NMR (5.38 mol L^{-1} in 1,2-dichloroethane) prior to use (17).

General procedure for the catalytic oxidation of anisoles

Protocol I

A mixture of anisole (1 mmol), TBHP in 1,2-dichloroethane (0.65 mL, 2.3 equiv.), and **1** (6.3 mg, 1.0 mol%) was stirred in CH_2Cl_2 (5 mL) at room temperature for 14 h. The reaction was quenched by the addition of sodium thiosulphate (100 mg), and the mixture was analyzed by GLC to determine the substrate consumption. To isolate the reaction products, the solvent was removed by rotary evaporation, and the residue was purified by flash column chromatography using 1% ethyl acetate in *n*-hexane as eluant.

Protocol II

A mixture of complex **1** (10.6 mg, 1.6 mol%, MeOH-*t*-BuOH, 1:1 by volume, 2 mL) and TBHP (3.5 equiv.) was

© 2005 NRC Canada

added dropwise (0.5 mL min^{-1}) to a solution of 1,2-dichloroethane (2 mL) containing anisole (1 mmol) and TBHP (3.5 equiv.) at 80 °C over 2 h. The reaction mixture was stirred for an additional 2 h. The reaction was quenched by adding sodium thiosulphate (100 mg), and the substrate consumption was determined by GLC analysis. After removal of solvent by rotary evaporation, the residue was purified by flash column chromatography using 0.5%–1% ethyl acetate in *n*-hexane as eluant.

3,4-Dimethoxy-4-*tert*-butoxy-2,5-cyclohexadienone (3a)

TLC: R_f = 0.5 (30% ethyl acetate in *n*-hexane). IR (neat KBr, υ cm^{-1}): 1670, 1634, 1607. ^{1}H NMR (400 MHz, $CDCl_3$) δ_H: 6.92 (d, *J* = 10.3 Hz, 1H), 6.25 (dd, *J* = 10.3, 1.7 Hz, 1H), 5.59 (d, *J* = 1.7 Hz, 1H), 3.80 (s, 3H), 3.42 (s, 3H), 1.24 (s, 9H). ^{13}C NMR (100 MHz, $CDCl_3$) δ_c: 187.89, 169.89, 141.68, 131.41, 104.99, 98.22, 83.14, 57.71, 53.86, 26.72. EI (%): 153 ([M – O-*t*-Bu], 100). HRMS (EI) calcd. for [M – O-*t*-Bu]$^+$: 153.1552; found: 153.1554 ($C_8H_9O_3$).

4-*tert*-Butoxy-4-methoxy-2,5-cyclohexadienone (3b)

TLC: R_f = 0.6 (20% ethyl acetate in *n*-hexane as developing solvent). IR (neat KBr, υ cm^{-1}): 1644. ^{1}H NMR (400 MHz, $CDCl_3$) δ_H: 6.94 (d, *J* = 10.3 Hz, 2H), 6.26 (d, *J* = 10.3 Hz, 2H), 3.45 (s, 3H), 1.25 (s, 9H). ^{13}C NMR (100 MHz, $CDCl_3$) δ_c: 185.13, 141.39, 129.59, 95.47, 81.11, 50.75, 26.29. EI (%): 123 ([M – O-*t*-Bu], 100). HRMS (EI) calcd. for [M – O-*t*-Bu]$^+$: 123.0447; found: 123.0446 ($C_7H_7O_2$).

3-Methyl-4-*tert*-butoxy-4-methoxy-2,5-cyclohexadienone (3c)

TLC: R_f = 0.6 (30% ethyl acetate in *n*-hexane as developing solvent). IR (neat KBr, υ cm^{-1}): 1678. ^{1}H NMR (400 MHz, $CDCl_3$) δ_H: 7.14 (d, *J* = 10.4 Hz, 1H), 6.32 (d, *J* = 10.4 Hz, 1H), 6.16 (m, 1H), 3.26 (s, 3H), 2.00 (s, 3H), 1.25 (s, 9H). ^{13}C NMR (100 MHz, $CDCl_3$) δ_c: 185.48, 153.85, 143.57, 130.69, 129.52, 98.02, 81.74, 52.04, 26.72, 17.56. EI (%): 137 ([M – O-*t*-Bu], 100). HRMS (EI) calcd. for [M – O-*t*-Bu]$^+$: 137.0598; found 137.0603 ($C_8H_9O_2$).

2-Methyl-4-*tert*-butoxy-4-methoxy-2,5-cyclohexadienone (3d)

TLC: R_f = 0.6 (30% ethyl acetate in *n*-hexane as developing solvent). IR (neat KBr, υ cm^{-1}): 1651. ^{1}H NMR (400 MHz, $CDCl_3$) δ_H: 6.94 (dd, *J* = 10.3 Hz, 1H), 6.67 (m, 1H), 6.24 (d, *J* = 10.3 Hz, 1H), 3.44 (s, 3H), 1.93 (s, 3H), 1.25 (s, 9H). ^{13}C NMR (100 MHz, $CDCl_3$) δ_c: 186.20, 141.91, 137.28, 136.64, 129.86, 96.43, 81.35, 51.12, 26.74, 16.00. EI (%): 137 ([M – O-*t*-Bu], 100). HRMS (EI) calcd. for [M – O-*t*-Bu]$^+$: 137.0598; found: 137.0603 ($C_8H_9O_2$).

4,4-Di-*tert*-butoxy-2,5-cyclohexadienone (3h)

TLC: R_f = 0.7 (20% ethyl acetate in *n*-hexane as developing solvent), colorless crystal. IR (neat KBr, υ cm^{-1}): 1644. ^{1}H NMR (400 MHz, $CDCl_3$) δ_H: 7.02 (d, *J* = 10.4 Hz, 2H), 6.25 (d, *J* = 10.4 Hz, 2H), 1.26 (s, 18H). ^{13}C NMR (100 MHz, $CDCl_3$) δ_c: 185.81, 140.33, 129.67, 99.05, 81.77, 26.72. EI (%): 123 ([M – O-*t*-Bu], 100). HRMS (EI) calcd. for [M – O-*t*-Bu]$^+$: 123.0447; found: 123.0448 ($C_7H_7O_2$).

3-Bromo-4-*tert*-butoxy-4-methoxy-2,5-cyclohexadienone (3k)

TLC: R_f = 0.6 (30% ethyl acetate in *n*-hexane as developing solvent). IR (neat KBr, υ cm^{-1}): 1674. ^{1}H NMR (400 MHz, $CDCl_3$) δ_H: 7.20 (d, *J* = 10.3 Hz, 1H), 6.82 (d, *J* = 1.9 Hz, 1H), 6.40 (dd, *J* = 10.3, 1.9 Hz, 1H), 3.35 (s, 3H), 1.27 (s, 9H). ^{13}C NMR (100 MHz, $CDCl_3$) δ_c: 182.83, 143.50, 143.24, 134.98, 129.86, 96.34, 82.00, 52.07, 26.38. EI (%): 203 ([M – O-*t*-Bu], 47), 201 ([M – O-*t*-Bu], 100). HRMS (EI) calcd. for [M – O-*t*-Bu]$^+$: 200.9550; found: 200.9551 ($C_7H_6BrO_2$).

Synthesis of a novel photocatalyst, $ZnBiVO_4$, for the photodecomposition of H_2S[1]

B.B. Kale, Jin-Ook Baeg, Jin S. Yoo, Sang Mi Lee, Chul Wee Lee, Sang-Jin Moon, and Hyunju Chang

Abstract: A novel metal-oxide photocatalyst, $ZnBiVO_4$, was investigated for the photodecomposition of hydrogen sulfide. $ZnBiVO_4$ was prepared using the solid-state method, as well as a solution route for the first time. Oxides of zinc, bismuth, and vanadium were used for the solid-state method, whereas the respective metal salts were used as precursors for the solution route synthesis. The microstructure of the newly prepared $ZnBiVO_4$ was examined using XRD and FESEM. Tetragonal and monoclinic crystallite systems were observed in this ternary oxide system. Nanocrystalline $ZnBiVO_4$ was obtained through the solution route. The catalyst was also characterized using UV–visible diffuse reflectance spectroscopy to evaluate its band gap. Photodecomposition of H_2S using this catalyst was observed for the first time. The influence of preparation methods on the photocatalytic activity of $ZnBiVO_4$ was examined and it was observed that the $ZnBiVO_4$ prepared by the solution route led to a higher photocatalytic activity during H_2S decomposition. It is noteworthy that the hydrogen evolution was enhanced by 100% using $ZnBiVO_4$ prepared by the solution route as compared with the $ZnBiVO_4$ prepared by the solid-state method.

Key words: photocatalyst, $ZnBiVO_4$, hydrogen sulfide, metal oxide, photodecomposition.

Résumé : On a étudié le $ZnBiVO_4$, un nouvel oxyde métallique, comme photocatalyseur pour la photodécomposition du sulfure d'hydrogène. On a préparé le $ZnBiVO_4$ utilisant une voie à l'état solide et, pour la première fois, une vois en solution. Les oxydes de zinc, de bismuth et de vanadium ont été utilisés dans la méthode en phase solide alors que les sels des métaux respectifs ont été utilisés comme précurseurs pour la méthode de synthèse en solution. La microstucture du $ZnBiVO_4$, qui était préparé pour la première fois, a été caractérisée par « XRD » et « FESEM ». On a observé des de cristallisation tétragonal et monoclinique dans ce système d'oxyde ternaire. Cette voie nous a permis d'obtenir du $ZnBiVO_4$ nanocristallin. Afin d'évaluer sa bande interdite, le catalyseur a aussi été caractérisé par spectroscopie de réflectance diffuse UV–visible. La photodécomposition du sulfure d'hydrogène à l'aide de ce catalyseur a été observée pour la première fois. On a examiné l'influence des méthodes de préparation sur l'activité catalytique du $ZnBiVO_4$ et on a observé que le $ZnBiVO_4$ préparé par la voie en solution possède une activité photocatalytique supérieure pour la décomposition du H_2S. Il est remarquable que l'évolution de l'hydrogène est augmentée de 100 % dans le $ZnBiVO_4$ préparé en solution par comparaison au $ZnBiVO_4$ préparé par la méthode à l'état solide.

Mots clés : photocatalyseur, $ZnBiVO_4$, sulfure d'hydrogène, oxyde métallique, photodécomposition.

[Traduit par la Rédaction]

Introduction

Decomposition of hydrogen sulfide is of considerable interest because of its environmental hazard. The well-established Claus process is currently used for the decomposition of hydrogen sulfide (1). This conventional Claus process involves the synproportionation reaction between H_2S and SO_2, yielding elemental sulfur and water vapor. If hydrogen can be recovered from H_2S instead of oxidizing it into H_2O (Claus process), an immense amount of hydrogen can be produced (2). Photocleavage of H_2S to H_2 by semiconductor particle photocatalyst has been considered as a process that could ultimately convert solar energy into fuels. This process requires less energy than the photodecomposition of water. In this connection, recovery of H_2 from H_2S has attracted more attention because of its economic and environmental advantages. Of late, development of a photocatalyst for the photodecomposition of hydrogen sulfide and water into hydrogen has been a subject matter of immense interest, owing to the energy production and pollution abatement. Extensive work has been carried out in the development of ultraviolet-driven photocatalysts for water and H_2S

splitting. However, there is a demand for a highly efficient photocatalyst for the photoproduction of hydrogen. In the development of efficient photocatalyst materials, it is essential to control the band structure of the photocatalyst.

The approach for the design of the photocatalyst is classified in three ways. Approach (*a*) is the doping of foreign transition elements into active, existing photocatalysts (3–6). Especially, Ni- and Cu-doped ZnS photocatalysts show activity for H_2 evolution under visible-light irradiation even without a Pt catalyst. Many researchers have reported the doping methods for CdS, ZnS, VS, VS_4, and WO_3 (7–12). Approach (*b*) is to find materials that have a stable valence band in a more negative position than the valence band of conventional metal-oxide photocatalysts. The nitrides (Ta_3N_5), oxynitrides (TaON, $LaTiO_2N$), and oxysulfides ($Sm_2Ti_2S_2O_5$) (13–18) have been reported as active photocatalysts. Approach (*c*) involves a control of the energy structure by making solid solutions between semiconductor photocatalysts with wide and narrow band gaps. The photophysical properties and photovoltaic efficiencies of Nb_2O_5-Bi_2O_3, Ga_2O_3-In_2O_3, $SrNb_2O_7$, $Sr_2Ta_2O_7$, SnO_2-TiO_2, ZnS-CdS, CdS-CdSe, and $(AgIn)_xZn_{2(1-x)}S_2$ (19–23) have been studied extensively. Several nanocrystalline photocatalysts have been reviewed by Beydoun et al. (24), where he described the effect of nanoparticles on photocatalytic activity. Recently, CdS-TiO_2 nanocomposite film (25) has been used for the photodecomposition of H_2S. The stable and suitable metal-oxide support is lacking in this work. In the past, the research for the photodecomposition of H_2S was focused on sulfide semiconductor photocatalysts, which are unstable because of photocorrosion of the catalyst. So, there is a need to find a stable, economical, and efficient new metal-oxide photocatalyst for hydrogen production.

In view of this, we have investigated a novel photocatalyst, $ZnBiVO_4$, for the photodecomposition of H_2S for the first time. We investigated the synthesis of this catalyst by both the solid-state and the solution route. The tentative structural and morphological study was carried out using XRD and FESEM. The nanosize $ZnBiVO_4$ was obtained using the solution route. The influence of the preparation method on the activity of the photocatalyst was demonstrated. This paper describes the novelty in the synthesis of this new product, its characterization, and its photocatalytic activity.

Experimental section

Materials

To prepare $ZnBiVO_4$ by the solid-state reaction, a stoichiometric (1:0.5:0.5) mixture of ZnO, Bi_2O_3, and V_2O_3 was thoroughly ground in a mortar, and this homogeneous reaction mixture was then calcined at 670 °C for 24 h in static air and recalcined at 725 °C for 12 h. To prepare $ZnBiVO_4$ by the solution route, a stoichiometric amount of $Zn(NO_3)_2{\cdot}5H_2O$, $Bi(NO_3)_3{\cdot}6H_2O$, and ammonium metavanadate (NH_4VO_3) was dissolved in water and heated slowly at 70 °C until evaporation. The powder obtained was calcined at 180 °C for 12 h. The resulting product was washed several times with water and ethanol and then dried at 120 °C for 5 h.

Characterization

Powder X-ray diffractograms were recorded with a Model Rigaku-D/MaX-2200V X-ray diffractometer with Cu Kα radiation and an Ni filter. The surface morphology and particle size were determined using a field emission scanning electron microscope (FESEM Model JEOL-JSM6700F). Spectroscopic study of the catalyst was carried out using a UV–vis (Model SHIMADZU UV-2450 diffuse reflectance mode) spectrophotometer and a Fourier Transform Infrared Spectrophotometer (Model, JASCO 610-FTIR). Specific surface area measurements were performed using a BET Surface Area Analyzer (Model BET-MICROMERITICS ASAP-2400).

Photodecomposition of H_2S

The photocatalyst was introduced as a suspension into a cylindrical pyrex photochemical reactor with a water-cooled quartz immersion well and a thermostated water-jacket. A high-pressure mercury lamp (Hanovia) source of intensity 450 W with pyrex cut-off filter was used. At a constant temperature of 25 ± 1 °C, the vigorously stirred suspension was purged with argon for 1 h, and then hydrogen sulfide (H_2S) was bubbled through the solution for about 1 h.

Each experiment was carried out using 1 g of catalyst in 500 mL of distilled water with an H_2S flow of 10 mL/min. The excess hydrogen sulfide was trapped in an NaOH solution. The amount of evolved hydrogen was measured using a graduated gas burette and gas chromatograph (Model Shimadzu GC-14B, MS-5A column, TCD, Ar carrier).

Results and discussion

Synthesis by the solid-state method: $ZnBiVO_4$ (s-s)

$ZnBiVO_4$ has been synthesized for the first time using the solid-state route. According to the thermodynamics and the phase diagrams of the individual components (i.e., ZnO, Bi_2O_3, and V_2O_3), the reaction temperature was expected to be 1000 °C. Since the phase diagram of the V_2O_3 component system was not available in the literature, assumptions were made with the help of the V_2O_5 data. The solid solution was homogenized for 15 h in an alumina crucible at 650 °C, and the compound formed from the reactant components at 670 °C on calcination. The product obtained was crushed, homogenized in mortar, and finally recalcined at 725 °C for 12 h to obtain $ZnBiVO_4$ with good crystallinity. The composition of the final product was verified using XRD and EDS analysis. The presence of the VO_4 group was confirmed by IR spectroscopy. No weight loss or gain after reaction suggested that the stoichiometry of the product was retained.

Synthesis by the solution route: $ZnBiVO_4$ (sol)

Zinc nitrate, bismuth nitrate, and ammonium metavanadate were taken in stoichiometric quantities in aqueous medium and evaporated slowly at 70 °C until dryness. The dried powder was crushed, homogenized, and calcined at 180 °C for 12 h. Ammonium vanadate is soluble in water and forms H_3VO_4 as per the following reaction:

[1] $$H_2O + NH_4VO_3 \rightarrow NH_3 + H_3VO_4$$

© 2005 NRC Canada

During the slow evaporation, Zn and Bi ions in water were reacted with H_3VO_4 and formed $ZnBiVO_4$. The detailed mechanism of the reaction is under investigation. XRD, UV–vis (DRS), and IR spectroscopy confirmed the phase purity of the product.

X-ray analysis

Powder XRD patterns of $ZnBiVO_4$, prepared by the solid-state and the solution route, are shown in Fig. 1. The differences in the XRD patterns of $ZnBiVO_4$ (s-s) and $ZnBiVO_4$ (sol) can be judged by the existence of the peaks at $2\theta = 13°$ and the splitting peaks at $2\theta = 18.5°$, 35°, and 46°. The main (100% relative intensity) peak was obtained at $2\theta = 28.8°$ and shows the existence of the $ZnBiVO_4$ phase. From the XRD pattern, sharp peaks observed at $2\theta = 13°$ and 18.8° reveal the existence of a mixture of tetragonal and monoclinic crystal systems in $ZnBiVO_4$ (sol). In the XRD pattern of $ZnBiVO_4$ (s-s), the peak at $2\theta = 13°$ is absent and the peak at 15° is not significant (relative intensity is very low), which clearly reveals the existence of a mostly tetragonal crystal system. It also shows that the crystal system of compound $ZnBiVO_4$ is dependent on the preparation method. The XRD pattern of $ZnBiVO_4$ (s-s) shows a few unknown weak peaks, which originated from the raw materials. However, peaks pertaining to impurities or the intermediate materials were not observed in the XRD pattern of $ZnBiVO_4$ (sol). This observation indicates that $ZnBiVO_4$ (sol) is of a better quality than $ZnBiVO_4$ (s-s). The XRD pattern of $ZnBiVO_4$ (sol) shows more peak broadening because of the nanocrystalline nature of the powder. A comparison of the experimental XRD data with the XRD data of the raw materials and their related compounds showed the absence of peaks corresponding to those raw materials in the experimental XRD data. Further structural investigation of the product is in progress and will be presented in our next communication.

Powder morphology

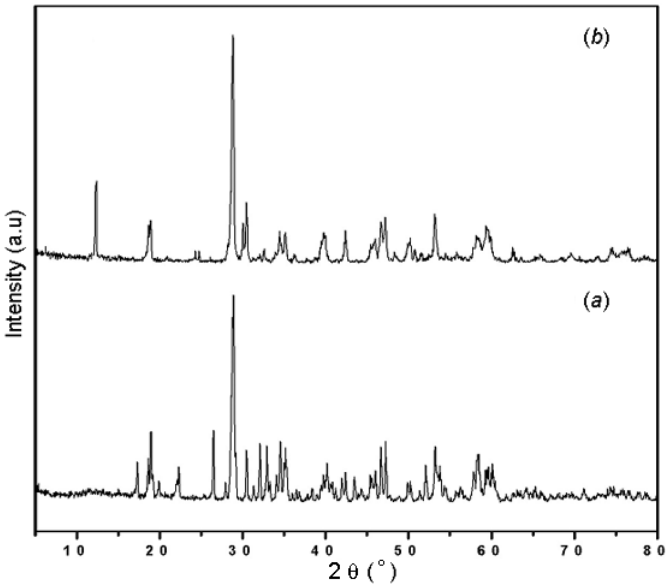
A FESEM micrograph of $ZnBiVO_4$ (s-s) is presented in Fig. 2. Spherical and plate-like crystallites with about 0.7–2 μm particle size were observed for $ZnBiVO_4$ (s-s). The FESEM micrograph also shows considerable agglomeration of the plate-like crystallites.

Figures 3*a* and 3*b* show the FESEM pictures of $ZnBiVO_4$ (sol) at lower and higher magnifications, respectively. The particle shapes were spherical. Some of the crystals possessed plate-like morphology with a plate diameter of about 28–200 nm. The minimum size of the crystallite was observed in the range of 20–30 nm. In fact, some of the crystals were less than 20 nm and thus could not be measured by FESEM. The morphology observed for $ZnBiVO_4$ (sol) was completely different than the solid-state route sample, i.e., $ZnBiVO_4$ (s-s). Since the synthesis was carried out at a low temperature, nanocrystalline $ZnBiVO_4$ was obtained. The SEM observations are thus in agreement with our XRD results. From the SEM results it is understood that the particle size and morphology are dependent on the preparation method of the product.

Spectroscopic study

Figure 4 shows a graph of the UV–vis diffuse reflectance of (*a*) $ZnBiVO_4$ (s-s) and (*b*) $ZnBiVO_4$ (sol). The absorption

Fig. 1. XRD pattern of (*a*) $ZnBiVO_4$ (s-s) and (*b*) $ZnBiVO_4$ (sol).



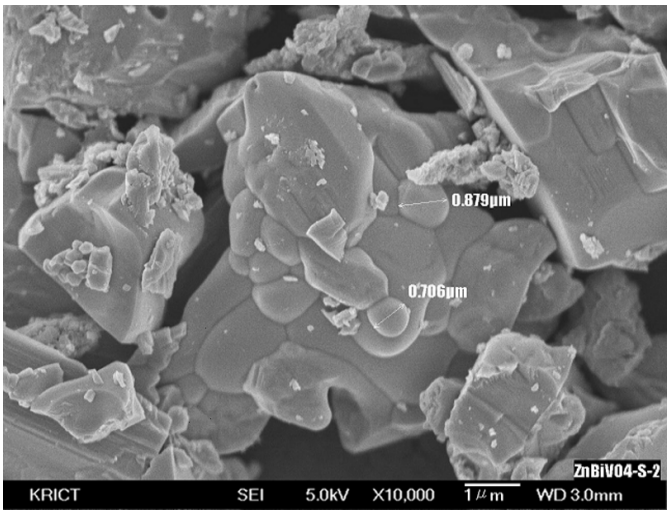


Fig. 2. FESEM micrograph of $ZnBiVO_4$ (s-s).

edge cut-off wavelengths for $ZnBiVO_4$ (s-s) and $ZnBiVO_4$ (sol) were 540 nm and 560 nm, respectively. $ZnBiVO_4$ (s-s) has a sharp absorption cut-off as compared with $ZnBiVO_4$ (sol). This implies that $ZnBiVO_4$ (s-s) is more crystalline with uniform particles, whereas $ZnBiVO_4$ (sol) has mixed crystal sizes with irregular-shaped particle morphology. These observations are in good agreement with the FESEM results. The nature of the broad steepness of the UV–vis DRS cut-off shows the nanocrystalline nature of the particle with agglomeration. Non-uniformity in particle size and shape is also one of the reasons for the broad UV cut-off of $ZnBiVO_4$. From the spectra, the estimated band gap energies (Table 1) of these materials were found to be 2.21 and 2.30 for $ZnBiVO_4$ (s-s) and $ZnBiVO_4$ (sol), respectively. The marginal difference in the band gaps shows the existence of a similar structure for both the products.

Fig. 3. FESEM micrographs of $ZnBiVO_4$ (sol).

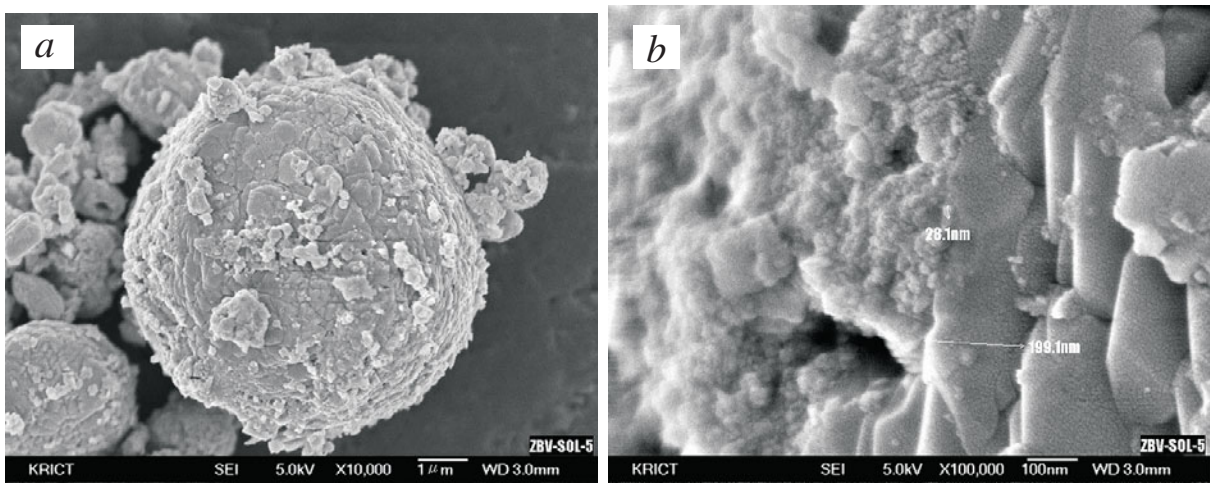

Fig. 4. UV–vis diffuse reflectance spectra of (*a*) $ZnBiVO_4$ (s-s) and (*b*) $ZnBiVO_4$ (sol).

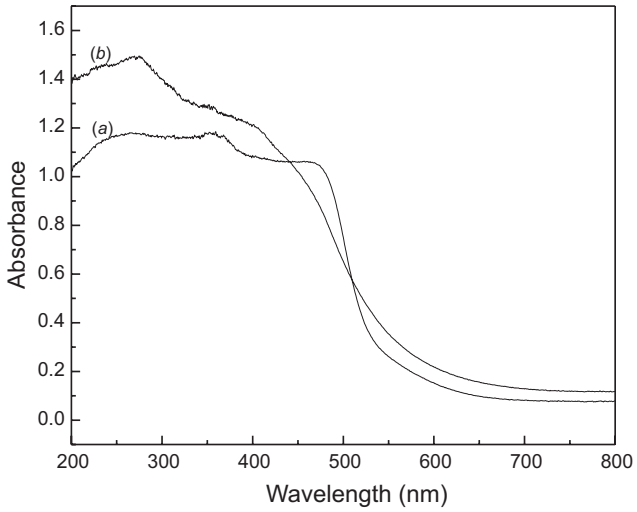

Figure 5 shows the IR spectrums of (*a*) $ZnBiVO_4$ (s-s) and (*b*) $ZnBiVO_4$ (sol). These represent a typical pattern built up by VO_4 tetrahydra (26). The absorption bands were characterized as follows: υ_1 (VO_4) and υ_3 (VO_4) = 500–900 cm^{-1} and υ_4 (VO_4) = 478 cm^{-1}. Accordingly, bands were assigned as shown in Fig. 5. A clear band centred at 734 cm^{-1} in $ZnBiVO_4$ (s-s) is the characteristic band of VO_4. This characteristic vibrational band is shifted to 743 cm^{-1} in the case of $ZnBiVO_4$ (sol). This may be because of the distortion in the metal—oxide bonds (26), which distortion indicates a monoclinic crystallite system. The bands centered at 1356 cm^{-1} and 1384 cm^{-1} are characteristic of the nitrates (present in $ZnBiVO_4$ (sol)) that originated from the starting materials. These bands were absent in the $ZnBiVO_4$ prepared by the solid-state method. A weak broad band centred at 3436 cm^{-1} was due to O–H stretching, which was present in both the samples. This O–H stretching was observed because of the adsorbed water present in the product.

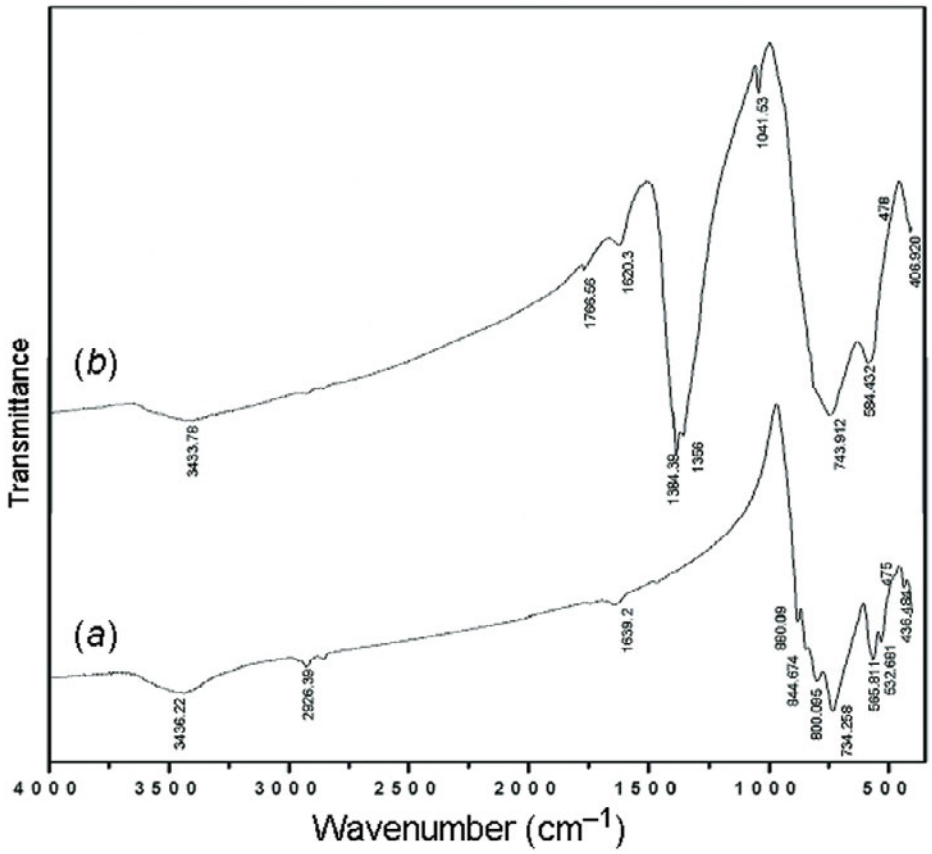
The infrared spectra for the samples (*a*) $ZnBiVO_4$ (s-s) and (*b*) $ZnBiVO_4$ (sol) are similar, except for the nitrate impurity in the latter. The sample (*a*) showed other unknown weak bands, which may have originated from starting oxide materials. The absence of bands from 900–1000 cm^{-1} implies the absence of other oxygen states. The present IR data reveals that $ZnBiVO_4$ consists of tetrahedral VO_4 groups, so that the chemical structure can be described by $ZnBiVO_4$. The IR data obtained is in good agreement with our XRD observations.

Table 1. Photocatalytic activities of the $ZnBiVO_4$ photocatalyst for H_2 evolution from H_2S.

Catalyst[a]	Band gap energy (eV)	Specific surface area BET (m^2/g)	H_2 evolution rate (mL/h)
$ZnBiVO_4$ (s-s)	2.21	0.27	57
$ZnBiVO_4$ (s-s)	2.21	0.27	52[b]
$ZnBiVO_4$ (sol)	2.30	4.70	122
$ZnBiVO_4$ (sol)	2.30	4.70	104[b]



[a]Catalyst: 1.0 g, 500 mL of H_2S saturated H_2O (pH = 4.4), H_2S (10 mL/min), 450 W Hg lamp ($\lambda \geq 325$ nm).
[b]An aqueous solution of KOH (0.5 mol/L) + H_2S (pH = 8.5).

Photodecomposition of H_2S

The photocatalytic activity of the $ZnBiVO_4$ for photodecomposition of hydrogen sulfide was investigated. Different series of experiments were carried out using catalysts prepared by both the solid-state and the solution route. Table 1 shows the rates of hydrogen evolution for photocatalytic decomposition of hydrogen sulfide using $ZnBiVO_4$ (s-s) and $ZnBiVO_4$ (sol). These results reveal that the photocatalytic activity has been enhanced by almost 100% for $ZnBiVO_4$ (sol) as compared with $ZnBiVO_4$ (s-s). This enhancement in catalytic activity may be due to the nanosize particles (less than 28 nm) and high surface area of $ZnBiVO_4$ (sol). The surface area of $ZnBiVO_4$ (s-s) was 0.27 m^2/g, whereas that of $ZnBiVO_4$ (sol) was around 4.7 m^2/g (Table 1), which shows a considerable enhancement in the BET surface area in the case of the sample prepared by the solution route. This could be one of the reasons for the enhancement of the photocatalytic activity. The photodecomposition carried out at higher pH (Table 1) did not show an appreciable effect on the photocatalytic activity. A marginal decrease in activity was observed while using

© 2005 NRC Canada

Fig. 5. IR spectra of (*a*) $ZnBiVO_4$ (s-s) and (*b*) $ZnBiVO_4$ (sol).

the $ZnBiVO_4$ (sol) sample, and this may be because of the low concentration of protons at high pH (24, 27). But overall, higher photocatalytic activity was observed in the case of $ZnBiVO_4$ (sol) when compared with $ZnBiVO_4$ (s-s).

Cited literature on $BiVO_4$ (26) shows that the tetragonal $BiVO_4$ has not shown any photocatalytic activity, whereas monoclinic $BiVO_4$ showed good photocatalytic activity. The reason quoted is that the monoclinic $BiVO_4$ is greatly distorted as compared with tetragonal $BiVO_4$. A similar phenomenon is observed in $ZnBiVO_4$, where the distortion has arisen because of the $6s^2$ loan pairs of Bi^{3+}. The photocatalytic activity has been enhanced significantly in $ZnBiVO_4$ (sol), owing to distortion caused by the $6s^2$ loan pairs of Bi^{3+}. Such effects have been reported earlier (26) for the same compound with a different crystal structure. This indicates that the distortion of the metal oxygen polyhedron is an important factor affecting the photocatalytic properties. The distortion probably affects the charge separation and dislocation of photogenerated electrons and holes. The high surface area and nanosize particles also help to enhance the photocatalytic activity in $ZnBiVO_4$ (sol).

A possible reaction mechanism for the photodecomposion of H_2S is proposed as per the following scheme (28):

[2] $2H_2S \rightarrow 2HS^- + 2H^+$

[3] $2HS^- + 2h^+_{VB} \rightarrow S_2^{2-} + 2H^+$

[4] $S_2^{2-} + 2h^+_{VB} \rightarrow 2S$

[5] $4H^+ + 4e^-_{CB} \rightarrow 2H_2$

[6] $2H_2S \rightarrow 2H_2 + 2S$

According to reaction [2], the bisulfide ion and the proton are produced by the dissociation of H_2S. The photogenerated hole on the surface of the photocatalyst oxidizes the bisulfide ion to give elemental sulfur (reactions [3] and [4]). Finally, hydrogen is formed via the reduction of protons by the photogenerated electrons (reaction [5]). Reaction [6] illustrates the overall process and corresponds to the cleavage of H_2S by two photons of light, which require a Gibbs energy of 7.892 kcal/mol (29).

Summary

A new compound, $ZnBiVO_4$, for use as a photocatalyst has been synthesized by a solid-state route for the first time. A new low-temperature and ambient-pressure aqueous process has also been developed for the synthesis of $ZnBiVO_4$. The product obtained by the solid-state method (i.e., $ZnBiVO_4$ (s-s)) exhibits a tetragonal crystal structure, whereas the product obtained by the solution route (i.e., $ZnBiVO_4$ (sol)) shows a monoclinic crystal structure. The sizes of the crystallites in the product prepared by the solution route were observed to be in the range of 20–28 nm. Some of the crystals possessed plate-like morphology with plate diameter of about 28–200 nm. The photodecomposition of hydrogen sulfide for the production of hydrogen using $ZnBiVO_4$ was studied for the first time. The photocatalytic activity has been enhanced almost 100% with use of $ZnBiVO_4$ (sol) as compared with the solid-state product

© 2005 NRC Canada

$ZnBiVO_4$ (s-s). This enhancement of the photocatalytic activity was attributed to the high surface area of the nanopowder and to distortion caused by the $6s^2$ loan pairs of Bi^{3+} in $ZnBiVO_4$ (sol). This indicates that the distortion of the metal oxygen polyhedron is an important factor affecting the photocatalytic properties. The distortion probably affects the charge separation and dislocation of photogenerated electrons and holes. Further structural investigations and the detailed catalytic activity of the photocatalyst are underway.

Catalytic asymmetric synthesis of cyclopropylphosphonates — Catalysts' scope and reactivity[1]

André B. Charette and Jean-Emmanuel Bouchard

Abstract: The transition metal-catalyzed cyclopropanation of alkenes using α-diazomethylphosphonates leads to cyclopropylphosphonate derivatives in high yields. The reaction proceeds well with copper, rhodium, and ruthenium catalysts. The best catalysts for the enantioselective version are either Evans' Cu•bis(oxazoline) or Nishiyama's Ru•pybox.

Key words: cyclopropylphosphonic acids, copper catalysts, ruthenium catalysts, cyclopropanation, diazo reagents.

Résumé : La cyclopropanation d'alcènes impliquant la décomposition de dérivés α-diazométhylphosphonate catalysée par des métaux de transition conduit aux dérivés cyclopropylphosphonate avec de bons rendements. La réaction s'effectue efficacement avec des catalyseurs dérivés du cuivre, rhodium et ruthénium. Les meilleurs catalyseurs pour la version énantiosélective sont le Cu•bis(oxazoline) d'Evans et le Ru•pybox de Nishiyama.

Mots clés : acides cyclopropylphosphoniques, catalyseurs de cuivre, catalyseurs de ruthénium, cyclopropanation, dérivés diazoïques.

Introduction

Phosphinic acid derivatives are quite important synthetic derivatives that have been used to mimic the biological activity of phosphates and carboxylic acids (1). They have found wide applications in medicinal chemistry and agrochemical sciences. Unlike the weak phosphorus–oxygen bond in phosphates, the carbon–phosphorus bond is not easily hydrolyzed and is, therefore, unsusceptible to the action of phosphatases. Some important examples are shown in Fig. 1. Compound **1** possesses antiviral properties (2, 3), **2** is a nucleoside analog (4), and finally, fosfomycin (**3**) is a commonly used antibiotic (5).

One attractive and expedient method for the generation of enantiomerically pure cyclopropylphosphonate derivatives would be to generate them from a catalytic asymmetric addition of a suitably functionalized metal carbene to an alkene to generate the cyclopropane (Fig. 2). Given the efficiency of the analogous reaction using an ester functionality in place of the phosphonate group, one should expect excellent enantio- and diastereocontrol if the appropriately substituted precursor is used. Traditionally these compounds have been prepared by carbene chemistry (6–8), by a Michaëlis–Arbuzov reaction from a *gem*-dibromocyclopropane (9), or by an alkylation – ring closure process (10, 11).

In this paper, we report our study towards the development of an efficient synthesis of enantiomerically enriched cyclopropylphosphonates (12). Various catalysts and phosphonate esters were surveyed to optimize both the enantioselectivities and the diastereoselectivities. This work complements Simonneaux and co-workers' (13–16) recent reports on the use of ruthenium porphyrin catalysts.

Results and discussion

Synthesis of racemic substituted cyclopropylphoshonate esters

Our first goal was to establish which were the best achiral catalysts to generate cyclopropylphosphonate derivatives (Table 1) (17). Although it is well-established that bulkier esters provide higher diastereocontrol in the cyclopropanation of alkenes using α-diazoacetate derivatives (18) and that such a trend should also be observed with the analogous phosphonate reagents, the initial catalyst calibration was done with the diethylphosphonate derivative **4**. Several catalysts were tested and, as expected, the most reactive were the rhodium-based catalysts (Table 1, entries 2–4). Copper(I) triflate was also quite effective but in all the examples, the diastereocontrol was extremely low (Table 1, entry 1). A ruthenium-based system provided a lesser reactive metal carbene, but the diastereoselectivity was much better (Table 1, entry 5).

Several alkenes were submitted to these reaction conditions using rhodium(II) pivalate and good to excellent yields

of the corresponding cyclopropane were obtained with mono-, di- and trisubstituted alkenes (Fig. 3). However, these reactions produced separable mixtures of the *cis*- and *trans*-cyclopropane isomers.

Enantioselective cyclopropanation — Copper-based catalysts

Although there is an extensive number of efficient copper-based catalysts for the cyclopropanation of α-diazoesters, the bis(oxazoline)-based catalysts were screened because of their accessibility and their efficiency in the cyclopropanation of mono- and disubstituted alkenes using α-diazoesters. As already highlighted by Evans et al. (19) for the cyclopropanation of α-diazoesters, the bis(oxazoline) **21** derived from *tert*-leucine provided not only the highest enantioselectivities but also the best diastereocontrol (Table 2). A similar level of enantiocontrol was also observed with the bis(oxazoline) **22** derived from serine. Increasing the steric bulk of the R groups of the phosphonate reagent led to a slightly improved diastereocontrol, but the enantioselectivities were mostly ligand-dependent. For example, the diisopropyl α-diazomethylphosphonate and the neopentyl α-diazomethylphosphonate reagents **13** and **14** led to higher diastereoselectivities, but the enantiomeric excesses of the products were similar. The scope of the reaction for the Cu·bis(oxazoline) **21** catalyzed cyclopropanation of disubstituted alkenes with diethyl α-diazomethylphosphonate is shown in Fig. 4. The general trend is that the diastereocontrol is relatively modest and the enantioselectivities are lower than those observed for the cyclopropanation of styrene. Furthermore, the cyclopropanation of 1,2-disubstituted alkenes produced the corresponding cyclopropane in modest yields and enantioselectivities.

Enantioselective cyclopropanation using ruthenium-based catalysts

Nishiyama's ruthenium catalysts (20) are among the most efficient ones for the cyclopropanation of alkenes with ethyl diazoacetate. Although the ruthenium carbene is usually less reactive than the analogous rhodium derivative, the corresponding cyclopropane is obtained with high diastereo- and enantiocontrol.

Table 3 illustrates the optimization process that led to the identification of the most efficient ligand and reagent combination. As previously reported by Nishiyama (20) for the cyclopropanation of alkenes using α-diazoesters, the ligand derived from valine was the most effective (Table 3, entry 1 vs. 2 vs. 4). Furthermore, the steric bulk of the phosphonate reagent was important in providing high diastereocontrol,

although even the diethyl derivative provided excellent diastereoselectivies (Table 3, entry 4).

The scope of the reaction is shown in Table 4. Monosubstituted alkenes led to the corresponding cyclopropane in high yield and enantiocontrol (Table 4, entries 1–3, 7). In all the reactions, the diastereoselectivity was greater than 95:5 favoring the trans isomer. The absolute stereochemistry was confirmed in one case (compound **31**) from the X-ray crystal structure (Fig. 5). 1,1-Disubstituted alkenes could also be used but the diastereocontrol was slightly lower (Table 4,

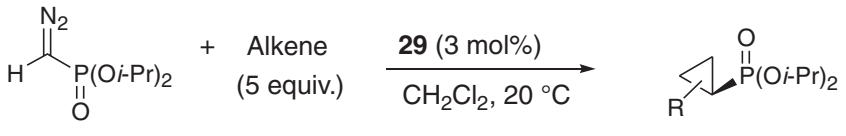
entry 4). Finally, when a diene was used, the cyclopropanation occurred at the least-hindered position (Table 4, entry 6).

It is also possible to further functionalize the cyclopropylphosphonate and to hydrolyze it to the corresponding phosphonic (21) acid. It is also possible to convert the styryl substituent into a primary alcohol through a oxidative cleavage – reduction sequence (eq. [1]).

Conclusion



We have shown that the preparation of enantiomerically enriched cyclopropylphosphonate derivatives can easily be accomplished using the copper- or ruthenium-catalyzed decomposition of diethyl or diisopropyl α-diazomethylphosphonate. The products are usually obtained in good enantiomeric excesses and excellent diastereocontrol.

0.449 mmol, 1 equiv.), CH_2Cl_2 (4 mL total). The purification of the 50:50 mixture (NMR) by flash chromatography on silica gel (80% EtOAc–hexanes) afforded (±)-*trans*-**10** as a colorless oil (63 mg, 53%) and (±)-*cis*-**10** (21 mg, 17%) as a colorless oil. (±)-*trans*-**10**: R_f 0.42 (EtOAc). IR (film, cm^{-1}): 2981, 2905, 1240, 1055, 1029, 963. ^1H NMR (300 MHz, $CDCl_3$) δ: 7.07–7.30 (m, 5H, C_6H_5), 4.10 (m, 4H, P-O-CH_2-CH_3), 2.35 (m, 1H, C_6H_5-$CH_{cycloprop}$), 1.85 (d, 3H, CH_3 (cis)) 1.57 (m, 1H, $CH_{cycloprop}$-P), 1.46 (d, J = 6.4 Hz, 3H, CH_3 (trans)), 1.36 (m, 6H, P-O-CH_2-CH_3), 1.20 (m, 2H, $CH_{2cycloprop}$). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 140.6, 140.58, 128.5, 126.3, 125.9, 62.8, 62.7, 61.6, 61.56, 61.51, 61.4, 29.5, 29.4, 22.4, 22.3, 22.0, 19.5, 16.5, 16.46, 16.4, 16.38, 14.0, 13.9. ^{31}P NMR (160 MHz, $CDCl_3$) δ: 29.3. HR-MS calcd. for $C_{14}H_{21}O_3P$ (M + H): 268.1228; found: 268.1230.

Dineopentyl diazomethylphosphonate (14)

To a solution of dineopentyl methylphosphonate (23) (3.00 g, 12.7 mmol, 1 equiv.) in THF (125 mL) at –78 °C was added dropwise 2.5 mol/L of *n*-BuLi in hexanes (2.50 mL, 1.5 equiv.). The mixture was stirred at –78 °C for 30 min and 2,2,2-trifluoroethyltrifluoroacetate (1.90 mL, 13.9 mmol, 1.1 equiv.) was added in one portion. The reaction was stirred at –78 °C for 25 min and then warmed to room temperaure. A 10% aqueous solution of HCl (5 mL) was added and the aqueous layer was extracted with two portions of EtOAc. The combined organic layers were washed with satd. aq. $NaHCO_3$, satd. aq. NaCl, dried over Na_2SO_4, and concentrated under reduced pressure. The residue was dissolved in acetonitrile (125 mL) and *p*-acetamidobenzenesulfonyl azide (3.05 g, 12.7 mmol, 1 equiv.) was added followed by triethylamine (1.80 mL, 12.7 mmol, 1 equiv.). The reaction mixture was stirred for 12 h at room temperature and satd. aq. NH_4Cl was added. The layers were separated and the aqueous layer was washed with EtOAc. The combined organic layers were washed with satd. aq. $NaHCO_3$, satd. aq. NaCl, dried over Na_2SO_4, and concentrated under reduced pressure. The residue was dissolved in $CHCl_3$ (30 mL) and the mixture was filtered through Celite®. The filtrate was concentrated under reduced pressure and the residue was purified by flash chromatography on silica gel (30% EtOAc–hexanes) to give the desired diazo reagent **14** as a yellow oil (1.10 g, 33%). R_f 0.50 (30% EtOAc–hexanes). IR (film, cm^{-1}): 2958, 2873, 2101, 1659, 1479, 1245, 999, 874, 850, 584. ^1H NMR (300 MHz, $CDCl_3$) δ: 3.77 (d, J = 11.1 Hz, 1H, CH=N_2), 3.75 (m, 4H, P-O-CH_2), 0.96 (s, 18H, C(CH_3)$_3$). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 75.75, 75.66, 32.2, 32.1, 32.06, 32.02, 26.0. ^{31}P NMR (160 MHz, $CDCl_3$) δ: 20.2. HR-MS calcd. for $C_{11}H_{23}N_2O_3P$ (M + H): 263.1511; found: 263.1513.

General procedure for the Cu·bis(oxazoline) 21 catalyzed cyclopropanation — Diethyl (1*R*,2*S*)-2-methyl-2-phenylcyclopropylphosphonate (23)

A solution of bis(oxazoline) **21** (3.70 mg, 0.0126 mmol, 0.031 equiv.) and copper(I) triflate (3.20 mg, 0.0124 mmol, 0.03 equiv.) in CH_2Cl_2 (2 mL) was stirred at room temperature for 3 h and α-methylstyrene (0.260 mL, 2.00 mmol, 5 equiv.) was added. A solution of diethyl α-diazomethylphosphonate (**4**) (73.2 mg, 0.411 mmol, 1 equiv.) in CH_2Cl_2 (2 mL) was added over 8 h via a syringe pump. The reaction was stirred for an additional 12 h at room temperature and was then concentrated under reduced pressure. The diastereomeric ratio (64:36) was determined by ^{31}P NMR of the crude reaction mixture (δ major: 30.5 and δ minor: 27.9). The crude mixture was then purified by flash chromatography on silica gel (80% EtOAc–hexanes) to give *trans*-**23** (46 mg, 47%) and *cis*-**23** (26 mg, 26%). The enantiomeric excesses (85%) were determined by SFC on a chiral stationary phase (Chiralcel OD, 1% MeOH, 1.2 mL/min: t_r (major) 19.9 min, t_r (minor), 18.1 min). *trans*-**23**: R_f 0.37 (EtOAc). IR (film, cm^{-1}): 2981, 1245, 1058, 1027, 960, 889, 769, 701. ^1H NMR (300 MHz, $CDCl_3$) δ: 7.31–7.26 (m, 5H, C_6H_5), 4.16 (m, 1H, P-O-CH_2CH_3), 1.66 (s, 3H, CH_3), 1.38 (m, 8H, P-O-CH_2CH_3, $CH_{2cycloprop}$), 1.33 (m, 1H, $CH_{cyclopropyl}$-P). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 146.3, 146.28, 128.7, 127.5, 126.7, 61.8, 61.76, 61.7, 27.6, 27.59, 22.1, 22.0, 19.8, 18.9, 18.87, 17.9, 16.8, 16.7, 16.69. ^{31}P NMR (160 MHz, $CDCl_3$) δ: 30.5. Anal. calcd. for $C_{14}H_{21}O_3P$: C 62.67, H 7.89; found: C 62.73, H 7.77. *cis*-**23**: R_f 0.25 (EtOAc). ^1H NMR (300 MHz, $CDCl_3$) δ: 7.17–7.44 (m, 5H, C_6H_5), 3.88 (m, 2H, P-O-CH_2CH_3), 3.70 (m, 1H, P-O-CH_2CH_3), 3.33 (m, 1H, P-O-CH_2CH_3), 1.64 (d, J = 2.4 Hz, 1H, $CH_{cycloprop}$-P), 1.60 (s, 3H, CH_3), 1.17 (m, 5H, P-O-CH_2CH_3, $CH_{2cycloprop}$), 0.96 (t, J = 7.1 Hz, 3H, P-O-CH_2CH_3). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 141.96, 141.9, 129.5, 128.2, 126.9, 61.5, 61.4, 61.35, 61.35, 61.3, 29.64, 29.6, 28.24, 28.2, 21.1, 19.1, 17.4, 17.3, 16.5, 16.46, 16.4, 16.3. ^{31}P NMR (160 MHz, $CDCl_3$) δ: 27.9. HR-MS calcd. for $C_{14}H_2O_3P$ (M + H): 268.1228; found: 228.1228.

Diethyl (1*R*)-2,2-diphenylcyclopropylphosphonate (24)

The general procedure described for the preparation of cyclopropane **23** was used on a 0.411 mmol scale. The purification was accomplished by flash chromatography on silica gel (80% EtOAc–hexanes) to give the desired cyclopropane **24** as a colorless oil (185 mg, 50%). The enantiomeric excesses (78%) was determined by SFC on a chiral stationary phase (Chiralcel OD, 1.5% MeOH, 1.0 mL/min: t_r (major) 23.9 min, t_r (minor) 18.4 min). R_f 0.34 (80% EtOAc–hexanes). IR (film, cm^{-1}): 2980, 1599, 1495, 1446, 1248, 1227, 1020, 953, 772, 695. ^1H NMR (300 MHz, $CDCl_3$) δ: 7.51–7.16 (m, 10H, C_6H_5), 3.95 (m, 2H, P-O-CH_2-CH_3), 3.76 (m, 1H, P-O-CH_2-CH_3), 3.50 (m, 1H, P-O-CH_2-CH_3), 2.03 (m, 1H, $CH_{2cycloprop}$), 1.83 (m, 1H, $CH_{2cycloprop}$), 1.57 (m, 1H, $CH_{cycloprop}$-P), 1.22 (t, J = 7.1 Hz, 3H, P-O-CH_2-CH_3), 1.05 (t, J = 7.1 Hz, 3H, P-O-CH_2-CH_3). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 145.4, 145.3, 140.3, 140.26, 130.1, 128.4, 128.0, 127.91, 127.90, 126.9, 126.6, 63.6, 61.5, 61.4, 61.35, 36.7, 36.63, 21.3, 18.7, 17.9, 17.8, 16.3, 16.24, 16.2, 16.1. ^{31}P NMR (160 MHz, $CDCl_3$) δ: 27.1. HR-MS calcd. for $C_{19}H_{23}O_3P$ (M + H): 331.1463; found: 331.1457.

Diethyl (1*R*,2*S*)-2-methyl-3-phenylcyclopropylphosphonate (25)

The general procedure described for the preparation of cyclopropane **23** was used on a 0.411 mmol scale. The diastereomeric ratio (85:15) was determined by ^{31}P NMR of the crude reaction mixture (δ major: 29.3 and δ minor: 28.2). The crude mixture was then purified by flash chromatography on silica gel (60% EtOAc–hexanes) to give *trans*-**25** (128 mg, 43%) and *cis*-**25** (22 mg, 7%) as colorless oils. The

enantiomeric excesses (85%) were determined by SFC on a chiral stationary phase (Chiralcel OD, 0.8% MeOH, 1.5 mL/min: t_r (major) 24.3 min, t_r (minor) 26.9 min). *trans*-**25**: R_f 0.42 (EtOAc). IR (film, cm^{-1}): 2981, 2905, 1240, 1055, 1029, 963. ^1H NMR (300 MHz, $CDCl_3$) δ: 7.07–7.30 (m, 5H, C_6H_5), 4.10 (m, 4H, P-O-CH_2-CH_3), 2.35 (m, 1H, C_6H_5-$CH_{cycloprop}$), 1.85 (d, 3H, CH_3 (cis)) 1.57 (m, 1H, $CH_{cycloprop}$-P), 1.46 (d, J = 6.4 Hz, 3H, CH_3 (trans)), 1.36 (m, 6H, P-O-CH_2-CH_3), 1.20 (m, 2H, $CH_{2cycloprop}$). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 140.6, 140.58, 128.5, 126.3, 125.9, 62.8, 62.7, 61.6, 61.56, 61.51, 61.4, 29.5, 29.4, 22.4, 22.3, 22.0, 19.5, 16.5, 16.46, 16.4, 16.38. 14.0, 13.9. ^{31}P NMR (160 MHz, $CDCl_3$) δ: 29.3. HR-MS calcd. for $C_{14}H_{21}O_3P$ (M + H): 268.1228; found: 268.1230.

General procedure for the Ru-pybox 29 catalyzed cyclopropanation — Diisopropyl (1*R*,2*S*)-2-phenylcyclopropylphosphonate (17)

To a solution of *trans*-$RuCl_2$((*S*,*S*)-*i*-Pr-pybox)(ethylene) (**29**) (5.1 mg, 0.0102 mmol, 0.03 equiv.) and styrene (0.194 mL, 1.70 mmol, 5 equiv.) in CH_2Cl_2 (2 mL) was added a solution of diisopropyl α-diazomethylphosphonate (**13**) (24) (70.0 mg, 0.340 mmol, 1 equiv.) in CH_2Cl_2 over 5 h via a syringe pump. After stirring for an additional 10 h at room temperature, the reaction mixture was concentrated under reduced pressure. The diastereomeric ratio (>98:2) was determined by ^{31}P NMR of the crude reaction product (δ major: 27.6, δ minor: 26.9). The crude residue was then purified by flash chromatography on silica gel (80% EtOAc–hexanes) to afford the desired cyclopropylphosphonate **17** as a colorless oil (67 mg, 70%). The enantiomeric excess (96%) was determined by SFC on chiral stationary phase (Chiralcel OD, 1.5% MeOH, 1.5 mL/min: t_r (major) 9.9 min, t_r (minor) 8.1 min). R_f 0.38 (EtOAc). $[\alpha]_D^{20}$ –80.0 (*c* 0.35, CH_2Cl_2). IR (film, cm^{-1}): 2978, 2933, 1732, 1385, 1243, 982, 918. ^1H NMR (300 MHz, $CDCl_3$) δ: 7.10–7.30 (m, 5H, C_6H_5), 4.71 (m, 2H, P-O-$CH(CH_3)_2$), 2.43 (m, 2H, C_6H_5-$CH_{cycloprop}$), 1.46 (m, 1H, $CH_{2cycloprop}$), 1.33 (m, 12H, P-O-$CH(CH_3)_2$), 1.20 (m, 1H, $CH_{2cycloprop}$), 1.17 (m, 1H, $CH_{cycloprop}$-P). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 140.34, 140.31, 128.5, 126.4, 126.1, 70.4, 70.4, 70.38, 70.33, 24.1, 24.08, 24.04, 21.3, 21.2, 17.2, 15.2, 13.0, 12.9. ^{31}P NMR (160 MHz, $CDCl_3$) δ: 27.6. Anal. calcd. for $C_{15}H_{23}O_3P$: C 63.82, H 8.21; found: C 63.73, H 8.55.

Dineopentyl (1*R*,2*R*)-2-phenylcyclopropylphosphonate (18)

To a solution of *trans*-$RuCl_2$((*S*,*S*)-*i*-Pr-pybox)(ethylene) **(29)** (4.6 mg, 0.0915 mmol, 0.03 equiv.) and styrene (0.175 mL, 1.53 mmol, 5 equiv.) in CH_2Cl_2 (2 mL) under reflux was added a solution of dineopentyl α-diazomethylphosphonate (**14**) (80.0 mg, 0.305 mmol, 1 equiv.) in CH_2Cl_2 over 5 h via a syringe pump. After stirring for an additional 13 h under reflux, the reaction mixture was cooled to room temperaure and was concentrated under reduced pressure. The diastereomeric ratio (>98:2) was determined by ^{31}P NMR of the crude reaction product (δ major: 29.5, δ minor: 28.9). The crude residue was then purified by flash chromatography on silica gel (50% EtOAc–hexanes) to afford the desired cyclopropylphosphonate **18** as a colorless oil (81 mg, 79%). The enantiomeric excess (96%) was determined by SFC on chiral stationary phase (Chiralcel OD, 2.0% MeOH, 1.6 mL/min: t_r (major) 6.7 min, t_r (minor) 5.9 min). R_f 0.43 (50% EtOAc–hexanes). IR (film, cm^{-1}): 2957, 2871, 1246, 1062, 1008, 921, 870. ^1H NMR (300 MHz, $CDCl_3$) δ: 7.20 (m, 5H, C_6H_5), 3.70 (m, 4H, $CH_2C(CH_3)_3$), 2.50 (m, 1H, C_6H_5-$CH_{cycloprop}$), 1.55 (m, 1H, $CH_{2cycloprop}$), 1.25 (m, 1H, $CH_{cycloprop}$-P), 1.15 (m, 1H, $CH_{2cycloprop}$), 0.95 (d, J = 14.8 Hz, 18H, $CH_2C(CH_3)_3$). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 140.1, 128.5, 126.5, 126.2, 75.3, 75.2, 75.1, 32.2, 32.1, 26.1, 26.0, 20.9, 15.8, 13.3, 12.4. ^{31}P NMR (160 MHz, $CDCl_3$) δ: 29.5. Anal. calcd. for $C_{19}H_{31}O_3P$: C 67.43, H 9.23; found: C 67.79, H 9.93.

Diisopropyl (1*R*,2*S*)-2-(4-methoxyphenyl)cyclopropylphosphonate (30)

The general procedure reported for compound **17** was followed using: *trans*-$RuCl_2$((*S*,*S*)-*i*-Pr-pybox)(ethylene) (**29**) (5.8 mg, 0.0116 mmol, 0.03 equiv.), 4-methoxystyrene (0.258 mL, 1.94 mmol, 5 equiv.), diisopropyl diazomethylphosphonate (**13**) (80.0 mg, 0.388 mmol, 1 equiv.). The diastereomeric ratio (>98:2) was determined by ^{31}P NMR of the crude reaction product (δ major: 28.0, δ minor: 27.9). The crude residue was then purified by flash chromatography on silica gel (80% EtOAc–hexanes) to afford the desired cyclopropylphosphonate **30** as a colorless oil (97 mg, 80%). The enantiomeric excess (94%) was determined by SFC on chiral stationary phase (Chiralcel OD, 1.0% MeOH, 1.3 mL/min: t_r (major) 23.7 min, t_r (minor) 26.1 min). R_f 0.40 (EtOAc). $[\alpha]_D^{20}$ –10.2 (*c* 1.65, CH_2Cl_2). IR (film, cm^{-1}): 2978, 2935, 1754, 1715, 1516, 1243, 979, 924, 826. ^1H NMR (300 MHz, $CDCl_3$) δ: 6.90 (m, 4H, C_6H_5), 4.70 (m, 2H, P-O-$CH(CH_3)_2$), 3.77 (s, 3H, $C_6H_5OCH_3$), 2.43 (m, 1H, C_6H_5-$CH_{cycloprop}$), 1.44 (m, 1H, $CH_{2cycloprop}$), 1.33 (m, 12H, P-O-$CH(CH_3)_2$), 1.20 (m, 1H, $CH_{2cycloprop}$), 1.14 (m, 2H, $CH_{cycloprop}$-P). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 158.1, 132.2, 127.2, 113.9, 70.4, 70.3, 70.2, 70.1, 55.2, 24.1, 24.09, 24.0, 20.7, 20.6, 17.0, 14.5, 12.7, 12.6. ^{31}P NMR (160 MHz, $CDCl_3$) δ: 28.0. Anal. calcd. for $C_{16}H_{25}O_4P$: C 61.53, H 8.07; found: C 61.01, H 8.45.

Diisopropyl (1*R*,2*S*)-2-(4-chlorophenyl)cyclopropylphosphonate (31)

The general procedure reported for compound **17** was followed using: *trans*-$RuCl_2$((*S*,*S*)-*i*-Pr-pybox)(ethylene) (**29**) (5.8 mg, 0.0116 mmol, 0.03 equiv.), 4-chlorostyrene (0.233 mL, 1.94 mmol, 5 equiv.), diisopropyl diazomethylphosphonate (**13**) (80.0 mg, 0.388 mmol, 1 equiv.). The diastereomeric ratio (>98:2) was determined by ^{31}P NMR of the crude reaction product (δ major: 27.1, δ minor: 26.5). The crude residue was then purified by flash chromatography on silica gel (50% EtOAc–hexanes) to afford the desired cyclopropylphosphonate **31** as a white solid (97 mg, 80%). The enantiomeric excess (98%) was determined by SFC on chiral stationary phase (Chiralcel OD, 1.0% MeOH, 1.0 mL/min: t_r (major) 21.7 min, t_r (minor) 24.4 min); mp 58 °C. R_f 0.30 (EtOAc). $[\alpha]_D^{20}$ –88.3 (*c* 0.40, CH_2Cl_2). IR (film, cm^{-1}): 2979, 2935, 1496, 1374, 1238, 1105, 980, 923, 729. ^1H NMR (300 MHz, $CDCl_3$) δ: 7.10 (m, 4H, C_6H_5), 4.69 (m, 2H, P-O-$CH(CH_3)_2$), 2.43 (m, 2H, C_6H_5-$CH_{cycloprop}$), 1.46 (m, 1H, $CH_{2cycloprop}$), 1.33 (m, 12H, P-O-$CH(CH_3)_2$), 1.20 (m, 1H, $CH_{2cycloprop}$), 1.15 (m, 1H, $CH_{cycloprop}$-P). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 138.9, 138.85, 132.0, 128.6,

Diisopropyl (1*R*,2*S*)-2(hydroxymethyl)cyclopropylphosphonate (36)

Ozone was bubbled through a solution of **34** (40.0 mg, 0.130 mmol, 1 equiv.) in methanol (15 mL) at –78 °C until a pale blue color persisted. Sodium borohydride (30.0 mg, 0.793 mmol, 6.1 equiv.) was then directly added and the clear solution was stirred at that temperature for 2 h. The mixture was warmed to room temperature and a satd. aq. solution of NH_4Cl was added. The mixture was concentrated under reduced pressure and the organic layer was extracted with three portions of CH_2Cl_2. The combined organic layers were dried over Na_2SO_4 and concentrated under reduced pressure. The residue was purified by flash chromatography on silica gel (95% EtOAc–hexanes) to afford the desired alcohol **36** (27.2 mg, 88%) as a colorless oil. R_f 0.13 (95% EtOAc–acetone). $[\alpha]_D^{20}$ –27.5 (*c* 0.80, CH_2Cl_2). IR (film, cm^{-1}): 3371, 2979, 2934, 1386, 1375, 1221, 982. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 4.70 (m, 2H, P-O-C*H*$(CH_3)_2$), 3.55 (m, 2H, CH_2-OH) 1.75 (t, *J* = 5.8 Hz, 1H, OH), 1.60 (m, 1H, CH_2-C$H_{cycloprop}$), 1.34 (m, 12H, P-O-CH(CH_3)$_2$), 1.10 (m, 1H, C$H_{cyclopropyl}$-P), 0.80 (m, 2H, C$H_{2cycloprop}$). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 70.3, 70.25, 70.2, 65.1, 65.0, 24.1, 24.0, 19.5, 19.4, 11.4, 8.8, 8.2, 8.1. ^{31}P NMR (160 MHz, $CDCl_3$) δ: 28.6. HR-MS calcd. for $C_{10}H_{21}O_4P$: 236.1177; found: 236.1174.

First examples of intramolecular addition of primary amidyl radicals to olefins[1]

Philippe Gaudreault, Christian Drouin, and Jean Lessard

Abstract: The first examples of intramolecular addition of primary amidyl radicals to olefins are described. Amidyl radicals were generated from *N*-(phenylthio)amides in refluxing benzene using a catalytic amount of 2,2′-azobis(isobutyronitrile) (5 mol%) and tributyltin hydride (~2.2 equiv.). The resulting yields of cyclic products ranged from 63% to 85%.

Key words: radical cyclization, amidyl radicals, nitrogen heterocycles.

Résumé : Les premiers exemples de cyclisation radicalaire impliquant un radical amidyle primaire et une oléfine sont décrits. Les radicaux amidyles sont obtenus à partir de *N*-(phénylthio)amides dans le benzène à reflux en présence d'une quantité catalytique de 2,2′-azobis(isobutyronitrile) (5 mol%) et d'hydrure de tributylétain (~2.2 équiv.). Des rendements en produits cyclisés variant de 63 % à 85 % sont obtenus.

Mots clés : cyclisation radicalaire, radicaux amidyles, hétérocycles azotés.

Introduction

Over the years, amidyl radicals have attracted continuous interest with regard to their structure (1, 2), their reactivity (3–5), and ways to generate them (3, 4). Clearly, it appears that intramolecular addition of an amidyl radical on a pendant olefin is a powerful synthetic tool for the formation of nitrogen-containing heterocycles. Numerous examples of cyclization involving secondary amidyl radicals can be found in the literature (4). However, as far as we know, there are no examples of a successful cyclization involving a primary amidyl radical (4*k*, 6), even if there are many examples of successful intermolecular additions of primary amidyl radicals to olefins (3). The main reason for the lack of data on the cyclization of primary amidyl radicals is that endeavours to prepare the usual radical precursors such as *N*-haloamides (3, 4*a*, 4*b*), *N*-(pyridine-2-thione-oxycarbonyl) amides (PTOC amides) (4*c*, 4*f*), and *N*-(ethoxythiocarbonylsulfanyl)amides (4*h*), have failed when applied to olefinic primary amides (7).[3] In the present paper, we report that *N*-(phenylthio) derivatives of olefinic primary amides can be easily prepared and that nitrogen heterocycles resulting from their radical cyclization can be obtained in good to very good yields.

The four olefinic primary amides **5**–**8** were selected as models for radical cyclization of primary amidyl radicals. They were prepared from the corresponding carboxylic acids **1**–**4** via the acid chlorides as shown in Scheme 1.[4] Carboxylic acids **1**, **2**, and **4** are commercially available and cyclohept-4-ene carboxylic acid **3** was synthesized in four steps from cyclopentanone following a method developed by Stork and Landesman (8).

Next, conversion of primary amides **5**–**8** into suitable amidyl radical precursors was examined. We found that *N*-(phenylthio)amides **9**–**12** could be easily prepared in good to very good yields (60%–84%) following a protocol developed by Esker and Newcomb (4*d*), but slightly modified, by reacting the anion of the amide with phenylsulfenyl chloride (9).[4] *N*-(Phenylthio)amides **9**–**12** were the sole amidyl precursors that could be obtained from olefinic primary amides **5**–**8**.[3]

Having the primary amidyl radical precursors in hand, intramolecular addition was next investigated. *N*-

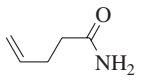
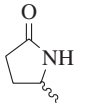
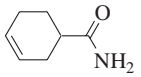
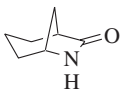
Scheme 1. Preparation of primary amides and *N*-(phenylthio) derivatives.

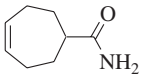
Scheme 2. Radical chain mechanism.

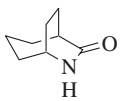


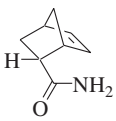


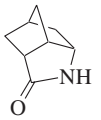












(Phenylthio)amides **9**–**12** were heated in refluxing benzene and a solution of 2,2′-azobis(isobutyronitrile) (AIBN) (5 mol%) and tributyltin hydride (~2.2 equiv.) in benzene was added. As shown in Table 1, all four models underwent radical cyclization to afford the corresponding heterocyles **13**–**16**[4] in good to very good yields (63%–85%). Interestingly, the use of less than ~2.2 equiv. of tributyltin hydride resulted in incomplete conversion of the starting olefinic *N*-(phenylthio) amide.

As expected (10), 5-*exo*-trig cyclizations were favoured over 6-*endo*-trig cyclizations for all concerned models (entries 1, 2, and 4). Also, 6-*exo*-trig cyclization occurred in good yield (71%) when this was the sole possibility (entry 3). The reactions also gave small amounts of the parent amide (8%–16% yield) as a result of the reduction of the amidyl radical by tributyltin hydride. The radical chain mechanism involved is illustrated in Scheme 2.

To the best of our knowledge, this paper reports the first examples of radical cyclizations involving a primary amidyl radical and a pendant olefin. Olefinic *N*-(phenylthio)amides were prepared in good yields (60%–84%) and used as primary amidyl radical precursors in a reaction with AIBN in catalytic amount (5 mol%) and tributyltin hydride (~2.2 equiv.), acting, respectively, as radical initiator and chain carrier. Good to very good yields of cyclization were obtained (63%–85%). Thus, it is no longer necessary to prepare an N-protected precursor and then remove the protecting group after cyclization (4*k*). Further studies are currently being conducted.

Table 1. Cyclization results.

Entry	Primary amide	*N*-(PhS)amide[a]	Cyclic product[b,c]
1	 **5**	**9** 84%	 84% **13**
2	 **6**	**10** 63%	 85% **14**
3	 **7**	**11** 64%	 71% **15**
4	 **8**	**12** 60%	 63% **16**

[a]Reaction conditions: (*i*) *n*-BuLi, (*ii*) PhSCl, THF, –78 °C → r.t.
[b]Reaction conditions: $AIBN_{cat}$–Bu_3SnH (slow addition), benzene, reflux.
[c]Yield of parent amide: 8%, 11%, 16%, and 16% in entries 1–4, respectively.

© 2005 NRC Canada

General procedure for cyclization

To a refluxing solution of *N*-(phenylthio)amide (0.5 mmol) in anhydrous and degassed benzene (20 mL) under a nitrogen atmosphere, 2,2′-azobis(isobutyronitrile) (4 mg, 0.024 mmol) and tributyltin hydride (0.28 mL, 1.0 mmol) dissolved in anhydrous and degassed benzene (10 mL) were added over 4 h. If required, a small additional amount of AIBN–Bu_3SnH in benzene was added to complete the reaction. The solvent was removed under reduced pressure and the residue was purified by flash chromatography (acetone–toluene, 2:3) monitored by GC to afford the desired lactam.

Palladium(II) complexes of bis(phosphine)monooxide and bis(phosphine)monosulphide ligands bearing *o*-*N*,*N*-dimethylanilinyl substituents[1]

Nathan D. Jones and Brian R. James

Abstract: Palladium(II) complexes of bis(phosphine)monooxide and bis(phosphine)monosulphide ligands with the general formula $Ar_2P(CH_2)_nP(E)Ar_2$ are described (n = 1 (dmapmE), E = O, S; n = 2 (dmapeE), E = O; Ar = *o*-*N*,*N*-dimethylanilinyl). The precursor, $PdCl_2$(dmapm), which exists in solution as an equilibrium mixture of the *P*,*P*- and *P*,*N*-ligated isomers, reacts with peroxides to form $PdCl_2$(*P*,*N*-dmapmO) and with sulphur to give [PdCl(*P*,*N*,*S*-dmapmS)]Cl, probably by direct oxidation of the "dangling" P atom of the *P*,*N*-isomer. $PdCl_2$(dmape), which exists in solution as a mixture of $PdCl_2$(*P*,*P*-dmape) and [PdCl(*P*,*P*,*N*-dmape)]Cl, reacts with hydroxide in H_2O–CH_2Cl_2 under argon to give the face-to-face $Pd(II)_2$ complex containing the cation $[Pd_2Cl_2(\mu\text{-}P,N:O\text{-dmapeO})_2]^{2+}$, which was isolated and crystallographically characterized as the PF_6 salt. The remarkable structure, consisting of two face-to-face Pd(II) square planes in a head-to-tail orientation, reveals a 12-membered ring containing the two non-bonded metal centres (Pd—Pd = 4.873(2) Å). The dmapmS complex shows marginal activity as a catalyst for the hydration of maleic to malic acid.

Key words: phosphine, phosphine oxide, phosphine sulphide, palladium.

Résumé : On décrit les complexes du palladium(II) de ligands bis(phosphine)monooxyde et bis(phosphine)monosulfure avec des composés de formule générale $Ar_2P(CH_2)_nP(E)Ar_2$ dans lesquels n = 1 (dmapmE), E = O, S; n = 2 (dmapeE), E = O; Ar = *o*-*N*,*N*-diméthylanilinyle. Le précurseur $PdCl_2$(dmapm), qui existe en solution sous la forme d'un mélange à l'équilibre des ligands isomères *P*,*P* et *P*,*N*, réagit avec les peroxydes pour former le $PdCl_2$(*P*,*N*-dmapmO) et avec le soufre pour donner le [PdCl(*P*,*N*,*S*-dmapmS)]Cl, probablement par une oxydation directe de l'atome de P qui se « balance » dans l'isomère *P*,*N*. Le $PdCl_2$(dmape), qui existe en solution sous la forme d'un mélange de $PdCl_2$(*P*,*P*-dmape) et de [PdCl(*P*,*P*,*N*-dmape)]Cl, réagit avec l'ion hydroxyde dans un mélange H_2O–CH_2Cl_2, sous argon, pour conduire à la formation du complexe face à face $Pd(II)_2$ contenant le cation $[Pd_2Cl_2(\mu\text{-}P,N:O\text{-dmapeO})_2]^{2+}$ qui a été isolé et caractérisé cristallographiquement sous la forme de sel de PF_6. La structure remarquable, formée de deux Pd(II) plans carrés, face à face et en position tête à queue, comporte un cycle à douze chaînons avec deux centres métalliques non liés (Pd—Pd = 4,873(2) Å). Le complexe dmapmS présente une activité marginale comme catalyseur pour l'hydratation de l'acide maléique en acide malique.

Mots clés : phosphine, oxyde de phosphine, sulfure de phosphine, palladium.

[Traduit par la Rédaction]

Introduction

Our group recently reported (1–4) on platinum(II) and palladium(II) complexes containing bis(phosphine) ligands bearing two *o*-*N*,*N*-dimethylanilinyl substituents at each P atom, including 1,1-bis(di(*o*-*N*,*N*-dimethylanilinyl)phosphino)-methane (dmapm) and 1,2-bis(di(*o*-*N*,*N*-dimethylanilinyl)-phosphino)ethane (dmape). The ligand structures, for example, are represented within complexes of formula $PdCl_2$(dmapm) and $PdCl_2$(dmape) in Schemes 1 and 2, respectively. We had designed such ligands primarily for the synthesis of water-soluble metal complexes, with one aim being to develop transition metal catalysts for olefin hydration, and indeed marginal activity for hydration of maleic to malic acid was noted for several of the complexes (4). The activity was better, for example, than that of the bridged-hydroxo complexes of the type $[(dppe)Pd(\mu\text{-}OH)]_2^{2+}$ (dppe = $Ph_2P(CH_2)_2PPh_2$) reported by Ganguly and Roundhill (5). This led us to attempts to synthesize bridged-hydroxo complexes of this type but using dmape as the bisphosphine. We thus reacted $PdCl_2$(dmape) with KOH in aqueous–CH_2Cl_2, but (to our surprise) a complex containing the bisphosphine

Scheme 1. Direct oxidation of one P atom of **1b** with peroxide and sulphur.

Scheme 2. Reaction of **5** with KOH in CH_2Cl_2–H_2O.

monoxide, dmapeO, was isolated, and because of the current interest in such ligands, we pursued this line of research, and the findings are reported here.

Bisphosphine monooxides (BPMOs) with the mixed P atom and O atom donors are within a class of chelating agents that, because of their potential for hemilabile coordination (6), have garnered attention in homogeneous catalysis. Transition metal complexes of such ligands have been used in a variety of catalyzed organic transformations such as hydroformylation and other carbonylation processes (7, 8), hydrosilylation (9), hydrovinylation (10), polymerization (11), and allylic alkylation (12), including asymmetric processes (9, 10, 12) Bis(phosphine)monosulphide (BPMS) complexes have also begun to attract interest and have found application in asymmetric allylic alkylation (13).

More generally, BPMO ligands can be made via metal-free organic synthesis (for example, by benzylation of a bis(tertiary phosphine) followed by basic hydrolysis of the resulting phosphonium salt) (14) or by a Pd-catalyzed process involving reaction of 1,2-bromoethane and hydroxide in a two-phase aqueous system (8). Metal-bound BPMOs may be synthesized via oxidation of a "dangling" (i.e., nonbonded)

© 2005 NRC Canada

P atom in complexes bearing polydentate ligands, exemplified in Co (15, 16), Mo (17), Rh (18), and Pd (9, 19) systems, but only in a few cases does this result in coordination of the phosphine oxide (16, 17). Less common is oxidation of a coordinated bis(phosphine) to give a BPMO in which both the P(III) atom and the O atom are bound. Examples that typically involve aerobic oxidation are those of RhCl(CO)(*P*,*P*-BINAP), which generates RhCl(CO)(*P*,*O*-BINAPO) (20), a Pd(II)-dppm species (dppm = $Ph_2PCH_2PPh_2$) that forms a Pd(II)-*P*,*O*-dppmO complex (21), and $RuCl_2$(BINAP)(N–N) complexes that give [RuCl(η^4-BINAPO)(N–N)]Cl (N–N = bipy, phen), where the BINAPO ligand is coordinated via the P(III) atom, the O atom, and two C atoms of the naphthyl ring proximate to the P(V) atom (22). An excellent introduction to the syntheses and uses of BPMOs can be found in Cyr's Ph.D. thesis (23).

This paper describes the oxidation of one P atom of $PdCl_2$(dmapm) (**1**) (3) to give $PdCl_2$(*P*,*N*-dmapmO) (**2**) and the salts [PdCl(*P*,*N*,*S*-dmapmS)]X (X = PF_6, **3**; Cl, **4**) and the similar oxidation of $PdCl_2$(dmape) (**5**) (4) to give, after anion exchange, the dipalladium complex [PdCl(μ-*P*,*N*:*O*-dmapeO)]$_2$[PF_6]$_2$ (**6**). This last reaction constitutes another example of the oxidation of a coordinated bis(phosphine) to give a complex in which both the P(III) and O atoms of the BPMO are coordinated, but it is unique in that the BPMO serves as a bridging ligand. The topic is particularly appropriate for a paper dedicated to Howard Alper because he must have experienced many times phosphine oxidation concomitant with reduction of Pd(II) to Pd(0) species, including the unwanted metal!

Experimental

Unless otherwise noted, synthetic procedures were performed using standard Schlenk techniques under an atmosphere of dry Ar or N_2. The precursors, *trans*-$PdCl_2$(PhCN)$_2$ (24), $PdCl_2$(dmapm) (**1**) (3), and $PdCl_2$(dmape) (**5**) (4), and the dmapm and dmape ligands (25) were made according to literature procedures. All other reagents were purchased from commercial sources and used as supplied. Solvents were dried over the appropriate agents and distilled under N_2 prior to use. NMR spectra were recorded in $CDCl_3$ solution on a Varian AV300 (121 MHz for ^{31}P) or AV400 (162 MHz for ^{31}P) spectrometer at 300 K. Residual solvent proton (^{1}H, relative to external $SiMe_4$ δ 0.00) and external $P(OMe)_3$ (^{31}P{^{1}H}, δ 141.00 vs. external 85% aq. H_3PO_4) were used as references. Downfield shifts were taken as positive; s = singlet, d = doublet, m = multiplet, br = broad, spt = septet, and all *J*-values are given in Hz. Conductivity measurements were obtained using a Thomas Serfass conductance bridge model RCM151B1 (Arthur H. Thomas Co. Ltd.) connected to a 3404 cell (Yellow Springs Instrument Co.); measurements were made at 25 °C using ~10^{-3} mol L^{-1} solutions of the complexes and are reported as Λ_M in Ω^{-1} mol^{-1} cm^2. Elemental analyses were conducted in the UBC Chemistry Department by Mr. Peter Borda using a Carlo Erba 1108 analyzer.

$PdCl_2$(*P*,*N*-dmapmO) (2)

This complex was prepared at room temperature either in a single phase using cumene hydroperoxide as oxidant or in a two-phase mixture using aqueous H_2O_2.

Cumene hydroperoxide

Precursor **1** was prepared in situ by the reaction of dmapm (140 mg, 0.25 mmol) and *trans*-$PdCl_2$(PhCN)$_2$ (94 mg, 0.25 mmol) in CH_2Cl_2 (10 mL), and to the yellow solution was added cumene hydroperoxide (75 μL, 0.41 mmol). The solution was stirred overnight and then reduced in vacuo to ~2 mL, when Et_2O (20 mL) was added to precipitate the yellow product, which was isolated by filtration, washed with Et_2O (3 × 3 mL), and dried under vacuum. Yield: 155 mg (84%).

H_2O_2

To a CH_2Cl_2 solution (5 mL) containing **1** (28 mg, 0.038 mmol) was added a 3% H_2O_2 (2 mL) solution. The two-phase mixture was stirred for 1 h, and the aqueous phase was removed. The volume of CH_2Cl_2 was reduced in vacuo to ~1 mL, and Et_2O (10 mL) was added to precipitate the product. Yield: 25 mg (88%). ^{1}H NMR δ: 1.7–3.3 (br, 12H, NCH_3), 2.35 (s, 3H, NCH_3), 2.51 (s, 3H, NCH_3), 3.47 (s, 3H, NCH_3), 3.70 (s, 3H, NCH_3), 4.27 (m, 1H, CH_2), 4.81 (m, 1H, CH_2), 6.8–7.9 (br m, 16H, Ar). ^{31}P{^{1}H} NMR δ: 26.2 (d, $^2J_{PP}$ = 7.0), 26.5 (d, $^2J_{PP}$ = 7.0). Λ_M (CH_2Cl_2): <1. Anal. calcd. for $C_{33}H_{42}ON_4Cl_2P_2Pd$: C 52.9, H 5.6, N 7.5; found: C 53.0, H 6.0, N 7.0.

[PdCl(*P*,*N*,*S*-dmapmS)]PF_6 (3)

To a mixture of **1** (44 mg, 0.060 mmol) and S_8 (13 mg, 0.42 mmol of S) was added 1,2-dichloroethane (5 mL), and the resulting yellow solution was refluxed for 3.5 h. The solvent was removed in vacuo, and the residue was dissolved in warm H_2O (20 mL). After filtration of the mixture through Celite 545 to remove excess S_8 and unreacted **1**, aq. KPF_6 solution (5 mL, 90 mg, 0.49 mmol) was added; this immediately precipitated a yellow-orange solid that was isolated by filtration and washed with H_2O (10 mL). Yield: 30 mg (56%). ^{1}H NMR δ: 2.15 (s, 12 H, NCH_3), 2.86 (s, 12 H, NCH_3), 4.50 (br m, 2H, CH_2), 7.30 (m, 4H, Ar), 7.46 (m, 4H, Ar), 7.57 (m, 4H, Ar), 7.87 (m, 2H, Ar), 8.50 (dd, 2H, Ar, $^2J_{HH}$ = 7.39, $^4J_{HP}$ = 15.3). ^{31}P{^{1}H} NMR δ: 37.0 (d, $^2J_{PP}$ = 33.6), 48.6 (d, $^2J_{PP}$ = 33.6), –145 (spt, $^1J_{PF}$ = 710, PF_6^-). Anal. calcd. for $C_{33}H_{42}N_4ClF_6P_3PdS$: C 45.3, H 4.8, N 6.4; found: C 45.2, H 5.0, N 6.2.

[PdCl(*P*,*N*,*S*-dmapmS)]Cl (4)

This compound was made in the same manner as outlined for **3**, except that, after the reaction of **1** (130 mg, 0.18 mmol) and S_8 (45 mg, 1.4 mmol), the reaction mixture was cooled to room temperature and then filtered through Celite 545. The filtrate volume was reduced in vacuo to ~1 mL, and Et_2O (20 mL) was added to precipitate the yellow product. Yield: 100 mg (71%). The NMR data for **4**, except for the absence of the PF_6^- resonance, are the same as for **3**. Λ_M (H_2O): 99.

[PdCl(μ-*P*,*N*:*O*-dmapeO)]$_2$[PF_6]$_2$ (6)

To a CH_2Cl_2 (10 mL) solution of **5** (30 mg, 0.041 mmol) was added aq. KOH solution (5 mL, 1 mol L^{-1}). This caused an immediate colour change in the organic layer from yellow to orange-red. The two phase mixture was stirred for 1 h at room temperature, and then the aqueous layer was removed. H_2O (5 mL) was then added to the organic layer, fol-

© 2005 NRC Canada

lowed by KPF_6 (83 mg, 0.45 mmol), and stirring was continued for 0.5 h. The aqueous layer was removed, and the CH_2Cl_2 phase was washed with H_2O (3 × 10 mL) before being filtered through Celite 545. The filtrate was reduced to dryness in vacuo, and the residue taken up in $CDCl_3$ for analysis by $^{31}P\{^1H\}$ NMR spectroscopy. About 10% of the dioxide, dmapeO$_2$ (δ_P 31.5), was apparent in the residue. A satisfactory elemental analysis was not obtained for **6**, but X-ray diffraction quality, pale yellow, irregular-shaped crystals of **6**·4$CDCl_3$ (~60% yield) were formed by slow evaporation of the $CDCl_3$ solution. $^{31}P\{^1H\}$ NMR δ: 28.1 (d, $^2J_{PP}$ = 62), 29.3 (d, $^2J_{PP}$ = 62), –145 (spt, PF_6^-, $^1J_{PF}$ = 710).

Catalytic hydration of maleic acid

Complex **4** was tested as a catalyst (at 10^{-3} mol L^{-1}) for hydration of maleic acid (0.1 mol L^{-1}) in aqueous solution at 100 °C. The experimental procedure has recently been described (4), including the determination, by ^1H NMR spectroscopy, of the conversion of the maleic acid (*cis*-$CH(CO_2H)$=$CH(CO_2H)$) to the hydration (malic acid) and isomerization (fumaric acid) products.

X-ray crystallographic analysis of complex 6

Data (see Table 1) were collected on a Siemens SMART system at 173(2) K. An initial set of cell constants was calculated from reflections harvested from three sets of 20 frames, oriented such that orthogonal wedges of reciprocal space were surveyed. This produced orientation matrices determined from 20 reflections. Final cell constants were calculated from a set of 7876 strong reflections from the actual data collection. The so-called hemisphere data collection technique, where a randomly oriented region of reciprocal space is surveyed to the extent of 1.3 hemispheres to a resolution of 0.84 Å, was used. Three major swaths of frames were collected with 0.30° steps in ω and, in case the lattice was found to be triclinic (as for **6**), additional sets of frames were collected to better model the absorption correction. The space group was determined based on systematic absences and intensity statistics (26), and a direct-methods solution provided the location of most of the non-H atoms, with several full-matrix least-squares – difference Fourier cycles locating the remaining non-H atoms. All non-H atoms were refined anistropically, and H atoms were included as riding atoms with relative isotropic displacement parameters. The structure is dimeric, with half being in the asymmetric unit that also contains one PF_6^- anion and two $CDCl_3$ molecules. Several SAME and DELU restraints were added to assist in the refinement of the solvent molecules, one of which had considerable translational motion that affected the apparent bond lengths. Complete crystallographic information is available.[4]

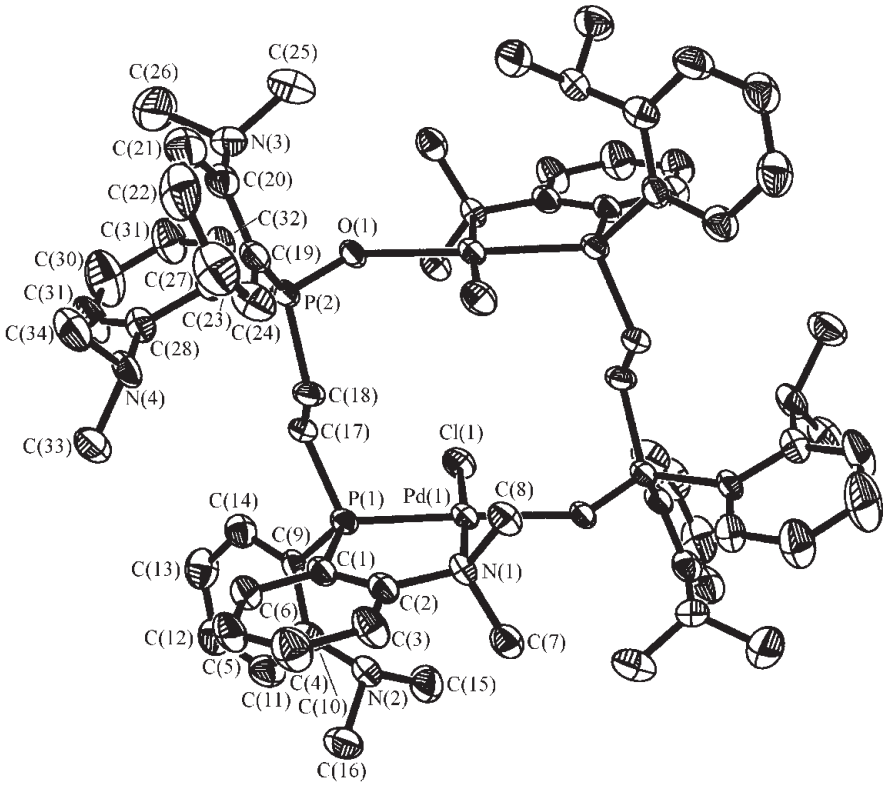
Results and discussion



The P(III)-containing precursor $PdCl_2$(dmapm) (**1**) exists in solution as an equilibrium mixture of the neutral *P*,*P*- (**1a**) and *P*,*N*-ligated (**1b**) isomers (3), as shown in Scheme 1. Net O atom or S atom addition to **1** results in formation of BPMO and BPMS complexes: room temperature reactions with cumene hydroperoxide in CH_2Cl_2 or with H_2O_2 in CH_2Cl_2–H_2O and with S_8 in refluxing 1,2-dichloroethane cleanly give $PdCl_2$(*P*,*N*-dmapmO) (**2**) and [PdCl(*P*,*N*,*S*-dmapmS)]Cl (**4**), respectively (Scheme 1). Presumably, the oxidations occur at the free P atom of isomer **1b**. Complex **2** is a non-electrolyte in CH_2Cl_2 solution (Λ_M < 1) and does not dissolve in H_2O, while **4** dissolves in H_2O as a 1:1 electrolyte (Λ_M = 99), and the Cl^- counterion is easily exchanged for PF_6^- by reaction with KPF_6 to give [PdCl(*P*,*N*,*S*-dmapmS)]PF_6 (**3**). That the NMR data for **4** in CH_2Cl_2 are the same as those for the cation of **3** (see below) argues strongly that it is not the dissolution of **4** in water that promotes dissociation of a chloride and that **4** is ionic, unlike the neutral **2**. The softer S atom of the P=S fragment (vs. the harder O atom of P=O fragment) is apparently a sufficiently good ligand to displace a coordinated chloride in these Pd(II) systems.

We recently observed a Pt analogue of **2**, PtI_2(*P*,*N*-

Fig. 1. ORTEP representation (50% ellipsoids) of the molecular structure of the cation of **6**. H atoms are omitted for clarity.

dmapmO), that formed as an aerobic decomposition product of the heterobimetallic catalyst precursor $PtPdCl_4$(μ-*N*,*P*:*P*′,*N*′-dmapm) during the Heck coupling of PhI and styrene in DMF–H_2O with K_2CO_3 as base (1).

Unlike **1**, $PdCl_2$(dmape) (**5**) exists in CH_2Cl_2 as an equilibrium mixture of the neutral $PdCl_2$(*P*,*P*-dmape) (**5a**) and ionic [PdCl(*P*,*P*,*N*-dmape)]Cl (**5b**) isomers (4), as shown in Scheme 2. Reaction of this mixture with KOH in a biphasic H_2O–CH_2Cl_2 medium at room temperature, followed by Cl^-–PF_6^- anion exchange, gives the remarkable dipalladium complex [PdCl(μ-*P*,*N*:*O*-dmapeO)]$_2$[PF_6]$_2$ (**6**, Scheme 2). An ORTEP of the structure of the cation is shown in Fig. 1, and selected bond distances and angles appear in Table 2.

The structure of **6** consists of two face-to-face, square planar Pd(II) moieties in a head-to-tail orientation (i.e., they are related by an inversion centre that lies at the mid-point of the Pd–Pd axis). The metal centres are separated by a distance of 4.873 Å, and each is *P*,*N*-chelated by the dmape(O) and *P*,*O*-bridged to the other, thus forming a 12-membered ring containing the metal centres. The ring is flanked on either side by two $CDCl_3$ molecules (not shown in Fig. 1). The P-C-C angles in the dmape(O) ligand "backbone" (113.8° and 111.2°) are very similar to that of 110.7° found for dmape (25), indicating that the dmape(O) ligand is unstressed, with the Pd centres being too far removed from one another to interact. The Pd—P and Pd—N bond lengths (2.182 and 2.114 Å), as well as the P-Pd-N angle (87.17°), are similar to those found for **1b** (2.180 Å, 2.132 Å, and 86.10°, respectively) (4).

The bond lengths of Pd—O (2.124 Å), Pd—P (2.182 Å), and P=O (1.515 Å), and the Pd-O=P angle (137.1(3)°) in **6**, are comparable to literature data that we have found for nine

Table 2. Selected bond lengths (Å) and angles (°) for **6**·4$CDCl_3$ (esds in parentheses).

Bond distances (Å)

P(2)-O(1)-Pd(1*)	137.1(3)		

other examples of crystallographically characterized Pd(II) complexes bearing *P*,*O*-bound BPMO ligands (12, 21, 27–31), where the average Pd—O, Pd—P, and P=O distances are 2.134, 2.241, and 1.507 Å, respectively, and the average P=O-Pd angle is 125°. There is no obvious correlation between these parameters, but it is interesting to note that in all cases, including **6**, the Pd—O distance is shorter than the Pd—P distance. The Pd-O=P angle in these complexes shows a wide variation between 108° and 144°. There are also very similar crystallographic data for Pd(II) complexes *P*,*O*-bonded to heterofunctional BPMOs of the type $R_2PN(H)P(O)R_2$ (32).

Complex **6** shows some similarities to a $Pd(II)_2$ compound made recently by Leung and co-workers via a fundamentally different route (30). Their complex was synthesized by an initial [4+2] cycloaddition reaction between a Pd-coordinated

© 2005 NRC Canada

phosphole and vinyl diphenylphosphine oxide, which generated a *P*,*O*-coordinated BPMO at a Pd(II) centre. Subsequent treatment with HCl to remove an ancillary cyclometallated benzylamine ligand afforded the $Pd(II)_2$ complex containing (like **6**) two bridging BPMO ligands, the cation of which can be formulated as $[Pd_2Cl_2(\mu\text{-}P{:}O\text{-BMPO})_2(\mu\text{-Cl})]^+$. This species contains a bridging chloride that serves to complete the square planar coordination at each Pd, and thus, instead of the 12-membered ring seen in **6**, the complex contains two fused eight-membered rings (30). We are not aware of any crystallographically characterized complexes other than **6** that contain two BPMO and no other bridging ligands. The observed P=O, Pd—P, and Pd—O bond lengths and the Pd-O=P angle in **6** are very similar to those found for Leung's compound.

The $^{31}P\{^1H\}$ data (δ and *J* values) for complexes **2** and **6** and for the cation within **3** and **4** reveal the expected doublet of doublet pattern for species containing two inequivalent P atoms, but there are insufficient data to assign the respective resonances of the P(III) and P(V) centres, even with knowledge of the $^{31}P\{^1H\}$ data for the precursor complexes **1** and **5** in both their isomeric forms (see Schemes 1 and 2) (3, 4). The two doublet resonances for **2** and **6** differ by only 0.3 and 1.2 ppm, respectively, and even though there is a larger difference of 11.6 ppm for the cation, assignments still cannot be made. The lower field resonances seen for **3/4** (δ 37.0, 48.6) vs. those seen for **2** (δ 26.2, 26.5) are, however, consistent with the usual trend of deshielding with formation of five-membered ring systems of metal bisphosphine chelate complexes (33).

The ^1H NMR data for **2** and **3/4** show the resonances of the CH_2 protons as two separate multiplets for the former complex (δ 4.27, 4.81) and one broad multiplet for the latter (δ 4.50); the signal is seen at δ 2.23 as a triplet ($^2J_{HP}$ = 4.2) for free dmapm (3). Peaks for all 24 NMe protons (δ 2.68 s for free dmapm) are also seen; for **2**, there is a very broad "background" signal (δ 1.7–3.3) and four other singlets of 3H each at δ 2.35, 2.51, 3.47, and 3.70. Complex **2** is clearly fluxional, but without low temperature ^1H NMR studies, like those done for the **1a** ↔ **1b** system (Scheme 1) (3), it is difficult to assign the NMe resonances. However, based on the δ values of 3.46 and 3.79 for the methyl protons of the coordinated NMe_2 group of **1b** (3), the singlets at δ 3.47 and 3.70 likely refer to the coordinated NMe_2 group of complex **2**. Fluxionality originating from exchange of free and coordinated anilinyl groups could arise via reversible formation of a five-coordinate $PdCl_2$(*P*,*N*,*O*-dmapeO) intermediate, analogous to the associative process envisioned for such exchange within $[PtCl(P,P,N\text{-dmapcp})]^+$ via a $[PtCl(P,P,N,N\text{-dmapcp})]^+$ intermediate (4); dmapcp is similar to dmape, but in place of the $-(CH_2)_2-$ backbone the ligand has the cyclopentane $-CH(CH_2)_3CH-$ moiety. The ^1H NMR data for **6**, consisting of broad, overlapping signals, were uninformative.

The mechanism of formation of complex **6** under an anaerobic atmosphere deserves comment, as we are unaware of other systems in which a metal–BMPO complex is isolated from a metal–bisphosphine precursor in the absence of an oxidant such as oxygen or some other O atom donor. It is well known that tertiary phosphines in the presence of base act as two-electron reductants, being themselves converted to the phosphine oxide, with the two electrons commonly reducing a metal centre (see eq. [1]). Such chemistry is of key importance in the reduction of Pd(II) to Pd(0) species, particularly in a range of Pd-catalyzed coupling reactions (e.g., Heck (34), Stille (35), and Suzuki (36) reactions), aminations (37), and formation of diaryl ethers (38), where the supposed Pd(0) active catalyst is generated in situ from Pd(II) precursors. In the Heck reaction, for example, the active catalyst is often derived from a mixture of $Pd(OAc)_2$ and a phosphine, and formation of Pd(0) from this combination has been studied by Amatore et al. (39). During a study of the Pd-catalyzed carbonylation of aryl halides, Grushin and Alper (40) showed by use of a chiral phosphine that Pd(II)–PR_3 complexes are reduced by OH^- to Pd(0) species (eq. [1]) via a *cis*-hydroxo(phosphine)–Pd(II) intermediate, and not via attack at the phosphine by external hydroxide:

$$[1] \qquad [L_nPd(II)\text{-}PR_3]^{2+} + OH^- \rightarrow L_nPd(0) + O{=}PR_3 + H^+$$

where L = a general ligand. The intermediate then decomposes to Pd(0) by deprotonation and reductive elimination of phosphine oxide. Formation of **6** almost certainly occurs via such an initial reduction, following substitution of hydroxide for coordinated chloride or amine of **5a** or **5b** to give, after generation of HCl, a species such as "Pd(0)(dmapeO)". Subsequent oxidation to **6** is thought to occur via reaction with the CH_2Cl_2 solvent. Some indirect evidence for this is that **6** was not detected spectroscopically in the organic phase when the reaction of **5** with hydroxide was conducted in the absence of chlorinated solvent (for example, in H_2O–CH_3NO_2). Oxidative addition reactions of M(0)(phosphine) complexes (M = Pd, Pt) with chlorinated solvents to generate M(II)-chloro species are not uncommon (41), but further work is needed to substantiate the suggestion here.

Complex **4** was tested as a catalyst precursor for hydration of maleic to malic acid in aqueous solution at 100 °C, for comparison with corresponding, recently reported data using $PdCl_2$(dmape) (**5**) and the related [PdX(*P*,*P*,*N*-dmapcp]X complexes as catalyst precursors (4); X = Cl or I, and dmapcp is defined above. The activity of **4** is very similar to that found for [PdCl(*P*,*P*,*N*-dmapcp]Cl (4), as follows: after 24 h, 15% of the maleic acid has been converted to 7% malic acid and 8% fumaric acid, these percentages corresponding to the turn-over numbers, which are three times greater than those reported for hydration of diethylmaleate in THF–H_2O at 120 °C using $[\{Ph_2P(CH_2)_2PPh_2\}Pd(\mu\text{-}OH)]_2^{2+}$ as the catalyst precursor (5). The activity remains marginal, and indeed is comparable to that of dilute HCl for the hydration. However, HCl gives about twice as much isomerization product than do our Pd-*P*,*P*,*N* and Pd-*P*,*P*,*S* complexes (4).

Conclusions

We have demonstrated the formation of bisphosphine monoxide (BPMO) complexes of Pd(II), both by direct oxidation of a "dangling" P(III) atom and by reaction with aqueous hydroxide in a mixed solvent system, where deprotonation and reductive elimination of phosphine oxide from a *cis*-hydroxophosphine-Pd(II) intermediate is favoured. In

© 2005 NRC Canada

addition, we have shown that analogous monosulfide (BPMS) complexes can be made by the direct oxidation route.

Synthesis and characterization of novel polysiloxane-grafted fluoropolymers[1]

Bilal Baradie, Patricia H.M. Lai, and Molly S. Shoichet

Abstract: Fluorosilicone polymers combine the properties of both fluorocarbons and siloxanes, yielding materials with unique properties. Novel crosslinked fluorosilicone polymers were synthesized by grafting diisocyanate-terminated polydimethylsiloxane (PDMS) to hydroxyl-functionalized fluoropolymers of poly(tetrafluoroethylene-co-vinyl acetate-co-vinyl alcohol) (PTFE-VAc-VA), as confirmed by elemental bulk and surface analysis. The fluorosilicone polymers containing 34 mol% of TFE were thermally stable with a degradation temperature of 267 °C. Fluorosilicone films were found to be more hydrophobic than the parent, non-grafted fluoropolymers; dynamic advancing and receding water contact angles for PTFE-co-VAc-co-VA-g-PDMS were 104° ± 1° and 61° ± 1°, respectively, whereas for PTFE-co-VAc they were 90° ± 2° and 59° ± 2°. The combined properties of thermal stability and hydrophobicity suggest that these fluorosilicones may be useful for coating and paint applications.

Key words: fluoropolymers, fluorosilicone, polydimethylsiloxane, supercritical carbon dioxide.

Résumé : Les polymères de fluorosilicone combinent les propriétés des fluorocarbones et des siloxanes qui leur donnent des propriétés uniques. On a réalisé la synthèse de nouveaux polymères de fluorosilicones réticulés en procédant à la greffe de polydiméthylsiloxane (PDMS) se terminant par une fonction diisocyanate à des fluropolymères à fonction hydroxyle de poly(tétrafluoroéthylène-co-acétate de vinyle-co-alcool vinylique) (« PTFE-VAc-VA ») et cette synthèse a été confirmée par une analyse élémentaire globale et une analyse de surface. Les polymères de fluorosilicone comportant au moins 34 mol% de TFE sont thermiquement stables, avec une température de dégradation de 267 °C. On a trouvé que les films de fluorosilicone sont plus hydrophobes que leurs fluoropolymères parents non réticulés; les angles de contact dynamiques de l'eau qui avance ou qui se retire pour le PTFE-co-VAc-co-VA-g-PDMS sont respectivement de 104° ± 1° et 61° ± 1° alors que pour le PTFE-co-VAc, ils sont de 90° ± 2° et 59° ± 2°. Les propriétés combinées de stabilité thermique et de caractère hydrophobe suggèrent que ces fluorosilicones pourraient avoir des applications utiles pour les revêtements et la peinture.

Mots clés : fluoropolymères, fluorosilicone, polydiméthylsiloxane, dioxyde de carbone superficiel.

[Traduit par la Rédaction]

Introduction

Fluorosilicones consist of fluorocarbons and siloxanes and are generally thought of as siloxane backbone polymers with fluorocarbon pendant groups. Fluorosilicones are generally considered resilient within a working temperature range from –60 to 200 °C. They have low surface tension (2.0–2.5 μN cm^{-1}) (1), low volatility, and excellent chemical inertness, resulting in good release properties. Moreover, fluorosilicones have low glass transition temperatures (i.e., –75 °C for polymethyl-trifluoropropylsiloxane (PMTFPS)), low brittle points (i.e., of –59 °C), and do not crystallize at low temperatures (e.g., PMTFPS does not crystallize at –40 °C). Thus, fluorosilicones combine the high thermal stability and low surface tension of fluoropolymers with the high thermal stability, low adhesion, and good low-temperature flexibility of silicones (2, 3).

Fluorosilicone elastomers are used as lubricants for pumps and compressors where harsh chemical solvents are utilized. Fluorosilicone rubber is fuel resistant and, therefore, widely used in the automotive and aerospace industries to make O-rings, gaskets, washers, and sealants that are used in fuel line connections, as well as exhaust gas recirculating diaphragms for automobiles (2).

Several types of fluorosilicones have been synthesized, most of which are conceptually similar to PMTFPS — that is, with a siloxane backbone and a fluorocarbon pendant group — yet some are different. For example, Mascia et al.

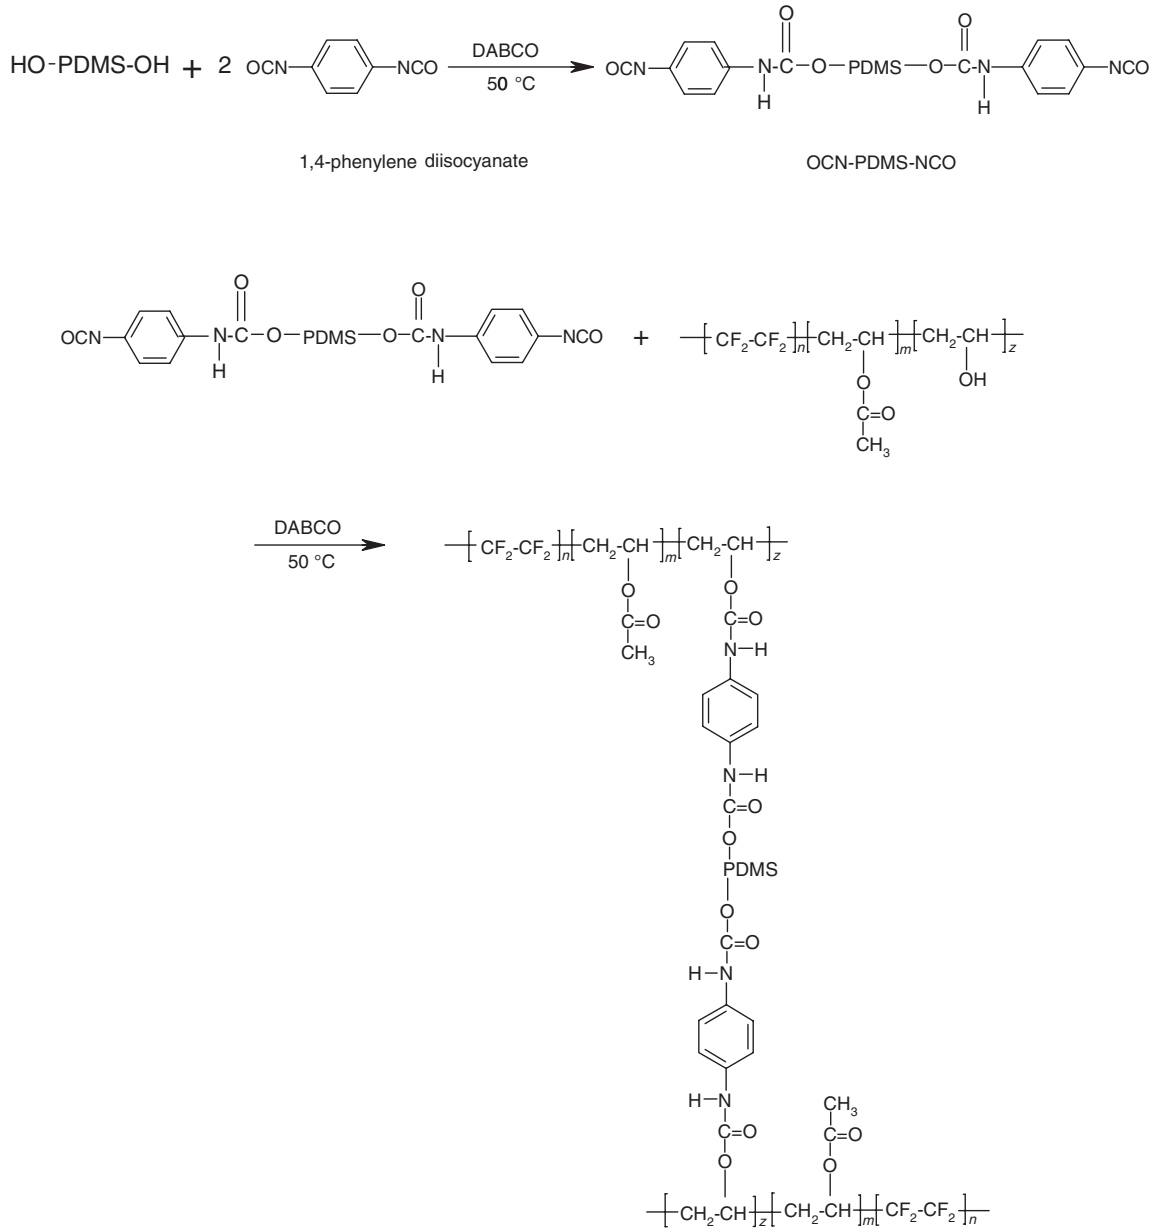
Scheme 1. Pre-polymer preparation and grafting reaction of PDMS-NCO onto PTFE-co-VAc-co-VA.

(4) blended poly(vinylidene fluoride) with a fluorosilicone elastomer with the thought that the vinylidene fluoride would reinforce the mechanical and thermal properties of the fluorosilicone polymer. This experimental compatibility was proven to be successful, and the polymer exhibited a peak melting temperature of approximately 120 °C (4). In a separate example, Kim et al. (5) synthesized a fluorosilicone polymer with a hydrocarbon backbone and fluorinated and siloxane pendant groups covalently bound by urethane bonds (5). Interestingly, Suzuki et al. (6) grafted polydimethylsiloxane (PDMS) onto a poly(chlorotrifluoroethylene) (CTFE) via an epoxide, yet this ether bond is non-ideal, with a low cohesion energy of 4.2 kJ mol^{-1} vs. that of a urethane bond at 36.5 kJ mol^{-1} (6, 7). In both Kim and Suzuki papers, the polymer surfaces were found to be hydrophobic. While these two systems use graft polymers as a way to achieve fluorosilicones, neither approach is ideal for thermally stable fluorosilicones because Kim's polymers have a hydrocarbon backbone and Suzuki's polymers use an ether bond for grafting. To overcome this void in thermal stability, we synthesized fluorosilicone polymers consisting of a fluorocarbon backbone and siloxane pendant groups, where urethane chemistry was utilized for the grafting.

Specifically, we investigated the use of supercritical carbon dioxide synthesized poly(tetrafluoroethylene-co-vinyl acetate) (PTFE-co-VAc) (8, 9), where the TFE-backbone polymers were found to be more thermally stable than those of CTFE and the vinyl acetate groups were hydrolyzed to vinyl alcohol (VA), yielding reactive functional groups for the covalent grafting of isocyanate-terminated PDMS. Monohydroxy- and dihydroxy-terminated PDMS were modified with 1,4-phenylene diiosocyanate, resulting in mono- and diisocyanate-terminated PDMS, respectively. As shown in Scheme 1, linear fluorosilicone polymers were synthesized by grafting monoisocyanate-terminated PDMS to PTFE-VAc-VA, whereas crosslinked fluorosilicone polymers were synthesized by grafting diisocyanate-terminated PDMS to PTFE-VAc-VA (as shown in Scheme 2). These polymers were characterized for bulk thermal stability and surface hydrophobicity of cast films.

Results and discussion



The ultimate goal of this research was to synthesize a crosslinked fluorosilicone with high thermal stability and high hydrophobicity; however, since crosslinked polymers are more difficult to analyze by, for example, ^{1}H NMR, we first synthesized linear fluorosilicones as model systems for the crosslinked polymers.

Linear fluorosilicones

PTFE-VAc was synthesized in supercritical fluid CO_2, as previously described, and found to have a linear backbone formed by hydrolysis of VAc repeats to VA (8). Three compositions of PTFE-VAc were examined for hydrolysis to PTFE-VAc-VA, each possessing TFE contents of 26 mol%, 34 mol%, and 63 mol%, respectively. However, only PTFE-VAc copolymers with TFE contents of 26 mol% and 34 mol% could be hydrolysed to PTFE-VAc-VA because of the insolubility of PTFE-VAc with 63 mol% TFE in the hydrolysis solution of THF. Thus only these two compositions were further analyzed. PDMS-isocyanate was successfully synthesized, as determined by FT-IR, which was also utilized to demonstrate the grafting of PDMS-isocyanate to

Scheme 2. Crosslinking of PTFE-co-VAc-co-VA backbone with the prepolymer NCO-PDMS-NCO.

PTFE-VAc-VA (shown in Fig. 1). The NH (3300 cm^{-1}) and C=O (1750 cm^{-1}) stretching vibrations correspond to the urethane bond, while the Si-O peak at 1260 cm^{-1} corresponds to PDMS and the CF_2 peak at 1152 cm^{-1} reflects the fluorinated backbone of PTFE-co-VAc-co-VA. The disappearance of the NCO peak at 2250 cm^{-1} indicates that the PDMS-NCO functional groups were consumed and likely grafted to the fluorinated PTFE-co-VAc-co-VA, yielding the linear fluorosilicone polymer.

The grafting reaction was confirmed by ^1H NMR, as shown in Fig. 2, where the peaks between 7.2 and 7.6 ppm correspond to phenyl protons of 1,4-phenylene diisocyanate. The three wide peaks between 5.2 and 6 ppm, as well the two peaks between 1.9 and 2.8 ppm, correspond to the methine, methyl, and methylene protons of VAc. The peak at 3.7 ppm corresponds to the N-H proton from the urethane link. The resonance peak at ~0 ppm corresponds to the methyl protons of the PDMS repeat (CH_3-Si-CH_3), and the peaks labelled (*d*) correspond to the methyl and methylene protons in the PDMS end groups, specifically the terminal butyl and ethylene groups (e.g., HO-C_2H_4-PDMS-C_4H_9) found in PDMS.

Crosslinked fluorosilicones

Surface properties

Reaction chemistries similar to those described for monoisocyanate-terminated PDMS (above) were repeated with diisocyanate-terminated PDMS with PTFE-VAc-VA, yielding crosslinked fluorosilicones. Diisocyanate-terminated PDMS 4000 and 700 were grafted to PTFE-VAc-VA, resulting in a product that possessed TFE:VAc:VA molar ratios of 34:44:22 and 26:48:26, respectively, as determined by a

combination of elemental analysis (for TFE:VAc molar ratio) and FT-IR (for VAc:VA molar ratio).

Films were cast from THF on glass slides, and the air–polymer surface was analyzed for hydrophobicity by dynamic advancing and receding water contact angles and for surface elemental composition by XPS. Moreover, the XPS surface composition was compared to the elemental-analysis-determined bulk composition. As shown in Table 1, PTFE-VAc-VA-g-PDMS films were hydrophobic, with greater contact angles measured for those polymers with both greater TFE molar content (i.e., 34 mol% vs. 26 mol%) and higher molar mass of PDMS (4000 vs. 700). Interestingly, the XPS elemental surface composition for both films had similar fluorine content (representative of TFE) yet different silicon content (representative of PDMS). The PDMS 4000 sample had more silicon at the surface than the PDMS 700 samples, which suggests that the greater contact angles measured reflect the greater siloxane surface composition. Interestingly, there was a surface enrichment of silicon relative to the bulk composition for both samples. Siloxane groups likely enrich the surface for several reasons, as follows: (*a*) PDMS has a lower critical surface tension (2.1 μN cm^{-1})

Table 1. Crosslinked fluorosilicones of PTFE-co-VAc-co-VA-g-PDMS: surface and bulk analysis.

			XPS (surface analysis)		Elemental analysis (bulk analysis)	
PTFE-VAc-VA mol% by elemental analysis	MW of PDMS	Advancing : receding water contact angles	F (%)	Si (%)	F (%)	Si (%)
34:44:22	4000	104°±1°:61°±1°	4.9	17.3	8.5	0.7
26:48:26	700	94°±3°:52°±3°	5.1	13	6.6	0.82

than that of either TFE (2.4 μN cm^{-1}) or that of PVAc (3.65 μN cm^{-1}) (10); (*b*) the siloxane groups have greater mobility, being pendant to the main chain, than do the TFE groups, which form the backbone, and thus PDMS groups have greater free volume of rotation and can orient themselves more easily at the air–polymer surface (11); and moreover, (*c*) polarity differences between PVAc (0.329) and PTFE (0.089) and PDMS (0.042) likely act to drive PTFE and PDMS away from each other and away from PVAc, driving PDMS to the surface and away from the bulk.

Thermal properties

Thermal stability was measured by thermogravimetric analysis (TGA) for the crosslinked PTFE-VAc-VA-g-PDMS 4000 that was most hydrophobic, and this thermal stability was compared with those of PVAc and PTFE homopolymers. The polymer films were heated from room temperature to 600 °C at a fixed heating rate of 5 °C min^{-1} in air, and mass loss vs. temperature was plotted, as shown in Fig. 3. While PTFE is clearly more stable than PTFE-VAc-VA-g-PDMS, the latter is more stable than PVAc.

To gain a greater understanding of the degradation behavior of crosslinked PTFE-VAc-VA-g-PDMS, its degradation behaviour was compared to that of PTFE and PVAc at two specific degradation temperatures, as follows: (*a*) the temperature of the initial (1%) mass loss ($T_{1\%}$) and (*b*) the temperature at 50% mass loss ($T_{50\%}$). These data are summarized in Table 2. Given that PVAc has lower $T_{1\%}$ and $T_{50\%}$ values than the PTFE-VAc-VA-g-PDMS, this suggests that TFE likely influences the decomposition temperature.

In summary, we achieved our goal of creating a thermally stable, hydrophobic fluorosilicone possessing a fluorocarbon backbone and siloxane pendant group by grafting PDMS to PTFE-VAc-VA via urethane chemistry. This chemistry may be applied to other systems, thereby extending its utility beyond the specific polymers described herein. Moreover, these fluorosilicones may be useful in coating applications where thermal stability and hydrophobicity are desirable. In ongoing studies, we are investigating other fluorosilicone systems that build on the fluorocarbon backbone and siloxane pendant chain approach.

PTFE	475	534

Experimental

General information

All chemicals were purchased from Aldrich (Ontario, Canada) and used as received unless otherwise specified. TFE was prepared by vacuum pyrolysis of PTFE (12) and stored at room temperature over *d*-limonene in a 300 mL stainless steel sample cylinder fitted with an 1800 psi (1 psi = 6.895 kPa) safety rupture disk. The *d*-limonene inhibitor was removed by inline filtration through chromatographic silica gel (200–425 mesh, Fisher Scientific, Ontario, Canada) prior to use. Monohydroxy-terminated PDMS (MW = 1000–1200 g mol^{-1}, referred to as PDMS 1100) and dihydroxy-terminated PDMS (MW = 600–850 g mol^{-1} and 3500–4500 g mol^{-1}, referred to as PDMS 700 and 4000, respectively) were used as received from Gelest Inc. (Tullytown, Pennsylvania).

All PTFE-co-VAc and PTFE-co-VAc-co-VA and PVAc were synthesized as previously reported by radical copolymerization in supercritical fluid CO_2 using diethyl peroxydicarbonate initiation (13). Water was deionized and distilled from Millipore Milli-RO 10 Plus and Milli-Q UF Plus (Bedford, Massachusetts) systems and used at 18 MΩ resistance.

Pre-polymer synthesis of PDMS-NCO and OCN-PDMS-NCO

All syntheses were anhydrous. Glassware was dried overnight in an oven at 110 °C. PDMS was purged with nitrogen gas (N_2) for at least 30 min. For the linear fluorosilicone, the NCO:OH molar ratio was 0.8:1, while it was 1:1 for the crosslinked form. DABCO was added at 1% mass fraction of all monomers. In a 50 mL round-bottom flask, 1,4-phenylene diisocyanate (PhDI) was dissolved in THF to a 50% mass fraction solution. In a 100 mL three-neck round-

© 2005 NRC Canada

bottom flask, 1,4-diazo[2,2,2]-bicyclo-octane (DABCO), PDMS, and THF were added to make a 40% mass fraction solution. Both flasks were continuously purged with N_2. THF was transferred into the flasks using a canula. The dissolved PhDI in THF was added to the flask that contained the PDMS via the canula.

Graft polymerization reaction

For both the linear and crosslinked fluorosilicone elastomers, PTFE-VAc-VA was dissolved in THF to make a 40% mass fraction solution, and it was purged under N_2 for 1 h. Under continuous stirring, the pre-polymer was added via cannula to the dissolved fluorinated polymer. For the linear form, the reaction was monitored by taking samples every 30 min for 2 h and analyzing them using FT-IR. At the end of the reaction, the graft solution was precipitated in a solution of 30% methanol and 70% distilled water. The product was washed and centrifuged in the methanol–water solution three times for 10 min. The product was then dried in the vacuum oven at 60 °C. FT-IR data of PDMS-O(CO)NH-Ph-NCO was as follows: NH (3300 cm^{-1}) and C=O (1750 cm^{-1}) correspond to the urethane bond; free isocyanate (-NCO) (2250 cm^{-1}) corresponds to the functional group at the end of the pre-polymer; and Si-O-Si (1260 cm^{-1}) corresponds to the PDMS (14).

For the crosslinked films, after the pre-polymer was completely added via cannula to the hydrolyzed polymer, the graft solution was immediately cast onto an aluminum dish. Casting of the film was performed at 40 °C. After crosslinking, all films were soaked in methanol for 3 days and then dried under vacuum at 60 °C.

Bulk characterization

Infrared spectra were recorded using the Mattson, Galaxy Series FT-IR 5000. FT-IR was used to monitor the pre-polymer and grafting reactions over time. The attenuated total reflection (ATR) FT-IR was used to analyze the crosslinked films.

Solution NMR analysis was performed using the Gemini 300 Spectrometer. ^1H and ^{19}F NMR were used to analyze the structure of the linear fluorosilicone elastomers.

Degradation and thermal stability analysis was performed using the TGA Q50 by TA Instruments. To identify the 1% mass loss temperature, the elastomer was heated from room temperature to 600 °C at 5 °C min^{-1}.

Surface characterization

Advancing and receding water contact angles were measured on air–film surfaces using a Ramé-Hart NRL telescopic goniometer equipped with a Gilmont syringe and a 22-gauge flat-tipped needle. The data presented are the average and standard deviation of at least six measurements made at different areas on the film surface. All contact angles had standard deviations of 1°–3°.

Surface elemental composition was determined by X-ray photoelectron spectroscopy (XPS, Leybold LHMax 200) using an AlK_α X-ray source at 15 kV and 25 mA emission current; data were collected at a take-off angle of 90° (between the sample plane and detector). Samples were exposed to X-ray for less than 5 min using pass energies of 192 and 42 eV for survey and C_{1s} region spectra, respectively. X-ray damage of film surfaces is negligible under these conditions, but is not negligible with longer acquisitions.

Competing Diels–Alder intramolecular pathways from cross-conjugated trienes: Fused hydrindenones (bicyclo[4.3.0]nonenones) vs. bridged-ring (bicyclo[3.3.1]nonenones) adducts from a diene-transmissive precursor[1]

Matthew D. Clay, Ditte Riber, and Alex G. Fallis

Abstract: D-Isoascorbic acid was converted to the tetraenone **12** to examine its behaviour in the intramolecular Diels–Alder reaction with pendant dienes in a diene-transmissive environment. These studies were directed toward the synthesis of the hydrindenone nucleus via a tether-controlled Diels–Alder reaction. It was anticipated that this would lead to a diene-transmissive strategy for steroids such as Desogestrel®. In contrast to our previous studies with decalins, the dominant isomer (150 °C) was the bicyclo[3.3.1]nonadieneone adduct **23**, and none of fused adduct **27** was detected. These products were accompanied by two minor hydrindenone adducts **24** and **25**. The isomer ratio was dependent on the temperature of the reaction.

Key words: Diels–Alder, hydrindane, pentadienylation, intramolecular cycloaddition, bicyclo[3.3.1]nonenone.

Résumé : L'acide D-isoascorbique a été transformé en tétraénone **12** dans le but d'étudier son comportement dans la réaction intramoléculaire de Diels–Alder avec des dièns pendants, dans un environnement permettant une transmission. Ces études ont été dirigées vers la synthèse du noyau hydrindénone via une réaction de Diels–Alder contrôlée par une laisse. Il était prévu que cette méthode permettrait de développer une stratégie diénique permettant une transmission pour réaliser la synthèse de stéroïdes tel le Desogestrel®. Par opposition aux études antérieures réalisées dans ce laboratoire avec des décalines, l'isomère dominant (150 °C) est l'adduit bicyclo[3.3.1]nonadiénone **23** et on n'a pas détecté la présence du produit condensé **27**. Ces produits étaient accompagnés de deux adduits hydrindénones mineurs, **24** et **25**. Le rapport des isomères varie avec la température de la réaction.

Mots clés : Diels–Alder, hydrindane, pentadiénylation, cycloaddition intramoléculaire, bicyclo[3.3.1]nonénone.

Introduction

Despite decades of research, the total synthesis of steroid nuclei by improved strategies continues to receive considerable attention. A short synthesis of unnatural steroids, such as the oral contraceptive Desogestrel®, has proved particularly challenging (1).

Previously we reported the enantioselective synthesis of *cis*-decalins via intramolecular Diels–Alder reactions (2). These strategies employed either planar or isopropylidene tether control groups to bias the stereochemistry of the adducts. We discovered that *cis*-acetonides are preferred compared with *trans*-acetonides. The cycloadditions directed by *cis*-acetonides (**1**) occurred under milder conditions and allowed for the introduction of an inside methyl group into the decalin adducts (Scheme 1). Because of the unfavourable *trans*-geometry of the diene induced by this substituent, its introduction is often a challenge in related intermolecular cycloadditions.

We have also extended this tether control group protocol to the stereoselective construction of highly oxygenated nor-steroid and nor-triterpenoid skeletons via a diene-transmissive Diels–Alder strategy (3). A key step in our approach was the selective indium-mediated γ-pentadienylation of the appro-

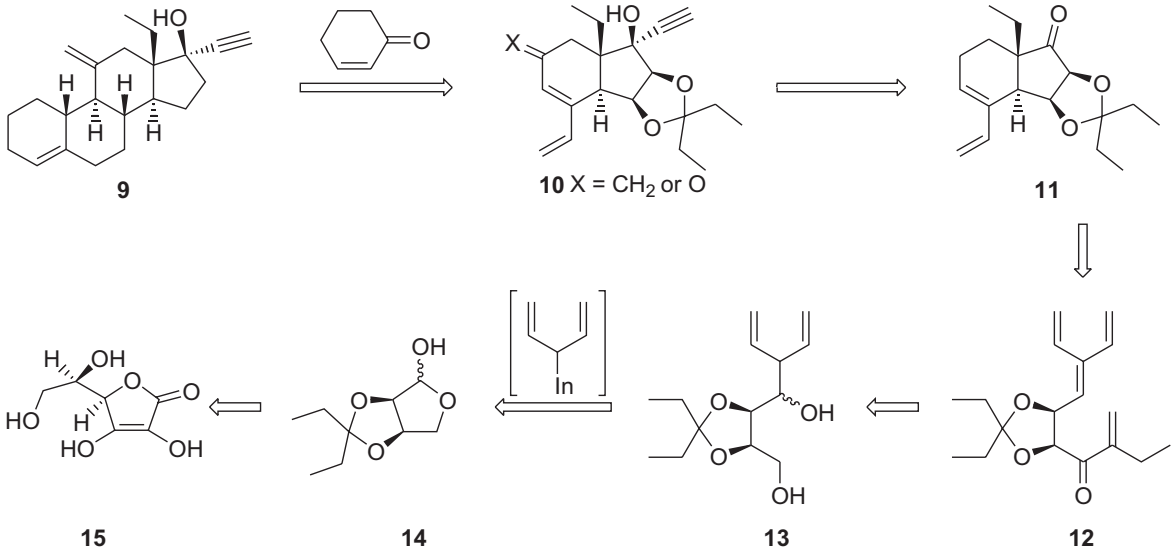
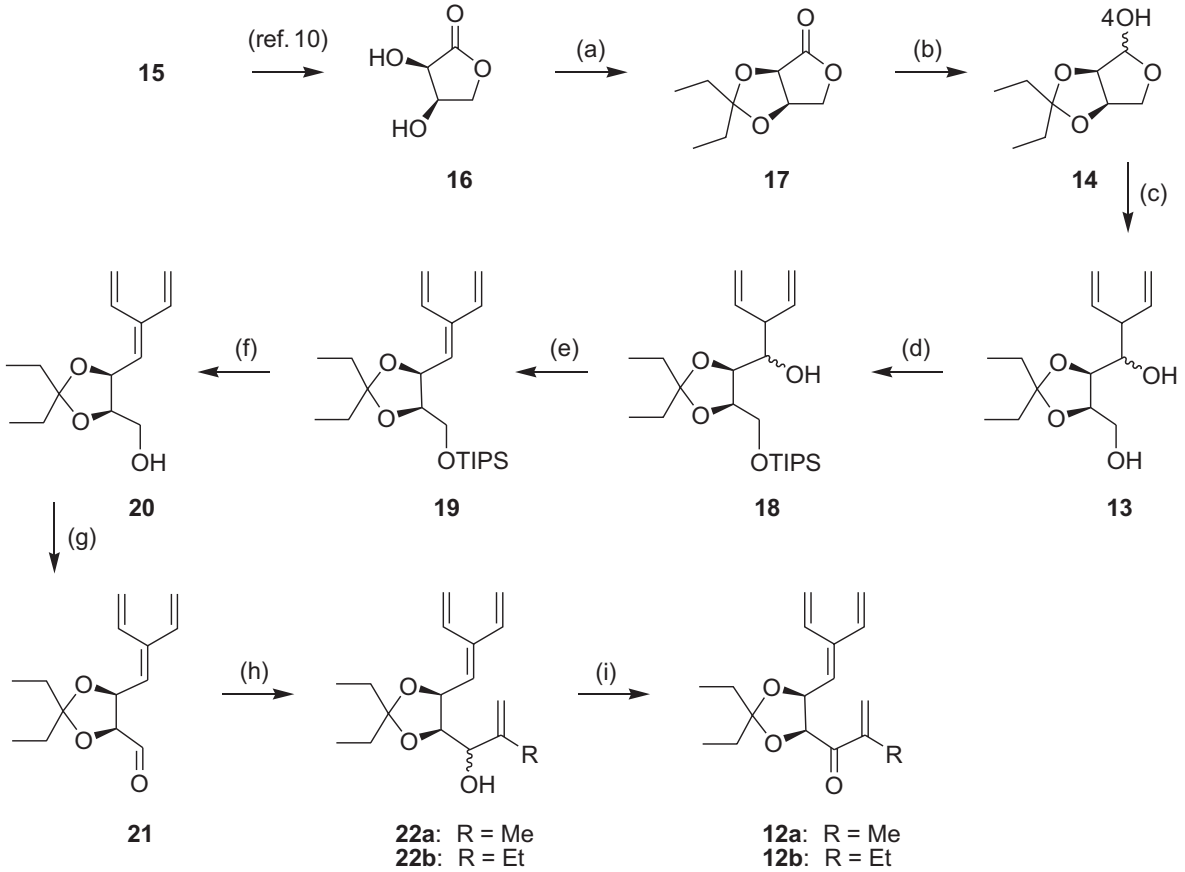
priate aldehyde-hemiacetal **4** derived from L-arabinose. Elimination of water from the product **5**, as illustrated in Scheme 2, afforded the cross-conjugated triene **6**. Sequential cycloaddition reactions rapidly produced the tetracyclic nor-steroid or nor-terpenoid core structures **8** (4).



The versatility of this protocol prompted us to investigate the reverse synthetic strategy for steroids in which the hydrindane portion would be constructed first by a related tether-controlled cycloaddition reaction, followed by a second intermolecular cyclization. The challenge of efficiently and stereoselectively synthesizing the *trans*-fused hydrindane system of steroids is well recognized. Previous successful solutions have been based on an intramolecular ester enolate alkylation (5) or on the Lewis acid assisted cyclization of a suitably substituted dienone (6). Strategies involving an intramolecular Diels–Alder cyclization as the key step have also been employed (7).

To explore the feasibility of our protocol for the construction of the *trans*-fused hydrindane ring system of steroids, a widely prescribed oral contraceptive, Desogestrel® (**9**), was selected as a commercially important and challenging target. The initial industrial synthesis of Desogestrel® required 24 steps from diosgenin, the cost of which was partially offset by the potent activity of the drug (0.150 mg per pill) (8). The ethyl group at C13 of Desogestrel® is responsible for a 50-fold enhancement in activity compared with the methyl analogue. Corey et al. (1*a*) have demonstrated that this modest structural change presents a significant complication in its synthesis. In his initial synthesis, Corey surmounted this challenge by starting with the ethyl substituted Wieland–Miescher ketone (1*a*). A more recent solution employs an oxazaborolidinium-catalyzed Diels–Alder reaction as a key step (1*b*).



Our strategy to Desogestrel® envisaged sequential Diels–Alder cycloadditions in which the CD ring system was initially constructed via a tether-controlled intramolecular Diels–Alder reaction, followed by an intermolecular cycloaddition to provide the AB rings, as outlined retrosynthetically in Scheme 3. The AB rings of Desogestrel® (**9**) should arise from a Diels–Alder reaction of **10** (exocyclic alkene or ketone) with a suitable cyclohexanone derivative using Northrup and MacMillan's imine-catalyzed protocol (9). The hydrindane portion **11** could be generated via a tether-controlled intramolecular Diels–Alder reaction of triene **12**. An unknown variable in this approach was whether the hydrindane portion could be generated in acceptable yield and with the desired stereoselectivity, especially in view of the large number of unsaturated centers in the tetraenone. An earlier model study using an isopropylidene acetal gave poor selectivity in the Diels–Alder reaction, so we chose to protect the diol of **14** as an isopentylidene acetal. It was anticipated that the additional steric bulk of the acetal would help to differentiate the competing Diels–Alder transition states and would improve the selectivity of the initial cycloaddition. The Diels–Alder precursor **12** can be synthesized from **13**, a product arising from an indium-mediated penta-

Scheme 4. Synthesis of Diels–Alder precursors **12a** and **12b**.

dienylation of lactol **14**. This enantiomerically pure lactol can be easily prepared from D-isoascorbic acid (**15**).

Results and discussion

Our synthesis commenced with the known oxidative degradation of D-isoascorbic acid to generate the enantiopure *cis*-diol **16** (Scheme 4) (10). Acetalization of **16** with 3-pentanone and a catalytic amount of *p*-toluenesulfonic acid using a Dean–Stark apparatus provided *cis*-isopentylidene acetal **17** in 92% yield after distillation. Reduction of the lactone moiety with diisobutylaluminum hydride gave lactol **14** in 87% yield as a 5:1 mixture of diastereomers, epimeric at C4. Indium-mediated pentadienylation onto the aldehyde

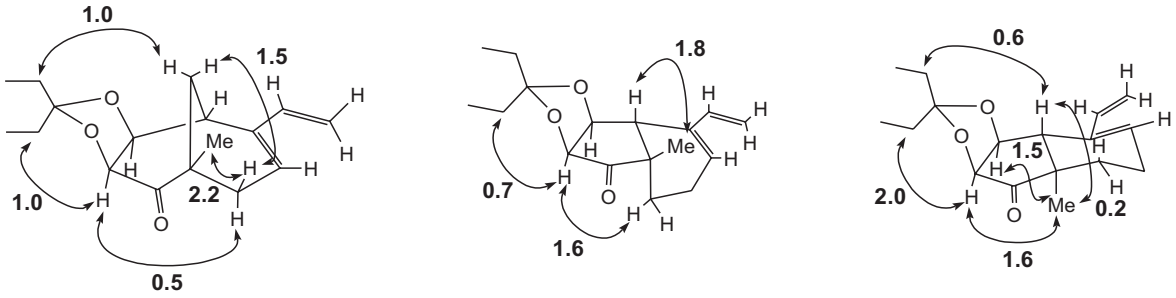
[a]Ratio determined by NMR integration.
[b]Ratio of **23**:**24**:**25**.

of the open-chain form of the lactol provided diol **13** in 82% yield as a variable mixture of diastereomers. This was inconsequential as this secondary alcohol stereocenter was removed later in the synthesis. Selective protection of the primary alcohol as a triisopropylsilyl ether provided **18** in 93% yield (as a mixture of diastereomers).

Mitsunobu-type dehydration of **18** with three equivalents each of triphenylphosphine and diethyl azodicarboxylate generated triene **19**. Interestingly, the minor isomer of **18** was resistant to dehydration. Whereas reaction of the major isomer (of the mixture) was complete within one day, dehydration of the minor isomer required three days, and often additional reagents (PPh_3 and DEAD) were required. This is likely because of steric hindrance about the reaction center caused by the isopentylidene acetal and the bulky triisopropylsilyl protecting group. Experimentally, triene **19** was isolated in 44% yield, and subsequent desilylation with tetrabutylammonium fluoride provided **20** in 82% yield. The low yield of the dehydration step was attributed to the instability of **19**, which readily decomposed during column chromatography or upon storage in a refrigerator for short periods. Thus a one-pot reaction sequence, in which **18** was first dehydrated and then desilylated to **20** without isolation of intermediate **19**, was investigated. We were gratified to achieve a higher yield of crude **20** from the one-pot procedure (~71%, compared with 36% over the two separate steps). However, **20** could not be easily separated from several impurities generated during the dehydration phase. Thus the preferred experimental method to ensure purity was the original two-step sequence.

Oxidation of the alcohol of trienol **20** also proved challenging. Oxidation occurred under a variety of conditions (e.g., Collins, Corey–Schmidt, IBX, Dess–Martin, Swern), but the product aldehyde slowly decomposed under the reaction conditions. In accord with earlier observations (11), a substantial rate enhancement occurred when water was added to the Dess–Martin oxidation of **20**. This technique pushed the oxidation to completion before noticeable decomposition of the product aldehyde had occurred and provided stable aldehyde **21** in an isolated yield of 74%. Addition of *iso*-propenyllithium or *sec*-butenyllithium (generated from the corresponding bromides via lithium–halogen exchange) to the aldehyde provided allyl alcohols **22a** and **22b**, respectively. It was subsequently discovered that addition of the Grignard reagent to the aldehyde was more efficient on larger scales and afforded **22a** and **22b** in 58% and 53% yields, respectively. Oxidation of both compounds was accomplished using the Dess–Martin periodinane–water combination (described above) and provided Diels–Alder precursors **12a** and **12b** in 78% and 72% yield, respectively.



We initially attempted the Diels–Alder reaction on the simpler model system **12a** (rather than the ethyl analogue **12b**). However, once this material was consumed, subsequent reactions were conducted using **12b**. The details of these Diels–Alder studies are presented in Table 1. It was initially believed that a Lewis acid mediated cycloaddition at low temperature would provide the best selectivity. Therefore, the cycloaddition was attempted with either diethylaluminum chloride or boron trifluoride etherate as Lewis acid catalysts. However, neither gave any trace of cycloaddition products at low temperatures, and only decomposition was observed at higher temperatures (entries 1–5). In both cases, the decomposition products were not the free diol from Lewis acid assisted cleavage of the isopentylidene acetal. Apparently the increased bulk created by Lewis acid association with the carbonyl inhibits the beneficial effect anticipated from the electronic activation.

An attempt to induce the cycloaddition using a variation of MacMillan's imine-catalyzed procedure was also examined (9). Diisopropylamine was employed as the amine component, in place of the more complex amine used by MacMillan. Unfortunately, despite several attempts, no reaction or decomposition occurred, even in the presence of perchloric acid and refluxing ethanol (entries 6–9).

We next attempted the cycloaddition under thermal conditions. Heating tetraene **12a** in the microwave at 150 °C for 3 h gave a mixture of Diels–Alder adducts in 78% yield. The individual isomers were separated by preparative HPLC, and their structures and relative stereochemistry were determined by NOESY and COSY NMR experiments. The significant

Fig. 1. Significant nOe interactions in Diels–Alder adducts **23**, **24**, and **25**.

23 **24** **25**

nOe interactions are illustrated in Fig. 1. We were intrigued to find that the major isomer was the unexpected bicyclo[3.3.1]nonadieneone **23** rather than one of the anticipated hydrindenone isomers.

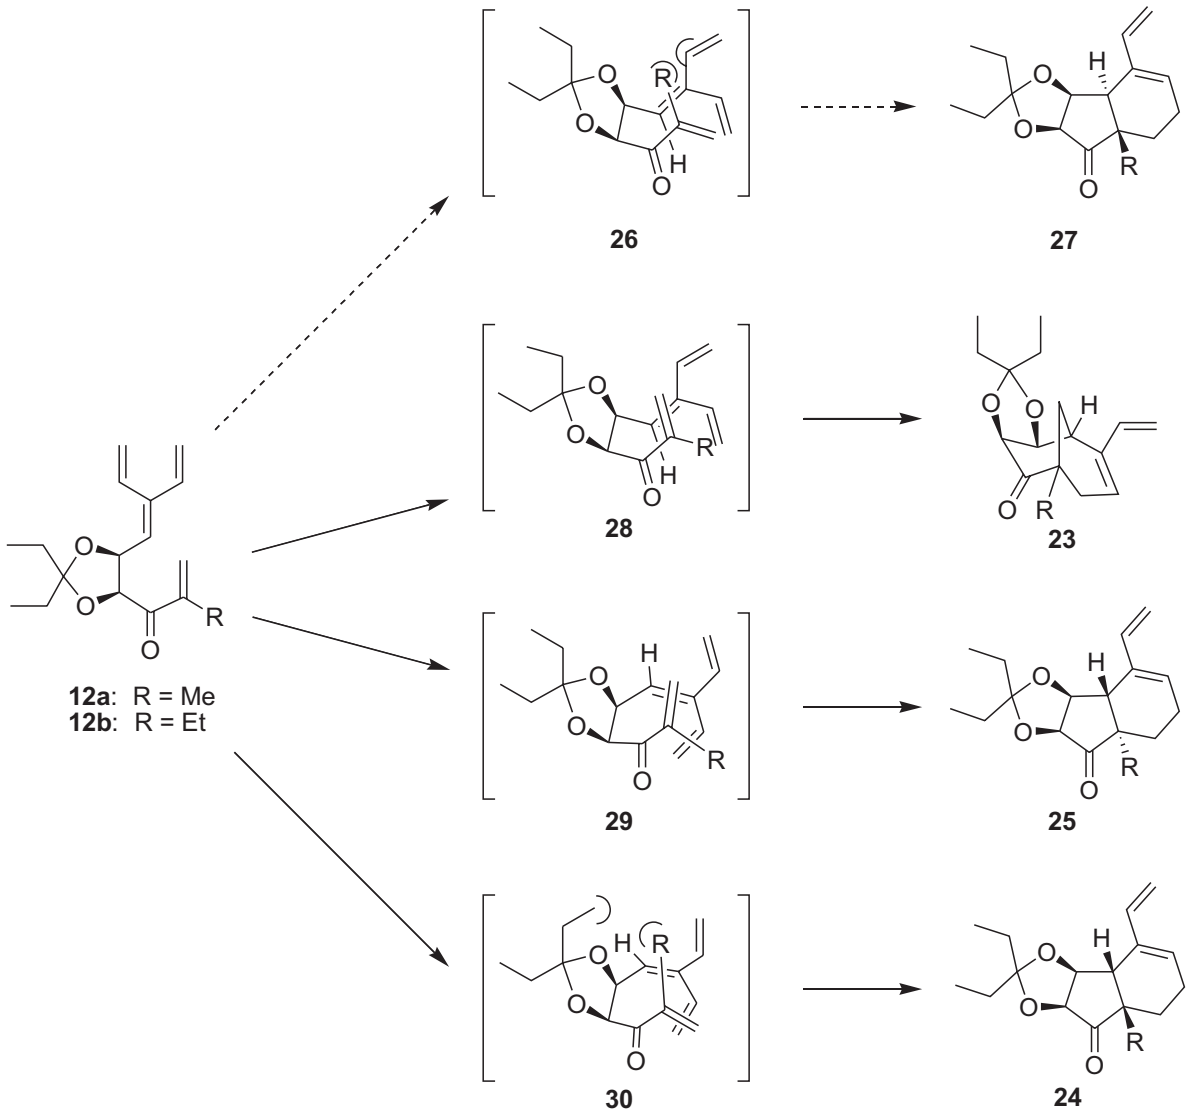
The highest ratio of the bicyclo[3.3.1]nonenone isomer **23** was obtained with the ethyl substrate **12b** (53:17:30, **23**:**24**:**25**) upon heating in a microwave oven at 150 °C for 3 h in toluene (entry 13). In contrast, under identical microwave conditions, the methyl substrate **12a** afforded only a slight excess of **23** (41:20:39) (entry 12). The ratio changed to favor formation of hydrindenone **25** (28:24:48) when the temperature was lowered to 75 °C. The reaction required 6 days at this temperature for completion (entry 11). In an attempt to change the electronic environment in the precursor **12b**, acetalization of the ketone of **12b** was attempted using ethylene glycol and catalytic *p*-toluenesulfonic acid in refluxing benzene (80 °C) for 20 h (entry 10). To our surprise, the acetal did not form; rather, **12b** underwent the Diels–Alder reaction to generate **25** as the major isomer in a ratio of 23:21:56 (**23**:**24**:**25**). This ratio was similar to the thermal reaction in toluene at 75 °C. The substantially shorter reaction time (20 h vs. 6 days) indicated the rate influence from ketone protonation by the *p*-toluenesulfonic acid.

Examination of the transition states in Fig. 2 suggests that formation of the desired *trans*-isomer **27** was disfavored by steric repulsion between the R group of the dienophile and the "extra" vinyl group of the diene as illustrated in **26**. This hypothesis was supported by the fact that this Diels–Alder precursor can rotate to avoid this interaction (**28**) and preferentially generate the bicyclic isomer **23**, with lesser amounts of **24** and **25**. It is also interesting that the *cis*-hydrindenone **24**, from transition state **30**, was formed in approximately the same quantity under all conditions. It was anticipated that the steric repulsion between the acetal ethyl group and the R group of the dienophile would disfavor this adduct formation. This is partly why the large isopentylidene acetal was chosen instead of the smaller isopropenyl acetal used in model studies.

General experimental

All non-aqueous reactions were performed under a positive pressure of dry nitrogen in flame-dried glassware using dry solvents. Tetrahydrofuran and diethyl ether were distilled from sodium–benzophenone. Dichloromethane, toluene, triethylamine, and methyl vinyl ketone were distilled from calcium hydride. Standard inert atmosphere techniques were employed in handling air- and moisture-sensitive reagents. *n*-BuLi solutions in hexanes from Aldrich Chemical Company (Oakville, Ont.) were titrated prior to use against diphenylacetic acid and used directly. Starting materials were purchased from Aldrich Chemical Company (Oakville, Ont.) and used without further purification unless otherwise stated.

Reactions were monitored by thin layer chromatography (TLC) using commercial aluminum-backed silica gel sheets coated with silica gel 60 F_{254} (E. Merck, Darmstad, Germany). TLC spots were developed by heating the plate after treatment with a 5% solution of ammonium molybdate in 10% aqueous sulphuric acid or a solution of $KMnO_4$ in aqueous potassium hydroxide. Room temperature corresponds to 21 °C. Anhydrous magnesium sulfate ($MgSO_4$) was used to dry solutions in organic solvents. Excess solvents were removed (concentrated) in vacuo at pressures obtained by a water or air aspirator connected to a Büchi rotary evaporator. Trace solvents were removed on a vacuum pump. Product purification by flash chromatography was performed with E. Merck Silica Gel 60 (230–400 mesh). Petroleum ether refers to a mixture of hydrocarbons with a boiling range of 30–60 °C.



Melting points were determined with a Thomas Hoover Unit melting point apparatus and are uncorrected. Infrared (IR) spectra were obtained as neat thin films or as a solution of the sample in $CDCl_3$ or $CHCl_3$ in a sodium chloride solution cell. All IR spectra were recorded on a Bomem Michelson 100 Fourier transform infrared spectrometer (FT-IR). ^{1}H NMR (500 MHz) and ^{13}C NMR (125 MHz) spectra were run on a Brucker AMX500 spectrometer. Chemical shifts are reported downfield from tetramethylsilane (δ scale) in ppm. ^{1}H NMR data are reported as follows: chemical shift (multiplicity (s = singlet, d = doublet, t = triplet, q = quartet), coupling constants (Hz), and integration). Low-resolution mass spectroscopy (MS), using electron impact (EI), was performed on a V.G. Micromass 7070 HS mass spectrometer with an electron beam energy of 70 eV. High-resolution mass spectroscopy (HR-MS) was performed on a Kratos Concept-11A mass spectrometer with an electron beam energy of 70 eV. The purity of all title compounds was judged to be >95% as determined by a combination of ^{1}H NMR and ^{13}C NMR analyses.

3,4-Dihydroxy-dihydro-furan-2-one (16)

The title compound was prepared according to the literature procedure (10). mp 103–104 °C (lit. (10) value mp 97.5–99.5 °C). IR (neat, cm^{-1}) ν: 3421, 3281, 2989, 2922, 2867, 1773, 1154, 1105, 1031, 970. ^{1}H NMR (500 MHz,

2,2-Diethyl-dihydro-furo[3,4-d][1,3]dioxol-4-one (17)

Diol **16** (14.00 g, 0.1186 mol), 3-pentanone (125 mL, 1.186 mol), and *p*-toluenesulfonic acid (2.0 g, catalytic) were dissolved in benzene (150 mL) and refluxed overnight using a Dean–Stark apparatus. The solution was then cooled to room temperature, and the majority of the solvent and excess 3-pentanone were removed by rotary evaporation at a bath temperature of ~50 °C. The remaining brown-coloured oil was distilled under aspirator pressure using a propane burner. The title compound collected as a pale brown oil (20.38 g, 92%) over a fluctuating (the aspirator pressure varied during the distillation) temperature range of 160–200 °C. IR (neat, cm^{-1}) ν: 2976, 2946, 2880, 1785, 1465, 1183, 1107, 1069, 921. ^{1}H NMR (500 MHz, C_6D_6) δ: 4.17–4.19 (m, 1H), 4.02–4.05 (m, 1H), 3.91 (d, *J* = 10.8 Hz, 1H), 3.54–3.58 (m, 1H), 1.41 (q, *J* = 7.5 Hz, 2H), 1.56 (q, *J* = 7.5 Hz, 2H), 0.75 (t, *J* = 7.5 Hz, 3H), 0.86 (t, *J* = 7.5 Hz, 3H). ^{13}C NMR (125 MHz, $CDCl_3$) δ: 174.0 (C), 117.7 (C), 75.6 (CH), 74.7 (CH), 70.3 (CH_2), 29.4 (CH_2), 29.0 (CH_2), 7.9 (CH_3), 7.0 (CH_3). EI-MS *m/z* (%): 157 ([M$^+$ – C_2H_5], 45), 57 (100), 29 (85). HR-MS calcd. for $C_7H_{11}O_4$ ([M$^+$ – C_2H_5]): 157.0501; found: 157.0492.

2,2-Diethyl-tetrahydro-furo[3,4-d][1,3]dioxol-4-ol (14)

Lactone **17** (19.0 g, 0.102 mol) was dissolved in CH_2Cl_2 (285 mL) and cooled to –78 °C. A 1.5 mol/L solution of DIBAL-H in THF (81.6 mL, 0.122 mol) was added dropwise over a period of 15 min, after which the solution was stirred for 5 h at –78 °C. The reaction was quenched at –78 °C with MeOH (16.0 mL) and brine (8.0 mL) and allowed to warm to room temperature. Ether (420 mL) and $MgSO_4$ (121 g) were then added under vigorous stirring, and stirring was continued overnight. The mixture was filtered (suction), and the filter cake was washed generously with ether (~1.0 L) in several portions until the presence of prod-

© 2005 NRC Canada

uct was no longer detected in the filtrate (use of a soxlet extractor to extract the product from the filter cake was also effective). The solvent was removed under reduced pressure to yield a colorless oil identified as a 5:1 mixture of diastereomers of the title compound (16.72 g, 87%). Major diastereomer: IR (neat, cm^{-1}) ν: 3425, 2975, 2943, 2883, 1464, 1102, 1075, 929. ^1H NMR (500 MHz, $CDCl_3$) δ: 5.38 (s, 1H), 4.79 (dd, *J* = 6.0, 3.3 Hz, 1H), 4.53 (d, *J* = 6.0 Hz, 1H), 4.03–3.92 (m, 2H), 3.18 (1H, bs), 1.65 (q, *J* = 7.5 Hz, 2H), 1.54 (q, *J* = 7.5 Hz, 2H), 0.87 (t, *J* = 7.5 Hz, 3H), 0.84 (t, *J* = 7.5 Hz, 3H). ^{13}C NMR (125 MHz, $CDCl_3$) δ: 116.5 (C), 101.9 (CH), 85.3 (CH), 80.2 (CH), 72.1 (CH_2), 29.3 (CH_2), 28.8 (CH_2), 8.3 (CH_3), 7.3 (CH_3). EI-MS *m/z* (%): 159 ([$M^+ - C_2H_5$], 64), 85 (17), 57 (100), 29 (37). HR-MS calcd. for $C_7H_{11}O_4$ ([$M^+ - C_2H_5$]): 159.0657; found: 159.0659.

1-(2,2-Diethyl-5-hydroxymethyl-[1,3]dioxolan-4-yl)-2-vinyl-but-3-en-1-ol (13)

Lactol **14** (5.00 g, 26.56 mmol) was dissolved in DMF (15 mL); the solution was cooled to 0 °C, and 5-bromo-1,3-pentadiene (15.62 g, 106.3 mmol) was added. Indium powder (100 mesh, 6.10 g, 53.13 mmol) was added to the vigorously stirred solution in small portions over a period of 55 min. The dark green mixture was then warmed to room temperature and stirred overnight. The reaction was poured into a vigorously stirred solution of ether (1000 mL) and water (3.2 mL) and stirred for a further 10 min. The mixture was then dried, filtered, and concentrated. Column chromatography (4:1, petroleum ether – ethyl acetate) yielded the title compound as a waxy solid mixture of diastereomers (5.55 g, 82%). Major diastereomer: mp 42.5–44.0 °C. IR (neat, cm^{-1}) ν: 3323, 3245, 2940, 2916, 2880, 1459, 1173, 1081, 920. ^1H NMR (500 MHz, C_6D_6) δ: 6.05–6.14 (m, 2H), 5.06–5.26 (m, 4H), 4.15–4.23 (m, 2H), 3.92 (m, 1H), 3.69–3.74 (m, 1H), 3.56–3.60 (m, 1H), 3.33–3.37 (m, 2H), 2.73 (bs, 1H), 1.57 (q, *J* = 7.5 Hz, 2H), 1.51 (q, *J* = 7.5 Hz, 2H), 0.86 (t, *J* = 7.5 Hz, 3H), 0.82 (t, *J* = 7.5 Hz, 3H). ^{13}C NMR (125 MHz, C_6D_6) δ: 139.6 (CH), 136.1 (CH), 118.4 (CH_2), 116.4 (CH_2), 112.4 (C), 78.0 (CH), 77.7 (CH), 72.7 (CH), 61.9 (CH_2), 51.4 (CH), 30.5 (CH_2), 29.4 (CH_2), 9.2 (CH_3), 8.4 (CH_3). EI-MS *m/z* (%): 227 ([$M^+ - C_2H_5$], 38), 209 (0.2), 159 (11), 87 (100), 57 (87). HR-MS calcd. for $C_{12}H_{19}O_4$ ([$M^+ - C_2H_5$]): 227.1284; found: 227.1283.

1-(2,2-Diethyl-5-triisopropylsilanyloxymethyl-[1,3]dioxolan-4-yl)-2-vinyl-but-3-en-1-ol (18)

Diol **13** (19.01 g, 74.2 mmol) was dissolved in a mixture of DMF (65 mL) and THF (200 mL) and cooled to 0 °C. Imidazole (10.12 g, 148.5 mmol) and triisopropylsilyl chloride (23.83 mL, 111.4 mmol) were added sequentially, and the solution was stirred overnight. Water was then added, and the mixture was extracted with ether. The ether extracts were washed once with saturated NH_4Cl, dried, filtered, and concentrated. Column chromatography (50:1, petroleum ether – ethyl acetate) yielded the title compound as a colorless oil (28.62 g, 93%). Major diastereomer: IR (neat, cm^{-1}) ν: 3467, 2965, 2940, 2867, 1638. ^1H NMR (500 MHz, C_6D_6) δ: 6.31–6.41 (m, 2H), 5.12–5.32 (m, 4H), 4.37–4.41 (m, 1H), 4.29–4.33 (m, 1H), 4.19 (ddd, *J* = 5.5, 2.5, 0.5 Hz, 1H), 4.00 (t, *J* = 10.2 Hz, 1H), 3.96 (dd, *J* = 3.3, 1.3 Hz, 1H), 3.73 (dd, *J* = 10.3, 3.4 Hz, 1H), 3.46 (t, *J* = 7.8 Hz, 1H), 1.64 (dq, *J* = 7.5, 1.5 Hz, 2H), 1.58 (q, *J* = 7.5 Hz, 2H), 0.92–1.00 (m, 21H), 0.93 (t, *J* = 7.5 Hz, 3H), 0.87 (t, *J* = 7.5 Hz, 3H). ^{13}C NMR (125 MHz, C_6D_6) δ: 140.5 (CH), 137.2 (CH), 117.6 (CH_2), 115.6 (CH_2), 112.5 (C), 78.6 (CH), 77.9 (CH), 72.8 (CH), 63.6 (CH), 51.9 (CH), 30.7 (CH_2), 29.4 (CH_2), 18.2_9 (CH_3), 18.2_8 (CH_3), 12.7 (CH), 12.4 (CH), 9.3 (CH_3), 8.5 (CH_3). EI-MS *m/z* (%): 383 ([$M^+ - C_2H_5$], 8), 187 (53), 131 (56), 67 (100). HR-MS calcd. for $C_{21}H_{39}O_4Si$ ([$M^+ - C_2H_5$]): 383.2618; found: 383.2628.

[2,2-Diethyl-5-(2-vinyl-buta-1,3-dienyl)-[1,3]dioxolan-4-ylmethoxy]-triisopropyl-silane (19)

Alcohol **18** (21.99 g, 53.3 mmol) was dissolved in benzene (1.20 L) and cooled to 0 °C, and PPh_3 (41.92 g, 159.8 mmol) and DEAD (25.16 mL, 159.8 mmol) were successively added. The solution was refluxed for two days and the majority of the solvent was removed in vacuo to yield a red oil. A slurry of silica gel (30:1, petroleum ether – ethyl acetate) was then added, and the mixture was quickly filtered through a thin (~7 cm) plug of silica gel to remove the majority of reaction byproducts. The silica gel plug was washed (30:1, petroleum ether – ethyl acetate) until no additional product was detected in the filtrate. The washes were combined and concentrated, and petroleum ether was added, and the triphenylphosphine oxide precipitate was filtered off and discarded. Column chromatography (100:1, petroleum ether – ethyl acetate) yielded the title compound as a colorless oil (9.36 g, 44%). Owing to the instability of the product in common NMR solvents, clean NMR spectra could not be obtained. IR (neat, cm^{-1}) ν: 3089, 2867, 2943, 2867, 1464, 1129, 1087, 939, 883. EI-MS *m/z* (%): 394 ([M]$^+$, 19), 265 (100), 108 (84). HR-MS calcd. for $C_{23}H_{42}O_3Si$ ([M]$^+$): 394.2903; found: 394.2925

[2,2-Diethyl-5-(2-vinyl-buta-1,3-dienyl)-[1,3]dioxolan-4-yl]-methanol (20)

Triene **19** (13.71 g, 34.7 mmol) was dissolved in THF (300 mL), cooled to 0 °C, and a 1.0 mol/L solution of TBAF in THF (41.7 mL, 41.7 mmol) was added dropwise over a period of 2 min. The reaction was stirred at 0 °C for 1 h. Water was added, and the reaction was extracted with ether, dried, filtered, and concentrated. Column chromatography (9:1, petroleum ether – ethyl acetate) yielded the title compound as a clear oil (6.79 g, 82%). IR (neat, cm^{-1}) ν: 3431, 3090, 2975, 2941, 2882, 1604, 1173, 1077, 1041, 927. ^1H NMR (500 MHz, C_6D_6) δ: 6.27 (dd, *J* = 17.4, 10.7 Hz, 1H), 6.23 (dd, *J* = 17.6, 11.2 Hz, 1H), 5.25 (dd, *J* = 17.4, 1.3 Hz, 1H), 5.16 (d, *J* = 17.5 Hz, 1H), 5.10 (d, *J* = 11.2 Hz, 1H), 5.02 (m, 1H), 4.96 (d, *J* = 10.7 Hz, 1H), 4.13 (dd, *J* = 11.5, 7.0 Hz, 1H), 3.47–3.57 (m, 2H), 2.16 (bs, 1H), 1.70 (q, *J* = 7.5 Hz, 2H), 1.58 (q, *J* = 7.5 Hz, 2H), 0.97 (t, *J* = 7.5 Hz, 3H), 0.86 (t, *J* = 7.5 Hz, 3H). ^{13}C NMR (125 MHz, C_6D_6) δ: 141.2 (C), 138.1 (CH), 132.2 (CH), 128.0 (CH), 119.8 (CH_2), 116.4 (CH_2), 113.1 (C), 79.9 (CH), 74.5 (CH), 62.8 (CH_2), 30.3 (CH_2), 29.5 (CH_2), 9.3 (CH_3), 8.5 (CH_3). EI-MS *m/z* (%): 238 ([M]$^+$, 4), 135 (38), 108 (38), 91 (78), 57 (100), 29 (88). HR-MS calcd. for $C_{14}H_{22}O_3$ ([M]$^+$): 238.1569; found: 238.1551.

2,2-Diethyl-5-(2-vinyl-buta-1,3-dienyl)-[1,3]dioxolane-4-carbaldehyde (21)

Triene-ol **20** (1.50 g, 6.29 mmol) was dissolved in CH_2Cl_2 (60 mL), and Dess–Martin reagent (5.45 g, 13.2 mmol) was added. The solution was stirred for 30 min at room temperature, and then water (0.113 mL, 6.29 mmol) was added. A white precipitate formed within a few minutes. After a further 15 min of stirring the reaction was quenched with a 1:1 mixture of 2 mol/L $Na_2S_2O_3$ and sat. $NaHCO_3$, and the reaction was extracted with CH_2Cl_2. The combined organics were dried, filtered, and concentrated. Column chromatography (12:1, petroleum ether – ethyl acetate) yielded the title compound as a clear oil (1.11 g, 74%). IR (neat, cm^{-1}) ν: 3093, 2976, 2942, 2884, 2812, 1736, 1464, 1172, 1075, 924. ^1H NMR (500 MHz, C_6D_6) δ: 9.45 (d, J = 3.5 Hz, 1H), 6.17 (dd, J = 17.4, 10.7 Hz, 1H), 6.16 (dd, J = 17.6, 11.2 Hz, 1H), 5.51 (d, J = 9.0 Hz, 1H), 5.22 (dd, J = 17.6, 1.9 Hz, 1H), 5.20 (dd, J = 17.4, 0.9 Hz, 1H), 5.12 (dd, J = 11.2, 1.7 Hz, 1H), 5.10 (t, J = 8.5 Hz, 1H), 4.94 (dd, J = 10.7, 0.9 Hz, 1H), 4.08 (dd, J = 8.0, 3.5 Hz, 1H), 1.75 (q, J = 7.5 Hz, 2H), 1.48 (q, J = 7.5 Hz, 2H), 0.98 (t, J = 7.5 Hz, 3H), 0.80 (t, J = 7.5 Hz, 3H). ^{13}C NMR (125 MHz, C_6D_6) δ: 199.5 (C), 142.7 (C), 137.7 (CH), 132.0 (CH), 125.7 (CH), 120.6 (CH_2), 117.2 (CH_2), 115.7 (C), 83.5 (CH), 76.2 (CH), 30.2 (CH_2), 29.5 (CH_2), 9.1 (CH_3), 8.5 (CH_3). EI-MS *m/z* (%): 207 ([$M^+ - C_2H_5$], 11), 133 (31), 99 (100), 57 (95), 29 (53). HR-MS calcd. for $C_{12}H_{15}O_3$ ([$M^+ - C_2H_5$]): 207.1021; found: 207.1016.

1-[2,2-Diethyl-5-(2-vinyl-buta-1,3-dienyl)-[1,3]dioxolan-4-yl]-2-methyl-prop-2-en-1-ol (22a)

2-Bromopropene (1.00 mL, 11.26 mmol) was dissolved in THF (10 mL) and added dropwise to a flask containing freshly washed (sequentially with 10% HCl, water, and acetone) and dried magnesium turnings (0.27 g, 11.26 mmol) in THF (10 mL). A small chip of iodine was added to initiate the Grignard reaction. When the Grignard had fully formed (as indicated by the complete consumption of Mg), 1.1 equiv. of it (13.3 mL, 7.49 mmol) was added dropwise to a solution of aldehyde **21** (1.61 g, 6.83 mmol) in THF (90 mL). The resultant pale yellow solution was stirred for 45 min. The reaction was quenched with saturated NH_4Cl, extracted with ether, dried, filtered, and concentrated. Column chromatography (30:1, petroleum ether – ethyl acetate) yielded the title compound as a waxy solid mixture of two diastereomers (1.10 g, 58%). IR (neat, both diastereomers, cm^{-1}) ν: 3422, 3089, 2973, 2941, 1648, 1460, 1172, 1073. Major diastereomer: ^1H NMR (500 MHz, C_6D_6) δ: 6.36 (dd, J = 17.3, 10.7 Hz, 1H), 6.29 (dd, J = 17.6, 11.2 Hz, 1H), 6.13 (d, J = 9.1 Hz, 1H), 5.34 (dd, J = 17.3, 1.5 Hz, 1H), 5.21 (dd, J = 17.7, 1.8 Hz, 1H), 5.14 (ddd, J = 11.2, 1.9, 0.7 Hz, 1H), 5.09 (dd, J = 9.1, 7.3 Hz, 1H), 5.01 (dd, J = 10.7, 1.5 Hz, 1H), 5.01 (quintet, J = 0.9 Hz, 1H), 4.87 (t, J = 1.5 Hz, 1H), 4.10 (dd, J = 7.9, 3.1 Hz, 1H), 2.58 (d, J = 6.9 Hz, 1H), 1.74 (q, J = 7.5 Hz, 2H), 1.73 (s, 3H), 1.58 (q, J = 7.5 Hz, 2H), 0.90 (t, J = 7.5 Hz, 3H), 0.85 (t, J = 7.5 Hz, 3H), (OH not detected). ^{13}C NMR (125 MHz, C_6D_6) δ: 146.0 (C), 141.0 (C), 138.2 (CH), 132.4 (CH), 129.1 (CH), 119.5 (CH_2), 116.5 (CH_2), 113.2 (CH_2), 112.9 (C), 80.5 (CH), 75.0 (CH), 74.1 (CH), 30.0 (CH_2), 28.8 (CH_2), 19.2 (CH_3), 9.3 (CH_3), 8.6 (CH_3). EI-MS (both diastereomers) *m/z* (%): 278 ([$M]^+$, 0.1), 249 (5), 121 (52), 105 (85), 91 (65), 57 (100), 29 (63). HR-MS calcd. for $C_{15}H_{21}O_3$ ([$M^+ - C_2H_5$]): 249.1491; found: 249.1488.

1-[2,2-Diethyl-5-(2-vinyl-buta-1,3-dienyl)-[1,3]dioxolan-4-yl]-2-methyl-propenone (12a)

Allyl alcohol **22a** (1.10 g, 3.96 mmol) was dissolved in CH_2Cl_2 (60 mL), and Dess–Martin reagent (3.35 g, 8.12 mmol) was added. The solution was stirred for 30 min at room temperature, and then water (0.071 mL, 3.96 mmol) was added. A white precipitate formed within a few minutes. After a further 15 min of stirring the reaction was quenched with a solution of 2 mol/L $Na_2S_2O_3$ and saturated $NaHCO_3$ (1:1), and the reaction was extracted with CH_2Cl_2. The solution was dried, filtered, and concentrated. Column chromatography (30:1, petroleum ether – ethyl acetate) yielded the title compound as a clear oil (0.85 g, 78%). IR (neat, cm^{-1}) ν: 3091, 2974, 2942, 2883, 1693, 1463, 1173, 1071, 1056, 930. ^1H NMR (500 MHz, C_6D_6) δ: 6.20 (dd, J = 17.6, 11.2 Hz, 1H), 6.12 (dd, J = 17.3, 10.7 Hz, 1H), 5.58 (d, J = 9.7 Hz, 1H), 5.33 (s, 1H), 5.10–5.23 (m, 6H), 4.88 (d, J = 10.7 Hz, 1H), 2.01 (qd, J = 7.5, 2.4 Hz, 2H), 1.69 (t, J = 0.6 Hz, 3H), 1.65 (q, J = 7.5 Hz, 2H), 1.13 (t, J = 7.5 Hz, 3H), 0.92 (t, J = 7.5 Hz, 3H). ^{13}C NMR (125 MHz, C_6D_6) δ: 196.5 (C), 144.9 (C), 141.3 (C), 137.7 (CH), 132.0 (CH), 127.8 (CH), 124.5 (CH_2), 119.8 (CH_2), 117.0 (CH_2), 115.3 (C), 80.3 (CH), 75.0 (CH), 30.5 (CH_2), 29.6 (CH_2), 18.3 (CH_3), 9.3 (CH_3), 8.9 (CH_3). EI-MS *m/z* (%): 276 ([$M]^+$, 0.2), 247 (11), 139 (50), 69 (100), 57 (44), 41 (58), 29 (33). HR-MS calcd. for $C_{15}H_{19}O_3$ ([$M^+ - C_2H_5$]): 247.1334; found: 247.1334.

1-[2,2-Diethyl-5-(2-vinyl-buta-1,3-dienyl)-[1,3]dioxolan-4-yl]-2-ethyl-prop-2-en-1-ol (22b)

The title compound was prepared by a method analogous to that used to prepare the methyl analogue (**22a**), except that *iso*-butenylmagnesium bromide was used as the Grignard reagent. (53% yield). IR (neat, both diastereomers, cm^{-1}) ν: 3475, 3089, 2971, 2940, 2882, 1463, 1172, 1074, 1056, 928. Major diastereomer: ^1H NMR (500 MHz, C_6D_6) δ: 6.33 (ddd, J = 17.3, 10.7, 0.6 Hz, 1H), 6.26 (dd, J = 17.5, 11.2 Hz, 1H), 6.10 (d, J = 9.1 Hz, 1H), 5.32 (dd, J = 17.4, 1.5 Hz, 1H), 5.19 (dd, J = 17.3, 1.9 Hz, 1H), 5.05–5.13 (m, 3H), 4.98 (dd, J = 10.7, 1.5 Hz, 1H), 4.89 (m, 1H), 4.21 (dd, J = 7.3, 3.9 Hz, 1H), 4.10–4.13 (m, 1H), 2.08–2.16 (m, 1H), 1.93–2.01 (m, 1H), 1.72 (q, J = 7.5 Hz, 2H), 1.57 (q, J = 7.5 Hz, 2H), 0.97 (t, J = 7.5 Hz, 3H), 0.96 (t, J = 7.5 Hz, 3H), 0.83 (t, J = 7.5 Hz, 3H) (OH not detected). ^{13}C NMR (125 MHz, C_6D_6) δ: 151.2 (C), 140.9 (C), 138.2 (CH), 132.4 (CH), 129.2 (CH), 119.4 (CH_2), 116.4 (CH_2), 112.9 (CH_2), 110.9 (C), 80.6 (CH), 75.0 (CH), 73.7 (CH), 30.1 (CH_2), 28.9 (CH_2), 25.7 (CH_2), 12.7 (CH_3), 9.3 (CH_3), 8.6 (CH_3). EI-MS (both diastereomers) *m/z* (%): 263 ([$M^+ - C_2H_5$], 3), 149 (34), 121 (54), 105 (74), 91 (61), 57 (100), 29 (79). HR-MS calcd. for $C_{16}H_{23}O_3$ ([$M^+ - C_2H_5$]): 263.1647; found: 263.1664.

Diels–Alder adducts 23, 24, 25

Diels–Alder precursor **12a** (0.051 g, 0.185 mmol) was dissolved in toluene (20 mL), and the solution was purged with argon for 20 min. The solution was then placed in the microwave oven (program: 300 W power, ramp temperature to 150 °C in 15 min, then hold at 150 °C for 3 h). After allowing the reaction to cool to rt, the toluene was removed under reduced pressure. Column chromatography (20:1, petroleum ether – ethyl acetate) afforded a 41:20:39 mixture of Diels–Alder adducts (0.039 g, 78%) (Table 1, entry 12). A pure sample of each isomer was obtained by exhaustive preparative HPLC (2% hexanes in ethyl acetate; Waters Nova-Pak 19 × 300 mm silica (6 μm) column).

Conclusions

Twenty years ago we commented that the then-current literature indicated that, for the synthesis of bicycle[4.3.0]nonenones from intramolecular Diels–Alder reactions, the following applied: "The ring fusion is determined by a complex interplay of conformational, steric, and electronic effects that may vary independently" (12). Clearly this still applies! We have discovered that, contrary to our expectations based on studies in the decalin series, these relatively flat tetraenes follow a novel pathway in which the *trans*-adduct bicycle[4.3.0]nonenone was not generated but instead the bicyclo[3.3.1]nonenone skeleton was formed preferentially at 150 °C in toluene in a microwave oven. At lower temperatures, the fused-ring hydrindenone products dominated, but the bridged-ring product was still produced. Indeed, once we understand more about nuances that control these competing reactions it may be possible to direct the product to either the fused- or bridged-ring pathway from related tetraenes. A contributing factor to begin to achieve this control is to examine the size and nature of the R group. Unfortunately, the adduct mixture from the synthesis made further study impractical, despite the attraction of generating the steroid framework from a second cycloaddition. Possibly future investigations, with simpler and (or) sterically more demanding dienophile–diene combinations, may permit the stereoselective synthesis of functionalized hydrindanes in this manner.

Pd(0)–PhCOOH catalyzed addition of oxygen pronucleophiles to allenes and internal alkynes[1]

Nitin T. Patil, Nirmal K. Pahadi, and Yoshinori Yamamoto

Abstract: We have developed a catalytic system that enables the addition of alcohols to allenes using a combination of 5 mol% $Pd(PPh_3)_4$ and 10 mol% benzoic acid. Likewise, the addition reaction of carboxylic acids to alkynes is described. In all cases the reaction proceeded well, giving the corresponding allylation products in good-to-high yields with high regio- and stereoselectivities.

Key words: addition, alcohols, carboxylic acids, allenes, alkynes, palladium.

Résumé : Nous avons développé un système catalytique qui utilise une combinaison de 5 mol% de $Pd(PPh_3)_4$ et de 10 mol% d'acide benzoïque et qui permet de réaliser l'addition d'alcools à des allènes. On décrit aussi la réaction d'addition d'acides carboxyliques à des alcynes. Dans tous les cas, la réaction se produit bien et conduit aux produits d'allylation correspondants avec des rendements allant de bons à élevés et avec des régio- et stéréosélectivités élevées.

Mots clés : addition, alcools, acides carboxyliques, allènes, alcynes, palladium.

[Traduit par la Rédaction]

Introduction

Transition metal catalyzed addition of nucleophiles to activated C—C bonds is one of the most important processes in organic synthesis. The addition of carbon pronucleophiles to activated C—C bonds is commonly referred to as a hydrocarbonation (1) reaction. Likewise, the addition reactions of amines and alcohols across an activated C—C bond are referred to as hydroamination (2) and hydroalkoxylation (3), respectively. All these processes are very important from the synthetic point of view because, in principle, the addition reactions can be performed with 100% atom efficiency, without any waste formation, and for this reason they fulfill the requirements of green chemistry, in contrast to substitution reactions. Although tremendous amounts of related work have been carried out in the field of hydrocarbonation and hydroamination reactions, very few reports have been found for the hydroalkoxylation and hydrocarboxylation reactions, partly because of the diminished nucleophilicity and the softer Lewis base character of oxygen nucleophiles as compared with amines.

Our interest in these type of addition reactions has prompted us to investigate a catalytic system for the addition of carbon and nitrogen pronucleophiles to allenes (2*a*, 4). As part of our ongoing interest in this area, we extended this approach to the intermolecular addition of carboxylic acids (5) to allenes (eq. [1]). In the latter case, it was found that the reaction was completed in a shorter time period (4 h), giving the allylation products in high yields with high stereo- and regioselectivity, in contrast to the previously reported cases (4) wherein the addition of carbon nucleophiles proceeded but the products were obtained in lower yields and consisted of a mixture of *E* and *Z* stereoisomers. This difference in reaction pathways in the case of carboxylic acid pronucleophiles and carbon pronucleophiles prompted us to study the catalytic system closely. To our delight, we found that, in this palladium catalyzed reaction, the addition of a catalytic amount of carboxylic acid is crucial for obtaining the allylation products in high yields and in a regio- and stereoselective manner. Our unique finding (Pd(0)–RCOOH combined catalyst) has also been successfully applied to the addition of nitrogen (6) and carbon (7) nucleophiles. However, the addition of alcohols to allenes under the newly developed procedure remains to be disclosed.

The addition of various pronucleophiles to alkynes is also a subject of interest in our laboratory (8). We recently reported a new approach for the allylation of carbon (8*a*–8*d*) and nitrogen (8*d*–8*g*) pronucleophiles with alkynes in the presence of a Pd(0)–carboxylic acid combined catalyst. Later we communicated the formal addition of alcohol to alkynes (eq. [2]) (8*h*). However, the addition of carboxylic acid to alkynes has not been addressed until now by our group. In the meantime, Zhang et al. (9) reported the addition of oxygen nucleophiles to alkynes using the catalytic system developed by us without citing our (8*h*) reference. In this paper we report, in detail, our efforts in the successful implementation of our newly developed Pd(0)–PhCOOH combined catalyst system for the addition of alcohols to

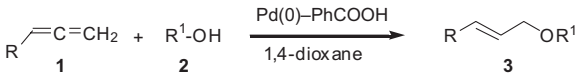
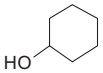
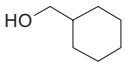
allenes (eq. [3]) and the addition of carboxylic acids to alkynes in a regio- and stereoselective manner (eq. [4]).



Results and discussion





Heating a mixture of phenyl allene **1a** and acetic acid in the presence of Pd_2dba_3·$CHCl_3$ and dppf in THF at 80 °C for 4 h under argon resulted in the formation of cinnamyl acetate in 83% yield, with excellent regio- and stereoselectivity (eq. [1], R = Ph, R^1 = CH_3) (5). However, when phenyl allene was treated with carbon pronucleophiles (for instance, methylmalononitrile) under similar conditions, the reaction time was increased to 48 h (4*a*). Moreover, in most cases, the products were obtained in lower yields and consisted of a mixture of *E* and *Z* stereoisomers. At this stage the exact reason behind the superiority of the addition of carboxylic acid pronucleophiles to allenes over carbon pronucleophiles was not known. After detailed investigation into the reaction, we found that the combination of Pd(0) and carboxylic acid was best (see mechanistic part mentioned later). A dramatic change was observed when a catalytic amount of a carboxylic acid was introduced into the reaction system. The discovery of the unique role of a carboxylic acid as an additive allowed us to perform the addition of nitrogen (6) and carbon (7) nucleophiles to allenes in a highly stereo- and regioselective manner and in a shorter time. As a part of our continuing interest in this area, we then decided to study the intermolecular addition of alcohols to allenes. The results are summarized in Table 1.

Treatment of phenyl allene **1a** with benzyl alcohol **2a** under standard conditions gave the corresponding allylation product **3a** in 71% yield (entry 1). Likewise, in the hydrocarbonation (7) and hydroamination (6) of allenes, the reaction of phenyl allene **1a** with various alcohols proceeded smoothly to afford the products **3b**–**3j** in good yields (entries 2–10). Substituents such as -CH_3 and -F in the aromatic nucleus of allenes do not affect the efficiency of the reaction. Thus, when **1b** and **1c** were treated with benzyl alcohol, the corresponding allylation products **3k** and **3l** were obtained in 68% and 72% yield, respectively (entries 11 and 12).

Next, we turned our attention towards the addition of carboxylic acids to alkynes. A mixture of 1-phenyl-1-propyne (**4a**) and acetic acid (1.5 equiv.) in the presence of $Pd(PPh_3)_4$ (5 mol%) was heated in 1,4-dioxane at 100 °C for 12 h. As anticipated, the starting materials were completely consumed, giving the allylation product **6a** in 81% isolated yield as a single stereoisomer (Table 2, entry 1) (8*a*). Other acids such as 2-furoic acid (**5b**), hexanoic acid (**5c**), 1-naphthoic acid (**5d**), and 2,2-diphenylacetic acid (**5e**) reacted

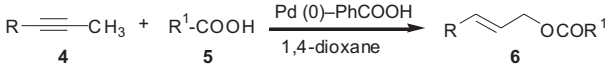
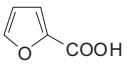
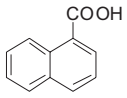
11	 **1b**	BnOH	**3k**	68
12	 **1c**	BnOH	**3l**	72

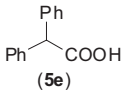


Note: All reactions were carried out as per the general procedure described in the Experimental section.
[a]Isolated yields.

well with alkyne **4a**, giving the corresponding allylation products in high yields (entries 2–5). The aryl alkynes bearing -OMe and -Cl substituents at the *para* position, **4b** and **4c**, reacted well with **5e** and **5c** to give the products **6f** and **6g**, respectively, in excellent yields (entries 6 and 7).







The mechanism of this reaction is presumably similar to those reported previously (8) and is shown in Fig 1. The initial step is the hydropalladation of alkynes **4** with the hydridopalladium species **8** generated from Pd(0) and benzoic acid (catalytic cycle I). The resulting vinyl palladium species **7** would produce phenyl allene **1** and the active catalyst **8** via β-elimination. Hydropalladation of **1** with **8** presumably gives the π-allylpalladium species **9**, which reacts with alcohols and carboxylic acids to give allylation products, along with the hydridopalladium species **8** (cycle II). short, in the case of alkynes both cycles I and II operate, while in the case of allenes only cycle II operates.

In conclusion, the Pd(0)–benzoic acid catalyzed allylation of alcohols and carboxylic acids with allenes and alkynes provides a new route to allyl ethers and allyl carboxylates, respectively. Although we proposed that a role of the carboxylic acid in this catalytic system would be the formation of the hydridopalladium species (8), the precise nature and a more detailed investigation on the catalytic species should be carried out in future (10).

Experimental section

General procedure for the addition of oxygen pronucleophiles to allenes–alkynes

To a mixture of phenyl allene – 1-phenyl-1-propyne (0.4304 mmol), alcohols – carboxylic acids (0.6456 mmol), and tetrakis(triphenylphosphine)palladium (0.022 mmol) in dry 1,4-dioxane (2 mL) was added acetic acid (0.043 mmol), and the mixture was stirred at 100 °C for 12 h in a screw-capped vial. The reaction mixture was then filtered through a short silica gel column using ether as an eluent, and the filtrate was concentrated. The residue was purified by recycling preparative HPLC (LC-918), using chloroform as an eluent to give the allylated products. Structures of **3a**–**3e** (8*h*), **3g** and **3h** (8*h*), **3j** (8*h*), **6a** (9), and **6b** (11) are known in the literature. The characterization data for the newly synthesized compounds **3f**, **3i**, **3k**, **3l**, and **6c**–**6g** are given below.

A MAS NMR and DRIFT study of the Ga species in Ga/H-ZSM5 catalysts and their effect on propane ammoxidation[1]

Prem Pal, Juliette Quartararo, Sharifah B. Abd Hamid, Eric G. Derouane, Jacques C. Védrine, Pieter C.M.M. Magusin, and Bruce G. Anderson

Abstract: ^{71}Ga, ^{27}Al, and ^{29}Si MAS NMR and DRIFT spectroscopies were used to characterize the state of gallium in Ga/H-ZSM5 catalysts tested for their ability to catalyse the ammoxidation of propane. Ga species were observed in two different possible environments: octahedrally coordinated gallium in small Ga_2O_3 particles at the external surface of the zeolite crystals, octahedrally coordinated gallium in GaO(OH) or related species, and tetrahedrally coordinated gallium in cationic-exchange positions inside the zeolite. Redox (H_2–O_2) cycles promote the migration of gallium from the GaO(OH) or Ga_2O_3 species at the external surface of the zeolite crystals to cationic-exchange sites within the zeolite channels. The redox treatment definitely had a beneficial effect on its catalytic performance for the ammoxidation of propane, which is known to occur via a bifunctional mechanism. The main product was acetonitrile at high Ga and Al contents while acrylonitrile was also observed as a side product at high Ga and low Al contents.

Key words: ZSM5, MFI, in situ studies, MAS NMR, DRIFT, propane activation, ammoxidation.

Résumé : On a fait appel à la spectroscopie RMN du ^{71}Ga, ^{27}Al et ^{29}Si à l'angle magique et à la technique « DRIFT » pour caractériser l'état du gallium dans des catalyseurs de Ga/H-ZSM5 évalués pour leur habilité à catalyser l'ammonoxydation du propane. On a observé des espèces de gallium dans deux environnements possibles : gallium à coordination octaédrique dans de petites particules de Ga_2O_3, à la surface externe des cristaux de zéolite, du gallium à coordination octaédrique dans le GaO(OH) et les espèces apparentées et du gallium à coordination tétraédrique dans les positions d'échange cationique dans la zéolite. Les cycles redox (H_2–O_2) favorisent la migration du gallium des espèces GaO(OH) ou Ga_2O_3 à la surface externe des cristaux de zéolite vers les sites d'échange cationique dans les canaux internes de la zéolite. Le traitement redox est définitivement bénéfique sur la performance catalytique pour l'ammonoxydation du propane qui se produit, par un mécanisme bifonctionnel bien connu. À contenus élevés de gallium et d'aluminium, le produit principal est l'acétonitrile alors qu'il se forme de l'acrylonitrile comme sous produit lorsque les quantités de gallium sont élevées alors que celle d'aluminium sont faibles.

Mots clés : ZSM5, MF1, études in situ, RMN à l'angle magique, DRIFT, activation du propane, ammonoxydation.

[Traduit par la Rédaction]

Introduction

Ga/H-ZSM5, zeolite H-ZSM5 modified with gallium, is known to catalyse the aromatization of light alkanes (C_3, C_4) (e.g., in the CYCLAR process (1–3). The reaction mechanism is based on the bifunctional properties of the catalyst, i.e., the activation and dehydrogenation of the alkane(s) over gallium species and the conjunct polymerization (including dehydrocyclization) of the olefins over the zeolite Brønsted acid sites. Ga/H-ZSM5 catalysts were also used more recently for other reactions such as the nitro-functionalization of propane, where gallium species were found to also play a decisive role in the activation of propane (4, 5).

A detailed characterization of a Ga/H-ZSM5 catalyst (Ga = 1.3 wt%, Si/Al = 18) recently demonstrated (6, 7)

that, after Ga ion exchange, drying at 293 K, and calcination at 823 K, gallium was mainly present as small (about 4 to 5 nm in diameter) particles of GaO(OH) in the hydrated sample and as Ga_2O_3 in the 823 K calcined sample. In both cases, these species were found to be located at the external surface of the zeolite crystallites. TG/DSC electron microscopy with EDAX analysis and ^{27}Al and ^{29}Si MAS NMR results indicated that H_2–O_2 redox cycles at 823 K induced the migration of the gallium species into the zeolite channels (7). Gallium migration to zeolite Brønsted sites was also observed with FT IR spectroscopy for Ga/H-ZSM5 and Ga/H-MOR prepared by chemical vapour deposition (8, 9). A possible intra-zeolite Ga species, postulated as essential for the aromatization of propane on Ga/H-ZSM5, is GaO^+ located in ion-exchange positions (10), which, when hydrated, should show gallium in tetrahedral coordination.

The objectives of the present study were: (1) to obtain direct information about the nature and environment of the Ga species in Ga/H-ZSM5 zeolites following H_2–O_2 redox treatments applied during their activation by use of magic-angle spinning (MAS) ^{71}Ga, ^{27}Al, and ^{29}Si NMR spectroscopy (Ga coordination) complemented by diffuse reflectance FT IR (DRIFT) spectroscopy (Brønsted acidity); and (2) to correlate this information with their catalytic behavior for the ammoxidation of propane.

Experimental

Materials

The parent ZSM5 zeolites were obtained in the Na form from Zeolyst (Valley Forge, Penn.). Prior to modification with gallium, all samples were calcined under N_2 flow at 723 K and then in air at 823 K for 2 h to remove any organic residue possibly present in the zeolite pores. Gallium nitrate (99.9%, Aldrich) was used as a Ga^{3+} precursor for ion exchange. Four samples differing by their unit cell (uc) composition, i.e., Ga(x)ZSM5(y) with x = Ga wt% (0.4 = 0.33 Ga/uc and 1.6 = 1.32 Ga/uc) and y = Si/Al ratio (27 = 3.43 Al/uc and 150 = 0.63 Al/uc) were studied.

H-ZSM5 zeolites were obtained by suspending the Na-ZSM5 zeolites in an aqueous solution of NH_4Cl–NH_4OH (295 K, pH 9.0) followed by stirring for 2 h. The solids were filtered and thoroughly washed. The products (NH_4-ZSM5) were then calcined at 773 K to yield the H-ZSM5 zeolite precursors.

Ga/H-ZSM5 samples were prepared by stirring a known quantity of gallium nitrate solution containing a known quantity of zeolite. The mixture was refluxed for 2 h at 373 K, the solid then filtered, washed with distilled water, and dried overnight in an air oven at 383 K. Higher Ga loadings were obtained by repeating this procedure. After oven drying at 383 K, the Ga/H-ZSM5 materials were calcined at 773 K in air to yield Ga_2O_3/H-ZSM5. Gallium contents were determined by atomic absorption spectroscopic analysis.

The samples were then subjected to successive H_2–O_2 treatment cycles according to the following procedure (10). The samples were initially heated to 423 K at a heating rate of 5 K min^{-1} under a 30 mL min^{-1} flow of nitrogen in a temperature-programmed oven and maintained at that temperature for 4 h. The gas flow was then changed to air and the solids further heated to 723 K at a rate of 10 K min^{-1} and kept at that temperature for 2 h. The temperature was then further raised to 823 K at a heating rate of 20 K min^{-1}. The samples were then flushed with nitrogen for 15 min and the gas flow switched to hydrogen. After reducing the catalysts for 2 h, the gas flow was changed back to nitrogen for 30 min and then to air for 2 h. This process was repeated three times. The catalysts were then allowed to cool under a flow of air.

Microcatalytic tests

The catalytic activity of the samples before and after H_2–O_2 treatments was measured using a custom-made microcatalytic reactor (MCR) optimized to study the ammoxidation of propane. The samples, placed in a tubular reactor made of stainless steel, were contacted with the mixture of reactant gases (propane, ammonia, oxygen, and N_2 or He as inert diluent) in a down-flow direction. The inlet feed lines were maintained at 473 K using heating tape. The reactor exit gases were analyzed on line using a Varian 3400 GC equipped with three different columns. The down-stream reactor line was maintained at 523 K to avoid any condensation of the reaction products and was directly fed to the GC fitted with a 15 m capillary CP-wax 52B column and two packed columns. The capillary column was used to separate the functionalized hydrocarbons (acids, alcohols, amines, amides, nitriles, aromatics, etc.), which were detected by flame ionization (FID). The nonpolar hydrocarbons (water, CO_2, and ammonia) were separated over a Haysep C packed column and detected using a thermal conductivity detector (TCD). The permanent gases (CO and CH_4) were separated over a molecular sieve A5 packed column and detected by TCD. The gas exiting from the furnace could alternatively be bubbled into a suitable reactant for analysis of NH_3 and HCN or sampled, after passing through a cooled condenser, by mass spectrometry.

Reactant conversions and product selectivities were calculated on a carbon and a nitrogen basis. Material balance evaluations were carried out to validate the GC calibrations and the quantification of the results.

Magic-angle spinning NMR spectroscopy

^{27}Al, ^{29}Si, and ^{71}Ga NMR spectra were recorded on a Bruker DMX500 spectrometer operating at ^{27}Al, ^{29}Si, and ^{71}Ga NMR frequencies of 130.29, 99.32, and 152.48 MHz, respectively. ^{29}Si and ^{27}Al MAS NMR spectra were collected with sample spinning frequencies of 5 and 12.5 kHz, respectively. For the ^{29}Si spectra, the recycling time was 20 s and a 90° pulse of 5 μs was used (^1H decoupling field ν_{1H} = 33 kHz). ^{27}Al spectra were obtained using a MAS-synchronized echo pulse sequence (p_1–τ–p_2–τ–r_d with pulse lengths p_1 = 2.4 μs, p_2= 4.8 μs, and delays τ = 76.4 μs and r_d = 3 s). ^{71}Ga MAS NMR spectra were recorded at a sample rotation rate (ν_r) between 25 and 35 kHz by use of a MAS-synchronized echo pulse sequence p_1–τ–p_2–r_d (p_1 = 0.6 μs, p_2 = 1.2 μs, $r_d \geq 0.1$s, and $\tau = \nu_r^{-1} - p_1/2 - p_2/2$) with the signal acquisition starting 16 μs after p_2. The whole signal was Fourier transformed, followed by a first-order spectral phase correction derived from the position of the echo in the time domain.

DRIFT spectroscopy

DRIFT spectra were recorded in situ using a Nicolet Protégé 460 FT IR spectrometer equipped with a SpectraTech Collector II™ DRIFT attachment fitted with a high-temperature chamber and an MCT detector. KBr windows were used on the chamber dome. Spectra were recorded at 4 cm^{-1} resolution; 256 scans were co-added. KBr powder was used as a reference material. All DRIFT spectra (measured in absorbance units) were normalized at 1870 cm^{-1} (an overtone of the zeolite lattice mode) and then transformed using the Kubelka–Munk function assuming the reflectance of the sample was 0.9 at 5000 cm^{-1}. Helium, used for drying, was purified by flowing through moisture (Varian CP17971), oxygen (Varian CP17970), and charcoal (Varian CP17972) filters. All Ga-ZSM5 catalysts (circa 20 mg) were dried in the DRIFT cell in flowing helium (30 mL min^{-1}) by ramping the temperature from 298 to 393 K at 5 K min^{-1}, holding for 30 min, then ramping to 748 K at the same rate. DRIFT spectra were then recorded following 30 min at 748 K.

Results and discussion

Magic-angle spinning ^{29}Si, ^{27}Al, and ^{71}Ga NMR spectroscopy

The ^{29}Si MAS NMR spectra of the calcined Ga(1.6)ZSM5 samples (Fig. 1) present the typical features of zeolite ZSM5 between –109 and –118 ppm. Several resolved signals corresponding to the different crystallographic sites are observed for Ga(1.6)ZSM5(150) and an unresolved resonance for Ga(1.6)ZSM5(27) owing to the aluminium-induced lattice distortion that occurs at high Al content. A resonance was also observed at –105 ppm in the latter case, attributed to Si^{4+} in a Si [1Al,3Si] configuration. No modification of the spectra attributable to the presence of gallium was observed. The latter is not surprising as most of the Ga species in the calcined Ga-modified zeolites were previously shown to decorate the external surface of the zeolite crystals in the absence of H_2–O_2 activation (7).

^{27}Al MAS NMR spectra are shown in Fig. 2. Ga(*x*)ZSM5(27) catalysts showed two main signals at 55 ppm (framework tetrahedral Al) and at 0 ppm (extra-framework octahedral Al). For the Ga(*x*)ZSM5(150) catalysts, only the resonance of framework Al was observed at 55 ppm (spectra not shown). Following calcination, a small amount of extra-framework Al, independent of Ga loading, was detected in the Ga(*x*)ZSM5(27) catalysts (Figs. 2*a*, 2*b*). After H_2–O_2 treatment, the spectrum remained essentially unchanged for the Ga(0.4)ZSM5(27) catalyst (Fig. 2*c*) whereas substantial changes in the intensities of the resonances were observed for the Ga(1.6)ZSM5(27) catalyst (Fig. 2*d*), corresponding to about equal amounts of framework and extra-framework Al. This observation reveals that Al is extracted from the ZSM5 framework when a substantial amount of Ga is present, either because of inadvertent steaming since the redox treatment produces more water when the Ga content is higher, or because some isomorphous substitution of Al by Ga in the ZSM5 framework occurred. If the latter is the correct explanation, similar changes should also have been observed for the H_2–O_2 treated Ga(1.6)ZSM5(150) catalyst, which is not the case. Thus, the extraction of framework Al upon redox treatments is attributed to inadvertent steaming.

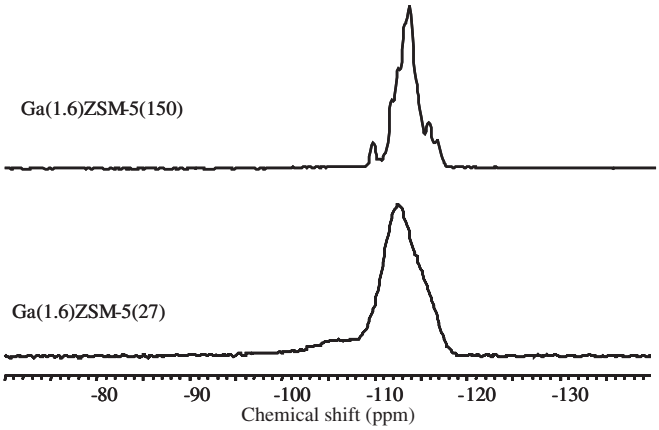

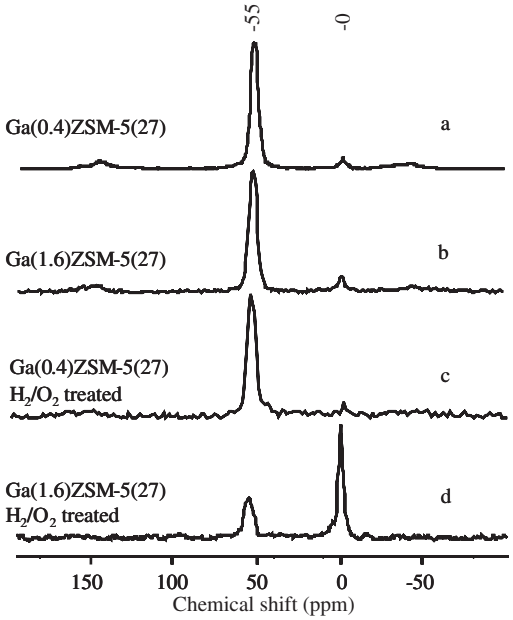

Fig. 2. MAS ^{27}Al NMR spectra of calcined (*a*, *b*) and H_2–O_2 treated (*c*, *d*) Ga(*x*)ZSM5(*y*) catalysts: *x* (Ga wt%) = 0.4 or 1.6 and *y* (Si/Al) = 27 or 150.

MAS ^{71}Ga NMR spectra for catalysts Ga(1.6)ZSM5(150), Ga(1.6)ZSM5(27), and Ga(0.4)ZSM5(27) are shown in Figs. 3 and 4. Gallium has a quadrupolar nucleus (I = 3/2) whose NMR line width is extremely sensitive to local electric field gradients. Magic-angle spinning alone does not completely remove the second-order quadrupolar line broadening, and for our catalysts, even *ultra-fast* sample rotation rates (25–35 kHz) were barely sufficient to remove the spinning sidebands from the centerband region. Further spectral improvement techniques to obtain spectra free of spinning sidebands and quadrupolar line broadening, like QPASS and MQMAS, do not work well for our zeolites with their huge ^{71}Ga quadrupolar couplings (11). The large line broadening observed in all cases probably reflects a combination of quadrupolar line broadening and chemical-shift heterogene-

ity. The first arises from local electric field gradients in the partially charged zeolite structure. The second is associated with the structure differences among the various Ga species formed.

The ^{71}Ga MAS NMR spectra obtained after calcination are shown in Fig. 3. Compared to a reference spectrum of Ga_2O_3 (not shown), the spectral integrals correspond within 10%–20% to the Ga content determined by element analysis. Thus, despite the large quadrupolar line broadening, most of the Ga species is NMR-visible, indeed, and the NMR spectum is representative for the total Ga species population. The spectra differ significantly as a function of the Ga loading and the Al content in the parent zeolite. These differences are attributed to the presence of Ga species with octahedral or tetrahedral oxygen coordination. For calcined Ga(1.6)ZSM5(150) (Ga:Al ~ 2), only one resonance was observed at ~0 ppm, which is attributed to Ga octahedrally coordinated in Ga_2O_3 (12, 13). The latter observation agrees with EDX-HRTEM results showing the presence of small particles of GaO(OH) or Ga_2O_3 on the external surface of the zeolite crystallites (7). In contrast, Ga(0.4)ZSM5(27) (Ga:Al ~ 0.1) shows a single resonance at ~150 ppm assigned to tetrahedral Ga species, either in cationic-exchange positions (e.g., GaO^+ or hydrated GaO^+) or at zeolite framework sites. The ^{71}Ga NMR spectrum of the intermediate case (Ga(1.6)ZSM5(27), Ga:Al ~ 0.4) contains both signals at 150 and 0 ppm. In fact, the spectrum is well described as a superposition of the spectra of Ga(1.6)ZSM5(150) and Ga(0.4)ZSM5(27) at a normalized intensity ratio of 0.25:0.75. Comparison of the two spectra in Fig. 3 shows that the fraction of tetrahedral Ga species relative to the octahedral-Ga fraction increases with the Ga:Al ratio. This is to be expected, since a higher amount of framework Al will promote either framework substitution by Ga or Ga exchange in cationic positions. ^{71}Ga MAS NMR spectra after H_2–O_2 treatment are shown in Fig. 4 for the Ga(0.4 and 1.6)ZSM5(27) catalysts with the highest Al content and thus also the highest amount of cationic exchangeable sites. Apart from relatively minor line width changes, the spectra are similar to the corresponding spectra before the treatment. The H_2–O_2 treatment appears not to affect the overall oxygen coordination of the Ga. This is surprising because the effect of the first reductive step with H_2 is commonly believed to break up the Ga_2O_3 clusters at the external zeolite surface into smaller Ga_2O molecules, which then enter the zeolite pores. Changes in the ^{27}Al NMR spectra of Ga(1.6)ZSM5(27) showed an increase in extra-framework Al species following H_2–O_2 treatment whereas this did not occur for the Ga(0.4)ZSM5(27) catalyst (Fig. 2). Isomorphous substitution of Al by Ga in the second coordination sphere of Si within the zeolite lattice has been reported to change the ^{29}Si NMR chemical shift by 3 ppm (14), but this was not observed in our experiments. Cationic substitution as proposed earlier (10) is therefore still favored as the dominant effect although some framework substitution cannot be fully excluded.

DRIFT spectroscopy

DRIFT spectra were recorded in the hydroxyl-stretching region with IR bands being observed at 3595, 3680, and 3735 cm^{-1} corresponding to acidic hydroxyl groups (Brønsted sites), Ga-OH groups, and Si-OH groups (silanols), respectively.

The spectra observed for samples H-ZSM5(150), Ga(0.4)ZSM5(150), and Ga(1.6)ZSM5(150) following calcination are shown in Fig. 5. Whereas the intensity of the silanol band at 3735 cm^{-1} remains unaffected, the intensity of the Brønsted site band at 3595 cm^{-1} decreases and a small Ga-OH band at 3680 cm^{-1} appears as the Ga loading is increased, indicating that some protonic sites have been

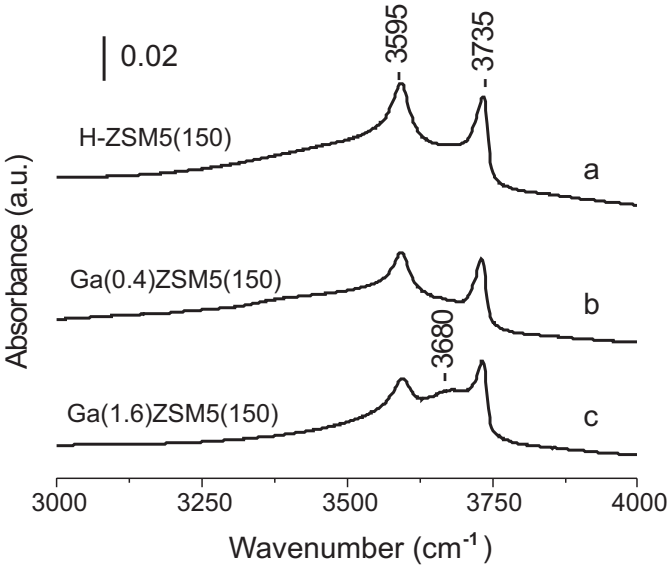
Fig. 5. DRIFT spectra (T = 748 K, He flow = 30 mL min^{-1}) in the hydroxyl-stretching region of calcined (*a*) H-ZSM5(150), (*b*) Ga(0.4)ZSM5(150), and (*c*) Ga(1.6)ZSM5(150).



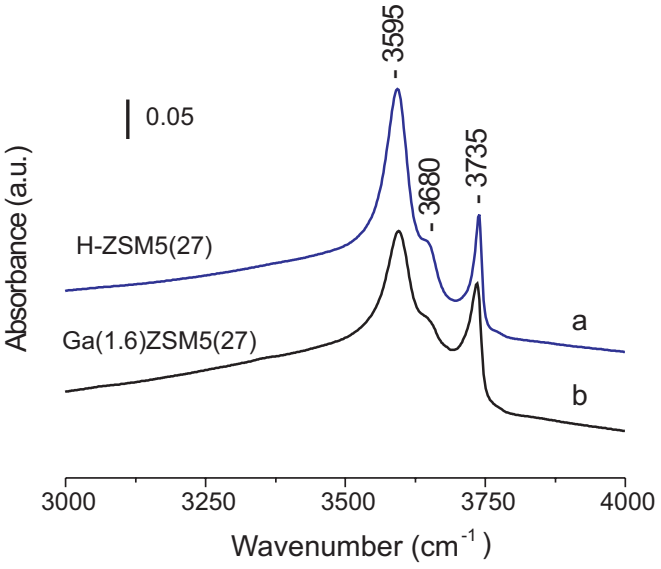


Fig. 6. DRIFT spectra (T = 748 K, He flow = 30 mL min^{-1}) in the hydroxyl-stretching region of (*a*) H-ZSM5(27) and (*b*) Ga(1.6)ZSM5(27).

exchanged by Ga species. However, given that H-ZSM5(150) contains 0.63 Al/uc and that Ga(0.4)ZSM5(150) and Ga(1.6)ZSM5(150) contain 0.33 and 1.32 Ga/uc, respectively, most of the Ga species appear not to be located at ion-exchange positions because, in that case, the Brønsted acid band at 3595 cm^{-1} should have completely disappeared for the Ga(1.6)ZSM5(150) catalyst. This is obviously not observed. Therefore, following calcination, Ga species are mostly located at the external surface of the zeolite crystals in agreement with previous observations (7) and the MAS NMR results discussed above. The Ga-OH band clearly observed for the Ga(1.6)ZSM5(150) catalyst (Fig. 5*c*) is likely to be associated with these external Ga species.

Figure 6 compares the spectra of the parent H-ZSM5(27) zeolite and of the Ga(1.6)ZSM5(27) catalyst after H_2–O_2 treatment. Again, the silanol band is not significantly affected. However, a decrease (about 30%) in the intensity of the IR band at 3595 cm^{-1} is observed and no IR band is clearly observed at 3680 cm^{-1}. These observations are consistent with the migration of Ga species from the zeolite external surface to ion-exchangeable sites within the zeolite. Indeed, the absence of a distinct IR band at 3680 cm^{-1} (Ga-OH) suggests that few Ga species are present at the surface of the zeolite crystals. As well, the decrease of the IR band at 3595 cm^{-1} is consistent with the above for Ga(1.6)ZSM5(27), the amount of Ga being 1.32/uc compared to the amount of (exchangeable) Brønsted sites of 3.43 if Ga species, as GaO^+, are in cationic-exchange positions.

In addition, a very small peak was observed at 1982 cm^{-1} for both Ga(0.4)ZSM5(27) and Ga(1.6)ZSM5(27), only after H_2–O_2 treatment. The peak was slightly larger for the higher gallium loading. Since this peak was absent in the spectra of the parent zeolite and of the calcined Ga-loaded samples, it is tentatively assigned to Ga-H groups in agreement with the frequency of Ga-H vibrations observed for gallane (Ga_2H_6) (15, 16).

Catalytic properties

The catalytic activity of the Ga/H-ZSM5 samples was evaluated for the ammoxidation of propane in a conventional fixed-bed microreactor as described above. It has been reported that propane can be activated at rather low temperatures (573–673 K) over Ga/H-ZSM5 catalysts via a protonated pseudo-cyclopropane (PPCP) intermediate that can lead to several primary products (methane, ethane, ethene, propene) as well as C1-C2 carbonium and carbenium ions (10). It was also shown that the latter species can react with various nucleophiles, e.g., CO, H_2O, and benzene (17–19). NH_3, another nucleophile, was thus another candidate expected to react with transient carbenium ions species, in the presence of oxygen, to form a C—N bond leading to acetonitrile and (or) acrylonitrile as products (16).

Figure 7 shows the influence of H_2–O_2 treatment, Ga content, and zeolite Si/Al ratio on the catalytic performance (rate in mol s^{-1} g^{-1} catalyst × 10^{-7}) of Ga(*x*)ZSM5(*y*) catalysts. Catalytic activity as well as the efficiency of the H_2–O_2 treatment increase in the order Ga(0.4)ZSM5(150) < Ga(1.6)ZSM5(150) < Ga(0.4)ZSM5(27) < Ga(1.6)ZSM5(27) as expected if the activation of propane occurs by a bifunctional mechanism, i.e., when Ga dispersion in the intracrystalline volume of the zeolite is enhanced by the redox treatments and the concentration of Brønsted acid sites is higher (lower zeolite Si/Al ratio). This observation is consistent with the findings from the ^{27}Al and ^{71}Ga MAS NMR and DRIFT results discussed above.

Table 1 shows the conversions and selectivities for the four catalysts mentioned previously, before (in parentheses) and after H_2–O_2 treatments, when the reaction is conducted at 748 K and a $GHSV_{total}$ of 1600 h^{-1} with a feed of composition C_3H_8:NH_3:O_2 = 11.5:10:22.7 (vol%). As mentioned previously, conversion increases when either the Ga or Al content increases and when the catalysts are exposed to H_2–O_2 treatment. The major products were propene (C_3^{2-}), acetonitrile (AcCN), carbon oxides (CO_x), and to a lesser ex-

Fig. 7. Catalytic activity of the Ga(*x*)ZSM5(*y*) catalysts (*x* (Ga wt%) = 0.4 or 1.6 and *y* (Si/Al) = 27 or 150) after calcination only (in grey) and after calcination and H_2–O_2 treatment (in black). The rate is expressed in 10^{-7} mol s^{-1} g^{-1} catalyst. Operating conditions were C_3H_8:NH_3:O_2 = 11.5:10:22.7 vol%, $GHSV_{total}$ = 1600 h^{-1}, *T* = 748 K.

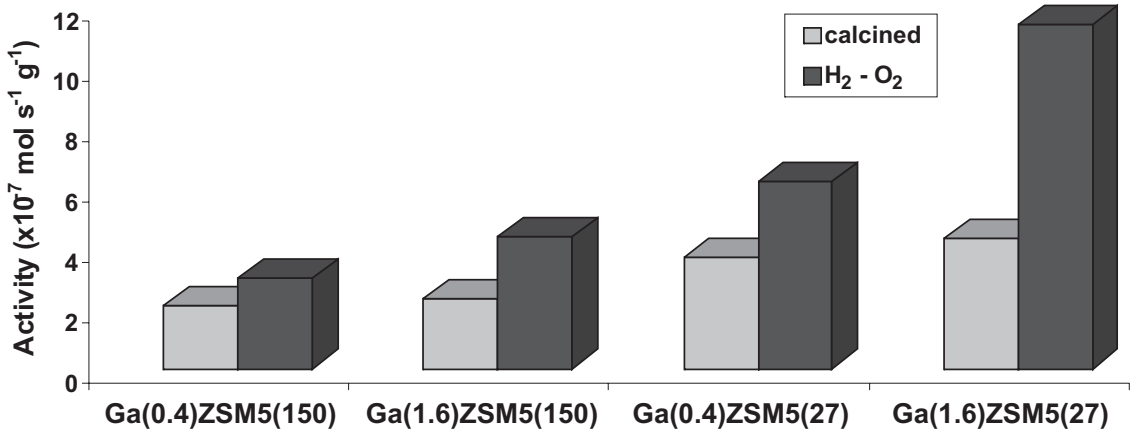

Table 1. Catalytic conversions and selectivities of different Ga(*x*)ZSM5(*y*) catalysts (*x* (Ga wt%) = 0.4 or 1.6, *y* (Si/Al) = 27 or 150) for the ammoxidation of propane without (values in parentheses) and with H_2–O_2 treatment.

		Selectivity (%)					
Catalysts	Conversion (%)	C_3^{2-}	AcCN	ACN	HCN	CO_x	ONCs
Ga(0.4)ZSM5(150)	13 (9)	36 (36)	25 (22)	7 (10)	2 (2)	23 (24)	— (6)
Ga(1.6)ZSM5(150)	18 (11)	32 (34)	26 (20)	10 (11)	3 (2)	26 (28)	— (5)
Ga(0.4)ZSM5(27)	23 (15)	29 (32)	41 (36)	1 (2)	2 (1)	25 (29)	— (1)
Ga(1.6)ZSM5(27)	41 (20)	25 (29)	47 (37)	1 (2)	2 (1)	23 (30)	— (1)

Note: Operating conditions: C_3H_8:NH_3:O_2 = 11.5:10:22.7 vol%, $GHSV_{total}$ = 1600 h^{-1}, *T* = 748 K.

tent acrylonitrile (ACN). Minor amounts of other products were also observed, namely HCN and other compounds containing N and (or) O (ONCs in Table 1). Increasing Ga and (or) Al content, as well as treatment with H_2–O_2, decreases the selectivity to propene and increases the combined selectivity to AcCN and ACN, which are final products, as expected. However, increasing the acidity of the zeolite dramatically decreases the selectivity to ACN and further promotes the formation of AcCN. As no increase in CO_x is observed, the former observation cannot be accounted for by the cracking of propene to ethylene with the C1 released fragment being oxidized. It is more likely that propene oligomers are cracked leading to a higher concentration of ethylene as an intermediate, which is obviously a precursor to AcCN.

In another study on propane oxidation to acrylic and acetic acids using MoNbSbV mixed oxides (20, 21) with low Brønsted acid site concentration and heteropolyacids (HPAs) (22) as catalysts, we observed that the reaction proceeds via two parallel pathways, one via propene leading mainly to acrylic acid and the second via isopropanol and acetone yielding mainly acetic acid. The second pathway was favoured in the presence of water and strong Brønsted acidity. As ZSM5 zeolite catalysts possess strong Brønsted acidity, it may therefore not be surprising that AcCN formation was also favored at the expense of ACN on a Ga/H-ZSM5 catalyst with higher acid site concentration. Interestingly, traces of isopropanol were also detected in the experiments reported herewith, which may further support the previous statement. Note: it was previously reported (4, 5) that Ga/H-ZSM5 catalysts were efficient for the ammoxidation of propane to acrylonitrile. It was, however, found later that the product identified as acrylonitrile in these publications was in fact acetonitrile, as mentioned in this work. The correct interpretation of the propane ammoxidation results is detailed in ref. 19.

Conclusions

^{71}Ga, ^{27}Al, and ^{29}Si MAS NMR data demonstrate that the Ga species formed by ion exchange on H-ZSM5 depend on the gallium loading and the aluminium content of the zeolite. At a low Ga:Al ratio, mainly tetrahedrally oxygen coordinated gallium is observed, probably at cation-exchange positions. At a high Ga:Al ratio, gallium is mainly present as a octahedrally oxygen coordinated species probably at the zeolite external surface of the ZSM5 zeolite crystals. DRIFT spectroscopy demonstrated that acid Brønsted sites were exchanged to a limited extent upon modification with Ga and calcination, with most of the Ga species being located at the external surface of the zeolite crystals as a result, and that indeed Ga species were present as cation-exchanged species following H_2–O_2 treatment.

The concentration of Brønsted acid sites supplied by the zeolite and its Ga content and dispersion (probably as GaO^+ species) play a direct role in the activation of propane and orient the selectivity to acetonitrile at the expense of acrylonitrile and propene at higher Al (acid site) concentration.

© 2005 NRC Canada

Gallium species working in tandem with the acidic functions of the zeolite promote the ammoxidation reaction. The results suggest that higher yields in acrylonitrile could be obtained by using Ga-modified zeolites with a higher Ga and a lower Al content.

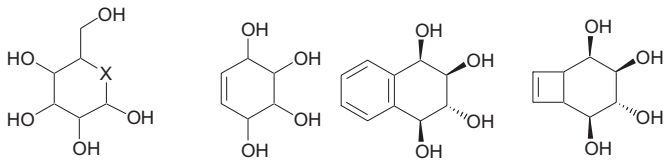
Polycyclitols — Novel conduritol and carbasugar hybrids as new glycosidase inhibitors[1]

Goverdhan Mehta and Senaiar S. Ramesh

Abstract: A family of novel carbasugar analogues (bicyclitols) based on *cis*-hydrindane and *cis*-decalin frameworks has been conceptualized. These novel entities can be regarded as conduritol and carbasugar hybrids. Syntheses of these polyhydroxylated entities have been achieved in stereo- and regioselective manners, starting from the readily available Diels–Alder adducts of 5,5-dimethoxy-1,2,3,4-tetrachlorocyclopentadiene and appropriate dienophiles like cyclopentadiene or *p*-benzoquinone, that embody a masked 7-ketonorbornenone moiety. Thermally induced chelotropic elimination of CO from the appropriately functionalized 7-ketonorbornenone derivatives to deliver annulated bicyclic 1,3-cyclohexadiene derivatives was the key step in this synthetic endeavor. Further oxy-functionalization of the 1,3-cyclohexadiene moiety delivered the targeted polycyclitols. A preliminary investigation of the glycosidase inhibitory potency of these bicyclitols, identified compounds **18** and **54** as potent and selective inhibitors of α-glucosidase (yeast).

Key words: carbasugar, conduritol, glycomimics, glycosidase inhibitors.

Résumé : On a conceptualisé une nouvelle famille d'analogues de carbasucres (bicyclitols) reposant sur des squelettes de *cis*-hydrindane et de *cis*-décaline. Ces nouvelles entités peuvent être considérées comme des hybrides du conduritol et des carbasucres. Des synthèses de ces entités polyhydroxylées ont été réalisées de façons stéréo- et régiosélectives à partir d'adduits de Diels–Alder facilement accessibles du 5,5-diméthoxy-1,2,3,4-tétrachlorocyclopentadiène et de diénophiles appropriés, tels le cyclopentadiène ou la *p*-benzoquinone, qui comportent une portion 7-cétonorbornénone marquée. L'étape clé de ces synthèses implique une élimination chélotropique thermiquement induite de CO à partir des dérivés fonctionnalisés d'une façon appropriée de la 7-cétonorbornénone qui permet d'obtenir les dérivés cyclohexa-1,3-diènes bicycliques annelés. Une oxy-fonctionnalisation subséquente de la portion cyclohexa-1,3-diène conduit aux polycyclitols recherchés. Une étude préliminaire du pouvoir inhibiteur de la glycosidase de ces bicyclitols a permis d'identifier les composés **18** et **54** comme actifs et comme inhibiteurs sélectifs de l'α-glucosidase (levure).



Mots clés : carbasucre, conduritol, glycomimique, inhibiteurs de la glycosidas.

[Traduit par la Rédaction]

Introduction

Glycosidases and related enzymes are crucial in many biological processes that are vital for the normal functioning of cells. Hence, inhibitors of these carbohydrate-processing enzymes have received increased attention in the past few decades from a synthetic as well as a biological activity perspective. These pursuits have been largely fuelled by the realization of their potential as therapeutic agents for the treatment of a variety of carbohydrate-mediated diseases like diabetes, cancer, AIDS, and viral infections (1, 2). The basic premise for the design of glycosidase inhibitors has been to generate transition state mimics by replacing the endocyclic oxygen atom of a monosaccahride by a carbon (carbasugar, **1**) or nitrogen atom (azasugar, **2**). The lack of a glycosidic linkage in these entities, which otherwise resemble the monosaccharides in shape, size, and functionalization, renders them hydrolytically stable. In this context, a range of carbasugars, azasugars, and their analogues, with diverse functionalization and stereochemical features have been devised, and their glycosidase inhibitory activities evaluated (1, 2). Additionally, conduritols **3** (1,2,3,4-tetrahydroxy-5-cyclohexenes) and their various derivatives have also attracted attention because of their glycosidase inhibitory properties (3). Several bicyclic and tricyclic conduritol variants like **4** and **5** have also been synthesized and evaluated for their efficacy against various glycosidases (4).

Naturally occurring alkaloids like 1-deoxynojirimycin (**6**) can be regarded as simple azasugar analogues of D-glucose and have been found to be potent inhibitors of α- and β-

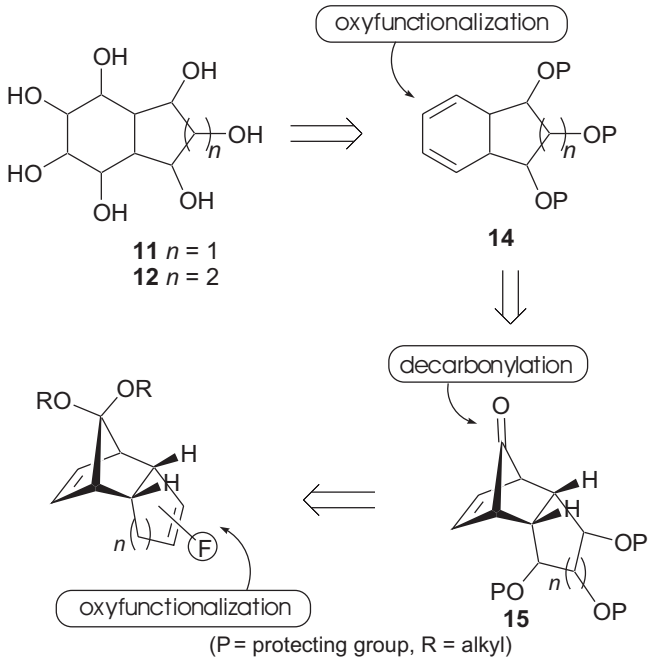
glucosidases. Besides nojirimycins, several other mono- and bicyclic alkaloids based on polyhydroxylated pyrrolidine, piperidine, pyrrolizidine, indolizidine, and quinolizidine frameworks have also been identified as carbohydrate mimics. Typical examples include bicyclic pyrrolizidine alkaloid alexine **7**, indolizidine alkaloid castanospermine **8**, and quinolizidine alkaloid **9** (5).

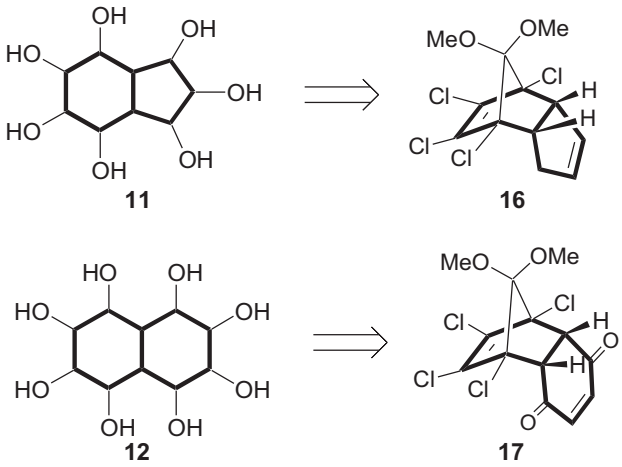


Spurred by the heightened interest in the design of potent inhibitors of glycosidases and inspired by the structures of bicyclic alkaloids **7**–**9**, we have conceived of a new family of polyhydroxylated diquinanes **10**, hydrindanes **11**, and decalins **12**, collectively termed as "polycyclitols", as potential glycomimics (6, 7). Among these bicyclitols, **11** and **12** can be considered as ring-annulated carbasugar entities and more interestingly, the decalin polyol **12** can be regarded as a hydrid of two carbasugars A and B (see bold portions in **13a** and **13b**). The presence of the additional hydroxyl groups on the annulus, it is presumed, may provide additional binding points for these analogues at the receptor site. The effect of annulation on the biological profile of biomolecules can be profound, as seen in the case of the natural glycosidase inhibitors, deoxynojirimycin **6** and castanospermine **8**. The former, a nitrogen analogue of glucose, inhibits yeast α-glucosidase, but is inactive against almond β-glucosidase. On the other hand **8**, a ring-annulated analogue of **6**, is a potent inhibitor of β-glucosidase, but exhibited no inhibition against yeast α-glucosidase (5). The bicyclitols **11** and **12** conceptualized here have a similar structural relationship to carbasugars as castanospermine **8** has to deoxynojirimycin **6**. Indeed, these bicyclitols can be visualized as the carbon analogues of castanospermine **8** and other bicyclic alkaloids exhibiting glycosidase activity. Alternatively, these novel bicyclic entities can be regarded as annulated conduritol, with **12** being a hydrid of two conduritols with shared, common ring junction carbon atoms.

Herein, we report the stereo- and regioselective synthesis of the newly conceptualized polyhydroxylated carbocyclic entities, with as many as nine (in **11**) and 10 (in **12**) stereogenic centers, starting from readily available Diels–Alder adducts, following fairly general and flexible synthetic sequences. We also report on the glycosidase inhibitory activity of the newly synthesized polycyclitols, two of which have exhibited an impressive and selective inhibition of yeast α-glucosidase.

Scheme 1. Retrosynthetic analysis of **11** and **12**.

Results and discussions



Retrosynthetic analysis

A general retrosynthetic analysis for accessing hydrindane **11** and decalin **12** based bicyclitols is depicted in Scheme 1. It was visualized that the hydroxyl group pattern on the six-membered ring could be generated through oxyfunctionalization of diene **14** (n = 1, 2), which in turn could be obtained by the thermal or photochemical decarbonylation of the 7-ketonorbornyl moiety in **15**. The precursor tricyclic ketones **15** (n = 1, 2) are readily obtainable via Diels–Alder cycloaddition between 5,5-dimethoxy-1,2,3,4-tetrachlorocyclopentadiene and an appropriate cyclic dienophile (Scheme 1).

Thus, tricyclic precursors **16** and **17** were obtained via a Diels–Alder reaction between 5,5-dimethoxy-1,2,3,4-tetrachlorocyclopentadiene and cyclopentadiene or *p*-benzoquinone, respectively. While the tricyclic endo-adduct **16** was to serve as the starting point for the hydrindane based polyols **11** (see bold portion), the benzoquinone derived Diels–Alder endo-adduct **17** was chosen as the starting material for the decalin based polyols **12** (bold portion) (Scheme 2). The main advantage in the choice of endo-adducts **16** and **17** as our basic launching pad was that their tricyclic framework built on a norbornyl matrix confers on them a topological bias towards exo-selectivity. This built-in facial bias in **16** and **17** was, therefore, expected to ensure stereoselective operations, particularly oxyfunctionalization maneuvers. The foregoing retrosynthetic analysis provided

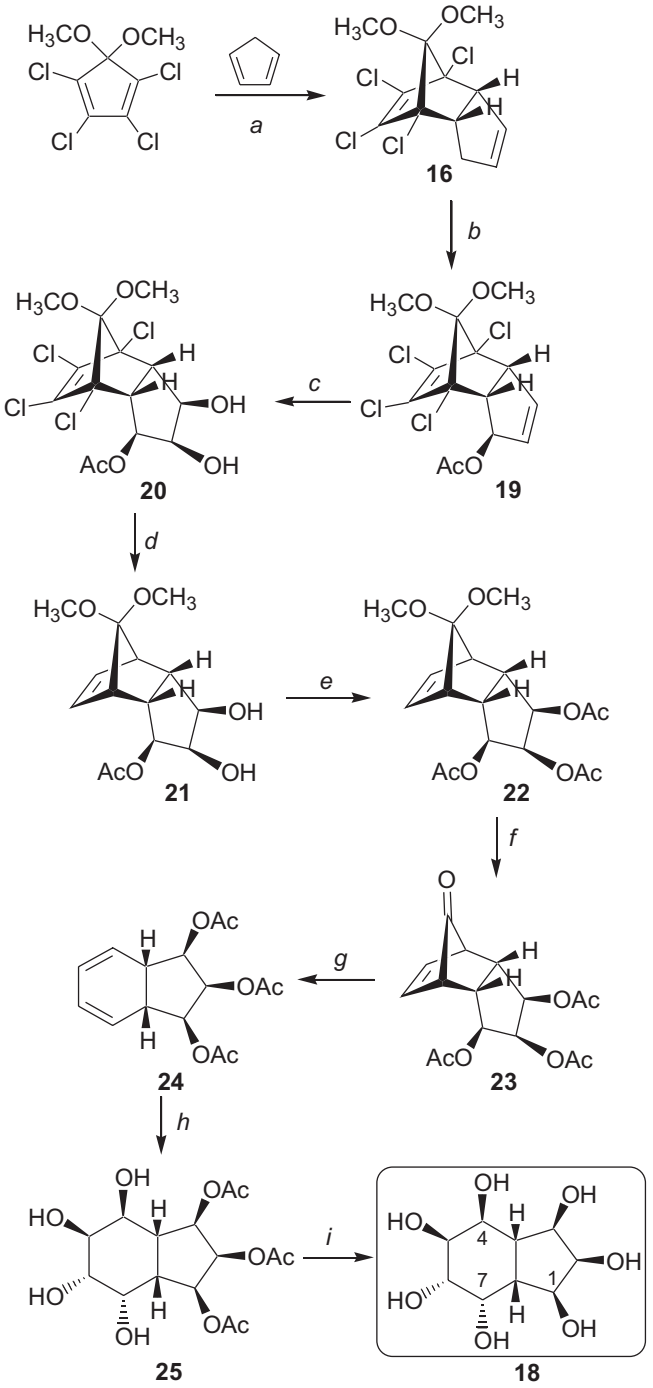
Scheme 2.

the road map for the synthesis of the targeted new family of bicyclitols.



Synthesis of hydrindane based bicyclitols

The synthesis of the first galacto-configured *cis*-hydrindane-based polyol **18**, emanated from the tricyclic Diels–Alder adduct **16**, obtained by the [4 + 2] cycloaddition of 5,5,-dimethoxy-1,2,3,4-tetrachlorocyclopentadiene and cyclopentadiene (Scheme 3) (8). Adduct **16** was subjected to allylic oxidation, using in-situ-generated $Mn(OAc)_3$, to deliver the exo-acetate derivative **19** (Scheme 3) (9). The exo-acetate **19** was subjected to dihydroxylation following the Upjohn catalytic OsO_4–NMMO protocol (10) to generate diol **20**, which on reductive dehalogenation (**21**) followed by acetylation furnished the C_s-symmetric triacetate **22** (Scheme 3) (8*a*). All three acetate functionalities in **22** were cis disposed, owing to the exo-propensity of the topology of the endo-fused system **19**.

The tricyclic 7-ketal derivative **22** upon exposure to Amberlyst-15 in moist acetone, resulted in ketal deprotection and furnished the 7-ketonorbornenone derivative **23** (Scheme 3). As contemplated earlier, decarbonylation in **23** through thermal activation by heating in nitrobenzene (~160 °C) furnished the C_s-symmetric cyclohexa-1,3-diene derivative **24** in moderate yield (Scheme 3) (11). The cyclic 1,3-diene moiety in **24** was subjected to exhaustive dihydroxylation employing the catalytic OsO_4–NMMO protocol (10) to furnish a single tetrahydroxy-triacetate **25**, which was devoid of any symmetry. Loss of symmetry during the double dihydroxylation reaction on the diene secured the stereochemistry of **25**, which required the two hydroxylations on diene **24** to occur from the exo- and endo-faces, respectively, of the *cis*-hydrindane (Scheme 3). Mild base hydrolysis of triacetate **25** gave the targeted heptahydroxy bicyclitol **18**, an annulated 5a-carbagalactose derivative.

The synthesis of diastereomeric *cis*-hydrindane-based carbasugar analogue **26** started from the readily available endo-tricyclic enone **27**. Enone **27** was obtained following the protocol reported by Schuda et al. (12) involving [4 + 2] dimerization of the ethylene ketal of 2,4-cyclopentadienone and chemoselective deketalization. Enone **27** was converted to endo-allylic alcohol **28** via DIBAL-H reduction from the exo-face and the norbornene double bond was protected

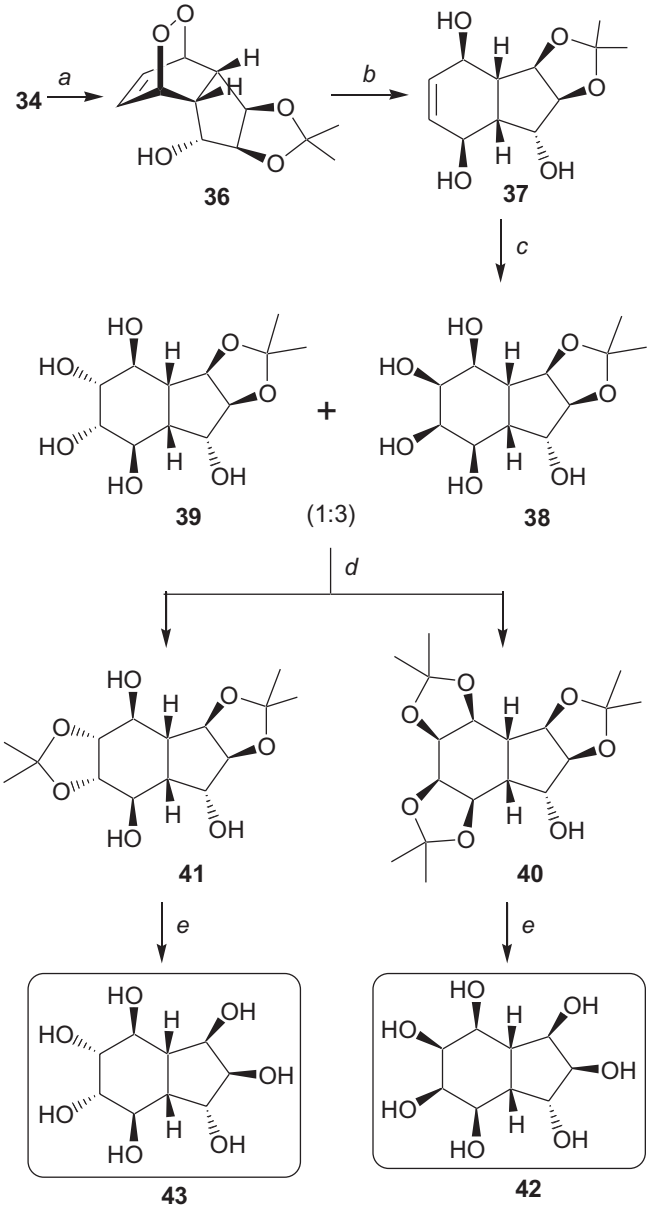
Scheme 4. Reagents and conditions: (*a*) DIBAL-H (1 mol/L in hexane), CH_2Cl_2, –78 °C, 15 min, 90%; (*b*) NBS, CH_2Cl_2, rt, 3 h, 80%; (*c*) OsO_4 (1 mol%), NMMO, Me_2CO–H_2O–*t*-BuOH, (5:5:2), rt, 12 h, 82%; (*d*) Amberlyst-15, acetone, 4 Å molecular sieves, rt, 3 h, 95%; (*e*) Zn dust, AcOH, MeOH, rt, 4 h, 85%; (*f*) Amberlyst-15, acetone, reflux, 3 h, 81%; (*g*) $C_6H_5NO_2$, 160 °C, 4 h, 67%; (*h*) OsO_4 (1 mol%), NMMO, Me_2CO–H_2O–*t*-BuOH (5:5:2), rt, 48 h, 83%; (*i*) 30% CF_3COOH, rt, 30 min, 89%.



was now unmasked with Zn metal to render **32** (Scheme 4) (8*a*). The ketal moiety in **32** was carefully deprotected in the presence of Amberlyst-15 to furnish the crystalline 7-norbornenone derivative **33** (Scheme 4). Tricyclic ketone **33**, on heating in nitrobenzene (160 °C), quite readily converted to the 1,3-cyclohexadiene derivative **34** through extrusion of CO (11). At this point, it was recognized that diene **34** was well suited for generating stereochemically diverse oxygenation patterns through appropriate sequencing of the oxyfunctionalization protocol.

Towards this end, the *cis*-hydrindane diene **34** was subjected to exhaustive dihydroxylation under catalytic OsO_4 conditions to furnish the pentahydroxy compound **35** (Scheme 4). The stereochemical assignment for **35** followed from an incisive analysis of the spectral data in analogy with that of compound **25**. In addition, it is expected that the directing influence of the free α-hydroxyl group at the peri position in diene **34** would lead to the preferred stereostructure of **35**. Mild acid hydrolysis of the acetonide protecting group in **35** furnished the targeted heptahydroxylated hydrindane **26**, which was an epimer of **18** at C1. Polyol **26**, like **18**, embodies a 5a-carbagalactose moiety, with the hydroxylated carbocyclic annulation spanning the C_{5a}-C_6 atoms of the carbasugar (Scheme 4).

In another stereochemical variation in the hydroxylation pattern on the hydrindane framework, [4 + 2] cycloaddition of singlet oxygen ($^1O_2$) was effected on **34** to deliver endoperoxide **36** as the sole product in good yield with the addition of $^1O_2$ to **34** from the preferred convex face of the molecule (Scheme 5) (13). The peroxide linkage in **36** was cleanly cleaved with lithium aluminum hydride to yield the 1,4-diol derivative **37** and further dihydroxylated under the standard catalytic OsO_4 conditions to give a 3:1 mixture of tetrols **38** and **39**, respectively. All attempts to separate the mixture of tetrols at this stage were unsuccessful. At this point, we reasoned that one of the stereoisomers from the dihydroxylation should have the hydroxyl groups in an all cis orientation while the other diastereomer would have a trans–syn–trans arrangement of the hydroxyl groups on the six-membered ring. Hence, it was reasoned that the protection of the hydroxyl groups in the mixture of **38** and **39** as the corresponding acetonides, would result in the formation of a tris-acetonide derivative in the case of **38** and a bis-acetonide in the case of **39** and would thus be rendered amenable to separation. Consequently, the mixture of **38** and **39** was treated with Amberlyst-15 in acetone medium to furnish, as anticipated, tris-acetonide **40** and bis-acetonide **41**, respectively, which were then readily separable by column chromatography (Scheme 5). The major isomer **40** originates from dihydroxylation of **37** from the syn-face of allylic alcohols, an outcome that is in conflict with Kishi's rule (14) for dihydroxylation of allylic alcohols. The stereochemical outcome in this case can be attributed to the overwhelming topological preference of the *cis*-hydrindane moiety in **37** to react from the less-hindered, convex face to yield syn-dihydroxylated **38** as the major product. The acetonide deprotection in **40** and **41** in the presence of 30% trifluoroacetic acid cleanly furnished the diastereomeric heptahydroxylated hydrindanes **42** and **43**, respectively (Scheme 5). The bicyclic carbasugar analogues **42** and **43** correspond to the

α-allopyranose and α-mannopyranose configurations, respectively.

Synthesis of *cis*-decalin-based bicyclitols

The synthetic venture towards *cis*-decalin-based carbasugar analogues of type **12** emanated from the readily available Diels–Alder adduct **17** of 5,5-dimethoxy-1,2,3,4-tetrachlorocyclopentadiene and *p*-benzoquinone (Scheme 6) (15). Tricyclic quinone **17** was elaborated to the symmetrical tricyclic diene **44** essentially following a literature procedure (16). Adduct **17** was subjected to Luche reduction ($NaBH_4$-$CeCl_3{\cdot}7H_2O$) (17) to give endo,endo-diol **45** and was further

Scheme 6. © 2005 NRC Canada

converted to dimesylate **46**, and NaI-mediated 1,4-elimination (via **47**) in **46** led to the desired C_s-symmetric tricyclic diene **44** (Scheme 6). Exhaustive catalytic-OsO_4-mediated dihydroxylation on tricyclic diene **44** furnished tetrol **48** (Scheme 6). The symmetrical nature of the ^1H and ^{13}C NMR spectra of **48** indicated an all cis relationship of the hydroxyl groups, which implied that the double dihydroxylation occurred from the exo-face of the tricyclic diene. Acetonide protection of the vicinal hydroxyl groups in tetrol **48** resulted in selective formation of the symmetrical monoacetonide **49** (Scheme 6). Acetonide **49** was subjected to reductive dechlorination in Na – liquid ammonia milieu to give the symmetrical olefin **50** in a modest yield (Scheme 6). The ketal deprotection in **50** proceeded quite uneventfully to furnish the crystalline 7-norbornenone derivative **51** in quantitative yield (Scheme 6). As contemplated earlier, thermally induced decarbonylation in tricyclic ketone **51** led to the C_s-symmetric bicyclic cyclohexadiene derivative **52** (11).

Bicyclic diene **52** was subjected to exhaustive dihydroxylation employing catalytic OsO_4 to stereoselectively furnish the hexahydroxylated decalin **53** as a single diastereomer (Scheme 6). The stereochemical assignments for **53** were done on the basis of loss of symmetry (NMR) during dihydroxylation and in analogy with earlier observations for compound **25** (see Scheme 3). The acetonide protection in **53** was relieved by exposure to 30% trifluoroacetic acid to deliver the targeted octahydroxylated decalin based carbasugar analogue **54**. Bicyclitol **54** can be regarded as embodying an α-carbagalactopyranose configuration on a *cis*-decalin framework (Scheme 6).

To generate stereochemical variations of hydroxyl groups on the decalin framework, tricyclic endo,endo-diol **45** was dihydroxylated stereoselectively to furnish tetrol **55** (Scheme 7). Dihydroxylation in **55** occurred exclusively from the convex face because of the exo-propensity of the tricyclic system built on a norbornyl scaffold, and the structure of **55** was secured on the basis of symmetry (C_s) revealed by its ^1H and ^{13}C NMR spectra. The cis-diol moiety in **55** was protected using Amberlyst-15 in acetone medium to furnish acetonide **56**. Reductive dechlorination in **56** under Birch reduction conditions delivered the C_s-symmetric olefin **57** (Scheme 7). The ketal moiety in **57** was next deprotected to unmask the carbonyl group and furnish norbornenone derivative **58** (Scheme 7). On thermal activation, tricyclic ketone **58** underwent smooth decarbonylation to furnish the C_s-symmetric bicyclic cyclohexadiene derivative **59** (Scheme 7) (11). Bicyclic diene **59** was diastereomeric with **52** (Scheme 6), and hence the protocol adopted earlier for the elaboration of **52** could be extended to diene **59** for the realization of the targeted octahydroxy polyol.

The 1,3-cyclohexadiene moiety in **59** was double dihydroxylated (OsO_4–NMMO) to furnish the hexahydroxylated *cis*-decalin derivative **60**, which was devoid of any symmetry as indicated by its NMR (^1H and ^{13}C) spectral analysis. Hence, as observed in the case of **25** and **53** (vide supra), the two sequential dihydroxylations on the diene moiety had occurred from opposite faces, thereby generating a cis–trans–cis arrangement of the hydroxyl groups in **60** (Scheme 7). The acetonide deprotection in **60** delivered octahydroxylated decalin **61**, a diastereomeric sibling of **54**.

Scheme 7. Reagents and conditions: (*a*) OsO_4 (1 mol%), NMMO, Me_2CO–H_2O–*t*-BuOH (5:5:2), rt, 1.5 h, 75%; (*b*) Amberlyst-15, acetone, 4 Å molecular sieves, rt, 1 h, 82%; (*c*) Na, liq. NH_3, THF, EtOH, –33 °C, 40 min, 88%; (*d*) Amberlyst-15, acetone, rt, 2 h, 95%; (*e*) $C_6H_5NO_2$, 160 °C, 3 h, 43%; (*f*) OsO_4 (1 mol%), NMMO, Me_2CO–H_2O–*t*-BuOH (5:5:2), rt, 48 h, 73%; (*g*) 30% CF_3COOH, rt, 30 min, 90%.

With the availability of the designer polycyclitols **18**, **26**, **42**, **43**, **54**, and **61**, our attention was turned towards the evaluation of their efficacy as glycosidase inhibitors.

Glycosidase inhibitory potencies of bicyclitols

Evaluation of the glycosidase inhibitory activity of the newly synthesized bicyclitols **18**, **26**, **42**, **43**, **54**, and **61** was carried out against various commercially available glycosidases, α-glucosidase (yeast), β-glucosidase (sweet almond), α-galactosidase (green coffee beans), β-galactosidase (*Escherichia coli*), α-mannnosidase (jack bean) and β-mannnosidase (snail acetone powder), using their corresponding *ortho*- or *para*-nitrophenylglycosides at the optimum pH and temperature for each enzyme (see Experimental) (18). All assays

© 2005 NRC Canada

were done up to 1 mmol/L concentration of the polyols. Gratifyingly, the decalin-based carbasugar analogue **54** exhibited an impressive inhibition of yeast α-glucosidase, with an inhibition constant K_i = 12 μmol/L (cf. K_i = 25 μmol/L for deoxynojirimycin). However, the same compound **54** did not show any significant inhibitory activity against almond β-glucosidase up to 1 mmol/L concentration, thus highlighting the selectivity of **54** towards α-glucosidase. To our further delight, the hydrindane-based polyol **18** exhibited a moderate and selective inhibition of yeast α-glucosidase (K_i = 84 μmol/L) but, like **54**, was totally inert to the almond β-glucosidase. Both these compounds failed to elicit any inhibition of the galactosidases and mannosidases. The other polyols **26**, **42**, **43**, and **61** failed to exhibit any significant (<1 mmol/L) inhibitory activity against the glycosidases examined. The lack of inhibitory activity of polyols **26**, **42**, **43**, and **61** when compared with their diastereomeric siblings **18** and **54**, which inhibited α-glucosidase, brings forth the effect of subtle variations in the stereochemical dispositions of the hydroxyl groups on their inhibitory potency against the carbohydrate processing enzymes. At present, the precise reasons for the selective affinity of **18** and **54** against α-glucosidase and the effect of subtle stereochemical variations on their inhibitory activity is not clear and remains a matter that still tickles our curiosity. Further investigations will hopefully illuminate this puzzling observation.

Conclusion

We have delineated a relatively short and fairly general synthetic access to novel bicyclic carbasugar analogues based on *cis*-decalin and *cis*-hydridane frameworks with as many as eight to seven hydroxyl groups, respectively. The synthetic approaches leading to secured stereochemistry at all the stereogenic centers (nine in **11** and 10 in **12**) in the bicyclitols are notable for their simplicity and stereoselectivity. The decalin-based polyol **54** and hydrindane bicyclitol **18** exhibited significant and selective inhibition of yeast α-glucosidase.

Experimental section

General

Melting points were recorded on a Büchi B-540 apparatus and are uncorrected. IR spectra were recorded on JASCO FT-IR 410 spectrometer. ^{1}H NMR spectra were recorded on a JEOL JNM-LA 300 or a Bruker AMX 400 or a Bruker DRX 500 instrument in $CDCl_3$ solutions, unless otherwise stated. Chemical shifts are reported with respect to tetramethylsilane (Me_4Si) as the internal standard (for ^{1}H NMR) and the central line (77.0 ppm) of $CDCl_3$ (for ^{13}C NMR). The chemical shifts are expressed in parts per million (δ) downfield from Me_4Si. The standard abbreviations s, d, t, q, and m refer to singlet, doublet, triplet, quartet, and multiplet, respectively. Coupling constants (*J*), whenever discernible, have been reported in Hz. Low resolution mass spectra (LR-MS) were recorded either on a Shimadzu GC–MS-QP 5050A spectrometer (EI or CI mode) or on a Q-TOF Micromass mass spectrometer. High resolution mass spectra (HR-MS) were recorded on a Q-TOF Micromass mass spectrometer. Elemental analyses were obtained on a Carlo Erba 1106 CHN analyzer. Silica gel from Acme (100–200 mesh particle size) was used for column chromatography. All moisture- and air-sensitive reactions were performed under an argon atmosphere with dry, freshly distilled solvents under anhydrous conditions using standard syringe–septum techniques. Yields reported are of isolated materials judged homogeneous by thin layer chromatography (TLC) and NMR. All solvent extracts were washed with water/brine as appropriate and dried over anhydr. Na_2SO_4 before removal of the solvent on a rotary evaporator under reduced pressure. The glycosidase enzymes and their corresponding substrates (*ortho*- or *para*-nitrophenolates) were purchased from the Sigma Chemical Company, USA.

1,7,8,9-Tetrachloro-10,10-dimethoxytricyclo[5.2.1.0^{2,6}]deca-4,8-dien-3-ylacetate (19)

Cyclopentadiene (12 g, 0.18 mol) was added to a solution of 5,5-dimethoxy-1,2,3,4-tetrachlorocyclopentadiene (50 g, 0.18 mol) in dry toluene (80 mL) and the resulting solution was refluxed for 24 h. Excess solvent was distilled off from the reaction mixture and the residue obtained was distilled under reduced pressure (130–140 °C/5 torr, 1 torr = 133.3224 Pa) to yield adduct **16** (41.6 g, 70%). To a solution of the $Mn(OAc)_2 \cdot H_2O$ (10.8 g, 44 mmol) in AcOH (40 mL) was added Ac_2O (14 mL) and the mixture was refluxed for 20 min. Solid $KMnO_4$ (1.74 g, 10.1 mmol) was carefully added and the resulting mixture was refluxed for an additional 30 min. After cooling to 70 °C, adduct **16** (12 g, 36.4 mmol) and KBr (720 mg, 6 mmol) were added and the reaction mixture was stirred at the same temperature until complete consumption of the starting material. The reaction mixture was cooled to room temperature and filtered through a Celite pad. The filtrate was extracted with hexane (3 × 100 mL) and the residue obtained after the usual work-up, was chromatographically purified on a silica gel column (5% ethyl acetate – hexane) to afford the exo-acetate **19** (9 g, 64%), mp 111 to 112 °C (lit. value (8*a*) mp 110 °C). IR (Nujol, cm^{-1}): 1740.

10,10-Dimethoxy-3,5-di(acetyloxy)tricyclo[5.2.1.0^{2,6}]dec-8-en-4-yl acetate (22)

To the solution of exo-acetate **19** (4 g, 10.3 mmol) in acetone–water–*t*-BuOH (5:5:1, 25 mL), OsO_4 (26 mg, 1 mol%), and 50% aq. NMMO solution (2.65 mL, 11.3 mmol) were added sequentially. The pale yellow reaction mixture was stirred at room temperature for 12 h prior to quenching of the reaction by addition of solid $NaHSO_3$ (1 g). The resulting mixture was filtered through a Celite pad and the filtrate was concentrated under reduced pressure to give a residue, which on chromatographic purification on a silica gel column furnished diol **20** (3.5 g, 80%). The solution of diol **20** (2.2 g, 5.2 mmol) in dry THF (25 mL) and absolute EtOH (10 mL) was added to freshly distilled liquid ammonia (250 mL) and to this solution, freshly cut pieces of sodium (1 g) were carefully added, until the blue color of the solution persisted. The reaction mixture was stirred for 15 min, prior to quenching the reaction with solid NH_4Cl (1 g). Ammonia was allowed to evaporate overnight, the residue obtained was diluted with ice-cooled water (100 mL) and extracted with ethyl acetate (3 × 100 mL). The usual work-up and evaporation of volatiles under reduced pressure fur-

© 2005 NRC Canada

nished a residue (**21**) that was dissolved in dry pyridine (10 mL), then Ac_2O (1 mL) and catalytic DMAP (100 mg) were added. The reaction mixture was stirred at room temperature for 2 h before diluting with water. The reaction mixture was extracted with CH_2Cl_2 (3 × 60 mL) and after the usual work-up was purified by silica gel column chromatography (20% ethyl acetate – hexane) to furnish triacetate **22** (1.2 g, 64%), mp 140–142 °C. IR (Nujol, cm^{-1}): 1725.

3,4,5-Tri(acetyloxy)tricyclo[5.2.1.0^{2,6}]dec-8-en-10-one (23)

A solution of ketal **22** (200 mg, 0.543 mmol) in moist acetone (8 mL) was stirred with Amberlyst-15 (~30 mg) at room temperature for 1 h. The resin was filtered through a cotton plug and the filtrate was concentrated to give a residue, which was subjected to chromatography on a silica gel column (15% ethyl acetate – hexane) to furnish ketone **23** (155 mg, 89%). IR (Nujol, cm^{-1}): 3036, 1778, 1743. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 6.69 (t, J = 2.4 Hz, 2H), 5.37 (t, J = 3.4 Hz, 1H), 4.55–4.49 (m, 2H), 3.16–3.13 (m, 2H), 2.98–2.96 (m, 2H), 2.14 (s, 3H), 2.05 (s, 6H). LR-MS (CI) m/z: 323 [M^+ + 1]. Anal. calcd. for $C_{16}H_{18}O_7$: C 59.62, H 5.63; found: C 59.66, H 5.69.

1,3-Di(acetyloxy)-2,3,3a,4,5,7a-hexahydro-1*H*-2-indenyl acetate (24)

Ketone **23** (85 mg, 0.264 mmol) was heated to 160 °C in nitrobenzene solvent (2 mL) for 2 h. The reaction mixture was cooled to 80 °C and the nitrobenzene was distilled under reduced pressure. The residue obtained was chromatographed on a silica gel column (10% ethyl acetate – hexane) to deliver the crystalline cyclohexadiene triacetate **24** (39 mg, 50%), mp 198.6–199.9 °C. IR (Nujol, cm^{-1}): 1740. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 5.88–5.84 (m, 2H, C=C*H*), 5.70–5.66 (m, 2H, C=C*H*), 5.25 (t, J = 4.5 Hz, 1H, C*H*OAc), 5.09–5.05 (m, 2H, C*H*OAc), 3.10 (br s, 2H), 2.09 (s, 3H, COCH_3), 2.07 (s, 6H, COCH_3). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 170.1 (2C, *C*OCH$_3$), 170.0 (*C*OCH$_3$), 124.7 (2C, C=CH), 122.4 (2C, C=CH), 78.0 (2C, *C*HOAc), 69.5 (*C*HOAc), 38.9 (2C, *C*H$_{bridgehead}$), 20.7 (2C, CO*C*H$_3$), 20.6 (CO*C*H$_3$). LR-MS (EI, 70 eV) m/z: 252 [M^+ – Ac + 1]. Anal. calcd. for $C_{15}H_{18}O_6$: C 61.22, H 6.16; found: C 61.70, H 6.42.

1,3-Di(acetyloxy)-4,5,6,7-tetrahydroxyperhydro-2-indenyl acetate (25)

To a solution of diene **24** (35 mg, 0.119 mmol) in acetone–water–*t*-BuOH (5:5:2, 2 mL), catalytic OsO_4 (0.3 mg, 1 mol%) and 50% aq. NMMO (83 μL, 0.357 mmol) were sequentially added at 0 °C. The resulting pale yellow reaction mixture was stirred at room temperature for 48 h. The reaction was cooled to 0 °C, prior to quenching by addition of solid $NaHSO_3$ (10 mg). The resulting mixture was diluted with ethyl acetate (15 mL), filtered through Celite, and the filtrate was concentrated under reduced pressure. The residue obtained was subjected to silica gel column chromatography (5% methanol – ethyl acetate) to afford tetrol **25** (38 mg, 88%). IR (Nujol, cm^{-1}): 3290, 1743. ^{1}H NMR (300 MHz, D_2O) δ: 5.38 (t, J = 6.3 Hz, 1H), 5.27 (dd, J = 6.3, 1.8 Hz, 1H), 5.08 (t, J = 6.9 Hz, 1H), 3.97 (br s, 1H), 3.90 (t, J = 3.9 Hz, 1H), 3.78 (dd, J = 7.8, 3.6 Hz, 1H), 3.66 (dd, J = 8.1, 3 Hz, 1H), 2.52 (m, 1H), 2.40 (br s, 1H), 1.99 (s, 6H, COCH_3), 1.95 (s, 3H, COCH_3). ^{13}C NMR (75 MHz, D_2O) δ: 174.2 (*C*OCH$_3$), 174.1 (*C*OCH$_3$), 173.2 (*C*OCH$_3$), 75.0, 74.7, 71.7, 71.1, 70.0, 69.0, 68.6, 45.6 (CH$_{bridgehead}$), 43.5 (CH$_{bridgehead}$), 20.9 (*C*OCH$_3$), 20.8 (CO*C*H$_3$), 20.5 (CO*C*H$_3$). Anal. calcd. for $C_{15}H_{22}O_{10}$: C 49.72, H 6.12; found: C 49.53, H 6.52.

Bicyclitol 18

Tetrol **25** (22 mg, 0.061 mmol) was stirred with aq. NaOH (0.5 mol/L, 200 μL) at room temperature for 1 h and the volatiles were removed under reduced pressure. The residue obtained was dissolved in double distilled water and the solution was filtered with Dowex cation-exchange resin (50 W × 8, H^+ form). The filtrate was concentrated to furnish **18** (8 mg, 60%). ^{1}H NMR (300 MHz, D_2O) δ: 4.13 (t, J = 4.3 Hz, 1H), 3.98–3.85 (m, 4H), 3.73 (dd, J = 7.3, 4.0 Hz, 1H), 3.61 (dd, J = 7.6, 2.8 Hz, 1H), 2.21–2.08 (m, 2H). ^{13}C NMR (100 MHz, D_2O) δ: 76.4 (*C*HOH), 75.0 (*C*HOH), 74.6 (*C*HOH), 74.4 (*C*HOH), 73.1 (*C*HOH), 71.9 (*C*HOH), 71.8 (*C*HOH), 48.3 (CH$_{bridgehead}$), 47.2 (CH$_{bridgehead}$). LR-MS (CI) m/z: 237 [M^+ + 1]. Anal. calcd. for $C_9H_{16}O_7$: C 45.76, H 6.83; found: C 45.84, H 6.79.

(2*R,3*R**,7*S**,8*R**,9*S**)-5,5-Dimethylspiro[dihydro[1,3]dioxolane]-2,13-4,6-dioxatetracyclo[8.2.1.0^{2,9}.0^{3,7}]tridecen-8-ol (32)**

To a magnetically stirred solution of alcohol **28** (8) (2 g, 9.7 mmol) in CH_2Cl_2 (20 mL), NBS (2.1 g, 11.6 mmol) was added in one portion at room temperature and the resulting suspension was stirred for 3 h. Upon complete consumption of the starting material (TLC), the reaction mixture was diluted with CH_2Cl_2 (80 mL) and water (50 mL). Following the usual work-up, subsequent evaporation of the solvent gave a residue, which on chromatographic purification on a silica gel column furnished **29** (2.2 g, 80%). Osmium tetroxide (16 mg, 1 mol%) and 50% aq. NMMO (2.28 mL, 9.75 mmol) was added to a solution of bromoether **29** (1.85 g, 6.5 mmol) in an acetone–water–*t*-BuOH (5:5:2, 25 mL) solvent system, and the resulting pale yellow reaction mixture was stirred at room temperature for 12 h. The reaction mixture was cooled to ice-bath temperature, diluted with ethyl acetate (70 mL), and the osmate ester was hydrolyzed by addition of solid $NaHSO_3$ (500 mg). The solution was filtered through a Celite pad and the filtrate was concentrated under reduced pressure to furnish the crude diol **30** (1.76 g). The crude diol **30** was dissolved in dry acetone (20 mL) and Amberlyst-15 (300 mg) and powdered molecular sieves (1 g) were added. The reaction mixture was stirred for 3 h at room temperature and then was filtered through a Celite pad. The filtrate obtained on complete removal of the solvent was chromatographed on a silica gel column to furnish acetonide **31** (1.76 g, 75%). To a solution of bromoether **31** (1 g, 2.78 mmol) in MeOH (15 mL), acetic acid (0.1 mL) and Zn dust (550 mg, 8.34 m atom) were added sequentially at room temperature and the resulting suspension was stirred for 4 h. The reaction mixture was filtered through a Celite pad and the filtrate was concentrated under reduced pressure. The residue obtained was diluted with CH_2Cl_2 (60 mL) and evaporation of the solvent furnished a residue, which on purification on a silica gel column gave alcohol **32** (660 mg, 85%), mp 96 to 97 °C (lit. value (8*a*) mp 98 °C). IR (Nujol, cm^{-1}): 3400.

(2*R,3*R**,7*S**,8*R**,9*S**)-8-Hydroxy-5,5-dimethyl-4,6-dioxatetracyclo[8.2.1.0^{2,9}.0^{3,7}]tridec-11-en-13-one (33)**

Ketal **32** (350 mg, 1.24 mmol) was stirred with Amberlyst-15 (~50 mg) in moist acetone (10 mL), under reflux for 3 h. Upon complete consumption of the starting material, the reaction mixture was cooled, diluted with acetone (25 mL), and the resin was filtered through a cotton plug. The filtrate was concentrated under reduced pressure and the residue obtained was chromatographed on a silica gel column (30% ethyl acetate – hexane) to give ketone **33** (237 mg, 81%), mp 179 to 180 °C. IR (Nujol, cm^{-1}): 1771. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 6.64 (m, 1H), 6.48 (m, 1H), 4.36 (dd, *J* = 9.3, 5.4 Hz, 1H), 4.10 (d, *J* = 5.4 Hz, 1H), 4.03 (t, *J* = 5.4 Hz, 1H), 3.20 (dt, *J* = 8.7, 3.9 Hz, 1H), 3.14–2.95 (m, 3H), 1.44 (s, 3H), 1.23 (s, 3H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 200.1 (C=O), 135.2 (C=*C*H), 130.3 (C=*C*H), 110.8 (C_q), 89.4 (*C*H$_{acetonide}$), 82.0 (*C*H$_{acetonide}$), 81.3 (*C*HOH), 49.2, 49.0 (CH), 47.1 (CH), 44.4 (CH), 27.9 (CH$_{3acetonide}$), 25.3 (CH$_{3acetonide}$). LR-MS (EI, 70 eV) *m*/*z*: 237 [M$^+$ + 1]. Anal. calcd. for $C_{13}H_{16}O_4$: C 66.09, H 6.83; found: C 66.46, H 7.22.

(3a*R,3b*S**,7a*R**,8*R**,8a*S**)-2,2-Dimethyl-3b,7a,8,8a-tetrahydro-3a*H*-indeno[1,2-*d*][1,3]dioxol-8-ol (34)**

A solution of ketone **33** (220 mg, 0.932 mmol) in nitrobenzene (6 mL) solvent was heated, with vigorous stirring, to 160 °C and reacted for 4 h. Upon complete consumption of the starting material (TLC), the reaction mixture was cooled to 80 °C and the solvent was distilled off under reduced pressure. The resulting dark brown residue was charged on the silica gel column and chromatographed (25% ethyl acetate – hexane) to give diene **34** (130 mg, 67%) as a white solid, mp 190.6–191.2 °C. IR (Nujol, cm^{-1}): 3470. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 6.17 (dd, *J* = 9.9, 5.1 Hz, 1H, C= C*H*), 5.80 (dd, *J* = 9.9, 4.8 Hz, 2H, C= C*H*), 5.72–5.70 (m, 1H), 4.74 (d, *J* = 6.0 Hz, 1H, H$_{acetonide}$), 4.45 (d, *J* = 6 Hz, 1H, H$_{acetonide}$), 4.03 (br s, 1H, C*H*OH), 3.08–3.05 (m, 2H, H$_{bridgehead}$), 2.26 (d, *J* = 2.4 Hz, 1H, H$_{bridgehead}$), 1.42 (s, 3H), 1.31 (s, 3H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 129.2 (C=*C*H), 127.6 (C=*C*H), 123.3 (C=*C*H), 122.9 (C=*C*H), 110.4 (C_q), 87.3 (*C*H$_{acetonide}$), 83.9 (*C*H$_{acetonide}$), 79.6 (*C*HOH), 45.3 (CH), 39.6 (CH), 26.8 (CH$_{3bridgehead}$), 24.3 (CH$_{3bridgehead}$). LR-MS (EI, 70 eV) *m*/*z*: 208 [M$^+$]. Anal. calcd. for $C_{12}H_{16}O_3$: C 69.21, H 7.74; found: C 68.88, H 7.52.

(3a*R,3b*R**,4*S**,5*S**,6*S**,7*S**,7a*S**,8*R**,8a*S**)-2,2-Dimethylperhydroindeno[1,2-*d*][1,3]dioxole-4,5,6,7,8-pentaol (35)**

To a solution of diene **34** (45 mg, 0.216 mmol) in an acetone–water–*t*-BuOH (5:5:2, 4 mL) solvent system, catalytic OsO_4 (1 mol%, 0.5 mg) and 50% aq. NMMO (151 μL, 0.648 mmol) were added at 0 °C. The resulting pale yellow reaction mixture was stirred at room temperature for 48 h, before diluting with ethyl acetate (10 mL) and quenching with solid $NaHSO_3$ (10 mg). The resulting mixture was filtered through a Celite pad and the filtrate was concentrated under reduced pressure. The residue was subjected to silica gel column chromatography (5% methanol – ethyl acetate) to afford pentaol **35** (49 mg, 83%). ^{1}H NMR (300 MHz, D_2O) δ: 4.70–4.65 (m, 1H), 4.35 (dd, *J* = 6.0, 1.8 Hz, 1H), 4.06 (m, 1H), 3.98–3.93 (m, 2H), 3.69–3.58 (m, 2H), 2.59–2.51 (m, 1H, H$_{bridgehead}$), 2.41–2.37 (m, 1H, H$_{bridgehead}$), 1.32 (s, 3H), 1.20 (s, 3H). ^{13}C NMR (75 MHz, D_2O) δ: 111.0 (C_q), 87.9 (*C*H$_{acetonide}$), 83.0 (*C*H$_{acetonide}$), 77.1 (*C*HOH), 70.5, 70.4, 70.3, 69.2, 45.8, 45.6, 25.8 (C$_{bridgehead}$), 23.4 (C$_{bridgehead}$). LR-MS (EI, 70 eV) *m*/*z*: 258 [M$^+$ – H_2O].

Bicyclitol 26

Acetonide **35** (25 mg, 0.09 mmol) was stirred in 30% trifluoroacetic acid (1 mL) at room temperature for 30 min until all the starting material had been consumed. The volatiles were removed under reduced pressure to furnish polyol **26** (19 mg, 89%). ^{1}H NMR (300 MHz, D_2O) δ: 4.19–4.15 (m, 1H), 4.01–3.81 (m, 4H), 3.68–3.64 (m, 1H), 3.61–3.56 (m, 1H), 2.40–2.33 (m, 1H), 2.13–2.07 (m, 1H). ^{13}C NMR (75 MHz, D_2O) δ: 77.9, 77.2, 73.6, 72.9, 72.3, 68.4, 67.4, 45.9, 41.8. LR-MS (CI) *m*/*z*: 237 [M$^+$ + 1]. Anal. calcd. for $C_9H_{16}O_7$: C 45.76, H 6.83; found: C 45.88, H 7.32.

(2*S,3*R**,7*S**,8*R**,9*R**)-5,5-Dimethyl-4,6,11,12-tetraoxatetracyclo[8.2.2.0^{2,9}.0^{3,7}]tetradec-13-en-8-ol (36)**

A slow stream of oxygen gas was bubbled through a solution of diene **34** (60 mg, 0.288 mmol) in chloroform (6 mL), contained in a specially designed reaction flask with an outer water jacket, in the presene of methylene blue (~5 mg) as the sensitizer and under irradiation from a 500 W tungsten lamp. The temperature of the reaction mixture was maintained at 20 °C by circulating cold water through the outer jacket of the reaction flask. Upon complete consumption of the starting material (TLC, 8 h), the solvent was evaporated under reduced pressure. The residue obtained was chromatographed over a silica gel column (20% ethyl acetate – hexane) to furnish the endo-peroxide **36** (62 mg, 90%). IR (KBr, cm^{-1}): 3445. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 6.78 (m, 1H, C=C*H*), 6.59 (m, 1H, C=C*H*), 4.85–4.80 (m, 2H, H$_{peroxy}$), 4.36 (dd, *J* = 9.0, 5.2 Hz, 1H, H$_{acetonide}$), 4.17 (t, *J* = 5.2 Hz, 1H, H$_{acetonide}$), 4.11 (d, *J* = 6.0 Hz, 1H), 3.33 (dt, *J* = 8.7, 4.0 Hz, 1H, H$_{bridgehead}$), 3.08 (dd, *J* = 8.7, 5.2 Hz, 1H), 1.47 (s, 3H, C*H*$_3$), 1.26 (s, 3H, C*H*$_3$). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 135.3 (C=*C*H), 130.2 (C=*C*H), 111.7 (C_q), 88.0, 80.9, 79.9, 70.9 (*C*H$_{peroxy}$), 70.8 (*C*H$_{peroxy}$), 44.5, 44.0, 27.8, 25.2. LR-MS (CI) *m*/*z*: 241 [M$^+$ + 1]. Anal. calcd. for $C_{12}H_{16}O_5$: C 59.99, H 6.71; found: C 60.21, H 6.83.

(3a*R,3b*R**,4*R**,7*S**,7a*S**,8*R**,8a*S**)-2,2-Dimethyl-3b,4,7,7a,8,8a-hexahydro-3a*H*-indeno[1,2-*d*][1,3]dioxole-4,7,8-triol (37)**

$LiAlH_4$ (12 mg, 0.312 mmol) was added to a solution of the endo-peroxide **36** (50 mg, 0.208 mmol) in dry THF (6 mL) at 0 °C under an atmosphere of N_2. The resulting suspension was stirred at room temperature for 1 h, before quenching the reaction by careful addition of ethyl acetate (15 mL) followed by addition of a cold, satd. Na_2SO_4 solution (2 mL). After dilution with ethyl acetate, the aluminium salts were filtered through a Celite pad. Evaporation of the solvent under reduced pressure, after the usual work-up, gave a residue that was chromatographed over a silica gel column (60% ethyl acetate – hexane) to furnish the 1,4-diol **37** (27 mg, 54%), mp 210 to 211 °C. IR (Nujol, cm^{-1}): 3444. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 5.69 (br s, 2H, C=CH), 4.71

(3a*R,3b*R**,4*S**,5*S**,6*R**,7*R**,7a*S**,8*R**,8a*S**)-2,2-Dimethylperhydroindeno[1,2-d][1,3]dioxole-4,5,6,7,8-pentaol (38) and (3a*R**,3b*R**,4*S**,5*R**,6*S**,7*R**,7a*S**,8*R**,8a*S**)-2,2-dimethylperhydroindeno[1,2-d][1,3]dioxole-4,5,6,7,8-pentaol (39)**

To a solution of diol **37** (55 mg, 0.227 mmol) in an acetone–water–*t*-BuOH (5:5:2, 5mL) solvent system, catalytic OsO_4 (0.6 mg, 1 mol%), and 50% aq. NMMO (64 μL, 0.272 mmol) were added sequentially at 0 °C and the resulting mixture was stirred at room temperature for 1 h. The reaction was quenched by addition of solid $NaHSO_3$ (10 mg), diluted with ethyl acetate (15 mL), and filtered through a Celite pad. The filtrate was concentrated under reduced pressure to yield a residue, whose ^{1}H NMR spectrum was found to be a mixture of diastereomers **38** and **39** (60 mg) in a 3:1 ratio. However, their chromatographic separation was unsuccessful and the mixture was used as such for the next step.

(3a*R,3b*S**,6a*S**,6b*S**,6*R**,9a*S**,10*R**,10a*R**,10b*R**)-2,2,5,5,8,8-Hexamethylperhydrodi[1,3]dioxolo-[4′,5′:1,2:4′,5′:6,7]indeno[4,5-*d*][1,3]dioxole-10-ol (40) and (3a*R**,3b*R**,4*S**,4a*R**,7a*S**,8*R**,8a*R**,9*R**,9a*S**)-2,2,6,6-tetramethylperhydro[1,3]dioxolo[4′,5′:1,2]indeno[5,6-*d*][1,3]dioxole-4,8,9-triol (41)**

The solution of mixture of **38** and **39** (60 mg) in dry acetone (10 mL) was treated sequentially with Amberlyst-15 resin (~5 mg) and 4 Å molecular sieves (~30 mg) and the resulting mixture was stirred at room temperature for 3 h. The reaction mixture was filtered through a Celite pad and the filtrate was concentrated under reduced pressure. The residue obtained was charged on a silica gel column and chromatographed with a 10% ethyl acetate – hexane solvent system to furnish trisacetonide **40** (48 mg, 62%). Further elution of the column with 30% ethyl acetate –hexane gave bisacetonide **41** (14 mg, 21%). Compound **40:** mp 210 to 211 °C. Bicyclitol 43

Bisacetonide **41** (10 mg, 0.032 mmol) was treated with 30% trifluoroacetic acid (150 μL) and the resulting biphasic mixture was stirred vigorously at room temperature for 30 min. The volatiles were removed under reduced pressure to furnish **43** (7 mg, 88%). ^{1}H NMR (300 MHz, D_2O) δ: 4.10 (t, 1H, *J* = 5.7 Hz), 4.00 (t, 1H, *J* = 5.4 Hz), 3.86 (t, *J* = 5.4 Hz, 1H), 3.83 (dd, *J* = 14, 7.2 Hz, 1H), 3.75–3.70 (m, 1H), 3.66–3.61 (m, 2H), 2.36 (dd, *J* = 15, 6.9 Hz, 1H), 1.93 (dd, *J* = 14.4, 6.9 Hz, 1H). ^{13}C NMR (75 MHz, D_2O) δ: 77.8, 77.1, 74.0, 73.2, 72.3, 72.0, 68.8, 48.6, 44.2. LR-MS (CI) *m*/*z*: 237 [M^+ + 1]. Anal. calcd. for $C_9H_{16}O_7$: C 45.76, H 6.83; found: C 45.77, H 6.98.

(2*R,3*S**,6*R**,7*S**)-1,8,9,10-Tetrachloro-11,11-dimethoxytricyclo[6.2.1.0^{2,7}]undeca-4,9-diene-3,6-diol (45)**

To a solution of 1,2,3,4-tetrachloro-5,5-dimethoxycyclopentadiene (63 mL, 0.36 mol) in dry toluene (300 mL), *p*-benzoquinone (40 g, 0.37 mol) was added and the resulting solution was refluxed for 24 h. Excess solvent was distilled off under reduced pressure and the residue obtained was recrystallized from hexane to furnish adduct **17** (110 g, 83%). Adduct **17** (10 g, 26.8 mmol) was dissolved in dry MeOH (150 mL) and to this solution at 0 °C under an inert atmosphere, $CeCl_3 \cdot 7H_2O$ (1 g, 10 mol%) and $NaBH_4$ (2 g, 53.6 mmol) were added in sequential portions. The resulting solution was stirred at the same temperature for 10 min until the starting material was completely consumed. The reaction mixture was diluted with ethyl acetate (150 mL) and quenched by the addition of water (80 mL). The organic layer was separated and after the usual work-up furnished residue **45** (6.9 g, 69%), mp 162 to 163 °C (lit. value (16) mp 167 to 168 °C). IR (Nujol, cm^{-1}): 3450.

(2*R,7*S**)-1,8,9,10-Tetrachloro-11,11-dimethoxytricyclo[6.2.1.0^{2,7}]undeca-3,5,9-triene (44)**

To a magnetically stirred solution of diol 45 (5 g, 13.3 mmol) in dry CH_2Cl_2 (25 mL), triethylamine (5.6 mL, 39.9 mmol), DMAP (162 mg, 10 mol%), and methanesulphonyl chloride (2.5 mL, 29.2 mmol) were added sequentially at 0 °C under an inert atmosphere and the resulting solution was stirred at room temperature for a further 24 h. The reaction mixture was diluted with CH_2Cl_2 (50 mL) prior to quenching the reaction by adding water (30 mL). The organic layer was separated and the aqueous layer was extracted with CH_2Cl_2 (3 × 60 mL). The residue obtained by the usual work-up was subjected to chromatographic purification on a silica gel column (35% ethyl acetate – hexane) to furnish dimesylate **46** (5.1 g, 72%). Dimesylate **46** (8.4 g, 15.7 mmol) was dissolved in 2-butanone (60 mL) and so-

© 2005 NRC Canada

dium iodide (8.2 g, 54.9 mmol) was added to this solution. The dark brown solution was then refluxed for 8 h. The reaction mixture was cooled to ice bath temperature and diluted with diethylether (100 mL) and water (80 mL). The usual work-up and evaporation of the solvent under reduced pressure gave a residue, which on purification on a silica gel column (hexane) furnished the tricyclic diene **44** (4.3 g, 80%), mp 162 to 163 °C (lit. value (16) mp 167 to 168 °C).

(2*R,3*S**,4*S**,5*R**,6*R**,7*S**)-1,8,9,10-Tetrachloro-11,11-dimethoxytricyclo[6.2.1.0^{2,7}]undec-9-ene-3,4,5,6-tetraol (48)**

A solution of diene **44** (1.2 g, 3.51 mmol) in an acetone–water–*t*-BuOH solvent system (5:5:2, 50 mL) was treated sequentially with catalytic OsO_4 (8 mg, 1 mol%) and 50% aq. NMMO (2.5 mL, 10.53 mmol). The resulting pale yellow solution was stirred vigorously at room temperature for 48 h, during which all the starting material was consumed (TLC). The reaction was quenched by addition of solid $NaHSO_3$ (500 mg), diluted with ethyl acetate (100 mL), and filtered through a Celite pad. The filtrate was concentrated under reduced pressure to give a residue, which was chromatographed on a silica gel column (70% ethyl acetate – hexane) to furnish tetrol **48** (950 mg, 66%). IR (Nujol, cm^{-1}): 3430. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 3.76 (br s, 2H), 3.66 (br s, 2H), 3.63 (s, 3H), 3.56 (s, 3H), 3.14 (m, 2H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 129.7 (2C, C=*C*Cl), 111.7 (C_q), 70.7 (2C, *C*HOH), 68.0 (2C, *C*HOH), 52.8 (2C, *C*-Cl), 52.5 (2C, OMe), 51.8 (2C, CH). LR-MS (EI, 70 eV) *m*/*z*: 410 [M$^+$ + 1].

(2*R,3*S**,4*S**,8*R**,9*R**,10*S**)-1,11,12,13-Tetrachloro-14,14-dimethoxy-6,6-dimethyl-5,7-dioxatetracyclo[9.2.1.0^{2,10}.0^{4,8}]tetradec-12-ene-3,9-diol (49)**

Tetrol **48** (950 mg, 2.32 mmol) was stirred with Amberlyst-15 (~100 mg) and 4 Å molecular sieves (500 mg) in dry acetone (30 mL) at room temperature for 3 h. Upon complete consumption of the starting material, the reaction mixture was filtered through a Celite pad. The filtrate was concentrated under reduced pressure to give a residue, which was chromatographed over a short silica gel column (25% ethyl acetate – hexane) to afford acetonide **49** (783 mg, 75%), mp 180.1–181.4 °C. IR (Nujol, cm^{-1}): 3346. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 4.44 (s, 2H), 3.63 (s, 3H), 3.59 (s, 3H), 3.11–3.01 (m, 2H), 2.29 (d, *J* = 6.6 Hz, 2H), 1.57 (s, 3H), 1.37 (s, 3H). (2*R,3*R**,4*R**,8*S**,9*S**,10*S**)-14,14-Dimethoxy-6,6-dimethyl-5,7-dioxatetracyclo[9.2.1.0^{2,10}.0^{4,8}]tetradec-12-ene-3,9-diol (50)**

Liquid ammonia (300 mL) was distilled into a 250 mL three-necked round-bottomed flask equipped with a condenser, KOH guard tube, and septum. Acetonide **49** (10 g, 22.22 mmol) in dry THF (40 mL) and absolute EtOH (40 mL) were added to the flask. Small pieces of freshly cut sodium were introduced into the reaction mixture with stirring at –33 °C until the blue color persisted. The mixture was stirred for 30 min and solid NH_4Cl (1 g) was added. The excess ammonia was allowed to evaporate, and a cold aq. satd. NH_4Cl solution (50 mL) and water (100 mL) were added to the resulting residue, which was subsequently extracted with ethyl acetate (3 × 200 mL). Removal of the volatiles, followed by purification of the residue by silica gel column chromatography (50% ethyl acetate – hexane) gave the dechlorinated product **50** (3.4 g, 49%), mp 173–175 °C. IR (Nujol, cm^{-1}): 3460, 3380. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 6.93 (s, 2H, C=C*H*), 4.38 (s, 2H), 3.24 (s, 3H), 3.17 (s, 5H), 3.05 (s, 2H), 2.60–2.50 (m, 2H), 1.91 (s, 1H), 1.88 (s, 1H), 1.53 (s, 3H), 1.35 (s, 3H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 133.8 (2C, C=*C*H), 118.9 (C_q), 110.0 (C_q), 76.6 (2C, $C_{acetonide}$), 68.8 (2C, *C*HOH), 52.0 (O*C*H$_3$), 50.0 (O*C*H$_3$), 46.8 (2C, CH), 40.4 (2C, CH), 25.9 (CH), 24.0 (CH). (2*R,3*R**,4*S**,8*R**,9*R**,10*S**)-1,11,12,13-Tetrachloro-14,14-dimethoxy-6,6-dimethyl-5,7-dioxatetracyclo[9.2.1.0^{2,10}.0^{4,8}]tetradec-12-ene-3,9-diol (56)**

To a solution of tetrol **55** (750 mg, 1.829 mmol) in dry acetone (25 mL), Amberlyst-15 (~100 mg) and 4 Å molecular sieve powder (250 mg) were added sequentially and the resulting mixture was stirred at room temperature for 1 h. Upon complete consumption of the starting material (TLC), the reaction mixture was filtered through a Celite pad and the filtrate was concentrated under reduced pressure to give a solid residue. The residue was chromatographed over a silica gel column (6% ethyl acetate – hexane) to afford acetonide **56** (675 mg, 82%), mp 210–212 °C. IR (KBr, cm^{-1}): 3260. ^1H NMR (300 MHz, $CDCl_3$) δ: 4.43 (s, 2H, $H_{acetonide}$), 4.29 (br s, 2H, *C*HOH), 3.79 (s, 3H, O*C*H_3), 3.57 (s, 3H, O*C*H_3), 3.04 (s, 2H, $H_{bridgehead}$), 1.45 (s, 3H), 1.34 (s, 3H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 129.4 (2C, C=*C*Cl), 114.7 (C_q), 108.4 (C_q), 76.7 (2C, $C_{acetonide}$), 75.6 (2C, *C*-Cl), 65.1 (2C, *C*HOH), 53.1 (OCH_3), 51.7 (OCH_3), 46.3 (2C, *C*H), 26.1 ($CH_{3acetonide}$), 23.3 ($CH_{3acetonide}$). (2*R,3*R**,4*R**,8*S**,9*R**,10*S**)-14,14-Dimethoxy-6,6-dimethyl-5,7-dioxatetracyclo[9.2.1.0^{2,10}.0^{4,8}]tetradec-12-ene-3,9-diol (57)**

Liquid ammonia (100 mL) was distilled into a three-necked round-bottomed flask equipped with a Dewar condenser, KOH guard tube, and septum. The solution of acetonide **56** (1 g, 2.22 mmol) in dry THF (10 mL) and absolute EtOH (5 mL) was added to the reaction flask. Small pieces of freshly cut sodium were introduced, with stirring, into the resulting mixture until the blue color of the solution persisted. The mixture was stirred for 40 min and quenched by addition of solid NH_4Cl (~1 g). The excess ammonia was allowed to evaporate and the residue obtained was diluted with cold aq. satd. NH_4Cl solution (20 mL) and water (50 mL). The residue, resulting from the usual work-up, was purified by silica gel column chromatography (70% ethyl acetate – hexane) to furnish the olefin diol **57** (610 mg, 88%), mp 200–202 °C. IR (Nujol, cm^{-1}): 3420, 1260. ^1H NMR (300 MHz, $CDCl_3$) δ: 6.17 (t, 2H, *J* = 3.0 Hz, C=C*H*), 3.94 (br s, 2H, $H_{acetonide}$), 3.32 (s, 3H, OCH_3), 3.13 (br s, 3H, OCH_3), 3.04 (br s, 2H, C*H*OH), 2.92 (s, 2H), 1.65 (s, 2H), 1.44 (s, 3H), 1.30 (s, 3H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 132.0 (2C, C=*C*H), 119.4 (C_q), 108.4 (C_q), 78.5 (2C, $C_{acetonide}$), 71.4 (2C, *C*HOH), 52.0 (2C, OCH_3), 49.8 (2C), 46.7 (2C), 26.7 ($CH_{3acetonide}$), 23.0. LR-MS (EI, 70 eV) *m*/*z*: 312 [M^+]. Anal. calcd. for $C_{16}H_{24}O_6$: C 61.52, H 7.74; found: C 61.90, H 7.52.

(2*R,3*R**,4*R**,8*S**,9*R**,10*S**)-3,9-Dihydroxy-6,6-dimethyl-5,7-dioxatetracyclo[9.2.1.0^{2,10}.0^{4,8}]tetradec-12-en-14-one (58)**

Ketal **57** (220 mg, 0.705 mmol) was dissolved in moist acetone (20 mL) and stirred with Amberlyst-15 resin (~50 mg) for 2 h, when all the starting material had been consumed (TLC). The reaction mixture was filtered through a Celite pad and the filtrate was concentrated under reduced pressure to give a solid residue, which was chromatographed over a silica gel column (50% ethyl acetate – hexane) to furnish the 7-ketonorbornene **58** (178 mg, 95%), mp 220–221.5 °C. IR (KBr, cm^{-1}): 3443, 1778.

(3a*R,4*S**,4a*S**,8a*R**,9*R**,9a*S**)-2,2-Dimethyl-3a,4,4a,8a,9,9a-hexahydronaphtho[2,3-*d*][1,3]dioxole-4,9-diol (59)**

A solution of ketone **58** (90 mg, 0.338 mmol) in nitrobenzene (10 mL) was heated to 160 °C, with vigorous stirring, for 3 h. Upon complete consumption of the starting material (TLC), the reaction mixture was cooled to 80 °C and the solvent was distilled off under reduced pressure. The

Bicyclitol 61

Acetonide hexol **60** (14 mg, 0.046 mmol) was stirred vigorously with 30% TFA (500 μL) at room temperature for 30 min. The volatiles were removed under reduced pressure to furnish **61** (11 mg, 90%). ^1H NMR (300 MHz, D_2O) δ: 4.06 (m, 1H), 3.93 (dd, *J* = 10.5, 3.0 Hz, 1H), 3.87 (br s, 1H), 3.81 (m, 1H), 3.75 (t, *J* = 3.9 Hz, 1H), 3.73 (t, *J* = 3.0 Hz, 1H), 3.68 (t, *J* = 3.3 Hz, 1H), 3.52 (dd, *J* = 10.5, 3.0 Hz, 1H), 2.35 (dt, *J* = 6.6, 2.7 Hz, 1H), 2.28 (m, 1H). ^{13}C NMR (75 MHz, D_2O) δ: 73.6, 72.8, 71.3, 70.7, 70.4, 69.3, 69.1, 67.4, 40.2, 38.4. LR-MS (CI) *m*/*z*: 266 [M^+]. Anal. calcd. for $C_{10}H_{18}O_8$: C 45.11, H 6.81; found: C 45.45, H 7.12.

General procedure for enzymatic assays

The enzymes assayed were α-glucosidase (EC 3.2.1.20) from yeast, β-glucosidase (EC 3.2.1.21) from sweet almonds, α-galactosidase (EC 3.2.1.22) from green coffee beans, β-galactosidase (EC 3.2.1.23) from *E. coli*, α-mannnosidase (EC 3.2.1.24) from jack bean, and β-mannosidase (EC 3.2.1.25) from snail acetone powder. The substrates for the glycosidase were the corresponding *ortho*- or *para*-nitrophenylglycosides. The α-glucosidase (0.135 units/mL)[3] was assayed using *p*-nitophenyl-α-D-glucopyranoside (2.53 mmol/L) as the substrate at pH 6.8 (100 mmol/L phosphate buffer) at 37 °C, while β-glucosidase (0.133 units/mL) was assayed using *p*-nitrophenyl-β-D-glucopyranoside (2.57 mmol/L) as the substrate at pH 5.0 (10 mmol/L acetate buffer) at 37 °C. The potency of α-galactosidase (0.1 units/mL) and β-galactosidase (0.91 units/mL) was studied using *p*-nitrophenyl-α-D-galactopyranoside (2.12 mmol/L) and *o*-nitrophenyl-β-D-galactopyranoside (2.34 mmol/L) as substrate at pH 6.5 (100 mmol/L phosphate buffer) and pH 7.3 (100 mmol/L phosphate buffer) at 25 and 37 °C, respectively. The assay involving α-mannosidase (0.116 units/mL) was carried out using *p*-nitrophenyl-α-D-mannopyranoside (2.01 μmol/L) as substrate at pH 4.5 (10 mmol/L acetate buffer) at 25 °C, while β-mannosidase (0.125 units/mL) was assayed using *p*-nitrophenyl-α-D-mannopyranoside (2.15 mmol/L) as substrate at pH 4 (10 mmol/L acetate buffer) at 25 °C.

Typical assays were carried out in 1.5 mL disposable Eppendorf tubes, with the reaction volume being maintained at 200 μL. The mixture of enzyme and potential inhibitor in the optimum buffer medium was preincubated for 5 min and the reaction was initiated by adding the corresponding substrate solution (prepared in double-distilled water) to the reaction mixture. After incubation for 30 min at the optimum temperature for the enzyme, the reaction was quenched by addition of 800 μL of Na_2CO_3 buffer (400 mmol/L) solution. The enzyme activity was determined by measuring the absorption of the nitrophenolate ion released at 400 nm (in the case of *p*-nitrophenol) or 410 nm (in the case of *o*-nitrophenol). In the control experiments, the inhibitor was replaced by a corresponding buffer solution. The K_i was calculated using the Lineweaver–Burk plot.

Oxidative addition chemistry of dimethyl(dipyridyl ketone)platinum(II)[1]

Fenbao Zhang, Michael E. Broczkowski, Michael C. Jennings, and Richard J. Puddephatt

Abstract: The dimethylplatinum(II) complex [$PtMe_2$(DPK)] (DPK = di-2-pyridyl ketone) undergoes easy oxidative addition to give platinum(IV) complexes. For example, reaction of [$PtMe_2$(DPK)] with MeI gave [$PtIMe_3$(DPK)], reaction with *N*-chlorosuccinimide in methanol gave [PtCl(OMe)Me_2(DPK)], and reaction with [$FN(CH_2CH_2)_2NCH_2Cl][BF_4]_2$ in MeCN gave [PtF(NCMe)Me_2(DPK)][BF_4]. In several cases, the ketone group of the DPK ligand took part in the reactions. For example, oxidation of [$PtMe_2$(DPK)] by air or hydrogen peroxide gave [Pt(OH)Me_2(DPKOH)] (DPKOH = κ^3-*NN′O*-(2-$C_5H_4N)_2C(OH)O$), which reacted with HCl to give [$PtClMe_2$(DPKOH)] or with excess acetyl chloride to give [$PtCl_2Me_2$(DPK)]. Reaction of [$PtMe_2$(DPK)] with methyl triflate in MeCN solution gave [$PtMe_3$(NCMe)(DPK)][OTf], which reacted with more MeOTf in the presence of base to give [$PtMe_3${DPC$(OMe)_2$}][OTf], where DPC$(OMe)_2$ = κ^3-*NN′O*-(2-$C_5H_4N)_2C(OMe)_2$. Hydrolysis of [PtF(NCMe)Me_2(DPK)][BF_4] gave [Pt{NHC(=O)Me}Me_2(DPKOH)], which crystallized in partially protonated form as an unusual supramolecular polymer [Pt{NHC(=O)Me}Me_2(DPKOH)]·0.5HBF_4.

Key words: platinum, oxidative addition, ketone, pyridyl.

Résumé : Le complexe de diméthylplatine(II) [$PtMe_2$(DPK)] (DPK = di-2-pyridyl cétone) subit une addition oxydante facile qui conduit aux complexes de platine(IV). Par exemple, la réaction du [$PtMe_2$(DPK)] avec le MeI conduit au [$PtIMe_3$(DPK)], la réaction avec le *N*-chlorosuccinimide dans le méthanol conduit à la formation du [PtCl(OMe)Me_2(DPK)] et la réaction avec du $[FH(CH_2CH_2)_2NCH_2Cl][BF_4]_2$ dans le MeCN fournit du [PtF(NCMe)Me_2(DPK)][BF_4]. Dans plusieurs cas, le groupe cétone du ligand DPK prend part aux réactions. Par exemple, l'oxydation du [$PtMe_2$(DPK)] par l'air ou le peroxyde d'hydrogène fournit du [Pt(OH)Me_2(DPKOH)] (DPKOH = κ^3-*NN′O*-(2-$C_5H_4N)_2C(OH)O$) qui, par réaction avec du HCl, conduit à la formation de [$PtClMe_2$(DPKOH)] ou, par réaction avec un excès de chlorure d'acétyle fournit du [$PtCl_2Me_2$(DPK)]. La réaction du [$PtMe_2$(DPK)] avec du triflate de méthyle dans le MeCN en solution conduit à la formation de [$PtMe_3$(NCMe)(DPK)][OTf] qui, par réaction avec un excès de MeOTf en présence de base fournit du [$PtMe_3${DPC$(OMe)_2$}][OTf] (DPC$(OMe)_2$ = κ^3-*NN′O*-(2-$C_5H_4N)_2C(OMe)_2$). L'hydrolyse du [PtF(NCMe)Me_2(DPK)][BF_4] conduit à la formation de [Pt{NHC(=O)Me}Me_2(DPKOH)] qui cristallise sous la forme partiellement protonée d'un polymère supramoléculaire inhabituel [Pt{NHC(=O)Me}Me_2(DPKOH)]·0,5HBF_4.

[Traduit par la Rédaction]

Introduction

Organoplatinum(II) complexes containing nitrogen-donor ligands are known to be particularly reactive in oxidative addition reactions, and this high reactivity is important in the activation of normally inert chemical bonds (1). For example, the activation of C—H bonds in alkanes or arenes by platinum(II) complexes usually occurs by oxidative addition, and is often favoured if there are chelating diamine or diimine ligands present (2, 3).

Many studies of oxidative addition to complexes [$PtMe_2$(LL)] have been carried out using complexes with LL = 2,2′-bipyridyl or its derivatives, which give five-membered chelate rings (1). The five-membered chelate rings are usually roughly planar, but six-membered chelate rings may be significantly distorted from planarity and this can have a significant effect on reactivity (4–8). Oxidative addition reactions are particularly easy in platinum(II) complexes of the hydridotripyrazolylborate ligand and related ligands that are bidentate in platinum(II) complexes but factridentate in platinum(IV) complexes (4). The tripyrazolylborate complexes contain six-membered chelate rings (Chart 1), but the significance of this factor is difficult to determine since the transition of the ligand from bidentate to tridentate is thought to be the primary cause of the high reactivity (4). Carbon–hydrogen bond activation is easy with platinum(II) complexes of anionic β-diiminate ligands, which give six-membered chelate rings (5), or with neutral bis(azaindolyl)methane ligands, which give eight-membered chelate

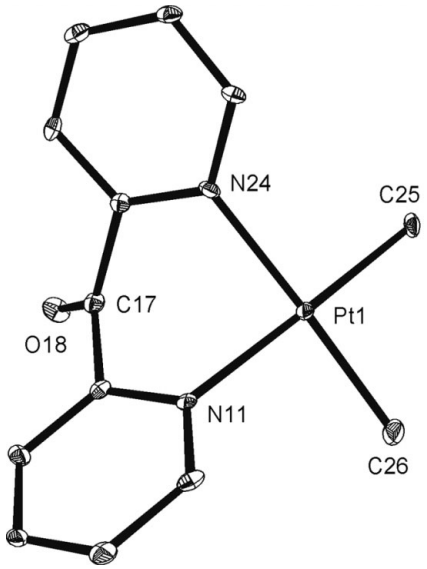
Chart 1. Methylplatinum complexes with six- or eight-membered chelate rings.

rings (6). These intriguing results prompted this study of the oxidative addition chemistry of the dimethylplatinum(II) complex of the ligand 2,2′-dipyridyl ketone (DPK) (7, 8), as a prelude to a study of C-H activation using $[PtMe_2(DPK)]$ (**1**, Chart 1).



One well-known property of DPK as a ligand is that the carbonyl group is activated towards forming the hydrate $(2\text{-}C_5H_4N)_2C(OH)_2$(DPKOH$_2$) or its deprotonated form $(2\text{-}C_5H_4N)_2C(OH)O^-$(DPKOH$^-$) on coordination to transition metals. The deprotonated form DPKOH$^-$ is particularly favoured in octahedral complexes where it acts as a fac-tridentate ligand (κ^3-*NN′O*) rather than bidentate as in DPK (κ^2-*NN′*). For example, the complex $[PtCl_4(DPK)]$ is readily hydrolysed to give $[PtCl_3(DPKOH)]$ (8*a*). Although the redox chemistry of DPK complexes has been studied electrochemically, there has been little research on oxidative addition chemistry (7, 8). It was therefore of interest to investigate how the six-membered Pt(DPK) chelate ring would affect the reactivity of $[PtMe_2(DPK)]$ towards oxidative addition, and whether the carbonyl group might also be activated during oxidative addition.

Results and discussion

Platinum(II) complexes

The complex $[PtMe_2(DPK)]$ (**1**) was readily prepared by reaction of $[Pt_2Me_4(\mu\text{-}SMe_2)_2]$ (9) with the ligand DPK, and was isolated as a red solid. In the IR spectrum, the carbonyl stretching vibration occurred at ν(C=O) = 1682 cm^{-1}, unchanged from the value for free DPK. In the ^{1}H NMR spectrum, the methylplatinum resonance occurred at δ(MePt) = 0.78, with coupling ^2J(Pt-H) = 86 Hz, while the ortho pyridyl protons occurred at δ(H6) = 8.83, with coupling ^3J(Pt-H) = 26 Hz.

Fig. 1. A view of the structure of complex **1**.

The structure of complex **1** is shown in Fig. 1. It confirms the expected molecular structure, with square-planar platinum(II) having *cis*-PtC_2N_2 coordination. The angle N(11)-Pt(1)-N(24) = 87.5(2)° is only slightly different from the ideal 90° angle. The Pt—N distances (2.084(7) and 2.081(7) Å) are slightly longer than in the other reported platinum(II) complex $[Pt\{(O_2C)_2C_4H_6\}(DPK)]$, which has Pt—N = 1.999(6) and 2.002(6) Å (8*b*), as a result of the higher trans-influence of the methyl groups in complex **1**. The chelate ring is in the nonplanar boat conformation, as found for other DPK complexes (7, 8), and the angles at the ketone group are all close to the ideal 120° (C(16)-C(17)-C(19) = 118.1(6)°). The pyridyl rings are twisted out of the coordination plane of the platinum atom by 50° (N(11)-C(16)) and 44° (C(18)-N(24)), and the carbonyl carbon lies 1.67 Å out of the plane. The adoption of the boat conformation serves to minimize angle strain in the chelate ring and to minimize steric effects between the ortho hydrogen atom of each pyridyl group and the neighbouring methylplatinum group (7, 8). As the boat conformation becomes more pronounced, the angles Θ between the pyridyl groups and the coordination plane of the platinum atom, and the deviation Δ of the carbonyl carbon atom from the coordination plane, will increase. Comparative structural data for the complexes studied here are given in Table 1.

Reaction of complex **1** in benzene solution with H$[BF_4]$ gave, as a minor product only, the bis(chelate) complex $[Pt(DPK)_2][BF_4]_2$ (**2**), which formed as yellow single crystals. The crystals were insoluble in common organic solvents, so it was not possible to obtain NMR spectra. The formation of complex **2** involves some disproportionation since the precursor contains only one DPK ligand, but the overall stoichiometry was not determined. Complex **2** was characterized crystallographically and the structure is shown in Fig. 2. The platinum atom lies on an inversion centre so the two DPK ligands are identical. Each Pt(DPK) unit forms a boat conformation, very similar to the conformation in **1** (Fig. 1, Table 1), and the inversion centre defines the anti

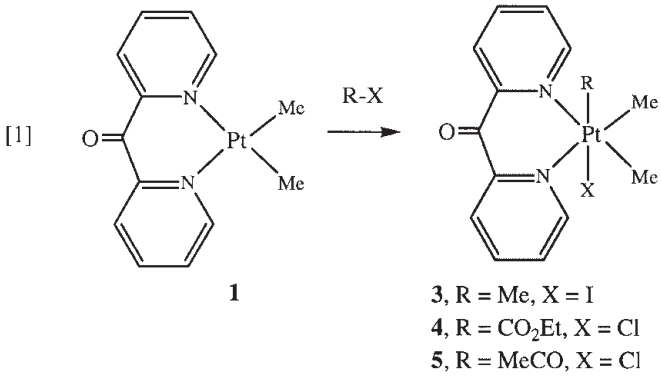

Fig. 2. A view of the structure of complex **2**, including two weakly bound tetrafluoroborate anions.

conformation of the two boats (Fig. 2). The Pt—N distances (Pt—N(1) = 2.025(3) Å, Pt—N(14) = 2.014(3) Å) are shorter than in complex **1**, as expected. The tetrafluoroborate anions lie above and below the plane of the platinum atom, with the closest Pt···F distance at Pt···F(22) = 3.14 Å, probably indicating a mostly ionic attraction.

Platinum(IV) complexes in which the DPK ligand is retained

Complex **1** reacted with organic halides (RX) according to eq. [1] to give the complexes $[PtXMe_2R(DPK)]$ (**3** (R-X = Me-I), **4** (R-X = EtO_2C-Cl), and **5** (R-X = MeC(=O)-Cl)). The complexes were characterized spectroscopically, and the structure of complex **3** was confirmed crystallographically. The IR spectrum of complex **3** contained a carbonyl band at ν(C=O) = 1687 cm^{-1} and the ^1H NMR spectrum contained two methylplatinum resonances in a 1:2 ratio for the methyl groups trans to I and N at δ(MePt) = 0.89 and 1.40 respectively, each with ^2J(Pt-Me) = 69 Hz. For each complex **3**–**5**, the pyridyl groups were equivalent and this proves the trans stereochemistry of the oxidative addition for complexes **4** and **5**. Oxidative addition of alkyl halides to platinum(II) usually occurs by the polar (S_N2) mechanism and trans addition is commonly observed (1, 10). For each complex, the ortho pyridyl protons showed coupling to platinum that was reduced compared to the value of ^3J(Pt-H6) = 26 Hz for the platinum(II) complex **1**. For example, complex **4** gave δ(H6) = 9.16, with ^3J(Pt-H6) = 15 Hz. Complexes **4** and **5** also gave the expected resonances for the carboethoxy and acetyl group, respectively.

The structure of complex **3** is shown in Fig. 3. It shows that the DPK ligand is retained in the octahedral trimethylplatinum(IV) complex and so that the carbonyl group is not directly involved in the oxidative addition reaction. The chelate ring again adopts the boat conformation, but it is flatter than in **1** or **2** (Table 1) and the carbonyl is syn to the axial methylplatinum group and anti to the iodoplatinum group. The Pt—N distances (Pt—N(1) = 2.175(6) Å, Pt—N(14) = 2.150(5) Å) are longer than in either platinum(II) complex **1** or **2** (Table 1).

Two isomeric forms of the complex $[PtCl_2Me_2(DPK)]$ (**6a** and **6b**, Chart 2) were obtained by indirect methods. Isomer **6a** was obtained by oxidation of complex **1** with hydrogen peroxide (vide infra), followed by reaction with acetyl chloride, and isomer **6b** was obtained by oxidation of complex **1** with excess *N*-chlorosuccinimide in methanol. The complexes were readily distinguished by their ^1H NMR spectra. Thus, complex **6a**, the effective product of trans oxidative addition of chlorine, gave a single methylplatinum resonance at δ = 1.77, ^2J(Pt-H) = 71 Hz, and a single set of pyridyl resonances, whereas the less symmetrical complex **6b** gave two equal intensity methylplatinum resonances at δ = 1.71, ^2J(Pt-H) = 70 Hz; δ = 1.79, ^2J(Pt-H) = 69 Hz, and two sets of pyridyl resonances. For the pyridyl resonances, those for the

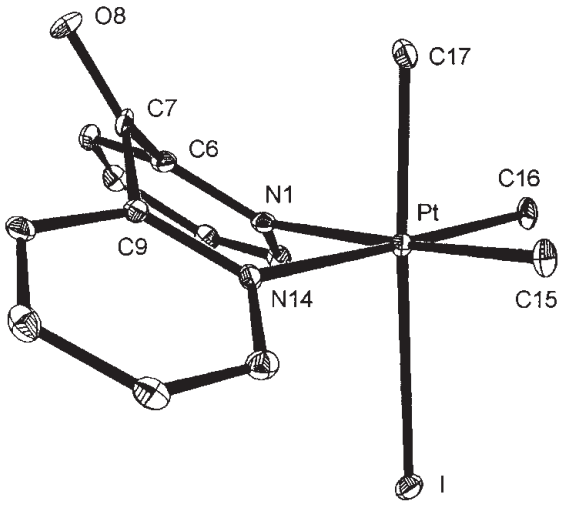

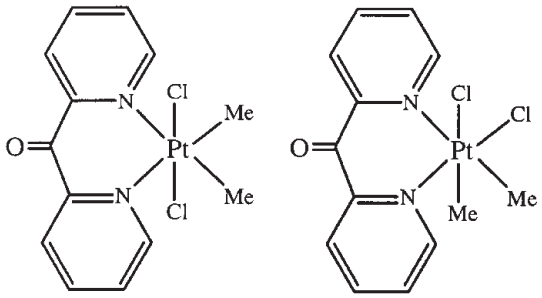

Chart 2. Isomers of complex **6**.

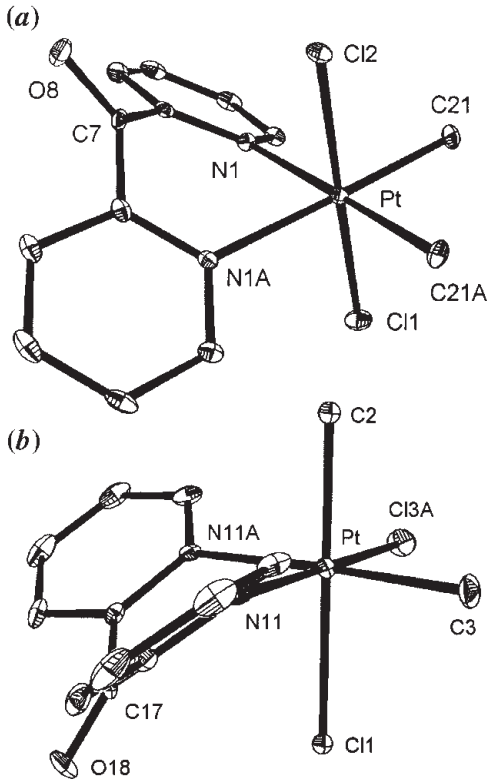

ortho protons showed very different couplings to ^{195}Pt for the pyridyl groups trans to the chloride (δ = 8.81, ^{3}J(Pt-H6) = 48 Hz) and methyl (δ = 9.10, ^{3}J(Pt-H6′) = 13 Hz).

The structures of complexes **6a** and **6b** are shown in Fig. 4. The complexes each have crystallographic mirror symmetry, and for the less symmetrical isomer **6b** this leads to a 50:50 disorder of the methyl and chloro groups trans to the DPK ligand. The axial methyl and chloro ligands were also disordered and this was modelled as a 90:10 disorder. Because of the disorder, the positions of the chlorine and methyl carbon atoms are not accurately determined, but the DPK ligand is well-defined. In **6b**, the carbonyl group is syn to the chloro ligand and anti to the axial methyl group (for the 90% occupation atoms). Since this is the opposite of the conformation for complex **3**, in which the carbonyl group is syn to the axial methyl group, we suggest that the boat conformation in complexes **3** and **6** is determined primarily by steric effects such that the carbonyl group is syn to the smaller axial ligand (Cl < Me << I). The conformation of the DPK ligand is similar in **6a** and **6b**, but the average Pt—N distance is significantly shorter in **6b** as a result of the lower trans influence of the chloride compared to the methyl (Table 1).

Several oxidation reactions of complex **1** were found to occur with the coordination of the solvent, as illustrated in Scheme 1. Thus, methyl triflate or Selectfluor® (FN-$(CH_2CH_2)_2NCH_2Cl][BF_4]_2$) in acetonitrile solution gave the acetonitrile solvate complexes, $[PtMe_3(NCMe)(DPK)]OTf$ (**7**) or $[PtFMe_2(NCMe)(DPK)][BF_4]$ (**8**) (along with $N(CH_2CH_2)_2NCH_2Cl][BF_4]$), respectively. The solvent coordination arises simply because MeCN is a better ligand for platinum(IV) than either the triflate or tetrafluoroborate anion. The presence of coordinated MeCN in **7** and **8** was proved by the presence of a singlet resonance in the ^{1}H NMR spectrum for the MeCN protons, with coupling to ^{195}Pt in complex **8** of ^{4}J(Pt-H) = 13 Hz, similar to values found in other acetonitrile complexes of platinum(IV) (3*d*, 4*g*). In addition, the ^{19}F NMR spectrum of complex **8** contained a singlet resonance for the Pt-F group at δ = 39.92, with coupling ^{1}J(Pt-F) = 1360 Hz, while the ^{1}H NMR spectrum contained a doublet resonance for the methylplatinum protons (δ(MePt) = 1.83, ^{2}J(Pt-H) = 66 Hz, ^{3}J(F-H) = 6 Hz), clearly proving the presence of the Pt-F group. The ^{195}Pt NMR spectrum contained a doublet resonance at δ(Pt) = 2114 with ^{1}J(Pt-F) = 1360 Hz, again proving the presence of a single fluoro ligand. Because complex **8** and co-product $[N(CH_2CH_2)_2NCH_2Cl][BF_4]$ had similar solubility and **8** had limited stability towards hydrolysis, it was not possible to obtain **8** in analytically pure form, but its structure is defined by the spectroscopic data.

Fig. 4. Views of the structures of the isomeric complexes **6a** and **6b**.

The reaction of complex **1** with an equimolar amount of *N*-chlorosuccinimide in methanol solution gave the chloro(methoxo)platinum(IV) complex $[PtCl(OMe)Me_2(DPK)]$ (**9**) in a similar reaction as discovered with a dimethyl-(diimine)platinum(II) complex (11). In a similar reaction, but using excess *N*-chlorosuccinimide, the dichloroplatinum(IV) complex **6b** was isolated. The formation of **6b** from initially formed complex **9** requires replacement of methoxide by chloride and stereochemical change at platinum(IV), the

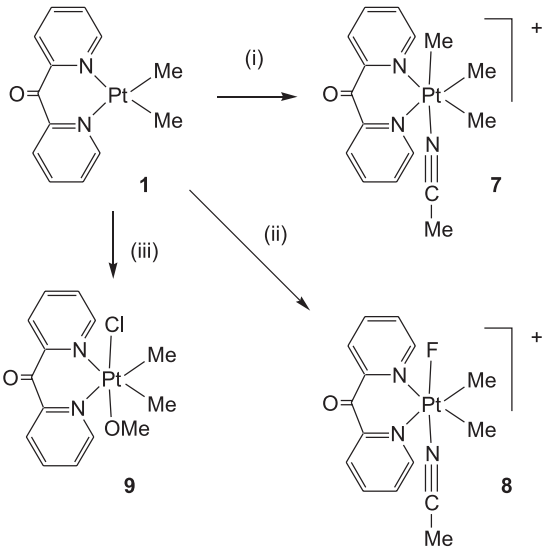

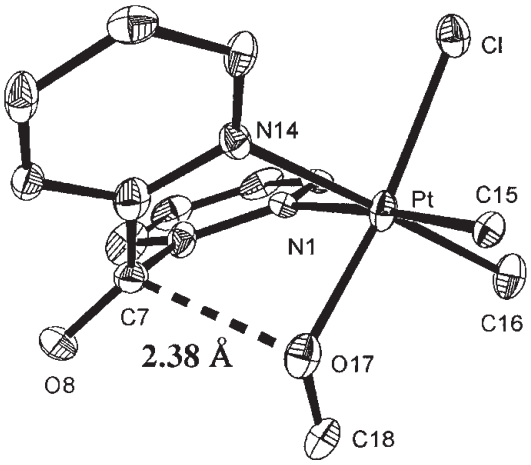

Fig. 5. A view of the structure of complex **9**, indicating the weak O···C interaction.

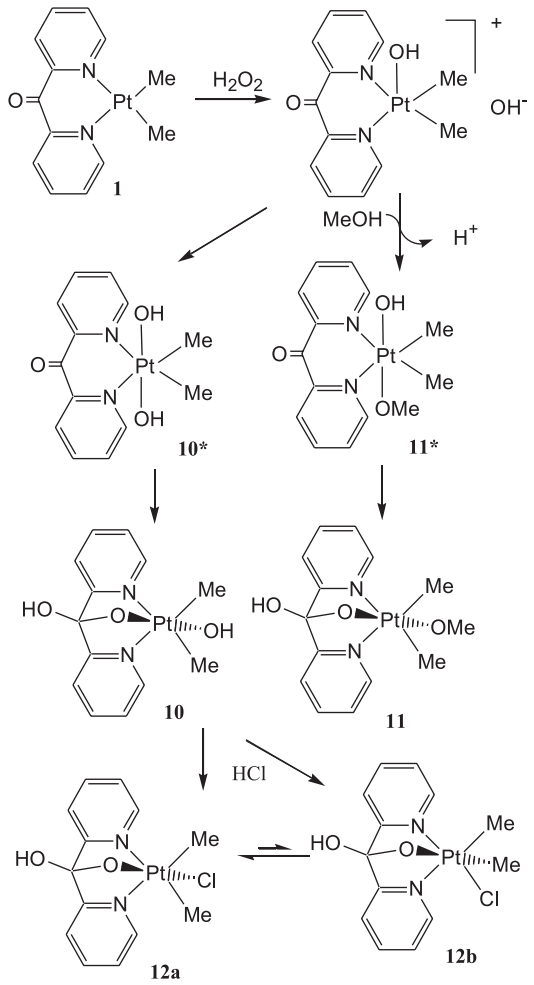
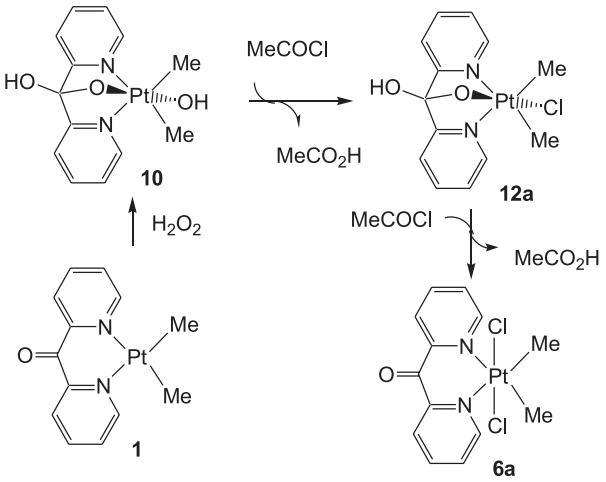


mechanism of which is unknown. The ^{1}H NMR spectrum of complex **9** gave a single methylplatinum resonance at δ = 1.53, with ^2J(Pt-H) = 72 Hz, and a methoxyplatinum resonance at δ = 2.45, with ^3J(Pt-H) = 53 Hz. A view of the structure of complex **9** is shown in Fig. 5. The DPK ligand in complex **9** is again in the boat conformation with the ketone group syn to the axial methoxide group and anti to the chloride ligand. The boat conformation is more accentuated than in the other DPK complexes of platinum(IV), as measured by the values of Θ and Δ (Table 1), and there is a short contact between the nucleophilic methoxide oxygen atom and the electrophilic carbonyl carbon atom (O(17)···C(7)= 2.38(2) Å), indicative of a secondary bonding interaction. In support, the carbonyl oxygen atom lies out of the plane defined by the atoms C(6)-C(7)-C(8) by 0.47 Å, and the sum of the bond angles at C(7) is 355°.

Platinum(IV) complexes in which the DPK ligand is modified



Complex **1** reacted with hydrogen peroxide in acetone solution to give [Pt(OH)Me_2(DPKOH)] (**10**) or in methanol solution to give [Pt(OMe)Me_2(DPKOH)] (**11**) (Scheme 2). These complexes did not yield crystals suitable for structure determination, so they were characterized spectroscopically. Complex **10** gave a single methylplatinum resonance in the ^{1}H NMR spectrum at δ = 1.45, ^2J(Pt-Me) = 72 Hz and a single set of pyridyl resonances, indicating the presence of a plane of symmetry between these groups. Complex **11** gave similar methylplatinum and pyridyl resonances and an additional resonance for the methoxyplatinum group at δ = 3.29, ^3J(Pt-H) = 39 Hz. In both complexes, the hydroxyl resonances were broad and did not show coupling to ^{195}Pt, perhaps indicating easy exchange, and so the NMR spectra did not distinguish unambiguously between the possible structures [Pt(OH)Me_2(DPKOH)] (**10**) or [Pt$(OH)_2Me_2$(DPK)] (**10***), or structures [Pt(OMe)Me_2(DPKOH)] (**11**) or [Pt(OH)(OMe)Me_2(DPK)] (**11***) (Scheme 2). However, in contrast to the characterized DPK complexes (vide supra), the IR spectra of complexes **10** and **11** did not contain a band owing to ν(C=O) in the region 1600–1700 cm^{-1}, indicating the absence of a carbonyl group and so supporting the proposed structures. In principle, the ^{13}C NMR spectra can distinguish between DPK and DPKOH forms, but the complexes have insufficient solubility to give good spectra. The ^{1}H NMR spectra of complex **10** were similar in dichloromethane or acetone solution and showed no sign of the pres-

Scheme 2.

Scheme 3.

ence of isomer **10*** in either case. Further support for the proposed structures of **10** and **11** is obtained from the structure determinations of the derivatives described in the following. The oxidative addition of hydrogen peroxide to complexes [$PtMe_2$(NN)] (NN = 2,2′-bipyridyl or its derivatives) is known and typically occurs by trans oxidative addition to give the corresponding derivative [$Pt(OH)_2Me_2$(NN)] (12).

The reaction of complex **1** with aqueous hydrogen peroxide followed by the addition of 1 equiv. of acetyl chloride (to produce HCl) gave the complex [$PtClMe_2$(DPKOH)] (**12**) by replacement of the hydroxide ligand by chloride (Scheme 2). Complex **12** existed very largely as the isomer **12a** with the chloro ligand trans to oxygen, but a minor amount of the isomer **12b** with the chloro ligand trans to nitrogen was also present (Scheme 2). Dissolution of isolated complex **10** in acetyl chloride led to the replacement of both the hydroxo ligand and the DPKOH hydroxyl group and gave [$PtCl_2Me_2$(DPK)] (**6a**), presumably via the formation of complex **12**. The mechanism of the formation of **6** from **12** is not known, but it clearly involves conversion of a DPKOH group to DPK (Scheme 3). Overall then, the conversion of DPK to DPKOH is shown to be reversible. The structure of complex **12** is shown in Fig. 6.

The structure of complex **12** confirms the presence of the DPKOH anion, which acts a fac-tridentate ligand for platinum(IV). There are also two methylplatinum groups and a chloroplatinum group to make up the octahedral coordination of the platinum(IV) center. There is some disorder at the Cl(1)/C(27) sites (refined as 87:13 occupation) with the chloro ligand trans or cis to oxygen. The most obvious changes in the ligand conformation compared to the DPK complexes of platinum(IV) is the accentuation of the boat conformation (Table 1) needed to form the C-O-Pt bridge. There is also a slight narrowing of the N-Pt-N angle and, of course, a change to tetrahedral stereochemistry of the former carbonyl carbon atom (C(16)-C(17)-C(20) = 109.4(8)°). The complex forms a dimer in the solid state by forming complementary O-H···O hydrogen bonds.

Another complex containing the DPKOH ligand was obtained fortuitously by hydrolysis of the complex [$PtFMe_2$(NCMe)(DPK)][BF_4] (**8**) in acetonitrile solution (Scheme 4). The product crystallized from solution and was characterized in the solid state as [$PtMe_2${NHC(=O)Me}(DPKOH)]-[$PtMe_2${NH=C(OH)Me}(DPKOH)][BF_4] (**13**) by X-ray structure determination (Fig. 7). The reaction was then monitored by ^{1}H NMR spectroscopy with hydrolysis by added D_2O. As the reaction proceeded slowly at room temperature, the MeCN resonance and the doublet MePt resonance of complex **8** (arising from the coupling ^3J(F-H)) decayed and new singlet resonances for the product grew in at δ(MePt) = 1.33, ^2J(Pt-H) = 72 Hz, and at δ(MeC) = 2.28. The rate of hydrolysis increased with the concentration of D_2O added and was typically complete in several days at room temperature. The mass spectrum, obtained either by ESI-MS in MeCN solution or EI-MS of the solid sample, contained a peak at *m/z* = 485, assigned to the cation [$PtMe_2${NH=C(OH)-Me}(DPKOH)] or its tautomeric acetamide complex form.

In the structure determination, the key hydrogen atoms were not directly located so the formulation of the product requires some explanation. There was one disordered tetrafluoroborate anion for every two platinum atoms, indicating an average charge of +0.5 for each complex, but

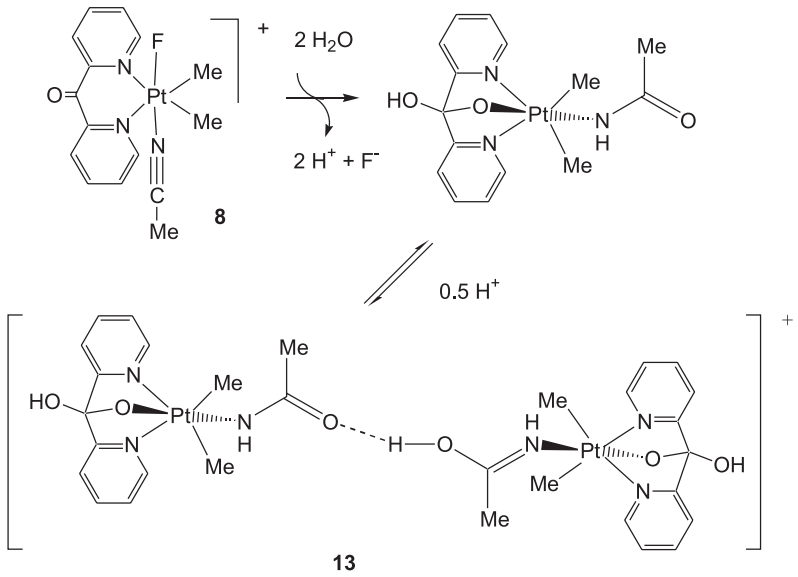
Scheme 4.



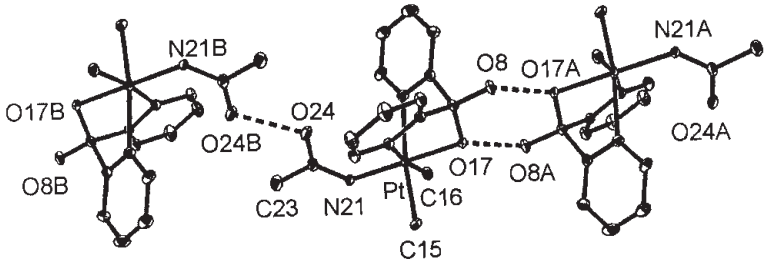


Fig. 8. A view of the supramolecular polymeric structure formed by hydrogen bonding in complex **13**.

only one unique platinum complex was present in the unit cell. The complexes self-assemble in the solid state to give a supramolecular polymer, as shown in Fig. 8. The self-assembly process has two components. Thus, each complex forms a dimer with its neighbour by complementary hydrogen bonding between DPKOH ligands (O(8)···O(17A)=O(17)···O(8A) = 2.668(7) Å), and these dimers are then linked by a strong hydrogen bond between the NHC(Me)=O···HOC(Me)=NH groups (O(24)···O(24A) = 2.42(1) Å). Since the hydrogen bond is strong and occurs between crystallographically equivalent atoms, it can be considered to be formed by the protonation of two acetamidate groups to give a rapid tautomeric equilibrium between the forms [NH-C(Me)=O···H-O-C(Me)=NH]$^-$ and [NH=C(Me)-O-H···O=C(Me)-NH]$^-$. The distances within the protonated acetamidate groups (N(21)—C(22) = 1.30(1) Å and C(22)—O(24) = 1.27(1) Å) are indicative of partial double bonds, as expected in terms of the proposed bonding scheme. There are many precedents for the hydrolysis of coordinated acetonitrile molecules to give acetamidate or acetamide complexes (13–15). For example, the complex *trans*-[Pt{NHC(=O)Me}(MeCN)$(NH_3)_2$]$^+$ is formed by partial hydrolysis of *trans*-[Pt$(MeCN)_2(NH_3)_2]^{2+}$ and has *d*(HN-C) = 1.28(2) and *d*(C=O) = 1.27(2) Å (13), while the "platinum blues" contain bridging acetamidate ligands formed by the partial hydrolysis of the acetonitrile ligands (14).

The reaction of complex **1** with excess methyl triflate in dichloromethane solution, followed by the addition of aqueous sodium hydroxide solution, gave the complex [$PtMe_3${DPC$(OMe)_2$}]OTf (**14**) containing the dimethyl ketal derivative of DPK as a fac-tridentate ligand (Scheme 5). In the ^{1}H NMR spectrum, there were two methylplatinum resonances in a 2:1 ratio for the methyl groups trans to nitrogen (δ(MePt) = 1.13, ^2J(Pt-H) = 70 Hz) and oxygen (δ(MePt) = 1.55, ^2J(Pt-H) = 83 Hz), respectively, and two equal intensity methoxy resonances for the groups coordinated (δ(MeO) = 3.43, ^3J(Pt-H) = 8 Hz) and not coordinated (δ(MeO) = 3.83) to platinum. The structure of the complex cation is shown in Fig. 9. It confirms the presence of the DPC$(OMe)_2$ ligand in a boat conformation that allows it to act as a fac-tridentate ligand. Though the hydrate DPC$(OH)_2$ and hemiketal DPC(OH)(OR) groups have been characterized in transition metal complexes, we are not aware of any other examples of ketal derivatives (7, 8).

The formation of the Pt(DPKOH) group in **10**–**13** or the Pt{DPC$(OMe)_2$} group in **14**, is likely to involve an intramolecular rearrangement of a Pt(OH)(DPK) unit at some stage, rather than the alternative external attack by hydroxide ion on the ketone group of a Pt(DPK) unit. Note in particular that the external attack mechanism in the reaction of complex **1** with hydrogen peroxide in methanol would be expected to give [Pt(OH)Me_2(DPKOMe)] and not the observed product [Pt(OMe)Me_2(DPKOH)] (**11**) (Scheme 2). The internal rearrangement mechanism involves nucleophilic attack by the oxygen atom of the PtOH group on the neigh-

© 2005 NRC Canada

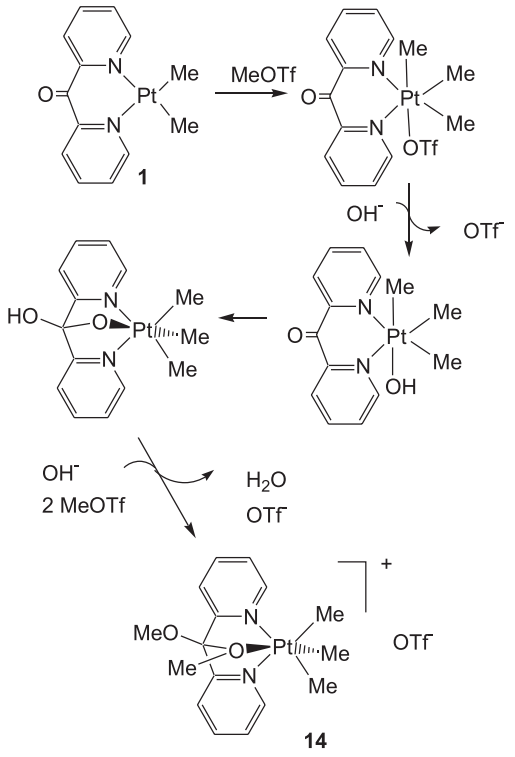

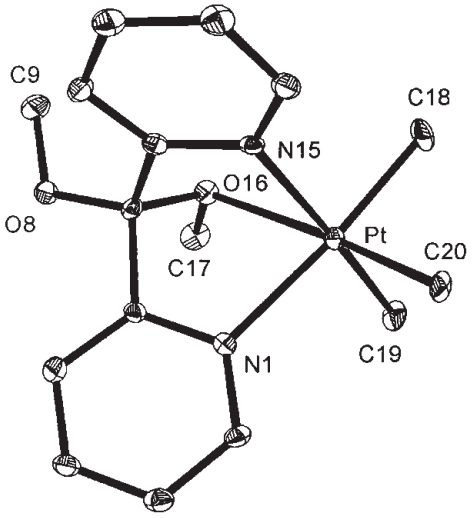

Fig. 9. A view of the structure of the cationic complex **14**.

bouring carbonyl group, as indicated in the structure of complex **9**, followed by 1,3-migration of the proton between the two oxygen atoms to give the Pt(DPKOH) group. The formation of the Pt{DPC(OMe)$_2$} group in **14** then requires initial formation of a Pt(DPKOH) group followed by deprotonation by base and methylation by methyl triflate (Scheme 5).

Experimental section

All reactions were carried under an N_2 atmosphere using standard techniques. ^{1}H NMR spectra were recorded by using a Varian Mercury or Inova 400 spectrometer, and ^{195}Pt NMR spectra were recorded by using a Varian Inova 600 spectrometer. ^{1}H NMR chemical shifts are reported relative to TMS, ^{19}F NMR chemical shifts relative to $CFCl_3$, and ^{195}Pt NMR chemical shifts relative to $[PtCl_2(SMe_2)_2]$ (16). The complex $[Pt_2Me_4(\mu\text{-}SMe_2)_2]$ was prepared as described in the literature (9).

[PtMe$_2$(DPK)] (1)

To a solution of $[Pt_2Me_4(\mu\text{-}SMe_2)_2]$ (0.25 g, 0.435 mmol) in CH_2Cl_2 (10 mL) was added a solution containing di-2-pyridyl ketone (0.16 g, 0.848 mmol) in CH_2Cl_2 (10 mL). The solution immediately turned orange and the product precipitated as dark orange solid over 30 min. The product was collected by filtration, washed with CH_2Cl_2–pentane, and dried under vacuum. Yield: 90%. IR (Nujol mull, cm^{-1}): 1682 υ(CO). ^{1}H NMR (acetone-d_6) δ: 0.78 (s, 6H, ^2J(Pt-H) = 86 Hz, Pt-Me), 7.73 (dd, 2H, ^3J(HH) = 5 Hz, 7 Hz, H5), 8.01 (d, 2H, ^3J(HH) = 7 Hz, H3), 8.24 (t, 2H, ^3J(HH) = 7 Hz, H4), 8.83 (d, 2H, ^3J(HH) = 5 Hz, ^3J(PtH) = 26 Hz, H6). ^{13}C NMR ($CDCl_3$) δ: –16.79 (s, ^1J(PtC) = 816 Hz, MePt), 125.79, 128.43, 137.53, 150.70, 153.24 (pyridyl C), 188.59 (CO). ^{195}Pt NMR ($CDCl_3$) δ: 332.8 (Pt). Anal. calcd. for $C_{13}H_{14}N_2OPt$ (%): C 38.14, H 3.45, N 6.84; found: C 38.33, H 3.21, N 6.76.

[PtIMe$_3$(DPK)] (3)

To a solution of complex **1** (0.041 g) in dry acetone (20 mL) was added excess MeI (0.05 mL). The color of the solution rapidly changed from red to yellow. After 10 min, the volume of the solution was reduced to 1 mL, and pentane (20 mL) was added to precipitate the product as a yellow solid, which was collected by filtration, washed with ether (3 × 2 mL) and pentane (3 × 8 mL), and dried under vacuum. Yield: 90%. IR (Nujol mull, cm^{-1}): 1687 υ(C=O). ^{1}H NMR (acetone-d_6) δ: 0.90 (s, 3H, ^2J(Pt-H) = 69 Hz, PtMe trans to I), 1.40 (s, 6H, ^2J(Pt-H) = 71 Hz, PtMe trans to N), 7.88 (t, 2H, ^3J(HH) = 6 Hz), 8.19 (d, ^3J(HH) = 7 Hz), 8.32 (t, 2H, ^3J(HH) = 7 Hz), 9.19 (d, 2H, ^3J(HH) = 6 Hz, ^3J(Pt-H) = 15 Hz). ^{195}Pt NMR (CD_2Cl_2) δ: 683.19 (Pt). Anal. calcd. for $C_{14}H_{17}IN_2OPt$ (%): C 30.5, H 3.11, N 5.08; found: C 31.06, H 2.99, N 5.87.

[PtClMe$_2$(CO$_2$Et)(DPK)] (4)

This was prepared similarly by reaction of excess ethyl chloroformate with a solution of complex **1** in CH_2Cl_2 for 22 h. Yield: 81%. ^{1}H NMR (CD_2Cl_2) δ: 1.07 (t, 3H, ^3J(HH) = 7 Hz, CH_3C), 1.50 (s, 6H, ^2J(Pt-H) = 71 Hz, PtMe), 3.99 (q, 2H, ^3J(HH) = 7 Hz, CH_2O), 7.68 (t, 2H, ^3J(HH) = 6 Hz), 8.10 (t, 2H, ^3J(HH) = 6 Hz), 8.22 (d, 2H, ^3J(HH) = 6 Hz), 9.16 (d, 2H, ^3J(HH) = 6 Hz, ^3J(Pt-H) = 15 Hz). EI-MS *m/z*: = 518.1 [M$^+$]. Anal. calcd. for $C_{16}H_{19}ClN_2O_3Pt$ (%): C 37.11, H 3.70, N 5.41; found: C 36.91, H 3.45, N 5.50.

[PtClMe$_2$(COMe)(DPK)] (5)

This was prepared similarly by the reaction of MeCOCl with complex **1** in acetone solution for 20 min. The product was isolated as a pale yellow solid. Yield: 78%. ^{1}H NMR (CD_2Cl_2) δ: 1.50 (s, 6H, ^2J(Pt-H) = 71 Hz, PtMe), 2.02 (s, 3H, ^3J(Pt-H) = 10 Hz, PtCOMe), 7.64 (t, 2H), 8.10 (t, 2H), 8.27 (d, 2H), 8.92 (d, 2H, ^3J(Pt-H) = 13 Hz). Anal. calcd. for

$C_{15}H_{17}ClN_2O_2Pt$: C 39.82, H 3.79, N 6.19; found: C 39.44, H 3.61, N 6.10.

[$PtCl_2Me_2$(DPK)] (6a)

To a solution of complex **1** (0.082 g) in acetone (15 mL) was added excess aq. H_2O_2 (0.1 mL, 30% solution) and then MeCOCl (36 μL). After 38 h, the product was isolated as a yellow powder. Yield: 65%. ^{1}H NMR (CD_3OD) δ: 1.77 (s, 6H, ^2J(Pt-H) = 71 Hz), 7.67 (t, 2H), 7.95 (d, 2H), 8.17 (t, 2H), 8.93 (d, 2H). Anal. calcd. for $C_{13}H_{14}Cl_2N_2OPt$ (%): C 32.51, H 2.94, N 5.83; found: C 32.41, H 2.90, N 5.81.

[$PtMe_3$(NCMe)(DPK)]OTf (7)

To a solution of complex **1** (0.41 g) in CH_3CN (20 mL) was added MeOTf (11 μL). The color of the solution immediately bleached. After 1 h, the product was isolated as an off-white powder. ^{1}H NMR (CD_3CN) δ: 0.93 (s, 3H, ^2J(Pt-H) = 75 Hz, MePt trans to NCMe), 1.11 (s, 6H, ^2J(Pt-H) = 68 Hz, MePt trans to N), 2.61 (s, 3H, PtNCMe), 7.88 (t, 2H), 8.19 (d, 2H), 8.20 (t, 2H), 8.81 (d, 2H, ^3J(Pt-H) = 16 Hz). Anal. calcd. for $C_{17}H_{20}F_3N_3O_4PtS$ (%): C 33.23, H 3.28, N 6.84; found: C 33.08, H 3.24, N 6.04.

[$PtFMe_2$(NCMe)(DPK)][BF_4] (8)

This was prepared similarly by reaction of complex **1** in MeCN solution with Selectfluor® ([$FN(CH_2CH_2)_2NCH_2Cl$]-[BF_4]$_2$). The color of the solution bleached immediately. After 30 min, the volume was reduced to 2 mL and pentane (10 mL) was added to precipitate both **8** and [$N(CH_2$-$CH_2)_2NCH_2Cl$][BF_4]. ^{1}H NMR for **8** (CD_3CN) δ: 1.83 (d, 6H, ^2J(Pt-H) = 67 Hz, ^3J(FH) = 6 Hz, PtMe), 2.69 (s, 3H, ^4J(Pt-H) = 13 Hz, PtNCMe), 7.93 (t, 2H), 8.21 (d, 2H), 8.34 (t, 2H), 8.97 (d, 2H). ^{19}F NMR (CD_3CN) δ: –151.45 (s, 4F, BF_4^-), 77.06 (br, 1F, Pt-F). At –30 °C, ^{19}F NMR (CD_3CN) δ: –146.680 (s, 4F, BF_4^-), 39.92 (s, ^1J(Pt-F) = 1360 Hz, Pt-F). EI-MS *m*/*z*: 469 [$PtFMe_2$(NCMe)(DPK)$^+$].

Attempts to grow single crystals of **8** gave instead either crystals of [$N(CH_2CH_2)_2NCH_2Cl$][BF_4] or, by hydrolysis of **8**, to crystals of the complex [$PtMe_2${NHC(=O)Me}-(DPKOH)][$PtMe_2${NH=C(OH)Me}(DPKOH)][BF_4] (**13**). ^{1}H NMR for **13** (CD_3CN) δ: 1.33 (s, 6H, ^2J(Pt-H) = 72 Hz, PtMe), 2.28 (s, 3H, MeC), 5.9, 6.4, 7.2 (br, NH, OH), 7.30 (dd, 2H, ^3J(HH) = 5, 7 Hz, H5), 7.67 (d, 2H, ^3J(HH) = 7 Hz, H3), 7.89 (t, 2H, ^3J(HH) = 7 Hz, H4), 8.47 (d, 2H, ^3J(HH) = 5 Hz, ^3J(PtH) = 12 Hz, H6). ^{19}F NMR (CD_3CN) δ: –151.45 (s, BF_4^-). EI-MS *m*/*z*: = 485 [$PtMe_2$(NHC(OH)Me)(DPKOH)$^+$].

[PtCl(OMe)Me_2(DPK)] (9)

To a solution of complex **1** (0.41 g) in MeOH (20 mL) was added a solution of *N*-chlorosuccinimide (0.14 g) in MeOH (10 mL). After 20 min, the volume was reduced to 2 mL, and pentane (10 mL) was added to precipitate the product as a yellow solid. Yield: 78%. ^{1}H NMR (CD_3OD) δ: 1.53 (s, 6H, ^2J(Pt-H) = 72 Hz, PtMe), 2.45 (s, 3H, ^3J(Pt-H) = 53 Hz, PtOMe), 7.83 (t, 2H), 8.20 (d, 2H), 8.28 (t, 2H), 8.94 (d, 2H, ^3J(Pt-H) = 12 Hz, PtNCH). Anal. calcd. for $C_{14}H_{17}ClN_2O_2Pt$ (%): C 35.34, H 3.60, N 5.89; found: C 35.75, H 3.70, N 6.27.

In a similar experiment using excess *N*-chlorosuccinimide, yellow single crystals of complex **6b** separated from the solution. ^{1}H NMR (DMSO-d_6) δ: 1.71 (s, 3H, ^2J(Pt-H) = 70 Hz, PtMe), 1.79 (s, 3H, ^2J(Pt-H) = 69 Hz, PtMe), 7.90, 8.01 (each dd, 1H, ^3J(HH) = 6, 8 Hz, H5, H5′), 8.18, 8.24 (each d, 1H, ^3J(HH) = 8 Hz, H3, H3′), 8.39, 8.43 (each t, 1H, ^3J(HH) = 8 Hz, H4, H4′), 8.81 (d, 1H, ^3J(HH) = 6 Hz, ^3J(Pt-H) = 48 Hz, H6), 9.10 (d, 1H, ^3J(HH) = 6 Hz, ^3J(Pt-H) = 13 Hz, H6′).

[Pt(OH)Me_2(DPKOH)] (10)

To a solution of complex **1** (0.41 g, 1 mmol) in acetone (25 mL) was added excess aq. H_2O_2 (0.5 mL, 30% solution). The mixture was immediately bleached. After 24 h, the product precipitated as a white solid, which was filtered, washed with pentane (3 × 5 mL), and dried under vacuum. Yield: 82%. ^{1}H NMR (CD_3COCD_3) δ: 1.45 (s, 6H, ^2J(Pt-H) = 72 Hz, PtMe), 5.55 (br, PtOH), 7.49 (t, 2H), 7.80 (d, 2H), 7.90 (t, 2H), 8.89 (d, 2H). ^{1}H NMR (CD_3CN–DMSO-d_6) δ: 1.39 (s, 6H, ^2J(Pt-H) = 73 Hz, PtMe), 3.15 (br, 1H, PtOH), 7.45 (dd, 2H, ^3J(HH) = 5, 7 Hz), 7.76 (d, 2H, ^3J(HH) = 7 Hz), 7.97 (t, 2H, ^3J(HH) = 7 Hz), 8.13 (br, 1H, PtOCOH), 8.65 (d, 2H, ^3J(HH) = 5 Hz). Anal. calcd. for $C_{13}H_{16}N_2O_3Pt$ (%): C 35.22, H 3.64, N 6.32; found: C 35.69, H 3.14, N 5.94.

[Pt(OMe)Me_2(DPKOH)] (11)

This was prepared similarly, but in methanol solution. Yield: 87%. ^{1}H NMR (CD_3OD) δ: 1.50 (s, 6H, ^2J(Pt-H) = 74 Hz, PtMe), 3.29 (s, 3H, ^3J(Pt-H) = 39 Hz, PtOMe), 4.84 (br, 1H, OH), 7.50 (t, 2H), 7.86 (d, 2H), 7.99 (t, 2H), 8.78 (d, 2H). Anal. calcd. for $C_{14}H_{18}N_2O_3Pt$ (%): C 36.76, H 3.97, N 6.12; found: C 36.67, H 3.99, N 5.84.

[PtClMe_2(DPKOH)] (12)

To a solution of complex **1** (0.04 g, 0.1 mmol) in CH_2Cl_2 (10 mL) was added aq. H_2O_2 (0.1 mmol, 30%) followed by acetyl chloride (0.1 mmol). After 30 min, the volume was reduced to 1 mL and pentane was added to precipitate the product as a yellow powder. Yield: 69%. For **12a** (ca. 90% abundance): ^{1}H NMR (CD_3CN) δ: 1.39 (s, 6H, ^2J(Pt-H) = 73 Hz, PtMe), 8.13 (s, 1H, OH), 7.45 (dd, 2H, ^3J(HH) = 5, 7 Hz, H5), 7.75 (d, 2H, ^3J(HH) = 7 Hz, H3), 7.97 (t, 2H, ^3J(HH) = 7 Hz, H4), 8.64 (d, 2H, ^3J(HH) = 5 Hz, H6). For minor isomer **12b** (ca. 10% abundance): ^{1}H NMR (CD_3CN) δ: 0.87 (s, 3H, ^2J(Pt-H) = 72 Hz, PtMe), 1.45 (s, 3H, ^2J(Pt-H) = 71 Hz, PtMe). Anal. calcd. for $C_{12}H_{13}ClN_2O_3Pt{\cdot}CH_2Cl_2$ (%): C 28.43, H 2.73, N 5.10; found: C 29.01, H 2.47, N 5.52.

[$PtMe_3${DPC$(OMe)_2$}] (14)

To a solution of complex **1** (0.041 g, 0.1 mmol) in dry CH_2Cl_2 (20 mL) was added excess MeOTf (0.01 mL). The colour of the solution immediately bleached. After 30 min, aq. NaOH (5 mL, 2 mol/L) was added. The organic layer was separated, dried with $MgSO_4$, filtered and evaporated to give the product as an off-white powder. Yield: 58%. ^{1}H NMR (CD_2Cl_2) δ: 1.13 (s, 6H, ^2J(Pt-H) = 70 Hz, PtMe), 1.55 (s, 3H, ^2J(Pt-H) = 83 Hz, PtMe), 3.43 (s, 3H, ^3J(Pt-H) = 8 Hz, PtOMe), 3.83 (s, 3H, Me, PtOCOMe), 7.72 (t, 2H, ^3J(HH) = 7 Hz), 8.08 (d, 2H, ^3J(HH) = 7 Hz), 8.23 (t, 2H, ^3J(HH) = 7 Hz), 8.55 (d, 2H, ^3J(HH) = 7 Hz, ^3J(PtH) = 14 Hz). ^{19}F NMR (CD_2Cl_2) δ: –79.362 [Otf]. Anal. calcd.

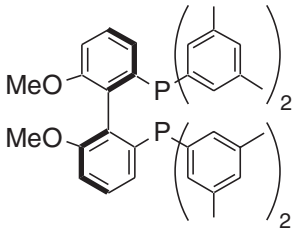
Thermally accelerated asymmetric hydrosilylations using ligated copper hydride[1]

Bruce H. Lipshutz, Bryan A. Frieman, John B. Unger, and Danielle M. Nihan

Abstract: Exposure of a variety of prochiral substrates to [(*R*)-(–)-DTBM-SEGPHOS]CuH + PMHS under microwave or conventionally heated conditions reduces reaction times for these hydrosilylations from hours to minutes without significant erosion in ee in most cases.

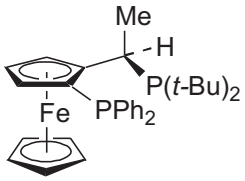
Key words: asymmetric hydrosilylation, copper hydride, microwave irradiation.

Résumé : Lorsqu'on soumet une variété de substrats prochiraux à l'effet combiné de [(*R*)-(–)-DTBM-SEGPHOS]CuH et du PMHS, dans des conditions de chauffage conventionnel oui par micro-ondes, on observe une réduction des temps de réaction de ces hydrosilylations qui passe d'heures à minutes sans érosion significative des ee, dans la plupart des cas.



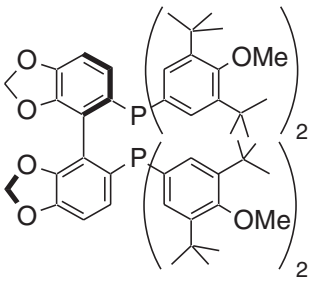
Mots clés : hydrosilylation asymétrique, hydrure de cuivre, irradiation micro-onde.

[Traduit par la Rédaction]



Introduction

Copper hydride (CuH) is notoriously heat sensitive (1). Complexation by ligands, usually phosphines (2), has allowed for its extensive use in synthesis at room temperature or below for effecting both 1,2- and 1,4-reductions of unsaturated carbonyl compounds (3). Since the advent of "Stryker's reagent", $[(Ph_3P)CuH]_6$, in 1988 as an especially useful reductant in synthesis (4*a*), many variations that alter the nature of the chelating phosphine (4*b*, 4*c*) have provided opportunities for utilizing CuH in an asymmetric context. Ligands such as Roche's 3,5-xylyl-MeO-BIPHEP (5) **1** and Solvias' JOSIPHOS analog (6) **2** and, in particular, Takasago's DTBM-SEGPHOS (7) **3** have spawned new technologies for controlling chirality in 1,2-reductions of aryl ketones (8*a*) and imines (8*b*), as well as 1,4-additions of hydride to acyclic (8*c*) and cyclic ketones (8*d*), enoates (8*e*), and unsaturated lactones (8*e*).



The innate bias of these ligands is remarkable, as is the reactivity they impart to CuH. In some cases, substrate-to-ligand (S:L) ratios over a hundred thousand to one have been documented (8*a*, 8*d*). In all cases reported to date, lower reaction temperatures have led to higher selectivities. Depending upon the substrate, reaction times with S:L ratios in the more convenient thousands to one range may still require hours for consumption of educt. One potential approach to increasing reaction rates is to take advantage of microwave irradiation (9). Given that this technique involves a mainly thermal component, its application to asymmetric CuH-based hydrosilylations seems counter-intuitive as the observed ees would be expected to drop. Moreover, elevated temperatures might be expected to decompose CuH at an increased pace and (or) alter ligand composition via oxidative

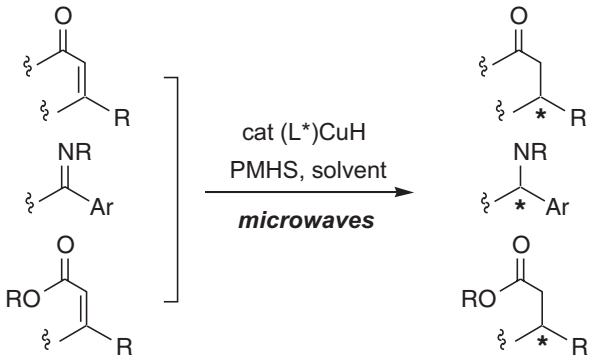
processes due to adventitious oxygen. Notwithstanding these potential pitfalls, it seemed plausible that the overriding bias of ligands **1**–**3** and the rapidity of microwave heating could lead to fast and efficient hydrosilylations. We now report that, indeed, such ligand-accelerated reactions can be carried out in minutes under the influence of mild heating, employing either microwave irradiation or conventional means, without significant compromise in enantioselectivities.



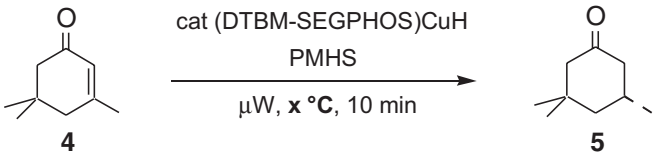


Table 1. Effect of temperature on asymmetric hydrosilylations with CuH.

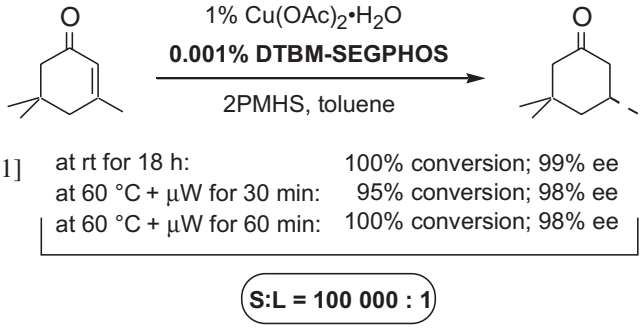

Temperature (°C)	Conversion (%)	ee (%)	
60	100	98.9	toluene
80	100	97.5	
100	73	97.2	
120	65	96.5	
80	10	86.2	CH_2Cl_2
80	70 [a]	98.0	THF
80	100	98.0

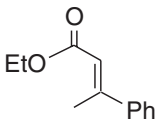
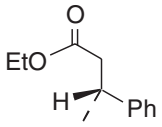
[a]Run for 15 min.

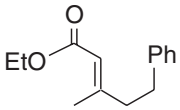
Results

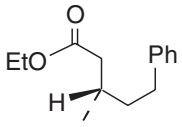
Initial experiments were conducted on isophorone **4** employing our recently developed "Copper hydride in a Bottle",[3] where (*R*)-DTBM-SEGPHOS-chelated CuH is presumed to function as the catalytically active species. These trials were aimed at establishing a temperature at which the enone is quickly consumed. Along with this determination would also come the evaluation of reagent lifetime and the potential cost in ee. Temperatures ranging from 60 °C to 120 °C at 20° intervals were examined using a Personal Chemistry (now Biotage) Emry's Optimizer microwave instrument (Table 1). The data clearly indicate that in toluene, with increasing temperature, the extent of conversion to nonracemic adduct **5** drops significantly above 80 °C presumably because of loss of reagent (decomposition is evident). Interestingly, good selectivity even at the highest temperature remains. It is noteworthy that at 60 °C, a reaction that normally requires 3 h at room temperature can be carried out in 10 min with comparable ee. Other solvents tested at 80 °C include CH_2Cl_2 and THF. Surprisingly, the former led to only 10% conversion after 10 min (86.2% ee), while in THF the reaction was 70% complete. Extending the time of exposure to microwaves to 15 min afforded complete conversion to the product ketone in 98.0% ee.

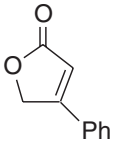
As noted above, these reactions were run at an S:L ratio of 1000:1. We have tested the same asymmetric hydrosilylation on isophorone at the 100 000 : 1 level as well (eq. [1]). Thus, while conventionally the reduction requires ca. 18 h at room temperature to reach completion, at 60 °C in the microwave, 95% conversion is achieved within 30 min at similar concentrations. Allowing another 30 min reaction time ensures full consumption of educt. At this temperature, the ee remained at 98%.

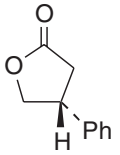


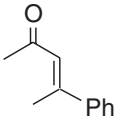


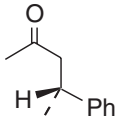


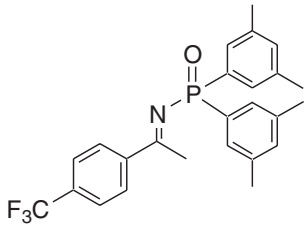


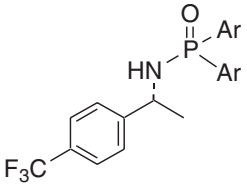












Using a microwave temperature limit of 60 °C, other substrates such as enoates, enones, an unsaturated lactone, and aryl imines were treated with cat. (DTBM-SEGPHOS)CuH–PMHS. Table 2 summarizes our observations, comparing reaction times and ees vs. those obtained previously under conventional conditions (where known). Modest erosion in observed ees at this higher temperature appears to be a consistent trend, independent of whether the nature of the addition of hydride is in the 1,4- (entries 1–4) or 1,2- (entry 5) mode. The option to switch solvents from toluene to more polar, lower boiling THF is worthy of mention and was, in fact, needed in the case of an unsaturated lactone (entry 3). Limited solubility and, hence, incomplete reaction were averted by employing ethereal media along with an 80 °C reaction temperature. This combination led smoothly and quickly to the desired nonracemic lactone in 98.6% ee, a result that compares remarkably well with the previously observed level of induction (99%) realized under conventional conditions at 0 °C (8*e*). Enone **A** (entry 4) was surprisingly unreactive to (DTBM-SEGPHOS)CuH–PMHS, returning only starting material in two separate experiments. Although WALPHOS **12** gave rise to complete conversion to keto product **B**, the ee was not particularly high. Much better results were obtained using the JOSIPHOS analog **2** as ligand for CuH (ee 93.5%). The absolute stereochemistry is indi-

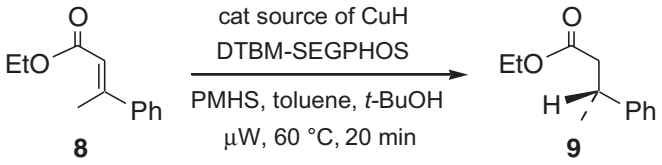
[2]



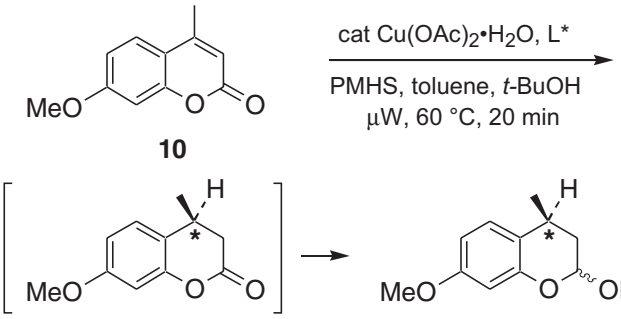
cated for known products shown in entries 1–3 and 5, while that for **B** was tentatively assigned on the basis of previous data on related enones (8*c*).

Acetophenone-derived imine **6** (eq. [2]), which, using microwave conditions at 60 °C, gave product **7** possessing an ee of 91.3%, was examined by conventional heating at 60 °C. Thus, the premixed catalyst–silane was added to a round-bottom flask, to which was added the imine immediately prior to placement in a preheated oil bath at 60 °C. After the same 30 min interval, workup and analysis by chiral HPLC indicated that the reaction had gone to completion and that the ee was 90.5%. Thus, as had been noted previously by Leadbeater and Marco (10), rapid conventional heating of reaction mixtures can on occasion give essentially the same results observed under microwave irradiation. Such appears to be the case with these asymmetric hydrosilylations when run in toluene.

Test reactions on cinnamate **8** (Table 3) were performed to assess the background reaction using Stryker's reagent as the source of CuH, rather than the in situ procedures based on

© 2005 NRC Canada

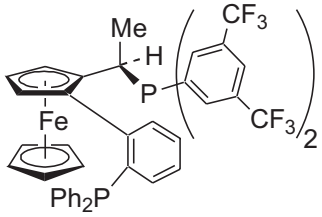
Table 3. Impact of Ph_3P on asymmetric hydrosilylations with CuH.



8 **9**

source of CuH	CuH : ligand : substrate	ee (%)
$Cu(OAc)_2•H_2O$	1 : 1 : 1000	97.7
$[(Ph_3P)CuH]_6$	1 : 1 : 1000	96.2
$[(Ph_3P)CuH]_6$	10 : 1 : 1000	84.5

either CuCl + NaO-*t*-Bu (11) or $Cu(OAc)_2•H_2O$ (12), which do not contain Ph_3P in solution. As illustrated, a 60 °C reaction temperature at an S:L ratio of 1000:1 causes an increase in the extent to which achiral $(Ph_3P)CuH$ competes for substrate, with the ee of product ester **9** dropping from 97.7 to 96.2. Using 1% rather than 0.1% of Stryker's reagent (i.e., an S:L = 100:1) causes a significant loss in selectivity (ee = 84.5%). Thus, as the temperature at which these asymmetric reductions are run goes up, the presence of Ph_3P should be avoided.



Other combinations of copper hydride and nonracemic ligands were also tested using coumarin derivative **10** (Table 4). This substitution pattern for an enoate has not previously been examined within the context of CuH-based asymmetric hydrosilylation chemistry. On first inspection, it was anticipated from prior art (8*e*) that its *Z*-cinnamate-like structure dictates that DTBM-SEGPHOS (**3**) would be the ligand of choice. When the reaction of **10** was run under conventional conditions using CuH ligated by this ligand at ambient temperature, the unexpected product of over-reduction, **11**, was obtained in 94% ee. In addition to DTBM-SEGPHOS, JOSIPHOS analog **2** and WALPHOS (**12**)[4] were screened, as were Sannicolo and co-workers's BITIANP (13) (**13**) and Boaz et al.'s BOPHOZ (14) (**14**) ligands. Unexpectedly, microwave experiments indicated that the ferrocenyl backbone common to **2** and **12** imparted the greatest enantioselectivities, significantly exceeding that observed with ligand **3**. The sense of induction for ligands **2** and **3** is the same, presumably affording the *S*-isomer from this *Z*-configured educt, while ligands **12**–**14** led to the enantiomeric product, as indicated by chiral capillary GC analyses.

Discussion

Given the history of copper hydride itself, dating back to Wurtz' report in 1844 (1*a*), it is not surprising that applications of ligated CuH at elevated temperatures have not previously been considered. Chelation by modern nonracemic bidentate phosphine ligands appears to induce not only an extreme stereochemical bias in reactions of CuH, but adds an unexpected element of stability such that mild heating of reaction mixtures is well tolerated, including those that may contain only trace amounts of the reactive catalyst relative to substrate.

Our approach to heating these reactions, at least initially, was to utilize microwave irradiation. This special, highly controlled technique, when applied within the confines of the Biotage instrument,[5] was anticipated to allow for reaction temperatures above the boiling point of the solvents to be used, along with the associated elevation in pressures. From the outset, however, as illustrated by the data in Table 1, it was clear that heating beyond 80 °C, which is well

[4] (*R*)-(*R*)-$Ph_2PPhFcCHCH_3P(3,5\text{-}CF_3Ph)_2$; Available from Solvias, Basel Switzerland (SL-W001–1; CAS Reg. No. 387868–06–6; cf. http://www.solvias.com.

© 2005 NRC Canada

below the boiling point of the reaction solvent toluene, was not viable. Nonetheless, in going from even room temperature to 60–80 °C, normal accelerations in rates were observed, while the intrinsic stereochemical bias imposed by the chelating phosphine ligand was not significantly compromised. The fact that essentially the same results (i.e., extent of conversion and observed ee; cf. eq. [2]) could be obtained by conventional heating strongly suggest that in this case, although far more convenient, microwave irradiation adds little to the chemistry. It is appreciated, however, that toluene is not likely to be the universal solvent for all substrate types. The switch to lower boiling THF would rely on the controlled temperature and pressure found under microwave conditions (cf. Table 1, last entries, and Table 2, entry 3). Although CH_2Cl_2 was surprisingly ineffective, reactions run in several other solvents that are lower boiling than toluene (bp 110 °C) can easily be envisioned to benefit from a microwave environment.

The interplay between substrate and the choice of ligand on CuH, especially under the influence of applied heat, could not have been predicted. Thus, while educt **10** had not previously been subjected to copper-hydride-based asymmetric hydrosilylation, all prior efforts on cinnamate enoates (8*e*, 15) pointed to DTBM-SEGPHOS **3** as the ligand that consistently affords extremely high levels of induction. JOSIPHOS analog **2** is also quite selective in such cases (8*e*) but typically is best utilized for β,β-*dialkyl*-substituted enoates. Thus, it was interesting to observe that both ferrocenyl-based ligand systems **2** and WALPHOS **12** led to significantly higher levels of enantioselectivity than did **3** (cf. Table 4). Curiously, the inverse of this observation, that a β,β-dialkyl-substituted enoate would best be reduced by (DTBM-SEGPHOS)CuH, as opposed to PPF-P(*t*-Bu)$_2$ **2** (cf. Table 2, entries 2 and 3), is also unexpected. These crossover results may reflect subtle changes in the degree of association of the ligand with CuH at varying temperatures, potential aggregation state issues, and (or) the likely impact of both steric and stereoelectronic factors in (L* = a nonracemic ligand)CuH that may be influential even when differences between educts are otherwise structurally quite small. Second-stage reduction, in this case of the initially formed lactone **C**, has not been observed previously with enoates or unsaturated lactones (8*e*, 15). Presumably this results from rapid quenching of the copper enolate by *t*-BuOH, followed by 1,2-reduction. None of the intermediate lactone was observed in the course of this asymmetric hydrosilylation.

What can be claimed from this study, in general, is that the increase in reaction rates gained upon mild heating to ca. 60 °C reduces the times for these asymmetric hydrosilylations to well under an hour, even where S:L ratios are in the thousands-to-one category. Several commonly studied substrate types successfully participate, and ees remain well within the synthetically useful range.

Conclusions and summary

The first study on the potential for microwave irradiation to be used to accelerate rates of asymmetric hydrosilylations by catalytic amounts of nonracemically ligated CuH is described. The results indicate that mild heating of reactions containing either complex [(*R*)-(–)-DTBM-SEGPHOS)]CuH or [(*R*)-(S)-PPF-P(*t*-Bu)$_2$]CuH via either microwave or conventional means can be tolerated and that a variety of synthetically useful 1,2- and 1,4-reductions can be realized in both good yields and excellent levels of stereoinduction.

Experimental section

General

Reactions were performed in oven-dried glassware under an argon atmosphere containing a Teflon coated stir bar and dry septum. Toluene, dichloromethane, and THF were used as is from an Innovative Technology, Inc. solvent filtration system. All commercially available reagents were distilled either from CaH_2 or molecular sieves under an inert atmosphere before use. CuCl, NaO-*t*-Bu, NaOMe, PPh_3, isophorone, and acetophenone oxime were purchased from Aldrich. Other oximes were prepared from the corresponding ketones following a literature procedure (2). Chloro bis(3,5-dimethylphenyl)phosphine was prepared according to a literature procedure (3). Phosphinylimines were prepared from the corresponding oximes by modification of a literature procedure (4). $Cu(OAc)_2 \cdot H_2O$, was purchased from Acros. Tetramethyldisiloxane was purchased from Alfa Aesar. Poly(methylhydrosiloxane) was purchased from Lancaster. Stryker's reagent was prepared by the general procedure (4). (*R*)-(–)-DTBM-SEGPHOS was generously supplied by Takasago International Corp. All microwave experiments were performed using Personal Chemistry Emry's Optimizer in 0.5–2 mL or 2–5 mL Pyrex reaction vessels that were flame dried under an argon atmosphere. Each reaction vessel contained a Teflon stir bar and a Teflon coated reaction vessel cap. Optical rotations were measured on a PerkinElmer 341 Polarimeter. HPLC analyses were performed on a Rainan Dynamax UV-1 with an HPXL solvent delivery system. GC analyses were performed on a Hewlett-Packard 6890 Series GC. GC analyses were carried out using an HP-5 capillary column (0.25 μm × 30 m; cross-linked 5% PH ME siloxane) and a time program beginning with 5 min at 50 °C, followed by a 20 °C/min ramp to 280 °C, then 20 min at this temperature. Column chromatography was performed using Davisil Grade 633 Type 60A silica gel. TLC analyses were performed on commercial Kieselgel 60 F_{254} silica gel plates. NMR spectra were obtained on Varian Inova systems using $CDCl_3$ or C_6D_6 as solvent, with proton and carbon resonances at 400 MHz and 100 MHz, respectively. FT-IR spectra were obtained on an ATI Mattson Infinity series spectrometer neat on NaCl plates or KBR pellets and are reported in cm^{-1}. Mass spectral data were acquired on a VF Autospec or an analytical VG-70-250 HF instrument.

Preparation of [(*R*)-(–)-DTBM-SEGPHOS]CuH in a Bottle (0.001 mol/L)

An oven-dried poly-coated amber glass bottle equipped with stir bar was purged under argon and brought into the glove box. $Cu(OAc)_2 \cdot H_2O$ (10 mg, 0.05 mmol) and (*R*)-DTBM-SEGPHOS (**3**, 59 mg, 0.05 mmol) were added, followed by dry toluene (44 mL), and the mixture was allowed to stir for 2 h at room temperature (rt). PMHS (6 mL) was added dropwise, and the mixture was allowed to stir for

© 2005 NRC Canada

30 min. The amber bottle was then sealed using a standard "sure–seal cap" and stored at 4 °C or rt.

(*R*)-3,3,5-Trimethylcyclohexanone (5; Table 1, entry 1)

To a 2–5 mL Emry's Optimizer glass vessel, flame dried and purged with argon, was added (DTBM-SEGPHOS)CuH in a Bottle (2 mL, 0.001 mol/L, 0.002 mmol). Isophorone (300 μL, 2 mmol) was added neat, and the reaction was immediately taken to the Emry's Optimizer. The following conditions were applied: temperature, 60 °C; time, 600 s; fixed hold time, on; sample absorption, normal; pre-stirring, 10 s. The reaction was quenched by diluting the reaction with THF (5 mL), followed by aqueous NaOH (5 mL, 3 mol/L), and the reaction was allowed to stir at rt for 2 h. The product was isolated as a colorless liquid; Chiral GC using a Chiraldex B-DM column with 75 °C isotherm showed 98.9% ee, R_t = 41.47 (minor) and 44.94 (major). The product spectral data matched previously reported spectral data (8*d*).

(*R*)-3,3,5-Trimethylcyclohexanone (temperature study; Table 1)

To a 2–5 mL Emry's Optimizer glass vessel that had been flame dried and purged with argon was added (DTBM-SEGPHOS)CuH in a Bottle (2 mL, 0.001 mol/L, 0.002 mmol). Isophorone (300 μL, 2 mmol) was added neat, and the reaction was immediately submitted to the Emry's Optimizer. The following conditions were applied: temperature, 60–120 °C; time, 600 s; fixed hold time, on; sample absorption, normal; pre-stirring, 10 s. Upon completion, the reaction was quenched by diluting with THF (5 mL) followed by aqueous NaOH (5 mL, 3 mol/L) and then allowed to stir at rt for 2 h. The product was analyzed by GC to determine the conversion; Chiral GC using a Chiraldex B-DM column with 75 °C isotherm was used to determine the ee. For the cases with dichloromethane and THF, the same protocol was used to prepare the CuH in a Bottle.

(*R*)-3,3,5-Trimethylcyclohexanone (100 000 : 1; eq. [1])

(a)

To a flame-dried, 500 mL, round-bottom flask equipped with stir bar and purged with argon was added CuCl (167.9 mg, 1.69 mmol), NaO-*t*-Bu (163 mg, 1.69 mmol), and (*R*)-DTBM-SEGPHOS (**3**, 2 mg, 1.695×10^{-3} mmol), followed by toluene (100 mL). The reaction was allowed to stir for 30 min at rt. PMHS (20.35 mL, 339.12 mmol H^-) was added dropwise via syringe and allowed to stir for 10 min. Isophorone (25.47 mL, 169.5 mmol) was then added dropwise, and the reaction was monitored by TLC. The reaction was complete in 18 h at rt, as indicated by TLC and GC.

(b)

As soon as the isophorone was added, 2 mL from the above reaction was syringed into a 2–5 mL Emry's Optimizer dry glass vessel under argon. The vessel was quickly introduced into the Emry's Optimizer, where the following reaction conditions were applied: temperature, 60 °C; time, 3600 s; fixed hold time, on; sample absorption, normal; pre-stirring, 10 s. After the 60 min reaction period, the reaction was quenched by diluting with THF (5 mL), followed by aqueous NaOH (5 mL, 3 mol/L), and was allowed to stir at rt for 2 h. The reaction was analyzed by GC to contain only product without any isophorone or byproducts; Chiral GC using a Chiraldex B-DM column with 75 °C isotherm showed 98% ee, R_t = 41.47 (minor) and 44.94 (major). The product spectral data matched previously reported spectral data (8*d*).

(*R*)-*N*-(1-Phenylethyl) bis(3,5-dimethylphenyl)phosphinamide (7; eq. [2])

CuCl (3.6 mg, 0.036 mmol), NaOMe (2.0 mg, 0.038 mmol), and (*R*)-DTBM-SEGPHOS (**3**, 42.6 mg, 0.036 mmol) were placed into a flame-dried, argon-purged round-bottom flask (RBF). Toluene (1.5 mL) was added to the RBF, and the resulting mixture was stirred at rt for 30–40 min. Meanwhile, *N*-(1-phenylethylidene) bis(3,5-dimethylphenyl)phosphinamide (75.1 mg, 0.200 mmol) was added to a 0.5–2.0 mL Emry's Optimizer glass vessel, which had been flame dried and purged with argon. *t*-BuOH (50 μL, 0.55 mmol) and toluene (450 μL) were added and allowed to stir for 5 min until the solution became homogeneous. The RBF was charged with tetramethyldisiloxane (TMDS; 0.318 mL, 1.6 mmol) and allowed to stir for 10 min. After this time, the CuH mixture (618 μL) was slowly added to the glass vessel via syringe, and the reaction was immediately taken to the Emry's Optimizer. The following conditions were applied: temperature, 60 °C; time, 1800 s; fixed hold time, on; sample absorption, normal. MeOH (1 mL) was slowly added, and after 30 min, 1 mol/L NaOH in MeOH (0.5 mL) was added. The mixture was stirred for 2–3 h, filtered through a plug of silica, and concentrated under vacuum. Purification by silica gel chromatography (10% acetone–CH_2Cl_2) gave the corresponding phosphinylamine (71 mg, 94% yield) as a white solid. HPLC analysis indicated 91.3% ee. (Daicel Chiralcel OD, hexane : isopropyl alcohol, 90:10, 1.0 mL/min, 220 nm; R_t = 5.3 min (*R*), 6.7 min (*S*)). The product spectral data matched previously reported spectral data (8*b*).

(*R*)-*N*-(1-Phenylethyl) bis(3,5-dimethylphenyl)phosphinamide, conventional heating (7; eq. [2])

CuCl (3.6 mg, 0.036 mmol), NaOMe (2.0 mg, 0.038 mmol), and (*R*)-DTBM-SEGPHOS (**3**, 42.6 mg, 0.036 mmol) were placed into a flame-dried, argon-purged round-bottom flask (RBF). Toluene (1.5 mL) was added to the RBF, and the resulting mixture was stirred at rt for 30–40 min. Meanwhile, *N*-(1-phenylethylidene) bis(3,5-dimethylphenyl)phosphinamide (75.1 mg, 0.200 mmol) was added to a 10 mL RBF, flame dried and purged with argon. *t*-BuOH (50 μL, 0.55 mmol) and toluene (450 μL) were added and allowed to stir for 5 min until the solution became homogeneous. The RBF was charged with tetramethyldisiloxane (TMDS; 0.318 mL, 1.6 mmol) and allowed to stir for 10 min. After this time, the CuH mixture (618 μL) was slowly added to the RBF via syringe, and the reaction was immediately placed into a preheated oil bath at 60 °C. After 30 min, MeOH (1 mL) was slowly added, and after 30 min, 1 mol/L NaOH in MeOH (0.5 mL) was added. The mixture was stirred for 2–3 h, filtered through a plug of silica, and concentrated under vacuum. Purification by silica gel chro-

matography (10% acetone–CH_2Cl_2) gave the corresponding phosphinylamines (70 mg, 93% yield) as a white solid. HPLC analysis indicated 90.5% ee. (Daicel Chiralcel OD, hexane : isopropyl alcohol, 90:10, 1.0 mL/min, 220 nm; R_t = 5.3 min (*R*), 6.7 min (*S*)). The product spectral data matched previously reported spectral data.

(*S*)-Ethyl 3-phenylbutanoate (9; Table 2, entry 1)

To a 2–5 mL Emry's Optimizer glass vessel, flame dried and purged with argon, was added (*E*)-ethyl 3-methyl-5-phenylpent-2-enoate (neat, 0.380 mg, 2 mmol). (DTBM-SEGPHOS)CuH in a Bottle (2 mL, 0.001 mol/L, 0.002 mmol) was added via syringe followed by *t*-BuOH (230 μL, 2.4 mmol), and the reaction was immediately taken to the Emry's Optimizer. The following conditions were applied: temperature, 60 °C; time, 1200 s; fixed hold time, on; sample absorption, normal. The TLC (9:1, hexanes:Et_2O) showed complete consumption of starting material. The reaction was quenched by diluting with THF (3 mL), followed by aqueous NaOH (2 mL, 3 mol/L), and was allowed to stir at rt for 2 h. The residue was purified by column chromatography and isolated (338 mg, 88% yield) as a clear oil; Chiral GC using a Chiraldex G-TA column with 100 °C isotherm showed 97.2% ee, R_t = 77.79 (minor) and 78.70 (major). The product spectral data matched previously reported spectral data (8*e*).

(*S*)-Ethyl 3-methyl-5-phenylpentanoate (Table 2, entry 2)

To a 25 mL round-bottom flask, flame dried and purged under argon, was added CuCl (4.2 mg, 0.042 mmol), NaO-*t*-Bu (3.7 mg, 0.039 mmol), and (*R*)-DTBM-SEGPHOS (**3**, 4.7 mg, 0.004 mmol) under an argon atmosphere. The flask was sealed with a rubber septum, and toluene (3.5 mL, dried through a column of alumina and degassed via 3 freeze–thaw cycles) was added with a dry glass syringe. The solution was stirred at rt for 45 min, at which point PMHS (0.5 mL, 0.279 mmol) was added. After 15 min of stirring, 1 mL of the solution was transferred via syringe to an Emry's Optimizer glass vial (sealed and argon purged) containing a dry stir bar and ethyl 3-methyl-5-phenylpent-2-enoate (218 mg, 1.0 mmol). *t*-BuOH (0.11 mL, 1.2 mmol) was added, and the vial was immediately taken to the Emry's Optimizer. The following conditions were applied: temperature, 60 °C; time, 1500 s; fixed hold time, on. Upon ejection of the reaction vial from the optimizer, the septum was removed and the reaction mixture poured into sat. $NaHCO_3$ (15 mL), where it was stirred for 4 h. The organic layer was extracted with diethyl ether (3 × 15 mL), washed with brine (1 × 15 mL), dried over anhydrous Na_2SO_4, and then concentrated under reduced pressure. Purification via silica gel chromatography (10 g, 2.5% Et_2O in hexanes) yielded a clear oil (206 mg, 93.6% yield). Chiral GC using a Chiraldex G-TA column with 95 °C isotherm showed 94.6% ee, R_t = 277.00 (minor) and 279.46 (major). The product spectra matched previously reported spectral data (8*e*).

(*R*)-Dihydro-4-phenyl-(3*H*)-furan-2-one (Table 2, entry 3)

A standard solution of (*R*)-(DTBM-SEGPHOS)CuH (10 mL, 0.001 mol/L) was prepared as follows: $Cu(OAc)_2 \cdot H_2O$ (2.0 mg, 0.010 mmol) and (*R*)-DTBM-SEGPHOS (11.8 mg, 0.010 mmol) were dissolved in THF (7.6 mL) and stirred at rt for 0.5 h. PMHS (2.4 mL, 40 mmol) was then added dropwise to the mixture via syringe. To a 2–5 mL Emry's Optimizer glass vessel, flame dried and purged with argon, was added 4-phenylfuran-2(5*H*)-one (80 mg, 0.50 mmol), CuH catalyst solution (0.5 mL), and *t*-BuOH (0.06 mL, 0.60 mmol). This solution was immediately transferred to the microwave and heated at 80 °C for 30 min. The reaction was quenched by diluting with ether (3 mL), followed by aqueous $NaHCO_3$ (3 mL), and then allowed to stir at rt for 0.5 h. The product lactone (75 mg, 93%) was isolated as a white solid; Chiral GC using a Chiraldex G-TA column with 160 °C isotherm showed 98.6% ee, R_t = 74.01 (minor) and 75.00 (major). The product matched previously reported spectral data (8*e*).

4-Phenylpentan-2-one (B, Table 2, entry 4)

To a 25 mL round-bottom flask, flame dried and purged under argon, was added CuCl (10 mg, 0.10 mmol), NaO-*t*-Bu (9.7 mg, 0.10 mmol), and (*R*,*S*)-PPF-P(*t*-Bu)$_2$ JOSIPHOS (5.2 mg, 0.01 mmol) under an argon atmosphere. The flask was sealed with a rubber septum and toluene (8.7 mL, dried through a column of alumina and degassed via 3 freeze–thaw cycles) was added with a dry glass syringe. The solution was stirred at rt for 45 min, at which point PMHS (1.3 mL, 0.73 mmol) was added. After 15 min of stirring, 0.87 mL of the solution was transferred via syringe to an Emry's Optimizer glass vessel (sealed and under argon) containing a dry stir bar and 4-phenylpent-3-en-2-one (**A**, 140 mg, 0.87 mmol). *t*-BuOH (0.1 mL, 1.05 mmol) was added, and the vial was immediately taken to the Emry's Optimizer. The following conditions were applied: temperature, 60 °C; time, 1500 s; fixed hold time, on. Upon ejection of the reaction vial from the optimizer, the septum was removed, and the reaction mixture poured into sat. $NaHCO_3$ (15 mL), where it was stirred for 3 h. The organic layer was extracted with diethyl ether (3 × 15 mL), washed with brine (1 × 15 mL), dried over anhydrous Na_2SO_4, and concentrated under reduced pressure. Purification via silica gel chromatography (20 g, 5% Et_2O in hexanes) yielded a clear oil (124 mg, 87% yield). Chiral GC using a Chiraldex G-TA column with 100 °C isotherm showed 93.5% ee, R_t = 51.40 (minor) and 53.00 (major). IR (neat) (cm^{-1}): 3035, 2964, 2927, 1716, 1495, 1358, 760, 700. ^1H NMR (400 MHz, $CDCl_3$) δ: 7.28–7.35 (m, 2H), 7.18–7.25 (m, 3H), 3.27–3.38 (m, 1H), 2.68 and 2.76 (dd, J = 6.4 Hz, 2H), 2.08 (s, 3H), 1.28 (d, J = 7.2 Hz, 3H). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 22.17, 30.75, 35.58, 52.13, 126.48, 126.92, 128.71, 146.44, 208.08. EI-MS *m/z* (%): 162 ($[M]^+$, 52), 147(81), 119(16), 105(100), 91(47), 77(29), 51(17). HR-EI-MS calcd. for $C_{11}H_{14}O$: 162.1044; found 162.1051.

(*R*)-*N*-(1-(4-Trifluoromethylphenyl)ethyl) bis(3,5-dimethylphenyl)phosphinamide (Table 2, entry 5)

CuCl (3.6 mg, 0.036 mmol), NaOMe (2.0 mg, 0.038 mmol), and (*R*)-DTBM-SEGPHOS (**3**, 42.6 mg, 0.036 mmol) were placed into a flame-dried, argon-purged round-bottom flask (RBF). Toluene (1.5 mL) was added to the RBF, and the resulting mixture was stirred at rt for 30–40 min. Meanwhile, *N*-(1-(4-trifluoromethylphenyl)ethylidene) bis(3,5-dimethylphenyl)phosphinamide (88.6 mg, 0.20 mmol) was added to a 0.5–2.0 mL Emry's Optimizer

© 2005 NRC Canada

glass vessel, flame dried, and purged with argon. *t*-BuOH (50 μL, 0.55 mmol) and toluene (450 μL) were added and allowed to stir for 5 min until the solution became homogeneous. The RBF was charged with tetramethyldisiloxane (TMDS; 0.318 mL, 1.60 mmol) and was allowed to stir for 10 min. After 10 min, the CuH mixture (618 μL) was slowly added to the glass vessel via syringe, and the reaction was immediately taken to the Emry's Optimizer. The following conditions were applied: temperature: 60 °C; time, 1800 s; fixed hold time, on; sample absorption, normal. MeOH (1 mL) was slowly added and after 30 min 1 mol/L NaOH in MeOH (0.5 mL) was added. The mixture was stirred for 2–3 h, filtered through a plug of silica, and concentrated under vacuum. Purification by silica gel chromatography (10% acetone–CH_2Cl_2) gave the corresponding phosphinylamines (82 mg, 92% yield) as a white solid. To a solution of the phosphinyl amine was added methanol (2 mL), followed by HCl (0.5 mL, 5 mol/L in IPA) at rt, and this was allowed to stir overnight. The mixture was extracted with Et_2O (3 × 10 mL) and washed with H_2O (3 × 10 mL). To the aqueous layer containing the ammonium salt was then added NaOH (10 mL, 5 mol/L), and the product was extracted with CH_2Cl_2 (3 × 10 mL). The combined organic layers were dried over anhydrous Na_2SO_4 and evaporated in vacuo. The amine was analyzed to be 95.7% ee by Chiral GC using a Chiraldex-GTA column with 90 °C isotherm, R_t = 14.75 (*S*) and 15.21 (*R*). The product matched previously reported spectral data (8*b*).

(*S*)-Ethyl 3-phenylbutanoate (9) using 0.1% Stryker's catalyst (Table 3, entry 2)

To a 2–5 mL Emry's Optimizer glass vessel, flame dried and purged with argon, was added the (*E*)-ethyl 3-methyl-5-phenylpent-2-enoate (neat, 0.380 mg, 2 mmol). To a 10 mL round-bottom flask (RBF), flame dried and purged with argon was added (*R*)-DTBM-SEGPHOS (**3**, 2.3 mg, 0.002 mmol) and Stryker's reagent (0.6 mg, 0.002 mmol), followed by toluene (1.75 mL). The mixture was allowed to stir for 30 min. Following dropwise addition of PMHS (240 μL, 4 mmol H^-), the reaction was stirred for 20 min. The CuH was transferred via cannula into the enoate, followed by addition of *t*-BuOH (230 μL, 2.4 mmol). The reaction vessel was immediately taken to the Emry's Optimizer. The following conditions were applied: temperature, 60 °C; time, 1200 s; fixed hold time, on; sample absorption, normal. The reaction was quenched by diluting with THF (3 mL), followed by aqueous $NaHCO_3$ (2 mL), and was allowed to stir at rt for 2 h. The reaction mixture was pushed through a plug of silica to discard the ligand. Chiral GC using a Chiraldex G-TA column with 100 °C isotherm showed the titled product to have 96.2% ee, R_t = 77.79 (minor) and 78.70 (major).

(*S*)-Ethyl 3-phenylbutanoate (9) using 1% Stryker's catalyst (Table 3, entry 3)

To a 2–5 mL Emry's Optimizer glass vessel, flame dried and purged with argon, was added the (*E*)-ethyl 3-methyl-5-phenylpent-2-enoate (neat, 0.380 mg, 2 mmol). To a 10 mL RBF, flame dried and purged with argon, was added (*R*)-DTBM-SEGPHOS (**3**, 2.3 mg, 0.002 mmol) and Stryker's reagent (6.3 mg, 0.020 mmol), followed by toluene (1.75 mL). The mixture was allowed to stir for 30 min, followed by dropwise addition of PMHS (240 μL, 4 mmol H^-), and the reaction was then stirred for 20 min. The CuH was transferred via cannula into the enoate, followed by addition of *t*-BuOH (230 μL, 2.4 mmol). The reaction vessel was immediately introduced into the Emry's Optimizer. The following conditions were applied: temperature, 60 °C; time, 1200 s; fixed hold time, on; sample absorption, normal. The reaction was quenched by diluting with THF (3 mL), followed by aqueous $NaHCO_3$ (2 mL), and was allowed to stir at rt for 2 h. The reaction mixture was pushed through a plug of silica to discard the ligand. Chiral GC using a Chiraldex G-TA column with 100 °C isotherm showed the titled product to have 84.5% ee, R_t = 77.79 (minor) and 78.70 (major).

(*S*)-3,4-Dihydro-7-methoxy-4-methylchromen-2-one (11); ligand study (Table 4)

To a 2–5 mL Emry's Optimizer glass vessel, flame dried and purged with argon, was added 7-methoxy-4-methylcoumarin (neat, 190.2 mg, 1 mmol). Toluene (3 mL) was added to the coumarin followed by (*R*)-(DTBM-SEGPHOS)CuH in a Bottle (1 mL, 0.001 mol/L in PhMe, 0.001 mmol). The corresponding reagents from ligands **2**, **12**, **13**, or **14** were made as described above, followed by addition of *t*-BuOH (115 μL, 1.2 mmol). The reaction vessel was immediately taken to the Emry's Optimizer. The following conditions were applied: temperature, 60 °C; time, 1200 s; fixed hold time, on; sample absorption, normal. Each reaction (all of which went to completion) was quenched by diluting with THF (3 mL), followed by aqueous $NaHCO_3$ (2 mL), and was allowed to stir at rt for 2 h. The residue was pushed through a plug of silica and analyzed by chiral GC, and the product showed the ees listed in Table 4, which were found using a Chiraldex-GTA column with 120 °C isotherm, R_t = 114.85 (minor) and 115.31 (major). Product **11** is extremely unstable and is a mixture of cis and trans isomers at rt, as described by Goldsmith et al. (16). ^{1}H NMR (400 MHz, C_6D_6) δ: 6.99–6.97 (m, 1H), 6.68–6.63 (m, 1H), 6.60–6.56 (m, 1H), 5.24 (dt, *J* = 2.5, 6.8 Hz, 1H), 3.34 (s, 3H), 3.01 (tq, *J* = 6.8, 7.1 Hz, 1H), 2.43 (d, *J* = 7.1 Hz, 2H), 1.05 (d, *J* = 6.8 Hz, 3H). ^{13}C NMR (100 MHz, C_6D_6) δ: 160.50, 153.52, 108.25, 108.08, 102.76, 102.56, 92.07, 55.16, 36.51, 24.16, 20.81. EI-MS *m*/*z* (%): 194 ($[M]^+$, 40), 179(21), 177(73), 151(100), 89(58), 61(54), 43(48). HR-EI-MS *m*/*z* calcd. for $C_{11}H_{14}O_3$: 194.0941; found: 194.0943.

Acknowledgements

We are indebted to Biotage, Amgen, the National Science Foundation (NSF), and the University of California, Santa Barbara (UCSB) for financial assistance in making our purchase of an Emry's Optimizer possible. We warmly thank the NSF for financial support and Takasago, Solvias, and Roche for their most generous gifts of their ligands used in this study.

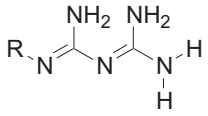
A practical guide to arylbiguanides — Synthesis and structural characterization[1]

Olivier LeBel, Thierry Maris, Hugues Duval, and James D. Wuest

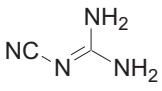
Abstract: Monohydrochloride salts of diverse 1-arylbiguanides and 1,5-diarylbiguanides were synthesized by the reaction of anilinium chlorides with dicyandiamide or sodium dicyanamide, and the biguanidinium chlorides were converted into the corresponding biguanides by deprotonation with methanolic $NaOCH_3$. The resulting biguanides and their salts were fully characterized by spectroscopic methods, and the structures of representative compounds were determined by X-ray crystallography.

Key words: biguanide, biguanidinium, synthesis, structure, hydrogen bonds, noncovalent interactions, supramolecular chemistry.



Résumé : On a effectué la synthèse de monochlorhydrates de divers 1-arylbiguanides et de 1,5-diarylbiguanides en faisant réagir des chlorures d'anilinium avec du dicyandiamide ou du dicyanamidure de sodium. Les chlorures de biguanidium ont été transformés en biguanides correspondants par déprotonation avec une solution méthanolique de $NaOCH_3$. Les biguanides correspondants et leurs sels ont été complètement caractérisés par des méthodes spectroscopiques et les structures de composés représentatifs ont été déterminées par diffraction des rayons X.

Mots clés : biguanide, biguanidinium, synthèse, structure, liaisons hydrogène, interactions non covalentes, chimie supramoléculaire.



[Traduit par la Rédaction]

Introduction

The general class of compounds called biguanides has been known for more than 100 years (1–3). An early method for preparing salts of biguanide itself (**1**) was reported in 1892 by Bamberger and Dieckmann (4), who heated dicyandiamide (**2**) with ammonium chloride and then isolated the product by forming an intermediate biguanide-copper (II) complex.[4] Since then, biguanides have proven to be broadly useful. In medicine, they have important applications as antiseptics (5), antimalarials (6, 7), serotoninergic antagonists (8), antitumoral agents (9), and hypoglycemic agents (10, 11). In addition, the ability of biguanides to chelate metals has been widely used in coordination chemistry since the initial observations of Bamberger and Dieckmann (1, 3). Moreover, biguanides are strong bases (12, 13), and they are also valuable precursors for synthesizing a wide range of heterocyclic compounds (2, 14). Of special interest among the heterocyclic derivatives of biguanides are aminotriazines, which are themselves an extremely useful family of compounds. For example, they are widely used in supramolecular chemistry because they incorporate a characteristic pattern of multiple sites that can donate or accept hydrogen bonds, thereby directing molecular recognition and association. In particular, recent applications of aminotriazines in crystal engineering have highlighted their ability to direct crystallization by self-associating according to reliable hydrogen-bonding motifs (15, 16).

1 (R = H)
3 (R = Ph)
13 (R = CH_2CH_2Ph)

2

Our motivation for studying substituted biguanides stems from their potential as precursors of novel aminotriazines and from the possibility that the multiple sites of hydrogen bonding in the biguanides themselves may make them valuable components in supramolecular assembly. Unfortunately, despite the demonstrated utility of biguanides and the likelihood of new applications, few detailed syntheses and structural characterizations have been previously reported, and information about 1-aryl- and 1,5-diarylbiguanides remains

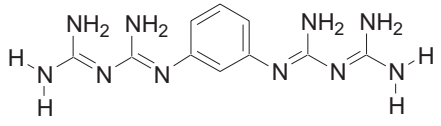
particularly sparse (17–38). To supply missing data and give other researchers a practical guide to the field, we report here the synthesis and full characterization of a series of arylbiguanides, along with crystal structures of representative compounds.

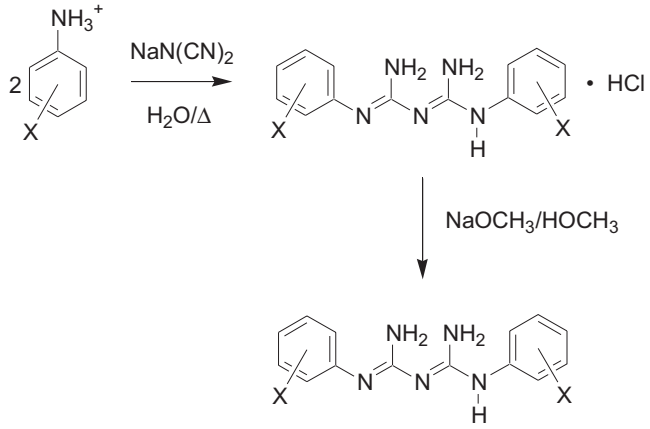


Results and discussion

Synthesis of 1-arylbiguanides

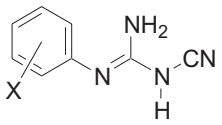
To synthesize monosubstituted 1-arylbiguanides, we used a modification of a procedure reported in a 1946 patent by Curd and Rose (23), who heated anilinium salts with dicyandiamide in water (Scheme 1). The hydrochloride salts of the arylbiguanides generally crystallize from the reaction mixture in good yield and in high purity, and they can be deprotonated with methanolic sodium methoxide in nearly quantitative yield. Detailed procedures for making 1-phenylbiguanide (**3**) and its hydrochloride salt by these methods are provided in the Experimental section, and other aryl-substituted derivatives can be made in the same way. When 1,4- or 1,3-phenylenediamine dihydrochloride reacted under these conditions with 2 equiv. of dicyandiamide, the corresponding bis(biguanide) (**4** or **5**) was obtained after deprotonation (39), whereas 1,2-phenylenediamine dihydrochloride gave 2-guanidinobenzimidazole (40).

4



5

Synthesis of 1,5-diarylbiguanides



1,5-Diarylbiguanides **6a–6j** could be synthesized in good yield by a one-pot procedure based on a method reported by Neelakantan (22), in which 2 equiv. of an anilinium chloride

Scheme 2.

6a (X = X' = H)

6c (X = X' = 3-CH_3)
6d (X = X' = 4-CH_3)
6e (X = X' = 4-OCH_3)
6f (X = X' = 4-CN)
6g (X = X' = 2-Br)
6h (X = X' = 4-Br)
6i (X = X' = 3,5-CH_3)
6j (X = X' = 2,4,6-CH_3)

are added to sodium dicyanamide in boiling water (Scheme 2). In the case of anilines with low solubility in water, the reaction can be performed in ethanol or in water–ethanol mixtures. Of all anilines tested, only 4-nitroaniline failed to give the desired product, presumably because its basicity and nucleophilicity are too low. A monosubstituted aryldicyandiamide (**7**) typically precipitated at an initial stage of each reaction, but the intermediate was eventually converted into the desired diarylbiguanide as its hydrochloride salt. It is possible to isolate the intermediate monoaryldicyandiamides and use them to synthesize unsymmetric 1,5-diarylbiguanides. For example, phenyldicyandiamide (**7**, X = H) was obtained in this way in 87% yield.

7

After the reaction of 2 equiv. of an anilinium chloride with sodium dicyanamide, the crude product typically consisted of the desired diarylbiguanide hydrochloride along with small amounts of the intermediate monoaryldicyandiamide. This impurity could be removed by dissolving the product in a small volume of DMF and then precipitating the biguanide hydrochloride by the addition of toluene. The resulting product normally required no further purification, but it could be recrystallized from hot water. Pure samples of the corresponding free base could be obtained in nearly quanti-

© 2005 NRC Canada

tative yield by treating the salt with methanolic sodium hydroxide.

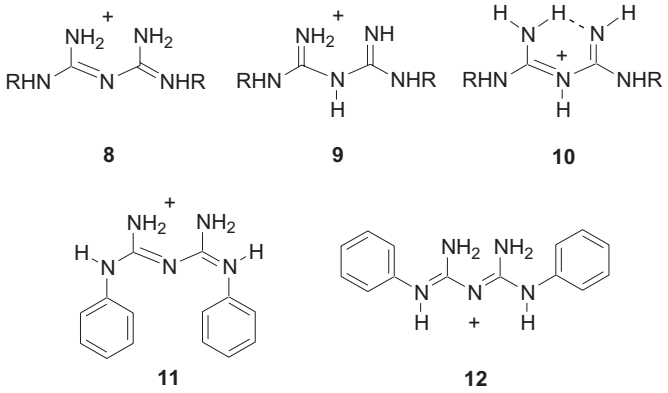
Spectroscopic characterization of arylbiguanides

Arylbiguanides typically have poor solubility in organic solvents and water, and DMSO-d_6 proved to be best suited for obtaining NMR spectra of most of the compounds synthesized. The -NH and -NH_2 protons in these compounds generally show broad, poorly resolved peaks in the range δ 5–9. However, the corresponding monohydrochloride salts produce spectra in which the -NH and -NH_2 signals are better resolved and easier to identify. In the salts, the aryl -NH protons tend to give rise to a singlet near δ 9 to 10, and -NH_2 groups yield signals in the range δ 7 to 8.

To assess the possible importance of slow interconversion of tautomers or slow rotations around C—N bonds, ^{1}H NMR spectra of 1,5-diphenylbiguanide (**6a**) and its hydrochloride salt were recorded in DMSO-d_6 at temperatures ranging from 298 to 378 K (see Supplementary material).[5] The spectra of both compounds are indeed temperature-dependent and become better resolved at higher temperatures, possibly because rotations or tautomeric interconversions are accelerated. Partial decomposition was noted in spectra of the free base recorded at higher temperatures.

In general, the hydrochloride salts of both 1-arylbiguanides and 1,5-diarylbiguanides gave well-resolved ^{13}C NMR spectra in DMSO-d_6 at 298 K. The biguanide carbons have characteristic chemical shifts in the range δ 155–165. In contrast, the ^{13}C NMR spectra of the corresponding free bases are less easy to analyze, and broad signals are often observed for the biguanide carbons.

FT-IR spectra of arylbiguanides and their monohydrochloride salts in KBr both show multiple strong broad bands in the range 2900–3300 cm^{-1}. In addition, the free bases exhibit a pair of sharper but weaker bands near 3440 and 3350 cm^{-1}, presumably owing to -NH_2 groups. In both the free bases and salts, strong C=N stretching bands normally appear near 1640–1610 cm^{-1}.



FAB and MAB mass spectra proved to be useful for characterizing arylbiguanides, and $[M + H]^+$ is typically the peak of highest intensity. Diagnostic fragments usually include $[M + H - NH_3]^+$, $[M + H - ArNH_2]^+$, $[M + H - ArNHCN]^+$, and $[M + H - ArN{=}C(NH_2)_2]^+$.

Crystal structures of 1,5-diphenylbiguanide (6a) and its monohydrochloride salt

Few structures of simple biguanidinium salts or biguanides have been reported (25–38), and in none of these cases have aryl groups been present at positions 1 and 5. As a result, we elected to determine the structures of 1,5-diphenylbiguanide (**6a**) and its monohydrochloride salt. The salt crystallized from hot water in the monoclinic space group $P2_1/n$ (Table 1).[5] The structure was determined by X-ray diffraction, and views of a single biguanidinium cation are shown in Fig. 1. The narrow range of guanidinium C—N bond lengths (1.343–1.394 Å) provides evidence of extensive delocalization, although the structure is not fully symmetric. It is noteworthy that the cation can be represented by localized structure **8** and its resonance hybrids, whereas alternatives in which the central nitrogen atom is protonated (**9**) or an intramolecular hydrogen bond is formed (**10**) are not favored in the solid state. Similar observations have been made in all previous structural studies of biguanidinium cations (25, 26, 28–34, 36–38), so protonation of biguanides to give struc-

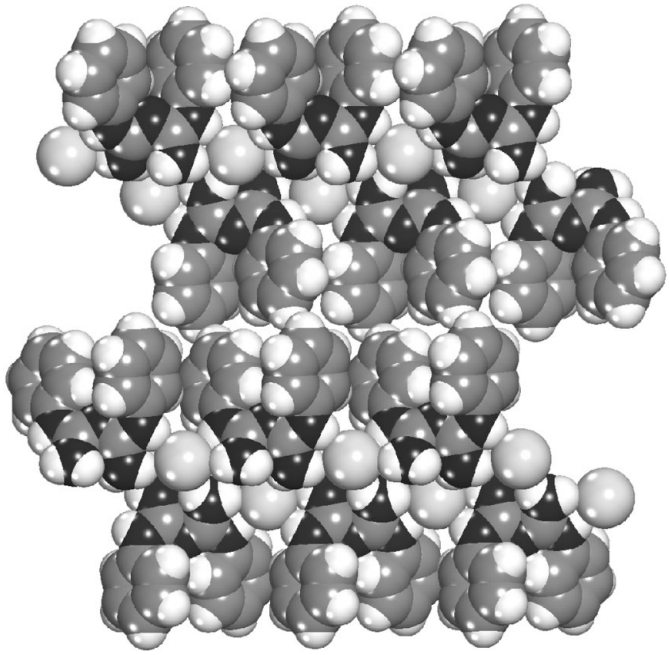

Fig. 1. Two views of the structure of individual biguanidinium cations in the crystals of the hydrochloride salt of 1,5-diphenylbiguanide (**6a**·HCl) grown from water. Hydrogen atoms appear in white, carbon atoms in gray, and nitrogen atoms in black. The upper view provides C—N bond lengths, and the lower view shows the intramolecular C-H···π interaction (broken line) present in the biguanidinium ion. All bond lengths are in Å (with standard deviations provided in the Supplementary material),[5] and the shortest C—C distance between the phenyl rings is used to define the aromatic interaction.

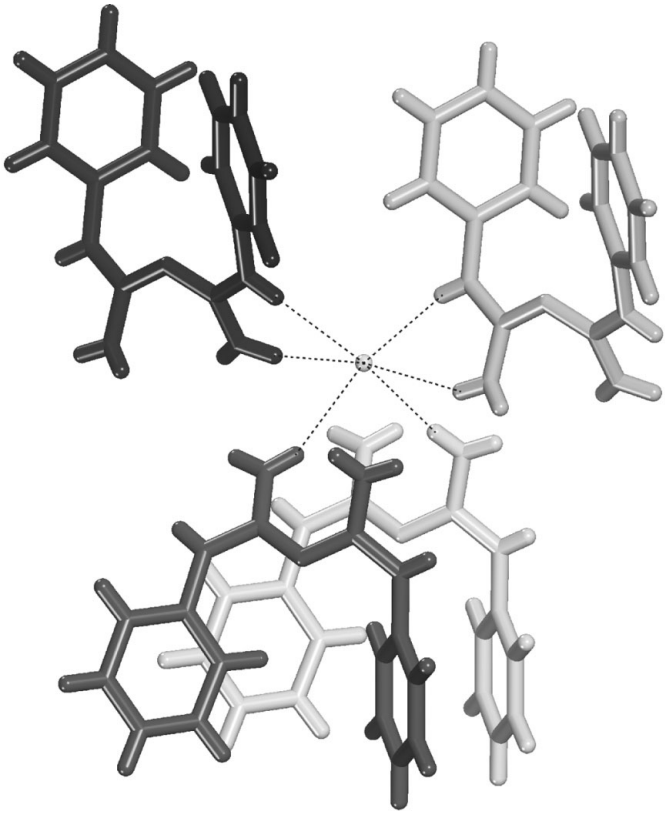
ture **8** appears to be a fundamental preference, both in the solid state and in solution (2).

The two guanidinium subunits that can be considered to make up the biguanidinium cation lie in two distinct planes that form an angle of 22.8(4)°. The nonplanarity of the biguanidinium core presumably reduces allylic strain while permitting a significant degree of conjugation. Again, similar observations have been made in all previous structural studies of biguanidinium salts, so nonplanarity of the

Fig. 2. View along the *b* axis of the structure of the crystals of the hydrochloride salt of 1,5-diphenylbiguanide (**6a**·HCl) grown from water. The image reveals bilayers with an ionic core and a hydrophobic exterior. The view shows a 3 × 1 × 1 array of unit cells with atoms represented by spheres of van der Waals radii. Hydrogen atoms appear in white, chlorine atoms in light gray, carbon atoms in dark gray, and nitrogen atoms in black.



biguanidinium core appears to be a universal characteristic. The two phenyl rings are tilted from the guanidinium planes by angles of 52.4(1)° and 39.5(1)°, and together they form an angle of 88.8(1)°, thereby permitting an intramolecular C-H···π interaction in which the shortest C—C distance is 3.773 Å (Fig. 1). This may explain why the 1,5-diphenylbiguanidinium cation adopts the compact conformation represented by structure **11**, rather than extended conformation **12**.

The crystal structure of diphenylbiguanidinium salt **6a**·HCl is closed-packed (Fig. 2) and can be considered to consist of bilayers, with hydrophilic biguanidium cations and chloride anions occupying the core and hydrophobic phenyl groups forming the exterior.[6] The bilayers then stack along the *c* axis. Within the core of each bilayer, the principal interactions are hydrogen bonds and ionic attractions between biguanidinium and chloride. The biguanidinium ions do not interact directly with each other by forming hydrogen bonds. The absence of inter-cationic hydrogen bonds has been noted in most other biguanidinium salts (28, 29, 31, 34, 36–38), but they are nevertheless present in certain cases (25, 26, 32). Each chloride ion accepts a total of six hydrogen bonds from four neighboring biguanidinium cations (Fig. 3), two of which chelate chloride by donating two hydrogen bonds and two of which each contribute a single hydrogen bond. In turn, each biguanidinium cation forms hydrogen bonds with a total of four neighboring chloride ions, of which two are chelated and the others each accept a

[6] A similar bilayer organization has been noted in the structure of the monohydrochloride salt of phenformin (**13**) (32).

© 2005 NRC Canada

Fig. 3. View of the structure of the crystals of the hydrochloride salt of 1,5-diphenylbiguanide (**6a**·HCl) showing how each chloride anion is surrounded by four biguanidinium cations and accepts six ionic N-H···Cl hydrogen bonds (broken lines). Two biguanidinium cations chelate chloride and two donate single hydrogen bonds.

single hydrogen bond. Similar interactions between biguanidinium ions and halide have been observed previously (25, 28, 31, 34, 36–38). In addition, the phenyl groups of each biguanidinium cation engage in multiple aromatic contacts or interactions with phenyl groups provided by neighboring cations (Fig. 4). In total, each biguanidinium cation has four face-to-face and six edge-to-face aromatic contacts with six neighbors.

The corresponding free base (1,5-diphenylbiguanide (**6a**)) crystallized from hot ethanol in the monoclinic space group *Pc*, and one of two symmetry-independent molecules in the unit cell is shown in Fig. 5.[5] The other molecule is closely similar and is not illustrated. Unlike the twisted biguanidinium cation, the biguanide unit has a roughly planar geometry, maintained by an intramolecular N-H···N hydrogen bond (2.06(1) Å). Similar features appear in all previous structural studies of biguanides (27, 33, 34), so a nearly planar geometry and an intramolecular hydrogen bond appear to be fundamental preferences. The C—N bond lengths within the biguanide unit range from 1.294(8) to 1.406(8) Å, suggesting significant delocalization of C—N single and double bonds, but slightly less than in the corresponding biguanidinium salt. Unlike the salt, free base **6a** favors a conformation in which no intramolecular aromatic interactions are present.

Like the corresponding biguanidinium salt, biguanide **6a** forms a closed-packed layered structure consisting of alternating hydrophobic and hydrophilic domains (Fig. 6). In the free base **6a**, however, the neutral biguanide units interact directly by hydrogen bonding. Each molecule donates two hydrogen bonds to one neighbor and accepts two hydrogen bonds from another, thereby forming a corrugated ribbon (Fig. 7). Similar intermolecular hydrogen bonding has been previously observed in the structures of biguanide (**1**) and 1-phenylbiguanide (**3**) (27, 33, 34). Curiously, the donor sites that form the shortest intermolecular hydrogen bonds are the $-NH_2$ groups already involved as donors in intramolecular hydrogen bonding. As expected, one of the acceptor sites is the unprotonated central nitrogen atom in each biguanide unit. The other acceptor site is the nitrogen atom of the $-NH_2$ group not involved in intramolecular hydrogen bonding, which forms the longest C—N bond in the biguanide unit (1.406 Å).

Individual corrugated ribbons formed by intermolecular hydrogen bonding form face-to-face aromatic interactions and stack along the *ab* diagonal to create layers (Fig. 8*a*). Stacking of the layers along the *c* axis then permits the formation of multiple C-H···π interactions (Fig. 8*b*), with the shortest C—C distances ranging from 3.600 to 3.764 Å.

Conclusions

Biguanides are an intrinsically interesting class of compounds with many known or potential applications. Despite these attractive properties, biguanides remain poorly studied. Few detailed procedures for their synthesis have been published, and full spectroscopic characterizations and structural studies are rare. As a practical guide to assist other researchers interested in using biguanides, we have summarized our experience with 1-arylbiguanides, 1,5-diarylbiguanides, and their monohydrochloride salts. Various substituted derivatives can be synthesized in good yields and high purity by simple methods based on published procedures, and these compounds can be fully characterized by standard spectroscopic methods. Structural analyses of representative compounds by X-ray diffraction confirm that arylbiguanides and their salts can form networks held together by characteristic patterns of hydrogen bonds. As a result, arylbiguanides and their salts show promise as components in supramolecular construction.

Experimental

Anilines were purified by recrystallization or distillation prior to use. All other reagents were commercial products that were used without further purification. All NMR spectra were recorded at 298 K unless noted otherwise. Mass spectra are provided only for the neutral biguanides.

1-Phenylbiguanide (3·HCl)

In a 2 L round-bottomed flask equipped with a magnetic stirrer, aniline (91.3 mL, 93.3 g, 1.00 mol) was added to aq. HCl (1 L, 1 mol/L), and the mixture was stirred until it became homogeneous. Dicyandiamide (84.1 g, 1.00 mol) was then added, and the mixture was heated at reflux with constant stirring for 12 h. The mixture was cooled to 25 °C, and

1,4-Phenylenebis(biguanide) (4·2HCl)

In a 250 mL round-bottomed flask equipped with a magnetic stirrer, 1,4-phenylenediamine (5.24 g, 48.5 mmol) was added to aq. HCl (96 mL, 1.0 mol/L, 96 mmol). Dicyandiamide (8.15 g, 96.9 mol) was then added, and the mixture was heated at reflux for 3 h. Solvent was then removed by evaporation under reduced pressure, and the residual oil was triturated with hot ethanol. The resulting solid was separated by filtration, washed with hot ethanol, and crystallized from water–acetone. The crystals were separated by filtration, washed with acetone, and dried under reduced pressure to provide pure 1,4-phenylenebis(biguanide) (**4**) dihydrochloride (10.3 g, 29.5 mmol, 61%) as a colorless solid, mp 254 to 255 °C (lit. value (39) mp 270–278 °C (dec.)). IR (KBr, cm^{-1}): 3428 (m), 3302 (s), 3186 (s), 3153 (s), 1632 (s), 1547 (s), 1497 (s), 1415 (s), 1377 (m), 1295 (w), 1240 (m), 1017 (m), 826 (m), 717 (m). ^{1}H NMR (300 MHz, DMSO-d_6) δ: 9.74 (s, 2H), 7.26 (s, 12H), 7.04 (s, 4H). ^{13}C NMR (75 MHz, DMSO-d_6) δ: 161.8, 156.4, 135.1, 122.4. Anal. calcd. for $C_{10}H_{18}Cl_2N_{10}$·1/4H_2O: C 33.95, H 5.27, N 39.60; found: C 34.17, H 5.56, N 39.60.

1,3-Phenylenebis(biguanide) (5·2HCl)

Applied to 1,3-phenylenediamine (5.24 g, 48.5 mmol), the preceding method gave pure 1,3-phenylenebis(biguanide) (**5**) dihydrochloride (8.59 g, 24.6 mmol, 51%) as a colorless solid, mp 220 to 221 °C. IR (KBr, m^{-1}): 3313 (s), 3148 (s), 1654 (s), 1544 (s), 1454 (m), 1382 (m), 1278 (w), 1193 (w), 1083 (w), 1045 (w), 920 (w), 780 (w), 733 (w). ^{1}H NMR (300 MHz, DMSO-d_6) δ: 9.78 (s, 2H), 7.34 (s, 8H), 7.21–7.08 (m, 4H), 7.05 (s, 4H). ^{13}C NMR (75 MHz, DMSO-d_6) δ: 162.0, 156.0, 139.8, 129.6, 116.7, 114.0. Anal. calcd. for $C_{10}H_{18}Cl_2N_{10}$: C 34.39, H 5.20; found: C 34.27, H 5.59.

1,4-Phenylenebis(biguanide) (4)

In a 100 mL round-bottomed flask equipped with a magnetic stirrer, the dihydrochloride of 1,4-phenylenebis(biguanide) (**4**, 1.05 g, 3.01 mmol) was added to a mixture of methanol (20 mL) and methanolic $NaOCH_3$ (1.6 mL, 25% by weight, 7.0 mmol). The resulting mixture was stirred at 25 °C for 1 h. The precipitate was separated by filtration, washed with cold water (10 mL) and ethanol (10 mL), and dried under reduced pressure to give pure 1,4-phenylenebis(biguanide) (**4**, 0.741 g, 2.68 mmol, 89%) as a colorless solid, mp 218 to 219 °C (lit. value (39) mp 218 to 219 °C (dec.)). IR (KBr, cm^{-1}): 3467 (m), 3434 (m), 3357 (m), 3329 (m), 3159 (m), 1641 (s), 1614 (s), 1548 (s), 1520 (s), 1493 (s), 1399 (s), 1378 (s), 1242 (s), 1090 (w), 883 (m), 840 (w), 758 (w), 722 (w). ^{1}H NMR (300 MHz, D_2O) δ: 6.86 (s, 4H). ^{13}C NMR (75 MHz, D_2O) δ: 159.8, 159.4, 142.0, 124.8. FAB-MS (3-nitrobenzyl alcohol) *m/e*: 277. FAB-HR-MS (3-nitrobenzyl alcohol) calcd. for $C_{10}H_{17}N_{10}$ *m/e*: 277.1638; found: 277.1649. Anal. calcd. for $C_{10}H_{16}N_{10}$·H_2O: C 40.81, H 6.16, N 47.59; found: C 40.68, H 6.19, N 47.17.

1,3-Phenylenebis(biguanide) (5)

Applied to the dihydrochloride of 1,3-diphenylenebis(biguanide) (**5**), the preceding method gave pure 1,3-phenylenebis(biguanide) (**5**) as a colorless solid, mp 206 °C (dec.). IR (KBr, cm^{-1}): 3479 (m), 3428 (m), 3335 (m), 3109 (m), 1610 (s), 1517 (s), 1470 (s), 1369 (s), 1284 (m), 1186 (m). ^{1}H NMR (300 MHz, D_2O) δ: 7.15 (t, ^3J = 7.8 Hz, 1H), 6.57 (dd, ^4J = 2.1 Hz, ^3J = 7.8 Hz, 2H), 6.46 (t, ^3J = 2.1 Hz, 1H). ^{13}C NMR (75 MHz, D_2O) δ: 159.7, 159.1, 148.3, 130.8, 118.6, 118.3. FAB-MS (3-nitrobenzyl alcohol) *m/e*: 277, 218. TOF-HR-MS calcd. for $C_{10}H_{17}N_{10}$ *m/e*: 277.1632; found: 277.1631. Anal. calcd. for $C_{10}H_{16}N_{10}$·1.5H_2O: C 39.60, H 6.31; found: C 39.79, H 5.97.

1,5-Diphenylbiguanide (6a·HCl)

In a 250 mL round-bottomed flask equipped with a magnetic stirrer, aniline (9.31 g, 100 mmol) was added to aq. HCl (100 mL, 1 mol/L, 100 mmol). The mixture was stirred until it became homogeneous. Sodium dicyanamide (4.45 g, 50.0 mol) was then added and the mixture was heated at reflux. Within 1 h, phenyldicyandiamide (**7**, X = H) had precipitated from the mixture and heating was continued. After a total of 12 h, the mixture was cooled to 25 °C, and the precipitate was separated by filtration, washed with water, and dried under reduced pressure. The solid was dissolved in hot DMF (20 mL) and toluene (150 mL) was then added, causing the formation of a gel-like precipitate. The precipitate was separated by filtration and washed successively with toluene, hexane, and water. The product could be used without further treatment, but further purification could be achieved by crystallization from hot water, which provided the monohydrochloride of 1,5-diphenylbiguanide (**6a**, 10.1 g, 34.9 mmol, 70%) as a colorless solid, mp 230–232 °C (lit. value (41) mp 232 °C; lit. value (22) mp 220 °C). IR (KBr, cm^{-1}): 3401 (w), 3307 (m), 3181 (w), 3120 (w), 1629 (m), 1602 (m), 1577 (m), 1519 (s), 1489 (m), 1445 (m), 1382 (w), 1245 (w), 754 (w), 732 (w), 688 (w). ^{1}H NMR (300 MHz, DMSO-d_6) δ: 9.90 (s, 2H), 7.44 (s, 4H), 7.29 (m, 8H), 7.08 (m, 2H). ^{13}C NMR (75 MHz, DMSO-d_6) δ: 157.7, 138.8, 129.7, 125.0, 122.4. Anal. calcd. for $C_{14}H_{16}ClN_5$: C 58.03, H 5.57, N 24.17; found: C 57.94, H 5.67, N 24.20.

The monohydrochloride salts of 1,5-bis(2-methylphenyl)biguanide (**6b**), 1,5-bis(3-methylphenyl)biguanide (**6c**), 1,5-bis(4-methylphenyl)biguanide (**6d**) (41), 1,5-bis(4-methoxyphenyl)biguanide (**6e**) (41, 42), 1,5-bis(4-cyanophenyl)biguanide (**6f**), 1,5-bis(2-bromophenyl)biguanide (**6g**), 1,5-bis(4-bromophenyl)biguanide (**6h**) (42), 1,5-bis(3,5-dimethylphenyl)biguanide (**6i**), and 1,5-bis(2,4,6-trimethylphenyl)biguanide (**6j**) were prepared in the same way. Yields, melting points, spectroscopic data, and elemental analyses are provided in the Supplementary material.[5]

1,5-Diphenylbiguanide (6a)

In a 200 mL round-bottomed flask equipped with a magnetic stirrer, the monohydrochloride of 1,5-diphenylbiguanide (8.69 g, 30.0 mmol) was added to a mixture of methanol (60 mL) and methanolic $NaOCH_3$ (8.2 mL, 25% by weight, 36 mmol). The mixture was stirred at 25 °C for 1 h and then water was added. The resulting precipitate was separated by filtration, washed with water, and dried under reduced pressure to give 1,5-diphenylbiguanide (**6a**, 7.30 g, 28.8 mmol, 96%) as a colorless solid, mp 147 to 148 °C (dec.) (lit. value (41) mp 145 to 146 °C). IR (KBr, cm^{-1}): 3439 (m), 3351 (m), 3214 (m), 3071 (m), 1621 (s), 1593 (m), 1544 (s), 1522 (s), 1495 (m), 1481 (m), 1443 (m), 1380 (m), 1349 (s), 1289 (w), 1231 (s), 1155 (w), 1067 (w), 757 (m), 738 (m), 716 (m), 688 (m), 611 (m). ^{1}H NMR

(400 MHz, DMSO-d_6) δ: 7.24 (m, 8H), 6.93 (m, 2H), 9–5 (bs, 5H). ^{13}C NMR (75 MHz, DMSO-d_6) δ: 156.6, 146.0, 129.7, 122.3. FAB-MS (3-nitrobenzyl alcohol) *m/e*: 254, 237, 161, 136, 119. FAB-HR-MS (3-nitrobenzyl alcohol) calcd. for $C_{14}H_{16}N_5$: 254.1406; found: 254.1402. Anal. calcd. for $C_{14}H_{15}N_5$: C 66.38, H 5.97, N 27.65; found: C 66.41, H 6.05, N 27.80.

1,5-Bis(2-methylphenyl)biguanide (**6b**), 1,5-bis(3-methylphenyl)biguanide (**6c**), 1,5-bis(4-methylphenyl)biguanide (**6d**) (41), 1,5-bis(4-methoxyphenyl)biguanide (**6e**), 1,5-bis(4-cyanophenyl)biguanide (**6f**) (43), bis(2-bromophenyl)biguanide (**6g**), 1,5-bis(4-bromophenyl)biguanide (**6h**), 1,5-bis(3,5-dimethylphenyl)biguanide (**6i**), and 1,5-bis(2,4,6-trimethylphenyl)biguanide (**6j**) were prepared in similar yields in the same way. Yields, melting points, spectroscopic data, and elemental analyses are provided in the Supplementary material.[5]

Phenyldicyandiamide (7, X = H)

In a 100 mL round-bottomed flask equipped with a magnetic stirrer, aniline (2.45 g, 26.3 mmol) was added to aq. HCl (25 mL, 1 mol/L, 25 mmol) and the mixture was stirred until it became homogeneous. Sodium dicyanamide (2.23 g, 25.0 mmol) was then added and the mixture was heated at reflux for 2 h with constant stirring. During this period the product precipitated, and it was separated by filtration and recrystallized from CH_3CH_2OH to give pure phenyldicyandiamide (**7**, X = H; 3.49 g, 21.8 mol, 87%) as a colorless solid, mp 197 to 198 °C (lit. value (41) mp 196 to 197 °C). IR (KBr, cm^{-1}): 3407 (m), 3319 (m), 3215 (m), 3154 (m), 2973 (m), 2176 (s), 2143 (m), 1660 (m), 1608 (m), 1585 (s), 1555 (s), 1495 (s), 1449 (m), 1393 (s), 1298 (m), 1208 (m), 1065 (m), 1051 (s), 895 (w), 744 (m), 714 (m), 686 (w), 637 (w). ^{1}H NMR (300 MHz, DMSO-d_6) δ: 9.03 (s, 1H), 7.35 (d, ^3J = 8.4 Hz, 2H), 7.30 (t, ^3J = 7.0 Hz, 2H), 7.07 (t, ^3J = 7.0 Hz, 1H), 6.98 (s, 2H). ^{13}C NMR (75 MHz, DMSO-d_6) δ: 160.4, 138.8, 129.7, 124.6, 122.2, 118.1. MAB-HR-MS (N_2) calcd. for $C_8H_8N_4$ *m/e*: 160.0749; found: 160.0750. Anal. calcd. for $C_8H_8N_4$: C 59.99, H 5.03, N 34.98; found: C 60.07, H 5.13, N 35.20.

X-ray crystallographic studies

The structures were solved by direct methods using SHELXS-97 (44) and refined with SHELXL-97 (45). All non-hydrogen atoms were refined anisotropically. Hydrogen atoms were refined as riding atoms. They were located by a difference Fourier map for compound **6a**·HCl, whereas they were placed in ideal positions for compound **6a**.

Crystallization of compounds 6a and 6a·HCl

Single crystals of compound **6a**·HCl suitable for analysis by X-ray diffraction were grown from hot water, and crystals of free base **6a** were grown from hot ethanol.

Acknowledgments

We are grateful to the Natural Sciences and Engineering Research Council of Canada (NSERC), the Ministère de l'Éducation du Québec, the Canada Foundation for Innovation, the Canada Research Chairs Program, and Merck Frosst for financial support.

In addition, we thank Professor Jurgen Sygusch for providing access to a Bruker SMART 6000 CCD diffractometer equipped with a rotating anode.

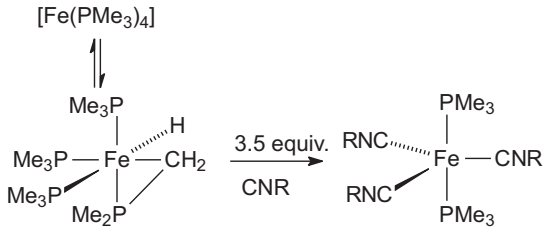
Kinetics and mechanism of dealkylation of coordinated isocyanide in $Fe(PMe_3)_2(t\text{-}BuNC)_3$[1]

Christine L. Tennent and William D. Jones

Abstract: The zerovalent iron complex $Fe(PMe_3)_2(t\text{-}BuNC)_3$ undergoes thermal cleavage of the C—N bond to give $Fe(PMe_3)_2(t\text{-}BuNC)_2(H)(CN)$ and isobutylene. The reaction follows first order kinetics, and addition of the hydrogen-atom donor 1,4-cyclohexadiene leads to the preferential formation of isobutane rather than isobutylene. Mechanistic studies are consistent with a rate determining homolysis of the C—N bond, giving rise to *tert*-butyl radicals.

Key words: iron, isocyanide, elimination, C—N cleavage.



Résumé : Le complexe ferrique zérovalent, $Fe(PMe_3)_2(t\text{-}BuNC)_3$, subit un clivage thermique de la liaison C—N et génère le $Fe(PMe_3)_2(t\text{-}BuNC)_2(H)(CN)$ et l'isobutylène. La réaction suit une cinétique du premier ordre, et l'addition du cyclohexadiène-1,4 comme source d'hydrogène mène à la formation préférentielle de l'isobutane plutôt que l'isobutylene. Les modèles mécanistes sont conformes à l'homolyse cinétiquement déterminante de la liaison C—N menant à la formation de radicaux de *tert*-butyl.

Mots clés : fer, isocyanure, élimination, clivage de la liaison C—N.

Introduction

Rathke and Muetterties (1) and Klein and co-workers (2), in independent studies, reported the synthesis of the complex $[Fe(PMe_3)_4]$, which was found to be in equilibrium with the intramolecular oxidative addition adduct $Fe(\eta_2\text{-}PMe_2CH_2)(PMe_3)_3H$. The reaction of this complex with σ-donor ligands and oxidative addition substrates gave evidence of this facile equilibrium (3). The preparation and structural examination of a series of low-valent iron phosphine isocyanide complexes using the above mentioned reactive iron species has been reported by our laboratory by the reaction of this reactive species with a variety of isocyanides (eq. [1]) (4). This article addresses the C—N cleavage reaction that is seen in one of these derivatives, $Fe(PMe_3)_2(t\text{-}BuNC)_3$ (**1**).

[1]

R = Me, Et, *i*-Pr, *t*-Bu, CH_2CMe_3, Ph, 2,6-xylyl

Several isocyanides were used, and all of the resulting complexes were found to be extremely air sensitive. Most of the complexes were found to be moderately thermally stable at room temperature. Stability was found to decrease in the sequence 2,6-xylyl > Ph > CH_2CMe_3 > *t*-Bu > Me > > *i*-Pr > Et. The reaction of the isocyanides where R = *i*-Pr and Et did not give an isolable crystalline product. The complex $Fe(PMe_3)_2(t\text{-}BuNC)_3$ could be isolated as a yellow crystalline solid, but was found to decompose at 25 °C over several days.

All of these complexes have similar ^1H NMR spectra with resonances for three equivalent isocyanide ligands and a pseudotriplet (5) for the two equivalent trimethylphosphine ligands. This suggests a trigonal-bipyramidal geometry, which was confirmed by X-ray crystallography for R = CH_2CMe_3, Ph, and 2,6-xylyl. An interesting observation is the severe bending of the C-N-C linkage in each of these complexes (Table 1). The general tendancy is for two of the isocyanides to display a higher degree of bending than the third. In the case of phenyl isocyanide, crystal packing forces one isocyanide ligand to be crystallographically linear and the remaining two ligands must then take up the excess metal electron density by π-back-bonding, resulting in the bent C-N-C. The other isocyanide complexes listed in Table 1 also show this pattern. The trimethylphosphine ligands always occupy the axial positions.

Benzene solutions of the $Fe(PMe_3)_2(CNR)_3$ complexes, when treated with the corresponding free isocyanide at 25 °C, were found to be in equilibrium with their mono- and disubstituted complexes (eq. [2]). The equilibrium constants

Table 1. C-N-C bond angles in iron isocyanide complexes (4).

Molecule	Angle C-N-C (°)
$Fe(PMe_3)_2(CNCH_2CMe_3)_3$	140, 146, 166
$Fe(PMe_3)_2(CNPh)_3$	131.8, 131.8, 180
$Fe(PMe_3)_2$(CN-2,6-xylyl)$_3$	147.7, 149.8, 161.3
$Fe(PMe_3)$(CN-2,6-xylyl)$_4$	174.5, 167.9, 166.7, 145.1

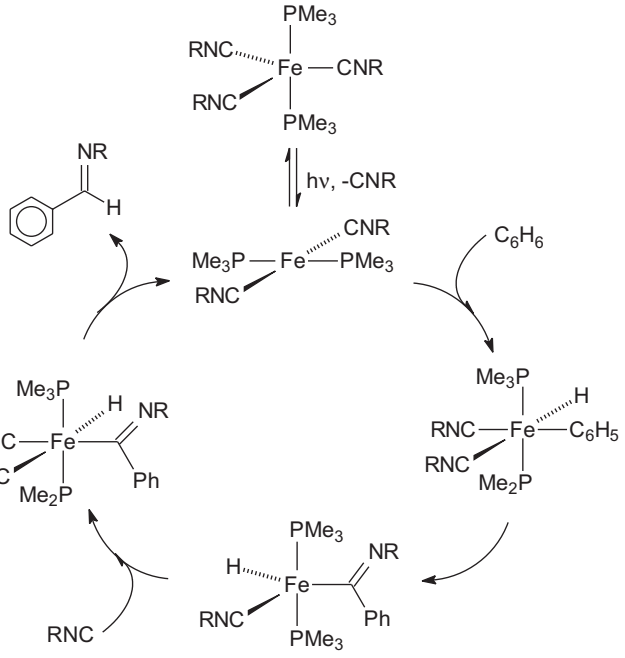
were found by comparison of the ^{1}H NMR integrations of the free and coordinated isocyanide and PMe_3 resonances. For R = *tert*-butyl, K_1 = 0.035(5) and K_2 = 0.0079(24). The equilibria for the other isocyanides were similar.

[2] $Fe(PMe_3)_2(CNR)_3 \underset{-PMe_3}{\overset{K_1 \ +CNR}{\rightleftharpoons}} Fe(PMe_3)(CNR)_4 \underset{K_2 \ -PMe_3}{\overset{+CNR}{\rightleftharpoons}} Fe(CNR)_5$

Irridation of a benzene solution of $Fe(PMe_3)_2(CNCH_2CMe_3)_3$ in the presence of excess PMe_3 resulted in the formation of a new species assigned the formula $Fe(PMe_3)_4(CNCH_2CMe_3)$ based on the ^{1}H NMR spectrum and the couplings observed (eq. [3]). All PMe_3 ligands were equivalent, suggesting the d^8 complex is fluxional.

[3] $Fe(PMe_3)_2(CNR)_3 \xrightarrow[PMe_3]{h\nu} Fe(PMe_3)_4(CNR)$

R = CH_2CMe_3



Dilute benzene solutions of $Fe(PMe_3)_2(CNCH_2CMe_3)_3$ upon irradiation gave the isocyanide insertion product, aldimine $PhCH{=}NCH_2CMe_3$, and $Fe(PMe_3)_3(CNCH_2CMe_3)_2$ (6). The reaction was found to be catalytic in iron when low concentrations of isocyanide are present. The two photochemical reactions of the neopentylisocyanide complex suggest the photochemical labilization of the isocyanide ligand. The proposed mechanism for the isocyanide insertion is shown in Scheme 1.

Results

Thermal reaction of $Fe(PMe_3)_2$(*t*-BuNC)$_3$

A benzene-d_6 solution of $Fe(PMe_3)_2$(*t*-BuNC)$_3$ (**1**), upon heating at 60 °C for 24 h, showed a gradual bleaching of its yellow color accompanied by a change in the ^{1}H NMR spectrum. A decrease of the resonances of **1** at δ 1.26 (s, 27H) and 1.55 (pseudo t, *J* = 4 Hz, 18H) was observed, while new resonances for $Fe(PMe_3)_2$(*t*-BuNC)$_2$(H)(CN) (**2**) as well as free isobutylene (δ 4.73, m, 1H; 1.58, m, 6H) appeared (eq. [4]). Cis and trans isomers of **2** are observed in a 10:1 ratio. The ratio is invariant over time. The resonances for the cis isomer appear at δ 1.51 (pseudo t, *J* = 4 Hz, 18H), 1.10 (s, 9H), 0.97 (s, 9H), and –10.6 (t, *J* = 56 Hz, 1H) while the resonances for the trans isomer are observed at δ 1.48 (pseudo t, *J* = 4 Hz, 18H), 1.06 (s, 18H), and –13.8 (t, *J* = 44 Hz, 1H). In a reaction run at room temperature over several months, only *cis*-**2** was seen. Heating the solution to 60 °C led to an equilibration with *trans*-**2**, indicating that *cis*-**2** is the initial kinetic product of the reaction. The reaction is quantitative as judged by ^{1}H NMR spectroscopy.

10 : 1, *cis* : *trans*

It has been observed that at room temperature in the solid state, **1** will also react thermally to give **2**. After several months, approximately 10% of **2** had formed. Analysis for isobutylene was not done. If the material is kept at low temperatures (<20 °C), no significant formation of **2** is observed.

Kinetics of the reaction of $Fe(PMe_3)_2$(*t*-BuNC)$_3$

UV–vis spectroscopy was found to be a convenient method for determining the rate of the isocyanide cleavage reaction. The UV–vis spectrum of **1** had two broad but well defined maxima at 309 and 390 nm, which, upon thermolysis (formation of **2**), decrease to baseline. The band at 390 nm was used for kinetic studies, as it was farthest from the large solvent absorption.

The effect of concentration of **1** on the rate of the reaction was examined in the range of $1 \times 10^{-4} - 9 \times 10^{-4}$ mol/L, as indicated in Table 2. The rate constant was found to be independent of [**1**], although a rather large variation (10%) in k_{obs} was observed (k_{obs} = 4.2 (0.4) $\times 10^{-5}$ s^{-1}).

0.98	0	DMSO	30.6(0.10)

Note: * = standard deviation for multiple runs. All others are first order fits for single determination.

The rate of the reaction was measured for temperatures ranging from 50 to 85 °C. An Eyring plot of these results gave $\Delta H^{\ddagger}$ = 26(1) kcal/mol and $\Delta S^{\ddagger}$ = 15(3) eu (Fig. 1). The value of 26(1) kcal/mol for the bond breakage of the C—N bond of coordinated isocyanide is not surprising considering the high stability of the -CN ligand that remains intact.

The rate of isobutylene elimination was examined in both low polarity (iso-octane) and high polarity (DMSO) solvents. The same reaction products were observed in each solvent. The resulting k_{obs} were found to be 4.2×10^{-5} and 30.6×10^{-5} s^{-1}, respectively, indicating only a small solvent effect (7×) on the rate of the reaction.

The effect of added PMe_3 on the rate of the reaction was also examined. Solutions of **1** containing trimethylphosphine in concentrations ranging from 0 to 0.97 mol/L were employed. The rates of disappearance of **1** were found to be comparable, within experimental error (Table 2). One interesting observation was that additions of small amounts of trimethylphosphine to the reaction resulted in smaller standard deviations in the k_{obs} than found using no trimethylphosphine.

Several benzene-d_6 solutions of **1** were made with varying amounts of the radical trap 1,4-cyclohexadiene. The samples were examined by ^{1}H NMR spectroscopy after heating at 67 °C for 24 h, showing the formation of both isobutylene and isobutane, plus benzene and **2**. The ratio of isobutane to isobutylene is given in Table 3 for various diene concentrations. Once again, the scatter in the data is large, but a general trend can be noted. As the amount of added 1,4-cyclohexadiene was increased, more isobutane was produced relative to isobutylene.

Fig. 1. Eyring plot for the elimination of isobutylene from $Fe(PMe_3)_2(t\text{-BuNC})_3$.

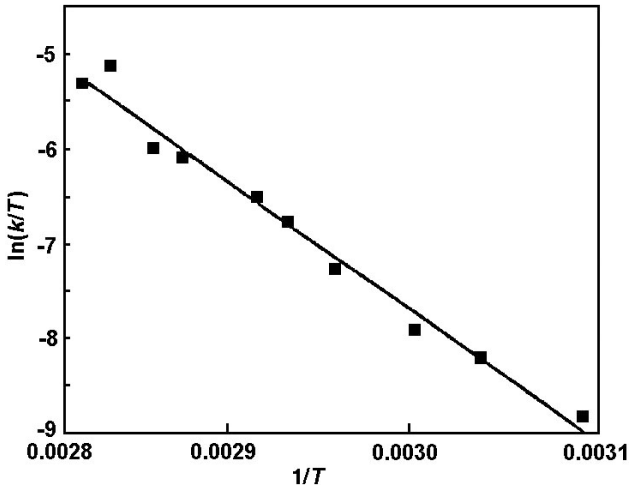

Table 3. Radical trap data for elimination of isobutylene from **1**.

[1,4-Cyclohexadiene] (mol/L)	Solvent	Isobutane/ isobutylene

0.3	Benzene	1.04
0.3	Benzene	0.51
0.4	Benzene	0.80
0.4	Benzene	0.80
0.6	Benzene	1.32
0.6	Benzene	0.82
0.6	Benzene	0.89
0.7	Benzene	0.96
2.0	Benzene	3.54
2.0	Benzene	3.17
10.6	1,4-Cyclohexadiene	3.54

In an attempt to determine if a solvent cage reaction was occurring, a sample was made in neat 1,4-cyclohexadiene. Samples of **1** in benzene or neat 1,4-cyclohexadiene were made as described in the Experimental section. The volatiles from the samples after heating for 14 h at 67 °C were examined by ^{1}H NMR spectroscopy. The benzene samples showed the trend previously observed; that is, an increase in [1,4-cyclohexadiene] gave a decrease in the amount of isobutylene produced. However, the sample made in neat 1,4-cyclohexadiene gave approximately 25% isobutylene (see Table 3).

The partially labeled compound $Fe(PMe_3)_2[CNC(CH_3)(CD_3)_2]_3$ was synthesized to measure the kinetic isotope effect of C—H vs. C—D elimination. Benzene solutions containing $Fe(PMe_3)_2(t\text{-BuNC-}d_6)_3$ were heated for 24 h at 67 °C in resealable NMR tubes. The reaction was complete after 24 h. The volatiles from the samples were then analyzed by GC–MS using low ionizing voltages to determine the ratio of d_6 to d_5 isobutylene, which was found to be 0.56(0.01). The statistically corrected isotope effect k_H/k_D is

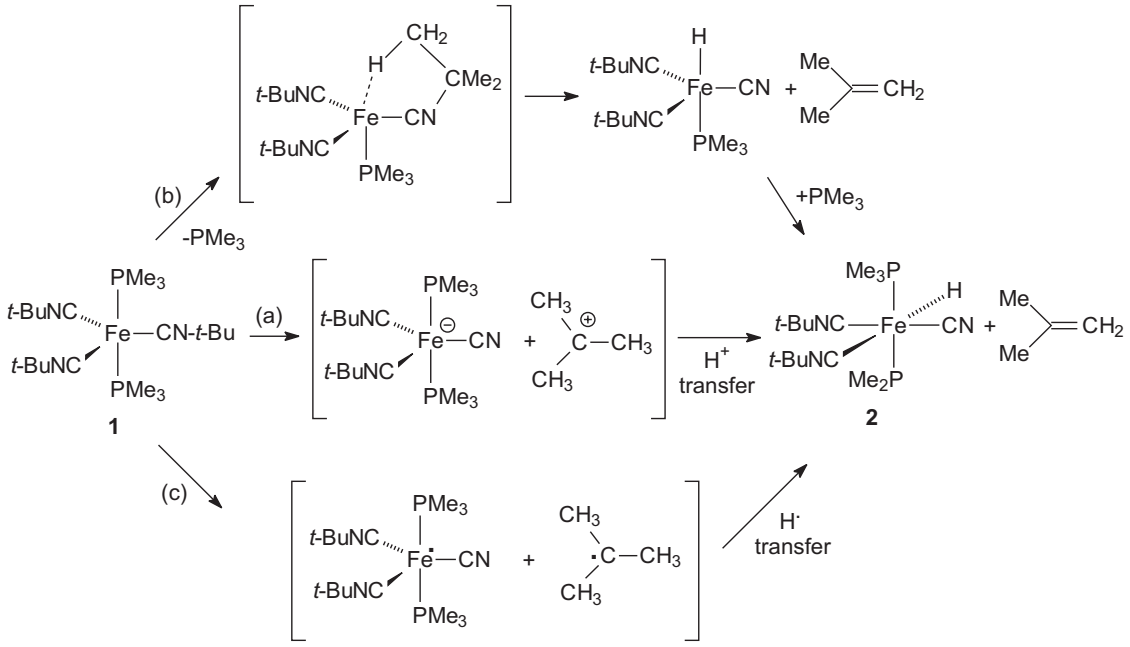

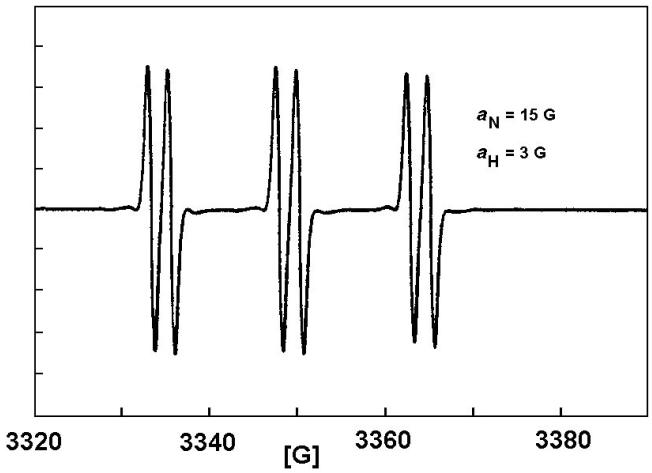

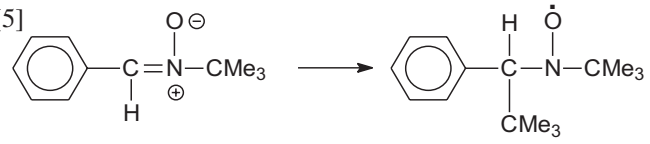

Fig. 2. ESR spectrum upon addition of *N-tert*-butyl-α-phenylnitrone (PBN) to a sample of **1** in benzene.

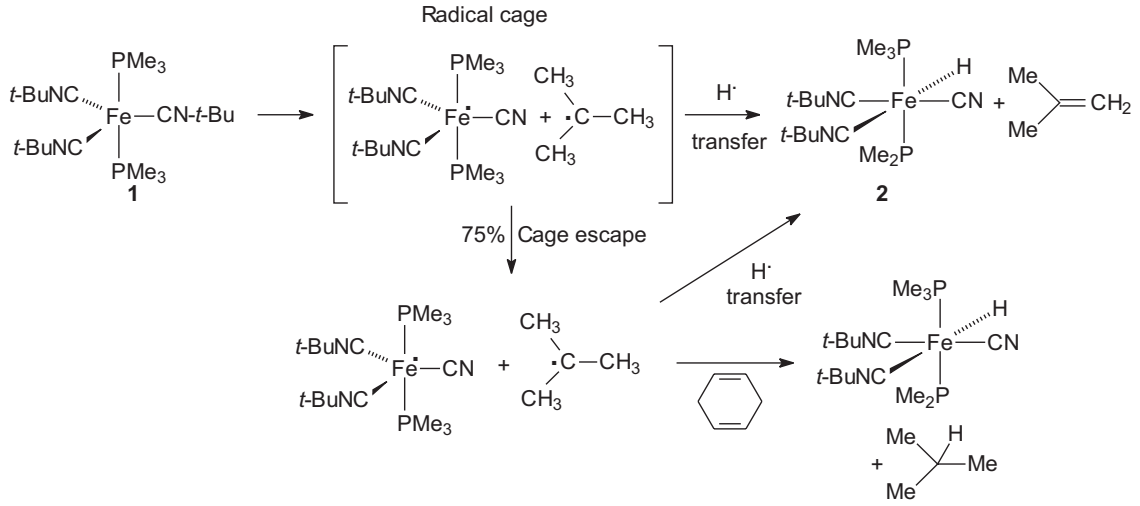
therefore 1.12. The overall k_{obs} for the reaction was observed to be approximately the same as for the nondeuterated material.

Addition of *N-tert*-butyl-α-phenylnitrone (PBN) to a sample of **1** in benzene showed an immediate ESR signal (Fig. 2). The signal intensity increased after heating, giving a strong triplet of doublets with a_H = 3 G and a_N = 15 G. These coupling values are reasonable for a *tert*-butyl radical coupled with PBN (eq. [5]) (7).

[5]

+ $Fe(PMe_3)_2(t\text{-BuNC})_3$

Discussion



The thermal reaction of $Fe(PMe_3)_2(t\text{-BuNC})_3$ (**1**) gives the products $Fe(PMe_3)_2(t\text{-BuNC})_2(H)(CN)$ (**2**) and free isobutylene in quantitative yield. This reaction formally involves the δ-elimination of the isocyanide C—H bond and cleavage of the isocyanide C—N bond to produce the observed olefin and the metal cyano hydride. Several mechanisms were considered for this elimination reaction (Scheme 2).

One could envision that thermal reaction of **1** leads to the formation of a *tert*-butyl carbonium ion intermediate that could then act as a proton donor towards the metal anion (Scheme 2*a*). Precedence for this pathway exists in the literature on *tert*-butyl isocyanide (8). The lack of a strong dependence of the rate of the reaction on solvent polarity, however, argues against this pathway. Solvent effects on ionic reaction rates are typically on the order of three to six orders of magnitude difference (9). The effect on the thermal reaction in this case was only a sevenfold difference.

A second possible mechanism would involve intramolecular elimination (Scheme 2*b*). If an intramolecular mechanism were occurring during the thermal reaction of **1**, trimethyl phosphine dissociation would be required as the initial step to generate a vacant site. The unsaturation at the metal center would allow coordination of a terminal hydrogen of the isocyanide (agostic interaction). Olefin elimination and recoordination of the trimethyl phosphine would result in **1** and isobutylene. One concern regarding this mechanism is the strain needed to achieve the appropriate geometry for agostic hydrogen coordination to the metal center. Earlier X-ray structural studies of **1** and similar iron complexes reported the C-N-C linkage to be bent (~130°). It is not clear if this deviation from linearity would be sufficient to allow hydrogen coordination. The observation that the rate of the reaction is insensitive to added PMe_3 at concentrations up to 1 mol/L argues against this pathway, al-

Scheme 3. Radical mechanism for C—N cleavage in **1**.

though rate determining PMe_3 loss in the first step would give first order kinetics.

A third mechanism would involve the homolytic cleavage of the N—C single bond in complex **1**, which would result in a 17-electron iron(I) species and a *tert*-butyl radical (Scheme 2*c*). The *tert*-butyl radical would act as a good hydrogen atom donor to the iron(I) complex, directly giving the cyano hydride product **2** and isobutylene.

Several lines of evidence point towards a radical mechanism. First, isobutane formation from the reaction of **1** in the presence of 1,4-cyclohexadiene reveals the intermediacy of *tert*-butyl radicals. 1,4-Cyclohexadiene could act as a hydrogen atom donor towards both *tert*-butyl radicals and the 17-electron metal complex to give isobutane and **2** (plus benzene). As the concentration of the hydrogen donor increases, the amount of isobutane also goes up since competitive reaction of the *tert*-butyl radicals with the Fe(I) intermediate becomes less important (Scheme 3). The small amount of isobutylene still observed in the presence of neat 1,4-cyclohexadiene suggests the possibility that some reaction occurs within the solvent cage. The limiting observation of 25% (minimum) isobutylene suggests that at least 1/4 of the radical pairs react within the cage. Though *tert*-butyl radical coupling to form isobutane and isobutylene is highly favored, none was observed. This may be because of the high reactivity of the 17-electron iron complex, which would be in excess after one pair of *tert*-butyl radicals coupled.

The appearance of an intense ESR signal when a benzene solution of **1** was treated with excess PBN also suggests a radical mechanism. A sample of *tert*-butyl isocyanide and PBN in benzene gave no apparent ESR signal. No ESR signal was observed when a benzene solution of $Fe(PMe_3)_2(CNCH_2CMe_3)_3$ and PBN was examined. This was significant since the neopentylisocyanide complex is known to be thermally stable and does not undergo the dealkylation observed with **1**. As a side note, the addition of the spin trap 2-methyl-2-nitrosopropane dimer to benzene solutions of **1** or $Fe(PMe_3)_2(CNCH_2CMe_3)_3$ gave ESR signals in both cases, though the intensity of the signal was smaller. It is likely that these trapped radicals were formed as a result of direct reaction of the metal complexes with the added spin trap, which is a common problem with ESR spin traps.

The isotope effect measured for the hydrogen abstraction reaction that is proposed to occur in the thermal rearrangement of **1**, where the hydrogen or deuterium atom is attached in an equivalent place in the same molecule, is commonly known as a competitive intramolecular isotope effect (10). The small isotope effect observed for this reaction may be due to a small zero point energy difference between the two reactant-like transition states of this exothermic reaction step (11).

The cleavage of isocyanide C—N single bonds by transition metals, while not unprecedented, is fairly rare. Lippard and co-workers reported the dealkylation of $[M(t\text{-BuNC})_7]^{2+}$ (M = Mo, W) in refluxing ethanol in low yield (12). Although the fate of the *tert*-butyl group was not determined, it was proposed to have formed either *tert*-butyl alcohol or isobutylene. Tschugaeff and Teearu reported the formation of $Pt(t\text{-BuNC})_2(CN)_2$ upon dissolving $[Pt(t\text{-BuNC})_4]^{2+}$ in methanol (13). Earlier work in our group also showed that coordination of *t*-BuNC to $[Ru(dmpe)_2]$ leads to the formation of $Ru(dmpe)_2(H)(CN)$, $Ru(dmpe)_2(CN)_2$, isobutylene, and isobutane (14). In none of these cases was the mechanism examined in detail.

Conclusions

The thermal reaction of **1** to eliminate isobutylene and form **2** has been found to proceed by the homolytic cleavage of the *N*-*t*-Bu bond, producing a free *tert*-butyl radical and a 17-electron Fe(I) complex. The transfer of H· from the *t*-Bu radical to the metal complex gives the observed products. The observation of at least 25% isobutylene (based on the amount of **2** formed) regardless of the amount of hydrogen atom donor present suggests that a minimum of one fourth of the radical reaction occurs in the radical cage.

Experimental

The solvents THF, DMSO, diethyl ether, tetraglyme, and benzene were distilled from dark purple solutions of sodium benzophenone ketyl under a nitrogen atmosphere. Iso-octane was dried by refluxing with sodium under nitrogen for 48 h. All compounds were handled in a Vacuum Atmospheres Dri-

© 2005 NRC Canada

Lab. All NMR samples were made using resealable or sealed NMR tubes that were prepared and degassed on a high vacuum line. The UV–vis samples were run under nitrogen in a 1 cm path length quartz cell equipped with a Teflon adaptor. The ESR samples were run in new NMR tubes capped with septa. *tert*-Butyl isocyanide and 1,4-cyclohexadiene were purchased from Aldrich Chemical Company and vacuum distilled before use. Trimethylphosphine was purchased from Strem Chemical Company and used as received. The Grignard MeMgI in diethyl ether (3 mol/L), 2-methyl-2-nitropropane dimer, and *N*-*tert*-butyl-α-phenylnitrone (PBN) were purchased from Aldrich Chemical Co. and used as received. $Fe(PMe_3)_2(t\text{-}BuNC)_3$ was prepared as previously described (4).

NMR spectra were obtained on a Bruker AMX-400 instrument. NMR chemical shifts are reported in units of δ vs. residual benzene protons (δ 7.15 for ^1H; 128.0 for ^{13}C). UV–vis spectra were obtained on an HP 8452A diode array spectrophotometer, and kinetics data were processed using HP 89531A MS DOS UV–vis operating software. Gas chromatography – mass spectrometry were obtained using an HP 5890 series II instrument equipped with a 30 m Carbowax column at 50 °C and an ionizing voltage of 10 eV to ensure only parent ion detection. Infrared data were obtained using a Bruker ESP300 IR spectrometer.

Thermal reaction of $Fe(PMe_3)_2(t\text{-}BuNC)_3$ (1)

A solution of $Fe(PMe_3)_2(t\text{-}BuNC)_3$ in C_6D_6 (10 mg in 0.6 mL) was placed in a resealable NMR tube and heated at 60 °C. Periodic examination of the reaction by ^1H NMR spectroscopy for 24 h showed the disappearance of **1** and the formation of two new products identified as *cis*-**2** and *trans*-**2** in a 10:1 ratio, along with isobutylene (δ 4.72, m, 2H; 1.58, m, 6H).

$Fe(PMe_3)_2$(t-BuNC)$_3$ (1)

^1H NMR (C_6D_6) δ: 1.264 (s, 27H), 1.547 (pseudo t, J = 3.7 Hz, 18H). ^{13}C NMR (C_6D_6) δ: 20.69 (t, J = 12 Hz), 31.49 (s), 54.18 (s), 208.10 (t, J = 33 Hz). ^{31}P NMR (C_6D_6) δ: 42.08 (s).

$Fe(PMe_3)_2$(t-BuNC)$_2$(H)(CN) (2)

^1H NMR (C_6D_6) (*cis*-**2**) δ: 1.51 (pseudo t, J = 4 Hz, 18H), 1.10 (s, 18H), –10.61 (t, J = 56 Hz, 1H); (*trans*-**2**) δ: 1.48 (pseudo t, J = 4 Hz, 18H), 1.06 (s, 18H), –13.78 (t, J = 44 Hz, 1H). ^{13}C NMR (C_6D_6) (*cis*-**2**) δ: 55.03 (s), 0.88 (s), 30.64 (s), 20.81 (t, J = 12 Hz). ^{31}P NMR (C_6D_6) (*cis*-**2**) δ: 29.97 (s); (*trans*-**2**) δ: 27.43 (s). Anal. calcd.: C 50.88, H 9.29, N 10.47; found: C 50.67, H 9.16, N 10.40.

Kinetics determinations

The solvent used for all UV–vis kinetics runs was dry iso-octane, chosen because of its high boiling point and low vapor pressure. A 1 cm quartz cuvette directly attached to a Teflon adaptor allowed the very air sensitive samples to be run on the bench top at a range of temperatures (50–85 °C). All of the UV–vis samples were prepared in the drybox and run under nitrogen. A UV–vis spectrum of **1** showed two broad bands at 309 and 390 nm. The band at 390 nm was used for the kinetic measurements as it was isolated from the solvent and product absorptions. A stock solution of **1** (0.0114 mol/L) was prepared, and dilutions were made to determine the molar extinction from a Beer's law plot (ε = 2180 M^{-1} cm^{-1}).

Concentration and solvent effects

Solutions of **1** from 1×10^{-4} – 9×10^{-4} mol/L were prepared by the following procedure: In a drybox, approximately 0.1–1.0 mg of **1** was placed into a 1 cm quartz cuvette and ~2 mL iso-octane was pipetted in. The resulting solution was mixed, and the cuvette was placed in a thermostated cell holder. Following an equilibration period of 10 min, the kinetics were followed by monitoring the absorption at 390 nm for 20 h. The initial absorbance of each run was used to calculate the concentration of **1** using Beer's law. The absorbance followed a first order decay, and the k_{obs} for each run was determined using the HP software. Similar runs were made by dissolving samples of **1** in THF, DMSO, and benzene.

Effect of excess PMe_3

Samples were made from a stock solution prepared by dissolving 15 mg of **1** into a 25 mL volumetric flask, adding 10 mL iso-octane and the appropriate amount of PMe_3, and filling to the final volume with iso-octane. Aliquots of the stock solution were pipetted into the cell for kinetic runs, and the stock solution was stored in a freezer between runs.

Reaction of 1 with 1,4-cyclohexadiene

A total of eight samples of **1** containing various amounts of 1,4-cyclohexadiene in benzene were prepared as follows: Benzene-d_6 solutions containing 10 mg of **1** were placed in resealable NMR tubes. Care was taken to add known amounts of C_6D_6 solvent to each. 1,4-Cyclohexadiene was added via syringe. The samples were degassed on the vacuum line, and the concentration of 1,4-cyclohexadiene was determined by comparison of the area of the CH_2 resonance at δ 5.60 to the area of the *tert*-butyl resonance (δ 1.26) of **1** immediately following sample preparation. ^1H NMR spectra were recorded after heating at 67 °C for 25 h. The amount of isobutylene formed was determined by comparing the area of the CH_2 resonance of isobutylene (δ 4.73) to the area of the hydride resonance (δ –10.6). The reaction was complete after 24 h of heating (~6 half-lives).

Samples were also prepared by dissolving 10 mg **1** in neat 1,4-cyclohexadiene. After heating at 67 °C for 24 h, the volatiles were vacuum transferred to resealable NMR tubes and examined by ^1H NMR spectroscopy. The amount of isobutane to isobutylene was determined by comparison of the integrated area of isobutane (δ 0.86, CH_3) to isobutylene (δ 4.73, CH_2).

ESR studies

A concentrated sample of **1** (15 mg) in benzene (0.3 mL) was made in an NMR tube. An excess of *N*-*tert*-butyl-α-phenylnitrone (~20 mg) was added, and the ESR was run initially and after heating at 60 °C for 24 h. The signal increased in intensity after heating but was otherwise unchanged. A triplet of doublets was observed with a_H = 3 G and a_N = 15 G. The same general procedure was used when preparing the samples containing *tert*-butylisocyanide plus PBN, PBN alone, $Fe(PMe_3)_2(CNCH_2CMe_3)_3$ plus PBN, and

© 2005 NRC Canada

$Fe(PMe_3)_2(CNCH_2CMe_3)_3$ plus nitrone dimer using benzene as the solvent.

Preparation of *tert*-butylisocyanide-d_6

The preparation of *tert*-butylisocyanide-d_6 was accomplished in 3 steps using known reactions. The first step was the synthesis of *tert*-butanol-d_6 from acetone-d_6 by a Grignard reaction (15). Into a 1000 mL round bottom flask fitted with a septum and a 50 mL addition funnel was placed 3 mol/L CH_3MgI in ether (220 mL, 0.66 mol) and 250 mL of diethyl ether. The solution was cooled to 0 °C under a nitrogen atmosphere, and acetone-d_6 (40 mL, 0.49 mol) was slowly added to the ether solution. The flask was allowed to warm to room temperature and was stirred overnight under nitrogen. After 18 h, the solution was again placed in an ice bath, and 50 mL of 10% HCl (aq) was slowly added to neutralize the excess MeMgI. The solution was warmed to room temperature, and the *tert*-butanol-d_6 was extracted from the aqueous layer using 3 × 50 mL aliquots of diethyl ether. The ether was removed from the combined extracts, giving *tert*-butanol-d_6 (15.8 g, 0.20 mol, 35% yield). ^1H NMR (C_6D_6) δ: 1.06 (s). Overnight reaction is required to give reasonable yields.

The second step was the formation of *tert*-butylformamide-d_6 from the *tert*-butanol-d_6 via a Ritter reaction (16). Caution must be taken in this step because of the formation of HCN. In a 250 mL Erlenmeyer flask, *tert*-butanol-d_6 (15.8 g, 0.20 mol) and potassium cyanide (15 g, 0.23 mol) were dissolved in 25 mL acetic acid. A solution of 25 mL H_2SO_4 and 25 mL acetic acid was added dropwise over a period of 2 h to the solution, keeping the temperature below 60 °C. The mixture was allowed to stir overnight at room temperature. After 16 h, the mixture was poured into 500 mL of ice water. The solution was placed in an ice bath, and 15% KOH (aq) was added slowly until the acid was neutralized. The pH was checked using litmus paper. The *tert*-butylformamide-d_6 was extracted using 5 × 100 mL portions of diethyl ether. The ether was dried over potassium carbonate overnight and then removed by distillation. Fractional distillation gave *tert*-butylformamide-d_6 (5.9 g, 0.06 mol, 30% yield). bp 200 °C. ^1H NMR (C_6D_6) δ: 0.89 (s), 1.19 (s). GC-MS (10 eV) *m/z*: 107 ($[M]^+$), 92 ($[M^+ - CH_3]$), 89 ($[M^+ - CD_3]$).

The final step was the dehydration of the formamide using $POCl_3$ (17). Into a 250 mL round bottom flask equipped with a 10 mL addition funnel, condenser, and a mechanical stirrer was placed *tert*-butylformamide-d_6 (5.9 g, 0.06 mol), pyridine (30 mL, 0.37 mol), and 100 mL diethyl ether. The solution was cooled to 0 °C in an ice bath. $POCl_3$ (7 mL, 0.09 mol) was placed into the addition funnel. After purging with nitrogen for 10 min, the $POCl_3$ was slowly added. Care must be taken to ensure rapid stirring during the addition. The solution was allowed to warm to room temperature and then refluxed for 1 h. The flask was again placed in an ice bath and distilled water was added to neutralize the excess $POCl_3$ and dissolve the salts that formed. The organic layer was separated from the aqueous layer, and the aqueous layer was washed with ether (5 × 50 mL). The combined organic layers were dried over magnesium sulfate. The ether was removed by distillation and *tert*-butylisocyanide was obtained by vacuum distillation (0.5 mL, 0.005 mol, 8% yield). ^1H NMR (C_6D_6) δ: 0.87 (t, J = 4 Hz). GC-MS (10 eV) *m/z*: 89 ($[M]^+$), 74 ($[M^+ - CH_3]$), 71 ($[M^+ - CD_3]$), 63 ($[M^+ - CN]$).

Preparation of $Fe(PMe_3)_2(t\text{-BuNC-}d_6)_3$

The synthesis was the same as described previously (4) for the protio isocyanide complex, using $FeCl_2$ (0.14 g), Mg (0.08 g), and PMe_3 (103 mmHg (1 mmHg = 133.322 Pa), 300 K, 1.056 L) in THF (50 mL) and adding 0.30 mL *t*-BuNC-d_6.

Isotope effect determinations

The determination of the isotope effect was accomplished using three separate samples prepared in resealable NMR tubes. A benzene solution of 20 mg $Fe(PMe_3)_2(t\text{-BuNC-}d_6)_3$ was heated at 67 °C for 24 h. The volatiles were vacuum distilled from the NMR tube to a two-neck flask equipped with an adapter and a septum. The benzene solutions were analyzed by GC–MS using the conditions stated above to determine the ratio of d_6:d_5 isobutylene. The three samples showed ratios of 0.56 (0.01), 0.55 (0.02), and 0.56 (0.01).

Phosphino-indenyl complexes of nickel(II)[1]

Laurent F. Groux, Francine Bélanger-Gariépy, and Davit Zargarian

Abstract: The BH_3-protected phosphinoindenyl ligand indenyl$(CH_2)_2PPh_2{\cdot}BH_3$ was used in the preparation of ($\eta^{5/3}$:η^0-indenyl$(CH_2)_2PPh_2{\cdot}BH_3$)Ni(PPh_3)Cl, which has been characterized by NMR spectroscopy and X-ray diffraction studies. On the other hand, all attempts at preparing the closely related complex ($\eta^{5/3}$:η^1-indenyl$(CH_2)_2PPh_2$)NiCl, in which the tethered phosphine moiety is coordinated to the Ni centre, were unsuccessful. One of these unsuccessful attempts yielded instead the novel indenyl-PCP pincer complex {κ^P,κ^C,κ^P-1,3-$(CH_2CH_2PPh_2)_2$-2-indenyl}NiCl, which has been characterized by X-ray diffraction studies.

Key words: indenyl complexes, tethered phosphines, PCP pincer complexes.

Résumé : Le ligand protégé indenyl$(CH_2)_2PPh_2{\cdot}BH_3$ a permis la préparation du composé ($\eta^{5/3}$:η^0-indenyl$(CH_2)_2$-$PPh_2{\cdot}BH_3$)Ni(PPh_3)Cl. Ce dernier a été complètement caractérisé par la spectroscopie RMN et études cristallographiques. Toutes les tentatives de préparer et isoler le complexe ($\eta^{5/3}$:η^1-indenyl$(CH_2)_2PPh_2$)NiCl ont échoué. En revanche, nous avons obtenu lors d'une de ces tentatives un nouveau complexe inattendu; une étude cristallographique a démontré que ce dernier était un complexe de type « pincer » PCP-indényle, soit {κ^P,κ^C,κ^P-1,3-$(CH_2CH_2PPh_2)_2$-2-indenyl}NiCl.

Mots clés : complexes d'indényle, phosphines attachées, complexe de type « pincer » PCP.

Introduction

Previous studies have shown that the complexes (Ind)Ni(PR_3)X (Ind = indenyl and its substituted derivatives; R = Ph, Me, Cy; X = Cl, Me, CC-Ph, etc.) (1) are active precatalysts for the oligo- and polymerization of alkenes (2), alkynes (3), and $PhSiH_3$ (4) and the hydrosilylation of olefins and ketones (5). The available mechanistic evidence indicates that the steric and (or) electronic properties of the phosphine ligand and its relative lability influence the rates of these reactions and the catalytic activities. Thus, the PMe_3 derivatives are much more active than their PPh_3 analogues in the polymerization of ethylene (2*a*) and $PhSiH_3$ (4), whereas the opposite order of reactivity is found in the hydrosilylation reactions (5).

To examine further the influence of phosphines on the above reactions, we considered studying a series of complexes featuring ligands of the type Ind^PR_2, with ^ representing a side chain connecting the PR_2 and Ind moieties. Our reasoning was that since the chelating phosphine moiety in (Ind^PR_2)NiX should be less prone to dissociation, studying the reactivities of such complexes should allow a direct measure of the impact of phosphine lability on the reactivities of this family of complexes. A search of the literature showed that complexes bearing the analogous Cp^PR_2 ligands are known for many transition metals (except those of group 10) (6), whereas complexes of Ind^PR_2 ligands are known only for Cr (7), Ru (8), Rh (9), and Ir (9*b*). Therefore, we set out to prepare (Ind^PR_2)NiX and probe the influence of the chelating PR_2 moiety on reactivities. The present report describes our attempts to prepare the complex ($\eta^{5/3}$:η^1-Ind$CH_2CH_2PPh_2$)NiCl.

Results and discussion

The ligand Ind$(CH_2)_2PPh_2$ (**1**) was prepared by slightly modified versions of previously reported procedures (10, 11), consisting of (*a*) successive nucleophilic displacements of Cl^- in $ClCH_2CH_2Cl$ by $[PPh_2]^-$ and $[Ind]^-$ or (*b*) the reductive cleavage of spiro(cyclopropane-1,1′-indene) (12) by $[PPh_2]^-$ (Scheme 1). Crude samples of **1** obtained from these routes were reacted with $BH_3{\cdot}THF$ to protect the phosphine moiety from oxidation; pure samples of Ind$(CH_2)_2PPh_2{\cdot}BH_3$ (**1**·BH_3) were then isolated by flash chromatography and completely characterized by NMR and X-ray diffraction studies (13). Treatment of **1**·BH_3 with H^+, followed by neutralization with Na_2CO_3, removed the protecting group and gave pure samples of **1**, which were used in subsequent experiments. Alternatively, crude samples of **1** were used in a few instances for the preparation of the target complex; for this purpose, route (*b*) proved more convenient because the in situ generated anion $[Ind(CH_2)_2PPh_2]^-$ obviated the need for an additional deprotonation step.

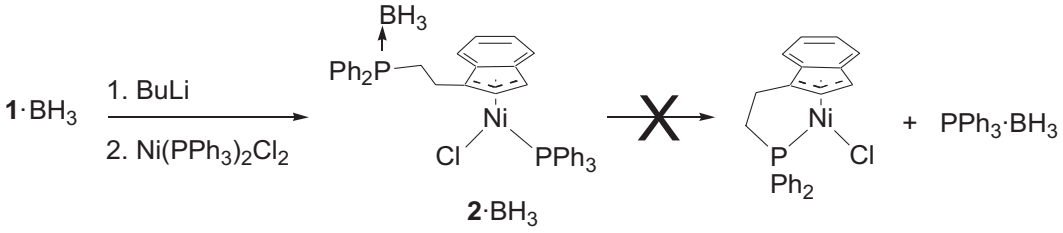
Scheme 1.

Scheme 2.

The main synthetic route used for the attempted synthesis of the target complex was based on the procedure used for the preparation of IndNi(PR_3)Cl (14). Thus, ligand **1** was deprotonated with BuLi and added to an Et_2O suspension of Ni(PPh_3)$_2Cl_2$. This addition changed the forest-green colour of the initial mixture to dark red, the typical colour of IndNi(PR_3)Cl; shortly thereafter, however, the reaction mixture turned beige-brown and a beige solid precipitated, implying the onset of a decomposition process. The $^{31}P\{^1H\}$ NMR spectrum of the filtrate obtained from filtration of the final mixture showed that the reaction had produced a number of phosphine-containing species,[3] while the observation of several broad signals in the ^1H NMR spectrum indicated that one or more paramagnetic species had also formed. The ^1H NMR spectrum of the beige solid obtained from the filtration also showed broad and featureless signals. Cooling the beige filtrate yielded yellow crystals that were identified as the Ni(I) complex (PPh_3)$_3$NiCl (15). The formation of this species has been observed in previous studies (16) and signals a side reaction involving the nickel-catalyzed coupling of two indenyl ligands (Scheme 2).



The above procedure was repeated several times under different reaction conditions (e.g., solvent, temperature, order of mixing, source of nickel, etc.), but no set of conditions allowed the successful isolation of ($\eta^{5/3}$:η^1-IndCH_2CH_2-PPh_2)NiCl. The precise reasons for the failure to obtain our target complex are not known; we speculate, however, that the dark-red species formed during the initial stages of these reactions is an intermediate species such as ($\eta^{5/3}$:η^0-Ind-$CH_2CH_2PPh_2$)Ni(PPh_3)Cl, **2**. The apparent instability of this species is in contrast to the stability of the analogous complexes ($\eta^{5/3}$:η^0-Ind^NR_2)Ni(PPh_3)Cl, which have been synthesized successfully (2*c*, 17). The discrepancy in the stabilities of these complexes leads us to suspect that the pitfall of our synthetic approach lies with the incompatible intramolecular interaction of the chelating phosphine moiety with the Ni centre.

The above hypothesis was borne out by the finding that the above-proposed intermediate is indefinitely stable when the PPh_2 moiety is coordinated by BH_3. Thus, using the BH_3-protected ligand **1**·BH_3 in our syntheses allowed the successful isolation of the complex ($\eta^{3/5}$:η^0-IndCH_2CH_2-PPh_2·BH_3)Ni(PPh_3)Cl, **2**·BH_3 (Scheme 3). The structure proposed for this complex was corroborated by the NMR spectra, as follows. For instance, the $^{31}P\{^1H\}$ NMR spectrum of **2**·BH_3 showed a sharp singlet at 29.9 ppm (parts per million), attributed to the Ni-PPh_3 moiety; for comparison, the corresponding signal in (Ind-$CH_2CH_2NMe_2$)Ni(PPh_3)Cl

[3] The $^{31}P\{^1H\}$ NMR spectrum (C_6D_6) displayed the following signals: 44.6, 33.6, 33.3, 32.8, 32.5, 30.3, 30.1, 29.9, 29.4, 29.1, 24.4 (O=PPh_3), 20.7, 3.2, –4.9 (free PPh_3). The signals displayed in the corresponding spectrum in $CDCl_3$ were as follows: 58.7, 57.9, 55.9, 34.2, 33.6, 32.5, 30.2, 29.5 (O=PPh_3), 24.8, 23.3, 21.6, 20.2, –3.5, –4.8 (free PPh_3), –14.0, –15.0.

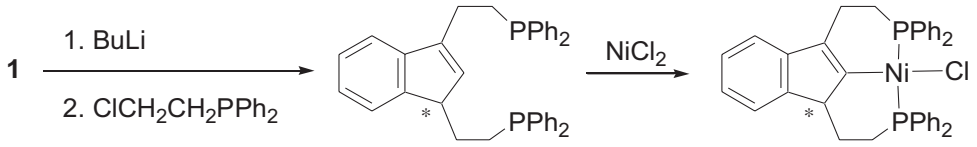
Scheme 4.



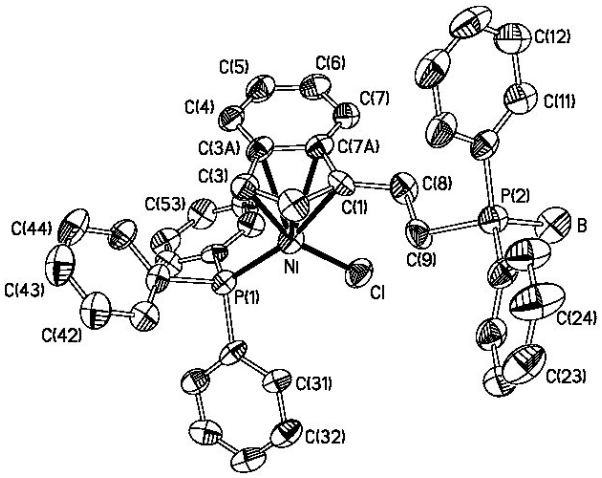


Fig. 1. ORTEP plot of **2**·BH_3. Hydrogen atoms have been omitted for clarity. Selected distances (Å) and angles (°): Ni—Cl 2.143(7), Ni—C2 2.054(6), Ni—C3 2.031(7), Ni—C3A 2.321(7), Ni—C7A 2.365(8), Ni—P1 2.179(3), Ni—Cl 2.170(2), C1—C2 1.435(8), C2—C3 1.419(8), C3—C3A 1.397(9), C3A—C7A 1.439(9), C7A—C1 1.462(8), P2—B 1.912(8); C1-Ni-P1 164.0(2), C3-Ni-C1 160.0(2), P1-Ni-C1 101.09(9), C1-Ni-C1 94.7(2), P1-Ni-C3 98.0(2), C1-Ni-C3 66.0(3).

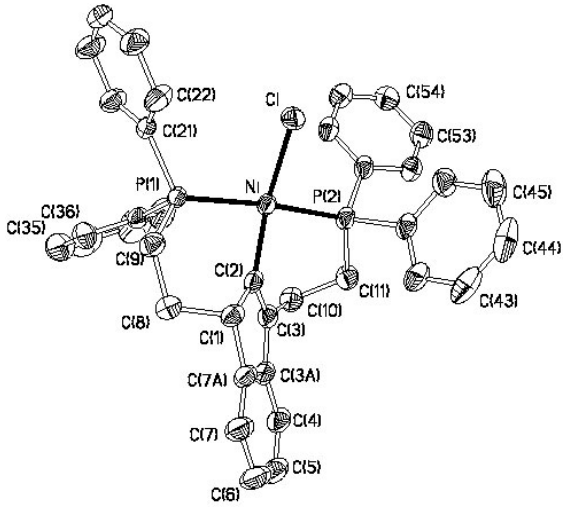
resonates at 30.8 ppm (see ref. 17*a*). In addition, we observed a peak at 17.5 ppm that was broadened as a result of coupling to the quadrupolar ^{11}B nucleus (cf. **1**·BH_3: 16.6 ppm). The ^1H NMR spectrum contained a broad singlet at ca. 1.2 ppm assigned to BH_3, in addition to the characteristic signals for the Ind protons (e.g., a signal at ca. 3.5 ppm assigned to H3). The unequivocal confirmation of the proposed structure was furnished by the results of X-ray diffraction studies, described below.

Complex **2**·BH_3 adopts virtually the same structure as many of the previously reported Ni-indenyl complexes (1). The coordination geometry around Ni (Fig. 1) can be described as a distorted square-planar geometry with the indenyl ligand perpendicular to the coordination plane. The tethered Ph_2P·BH_3 moiety points away from the metal centre, and the absence of any P–Ni interaction results in a virtually unchanged P—BH_3 distance (1.912(3) Å in **2**·BH_3 vs. 1.923(3) Å in **1**·BH_3). The Ind hapticity is distorted toward an unsymmetrical, trihapto mode, as reflected in the following structural parameters: (*i*) the Ni—C3a and Ni—C7a bond distances (avg. 2.34 Å) are much longer than the Ni—C1 and Ni—C3 distances (avg. 2.08 Å); (*ii*) the Ni—C1 distance (ca. 2.14 Å) is significantly longer than the Ni—C3 distance (ca. 2.03 Å); (*iii*) the slip parameters[4] Δ(M—C) (0.26 Å), HA (ca. 8.7°), and FA (ca. 8.3°) are in the expected range for η^5/η^3-Ind ligands (18). This type of "slippage" is attributed to (*a*) the tendency of Ni(II) to avoid an 18-electron configuration and (*b*) the different trans influences of PPh_3 and Cl ligands, respectively (1).

With complex **2**·BH_3 at hand, we attempted to prepare **2** by thermally inducing the transfer of BH_3 from the tethered PPh_2 moiety to the PPh_3 ligand and the subsequent elimination of Ph_3P·BH_3; unfortunately, however, no BH_3-exchange was observed between the phosphine moieties. On the other hand, direct deprotection of the tethered PPh_2 moiety by amines led instead to decomposition. It appears, therefore, that the target complex ($\eta^{5/3}$:η^1-Ind$CH_2CH_2PPh_2$)NiCl is inherently unstable. Although modeling studies do not support the hypothesis that this instability is caused by the CH_2CH_2 tether, future attempts will investigate the feasibility of preparing analogous complexes bearing longer side chains.



A new PCP–Ni complex

One of the attempts to synthesize the target complex resulted in the unexpected formation of a Ni complex bearing the new ligand Ph_2P^Ind^PPh_2, shown in Scheme 4. Thus, reacting $NiCl_2$ with a crude batch of **1**, prepared according to route (*a*) in Scheme 1, gave a red mixture that yielded a small quantity of red crystals identified by X-ray diffraction studies as the novel pincer complex (PCP-Ind($(CH_2)_2$-$PPh_2)_2$)NiCl, **3**. The $^{31}P\{^1H\}$ NMR spectrum of **3** showed two AB doublets displaying large coupling constants ($^2J_{P\text{-}P}$ =

[4] These slip parameters are defined as follows: ΔM—C = 1/2[(M—C3a + M—C7a) – (M—C1 + M—C3)]; HA is the angle between the planes formed by the atoms C(1), C(2), C(3) and C(1), C(3), C(3a), C(7a); FA is the angle between the planes formed by the atoms C(1), C(2), C(3) and C(3a), C(4), C(5), C(6), C(7), and C(7a).

Fig. 2. ORTEP plot of **3**. Hydrogen atoms and disordered solvent have been omitted for clarity. Selected distances (Å) and angles (°): Ni—Cl 2.2086(12), Ni—P1 2.1772(10), Ni—P2 2.2146(9), Ni—C2 1.888(3), C1—C2 1.525(4), C2—C3 1.360(4), C3—C3A 1.457(4), C3A—C7A 1.391(5), C1—C7A 1.522(4); C1-Ni-P1 98.32(4), C1-Ni-P2 91.95(4), C2-Ni-P1 85.08(9), C2-Ni-P2 88.96(9), C1-Ni-C2 162.46(9), P1-Ni-P2 163.64(3).

330 Hz), indicative of inequivalent trans phosphine moieties. The ^{1}H NMR spectrum displayed a broad singlet at ca. 3.6 ppm, which was assigned to H1, in addition to a number of multiplets in the aromatic and aliphatic regions; the latter are assigned to the chemically inequivalent[5] protons on the ethyl side chains.

X-ray diffraction studies showed that the coordination geometry around the Ni centre in **3** is slightly distorted square planar (Fig. 2), the main source of distortion arising from inter-ligand angles of ca. 163° for the trans ligands and 98°–85° for the cis ligands. Two trans coordination sites are occupied by the PPh_2 moieties, which form unequal Ni—P bond lengths (ca. 2.177 and 2.215 Å). The presence of an asymmetric centre at C1 results in the formation of two enantiomers, but the molecule crystallizes in the centrosymmetric space group $P\bar{1}$ because these enantiomers exist in a racemic mixture.

The most novel feature of complex **3** is the 2-indenyl ligand that is η^1-bonded to Ni via C2 (Ni—C(sp^2) = 1.89 Å). The localized nature of bonding within the 5-membered ring portion of the Ind ligand is evident from the much longer bond lengths for C1—C2 (1.525(4) Å), C7a—C1 (1.522(4) Å), and C3—C3a (1.457(4) Å) compared with C2—C3 (1.360(4) Å). We believe that **3** is the first isolated η^1-indenyl nickel complex and one of very few 2-η^1-indenyl complexes ever reported (19). The unanticipated formation of this compound likely results from the side reactions shown in Scheme 4: a small amount of deprotonated **1** reacts with a second equivalent of $ClCH_2CH_2PPh_2$ to give the doubly functionalized indene, 1,3-$(CH_2CH_2PPh_2)_2$IndH; the latter then reacts with $NiCl_2$ by C-H activation at the 2-position to give **3**.

Pincer compounds have attracted much attention recently owing to the many interesting reactions they promote and (or) catalyze (20), including alkane dehydrogenations (21), ketone hydrogenations (22), Heck coupling (23), olefin aminations (24), etc. (25). Most pincer complexes have a C_2 symmetric skeleton based on an *ortho*,*ortho*-disubstituted aryl ring, a 1,5-disubstituted pentyl chain, or a 1,3-disubstituted Cp moiety; what sets complex **3** apart is the presence of an optically active centre at C1. Efforts are underway to develop a reliable and high-yielding synthetic route for ligands of the type R_2P^Ind^PR_2 and their complexes. The reactivities of these complexes will then be investigated with a view to exploiting the optically active character of this type of PCP complex.

Concluding remarks

The results described in this paper indicate that ($\eta^{3/5}$:η^0-$IndCH_2CH_2PPh_2$·BH_3)$Ni(PPh_3)Cl$ owes its stability to the protection of the PPh_2 moiety by BH_3, because all attempts at preparing the original target complex wherein PPh_2 is coordinated to the Ni centre led to decomposition. We conclude, therefore, that tethering the phosphine moiety to the Ind ligand has a destabilizing effect on the complexes $IndNi(PR_3)Cl$. In contrast, many related complexes are stable and isolable (e.g., (η^5:η^1-Ind^PPh_2)$Rh^I(CO)$ (9), (η^5:η^1-Ind^PPh_2)Rh^{III}(C(=O)R)X (R = Me, Et; X = Br, I) (26), and (η^5:η^1-Ind^PR_2)Cr(X)Cl (X = Cl, Me) (7)), implying that the chelation of the tethered phosphine is not inherently destabilizing in all cases. It remains to be seen whether Ni complexes of Ind^PR_2 bearing longer tethers will be stable to isolation.

Experimental

General considerations

All manipulations were performed under an inert atmosphere of N_2 using standard Schlenk techniques and a drybox. Dry, oxygen-free solvents were employed throughout. Ind$(CH_2)_2PPh_3$ (**1**) has been prepared according to modified procedures (11, 12). All other reagents used in the experiments were obtained from commercial sources and used as received. The NMR spectra were recorded on a Bruker AMXR400 spectrometer (^{1}H (400 MHz), ^{13}C{^{1}H} (100.56 MHz), and ^{31}P{^{1}H} (161.92 MHz)).

Preparation of 2·BH_3

BuLi (0.47 mL of a 2.5 mol/L solution in hexane) was added to a solution of **1**·BH_3 (400 mg, 1.17 mmol) in Et_2O (200 mL) and stirred for 2 h. This solution was then added dropwise to a suspension of $Ni(PPh_3)_2Cl_2$ (1.48 g, 2.27 mmol) in Et_2O (50 mL), whereupon the solution turned dark red immediately. The mixture was evaporated, and the residues were dissolved in CH_2Cl_2 (30 mL); diluting this solution with hexane (120 mL) and storing the mixture at –20 °C gave a dark red solid precipitate (450 mg, 55% yield). ^{1}H NMR ($CDCl_3$): 7.9–7.2 (PPh_3 and PPh_2), 7.16 (t, $^3J_{H\text{-}H}$ = 7.4 Hz, H6), 7.09 (d, $^3J_{H\text{-}H}$ = 8.0 Hz, H7), 6.91 (t, $^3J_{H\text{-}H}$ = 7.3 Hz, H5), 6.56 (d, $^3J_{H\text{-}H}$ = 3.0 Hz, H2), 6.08 (d,

[5] The rigid geometry imposed by the chelating PPh_2 moieties and the presence of an asymmetric centre at C1 render the methylene protons diastereotopic.

Crystal structure determinations[6]

Dark red crystals of **2**·BH_3 and red crystals of **3** were obtained from CH_2Cl_2–hexane solutions kept at –20 °C. The crystal data for **2**·BH_3 and **3** were collected on a Nonius CAD-4 diffractometer with graphite-monochromated Cu Kα radiation at 223(2) K using the CAD-4 software (27). Refinement of the cell parameters was done with the CAD-4 software, while the data reduction used NRC-2 and NRC-2A (28). Both structures were solved by direct methods using SHELXS97 (29) and difmap synthesis (SHELXL96) (30). The refinements were done on F^2 by full-matrix least squares. All non-hydrogen atoms were refined anisotropically, while the hydrogens (isotropic) were constrained to the parent atom using a riding model. Crystal data and experimental details for **2**·BH_3 and **3** are listed in Table 1, and selected bond distances and angles are given in the figure captions.

Activation of chlorobenzene with Ni(0) *N*,*N*-chelates — A remarkably profound effect of a minuscule change in ligand structure[1]

William J. Marshall and Vladimir V. Grushin

Abstract: Activation of the C—Cl bond of chlorbenzene with [$(COD)_2$Ni] and a bidentate *N*,*N*-ligand such as *N*,*N*,*N*′,*N*′-tetramethylethylenediamine (tmeda) and 2,2′-bipyridyl (bipy) has been reported to produce σ-phenyl complexes [(tmeda)Ni(Ph)Cl] (**1**) and [(bipy)Ni(Ph)Cl], respectively. However, in sharp contrast, we found that similar reactions involving almost the identical ligands *N*,*N*,*N*′,*N*′-tetraethylethylenediamine (teeda) and 6,6′-dimethyl-2,2′-bipyridyl (6,6′-Me_2bipy) resulted in homocoupling and the formation of non-organometallic dichlorocomplexes [(teeda)$NiCl_2$] and [(6,6′-Me_2bipy)$NiCl_2$]. The latter two compounds and **1** were characterized by single-crystal X-ray diffraction data. The remarkable change in the reaction outcome points to its extremely high sensitivity to minor alterations in the structure of the stabilizing *N*,*N*-ligand. In contrast, analogous reactions of [$Pd(dba)_2$] with PhI in the presence of teeda or 1,2-dipiperidinoethane (dpe) produced the expected σ-phenyl complexes [(teeda)Pd(Ph)I] and [(dpe)Pd(Ph)I], much like the previously reported reaction with tmeda.

Key words: C-Cl activation, zerovalent nickel complexes, *N*,*N*-ligands, oxidative addition, homocoupling, X-ray analysis.

Résumé : Il a été rapporté antérieurement que l'activation de la liaison C—Cl du chlorobenzène à l'aide de [$(COD)_2$Ni] et d'un ligand *N*,*N* bidentate, tel la *N*,*N*,*N*′,*N*′-tétraméthyléthylènediamine (tmeda) ou le 2,2′-bipyridyle (bipy), conduit à la formation de complexes σ-phényles, tels le [(tmeda)Ni(Ph)Cl] (**1**) et le [(bipy)Ni(Ph)Cl] respectivement. Les observations faites dans ce travail contrastent fortement avec ces résultats alors que des réactions semblables impliquant les ligands très semblables *N*,*N*,*N*′,*N*′-tétraéthyléthylènediamine (teeda) et 6,6′-diméthyl-2,2′-bipyridyle (6,6′-Me_2bipy) conduisent à un homocouplage et à la formation des dichlorocomplexes non-organométalliques [(teeda)$NiCl_2$] et [(6,6′-Me_2bipy)$NiCl_2$]. Ces deux derniers complexes et le composé **1** ont été examinés par diffraction des rayons X sur un cristal unique. Les changements remarquables observés dans les résultats de ces réactions indiquent qu'ils sont extrêmement sensibles à des changements mineurs dans la structure du ligand *N*,*N* stabilisateur. Au contraire, les réactions analogues du [$Pd(dba)_2$] avec le PhI en présence de teeda ou de 1,2-dipipéridinoéthane (dpe) ont conduit aux complexes σ-phényles attendus [(teeda)Pd(Ph)I] et [(dpe)Pd(Ph)I], tel qu'il avait été observé antérieurement dans les réactions avec le tmeda.

Mots clés : activation de la liaison C-Cl, complexes zérovalent du nickel, ligands *N*,*N*, addition oxydante, homocouplage, analyse de diffraction des rayons X.

[Traduit par la Rédaction]

Introduction

Catalysis with metal complexes is the primary tool for solving the problem of the notoriously low reactivity of non-activated (1, 2) haloarenes toward nucleophiles. Considerable progress (3–16) has been made in the development of catalytic transformations of aryl halides and triflates, Ar–X (X = Cl, Br, I, OTf), such as Kumada, Suzuki–Miyaura (11), and Negishi (12) coupling, the Mizoroki–Heck olefin arylation (13), and various carbonylation, amination (14, 15), and cyanation (16) reactions. Palladium tertiary phosphine complexes are most often used as catalysts for these reactions. Some bidentate nitrogen (17) and *N*-heterocyclic carbene (18–21) ligands have recently been offered as an alternative to organic phosphines for Pd catalysis. While in general tertiary amines are poorly efficient stabilizing ligands in Pd catalysis, the recently reported $Pd(OAc)_2$–Dabco catalytic system demonstrates high efficiency in Suzuki–Miyaura coupling (22).

Nickel, a metal that is considerably less costly than palladium, is also often used for cross-coupling reactions of haloarenes. The Ar—X bond is activated by Ni(0) more easily than by Pd(0), as illustrated by the chemistry of poorly

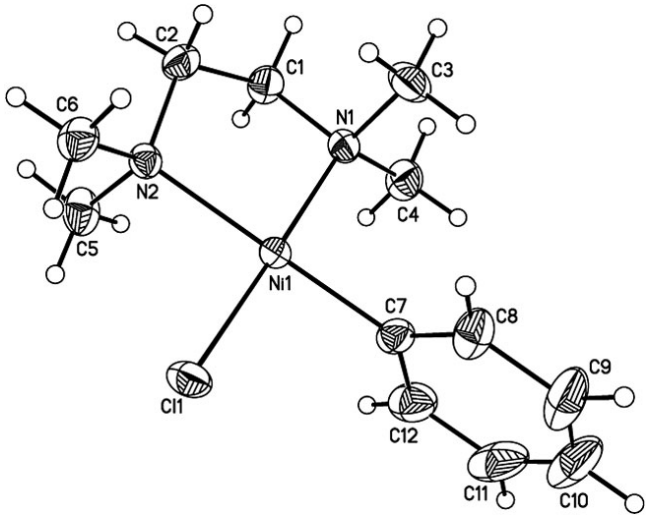
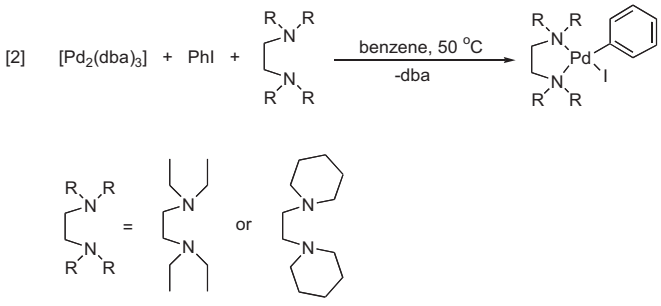
reactive chloroarenes (6, 23). However, oxidative addition of the Ar—X bond to Ni(0), the first key step of the catalytic loop, is often complicated, especially for X = I and Br, by radical processes (6, 24, 25) and homocoupling, also known as the Semmelhack reaction (8, 26, 27). We were interested in the oxidative addition of chloroarenes to Ni(0) stabilized with diamine ligands, to explore the possibility of using such systems as catalysts for carbon–heteroatom bond formation.

Results and discussion



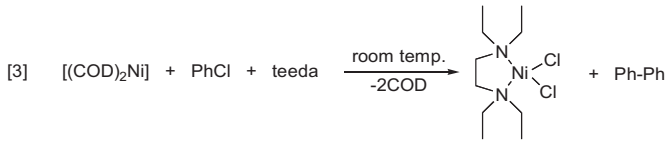
In 1987, Wenschuh and Zimmering (28) reported the formation of [(tmeda)Ni(Ph)Cl] (**1**) (tmeda = *N*,*N*,*N*′,*N*′-tetramethylethylenediamine) in 76% isolated yield upon oxidative addition of PhCl to [$(COD)_2$Ni] (COD = 1,5-cyclooctadiene) in the presence of tmeda at room temperature (eq. [1]).

No characterization of **1** was presented in the article (28), although SO_2 insertion into the Ni—C bond was later reported by the same group (29). Having prepared orange-yellow **1** in 70%–89% yield via the Wenschuh–Zimmering procedure, we attempted characterization of this complex. The composition of **1** was confirmed by satisfactory C, H, N microanalysis data. It was found that **1** is insoluble in alkanes, benzene, toluene, and ether, and slightly soluble in THF (28). Although **1** is easily soluble in CH_2Cl_2 and 1,2-dichloroethane (dce), these chlorinated solvents decompose **1** even at room temperature within a few minutes (CH_2Cl_2) or several hours (dce). We succeeded in obtaining ^{1}H and ^{13}C NMR data for **1** in dce-d_4. At room temperature, the ^{1}H NMR spectrum of **1** exhibited three sharp aromatic resonances at 6.6 (1H, *p*-Ph), 6.7 (2H, *m*-Ph), and 7.5 (2H, *o*-Ph) ppm along with a broadened multiplet at 2.0–2.7 ppm from the aliphatic protons. The ^{13}C NMR spectrum recorded at 20 °C displayed two signals from the methyl groups (47.1 and 49.3 ppm), two methylene resonances (56.9 and 61.1 ppm), and four aromatic peaks (121.4, 124.5, 136.8, and 147.5 ppm). The aromatic lines were sharp, whereas considerable line broadening ($\Delta\nu_{1/2}$ = 15–20 Hz) was observed for the methyl and methylene resonances. The latter sharpened to $\Delta\nu_{1/2}$ = 10 Hz upon cooling to 10 °C, indicating that some exchange processes were occurring. Although studying these dynamic processes was beyond the scope of our work, the ambient temperature NMR spectra were fully consistent with the structural formula of **1** as shown in eq. [1].



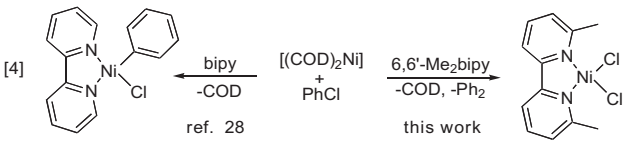
X-ray quality crystals of **1** were obtained from dce–hexanes. Two polymorphic crystalline forms of **1** were observed, thin needles (major) and irregular blocks (minor). Both forms were analyzed by X-ray diffraction. The structure of **1** determined for the thin needle polymorph (*C*2/*c*, *a* = 22.96(2) Å, *b* = 7.828(8) Å, *c* = 16.56(1) Å, β = 115.04(4)°) was of poor quality due to its small crystal size. A good quality X-ray structure of **1** (Fig. 1) was obtained for one of the irregular block crystallites. The molecule of **1** is square-planar, as expected from a diamagnetic (see the NMR data above) Ni(II) complex. In accord with trans-influence considerations, the Ni—N bond trans to Ph (2.053(1) Å) is longer than that trans to Cl (1.971(1) Å). The aromatic ring is orthogonal to the coordination plane of the complex, as in the closely related structure [(tmeda)Pd(Ph)I] (30).

Fig. 1. An ORTEP drawing of **1** with thermal ellipsoids drawn to the 50% probability level. Selected bond distances (Å) and angles (°): Ni(1)—C(7) 1.891(2), Ni(1)—N(1) 1.971(1), Ni(1)—N(2) 2.053(1), Ni(1)—Cl(1) 2.184(1); C(7)-Ni(1)-N(1) 92.61(6), C(7)-Ni(1)-N(2) 179.33(6), N(1)-Ni(1)-N(2) 86.72(5), C(7)-Ni(1)-Cl(1) 88.49(5), N(1)-Ni(1)-Cl(1) 178.80(4), N(2)-Ni(1)-Cl(1) 92.17(3).



The aforementioned decomposition of **1** in chlorinated solvents was found to produce pale green crystals, which we identified by X-ray analysis as [$(tmeda)_3Ni_3(\mu\text{-}Cl)_3(\mu^3\text{-}Cl)(\mu^3\text{-}OH)]^+Cl^-$ whose X-ray structure has been reported previously (31, 32). Because **1** was handled under rigorously anhydrous conditions, the source of OH for the trinuclear complex was probably the surface of the glass.

Although the structure of **1** was established, the complex was of limited further use for stoichiometric and catalytic studies because of its poor solubility. It was then reasoned that the teeda analogue of **1** ([(teeda)Ni(Ph)Cl], teeda = *N*,*N*,*N*′,*N*′-tetraethylethylenediamnie), should be more readily soluble in organic solvents and hence suitable for further studies. Indeed, the closely related Pd complexes [(teeda)Pd(Ph)I] and [(dpe)Pd(Ph)I] (dpe = 1,2-dipiperidinoethane) were prepared (eq. [2]) by the procedure reported (30) for [(tmeda)Pd(Ph)I] and were found to be more soluble than the latter.



© 2005 NRC Canada

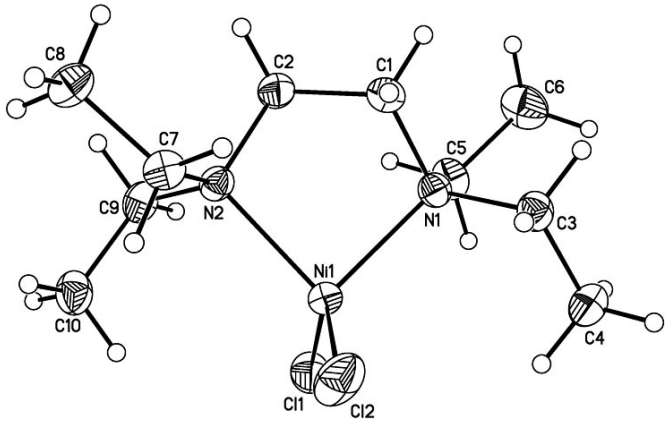
Surprisingly, however, the reaction of $[(COD)_2Ni]$ with PhCl in the presence of teeda did not afford [(teeda)Ni(Ph)Cl], but rather Semmelhack-type coupling occurred to produce deep-purple, paramagnetic $[(teeda)NiCl_2]$ (eq. [3]).

The structure of the complex $[(teeda)NiCl_2]$ was established by X-ray analysis, showing tetrahedral coordination geometry around Ni (Fig. 2). In accord with the tetrahedral structure, two broad lines at 7.5 and 11.9 ppm were observed in the ^1H NMR spectrum of paramagnetic $[(teeda)NiCl_2]$ in benzene-d_6.

Considering the minor change in the structures of tmeda and teeda, the difference in the outcomes of the two reactions (eqs. [1] and [3]) is remarkable. The tmeda vs. teeda case, however, is not unique. While it has been reported (28) that the reaction of $[(COD)_2Ni]$ with 2,2′-bipyridyl (bipy) and PhCl leads to a nickel aryl ([(bipy)Ni(Ph)Cl]), we found that 6,6′-dimethyl-2,2′-bipyridyl (6,6′-Me_2bipy) produces the paramagnetic inorganic dichloride $[(6,6'\text{-}Me_2bipy)NiCl_2]$ under similar conditions (eq. [4] and Fig. 3). No *N*-chelated Ni complexes were formed when $[(COD)_2Ni]$ was reacted with PhCl and *N*,*N*,*N*′,*N*′-tetraisopropylethylenediamine (tipeda). Considering the well-known low nucleophilicity of sterically hindered Hunig's base (i-Pr_2NEt), this observation is not surprising. Nonetheless, a simple high-yield preparation of tipeda is presented in the Experimental section.

At this point, it is unclear if the change in the reaction paths when going from tmeda to teeda or from bipy to 6,6′-Me_2bipy is largely due to electronic or steric (33) factors, or a combination of both. While considerable progress has been made in understanding the mechanisms of Semmelhack homocoupling of aryl halides (25, 27, 34), the results reported by different groups are not completely without controversy (34). The first step of the process is oxidative addition of Ar–X to Ni(0) to produce an aryl Ni(II) halide complex. Since chloroarenes are known to be almost unreactive toward $[(COD)_2Ni]$ (26), a bidentate *N*-ligand should displace at least one COD in $[(COD)_2Ni]$ before oxidative addition of PhCl can occur. As described by Tsou and Kochi (25) and discussed, most recently, in detail in an excellent review by Nelson and Crouch (34), an intermediate Ni(III) aryl species might play a key role in the homocoupling reaction. Aryl transfer from Ar–Ni(III) to Ar–Ni(II), possibly via a bridging intermediate, would produce a diaryl Ni(III) species that leads to biaryl upon C–C reductive elimination. Such Ar–Ni(III) species are more likely to emerge when more electron-rich teeda (vs. tmeda) and 6,6′-Me_2bipy (vs. bipy) are employed. On the other hand, one may not rule out the solubility factor, i.e., it is conceivable that the poorly soluble tmeda derivative **1** precipitates out immediately upon formation, whereas its more soluble teeda analogue may undergo further transformations in solution.

Fig. 2. An ORTEP drawing of $[(teeda)NiCl_2]$ with thermal ellipsoids drawn to the 50% probability level. Selected bond distances (Å) and angles (°): Ni(1)—N(1) 2.050(2), Ni(1)—N(2) 2.059(2), Ni(1)—Cl(1) 2.232(1), Ni(1)—Cl(2) 2.232(1); N(1)-Ni(1)-N(2) 89.32(6), N(1)-Ni(1)-Cl(1) 107.12(4), N(2)-Ni(1)-Cl(1) 110.87(5), N(1)-Ni(1)-Cl(2) 110.60(5), N(2)-Ni(1)-Cl(2) 106.14(4), Cl(1)-Ni(1)-Cl(2) 126.50(2).



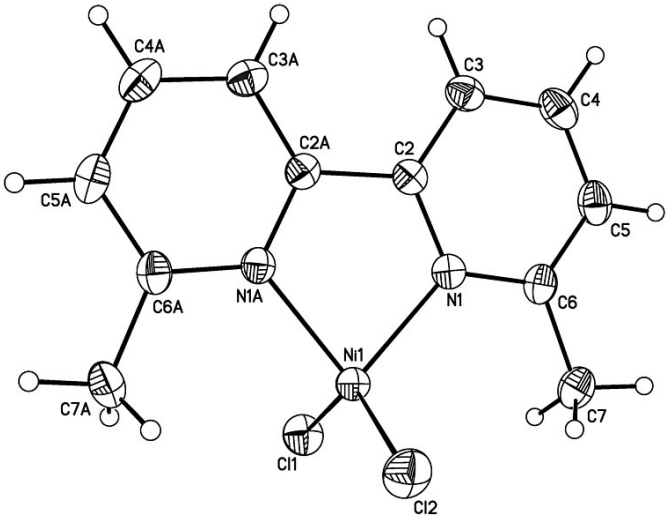


Fig. 3. An ORTEP drawing of $[(6,6'\text{-}Me_2bipy)NiCl_2]$ with thermal ellipsoids drawn to the 50% probability level. Selected bond distances (Å) and angles (°): Ni(1)—N(1) 1.985(1), Ni(1)—N(1A) 1.985(1), Ni(1)—Cl(2) 2.211(1), Ni(1)—Cl(1) 2.218(1); N(1)-Ni(1)-N(1A) 82.76(7), N(1)-Ni(1)-Cl(2) 109.05(4), N(1A)-Ni(1)-Cl(2) 109.05(4), N(1)-Ni(1)-Cl(1) 105.80(4), N(1A)-Ni(1)-Cl(1) 105.81(4), Cl(2)-Ni(1)-Cl(1) 132.93(3).

In conclusion, we have demonstrated that Ph–Cl activation by Ni(0) stabilized with *N*-chelating ligands does not

© 2005 NRC Canada

necessarily form a σ-phenyl Ni species as the final product, but can also result in homocoupling and formation of the corresponding dichloro complex. The outcome of such reactions is remarkably sensitive to even small changes in the structure of the stabilizing *N*,*N*-ligand, as illustrated by the differing behavior of the tmeda and teeda systems. These observations might be important for the design of reactions of haloarenes, catalyzed by Ni *N*,*N*-chelate complexes.

Experimental

Materials and instruments

All manipulations with Ni complexes were conducted in a glovebox under N_2. All chemicals were purchased from Aldrich, Acros Organics, and Strem Chemical Companies. The diamines were distilled from CaH_2 under N_2 prior to use. Both [$(COD)_2$Ni] and 6,6′-Me_2bipy were used as received. All solvents were purified and (or) dried by standard techniques and stored over freshly activated molecular sieves (4 Å) in the glovebox. NMR spectra were obtained with Bruker Avance DPX 300 and DRX 400 instruments. A Bruker Smart 1 K CCD system was used for single crystal X-ray diffraction studies. Microanalyses were performed by Micro-Analysis, Inc., Wilmington, Delaware, USA.

Synthesis of [(tmeda)Ni(Ph)Cl] (1)

A slight modification of the reported procedure (28) was used. A solution of tmeda (0.28 mL) in chlorobenzene (2 mL) was added to [$(COD)_2$Ni] (0.42 g), and the mixture was stirred at room temperature for 6 h. Hexanes (10 mL) were added and the mixture was left at room temperature overnight. The orange-yellow precipitate was separated by filtration, thoroughly washed with hexanes, and dried under vacuum. The yield of **1** was 0.39 g (89%). ^{1}H NMR (1,2-dichloroethane-d_4, 20 °C) δ: 2.0–2.7 (m, 16H, CH_3 and CH_2), 6.6 (1H, *p*-Ph), 6.7 (2H, *m*-Ph), 7.5 (2H, *o*-Ph). ^{13}C NMR (1,2-dichloroethane-d_4, 20 °C) δ: 47.1 (br), 49.3 (br), 56.9 (br), 61.1 (br), 121.4, 124.5, 136.8, 147.5. Anal. calcd. for $C_{12}H_{21}ClN_2Ni$ (%): C 50.1, H 7.4, N 9.7; found: C 49.9, H 7.0, N 9.7.

Preparation of [(teeda)Pd(Ph)I]

Under N_2, a stirring mixture of $Pd(dba)_2$ (1.00 g), teeda (0.39 g), iodobenzene (0.51 g), and benzene (25 mL) was slowly heated to 50 °C and kept at that temperature for 15 min. The greenish reaction mixture was filtered through Celite®, which was then washed with benzene (2 × 10 mL). After the combined filtrate and washings were evaporated, the residue was washed with ether (3 × 10 mL) to remove dba. Recrystallization of the orange residue from dichloromethane–ether produced 0.30 g (36%) of [(teeda)Pd(Ph)I] as a pale yellow crystalline solid. ^{1}H NMR (dichloromethane-d_2, 20 °C) δ: 1.4 (t, J = 7.1 Hz, 6H, CH_3), 1.5 (t, J = 7.1 Hz, 6H, CH_3), 2.7 (m, 6H, CH_2), 2.8 (m, 2H, CH_2), 3.0 (m, 2H, CH_2), 3.2 (m, 2H, CH_2), 6.7 (m, 1H, *p*-Ph), 6.9 (m, 2H, *m*-Ph), 7.3 (m, 2H, *o*-Ph). Anal. calcd. for $C_{16}H_{29}IN_2Pd$ (%): C 39.8, H 6.0, N 5.8; found: C 39.7, H 6.0, N 5.7.

Preparation of [(dpe)Pd(Ph)I]

Under N_2, a stirring mixture of $Pd(dba)_2$ (1.00 g), dpe (0.44 g), iodobenzene (0.51 g), and benzene (25 mL) was slowly heated to 50 °C and kept at that temperature for 15 min. The greenish reaction mixture was filtered through Celite®, which was then washed with benzene (2 × 10 mL). After the combined filtrate and washings were evaporated, the residue was washed with ether (3 × 10 mL) to remove dba. Recrystallization of the residue from dichloromethane–ether produced 0.40 g (46%) of [(dpe)Pd(Ph)I] as "copper" orange flakes. ^{1}H NMR (dichloromethane-d_2, 20 °C) δ: 1.0–1.8 (m, CH_2), 2.7–3.1 (m, CH_2), 3.8 (m, CH_2), 6.8 (m, 1H, *p*-Ph), 6.9 (m, 2H, *m*-Ph), 7.3 (m, 2H, *o*-Ph). Anal. calcd. for $C_{18}H_{29}IN_2Pd$ (%): C 42.7, H 5.8, N 5.5; found: C 42.3, H 5.7, N 5.4.

Preparation of [(teeda)$NiCl_2$]

A solution of teeda (1.00 g) in chlorobenzene (2 mL) was added to [$(COD)_2$Ni] (1.22 g), and the mixture was stirred at room temperature overnight. Hexanes (8 mL) were added. After 30 min, the deep-purple solid was separated by filtration, washed with hexanes (4 × 10 mL), and dried under vacuum. The yield was 0.89 g (66%). Anal. calcd. for $C_{10}H_{24}Cl_2N_2Ni$ (%): C 39.8, H 8.0, N 9.3; found: C 39.8, H 7.3, N 9.2. X-ray quality crystals were grown from dichloromethane–hexanes.

Preparation of [(6,6′-Me_2bipy)$NiCl_2$]

A mixture of 6,6′-Me_2bipy (0.50 g), [$(COD)_2$Ni] (0.70 g), and chlorobenzene (6 mL) was stirred at room temperature for 1 day. A green color emerged immediately upon mixing the reagents, which then turned dark-blue within seconds, and finally light-purple. The light-purple solid was separated by filtration, washed with chlorobenzene (2 × 2 mL) and hexanes (2 × 3 mL), and dried under vacuum. The yield was 0.79 g (99%). Anal. calcd. for $C_{12}H_{12}Cl_2N_2Ni$ (%): C 45.9, H 3.8, N 8.9; found: C 46.0, H 3.7, N 8.7. X-ray quality crystals were grown from hot 1,2-dichloroethane.

Synthesis of *N*,*N*,*N*′,*N*′-tetraisopropylethylenediamine (tipeda)

In air, a mixture of 2-iodopropane (20 mL), ethylenediamine (1.1 mL), and potassium carbonate (9.2 g) was stirred under reflux for 58 h. The tan liquid phase was separated from the solids, which were then thoroughly washed with ether (10 × 5 mL). The mother liquor and the washings were combined, evaporated, and the residue distilled under vacuum (86–98 °C at 9.5 mm Hg, (1 mm Hg = 133.322 4 Pa) to produce 3.32 g (87%) of spectroscopically pure tipeda. ^{1}H NMR (benzene-d_6, 20 °C) δ: 1.1 (t, J = 6.6 Hz, 24H, CH_3), 2.7 (s, 4H, CH_2), 3.1 (heptet, J = 6.6 Hz, 4H, CH). ^{13}C NMR (benzene-d_6, 20 °C) δ: 21.4, 48.1, 49.4.

Crystallographic studies

All crystallographic data were collected using a Bruker Smart 1 K CCD system equipped with Mo Kα radiation at –100 °C. The structures were solved using direct methods and refined with the SHELXTL program suite (35). Scattering factors were obtained from the *International Tables for X-ray Crystallography* (36). Additional data and refinement

An alternative convergent synthesis of silole-core dendrimers[1]

Takanobu Sanji, Hiroyuki Ishiwata, Tomoyoshi Kaizuka, Masato Tanaka, Hideki Sakurai, Ritsuko Nagahata, and Kazuhiko Takeuchi

Abstract: Silole-core dendrimers having benzyl-ether-type dendron units in the periphery are readily synthesized by the Ni-catalyzed reaction of benzyloxy-substituted diphenylacetylenes with 1,1,2,2-tetramethyldisilane.

Key words: silole, dendrimer, nickel-catalyzed reaction, convergent synthesis.

Résumé : La synthèse de dendrimères à coeur de silole possédant des dendrones de type éther benzylique à la périphérie peut être réalisée facilement en faisant appel à la réaction du 1,1,2,2-tétraméthyldisilane avec des diphénylacétylènes substitués par un groupe benzyloxy, catalysée par du nickel.

Mots clés : silole, dendrimère, réaction catalysée par le nickel, synthèse convergente.

[Traduit par la Rédaction]

Introduction

Dendrimers are a unique class of macromolecules having highly ordered, three-dimensional, and tree-like structures, and they have great potential as building blocks for the construction of functional materials (1). They are generally synthesized by "divergent" or "convergent" approaches. The divergent approach initiates growth at the core, and the generation grows outward by repetition of coupling and activation steps. The convergent method, on the other hand, propagates inward by coupling the focal point of the dendrons to the core. The convergent synthesis allows control over the number and location of functional moieties in the resultant dendrimers. This is a useful and important feature in molecular design. Indeed, quite a few reports on the derivatization of dendrimers have addressed chemical modification of the core and (or) peripheral moieties for a variety of fundamental studies and applications (2).

Recently, many groups reported accelerated approaches that combine the convergent and divergent strategies to reduce the number of tedious and iterative synthetic steps (3). In view of the synthetic improvement of the convergent approach, one-step synthesis of dendrimers, involving simultaneous construction of the core by the reaction of starting materials with the appropriate dendron units, appears promising as compared with the conventional convergent synthesis involving installation of the core in the final step. Hecht and Fréchet (4) reported the cobalt-catalyzed [2+2+2] cyclotrimerization of dendritically substituted alkynes to produce benzene-core dendrimers. This approach successfully yielded highly compact cores. Dehaen and co-workers (5) reported the synthesis of poly(1,2,3-triazolylmethyl)benzene cores via 1,3-dipolar cycloaddition reaction between poly(azidomethyl)benzenes and dendritically disubstituted acetylenedicarboxylates. Sharpless and co-workers (6) and Fokin and co-workers (7) also recently reported, on the basis of their "click chemistry" approach (6), an efficient route to triazole dendrimers by Cu(I)-catalyzed reaction of azides with alkynes (7).

Siloles and silacyclopentadienes have attracted great interest over the past decade because of their unique photophysical and electronic properties (8) and potential applications as organic electroluminescent (EL) devices (9). The silole has a relatively low LUMO energy level, due to the σ^*–π^* conjugation, in comparison with its carbon analogue, cyclopentadiene. Recently, several reports have addressed synthesis of siloles with a variety of substituent groups (10) and silole-based polymers (11). The silole-core dendrimer systems are envisioned to constitute an interesting class of macromolecule because the silole incorporated at the core acts as a functional conjugated unit and the dendritic framework provides for a site-isolation of chromophores, a light-harvesting antenna, and an energy-transfer interaction (12).

In 1972, Kumada and co-workers (13) reported the nickel-catalyzed reaction of 1,1,2,2-tetramethyldisilane and disubstituted acetylenic compounds to give siloles in good yields

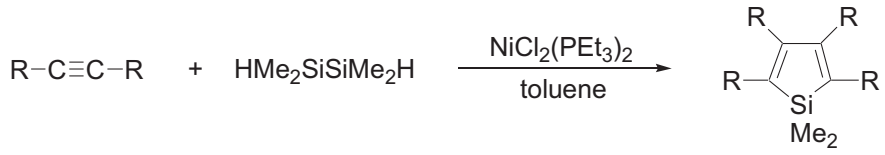
Scheme 1.

Scheme 2.

(Scheme 1). The reaction is envisioned to proceed with the involvement of an intermediate nickel-silylene complex and its addition to acetylenes. We have found that this reaction works well with heavy acetylenes bearing dendritic substituents, affording silole-core dendrimers. This paper discloses a facile one-pot synthesis of silole-core dendrimers by the alternative convergent method.

Results and discussion



Our synthetic strategy for the silole-core dendrimers is based on the nickel-catalyzed reaction of 1,1,2,2-tetramethyldisilane with disubstituted alkynes, which has proved to work well for dendritic alkynes affording silole-core dendrimers.

The alkynes with poly(benzyl ether) dendrons, **2a**–**2c**, were prepared by the convergent method as shown in Scheme 2. 1,2-Bis(3,5-dihydroxyphenyl)acetylene was readily prepared by deprotection of 1,2-bis(3,5-dimethoxyphenyl)acetylene with boron tribromide. The benzyl ether-type dendritic bromides **1b** and **1c** were obtained according to the previously reported procedures (14). The reaction of bromides **1a**–**1c** (4 equiv.) with 1,2-bis(3,5-dihydroxydiphenyl)acetylene (1 equiv.) in the presence of potassium carbonate and 18-crown-6 proceeded smoothly to give the acetylenes with poly(benzyl ether) dendrons **2a**–**2c**. Table 1 lists the results. The dendritic acetylenes **2a**–**2c** were obtained in good yields even for the higher generation substrates (91%, 62%, and 79%, respectively). The ^{1}H and ^{13}C NMR spectra of **2a**–**2c** showed the high molecular symmetry in these products and conformed to the proposed structures. FAB mass or MALDI-TOF mass spectra were also consistent with the dendritic structures.

Next, the dendritic alkynes **2a**–**2c** were treated with 1,1,2,2-tetramethyldisilane in the presence of $NiCl_2(PEt_3)_2$

Scheme 3.

2a-2c **3a-3c**

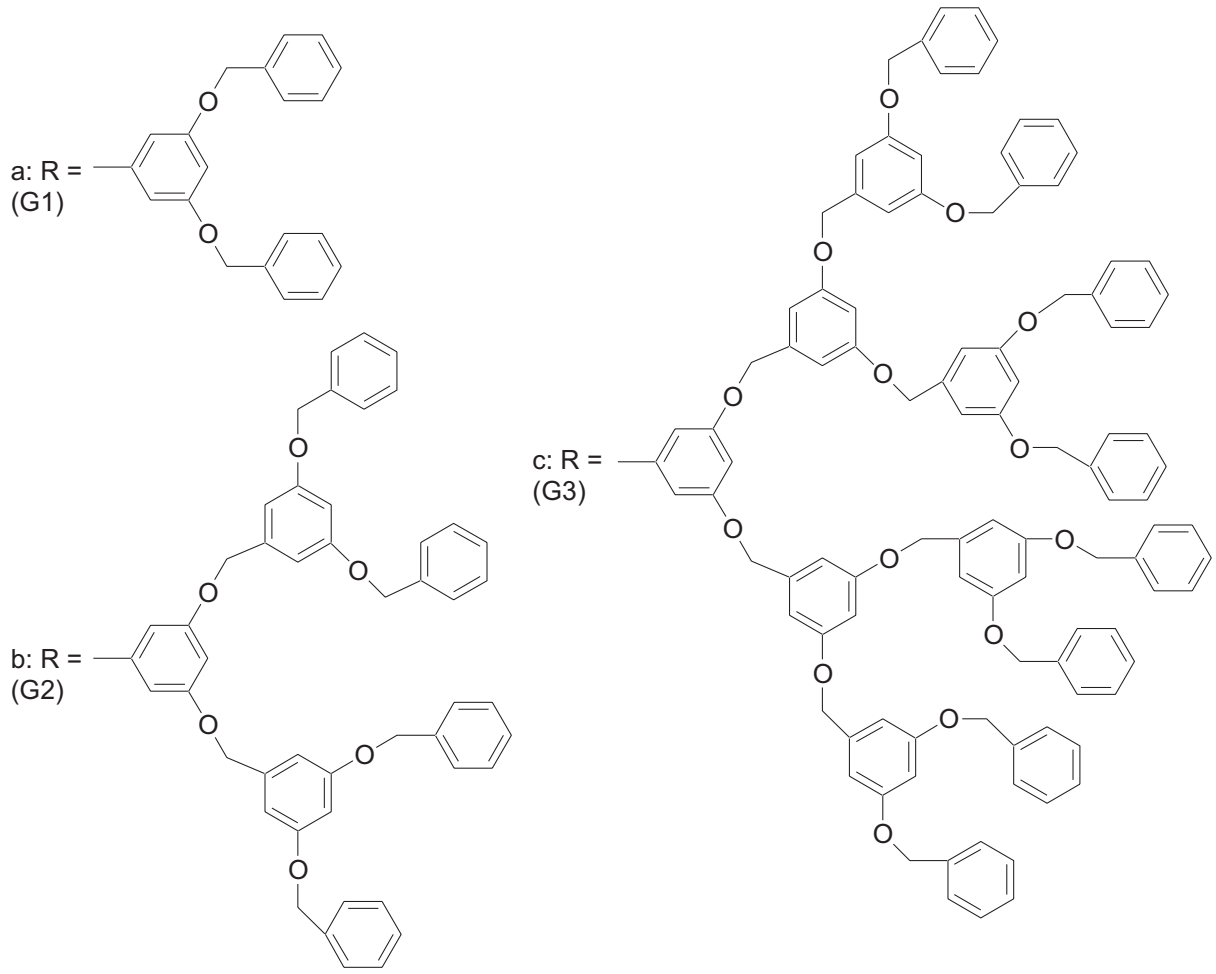

Table 1. Synthesis of dendritic acetylene **2a**–**2c** and silole-core dendrimers **3a**–**3c**.

	2	**3**		
Compound (G*n*)	Yield (%)	Time (h)	Amount of cat. (mol%)	Yield (%)
a (G1)	91	20	3	50
b (G2)	62	44	3	47
c (G3)	79	136	10	13

Note: G*n* = generation number; cat. = catalyst.

(3 mol%) in refluxing toluene (Scheme 3). The reaction, monitored by TLC, was continued until the disappearance of the starting alkynes. The results are also listed in Table 1, which shows that even though longer times are required to complete the reaction, as the generation of the desired dendrimers grows, the silole-forming reaction proceeds satisfactorily. Thus, silole-core dendrimers **3a** and **3b** were obtained in 50% (20 h) and 47% (44 h) yields, respectively. These yields are comparable to that of parent 1,1-dimethyl-2,3,4,5-tetraphenylsilole prepared from diphenylacetylene and tetramethyldisilane under the same conditions (53%, 16 h).[3] However, for the even higher generation dendrimer **3c**, the yield decreased to 13%, even after prolonged heating

[3] 1,1-Dimethyl-2,3,4,5-tetraphenylsilole was prepared as a reference compound by the nickel-catalyzed reaction of 1,1,2,2-tetramethyldisilane and diphenylacetylene. NMR data for 1,1-dimethyl-2,3,4,5-tetraphenylsilole: ^{1}H NMR (300 MHz, acetone-d_6) δ: 7.13–6.95 (m, 16H, Ph), 6.94–6.81 (m, 4H, Ph), 0.41 (s, 6H, SiCH_3). ^{13}C NMR (75 MHz, acetone-d_6) δ: 154.9 (Ph_4C_4Si), 142.6 (Ph_4C_4Si), 140.6, 139.8, 130.7, 129.5, 128.8, 128.3, 127.1, 126.5, –4.0 (SiCH_3). ^{29}Si NMR (60 MHz, acetone-d_6) δ: 8.2.

(136 h) using an increased amount of the catalyst (10 mol%). This is clearly suggestive of steric crowding around the core hindering the reaction at the higher generation. In addition, the reaction became less clean, although **3c** could be readily isolated and purified by column chromatography, as in the other cases.

Silole-core dendrimers **3a**–**3c** were fully characterized by a variety of spectroscopic techniques. The GPC analysis confirmed their monodispersity. The FAB or MALDI-TOF mass spectra showed peaks for *m*/*z* 1264 ($[M + H]^+$), 2984.5 ($[M + Na]^+$), and 6465.0 ($[M + Ag]^+$), associated with **3a**–**3c**, respectively. The ^1H and ^{13}C NMR spectra displayed the signals of methyl on the silole ring at the core along with those of the benzyl ether units (15).[3] In the ^{29}Si NMR spectra, the signals assigned to Si–Me on the silole ring core were observed at about 8 ppm for these dendrimers. All these spectral observations support the structure of the silole-core dendrimers.

In conclusion, we have prepared silole-core dendrimers by the nickel-catalyzed reaction of tetramethyldisilane and dendritic acetylenes containing poly(benzyl ether) units through the third generation. This synthetic procedure demonstrates the alternative convergent approach via a one-pot synthesis of the core, for the construction of a precise macromolecular structure. To the best of our knowledge, these are the first examples of silole-core dendrimers. The photophysical properties of the dendrimers will be reported in a forthcoming paper.

Experimental

Measurements

^1H, ^{13}C, and ^{29}Si NMR spectra were recorded on a Bruker DPX 300 FT-NMR spectrometer at 300, 75.4, and 59.6 MHz, respectively. The ^1H and ^{13}C chemical shifts were referenced to solvent residues (^1H, δ = 7.24 ppm; ^{13}C, δ = 77.0 ppm for $CDCl_3$). The ^{29}Si chemical shift was referenced to external Me_4Si (0 ppm). Mass spectra were measured by matrix-assisted laser desorption ionization time-of-flight (MALDI-TOF) technique on a Bruker reflex III. Gel permeation chromatography (GPC) was performed on a Shimadzu LC 10 HPLC equipped with PL-gel mixed-C columns calibrated with polystyrene standards.

Materials

All solvents and reagents were of reagent quality, purchased from commercial sources and used without further purification, unless otherwise noted below. Toluene was dried and distilled from sodium–benzophenone just before use. Acetone was distilled from calcium hydride. 1,2-Bis(3,5-dihydroxyphenyl)acetylene (16) and poly(benzyl ether)-dendritic bromides (14) were prepared according to the previously reported procedures.

General procedure for synthesis of poly(benzyl ether)-type dendritic acetylenes (2a–2c)

A mixture of an appropriate dendritic bromide (4 equiv.), 1,2-bis(3,5-dihydroxydiphenyl)acetylene (1 equiv.), K_2CO_3 (6 equiv.), and 18-crown-6 (0.4 equiv.) in acetone (10–100 mL) was heated under reflux under nitrogen (24–132 h). After the mixture was cooled to room temperature, water (30 mL) was added to the mixture, and then the mixture was extracted with CH_2Cl_2 (20–100 mL × 3). The combined organic layer was washed successively with water, sat. NH_4Cl solution, and sat. NaCl solution and evaporated after being dried over anhydrous $MgSO_4$. The residue was chromatographed over silica gel to give the corresponding poly(benzyl ether)-type dendritic acetylene (**2a**–**2c**).

2a

This was prepared by the reaction of 1,2-bis(3,5-dihydroxyphenyl)acetylene and benzyl bromide **1a** and purified from silica gel column chromatography with CH_2Cl_2 to give **2a** as a pale yellow solid. Yield 91%; mp 149–151 °C. ^1H NMR (300 MHz, $CDCl_3$) δ: 7.44–7.33 (m, 20H, Ar*H*), 6.80 (d, 4H, *J* = 2.2 Hz, Ar*H*), 6.63 (t, 2H, *J* = 2.2 Hz, Ar*H*), 5.04 (s, 8H, -C*H*$_2$O-). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 159.7, 136.6, 128.6, 128.0, 127.5, 124.4, 110.6, 103.5, 89.0 (-*C*≡C-), 70.1 (-*C*H$_2$O-). MS (FAB) *m*/*z*: 603 ($[M + H]^+$). Anal. calcd. for $C_{42}H_{34}O_4$: C 83.70, H 5.69; found: C 83.94, H 6.00.

2b

This was prepared by the reaction of 1,2-bis(3,5-dihydroxyphenyl)acetylene and **1b** and purified from silica gel column chromatography with CH_2Cl_2 to give **2b** as a pale yellow solid. Yield 62%; mp 150–154 °C. ^1H NMR (300 MHz, $CDCl_3$) δ: 7.43–7.30 (m, 40H, Ar*H*), 6.78 (d, 4H, *J* = 2.2 Hz, Ar*H*), 6.68 (d, 8H, *J* = 2.2 Hz, Ar*H*), 6.58 (m, 6H, Ar*H*), 5.02 (s, 16H, -C*H*$_2$O-), 4.99 (s, 8H, -C*H*$_2$O-). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 160.1, 159.6, 139.0, 136.7, 128.6, 128.0, 127.5, 124.4, 110.6, 106.3, 103.4, 101.6, 89.1 (-*C*≡C-), 70.1 (-*C*H$_2$O-), 70.0 (-*C*H$_2$O-). MS (FAB) *m*/*z*: 1451 ($[M]^+$). Anal. calcd. for $C_{98}H_{82}O_{12}$: C 81.08, H 5.69, O 13.23; found: C 80.98, H 5.93, O 13.01.

2c

This was prepared by the reaction of 1,2-bis(3,5-dihydroxyphenyl)acetylene and **2c** and purified from silica gel column chromatography with CH_2Cl_2–hexane (1:1) to give **2c** as a pale yellow solid. Yield 62%; mp 59–61 °C. ^1H NMR (300 MHz, $CDCl_3$) δ: 7.41–7.27 (m, 80H, Ar*H*), 6.80 (d, 4H, *J* = 2.1 Hz, Ar*H*), 6.68–6.65 (m, 24H, Ar*H*), 6.62 (t, 2H, *J* = 2.0 Hz, Ar*H*), 6.57–6.55 (m, 12H, Ar*H*), 5.00 (s, 32H, -C*H*$_2$O-), 4.95–4.93 (m, 24H, -C*H*$_2$O-). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 160.1, 160.0, 159.6, 139.1, 138.9, 136.7, 128.5, 127.9, 127.5, 124.4, 110.6, 106.4, 106.3, 101.5, 89.1 (-*C*≡C-), 70.0 (-*C*H$_2$O-), 69.9 (-*C*H$_2$O-). MS (MALDI-TOF) *m*/*z*: 3172.5 ($[M + Na]^+$). Anal. calcd. for $C_{210}H_{178}O_{28}$: C 80.08, H 5.70, O 14.22; found: C 80.01, H 5.79, O 14.39.

Synthesis of silole-core dendrimer 3a

A mixture of **2a** (250 mg, 0.42 mmol), 1,1,2,2-tetramethyldisilane (72 mg, 0.60 mmol), and $Ni(PEt_3)_2Cl_2$ (4 mg, 0.01 mmol) in toluene (10 mL) was heated under reflux for 20 h under nitrogen. The mixture was cooled to room temperature and evaporated. The residue was chromatographed over silica gel with toluene–hexane (3:1) to give **3a** (130 mg, 0.103 mmol) as a greenish-yellow glass. Yield 50%. ^1H NMR (300 MHz, acetone-d_6) δ: 7.38–7.20 (m, 40H, Ar*H*), 6.46–6.44 (m, 4H, Ar*H*), 6.35 (d, 4H, *J* = 2.2 Hz, Ar*H*), 6.32 (d, 4H, *J* = 2.2 Hz, Ar*H*), 5.00 (s, 8H,

-CH_2O-), 4.89 (s, 8H, -CH_2O-), 0.37 (s, 6H, Si-CH_3). ^{13}C NMR (75 MHz, acetone-d_6) δ: 160.6, 160.5, 154.9 (Ar$_4$*C*$_4$Si), 142.3 (Ar$_4$*C*$_4$Si), 142.1, 138.3, 138.1, 129.22, 129.18, 128.51, 128.47, 128.3, 128.2, 128.1, 109.8, 108.6, 101.8, 101.4, 70.7 (-*C*H$_2$O-), 70.4 (-*C*H$_2$O-), –3.7 (Si-*C*H$_3$). ^{29}Si NMR (60 MHz, acetone-d_6) δ: 8.1. MS (FAB) *m*/*z*: 1264 ([M + H]$^+$). Anal. calcd. for $C_{86}H_{74}O_8Si$: C 81.74, H 5.90; found: C 81.58, H 6.15.

Synthesis of silole-core dendrimer 3b

A mixture of **2b** (502 mg, 0.34 mmol), 1,1,2,2-tetramethyldisilane (72 mg, 0.60 mmol), and Ni(PEt$_3$)$_2$Cl$_2$ (4 mg, 0.01 mmol) in toluene (10 mL) was heated under reflux for 44 h under nitrogen. The mixture was cooled to room temperature and evaporated. The residue was chromatographed over silica gel with toluene–hexane (10:1) to give **3b** (240 mg, 0.081 mmol) as a greenish-yellow glass. Yield 47%. ^{1}H NMR (300 MHz, acetone-d_6) δ: 7.38–7.23 (m, 80H, Ar*H*), 6.65–6.40 (m, 36H, Ar*H*), 5.02–4.74 (m, 48H, -CH_2O-), 0.41 (s, 6H, SiCH_3). ^{13}C NMR (75 MHz, acetone-d_6) δ: 160.92, 160.88, 160.7, 160.4, 154.8 (Ar$_4$*C*$_4$Si), 142.4 (Ar$_4$*C*$_4$Si), 142.0, 141.8, 140.6, 140.3, 138.1, 138.0, 129.17, 129.13, 128.53, 128.49, 128.4, 128.1, 108.7, 106.9, 102.1, 101.9, 70.8 (-*C*H$_2$O-), 70.4 (-*C*H$_2$O-), 70.3 (-*C*H$_2$O-), –3.4 (Si-*C*H$_3$). ^{29}Si NMR (60 MHz, acetone-d_6) δ: 8.1. MS (MALDI-TOF) *m*/*z*: 2984.5 ([M + Na]$^+$). Anal. calcd. for $C_{198}H_{170}O_{24}Si$: C 80.30, H 5.79; found: C 79.91, H 5.95.

Synthesis of silole-core dendrimer 3c

A mixture of **2c** (501 mg, 0.16 mmol), 1,1,2,2-tetramethyldisilane (38 mg, 0.32 mmol), and Ni(PEt$_3$)$_2$Cl$_2$ (6 mg, 0.016 mmol) in toluene (5 mL) was heated under reflux for 136 h under nitrogen. The mixture was cooled to room temperature and evaporated. The residue was chromatographed over silica gel with CH_2Cl_2–hexane (2:1) to give **3c** (68 mg, 0.011 mmol) as a greenish-yellow glass. Yield 13%. ^{1}H NMR (300 MHz, acetone-d_6) δ: 7.32–7.20 (m, 160H, Ar*H*), 6.68–6.36 (m, 84H, Ar*H*), 4.92–4.64 (m, 112H, -CH_2O-), 0.38 (s, 6H, Si-CH_3). ^{13}C NMR (75 MHz, acetone-d_6) δ: 160.9, 160.8, 140.5, 140.4, 138.0, 129.2, 128.5, 128.4, 107.2, 106.8, 102.0, 70.4 (-*C*H$_2$O-). ^{29}Si NMR (60 MHz, acetone-d_6) δ: 7.9. MS (MALDI-TOF) *m*/*z*: 6465.0 ([M + Ag]$^+$). Anal. calcd. for $C_{422}H_{362}O_{56}Si$: C 79.73, H 5.74; found: C 79.90, H 6.09.

Activation and cleavage of alkynes by the dinuclear tantalum complexes $([NPN]Ta)_2(\mu\text{-}H)_4$ and $([NPN]Ta)_2(\mu\text{-}\eta^1{:}\eta^2\text{-}N_2)(\mu\text{-}H)_2$ (where NPN = $PhP(CH_2SiMe_2NPh)_2$)[1]

Michael P. Shaver, Samuel A. Johnson, and Michael D. Fryzuk

Abstract: Reaction of phenylacetylene with the dinuclear tetrahydride complex $([NPN]Ta)_2(\mu\text{-}H)_4$ gives the product $([NPN]Ta)_2(\mu\text{-}PhCCH)(\mu\text{-}H)_2$ (where NPN is $PhP(CH_2SiMe_2NPh)_2$). Activation of other terminal alkynes by $([NPN]Ta)_2(\mu\text{-}H)_4$ accesses $([NPN]Ta)_2(\mu\text{-}RCCH)(\mu\text{-}H)_2$ (R = *n*-Pr, *t*-Bu). Crystallographic analysis of the R = Ph derivative showed it to be a bis(μ-alkylidene) bound asymmetrically to the two tantalum centres. Storage of solutions of $([NPN]Ta)_2(\mu\text{-}PhCCH)(\mu\text{-}H)_2$ under vacuum promotes the loss of H_2 and cleavage of the C—C bond to give a bis(μ-alkylidyne) complex, $([NPN]Ta)_2(\mu\text{-}CPh)(\mu\text{-}CH)$. Addition of diphenylacetylene did not give the desired $([NPN]Ta)_2(\mu\text{-}CPh)_2$, but rather promotes a complex decomposition of the supporting [NPN] ligands. Reaction of phenylacetylene with the dinitrogen complex $([NPN]Ta)_2(\mu\text{-}\eta^1{:}\eta^2\text{-}N_2)(\mu\text{-}H)_2$ results in the dissociation of the bound dinitrogen and the formation of $([NPN]Ta)_2(\mu\text{-}PhCCH)(\mu\text{-}H)_2$, which is identical to that derived from the reaction with the dinuclear tetrahydride.

Key words: tantalum, alkyne, alkylidene, alkylidyne, amidodiphosphine, dinuclear hydride dinitrogen, activation of small molecules.

Résumé : La réaction du phénylacétylène avec le complexe tétrahydrure dinucléaire $([NPN]Ta)_2(\mu\text{-}H)_4$ conduit au produit $([NPN]Ta)_2(\mu\text{-}PhCCH)(\mu\text{-}H)_2$ dans lesquels NPN = $PhP(CH_2SiMe_2NPh)_2$. L'activation d'autres alcynes terminaux par du $([NPN]Ta)_2(\mu\text{-}H)_4$ permet d'accéder aux composés $([NPN]Ta)_2(\mu\text{-}RCCH)(\mu\text{-}H)_2$ dans lesquels R = *n*-propyle et *t*-butyle. Une analyse cristallographique du dérivé avec R = Ph montre qu'il s'agit d'un bis(μ-alkylidène) lié d'une façon asymétrique aux deux centres de tantale. L'entreposage de solutions de $([NPN]Ta)_2(\mu\text{-}PhCCH)(\mu\text{-}H)_2$ sous vide facilite la perte de H_2 et le clivage de la liaison C—C pour conduire à la formation d'un complexe bis(μ-alkylidyne), $([NPN]Ta)_2(\mu\text{-}CPh)(\mu\text{-}CH)$. L'addition de diphénylacétylène n'a pas conduit au $([NPN]Ta)_2(\mu\text{-}CPh)_2$ attendu, mais a plutôt favorisé une décomposition complexe des ligands supports [NPN]. La réaction du phéhylacétylène avec le complexe de diazote $([NPN]Ta)_2(\mu\text{-}\eta^1{:}\eta^2\text{-}N_2)(\mu\text{-}H)_2$ conduit à une dissociation du diazote lié et à la formation de $([NPN]Ta)_2(\mu\text{-}PhCCH)(\mu\text{-}H)_2$ identique à celui obtenu par réaction avec le tétrahydrure dinucléaire.

Mots clés : tantale, alcyne, alkylidène, alkylidyne, amidodiphosphine, hydrure de diazote dinucléaire, activation de petites molécules.

Introduction

To cleave an element–element triple bond as found in dinitrogen (N≡N) and alkynes (RC≡CR′) formally requires the addition of six electrons. Such cleavage processes are critical to the alkyne metathesis process (1) and could be an important method to convert molecular nitrogen into higher value organic materials (2). There are a number of recent studies that have detailed cleavage of N_2 using group 5 (3–5) and group 6 (6–8) derivatives to generate metal nitride species. While the product nitrides are generally extremely stable, further functionalization of the molybdenum nitride $N{\equiv}Mo(N[Ar]\text{-}t\text{-}Bu)_3$, formed from $Mo(N[Ar]\text{-}t\text{-}Bu)_3$ and N_2, has recently been reported (9). With regard to alkyne metathesis, the prototypical reactions involve group 6 alkoxide systems, typically $RC{\equiv}W(O\text{-}t\text{-}Bu)_3$ (1), and related Mo derivatives (10), along with a variety of in-situ-generated active catalysts (11). Although the cleavage of dinitrogen and alkynes occurs via quite different mechanisms, it is remarkable that very similar systems are found for both processes albeit with quite distinct ancillary ligand sets.

A somewhat related outcome has been reported (12) for the reaction of alkynes with the dinuclear tungsten(III) hydride derivative, $[silox]_2HW{\equiv}WH[silox]_2$. In this case, a sta-

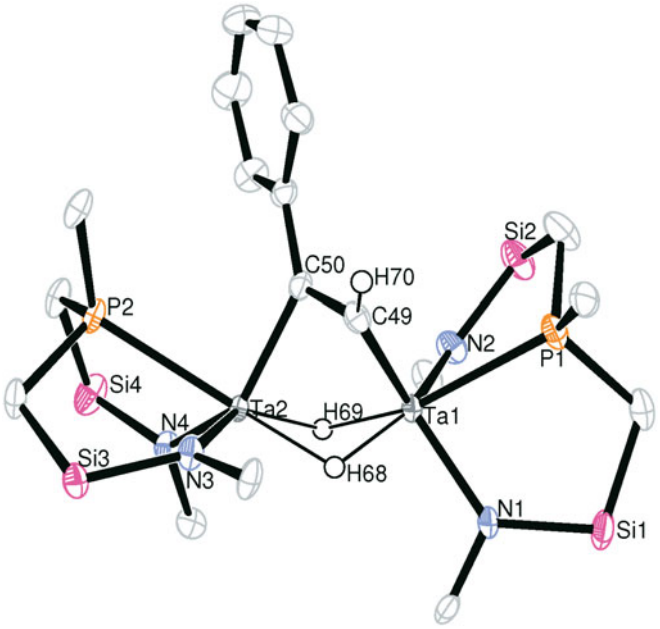
Scheme 2.

ble intermediate having the formula $([silox]_2W)_2(\mu\text{-}\eta^2\text{:}\eta^2\text{-}RCCR')(\mu\text{-}H)_2$ is formed and contains an activated bridging alkyne unit, which is subsequently cleaved by loss of H_2 to generate a ditungsten species with bridging alkylidyne units (Scheme 1); the starting dinuclear hydride does not react with N_2.

We have previously reported that the ditantalum tetrahydride complex $([NPN]Ta)_2(\mu\text{-}H)_4$ (**1**) (where NPN = $PhP(CH_2SiMe_2NPh)_2$) can activate dinitrogen to generate $([NPN]Ta)_2(\mu\text{-}\eta^1\text{:}\eta^2\text{-}N_2)(\mu\text{-}H)_2$ (**2**) via loss of H_2 (13). Although cleavage of coordinated N_2 in **2** is not directly observed, subsequent reaction of **2** with boranes and silanes does result in both cleavage and functionalization of the dinitrogen moiety (14, 15). Given the analogy described previously for cleavage of N_2 and alkynes with group 6 systems, we examined the reaction of the group 5 dinuclear tetrahydride **1** with alkynes to determine if both alkynes and N_2 could be activated using the same metal with the same ligand set. In this paper, we report both activation and cleavage of terminal alkynes using both the tetrahydride (**1**) and the dinitrogen complex (**2**) as starting materials. In addition, we also describe the reaction of diphenylacetylene with **1** that results in a completely different kind of product.



Results and discussion

The tetrahydride derivative **1** is formally a d^1–d^1 dinuclear system. It reacts with substrates by loss of H_2 to generate the reactive, unobserved d^2–d^2 dihydride $([NPN]Ta)_2(\mu\text{-}H)_2$ (**3**), a species with a Ta=Ta double bond. With N_2, only four electrons are involved in the formation of **2** (Scheme 2) (13), although if H_2 could be eliminated, the total number of electrons available would be six, ideal for cleavage of both N_2 and alkynes.

The reaction of PhC≡CH with **1** results in the formation of a new complex that displays two resonances in the ^{31}P

Fig. 1. ORTEP drawing (spheroids at 50% probability) of $([NPN]Ta)_2(\mu\text{-PhCCH})(\mu\text{-H})_2$ (**4**). Silyl methyl and phenyl ring carbons other than ipso and methine carbons have been omitted for clarity. Hydrides H68, H69, and terminal proton H70 were located in the diffraction pattern and refined isotropically.

NMR spectrum, at δ 18.1 and 20.0 ppm. In addition, there are two multiplets in the ^{1}H NMR spectrum at 13.14 and 11.65 ppm, which can be assigned to two bridging hydrides that are coupled to each other, as well as to both ligand ^{31}P nuclei. A third resonance at 11.72 ppm is coupled only to a single ^{31}P environment, with a J_{HP} value of 11.8 Hz, and corresponds to the terminal proton of the intact, coordinated phenylacetylene unit. Resonances due to eight silyl methyl environments are observed, consistent with a molecule of C_1 symmetry. On the basis of this information, the product of this reaction has the formula, $([NPN]Ta)_2(\mu\text{-PhCCH})(\mu\text{-H})_2$ (**4**).

Crystals of **4** were examined using X-ray diffraction; the solid-state molecular structure of complex **4** is shown in Fig. 1. Relevant bond lengths and angles are listed in Table 1 and crystallographic data are located in Table 2. The X-ray structure of complex **4** displays a highly unsymmetrical bonding of the phenylacetylene moiety. The Ta(1)—C(49) bond length of 2.061(4) Å is much shorter than the Ta(2)—C(49) distance of 2.511(4) Å. Likewise, the Ta(2)—C(50) bond length of 2.055(4) Å is much shorter than the Ta(1)—C(50) distance of 2.526(4) Å. A similar bonding mode was observed in $[(THF)Cl_2Ta]_2(\mu\text{-}\eta^2\text{:}\eta^2\text{-}t\text{-BuCC-}t\text{-Bu})(\mu\text{-Cl})_2$ (16). In this latter example, the asymmetry was attributed to steric factors. The differences in Ta—C bond lengths in $[(THF)Cl_2Ta]_2(\mu\text{-}\eta^2\text{:}\eta^2\text{-}t\text{-BuCC-}t\text{-Bu})(\mu\text{-Cl})_2$ are not as large (2.214(11) vs. 2.416(11) Å), corresponding to a twist of only 7° from a perfectly perpendicular projection of the acetylene C—C bond upon the Ta-Ta axis. In complex **4**, the projection of the C(49)—C(50) bond on Ta(1)—Ta(2) is closer to 45° away from a perpendicular arrangement of these two units, and is difficult to attribute to steric factors. The Ta(1)—C(49) and Ta(2)—C(50) distances are considerably shorter than that expected for Ta—C single bonds, and are similar to the Ta=C bond lengths found in tantalum alkylidene complexes. The bonding of phenylacetylene in **4** can, therefore, be viewed as a bis(μ-alkylidene) as is depicted in eq. [1]. The sum of the bond angles Ta(2)-C(50)-C(51), Ta(2)-C(50)-C(49), and C(49)-C(50)-C(51) is 356.5(10)°; the geometry at C(50) is essentially trigonal planar, as antic-

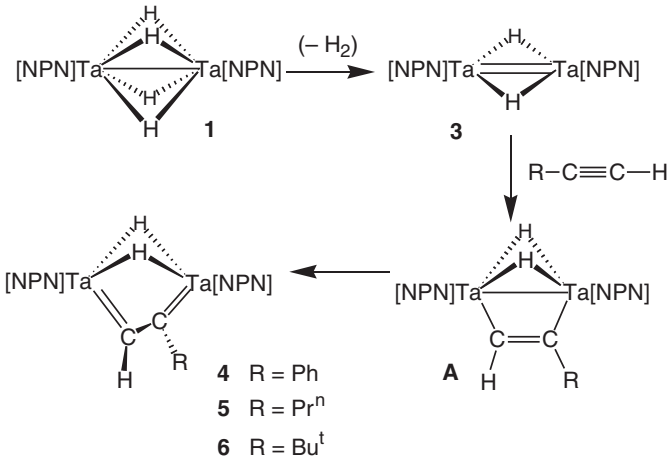
ipated for an alkylidene carbon. The C(49)—C(50) distance is 1.397(6) Å, which is intermediate between typical single and double C—C bond lengths. In a mononuclear tantalum alkyne complex that was also described as a bis(μ-alkylidene), a slightly shorter alkyne C—C bond length of 1.329(6) Å was reported (17).

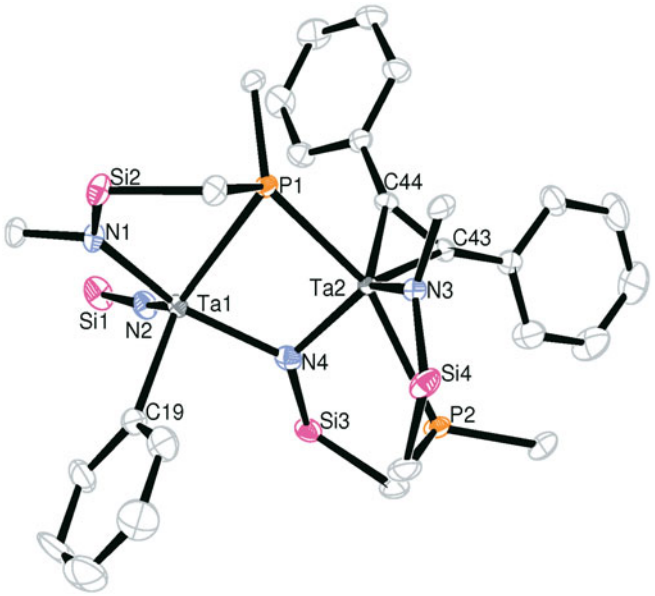


The outcome is identical for the reaction of **1** with other terminal alkynes such as *n*-PrC≡CH and *t*-BuC≡CH to produce **5** and **6**, respectively (eq. [1]). These products are readily characterized by multinuclear NMR spectroscopy. Each product exhibits two ^{31}P chemical shifts; 11.91 and 12.48 ppm for **5**, and 6.10 and 9.17 ppm for **6**. Similarly, each has a distinctive hydride region, with two asymmetric, bridging tantalum hydrides. The hydride resonances in complexes **5** and **6** do not exhibit clear AMXY patterns as in **4**, instead they appear as complicated multiplets at 11.03 and 11.56 ppm for **5**, and at 11.51 and 12.08 ppm for **6**. In each case, ^{13}C NMR studies support the assignment of products as bis(μ-alkylidene) type species as the individual alkylidene carbons can be assigned to resonances in the region 205–220 ppm. Unfortunately, attempts to characterize these products by crystallographic techniques were unsuccessful. The reaction of the dinitrogen complex **2** with terminal alkynes also produces the identical products via loss of N_2; the yields via the reaction of the tetrahydride **1** are slightly higher.

As already mentioned, the likely pathway for the formation of these products is via initial loss of H_2 to generate the coordinatively unsaturated, highly reactive dihydride **3**. A possible intermediate before formation of the bis(μ-alkylidene) species is the ditantalocyclobutene species **A** formed via a parallel approach of the terminal alkyne to the Ta=Ta double bond (18); rearrangement of **A** to the bis(μ-alkylidene) requires further reduction of the bridging alkyne moiety by the remaining Ta—Ta bond (Scheme 3).

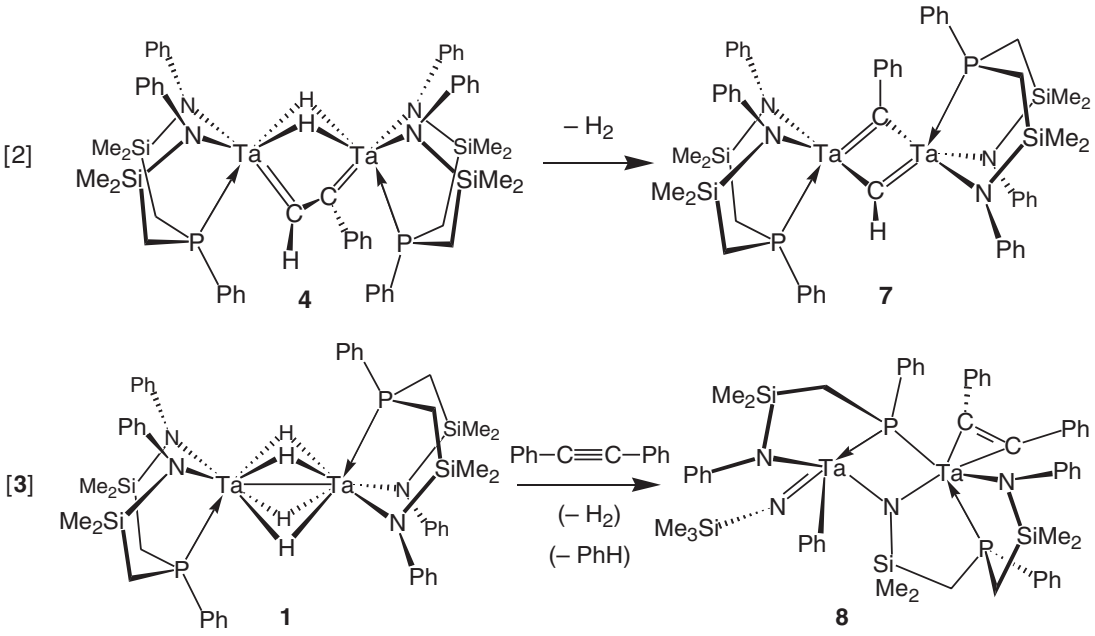
Storing solutions of **4** under vacuum leads to the quantitative formation of a symmetrical product as evidenced by a singlet at 11.5 ppm in the ^{31}P NMR spectrum. The two downfield resonances at 11.65 and 13.14 ppm, owing to the bridging hydrides in **4**, have disappeared and the alkyne pro-

© 2005 NRC Canada



Scheme 3.

ton resonance has shifted from 11.72 to 4.95 ppm. Evidence of a symmetrical product is also seen in the reduction in the number of silyl methyl resonances from eight to four. In analogy to the W[silox] system shown in Scheme 1 (12), loss of H_2 could provide the final two electrons required to cleave the remaining C—C bond in **4** and generate a bis(μ-alkylidyne) complex. ^{13}C NMR experiments reveal that the alkylidene carbon resonances at 224.2 and 224.3 ppm in **4** have disappeared and have been replaced by two new resonances at 308.8 and 311.2 ppm, all of which support this cleavage process and the formation of $([NPN]Ta)_2(\mu\text{-}CH)(\mu\text{-}CPh)$ (**7**), as shown in eq. [2]. Unfortunately, numerous attempts to obtain X-ray quality crystals have failed; nevertheless, the analogy to the W[silox] system, the high symmetry of the product, and the ^{13}C NMR data are compelling.



To extend this reaction further, the addition of diphenylacetylene (PhC≡CPh) to the tetrahydride **1** was examined in an effort to generate the symmetrical bis(μ-alkylidyne) $([NPN]Ta)_2(\mu\text{-}CPh)_2$; however, a completely different outcome ensued. The reaction was quite slow as evidenced by

Fig. 2. ORTEP drawing (spheroids at 50% probability) of product of $([NPN]Ta)_2(\mu\text{-}H)_4$ and PhC≡CPh (**8**). Ligand silyl methyl and phenyl ring carbons other than ipso positions have been omitted for clarity.

the slow change in colour from a purple to orange solution over a 24 h period. The NMR spectrum of the resulting isolated product indicated vastly increased complexity and loss of symmetry, not at all consistent with the desired bis(μ-alkylidyne) outcome. For example, instead of observing two singlets for the silyl methyl resonances, seven peaks were observed with different integrations. Fortunately, a single crystal X-ray diffraction study provided the identity of this unsymmetrical product, as shown in Fig. 2; a schematic of this reaction outcome is given in eq. [3].

What is most evident is that each ancillary [NPN] ligand has fractured in a unique way. One ligand has degraded through scission of a N—C bond to give a bridging imide

© 2005 NRC Canada

ligand and an η^1-phenyl ring. The other ligand has undergone P—C bond cleavage producing a new terminal trimethylsilyl-imido group that has lost its phenyl substituent and a bridging phosphide. Diphenylacetylene has been incorporated in an η^2-manner and is bound to one tantalum centre. The asymmetrical unit also contained a half equivalent of co-crystallized benzene. The bridging imide and phosphide ligands are bound asymmetrically. N(4)—Ta(1) and N(4)—Ta(2) distances are 2.121(4) and 1.961(4) Å, respectively, while P(1)—Ta(1) and P(1)—Ta(2) interatomic distances of 2.7563(11) and 2.4555(11) Å exhibit an even stronger asymmetry. Tantalum carbon bond lengths are typical: Ta(1)—C(19), Ta(2)—C(43), and Ta(2)—C(44) distances are 2.190(4), 2.124(4), and 2.129(4) Å, respectively. The C(43)—C(44) distance in the coordinated alkyne is lengthened to 1.313(6) Å and can be considered a C=C bond. For reference, the molecular structure of Ta($OC_6H_3Ph_2$-2,6)$_2$(η^2-EtCCEt)Cl(PMe_3) has a C=C distance of 1.291(6) Å, and Ta—C distances of 2.045(3) and 2.092(4) Å (19). The terminal imido ligand has a much shorter bond length with the metal centre than these tantalum amides; the Ta(1)—N(2) interatomic distance is 1.782(4) Å. These and other selected bond lengths and angles for **8** are located in Table 3 while the corresponding crystallographic data[3] can be found in Table 2.

^{1}H and ^{31}P NMR data are consistent with the product assignment. Integration of the complicated aryl region indicates that seven phenyl ring systems are present in the final complex. Seven silyl methyl resonances are also present, six of which integrate to 3H with one at 0.22 ppm that integrates to 9H. Isotopic labeling studies, tracked by the addition of diphenylacetylene to ([NPN]Ta)$_2$(μ-D)$_4$ (d_4-**1**), show clean deuterium incorporation only into the imine silylmethyl resonances. Addition of other internal alkynes (*t*-BuC≡C-*t*-Bu, *n*-BuC≡C-*n*-Bu) to the tetrahydride **1** also appears to promote ligand decomposition, although no characterizable products could be cleanly isolated. The formation of **8** is yet another example of the fragile nature of the [NPN] ligand (3, 14, 20, 21).

A mechanistic proposal for this transformation is challenging. The alkyne is presumably too bulky and thus cannot react with the dihydride intermediate in the same manner as terminal alkynes (Scheme 3), and this results in the ligand undergoing a series of oxidative cleavage and rearrangement processes. Speculation beyond such obvious statements is not useful.

Concluding remarks

The dinuclear tetrahydride ([NPN]Ta)$_2$(μ-H)$_4$ (**1**) activates terminal alkynes in a manner that is reminiscent of the activation of molecular nitrogen. In both cases, unsymmetrical bridging modes are observed in which considerable bond activation has occurred. In the case of terminal acetylenes, the adduct is best described as a bis(μ-alkylidene), wherein the original C≡C triple bond has been reduced to a C—C bond. The same bis(μ-alkylidene) product is observed when phenylacetylene is added to the dinitrogen complex ([NPN]Ta)$_2$(μ-η^1:η^2-N_2)(μ-H)$_2$ (**2**) and suggests the intermediacy of a common species in the formation of ([NPN]Ta)$_2$(μ-PhCCH)(μ-H)$_2$ (**4**), likely the d^2–d^2 dinuclear dihydride ([NPN]Ta)$_2$(μ-H)$_2$ (**3**). Upon standing, **4** loses H_2 under vacuum, which results in the cleavage of the C≡C bond to give a bis(μ-alkylidyne) complex, ([NPN]Ta)$_2$(μ-CPh)(μ-CH) (**7**). This represents a formal reduction of the C≡C triple bond by six electrons, supplied by the d^2–d^2

dihydride **3** coupled with loss of H_2. Attempts to extend this activation process to internal alkynes were not successful, likely because of increased steric effects in the substrates. In the case of diphenylacetylene, ancillary ligand degradation and rearrangement were observed.

Experimental

General considerations

Unless otherwise stated, all manipulations were performed under an inert atmosphere of dry, oxygen-free dinitrogen or argon by means of standard Schlenk or glovebox techniques. Where choice of atmosphere affects reaction outcomes, the distinction between dinitrogen and argon use will be made. Anhydrous hexanes and toluene were purchased from Aldrich, sparged with dinitrogen, and passed through activated alumina and Ridox catalyst columns under a positive pressure of nitrogen prior to use (22). Anhydrous pentane, benzene, tetrahydrofuran, and diethylether were purchased from Aldrich, sparged with dinitrogen, and passed through an Innovative Technologies Pure-Solv 400 solvent purification system. All organic solvents were tested by addition of a toluene solution of sodium benzophenone ketyl prior to use to ensure the absence of oxygen and water. Alternatively, anhydrous diethylether was stored over sieves and distilled from sodium benzophenone ketyl under argon. Tetrahydrofuran was refluxed over CaH_2 prior to distillation from sodium benzophenone ketyl under argon, and pentane was stored over sieves and distilled from sodium benzophenone ketyl solubilized by tetraglyme under argon prior to storage over a potassium mirror. Nitrogen gas was dried and deoxygenated by passage through a column containing activated molecular sieves and MnO. Deuterated benzene was dried by heating at reflux with a sodium–potassium alloy in a sealed vessel under partial pressure, then trap-to-trap distilled, and freeze–pump–thaw degassed three times. Unless otherwise stated, ^{1}H, ^{31}P, ^{1}H{^{31}P}, and ^{31}P{^{1}H} NMR spectra were recorded on a Bruker AMX-500 instrument with a 5 mm BBI probe operating at 500.1 MHz for ^{1}H. ^{1}H NMR spectra were referenced to residual protons in C_6D_5H (δ 7.15 ppm) with respect to tetramethylsilane at δ 0.0 ppm. ^{31}P NMR spectra were referenced to either external or internal $P(OMe)_3$ (δ 141.0 ppm with respect to 85% H_3PO_4 at δ 0.0 ppm). Elemental analyses were performed by Mr. P. Borda and M. Lakha of the Department of Chemistry, University of British Columbia. Complexes $([NPN]Ta)_2(\mu\text{-}H)_4$, $([NPN]Ta)_2(\mu\text{-}D)_4$, and $([NPN]Ta)_2(\mu\text{-}\eta^1\text{:}\eta^2\text{-}N_2)(\mu\text{-}H)_2$ were prepared following literature procedures (13). PhC≡CH, *t*-uC≡CH, *n*-PrC≡CH, and PhC≡CPh were purchased from Aldrich and purified by standard procedures prior to use.

Preparation of $([NPN]Ta)_2(\mu\text{-PhCCH})(\mu\text{-}H)_2$ (4), $([NPN]Ta)_2(\mu\text{-}n\text{-PrCCH})(\mu\text{-}H)_2$ (5), and $([NPN]Ta)_2(\mu\text{-}t\text{-BuCCH})(\mu\text{-}H)_2$ (6)

A solution of $([NPN]Ta)_2(\mu\text{-}H)_4$ (500 mg, 0.405 mmol) in 20 mL Et_2O under argon was prepared in a vessel equipped with a Kontes valve. The neat alkyne RCCH (0.405 mol) was added to the flask via microsyringe, the vessel was sealed, and its contents stirred for 6 h. A colour change from deep purple to brown was observed, along with the evolution of a gas. Removal of solvent in vacuo left a dark brown solid. This solid was triturated with pentane and dried under vacuum to afford $([NPN]Ta)_2(\mu\text{-PhCCH})(\mu\text{-}H)_2$ (**4**), $([NPN]Ta)_2(\mu\text{-}n\text{-PrCCH})(\mu\text{-}H)_2$ (**5**), and $([NPN]Ta)_2(\mu\text{-}t\text{-BuCCH})(\mu\text{-}H)_2$ (**6**) in 92%, 80%, and 88% yields.

Anal. calcd. for $C_{56}H_{70}N_6P_2Si_4Ta_2$: C 50.37, H 5.28, N 4.20; found: C 50.24, H 5.50, N 4.26.

5: ^{1}H NMR (C_6D_6, 25 °C, 500 MHz) δ: –0.20, –0.12, 0.06, 0.10, 0.15, 0.29, 0.31, 0.33 (s, 24H, SiCH_3), 0.46–1.61 (m, 13H, $CH_2CH_2CH_3$, PCH_2Si), 3.08 (br, 2H, TaCCH_2), 6.51–7.75 (m, 30H, NPh-*H*, PPh-*H*), 10.84 (d of d, 1H, $^3J_{HP}$ = 14.5, 20.5 Hz, CH_2CC*H*), 11.03 (d of d of d, 1H, Ta*H*Ta), 11.56 (m, 1H, Ta*H*Ta). ^{13}C NMR (C_6D_6, 25 °C, selected resonances) δ: 212.9 and 214.3 (TaH*CC*C). ^{31}P NMR (C_6D_6, 25 °C, 202.5 MHz) δ: 11.91 (d, J_{PP} = 4 Hz), 12.48 (d, J_{PP} = 4 Hz).

6: ^{1}H NMR (C_6D_6, 25 °C, 500 MHz) δ: –0.14, –0.11, 0.01, 0.06, 0.18, 0.19, 0.26, 0.34 (s, 24H, SiCH_3), 0.58–1.70 (m, 8H, PCH_2Si), 1.45 (s, 9H, C(CH_3)$_3$), 6.44–7.89 (m, 30H, NPh-*H*, PPh-*H*), 11.09 (d, 1H, J_{HP} = 12.6 Hz, ^{t}BuCC*H*), 11.51 (m, 1H, Ta*H*Ta), 12.08 (m, 1H, Ta*H*Ta). ^{13}C NMR (C_6D_6, 25 °C, selected resonances) δ: 205.5 and 205.3 (TaH*CC*C). ^{31}P NMR (C_6D_6, 25 °C, 202.5 MHz) δ: 6.10 (s), 9.17 (s).

Alternative preparation of $([NPN]Ta)_2(\mu\text{-PhCCH})(\mu\text{-}H)_2$ (4)

Phenylacetylene (0.0656 g, 0.642 mmol) was added to a solution of $([NPN]Ta)_2(\mu\text{-}\eta^1\text{:}\eta^2\text{-}N_2)(\mu\text{-}H)_2$ (0.810 g, 0.642 mmol) in toluene. The solution underwent a noticeable colour change to a darker brown. The solution was stirred for 24 h to ensure complete reaction and then evaporated to dryness. The product was washed with pentanes and dried under vacuum to yield **4** as a dark brown powder in 83% yield.

Preparation of $([NPN]Ta)_2(\mu\text{-CH})(\mu\text{-CPh})$ (7)

$([NPN]Ta)_2(\mu\text{-PhCCH})(\mu\text{-}H)_2$ (250 mg) was dissolved in 20 mL Et_2O in a vessel equipped with a Kontes valve. The contents of the flask were frozen, and the vessel was evacuated. The brown solution was warmed to room temperature and stirred for 12 h prompting a distinct lightening in the solution colour. Removal of volatiles in vacuo gave a light brown solid. Washing this solid with hexanes afforded $([NPN]Ta)_2(\mu\text{-CH})(\mu\text{-CPh})$ in 75% yield. ^{1}H NMR (C_6D_6, 25 °C, 500 MHz) δ: 0.01, 0.10, 0.21, 0.33 (s, 24H, SiCH_3), 1.22 (m, 8H, PCH_2Si), 4.95 (s, 1H, Ta-C*H*), 6.62–7.37 (m, 35H, NPh-*H*, PPh-*H*, CPh-*H*). ^{13}C NMR (C_6D_6, 25 °C, selected resonances) δ: 308.8 and 311.2 (s, Ta-*C*-Ta). ^{31}P NMR (C_6D_6, 25 °C, 202.5 MHz) δ: 11.5 (s).

Preparation of 8 via addition of PhC≡CPh to $([NPN]Ta)_2(\mu\text{-}H)_4$

A solution of $([NPN]Ta)_2(\mu\text{-}H)_4$ (500 mg, 0.405 mmol) in

© 2005 NRC Canada

20 mL Et_2O under argon was prepared in a vessel equipped with a Kontes valve. A solution of diphenylacetylene (72.2 mg, 0.405 mol) in Et_2O (1 mL) was added to the flask via syringe, the vessel sealed, and its contents stirred. A slow colour change from deep purple to orange was observed, along with the evolution of a gas. After 24 h, removal of solvent in vacuo left an orange solid. This solid was triturated with pentane and dried under vacuum to afford **8** as an orange powder in 72% yield. Crystals of this product were grown from a saturated benzene solution. ^{1}H NMR (C_6D_6, 25 °C, 500 MHz) δ: –0.72 (s, 3H, SiCH_3), –0.01 (s, 3H, SiCH_3), 0.02 (s, 3H, SiCH_3), 0.03 (s, 3H, SiCH_3), 0.22 (s, 9H, Si(CH_3)$_3$), 0.50 (s, 3H, SiCH_3), 0.84 (s, 3H, SiCH_3), 1.36–2.10 (m, 6H, PCH_2Si), 6.69–8.09 (m, 35H, NPh-*H*, PPh-*H*, TaPh-*H*, CPh-*H*). ^{31}P NMR (C_6D_6, 25 °C, 202.5 MHz) δ: 13.36 (d, $^2J_{PP}$ = 141 Hz), 130.61 (d, $^2J_{PP}$ = 141 Hz). Anal. calcd. for $C_{60}H_{84}N_4P_2Si_4Ta_2$: C 51.57, H 6.06, N 4.01; found: C 51.90, H 6.39, N 3.70.

Addition of PhC≡CPh to ([NPN]Ta)$_2$(μ-D)$_4$

The experiment was conducted analogously to the preparation of **8** above via the addition of diphenylacetylene (72.2 mg, 0.405 mol) to the dinuclear tetradeuteride ([NPN]Ta)$_2$(μ-D)$_4$ (501.6 mg, 0.405 mmol). Characterization of the crude orange powder by ^{1}H and ^{31}P NMR spectroscopy showed identical resonances to **8**, except where indicated. ^{1}H NMR (C_6D_6, 25 °C, 500 MHz) δ: 0.23 (m, 8H, Si(CH_3)$_2$(CH_2D)).

X-ray crystal structure experimental information

Suitable crystals were selected and coated in Paratone-N oil or an acceptable substitute under an inert atmosphere. Crystals were then mounted on a glass fiber external to the glovebox environment. All measurements were made on a Rigaku/ADSC CCD area detector with graphite monochromated Mo-Kα radiation. The structure for compound **2** was collected and solved by Dr. Brian Patrick. The structure for compound **7** was collected with the assistance of Mr. Chris Carmichael and solved by the author (M.P.S). The data were collected at a temperature of –100 ± 1 °C. The data were processed using the d*TREK program (23) in the CrystalClear software package (version 1.3.5), and corrected for Lorentz and polarization effects, and absorption. Neutral atom scattering factors for all non-hydrogen atoms were taken from Cromer and Waber (24). Anomalous dispersion effects were included in Fcalc (25). The structures were solved by direct methods using SIR92 (26) or SIR2002 (27) and expanded using Fourier techniques. All non-hydrogen atoms were refined anisotropically using SHELXL-97 (28). When hydrogen atom locations were important in determining compound composition or connectivity, hydrogen atoms were located and refined isotropically. Otherwise, hydrogen atoms were included in fixed positions. Their positional parameters were calculated with fixed C—H bond distances of 0.99 Å for sp^2 C, 0.98 Å for sp^3 C, and 0.95 Å for aromatic *sp* C, with U_{iso} set to 1.2 times the U_{eq} values of the attached *sp* or sp^2 C and 1.5 times the U_{eq} value of the attached sp^3 C atoms. Methyl hydrogen torsion angles were determined from electron density. Structure solution and refinements were conducted using the WinGX software package (version 1.64.05) (29).

Synthesis and catalysed hydroboration of styryl sulfonamides[1]

Natalie A. Wynberg, Lisa J. Leger, Maren L. Conrad, Christopher M. Vogels, Andreas Decken, Stephen J. Duffy, and Stephen A. Westcott

Abstract: We have prepared the aryl sulfonamides 4,4′-R-$C_6H_4SO_2NHC_6H_4CH{=}CH_2$ (R = CH_3, **1a**; NO_2, **1b**) by addition of 2 equiv. of 4-vinylaniline to the corresponding sulfonyl chlorides. The disulfonamides 4,4,4′-(R-$C_6H_4SO_2)_2$-$NC_6H_4CH{=}CH_2$ (R = CH_3, **2a**; NO_2, **2b**) were also prepared using 4-vinylaniline and 2 equiv. of the sulfonyl chlorides in the presence of DMAP. Although hydroborations of sulfanilamide derivatives **1** suffered from competing hydrogenation reactions, judicious choice of the transition metal catalyst gave selective formation of either the primary or secondary boronate esters in hydroborations of **2a**.

Key words: boronate esters, catalysed hydroborations, sulfanilamides, vinylaniline.

Résumé : On a préparé les aryl sulfonamides, 4,4′-R-$C_6H_4SO_2NHC_6H_4CH{=}CH_2$ (R = CH_3, **1a**; NO_2, **1b**) par l'addition de deux équivalents de 4-vinylaniline aux chlorures de sulfonyle correspondants. On a aussi préparé les disulfonamides 4,4,4′-(R-$C_6H_4SO_2)_2NC_6H_4CH{=}CH_2$ (R = CH_3, **2a**; NO_2, **2b**) à partir de la 4-vinylaniline et de deux équivalents de chlorures de sulfonyle, en présence de DMAP. Quoique les réactions d'hydroboration des dérivés sulfanilamides **1** soient en compétition avec les réactions d'hydrogénation, un choix judicieux d'un catalyseur à base d'un métal de transition permet d'obtenir la formation sélective des boronates soit primaires ou secondaires lors des hydroborations du composé **2a**.

Mots clés : esters de l'acide boronique, hydroborations catalysées, sulfanilamides, vinylaniline.

[Traduit par la Rédaction]

Introduction

The hydroboration of alkenes and alkynes, which constitutes the addition of a B—H bond across a carbon—carbon multiple bond, is a remarkably important reaction in organic synthesis (1). Although simple boron hydride reagents such as borane ($H_3B{\cdot}X$, where X is a Lewis base) and 9-borabicyclo[3.3.1]nonane react readily with alkenes at room temperature, hydroborations with catecholborane (HBcat, cat = 1,2-$O_2C_6H_4$) generally require elevated temperatures. The discovery that transition metals can be used to catalyse the addition of HBcat to substrates has become an important and well-established technique in organic synthesis (2–6). These reactions can have regio-, chemo-, or stereoselectivities complementary, or more remarkably, opposite to those from products obtained via the uncatalysed variant. For example, hydroborations of styrenes ($ArCH{=}CH_2$) with HBcat proceed to give selectively either the expected primary boronate ester ($ArCH_2CH_2Bcat$) or the secondary boronate ester ($ArCH(Bcat)CH_3$), depending upon the choice of catalyst used to affect this transformation (Scheme 1) (3). Rhodium-catalysed hydroborations are the most common and synthetically useful of these reactions. They are believed to proceed via initial oxidative addition of HBcat (7), followed by coordination of the alkene to the metal centre with subsequent insertion of the alkene into either the Rh—H (8) or the Rh—B bond (9) and reductive elimination to yield the desired product (10). The unusual secondary boronate ester product is believed to arise when the metal centre can best stabilize a benzylic intermediate during the catalytic cycle.

Although a considerable amount of research has focused on the catalysed hydroboration of simple unsaturated hydrocarbon systems, much less is known about analogous reactions with heteroatom-containing substrates (3, 11–17). For instance, catalysed hydroborations of pyrrolidinyl amides with HBcat gave, after oxidation, *syn* 1,3-hydroxy amides with high levels of regio- and stereochemical control (18). The remarkable selectivities observed in these reactions are believed to arise from a directing effect of the amide moiety. As part of our ongoing investigation into generating biologically active boron compounds (19) and, in an effort to expand the scope of metal-catalysed hydroborations, we de-

cided to examine the synthesis and hydroboration of sulfanilamide derivatives containing a pendant styryl moiety. Initial results are presented herein.

Experimental

Materials and methods

Reagents and solvents used were obtained from Aldrich Chemicals. $RhCl(PPh_3)_3$ (20), $Rh(acac)(coe)_2$ (21), and $[Cp^*IrCl_2]_2$ (22) were prepared as described elsewhere. NMR spectra were recorded on a JEOL JNM-GSX270 FT NMR spectrometer. ^{1}H NMR chemical shifts are reported in parts per million (ppm) and are referenced to residual protons in deuterated solvent at 270 MHz. ^{11}B NMR chemical shifts are referenced to external $BF_3{\cdot}OEt_2$ at 87 MHz. ^{13}C NMR chemical shifts are referenced to solvent carbon resonances as internal standards at 68 MHz. Multiplicities are reported as singlet (s), doublet (d), triplet (t), quartet (q), multiplet (m), broad (br), and overlapping (ov). Infrared spectra were obtained using a Mattson Genesis II FT-IR spectrometer and are reported in cm^{-1}. Melting points were measured uncorrected with a Mel-Temp apparatus. GC-MS analyses were conducted using a Varian Saturn 2000 GC/MS/MS coupled to a CP-3800 GC. The GC was equipped with both the 1177 injection port with a CP-8410 liquid autoinjector connected to an SPB-1 (Supelco) fused silica column (30 m × 0.25 mm i.d. × 0.25 μm) and the 1079 solid injector chromatoprobe, attached to a 50 cm transfer line. The GC-MS spectrometer is controlled by the Saturn Workstation software, Version 5.51.

Synthesis

General synthesis of 1a and 1b

Under an atmosphere of dinitrogen, an Et_2O (2 mL) solution of 4-vinylaniline (2 equiv.) was added dropwise to a stirred Et_2O (5 mL) solution of the appropriate sulfonyl chloride. The mixture was allowed to stir for 18 h, at which point the resulting solid was removed by filtration and the filtrate stored at –30 °C for 2 days. Any subsequent precipitate was also removed by filtration and discarded. Compounds **1a** and **1b** were recovered upon removal of solvent under vacuum and washed with hexane (3 × 3 mL).

Compound 1a

Yield: 70%, mp 80–82 °C. ^{1}H NMR ($CDCl_3$) δ: 7.65 (d, J = 8 Hz, 2H, Ar), 7.26 (d, J = 8 Hz, 2H, Ar), 7.21 (d, J = 8 Hz, 2H, Ar), 7.01 (d, J = 8 Hz, 2H, Ar), 6.76 (br s, 1H, N*H*), 6.60 (d of d, J = 18, 10 Hz, 1H, C*H*=CH_2), 5.64 (d, J = 18 Hz, 1H, CH=C*H*H), 5.18 (d, J = 10 Hz, 1H, CH=CH*H*), 2.36 (s, 3H, CH_3). ^{13}C NMR ($CDCl_3$) δ: 144.0, 136.1, 136.0, 135.9, 134.9, 129.7, 127.3, 127.2, 121.7, 113.8, 21.6. IR (Nujol): 3271, 2943, 2922, 1597, 1508, 1392, 1333, 1159, 1090, 906, 814, 681, 492. EI-MS *m*/*z* (relative intensity): 273 (73, $[M]^+$), 155 (5), 118 (100), 91 (58).

Compound 1b

Yield: 60%, mp 182–184 °C. ^{1}H NMR (DMSO-d_6) δ: 10.68 (br s, 1H, N*H*), 8.37 (d, J = 8 Hz, 2H, Ar), 7.99 (d, J = 8 Hz, 2H, Ar), 7.36 (d, J = 8 Hz, 2H, Ar), 7.08 (d, J = 8 Hz, 2H, Ar), 6.58 (d of d, J = 18, 10 Hz, 1H, C*H*=CH_2), 5.71 (d, J = 18 Hz, 1H, CH=C*H*H), 5.17 (d, J = 10 Hz, 1H, CH=CH*H*). ^{13}C NMR (DMSO-d_6) δ: 150.4, 145.4, 137.0, 136.3, 134.3, 128.8, 127.7, 125.2, 121.2, 114.4. IR (Nujol): 3224, 2935, 2912, 1606, 1527, 1348, 1165, 1086, 924, 854, 735, 604, 542. EI-MS *m*/*z* (relative intensity): 304 (41, $[M]^+$), 118 (100).

Reaction of 1a with 1 equiv. of HBcat in the presence of $RhCl(PPh_3)_3$

Under an atmosphere of dinitrogen, a 0.5 mL C_6D_6 solution of HBcat (1 equiv.) was added to a mixture of **1a** and $RhCl(PPh_3)_3$ (0.05 equiv.) in 0.5 mL of C_6D_6. The reaction was allowed to proceed for 4 h, at which point NMR spectroscopic data was collected. ^{1}H NMR δ: 7.92 (d, J = 8 Hz, 2H, Ar), 7.00 (d, J = 8 Hz, 2H, Ar), 6.96–6.82 (ov m, 4H, Ar and Bcat), 6.70–6.64 (ov m, 4H, Ar and Bcat), 2.31 (q, J = 8 Hz, 2H, CH_2CH_3), 1.82 (s, 3H, CH_3), 0.94 (t, J = 8 Hz, 3H, CH_2CH_3). ^{11}B NMR δ: 24.8 ($ArSO_2N(Bcat)CH_2CH_3$).

Reaction of 1b with 1 equiv. of HBcat in the presence of $RhCl(PPh_3)_3$

Under an atmosphere of dinitrogen, a 0.5 mL $CDCl_3$ solu-

tion of HBcat (1 equiv.) was added to a suspension of **1b** and $RhCl(PPh_3)_3$ (0.05 equiv.) in 0.5 mL of $CDCl_3$. The reaction was allowed to proceed for 18 h, at which point spectroscopic NMR data of the resulting hydrogenation product ($ArN(Bcat)CH_2CH_3$, 98% by NMR spectroscopy) was collected. ^{1}H NMR δ: 8.21 (d, *J* = 8 Hz, 2H, Ar), 7.93 (d, *J* = 8 Hz, 2H, Ar), 7.24–7.04 (ov m, 8H, Ar and Bcat), 2.56 (q, *J* = 8 Hz, 2H, CH_2CH_3), 1.16 (t, *J* = 8 Hz, 3H, CH_2CH_3). ^{11}B NMR δ: 24.5 ($ArN(Bcat)CH_2CH_3$).

General synthesis of 2a and 2b

Under an atmosphere of dinitrogen, a toluene (2 mL) solution of 4-vinylaniline was added dropwise to a stirred toluene (5 mL) mixture of the appropriate sulfonyl chloride (2.5 equiv.) and 4-DMAP (2.5 equiv.). The mixture was heated at reflux for 2 days, at which point solvent was removed under vacuum, and the resultant white solid was washed with Et_2O (3 × 5 mL). The filtrate was collected, and the Et_2O was removed under vacuum. The resulting solid was then washed with EtOH (4 × 5 mL) to afford **2**.

Compound 2a

Yield: 70%, mp 176–178 °C. ^{1}H NMR ($CDCl_3$) δ: 7.81 (d, *J* = 8 Hz, 4H, Ar), 7.36 (d, *J* = 8 Hz, 2H, Ar), 7.32 (d, *J* = 8 Hz, 4H, Ar), 6.97 (d, *J* = 8 Hz, 2H, Ar), 6.69 (d of d, *J* = 18, 10 Hz, 1H, CH=CH_2), 5.77 (d, *J* = 18 Hz, 1H, CH=C*H*H), 5.33 (d, *J* = 10 Hz, 1H, CH=CH*H*), 2.45 (s, 6H, CH_3). ^{13}C NMR ($CDCl_3$) δ: 145.1, 139.5, 136.7, 135.8, 133.6, 131.7, 129.7, 128.7, 127.0, 116.1, 21.8. IR (Nujol): 2970, 2951, 1595, 1462, 1377, 1167, 908, 806, 661, 550, 488. EI-MS *m*/*z* (relative intensity): 427 (98, $[M]^+$), 272 (53), 208 (100), 155 (13), 118 (16), 91 (20).

Compound 2b

Yield: 55%, mp 274 to 275 °C. ^{1}H NMR (DMSO-d_6) δ: 8.51 (d, *J* = 8 Hz, 4H, Ar), 8.12 (d, *J* = 8 Hz, 4H, Ar), 7.59 (d, *J* = 8 Hz, 2H, Ar), 7.10 (d, *J* = 8 Hz, 2H, Ar), 6.80 (d of d, *J* = 18, 10 Hz, 1H, CH=CH_2), 5.96 (d, *J* = 18 Hz, 1H, CH=C*H*H), 5.42 (d, *J* = 10 Hz, 1H, CH=CH*H*). ^{13}C NMR (DMSO-d_6) δ: 151.5, 143.6, 140.3, 135.8, 132.2, 132.1, 130.4, 128.1, 125.6, 117.9. IR (Nujol): 2935, 2902, 2863, 1710, 1531, 1462, 1377, 1169, 1082, 960, 920, 852, 733, 642, 602, 552. EI-MS *m*/*z* (relative intensity): 489 (2, $[M]^+$), 304 (57), 273 (3), 118 (100).

General procedure for the hydroboration of compounds 3 and 4

Under an atmosphere of dinitrogen, 1 equiv. of catecholborane in 0.5 mL of $CDCl_3$ was added to a 0.5 mL $CDCl_3$ solution of the appropriate catalyst and substrate. The reactions were allowed to proceed for 18 h, at which point NMR data were collected. Compounds **3** and **4** were isolated by recrystallization from a solution of $CDCl_3$:hexane (1:2) stored at –30 °C.

Compound 3

^{1}H NMR ($CDCl_3$) δ: 7.79 (d, *J* = 8 Hz, 4H, Ar), 7.29 (d, *J* = 8 Hz, 4H, Ar), 7.25–7.20 (ov m, 4H, Ar and Bcat), 7.08 (2nd order m, 2H, Bcat), 6.92 (d, *J* = 8 Hz, 2H, Ar), 2.99 (t, *J* = 8 Hz, 2H, CH_2CH_2Bcat), 2.44 (s, 6H, CH_3), 1.66 (t, *J* = 8 Hz, 2H, CH_2CH_2Bcat). ^{13}C NMR ($CDCl_3$) δ: 148.2, 146.0, 145.0, 136.8, 132.2, 131.5, 129.6, 128.8, 128.7, 122.7, 112.4, 29.4, 21.8, 12.1 (br, *C*-B). ^{11}B NMR ($CDCl_3$) δ: 34.8. EI-MS *m*/*z* (relative intensity): 547 (12, $[M]^+$), 429 (100), 273 (68), 155 (8), 118 (33).

Compound 4

^{1}H NMR ($CDCl_3$) δ: 7.81 (d, *J* = 8 Hz, 4H, Ar), 7.31 (d, *J* = 8 Hz, 4H, Ar), 7.30 (d, *J* = 8 Hz, 2H, Ar), 7.22 (2nd order m, 2H, Bcat), 7.09 (2nd order m, 2H, Bcat), 6.96 (d, *J* = 8 Hz, 2H, Ar), 3.01 (q, *J* = 8 Hz, 1H, $CH(Bcat)CH_3$), 2.45 (s, 6H, CH_3), 1.58 (d, *J* = 8 Hz, 3H, $CH(Bcat)CH_3$). ^{13}C NMR ($CDCl_3$) δ: 148.2, 145.7, 145.0, 136.9, 132.0, 131.6, 129.6, 128.7, 128.6, 122.9, 112.6, 24.8 (br, *C*-B), 21.8, 16.6. ^{11}B NMR ($CDCl_3$) δ: 34.1. EI-MS *m*/*z* (relative intensity): 547 (2, $[M]^+$), 428 (18), 246 (100), 155 (8), 118 (16).

X-ray data

Crystals of **3** were grown by slow evaporation using $CHCl_3$ at –30 °C. Crystals were coated with Paratone-N oil, mounted using a glass fibre, and frozen in the cold nitrogen stream of the goniometer. A hemisphere of data was collected on a Bruker AXS P4/SMART 1000 diffractometer using ω and θ scans with a scan width of 0.3° and with 90 s exposure times. The detector distance was 6 cm. The crystal was twinned, and the orientation matrixes for two components were determined (23, 24), and the data were reduced (25). The structure was solved by direct methods and refined by full-matrix least squares on F^2 (SHELXTL) (26) using all reflections. One of the ethyl linkages was disordered, and the site occupancy was determined using an isotropic model as 0.7 (C(41)—C(42)) and 0.3 (C(41′)—C(42′)) and was fixed in subsequent refinement cycles. All non-hydrogen atoms were refined anisotropically. Hydrogen atoms were included in calculated positions and refined using a riding model.

Results and discussion

N-Aryl sulfonamides are an important class of compounds, particularly in pharmaceutical research (27), where a number of these compounds have been reported to act as class III antiarrhythmic agents (28), non-nucleotide reverse transcriptase inhibitors (29), and as HIV-1 protease inhibitors (30). We have recently undertaken a study to investigate the synthesis and biological activity of novel borosulfonamides (31, 32). Interest in compounds containing boronic acids ($RB(OH)_2$) or boronate esters ($RB(OR')_2$) arises from their remarkable versatility in organic synthesis (33), as well as from their potent biological activities (34–42). For instance, the boron compounds boromycin and aplasmomycin are powerful antibiotics, and *L*-4-borono-phenylalanine has found significant application in boron neutron capture therapy for the treatment of certain cancers (43). These properties, along with their ability to transport water-insoluble reagents through membranes (44), make boronate ester compounds useful carrier ligands for biologically active compounds.

In this study, we have prepared the novel aryl sulfonamides 4,4′-R-$C_6H_4SO_2NHC_6H_4CH$=CH_2 (R = CH_3, **1a**; NO_2, **1b**) (Fig. 1) by addition of 2 equiv. of 4-vinylaniline to the corresponding sulfonyl chlorides. Varying the physical

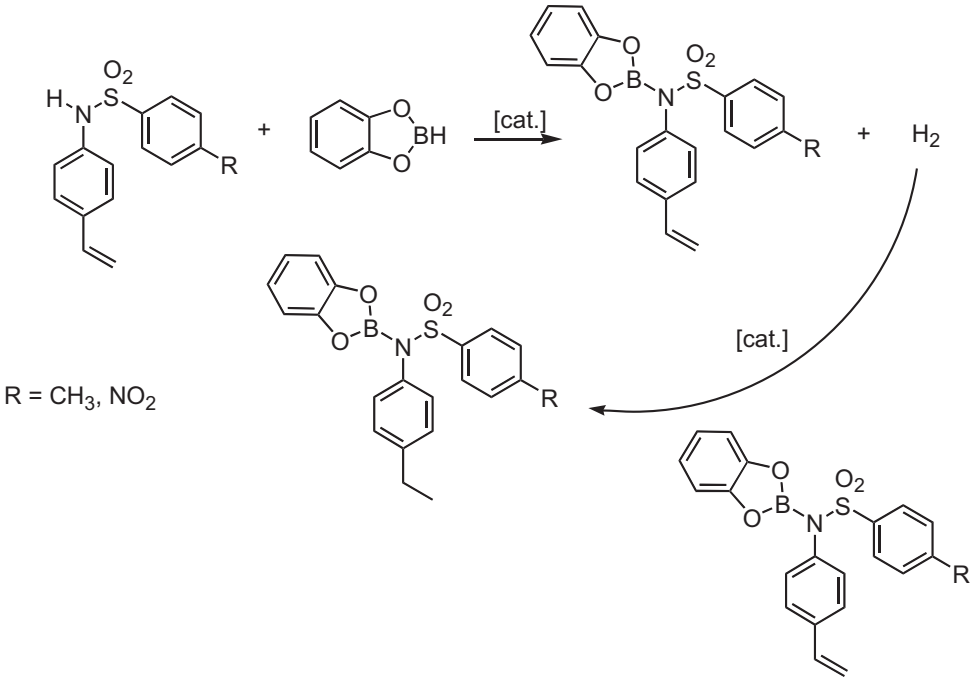
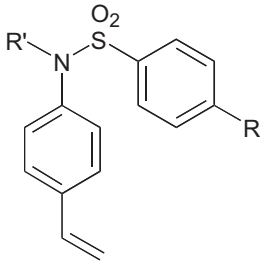
Scheme 2.





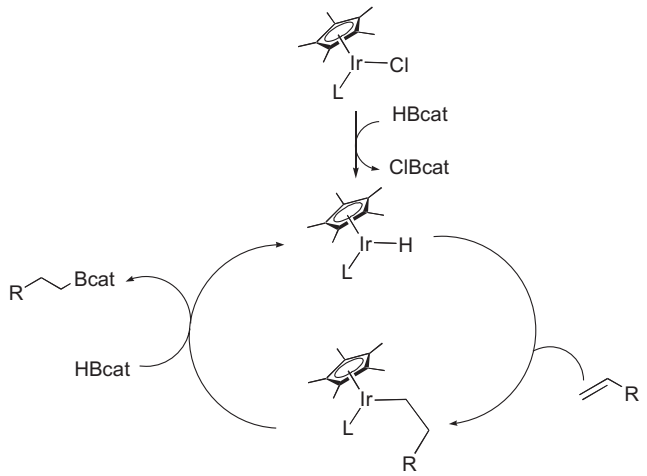


Fig. 1. Styryl sulfanilamides.

1a: R = CH_3, R' = H
1b: R = NO_2, R' = H
2a: R = CH_3, R' =4-$SO_2C_6H_4CH_3$
2b: R = NO_2, R' =4-$SO_2C_6H_4NO_2$

and electronic properties of the sulfonyl chlorides will allow for the general synthesis of a wide variety of styryl sulfanilamide derivatives. Unfortunately, we have found that metal-catalysed addition of 1.1 equiv. of HBcat to styryl sulfonamides **1a** and **1b** gave significant amounts (>95% by ^{1}H NMR spectroscopy) of hydrogenation products R-$C_6H_4SO_2N$(Bcat)$C_6H_4CH_2CH_3$ (R = CH_3 or NO_2). These products presumably arise as a result of an initial interaction of the borane with the sulfonamide N—H bond to generate a new N—Bcat bond while liberating dihydrogen, which can subsequently add to the styryl group in the presence of a catalyst (Scheme 2). Indeed, a new N—B resonance is observed in the ^{11}B NMR spectra at 25 ppm. Furthermore, reactions with excess HBcat gave a complicated mixture of products arising from competing hydrogenation and (or) hydroboration reactions, regardless of the catalyst used to affect these transformations. We therefore investigated the analogous reactions of sulfonamides **2**, which do not contain an active N—H bond.

Scheme 3.

The novel disulfonamides 4,4,4′-(R-$C_6H_4SO_2)_2NC_6H_4$-CH=CH_2 (R = CH_3, **2a**; NO_2, **2b**) could be prepared in moderate to good yields using 4-vinylaniline and 2.5 equiv. of the sulfonyl chlorides in the presence of excess DMAP. However, the introduction of a second nitrobenzene group in **2b** made this sulfonamide derivative insoluble in non-coordinating organic solvents, and as a result, hydroboration studies could not be conducted on this substrate. Addition of HBcat to **2a** using the iridium catalyst [Cp*$IrCl_2]_2$ (45) proceeded smoothly to give the expected primary boronate ester product **3** in high yields (by multinuclear NMR spectroscopy), along with minor amounts (<5%) of the corresponding hydrogenation product. A small amount of hydrogenated alkene, arising from the degradation of HBcat, is almost always observed in reactions using a late metal catalyst (46). Although it is possible that reactions using this catalyst precursor proceed via an oxidative addition mechanism, similar

to those purported for reactions using rhodium-based catalysts, it is also possible that these reactions may be occurring via a σ-bond metathesis pathway to give **3** (Scheme 3). This reaction could proceed via initial metathesis of an Ir—Cl bond with HBcat to give a transient iridium hydride species. The formation of Ir-H species in hydroborations using HBcat has been reported previously (45). Subsequent insertion of the alkene into the Ir—H bond, followed by a σ-bond metathesis with HBcat would give the primary boronate ester while regenerating the active Ir-H catalyst. A similar mechanism has been proposed for reactions of HBcat using early metal and lanthanide catalysts (47). The iridium-catalysed hydroboration of alkenes using pinacolborane is also known to give the corresponding primary boronate ester products (48, 49).

Selective formation of the unusual secondary boronate ester **4** could be achieved in these reactions using either $RhCl(PPh_3)_3$ or Rh(acac)(dppe) (acac = acetylacetonato, dppe = 1,2-bis(diphenylphosphino)ethane) as the catalyst precursor (Scheme 4). The latter is a very active and selective catalyst precursor for a wide range of alkenes, where the resting state of the catalytically active species is the zwitterionic complex, Rh(dppe)(η^6-catBcat) (50). Compounds **3** and **4** have been characterized using a number of physical techniques, including multinuclear NMR spectroscopy. A broad peak at approximately δ 30 ppm in the ^{11}B NMR spectra is

observed for both sulfonamides, indicating that the boron atom lies in a three-coordinate C-Bcat environment (51). Compound **3** has also been characterized by a single crystal diffraction study, and the molecular structure is shown in Fig. 2;[4] crystallographic data are given in Table 1, and selected bond distances and angles are shown in Table 2. The B—O bond distances (avg. = 1.3955(5) Å) are also typical for three-coordinate Bcat groups (52–55) and are significantly shorter than those observed in chelate complexes with diphenylborinic acid (ca. 1.5 Å), where the boron atom is four coordinate (56).

In summary, we have prepared novel sulfanilamide derivatives containing styryl groups and have examined metal-catalysed hydroborations of these substrates using HBcat. Judicious choice of the catalyst precursor used to affect these transformations allows for the selective generation of either the primary or secondary boronate ester. Preliminary work has shown that these reactions are general, as analogous compounds could be obtained in metal-catalysed hydroborations of thiophene sulfonamide derivatives. Future work will investigate the potential biological activities of a wide range of novel styryl sulfonamides and the corresponding boron-containing derivatives, the results of which will be presented in due course.

Coordination polymers with Co(II) sulfate layers linked by alkanediamines of varying chain length[1]

J.N. Behera and C.N.R. Rao

Abstract: Coordination polymers of the general formula $Co[HN(CH_2)_nNH]SO_4$ possessing layers formed by CoO_4N_2 octahedra and SO_4 tetrahedra have been synthesized under solvothermal conditions. The layers, linked by diaminoalkanes, cause apertures of varying widths, which are determined by the chain length of the amine. These materials appear to possess weak ferromagnetic interaction at low temperatures.

Key words: coordination polymers, cobalt sulfate, solvothermal synthesis.

Résumé : Opérant dans des conditions solvothermiques, on a réalisé la synthèse de polymères de coordination de formule générale $Co[HN(CH_2)_nNH]SO_4$ possédant des couches formées d'octaèdres CoO_4N_2 et de tétraèdres SO_4. Les couches sont reliées par des diaminoalcanes qui provoquent des ouvertures de grandeurs variables déterminées par la longueur de la chaîne amine. À basses températures, ces matériaux semblent posséder de faibles interactions ferromagnétiques.

Mots clés : polymères de coordination, sulfate de cobalt, synthèse solvothermique.

[Traduit par la Rédaction]

Introduction

Metal-organic frameworks possess not only fascinating architectures but also give rise to materials with potential applications. Thus, hybrid materials constructed from V–Co–P–O layers comprise both left- and right-handed helical chains in the same compound (1), while in the porous extended 4,4′-bipyridyl network with Ni they exhibit a railroad 1D motif (2). In the coordination network of $[Co(bix)_2(H_2O)_2](SO_4)\cdot 7H_2O$, ribbons of rings catenated to a 3D single frame produce an open channel with nanoporous behavior (3). A metal-organic structure involving a benzene dicarboxylate of zinc is found to store hydrogen (4). Some coordination polymers and metal-organics exhibit interesting magnetic properties as well. For example, an organo-pillared octahedral cobalt sulfate is porous and metamagnetic (5). Benzene-1,2,3-tricarboxylates of cobalt possessing arrays of Δ-chains exhibit unusual magnetic properties (6). Infinite $^2[Co(ox)(bpy)]$ with a two-dimensional layered network shows canted antiferromagnetism (7). The chemistry of metal carboxylates with open architectures and porous coordination polymers has recently been reviewed (8). We have been interested in synthesizing coordination polymers of transition metals with alkanediamines acting as ligands as well as spacers between the layers. In this article, we describe the synthesis and structure of a family of three-dimensional coordination polymers of Co(II) of the general formula $[Co(HN(CH_2)_nNH)SO_4]$ (n = 3–6), obtained under mild solvothermal conditions wherein the Co(II) sulfate layers are linked by diaminoalkanes of differing chain lengths.

Experimental section

Synthesis and characterization

Compounds **I**–**IV** were synthesized under mild solvothermal conditions. In a typical synthesis, 0.237 g of $CoCl_2\cdot 6H_2O$ was dissolved in 4.6 mL of ethylene glycol and 0.9 mL of water with constant stirring. To this mixture, 0.22 mL of sulfuric acid (98%) and 0.45 mL of 1,3-diamino propane for **I**, 0.6 mL of 1,4-diamino butane for **II**, 0.7 mL of 1,5-diamino pentane for **III**, and 0.697 g of hexamethylene diamine for **IV** were added and the mixture was stirred for 1 h. The final mixture with the molar composition of $CoCl_2\cdot 6H_2O : H_2SO_4 : [H_2N\text{-}(CH_2)_n\text{-}NH_2] :$ ethylene glycol : H_2O of 1:4:6:50:50 at an initial pH of 8 was transferred into a 23 mL PTFE-lined acid digestion bomb and heated at 180 °C for 4 days. The products containing pink colored hexagonal plate-shaped crystals (yield 70% with respect to Co) were filtered and washed with ethanol. The compounds were characterized by single crystal X-ray diffraction, powder X-ray diffraction (XRD), thermogravimetric analysis (TGA), energy dispersive X-ray analysis (EDAX), elemental CNH analysis, and IR

spectroscopy. Magnetic measurements on powdered samples of **I** and **IV** were performed over a 2–300 K temperature range using a Quantum design SQUID magnetometer.

EDAX analysis indicated the ratio of Co and S to be 1:1 in **I–IV** in accordance with the formula. The C, N, and H analysis (in wt%): calcd. for **I**: C 15.8, N 12.3, H 3.6; found: C 15.03, N 12.2, H 4.7; calcd. for **II**: C 19.9, N 11.6, H 4.2; found: C 19.5, N 11.4, H 4.9; calcd. for **III**: C 23.5, N 10.97, H 4.74; found: C 23.1, N 10.8, H 5.2; calcd. for **IV**: C 26.74, N 10.4, H 5.24; found: C 26.5, N 10.2, H 5.5, were in agreement with the formulae, $[Co(C_3N_2H_8)SO_4]$, $[Co(C_4N_2H_{10})SO_4]$, $[Co(C_5N_2H_{12})\ SO_4]$, and $[Co\ (C_6N_2H_{14})\ SO_4]$, respectively, as derived from crystallography.

IR spectra showed the characteristic bands for amine and sulfate moieties. The bending and stretching modes of the methylene group were observed at 1463, 1408, and 2889 cm^{-1}, and the N–H stretching band at 3276 cm^{-1}. The SO_4 bands were at 1122 (asymmetric stretch), 980 (symmetric stretch), and 662 cm^{-1} (bending).

The TGA curves (N_2 atmosphere) of **I–IV** exhibited remarkable thermal stability showing no weight losses up to 300 °C but then two major weight losses, consistent with the molecular formulae, were observed. The first weight loss at around 350 °C corresponds to the loss of diamine while the second weight losses occur at around 600 °C in **I** and **II**, and at around 800 °C in **III** and **IV** corresponding to decomposition of sulfate. The total weight loss obtained was 67%, 69%, 73%, and 71% between 120 and 800 °C in **I–IV**, respectively. The final product contained a mixture of CoO and Co_3O_4 (JCPDS file card Nos. 09-0402 and 09-0418, respectively).

Single crystal structure determination

Single crystal data were collected on a Siemens SMART-CCD diffractometer (graphite-monochromated MoKα radiation, λ = 0.710 73 Å (*T* = 298 K)). An absorption correction based on symmetry-equivalent reflections was applied using the Siemens area detector absorption (SADABS) program (9). The structure was solved by direct methods using SHELXS-86 (10) and difference Fourier synthesis. The direct methods solution readily revealed the heavy atom positions (Co and S) and facilitated the identification of the other fragments (O, C, and N) from difference Fourier maps. The last cycles of refinement included atomic positions for all the atoms, anisotropic thermal parameters for the non-hydrogen atoms, and isotropic thermal parameters for all hydrogen atoms. Full-matrix least-squares structure refinement against $|F^2|$ was carried out using the SHELXTL-PLUS (11) package of programs. Details of the final refinement are given in Table 1 along with the crystal data.[3] The atomic coordinates and equivalent isotropic displacement parameters for **I** are given in Table 2. We have not given the atomic co-

ordinates of **II**–**IV** in view of their structural similarity. The powder X-ray diffraction pattern of the compounds was in good agreement with the simulated pattern generated from the single crystal XRD data, indicating the phase purity of the compounds.

Results and discussion

Compounds of the general formula, $Co(HN(CH_2)_nNH)SO_4$, where n = 3 (**I**), 4 (**II**), 5 (**III**), and 6 (**IV**), were synthesized under solvothermal conditions by the reaction of $CoCl_2 \cdot 6H_2O$ with the diaminoalkane and H_2SO_4. The pink colored crystals obtained as products were investigated by X-ray crystallography. Compounds **I**–**IV** are isostructural and therefore belong to the orthorhombic crystal system (space group *Pbcm*), with comparable a and b parameters while the c parameter increases with n or the chain length of the diamine. In Fig. 1, the asymmetric units of **I** and **IV** are given. The asymmetric units of these compounds consist of one cobalt atom, one sulfur atom, four oxygen atoms, and one diamine moiety, with the metal atom in a distorted octahedral geometry. Each metal ion center is coordinated by four oxygens from three different sulfate groups and by two nitrogen atoms from two different amine units. The sulfur atom makes four S–O–Co linkages by sharing both edges and corners with the metal atom. In Table 3, we have listed

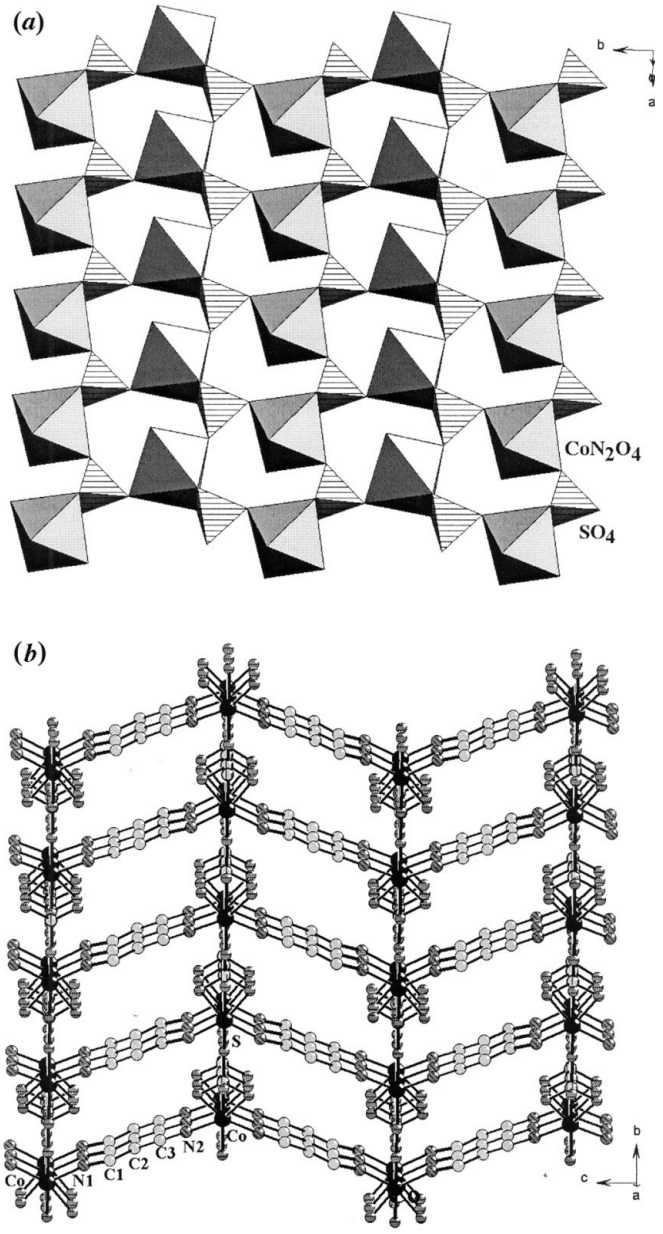
Fig. 2. (*a*) Layer in the *ab* plane of **I–IV**, formed by CoN_2O_4 octahedra and SO_4 tetrahedra, showing the presence of six-membered apertures. (*b*) View of the infinite three-dimensional framework in **I** along the *a* axis showing the apertures.



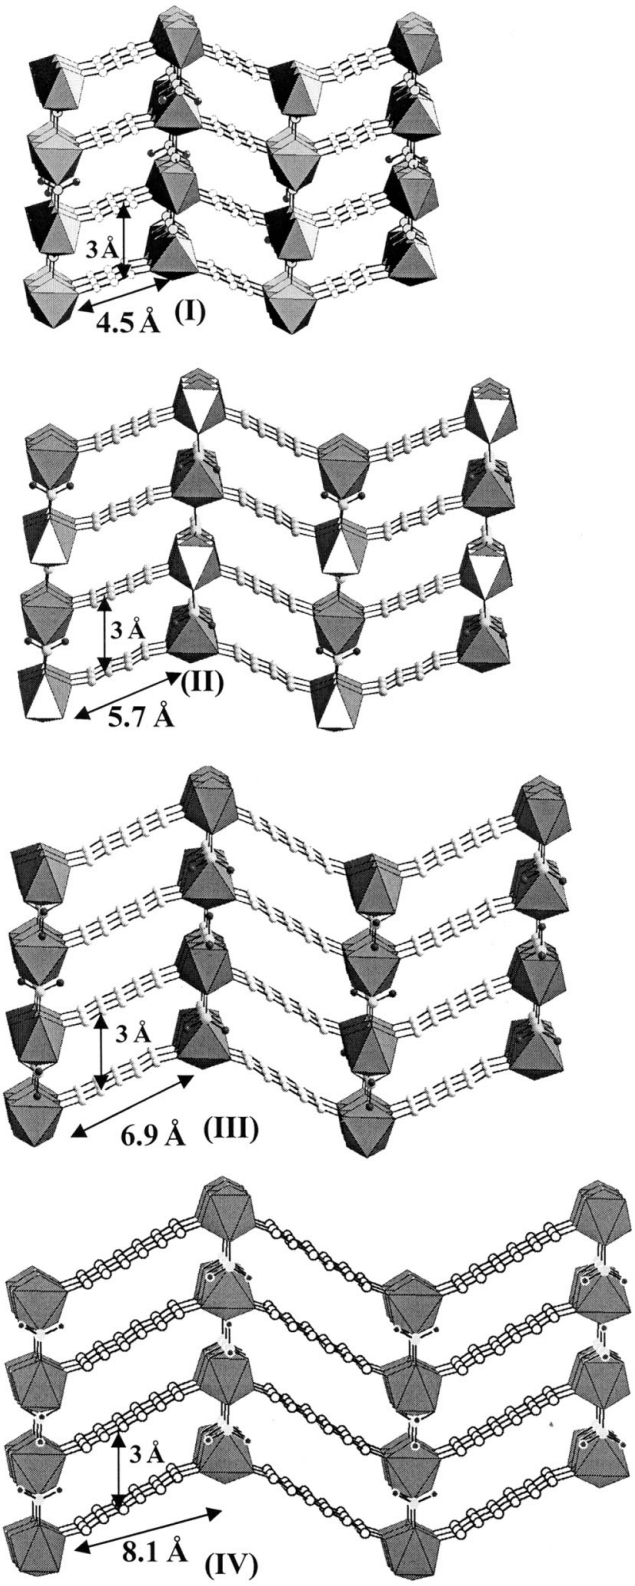


Fig. 3. Layers in **I–IV** showing the variation in aperture size with chain length for the diamine.

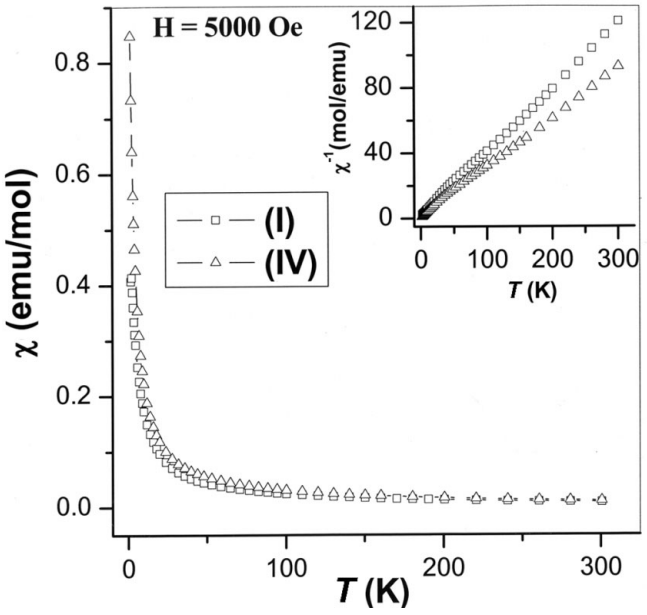

the important structural parameters for **I**, the crucial distances being the same in compounds **II–IV**. The Co—O/N bond distances are in the range 2.097(4)–2.234(3) Å. The trans N/O-Co-O/N bond angles are in the range 158.38(13)–175.0(2)° (avg. 166.7°) and the cis N/O-Co-O/N bond angles are in the range 86.22(13)–106.1(2)° (avg. 92.2°). The average S—O distance in the sulfate unit is 1.481 Å. Bond valence sum calculations (12) indicate that the oxidation states for Co and S are +2 and +6, respectively.

The structures of **I–IV** involve a three-dimensional coordinated network consisting of CoO_4N_2 octahedra and SO_4 tetrahedra sharing both the edges and vertices as shown in Fig. 2. Each sulfate unit shares an edge and two corners with three neighboring cobalt centers to form a two-dimensional sheet resulting in the formation of six-membered apertures along the *ab* plane. The layers are linked by the diamine

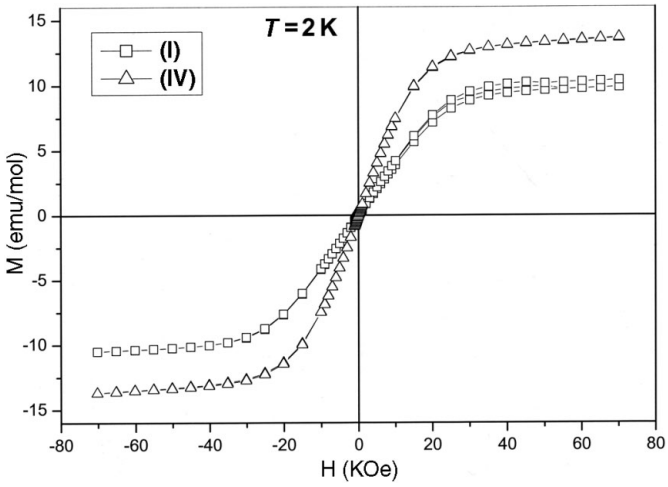
Fig. 4. Temperature variation of the magnetic susceptibility (χ) of **I** and **IV**. Inset shows the temperature variation of the inverse susceptibility (χ_M^{-1}).



along the *c* axis to form an infinite three-dimensional (3D) coordinate network. The 3D network possesses channels along both the *a* and *b* axes. The bridged Co—Co distances are 8.6, 9.9, 11.2, and 12.5 Å in **I**, **II**, **III**, and **IV**, respectively. The estimated sizes of the aperture (excluding the van derWaals radii of the surrounding atoms) are 3 × 4.5, 3 × 5.7, 3 × 6.9, and 3 × 8.1 $Å^2$ in **I**, **II**, **III**, and **IV**, respectively. The aperture size is determined by the length of the diamine chain (Fig. 3). Calculations using SQUEEZE from the PLATON (13) package, however, gave the percentage of filled space to be 72%, 71%, 71%, and 70%, respectively in **I**–**IV**.

It is instructive to compare the structures of **I**–**IV** with the structures of $Co_4(SO_4)(OH)_6(H_2NC_2H_4NH_2)_{0.5}{\cdot}3H_2O$ (5) and $Co_4(SO_4)(OH)_6(C_6N_2H_{12})_{0.5}{\cdot}H_2O$ (14). In the last two compounds, tetrahedral–octahedral–tetrahedral (T–O–T) cobalt hydroxide layers are connected to one another by en/DABCO pillars through tetrahedral Co ions, with the sulfate group projecting into the interlayer gallery. In **I**–**IV**, however, we have layers of $CoN_2(SO_4)$ connected to each other by diamines through octahedral cobalt(II) ions.

In Fig. 4, we show the temperature variation of both the magnetic susceptibility and the inverse susceptibility of two typical compounds, **I** and **IV,** corresponding to the extremes in the diamine chain lengths. Extrapolation of the inverse susceptibility data at high temperatures gives paramagnetic Curie temperatures (θ_p) of 10 and –16 K for **I** and **IV**, respectively. The effective magnetic moment per cobalt atom is around 4.8 μ_B, a value comparable to that in other Co^{2+} compounds (15). The M–H curves (M = magnetization, H = applied field), (Fig. 5) at low temperatures do not show hysteresis but show a sigmoidal variation with saturation, similar to other cobalt compounds with weak ferromagnetic interactions (16). We are, therefore, inclined to consider **I**–**IV** as being weakly ferromagnetic in nature at low temperatures, the interaction being confined to the Co(II) sulfate layers.

Fig. 5. Isothermal M–H cycles of **I** and **IV** at 2 K.

Conclusions

In conclusion, four isostructural coordination polymers of Co(II), wherein the layers formed by CoN_2O_4 octahedra and SO_4 tetrahedra are linked by diaminoalkanes, have been synthesized and characterized. The diamine acts not only as a ligand but also as a spacer between the layers. A comparable case, in the literature, is that of 3D α,ω-dicarboxylate Mn(II) compounds where the interlayer spacing was varied by the alkyl chain length in the dicarboxylate (17). This family of coordination polymers also demonstrates how simple networks formed by transition metal polyhedra and sulfate tetrahedra can yield novel architectures.

Palladium-catalyzed asymmetric cyclocarbonylation of allyl naphthols[1]

Giuseppe Vasapollo and Giuseppe Mele

Abstract: The asymmetric cyclocarbonylation reaction of allyl naphthol catalyzed by palladium complexes and chiral phosphine is reported. The reaction was performed under *syn*-gas conditions at relatively mild experimental conditions (80–100 °C, 300–600 psi (1 psi = 6.895 kPa)) in CH_2Cl_2 as the solvent.

Key words: enantioselective, carbonylation, cyclocarbonylation, lactones, palladium acetate.

Résumé : On a réalisé la réaction de cyclocarbonylation asymétrique de l'allylnaphtol catalysée par des complexes du palladium et une phosphine chirale. La réaction a été effectuée dans des conditions *syn*-gaz, en utilisant le dichlorométhane comme solvant et des conditions expérimentales relativement douces (80 à 100 °C, 300 à 600 psi (1 psi = 6,895 kPa)).

Mots clés : énantiosélective, carbonylation, cyclocarbonylation, lactones, acétate de palladium.

[Traduit par la Rédaction]

Introduction

The synthesis of optically active compounds including lactones and lactams is of great interest because of their biological properties (anti-inflammatory, analgesic, etc.). These molecules often exhibit higher biological activity in one enantiomeric form and asymmetric synthesis still represents an important method for the synthesis of chiral compounds.

Numerous strategies to pursue this goal have been developed over the last years, and transition-metal-catalyzed reactions in particular (hydrogenation, carbon—carbon bond forming, hydrosilation, carbonylation) are the most investigated, providing efficient entries to a variety of useful functionalized heterocyclic compounds (such as lactones, lactams, and pyrrolidinones) and achieving at the same time relatively high enantioselectivity (1).

A large variety of transition-metal-catalyzed cyclocarbonylation reactions of alcohols or phenols to lactones have been reported in the literature (2); on the contrary, only a few examples of enantioselective lactonization have been reported.

Alper and co-workers, pioneers of enantioselective cyclocarbonylation chemistry, have extensively studied the palladium-catalyzed cyclocarbonylation of allylic nonaromatic alcohols and have developed the first enantioselective variant of this reaction using commercially available chiral bisphosphine ligands, obtaining reasonable ees. For example, treatment of but-2-en-1-ol with carbon monoxide, oxygen, copper(II) chloride, and HCl in THF containing palladium chloride and polyleucine as chiral ligand afforded (*R*)-α-methy-γ-butyrolactone in 61% enantiomeric excess (ee). (*L*)-Diethyl tartrate and (*R*)- and (*S*)-bis(diphenylphosphino)-1,1′ binaphthyl (BINAP) have also been used as chiral ligands but gave low yields of optically active lactones (Scheme 1) (3).

Alper and co-workers have demonstrated that the commercially available chiral reagents diethyltartrate and poly-L-leucine were useful chiral ligands for the preparation of optically active lactones. This study represents the first example of the use of poly-α-amino acids as added chiral ligands in homogeneous catalysis. Other studies on asymmetric carbonylation reactions reported in the literature are, however, restricted to β-substituted allylic alcohols with dialkyl substitution at the α position (geminal dialkyl effect) (Scheme 2). For example, the cyclocarbonylation reaction of allylic alcohols catalyzed by palladium complexes and BICP [(2*R*,2′*R*)-bis[bis-(phenyl)phosphino]-(1*R*,1′*R*)-dicyclopentane or Xyl-BICP [(2*R*,2′*R*)-bis[bis-(3,5-dimethylphenyl)phosphino]-(1*R*,1′*R*)-dicyclopentane (Fig. 1) as ligands proceeded with good enantiomeric excess (4).

A major advance in these studies was the development of the first highly enantioselective cyclocarbonylation of β,γ-substituted allylic alcohols bearing geminal dialkyl substituents in the α-position (Scheme 3), which significantly increases the scope and synthetic utility of the asymmetric carbonylation reaction (5).

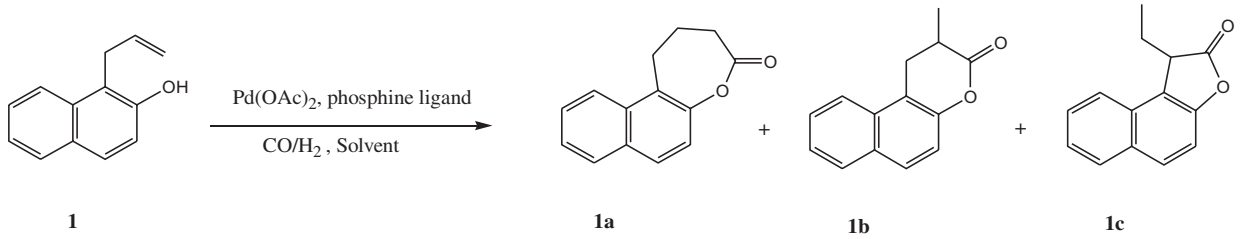
9 examples

Other examples include the catalytic system $Pd(OCOCF_3)_2$–(*S*)-BINAP, which has been used to enhance the asymmetric carbonylative cyclization of prochiral *o*-allylaryl triflates and 2-allylalkenyl triflates and to produce high yields of enantiomerically enriched cyclopentenones (up to 96% ee) (Scheme 4) (6).

The asymmetric cyclocarbonylation of 2-vinylaniline derivatives catalyzed by palladium acetate and 2(–)-DIOP produced 3,4-dihydro-4-methyl-2(1*H*)-quinolin-2-ones in up to 54% ee (Scheme 5) (7).

Iridium salts in the presence of chiral diphosphine were also able to catalyze (with high enantioselectivity) intra- and intermolecular Pauson–Khand type reactions, producing various chiral cyclic enones in high enantiomeric excesses (8). So, whilst the cyclocarbonylation of unsaturated alcohols catalyzed by transition metals is well known, few examples of the asymmetric synthesis of fused aromatic ring lactones are reported (9).



Several of us have recently reported the regioselective cyclocarbonylation of 2-allyl phenols by palladium catalysts (10), leading to five-, six-, or seven-membered lactones (Scheme 6). In this case the selectivity strongly depended on the nature of the catalyst, the solvent, and the $CO:H_2$ ratio. For example, the regioselective cyclocarbonylation of 2-allyl phenols using palladium acetate, dppb, and dichoromethane as the solvent led predominantly to six-membered ring lactones (10).

In this study we have examined the feasibility of the asymmetric cyclocarbonylation, observing that a stereogenic center can be formed during the six- and five-membered ring lactone formation if the reaction is performed in the presence of a chiral ligand.

In continuation of our previous work in this field we now wish to report our preliminary results on the regioselective and enantioselective synthesis of optically active compounds using palladium acetate and chiral phosphine ligands.

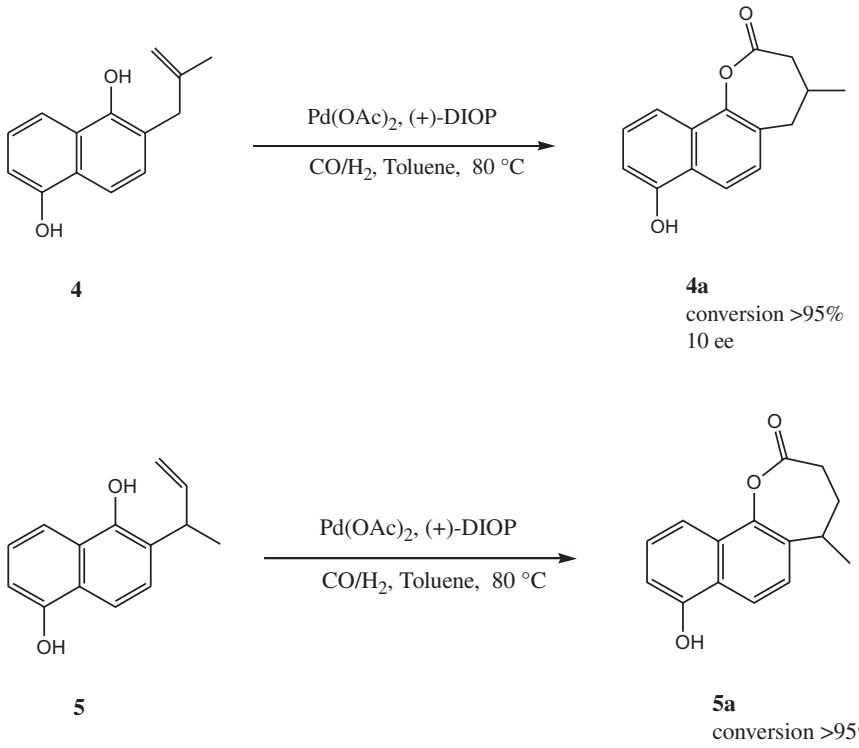
[c]Refers to **3a**.

We describe here the asymmetric cyclocarbonylation reaction of allyl naphthols under *syn*-gas conditions for the formation of fused-ring lactones.

Results and discussion

The asymmetric cyclocarbonylation reaction of the allylnaphthol derivatives **1–3** using Pd(II)-(+)-DIOP as a homogeneous catalytic system is shown in Scheme 7.



The reaction conditions used previously in our study of the palladium-catalyzed cyclocarbonylation of allyl phenol were employed in the present case. For example, allyl naphthol, **1**, reacts with CO and H_2 in the presence of 10% Pd(OAc)$_2$ and (+)-DIOP in CH_2Cl_2 at 100 °C to give seven- and six-membered ring lactones **1a** and **1b** in good yields. CH_2Cl_2 was used as a solvent because, as reported previously, the formation of the six-membered ring was favored with this solvent.

The enantiomeric excesses of the chiral cyclocarbonylation products induced by the chiral ligand were found to depend on the reaction conditions (see Table 1).

The catalyst for the enantioselective cyclocarbonylation was prepared in situ by treatment of palladium acetate with chiral phosphine ligand in CH_2Cl_2 at room temperature, and

© 2005 NRC Canada

Scheme 8.

the resulting mixture was used for cyclocarbonylation under CO and H_2.

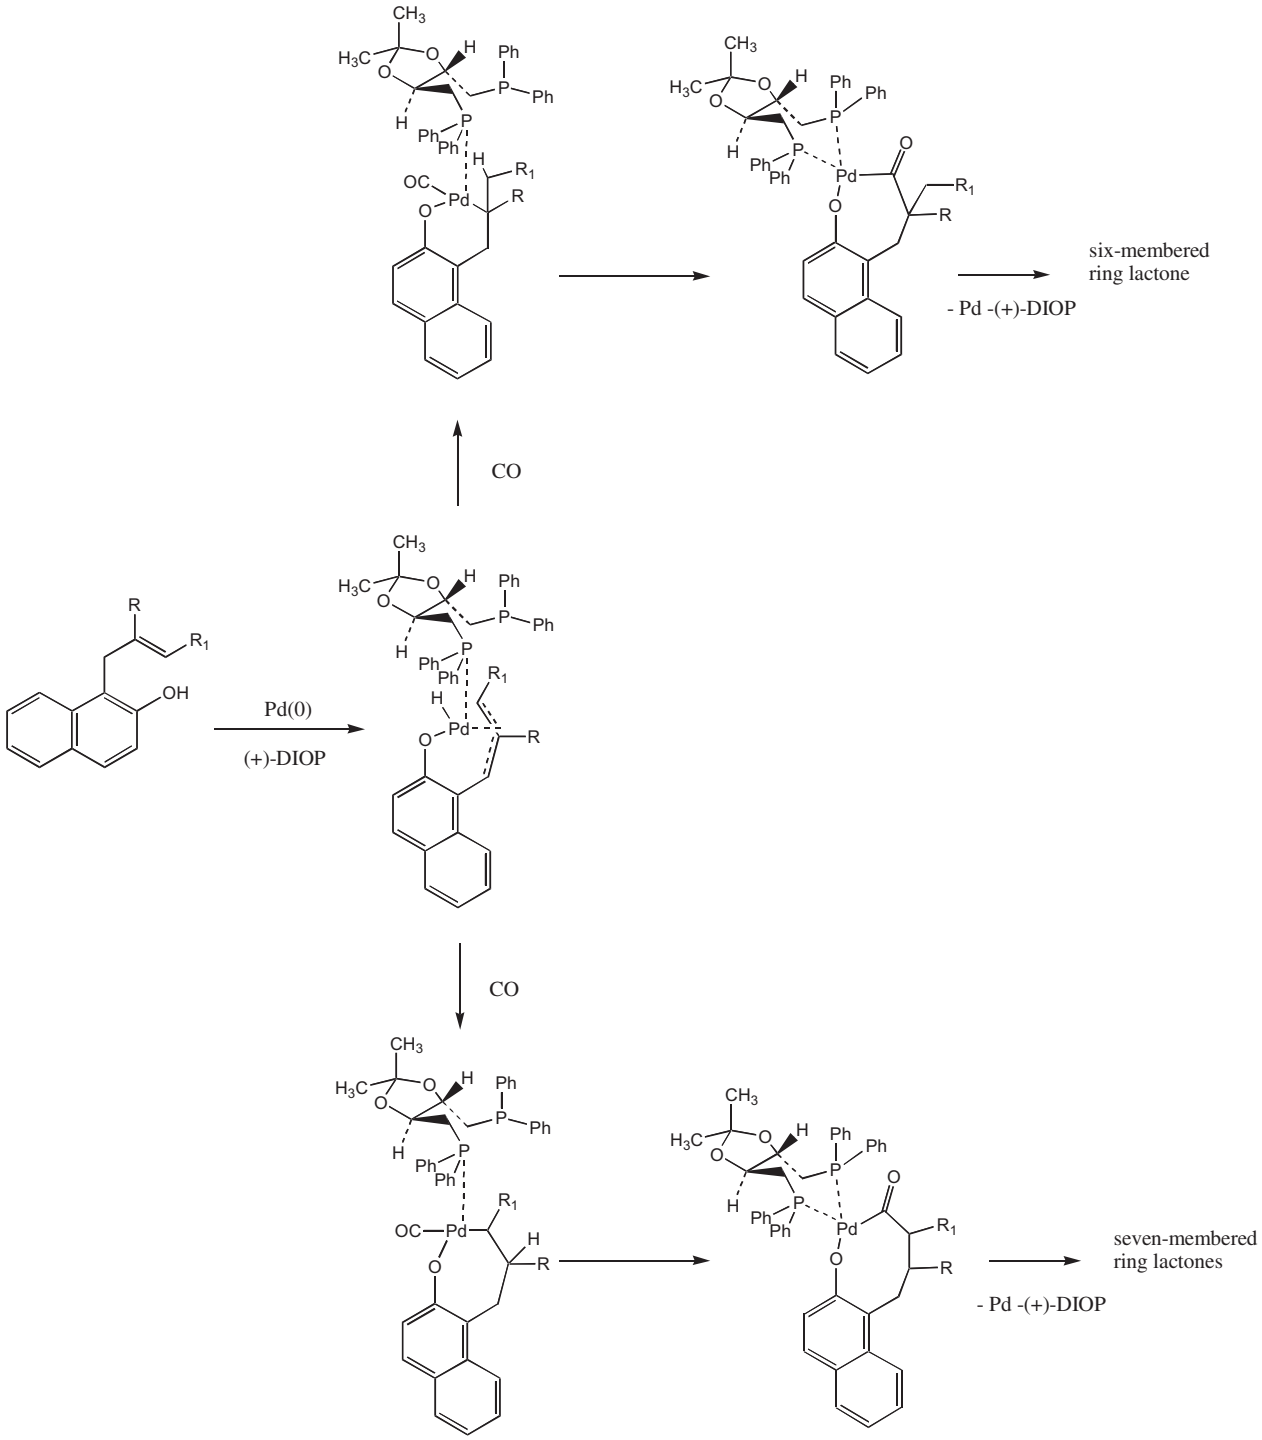
As previously reported, allyl naphthol, **1**, reacted with CO and H_2 in the presence of 10% $Pd(OAc)_2$ and phosphine ligand at 100 °C to give seven- and six-membered ring lactones **1a** and **1b** in 90% isolated yields (Scheme 6); small amounts of five-membered-ring lactone were also obtained.

Because the phosphine units of (+)-DIOP are structurally very similar to that of dppb (used as a ligand for the palladium-catalyzed cyclocarbonylation reaction), we can predict that (+)-DIOP or similar chiral ligands would exhibit significant chiral discrimination in the palladium-catalyzed reaction. Therefore, when the reaction was carried out in the presence of a chiral phosphine such as (+)-DIOP, 90% of **1** was converted into **1a** and **1b** with distributions of 80% and 20%, respectively (Table 1, entry 3). The enantiomeric excess of **1b** (61%) was determined by HPLC analysis using a chiral stationary phase column.

Several other chiral ligands, such as (–)-bppm (98% yield, 9% ee), (+)-Binap (43% yield, 7% ee), and *R*,*R*-BDP (20% yield, 6% ee), were inferior to (+)-DIOP in terms of yields and enantioselectivity. When the reaction was performed at different temperatures, the chemical yield changed significantly, along with the enantiomeric excess (see Table 1). For example, when the reaction was performed at 70 °C and 80 °C, the conversion was 33% and 90%, respectively, while the enantiomeric excesses were 63% and 61%, respectively. At 100 °C, the chemical conversion increased but the enantiomeric excess dropped to 30%. At 60 °C, the conversion obtained was 8%, while the enantiomeric excess was 64%. The product distribution remains almost constant regardless of temperature. Although 60 °C is the best temperature for better enantiomeric excess (Table 1, entry 1), a low chemical conversion is observed at this temperature. The influence of the $CO:H_2$ ratio was not investigated because, as reported in the previous work, a $CO:H_2$ ratio of 5:1 and dichoromethane as a solvent are the best conditions for the preparation of the desired chiral six-membered ring lactone.

The cyclocarbonylation reactions of **2** and **3** afforded, respectively, lactones **2a** and **3a** in moderate enantiomeric excess. In this case, the moderate influence of the solvent on the enantioselectivity may be ascribed to the presence of methyl groups as substituents in the double bond of the allylic moiety. However, as observed in the previous work, seven-membered ring lactones were always formed (10) as the main product when toluene was used as the solvent.

High conversion into the seven-membered ring lactone, **4a**, with moderate enantiomeric excess was also observed when 2-(2-methyl-allyl)-naphthalene-1,5-diol (**4**) was used as the starting material; no enantiodiscrimination in the carbonylation products of **5** was observed (Scheme 8).



Proposed mechanism

According to that mechanism reported by Alper and coworkers (9–11), different pathways are possible for the formation of differently sized lactones (six- or seven-membered ring). These are depicted in Scheme 9. Firstly, there is an oxidative addition of Pd(0) into the O—H bond to produce a palladium hydride. Subsequently, the olefin coordinates to Pd, which also binds the chiral ligand, (+)-DIOP. Intramolecular hydropalladation, followed by coordination and insertion of carbon monoxide into the Pd—C bond, followed by reductive elimination has been hypothesized to justify the formation of different lactones with the regeneration of the catalysts.

In the light of these considerations, the enantiodiscrimination step could be either the enantioselective intramolecular

© 2005 NRC Canada

Scheme 9.

hydropalladation or the enantioselective coordination and insertion of carbon monoxide.

The catalytic reactivity observed for the Pd-catalyzed cyclocarbonylation with a 1,4-bisphosphine ligand is associated with a relatively flexible ligand–metal seven-membered ring chelate.

The higher enantiomeric excesses observed in the formation of the six-membered ring could be due to the closer distance of the chiral phosphine ligand to the metal centre.

The lower ees observed in the formation of seven-membered ring lactones could also be due to the steric hindrance of methyl groups.

Experimental section

Materials and measurements

Most chemicals were used as obtained from commercial sources. $Pd(OAc)_2$ and (+)-DIOP are commercial available,

© 2005 NRC Canada

while the allyl naphthol derivatives were prepared according to literature procedures (12). CH_2Cl_2 was dried, distilled, stored, and handled under nitrogen.

Melting points were taken on an electro thermal apparatus. ^1H and ^{13}C NMR spectra were recorded on a Bruker AC-200 at room temperature, and chemical shifts are reported relative to Me_4Si. IR and MS spectra were performed, respectively, on an FT-IR Jasco or IR Perkin Elmer 683 and on a Hewlett-Packard GC/Mass MSD 5971 instrument. The enantiomeric excesses were determined by HPLC, using a Chiralcel OB-H column (length 25 cm, $\phi = 0.45$ cm), with ethanol (9%) in hexane as the eluent, using a flow of 0.5 mL/min.

General procedure for the cyclocarbonylation reactions

Palladium acetate (0.10 mmol) and (+)-DIOP (0.15 mmol) were dissolved in 5 mL of dry CH_2Cl_2, and the allyl naphthol derivative (1.00 mmol) was added. The autoclave was purged three times with CO and pressurized with CO and H_2. The reaction mixture was heated with stirring for 24 h at 80–100 °C (oil bath temperature). The reaction mixture was cooled to room temperature, the solution was concentrated, and the residue was extracted with ether. The lactones were purified by chromatography using petroleum ether and diethyl ether as eluant.

Lactone **1a** is a known compound, and the spectral data are in accord with the literature data (9).

Conclusions

In summary, we have reported the asymmetric cyclocarbonylation of allyl naphthol catalyzed by palladium and chiral phosphine. Use of a lower temperature for the reaction in CH_2Cl_2 gives the seven-membered, rather than the six-membered, ring tricyclic lactones and increases the ees. The reaction was performed under H_2 (100 psi (1 psi = 6.895 kPa)) and CO (500 psi) at 80 °C; when CH_2Cl_2 was used as the solvent, the formation of the six-membered ring lactone was favored, and higher ees were obtained. We have reported the first example of an enantioselective cyclocarbonylation reaction for the synthesis of seven-membered ring lactones, although with low ees.

Recent advances in cyclohydrocarbonylation reactions[1]

Wen-Hua Chiou, Seung-Yub Lee, and Iwao Ojima

Abstract: This article describes recent advances in the cyclohydrocarbonylation reactions catalyzed by transition-metal complexes and their applications in organic synthesis as a review covering the relevant literature up to the middle of 2004. The reactions are categorized into four types, i.e., intramolecular amidocarbonylation reactions, intramolecular aminocarbonylation reactions, cyclohydrocarbonylation reactions involving carbon–nucleophiles, and other cyclohydrocarbonylation reactions. Cyclohydrocarbonylation reactions provide efficient routes to various monocyclic, bicyclic, and polycyclic compounds as a one-step cascade process or a one-pot process. Reaction mechanisms for these cascade processes are discussed as needed for clarification. The heterocyclic and carbocyclic compounds, thus obtained, can be further transformed to specific targets. Examples of such applications are also discussed.

Key words: catalysis, cyclohydrocarbonylation, hydroformylation, amidocarbonylation, cyclization, regioselectivity, aldehydes, regioselective, cascade, heterocycles, rhodium.

Résumé : Cet article de revue couvre la littérature appropriée jusqu'au milieu de l'année 2004 et décrit les progrès récents réalisés dans les réactions de cyclohydrocarbonylation catalysées par des complexes de métaux de transition et leurs applications en synthèse organique. Les réactions sont divisées en quatre groupes, soit les réactions d'amidocarbonylation intramoléculaire, les réactions d'aminocarbonylation intramoléculaire, les réactions de cyclohydrocarbonylation impliquant une liaison carbone–nucléophile et les autres réactions de cyclohydrocarbonylation. Les réactions de cyclohydrocarbonylation fournissent des voies efficaces conduisant à divers composés monocycliques, bicycliques et polycycliques par des processus en cascade d'une étape ou monotopiques. On discute des mécanismes réactionnels de ces processus en cascade lorsque cela est nécessaire pour clarifier la situation. Les composés hétérocycliques ou carbocycliques ainsi obtenus peuvent ensuite être encore transformés en cibles spécifiques. On discute aussi de quelques exemples de telles applications.

Mots clés : catalyse, cyclohydrocarbonylation, hydroformylation, amidocarbonylation, cyclisation, régiosélectivité, aldéhydes, régiosélectif, cascade, hétérocycles, rhodium.

[Traduit par la Rédaction]

Introduction

The development of highly efficient catalytic processes for the synthesis of natural and unnatural compounds of biological interest or as useful intermediates for the construction of functional materials is a central focus in modern organic synthesis. One of the most productive approaches to the development of such methodologies is to apply transition metal catalyzed cyclization reactions to transform simple starting materials to monocyclic, bicyclic, and polycyclic compounds that can be further elaborated into specific targets.

Among these catalytic cyclization reactions, cyclohydrocarbonylation of functionalized alkenes catalyzed mainly by Rh or Co complexes provides powerful catalytic processes for the synthesis of heterocycles as well as carbocycles (1–5). Cyclohydrocarbonylation is an intramolecular cascade process, consisting of the hydroformylation of a functionalized alkene to form an aldehyde intermediate, followed by the addition of a nucleophile in the same molecule to the aldehyde, leading to the formation of the corresponding cyclization product(s). As a variant, the cyclohydrocarbonylation also includes an intramolecular cascade process involving the hydrocarbonylation of an functional alkene, generating an acyl–metal intermediate, which undergoes intramolecular nucleophilic substitution to give the corresponding cyclic carbonyl compounds. Amide, amine, and hydroxyl groups as well as carbon–nucleophiles are representative functional groups in the alkene substrates in these processes. The cyclohydrocarbonylation reaction has been incorporated into more sophisticated cascade processes, forming bicyclic and polycyclic compounds in one-step or one-pot. This article describes recent advances in the cyclohydrocarbonylation reactions and their applications to organic synthesis as a re-

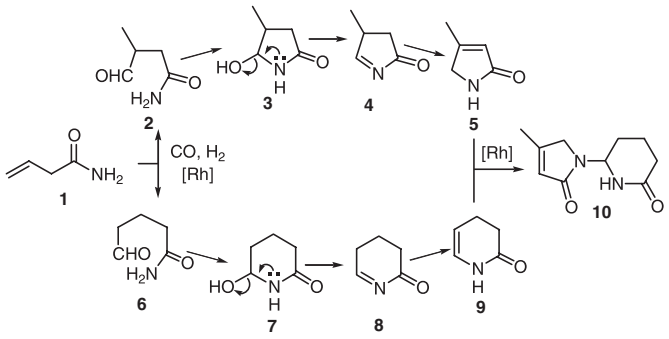
Scheme 1.

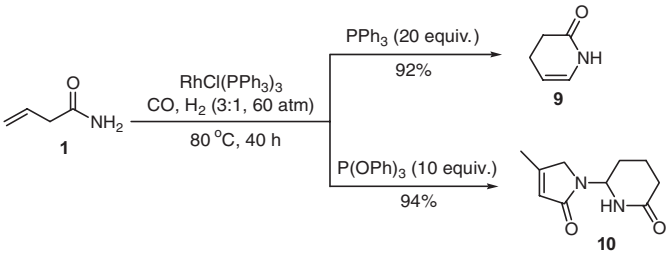
view covering the relevant literature up to the middle of 2004.

In this article, the cyclohydrocarbonylation reactions are categorized into four types as illustrated in Scheme 1, i.e., intramolecular amidocarbonylation reactions (eq. [1], Scheme 1), intramolecular aminocarbonylation reactions (eq. [2], Scheme 1), cyclohydrocarbonylation reactions involving carbon-nucleophiles (eq. [3], Scheme 1), and other cyclohydrocarbonylation reactions (eq. [4], Scheme 1).



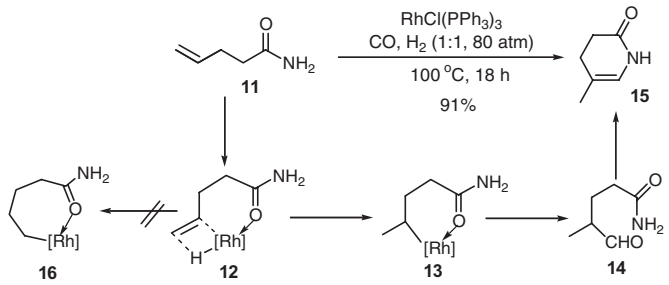
Intramolecular amidocarbonylation reactions

"Amidocarbonylation" is defined as a process involving the hydroformylation of an alkene, followed by the reaction of the resulting aldehyde with an amide or a carbamante. The intramolecular version of this process affords the corresponding nitrogen–heterocycles. For example, the intramolecular amidocarbonylation of but-3-enamide (**1**) catalyzed by $RhCl(PPh_3)_3$, $RhCl(CO)(PPh_3)_2$, or $Rh_4(CO)_{12}$ at 80–100 °C and at 82 atm (1 atm = 101.325 kPa) of "syngas" ($CO:H_2$ = 1:1 or 3:1) gives a mixture of 4-methyl-3-pyrrolin-2-one (**5**), 3,4-dihydro-2-pyridone (**9**), and 6-(4-methyl-3-pyrrolin-2-on-1-yl)-2-piperidone (**10**) (Scheme 2) (6, 7). It is reasonable to assume that **5** and **9** are formed via the intramolecular cyclization of 4-formylbutanamide (**2**) and 5-formylbutamide (**6**), respectively, whereas **10** arises from the cross coupling of **5** and **9** as illustrated in Scheme 2.



It is noteworthy that the highly selective synthesis of **9** or **10** is achieved simply by a proper choice of a phosphorus ligand to be used. As Scheme 3 shows, dihydropyridinone **9** is obtained in 92% yield by using $RhCl(PPh_3)_3$-PPh_3 (20 equiv.), whereas the reaction catalyzed by $RhCl(PPh_3)_3$-$P(OPh)_3$ (10 equiv.) affords the heterodimer **10** in 94% yield. The latter reaction is claimed to be the first example of the transition metal catalyzed cross coupling between an enamide and an amide (Scheme 3) (7).

In the case of pent-4-enamide (**11**), the reaction catalyzed by $RhCl(PPh_3)_3$ affords 4-methyl-3,4-dihydro-2-pyridone (**15**) exclusively (Scheme 4). No seven-membered ring lactam is formed even in the presence of a large excess of PPh_3 (6, 7). It has been shown that the phosphine–Rh com-



Scheme 2.

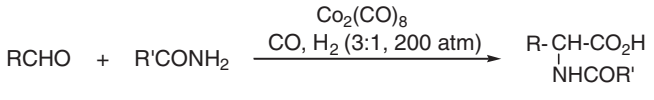
Scheme 4. Note: 1 atm = 101.325 kPa.



plex catalyzed hydroformylation of 1-alkenes usually gives linear aldehydes as major products (1, 2). Thus, the observed result indicates that branched aldehyde **14** is exclusively formed through a strong, amide-directed chelation control (6–11) that favors the branched alkyl–[Rh] complex **13** over the linear alkyl–[Rh] complex **16**. Then, complex **13** leads to the formation of branched aldehyde **14**, followed by cyclization to **15**.

The "Wakamatsu reaction", wherein an aldehyde is transformed to the corresponding *N*-acyl-α-amino acid through the reaction with an amide and syngas catalyzed by $Co_2(CO)_8$, was extensively studied in the 1970s (Scheme 5) (12). This unique amidocarbonylation process including double CO incorporation is applicable to the synthesis of cyclic *N*-acyl-α-amino acids (11, 13–16). For instance, the reaction of homoallylic amide **20** catalyzed by $Co_2(CO)_8$ at 100 °C and 100 atm (1 atm = 101.325 kPa) ($CO:H_2$ = 1:1) gives *N*-acylpipecolic acid (**21**) in one step (Scheme 6) (15).

The amide-directed cyclohydrocarbonylation of *N*-alkenylamides has been successfully applied to the syntheses of a variety of bicyclic nitrogen–heterocycles such as **23** and **26** (Scheme 7) (1, 8). Treatment of the resulting crude products with trifluoroacetic acid (TFA) affords enamide **24** and **27** in 86% and 92% yields, respectively.

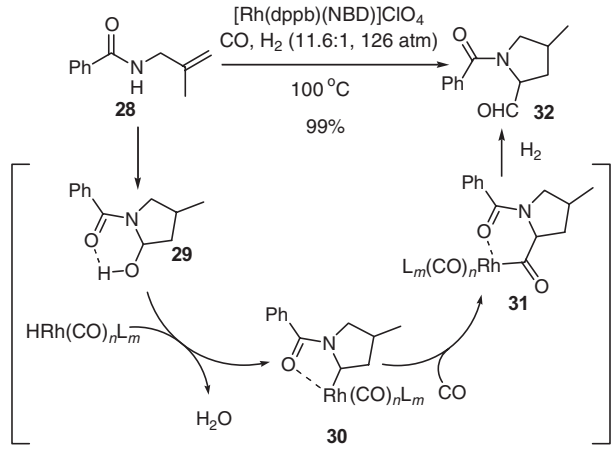
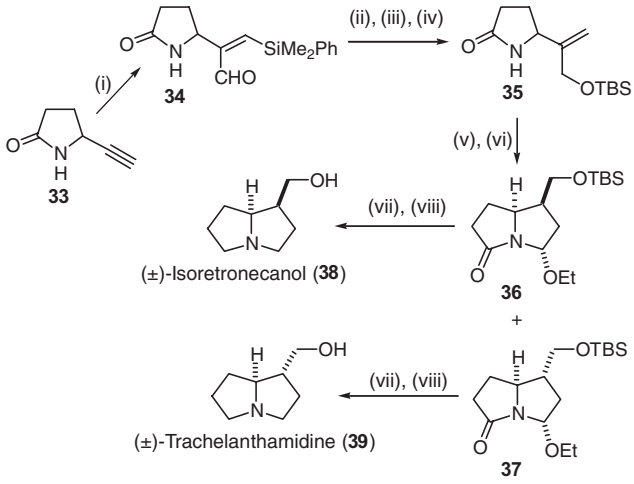
Bn	$C_{11}H_{23}$	120	15	EtOAc	40

Scheme 6. Note: 1 atm = 101.325 kPa.

Scheme 7. Note: 1 atm = 101.325 kPa.



The Rh-catalyzed sequential double carbonylation of *N*-(2-methyl-2-propenyl)benzamide (**28**) gives *N*-benzoyl-2-formylpyrrolidine (**32**) (Scheme 8) (8, 9, 17). In this process, the hemiamidal **29** arising from the regioselective intramolecular amidocarbonylation of **28** is converted to alkyl–[Rh] complex **30**, and the subsequent insertion of CO gives acyl–[Rh] complex **31**. An oxidative addition of molecular hydrogen, followed by reductive elimination affords **32**.

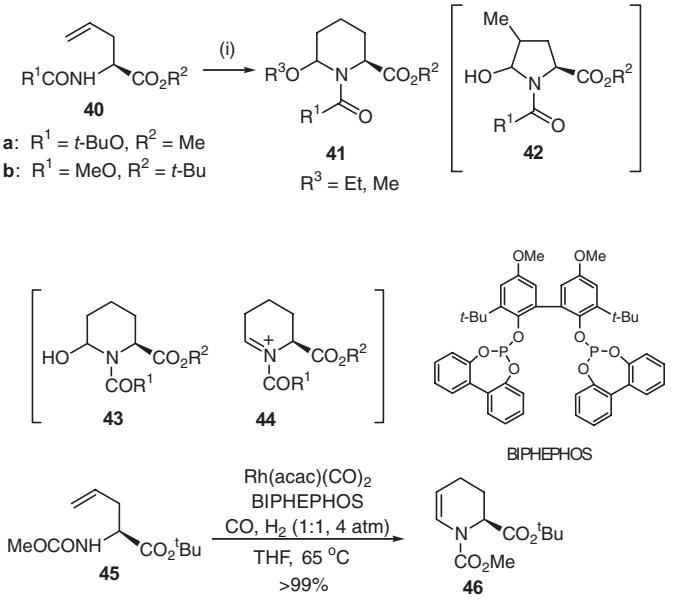


A combination of intermolecular silylformylation and amidocarbonylation provides an efficient route to pyrrolizidine alkaloids (18, 19). The regio- and diastereoselective Rh-catalyzed silylformylation of 5-ethynyl-2-pyrrolidinone (**33**) affords (*Z*)-**34** in excellent yield. Subsequent reduction and protodesilylation, followed by protection of the hydroxyl group as *tert*-butyldimethylsilyl (TBS) ether gives **35**. Cycloydrocarbonylation of **35** catalyzed by $HRh(CO)(PPh_3)_3$ affords a diastereoisomeric mixture (syn:anti = 2:1) of bicyclic products **36** and **37**, which are readily separable by flash chromatography. Removal of the silyl protecting group and reduction of both the amidal and amido group gives (±)-isoretronecanol (**38**) and (±)-trachelanthamidine (**39**), respectively (Scheme 9) (18, 19).

The combination of $Rh(acac)(CO)_2$ and a diphosphite ligand (BIPHEPHOS (21)) is an excellent catalyst system for the linear-selective hydroformylation of a wide range of alkenes (1, 19–22). This catalyst system has been successfully applied to the cyclohydrocarbonylation reactions of alkenamides and alkenylamines, which are employed in the

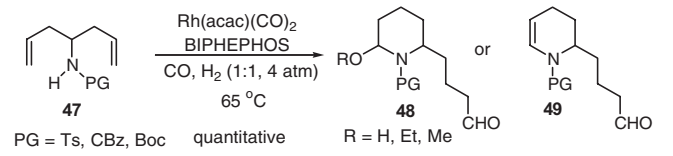
Scheme 8. Note: 1 atm = 101.325 kPa.

Scheme 9. Reaction conditions: (*i*) $HSiMe_2Ph$, CO (20 atm, 1 atm = 101.325 kPa), $Rh(acac)(CO)_2$, RT, 98%; (*ii*) $NaBH_4$, 0 °C, 100%; (*iii*) TsH, MeCN (2% H_2O), 75%; (*iv*) TBS-Cl, imidazole, 98%; (*v*) CO, H_2, $HRh(CO)(PPh_3)_3$, $HC(OEt)_3$, 72% (syn:anti = 2:1); (*vi*) SiO_2 column; (*vii*) *n*-Bu_4NF, RT, 96%; (*viii*) $LiAlH_4$, 65%–70%.



key steps for the syntheses of piperidine (23–25), indolizidine, and pyrrolizidine alkaloids (22).

Cyclohydrocarbonylation of *N*-carbalkoxyallylglycinate (**40**) catalyzed by $Rh(acac)(CO)_2$–BIPHEPHOS in an alcohol solvent gives 1-carbalkoxy-6-alkoxypipecolate (**41**) in quantitative yield (Scheme 10) (25). In this reaction, the use of the BIPHEPHOS ligand is essential for the exclusive formation of the piperidine ring via a linear aldehyde intermediate. When the same reaction is carried out using a classical catalyst, such as $HRh(CO)(PPh_3)_3$ in the presence of a large excess of PPh_3 (20 equiv.), a 1:1 mixture of regioisomers **41** and **42** is formed.



This process includes the extremely linear-selective hydroformylation of an olefin moiety, generating the corresponding terminal aldehyde, followed by the formations of hemiamidal **43** and then acyliminium ion **44**. Addition of an alcohol to the acyliminium ion intermediate **44** gives **41**. When the reaction of **45** is performed in an aprotic solvent such as THF, toluene, hexane, ethyl acetate, etc., 5,6-

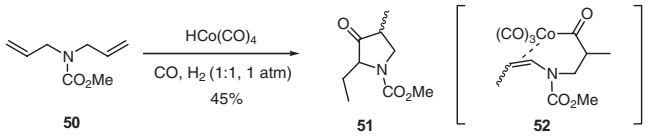
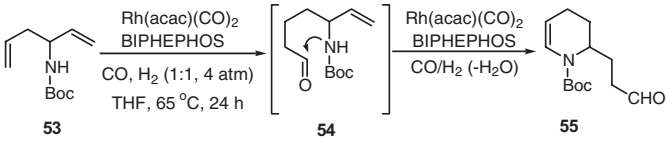
Scheme 10. Reaction conditions: (*i*) Rh(acac)$(CO)_2$BIPHEPHOS, CO, H_2 (1:1, 4 atm, 1 atm = 101.325 kPa), R_3OH, 65 °C, quantitative.

Scheme 11. Note: 1 atm = 101.325 kPa.



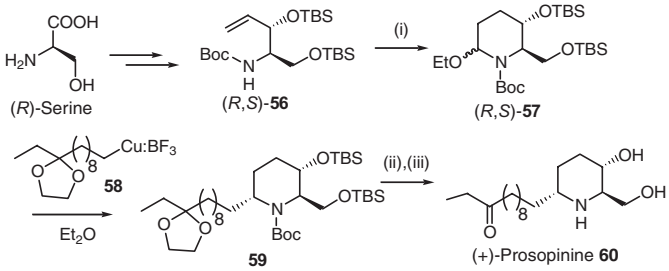
didehydropipecolate (**46**) is obtained in 99% yield via deprotonation and double bond migration of the common acyliminium ion intermediate **44** (Scheme 10) (25).

The cyclohydrocarbonylation of 4-tosylamino-1,6-heptadiene (**47**) catalyzed by Rh(acac)$(CO)_2$–BIPHEPHOS in THF gives *N*-tosyl-2-hydroxypiperidine (**48**) (R = H) and (or) *N*-tosyl-5,6-didehydropiperidine (**49**), depending on the duration of the reaction (Scheme 11) (24). When the reaction is stopped after 2 h, **48** is quantitatively formed as the sole product, but a prolonged reaction time (18 h) gives **49** exclusively in quantitative yield. This strongly indicates that the hemiamidal **48** is the precursor of the acyliminium ion intermediate similar to **44**. When the reaction is carried out in ethanol, *N*-tosyl-2-ethoxylpiperidine aldehyde (**48**) (R = Et or Me) is obtained in quantitative yield. As protecting groups for the amine moiety, carbobenzoxy (Cbz) and *tert*-butoxycarbonyl (*t*-Boc) groups are employed in addition to the tosyl group. 2-Alkoxypiperidine aldehyde (**48**) (R = Et, Me) and 5,6-didehydropiperidine aldehyde (**49**) serve as useful intermediates for the syntheses of various piperidine and indolizine alkaloids.



The reaction of **50** catalyzed by $HCo(CO)_4$ under the ambient pressure of CO and H_2 (1:1) gives 2-ethyl-4-methyl-3-pyrrolidinone (**51**) in 45% yield via acyl–[Co] species **52** in which an olefin isomerization takes place prior to carbocyclization (Scheme 12) (26).

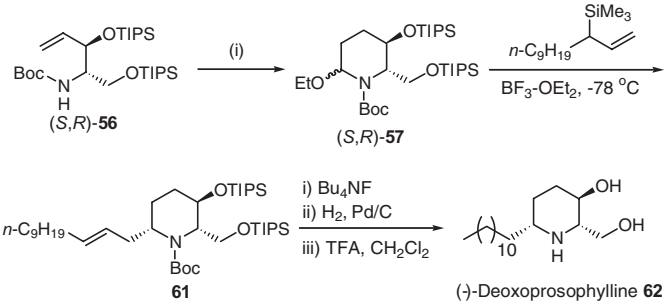
The reaction of unsymmetrical amidodiene **53** catalyzed by the Rh–BIPHEPHOS complex gives dehydropiperidine



Scheme 12. Note: 1 atm = 101.325 kPa.

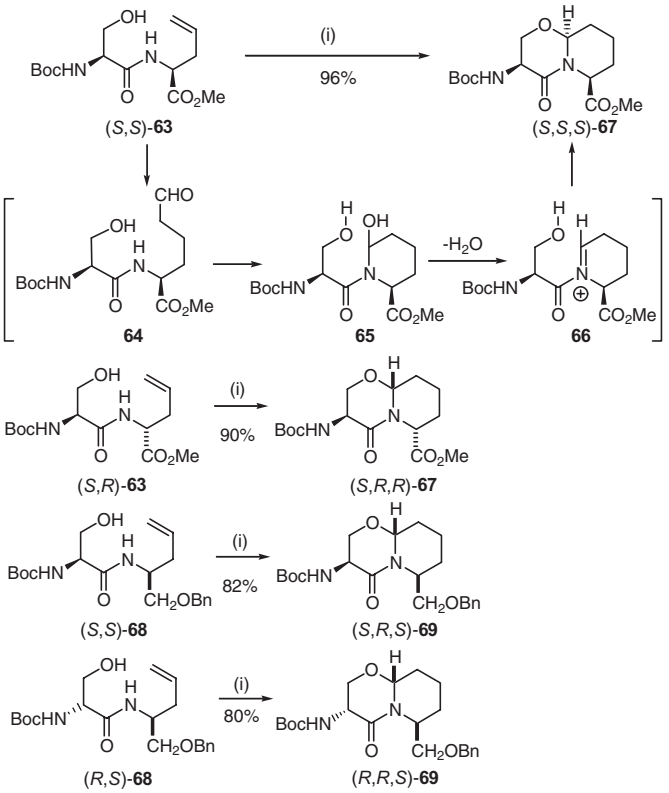
Scheme 13. Note: 1 atm = 101.325 kPa.

Scheme 14. Reaction conditions: (*i*) Rh(acac)$(CO)_2$ (1 mol%), BIPHEPHOS (2 mol%), CO, H_2 (1:1, 4 atm, 1 atm = 101.325 kPa), 92%; (*ii*) *n*-Bu_4NF, THF; (*iii*) TFA, CH_2Cl_2.



aldehyde (**55**) as the sole product, i.e., no pyrroline is formed (Scheme 13) (27). The fact that no pyrroline is formed indicates that this reaction is extremely site- and regioselective in that the hydroformylation takes place at the homoallylic olefin moiety exclusively, only yielding the linear aldehyde intermediate **54**.

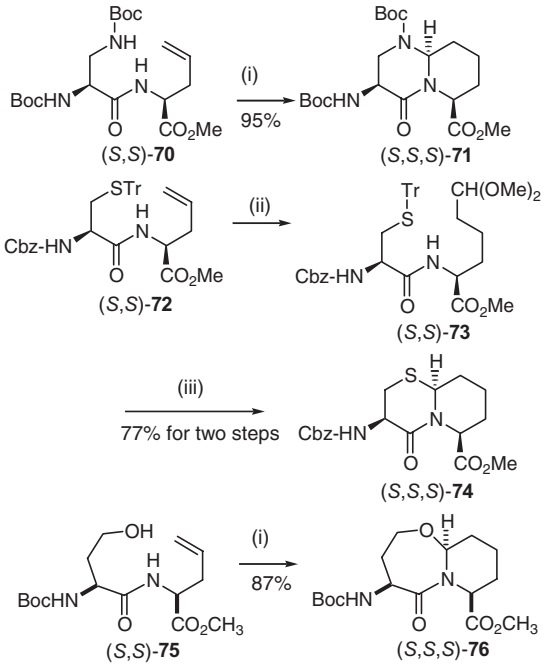
A short total synthesis of (+)-prosopinine (**60**) from (*R*)-serine is achieved via cyclohydrocarbonylation catalyzed by the Rh–BIPHEPHOS complex for the construction of the key piperidine ring (2*R*,3*S*)-**57** (Scheme 14) (28). The resulting (2*R*,3*S*)-**57** is converted to (+)-prosopinine (**60**) via the nucleophilic displacement of the ethoxy group with organocopper reagent **58**. A similar strategy is used for the total synthesis of (–)-deoxoprosophylline (**62**), featuring the cyclohydrocarbonylation of (2*S*,3*R*)-**57** derived from (*S*)-serine as the key step. The C-6 side chain is introduced by a Lewis acid promoted allylsilane addition to (2*S*,3*R*)-**57** via the acyliminium ion intermediate to secure the required 2,6-cis stereochemistry of the target molecule (Scheme 15).



The Rh–BIPHEPHOS catalyzed cyclohydrocarbonylation has also been successfully applied to the rapid synthesis of a variety of 1-azabicyclo[X.Y.0]alkane amino acids, which serve as conformationally restricted dipeptide surrogates for enzyme inhibitors and receptor antagonists, directly from dehydrodipeptide substrates (Scheme 16) (29). Reaction of (*S*,*S*)-*N*-Boc-serinylallylglycinate ((*S*,*S*)-**63**) under the standard cyclohydrocarbonylation conditions gives 5-oxa-1-azabicyclo[4.4.0]decanecarboxylate ((*S*,*S*,*S*)-**67**) in excellent yield. This reaction includes an extremely selective hydroformylation to form linear aldehyde **64**, followed by the formation of hemiamidal **65**. Subsequent generation of acyliminium ion **66** and intramolecular nucleophilic addition

© 2005 NRC Canada

Scheme 15. Reactions conditions: (*i*) Rh(acac)$(CO)_2$ (1mol%), BIPHEPHOS (2 mol%), CO, H_2 (1:1, 4 atm, 1 atm = 101.325 kPa), EtOH, 65 °C, 96%.



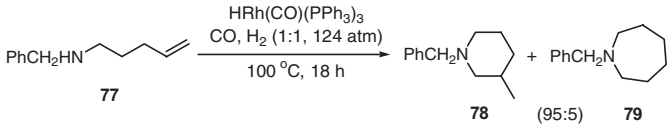
Scheme 16. Reaction conditions: (*i*) Rh(acac)$(CO)_2$ (2 mol%), BIPHEPHOS (4 mol%), CO, H_2 (1:1, 4 atm, 1 atm = 101.325 kPa), PTSA (10 mol%), toluene, 65 °C, 20 h.

of the hydroxyl group of the serine moiety yields (*S*,*S*,*S*)-**67** with excellent diastereoselectivity at C-6 (Scheme 16) (30). The reaction of the other diasteromer ((*S*,*R*)-**63**) gives (*S*,*R*,*R*)-**67** as the single product in 90% yield. Thus, the C-10 position appears to be the stereogenic center in these reactions. The stereochemistry at the C-6 position, however, is also dependent on the nature of the C-10 substituent. For example, the reaction of (*S*,*S*)-**68**, bearing a CH_2OBn group in place of a CO_2Me group at C-10, gives (*S*,*R*,*S*)-**69**, in which the absolute configuration at C-6 is *R*. In the same manner, the reaction of (*R*,*S*)-**68**, gives (*R*,*R*,*S*)-**69**, i.e., the absolute configuration at C-6 is *R* as well. The results confirm that the C-10 position is the stereogenic center in this process, but also indicate that the stereoelectronic nature of the C-10

Scheme 17. Reaction conditions: (*i*) Rh(acac)$(CO)_2$ (2 mol%), BIPHEPHOS (4 mol%), CO, H_2 (1:1, 4 atm, 1 atm = 101.325 kPa), PTSA (10 mol%), toluene, 65 °C, 20 h; (*ii*) Rh(acac)$(CO)_2$ (2 mol%), BIPHEPHOS (4 mol%), CO, H_2 (1:1, 4 atm, 1 atm = 101.325 kPa), MeOH, 65 °C, 20 h; (*iii*) TFA (cat), CH_2Cl_2.

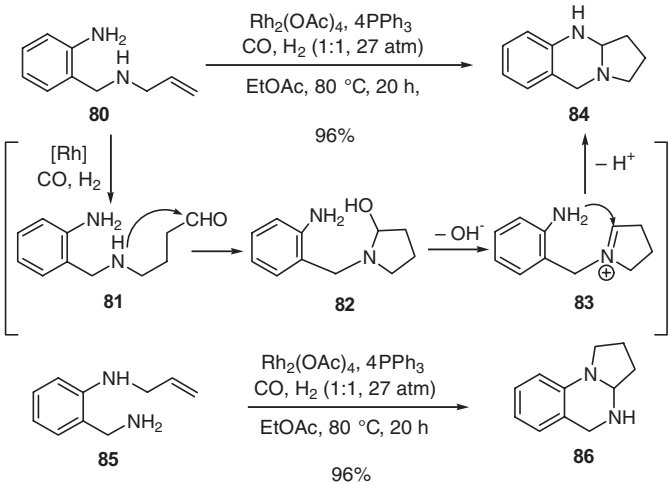
substituent governs the diastereoface selection in the cyclization step (30).

In a similar manner, the reaction of (*S*,*S*)-**70** bearing a β-aminoalanine residue in place of the serine residue, proceeds efficiently in the presence of *p*-toluenesulfonic acid (PTSA) to give (*S*,*S*,*S*)-**71** as the single product in 95% yield (Scheme 17) (29). It should be noted that no 1-azabicyclo[4.3.0] product is formed in spite of the fact that either Boc-amino group in the β-aminoalanine residue could react with the acyliminium intermediate. In the case of a dipeptide substrate bearing a cysteine residue, an *S*-trityl derivative ((*S*,*S*,*S*)-**72**) has been used. Since the thiol group is protected, a spontaneous cyclization cannot take place. Thus, the reaction of (*S*,*S*,*S*)-**72** is carried out in MeOH to trap the resulting aldehyde moiety by converting it in situ to the corresponding acetal (*S*,*S*)-**73** (Scheme 17). The subsequent deprotection–cyclization with a catalytic amount of TFA afforded (*S*,*S*,*S*)-**74** in 77% isolated yield for two steps in one pot (Scheme 17) (29).



The reaction is readily applicable for the construction of 1-azabicyclo[5.4.0] system. Thus, the reaction of (*S*,*S*)-**75** under the standard conditions affords (*S*,*S*,*S*)-**76** in 87% yield (Scheme 17) (30). The stereocontrol at the C-6 position is governed by the C-10 ester group in accordance with the general mechanism proposed for this cascade process (vide supra).

Intramolcular aminocarbonylation reactions

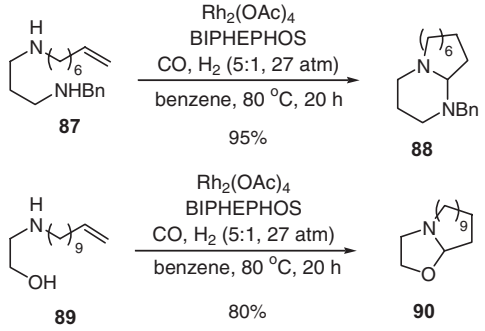


"Aminocarbonylation" is defined as a process involving the hydroformylation of an alkene, followed by the reaction

© 2005 NRC Canada

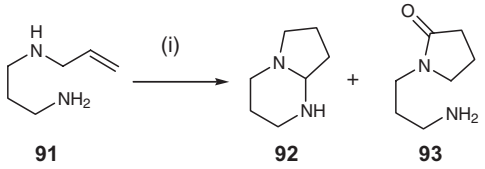
Scheme 18. Note: 1 atm = 101.325 kPa.

Scheme 19. Note: 1 atm = 101.325 kPa.



of the resulting aldehyde with an amine. In a manner similar to the amidocarbonylation discussed previously, the intramolecular version of aminocarbonylation provides unique and efficient routes to various nitrogen–heterocycles.

Cyclohydrocarbonylation of 5-benzylaminopentene (**77**) catalyzed by $HRh(CO)(PPh_3)_3$ at 100 °C and 124 atm (1 atm = 101.325 kPa) of syngas ($CO:H_2$ = 1:1) leads to the regioselective formation of piperidine **78** and a small amount of azepane **79** (Scheme 18) (31). The regioselectivity-determining step in this reaction is the hydroformylation of the olefin moiety of **77**, which strongly favors the formation of the corresponding branched aldehyde. This regioselectivity is opposite to that for the reaction of the usual alkenes. This indicates the presence of a strong amine-directed chelation control (1, 2), which is very similar to the amide-directed chelation control mentioned in the preceding section. The branched aldehyde, thus formed, undergoes intramolecular reductive amination to give **78**.



A rapid synthesis of a quinazoline skeleton has been developed by means of the Rh-catalyzed cascade cyclization of diaminoalkenes via intramolecular aminocarbonylation (32, 33). The cyclohydrocarbonylation of 2-(*N*-allylaminomethyl)aniline (**80**) gives quinazoline **84** in excellent yield through the highly linear-selective hydroformylation of **80**, followed by the sequential formations of hemiaminal **82** and iminium ion **83** as intermediates and then the subsequent intramolecular amine addition (Scheme 19) (32). In the same manner, the reaction of *N*-allyl-2-aminomethylaniline (**85**) affords **86** in 96% yield (33).

The same type of cascade cyclization has been applied to the one-step synthesis of fused azabicyclic compounds with medium to large-membered rings (Scheme 20) (34). For example, the reaction of alkenyldiamine **87** catalyzed by $Rh_2(OAc)_4$–BIPHEPHOS at 80 °C and 27 atm (1 atm = 101.325 kPa) of syngas ($CO:H_2$ = 5:1) gives diazabicyclo-[8.4.0]tetradecane (**88**) in 95% yield. In the same manner, the reaction of alkenylaminoalcohol **89** affords oxazabicyclo[11.3.0]hexadecane (**90**) in 80% yield.

Scheme 20. Note: 1 atm = 101.325 kPa.

Scheme 21. Reaction conditions: (*i*) $Rh_2(OAc)_4$, (0.5 mol%), ligands (2 mol%), CO, H_2 (27 atm, 1 atm = 101.325 kPa), C_6H_6 (0.26 mol/L), 80 °C, 20 h.

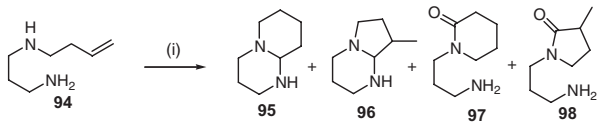
10	BIPHEPHOS	1:1	100	0



[a] Determined by ^{13}C-NMR.

Cyclohydrocarbonylation of *N*-allylpropanediamine (**91**) catalyzed by $Rh_2(OAc)_4$ in benzene at 80 °C and 27 atm (1 atm = 101.325 kPa) of syngas ($CO:H_2$ = 1:1) gives a 2:3 mixture of 1,5-diazabicyclo[4.3.0]nonane (**92**) and *N*-aminopropylpyrrolidinone (**93**, Scheme 21, entry 1) (35). The product ratio is highly dependent on the syngas composition as well as the nature of the ligand used. Thus, the higher hydrogen pressure (e.g., $CO:H_2$ = 1:9) dramatically increases the yield of **92** (Scheme 21, entry 2), while the higher CO pressure (e.g., $CO:H_2$ = 9:1) favors the formation of **93** (Scheme 21, entry 3). The higher basicity of the ligand used appears to favor the formation of **92** (Scheme 21, entries 8 and 9), but the steric factor is also playing an important role. Thus, the use of $P(O\text{-}o\text{-}Tol)_3$ leads to the predominant formation of **93**. The use of BIPHEPHOS affords only **92** in quantitative yield (Scheme 21, entry 10), which provides synthetic usefulness to this cyclohydrocarbonylation process.

In a similar manner, the reaction of *N*-homoallylpropanediamine (**94**) gives the corresponding 1,5-diazabicyclo-[4.4.0]decane) (**95**) (exclusively with the use of $Rh_2(OAc)_4$–

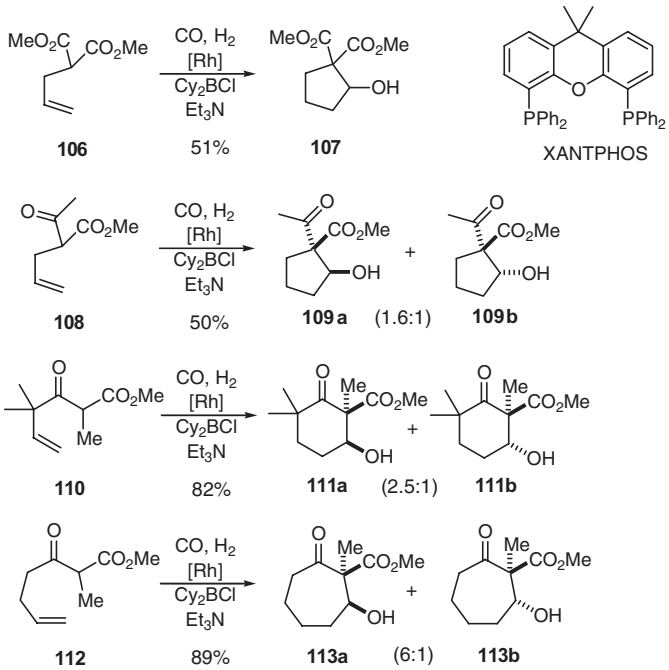
Scheme 23. Reaction conditions: (*i*) Rh(acac)$(CO)_2$, BIPHEPHOS, CO, H_2 (1:1, 5 atm, 1 atm = 101.325 kPa), 60 °C.

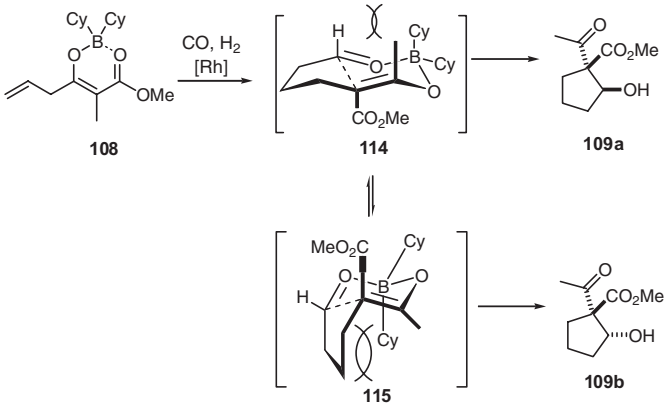


BIPHEPHOS as the catalyst and syngas with equal pressures of CO and H_2 (Scheme 22, entry 1)) (35). Since the use of BIPHEPHOS as the ligand strongly drives the reaction to linear-selective hydrocarbonylation, the ratio of CO and H_2 does not affect the product ratio (Scheme 22, entries 2 and 3). For other ligands, however, clear effects of the partial pressure of CO (or H_2) as well as the nature of ligands on the product ratio is observed in a manner similar to the reaction of **91** mentioned previously. It is interesting to note that the regioselectivity of the cyclohydrocarbonylation leading to the formation of **95** and **96** is linear selective in all cases examined, while the branched product **98** is favorable in the side reaction (Scheme 22, entries 4, 6, and 8).

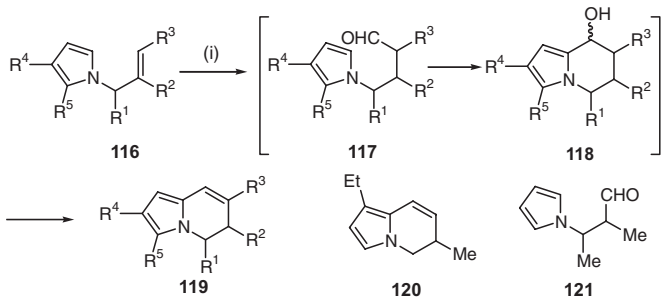
Cyclohydrocarbonylation reactions involving carbon–nucleophiles

The cascade hydroformylation–allylboration–hydroformylation of (*E*)-aminoallylborate (**99**) catalyzed by Rh(acac)$(CO)_2$–BIPHEPHOS affords oxazabicyclic lactol **101** via linear aldehyde **100** in 83% yield (Scheme 23) (36). The regioselective hydroformylation of γ-amidoallylboronate (**102**) gives linear aldehyde **103**, which spontaneously cyclizes to give an equilibrium mixture of aldehyde **103** and lactol **104**. Removal of the Cbz group by hydrogenolysis initiates another cascade process, i.e., amination–hydrogenation, affording indolizidine **105** in 60% overall yield (Scheme 23) (36–38).

Scheme 24. Reaction conditions: Rh(acac)$(CO)_2$ (0.9 mol%), XANTPHOS (1.8 mol%), CO, H_2 (1:1, 60 atm, 1 atm = 101.325 kPa), Cy_2BCl (1.05 equiv.), Et_3N, CH_2Cl_2, 80 °C.



The Rh–XANPHOS catalyzed reactions of allylmalonate (**106**), 2-allylacetoacetate (**108**), 2-(3-butenoyl)propanoate (**110**), and 2-(4-pentenoyl)propanoate (**112**) with syngas in the presence of Cy_2BCl and triethylamine gave the corresponding cycloalkanols, **109**, **111**, and **113**, in fairly good to high yields (Scheme 24) (39). The cycloalkanols, **109**, **111**, and **113**, thus formed, possess a quaternary carbon center next to the hydroxyl group in a molecule, and would serve as useful polyfunctionalized synthetic intermediates in organic synthesis. The observed diastereoselectivity in these reactions can be accommodated by taking into account the relative extent of 1,3-diaxial interactions in the bicyclic transition states, involving a chair structure, e.g., **114** and **115**, for the preferential formation of **109a** (Scheme 25) (39).



Cyclohydrocarbonylation of 1-allylpyrroles (**116a**–**116d**) catalyzed by $Rh_4(CO)_{12}$ at 100 °C and at 100 atm (1 atm = 101.325 kPa) of syngas ($CO:H_2$ = 1:1) gave the corresponding 5,6-dihydroindolizines (**119a**–**119d**) in good yield and excellent regioselectivity (Scheme 26) (40). This reaction proceeds through a cascade hydroformylation–cyclization–dehydration sequence (Scheme 26). Exclusive introduction of a formyl group at the terminal position of a gem-disubstituted olefin or at the carbon α to a phenyl group is typical for Rh-catalyzed hydroformylation reactions. However, in the reaction of **116e**, which has an unsubstituted terminal vinyl group (i.e., $R^2 = R^3 = H$), a mixture of the linear and branched aldehydes is formed, which are converted to

119e and **121**, respectively, in a 59:41 ratio (Scheme 26) (40).

In a similar manner, the cyclohydrocarbonylation of *N*-1-allyl-2-formylpyrroles (**122a**–**122c**) affords 7-formyl-5,6-dihydroindozilines (**126a**–**126c**) in good yield through a one-pot cascade hydroformylation – aldol condensation process (Scheme 27) (41). In this process, the crude hydroformylation product **122** is treated with a base in a one-pot process to give the final product (**126**).

Other cyclohydrocarbonylation reactions

Reaction of 3,3-disubstituted-1,4-pentadiene (**127**) with a primary amine under cyclohydrocarbonylation conditions gives cyclopenta[*b*]pyrrole (**131**) as the predominant product accompanied by a small amount of cyclopentanone (**130**) (Scheme 29) (42). This unique reaction is proposed to proceed through a cascade hydrocarbonylation–carbonylation process. The first hydrocarbonylation of **127** and the subsequent carbocyclization forms cyclopenatonylmethyl–Rh complex **128**. If **128** immediately reacts with molecular hydrogen, 2-methylcyclopentanone (**130**) is formed. However, if CO insertion takes place faster than the hydrogenolysis, cyclopentanoylacetyl–Rh complex **129** is generated, which undergoes the "Paal–Knorr" condensation (43) with a primary amine to yield cyclopenta[*b*]pyrrole (**131**).

Scheme 27. Reactions conditions: (*i*) $Rh_4(CO)_{12}$ (0.25 mol%), CO, H_2 (1:1, 100 atm, 1 atm = 101.325 kPa), 100 °C, toluene (0.4 mol/L), 0.5–2 h; (*ii*) 100 °C under N_2 for 70 h (R^1 = H) or EtONa–EtOH for 5 min (R^1 = Me).

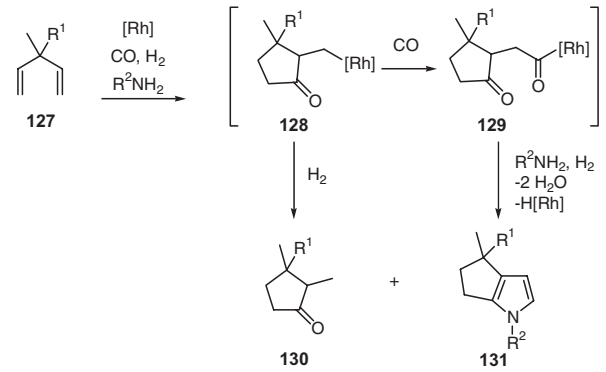
[a] Isolated yield.

Cyclohydrocarbonylation of propargylamine **132** catalyzed by $Rh_2(OAc)_4$-PPh_3 gives a mixture of pyrrole **133** (70%), pyrrolidine **134** (20%), and a small amount of lactone **135** through a deamination–cyclocarbonylation process (Scheme 29) (44).



Hydroformylation of phenylacetylene **136** in the presence of *n*-hexylamine (**137**) catalyzed by $[Rh(COD)]^+[(\eta^6\text{-}C_6H_5BPh_3)]^-$ at 100 °C and at 100 atm (1 atm = 101.325 kPa) of syngas (CO:H_2 = 1:1) gives the corresponding 2-pyrrolidone (**140**). However, the reaction suffers from competing side reactions such as furanone formation and hydrogenation of allylamine intermediate **139** (Scheme 30) (45).

Cyclohydrocarbonylation of 3-TMS-propargyl alcohols cleanly gives the corresponding 2(5*H*)-furanones (**142**). For instance, the reaction of **141** catalyzed by $Rh_4(CO)_{12}$ gives spirobicyclic furanone **142** almost exclusively in 97% yield (Scheme 31) (46).

Furanones **145** or **146** can also be synthesized through the cyclohydrocarbonylation of ynones **144** catalyzed by $[Rh(COD)]^+[(\eta^6\text{-}C_6H_5BPh_3)]^-$–$P(OPh)_3$ (47). The reaction requires a total pressure of 20–40 atm (1 atm = 101.325 kPa) with an increased CO:H_2 ratio (up to 11:1) to prevent undesirable reductions. The nature of the substituent of the alkyne

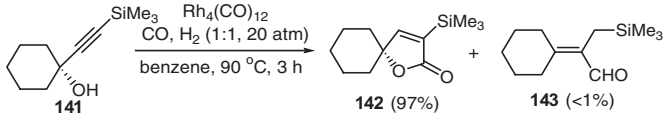
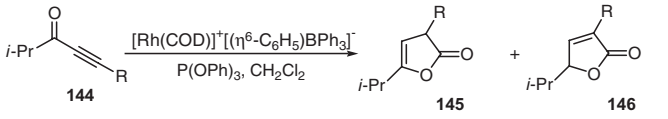


Scheme 30. Note: 1 atm = 101.325 kPa.



moiety has significant influence on the regioselectivity of the reaction. For example, the reactions of **144a**, **144c**, and **144d** afford corresponding **145a**, **145c**, and **145d**, while the reaction of **144b** gives **146b** in high yields (Scheme 32) (47).

A proposed mechanism for this transformation is illustrated in Scheme 33. Complexation of **144** to the [Rh]-H species forms intermediate **147**. The acetylene moiety of **147** undergoes a stereoselective intramolecular insertion into the [Rh]—H bond to give **148**. Two pathways are possible for the generation of key intermediate **153** from **148**, i.e., (*i*) through CO insertion to **149**, followed by rearrangement to zwitterionic ketene **150** and the subsequent cyclization to

Scheme 31. Note: 1 atm = 101.325 kPa.

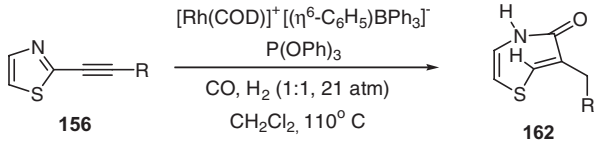
Scheme 33.



153, or (*ii*) through isomerization to **151** followed by CO insertion to **152** and subsequent cyclization to **153**. Then, intermediate **153** gives furanonyl–[Rh] complexes **154** and **155**, which afford **145** and **146**, respectively, through oxidative addition of molecular hydrogen to the [Rh] moiety followed by reductive elimination (47).

2-Alkynylthiazoles (**156**) undergo unique cyclohydrocarbonylation involving ring expansion catalyzed by $[Rh(COD)]^+[(\eta^6\text{-}C_6H_5BPh_3)]^-$ to give 2*Z*,6*E*-4*H*-[1,4]thiazepin-5-ones (**162**) (Scheme 34) (48).

A possible mechanism for this unique transformation is shown in Scheme 35 (48). The insertion of the alkyne moiety of **156** into the [Rh]—H bond of the active catalyst species [Rh]-H gives **157** regioselecively. The regioselectivity is

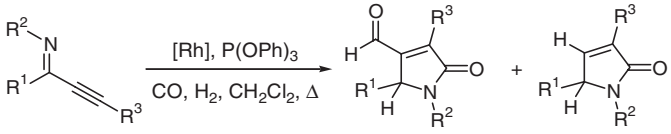
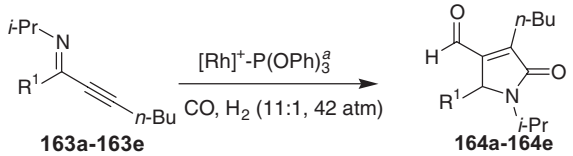


Scheme 35.



attributed to heteroatom–[Rh] interactions. The CO insertion to intermediate **157** forms acyl–[Rh] intermediate **158** in which the nitrogen atom coordinates to [Rh]. Reductive elimination and [Rh] shift gives the π-allyl–[Rh] complex with a penem skeleton **159**. Oxidative addition of molecular hydrogen, followed by a H shift affords the π-olefin–[Rh] intermediate **160**. Ring opening of **160** via formal σ-bond metathesis between the [Rh]—H and the N—C bonds yield N-[Rh]–thiazepinone complex **161**. Subsequent oxidative addition of molecular hydrogen to **161**, followed by reductive elimination gives thiazepinone **162** and regenerates the active catalyst species [Rh]-H.

Another variant of cyclohydrocarbonylation has been reported for the reaction of alkynylimines with syngas (49). The cyclohydrocarbonylation of alkynylimines **163** catalyzed by $[\eta^6\text{-}C_6H_5BPh_3]^-[Rh(1,5\text{-}COD)]^+$–$P(OPh)_3$ affords the corresponding 4-formylpyrrolinones **164** through a cascade carbonylation–hydroformylation process (Scheme 36) (49). However, this reaction is accompanied by the formation of pyrrolinone **165** as well as polymeric side products, depending on the reaction conditions, especially the pressure of syngas. The optimized conditions are at 70–100 °C and at 42 atm (1 atm = 101.325 kPa) of syngas ($CO:H_2$ = 5:1 ~ 11:1), which predominantly gave **164**. When **163j**–**163m**, bearing a phenyl group conjugated to the imine moiety, were used as the substrate, a double bond migration from the $\Delta^{3,4}$ position to the $\Delta^{4,5}$ position takes place to yield **164j**–**164m** in which the double bond is conjugated to the phenyl group

Scheme 38.

at C-5 as shown in the third equation of Scheme 37. Relatively bulky substiuents at the acetylene moiety of **163**, e.g., isopropyl and cyclohexylmethyl, are tolerated in this reaction, but the introduction of a *tert*-butyl group to this position (see **163m** in the third equation of Scheme 37) shuts down the reaction.

A proposed mechanism for this process is illustrated in Scheme 38 (49). The imine nitrogen of **163** coordinates to the active catalyst species ([Rh]-H) to form **166** or **167** (these two intermediates are probably in equilibrium). A subsequent hydride shift to the carbon of the imine moiety gives alkynylamino–Rh complex **168**, which is further converted to alkynylamido–Rh complex **169** by CO insertion. Then, the endo-carboyclization of **169** gives pyrrolinon-4-yl–Rh complex **170**, to which the oxidative addition of molecular hydrogen and the subsequent reductive elimination take place to yield **165**, or the CO insertion occurs to form pyrrolinone-4-carbonyl–Rh complex **171**. Finally, 4-formylpyrrolinone (**164**) is yielded and the active catalyst species is regenerated through the reaction of **171** with molecular hydrogen.

In summary, recent advances in the transition metal catalyzed cyclohydrocarbonylation reactions are described. A variety of cyclohydrocarbonylation processes provide efficient and versatile methods for the construction of monocyclic, bicyclic, and polycyclic heterocycles as well as carboncycles, starting from readily accessible materials. It is noteworthy that many of the cyclohydrocarbonylation reactions can be performed under the mild conditions and low pressure of syngas, which may add more value to these processes as useful synthetic methods. The authors hope that this review encourages many synthetic chemists to explore new and creative applications of cyclohydrocarbonylation reactions in organic synthesis.

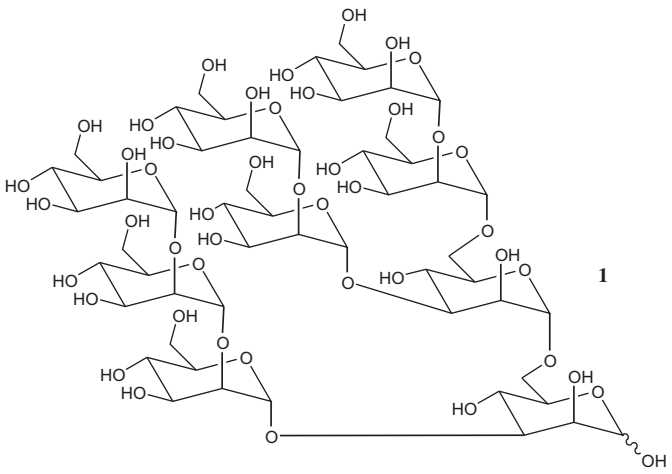
Efficient synthesis of the nonamannoside residue of high mannose glycoproteins[1]

Lu Jiang and Tak Hang Chan

Abstract: An efficient synthesis of the nonamannoside residue **1** of high mannose glycoproteins was achieved using an oligomer-supported solution synthesis with low-molecular-weight polyethylene glycol as the anchor. The synthesis required only five coupling steps from only two monosaccharide building blocks with an overall yield of 12%.

Key words: nonamannoside, oligosaccharide synthesis, soluble polymer support synthesis, glycoproteins.



Résumé : On a réalisé une synthèse efficace de la portion nonamannoside **1** des glycoprotéines à haute teneur en mannose en faisant appel à une méthode de synthèse en solution, supportée par un oligomère, dans laquelle du polyéthylène glycol de faible poids moléculaire sert d'ancre. La synthèse qui a été effectuée avec un rendement global de 12 % ne comporte que cinq étapes de couplage qui n'utilisent que deux monosaccharides comme blocs de synthèse.

Mots clés : nonamannoside, synthèse d'oligosaccharide, synthèse sur un support de polymère soluble, glycoprotéines.

[Traduit par la Rédaction]

Introduction

The branched chain nonasaccharide **1**, Man_9, plays an essential role in the biosynthesis and processing of N-linked glycoproteins. Through the dolichol pathway, the oligosaccharide core with the composition $GlcNAc_2Man_9Glc_3$ is transferred to a polypeptide chain. The glucose and some of the mannose residues are then trimmed, and other carbohydrate residues are added by various processing enzymes to give diverse N-linked glycoproteins (1). The completed glycoproteins are targeted for secretion, incorporation into cellular organelles, or insertion into cell membranes. For membrane-bound glycoproteins, the carbohydrate moieties have been implicated in many cell–cell recognition processes, such as adhesion and infection (2). In this connection, it is interesting to note that nonasaccharide **1** is present on the conserved V3 loop of glycoprotein (Gp) 120 of the viral coat of HIV-1 (3). Gp120 plays an important role in the HIV infection of cells, being responsible for the attachment and penetration of cells to be infected, and is thus a target for immunotherapy or vaccine development. Indeed, antibodies directed against the mannose residues of HIV-1 glycoprotein Gp120 in vitro have been developed (4). Because of these considerations, nonasaccharide **1** presents itself as an attractive synthetic target, and several syntheses of the nonasaccharide structure have been described in the literature. Fraser-Reid and co-workers (5) and Ley and co-workers (6) used a highly convergent block synthesis approach to prepare a highly protected derivative of **1** (5) or its methyl and 8-(methoxycarbonyl)octyl glycoside derivatives (6). More recently, Seeberger and co-workers reported a linear synthesis of the pentyl glycoside derivative of **1** (7). Even though **1** itself was not synthesized, the total chemical synthesis of $Man_9GlcNAc_2$ was recently accomplished by Danishefsky and co-workers as part of their effort to prepare artificial HIV vaccines (8).

1

It is generally recognized that the synthesis of complex oligosaccharides is a matter of considerable challenge and a subject of extensive contemporary research attention. In addition to the classical solution synthesis, some of the current methods developed for the synthesis of oligosaccharides have involved the use of solid phase, which can now be automated (9), or high-molecular-weight polymer supported solution-phase synthesis, which facilitates separation and purification of the intermediates (10). Despite this recent progress in the solid-phase and polymer-supported solution synthesis of oligosaccharides, many issues remain to be ad-

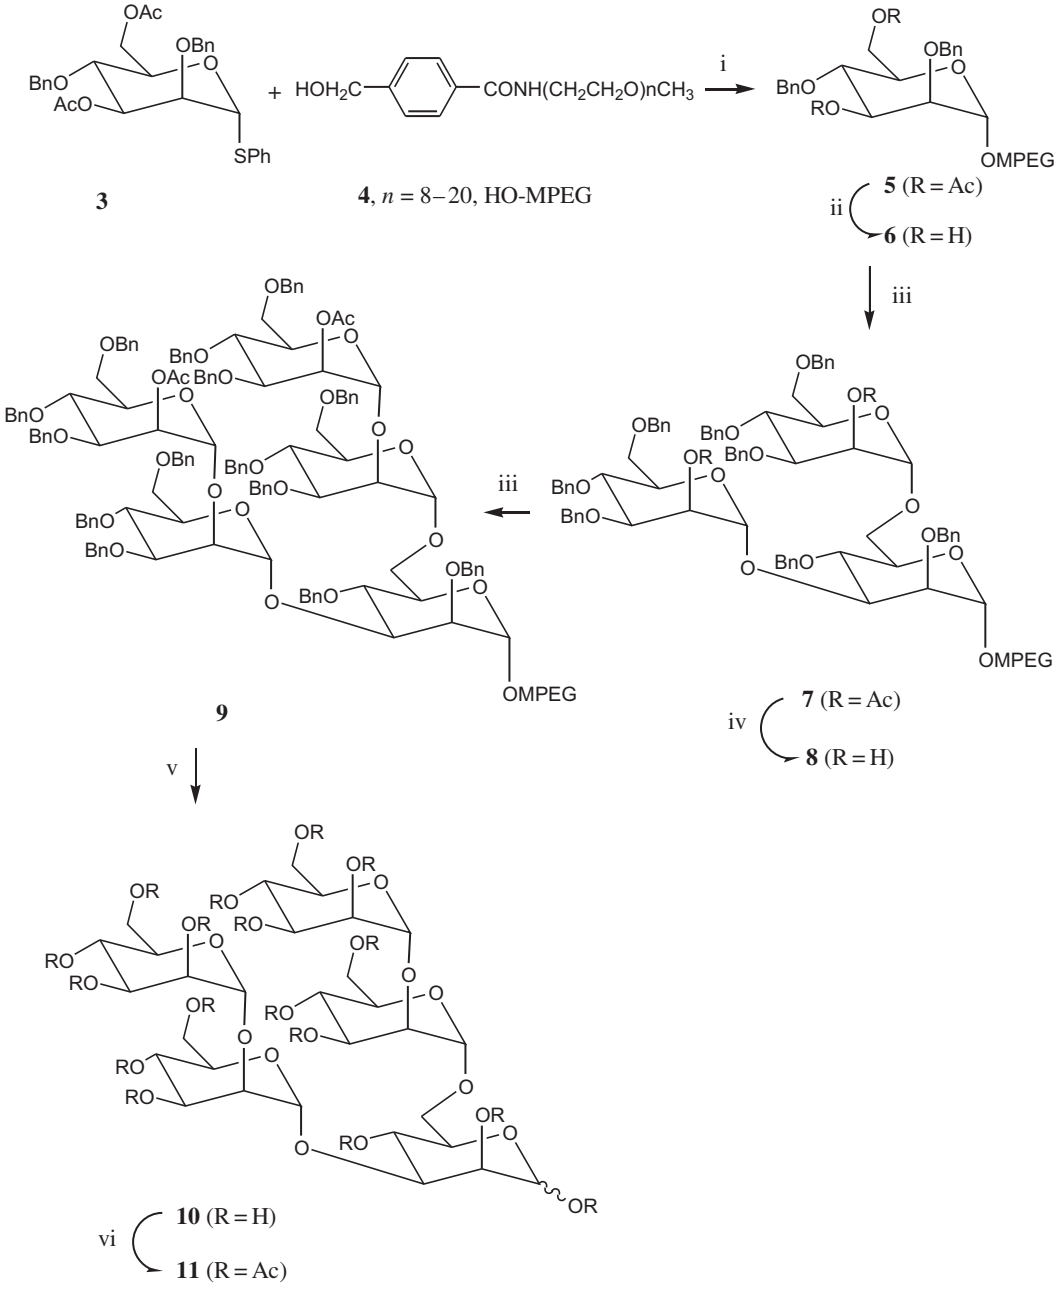
dressed. To make enough of the complex oligosaccharides for biological evaluation, one major obstacle is the scale of the synthesis. Loading of both solid-phase resins and high-molecular-weight poly(ethylene glycol)s are inherently limited. Although there is no limit on how much compound can be used in the conventional solution synthesis, the involvement of column chromatography during the separation process is a major bottleneck. To overcome the purification problem and to develop a method that can enable the synthesis of complex oligosaccharides on a large scale, we employed low-molecular-weight poly(ethylene glycol) methyl ethers (MPEG, average MW = 550, n = ca. 8–20) as polar tags for solution synthesis of oligosaccharides (11). The use of low-molecular-weight MPEGs as polar tags retains the normal advantages of polymer-supported solution synthesis of oligosaccharides, such as the following: (*i*) the MPEG-linker and its bonded synthons are completely soluble in the normal reaction solvents, and the efficiency of the various steps follows that expected of solution chemistry; and (*ii*) the reaction can be monitored readily by the conventional arsenal of spectroscopic techniques. Furthermore, purification of the MPEG-linker and its derivatives by fast column chromatography on silica gel 60 (230–400 mesh, E. Merck) is facilitated by the fact that even in neat ethyl acetate, the MPEG conjugates remain on the baseline while the much less polar by-products move rapidly through the column. Changing the eluent to dichloromethane–methanol (4:1) or to ethyl acetate – methanol (4:1) allows quick elution of the MPEG derivatives, free of silica gel contamination.

Results and discussions

General strategy

In classic oligosaccharide synthesis, to make the purification and identification of the intermediates easier as well as to maximize the overall yield, highly convergent synthetic strategies are generally desired. However, the less common linear strategy offers more advantages in the case of **1**, which is illustrated in Scheme 1. One can easily assemble the Manα1-2Man (A-A) linkage using compound **2** (representing A) (12), with the phenylthio moiety as the potential glycosyl donor. Compound **3** (representing B) (13), on the other hand, with the regioselectively available 3,6 diol moiety, can serve as the potential glycosyl acceptor to give the branched structure. Furthermore, to make the synthesis efficient, we chose to first construct the B-B-A fragment. It was anticipated that once this trisaccharide core was reached, only two triple glycosylations with **2** were needed for the construction of nonamannoside **1**.



Using regioselective acylation and regioselective reductive ring opening of benzylidene acetals methods previously reported by us, compound **3** was readily obtained from methyl α-D-mannopyranoside in high overall yield (13). Coupling of **3** with the poly(ethylene glycol) linker **4**, using the combination of *N*-iodosuccinimide and trimethylsilyl triflate (NIS–Me_3SiOTf) (14), went smoothly and gave compound **5** in almost quantitative yield. Purification of the product **5** employing flash column chromatography was facilitated by the use of low-molecular-weight poly(ethylene glycol) methyl ether (MPEG) as the polar tag. The excess reagents in the reaction mixtures were readily separated from the oligomer-bonded product. The two acetyl groups of **5** were then removed by base treatment to yield the diol **6**. Double glycosylation of **6** with 3.0 equiv. of the donor **2** was carried out with NIS–TMSOTf as the promoter to afford the MPEG-trisaccharide **7**. The amount of the Lewis acid (TMSOTf) used in the glycosylation was quite critical. When less than 0.8 equiv. of TMSOTf was employed in the coupling reaction, formation of 1,2-orthoacetates resulted. The success of the double glycosylation in **7** was evidenced by the fact that its ^{1}H-^{1}H COSY NMR spectrum showed the two new anomeric protons at 5.19 and 4.97 ppm (parts per million). Incorporation of the two new mannopyranoside units was also confirmed by the ^{1}H-^{13}C HMQC NMR spectrum, revealing the existence of three anomeric cross peaks. Repetition of the deacetylation step and double glycosylation with glycosyl donor **2** gave the protected MPEG-pentasaccharide **9** through the formation of MPEG-trisaccharide diol **8**. Progress of the assembly was readily monitored by ^{1}H NMR spectroscopy, and the chemical shifts of protons and carbons could be assigned by 2D ^{1}H-^{1}H COSY and ^{1}H-^{13}C HMQC NMR spectroscopy. Hydrogenolysis of **9** over Pd–C in acetic acid released the pentasaccharide **10** from the polar tag smoothly. Purification and characterization of **10** were achieved by conversion to the peracetate derivative **11** (as a mixture of α- and β-anomers) (Scheme 2). The overall yield of the peracetylated pentamannopyranoside **11** was found to be 19% based on the starting **4**. Compound **11** was characterized by electrospray mass spectrometry, ^{1}H NMR, and ^{13}C NMR.

Synthesis of the nonamannoside 1 via triple glycosylation (Scheme 3)

Having established the feasibility and efficiency of the

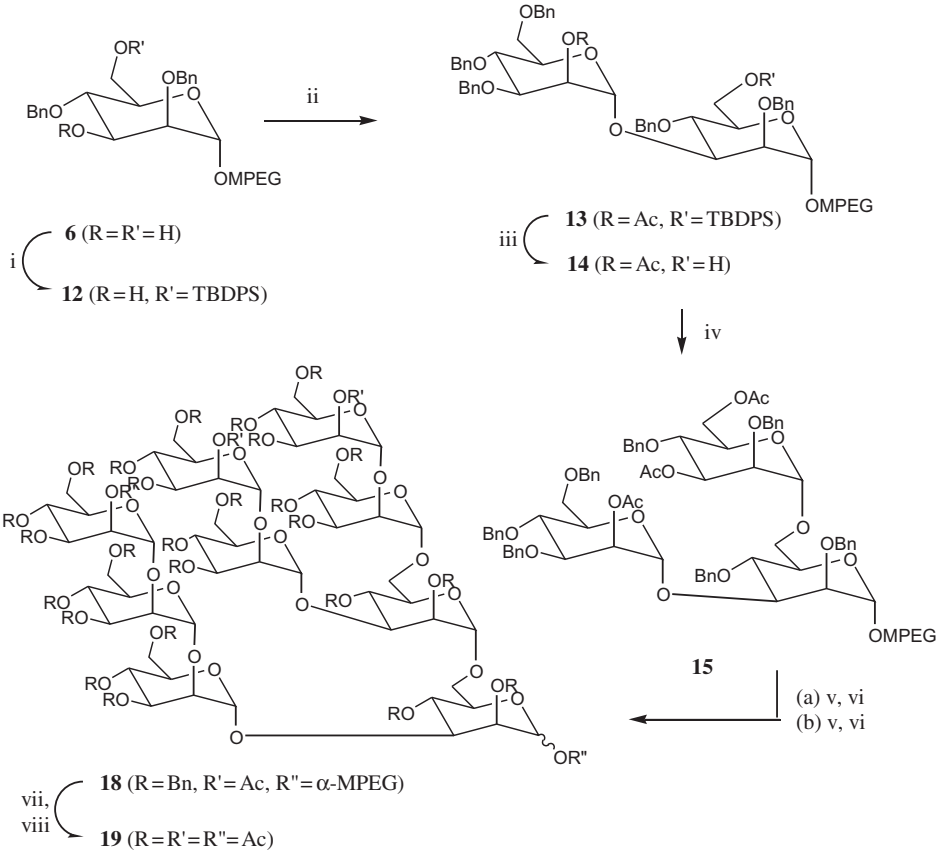

Scheme 2. Reagents and conditions: (*i*) 2.0 equiv. of thiomannoside **3**, 2.2 equiv. of NIS, 0.8 equiv. of TMSOTf, 4 Å molecular sieves, CH_2Cl_2, 0 °C to rt, 4 h; (*ii*) K_2CO_3, wet MeOH, 4 h; (*iii*) 3.0 equiv. of thiomannoside **2**, 3.3 equiv. of NIS, 0.8 equiv. of TMSOTf, 4 Å molecular sieves, CH_2Cl_2, 0 °C to rt, 4 h; (*iv*) NaOMe, MeOH, CH_2Cl_2, 12 h; (*v*) 50 psi H_2, 10% Pd–C, CH_3COOH, 5 days; (*vi*) Ac_2O, Py, DMAP, 48 h.

solution phase chemistry, attention was then turned to the construction of the complex nonamannoside residue **1** (Scheme 3). This required the differentiation of the 3- and 6-hydroxyl functions of **6**. The primary hydroxyl group in the MPEG-monosaccharide diol **6** was selectively protected by the *tert*-butyldiphenylsilyl (TBDPS) group (15), and then the partially protected **12** was glycosylated with phenyl 2-*O*-acetyl-1-thio-3,4,6-tri-*O*-benzyl-α-D-mannopyranoside (**2**) to yield the MPEG-disaccharide **13**. Removal of the silicon protecting group gave the MPEG-bound acceptor **14**, which was glycosylated with donor **3** to form MPEG-trisaccharide **15**. To avoid using TBAF (whose ammonium cation may cause problems during chromatographic separation) in the desilylation step, dilute HF was employed in the desilylation of **15** to give **16**. As anticipated, the triple glycosylation of MPEG-trisaccharide triol **16** with 4.5 equiv. of the thiomannoside **2** went smoothly to furnish the MPEG-bound hexasaccharide **17**, the ^1H and ^{13}C NMR spectra of which exhibited the anticipated three acetate peaks. The ^1H-^{13}C HMQC NMR spectrum of **17** also revealed the presence of six anomeric cross peaks. Reiteration of the deacetylation and the triple glycosylation steps gave the protected MPEG-nonasaccharide **18**. It is worth mentioning that the MPEG-bound hexasaccharides and nonasaccharide can be more

Scheme 3. Reagents and conditions: (*i*) 2.0 equiv. of *t*-$BuPh_2SiCl$, 2.0 equiv. of DMAP, CH_2Cl_2, rt, 24 h; (*ii*) 2.0 equiv. of thiomannoside **2**, 2.2 equiv. of NIS, 0.8 equiv. of TMSOTf, 4 Å molecular sieves, CH_2Cl_2, 0 °C to rt, 4 h; (*iii*) 5% HF in MeOH, 3 days; (*iv*) 2.0 equiv. of thiomannoside **3**, 2.2 equiv. of NIS, 0.8 equiv. of TMSOTf, 4 Å molecular sieves, CH_2Cl_2, 0 °C to rt, 4 h; (*v*) NaOMe, MeOH, CH_2Cl_2, 12 h; (*vi*) 4.5 equiv. of thiomannoside **2**, 4.8 equiv. of NIS, 0.8 equiv. of TMSOTf, 4 Å molecular sieves, CH_2Cl_2, 0 °C to rt, 4 h; (*vii*) 1000 psi H_2, 20% $Pd(OH)_2$–C, MeOH, 7 days; (*viii*) Ac_2O, Py, DMAP, 48 h.

easily washed out from silica gel columns than the MPEG-bound smaller saccharides, probably because of the fact that the hydrophobic portions of the MPEG-bound larger saccharides reduced the affinity of the MPEG-saccharides towards silica gel.

The final debenzylation of **18** turned out to be somewhat troublesome, in that hydrogenolysis over Pd–C in various media did not proceed even after prolonged exposure. Eventually, hydrogenolysis of **18** over Pearlman's catalyst in methanol under high pressure (1000 psi (1 psi = 6.895 kPa)) for seven days released the nonasaccharide from the MPEG oligomer. The nonamannoside was characterized as its α- and β-peracetate derivative (**19**, ca. 12% overall yield from **4**), whose electrospray mass spectrum was consistent with the expected structure. The experimental spectrum matched the theoretical spectrum created by isotopic modeling (Fig. 1). Furthermore, the ^1H-^{13}C HMQC spectrum (Fig. 2) also provided confirmation of the structure of **19** by revealing the presence of the cross peaks of nine anomeric centers.

Conclusions

In summary, a chemical synthesis of the nonamannoside residue of a highly branched mannose-type oligosaccharide present on the viral coat of HIV-1 has been achieved from only two monosaccharide building blocks (**2** and **3**). The use of low-molecular-weight MPEG aided considerably in the purification of the intermediates and in the analyses of the progress of the assembly with the use of conventional spectroscopic techniques. It should be noted that besides these advantages, this methodology also gives access to large-scale synthesis. In the present case, over 300 mg of final product **19** was obtained, and it is conceivable to work on even larger scale synthesis. This synthesis demonstrates that solution synthesis using a low-molecular-weight poly(ethylene glycol) as a polar tag to aid separation is a useful tool for the rapid and efficient preparation of complex oligosaccharides. The ability to introduce two or three saccharide units via double or triple glycosylation in one operation is particularly remarkable. On the other hand, the approach does have some limitations. Since no chromatography was used throughout the synthesis, all glycosylated products, both alpha and beta, would be accumulated. For glycosylation reactions that are not highly stereoselective, this would inevitably lead to an intractable mixture of final compounds. Another potential problem is the difficulty of the hydrogenation step in the final release of the oligosaccharide from the PEG support. This may be due to the presence of sulfur-containing contaminants that would have been removed normally in sequentially purified solution chemistry.

Experimental

General

^{1}H and ^{13}C NMR spectra were recorded at 500 and 125 MHz, respectively, and the chemical shifts are reported in parts per million on the δ scale relative to $CDCl_3$ (δ 7.24 ppm) for ^{1}H NMR and $CDCl_3$ (δ 77.0 ppm) for ^{13}C NMR. Solvents and reagents were used as received from commercial sources. Analytical thin-layer chromatography (TLC) was performed using E. Merck silica gel 60 F-254 polyester-backed plates (250 μm thick). Compounds **2** and **3** were prepared according to literature procedures (12, 13). Poly(ethylene glycol) methyl ether 550 (average MW = 550, n = 8–20) was purchased from Aldrich.

Preparation of compound 4

Me(OCH$_2$CH$_2$)$_n$OMs

Poly(ethylene glycol) methyl ether 550 (12.54 g, 20.0 mmol OH) was dissolved in CH_2Cl_2 (20 mL) and NEt_3 (10 mL). Methanesulfonyl chloride (8.02 g, 5.5 mL, 70 mmol) was added at 0 °C. Upon removal of the ice bath right after completion of the addition, the reaction mixture was allowed to warm up to room temperature slowly and kept for 4 h. Chloroform and an aqueous $NaHCO_3$ solution were then added to quench the reaction. After it was washed with 5% HCl solution (1 × 100 mL), saturated $NaHCO_3$ solution (1 × 100 mL), and brine (1 × 100 mL), the organic layer was dried over anhydrous Na_2SO_4 and evaporated to dryness under reduced pressure. A clear light yellow liquid (13.9 g, 98.5%) was obtained after drying on a high vacuum pump. ^{1}H NMR (500 MHz, $CDCl_3$) δ: 4.36 (2H, t, 4.5 Hz, C*H*$_2$OSO$_2$), 3.74 (2H, t, 4.5 Hz, C*H*$_2$CH$_2$OSO$_2$), 3.64–3.61 (48H, m, PEG), 3.54–3.51 (2H, m), 3.36 (3H, s, C*H*$_3$O), 3.06 (3H, s, C*H*$_3$SO$_3$).

Me(OCH$_2$CH$_2$)$_n$N$_3$

The mesylate obtained above (13.9 g) and sodium azide (4.55 g, 70 mmol) were dissolved in DMF (50 mL), and the reaction mixture was heated at 80 °C for 5 h. Water was added after DMF was removed under reduced pressure. The aqueous solution was extracted with chloroform (3 × 50 mL), and the organic layer was washed with brine and then dried over anhydrous Na_2SO_4. Evaporation of the organic layer to dryness under reduced pressure left a darker liquid (12.2 g, 95%). ^{1}H NMR (500 MHz, $CDCl_3$) δ: 3.66–3.61 (50H, m, PEG), 3.53 (2H, t, 2.4 Hz, OC*H*$_2$CH$_2$N$_3$), 3.36 (2H, t, 2.4 Hz, OCH$_2$C*H*$_2$N$_3$), 3.35 (3H, s, C*H*$_3$O).

Me(OCH$_2$CH$_2$)$_n$NH$_2$

A mixture of the azide (12.2 g), 10% Pd–C (0.8 g), and methanol (40 mL) was stirred under 40 psi H_2 for 3 h at room temperature. The solution was filtered, and the Pd–C was washed with methanol. The filtrate was evaporated to dryness under reduced pressure to give a clear light reddish liquid (11.7 g, 100%). ^{1}H NMR (500 MHz, $CDCl_3$) δ: 3.62–3.58 (48H, m, PEG), 3.50 (2H, m), 3.47 (2H, t, 5.2 Hz, OC*H*$_2$CH$_2$NH$_2$), 3.34 (3H, s, C*H*$_3$O), 2.81 (2H, t, 5.5 Hz, OCH$_2$C*H*$_2$NH$_2$).

Me(OCH$_2$CH$_2$)$_n$NHCOPhCH$_2$Cl

A mixture of the amine (5.5 g) obtained above, dicyclohexylcarbodiimide (3.1 g, 15 mmol), 4-chloromethylbenzoic acid (2.2 g, 13 mmol), CH_2Cl_2 (20 mL), and a catalytic amount of DMAP was stirred at room temperature overnight. Water was added after removing CH_2Cl_2 under reduced pressure. The precipitate dicyclohexylurea was filtered, and the aqueous solution was extracted with chloroform (3 × 20 mL). The organic layer was washed with an aqueous $NaHCO_3$ solution and brine and then dried over anhydrous Na_2SO_4. The product was obtained, after solvent removal, as a sticky light-yellow liquid (6.6 g, 96%). ^{1}H NMR (500 MHz, $CDCl_3$) δ: 7.80 (2H, d, 7.6 Hz, Ar-*H*), 7.43 (2H, d, 7.6 Hz, Ar-*H*), 6.90 (1H, s (br), PhCON*H*), 4.59 (2H, s, ClC*H*$_2$Ph), 3.70–3.50 (54H, m, PEG), 3.36 (3H, s, C*H*$_3$O).

Me(OCH$_2$CH$_2$)$_n$NHCOPhCH$_2$OH (4)

A mixture of the chloromethylbenzamide (4.3 g), Ag_2CO_3 (1.6 g, 5.8 mmol), $AgClO_4$ (0.1 g), and water (25 mL) was stirred at room temperature for two days. The reaction mixture was first filtered through celite and then extracted with chloroform (3 × 20 mL). The organic layer was dried over anhydrous Na_2SO_4 and evaporated to dryness under reduced pressure to give a dark syrup, which still contained the silver salts. The syrup was dissolved in a small quantity of ethyl acetate and added onto the top of a silica gel column for flash column chromatography. Elution with ethyl acetate – methanol (4:1 and 3:1, 150 mL each) gave **4** (4.0 g, 95%) as a sticky light-yellow liquid. ^{1}H NMR (500 MHz, $CDCl_3$) δ: 7.79 (2H, d, 7.6 Hz, Ar-*H*), 7.39 (2H, d, 7.6 Hz, Ar-*H*), 7.06 (1H, s (br), PhCON*H*), 4.70 (2H, d, 4.1 Hz, PhC*H*$_2$OH), 3.70–3.40 (54H, m, PEG), 3.35 (3H, s, C*H*$_3$O), 2.61 (1H, s (br), CH$_2$O*H*).

Protocol for the solution-phase glycosylations

After thiomannoside **2** (or **3**) (2.0 mmol) and an MPEG-acceptor (1 mmol) were co-distillated with toluene 5 times under reduced pressure, dry 4 Å molecular sieve powder (1 g/g reactant) and dichloromethane (2.5 mL/g reactant) were added into the flask. The mixture was stirred for 10–15 min under Ar and then cooled to 0 °C, followed by the addition of NIS. The color of the reaction mixture turned pink immediately as a 2 mol/L solution of TMSOTf (0.8 mmol) in dichloromethane was syringed into the flask slowly. Upon removal of the ice bath right after completion of the addition, the reaction mixture was allowed to warm to room temperature slowly and kept for 2 h. Chloroform and an aqueous $NaHCO_3$ solution were added to quench the reaction, followed by filtration of the mixture through a pad of celite to remove the molecular sieve powder. After having been washed with an aqueous $Na_2S_2O_3$ solution and brine, the organic layer was dried over anhydrous Na_2SO_4 and evaporated to dryness under reduced pressure. The resulting syrup was dissolved in a small amount of ethyl acetate and put onto the top of a silica gel column (15 times weight of the syrup) for flash column chromatography. Gradient elution with hexanes – ethyl acetate (2:1, 1:1, 1:2, 1:4, and neat EtOAc, 50 mL each) removed the side products, and further elution with ethyl acetate – methanol (4:1 and 3:1, 150 mL each) gave the MPEG–sugar conjugate.

Protocol for the deacetylation with K_2CO_3

Potassium carbonate was added to a stirred solution of MPEG–sugar in wet methanol, and the reaction was monitored by ^{1}H NMR spectroscopy. Upon completion of the deacetylation, as indicated by the disappearance of the acetyl peak (or peaks) in the ^{1}H NMR spectrum, the methanol was evaporated under reduced pressure, and brine was added. After the aqueous solution was extracted with chloroform (3 × 50 mL), the organic layer was dried over anhydrous Na_2SO_4 and evaporated to dryness under reduced pressure. Purification of the MPEG-bound products by chromatographic separation procedure was the same as described above.

Protocol for the deacetylation with NaOMe

The procedure was essentially the same as above, except that sodium methoxide was used as the base and methanol–dichloromethane (1:2) was the solvent.

Colorless syrup. ^{1}H NMR (500 MHz, $CDCl_3$) δ: 7.71 (2H, s (br), Ar-*H*), 7.38–7.08 (m, Ar-*H*), 6.55 (1H, s (br), PhCON*H*), 5.50 (2H, m (br), *H*-2a and *H*-2b), 5.19 (1H, s (br), *H*-1a), 5.05 (1H, s (br), *H*-1b), 5.03 (1H, s (br), *H*-1c), 4.93 (1H, s (br), *H*-1d), 4.86–4.22 (m, *H*-1e and PhCH_2), 4.06–3.46 (m), 3.36 (3H, s, OCH_3), 2.10 (3H, s, CH_3CO), 2.08 (3H, s, CH_3CO).

Pentamannoside peracetate (11)

A mixture of **9** (from 1 mmol of **4**) and 10% Pd–C (0.5 g) in acetic acid (40 mL) was stirred under 50 psi H_2 for 5 days at room temperature. The solution was filtered, and the 10% Pd–C was washed with methanol (2 × 10 mL). After the filtrate was evaporated under reduced pressure to afford clear syrup, acetic anhydride (15 mL), pyridine (25 mL), and a catalytic amount of DMAP (50 mg) were added. The mixture was stirred at room temperature for two days, and usual work-up gave a glassy solid, which was subject to flash column chromatography over silica gel (40 g, EtOAc–hexanes 2:1) to afford the peracetylated pentasaccharide **11** (a mixture of α- and β-anomers) in 19% yield (285 mg) based on **4**. Colorless glassy solid. R_f = 0.30 (5:2 EtOAc–hexanes). ^{1}H NMR (500 MHz, $CDCl_3$) δ: 6.01 (d, 1.7 Hz, *H*-1aα), 5.76 (d, 1.0 Hz, *H*-1aβ), 5.46 (dd, 1.0 and 2.1 Hz, *H*-2aβ), 5.38–5.15 (m), 5.12 (d, 1.7 Hz, *H*-1bα), 5.10–5.07 (m), 4.92 (d, 1.0 Hz, *H*-1cβ), 4.89 (d, 1.5 Hz, *H*-1cα), 4.88 (d, 1.0 Hz, *H*-1dβ), 4.86 (d, 1.5 Hz, *H*-1dα), 4.82 (d, 1.5 Hz, *H*-1eα), 4.80 (d, 1.0 Hz, *H*-1eβ), 4.22–3.51 (m), 2.19 (s, CH_3CO), 2.14 (s, CH_3CO), 2.13 (s, CH_3CO), 2.12 (s, CH_3CO), 2.11 (s, CH_3CO), 2.10 (s, CH_3CO), 2.09 (s, CH_3CO), 2.08 (s, CH_3CO), 2.05 (s, CH_3CO), 2.04 (s, CH_3CO), 2.03 (s, CH_3CO), 2.02 (s, CH_3CO), 2.01 (s, CH_3CO), 1.97 (s, CH_3CO). ^{13}C NMR (125 MHz, $CDCl_3$) δ: 170.7, 170.6, 170.4, 170.2, 170.1, 170.0, 169.9, 169.7, 169.6, 169.5, 169.4, 169.3, 169.2, 167.7, 99.7, 99.6, 99.4, 99.0, 98.2, 90.5, 90.2, 77.8, 74.3, 71.0, 69.6, 69.5, 69.4, 69.3, 69.2, 69.0, 68.4, 68.2, 68.1, 66.8, 66.1, 66.0, 65.6, 65.3, 62.3, 62.1, 61.9, 61.8, 21.1, 20.9, 20.8, 20.7, 20.6, 20.5, 20.4, 20.3. ES-MS calcd. for $C_{64}H_{86}O_{43}Na$ ([M + Na]$^+$): 1565.4; found: 1565.6. The experimental spectrum matches the theoretical spectrum calculated by isotopic modeling.

MPEG-Man3OH6OTBDPS (12)

MPEG derivative **6** (1 mmol) and DMAP (2 mmol) were dissolved in CH_2Cl_2 (15 mmol). *tert*-Butyldiphenylsilyl chloride (2 mmol) was added, and the reaction mixtures were stirred at room temperature for 24 h. After it was washed with a 1 mol/L HCl solution (2 × 75 mL), the organic layer was dried over anhydrous Na_2SO_4 and loaded onto the top of a silica gel column (15 times weight of compound **6**) for flash column chromatography. Gradient elution with hexanes – ethyl acetate (2:1, 1:1, 1:2, 1:4, and neat EtOAc, 50 mL each) removed the side products, and further elution with ethyl acetate – methanol (4:1 and 3:1, 150 mL each) gave the MPEG–sugar conjugate as colorless syrup. ^{1}H NMR (500 MHz, $CDCl_3$) δ: 7.76 (2H, d, 7.1 Hz, Ar-*H*), 7.74 (2H, d, 7.1 Hz, Ar-*H*), 7.71 (2H, d, 7.1 Hz, Ar-*H*), 7.44–7.19 (18H, m, Ar-*H*), 6.83 (1H, s (br), PhCON*H*), 4.97 (1H, d, <1.0 Hz, *H*-1), 4.88 (1H, d, 11.0 Hz, PhCH_2), 4.73 (1H, d, 12.4 Hz, PhCH_2), 4.71 (1H, d, 11.8 Hz, PhCH_2),

Oppenauer-type oxidation of secondary alcohols catalyzed by homogeneous water-soluble complexes[1]

Abdelaziz Nait Ajjou and Jean-Louis Pinet

Abstract: The catalytic system composed of $[Ir(COD)Cl]_2$, 2,2′-biquinoline-4,4′-dicarboxylic acid dipotassium salt (BQC), and sodium carbonate is highly efficient for the selective oxidation of benzylic, 1-heteroaromatic, aliphatic, and allylic secondary alcohols using catalyst:substrate ratios ranging from 0.4% to 2.5%. Sterically hindered allylic alcohols undergo selectively good conversions to the corresponding enones, while unhindered ones are completely isomerized to saturated ketones. Mercury tests indicate that the catalytic process is likely homogeneous. The mechanism proposed for this Oppenauer-type oxidation including the isomerization process is based on iridium-alkoxide species.

Key words: Oppenauer oxidation, water, catalysis, isomerization, secondary alcohols.

Résumé : Le système catalytique composé de $[Ir(COD)Cl]_2$, 2,2′-biquinoléine-4,4′-dicarboxylate de potassium (BQC), et du carbonate de sodium est très efficace pour l'oxydation sélective des alcools secondaires benzyliques, 1-hétéroaromatiques, aliphatiques, et allyliques en cétones correspondantes en utilisant des quantités du catalyseur allant de 0,4 % à 2,5 %, par rapport aux substrats. Les alcools allyliques encombrés sont transformés, sélectivement, en énones correspondantes, alors que les alcools non-encombrés sont complètement isomérisés en cétones saturées. Les tests avec le mercure indiquent que le processus catalytique est, probablement, homogène. Le mécanisme proposé pour cette oxydation de type Oppenauer ainsi que pour l'isomérisation des alcools allyliques est basé sur la formation de l'espèce iridium-alkoxyde.

Mots clés : oxydation d'Oppenauer, eau, catalyse, isomérisation, alcools secondaires.

Introduction

The oxidation of alcohols to the corresponding aldehydes and ketones is one of the most fundamental and indispensable reactions in organic synthesis (1). For such transformations, the use of stoichiometric amounts of harmful inorganic oxidants, mainly chromium (VI) reagents, remains widespread (2). As a consequence for the increasing demand for efficient, cleaner, and environmentally friendly methods (3), numerous catalytic methods using small amounts of metallic derivatives and clean oxidants have been developed (4). Unfortunately, most of these catalytic transformations are accomplished in costly and toxic organic solvents. Furthermore, in the homogeneous processes, separation of the catalysts from the reaction products and their quantitative recovery in an active form are still the most important goals but practical problems remain. To overcome these disadvantages, aqueous organometallic catalysis has, recently, emerged as a very useful alternative technology (5). The water-soluble catalyst that operates and resides in water is, easily, separated from the reaction products by simple decantation. In addition, the products are not contaminated with traces of metal catalyst, and the use of organic solvents, such as benzene and chlorinated hydrocarbons is circumvented. Despite the obvious economical and ecological advantages of aqueous-phase catalysis, very few water-soluble catalysts have been reported for the oxidation of alcohols in water (6).

Oppenauer oxidation is an elegant and highly selective process for the oxidation of secondary alcohols to the corresponding ketones, with aluminum alkoxides (7). It can be carried out under mild conditions, and is compatible with many functional groups such as carbon–carbon double and triple bonds, halogens, amino groups, aldehydes, or sulphur atom-containing groups. The advantages of Oppenauer oxidation have led to the development of more efficient methods based on modified aluminum alkoxides (8) and the use of transition-metal complexes as catalysts (9).

In the past few years, we have developed different catalytic transformations in water including the hydration of nitriles to the corresponding amides catalyzed by $[Rh(COD)Cl]_2$–$P(m\text{-}C_6H_4SO_3Na)_3$ (TPPTS) (10), organic solvent-free oxidation of alcohols with *tert*-butyl hydroperoxide catalyzed by water-soluble copper complexes (11), and transfer hydrogenation of aldehydes and ketones with isopropanol catalyzed by water-soluble rhodium complexes (12). In the present work, we describe the results for the hydrogen transfer oxidation (Oppenauer-type oxidation) of secondary alcohols with acetone, as the oxidant, catalyzed

by water-soluble iridium and rhodium complexes containing 2,2′-biquinoline-4,4′-dicarboxylic acid dipotassium salt (BQC) (eq. [1]). Some preliminary results have been published in a communication where we have reported the first example of a water-soluble transition-metal catalyst for Oppenauer-type oxidation of secondary alcohols with acetone (13).

[1]

Results and discussion

A number of catalytic systems based on different catalyst precursors and the water-soluble ligand P(*m*-$C_6H_4SO_3Na)_3$ (TPPTS) or BQC were tested for the oxidation of 1-phenylethanol, which was chosen as the model substrate. The first experiments showed that the presence of the catalyst precursor, together with acetone and sodium carbonate is required to achieve oxidation of 1-phenylethanol. While $RuCl_3 \cdot xH_2O$ and $PdCl_2(PhCN)_2$ exhibited no catalytic activity, $[Rh(COD)Cl]_2$ and $[Ir(COD)Cl]_2$ gave rise to active water-soluble systems (Table 1). The results in Table 1 indicate that the least active catalytic systems were provided by TPPTS (Table 1, entries 1 and 4). Nevertheless, we recently reported that $[Rh(COD)Cl]_2$–TPPTS was found to be quite an effective catalyst for transfer hydrogenation of aldehydes and ketones with isopropanol, under basic conditions (12). Treatment of 1-phenylethanol (2.5 mmol) in the presence of Na_2CO_3 (2.5 mmol), with catalytic amounts of $[Rh(COD)Cl]_2$ (0.01 mmol) and BQC (0.15 mmol) in a deoxygenated mixture of water (10 mL) and acetone (5 mL) at 90 °C afforded, selectively, acetophenone in 15% yield after 2 h (Table 1, entry 2). Increasing the reaction time to 17 h lead to a 57% yield (Table 1, entry 3). Remarkably, when $[Rh(COD)Cl]_2$ was substituted for its iridium analog much more active catalyst was generated. Indeed, acetophenone was obtained in 82% and 98% yields, respectively, after 2 and 4 h (Table 1, entries 5 and 6). This catalytic system has been shown to be much less active than $[Rh(COD)Cl]_2$–TPPTS for transfer hydrogenation of carbonyl groups with *i*-PrOH (12). In aqueous-phase catalysis, the most important aspects are product separation as well as catalyst recovery and recycling in further experiments. The durability of the $[Ir(COD)Cl]_2$–BQC system was tested by carrying out three consecutive cycles with the same catalyst aqueous solution, carefully separated from the organic phase under a nitrogen atmosphere at the end of each run (Table 1, entries 6–8). Only a slight decrease in catalytic activity was observed among each of the three recycling experiments demonstrating the continuing viability of the catalyst. It is relevant to point out that no metallic iridium formation was observed after the reactions and the aqueous phases remained as clear-brown solutions, indicating that there was no decomposition of the catalyst. Analysis of the organic phases, which remained clear, by atomic absorption indicated that acetophenone was extracted without leaching of the catalyst. When the oxidation was performed with $[Ir(COD)Cl]_2$ alone or in combination with 2,2′-biquinoline (BQ) in acetone containing only 0.5% water very low yields were obtained (Table 1, entries 9 and 10). Addition of water (10 mL) increased the rate of oxidation and acetophenone was isolated in 39% yield (Table 1, entry 11). An analogous positive effect of water on the rate of this homogeneous Oppenauer-type oxidation has already been observed for $RuCl_2(PPh_3)_3$ (9*a*). These results, which demonstrate the superiority of aqueous-phase catalysis over the homogeneous one in this Oppenauer-type oxidation, are even more interesting since BQC is cheaper than BQ.[3]

[g]The reaction conditions are the same as in entry 9 except that BQ (0.15 mmol) was added to the mixture.
[h]The reaction conditions are the same as in entry 10 except that water (10 mL) was added to the mixture.

To demonstrate the synthetic utility and to explore the scope and limitations of the $[Ir(COD)Cl]_2$–BQC system, a range of different alcohols were subjected to oxidation by acetone in a series of batch autoclave experiments. A variety of benzylic secondary alcohols were smoothly and selectively oxidized in very high yields, with full conversions in some cases within 4 h (Table 2, entries 1–7). Under the same reaction conditions, 1-indanol led to 1-indanone with only a 53% yield. A better result was obtained by increasing the reaction time to 17 h (Table 2, entry 8). With a sterically encumbered alcohol, namely 2-methyl-1-phenyl-1-propanol, a 58% yield was achieved, while the substrate was sluggishly oxidized after 4 h (Table 2, entry 9). A special situation was observed in the case of 4-chromanol, which underwent, in addition to an oxidation of the benzylic alcohol, a hydrogenolysis of the ArO—CH_2 (Ar is the aromatic ring) bond

[3]BQC and BQ cost $4166.70 and $5854.12CAN per mol, respectively, from the Aldrich Chemical Co.

leading to *ortho*-hydroxypropiophenone as the sole product (Table 2, entry 10). When the reaction was performed in the absence of acetone the same product was obtained and no 4-chromanone was detected. These results indicate that the production of *ortho*-hydroxypropiophenone from 4-chromanol is, probably due to an intramolecular transfer hydrogenolysis. The catalytic process is envisioned as a reaction between 4-chromanol and the water-soluble iridium system resulting in an iridium alkoxide complex, which, in turn, undergoes β-hydride elimination to produce a η^2-ketone hydride species, where the 4-chromanone is still coordinated to the iridium. The transfer of iridium hydride to the methylene group of $ArO–CH_2$ of the coordinated 4-chromanone (intramolecular 1,3-hydride shift) leads to an iridium *ortho*-propionylphenoxide complex. Protonation with another 4-chromanol molecule liberates *ortho*-hydroxypropiophenone and regenerates the iridium alkoxide species. The transfer of hydride to $ArO–CH_3$ did not occur in the case of 1-(4-methoxyphenyl)ethanol (Table 2, entry 3) since the methoxy group is located far from the metal hydride core.

To explore substrate scope further, we tested the efficiency of the $[Ir(COD)Cl]_2$–BQC system to oxidize secondary 1-heteroaryl alcohols (Table 3). Good to excellent yields were obtained in all cases, although the reaction time was extended to 17 h for the oxidation of 1-(2-furyl)-2-methyl-1-propanol and the thienyl analog, which gave, respectively, 74% and 65% yields (Table 3, entries 3 and 4). The sluggishness in these two cases is attributed to steric hindrance from the isopropyl group.

The reaction was, also, extended to a variety of secondary

aliphatic alcohols (Table 4). However, these inactivated alcohols proved to be sluggish substrates under our standard conditions, and only poor yields were obtained. Fortunately, a higher catalyst:substrate ratio (2.5 mol%) and longer reaction times greatly improve the yields (Table 4, entries 3, 6, 8, and 9). Remarkably, cyclooctanol showed a higher reactivity than cyclohexanol and the former was oxidized in 76% yield with only 0.4 mol% of $[Ir(COD)Cl]_2$ after 4 h (Table 4, entry 1).

To investigate the extent of $[Ir(COD)Cl]_2$–BQC oxidation, different allylic alcohols have been studied (Table 5). The oxidation of 1-octen-3-ol afforded 3-octanone as the sole product after only 1 h of reaction time (Table 5, entry 1). The reaction performed in the absence of acetone led to the same result after 4 h. However, this reaction was not optimized. The isomerization of allylic alcohols to saturated carbonyl compounds is an important reaction in organic chemistry that still suffers from several drawbacks (14). Surprisingly, the water-soluble catalytic systems reported for the isomerization of allylic alcohols are rare, despite their synthetic utility (15). Thus, other water-soluble catalysts were tested for the oxidation of 1-octen-3-ol (Table 5, entries 2–5). Excellent to full conversions to the isomerization product were obtained except in the case of $RuCl_3$–BQC, which is inactive. Although these reactions were not optimized, the result obtained with $[Ir(COD)Cl]_2$–BQC is promising since its catalytic frequency for the isomerization of 1-octen-3-ol (125 h^{-1} at 90 °C) is slightly better than the reported activities for other water-soluble catalysts based on $[RuCl_2(\eta^6\text{-arene})\{P(CH_2OH)_3\}]$ (4–67 h^{-1} at 75 °C) (15*a*), $Rh_2(SO_4)_3$ (30 h^{-1} at 80 °C) (15*b*), $RhCl_3$ (60 h^{-1} at 70 °C) (15*b*), and $(COD)RhCl(PAr_3)$ (15–48 h^{-1} at 104 °C) (15*c*). We are currently continuing to investigate the isomerization of allylic alcohols in the aqueous phase. The oxidation of 1-

Scheme 1. Proposed mechanism for the Oppenauer-type oxidation and isomerization of allylic alcohols.

phenyl-2-propen-1-ol, under the same conditions, also gave propiophenone as the isomerization product, with full conversion (Table 5, entry 6), whereas cyclic allylic alcohols are, surprisingly, oxidized to their corresponding unsaturated ketones albeit in low yields (Table 5, entries 7 and 9). Fortunately, under the conditions used for the oxidation of aliphatic alcohols (Table 4, entry 3), isophorol and 3-methyl-2-cyclohexenol were fully converted to their corresponding unsaturated ketones (Table 5, entries 8 and 10). Bäckvall and co-workers (9*a*) have also reported that 1-octen-3-ol was isomerized under their reaction conditions to 3-octanone using ruthenium complexes, while 2-cyclohexenol was converted to an unsaturated ketone.

Although the structure of the water-soluble active complex is not identified, a rational mechanism for this Oppenauer-type oxidation, including the isomerization process, is presented in Scheme 1.

Since no iridium mirror (black metallic iridium) was observed after the reactions and the aqueous phases remained as clear-brown solutions, we carried out mercury poisoning experiments (see the Experimental section) to rule out the possibility of catalysis by colloidal metal. Mercury poisoning is a well-known and widely used test to distinguish between heterogeneous and homogeneous processes (16). The addition of a large excess of mercury(0) (Hg:Ir molar ratio of 872) with vigorous stirring did not suppress the catalysis.

[b]Yields were estimated by ^1H NMR.

These results suggest that nanoparticles are not the key species in the present system and that the process is likely homogeneous.

The first step of the proposed mechanism would involve the formation of iridium alkoxide **II** (9*a*, 17). Stoichiometric amounts of Na_2CO_3 were used in our experiments. However, oxidation of 1-phenylethanol with smaller amounts of Na_2CO_3 also gave excellent results (Table 6). When the reaction was performed in the absence of base, its remarkable effect was particularly noticeable because no reaction occurred (Table 6, entry 1). This effect of base in Oppenauer-type oxidations has been observed in previous reports (9*a*, 9*b*). Consequently, the primary role of the base is to facilitate formation of iridium alkoxide complex **II**. This latter species can undergo β-hydride elimination of the coordinated alkoxide to produce the desired ketone and iridium hydride species **IV**, via complex **III** where the ketone is still coordinated to the metal (η^2-ketone ligand). β-hydride elimination from metal alkoxides has been observed (17, 18) and proposed for hydrogen transfer reactions (9*a*, 19). In our case, the production of *ortho*-hydroxypropiophenone from 4-chromanol is in agreement with the formation of complex **III**. Comparison of the oxidation rates for $PhCH(OH)CH_3$ and $PhCD(OH)CH_3$, under the same conditions (Fig. 1), indicates that the rate-limiting step does not involve β-hydride elimination from **II** since the isotope effect is low (k_H/k_D = 1.2). The reaction of acetone with **IV** would produce complex **V**, which leads to iridium isopropoxide **VI** by insertion of acetone into the Ir—H bond. An exchange of alkoxy moiety would regenerate species **II** and liberate isopropanol. In the case of allylic alcohols, an additional pathway for the isomerization process is proposed. Three mechanisms have been proposed for transition metal catalyzed isomerization of allylic alcohols. The first one involves a π-allyl metal hydride complex (20), while a second one is based on metal hydride addition–elimination (21). A third mechanism, suggested by Trost and Kulawiec (22), involves the coordination of allylic alcohol as a bidentate ligand and the formation of metal alkoxide species. Our results from oxidation with $[Ir(COD)Cl]_2$–BQC (Table 5) are consistent with the alkoxide mechanism. Thus, in the case of allylic alcohols, **II** is reorganised as $\mathbf{II_{isom.}}$ to allow the coordination of Ir with R_2 (R_2 is an olefinic moiety). $\mathbf{II_{isom.}}$ undergoes β-hydride elimination to produce the enone hydride species $\mathbf{III_{isom.}}$. This latter is expected to evolve in two different ways depending on the steric requirements of the enone. In the case of bulky substrates such as isophorol, $\mathbf{III_{isom.}}$ releases the enone through path **A** and follows the catalytic cycle for the Oppenauer-type oxidation. This is in agreement with previous reports regarding the isomerization of allylic alcohols catalyzed by ruthenium complexes (21, 22). The steric unhindered enones, on the other hand, are not released and allow $\mathbf{III_{isom.}}$ to rearrange to π-oxallyl species $\mathbf{IV_{isom.}}$ through path **B**. Protonation with another allylic alcohol molecule liberates the saturated ketone and regenerates the initial species $\mathbf{II_{isom.}}$.

Fig. 1. Oxidation profiles of $PhCH(OH)CH_3$ (+) and $PhCD(OH)CH_3$ (o). Substrate (2.5 mmol), $[Ir(COD)Cl]_2$ (0.01 mmol), BQC (0.15 mmol), Na_2CO_3 (2.5 mmol), water (10 mL), acetone (5 mL), 90 °C, N_2.

Summary

In conclusion, the system composed of $[Ir(COD)Cl]_2$ and the cheap water-soluble ligand BQC is a new and highly efficient catalyst for Oppenauer-type oxidation of benzylic, 1-heteroaromatic, aliphatic, and allylic secondary alcohols. The system showed much better activity than the water-insoluble analogs. The catalytic process is likely homogeneous and the mechanism proposed for this Oppenauer-type oxidation including the isomerization process is based on iridium-alkoxide species.

Experimental

Materials and instruments

All the substrates, BQ, and BQC were purchased from Aldrich Chemical Co. and used without further purification. $[Rh(COD)Cl]_2$, $RuCl_3{\cdot}xH_2O$, $PdCl_2(PhCN)_2$, and $[Ir(COD)Cl]_2$ were acquired from Strem Chemical Co.

TPPTS was prepared according to the literature method (23) and $PhCD(OH)CH_3$ was prepared using $LiAlD_4$ (24).

Routine NMR measurements were performed on a Bruker AC-200 spectrometer at 200 MHz and 50 MHz, respectively, for ^1H and ^{13}C, using tetramethylsilane (TMS) as an internal standard and $CDCl_3$ as the solvent.

Typical procedure for this Oppenauer type oxidation with acetone

In the glass liner of a 45 mL autoclave, under an atmosphere of nitrogen, $[Ir(COD)Cl]_2$ (0.01 mmol), BQC (0.15 mmol), and Na_2CO_3 (2.5 mmol) were dissolved in degassed water (10 mL) at room temperature. Next a solution of the substrate (2.5 mmol) in degassed acetone (5 mL) was introduced. The autoclave, was then flushed several times with 80 psi (1 psi = 6.894 757 kPa) of N_2 and then placed in an oil bath at 90 °C for the required reaction time. The autoclave was cooled to room temperature and the mixture was extracted three times with degassed diethyl ether (20 mL). The combined organic layers were dried ($MgSO_4$), evaporated to dryness, and then analyzed by TLC and ^1H and ^{13}C NMR. Literature data and (or) authentic samples were used for comparison. The ^1H NMR spectra for all samples showed the presence of remaining substrate (where the conversions were not complete), the product, and small amounts of 4-hydroxy-4-methyl-2-pentanone formed by aldol condensation of acetone. In the case of isolated yields, the ketones were purified using column chromatography with ethyl acetate – petroleum ether (5:95) as the eluent.

The recycled aqueous phase obtained, after removal of solvents under a nitrogen atmosphere, was reused with only a fresh charge of solution consisting of the alcohol (2.5 mmol) in degassed acetone (5 mL).

Mercury poisoning experiments

Three experiments were performed to determine the effect of mercury (0) on the reaction.

A solution of $[Ir(COD)Cl]_2$ (13.4 mg, 0.02 mmol) and BQC (0.3 mmol, 142 mg) in water (20 mL) was stirred in the presence of excess mercury (7 g, 34.9 mmol, ca. 872 equiv.) for 24 h. The solution was decanted from the mercury and divided into two equal parts, which were used for the Oppenauer-type oxidation of 1-phenylethanol for 4 h. After 1 h of reaction time, one autoclave was cooled to room temperature, vented, and opened under a nitrogen atmosphere. Next 3.5 g of Hg(0) was added to the clear-brown catalytically active solution and the autoclave was then purged with nitrogen, resealed, and stirred for 30 min. The mixture was then heated at 90 °C for the remaining reaction time. The two experiments showed the same excellent catalytic activity.

A third experiment was done just to confirm the previous ones. In this experiment, the oxidation was initiated in the presence of excess Hg(0) (872 equiv.). The result was identical to the previous ones.

These experiments indicate that Hg(0) does not react with the precatalyst $[Ir(COD)Cl]_2$ and that the process is likely homogeneous.

Synthesis of acetylenic ketones by a Pd-catalyzed carbonylative three-component coupling reaction in [bmim]PF_6[1]

Takahide Fukuyama, Ryo Yamaura, and Ilhyong Ryu

Abstract: A carbonylative three-component coupling reaction of aryl iodides with terminal alkynes catalyzed by $PdCl_2(PPh_3)_2$ was carried out using an ionic liquid, [bmim]PF_6, as the reaction medium, which resulted in good yields of α,β-acetylenic ketones. The low-viscosity ionic liquid, [bmim]NTf_2, was not suitable for this reaction, since the background Sonogashira coupling reaction, a competing reaction, also proceeded.

Key words: carbonylation, palladium, three-component coupling, ionic liquid, α,β-acetylenic ketones.

Résumé : Nous avons procédé à la préparation, avec de bons rendements, de cétones α,β-acétyléniques. Pour cela, nous avons réalisé une réaction de couplage à trois composants, catalysée par le $PdCl_2(PPh_3)_2$ et réalisée dans un milieu liquide ionique formé de [bmim]PF_6, conduisant à la carbonylation des iodures d'aryles. La faible viscosité du liquide ionique [bmim]NTf_2 n'est pas appropriée pour cette réaction puisque la réaction de couplage de Sonogashira qui est en compétition avec se produit.

Mots clés : carbonylation, palladium, couplage à trois composants, liquide ionique, cétone α,β-acétylénique.

[Traduit par la Rédaction]

Introduction

α,β-Acetylenic ketones are useful intermediates for the synthesis of a variety of important heterocyclic and biologically active compounds (1). While traditional approaches to the synthesis of acetylenic ketones relied on the coupling of a carboxylic acid chloride with a metal acetylide, recent methods have employed Pd- and (or) Cu-catalyzed coupling reactions of acid halides and terminal alkynes (eq. [1]) (2). The carbonylative three-component coupling reaction of aryl halides with terminal alkynes has also been reported (eq. [2]) (3). Kobayashi and Tanaka (3*a*) reported that a three-component coupling reaction of aryl halides with terminal alkynes and CO can be achieved when $PdCl_2$(dppf) is used as a catalyst and Et_3N as a solvent. Alper and coworkers (3*b*) reported that the dimeric palladium hydroxide $[(Ph_3P)Pd(Ph)(\mu\text{-}OH)]_2$ functions as an efficient catalyst for a similar three-component coupling reaction. Mohamed Ahmed and Mori (3*c*) recently reported on a three-component coupling using $PdCl_2(PPh_3)_2$ as the catalyst and aqueous NH_3 (2 equiv.) as a base with THF as the solvent.

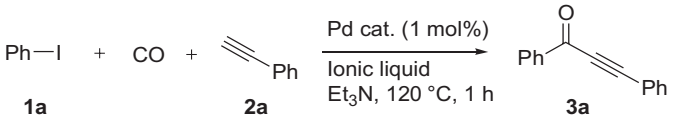
Two component method

[1] 

Three component method

[2] 



In recent years, ionic liquids have attracted broad attention in organic synthesis as alternatives to volatile organic solvents (4), and we previously reported that the Pd-catalyzed coupling reaction of aryl iodides with terminal alkynes — the Sonogashira coupling reaction — proceeds effectively in an ionic liquid, 1-butyl-3-methylimidazolium hexafluorophosphate ([bmim]PF_6), without the need for a copper co-catalyst (5). We also reported that a low-viscosity ionic liquid, [bmim]NTf_2, is an excellent reaction medium for Pd-catalyzed Mizoroki–Heck, Suzuki–Miyaura, and Stille coupling reactions (6). Herein we report on the carbonylative three-component coupling reaction of an aryl iodide with terminal alkynes, which proceeds smoothly when [bmim]PF_6 is used as the reaction medium (7).

Results and discussion

When iodobenzene (**1a**) was treated with phenylacetylene (**2a**, 1.2 equiv.) and pressurized CO (20 atm (1 atm = 101.325 kPa)) in the presence of 1 mol% $PdCl_2(PPh_3)_2$ and Et_3N (3.6 equiv.) in [bmim]PF_6 at 120 °C for 1 h, the reac-

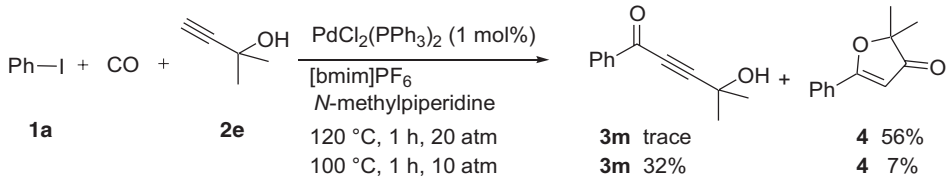
[b]Yield of diphenylacetylene is shown in parentheses.
[c]Reaction was carried out for 2 h.



tion proceeded smoothly to give the acetylenic ketone **3a** in 82% yield (Table 1, entry 1). The reaction was clean, and diphenylacetylene, the noncarbonylated product of the Sonogashira coupling reaction, was not observed. Mohamed Ahmed and Mori (3*c*) previously reported that the reaction proceeded smoothly with aqueous NH_3 as a base. However, when aqueous NH_3 was used as a base in the present system, Michael addition of NH_3 to **3a** became a major reaction course. We also examined a low-viscosity ionic liquid, [bmim]NTf_2 (6); however, in this case, the background Sonogashira coupling reaction competed under the conditions employed (entry 2). Reactions using other Pd(II) complexes such as $PdCl_2$, $PdCl_2(CH_3CN)_2$, and $Pd(OAc)_2$ were sluggish, and significant amounts of unreacted **1a** were recovered (entries 3–5). When $Pd(PPh_3)_4$ was used as the catalyst, the Sonogashira coupling reaction competed, giving diphenylacetylene (entry 6). Reducing the amount of amine from 3.6 equiv. to 2 equiv. resulted in lower conversions even when the reaction time was prolonged (2 h) (entry 7). When the reaction was carried out at reduced CO pressure (10 atm), the Sonogashira coupling reaction competed again (entry 8).

Some results for reactions in which various aryl iodides and terminal alkynes were used are shown in Table 2. The reaction of substituted aryl iodides gave the corresponding acetylenic ketones in good yields (entries 1–6). Iodobenzenes containing a halogen atom (Br, Cl, or F) at the 4-position gave the coupling products, with the halogen atoms intact (entries 4–6). The reaction of 1-iodonaphthalene (**1h**) and 2-iodothiophene (**1i**) with **2a** also gave carbonylated products **3h** and **3i**, respectively (entries 7 and 8). Both *p*-acetylphenylacetylene and *p*-methoxyphenylacetylene could be used in this reaction (entries 9 and 10). The reaction of *tert*-butylacetylene (**2d**) gave the coupling product **3l** in relatively low yield, but when *N*-methylpiperidine was employed as a base, the yield was increased to 76% (entry 11).

When the reaction of **1a** with 2-methyl-3-butyne-2-ol (**2e**) was carried out using *N*-methylpiperidine as the base, 3-furanone **4** was obtained as the major product (eq. [3]) (8). An experiment using milder reaction conditions (100 °C, 10 atm) gave a mixture of acetylenic ketone **3m** and **4**. When the isolated **3m** was exposed to the same reaction system, furanone **4** was formed, suggesting that the initially formed **3m** served as the precursor for **4** (9).

It is well known that imidazolium-based ionic liquids react with Pd complexes to give Pd *N*-heterocyclic carbene complexes, which are thought to be the key catalyst species in many reactions in which a Pd–ionic liquid system is used (10). This may also be true for the present system, since the Pd carbene complex (which contains one imidazolylidene, one triphenylphosphine, and two chlorine ligands (6)) readily catalyzed the reaction of **1a** with **2a** to give **3a** in 73% yield (eq. [4]). We also investigated the reusability of the catalyst and the reaction medium for this reaction system. Both the catalyst and the reaction medium can be reused but with a slight decrease in efficiency (Scheme 1).

[4]

Conclusions

The findings herein show that when using $[bmim]PF_6$ as a reaction medium, the Pd-catalyzed carbonylative three-component coupling reaction of aryl iodides with terminal alkynes proceeds efficiently to give α,β-acetylenic ketones in good yields. The low-viscosity ionic liquid, $[bmim]NTf_2$, which is an excellent reaction medium for typical Pd-catalyzed coupling reactions, is not suitable for the present reaction because of the competing Sonogashira coupling reaction.

Experimental section

General information

^1H NMR spectra were recorded on a JEOL JMN-AL400 (400 MHz) spectrometer in $CDCl_3$. Chemical shifts are reported in parts per million (δ) downfield from internal tetramethylsilane. ^{13}C NMR spectra were recorded with a JEOL JMN-AL400 (100 MHz). Infrared spectra were obtained on a JASCO FT/IR-4100 spectrometer; absorptions are reported in reciprocal centimeters. Mass spectra were obtained on a Shimadzu GCMS-QP 5050A instrument. High resolution mass spectra were recorded with a JEOL MS700 spectrometer. Coupling products were purified by flash chromatography on silica gel (nacalai tesque, Silica Gel 60, 230–400 mesh) and, if necessary, were further purified by recycling preparative HPLC (JAI LC-908) equipped with a GPC column and using $CHCl_3$ as eluant. All products, except for **3j**, were known compounds and were identified by comparison with literature data.

Typical procedure for the $PdCl_2(PPh_3)_2$-catalyzed three-component coupling reaction

A magnetic stirring bar, [bmim]PF_6 (3 mL), $PdCl_2(PPh_3)_2$ (0.01 mmol, 7 mg), iodobenzene (**1a**) (1 mmol, 204 mg), Et_3N (3.6 mmol, 0.5 mL), and phenylacetylene **2a** (1.2 mmol, 122 g) were placed in a 50 mL stainless autoclave lined with a glass liner. The autoclave was closed, purged three times with 10 atm of carbon monoxide, pressurized to 20 atm with CO, and then heated at 120 °C for 1 h. Excess CO was discharged at room temperature. The product was extracted from the reaction mixture by the addition of Et_2O (5 mL), followed by decantation of the ether solution of the product. This was repeated an additional four times. The residue was purified by flash chromatography on silica gel (eluant hexane : EtOAc = 10:1) to give 166 mg (82%) of **3a**.

Recycling of Pd catalyst and [bmim]PF_6

After the reaction, the product was extracted from the reaction mixture with Et_2O (5 × 5 mL), and ammonium salts were removed by extraction with water (5 × 5 mL). Both the Et_2O and water were degassed by N_2 bubbling prior to use. Excess Et_2O and water were removed under reduced pressure, and the remaining ionic liquid layer, containing the Pd catalyst, was used in the next run.

Double elimination protocol for the synthesis of arylene ethynylenes containing heteroaromatic rings[1]

Akihiro Orita, Fangguo Ye, Govindarajulu Babu, Tomohiro Ikemoto, and Junzo Otera

Abstract: The double elimination reaction of β-substituted sulfones offers a versatile strategy for synthesis of arylene ethynylene kits containing heteroaromatic rings. A sequence of aldol reaction between α-sulfonyl carbanion and aldehyde, trapping the resulting aldolate to give β-substituted sulfone, and double elimination of this intermediate can be integrated in one pot. This protocol allows thiophene, pyridine, and ferrocene units to be accommodated in phenylene ethynylene arrays.

Key words: arylene–ethynylenes, heteroaromatic rings, ferrocene, double elimination, sulfones.

Résumé : La réaction de double élimination des sulfones β-substituées offre une possibilité de stratégie versatile pour la synthèse de trousses d'arylène éthynylène contenant des noyaux hétéroatomiques. Une séquence de réaction impliquant une réaction aldolique entre un carbanion α-sulfonyle et un aldéhyde, le piégeage de l'aldolate qui en résulte qui conduit à une sulfone β-substituée et la double élimination de cet intermédiaire peut être intégrée dans un système monotopique. Ce protocole permet d'accommoder des unités thiophène, pyridine et ferrocène dans des arrangements phénylène éthynylène.

Mots clés : arylène–éthynylènes, noyaux hétéroatomiques, ferrocène, double élimination, sulfones.

[Traduit par la Rédaction]

Introduction

The synthesis of arylene ethynylene molecular wires is the focus of current extensive research in view of developing new materials for molecular electronic devices (1). In addition to simple arylene ethynylenes that are only composed of hydrocarbon aromatics, incorporation of heteroaromatic rings into these arrays is of great promise for imparting novel functions. For example, attachment of thiophene will induce alterations of electronic and optical properties by purturbing π-electron delocalization in arylene ethynylene conjugated systems. In fact, a considerable number of oligomers or polymers are known in which thiophene and acetylene units are directly assembled (2), yet some examples are known for the integration of phenylene ethynylene and thiophene pieces (3). Pyridine derivatives are another class of blocks to be built in. Besides changing electronic properties, pyridine can serve as a ligand for metal complexes, giving rise to unique structures that are otherwise difficult to attain (4). Utilization of ferrocene is also intriguing from the electrochemical point of view, and redox profiles of some ferrocene-containing arylene ethynylenes were reported (5).

Notably, almost all of the above compounds were framed with recourse to iterative Sonogashira couplings (6). This method, though being highly versatile, suffers from some drawbacks: products are colored and occasionally contaminated by Pd or Cu catalysts residues. In this context, we advanced a double elimination protocol of β-substituted sulfones as the alternative, which is essentially free from these drawbacks, to allow us to synthesize a variety of phenylene ethynylenes (7). Herein, we report that the double elimination reaction works nicely with heteroaromatic substrates as well as resulting in the convenient synthesis of arylene ethynylenes containing such heteroaromatic rings as described previously.

Results and discussion

Thiophene-containing arylene ethynylenes

2,5-Bis(arylethynyl)thiophenes (**1**) were readily obtained by the double elimination method using benzyl sulfone derivatives **2** and 2-formyl-5-phenylethynylthiophene (**3**) (Scheme 1). In this procedure, the following operations were sequentially conducted in one pot without the isolation of any intermediates: (1) lithiation of **2** with BuLi; (2) silylation of the resulting anion with TMSCl; (3) lithiation of the silylated sulfone with BuLi; (4) aldol-type addition of the resulting anion to **3** followed by Peterson-type elimination;

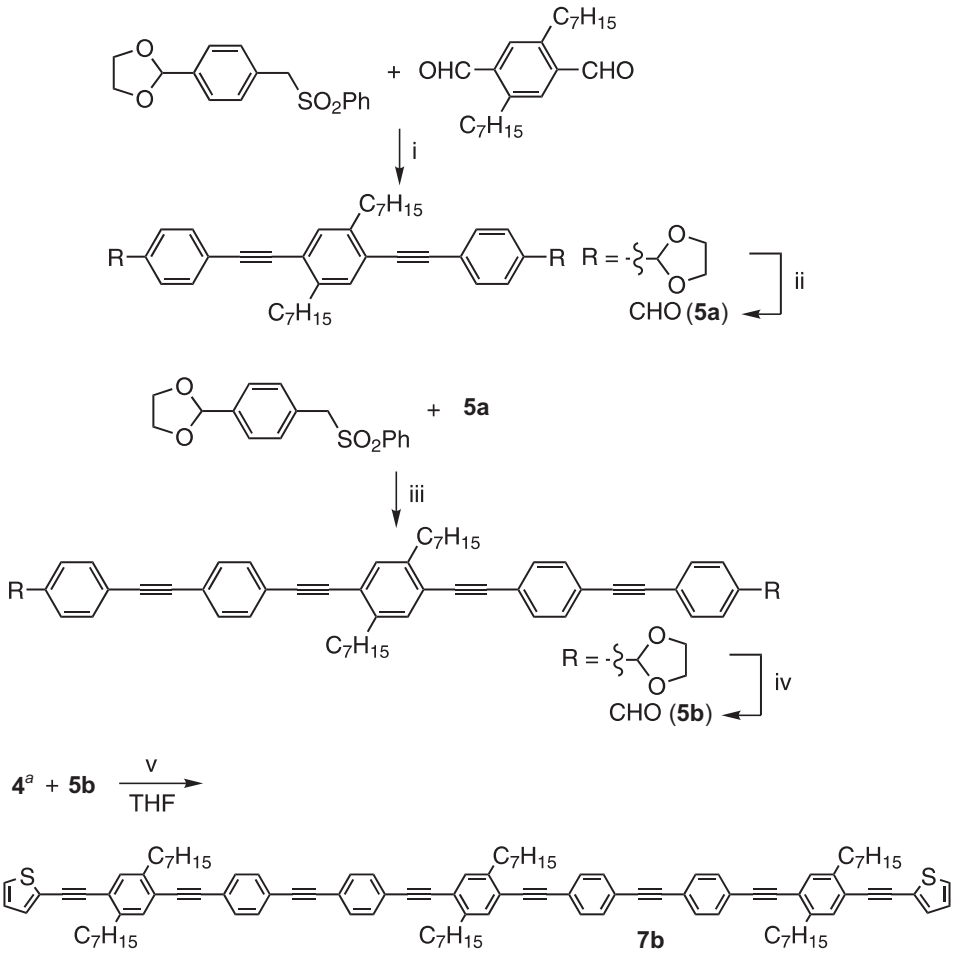
and (5) conversion of the resulting vinyl sulfone to **1**. No serious problems were encountered by the use of the thienyl aldehyde in place of simple aromatic aldehydes and a variety of thiophene derivatives substituted unsymmetrically at the 2,5-positions were accessible. The overall yields through the four consecutive reactions (silylation, aldol, Peterson and final elimination reactions) were excellent (64%–77%) indicating that each reaction proceeded in more than 90% yield on average.

As shown in Schemes 2 and 3, the thiophene stoppers were installed. Reaction of thiophene-terminated building block **4** with terephthalaldehyde (**6a**) or a longer dialdehyde (**5b**) furnished **7a** and **7b** in satisfactory yields.



Pyridine-containing arylene ethynylenes (8)

The synthesis of some simple pyridine-containing arylene ethynylenes is illustrated in Scheme 4. First, 2-pyridylmethyl sulfone (**8**) was coupled with benzaldehyde (**9**) to give the desired product **10** in 84% yield. An alternative combination of benzyl sulfone (**2a**) and 2-pyridylcarboxaldehyde (**11**) also produced **10** in 76% yield. Dialdehydes were employable as well. Treatment of **2a** with 2,6-pyridinedicarboxaldehyde (**12**) afforded the desired diyne **13**, and enantiopure dialdehyde **14** reacted with **8** to provide tetrayne **15**.

This technology was applied to synthesize chiral arylene ethynylene (**16**), which had been found to form a unique double helicate **A** upon complexation with copper(I) and silver(I) salts (Fig. 1) (9). Previously, this compound was synthesized by Sonogashira coupling, yet iteration of Sonogashira coupling resulted in coloration of the product and required repeated operations of column chromatography for purification. Two alternative routes are possible for construction of **16** as shown in Fig. 1: connection between two pyridine rings (route A) or between the phenyl and pyridine rings (route B). However, it soon turned out that route A was not feasible because a model reaction between **8** and **11** did

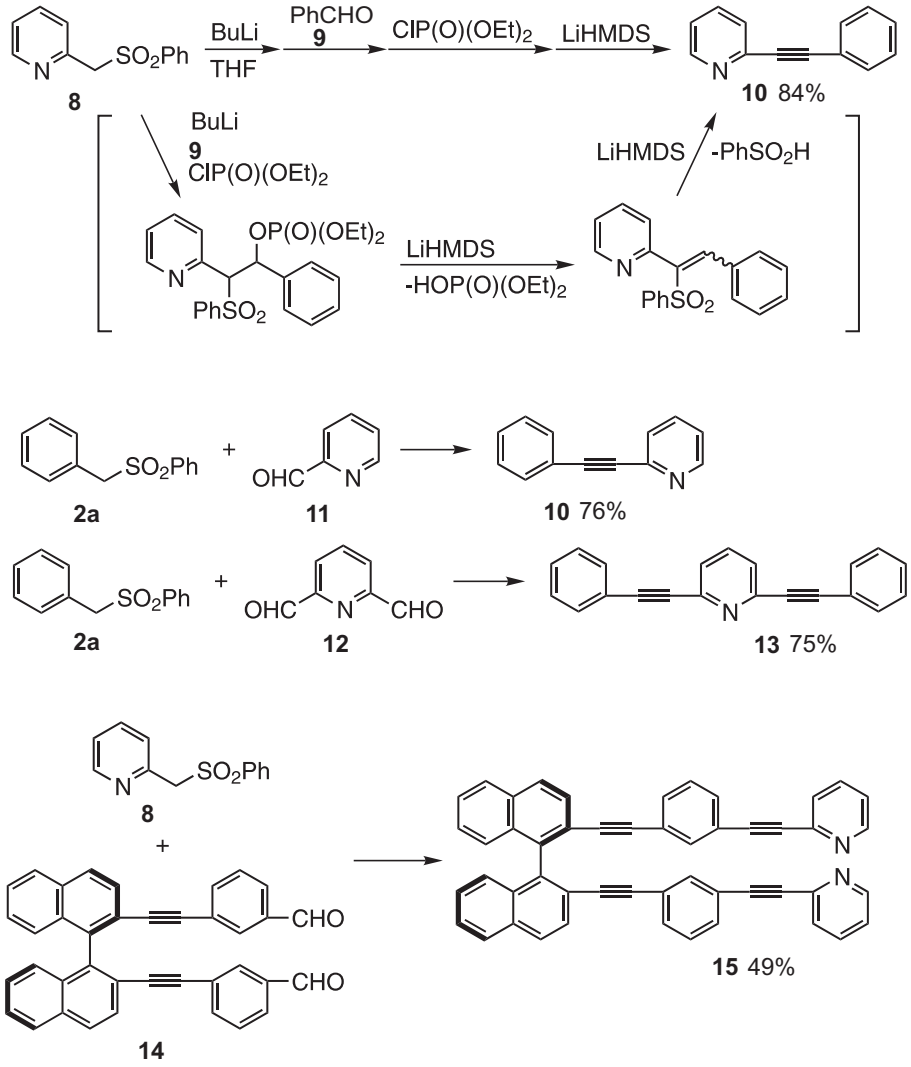
Scheme 3. Reagents: (*i*) BuLi–aldehyde–ClP(O)(OEt)$_2$–*t*-BuOK (80%); (*ii*) *p*-TSA, THF, water (quant.); (*iii*) BuLi–**5a**–ClP(O)(OEt)$_2$–*t*-BuOK (81%); (*iv*) *p*-TSA, THF, water (quant.); (*v*) BuLi–**5b**–ClP(O)(OEt)$_2$–*t*-BuOK (65%). [a]See Scheme 2.

not proceed smoothly to afford only a trace amount of the desired dipyridylacetylene.[3] In sharp contrast to this disappointing result, acetylene formation was effected by use of sulfone **17** and benzaldehyde (**9**), though in a modest yield (Scheme 5). However, use of sulfoximine in place of the sulfone improved the yield: reaction between sulfoximine **19** and aldehyde **20** proceeded smoothly to give **18** in 83% yield. These results prompted us to employ route B (Scheme 6). The procedure for requisite disulfoximine **21** was already reported (7*c*), and pyridylcarboxaldehyde **22** was obtained according to the procedure shown in Scheme 7. The aldol-type coupling between **21** and **22** followed by double elimination furnished **16** in 53% yield. Notably, the product thus obtained suffered no coloration to enable facile purification by column chromatography. When the corresponding disulfone was employed instead of **21**, the desired product **16** was only obtained in 30% yield.

Ferrocene-containing arylene ethynylenes



The double elimination method also led us to join phenylene ethynylene backbones to ferrocene termini. Those having symmetrical structures (**23** and **24**) are illustrated in Fig. 2. The synthetic strategy for these compounds are based on the use of ferrocene-containing benzyl sulfone (**25**), which was prepared as shown in Scheme 8. Coupling of **25a** and **25b** with **6a** afforded **23a** and **23b** in excellent yields (90% and 81%, respectively) (Table 1, entries 1 and 2). Use of **26** as a dialdehyde component led to **23c** (Table 1, entry 3). Combination of **25b** with **5a** and **5b** furnished longer molecular wires (**24a** and **24b**) in satisfactory yields (Table 1, entries 4 and 5). Quite naturally, exposure of *meta*- and *ortho*-phthalaldehydes (**6b** and **6c**) to **25a** provided the corresponding bent molecules, **27** and **28** (Table 1, entries 6 and 7).

Compounds with unsymmetrical structures were also accessible (Scheme 9). Coupling of **25a** with aldehyde **29** furnished **30** in 91% yield. Finally, an arylene ethynylene motif end-capped with both ferrocene and thiophene **31** was constructed (10). Thiophene-containing benzyl sulfone **4** was treated with 1.1 equiv. of BuLi and the resulting anion was exposed to 1.5 equiv. of **6a**. The monoaldol product was trapped with benzoyl chloride to give benzoate **32**. It is crucial to stop the reaction at this stage although the yield is not satisfactory. If more base was used to obtain the monovinyl sulfone or monoacetylene derivative directly, the remaining aldehyde was attacked and the reaction mixture became messy. Then, coupling of **32** with **25b** successfully provided **31** in 75% yield.

[3] It is not clear at present why the reaction between pyridylmethyl sulfone and formylpyridine was unsuccessful.

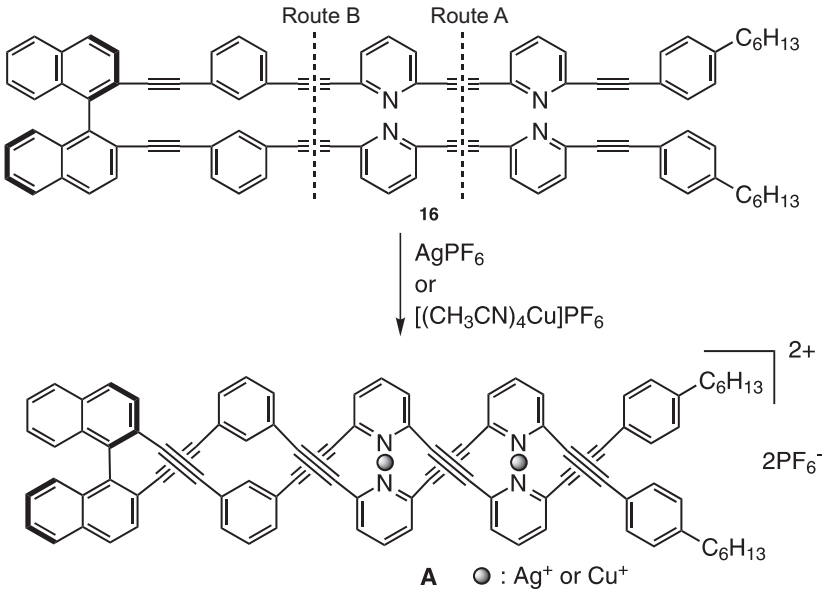
Scheme 4.

Conclusion

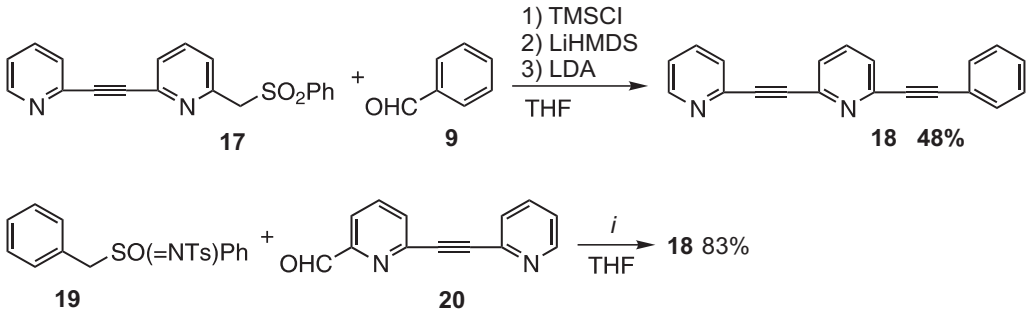
The double elimination protocol has now proved to be versatile for the synthesis of a variety of arylene ethynylenes containing heteroaromatic rings. The compounds thus obtained are potentially useful as liquid crystals, chemical sensors, electroluminescent materials, molecular wires, etc. In addition to the facileness of synthetic procedure, it is of great significance in a practical sense that the product obtained by this protocol is free from transition metal catalyst residues, which inevitably contaminate the Sonogashira coupling products. We hope, therefore that our methodology will serve in the synthesis of a wide range of arylene ethynylene molecular wires.

Experimental section



General remarks

All reactions were carried out under an atmosphere of nitrogen with freshly distilled solvents, unless otherwise noted. Tetrahydrofuran (THF) was distilled from sodium–benzophenone. Other solvents such as toluene, diisopropylamine, and methanol were distilled from CaH_2. BuLi in hexanes was purchased from Aldrich and titrated before use by the Gilman method (11). LiHMDS (lithium hexamethyldisilazide) in THF solution was purchased and used without titration. LDA (lithium diisopropylamide) was prepared prior to use from freshly distilled diisopropylamine and BuLi–hexane solution in THF. $Pd(PPh_3)_4$ was prepared according to the reported method (12). Silica gel (Daiso gel IR-60) was used for column chromatography. NMR spectra were recorded at 25 °C on JEOL Lambda 300 and JEOL Lambda 500 instruments and calibrated with tetramethylsilane (TMS) as an internal reference. Elemental analyses were performed on a PerkinElmer PE 2400.



Starting compounds **6a**–**6c**, **9**, **11**, and **12** were commercially available, and sulfones **2a**–**2e** were prepared from the corresponding arylmethyl bromides. Sulfones **4** were prepared from Sonogashira coupling between 2-ethynylthiophene and 2,5-diheptyl-4-iodobenzyl phenyl sulfone (**33b**), and sulfones **25a** and **25b** were prepared from the reaction of ethynylferrocene with 2,5-dimethyl-4-iodobenzyl phenyl sulfone (**33a**) and **33b**, respectively. Dialdehyde **5a** was pre-

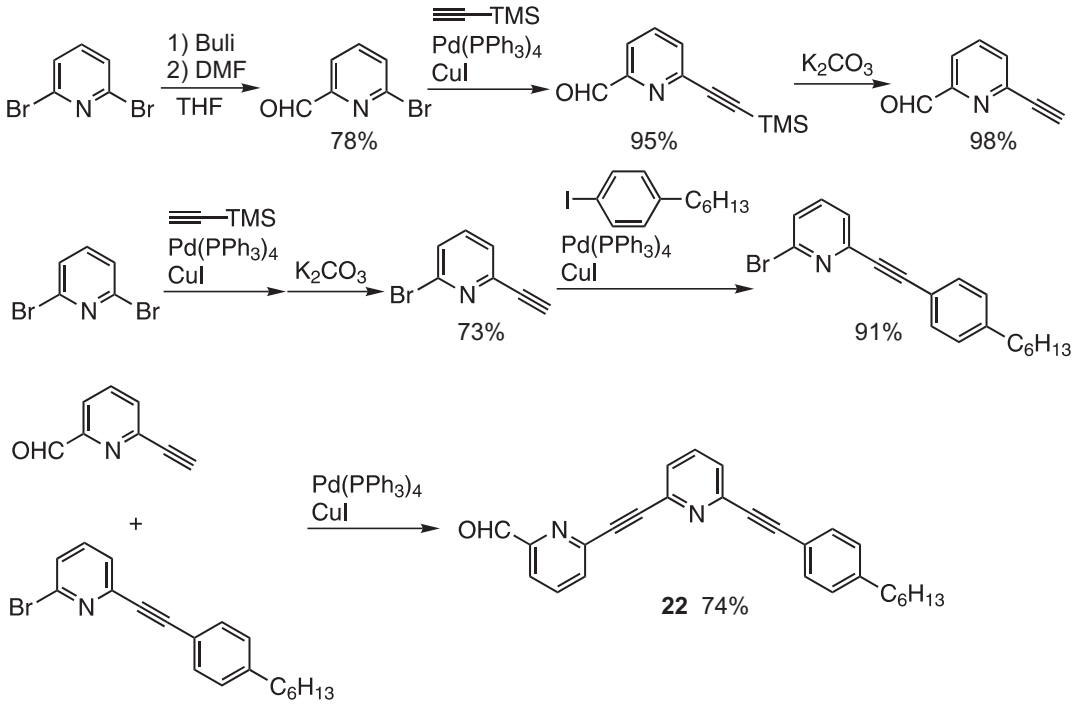
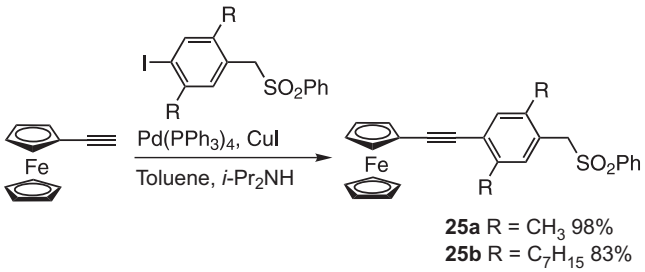
Scheme 6. Reagents: (*i*) BuLi–**22**–$ClP(O)(OEt)_2$–LiHMDS.



pared by hydrolysis of **36a**, which had been derived from the reaction of 2,5-diheptylbenzene-1,4-dialdehyde (**34**) with 4-(1,3-dioxolan-2-yl)benzyl phenyl sulfone (**35**). Dialdehyde **5b** was prepared similarly from the reaction of **5a** with **35**.



Dialdehydes **14** (7*c*), **21** (7*c*), and sulfone **8** (13) were prepared according to the reported procedure. Sulfoximine **19** was prepared from benzyl phenyl sulfide according to the reported method (7*c*).

Scheme 7.

Scheme 8.

Syntheses of **2a**–**2e**, **17**, **19**, **20**, **26**, **33a**, **33b**, **34**, and **35** are described in the Supporting information.[4]

2-Formyl-5-(phenylethynyl)thiophene (3)

Phenylacetylene (571.8 mg, 5.6 mmol) was added to a suspension of CuI (38.1 mg, 0.20 mmol), $Pd(PPh_3)_4$ (231.2 mg, 0.20 mmol), and 2-bromo-5-formylthiophene (764.4 mg, 4.0 mmol) in toluene (20 mL) and diisopropylamine (5 mL), and the mixture was stirred at r.t. for 13 h. After the usual work up with ethyl acetate and aq. NH_4Cl, drying over $MgSO_4$, and evaporation, the residue was subjected to column chromatography on silica gel to furnish **3** in a pure form (602.9 mg, 71%).

3

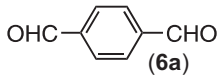
^{1}H NMR (500 MHz, $CDCl_3$) δ: 7.32 (d, J = 4.0 Hz, 1H), 7.36–7.42 (m, 3H), 7.54–7.56 (m, 2H), 7.67 (d, J = 4.0 Hz, 1H), 9.87 (s, 1H). ^{13}C NMR (125 MHz, $CDCl_3$) δ: 82.0, 97.9, 121.9, 128.5, 129.4, 131.7, 132.5, 132.9, 136.1, 143.8, 182.4.

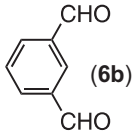
Preparation of 1a through double elimination of β-substituted sulfone derived from the reaction of 2a with 3 (representative)

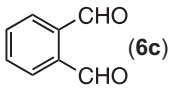
To a THF solution (2 mL) of benzyl phenyl sulfone **2a** (46.5 mg, 0.20 mmol) was added a hexane solution of BuLi (1.60 mol/L, 0.13 mL, 0.21 mmol) at –78 °C, and the mixture was stirred for 0.5 h. TMSCl (25.4 μL, 0.20 mmol) was added at –78 °C, and the mixture was stirred for 1.0 h. A hexane solution of BuLi (1.60 mol/L, 0.13 mL, 0.21 mmol) was added at –78 °C, and the mixture was stirred for 0.5 h. A toluene solution (10 mL) of 5-(phenylethynyl)thiophene-2-carbaldehyde (**3**) (50.9 mg, 0.24 mmol) was added at –78 °C, and the mixture was stirred at r.t. for 2 h. A THF–hexane solution of LDA (1.0 mol/L, 0.6 mL, 0.6 mmol) was added at –78 °C, and the mixture was stirred for 0.5 h. After the usual work up with ethyl acetate and aq. NH_4Cl, drying over $MgSO_4$, and evaporation, the residue was subjected to column chromatography on silica gel to furnish **1a** in a pure form (44.0 mg, 77%).

2,5-Bis(phenylethynyl)thiophene (1a) (14)

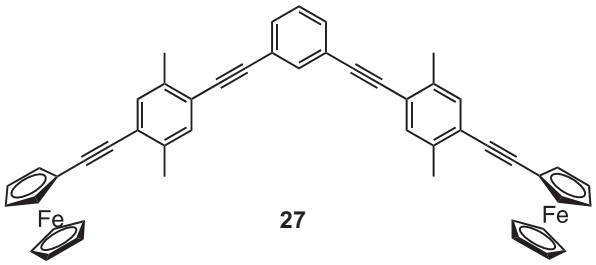
^{1}H NMR (500 MHz, $CDCl_3$) δ: 7.16 (s, 2H), 7.32–7.39 (m, 6H), 7.49–7.56 (m, 4H). ^{13}C NMR (125 MHz, $CDCl_3$) δ: 82.3, 94.1, 122.6, 124.6, 128.4, 128.7, 131.5, 131.8.







2-Phenylethynyl-5-(*p*-tolylethynyl)thiophene (1b)



Yield: 67%. mp 103 to 104 °C. ^{1}H NMR (500 MHz, $CDCl_3$) δ: 2.37 (s, 3H), 7.13–7.17 (m, 4H), 7.34–7.36 (m, 3H), 7.41 (d, J = 7.9 Hz, 2H), 7.50–7.54 (m, 2H). ^{13}C NMR (125 MHz, $CDCl_3$) δ: 21.6, 81.7, 82.4, 93.9, 94.3, 119.5, 122.6, 124.4, 124.9, 128.4, 128.6, 129.2, 131.4, 131.5,

3H), 8.05 (s, 1H). ^{13}C NMR (125 MHz, $CDCl_3$) δ: 82.3, 82.7, 94.2, 94.6, 119.9, 122.6, 124.7, 124.8, 126.7, 126.9, 127.8, 127.9, 128.0, 128.1, 128.4, 128.7, 131.5, 131.6, 131.8, 131.9, 133.0. HR-MS *m/z* calcd. for $C_{24}H_{14}S$: 334.0816; found: 334.0790.

2,5-Diheptyl-4-(thienylethynyl)benzyl phenyl sulfone (4)

Ethynylthiophene (119.0 mg, 1.1 mmol) was added to a suspension of CuI (9.5 mg, 0.05 mmol), $Pd(PPh_3)_4$ (57.8 mg, 0.05 mmol) and **33b** (554.6 mg, 1.0 mmol) in toluene (10 mL) and diisopropylamine (1.0 mL). The mixture was stirred at 60 °C for 3 h. After the usual work up with CH_2Cl_2 and aq. NH_4Cl, drying over $MgSO_4$, and evaporation, the residue was subjected to column chromatography on silica gel to furnish **4** in a pure form (460.0 mg, 86%).

4

^{1}H NMR (500 MHz, $CDCl_3$) δ: 0.86–0.90 (m, 6H), 1.25–1.33 (m, 16H), 1.38–1.44 (m, 2H), 1.49–1.54 (m, 2H), 2.32 (t, *J* = 8.1 Hz, 2H), 2.65 (t, *J* = 8.0 Hz, 2H), 4.37 (s, 2H), 6.83 (s, 1H), 7.01–7.03 (m, 1H), 7.24–7.26 (m, 2H), 7.29–7.31 (m, 1H), 7.46 (d, *J* = 7.8 Hz, 2H), 7.60–7.66 (m, 3H). ^{13}C NMR (125 MHz, $CDCl_3$) δ: 14.1, 14.2, 22.6, 22.7, 29.1, 29.2, 29.4, 29.5, 30.6, 30.7, 31.7, 31.8, 31.9, 34.0, 59.5, 86.5, 91.7, 122.9, 123.3, 126.3, 127.1, 127.3, 128.7, 128.9, 131.7, 132.2, 132.6, 133.7, 138.0, 140.2, 142.3.

Dialdehyde **5a** was prepared by the hydrolysis of **36a**, which had been derived from the reaction of **34** with **35**. Dialdehyde **5b** was prepared similarly from the reaction of **5a** with **35**.

1,4-Bis[4-(1,3-dioxolan-2-yl)phenyl]ethynyl-2,5-dihepthylbenzene (36a)

To a THF solution (10 mL) of **35** (289.1 mg, 0.95 mmol) was added a hexane solution of BuLi (1.60 mol/L, 0.60 mL, 0.96 mmol) at –78 °C, and the mixture was stirred for 0.5 h. A THF solution (3 mL) of 2,5-diheptylbenzene-1,4-dialdehyde (142.1 mg, 0.43 mmol) was added at –78 °C, and the mixture was stirred for 1.0 h. To the mixture was added $Cl(O)P(OEt)_2$ (0.14 mL, 0.95 mmol) at –78 °C, and the mix-

© 2005 NRC Canada

ture was stirred at r.t. for 1 h. *t*-BuOK (964.9 mg, 8.6 mmol) was added at –78 °C, and the mixture was stirred at r.t. for 1 h. After the usual work up with ethyl acetate and aq. NH_4Cl, drying over $MgSO_4$, and evaporation, the residue was subjected to column chromatography on silica gel to furnish **36a** in a pure form (223.5 mg, 84%).

36a

^{1}H NMR (500 MHz, $CDCl_3$) δ: 0.85–0.88 (m, 6H), 1.27–1.39 (m, 16H), 1.66–1.70 (m, 4H), 2.80 (t, *J* = 7.8 Hz, 4H), 4.04–4.15 (m, 8H), 5.84 (s, 2H), 7.36 (s, 2H), 7.46–7.55 (m, 8H).

1,4-Bis{4-[4-(1,3-dioxolan-2-yl)phenylethynyl]phenylethynyl}-2,5-diheptylbenzene (36b)

^{1}H NMR (500 MHz, $CDCl_3$) δ: 0.86–0.89 (m, 6H), 1.28–1.43 (m, 16H), 1.67–1.73 (m, 4H), 2.81 (t, *J* = 7.8 Hz, 4H), 4.02–4.17 (m, 8H), 5.83 (s, 2H), 7.37 (s, 2H), 7.47–7.57 (m, 16H). ^{13}C NMR (125 MHz, $CDCl_3$) δ: 14.1, 22.7, 29.2, 29.5, 30.7, 31.8, 34.1, 65.3, 89.6, 90.4, 91.0, 93.7, 103.3, 122.5, 122.9, 123.4, 123.9, 126.5, 131.4, 131.4, 131.6, 132.4, 138.1, 142.3.

1,4-Bis(4-formylphenyl)ethynyl-2,5-diheptylbenzene (5a)

Diacetal **36a** (445.5 mg, 0.72 mmol) and *p*-toluenesulfonic acid monohydrate (13.3 mg, 0.07 mmol) were dissolved in a mixture of THF (8 mL), acetone (4 mL), and water (4 mL), and the mixture was stirred at 50 °C for 14 h. After the usual work up with ethyl acetate and aq. $NaHCO_3$, drying over $MgSO_4$, and evaporation, the residue was subjected to column chromatography on silica gel to furnish **5a** in a pure form (374.5 mg, 98%).

5a

^{1}H NMR (500 MHz, $CDCl_3$) δ: 0.85–0.88 (m, 6H), 1.28–1.43 (m, 16H), 1.68–1.72 (m, 4H), 2.82 (t, *J* = 7.8 Hz, 4H), 7.41 (s, 2H), 7.67 (t, *J* = 7.9 Hz, 4H), 7.89 (d, *J* = 8.2 Hz, 4H), 10.04 (s, 2H). ^{13}C NMR (125 MHz, $CDCl_3$) δ: 14.1, 22.7, 29.2, 29.5, 30.7, 31.8, 34.1, 92.3, 93.3, 122.5, 129.6, 129.7, 132.0, 132.6, 135.4, 142.7, 191.4.

1,4-Bis[4-(4-formylphenylethynyl)phenylethynyl]-2,5-diheptylbenzene (5b)

^{1}H NMR (500 MHz, $CDCl_3$) δ: 0.86–0.89 (m, 6H), 1.28–1.43 (m, 16H), 1.67–1.74 (m, 4H), 2.81 (t, *J* = 7.8 Hz, 4H), 7.38 (s, 2H), 7.54 (td, *J* = 11.4, 5.8 Hz, 8H), 7.69 (d, *J* = 8.3 Hz, 4H), 7.88 (d, *J* = 8.3 Hz, 4H), 10.03 (s, 2H). ^{13}C NMR (125 MHz, $CDCl_3$) δ: 14.1, 22.7, 29.2, 29.5, 30.7, 31.8, 34.1, 90.3, 90.7, 93.1, 93.6, 122.2, 122.5, 124.0, 129.3, 129.6, 131.5, 131.8, 132.1, 132.4, 135.5, 142.4, 191.4.

Preparation of thiophene-containing phenylene ethynylene 7a (representative)

To a THF solution (10 mL) of **4** (112.3 mg, 0.21 mmol) was added a hexane solution of BuLi (1.6 mol/L, 0.14 mL, 0.22 mmol) at –78 °C, and the solution was stirred for 5 min. A THF solution (3 mL) of terephthalaldehyde (13.4 mg, 0.10 mmol) was added, and the mixture was stirred for 1 h. To the mixture was added $ClP(O)(OEt)_2$ (32 μL, 0.22 mmol) at –78 °C, and the mixture was stirred at r.t. for 1 h. *t*-BuOK (224.4 mg, 2.0 mmol) was added at –78 °C, and the mixture was stirred at r.t. for 2 h. After the usual work up with CH_2Cl_2 – aq. NH_4Cl, the organic layer was dried over $MgSO_4$. After evaporation, the crude product was subjected to column chromatography on silica gel to afford **7a** in a pure form (61.8 mg, 70%).

1,4-Bis[2,5-diheptyl-4-(2-thienylethynyl)phenylethynyl]benzene (7a)

^{1}H NMR (500 MHz, $CDCl_3$) δ: 0.86–0.89 (m, 12H), 1.25–1.42 (m, 32H), 1.65–1.73 (m, 8H), 2.75–2.82 (m, 8H), 7.02 (dd, *J* = 4.9, 3.7 Hz, 2H), 7.27 (dd, *J* = 3.5, 0.8 Hz, 2H), 7.30 (dd, *J* = 5.2, 0.8 Hz, 2H), 7.50 (s, 4H), 7.35 (s, 2H), 7.36 (s, 2H). ^{13}C NMR (125 MHz, $CDCl_3$) δ: 14.0, 14.1, 22.7, 29.1, 29.2, 29.5 (2C), 30.6, 30.7, 31.8 (2C), 34.1, 87.2, 90.4, 92.2, 93.7, 122.3, 122.4, 123.2, 123.5, 127.2, 127.3, 131.4, 131.6, 132.0, 132.3, 142.2, 142.3. Elemental anal. calcd. for $C_{62}H_{74}S_2$ (%): C 84.30, H 8.44; found: C 84.14, H 8.50.

1,4-Bis(4-{4-[2,5-diheptyl-4-(2-thienylethynyl)phenylethynyl]phenylethynyl}phenylethynyl)-2,5-diheptylbenzene (7b)

Yield: 65%. ^{1}H NMR (500 MHz, $CDCl_3$) δ: 0.86–0.89 (m, 18H), 1.25–1.43 (m, 48H), 1.65–1.74 (m, 12H), 2.75–2.83 (m, 12H), 7.02 (dd, *J* = 5.0, 3.5 Hz, 2H), 7.27 (dd, *J* = 5.2, 3.7 Hz, 2H), 7.30 (dd, *J* = 5.2, 1.3 Hz, 2H), 7.35 (s, 2H), 7.36 (s, 2H), 7.37 (s, 2H), 7.49–7.53 (m, 16H). ^{13}C NMR (125 MHz, $CDCl_3$) δ: 14.1, 22.7, 29.2 (2C), 29.5 (2C), 30.6, 30.7, 31.8, 34.1, 87.2, 90.5 (2C), 91.0, 91.1, 92.2, 93.7, 93.8, 122.4, 122.5 (2C), 122.8 (2C), 123.5 (2C), 127.2, 127.3, 131.4 (2C), 131.6 (2C), 132.0, 132.4 (2C), 142.2, 142.3 (2C). Elemental anal. calcd. for $C_{108}H_{118}S_2$ (%): C 87.63, H 8.04; found: C 87.44, H 8.12.

Preparation of pyridine-containing phenylene ethynylene 10 (representative)

To a THF solution (6 mL) of 2-pyridylmethyl sulfone **8** (233.3 mg, 1.0 mmol) was added a hexane solution of BuLi (1.29 mol/L, 0.93 mL, 1.2 mmol) at –78 °C, and the mixture was stirred for 0.5 h. A THF solution (2 mL) of benzaldehyde (95.5 mg, 0.90 mmol) was added at –78 °C, and the mixture was stirred for 1 h. After $ClP(O)(OEt)_2$ (0.174 mL, 1.20 mmol) had been added at –78 °C, the mixture was stirred at r.t. for 2 h. After a THF solution of lithium hexamethyldisilazide (1.0 mol/L, 10.0 mL, 10.0 mmol) had been added at –78 °C, the mixture was stirred at –78 °C for 1 h and at r.t. for 1 h. After the usual work up with aq. NH_4Cl – EtOAc, the combined organic layer was washed with brine and dried over anhydr. $MgSO_4$. After evaporation, the residue was subjected to column chromatography on silica gel to give **10** in a pure form (135.8 mg, 84%).

2-(Phenylethynyl)pyridine (10) (15)

^{1}H NMR (300 MHz, $CDCl_3$) δ: 7.39 (m, 3H), 7.25 (dt, *J* = 4.8, 1.2 Hz, 1H), 7.54 (td, *J* = 7.8, 0.9 Hz, 1H), 7.62 (m, 2H), 7.71 (dt, *J* = 7.8, 1.8 Hz, 1H), 8.63 (dd, *J* = 4.8, 0.6 Hz, 1H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 88.5, 89.1, 122.1, 122.6, 127.0, 128.2, 128.8, 131.9, 136.0, 143.3, 149.9.

2,6-Bis(phenylethynyl)pyridine (13) (16)

^{1}H NMR (500 MHz, $CDCl_3$) δ: 7.37 (m, 6H), 7.48 (d, *J* = 4.5 Hz, 2H), 7.61 (m, 4H), 7.69 (t, *J* = 4.5 Hz, 1H). ^{13}C

NMR (125 MHz, $CDCl_3$) δ: 88.2, 89.5, 122.0, 126.1, 128.3, 129.0, 132.0, 136.3, 143.7.

2,2′-Bis[3-(2-pyridylethynyl)phenylethynyl]-1,1′-binaphthyl (15)

^{1}H NMR (500 MHz, $CDCl_3$) δ: 6.72 (d, *J* = 7.8 Hz, 1H), 7.00 (s, 1H), 7.10 (t, *J* = 7.5 Hz, 1H), 7.25 (m, 1H), 7.38 (m, 3H), 7.53 (m, 2H), 7.70 (dt, *J* = 7.5, 0.9 Hz, 1H), 7.79 (d, *J* = 5.1 Hz, 1H), 8.02 (dd, *J* = 7.5, 5.1 Hz, 2H), 8.63 (d, *J* = 2.4 Hz, 1H). ^{13}C NMR (125 MHz, $CDCl_3$) δ: 88.2, 88.7, 90.1, 92.5, 121.3, 122.1, 122.8, 123.5, 126.5, 126.6, 126.8, 127.1, 128.0, 128.1, 131.2, 131.6, 132.5, 133.0, 134.4, 136.1, 140.3, 143.1, 149.9.

2-Phenylethynyl-6-(2-pyridylethynyl)pyridine (18)

^{1}H NMR (500 MHz, $CDCl_3$) δ: 7.28–7.33 (m, 1H), 7.34–7.43 (m, 3H), 7.52–7.56 (m, 1H), 7.57–7.68 (m, 4H), 7.70–7.76 (m, 2H), 8.60–8.73 (m, 1H). ^{13}C NMR (125 MHz, $CDCl_3$) δ: 87.4, 88.0, 88.1, 89.8, 122.0, 123.5, 126.7, 126.8, 127.8, 128.4, 129.1, 132.1, 136.3, 136.6, 142.5, 143.0, 143.9, 150.1. HR-MS *m*/*z* calcd. for $C_{20}H_{12}N_2$: 280.1000; found: 280.1033.

2-Formyl-6-[6-(4-hexylphenylethynyl)pyridn-2-ylethynyl]pyridine (22)

To a suspension of CuI (28.6 mg, 0.15 mmol), $Pd(PPh_3)_4$ (173.3 mg, 0.15 mmol), and **24** (1.027 g, 3 mmol) in toluene (20 mL) and diisopropylamine (2 mL) was added 2-formyl-6-ethynylpyridine (**23**) (472.1 mg, 3.6 mmol). The mixture was stirred at 40 °C for 12 h. After filtration, the usual work up with CH_2Cl_2 and aq. NH_4Cl, drying over $MgSO_4$, and evaporation, the residue was subjected to column chromatography on silica gel to furnish **22** in a pure form (871.3 mg, 74%).

22

^{1}H NMR (300 MHz, $CDCl_3$) δ: 0.86–0.88 (m, 3H), 1.30–1.50 (m, 6H), 1.59–1.65 (m, 2H), 2.62 (t, *J* = 7.7 Hz, 2H), 7.18 (d, *J* = 8.0 Hz, 2H), 7.51–8.00 (m, 8H), 10.10 (s, 1H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 14.0, 22.5, 28.9, 31.1, 31.6, 35.9, 86.8, 87.5, 88.7, 90.5, 118.9, 121.0, 126.6, 127.1, 128.5, 131.7, 132.0, 136.5, 137.5, 142.4, 143.1, 144.3, 144.6, 153.0, 192.7.

Preparation of 2,5-dimethyl-4-(ferrocenylethynyl)benzyl phenyl sulfone (25a) (representative)

To a toluene solution (10 mL) of CuI (9.5 mg, 0.05 mmol), $Pd(PPh_3)_4$ (57.8 mg, 0.05 mmol), **33a** (386.3 mg, 1.0 mmol), and diisopropylamine (1.0 mL) was added ferrocenylacetylene (231.1 mg, 1.1 mmol) at r.t. After the mixture had been heated at 60 °C for 3 h, the mixture was filtered. After the usual work up with CH_2Cl_2 – aq. NH_4Cl, the combined organic layer was washed with brine and dried over $MgSO_4$. After evaporation, the residude was subjected to column chromatography on silica gel to afford **25a** in a pure form (459.0 mg, 98%).

25a

^{1}H NMR (500 MHz, $CDCl_3$) δ: 2.01 (s, 3H), 2.35 (s, 3H), 4.24 (s, 5H), 4.25 (t, *J* = 1.8 Hz, 2H), 4.33 (s, 2H), 4.49 (t, *J* = 1.7 Hz, 2H), 6.86 (s, 1H), 7.20 (s, 1H), 7.49 (d, *J* = 7.9 Hz, 2H), 7.62–7.68 (m, 3H). ^{13}C NMR (125 MHz, $CDCl_3$) δ: 18.6, 20.1, 59.9, 65.1, 68.9, 69.9, 71.4, 84.0, 93.1, 124.3, 125.8, 128.7, 128.9, 132.9, 133.5, 133.8, 135.3, 137.3, 138.2.

2,5-Diheptyl-4-(ferrocenylethynyl)benzyl phenyl sulfone (25b)

^{1}H NMR (500 MHz, $CDCl_3$) δ: 0.87–0.91 (m, 6H), 1.26–1.41 (m, 18H), 1.54 (m, 2H), 2.32 (t, *J* = 8.1 Hz, 2H), 2.66 (t, *J* = 7.9 Hz, 2H), 4.24 (s, 5H), 4.26 (t, *J* = 1.8 Hz, 2H), 4.36 (s, 2H), 4.49 (t, *J* = 1.8 Hz, 2H), 6.80 (s, 1H), 7.21 (s, 1H), 7.47 (d, *J* = 7.8 Hz, 2H), 7.60–7.66 (m, 3H). ^{13}C NMR (125 MHz, $CDCl_3$) δ: 14.0, 14.1, 22.5, 22.6, 29.0, 29.1, 29.4, 29.5, 30.5, 30.6, 31.7, 31.8, 34.1, 59.4, 65.2, 68.8, 69.8, 71.2, 84.1, 92.3, 123.7, 125.3, 128.6, 128.8, 132.1, 132.5, 133.6, 138.1, 140.0, 141.8.

Preparation of ferrocene containing phenylene ethynylene 23a (representative)

To a THF solution (10 mL) of **25a** (98.4 mg, 0.21 mmol) was added a hexane solution of BuLi (1.60 mol/L, 0.14 mL, 0.23 mmol) at –78 °C, and the mixture was stirred for 5 min. A THF solution (3 mL) of terephthalaldehyde (13.4 mg, 0.10 mmol) was added at –78 °C, and the mixture was stirred for 1 h. After $ClP(O)(OEt)_2$ (32 μL, 0.22 mmol) had been added at –78 °C, the mixture was stirred at r.t. for 1 h. After *t*-BuOK (224 mg, 2.0 mmol) had been added at –78 °C, the mixture was stirred at r.t. for 2 h. After the usual work up with aq. NH_4Cl – CH_2Cl_2, the combined organic layer was washed with brine and dried over anhydr. $MgSO_4$. After evaporation, the residue was subjected to column chromatography on silica gel to give **23a** in a pure form (83.4 mg, 90%).

1,4-Bis[2,5-dimethyl-4-(ferrocenylethynyl)phenylethynyl]benzene (23a)

^{1}H NMR (500 MHz, CD_2Cl_2) δ: 2.45 (s, 6H), 2.47 (s, 6H), 4.25 (s, 10H), 4.28 (t, *J* = 1.7 Hz, 4H), 4.52 (t, *J* = 1.8 Hz, 4H), 7.33 (s, 2H), 7.38 (s, 2H), 7.54 (s, 4H). ^{13}C NMR (125 MHz, CD_2Cl_2) δ: 20.2, 20.3, 65.5, 69.2, 70.4, 71.8, 84.6, 90.7, 94.3, 94.4, 122.2, 123.6, 124.4, 131.8, 132.6, 132.9, 137.4, 137.8. Elemental anal. calcd. for $C_{50}H_{38}Fe_2$ (%): C 80.02, H 5.10; found: C 79.75, H 4.88.

1,4-Bis[2,5-diheptyl-4-(ferrocenylethynyl)phenylethynyl]benzene (23b)

^{1}H NMR (500 MHz, $CDCl_3$) δ: 0.86–0.91 (m, 12H), 1.28–1.45 (m, 32H), 1.66–1.74 (m, 8H), 2.76–2.81 (m, 8H), 4.25 (s, 10H), 4.26 (t, *J* = 1.7 Hz, 4H), 4.51 (t, *J* = 1.8 Hz, 4H), 7.31 (s, 2H), 7.35 (s, 2H), 7.50 (s, 4H). ^{13}C NMR (125 MHz, $CDCl_3$) δ: 14.1, 14.2, 22.6, 22.7, 29.2, 29.3, 29.6, 29.7, 30.7, 30.8, 31.8, 31.9, 34.2, 34.3, 65.4, 68.9, 69.9, 71.3, 84.6, 90.6, 93.2, 93.4, 121.5, 123.3, 123.5, 131.4, 132.0, 132.3, 141.8, 142.3. Elemental anal. calcd. for $C_{74}H_{86}Fe_2$ (%): C 81.75, H 7.97; found: C 81.46, H 7.86.

1,2-Bis{4-[2,5-diheptyl-4-(ferrocenylethynyl)phenylethynyl]phenyl}ethyne (23c)

^{1}H NMR (500 MHz, $CDCl_3$) δ: 0.86–0.91 (m, 12H), 1.28–1.47 (m, 32H), 1.67–1.73 (m, 8H), 2.76–2.81 (m, 8H), 4.26 (s, 10H), 4.27 (t, *J* = 1.7 Hz, 4H), 4.51 (t, *J* = 1.7 Hz, 4H),

© 2005 NRC Canada

7.35 (s, 2H), 7.50 (d, J = 8.3 Hz, 4H), 7.53 (d, J = 8.6 Hz, 4H). ^{13}C NMR (125 MHz, $CDCl_3$) δ: 14.1, 14.2, 22.6, 22.7, 29.2, 29.3, 29.6, 29.7, 30.6, 30.7, 31.8, 31.9, 34.2, 34.3, 65.5, 69.0, 70.0, 71.4, 84.7, 90.7, 91.2, 93.2, 93.3, 121.5, 122.7, 123.5, 123.6, 131.4, 131.6, 132.0, 132.3, 141.9, 142.3. Elemental anal. calcd. for $C_{82}H_{90}Fe_2$ (%): C 82.95, H 7.64; found: C 82.87, H 7.65.

1,4-Bis{4-[2,5-diheptyl-4-(ferrocenylethynyl)phenylethynyl]phenylethynyl}-2,5-diheptylbenzene (24a)

^{1}H NMR (500 MHz, $CDCl_3$) δ: 0.86–0.91 (m, 18H), 1.25–1.41 (m, 48H), 1.67–1.74 (m, 12H), 2.77–2.83 (m, 12H), 4.25 (s, 10H), 4.26 (t, J = 1.5 Hz, 4H), 4.50 (t, J = 2.0 Hz, 4H), 7.32 (s, 2H), 7.35 (s, 2H), 7.38 (s, 2H), 7.51 (s, 8H). ^{13}C NMR (125 MHz, $CDCl_3$) δ: 14.0, 14.1, 22.6, 22.7, 29.2, 29.3, 29.5, 29.6, 29.7, 30.7, 30.8, 31.8 (2C), 31.9, 34.1, 34.2, 34.2, 65.4, 68.9, 69.9, 71.3, 84.7, 90.3, 90.6, 93.2, 93.3, 93.8, 121.5, 122.5, 123.1, 123.4, 123.5, 131.3, 131.4, 132.0, 132.3, 132.4, 141.8, 142.2, 142.3. Elemental anal. calcd. for $C_{104}H_{122}Fe_2$ (%): C 84.18, H 8.29; found: C 83.83, H 8.35.

1,4-Bis(4-{4-[2,5-diheptyl-4-(ferrocenylethynyl)phenylethynyl] phenylethynyl}phenylethynyl)-2,5-diheptylbenzene (24b)

^{1}H NMR (500 MHz, $CDCl_3$) δ: 0.86–0.91 (m, 18H), 1.29–1.41 (m, 48H), 1.66–1.72 (m, 12H), 2.76–2.83 (m, 12H), 4.25 (s, 10H), 4.26 (t, J = 1.7 Hz, 4H), 4.51 (t, J = 2.0 Hz, 4H), 7.31 (s, 2H), 7.35 (s, 2H), 7.38 (s, 2H), 7.49–7.51 (m, 16H). ^{13}C NMR (125 MHz, $CDCl_3$) δ: 14.1, 14.2, 22.6, 22.7, 29.2, 29.3, 29.5, 29.6, 29.7, 30.6, 30.7, 31.8 (2C), 31.9, 34.1, 34.2, 34.3, 65.4, 68.9, 69.9, 71.4, 84.7, 90.5, 90.5, 91.0, 91.1, 93.2, 93.3, 93.7, 121.5, 122.5, 122.7, 122.8, 123.4, 123.5, 123.6, 131.3, 131.4, 131.5, 131.6, 132.0, 132.3, 132.4, 141.8, 142.2, 142.3. Preparation of 1-(4-formylphenyl)-2-[2,5-diheptyl-4-(2-thienylethynyl)phenyl]-2-(phenylsulfonyl)ethyl benzoate (32)

To a THF solution (5 mL) of **4** (107.0 mg, 0.20 mmol) was added a hexane solution of BuLi (1.60 mol/L, 0.14 mL, 0.23 mmol) at –78 °C, and the mixture was stirred for 5 min. A THF solution (3 mL) of **6a** (40.2 mg, 0.30 mmol) was added at –78 °C, and the mixture was stirred for 1 h. After benzoyl chloride (39.4 mg, 0.28 mmol) had been added at –78 °C, the mixture was stirred at –78 °C for 0.5 h and at r.t. for 2 h. After the usual work up with aq. NH_4Cl – AcOEt, the combined organic layer was washed with brine and dried over anhydr. $MgSO_4$. After evaporation, the residue was subjected to column chromatography on silica gel to give **32** in a pure form (77.3 mg, 50%).

32

^{1}H NMR (300 MHz, CD_2Cl_2) δ: 0.87–1.43 (m, 24H), 1.66–1.69 (m, 2H), 1.97–2.13 (m, 2H), 2.79–2.84 (m, 2H), 5.19 (d, J = 10.1 Hz, 1H), 6.90–6.93 (m, 2H), 7.00–7.03 (m, 1H), 7.23–7.31 (m, 4H), 7.36–7.46 (m, 5H), 7.56–7.66 (m, 6H), 8.02–8.05 (m, 2H), 9.86 (s, 1H). ^{13}C NMR (125 MHz, CD_2Cl_2) δ: 14.07, 14.11, 22.61, 22.68, 29.08, 29.22, 29.46, 29.55, 29.88, 31.01, 31.68, 31.73, 31.92, 34.30, 68.75, 75.31, 86.84, 91.39, 123.04, 123.21, 127.16, 127.51, 127.70, 127.93, 128.40, 128.66, 129.18, 129.50, 129.54, 130.07, 131.78, 132.60, 133.46, 133.47, 136.12, 139.28, 139.58, 142.63, 143.54, 164.92, 191.31.

Preparation of 1-[2,5-diheptyl-4-(ferrocenylethynyl)phenylethynyl]-4-[2,5-diheptyl-4-(2-thienylethynyl)phenylethynyl]benzene (31)

To a THF solution (10 mL) of **25b** (91.7 mg, 0.14 mmol) was added a hexane solution of BuLi (1.60 mol/L, 0.10 mL,

© 2005 NRC Canada

0.16 mmol) at –78 °C, and the mixture was stirred for 5 min. A THF solution (3 mL) of **32** (92.8 mg, 0.12 mmol) was added at –78 °C, and the mixture was stirred for 1 h. After $ClP(O)(OEt)_2$ (20 μL, 0.14 mmol) had been added at –78 °C, the mixture was stirred at r.t. for 1 h. After *t*-BuOK (269.3 mg, 2.4 mmol) had been added at –78 °C, the mixture was stirred at r.t. for 2 h. After the usual work up with aq. NH_4Cl – CH_2Cl_2, the combined organic layer was washed with brine and dried over anhydr. $MgSO_4$. After evaporation, the residue was subjected to column chromatography on silica gel to give **31** in a pure form (88.7 mg, 75%).

31

^{1}H NMR (500 MHz, $CDCl_3$) δ: 0.86–0.91 (m, 12H), 1.28–1.46 (m, 32H), 1.65–1.75 (m, 8H), 2.75–2.82 (m, 8H), 4.25 (s, 5H), 4.26 (t, *J* = 1.8 Hz, 2H), 4.50 (t, *J* = 1.8 Hz, 2H), 7.03 (dd, *J* = 5.2, 3.7 Hz, 1H), 7.27 (dd, *J* = 3.7, 0.9 Hz, 1H), 7.30–7.31 (m, 2H), 7.35 (s, 2H), 7.36 (m, 2H), 7.50 (s, 4H). ^{13}C NMR (125 MHz, $CDCl_3$) δ: 14.1 (3C), 22.7 (2C), 29.2 (3C), 29.3, 29.5 (2C), 29.6, 29.7, 30.7 (3C), 31.8 (2C), 31.9, 34.1, 34.2, 34.3, 65.4, 68.9, 69.9, 71.3, 84.7, 87.2, 90.4, 90.6, 92.2, 93.2, 93.4, 93.8, 121.5, 122.4, 122.5, 123.1, 123.4, 123.5 (2C), 127.1, 127.3, 131.3, 131.4, 131.6, 132.0, 132.2, 132.3, 141.8, 142.2, 142.3 (2C). Studies towards the total synthesis of ouabagenin[1]

Ling Chen and Pierre Deslongchamps

Abstract: An anionic cyclization strategy developed in our laboratory was used to produce a versatile and convergent synthesis of an advanced tetracyclic intermediate for the construction of ouabagenin and closely related analogs.

Key words: organic chemistry, synthesis, cycloaddition, polycyclization, Michael reaction, Diels–Alder reaction, steroids, oubain, ouabagenin, natural products.

Résumé : L'utilisation d'une réaction de cyclisation anionique développée dans nos laboratoires a permis d'élaborer une route convergente et versatile d'un intermédiaire tétracyclique pour la synthèse de la ouabagénine et ses dérivés.

Mots clés : chimie organique, synthèse, cycloaddition, polycyclisation, reaction Michaël, reaction Diels–Alder, stéroïdes, ouabaïne, ouabagénine, produits naturels.

Introduction

Ouabain (**1a**), a cardioactive glycoside, was isolated from the bark of the African ouabio tree (*Acokanthera ouabio*) by Arnaud in 1888 (1). A similar compound was also isolated from bovine and other mammalian sources and it has since been established that the endogenous and the plant-derived ouabain are in fact one and the same (2). Ouabagenin (**1b**), the aglycone of ouabain, was isolated for the first time in 1942 by Mannich and Siewert (3), who proposed a structure for the aglycone, and therefore the structure for ouabain as well, which was later proven by Florey and Ehrenstein (4).

In 1988, a stereocontrolled approach to access 14-hydroxy steroid skeletons was reported by our research group (5). Under basic conditions, an α,β-unsaturated β′-ketoester can react with a γ,δ-unsaturated β-ketoester (a Nazarov intermediate)[3] to afford a tetracylic compound in good yield and with excellent diastereoselectivity. This reaction is believed to go through a cascade of anionic cyclization and aldol condensation known as anionic polycyclization, and would provide a very efficient way to construct highly oxygenated polycyclic compounds such as ouabagenin.

There are many examples in the recent literature of studies towards the total synthesis of ouabagenin by various methods from the groups of Overman (6) and Jung (7). Herein we report some of our recent efforts at completing this challenging total synthesis. In 2002, our group reported an important development for the asymmetric synthesis of ouabagenin via anionic cyclization. The reaction of an α,β-unsaturated β′-ketoester **2** with Nazarov intermediate **3** afforded, after decarboxylation and aldol condensation, steroid **6** with great control of stereochemistry (Scheme 1) (8). These reactions, which led to the stereoselective generation of five contiguous chiral centres, have laid a solid foundation for the asymmetric total synthesis of ouabain or its aglycone ouabagenin. The issues that remained unaddressed were the methods of introduction of the 3- and 5-OH groups, deoxygenation of the 7 position, synthesis of the butenolide (for which there are excellent known methods in the literature (9)), along with some relatively straight forward functional group transformations.

To achieve the total synthesis of **1b** via the previously stated strategy it was important to obtain an A-ring precursor (α,β-unsaturated β′-ketoester) that would give comparable selectivity to that obtained with **2** but with a better handle for the introduction of the 3- and 5-OH groups. With this goal in mind, we envisioned the potential use of compounds **A1–A3** (Scheme 2). A-ring precursors **A1** and **A2** could be subjected to ozonolysis with concomitant Baeyer–Villager oxidation to obtain the protected 3-OH group, thus relying solely on an enone derived from the C-7 ketone as a handle to introduce the 5-OH as illustrated. Alternatively, the use of **A3** would allow for reduction of an analogous enone to fragment the ketal, affording a chiral allylic alcohol at C-3, which would offer a variety of options for the introduction of the C-5 OH.

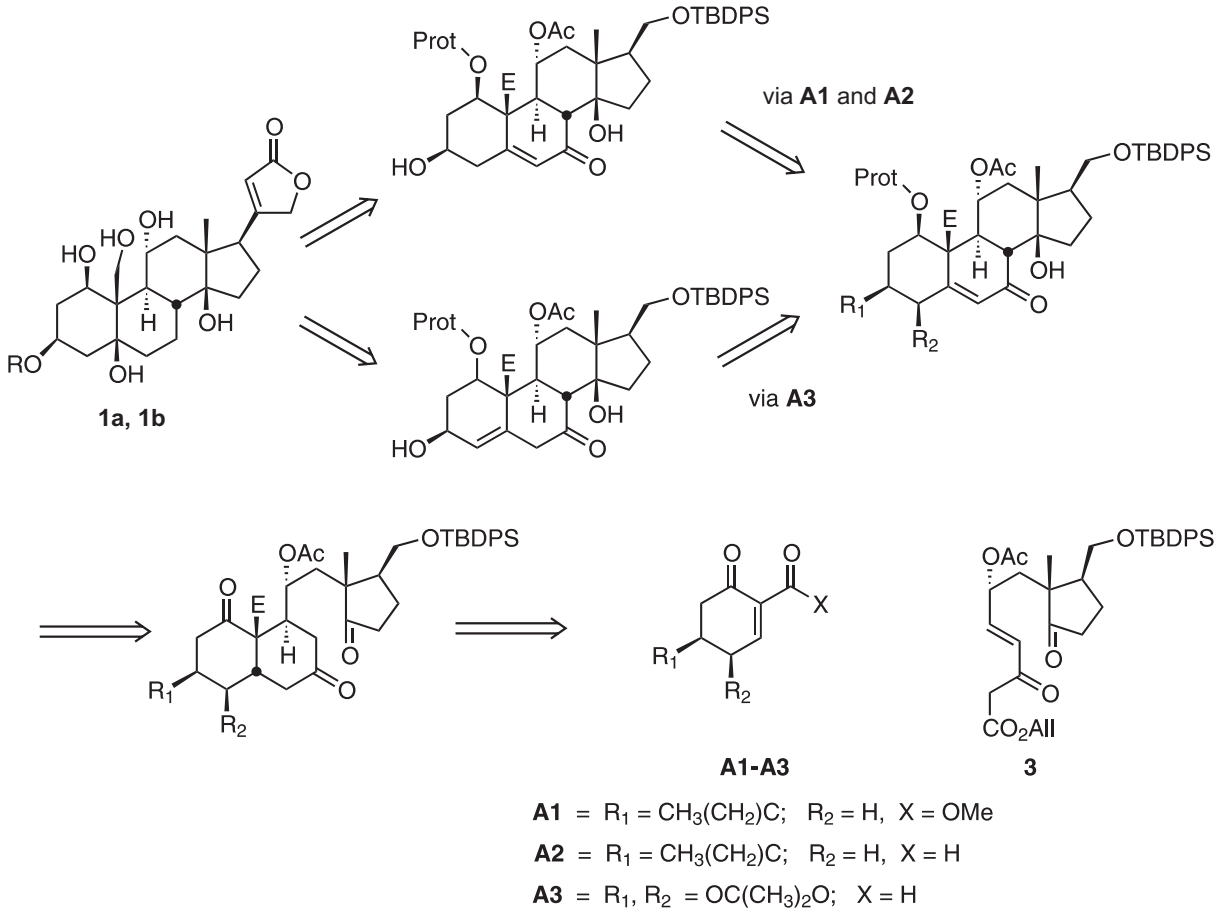
Results and discussion



With the above synthetic strategy in mind, we proceeded to synthesize the three targeted ring-A precursors proposed above. Ring **A1** was prepared as described in the literature (10). Ring **A2** was prepared from acid **7**, an intermediate in the synthesis of **A1** (Scheme 3). Compound **7** was first converted to the corresponding Weinreb amide (11), which was then treated with methyl magnesium bromide to afford methyl ketone **8** in 80% overall yield (12). Deprotection of the acetal followed by acidic cyclization gave the cyclohexenone **9** in 62% overall yield (13). The Baylis–Hillman reaction between **9** and formaldehyde was used to introduce the hydroxylmethyl group. This β-hydroxy ketone **10** can be furnished in 54% yield. The hydroxyl group in **10** was then oxidized with Dess–Martin periodinane (14) to afford the desired aldehyde (**A2**) in 83% yield. Ring **A2** proved to be very unstable and was prepared immediately before use in the next step.

The synthesis of **A3**, with its 3,4-hydroxyl groups protected as an acetonide for potential reductive fragmentation to the allylic alcohol, began from 2-deoxy-D-ribose (Scheme 4). The sugar was converted to the lactone (**11**) according to the procedure in the literature (15). The lactone ring was opened with isopropyl magnesium chloride (16) and *N*,*O*-dimethylhydroxyamine to give Weinreb amide **12** in 86% yield. The hydroxyl group of **12** was oxidized by the Swern method (17) to afford aldehyde **13** in 75% yield. The optimum yield for the Wittig reaction (92%) was obtained with $MePPh_3Br$ and slightly less than 1 equiv. of potassium bistrimethylsilylamide (KHMDS). The Weinreb amide (**14**) was then reduced to the aldehyde (**15**) by diisobutylaluminum hydride (DIBAL-H) in 92% yield. The lithium dianion of 2-bromoallylic alcohol (18) was added to the aldehyde to afford the ring-closing metathesis (RCM) precursor **16** in 98% yield. The ring-closing metathesis reaction went smoothly using Grubb's second generation catalyst (19) to deliver cyclohexene **17** in 73% yield. Oxidation of the diol to the desired ketone aldehyde was effected by using 3 equiv. of Dess–Martin periodinane to afford **A3** in 80% yield.

With the three A-ring precursors (**A1**–**A3**) in hand, their reactions with Nazarov intermediate **3** were investigated. The preliminary results are summarized in Table 1. When ring **A1** was allowed to react with Nazarov intermediate **3** in the presence of 2 equiv. of cesium carbonate (Table 1, entry 1), all starting material was consumed after 10 h by ^1H NMR (by TLC, the products overlapped with **3**), but the desired anionic cyclization adduct (**18**) was only isolated in 7%

Scheme 2.

A1 = $R_1 = CH_3(CH_2)C$; $R_2 = H$, X = OMe

A2 = $R_1 = CH_3(CH_2)C$; $R_2 = H$, X = H

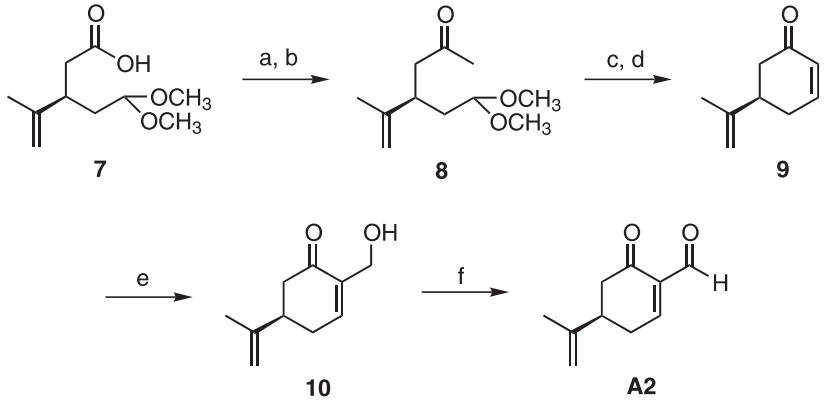
A3 = $R_1, R_2 = OC(CH_3)_2O$; X = H

yield with other unwanted products. From the previous result, it was clear that **A1** was not a good choice for the synthesis.

As expected, the reaction between ring **A2** and Nazarov intermediate **3** (Table 1, entry 2) was much faster than with **A1** owing to the more electron-withdrawing nature of the aldehyde with respect to the ester. After 2 h, the starting materials could not be detected by ^{1}H NMR. The desired anionic cyclization adduct (**19**) was isolated in 22% yield, along with another diastereomer in 24% yield (stereochemistry not determined). When subjected to the decarboxylation conditions, anionic cyclization adduct **19** gave compound **20** in 72% yield.

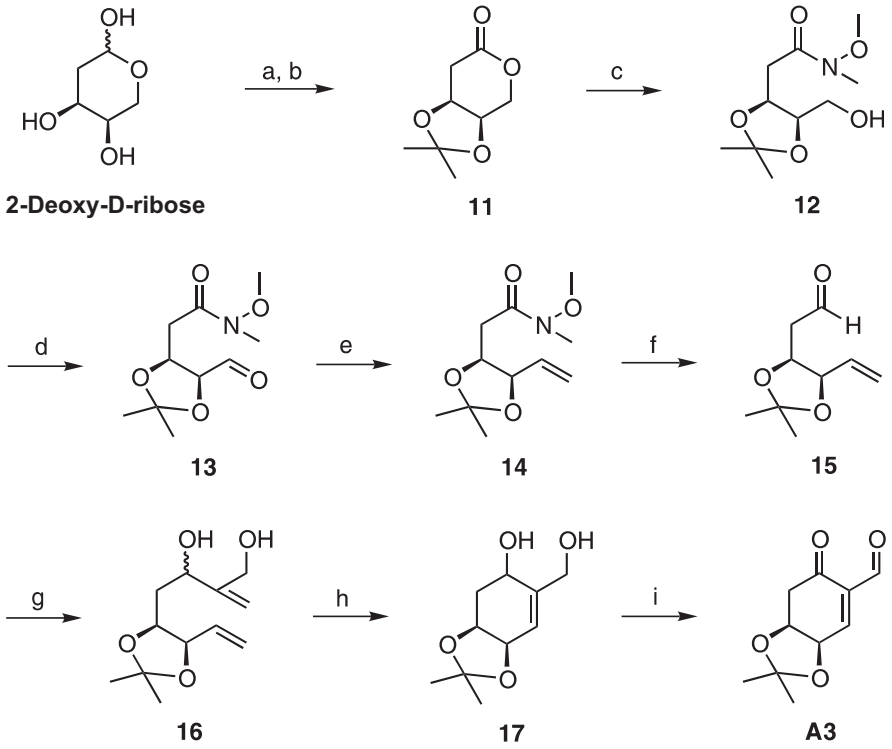
Finally, the anionic cyclization between ring **A3** and **3** was studied. Based on the previous work in our group (20), a catalytic amount of cesium carbonate was used to avoid the decomposition of **A3**. To our surprise, the only compound isolated appeared to be a mono-Michael addition product[4] and treating this crude product with 1 equiv. of cesium carbonate, produced the anionic cyclization adduct **21** in 36% overall yield (Scheme 5). The anionic cyclization reaction between ring **A3** and **3** was then repeated using 2 equiv. of cesium carbonate (as in the cases of the previous A-ring precursors) to afford the desired anionic cyclization product **21** in 78% yield with excellent stereoselectivity. These results suggest the possibility that the reaction could proceed via a double Michael process instead of a concerted anionic cyclization. After decarboxylation of **21**, compound **22** was obtained in 95% yield as a single diastereomer.

Based on the preliminary results from the above studies, we decided to advance on the total synthesis of ouabagenin with **A3**. The next step was to selectively reduce the aldehyde in compound **22**. This could be achieved by either $LiAlH(OCEt_3)_3$ (21) or $LiAlH(O\text{-}t\text{-}Bu)_3$. The best yield was obtained when the reaction was quenched with 5% acetic acid to afford compound **23** in 99% yield.[5]



The hydroxyl group in **23** was protected as a 2-(trimethylsilyl)ethoxymethyl ether (SEM) ether (22). The intramolecular aldol condensation was examined on **24** to complete the steroid skeleton of ouabagenin. Several differ-

[4] The mono-Michael product was isolated as a continually equilibrating mixture of diastereomers and keto–enol tautomers owing to the β-ketoester and was therefore very difficult to completely characterize. Its structure was proposed based on the complex ^{1}H NMR spectra of this mixture (not given) and its subsequent reaction with Cs_2CO_3 to give the fully cyclized product (**22**), which was, after decarboxylation, identical to that obtained via the one-step reaction. Based on these results, we feel that the assignment of the structure of a single Michael addition product to compound **23** is a strong possibility, but certainly not an absolute.



[5] Significantly lower yields were obtained when the reactions were quenched with aqueous ammonium chloride or HCl solutions or with water alone.

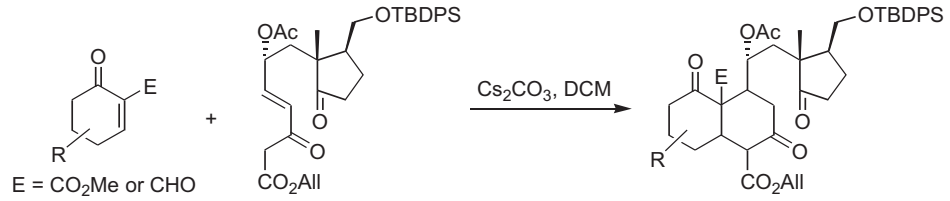
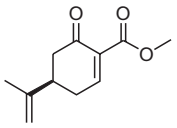
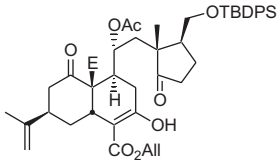
Scheme 3. (*a*) (*i*) Im_2CO, DCM; (*ii*) MeONHMe·HCl, NEt_3; (*b*) MeMgBr, THF, 0 °C, 80% for two steps; (*c*) 66% aq. AcOH, 40 °C; (*d*) PTSA, toluene, 100 °C, 62% for two steps; (*e*) 37% HCHO, DMAP, THF, 54%; (*f*) Dess–Martin periodinane, DCM, 83%.

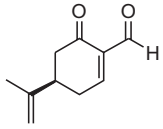
Scheme 4. (*a*) 2-Methoxypropene, PPTS, AcOEt, 70%; (*b*) Br_2, $CaCO_3$, CH_3CN–H_2O (5:1), 88%; (*c*) *i*-PrMgCl, MeNHOMe·HCl, THF, –20 °C, 86%; (*d*) $(COCl)_2$, DMSO, *i*-Pr_2NEt, DCM, –78 °C, 75%; (*e*) $MePPH_3Br$, KHMDS in toluene, THF, 0 °C, 92%; (*f*) DIBAL-H in toluene, THF, –78 °C, 92%; (*g*) *t*-BuLi in pentane, CH_2CBrCH_2OH, Et_2O, 0 °C, 98%; (*h*) Grubb's second generation catalyst, DCM, 40 °C, 73%; (*i*) Dess–Martin periodinane, DCM, 80%.

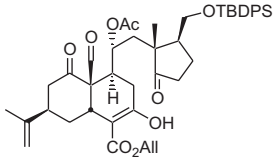


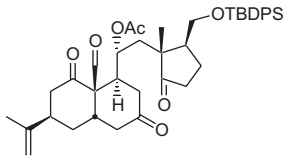
ent bases were used, however, either product **25** or **26** resulting from β elimination was obtained under the conditions shown in Table 2. By TLC, it appeared that the elimination occurred before the desired aldol.

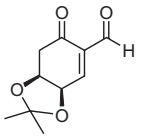


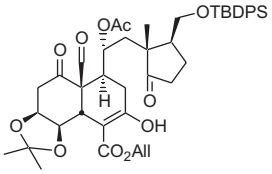


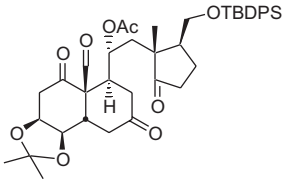












To circumvent the undesired β elimination, we proceeded to reduce the carbonyl group at C-1 before attempting the aldol. The selective reduction of the C-1 carbonyl group was effected via a hydroxyl group directed reduction with $Me_4NBH(OAc)_3$ (23), thus avoiding reduction of the other two ketones, which were less hindered and would react more rapidly with conventional reducing agents to afford compound **27** in 96% yield (Scheme 6). Unfortunately, this directed reduction allowed access to only the undesired α-OH at the 1 position, but we were confident that this could be easily corrected through a later oxidation–reduction sequence on the tetracycle. Thus, this diol (**27**) was protected as an acetonide at which point the aldol condensation of **28** went smoothly, giving the desired product **29** in 86% yield.

At this point, our efforts were directed towards the installation of a hydroxyl group at C-5. As per our original plan, this would be carried out via the reductive fragmentation of the 7,5-enone. Several conditions were examined in attempt to introduce the 5,6-double bond directly in compound **29**. Unfortunately, SeO_2 with catalytic acetic acid, SeO_2 in pyridine, 2,3-dichloro-5,6-dicyano-1,4-benzoquinone (DDQ) in benzene, and 2-iodoxybenzoic acid (IBX) in dimethylsulfoxide

Table 1. Preliminary results of the reactions between A ring units and **3**.

Entry	A ring units	Anionic cyclization (yield)[a]	Decarboxylation (yield)[a]
1	 **A1**	 **18** (7%)[b]	
2	 **A2**	 **19** (22%)[c]	 **20** (72%)
3	 **A3**	 **21** (78%)	 **22** (95%)

[a]Isolated yield.
[b]Along with three unidentified compounds.
[c]Along with 24% of an unidentified diastereomer.

(DMSO) gave no reaction at all. Trapping **29** as a *tert*-butyldimethylsilyl (TBS), enol ether **30** (24) and oxidation with $Pd(OAc)_2$ (25) over the course of 4 days allowed access to the desired enone, but in poor yield and with epimerization of the C-8 position. Fortunately, treatment of **30** with PhSeCl afforded phenyl selenide **31** in 71% yield (26). Oxidative elimination of **31** with hydrogen peroxide produced the desired compound **32** in 57% yield.

With compound **32** in hand, the reductive elimination was attempted to remove the C-4 alkoxy group and introduce the targeted allylic alcohol. In the presence of a catalytic amount of acetic acid, **32** was treated with zinc dust in ethanol at reflux (27). The desired product **33** was obtained in 32% yield, along with compound **29** in 29% yield. Compound **29**, which could be recycled, was obtained by the simple reduction of the double bond without the expected elimination.

Further optimization of this reaction is still required before undertaking the endgame of the synthesis, but we feel that we have in hand a viable method for the synthesis of a steroidal tetracycle with appropriate handles to complete the total synthesis of ouabagenin (**1b**) or closely related analogues for a structure activity relationship study.

Experimental

General

All the reactions were performed under a N_2 atmosphere with oven-dried glassware when necessary. Solvents were distilled and dried according to standard procedures. Analytical TLC was performed on precoated glass plates (0.25 mm) with silica gel 60F-250 (Merck). Flash chromatography was performed with 230–400 mesh gel 60 (Merck). ^1H and ^{13}C NMR spectra were recorded on a Brüker AC-300 and are referenced with respect to the residual signals of the solvent; they are described using standard abbreviations. IR spectra were recorded on a PerkinElmer 1600 FT-IR. Mass spectra were recorded on a ZAB-1F micromass spectrometer.

β-Hydroxyketone (10)

To a solution of **9** (20 mg, 0.147 mmol) in THF (0.25 mL) was added 37% HCHO (66 μL, 0.88 mmol) and *N,N*-dimethylaminopyridine (DMAP) (3.6 mg, 0.029 mmol). The mixture was stirred at 60 °C for 16 h. It was directly purified by preparative TLC (silica gel, hexanes – ethyl acetate

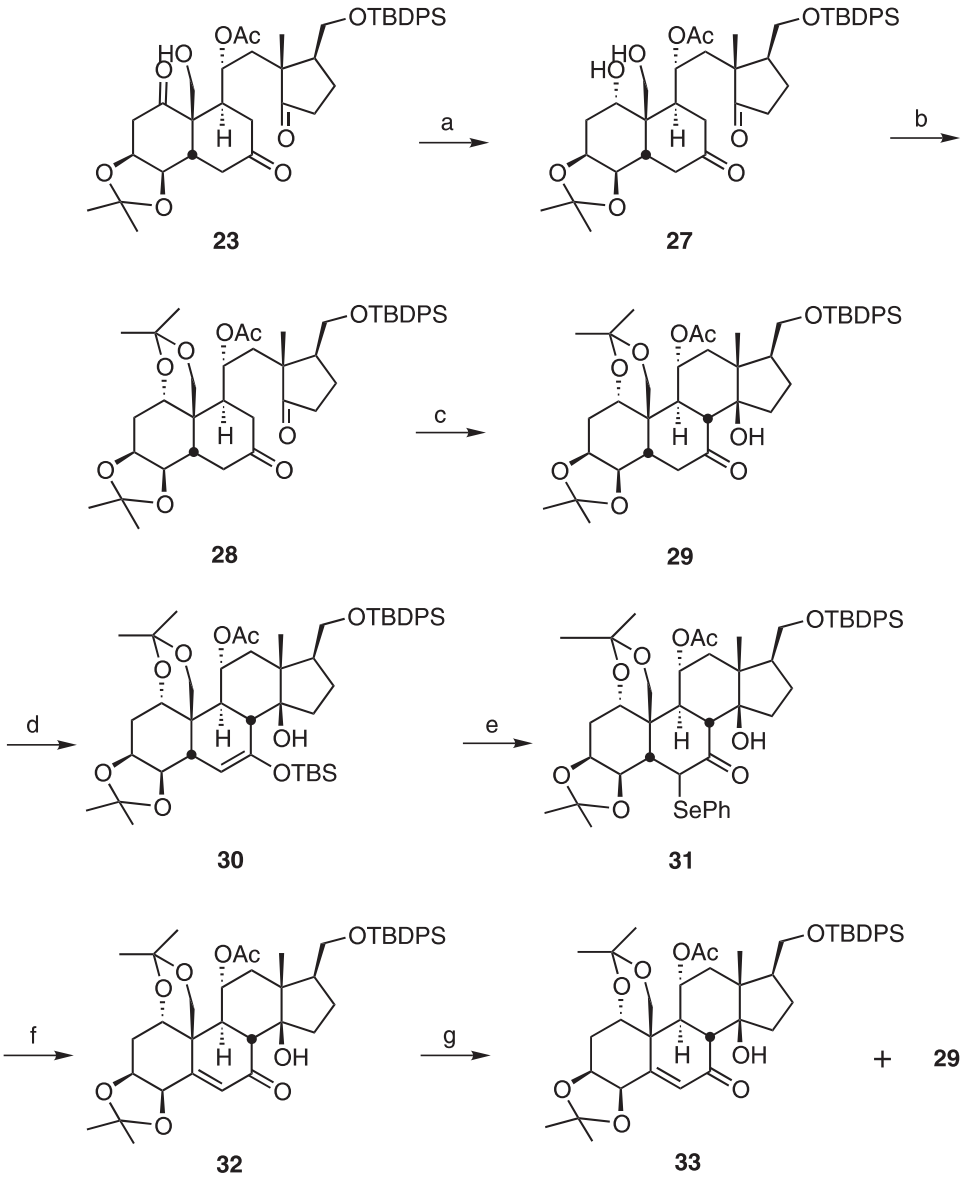
(Hex:EA = 1:1)) to afford **10** (13 mg, 54%) as a colourless oil. $[\alpha]_D^{20}$ –35.3 (*c* 1.62, $CHCl_3$). IR (neat, cm^{-1}) ν: 3416, 3083, 2920, 1668, 1434, 1384, 904. ^1H NMR (300 MHz, $CDCl_3$) δ: 6.94 (1H, m), 4.80 (1H, br s), 4.74 (1H, br s), 4.24 (2H, br s), 2.75–2.26 (5H, m), 1.73 (3H, s). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 200.24, 146.2, 146.0, 138.0, 110.8, 61.6, 43.1, 42.0, 30.8, 20.4. EI-MS (70 eV) *m/e*: 166 (M^+), 97 (100%). HR-MS calcd. for $C_{10}H_{14}O_2$: 166.0994; found: 166.0991.

α,β-Unsaturated-β′-ketoaldehyde (A2)



To a solution of **10** (14.3 mg, 0.036 mmol) in dichloromethane (DCM) (1 mL) was added Dess–Martin periodinane (54.7 mg, 0.129 mmol). The mixture was stirred at room temperature (r.t.) for 1 h. After removal of solvent in vacuo, the residue was purified by flash chromatography (silica gel, Hex:EA = 1:1 with 1% acetic acid (AcOH)) to give ring **A2** (11.7 mg, 83%) as a yellowish oil, which is very unstable and should be used immediately for the next step. ^1H NMR (300 MHz, $CDCl_3$) δ: 10.07 (1H, s), 7.82 (1H, dd, *J* = 2.6, 5.6 Hz), 4.90 (1H, br s), 4.81 (1H, br s), 2.80–2.43 (5H, m), 1.76 (3H, s).

Weinreb amide (12)

To a suspension of **11** (0.89 g, 5.17 mmol) and *N*,*O*-dimethylhydroxylamine (0.80 g, 8.00 mmol) in THF (10 mL) was added dropwise a 2 mol/L solution of *i*-PrMgCl in THF (10.8 mL, 21.7 mmol) at –20 °C. The reaction was stirred at –20 °C for 20 min. Aqueous (aq.) NH_4Cl solution (12 mL, satd. NH_4Cl – H_2O = 1:1) was added to quench the reaction. It was extracted with a mixture of ether and DCM (1:1, 5 × 20 mL), the combined organic layers were dried over $MgSO_4$ and concentrated. The residue was purified by flash column chromatography (silica gel, EA) to give **12** (1.04 g, 86%) as a colourless oil. $[\alpha]_D^{20}$ +33.0 (*c* 0.26, $CHCl_3$). IR (thin film, cm^{-1}) ν: 3444, 1659, 1644, 1633. ^1H NMR (300 MHz, $CDCl_3$) δ: 4.66 (1H, dt, *J* = 5.9, 8.1 Hz), 4.31 (1H, t, *J* = 5.5 Hz), 3.70 (3H, s), 3.63 (2H, br

d), 3.18 (3H, s), 2.94 (1H, dd, *J* = 5.3, 16.9 Hz), 2.77 (1H, dd, *J* = 8.5, 16.8 Hz), 2.58 (1H, br s), 1.45 (3H, s), 1.36 (3H, s). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 171.8, 107.7, 77.4, 73.2, 61.3, 61.1, 32.5, 32.0, 27.8, 25.1. EI-MS (70 eV) *m/e*: 218 ($M^+ - CH_3$), 144 (100%). HR-MS calcd. for $C_9H_{16}NO_5$ ($M^+ - CH_3$): 218.1028; found: 218.1024.

Aldehyde (13)

To a solution of $(COCl)_2$ (0.084 mL, 0.96 mmol) in DCM (3.0 mL) at –78 °C DMSO was added dropwise (0.148 mL, 2.09 mmol). It was then stirred for 10 min. To this mixture a solution of **12** was added dropwise (204 mg, 0.870 mmol) in DCM (1.0 mL) at –78 °C. The mixture was stirred for 30 min before diisopropylethylamine (DIPEA) (0.364 mL, 2.09 mmol) was added. It was stirred at r.t. for 15 min. Water (3 mL) was added to quench the reaction. After stirring for 5 min, the organic layer was separated. The aqueous layer was extracted with DCM (4 × 5 mL). The combined organic layers were dried over $MgSO_4$ and concentrated. The residue was purified by flash column chromatography (silica gel, EA) to afford **13** (150 mg, 75%) as a white solid. Mp: 57–59 °C. $[\alpha]_D^{20}$ +14.1 (*c* 2.29, $CHCl_3$). IR (thin film, cm^{-1}) ν: 1742, 1668, 1644. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 9.69 (1H, dd, *J* = 0.5, 2.2 Hz), 4.81 (1H, q, *J* = 7.0 Hz), 4.53 (1H, dd, *J* = 2.3, 7.1 Hz), 3.67 (3H, s), 3.18 (3H, s), 2.90 (1H, dd, *J* = 6.7, 16.9 Hz), 2.67 (1H, dd, *J* = 7.2, 16.8 Hz), 1.56 (3H, s), 1.43 (3H, s). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 202.4, 170.4, 110.3, 81.3, 74.2, 61.3, 32.4, 32.0, 27.4, 25.3. EI-MS (70 eV) *m/e*: 216 ($M^+ - CH_3$), 144 (100%); HR-MS calcd. for $C_9H_{14}NO_5$ ($M^+ - CH_3$): 216.0875; found: 216.0872.

Weinreb amide (14)

CH_3PPh_3Br (6.10 g, 17.1 mmol) was dried under vacuum at 110 °C for 2 h then cooled to r.t. THF (33 mL) was

© 2005 NRC Canada

added. To this suspension at 0 °C was slowly added KHMDS (0.5 mol/L in toluene, 27.0 mL, 13.5 mmol) with vigorous stirring. After addition, the temperature was raised to r.t. and the mixture was stirred for 30 min. It was cooled to –78 °C and a solution of **13** (3.29 g, 14.2 mmol) in THF (33 mL) was transferred into the above suspension by cannula. The mixture was stirred at 0 °C for 1 h. Satd. aq. NH_4Cl (0.35 mL) was added to quench the reaction. Pentane (132 mL) was added to precipitate the $POPh_3$. After filtration, the filtrate was concentrated in vacuo. The residue was purified by flash column chromatography (silica gel, Hex:EA = 1:2) to afford **14** (3.00 g, 92%) as a colourless oil. $[\alpha]_D^{20}$ –3.5 (*c* 3.33, $CHCl_3$). IR (thin film, cm^{-1}) ν: 2986, 2937, 1666, 1380, 1046. ^1H NMR (300 MHz, $CDCl_3$) δ: 5.81–5.70 (1H, m), 5.30–5.18 (2H, m), 4.73–4.64 (2H, m), 3.65 (3H, s), 3.14 (3H, s), 2.78 (1H, dd, *J* = 6.3, 16.7 Hz), 2.50 (1H, dd, *J* = 6.5, 16.6 Hz), 1.47 (3H, s), 1.36 (3H, s). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 171.4, 134.0, 118.3, 108.4, 79.0, 74.3, 61.3, 33.4, 32.0, 27.9, 25.3. EI-MS (70 eV) *m/e*: 229 (M^+), 83 (100%). HR-MS calcd. for $C_{11}H_{19}NO_4$: 229.1314; found: 229.1319.

Aldehyde (15)

To a solution of **14** (1.24 g, 5.41 mmol) in THF (40 mL) was added 1.5 mol/L DIBAL-H in toluene (7.2 mL, 10.8 mmol) at –78 °C and the mixture was stirred at this temperature for 1 h. Acetone (0.6 mL) was added to consume the excess DIBAL-H and it was stirred for 5 min. The reaction solution was transferred to a mixture of 0.5 mol/L aq. tartaric acid and hexane (108 mL : 108 mL) by cannula, then it was vigorously stirred for 30 min. The organic phase was separated and washed with 45 mL of water and brine, respectively. The combined aqueous phase was extracted with 100 mL of 25% DCM in pentane. The combined organic phase was dried over Na_2SO_4 and concentrated in vacuo. The residue was purified by flash column chromatography (silica gel, Hex:EA = 2:1) to afford **15** (0.85 g, 92%) as a clear oil. $[\alpha]_D^{20}$ –16.1 (*c* 1.68, $CHCl_3$). IR (thin film, cm^{-1}) ν: 3085, 2988, 2937, 2733, 1728, 1645, 1372, 1249, 1217, 1167, 1050, 1004, 933, 869. ^1H NMR (300 MHz, $CDCl_3$) δ: 9.68 (1H, br s), 5.71–5.60 (1H, m), 5.30–5.16 (2H, m), 4.65–4.59 (2H, m), 2.67–2.58 (1H, m), 2.52–2.44 (1H, m), 1.43 (3H, s), 1.31 (3H, s). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 199.9, 133.4, 118.8, 108.7, 78.6, 72.9, 45.1, 27.8, 25.3.

RCM precursor (16)

To a solution of 2-bromoallylic alcohol (6.37 g, 46.5 mmol) in ether (154 mL) was slowly added a solution of 1.47 mol/L *t*-BuLi in pentane (79 mL, 0.116 mol) at −78 °C. It was quickly warmed to 0 °C and stirred at this temperature for 4 h. **15** (2.64 g, 15.5 mmol) in ether (21 mL) was added to this mixture at –78 °C, then it was stirred at 0 °C for 30 min. MeOH (4.4 mL) was added to quench the reaction, followed by water (110 mL). The mixture was stirred for 10 min. The organic layer was separated and the aqueous layer was extracted with DCM (4 × 100 mL). The combined organic phase was dried over $MgSO_4$ and concentrated in vacuo. The residue was purified by flash column chromatography (silica gel, Hex:EA = 1:2) to give **16** (3.48 g, 98%) as a colourless oil. IR (thin film, cm^{-1}) ν: 3418, 2987, 2932, 1372, 1218, 1044. ^1H NMR (300 MHz, $CDCl_3$) two isomers δ: 9.68 (1H, br s), 5.71–5.60 (1H, m), 5.30–5.16 (2H, m), 4.65–4.59 (2H, m), 2.67–2.58 (1H, m), 2.52–2.44 (1H, m), 1.43 (3H, s), 1.31 (3H, s). ^{13}C NMR (75 MHz, $CDCl_3$) two isomers δ: 150.1, 149.2, 133.9, 133.6, 119.0, 118.6, 112.7, 112.0, 109.1, 79.7, 78.0, 74.8, 74.1, 70.9, 64.2, 64.1, 36.7, 36.1, 28.1, 28.0, 25.6, 25.5. EI-MS (70 eV) *m/e*: 213 ($M^+ - CH_3$), 83 (100%). HR-MS calcd. for $C_{11}H_{17}O_4$ ($M^+ - CH_3$): 213.1127; found: 213.1131.

Cyclohexene (17)

A solution of **16** (617 mg, 2.70 mmol) in DCM (30 mL) was degassed. To this solution was added Grubb's second generation catalyst (229 mg, 0.27 mmol). The mixture was stirred at 40 °C overnight. After removal of the solvent in vacuo, the residue was purified by flash column chromatography (silica gel, 1% MeOH in EA) to afford **17** (395 mg, 73%) as a green oil. Conformer **a**: ^1H NMR (300 MHz, $CDCl_3$) δ: 5.67 (1H, dd, *J* = 1.3, 2.9 Hz), 4.57–4.51 (1H, m), 4.50–4.48 (1H, m), 4.29–4.23 (2H, m), 4.15–4.09 (1H, m), 2.46 (1H, ddd, *J* = 2.7, 3.8, 15.2 Hz), 2.01 (1H, ddd, *J* = 2.3, 4.5, 15.2 Hz), 1.45 (3H, s), 1.37 (3H, s). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 140.6, 122.6, 109.6, 72.8, 72.5, 65.3, 64.0, 31.9, 28.3, 26.5. Conformer **b**: IR (thin film, cm^{-1}) ν: 3418, 2987, 2932, 1372, 1218, 1044. ^1H NMR (300 MHz, $CDCl_3$) δ: 5.69 (1H, br s), 4.55–4.53 (2H, m), 4.50–4.45 (1H, m), 4.33–4.22 (2H, m), 2.39 (1H, dt, *J* = 4.9, 13.8 Hz), 1.85 (1H, ddd, *J* = 3.2, 8.7, 13.8 Hz), 1.36 (6H, s). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 142.2, 123.7, 108.6, 72.2, 71.6, 65.5, 65.3, 35.1, 27.8, 26.1. EI-MS (70 eV) *m/e*: 185 ($M^+ - CH_3$), 95 (100%). HR-MS calcd. for $C_9H_{13}O_4$ ($M^+ - CH_3$): 185.0814; found: 185.0808.

α,β-Unsaturated-β′-ketoaldehyde (A3)

To a solution of **17** (715 mg, 3.57 mmol) in DCM (75 mL) was added Dess–Martin periodinane (4.54 g, 10.7 mmol). The mixture was stirred at r.t. for 1 h. It was filtered through a short pad of silica gel (about 5 g), and washed with a mixture of hexane, ethyl acetate, and AcOH (50:50:1). The filtrate was concentrated in vacuo and the residue was purified by flash column chromatography (silica gel, Hex:EA:AcOH = 50:50:1) to afford **A3** (560 mg, 80%) as a colourless oil, which is not stable and should be used directly in the next step. ^1H NMR (300 MHz, $CDCl_3$) δ: 10.1 (1H, br s), 7.30 (1H, dd, *J* = 2.2, 2.5 Hz), 4.89 (1H, dd, *J* = 4.8, 2.7 Hz), 4.70 (1H, m), 3.04 (1H, dd, *J* = 2.7, 7.6 Hz), 2.80 (1H, dd, *J* = 3.7, 7.5 Hz), 1.38 (3H, s), 1.29 (3H, s). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 193.9, 188.9, 150.3, 128.9, 110.4, 73.1, 71.1, 39.3, 27.8, 26.3.

Anionic cyclization adduct (18)

To a solution of **3** (29.4 mg, 0.0486 mmol) in DCM (1 mL) was added Cs_2CO_3 (31.7 mg, 0.0972 mmol). The mixture was stirred at r.t. for 10 min. A solution of **A1** (19.0 mg, 0.0972 mmol) in DCM (1.0 mL) was added to the above mixture over 10 min. The reaction mixture was stirred at r.t. for 10 h. It was then filtered through a pad of Celite® and washed with DCM. After removal of the solvent in vacuo, the residue was purified by flash column chromatography (silica gel, Hex:EA = 4:1) to afford **29** (2.8 mg, 7.2%) as a colourless oil. ^1H NMR (300 MHz, $CDCl_3$) δ: 12.09 (1H, s), 7.70–7.63 (4H, m), 7.42–7.38 (6H, m), 5.92

© 2005 NRC Canada

(1H, m), 5.53 (1H, m), 5.35–5.24 (2H, m), 4.93 (1H, s), 4.84 (1H, s), 4.68 (2H, m), 3.84–3.62 (2H, m), 3.60 (3H, s), 1.84 (3H, s), 1.05 (9H, s), 0.87 (3H, s).

Anionic cyclization adduct (19)

To a solution of **3** (36 mg, 0.059 mmol) in DCM (1 mL) was added Cs_2CO_3 (40 mg, 0.122 mmol). The mixture was stirred at r.t. for 10 min. A solution of aldehyde (14 mg, 0.085 mmol) in DCM (1 mL) was added to the above mixture over 10 min. The reaction mixture was stirred at r.t. for 2 h. It was then filtered through a pad of Celite® and washed with DCM. After removal of the solvent in vacuo, the residue was purified by flash column chromatography (silica gel, Hex:EA = 2:1) to afford an unidentified isomer (11.2 mg) and **19** (10.3 mg, 22%) as a colourless oil. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 12.17 (1H, s), 9.29 (1H, d, *J* = 2.0 Hz), 7.70–7.68 (4H, m), 7.43–7.39 (6H, m), 5.99–5.86 (1H, m), 5.36–5.27 (3H, m), 4.95 (1H, s), 4.85 (1H, s), 4.72 (1H, dd, *J* = 6.0, 13.0 Hz), 4.62 (1H, dd, *J* = 6.0, 13.0 Hz), 3.74 (1H, dd, *J* = 5.7, 10.3 Hz), 3.63 (1H, dd, *J* = 6.5, 10.3 Hz), 3.26 (1H, dd, *J* = 3.5, 11.9 Hz), 2.96 (1H, dd, *J* = 6.5, 14.3 Hz), 2.84–2.49 (5H, m), 2.39–1.90 (7H, m), 1.88 (3H, s), 1.84 (1H, d, *J* = 1.4 Hz), 1.77 (3H, s), 1.66 (1H, m), 1.07 (9H, s), 0.87 (3H, s). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 221.9, 210.2, 198.6, 172.1, 170.7, 170.3, 145.3, 135.6, 133.3, 133.2, 131.5, 129.7, 127.7, 119.4, 113.3, 98.3, 69.8, 65.6, 64.2, 63.5, 49.2, 43.6, 42.2, 40.7, 38.5, 37.5, 36.5, 33.1, 30.5, 29.1, 26.9, 22.4, 22.2, 20.9, 19.5, 19.2.

Triketone (20)

To a solution of **19** (10.3 mg, 0.0134 mmol) in THF (1.5 mL) was added $Pd(PPh_3)_4$ (ca. 1 mg) and morphiline (6.5 μL, 0.0745 mmol). The reaction mixture was stirred at r.t. for 4 h. After removal of the solvent in vacuo, the residue was purified by flash column chromatography (silica gel, Hex:EA = 7:3) to afford **20** (6.6 mg, 72%) as a colourless oil. IR (thin film, cm^{-1}) ν: 2931, 2127, 1742, 1428, 1373, 1230, 1112, 910, 823, 736, 704. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 9.70 (1H, s), 7.70–7.65 (4H, m), 7.43–7.39 (6H, m), 5.20 (1H, dd, *J* = 6.7, 8.7 Hz), 4.89 (1H, s), 4.76 (1H, s), 3.72 (1H, dd, *J* = 6.6, 10.4 Hz), 3.67 (1H, dd, *J* = 6.6, 10.4 Hz), 2.98 (1H, q, *J* = 7.2 Hz), 2.90 (1H, m), 2.79 (1H, dd, *J* = 5.6, 14.0 Hz), 2.67 (1H, m), 2.53–1.94 (11H, m), 1.89 (3H, s), 1.76 (1H, m), 1.71 (3H, s), 1.59–1.46 (2H, m), 1.07 (9H, s), 0.87 (3H, s). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 221.7, 208.4, 207.7, 199.7, 170.4, 145.4, 135.63, 135.55, 133.3, 133.17, 129.8, 127.8, 112.5, 77.2, 69.7, 65.0, 64.3, 49.4, 43.5, 43.1, 42.8, 42.3, 40.7, 40.3, 39.4, 36.5, 35.3, 30.1, 26.9, 22.1, 21.4, 21.0, 19.2, 19.0.

Anionic cyclization adduct (21)

To a solution of **3** (57 mg, 0.094 mmol) in DCM (4 mL) was added Cs_2CO_3 (61 mg, 0.187 mmol). The mixture was stirred at r.t. for 10 min. A solution of **A3** (38 mg, 0.19 mmol) in DCM (2.0 mL) was added into this mixture over 10 min. The reaction mixture was stirred at r.t. for 2 h. It was then filtered through a pad of Celite® and washed with DCM. After removal of the solvent in vacuo, the residue was purified by flash column chromatography (silica gel, Hex:EA = 2:1) to afford **21** (58 mg, 77%) as a white foam. Mp: 57–59 °C. $[\alpha]_D^{20}$ +30.4 (*c* 0.51, $CHCl_3$). IR (thin film, cm^{-1}) ν: 2934, 2859, 1746, 1732, 1711, 1659, 1651, 1230. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 12.3 (1H, s), 9.40 (1H, d, *J* = 1.8 Hz), 7.70–7.66 (4H, m), 7.43–7.38 (6H, m), 5.98–5.84 (1H, m), 5.49 (1H, t, *J* = 8.8 Hz), 5.36–5.23 (2H, m), 4.78–4.61 (2H, m), 4.53 (1H, t, *J* = 5.0 Hz), 4.29 (1H, dd, *J* = 5.2, 8.0 Hz), 3.68 (2H, ddd, *J* = 6.4, 10.3, 13.5 Hz), 3.58 (1H, d, *J* = 8.0 Hz), 3.08 (1H, dd, *J* = 6.1, 16.2 Hz), 2.75 (1H, dd, *J* = 1.4, 16.2 Hz), 2.68–2.54 (2H, m, H-17), 2.44–2.05 (5H, m), 1.95 (1H, dd, *J* = 9.9, 14.9 Hz), 1.82 (3H, s), 1.76 (1H, dd, *J* = 1.3, 14.9 Hz), 1.55–1.48 (1H, m), 1.46 (3H, s), 1.32 (3H, s), 1.07 (9H, s), 0.86 (3H, s). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 222.1, 207.3, 197.4, 172.3, 170.6, 169.8, 135.6, 135.6, 133.3, 133.1, 131.7, 129.8, 129.7, 127.8, 127.8, 119.0, 109.5, 97.7, 78.1, 73.7, 70.0, 65.7, 64.3, 61.2, 49.3, 43.1, 40.6, 40.1, 39.8, 38.0, 36.5, 30.1, 27.8, 26.9, 25.7, 22.2, 20.7, 19.7, 19.2. Triketone (22)

To a solution of **21** (190 mg, 0.237 mmol) in THF was added $Pd(PPh_3)_4$ (13.7 mg, 0.012 mmol) and morphiline (0.103 mL, 1.19 mmol). The reaction mixture was stirred at r.t. for 5 min at which time the reaction was complete by TLC. After removal of the solvent in vacuo, the residue was purified by flash column chromatography (silica gel, Hex:EA = 1:1) to afford **22** (146 mg, 86%) as a white solid. Mp: 139–142 °C. $[\alpha]_D^{20}$ +16.7 (*c* 0.33, $CHCl_3$). IR (thin film, cm^{-1}) ν: 2932, 2859, 1738, 1731, 1714, 1471, 1428, 1372, 1223, 1112. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 9.94 (1H, s), 7.68–7.59 (4H, m), 7.48–7.36 (6H, m), 5.39 (1H, dd, *J* = 5.8, 9.0 Hz), 4.57 (1H, m), 4.08 (1H, dd, *J* = 5.5, 6.8 Hz), 3.69 (2H, ddd, *J* = 6.7, 10.5, 16.9 Hz), 3.08–2.98 (2H, m), 2.69 (1H, dd, *J* = 1.8, 15.8 Hz), 2.54–2.43 (4H, m), 2.38–2.25 (3H, m), 2.17–2.07 (2H, m), 1.96 (1H, dd, *J* = 10.3, 15.1 Hz), 1.89 (3H, s), 1.60–1.43 (2H, m), 1.38 (3H, s), 1.31 (3H, s), 1.07 (9H, s), 0.85 (3H, s). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 221.5, 206.4, 206.3, 200.6, 170.2, 135.6, 135.5, 133.3, 133.2, 129.8, 127.8, 109.6, 74.0, 74.0, 69.3, 64.4, 59.8, 49.2, 43.8, 43.3, 40.6, 39.5, 39.1, 39.0, 38.9, 36.4, 27.4, 26.9, 25.6, 22.2, 20.9, 19.2, 18.7. EI-MS *m/e*: 701 (M^+ – CH_3), 495 (100%). HR-MS calcd. for $C_{40}H_{49}O_9Si$ (M^+ – CH_3): 701.3146; found: 701.3140.

Alcohol (23)

To a solution of **22** (35.7 mg, 0.0498 mmol) in THF (2.0 mL) at –78 °C was slowly added $LiAlH[OC(C_2H_5)_3]_3$ (0.50 mol/L in THF, 0.130 mL, 0.0650 mmol). The temperature was raised to 0 °C and the mixture was stirred at this temperature for 1 h. Ether (5.0 mL) was added to dilute the reaction solution, then 5% aq. AcOH (4.0 mL) was added to quench the reaction. The mixture was stirred for 15 min. It was extracted with ether (3 × 10 mL), the combined organic layers were washed with satd. $NaHCO_3$ (4.0 mL) and brine (4.0 mL), and dried over $MgSO_4$. After removal of the solvent in vacuo, the residue was purified by flash column chromatography (silica gel, Hex:EA = 1:1 with 0.5% MeOH) to afford **23** (35.6 mg, 99%) as a colourless oil. ^{1}H NMR (300 MHz, $CDCl_3$) at least two conformations in $CDCl_3$ δ: 7.72–7.59 (4H, m), 7.47–7.37 (6H, m), 5.20 (0.4H, t, *J* = 9.2 Hz), 4.91 (0.6H, t, *J* = 8.8 Hz), 4.56–4.50 (1H, m),

Diol (27)

To a stirred solution of glacial AcOH (0.5 mL) was added $Me_4NHB(OAc)_3$ (76 mg, 0.29 mmol) in two batches. It was stirred at r.t. for 1.5 h and then cooled to 0 °C. It was transferred to a solution of **23** (20.8 mg, 0.029 mmol) in CH_3CN at 5 °C by cannula. The mixture was stirred at 5 °C for 3 h before the temperature was raised to 0 °C and stirred at 0 °C for 16 h. MeOH (0.10 mL) was added to quench the reaction. The solvent was removed in vacuo. The residue was diluted with DCM (15 mL) and washed with satd. $NaHCO_3$ (5.0 mL). The aqueous layer was extracted with DCM (2 × 5.0 mL). The combined organic layers were dried over $MgSO_4$ and concentrated in vacuo. The residue was purified by flash column chromatography (silica gel, Hex:EA = 1:1 with 0.5% MeOH) to afford **27** (17.3 mg, 96%) as a white solid, along with the recovered starting material (2.8 mg, 87% conversion (conv.)). Mp: 85–88 °C. IR (thin film, cm^{-1}) ν: 3453, 2933, 1730, 1428, 1371, 1244, 1112, 911, 733. ^1H NMR (300 MHz, $CDCl_3$) at least two conformations in $CDCl_3$ δ: 7.69–7.61 (4H, m), 7.48–7.36 (6H, m), 5.75 (0.56H, d, *J* = 10.5 Hz), 5.46 (0.45H, d, *J* = 11.2 Hz), 4.34–3.42 (7H, m), 2.80–1.98 (12H, m), 1.96 (3H, s), 1.94 (3H, s), 1.92–1.53 (4H, m), 1.45 (1.5H, s), 1.40 (1.8H, s), 1.31 (1.4H, s), 1.28 (1.3H, s), 1.27 (1.3H, s), 1.06 (4.5H, s), 1.05 (4.5H, s), 0.89 (2.3H, s), 0.85 (1.2H, s). ^{13}C NMR (75 MHz, $CDCl_3$) at least two conformations in $CDCl_3$ δ: 221.8, 210.4, 171.4, 135.6, 133.5, 133.3, 129.8, 129.7, 127.9, 127.8, 127.7, 79.2, 78.1, 75.4, 74.3, 72.7, 72.0, 71.1, 70.5, 70.1, 69.9, 68.4, 64.4, 64.1, 63.3, 62.2, 48.7, 44.9, 44.6, 44.2, 44.0, 43.1, 42.9, 40.6, 40.4, 40.0, 37.9, 37.5, 37.4, 37.1, 36.9, 36.7, 34.3, 34.0, 33.6, 32.8, 31.8, 31.4, 28.3, 28.1, 26.9, 25.9, 22.9, 22.6, 22.3, 21.3, 19.3, 18.3, 18.2. Silylenol ether (30)

To a solution of **29** (276 mg, 0.36 mmol) in DCM (12 mL) was added triethylamine (1.52 mL, 10.9 mmol) and then *tert*-butyldimethylsilyltrifluoromethanesulfonate (TBSOTf) (1.67 mL, 7.25 mmol) at 8 °C. The mixture was stirred at this temperature for 20 min then the temperature was raised to r.t. The mixture was then stirred at r.t. for 3 h. 2-Propanol (0.50 mL) was added at 0 °C to consume the excess TBSOTf. After stirring at r.t. for 10 min, satd. $NaHCO_3$ (80 mL) was added. The mixture was extracted with ethyl acetate (2 × 100 mL). The combined organic layers were dried over Na_2SO_4 and concentrated. The residue was purified by flash column chromatography (silica gel, Hex:EA = 9:1 to 1:1) to give recovered **29** (80 mg, 71% (conv.) and **30** (225 mg, 100% based on recovered starting material (borsm)) as a colourless oil. $[\alpha]_D^{20}$ +2.8 (*c* 0.21, $CHCl_3$). IR (neat, cm^{-1}) ν: 3523, 3049, 2930, 2858, 1739, 1666, 1471, 1428, 1368, 1247, 1189, 1112, 1045, 866, 838, 759, 704. ^1H NMR (300 MHz, $CDCl_3$) δ: 7.66–7.63 (4H, m), 7.44–7.34 (6H, m), 5.72 (1H, m), 5.09 (1H, dd, *J* = 1.2, 6.6 Hz), 4.45 (1H, t, *J* = 3.7 Hz), 4.37 (1H, s, OH), 4.22 (1H, dd, *J* = 4.1, 12.8 Hz), 3.99 (1H, d, *J* = 12.2 Hz), 3.88 (1H, dd, *J* = 5.1, 8.7 Hz), 3.68 (1H, *J* = 5.2, 9.9 Hz), 3.57 (1H, dd, *J* = 7.2, 9.8 Hz), 3.45 (1H, d, *J* = 12.3 Hz), 2.71 (1H, m), 2.36 (1H, d, *J* = 11.8 Hz), 2.23–1.94 (5H, m), 1.89 (3H, s), 1.85–1.82 (1H, m), 1.74–1.60 (5H, m), 1.53 (3H, s), 1.46 (3H, s), 1.37 (3H, s), 1.35 (3H, s), 1.04 (9H, s), 0.91 (9H, s), 0.83 (3H, s), 0.23 (3H, s), 0.20 (3H, s). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 170.0, 151.2, 135.6, 133.9, 129.53, 129.50, 127.6, 108.5, 106.3, 99.7, 83.5, 80.7, 73.7, 71.5, 70.7, 68.1, 65.2, 50.3, 46.0, 45.8, 44.6, 38.7, 37.2, 36.8, 36.0, 28.6, 28.5, 27.3, 26.9, 26.3, 26.1, 25.9, 21.6, 19.2, 18.8, 17.5, –3.8, –4.7. Palladium-catalysed synthesis of nonsymmetrically disubstituted-1,1′-biphenyls from *o*-substituted aryl iodides through aryl coupling and delayed hydrogenolysis[1]

Sara Deledda, Elena Motti, and Marta Catellani

Abstract: In the presence of $Pd(OAc)_2$ and norbornene as catalysts, two molecules of an ortho-substituted aryl iodide undergo aryl–aryl coupling to a palladium-bonded biphenylyl intermediate, which is hydrogenolyzed by benzyl alcohol to give 2,3′-disubstituted biaryl derivatives in satisfactory yields. A curious behaviour was observed with *o*-chloroiodobenzene, which gave activation of the C—Cl bond with four-membered ring formation.

Key words: biphenyls, aryl–aryl coupling, multistep reactions, palladium, palladacycles, C-H activation, catalysis.

Résumé : En présence de $Pd(OAc)_2$ et de norbornène agissant comme catalyseurs, deux molécules d'iodure d'aryle substituées en ortho subissent une réaction de couplage aryle–aryle conduisant à un intermédiaire biphénylyle lié au palladium qui peut subir une réaction d'hydrogénolyse sous l'action de l'alcool benzylique pour conduire à la formation de dérivés biaryles 2,3′-disubstitués, avec des rendements satisfaisants. On a observé un comportement bizarre avec l'*o*-chloroiodobenzène donne lieu à une activation de la liaison C—Cl avec formation d'un cycle à quatre membres.

Mots clés : biphényles, couplage aryle–aryle, réactions en plusieurs étapes, palladium, palladacyles, activation C-H, catalyse.

[Traduit par la Rédaction]

Introduction

Biphenyls are an important class of organic compounds, the biphenyl unit being the building block of several types of structures of current interest, including natural products, polymers, advanced materials, liquid crystals, ligands, and drugs (1).

The most successful catalytic methods in biphenyl synthesis are based on palladium catalysis (2–7). We used a catalytic system involving palladacycles (8–13). Different types of the latter have been extensively studied by several groups (14–17).

According to our methodology, aryl–aryl coupling through palladacycles occurs regioselectively. As shown in the simplified Scheme 1 (L = solvent or coordinating molecule), these palladacycles are formed by the reaction of an aryl iodide with palladium(0) and norbornene. In the presence of an *ortho*-R substituent (alkyl, aryl, and other functional groups), the palladacycle reacts selectively with the aryl iodide to form an sp^2–sp^2 carbon–carbon bond at the aryl site (pathway a), while the remaining norbornylpalladium bond readily deinserts norbornene to afford a biphenylylpalladium complex (18). By contrast, when the R substituent is H or a small group like F, the aryl group preferentially migrates on the norbornyl site of the palladacycle (pathway b) (18).

Causing the biphenylylpalladium complex to undergo a reaction able to liberate the organic product and palladium(0) renders the process catalytic. In this way the synthesis of a variety of interesting classes of organic compounds such as selectively substituted phenanthrenes (19), terphenyls (20), and biphenyl derivatives containing an oxoalkyl (21) or a vinyl (22) chain has been achieved.

We now report a catalytic synthesis of 2,3′-disubstituted-1,1′-biphenyls, based on the combination of the stoichiometric sequence leading to the biphenylylpalladium species with a delayed hydrogenolysis reaction.

Results and discussion

As shown in Scheme 2, two molecules of an ortho-substituted aryl iodide and one of a hydrogen donor react in the presence of $Pd(OAc)_2$ and norbornene as catalysts, and K_2CO_3 as a base in a dipolar aprotic solvent such as 1-methyl-2-pyrrolidinone (NMP) at 105 °C for 24 h to give 2,3′-disubstituted-1,1′-biphenyls (**1**).

The main difficulty for the achievement of this synthesis laid in obtaining an efficient hydrogenolysis of the

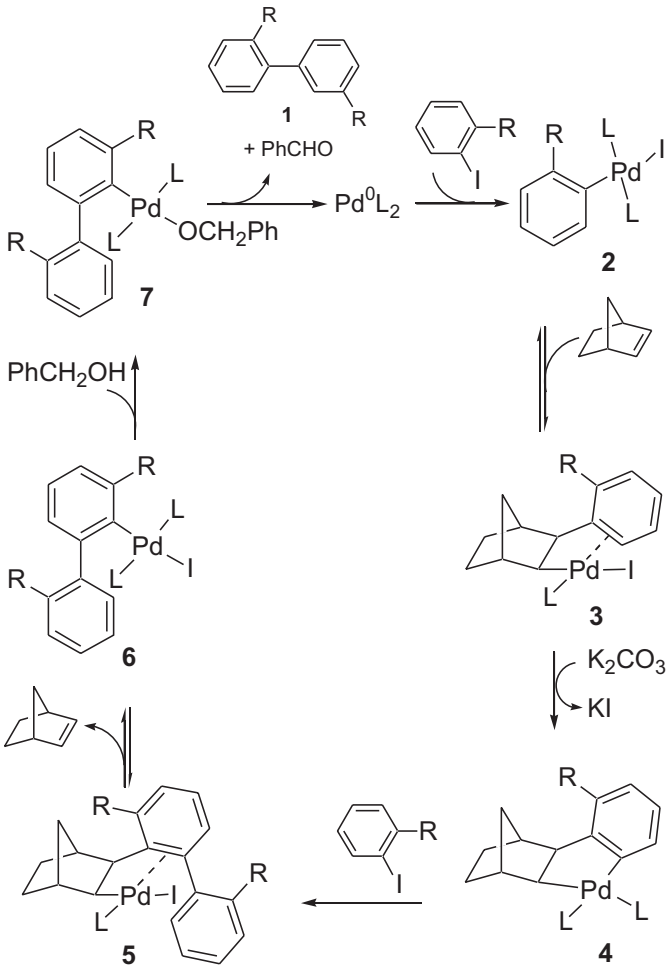
biphenylylpalladium species without interfering with the previous steps. To effect hydrogenolysis, two main methods were available: hydrogenation of the C-Pd-I bond with dihydrogen and hydrogen transfer from suitable sources. In principle, with both methods a selectivity problem could be expected since hydrogenolysis can occur at any step of the sequence. However, while hydrogenation with dihydrogen at atmospheric pressure gave a nonselective outcome, the appropriate use of the hydrogen transfer methodology led to delayed hydrogenolysis to the end of the catalytic sequence with good selectivity.



Among the combination of palladium sources, solvents, and bases examined, $Pd(OAc)_2$, NMP, and K_2CO_3 proved to be the most effective. The norbornene to aryl iodide molar ratio was found to play an important role, better results being obtained when using a ratio as low as 0.25 equiv. The reaction of *o*-isopropyliodobenzene (80 equiv.) with different hydrogen donors (80 equiv.) was thus carried out in the presence of $Pd(OAc)_2$ (1 equiv.), K_2CO_3 (160 equiv.), norbornene (20 equiv.) in NMP at 105 °C for 24 h under nitrogen. Various hydrogen donors were tested in a 1:1 molar ratio to *o*-isopropyliodobenzene as the substrate. Table 1 reports the yield of the biphenyl **1** (Scheme 2, R = *i*-Pr) obtained. Among the examined hydrogen sources, benzyl

alcohol and benzhydrol appear the most effective ones (Table 1, runs 1 and 2). Butanol (Table 1, run 3) and isobutyl formate (Table 1, run 4) behave analogously affording satisfactory results, while sodium formate (23) (Table 1, run 5) gives a low yield because of the formation of products resulting from Pd-C hydrogenolysis of the intermediate complexes **3** and **4** reported in Scheme 3. Water also is effective (Table 1, run 6) but only if used in large excess (2.5×10^2 molar ratio to palladium) otherwise the reaction leads to

poor results. An aryl iodide to benzyl alcohol molar ratio of 1:1 was found to be optimal, an excess of benzyl alcohol being detrimental.

Scheme 3 shows the proposed reaction pathway. The catalytic cycle is initiated by the oxidative addition of the *o*-substituted aryl iodide to palladium(0) formed in situ by $Pd(OAc)_2$ reduction. Norbornene insertion into the resulting arylpalladium complex **2** occurs stereoselectively leading to the *cis*,*exo* arylnorbornylpalladium species **3** (24–28). In the presence of a base such as K_2CO_3, the open precursor undergoes ring closure to **4** (10–13) through an electrophilic aromatic substitution (11) facilitated by an η^2-interaction of palladium with one double bond of the aromatic ring (25, 28). Palladacycle formation implies activation of an usually inert aromatic C—H bond (29–31). Because of the presence of the ortho substituent in the aromatic ring of palladacycle **4**, a second molecule of aryl iodide selectively attacks the aromatic moiety of the same palladacycle **4** affording complex **5**, which deinserts norbornene with formation of the biphenylylpalladium species **6** (18). At this stage, complex **6** reacts with benzyl alcohol to give **7**, which promotes hydrogen transfer via a Pd-H intermediate to form biphenyl **1** together with palladium(0) and benzaldehyde.

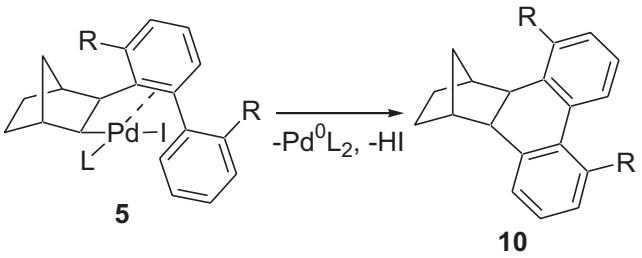
Table 2 reports the results obtained carrying out the reaction with an *o*-substituted aryl iodide (80 equiv.), benzyl alcohol (80 equiv.), palladium acetate (1 equiv.), norbornene (20 equiv.), and potassium carbonate (160 equiv.) in NMP under nitrogen at 105 °C for 24 h. Satisfactory results were obtained with different primary and secondary alkyl groups as well as with electron-withdrawing substituents (Table 2, runs 1–5) while the presence of an electron-releasing group such as the methoxy one (Table 2, run 6) led only to poor results. 1-Iodonaphthalene (Table 2, run 7) behaved as an ortho-substituted arene, which is a requirement for the aryl coupling to occur, and gave acceptable yields.

By-products result from hydrogen transfer to intermediate complexes. The hydrogen donor mostly reacts with the species containing a norbornyl– rather than an aryl–palladium bond. In particular, arylnorbornylpalladium iodide **3** is readily hydrogenolysed to the corresponding arylnorbornane and

Scheme 4.

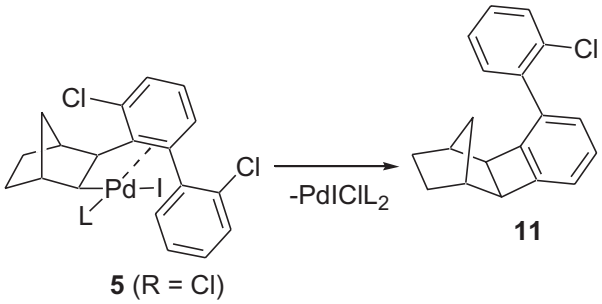
palladacycle **4**, after hydrogenolysis of the norbornylpalladium bond, inserts a new molecule of norbornene in the resulting Pd–aryl bond to form **9** according to pathway b of Scheme 4. Compound **8** also derives from palladacycle **4** as shown in Scheme 4. The steric effect of the ortho substituent favours reductive elimination to compound **8**, containing a four-membered ring (pathway a) (32), in place of the reaction with a second molecule of aryl iodide. By-products **8** and **9** were usually formed with a yield from 1% to 5%.

A 5,9-disubstituted 1,2,3,4,4a,12b-hexahydro-1,4-methanotriphenylene derivative of type **10** (33, 34), was usually formed to a large extent when the hydrogen donor became deficient owing to secondary reactions. As shown in Scheme 5, **10** derives from complex **5**, which, in the absence of an efficient terminating agent, prefers to undergo reductive elimination by ring closure instead of norbornene deinsertion.



As previously reported, if R is a methyl group, two additional by-products resulting from activation of the benzylic C-H (35) were formed to a small extent (5%).

Anomalous behaviours were observed with *o*-chloro- and *o*-fluoroiodobenzene.



o-Chloroiodobenzene, used in a 40:1 molar ratio to palladium, gave poor conversion (28%) and only a small amount (6%) of **1** was formed. The main product was the hexahydromethanobiphenylene derivative **11** (15%), which derives from C—Cl bond activation (Scheme 6). This result is surprising not only because it implies activation of an usually inert C—Cl bond, but also because it should be regarded as involving the C—Cl bond of the norbornyl-bonded *o*-

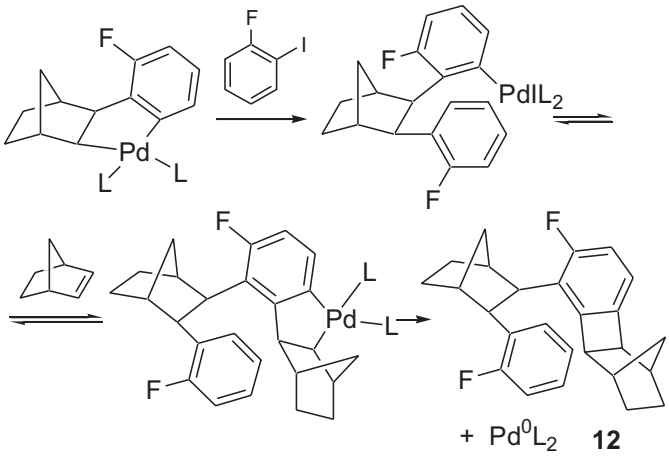
Scheme 5.

Scheme 6.



chloroaryl group of complex **5** (Scheme 6), C—Cl bond activation occurring only in the presence of a second *o*-chloroaryl unit. The alternative formation of a type **10** compound does not occur. The origin of this behaviour is probably to be attributed to a Pd-Cl interaction that favours C-Cl activation, thus preventing not only formation of a type **10** compound but also norbornene deinsertion.

As previously reported (22), the different reactivity of the F group is likely to be ascribed to the small size of the fluorine atom. The latter is not large enough to give "the ortho effect", which would cause the formation of the aryl–aryl bond of intermediate **5** by reaction of palladacycle **4** with *o*-fluoroiodobenzene (Scheme 3, R = F), and so the *ortho*-fluorophenyl group migrates to the norbornyl site of the palladacycle. Ring closure to hexahydromethanotriphenylene does not occur, however, because of the deactivation of the aromatic nucleus towards the arylpalladium electrophilic attack and norbornene is instead inserted. The reaction thus terminates with the formation of the hexahydromethanobiphenylene **12** in 67% yield, as reported in Scheme 7.

Conclusion

In conclusion, the catalytic method we have worked out offers a ready access to nonsymmetrically disubstituted biphenyls starting from two molecules of an *o*-substituted aryl iodide and represents a useful alternative to the Suzuki reaction and to other organometallic processes. The failure of *o*-fluoroiodobenzene to give the expected reaction confirms the need for a sufficiently bulky group ortho to iodobenzene, while the observation that the usually unreactive arene C—Cl bond is readily cleaved shows that competitive steps readily occur in sequential reactions when usually inert bonds are forced into the appropriate position for the interaction with the metal.

Scheme 7.

Experimental

General

All reactions were carried out under a nitrogen atmosphere, using standard Schlenk techniques. Most chemicals were obtained commercially and used as received. Compounds **1** (R = Me (36), Et (37), OMe (38), CO_2Me (39), -$(CH)_4$- (40), Cl (41)), **8** (R = Me, OMe (32), Et, *n*-Bu, *i*-Pr (42), -$(CH)_4$- (43)), **9** (R = Me, Et, *n*-Bu, *i*-Pr (20), -$(CH)_4$- (43)), and **12** (22) were previously reported. ^{1}H and ^{13}C NMR spectra were carried out in $CDCl_3$ at 20 °C using Bruker AC300 and AVANCE300 spectrometers at 300.1 and 75.4 MHz, respectively. Chemical shifts are reported in ppm using the solvent as the internal reference. The assignments of NMR resonances are based on decoupling and 2D experiments; one or more asterisks indicates interchangeable assignments. Mass spectra (EI) were recorded using a Finnigan Mat SSQ 710 spectrometer operating at 70 eV and are reported as *m*/*z* (relative intensity). IR spectra were run on a PerkinElmer 298 FT-IR spectrophotometer and are reported as wavenumbers (cm^{-1}). GC analyses were performed with a Carlo Erba HRGC 5300 instrument using a 30 m long SE-30 capillary column and a Hewlett-Packard 3394 integrator. Flash column chromatography was performed on Merck Kieselgel 60 and analytical TLC on Merck 60F_{254} plates. Melting points were determined on an Electrothermal apparatus and are uncorrected. Elemental analyses were performed with a Carlo Erba EA 1108 elemental analyser.

Reaction of *o*-substituted aryl iodides with benzyl alcohol

General procedure

A mixture of $Pd(OAc)_2$ (5 mg, 0.022 mmol), K_2CO_3 (498 mg, 3.6 mmol), the desired aryl iodide (1.8 mmol), norbornene (42 mg, 0.45 mmol), and benzyl alcohol (195 mg, 1.8 mmol) in NMP (10 mL) under nitrogen was heated at 105 °C with stirring for 24 h. The mixture was cooled to room temperature, diluted with CH_2Cl_2 (20 mL), and extracted twice with a 5% solution of H_2SO_4 (2 × 15 mL). The organic layer was washed with water (20 mL) and dried over anhydr. Na_2SO_4. The crude product was ana-

© 2005 NRC Canada

lysed by GC, GC–MS, and TLC. Products were isolated by flash column chromatography using hexane or mixtures of hexane–EtOAc as the eluents. By-product yields were determined by GC analysis.

2,3′-Dimethyl-1,1′-biphenyl (1, R = Me)

The reaction was carried out following the general procedure using 393 mg (1.8 mmol) of *o*-iodotoluene. Compound **1** (R = Me) (36) was isolated as a colourless oil in 72% yield (118 mg) by column chromatography, using hexane as the eluent. Compounds **8** (R = Me) (32) and **9** (R = Me) (20) were formed in 2% and 3% yield, respectively, together with two by-products resulting from the activation of the benzylic C—H bond (35) (2% yield each) and *exo*,*o*-tolylnorbornane (4%) (44) resulting from hydrogenolysis of complex **3** (R = Me).

2,3′-Diethyl-1,1′-biphenyl (1, R = Et)

The reaction was carried out following the general procedure using 418 mg (1.8 mmol) of *o*-ethyliodobenzene. Compound **1** (R = Et) (37) was isolated as a colourless oil in 84% yield (159 mg) by column chromatography, using hexane as the eluent. Compounds **8** (R = Et) (42) and **9** (R = Et) (20) were formed in 4% and 5% yield, respectively.

2,3′-Di*-i-*propyl-1,1′-biphenyl (1, R = i-Pr)

The reaction was carried out following the general procedure using 443 mg (1.8 mmol) of *o*-*i*-propyliodobenzene. Compound **1** (R = *i*-Pr) was isolated as a white solid in 83% yield (178 mg) by column chromatography, using hexane as the eluent. Compounds **8** (R = *i*-Pr) (42), **9** (R = *i*-Pr) (20), and **10** (R = *i*-Pr) were formed in 5%, 3%, and 2% yield, respectively.

2,3′-Dimethoxy-1,1′-biphenyl (1, R = OMe)

The reaction was carried out following the general procedure using 421 mg (1.8 mmol) of 2-iodoanisole. Compound **1** (R = OMe) (38) was isolated as a colourless oil in 48% yield (93 mg) by column chromatography, using hexane – ethyl acetate (9:1) as the eluent. Compound **8** (R = OMe) (32) was formed in 2% yield. Various by-products were also isolated but not further investigated.

1,2′-Binaphthyl (1, R = -(CH)$_4$-)

The reaction was carried out following the general procedure using 457 mg (1.8 mmol) of 1-iodonaphthalene. Compound **1** (R = -$(CH)_4$-) (40) was isolated as a white solid in 78% yield (179 mg) by column chromatography, using hexane as the eluent. Compounds **8** (R = -$(CH)_4$-) and **9** (R = -$(CH)_4$-)) (43) were formed in 2% yield each.

2,3′-Dichloro-1,1′-biphenyl (1, R = Cl)

The reaction was carried out following the general procedure using 215 mg (0.9 mmol) of *o*-chloroiodobenzene. Compound **1** (R = Cl) (41) was isolated as a colourless oil in 6% yield (6 mg) by column chromatography, using hexane as the eluent together with 72% of unconverted *o*-chloroiodobenzene (155 mg) and 15% yield (19 mg) of compound **11**.

*5-(2′-Chlorophenyl)-1,2,3,4,4a,8b-hexahydro-1,4-methanobiphenylene (**11**)*

^{1}H NMR δ: 7.50–7.42 (1H, m), 7.35–7.24 (5H, m), 7.21 (1H, br d, J = 7.1 Hz), 7.01 (1H, dd, J = 7.1, 1.0 Hz), 3.26–3.19 (2H, m), 2.32–2.28 (1H, m), 2.10–2.07 (1H, m), 1.65–1.44 (2H, m), 1.28–1.05 (2H, m), 1.00–0.89 (2H, m). ^{13}C NMR δ: 146.50, 144.91, 137.89, 133.92, 132.65, 131.13, 129.72, 128.42, 128.03, 127.17, 126.44, 121.30, 50.69, 49.97, 36.61, 36.31, 32.05, 27.85, 27.67. MS *m/z* (%): 280 (M^+, 11), 241 (32), 240 (18), 239 (100), 215 (19), 204 (19), 203 (209), 202 (33). Anal. calcd. for $C_{19}H_{17}Cl$: C 81.27, H 6.10; found: C 81.42, H 6.17.

Reaction of* o-*fluoroiodobenzene

The reaction was carried out following the general procedure using 200 mg (0.9 mmol) of *o*-fluoroiodobenzene. Compound **12** (22) was isolated in 67% yield (based on norbornene, 57 mg) by column chromatography, using hexane as the eluent. Other products were isolated but not further investigated.

New pseudohalide ligands in Ru-catalyzed olefin metathesis — A robust, air-activated iminopyrrolato catalyst[1]

Samantha D. Drouin, Heather M. Foucault, Glenn P.A. Yap, and Deryn E. Fogg

Abstract: Reaction of the Grubbs catalyst $RuCl_2(PCy_3)_2(CHPh)$ (**1**) with lithium 2-[(2,6-diisopropylphenyl)imino]pyrrolide·Et_2O (LiNN′·Et_2O) gives alkylidene complex **5**, containing a chelating, σ-bound iminopyrrolato unit. The structure of **5** is confirmed by X-ray crystallography. Treatment of **5** with pyridine generates $RuCl(NN')(py)_2(CHPh)$ (**6**) via displacement of PCy_3. Complex **5** effects ring-closing metathesis in air, displaying high reactivity relative to **6**.

Key words: ruthenium, alkylidene, metathesis, pyrrolimine, iminopyrrolato.

Résumé : La réaction du catalyseur de Grubbs, $RuCl_2(PCy_3)_2(CHPh)$ (**1**) avec le dérivé 2-[(2,6-diisopropylphényl)imino]pyrrolidure·Et_2O (LiNN′·Et_2O) conduit au complexe alkylidène **5** qui contient une unité iminopyrrolato chélatant à liaison σ. La structure du composé **5** a été confirmée par diffraction des rayons X. Le traitement du complexe **5** par de la pyridine génère le produit $RuCl(NN')(py)_2(CHPh)$ (**6**) par déplacement du PCy_3. Dans l'air, le complexe **5** subit une métathèse avec fermeture de cycle en démontrant une réactivité élevée comparée à celle du composé **6**.

Mots clés : ruthénium, alkylidène, métathèse, pyrrolimine, iminopyrrolato.

[Traduit par la Rédaction]

Introduction

Ring-closing metathesis (RCM) and cross-metathesis (CM) reactions hold tremendous interest for pharmaceutical synthesis, as well as "green chemistry" initiatives aimed at transforming seed oils into α-olefin feedstocks (1). The advent of robust, functional-group tolerant ruthenium catalysts such as **1** and **2** (Fig. 1) has significantly expanded the deployment of olefin metathesis methodologies by the organic community (1). Despite important recent advances in metathesis activity (2–6), however, major issues remain to be addressed. Chief among these — particularly from the perspective of industrial deployment of RCM and CM methodologies — is the problem of short catalyst lifetimes, which increases catalyst loading requirements, as well as heavy-metal contamination of the organic products. In 2002, we reported that the chloride ligands of Grubbs-class $RuCl_2LL'(CHR)$ catalysts are implicated in catalyst deactivation, promoting dimerization to unreactive, $Ru_2(\mu\text{-}Cl)_3$ species (7, 8). We subsequently described the synthesis of highly productive "pseudohalide" catalysts **3**, in which the chloride ligands are replaced by aryloxide groups (9, 10). Among these, complex **3a** is particularly long-lived, achieving >40 000 turnovers in RCM.

The present work is directed at exploring the accessibility of Ru alkylidene complexes containing N-donor pseudohalide ligands, a broad ligand class that may offer expanded opportunities in olefin metathesis, particularly in terms of stereocontrol and anchoring. A potential limitation, however, is a tendency toward π coordination of the heterocyclic ring to give piano-stool complexes. We have previously noted the ease with which the phenoxide ligand undergoes $\sigma \rightarrow \pi$ isomerization in late transition metal complexes containing labile ancillary ligands (11, 12), and indeed one of our motivations in incorporating electron-deficient aryloxides in complexes **3** is the diminished π-donor ability of these ligands (9, 10). π-Pyrrolide complexes have ample precedent in transition metal chemistry (13–15), and the facile formation of a Ru(π-pyrrolide) complex on reaction of $RuCl_2(PPh_3)_3$ with LiC_4H_3N (Scheme 1, (16)) may reveal a similar driving force. Keshner and Basolo (13) have pointed out, however, a preference for formation of σ-pyrrole complexes, over the corresponding π-bound species, and examples of $\pi \rightarrow \sigma$ isomerization in pyrrolide complexes have also been noted (14).

Several structural features of the iminopyrrolide ligand are attractive for their potential to stabilize σ donation. These include the narrow chelate bite angle of 70°–85° (17–22); we note that chelation does *not* prevent isomerization of aryloxide ligands that form larger, seven-membered chelate rings (11, 12). The enthalpically favoured conjugation of the pyrrolide and olefinic units may also favour retention of planarity in the ligand system. Chelating mono(imino)pyrrolato

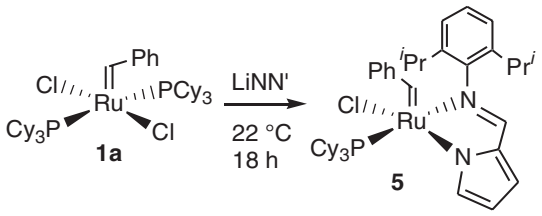
complexes have indeed been reported for a range of transition metals (17–22), including Ti complexes that prove potent polymerization catalysts (23). The ligands are attractive for their ease of access from commercially available precursors, as well as the potential for electronic and steric tuning via functionalization of the imino moiety (18). The iminopyrrolato ligand class has not previously been explored for olefin metathesis. Among existing metathesis catalysts, the closest relatives are salicylaldiminato Schiff base derivatives (24–26), which, however, form six-membered, rather than five-membered, chelate rings (Fig. 2). We now describe the synthesis of new ruthenium alkylidene complexes containing a K^2-*N*,*N*′-iminopyrrolato ligand, one of which shows impressive activity for RCM of diethyl diallylmalonate in air.

Results and discussion



Reaction of the Grubbs catalyst **1** with 1.6 equiv. of LiNN′ in benzene effects conversion to σ-iminopyrrolide complex **5** within 18 h at room temperature (Scheme 2). Isolated yields are limited to ca. 70% by the high solubility of **5** in all solvents, including pentane. The requirement for excess LiNN′ is imposed by competing protonation to yield HNN′. Control experiments indicate that LiNN′ does not react with PCy_3 or **5** in C_6D_6, suggesting that **1** itself may be implicated in this side reaction. Complex **5** is stable in chlorinated solvents and undergoes no oxidation on exposure to air in solution for 72 h, as indicated by NMR experiments in which the alkylidene resonance for **5** is integrated against triphenylmethane as an internal standard.

Diagnostic for the presence of both the alkylidene and the PCy_3 ligand in **5** is the observation of a ^{13}C NMR doublet far downfield (303.5 ppm, $^2J_{CP}$ = 14.1 Hz), which in HMQC experiments correlates with an alkylidene doublet (δ_H 20.0 ppm, $^3J_{HP}$ = 11.6 Hz). Coupling of the alkylidene proton to phosphorus implies that the Ru=CHPh plane is oriented parallel to the Ru—P bond axis (27). A doublet is also observed for the azomethine proton (δ 7.8, d, $^4J_{HP}$ = 3.9 Hz): both of these resonances collapse to singlets in the $^1H\{^{31}P\}$ NMR spectrum. The isopropyl groups give rise to two

Fig. 2. Representative K^2-iminopyrrolato and salicylaldiminato complexes.

Scheme 2.

methine septets and four methyl doublets, implying restricted rotation about each aryl-nitrogen bond. Consistent with retention of the chelate ring, we see no coalescence of these signals, or those due to the aromatic *C*-*i*-Pr carbon nuclei (142.9, 142.0 ppm; assignment supported by HMBC correlation with isopropyl signals), up to 70 °C.

The chemical shifts of the proton and carbon nuclei in the pyrrolyl ring provide key insight into the bonding mode and hapticity of the ring, strong upfield shifts being characteristic of π-bound pyrrole (Table 1). We undertook detailed COSY, HMQC, and HMBC analysis of **5** to make unequivocal assignments, and to deconvolute the signals due to the pyrrolide ring from those due to the benzylidene or arylimine groups. Chemical shifts for the pyrrole ring protons are in good agreement with values reported for η^1-iminopyrrole complexes (17, 18, 21, 22), and are little perturbed relative to values for the parent lithium salt, consistent with σ coordination of the pyrrolide unit. The ^{13}C NMR data likewise agree with the literature values, showing little sensitivity to the identity of the metal or ancillary ligands. In comparison, the ^1H NMR resonances for the pyrrole ligand in $RuX(\eta^5\text{-}C_5H_4N)(PPh_3)_2$ (X = H, Cl) are shifted ca. 1 to 2 ppm upfield, and the ^{13}C NMR signals ca. 30 ppm upfield.

Unanswered by the NMR analysis is the question of whether the phosphine ligand is located trans to the pyrrolyl or the imine nitrogen. X-ray analysis was therefore undertaken on crystals of **5** grown from a concentrated toluene solution. An ORTEP diagram is shown in Fig. 3. The geometry at ruthenium is distorted square pyramidal, with the benzylidene ligand located in the apical site (as expected for this high trans influence ligand); consistent with the NMR data, the pyrrolyl ligand is σ-bound to the metal. The chloride and pyrrolyl nitrogen are trans-disposed in the basal plane, possibly enabling some "push–pull" interaction between the π-donor chloride ligand and the pyrrolyl group. The four basal bonds are angled toward the vacant site: the P-Ru-N(2) angle is 159.56(8)°, the N(1)-Ru-Cl angle is 164.39(8)°. As expected from the large J_{HP} value for the alkylidene ligand, the torsion angle about P-Ru-C(18)-C(24) is 129.6(3)°, resulting in a near-zero dihedral angle for P-Ru-C(18)-H_α. The bite angle of the iminopyrrolato ligand (79.04(10)°) is slightly larger than in related complexes

[a]Assignments (where reported) are shown in bold face.
[b]NN″ = (*R*)-2-[(1-phenylethylimino)methyl]pyrrolide.

Fig. 3. ORTEP diagram for $RuCl(NN')(PCy_3)(CHPh)$ (**5**). Thermal ellipsoids shown at 30% probability level; hydrogen atoms are omitted for clarity. Selected bond distances (Å) and angles (°): Ru—C(18) 1.828(4), Ru—P 2.3474(8), Ru—N(1) 2.065(3), Ru—N(2) 2.149(2), Ru—Cl 2.3869(8), C(18)—C(24) 1.479(5), N(2)—C(5) 1.307(4); C(18)-Ru-N(1) 98.49(13), C(18)-Ru-N(2) 105.72(12), N(1)-Ru-N(2) 79.04(10), N(1)-Ru-Cl 164.39(8), N(2)-Ru-P 159.56(8), C(18)-Ru-Cl 93.74(11), C(18)-Ru-P 94.69(10), C(24)-C(18)-Ru 134.2(2).

$(Zr(NN')_2(NMe_3)_2$ avg. 70.1° (17); $Ti[2\text{-}(PhN{=}CH)C_4H_3N]_2Cl_2$ avg. 75.9° (20)), but is considerably more acute than the O-Ru-N angle of 88.9(2)° reported for the salicylaldiminato analogue $RuCl(ON')(PCy_3)(=CHPh)$ (**4**) (ON′ = 2-(ArN=CHC_4H_3N) (24)). The sum of the bond angles around N(1) is 360°, indicating that the pyrrolyl ring remains planar. The exocyclic angle of 132.6(3)° for C(3)-C(4)-C(5) agrees with values found in previous work; this value is maintained in both free and coordinated iminopyrrolato ligands (17). The aromatic plane of the diisopropylphenyl unit is orthogonal to the chelated ring, an orientation that accommodates the steric demand of the isopropyl substituents and which is retained on dissolution, as judged from the ^{1}H NMR data above. The Ru—C(18) (alkylidene) bond distance of 1.828(4) Å is similar to that in **4** (1.850(6) Å) (24) and in $RuCl_2(PCy_3)_2(=CH\text{-}p\text{-}C_6H_4Cl)$ (1.838(3) Å) (29). The Ru—N(2) (imine) bond length of 2.149(2) Å is marginally longer than the Ru—N(1) (pyrrolyl) distance (2.065(3) Å), as found for other iminopyrrolato complexes (17, 18). Ru—Cl and Ru—P bond distances of 2.3869(8) and 2.3474(8) Å, respectively, are similar to those in **4** (2.382(2) and 2.345(2) Å) (24).

Scheme 3.

While formation of σ-pyrrolyl complex **5**, as opposed to a π-pyrrolyl piano-stool structure, tends to validate the relevance of the structural features discussed in the Introduction, we wished to examine the possibility that π → σ isomerization might simply be curbed by the low lability of the PCy_3 ligand in **5**. To probe this point, we undertook replacement of the PCy_3 ligand of **5** by a potentially more labile pyridine donor, loss of which would enable access to the three coordination sites required for π coordination of the heterocyclic ring (Scheme 3). Sequential reaction of **1** with LiNN′, fol-

[b]Determined by ^{1}H NMR analysis.
[c]Reaction in neat substrate: 13 μmol Ru in 500 μL (2.1 mmol) diethyl diallylmalonate.
[d]Performed under nitrogen in degassed C_6D_6.
[e]5.8 μmol (1 equiv. per Ru).
[f]58 μmol (10 equiv. per Ru).
[g]29 μmol (5 equiv. per Ru).

lowed by pyridine, afforded RuCl(NN′)$(py)_2$(CHPh) (**6**) as the major product, as judged by in situ NMR analysis. Complex **6** was isolated as a yellow-green microcrystalline solid; again, yields are limited (in this case to ca. 50%) by high solubility. ^{1}H and ^{13}C NMR analysis offer unequivocal evidence for retention of the σ-pyrrolide unit. Loss of phosphine is evident from the multiplicity of the signal for the alkylidene carbon (316.6 ppm), which appears as a singlet, in place of the doublet observed for **5**. The alkylidene proton gives rise to a singlet at 20.51 ppm, and the presence of two pyridine ligands is supported by integration of the aromatic region. Exposure of solid **6** to vacuum for 18 h causes ca. 10% loss of pyridine to give **7**, identified as a monopyridine species on the basis of the decrease in the integrated intensity of the aromatic signals in the ^{1}H NMR spectrum, and emergence of a new alkylidene peak at 19.70 ppm, which disappears on addition of pyridine to the sample. Similar behaviour was previously reported for **2** (2).

RCM catalysis

Complex **5** proves a robust olefin metathesis catalyst, effecting RCM of the benchmark substrate diethyl diallylmalonate at 70 °C in air, in nondistilled and nondegassed solvent (Table 2, entry 1). The reaction shows complete selectivity for RCM over intermolecular ADMET (acyclic diene metathesis) processes, even in the absence of solvent, as indicated by ^{1}H NMR analysis. A control experiment with the Grubbs catalyst **1a** resulted in ca. 30% ADMET under these conditions. As we have previously commented (30), olefin metathesis via any square-pyramidal complex in which alkylidene occupies the apical site necessitates dissociation of one of the ligands in the basal plane. Complex **5** is inactive at ambient temperature, implying that all four basal donors are rather nonlabile, a feature also exhibited by the Schiff base catalysts of type **4** (24, 25). Even at 70 °C, no exchange is observed between coordinated and free (added) PCy_3 in EXSY experiments, and the ^{1}H NMR signals for the NN′ ligand remain fully resolved, indicating retention of the chelate. Catalysis is thus presumably carried by a spectroscopically unobservable active species, as indeed also proposed for salicylaldiminato complex **4** (25). While the latter is thought to operate via decoordination of imine, we believe that **5** is activated by loss of PCy_3. Consistent with this is the inhibition of activity on addition of free PCy_3 or on use of N_2 atmosphere, but rate enhancements on addition of CuCl as a phosphine scavenger (31). Trapping of the eliminated PCy_3 as O=PCy_3, a weaker donor ligand, would account for the effect of oxygen. Ample precedent exists for the accelerating effect of oxygen in reactions catalyzed by precursors activated by phosphine loss: these include hydrogenations via $RhCl(PPh_3)_3$ (32) and *trans*-$IrCl(CO)(PPh_3)_2$ (33), and hydrosilylation via $RuCl_2(PPh_3)_3$ (34).

As an alternative to the loss of a neutral donor ligand, chloride abstraction can also create a vacant site cis to alkylidene. Addition of $TlPF_6$ dramatically increases the activity of **5**: vigorous evolution of ethylene is observed at the surface of the $TlPF_6$ granules, and RCM is complete within 10 min at 70 °C. The need for elevated temperatures in this case may reflect the poor solubility of $TlPF_6$ in C_6D_6.

The low RCM activity of pyridine complex **6** is noteworthy, given the emerging view that substitution of phosphine by pyridine enhances metathesis activity by providing a more labile "placeholder" ligand (2, 9). The effect in **6** is evidently insufficient to confer metathesis activity at room temperature. RCM via this catalyst at 70 °C in air also results in essentially zero activity, owing to rapid decomposition, as indicated by the disappearance of the alkylidene signal in the ^{1}H NMR spectrum. This observation reinforces our suggestion that the activating effect of air in RCM via **5** is due to PCy_3 oxidation. The poor performance of **6** at 70 °C under N_2 (Table 2, entries 3, 9) is more unexpected. As catalysts **5** and **6** should afford the identical active species, the difference in their performance probably reflects a shorter lifetime for the py catalyst at elevated temperatures. We speculate that the slow, reversible release of PCy_3 from **5** leaves a pool of uninitiated (pre)catalyst that functions as a reservoir, conferring activity over a longer reaction period. The weakly coordinating phosphine oxide may also play a stabilizing role.

Conclusions

The foregoing describes deployment of the iminopyrrolato group as a new pseudohalide ligand in Ru-catalyzed olefin metathesis. RuCl(NN′)(PCy_3)(CHPh) (**5**) is activated via loss of phosphine. In consequence, the catalyst achieves maximum activity in the presence of air, offering a very convenient experimental protocol for metathesis chemistry. Replacement of the PCy_3 ligand in **5** by two pyridine ligands results in a dramatic decrease in both robustness and, more surprisingly, catalytic activity. Pyridine binding is sufficiently strong that **6** is inactive for RCM at room temperature. This observation may have more fundamental implications: it raises the possibility that the apparent stability of the Ru(σ-iminopyrrolato) motif against isomerization is an artifact of the nonlability of the ancillary (PCy_3, pyridine) ligands in **5** and **6**. Indeed, this may account for the inactivity of **6** at elevated temperature, as rapid π → σ isomerization following

ligand loss could provide a facile deactivation pathway. Studies examining this possibility within iminopyrrolato complexes containing labile donor ligands are in progress and will be reported in due course.

Experimental

Synthetic operations were performed under N_2 using standard Schlenk or drybox techniques, unless otherwise stated. Catalysis was carried out under N_2 or in air. Dry, oxygen-free solvents were obtained using an Anhydrous Engineering or a Glass Contour solvent purification system and stored over Linde 4 Å molecular sieves. $CDCl_3$ and C_6D_6 were dried over activated sieves (Linde 4 Å) and degassed by consecutive freeze–pump–thaw cycles. Diethyl diallylmalonate (Aldrich) was distilled from sodium under N_2. Grubbs catalyst **1** (35), 2-[(2,6-diisopropylphenyl)imino]pyrrole (HNN′) (28), and lithium 2-[(2,6-diisopropylphenyl)imino]pyrrolide·Et_2O (LiNN′·Et_2O) (17) were prepared according to literature procedures. ^{1}H NMR analysis of the lithium salt showed reproducibly 1 mol Et_2O, indicating formation of an ether solvate.

RuCl(κ²-*C*, *N*-ArN=CHC$_4$H$_3$N)(PCy$_3$)(CHPh) (5) (Ar = 2,6-*i*-Pr$_2$C$_6$H$_3$)

A solution of **1** (0.30 g, 0.36 mmol) in 6 mL C_6H_6 was stirred as LiNN′·Et_2O (190 mg, 0.57 mmol) in 6 mL C_6H_6 was added. Complete conversion to **5** was evident after 18 h at room temperature (RT), over which time the dark purple solution turned brown. The mixture was filtered through neutral alumina and stripped of solvent. The resulting red-brown powder was extracted with pentane (5 × 3 mL) and dried under vacuum. Yield: 183 mg (66%). Low yields were incurred by the high solubility of **5** in hydrocarbon solvents, including pentane. A small amount of the product was further purified by reprecipitation from Et_2O–C_6H_6 (1:1) by addition of cold pentane. Crystals suitable for X-ray analysis were grown at RT by slow evaporation of a toluene solution. IR (Nujol, cm^{-1}): 1569 (s). ^{1}H NMR ($CDCl_3$) δ: 19.65 (d, $^3J_{HP}$ = 11.0 Hz, 1H, Ru=C*H*), 7.84 (d, $^4J_{HP}$ = 3.9 Hz, 1H, C(*H*)=N), 7.50 (t, ^3J_H = 7.3 Hz, 1H, Ph, H_{para}), 7.39 (d, ^3J_H = 7.5 Hz, 2H, Ph, H_{ortho}), 7.18 (t, ^3J_H = 7.8 Hz, 2H, Ph, H_{meta}), 7.09–7.01 (m, 3H, Ar H_3, H_4 + pyr H_3), 6.88 (m, 1H, Ar H_3), 6.51 (br, 1H, pyr H_5), 6.18 (dd, $^3J_{HH}$ = 4.0, 1.6 Hz, 1H, pyr H_4), 3.05 (sept, $^3J_{HH}$ = 6.8 Hz, 1H, C*H*Me$_2$), 2.50 (br m, 4H, C*H*Me$_2$ + 3 × Cy C*H*), 1.91–1.10 (m, 36H, 15 × CH_2 + 2 × CH_3; includes methyl doublets at 1.28 (d, $^3J_{HH}$ = 6.7 Hz) and 1.19 (d, $^3J_{HH}$ = 6.7 Hz)), 0.66 (d, $^3J_{HH}$ = 6.6 Hz, 3H, CH_3), 0.45 (d, $^3J_{HH}$ = 6.6 Hz, 3H, CH_3). ^{13}C{^{1}H} NMR ($CDCl_3$) δ: 303.7 (d, Ru=*C*, $^2J_{CP}$ = 14.1 Hz), 163.0 (s, *C*H=N), 152.6 (d, $^3J_{CP}$ = 1.7 Hz, Ph C_i), 146.1 (s, Ar C_i), 142.9 (s, Ar *C*-*i*-Pr), 142.8 (d, $^3J_{CP}$ = 2.0 Hz, pyr C_2), 142.0 (s, Ar *C*-*i*-Pr), 141.7 (s, pyr C_5), 129.3 (s, Ph, C_o), 128.93 (s, Ph, C_m or C_p), 128.88 (s, Ph, C_m or C_p), 125.8 (s, Ar, C_4), 122.5 (s, Ar, 2 × C_3), 120.2 (s, pyr C_3), 114.0 (s, pyr C_4), 33.5 (d, *C*H of Cy, $^1J_{CP}$ = 20 Hz), 30.3, 29.4, 29.3, 27.8, 27.7, 27.6, 26.8, 26.4, 25.4, 24.2, 23.3, 21.9. ^{31}P{^{1}H} NMR ($CDCl_3$) δ: 49.20 (s). General procedure for RCM of diethyl diallylmalonate

In C$_6$D$_6$

Diethyl diallylmalonate (28 µL, 0.12 mmol) was added to a solution of Ru catalyst **5** or **6** (6 µmol) in 0.75 mL C_6D_6. Any additives were included at this point: $TlPF_6$ (10 mg, 29 µmol, 5 equiv. or 2 mg, 1 equiv.), PCy_3 (20 µL of a 0.30 mol/L solution in C_6D_6, 1 equiv.), or CuCl (6 mg, 60 µmol, 10 equiv.). The reaction was then stirred at 70 °C in an oil bath (where relevant), under an air or a N_2 atmosphere. Conversions were assessed by ^{1}H NMR analysis. The identity of the RCM product was verified by GC–MS analysis. EI-MS calcd. for $C_{11}H_{16}O_4$ $[M - H]^{+\cdot}$: 212; found: 212.

In neat substrate

Catalyst **5** (13 µmol) was added to diethyl diallylmalonate (500 µL, 2.1 mmol) in air. The reaction was stirred at 70 °C and aliquots were withdrawn periodically for ^{1}H NMR analysis.

X-ray crystallographic analysis of 5

Crystal and data collection parameters for **5** are provided in Table 3.[3] A suitable crystal was selected, mounted on a thin glass fiber using paraffin oil, and cooled to the data collection temperature. Data were collected on a Bruker AXS SMART 1 k CCD diffractometer using 0.3° ω-scans at 0°,

R indices (all data)	R_1 = 0.073 1, wR_2 = 0.103 8
Largest diff. peak and hole (e Å^{-3})	0.562 and –1.298

[a]Definition of R indices: $R_1 = \Sigma(F_o - F_c)/\Sigma(F_o)$; $wR_2 = [\Sigma[w(F_o^2 - F_c^2)^2]/\Sigma[w(F_o^2)^2]]^{1/2}$.

90°, and 180° in ϕ. Initial unit-cell parameters were determined from 60 data frames collected at different sections of the Ewald sphere. Semi-empirical absorption corrections based on equivalent reflections were applied (36). Systematic absences in the diffraction data are consistent with *C*2/*c* (No. 15) and *Cc* (No. 9). Solution in the centrosymmetric space group option yielded chemically reasonable and computationally stable results of refinement. The structure was solved by direct methods, completed with difference Fourier syntheses, and refined with full-matrix least-squares procedures based on F^2. One of the cyclohexyl rings in the phosphine ligand was found disordered in two conformations with an approximately 1:1 refined site occupancy distribution. Each was restrained to an ideal chair conformation, with chemically identical atoms refined with common atomic displacement parameters. All hydrogen atoms were treated as idealized contributions. All scattering factors are contained in the SHELXTL 6.12 program library (36).

Rhodium-catalyzed C-H–CO–olefin coupling reactions — A chelation-assisted direct carbonylation at the ortho C—H bond in the benzene ring of 2-arylpyridines[1]

Naoto Chatani, Takeshi Uemura, Taku Asaumi, Yutaka Ie, Fumitoshi Kakiuchi, and Shinji Murai

Abstract: The reaction of 2-arylpyridines with ethylene and carbon monoxide in the presence of a catalytic amount of $Rh_4(CO)_{12}$ results in selective carbonylation at the ortho C—H bond. The reaction is heavily dependent on the solvents used, with DMA (*N*,*N*-dimethylacetamide) being the solvent of choice. Steric factors are also important determinants of the efficiency of the reaction.

Key words: C—H bond activation, carbonylation, chelation, rhodium, carbon monoxide.

Résumé : La réaction des 2-arylpyridines avec l'éthylène et le monoxyde de carbone, en présence d'une quantité catalytique de $Rh_4(CO)_{12}$ conduit à une carbonylation sélection au niveau de la liaison C—H en ortho. La réaction dépend fortement de la nature du solvant utilisé et le DMA (*N*,*N*-diméthyacétamide) est le solvant de choix. Les facteurs stériques sont aussi déterminants dans l'efficacité de la réaction.

Mots clés : activation d'une liaison C—H, carbonylation, chélation, rhodium, monoxyde de carbone.

[Traduit par la Rédaction]

Introduction

The chelation-assisted cleavage of unreactive bonds has recently emerged as one of the most useful and effective methods for developing the new transition metal catalyzed reactions. Various types of catalytic reactions, such as C-H–olefin coupling (1, 2), C-H phenylation (3, 4), C-H oxidation (5), C-H silylation (6), C—C bond cleavage (7, 8), C—F bond cleavage (9), C—O bond cleavage (10), and O—H bond cleavage (11) have been reported. A variety of functional groups can be used as chelating groups, such as a carbonyl oxygen, sp^2 nitrogen, and sulfur. Various late transition metals have been used as catalysts. The methodology is also applicable to the C-H–CO–olefin coupling of nitrogen-containing compounds in which the coordination of sp^2 nitrogen of the substrates to the catalysts is a key step in the progress of the reactions (12). In most of the carbonylation reactions at C—H bonds reported thus far, only ruthenium carbonyl complexes have shown a high catalytic activity, and a rhodium carbonyl complex was also found to be fairly active. Other metals, such as Co, Pd, Ni, and Ir, were not active. However, we recently found that rhodium complexes also show a high degree of catalytic activity in C-H–CO–olefin coupling reactions of *N*-phenylimidazoles when *N*,*N*-dimethylacetamide (DMA) is used as the solvent (12*o*). This prompted us to reexamine various nitrogen-containing compounds, which are known to undergo the direct carbonylation of C—H bonds catalyzed by $Ru_3(CO)_{12}$ (12), in the $Rh_4(CO)_{12}$-catalyzed C-H–CO–olefin coupling in DMA. As expected, 2-arylpyridines were also found to undergo direct carbonylation at the ortho C—H bonds in the benzene ring in the presence of $Rh_4(CO)_{12}$. In this paper, we wish to report on the direct, Rh-catalyzed carbonylation of a C—H bond in the benzene ring of 2-arylpyridines based on chelation assistance.

Results and discussion

The reaction of 2-phenylpyridine (**1a**) was first carried out under the optimal reaction conditions employed in $Ru_3(CO)_{12}$-catalyzed carbonylation reactions, but using $Rh_4(CO)_{12}$ as the catalyst. Thus, the reaction of 2-phenylpyridine (**1a**, 2 mmol) with carbon monoxide (20 atm at room temperature (r.t.)) and ethylene (7 atm) (1 atm =

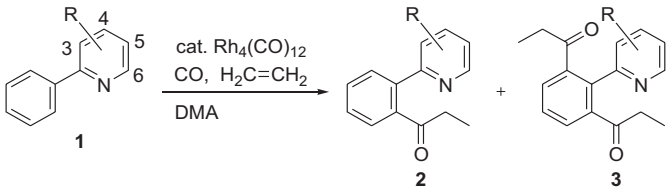
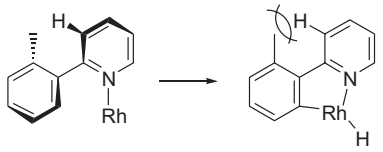
101.325 kPa) in the presence of $Rh_4(CO)_{12}$ (0.05 mmol) in toluene (6 mL) at 160 °C for 20 h gave 1-[2-(2-pyridinylphenyl)]-1-propanone (**2a**) in only 12% yield, along with 88% unreacted **1a** (eq. [1], the numbers in parentheses are the recoveries for the starting materials). The effect of the solvent on the carbonylation was next examined. As a result, it was found that the use of 1,3-dimethyl-2-imidazolidinone (DMI) and DMA dramatically improve the yield of **2a** to 53% and 57%, respectively. In addition to the screening of solvents, the reaction conditions were again optimized, e.g., the pressure of both CO and ethylene and the additives used, but this did not result in increased yields. It is noteworthy, however, that nearly comparable yields are obtained, even when ordinary solvents, such as dioxane and THF, are used when the reaction is carried out at an elevated temperature, such as 180 °C. At lower temperatures, such as 140 and 160 °C, DMA was the preferred solvent.



The effects of the substituent on the pyridine ring were examined (Table 1). Changing the reaction temperatures (160 and 180 °C) and reaction times (10 and 40 h) had no significant effect on the yield of **1a**. The presence of a methyl group at the 4-position and the 5-position, as in **1c** and **1d**, respectively, did not improve the product yields, although this has been reported, in some cases, to be effective (12*k*, 12*m*). However, the presence of a methyl group at the 3-position, as in **1b**, resulted in a decreased product yield because of the steric hindrance between the ortho hydrogen on the benzene ring and the methyl group on the pyridine ring in the cleavage of a C—H bond.

The reaction of **1e** led to a low conversion and gave the corresponding ketone **2e** in 16% yield even for a reaction time of 40 h because of steric hindrance around the pyridine nitrogen. This indicates that the coordination of the pyridine nitrogen to Rh is important for the carbonylation at C—H bonds to proceed with a high efficiency, as has been observed in previous Ru-catalyzed carbonylation reactions (12).



As shown in Table 2, the presence of an electron-donating group at the meta and para positions on the phenyl ring gave the corresponding ketones in moderate yields. On the other hand, the presence of a methyl group at the ortho position on the phenyl ring, as in **4a**, led to a dramatic decrease in the product yield. This is also due to steric congestion between the tolyl ring and the pyridine ring, as in the case of **1b**. A methoxy group at the ortho position, however, had no effect on the product yield. The reaction of **4f**, bearing a trifluoromethyl group, gave the corresponding carbonylation products **5f** and **6f**, albeit in low yields.

In addition to the benzene ring, the carbonylation can be applied to naphthalene and thiophene rings as well. The reaction of 1-naphtylpyridine (**7**) gave the ketone in only 22% yield. On the other hand, the reaction of 2-naphtylpyridine (**9**) afforded the corresponding product **10** in good yield with a high regioselectivity. The carbonylation took place selectively at the β position. It is likely that such a dramatic difference is derived from the steric repulsion, as mentioned previously. These are in sharp contrast to the results for the $Ru_3(CO)_{12}$-catalyzed reactions of **7** and **9**, which both gave the corresponding carbonylation products **8** and **10** in 88% and 86% yields, respectively, in a $Ru_3(CO)_{12}$-catalyzed reaction (12*d*). Thiophenylpyridines **11** and **13** underwent carbonylation to give the corresponding ketones **12** and **14** in good yields. In the case of **11**, a small amount of unidentified product was also obtained as a by-product.

Scheme 1. A proposed reaction mechanism.

As observed in the case of **1b**, **1e**, **4e**, and **7** in the Rh-catalyzed reaction, steric factors had a dramatic effect on the progress of the reaction. To obtain information concerning the reaction mechanism and to make a comparison with the Ru-catalyzed reaction, the reaction of **15**, **17**, **19**, and **21** were conducted (eqs. [2]–[5], the numbers in parentheses are the recoveries for the starting materials). The reaction of **15** in which the sp^2 nitrogen and the C—H bond are in the same plane with CO and ethylene gave the carbonylated product **16** in high yield. Although the reaction of **17**, **19**, and **21** in the presence of $Ru_3(CO)_{12}$ proceeded,[4] the rhodium-catalyzed system did not.

A thiazole ring could also function as a directing group in the Rh-catalyzed carbonylation as shown in eqs. [6] and [7] (the numbers in parentheses are the recoveries for the starting materials).

A proposed mechanism is pictured in Scheme 1. The proposed mechanism for the Rh-catalyzed carbonylation of 2-phenylpyridine is essentially the same as that for the Ru-catalyzed reactions that have previously been reported (12*d*). The pyridine nitrogen in the substrate coordinates to the Rh, and the site-selective cleavage of the ortho C—H bond takes place to provide the Rh-H species **29**. The hydrometallation of ethylene followed by the insertion of CO gives the acyl-Rh intermediate **31** from which reductive elimination via the zwitterionic intermediate **32** affords the carbonylated product **2a**, and regenerates the active Rh species. We speculate that the coordination of the sp^2 nitrogen to Rh complexes is maintained during the reaction. In the key intermediates **29**–**31**, pyridine and the phenyl group must be coplanar. Since the presence of a substituent at the 2-position of the phenyl ring and (or) the 3-position of the pyridine ring, as in **1b**, **4a**, **7**, **17**, **19**, **21**, prevents coplanarity from being achieved, the reaction does not proceed. In contrast, coordination of the sp^2 nitrogen might not be always necessary in the Ru-catalyzed reaction. In fact, Goldman and co-workers (13) quite recently reported that coordination is not required in the C—H bond cleavage step, and that cleavage at the meta and para positions is kinetically more favorable than that at the ortho position, however the chelated ortho isomer is thermodynamically stable. On the other hand, coordination is required for the cleavage of C—H bonds and reductive elimination. This explains why the reaction is significantly affected by steric factors. The role of DMA as the solvent is not clear at the present time; one possibility is the stabilization of **32** by the polar solvent. Another possibility is the generation of rhodium nanoparticles from the rhodium cluster in DMA, which is very active.

In summary, rhodium complexes were also found to catalyze the direct carbonylation of 2-arylpyridines. The dramatic solvent effect of DMA could permit the scope of applicable substrates in carbonylation reactions to be expanded and significantly improve product yield. Detailed studies of the mechanism of this carbonylation, especially regarding the solvent effect of DMA and the difference between the Rh and Ru catalytic systems, and an examination of new types of C-H carbonylation reactions catalyzed by metal complexes other than Ru and Rh, are currently underway.

Experimental

General methods

^{1}H NMR and ^{13}C NMR spectra were recorded on a JEOL JMN-270 spectrometer in $CDCl_3$ with tetramethylsilane as the internal standard. Data are reported as follows: chemical shifts in ppm (δ), multiplicity (singlet (s), doublet (d), triplet (t), quartet (q), multiplet (m), and complex (c)), coupling

[4] The $Ru_3(CO)_{12}$-catalyzed reaction of **17** gave **20** in 54% yield along with the recovery of **17** in 44% yield (in toluene at 160 °C for 40 h). The $Ru_3(CO)_{12}$-catalyzed reaction of **19** gave **20** in 40% yield along with the recovery of **19** in 58% yield (in toluene at 160 °C for 40 h). The $Ru_3(CO)_{12}$-catalyzed reaction of **21** gave **23** in 24% yield along with the recovery of **24** in 74% yield.

constant (Hz), integration, and interpretation. IR spectra were obtained on a Hitachi 270-50 spectrometer or a Horiba FT-700 spectrometer. Mass spectra were obtained on a Shimadzu GC–MS-QP 5000 instrument with ionization voltages of 70 eV. Elemental analyses were performed by the Elemental Analysis Section of Osaka University. Analytical GC was carried out on a Shimadzu GC-14A gas chromatograph equipped with a flame ionization detector. Column chromatography was performed with SiO_2 (Merck SilicaGel 60, 230–400 mesh).

Materials

N,*N*-Dimethylacetamide (DMA) was distilled over BaO. Toluene was distilled over CaH_2. $Rh_4(CO)_{12}$ was purchased from Strem Chemicals Inc. and was used as received. $Ru_3(CO)_{12}$ was prepared from $RuCl_3 \cdot nH_2O$ and carbon monoxide according to the literature procedure (14) and used after recrystallization from hexane. 2-Phenylpyridine (**1a**), 2-(4-methylphenyl)pyridine (**1c**), and benzo[*h*]quinoline (**14**) were obtained commercially. Substituted 2-arylpyridines were obtained from the corresponding substituted arylbromides or arylboronic acids and 2-bromopyridines using the Kumada–Tamao–Corriu coupling procedure (15) or the Suzuki–Miyaura coupling procedure (16). Spectral data for known compounds have already been reported.[5,6] The purity of all known compounds was verified by ^{1}H NMR, ^{13}C NMR, and GC analyses.

General procedure for the Rh-catalyzed carbonylation reactions of 2-arylpyridines

In a 50 mL stainless autoclave were placed $Rh_4(CO)_{12}$ (37 mg, 0.05 mmol), 2-phenylpyridine (310 mg, 2 mmol), and DMA (6 mL). After flushing the system was with 10 atm (1 atm = 101.325 kPa) of ethylene three times, it was pressurized with ethylene to 7 atm and then with carbon monoxide to an additional 20 atm (1 atm = 101.325 kPa). The autoclave was then immersed in an oil bath at 160 °C. After 10 h had elapsed, it was removed from the oil bath, allowed to cool for ca. 1 h, and the gases were then released. The contents were transferred to a round-bottomed flask with EtOAc. After evaporation, the resulting residue was subjected to column chromatography on silica gel with hexane–EtOAc as the eluent to give 1-[2-(2-(pyridinyl)phenyl)]-1-propanone (**2**) (264 mg, 62% yield) and 1-[2-(3-propionyl-2-pyridinyl)phenyl]-1-propanone (**3**) (34 mg, 6% yield) as an oil.

Oxidative carbonylation of aniline with new cobalt catalytic systems[1]

Aránzazu Orejón, Aída Castellanos, Pilar Salagre, Sergio Castillón, and Carmen Claver

Abstract: New neutral cobalt(II) complexes containing 2,9-bis(2-hydroxyphenyl)-1,10-phenanthroline and 2,9-bis(2-hydroxyphenyl)-2,2′-bipyridine ligands have been synthesized. These complexes are active catalysts in the oxidative carbonylation of aniline in 1-butanol and NaI as a promoter. The principal products obtained are *N*,*N*′-diphenylurea and 1-butyl-*N*-phenylcarbamate.

Key words: cobalt, oxidative carbonylation, aniline, *N*,*N*′-diphenylurea, 1-butyl-*N*-phenylcarbamate.

Résumé : Des complexes du cobalt(II) contenant les ligands 2,9-bis(2-hydroxyphenyl)-1,10-phénanthroline et 2,9-bis(2-hydroxyphényl)-2,2′-bipyridine ont été synthétisés. Ces complexes sont des catalyseurs actifs pour la réaction de carbonylation oxydante de l'aniline dans le 1-butanol, en utilisant le NaI comme promoteur. Les produits principaux de la réaction sont le *N*,*N*′-diphénylurée et le *N*-phenylcarbamate de 1-butyle.

Mots clés : cobalt, carbonylation oxydante, aniline, *N*,*N*′-diphénylurée, *N*-phenylcarbamate de 1-butyle.

Introduction

Industrially important materials, such as high-performance plastics, polyurethane elastomers, and adhesives, are usually obtained from isocyanates. The reaction of phosgene with amines is one of the most important industrial methods for the formation of isocyanates, carbamates, and ureas (1). As there are restrictions on the use of very toxic materials such as phosgene, and since large amounts of corrosive HCl are produced as a side product in the conversion of aromatic amine to isocyanate, interest has been increasing in the development of alternative methods for isocyanate production (1).

One of the proposed approaches is to first synthesize the carbamate, either by the oxidative carbonylation of amines or by the reductive carbonylation of nitro compounds in the presence of an alcohol, followed by thermal elimination of alcohol to form isocyanates (2) (Scheme 1).

The interest in developing the reductive carbonylation of nitro compounds is demonstrated by the numerous patents and papers in the literature (3). However, the commercial production of isocyanates by this route has not been industrially developed, mainly because the use of a precious metal such as palladium is necessary and also because the process involves three CO molecules and, unless CO is available at a negligible cost, the process is uneconomical.

With regard to oxidative carbonylation, several processes based on metal catalysts promoting the formation of carbamates from organic hydroxyl compounds, carbon monoxide, amines, and an oxygen-containing oxidizing agent have also been reported (4, 5). It is known that cobalt complexes are active catalysts in the oxidative carbonylation of amines. The most widely used cobalt complexes are *N*,*N*′-bis(salicylidene)ethylenediaminocobalt(II) ([Co(salen)], **1**), [Co(tetrakis-(4-methoxyphenyl)porphine)], [Co(phthalocyanine)], and [CoTTP] (TTP = mesotetraphenylporphinato dianion) (4*b*, 5). In this context, [Co(salen)] (**1**) catalyzes the oxidative carbonylation of ortho-, meta-, and para-substituted aromatic primary amines in methanol to give ureas, isocyanates, carbamates, and azo derivatives (5).

Concerning the mechanism of this reaction, it has been proposed that the oxidative reaction takes place through the formation of a superoxo complex of cobalt(III), known to be formed by coordination of the dioxygen on the [Co(salen)]-type complexes. These complexes undergo carbonylation to give the carbamoyl complexes that could be the origin of the free isocyanate or the carbamate (5).

Modification of [Co(salen)] complexes has enabled the improvement of the efficiency of many catalytic processes, but as far as we know cobalt complexes with modified salen ligands have never been studied before in the oxidative carbonylation of amines. In this paper, we study the reaction of oxidative carbonylation with salen-modified complexes such as the already known complexes **2**–**4** (6) to determine the effects in the catalytic activity of electron-donating **2** and electron-withdrawing groups **3** and **4** in the aromatic rings. We also prepared the new complexes **5** and **6** in which the

imine groups have been substituted by the heteroaromatic rings 2,2′-bipyridine and 1,10-phenathroline (Scheme 2).

Experimental

General procedures

All syntheses were carried out in a nitrogen atmosphere at room temperature using standard Schlenk techniques. Solvents were distilled and deoxygenated prior to use unless otherwise stated. Aniline and the catalyst *N*,*N*-bis(salicylidene)ethylenediaminocobalt(II) are commercial products. Cobalt–salen derivative complexes were synthesized according to literature procedures (6). Aniline was distilled with Na prior to use. Elemental analyses were carried out in a Carlo Erba microanalyser EA 1108. ^{1}H NMR spectra were recorded on a Varian Gemini spectrometer with a ^{1}H resonance frequency of 400 MHz.

Synthesis of the ligands

Synthesis of 2,9-bis(2-hydroxyphenyl)-1,10-phenanthroline (7)

n-Butyllithium (16.2 mL, 25.8 mmol of a 1.6 mol/L solution) was added to a stirred solution of 2-bromophenol (1.2 mL, 11.3 mmol) in 40 mL of anhydrous diethyl ether. After 24 h at room temperature, the white suspension obtained was slowly added to a warm solution (50 °C) of 1,10-phenanthroline (0.388 g, 2.15 mmol) in 25 mL of anhydrous toluene. Immediately, a red solution was formed, which was maintained at 50 °C for 48 h. The resulting brown solution was then cooled to 0 °C and slowly hydrolyzed with H_2O

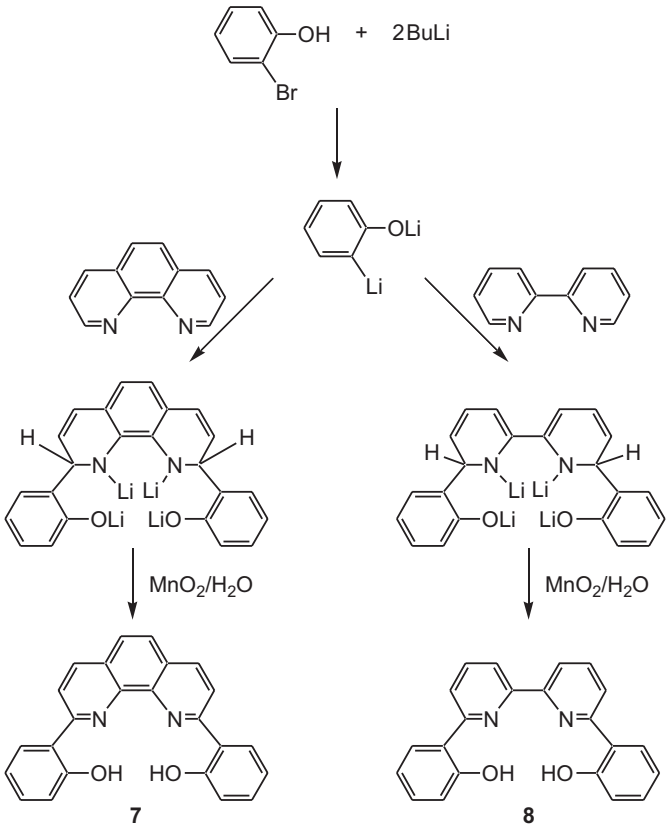
(20 mL). The organic phase was separated and the aqueous phase was extracted with ethyl acetate. The organic phases were combined, 2 g of MnO_2 (Fluka No. 63548) was added, and the reaction mixture was stirred at room temperature for 24 h. After this time, the solution was dried over $MgSO_4$ for 2 h and then filtered through Celite®. The solution was evaporated to dryness with a rotatory evaporator and purified using flash chromatography with a mixture of hexane – ethyl acetate (2:1) to yield 0.253 g (33% yield) of **7** as a yellow solid. ^{1}H NMR (400 MHz, DMSO, 298 K) δ: 7.03 (td, *J* = 6.6, 1.5 Hz, 2H, arom), 7.09 (dd, *J* = 8.1, 0.9 Hz, 2H, arom), 7.42 (td, *J* = 6.9, 1.5 Hz, 2H, arom), 8.08 (s, 2H, phenanthroline), 8.28 (dd, *J* = 7.8, 1.4 Hz, 2H, arom), 8.61 (d, *J* = 8.7 Hz, 2H, phenanthroline), 8.70 (d, *J* = 8.7 Hz, 2H, phenanthroline), 13.95 (s, 2H, -OH). ^{13}C NMR (300 MHz, DMSO, 298 K) δ: 117.86, 119.16, 120.36, 121.31, 126.29, 127.38, 128.61, 132.0, 138.29, 141.57, 157.12, 159.11. FAB-MS *m*/*z*: 364.4 [M]. Elemental anal. calcd.: C 79.1, H 4.42, N 7.69; found: C 78.4, H 4.44, N 7.29.

Synthesis of 2,9-bis(2-hydroxyphenyl)-2,2′-bipyridine (8)



n-Butyllithium (16.2 mL, 25.8 mmol of a 1.6 mol/L solution) was added to a stirred solution of 2-bromophenol (1.2 mL, 11.3 mmol) in 40 mL of anhydrous diethyl ether. After 24 h at room temperature, the white suspension obtained was slowly added to a warm solution (50 °C) of 2,2′-bipyridine (0.35 g, 2.3 mmol) in 25 mL of anhydrous toluene. Immediately, a red solution was obtained, which was maintained at 50 °C for 48 h. The brown solution obtained was then cooled to 0 °C and hydrolyzed slowly with H_2O (20 mL). The organic phase was separated and the aqueous phase was extracted with ethyl acetate. The organic phases were combined, 2 g of MnO_2 (Fluka No. 63548) was added, and the reaction mixture was stirred at room temperature for 24 h. After this time, the solution was dried over $MgSO_4$ for 2 h and then filtered through Celite®. The solution was evaporated to dryness with a rotatory evaporator and purified using flash chromatography with a mixture of CH_2Cl_2–hexane (5:1) to yield 0.11 g (14% yield) of **8** as a yellow solid. ^{1}H NMR (400 MHz, DMSO, 298 K) δ: 6.98 (t, *J* = 7.2 Hz, 2H, arom), 7.08 (d, *J* = 8.4 Hz, 2H, arom), 7.37 (td, *J* = 7.2, 0.8 Hz, 2H, arom), 7.87 (dd, *J* = 8.0, 0.8 Hz, 2H, arom), 8.02 (m, 4H, bipyridine), 8.13 (dd, *J* = 7.2, 1.6 Hz, 2H, bipyridine), 14.20 (s, 2H, -OH). ^{13}C NMR (300 MHz, DMSO, 298 K) δ: 117.86, 119.16, 120.36, 121.31, 126.29, 127.38, 128.61, 132.0, 138.29, 141.57, 157.12, 159.11. Elemental anal. calcd.: C 77.63, H 4.74, N 8.23; found: C 77.00, H 4.78, N 7.98.

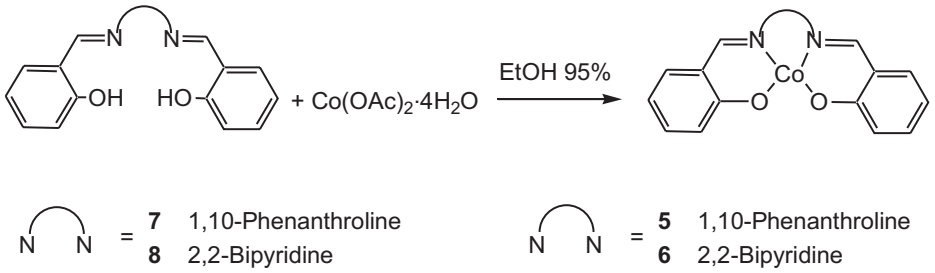
Synthesis of the neutral cobalt(II) complexes

Synthesis of 2,9-bis(2-hydroxyphenyl)-1,10-phenanthroline cobalt (5)

In a three-necked round flask equipped with a pressure-equalizing funnel and a water condenser, 2,9-bis(2-hydroxyphenyl)-1,10-phenanthroline (**7**) (0.189 g, 0.52 mmol) was dissolved in 95% ethanol (12 mL) under a nitrogen atmosphere. A solution of $Co(OAc)_2{\cdot}4H_2O$ (0.121 g, 0.486 mmol) in 3 mL of water was introduced into the pressure-equalizing funnel and added dropwise over the reluxing solution of the ligand under a nitrogen atmosphere. Initially, the solution became orange and a red precipitate started to appear. After 1 h of heating, the solution was immersed in a cold bath. The solid was filtered and washed with water and absolute ethanol. The red precipitate was dried under vacuum to yield 0.192 g (94% yield) of **5**. Elemental anal. calcd.: C 68.42, H 3.35, N 6.65; found: C 69.00, H 3.75, N 6.69.

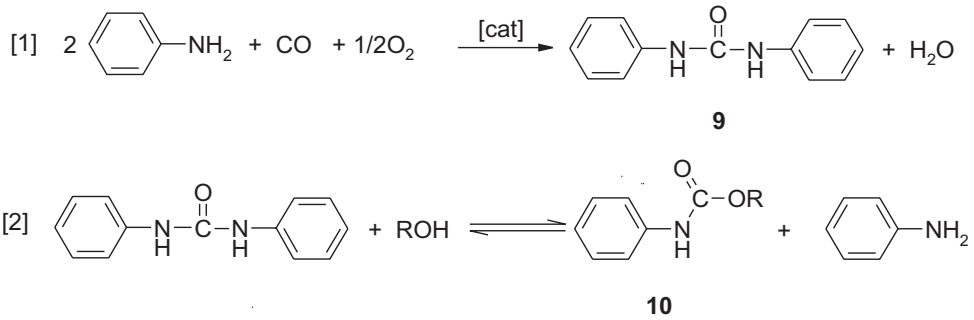
Scheme 3. Method for the preparation of 9-bis(2-hydroxyphenyl)-1,10-phenantroline (**7**) and 2,9-bis(2-hydroxyphenyl)-2,2′-bipyridine (**8**) ligands.

Synthesis of 2,9-bis(2-hydroxyphenyl)-2,2′-bipyridine cobalt (6)



In a three-necked round flask equipped with a pressure-equalizing funnel and a water condenser, 2,9-bis(2-hydroxyphenyl)-2,2′-bipyridine (**8**) (0.04 g, 0.12 mmol) was dissolved in 95% ethanol (3 mL) under a nitrogen atmosphere. A solution of $Co(OAc)_2{\cdot}4H_2O$ (0.03 g, 0.11 mmol) in 0.6 mL of water was introduced into the pressure-equalizing funnel and added dropwise to the refluxing solution of the ligand. Initially, the solution became orange and a brown precipitate started to appear. After 1 h of heating, the solution was immersed in a cold bath. The solid was filtered, then washed with water and absolute ethanol. The brown precipitate was dried in a vacuum desiccator to yield 0.046 g (90% yield) of **6**. Elemental anal. calcd.: C 66.50, H 3.55, N 7.05; found: C 66.12, H 3.76, N 6.90.

General procedure for the oxidative carbonylation of amines



A mixture of the substrate (13.2 mmol), cobalt complex (0.25 mmol), NaI (2.72 mmol for sust/NaI = 5 or 1.89 mmol for sust/NaI = 7), and 1-butanol (20 mL) was charged in a 100 mL autoclave. The autoclave was flushed with carbon

Scheme 5. Oxidative carbonylation of aniline.

monoxide and pressurized to 50.1 bar (1 bar = 100 kPa), then carefully pressurized with oxygen to a total pressure of 52.7 bar (4.93% O_2–CO) (1 bar = 100 kPa). (*Caution!* Reverse addition, i.e., O_2 before CO, is dangerous). The autoclave was heated electrically to the desire temperature and stirred for 3 h. The reaction mixture was cooled to room temperature, then concentrated by rotatory evaporation. The crude material was analyzed by ^{1}H NMR in deuterated acetone.

Results and discussion

Synthesis of the ligands 9-bis(2-hydroxyphenyl)-1,10-phenanthroline (7) and 2,9-bis(2-hydroxyphenyl)-2,2′-bipyridine (8)

In this paper we prepared the ligands 9-bis(2-hydroxyphenyl)-1,10-phenanthroline (**7**) and 2,9-bis(2-hydroxyphenyl)-2,2′-bipyridine (**8**) (Scheme 3) following the method published by Burger and Baumeister (7).

This method is shown in Scheme 3. First, a solution of *n*-butyllitium (1.6 mol/L) in hexanes was added to a solution of 2-bromophenol in diethyl ether. After 12 h at room temperature, the lithium salt was obtained as a white suspension. This salt was added dropwise to a solution of 1,10-phenathroline or 2,2′-bipyridine in toluene, which was heated at 50 °C. The solution became red and after 48 h at 50 °C, hydrolysis and treatment with MnO_2 led to the isolation of the ligands. The yields were generally low, but attempts to increase them failed.

Synthesis of the neutral cobalt(II) complexes 9-bis(2-hydroxyphenyl)-1,10-phenanthrolinecobalt(II) (5) and 2,9-bis(2-hydroxyphenyl)-2,2′-bipyridinecobalt(II) (6)

Reaction of the ligands 9-bis(2-hydroxyphenyl)-1,10-phenanthroline (**7**) and 2,9-bis(2-hydroxyphenyl)-2,2′-bipyridine (**8**) with $Co(OAc)_2 \cdot 4H_2O$ in an ethanolic solution gave the 9-bis(2-hydroxyphenyl)-1,10-phenanthrolinecobalt(II) (**5**) and 2,9-bis(2-hydroxyphenyl)-2,2′-bipyridinecobalt(II) (**6**) in good yields (Scheme 4). Elemental analysis confirmed the formation of the cobalt complexes.

Oxidative carbonylation of aniline

To avoid the use of phosgene, carbamates were synthesized from the oxidative carbonylation of aniline according to the following reaction (Scheme 5), where aniline reacted catalytically with carbon monoxide and oxygen to form *N*,*N*′-diphenylurea, which further reacted to form the carbamate.

Reaction [1] (Scheme 5) is a catalytic reaction, while rxn. [2] (Scheme 5) is essentially thermal. However, the second reaction can be catalysed by Lewis acids. Although the two steps are independent, the alcoholisis of the urea to form the carbamate releases aniline, which is the starting material in the first reaction. Both reactions therefore become dependent on one another, and full conversion is achieved by an iterative process.

Therefore, at a given temperature, the reaction of the conversion of ureas into carbamates will be similar and the ratio of carbamate to urea will be an indicator of the activity of the catalysts in the oxidative carbonylation. Iodide as the additive has a beneficial effect on the reaction rate (8).

Results for the cobalt precursors **1**–**6** are summarized in Table 1. To compare the activity with other cobalt catalytic systems, the [Co(salen)] complex **1** was first used as the catalyst precursor in the oxidative carbonylation of aniline. Initially, the reaction was performed in 1-butanol at 130 °C (internal temperature of 110 °C) at 60 bar (1 bar = 100 kPa) and with NaI as the additive. Carbamate (44%) and 56% of urea were obtained with a total conversion (Table 1, entry 1). When *tert*-butyl groups were introduced into the aromatic rings of the salen ligand (precursor **2**) only the urea derivative was obtained (Table 1, entry 3). As expected, when the

[a]0.26 mmol catalyst; 3%–5% O_2/CO; 13.2 mmol aniline; 20 mL 1-BuOH; 2.72 mmol NaI; P = 60 bar (1 bar = 100 kPa); (sust/NaI = 7, sust/cat = 50).
[b]Total conversion in 3 h.

reaction with the [Co(salen)] precursor was performed at 160 °C (internal temperature of 130 °C), the ratio of carbamate to urea increased to 62:38 (Table 1, entry 2).

To study the effect of withdrawing substituents in the ligand, we also examined the activity of complexes **3** and **4** with nitro groups in the phenyl rings of the ligand. Introducing a nitro group in the para position to the oxygen atom led to an active catalyst that provided a similar carbamate:urea ratio to the one obtained using [Co(salen)] as the catalyst precursor (Table 1, entries 2 and 4). When the nitro group was present in the ring bearing the amino groups (precursor **4**), the results were better, and 83% of the carbamate was obtained with a carbamate:urea ratio of 83:17 (Table 1, entry 5).

The cobalt precursor **5** at 130 °C (internal temperature of 110 °C) provided urea in an almost exclusive way (Table 1, entry 6), while at 160 °C the ratio of carbamate to urea increased to 28:72 (Table 1, entry 7), but this was smaller than when [Co(salen)] (**1**) was used (Table 1, entry 2), so the activity of this complex was low. Therefore, when the temperature increased, the overall yield of the process also increased, mainly because the conversion rate of urea into carbamate increased.

The cobalt compound with the bipyridine ligand **6** was also active at 160 °C (internal temperature of 130 °C) in the oxidative carbonylation of aniline. Complete conversion was obtained and the carbamate:urea ratio was 50:50 (Table 1, entry 8), i.e., the activity was higher than with complex **5**, which had a phenathroline ligand (Table 1, entry 7).

Conclusions

New cobalt catalytic systems **5** and **6** have been prepared and characterized.

Complexes **5** and **6**, together with the already known **1**–**4**, were active as catalyst precursors in the oxidative carbonylation of aniline to give *N*,*N*′-diphenylurea and carbamates.

The use of [Co(salen)] derivatives with withdrawing groups in the ligand, particularly in the case of complex **4**, led to a higher conversion into the carbamate than with complex **1**. This shows that the modification of salen complexes can be an efficient way to improve conversions in the oxidative carbonylation of amines.

Hydration of the carbonyl group — Acetic acid catalysis in the co-operative mechanism[1]

Yih-Huang Hsieh, Noham Weinberg, Kiyull Yang, Chan-Kyung Kim, Zheng Shi, and Saul Wolfe

Abstract: In a co-operative reaction, solvent molecules, specifically water molecules, participate actively in the mechanism to circumvent the formation of charged intermediates. This paper extends our earlier theoretical treatment of the neutral co-operative hydration of acetone to include general acid catalysis by acetic acid. As before, the predominant neutral channel employs three catalytic water molecules. The principal acetic acid catalyzed channels employ one catalytic water molecule and, in approximately equal proportions, one or both oxygens of the carboxyl group. The theoretical rate constant for general acid catalysis is calculated to be 0.49 M^{-1} s^{-1} at 298 K. This compares to an estimated experimental value of 0.30 M^{-1} s^{-1} for acetic acid catalyzed hydration of acetone at 298 K in water solvent, determined by using the ^{18}O-isotope shift in the ^{13}C NMR spectrum of 2-^{13}C-labelled acetone as a kinetic probe. It is concluded that the notion of co-operativity can be extended to include general acid catalysis of the hydration of a carbonyl group in water solvent. This creates an obvious problem for the generally accepted view that multistep ionic mechanisms are operative in the low dielectric media that exist at the active sites of hydrolytic enzymes. The relevance of this finding to the mechanisms of action of β-lactam antibiotics has been noted.

Key words: hydration, reaction mechanism, co-operativity, general acid catalysis, ab initio, SCRF, ^{18}O-isotope shift.

Résumé : Dans une réaction coopérative, des molécules de solvants, en particulier des molécules d'eau, participent activement au mécanisme afin de contourner la formation d'intermédiaires chargés. Dans ce travail, on étend notre traitement théorique antérieur de l'hydratation coopérative neutre de l'acétone afin d'y incorporer la catalyse acide générale par l'acide acétique. Tel qu'observé antérieurement, la voie neutre prédominante fait appel à trois molécules d'eau catalytiques. Les voies principales catalysées par l'acide acétique font appel à une molécule d'eau catalytique et, dans des proportions approximativement égales, un ou les deux atomes d'oxygène du groupe carboxyle. Il a été calculé que la constante de vitesse théorique pour la catalyse acide générale est de 0,49 M^{-1} s^{-1} à 298 K. Ceci se compare à l'évaluation de la valeur expérimentale de 0,30 M^{-1} s^{-1} pour l'hydratation catalysée par l'acide acétique, à 298 K, dans l'eau comme solvant, telle que déterminée en faisant appel au déplacement chimique du ^{18}O dans les spectres RMN d'une sonde cinétique de ^{13}C d'acétone marquée au ^{13}C en position 2. On en conclut que la notion de coopération peut être étendue de façon à inclure la catalyse acide générale de l'hydratation d'un groupe carbonyle dans l'eau. Cette conclusion crée un problème évident pour la façon généralement acceptée de considérer cette réaction qui serait sensée impliquer des mécanismes ioniques par étape dans les milieux de faibles constantes diélectriques qui existent au niveau des sites actifs des enzymes hydrolytiques. On note la pertinence de ces observations sur les mécanismes d'action des antibiotiques à base de β-lactames.

Mots clés : hydratation, mécanisme réactionnel, coopération, catalyse acide générale, ab initio, SCRF, déplacement chimique du ^{18}O.

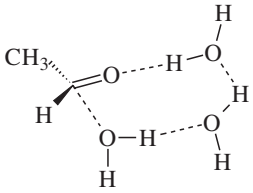
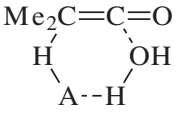
Introduction

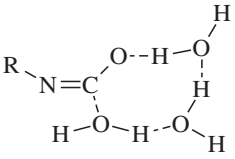
Carbonyl addition reactions, of which hydration is the prototypical example, are commonly thought to be multistep processes that proceed via charged intermediates, even under strictly neutral conditions in water solvent (1), and even at the nonpolar (2) active sites of hydrolytic enzymes (3). Nonetheless, there is mounting evidence that at least some of these reactions employ water molecules and (or) other species in a cyclic, co-operative manner (4) to *avoid* the formation of charged intermediates that would have to undergo continuous solvation and desolvation as they appear and disappear.

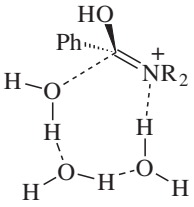
Early experimental evidence consistent with a co-operative mechanism of hydration of a carbonyl group was provided by Bell and co-workers (5), who found the hydration kinetics of 1,3-dichloroacetone in dioxane and acetonitrile to be at least third order in water. Some of the diverse experimental studies that have followed and have been interpreted in terms of co-operative mechanisms are collected in Table 1.

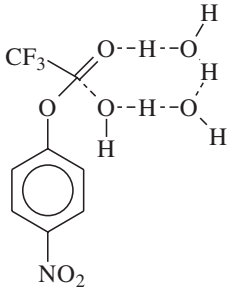
These experimental findings have stimulated much theoretical research (13), and there are now numerous computational examples of co-operative processes, both in the gas phase and in water solvent. Table 2 shows some of the aqueous phase results. The experimental free energy of activation for the hydration of carbon dioxide (Table 2, entries 1 and 2) is 18.4 kcal/mol (1 cal = 4.184 J) (14).

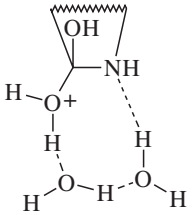


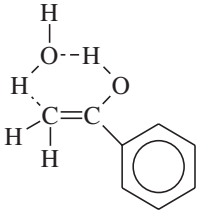












Co-operativity and the action of β-lactam antibiotics

Our interest in co-operative mechanisms began with the findings that one water molecule reduces the gas phase MP2/6-31G*//3-21G* barrier for the methanolysis of 3α-carboxypenam by 10 kcal/mol, that a second water molecule has little additional effect, and that the one-step co-operative process depicted in **1**, in which C···O and N···H bonds are formed concurrently, has a significantly lower barrier than a competing two-step process leading to a tetrahedral intermediate (18).

With the substitution of a serine side chain for methanol, and the hydroxyl groups of serine, threonine, or tyrosine for the catalytic water molecule (**1**), published 10 years ago, has recently been found[7] to resemble **2**, a portion of the complex formed when penicillin G is docked (19) to the crystal structure (20) of an exocellular penicillin-binding protein from *Streptomyces* R61, and also **3**, a portion of the complex formed upon docking (19) of penicillin G to the crystal structure (21) of the RTEM Class A β-lactamase from *Escherichia coli*. In the cases of **2** and **3**, the chemical reaction that ensues is acylation of the hydroxyl groups of Ser62 or Ser70 by the β-lactam ring. The acyl-enzyme that is formed from **2** is relatively stable (22), but the acyl-enzyme formed from **3** undergoes rapid hydrolysis, assisted by the carboxyl group of Glu166 and a water molecule that are present in the active site (23). This hydrolysis reaction and its catalysis by Glu166 and the water molecule are general to the Class A β-lactamases. As these enzymes are a major source of bacterial resistance to β-lactam antibiotics (24), the hydrolysis mechanism has received much discussion (3), most of which has been framed in terms of multistep ionic mechanisms.[8]

Because of their hydrolytic instability, acyl-enzymes of

Class A β-lactamases have not yet submitted to crystallization. However, in an important contribution, Strynadka et al. (21) were able to obtain the crystal structure of a deacylation defective penicilloylated TEM1 enzyme in which the terminal COOH of Glu166 was replaced by the terminal $CONH_2$ of asparagine. Structures **4** and **4a** are mono and stereo views showing the C-O-C(=O)-C of the acylated serine, the CON terminus of Asn166, and the oxygen of the water molecule in this crystal structure. We comment that, if the primary amide of **4** becomes the carboxyl group of the native acyl-enzyme, the resulting structure **5**, like **1**–**3**, is poised for a co-operative one-step ester hydrolysis.

The foregoing considerations have led us to a systematic experimental and theoretical examination of co-operativity in the neutral, general, and hydronium ion catalyzed hydration of acetone, the neutral hydrolysis of methyl acetate, and the catalysis of this hydrolysis by acetic acid. In our earlier publications (26), we proposed a theoretical treatment of the co-operative aqueous neutral hydration of aldehydes and ketones, based on ab initio 3-21G calculations (27, 28) and the SCRF (self consistent reaction field) (29, 30) procedure. The treatment requires the calculation of the free energies of each of the stationary structures shown in Scheme 1 in water solvent, where RC_n is a cyclic complex of a carbonyl compound RR′C=O with n water molecules (n = 1–4), TS_n is a cyclic transition structure derived from

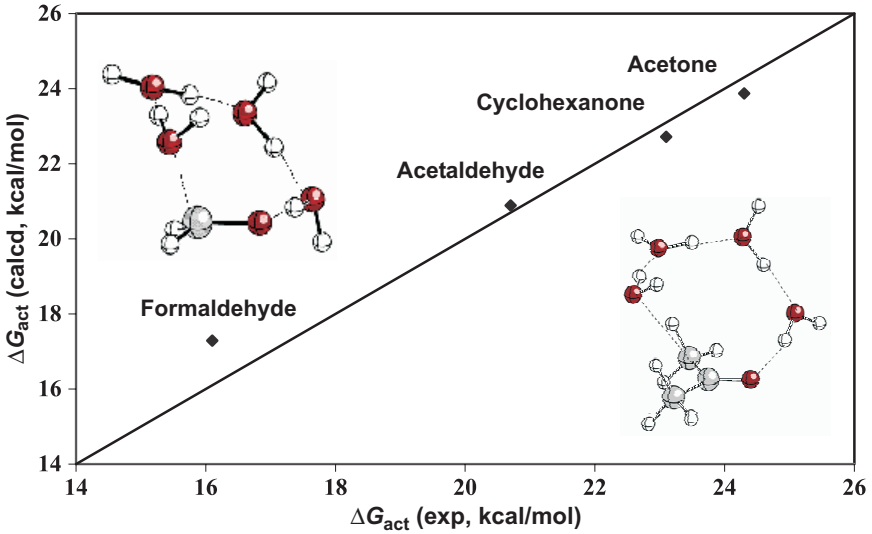
Scheme 1.

Scheme 2.



RC_n, and PC_n is a 1,1-diol, solvated by $(n - 1)$ water molecules.

The assumptions that the water clusters $(H_2O)_n$ are in rapid equilibrium with each other and with the RC_n complexes allows the hydration kinetics to be analyzed according to Scheme 2, in which C is the carbonyl compound, and this leads to eq. [1], an expression for the pseudo-first-order rate constant (k) in terms of the contributions of the individual reaction channels, and eq. [2], the theoretical free energy of activation.

$$[1] \qquad k = \frac{\boldsymbol{K_1}k'_1[\boldsymbol{W_1}] + \boldsymbol{K_2}k'_2[\boldsymbol{W_2}] + \boldsymbol{K_3}k'_3[\boldsymbol{W_3}] + \boldsymbol{K_4}k'_4[\boldsymbol{W_4}]}{1 + \boldsymbol{K_1}[\boldsymbol{W_1}] + \boldsymbol{K_2}[\boldsymbol{W_2}] + \boldsymbol{K_3}[\boldsymbol{W_3}] + \boldsymbol{K_4}[\boldsymbol{W_4}]}$$

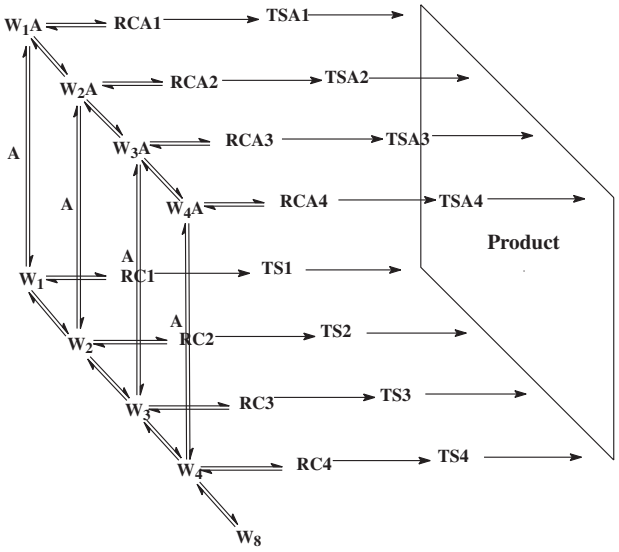
Fig. 1. A plot of the experimental free energies of activation for the neutral aqueous hydrations of formaldehyde, acetaldehyde, acetone, and cyclohexanone vs. the theoretical free energies of activation calculated according to ref. 26*b*. The inserted structures are the formaldehyde and acetone reactant complexes.

$$[2] \qquad \Delta G^{\ddagger} = RT \ln\left(\frac{\kappa T}{h}\right) - RT \ln(k)$$

The result of this treatment is shown in Fig. 1, which compares the experimental and theoretical free energies of activation for the uncatalyzed hydrations of formaldehyde, acetaldehyde, acetone, and cyclohexanone. In each case, the principal co-operative channel, shown in Fig. 1 for formaldehyde and acetone, contains four water molecules in the cyclic complex.

To extend the theoretical treatment of acetone hydration to include catalysis by acetic acid, it is necessary to expand Scheme 1 to Scheme 3 so as to allow an acid (**A**) to complex to each of the structures of Scheme 1.

There are, however, several complications. Firstly, **A** can occupy more than one site in a complex, for example, **6a** and **6b** for **RCA1** and **7a–7d** for **RCA2**. All possible structures would have to be taken into account.



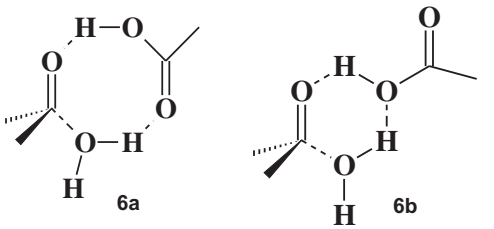
A second complication arises from basis set superposition error (BSSE) (31). When two or more molecules form a complex, the basis set that describes the complex is the combination of the basis sets of the individual molecules. Since individual reactants are described by a smaller basis than the complexes, their relative energies are artificially too high. It is, therefore, necessary to correct, the complexation energy (ΔE) by the quantity E^{BSSE} (eq. [3]), where E^{BSSE} is the basis set superposition error, $E_{\mathrm{A-B}}$ is the energy of the complex, and E_{A} and E_{B} are the energies of A and B (26*b*).

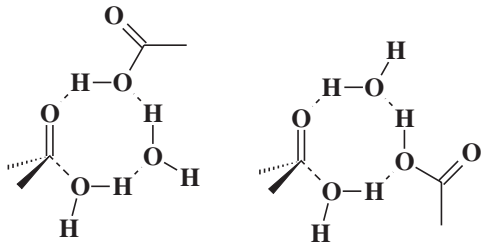
$$[3] \qquad \Delta E = E_{\mathrm{A-B}} - (E_{\mathrm{A}} + E_{\mathrm{B}}) + E^{\mathrm{BSSE}}$$

Table 3 illustrates the calculation of the BSSE correction for **8** (≡**10a**), a complex of acetic acid with two water molecules.

A third complication is that in the GAUSSIAN programme (28) the ideal gas statistical mechanical procedure is used to calculate thermodynamic parameters in the SCRF treatment.

Scheme 3.





This protocol is reasonable for the description of the enthalpy of reaction in solution, but entropic effects are greatly overestimated. The reason for this is that, in the gas phase, the major contribution to the entropy change calculated for an association reaction A + B → AB arises from the loss of six degrees of freedom, representing free translations and rotations of A and B, and the conversion of these into six vibrational modes of AB. In solution, rotational and translational motions are restricted and are better described by a set of low frequency vibrations. In the simplest approximation, these vibrations can be described by a single effective frequency (ν), determined (26*b*) to be 115 cm^{-1} for the water monomer and $115(18/m)^{1/2}$ cm^{-1} for other species, where m is the mass of the species. Equation [4] gives the corrected expression for ΔG in solution. The first and second terms on the right-hand side are the BSSE-corrected enthalpy change

and the gas-phase vibrational entropy change calculated by the GAUSSIAN programme, and the third term is the correction for low frequency vibrations in solution.

Scheme 4.

$$[4]\qquad \Delta G_{liq} = \Delta H_{gas} - T\Delta S_{vib} - 6RT\left[\frac{\frac{h\nu}{kT}}{\exp\left(\frac{h\nu}{kT}\right)-1} - \ln\left[1-\exp\left(\frac{h\nu}{kT}\right)\right]\right]$$

Computational details

As in our previous work (26*a*, 26*b*) all calculations were performed using the 3-21G level of theory (27, 28) and the SCRF procedure (29, 30). Transition structures were located by the reaction coordinate method. Using a reactant complex as a starting point, trial values of the forming O···C=O and C=O···H bond lengths were selected, all other geometrical parameters were optimized, and the magnitudes and signs of the gradients of the two reaction coordinates were used to improve the trial values. After several such calculations, a structure close to the saddle point was reached; at this stage, a final refinement was achieved using the OPT=CALCALL option, in which force constants are calculated in every iteration. All transition structures exhibited one imaginary frequency.

For SCRF calculations, the previously optimized gas-phase structures were used to estimate the radius of the cavity, and this value was employed in the optimization. A dielectric constant of 78.5 was used to describe the water solvent.

Results

In an initial set of computations, the truncated Scheme 4 was employed to treat acetic acid catalysis. Structures **9a**–**9d** are the 1:1 complexes. Table 4 summarizes the data obtained for these complexes at 298 K in water solvent.

Structures **10a**–**10d** are the 2:1 complexes; Table 5 lists the ΔG values calculated for these complexes at 298 K in water solvent.

Structures **11a**–**11d** are the reactant complexes (acetone + acetic acid + $(H_2O)_n$), and **12a**–**12d** are the transition structures. Table 6 lists the ΔG and $\Delta G^{\ddagger}$ calculated at 298 K for an acetone concentration of 1.00 mol/L and an acetic acid concentration of 1.00 mmol/L. The theoretical $\Delta G^{\ddagger}$ for the neutral reaction (11.34 kcal/mol) was reported previously (26*b*).

To assess the contributions of the different pathways to the overall rate constant, it is necessary to take into account the concentrations of the different reactant complexes, and this is possible if the reasonable assumption is made that acetone, $(H_2O)_n$, acetic acid, **RCn**, and **RCAn** are in equilibrium in solution. The contributions of the different reaction channels to the overall pseudo-first-order rate constant for the acetic acid catalyzed hydration of acetone will then depend on the concentrations of **RCAn** and on the individual free energies of activation **RCAn** → **TSAn**.

This situation has been summarized in Scheme 1 for the case of neutral hydration. With the addition of the acid-catalyzed channels, Scheme 1 is expanded to Scheme 5, in which $\mathbf{W_n}$ is a water cluster, $\mathbf{WA_n}$ is a water–acid complex, K_{nn}, K_{Ann}, K'_{Ann}, K_n, and K_{nA} are equilibrium constants, and k'_n and k'_{nA} are rate constants.

Using [*S*] as the concentration of acetone and [*A*] as the concentration of acetic acid, the independent relationships among the concentrations of $(H_2O)_n$, $\mathbf{W_nA}$, **RCn**, and **RCAn** are as follows: $[\mathbf{W_2}] = K_{12}[\mathbf{W_1}]^2$, $[\mathbf{W_3}] = K_{13}[\mathbf{W_1}]^3$, $[\mathbf{W_4}] = K_{14}[\mathbf{W_1}]^4$, $[\mathbf{W_8}] = K_{18}[\mathbf{W_1}]^8$, $[\mathbf{RC1}] = K_1[\mathbf{W_1}][S]$, $[\mathbf{RC2}] = K_2[\mathbf{W_2}][S]$, $[\mathbf{RC3}] = K_3[\mathbf{W_3}][S]$, $[\mathbf{RC4}] = K_4[\mathbf{W_4}][S]$, $[\mathbf{W_1A}] = K_{A11}[\mathbf{W_1}][A]$, $[\mathbf{W_2A}] = K_{A22}[\mathbf{W_2}][A]$, $[\mathbf{RCA1}] = K_{1A}[\mathbf{W_1A}][S]$, $[\mathbf{RCA2}] = K_{2A}[\mathbf{W_2A}][S]$.

Equations [5]–[7] relate these concentrations to the analytical concentrations of water (C_W), acetone (C_S), and acetic acid (C_A).

$$[5]\quad C_W = [\mathbf{W_1}] + 2[\mathbf{W_2}] + 3[\mathbf{W_3}] + 4[\mathbf{W_4}] + 8[\mathbf{W_8}] + [\mathbf{RC_1}] + 2[\mathbf{RC_2}] + 3[\mathbf{RC_3}] + 4[\mathbf{RC_4}] + [\mathbf{W_1A}] + 2[\mathbf{W_2A}] + [\mathbf{RCA1}] + 2[\mathbf{RCA2}]$$

$$[6]\quad C_S = [S] + [\mathbf{RC1}] + [\mathbf{RC2}] + [\mathbf{RC3}] + [\mathbf{RC4}] + [\mathbf{RCA1}] + [\mathbf{RCA2}]$$

[7] $$C_A = [A] + [W_1A] + [W_2A] + [RCA1] + [RCA2]$$

The concentrations of all species present in the solution were calculated to self-consistency using a water concentration of 55.5 mol/L. The calculated rate (v) is then given by

Scheme 5.

[8] $$v = \sum \{k'_n[RCn] + k'_{nA}[RCAn]\} = (k_o + k_{HA}C_A)C_S = k_{obs}C_S$$

where k_{obs} is the rate constant and contains contributions from the neutral reaction (k_o) and the acid-catalyzed reaction ($k_{HA}C_A$). Table 7 summarizes the calculated concentrations of the complexes and the contributions of the different reaction channels to the hydration of acetone at 298 K for a solution that is 1.00 mol/L in acetone and 1.00 mmol/L in acetic acid.

The principal contributors to general acid catalysis are **11b** (47.3%) and **11d** (44.7%), which exhibit $\Delta G^{\ddagger}$ = 8.14 and 7.74 kcal/mol, respectively. Minor contributors are **11a** (4.4%), which exhibits $\Delta G^{\ddagger}$ = 10.45 kcal/mol, and **RC4** (3.6%), which exhibits $\Delta G^{\ddagger}$ = 11.34 kcal/mol. Although the

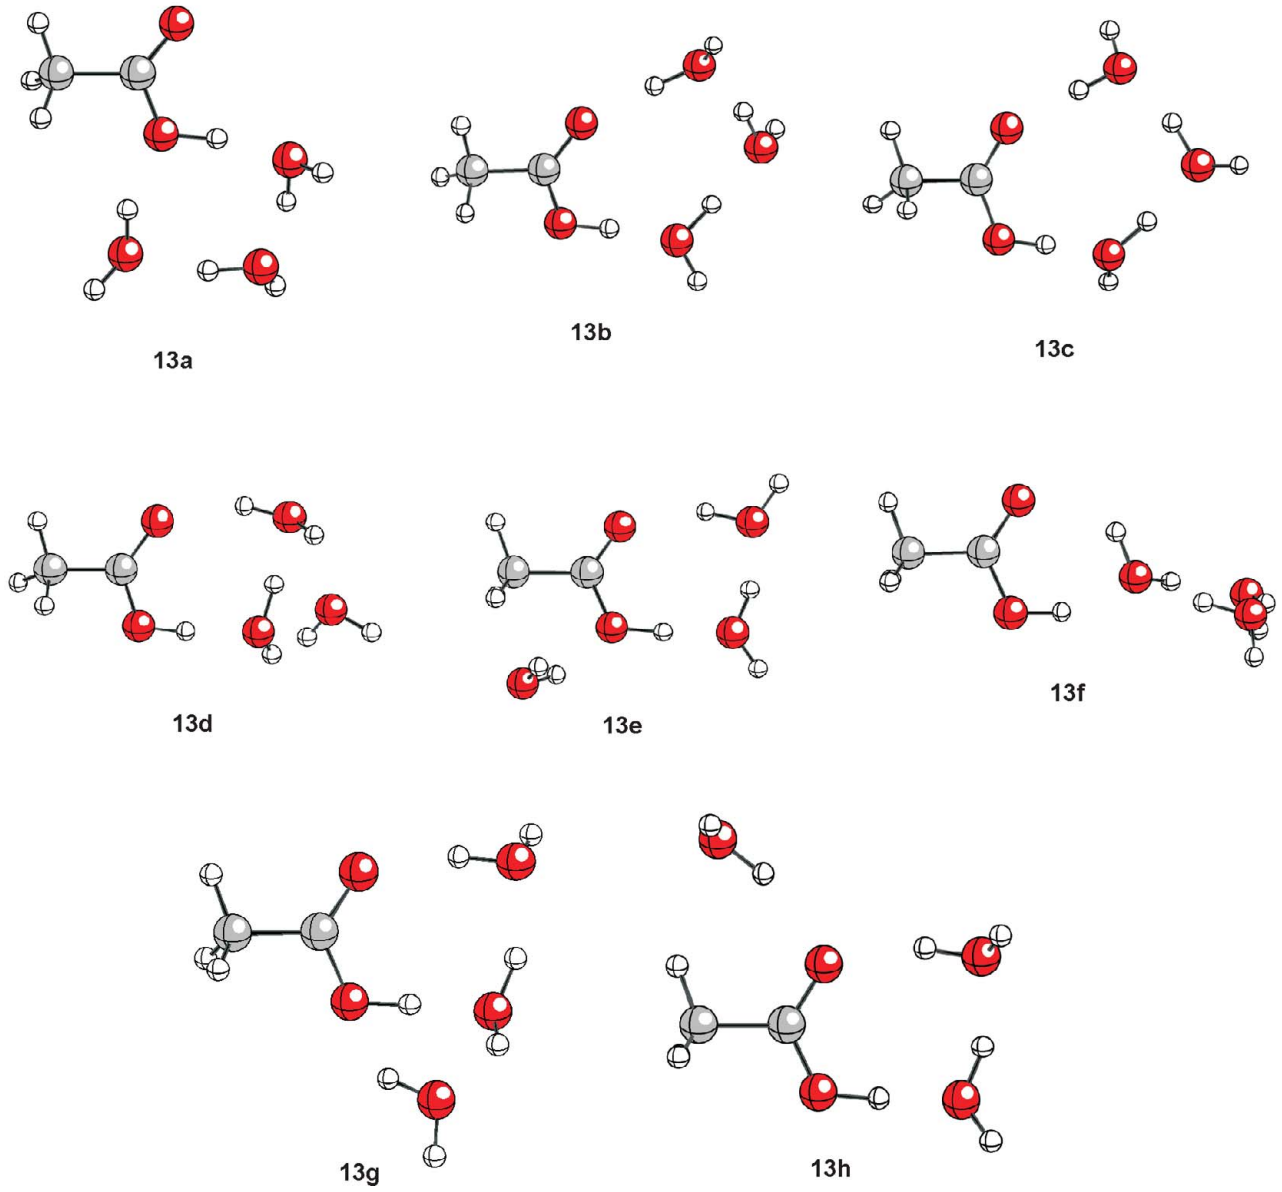
Scheme 6.

relative concentrations of these species (mol/L) are **11b** (1), **11d** (0.5), **11a** (4.6), and **RC4** (16.7), **11b** and **11d** make the major contributions to the overall reaction because of their lower barriers.

Scheme 4 was then expanded to Scheme 6 to incorporate an additional channel of acetic acid catalysis.



Structures **13a–13h** are the 3:1 complexes and Table 8 lists the free energies of formation of these complexes at 298 K.

Structures **14a–14f** are the reactant complexes (acetone + acetic acid + $(H_2O)_3$), and **15a–15f** are the transition structures reached from these complexes. Table 9 lists the ΔG and $\Delta G^{\ddagger}$ calculated at 298 K for an acetone concentration of 1.00 mol/L and an acetic acid concentration of 1.00 mmol/L.

Table 10 summarizes the calculated concentrations of the complexes and the contributions of the different reaction channels to the hydration of acetone at 298 K for a solution that is 1.00 mol/L in acetone and 1.00 mmol/L in acetic acid.

The resulting rate and the principal contributors to this rate are almost the same as in Scheme 4. The reason for this is that the concentrations of the six three-water molecule

© 2005 NRC Canada

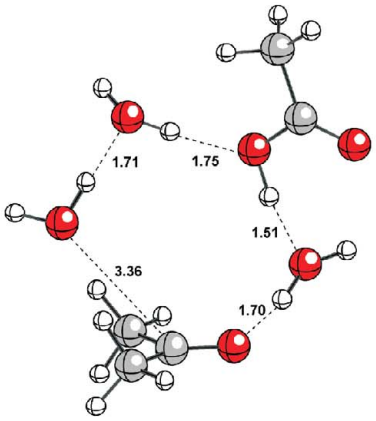
complexes (**14a**–**14f**) are many orders of magnitude lower than the concentrations of the one- and two-water molecule complexes (**11a**–**11c**).

Experimental

In the presence of a general acid, the hydration of acetone can proceed with contributions from the neutral reaction (k_o), the hydronium ion catalyzed reaction ($k_H[H_3O^+]$), the co-operative acid-catalyzed reaction ($k_{HA}[HA]$), and the hydroxide ion catalyzed reaction ($k_{OH}[OH^-]$) (eq. [9]).

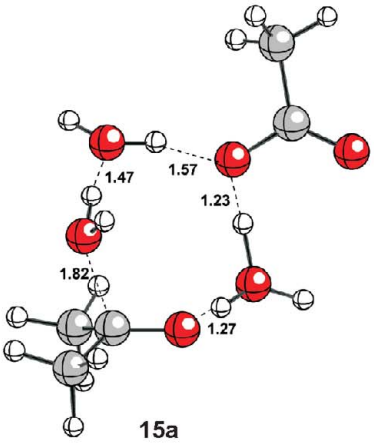
$$[9] \qquad k_{obs} = k_o + k_H[H_3O^+] + k_{HA}[HA] + k_{OH}[OH^-]$$

Experiments were performed at an acetic acid concentration of 0.01 mol/L in 1 mol/L acetone. At this concentration of acetic acid, [HOAc] = 9.6×10^{-3} mol/L, $[H_3O^+] = 4.1 \times 10^{-4}$ mol/L, and $[OH^-] < 10^{-10}$ mol/L (32). Since k_o is 8.9×10^{-6} s^{-1} (26*b*), eq. [9] can be truncated to



$$[10] \qquad k_{obs} \sim k_{HA}[HOAc] + k_H[H_3O^+]$$

A bulk solution of acetic acid in $H_2{}^{18}O$ was prepared by dilution of 5.00 mL of 1.000 mol/L acetic acid to 50.00 mL in H_2O and addition of 60.0 µL of this 0.100 mol/L solution to 540.0 µL of 49.1% $H_2{}^{18}O$ to give 1.00×10^{-2} mol/L [HOAc] in 44.2% enriched $H_2{}^{18}O$.



To initiate a run, 8.0 µL (6.4 µg, 0.11 µmol) of 2-^{13}C-acetone were syringed into 100 µL of the acetic acid solution in a 1 dram vial (1 fluid dram = 3.551 633 cm^3) and the reaction mixture (1.1 mol/L in acetone) was transferred immediately to a micro NMR tube maintained at 298 ± 0.1 K in the probe of a Bruker 600 AMX spectrometer operating at a frequency of 150.03 MHz. Temperature control was achieved with a Euroterm VT temperature regulator. The proton decoupled ^{13}C NMR spectrum was recorded as a single scan at appropriate intervals to obtain the peaks of $(CH_3)_2{}^{13}C={}^{16}O$ [^{16}O] and $(CH_3)_2{}^{13}C={}^{18}O$ [^{18}O], whose chemical shifts differ by 0.05 ppm (33). These spectra were integrated to obtain the [^{18}O]/[^{16}O] ratio (ρ) as a function of time.

The data were analyzed by application of version 5.1 of

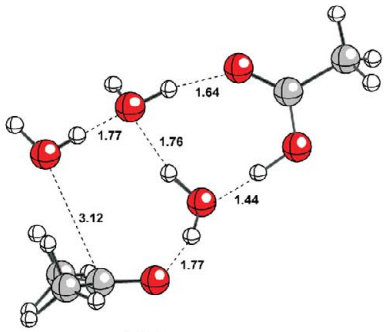
the computer programme GRAFIT, obtained from Erithacus Software Ltd., Horley, Surrey, UK, to eq. [11],

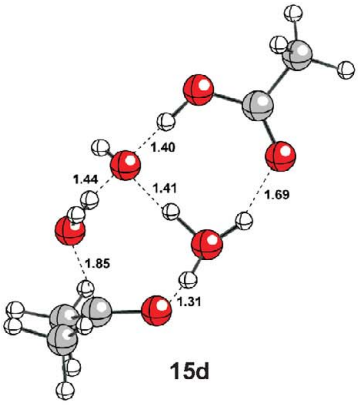
$$[11] \quad \frac{1}{1+\rho} = A\exp(-k^{t}_{obs}) + C$$

which is derived in the following manner.[9]



For a reaction $^{16}O \underset{k_{-1}}{\overset{k_1}{\rightleftharpoons}} {}^{18}O$, where $k_1 = k[H_2{}^{18}O]$ and $k_{-1} = k[H_2{}^{16}O]$, the time dependence of the concentration of ^{18}O is given by (34),

$$[12] \quad (k_1 + k_{-1})t = \ln\left(\frac{[^{18}O]_e}{[^{18}O]_e - [^{18}O]}\right)$$



where $[^{18}O]_e$ is the concentration of ^{18}O at equilibrium. Since $[^{16}O]_o = 1$, $[^{18}O]_o = 0$, and $[^{16}O] + [^{18}O] = [^{16}O]_o = [^{16}O]_e + [^{18}O]_e = 1$, eq. [12] becomes

[9] The authors thank Professor Andrew Bennet for suggesting eq. [11], and for instruction in the use of GRAFIT.

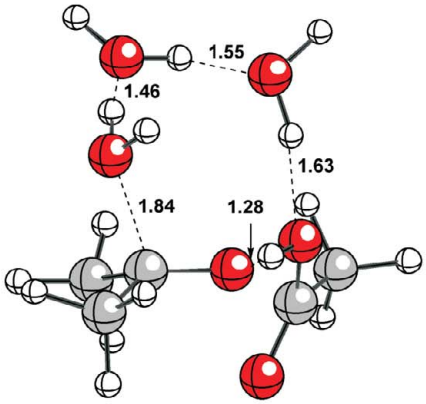
15d



14e

15e

14f

15f

[13] $[^{18}O] = [^{18}O]_e(1 - e^{-(k_1 + k_{-1})t})$

Substitution of $[^{18}O]$ by $[^{16}O]_o - [^{16}O]$ and $[^{18}O]_e$ by $[^{16}O]_o - [^{16}O]_e$ gives

[14] $[^{16}O] = ([^{16}O]_o - [^{16}O]_e)e^{-(k_1 + k_{-1})t} + [^{16}O]_e$

Writing $\rho = [^{18}O]/[^{16}O]$, the ratio $[^{16}O]/[^{16}O]_o$ is

[15] $$\frac{[^{16}O]}{[^{16}O]_o} = \frac{1}{1+\rho}$$

Dividing eq. [14] by $[^{16}O]_o$ and substitution of eq. [15] into eq. [14] gives

[16] $$\frac{1}{1+\rho} = Ae^{-k_{obs}t} + C$$

where $A = \left(1 - \frac{[^{16}O]}{[^{16}O]_o}\right)$, $C = \frac{[^{16}O]}{[^{16}O]_o}$, and $k_{obs} = k[H_2O]$.

The results are summarized in Table 11. Figure 2 shows the result of run 1.

We conclude that, in the high dielectric medium provided by water solvent, acetic acid catalysis of the hydration of acetone is predominantly a co-operative, i.e., *non-ionic*, process. It is therefore necessary to reexamine the dogma (2, 3) that multistep ionic mechanisms are operative in the *low* dielectric media that exist at the active sites of hydrolytic enzymes, in particular penicillin-recognizing enzymes. Such a reexamination is the subject of a forthcoming publication in this series.[10]

Electron-rich siloxane–platinum complexes — Synthesis, structures, and reactivity[1]

Roman Goikhman, Tanya Karakuz, Linda J.W. Shimon, Gregory Leitus, and David Milstein

Abstract: New platinasiloxanes were synthesized and their reactivity was studied. Oxidative addition of $(HSiMe_2)_2O$ to $Pt(PEt_3)_3$ led to dehydrogenation and quantitative formation of the four-membered platinacyclosiloxane $[(PEt_3)_2Pt-((SiMe_2)_2O)]$ which was characterized by X-ray diffraction. This complex was stable towards non-polar substrates and aerobic conditions, but reacted readily with electrophiles and Lewis acids. Reaction with MeI resulted in ring opening, while MeOTf gave an oxonium complex, with retention of the platinacycle structure. A complex resulting from BF_3 coordination to the ring oxygen atom was also obtained. An unprecedented open-chain diplatinasiloxane containing the Pt–Si–O–Si–O–Si–Pt fragment was formed by oxidative addition of H–$SiMe_2$–O–$SiMe_2$–O–$SiMe_2$–H to $Pt(PEt_3)_3$ and it was characterized by X-ray diffraction.

Key words: cyclosiloxane, metallacycle, platinum silyl, Lewis base, oxidative addition.

Résumé : On a réalisé la synthèse de nouveaux platinasiloxanes et on en a étudié la réactivité. L'addition oxydante du $(HSiMe_2)_2O$ à du $Pt(PEt_3)_3$ conduit à une déshydrogénation et à la formation quantitative du platinacyclosiloxane à quatre chaînons $[(PEt_3)_2Pt((SiMe_2)_2O)]$ qui a été caractérisé par diffraction des rayons X. Ce complexe est stable vis-à-vis des substrats non polaires et des conditions aérobiques, mais il réagit facilement avec les électrophiles et les acides de Lewis. Sa réaction avec du MeI conduit à une ouverture de cycle, alors que sa réaction avec du MeOTf conduit à la formation d'un complexe d'oxonium, avec rétention de la structure platinacyclique. Un complexe résultant de la coordination du BF_3 à l'atome d'oxygène du cycle a aussi été obtenu. L'addition oxydante de H–$SiMe_2$–O–$SiMe_2$–O–$SiMe_2$–H à du $Pt(PEt_3)_3$ conduit d'un diplatinasiloxane à chaîne ouverte contenant le fragment Pt–Si–O–Si–O–Si–Pt inconnu jusqu'à maintenant et qui a été caractérisé par diffraction des rayons X.

Mots clés : cyclosiloxane, métallacyclique, silyle platine, base de Lewis, addition oxydante.

[Traduit par la Rédaction]

Introduction

Siloxanes are important components in the organosilicon polymer industry (1). Siloxanes bearing the terminal Si–H group are used in hydrosilylation reactions catalyzed by transition metal compounds, particularly platinum complexes (2). Moreover, symmetrical dihydridosiloxanes can form cyclic compounds with transition metal complexes (3). Such silametallacycles have attracted considerable interest because of the potential use of these species in catalytic double silylation reactions of various organic substrates to form precursors for the synthesis of functional organosilicon polymers (4). Among various silametallacycles, relatively limited information has been reported regarding the reactivity of small metallocyclosiloxanes, including Si–Si addition to carbon–carbon triple bonds using cyclic platinasiloxanes (5). An intriguing theoretical possibility for the four-membered ring metallosiloxane system is metathesis via a silanone-silylene intermediate complex. It was proposed (6) that this might involve unusual transformations at the metal center and lead to various rearrangements and oligomerization or polymerization reactions. In the present work new metallosiloxanes are described and their reactivity towards various substrates is reported for the first time.

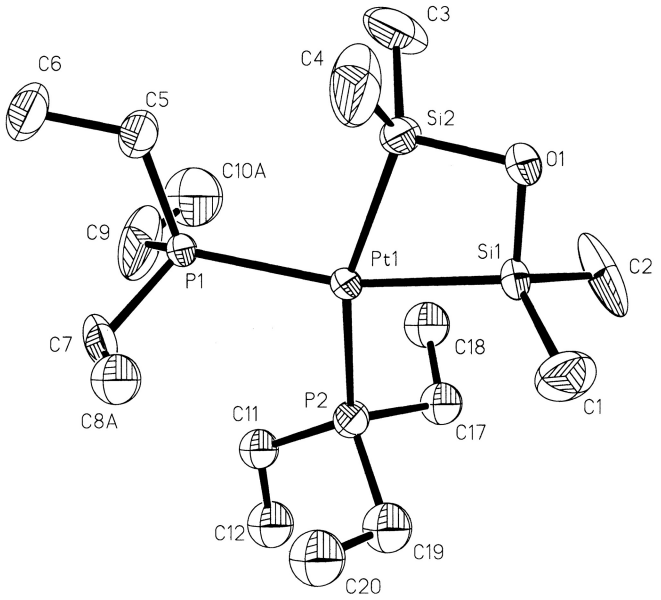
Results and discussion

Addition of $(HSiMe_2)_2O$ to $Pt(PEt_3)_3$ in pentane, followed by evaporation of the volatiles resulted in formation of a siloxane-bridged diplatinum complex *cis*-$(PEt_3)_2Pt(H)$-$SiMe_2$-O-$SiMe_2$-$Pt(H)(PEt_3)_2$ (**1**). Noteworthy, no mononuclear adduct was detected despite an initial 50% excess of the siloxane substrate. When the reaction was performed in a C_6D_6 solution, very broad peaks were observed in the ^{31}P and ^1H NMR spectra (prior to evaporation), indicating a rapid phosphine exchange process. We propose that the initial Si–H oxidative addition is reversible in the presence of free PEt_3, as previously observed by us (7). Under vacuum,

 doi: 10.1139/V05-041 © 2005 NRC Canada

Scheme 1.



the liberated PEt_3 (together with the solvent) is removed, resulting in an equilibrium shift towards formation of the adduct. However, the vacuum conditions also promote the opposite reaction owing to the volatility of the disiloxane substrate. Phosphine deficiency makes the second Si–H addition easier, ultimately resulting in the dinuclear product **1** (Scheme 1). The latter complex slowly disproportionates at room temperature to a 1:1 mixture of the very stable new platinacycle **2** and the known dihydride *trans*-$(PEt_3)_2PtH_2$ (8) (Scheme 1).

The new compounds **1** and **2** were unambiguously characterized by multinuclear NMR spectroscopy. Complex **1** exhibits two different signals in its ^{31}P NMR spectrum with characteristic $^1J_{P,Pt}$ constants equal to 1262 Hz (P trans to Si) and 2395 Hz (P trans to H). The hydride signal appears as dd at –1.96 ppm with large $^1J_{H,Ptrans}$ and small $^1J_{H,Pcis}$ constants of 153 and 25 Hz, respectively. Integration and the lack of a Si–H peak in the ^1H NMR spectrum is consistent with the binuclear structure of **1**. We are unaware of any previously reported binuclear hydrido-disiloxane Pt complexes.

Platinacycle **2** exhibits an expected singlet with ^{195}Pt satellites ($^1J_{Pt,P}$ = 1548 Hz) in the ^{31}P NMR spectrum, the $^1J_{Pt,P}$ being similar to the $^1J_{Pt,P}$ = 1560 Hz reported for $(PhEt_2P)_2Pt((SiMe_2)_2O)$ (3*b*). The Si–Me signals in the $^1H\{^{31}P\}$ NMR and $^{13}C\{^1H\}$ NMR spectra are very characteristic, both having strong ^{195}Pt satellites with $^3J_{Pt,H}$ = 17.8 Hz, and $^2J_{Pt,C}$ = 98 Hz. For compound **1**, these constants are 24 and 151 Hz, respectively. This indicates that the Pt—Si bond is probably longer in platinacycle **2** as compared with the one in hydrido-platinum complex **1**.

Fig. 1. Perspective view (ORTEP) of **2**. Hydrogen atoms are omitted for clarity.

Similar platinacycles have been described (3).[3] ^{13}C NMR data for platinacyclosiloxanes is reported here for the first time.

Compound **2** can be obtained directly in high yield by stirring a fivefold excess of $(HSiMe_2)_2O$ with $Pt(PEt_3)_3$ in pentane overnight, and it can be easily recrystallized from pentane as colorless needles. Crystals of **2** suitable for a single crystal X-ray diffraction study were obtained from pentane solution at –30 °C. The X-ray structure of **2** is shown in Fig. 1.[3] Selected bond lengths and angles are given in Table 1. Complex **2** is the second crystallographically characterized platinacyclosiloxane (9). The structural features are similar to those reported for the analogous complex [(DPPE)Pt($(SiMe_2)_2O$)] (DPPE is bis(diphenylphosphinoethane) (9). Complex **2** exhibits a distorted square-planar structure with a very small Si-Pt-Si angle (64.4°) (65° in the DPPE analog). The Pt—Si bonds are slightly shorter than those of the DPPE analog (2.363–2.366 Å vs. 2.373–2.374 Å) probably because of steric factors. The Si-O-Si angle is also slightly smaller (97.0° vs. 97.8° in the DPPE analog). The Pt-Si-O-Si core is planar (the torsion angle for Si-Pt-Si/Si-O-Si is just 1.0°).

Complex **2** is a very stable compound and it is inert towards air and water. It is stable in the presence of a large excess of norbornene, no silylation being observed, and it does not react with nonpolar substrates such as dihydrogen and silanes. However, the platinacycle is quite a strong nucleophile and Lewis base. For example, it reacts with MeI, resulting in opening of the cycle and formation of a *trans*-$(PEt_3)_2Pt(I)(SiMe_2\text{-}O\text{-}SiMe_3)$ (**3**). The reaction proceeds overnight at room temperature in benzene. Interestingly, un-

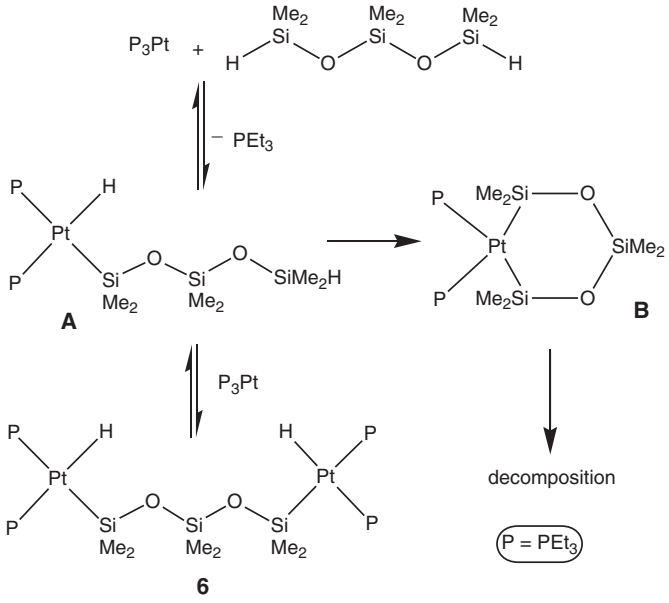
Scheme 2.



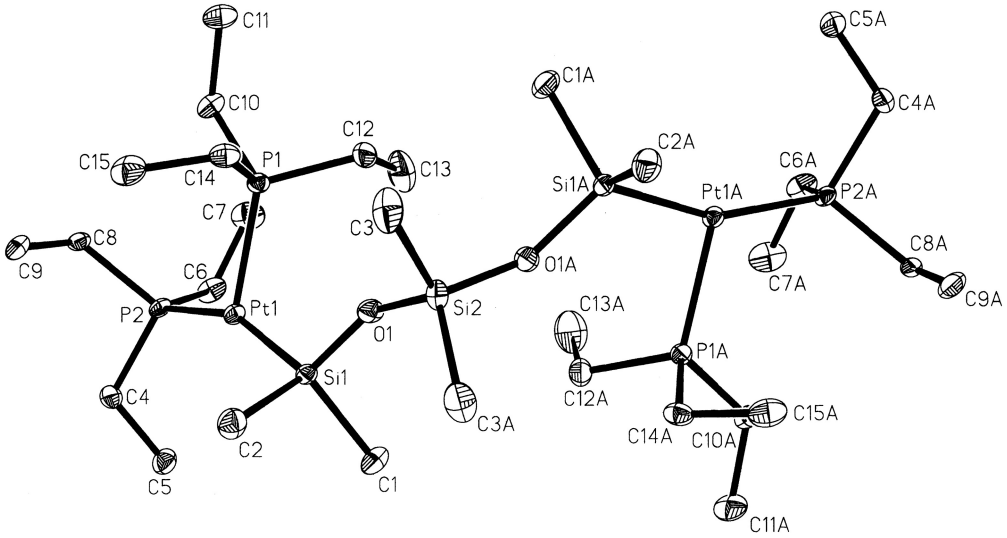
like the reaction with MeI, the reaction with MeOTf is *O*-directed, complex **2** acting as a strong Lewis base producing the cationic complex **4** (Scheme 2), which partially precipitates from benzene solution as a yellow oil.

A similar result is observed with the reagent Et_2O–BF_3. Platinacycle **2** readily abstracts BF_3 from the ether complex, producing a new complex **5** (Scheme 2). The complex is colorless and slightly less soluble in benzene than **2**, apparently becasue of a higher polarity. Scheme 2 summarizes the reactivity of complex **2**.

The reactions are easily followed by NMR spectroscopy. The ^{31}P NMR of the starting complex **2** exhibits a singlet at 18.7 ppm with a characteristic low $^1J_{Pt,P}$ = 1548 Hz. The ^{31}P NMR signal of adduct **3** appears at 16.3 ppm with $^1J_{Pt,P}$ = 2855 Hz (typical for mutually trans phosphines). Adduct **5** gives rise to a signal at 16 ppm with $^1J_{Pt,P}$ = 1705 Hz in the

Scheme 3.

^{31}P NMR spectrum. The larger coupling constant value when compared with the one observed for the starting complex **2** reflects a weakening of the (normally strong) trans influence of the Si ligand, which is affected by BF_3 binding.



Addition of MeOTf, which results in formation of a cationic complex, causes even more dramatic changes in the NMR spectrum. Thus, the ^{31}P NMR signal of complex **4** appears at 14.8 ppm with a larger $^1J_{Pt,P}$ = 1792 Hz.

Although the reaction of BF_3 with polysiloxanes is used in polymer chemistry (10), very little is known about the reactivity of siloxanes towards BF_3. Siloxane–BF_3 adducts are unstable compounds, which either cannot be detected at all or readily decompose at room temperature to fluorosilanes (11). In particular, the adduct of BF_3 with free tetramethyldisiloxane was not observed (11*d*), but a mixture of fluorosilanes was obtained instead. Our metallosiloxane–BF_3 complex is stable at room temperature in the solid state and slowly decomposes in solution within days.

In an attempt to obtain a larger platinacycle and to compare its properties with those of **2**, the trisiloxane $HSiMe_2$-O-$SiMe_2$-O-$SiMe_2H$ was used as a substrate. Its reaction with $Pt(PEt_3)_3$ proceeds in a more complicated manner. When a stoichiometric amount of the trisiloxane was used, a mixture of two compounds was formed, and after several hours the reaction ended with the new binuclear complex **6** (Scheme 3). The product was crystallized from cold pentane and studied by X-ray crystallography (Fig. 2).[3] Selected bond lengths and angles are given in Table 1. This is a rare example of a crystallographically characterized acyclic platinasiloxane complex (12). Compound **6** exhibits the previously unreported feature of a bridging trisiloxane unit between two Pt centers. The phosphines are located cis to each other and the Pt centers exhibit a distorted square-planar structure. As expected, the Si centers are tetrahedral. The Si-O-Si angle of 149.6° is typical for long chain siloxanes, and it falls within the range of 139°–167° reported for the platinasiloxane cluster (13). The P—Pt bond lengths reflect a weaker trans-influence of the hydride ligand as com-

© 2005 NRC Canada

Fig. 2. Perspective view (ORTEP) of **6**. Hydrogen atoms are omitted for clarity.

pared with the Si ligand. Thus, P trans to Si exhibits a longer bond length (2.34 Å) than P trans to H (2.29 Å), which correlates well with the ^{31}P NMR data ($^{1}J_{P,Pt}$ is 1319 and 2366 Hz, respectively). In the Pt-Si(1)-O-Si(2) fragment, the Si(1)—O bond is considerably longer than the Si(2)—O bond (1.671 vs. 1.625 Å). There are smaller changes in the Si(1)—CH_3 vs. Si(2)—CH_3 bonds (1.884 and 1.890 Å vs. 1.874 Å), which allow us to conclude that not only steric but electronic factors as well affect the Si—O bond length. Obviously, back-donation from a Pt to Si atom lengthens the Si(1)—O bond.

Comparing the NMR data of complexes **1** and **6**, we can see that these compounds are very similar. The only noteworthy feature is that the $^{1}J_{P,Pt}$ value of P trans to Si is smaller in **1** (1262 vs. 1319 Hz in **6**), which suggests that the disiloxane ligand in **1** is bound slightly more strongly than the trisiloxane ligand in **6**. The very few crystallographically characterized Pt hydrido-silyl complexes with *cis*-phosphine geometry exhibited similar structural features (12).

Interestingly, formation of the binuclear complex **6** is also preferred over that of the mononuclear adduct, as observed in the case of disiloxane reaction with $Pt(PEt_3)_3$. A new complex, probably the mononuclear complex (compound **A** in Scheme 3) is formed initially in a mixture with dimer **6**, and then disappears upon stirring. Compound **A** was not characterized because of severe overlapping of all NMR signals with those of the starting substrate and complex **6**. Addition of 2 equiv. of Pt(0) to 1 equiv. of the trisiloxane had no obvious influence on the formation rate of dimer **6**. However, the process could be accelerated by evaporation of the liberated phosphine and by redissolving the resulting mixture.

In an attempt to prepare a six-membered cyclic platinacycle, the initial mixture of trisiloxane and $Pt(PEt_3)_3$ was heated at 45 °C for 1 h. The platinacycle (compound **B**, Scheme 3) was probably formed, as detected by ^{31}P NMR in the mixture (less than 20%), and exhibited a characteristically low $^{1}J_{Pt,P}$ = 1470 Hz. However, this cycle appears to be far less stable than the four-membered ring **2**, and decomposes during formation to an unidentified mixture (14). Prolonged stirring of **6** at room temperature gave similar results and only a small percentage of what appears to be platinacycle B was detected in the reaction mixture during decomposition of **6** (followed by NMR).

Thus, comparing the stability of the described platinasiloxanes we can conclude that: (*i*) in contrast to reported similar systems (3, 12*a*), triethylphosphine–platinum mononuclear siloxane adducts are unstable under stoichiometric reaction conditions and $(Et_3P)_2Pt(H)(SiMe_2\text{-}O\text{-}SiMe_2H)$ is far less stable than $(Et_3P)_2Pt(H)(SiMe_2\text{-}O\text{-}SiMe_2\text{-}O\text{-}SiMe_2H)$. Under analogous conditions the first species was not observed, whereas the second one was observed in the reaction mixture in its initial stages; (*ii*) the dinuclear compounds $(Et_3P)_2Pt(H)(SiMe_2\text{-}O\text{-}SiMe_2)Pt(H)(PEt_3)_2$ (**1**) and $(Et_3P)_2Pt(H)(SiMe_2\text{-}O\text{-}SiMe_2\text{-}O\text{-}SiMe_2)Pt(H)(PEt_3)_2$ (**6**) can be isolated in the solid state. They are both unstable in solution, but **1** decomposes much faster at room temperature in solution than does **6** ($t_{1/2}$ is approximately 4 h and 2 days, respectively). The initial decomposition pathways are similar and lead to mononuclear cyclization products; (*iii*) the four-membered platinacyclosiloxane **2** is a stable compound both in the solid state and in solution at room temperature, whereas the (presumed) six-membered platinacyclosiloxane B (Scheme 3) rapidly decomposes and cannot be isolated.

Overall, the reactivity of a Pt(0) complex towards Si-H containing di- and trisiloxane substrates was examined, cyclization and dimerization processes were described and discussed, reactivity of platinacycles towards various substrates was studied for the first time, and X-ray structures of platinasiloxanes were determined.

Experimental

General

All the manipulations of air- and moisture-sensitive compounds were carried out using a nitrogen-filled Vacuum Atmospheres glovebox. Solvents were purified by standard procedures, degassed, and stored over molecular sieves in the glovebox. All reagents used were of reagent grade. Commercially available 1,1,3,3-tetramethyldisiloxane was distilled prior to use while 1,1,3,3,5,5-hexamethyltrisiloxane was

© 2005 NRC Canada

used without further purification. The complex $Pt(PEt_3)_3$ was synthesized according to a literature procedure (15). NMR spectra were obtained with a Bruker AMX 400 spectrometer at ambient probe temperature in benzene-d_6 solutions unless otherwise specified.

Preparation of 1

A solution of 110 mg (0.2 mmol) of $Pt(PEt_3)_3$ in 5 mL of pentane was treated with 40 mg (53 µL, 0.3 mmol) of freshly distilled $(HSiMe_2)_2O$ and the mixture was evaporated to dryness. The residue was dissolved in pentane and kept overnight at –30 °C, resulting in the precipitation of colorless needles. The solution was decanted and the crystals were washed with 3 mL of cold pentane and dried under vacuum to afford 75 mg (75%) of **1**. The crystals contained a small amount of **2**.

NMR data for 1

$^1H\{^{31}P\}$ NMR: 1.95 (m, 12H, P-CH_2), 1.56 (m, 12H, P-CH_2), 1.04 (m, 18H, P-CH_2-CH_3), 1.03 (s, with ^{195}Pt satellites $^3J_{Pt,H}$ = 24 Hz, 12H, Si-CH_3), 0.96 (m, 18H, P-CH_2-CH_3). Methyl signals were partially overlapped. –1.96 (dd, $^2J_{H,Ptrans}$ = 153 Hz, $^2J_{H,Pcis}$ = 25 Hz, $^1J_{H,Pt}$ = 1020 Hz, 1H, Pt-H). ^{13}C NMR: 22.5 (dd, with ^{195}Pt satellites, $^1J_{C,P}$ = 22.5 Hz, $^3J_{C,P}$ = 2.4 Hz, $^2J_{C,Pt}$ = 22.1 Hz, P-CH_2), 19.6 (dd, with ^{195}Pt satellites, $^1J_{C,P}$ = 25.9 Hz, $^3J_{C,P}$ = 5.8 Hz, $^2J_{C,Pt}$ = 31.7 Hz, P-CH_2), 15.6 (dd, with ^{195}Pt satellites, $^3J_{C,Ptrans}$ = 12.5 Hz, $^3J_{C,Pcis}$ = 2.0 Hz, $^2J_{C,Pt}$ = 151 Hz, Si-CH_3), 9.2 (s, with ^{195}Pt satellites, $^3J_{C,Pt}$ = 25 Hz, P-CH_2-CH_3), and 9.0 (s, with ^{195}Pt satellites, $^3J_{C,Pt}$ = 18 Hz, P-CH_2-CH_3). ^{31}P NMR: 23.0 (d, with ^{195}Pt satellites, $^2J_{P,P}$ = 14.8 Hz, $^1J_{Pt,P}$ = 1262 Hz), 22.1 (d, with ^{195}Pt satellites, $^2J_{P,P}$ = 14.8 Hz, $^1J_{Pt,P}$ = 2395 Hz).

Preparation of 2

A solution of 275 mg (0.5 mmol) of $Pt(PEt_3)_3$ in 5 mL of pentane was treated with 335 mg (440 µL, 2.5 mmol) of $(HSiMe_2)_2O$, and the mixture was stirred at room temperature for 3 h. The color of the solution changed immediately from orange to yellowish. The solution was kept overnight at –30 °C resulting in the precipitation of colorless needles. The solution was decanted and the crystals were washed with 3 mL of cold pentane and dried under vacuum to afford 200 mg (71%) of **2**.

NMR data for 2

^1H NMR: 1.68 (m, 12H, P-CH_2), 0.95 (m, 18H, P-CH_2-CH_3), 0.82 (s, with ^{195}Pt satellites, $^3J_{Pt,H}$ = 17.8 Hz, 12H, Si-CH_3). ^{13}C NMR: 20.2 (dd, with ^{195}Pt satellites, $^1J_{C,P}$ = 13.8 Hz, $^3J_{C,P}$ = 11.4 Hz, $^2J_{C,Pt}$ = 24.5 Hz, P-CH_2), 15.6 (vt, with ^{195}Pt satellites, $^3J_{C,P}$ = 5.9 Hz, $^2J_{C,Pt}$ = 98 Hz, Si-CH_3), and 8.5 (v. quin., J = 10 Hz, P-CH_2-CH_3). ^{31}P NMR: 19.7 (s, with ^{195}Pt satellites, $^1J_{Pt,P}$ = 1548 Hz).

Preparation of 3

To a solution of 34 mg (0.06 mmol) of **2** in 0.6 mL of benzene-d_6 was added MeI (5 µL, 0.08 mmol) and the reaction was stirred at room temperature overnight, producing complex **3** quantitatively. After measuring the NMR spectrum, the solvent was evaporated to afford 40 mg (94%) of off-white compound **3**.

NMR data for 3

^1H NMR: 2.11 (m, 12H, P-CH_2), 0.97 (m, 18H, P-CH_2-CH_3), 0.56 (s, with ^{195}Pt satellites, $^3J_{Pt,H}$ = 19.9 Hz, 6H, Si-CH_3), 0.17 (s, 9H, Si-CH_3). ^{13}C NMR: 18.8 (vt, $^1J_{C,P}$ = $^3J_{C,P}$ = 17.2 Hz, P-CH_2), 11.0 (t, $^3J_{C,P}$ = 2 Hz, Si-CH_3), 8.9 (s, P-CH_2-CH_3), 2.8 (s, O-$SiMe_3$). ^{31}P NMR: 17.3 (s, with ^{195}Pt satellites, $^1J_{Pt,P}$ = 2855 Hz).

Preparation of 4

To a solution of 28 mg (0.05 mmol) of **2** in 1 mL of benzene was added methyl triflate (8 mg, 5.5 µL, 0.05 mmol) at 6 °C. Slow precipitation of a yellow oil started and after 3 h, the oil was separated from the solution. NMR measurement of a sample of the oil in C_6D_6 showed formation of compound **4** in 80% purity. Attempts to isolate complex **4** failed because of its instability.

NMR data for 4

^1H NMR: 3.5 (br., O-Me), 1.70 (m, 12H, P-CH_2), 0.84 (m, 18H, P-CH_2-CH_3), 0.37 (s, with ^{195}Pt satellites, $^3J_{Pt,H}$ = 18 Hz, 12H, Si-CH_3). ^{31}P NMR: 15.8 (s, with ^{195}Pt satellites, $^1J_{Pt,P}$ = 1792 Hz).

Preparation of 5

To a solution of 28 mg (0.05 mmol) of **2** in 1 mL of benzene-d_6 was added an Et_2O–BF_3 complex (7 mg, 0.05 mmol). NMR measurements showed immediate quantitative formation of compound **5**. Evaporation of the solvent gave 30 mg (95%) of the pure colorless complex **5**.

NMR data for 5

^1H NMR: 1.55 (m, 12H, P-CH_2), 1.01 (m, 18H, P-CH_2-CH_3), 0.82 (s, with ^{195}Pt satellites, $^3J_{Pt,H}$ = 15.4 Hz, 12H, Si-CH_3). ^{13}C NMR: 19.4 (dd, with ^{195}Pt satellites, $^1J_{C,P}$ = 14.5 Hz, $^3J_{C,P}$ = 12.8 Hz, $^2J_{C,Pt}$ = 23.8 Hz, P-CH_2), 8.2 (v. quin., J = 10 Hz, P-CH_2-CH_3), 7.3 (vt, with ^{195}Pt satellites, $^3J_{C,P}$ = 5.0 Hz, $^2J_{C,Pt}$ = 74.8 Hz, Si-CH_3). ^{19}F NMR: –142 (m). ^{31}P NMR: 17.0 (s, with ^{195}Pt satellites, $^1J_{Pt,P}$ = 1705 Hz).

Preparation of 6

To a solution of 55 mg (0.1 mmol) of $Pt(PEt_3)_3$ in 2 mL of pentane was added $HSiMe_2$-O-$SiMe_2$-O-$SiMe_2H$ (12.5 mg, 15 µL, 0.06 mmol), and the mixture was stirred for 3 h at room temperature. The resulting solution was evaporated to dryness, redissolved in 1 mL of pentane, and left in the freezer at –30 °C for 2 days, resulting in precipitation of colorless crystals. The solution was decanted and the crystals were washed with 3 mL of cold pentane and dried to afford 40 mg (65%) of **6**.

NMR data for 6

^1H NMR: 2.07 (m, 12H, P-CH_2), 1.62 (m, 12H, P-CH_2), 1.14 (m, 18H, P-CH_2-CH_3), 1.12 (s, with ^{195}Pt satellites, $^3J_{Pt,H}$ = 27.4 Hz, 12H, Si-CH_3), 1.01 (m, 18H, P-CH_2-CH_3), 0.51 (s, 6H, Si-CH_3), –2.21 (dd, $^2J_{H,Ptrans}$ = 149 Hz, $^2J_{H,Pcis}$ = 23.7 Hz, $^1J_{H,Pt}$ = 1007 Hz, 1H, Pt-H). ^{13}C NMR: 22.4 (dd, with ^{195}Pt satellites, $^1J_{C,P}$ = 19.2 Hz, $^3J_{C,P}$ = 2.4 Hz, $^2J_{C,Pt}$ = 21 Hz, P-CH_2), 19.3 (dd, with ^{195}Pt satellites, $^1J_{C,P}$ = 27 Hz, $^3J_{C,P}$ = 5.0 Hz, $^2J_{C,Pt}$ = 30 Hz, P-CH_2), 15.2 (d, with ^{195}Pt satellites, $^3J_{C,Ptrans}$ = 12 Hz, $^2J_{C,Pt}$ = 157 Hz, Si-CH_3), 9.1 (overlapped signal, P-CH_2-CH_3), 4.2 (br. s, Si-CH_3). ^{31}P NMR: 23.4 (d, with ^{195}Pt satellites, $^2J_{P,P}$ = 16.6 Hz, $^1J_{Pt,P}$ =

X-ray crystal structure determination of 2

Colorless needles of complex **2** were obtained from a pentane solution at –30 °C. Crystallographic parameters are given in Table 2.

Data collection and treatment

A Nonius Kappa CCD diffractometer equipped with a MoKα graphite monochromator (λ = 0.710 73 Å) was used for X-ray measurements under the following conditions: total of 53 657 reflections collected, $-121 \le h \le 12$, $0 \le k \le 18$, $0 \le l \le 22$, frame scan width 1.0°, scan speed 1° per 60 s, typical peak mosaicity 1.336°, 6240 independent reflections (R_{int} = 0.061). The data were processed with a Denzo-Scalepack.

Solution and refinement

The structure was solved by direct methods (SHELXS-97), full-matrix least-squares refinement based on F^2 (SHELXL-97), 205 parameters with 4 restrains, final R_1 = 0.0392 (based on F^2) for data with $I > 2\sigma(I)$, and R_1 = 0.0523 on 5355 reflections, goodness-of-fit on F^2 = 1.094, and largest electron density peak = 2.314 e $Å^{-3}$.

X-ray crystal structure determination of 6

Colorless plates of complex **6** were obtained from cold pentane. Crystallographic parameters are given in Table 2.

Data collection and treatment

A Nonius Kappa CCD diffractometer equipped with a MoKα graphite monochromator (λ = 0.710 73 Å) was used for X-ray measurements under the following conditions: total of 16 955 reflections collected, $-41 \le h \le 36$, $0 \le k \le 12$, $0 \le l \le 19$, frame scan width 1.0°, scan speed 1° per 90 s, typical peak mosaicity 0.595°, 4992 independent reflections (R_{int} = 0.055). The data were processed with a Denzo-Scalepack.

Solution and refinement

The structure was solved by direct methods (SHELXS-97), full-matrix least-squares refinement based on F^2 (SHELXL-97), 195 parameters with 0 restrains, final R_1 = 0.0296 (based on F^2) for data with $I > 2\sigma(I)$, and R_1 = 0.0377 on 4716 reflections, goodness-of-fit on F^2 = 1.030, largest electron density peak = 1.355 e $Å^{-3}$.

Synthesis and application of L-*N*-Boc-*N*-methyl-β-hydroxyvaline in the preparation of a depsipeptide[1]

James E. Dettwiler, Laurent Bélec, and William D. Lubell

Abstract: Enantiopure (>99% ee) L-*N*-*tert*-butyloxycarbonyl-*N*-methyl-β-hydroxyvaline (**2**) was synthesized in six steps and 43% overall yield from D-serine methyl ester (**5**). Methyl (4*S*)-*N*-(9-phenylfluoren-9-yl)-oxazolidine-4-carboxylate (**7**) was prepared in two steps and 73% yield by *N*-phenylfluorenation of **5** followed by cyclization of *N*-(PhF)amino alcohol **6** with formaldehyde and catalytic *p*-toluenesulfonic acid (PhF = 9-phenylfluoren-9-yl). The addition of MeLi to oxazolidine carboxylate **7** produced the tertiary alcohol **8** in 91% yield. Oxazolidines **8** equilibrated with oxazolidine **9** under acidic conditions. Reduction of pure **8** or the mixture of oxazolidines **8** and **9** with $NaCNBH_3$ and hydrochloric acid in anhydrous dioxane afforded *N*-methyl amino diol **11** in 86%–92% yields. Attempts to selectively oxidize *N*-(PhF)amino diol **11** were unsuccessful; however, hydrogenation of **11** in the presence of di-*tert*-butyl dicarbonate gave the corresponding *N*-(Boc)amino diol **12** in 82% yield. Selective oxidation of diol **12** was performed using a cocktail containing TEMPO free radical, $NaClO_2$, and NaOCl to give L-*N*-Boc-*N*-methyl-β-hydroxyvaline (**2**) in 87% yield. Coupling of β-hydroxyvaline **2** and (*S*)-2-hydroxy-3-methylbutanoate (**15**) was accomplished by using the methodology of Mitsunobu to provide depsipeptide Boc-(*S*)-HOMeVal-(*R*)-Hmb (**4**) for use as a building block in the synthesis of the cyclic antifungal depsipeptide aureobasidin B.

Key words: *N*-methylated amino acid, serine, depsipeptide, aureobasidin.

Résumé : La L-*N*-*tert*-butyloxycarbonyl-*N*-méthyl-β-hydroxyvaline (**2**) a été synthétisée sous sa forme énantiopure (>99 % ee) par un protocole comprenant six étapes à partir de l'ester méthylique de la D-sérine (**5**) avec un rendement total de 43 %. Le méthyle (4*S*)-*N*-(9-phénylfluoren-9-yl)-oxazolidine-4-carboxylate (**7**) a été préparé en deux étapes avec un rendement de 73 % par une *N*-phénylfluorénation de **5**, suivie par une cyclisation de l'alcool *N*-(PhF)amino **6** avec du formaldéhyde en présence catalytique d'acide *p*-toluène sulfonique (PhF = 9-phenylfluoren-9-yl). L'addition de MeLi sur l'oxazolidine carboxylate **7** a donné l'alcool tertiaire **8** avec un rendement de 91 %. L'oxazolidine **8** a équilibré avec l'oxazolidine **9** dans des conditions acides. La réaction de **8** pur ou du mélange des oxazolidines **8** et **9** avec du $NaCNBH_3$ et de l'acide chlorhydrique dans du dioxane anhydre a donné l'amino diol *N*-méthylé **11** avec des rendements de 86 % – 92 %. Les essais d'oxydation du *N*-(PhF)amino diol **11** ont échoué, cependant, le *N*-(Boc)amino diol **12** a été obtenu à partir de l'hydrogénation de **11** en présence de di-*tert*-butyle dicarbonate avec un rendement de 82 %. L'oxydation sélective du diol **12** a été effectuée avec un mélange du radical libre TEMPO, $NaClO_2$ et NaOCl pour donner la L-*N*-Boc-*N*-méthyl-β-hydroxyvaline (**2**) avec un rendement de 87 %. Le couplage entre la β-hydroxyvaline **2** et le (*S*)-2-hydroxy-3-méthylbutanoate (**15**) a été effectué avec la méthode de Mitsunobu pour donner le depsipeptide Boc-(*S*)-HOMeVal-(*R*)-Hmb (**4**) qui est un fragment pour la synthèse de l'auréoabsidine B, un depsipeptide antifongique et cyclique.

Mots clés : acide aminé *N*-méthylé, serine, depsipeptide, auréobasidine.

Introduction

L-*N*-Methyl-β-hydroxyvaline (**1**) is an important component of biologically active peptides such as the anti-HIV antibiotic luzopeptin (1) as well as members of the aureobasidin (2) family of antifungal peptides (Fig. 1). Featuring hydroxyl, amino, carboxylate, and *N*-alkyl substituents as well as a quaternary carbon, **1** is a synthetic challenge for which no efficient route presently exists. Methods to prepare L-*N*-methyl-β-hydroxyvaline (**1**) have usually required multiple steps and have often resulted in low enantiomeric purity (3–6). First synthesized in racemic form (3) and resolved, L-*N*-Boc-*N*-methyl-β-hydroxyvaline (**2**) was most recently prepared from D-*N*-Boc-serine methyl ester in eight steps with

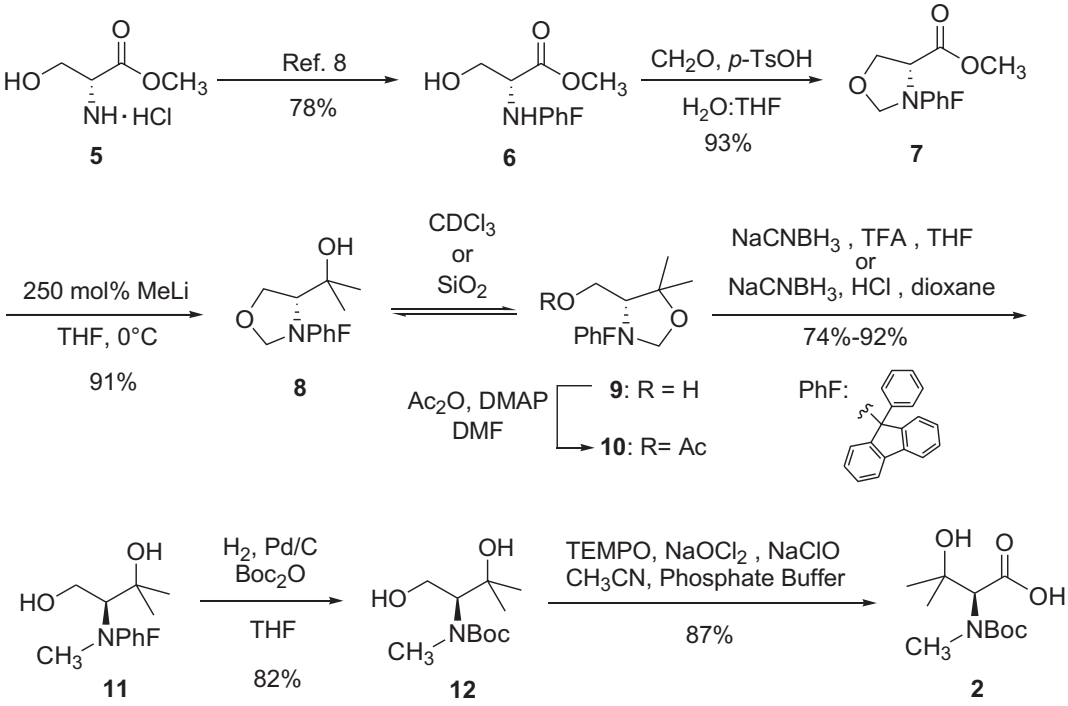
Scheme 1. Synthesis of L-*N*-*tert*-butyloxycarbonyl-*N*-methyl-β-hydroxyvaline (**2**).



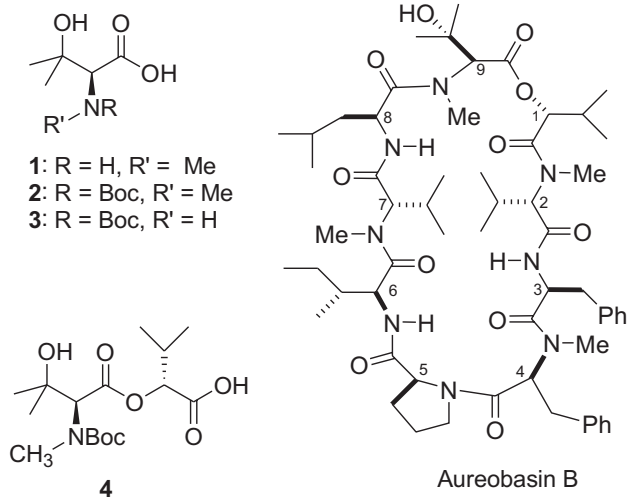


Fig. 1. L-Hydroxymethyl-*N*-methyl-β-hydroxyvaline (**1**), L-*N*-*tert*-butyloxycarbonyl-*N*-methyl-β-hydroxyvaline (**2**), L-*N*-*tert*-butyloxycarbonyl-β-hydroxyvaline (**3**), depsipeptide Boc-(*S*)-HOMeVal-(*R*)-Hmb (**4**), and aureobasidin B.

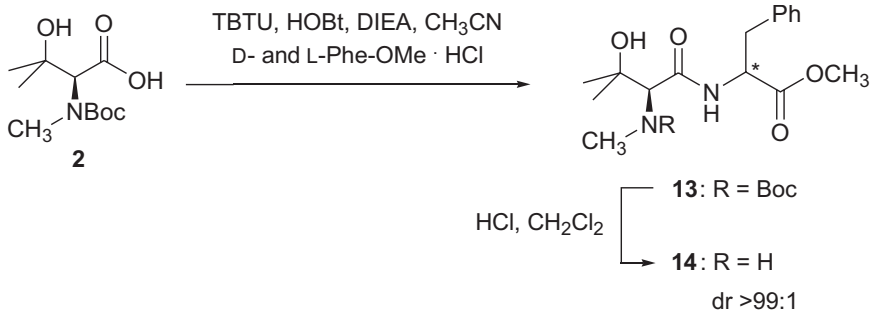
an overall yield of 66%, albeit with an enantiomeric purity of 90% (4, 5). Racemization during this synthesis was likely due to the employment of a configurationally labile α-amino aldehyde intermediate (7). Considering the requirement of enantiopure building blocks for effective peptide synthesis, alternative methodology is still necessary for synthesizing enantiopure **1** in protected form.

We have recently reported a two-step approach for synthesizing L-*N*-Boc-β-hydroxyvaline (**3**) from D-*N*-Boc-serine methyl ester (8), which involved treatment with MeMgBr followed by selective catalyzed TEMPO oxidation (9, 10) Direct *N*-methylation of L-*N*-Boc-β-hydroxyvaline (**3**) was, however, unsuccessful using various methods. Protocols using CH_3I and $(CH_3)_2SO_4$ as methylating agents in the presence of various bases (NaH, Ag_2O, Ag_2CO_3, or *n*-BuLi) were unsuccessful and either resulted in alcohol methylation or recovered starting material (11). For example, treatment of **3** with CH_3I and NaH in THF gave L-*N*-Boc-β-methoxyvaline in 65% yield. Attempts to convert **3** to an oxazolidine or oxazolidinone were also unsuccessful and resulted predominantly in recovered starting material. Instead of trying a selective *O*-protection, *N*-alkylation, and *O*-deprotection strategy, we decided to develop an alternative route to obtain L-*N*-Boc-*N*-methyl-β-hydroxyvaline (**2**) in enantiopure form (Scheme 1) (12). Our protocol involves a six-step synthesis from D-serine methyl ester (**5**) in 43% overall yield. This route employs *N*-(9-phenylfluoren-9-yl)serine methyl ester (8) as a chiral educt to deliver enantiopure **2** (>99% ee).



Results and discussion

The starting material D-*N*-(PhF)serine methyl ester (**6**) was synthesized according to the literature method by phenylfluorenation of D-serine methyl ester (Scheme 1) (8). Treatment of amino alcohol **6** with formaldehyde and catalytic *p*-toluenesulfonic acid in THF at room temperature afforded oxazolidine carboxylate ester **7** in 93% yield (13). The quaternary carbon was constructed using our best conditions by adding 250 mol% of MeLi to a solution of **7** in THF at 0 °C. Tertiary alcohol **8** could be isolated after filtration through a plug of silica gel; however, on prolonged exposure to silica gel, **8** equilibrated with oxazolidine primary alcohol **9**.

In chloroform, oxazolidine **8** existed in equilibrium with oxazolidine primary alcohol **9**, the latter of which could be selectively acetylated. Treatment of a 1:1 mixture of **8** and **9** with acetic anhydride and catalytic 4-dimethylaminopyridine (DMAP) in chloroform gave **8** and ester **10**. Separation of

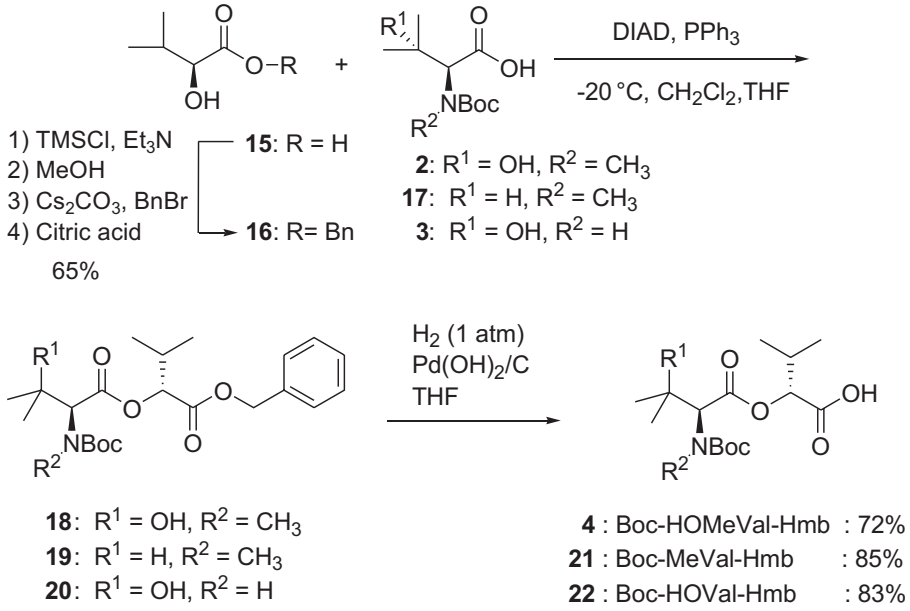
Scheme 2. Enantiomeric purity of L-*N*-*tert*-butyloxycarbonyl-*N*-methyl-β-hydroxyvaline (**2**).

the mixture by chromatography on silica gel gave a new equilibrium and the three compounds (**8**–**10**) were isolated in pure form. In $CDCl_3$, pure **8** was found to equilibrate to a 1:1 mix of **8** and **9** after 12 h. Residual acid in chloroform may be responsible for this transformation because spectra of pure **8** and **9** could be obtained in DMSO-d_6. The assignment of the structures of oxazolidine alcohols **8** and **9** was made based on their ^{1}H NMR spectra in DMSO-d_6 in comparison to acetate **10**. Of particular note, large differences in the chemical shifts for the signals of the diastereotopic methylene and methyl protons were indicative of groups held in fixed environments by the oxazolidine ring. In the case of the primary alcohol oxazolidine **9**, the difference in the chemical shifts of the diastereotopic signals for the constrained methyl groups were larger (Δδ = 162.4 Hz) than those observed for tertiary alcohol oxazolidine **8** (Δδ = 94.6 Hz). The chemical shift differences for the diastereotopic methylene protons were greater (Δδ = 71.1 Hz) for the tertiary alcohol oxazolidine **8** relative to those of the primary alcohol oxazolidine **9** (Δδ = 26.6 Hz). Acetate **10** exhibited a similar difference in the chemical shifts of its diastereotopic methyl singlets (Δδ = 143.3 Hz) and methylene protons (Δδ = 28.2 Hz) as was seen for the primary alcohol oxazolidine **9**. Moreover, relative to the methylene signals of **9**, those for **10** were observed to be downfield shifted indicative of acylation of the primary alcohol.

The conversion of oxazolidines **8** and **9** to *N*-methyl diol **11** was accomplished by treatment with $NaCNBH_3$ under acidic conditions (13). Two conditions were tested. In the first condition, oxazolidine **8** at 0 °C was treated with $NaCNBH_3$ in anhydr. THF containing trifluoroacetic acid to give *N*-methylamino diol **11** in 74% yield after purification. In the second condition, oxazolidine **8** in 0.1 mol/L HCl in dioxane was treated with $NaCNBH_3$ to give *N*-methylamino diol **11** in 86% yield after purification. Employing these later conditions to reduce a mixture of oxazolidines **8** and **9** gave amino diol **11** in similar yield. In the ^{1}H NMR spectrum of *N*-PhF-*N*-methylamino diol **11** in $CDCl_3$, a doubling of signals was observed suggesting an equilibrium between two hydrogen-bonded forms. The doubling of signals could be avoided by recording the spectrum of **11** in deuterated methanol containing a trace of trifluoroacetic acid.



Selective oxidation of *N*-PhF-*N*-methylamino diol **11** was unsuccessful using a wide variety of oxidation methods presumably because of the oxidation of the tertiary amine. On the other hand, exchanging *N*-PhF to *N*-Boc protection could be effected by hydrogenation in the presence of di-*tert*-butyl dicarbonate and palladium hydroxide to give the *N*-(Boc)amino diol **12** in 82% yield (14). As in our synthesis of β-hydroxyvaline (10), selective primary alcohol oxidation was accomplished by treating *N*-(Boc)amino diol **12** with TEMPO (2,2,6,6-tetramethyl-1-piperidyloxy) free radical, sodium chlorite, and sodium hypochlorite in a sodium phosphate buffered acetonitrile solution (15). L-*N*-Boc-*N*-Methyl-β-hydroxyvaline (**2**) was then isolated in pure form after aqueous extraction in 87% yield.

To ascertain if any racemization had occurred during the synthesis, the enantiomeric purity of **2** was investigated by coupling to L- and D-Phe-OMe·HCl using benzotriazol-1-yl-1,1,3,3-tetramethyluronium tetrafluoroborate (TBTU) (16), 1-hydroxybenzotriazole (HOBt), and diisopropylethylamine (DIEA) in acetonitrile to produce dipeptides **13**, which existed as mixtures of carbamate isomers (Scheme 2). The *N*-Boc protecting group of the crude product was removed by bubbling a stream of HCl gas into a solution of **13** in CH_2Cl_2. The 400 MHz ^{1}H NMR spectrum of crude dipeptide (*R*)-**14** was examined during incremental additions of (*S*)-**14** in CD_3OD. Measurement of the signals for the diastereomeric methyl amine singlets at 2.52 and 2.04 ppm demonstrated dipeptide (*S*)-**14** to be of >99% diastereomeric purity. Hence, L-*N*-Boc-*N*-methyl-β-hydroxyvaline (**2**) is considered to be of the same high enantiomeric purity.

The depsipeptide Boc-(*S*)-HOMeVal-(*R*)-Hmb (**4**) was targeted to serve as a building block for the synthesis of analogs of the cyclic antifungal depsipeptide aureobasidin B (17). The preparation of depsipeptides **4**, **21**, and **22** was accomplished by the coupling of the corresponding *N*-Boc protected amino acid (**2**, **3**, and **17**) and (*S*)-2-hydroxy-3-methylbutanoic benzyl ester (**16**) using the Mitsunobu reaction, followed by benzyl ester deprotection (Scheme 3). Benzyl ester **16** was prepared from (*S*)-2-hydroxy-3-methylbutanoic acid (**15**), which was synthesized with retention of configuration via a double inversion from L-valine using the literature procedure in 52% overall yield (18). Because direct alkylation of **15** resulted in mixtures of ether and ester products, a four-step, one-pot procedure was developed to prepare the benzyl ester **16**. First, the hydroxyl and carboxylate groups were both protected with trimethylsilyl (TMS) groups. Then, the carboxylic acid was liberated selectively using MeOH and alkylated with benzyl bromide and Cs_2CO_3 to provide the silylether benzyl ester, which on treatment with citric acid gave α-hydroxy ester **16** in 65% overall yield. The conditions for formation of the depsi bonds were first optimized with Boc-MeVal (**17**) and Boc-

Scheme 3. Synthesis of the depsipeptides **4**, **21**, and **22** (1 atm = 101.325 kPa).

HOVal (**3**). Optimal conditions were then applied to Boc-HOMeVal (**2**). Formation of the depsipeptide bond was performed by an initial reaction of the secondary alcohol of **16** with triphenylphosphine and diisopropyldiazodicarboxylate (DIAD) in dichloromethane, followed by S_N2 displacement of the phosphine intermediate on addition of the *N*-Boc protected amino acid (**2**, **3**, and **17**) to form depsipeptides **18**–**20** and triphenylphosphine oxide (19). Crude depsipeptides **18**–**20** were isolated by chromatography on silica gel to remove the triphenylphosphine oxide. Hydrogenolysis by using $Pd(OH)_2$ on carbon cleaved the benzyl ester affording acids **4**, **21**, and **22**, in 72%, 85%, and 83% overall yields, respectively (14).[3]

Conclusion

Enantiopure (>99%) L-*N*-*tert*-butyloxycarbonyl-*N*-methyl-β-hydroxyvaline (**2**) was synthesized in six steps and 43% overall yield from D-serine methyl ester (**5**). Application of **2**, as well as Boc-MeVal and Boc-HOVal (**3**), in Mitsunobu reactions with (*S*)-benzyl-2-hydroxy-3-methylbutanoate (**16**) has provided three depsipeptides: Boc-(*S*)-HOMeVal-(*R*)-Hmb (**4**), Boc-(*S*)-MeVal-(*R*)-Hmb (**21**), and Boc-(*S*)-HOVal-(*R*)-Hmb (**22**). These building blocks are presently being employed in our program on antimicrobial peptide synthesis (17, 20).

Experimental section

General

For reactions performed under anhydrous conditions, glassware was either oven- or flame-dried and the reaction was run under a positive pressure of argon or nitrogen. Tetrahydrofuran (THF) was freshly distilled from sodium/benzophenone, CH_2Cl_2 from P_2O_5, dioxane from sodium. Triethylamine (Et_3N) was distilled from ninhydrin then CaH_2. The 0.2 N HCl – dioxane solution was prepared by passing a stream of HCl gas bubbles through dry dioxane and the concentration of the solution was determined by titration of 1 mL aliquots diluted with 1 mL H_2O using a 0.1 N standard NaOH solution and phenolphtalein as the indicator. Chromatography was performed using 230–400 mesh silica gel. Amines were revealed with ninhydrin on TLC plates; Boc groups were removed by dipping the plates in TFA before exposure to ninhydrin. Unless otherwise noted, ^1H and ^{13}C NMR spectra were recorded in $CDCl_3$ or CD_3OD at 300/75 or 400/100 MHz. Chemical shifts (δ) are reported in parts per million (ppm) downfield of internal tetramethylsilane ($(CH_3)_4Si$) or referenced to the residual solvent peak ($CHCl_3$ δ 7.26, 77.16 ppm; methanol δ 3.31, 49.00 ppm). Coupling constants are reported in Hz. Chemical shifts of PhF aromatic carbons are omitted for clarity in the ^{13}C NMR spectra. HR-MS (EI and FAB) were obtained by the Université de Montréal Mass Spectrometry facility. Specific rotations are reported as follows: $[\alpha]_D^{20}$, concentration (*c* in g/100 mL), and solvent. Analytical LC–MS was performed on an inverse phase column (Anal Waters C18, 250 × 4.6 mm) with a flow rate of 0.5 mL/min. A volume of 20 µL of sample with a concentration of 1 mg/mL was injected. Preparative reversed-phase HPLC was performed on an inverse phase column (Prep Prevail C18, 250 × 22 mm) with a flow rate of 15 mL/min: elution condition A, gradient 20% CH_3CN with 0.1% TFA–H_2O with 0.1% TFA to 80% CH_3CN with 0.1% TFA–H_2O with 0.1% TFA over 20 min; condition B, 70% CH_3CN with 0.1% TFA–H_2O with 0.1% TFA.

acid (6 mol%, 331 mg, 1.92 mmol), and a 37% aqueous formaldehyde solution (1500 mol%, 39 mL, 480 mmol) in THF (320 mL) was stirred for 24 h at room temperature, washed with a solution of satd. $NaHCO_3$ (2 × 200 mL) and brine, dried with $MgSO_4$, filtered and evaporated to a solid residue. Chromatography on silica gel using 10% EtOAc in hexanes as the eluant gave a white solid (11.05 g, 93%). TLC R_f = 0.41 (20% EtOAc in hexanes); mp 106 to 107 °C. $[\alpha]_D^{20}$ –267.3 (*c* 1.0 $CHCl_3$). ^{1}H NMR (400 MHz, $CDCl_3$) δ: 3.30 (t, 1H, *J* = 6.8), 3.54 (s, 3H), 3.61 (d, 2H), 4.73 (d, 1H, *J* = 6.4), 4.93 (d, 1H, *J* = 6.4), 7.22–7.70 (m, 13H). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 52.0, 60.8, 69.1, 85.1, 119.8, 173.6. HR-MS calcd. for $C_{24}H_{22}NO_3$ ($[M + H]^+$): 372.1600; found: 372.1582.

(4*S*)-4-(1-Hydroxymethylethyl)-3-(9-phenylfluoren-9-yl)-oxazolidine (8)

To a solution of oxazolidine **7** (3.72 g, 10 mmol) in THF (182 mL) at 0 °C, a solution of 1.4 mol/L MeLi in Et_2O (250 mol%, 18 mL, 25 mmol) was added dropwise. The reaction mixture was stirred for 2 h at 0 °C and partitioned between equal volumes of EtOAc and a satd. NaH_2PO_4 solution (100 mL). The phases were separated and the aqueous phase was extracted with EtOAc (3 × 50 mL). The combined organic phase was washed with brine, dried with $MgSO_4$, filtered and evaporated to a solid residue. Chromatography on silica gel using 20% EtOAc in hexanes as the eluant provided **8** as a white solid (3.38 g, 91%). TLC R_f = 0.34 (30% AcOEt in hexanes); mp 156 to 157 °C. $[\alpha]_D^{20}$ –519.3 (*c* 0.3 DMSO). ^{1}H NMR (400 MHz, $CDCl_3$) δ: 0.91 (s, 3H), 1.05 (s, 3H), 1.95 (s, 1H), 2.49 (dd, 1H, J_1 = 3.1, J_2 = 7.5), 2.96 (t, 1H, *J* = 7.8), 3.49 (dd, 1H, J_1 = 3.1, J_2 = 8.1), 4.79 (d, 1H, *J* = 6.7), 5.10 (d, 1H, *J* = 6.7), 7.15–7.73 (m, 13H). ^{1}H NMR (400 MHz, DMSO-d_6) δ: 0.78 (s, 3H), 1.01 (s, 3H), 2.32 (dd, 1H, J_1 = 2.4, J_2 = 7.2), 2.32 (t, 1H, *J* = 7.4), 3.63 (dd, 1H, J_1 = 2.5, J_2 = 7.2), 4.13 (s, 1H), 4.71 (d, 1H, *J* = 6.3), 4.89 (d, 1H, *J* = 6.3), 7.10–7.97 (m, 13H). ^{13}C NMR (100 MHz, DMSO-d_6) δ: 26.2, 29.0, 65.2, 66.7, 71.1, 77.6, 85.5. HR-MS calcd. for $C_{25}H_{25}NO_2$ (TOF EI): 371.1885; found: 371.1886.

(4*R*)-*O*-Acetoxymethyl-5,5-dimethyl-3-(9-phenylfluoren-9-yl)-oxazolidine (10)

A solution of oxazolidine **8** (50 mg, 0.135 mmol) in $CDCl_3$ (1.4 mL) was stirred for 12 h at room temperature, treated with DMAP (10 mol%, 1.6 mg, 13.5 µmol), and dropwise with acetic anhydride (240 mol%, 42 µL, 0.324 mmol). The reaction mixture was stirred for 24 h and concentrated under reduced pressure to give a residue that was purified by chromatography on silica gel using 15% EtOAc in hexanes as the eluant. First to elute was the acetylated oxazolidine **10** as a white foam (28.0 mg, 50%). TLC R_f = 0.45 (20% AcOEt in hexanes). $[\alpha]_D^{20}$ 229.3 (*c* 0.3 DMSO). ^{1}H NMR (400 MHz, $CDCl_3$) δ: 0.70 (s, 3H), 1.15 (s, 3H), 1.87 (s, 3H), 2.30 (dd, 1H, J_1 = 4.5, J_2 = 10.3), 3.72 (dd, 1H, J_1 = 4.5, J_2 = 11.1), 3.90 (t, 1H, *J* = 10.7), 4.73 (d, 1H, *J* = 7.3), 4.88 (d, 1H, *J* = 7.3), 7.16–7.60 (m, 13H). ^{1}H NMR (300 MHz, DMSO-d_6) δ: 0.56 (s, 3H), 1.07 (s, 3H), 1.83 (s, 3H), 2.17 (dd, 1H, J_1 = 4.5, J_2 = 10.3), 3.57 (dd, 1H, J_1 = 4.5, J_2 = 11.1), 3.86 (t, 1H, *J* = 10.7), 4.65 (d, 1H, *J* = 7.2), 4.75 (d, 1H, *J* = 7.1), 7.17–7.94 (m, 13H). ^{13}C NMR (75 MHz, DMSO-d_6) δ: 20.5, 27.9, 63.4, 63.9, 76.9, 79.2, 80.9, 81.2, 169.7. HR-MS calcd. for $C_{27}H_{28}NO_3$ ($[M + H]^+$): 414.2064; found: 414.2065. Second to elute was (4*R*)-4-hydroxymethyl-5,5-dimethyl-(9-phenylfluoren-9-yl)-oxazolidine (**9**) as a white foam (12.5 mg, 25%). TLC R_f = 0.53 (30% AcOEt in hexanes). $[\alpha]_D^{20}$ 326.0 (*c* 0.2 DMSO). ^{1}H NMR (400 MHz, $CDCl_3$) δ: 0.70 (s, 3H), 1.24 (s, 3H), 2.15 (d, 1H, *J* = 4.9), 2.80 (dd, 1H, J_1 = 6.1, J_2 = 11.1), 3.20 (d, 1H, *J* = 11.0), 4.78 (d, 1H, *J* = 7.1), 4.96 (d, 1H, *J* = 7.0), 7.16–7.76 (m, 13H). ^{1}H NMR (300 MHz, DMSO-d_6) δ: 0.62 (s, 3H), 1.16 (s, 3H), 1.99 (m, 1H), 3.06 (m, 1H), 3.24 (m, 1H), 4.22 (t, 1H, *J* = 4.7), 4.59 (d, 1H, *J* = 7.0), 4.68 (d, 1H, *J* = 7.0), 7.14–7.96 (m, 13H). ^{13}C NMR (75 MHz, DMSO-d_6) δ: 20.2, 28.5, 61.6, 66.2, 77.1, 80.8, 81.6. HR-MS calcd. for $C_{25}H_{26}NO_2$ ($[M + H]^+$): 372.1958; found: 372.1961. Last to elute was oxazolidine **8** as a white foam (8.9 mg, 18%).

(2*R*)-2-*N*-(9-Phenylfluoren-9-yl)amino-3-methyl-1,3-butanediol (11)

Method 1

A solution of oxazolidine **8** (2.22 g, 6 mmol) in 0.2 mol/L HCl in dioxane (60 mL) was treated with $NaCNBH_3$ (320 mol%, 1.21 g, 19.2 mmol). The reaction mixture was stirred for 1 h at r.t.

Method 2

A solution of oxazolidine **8** (4.5 g, 14.2 mmol) and $NaCNBH_3$ (800 mol%, 4.9 g, 114 mmol) in THF (120 mL) was cooled to 0 °C and treated dropwise with trifluoroacetic acid (300 mol%, 3.3 mL, 42.6 mmol). The reaction mixture was stirred for 30 min at 0 °C. After stirring for the designated time, both reaction mixtures were washed, respectively, with a solution of satd. $NaHCO_3$ and brine, dried with $MgSO_4$, filtered and evaporated to a solid. Chromatography on silica gel using 20% EtOAc in hexanes as eluant gave a white solid (Method 1: 1.93 g, 86%; Method 2: 3.35 g, 74%). TLC R_f = 0.54 (50% AcOEt in hexanes); mp 85 to 86 °C. $[\alpha]_D^{20}$ –449.8 (*c* 1.0 MeOH). ^{1}H NMR (400 MHz, CD_3OD + TFA) δ: 0.99 (s, 3H), 1.36 (s, 3H), 2.82 (dd, 1H, J_1 = 2.0, J_2 = 5.4), 3.12 (dd, 1H, J_1 = 6.6, J_2 = 5.0), 3.15 (s, 3H), 3.42 (dd, 1H, J_1 = 3.5, J_2 = 8.1), 7.22–8.10 (m, 13H). ^{13}C NMR (100 MHz, CD_3OD) showed a mixture of conformers; the chemicals shifts are listed in order of appearance (δ): 26.8, 28.5, 29.6, 33.2, 33.4, 58.2, 60.7, 61.3, 63.0, 75.5, 76.7, 78.5, 79.1, 79.2. HR-MS calcd. for $C_{25}H_{27}NO_2$ (TOF EI): 373.2042; found: 373.2051. Employing a 1:1 mixture of oxazolidines **8** and **9** (155 mg, 0.147 mmol) using method 2 gave diol **11** in 92% yield.

(2*R*)-2-*N*-(Boc)Amino-3-methyl-1,3-butanediol (12)

A solution of diol **11** (900 mg, 2.41 mmol) and di-*tert*-butyl dicarbonate (140 mol%, 737 mg, 3.37 mmol) in THF (100 mL) was treated with palladium hydroxide on carbon (270 mg, 20 wt% in Pd) and stirred under 5 atm of hydrogen (1 atm = 101.325 kPa) for 24 h at room temperature. The catalyst was removed by filtration on Celite® and washed with THF (2 × 20 mL) and MeOH (2 × 20 mL). The combined organic phase was evaporated to a residue that was purified by chromatography on silica gel using 70% EtOAc in hexanes as the eluant. Evaporation of the ninhydrin positive fractions (visualized on TLC after treatment with TFA va-

© 2005 NRC Canada

pors) gave *N*-(Boc)amino diol **12** as a white solid (461 mg, 82%). TLC R_f = 0.49 (80% AcOEt in hexanes); mp 138 to 139 °C. $[\alpha]_D^{20}$ 37.1 (*c* 1.0 MeOH). ^{1}H NMR (400 MHz, CD_3OD) showed a 1:1.3 mixture of carbamate isomers (δ): 1.15 (s, 1.6H), [1.16 (s, 1.2H)], [1.25 (s, 1.5H)], 1.26 (s, 1.6H), 1.46 (s, 4.2H), 1.48 (s, 4.5H), [2.89 (s, 1.1H)], 2.93 (s, 1.7H), 3.83–3.92 (m, 2.5H), [4.04 (dd, 0.5H, J_1 = 4.0, J_2 = 8.0)]. ^{13}C NMR (100 MHz, CD_3OD) showed a mixture of carbamate isomers; the chemical shifts are listed in order of appearance (δ): 26.7, 27.8, 28.0, 28.3, 28.9, 57.7, 58.0, 64.8, 72.6, 72.7, 79.9, 80.1, 157.9, 158.0. HR-MS calcd. for $C_{11}H_{24}NO_4$ ([M + H]$^+$): 234.1705; found: 234.1709. Anal. calcd. for $C_{11}H_{23}NO_4$: C 56.63, H 9.94, N 6.00; found: C 56.50, H 10.28, N 5.92.

(*S*)-β-Hydroxy-*N*-(Boc)-*N*-(methyl)valine (2)

A mixture of diol **12** (278 mg, 1.19 mmol), sodium phosphate buffer (4.6 mL, 0.67 mol/L, pH 6.7), and TEMPO (10 mol%, 24 mg, 0.119 mmol) in acetonitrile (6 mL) was heated to 35 °C and treated dropwise simultaneously over 2 h (Caution! Do not mix bleach and sodium chlorite before adding to reaction mixture) (15) with a solution of sodium chlorite ($NaClO_2$, 200 mol%, 2.38 mmol, 1.2 mL of solution : 5.71 g 80% *w*/*w*, 50.5 mmol in 25 mL of water) and diluted bleach (NaOCl, 2 mol%, 0.04 mmol, 1050 µL of solution : 0.66 mL commercial bleach 10.8% *v*/*v* 25 mL of water). The mixture was stirred at 35 °C overnight, cooled to r.t., acidified with citric acid to pH 3, and extracted with EtOAc (3 × 10 mL). The organic phases were combined and evaporated. The residue was dissolved in a solution of satd. Na_2CO_3 (15 mL) and washed with EtOAc (2 × 10 mL). The aqueous phase was acidified with 1 mol/L H_3PO_4 to pH 3, saturated with NaCl, and extracted with EtOAc (3 × 15 mL). The organic phases were combined, dried with $MgSO_4$, filtered and evaporated to give an oil (256 mg, 87%). TLC R_f = 0.43 ($CHCl_3$–MeOH–AcOH, 89:10:1). $[\alpha]_D^{20}$ –34.4 (*c* 0.5 MeOH). ^{1}H NMR (400 MHz, CD_3OD) showed a 0.7:1 mixture of carbamate isomers (δ): 1.22 (s, 1.9H), [1.26 (1.2H)], [1.38 (s, 1.2H)], 1.42 (s, 1.9H), [1.46 (s, 3.6H)], 1.47 (s, 5.4H), [2.95 (s, 1.2H)], 2.96 (s, 1.8H), [4.46 (s, 0.4H)], 4.59 (s, 0.6H). ^{13}C NMR (100 MHz, CD_3OD) showed a mixture of carbamate isomers; the chemicals shifts are listed in order of appearance (δ): 26.4, 27.6, 27.9, 28.1, 33.2, 33.3, 65.3, 66.2, 72.8, 78.5, 80.5, 81.1, 156.5, 157.4, 172.2, 172.3. HR-MS calcd. for $C_{11}H_{22}NO_5$ ([M + H]$^+$): 248.1498; found: 248.1500. LC–MS: 98% purity (condition A), R_T = 14.5.

Enantiomeric purity of (*S*)-β-hydroxy-*N*-(Boc)-*N*-(methyl)valine (2)

A solution of **2** (30 mg, 0.12 mmol) in acetonitrile (1 mL) at 0 °C was treated with HOBt (100 mol%, 22 mg, 0.12 mmol) and TBTU (150 mol%, 58 mg, 0.18 mmol), stirred for 30 min, and treated with a premixed solution of (*S*)- or (*R*)-phenylalanine methyl ester hydrochloride (300 mol%, 78 mg, 0.36 mmol) and diisopropylethylamine (DIEA, 400 mol%, 0.84 µL, 0.48 mmol) in acetonitrile (1 mL) at 0 °C. The reaction mixture was stirred for 48 h at room temperature until TLC showed the complete disappearance of starting acid **2**. TLC R_f = 0.43 ($CHCl_3$–MeOH–AcOH, 89:10:1). The solvent was evaporated and the solid residue was resuspended in CH_2Cl_2 (3 mL). The organic phase was washed with an aq. satd. solution of $NaHCO_3$ (2 × 3 mL), 1 N NaH_2PO_4 (2 × 3 mL), and brine (3 mL), dried with $MgSO_4$, filtered and evaporated to a solid residue. The Boc group was subsequently removed by treating the residue in dry CH_2Cl_2 at 0 °C with a stream of HCl gas bubbles, stirring for 15 min, and concentrating the reaction mixture under reduced pressure to give a solid that was directly examined by 400 MHz ^{1}H NMR spectroscopy in CD_3OD. Measurement of the signals for the diastereomeric methyl amine singlets at 2.04 and 2.52 ppm during incremental additions of (*S*)-**14** in (*R*)-**14** demonstrated dipeptide (*R*)-**14** to be of >99% diastereomeric purity. Hence, (*S*)-β-hydroxy-*N*-(Boc)-*N*-(methyl)valine (**2**) is considered to be of the same high enantiomeric purity.

(*S*,*S*)-β-Hydroxy-*N*-(Boc)-*N*-(methyl)valinylphenylalanine methyl ester ((*S*)-13)

TLC R_f = 0.30 (30% AcOEt in hexanes). ^{1}H NMR (400 MHz, CD_3OD) showed a 1:2 mixture of carbamate isomers (δ): 1.13 (s, 3H), 1.20 (s, 3H), 1.47 (s, 9H), 2.68 (s, 2.0H), [2.71 (s, 1.1H)], 2.97 (m, 1H), 3.23 (m, 1H), [3.68 (s, 1.5H)], 3.73 (s, 3.8H), [4.44 (s, 0.28H)], 4.54 (s, 0.65H), 4.76 (dd, 1H, J_1 = 4.8, J_2 = 9.5), 7.08–7.35 (m, 5H). MS (TIC) *m*/*z*: 309.2 ([M + H]$^+$).

(*S*,*R*)-β-Hydroxy-*N*-(Boc)-*N*-(methyl)valinylphenylalanine methyl ester ((*R*)-13)

TLC R_f = 0.35 (30% AcOEt in hexanes). ^{1}H NMR (400 MHz, CD_3OD) showed a 1:2 mixture of carbamate isomers (δ): 1.08 (s, 3H), 1.15 (s, 3H), 1.46 (s, 9H), [2.70 (s, 1.1H)], 2.93 (s, 1.9H), 3.00 (m, 1H), 3.24 (m, 1H), [3.66 (s, 1.8H)], 3.72 (s, 3.6H), [4.40 (s, 0.3H)], 4.49 (s, 1H), 4.77 (dd, 0.6H, J_1 = 4.50, J_2 = 8.9), 7.01–7.34 (m, 5H). MS (TIC) *m*/*z*: 309.2 ([M + H]$^+$).

(*S*,*S*)-β-Hydroxy-*N*-(methyl)valinylphenylalanine methyl ester hydrochloride ((*S*)-14)

^{1}H NMR (400 MHz, CD_3OD) δ: 1.07 (s, 3H), 1.29 (s, 3H), 2.04 (s, 3H), 2.84 (dd, 1H, J_1 = 10.9, J_2 = 14.0), 3.17–3.23 (m, 2H), 3.58 (s, 3H), 4.82 (m, 1H), 7.14–7.20 (m, 5H).

(*S*,*R*)-β-Hydroxy-*N*-(methyl)valinylphenylalanine methyl ester hydrochloride ((*R*)-14)

^{1}H NMR (400 MHz, CD_3OD) δ: 0.84 (s, 3H), 0.87 (s, 3H), 2.52 (s, 3H), 2.83 (dd, 1H, J_1 = 11.5, J_2 = 14.2), 3.21 (m, 1H), 3.26 (dd, 1H, J_1 = 4.5, J_2 = 14.2), 3.66 (s, 3H), 4.70 (dd, 1H, J_1 = 4.5, J_2 = 11.4), 7.14–7.19 (m, 5H).

(*S*)-*N*-(Boc)-β-methoxyvaline

To a solution of (*S*)-β-hydroxy-*N*-(Boc)valine (**3**, 100 mg, 429 µmol, prepared according to ref. 10) and methyl iodide (800 mol%, 214 µL, 3.43 mmol) in THF (1.5 mL) at 0 °C, sodium hydride (60% dispersion in mineral oil, 300 mol%, 52 mg, 29 mmol) was added cautiously with gentle stirring. The suspension was stirred for 24 h, diluted with EtOAc (2 mL), treated dropwise with water to destroy the excess sodium hydride, and evaporated to an oily residue that was partitioned between ether (5 mL) and water (10 mL). The ether layer was washed with a solution of satd. $NaHCO_3$ (10 mL). The combined aqueous extracts were acidified with citric acid to pH 3 and extracted with EtOAc (3 × 10 mL).

© 2005 NRC Canada

The organic phases were combined, washed with water (2 × 10 mL), 5% aqueous sodium thiosulfate (2 × 10 mL), and water (2 × 10 mL), dried with $MgSO_4$, filtered and evaporated to give an oil that was purified by chromatography on silica gel using a mixture of $CHCl_3$, methanol, and acetic acid (94:4:1) to give an oil (69 mg, 65%). TLC R_f = 0.56 ($CHCl_3$–MeOH–AcOH, 89:10:1). $[\alpha]_D^{20}$ 9.5 (*c* 1.0 MeOH). ^{1}H NMR (400 MHz, CD_3OD) δ: 1.26 (s, 3H), 1.28 (s, 3H), 1.45 (s, 9H), 3.23 (s, 3H), 4.2 (s, 1H). ^{13}C NMR (100 MHz, CD_3OD) δ: 21.7, 21.8, 27.7, 49.0, 60.6, 76.1, 79.7, 156.8, 173.0. HR-MS calcd. for $C_{11}H_{21}NO_5Na$ ($[M + Na]^+$): 270.1312; found: 270.1319.

(*S*)-Benzyl-2-hydroxy-3-methylbutanoate (Hmb-OBn, 16)

To a solution of (*S*)-2-hydroxy-3-methylbutanoic acid (**15**, 2 g, 16.9 mmol, prepared according to ref. 18) and TMSCl (600 mol%, 8.8 mL, 101.4 mmol) in CH_2Cl_2 (170 mL) at 0 °C, Et_3N (600 mol%, 14.2 mL, 101.4 mmol) was added dropwise. The mixture was heated at reflux for 1 h, cooled to 0 °C, and treated with dry MeOH (110 mol%, 732 µL, 18.6 mmol). The reaction was stirred for 1 h at room temperature. The volatiles were removed under reduced pressure on a rotary evaporator. The residue was dissolved in acetonitrile (170 mL) and treated with anhydrous cesium carbonate (150 mol%, 8.3 g, 25.4 mmol) and benzyl bromide (500 mol%, 10 mL, 84.5 mmol), heated at reflux and stirred vigorously for 1 h, cooled to room temperature, treated with solid citric acid (1000 mol%, 32.5 g, 169 mmol), and stirred vigorously for 1 h at room temperature. The precipitate was filtered off and the filtrate was concentrated under reduced pressure. The residue was dissolved in $CHCl_3$ (150 mL), washed with a solution of satd. $NaHCO_3$ (2 × 50 mL) and brine, dried with $MgSO_4$, filtered and evaporated to a residue. Chromatography on silica gel using a gradient 20%–30% EtOAc in hexanes as the eluant and evaporation of the collected fractions provided an oil (2.3 g, 65%). TLC R_f = 0.37 (50% EtOAc in hexanes). $[\alpha]_D^{20}$ –11.3 (*c* 2.0 $CHCl_3$). ^{1}H NMR (400 MHz, $CDCl_3$) δ: 0.82 (d, 3H, *J* = 6.9), 0.98 (d, 3H, *J* = 6.9), 2.00–2.14 (m, 1H), 3.06–3.21 (m, 1H), 4.01–4.11 (m, 1H), 5.14 (d, 1H, *J* = 12.1), 5.21 (d, 1H, *J* = 12.2), 7.25–7.38 (m, 5H). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 15.9, 18.7, 32.1, 67.0, 75.0, 128.3, 128.4, 128.5, 135.2, 174.7. HR-MS calcd. for $C_{12}H_{16}NO_3$ (TOF EI): 208.1099; found: 208.1098.

General procedure for the preparation of depsipeptide benzyl esters

A 0.1 mol/L solution of Hmb-OBn (**16**, 100 mmol%), Ph_3P (250 mol%), and the amino acid (Boc-HOMeVal (**2**, 100 mol%), Boc-HOVal (**3**, 150 mol%), or Boc-MeVal (**17**, 150 mol%)) in CH_2Cl_2–THF (1:1) was cooled to –20 °C, treated with diisopropyl azodicarboxylate (DIAD, 255 mol%) dropwise over 30 min, and stirred at –20 °C for 30 min. The reaction mixture was removed from the ice bath and allowed to stir at room temperature overnight. The volatiles were removed under reduced pressure on a rotary evaporator.

Boc-(*S*)-HOMeVal-(*R*)-Hmb-OBn (**18**, 169 mg) was isolated from the reaction of Hmb-OBn (**16**, 80 mg, 0.384 mmol) and Boc-HOMeVal (**2**, 91 mg, 0.384 mmol) by chromatography on silica gel using 18% EtOAc in hexanes as the eluant and directly employed in the hydrogenation step. An analytically pure sample (LC–MS: 96% purity, condition B, R_T = 23.7) was obtained by purification on RP-HPLC using condition A. TLC R_f = 0.28 (20% AcOEt in hexanes). $[\alpha]_D^{20}$ –22.2 (*c* 0.5 MeOH). ^{1}H NMR (300 MHz, CD_3OD) showed a 1:2 mixture of carbamate isomers (δ): 0.92 (d, 3H, *J* = 6.9), 0.99 (d, 3H, *J* = 6.9), [1.38 (s, 1.08H)], 1.41 (s, 1.98H), 1.22 (s, 2.01H), [1.25 (s, 1.08H)], 1.47 (s, 9H), 2.16–2.31 (m, 1H), [2.93 (s, 1.16H)], 2.94 (s, 1.96H), [4.75 (s, 0.33H)], 4.78 (s, 0.62H), 5.15 (d, 1H, *J* = 12.1), 5.21 (d, 1H, *J* = 12.1), 7.31–7.38 (m, 5H). ^{13}C NMR (75 MHz, CD_3OD) showed a mixture of carbamate isomers; the chemical shifts are listed in order of appearance (δ): 16.5, 18.1, 21.3, 26.4, 26.5, 27.6, 28.1, 30.4, 32.3, 33.3, 65.1, 65.6, 67.0, 72.5, 72.6, 77.6, 80.6, 81.0, 128.5, 128.6, 135.9, 156.5, 157.5, 196.6, 170.1. HR-MS calcd. for $C_{23}H_{36}NO_7$ ($[M + H]^+$): 438.2486; found: 438.2478.

Boc-(*S*)-MeVal-(*R*)-Hmb-OBn (**19**, 649 mg) was isolated from the reaction of Hmb-OBn (**16**, 313 mg, 1.50 mmol) and Boc-MeVal (**17**, 521 mg, 2.25 mmol) by chromatography on silica gel using 15% EtOAc in hexanes as the eluant and directly employed in the hydrogenation step. An analytically pure sample (LC–MS: 99% purity, condition A, R_T = 8.0) was obtained by purification on RP-HPLC using condition A. TLC R_f = 0.35 (10% AcOEt in hexanes). $[\alpha]_D^{20}$ –46.6 (*c* 0.5 $CHCl_3$). ^{1}H NMR (400 MHz, $CDCl_3$) showed a 1:1 mixture of carbamate isomers (δ): 0.85–0.95 (m, 6H), 0.95–1.06 (m, 6H), 1.46 (s, 9H), 2.22 (m, 2H), 2.78 (s, 1.6H), [2.83 (s, 1.4H)], [4.29 (d, 0.4H, *J* = 10.3)], 4.59 (d, 0.4H, *J* = 10.3), 4.87 (d, 1H, *J* = 4.1), 7.24–7.46 (m, 5H). ^{13}C NMR (100 MHz, $CDCl_3$) showed a mixture of carbamate isomers; the chemical shifts are listed in order of appearance (δ): 17.2, 19.0, 19.3, 20.0, 27.6, 27.8, 28.5, 30.2, 30.7, 63.1, 64.8, 66.9, 80.0, 80.3, 128.5, 128.7, 135.4, 155.8, 156.4, 169.1, 169.3, 170.8, 171.1. HR-MS calcd. for $C_{23}H_{35}NO_7$ (TOF EI): 421.2464; found: 421.2471.

Boc-(*S*)-HOVal-(*R*)-Hmb-OBn (**20**, 1.3 mg) was isolated from the reaction of Hmb-OBn (**16**, 625 mg, 3.0 mmol) and Boc-HOVal (**3**, 1050 mg, 4.5 mmol) by chromatography on silica gel using 15% EtOAc in hexanes as the eluant and directly employed in the hydrogenation step. An analytically pure sample (LC–MS: 99% purity, condition B, R_T = 16.0) was obtained by purification on RP-HPLC using condition A. TLC R_f = 0.38 (25% AcOEt in hexanes). $[\alpha]_D^{20}$ –2.8 (*c* 0.5 MeOH). ^{1}H NMR (400 MHz, CD_3OD) δ: 0.93 (d, 3H, *J* = 6.8), 0.98 (d, 3H, *J* = 6.8), 1.25 (s, 3H), 1.28 (s, 3H), 1.44 (s, 9H), 2.22 (dsept, 1H, J_1 = 4.6, J_2 = 6.8), 4.17 (s, 1H), 4.86 (d, 1H, *J* = 4.4), 5.16 (d, 1H, *J* = 12.2), 5.21 (d, 1H, *J* = 12.2), 7.28–7.40 (m, 5H). ^{13}C NMR (100 MHz, CD_3OD) δ: 16.6, 18.2, 25.8, 26.0, 27.7, 30.4, 63.1, 67.0, 71.3, 77.7, 79.8, 128.4, 128.5, 128.6, 135.9, 156.8, 169.9, 170.9. General procedure for benzyl ester removal from depsipeptides

A 0.033 mol/L solution containing the depsipeptide benzyl ester (100 mol%) in THF was treated with palladium hydroxide on carbon (30 wt% of 20 wt% palladium (wet)), stirred under 1 atm of hydrogen for 1 h, filtered onto Celite®, and washed with THF (2×) and MeOH (2×). The filtrate was concentrated under reduce pressure to a residue that was

© 2005 NRC Canada

passed through a pad of silica gel, first using 20% EtOAc in hexanes as the eluant, then followed by 99% EtOAc containing 1% AcOH.

Boc-(S)-HOMeVal-(R)-Hmb (4)

The reaction of ester **18** (89 mg) afforded **4** as a white foam (51 mg, 72%). TLC R_f = 0.40 ($CHCl_3$–MeOH–AcOH, 89:10:1). $[\alpha]_D^{20}$ –28.2 (*c* 0.5 MeOH). ^{1}H NMR (300 MHz, CD_3OD) showed a 1:1.5 mixture of carbamate isomers (δ): 0.99 (d, 3H, *J* = 6.9), 1.03 (d, 3H, *J* = 6.9), 1.26 (d, 3H, *J* = 9.5), 1.41 (d, 3H, *J* = 8.6), 1.48 (s, H), 2.26 (dsept, 1H, J_1 = 4.0, J_2 = 6.7), [3.01 (s, 1.17H)], 3.03 (s, 1.78H), [4.75 (s, 0.37H)], 4.78 (s, 0.64H), 4.88 (d, 1H, *J* = 3.9), 4.95 (br s, 1OH). ^{13}C NMR (75 MHz, CD_3OD) showed a mixture of carbamate isomers; the chemical shifts are listed in order of appearance (δ): 16.4, 18.3, 21.1, 21.3, 26.4, 27.6, 28.1, 30.1, 32.3, 33.3, 65.2, 65.6, 69.4, 72.5, 72.7, 77.5, 78.5, 80.6, 81.0, 156.6, 157.5, 170.1, 171.5. HR-MS calcd. for $C_{16}H_{30}NO_7$ ($[M + H]^+$): 348.2017; found: 348.2016. LC–MS: 99% purity (condition A), R_T = 21.1.

Boc-(S)-MeVal-(R)-Hmb (21)

The reaction of ester **19** (250 mg) afforded **21** as an oil (167 mg, 85%). TLC R_f = 0.58 ($CHCl_3$–MeOH–AcOH, 89:10:1). $[\alpha]_D^{20}$ –75.6 (*c* 0.5 MeOH). ^{1}H NMR (300 MHz, CD_3OD) δ: 0.91 (m, 3H), 0.95–1.07 (m, 6H), 1.25 (d, 3H, *J* = 6.2), 1.45 (s, 9H), 2.13–2.33 (m, 2H), 2.84 (s, 3H), [4.27 (d, 0.43H, *J* = 10.5)], 4.45 (d, 0.45H, *J* = 10.4), 4.8 (d, 1H, *J* = 4.0), 4.84–5.00 (br s, 1OH). ^{13}C NMR (75 MHz, CD_3OD) showed a mixture of carbamate isomers; the chemical shifts are listed in order of appearance (δ): 16.5, 18.2, 18.4, 18.5, 19.3, 21.3, 27.4, 27.6, 27.8, 29.8, 30.1, 30.3, 63.6, 65.1, 69.4, 77.3, 80.5, 80.8, 156.5, 157.1, 170.9. HR-MS calcd. for $C_{16}H_{30}NO_6$ ($[M + H]^+$): 332.2073; found 332.2074. LC–MS: 97% purity (condition A), R_T = 26.0.

Boc-(S)-HOVal-(R)-Hmb (22)

The reaction of ester **20** (330 mg) afforded **22** as a white solid (224 mg, 83%). TLC R_f = 0.38 ($CHCl_3$–MeOH–AcOH, 89:10:1). $[\alpha]_D^{20}$ –29.4 (*c* 0.5 MeOH). ^{1}H NMR (400 MHz, CD_3OD) δ: 1.00 (d, *J* = 6.9, 3H), 1.03 (d, *J* = 7.0, 3H), 1.29 (s, 3H), 1.31 (s, 3H), 1.45 (s, 9H), 2.26 (dsept, J_1 = 4.1, J_2 = 6.7, 1H), 4.14 (s, 1H), 4.87 (d, *J* = 3.9, 1H). ^{13}C NMR (100 MHz, CD_3OD) δ: 14.4, 19.4, 26.9, 27.0, 28.7, 31.2, 64.2, 72.3, 78.5, 80.8, 157.8, 171.7, 173.0. HR-MS calcd. for $C_{15}H_{28}NO_7$ ($[M + H]^+$): 334.1866; found 334.1876. LC–MS: 98% purity (condition A), R_T = 18.5.

Acknowledgments

This research was supported in part by the Natural Sciences and Engineering Research Council of Canada (NSERC), the Ministère de l'Éducation du Québec, and Valorisation-Recherche Québec. We would like to thank Mr. Dalbir Sekhon for performing the LC–MS experiments.

Design and synthesis of oxazolidinone ketolide antibiotic segment mimetics[1]

Stephen Hanessian and Kiran Kumar Kothakonda

Abstract: Macrolides have been modified to a large extent by structural and functional variants to expand their spectrum of activity and overcome resistance. Ketolides are new generation 14-membered ring macrolides derived by chemical modification of the readily available erythromycin A. We have designed and synthesized bicyclic oxazolidinone-δ-lactones to mimic the "left segment" periphery of ketolides.

Key words: macrolide, ketolide, 50S r-RNA, segment mimetics.

Résumé : Des macrolides ont été beaucoup modifiés par des variations de structure et de fonction afin d'élargir leur spectre d'activité et pour vaincre la résistance. Les cétolides correspondent à une nouvelle génération de macrolides à quatorze chaînons qui dérivent de modifications chimiques de l'érythromycine A qui est facilement accessible. Pour imiter le segment de gauche de la périphérie des cétolides, de nouvelles δ-lactones bicycliques de l'oxazolidinone ont été développées et synthétisées.

Mots clés : macrolide, cétolide, 50S r-ARN, imitation d'un segment.

[Traduit par la Rédaction]

Introduction

Macrolides have been used as effective antibiotics to combat infection caused by various Gram-positive bacteria such as *Staphylococcus aureus*, *Streptococcus pneumoniae*, and *Streptococcus pyogenes* for over 50 years (1). The discovery of the 14-membered macrolide erythromycin (**1**) (2) was a major breakthrough in antimicrobial research, exhibiting activity against penicillin-resistant *S. aureus*. Erythromycin has been widely prescribed for the treatment of upper and lower respiratory tract infections in children because of its excellent record of safety. However, the main disadvantage of erythromycin is its instability in the acidic medium in the stomach, which results in degradation (3). The semisynthetic macrolides such as clarithromycin (**2**) (4) and azithromycin (**3**) (5) are stable in acidic medium and also possess activity against *Haemophilus influenzae*, among other pathogenic organisms. Unfortunately, erythromycin, clarithromycin, and azithromycin are ineffective against organisms that show macrolide – lincosamide – streptogramin B (MLS_B) cross-resistance (6). As a result of extensive research aimed at discovering new analogues (7), erythromycin has been replaced to a large extent by structural and chemically modified variants such as flurithromycin, roxitromycin, and dirithromycin (8). More recently, a new class of potent antibiotics called ketolides as exemplified by telithromycin (HMR-3647) (**4**) (9) and cethromycin (ABT-773) (**5**) (10), was discovered (Fig. 1). These macrolide structures are derived from erythromycin via substantial functional modification, notably the omission of cladinose, the presence of a carbonyl group at C-3, and an oxazolidinone ring at the C-11 and (or) C-12. The presence of heterocyclic side-chain appendages on the oxazolidinones greatly enhances the antibacterial profile. Ketolides were found to be active against penicillin-resistant and erythromycin resistant *S. pneumoniae*, hence, their great potential as a new generation of macrolide antibiotics targeted to the resistant organisms.

Macrolide antibiotics exert their antibacterial action by stimulating the dissociation of peptidyl t-RNA from the bacterial ribosome during the translocation process, thereby inhibiting protein synthesis. They bind to the 2058–2062 region of 23S ribosomal RNA of the 50S ribosomal subunit in the vicinity of peptide exit channel (11).

Results and discussion

Design

As part of a research program aimed at new antibacterial RNA-binding small molecules (12, 13), we were interested in studying the functional role of the oxazolidinone subunit spanning C-11 and C-12 in the ketolides. Recently available X-ray data on ketolides (14), and classical X-ray structural (15), and NMR studies (16) on erythromycin many years ago, have revealed the prevalence of a unique three-dimensional, crown-like conformation with the edges of hypothetical chair-like cyclohexanes (Fig. 2). A better visualization of the topology of 14-membered macrolides can be considered in conjunction with a virtual diamond lattice

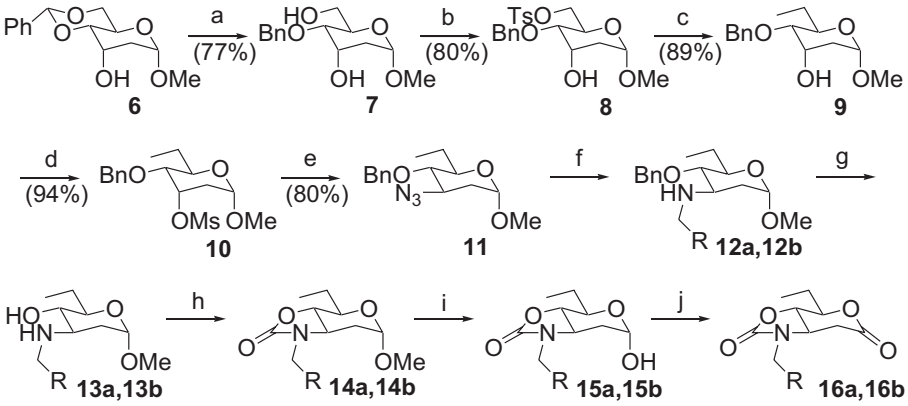
(17). We therefore hypothesized that bicyclic *cis*- and *trans*-oxazolidinone-δ-lactones represented by structures A and B could simulate the minimal spatial requirements of the ketolides "western" landscape, by occupying a corresponding region of the lattice. Although the proposed prototypes were substantially different in overall topology, and lacked the all-important desosamine sugar, compared with the ketolides, they shared a common oxazolidinone subunit. It was surmised that the diversification at nitrogen with a variety of heterocyclic side-chain appendages similar to those found in the ketolides, would prove to be an asset (18).



Synthesis

The synthesis of *cis*- and (or) *trans*-oxazolidinone-δ-lactones started from methyl 2-deoxy-4,6-*O*-benzylidene-α-D-*ribo*-hexopyranoside (**6**), which is readily obtained from methyl α-D-glucopyranoside (19) (Scheme 1). Regioselective reductive ring opening of the benzylidene acetal was achieved in an 85:15 ratio using LAH–$AlCl_3$ to afford **7** in 77% yield (20). Selective protection of the primary hydroxyl group with tosyl chloride gave **8**, which was treated with Me_2CuLi at –78 °C to afford the chain-extended analogue **9**. There are few reported examples of cuprate-mediated functionalizations of the terminal carbon atoms in the sugar series (21).

To obtain the *trans*-oxazolidinones, the mesylate **10** was treated with NaN_3 in refluxing DMF to give the azido analogue **11** in 80% yield. Treatment with Me_3P in THF under Staudinger (22) conditions reduced the azide to the amine, which was then subjected to reductive amination with two aldehydes using $NaCNBH_3$–AcOH in MeOH, giving **12a** and **12b** in good yields. Benzyl deprotection was achieved with 10% $Pd(OH)_2$-on-carbon in EtOAc under a hydrogen

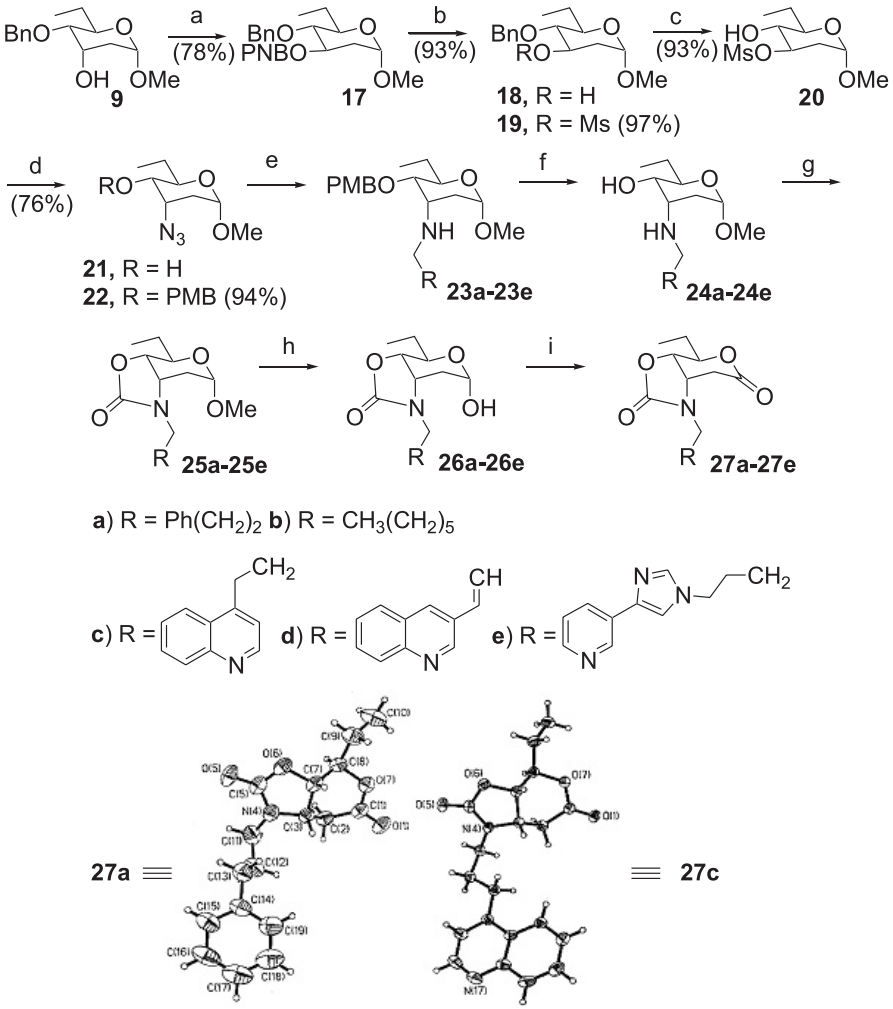
atmosphere to obtain **13a** and **13b**. Treatment with carbonyl diimidazole (23) in Et_3N gave the required oxazolidinones **14a** and **14b**. Hydrolysis of the glycosides in 6 N HCl – dioxane gave the hemiacetals **15a** and **15b**, which were oxidized with PCC to afford the desired target *trans*-oxazolidinone lactones **16a** and **16b** in good yields.

The *cis*-oxazolidinones were prepared from the common intermediate **9** (Scheme 2). Thus, a Mitsunobu reaction with *p*-nitrobenzoic acid gave the inverted ester **17** in 78% yield (24). Saponification gave **18**, which was mesylated to give **19** and the latter was treated with catalytic 10% Pd-on-carbon under a hydrogen atmosphere affording **20**. Nucleophilic displacement with NaN_3 in DMF led to **21**, which was converted to PMB **22**. Reduction under Staudinger conditions (22) reduced the azide to the amine, which was subjected to reductive amination with various aldehydes using $NaCNBH_3$–AcOH in MeOH to obtain the corresponding amines (**23a**–**23e**) in good yields. The PMB ether group was cleaved with ceric ammonium nitrate to obtain **24a**–**24e**. Treatment of the *cis*-amino alcohols with carbonyl diimidazole (23) in Et_3N gave the intended oxazolidinones **25a**–**25e**. Cleavage of the glycosides in 6 N HCl – dioxane led to the hemiacetals **26a**–**26e**, which, upon oxidation with PCC, gave the *cis*-oxazolidinone lactones **27a**–**27e** in good yields. Single crystal X-ray structure analysis of **27a** and **27c** confirmed the stereochemistry of the *cis*-oxazolidinone ring.[3]

The bicyclic oxazolidinone lactones **16a** and **16b** and **27a**–**27e** did not inhibit the growth of *S. aureus* at minimum inhibitory concentrations of >50 μg/mL (25). Lack of inhibition in the macrolide series is generally attributed to cell penetration, efflux, resistance, and ineffective binding to the ribosomal RNA target. It is clear that the simplification of the macrolide structure of the ketolides to bicyclic lactone prototypes resulted in the loss of several important contact points with the RNA targets, without alternative compensatory binding. Such an outcome was not entirely unexpected, given the drastic departure from the traditional macrolide structure, including the omission of the desosamine glycoside. Nevertheless, it was hoped that the minimal oxazolidinone motif, harboring an optimized heterocyclic side-chain appendage (as in **27e**) would contribute to a modest level of inhibition of bacterial growth. In this context, it is of interest that simple, *N*-aryl oxazolidinones such as linezolid (Fig. 1) have emerged as a new generation of antibacterial agents (26).

In conclusion, we have synthesized a series of bicyclic δ-lactone oxazolidinones as segment mimetics of ketolides. Their lack of inhibitory activity in vitro emphasizes the importance of the macrolide structure and the desosamine unit for achieving effective binding to bacterial ribosomes.

Experimental



General procedure

Flash chromatography was carried out using 230–400 mesh silica gel. Mixtures of ethyl acetate and hexanes were used as the eluents, unless otherwise specified. Analytical TLC was performed on glass plates coated with a 0.02 mm layer of silica gel 60 F-254. Melting points were uncorrected. IR spectra were recorded as films. ^1H and ^{13}C NMR spectra were recorded at 300 and 400 MHz, respectively, and the chemical shifts are reported in ppm on the δ scale, with $CDCl_3$ as the reference, unless otherwise specified. MS and HR-MS spectra were recorded using electron ionization or by the FAB technique. Optical rotations were measured in $CHCl_3$ or MeOH at 23 °C. All reactions were carried out under nitrogen or argon unless otherwise specified. The –78 °C

temperature is approximate, as achieved by a dry ice – acetone bath.

Methyl 4-*O*-benzyl-2-deoxy-α-D-*ribo*-hexopyranoside (7)

To a well-stirred mixture of compound **6** (5 g, 18.8 mmol), lithium aluminium hydride (1.36 g, 35.7 mmol) in ether (65 mL), and DCM (65 mL) was added aluminium chloride (3.76 g, 28.2 mmol) under reflux for 15 min and refluxing was continued for 3 h. The mixture was cooled to 0 °C, quenched with ice, filtered, and washed with EtOAc (100 mL); the filtrate was washed with brine, dried over Na_2SO_4, concentrated under vacuum, and the residue was purified by column chromatography (EtOAc–hexanes, 1:1) to give **7** as a thick syrup (3.9 g, 77%). $[\alpha]_D$ +205 (*c* 0.75, $CHCl_3$). IR (neat, cm^{-1}): 3470. ^1H NMR (400 MHz, $CDCl_3$) δ: 1.82 (m, 1H), 2.18 (dd, 1H, *J* = 1.7, 15.4 Hz), 3.38 (s, 1H), 3.42 (dd, 1H, *J* = 1.7, 11.1 Hz), 3.84 (m, 2H), 3.96 (m, 1H), 4.21 (brm, 1H), 4.56 (d, 2H, *J* = 12.5 Hz), 4.77, (d, 2H, *J* = 12.5 Hz), 4.79 (m, 1H), 7.37 (m, 5H). ^{13}C NMR (400 MHz, $CDCl_3$) δ: 35.2, 55.6, 62.8, 64.4, 66.8, 70.9, 74.7, 98.8, 128.3, 128.9, 138.2. MS calcd. for $C_{14}H_{20}NO_5$: 268.3 (M^+); found: 286.2 (M + H_2O^+).

Methyl 4-*O*-benzyl-2-deoxy-6-*O*-*p*-tolylsulfonyl-α-D-*ribo*-hexopyranoside (8)

To a solution of compound **7** (3.98 g, 14.85 mmol) in pyridine (12 mL) and DCM (40 mL) was added *p*-toluenesulfonyl chloride (2.92 g, 15.29 mmol) at 0 °C under an argon atmosphere and the solution was stirred at room temperature for 16 h. The mixture was concentrated under vacuum at low temperature, the residue was taken up in DCM (100 mL), washed with water then with brine, dried over Na_2SO_4, concentrated, and purified by column chromatography (EtOAc–hexanes, 3:7) to afford **8** (5 g, 80%). $[\alpha]_D$ +112.7 (*c* 1, $CHCl_3$). IR (neat, cm^{-1}): 3526. ^1H NMR (400 MHz, $CDCl_3$) δ: 1.82 (m, 1H), 2.15 (dd, 1H, *J* = 1.7, 15.4 Hz), 2.42 (s, 3H), 3.35 (s, 1H), 3.41 (dd, 1H, (dd, 1H, *J* = 1.7, 11.1 Hz)), 4.04 (m, 1H), 4.11 (brm, 1H), 4.22–4.36 (m, 2H), 4.44 (d, 2H, *J* = 12.5 Hz), 4.75 (m, 1H), 7.22–7.39 (m, 7H), 7.79 (d, 2H, *J* = 12.1 Hz). ^{13}C NMR (400 MHz,

$CDCl_3$) δ: 22.1, 34.9, 55.8, 64.1, 64.9, 70.1, 70.9, 74.0, 98.7, 128.3, 128.9, 130.1, 133.3, 137.7, 145.1.

Methyl 4-*O*-benzyl-2,6-dideoxy-6-*C*-methyl-α-D-*ribo*-hexopyranoside (9)

MeLi (45 mL, 1.6 mol/L in Et_2O) was added slowly to CuI (6.77 g, 35.5 mmol) in ether (180 mL) at –20 °C under an argon atmosphere and stirred at –5 °C for 20 min. Compound **8** (2.5 g, 5.93 mmol) in Et_2O (20 mL) was added to the mixture at –78 °C for 15 min and the mixture was stirred for 1 h allowing it to warm to 0 °C, then for 3 h at room temperature. The mixture was quenched with NH_4OH and NH_4Cl (1:1, 20 mL), extracted with ether (100 mL), washed with brine, dried over Na_2SO_4, and concentrated under vacuum. The residue was purified by column chromatography (EtOAc–hexanes, 2:8) to give compound **9** (1.4 g, 89%). $[\alpha]_D$ +187.2 (*c* 1, $CHCl_3$). IR (neat, cm^{-1}): 3480. ^1H NMR (400 MHz, $CDCl_3$) δ: 0.98 (t, 3H, *J* = 8.4 Hz), 1.45 (m, 1H), 1.83 (m, 1H), 1.99 (m, 1H), 2.18 (dd, 1H, *J* = 1.7, 15.4 Hz), 3.15 (dd, 1H, *J* = 1.7, 11.1 Hz), 3.37 (s, 3H), 3.82 (m, 1H), 4.22 (brs, 1H), 4.55 (d, 1H, *J* = 12.4 Hz), 4.76 (d, 1H, *J* = 12.4 Hz), 4.79 (d, 1H, *J* = 4.1 Hz), 7.23–7.38 (m, 5H). ^{13}C NMR (400 MHz, $CDCl_3$) δ: 10.1, 24.9, 35.5, 55.3, 64.4, 67.3, 70.8, 78.4, 128.1, 128.3, 128.8, 138.4. MS calcd. for $C_{15}H_{22}NO_4$: 266.3 (M^+); found: 284.2 ($M + H_2O^+$).

Methyl 4-*O*-benzyl-2,6-dideoxy-3-*O*-methanesulfonyl-6-*C*-methyl-α-D-*ribo*-hexopyranoside (10)

To a solution of compound **9** (0.33 g, 1.24 mmol) in pyridine (6 mL) was added methanesulfonyl chloride (0.24 mL, 3.1 mmol) at 0 °C and the solution was stirred for 12 h allowing it to warm to room temperature. The mixture was diluted with Et_2O (20 mL), washed sequentially with cold dilute 5% HCl, aq. 5% $NaHCO_3$ solution, water, and brine, dried over Na_2SO_4, and concentrated under vacuum. The residue was purified by column chromatography (EtOAc–hexanes, 2:8) to obtain **10** (0.4 g, 94%). $[\alpha]_D$ +177.7 (*c* 1, $CHCl_3$). IR (neat, cm^{-1}): 1346. ^1H NMR (400 MHz, $CDCl_3$) δ: 0.98 (t, 3H, *J* = 8.3 Hz), 1.21 (m, 1H), 1.93 (m, 2H), 2.37 (dd, 1H, *J* = 1.7, 15.4 Hz), 3.2 (s, 3H), 3.25 (m, 1H), 3.35 (m, 1H), 3.87 (t, 1H, *J* = 8.3 Hz), 4.51 (d, 1H, *J* = 12.4 Hz), 4.69 (m, 1H), 4.79 (d, 1H, *J* = 12.4 Hz), 5.24 (m, 1H), 7.29–7.42 (m, 5H). ^{13}C NMR (400 MHz, $CDCl_3$) δ: 9.9, 24.7, 34.8, 39.6, 55.4, 67.5, 71.8, 74.1, 76.7, 96.9, 128.5, 128.7, 128.9, 137.6.

Methyl 3-azido-4-*O*-benzyl-6-*C*-methyl-2,3,6-trideoxy-α-D-*arabino*-hexopyranoside (11)

A mixture of compound **10** (395 mg, 1.15 mmol) and NaN_3 (395 mg, 5.3 mmol) in DMF (6 mL) was heated at 160 °C for 1.5 h under an argon atmosphere. The mixture was filtered, washed with Et_2O (20 mL), concentrated, and the filtrate was purified by column chromatography (EtOAc–hexanes, 3:97) to afford **11** (264 mg, 80%). $[\alpha]_D$ +105.6 (*c* 1.1, $CHCl_3$). IR (neat, cm^{-1}): 2101. ^1H NMR (400 MHz, $CDCl_3$) δ: 1.96 (t, 1H, *J* = 8.3 Hz), 1.51 (m, 1H), 1.61 (m, 1H), 1.96 (m, 1H), 2.19 (dd, 1H, *J* = 4.1, 13.5 Hz), 3.09 (t, 1H, *J* = 11 Hz), 3.34 (s, 3H), 3.54 (m, 1H), 3.91 (m, 1H), 4.63 (d, 1H, *J* = 12.8 Hz), 4.79 (m, 1H), 4.91 (d, 1H, *J* = 12.8 Hz), 7.28–7.44 (m, 5H). ^{13}C NMR (400 MHz, $CDCl_3$) δ: 10.3, 24.9, 36.0, 54.8, 60.8, 72.3, 75.5, 82.4, 97.6, 128.4, 128.6, 128.9, 139.2.

Methyl 4-*O*-benzyl-6-*C*-methyl-3-phenylethylamino-2,3,6-trideoxy-α-D-*arabino*-hexopyranoside (12a)

To a solution of compound **11** (40 mg, 0.137 mmol) in THF was added trimethylphosphine (0.53 mL, 1 mol/L in toluene) and the solution was stirred under an argon atmosphere for 30 min. Water (16 μL) was added to the mixture and stirred under reflux condition for 45 min. The mixture was concentrated under vacuum, and the residue was dissolved in dry MeOH (3 mL) under an argon atmosphere. The requisite aldehyde (0.135 mmol) was added followed by the addition of AcOH (32 μL), and the solution was stirred. $NaCNBH_3$ (18 mg, 0.274 mmol) was added, the mixture stirred for 12 h, then concentrated under vacuum. The residue was diluted with EtOAc (10 mL), washed with 10% $NaHCO_3$ solution and brine, and the organic phase was dried over Na_2SO_4, concentrated, and then purification of the residue by column chromatography (EtOAc–hexanes, 2:3) gave **12a** (89%). $[\alpha]_D$ +53.1 (*c* 1.85, $CHCl_3$). IR (neat, cm^{-1}): 3825. ^1H NMR (400 MHz, $CDCl_3$) δ: 1.02 (t, 3H, *J* = 8.3 Hz), 1.52 (m, 2H), 1.78 (brm, 3H), 1.98 (m, 1H), 2.1 (m, 1H), 2.41–2.71 (m, 3H), 3.03 (m, 2H), 3.35 (s, 3H), 3.58 (t, 1H, *J* = 11.2 Hz), 4.59–4.69 (m, 3H), 7.11–7.39 (m, 10H). ^{13}C NMR (400 MHz, $CDCl_3$) δ: 10.4, 25.3, 32.3, 33.9, 36.0, 46.8, 54.8, 55.8, 72.3, 75.2, 84.0, 98.2, 126.2, 128.2, 128.4, 128.7, 128.8, 129.0, 138.5, 142.4. MS calcd. for $C_{24}H_{33}NO_3$: 383.5 (M^+); found: 384.4.

Methyl 4-*O*-benzyl-3-heptylamino-6-*C*-methyl-2,3,6-trideoxy-α-D-*arabino*-hexopyranoside (12b)

Following the same procedure as for compound **11** gave **12b** in 62% yield. $[\alpha]_D$ +26 (*c* 1.1, $CHCl_3$). IR (neat, cm^{-1}): 3820. ^1H NMR (400 MHz, $CDCl_3$) δ: 0.87 (m, 3H), 1.05 (m, 3H), 1.25 (brs, 6H), 1.39 (m, 2H), 1.51 (m, 2H), 1.63 (brs, 1H), 1.95 (m, 1H), 2.13 (m, 1H), 2.43 (m, 1H), 2.61 (m, 1H), 3.06 (m, 2H), 3.33 (s, 3H), 3.56 (t, 1H, *J* = 9.4 Hz), 4.61–4.75 (m, 3H), 7.29 (m, 5H). ^{13}C NMR (400 MHz, $CDCl_3$) δ: 10.4, 14.5, 23.0, 25.3, 27.7, 29.6, 30.6, 32.2, 36.0, 47.4, 54.8, 55.8, 72.3, 75.1, 84.0, 98.2, 128.2, 128.3, 129.0, 138.7. MS calcd. for $C_{22}H_{37}NO_3$: 363.5 (M^+); found: 364.3.

Methyl 6-*C*-methyl-3-phenylethylamino-2,3,6-trideoxy-α-D-*arabino*-hexopyranoside (13a)

A mixture of compound **12a** (35 mg, 0.0914 mmol) and 10% Pd $(OH)_2$-on-carbon (3 mg) in EtOAc (2 mL) was stirred under a hydrogen atmosphere for 14 h, the suspension was filtered, washed with MeOH (10 mL), concentrated, and purified by column chromatography (MeOH–EtOAc, 1:99) to afford **13a** (21 mg, 80%). $[\alpha]_D$ +17 (*c* 0.5, $CHCl_3$). IR (neat, cm^{-1}): 3860, 3720. ^1H NMR (400 MHz, $CDCl_3$) δ: 1.01 (t, 3H, *J* = 8.3 Hz), 1.42 (m, 2H), 1.94 (m, 3H), 2.09 (dd, 1H, *J* = 2 Hz), 2.56 (m, 1H), 2.69 (t, 2H, *J* = 6.9 Hz), 2.83 (m, 2H), 3.05 (t, 3H, *J* = 9.6 Hz), 3.32 (s, 3H), 3.42 (t, 1H, *J* = 11.2 Hz), 4.78 (brs, 1H), 7.19 (m, 3H), 7.29 (d, 2H, *J* = 7Hz). ^{13}C NMR (400 MHz, $CDCl_3$) δ: 10.2, 25.2, 32.1, 33.8, 35.5, 46.0, 54.8, 57.0, 73.5, 73.9, 98.5, 126.3, 128.8. MS calcd. for $C_{17}H_{27}NO_3$: 293.2 (M^+); found: 294.3.

MS calcd. for $C_{16}H_{24}O_6S$: 344.1 (M^+); found: 362.3 ($M^+ + H_2O$).

Methyl 2,6-dideoxy-3-*O*-methanesulfonyl-6-*C*-methyl-α-D-*arabino*-hexopyranoside (20)

A mixture of compound **19** (1.0 g, 2.91 mmol) and 10% Pd-on-carbon (10 mg) in EtOAc (10 mL) was stirred under a hydrogen atmosphere for 10 h; the mixture was filtered, washed with EtOAc (10 mL), concentrated, and purified by column chromatography (EtOAc–hexanes, 3:7) to afford **20** as a solid (0.69 g, 93%); mp 88 °C. $[\alpha]_D$ +65.2 (*c* 0.5, $CHCl_3$). IR (KBr, cm^{-1}): 3540. ^1H NMR (400 MHz, $CDCl_3$) δ: 1.01 (t, 3H, *J* = 6.9 Hz), 1.49 (m, 1H), 1.95 (m, 2H), 2.34 (dd, 1H, *J* = 4.8, 12.4 Hz), 3.11 (s, 3H), 3.32 (s, 3H), 3.41 (t, 1H, *J* = 8.9 Hz), 3.49 (t, 1H, *J* = 9.4 Hz), 4.80 (s, 1H), 4.91 (m, 1H). ^{13}C NMR (300 MHz, $CDCl_3$) δ: 10.1, 23.9, 36.5, 38.1, 54.8, 72.2, 73.3, 80.9, 97.5.

Methyl 3-azido-6-*C*-methyl-2,3,6-trideoxy-α-D-*ribo*-hexopyranoside (21)

A mixture of compound **20** (0.65 g, 2.56 mmol) and NaN_3 (0.97 g, 14.84 mmol) in DMF (12 mL) was heated at 125 °C for 12 h under an argon atmosphere. The mixture was filtered, washed with Et_2O (40 mL), the filtrate concentrated and purified by column chromatography (EtOAc–hexanes, 1:9) to afford **21** as a crystalline white solid (0.39 g, 76%); mp 75 °C. $[\alpha]_D$ +277.8 (*c* 0.5, $CHCl_3$). IR (KBr, cm^{-1}): 2102. ^1H NMR (300 MHz, $CDCl_3$) δ: 0.99 (t, 3H, *J* = 7.4 Hz), 1.48 (m, 1H), 1.58 (s, 1H), 1.86–2.11 (m, 2H), 2.23 (m, 1H), 3.36 (s, 3H), 3.39 (m, 1H), 3.61 (m, 1H), 4.05 (m, 1H), 4.69 (d, 1H, *J* = 4.2 Hz). ^{13}C NMR (300 MHz, $CDCl_3$) δ: 10.1, 24.1, 32.2, 55.6, 59.5, 69.4, 70.3, 96.3.

Methyl 3-azido-4-*p*-methoxybenzyl-6-*C*-methyl-2,3,6-trideoxy-α-D-*ribo*-hexopyranoside (22)

To a solution of compound **21** (190 mg, 0.946 mmol) in DMF was added 60% NaH (62 mg, 1.61 mmol) at 0 °C and the mixture was stirred for 10 min. *p*-Methoxybenzyl bromide (5.6 mL, 0.27 mol/L in toluene) was added to the mixture and the mixture stirred for 6 h allowing it to warm to room temperature. The mixture was quenched with ice, extracted with Et_2O (50 mL), washed with brine, dried over Na_2SO_4, and concentrated under vacuum. The residue was purified by column chromatography (EtOAc–hexanes, 1:9) to afford **22** (285 mg, 94%). $[\alpha]_D$ +174.8 (*c* 1.2, $CHCl_3$). IR (neat, cm^{-1}): 2099. ^1H NMR (400 MHz, $CDCl_3$) δ: 0.97 (t, 3H, *J* = 7.4 Hz), 1.36 (m, 1H), 1.93 (m, 2H), 2.09 (dd, 1H, *J* = 2.3, 4.9 Hz), 3.29 (dd, 1H, *J* = 3.5, 9.4 Hz), 3.36 (s, 3H), 3.81 (s, 3H), 3.87 (t, 1H, *J* = 7.1 Hz), 4.02 (m, 1H), 4.47 (d, 1H, *J* = 11.3 Hz), 4.62 (m, 2H), 6.89 (d, 2H, *J* = 8.4 Hz), 7.29 (d, 2H, *J* = 8.4 Hz). ^{13}C NMR (400 MHz, $CDCl_3$) δ: 10.1, 24.6, 33.6, 55.6, 68.1, 71.6, 78.2, 97.0, 114.3, 130.2.

Methyl 4-*p*-methoxybenzyl-6-*C*-methyl-3-phenylethylamino-2,3,6-trideoxy-α-D-*ribo*-hexopyranoside (23a)

To a solution of compound **22** (46 mg, 0.144 mmol) in THF was added trimethylphosphine (0.55 mL, 1 mol/L in toluene) and the mixture was stirred under an argon atmosphere for 30 min. Water (25 μL) was added to the mixture and it was stirred under reflux conditions for 45 min. The mixture was concentrated under vacuum and dried properly. The residue was diluted with dry MeOH (3 mL) under an argon atmosphere, the requisite aldehyde (0.14 mmol) was added, followed by the addition of AcOH (32 μL), then the mixture was stirred for 1 h. $NaCNBH_3$ (18 mg, 0.287 mmol) was added and the mixture stirred for 12 h at room temperature. The mixture was concentrated under vacuum, diluted with EtOAc (10 mL), washed with 10% $NaHCO_3$ and brine, the organic phase was dried over Na_2SO_4, concentrated under vacuum, and the residue was purified by column chromatography (EtOAc–hexanes, 1:1) to afford **23a** (79%). $[\alpha]_D$ +134 (*c* 1, $CHCl_3$). IR (neat, cm^{-1}): 3309. ^1H NMR (400 MHz, $CDCl_3$) δ: 0.97 (t, 3H, *J* = 7.4 Hz), 1.35 (m, 2H), 1.84 (m, 2H), 2.04 (m, 3H), 2.64 (m, 2H), 2.81 (m, 1H), 2.91 (m, 1H), 3.20 (m, 1H), 3.32 (m, 1H), 3.37 (s, 3H), 3.68 (m, 1H), 3.79 (m, 3H), 4.52 (m, 2H), 4.69 (m, 1H), 6.88 (d, 2H, *J* = 8.1 Hz), 7.19 (t, 3H, *J* = 7.6 Hz), 7.35 (d, 4H, *J* = 8.1 Hz). ^{13}C NMR (400 MHz, $CDCl_3$) δ: 9.9, 24.9, 29.8, 30.8, 33.4, 47.3, 53.6, 55.7, 68.9, 72.1, 97.8, 114.3, 126.6, 128.8, 128.9, 130.5, 141.3, 159.9. MS calcd. for $C_{25}H_{35}NO_4$: 413.3 (M^+); found: 414.4.

Methyl 3-heptylamino-4-*p*-methoxybenzyl-6-*C*-methyl-2,3,6-trideoxy-α-D-*ribo*-hexopyranoside (23b)

Following the same procedure as for compound **22** gave **23b** in 65% yield. $[\alpha]_D$ +118 (*c* 1, $CHCl_3$). IR (neat, cm^{-1}): 3219. ^1H NMR (400 MHz, $CDCl_3$) δ: 0.91 (t, 3H, *J* =

Review of gold(I) *N*-heterocyclic carbenes[1]

Ivan J.B. Lin and Chandra Sekhar Vasam

Abstract: This review presents an overview of the work on Au(I)–NHC chemistry. The efficiency of different synthetic strategies of Au(I)–NHCs is discussed. Transmetallation of Ag(I)–NHCs appears to be an easy method as compared with the others. The influence of aurophilicity "a traditional property of a Au(I) center" in making the supramolecular assemblies is also covered. The combination of the Au(I) center with NHCs has great potential in the fields of medicine, catalysis, liquid crystal, and optoelectronic.

Key words: gold–carbenes, silver–carbenes, carbene transfer, aurophilicity.

Résumé : Dans ce travail, on présente une revue des travaux effectués dans le domaine de la chimie du Au(I)–NHC. On discute de l'efficacité des diverses stratégies de synthèse des Au(I)–NHC. Par rapport à d'autres méthodes, la transmétallation des Au(I)–NHC semble la méthode la plus appropriée. On a aussi examiné l'influence du caractère aurophile, une propriété traditionnelle du centre Au(I), dans l'élaboration d'assemblages supramoléculaires. La combinaison du centre Au(I) avec des NHC possède un grand potentiel dans les domaines de la médecine, de la catalyse, des cristaux liquides et de l'optoélectronique.

Mots clés : or–carbènes, argent–carbènes, transfert de carbène, caractère aurophile.

Background and the scope

N-Heterocyclic carbenes (NHCs) are a novel class of electron-donating ligands, which have the advantage of forming strong metal–ligand bonds and have become universal ligands in organometallic and coordination chemistry (1). A similarity between the NHCs and phosphines in terms of their metal coordination chemistry has been proposed (2). NHCs, however, have the advantage of being easy to derivatize by varying the N- or C functionalization in the corresponding NHC precursors (3). They not only bind to many transition metals, be it in low or high oxidation states (4), but also to main group elements (5). The existence of free and stable NHC **III** (Chart 1) was initially investigated by Wanzlick et al. (6). Although a free NHC was not isolated, the predictions by Wanzlick et al. inspired the related researches.

The metal complexes with NHCs as ligands were first synthesized by Wanzlick and Öfele and co-workers (7) and later extended by Lappert and co-workers (8). It was not until the isolation of free and stable NHCs by Arduengo et al. in 1991 (9) that the chemistry of metal–NHCs was revived. Since then information about their fundamental chemical and physical properties has been obtained (10), especially, with the precursors of NHCs being the ever popular ionic liquids (11). NHCs have found tremendous application in the field of catalysis; for example, C—H activation, C—C, C—H, C—O, and C—N bond formation, and many more. Herrmann and co-workers (12) have an excellent review on the aspects of NHC complexes in catalysis. The successful application of Ru(I)–NHCs in olefin metathesis reactions and Pd(II)–NHCs in cross-coupling reactions almost revolutionized the area of catalysis. There is now significant evidence that phosphines will be supplemented, and, in part, replaced by NHCs (12). It has been described that because of the high thermal stability of the M—$C_{carbene}$ bond, excess ligand is not necessary during the catalytic reactions and orthometallation does not occur with metal–NHCs (13). NHCs as nucleophiles have a catalytic application even in nature; it was shown in the ylidene-catalyzed benzoin condensations that the vitamin B_1 enzyme cofactor thiamin, a naturally occurring thiazolium salt, plays a key role in biochemical processes (14). In recent years, the applications of metal–NHCs are being spread toward many other fields like material science (15) and medicinal chemistry (16).

The study of Au(I) complexes has received much attention lately because they have been used in pharmaceuticals (17), chemical vapour depositions (18), liquid crystals (19), and optical devices (20). Furthermore, since the discovery of the Au(I) catalyzed asymmetric aldol reaction by Ito et al. (21), the opinion in homogeneous catalysis that gold is inert and expensive has been changed. After seeing their successful role in the C—C bond formation and activation of C—C multiple bonds, the interest in gold complexes for homoge-

neous catalysis is increasing (22). Their importance has led to a great variety of research concerning synthesis, structure, and reactivity.

Interest has also been growing in the pervasive "aurophilicity" phenomenon, i.e., the widespread observations of gold–gold interactions (closed shell d^{10}–d^{10}) in the solid phase of Au(I) complexes (23). This interaction, which has energy comparable to hydrogen bonding, may provide additional stability in the formation of supramolecules (23, 24). The aggregation is obviously dependent on the steric and electronic nature of the ligands. Much of the present basic research devoted to Au(I) complexes is aimed at the synthesis and structural characterization of new complexes to better understand the aurophilic interaction.

Despite the fact that Au(I) complexes have been investigated extensively with phosphine and thiolates, Au(I) complexes with NHCs have been less studied. The earlier information on Au(I)–NHCs, which have been known for more than a quarter century, deals only with oxidative addition reactions (25). Much effort has been diverted after the report on unexpected isolation of Au(I)–NHC by Burini and co-workers in 1989 (26). Recently, reports on antimitochondrial, antitumor (16*b*, 16*c*), antimicrobial (16*e*), and catalytic activity (27) of Au(I)–NHCs have appeared. In addition to this, as a compliment, recent investigations concerning the density functional calculations on coinage metal–NHCs including Au(I)–NHCs provide new insights into the nature of metal–NHC ligand bonding (28). Since our research interest is also confined to the synthesis and characterization of coinage metal–NHCs, we wish to present a comprehensive summary of articles that report on the synthesis, structure, and properties of Au(I)–NHC complexes and the scope for further development.

Preparation

According to the literature survey the following methods have so far been adopted to obtain Au(I)–NHC complexes: (*a*) cleavage of electron-rich olefins; (*b*) transfer of carbene from Group 6 carbonyl complexes; (*c*) reaction of azolium salts or NHCs with a Au(I) source; (*d*) protonation or alkylation of gold azolyl compounds; (*e*) transmetallation between Ag(I)–NHCs and Au(I) precursors.

Cleavage of electron-rich olefins

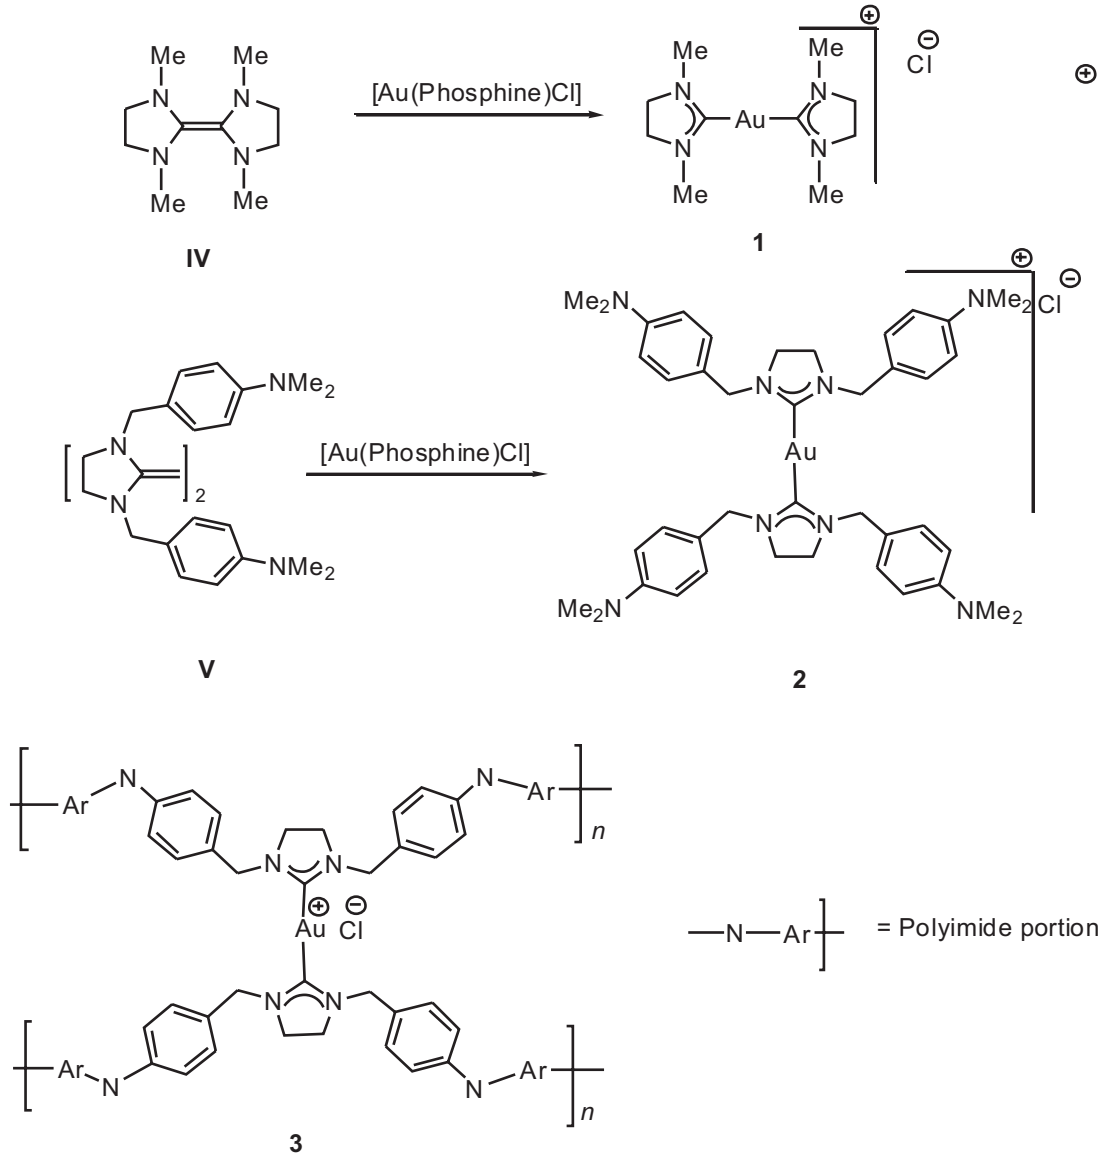
This strategy was introduced by Cetinkaya et al. (29) in 1974, to isolate several transition metal – NHC derivatives. The interaction between [Au(PPh_3)Cl] and electron-rich olefin based on imidazolidinylidene (**IV**) initially produced the hygroscopic Au(I)–NHC complex **1** (Scheme 1). In this way, the olefins behaved as nucleophilic NHC transfer reagents. Recently, this method was again applied during the preparation of polyimide-containing Au(I)–NHC complexes. In this reaction, the olefin (1,1,3,3-tetrakis(*p*-dimethylaminobenzyl)-2,2-biimidazolidinylidene) (**V**) and [Au(PPh_3)Cl] in refluxing toluene produced Au(I)–NHC complex **2** (Scheme 1) (30). Later, the Au(I)–NHC **2** was condensed with several aromatic dianhydrides to produce the polyimide-containing Au(I)–NHCs of type **3**. These polymers exhibited higher glass transition temperatures, better solubilities in polar solvents, higher thermal and thermo-oxidative stabilities as compared with the uncomplexed polyimides.

Transfer of carbene from Group 6 complexes

The transfer of carbene from the Group 6 complexes to other metal ions was initially studied by Fischer, and later applied by Liu's research group (31). As shown in Scheme 2, it was claimed that the interaction of different W(I)–NHCs (**VI**) with Au(SMe_2)Cl in dichloromethane gave Au(I)–NHCs **4a**–**4d**. There is no further information available on this technique.

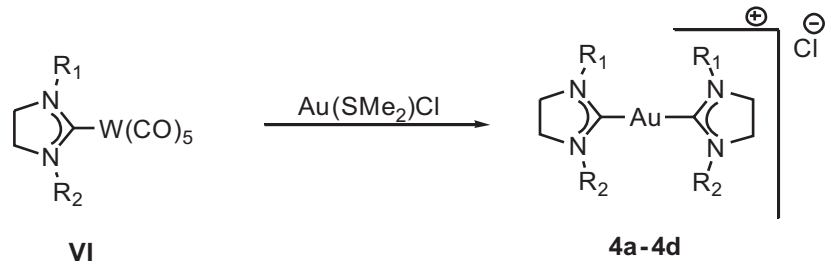
From azolium salts or free NHCs

The Au(I)-containing metallomesogens have attracted interest in the elucidcation of the best structure – mesogenic behavior relationship. In view of the strong σ-coordination properties of NHCs and high thermal stability of their metal complexes, in 1997, we designed the first liquid crystalline compounds of Au(I)–NHCs (Chart 2) (32).



To avoid the tedious precautions required with the use of strong bases and to increase the product yields, we used the phase transfer catalysis (PTC) technique in the reaction of benzimidazolium bromide and Au(SMe_2)Cl to obtain the Au(I)–NHCs **5a**–**5c**. The crystal structure of **5c** (n = 16) revealed a head-to-tail packing with interpenetrating long alkyl chains to give a bilayer lamellar structure with Au···Au distances of ~3.6 Å. In contrast to the other Au(I) metal-containing liquid crystals (MLCs), these Au(I)–NHCs exhibited relatively low transition temperatures, broad mesophase temperature ranges, and higher thermal stabilities.

Dicationic imidazolium-linked cyclophane or cyclophane-like building units presented as one of the unusual and new classes of NHC precursors and formed thermally stable complexes with structural diversity. Considering this fact and the medicinal application of Au(I), Baker and his co-workers (33) designed Au(I)–NHCs **6**–**10** (Scheme 3), and for the first time demonstrated their antimitochondrial and antitumor activity (16*b*, 16*c*).



Reaction of imidazolium-linked cylcophanes with Au(SMe_2)Cl in the presence of lithium or sodium carboxylates salts was described as a useful method to obtain the Au(I)–NHCs **6**–**10** (33). However, the reported yields were

low when compared to the PTC technique. According to the NMR studies, those with cyclophane frameworks were rigid in solution, but the non-cyclophane analogs were fluxional. In all these dinuclear complexes, the two Au(I) centers were linked by bridging μ-dicarbene ligands. Complexes **6** and **9** displayed intra Au(I)···Au(I) interactions in the solid state. The emission spectrum of **9** in aqueous solution showed both high-energy and low-energy bands, which was attrib-

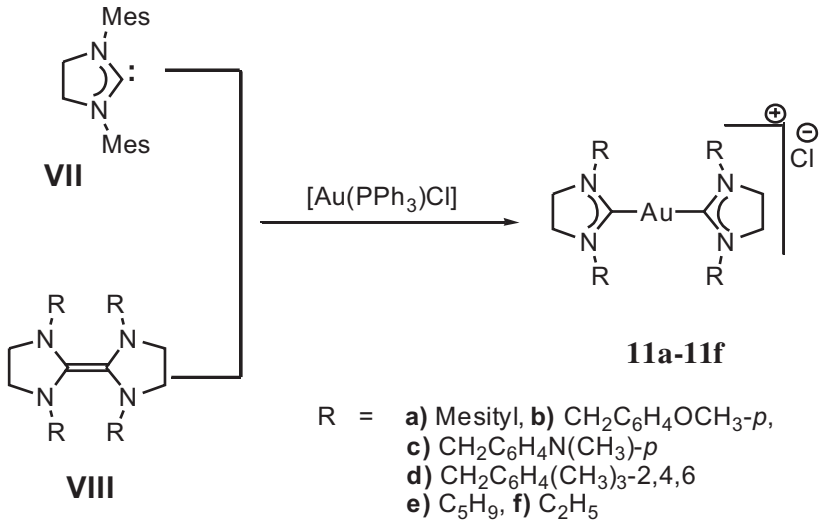
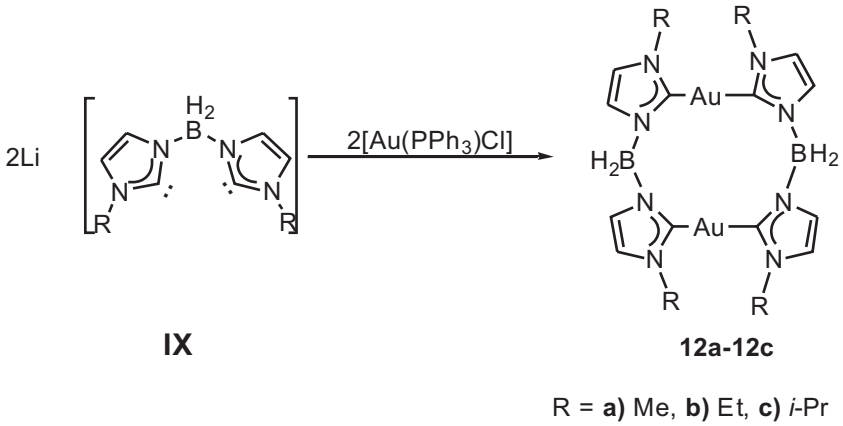
uted to arising from electronic transitions involving Au···Au interactions. The antimitochondrial activity of these lipophilic cationic Au(I)–NHCs appeared to be different from those of lipophilic cationic Au(I) complexes with phosphines (16*b*, 16*c*).



Application of Au(I)–NHCs as antimicrobial agents was described for the first time by Cetinkaya's group (16*e*). The ligand substitution reaction between [Au(PPh_3)Cl] and a free NHC (**VII**) or its dimer (**VIII**) produced the Au(I)–NHCs **11a**–**11f** (Scheme 4). The vibrational bands of NCN were observed between 1450 and 1525 cm^{-1}. The nature of the N substituents had a profound effect on the antimicrobial activity and selectivity. Complexes **11a**–**11c** showed effective biological activities.

Fehlhammer and co-workers (34) described the synthesis of the first structurally characterized tetraNHC complexes of bridging dinuclear Au(I). Interaction of the borate-bridged diNHC ligands (**IX**) with [Au(PPh_3)Cl] produced the Au(I)–NHCs **12a**–**12c** with high yields (Scheme 5). The closest approach between the two Au(I) centers of **12b** was 3.36 Å, indicating the presence of aurophilicity.



An investigation by Lock and co-workers (35) described that the reaction between tris(4,5-dimethylimidazol-2-yl)phosphine (**X**) and tetrachloroaurate did not form the targeted Au(I)–phosphine, but produced the unexpected Au(I)–NHC of type **13** instead (Scheme 6). It was suggested that the generation of NHC was possibly due to the cleavage of one of the imidazolium groups from the ligand. Structural data showed that the Au—C bond did not have much multiple-bond character. The molecules were stacked pair-wise with a short Au(I)···Au(I) interaction of about 3.37 Å. Further interpair ring π–π interactions and hydrogen bonding were also observed.

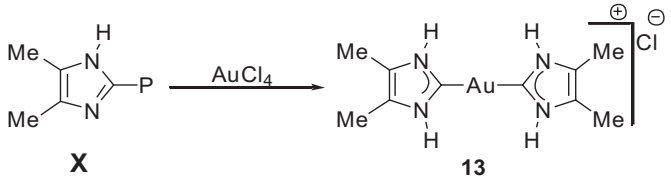
Scheme 6. Unexpected formation of Au(I)–NHC **13**.



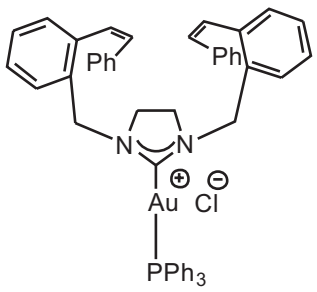


Chart 3.

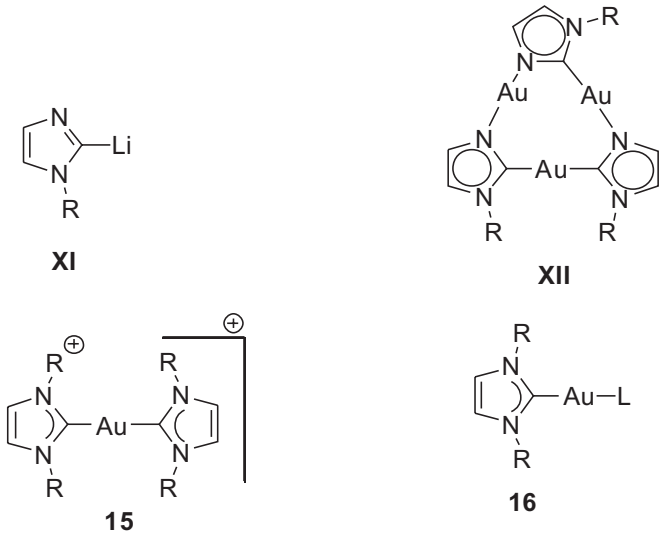
The first example of a mixed phosphane–NHC–gold complex was reported by Grutzmacher's research group (Chart 3) (36). The reaction of bistropimidazolium salt, a special type of NHC precursor, with [Au(PPh$_3$)Cl] in the presence of potassium tertiarybutoxide gave complex **14**. The Au—$C_{carbene}$ bond lengths are somewhat longer than those in many other biscarbene–gold(I) complexes because of the trans influence of phosphine. Although steric congestion appears in the crystal structure, the reaction of this complex with strong acid did not lead to a replacement of the phosphine ligand, indicating the complex stability.



Protonation or alkylation of gold azolyl compounds

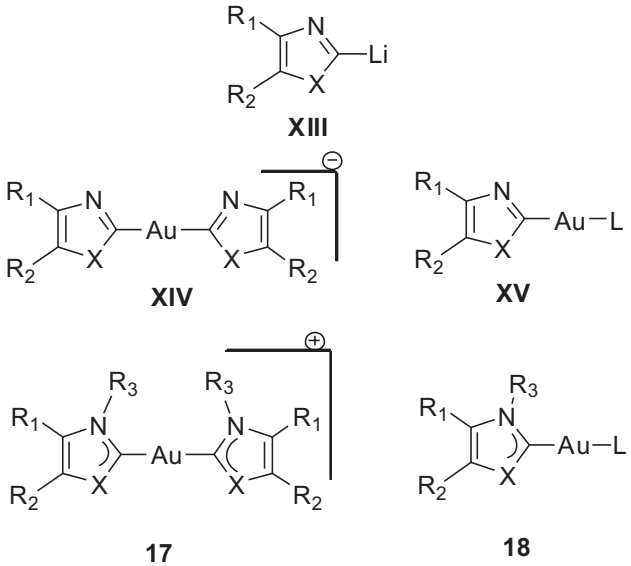
This synthetic strategy has been introduced by Burini's group (26, 37, 38) and widely applied and studied in the prolific work of Raubenheimer's group (39) to synthesize Au(I)–NHCs from the reaction of lithiated imidazoles or thiazoles with an appropriate Au(I) precursor followed by protonation or alkylation.

Firstly, we will discuss the observations by Burini and coworkers (26) during the study of the interaction of the imidazolato-N^3,C^2 ligand towards gold (Scheme 7). The unexpected isolation of a bisAu(I)–NHC of type **15** (R = benzyl) happened by the ligand substitution reaction of

© 2005 NRC Canada

Scheme 7. Au(I)–NHCs from cyclic Au(I)–imidazolate.

$(PPh_3)AuCl$ with lithiated benzylimidazolium (**XI**) in acidic media. Short Au(I)···Au(I) interactions of 3.26 Å were observed in **15** in the solid state. If the acid was not used then a cyclic trimer (**XII**) resulted. Reactions of this cyclic trimer with reagents like ClCOOEt, ClOPh, and EtI produced the mononuclear Au(I)–NHCs of type **16** and also the biscarbenes of type **15**. Crystal structures of two Au(I)–NHC-chlorides of type **16** (R_1 = benzyl, R_2 = 3-carboethoxy or 3-benzoyl, and L = Cl) showed that NHCs exhibited a stronger trans influence than the chloride. Aurophilic interactions were observed in the compound with R = benzoyl (37*a*), but not with R = carboethoxy (37*b*). According to the Mössbauer spectral data, the quadruple splitting values for the complexes of type **16** were influenced by aurophilic interactions (38).



Scheme 8 gives a general overview of Raubenheimer's work to synthesize Au(I) complexes of various azolylidenes (thiazolylidene, imidazolylidene, and benzimidazolyldene) (39). The reaction between lithiated azole (**XIII**) and Au(I) sources produced the Au(I)–NHCs of type **17** and type **18** via the intermediates [Au(azolate)$_2$] (**XIV**) and [Au(azolate)L] (**XV**) (L = PPh_3, C_6F_5, azolate). Side reactions such as homoleptic rearrangement (eq. [1]) and protonation on carbon rather than nitrogen were observed.

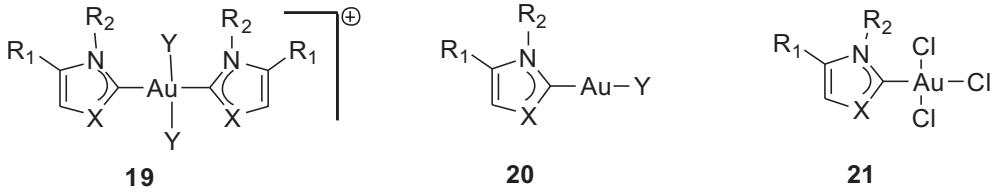
$$[1] \qquad 2[AuL^1(L^2)] \longrightarrow [AuL^1{}_2] + [AuL^2{}_2]$$

The crystal structure of the type **17** complex (NHC = thiazolylidene, R = H) showed that the dimeric units were formed in a staggered conformation with Au(I)···Au(I) interactions of about 3.33 Å (39*d*). The crystal structure of the type **18** complex (NHC = thiazolylidene, R = H, L = thiazolate) showed a dimeric unit with the shortest Au(I)···Au(I) contacts of ~3.07 Å (39*b*). In one instance, a free imidazolium carbene (R_1 = Me, R_2 = Bu) was employed to obtain both type **17** and **18** Au(I)–NHCs (40).

Oxidative addition (Scheme 9) of halogens to Au(I)–NHCs of type **17** produced the Au(III)–NHCs of type **19** or a Au(I)–NHC of type **20** (25). Oxidative addition to the type

Scheme 8. Formation of Au(I)–NHCs derived from Au(I)–thiazolates.

18 complexes also produced the Au(I)–NHCs of type **20**, which were anticipated to form via the reductive elimination of the bisNHC–Au(III)-halide intermediate. Formation of Au(III)–(NHC)-trichloride of type **21** was observed by using excess chlorine. However, a type **21** Au(III)–NHC based on thiazolium carbene was obtained from the reaction of thiazolium bromide with $HAuCl_4$ followed by the treatment of the intermediate with a base (40). The crystal structure of chloro(imidazolylidene) gold(III) (type **19**) showed that the coordination around the gold(III) center was square-planar and the chemically equivalent ligands were trans to one another. Very little π-back donation was believed to occur. The structural analysis was further complimented by DFT calculations, where the experimentally determined bonding parameters were in good agreement with the theoretical calculations.



The formation of Au(I)–NHCs of type **22** and **23** were stoichiometric dependent reactions (Scheme 10). The crystal structure of **23** (X = H) revealed that the intermolecular Au(I)···Au(I) interactions were absent due to the presence of a hydrogen bonding network (41).

Transmetallation between Ag(I)–NHCs and Au(I) precursors

It is not always convenient to employ the free NHCs as they are air and moisture sensitive. It is also not that easy to selectively deprotonate imidazolium salts with strong bases, as there is a possibility of the decomposition of the imidazolium salt or the formation of side products. To avoid these difficulties, our group reported a very convenient technique in 1998 to obtain Au(I)–NHCs from Ag(I)–NHCs by carbene transfer (42, 43). Simply mixing an imidazolium salt with Ag_2O afforded a complex of Ag(I)–NHC, which was used either as isolated or generated in situ to react with Au(I) precursors by transmetallation. As both the reactants

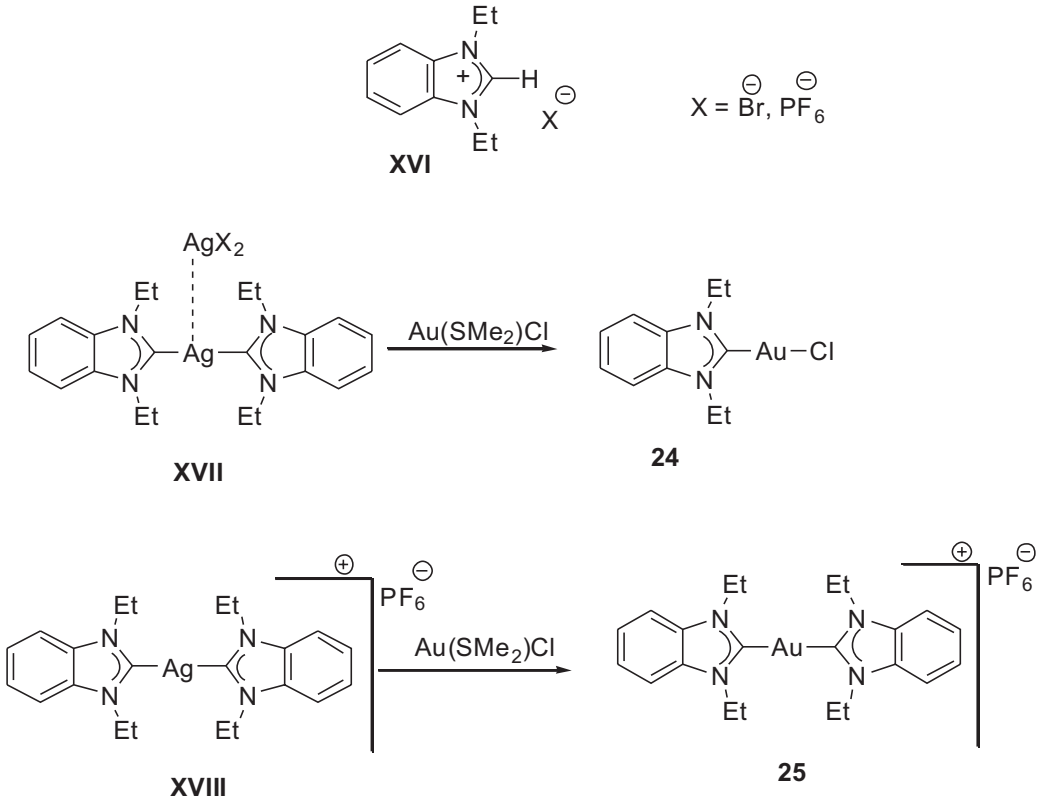
R = H, Me

are air-stable, the technique of carbene transfer is regarded as a convenient entry point into metal–carbene chemistry without the need for the rigorously anaerobic conditions and additional bases to synthesize NHCs.

As shown in Scheme 11, reaction of 1,3-diethylbenzimidazolium bromide (**XVI**) with Ag_2O in dichloromethane gave an ion-pair biscarbene complex of Ag(I) (**XVII**) (42). The lack of $^{13}C^{107,109}$–Ag couplings in the ^{13}C NMR spectrum of the ion-pair compound indicated the labile nature of the Ag—$C_{carbene}$ bond and suggested an equilibrium between $[Ag(Et_2\text{-bimy})_2][AgBr_2]$ and $[Ag(Et_2\text{-bimy})Br]$ in solution. In view of this fluxional behavior, it was considered that these Ag(I)–NHCs would be efficient carbene transfer agents, and the very first time we applied this technique successfully to produce the Au(I)–NHC **24**. Similarly, reaction of $[Ag(Et_2\text{-bimy})_2][PF_6]$ (**XVIII**) with $[Au(SMe_2)Cl]$ produced a bisAu(I)–NHC complex **25**.

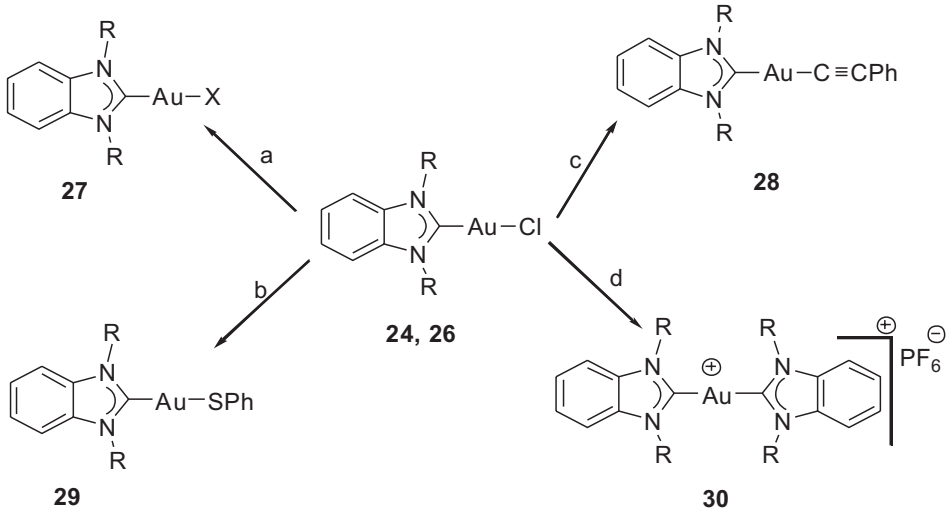
Later, the isolation of Au(I)-bimy carbene **26** with R = Me was reported by using the in situ generated Ag(I)-bimy carbene. The easy synthesis of $[Au(R_2\text{-bimy})Cl]$ (**24**, R = ethyl; **26**, R = methyl) allowed us to derive the Au-(R_2-bimy) core containing compounds **27**–**30** as shown in Scheme 12 (44).

Attempts to prepare the mixed-carbene compound $[Au(R_2\text{-bimy})(R'_2\text{-bimy})]PF_6$ produced a mixture of $[Au(R_2\text{-bimy})(R'_2\text{-bimy})][PF_6]$, $[Au(R_2\text{-bimy})_2][PF_6]$, and $[Au(R'_2\text{-bimy})_2][PF_6]$. Mixing the last two compounds, however, did not give the mixed-carbene compound, suggesting that the homoleptic carbene compounds were not labile. Note that analogous phosphine compounds such as [Au(phosphine)X] (X = Cl, Br, I), $[Au(phosphine)_2][PF_6]$, [Au(phosphine)(C≡CPh)], [Au(phosphine)(SR)], and $[Au(phosphine)(py)]^+$ have been reported. We also tried to synthesize $[Au(R_2\text{-bimy})(PPh_3)]^+$ without success. Reaction of $[Au(R_2\text{-bimy})Cl]$ with $AgBF_4$ followed by PPh_3 produced $[Au(PPh_3)_2]^+$ and $[Au(R_2\text{-bimy})_2]^+$ instead of the expected $[Au(R_2\text{-bimy})(PPh_3)]^+$. According to the ^1H NMR spectral results, there was no dynamic equilibrium between the monomeric and dimeric forms of these complexes as was observed in $[Au(PPh_2Me)I]$.



The crystal packing of $[Au(Me_2\text{-bimy})Cl]$ (**26**) exhibited both Au^I–Au^I and ring π–π type intermolecular interactions. Two linear molecules were crossed at approximately 90° with a short Au^I–Au^I contact (3.16 Å) to form a pair. Each molecule in a pair further interacted with neighboring pairs through ring π–π interactions (ring–ring distance = 3.45 Å) in a head-to-tail fashion. The molecular packing of this compound can be viewed as a polymeric chain with alternating Au(I)···Au(I) and ring–ring interactions. On the other hand, the crystal packing of [Au(Et-bimy)Cl] (**24**) showed that the oppositely oriented ethyl groups on each bimy plane allowed a columnar stacking and caused only ring π–π interactions (ring–ring distance = 3.53 Å). Each molecule interacted through the bimy ring with upper and lower bimy rings of the neighboring molecules in a head-to-tail fashion.

After the experience with Au-bimy carbenes, we intended to extend our efforts towards the imidazolium and triazolium derived carbenes (45). Our objective was to generalize the preparation method of [Au(NHC)(halide)], which appeared to be useful starting material for the synthesis of many other Au(I)–NHC core containing compounds. Another objective was to study the photophysical properties of Au(I)–NHCs, as their analogous Au(I)–phosphines have been known to display interesting luminescent properties. $[Au(Me_2\text{-azy})Cl]$ (**31** and **32**) (azy = imidazol-2-ylidene or triazol-2-ylidene) were isolated successfully by using the carbene transfer technique (Scheme 13). The crystal structures of both **31** and **32** showed that these neutral molecules were stacked to form a linear polymer with weak Au···Au interactions of 3.3–3.5 Å. Luminous carbazolate was introduced into [Au(NHC)Cl] complexes under basic PTC conditions to synthesize [Au(NHC)(cbz)] type complexes **33**–**36** (Scheme 13), which were expected to exhibit rich photophysical properties. The crystal structure of **33** showed that the imy and cbz rings were coplanar, and that two of these molecules were stacked pair-wise in a head-to-tail fashion. Cationic Au(I) complexes **37** and **38** based on Me_2-bimy and Me_2-tazy carbenes were also derived from the corresponding [Au(NHC)Cl] in acetone by reacting them with the azolium salt of $[PF_6]$ (Scheme 13). For the synthesis of mixed Au(I)–Au(III) NHC compounds, $[Au^I(R_2\text{-bimy})_2][PF_6]$ (R = Me, Et) were treated with $[(NEt_4)][Au(mnt)_2]$ (mnt = maleonitriledithiolate) to give brown $[Au^I(R_2\text{-bimy})_2][Au^{III}(mnt)_2]$ compound **39** (Scheme 13). Secondary interactions like hydrogen bonding appeared to play an important role in the crystal packing.



All the complexes of Schemes 12 and 13 were luminous in the solid state. In addition to the high-energy emission

R = Et, Me: **(a)** $AgBF_4$ and KX (X = Br, I); **(b)**HSPh, KOH; **(c)** HC=CPh, K_2CO_3; **(d)** [R_2-bimyH][PF_6]

bands observed for all these carbene complexes, the [Au(NHC)Cl] complexes **26**, **31**, and **32** exhibited additional low-energy emission bands at 580–650 nm, which were attributed to Au-centered transitions involving Au···Au interactions. The [Au(NHC)(cbz)] complexes (**33**–**35**) also displayed intense low-energy emission bands at 584–592 nm with fine structures arising from carbazolate intra-ligand transitions modified by Au(I), which was also suggested by density functional calculations.

Further, the carbene transfer technique applied on the reported disilver–dicarbene complex (**XIX**) (46) also efficiently produced the corresponding digold–dicarbene

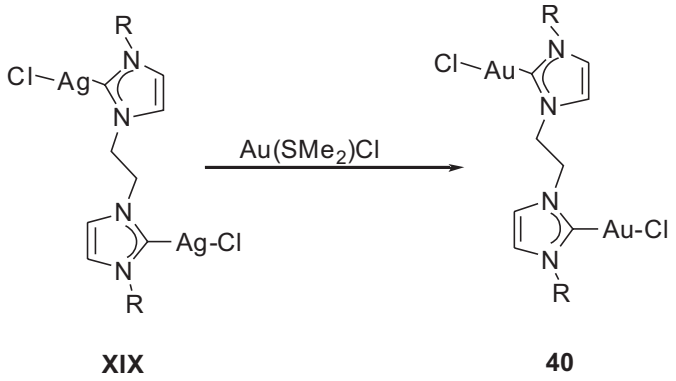
Scheme 13. Formation of [Au(NHC)(cbz)] and $[Au(NHC)_2]^+$.

complex **40** (Scheme 14).[3] Details of the reaction and structural information will be provided in future communications.

It is worth revealing that we have also reported the carbene transfer from Ag(I)–NHC (**XX** and **XXI**) of a long alkyl chain to the Au(I) center (Scheme 15) (47). Contrary to the results obtained with carbenes containing a short alkyl chain, a heteronuclear (Au_2–Ag_2) compound **41** was isolated. However, the carbene units were coordinated to the Au(I) center only; the $[Ag_2Br_4]^{2-}$ anion was intercalated between the two bisAu(I)–NHC units. It could be possible to remove the anionic unit by using appropriate methods. Instead of using the Ag–carbene transfer technique, liquid crystalline Au^I–carbene complexes (**5a**–**5c**) were best prepared by the reaction of Au^I with imidazolium salts under PTC conditions (32).

The first catalytic application of Au(I)–NHCs was explored by Herrman's group (27). As shown in Scheme 16, the carbene transfer agent (**XXII**) was treated with [Au(tht)Cl] to obtain [Au(NHC)Cl] **42**. The crystal structural parameters were found to be similar to the related Au(I)–NHCs. The NHC ligand showed significant trans influence to the Au—Cl bond length. The Au···Au separations of 4.16 Å were much longer than the van der Waals Au···Au distance of 3.6 Å.



The first Au(I)–NHC containing a gold–oxygen bond (**43**) was prepared from the reaction of **42** with $AgOC(O)CH_3$ (Scheme 16). The crystal arrangement regarding the Au–NHC core was found to be similar to the parent compound. The reason for the absence of Au···Au interactions was explained on the basis of the Ahrland proposal that aurophilic interactions decrease with increasing hardness of the supporting ligands. Compound **43** was employed as the first Au(I)–NHC catalyst during the addition reaction of water to 3-hexyne. Although good results were not observed as compared to the analogous [Au(phosphane)(carboxylate)], this effort would certainly show an impact in the Au(I) based homogeneous catalysis.

Mayer and co-workers (28*a*) reported the synthesis of homoleptic trinuclear Au(I) complexes of tripodal NHC **44** via the Ag(I)–NHC route (Scheme 17). As shown in Scheme 17, carbene transfer from Ag(I)–NHC (**XXIII**) to $Au(SMe_2)Cl$ produced the corresponding isostructural

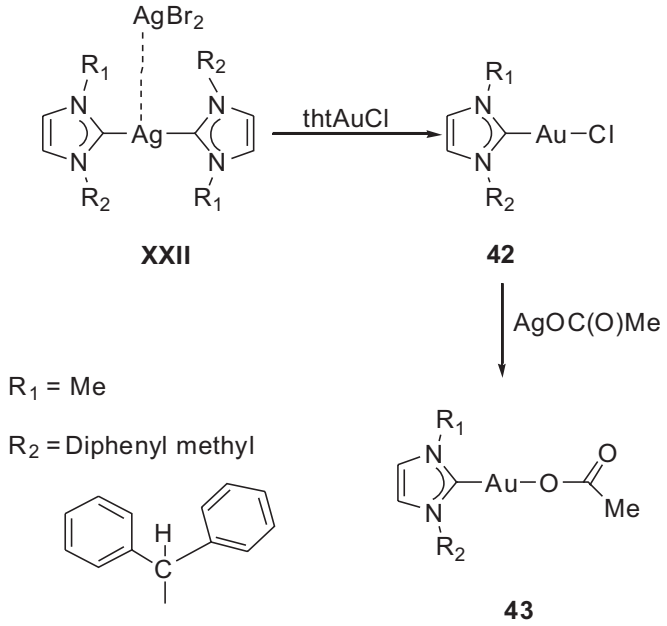
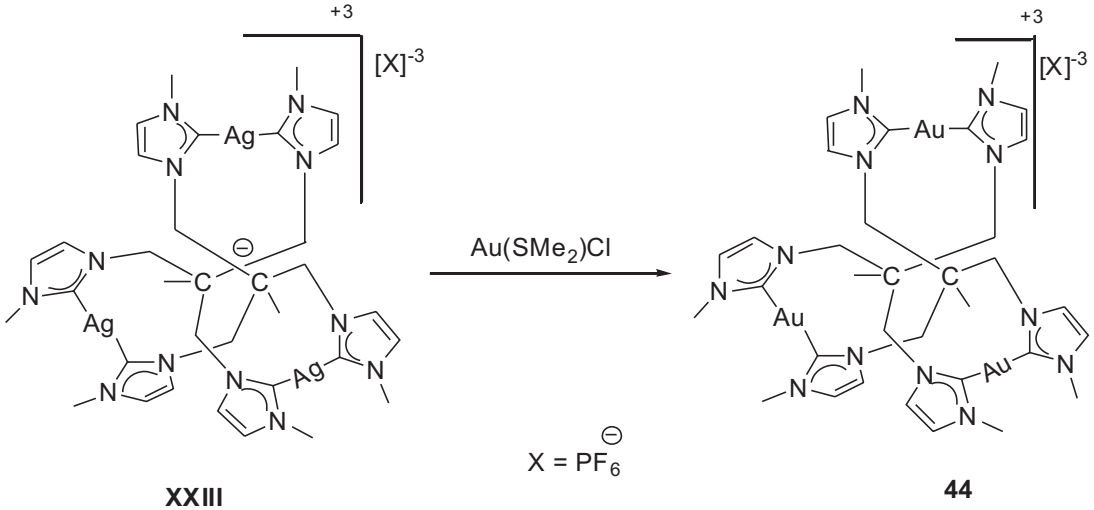


Scheme 15. Formation of the Ag_2Au_2 heterotetranuclear NHC complex.

Au(I)–NHC **44** under dry nitrogen. It was mentioned that such carbene transfer reactions performed in air produced only the imidazolium salts, and this suggested that this reaction proceeded via a free carbene intermediate as was reported for the formation of the tungsten diaminocarbene complex. The IR spectral band observed around ~1570 cm^{-1} in both the trinuclear Ag(I)–NHC and Au(I)–NHCs were ascribed for the N-C-N stretching environment. The electronic absorption spectral bands were observed between 210 and 290 nm and they proposed that they might originate from

Scheme 16. Synthesis of the first Au(I)–NHC catalyst.

ligand centered as well as ligand-to-metal and metal-to-ligand charge transfer transitions. The crystal structure of Au(I)–NHC **44** showed the nearest approach between two Au(I) centers was found to be 5.54 Å.



DFT studies carried on Au(I)–NHC **44** along with the parent Ag(I)–NHC and Cu(I)–NHC produced interesting results for the nature of metal–NHC bondings. Computational calculations concerning moleculear orbital interactions in these three Group 11 metal–NHCs showed a significant interaction between the metal $d(xz)$ and the $d(yz)$ orbitals and partially empty ligand π/π^* hybrid orbitals (15%–18%), and these calculations proposed that with electron-rich metal centers, π bonding could be significant (20%–30%). The elongation of C—N bond lengths in the crystal structures is consistent with the results obtained by DFT study. This phenomenon has been further supported by comparing the structural parameters of three isostructural biscarbene complexes $M(NHC)_2$ (M = I^+, Ag^+, and Ni^0).

Catalano et al. (48) reported the synthesis of Au(I) complexes with picolyl and pyridyl functionalized NHCs and extended the efforts to produce the mixed metal Ag(I)–Au(I) complexes to study the argentophilic–aurophilic interactions in the presence of functionalized NHCs (Scheme 18). Firstly, the Ag(I)–NHCs were obtained from the reaction between the pyridyl or picolyl functionalized imidazolium tetraflouroborate salt and Ag_2O. Carbene transfer performed between the Ag(I)–NHCs (**XXIV** and **XXV**) and Au(tht)Cl in dichloromethane easily produced the corresponding Au(I)–NHCs **45** and **46**. Interestingly, the Au(I)—$C_{carbene}$ bond distances in **46** were found to be slightly shorter than those observed in the corresponding parent Ag(I)–NHC. A reason owing to the smaller size of Au vs. Ag was proposed. None of these two compounds showed short aurophilic interactions.

Incorporation of additional Ag(I) atoms to **45** and **46** by treating with $AgBF_4$ resulted in two structurally different heterobimetallic complexes. Addition of $AgBF_4$ to **45** in MeCN yielded the heterotrimetallic (Ag_2Au_I) compound **47**,

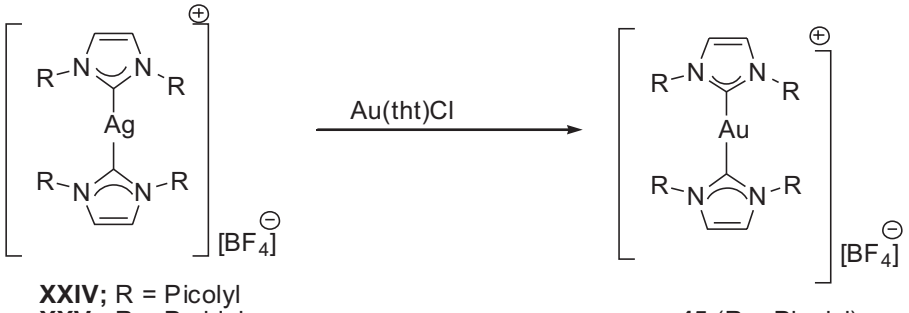
Scheme 17. Formation of trinuclear Au(I)–NHC via the Ag(I)–NHC route.

in which the newly incorporated Ag^I centers were coordinated with two pyridyl side arms of the NHC fragment. Weak argentophilic–aurophilic (Ag(I)···Au(I) ~ 3.2 Å) and argentophilic–argentophilic (Ag(I)···Ag(I) ~ 3.43 Å) interactions were found in compound **47** from the X-ray crystal study. Reaction of **46** with $AgBF_4$ did not provide the expected corresponding heterotrimetallic compound, rather, an unusual helical structured heteronuclear polymer **48** was formed, as a result of the rigidity of the NHC. Formation of compound **48** was observed to be independent of reaction conditions and stoichiometry. In **48**, one of the two pyridyl groups on opposing NHCs of a Au(I)–NHC fragment was coordinating to the two alternate Ag(I) centers and formed a polymer. The Ag(I)···Au(I) separations (~2.8–2.9 Å) in **48** were found to be shorter than those in **47** (~3.2 Å) possibly owing to the strain imposed by the rigid ligand backbone of **48**.



Concluding remarks

The literature survey reveals that the Au(I) metal center forms very strong bonds to NHCs. Although vast amounts of publications are not available, the reported information indicates the potential usefulness of Au(I)–NHCs in various fields. Different methods have been adopted to prepare the Au(I)–NHCs. The synthetic strategies of Au(I)–NHCs from the cleavage of electron-rich olefins or the transfer of NHC from Group 6 metal–NHCs have been less explored, probably because the starting materials are not easily accessible or the precursors are complicated. On the other hand, transmetallation of lithiated azoles followed by protonation or alkylation was applied widely as one of the easy methods in the isolation of several simple Au(I)–NHCs. It is, however, not advanced by other research groups and the validity of this method with functionalized substituents is not known. There are some Au(I)–NHCs obtained in high yields by using free NHCs, but the generation of free NHCs was hampered by the rigorous reaction conditions. Reaction of imidazolium salts with the appropriate Au(I) precursors in the presence of weak base, such as acetate salts, can also produce Au(I)–NHCs, but the yields are relatively low. On the other hand, the same kind of reaction carried out under PTC conditions produced the Au(I)–NHCs with high yields. However, much care has to be taken to remove the PTC from the final products. Carbene transfer from the Ag(I)–NHC to the Au(I) source was employed very effectively in the isolation of both simple and functionalized Au(I)–NHCs. Because the azolium salts and Ag(I)–NHCs are both air-stable, this method is recognized as a convenient entry point not only into Au(I)–NHCs, but also to other metal–NHCs. There is much evidence that the transfer of carbene from Ag(I)–NHCs to many other transition metals is particularly effective when the N-side arm contains base-sensitive functional groups. The easy synthesis of [Au(NHC)(halide)] and its high efficiency in the displacement of the halide by other ligands provides a way to the rational design of compounds containing a Au(I)–NHC core. Although anaerobic conditions are generally not necessary during the NHC transfer, the synthesis of Au(I)–NHC **44** was claimed to be carried out under a dry N_2 atmosphere to avoid the formation of imidazolium salts. These results suggest that this specific reaction proceeds via a free carbene intermediate as was observed during the synthesis of the tungsten diamino carbene complex. The carbene transfer reaction needs further study to understand the detailed mechanism.

The crystal structural study shows that in all these Au(I)–NHCs, the Au(I) center is linearly coordinated. Depending on the nature of NHCs, inter- and intramolecular aurophilic associations have been observed in several of these Au(I)–NHCs in the solid state. The aurophilic associations have been reflected in their luminescent properties in both the solid and solution state. Several other secondary interactions such as Au···H, ring π–π, and hydrogen bonding networks are also found to play an important role in the molecular assembly and properties. It is interesting to observe the mixed metal interactions, i.e., aurophilic and argentophilic interactions in the complexes of **47** and **48** with respect to the electronic and steric properties of NHCs. Computational calculations performed on Au(I)–NHCs along with other coinage metal–NHCs suggest the presence of nonnegligible π-back bonding (28) in the electron-rich metal–NHC derivatives.

Au(I)–NHCs can be applied as pharmaceuticals, homogeneous catalysts, liquid crystals, and optical devices. The performance of the Au(I)–NHCs in any application is observed to be influenced by the nature of the N substituent. The catalytic efficiency of NHC with other metal ions has already been established. In view of the facts that (*a*) gold often reacts much faster than other transition metals in the specific reactions like C—C bond formation (22), activation of C—C multiple bonds for the addition of N and O nucleophiles (22), and certain oxidations (22), (*b*) the NHC forms much stronger bonds with Au(I) than with other ligands, and (*c*) easily variable electronic or steric properties of NHCs via N- or C functionalization, we believe with certainty that the Au(I)–NHCs will show a great impact on homogeneous catalysis and other applications as mentioned previously. The generation of Au(I)–NHC polymers through short Au(I)···Au(I) interactions, their polymeric coordination mode, and photoluminescence shows the possibilities for optoelectronic and material applications. Because of the strong Au(I)—NHC bond and the linear coordination of Au(I), these complexes would be the best candidates to study the "structure – mesogenic behaviour relationship".

Microwave-accelerated, palladium-catalyzed carbonylative cyclization reactions of 2-iodophenol with alkynes — Rapid and efficient synthesis of chromen-2-one derivatives[1]

Hong Cao and Wen-Jing Xiao

Abstract: Rapid palladium-catalyzed carbonylative cyclization reactions of 2-iodophenol with various alkynes have been carried out by the use of commercially available molybdenum hexacarbonyl as a convenient and solid carbon monoxide source. The reactions were conducted at 160 °C for 30 min with microwave heating in the presence of DIEA and DMAP in 1,4-dioxane, and afford the corresponding chromen-2-one derivatives in good yields.

Key words: microwave, palladium, carbonylation, 2-iodophenol, chromen-2-one.

Résumé : Faisant appel à l'hexacarbonyle de molybdène disponible commercialement comme source solide et pratique de monoxyde de carbone, il est possible d'effectuer des réactions du 2-iodophénol avec de divers alcynes qui conduisent rapidement à des cyclisations accompagnées d'une carbonylation. Les réactions ont été en 30 min par chauffage microonde à 160 °C, en présence de DIEA et de DMAP dans le 1,4-dioxane, et elles ont conduit aux chrom-2-énones correspondantes avec de bons rendements.

Mots clés : microonde, palladium, carbonylation, 2-iodophénol, chrom-2-énone.

[Traduit par la Rédaction]

Introduction

Palladium-catalyzed carbonylative cyclizations are widely recognized as a unique, powerful, and versatile synthetic approach toward various structural cores of complex organocarbo- and heterocycles (1). Mainly because of the contributions from Alper (2), Larock (3), and Negishi (4) as well as their co-workers, the intra- and intermolecular carbo- and heteroannulations of unsaturated substrates such as alkynes, 1,2- and 1,3-dienes, vinyl cyclopropanes, homoallylic alcohols, and imines with functionally substituted aromatic or vinyl halides have been well documented in the literature (5). Although a large number of catalytic systems have been developed for the carbonylative cyclizations of a wide range of compounds, there are some limitations associated with this methodology: (1) slow reaction rate that results in long reaction time; (2) high pressure in the reaction system; and (3) less efficient utilization of toxic carbon monoxide gas. The second and third limitations are of particular concern since special gas delivery systems are needed. Therefore, the search for the improvement of carbonylation technology continues, with the goal of the development of fast, reliable, and convenient protocols. During the past 10 years, the techniques of high-throughput chemistry have been well-established and have been widely used in organic synthesis and pharmaceutical industry (6). In particular, microwave irradiation has emerged as a potential energy source for accelerated transition metal catalyzed reactions, and has proven very useful in many different applications (7). These modern methodologies offer an opportunity for the improvement of carbonylation. Consequently, Alterman and Hallberg and co-workers developed a microwave-assisted, palladium-catalyzed aminocarbonylation of aryl halides using dimethylformamide (DMF) (8) or formamide (9) as a liquid carbon monoxide source. Based on the concept that microwave-promoted thermal decomposition of metal carbonyl complexes, Larhed and co-workers reported a palldium-catalyzed carbonylation using molybdenum hexacarbonyl ($Mo(CO)_6$) as a solid carbon monoxide source (10, 11). This method, to some extent, overcomes the trouble caused by using gaseous carbon monoxide from a cylinder, and it could be suitable for high-throughput synthesis of amides and esters. Thus, Alterman and co-workers (12) subsequently explored the microwave-mediated intramolecular carbonylative cyclization reactions of bromobenzyl alcohols utilizing DMF and $Mo(CO)_6$ as two alternative CO sources.

Accordingly, we started to investigate the carbonylation reaction of 2-iodophenol with alkynes under microwave irradiation using $Mo(CO)_6$ as the CO source, and herein we

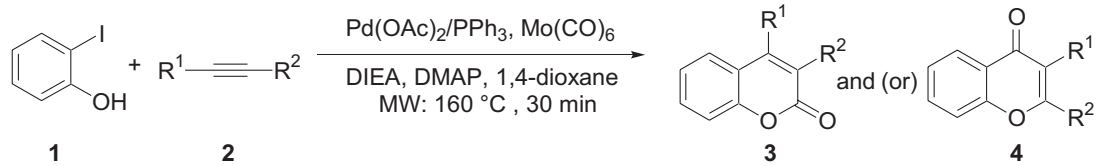
wish to describe the first example of microwave-accelerated, palladium-catalyzed intermolecular carbonylative cyclization, resulting in chromen-2-one derivatives (eq. [1]).



Of particular interest is the fact that some chromen-2-one derivatives possess remarkable biological activity, including anticancer and HIV-1-specific reverse transcriptase inhibitor properties (13). They are also very useful precursors of other heterocyclic compounds (14). Of the various routes to their preparation (15), the methodology presented herein is one of the most straightforward and efficient ways to afford such compounds, with small reaction scales and short reaction times.

Results and discussion

Initial studies were focused on examining the feasibility of the microwave-accelerated, intermolecular carbonylative cyclization reaction, and optimizing reaction conditions that could be applied to a variety of alkynes and 2-iodophenol. The reaction of 3-hexyne (**2a**) and 2-iodophenol (**1**) was chosen as a model reaction. On the basis of the knowledge gained from previous findings (8), DMF was initially employed as the solvent as well as a CO source. The reaction was run on a 1 mmol scale, using 5 mol% $Pd(OAc)_2$ as the catalyst, 20 mol% PPh_3 as the ligand, 2 equiv. of alkyne, and 1 equiv. of diethyl amine (DIEA) in 5 mL of DMF at 180 °C for 30 min under microwave irradiation. However, the reaction did not give the corresponding carbonylation product under these conditions. The addition of 0.5 equiv. of $Mo(CO)_6$ to the above reaction resulted in the formation of 3,4-diethyl-chromen-2-one (**3a**) and 2,3-diethyl-chromen-4-one (**4a**) in 18% and 36% isolated yields, respectively (eq. [2]). Thus, the effects of varying the base, solvent, reaction temperature, and reaction time on the model reaction were then examined.

Table 1 shows the results of the model reaction under different conditions. It was found that $Mo(CO)_6$ was not active itself as an efficient catalyst in the model reaction under mi-

crowave irradiation (Table 1, entry 1), while $Pd(OAc)_2$ with 4 equiv. of PPh_3 worked very well in most cases (Table 1, entries 2–10). It can be concluded from Table 1 that the reaction is significantly influenced by the solvent and base employed. For example, when *N*-ethyldiisopropylamine (DIEA) and 4-(dimethylamino)pyridine (DMAP) were used as a co-base, the reaction gave the carbonylation products in 60% isolated yield in 1,4-dioxane (Table 1, entry 4). Other solvents, such as toluene, THF, and DMSO can be employed as the solvent for the reaction, but none appears to be as good as 1,4-dioxane (Table 1, entries 5–7). In addition to DIEA–DMAP, we have examined other bases, such as diethyl amine and pyridine, for the reaction (Table 1, entries 2 and 3). The results show that both of them are inferior to DIEA–DMAP. The use of inorganic bases (K_2CO_3 or KOAc) resulted in the formation of a complicated mixture; therefore, they were ruled out for further investigation.

The reaction temperature is another critical factor for the carbonylative cyclization, with the best result being attained at 160 °C. Variations of the temperature from this value have been proven to be detrimental to the reaction. For example, increasing the temperature to 180 and 200 °C gave only 60% and 55% yields, respectively (Table 1, entries 8 and 10). Decreasing the temperature to less than 150 °C did not give any carbonylation product because $Mo(CO)_6$ could not thermally decompose to generate carbon monoxide at this temperature (16).

We did not rigorously examine the effect of the CO source on the reaction. In principle, any compounds that could liberate CO under the above conditions might be used as a CO source in the reaction. However, compared with $Cr(CO)_6$, $Fe(CO)_5$, $Co_2(CO)_8$, and $Ni(CO)_4$, $Mo(CO)_6$ was found to be the best choice for the present reaction.

Thus, the final optimized reaction conditions for the microwave-accelerated carbonylative cyclization of 2-iodophenol and 3-hexyne with $Mo(CO)_6$ as the CO source have been determined to be 1 mmol of 2-iodophenol, 2 equiv. of 3-hexyne, 0.5 equiv. of $Mo(CO)_6$, 5 mol% $Pd(OAc)_2$, 20 mol% PPh_3 in the presence of 1 equiv. of DIEA, and 1 equiv. of DMAP in 1–1.5 mL of 1,4-dioxane under microwave irradiation at 160 °C for 30 min. Using these reaction conditions, reactions of a variety of internal and terminal alkynes with 2-iodophenol were studied, and the results are summarized in Table 2.

Internal and terminal alkynes can be successfully employed in the microwave-accelerated, palladium-catalyzed carbonylative cyclization reactions with 2-iodophenol using $Mo(CO)_6$ as a solid carbon monoxide source, to give the corresponding chromenone derivatives in good isolated yields (Table 2). The regioselectivity of this reaction depends on the substrate employed. The terminal alkynes reacted with 2-iodophenol to exclusively afford the chromen-2-one derivatives in pretty good yields (Table 2, entries 3–7). Mixtures of regioisomers were obtained with modest regioselectivity when internal alkynes were applied in the reaction (Table 2, entries 1 and 2). Both the regioselectivity and the yield of the reactions of internal alkynes are affected by the steric bulk of the alkyl substituent. Increasing the size of the alkyl group from ethyl to propyl resulted in an increase in the regioselectivity (Table 2, entries 1 and 2), but a decrease in the yield of the reaction. For the reactions of terminal alkynes, in principle, they might also give two regioisomers (Scheme 1). However, during the insertion of the alkyne into the aryl–palladium bond, route a is much more favorable than route b because of the interaction of the bigger alkyl group (compare with H) with the palladium species (Scheme 1). Therefore, chromen-2-one **8**, rather than **9**, was formed as a sole product in the reaction.

The formation of two regioisomers in the reaction of internal alkynes could be rationalized according to Scheme 2. The reaction may start from the oxidative addition of 2-iodophenol to Pd(0) to form an arylpalladium complex **10**, and then both CO and the internal alkyne insert subsequently to the aryl–Pd bond to form complexes **11** and **12**, respectively. Depending on the rate difference of the insertion and (or) the stabilities of **11** and **12**, the reaction exhibits regioselectivity and eventually affords chromenones **3** and **4** in different ratios (Scheme 2).

Conclusions

In summary, this research has resulted in the first example of microwave-accelerated, palladium-catalyzed intermolecular carbonylative cyclization of 2-iodophenol and alkynes with the solid molybdenum hexacarbonyl as an efficient source of carbon monoxide. The methodology presented here is attractive because of the short reaction time, the experimental simplicity, and the fact that no external carbon monoxide needs to be added.

Experimental section

General methods

Unless otherwise noted, materials were purchased from commercial suppliers and used without further purification. Solvents and liquid organic bases were freshly distilled according to the known procedures (16). Column chromatography was performed using 200–300 mesh silica gel. IR was recorded on a PerkinElmer PE-983 IR spectrometer as KBr film with absorption in cm^{-1}. ^1H NMR spectra were recorded on Varian Mercury 400 (400 MHz) spectrometers. Chemical shifts are reported in ppm from TMS with the solvent resonance as the internal standard ($CDCl_3$: δ 7.24). Data are reported as follows: chemical shift, multiplicity (singlet (s), doublet (d), triplet (t), quartet (q), broad (br), multiplet (m)), coupling constants (Hz). ^{13}C NMR spectra were recorded on Varian Mercury 400 (100 MHz) with complete proton decoupling spectrophotometers ($CDCl_3$: δ 77.7).

All experiments were performed in a Smith Synthesizer producing controlled irradiation at 2450 MHz with a power of 0–300 W.

Typical procedure for the microwave-accelerated, palladium-catalyzed carbonylative cyclization

A 2.0–5.0 mL process vial was charged with 2-iodophenol (1 mmol) and $Pd(OAc)_2$ (0.05 mmol), PPh_3 (0.2 mmol), $Mo(CO)_6$ (0.5 mmol), alkyne (2 mmol), DIEA (1 mmol), DMAP (1 mmol), and dry 1,4-dioxane (1.0 mL). The vial was immediately capped with a Teflon septum under N_2 and irradiated with microwaves to 60 °C for 10 min, then to 160 °C for another 30 min. After cooling, the reaction mixture was filtered through a short Celite pad, and the solvent

Preparation, characterization, and structure of two dipyrrolide thorium homoleptic complexes — Isolation of a dipyrrolide dipotassium salt with an inverted-sandwich type of structure[1]

Arunachalampillai Athimoolam, Sandro Gambarotta, and Ilia Korobkov

Abstract: Reactions of the in-situ-generated potassium salts of the dipyrroles $(C_4H_3NH)_2C(CH_3)_2$ and of $(C_4H_3NH)_2C(CH_3)(C_6H_5)$ with $ThCl_4(DME)_2$ has afforded the corresponding homoleptic $(\{[(C_4H_3N)_2C(CH_3)_2]_3Th\}[K_2(DME)])_n$ (**1**) and $\{[(C_4H_3N)_2C(CH_3)(C_6H_5)]_3Th\}[K_2(DME)]$ (**2**). In the case of **1**, the solid state polymeric structure was elucidated by X-ray diffraction analysis. Preliminary attempts to reduce these species have so far afforded only intractable materials. Just in the case of **2**, it was possible to isolate the corresponding ligand dipotassium salt $\{(C_4H_3NH)_2C(CH_3)(C_6H_5)[K(DME)]_2\}_n$ (**3**) as the only characterizable material. This species possesses an unprecedented inversed-sandwich type of structure.

Key words: thorium, homoleptic, dipyrrolide.

Résumé : Les réactions du $ThCl_4(DME)_2$ avec des sels de potassium générés in situ des pyrroles $(C_4H_3NH)_2C(CH_3)_2$ et $(C_4H_3NH)_2C(CH_3)(C_6H_5)$ conduit à la formation des composés homoleptiques correspondants $(\{[C_4H_3N)_2C(CH_3)_2]_3Th\}[K_2(DME)])_n$ (**1**) et $\{[C_4H_3N)_2C(CH_3)(C_6H_5)]_3Th\}[K_2(DME)]$ (**2**). Dans le cas du composé **1**, on a élucidé la structure polymère de l'état solide par diffraction des rayons X. Des essais préliminaires en vue de réduire ces espèces n'ont fourni que des produits intraitables. Dans le cas du composé **2**, il a toutefois été possible d'isoler le sel dipotassique du ligand $\{(C_4H_3NH)_2C(CH_3)(C_6H_5)[K(DME)]_2\}_n$ (**3**) comme seul produit pouvant être caractérisé. Cette espèce possède une structure de type sandwich inversé, inconnue jusqu'à maintenant.

Mots clés : thorium, homoleptique, dipyrrolure.

[Traduit par la Rédaction]

Introduction

There is a revival of interest in the recent literature for the chemistry of reduced actinide complexes and in particular for the preparation of trivalent uranium derivatives (1). Recent discoveries in this direction include three cases of dinitrogen fixation (2), which have indicated that in fact these species may be versatile agents for molecular activation purposes. This has prompted a multiplication of efforts in this direction that has resulted in spectacular findings such as a unique way of reversibly bonding CO_2 (3) and the ability to coordinate a saturated hydrocarbon (4). This exciting background is obviously encouraging further efforts for the preparation and characterization of highly reduced actinide species with varied ligand systems.

As usual, the choice of a suitable ligand system is central to the fine tuning for the control of very high reactivity. With this respect, pyrrole-based anions provide a family of ligands that has proven versatile for the stabilization of low oxidation states with a large variety of elements (5), and for sustaining a high level of reactivity with lanthanides (6) and actinides (7). Tetrapyrrolide tetra-anion complexes in particular have afforded dinitrogen labile fixation (8), reduction (9), and cleavage (10). In addition, these ligands have allowed the preparation of thorium species carrying reduced naphtalenide anions, which, in turn, work as an electronic reservoir for two-electron reduction of several substrates including solvent fragmentation (11). In other words, intact arene could be dissociated and two-electron reductions conveniently performed on a variety of substrates (11).[3] Furthermore, reduction of a trivalent uranium tetrapyrrolide derivative has provided the sole example of dinitrogen cleavage in the chemistry of *f*-block elements (10), once more reiterating the potential offered by reduced actinides for molecular activation purposes.

Dipyrrolide dianions also belong to this family of ligands and are able to stabilize low-valent *f*-block elements via clusterification that occurs by crossing σ- and π-bonding interactions with the pyrrolide rings (12). These thermally robust clusters have displayed a unique inclination towards cooperative four-electron reduction of N_2 (13). Furthermore,

 doi: 10.1139/V05-086 © 2005 NRC Canada

since a simple *bidentate* bisaryloxide complex of thorium has also afforded dinitrogen cleavage and protonation during the reduction (14), we became interested in the synthesis, characterization, and reduction of thorium complexes supported by the bidentate dipyrrolide dianions. This background has prompted us to study the chemistry of actinides supported by the dipyrrolide ligand system, which may work as a precursor towards further preparation of reduced species.

In this paper, we describe the results of our attempts.

Experimental section

All operations were performed under an inert atmosphere by using standard Schlenk techniques or inside a drybox. $ThCl_4(DME)_2$ was prepared from thorium nitrate by boiling with concd. HCl and then dehydrated with thionyl chloride, followed by recrystallization and extraction from DME. Dipyrromethanes were synthesized according to literature procedure (15). NMR spectra were recorded on a Bruker Avance 300 spectrometer. Elemental analyses were performed on a PerkinElmer 2400 CHN analyzer. Data for X-ray crystal structure determinations were obtained with a Bruker diffractometer equipped with a Smart CCD area detector. NMR spectra were recorded on a Varian AMX-300 spectrometer.

Preparation of $\{[(C_4H_3N)_2C(CH_3)_2]_3Th\}[K_2(DME)]$ (1)

A solution of the potassium salt of $(C_4H_3NH)_2C(CH_3)_2$ in THF, prepared by reacting $(C_4H_3NH)_2C(CH_3)_2$ (0.5 g, 2.9 mmol) with KH (0.23 g, 5.8 mmol) in THF, was added to a solution of $ThCl_4(DME)_2$ (0.44 g, 0.96 mmol) in THF. Stirring was continued for another 6 h. The resulting solution was evaporated to dryness and the solid residue was redissolved in DME, filtered, and layered with hexane. Colorless crystals of **1** were obtained after standing for 24 h at –35 °C (0.46 g, 53%). ^{1}H NMR (THF-d_8, 300 MHz) δ: 6.38 (d, pyrrole H, 6H), 6.04 (d, pyrrole H, 6H), 5.86 (m, pyrrole H, 6H), 3.42 (s, DME, 4H), 3.26 (s, DME, 6H), 1.56 (s, methyl, 18H). ^{13}C NMR (THF-d_8, 75.43 MHz) δ: 127.22, 126.46 (quaternary C), 124.53, 123.59, 114.81, 106.20, 104.92, 103.36, 101.60 (pyrrole C), 70.30 (DME), 56.12 (DME), 37.15 (bridging C, ligand), 31.20, 27.56 (methyl C, ligand). Elemental anal. calcd. for $C_{37}H_{46}K_2N_6O_2Th$: C 48.46, H 5.06, N 9.16; found: C 48.41, H 5.00, N 9.08.

Preparation of $\{[(C_4H_3N)_2C(CH_3)(C_6H_5)]_3Th\}[K_2(DME)]$ (2)

A solution of the potassium salt of $(C_4H_3NH)_2C(CH_3)(C_6H_5)$ in DME, prepared by reacting $(C_4H_3NH)_2C(CH_3)(C_6H_5)$ (0.5 g, 2.12 mmol) with KH (0.23 g, 5.8 mmol) in DME, was added to a solution of $ThCl_4(DME)_2$ (0.32 g, 0.71 mmol) in DME. Stirring was continued for another 6 h, after which the solution was filtered and evaporated. Analytically pure **2** was obtained upon recrystallization from the DME–hexane mixture (0.62 g, 81%). ^{1}H NMR (THF-d_8, 300 MHz) δ: 6.90 (m, phenyl H, 15H), 6.30 (t, pyrrole H, 3H), 5.89 (m, pyrrole H, 6H), 5.63 (m, pyrrole H, 6H), 5.37 (m, pyrrole H, 3H), 3.46 (s, DME, 4H), 3.29 (s, DME, 6H), 1.85 (s, methyl, 9H). ^{13}C NMR (THF-d_8, 75.43 MHz) δ: 156.49, 148.11, 144.98 (quaternary C), 127.87, 127.75, 127.34, 126.83, 126.80 (aromatic C), 125.55, 124.60, 105.20, 105.04, 103.91, 103.79, 103.72, 103.64, 103.48 (pyrrole C), 72.15 (CH_2, DME), 58.33 (CH_3, DME), 47.20 (bridging C, ligand), 30.47 (CH_3, ligand). Elemental anal. calcd. for $C_{52}H_{52}K_2N_6O_2Th$: C 56.61, H 4.75, N 7.62; found: C 56.48, H 4.71, N 7.59.

Reduction of 2 with potassium naphthalenide and isolation of $\{[(C_4H_3N)_2C(CH_3)(C_6H_5)][K(DME)]_2\}_n$ (3)

To a solution of potassium naphthalenide, prepared in situ by stirring potassium (0.04 g, 0.9 mmol) in DME (30 mL) with naphthalene (0.12 g, 0.9 mmol), compound **2** (0.5 g, 0.45 mmol) was added at –30 °C. The mixture was brought to room temperature and stirring was continued overnight. The resulting dark-red solution was filtered and concentrated to 5 mL and layered with hexane. Colorless crystals of **3** (0.13 g, 59%) were obtained along with an oily and intractable mass. Two subsequent recrystallizations of the sticky mass afforded analytically pure **3**. ^{1}H NMR ($CDCl_3$, 300 MHz) δ: 7.23 (m, phenyl H, 5H), 6.62 (dd, pyrrole H, 2H), 6.15 (t, pyrrole H, 2H), 5.93 (dd, pyrrole H, 2H), 3.25 (s, DME, 4H), 3.15 (s, DME, 6H), 2.03 (s, methyl, 3H). ^{13}C NMR ($CDCl_3$, 300 MHz) δ: 147.63, 137.65 (quaternary C), 128.53, 127.63 (aromatic C), 117.08, 108.55, 106.58 (pyrrole C), 72.17 (CH_2, DME), 59.45 (CH_3, DME), 45.06 (bridging C, ligand), 29.17 (CH_3, ligand). Elemental anal. calcd. for $C_{20}H_{24}K_2N_2O_2$: C 59.66, H 6.01, N 6.96; found: C 59.44, H 5.96, N 6.88.

X-ray crystallography

The product crystals of **1** and **3** were selected, mounted on thin glass fibers using thick paraffin oil, and cooled to the data collection temperature. Data were collected on a Bruker AXS SMART 1 k CCD diffractometer using 0.3° ω scans at 0.90 and 180 in ϕ. Initial unit-cell parameters were determined from 60 data frames collected at different sections of the Edwald sphere. Semiempirical absorption corrections based on equivalent reflections were applied (16). Systematic absences in the diffraction data sets and unit-cell parameters were consistent with *P*2(1)/*c* for **1** and *Pbca* for **3**. The structures were solved by direct methods, completed with difference Fourier syntheses, and refined with full-matrix least-squares procedures based on F^2. All hydrogens were defined with anisotropic displacement coefficients. All hydrogen atoms were treated as idealized contributions. All scattering factors are contained in several versions of the SHELTX program library with the latest used version being v. 6.12 (17). Crystallographic data and relevant bond distances and angles are reported in Tables 1 and 2, respectively.[4]

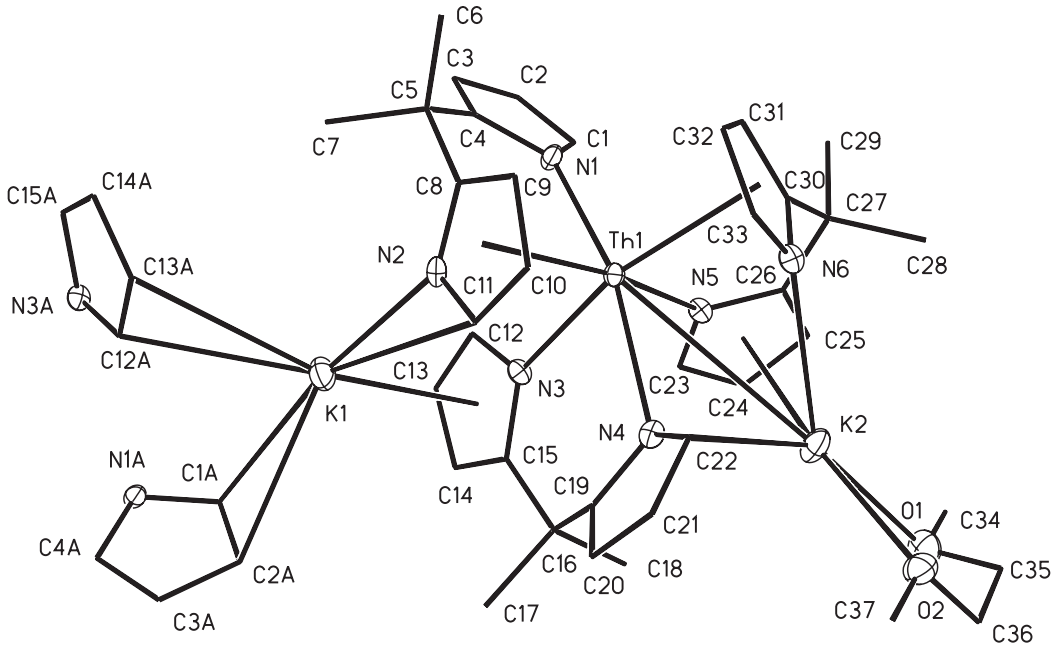
Results and discussion

Reaction of the dipotassium salt of either dimethyl or methyl/phenyl dipyrrole with $ThCl_4(DME)_2$ afforded the corresponding $\{[(C_4H_3N)_2C(CH_3)_2]_3Th\}[K_2(DME)]$ (**1**) and $\{[(C_4H_3N)_2C(CH_3)(C_6H_5)]_3Th\}[K_2(DME)]$ (**2**). Reactions carried out with different ligand to metal stoichiometric ratios also afforded the same compounds albeit in lower yield. The NMR spectra of both complexes display similar features, thus suggesting that the two compounds might in fact be isostructural. In the case of **1**, it was possible to grow crystals of suitable quality to undertake an X-ray crystal structure determination.



The structure of **1** consists of a thorium atom surrounded by three dipyrrolide dianions and two potassium atoms (Fig. 1). Two of the three dianions adopt the usual σ- and (or) π-bonding mode, each having one of the two rings η^5-bonded to the thorium atom (Th—N(2) = 2.787(7) Å, Th—N(6) = 2.735(7) Å, Th—C(8) = 2.907(8) Å, Th—C(9) = 3.022(8) Å, Th—C(10) = 2.975(9) Å, Th—C(11) = 2.827(9) Å, Th—C(30) = 2.903(10) Å, Th—C(31) = 3.017(10) Å, Th—C(32) = 2.996(10) Å, Th—C(33) = 2.800(9) Å), and the other that is acting as a regular N-based, σ-donor (Th—N(1) = 2.460(7) Å, Th—N(5) = 2.562(7) Å). The third ligand instead adopts the bidentate σ-bonding mode as a regular chelating diamide (Th—N(3) = 2.489(7) Å, Th—N(4) = 2.543(7) Å). Thus, the coordination geometry around each thorium atom can be described as distorted pseudo-octahedral (N(1)-Th-N(3) = 87.7(3)°, N(1)-Th-N(4) = 159.7(3)°, N(1)-Th-N(5) = 87.9(2)°, N(3)-Th-N(4) = 72.3(2)°, N(3)-Th-N(5) = 76.7(2)°, N(4)-Th-N(5) = 84.1(2)°) considering the centroids of the two π-bonded rings as occupying two cis positions of the coordination octahedron (cent-Th-cent = 107.8(3)°). The two potassium atoms that counterbalance the two negative charges of the complex have very different coordination environments. The first is partly π bonded to the pyrrole ring, which in turn is π bonded to the thorium atom (K(1)—N(2) = 2.772(8) Å, K(1)—C(11) = 3.483(11) Å), and fully π bonded to that which is σ bonded to the actinide (K(1)—N(3) = 3.140(8) Å,

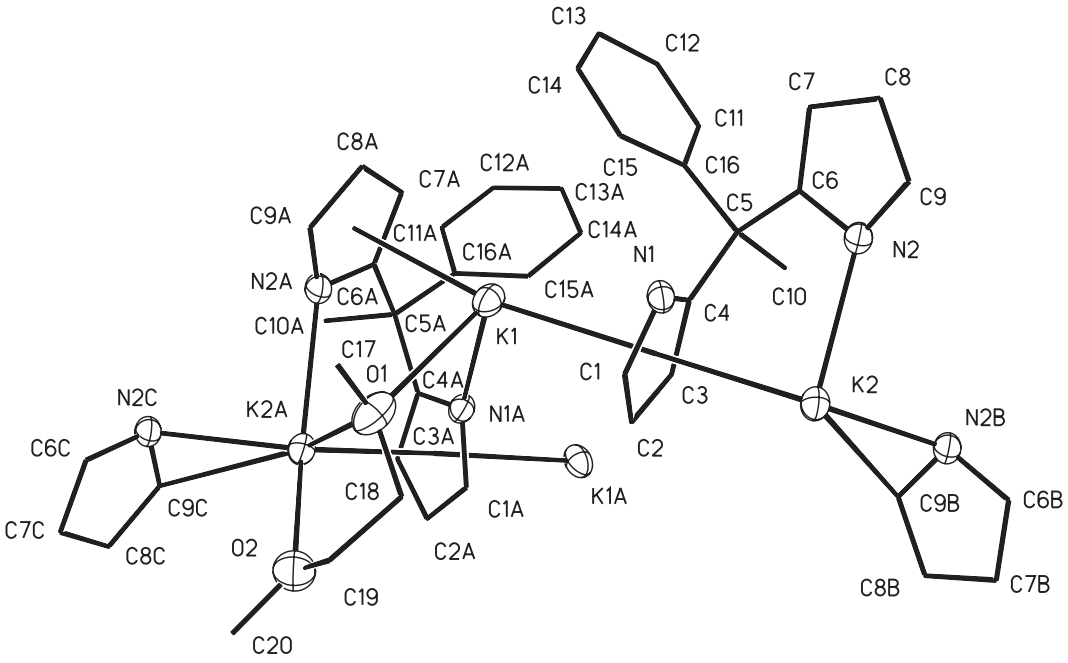
Fig. 1. Plot of **1** showing the thermal ellipsoids drawn at 30% probability level. Anisotropic ellipsoids are shown only for relevant atoms for reasons of clarity.

K(1)—C(12) = 2.957(10) Å, K(1)—C(13) = 3.058(11) Å, K(1)—C(14) = 3.257(11) Å, K(1)—C(15) = 3.287(10) Å). In addition, the partial π bonding to the rings of the dipyrrolide anion of two other identical units (K(1)—C(1A) = 3.242(10) Å, K(1)—C(2A) = 3.352(11) Å, K(1)—C(12A) = 3.150(9) Å, K(1)—C(13A) = 3.324(10) Å) assembles an infinite polymer type of structure. The second potassium is also π bonded to the ring, which is σ bonded to thorium (K(2)—N(5) = 3.101(8) Å, K(2)—C(23) = 3.389(9) Å, K(2)—C(24) = 3.515(11) Å, K(2)—C(25) = 3.278(10) Å, K(2)—C(26) = 3.035(9) Å), but also partly π bonded to a section of the ring (K(2)—N(4) = 2.812(8) Å, K(2)—C(22) = 3.212(10) Å), which, by also being σ bonded to thorium, adopts an uncommon bridging bonding mode. One molecule of coordinated DME completes the coordination sphere of this particular potassium.

The polymeric structure observed in the solid state is unlikely to be preserved in solution since the ^{1}H NMR spectrum of **1** showed only three resonances for the three protons of the pyrrolide rings. In the case of complex **2**, the pyrrolyl rings produced two well-separated resonances for the pyrrolide ring β-H atoms, probably as a result of the presence of two different substituents (i.e., methyl and phenyl) on the connecting quaternary carbon atom.



Attempts to reduce both **1** and **2** were carried out with 2 equiv. of K(naphthalenide) in DME. Both reactions gave, upon mixing, a sudden color change from dark-green to very deep-red. Unfortunately, in both cases no thorium-containing materials could be isolated. Only in the case of **2**, and after several attempts, were colorless crystals of the corresponding dipyrrolide dipotassium salt **3** isolated in crystalline form.

The structure of **3** consists of one dipyrrolide dianion surrounded by two potassium atoms (Fig. 2). A salient feature of the structure is the presence of the two metals located on the two sides of one of the two pyrrolide rings in an overall inverted-sandwich type of structure (K(1)—N(1) = 3.114(5) Å, K(1)—C(1) = 2.956(6) Å, K(1)—C(2) = 3.105(6) Å, K(1)—C(3) = 3.304(6) Å, K(1)—C(4) = 3.300(5) Å, K(2)—N(1) = 2.954(5) Å, K(2)—C(1) = 3.0191(5) Å, K(2)—C(2) = 3.144(6) Å, K(2)—C(3) = 3.130(6) Å, K(2)—C(4) = 2.993(6) Å). The coordination environments of the two alkali cations are very different. One of the two potassium atoms has its coordination sphere consisting of a σ-bonded N atom of the second dipyrrolide ring (K(2)—N(2) = 2.747(5) Å) and of another σ-bonded N atom of one identical unit. Therefore, while one of the two pyrrolide rings is used for assembling the inverted sandwich structure, the second is bridging two identical potassium atoms using the σ-bonded N atom. The π-bonded ring of the inverted sandwich structure and one coordinated molecule of DME completes the coordination sphere of this particular potassium atom (K(2A)—O(1) = 2.974(5) Å, K(2A)—O(2) = 2.681(5) Å). The coordination sphere of the other potassium atom comprises, besides the π-bonded ring of the inverted sandwich structure, the π bonding of a second ring of another unit (K(1)—N(2A) = 3.163(5) Å, K(1)—C(6A) = 3.024(6) Å, K(1)—C(7A) = 3.025(6) Å, K(1)—C(8A) = 3.152(6) Å, K(1)—C(9A) = 3.221(6) Å), which is used by the first potassium atom for σ bridging of a symmetry generated unit. The coordination sphere of the second potassium atom is completed by the σ bonding of the N atom of the ring used for the inverted sandwich structure of another unit (K(1)—N(1A) = 2.728(5) Å) and by one of the two oxygen atoms of a DME molecule (K(1)—O(1) = 3.047(5) Å), which is chelating the other potassium. All these bridging interactions generate a three-dimensional polymeric structure.

The asymmetric polymeric structure is unlikely to be preserved in solution. The NMR spectrum of **3** shows in fact only one set of pyrrolide ring H atoms appearing as a triplet for the H atom in position 4 of the ring and two well-resolved double doublets for the other two hydrogen atoms

Fig. 2. Plot of the single unit of the polymeric **3** showing the thermal ellipsoids drawn at 30% probability level. Anisotropic ellipsoids are shown only for relevant atoms for reasons of clarity.

with the correct integration ratio. This indicates that not even the inverted sandwich structure is preserved in a solution of the coordinating solvent. Unfortunately, the very poor solubility of **3** in hydrocarbon solvents has prevented the recording of spectra in a noncoordinating environment where at least some of the solid state features could be conserved.

The formation of **3** during the reduction of **2** implies dissociation of one ligand from the thorium center. This is most likely the consequence of the formation of a thorium naphthalenide complex similar to those isolated with tetrapyrrolide (11) or diphenoxide thorium complexes (14). The NMR spectra of the diamagnetic dark-red solutions showed in fact the characteristic resonances of the coordinated naphthalenide anion (11, 14). It is, therefore, most unfortunate that so far only intractable residues have been isolated in spite of reiterated attempts. Further attempts to isolate and characterize reduced dipyrrolide thorium species are in progress.

Rh(I)-catalyzed cleavage of unactivated C—O bonds — Carbonylative rearrangement reactions of allenyl ethers to 2-carboalkoxy-1,3-dienes[1]

Paul A. Wender, Nicole M. Deschamps, and Robert Sun

Abstract: The initial examples of a Rh(I)-catalyzed carbonylative rearrangement reaction of allenyl ethers are described. The key reaction proceeds under remarkably mild conditions to provide good to excellent yields of 2-carboalkoxy-1,3-dienes.

Key words: carbonylative rearrangement, C-O cleavage, σ bond activation, rhodium catalysis, allenyl ethers.

Résumé : On décrit les premiers exemples de réactions, catalysées par le Rh(I), de réarrangements d'éthers allényles accompagnées d'une carbonylation. La réaction clé se produit dans des conditions particulièrement douces pour conduire à la formation de dérivés 2-carboalkoxy-1,3-dièns avec des rendements allant de bons à excellents.

Mots clés : réarrangement avec carbonylation, clivage C-O, activation d'une liaison σ, catalyse par le rhodium, éthers allényles.

[Traduit par la Rédaction]

Introduction

Metal-catalyzed σ bond activation, particularly of unreactive bonds, is an important objective in organometallic and synthetic organic chemistry (1). The ability to convert, for example, the C—O bonds in ethers and alcohols to C—C bonds without the need to prepare activated oxygen derivatives (carbonates, triflates, halogens, etc.) offers, in many situations, step-economic and strategic advantages in synthesis (2, 3). As illustrated in Scheme 1, the metal-catalyzed insertion into a C—O bond and reaction with an additional component (R″) could provide an organometallic intermediate(s) that could lead to the formation of substitution or insertion products.

Illustrative of processes that give rise to substitution products are the copper- (4), nickel- (5), palladium- (6), and zirconium-catalyzed (7) transformations of allylic ethers and allylic alcohols to the corresponding substituted alkenes with alkyl and phenyl magnesium salts and the ruthenium-catalyzed progargylation and allylation of aromatic compounds with propargylic and allylic alcohols (8). Carbonylation reactions (9) have also been achieved through metal-catalyzed cleavage of unreactive C—O bonds and the subsequent incorporation of carbon monoxide to give the corresponding insertion products. For example, cobalt- (10) and rhodium-catalyzed (11) carbonylative ring expansion reactions of unstrained cyclic ethers provide novel routes to lactones (12). Rhodium (13) and palladium (14) catalysts have been reported for the carbonylation of allylic ethers and alcohols to the corresponding esters and palladium catalysts have been reported for the carbonylation of allenyl alcohols to esters and acids (15). These carbonylation reactions often require the use of high pressures of carbon monoxide and elevated temperatures. During the course of our studies on metal-catalyzed σ bond activation, we identified a novel Rh(I)-catalyzed carbonylative rearrangement that provides for the conversion of allenyl ethers to 2-carboalkoxy-1,3-dienes. Herein, we report the initial examples of this process, which occurs under remarkably mild conditions (1 atm CO, 1 atm = 101.325 kPa) and proceeds efficiently to give a variety of 2-carboalkoxy-1,3-dienes.

At the start of this study, it was found that treatment of allenyl ether **1** with 10 mol% $[RhCl(CO)_2]_2$ in toluene at 80 °C under only 1 atm CO gave the 2-carboalkoxy-1,3-diene **2** in 77% yield (Table 1, entry 1). Investigations to determine the effects of solvent and catalyst loading on the efficiency of this carbonylative rearrangement reaction were next carried out. While the use of 1,4-dioxane as the solvent was found to have a negligible effect on the yield and reaction time (Table 1, entry 2), the use of DCE (1,2-dichloroethane) as the solvent affords a faster reaction and allows for the use of less (5 mol%) catalyst (Table 1, entries 3 and 4).

This process has thus far been shown to be unique for allenyl ethers using the above reaction conditions. Treatment of *allyl* ether **3** with 10 mol% $[RhCl(CO)_2]_2$ and CO (Scheme 2) did not provide the corresponding carbonylative rearrangement products, but instead gave a mixture of dienes

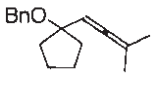
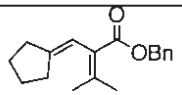
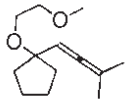
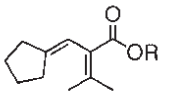
Table 1. Effect of solvent, concentration, and catalyst loading on the carbonylative rearrangement of **1**.

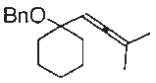
Entry	Solvent	Conc. (mol/L)	Cat.[a] (mol%)	Time (h)	Yield[b] (%)
1	Toluene	0.50	10	22	77
2	Dioxane	0.50	10	24	76
3	DCE	0.50	5	18	86
4	DCE	0.25	5	36	87

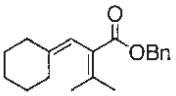


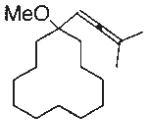


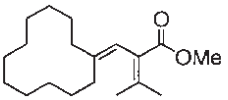


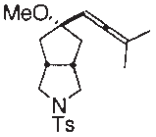


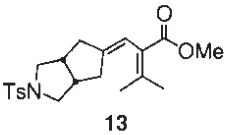


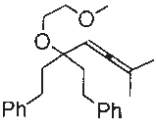


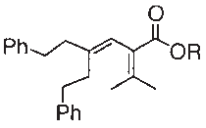


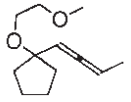












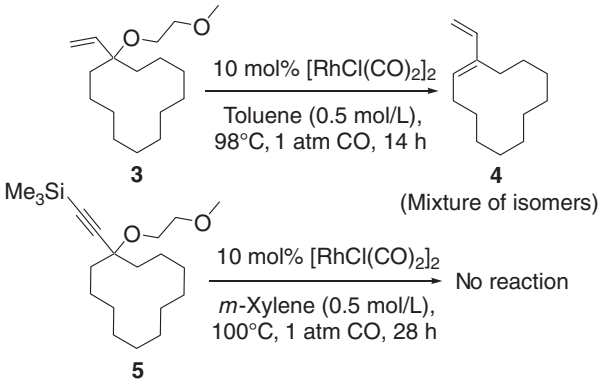
[a][RhCl(CO)$_2$]$_2$ (mol%).
[b]Isolated yield.

4. The *propargyl* ether **5** was shown to be unreactive, even after heating at 100 °C for a prolonged time (28 h).

Preliminary studies on the scope of the Rh(I)-catalyzed carbonylative rearrangement reaction were conducted. In general, the reactions proceed efficiently to provide 2-carboalkoxy-1,3-dienes in good to excellent yields. As illustrated in Table 2, the use of a methoxyethyl ether instead of a benzyl ether affords a slightly higher yield (Table 2, entries 1 and 2). The six-membered ring substrate **8** reacts more slowly than **1** and gives a somewhat lower yield of product. In contrast, the reaction of **10**, which contains a 12-membered ring, gave the corresponding 2-carboalkoxy-1,3-diene **11** in excellent yield with rates comparable to the reaction of **1**. The carbonylative rearrangement of the bicyclic heterocycle **12** gave **13** in 87% yield. Exemplifying the chemistry of these 2-carboalkoxy-1,3-dienes, **13** was converted to the spirolactone **14** in high yield upon treatment with trimethylsilyl chloride and sodium iodide (Scheme 3). The acyclic allenyl ether substrate **15** is also well-tolerated in this process, giving the 2-carboalkoxy-1,3-diene **16** in 66% yield (Table 2, entry 6). Thus far, attempts to carry out the carbonylative rearrangement reaction with allenyl ether **17** (Table 2, entry 7), which contains only one methyl group on the distal double bond of the allene, were unsuccessful.

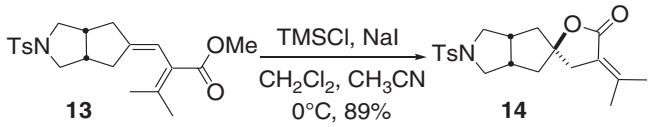
The mechanism of the palladium-catalyzed carbonylation reaction of allenyl alcohols is proposed to involve the hydrolysis or alcoholysis of a palladium acyl species similar to that illustrated in Scheme 4 (15). We examined the effects of adding an exogenous alcohol to the Rh(I)-catalyzed reaction

Table 2. Representative carbonylative rearrangement reactions.[a]



Entry	Substrate	Time (h)	Product	Yield (%)[b]
1	 **1**	18	 **2**	86
2[c]	 **6**	16	 **7**	92
3	 **8**	30	 **9**	78
4	 **10**	15	 **11**	93
5[d, e]	 **12**	24	 **13**	87
6[c, f]	 **15**	22	 **16**	66
7	 **17**	36	Decomposition	–

[a]Unless otherwise noted, reaction conditions are as follows: 5 mol% [RhCl(CO)$_2$]$_2$, DCE (0.5 mol/L), 80 °C, 1 atm CO (1 atm = 101.325 kPa).
[b]Isolated yield.
[c]R = $(CH_2)_2OCH_3$.
[d]Ts = *p*-toluenesulfonyl.
[e][RhCl(CO)$_2$]$_2$ (10 mol%), *m*-xylene (0.5 mol/L), 80 °C, 1 atm CO.
[f][RhCl(CO)$_2$]$_2$ (10 mol%), DCE (0.5 mol/L), 80 °C, 1 atm CO.



and found that crossover is observed. Thus, the addition of 10 equiv. of methoxyethanol to the reaction of **1** in DCE gave a 2:1 mixture of **2** and **7**. Similarly, the addition of 10 equiv. of benzyl alcohol to the reaction of **6** in DCE gave a 3:2 mixture of **7** and **2**. These results are consistent with the mechanistic possibilities depicted in Scheme 4. A step involving the direct reductive elimination of the acyl–alkoxy moiety from the metal, although rare (16, 17), is possible, as is the alcoholysis of the metal acyl species.

Scheme 2. Behaviour of allyl ether **3** and propargyl ether **5** in the presence of $[RhCl(CO)_2]_2$ and CO (1 atm = 101.325 kPa).

Scheme 3. Spirolactonization of 2-carboalkoxy-1,3-diene **13**.

In summary, a new Rh(I)-catalyzed carbonylative rearrangement reaction of allenyl ethers to give 2-carboalkoxy-1,3-dienes in good to excellent yields has been reported. This method allows for the selective cleavage and derivatization of allenyl ether C—O bonds under mild catalytic conditions. Further studies on the scope and mechanism of this process are ongoing.

Experimental

General methods

Elevated temperatures were maintained in a thermostat-controlled silicone oil bath. Reactions were carried out under a positive pressure of carbon monoxide from a balloon. Carbon monoxide (2.5 grade) was purchased from Praxair. $[RhCl(CO)_2]_2$ was purchased from Strem Chemicals. DCE (99+%, ACS reagent grade) was purchased from Aldrich Chemical Co. and stored over molecular sieves (4 Å). *m*-Xylene (anhydrous, 99+%, packaged in a Sure/Seal™ bottle) was purchased from Aldrich Chemical Co.

NMR spectra were measured in $CDCl_3$ on a Varian Inova 500 (^{1}H at 500 MHz, ^{13}C at 125 MHz) or Varian Mercury 400 (^{1}H at 400 MHz, ^{13}C at 100 MHz). Data for ^{1}H NMR spectra are reported as follows: chemical shift (δ ppm, referenced to solvent), multiplicity (singlet (s), doublet (d), triplet (t), doublet of doublets (dd), multiplet (m)), coupling constant (Hz), and integration. Data for ^{13}C NMR spectra are reported in terms of chemical shift (δ ppm, referenced to solvent) and quantity of carbons (if more than one). IR spectra were recorded on a PerkinElmer Spectrum BX Fourier transform spectrometer and are reported as follows: wavenumbers (cm^{-1}), description (weak (w), medium (m), strong (s)). High-resolution mass spectra (HR-MS) were recorded at the NIH regional mass spectrometry facility at the University of California, San Francisco. Elemental analyses (%C, %H) were determined by Desert Analytics, Tucson, Arizona. Melting points (uncorrected) were measured using a Unimelt capillary melting point apparatus (Arthur H. Thomas Company, 0–360 °C).

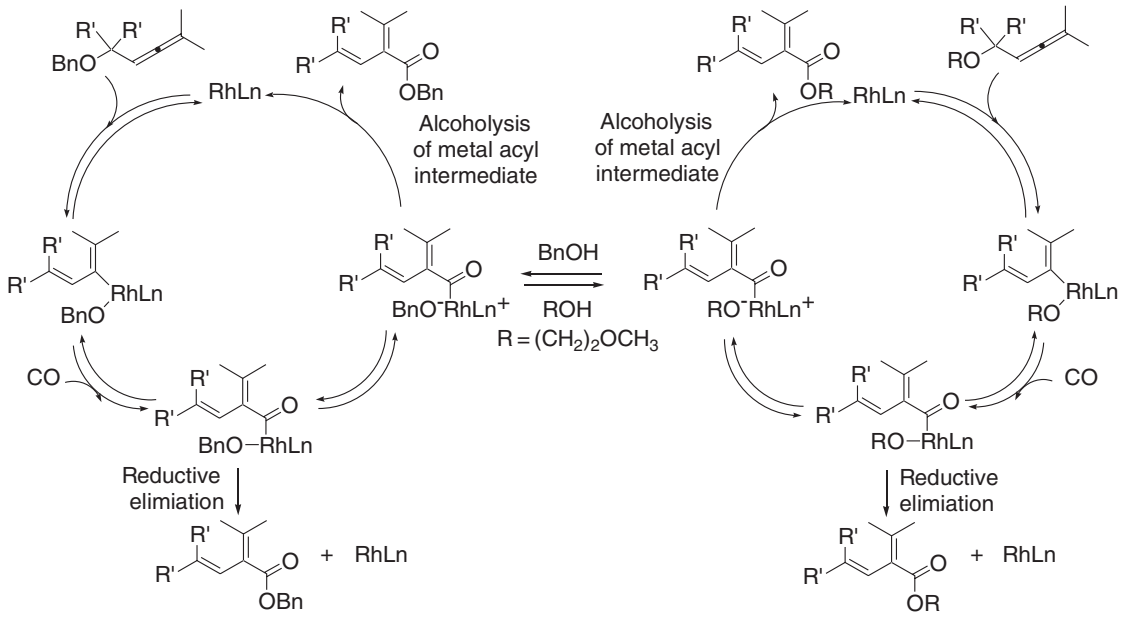
General procedure for the carbonylative rearrangement reaction

To an oven-dried 10 mm × 75 mm borosilicate glass test tube equipped with a Teflon®-coated magnetic stir bar was added the allenyl ether and $[RhCl(CO)_2]_2$ (5 mol%). DCE (volume required to give 0.5 mol/L solution of the allenyl ether) was added and the test tube was capped with a rubber septum. The resulting yellow mixture was stirred under a balloon of CO, vented to a bubbler for 5 min. This solution was then immersed into a preheated oil bath at 80 °C and was stirred under a balloon of CO until the starting material was consumed (as determined by analysis of the reaction mixture by TLC). After cooling to room temperature, the residue was purified via flash chromatography on silica gel eluting with a mixture of diethyl ether and pentane.

2-Cyclopentylidenemethyl-3-methyl-but-2-enoic acid benzyl ester (2)

Allenyl benzyl ether **1** (50 mg, 0.206 mmol) was converted to **2** (48 mg, 0.177 mmol, 86%, slightly yellow-coloured oil) using the general procedure. TLC: R_f 0.27 (hexane–Et_2O, 9:1); one spot. IR (thin film, cm^{-1}) υ: 2953 (m), 1721 (s), 1211 (s), 1147 (s), 1073 (s), 697 (m). ^{1}H NMR (500 MHz, $CDCl_3$, ppm) δ: 7.38–7.29 (m, 5H), 6.00 (s, 1H), 5.19 (s, 2H), 2.35–2.34 (m, 2H), 2.03–1.98 (m, 2H), 1.86 (s, 3H), 1.77 (s, 3H), 1.61–1.56 (m, 4H). ^{13}C NMR (125 MHz, $CDCl_3$, ppm) δ: 169.9, 147.2, 139.2, 136.0, 128.4 (2C), 128.3 (2C), 128.0, 127.5, 115.5, 66.2, 34.7, 29.5, 26.7, 25.9, 22.3, 21.4. HR-MS calcd. for $C_{18}H_{22}O_2$ (*m*/*z*): 270.1620; found: 270.1628.

2-Cyclopentylidenemethyl-3-methyl-but-2-enoic acid methoxyethyl ester (7)



Allenyl methoxyethyl ether **6** (42 mg, 0.20 mmol) was converted to **7** (43.7 mg, 0.184 mmol, 92%, colourless oil) using the general procedure. TLC: R_f 0.12 (hexane–Et_2O, 9:1); one spot. IR (thin film, cm^{-1}) υ: 2951 (m), 1721 (s), 1617 (w), 1213 (s), 1078 (s). ^{1}H NMR (400 MHz, $CDCl_3$, ppm) δ: 4.31–4.29 (m, 2H), 3.64–3.63 (m, 2H), 3.37 (s, 3H), 2.35 (t, J = 6.8 Hz, 2H), 2.08 (t, J = 7.0 Hz, 2H), 1.88 (d, J = 0.3 Hz, 3H), 1.77 (s, 3H), 1.69–1.55 (m, 4H). ^{13}C NMR (100 MHz, $CDCl_3$, ppm) δ: 170.2, 147.1, 138.8, 127.6, 115.4, 70.3, 63.4, 58.9, 34.8, 29.4, 26.8, 25.9, 22.3, 21.3. HR-MS calcd. for $C_{14}H_{22}O_3$ (*m*/*z*): 238.1569; found: 238.1559.

2-Cyclohexylidenemethyl-3-methyl-but-2-enoic acid benzyl ester (9)

Allenyl benzyl ether **8** (52 mg, 0.203 mmol) was converted to **9** (45 mg, 0.158 mmol, 78%, slightly yellow-coloured oil) using the general procedure. TLC: R_f 0.29 (hexane–Et_2O, 9:1); one spot. IR (thin film, cm^{-1}) υ: 2928 (s), 1715 (s), 1215 (s), 1190 (m), 1065 (s), 696 (m). ^{1}H NMR (400 MHz, $CDCl_3$, ppm) δ: 7.48–7.27 (m, 5H), 5.72 (s, lH), 5.17 (s, 2H), 2.18–2.15 (m, 2H), 2.00 (d, J = 1.5 Hz, 3H), 1.96–1.93 (m, 2H), 1.76 (s, 3H), 1.58–1.50 (m, 4H), 1.44–1.40 (m, 2H). ^{13}C NMR (100 MHz, $CDCl_3$, ppm) δ: 169.0, 144.4, 143.9, 136.4, 128.4 (2C), 127.8 (3C), 125.5,

Scheme 4. Possible mechanistic pathways for the carbonylative rearrangement reaction.

117.3, 65.7, 36.6, 30.0, 28.4, 27.0, 26.5, 22.9, 22.1. HR-MS calcd. for $C_9H_{24}O_2$ (*m/z*): 284.1776; found: 284.1772. Anal. calcd. for $C_{19}H_{24}O_2$: C 80.24, H 8.51; found: C 80.38, H 8.63.

2-Cyclododecylidenemethyl-3-methyl-but-2-enoic acid methyl ester (11)

Allenyl methyl ether **10** (53 mg, 0.20 mmol) was converted to **11** (54.5 mg, 0.187 mmol, 93%, colourless oil) using the general procedure. TLC: R_f 0.34 (hexane–Et_2O, 9:1); one spot. IR (thin film, cm^{-1}) υ: 2931 (s), 1718 (s), 1217 (s), 1077 (m). ^1H NMR (400 MHz, $CDCl_3$, ppm) δ: 5.80 (s, 1H), 3.68 (s, 3H), 2.11 (td, *J* = 6.9, 1.1 Hz, 2H), 2.03 (d, *J* = 1.7 Hz, 3H), 1.92–1.89 (m, 2H), 1.74 (d, *J* = 1.1 Hz, 3H), 1.90 (t, *J* = 6.7 Hz, 2H), 1.43–1.27 (m, 14H), 1.99–1.15 (m, 2H). ^{13}C NMR (100 MHz, $CDCl_3$, ppm) δ: 169.4, 145.1, 142.4, 125.7, 121.2, 51.2, 31.1, 29.5, 24.8, 24.5, 24.21, 24.17, 24.1, 23.5, 23.4, 23.2, 23.1, 22.6, 22.1. HR-MS calcd. for $C_{19}H_{32}O_2$: 292.2402; found: 292.2405. Anal. calcd. for $C_{19}H_{32}O_2$: C 78.03, H 11.03; found: C 78.31, H 11.24.

But-2-enoic acid methyl ester (13)

Allenyl methyl ether **12** (32 mg, 0.089 mmol) was converted to **13** (30 mg, 0.077 mmol, 87%, colourless oil) using the general procedure except that *m*-xylene was used in place of DCE and 10 mol% $[RhCl(CO)_2]_2$ was used instead of 5 mol% $[RhCl(CO)_2]_2$. TLC: R_f 0.22 (hexane–EtOAc, 7:3); one spot. IR (thin film, cm^{-1}) υ: 2948 (m), 1716 (s), 1433 (m), 1345 (s), 1219 (s), 1162 (s), 665 (m). ^1H NMR (500 MHz, $CDCl_3$, ppm) δ: 7.65 (d, *J* = 8.3 Hz, 2H), 7.29 (d, *J* = 8.3 Hz, 2H), 5.86 (s, 1H), 3.66 (s, 3H), 3.31–3.26 (m, 2H), 2.92 (dd, *J* = 9.8, 4.3 Hz, 1H), 2.87 (dd, *J* = 9.8, 4.3 Hz, 1H), 2.61–2.51 (m, 3H), 2.40 (s, 3H), 2.24–2.21 (m, 1H), 2.12–2.05 (m, 1H), 1.89 (s, 3H), 1.79–1.74 (m, 1H), 1.68 (s, 3H). ^{13}C NMR (125 MHz, $CDCl_3$, ppm) δ: 169.8, 144.2, 143.4, 142.0, 133.0, 130.0 (2C), 127.6 (2C), 126.4, 117.8, 53.5, 53.3, 51.5, 42.6, 41.5, 38.7, 34.0, 22.4, 21.9, 21.5. HR-MS calcd. for $C_{21}H_{27}NO_4S$ (*m/z*): 389.1661; found: 389.1668.

Spirolactone (14)

To a solution of methyl ester **13** (20 mg, 0.051 mmol) in CH_2Cl_2 (1.2 mL) and CH_3CN (0.8 mL) at 0 °C were added NaI (78 mg, 0.51 mmol) in one portion followed by TMSCl (0.12 mL, 0.92 mmol) via syringe in one portion. The mixture was allowed to stir at 0 °C for 5 h, at which point TLC indicated the starting material was consumed. The reaction was quenched with a 1:1 mixture of satd. Na_2SO_3 and satd. $NaHCO_3$ (2.5 mL) at 0 °C (added in one portion via glass pipette). The mixture stirred at room temperature for 10 min and then was diluted with ether. The organic layer was washed with H_2O, brine, and dried over $MgSO_4$. After removal of the solvent, the residue was purified via flash chromatography on silica gel (pentane–ether (3:1), then pentane–ether (5:2)) to afford lactone **14** (17 mg, 0.045 mmol, 89%, white solid). Mp: 197.9–199.1 °C. TLC: R_f = 0.17 (hexane–EtOAc, 7:3); one spot. IR (thin film, cm^{-1}) υ: 2934 (m), 1737 (s), 1660 (m), 1331 (s), 1166 (s), 1155 (s), 1041 (s), 665 (m). ^1H NMR (500 MHz, $CDCl_3$, ppm) δ: 7.67 (d, *J* = 8.1 Hz, 2H), 7.32 (d, *J* = 8.1 Hz, 2H), 3.26 (dd, *J* = 9.6, 7.9 Hz, 2H), 2.99 (dd, *J* = 9.9, 4.3 Hz, 2H), 2.69–2.62 (m, 4H), 2.42 (s, 3H), 2.19 (s, 3H), 1.87–1.77 (m, 4H), 1.79 (s, 3H). ^{13}C NMR (125 MHz, $CDCl_3$, ppm) δ: 168.9, 150.3, 143.8, 132.3, 129.6 (2C), 127.9 (2C), 119.4, 88.4, 53.8 (2C), 43.4 (2C), 40.3 (2C), 39.0, 24.5, 21.6, 19.9. HR-MS calcd. for $C_{20}H_{25}NO_4S$ (*m/z*): 375.1504; found: 375.1509.

2-Isopropylidene-4-phenethyl-6-phenyl-hex-3-enoic acid methyl ester (16)

Allenyl methoxyethyl ether **15** (74 mg, 0.20 mmol) was converted to **16** (52 mg, 0.133 mmol, 66%, colourless oil) using the general procedure except that 10 mol% $[RhCl(CO)_2]_2$ was used instead of 5 mol% $[RhCl(CO)_2]_2$. TLC: R_f = 0.10

Furoyl and thiophene carbonyl linker pyrazolyl palladium(II) complexes — Synthesis, characterization, and evaluation as ethylene oligomerization catalysts[1]

Stephen O. Ojwach, Mmboneni G. Tshivhase, Ilia A. Guzei, James Darkwa, and Selwyn F. Mapolie

Abstract: Reactions of 2-furoyl chloride and 2-thiophene carbonyl chloride with substituted pyrazoles produced the modified pyrazolyl compounds: {(3,5-Me_2pzCO)-2-C_4H_3O} (**L1**), {(3,5-Me_2pzCO)-2-C_4H_3S} (**L2**), {(3,5-*t*-Bu_2pzCO)-2-C_4H_3O} (**L3**), {(3,5-*t*-Bu_2pzCO)-2-C_4H_3S} (**L4**), {(3,5-Ph_2pzCO)-2-C_4H_3S} (**L5**), and {(pzCO)-2-C_4H_3O} (**L6**) in good yields. Reactions of these synthons with [Pd$(NCMe)_2Cl_2$] afforded the corresponding mononuclear palladium(II) complexes: [Pd(**L1**)$_2Cl_2$] (**1**), [Pd(**L2**)$_2Cl_2$] (**2**), [Pd(**L3**)$_2Cl_2$] (**3**), [Pd(**L4**)$_2Cl_2$] (**4**), [Pd(**L5**)$_2Cl_2$] (**5**), and [Pd(**L6**)$_2Cl_2$] (**6**) in moderate to high yields. All compounds synthesized were characterized by a combination of ^{1}H NMR, ^{13}C NMR, and IR spectroscopy. Compounds **L1**, **1**, and **2** were examined by single crystal X-ray crystallography. DFT theoretical studies at the B3LYP/6-31+G(*d*) level of theory with GAUSSIAN98 have been used to rationalize some of the results. When the complexes were activated with ethylaluminium dichloride ($EtAlCl_2$), they catalysed the oligomerization of ethylene to mostly C_{10} and C_{12} oligomers. Oligomer distribution greatly depends on the oligomerization conditions; for example, an increase in temperature and pressure produced a higher percentage of C_{12} compared to C_{10}.

Key words: furoyl and thiophene carbonyl linker pyrazolyl compounds, palladium complexes, ethylene oligomerization.

Résumé : Les réactions du chlorure de 2-furoyle et le chlorure de thiophène-2-carbonyle avec des pyrazoles substitués conduisent avec de bons rendements aux composés pyrazolyles modifiés: {(3,5-Me_2pzCO)-2-C_4H_3O} (**L1**), {(3,5-Me_2pzCO)-2-C_4H_3S} (**L2**), {(3,5-*t*-Bu_2pzCO)-2-C_4H_3O} (**L3**), {(3,5-*t*-Bu_2pzCO)-2-C_4H_3S} (**L4**), {(3,5-Ph_2pzCO)-2-C_4H_3S} (**L5**) et {(pzCO)-2-C_4H_3O} (**L6**). Les réactions de ces synthons avec du [Pd$(NCMe)_2Cl_2$] conduisent avec des rendements allants de modérés à élevés aux complexes mononucléaires correspondants du palladium(II): [Pd(**L1**)$_2Cl_2$] (**1**), [Pd(**L2**)$_2Cl_2$] (**2**), [Pd(**L3**)$_2Cl_2$] (**3**), [Pd(**L4**)$_2Cl_2$] (**4**), [Pd(**L5**)$_2Cl_2$] (**5**) et [Pd(**L6**)$_2Cl_2$] (**6**). Tous les composés synthétisés ont été caractérisés par une combinaison de spectroscopie infrarouge et RMN du ^{1}H et du ^{13}C. Les composés **L1**, **1** et **2** ont été examinés par diffraction des rayons X. Des études selon la théorie de la densité fonctionnelle au niveau B3LYP/6-31+G(*d*) de la théorie avec une GAUSSIAN98 ont été utilisées pour rationaliser un certain nombre de résultats. Lorsqu'ils sont activés par du dichlorure d'éthylaluminium ($EtAlCl_2$), ils catalysent l'oligomérisation de l'éthylène, principalement en oligomères en C_{10} et en C_{12}. La distribution des oligomères dépend fortement des conditions d'oligomérisation; par exemple, une augmentation de la température et de la pression conduit à des pourcentages plus élevés de produit en C_{12} par rapport à celui en C_{10}.

Mots clés : furoyle et thiophène carbonyle, lieur, composés pyrazolyles, complexes du palladium, oligomérisation de l'éthylène.

[Traduit par la Rédaction]

Introduction

Nitrogen donor compounds represent an important class of ligands in coordination chemistry. In particular, pyrazoles and pyrazolyl ligands have been widely used as terminal and bridging ligands and as precursors for various multidentate ligands in coordination chemistry (1). Indeed, the chemistry of pyrazole and pyrazolyl complexes with transition metals has been extensively reviewed (2), but despite the numerous reports on the synthesis and properties of pyrazolyl late transition metal complexes, very little is known about their catalytic activity in olefin oligomerization. Olefin oligomeri-

zation is typically catalysed by late transition metal complexes, particularly those of Ni(II) with P, N, and O ligands (3) because of the propensity of such reactions to undergo β-hydride elimination.

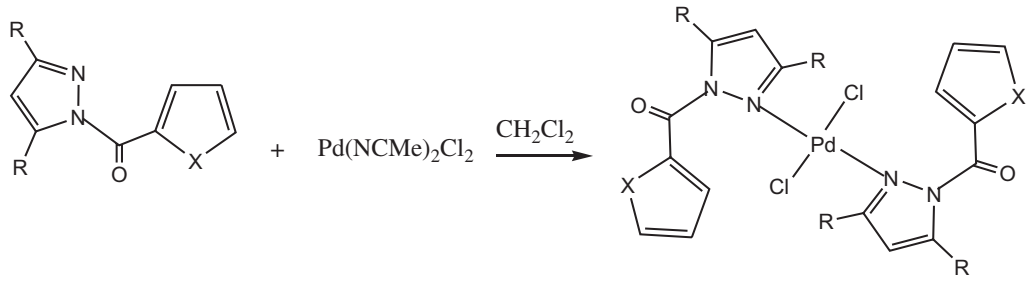
However, in the last decade it has become clear that careful tuning of ligand properties and choice of appropriate co-catalysts can lead to either oligomers or polymers after this phenomenon was first observed by Keim (4). For example, reports by Brookhart and co-workers (5) clearly demonstrate the effect of bulky substituents in pseudo axial sites in nickel catalysts. Bulky ligands block these axial sites and reduce chain transfer, whereas less bulky ligands form catalysts that produce oligomers. Another example of the role of bulky substituents on catalysts is provided by diimine–pyridine ligands. Gibson and co-workers (6) have used Fe(II) and Co(II) complexes of this ligand system, with bulky ligands, as catalysts to polymerize ethylene. However, by reducing the steric bulk of the ligand backbone, the Brookhart group found the Fe(II) catalyst to oligomerize ethylene to linear α-olefins with remarkable activity and selectivity (7).

Recently, pyrazolyl nitrogen donor ligands have been found to be tunable to produce electronic and steric effects that have resulted in the use of their late transition metal complexes as catalysts for the transformation of unsaturated hydrocarbons. The report on the polymerization of ethylene by $[\{R_2C(3\text{-}t\text{-}Bu_2pz)_2\}PdCl_2]$ (R = Me, Ph) represents one of the first examples of the use of pyrazolyl late-transition metal complexes in olefin polymerization catalysis (8). Reports by our group clearly indicate that electrophilicity of the catalyst plays a crucial role in polymer formation. We have found simple pyrazole Ni(II) and Pd(II) complexes that are good catalysts for ethylene polymerization (9), and by introducing carbonyl linkers to form benzenedicarbonyl and benzenetricarbonyl linker pyrazolyl palladium(II) complexes, catalytic activities for ethylene polymerization are significantly higher than for the analogous simple pyrazole systems (10). Steric factors also play a role (11). Our calculations of the steric encumbrance about the central metals indicate that in complex $[(3,5\text{-}t\text{-}Bu_2pz)_2PdCl_2]$ the ligands shield 92.1(3)% of the Pd surface while in $[(3,5\text{-}Mepz)_2PdCl_2]$ only 83.5(6)% of the central Pd is shielded by the coordinated moieties (12). In producing polyethylene, we have used mainly methylaluminoxane (MAO), but generally ethylaluminium halides can also activate precatalysts to polymerize ethylene (3).

In this report we describe the preparation and characterization of new furoyl and thiophene carbonyl Pd(II) complexes and their ability to catalyse ethylene oligomerization when activated by ethylaluminium dichloride ($EtAlCl_2$) as the co-catalyst. The potential for controlling the catalytic properties by varying substituents on the ligands is demonstrated by using different substituted pyrazolyl compounds. The influence of various conditions such as reaction time and temperature on the catalyst activity and selectivity in ethylene oligomerization is described.

Results and discussion

Synthesis and characterization of 2-furoyl and thiophene carbonyl pyrazolyl compounds and their palladium(II) complexes



The compounds **L1**–**L6** were readily prepared from either 2-furoyl chloride or 2-thiophene carbonyl chloride and an equivalent amount of the appropriate pyrazole (Scheme 1) following the procedure previously described by us (10). The yields were moderate to high (53%–85%).

Reactions of **L1**–**L6** with $[Pd(NCMe)_2Cl_2]$ in a 2:1 ratio produced the corresponding complexes **1**–**6** (Scheme 2). While **1**–**5** were soluble in dichloromethane and could be purified by recrystallization from dichloromethane and hexane (1:1), **6** was insoluble in common organic solvents like dichloromethane, toluene, and acetonitrile. Complex **6** precipitated from the reaction mixture essentially as an analytically pure solid.

All compounds were characterized by a combination of IR, ^{1}H NMR, and ^{13}C NMR spectroscopy and elemental analyses. Structures for **L1**, **1**, and **2** were confirmed by X-ray crystallography. ^{1}H NMR spectroscopy, however, offered signals that allowed easy identification of both ligands and complexes. For example, the 3,5-disubstituted alkyl pyrazolyl compounds typically have two upfield signals for the alkyl substituents, a signal at about 6 ppm and three doublets of doublets with an AMX splitting pattern (13). As expected, the heteroatom in the linker affected the chemical shift, par-

ticularly those close to these atoms. Complexation of pyrazolyl compounds with Pd resulted in slight changes of the ligands NMR chemical shifts, but there were essentially no changes in the signals in the splitting patterns.

Molecular structure determination by single crystal X-ray analysis

Single crystals suitable for X-ray analysis for compound **L1**, complexes **1** and **2** were grown by slow diffusion of hexane into dichloromethane at –4 °C and used to determine their molecular structures. Crystallographic data for **L1**, **1**, and **2** are presented in Table 1 while selected bond distances and angles are tabulated in Tables 2–4, respectively. The molecular diagrams are presented in Figs. 1–3, respectively.

The solid-state conformation of **L1** is consistent with the results of the DFT studies (vide infra) of its simplified analogue pz-C(O)-C_4H_3O. In the structure of **L1**, atoms N(1) and O(1) are on the opposite sides of the N(2)—C(6) bond owing to electrostatic interactions (14) and atoms O(1) and O(2) are on the same side of the C(6)—C(7) bond. This spatial arrangement is also observed in the structure of **1**, revealing that the preferred orientation is not altered upon coordination.

The two palladium complexes **1** and **2** contain the central metal in slightly distorted square-planar arrangements. In both cases, the pyrazolyl ligands are trans to each other rendering C_i molecular symmetry. This is in line with our density functional theory studies of *trans*-$(pzH)_2PdCl_2$ (symmetry C_{2h}) and *cis*-$(pzH)_2PdCl_2$ (symmetry C_2) at the B3LYP/LANL2DZ level of theory that indicate that the trans-complex is 12.82 kcal mol^{-1} (1 cal = 4.184 J) more stable. Compounds **L1** and **L2** are not planar in their respective complexes and are monodentate with the heteroatoms sulfur and oxygen pointing away from the metal centres.

The average Pd—N bond lengths of 2.032(2) and 2.025(7) Å in complexes **1** and **2**, respectively, are statistically indistinguishable and agree well with the average Pd—N(pz) bond length of 2.06(9) Å determined by averaging 607 bonds in 229 relevant complexes reported to the Cambridge Structural Database (CSD, (15)). The Pd—Cl bond distances in **1** and **2** (2.306(9) and 2.306(3) Å, respectively) are in good agreement with the distance of 2.33(5) Å obtained by averaging 2055 Pd—Cl bonds in 1268 relevant complexes reported to the CSD.

An interesting structural aspect was revealed by examining the ligand conformations in complexes **1** and **2**. The ligands differ only by the nature of the heteroatom (sulfur vs. oxygen) in their non-pyrazole five-membered rings and one could have reasonably expected to observe very similar structures. Indeed, in both cases the heteroatom (S or O) is located on the same side of the C—C bond of the X-C-C=O link in each ligand. Recall that in free **L1** (Fig. 1), the two oxygen atoms reside on the same side of the O-C-C=O linkage. This logical result is in line with expectations, however, DFT theoretical studies of simplified analogues of the compounds **L1** and **L2** (Figs. 4 and 5) at the B3LYP/6-31+G(*d*) level of theory with GAUSSIAN98 (16) indicate that a different outcome could have been predicted. The compounds (**L1** and **L2**) can exist in several stable conformations; the two most stable are shown in Figs. 4 and 5. In the case of furoyl, the conformation in which the furan oxygen is positioned on the same side as the carbonyl oxygen in the O-C-C=O sequence is more stable. This conformation (A in Fig. 4) is observed in the crystal structures of both **L1** and **1**. On the other hand, in the case of the thiophene carbonyl compound, the other conformation (D in Fig. 5), in which the thiophene S atom is on the opposite side from the carbonyl ligand in the S-C-C=O sequence is slightly more stable. Thus, the free compound **L2** changes its conformation upon coordinating to the Pd metal centre during the formation of **2**. The activation energies for the rotation about the C—C bond of the X-C-C=O linkage are calculated to be 13.4 kcal mol^{-1} for the A to B and 7.1 kcal/mol for C to D transitions.

We have also examined the steric crowding around the Pd centres in **1** and **2** with the program SOLID-G to determine

that the metal centres are shielded by the ligands to the extent of 93.1(3)% and 92.3(5)%, respectively. Since the difference between these values, determined from the crystal structures reported herein, is not statistically significant, any variation in the reactivity of these complexes towards the same reagents ought to be attributed to the differences in the electronic properties of the ligands and their conformations.

Evaluation of the complexes as catalysts for ethylene oligomerization

When complexes **1**–**5** were activated with $EtAlCl_2$, they were found to oligomerize ethylene to mainly C_{10} and C_{12}. No oligomers were obtained when controlled reactions were carried out at 25 °C and 5 atm (1 atm = 101.325 kPa) with the co-catalyst and ethylene in the absence of the complexes. Complex **6** was not evaluated because it is insoluble in toluene, the oligomerization solvent. There were a number of factors that influenced the oligomerization: First, the nature of the ligands influenced both the catalyst activity and product distribution. Complex **1**, with the furoyl linker and methyl groups, was less active (TON = 60 kg mol^{-1} Pd h^{-1}) than the analogous complex **3** with *tert*-butyl substituents (TON = 70 kg mol^{-1} Pd h^{-1}) (Table 5, entries 1 and 3). A similar trend was observed for the thiophene carbonyl analogue (Table 5, entries 2 and 5). Catalyst **5**, with the phenyl substituent on the pyrazolyl ring, was the most active.

A report by Guan and Marshall (17) on the catalytic behaviour of phosphine–imine Pd(II) complexes shows that the phenyl analogue has higher activity (TON = 17 200 kg mol^{-1} Pd h^{-1}) compared to that of the *tert*-butyl (TON = 1670 kg mol^{-1} Pd h^{-1}) and the methyl (TON = 960 kg mol^{-1} Pd h^{-1}) systems. The observed trend could be ascribed to the difference in the electronic structure of the complexes (18) where the less electron-donating phenyl group produces a more electrophilic metal centre in the catalyst. This could explain why complex **5** is the best catalyst in our study.

The nature of the linker in the ligand systems appears to have some effect on the oligomer distribution. For example, the catalysts with furoyl linkers gave higher percentages of the C_{12} than C_{10} oligomers (Table 5, entries 1 and 3) whereas the thiophene carbonyl analogues gave higher percentages of

C_{10} than C_{12} (Table 5, entries 2 and 4). There was, however, no clear trend in oligomer distribution as the steric bulk of the ligands in the catalysts changed.

The co-catalyst to catalyst ratio was found to be crucial in determining activity. Complex **2** was used to establish the effective ratio for optimum activity. No activity was observed for an Al:Pd ratio below 20. This indicates that not much activation occurs below this ratio. An increase in the Al:Pd from 20 to 2000 resulted in a general increase in oligomer yield to give an optimum ratio of 1000. Above this ratio, the yield decreased (Table 6, entry 6). Catalyst **1** showed a similar trend (Table 6, entries 7–9). The co-catalyst to catalyst ratio in ethylene oligomerization catalysed by phosphinitooxazoline and pyridine Ni(II) complexes is known to increase turnover frequency from 11 600 to 49 000 mol C_2H_4 mol^{-1} Ni h^{-1} when the $EtAlCl_2$:Ni ratio is increased from 1.3 to 6 (19). Our catalyst requires much higher co-catalyst to catalyst ratio. This is probably due to the ability of the co-catalyst to interact with both the carbonyl oxygen and the heteroatom in the ligands. We found a higher Al:Pd ratio, however, resulted in an increase in the percentage of C_{10} oligomers. For instance, an Al:Pd of 50 gave 49% of C_{10} and 45% of C_{12},

while an Al:Pd of 1000 gave 66% C_{10} and 30% C_{12}. It is not clear why the changes in co-catalyst to catalyst ratio affect product distribution.

The effects of time, temperature, and pressure on ethylene oligomerization were mainly investigated using catalysts **1** and **5**. The effect of time on ethylene oligomerization activity using catalyst **1** at 25 °C, 5 atm, and an Al:Pd ratio of 500 was investigated. Longer reaction times resulted in a significant decrease in activity (Table 7). The maximum turnover number (177 kg mol^{-1} Pd h^{-1}) was obtained at 30 min (Table 7, entry 2), but at 15 min, it was evident that the process to produce the active species was still incomplete, resulting in lower yields (120 kg mol^{-1} Pd h^{-1}). The same trend was observed for catalyst **5** (Table 7, entries 5 and 6). Generally, reaction time is known to affect catalyst activity. This is usually the result of catalyst decomposition. Our catalysts appear to be stable up to about 30 min and thereafter begin to decompose, even at room temperature. A similar phenomenon is seen for ethylene oligomerization using cationic Ni(II) and Pd(II) complexes containing bidentate phen-

acyldiarylphosphine ligands (20), where TOF increases for the Pd(II) catalyst from 1.2×10^3 h^{-1} in 15 min to 5.3×10^4 h^{-1} of ethylene consumed in 1 h, but after 3 h of activity dropped to 3.3×10^4 h^{-1}, signifying some catalyst decomposition.

Reaction time was also found to have a profound effect on the nature of the oligomers produced. A higher percentage of C_{10} (77%) was obtained for the 15 min run as compared to 38% for the 2 h run (Table 7, entries 1 and 4). This indicates that oligomer molecular weight increases with time, a result of co-oligomerization of the released matured oligomers, hence, production of higher oligomers. An opposite

trend is seen with phosphinidine Pd(II) complexes where prolonged reaction time from 3 to 15 h resulted in reduced oligomer molecular weight from 215 to 180 (18).

An increase in temperature was found to increase the activity of catalyst **1** and a maximum activity was obtained at 60 °C (Table 7). Above 60 °C, the activity of the catalyst dropped (Table 7, entries 8 and 9), usually an indication of catalyst decomposition. This observation is consistent with Pd(II) α-diimine catalysts, which are known to decompose rapidly above 50 °C (21), and that of Guan and Salo (22) that uses bisazaferrocene Pd(II) complexes.

The influence of pressure on ethylene oligomerization is well-established, especially on catalytic activity (21). The effect of ethylene concentration on oligomerization using catalyst **1** was studied by varying the ethylene pressure from 5 to 35 atm (Table 7, entries 2, 10–12). An increase in ethylene concentration resulted in a significant increase in oligomer yield. We also observed selectivity towards higher oligomers with an increase in pressure (Table 7, entries 2 and 12). For instance, at 5 atm, 71% of C_{10} and 23% of C_{12} were produced, respectively, while at 35 atm, 48% of C_{10} and 41% of C_{12} were obtained. At high pressures, it has been postulated that ethylene co-oligomerizes with the preformed olefins resulting in a significant increase in oligomer molecular weight (3). A report on bis(salicylaldiminate)nickel catalysed

Note: 1 atm = 101.325 kPa.
[a]Reaction conditions: solvent, toluene (50 mL); amount of catalyst, 9.00 μm; catalyst **1** used unless stated otherwise; co-catalyst, $EtAlCl_2$; Al:Pd = 500.
[b]Product distribution determined by GC–MS.
[c]Yield of products determined by the total mass of oligomers produced after the solvent was evaporated.
[d]Catalyst **5**.

ethylene oligomerization found the C_6–C_{12} yield go up from 23% to 70% when the ethylene pressure was increased from 1 to 20 atm, but the butene content of the oligomerization product dropped from 76% to 30% (23). Our result is in line with this observation, though not as drastic.

Conclusions

Furoyl and thiophene carbonyl pyrazolyl ligands form complexes with palladium(II) that have the same structural motifs as complexes formed by simple substituted pyrazoles with palladium(II). X-ray structures of **1** and **2** confirm that in the solid state of $[Pd(L)_2Cl_2]$ a trans geometry is preferred to cis. Activation of these complexes with the alkyl aluminium compound, $EtAlCl_2$, results in active catalysts for the oligomerization of ethylene. The major oligomers produced are C_{10} and C_{12}, and no lower oligomers in the C_4–C_8 range were obtained. This shows that the catalysts favour chain propagation relative to chain termination. The activities of these palladium(II) catalysts are lower compared with the α-diimine Pd(II) complexes, possibly because of the presence of the noncoordinating donor atoms (sulfur and oxygen), which might cause catalyst deactivation by forming adducts with the aluminium co-catalyst. Thermal instability of these catalysts could also contribute to their observed low catalytic activity, as would weakly bound pyrazolyl ligands that could lead to ligand dissociation from the metal centre.

Experimental section

All ligand and complex syntheses were performed under a nitrogen atmosphere using standard Schlenk techniques. All solvents were of analytical grade and were dried and distilled prior to use. Toluene and dichloromethane were dried and distilled from sodium/benzophenone and P_2O_5, respectively. The carbonyl linkers (2-furoyl chloride and 2-thiophene carbonyl chloride) were obtained from Sigma-Aldrich and used as received. The NMR spectra were recorded on a Varian Gemini 2000 instrument (^{1}H at 200 MHz, ^{13}C at 50.3 MHz) at room temperature. The chemical shifts are reported in δ (ppm) and referenced to the residual $CHCl_3$ in the NMR solvent. Elemental analyses and IR spectroscopy were performed on a Carlo Erba NA analyzer and a PerkinElmer FT-IR Paragon 1000PC, respectively, at the Chemistry Department, University of the Western Cape.

Synthesis of the ligands and complexes

2-(3,5-Dimethylpyrazolyl-1-carbonyl)furan (L1)

To a solution of 2-furoyl chloride (2.12 g, 15.60 mmol) in toluene (40 mL) was added 3,5-dimethylpyrazole (1.49 g, 15.60 mmol) and Et_3N (2 mL). The mixture was refluxed for 24 h, filtered to remove the Et_3NHCl by-product, and the solvent removed in vacuo to give a white residue. Purification by column chromatography on silica gel with dichloromethane–hexane (1:1) as the eluent afforded a white solid. Recrystallization from CH_2Cl_2–hexane gave single crystals suitable for X-ray analysis. Yield: 2.52 g (85%). IR (Nujol, cm^{-1}) $\nu_{(C=O)}$: 1702. ^{1}H NMR ($CDCl_3$) δ: 2.29 (s, 3H, CH_3, pz), 2.62 (s, 3H, CH_3, pz), 6.02 (s, 1H, pz), 6.61 (dd, 1H, furan, $^4J_{HH}$ = 1.6 Hz, $^3J_{HH}$ = 3.6 Hz), 7.71 (dd, 1H, furan, $^4J_{HH}$ = 0.8 Hz, $^3J_{HH}$ = 3.6 Hz), 7.94 (dd, 1H, furan, $^4J_{HH}$ = 0.8 Hz, $^3J_{HH}$ = 3.8 Hz). ^{13}C{^{1}H} NMR ($CDCl_3$) δ: 13.2, 13.8, 110.4, 111.7, 123.4, 144.8, 146.9, 152.1, 156.1, 161.8. EI-MS (70 eV) *m*/*z* (%): 190 (20) [M^+], 162 (100) [$M^+ - C_2H_4$], 95 (40) [$M^+ - C_5N_2H_7$], 67 (5) [$M^+ - C_6N_2H_7CO$]. 2-(3,5-Di*-tert-*butylpyrazolyl-1-carbonyl)furan (L3)

Compound **L3** was prepared using 2-furoyl chloride (1.42 g, 10.52 mmol) and 3,5-di-*tert*-butylpyrazole (2.90 g, 10.52 mmol). Yield: 2.31 g (80%). IR (Nujol, cm^{-1}) $\nu_{(C=O)}$: 1716. ^1H NMR ($CDCl_3$) δ: 1.35 (s, 9H, CH_3, pz), 1.46 (s, 9H, CH_3, pz), 6.18 (s, 1H, pz), 6.60 (dd, 1H, furan, $^4J_{HH}$ = 1.6 Hz, $^3J_{HH}$ = 3.4 Hz), 7.71 (dd, 1H, furan, $^4J_{HH}$ = 0.8 Hz, $^3J_{HH}$ = 1.6 Hz), 7.82 (dd, 1H, furan, $^4J_{HH}$ = 0.8 Hz, $^3J_{HH}$ = 3.8 Hz). $^{13}C\{^1H\}$ NMR ($CDCl_3$) δ: 29.0, 29.3, 31.9, 32.8, 105.5, 111.7, 123.1, 146.5, 156.1, 158.0, 161.6. EI-MS (70 eV) *m*/*z* (%): 274 (45) [M^+], 244 (30) [$M^+ - C_2H_6$], 232 (100) [$M^+ - C_3H_6$], 217 (95) [$M^+ - C_{11}N_2H_{19}$], 67 (5) [$M^+ - C_{11}N_2H_{19}CO$]. Anal. calcd. for $C_{16}H_{22}N_2O_2$ (%): C 69.82, H 8.36, N 10.18; found: C 69.77, H 8.26, N 10.02.

2-(3,5-Di*-tert-*butylpyrazolyl-1carbonyl)thiophene (L4)

Compound **L4** was prepared by reacting 3,5-di-*tert*-butylpyrazole (1.82 g, 10.34 mmol) with 2-thiophene carbonyl chloride (1.37 g, 9.35 mmol). Yield: 1.50 g (52%). IR (Nujol, cm^{-1}) $\nu_{(C=O)}$: 1686. ^1H NMR ($CDCl_3$) δ: 1.37 (s, 9H, CH3, pz), 1.46 (s, 9H, CH_3, pz), 6.17 (s, 1H, pz), 7.12 (dd, 1H, thiophene, $^4J_{HH}$ = 1.8 Hz, $^3J_{HH}$ = 5.2 Hz), 7.71 (dd, 1H, thiophene, $^4J_{HH}$ = 1.4 Hz, $^3J_{HH}$ = 5.2 Hz), 8.83 (dd, 1H, thiophene, $^4J_{HH}$ = 1.6 Hz, $^3J_{HH}$ = 4.0 Hz). $^{13}C\{^1H\}$ NMR ($CDCl_3$) δ: 28.9, 29.4, 32.1, 32.8, 106.0, 125.8, 137.2, 157.4, 159.7, 169.8. EI-MS (70 eV) *m*/*z* (%): 290 (63) [M^+], 275 (20) [$M^+ - CH_3$], 233 (65) [$M^+ - C_4H_9$], 191 (30) [$M^+ - C_7H_{15}$], 111 (100) [$M^+ - C_{11}N_2H_{19}$], 83 (5) [$M^+ - C_{11}N_2H_{19}CO$]. Dichloro{bis-2-(3,5-dimethylpyrazolyl-1-carbonyl)furan}palladium(II) (1)

To a solution of [$Pd(NCMe)_2Cl_2$] (0.20 g, 0.68 mmol) in dichloromethane (20 mL) was added **L1** (0.26 g, 1.43 mmol). The mixture was stirred at room temperature for 6 h and the resultant solution was concentrated in vacuo to about 10 mL. An analytically pure yellow powder was obtained upon addition of an equal volume of hexane. Yield: 0.28 g (79%). IR (Nujol, cm^{-1}) $\nu_{(C=O)}$: 1694. ^1H NMR ($CDCl_3$) δ: 2.34 (s, 6H, CH_3, pz), 2.44 (s, 6H, CH_3, pz), 6.03 (s, 2H, pz), 6.77 (d, 2H, furan, $^3J_{HH}$ = 3.6 Hz), 7.70 (d, 2H, furan, $^3J_{HH}$ = 3.6 Hz), 7.91 (d, 2H, furan, $^3J_{HH}$ = 3.6 Hz). $^{13}C\{^1H\}$ NMR ($CDCl_3$) δ: 12.8, 15.1, 110.9, 113.3, 126.8, 146.1, 147.1, 149.4, 154.8, 155.9. Anal. calcd. for $C_{20}H_{20}N_4O_4PdCl_2$ (%): C 43.09, H 3.59, N 10.05; found: C 42.57, H 3.20, N 9.65.

Complexes **2**–**4** and **6** were prepared in a similar manner as described for **1**.

Dichloro{bis-2-(3,5-dimethylpyrazolyl-1-carbonyl)thiophene}palladium(II) (2)

Complex **2** was prepared using ligand **L2** (0.50 g, 3.42 mmol) and [$PdCl_2(NCMe)_2$] (0.45 g, 1.71 mmol). Recrystallization from dichloromethane–hexane gave yellow single crystals suitable for X-ray analysis. Yield: 0.61 g (62%). IR (Nujol, cm^{-1}) $\nu_{(C=O)}$: 1688. ^1H NMR ($CDCl_3$) δ: 2.30 (s, 6H, CH_3, pz), 2.32 (s, 6H, CH_3, pz), 6.00 (s, 2H, pz), 7.29 (dd, 2H, thiophene, $^4J_{HH}$ = 1.6 Hz, $^3J_{HH}$ = 3.8 Hz), 7.73 (dd, 2H, thiophene, $^4J_{HH}$ = 1.6 Hz, $^3J_{HH}$ = 3.8 Hz), 8.02 (dd, 2H, thiophene, $^4J_{HH}$ = 6 Hz, $^3J_{HH}$ = 3.8 Hz). $^{13}C\{^1H\}$ NMR ($CDCl_3$) δ: 12.6, 14.4, 110.1, 126.4, 128.4, 136.2, 136.5, 140.1, 146.1, 155.2, 160.0. Anal. calcd. for $C_{20}H_{20}N_4O_2S_2PdCl_2$ (%): C 40.83, H 3.43, N 9.51; found: C 40.84, H 2.69, N 9.53.

Dichloro{bis-2-(3,5-di*-tert-*butylpyrazolyl-1-carbonyl)furan}palladium(II) (3)

Complex **3** was prepared using ligand **L3** (0.37 g, 1.35 mmol) and [$Pd(NCMe)_2Cl_2$] (0.18 g, 0.68 mmol). Yield: 0.25 g (52%). IR (Nujol, cm^{-1}) $\nu_{(C=O)}$: 1705. ^1H NMR ($CDCl_3$) δ: 1.32 (s, 18H, CH_3, pz), 1.46 (s, 18H, CH_3, pz), 6.17 (s, 2H, pz), 6.58 (dd, 2H, furan, $^4J_{HH}$ = 1.7 Hz, $^3J_{HH}$ = 3.6 Hz), 7.71 (dd, 2H, furan, $^4J_{HH}$ = 1.8 Hz, $^3J_{HH}$ = 3.4 Hz), 7.82 (dd, 2H, furan, $^4J_{HH}$ = 1.8 Hz, $^3J_{HH}$ = 3.4 Hz). $^{13}C\{^1H\}$ NMR ($CDCl_3$) δ: 28.8, 29.7, 30.5, 31.6, 100.1, 111.7, 119.3, 125.8, 137.2, 146.7, 156.1, 157.8. Ethylene oligomerization

Ethylene oligomerization was performed in a 300 mL stainless steel autoclave loaded with the respective catalyst and the appropriate amount $EtAlCl_2$ as the co-catalyst. This was carried out in a nitrogen-purged glovebox. The general procedure involved charging the autoclave with a palladium complex and $EtAlCl_2$ (25% in toluene) in 100 mL of dry toluene. The Al:Pd ratio used was between 20–2000. The autoclave was sealed, removed from the glovebox and loaded into the reactor chamber. The autoclave was flushed three times with ethylene and heated to the required temperature. The desired ethylene pressure was set and a constant flow of ethylene was maintained throughout the reaction. At the end of the reaction, an aliquot of the reaction mixture was taken for the GC analysis. The reaction was quenched by the addition of ethanol after which the solvent was removed in vacuo and the mass of the total nonvolatile products determined. Analysis of the oligomers was performed using a Finnigan-MAT GCQ GC–MS, equipped with an electron impact ionization source at 70 eV and a 30 m HP PONA capillary column with a stationary phase based on 5% poly(methylphenylsiloxane). The rate of increase in oven temperature of the GC was set at 20 °C min^{-1} and then increased by 10 °C min^{-1} until a temperature of 260 °C was reached. Under these conditions, it was possible to separate C_4 to C_{20} olefins. The retention times of the individual components were determined using standard samples of each olefin. Quantitative analysis of the olefins was done by the internal standard reference method using pentadecane as the internal reference.

X-ray crystallography

Crystal evaluation and data collection for **L1**, **1**, and **2** were performed on a Bruker CCD-1000 diffractometer with Mo Kα (λ = 0.710 73 Å) radiation and the diffractometer to crystal distance of 4.9 cm. The initial cell constants were obtained from three series of ω scans at different starting angles. The reflections were successfully indexed by an automated indexing routine built in the SMART program. The absorption correction was based on fitting a function to the empirical transmission surface as sampled by multiple equivalent measurements (24). The structures were solved by direct methods and refined by least-squares techniques using the SHELXTL program (24). All non-hydrogen atoms were refined with anisotropic displacement coefficients. All hydrogen atoms were included in the structure factor calculation at idealized positions and were allowed to ride on the neighbouring atoms with relative isotropic displacement coefficients. Additional crystallographic data for the structures are deposited with the Cambridge Crystallographic Data Centre as supplementary publication numbers CCDC 257819 (**L1**), CCDC 257820 (**1**), and CCDC 257818 (**2**).[4]

Acknowledgements

Financial support by the National Research Foundation (NRF) South Africa is highly appreciated. We thank Professor Len Barbour, University of Stellenbosch, South Africa, for solving the structure of compound **2** as a service.

Aluminium triflate as catalyst for epoxide ring-opening and esterification reactions — Mechanistic aspects[1]

Yvette M. Terblans, Johannes J. Huyser, Michelle Huyser, Michael J. Green, Desmond A. Young, and Mike S. Sibiya

Abstract: $Al(CF_3SO_3)_3$ is a highly effective catalyst for the ring opening of epoxides with methanol, as well as for the esterification of carboxylic acids with alcohols. Factors that influence the rate of the ring opening of butene oxide with methanol and the esterification of acetic acid with *n*-propanol and ethanol were investigated. It was found that low concentrations (e.g., ~5 ppm) of $Al(CF_3SO_3)_3$ catalyze the ring-opening reactions, whereas considerably higher concentrations are required for esterification reactions. Molecular modeling studies suggest that these differences can be rationalized in terms of the formation energies of the active intermediates of these reactions.

Key words: epoxide, ring opening, esterification, aluminium triflate.

Résumé : Le $Al(CF_3SO_3)_3$ est un catalyseur très efficace pour effectuer des ouvertures de cycles d'époxydes avec le méthanol ainsi que pour l'estérification d'acides carboxyliques par les alcools. On a étudié les facteurs qui influencent la vitesse d'ouverture de cycle de l'oxyde de butène par le méthanol et d'estérification de l'acide acétique par l'éthanol et le propan-1-ol. On a trouvé que, à de faibles concentrations, environ 5 ppm, le $Al(CF_3SO_3)_3$ catalyse les réactions d'ouverture de cycle alors que des concentrations beaucoup plus élevées sont nécessaires pour les réactions d'estérification. Des études de modélisation moléculaire suggèrent que ces différences peuvent être rationalisées en fonction des énergies de formation des intermédiaires actifs de ces réactions.

Mots clés : époxyde, ouverture de cycle, estérification, triflate d'aluminium.

[Traduit par la Rédaction]

Introduction

Esterification reactions between alcohols and carboxylic acids and ring-opening reactions of epoxides with alcohols have been successfully carried out for many decades. Traditionally, esterification reactions have been acid-catalyzed using mineral acids, e.g., HCl and H_2SO_4, as well as organic acids including *p*-toluene sulfonic acid and methane sulfonic acid. Epoxide ring-opening reactions can be either base- or acid-catalyzed (1).

In recent years, the use of triflate salts (also known as trifluoromethane sulfonate salts) as catalysts for both these types of reactions has become increasingly popular. Metal triflates and *N*-heterocyclic base triflates have been employed in the direct esterification of alcohols and carboxylic acids, as well as the transesterification of carboxylic acid esters and alcohols. Examples of the use of these catalysts in esterification reactions include the acylation of alcohols by anhydrides, which is catalyzed by a wide range of metal triflates (e.g., $Yb(CF_3SO_3)_3$, $Bi(CF_3SO_3)_3$, $In(CF_3SO_3)_3$, $Sc(CF_3SO_3)_3$, $Ce(CF_3SO_3)_3$) (2, 3). Rare earth triflates (lanthanide triflates), such as scandium triflate, have been successfully used to catalyze the reaction of alcohols with carboxylic anhydrides, activated esters, mixed anhydrides, acylurea, and *N*-hydroxysuccinimide at low temperatures. Reactions such as the esterification of aliphatic alcohols with carboxylic acids at room temperature and the direct polycondensation of dicarboxylic acids (succinic acids) with diols (ethylene glycol, 1,3-propanediol, and 1,4-butanediol) at 35–180 °C to synthesize polyalkylene succinates have also been reported (4). Scandium triflate has been used as a catalyst for the condensation of carboxylic acids with soluble polymers such as polyethylene glycol in toluene (5). Gadolinium triflate has been found to be a simple and efficient catalyst for the acetylation of alcohols and amines using acetic anhydride at ambient temperatures (6). Furthermore, the selective preparation of secondary esters from terminal *vic*-diols has successfully been achieved in a one-pot synthesis via the $Yb(CF_3SO_3)_3$ catalyzed formation and partial hydrolysis of cyclic orthoesters (7). *N*-Heterocyclic base triflates (e.g., diphenylammonium triflate (DPAT)) have been found to be excellent catalysts for sterically hindered esterification reactions in specific fluorous media under mild conditions using equimolar amounts of carboxylic acids and

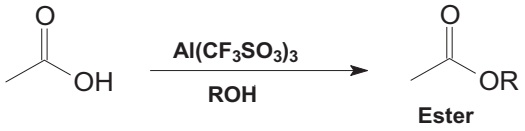
Scheme 1. Ring opening of butene oxide with methanol.



alcohols (8), as well as for the transesterification of carboxylic acid esters with a slight excess of alcohols via the use of trimethylsilyl chloride (TMSCl) as a co-catalyst (9). Other organic base triflates that have successfully been employed in esterification reactions include 4-(benzylaminocarbonyl)diphenylammonium triflate (BDPAT) (10) and polymer-supported 4-aminoforoyldiphenylammonium triflate (PS-AFDPAT) (11).

IR thermography has been used to screen the catalytic acitivity of rare earth triflates (e.g., $Eu(CF_3SO_3)_3$, $La(CF_3SO_3)_3$, $Lu(CF_3SO_3)_3$, $Nd(CF_3SO_3)_3$, $Sm(CF_3SO_3)_3$, $Sc(CF_3SO_3)_3$, $Y(CF_3SO_3)_3$, and $Ce(CF_3SO_3)_4$) for the ring opening of epoxides by alcohols as well as the Baeyer–Villiger oxidation of cyclobutanones with hydrogen peroxide. In the case of the ring opening of epoxides, scandium triflate was found to be an exceptionally active catalyst, whereas in the case of the Baeyer–Villiger oxidation, it was again the most active, followed by neodymium triflate (12). Furthermore, it has been reported that $Yb(CF_3SO_3)_3$ catalyzes intermolecular ring-opening reactions of epoxides with alcohols to give β-alkoxy alcohols in good to high yields with high regio- and stereoselectivity (13).

Aluminium triflate has been used as a catalyst in organic synthesis for reactions such as the ring opening of epoxides in the presence of alcohols or amines (14–16), Friedel–Crafts acylation and alkylation (17, 18), the epoxidation of olefins with iodosylbenzene (19), and the preparation of esters and lactones (20). It has also been used as an initiator for cationic polymerization (21) and as co-catalyst in the polymerization of olefins (22).

We now report on the considerable difference in the required concentration of $Al(CF_3SO_3)_3$ vs. $KOCH_3$ as catalysts for the ring opening of butene oxide (BuO) with methanol (MeOH) (Scheme 1) on the one hand, and the similar concentration requirements of $Al(CF_3SO_3)_3$ and *p*-TSA as catalysts for the esterification of *n*-propanol (*n*-PrOH) or ethanol (EtOH) with acetic acid (Scheme 2) on the other hand. Low $Al(CF_3SO_3)_3$ concentrations (e.g., ~5 ppm) are sufficient to obtain excellent conversions and high reaction rates when performing the ring-opening reaction of butene oxide with methanol, whereas much higher catalyst concentrations (e.g., ~1000 ppm or higher) are needed to obtain similar results for the $KOCH_3$ catalysed reactions. A related observation was that both acid (*p*-TSA) and $Al(CF_3SO_3)_3$ catalysed esterification reactions of propanol and (or) ethanol with acetic acid require similar catalyst concentrations of ~1000 ppm to get reasonable activities. A molecular modeling study was undertaken with a view to rationalizing the experimental observations and to postulate a reasonable explanation for the low levels of $Al(CF_3SO_3)_3$ needed in the ring-opening reactions. These calculations showed that ΔH_f values for the formation of the catalytically active species in the potassium methoxide and aluminium triflate catalyzed ring-opening reactions differ significantly, with ΔH_f = –3.3 kcal/mol (1 cal = 4.184 J) for the aluminium triflate reaction and ΔH_f = +12.8 kcal/mol for the potassium methoxide ring-opening reaction. It appears that the differences in catalyst concentrations required for the reactions under investigation are in line with the differences in the formation energies of the active intermediate.

ROH = CH_3CH_2OH or $CH_3CH_2CH_2OH$

Experimental

Materials

Unless otherwise stated, all chemicals used in this study were purchased from Sigma-Aldrich and used without further purification. Aluminium triflate was prepared as described in the literature (16). For the ring-opening reactions, a stock solution of 500 ppm $Al(CF_3SO_3)_3$ was prepared in methanol and the desired quantity thereof was weighed for every reaction. In the case of the esterification reactions, a fresh catalyst solution (of the desired concentration) was prepared in the alcohol substrate prior to each reaction.

Kinetic reactions

Kinetic reactions were carried out in a Parr autoclave. The catalyst concentration was varied between 0 and 10 ppm for the ring-opening reactions and between 10 and 5000 ppm for the esterification reactions. In most cases, the esterification reactions were allowed to proceed to equilibrium, since none of the reaction products (including water) were removed. Gas chromatography was performed on a Shimadzu GC-17A, equipped with a flame ionization detector and a PONA capillary column (50 m × 0.21 mm × 0.5 μm). Each sample was weighed into a GC vial and heptane was used as an internal standard.

Typical experimental procedure for the ring opening of butene oxide

Methanol (192.25 g, 6.00 mol) and butene oxide (72.11 g, 1.00 mol) were combined in a 300 mL Parr reactor. On closing, the reactor was degassed and flushed with nitrogen to remove all the air present. This flushing procedure was repeated three times.

A catalyst bomb was placed under vacuum prior to the run. The stock solution was weighed out (2.644 g, 5 ppm) and transferred via a syringe to this bomb, which was then connected to the inlet of the autoclave. A high-pressure nitrogen line was connected to the opposite side of the catalyst

© 2005 NRC Canada

bomb after which stirring of the reactor commenced. The reactor was subsequently heated to 100 °C after which the catalyst solution was discharged into the reactor and a sample taken immediately (0 min) and weighed. The sample was weighed to determine the amount removed from the reactor. Further sampling from the reactor was carried out at the following intervals; 5, 10, 15, 20, 30, 60, and 120 min, and each sample weighed. A satd. NaOH – water solution (0.5 mL) was added to all of the samples to quench the catalyst.

Typical experimental procedure for the esterification reaction between* n-*propanol and acetic acid

Acetic acid (60.10 g, 1.00 mol) and propanol (60.21 g, 1.00 mol) were combined in a 300 mL Parr reactor. The reactor was closed and heated to an operating temperature of 100 °C while stirring at 900 rpm. Upon reaching this temperature, a solution of $Al(CF_3SO_3)_3$ (0.05 g dissolved in 10.0 g of propanol, 5000 ppm) was charged into the reactor using a syringe. A sample was taken immediately and thereafter every 5 min for the first 30 min, after which samples were taken every 30 min. All samples were weighed.

Molecular modeling

All geometries were optimized with the DMol[3] DFT code in MaterialsStudio 3.0 (Accelrys, Inc.) (23) by applying the all electron nonlocal GGA/RPBE/DNP method, employing a med integration grid and 4.2 Å orbital cut-off values. All reported energies are electronic energies, which correspond to *G* at 0 K.

Results and discussion

The epoxide ring-opening and esterification reactions were probed experimentally, as well as via molecular modeling. The ring-opening reaction of butene oxide with methanol was studied at different catalyst concentrations, temperatures, and methanol – butene oxide molar ratios. For comparison, the epoxide ring opening was also carried out with a base catalyst KOMe. The esterification reaction of acetic acid with *n*-propanol and ethanol was studied at different catalyst concentrations, whereas the influence of substrate concentrations was studied by varying the ethanol – acetic acid molar ratio.

A molecular modeling study was carried out to assist in formulating a reasonable explanation for the low levels of $Al(CF_3SO_3)_3$ needed to catalyse the ring-opening reactions compared to using $KOCH_3$ as catalyst. In addition, calculations were carried out for the $Al(CF_3SO_3)_3$ and Brønsted acid catalysed esterification reactions.

Model substrates were used for the calculations to save on computational time. Propylene oxide and methanol were used as models for the ring-opening reactions and acetic acid and methanol for the esterification reactions. In the calculations involving $Al(CF_3SO_3)_3$, possible stabilization effects involving, for example, methanol coordination or other solvation effects were not taken into consideration. $KOCH_3$ was used as the model for the base-catalysed epoxide ring-opening reactions and a protonated AcOH–MeOAc complex used to describe the acid-catalysed esterification reaction.

The limited objective of these simplified modelling studies was to calculate formation energies from geometry optimizations with a view to rationalizing the experimental results rather than the more time consuming location of transition states to obtain activation energies.

Table 1. Conversion of butene oxide (mol%) at different $Al(CF_3SO_3)_3$ catalyst concentrations.

	Catalyst concentration (ppm)

120	95.86	97.15	100.00	100.00

Note: $Al(CF_3SO_3)_3$ catalyst concentration = 5 ppm, MeOH:BuO = 6:1.

Ring opening of butene oxide

The conversion of butene oxide was calculated for each reaction carried out with $Al(CF_3SO_3)_3$ and KOH as the catalyst and the data are presented in Tables 1–4. Graphs obtained from the data are shown in the Supplementary material to the publication.[4]

In the molecular modelling study, two steps in the catalytic cycle of the ring-opening reaction with $Al(CF_3SO_3)_3$ and $KOCH_3$ were considered, i.e., the ring-opening step, as well as the regeneration of the active intermediate; these steps are shown in Schemes 3 and 4.

As can be seen from the data in Table 1, butene oxide was converted to the corresponding glycol ethers with $Al(CF_3SO_3)_3$ concentrations of 10 ppm or less. When using 10 ppm of $Al(CF_3SO_3)_3$, 100% conversion was achieved within 10 min of reaction time. With a very low $Al(CF_3SO_3)_3$ concentration of 1 ppm, 88% conversion was achieved within 2 h. In all of these reactions, both isomers of the glycol ether, i.e., 1-methoxy-2-butanol and 2-methoxy-1-butanol, were formed as the main products.

5	70.01	50.72
10	89.65	71.65
15	98.48	85.12
20	99.42	88.83
30	99.70	92.28
60	99.96	96.89

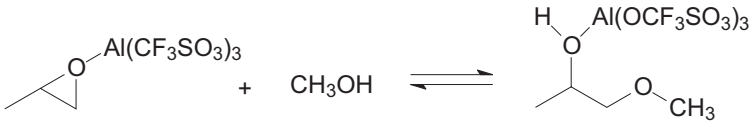
Note: T = 160 °C, catalyst concentration = 100 ppm.

These products were formed in a ratio of approximately 1:1, with the yield of each ranging from 40%–47%. By-products like dimers, diols, and in some instances trimers were also formed during these reactions. All products were identified using GC–MS via comparison with the literature data (16).

The effect of temperature on the ring-opening reaction of butene oxide was as expected, in that the reaction rates and conversions increased as the temperature was increased (Table 2). It was found that as the reaction temperature was increased, the formation of by-products, especially dimers and trimers, increased over time.

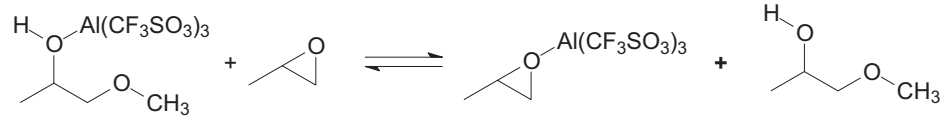
It is seen from the data in Table 3 that as the ratio of MeOH:BuO was increased, the rate of the reaction decreased. As the ratio was increased from 4 to 6, a decrease in the rate was clearly observed. The decrease in the rate became less as the ratio was further increased to 8. With even further increases from 8 to 14, the decrease in the rate became even less. Similarly, when KOH was used as the catalyst, it was seen that as the ratio of MeOH:BuO was increased, the rate of the reaction decreased. However, these reactions had to be carried out with higher catalyst concentrations (100 ppm KOH compared to 10 ppm $Al(CF_3SO_3)_3$) and at higher reaction temperatures (160 °C for KOH compared to 100 °C for $Al(CF_3SO_3)_3$). An explanation for this decrease in rate with an increase in MeOH:BuO ratio could be that the transfer of the $Al(CF_3SO_3)_3$ to BuO to form the active intermediate is dependant on the concentration of BuO in the reaction mixture. Since the increase in the MeOH:BuO ratio will lead to a lowering in BuO concentration, it is to be expected that a drop in rate will be seen (Scheme 3).

The mechanism of the ring-opening reaction involves the coordination of the epoxide oxygen to the aluminum, thus forming the active intermediate, a strained three-membered epoxide ring. This is seen when geometry optimized structures of a "free" epoxide are compared with those of an epoxide coordinated to the aluminum. A C—O bond lengthening from 1.44 to 1.477 Å (O—C_α) and 1.507 Å (O—C_β) is observed when Al is coordinated. Nucleophilic attack by methanol can then take place on either the C_α or C_β position. Electronic factors will favor the C_β position (the O—C_β is longer than the O—C_α bond) while steric factors will favor the C_α position (less substituted). In the case of methanol as the nucleophile, these two factors contribute equally, as is evident by the product distribution of approximately 1:1 (Scheme 5).



As can be expected, the formation energies for the ring-opening reactions are highly exothermic because of the release of the strained three-membered epoxide ring. In line with the Hammond postulate, it would be reasonable to assume that the activation energies for the ring-opening reactions would be low (the transition state for the ring-opening reactions should be very early and resemble the reagents because of the highly exothermic reaction). The interesting aspect about the base-catalysed ring-opening reaction is the high stability of the potassium salt of the product. The significance of this is that the regeneration of the active intermediate, $KOCH_3$, represents a highly endothermic reaction. This will explain the high levels of $KOCH_3$ necessary to obtain a reasonable rate. The ring-opening reaction itself will be facile and the rate-determining step will be the regeneration of the $KOCH_3$ species to start the catalytic cycle again (Scheme 4). The $Al(CF_3SO_3)_3$ catalysed reaction, on the other hand, does not have such a thermodynamic sink with the regeneration of the activated epoxide ring coordinated to the $Al(CF_3SO_3)_3$ being only a slightly exothermic reaction (Scheme 3). Together with the low activation energy for the ring-opening reaction, this will explain the low levels of $Al(CF_3SO_3)_3$ necessary to obtain very high rates. A reasonable explanation would then be that the difference in catalyst concentration needed for the ring-opening reaction is due to the highly endothermic and (or) unfavourable reaction for the regeneration of the $KOCH_3$ species compared to the facile reaction for the $Al(CF_3SO_3)_3$.

Esterification reaction



The conversion of acetic acid at different acid catalyst concentrations with *n*-propanol is shown in Table 5 and for ethanol in Table 6. The results for the variation of the acetic acid – ethanol molar ratio are shown in Table 7. Graphs ob-

tained from the data are shown in the Supplementary material[4] to the publication.

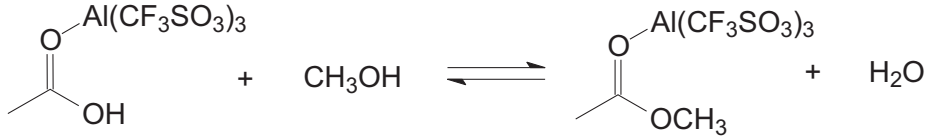
In the molecular modelling study, two steps in the catalytic cycle of the esterification reaction with $Al(CF_3SO_3)_3$ and an acid were considered, i.e., the esterification step as well as the regeneration of the active intermediate; these steps are shown in Schemes 6 and 7.

As esterification reactions are equilibrium reactions and are known to proceed very slowly in the absence of an acid catalyst (1), the addition of small quantities of the catalyst will ensure that they reach equilibrium much faster. This can clearly be seen upon comparing the data for the esterification reaction in Tables 5 and 6. It is evident that equilibrium (equilibrium conversion ≅ 66%) is reached after 1 h,

Table 7. Conversion of acetic acid (mol%) with $Al(CF_3SO_3)_3$ catalyst at different ethanol – acetic acid ratios.[a]

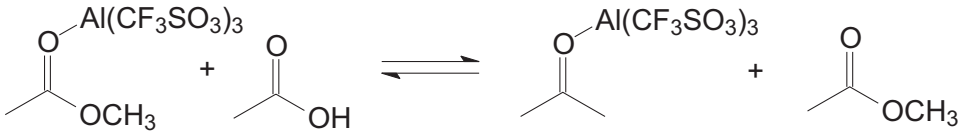
	Ethanol – acetic acid ratio		
Time (min)	1	4	8
5	10.02	28.47	47.82
10	15.10	34.28	57.21
15	20.22	50.65	63.04
20	25.43	55.72	71.54
25	30.05	59.94	77.67
30	32.97	64.99	84.41
60	40.07	79.65	93.20
90	45.10	85.43	97.80
120	46.21	87.46	98.68
150	49.80	90.46	98.63

Note: T = 100 °C, catalyst concentration = 5000 ppm.



[a]These reactions were run to completion, hence the yields of ethyl acetate were ≅98%.

when using 5000 ppm of $Al(CF_3SO_3)_3$ for the esterification reaction of acetic acid and *n*-propanol. However, equilibrium is not reached for this reaction even after 210 min when using 10 ppm of the catalyst. Similar results were observed for the esterification reaction of acetic acid and ethanol when 10 ppm of catalyst is used, as equilibrium is not reached after 180 min. The main products that were formed in the esterification reactions are the corresponding esters: *n*-propyl acetate in the case of *n*-propanol and ethyl acetate in the case of ethanol. The equilibrium yields of the main products ≅64%. Some by-products were also formed in low yields; these were identified as ethers (e.g., diethyl ether or dipropyl ether) via GC–MS.



In the esterification reaction, electron density is donated from the carbonyl oxygen atom of the carboxylic acid by coordinating to the aluminum, thus forming the active intermediate. Geometry optimized structures of the free acetic acid compared to one coordinated to aluminum show the C=O bond lengthening from 1.208 to 1.245 Å. Nucleophilic attack by the methanol then takes place on the carbonyl carbon of the carboxylic acid (Scheme 8).

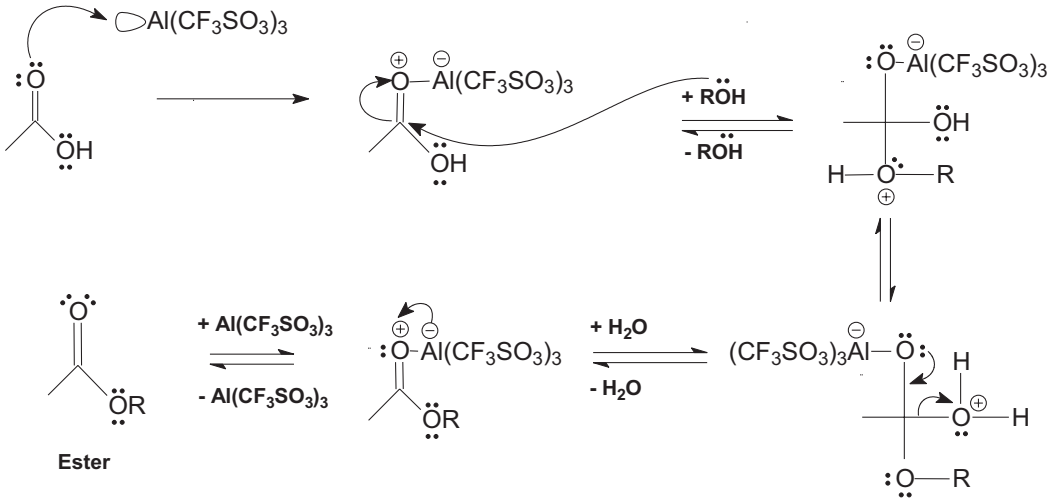
Scheme 7. Formation energies for the $Al(CF_3SO_3)_3$ catalysed esterification reaction (1 cal = 4.184 J).



ΔH_f = -4.2 kcal/mol

ΔH_f = -2.8 kcal/mol

Scheme 8. Reaction mechanism for esterification.

Formation energies for the esterification reactions are, however, only slightly endothermic. In line with the Hammond postulate, it would thus be reasonable to assume the activation energies for the esterification reactions to be higher than those for the ring-opening reactions (ΔH_f = –4.2 kcal/mol for the esterification compared to ΔH_f = –27.3 kcal/mol for the ring-opening reaction).

Unlike the epoxide ring-opening reaction, the esterification reaction does not show any discrepancy between the $Al(CF_3SO_3)_3$ and the acid-catalysed reactions. Similar formation energies are observed for both reactions and thus similar catalyst concentrations should give similar reaction rates; this was in fact the case.[5] The only difference will be the slight variation in the energy of the transition state for the $Al(CF_3SO_3)_3$ and acid-catalysed reaction.

Conclusion

The ring-opening reaction of butene oxide with methanol is easily achieved at low concentrations (10 ppm or less) of $Al(CF_3SO_3)_3$ as the catalyst. When using 10 ppm of $Al(CF_3SO_3)_3$, 100% conversion of butene oxide is achieved within 10 min. This is, however, not the case for the $KOCH_3$ catalysed ring-opening reaction, which requires at least a 1000 ppm catalyst concentration to achieve a reasonable rate. A plausible explanation is the energy difference in the regeneration of the active intermediate that is unfavourable for the $KOCH_3$ catalysed reaction, implying the necessity of higher catalyst loading to get similar rates. Esterification of acetic acid with *n*-propanol and (or) ethanol gave similar energies for both acid and $Al(CF_3SO_3)_3$ catalysed reactions,

[5] On comparing the conversion of acetic acid using $Al(CF_3SO_3)_3$ and a conventional acid catalyst in the esterification of 1-methoxy-2-propanol with acetic acid, it was seen that the reaction rate with $Al(CF_3SO_3)_3$ was only slightly faster than that with the acid catalyst when the same catalyst concentration was used.

thus explaining the need for similar catalyst loadings to give similar rates

Reaction of $[Fe(CO)_4(\eta^2\text{-}Me_3SiC{\equiv}CSiMe_3)]$ with PMe_3 — CO rather than alkyne substitution[1]

James N.L. Dennett, Michael J. Ferguson, Robert McDonald, and Josef Takats

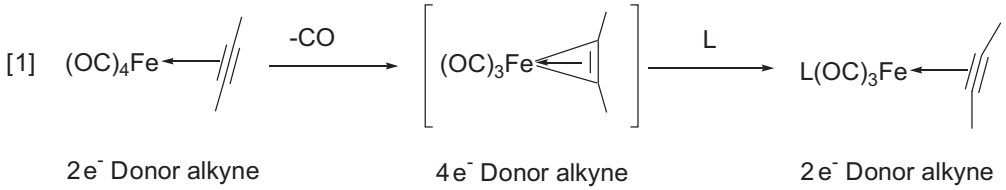
Abstract: Reaction of $[Fe(CO)_4(\eta^2\text{-BTMSA})]$ (**1**) (BTMSA = $Me_3SiCCSiMe_3$) with trimethylphosphine proceeds by stepwise loss of CO ligands yielding $[Fe(CO)_3(PMe_3)(\eta^2\text{-BTMSA})]$ (**2**) and $[Fe(CO)_2(PMe_3)_2(\eta^2\text{-BTMSA})]$ (**3**), respectively. This demonstrates the CO dissociative nature of substitution in **1** toward PMe_3, as established in analogous $M(CO)_4(\eta^2\text{-alkyne})$ (M = Fe, Ru, Os) compounds. The structures of all three compounds have been determined by X-ray crystallography to assess the effect of CO substitution by PMe_3 on the metal–alkyne bonding in these molecules.

Key words: iron, carbonyl, alkyne, substitution, phosphine, steric effects.

Résumé : La réaction du $[Fe(CO)_4(\eta^2\text{-BTMSA})]$ (**1**) (BTMSA = $Me_3SiCCSiMe_3$) avec la triméthylphosphine se produit avec des pertes successives de ligands CO qui conduisent respectivement aux complexes $[Fe(CO)_3(PMe_3)(\eta^2\text{-BTMSA})]$ (**2**) et $[Fe(CO)_2(PMe_3)_2(\eta^2\text{-BTMSA})]$ (**3**). Ces résultats confirment la nature dissociative du CO qui permet de le substituer dans le composé **1** par des groupes PMe_3, tel qu'il avait été établi avec les analogues $M(CO)_4(\eta^2\text{-alcyne})$ (M = Fe, Ru, Os). Les structures des trois composés ont été déterminées par cristallographie aux rayons X afin d'évaluer l'effet de la substitution du CO par un PMe_3 sur la liaison métal–alcyne de ces molécules.

Mots clés : fer, carbonyle, alcyne, substitution, phosphine, effets stériques.

[Traduit par la Rédaction]



Introduction

Work from our laboratories (1) has conclusively demonstrated the intermediacy of $[Fe(CO)_4(\eta^2\text{-alkyne})]$ species in the iron carbonyl mediated alkyne–CO coupling reactions first investigated by Wender and co-workers (2) and Hübel and co-workers (3). We have also shown that the spectacular enhancement of CO lability toward substitution in these, and ruthenium and osmium analogues, was due to the ability of the alkyne ligand to act as a four-electron donor and hence stabilize the CO-dissociated intermediate in the reaction (4) (eq. [1]).

Thus, it seemed surprising that $[Fe(CO)_4(\eta^2\text{-BTMSA})]$ (**1**), the first well-characterized simple iron–carbonyl–alkyne, reported by Pannell and Crawford (5) more than 30 years ago, reacted with PPh_3 to give only bis(triphenyl)phosphine tricarbonyl iron ($Fe(CO)_3(PPh_3)_2$, eq. [2]) without any evidence of $[Fe(CO)_3(PPh_3)(\eta^2\text{-BTMSA})]$. This despite the fact that the mass spectrum of the molecule showed stepwise loss of CO groups from the parent molecular ion and carbonyl-free $Fe(BTMSA)^+$ as the base ion fragment indicating that, under mass spectrometry conditions, the Fe–BTMSA bonding is stronger than that of Fe–CO (5).

$$[2]\qquad [Fe(CO)_4(BTMSA)] + 2PPh_3 \rightarrow [Fe(CO)_3(PPh_3)_2] + CO + BTMSA$$

In view of our demonstration that substitution reactions of $[Fe(CO)_4(\eta^2\text{-alkyne})]$ compounds proceed by initial CO loss, the failure to detect BTMSA-containing products by Pannell and Crawford may have been due to the bulky nature of the PPh_3 ligand, which promotes loss of the also bulky BTMSA

moiety from the putative $[Fe(CO)_3(PPh_3)(\eta^2\text{-BTMSA})]$ initial product via addition of the second PPh_3 ligand.

To test this hypothesis, the reaction of **1** with the sterically less-demanding PMe_3 was investigated and we report here that the substitution reaction does indeed proceed by stepwise loss of CO to yield $[Fe(CO)_3(PMe_3)(\eta^2\text{-BTMSA})]$ (**2**) and $[Fe(CO)_2(PMe_3)_2(\eta^2\text{-BTMSA})]$ (**3**), respectively.

Experimental section

All reactions were carried out using standard Schlenk techniques under a dry and oxygen-free nitrogen atmosphere. Hydrocarbon solvents were dried over CaH_2 and distilled under nitrogen using normal procedures prior to use. $[Fe(CO)_4(\eta^2\text{-BTMSA})]$ (**1**) was prepared as described in the literature (5). Carbon-13 carbon monoxide (Isotec, Inc.) and trimethylphosphine (Aldrich) were used as supplied. IR solution spectra (KBr cell) were recorded on a Bomem MB-100 FT IR spectrometer. NMR samples were prepared under a nitrogen atmosphere. NMR spectra were recorded on a Bruker AM-400 MHz operating at 400 MHz for ^1H, 161.9 MHz for ^{31}P, and 100.6 MHz for ^{13}C NMR nuclei. Elemental analyses were performed by the Microanalytical Laboratory, Department of Chemistry, University of Alberta. Electron impact (EI) mass spectra were recorded on a AEI/Kratos MS 50 spectrometer.

Preparation of $[Fe(CO)_3(PMe_3)(\eta^2\text{-BTMSA})]$ (2)

Trimethylphosphine (24.6 μL, 0.238 mmol) was added to a hexane solution (25 mL) of $[Fe(CO)_4(\eta^2\text{-BTMSA})]$ (**1**, 64.0 mg, 0.189 mmol) at 10 °C and the solution stirred for 5 h. The solvent was removed in vacuo at –20 °C. The yellow residue was dissolved in pentane and the solution filtered, concentrated, and cooled to –80 °C. Yellow crystals of $[Fe(CO)_3(PMe_3)(\eta^2\text{-BTMSA})]$ (**2**, 56.0 mg) were obtained in 76.6% yield. IR (*n*-pentane, cm^{-1}): υ_{CO} 2018 (s), 1949 (s), 1920 (s); $\upsilon_{C\equiv C}$ 1823 (w/br). ^1H NMR (CD_2Cl_2, –70 °C) δ: 1.01 (d, $^2J_{PH}$ = 8 Hz, 9H, $P(CH_3)_3$), 0.22 (s/br, 18H, $Si(CH_3)_3$). $^{13}C\{^1H\}$ NMR (CD_2Cl_2, –70 °C) δ: 220.9 (d, $^2J_{CP}$ = 35 Hz, $2CO_{eq}$), 214.6 (d, $^2J_{CP}$ = 59 Hz, CO_{ax}), 99.5 (s, $CSiMe_3$), 16.5 (d, $^1J_{CP}$ = 28 Hz, $P(CH_3)$), –0.3 (s, $Si(CH_3)$). $^{31}P\{^1H\}$ NMR (CD_2Cl_2, room temperature (r.t.)) δ: 22.4 (s). MS (EI, 16 eV) *m/z*: 386 (M^+), 302 (M^+ – 3CO). Anal. calcd. for $C_{14}H_{27}FeO_3P_1Si_2$ (%): C 43.52, H 7.00; found: C 43.23, H 7.09.

$[Fe(^{13}CO)_3(PMe_3)(\eta^2\text{-BTMSA})]$ (2*)

$[Fe(^{13}CO)_3(PMe_3)(\eta^2\text{-BTMSA})]$ (**2***) was prepared by the same procedure using $[Fe(^{13}CO)_4(\eta^2\text{-BTMSA})]$ (**1***) as the starting material. IR (*n*-pentane, cm^{-1}): υ_{CO} 1971 (s), 1902 (s), 1875 (s); $\upsilon_{C\equiv C}$ 1822 (w/br).

Preparations of $[Fe(CO)_2(PMe_3)_2(\eta^2\text{-BTMSA})]$ (3)

Method 1

Trimethylphosphine (2 equiv., 36.0 μL, 0.348 mmol) was added to a hexane solution (25 mL) of $[Fe(CO)_4(\eta^2\text{-BTMSA})]$ (**1**, 59.0 mg, 0.175 mmol) at r.t. and the solution stirred for 2 h. The solvent was removed in vacuo at 0 °C. The yellow residue was dissolved in pentane and the solution filtered, concentrated, and cooled to –80 °C. Yellow-orange crystals of $[Fe(CO)_2(PMe_3)_2(\eta^2\text{-BTMSA})]$ (**3**, 31.5 mg, 41.6%) were formed, which proved suitable for an X-ray crystallographic study.

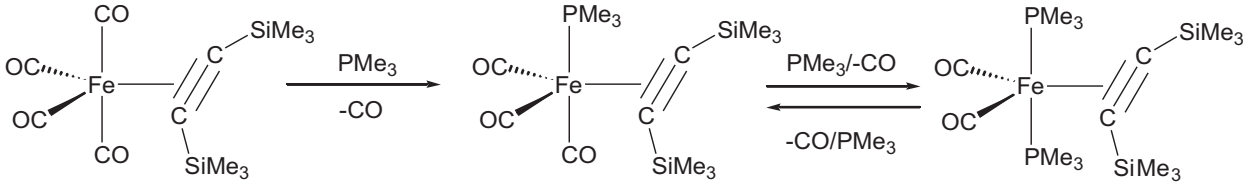
Method 2

Trimethylphosphine (3.4 μL, 0.033 mmol) was added to a hexane solution (5 mL) of $[Fe(CO)_3(PMe_3)(\eta^2\text{-BTMSA})]$ (**2**, 12.5 mg, 0.0324 mmol) at r.t. and the solution stirred for 2 h. The solvent was removed in vacuo at r.t. The residue was dissolved in pentane and the solution filtered, concentrated, and cooled to –80 °C. Yellow-orange crystals of $[Fe(CO)_2(PMe_3)_2(\eta^2\text{-BTMSA})]$ (**3**, 5.0 mg) were obtained in 35% yield.

Method 3

Excess trimethylphosphine (50.0 μL, 0.483 mmol) was added to a hexane solution (10 mL) of $[Fe(CO)_4(\eta^2\text{-BTMSA})]$ (**1**, 39.0 mg, 0.115 mmol) at r.t. and the solution stirred for 3 h. The solvent was removed in vacuo at r.t. The yellow residue was dissolved in pentane and the solution filtered, concentrated, and cooled to –80 °C. Yellow-orange crystals of $[Fe(CO)_2(PMe_3)_2(\eta^2\text{-BTMSA})]$ (**3**, 30.0 mg) were obtained in 59.9% yield. IR (*n*-pentane, cm^{-1}): υ_{CO} 1930 (m), 1868 (s); $\upsilon_{C\equiv C}$ 1774 (w). ^1H NMR (CD_2Cl_2, r.t.) δ: 1.05 (vt, apparent J_{PH} = 3.7 Hz, 18H, $P(CH_3)_3$), 0.28 (s/br, 18H, $Si(CH_3)_3$). $^{13}C\{^1H\}$ NMR (CD_2Cl_2, r.t.) δ: 225.0 (s/br, *C*O), 116.3 (s, $CSiMe_3$), 18.6 (vt, apparent J_{PC} = 12.5 Hz, $P(CH_3)$), 1.7 (s, $Si(CH_3)$). $^{31}P\{^1H\}$ NMR (CD_2Cl_2, r.t.) δ: 26.6 (s). MS (EI, 16 eV) *m/z*: 434 (M^+), 302 (M^+ – 2CO – PMe_3). Anal. calcd. for $C_{16}H_{36}FeO_2P_2Si_2$ (%): C 44.24, H 8.35; found: C 44.25, H 8.41.

$[Fe(^{13}CO)_2(PMe_3)_2(\eta^2\text{-BTMSA})]$ (3*)



$[Fe(^{13}CO)_2(PMe_3)_2(\eta^2\text{-BTMSA})]$ (**3***) was prepared by method 1 using $[Fe(^{13}CO)_4(\eta^2\text{-BTMSA})]$ (**1***) as the starting material. IR (*n*-pentane, cm^{-1}): υ_{CO} 1888 (m), 1824 (s); $\upsilon_{C\equiv C}$ 1771 (w). ^1H NMR (CD_2Cl_2, –80 °C) δ: 0.95 (vt, apparent J_{PH} = 3.7 Hz, 18H, $P(CH_3)_3$), 0.18 (s, 18H, $Si(CH_3)_3$). $^{13}C\{^1H\}$ NMR (CD_2Cl_2, –80 °C) δ: 224.7 (t, $^2J_{CP}$ = 31 Hz, *C*O), 114.0 (s, $CSiMe_3$), 17.8 (vt, apparent J_{PC} = 12.5 Hz, $P(CH_3)$), 1.0 (s, $Si(CH_3)$). $^{31}P\{^1H\}$ NMR (CD_2Cl_2, –80 °C) δ: 29.2 (t, $^2J_{CP}$ = 31 Hz). MS (EI, 16 eV) *m/z*: 436 (M^+); estimated ratios: $[Fe(^{13}CO)_2(PMe_3)_2(\eta^2\text{-BTMSA})]$ 75%, $[Fe(^{13}CO)(^{12}CO)(PMe_3)_2(\eta^2\text{-BTMSA})]$ 25%.

Preparation of $[Fe(^{13}CO)_4(\eta^2\text{-BTMSA})]$ (1*)

$[Fe(^{13}CO)_4(\eta^2\text{-BTMSA})]$ (**1***) was prepared by stirring a hexane (20 mL) solution of $[Fe(CO)_4(\eta^2\text{-BTMSA})]$ (**1**, 191.5 mg, 0.567 mmol) in a 100 mL round-bottomed flask, under an atmosphere of ^{13}CO (approx. 3.23 mmol) for 2 days. The solvent was removed in vacuo at –20 °C. The yellow residue was dissolved in pentane and the solution filtered, concentrated, and cooled to –80 °C. Yellow crystals of $[Fe(^{13}CO)_4(\eta^2\text{-BTMSA})]$ (**1***, 125.5 mg) were obtained in 64.8% yield. IR (*n*-pentane, cm^{-1}): υ_{CO} 2029 (w), 1958 (vs), 1924 (s); $\upsilon_{C\equiv C}$ 1873 (w) (for comparison, **1**: IR (*n*-pentane, cm^{-1}): υ_{CO} 2077 (w), 2001 (vs), 1968 (s); $\upsilon_{C\equiv C}$ 1874 (w)).

Scheme 1.

1 **2** **3**

Reaction of [Fe(CO)$_4$(η^2-BTMSA)] (1) with CO

Carbon monoxide was bubbled through a pentane (10 mL) solution of [Fe(CO)$_4$(η^2-BTMSA)] (**1**) overnight (11 h). No change was observed in the solution or the IR spectrum over this period.

Reaction of [Fe(CO)$_2$(PMe$_3$)$_2$(η^2-BTMSA)] (3) with CO

A pentane (10 mL) solution of [Fe(CO)$_2$(PMe$_3$)$_2$(η^2-BTMSA)] (**3**, 10.5 mg, 0.0242 mmol) was frozen, degassed, and allowed to warm to –80 °C. The flask was then backfilled with CO via a CO line. The CO line was fitted with an oil bubbler, which maintained a constant pressure of CO (ca. 1 atm, 1 atm = 101.325 kPa). The solution was allowed to warm slowly to r.t. and the reaction monitored by IR spectroscopy. After 6 h, the reaction solution reached r.t. and contained mainly **2**, with small amounts of **3** and [Fe(CO)$_3$(PMe$_3$)$_2$] (**4**) (IR (*n*-pentane, cm^{-1}): υ_{CO} 1880 (s); compared to **4**: IR (CH_2Cl_2, cm^{-1}): υ_{CO} 1863 (s) (6)). On stirring for a further 1.5 h, the proportion of **2** and **4** to **3** continued to rise. Longer reaction times led to minor changes in the IR spectrum, but the identities of the new species were difficult to ascertain with confidence.

Reaction of [Fe(^{13}CO)$_2$(PMe$_3$)$_2$(η^2-BTMSA)] (3*) with ^{13}CO

A pentane (10 mL) solution of [Fe(^{13}CO)$_2$(PMe$_3$)$_2$(η^2-BTMSA)] (**3***) (10.0 mg, 0.0229 mmol) was frozen, degassed, and backfilled with ^{13}CO at –80 °C. The flask was then sealed. The solution was allowed to warm slowly to r.t. and the reaction monitored by IR spectroscopy. After 6 h, the reaction solution reached r.t. and contained mainly **2*** with a trace of **3***. On stirring for a further 1.5 h, [Fe(^{13}CO)$_3$(PMe$_3$)$_2$] (**4***) (IR (*n*-pentane, cm^{-1}): υ_{CO} 1835 (s); compared to **4**: IR (CH_2Cl_2, cm^{-1}): υ_{CO} 1863 (s) (6)) was also detected.

Reaction of [Fe(CO)$_4$(η^2-BTMSA)] (1) with triphenylphosphine–tricyclohexylphosphine

To a cooled (–70 °C) solution of **1** was added equimolar quantities of PPh_3 (in CH_2Cl_2) or PCy_3 (in hexane). Progress of the reaction was monitored by IR spectroscopy as the solution was slowly allowed to warm to r.t. (ca. 7 h). In the case of PPh_3, no other product but starting material **1** and [Fe(CO)$_3$(PPh$_3$)$_2$] (7*a*) (IR (CH_2Cl_2, cm^{-1}): υ_{CO} 1881 (s)) could be detected. With PCy_3, in addition to **1** and [Fe(CO)$_3$(PCy$_3$)$_2$] (7*b*) (IR (CH_2Cl_2, cm^{-1}): υ_{CO} 1850 (s)), bands at 2045 (m), 1969 (w), and 1930 (s) (cm^{-1} in *n*-hexane) were observed also.

Crystal structure determinations

Yellow crystals of **1** and **2** and yellow–orange crystals of **3** were obtained by cooling pentane solutions to –80 °C. Data were collected on a Bruker PLATFORM/SMART 1000 CCD diffractometer using Mo Kα radiation at –80 °C. For a summary of the crystal data X-ray collection data see Table 1. The structures of **1**–**3** are shown in Fig. 1.[3]

Results and discussion

Synthesis and characterization

Reaction of [Fe(CO)$_4$(η^2-BTMSA)] (**1**) with 1 equiv. of trimethylphosphine gave the monophosphine substituted [Fe(CO)$_3$(PMe$_3$)(η^2-BTMSA)] (**2**) in good yield (76%) (Scheme 1). The disubstituted [Fe(CO)$_2$(PMe$_3$)$_2$(η^2-BTMSA)] (**3**) could be prepared either by reaction of **1** with 2 or more equiv. of trimethylphosphine or by reaction of **2** with 1 or more equiv. of trimethylphosphine. The formation of **3** from **2** could be reversed by placing a pentane solution of **3** under an atmosphere of carbon monoxide. However, longer reaction time (6 h) resulted in the loss of BTMSA and formation of [Fe(CO)$_3$(PMe$_3$)$_2$] (**4**). It should also be noted that **1** does not lose BTMSA to form [Fe(CO)$_5$] under carbon monoxide overnight.

Compound **1** undergoes facile carbonyl ligand exchange. Placing a hexane solution of **1** under ^{13}CO readily gave ^{13}CO enriched **1***. Subsequent reactions with PMe_3 allowed the preparation of ^{13}CO enriched samples of **2*** and **3***.

Complex **2** was fully characterized by IR and NMR (^{1}H, ^{31}P{^{1}H}, and ^{13}C{^{1}H}) spectroscopy, mass spectrometry, and elemental analysis, the data comparing well with similar complexes prepared in this laboratory (8). Three IR active carbonyl stretching bands are expected on the basis of the C_s symmetry of **2** and are seen at 2018 (s), 1949 (s), and 1920 (s) cm^{-1}. Another IR band is seen at 1822 cm^{-1} owing to the coordinated alkyne. The identity of this last band is corroborated by comparing the IR spectra of **2** and **2***, in which, unlike the carbonyl stretching frequencies, it remains unchanged. The ^{13}C{^{1}H} NMR spectrum of **2** shows two carbonyl resonances in a 2:1 ratio at δ 220.9 (d, $^2J_{CP}$ = 35 Hz, 2CO_{eq}) and 214.6 (d, $^2J_{CP}$ = 59 Hz, CO_{ax}). The coupling constants to phosphorus confirm the geometry of **2**, with a larger trans phosphorus–carbon coupling to one carbonyl

[g]Reference 15. The Flack parameter will refine to a value near zero if the structure is in the correct configuration and will refine to a value near one for the inverted configuration. The value observed herein is indicative of racemic twinning, and was accomodated during the refinement (using the SHELXL-93 TWIN instruction (see footnote *d*)).
[h]$S = [\Sigma w(F_o^2 - F_c^2)^2/(n-p)]^{1/2}$ (n = number of data, p = number of parameters varied, $w = [\sigma^2(F_o^2) + (a_0P)^2]^{-1}$ where $P = [\mathrm{Max}(F_o^2, 0) + 2F_c^2]/3$ and a_0 is adjusted as suggested by the refinement program (for **1**, a_0 = 0.1126; for **2**, a_0 = 0.0402; for **3**, a_0 = 0.0929).
[i]$R_1 = \Sigma\|F_o|-|F_c\|/\Sigma|F_o|$; $wR_2 = [\Sigma w(F_o^2 - F_c^2)^2/\Sigma w(F_o^4)]^{1/2}$.

and a smaller coupling to the equatorial carbonyls. Crystals of **2** suitable for an X-ray crystallographic study were obtained through the cooling (–80 °C) of a saturated pentane solution of **2**. The study is detailed in the following text.

Complex **3** was also fully characterized by IR and NMR (^1H, $^{31}P\{^1H\}$, and $^{13}C\{^1H\}$) spectroscopy, mass spectrometry, and elemental analysis. The data compare well with similar complexes prepared in this laboratory and elsewhere (9), and with the analogous $Fe(CO)_2(PEt_3)_2$(η-BTMSA) prepared by a very different route (9*b*). The IR spectrum shows two carbonyl stretching bands at 1930 (m) and 1823 (s) cm^{-1}, consistent with the C_{2v} molecular symmetry. In addition to the carbonyl stretches a band at 1774 cm^{-1} is observed owing to the bound alkyne. The $^{13}C\{^1H\}$ NMR spectrum of **3*** shows a resonance at δ 224.7 (t, $^2J_{CP}$ = 31 Hz) for the two equivalent carbonyl carbons. The observation of virtual triplets for the PMe_3 carbons and hydrogens confirm the trans-diaxial disposition of these ligands (10). The single ^{31}P

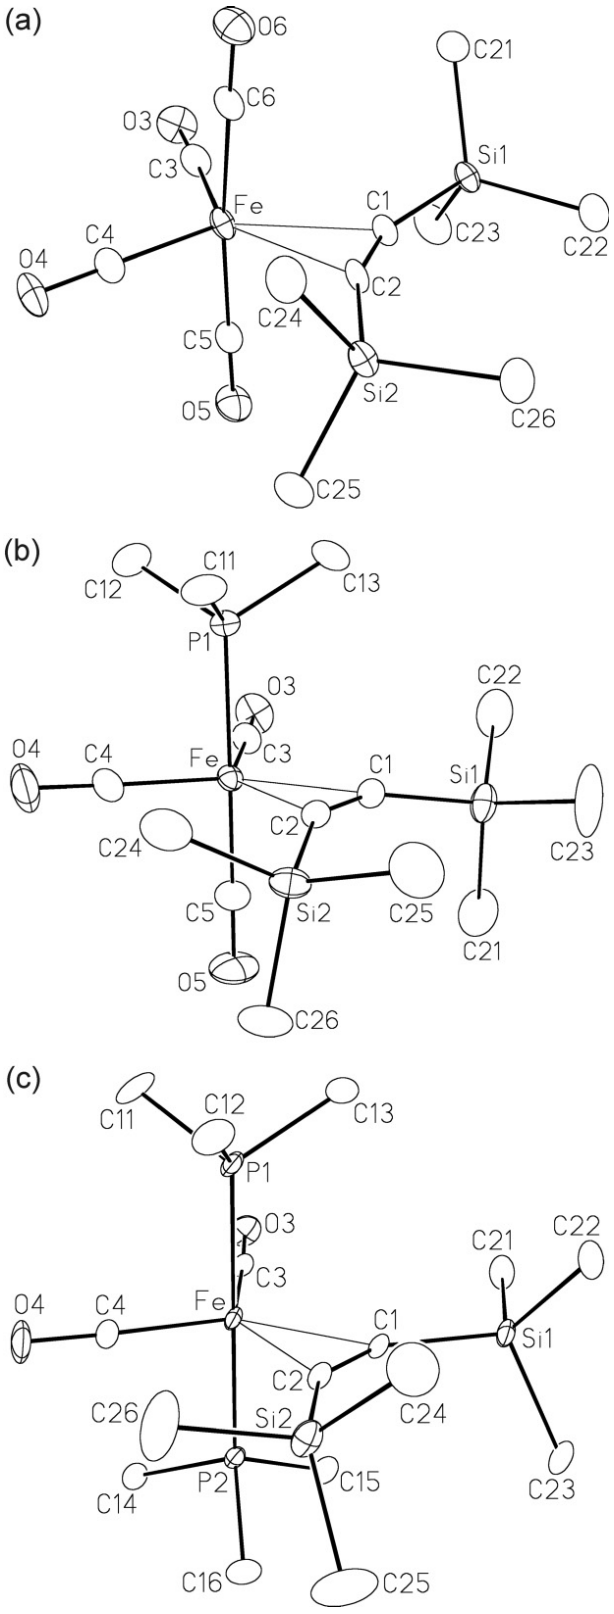

Fig. 1. Perspective views of: (*a*) one of the two crystallographically independent molecules of $[Fe(CO)_4\{\eta^2\text{-}C(SiMe_3)C(SiMe_3)\}]$ (**1**) (molecule 1) showing the atom labelling scheme; (*b*) $[Fe(CO)_3(PMe_3)\{\eta^2\text{-}C(SiMe_3)C(SiMe_3)\}]$ (**2**); and (*c*) $[Fe(CO)_2(PMe_3)_2\{\eta^2\text{-}C(SiMe_3)C(SiMe_3)\}]$ (**3**). Non-hydrogen atoms are represented by Gaussian ellipsoids at the 20% probability level. Hydrogen atoms are not shown.

resonance owing to the two equivalent PMe_3 ligands in **3*** is observed at δ 29.2 as a triplet with an inner doublet (the triplet dominant) because of incomplete ^{13}CO enrichment. It was not possible to reliably integrate the two multiplets to determine the extent of enrichment, but from the mass spectrum of the compound, we estimate a 3:1 ratio between the di- and mono-^{13}CO material. Crystals of **3** suitable for an X-ray crystallographic study were obtained by cooling (–80 °C) a saturated pentane solution of **2**. The study is detailed in the following text.

Having established that substitution of **1** also proceeds by initial CO dissociation with production of the mono- and bisphosphine alkyne carbonyls **2** and **3**, it was of interest to reinvestigate the reaction with bulky phosphines to see whether analogues of **2** and (or) **3** could be isolated or at least spectroscopically detected.

The only isolable products from the reaction of **1** with triphenylphosphine and tricyclohexylphosphine were the known compounds $[Fe(CO)_3(PPh_3)_2]$ and $[Fe(CO)_3(PCy_3)_2]$, respectively (7). Although IR monitoring of the PCy_3 reaction in hexane, where the CO stretching bands are narrow and sharp, revealed additional CO bands at 2045, 1969, and 1930 cm^{-1}, the alkyne region remained ambiguous. In the absence of additional data and no isolated product, the origin of these bands is uncertain, but most probably due to advantageous $Fe(CO)_4(PCy_3)$ (11).

Solid state structures of compounds 1–3

To corroborate the structural assignments and to assess the effect of CO substitution by PMe_3 on the metal–alkyne bonding in this series, the solid structure of the previously reported **1** was also determined by X-ray crystallography. Perspective views of the structures of compounds **1**–**3** are shown in Fig. 1 and selected bond lengths and angles are given in Table 2. All three compounds have a trigonal bipyramidal arrangement of ligands, with the bis(trimethylsilyl)acetylene and two carbonyl ligands occupying the trigonal plane. The solid state structure of **1** shows that the axial carbonyl ligands are bent towards the alkyne with C-Fe-C bond angles (for the two chemically equivalent, yet crystallographically different molecules) of 174.3(2)° and 174.5(2)°. A similar situation is seen in the solid state structure of $[Os(CO)_4(\eta^2\text{-BTMSA})]$ (**5**) (12).

As noted previously and in the Experimental section, the unit cell of **1** contains two chemically equivalent, but crystallographically independent molecules. As a consequence, in the following discussion, average values will be used for discussion and comparison.

The two incoming trimethylphosphine ligands sequentially occupy the axial positions: one in **2** and both in compound **3**. The substitution of the first axial π-acidic CO ligand by the σ-donating trimethylphosphine has the expected effect of shortening the metal–carbonyl bond distance trans to it (Fe—C5 = 1.780(3) Å in **2** compared to 1.827(9) Å for the axial Fe—C5/C6 bond distances in **1**). The differences between Fe—CO_{eq} distances are hardly significant. However, there is a significant effect on the metal–alkyne

Si2-C2-C1	160.1(4)	162.1(4)	150.6(2)	146.3(3)

bonds, with a decrease in the iron–carbon distances between **1** and **2** (2.172(5) Å in **1** and 2.119(3) Å in **2**). The shortening of these bonds shows that the alkyne also benefits from the increased electron density on the metal, with increased π backdonation from iron into the alkyne $\pi_\parallel$* orbitals. The C≡C-Si bond angles also decrease from 160.1(6)° in **1** to 150.9(3)° for **2** as the metal–alkyne bonding develops greater metallacyclopropene character.

In compound **3**, the second phosphine occupies the second axial position, trans to the other phosphine. The effect of the second phosphine on the metal–ligand bonding is slighter than that of the first. All of the relevant bond lengths in **3** are comparable to those in **2**.[4] However, the C≡C-Si bond angles decrease slighty from 150.9(3)° in **2** to 146.8(5)° for **3**, illustrating again the increasing metallacyclopropene character of the metal–alkyne bonding. It may be that the anticipated increase is attenuated by the increased four-electron repulsion between filled Fe d_π and $\pi_\perp$ BTMSA orbitals as a result of the absence of π-acidic CO in **3** along the apical positions, which could drain some electron density from the later.

It should be noted that the increased back-bonding ability, and hence increased metallacyclopropene character in the series **1** < **2** < **3**, is not reflected in a similar reduction in the BTMSA C≡C bond distance. Indeed the C1—C2 distance remains virtually unchanged: 1.250(7) Å (**1**), 1.252(4) Å (**2**), and 1.262(5) Å (**3**). A more sensitive probe is needed to gauge the changes in the C≡C bond strength. Such a probe is the C≡C stretching frequency, which decreases in the expected order: **1** (1873 cm^{-1}) > **2** (1823 cm^{-1}) > **3** (1774 cm^{-1}), the difference an almost constant 50 cm^{-1}.

Conclusion

We have demonstrated that ligand substitution in [$Fe(CO)_4(\eta^2$-BTMSA)] (**1**) proceeds by initial CO loss as in other Group 8 [$M(CO)_4(\eta^2$-alkyne)] compounds. However, the nature of the isolated products is strongly influenced by steric and electronic factors. Thus, while reaction of **1** with PMe_3 allowed isolation of [$Fe(CO)_3(PMe_3)(\eta^2$-BTMSA)] (**2**) and [$Fe(CO)_2(PMe_3)_2(\eta^2$-BTMSA)] (**3**), the bulky PPh_3 and PCy_3 ligands led only to [$Fe(CO)_3(PR_3)_2$]. Clearly steric repulsion between bulky phosphine and BTMSA ligands in the putative [$Fe(CO)_3(PR_3)(\eta^2$-BTMSA)] intermediate results in rapid loss of the BTMSA ligand and formation of [$Fe(CO)_3(PR_3)_2$].[5] That electronic factors can also influence the outcome of the substitution is evidenced from the reaction of **3** with CO. Long-term reaction time leads to formation of [$Fe(CO)_3(PMe_3)_2$] via loss of BTMSA. This is presumably the result of four-electron repulsion between the electron-rich Fe centre and the filled $\pi_\perp$ of the BTMSA ligand, which labilizes the alkyne ligand. Replacing BTMSA with strongly π-acidic alkyne HFB ($CF_3C{\equiv}CCF_3$) reduces this four-electron repulsion and both [$Fe(CO)_2(PR_3)_2(\eta^2$-HFB)] (R = Me and Ph) are resistant to HFB loss. Furthermore, reaction of [$Fe(CO)_4(\eta^2$-HFB)] with bulky phosphine ligands, including PCy_3, leads not to HFB, but further CO loss and formation of the interesting [$Fe(CO)_2(PR_3)(\eta^2$-HFB)] compounds that contain a four-electron alkyne ligand (8*b*).

Acknowledgements

We wish to thank the reviewers for their constructive com-

[4] The metrical parameters of **3** are very similar to those of the analogous $Fe(CO)_2(PEt_3)_2$(BTMSA) (9); the one exception is the C-C-Si angle (141.9(5)°) compared to 146.8(5)° in **3**.

[5] The detection of $Fe(CO)_4(PCy_3)$ in the reaction of **1** with PCy_3 may signal the existence of a minor parallel reaction path of alkyne dissociation. We have observed such an outcome with the exceedingly thermolabile $Ru(CO)_4(\eta^2$-BTMSA), which is unstable above –25 °C in solution and rapidly forms $Ru_3(CO)_{12}$ (12). The clean conversion of **1** to **2**, with no observable $Fe(CO)_4(PMe_3)$, and overnight stability of **1** under a CO atmosphere, indicate that CO loss is the predominant mode of reactivity of compound **1**.

Use of fluorescent probes to determine catalytic chain length in chemically amplified resists[1]

Mathieu Frenette, Marius Gabriel Ivan, and J.C. Scaiano

Abstract: Acid-catalyzed deprotection of *tert*-butoxycarbonyl (*t*-Boc) pendant groups present in a polymer film is one of the most common chemical reactions in photolithography. We present here a novel method to determine the catalytic chain length of this reaction under different development conditions. We demonstrate this in model PMMA thin films containing triphenylsulphonium triflate as a photoacid generator, acid sensor coumarin 6, *t*-Boc protected coumarin 4, and base 2-piperidin-1-yl-ethanol (2-PE). Deprotection of the *t*-Boc group, catalyzed by the photogenerated acid, during the post-exposure bake leads to formation of coumarin 4, a strongly fluorescent molecule whose concentration is monitored using fluorescence. We take advantage of the change in the emission spectra of coumarin 6 upon protonation to monitor acid formation. To quantify the amount of acid, an acid–base titration is done in the polymer film using 2-PE. Knowing the amount of deprotected probe and the amount of acid, we are able to calculate the number of moles of deprotected C4-*t*-Boc per mol of acid, which is the actual catalytic chain length.

Key words: photolithography, chemical amplification, catalytic chain length, fluorescent sensors, photoacid generator.

Résumé : La déprotection acidocatalysée des groupes pendants *tert*-butoxycarbonyles (*t*-Boc) présents dans un film de polymère est une des réactions chimiques les plus communes en photolithographie. Dans ce travail, on présente une nouvelle méthode pour déterminer la longueur de la chaîne catalytique de cette réaction dans diverses conditions de développement. Ceci est démontré dans des films minces modèles de PMMA contenant du triflate de triphénylsulfonium comme générateur photoacide, le détecteur d'acide coumarine 6, la coumarine 4 portant un groupe protecteur *t*-Boc et la base 2-pipéridin-1-yl-éthanol (2-PE). La déprotection du groupe *t*-Boc, catalysée par l'acide photogénéré au cours de la cuisson suivant l'exposition, conduit à la formation de la coumarine 4, une molécule fortement fluorescente dont on peut déterminer la concentration par fluorescence. On tire avantage du changement dans le spectre d'émission de la coumarine 6 lors de la protonation pour déceler la formation d'acide. Afin de quantifier la quantité d'acide, on réalise un titrage acide–base dans le film de polymère à l'aide du 2-PE. Connaissant la quantité de sonde déprotonée et la quantité d'acide, il est possible de calculer le nombre de moles de C4-*t*-Boc déprotégé par mol d'acide, ce qui correspond à la longueur de la chaîne catalytique.

Mots clés : photolithographie, amplification chimique, longueur d'une chaîne catalytique, détecteurs fluorescents, générateur photoacide.

[Traduit par la Rédaction]

Introduction

The introduction of chemically amplified resists in the early 1980s radically changed resist chemistry and made possible many of the advances in lithography of the last two decades. The chemistry was largely developed by Ito, Fréchet, Willson, and co-workers (1–3). The key concept is that a hydrophobic acid-sensitive group can be deprotected to a base soluble structure in a catalytic process mediated by Brønsted acids. One of the common reactions, particularly applied in 248 nm lithography, is deprotection of the *tert*-butoxycarbonyl (*t*-Boc) group to yield phenol-derived materials, e.g., Scheme 1.

The regeneration of the proton in the last stage of Scheme 1 is responsible for the catalytic nature of the process. The number of *t*-Boc groups deprotected by one proton gives the catalytic chain length. The acid is normally produced by photolysis of a photoacid generator (PAG). Numerous PAGs have been developed in the last two decades, capable of accommodating the speed, spectral and chemical characteristics required by various resists, as the wavelengths in use have become shorter to accommodate the demand for smaller lithographic features.

In the past, our research group and others have used fluorescent probes to monitor photoacid generation (4–6) and *t*-Boc deprotection (7–9) in polymer films. Beyond its excellent sensitivity, fluorescence lends itself readily to imaging applications, and particularly in lithography, to the examination of latent images before processing (such as post-

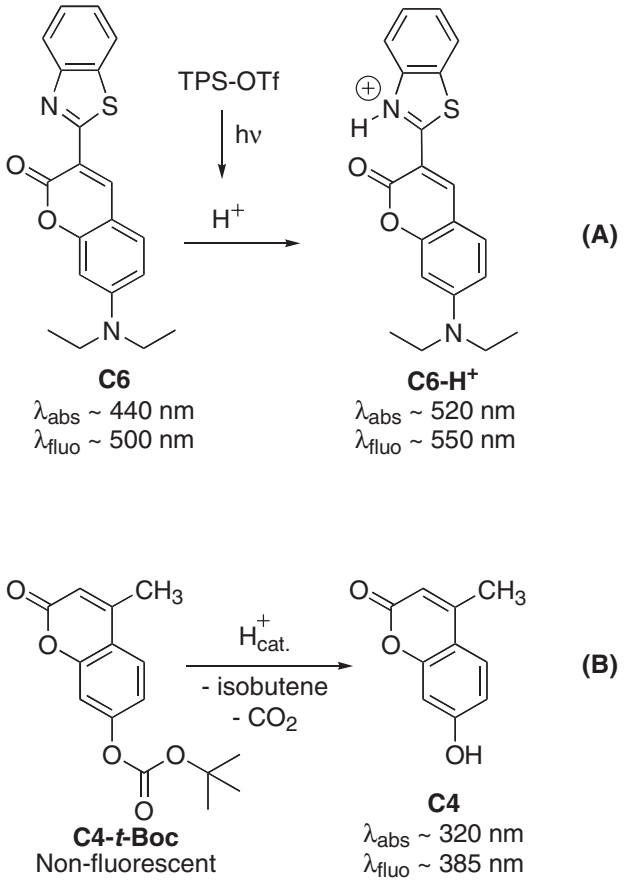
Scheme 1. Acid-catalyzed deprotection of *t*-Boc protected phenols.



exposure bake and developing) takes place (10, 11). This is particularly important as feature size decreases, and problems such as acid diffusion are a likely candidate for loss of image integrity (12).

In this paper we develop a novel methodology based on fluorescent sensors, previously used for imaging purposes, to quantify an important parameter in chemically amplified resists: the catalytic chain length of *t*-Boc deprotection.

Determining the chain length for Scheme 1 requires knowledge of the efficiency of deprotection for a given concentration of acid. For the results to be meaningful, they need to be determined in thin polymer films and under exposure conditions similar to those employed in lithographic applications. In practice this means independently measuring proton generation and deprotection yields; a few reports in the literature generally use IR spectroscopy for the latter, since the carbonyl function (at around 1760 cm^{-1}) bleaches in the deprotection reaction. Reported catalytic chain lengths are in the range of ~100 (13) to 1000 (14) depending on the reaction conditions.

Two different coumarin dyes have been used (Scheme 2). Coumarin 6 (C6) is a convenient tool to determine acid yields since it dramatically changes its absorption and emission properties upon protonation. In this case, we have developed a titration approach that allows easy end-point determinations in thin films (vide infra). For the deprotection yields, the fluorescent 7-hydroxy-4-methylcoumarin (C4) was modified to yield the nonfluorescent 7-(*tert*-butoxycarbonyloxy)-4-methylcoumarin (C4-*t*-Boc). As deprotection occurs, C4 is released, with a concomitant increase in fluorescence.

Scheme 2. (A)"Prefluorescent" probes used to quantify acid formation, and (B) *t*-Boc deprotection. See the Supplemental information[3] for the absorbance and fluorescence spectra of the probes.

Experimental section

Materials

7-*tert*-Butoxycarbonyloxy-4-methylcoumarin (C4-*t*-Boc) was readily prepared from 7-hydroxycoumarin (C4) and di-*tert*-butyl-dicarbonate as previously described (9). Triphenyl sulfonium triflate (TPS-OTf) was a generous gift from Rohm and Haas Electronic Materials and used as received. Poly(methyl methacrylate) (PMMA, MW ~ 1.0×10^6, M_W/M_N ~ 1.10) was purchased from Polysciences, Inc. 2-Heptanone (99%) and 2-piperidin-1-yl-ethanol (2-PE, 99%) were purchased from Aldrich and used as received. Coumarin 6 (C6, 98%) was obtained from Aldrich and used as received.

Determination of catalytic chain length

All thin polymer films were spin coated on 1 inch (1 inch = 25.4 mm) quartz disks (Esco Products) at 3000 rpm for 20 s from polymer solutions previously filtered through 0.45 μm filters (Whatman Puradisk® 13 mm PTFE syringe filter). A post-application bake for 60 s on a metal plate contained in an oven at 90 °C was then performed to remove the residual solvent. Immediately after any baking, the quartz disks were rapidly cooled to room temperature on a metallic surface. The PMMA films obtained were 854 ± 14 nm thick as measured using a TFA-11CT thin film analyzer from Luzchem Research. Following post-application baking, the films were irradiated for up to 100 s in a Hybrid Technology Group exposure tool, model 64-10X, equipped with a 249 (±5) nm filter. The exposure spectral power dis-

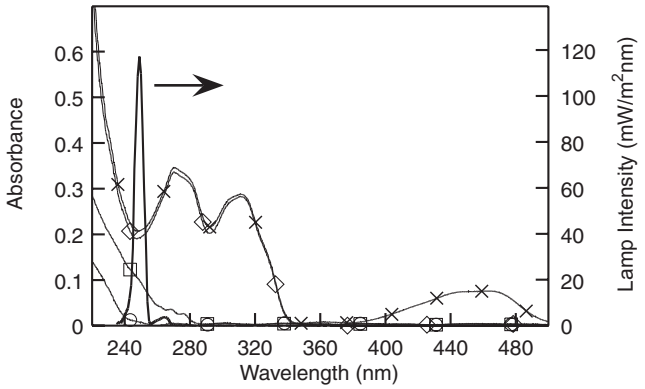
tribution was determined using a Luzchem SPR-1 spectroradiometer.

A stock polymer solution (PMMA stock) consisting of a 15:85 weight ratio of PMMA to 2-heptanone was used to prepare all solutions. Fluorescence measurements were done using a front face setup in a LS-50 PerkinElmer luminescence spectrometer.

Quantification of *t*-Boc group deprotection

In these experiments, a solution of C4-*t*-Boc (10% of the dry polymer weight) and TPS-OTf (3% of the dry polymer weight) dissolved in the PMMA stock was freshly prepared before each experiment to prevent the eventual thermal degradation of TPS-OTf or C4-*t*-Boc. The films were prepared as described in the previous section and immediately following UV exposure they were subject to a post-exposure bake (PEB) to minimize acid neutralization with air-borne bases (15). The PEB step was conducted either in the oven or using the temperature-controlled hotplate from a Luzchem TFA-11CT instrument. A new film was used for each individual data point; this probably accounts for some of the dispersion observed in our measurements.

The extent of C4-*t*-Boc deprotection was quantified by measuring the fluorescence of C4, i.e., deprotected C4-*t*-Boc, by exciting at 320 nm and monitoring emission at 385 nm. The fluorescence intensity was assumed to be proportional to C4 concentration in the range measured. A near-plateau in fluorescence intensity was found in all experiments, taken as 100% deprotection (vide infra). This enabled the quantification of *t*-Boc deprotection from fluorescence intensity data, scaled to the near-plateau slope, as a function of exposure time. A correlation between exposure time and acid yield, thus allowing catalytic chain length calculations, is described in the following.



Acid quantification

The amount of acid generated during irradiation was quantified by "*in polymer*" titration experiments using 2-PE as the strong base (16) and C6 as the indicator. C6, a weak base, fluoresces green when neutral and red when protonated (4), thus giving a clear end point for acid neutralization of 2-PE.

The polymer solutions used for acid quantification were made by directly adding C6 (0.5% of the dry polymer weight) and 2-PE (as molar ratios of TPS-OTf, ranging from 0.0 to 0.5) to the solution used for *t*-Boc quantification (vide supra). The film developing procedure for acid quantification is identical to *t*-Boc quantification. It was found that acid neutralization by the bases, 2-PE and C6, in PMMA films occurs very slowly at room temperature. A PEB (90 °C in the oven for 60 s) in all acid quantification experiments corrected this lag in acid neutralization.

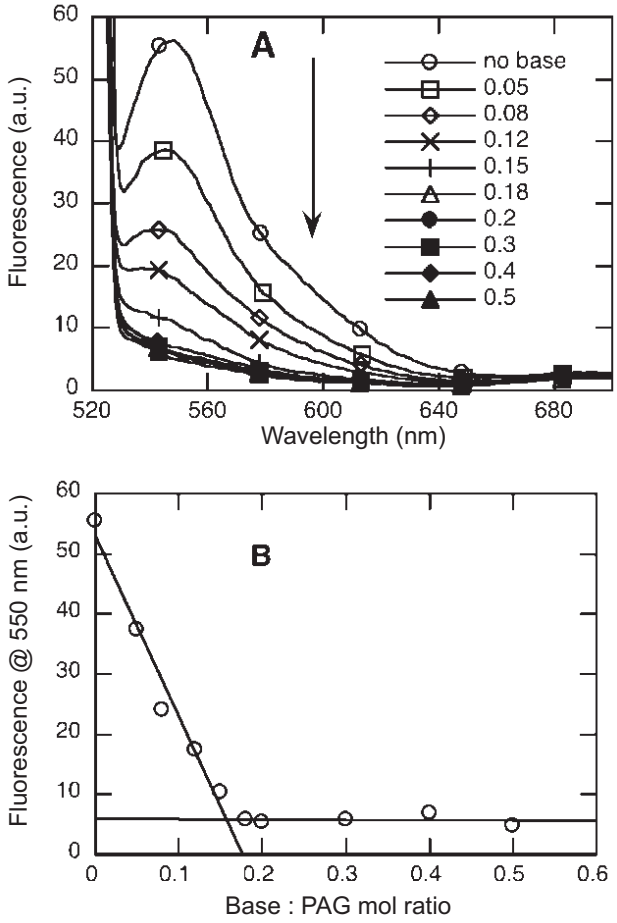
The presence of protonated C6 (i.e., C6-H^+) after exposure was measured by exciting at 510 nm, where C4 does not absorb. The fluorescence intensity decreased to baseline levels as the concentration of 2-PE in the casting solutions increased. Separate linear fits of the fluorescence intensity at 550 against of 2-PE concentration for both decreasing and baseline regions intersect at the neutralization point, thus providing a readily accessible end point. A correlation between exposure time and acid yield is constructed from neutralization point measurements at different exposure times (vide infra).

Fig. 1. The UV–vis absorption of typical PMMA thin films containing various additives. Legend: TPS-OTf = 3 wt.%, C4-*t*-Boc = 10 wt.%, and C6 = 0.5 wt.% of the dry PMMA weight, e.g., 3 wt.% would mean 3 g for 100 g of dry PMMA. PMMA (○), PMMA + TPS-OTf (□), PMMA + TPS-OTf + C4-*t*-Boc (◇), PMMA + TPS-OTf + C4-*t*-Boc + C6 (×). The scale on the right corresponds to the exposure tool spectrum.

Results

The objective of the present work is to establish a new useful methodology for the determination of the amplification chain length for *t*-Boc deprotection under typical lithographic conditions. An important requirement for these studies is the correct matching of absorbances at 249 nm, the exposure wavelength. The absorption spectra of typical samples, averaged over three films, as well as the exposure dose profile are shown in Fig. 1. All measurements were carried out in PMMA films, spin-coated from 2-heptanone containing 15 wt.% PMMA and various other components. The films had approximately the same thickness (vide supra).

The rest of this section is divided according to the two types of measurements carried out: quantification of acid generation by titration using C6 as the indicator and removal of *t*-Boc protecting groups.



Acid quantification

Under the conditions of Fig. 1, from the fraction of light absorbed by the resist film at 249 nm, the following absorption distribution was calculated: TPS-OTf absorbs 44.1% while C4-*t*-Boc and C6 absorb 44.3% and 7.7%, respectively.

The titration strategy relies on the quantitative addition of small and variable amounts of 2-PE, acting as the strong base, at a constant concentration of TPS-OTf. The base (2-PE) does not show significant absorption at 249 nm. Figure 2A shows the decrease in fluorescence as different amounts of base are used for a series of samples exposed for 20 s. The fluorescence spectra were obtained using 510 nm excitation, a wavelength where the neutral C6 does not absorb. Figure 2B shows the C6-H^+ fluorescence intensity at 550 nm (C4 does not fluoresce at this wavelength). By detecting the ratio of base to PAG where the onset of fluores-

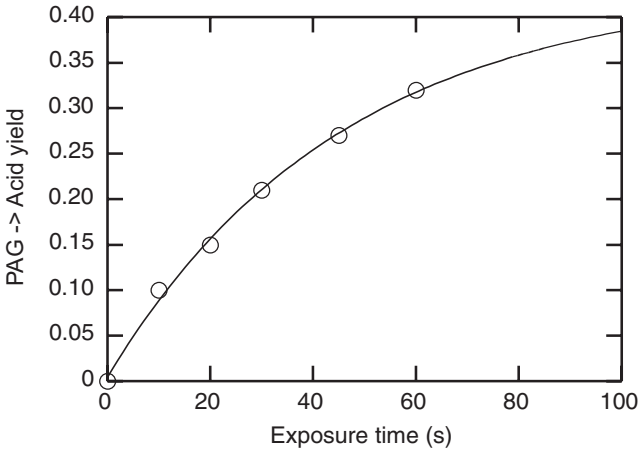
Fig. 2. Typical in-polymer titration experiment. (A) Fluorescence spectra (λ_{exc} = 510 nm) of C6-H^+ in PMMA, 3 wt.% TPS-OTf, and 2-PE in a different molar ratio to TPS-OTf (see legend inset in the figure), after 20 s of exposure. (B) Fluorescence intensity measured at 550 nm as a function of base to PAG mol ratio, i.e., 2-PE:TPS-OTf.



cence occurs, it is possible to evaluate the amount of acid generated for a given 249 nm exposure time.

We note that after exposure at 249 nm the samples were subject to a PEB for 60 s at 90 °C. This PEB had two purposes. First, to match the protocol used in the deprotection studies (vide infra), and the second and most important, to speed up the diffusion of H^+, because in PMMA films acid diffusion leading to protonation of C6 can take over 1 h at room temperature, while at 90 °C this process is complete in less than 1 min. Control experiments show that the presence of C4-*t*-Boc (added for absorbance matching) does not interfere with these experiments; clearly, both 2-PE and C6 are sufficiently strong bases that no deprotection occurs if base is present.

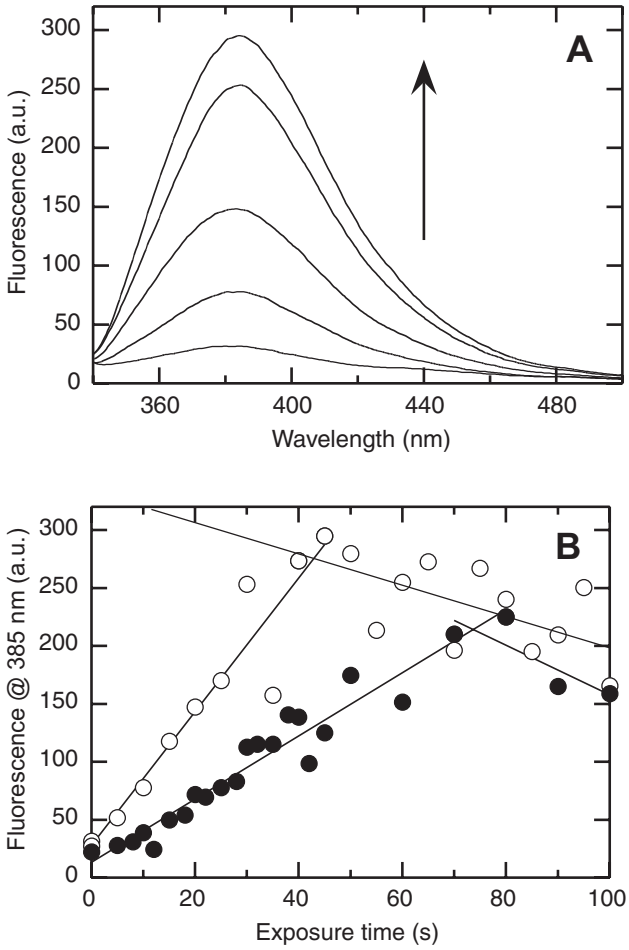
Similar results can be obtained for various irradiation times, and from these data a plot of acid yield as a function of exposure time can be constructed. It should be noted that this plot is specific for a given PAG and light intensity and for a constant fraction of the incident light absorbed by the PAG (Fig. 3).

Fig. 3. Yields of H^+ from TPS-OTf (3 wt.%) in PMMA films as a function of the exposure time at 249 nm shown as a fraction of molar PAG loading.

Deprotection studies

The PEB of samples containing C4-*t*-Boc, but with no added base, led to deprotection (Scheme 2, rxn. B) and an increase in fluorescence at ~385 nm as the highly fluorescent C4 is formed. The deprotection of C4-*t*-Boc as a function of exposure time is illustrated in Fig. 4 for a 60 s PEB. Fluorescence measurements were taken at room temperature following rapid cooling of the sample on a metal surface.

Our experiments were performed using an aluminum plate for PEB, held in an oven at 90 °C; that is, not only the surface, but also the air surrounding the sample were at 90 °C. This is not common practice in industry, where a 90 °C bake usually means that the sample is placed on a surface held at 90 °C, but exposed also at room temperature on the film side of the sample. A comparison of both conditions is shown in Fig. 4B. Clearly, the real temperature of the sample is lower in the open bake, i.e., hotplate, normally used in industry. The scatter in plots of this type (Fig. 4B) likely results from the fact that each point is the measurement of a separate exposure and PEB on a different film (the same applies to the plot in Fig. 2B).



Increasing fluorescence intensity was also recorded with increasing PEB time, although the dependence is not linear; for example, between 30 and 90 s, the amount of C4 formed does not triple, but only increases by about 70%.

Discussion

Deprotection is assumed complete when the near-plateau region of plots such as those shown in Fig. 4B is attained. This assumption is based on thermogravimetric analysis (TGA) previously reported for C4-*t*-Boc (9) and the study of *t*-Boc deprotection using IR spectroscopy, which shows a complete disappearance of the *t*-Boc signal under similar conditions (14, 16). Fluorescence calibration curves using known amounts of C4 were attempted, but this methodology was not successful. For example, in equimolar concentrations with similar development conditions, the fluorescence of films containing C4 was less intense than those containing C4-*t*-Boc (following complete deprotection). The lower fluo-

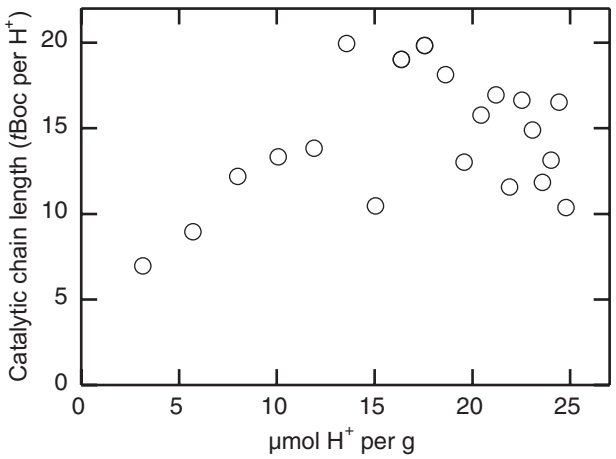
Fig. 4. (A) Increase in fluorescence intensity (λ_{exc} = 320 nm) owing to the formation of C4 (i.e., deprotected C4-*t*-Boc) with increasing exposure time: (from bottom) 0, 10, 20, 30, and 45 s. PEB is constant in this case, i.e., oven baked at 90 °C for 60 s. (B) Fluorescence intensity (λ_{mon} = 385 nm) as a function of exposure time comparing oven (○) and hotplate (●) PEB, both at 90 °C for 60 s.

rescence intensity of C4 (cf. deprotected C4-*t*-Boc) may be a result of C4 clusters forming in PMMA after spin coating from solution. It would appear that aggregation can be prevented by in situ production of the dye.

Plots such as those shown in Fig. 4B normally show a small depletion slope after the anticipated plateau region is reached. This may result from the acid that negatively affects the efficiency of C4 fluorescence (17), or simply that once deprotected, the C4 molecules aggregate to less fluorescent clusters. Nonetheless, linear fits were successfully applied to the depleting plateau as well as the increasing fluorescent region. Consequently, the intercept of the two linear fits is the shortest exposure time leading to complete deprotection (see Table 1). The correlation between exposure time and acid yield (see Fig. 3) allowed the determination of the catalytic chain lengths at the onset of complete deprotection, also tabulated in Table 1.



These catalytic chain lengths are low when compared with previously reported values, some of which are as high as 1000 *t*-Boc cleavages per proton (14). This is expected when

considering the differences between the systems studied. Most importantly, the *t*-Boc groups in our experiments are very dilute in comparison to the density of the protecting groups found in actual polymer resists. Approximately 3.3% of the sample weight is *t*-Boc in our system, the remainder is mainly inert PMMA, well below its T_g, while in actual polymer resists the protecting group can account for as much as 45% of the total sample weight. In our case this means the protons have to migrate through PMMA to continue the catalytic deprotection process, obviously lowering the chain length.

While the chain lengths are quite different, it is still possible to compare acid diffusion in both systems. Assuming spherical diffusion of acid and a matrix density of 1.15 g/mL (same as bulk PMMA), we can calculate an average proton diffusion radius of 27 Å to deprotect 19 groups, i.e., after a 60 s PEB at 90 °C in an oven. A value of approximately 50 Å was reported when a proton deprotects 1000 units of poly(4-*tert*-butoxycarbonyloxystyrene) (14), i.e., of the same order of magnitude as our results. Interestingly, these diffusion radii (3–5 nm) are within an order of magnitude of the anticipated feature sizes in the near future (30–90 nm).

It is also possible to plot catalytic chain length at varying acid concentrations (Fig. 5) with the following data analysis: CCL = (*t*-Boc:PAG)($\varphi_{t\text{-Boc}}/\varphi_{acid}$), where CCL is the catalytic chain length in mol of *t*-Boc deprotected per mol of photogenerated acid, *t*-Boc:PAG is the initial molar ratio of C4-*t*-Boc to PAG (TPS-OTf in our case), $\varphi_{t\text{-Boc}}$ is the

© 2005 NRC Canada

deprotection efficiency calculated from fluorescence intensity data (scaled to the near-plateau slope, see Fig. 4B), and φ_{acid} is the acid conversion efficiency from the PAG (see Fig. 3).

It is useful to see the efficiency of deprotection when either the proton or *t*-Boc is the limiting reagent. A small decrease in catalytic chain length after quantitative *t*-Boc deprotection is expected since the number of events is held constant while the catalyst concentration is increased; this decrease is apparent at proton yields above 15 μmol/g, even if the dispersion of the data tends to mask this effect. The more interesting result happens when the acid is the limiting reagent. In this case, one might expect the catalytic chain length to be equal, or even higher, than the conditions when total deprotection is first achieved, i.e., as we approach the intercept in Fig. 4B. While the data is accompanied by a considerable uncertainty, there is a clear increase in catalytic chain length from the lower acid concentrations to the point of quantitative *t*-Boc cleavage. This lower chain length when *t*-Boc groups are in excess is counterintuitive; the proton has the "choice" of more *t*-Boc groups to deprotect without competition from other acids in these conditions.

We propose that the unusual increase in catalytic chain length at low acid concentrations in Fig. 5 is due to base contamination. The presence of air-borne base is common in chemistry laboratories, and is frequently a problem in industries employing microlithography based on PAGs (1, 2). Thus, some acid is used in a sacrificial manner to neutralize unwanted base. At low acid concentrations this has significant impact on the chain length, while at high acid concentrations the amount of sacrificial acid used is too small to impact on the overall result.

Conclusion

A novel method was developed to measure catalytic chain lengths for *t*-Boc deprotection in polymer films using fluorescent probes for both acid and deprotection yields. We used fluorescence, a very sensitive spectroscopic technique, as a tool to characterize the processes occurring in the polymer film. C6 and C4-*t*-Boc proved to be excellent probes, with considerable shifts in their absorbance and fluorescence spectra after protonation and deprotection, respectively, thus allowing easy monitoring; further, the emission spectra of these two probes are very distinct, readily allowing selective monitoring. The lower catalytic chain lengths obtained in this study apply to the low concentration of *t*-Boc group in the film. The protocol developed will be examined further and applied to resists containing polymers with pendant *t*-Boc protected groups. For the catalytic chain length, we obtained values in the 14–22 range depending on the PEB conditions.

Metal-catalysed tandem metathesis–hydrogenation reactions for the synthesis of carba analogues of cyclic peptides[1]

Amanda N. Whelan, Jomana Elaridi, Roger J. Mulder, Andrea J. Robinson, and W. Roy Jackson

Abstract: Dicarba cyclic peptide analogues of the cystine-containing octapeptides octreotide, lanreotide, and vapreotide, all known somatostatin analogues, have been synthesized via an on-resin homogeneous metal-catalysed sequence involving ruthenium-catalysed ring-closing metathesis followed by rhodium-catalysed hydrogenation.

Key words: dicarba-analogues of cystine-containing peptides, octreotide, vapreotide, and lanreotide; tandem ring-closing metathesis and hydrogenation.

Résumé : Des peptides cycliques dicarbonés analogues de la cystine contenant les octapeptides octréotide, lanréotide et vapréotide, tous connus comme étant des analogues de la somatostatine, ont été synthétisés sur résine via une série de catalyses homogènes impliquant une métathèse de fermeture de cycle catalysée par du ruthénium et une hydrogénation catalysée par du rhodium.

Mots clés : analogues dicarbonés de la cystine contenant des peptides, octréotide, vapréotide et lanréotide; réaction tandem de fermeture de cycle par métathèse et hydrogénation.

Introduction

Cystine bridges are common structural motifs in naturally occurring cyclic peptides. In some cases, as in spiruchostatin A (1), the disulphide bridge acts as a reactive functional group undergoing reduction within the cell to release metal-chelating thiol groups (2, 3). In many other cases, however, the cystine bridge serves only a skeletal, structural role, maintaining secondary and tertiary structure and may be replaced with a nonreducible structural mimic without significantly affecting biological activity (4). Indeed, thioether linkages (-S–CH_2-) (5) and the all carbon (-CH_2–CH_2-) bridge (6) have both been successfully implemented as cystine (-S–S-) isosteres producing peptides with enhanced biostability.

The cyclic peptide octreotide **1a** (7), a synthetic analogue of the tetradecapeptide somatostatin, has one cystine bridge that is remote from the receptor binding site. When labelled with ^{111}In, it is marketed as OctreoScan® (8) and used for the imaging of neuroendocrine tumours (9). It has also been conjugated with ^{123}I, ^{64}Cu, and ^{99m}Tc (10). The ^{99m}Tc radionuclide possesses a convenient physical half life ($t_{1/2}$ = 6 min), an attractive radiation profile, is inexpensive, and readily available as pertechnate ($^{99m}TcO_4^-$).[3] Incorporation of this isotope into cystine-containing peptides, however, is often complicated by the need for a reductive step to generate Tc^{5+} for stable chelate formation (11). In the case of octreotide, a concomitant reduction of the disulphide bridge opens the cyclic peptide and results in the loss of receptor binding affinity (12). This problem is not exclusive to octreotide and also occurs during the Tc labelling of other cyclic peptides containing cystine bridges, including the octreotide analogues lanreotide **2a** and vapreotide **3a**. Given the high desirability to label these peptides with technetium, the replacement of the reductively labile disulphide bridge with a carbon-based manifold has been investigated leading to the dicarba analogues **1b**, **2b**, and **3b**. This structural alteration would be inert to cellular reductases and also with-

stand chemical reducing agents, such as stannous chloride, used in the preparation of Tc-labelled radiopharmaceuticals.

A highly generic, on-resin, tandem-homogeneous catalysis strategy has been devised, which involves: (*i*) construction of the linear peptide sequence replacing cysteine residues with allyl glycine; (*ii*) Ru(II)-catalysed metathesis of the allyl groups to affect carbocycle formation; and (*iii*) Rh(I)-catalysed homogeneous reduction of the newly formed olefin to yield the desired sp^3-hybridized bridge (13) (Scheme 1).

Scheme 1.

Grubbs catalysts (14) have previously been used to facilitate the formation of cyclic peptides via metathesis (15), but only Vederas and co-workers (16), in a recent paper targeting oxytocin, have used bis(allyl glycine) containing peptides to form dicarba mimics of the cystine bridge. We believe that the protocol outlined in this paper demonstrates some clear advantages over the previously published method. It is also highly generic and can be applied to any peptide containing a cystine bridge.

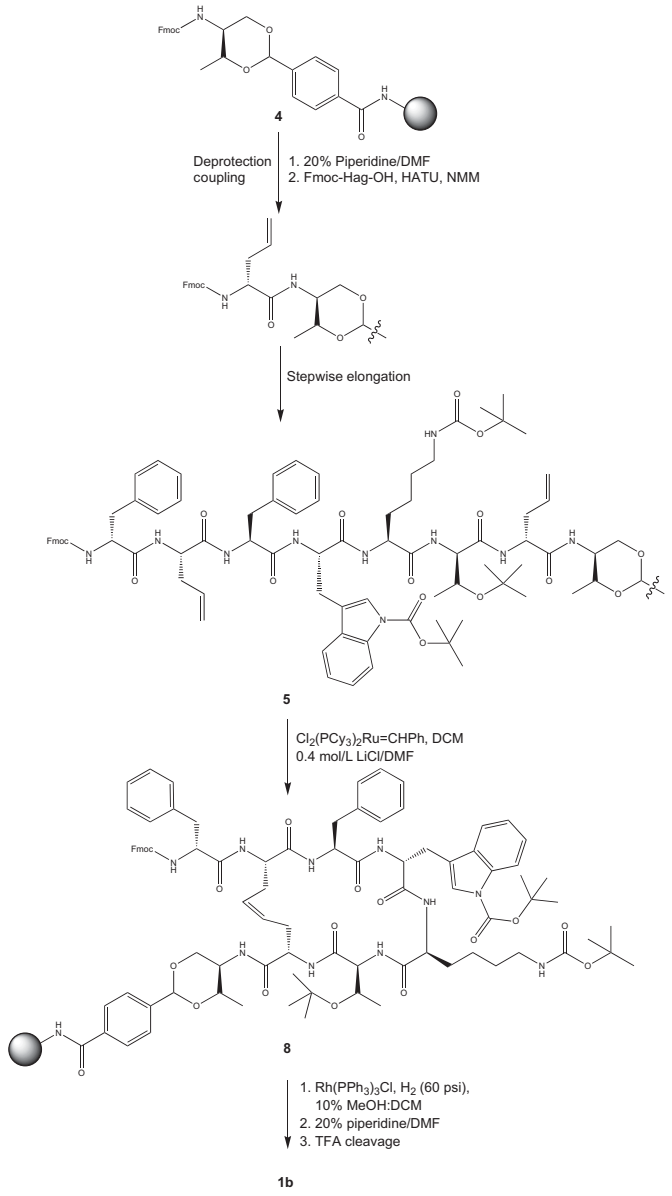
Results and discussion

Synthesis of linear peptides

The protocol described utilizes the non-proteinaceous amino acid allyl glycine, which we have previously reported can be conveniently generated in both enantiomeric forms, via Rh(I)-catalysed hydrogenation of α-*N*-acyl dienamides with excellent stereoselectivity (95% ee) and yield (90%) (17). It is also commercially available, albeit at high cost.

The synthesis of dicarba-octreotide analogue **1b** also requires a second non-proteinaceous residue, Fmoc-protected threoninol. This residue is readily formed by the reduction of the protected amino acid threonine to the corresponding alcohol, although it is also commercially available. The resultant diol is functionalized as the *p*-carboxybenzaldehyde acetal in preparation for attachment to the resin.

The linear peptide precursor of the dicarba-octreotide analogue was synthesized on Rink amide resin using a modified solid-phase protocol described by Hsieh and co-workers (18). The above described acetal is attached to the resin using the coupling reagents DIC and HOBt to give **4**. The remaining sequence was constructed manually using standard solid-phase peptide synthesis techniques, utilizing Fmoc-protected amino acids and the coupling reagents HATU and NMM (Scheme 2). Intermediates were carried through without purification or characterization up to the octapeptide **5**. A sample of the linear peptide was obtained by cleavage from the resin and was determined to be of >95% purity by reverse-phase analytical chromatography and had the required molecular mass by mass spectral analysis.



The resin-bound linear peptide precursors for the synthesis of dicarba-analogues of lanreotide **2b** and vapreotide **3b** were also prepared on Rink amide resin (Scheme 3). Use of this resin allowed the direct generation of the required C-terminal amide found in **2b** and **3b** upon acid cleavage from the resin. All couplings were accomplished utilizing HATU and NMM. After complete sequence construction, a small sample was cleaved from the resin and the presence of the desired peptide was confirmed by mass spectral analysis.

Cyclisation by ring-closing metathesis of the linear peptides

Ring-closing metathesis was carried out using the resin-attached linear peptides **5–7** to eliminate any potential problems arising from dimerization and (or) poor peptide solubility.

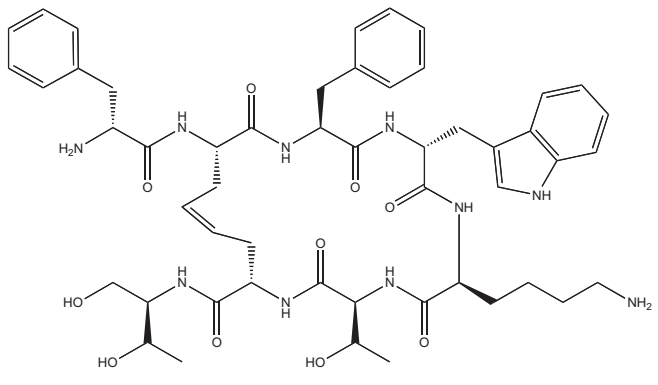
Scheme 2.

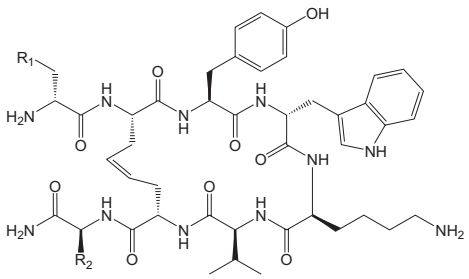


Exposure of the fully protected allyl glycine containing octreotide sequence **5** to the ruthenium benzylidene complex $Cl_2(PCy_3)_2Ru$=CHPh (Grubbs catalyst) (14) resulted in formation of the carbocycle **8** in 65% yield[4] (Scheme 2). It was necessary to react the peptide whilst fully protected as it was found that exposed amino and carboxylate groups prevented metathesis, in agreement with previous observations with other systems (19). To prevent aggregation of the resin-tethered peptide during the metathesis reaction, it was vital that a salt be added, in this case a solution of lithium chloride in DMF. Also essential for complete reaction were extended reaction times; reaction times less than 48 h yielded a significant amount of starting material. Significantly, no oligomerization or dimerization by acyclic diene metathesis (ADMET) (20) was observed.

Scheme 3.

On completion of the metathesis, an aliquot of peptide was cleaved from the resin for analysis. Analytical LC–MS analysis of the cleaved material revealed one major product with molecular mass consistent with that of **9** and a pure sample (>98%) was obtained in 46% yield after purification by preparative HPLC.

9



The geometry of the newly formed olefinic bond of **9** was investigated by NMR spectroscopy. The olefinic protons are represented in the ^{1}H NMR spectrum by a broad and ill-

[4] Yields of peptides were determined after cleavage of the peptide from the resin and calculated using an average peptide loading of 0.71 mmol/g of resin.

© 2005 NRC Canada

resolved signal, centred on 5.38 ppm, which integrates to two hydrogens. COSY and TOCSY experiments correlated this signal to both methylene groups adjacent to the newly formed carbon–carbon double bond (2.20/2.36 and 2.27 ppm). Whilst coupling constants could not be accurately extracted from the one-dimensional ^{1}H NMR spectrum or from the phase-sensitive COSY spectrum, simulation[5] of the NMR signals using the estimates of the coupling constants from these spectra indicates that the newly formed olefin is cis in geometry. The simulated spectrum that achieved very good similarity with the experimental data was obtained using a vicinal olefinic coupling constant of 10.2 Hz, which is consistent with the cis geometry. Good agreement between the simulated and experimental spectra could not be achieved using values of 14–19 Hz, which would be consistent with a trans double bond.

Cyclisation of the resin-attached dicarba-lanreotide **6** and dicarba-vapreotide **7** precursors proceeded via the same technique as described above (Scheme 3). The reactions did, however, require longer reaction times, with both reactions reaching completion after 96 h. In each case, mass spectral analysis of the Fmoc- and resin-cleaved peptides showed only the desired product and no remaining linear precursor or higher oligomers. Preparative HPLC of the crude unsaturated cyclic peptides **10** and **11** resulted in high purity material albeit at reduced yield. The lanreotide **10** and vapreotide **11** analogues were subsequently isolated in 25% and 2% yield with 98.6% and 99.2% purity, respectively.

10 R_1 = 2-naphthyl, R_2 = CH(OH)CH$_3$ **11** R_1 = Ph, R_2 = CH$_2$(3-indolyl)

Reduction of olefinic dicarba-peptides

Reduction of the newly installed olefinic bond is necessary to complete the synthesis of the dicarba analogues of octreotide **1b**, lanreotide **2b**, and vapreotide **3b**. A homogeneous hydrogenation catalyst, the Rh(I)-based Wilkinson's catalyst, was chosen to facilitate the reduction of the resin-bound material. This catalyst was chosen for its ease of use and facile removal from resin-bound peptides.

Reduction in dichloromethane alone, a solvent preferred for efficient swelling of the Rink amide resin but non-ideal for hydrogenation, was found to be exceptionally slow and often incomplete. The addition of a coordinating solvent subsequently enabled quantitative reduction (21). Traditional hydrogenation solvents such as methanol have very poor resin-swelling abilities, resulting in limited availability of reactive sites. Rh(I)-catalysed hydrogenation in 10% methanol – dichloromethane was investigated and this system was found to effect quantitative reduction at room temperature under mild hydrogen pressure (60 psi, 1 psi = 6.894 757 kPa). The peptide **1b** was purified using reverse-phase preparative chromatography to give material of >98.9% purity in 26% isolated yield and characterized using mass spectrometry and ^{1}H NMR spectroscopy.

Table 1. ^{1}H NMR chemical shifts (ppm) of dicarba-octreotide analogue **1b** (500.13 MHz, DMSO-d_6).

	NH	α-H	β-H	Others

Hag[7]	7.66	4.22	1.58	γ-H 4.10
Thr(ol)[8]	7.15	3.58	3.82	γ-H 0.95
				δ-H 2.62

The hydrogenation conditions established for the resin-tethered octreotide analogue were then applied to the olefinic dicarba analogues of lanreotide **12** and vapreotide **13** yielding the saturated carbocycles **2b** and **3b** as indicated by MS and NMR (Scheme 3). Preparative HPLC again gave significantly reduced mass recoveries of highly pure materials, 4% and 20% yields, respectively, for **2b** and **3b**, with purities of >97%.

Molecular modelling studies of carbocycle **1b** (22) based on X-ray diffraction data of octreotide (23) suggests that the structural modification should not significantly perturb the Phe^7-D-Trp^8-Lys^9-Thr^{10} binding domain and hence somatostatin receptor affinity. A detailed NMR study is in progress and ^{1}H chemical shifts for **1b** and its unsaturated analogue **9** are summarized in Tables 1 and 2, respectively. ^{1}H NMR data for the dicarba-lanreotide **2b** is shown in Table 3. The preliminary data suggests the presence of a β-turn, in agreement with the results of molecular modelling studies.

Competitive binding experiments of the six dicarba analogues **1b**–**3b** and **9**–**11** against ^{111}In-DOTA-octreotate for the sst2-expressing AR42J cell membranes is currently being investigated. Further work will involve testing the binding affinity of the new dicarba somatostatin analogues for other somatostatin receptor sub-types and the effect of conjugating bifunctional ligands on their affinity.

[5] Simulation was performed using Bruker-Biospin's NMR-Sim® v3.5. Spectral simulations were performed using the same acquisition and processing parameters that were used to acquire the original data.

Conclusion

The methodology described in this paper is a highly efficient, generic, on-resin route to carbon-based somatostatin mimics, which could find wide-spread use in peptidomimetic research. Our group is currently applying this methodology to other peptides, particularly cystine-containing cyclic peptides.

Experimental

Instrumentation and general procedures

^{1}H and ^{13}C NMR spectra were recorded on a Bruker DPX300 spectrometer operating at 300.13 MHz (^{1}H) and 75.48 MHz (^{13}C).

The NMR spectra of the peptides were recorded in DMSO-d_6 (referenced to δ_H 2.49 ppm) at 298 K using a Bruker DRX500 spectrometer at 500.13 MHz for ^{1}H using a 5 mm inverse-detection ^{1}H–^{13}C–^{15}N TXI probe with z gradients. Pulse sequences are from the Bruker XWIN-NMR v3.5 library. Chemical shift data were derived from a combination of the COSY45, COSY, and TOCSY experiments. Assignments were made using standard peptide NMR assignment techniques (24).

The two-dimensional COSY45 experiments were performed in magnitude mode using gradient selection and a 45° pulse: 4096 points in t_2 and 512 points in t_1 were acquired with 16 scans per t_1 point and a 0.8 s relaxation delay between scans. The spectral width was 6000 Hz in both dimensions. 2048 Points in t_2 and zero-filling to 1024 points in t_1 were used. An unshifted sine-bell window function was applied in both dimensions prior to Fourier transformation.

The two-dimensional COSY experiments were performed in phase-sensitive mode using echo/antiecho–TPPI gradient selection: 4096 points in t_2 and 512 points in t_1 were acquired with 64 scans per t_1 point and a 0.8 s relaxation delay between scans. The spectral width was 6000 Hz in both dimensions. Zero-filling to 4096 points in t_2 and forward linear prediction to 1024 points and zero-filling to 4096 points in t_1 were used. An unshifted sine-bell window function was applied in both dimensions prior to Fourier transformation.

The two-dimensional TOCSY experiments were performed in phase-sensitive mode using echo/antiecho–TPPI gradient selection: 4096 points in t_2 and 512 points in t_1 were acquired with 32 scans per t_1 point and a 0.8 s relaxation delay between scans. The spectral width was 6000 Hz in both dimensions. The TOCSY mixing time was 120 ms. 2048 Points in t_2 and zero-filling to 1024 points in t_1 were used. A π/4-shifted, sine-squared-bell window function was applied in both dimensions prior to Fourier transformation.

The two-dimensional NOESY experiments were performed in phase-sensitive mode using States gradient selection: 4096 points in t_2 and 512 points in t_1 were acquired with 64 scans per t_1 point and a 0.8 s relaxation delay between scans. The spectral width was 6000 Hz in both dimensions. The NOESY mixing time was 400 ms. 2048 Points in t_2 and zero-filling to 1024 points in t_1 were used. An exponential window function of 3.0 Hz was applied in the t_2 dimension and a π/4-shifted, sine-squared-bell window function was applied in the t_1 dimension prior to Fourier transformation.

Positive electrospray mass spectral data were obtained on a VG Platform mass spectrometer using a cone voltage of 50 V.

Analytical HPLC spectra were recorded on a Waters Alliance 2695 Separations Module equipped with a Waters PDA 2996 detector monitoring 190–300 nm. Components were separated on either an Altima 150 mm × 4.6 mm C18 5 μm

packed column or a Waters 50 mm × 4.6 mm Xterra C18 2.5 μm packed column. Purification via preparative HPLC was achieved using a Shimadzu LC-4A with an SPD-2AS detector (227 nm) and a C18 Altima 250 mm × 22 nm 5 μm packed column.

Solvents were purified, dried, and degassed according to standard procedures. Degassed methanol and dichloromethane were used in hydrogenation reactions. Deuterated chloroform was used as supplied by Merck. Deuterated dimethylsulphoxide (99.96% D, DLM-34) was used as supplied by Cambridge Isotope Laboratories. Chemical reagents, including amino acids, were purchased from Sigma-Aldrich, AusPep, or GL Biochem and were used without further purification. Catalysts were used as received from Strem chemicals. Grubbs catalyst refers to bis(tricyclohexylphosphine)benzylidene ruthenium dichloride. Wilkinson's catalyst refers to chlorotris(triphenylphosphine)rhodium(I). All ruthenium-catalysed metathesis reactions were performed using standard Schlenk techniques under an atmosphere of nitrogen. In all rhodium-phosphine hydrogenations, high purity (<10 ppm of oxygen) hydrogen and argon (supplied by BOC gases) were used and purified by passage through a series of traps to remove water, oxygen, and hydrocarbons.

Synthesis of the linear peptides

Fmoc-L-threoninol p-*carboxybenzacetal*

Fmoc-threoninol (1.0 g, 3.05 mmol), *p*-carboxybenzaldehyde (0.5 g, 3.36 mmol), and a catalytic amount of *p*-toluenesulphonic acid were suspended in dry toluene (70 mL) and stirred at reflux for 20 h using a Dean–Stark apparatus. The solvent was removed under reduced pressure to yield a clear yellow oil, which was extracted into dichloromethane and washed with water and saturated sodium chloride and dried over sodium sulphate. Purification of the yellow oil by flash chromatography (SiO_2, dichloromethane – ethyl acetate, 3:1) yielded the desired acetal (0.71 g, 51%), mp 86–88 °C (lit. value (18) mp 86–88 °C). ^{1}H NMR (300 MHz, $CDCl_3$) δ: 1.29 (d, *J* = 6.4 Hz, 3H, C*H*$_3$), 3.73 (dd, *J* = 10.1, 1.6 Hz, 1H, NHCHC*H*(H)), 4.11–4.27 (m, 4H, C*H*CH$_3$, C*H*$_2$OCO, and NHCHCH(*H*)), 4.51–4.38 (m, 2H, H9 and NHC*H*), 5.57 (d, *J* = 9.9 Hz, 1H, N*H*), 5.65 (s, 1H, OC*H*O), 7.32 (t, *J* = 7.4 Hz, 2H, H2, H7), 7.40 (t, *J* = 7.6 Hz, 2H, H3, H6), 7.62 (d, 2H, *J* = 7.2 Hz, H2′, H6′), 7.63 (d, *J* = 8.4 Hz, 2H, H3′, H5′), 7.77 (d, *J* = 7.3 Hz, 2H, H1, H8), 8.14 (d, *J* = 8.3 Hz, 2H, H4, H5), 10.05 (s, 1H, COO*H*). ^{13}C NMR (75 MHz, DMSO-d_6) δ: 17.78 (*C*H$_3$), 47.45 (C9), 48.90 (NH*C*H), 67.12 (NHCH*C*H$_2$), 72.00 (*C*H$_2$OCO), 75.61 (CHCH$_3$), 100.84 (O*C*HO), 120.07 (C3, C6), 124.74 (C2′, C6′), 126.21 (C2, C7), 127.11 (C4, C5), 127.77 (C1, C8), 129.83 (C4′), 130.30 (C3′, C5′), 141.31 (C4a, C4b), 143.82 (C1′), 143.85 (C8a, C9a), 156.52 (*C*O), 170.94 (*C*OOH). MS (ESI$^+$, DCM–MeOH) *m/z*: 350.2 (M + Na$^+$), $C_{19}H_{21}NO_4Na$.

Peptide synthesis

Linear peptides were synthesized using manual solid-phase peptide synthesis techniques on Rink amide resin, utilizing 3 equiv. each of 9-fluorenylmethoxycarbonyl (Fmoc) protected amino acids and the coupling reagent HATU (*O*-(7-azabenzotriazol-1-yl)-*N*,*N*,*N*′,*N*′-tetramethyluronium hexafluorophosphate) and 6 equiv. of NMM (4-methyl morpholine). Fmoc-L-threoninol *p*-carboxybenzacetal was coupled directly to the resin in the synthesis of **5** using 3 equiv. each of the coupling reagents DIC (diisopropylcarbodiimide) and HOBt (1-hydroxybenzotriazole), as well as 3 equiv. of the acetal.

Upon completion of the synthesis of the linear Fmoc-protected octapeptide, a resin aliquot was removed and the peptide cleaved from the resin with trifluoroacetic acid (9 mL) containing the scavengers ethanedithiol (0.25 mL), thioanisole (0.5 mL), and phenol (0.79 g), as well as water (0.25 mL). The filtrate was concentrated by application of high pressure air. The peptide was precipitated by the addition of ice cold diethyl ether and was extracted into a 50% aqueous solution of acetonitrile and lyophilized to give a white solid that was characterized by mass spectral analysis.

General procedure for ring-closing metathesis

A Schlenk flask was charged with resin-tethered peptide (50–200 mg) to which dry dichloromethane (20 mL) and degassed 0.4 mol/L lithium chloride in dimethylformamide (1 mL) were added and the resin allowed to swell for 1 h before addition of a solution of Grubbs catalyst (20 mol%) in dry dichloromethane. The suspended resin was stirred at 50 °C for a prescribed period of time (48–96 h) and collected via filtration, washed with dichloromethane, dimethylformamide, and methanol, and finally dried in vacuo. An aliquot of the resin was removed and the peptide cleaved from the resin as described previously.

The peptide was purified using preparative reverse-phase high performance liquid chromatography (RP-HPLC) (20%–100% aqueous acetonitrile with 0.1% TFA over 2 h, 10 mL/min). Fractions were collected, lyophilized, and analysed by analytical HPLC, NMR, and mass spectral analysis (Table 4).

© 2005 NRC Canada

General procedure for hydrogenation

A Fischer–Porter tube was charged in a drybox with resin-tethered peptide (50–200 mg), Wilkinson's catalyst (1–5 mg), dry and deoxygenated dichloromethane (9 mL), and dry and deoxygenated methanol (1 mL). The line and reaction vessel were degassed with three vacuum–argon cycles each before the tube was pressurised to 60 psi of hydrogen. The reaction was stirred gently at room temperature overnight. The resin was collected via filtration and washed with dichloromethane, dimethylformamide, and finally methanol, before being allowed to dry in vacuo. An aliquot of the resin was removed and the peptide cleaved from the resin as described previously.

The peptide was purified using preparative reverse-phase HPLC (20%–100% aqueous acetonitrile with 0.1% TFA over 2 h, 10 mL/min). Individual fractions were collected, lyophilized, and analysed by analytical HPLC, NMR, and mass spectral analysis (Table 4). ^{1}H NMR data for dicarba octreotide **1b**, unsaturated dicarba octreotide **9**, and dicarba lanreotide **2b** are reported in Tables 1–3.
