A mixture of aldehyde (2 mmol), amine (4 mmol), and $MgBr_2{\cdot}OEt_2$ (5 mol% in respect to aldehyde) was stirred at room temperature for 5 min. TMSCN (2.4 mmol) was added to this mixture and stirring continued for an appropriate length of time until TLC showed completion of the reaction. The product was extracted three times by 10 mL portions of diethyl ether and the combined etheral phases were washed with brine and dried over sodium sulphate. The solvent was removed under reduced pressure and the product was purified by column chromatography over silica gel using an EtOAc–hexane eluant, if necessary. The isolated yields of the products were 88%–98%. All products were identified by ^{1}H NMR, ^{13}C NMR, IR, and mass spectroscopic methods and the results were compared with those available in the literature.[2]

Selected spectral data

(4-Methoxy-phenyl)-piperidin-1-yl-acetonitrile (3f)

IR (neat, cm^{-1}) ν: 2219, 1513, 1250. ^{1}H NMR (80 MHz, $CDCl_3$) δ: 1.22–1.50 (m, 6H), 2.25–2.50 (m, 4H), 3.65 (s, 3H), 4.61 (s, 1H), 6.77 (d, J = 8 Hz, 2H), 7.27 (d, J = 8 Hz, 2H). ^{13}C NMR (20 MHz, $CDCl_3$) δ: 23.7, 25.5, 50.4, 54.9, 61.9, 113.7, 115.5, 125.3, 128.7, 159.5. MS *m*/*z*: 230 (M^+), 204, 146, 121, 84.

Piperidin-1-yl-thiophen-2-yl-acetonitrile (3h)

IR (neat, cm^{-1}) ν: 3107, 2937, 2368, 1442. ^{1}H NMR (80 MHz, $CDCl_3$) δ: 1.30–1.75 (m, 6H), 2.25–2.70 (m, 4H), 4.85 (s, 1H), 6.80–7.32 (m, 3H). ^{13}C NMR (20 MHz, $CDCl_3$) δ: 23.7, 25.5, 50.7, 58.5, 114.7, 126.2, 126.5, 126.7, 137.8. MS *m*/*z*: 206 (M^+), 122, 97, 84.

(4-Fluoro-phenyl)-piperidin-1-yl-acetonitrile (3i)

IR (neat, cm^{-1}) ν: 2928, 2808, 2224, 1608. ^{1}H NMR (80 MHz, $CDCl_3$) δ: 1.30–1.75 (m, 6H), 2.38–2.45 (m, 4H), 4.72 (s, 1H), 6.89–7.54 (m, 4H). ^{13}C NMR (20 MHz, $CDCl_3$) δ: 23.6, 25.5, 50.6, 63.4, 115.3, 116.4, 129.1, 129.5, 214.8. MS *m*/*z*: 218 (M^+), 217, 134, 123, 107.

4-Phenyl-2-piperidin-1-yl-butyronitrile (3m)

IR (neat, cm^{-1}) ν: 3027, 2937, 2222, 1684. ^{1}H NMR (80 MHz, $CDCl_3$) δ: 1.32–1.80 (m, 6H), 2.03 (t, J = 7 Hz, 2H), 2.20–2.82 (m, 6H), 3.40 (t, J = 8 Hz, 1H), 7.14–7.19 (m, 5H). ^{13}C NMR (20 MHz, $CDCl_3$) δ: 23.9, 25.6, 31.5, 32.2, 50.8, 57.1, 115.6, 126.1, 128.3, 139.8, 215.0. MS *m*/*z*: 228 (M^+), 201, 123, 110.

Antimony(III) chloride impregnated on alumina — An efficient and economical Lewis acid catalyst for one-pot synthesis of dihydropyrimidinones under solvent-free conditions

Kamal. K. Kapoor, Bilal A. Ganai, Satish Kumar, and Charanjeet S. Andotra

Abstract: The antimony(III) chloride impregnated on alumina efficiently catalyses a one-pot, three-component condensation reaction among an aldehyde, a β-ketoester, and urea or thiourea to afford the corresponding dihydropyrimidinones in good to excellent yields. The reactions are probed in microwave (MW), ultrasonic, and thermal conditions and the best results are found using MW under solvent-free conditions.

Key words: Biginelli dihydropyrimidinones synthesis, $SbCl_3$–Al_2O_3, MW, sonication, solid supported.

Résumé : Le chlorure d'antimoine(III) imprégné sur de l'alumine catalyse efficacement la réaction de condensation monotope de trois composants, un aldéhyde, un β-cétoester et une urée ou une thiourée, pour conduire à la formation des dihydropyrimidinones correspondants avec des rendements allant de bons à excellents. Les réactions ont été réalisées sous l'influence de micro-ondes (MO), d'ultrasons ou de la chaleur et on a trouvé que les conditions de micro-ondes, sans solvant, donnent les meilleurs résultats.

Mots clés : synthèse de Biginelli de dihydropyrimidinones, $SbCl_3$–Al_2O_3, micro-ondes, soniquation, supporté sur un solide.

[Traduit par la Rédaction]

Introduction

The dihydropyrimidinones (DHPMs) and their derivatives have attracted considerable interest in organic and medicinal chemistry because of their fascinating array of pharmacological and therapeutic properties such as antiviral, antitumor, antibacterial, and antiinflammatory calcium channel blockers, antihypertensives, α_{1a}-adrenergic antagonists, and neuropeptide Y (NPY) antagonists (1, 2). Moreover, the potent HIVgp–120–CD_4 inhibitor batzelladine alkaloids (3) basically contain a dihydropyrimidine core unit. A simple synthesis of this biologically important pharmacophore was reported (4) by Biginelli in 1893 by one-pot reflux of a β-ketoester, an aromatic aldehyde, and urea in ethanol containing a catalytic amount of HCl. The major drawbacks of this protocol are low yields of products (20%–50%) and less functional group tolerance on the reactants. Consequently, this has led to the discovery of multistep strategies producing somewhat higher yields, but lacking the simplicity of original Biginelli reaction (5). Therefore, this reaction continues to be the focus of the researchers striving to find milder and more efficient procedures for the synthesis of DHPMs. This has led to the development of several synthetic methodologies using various catalysts (6) such as $BF_3{\cdot}OEt_2$, $InCl_3$, $BiCl_3$, $LiCl_4$, $ZrCl_4$, $La(OTf)_3$, $NiCl_2$, $FeCl_3$, KSF, $Yb(OTf)_3$, PPE, $Bi(OTf)_3$, CAN, $CuCl_2$, $CeCl_3$, $Cu(OTf)_2$, Me_3SiI, $LiBr_2$, $MgBr_2$, $InBr_3$, NH_4Cl, $SrCl_2$, silica-sulphuric acid, boric acid, and ionic liquids. However, in spite of their potential utility, many of these methods involve expensive reagents, a stoichiometric amount of catalysts, strongly acidic conditions, longer reaction times, high temperature, unsatisfactory yields, and tedious work-up.

The use of reagents impregnated on inorganic supports (7) offer advantages such as (*a*) simple work-up and product purification, (*b*) enhanced or reduced reactivity of the functional groups, (*c*) selectivity that may be different from that in solution, and (*d*) manipulative simplicity. Among the large number of Lewis acids used in organic synthesis, antimony(III) chloride has not been explored much for its catalytic activity. Recently, synthesis of some novel heterocycles catalyzed by antimony(III) chloride under solvent-free conditions has been reported from our laboratory (8). We wished to explore the use of antimony(III) chloride impregnated on alumina for the synthesis of DHPMs.

The condensation reaction between benzaldehyde (10 mmol), ethyl acetoacetate (10 mmol), and urea (10 mmol) was carried out in a microwave (MW) under solvent-free conditions for 1 min with 0.5 mmol (5 mol%, 0.05 equiv.) of antimony(III) chloride, (*i*) alone and (*ii*) impregnated on different amounts of alumina (1–8 g), which gave yields of 42%, 70%, 96%, 93%, 90%, 74%, 60%, and 45%, respectively, as shown in Fig. 1. In the absence of alumina, the reaction gave a low yield of the product (**4a**). However, increasing the amounts of antimony(III) chloride to 0.1, 0.2, 0.5, and 1.0 equiv. resulted in the formation of an unidentifiable tarry

Fig. 1. The influence of the amount of alumina on the yields of reaction.

material. It is evident that the amount of alumina used for impregnation is decisive in the completion of the three-component reaction. The results reveal that the most appropriate ratio of antimony(III) chloride and alumina is approximately 1:26 (*w*/*w*), which gives 96% isolated yield of **4a**. The decrease or increase of the amount of alumina led to the decrease in the yield of the desired product. It is presumed that the alumina acts as a carrier increasing the surface area of the heterogeneous reaction, and it is very probable that the antimony salt interacts with the oxide groups at the surface of the support forming new active sites on the alumina local structure.

In another set of experiments, when the reaction mixture comprised of benzaldehyde (10 mmol), ethyl acetoacetate (10 mmol), urea (10 mmol), and 5 mol% of antimony(III) chloride (0.5 mmol) impregnated on 3 g of alumina was (*i*) heated at 100 °C on an oil bath without any solvent, a clean conversion to **4a** (95% yield) was noticed in less than 1 h and (*ii*) sonicated in an ultrasonicator in a variety of solvents such as water, tetrahydrofuran, acetonitrile, chloroform, toluene, and THF–H_2O, produced the results summarized in Table 1. From Table 1, acetonitrile appears to be the best solvent (yield 94% in 1 h) of all the solvents tested under similar reaction conditions. The present findings in the ultrasonicator are superior in terms of yield and time to the earlier reported method (6*q*).

Encouraged by these results and to establish the versatility of antimony(III) chloride impregnated on alumina, various substrates were subjected to the optimized condensation reaction and the results are depicted in Table 2.

The efficiency of $SbCl_3$–Al_2O_3 as a Lewis acid catalyst is comparable to those reported in the literature (6), such as BF_3·OEt, $FeCl_3$, $Bi(OTf)_3$, $Yb(OTf)_3$, $InCl_3$, $Sc(OTf)_3$, $YbCl_3$, $MgBr_3$, and $SrCl_2$, as is evident from Table 3. The present catalyst, $SbCl_3$–Al_2O_3, enjoys benefits in terms of easy handling, economy, and simple workup (Scheme 1).

The reaction is believed to proceed through the acylimine intermediate formed in situ by reaction of the aldehyde with urea. The subsequent addition of the β-diketon enolate to the acylimine, followed by cyclization and dehydration, afforded the corresponding DHPMs (Scheme 2).

Conclusion

In conclusion, we have unraveled a newer application of $SbCl_3$ as a Lewis acid supported on alumina for the synthesis of DHPMs.The present catalyst is cheap, easily available, easy to handle, and works efficiently in MW, thermal, and ultrasonic conditions.

Table 1. Various solvents used for the synthesis of **4a** in an ultrasonicator.

Experimental

General

Melting points were measured in open capillaries on a Perfit melting point apparatus and are uncorrected. IR on KBr were recorded on a Bruker-4800 IR spectrometer. ^1H and ^{13}C NMR spectra were recorded on a Bruker AC-200 spectrometer. The mass spectra were obtained on a JEOL D-300 mass spectrometer. TLC was performed on 0.5 mm thick plates using BDH silica gel G as adsorbent and eluted in a 1:1 mixture of EtOAc and petroleum ether. The plates were developed with iodine vapors, 2,4-dinitrophenylhydrazone in acidic methanol solution, and anisaldehyde solution in acidic alcohol. All solvents were distilled before use. Microwave irradiation was carried out in an IFB microwave oven at the 5 power level and the sonication was carried out in a Bransonic-2510 ultrasonic cleaner.

General procedures

Preparation of the catalyst $SbCl_3$–Al_2O_3

To an antimony(III) chloride (2.28 g, 10 mmol) solution in 100 mL of distilled ethanol was added 60 g of neutral alumina. The mixture was stirred at room temperature for 1 h, followed by removal of solvent under reduced pressure on a rotovap. The resultant free-flowing powder was then activated at 110 °C in an oven for 2 h and was used throughout the experimentation.

Typical procedures for the three-component condensation reaction

(i) Under microwave irradiation

A mixture of ethyl acetoacetate (10 mmol), aryl aldehyde (10 mmol), urea (10 mmol), and the 3.1 g of the catalyst was placed in a 100 mL beaker. It was then irradiated in an IFB microwave oven at the 5 power level until the completion of reaction as monitored by TLC. The reaction mixture was cooled to room temperature and ethyl acetate (100 mL) was added, stirred well, and filtered through Celite under suction. The organic layer was washed twice with water (30 mL) and brine (30 mL). After drying over anhydr. Na_2SO_4, the solvent was evaporated under reduced pressure and the residue was recrystallized from ethanol to afford the pure product.

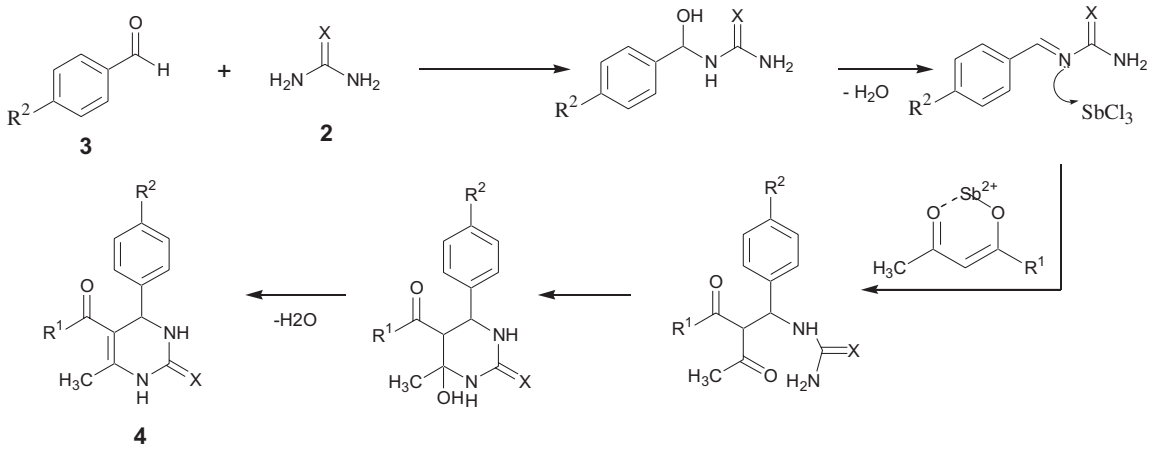
Scheme 1.

(ii) Under thermal conditions



A mixture of ethyl acetoacetate (10 mmol), aryl aldehyde (10 mmol), urea (10 mmol), and 3.1 g of the catalyst was placed in a 100 mL round bottom flask was heated on an oil bath at 100 °C until the completion of the reaction as monitored by TLC. The reaction mixture was cooled to room temperature and worked up in the same manner as mentioned in (*i*).

(iii) Under sonication

A mixture of ethyl acetoacetate (10 mmol), aryl aldehyde (10 mmol), urea (10 mmol), and the 3.1 g of catalyst was

Scheme 2.

placed in a 100 mL round bottom flask containing 15 mL of acetonitrile. After the completion of the reaction (TLC), the solvent was removed and ethyl acetate was added to the residue and worked up in the same manner as mentioned in (*i*).

5-Ethoxycarbonyl-6-methyl-4-phenyl-3,4-dihydropyrimidin-2(1*H*)-one (4a)

Melting point 203 to 204 °C. IR (KBr, cm^{-1}): 3233, 3110, 2975, 2938, 1725, 1708, 1650, 1595. ^{1}H NMR (DMSO-d_6) δ: 1.12 (t, *J* = 7.2 Hz, 3H), 2.29 (s, 3H), 4.02 (q, *J* = 7.2 Hz, 2H), 5.19 (d, *J* = 2.7 Hz), 7.27–7.42 (m, 5H), 7.75 (d, *J* = 2.7 Hz, 1H), 9.21 (s, 1H). ^{13}C NMR (DMSO-d_6, 75 MHz) δ: 14.1, 17.9, 54.2, 59.3, 99.5, 126.4, 127.4, 128.5, 145.0, 148.5, 152.3, 165.5. MS *m*/*z*: 261 (M^+ + 1).

5-Ethoxycarbonyl-4-(4-methoxyphenyl)-6-methyl-3,4-dihydropyrimidin-2(1*H*)-one (4b)

Melting point 202 to 203 °C. IR (KBr, cm^{-1}): 3222, 3095, 2932, 2831, 1713, 1650, 1615, 1584, 1516. ^{1}H NMR (DMSO-d_6) δ: 1.09 (t, *J* = 7 Hz, 3H), 2.23 (s, 3H), 3.70 (s, 3H), 3.97 (q, *J* = 7 Hz, 2H), 5.09 (d, *J* = 3.1 Hz), 6.87–7.15 (m, 4H), 7.66 (s, 1H), 9.12 (s, 1H). ^{13}C NMR (DMSO-d_6) δ: 15.0, 18.6, 54.3, 55.9, 60.1, 100.5, 114.6, 128.3, 138.0, 148.9, 153.1, 159.4, 166.3. MS *m*/*z*: 291 (M^+ + 1).

4-(4-Chlorophenyl)-5-ethoxycarbonyl-6-methyl-3,4-dihydropyrimidin-2(1*H*)-one (4c)

Melting point 213 to 214 °C. IR (KBr, cm^{-1}): 3230, 3091, 2974, 2935, 1700, 1642. ^{1}H NMR (DMSO-d_6) δ: 1.10 (t, *J* = 6.7 Hz, 3H), 2.24 (s, 3H), 3.97 (q, *J* = 6.7 Hz, 2H), 5.14 (d, *J* = 3.1 Hz), 7.23–7.38 (m, 4H), 7.76 (s, 1H), 9.23 (s, 1H). ^{13}C NMR (DMSO-d_6) δ: 14.9, 18.7, 54.3, 60.1, 99.7, 129.0, 129.2, 132.7, 144.6, 149.6, 152.8, 166.2. MS *m*/*z*: 295 (M^+ + 1).

4-(4-Fluorophenyl)-5-ethoxycarbonyl-6-methyl-3,4-dihydropyrimidin-2(1*H*)-one (4d)

Melting point 177 to 178 °C. IR (KBr, cm^{-1}): 3235, 3090, 2975, 2930, 1705, 1645. ^{1}H NMR (DMSO-d_6) δ: 2.0 (t, *J* = 6.9 Hz, 3H), 2.26 (s, 3H), 3.99 (q, *J* = 6.9 Hz, 2H), 5.15 (d, *J* = 3.1 Hz), 7.21–7.40 (m, 4H), 7.76 (s, 1H), 9.23 (s, 1H). ^{13}C NMR (DMSO-d_6) δ: 14.5, 17.5, 53.3, 60.1, 99.1, 116.0, 129.2, 142.7, 148.6, 153.6, 165.2.

5-Ethoxycarbonyl-6-methyl-4-(4-nitrophenyl)-3,4-dihydropyrimidin-2(1*H*)-one (4e)

Melting point 208–211 °C. IR (KBr, cm^{-1}): 3232, 3108, 2977, 1701, 1641, 1591, 1522. ^{1}H NMR (DMSO-d_6) δ: 9.37 (s, 1H), 8.20–7.50 (m, 4H), 7.91 (d, *J* = 2.46 Hz, 1H), 5.27 (d, *J* = 1.6 Hz, 1H), 3.98 (q, *J* = 7.1 Hz, 2H), 2.27 (s, 3H), 1.09 (t, *J* = 7.1 Hz, 3H). ^{13}C NMR (DMSO-d_6) δ: 164.9, 151.9, 151.7, 149.3, 146.6, 127.5, 123.7, 59.3, 53.6, 17.8, 13.9. MS *m*/*z*: 306 (M^+ + 1).

5-Ethoxycarbonyl-6-methyl-4-(4-hydroxyphenyl)-3,4-dihydropyrimidin-2(1*H*)-one (4f)

Melting point 233–235 °C. IR (KBr, cm^{-1}): 3510, 3276, 3125, 2970, 1682, 1642. ^{1}H NMR (DMSO-d_6) δ: 1.06 (t, 3H, *J* = 6.90 Hz), 2.21 (s, 3H), 3.94 (q, 2H, *J* = 6.90 Hz), 5.02 (d, 1H, *J* = 2.76 Hz), 6.67–7.0 (m, 4H), 7.64 (s, 1H), 9.11 (s, 1H), 9.30 (s, 1H).

5-Acetyl-6-methyl-4-phenyl-3,4-dihydropyrimidin-2(1*H*)-one (4g)

Melting point 240–242 °C. IR (KBr, cm^{-1}): 3270, 3008, 2975, 2835, 1702, 1645, 1588. ^{1}H NMR (DMSO-d_6) δ: 2.12 (s, 3H), 2.30 (s, 3H), 5.28 (s, 1H), 7.24–7.32 (m, 5H), 7.82 (s, 1H), 9.20 (s, 1H).

5-Methoxycarbonyl-6-methyl-4-phenyl-3,4-dihydropyrimidin-2(1*H*)-one (4h)

Melting point 209–212 °C. IR (KBr, cm^{-1}): 3368, 3240, 3092, 3032, 2948, 1750, 1708, 1655. ^{1}H NMR (DMSO-d_6) δ: 8.06 (s, 1H), 7.32 (m, 5H), 5.74 (s, 1H), 5.40 (d, *J* = 2.7 Hz, 1H), 3.64 (s, 3H), 2.34 (s, 3H). ^{13}C NMR (DMSO-d_6) δ: 165.5, 152.2, 148.8 144.5, 128.3, 127.2, 126.0, 98.9, 53.9, 50.7, 17.8. MS *m*/*z*: 247 (M^+ + 1).

5-Methoxycarbonyl-4-(4-methoxyphenyl)-6-methyl-3,4-dihydropyrimidin-2(1*H*)-one (4i)

Melting point 192–194 °C. IR (KBr, cm^{-1}): 3238, 3102, 3000, 2952, 2838, 1692, 1640, 1609, 1516. ^{1}H NMR (DMSO-d_6) δ: 8.58 (s, 1H), 7.25–6.80 (m, 4H), 5.95 (s, 1H), 5.30 (d, *J* = 2.0 Hz, 1H), 3.76 (s, 3H), 3.65 (s, 3H), 2.30 (s, 3H). ^{13}C NMR ($CDCl_3$) δ: 163.5, 151.2, 143.6, 133.5, 125.4, 111.2, 52.7, 52.5, 48.5, 16.2. Synthesis of some new 1-aryl-4-formyl-3-(4-hydroxy-6-methyl-2-oxo-2*H*-pyran-3-yl)pyrazoles using the Vilsmeier–Haack reaction — Isolation of the key intermediate 1-aryl-3-(4-hydroxy-6-methyl-2-oxo-2*H*-pyran-3-yl)pyrazoles

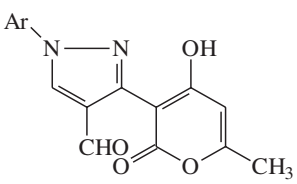
Ajay Kumar, Om Prakash, Mayank Kinger, and Shiv P. Singh

Abstract: Arylhydrazones of dehydroacetic acid (DHA) underwent Vilsmeier–Haack reaction to generate the corresponding 1-aryl-4-formyl-3-(4-hydroxy-6-methyl-2-oxo-2*H*-pyran-3-yl)pyrazoles (**1**) with the pyrone moiety of the DHA remaining intact. However, when the reaction was performed using 1 equiv. of the reagent, compounds of 1-aryl-3-(4-hydroxy-6-methyl-2-oxo-2*H*-pyran-3-yl)pyrazoles (**2a**–**2f**) were obtained, which underwent smooth conversion to 1-aryl-4-formyl-3-(4-hydroxy-6-methyl-2-oxo-2*H*-pyran-3-yl)pyrazoles (**1**) on further treatment with another equivalent of the Vilsmeier–Haack reagent. This unreported observation suggests the intermediacy of 1-aryl-3-(4-hydroxy-6-methyl-2-oxo-2*H*-pyran-3-yl)pyrazoles (**2**) in Vilsmeier–Haack reactions of hydrazones with a pyrone moiety. Several analogous compounds were also prepared using arylhydrazones of DHA.

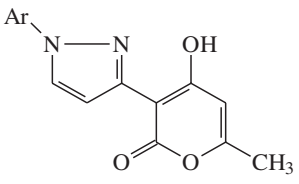
Key words: dehydroacetic acid, pyrazoles, Vilsmeier–Haack reaction, 3-acetyl-4-hydroxy-6-methyl-2*H*-pyran-2-one.

Résumé : Les arylhydrazones de l'acide déhydroacétique (DHA) subissent la réaction de Vilsmeier–Haack pour conduire à la formation des 1-aryl-4-formyl-3-(4-hydroxy-6-méthyl-2-oxo-2*H*-pyran-3-yl)pyrazoles (**1**) dans lesquelles la portion pyrone de l'acide DHA demeure intacte. Toutefois, lorsque la réaction est effectuée en utilisant un équivalent de réactif, on obtient plutôt les 1-aryl-3-(4-hydroxy-6-méthyl-2-oxo-2*H*-pyran-3-yl)pyrazoles (**2a**–**2f**) qui, sous l'influence d'un autre équivalent de réactif de Vilsmeier–Haack, se transforment facilement en 1-aryl-4-formyl-3-(4-hydroxy-6-méthyl-2-oxo-2*H*-pyran-3-yl)pyrazoles (**1**). Cette observation qui n'avait jamais été rapportée antérieurement suggère que les 1-aryl-3-(4-hydroxy-6-méthyl-2-oxo-2*H*-pyran-3-yl)pyrazoles (**2**) sont des intermédiaires dans les réactions de Vilsmeier-Haack comportant une portion pyrone. On a préparé plusieurs composés analogues à partir d'autres arylhydrazones de l'acide DHA.



Mots clés : acide déhydroacétique, pyrazoles, réaction de Vilsmeier–Haack, 3-acétyl-4-hydroxy-6-méthyl-2*H*-pyran-2-one.

[Traduit par la Rédaction]



Introduction

Significant interest in the chemistry of pyrazoles is reflected by the design of new synthetic approaches, theoretical calculations on the reactions leading to their formation, applications of new spectroscopic techniques and their significance in pharmaceuticals, agrochemicals, and dye stuffs, etc. (1–3). In the course of our studies on the synthesis of heterocyclic compounds from the reactions of dehydroacetic acid (DHA) and its derivatives (4–6), we have reported the synthesis of pyrazoles (**2**) and bipyrazoles (**3**) from the rearrangement of hydrazones of DHA (**1**) (7) (Scheme 1).

In the conversion of **1** to **2**, there is involvement of the pyrone ring of DHA, leading to the formation of a β-dicarbonyl moiety through a novel rearrangement process. In continuation of our studies dealing with the synthesis and properties of new pyrazole derivatives, we became interested in the synthesis of the pyrazoles in which the pyrone moiety of the DHA remains intact. We now report herein the synthesis of pyrazoles **4** and **5** from DHA by using the Vilsmeier–Haack reagent.

Scheme 1.

There are several recent reports involving the cyclization of some ketone hydrazones to 1-substituted 4-formylpyrazoles by using the Vilsmeier–Haack reagent ($POCl_3$–DMF, Scheme 2) (8–10). This transformation involves double formylation and its mechanistic pathways are not certain. Based on this important variation of the Vilsmeier–Haack reaction, we have adopted the same approach for the synthesis of **4**.

Results and discussion

1-Aryl-4-formyl-3-(4-hydroxy-6-methyl-2-oxo-2*H*-pyran-3-yl)pyrazoles (1a–1e)

Initially, DHA phenylhydrazone (**1a**) was prepared by the condensation of phenylhydrazine and DHA in ethanolic solution containing a small amount of acetic acid, and was subjected to the Vilsmeier–Haack reaction under standard conditions, i.e., treating 2 equiv. of $POCl_3$–DMF with hydrazone **4a** at 55–60 °C for 5 h. The usual work up, followed by the purification of the resulting crude product by recrystallization from ethanol, gave the expected 4-formylpyrazole derivative **1a** as a crystalline solid in 75% yield. Similarly, several DHA hydrazones (**1b**–**1e**), which were obtained by treating DHA with arylhydrazines, also underwent the Vilsmeier–Haack reaction to afford the corresponding 1-aryl-4-formyl-3-(4-hydroxy-6-methyl-2-oxo-2*H*-pyran-3-yl)pyrazoles (**4b**–**4e**) in good yields (Scheme 3). The structures of all products were established by their spectral properties, i.e., IR, ^{1}H NMR, MS, and elemental analyses.

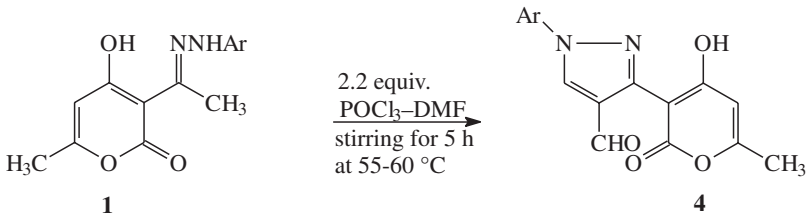
The successful conversion of **3** to **4** reveals that the 4-hydroxy-6-methyl-2*H*-pyran-2-one system remains intact in the presence of the Vilsmeier–Haack reagent.

1-Aryl 3-(4-hydroxy-6-methyl-2-oxo-2*H*-pyran-3-yl)pyrazoles (5a–5e)

After the successful conversion of **1** to **4**, we focused our attention on the synthesis of the related compounds **5**. The reaction was carried out using controlled conditions, such as the use of 1 equiv. of Vilsmeier–Haack reagent to carry out the monoformylation of hydrazone **1a** to generate the pyrazole **5a**. Interestingly, the reaction afforded the desired product 1-aryl-3-(4-hydroxy-6-methyl-2-oxo-2*H*-pyran-3-yl)pyrazole (**5a**), in 60% yield (Scheme 4). Using identical reaction conditions, syntheses of similarly constituted pyrazoles (**5b**–**5e**) were achieved.

To the best of our knowledge, all the reported cases of Vilsmeier–Haack reactions of hydrazones give 4-formylpyrazoles, as shown in Scheme 2. This study represents the first example of the preparation of pyrazoles **5** from the corresponding hydrazones.

Conversion of 5 to 4



It is significant that pyrazoles **5a**–**5e** upon Vilsmeier–Haack reaction underwent smooth conversion into the corresponding 4-formylpyrazoles (**4a**–**4e**). The physical and spectral data of **4a**–**4e** were found to be identical with those obtained directly from **1**. The synthesis of **4** from **5**, not only provides additional examples of the Vilsmeier–Haack formylation of pyrazole derivatives, but also gives a clear indication of the involvement of **5** as an intermediate in the conversion of **1** to **4**.

Mechanistic pathways

Although the mechanism of the Vilsmeier–Haack reaction is not certain, two alternative pathways (Scheme 5) can be envisaged. According to Scheme 5 (path a), formation of the products **4** involves double formylation at the CH_3 group of the hydrazones **1**, followed by cyclization. In the second pathway (path b), single formylation at the CH_3 group followed by cyclization, initially gives 4-unsubstituted pyrazoles (**5**), which subsequently undergo another formylation to produce **4**.

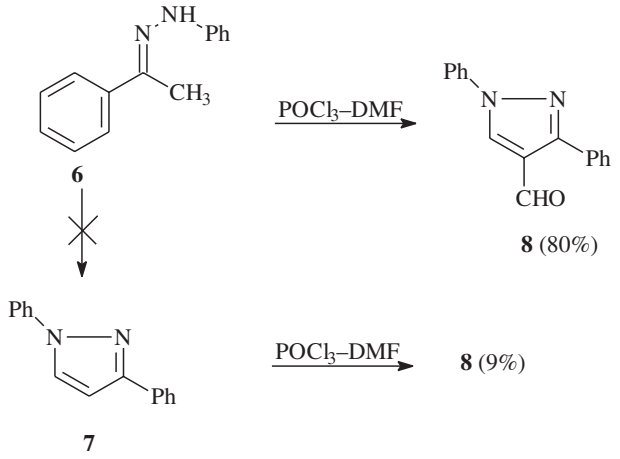
Scheme 4.

Compounds	Ar	Compounds	Ar
1a, 5a	C_6H_5	**1d, 5d**	4-$NO_2C_6H_4$
1b, 5b	4-$CH_3C_6H_4$	**1e, 5e**	2,4-$(NO_2)_2C_6H_3$
1c, 5c	4-ClC_6H_4		

Scheme 5.



Since we were able to isolate the products **5** by using 1 equiv. of the Vilsmeier–Haack reagent (in this study), path b (Scheme 5) appears to be more reasonable. The observation in the present work that the second formylation of the pyrazole **5**, using similar reaction conditions and the reagent, indeed, afforded **4**, supports this pathway. However, in the presence of 2 equiv. of the Vilsmeier–Haack reagent, this study does not permit us to speculate on the operation of either of the two mechanisms as outlined in Scheme 5.

It is to be noted that in contrary to our observations, Kira

Scheme 6.

et al. (11) reported that in the case of Vilsmeier–Haack reaction of acetophenone phenylhydrazone (**6**), pyrazoles **7** are not intermediates in the reaction. They obtained 4-formyl-1,3-diphenylpyrazole (**8**) in 80% yield from the Vilsmeier–Haack reaction of **6**. However, formylation of 1,3-diphenylpyrazole (**7**) under identical conditions gave the same product (**8**), only in 9% yield (Scheme 6). Repetition of this work confirmed these observations.

Obviously, the presence of the 4-hydroxypyran-2-one moiety plays an important role in the conversions of **1** to **4** and of **5** to **4**. Further studies on related examples might be helpful to determine the actual effect of structural changes on the mechanistic pathways of these transformations.

Finally, noteworthy features of the present study are as follows:

(*i*) New pyrazole derivatives of **4** and **5** containing the 2-pyrone moiety are available through the Vilsmeier–Haack reaction using a simple experimental procedure. The mild reaction conditions do not allow attack at other nucleophilic positions (C(6) and C(4)-OH) of the pyrone moiety.

(*ii*) The synthesis of **5** represents the first example of monoformylation in the Vilsmeier–Haack reaction of the hydrazones of the $R(CH_3)C{:}NNHAr$ type.

(*iii*) The isolation of **5** and its subsequent formylation provides a valuable clue regarding the mechanistic pathways followed in these transformations.

(*iv*) The new pyrazole derivatives **4** and **5**, synthesized in the present work, are needed as precursors for the synthesis of several novel fused pyrazoloquinolone derivatives, particularly through the use of hypervalent iodine reagents.

Experimental

Instrumentation and general procedures

Melting points were taken in open capillaries and are uncorrected. ^{1}H NMR spectra were recorded on a Bruker 300 MHz instrument using TMS as an internal standard. IR spectra were recorded on a Buck Scientific IR M500 spectrophotometer. Elemental analyses were carried out in a PerkinElmer 2400 instrument, and mass spectra were recorded on a Kratos MS-50 mass spectrometer. Most of the common chemicals such as dehydroacetic acid, aldehydes, phenylhydrazine, 2,4-dinitrophenylhydrazine, etc., were obtained from commercial suppliers.

General procedure for the preparation of the hydrazone of DHA

DHA (0.02 molar equiv.) was dissolved in ethanol (50 mL) by warming, and arylhydrazine (0.02 molar equiv.) was added to the mixture while it was being shaken. The contents were stirred for 10 min and allowed to stand at room temperature for 2 h. The yellow solid (**1**) obtained was filtered and crystallized from acetonitrile.

Compounds **1a**–**1e** were similarly prepared.

General procedure for the preparation of 1-aryl-3-(4-hydroxy-6-methyl-2-oxo-2*H*-pyran-3-yl)pyrazoles (5)

Hydrazone **1** (0.004 molar equiv.) was added to the Vilsmeier–Haack reagent (prepared from DMF (10 mL) and $POCl_3$ (0.0044 molar equiv.)), and the reaction mixture was stirred at 55–60 °C for 1 h and then poured into ice-cold water. The solid that separated upon neutralization with $NaHCO_3$ was filtered, washed with water, and crystallized from ethanol to afford **5**.

Compounds **5a**–**5e** were similarly prepared.

*3-(4-Hydroxy-6-methyl-2-oxo-2*H*-pyran-3-yl)-1-phenylpyrazole (5a)*

Yield: 65%; mp 158 to 159 °C. IR (KBr, cm^{-1}): 1720 (C=O). ^{1}H NMR ($CDCl_3$, 300 MHz) δ: 2.4 (s, 3H, CH_3), 6.0 (s, 1H, C_5-H, DHA), 7.3 (d, 1H, C_4-H, J = 2.1 Hz), 7.31 (m, 1H, Ph), 7.50 (m, 2H, Ph), 7.62 (m, 2H, Ph), 8.0 (d, 1H, C_5-H, J = 2.1 Hz), 13.0 (s, 1H, OH). Reactions of $MAlH_4$ (M = Li, Na) with primary amines — Synthetic and structural studies of alkali metal tetrakis(amido)aluminates and related dinuclear complexes

Dana J. Eisler and Tristram Chivers

Abstract: The reactions of $MAlH_4$ (M = Li, Na) with primary amines NH_2R (R = *t*-Bu, *i*-Pr, *p*-tolyl) in a 1:4 molar ratio in THF produce the tetrakis(amido)aluminates, $[M(THF)_n][Al(NHR)_4]$, in yields of 46%–82% together with secondary products. The extent of solvation of the alkali-metal cation varies from none (n = 0) for $M[Al(NH\text{-}i\text{-}Pr)_4]$ (**2b**, M = Li; **3b**, M = Na) to n = 4 in the complex $[Li(THF)_4][Al(NH\text{-}p\text{-tolyl})_4]$ (**2c**), which exists as a solvent-separated ion pair. The complexes **2b**, **3b**, and $[Na(THF)][Al(NH\text{-}p\text{-tolyl})_4]_\infty$ (**3c**) all exhibit one-dimensional polymeric structures in which the bis-N,N′-chelating tetrakis(amido)aluminate anions are bridged by four- (**2b**, **3b**) and five-coordinate (**3c**) metal ions, respectively. The structures of two of the secondary products, $\{[Na(THF)_2][(NH\text{-}t\text{-Bu})Al(H)(\mu\text{-N-}t\text{-Bu})]\}_2$ (**4**) and $\{[Na(THF)_3][(NH\text{-}p\text{-tolyl})_2Al(\mu\text{-N-}p\text{-tolyl})]\}_2$ (**5**), were established by X-ray crystallography. Complex **4** is a dimer of the $[HAl(NH\text{-}t\text{-Bu})(N\text{-}t\text{-Bu})]^-$ anion, which forms a central Al_2N_2 ring with each monoanion N,N′-chelated to a $[Na(THF)_2]^+$ cation. Complex **5** is a dimer of the $[Al(NR)(NHR)_2]^-$ (R = *p*-tolyl) anion in which the bridging *p*-tolyl groups are coordinated in an N-monodentate fashion to the trisolvated $[Na(THF)_3]^+$ cations.

Key words: aluminohydrides, alkali metals, primary amines, tetrakis(amido)aluminates, structures.

Résumé : Les réactions des $MAlH_4$ (M = Li, Na) avec des amines primaires, NH_2R (R = *t*-Bu, *i*-Pr, *p*-tolyle), dans un rapport molaire de 1 : 4, dans le THF, conduit à la formation des tétrakis(amido)aluminates, $[M(THF)_n][Al(NHR)_4]$, avec des rendements allant de 46 % à 82 % aux côtés de produits secondaires. Le degré de solvatation du cation du métal alcalin varie de zéro (n = 0) pour $M[Al(NH\text{-}i\text{-Pr})_4]$ (**2b**, M = Li; **3b**, M = Na) à n = 4 pour le complexe $[Li(THF)_4]$-$[Al(NH\text{-}p\text{-tolyl})_4]$ (**2c**) qui existe sous la forme de paire d'ions séparés par le solvant. Les complexes **2b**, **3b** et $[Na(THF)][Al(NH\text{-}p\text{-tolyl})_4]_\infty$ (**3c**) présentent tous des structures polymériques monodimensionnelles dans lesquelles les anions tétrakis(amido)aluminates bis-N,N′-chélatants sont liés par des ponts d'ions métalliques respectivement tétra- (**2b**, **3b**) et penta-coordinés (**3c**). Les structures de deux des produits secondaires, le $\{[Na(THF)_2][(NH\text{-}t\text{-Bu})Al(H)(\mu\text{-N-}t\text{-Bu}]\}_2$ (**4**) et $\{[Na(THF)_3)][(NH\text{-}p\text{-tolyl})_2Al(\mu\text{-N-}p\text{-tolyl})]\}_2$ (**5**) ont été établies par diffraction des rayons X. Le complexe **4** est un dimère de l'anion $[HAl(NH\text{-}t\text{-Bu})(N\text{-}t\text{-Bu})]^-$ qui forme un cycle Al_2N_2 central dans chacun des monoanions N,N′-chélatés à un cation $[Na(THF)_2]^+$. Le complexe **5** est un dimère de l'anion $[Al(NR)(NHR)_2]^-$ (R = *p*-tolyle) dans lequel les groupes *p*-tolyles servant de pont sont coordinés d'une façon N-monodentate aux cations $[Na(THF)_3]^+$ trisolvatés.

Mots clés : hydrures d'aluminium, métaux alcalins, amines primaires, tétrakis(amido)aluminates, structures.

[Traduit par la Rédaction]

Introduction

The reactions of secondary amines with $LiAlH_4$ have been studied extensively (1–4). Several tetrakis(amido)aluminate complexes of the type $[L_2Li][Al(NR_2)_4]$ (L = electron-pair donor ligand) (1, 2) as well as the intermediate lithium amidohydridoaluminates formed in this process, e.g., $[H_3AlN(SiMe_3)_2Li(Et_2O)_2]_2$ (3) and $[Li(THF)_4][HAl(NPh_2)_3]$ (4), have been structurally characterized. Aluminum-nitrogen cage compounds of the type $(HAlNR)_n$ (imidoalanes) may be prepared by treatment of primary amines with $MAlH_4$ (M = Li, Na) in a 1:1 molar ratio in boiling hydrocarbon solvents (M = Li) or diethyl ether (M = Na) (5*a*) (eq. [1]) or by reaction of $RNH_2{\cdot}HCl$ with $LiAlH_4$ in diethyl ether at room temperature (5*b*). The value of n is determined by the nature of the R group and by the solvent used for the reaction (6). In 1997 Roesky and co-workers (7) prepared the first aluminum amides derived from primary amines via the reaction of $LiAlH_4$ with the sterically demanding amine, $DippNH_2$ (Dipp = 2,6-diisopropylphenyl). Molar ratios of 1:2 and 2:5

produced structurally characterized dinuclear complexes containing either one or two Al-H functionalities, respectively.

$$[1] \quad MAlH_4 + RNH_2 \rightarrow 1/n(HAlNR)n + 2H_2 + MH \ (M = Li, Na)$$

The reactions of lithium amides with aluminum(III) compounds have also been investigated. Tetrakis(amido)aluminates of the type $[Al(NHR)_4]^-$ are obtained as the monomeric ion-paired complex $[(DippNH)_2Al(\mu\text{-}NHDipp)_2\text{-}Li\cdot THF]$ (**1a**) (8) or the dimer $[(t\text{-}BuNH)Al(\mu\text{-}NH\text{-}t\text{-}Bu)_2Li(\mu\text{-}NH\text{-}t\text{-}Bu)]_2$ (**2a**) (9) from reactions of LiNHR (R = Dipp, *t*-Bu) with $AlCl_3$ in THF or hexane, respectively. The related complex, $[\{(Me_2N)_3SiNH\}_2Al(\mu\text{-}NHSi(NMe_2)_3\}_2\text{-}Li\cdot 2THF]$, which is structurally analogous to **1a** but incorporates a bis-solvated Li^+ cation, is prepared from $AlCl_3$ and $(Me_2N)_3SiNHLi$ in a 1:4 molar ratio in pentane (followed by recrystallization from THF) (10). The diethyl-ether-solvated complex, $[(DippNH)_2Al(\mu\text{-}NHDipp)_2Li\cdot OEt_2]$ (**1b**), isostructural with **1a**, was obtained as a minor product from the reaction of $H_3Al\cdot NMe_3$ with $DippNH_2$ (11). The open rhombododecahedral cage $[(HAl)_4(NPh)_6\{Li(OEt_2)\}_3]^-$ is formed by treatment of the adduct $AlH_3\cdot N(Me)C_5H_8$ with LiNHPh (12).

1a (R = Dipp, L = THF)
1b (R = Dipp, L = OEt_2)

2a

In connection with our interest in generating polyimido anions of p-block elements (13), we have previously investigated the reaction of the trialkylamidoalane dimer $[(t\text{-}BuNH)_2Al(\mu\text{-}NH\text{-}t\text{-}Bu)_2Al(NH\text{-}t\text{-}Bu)_2]$ with alkyl-lithium reagents and shown by NMR spectroscopy that the initial lithiation occurs at a bridging NH-*t*-Bu group to give mono- and di-lithiated derivatives, $Li_x[Al_2(N\text{-}t\text{-}Bu)_x(NH\text{-}t\text{-}Bu)_{6-x}]$ (x = 1, 2) (14). In the case of *n*-BuLi, the use of 5 equiv. of the organolithium reagent (per dimer) generates the trilithiated derivative, which acts as a template to trap the unsolvated dimer $(n\text{-}BuLi)_2$. By contrast, the reaction of the tris(arylamido) alane, $[Al(NHAr)_3]$ (Ar = 2-$MeOC_6H_4$), which is assumed to be dimeric (15), with 3 equiv. of *n*-BuLi (per monomer) leads to lithiation of all three N-H protons and nucleophilic addition of the *n*-Bu group to aluminum to give a tetraanionic organotriimidoaluminate, $[n\text{-}BuAl(NAr)_3]^{4-}$ (16). This anion, as the tetralithium derivative, forms the dimeric ion-separated cluster, $[Li(THF)_4]_2\text{-}[Li_6\{n\text{-}BuAl(NAr)_3\}_2]$ (16).

In view of the lack of a general, high-yield synthesis to tetrakis(amido)aluminates, we have undertaken a systematic investigation of the reactions of alkali metal aluminum hydrides, $M[AlH_4]$ (M = Li, Na), with primary amines, RNH_2 (R = *t*-Bu, *i*-Pr, *p*-tolyl), under mild conditions as a route to the potentially useful tetradentate, monoanionic ligands $[Al(NH\text{-}t\text{-}Bu)_4]^-$. We describe here the synthesis of six alkali metal tetrakis(amido)aluminates; the X-ray structures of four of them are compared with those of **1a**, **1b**, and **2a**. We also report the X-ray structures of two of the secondary products of these reactions, both of which are novel dinuclear clusters containing amido–imido aluminum anions.

Experimental section

Reagents and general procedures

Solvents were dried and distilled before use (*n*-hexane, THF, diethyl ether, and toluene (Na/benzophenone)). The reagents NH_2-*t*-Bu, NH_2-*i*-Pr, and NH_2-*p*-tolyl were commercial samples (Sigma-Aldrich) and used as received. A commercial sample of $NaAlH_4$ was dissolved in THF and, after 45 min at 23 °C, insoluble black material was removed by filtration to give pure $NaAlH_4$ as an off-white solid after the removal of solvent. $LiAlH_4$ was purified by recrystallization from diethyl ether. The handling of air- and moisture-sensitive materials was performed under an atmosphere of argon gas using standard Schlenk techniques or a glovebox.

^1H, ^7Li, ^{13}C, and ^{27}Al NMR spectra were collected on a Bruker AMX-300 spectrometer and chemical shifts are reported relative to Me_4Si in $CDCl_3$ (^1H, ^{13}C), LiCl in D_2O (^7Li), or $Al(NO_3)_3$ in D_2O (^{27}Al). All NMR spectra were collected at 23 °C unless otherwise stated. Fourier transform infrared (FT IR) spectra were obtained as Nujol mulls using KBr windows on a Mattson Genesis Series instrument. The Analytical Services Laboratory of the Department of Chemistry, University of Calgary, provided elemental analyses.

Preparation of Li[Al(NH-*t*-Bu)$_4$] (2a)

A slurry of $LiAlH_4$ (0.125 g, 3.30 mmol) in *n*-hexane or toluene (10 mL) was added to a clear colorless solution of NH_2-*t*-Bu (2.74 mL, 1.907 g, 26.1 mmol) in *n*-hexane or toluene (10 mL) at 23 °C. Immediate, vigorous bubbling was observed. The mixture was stirred for 3 h and then the volume of solution was reduced to 10 mL under vacuum. The resulting clear solution was cooled to –25 °C for 24 h to give colorless crystals of $LiAl(NH\text{-}t\text{-}Bu)_4$ (0.872 g, 2.70 mmol, 82%) with *n*-hexane as solvent and (0.810 mg, 2.51 mmol, 76%) when toluene was used. ^1H NMR (in C_6D_6) δ: 1.45 (s, C*Me*$_3$), cf. lit. δ 1.43 in C_6D_6 (7).

Preparation of Li[Al(NH-*i*-Pr)$_4$] (2b)

A solution of $LiAlH_4$ (0.223 g, 5.88 mmol) in THF (40 mL) was added to a solution of NH_2-*i*-Pr (2.00 mL, 1.388 g, 23.48 mmol) in THF (15 mL) at 23 °C resulting in immediate, vigorous evolution of H_2. The mixture was stirred for 1 h and the resulting slightly cloudy solution was filtered though a 0.45 μm pore size filter disk. The solvent was removed in vacuo and the residue was washed with diethyl ether (20 mL) leaving a white solid (0.892 g, 57%). IR (cm^{-1}): 3365 ν(N-H). ^1H NMR (in D_8-THF) δ: 3.05 (m, 1H, C*H*Me$_2$), 0.98 (d, 6H, CH*Me*$_2$, $^3J(^1H\text{-}^1H)$ = 6 Hz), –0.94 (d, 1H, N*H*, $^3J(^1H\text{-}^1H)$ = 11 Hz). ^{13}C NMR δ: 45.3 (*C*HMe$_2$), 31.0 (CH*Me*$_2$). ^{27}Al NMR δ: 107.1. ^7Li NMR δ: –1.31. Anal. calcd. for $C_{12}H_{32}AlLiN_4$ (%): C 54.12, H 12.11, N 21.01; found: C 53.60, H 13.08, N 20.92.

Preparation of [Li(THF)$_4$][Al(NH-*p*-tolyl)$_4$] (2c)

A solution of $LiAlH_4$ (0.089 g, 2.35 mmol) in THF (40 mL) was added slowly to a solution of *p*-toluidine (1.00 g, 9.33 mmol) in THF (15 mL) resulting in immediate, vigorous evolution of H_2. The mixture was stirred for 1 h and the resulting slightly cloudy solution was filtered though a 0.45 μm pore size filter disk and then concentrated to ca. 10 mL. Slow addition of *n*-hexane (25 mL) combined with vigorous stirring of the solution resulted in the precipitation of [Li(THF)$_4$][Al(NH-*p*-tolyl)$_4$] as a white solid. The solution was decanted and the solid dried in vacuo (1.385 g, 1.85 mmol, 79%). ^{1}H NMR (in D_8-THF) δ: 6.55 (m, 4H, C_6H_4), 3.63 (m, *THF*), 3.16 (s, 1H, N*H*), 2.08 (s, 3H, *Me*), 1.78 (m, *THF*). ^{13}C NMR δ: 154.1, 129.6, 120.2, 116.5 (C_6H_4), 68.4 (*THF*), 26.4 (*THF*), 20.8 (*Me*). ^{27}Al NMR δ: 96.7. ^{7}Li NMR δ: –2.68. Anal. calcd. for $C_{44}H_{64}AlLiN_4O_4$ (%): C 70.65, H 8.64, N 7.50; found: C 69.97, H 8.52, N 7.21.

Preparation of [Na(THF)][Al(NH-*t*-Bu)$_4$] (3a)

A solution of $NaAlH_4$ (0.251 g, 4.65 mmol) in THF (40 mL) was added to a solution of NH_2-*t*-Bu (2.0 mL, 1.358 g, 18.57 mmol) in THF (10 mL) at 23 °C resulting in immediate, slow evolution of H_2. The mixture was stirred for 3 h and the resulting slightly cloudy solution was filtered though a 0.45 μm pore size filter disk. The volume of solution was then reduced to 10 mL in vacuo and cooled to –10 °C for 2 h to give colorless crystals of [Na(THF)][Al(NH-*t*-Bu)$_4$] (0.872 g, 2.12 mmol, 46%). ^{1}H NMR (in D_8-THF) δ: 3.63 (m, 4H, *THF*), 1.78 (m, 4H, *THF*), 1.13 (s, 36H, C*Me*$_3$), –0.68 (s, 4H, N*H*). ^{13}C NMR δ: 68.4 (*THF*), 49.9 (*C*Me$_3$), 36.4 (C*Me*$_3$), 26.4 (*THF*). ^{27}Al NMR δ: 110.0. Anal. calcd. for $C_{20}H_{48}AlN_4NaO$ (%): C 58.50, H 11.78, N 13.65; found: C 56.15, H 10.74, N 13.10. The obtained carbon analysis for this complex was consistently low, however, the complex was pure by both ^{1}H and ^{13}C NMR spectroscopy.

Preparation of [Na][Al(NH-*i*-Pr)$_4$] (3b)

A solution of $NaAlH_4$ (0.315 g, 5.83 mmol) in THF (40 mL) was added to a solution of NH_2-*i*-Pr (2.00 mL, 1.388 g, 23.48 mmol) in THF (15 mL) at 23 °C resulting in immediate, vigorous evolution of H_2. The mixture was stirred for 1 h and the resulting slightly cloudy solution was filtered though a 0.45 μm pore size filter disk. The solvent was removed in vacuo and the residue was washed with diethyl ether (20 mL) leaving a white solid (1.068 g, 65%). ^{1}H NMR (in D_8-THF) δ: 3.12 (m, 1H, C*H*Me$_2$), 0.98 (d, 6H, CH*Me*$_2$, $^3J(^1H\text{-}^1H)$ = 6 Hz), –0.85 (d, 1H, N*H*, $^3J(^1H\text{-}^1H)$ = 9 Hz). ^{13}C NMR δ: 45.5 (*C*HMe$_2$), 31.1 (CH*Me*$_2$). ^{27}Al NMR δ: 108.5. Anal. calcd. for $C_{12}H_{32}AlN_4Na$ (%): C 51.04, H 11.42, N 19.84; found: C 50.31, H 11.81, N 19.44.

Preparation of [Na(THF)][Al(NH-*p*-tolyl)$_4$] (3c)

A solution of $NaAlH_4$ (0.126 g, 2.33 mmol) in THF (40 mL) was added slowly to a solution of *p*-toluidine (1.00 g, 9.33 mmol) in THF (15 mL) at 23 °C resulting in immediate, vigorous evolution of H_2. The mixture was stirred for 1 h and the resulting slightly cloudy solution was filtered though a 0.45 μm pore size filter disk. The solvent was removed in vacuo and the residue was washed with diethyl ether (40 mL) leaving a white solid (0.893 g, 70%). ^{1}H NMR (in D_8-THF) δ: 6.54 (m, 4H, C_6H_4), 3.63 (m, *THF*), 3.15 (s, 1H, N*H*), 2.06 (s, 3H, *Me*), 1.78 (m, *THF*). ^{13}C NMR δ: 154.0, 129.7, 120.6, 116.7 (C_6H_4), 68.4 (*THF*), 26.4 (*THF*), 20.8 (*Me*). ^{27}Al NMR δ: 95.4. Anal. calcd. for $C_{32}H_{40}AlN_4NaO$ (%): C 70.31, H 7.38, N 10.25; found: C 69.74, H 6.67, N 9.98.

Preparation of {[Na(THF)$_2$][(NH-*t*-Bu)Al(H)(μ-N-*t*-Bu)]}$_2$ (4)

This complex is a minor product (ca. 20%) obtained in the preparation of **3a**. In addition to complex **4**, an additional minor product (ca. 10%), which was not identified, is also present in reaction solutions of **3a**. Significantly larger quantities of **4** and this unidentified complex (ca. 50% combined) are observed when the reaction is carried in a 1:2 mixture of THF and *n*-hexane. An analytically pure sample of **4** could not be obtained, as this material was always contaminated with the other reaction products. X-ray quality crystals of **4** were isolated manually from a mixture of crystals of **3a** and **4** grown from a concentrated solution of the complexes in THF–hexane at –10 °C. ^{1}H NMR (in D_8-THF, 298 K) δ: 3.63 (m, *THF*), 1.78 (m, *THF*), 1.22 (s, 9H, C*Me*$_3$), 1.18 (s, 9H, C*Me*$_3$), 0.46 (s, 1H, N*H*). ^{13}C NMR δ: 68.4 (*THF*), 52.9, 50.9 (*C*Me$_3$), 38.9, 36.3 (C*Me*$_3$), 26.4 (*THF*). ^{1}H NMR (in D_8-THF, 233 K) δ: 4.38 (v br, $\Delta\omega_{1/2}$ ~ 70 Hz, 1H, Al-*H*), 3.63 (m, *THF*), 1.78 (m, *THF*), 1.19 (s, 9H, C*Me*$_3$), 1.14 (s, 9H, C*Me*$_3$), 0.60 (s, 1H, N*H*). ^{27}Al NMR δ: 110.0.

Preparation of {[Na(THF)$_3$][(NH-*p*-tolyl)$_2$Al(μ-N-*p*-tolyl)]}$_2$ (5)

This complex is the minor product (ca. 30%) obtained in the preparation of complex **3c**. An analytically pure sample of **5** could not be obtained, as this material was always contaminated with **3c**. X-ray quality crystals of **5** were isolated manually from a mixture of crystals of **3c** and **5** grown from a concentrated solution of the complexes in THF–hexane at –10 °C. ^{1}H NMR (in D_8-THF) δ: 6.72 (m, 8H, C_6H_4), 6.70 (m, 16H, C_6H_4), 3.63 (m, *THF*), 3.28 (s, 4H, N*H*) 2.06 (s, br, 18H, *Me*), 1.78 (m, *THF*). ^{13}C NMR δ: 157.4, 152.8, 130.4, 130.2, 122.5, 122.0, 117.3, 116.8 (C_6H_4), 68.4 (*THF*), 26.4 (*THF*), 20.6 (*Me*). ^{27}Al NMR δ: 97.2.

X-ray structural analyses

Crystal data for **2b**, **2c**, **3b**, **3c**, **4**, and **5** are summarized in Table 1.[2] A suitable crystal of the complex was selected, coated in Paratone oil, and mounted on a glass fibre. Data were collected at 173 K on a Nonius Kappa CCD diffractometer using Mo Kα radiation (λ = 0.710 73 Å) via ω and φ scans. The unit cell parameters were calculated and refined from the full data set. Crystal cell refinement and data

reduction were carried out using the Nonius DENZO package. After data reduction, the data were corrected for absorption based on equivalent reflections using SCALEPACK (Nonius, 1998). The structures were solved by direct methods using SHELXS-97 (17) and refinement was carried out on F^2 against all independent reflections by the full-matrix least-squares method using the SHELXL-97-2 program (18). The hydrogen atoms were calculated geometrically and were riding on their respective atoms unless otherwise noted. Except as mentioned, all non-hydrogen atoms were refined with anisotropic thermal parameters.

2b

The molecule was well-ordered and no special considerations for the refinement were necessary. The complex crystallizes with two independent, but chemically equivalent molecules in the unit cell, for which two independent halves of the molecules are present in the asymmetric unit (the other half in each case being generated by the crystallographic twofold axis). The lithium atoms were refined isotropically.

2c

The amidoaluminate anion was well-ordered, however the $[Li(THF)_4]^+$ cation was highly disordered around a crystallographic twofold rotation axis. Only one-half of the anion and cation are present in the asymmetric unit, with the second half of each being generated by the twofold axis. One of the THF molecules of the cationic moiety was modeled with a 75:25 disorder of the oxygen and one carbon atom; the 25% component of this disorder was refined isotropically. The second THF molecule was severely disordered and was modeled as a 25:25:25:25 isotropic mixture with geometric restraints applied.

3b

The molecule was well-ordered and no special considerations for the refinement were necessary. Due to symmetry only one-quarter of the molecule was located in the difference Fourier map, as the molecule is situated on a fourfold rotary inversion axis.

3c

The molecule was well-ordered with the exception of the coordinated THF molecule, which was modeled with a 65:35 isotropic mixture of two of the carbon atoms with mild geometric restraints.

4

The molecule was well-ordered and no special considerations for the refinement were necessary. The hydrogen atoms on the amido nitrogen and aluminum centers (H2D and H1D, respectively) were located and refined.

5

The molecule was well-ordered with the exception of one THF molecule, which was modeled with a 55:45 disorder of two of the carbon atoms that were refined with isotropic thermal parameters.

Results and discussion

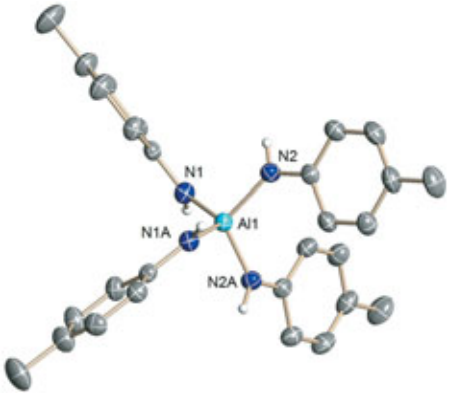
Synthesis of lithium and sodium tetrakis(amido)aluminates

The reaction of lithium or sodium aluminum hydride with 4 equiv. of primary amine RNH_2 in THF at room temperature results in the immediate evolution of H_2 gas to give the corresponding lithium or sodium tetrakis(amido)aluminate (eq. [2]), as well as secondary products, which are observed in varying quantities (<5% to ca. 30%). However, the tetrakis(amido)aluminate complexes are readily purified owing to the higher solubility of the secondary products in diethyl ether, in comparison to the desired tetrakis(amido)aluminates. Although the quantities of the minor components formed vary with reaction conditions, the identities of the products do not change. All attempts to obtain analytically pure samples of the secondary products were unsuccessful owing to persistent contamination with the tetrakis(amido)aluminate complexes.

$$[2] \qquad MAlH_4 + 4NH_2R \rightarrow M[Al(NHR)_4] + 4H_2$$

(**2a**, M = Li, R = *t*-Bu; **3a**, M = Na, R = *t*-Bu; **2b**, M = Li, R = *i*-Pr; **3b**, M = Na, R = *i*-Pr; **2c**, M = Li, R = *p*-tolyl; **3c**, M = Na, R = *p*-tolyl)

Complex **2a** is obtained in 82% yield when *n*-hexane is used as solvent, cf. 60% yield of **2a** from the reaction of $AlCl_3$ with LiNH-*t*-Bu in hexane (9); it was identified by comparison of the ^{1}H NMR chemical shift (a broad singlet at δ 1.45) and unit cell constants with those reported in the literature (9).[3] The other tetrakis(amido)aluminate complexes (**2b**, **2c**, **3a**–**3c**), four of which have been identified by X-ray structural analyses (vide infra), were prepared in THF in yields ranging from 46% to 79%. They are accompanied by the formation of secondary products, and two of these have also been structurally characterized. The complexes **2b**, **2c**, and **3a**–**3c** are each obtained with a varying degree of THF-solvation of the alkali metal cations, as indicated by the ^{1}H NMR spectra. For example, the isopropyl complexes **2b** and **3b** are isolated as the unsolvated complexes $M[Al(NH\text{-}i\text{-}Pr)_4]$, whereas the arylamido complex **2c** is obtained as a highly solvated complex with four molecules of THF for each Li^+ ion.



X-ray structures of lithium and sodium tetrakis(amido)aluminates

The solid-state structure of complex **2c**, which was determined crystallographically, confirmed the presence of an ion-separated complex consisting of a $[Li(THF)_4]^+$ cation and a $[Al(NH\text{-}p\text{-}tolyl)_4]^-$ anion, in contrast to the solvated monomeric structure of **1a** and the unsolvated dimeric structure of **2a**. The anion in **2c** is depicted in Fig. 1. The Al—N distances are identical within error (Al(1)—N(1) = 1.841(2) Å, Al(1)—N(2) = 1.844(2) Å), and are comparable to those observed for the terminal DippNH ligands in **1a** (1.845(9) Å) (8). The aluminum centre in **2c** adopts a distorted tetrahedral geometry with the N-Al-N bond angles ranging from 105.5(1)° to 116.6(2)°.

[3] As reported by Cowley and co-workers (9), the NH resonances of **2a** were not observed in the ^{1}H NMR spectrum. The broad singlet observed for the *t*-Bu groups at 23 °C is indicative of dynamic behaviour.

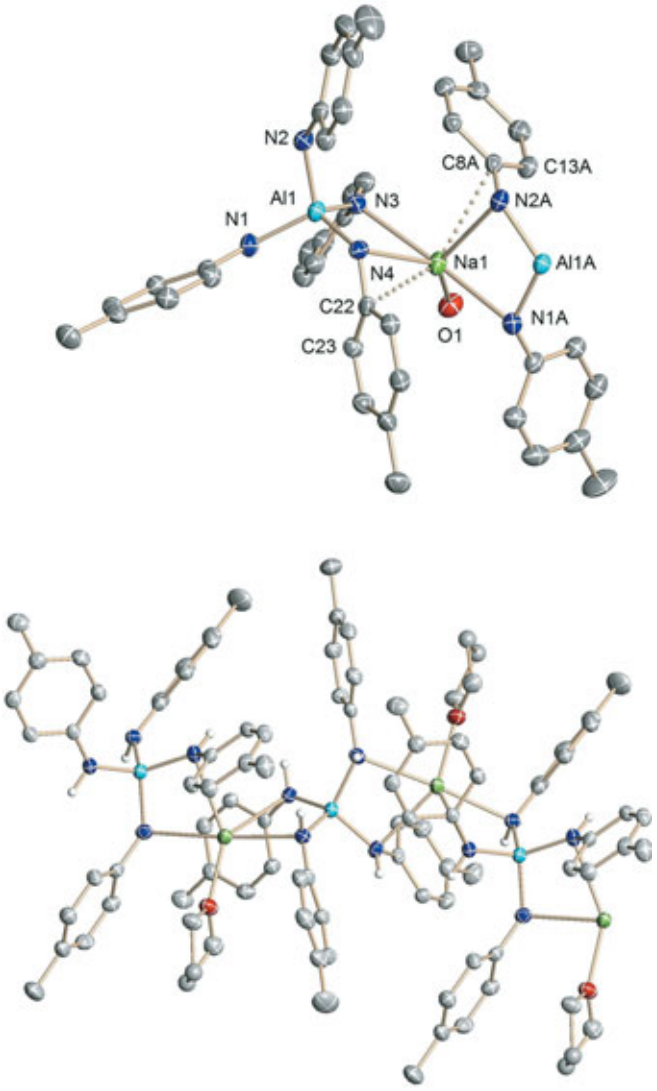
Fig. 1. Molecular structure of the anion $[Al(NH\text{-}p\text{-}tolyl)_4]^-$ in **2c**. Thermal ellipsoids are shown at 30% probability. Hydrogen atoms on carbon atoms have been removed for clarity. Selected bond lengths (Å) and angles (°): Al(1)—N(1), 1.841(2) Å; Al(1)—N(2), 1.844(2) Å; N(1)-Al(1)-N(1A), 116.6(2)°; N(1)-Al(1)-N(2), 107.3(1)°; N(1)-Al(1)-N(2A), 105.5(1)°; N(2)-Al(1)-N(2A), 115.2(2)°.

An X-ray analysis of the solid-state structures of complexes **2b** and **3b** verified that there are no solvent molecules present in either case (Fig. 2). The two structures are very similar, although there are variations that arise from the presence of different alkali metal cations. For complex **2b**, two independent, but chemically equivalent, molecules are present in the asymmetric unit, and only one is shown in Fig. 2. The two molecules are adjacent to each other, but are slightly skewed along the crystallographic twofold axis (torsion angles N-Al-Al-N, ca. 34°). In contrast, the $(HN\text{-}i\text{-}Pr)_2Al(HN\text{-}i\text{-}Pr)_2Na$ molecule in **3b** is highly symmetrical, with both the sodium and the aluminum centres situated on a fourfold rotary inversion axis. Presumably, the lower symmetry in **2b** arises owing to distortions resulting from the smaller size of the lithium cation in comparison to the sodium cation in **3b**. This rationale is supported by the observed distortions from regular tetrahedral geometry around the aluminum centres in **2b**. The smallest N-Al-N angles are those involved in the AlN_2Li rings (range 100.5(2)°–101.5(2)°). The exocyclic N-Al-N angles are considerably larger, ranging from 113.5(1)° to 114.2(1)°. By comparison, the aluminum centre in **3b** is only slightly distorted from tetrahedral, with bond angles in the narrow range of 107.61(9)°–110.41(5)°; the smallest angles are those in the AlN_2Na rings. The Al—N bond distances are identical within experimental error in both structures (**2b**, 1.857(2)–1.865(2) Å; **3b**, 1.862(2) Å) and are comparable to those observed for complex **2c**. Interestingly, the overall crystal structures of complexes **2b** and **3b** are one-dimensional polymers (Fig. 2, bottom). The polymeric structure is a result of the coordination of the lithium or sodium cation to two amido nitrogen centres from each of two adjacent tetrakis(amido)aluminate anions. The lithium and sodium cations are thus four-coordinate, and are highly distorted from tetrahedral (**2b**, N-Li-N bond angles 83.2(3)°–84.3(3)° in the AlN_2Li rings and exocyclic bond angles of 107.58(9)°–143.76(9)°; **3b**, N-Na-N bond angles of 72.80(7)° in the AlN_2Na rings and exocyclic N-Na-N bond angles of 130.38(4)°). A similar structure has been observed for the methyl derivative, $Li[Al(NHMe)_4]$ (19).

Fig. 2. Top left: Molecular structure of **2b**. Top right: Molecular structure of **3b**. Bottom: Polymeric crystal structure of **3b**. Thermal ellipsoids are shown at 30% probability. Hydrogen atoms on carbon atoms have been removed for clarity. Selected bond lengths (Å) and angles (°): **2b**: Al(1)—N(1), 1.857(2) Å; Al(1)—N(2), 1.863(2) Å; Li(1)—N(1), 2.166(6) Å; N(1)-Al(1)-N(2), 113.5(1)°; N(1)-Al(1)-N(1A), 101.5(2)°; N(1)-Al(1)-N(2A), 113.8(1)°; N(2)-Al(1)-N(2A), 101.4(2)°. **3b**: Al(1)—N(1), 1.862(2) Å; Na(1)—N(1), 2.532(2) Å; N(1)-Al(1)-N(1A), 107.61(9)°; N(1)-Al(1)-N(1B), 110.41(5)°.

The solid-state structure for **3c**, which is depicted in Fig. 3, was determined by X-ray crystallography; pertinent metrical parameters are given in Table 2. The molecular structure is similar to that of **3b** except that the sodium ion is monosolvated by THF. The four-coordinate aluminum centre adopts a distorted tetrahedral geometry, with the N-Al-N angles ranging from 106.9(1)° to 114.6(1)°. The Al—N bond lengths are equal within the limits of error, falling in the narrow range of 1.843(3)–1.855(3) Å.



Similar to the structures of **2b** and **3b**, complex **3c** forms a one-dimensional polymer involving coordination of the sodium cations to amido groups of adjacent aluminate anions. In addition to the amido substituents and the single molecule of THF, each sodium ion displays interactions with the aromatic rings of two *p*-tolyl substituents. Thus, the sodium ions are overall seven-coordinate. The strongest Na—C interactions are with the ipso carbon atoms of the two rings with distances of 2.839(3) Å (C8A—Na1) and 2.868(3) Å (C22—Na1). There are also weaker contacts with one of the ortho carbon atoms (C13A—Na1 = 3.174(3) Å; C23—Na1 = 3.063(3) Å). These distances are within the typical range of 2.6–3.2 Å observed for Na—C aromatic interactions (20). The Na—N bond distances are considerably longer and more varied in **3c** (2.561(3)–2.785(3) Å) than those in **3b** (2.532(2) Å), presumably as a result of the higher coordination number of the sodium centre.

NMR spectra of lithium and sodium tetrakis(amido)aluminates

The NMR spectra for **2b**, **2c**, **3b**, and **3c** should provide a good indication of whether the solid-state structures (vide supra) are maintained in solution. In addition, the NMR

Fig. 3. Top: Molecular structure of **3c**; portions of an adjacent molecule are shown, and all hydrogen atoms and THF carbon atoms have been removed to clarify the full coordination environment of the sodium centre. Bottom: Polymeric crystal structure of **3c**; hydrogen atoms on carbon atoms have been removed for clarity. Thermal ellipsoids are shown at 30% probability.

spectra will furnish information about the solution structure of **3a**, which could not be determined in the solid state. The multinuclear NMR data obtained for **2c** were in keeping with the observed solid-state structure. For example, a single resonance was observed for the methyl groups of the *p*-tolyl substituents in the ^{1}H and ^{13}C NMR spectra, as well as a single resonance for the four equivalent N-H protons in the ^{1}H NMR spectrum. The integration of the ^{1}H NMR spectrum indicated the presence of four THF molecules of solvation. A single broad resonance ($\Delta\omega_{1/2}$ ~ 390 Hz) was observed in the ^{27}Al NMR spectrum, and a singlet was observed at δ –2.68 in the ^{7}Li NMR spectrum attributable to the $[Li(THF)_4]^+$ cation.

The NMR data obtained for the isopropyl derivatives **2b** and **3b** were consistent with the observed solid-state structures. There were no observable resonances in the ^{1}H or ^{13}C NMR spectra attributable to coordinated solvent molecules.

Table 2. Selected bond lengths (Å) and bond angles (°) for **3c**.

Bond lengths (Å)	
Al(1)—N(1)	1.855(3)

N(2A)-Na(1)-N(4)	82.24(8)
N(3)-Na(1)-N(4)	70.57(8)

However, the complexes **2b** and **3b** are completely insoluble in noncoordinating solvents such as benzene and toluene, whereas they are freely soluble in THF. Presumably, there is some degree of solvation of the alkali metal cations that allows the complex to dissolve in the coordinating solvent, THF. In the respective ^{1}H NMR spectra for these isopropyl complexes, the methyl groups appear as a doublet owing to coupling with the methine protons. The resonances for the N-H protons appear as doublets owing to long-range coupling with the methine protons, which in turn appear as two overlapping septets. A single resonance is observed in each ^{27}Al NMR spectrum. In addition, a singlet is observed at δ –1.31 in the ^{7}Li NMR spectrum of **2b**, which is in keeping with a THF-solvated lithium ion (typical range ~δ –0.5 to –2.5) (21). These data suggest that these complexes exist in THF solution either as solvent-separated cation–anion pairs, as was observed for **2c**, or that the cation is partially solvated, and the complexes are present as contact-ion pairs. In the latter case, any association between the cation and the complex would have to be dynamic on the NMR timescale as all of the amido substituents are equivalent in solution, even down to –80 °C.

Complex **3c** is also insoluble in noncoordinating solvents, but it is freely soluble in THF. In keeping with the solid-state structure, resonances attributable to a single molecule of coordinated THF were present in the ^{1}H NMR spectrum of **3c**. However, in contrast to the solid-state structure, the multinuclear NMR data obtained for complex **3c** are consistent with a highly symmetrical structure, with only a single

Al(1A)-N(1)-Na(1A)	84.68(6)

resonance observed for the N-H and methyl protons, for example. These data suggest that, like the isopropyl complexes, **3c** exists in solution as a solvent-separated cation–anion pair, or that the complex is present as a dynamic contact-ion pair.

All attempts to obtain crystals of **3a** suitable for X-ray diffraction studies were unsuccessful, and so the complex was characterized by multinuclear NMR spectra. In the ^{1}H NMR spectrum, a single resonance is observed for the *tert*-butyl methyl protons, as well as a single N-H resonance. Furthermore, the integrated ^{1}H NMR spectrum indicates that the complex is isolated in the solid state with a single molecule of THF, presumably coordinated to the sodium cation. A broad resonance is observed in the ^{27}Al NMR spectrum, similar to the resonances of the other complexes reported here. Thus, while the NMR data are in keeping with a symmetrical tetrakisimidoaluminate anion, the exact structure of the complex cannot be unambiguously established from these data.

X-ray structures and NMR spectra of the dinuclear complexes $\{[Na(THF)_2][(NH\text{-}t\text{-}Bu)Al(H)(\mu\text{-}N\text{-}t\text{-}Bu)]\}_2$ (4) and $\{[Na(THF)_3][(NH\text{-}p\text{-}tolyl)_2Al(\mu\text{-}N\text{-}p\text{-}tolyl)]\}_2$ (5)

As mentioned previously, the reactions of $MAlH_4$ with a primary amine result in the formation of small amounts of secondary products in addition to the desired tetrakis(amido)aluminate anion. We were able to unambiguously identify the minor products formed in two of the syntheses. The first of these is the dimeric complex $\{[Na(THF)_2][(NH\text{-}t\text{-}Bu)Al(H)(\mu\text{-}N\text{-}t\text{-}Bu)]\}_2$ (**4**), obtained from the reaction of $NaAlH_4$ with *t*-$BuNH_2$. Complex **4** was identified by an X-ray structural determination (Fig. 4); pertinent metrical parameters are given in Table 3.

Complex **4** can be viewed as a contact-ion pair involving the dianion $\{[(NH\text{-}t\text{-}Bu)Al(H)(\mu\text{-}N\text{-}t\text{-}Bu)]_2\}^{2-}$, a dimer of the $[AlH(N\text{-}t\text{-}Bu)(NH\text{-}t\text{-}Bu)]^-$ monoanion, and two THF-solvated sodium ions. The exocyclic amido groups in the dianion exhibit a slightly elongated Al—N bond (1.891(2) Å) in comparison to the bridging imido Al—N bonds (1.858(2) and 1.869(2) Å). The aluminum centres are highly distorted tetrahedral, with the bond angles ranging from 88.69(6)° to 111.86(7)°. The amido and imido Na—N bond distances are nearly identical (2.486(2) and 2.493(2) Å, respectively). The donation of the lone pair on the imido nitrogen centre to the sodium cation is evident from the pyramidal geometry of the nitrogen (bond angles range from 84.68(6)° to 98.06(7)°). The Na—N bond lengths are shorter than those observed for any of the previous complexes reported here. Presumably, the shorter distances are a reflection of the higher ionic character of these bonds in the dianionic complex **4** in comparison to that in the monoanionic complexes **3b** and **3c**.

The NMR data obtained for **4** indicate that the solid-state structure is maintained in solution. In the ^{1}H NMR spectrum, two resonances of equal intensity are apparent for the methyl groups of the two different *tert*-butyl substituents. A single resonance is observed for the N-H protons of the two amido substituents. At room temperature, no resonance was observed for the Al-H proton. However, at 233 K, a single broad resonance ($\Delta\omega_{1/2}$ ~ 70 Hz) at δ 4.38 was detected for this proton. While a large range of values has been reported for Al-H chemical shifts, values in the range of 4.3–5.8 ppm are typical (22), and the value observed for **4** correlates well with the shift δ 4.31 obtained for the structurally similar complex $[(SiMe_3N\text{-}CH_2CH_2\text{-}\mu\text{-}N\text{-}SiMe_3)AlH]_2$ (22*c*).

The by-product obtained from the reaction of *p*-toluidine with $NaAlH_4$ is related to complex **4**, and the structure is shown in Fig. 5 with selected bond distances and angles given in Table 4. In complex **5** a dimeric, dianionic aluminate core structure is observed, however, the hydrido ligand that was present in **4** has been replaced by an additional amido ligand. Thus, the dianion in **5** is $\{[(NH\text{-}p\text{-}tolyl)_2Al(\mu\text{-}N\text{-}p\text{-}tolyl)]_2\}^{2-}$, a dimer of the monoanion $[Al(NH\text{-}p\text{-}tolyl)_2(N\text{-}p\text{-}tolyl)]^-$. The Al—N bond distances fall in a narrow range (1.841(2)–1.860(2) Å), and the aluminum centres exhibit distorted tetrahedral geometries (Table 4). The Na—N distance of 2.493(2) Å is similar to that observed in complex **4**, presumably as a result of the ionic character of the bonding. The sodium centre is only coordinated to the pyramidal imido centre (and three molecules of THF), which suggests a preference for the more ionic imido nitrogen centre in comparison to the amido centres.

The multinuclear NMR data obtained for complex **5** are in accordance with the solid-state structure. In the ^{1}H NMR spectrum, two sets of resonances in a 2:1 ratio are apparent for the aromatic protons of the amido and imido *p*-tolyl substituents, respectively. Consistently, eight carbon resonances for these inequivalent *p*-tolyl groups were observed in the

^{13}C NMR spectrum. Curiously, however, the methyl groups of the *p*-tolyl substituents exhibit only a single resonance in both the ^{1}H and ^{13}C NMR spectra, indicating coincidental equivalence of these substituents.

The isolation and structural characterization of complexes **4** and **5** provides some insight into the possible different pathways for the reactions of $MAlH_4$ with primary amines. As illustrated in Scheme 1, under mild conditions these reactions likely proceed readily to the formation of the trisamido complex $[M][(RNH)_3Al(H)]$, cf. the formation of $[Li(THF)_4][HAl(NPh_2)_3]$ (4). Once this complex is formed, there is a competition among two possible reaction pathways. The first, predominant route involves reaction with a fourth equivalent of amine, resulting in the substitution of the final hydrido ligand with an amido ligand, to form the tetrakis(amido)aluminate complexes (**I**, Scheme 1). The second route, (**II**, Scheme 1), involves the condensation of two $[(RNH)_3Al(H)]^-$ anions, resulting in the elimination of 2 equiv. of primary amine (RNH_2) and the formation of the dianion $[(RNH)Al(H)(\mu\text{-}NR)]_2^{2-}$, as observed in complex **4** (R = *t*-Bu). Reaction of the Al-H functionality in this dianion with two additional equivalents of amine (**III**, Scheme 1) would result in the formation of the diamido imido dianion$[(RNH)_2Al(\mu\text{-}NR)]_2^{2-}$, which was identified in **5** (R = *p*-tolyl). Alternatively, condensation of two tetrakis(amido)aluminate anions, with the loss of primary amine (**IV**, Scheme 1), could also result in the production of the dianion $[(RNH)_2Al(\mu\text{-}NR)]_2^{2-}$. However, this pathway seems unlikely since it was possible to isolate the pure tetrakis(amido)aluminate complexes in good to excellent yields. Under more forcing conditions, the reactions of primary amines with $MAlH_4$ proceed according to eq. [1] (vide supra).

Conclusions

The reactions of alkali metal aluminum hydrides $MAlH_4$ (M = Li, Na) with primary alkyl- or aryl-amines produces tetrakis(amido)aluminate complexes in good to excellent yields. For the lithium derivatives, the established solid-state

© 2006 NRC Canada

structures of these complexes include mono- or bis-solvated monomeric contact-ion pairs, a solvent-separated ion pair, an unsolvated dimeric contact-ion pair, and a polymeric structure. By contrast, only polymeric structures, either unsolvated or monosolvated, are observed for sodium derivatives of the same primary amines. The $[Al(NHR)_4]^-$ anions represent potentially interesting tetradentate ligands. Although they have been known since 1998 (8, 9), their coordination chemistry has yet to be investigated. The facile synthetic procedure reported herein will facilitate such studies.

Effect of the nature of substituents on aromatic aldehydes in microwave induced *N*-cyclohexylamidine–aldehyde condensation reactions

Vipan Kumar, Manish Gupta, and M.P. Mahajan

Abstract: A simple, environmentally friendly protocol for the selective synthesis of the 4-aryl substituted acyclic 1,3-dienes and the medicinally potent triazines has been developed using a domestic microwave oven with excellent yields and reproducibility.

Key words: microwave, dihydrotriazine, triazine, imine metathesis.

Résumé : Utilisant un four microonde domestique, on a développé un protocole soucieux de l'environnement et reproductible pour la synthèse sélective, avec d'excellents rendements, de 1,3-diènes acycliques substitués par un groupe aryle en position 4 et de triazines efficaces d'un point de vue médicinal.

Mots clés : microonde, dihydrotriazine, triazine, métathèse d'imines.

[Traduit par la Rédaction]

Introduction

Azadienes have proved to be of great synthetic potential in heterocyclic synthesis, acting as 4π components in hetero Diels Alder cycloaddition reactions with various dienophiles (1). They have been explored in the synthesis of pyrimidines, pyrimidinones, thioxopyrimidines, and other aza-heterocyclic compounds. One of the crucial and common steps in most synthetic approaches for such heterocycles involves the formation of a new carbon–nitrogen double bond. The reaction of iminophosphoranes with carbonyl compounds is an excellent method for the construction of carbon–nitrogen double bonds under mild and neutral conditions (2). On the other hand, aza-Wittig type reactions with heterocumulenes like carbon dioxide, carbon disulphide, isocyanates, isothiocyanates, and ketenes, provide access to functionalized heterocumulenes, which are highly reactive intermediates able to undergo a plethora of heterocyclization reactions (3). It has been observed that 1-aryl-2-phenyl-5-alkyl/aryl-1,3-diazapenta-1,3,4-triene, generated in situ via aza-Wittig reactions of *N′*-aryl-*N*-(triphenylphosphoranilidene)carboximidamides, selectively undergo [4+2] cycloaddition and electrocyclization reactions leading to the formation of novel pyrimidinones and quinazolines with monosubstituted ketenes and diphenyl ketenes, respectively (4). A conceptually similar annulation involved the aza-Wittig reaction of *N*-imidoyliminophosphoranes with aldehydes to give 3,4-dihydroquinazolines and quinazolines via electrocyclization of initially formed 1,3-diazabuta-1,3-dienes as intermediates (5). Recent work from our laboratory has shown a simple and convenient version of the aza-Wittig reaction between *N*-imidoyliminophosphoranes and aldehydes using a domestic microwave oven (6). The strategy was further simplified by employing the condensation reactions of *N*-arylamidines with aldehydes (7). This simplified version to quinazolines is of significance because of the lack of reports on the condensation reactions of *N*-arylbenzamidines with aldehydes. Even the reported reactions of *N*-alkylamidines with aldehydes involve the use of Lewis acid catalysts (8), have longer reaction periods, suffer from the irreproducibility of the results, and have lower reaction yields (9). It was felt that the problem of spontaneous electrocyclization experienced with *N*-aryl-4-phenyl-1,3-diazabuta-1,3-dienes could be circumvented by the condensation reactions of *N*-alkylamidines with aldehydes.

Results and discussion

Thus, in continuation of our pursuits towards the synthesis and reactivity of azadienes (10), we report herein the results of a few condensation reactions of *N*-cyclohexylbenzamidines with various aldehydes using microwave irradiation. Interestingly, the reaction of *N*-cyclohexylbenzamidine with aromatic aldehydes containing p-electron-donating (-OCH_3) substituent under microwave irradiation resulted in a good yield of 1-(4-methoxy-benzyl)-2-(4-methoxy-phenyl)-4,6-

Scheme 1.

diphenyl-1,2-dihydro-[1,3,5]triazine (**3**), while other aldehydes led to the formation of *N*-cyclohexyl-1,3-diazabuta-1,3-dienes (**4**) (Scheme 1).

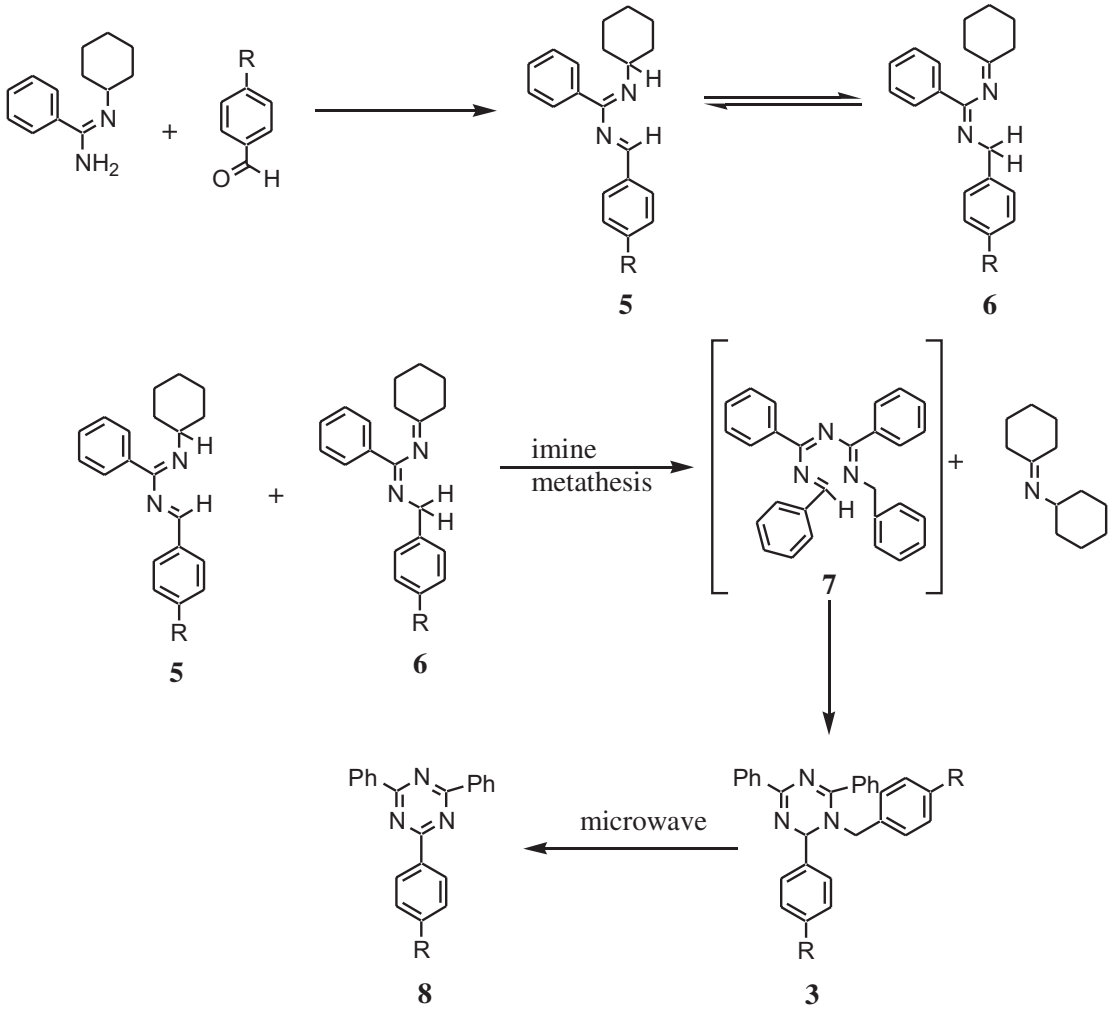
The structure of the dihydrotriazine (**3a**) was confirmed with the help of its spectral data. ^{1}H NMR spectrum of the compound showed the presence of a pair of doublets corresponding to methylene protons with a coupling constant of 14.8 Hz at δ 4.12 and 4.90 and a sharp singlet for a methine proton at δ 5.95. Its mass spectrum exhibited the molecular ion peak at 461.5. The structure of the product was further confirmed using ^{1}H–^{1}H correlation spectroscopic data.

In an attempt to generalize the previous observation, the reaction was repeated with another readily available aldehyde having a strong electron-donating substituent at its *p*-position (*p*-dimethylamino benzaldehyde), which also resulted in a good yield of the desired dihydrotriazine (**3b**). The probable mechanistic pathway leading to the formation of dihydrotriazines (**3a** and **3b**) is outlined in Scheme 2. In this scheme it is assumed that the initially formed 1,3-diazabuta-1,3-diene (**5**) and its tautomer (**6**) undergoes imine metathesis (imine exchange between the cyclohexylideneamine group of **6** and the cyclohexylimine group of **5**, forming *N*-cyclohexylcyclohexylideneamine and the 1,3,5-triaza-1,3,5-hexatriene derivative (**7**)). The 1,3,5-triaza-1,3,5-hexatriene thus formed underwent electrocyclization to yield dihydrotriazines (**3**). These dihydrotriazines were easily converted to the corresponding triazines (**8**) by their exposure to microwave irradiation (oxidative debenzylation) (11) at a power of 200 W for a period of 10 min (5 cycles of 2 min each) (Scheme 2).

Experimental

Melting points were determined by open capillary using a Veego Precision digital melting point apparatus (MP-D) and are uncorrected. IR spectra were recorded on a Shimadzu D-8001 spectrophotometer. ^{1}H NMR spectra were recorded in deuterochloroform with Bruker AC-E 200 (200 MHz) spectrometers using TMS as an internal standard. Chemical shift values are expressed as ppm downfield from TMS and *J* values are in Hz. Splitting patterns are indicated as singlet (s), doublet (d), triplet (t), multiplet (m), quartet (q), and broad peak (br). ^{13}C NMR spectra were also recorded with Bruker AC-200E (50.4 MHz) spectrometers, in deuterochloroform, and using TMS as an internal standard. Mass spectra were recorded on a Shimadzu GCMS-QP-2000 mass spectrometer. Elemental analyses were performed on a Heraus CHN-O-Rapid elemental analyzer.

General procedure



The typical procedure involved the irradiation of *N*-cyclohexylbenzamidine with 1.5 equiv. of aldehydes at a power of 100 W for a period of 20 min (10 cycles of 2 min each). The progress of the reaction was monitored using TLC. The product was then isolated by trituration using hexane and was recrystallized using an ethyl acetate – hexane mixture (1:10).

Conclusion

The simple and convenient method presented for the synthesis of 1,3,5-triazines (12) is of significance because of the limited methods available and the broad range of their biological activities, including antiangiogenesis (13), herbicidal effects (14), antimetastatic effects (15), Erm methylenetransferase inhibition (16), and anti-microbial effects (17). The strategy is of further significance because of the lack of suitable methods for the synthesis of acyclic 1,3-diazabuta-1,3-dienes with aryl substituents at the C-4 position. Such acyclic dienes can prove to be useful substrates for studying the stereochemical aspects of their cycloaddition reactions.

QSAR modeling of neonicotinoid insecticides for their selective affinity towards Drosophila nicotinic receptors over mammalian $\alpha_4\beta_2$ receptors

Anindya Basu, Shovanlal Gayen, Soma Samanta, Parthasarathi Panda, Kolloru Srikanth, and Tarun Jha

Abstract: Neonicotinoids are emerging as a major class of insecticides with promising insecticidal activity having a specific affinity towards the nicotinic acetylcholine receptors (nAChR). A quantitative structure–activity relationship (QSAR) study was performed on some azidopyridinyl neonicotinoids for their selective insecticidal activity over mammalian toxicity. The result showed that increased surface area of the molecules may help to increase the binding affinity of the compounds towards the Drosophila receptor and the presence of the azido group on the other hand may be detrimental towards the affinity. Compounds having low polarity, increased probability of nucleophilic attack at the particular position (N-1), and a higher positive charge at the C-12 position can reduce the binding affinity of these compounds towards the mammalian receptor.

Key words: QSAR, neonicotinoids, Drosophila nicotinic receptor, mammalian $\alpha_4\beta_2$ receptor, AM1.

Résumé : Les néonicotinoïdes émergent comme une classe majeure de composés possédant une activité insecticide intéressante et une activité spécifique pour les récepteurs de l'acétylcholine nicotinique (« nAChR »). Une étude de relation structure–activité quantitative (RSAQ) a été réalisée sur quelques néonicotinoïdes de l'azidopyridinyle pour évaluer leur activité insecticide sélective sur la toxicité mammifère. Le résultat montre que la superficie accrue de la surface des molécules pourrait éventuellement leur permettre d'augmenter les affinités de fixation des composés sur le récepteur Drosophila alors que, par ailleurs, la présence du groupe azido pourrait nuisible à cette affinité. Les composés de faible polarité augmentent la probabilité d'une attaque nucléophile à la position particulière (N-1) et d'une charge plus positive en position C-12 et peuvent réduire l'affinité de fixation de ces composés vis-à-vis des récepteurs mammifères.

Mots clés : RSTQ, néonicotinoïdes, récepteur nicotinique Drosophila, récepteur mammifère $\alpha_4\beta_2$, AM1.

[Traduit par la Rédaction]

Introduction

The neonicotinoids (1) are one of the major classes of insecticides, having very promising potency (2). They are nicotinic agonists that interact with nicotinic acetylcholine receptors (nAChR) in a different way than the conventional nicotinoids. Unlike the protonated nicotinoids, which require a cation–π interaction for binding to the vertebrate receptor, the neonicotinoids do not get protonated at physiological pH. This difference provides the neonictinoids with favourable toxicological profiles (3). The neonicotinoids act as agonists at the nAChR of insects and mammals (particularly the $\alpha_4\beta_2$ subtype) (3), which are mainly responsible for the toxicity of the compounds.

Nicotine, together with other nicotinoids, are also considered as candidate analgesics and for the treatment of neurodegenerative diseases (4–7). The potential activity of neonicotinoids is therefore of particular interest. However, the physical, chemical, or biological properties of a compound depend on the 3D arrangement of the atoms in the molecule. As a part of our composite program of rational drug design (8–22), an attempt was made to explore the quantitative structure–activity relationship (QSAR) study on a series of 20 azidopyridinyl neonicotinoids reported by Zhang et al. (1). Previously, we have reported the QSAR studies of these derivatives using topological descriptors, i.e., electrotopological state atom (ETSA) (8) and refractotopological state atom (RTSA) (9) indices. In the present QSAR study, we used semiempirical quantum descriptors, along with physicochemical and indicator parameters, to understand the structural and physicochemical properties requisite for insecticidal activity at the molecular level. The general structure

of the neonicotinoids used in the present study is shown in Fig. 1.

Materials and methods

For the QSAR study, the binding affinities of azidopyridinyl neonicotinoids for mammalian $\alpha_4\beta_2$ [$K_i(\alpha_4\beta_2)$] and Drosophila [K_i Drosophila)] nicotinic receptors were taken as dependent parameters. Zhang et. al. (1) measured the binding affinities of these neonicotinoids. These were determined with mammalian $\alpha_4\beta_2$ and Drosophila nAChRs using radiopharmaceuticals. Semiempirical calculations of the neonicotinoids, whose activity data are shown in Table 1, were done according to the AM1 method (23) using the Hyperchem Release 7.0 Pro. Package. AM1 is a semiempirical, self-consistent implementation of the Hartree–Fock–Roothaan equations based on the neglect of differential diatomic overlap (NDDO) approximation. The AM1 method produces reliable total energies as a function of atomic positions and is able to probe the energy surface to find the minimum energy configurations (24). The structures of the compounds were drawn and model-built by the HyperChem software (25) to convert the 2D sketch into 3D structures. To shorten the total time required for energy minimization by the semiempirical method, the structures were first energy minimized using the molecular mechanics (MM+) method based on the classical force field without any cutoffs for nonbonded interactions, solvation, and constraints. These energy-minimized structures were then used as the starting structures for geometry optimization by the AM1 method using the Polak–Ribiere (conjugate gradient) algorithm with a RMS gradient of 0.1 kcal/Å mol (1 cal = 4.184 J). During calculations we used a Pentium IV 2.40 GHz computer with 512 MB RAM.

Quantum chemical descriptors such as atomic charges, molecular orbital energies (HOMO, LUMO), frontier electron density, approximate surface area (SA), polarizability, dipole moment, energies (total energy, binding energy, heat of formation), etc., were calculated by the method described in the previous paragraph.

These were subjected to a correlation study. Multiple linear regressions (MLR) were performed with different combinations of the parameters and the biological activity (mammalian $\alpha_4\beta_2$ and Drosophila nAChR agonistic activity) of the neonicotinoids. The correlation and regression analy-

[a]SA is the approximate surface area scaled by 0.01 (Å^2).
[b]IN3 is an indicator parameter indicating the presence of the azido group in the compounds.
[c]log P is the logarithm of the partition coefficient of the whole molecule.
[d]N1L is the frontier electron density for nucleophilic attack at the N1 position.
[e]qC12 is the charge at atom C-12.

ses were carried out by a computer program called Multi Regress, developed in our laboratory (26). The frontier electron densities, charge on the different atoms, approximate surface area (SA), and log P values were used to develop the QSAR equations and are recorded in Table 2.

The statistical quality of the regression equations were justified by parameters such as the correlation coefficient (R), the percentage of explained variance (%EV), the variance ratio (F), the probability factor related to the F ratio (p), and the standard error of estimate (s). The predictive powers of the equations were validated by the leave-one-out (LOO) cross validation method (20–23). Predicted residual sum of squares (PRESS), total sum of squares (SSY), cross-validated R^2 (R^2_{cv}), standard deviation error of prediction (SDEP), and standard error of PRESS (S_{PRESS}) were considered for the validation of the QSAR models.

Results and discussion

Attempts were made to develop QSAR models for the insecticidal activity (pK_i(Drosophila)) of azidopyridinyl neonicotinoids. The best univariate relation (eq. [1]) was obtained by taking the approximate surface area (SA) of the whole molecule as an independent parameter.

$$[1]\quad \text{p}K_i(\text{Drosophila}) = -12.675\ (\pm 2.776) + 3.059\ (\pm 0.776)\text{SA}$$

where n = 20; R = 0.681; %EV = 46.34; F(1,18) = 15.544; p < 0.001; s = 1.246; PRESS = 32.395; SSY = 52.101; R^2_{cv} = 0.378; SDEP = 1.273; and S_{PRESS} = 1.342.

Values within the parenthesis are the standard error of corresponding parameters. Equation [1] explains up to 46.34% of the variances in the activity data and suggests the importance of the approximate surface area of the whole molecules in biological activity. The positive coefficient of the approximate surface area implies that higher values of the whole molecular surface area correspond to higher binding affinity towards the Drosophila receptor.

An indicator parameter (IN3) was used to understand the importance of the azido moiety towards insecticidal activity. The indicator parameter was found to have a good correlation to the biological activity under consideration, and was thus used for the QSAR study. The model obtained is shown in eq. [2].

$$[2]\quad \text{p}K_i(\text{Drosophila}) = -12.775\ (\pm 1.208) - 2.271\ (\pm 0.257)\text{IN3} + 3.502\ (\pm 0.341)\text{SA}$$

where n = 20; R = 0.951; %EV = 90.40; F(2,17) = 80.038; p < 0.000; s = 0.542; PRESS = 7.338; SSY = 52.101; R^2_{cv} = 0.859; SDEP = 0.606; and S_{PRESS} = 0.657.

Compared with eq. [1], eq. [2] has a better statistical quality. It explains up to 90.44% of the variances of the activity data. The negative coefficient of IN3 strongly suggested the detrimental effect of the azido group towards insecticidal activity.

Attempts were also made to obtain QSAR models using the mammalian activity data. The different possible combinations of semiempirical and physicochemical parameters, together with the indicator parameter, were used for the study. Combinations of N1L, qC12, and log P (frontier electron density for nucleophilic attack at the N1 atom, charge at the C12 position, and the logarithm of the octanol–water partition coefficient of the compounds under consideration, respectively) values produced a model for mammalian $\alpha_4\beta_2$ agonistic activity as shown in eq. [3].

$$[3]\quad \text{p}K_i(\alpha_4\beta_2) = 0.708\ (\pm 0.472) - 9.909\ (\pm 2.315)\text{N1L} - 2.842\ (\pm 1.480)\text{qC12} - 0.486\ (\pm 0.115)\ \log P$$

where n = 20; R = 0.865; %EV = 74.87; F(3,16) = 15.885; p < 0.000; s = 0.765; PRESS = 14.020; SSY = 37.268; R^2_{cv} = 0.624; SDEP = 0.837; and S_{PRESS} = 0.936.

Equation [3] explains up to 74.87% of the variances of the activity data. However, the deletion of compounds **19** and **20**, which have different substituents than compounds **1**–**18** and may act through a different mechanism of action, produced eq. [4].

$$[4]\quad \text{p}K_i(\alpha_4\beta_2) = 1.089\ (\pm 0.443) - 10.878\ (\pm 2.092)\text{N1L} - 3.830\ (\pm 1.364)\text{qC12} - 0.507\ (\pm 0.102)\ \log P$$

where the deleted compounds (DC) = **19**, **20**; n = 18; R = 0.910; %EV = 82.84; F(3,14) = 22.529; p < 0.000; s = 0.676; PRESS = 10.443; SSY = 37.267; R^2_{cv} = 0.720; SDEP = 0.762; and S_{PRESS} = 0.864.

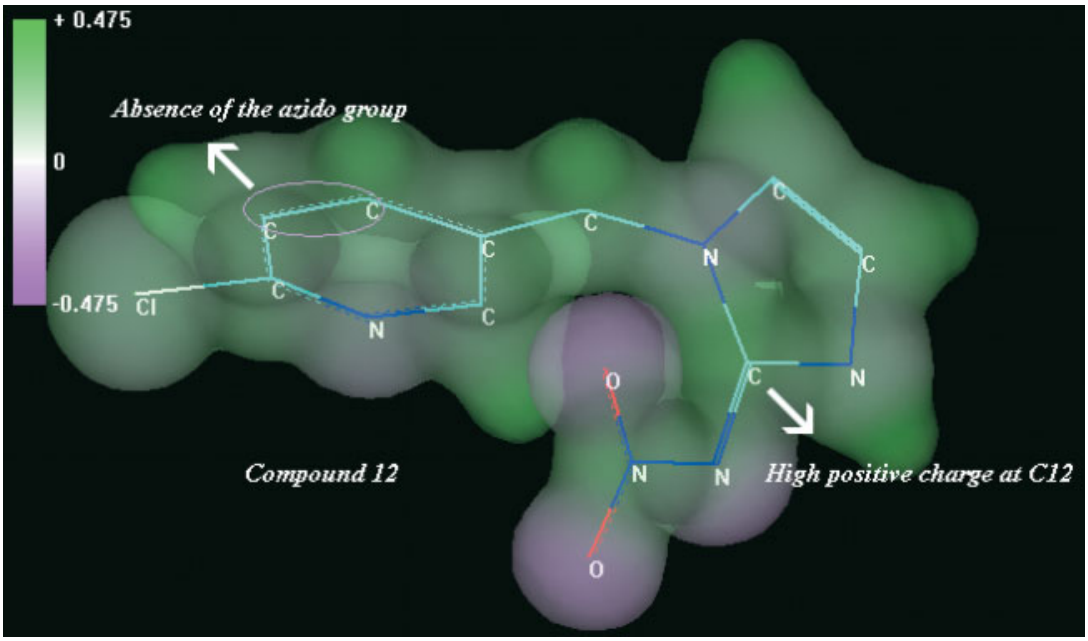
Fig. 2. Three-dimensional isosurface electrostatic potential map of compound **6**.

Equation [4] is of much better statistical quality and explains up to 82.84% of the variances. The equation suggests the importance of atoms N1 and C12 with respect to the toxicity of the compounds towards mammals. The negative coefficient of N1L in eq. [4] suggests that a higher probability of a nucleophillic attack at N1 reduces the binding affinity of the compound with the mammalian receptor, thus reducing the mammalian toxicity of the compounds under consideration. Further, the negative coefficient of qC12 suggests that increased positive charge at C12 diminishes the binding affinity of the compounds towards the mammalian receptor and thus helps in reducing the toxicity of the compounds. Another important parameter of eq. [4] is log *P*. A negative coefficient of this parameter in this equation indicates that compounds having low polarity will have reduced toxic effects on the mammals.

The correlation matrix of the dependent and independent variables used in this study are shown in Table 3. Table 4 represents the *t* and *p* values of the coefficients obtained in the different equations. The final equations obtained in both the cases, i.e., eqs. [2] and [4], were further validated by the LOO method. The LOO predicted values as obtained utilizing eqs. [2] and [4] and are shown in Table 5.

Conclusion

The QSAR study suggests that increased surface area of the molecules helps to increase the insecticidal properties of the compounds by increasing the binding affinity of the compound with the receptor nAChR (insect). The presence of the azido group on the other hand is detrimental to this activity. The study also reveals the importance of atoms N1 and C12 with respect to the binding affinity of the compounds towards the receptor nAChR (mammals). The model showed that a higher probability of a nucleophillic attack at the N1 position may reduce the binding affinity of the compound towards the mammalian receptor. It also explained that increased positive charge at C12 may diminish the binding affinity of the compounds towards the mammalian receptor and thus helps in reducing the toxicity of the compounds. The model also demonstrates that compounds having low polarity may inhibit the binding affinity of the compound to the mammalian nAChR receptor and may reduce the toxic effects to the mammals. Thus, designing compounds having low polarity, increased probability of nucleophilic attack at the N-1 position, and a higher positive charge at the C-12 position can reduce toxicity of these compounds towards the mammalian receptor.



Our prediction is supported by the 3D isosurface electrostatic potential maps of compounds **6** and **12** obtained by AM1 calculations and shown in Figs. 2 and 3, respectively. The N1 atom of compound **6** possesses a low probability of nucleophilic attack as is evident from the value of the frontier electron density for nucleophilic attack at that particular position, recorded in Table 2. Compound **12**, on the other hand, possesses low toxicity towards mammals and a high insecticidal action. Fig. 3 clearly depicts the absence of the azido moiety in the compound, as well as the presence of a high positive charge at position C12, which according to our study should be one of the criteria for an ideal neonicotinoid insecticide. We have already shown that the binding affinity of these azido-pyridinyl neonicotinoids were quantitatively related with topological indices (8, 9). In this article, we also demonstrate that the pharmacological activity may also be explained with quantum chemical parameters.

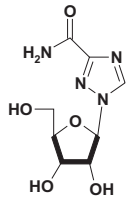
Chiral shift reagent catalyzed, diastereoselective imino Diels–Alder reaction — Synthesis of pyrazolyltetrahydroquinolines

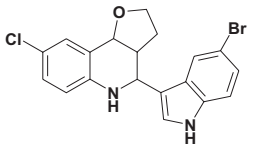
Radhakrishnan Sridhar and Paramasivan T. Perumal

Abstract: A new, target oriented, highly diastereoselective synthesis of pyrazolyltetrahydroquinolines was attempted successfully. The chiral shift reagent Eu(tfc) was found to be a better choice for inducing diasteroselectivity.



Key words: imino Diels–Alder reaction, chiral shift reagent catalyst, pyrazolyltetrahydroquinolines, diastereoselectivity, antibacterial activity.

Résumé : On a réalisé avec succès une nouvelle synthèse hautement diastéréosélective orientée en fonction de la cible de pyrazolyltétrahydroquinoléines. On a trouvé que le réactif chiral de déplacement chimique Eu(tfc) est le meilleur choix pour induire la diastéréosélectivité.



Mots clés : réaction imino de Diels–Alder, catalyseur à base de réactif chiral de déplacement chimique, pyrazolyltétrahydroquinoléines, diastéréosélectivité, activité antibactérienne.

[Traduit par la Rédaction]

Ribavirin (1-β-D-ribofuranosyl-1,2,4-triazole-3-carboxamide) **1**, a synthetic nucleoside analogue, possesses broad spectrum activity against both RNA and DNA viruses in vitro and in vivo (1). Several modifications were carried out in the sugar as well as in the base units to explore more of these nucleosides and their biological efficiency (2, 3). During our studies on the synthesis of similar base units (4, 5), we found that pyrazole-3-ester posses bacterial and fungal inhibition (4).

2

A number of tetrahydroquinoline derivatives exhibit a wide range of biological properties (6–8). Substituted tetrahydroquinolines are the core structures in many important pharmacological agents and drug molecules, such as antiarrhythmic and cardiovascular agents, anticancer drugs, immunosuppressants, and ligands for 5-HT1A and NMDA receptors (9). Hence, there has been considerable interest in the development of new and efficient methodologies for the synthesis of tetrahydroquinoline derivatives (8, 10).

The frequency of methicillin-resistant *Staphylococcus aureus* (MRSA) infections has been increasing for the last decade and has developed into a problem throughout the world. Novel antibacterial agents, 2-(1*H*-indol-3-yl)tetrahydroquinolines **2**, were prepared using hetero Diels–Alder chemistry and were found to be effective in vitro against MRSA. From the SAR study it was observed that among the two diastereomers, the *cis*-2-(1*H*-indol-3-yl)tetrahydroquinolines was found to be more potent in antibacterial inhibition than the trans isomer (11).

The imino Diels–Alder reaction provides a useful entry to the preparation of tetrahydroquinoline derivatives (8). Generally, Lewis acids (12–14) are known to catalyze the imino Diels–Alder reaction to produce quinoline derivatives. A few reports are available on the imino Diels–Alder reaction catalyzed by lanthanide catalysts (15). Lanthanide shift reagents have been shown to act as efficient catalysts for the inverse electron demand Diels–Alder reactions with complete diastereoselectivity (16). It was also observed that the usage of $Eu(thd)_3$ showed a dramatical reversal in diastereoselectivity (17). Cycloaddition reactions between the chiral 2-pyrone derivatives and various dienophiles were also reported with lanthanide shift reagents to afford bicyclic lactones in high diastereomeric excesses (18). A catalytic asymmetric version of these reactions, using optically active lanthanide catalysts, was also successfully investigated by Markó and co-workers (19).

Based on the report available on the antibacterial inhibition of tetrahydroquinolines (11) and results of our earlier studies on the antibacterial inhibition of pyrazole-3-esters (4), we planned to synthesize pyrazolyl tetrahydroquinolines

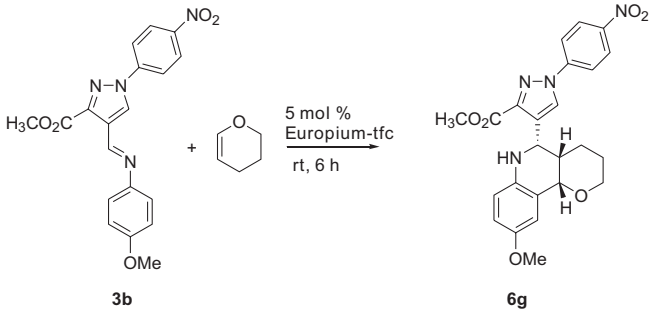
that we expect to be effective bactericides, through imino Diels–Alder reaction using the chiral shift reagent. Also, our aim was to synthesize the cis diastereomer in excess over the less potent antibacterial trans isomer, which we intend to achieve through the versatility of the chiral shift reagent (19).

Pyrazole aldimines were prepared from 4-formyl-1*H*-pyrazole-3-carboxylate (4, 5) and aniline using $InCl_3$ as catalyst following the reported procedure for the preparation of imines (20). These imines upon stirring at room temperature with cyclopentadiene (Scheme 1) in the presence of 5 mol% Eu(tfc) gave corresponding pyrazolyl tetrahydro-3*H*-cyclopenta[*c*]quinolines in excellent yield as a single product (Table 1). Pyrazolyl tetrahydrofuroquinolines (Scheme 2) or pyrazolyltetrahydropyranoquinoline (Scheme 3) were obtained in good to excellent yields by treating the respective imines with 2,3-dihydrofuran or 3,4-dihydropyran in the presence of 5 mol% Eu(tfc) at room temperature.



The structures of the products were confirmed through IR, NMR, and mass spectral data (see Experimental), and the diastereomeric excess of the products was determined based on column chromatographic yield. All the pyrazolyltetrahydroquinolines exhibited a resultant optical rotation owing to the excess of one enantiomer over the other, but the detailed study on enantiomeric excess will be demonstrated using chiral HPLC technique in due course.

In the case of tetrahydrofuroquinolines, two diastereomers were obtained and the orientation of H-3a and H-4 corresponding to cis and trans diastereomers were confirmed by their coupling constant values, J = 3.4 Hz and J = 10.3 Hz, respectively, from the NMR spectra. Further, the diastereomers show different fragmentation patterns in mass spectra (see Experimental). Our observations (Table 2) showed that the diastereoselectivity was improved by exchanging the catalyst $InCl_3$ with Eu(tfc). Hence, by employing Eu(tfc) the

Scheme 3. Synthesis of pyrazolyltetrahydropyranoquinolines.

yield of the more potent antibacterial cis diastereomer (8) was selectively increased over the trans.

Only one isomer was isolated and it was found to be in cis orientation (J = 2.3 Hz) for the tetrahydropyranoquinolines.

One-pot synthesis of tetrahydroquinolines was also attempted starting directly from pyrazole aldehydes, substituted anilines, and dienophiles in the presence of Eu(tfc) (Table 3). The yield obtained and diastereoselectivities from the table also clearly indicate the versatility of the europium D-3-trifluoroacetyl camphorate catalyst over the $InCl_3$ catalyst in the multicomponent reaction.

The higher diastereoselectivity in the product formation depending on the chiral catalyst used may be due to the unsymmetric nature of the aldehydic portion of the imine and the bulkiness of the chiral catalyst. The same reason can be extended for the formation of the product **6g** in 99% diastereomeric excess. On the other hand, this reason will be invalid in the use of $InCl_3$ as the catalyst because of its symmetric nature.

From the investigation it is clear that the catalyst is more versatile in selectivity and, hence, in the synthesis of the cis isomer, which we expect to be more potent over the trans (11). Herein we have synthesized pyrazolyltetrahydroquinolines and our ultimate goal is to prove them as novel and potent bactericides, which will be demonstrated in future articles. In summary, we report a target-oriented, highly diastereoselective synthesis for pyrazolyltetrahydroquinolines using Eu(tfc) catalyst.

Experimental

General procedure for the synthesis of pyrazolyl tetrahydroquinolines from corresponding imines

To a solution of an imine (2 mmol) in acetonitrile (10 mL), was added 5 mmol of dienophile (cylopentadiene, 2,3-dihydrofuran, or 3,4-dihydropyran) and 5 mol% of Eu(tfc) or 20 mol% of $InCl_3$. The reaction mixture was stirred for an adequate time at room temperature until TLC showed the completion of the reaction. Water was then added to the mixture and extracted with $CHCl_3$. The combined organic layers were treated with brine solution, then with water, and the product dried over anhydrous sodium sulfate. After evaporation of the solvent, the residue was column chromatographed with 15% ethyl acetate – petroleum ether mixture to afford the pure cycloadduct.

Synthesis of pyrimidine annulated furothiopyrans — An efficient sequential and tandem catalyzed Claisen rearrangement – intramolecular hydroaryloxylation

K.C. Majumdar and S.K. Chattopadhyay

Abstract: Regioselective synthesis of a hitherto unreported furothiopyran moiety fused at the C-5 and C-6 positions of a pyrimidine heterocycle was achieved by the application of sequential Claisen rearrangement in which a second aromatic Claisen rearrangement and intramolecular hydroaryloxylation were catalyzed by aluminum chloride. The second aromatic Claisen rearrangement step was also studied under thermal conditions to give mostly isomerized exocyclic compounds. The precursor endocyclic compounds were synthesized by thermal [3,3] sigmatropic rearrangement of the corresponding sulfide.

Key words: aluminum chloride, sequential Claisen rearrangement, hydroaryloxylation, furothiopyran, pyrimidine.

Résumé : Faisant appel à une séquence des réarrangements de Claisen dans laquelle le deuxième réarrangement aromatique de Claisen et l'hydroaryloxylation sont catalysées par du chlorure d'aluminium, on a effectué la synthèse régiosélective qui n'avait pas été réalisée jusqu'à maintenant de la portion furothiopyrane condensée aux positions C-5 et C-6 de l'hétérocycle pyrimidine. On a aussi étudié le deuxième réarrangement de Claisen dans des conditions thermiques et il conduit principalement à des composés isomérisés exocycliques. On a réalisé la synthèse des composés endocycliques précurseurs en procédant à un réarrangement thermique [3,3] du sulfure correspondant.

Mots clés : chlorure d'aluminium, séquence de réarrangements de Claisen, hydroaryloxylation, furothiopyrane, pyrimidine.

[Traduit par la Rédaction]

Introduction

Claisen rearrangement, since its discovery in 1912, has been proven to be one of the preeminent methodologies for the construction of carbon–carbon bonds in synthetic organic chemistry (1). A high level of stereocontrol, securing its widespread use in the synthesis of natural products and medicinal agents, can be achieved by this concerted [3,3] sigmatropic rearrangement (1). The traditional methodologies for accomplishing the rearrangement are based on thermally controlled procedure; however, the development of new methodologies employing a catalyst in the Claisen rearrangement have been the focus of many recent investigations in organic synthesis (2). Over the past few years we embarked on the development of new synthetic methodologies for the synthesis of novel heterocycles based on sequential Claisen rearrangement (3). During the investigation of the synthetic perspectives of the aforementioned thermally controlled rearrangement, we observed interesting results in the second Claisen rearrangement (3*a*, 3*b*). We sought to extend this chemistry to encompass a new synthetic route leading to a [6,5]-furothiopyran moiety.

The incorporation of the pyrimidine moiety in the present investigation is due to its wide biological and pharmacological activities (4). Numerous pyrimidine- and uracil-based molecules, e.g., AZT, DDC, and BVDU, have been known to be active agents against cancer and the AIDS virus (5). Some pyrido-[2,3-*d*]-pyrimidines exhibit antibacterial activity and antitumor activities (6). Extensive investigations have been carried out with these heterocyclic systems (7). In contrast, a few examples dealing with the chemistry of an 8-sulfurisostere, thiopyrano-[2,3-*d*]-pyrimidine system, which may have potential biological activity, are reported in the literature (8). This has prompted us to undertake a study of sequential Claisen rearrangement with the development of broadly useful new routes to a [6,5]-furothiopyran system fused at the C-5 and C-6 positions of the pyrimidine moiety. Herein we report the results of our investigation.

Results and discussion

The requisite sulfides (**3a**–**3g**) for the present investigation were synthesized in 75%–92% yields by phase-transfer-catalyzed alkylation of 6-mercaptouracil (**2**) with different 1-chloro-4-aryloxybut-2-ynes. Compound **2** was in turn prepared by the reaction of 6-chlorouracil (**1**) with NaSH in dry ethanol at 0 °C. Compounds **3a**–**3g** were all solid and were

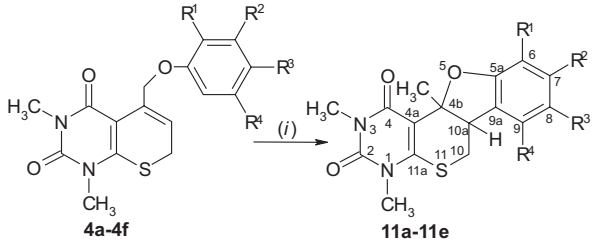
characterized from their elemental analyses and spectral data (Scheme 1).



The substrates **3a**–**3g** possess two potential sites for [3,3] sigmatropic rearrangement: a vinyl propargyl sulfide moiety and an aryl propargyl ether moiety. Compounds with this structural feature offer an excellent scope for the study on the competition between oxy- and thio-Claisen rearrangement along with the synthesis of new heterocycles through [3,3] sigmatropic rearrangement. To accomplish the thio-Claisen rearrangement, the substrate **3a** was first subjected to thermal rearrangement by refluxing in the lower boiling solvent chlorobenzene (132 °C) for 4 h to give crystalline solid **4a** in 94% yield (Scheme 2). Elemental analysis and spectral data of compound **4a** established its endocyclic nature, which is necessary for further Claisen rearrangement. Encouraged by the initial accomplishment, the remaining substrates (**3b**–**3g**) were similarly treated to afford **4b**–**4f** (84%–95% yield) and **5g** (88% yield) (Scheme 2). The exocyclic nature of the product **5g** was established from the high field (300 MHz) ^{1}H NMR spectrum. The ^{13}C NMR chemical shift values of compound **5g** and multiplicities were assigned from the DEPT experiment. The DEPT spectrum obtained showed 10 protonated carbons, four -CH_3, two >CH_2, and four >CH-.

The mechanistic rationalization (Scheme 3) for the formation of compounds **4a**–**4f** and **5g** can be explained by assuming initial [3,3] sigmatropic rearrangement of **3a**–**3g**, followed by rapid enolization to form the allenylene–thiol intermediate **7**, which then undergoes a [1,5]-hydrogen shift, followed by 6π electrocyclic ring closure to give the products **4a**–**4f**. The product **5g** may also be formed because of the [1,3] protropic rearrangement of the thermally unstable endocyclic compound **9** to afford **5g** (Scheme 3). It is noteworthy that all the substrates **3a**–**3f**, except **3g**, regioselectively afforded exclusive products **4a**–**4f** in excellent yield. A lesser energy requirement for the sigmatropic rearrangement in vinyl propargyl sulfide systems (9) compared with that in aryl propargyl ether moieties (10) might be responsible for this excellent regioselectivity.

Scheme 3.

Scheme 4. Reagents and conditions: (*i*) $AlCl_3$, CH_2Cl_2, rt, 1 h.

	R^1	R^2	R^3	R^4	Yield (%)
11a	H	H	OMe	H	96
11b	H	Me	Cl	Me	90
11c	Cl	H	H	H	92
11d	Me	Me	H	H	94
11e	H	Me	Me	H	90
11f	Cl	H	Cl	H	—

Compound **4** still posses an allyl aryl ether segment requisite for further study on the [3,3] sigmatropic rearrangement. In our earlier efforts, we found different regioselectivity with different substrates in the thermal second aromatic Claisen rearrangement (3). In some cases, [1,3] prototropic rearrangement was an important side reaction along with [3,3] sigmatropic rearrangement (11). To circumvent this unwanted problem in thermal second Claisen rearrangement, we turned our attention to the Lewis acid catalyzed Claisen rearrangement approach (2). Among the different Lewis acid catalysts available for the aromatic oxy-Claisen rearrangement, aluminum chloride and its different derivatives have received the most attention (1*d*, 2*a*). So we subjected compound **4a** to catalyzed Claisen rearrangement using aluminum chloride as the catalyst in dry dichloromethane at room temperature to afford the cyclized product **11a** (96% yield), which was characterized by its elemental analysis and spectral data. To test the generality of the reaction, other substrates (**4b**–**4f**) were similarly treated to afford the cyclized

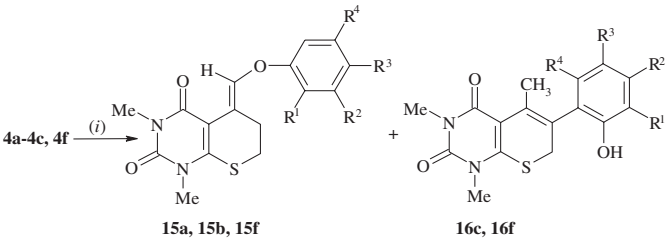
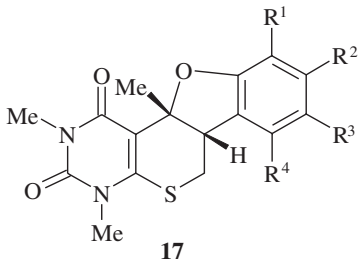
Scheme 5.



products **11b–11e** (90%–96% yield) (Scheme 4). No cyclized product corresponding to **11** was obtained in the case of compound **4f**, as several other unwanted products (TLC observation) were formed during the reaction that were not characterized. We have tried the reaction with other Lewis acids, e.g., $BF_3{\cdot}Et_2O$ and Cp_2TiCl_2. In the case of Cp_2TiCl_2, no reaction occurred. The reaction is quite sluggish with $BF_3{\cdot}Et_2O$ with the formation of undesired products, which were not characterized.



The conversion of **4** into **11** may take a pathway similar to that observed in thermal Claisen rearrangement via the 2-allylphenol intermediate **13** (Scheme 5). From the literature it may be assumed that this transformation may be a charge-induced Claisen rearrangement similar in mechanism to the process reported for BCl_3 by Schmid and co-workers (12). The reaction may be facilitated by the coordination of the oxygen atom, which itself is a strong Lewis base, to the hard Lewis acid, aluminum chloride. The hydroaryloxylation step leading to the formation of the benzofuran moiety may occur by the addition of H^+ to the position of the homothioenol ether followed by simultaneous conjugate addition of a phenolic OH group to the resulting thionium ion. To isolate the 2-allylphenol intermediate **13**, we tried the reaction in the presence of additives such as PPh_3 or amine base, e.g., morpholine and triethylamine. There too no reaction was observed. It is noteworthy that in the present investigation aluminium chloride promotes both Claisen rearrangement and hydroaryloxylation and the unusual ring contraction pertinent to the $AlCl_3$-catalyzed oxy-Claisen rearrangement (13) was unobserved, mainly owing to the soft basic character of sulfur being unable to form a complex with aluminum chloride. The overall regioselectivity of the catalyzed reaction leading to the formation of tetracyclic heterocycles **11** is excellent.

We have also examined the thermal second Claisen rearrangement of the same substrates. For compounds **4a**–**4c** and **4f**, when subjected to thermal rearrangement in refluxing dichlorobenzene in the presence of *N*,*N*-diethylaniline for 8 h (Scheme 6), the observed results were quite interesting as compounds **4a** and **4b** exclusively gave the exocyclic compounds **15a** and **15b** in 40% and 45% yield, respectively, and from compound **4c** the endocyclic phenolic compound **16c** was obtained in 10% yield. Both products **15f** and **16f** were isolated; in the case of substrate **4f**, in almost 38% and 25% yield, respectively. In each case, an appreciable amount of starting material was recovered. We have also attempted the reaction in dichlorobenzene and *N*,*N*-diethylaniline separately. There too the same products were obtained in very poor yield. All the compounds were solid and were characterized from their elemental analysis and spectral data.

Scheme 6. Reagents and conditions: (*i*) dichlorobenzene, *N*,*N*-diethylaniline, reflux, 8 h.

The formation of products **15a**, **15b**, **15f**, **16c**, and **16f** can be mechanistically interpreted as follows (Scheme 5). Compounds **15a**, **15b**, and **15f** can be obtained by [1,3] prototropic rearrangement in compounds **4a**, **4b**, and **4f**. Initial [3,3] sigmatropic rearrangement followed by rapid tautomerization may result in the formation of **16c** and **16f** from **4c** and **4f** via the 2-allyl phenol intermediate **13**. In the present investigation, the [1,3] prototropic rearrangement with the formation of an exocyclic compound as the major product is quite unusual. In two cases we were successful in isolating the endocyclic phenolic product, but in very poor yield. The presence of different substituents in the benzene nuclei of compounds **4a**, **4b**, and **4f** thus results in a change in the mode of rearrangement. However, the role of the substituent in the formation of products **15** and **16** is not clear. It may be conceivable that the thermal stability of the resulting compounds might be responsible for their formation.

© 2006 NRC Canada

From a molecular modelling (Dreiding model) study and comparison with the stereochemistry of natural pterocarpin (14), the stereochemistry of the ring fusion in the tetracyclic system may be assumed to be cis and is represented as **17**.

In conclusion, we have demonstrated a broadly useful new route based on a sequential thermal plus tandem-catalyzed Claisen rearrangement – intramolecular hydroaryloxylation approach that we expect to provide an expedient avenue for the synthesis of a furothiopyran system, quite similar to the petrocarpin system. This protocol is complementary to our preliminary thermal methodology. The mild reaction conditions and compatibility with various substituents on the aromatic ring make this route a significant addition to the existing methodologies for the synthesis of a synthetically challenging furothiopyran moiety fused with other heterocycles.

Experimental

General remarks

Melting points were determined in open capillaries and are uncorrected. IR spectra were recorded on a PerkinElmer L120-000A spectrometer (γ_{max} in cm^{-1}) using samples as neat liquids, solid samples were recorded in KBr disks, and UV absorption spectra were recorded in EtOH on a Shimadzu UV-2401PC spectrophotometer (λ_{max} in nm). ^1H NMR (300 MHz, 500 MHz) spectra were recorded on Bruker DPX-300 and Bruker DRX-500 spectrometers in $CDCl_3$ (chemical shifts in δ) with TMS as the internal standard. Elemental analyses and mass spectra were recorded on a JEOL JMS600 instrument. Silica gel (60–120 mesh, Spectrochem, India) was used for chromatographic separation. Silica gel G (E-Merck, India) was used for TLC. Petroleum ether refers to the fraction boiling between 60 and 80 °C.

The 1-aryloxy-4-chlorobut-2-ynes were prepared according to the published procedure (15).

General procedure for the preparation of 6-mercaptouracil (2)

To a magnetically stirred solution of NaSH (1.2 g, 20.8 mmol) in dry ethanol (50 mL), a solution of 6-chlorouracil (**1**) (1.5 g, 8.6 mmol) in dry ethanol (50 mL) was added dropwise for a period of 2 h. After the addition was complete, the stirring was continued for an additional 4 h. Ethanol was removed under vacuum at room temperature. The residue was acidified with concd. HCl (25 mL). This was then extracted with CH_2Cl_2 (4 × 20 mL). The dichloromethane solution was washed with water (2 × 10 mL) and dried (Na_2SO_4). Attempts to evaporate dichloromethane led to considerable decomposition of compound **2**. Therefore, this dichloromethane solution was directly used in the next phase-transfer-catalyzed alkylation step.

General procedure for the preparation of sulfides (3a–3g)

To a stirred solution of 6-mercaptouracil (**2**) (obtained from 1.5 g, 8.6 mmol of compound **1**) and 1-aryloxy-4-chlorobut-2-yne (8.6 mmol) in dichloromethane (100 mL), a solution of benzyltriethylammonium chloride (BTEAC) (0.5 g, 1.8 mmol) in 1% aq. NaOH solution (100 mL) was added, and the mixture was stirred for 12 h at room temperature. It was then diluted with water (25 mL). The dichloromethane layer was then separated and washed with 2 N HCl (25 mL), brine (25 mL), and water (25 mL), and dried (Na_2SO_4). The crude mass obtained upon evaporation of CH_2Cl_2 was subjected to column chromatography. Elution with petroleum ether – ethyl acetate (7:3) afforded the products **3a**–**3g**.

Compound 3a

Yield: 84%; brown solid, mp 70 °C. IR (KBr, cm^{-1}) ν_{max}: 1645, 1702, 2963. ^1H NMR ($CDCl_3$, 300 MHz) δ_H: 3.34 (s, 3H, -*N*CH_3), 3.45 (s, 3H, -*N*CH_3), 3.69 (s, 2H, -SCH_2), 3.77 (s, 2H, -OCH_3), 4.63 (s, 2H, -OCH_2), 5.66 (s, 1H, =CH), 6.81–6.88 (m, 4H, ArH). MS *m*/*z*: 346 (M^+). Anal. calcd. for $C_{17}H_{18}N_2O_4S$ (%): C 58.95, H 5.20, N 8.09; found: C 59.15, H 5.44, N 8.25.

Compound 3b

Yield: 78%; brown solid, mp 130 °C. General procedure for the preparation of 4a–4f and 5g

Compounds **3a**–**3h** (250 mg, 0.72 mmol) were refluxed in chlorobenzene (10 mL) for 5 h. The reaction mixture was then cooled and directly subjected to column chromatography over silica gel. Chlorobenzene was eluted out with petroleum ether. On eluting the column with petroleum ether – ethyl acetate (4:1), compounds **4a**–**4g** and **5h** were obtained. All compounds were recrystalized from dichloromethane – petroleum ether.

Compound 4a

Yield: 94%; white solid, mp 102 °C. IR (KBr, cm^{-1}) ν_{max}: 1633, 1705, 2928. ^1H NMR ($CDCl_3$, 500 MHz) δ_H: 3.36 (s, 3H, -*N*CH_3), 3.39 (d, 2H, *J* = 6 Hz, -SCH_2), 3.56 (s, 3H, -*N*CH_3), 3.75 (s, 3H, -OCH_3), 5.04 (s, 2H, -OCH_2), 5.86 (t, 1H, *J* = 6 Hz, =CH), 6.78–6.88 (m, 4H, ArH). ^{13}C NMR ($CDCl_3$, 125 MHz) δ_C: 26.60, 28.62, 33.76, 56.11, 69.71, 107.74, 111.45, 114.45, 116.51, 136.53, 151.16, 153.18, 154.34, 155.19, 159.78. General procedure for the aluminum chloride catalyzed reaction

To a stirred solution of the compounds **4a**–**4f** (0.28 mmol) in dry dichloromethane (10 mL), anhydrous aluminium chloride (36 mg, 0.28 mmol) was added at room temperature. The stirring was continued for about 1 h. After completion of the reaction, 1% HCl solution (5 mL) was added. The reaction mixture was then extracted with dichloromethane (2 × 10 mL). The organic layer was washed with water (2 × 10 mL) and brine (10 mL) and dried (Na_2SO_4). Dichloromethane was distilled off and the residue obtained was subjected to flash chromatography. On eluting the column with ethyl acetate – petroleum ether (1:10), compounds **11a**–**11e** were obtained as white solids. All compounds were recrystalized from dichloromethane.

Compound 11a

Yield: 96%; white solid, mp 132 °C. IR (KBr, cm^{-1}) ν_{max}: 1646, 1701, 2927. ^1H NMR ($CDCl_3$, 500 MHz) δ_H: 1.78 (s, 3H, C_{4b}-CH_3), 2.80 (dd, 1H, *J* = 11, 13 Hz, C_{10}-H), 3.02 (dd, 1H, *J* = 3, 13 Hz, C_{10}-H), 3.29 (dd, 1H, *J* = 3, 11 Hz, C_{10a}-H), 3.39 (s, 3H, -*N*CH_3), 3.51 (s, 3H, -*N*CH_3), 3.77 (s, 3H, -OCH_3), 6.72–6.86 (m, 3H, ArH). ^{13}C NMR ($CDCl_3$, 125 MHz) δ_C: 25.05, 28.57, 30.20, 32.89, 51.26, 56.41, 86.30, 108.54, 111.04, 111.69, 111.53, 129.13, 151.19, 151.77, 153.09, 154.67, 160.39. MS *m/z*: 346 (M^+). Anal. calcd. for $C_{17}H_{18}N_2O_4S$ (%): C 58.95, H 5.20, N 8.09; found: C 59.18, H 5.34, N 8.27.

Compound 11b

Yield: 90%; white solid, mp 102 °C. IR (KBr, cm^{-1}) ν_{max}: 1640, 1700, 2924, 2976. ^1H NMR ($CDCl_3$, 500 MHz) δ_H: 1.71 (s, 3H, C_{4b}-CH_3), 2.32 (s, 3H, Ar-CH_3), 2.37 (s, 3H, Ar-CH_3), 2.62 (dd, 1H, *J* = 11, 13 Hz, C_{10}-H), 2.93 (dd, 1H,

© 2006 NRC Canada

J = 3, 13 Hz, C_{10}-H), 3.22 (dd, 1H, J = 3, 11 Hz, C_{10a}-H), 3.40 (s, 3H, -NCH_3), 3.54 (s, 3H, -NCH_3), 6.71 (s, 1H, ArH). MS *m*/*z*: 378, 380 (M^+). Anal. calcd. for $C_{18}H_{19}N_2O_3SCl$ (%): C 56.99, H 5.01, N 7.38; found: C 57.19, H 5.29, N 7.62.

Compound 11c

Yield: 92%; white solid, mp 198 °C. IR (KBr, cm^{-1}) ν_{max}: 1629, 1692, 2895. ^{1}H NMR ($CDCl_3$, 500 MHz) δ_H: 1.83 (s, 3H, C_{4b}-CH_3), 2.82 (dd, 1H, J = 11, 13 Hz, C_{10}-H), 3.02 (dd, 1H, J = 3, 13 Hz, C_{10}-H), 3.39 (s, 3H, -NCH_3), 3.40 (dd, 1H, J = 3, 11 Hz, C_{10a}-H), 3.51 (s, 3H, -NCH_3), 6.83–6.86 (m, 1H, ArH), 7.12 (d, 1H, J = 7 Hz, Ar-H), 7.19 (d, 1H, J = 7 Hz, Ar-H). MS *m*/*z*: 350, 352 (M^+). Anal. calcd. for $C_{16}H_{15}N_2O_3SCl$ (%): C 54.70, H 4.27, N 7.97; found: C 54.92, H 4.46, N 8.21.

Compound 11d

Yield: 94%; white solid, mp 216 °C. IR (KBr, cm^{-1}) ν_{max}: 1651, 1702, 2926. ^{1}H NMR ($CDCl_3$, 300 MHz) δ_H: 1.76 (s, 3H, C_{4b}-CH_3), 2.16 (s, 3H, Ar-CH_3), 2.24 (s, 3H, Ar-CH_3), 2.76 (dd, 1H, J = 11, 13 Hz, C_{10}-H), 2.99 (dd, 1H, J = 3, 13 Hz, C_{10a}-H), 3.28 (dd, 1H, J = 3, 11 Hz, C_{10a}-H), 3.39 (s, 3H, -NCH_3), 3.51 (s, 3H, -NCH_3), 6.70 (d, 1H, J = 7 Hz, ArH), 6.95 (d, 1H, J = 7 Hz, ArH). ^{13}C NMR ($CDCl_3$, 125 MHz) δ_C: 12.35, 19.93, 25.18, 28.55, 30.29, 32.85, 51.16, 85.79, 108.72, 120.33, 121.07, 122.38, 125.15, 138.71, 151.31, 153.03, 156.46, 160.23. MS *m*/*z*: 344 (M^+). Anal. calcd. for $C_{18}H_{20}N_2O_3S$ (%): C 62.79, H 5.81, N 8.13; found: C 62.95, H 6.03, N 8.32.

Compound 11e

Yield: 90%; white solid, mp 188 °C. IR (KBr, cm^{-1}) ν_{max}: 1643, 1700, 2923. ^{1}H NMR ($CDCl_3$, 300 MHz) δ_H: 1.71 (s, 3H, C_{4b}-CH_3), 2.27 (s, 3H, Ar-CH_3), 2.31 (s, 3H, Ar-CH_3), 2.63 (dd, 1H, J = 11, 13 Hz, C_{10}-H), 2.96 (dd, 1H, J = 3, 13 Hz, C_{10}-H), 3.21 (dd, 1H, J = 3, 11 Hz, C_{10a}-H), 3.40 (s, 3H, -NCH_3), 3.53 (s, 3H, -NCH_3), 6.54 (s, 1H, Ar-H), 6.61 (s, 1H, Ar-H). MS *m*/*z*: 344 (M^+). Anal. calcd. for $C_{18}H_{20}N_2O_3S$ (%): C 62.79, H 5.81, N 8.13; found: C 63.00, H 5.98, N 8.33.

General procedure for the preparation of 15a, 15b, 15f, 16c, and 16f

Compounds **4a**–**4c** and **4f** (100 mg, 0.28 mmol) were refluxed in dichlorobenzene (10 mL) in the presence of *N*,*N*-diethylaniline (2 mL) for 8 h. The reaction mixture was then cooled and directly subjected to column chromatography over silica gel. Dichlorobenzene along with *N*,*N*-diethylaniline was eluted out with petroleum ether. On eluting the column with petroleum ether – ethyl acetate (4:1), compounds **15a**, **15b**, **15f**, **16c**, and **16f** were obtained. All compounds were solid and were recrystalized from dichloromethane – petroleum ether.

Compound 15a

Yield: 40%; white solid, mp 148 °C. IR (KBr, cm^{-1}) ν_{max}: 1647, 1707, 2932. ^{1}H NMR ($CDCl_3$, 500 MHz) δ_H: 2.93–2.96 (m, 2H, =C-CH_2), 3.11–3.13 (m, 2H, -SCH_2), 3.39 (s, 3H, -NCH_3), 3.55 (s, 3H, -NCH_3), 3.78 (s, 3H, -OCH_3), 6.83–7.25 (m, 4H, ArH), 8.02 (s, 1H, =CH). MS *m*/*z*: 346 (M^+). Anal. calcd. for $C_{17}H_{18}N_2O_4S$ (%): C 58.95, H 5.20, N 8.09; found: C 59.17, H 5.39, N 8.31.

Compound 15b

Yield: 45%; white solid, mp 168 °C. IR (KBr, cm^{-1}) ν_{max}: 1629, 1697, 2934. ^{1}H NMR ($CDCl_3$, 500 MHz) δ_H: 2.36 (s, 6H, -Ar$(CH_3)_2$), 2.91–2.95 (m, 2H, =C-CH_2), 3.09–3.11 (m, 2H, SCH_2), 3.40 (s, 3H, -NCH_3), 3.54 (s, 3H, -NCH_3), 6.81 (S, 2H, ArH), 8.05 (s, 1H, =CH). MS *m*/*z*: 378, 380 (M^+). Anal. calcd. for $C_{18}H_{19}N_2O_3SCl$ (%): C 56.99, H 5.01, N 7.38; found: C 57.17, H 5.22, N 7.64.

Compound 15f

Yield: 38%; white solid, mp 174 °C. IR (KBr, cm^{-1}) ν_{max}: 1632, 1699, 2917. ^{1}H NMR ($CDCl_3$, 300 MHz) δ_H: 2.97–3.01 (m, 2H, =C-CH_2), 3.13–3.16 (m, 2H, -SCH_2), 3.39 (s, 3H, -NCH_3), 3.55 (s, 3H, -NCH_3), 7.11–7.39 (m, 3H, ArH), 8.07 (s, 1H, =CH). MS *m*/*z*: 384, 386, 388 (M^+). Anal. calcd. for $C_{16}H_{14}N_2O_3SCl_2$ (%): C 49.87, H 3.64, N 7.27; found: C 50.11, H 3.83, N 7.48.

Compound 16c

Yield: 10%; white solid, mp 186 °C. IR (KBr, cm^{-1}) ν_{max}: 1648, 1698, 2927, 3322. ^{1}H NMR ($CDCl_3$, 300 MHz) δ_H: 2.06 (s, 3H, =C-CH_3), 3.40 (s, 3H, -NCH_3), 3.51 (s, 2H, -SCH_2), 3.57 (s, 3H, -NCH_3), 5.77 (s, 1H, -OH, D_2O exchangeable), 6.89–7.12 (m, 3H, ArH). MS *m*/*z*: 350, 352 (M^+). Anal. calcd. for $C_{16}H_{15}N_2O_3SCl$ (%): C 54.70, H 4.27, N 7.97; found: C 54.94, H 4.50, N 8.21.

Compound 16f

Yield: 25%; white solid, mp 208 °C. IR (KBr, cm^{-1}) ν_{max}: 1640, 1683, 2938, 3444. ^{1}H NMR ($CDCl_3$, 300 MHz) δ_H: 2.06 (s, 3H, =C-CH_3), 3.40 (s, 3H, -NCH_3), 3.48 (s, 2H, SCH_2), 3.57 (s, 3H, -NCH_3), 5.76 (s, 1H, -OH, D_2O exchangeable), 7.10 (d, 1H, J = 2 Hz, ArH), 7.31 (d, 1H, J = 2 Hz, ArH). MS *m*/*z*: 384, 386, 388 (M^+). Anal. calcd. for $C_{16}H_{14}N_2O_3SCl_2$ (%): C 49.87, H 3.64, N 7.27; found: C 50.03, H 3.87, N 7.49.

7-Azaindolyl- and indolyl-functionalized starburst molecules with a 1,3,5-triazine or a benzene core — Syntheses and luminescence[1]

Wei-Hua Huang, Wen-Li Jia, and Suning Wang

Abstract: The syntheses of several new 7-azaindolyl-, indolyl-, and 3-methylindolyl-functionalized starburst molecules that contain either a 1,3,5-triazine, a benzene, a 2,4,6-triphenyl-2,4,6-triazine, a 1,3,5-triphenylbenzene, a 2,4,6-tris(biphenyl)-1,3,5-triazine, or a 1,3,5-tris(biphenyl)benzene core have been achieved. The synthetic methods used for these new compounds involve mostly Ullmann condensation and Suzuki coupling reactions. The thermal properties of the new molecules have been found to be highly dependent on the molecular weight and the central core. Glass transition temperatures greater than 150 °C were observed for the large starburst molecules based on the 2,4,6-tris(biphenyl)-1,3,5-triazine or the 1,3,5-tris(biphenyl)benzene core. The new starburst molecules are luminescent in the violet-blue region in solution and in the solid state. The emission energy and the quantum efficiency were found to be highly dependent on the central core and the functional group. In general, the triazine-based molecules were found to have a smaller HOMO–LUMO energy gap than the benzene-based analogues. The triphenyltriazine- or triphenylbenzene-based molecules were found to display a higher emission quantum efficiency than the large tris(biphenyl)triazine- or tris(biphenyl)benzene-based molecules.

Key words: 7-azaindolyl, indolyl derivative, triazine and benzene cores, starburst molecule, blue luminescence.

Résumé : On a réalisé la synthèse de plusieurs nouvelles molécules à base d'indolyle, de 3-méthylindolye et de 7-azaindolyle fonctionnalisés qui donnent l'impression d'une explosion d'étoiles et qui contiennent comme partie centrale une 1,3,5-triazine, un benzène, un 2,4,6-triphényl-2,4,6-triazine, un 1,3,5-triphénylbenzène, un 2,4,6-tris(biphényl)-1,3,5-triazine ou un 1,3,5-tris(biphényl)benzène. Les méthodes de synthèse utilisées pour ces nouveaux produits impliquent principalement des réactions de condensation de Ullmann et de couplage de Suzuki. On a trouvé que les propriétés des nouvelles molécules dépendent fortement du poids moléculaire et de la nature de la partie centrale. On a observé des températures de transition de verre supérieures à 150 °C pour les grosses molécules qui donnent l'impression d'une explosion d'étoiles à base d'une partie centrale de 2,4,6-tris(biphényl)-1,3,5-triazine ou de 1,3,5-tris(biphényl)benzène. Tant en solution qu'à l'état solide, les nouvelles molécules qui donnent l'impression d'une explosion d'étoiles sont luminescentes dans la région du violet-bleu. On a trouvé que l'énergie d'émission et l'efficacité quantique dépendent fortement de la nature de la partie centrale et du groupe fonctionnel. On a trouvé que, en général, l'écart entre les énergies des orbitales moléculaires hautes occupées (HO) et basses vacantes (BV) des molécules à base de triazine sont plus faibles que celles de leurs analogues à base de benzène. On a observé que les efficacités quantiques d'émission des molécules à base de triphényltriazine ou de triphénylbenzène sont plus grandes que celles des molécules à base de tris(biphényl)triazine ou de tris(biphényl)benzène.

Mots clés : 7-azaindolyle, dérivé de l'indolyle, partie centrale à base de triazine et de benzène, molécule qui donne l'impression d'une explosion d'étoiles, luminescence bleue.

[Traduit par la Rédaction]

Introduction

Starburst or star-shaped molecules have been shown to have the tendency to form amorphous films with a relatively high T_g, a property that is highly desired for applications of organic materials in photonic and optoelectronic devices such as organic light emitting diodes (OLEDs) (1). Our group has recently demonstrated that 2,2′-dipyridylamino- or 7-azaindolyl-functionalized aromatic molecules can be used as effective blue emitters in OLEDs (2). In addition, the 2,2′-dipyridylamino and 7-azaindolyl functionalities allow the attachment of metal ions to the aromatic molecules for emission color tuning and supramolecular assembly (3). Several series of starburst molecules with a C_3 symmetry that are functionalized by 2,2′-dipyridylamino groups on a 1,3,5-triazine, benzene, triphenyltriazine, or triphenylbenzene core

were reported previously by our group (3). These molecules indeed displayed good film-forming properties and were shown to be effective as emitters for blue OLEDs (2). Our current work focuses on the development of starburst molecules that are functionalized by the 7-azaindolyl group. In contrast to the 2,2′-dipyridylamino group, which can act as either a chelate ligand or a terminal ligand to metal ions, the 7-azaindolyl group can only bind to the metal center as a terminal ligand, which offers new binding modes for coordination compounds and supramolecular assembly (4). In our previous work, three starburst molecules containing the 7-azaindolyl group were investigated (1,3,5-tris(*N*-7-azaindolyl)benzene, 1,2,4,5-tetrakis(*N*-7-azaindolyl)benzene (4), and hexakis(*p*-*N*-7-azaindolylphenyl)benzene (3*e*)). Although these three compounds were found to form unusual complexes with a variety of metal ions and may be used as blue emitters in OLEDs (2*b*), they have the tendency to remain crystalline, which limits their applications in OLEDs. Our current efforts therefore focus on the synthesis of large starburst molecules containing the 7-azaindolyl or the indolyl group with the aim to enhance the T_g of the amorphous films. In this report, the syntheses, characterization, and thermal and luminescent properties of several new starburst molecules are presented.

Experimental

All reactions were carried out under a nitrogen atmosphere and monitored by thin layer chromatography (TLC). All starting materials were purchased from the Sigma-Aldrich Chemical Company and used without further purification. NMR spectra were recorded on Bruker 300, 400, or 600 MHz spectrometers. High-resolution mass spectra were recorded on an Applied Biosystems/MDS Sciex QSTAR XL instrument with an Agilent HP1100 Cap-LC system by electron spray ionization (ESI) and a Waters/Micromass GC–TOF instrument with an Agilent HP6890 GC system by electron impact (EI). Elemental analyses were performed by Canadian Microanalytical Service Ltd., Delta, British Columbia. TLC was carried out on SiO_2. Column chromatographic separation was carried out on silica (silica gel, 70–230 mesh 60). Melting points were measured on a Fisher-Johns melting point apparatus. Excitation and emission spectra were recorded on a Photon Technologies International QuantaMaster Model C-60 spectrometer at room temperature. DSCs were performed on a PerkinElmer Pyris DSC 6. Heating scans were performed at 10° min^{-1}. Cooling scans were performed at 20° min^{-1}. Cyclic voltammetry was performed on a BAS CV-50W analyzer with scan rates of 100 mV s^{-1}. The electrolytic cell used was a conventional three-compartment cell with a Pt working electrode, Pt auxiliary electrode, and Ag/AgCl reference electrode. All experiments were performed at room temperature in CH_2Cl_2 or THF with 0.10 mol/L tetrabutylammonium hexafluorophosphate as the supporting electrolyte. The ferrocenium/ferrocene couple was used as the internal standard. 1,3,5-Tris(*p*-bromophenyl)benzene and 2,4,6-tri(*p*-bromophenyl)-1,3,5-triazine were synthesized by a modified literature method (2*a*). Melting points were determined on a Fisher-Johns melting point apparatus (maximum temperature 330 °C) and were confirmed by DSC measurements.

Synthesis of 2,4,6-tris(1-*N*-7-azaindolyl)-1,3,5-triazine (1)

To a vigorously stirred solution of 7-azaindole (0.400 g, 3.4 mmol) in dry THF (15 mL), *n*-butyllithium solution in hexanes (1.6 mol/L, 2.2 mL, 3.5 mmol) was added slowly at –78 °C. After stirring for 30 min at –78 °C, a cyanuric chloride (0.186 g, 1.0 mmol) solution in THF (10 mL) was slowly added to the mixture. A yellow solid quickly appeared. After stirring for 1 h at –78 °C, the mixture was warmed to room temperature and stirred for 12 h. The mixture was then concentrated under vacuum. Water (40 mL) was added and the crude product was extracted with CH_2Cl_2 (3 × 40 mL). The organic layer was dried over $MgSO_4$ and then concentrated under vacuum to give a yellow solid. Recrystallization from CH_2Cl_2 and hexanes produced a white solid (0.350 g, yield 82%, mp 289 °C). ^{1}H NMR (400 MHz, $CDCl_3$, 298 K, ppm) δ: 8.70 (d, J = 4.8 Hz, 3H, 7-aza), 8.69 (d, J = 4.0 Hz, 3H, 7-aza), 8.00 (d, J = 7.8 Hz, 3H, 7-aza), 7.31 (dd, J_1 = 7.8 Hz, J_2 = 4.8 Hz, 3H, 7-aza), 6.80 (d, J = 4.0 Hz, 3H, 7-aza). ^{13}C NMR (400 MHz, $CDCl_3$, 298 K, ppm) δ: 163.5, 148.7, 145.1, 129.3, 127.1, 124.6, 118.9, 106.4. HRMS (ESI, *m*/*z*) calcd. for $C_{24}H_{16}N_9$: 430.1523; found: 430.1513.

Synthesis of 1,3,5-tris[*p*-(1-*N*-7-azaindolyl)phenyl]benzene (2)

A mixture of 1,3,5-tris(*p*-bromophenyl)benzene (1.100 g, 2.02 mmol), 7-azaindole (1.071 g, 9.08 mmol), CuI (0.115 g, 6.05 mmol), Cs_2CO_3 (4.160 g, 12.8 mmol), 1,10-phenanthroline (0.218 g, 1.21 mmol), and DMF (5 mL) was heated to 150 °C. After stirring for 48 h at 150 °C, the mixture was cooled to room temperature and was dissolved in CH_2Cl_2 (50 mL) and water (50 mL). The water layer was separated and was extracted with CH_2Cl_2 (2 × 50 mL). The combined organic layer was dried over $MgSO_4$, and the solvents were evaporated under reduced pressure to give a brown solid that was purified by a chromatographic column using THF–hexanes (1:2.5) as the eluent to obtain a white solid. Recrystallization from THF and hexanes yielded a colorless compound (0.842 g, yield 64%, mp 287 °C). ^{1}H NMR (300 MHz, $CDCl_3$, 298 K, ppm) δ: 8.45 (d, J = 4.7 Hz, 3H, 7-aza), 8.03 (d, J = 7.8 Hz, 3H, 7-aza), 7.96 (d, J = 8.8 Hz, 6H, ph), 7.92 (s, 3H, ph), 7.90 (d, J = 8.8 Hz, 6H, ph), 7.63 (d, J = 3.6 Hz, 3H, 7-aza), 7.20 (dd, J_1 = 7.8 Hz, J_2 = 4.7 Hz, 3H, 7-aza), 6.71 (d, J = 3.6 Hz, 3H, 7-aza). ^{13}C NMR (300 MHz, $CDCl_3$, 298 K, ppm) δ: 148.3, 144.4, 142.5, 139.6, 138.7, 129.8, 128.9, 128.4, 125.7, 125.0, 122.3, 117.5, 102.6. HRMS (ESI, *m*/*z*) calcd. for $C_{45}H_{31}N_6$: 655.2604; found: 655.2605.

Synthesis of 2,4,6-tris[*p*-(1-*N*-7-azaindolyl)phenyl]-1,3,5-triazine (3)

A mixture of 2,4,6-tri(*p*-bromophenyl)-1,3,5-triazine (0.789 g, 1.46 mmol), 7-azaindole (0.776 g, 6.58 mmol), CuI (0.083 g, 0.44 mmol), Cs_2CO_3 (3.00 g, 9.2 mmol), 1,10-phenanthroline (0.158 g, 0.87 mmol), and DMF (4 mL) was heated to 150 °C and stirred for 48 h at 150 °C. After cooling to room temperature, the mixture was dissolved in CH_2Cl_2 (100 mL) and water (100 mL). Two phases were separated and the water layer was extracted with CH_2Cl_2 (3 × 50 mL). All organic layers were combined and the solvents were evaporated to give a dry brown solid. The solid

© 2006 NRC Canada

was purified by column chromatography using THF–hexanes (2:5) first and then pure THF as the eluent to obtain a crude yellow product. The crude product was decolored with activated carbon in hot DMF and recrystallized in hot DMF three times. A pale yellow solid (0.464 g, yield 48%, mp 333 °C) was obtained. ^{1}H NMR (600 MHz, $CDCl_3$, 298 K, ppm) δ: 8.97 (d, J = 6.8 Hz, 6H, ph), 8.44 (d, J = 4.6 Hz, 3H, 7-aza), 8.10 (d, J = 6.8 Hz, 6H, ph), 8.01 (d, J = 7.8 Hz, 3H, 7-aza), 7.67 (d, J = 3.6 Hz, 3H, 7-aza), 7.19 (dd, J_1 = 7.8 Hz, J_2 = 4.6 Hz, 3H, 7-aza), 6.71 (d, J = 3.6 Hz, 3H, 7-aza). ^{13}C NMR (600 MHz, $CDCl_3$, 298 K, ppm) δ: 170.8, 147.5, 143.6, 142.0, 133.5, 130.1, 129.1, 122.9, 127.1, 122.0, 117.0, 102.5. Elemental anal. calcd. for $C_{42}H_{27}N_9$: C 76.71, H 4.10, N 19.18; found: C 76.64, H 4.04, N 19.21.

Synthesis of 1,3,5-tris{*p*-[*N*-(3-methyl-indolyl)]phenyl}-benzene (4)

A mixture of 1,3,5-tris(*p*-bromophenyl)benzene (1.00 g, 1.84 mmol), 3-methylindole (1.09 g, 8.29 mmol), CuI (0.11 g, 0.55 mmol), Cs_2CO_3 (3.78 g, 11.6 mmol), 1,10-phenanthroline (0.20 g, 1.10 mmol), and DMF (5 mL) was heated to 150 °C. After stirring for 48 h at 150 °C, the mixture was cooled to room temperature and dissolved in CH_2Cl_2 (20 mL) and water (20 mL). Two phases were separated and the water layer was extracted with CH_2Cl_2 (3 × 20 mL). All organic layers were combined, dried over $MgSO_4$, and concentrated to give a brown solid. The crude product was purified twice by a chromatographic column using chloroform–hexanes (at a 1:1.7 concentration initially and secondly, a 2:1 concentration) as the eluent to obtain a white solid. Recrystallization from CH_2Cl_2 and hexanes yielded the colorless compound **4** (0.65 g, yield 51%, mp 275 °C). ^{1}H NMR (400 MHz, $CDCl_3$, 298 K, ppm) δ: 7.93 (s, 3H, ph), 7.90 (d, J = 8.2 Hz, 6H, phenyl), 7.69 (d, J = 7.2 Hz, 3H, indolyl), 7.68 (d, J = 7.6 Hz, 3H, indolyl), 7.66 (d, J = 7.2 Hz, 6H, phenyl), 7.31 (dd, J_1 = 7.8 Hz, J_2 = 7.2 Hz, 3H, indolyl), 7.25 (s, 3H, indolyl), 7.24 (dd, J_1 = 7.8 Hz, J_2 = 7.6 Hz, 3H, indolyl), 2.46 (s, 9H, Me). ^{13}C NMR (400 MHz, $CDCl_3$, 298 K, ppm) δ: 141.79 (ph), 139.6 (ph), 138.4 (ph), 135.9, 129.9, 128.4, 125.3, 124.9, 124.2, 122.5, 119.9, 119.3, 113.2, 110.4, 9.6. HRMS (EI, *m*/*z*) calcd. for $C_{51}H_{39}N_3$: 693.3144; found: 693.3135.

Synthesis of intermediate 1-bromo-3,5-bis[*N*-(3-methyl-indolyl)]benzene (a)

A mixture of 1,3,5-tribromobenzene (2.160 g, 6.86 mmol), 3-methyl indole (1.807 g, 13.7 mmol), $CuSO_4{\cdot}5H_2O$ (0.086 g, 0.05 mmol), K_2CO_3 (1.89 g, 13.7 mmol), and dodecane (4 mL) was heated to 190 °C and stirred for 10 h at 195 °C. After cooling to room temperature, the mixture was dissolved in CH_2Cl_2 (50 mL) and water (50 mL). Two phases were separated and the water layer was extracted with CH_2Cl_2 (3 × 20 mL). All of the organic layers were combined, dried over $MgSO_4$, and concentrated to give a brown solid. The crude product was purified by a chromatographic column using CH_2Cl_2–hexanes (1:4) as the eluent to obtain a colorless solid (0.628 g, yield 22%, mp 184 to 185 °C). ^{1}H NMR (400 MHz, $CDCl_3$, 298 K, ppm) δ: 7.63 (d, J = 7.8 Hz, 2H, indolyl), 7.64 (d, J = 8.1 Hz, 2H, indolyl), 7.61 (s, 1H, ph), 7.59 (s, 2H, ph), 7.31 (dd, J_1 = 8.1 Hz, J_2 = 8.0 Hz, 2H, indolyl), 7.24 (dd, J_1 = 8.0 Hz, J_2 = 7.6 Hz, 2H, indolyl), 7.18 (s, 2H, indolyl), 2.41 (s, 6H, Me).

Synthesis of intermediate 1,3,5-tris[(*p*-boronic acid)phenyl]benzene (b)

To a vigorously stirred solution of 1,3,5-tris(*p*-bromophenyl)benzene (2.72 g, 4.98 mmol) in dry THF (100 mL), butyllithium solution in hexanes (1.6 mol/L, 15.6 mL, 24.9 mmol) was added slowly at –78 °C. After stirring for 1 h at –78 °C, triisopropyl borate (6.3 mL, 27.4 mmol) was added slowly. The solution was stirred for 1 h at –78 °C then warmed to room temperature and stirred for 12 h. The reaction was quenched by adding satd. aq. NH_4Cl (30 mL). The water phases were separated and extracted with CH_2Cl_2 (3 × 20 mL). All of the organic layers were combined and concentrated to give a white solid. Recrystallization from methanol and hexanes yielded a white compound (1.31 g, yield 64%, mp > 300 °C). ^{1}H NMR (400 MHz, acetone-d_6, 298 K, ppm) δ: 8.05 (d, J = 8.2 Hz, 6H, ph), 8.00 (s, 3H, ph), 7.88 (d, J = 8.2 Hz, 6H, ph), 7.27 (s, 6H, OH).

Synthesis of intermediate 1-bromo-3,5-bis(*N*-indolyl)benzene (c)

A mixture of 1,3,5-tribromobenzene (3.780 g, 12 mmol), indole (2.808 g, 24 mmol), $CuSO_4{\cdot}5H_2O$ (0.150 g, 0.6 mmol), and K_2CO_3 (3.312 g, 24 mmol) was heated to 195 °C and stirred for 16 h at 195 °C. After cooling to room temperature, the mixture was dissolved in CH_2Cl_2 (100 mL) and water (100 mL). Two phases were separated and the water layer was extracted with CH_2Cl_2 (3 × 30 mL). All of the organic layers were combined, dried over $MgSO_4$, and concentrated to give a brown solid. The crude product was purified by a chromatographic column using ethyl acetate – hexanes (1:20) as the eluent to obtain a colorless solid (0.580 g, yield 13%, mp 117 to 118 °C). ^{1}H NMR (400 MHz, $CDCl_3$, 298 K, ppm) δ: 7.65 (d, J = 7.8 Hz, 2H, indolyl), 7.64 (d, J = 8.1 Hz, 2H, indolyl), 7.61 (s, 1H, ph), 7.54 (s, 2H, ph), 7.29 (d, J = 3.3 Hz, 2H, indolyl), 7.21 (dd, J_1 = 8.1 Hz, J_2 = 7.2 Hz, 2H, indolyl), 7.14 (dd, J_1 = 8.0 Hz, J_2 = 7.8 Hz, 2H, indolyl), 6.66 (d, J = 3.3 Hz, 2H, indolyl).

Synthesis of intermediate 3,5-bis(1-*N*-indolyl)-1-phenylboronic acid (d)

A solution of *tert*-butyllithium (1.6 mol/L in hexanes, 4.85 mL, 7.76 mmol) was added slowly to a THF (50 mL) solution of 1-bromo-3,5-bis(1-*N*-indolyl)benzene (2.00 g, 5.17 mmol) at –78 °C. After stirring for 1 h at –78 °C, triisopropyl borate (2.02 mL, 8.79 mmol) was added slowly. The solution was stirred for 1 h at –78 °C then slowly warmed to room temperature and stirred for 12 h. The reaction was quenched by adding satd. aq. NH_4Cl solution (20 mL). The water phases were separated and extracted with CH_2Cl_2 (3 × 30 mL). All organic layers were combined and then concentrated to give a brown solid. The crude product was purified by a chromatographic column using THF–hexanes (2:5) as the eluent. Recrystallization from CH_2Cl_2 and hexanes yielded a colorless solid (1.15 g, yield 63%). ^{1}H NMR (400 MHz, actone-d_6, 298 K, ppm) δ: 8.10 (s, 2H, ph), 7.86 (s, 1H, ph), 7.75 (d, J = 7.7 Hz, 2H, indolyl), 7.73 (d, J = 3.3 Hz, 2H, indolyl), 7.70 (d, J = 7.8 Hz, 2H, indolyl), 7.54 (s, 2H, ph), 7.66 (s, 2H, OH), 7.26 (dd, J_1 = 8.0 Hz,

© 2006 NRC Canada

J_2 = 7.8 Hz, 2H, indolyl), 7.17 (dd, J_1 = 8.0 Hz, J_2 = 7.7 Hz, 2H, indolyl), 6.76 (d, J = 3.3 Hz, 2H, indolyl).

Synthesis of 1,3,5-tris[3,5-bis(*N*-indolyl)-4′-biphenyl]benzene (5)

A mixture of 1,3,5-tris[(*p*-boronic acid)phenyl]benzene (0.192 g, 0.439 mmol), 1-bromo-3,5-bis(*N*-indolyl)benzene (0.595 g, 1.537 mmol), $Pd(PPh_3)_4$ (0.020 g, 0.018 mmol), Na_2CO_3 solution (2 N, 30 mL), toluene (50 mL), and ethanol (20 mL) was refluxed for 40 h. A white precipitate formed. After cooling to room temperature, the mixture was extracted with CH_2Cl_2 (3 × 50 mL). All of the organic layers were combined and concentrated to give a colorless solid. The crude product was dried and purified by a chromatographic column using THF–hexanes (2:5) as the eluent to obtain a pale white solid. Recrystallization from CH_2Cl_2 and hexanes twice yielded compound **5** (0.47 g, yield 88%, mp > 330 °C). ^{1}H NMR (400 MHz, $CDCl_3$, 298 K, ppm) δ: 7.96 (s, 3H, ph), 7.91 (d, J = 8.2 Hz, 6H, ph), 7.85 (d, J = 8.2 Hz, 6H, ph), 7.84 (s, 6H, ph), 7.76 (d, J = 7.5 Hz, 6H, indolyl), 7.75 (d, J = 8.1 Hz, 6H, indolyl), 7.70 (s, 3H, ph) 7.50 (d, J = 3.2 Hz, 6H, indolyl), 7.32 (dd, J_1 = 8.1 Hz, J_2 = 7.2 Hz, 6H, indolyl), 7.22 (dd, J_1 = 7.5 Hz, J_2 = 7.2 Hz, 6H, indolyl), 6.80 (d, J = 3.2 Hz, 6H, indolyl). ^{13}C NMR (400 MHz, $CDCl_3$, 298 K, ppm) δ: 143.7, 141.8, 141.6, 141.0, 138.8, 135.7, 129.5, 128.1, 127.8, 127.7, 125.3, 122.8, 121.4, 120.8, 120.5, 118.6, 110.4, 104.4. Elemental anal. calcd. for $C_{90}H_{60}N_4$: C 88.24, H 4.90, N 6.86; found: C 87.87, H 4.96, N 6.78.

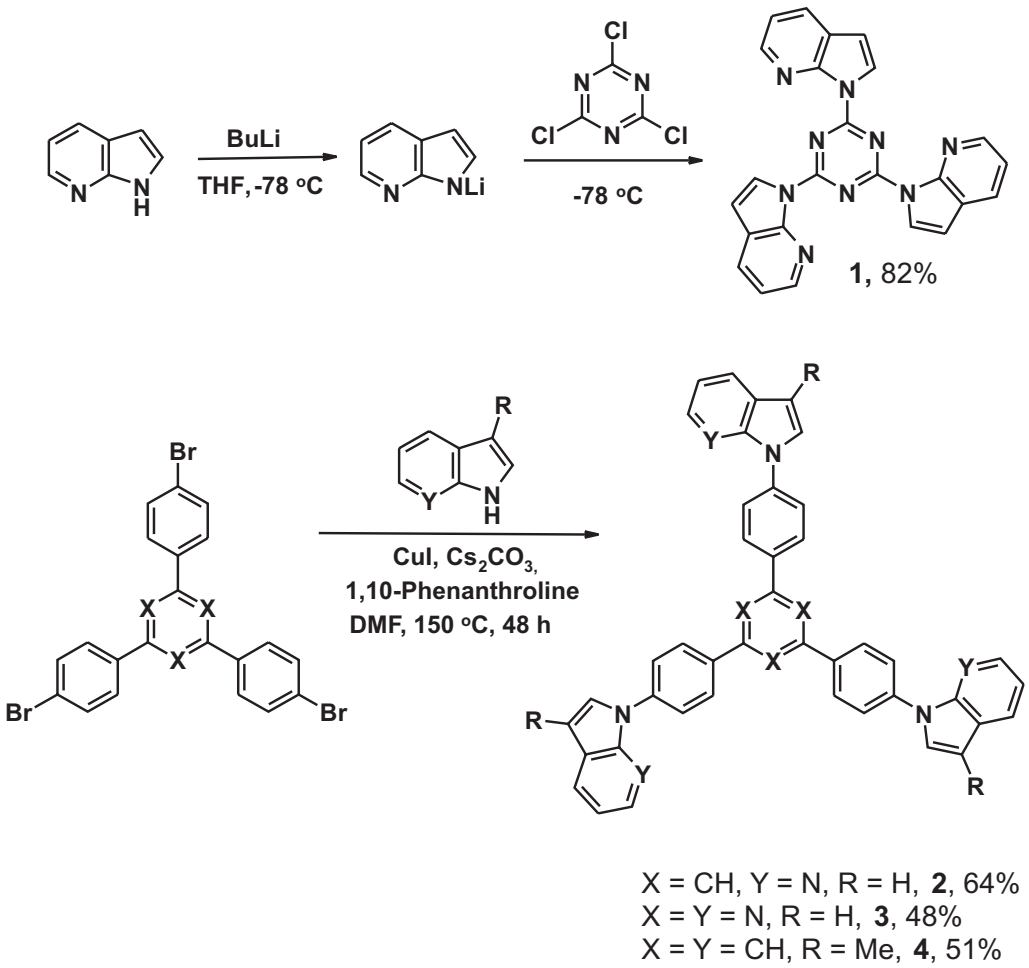
Synthesis of 1,3,5-tris{3,5-bis[*N*-(3-methyl-indolyl)]-4′-biphenyl}benzene (6)

A mixture of 1,3,5-tris[(*p*-boronic acid)phenyl]benzene (0.150 g, 0.343 mmol), 1-bromo-3,5-bis[*N*-(3-methyl-indolyl)]benzene (0.498 g, 1.20 mmol), $Pd(PPh_3)_4$ (0.016 g, 0.014 mmol), Na_2CO_3 solution (2 N, 30 mL), toluene (50 mL), and ethanol (20 mL) was refluxed for 40 h. A white precipitate formed. After cooling to room temperature, CH_2Cl_2 (50 mL) and water (50 mL) were added to the mixture. The water layer was separated and extracted with CH_2Cl_2 (2 × 50 mL). The combined organic layers were dried over $MgSO_4$, and the solvents were evaporated under reduced pressure. Purification of the crude product by column (THF–hexanes, 1:16) afforded a white solid. Recrystallization from CH_2Cl_2 and hexanes yielded compound **6** (0.254 g, yield 57%, mp 318 °C). ^{1}H NMR (600 MHz, $CDCl_3$, 298 K, ppm) δ: 7.93 (s, 3H, ph), 7.87 (d, J = 8.3 Hz, 6H, ph), 7.82 (d, J = 8.3 Hz, 6H, ph), 7.74 (s, 6H, ph), 7.71 (d, J = 8.2 Hz, 6H, indolyl), 7.66 (d, J = 7.7 Hz, 6H, indolyl), 7.61 (s, 3H, ph), 7.28 (dd, J_1 = 7.7 Hz, J_2 = 7.2 Hz, 6H, indolyl), 7.26 (s, 6H, indolyl), 7.22 (dd, J_1 = 8.0 Hz, J_2 = 7.2 Hz, 6H, indolyl), 2.42 (s, 18H, Me). ^{13}C NMR (600 MHz, $CDCl_3$, 298 K, ppm) δ: 143.5, 141.8, 141.7, 140.8, 139.1, 135.8, 130.0, 128.0, 127.7, 127.5, 125.2, 122.8, 120.2, 119.6, 119.4, 117.8, 113.6, 110.4, 9.6. Elemental anal. calcd. for $C_{96}H_{72}N_6$: C 88.07, H 5.50, N 6.42; found: C 88.26, H 5.21, N 6.18.

Synthesis of 2,4,6-tris[3,5-bis(1-*N*-indolyl)-4′-biphenyl]-1,3,5-triazine (7)

A mixture of 2,4,6-tris(*p*-bromophenyl)-1,3,5-triazine (0.412 g, 0.75 mmol), 3,5-bis(*N*-indolyl)-1-phenylboronic acid (0.930 g, 2.64 mmol), $Pd(PPh_3)_4$ (0.04 g, 0.03 mmol), Na_2CO_3 solution (2 N, 30 mL), toluene (50 mL), and ethanol (20 mL) was refluxed for 40 h. A white precipitate formed. After cooling to room temperature, CH_2Cl_2 (100 mL) and water (100 mL) were added to the mixture. The water layer was extracted with CH_2Cl_2 (3 × 30 mL). All of the organic layers were combined and concentrated to give a white solid. The crude product was dried and purified by a chromatographic column using THF–hexanes (2:5) as the eluent to obtain a yellow solid. Recrystallization from THF and hexanes initially, then from CH_2Cl_2 and hexanes three times yielded the colorless compound **7** (0.561 g, yield 61%, mp > 330 °C). ^{1}H NMR (600 MHz, $CDCl_3$, 298 K, ppm) δ: 8.94 (d, J = 8.5 Hz, 6H, ph), 7.92 (d, J = 8.5 Hz, 6H, ph), 7.85 (s, 6H, ph), 7.74 (d, J = 7.8 Hz, 6H, indolyl), 7.72 (d, J = 8.3 Hz, 6H, indolyl), 7.71 (s, 3H, ph), 7.30 (dd, J_1 = 8.3 Hz, J_2 = 8.0 Hz, 6H, indolyl), 7.48 (d, J = 3.2 Hz, 6H, indolyl), 7.22 (dd, J_1 = 8.0 Hz, J_2 = 7.8 Hz, 6H, indolyl), 6.78 (d, J = 3.2 Hz, 6H, indolyl). ^{13}C NMR (600 MHz, $CDCl_3$, 298 K, ppm) δ: 171.1, 143.4, 143.3, 141.7, 136.0, 135.5, 129.9, 129.6, 127.5, 127.3, 122.7, 121.2, 120.7, 120.5, 118.9, 110.2, 104.4. Elemental anal. calcd. for $C_{87}H_{57}N_9$: C 85.09, H 4.65, N 10.27; found: C 85.16, H 4.76, N 9.94.

Results and discussion



Synthesis and characterization

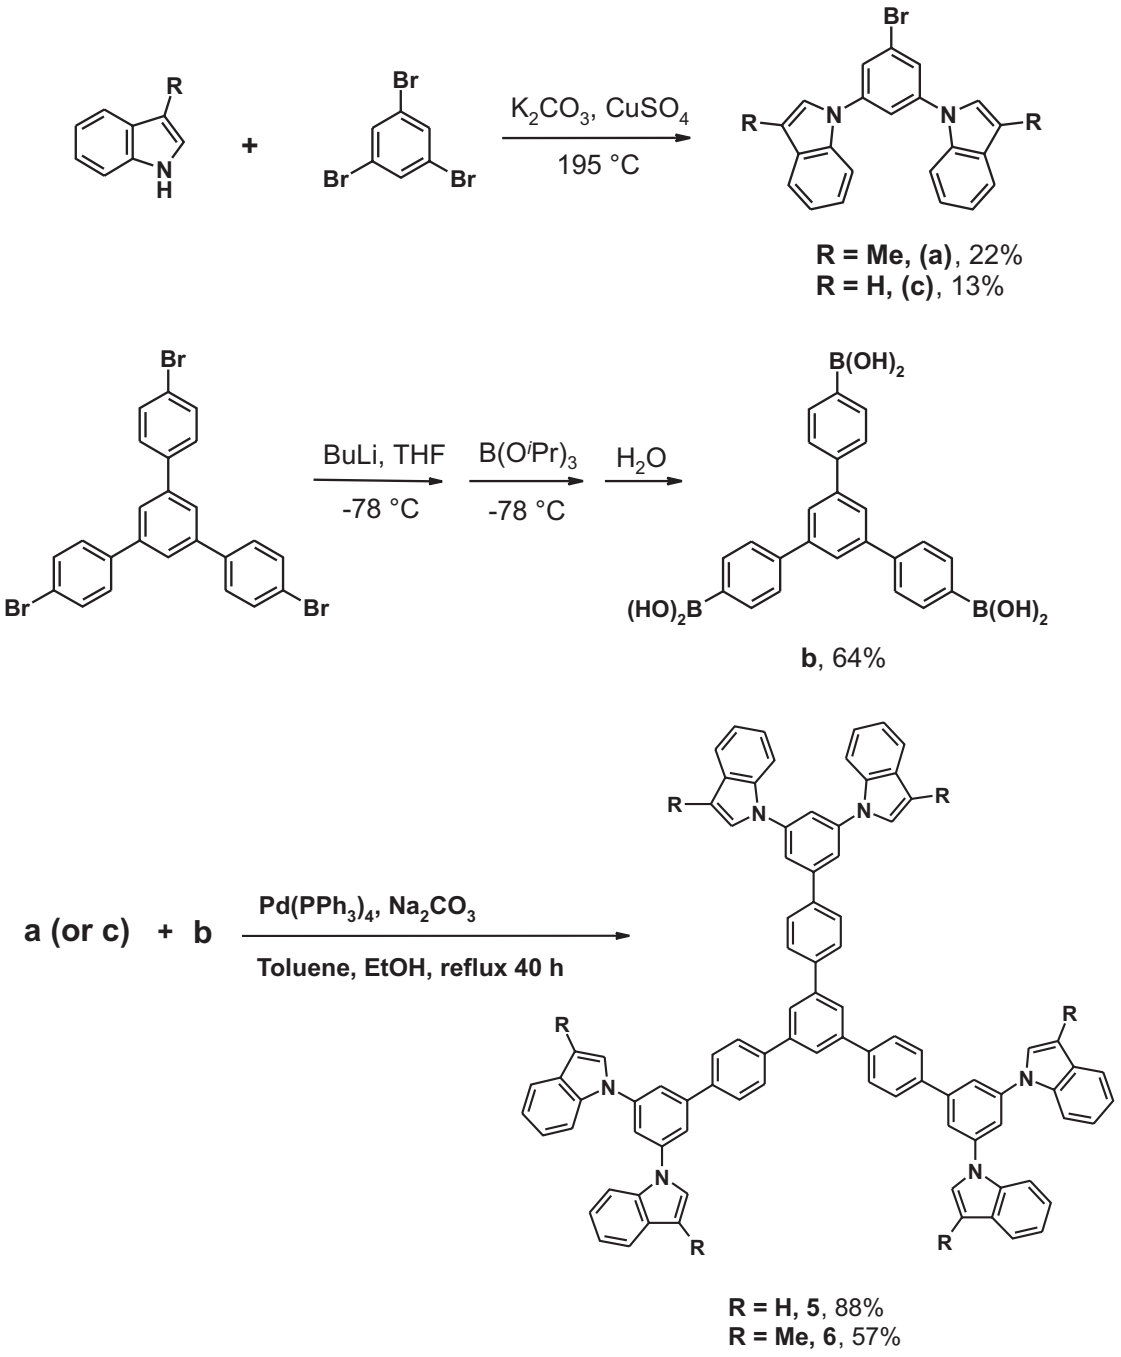
The new starburst molecules were obtained by using either the Ullmann condensation methods (5) or the Suzuki coupling methods (6) as depicted in Schemes 1–3.

Compound **1** was synthesized by the reaction of 7-azaindolyl lithium with cyanuric chloride in high yield (82%). Compounds **2**–**4** were prepared in moderate yields (48%–64%) from the reaction of 7-azaindole or 3-methylindole with 1,3,5-tris(*p*-bromophenyl)benzene or 2,4,6-tris(*p*-bromophenyl)-1,3,5-triazine using the modified Ullmann condensation procedure (5) where CuI and 1,10-phenanthroline acted as the catalysts and Cs_2CO_3 as the HBr scavenger. The intermediates, 1,3,5-tris(*p*-bromophenyl)benzene and 2,4,6-tris(*p*-bromophenyl)-1,3,5-triazine for compounds **2**–**4**, were synthesized by using modified literature methods (2). The syntheses of compounds **5** and **6** were achieved in good or moderate yields by Pd-catalyzed Suzuki–Miyaura cross couplings of 1,3,5-tris[(*p*-boronic acid)phenyl]benzene (intermediate **b**) with the corresponding disubstituted bromobenzene (intermediates **a** or **c**), as shown in Scheme 2. The intermediates **a** and **c** were synthesized by Ullmann condensation reactions between 2 equiv. of indole or 3-methylindole and 1,3,5-tribromobenzene (2). The intermediates 1,3,5-tris[(*p*-boronic acid)phenyl]benzene and 3,5-bis(1-*N*-indolyl)-1-phenylboronic acid were obtained by the reaction of B(O-*i*-Pr)$_3$ with 1,3,5-tris(4-lithium-phenyl]benzene and 3,5-bis(1-*N*-indolyl)phenyllithium, respectively. Compound **7** was obtained in good yield by Suzuki coupling between 2,4,6-tris(*p*-bromophenyl)-1,3,5-triazine and the intermediate **d** (Scheme 3). The switching from the boric acid triphenyltriazine core **c** as the one used in the syntheses of **5** and **6** to the brominated triphenyl-triazine core and the change of the bromo-substituted intermediate **a** to the boric acid intermediate **d** were necessary to ensure the successful synthesis of compound **7** (when the

© 2006 NRC Canada

Scheme 1.

bromide and the boronic acid starting materials were reversed as for **5** and **6**, no compound **7** was isolated).



Based on the functional group, compounds **1**–**7** can be divided into three categories: 7-azaindolyl-substituted compounds (**1**–**3**), indolyl-substituted compounds (**5** and **7**), and 3-methyl-substituted compounds (**4** and **6**). Because of their potential use in coordination and supramolecular assembly, our initial synthetic effort focused on 7-azaindolyl derivatives with the triazine core (the benzene analogue of **1** was reported earlier by our group), the triphenyl triazine–triphenylbenzene core, and the tris(biphenyl)triazine–tris(biphenyl)benzene core. Although the smaller molecules (**1**–**3**) with 7-azaindolyl groups were obtained successfully, we were not able to isolate 7-azaindolyl products that contained the larger triphenyltriazine–triphenylbenzene or the tris(biphenyl)triazine–tris(biphenyl)benzene core. The problem appeared to be mostly caused by the poor solubility of the products in organic solvents (e.g., THF, CH_3CN, CH_2Cl_2, and DMF), which made the purification and (or) isolation and characterization difficult. The indolyl group is an analogue of 7-azaindolyl, but its derivatives are in general more soluble in organic solvents than the corresponding 7-azaindolyl derivatives. For the larger cores, we therefore attempted the syntheses of indolyl derivatives. The hexaindolyl-substituted compounds **5** and **7** were obtained successfully. To further enhance the solubility of the products, we also attempted the syntheses of 3-methylindolyl derivatives for the larger cores. Two 3-methylindolyl-substituted compounds (**4** and **6**) were obtained successfully. Compound **6** was found to be more soluble than the indolyl analogue **5** in organic solvents. Compounds **1**–**7** were characterized by ^1H, ^{13}C NMR, HRMS, or elemental analyses (for compounds whose HRMS data could not be obtained owing to either being too high in molecular weight or too insoluble in the solvent matrix).

Thermal properties

The glass-forming properties and phase transition of compounds **1**–**7** were studied by DSC experiments. All seven compounds were heated under argon with a heating rate of 10 °C min^{-1}. After heating, all compounds were cooled to 50 °C at a cooling rate of 20 °C min^{-1}. The second heating was carried out with a heating rate of 10 °C min^{-1}. Well-defined melting points were observed for all compounds except compounds **5** and **7** in the DSC diagrams. These melting point values are consistent with those obtained by using a melting point apparatus. The high melting points (275 to >330 °C, Table 1) displayed by compounds **1**–**7** support that they have a high thermal stability. Compounds **2** and **3** are 7-azaindolyl derivative molecules with similar structures, but a different central core (benzene for **2** and triazine for **3**). Interestingly, however, the melting point of compound **3** is

© 2006 NRC Canada

Scheme 2.

about 44 °C higher than that of **2**. The same trend was also observed previously in 2,2′-dipyridylamino-substituted triphenyltriazine–triphenylbenzene or tris(biphenyl)triazine–tris(biphenyl)benzene compounds, where the triazine-based compounds consistently have a much higher melting point than the corresponding benzene-based analogue (2, 7). This perhaps can be attributed to the fact that the electronegative nitrogen atoms in the triazine core makes the molecule more polar, hence the presence of stronger intermolecular interactions in the crystal lattice, compared with the benzene core analogue.

Glass transition temperatures were observed for compounds **5** (T_g ~ 168 °C), **6** (T_g ~ 188 °C), and **7** (T_g ~ 187 °C) in the second heating–cooling curve of the DSC experiments (Table 1). No glass transition temperatures were observed for compounds **1**–**4** in either the first or the second heating cycles, an indication that these smaller molecules have the tendency to remain crystalline. The DSC diagram (second and third heating and cooling cycles) of compound **6** is shown in Fig. 1 as a representative example. In addition to T_g and T_m, a well-defined crystallization temperature (T_c) was also observed for **6**. Compounds **5** and **7** are another pair of benzene core – triazine core analogues that contain six indolyl groups. Although no melting points were observed for either compound in the DSC experiments, the DSC data again support that triazine compound **7** has a

much higher T_g than its benzene analogue **5**. The inclusion of the methyl groups in **6** also appears to enhance the glass transition temperature of the molecule as shown by the higher T_g of **6**, compared with that of **5**. The exceptionally high T_g values of compounds **5**–**7** indicate that these large molecules are capable of forming stable amorphous phases, a property highly desired for applications in organic photonic devices such as organic light emitting diodes. The remarkable high thermal stability of compounds **5**–**7** can be attributed to their high molecular weights and their highly branched structures, in comparison with compounds **1**–**4**.

Electronic and luminescent properties

Compounds **1**–**7** have intense absorption bands in the UV–vis region that can be attributed to π–π* transitions. Attempts were made to measure the oxidation and reduction potentials of compounds **1**–**7** by using cyclic voltammetry.

Fig. 1. DSC diagrams of compound **6** (second and third) heating (10 °C min^{-1}) and cooling (20 °C min^{-1}) (the first heating and cooling diagram is identical to these).

For all seven compounds, no reliable reduction peaks were detected within the solvent limit (THF was used as the solvent for reduction potential measurements). For compounds **2** and **4**, well-defined oxidation peaks were observed in CH_2Cl_2. For the remaining compounds, no reliable oxidation peaks were detected in CH_2Cl_2. The failure to observe oxidation potentials for some of the compounds can be partially attributed to the poor solubility of the materials, especially the large molecules (**5**–**7**). The first oxidation potential of **2** and **4** were found to be 1.57 and 1.14 V (vs. Ag/AgCl), re-

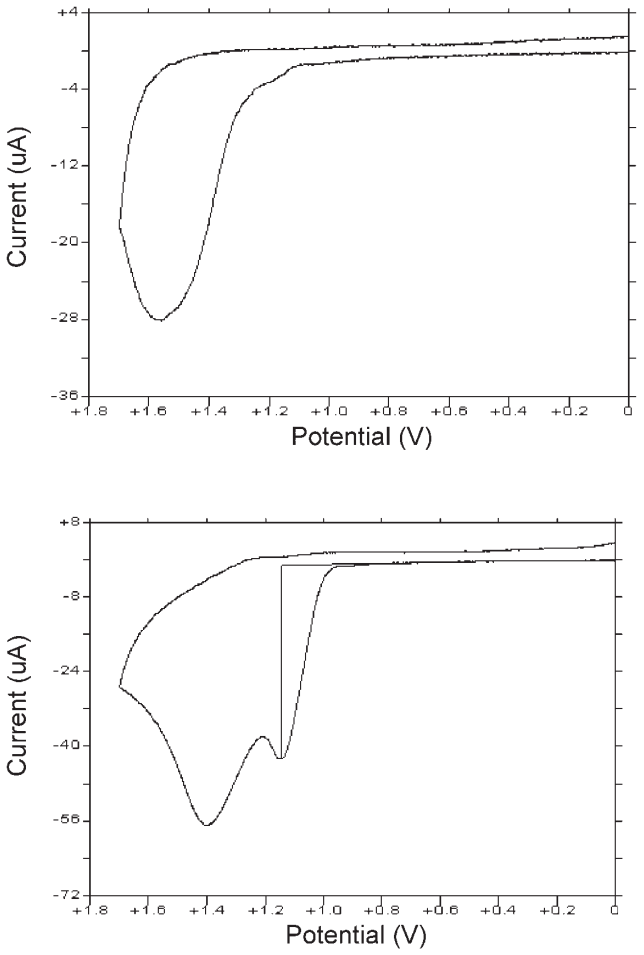

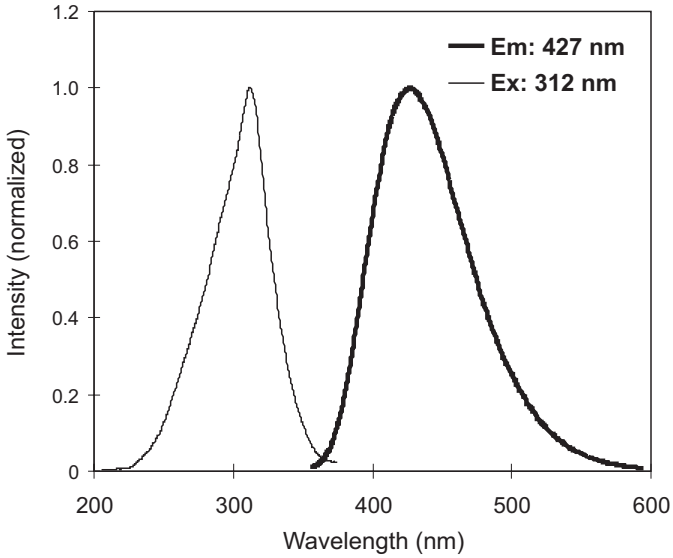

Fig. 3. The excitation and emission spectra of **6** in CH_2Cl_2.

spectively (Fig. 2). The HOMO energy levels for **2** and **4** were calculated to be –5.9 and –5.4 eV, respectively, by using the oxidation potential and the ferrocene HOMO energy level of –4.8 eV (relative to the vacuum level) as the standard (8). Clearly, the 7-azaindolyl derivative **2** has a much deeper HOMO level than that of the 3-methyl indolyl derivative **4**, which can be attributed to the extra electronegative nitrogen atom on the 7-azaindolyl ring that stabilizes the HOMO level, relative to that of the indolyl compound. By using the optical band gap obtained from the UV–vis absorption spectra (absorption edge), the LUMO energy levels of **2** and **4** were calculated to be –2.2 and –2.1 eV, respectively. The HOMO energy levels of **2** and **4** are considerably deeper than that of the well-known hole-transport material (9) NPB and the LUMO levels are much higher than those of the well-known electron-transport materials (Alq_3 and phenanthroline derivatives) (10). As a result, these compounds are not good candidates to act as hole- or electron-transport layers because of their relatively deep HOMO and high LUMO. However, they could be used as blue emitters or hosting materials in OLEDs.

Compounds **1**–**7** emit a blue or violet color in solution and the solid state when irradiated by UV light. The luminescent spectra of **1**–**7** are typical of fluorescence as shown by the spectra of **6** in Fig. 3. The absorption data and luminescent data are summarized in Table 2. Compared to the corresponding free 7-azaindole, indole, or 3-methylindole molecules, the absorption and emission spectra of compounds **1**–**7** are all red-shifted, which is clearly caused by the conjugation of the 7-azaindolyl, indolyl, or 3-methylindolyl chromophore with the aromatic central core. One obvious trend is the difference between the triazine and benzene core analogues (**2** and **3** and **5** and **7**). As shown by the data in Table 2, the triazine derivative consistently has smaller absorption–excitation and emission energies (i.e., the red shift of the absorption and emission band), compared with the corresponding benzene derivative. The same trend was also observed in 2,2′-dipyridylamino-functionalized triazine and benzene derivatives (2, 7). The methyl-substituted compound **6** has an emission energy that is about 25 nm red-shifted, compared with the nonsubstituted indolyl analogue **5**, which can be attributed to the electron-donating nature of the methyl group that effectively destablizes the HOMO level (π) and stablizes the LUMO level (π^*), hence decreasing the band gap. Similar emission energy red shift induced by electron-donating groups has been observed in BPh_2(2-Py-indolyl-X) compounds, where X is a substituent on the indolyl ring (11). The quantum efficiencies of compounds **1**–**7** vary considerably. Molecules (**2**–**4**) that have either a triphenyltriazine or triphenybenzene core display the highest emission quantum efficiencies. The quantum efficiencies of the large molecules (**5**–**7**) are substantially lower. For applications as emitters in organic light emitting diodes, it is required for the molecule to have both a high T_g and a high emission quantum efficiency. The high T_g is to ensure the morphological stability of the organic layer. Taking both factors into consideration, compounds **5** and **6** are the most promising as emitters in OLEDs, which are being examined by our group, and the results will be disclosed in due course. Although no T_g was detected, compound **2** has a fairly large band gap and a deep HOMO level, which makes it potentially useful as either a host material for phosphorescent dopants or as a hole-blocking layer.

Facile synthesis of α-D-Ara*f*-(1→5)-D-Gal*f*, the linker unit of the arabinan to the galactan in *Mycobacterium tuberculosis*[1]

Lucía Gandolfi-Donadío, Carola Gallo-Rodriguez, and Rosa M. de Lederkremer

Abstract: The arabinogalactan is a crucial constituent of the cell wall of mycobacteria. Both monosaccharides (arabinose and galactose) are found in the furanose configuration, absent in mammals. An efficient synthesis of α-D-Ara*f*-(1→5)-D-Gal*f*, the linker unit of the arabinan to the galactan, is described. The strategy relies on the use of a conveniently substituted D-galactono-1,4-lactone as a precursor of the reducing furanose ring. The glycosylation step was performed by the tin(IV) chloride promoted method using 1,2,3,5-tetra-*O*-benzoyl-α,β-D-arabinofuranose. The arabinose donor was obtained in a crystalline state in one step by benzoylation of arabinose in hot pyridine. Selective glycosylation of the exocyclic OH-5 was obtained in 75% yield to give 2,3,5-tri-*O*-benzoyl-α-D-arabinofuranosyl-(1→5)-2,6-di-*O*-pivaloyl-D-galactono-1,4-lactone. Reduction with disiamylborane gave the disaccharide synthon, useful for further glycosylations. Dec-9-enyl α-D-Ara*f*-(1→5)-β-D-Gal*f*, a convenient substrate for arabinofuranosyl transferases studies, was obtained by the trichloroacetimidate method of glycosylation.

Key words: arabinofuranose, galactofuranose, *Mycobacterium* arabinogalactan, trichloroacetimidate, tin(IV) chloride.

Résumé : L'arabinogalactane est un constituant crucial de la paroi de la cellule des mycobactéries. Les deux monosaccharides, arabinose et galactose, se retrouvent dans la configuration furanose qu'on ne retrouve pas chez les mammifères. On décrit une synthèse efficace du α-D-Ara*f*-(1→5)-D-Gal*f*, l'unité de liaison de l'arabinane au galactane. La stratégie repose sur l'utilisation d'une D-galactono-1,4-lactone substituée d'une façon appropriée comme précurseur du cycle réducteur du furanose. L'étape de glycosylation a été réalisée par la méthode de catalyse à l'aide de chlorure d'étain(IV) en utilisant le 1,2,3,5-tétra-*O*-benzoyl-α,β-D-arabinofuranose. Le donneur arabinose a été obtenu à l'état cristallin en une étape benzoylation de l'arabinose dans de la pyridine à chaud. La glycosylation sélective de OH-5 exocyclique a été réalisée avec un rendement de 75 % pour conduire à la formation de la 2,3,5-tri-*O*-benzoyl-α-D-arabinofuranosyl-(1→5)-2,6-di-*O*-pivaloyl-D-galactono-1,4-lactone. Sa réduction par du disiamylborane fournit le synthon disaccharide utile dans des glycosylations subséquentes. Par ailleurs, le dec-9-enyl α-D-Ara*f*-(1→5)-β-D-Gal*f*, un substrat approprié pour les études de transférases d'arabinofuranosyle a été préparé par la méthode de glycosylation au trichloroacétimidate.

Mots clés : arabinofuranose, galactofuranose, arabinogalactane *Mycobacterium*, trichloroacétimidate, chlorure d'étain(IV).

[Traduit par la Rédaction]

Introduction

Mycobacterial diseases have reemerged in the last years because of the appearance of multidrug-resistant strains of *Mycobacterium* and the relation of tuberculosis with AIDS (1). The integrity of the mycobacterial cell wall is essential for the viability of mycobacteria (2).

One of the components of this unique cell wall is arabinogalactan (AG) (3) in which both arabinose and galactose are found in the furanose form, which is absent in mammals. The galactan region consists of alternating β(1→5)- and β(1→6)-linked D-Gal*f* residues. This linear galactofuranose chain has branch points at OH-5 at which the arabinan chains are α-attached. Thus, an α-D-Ara*f*-(1→5)-D-Gal*f* linkage anchors the arabinan component to the galactan structure. The disaccharide has been previously synthesized as the *n*-octyl (4) and the ethyl glycosides (5*a*, 5*b*). These derivatives are not precursors for further elongation of the chain. In both procedures, the trichloroacetimidate method (6) was employed for the glycosylation step. The 2,3,5-tri-

Scheme 1.

O-acyl-α-D-arabinofuranosyl trichloroacetimidate donors were prepared from D-arabinose via the methyl arabinofuranoside in five steps.

The synthesis of a closely related trisaccharide fragment of the arabinogalactan was described by two groups (5). The procedures also employed the trichloroacetimidate method for the introduction of the Ara*f* unit.

The synthesis and conformation of D-arabinofuranosides from mycobacteria have been reviewed (7).

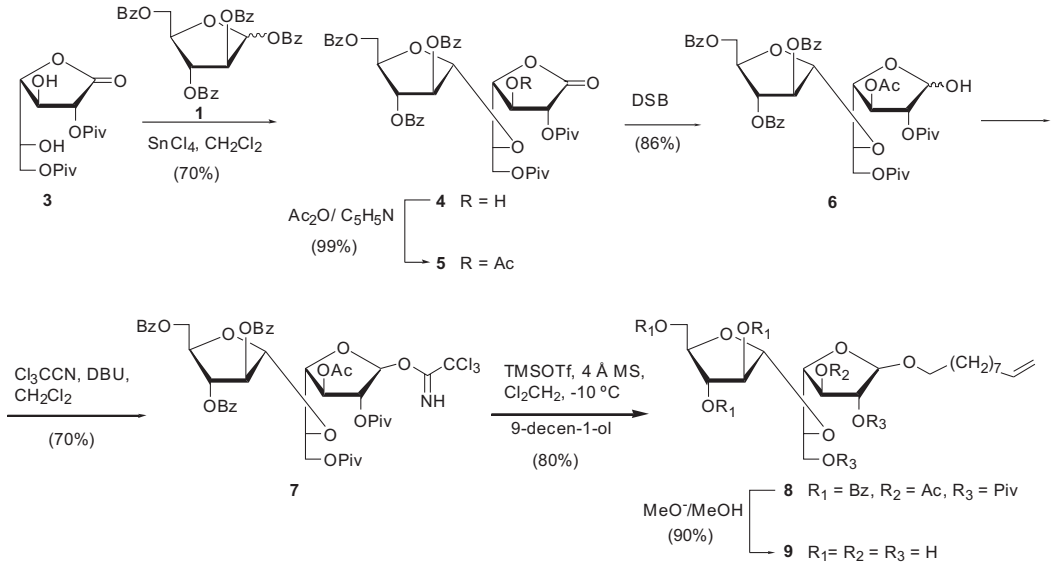
In the present work, we optimized the conditions for the one-step preparation of crystalline tetra-*O*-benzoyl-α,β-D-arabinofuranose (**1**) from D-arabinose. The D-arabinofuranose derivative **1** was used for tin(IV) chloride promoted glycosylation.

Results and discussion

The synthetic strategy relied on the use of a conveniently substituted D-galactono-1,4-lactone as the precursor of the reducing furanose ring (8, 9). Thus, after glycosylation, the disaccharide–lactone is reduced, acting as a virtually protected anomeric center. Activation of the anomeric center would allow further construction of different oligosaccharides.

We have extensively used the tin(IV) chloride promoted glycosylation method (10–12) for the activation of a peracylated galactofuranose. We employed α,β-perbenzoylgalactofuranose, which is obtained in the crystalline state in a one step-reaction from galactose (13). This is a very simple, direct, and convenient method for the construction of the β-D-galactofuranosyl linkage. Taking into account the stereochemical relationship between arabinose and galactose, we applied this glycosylation method to perbenzoyl arabinofuranose derivatives.

Tin(IV) chloride has been previously employed to achieve 1,2-*trans* α-arabinofuranosidic linkages. Tetra-*O*-acetyl-α-D-arabinofuranose, which was obtained in four steps as a syrup from arabinose, was used to give the expected 1,2-*trans* α-glycosidic linkage provided by the acetyl assistance in O-2 (14). On the other hand, it was described (15) that tetra-*O*-acetyl-α,β-D-arabinofuranose, obtained by ozonolysis of tri-*O*-acetyl-D-glucal, was employed as a glycosyl donor. However, the reaction gave low diastereoselectivity leading to a 2:1α:β ratio in the glycosylation of methyl 2,3,4-tri-*O*-benzyl-α-D-glucopyranoside (15). Similar results were obtained using the L-enantiomer (16).



In the galactofuranose series, we have also noticed that glycosylation yields diminished when employing the peracetylated analog, which could be attributed to the lability of the acetyl compared with the benzoyl group in the presence of the strong Lewis acid tin(IV) chloride. Excellent yields were obtained when the benzoylated analog was employed (10–12). For that reason, we thought that 1,2,3,5-tetra-*O*-benzoyl-arabinofuranose (**1**) could be a good precursor for the tin(IV) chloride promoted glycosylation reaction. Compound **1** was synthesized, in one step, by the benzoylation of arabinose in hot pyridine (Scheme 1). The crude product was a mixture of β-furanose, α-furanose, and α-pyranose perbenzoates in a 30:27:43 ratio, respectively, as shown by the integration of the anomeric protons in the ^{1}H NMR spectrum: 6.88 (d, 0.30H, J = 4.4 Hz, H-1β furanose), 6.76 (s, 0.27H, H-1α furanose), 6.26 (d, 0.43H, J = 5.6 Hz, H-1α pyranose). No tetra-*O*-benzoyl-β-D-arabinopyranose was detected in the perbenzoylation reaction mixture. Crystallization of the crude product from ethanol gave a first crop of pure crystalline 1,2,3,4-tetra-*O*-benzoyl-α-D-arabinopyranose (**2**, 26%). Perbenzoyl arabinofuranose (**1**, 29%) crystallized from the mother liquors. On purification of a sample of the anomeric mixture by column chromatography, pure 1,2,3,5-tetra-*O*-benzoyl-α-D-arabinofuranose (**1α**) was obtained and fully characterized. Compound **1α** was previously obtained on reaction of 2,3,5-tri-*O*-benzoyl-α-D-arabinofuranosyl bromide with silver benzoate (17). The anomeric mixture was used for glycosylation. Although the furanose perbenzoate was isolated in a modest yield, its use as a donor in the route described in this paper has the advantage that it was obtained in a crystalline state in one step from D-arabinose.

With the arabinofuranosyl donor **1**, a tin(IV) chloride promoted glycosylation reaction could be performed with a Gal*f* template acceptor. Crystalline 2,6-di-*O*-pivaloyl-D-galactone-1,4-lactone (**3**) (9), obtained in one step from D-galactone-1,4-lactone, was employed as a precursor of the galactofuranose reducing end (Scheme 2). Compound **3** was previously used in our laboratory for the construction of β-D-Gal*f*-(1→5)-β-D-Gal*f*-(1→6)-D-Gal*f* (9). Thus, on treatment of 1.3 equiv. of acceptor **3** with 1 equiv. of arabinose donor **1**, and tin(IV) chloride as the promoter in CH_2Cl_2, selective glycosylation of the exocyclic OH-5 of **3** gave 2,3,5-tri-*O*-benzoyl-α-D-arabinofuranosyl-(1→5)-2,6-di-*O*-pivaloyl-D-galactono-1,4-lactone (**4**) in 70% yield. No product of condensation at the OH-3 of **3** was detected. The same regioselectivity was found when perbenzoyl galactofuranose or other galactofuranosyl derivatives were glycosylated with 2,6-di-*O*-substituted D-galactono-1,4-lactones (9, 11).

The diastereoselectivity of the glycosylation was determined from the coupling constants. In fact, the ^{1}H NMR spectrum of **4** showed a singlet at 5.44 ppm for the H-1′ and a doublet at 5.43 ppm (J = 1.7 Hz) for the H-2′, in agreement with an α-D-Ara*f* linkage. The ^{13}C NMR spectrum showed the resonance of the anomeric carbon at 107.6 ppm confirming the α-D-arabinofuranosyl linkage. The β linkage was not observed.

© 2006 NRC Canada

Scheme 2.

Previous to reducing the lactone function, acetylation of **4** was performed carefully to avoid β-elimination by-products. In this case, the ^{1}H NMR signal of H-3 in **5** was shifted 0.97 ppm downfield compared with H-3 in **4**, confirming that glycosylation had taken place regioselectively at OH-5. Further reduction of the lactone derivative **5** with disiamylborane gave 2,3,5-tri-*O*-benzoyl-α-D-arabinofuranosyl-(1→5)-3-*O*-acetyl-2,6-di-*O*-pivaloyl-D-galactofuranose (**6**); the target disaccharide showed both anomers in a 1:1 α:β ratio as indicated by the integration of the anomeric protons in the ^{1}H NMR spectrum at 5.53 ppm (d, J = 4.8 Hz, H-1α) and 5.33 (s, H-1β).

To synthesize the decenyl glycoside, the trichloroacetimidate method was chosen. This method has been successfully used for β-D-galactofuranosyl glycosylation (8, 9, 18–20). Thus, activation of the anomeric center of **6** with Cl_3CCN and DBU gave a mixture of β- and α-trichloroacetimidates (**7**) in 88% yield. Disaccharide imidate **7** was stable for 1 day at –20 °C. On reaction of **7** with 1.3 equiv. of 9-decen-1-ol in CH_2Cl_2 with TMSOTf as the catalyst, decenyl β-glycoside (**8**) was obtained diastereoselectively (80%). In the ^{1}H NMR spectrum, the galactofuranosyl anomeric proton of **8** gave a signal at 4.94 (s, H-1) indicating the β-configuration. This assignment was confirmed by the ^{13}C NMR spectrum, which showed the signal of C-1 at 106.5 ppm. Full assignments for compound **8** were supported by COSY and HETCOR experiments. Sodium methoxide deprotection of **8** afforded 1-decenyl α-D-Ara*f*-(1→5)-β-D-Gal*f* (**9**) in 90% yield. The ^{1}H NMR spectrum of **9** is shown in Fig. 1.

Conclusion

A facile synthesis of a synthon for the α-D-Ara*f*-(1→5)-D-Gal*f* (**4**) unit of *M. tuberculosis* arabinogalactan was achieved in 70% yield from **1** and **3**. The aldonolactone approach followed by DSB reduction produced the disaccharide **6**, conveniently protected for further coupling in the synthesis of oligosaccharide units, useful for studies on its biosynthesis. The decenyl glycoside was also synthesized allowing further functionalization of the double bond.

Experimental section

General

TLC was performed on 0.2 mm silica gel 60 F254 aluminium-supported plates. Detection was effected by exposure to UV light or by spraying with 5% (*v*/*v*) sulfuric acid in EtOH and charring. Column chromatography was performed on silica gel 60 (230–400 mesh). Melting points are uncorrected. Optical rotations were measured at 25 °C. High-resolution mass spectra (HRMS) were recorded on a VG ZAB2SE (1996) high-resolution mass spectrometer, with Opus V3.1 and DEC 3000 Alpha Station. NMR spectra were recorded at 500 MHz (^{1}H) and 125.8 MHz (^{13}C), or as indicated. Homo- and hetero-nuclear correlation spectroscopy experiments were performed when indicated.

1,2,3,5-Tetra-*O*-benzoyl-α,β-D-arabinofuranose (1αβ), 1,2,3,5-tetra-*O*-benzoyl-α-D-arabinofuranose (1α), and 1,2,3,4-tetra-*O*-benzoyl-α-D-arabinopyranose (2)

Arabinose (3.05 g, 20.3 mmol) in dry pyridine (63.9 mL) was heated in a boiling water bath for 45 min with the exclusion of moisture. The water bath was rapidly cooled to 60–65 °C and freshly distilled benzoyl chloride (11.3 mL, 97.4 mmol) was slowly added to the reaction mixture. After stirring at 60 °C for 1.3 h, water (6 mL) was added, and the stirring was continued for 30 min at room temperature. The solution was slowly poured into ice water (400 g) with vigorous stirring, affording an amorphous solid. After decantation, the remaining solid was washed five times with water. The ^{1}H NMR spectrum ($CDCl_3$) of the solid showed the anomeric signals with the following integrations: δ 6.88 (d, 0.30H, J = 4.4 Hz, H-1β furanosic), 6.76 (s, 0.27H, H-1α furanosic), 6.26 (d, 0.43H, J = 5.6 Hz, H-1α pyranosic). The

© 2006 NRC Canada

solid was dissolved in boiling EtOH (400 mL) and slow crystallization took place. After 1 day, crystals of 1,2,3,4-tetra-*O*-benzoyl-α-D-arabinopyranose (**2**, 3.02 g, 26%, R_f 0.46, hexane–EtOAc (3:1), twice developed) were obtained; mp 161 to 162 °C. $[\alpha]_D$ –113.8° (*c* 1, $CHCl_3$) (lit. value (21) mp 164 to 165 °C, MeOH–AcOH, 80:5.7; $[\alpha]_D$ –114.4° (*c* 0.848, $CHCl_3$)). ^{1}H NMR ($CDCl_3$) δ: 8.08–7.33 (m, 20H), 6.26 (d, 1H, *J* = 5.6 Hz, H-1), 5.95 (dd, 1H, *J* = 5.6, 7.3 Hz, H-2), 5.80 (ddd, 1H, *J* = 2.9, 3.6, 5.2 Hz, H-4), 5.78 (dd, 1H, *J* = 3.6, 7.3 Hz, H-3), 4.43 (dd, 1H, *J* = 5.2, 12.6 Hz, H-5a), 4.14 (dd, 1H, *J* = 2.9, 12.6 Hz, H-5b) (lit. value (22) ^{1}H NMR (acetone-d_6, 100 MHz)). ^{13}C NMR ($CDCl_3$) δ: 164.5–164.7 (*C*OPh), 133.7–128.5 (aromatic), 92.4 (C-1), 69.9 (C-3), 68.9 (C-2), 67.5 (C-4), 62.7 (C-5).

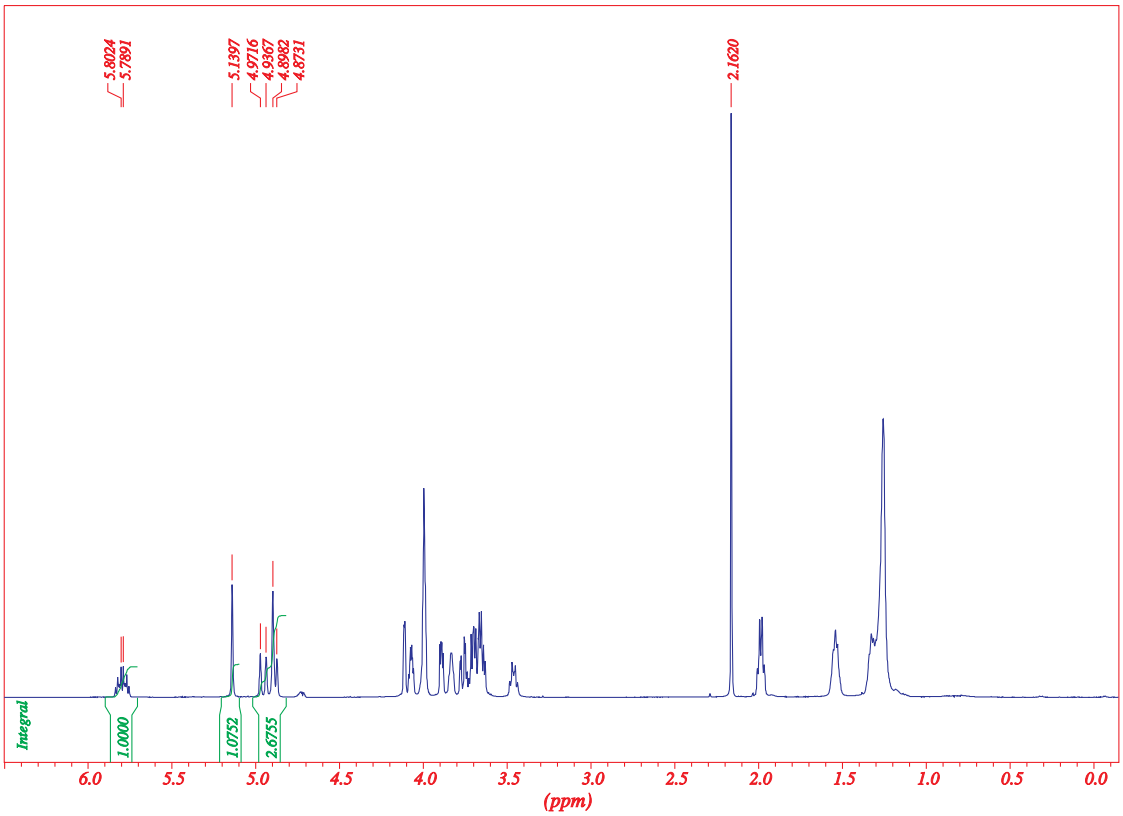
The mother liquors were kept at room temperature (20–23 °C) for 2 days and the second crop of crystals was filtered and characterized as 1,2,3,5-tetra-*O*-benzoyl-α,β-D-arabinofuranose (**1αβ**, 3.34 g, 29%, R_f 0.53 and 0.49, hexane–EtOAc (3:1), twice developed) in a 7:3 α:β ratio. ^{1}H NMR ($CDCl_3$) δ: 8.13–7.24 (m, 20H), 6.87 (d, 0.3H, *J* = 4.7 Hz, H-1 β anomer), 6.76 (s, 0.7H, H-1 α anomer), 6.11 (dd, 0.3H, *J* = 5.2, 7.0 Hz, H-3), 5.94 (dd, 0.3H, *J* = 4.7, 7.0 Hz, H-2), 5.82 (d, 0.7H, *J* = 0.8 Hz, H-2), 5.68 (dd, 0.7H, *J* = 3.7, 0.8 Hz, H-3), 4.83 (dd, 0.7H, *J* = 3.9, 12.7 Hz, H-5a), 4.82 (m, 0.7H, H-4), 4.81 (dd, 0.3H, *J* = 6.7, 14.1 Hz, H-5a), 4.73 (dd, 0.7H, *J* = 6.4, 12.7 Hz, H-5b), 4.67 (m, 0.3H, H-4), 4.66 (dd, 0.3H, *J* = 6.1, 14.1 Hz, H-5b). ^{13}C NMR ($CDCl_3$) δ: 166.2–164.6 (*C*OPh), 133.7–128.2 (aromatic), 99.8 (C-1 α anomer), 94.5 (C-1 β anomer), 83.9 (C-4 α anomer), 80.9 (C-2 α anomer), 79.8, 77.5, 76.2, 75.5, 64.7, 63.7.

A sample of **1αβ** was purified by column chromatography (toluene) to yield pure 1,2,3,5-tetra-*O*-benzoyl-α-D-arabinofuranose (**1α**). Crystallization from EtOH gave: mp 100 to 101 °C (EtOH). $[\alpha]_D$ +26.7° (*c* 1, $CHCl_3$) (lit. value (17) mp 117–121 °C (EtOH). $[\alpha]_D$ +27.9° (*c* 2.13, $CHCl_3$)). ^{1}H NMR ($CDCl_3$) δ: 8.14–7.26 (m, 20H), 6.76 (s, 1H, H-1), 5.82 (d, 1H, *J* = 0.8 Hz, H-2), 5.68 (dd, 1H, *J* = 3.7, 0.8 Hz, H-3), 4.83 (dd, 1H, *J* = 3.9, 12.7 Hz, H-5a), 4.82 (m, 1H, H-4), 4.73 (dd, 1H, *J* = 6.4, 12.7 Hz, H-5b). ^{13}C NMR ($CDCl_3$) δ: 166.2–164.6 (*C*OPh), 133.8–128.3 (aromatic), 99.8 (C-1), 83.9 (C-4), 80.9 (C-2), 77.5 (C-3), 63.7 (C-5). These assignments were supported by HETCOR experiments.

2,3,5-Tri-*O*-benzoyl-α-D-arabinofuranosyl-(1→5)-2,6-di-*O*-pivaloyl-D-galactono-1,4-lactone (4)

To an externally cooled (0 °C) solution of tetra-*O*-benzoyl-α,β-D-arabinofuranose (**1αβ**, 1.07 g, 1.9 mmol) in dry CH_2Cl_2 (50 mL) was added $SnCl_4$ (0.22 mL, 1.9 mmol) with stirring in an argon atmosphere. After 10 min, this solution was added to a solution of compound **3** (9) (0.86 g, 2.5 mmol) in CH_2Cl_2 (50 mL) over a 25 min period and then the mixture was stirred for 3 h at 0 °C. The solution was poured into aq. $NaHCO_3$ and extracted with CH_2Cl_2 (2 × 200 mL). The organic extract was washed with water (3 × 100 mL), dried (Na_2SO_4), filtered, and concentrated under reduced pressure. Purification of the residue by column chromatography (toluene–EtOAc, 20:1) gave 1.05 g of **4** (70% yield) as a foamy solid. R_f 0.45 (toluene–EtOAc, 3:1). $[\alpha]_D$ –28.1° (*c* 1, $CHCl_3$). ^{1}H NMR ($CDCl_3$) δ: 8.07–7.14 (m, 15H), 5.68 (dd, 1H, *J* = 1.7, 4.8 Hz, H-3′), 5.44 (bs, 1H, H-1′), 5.43 (d, 1H, *J* = 1.7 Hz, H-2′), 5.37 (d, 1H, *J* = 8.0 Hz, H-2), 4.80 (dd, 1H, *J* = 2.6, 11.2 Hz, H5a′), 4.79 (dt, 1H, *J* = 3.0, 8.0 Hz, H-3), 4.70 (m, 1H, H-4′), 4.67 (dd, 1H, *J* = 5.0, 11.2 Hz, H-5b′), 4.46 (dd, 1H, *J* = 5.5, 11.5 Hz, H-6a), 4.44 (dd, 1H, *J* = 3.5, 8.0 Hz, H-4), 4.34 (dd, 1H, *J* = 6.7, 11.5 Hz, H-6b), 4.20 (ddd, 1H, *J* = 3.5, 5.5, 6.7 Hz, H-5), 3.87 (d, 1H, *J* = 3.0, OH), 1.26, 1.19 (2s, 18H, $(CH_3)_3CCO$). ^{13}C NMR ($CDCl_3$) δ: 179.1, 177.0 ($(CH_3)_3C\mathit{C}O$), 168.7 (C-1), 166.1–165.8 (*C*OPh), 137.8–128.2 (aromatic), 107.6 (C-1′), 83.0 (C-2′), 81.2 (C-4′), 79.8 (C-4), 77.0 (C-3′), 76.4 (C-2), 74.8 (C-5), 72.4 (C-3), 63.4 (C-5′), 62.6 (C-6), 38.9, 38.7 ($(CH_3)_3\mathit{C}CO$), 27.1, 26.9 ($(\mathit{C}H_3)_3CCO$). These assignments were supported by COSY and HETCOR experiments. Anal. calcd. for $C_{42}H_{46}O_{15}$: C 63.79, H 5.86; found: C 63.72, H 6.13.

2,3,5-Tri-*O*-benzoyl-α-D-arabinofuranosyl-(1→5)-3-*O*-acetyl-2,6-di-*O*-pivaloyl-D-galactono-1,4-lactone (5)



To a solution of **4** (1.29 g, 1.63 mmol) in dry pyridine (13 mL), cooled at 0 °C, was added acetic anhydride (13 mL, dropwise) and the mixture was stirred at room temperature for 30 min. After cooling to 0 °C, the reaction was quenched by a slow addition of MeOH (20 mL) and the stirring continued for 30 min at room temperature. The solution was diluted with CH_2Cl_2 (200 mL) and then sequentially washed with 10% HCl (2 × 200 mL), water (200 mL), satd. aq. $NaHCO_3$ (200 mL), water, dried (Na_2SO_4), and then concentrated to give **5** (1.34 g, 99%) as a chromatographically pure syrup. R_f 0.66 (toluene–EtOAc, 3:1). $[\alpha]_D$ –21.3° (*c* 1, $CHCl_3$). ^{1}H NMR ($CDCl_3$) δ: 8.04–7.16 (m, 15H, aromatic), 5.76 (t, 1H, *J* = 6.6 Hz, H-3), 5.66 (d, 1H, *J* = 6.9 Hz, H-2), 5.63 (dd, 1H, *J* = 1.4, 4.6 Hz, H-3′), 5.59 (bs, 1H, H-1′), 5.56 (d, 1H, *J* = 1.4 Hz, H-2′), 4.80 (dd, 1H, *J* = 5.3, 13.5 Hz, H-5a′), 4.67 (m, 2H, H-4′, H-5b′), 4.55 (dd, 1H, *J* = 3.0, 6.4 Hz, H-4), 4.48 (dd, 1H, *J* = 4.4, 11.0 Hz, H-6a), 4.29 (dd, 1H, *J* = 7.1, 11.0 Hz, H-6b), 4.25 (ddd, 1H, *J* = 3.0, 4.4, 7.1 Hz, H-5), 2.11 (s, 3H, CH_3), 1.20, 1.18 (2s, 18H, $(CH_3)_3CCO$)). ^{13}C NMR ($CDCl_3$) δ: 177.6, 177.1 ($(CH_3)_3C\mathit{C}O$), 169.9 (C-1), 168.4 ($\mathit{C}OCH_3$), 166.1–165.4 (*C*OPh), 133.5–128.3 (aromatic), 107.6 (C-1′), 82.4 (C-2′), 81.7 (C-4′), 79.1 (C-4), 77.2 (C-3′), 75.4 (C-5); 72.9, 72.0 (C-2, C-3), 63.6 (C-5′), 62.4 (C-6), 38.7, 38.6 ($(CH_3)_3\mathit{C}CO$), 27.1, 26.8 ($(\mathit{C}H_3)_3CCO$), 20.5 ($CO\mathit{C}H_3$). These assignments were supported by COSY and HETCOR experiments. Anal. calcd. for $C_{44}H_{48}O_{16}$: C 63.45, H 5.81; found: C 63.48, H 5.83.

2,3,5-Tri-*O*-benzoyl-α-D-arabinofuranosyl-(1→5)-3-*O*-acetyl-2,6-di-*O*-pivaloyl-D-galactofuranose (6)

A solution of bis(2-butyl-3methyl)borane (9.24 mmol) in anhydr. THF (2.6 mL), cooled to 0 °C and under an argon atmosphere, was added to a flask containing previously dried compound **5** (1.28 g, 1.54 mmol). The resulting solution was stirred for 22 h at room temperature and then processed as previously described (23). The organic layer was washed with water, dried (Na_2SO_4), and concentrated. Boric acid was eliminated by coevaporation with MeOH (5 × 20 mL) at room temperature. The residue was purified by column chromatography (toluene–EtOAc, 15:1) to give

Fig. 1. ^{1}H NMR spectrum of compound **9** (D_2O, 500 MHz, acetone was used as internal reference).

1.05 g (86%) of **6** (syrup) as a 2:3 α:β anomeric mixture. R_f 0.43 (toluene–EtOAc, 3:1). $[\alpha]_D$ –2.4° (*c* 1, $CHCl_3$). ^{1}H NMR ($CDCl_3$) anomeric protons δ: 5.67 (bs, 0.5H, H-1′ for β anomer), 5.63 (bs, 0.5H, H-1′ for α anomer), 5.53 (d, 0.5H, J = 4.7 Hz, H-1 α anomer), 5.33 (bs, 0.5H, H-1 β anomer). ^{13}C NMR ($CDCl_3$) δ: 178.0–177.4 (($CH_3)_3CCO$)), 170.6, 170.1 ($COCH_3$), 166.1–165.3 ($COPh$), 133.7–125.3 (aromatic), 107.6 (C-1′β anomer), 106.5 (C-1′α anomer), 100.6 (C-1 β anomer), 95.0 (C-1 α anomer), 82.8, 82.1, 82.0, 81.7, 81.2, 80.9, 80.3, 77.7, 77.2, 77.1, 76.9, 76.7, 75.5, 75.2, 63.7, 63.6, 63.5, 63.0, 38.7 (($CH_3)_3CCO$)), 27.1, 27.0, 26.9 (($CH_3)_3CCO$), 20.7, 20.6 (CH_3). These assignments were supported by COSY and HETCOR experiments. Anal. calcd. for $C_{44}H_{50}O_{16}$: C 63.30, H 6.04; found: C 63.65, H 6.44.

9-Decenyl 2,3,5-tri-*O*-benzoyl-α-D-arabinofuranosyl-(1→5)-3-*O*-acetyl-2,6-di-*O*-pivaloyl-D-galactofuranoside (8)

To a stirred solution of **6** (314 mg, 0.40 mmol) and trichloroacetonitrile (0.20 mL, 2.0 mmol) in dry CH_2Cl_2 (10 mL), cooled to 0 °C, DBU (28.4 µL, 0.18 mmol) was slowly added. After 1 h, the solution was concentrated under reduced pressure, and the residue was purified by column chromatography (toluene–EtOAc–TEA, 40:1:0.4) to give 342 mg (88%) of *O*-(2,3,5-tri-*O*-benzoyl-α-D-arabinofuranosyl-(1→5)-3-*O*-acetyl-2,6-di-*O*-pivaloyl-α,β-D-galactofuranosyl) trichloroacetimidate (**7**) as an amorphous solid (R_f 0.33 and 0.47 in toluene–EtOAc–TEA (9:1:0.09) for the α and β anomers, respectively). Compound **7** was stable for 1 day at –20 °C. ^{1}H NMR ($CDCl_3$, 200 MHz) δ: 8.61 (s, 0.8H, N*H*), 8.44 (s, 0.2H, N*H*), 6.55 (d, 0.2H, J = 4.6 Hz, H-1 α anomer), 6.30 (s, 0.8H, H-1 β anomer). ^{13} C NMR ($CDCl_3$, 25 MHz) for the β anomer δ: 177.8, 177.0 (($CH_3)_3CCO$), 170.0 (CH_3CO), 166.2–165.2 ($COPh$), 160.2 ($NHCOCl_3$), 133.5–125.3 (aromatic), 106.5 (C-1′), 102.8 (C-1), 97.9 (C-1 α anomer), 84.0, 82.1, 81.3, 80.4, 77.6, 75.8, 74.3, 63.6, 63.4, 38.6 (($CH_3)_3CCO$ × 2), 27.1, 26.9 (($CH_3)_3CCO$), 20.6 (CH_3CO).

A vigorously stirred suspension of the trichloroacetimidate **7** (241 mg, 0.25 mmol), 9-decen-1-ol (60.4 µL, 0.33 mmol), and powdered activated 4 Å molecular sieves (0.5 g) in anhydr. CH_2Cl_2 (9 mL) was cooled to –20 °C, and TMSOTf (13.3 µL, 0.073 mmol) was slowly added. After 30 min of stirring, the mixture was filtered into aq. $NaHCO_3$ (15 mL) and then extracted with CH_2Cl_2 (2 × 25 mL). The organic layer was washed with water (3 × 40 mL), dried (Na_2SO_4), filtered, and concentrated under reduced pressure. The residue was purified by column chromatography (toluene–EtOAc, 45:1) affording **8** (243 mg, 80%) as a syrup. R_f 0.60 (toluene–EtOAc, 9:1). $[\alpha]_D$ –23.9° (*c* 1, $CHCl_3$). ^{1}H NMR ($CDCl_3$) δ: 8.07–7.26 (m, 15H, aromatic), 5.80 (ddt, 1H, J = 6.7, 10.2, 17.2 Hz, C*H*=CH_2), 5.65 (s, 1H, H-1′), 5.61 (dd, 1H, J = 1.5, 5.0 Hz, H-3′), 5.57 (d, 1H, J = 1.5 Hz, H-2′), 5.23 (dd, 1H, J = 1.7, 5.5 Hz, H-3), 5.07 (d, 1H, J = 1.7 Hz, H-2), 4.98 (ddt, 1H, J = 1.2, 1.7, 17.2 Hz, HC=CH_aH), 4.94 (bs, 1H, H-1), 4.92 (ddt, 1H, J = 1.3, 2.5, 10.2 Hz, HC=CH_bH), 4.80 (dd, 1H, J = 3.2, 11.4 Hz, H-5a′), 4.71 (m, 1H, H-4′), 4.67 (dd, 1H, J = 4.8, 11.4 Hz, H-5b′), 4.36 (m, 1H, H-5), 4.24–4.30 (m, 3H, H-6a, H-6b, H-4), 3.67 (dt, 1H, J = 6.7, 9.7 Hz, CH_aHO), 3.40 (dt, 1H, J = 6.5, 9.7 Hz, CH_bHO), 2.07 (s, 3H, CH_3), 2.04 (m, 2H, CH_2), 1.58 (m, 2H, CH_2), 1.27 (m, 12H, CH_2), 1.17, 1.16 (2s, 18H,

((CH_3)$_3$CCO). ^{13}C NMR ($CDCl_3$) δ: 177.9, 177.4 ((CH_3)$_3$*C*CO), 170.2 (CH_3*C*O), 166.1–165.2 (*C*OPh), 139.1 (*C*H=CH_2), 133.5–128.3 (aromatic), 114.1 (CH=*C*H$_2$), 106.5 (C-1′), 105.3 (C-1), 82.2 (C-2′), 81.9 (C-2), 81.0 (C-4′), 80.9 (C-4), 77.7 (C-3′), 76.9 (C-3), 74.6 (C-5), 67.6 (CH_2O), 63.7 (C-5′), 63.6 (C-6), 38.7, 38.6, ((CH_3)$_3$*C*CO), 33.8, 29.4, 29.3, 29.0, 28.9, 27.1, 26.9, 26.0 (*C*H$_3$)$_3$CCO), 20.7 (CH_3). These assignments were supported by COSY and HETCOR experiments. Anal. calcd. for $C_{54}H_{68}O_{16}$: C 66.65, H 7.04; found: C 66.48, H 7.09.

9-Decenyl α-D-arabinofuranosyl-(1→5)-β-D-galactofuranoside (9)

Compound **8** (112 mg, 0.12 mmol) was suspended in 0.48 mol/L sodium methoxide in a methanol solution (1.7 mL) and cooled at 0 °C. After stirring for 1 h at 0 °C, the resulting solution was warmed to room temperature, stirred for 2 h, and water (0.5 mL) was added. The solution was passed through a column containing Amberlite IR-120 plus (H^+) resin (3 mL) and the column washed with MeOH–H_2O (9:1). The combined eluates were evaporated and the remaining methyl benzoate was eliminated by five successive coevaporations with water. The residue was dissolved in water, further purified through a C8-Maxi-Clean cartridge, and the solution lyophilized. Glycoside **9** (49 mg, 90%) was obtained as a hygroscopic syrup. R_f 0.86 (*n*-propanol–EtOH–H_2O, 7:1:1). $[\alpha]_D$ –4.4° (*c* 0.6, H_2O). ^{1}H NMR (D_2O) δ: 5.79 (ddt, 1H, *J* = 6.7, 10.4, 17.0 Hz, C*H*=CH$_2$), 5.14 (d, 1H, *J* = 1.9 Hz, H-1′), 4.95 (ddt, 1H, *J* = 1.5, 3.7, 17.0 Hz, HC=C*H*$_a$H), 4.90 (bs, 1H, H-1), 4.88 (ddt, 1H, *J* = 1.1, 2.2, 10.4 Hz, HC=C*H*$_b$H), 4.11 (dd, 1H, *J* = 1.9, 3.7 Hz, H-2′), 4.07 (ddd, 1H, *J* = 3.3, 5.9, 6.1 Hz, H-4′), 4.01–3.98 (m, 3H, H-2, H-3, H-4), 3.89 (dd, 1H, *J* = 3.7, 6.1 Hz, H-3′), 3.83 (m, 1H, H-5), 3.76 (dd, 1H, *J* = 3.3, 12.6 Hz, H-5a′), 3.74–3.63 (m, 3H, H-6a, H-6b, C*H*$_a$HO), 3.65 (dd, 1H, *J* = 5.9, 12.6 Hz, H-5b′), 3.46 (dt, 1H, *J* = 6.7, 10.0 Hz, C*H*$_b$HO), 1.98 (m, 2H, CH_2), 1.54 (m, 2H, CH_2), 1.36–1.22 (m, 10H, CH_2). ^{13}C NMR (D_2O) δ: 140.3 (*C*H=CH$_2$), 114.6 (CH=*C*H$_2$), 109.1 (C-1′), 107.6 (C-1), 84.4 (C-4′), 82.4 (C-2′), 81.9, 81.7 (C-4, C-2), 78.4 (C-5), 77.0, 76.9 (C-3′, C-3), 69.6 (CH_2O), 62.1 (C-6), 61.8 (C-5′), 34.0, 29.6, 29.5, 29.4, 29.2, 29.1, 26.1. Towards C-2 symmetrical macrocyles with an incorporated sucrose unit[1]

Sławomir Jarosz and Arkadiusz Listkowski

Abstract: The first C_2 symmetrical macrocyclic receptor containing two sucrose molecules has been prepared, albeit in low yield, by reaction of hexa-*O*-benzyl-6′-*O*-acroyl-6-*O*-allylsucrose in the presence of a second generation Grubbs catalyst (1,3-dimesityl-4,5-dihydroimidazol-2-ylidene ruthenium alkylidene complex). Highly selective protection of the 6′-OH group in 1′,2,3,3′,4,4′-hexa-*O*-benzylsucrose was a key step in the preparation of the precursor used under ring closing metathesis (RCM) conditions.

Key words: sucrose, macrocyclic receptors, metathesis, regioselective transformations.

Résumé : La réaction du hexa-*O*-benzyl-6′-*O*-acroyl-6-*O*-allylsucrose en présence du catalyseur de Grubbs de deuxième génération (complexe alkylidène 1,3-dimésityl-4,5-dihydroimidazol-2-ylidène ruthénium) nous a permis de préparer, avec un faible rendement, le premier récepteur macrocyclique de symétrie C_2 contenant deux molécules de sucrose. La protection hautement sélective du groupe OH en 6′ du 1′,2,3,3′,4,4′-hexa-*O*-benzylsucrose est l'étape clé dans la préparation du précurseur utilisé dans les conditions de fermeture de cycle par métathèse (RCM).

Mots clés : sucrose, récepteurs macrocycliques, métathèse, transformations régiosélectives.

[Traduit par la Rédaction]

Introduction

Sucrose, a cheap raw material, is available in more than 130 million tons per year; most of it is consumed on the food market. This chemical is very demanding to work with because of its very poor solubility in organic solvents (except DMF, pyridine, and DMSO), presence of eight hydroxyl groups that are difficult to differentiate, and the high sensitivity of the glycosidic bond in acidic media. However, this disaccharide is a subject of interest for several laboratories, which use it as a starting material for the preparation of fine chemicals (1–3), as well as biodegradable polymers or surfactants (4). Recently, a biocatalytic approach to sucrose analogs has been published (5).

As part of an on-going program, we elaborated a convenient route to 2,3,3′,4,4′-penta-*O*-benzylsucrose (6) (**1**), a useful starting material for the preparation of derivatives modified at the terminal (C1′, C6, C6′) positions. Differentiation of the primary hydroxyl groups in **1** is possible, which allows for the production of all three monoalcohols, as well as the 6,6′-diol **2**, in good yields (3, 7). Recently, we prepared another useful sucrose diol, compound **3** (8), and applied it in the preparation of a variety of crown ether analogs (**4**, Fig. 1) (9).

In this paper a methodology leading to complex sucrose macrocycles possessing higher symmetry will be described. Differentiation of the primary hydroxyl groups in **3** is required for regioselective introduction of the proper olefinic fragments needed for cyclization under ring closing metathesis (RCM) conditions.

Synthesis of selectively protected derivatives of hexa-*O*-benzylsucrose

Reaction of the free sucrose with 1 equiv. of silylating agent preferentially protects the 6′-OH group (10). Since the same feature applies for diol **2** (7), similar selective protection of **3** was also expected. Diol **3** was reacted with *tert*-butyldimethylsilyl chloride to afford alcohol **5** in 48% yield. Protection at the C-6′ position was confirmed by advanced NMR experiments performed on derivative **7** in which the COSY correlations between H-5 (glucose part) and both olefinic protons were visible. Since the yield of product **5** was not particularly impressive, we used the more bulky silyl reagent, *tert*-butyldiphenylsilyl chloride, and obtained alcohol **6** in 60% yield. Its structure was also confirmed by the NMR experiments performed on methyl uronate (**11**); the significant lowfield shift of the H-5 resonance (δ 4.56 ppm) proved that this proton is in close vicinity to the ester group, hence the 6-OH (and not 6′-OH) group in alcohol **7** was not protected (Scheme 1).

Synthesis of 6-*O*-allyl-6′-*O*-acroyl derivative **10**, the direct precursor of the C_2-symmetrical macrocycle, was achieved in 37% overall yield from **6** by allylation of the 6-

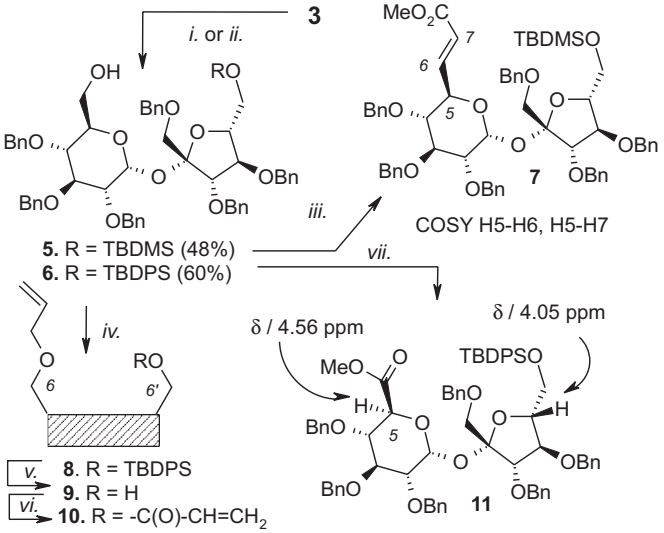
OH group with allyl bromide,[3] followed by removal of the silyl protection from the 6′-OH and subsequent acroylation (Scheme 1).

Cyclization of sucrose derivative 11 to the C_2-symmetrical receptor



Reaction of **11** performed in the presence of a second generation Grubbs catalyst (1,3-dimesityl-4,5-dihydroimidazol-2-ylidene ruthenium alkylidene complex (11)) afforded a mixture of products in a total yield of about 35%. Four different compounds (**12**–**15**) were isolated by HPLC (Scheme 2).

Structures of all these products were established by MS and high-resolution NMR spectroscopy. The MS spectra of compounds **12** and **13** clearly pointed at the presence of only one molecule of sucrose (in both spectra, the signals *m*/*z* 971 [M($C_{58}H_{60}O_{12}$) + Na^+] and 987 [M($C_{58}H_{60}O_{12}$) + K^+] were seen). The geometry across the newly created double bonds was determined from the ^{1}H NMR spectra of these macrocycles. Thus, the large coupling constant (J = 16.1 Hz) pointed at the E geometry in **12**, while the smaller constant (J = 12.0 Hz) proved the Z geometry in **13**.

The MS data of one of the two remaining derivatives were in accordance with the dimeric structure; the signal at *m*/*z* 1919 [($C_{116}H_{120}O_{24}$) + Na^+] could be assigned to the expected cyclic derivative **14**. In the ^{13}C NMR spectrum of this compound, only one -CH=CH-C(O)- group was seen (δ 165.8, 145.6, and 120.0 ppm), which strongly supported the symmetrical structure. Further information was obtained from the ^{1}H NMR spectrum; the large coupling constant (J = 15.8 Hz) among two olefinic protons (at δ 6.83 and 5.96 ppm) clearly pointed at the E geometry across this double bond. This is consistent with the literature data reporting on a preferential synthesis of the E isomers under such conditions (12).

In the MS spectrum of the last identified product, the signal at *m*/*z* 1947 (differing by 28 Da (2 × CH_2 groups) from the dimer **14**) was detected. In the ^{13}C NMR spectrum, only

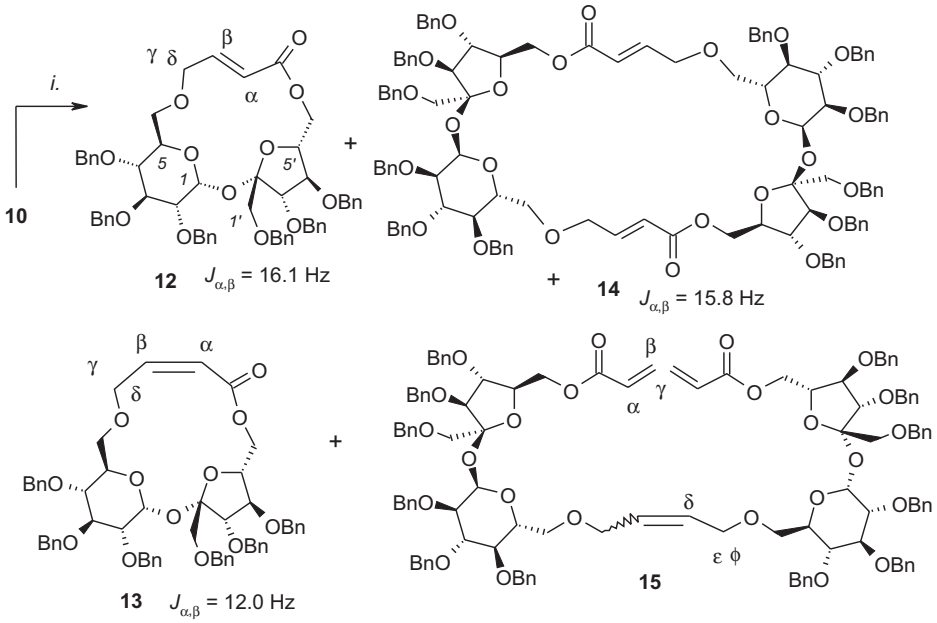
three olefinic carbon resonances (at δ 131.1 (=CH_2), 129.4, and ~128.2 ppm, respectively; assigned from the HETCOR correlations), one carbonyl resonance (at δ 165.9 ppm), and one set of signals connected with the sucrose skeleton (representative resonances at δ 104.7 (C-2′) and 90.3 (C-1)) were seen, which pointed at structure **15**. The geometry across the newly created double bond is most likely E (assumption based on the literature examples (12)), but because of the symmetry of **15**, it cannot be assigned by NMR.

We plan to assign this geometry by desymmetrization of the molecule; the results will be reported in a separate paper.

Conclusion

The first synthesis of a C_2-symmetrical macrocycle containing two sucrose units was realized by dimerization of the 6-*O*-allyl-6′-*O*-acroylsucrose monomer under RCM conditions with Grubbs II catalyst (1,3-dimesityl-4,5-dihydroimidazol-2-ylidene ruthenium alkylidene complex). Besides the expected receptor **14**, two compounds (with E and *Z* geometry, respectively, across the newly created double bond) resulting from the *intramolecular* cyclization and one dimeric open-chain product (from reaction among two allyl moieties) were produced. The overall yield of this process was low (ca. 35%).

Experimental



General

NMR spectra were recorded with a Bruker AM 500 spectrometer for solutions in $CDCl_3$ (internal Me_4Si) unless otherwise stated. Most of the resonances were assigned by COSY (^{1}H–^{1}H) and (or) HETCOR and DEPT correlations.

[3] Interestingly, the reaction with allyl chloride was not effective under PTC conditions; removal of the silyl block from the C-6′ end, followed by allylation of both 6-OH and 6′-OH groups, led to known 6,6′-di-*O*-allyl-1′2,3,3′,4,4′-hexa-*O*-benzylsucrose (ref. 3).

Scheme 2. (*i*) CH_2Cl_2, second generation Grubbs catalyst, reflux, 3.5 h.

The ^1H and ^{13}C aromatic resonances occurring at the typical δ values were omitted for simplicity. Mass spectra were recorded with an ESI/MS Mariner (PerSeptive Biosystem) mass spectrometer. Optical rotations were measured with a Jasco P-1020 polarimeter for solutions in $CHCl_3$ (*c* = 1) at room temperature (rt). IR spectra (film) were recorded with a PerkinElmer Spectrum 2000 apparatus. Column chromatography was performed on silica gel (Merck, 70–230 or 230–400 mesh). Methylene chloride was distilled from CaH_2 and THF from potassium prior to use. Organic solutions were dried over anhydrous sodium sulfate.

1′,2,3,3′,4,4′-Hexa-*O*-benzyl-6′-*O*-*tert*-butyldimethylsilylsucrose (5)

To a solution of diol **3** (1.25 g, 1.4 mmol), DMAP (0.12 g), and diisopropylethylamine (0.8 mL) in CH_2Cl_2 (50 mL), a solution of *tert*-butyldimethylsilyl chloride (0.27 mL, 1.4 mmol) in CH_2Cl_2 (5 mL) was added over 60 min and the mixture was stirred for 24 h at rt. Water (70 mL) was added, the organic phase was separated, and the aqueous one extracted with ether (70 mL). The combined organic solutions were dried, concentrated, and the crude product was isolated by column chromatography (hexane – ethyl acetate, 7:1 to 1:1) to give the title compound (**5**) (0.48 g, 0.48 mmol, 48% calcd. on consumed **3**) as a colorless oil and unreacted alcohol **3** (0.36 g, 0.41 mmol). Data for **6**: $[\alpha]_D$ +33.5°. ^1H NMR (200 MHz) δ: 5.97 (d, 1H, $J_{1,2}$ = 3.8 Hz, H-1), 0.88 (s, 9H, 3×CCH_3), 0.06, 0.05 (2×s, SiMe_2). ^{13}C NMR (50 MHz) δ: 104.3 (C-2′), 88.6 (C-1), 83.6, 81.9, 80.7, 80.6, 80.1, 77.8 and 71.2 (C-2,3,3′,4,4′,5,5′), 75.6, 74.9, 73.5, 73.1, 72.6, 72.0, 71.8, and 62.9, 62.0 (C-1′,6,6′, 6×OCH_2Ph), 25.9 (CMe_3), 18.3 (CMe$_3$), –5.0 (SiMe_2). DMSO (1 mL) was added dropwise to a solution of oxalyl chloride (0.4 mL) in CH_2Cl_2 (25 mL) at –78 °C under an argon atmosphere. After 5 min, alcohol **6** (1.2 g, 1.1 mmol in 15 mL CH_2Cl_2) was added and the mixture was stirred at –78 °C for 30 min. Triethylamine (1 mL) was added, stirring was prolonged for an additional 15 min at –78 °C, and the mixture was allowed to reach rt. It was then partitioned between water (40 mL) and ether (150 mL), the organic phase was separated, washed with water (2 × 50 mL) and brine (50 mL), dried, and concentrated. The oily residue was dissolved in acetone (20 mL) and titrated with Jones reagent (3 mL) until TLC (hexane – ethyl acetate, 1:1) indicated the disappearance of the starting material (ca. 20 min). The excess of the Jones reagent was decomposed with isopropanol (5 mL), most of the acetone was removed by vacuum, and the residue was partitioned between water (50 mL) and ethyl acetate (100 mL). The organic phase was separated, washed with brine (50 mL), dried, concentrated, and the crude acid was methylated with diazometane under standard conditions. Evaporation of the solvent left an oily residue, which was purified by column chromatography (hexane – ethyl acetate, 5:1) to give the title methyl uronate (**11**) (0.80 g, 0.698 mmol, 64%) as a colorless oil. $[\alpha]_D$ +19.9°. IR (film, cm^{-1}) υ: 2930, 2859, 1750 (CO), 1454, 1089, 1028, 737, 698. ^1H NMR δ: 5.77 (d, $J_{1,2}$ = 3.6 Hz, 1H, H-1), 4.78–4.40 (m, 14H, 12×CH_2Ph, H-3′, H-5), 4.30 (dd, $J_{3'4'}$ = 6.9 Hz, $J_{4'5'}$ = 6.9 Hz, 1H, H-4′), 4.07–4.03 (m, 1H, H-5′), 3.97–3.91 (m, 2H, both H-6′), 3.87 (dd, $J_{2,3}$ = 9.3 Hz, $J_{3,4}$ = 9.3 Hz, 1H, H-3), 3.69 (dd, $J_{4,5}$ = 9.4 Hz, 1H, H-4), 3.68 (d, $J_{1'A,1'B}$ = 11.2 Hz, 1H, H-1′A) 3.48 (d, 1H, H-1′B) 3.47 (dd, 1H, H-2), 3.469 (s, 3H, OCH_3), 1.05 (s, 9H, Me_3CSi). ^{13}C NMR δ: 170 (CO), 104.8 (C-2′), 90.1 (C-1), 83.8 (C-3′), 82.7 (C-4′), 81.6 (C-5′), 81.3 (C-3), 79.6 (C-4), 79.4 (C-2), 75.6, 74.9, 73.4, 73.0, 72.6, 72.3 (6×CH$_2$Ph), 70.9 (C-1′), 70.5 (C-5), 64.9 (C-6′), 51.9 (OCH$_3$), 26.9 (Me_3CSi), 19.3 (Me$_3$$C$Si). MS *m/z*: 1071.8 [M($C_{71}H_{76}O_{12}Si$) + Na^+].

6-*O*-Allyl-1′,2,3,3′,4,4′-hexa-*O*-benzylsucrose (9)

To a solution of **6** (1.71 g, 1.52 mmol) and allyl bromide (6 mL) in CH_2Cl_2 (40 mL), 50% NaOH (40 mL) and Bu_4NBr (0.15 g, 0.47 mmol) were added. The mixture was stirred vigorously for 24 h at rt. A second portion of allyl bromide (4 mL) was added, the stirring was continued overnight, and the mixture was then partitioned between water (30 mL) and ether (70 mL). The organic layer was separated, washed with water (40 mL), dried, concentrated, and the product was isolated by column chromatography (hexane – ethyl acetate, 7:1 to 4:1) to give 6-*O*-allyl-1′,2,3,3′,4,4′-hexa-*O*-benzyl-6′-*O*-*tert*-butyl-diphenylsilylsucrose (**8**) (0.91 g, 0.782 mmol, 52%; 66% calcd. on consumed **6**) as a colorless oil and unreacted alcohol **6** (0.38 g, 0.339 mmol). $[\alpha]_D$ +24.8°. IR (film, cm^{-1}) υ: 2929, 2859, 1453, 1090, 1027, 737, 698. MS *m/z*: 1184.6 [M($C_{73}H_{80}O_{11}Si$) + Na^+].

When the allyl bromide was replaced with allyl chloride, removal of the silyl protection from the C-6′ position was noted and the diallylated product was isolated from the reaction mixture in good yield.

To a solution of **8** (0.91 g, 0.782 mmol) in THF (20 mL), $Bu_4NF{\cdot}3H_2O$ (0.32 g, 1.0 mmol) was added and the mixture was stirred overnight at rt. The solvent was removed under reduced pressure and the residue was partitioned between ethyl acetate (40 mL) and water (40 mL). The organic layer was separated, dried, concentrated, and the residue was purified by column chromatography (hexane – ethyl acetate, 3:1 to 2:1) to give alcohol **9** (0.54 g, 0.58 mmol, 74%) as a colorless oil. $[\alpha]_D$ +35.2°. IR (film, cm^{-1}) υ: 2917, 2867, 1496, 1454, 1088, 1073, 1028, 736, 697. ^1H NMR δ: 5.93–5.83 (m, 1H, CH=CH$_2$), 5.52 (d, $J_{1,2}$ = 3.5 Hz, 1H, H-1), 5.27–5.22 (m, 1H, -CH$_2$-CH=CH_2, J = 17.2 Hz), 5.15 (1H, -CH$_2$-CH=CH_2, J = 10.4 Hz). ^{13}C NMR δ: 134.5 (-CH$_2$-CH=CH$_2$), 117.3 (-CH$_2$-CH=CH$_2$), 103.9 (C-2′), 91.1 (C-1), 83.7, 81.7, 81.3, 79.6, 79.4, 77.4, 71.3 (C-2,3,3′,4,4′,5,5′), 75.5, 74.9, 73.4, 73.3, 72.9, 72.49, 72.47, 71.2 (6×CH$_2$Ph, C-1′ and -CH$_2$-CH=CH$_2$), 67.9, 61.2 (C-6 and C-6′). MS *m/z*: 945 [M($C_{57}H_{62}O_{11}$) + Na^+]. Anal. calcd. for $C_{57}H_{62}O_{11}$: C 74.17, H 6.77; found: C 74.0, H 6.8.

6-*O*-Allyl-6′-*O*-acroyl-1′,2,3,3′,4,4′-hexa-*O*-benzylsucrose (10)

Alcohol **9** (0.355 g, 0.385 mmol) was dissolved in CH_2Cl_2 (20 mL) containing triethylamine (1 mL) and DMAP (ca. ~20 mg). Acroyl chloride (0.13 mL, 1.5 mmol) was added, the mixture was stirred for 1 h at rt and then partitioned between ether (70 mL) and water (50 mL). The organic phase was separated, dried, concentrated, and the residue was purified by column chromatography (hexane – ethyl acetate, 3:1) to give **10** (0.268 g, 0.29 mmol, 75%) as a yellowish oil. $[\alpha]_D$ +41.2°. IR (film): 3070, 3031, 2930, 2857, 1727, 1636, 1497, 1454, 1428, 1361, 821, 739, 700. ^1H NMR δ: 6.39 (dd, J = 1.3, 17.4 Hz, 1H, COCH=CH_2), 6.11 (dd, J = 10.5 Hz, 1H, second COCH=CH_2), 5.90–5.80 (m, 1H, CH$_2$CH=CH$_2$), 5.75 (dd, 1H, COCH=CH$_2$), 5.64 (d, $J_{1,2}$ = 3.6 Hz, 1H, H-1), 5.22 (dd, J = 17.2, 1.6 Hz, 1H, CH$_2$CH=CH_2), 5.12 (dd, J = 10.4 Hz, 1H, second CH$_2$CH=CH_2). ^{13}C NMR δ: 165.8 (CO), 134.7 (-CO$_2$$C$H=CH$_2$), 131.0 (-CO$_2$CH=$CH_2$), 128.5–127 (-CH$_2$$C$H=CH$_2$), 117.1 (-CH$_2$CH=$CH_2$), 104.7 (C-2′), 90.2 (C-1), 83.8, 82.2, 81.9, 79.7, 78.2, 77.7 and 70.7 (C-2,3,3′,4,4′,5,5′), 75.5, 74.8, 73.4, 72.9, 72.6, 72.5, 72.3, 70.9, 68.5, 65.3 (C-1′, C-6, C-6′, -CH$_2$CH=CH$_2$, and 6×OCH$_2$Ph). MS *m/z*: 999 [M($C_{60}H_{64}O_{12}$) + Na^+].

Metathesis reaction of 6-*O*-allyl-6′-*O*-acroyl-1′,2,3,3′,4,4′-hexa-*O*-benzylsucrose (10) catalyzed by Grubbs II catalyst

Compound **10** (0.250 g, 0.256 mmol) was dissolved in CH_2Cl_2 (7 mL) to which Grubbs II catalyst (13.1 mg, 0.015 mmol) was added and the mixture was boiled under reflux for 3.5 h. The mixture was then partitioned between

CH_2Cl_2 (20 mL) and water (30 mL), the organic phase was separated, and the aqueous one extracted with ether (10 mL). The combined organic layers were dried, concentrated, and the products were partially purified by column chromatography (hexane – ethyl acetate, 5:1 to 3:1) to afford unreacted compound **10** (30 mg) and a mixture of four compounds (76 mg) from which the individual products were isolated by HPLC (hexane – ethyl acetate, 5:2).

E-Isomer **12** was the first to be isolated. IR (film, cm^{-1}) υ: 2923, 2856, 1726 (CO), 1454, 1091, 1073, 1028, 736, 697. ^1H NMR (for numbering see Scheme 2) δ: 7.13 (ddd, $J_{\alpha,\beta}$ = 16.1 Hz, $J_{\beta,\delta}$ = 7.0 Hz, $J_{\beta,\gamma}$ = 5.2 Hz, 1H, H-β), 5.81–5.76 (m, 1H, H-α), 5.67 (d, $J_{1,2}$ = 3.8 Hz, H-1). ^{13}C NMR δ: 165.7 (CO), 147.8 (-CH_2*C*H=CHCO-), 22.3 (-CH=*CH*-CO-), 102.8 (C-2′), 88.6 (C-1), 84.2, 81.6, 79.9, 78.31, 78.25, 78.18, 71.2 (C-2,3,3′,4,4′,5,5″), 75.19, 75.13, 74.6, 73.3, 73.1, 72.4, 72.2, 69.9, 67.6, 60.0 (C-1′,6,6′, -*C*H_2CH=CH_2 and 6×O*C*H_2Ph). MS *m*/*z*: 971 (main signal) [M($C_{58}H_{60}O_{12}$) + Na^+] and 987 [M($C_{58}H_{60}O_{12}$) + K^+] (minor).

Z-Isomer **13** was the second to be isolated (contaminated with ca. 30% of **12**). ^1H NMR δ: 6.21 (ddd, $J_{\beta,\gamma}$ = 12.0 Hz, $J_{\beta,\delta}$ = 12.0 Hz, $J_{\alpha,\beta}$ = 5.2 Hz, 1H, H-β), 5.77 (ddd, $J_{\alpha,\gamma}$ = 1.8 Hz, $J_{\alpha,\delta}$ = 1.8 Hz, 1H, H-α), 5.54 (d, $J_{1,2}$ = 3.6 Hz, H-1). ^{13}C NMR δ: 166.1 (CO), 144.8 (-*C*H=CHCO-), 121.5 (-*C*H=CH-CO_2), 103.7 (C-2′), 90.2 (C-1), 83.7, 81.7, 80.7, 79.7, 79.0, 77.8, 71.6 (C-2,3,3′,4,4′,5,5′), 75.4, 74.6, 73.3, 73.1, 72.4, 72.3 (2×), 70.5, 67.2, 61.9 (C-1′,6′,6, -*C*H_2CH=CH_2 and 6×O*C*H_2Ph). MS *m*/*z*: 971 (minor signal) [M($C_{58}H_{60}O_{12}$) + Na^+] and 987 [M($C_{58}H_{60}O_{12}$) + K^+] (main).

Macrocyclic dimer **14** was the third to be isolated (contaminated with **12**, **13**, and **15**; ca. 5%–10% each). ^1H NMR δ: 6.83 (ddd, $J_{\alpha,\beta}$ = 15.8 Hz, $J_{\beta,\gamma}$ = 4.0 Hz, $J_{\beta,\delta}$ = 4.0 Hz, 1H, H-β), 5.96 (ddd, $J_{\alpha,\gamma}$ = 2.0 Hz, $J_{\alpha,\delta}$ = 2.0 Hz, 1H, H-α), 5.66 (d, $J_{1,2}$ = 3.7 Hz, H-1). ^{13}C NMR δ: 165.8 (CO), 145.6 (-CH_2*C*H=CHCO-), 120.0 (-CH_2CH=*C*HCO-), 104.6 (C-2′), 89.4 (C-1), 89.4, 83.6, 82.1, 81.3, 80.0, 77.7, 70.9 (C-2,3,3′,4,4′,5,5′), 75.5, 74.9, 73.5, 72.9, 72.5, 72.3, 71.6, 70.1, 69.3, 64.1 (C-1′,6,6′, -*C*H_2CH=CH_2 and 6×*C*H_2Ph). MS *m*/*z*: 1919 [M($C_{116}H_{120}O_{24}$) + Na^+] (strongest signal: 1920 [M + 1 + Na^+]).

Open-chain dimer **15** was the fourth to be isolated. ^1H NMR δ: 6.36 (dd, $J_{\alpha,\beta}$ = 17.4 Hz, $J_{\beta,\gamma}$ = 1.4 Hz, 1H, H-β), 6.09 (dd, $J_{\alpha,\gamma}$ = 10.4 Hz, 1H, H-α), 5.72 (dd, 1H, H-γ), 5.70 (dd, $J_{\delta,\phi}$ = 3.0 Hz, $J_{\delta,\varepsilon}$ = 3.0 Hz, 1H, H-δ), 5.62 (d, $J_{1,2}$ = 3.6 Hz, H-1). ^{13}C NMR δ: 165.9 (CO), 131.1 (-CO_2CH=*C*H_2), 129.5 (-CO_2*C*H=CH_2), 104.7 (C-2′), 90.3 (C-1), 83.9, 82.3, 81.8, 79.8, 78.3, 77.6, 70.70 (C-2,3,3′,4,4′,5,5′), 75.5, 74.8, 73.4, 72.9, 72.59, 72.50, 71.4, 70.8, 68.6, 65.4 (C-1′,6,6′, -*C*H_2CH=CH_2 and 6×*C*H_2Ph). MS *m*/*z*: 1947 [M($C_{118}H_{124}O_{24}$) + Na^+] (strongest signal: 1948 [M + 1 + Na^+]).

Synthesis of zwitterionic selenonium and sulfonium sulfates from D-mannose as potential glycosidase inhibitors[1]

Hui Liu and B. Mario Pinto

Abstract: Four chain-extended analogues of the naturally occurring glycosidase inhibitor salacinol were synthesized for structure–activity studies with different glycosidase enzymes. The syntheses involved the reaction of isopropylidene-protected 1,4-thio- and 1,4-seleno-D-talitols and 1,5-thio- and 1,5-seleno-L-gulitols, derived from D-mannose, with a benzylidene- and isopropylidene-protected 1,3-cyclic sulfate, also derived from D-mannose. Deprotection of the products afforded the novel selenonium and sulfonium sulfates composed of heterocyclic five- and six-membered ring core structures with pendant polyhydroxylated, acyclic chains of six carbon atoms.

Key words: glycosidase inhibitors, zwitterionic selenonium and sulfonium sulfates, cyclic sulfate.

Résumé : Afin de pouvoir procéder à des études de structure–activité avec divers enzymes de glycosidase, on a synthétisé quatre analogues à chaîne allongée du salacinol, un inhibiteur de la glycosidase qu'on retrouve à l'état naturel. Ces synthèses ont impliquées les réactions de dérivés isopropylidènes de 1,4-thio et 1,4-séléno-D-talitols ainsi que de 1,5-thio- et 1,5-séléno-L-gulitols obtenus à partir du D-mannose avec des dérivés benzylidènes et isopropylidènes de sulfates cycliques-1,3 aussi obtenus à partir du D-mannose. La déprotection des produits a permis d'obtenir de nouveaux sulfates de sélénonium et de sulfonium formés structures à cycle central formé d'hétérocycles à cinq et à six chaînons portant des chaînes pendantes polyhydroxylées de six atomes de carbone.

Mots clés : inhibiteurs de glycosidase, sulfates de sélénonium et de sulfonium zwitterioniques, sulfate cyclique.

[Traduit par la Rédaction]

Introduction

The controlled inhibition of glycosidase enzymes plays important roles in the biochemical processing of biopolymers containing carbohydrates (1, 2). Recently, a new class of glycosidase inhibitors, namely salacinol (**1**) and kotalanol (**2**), with an intriguing inner-salt sulfonium sulfate structure was isolated from the roots and stems of the plant *Salacia reticulata*. These compounds have been found to be potent inhibitors of intestinal glucosidase enzymes (3, 4). Salacinol (**1**) and kotalanol (**2**) presumbly compete for substrate binding in the active site, thus preventing glucose oligosaccharides from being processed and thereby inhibiting a surge in blood glucose levels after a meal rich in carbohydrates (Chart 1). Hence, they have potential as therapeutics in the management of blood glucose levels for patients suffering from type II diabetes (5). The absolute configuration of the heptitol side chain of kotalanol has yet to be determined. However, kotalanol has shown more potent glucosidase inhibitory activity towards sucrase than salacinol (6). It is believed that the inhibitory activities of salacinol and kotalanol come from their ability to mimic both the shape and charge of the oxacarbenium-ion-like transition state involved in the enzymatic reactions (7–9). However, the details of the mechanism of action of these compounds are yet to be elucidated.

In our current research program, we have undertaken a limited structure–activity study of salacinol and related compounds. The synthesis of salacinol and its ammonium and selenonium analogues have been reported by us and others (10–14). We also have synthesized analogues containing six-membered heterocyclic rings and chain-extended analogues of salacinol, some of which have shown inhibitory activity in the micromolar range of recombinant human maltase glucoamylase, a key intestinal glucosidase (15–18). These studies have revealed an interesting variation in the inhibitory power of these compounds against glycosidase enzymes of different origin (11–14). The molecular basis for this selectivity is being investigated through structural studies of the enzyme-bound inhibitors using molecular modeling in conjunction with NMR techniques (19) and X-ray crystallography (20). To further understand this selectivity, additional examples of analogues of salacinol that differ in stereochemistry on both the heterocyclic ring and the side chain, in chain length of the acyclic chain, and in size of the heterocyclic ring are required.

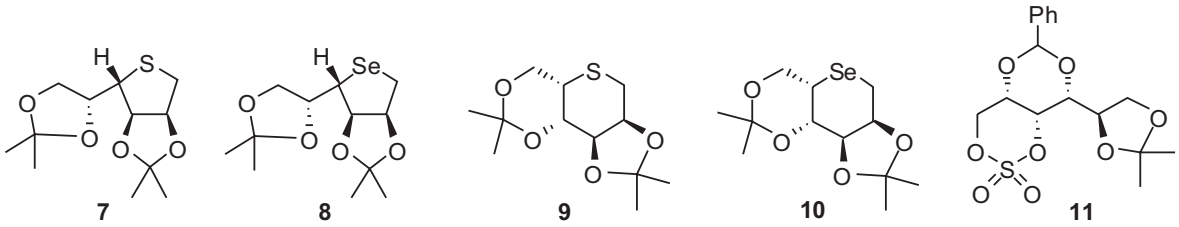
Herein, we report the synthesis of two series of selenonium and sulfonium sulfates (**3**–**6**) based on seleno- and thio-anhydroalditols derived from D-mannose (Chart 2).

Results and discussion

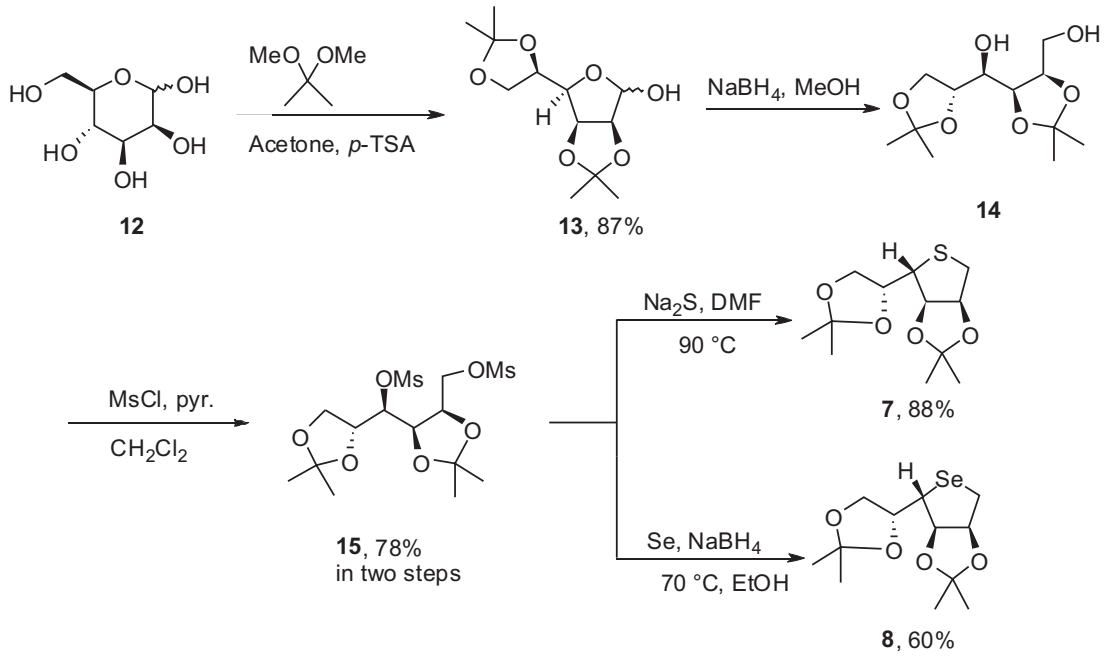
Retrosynthetic analysis indicated that the analogues **3**–**6** could be synthesized by alkylation of the protected anhydroheteroalditols at the ring heteroatom with a terminal 1,3-cyclic sulfate derived from D-mannose (Scheme 1).

The choice of protecting groups for the seleno- and thio-anhydroalditols and the cyclic sulfate, however, merited careful consideration, especially in the case of the selenonium analogues. Our previous work suggested that hydrogenolysis and strongly basic conditions as deprotection steps were problematic for the selenonium analogues (12–14). Therefore, we envisioned the use of only isopropylidene and benzylidene acetals as the protecting groups for the seleno- and thio-anhydroalditols (**7**–**10**) and the cyclic sulfate (**11**), since these acetals would be subject to acidic hydrolysis (Chart 3).



Our previous work also suggested that the release of ring strain in the opening of a cyclic sulfate was beneficial (11–14). Therefore, the benzylidene acetal at the 2,4-positions of the cyclic sulfate **11** played a dual role as both a protecting group and also as a facilitator of the coupling reactions with the heterocyclic ethers **7**–**10**. After the coupling reactions, the products could then be readily deprotected by simple treatment with trifluoroacetic acid.

The synthesis of the isopropylidene-protected 1,4-anhydro-1-thio-D-talitol (**7**) and 1,4-anhydro-1-seleno-D-talitol (**8**) started from D-mannose (**12**, Scheme 2). D-Mannose was first treated with 2,2-dimethoxypropane in dry acetone with *p*-toluenesulfonic acid as a catalyst to give 2,3,5,6-di-*O*-isopropylidene-D-mannose (**13**) (21). Compound **13** was subsequently subjected to reduction with sodium borohydride to afford the corresponding diol **14**. The diol was then converted to the corresponding dimesylate **15** in 80% yield by treatment with methanesulfonyl chloride and pyridine. The isopropylidene-protected 1,4-anhydro-1-thio-D-talitol (**7**) was prepared in 92% yield by treatment of the dimesylate **15** with sodium sulfide in DMF in 92% yield. When the dimesylate **15** was reacted with selenium and sodium borohydride in EtOH at 60–65 °C, the isopropylidene-protected 1,4-anhydro-1-seleno-D-talitol (**8**) was obtained in a 60% yield (Scheme 2).



With D-mannose as a starting material, the isopropylidene-protected 1,5-anhydro-1-thio-L-gulitol (**9**) and 1,5-anhydro-1-seleno-L-gulitol (**10**) were also synthesized (Scheme 3). D-Mannose (**12**) was treated with 2-methoxypropene in dry DMF with *p*-toluenesulfonic acid as a catalyst to give the kinetically controlled product, 2,3,4,6-di-*O*-isopropylidene-D-mannose (**16**) (22). Compound **16** was subsequently subjected to sodium borohydride reduction to afford the corresponding diol **17**. The diol **17** was then converted to the corresponding dimesylate **18** in 90% yield by treatment with methanesulfonyl chloride and pyridine. The isopropylidene-protected 1,5-anhydro-1-thio-L-gulitol (**9**) was prepared in 85% yield by treatment of the dimesylate **18** with sodium sulfide in DMF. Reaction of dimesylate **18** with selenium

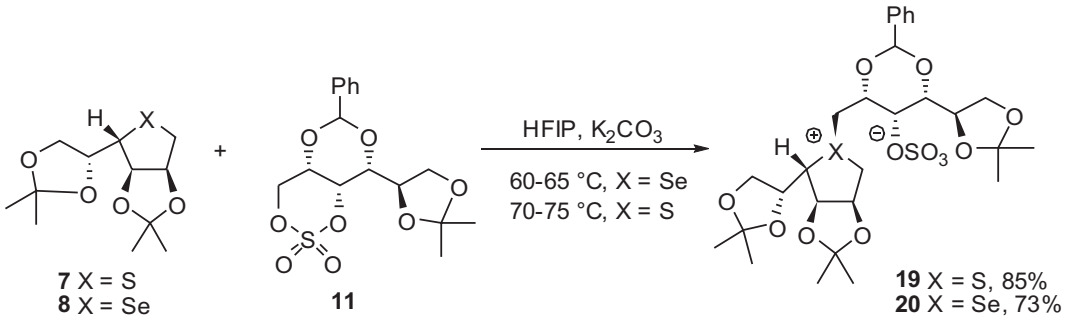
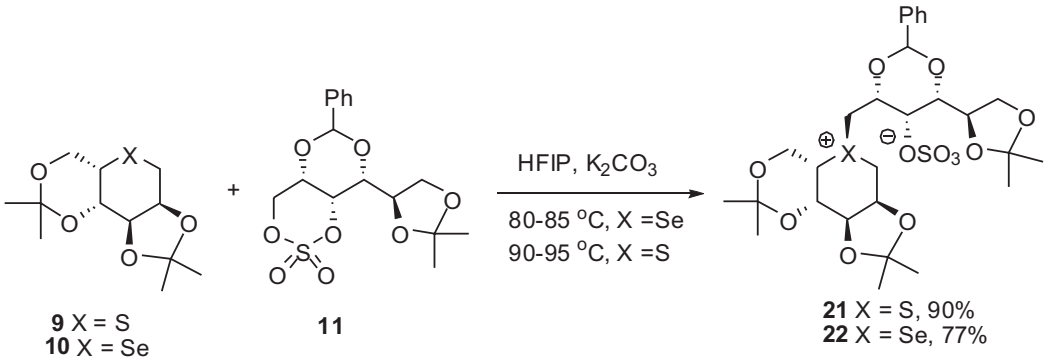
Scheme 3.



and sodium borohydride in EtOH at 60–65 °C gave isopropylidene-protected **10** in 62% yield (Scheme 3).



The coupling reactions of protected **7** and **8** were then investigated (Scheme 4). The solvent chosen for the coupling reactions was the unusual solvent 1,1,1,3,3,3-hexafluoroisopropanol (HFIP), which was demonstrated in our earlier work to offer significant advantage in analogous reactions. Cyclic sulfate (**11**), prepared by a method developed in our earlier work (16), was used as the coupling partner. **11** was reacted with isopropylidene-protected **7** and **8** to give the corresponding protected sulfonium and selenonium compounds **19** and **20**, respectively (Scheme 4).

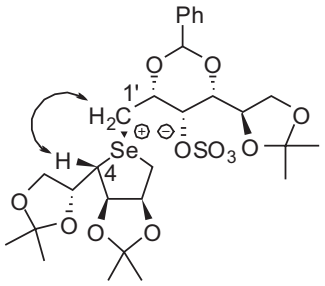
Scheme 4.

Scheme 5.



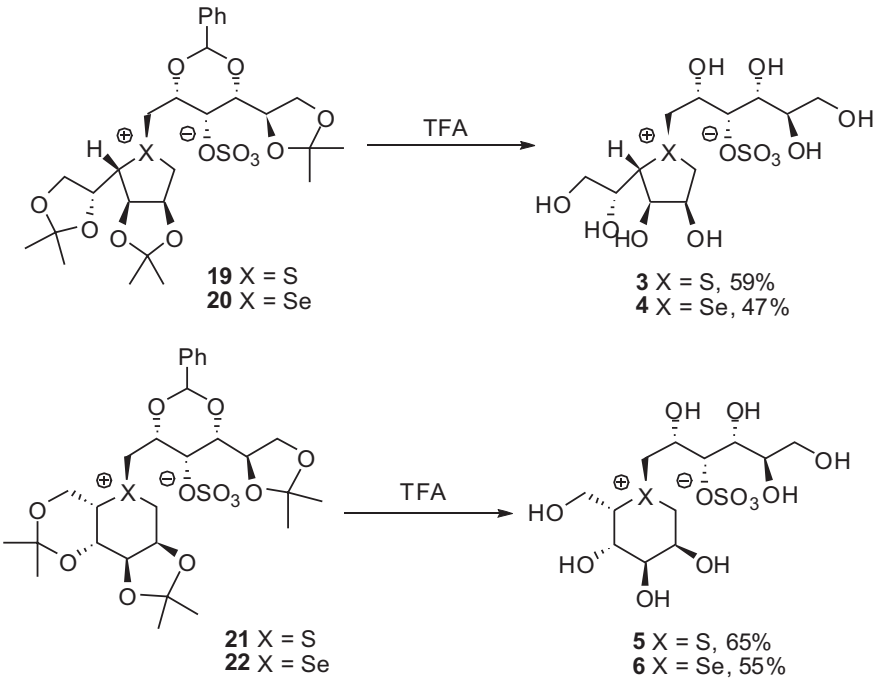
In analogous fashion, the coupling reactions of protected **9** and **10** with **11** afforded the protected sulfonium and selenonium compounds **21** and **22**, respectively (Scheme 5).

The reactivities of **7**, **8**, **9**, and **10** with **11** varied slightly. The five-membered-ring anhydroalditols **7** and **8** were more reactive than their six-membered-ring counterparts, **9** and **10**, as illustrated by the higher temperatures required for the coupling reactions in the latter cases. Compounds **7** and **8** reacted readily with **11** at 70–75 °C and 60–65 °C, respectively, while compounds **9** and **10** reacted very slowly and gave low yields of the coupling products at these temperatures. When the temperature was increased to 90–95 °C and 80–85 °C, respectively, compounds **9** and **10** reacted readily with **11**. Within the same series, the selenoalditols were found to be slightly more reactive than their sulfur counterparts. Selectivity for the attack at the primary center of **11** over possible alternative attack at the secondary center by compounds **7**–**10** was invariably excellent and in no case were isolable quantities of the regioisomers detected. In the case of the coupling reaction of **8** with **11**, there was a small amount (<10%) of the diastereomer formed resulting from electrophilic attack on the β-face of compound **8**. However, diastereoisomers at the stereogenic heteroatom centers were not detected in all other cases.

The absolute stereochemistry at the heteroatom centre of compounds **19**–**22** was established by 1D-NOE NMR spectroscopy (Fig. 1). Thus, for example, the 1D NOE spectra of compound **20** indicated an H-4 to H-1′b correlation, implying that these hydrogens are syn-facial, and consequently, C-1′ of the side chain must be anti to C-5 of the heterocyclic moiety.

Deprotection of the coupled products **19**–**22** was carried out by treatment with trifluoroacetic acid (Scheme 6). After rinsing away the cleaved protecting groups with dichloromethane, the resulting residues were purified by flash chromatography to yield compounds **3**–**6** as amorphous, hygroscopic solids. These compounds were characterized by spectroscopic methods.

Fig. 1. NOE correlations observed in the 1D-NOE spectrum of **20**.



Conclusions

Two series of selenonium and sulfonium sulfates were synthesized from D-mannose. The analogues contained extended acyclic chains of six carbon atoms, as well as ring heteroatom substitution (S, Se) and five- and six-membered heterocyclic rings. These syntheses utilized a 1,3-cyclic sulfate, also derived from D-mannose, in four steps. The isopropylidene acetal and benzylidene acetal protecting groups on the coupled products ensured facile deprotection with TFA to yield the final compounds (**3**–**6**). These compounds are being tested for their enzymatic activities.

Experimental section

General

Optical rotations were measured at 23°. ^{1}H and ^{13}C NMR spectra were recorded at 500 and 125 MHz, respectively. All assignments were confirmed with the aid of two-dimensional ^{1}H, ^{1}H (COSYDFTP), or ^{1}H, ^{13}C (INVBTP) experiments using standard Bruker pulse programs. Column chromatography was performed with Merck Silica gel 60 (230–400 mesh). MALDI mass spectra were obtained on a PerSeptive Biosystems, Voyager DE time-of-flight spectrometer for samples dispersed in a 2,5-dihydroxybenzoic acid matrix. High-resolution mass spectra were obtained by the electrospray ionization (ESI) technique, using a ZabSpec oaTOF mass spectrometer at 10 000 RP.

2,3,5,6-Di-*O*-isopropylidene-1,4-di-*O*-methanesulfonyl-D-mannitol (15)

2,3,5,6-Di-*O*-isopropylidene-D-mannose (**13**) was prepared by the literature method (23). To a solution of **13** (20 g, 77 mmol) in MeOH (200 mL), $NaBH_4$ (5.8 g, 0.15 mol) was added portionwise at 0 °C. The progress of the reaction was followed by TLC analysis of the aliquots (developing solvent, hexane–EtOAc, 1:1). When starting material **13** had been essentially consumed, the solvent was evaporated under reduced pressure. The residue was redissolved in EtOAc (150 mL), washed with satd. NH_4Cl solution (200 mL) and brine (50 mL), and dried over Na_2SO_4. After evaporating the solvent, the crude diol (**14**) was used without further purification. Diol **14** was dissolved in CH_2Cl_2 (50 mL) and then added dropwise to a mixture of pyridine (100 mL) and methanesulfonyl chloride (26 mL, 0.34 mol) cooled to 0 °C. The reaction mixture was stirred at 0 °C for 30 min, then allowed to rise to room temperature for 6 h. When TLC analysis of the aliquots (developing solvent, hexane–EtOAc, 1:1) showed total consumption of the starting material, the reaction mixture was poured into ice water, extracted with CH_2Cl_2 (3 × 100 mL), washed with brine (50 mL), and dried over Na_2SO_4. Purification by column chromatography (hexane–EtOAc, 2:1) yielded compound **15** as a colorless syrup (25 g, 78%). $[\alpha]^{22}_D$ +18.0° (*c* 0.5, CH_2Cl_2). ^{1}H NMR ($(CD_3)_2O$) δ: 4.86 (1H, dd, $J_{3,4}$ = 6.8, $J_{4,5}$ = 6.5, H-4), 4.55–4.50 (3H, m, H-2, H-3, H-1b), 4.47 (1H, dd, $J_{1a,1b}$ = 11.1, $J_{1a,2}$ = 7.6, H-1a), 4.29 (1H, ddd, $J_{4,5}$ = 6.5, H-5), 4.16 (1H, dd, $J_{5,6b}$ = 6.4, $J_{6a,6b}$ = 8.5, H-6b), 3.99 (1H, dd, $J_{5,6a}$ = 7.5, $J_{6a,6b}$ = 8.5, H-6a), 3.22 and 3.16 (6H, 2 s, $2OSO_2CH_3$), 1.53, 1.43, 1.38, and 1.33 (12H, 4 s, 4 CH_3). ^{13}C NMR ($(CD_3)_2O$) δ: 109.97, 109.44 ($(CH_3)_2C(OR)_2$), 78.72 (C-4), 76.79 (C-3), 75.11 (C-5), 75.02 (C-2), 68.92 (C-1), 66.43 (C-6), 38.93, 36.75 (2 SO_2CH_3), 26.89, 25.68, 25.34, 24.82 ($4CH_3$). Anal. calcd. for $C_{14}H_{26}O_{10}S_2$: C 40.18, H 6.26; found: C 40.45, H 6.14.

2,3,4,6-Di-*O*-isopropylidene-1,5-di-*O*-methanesulfonyl-D-mannitol (18)

2,3,4,6-Di-*O*-isopropylidene-D-mannose (**16**) was prepared by the literature method (24). To a solution of **16** (20 g, 77 mmol) in MeOH (200 mL), $NaBH_4$ (5.8 g, 0.15 mol) was added portionwise at 0 °C. The progress of the reaction was followed by TLC analysis of the aliquots (developing solvent, hexane–EtOAc, 1:1). When starting material **13** had been essentially consumed, the solvent was evaporated under reduced pressure. The residue was redissolved in EtOAc (150 mL), washed with satd. NH_4Cl solution (200 mL) and brine (50 mL), and dried over Na_2SO_4. After evaporating the solvent, the crude diol (**17**) was used without further purification. Diol **17** was dissolved in CH_2Cl_2 (50 mL) and then added dropwise to a mixture of pyridine (100 mL) and methanesulfonyl chloride (26 mL, 0.34 mol) cooled to 0 °C. The reaction mixture was stirred at 0 °C for 30 min, then allowed to rise to room temperature

for 6 h. When TLC analysis of the aliquots (developing solvent, hexane–EtOAc, 1:1) showed total consumption of the starting material, the reaction mixture was poured into ice water, extracted with CH_2Cl_2 (3 × 100 mL), washed with brine (50 mL), and dried over Na_2SO_4. Purification by column chromatography (hexane–EtOAc, 2:1) yielded compound **18** as a colorless syrup (24 g, 75%). $[\alpha]^{22}_D$ +2.4° (*c* 0.5, CH_2Cl_2). ^{1}H NMR ($CDCl_3$) δ: 4.82 (1H, ddd, $J_{5,6a}$ = 7.3, $J_{5,6b}$ = 5.1, $J_{4,5}$ = 8.8, H-5), 4.54 (1H, ddd, $J_{1a,2}$ = 4.1, $J_{1b,2}$ = 7.5, $J_{2,3}$ = 6.3, H-2), 4.50 (1H, dd, $J_{1a,1b}$ = 10.3, $J_{1b,2}$ = 7.5, H-1b), 4.40 (1H, dd, $J_{3,4}$ = 1.1, H-3), 4.38 (1H, dd, H-1a), 4.14 (1H, dd, $J_{6a,6b}$ = 12.0, H-6b), 3.89 (1H, dd, H-6a), 3.82 (1H, dd, H-4), 3.09 and 3.08 (6H, 2 s, $2OSO_2CH_3$), 1.52, 1.49, 1.41, and 1.37 (12H, 4 s, $4CH_3$). ^{13}C NMR ($CDCl_3$) δ: 110.55, 100.03 ($(CH_3)_2C(OR)_2$), 74.94 (C-2), 73.85 (C-3), 72.22 (C-5), 69.58 (C-4), 68.13 (C-1), 62.64 (C-6), 38.11, 38.04 ($2SO_2CH_3$), 27.45, 26.83 25.82, 20.37 (four CH_3). Anal. calcd. for $C_{14}H_{26}O_{10}S_2$: C 40.18, H 6.26; found: C 39.99, H 6.02.

2,3,5,6-Di-*O*-isopropylidene-1,4-anhydro-1-thio-D-talitol (7)

To a solution of dimesylate **15** (4.0 g, 9.6 mmol) in DMF (80 mL), $Na_2S{\cdot}9H_2O$ (2.8 g, 11.5 mmol) was added and the reaction mixture was heated at 90 °C for 12 h. The reaction mixture was poured into water (100 mL), extracted with Et_2O (4 × 50 mL), washed with water (10 × 20 mL), and dried over Na_2SO_4. After evaporating the solvent, the crude product was purified by column chromatography (hexane–EtOAc, 3:1) to give **7** as a colorless oil (2.2 g, 88%). $[\alpha]^{22}_D$ –47° (*c* 0.5, CH_2Cl_2). ^{1}H NMR ($(CD_3)_2O$) δ: 4.93 (1H, ddd, $J_{2,3}$ = 5.7, $J_{1a,2}$ = 1.3, $J_{1b,2}$ = 5.1, H-2), 4.75 (1H, dd, $J_{3,4}$ = 1.6, $J_{2,3}$ = 5.7, H-3), 4.06 (1H, dd, $J_{6a,6b}$ = 7.7, $J_{5,6b}$ = 6.2, H-6b), 3.72 (1H, dd, $J_{5,6a}$ = 7.4, H-6a), 3.34 (1H, dd, H-4), 3.17 (1H, dd, $J_{1a,1b}$ = 12.2, H-1b), 2.74 (1H, dd, H-1a), 1.43, 1.38, 1.29, and 1.28 (12H, 4 s, $4CH_3$). ^{13}C NMR ($(CD_3)_2O$) δ: 110.85, 109.27 ($(CH_3)_2C(OR)_2$), 87.33 (C-3), 84.09 (C-2), 78.25 (C-5), 68.03 (C-6), 56.34 (C-4), 38.47 (C-1), 26.45, 25.93, 25.38, 24.24 ($4CH_3$). Anal. calcd. for $C_{12}H_{20}O_4S$: C 55.36, H 7.74; found: C 55.62, H 7.73.

2,3,5,6-Di-*O*-isopropylidene-1,4-andydro-1-seleno-D-talitol (8)

To a suspension of Se (1.6 g, 20.2 mmol) and 95% EtOH (100 mL), $NaBH_4$ (1.5 g, 40.4 mmol) was added portionwise until the black selenium color disappeared. To this mixture a solution of dimesylate **15** (6.0 g, 14.3 mmol) in THF (10 mL) was added and the reaction mixture was heated at 70 °C for 12 h. The solvent of the reaction mixture was evaporated under reduced pressure, redissolved in EtOAc, washed with water (20 mL) and brine (20 mL), and dried over Na_2SO_4. After evaporating the solvent, the crude product was purified by column chromatography (hexane–EtOAc, 3:1) to give **8** as a colorless oil (3.1 g, 71%). $[\alpha]^{22}_D$ –40° (*c* 1, CH_2Cl_2). ^{1}H NMR ($(CD_3)_2O$) δ: 4.97 (1H, ddd, $J_{2,3}$ = 5.7, $J_{1a,2}$ = 2.4, $J_{1b,2}$ = 5.5, H-2), 4.71 (1H, dd, $J_{3,4}$ = 2.9, $J_{2,3}$ = 5.7, H-3), 4.28 (1H, ddd, $J_{5,6a}$ = 7.4, $J_{5,6b}$ = 6.1, H-5), 4.09 (1H, dd, $J_{6a,6b}$ = 8.1, H-6b), 3.69 (1H, dd, $J_{5,6a}$ = 7.4, H-6a), 3.61 (1H, dd, $J_{4,5}$ = 5.1, H-4), 3.23 (1H, dd, $J_{1a,1b}$ = 11.3, H-1b), 2.87 (1H, dd, H-1a), 1.43, 1.38, 1.29, and 1.27 (12H, 4 s, $4CH_3$). ^{13}C NMR ($(CD_3)_2O$) δ: 110.59, 109.16 ($(CH_3)_2C(OR)_2$), 88.44 (C-3), 85.37 (C-2), 78.42 (C-5), 68.97 (C-6), 51.34 (C-4), 29.17 (C-1), 26.73, 26.06, 25.37, 24.31 (4 CH_3). Anal. calcd. for $C_{12}H_{20}O_4Se$: C 46.91, H 6.56; found: C 46.71, H 6.62.

2,3,4,6-Di-*O*-isopropylidene-1,5-anhydro-1-thio-L-gulitol (9)

To a solution of dimesylate **18** (6.0 g, 14.3 mmol) in DMF (100 mL), $Na_2S{\cdot}9H_2O$ (4.1 g, 18.2 mmol) was added and the reaction mixture was heated at 100 °C for 12 h. The reaction mixture was poured into water (100 mL), extracted with Et_2O (4 × 50 mL), washed with water (10 × 20 mL), and dried over Na_2SO_4. After evaporating the solvent, the crude product was purified by column chromatography (hexane–EtOAc, 3:1) to give **9** as a colorless oil (3.5 g, 93%). $[\alpha]^{22}_D$ –41° (*c* 0.5, CH_2Cl_2). ^{1}H NMR ($(CD_3)_2O$) δ: 4.51 (1H, ddd, $J_{2,3}$ = 2.9, $J_{1b,2}$ = 4.2, H-2), 4.30–4.24 (2H, m, H-4, H-6b), 4.06 (1H, dd, $J_{3,4}$ = 6.2, $J_{5,6b}$ = 6.2, H-3), 3.63 (1H, dd, $J_{5,6a}$ = 1.9, $J_{6a,6b}$ = 12.5, H-6a), 2.95 (1H, dd, $J_{1a,1b}$ = 13.5, H-1b), 2.92 (1H, m, H-5), 2.57 (1H, dd, $J_{1b,2}$ = 7.2, H-1a), 1.45, 1.39, 1.32, and 1.25 (12H, 4 s, $4CH_3$). ^{13}C NMR ($(CD_3)_2O$) δ: 112.52, 103.61 ($(CH_3)_2C(OR)_2$), 79.65 (C-3), 75.26 (C-4), 71.63 (C-2), 68.40 (C-6), 39.94 (C-5), 33.77 (C-1), 31.53, 29.55, 29.49, 23.22 ($4CH_3$). General procedure for the preparation of sulfonium and selenium sulfates (19–22)

A mixture of 2,3,5,6-di-*O*-isopropylidene-1,4-anhydro-1-thio-D-talitol (**7**), 2,3,4,6-di-*O*-isopropylidene-1,5-anhydro-1-thio-L-gulitol (**9**), 2,3,5,6-di-*O*-isopropylidene-1,4-anhydro-1-seleno-D-talitol (**8**), or 2,3,4,6-di-*O*-isopropylidene-1,5-anhydro-1-seleno-L-gulitol (**10**) and cyclic sulfate **11** in HFIP were placed in a reaction vessel and K_2CO_3 (20 mg) was added. The stirred reaction mixture was heated in a sealed tube at the indicated temperature for the indicated time, as given in the following. The progress of the reaction

© 2006 NRC Canada

was followed by TLC analysis of the aliquots (developing solvent, EtOAc–MeOH, 10:1). When the limiting reagent had been essentially consumed, the mixture was cooled, then diluted with CH_2Cl_2 and evaporated to give a syrupy residue. Purification by column chromatography (EtOAc to EtOAc–MeOH, 10:1) gave the purified and sulfonium salts **19** and **21** and selenonium salts **20** and **22**.

*1,4-Anhydro-2,3,5,6-di-*O*-isopropylidene-1-[(S)-[(2′R,3′S,4′R,5′R)-2′,4′-benzylidenedioxy-5′,6′-isopropylidenedioxy-3′-(sulfooxy)hexyl]sulfonio]-D-talitol inner salt (19)*

Reaction of compound **7** (400 mg, 1.53 mmol) with **11** (740 mg, 1.99 mmol) in HFIP (2.0 mL) for 12 h at 70–75 °C gave compound **19** as a colorless, amorphous solid (820 mg, 85% based on **7**). $[\alpha]^{22}_D$ –40° (*c* 0.5, CH_2Cl_2). ^{1}H NMR (CD_2Cl_2) δ: 7.48–7.30 (5H, m, Ar), 5.68 (1H, s, C*H*Ph), 5.15 (1H, ddd, $J_{2,3}$ = 5.6, $J_{1a,2}$ = 1.9, $J_{1b,2}$ = 5.6, H-2), 4.98 (1H, dd, H-3), 4.55–4.51 (2H, m, H-4, H-2′), 4.46 (1H, ddd, $J_{4,5}$ = 4.1, $J_{5,6\ a}$ = 6.3, $J_{5,6b}$ = 6.3, H-5), 4.40 (1H, dd, $J_{1a,1b}$ = 13.4, $J_{1b,2}$ = 5.6, H-1b), 4.18 (2H, dd, H-6a, H-6b), 4.16–4.04 (4H, m, H-1a, H-3′, H-4′, H-5), 3.76 (2H, dd, H-1a, H-1b), 3.35 (1H, dd, $J_{6a,6b}$ = 9.5, $J_{5,6b}$ = 7.6, H-6b), 3.16 (1H, dd, $J_{5,6a}$ = 6.4, H-6a), 1.52, 1.33, 1.31, 1.28, 1.26, and 1.16 (18H, 6 s, 6C*H*$_3$). ^{13}C NMR (CD_2Cl_2) δ: 137.28, 129.65, 128.63, 126.37 (4C_{Ar}), 112.85, 111.37, 108.64 (three $(CH_3)_2C(OR)_2$), 100.87 (*C*HPh), 89.77 (C-3), 84.24 (C-2), 79.32 (C-3′), 75.48 (C-5′), 75.33 (C-5), 74.36 (C-4), 70.47 (C-2′), 67.92 (C-4′), 67.05 (C-6), 65.18 (C-6′), 50.12 (C-1), 44.42 (C-1′) 26.56, 26.15, 25.62, 25.57, 25.03, 22.86 (6*C*H$_3$). Anal. calcd. for $C_{28}H_{40}O_{12}S_2$: C 53.15, H 6.37; found: C 52.92, H 6.17.

*1,4-Anhydro-2,3,5,6-di-*O*-isopropylidene-1-[(S)-[(2′R,3′S,4′R,5′R)-2′,4′-benzylidenedioxy-5′,6′-isopropylidenedioxy-3′-(sulfooxy)hexyl]selenonio]-D-talitol inner salt (20)*

Reaction of compound **8** (500 mg, 1.63 mmol) with **11** (780 mg, 2.09 mmol) in HFIP (2.0 mL) for 12 h at 60–65 °C gave compound **20** and a minor product (<10%) as a colorless, amorphous solid (810 mg, 73% based on **8**). The major product (**20**): $[\alpha]^{22}_D$ –46° (*c* 0.5, CH_2Cl_2). ^{1}H NMR ($(CD_3)_2O$) δ: 7.62–7.38 (5H, m, Ar), 5.92 (1H, s, C*H*Ph), 5.47 (1H, ddd, $J_{2,3}$ = 5.6, $J_{1a,2}$ = 1.3, $J_{1b,2}$ = 5.9, H-2), 5.35 (1H, dd, H-3), 4.92 (1H, ddd, H-2′), 4.60 (1H, dd, $J_{1'b,2'}$ = 6.4, $J_{1'a,1'b}$ = 12.3, H-1′b), 4.57 (1H, m, H-4), 4.55 (1H, ddd, $J_{5,6b}$ = 6.9, $J_{5,6a}$ = 6.6, $J_{4,5}$ = 1.5, H-5), 4.48 (1H, ddd, $J_{5',6'b}$ = 6.7, $J_{5',6'a}$ = 7.4, $J_{4',5'}$ = 2.5, H-5′), 4.42–4.34 (3H, m, H-3′, H-6′b, H-4), 4.24 (1H, dd, $J_{6'a,6'b}$ = 8.1, H-6′a), 4.09 (1H, dd, $J_{1'a,2'}$ = 1.5, H-1′a), 3.89 (1H, dd, $J_{1a,1b}$ = 14.1, H-1b), 3.84 (1H, dd, H-1a), 3.70 (1H, dd, $J_{6a,6b}$ = 9.4, H-6b), 3.34 (1H, dd, H-6a),1.59, 1.38, 1.35, 1.30, 1.29, and 1.24 (18H, 6 s, 6C*H*$_3$). ^{13}C NMR ($(CD_3)_2O$) δ: 138.21, 129.24, 128.42, 126.48 (4C_{Ar}), 111.32, 107.67, 100.47 ($3(CH_3)_2C(OR)_2$), 100.41 (*C*HPh), 91.54 (C-3), 85.82 (C-2), 78.92 (C-3′), 76.67 (C-5), 75.54 (C-5), 74.18 (C-2), 70.82 (C-4′), 67.97 (C-6), 67.45 (C-4), 64.74 (C-6′), 46.24 (C-1), 41.78 (C-1) 26.02, 25.85, 25.67, 25.44, 24.02, 22.75 (6*C*H$_3$). General procedure for the deprotection of the coupling products to yield the final compounds (3–6)

The protected coupling products **19–22** were dissolved in CH_2Cl_2 (2 mL), TFA (10 mL) was then added, and the mixture was stirred for 6–8 h at room temperature. The progress of the reaction was followed by TLC analysis of the aliquots (developing solvent, EtOAc–MeOH–H_2O, 7:3:1). When the

© 2006 NRC Canada

starting material had been consumed, the TFA and CH_2Cl_2 were removed under reduced pressure. The residue was rinsed with CH_2Cl_2 (4 × 2 mL) and the CH_2Cl_2 was decanted to remove the cleaved protecting groups. The remaining gum was dissolved in MeOH and purified by column chromatography (EtOAc and EtOAc–MeOH, 2:1) to give the purified compounds **3**–**6** as colorless, amorphous, and hygroscopic solids.

1,4-Anhydro-1-[(S)-[(2′R,3′S,4′R,5′R)-2′,4′,5′,6′-tetrahydroxy-3′-(sulfooxy)hexyl]sulfonio]-D-talitol inner salt (3)

To a solution of **19** (400 mg, 0.63 mmol) in CH_2Cl_2 (2 mL) was added TFA (10 mL) to yield compound **3** as a colorless, amorphous, and hygroscopic solid (150 mg, 59%). $[\alpha]^{22}_D$ –29° (*c* 0.1, H_2O). ^{1}H NMR (D_2O) δ: 4.60 (1H, m, H-2), 4.56 (1H, dd, $J_{3',4'}$ = 1.1, $J_{2',3'}$ = 5.0, H-3′), 4.50 (1H, ddd, $J_{1'b,2'}$ = 10.5, $J_{1'a,2'}$ = 2.8, H-2′), 4.32 (1H, dd, $J_{2,3}$ = 9.6, $J_{3,4}$ = 2.8, H-3), 4.17 (1H, ddd, H-5), 4.00 (1H, dd, $J_{1'a,1'b}$ = 13.2, H-1′b), 3.92 (1H, dd, $J_{4,5}$ = 9.5, H-4), 3.91 (1H, dd, H-1′a), 3.80 (1H, dd, $J_{4',5'}$ = 9.0, H-4′), 3.78 (1H, dd, $J_{6a,6b}$ = 12.2, $J_{5,6b}$ = 3.5, H-6b), 3.73 (1H, dd, $J_{5',6'b}$ = 2.7, $J_{6'a,6'b}$ = 11.8, H-6′b), 3.69 (1H, ddd, $J_{5',6'a}$ = 6.1, H-5′), 3.66 (1H, dd, $J_{5,6a}$ = 4.1, H-6a), 3.56 (1H, dd, $J_{1b,2}$ = 7.6, $J_{1a,1b}$ = 11.4, H-1b), 3.55 (1H, dd, $J_{1a,2}$ = 5.8, H-1a), 3.54 (1H, m, H-6′a). ^{13}C NMR (D_2O) δ: 77.81 (C-3′), 76.26 (C-3), 72.93 (C-2), 70.52 (C-5′), 68.98 (C-4′), 67.91 (C-2′), 67.55 (C-5), 64.62 (C-6), 64.53 (C-4), 62.85 (C-6′), 49.41 (C-1′), 44.57 (C-1). Synthesis of the tetrasaccharide repeat unit of the O-antigen polysaccharide from *Escherichia coli* O77 employing the 2′-carboxybenzyl glycoside[1]

Bo Ram Lee, Joo Mi Jeon, Jae Hyuk Jung, Heung Bae Jeon, and Kwan Soo Kim

Abstract: The synthesis of the suitably protected form (**1**) of the tetrasaccharide repeat unit, →2)-α-D-Man*p*-(1→2)-β-D-Man*p*-(1→3)-α-D-Glc*p*NAc-(1→6)-α-D-Man*p*-(1→ (**A**), of the O-antigen polysaccharide of the lipopolysaccharide from *Escherichia coli* O77 has been accomplished by latent–active glycosylation employing the 2′-carboxybenzyl (CB) glycoside method. In addition to previously used latent glycosyl donors, 2′-(benzyloxycarbonyl)benzyl (BCB) glycosides, new latent glycosyl donors, 2′-(allyloxycarbonyl)benzyl (ACB) glycosides, have been introduced as a direct precursor for the active CB glycosides. We also demonstrate that 4,6-*O*-benzylidene-2-azido-2-deoxy-α-D-mannopyranoside (**7**) has been readily prepared from D-glucosamine in good yield.

Key words: Escherichia coli O77, glycosylation, 2′-carboxybenzyl (CB) glycosides, 2′-(allyloxycarbonyl)benzyl (ACB) glycosides, glycosyl donor.

Résumé : Faisant appel à une glycosilation latente active à l'aide de la méthode du glycoside de 2′-carboxybenzyle (CB), on a réalisé la synthèse de la forme adéquatement protégée du composé **1**, le tétrasaccharide →2)-α-D-Man*p*-(1→2)-β-D-Man*p*-(1→3)-α-D-Glc*p*NAc-(1→6)-α-D-Man*p*(1→ (**A**) qui est le motif constitutif du polysaccharide O-antigène du lipopolysaccharide du *Escherichia coli* O77. En plus des donneurs latents de glycosyle utilisés antérieurement, les glycosides de 2′-benzyloxycarbonyl)benzyle (BCB), on a introduit de nouveaux donneurs latents de glycosyle, les glycosides de 2′-(allylcarbonyl)benzyle (ACB), comme précurseurs directs de glycosides de CB actifs. On a aussi préparé facilement le 4,6-*O*-benzylidène-2-azido-2-désoxy-α-D-mannopyranoside (**7**) à partir de la D-glucosamine avec un bon rendement.

Mots clés : Escherichia coli O77, glycosylation, glycoside de 2′-carboxybenzle (CB), glycosides de 2′-(allyloxycarbonyl)benzyle (ACB), donneur de glycosyle.

[Traduit par la Rédaction]

Introduction

Escherichia coli is a facultative anaerobic Gram-negative rod and is a predominant specie of the human colonic flora. Normal nonpathogenic strains of *E. coli* usually remain harmlessly confined to the intestinal lumen. However, infections owing to inherently pathogenic *E. coli* strains result in clinical syndromes such as urinary tract infections, sepsis/meningitis, and enteric/diarrheal disease. The species is subdivided into different serotypes based on the immunogenicity of bacterial surface structures (1, 2). *E. coli* O77, which belongs to an O-serotype, causes diarrheal infections (3) and has been identified as producing a Shiga-like toxin in both humans and animals (4–7). Recently, Widmalm and coworkers (8) have reported that the lipopolysaccharide (LPS) from the *E. coli* O77 contains the O-antigen polysaccharide as its substructure. As shown in Fig. 1, this particular polysaccharide is composed of a series of the repeat unit of a tetrasaccharide with the following structure: →2)-α-D-Man*p*-(1→2)-β-D-Man*p*-(1→3)-α-D-Glc*p*NAc-(1→6)-α-D-Man*p*-(1→ (**A**).

One of the challenges in the synthesis of this tetrasaccharide repeat unit would be the elaboration of the β-mannopyranosyl linkage. Although several strategies for the β-mannopyranosylation have been developed (9), including Crich and co-workers' recent approach (10) employing 4,6-*O*-benzylidene-protected glycosyl sulfoxides or thioglycosides as glycosyl donors, the construction of β-mannopyranosyl linkages still poses a great challenge. Recently, we have developed an efficient glycosylation method that em-

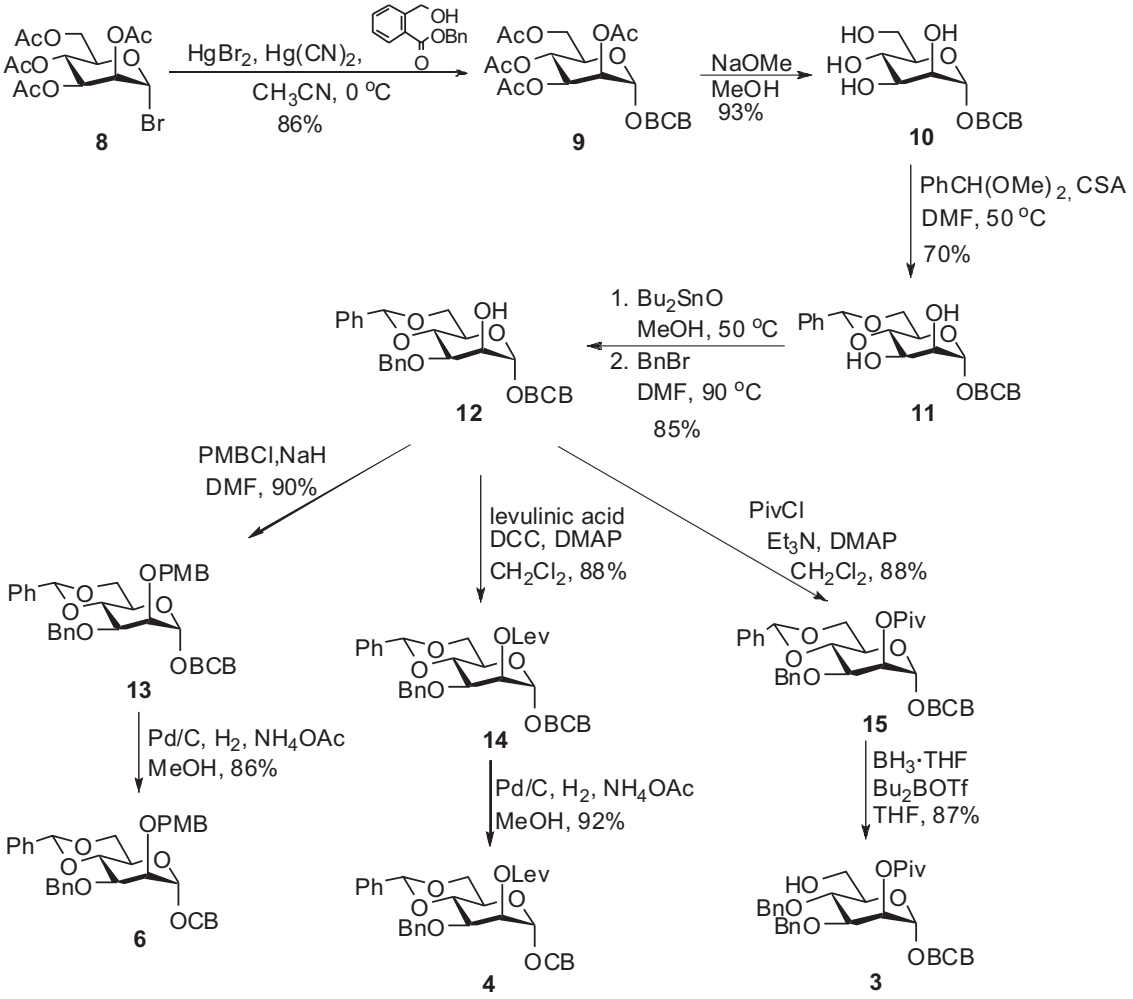
A



ploys a new type of glycosyl donor, 2′-carboxybenzyl (CB) glycoside. This methodology has been employed in the stereoselective β-mannopyranosylation and 2-deoxyglycosylation of various glycosyl acceptors (11–14). As an ongoing effort to explore the application and to understand the limitation of the CB-glycoside-mediated glycosylation, we disclose the synthesis of the protected tetrasaccharide **1**, which represents the elemental subunit of the O-antigen polysaccharide of the LPS from *E. coli* O77.

Results and discussion

The protective groups were carefully chosen in synthesizing the target tetrasaccharide **1**, since it was of importance to realize the selective deprotection during the future synthesis of an octasaccharide or a dodecasaccharide from **1** by dimerization or trimerization, respectively. Thus, the latent 2′-(benzyloxycarbonyl)benzyl (BCB) group at C-1 in the reducing end of the tetrasaccharide **1** would be readily converted into the active CB group to give a tetrasaccharide donor. The levulinyl (Lev) group at the C-2 in the nonreducing end of **1** would be selectively cleaved to provide a tetrasaccharide acceptor.

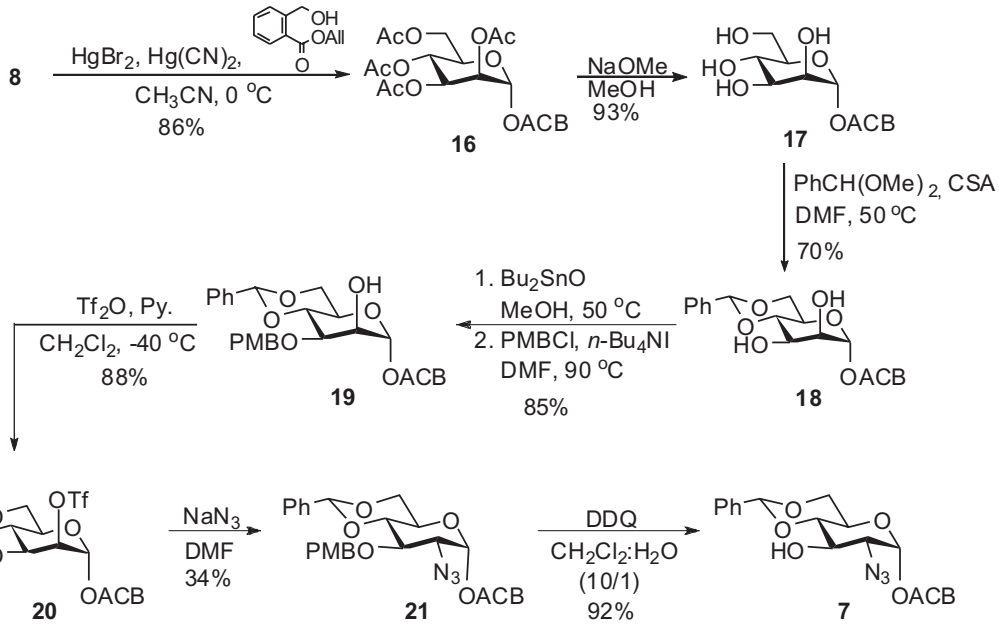
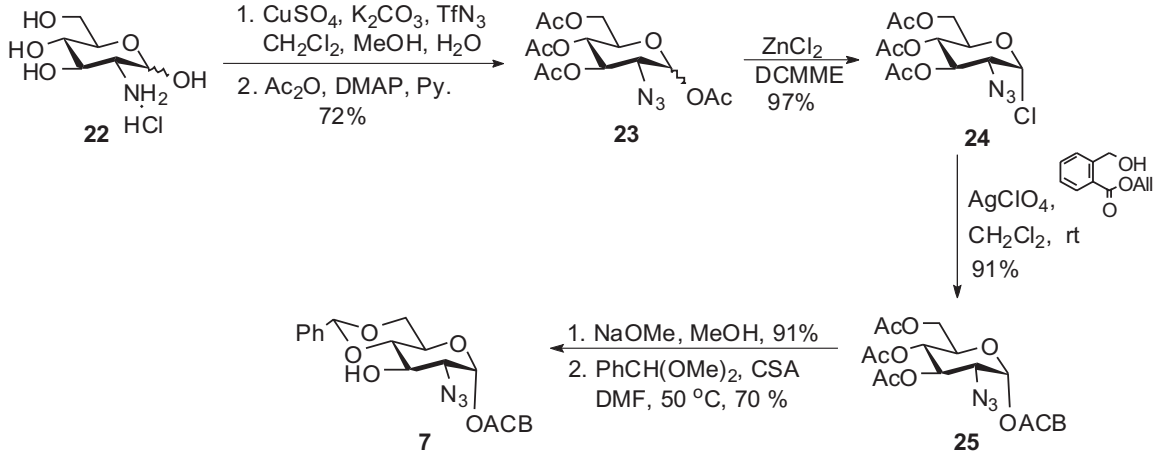
Scheme 2. Synthesis of monosaccharide building blocks **3**, **4**, and **6**.



Retrosynthesis of **1** leads to trisaccharide donor **2** and pivaloyl (Piv)-protected mannosyl acceptor **3**, then further analysis of **2** provides levulinyl-protected mannosyl donor **4** and 2′-(allyloxycarbonyl)benzyl (ACB) glycoside **5** as an acceptor (Scheme 1). The acceptor **5** can be derived from *p*-methoxybenzyl(PMB)-protected mannosyl donor **6** and 2-azido-2-deoxy-glucospyranosyl acceptor **7**.

The monosaccharide building blocks **3**, **4**, and **6** were synthesized from a common intermediate **12**, which was prepared by the dibutyltinoxide-mediated selective benzylation of diol **11** (Scheme 2) (14). Diol **11** was efficiently prepared from tetraacetylmannosyl bromide (**8**) by the following sequence: (*i*) coupling of **8** and crystalline benzyl 2-(hydroxymethyl)benzoate, which was readily obtained in large quantities from inexpensive phthalide, in the presence of $HgBr_2$ and $Hg(CN)_2$ in acetonitrile; (*ii*) deacetylation of the resulting tetraacetylmannoside **9** under basic conditions; and (*iii*) subsequent benzylidenation of the resulting tetrol **10** (11). *P*-Methoxybenzylation of **12** followed by selective hydrogenolysis of the resulting BCB glycoside **13** in the presence of NH_4OAc gave the desired CB glycoside **6**. Pivaloylation of **12** and subsequent reductive cleavage of the resultant benzylidene acetal **15** with borane – dibutylboron triflate (15) provided C-6 alcohol **3**. Protection of **12** with levulinic acid in the presence of dicyclohexylcarbodiimide (DCC) and 4-(*N*,*N*-dimethylamino)pyridine (DMAP) followed by hydrogenolysis of the resulting levulinyl BCB glycoside **14** in the presence of NH_4OAc afforded the CB glycoside **4**.



For the synthesis of the azidomonosaccharide building block **7**, **8** was used as a starting material (Scheme 3). The ACB mannoside **16** was prepared by coupling of **8** and allyl 2-(hydroxymethyl)benzoate in the presence of $HgBr_2$ and $Hg(CN)_2$. Introduction of the new ACB group in the place of the previously used BCB group was necessary because the azide functionality at C-2 was also reduced during the conversion of the BCB group into the CB group under the hydrogenolysis conditions. Deacetylation of **16** by NaOMe followed by benzylidenation of the resulting tetrol **17** afforded 4,6-*O*-benzylidene-protected ACB mannoside **18**. The hydroxy group at C-3 of diol **18** was selectively protected with the *p*-methoxybenzyl (PMB) group by using the dibutyltin oxide method to give PMB-protected alcohol **19**. Then, compound **19** was treated with triflic anhydride in the presence of pyridine to afford triflate **20**. Treating **20** with sodium azide in DMF gave the desired 2-azido-2-deoxy-glucospyranoside **21** in only 34% yield. The major by-product was the C-2,3 alkene, which was presumably to be

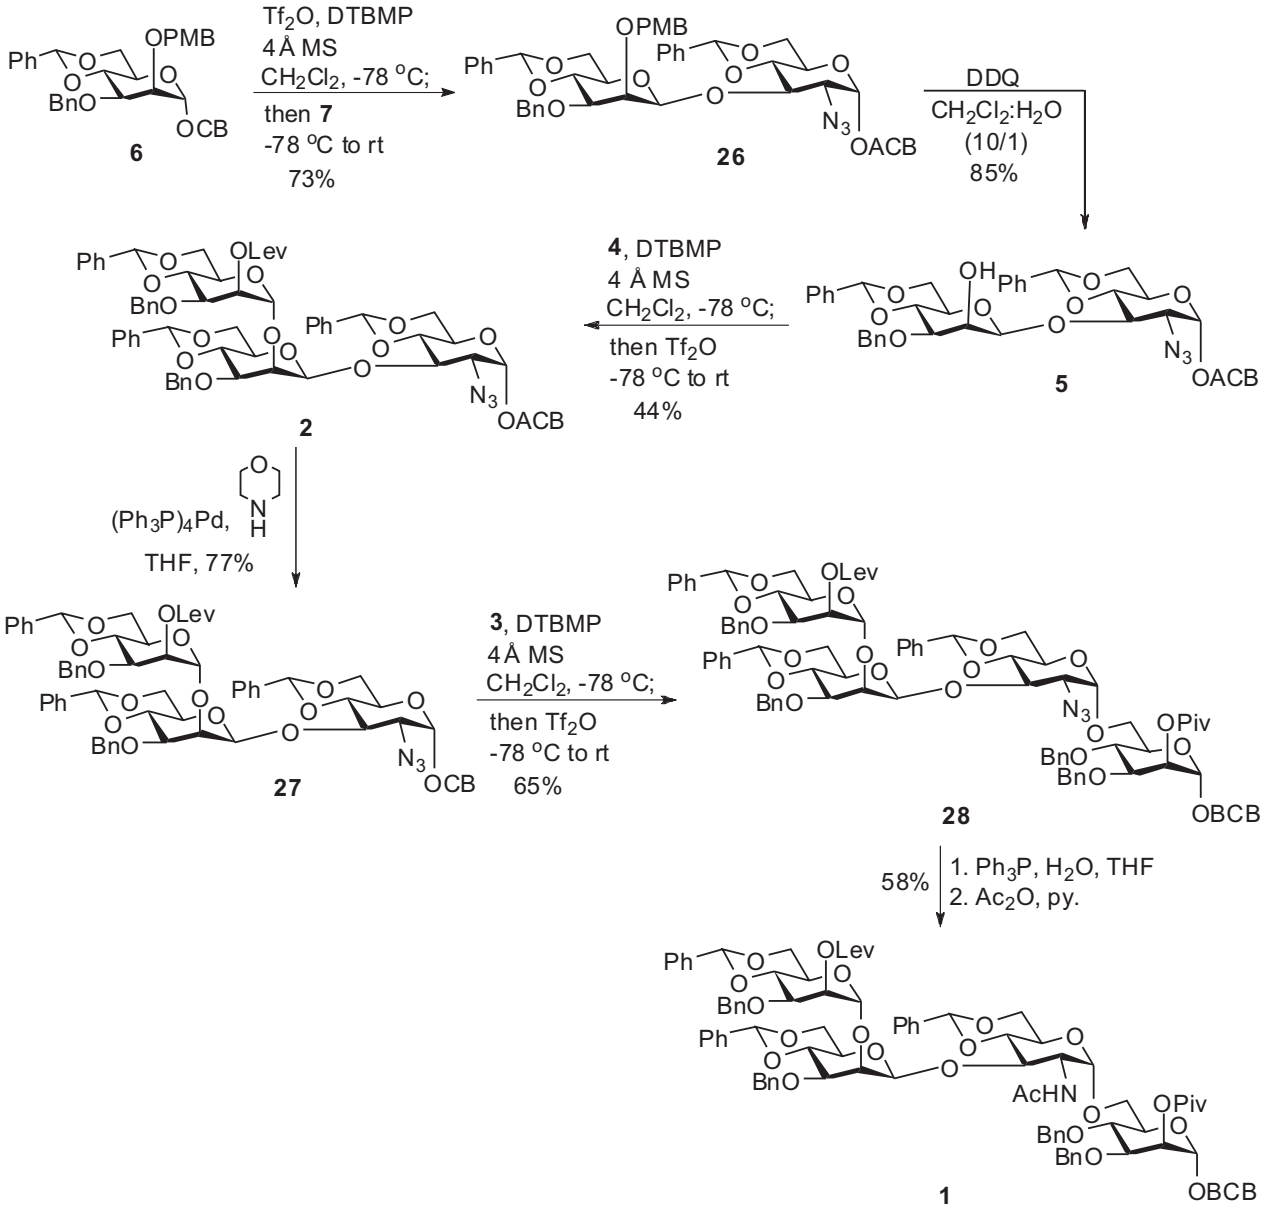
Scheme 3. Synthesis of monosaccharide building block **7** from **8**.

Scheme 4. Synthesis of monosaccharide building block **7** from glucosamine **22**.



formed via the E_2 mechanism. To favor the nucleophilic substitution, a number of different reaction conditions were attempted. Unfortunately, there was no improvement.

A different route to compound **7** was realized using D-glucosamine hydrochloride (**22**) as a starting material (Scheme 4). Treating **22** with triflyl azide (TfN_3) in the presence of a catalytic amount of $CuSO_4$ in a cosolvent of CH_2Cl_2, MeOH, and H_2O to make a homogenous solution followed by acetylation provided tetraacetyl 2-azido-2-deoxyglucopyranoside (**23**) in 72% yield (16). Compound **23** was smoothly transformed into glucopyranosyl chloride **24** by using dichloromethyl methyl ether (DCMME) in the presence of a catalytic amount of zinc chloride (17). Reaction of **24** with allyl 2-(hydroxymethyl)benzoate using $AgClO_4$ as a promoter afforded α-ACB glycoside **25** as a single isomer in 91% yield, while the same reaction using AgOTf as a promoter gave **25** in 86% yield as a mixture of α and β anomers in a ratio of 4:1. Deacetylation of **25** with NaOMe followed by benzylidenation with benzaldehyde dimethyl acetal afforded the C-3 alcohol **7**.

The stage was set for the assembly of the properly protected monosaccharide building blocks **3**, **4**, **6**, and **7** to make tetrasaccharide **1**. The crucial stereoselective β-mannopyranosylation was achieved by activation of the glycosyl donor **6** with Tf_2O in the presence of 2,6-di-*tert*-butyl-4-methylpyridine (DTBMP) and 4 Å molecular sieves in CH_2Cl_2, followed by the addition of the acceptor **7** at –78 °C. The desired β-mannopyranosyl disaccharide **26** was obtained in 59% yield along with α-disaccharide as a by-product in 14% yield, as shown in Scheme 5. It was essential to activate the donor **6** with Tf_2O in the presence of DTBMP before the addition of the acceptor **7** to maximize the yield of **26**. The stereochemistry at the newly generated anomeric center of the disaccharide **26** was determined on the basis of its ^1H and ^{13}C NMR spectral data, especially the chemical shift in the ^{13}C NMR: δ 101.6 ppm for the β-

© 2006 NRC Canada

Scheme 5. Completion of the synthesis of tetrasaccharide **1**.

disaccharide in comparison with δ 100.1 ppm for the α-disaccharide. Removal of the PMB group in **26** with DDQ and the subsequent glycosylation of the resulting monohydroxy disaccharide acceptor **5** with the CB glycosyl donor **4** provided the desired α-trisaccharide **2** in 44% yield and the β-trisaccharide in 21% yield. Then, the ACB trisaccharide **2** was readily converted into the active CB trisaccharide **27** in 77% yield by deallylation with a catalytic amount of $Pd(Ph_3P)_4$ in the presence of morpholine (18). This result indicated that ACB glycosides were a useful precursor for CB glycosides, especially in the presence of the azide functionality, which could not survive during the conversion of the BCB glycosides into CB glycosides by hydrogenolysis. Finally, the coupling of the CB trisaccharide donor **27** and the BCB monosaccharide acceptor **3** in the presence of Tf_2O and DTBMP afforded α-tetrasaccharide **28** as a single isomer in 65% yield. Reduction of the azido group by treatment of **28** with triphenylphosphine (19), followed by acetylation of the resulting amine, furnished the desired target tetrasaccharide **1** in 58% yield.

Conclusion

We have described the synthesis of the suitably protected tetrasaccharide repeat unit **1** of the O-antigen polysaccharide of the LPS from *E. coli* O77. The 2′-carboxybenzyl (CB) glycoside method proved to be effective in the coupling of four monosaccharide components of the tetrasaccharide, **3**, **4**, **6**, and **7**. The newly introduced ACB glycoside was readily converted into the active CB glycosyl donors without affecting the azide functionality. Additionally, 4,6-*O*-benzylidene-2-azido-2-deoxy-α-D-mannopyranoside (**7**) was readily prepared from D-glucosamine hydrochloride in good yield.

Experimental

The known compounds **9** (11), **10** (11), **11** (11), **23** (16), and **24** (17) were prepared according to the procedures reported previously.

BCB 3-*O*-benzyl-4,6-*O*-benzylidene-α-D-mannopyranoside (12)

A solution of BCB 4,6-*O*-benzylidene-α-D-mannopyranoside (**11**) (450 mg, 0.9 mmol) and Bu_2SnO (228 mg, 0.9 mmol) in MeOH (40 mL) was stirred at 50 °C for 1 h. After removal of the solvent in vacuo, the residue was dissolved in DMF (10 mL) and then BnBr (0.19 mL, 1.6 mmol) was added to the reaction mixture. After stirring at 90 °C for 3 h, the reaction mixture was quenched with H_2O and then extracted with EtOAc. The combined organic layer was washed with satd. aq. NH_4Cl and brine, dried over $MgSO_4$, and concentrated in vacuo. The residue was purified by flash column chromatography (hexane–EtOAc, 2:1) to afford compound **12** (506 mg, 85%) as a colorless oil. R_f 0.36 (hexane–EtOAc, 2:1, *v*/*v*). $[\alpha]^{20}_D$ +42.9° (*c* 6.75, $CHCl_3$). IR ($CHCl_3$, film, cm^{-1}): 3447, 2921, 1637, 1460, 1381, 1098, 979. ^1H NMR (250 MHz, $CDCl_3$) δ: 2.79 (s, 1H), 3.83–3.89 (m, 2H), 3.97 (dd, *J* = 3.5, 9.5 Hz, 1H), 4.07–4.19 (m, 2H), 4.26 (dd, *J* = 2.7, 8.0 Hz, 1H), 4.71 (d, *J* = 11.7 Hz, 1H), 4.87 (d, *J* = 11.7 Hz, 1H), 4.93 (d, *J* = 14.0 Hz, 1H), 4.96 (s, 1H), 5.11 (d, *J* = 14.0 Hz, 1H), 5.31 (s, 2H), 5.61 (s, 1H) 7.25–7.54 (m, 18H), 8.00 (d, *J* = 7.5 Hz, 1H). ^{13}C NMR (63 MHz, $CDCl_3$) δ: 63.7, 66.9, 67.6, 68.9, 70.1, 73.2, 75.9, 79.0, 99.9, 101.6, 125.9, 127.3, 127.8, 127.8, 128.0, 128.1, 128.2, 128.3, 128.5, 128.7, 130.6, 132.5, 135.9, 137.7, 138.1, 139.5, 166.7.

BCB 3-*O*-benzyl-4,6-*O*-benzylidene-2-*O*-*p*-methoxybenzyl-α-D-mannopyranoside (13)

A solution of **12** (622 mg, 1.07 mmol), PMBCl (0.24 mL, 1.39 mmol), and NaH (51 mg, 2.14 mmol) in DMF (4 mL) was stirred at 0 °C for 10 min and at room temperature (rt) for 1 h. The reaction mixture was quenched with H_2O and then extracted with EtOAc. The combined organic layer was washed with satd. aq. NH_4Cl and brine, dried over $MgSO_4$, and concentrated in vacuo. The residue was purified by flash column chromatography (hexane–EtOAc, 2:1) to afford compound **13** (675 mg, 90%) as a colorless oil. R_f 0.47 (hexane–EtOAc, 2:1, *v*/*v*). $[\alpha]^{20}_D$ +52.9° (*c* 1.3, $CHCl_3$). IR ($CHCl_3$, film, cm^{-1}): 3420, 2920, 1720, 1624, 1430, 1381, 1088, 1021, 979. ^1H NMR (250 MHz, $CDCl_3$) δ: 3.78 (s, 3H), 3.79–3.91 (m, 3H), 4.02 (dd, *J* = 3.2, 10.0 Hz, 1H), 4.20–4.30 (m, 2H), 4.65 and 4.86 (ABq, *J* = 12.0 Hz, 2H), 4.67 and 4.74 (ABq, *J* = 12.0 Hz, 2H), 4.88 and 5.05 (ABq, *J* = 14.0 Hz, 2H), 4.89 (d, *J* = 1.2 Hz, 1H), 5.21 (s, 2H), 5.64 (s, 1H), 6.82–6.90 (m, 2H), 7.24–7.51 (m, 21H), 7.95 (d, *J* = 7.5 Hz, 1H). ^{13}C NMR (63 MHz, $CDCl_3$) δ: 55.3, 55.4, 64.6, 66.7, 67.4, 68.9, 73.1, 73.3, 75.8, 76.5, 79.3, 99.3, 101.5, 113.9, 114.1, 126.1, 127.3, 127.6, 127.7, 128.0, 128.2, 128.4, 128.8, 129.8, 130.2, 130.8, 132.4, 137.8, 139.6, 159.4, 159.8, 166.8. Anal. calcd. for $C_{43}H_{42}O_9$: C 73.49, H 6.02; found: C 73.47, H 6.03.

CB 3-*O*-benzyl-4,6-*O*-benzylidene-2-*O*-*p*-methoxybenzyl-α-D-mannopyranoside (6)

After compound **13** (416 mg, 0.59 mmol) was stirred under a hydrogen atmosphere using a balloon in the presence of Pd/C (10%, 63 mg) and ammonium acetate (46 mg, 0.59 mmol) in MeOH (10 mL) at rt for 1 h, the reaction mixture was filtered through Celite and the filtrate was concentrated in vacuo. The residue was purified by flash column chromatography (hexane–EtOAc, 1:1) to afford compound **6** (330 mg, 91%) as a white solid; mp 81 to 82. R_f 0.12 (hexane–EtOAc, 2:1, *v*/*v*). $[\alpha]^{20}_D$ +53.7° (*c* 1.3, $CHCl_3$). IR ($CHCl_3$, film, cm^{-1}): 2920, 1720, 1624, 1454, 1460, 1430, 1381, 1088, 1021, 979. ^1H NMR (250 MHz, $CDCl_3$) δ: 3.77 (s, 3H), 3.84–3.93 (m, 3H), 4.04 (dd, *J* = 3.2, 10.0 Hz, 1H), 4.25–4.32 (m, 2H), 4.65 and 4.86 (ABq, *J* = 12.0 Hz, 2H), 4.67 and 4.74 (ABq, *J* = 12.0 Hz, 2H), 4.88 and 5.05 (ABq, *J* = 14.0 Hz, 2H), 4.89 (d, *J* = 1.2 Hz, 1H), 5.64 (s, 1H) 6.84 (d, *J* = 8.5 Hz, 2H), 7.14–7.55 (m, 36H), 8.00 (d, *J* = 7.5 Hz, 1H). ^{13}C NMR (63 MHz, $CDCl_3$) δ: 55.3, 64.6, 66.9, 67.8, 71.6, 72.2, 74.2 78.5, 78.8, 100.0, 101.4, 101.7, 126.1, 126.2, 127.4, 127.6, 127.7, 128.2, 128.4, 128.5, 128.7, 128.9, 130.4, 130.6, 130.8, 132.6, 137.6, 138.4, 138.9, 139.5, 159.2, 171.9. Anal. calcd. for $C_{36}H_{36}O_9$: C 70.57, H 5.92; found: C 70.52, H 5.92.

BCB 3-*O*-benzyl-4,6-*O*-benzylidene-2-*O*-levulinyl-α-D-mannopyranoside (14)

After a solution of **12** (360 mg, 0.62 mmol), levulinic acid (107 mg, 0.93 mmol), DMAP (75 mg, 0.62 mmol), and DCC (191 mg, 0.93 mmol) in CH_2Cl_2 (10 mL) was stirred at rt for 1 h, the reaction mixture was filtered and the filtered solid was washed with further CH_2Cl_2. The filtrate was washed with satd. aq. $NaHCO_3$ and brine, dried over $MgSO_4$, and concentrated in vacuo. The residue was purified by flash column chromatography (hexane–EtOAc, 3:1) to afford compound **14** (371 mg, 88%) as a white solid. R_f 0.25 (hexane–EtOAc, 2:1, *v*/*v*). $[\alpha]^{20}_D$ +51.3° (*c* 1.5, $CHCl_3$). IR ($CHCl_3$, film, cm^{-1}): 3027, 2925, 2854, 1754, 713, 1617, 1499, 1372, 1275, 1036, 924, 751, 700. ^1H NMR (250 MHz, $CDCl_3$) δ: 2.16 (s, 3H), 2.65–2.80 (m, 4H), 3.78–3.94 (m, 2H), 4.02–4.12 (m, 2H), 4.24 (dd, *J* = 3.5, 9.0 Hz, 1H), 4.65 (s, 2H), 4.95 and 5.17 (ABq, *J* = 12.0 Hz, 2H), 4.93 (d, *J* = 1.5 Hz, 1H), 5.32 (s, 2H), 5.47 (br s, 1H), 5.63 (s, 1H), 7.23–7.53 (m, 18H), 8.02 (d, *J* = 7.7 Hz, 1H). ^{13}C NMR (63 MHz, $CDCl_3$) δ: 28.2, 29.9, 35.0, 38.1, 64.2, 66.9, 67.8, 68.9, 70.0, 72.3, 74.1, 78.5, 98.8, 101.7, 126.2, 127.6, 127.7, 127.9, 128.2, 128.3, 128.5, 129.0, 130.9, 132.7, 135.9, 137.6, 138.1, 139.4, 166.7, 172.1, 206.3. Anal. calcd. for $C_{40}H_{40}O_{10}$: C 70.57, H 5.92; found: C 70.58, H 5.93.

CB 3-*O*-benzyl-4,6-*O*-benzylidene-2-*O*-levulinyl-α-D-mannopyranoside (4)

Compound **14** was subjected to the same reaction conditions as that for the preparation of **6** from **13** to give the title compound **4** (92%) as a white solid. R_f 0.05 (hexane–EtOAc, 2:1, *v*/*v*). $[\alpha]^{20}_D$ +61.6° (*c* 3.7, $CHCl_3$). IR ($CHCl_3$, film, cm^{-1}): 3027, 2920, 1718, 1693, 1454, 1377, 1224, 1097, 914, 756, 695. ^1H NMR (250 MHz, $CDCl_3$) δ: 2.16 (s, 3H), 2.65–2.82 (m, 4H), 3.80–3.97 (m, 2H), 4.09 (dd, *J* = 1.2, 5.0 Hz, 1H), 4.26 (dd, *J* = 3.5, 9.0 Hz, 1H), 4.67 and 4.72 (ABq, *J* = 12.5 Hz, 2H), 4.95 and 5.16 (ABq, *J* = 12.0 Hz, 2H), 4.98 (d, *J* = 1.5 Hz, 1H), 5.48 (brs, 1H), 5.63 (s, 1H), 7.24–7.61 (m, 13H), 8.08 (d, *J* = 7.7 Hz, 1H). ^{13}C NMR (63 MHz, $CDCl_3$) δ: 28.2, 29.9, 38.1, 64.2, 67.8, 68.8, 70.1, 72.3, 73.9, 78.5, 98.8, 101.6, 126.1, 127.1, 127.5, 127.6, 127.7, 127.9,

ACB 4,6-*O*-benzylidene-2-azido-2-deoxy-α-D-glucopyranoside (7) (from 25)

To a solution of **25** (700 mg, 1.38 mmol) in MeOH (10 mL) was added NaOMe (8 mg, 0.15 mmol) at 0 °C. After stirring at 0 °C for 2 h, the reaction mixture was neutralized with DOWEX-MAC-3 (H^+ mode), filtered through Celite, and concentrated in vacuo. The residue was purified by flash column chromatography ($CHCl_3$–MeOH, 9:1) to afford the trihydroxy intermediate (478 mg, 91%) as a white solid.

The trihydroxy intermediate (300 mg, 0.79 mmol) was dissolved in DMF (5 mL) and then benzaldehyde dimethylacetal (0.14 mL, 0.87 mmol) and camphorsulfonic acid (10 mg, 0.04 mmol) were added to the solution. After stirring at 50 °C for 2 h, the reaction mixture was quenched with satd. aq. $NaHCO_3$ and then extracted with EtOAc. The combined organic layer was washed with satd. aq. NH_4Cl and brine, dried over $MgSO_4$, and concentrated in vacuo. The residue was purified by flash column chromatography (hexane–EtOAc, 3:1) to afford compound **7** (259 mg, 70%) as a colorless oil.

ACB (3-*O*-benzyl-4,6-*O*-benzylidene-2-*O*-*p*-methoxybenzyl-β-D-mannopyranosyl)-(1→3)-4,6-*O*-benzylidene-2-azido-2-deoxy-α-D-glucopyranoside (26)

A solution of donor **6** (55 mg, 0.089 mmol) and DTBMP (44 mg, 0.26 mmol) in CH_2Cl_2 (5 mL) in the presence of 4 Å molecular sieves was stirred for 30 min at rt and cooled to –78 °C, then Tf_2O (18 μL, 0.11 mmol) was added. After the resulting solution was stirred at –78 °C for 10 min, acceptor **7** (50 mg, 0.11 mmol) was added and stirred at –78 °C for 1 h and allowed to warm over 2 h to 0 °C. The reaction mixture was quenched with satd. aq. $NaHCO_3$ and then extracted with CH_2Cl_2. The combined organic layer was washed with satd. aq. $NaHCO_3$ and brine, dried over $MgSO_4$, and concentrated in vacuo. The residue was purified by flash column chromatography (hexane–EtOAc, 3:1) to afford compound **26** (61 mg, 73%, α:β = 1:4) as a colorless oil. R_f 0.20 (hexane–EtOAc, 3:1, *v*/*v*). $[\alpha]^{20}_D$ +37.0° (c 0.1, $CHCl_3$). IR ($CHCl_3$, film, cm^{-1}): 2922, 2855, 2105, 1717, 1513, 1454, 1373, 1251, 1095, 1037, 744, 698. ^{1}H NMR (250 MHz, $CDCl_3$) δ: 3.19 (m, 1H), 3.39 (dd, *J* = 3.7, 9.9 Hz, 1H), 3.57 (dd, *J* = 3.1, 9.8 Hz, 1H), 3.70 (d, *J* = 9.4 Hz, 1H), 3.76–3.82 (m, 2H), 3.77 (s, 3H), 3.86–3.94 (m, 2H), 4.03 (d, *J* = 2.9 Hz, 2H), 4.06–4.30 (m, 4H), 4.56 and 4.71 (ABq, *J* = 12.5 Hz, 2H), 4.75 (s, 1H), 4.80 and 4.90 (ABq, *J* = 11.7 Hz, 2H), 4.80 (t, *J* = 1.3 Hz, 1H), 4.83 (d, *J* = 0.9 Hz, 1H), 5.04 and 5.20 (ABq, *J* = 13.9 Hz, 2H), 5.13 (d, *J* = 3.7 Hz, 1H), 5.28–5.46 (m, 2H), 5.54 (s, 2H), 5.97–6.12 (m, 1H), 6.80 (d, *J* = 8.7 Hz, 2H), 7.28–7.72 (m, 20H), 8.05 (dd, *J* = 1.2, 7.8 Hz, 1H). ^{13}C NMR (63 MHz, $CDCl_3$) δ: 29.9, 55.3, 63.1, 63.3, 65.8, 67.6, 68.2, 68.7, 68.9, 72.5,

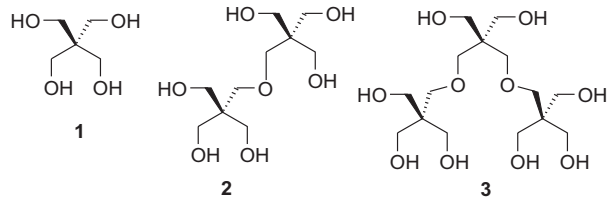
Selective chemistry of tripentaerythritol — Synthesis of acetals and their derivatives[1]

Hussein Al-Mughaid and T. Bruce Grindley

Abstract: Tripentaerythritol was converted efficiently into 2′,2″:6′,6″:10′,10″-tri-*O*-cyclohexylidene-2,2,6,6,10,10-hexakis(hydroxymethyl)-4,8-dioxa-1,11-undecandiol (**4**) by the toluenesulfonic acid catalysed reaction with cyclohexanone in a mixture of *N*,*N*-dimethylformamide and benzene. Reaction of tripentaerythritol with benzaldehyde under similar conditions gave an easily separated mixture of the four possible stereoisomers. Structures of these stereoisomers were assigned based on ^{1}H and ^{13}C NMR chemical shifts using trends previously observed for the dibenzylidene acetals of dipentaerythritol, whose structures had been established unambiguously by X-ray crystallography. It was found that reduction of the mixture of benzylidene acetals to 2,6,10-tris(benzyloxymethyl)-4,8-dioxa-1,11-undecanediol could be accomplished using triethylsilane with ethylaluminium dichloride as the Lewis acid after a number of commonly used conditions for this transformation failed.

Key words: pentaerythritol, tripentaerythritol, dipentaerythritol, acetals, benzylidene acetals, reduction.



Résumé : La réaction du tripentaérythritol avec la cyclohexanone, en solution dans un mélange de *N*,*N*-diméthylformamide et de benzène et catalysée par l'acide toluènesulfonique, conduit à la formation de 2′,2″:6′,6″:10′,10″-tri-*O*-cyclohexylidène-2,2,6,6,10,10-hexakis(hydroxyméthyl)-4,8-dioxaundécane-1,11-diol (**4**). La réaction du tripentaérythritol avec le benzaldéhyde dans des conditions semblables conduit à un mélange des quatre stéréoisomères possibles qui ont pu être séparés facilement. Les structures de ces stéréoisomères ont été attribuées sur la base de déplacements chimiques dans les spectres RMN du ^{1}H et du ^{13}C et en faisant appel aux tendances observées antérieurement pour les acétals dibenzylidènes du pentaérythritol dont les structures avaient été déterminées sans ambiguïté par diffraction des rayons X. Après avoir essayé en vain de le faire en utilisant un certain nombre de conditions régulièrement à cette fin, on a trouvé qu'il est possible de réaliser la réduction du mélange d'acétals dibenzylidènes en 2,6,10-tris(benzoloxyméthyl)-4,8-dioxaundécane-1,11-diol en utilisant le triéthylsilane en présence de dichlorure d'éthylaluminium utilisé comme acide de Lewis.

Mots clés : pentaérythritol, tripentaérythritol, dipentaérytrhitol, acétals, acétals dibenzylidène, réduction.

[Traduit par la Rédaction]

Introduction

Dendrimers have become the subject of intense interest in the last few years (1–7). One of the molecules that has attracted the most attention as either the central core or a branching point of clusters and dendrimers is pentaerythritol (**1**) (8–20). The chemistry of pentaerythritol has been extensively investigated and there are now methods available to selectively prepare a wide range of derivatives (21–35). Dipentaerythritol (**2**), a commercially available compound with many of the favorable characteristics of pentaerythritol, had been comparatively neglected until we demonstrated that it was possible to make a variety of acetals regioselectively (36). Tripentaerythritol (**3**) also has many of the favourable characteristics of pentaerythritol and its chemistry also has been neglected. The only report of the selective chemistry of **3** deals with methylene acetals (37), derivatives that require vigorous conditions for removal.

Murguía et al. (38) recently used DMF–benzene mixtures to form acetals from diols and polyols that are very insoluble in benzene or toluene, particularly from pentaerythritol, and we have shown that these conditions also work efficiently with dipentaerythritol (36). In this publication, we demonstrate that these conditions also are very effective with

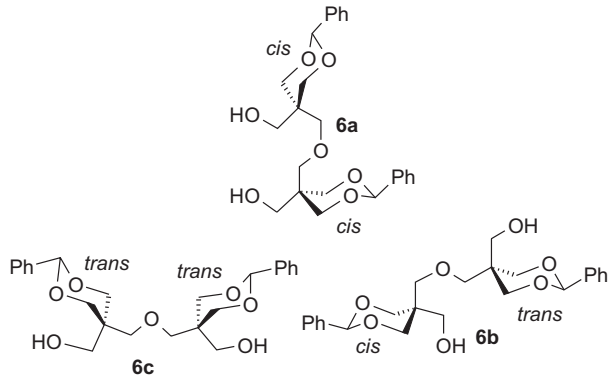
Scheme 1. Formation of the tricyclohexylidene acetal of tripentaerythritol.



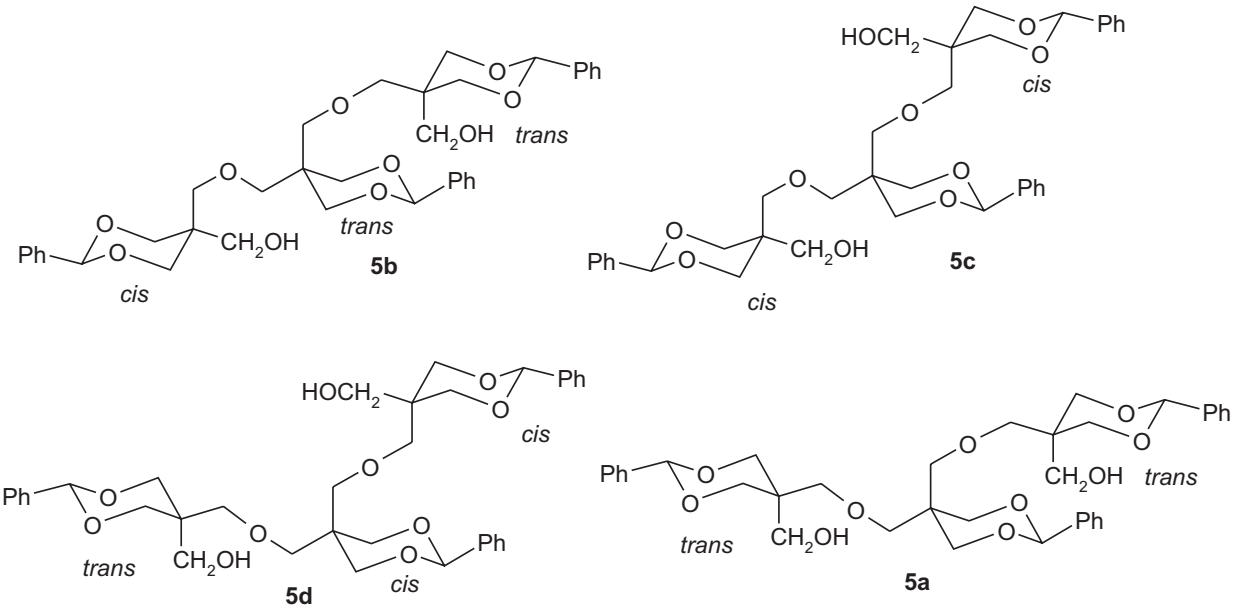
tripentaerythritol (**3**). We also show that these acetals can be transformed into other potentially useful compounds.

Results and discussion

Application of the conditions of Murguía et al. (38) to tripentaerythritol (**3**) using cyclohexanone as the carbonyl-containing component yielded 2′,2″:6′,6″:10′,10″-tri-*O*-cyclohexylidene-2,2,6,6,10,10-hexakis(hydroxymethyl)-4,8-dioxa-1,11-undecandiol (**4**), the tri-*O*-cyclohexylidene acetal of **3** in 96% yield (Scheme 1). This name is based on naming tripentaerythritol as having six hydroxymethyl substituents on the linear diether main chain, 4,8-dioxa-1,11-undecanediol. This product is the only possible fully acetalated product, if it is accepted that 10-membered ring acetals spanning hydroxyls from two different pentaerythritol units in **3** are too unstable to be formed. The chemical shifts of acetal carbons are strongly affected by ring size (39–41) and cyclohexylidene acetals also exhibit this trend (42). The chemical shifts observed for the acetal carbons of **4** (98.7 (2) and 98.8 ppm) fit what is expected for six-membered acetal rings, in agreement with the structure assigned.

The reaction of benzaldehyde with **3** under similar conditions yielded four compounds as the major products, which were shown to be isomeric tri-*O*-benzylidene acetals. Even although cis–trans isomerism can occur in each of the three benzylidene acetal rings derived from **3**, only four diastereomers are possible because of the C_{2v} symmetry of the parent compound (**3**). For the terminal rings, which bear CH_2OH and CH_2OR groups on the same carbon, the configuration is termed cis here and earlier (36) if the phenyl group is cis to the group with the higher Cahn–Ingold–Prelog priority. There is no stereoisomerism in the central benzylidene acetal ring if the two end rings have the same stereochemistry. If the terminal rings have different stereochemistries, the central benzylidene acetal ring is designated cis or trans if the phenyl group in that ring is cis or trans to the substituent bearing the cis-ring, respectively. These four products exhibited surprisingly different behaviour on TLC on silica gel, with R_fs of 0.77, 0.68, 0.60, and 0.49 in hexane – ethyl acetate (1:3) for **5a**, **5b**, **5c**, and **5d**, respectively, and were readily separated by flash column chromatography. The structures of these products are shown in Fig. 1.

Structures were assigned based on the NMR parameters of the three di-*O*-benzylidene acetals of dipentaerythritol (**6a**–**6c**), whose structures had been determined definitively by us previously using X-ray crystallography (36). Some of the observations about the NMR parameters of **6a**–**6c** were noted earlier (36); some are developed here.



Each terminal benzylidene acetal ring of **5a**–**5d** has one hydroxymethyl group. It was previously noted that the chemical shifts of the carbon atoms of hydroxymethyl groups were 64 to 65 ppm if they were equatorially oriented in *cis*-benzylidene acetals, but 61–62.5 ppm if they were axially oriented in *trans*-benzylidene acetals (36). As noted above, a cis-configuration has the phenyl and CH_2OCH_2-groups on the same side of the ring with an equatorial CH_2OH group, while the trans-isomer has an axial CH_2OH group. On this basis, **5a** is the trans,trans-isomer (chemical shifts 61.3 and 61.8 ppm), while **5c** is the cis,cis-isomer (chemical shifts 64.3 and 65.0 ppm). Compounds **5b** (chemical shifts 62.8 and 64.3 ppm) and **5d** (chemical shifts 62.2 and 65.1 ppm) both have one terminal ring with the cis-configuration and one with the trans-configuration.

The ^{1}H NMR signals of isolated OCH_2 groups, where the oxygen atom is ethereal rather than hydroxylic, are easily identified because they can be correlated by HMQC or HSQC experiments to signals of carbon atoms with chemical shifts of 70.5–73.2 ppm. The values of these ^{1}H NMR chemical shifts can be used to make assignments. All of these CH_2OR groups are attached to C-5 of 2-phenyl-1,3-dioxane rings. The signals of the axial CH_2 groups appear between 3.75 and 4.05 ppm, while those of equatorially oriented CH_2 groups appear between 3.15 and 3.45 ppm. Weber (26) had previously assigned signals for analogous pentaerythritol signals in the same way, and it is well-known that ^{1}H NMR signals of axial substituents at C-5 of 1,3-dioxane derivatives are more deshielded than those of equatorial substituents (43–46).

All of these 5,5-disubstituted-2-phenyl-1,3-dioxane rings will be highly biased conformationally towards the chair conformation with the phenyl group equatorially oriented because the *A* value for a phenyl group at the 2-position in a 1,3-dioxane ring is >3 kcal/mol (1 cal = 4.184 J) (47), while those of the CH_2OR groups at the 5-position are small and almost identical (Fig. 1). To assign the structures of the two unassigned tri-*O*-benzylidenetripentaerythritols (**5b**, **5d**), the data for the di-*O*-benzylidenedipentaerythritols (**6a**–**6c**) will be reexamined and compared with that for the assigned tri-*O*-benzylidenetripentaerythritols (**5a**, **5c**). In the cis,cis-isomer **6a**, the ^{1}H NMR signal of the axial CH_2 attached to an axial CH_2 appears at 3.97 ppm. In the trans,trans-isomer **6c**, the ^{1}H NMR signal of the equatorial CH_2 attached to an

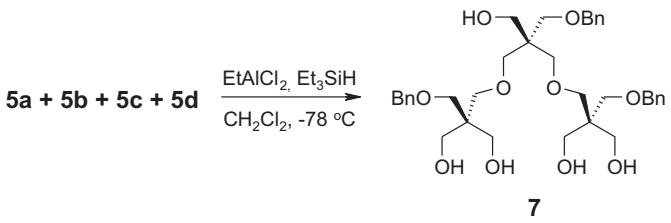
© 2006 NRC Canada

Fig. 1. The possible tribenzylidene acetals of tripentaerythritol.

equatorial CH_2 appears at 3.21 ppm. In the cis,trans-isomer **6b**, the ^{1}H NMR signal of the axial CH_2 attached to an equatorial CH_2 appears at 3.82 ppm and that of the equatorial CH_2 attached to an axial CH_2 appears at 3.32 ppm. In the next section, we determine whether similar values are observed for the same types of linkages in the spectra of the benzylidene acetals whose structures have already been assigned.

In the spectrum of the tri-*O*-benzylidene tripentaerythritol isomer **5a**, whose configuration has already been assigned as trans,trans- (see Fig. 1), there are four of these CH_2 signals at 3.21, 3.25, 3.36, and 3.79 ppm. This last signal can be assigned immediately to the axial CH_2 on the central ring attached to an equatorial CH_2 group. This structure contains two CH_2 groups that are equatorial and attached to each other; in accordance with the observations for **6c** made above, these can be assigned to the signals at 3.21 and 3.25 ppm. The remaining signal (at 3.36 ppm) fits that expected for an equatorial CH_2 attached to an axial CH_2. Thus, all the chemical shifts observed fit what was expected based on the di-*O*-benzylidene dipentaerythritol data.

In the spectrum of the cis,cis-isomer of the tri-*O*-benzylidene tripentaerythritol (isomer **5c**), the four signals of this type appear at 3.35, 3.83, 3.98, and 4.00 ppm. Clearly, the first signal is of an equatorial CH_2, and this structure only contains one (see Fig. 1) on the central ring attached to an axial CH_2 group. The two largest chemical shifts are the same size as those from **6a**, the cis,cis-isomer, and thus are assigned to the two axial CH_2s attached to each other. Finally, the 3.83 ppm value is assigned to the remaining axial CH_2, which is attached to the lone equatorial CH_2 group. The total agreement with the assignments made on the basis of the di-*O*-benzylidene dipentaerythritol data lends confidence to the use of this data for assigning the structures of the two unknown structures remaining.



One of the remaining structures has two equatorial CH_2 groups linked to each other and two axial CH_2s linked to each other. Thus, its ^{1}H NMR spectrum is expected to exhibit two singlets in the range 3.20–3.25 ppm and two in the range 3.95–4.00 ppm. The ^{1}H NMR spectrum of **5d** fits these expectations exactly, with chemical shifts of 3.21, 3.23, 3.95, and 4.00 ppm. The other remaining structure has two equatorial CH_2s linked to axial CH_2s and two axial CH_2s linked to equatorial CH_2s. Hence, it would be expected to have two signals in the 3.30–3.35 ppm range and two in the 3.80–3.85 ppm range. The chemical shifts measured for **5b** were 3.34, 3.35, 3.82, and 3.86 ppm, again in near perfect agreement with expectation. Thus, the spectra of all four isomers fit the chemical shift relationships derived from the observations made for the di-*O*-benzylidene dipentaerythritols without exception.

A number of different reagents are commonly employed for the reduction of benzylidene acetals to hydroxy benzyl ethers, including $LiAlH_4$–$AlCl_3$ (48), $NaCNBH_3$–HCl (49), Et_3SiH–TFA (50), Et_3SiH–$BF_3{\cdot}Et_2O$ (51), and DIBAL (52). None of these methods was successful in the reduction of the tri-*O*-benzylidene acetals of tripentaerythritol. In a recent publication, Baskaran and co-workers (53) described a facile and efficient cleavage of benzylidene acetals using $EtAlCl_2$ and Et_3SiH in CH_2Cl_2. Application of the conditions of Baskaran and co-workers to the chromatographically purified mixture of the four possible tri-*O*-benzylidene acetals of tripentaerythritol resulted in the formation of the corresponding tri-*O*-benzyl ether of tripentaerythritol (**7**) in 65% yield (Scheme 2).

In summary, tripentaerythritol was efficiently converted into 2′,2″:6′,6″:10′,10″-tri-*O*-cyclohexylidene-2,2,6,6,10,10-hexakis(hydroxymethyl)-4,8-dioxa-1,11-undecandiol (**4**) by the toluenesulfonic acid catalysed reaction with cyclohexanone in a mixture of *N*,*N*-dimethylformamide and benzene. Reaction of tripentaerythritol with benzaldehyde under similar conditions gave an easily separated mixture of the four possible stereoisomers. Structures of these stereoisomers were assigned based on ^{1}H and ^{13}C NMR chemical shifts using trends previously observed for the dibenzylidene acetals of dipentaerythritol, whose structures had been established

7

unambiguously by X-ray crystallography. These acetals provide tripentaerythritol derivatives with two symmetrical hydroxyl groups unprotected, suitable for further elaboration into dendrimers or other larger derivatives.

The mixture of benzylidene acetals to 2,6,10-tris(benzyloxymethyl)-4,8-dioxa-1,11-undecanediol was accomplished using triethylsilane with ethylaluminium dichloride as the Lewis acid, after a number of commonly used conditions for this transformation failed. This product, two steps from inexpensive tripentaerythritol, is also well-positioned for further transformations, having five free hydroxyls, four of which could be protected by acetal formation. Results along these lines will be reported in due course.

Experimental section

The general methods and ^{1}H and ^{13}C NMR spectra of products described in the paper are given in the Supplemental material.[3]

2′,2″:6′,6″:10″,10″-Tri-*O*-cyclohexylidene-2,2,6,6,10,10-hexakis(hydroxymethyl)-4,8-dioxa-1,11-undecanediol (4)

A 250 mL round-bottomed flask containing a magnetic stir bar was charged with tripentaerythritol (**3**, 2.0 g, 0.0054 mol), freshly distilled cyclohexanone (0.019 mol, 3.5 eq), *p*-toluenesulfonic acid (0.45 g), dry benzene (60 mL), and dry dimethylformamide (90 mL), and the mixture was refluxed for 5 h with azeotropic removal of water. The stirred solution was cooled and then aqueous potassium carbonate (5%, 30 mL) was added. The reaction mixture was stirred for about 5 min, then extracted with dichloromethane (3 × 30 mL). The combined organic layers were dried over $MgSO_4$ and concentrated to give the title compound (3.2 g, 96%) as a pure colourless solid that was recrystallized from $CHCl_3$–hexane; mp 197 °C. ^{1}H NMR δ: 3.68, (s, 2 × H2′, H2″, H10′, H10″, 8H), 3.66, (s, H6′, H6″, 4H), 3.59 (s, C*H*$_2$OH, 4H), 3.44, 3.53 (2 × CC*H*$_2$OC*H*$_2$C, 8H), 1.42–1.73 (complex m, 3 × cyh H, 30H). ^{13}C NMR δ: 98.84, 98.72 (2 × acetal C), 72.51, 71.74 (2 × CCH_2OCH_2C), 64.12 (2 × CH_2OH), 62.25 (C2′, C2″, C10′, C10″), 62.46 (C6′, C6″), 39.63, 39.54 (3 × C quat), 33.56, 32.67, 31.79 (3 × cyh C2, C6), 25.80 (3 × cyh C4), 22.72 (3 × cyh C3, C5). HR ESI MS *m*/*z* calcd. for $C_{33}H_{56}O_{10}Na^+$: 635.3771; found: 635.3772.

Trans,*trans*-, *cis*,*trans*,*trans*-, *cis*,*cis*-, and *trans*,*cis*,*cis*-2′,2″:6′,6″:10′,10″-tri-*O*-benzylidene-2,2,6,6,10,10-hexakis(hydroxymethyl)-4,8-dioxa-1,11-undecanediol (5a, 5b, 5c, and 5d, respectively)

To a suspension of compound **3** (1.82 g, 4.90 mmol) in dry benzene and dry *N*,*N*-dimethylformamide (150 mL, 4:6 *v*/*v*) was added benzaldehyde (3.40 mL, 33.5 mmol) and *p*-toluenesulfonic acid (0.26 g). The reaction mixture was refluxed in a Dean–Stark trap with continous removal of water for 12 h, then cooled to room temperature, neutralized with solid $CaCO_3$ (1 g), filtered, and the filtrate was concentrated. The residue was separated by flash column chromatography on silica gel (hexane–EtOAc, 3:1 to 2:1 to 1:1). First to elute was *trans*,*trans*-2′,2″:6′,6″:10′,10″-tri-*O*-benzylidene-2,2,6,6,10,10-hexakis(hydroxymethyl)-4,8-dioxa-1,11-undecanediol (**5a**), an amorphous solid (0.23 g, 16%); mp 82–85 °C. R_f 0.77 (hexane–EtOAc, 1:3). ^{1}H NMR δ: 7.34–7.46 (complex m, phenyl protons, 15H), 5.44, 5.42 (2s, ratio 1:2, 3 × acetal H), 4.15, 4.14, 4.07 (3 overlapping d, 6H, *J* = 11.6 Hz, eq H2′, H2″, H6′, H6″, H10′, H10″), 4.03, 4.01 (2s, 2C*H*$_2$OH, 4H), 3.79 (s, ax CCH_2O, 2H), 3.77, 3.76, 3.76 (3 overlapping d, ax H2′, H2″, H6′, H6″, H10′, H10″, 6H), 3.36, 3.25, 3.21 (3s, eq CCH_2O, 6H). ^{13}C NMR δ: 126.00–138.10 (aromatic carbons), 102.21, 102.20 (ratio 2:1, 3 × acetal C), 72.80, 72.60, 71.90 (3 eq C*C*H$_2$O*C*H$_2$C), 70.40 (ax C*C*H$_2$O*C*H$_2$C), 70.50, 70.20, 70.00 (C2′, C2″, C6′, C6″, C10′, C10″), 62.70, 62.10 (2 × CH_2OH), 39.43, 39.38, 39.22 (3 × C quat.).

The second component was *cis*,*trans*,*trans*-2′,2″:6′,6″:10′,10″-tri-*O*-benzylidene-2,2,6,6,10,10-hexakis(hydroxymethyl)-4,8-dioxa-1,11-undecanediol (**5b**), an amorphous solid (0.39 g, 22%); mp 157–160 °C. R_f 0.68 (hexane–EtOAc, 1:3). ^{1}H NMR δ: 7.34–7.46 (complex m, phenyl protons, 15H), 5.42, 5.40, 5.39 (3 × acetal H), 4.15, 4.13, 4.10 (3 overlapping d, *J* = 11.8 Hz, eq H2′, H2″, H6′, H6″, H10′, H10″, 6H), 4.01 (s, C*H*$_2$OH in trans-ring, 2H), 3.86, 3.82 (2s, 2 ax CCH_2O, 4H), 3.75, 3.72, 3.70 (3 overlapping d, ax H2′, H2″, H6′, H6″, H10′, H10″, 6H), 3.45 (s, C*H*$_2$OH in cis-ring, 2H), 3.35, 3.26, (2s, 2 eq CCH_2O, 4H). ^{13}C NMR δ: 126.19–138.30 (aromatic carbons), 102.26, 102.23, 102.19 (3 × acetal C), 73.09, 72.25 (2 eq C*C*H$_2$O*C*H$_2$C), 71.45, 70.90 (2 ax C*C*H$_2$O*C*H$_2$C), 70.70, 70.57, 70.10 (C2′, C2″, C6′, C6″, C10′, C10″), 64.25, 62.84 (2 × CH_2OH), 39.35, 39.24, 39.14 (3 × *C* quat.).

The third component was *cis*,*cis*-2′,2″:6′,6″:10′,10″-tri-*O*-benzylidene-2,2,6,6,10,10-hexakis(hydroxymethyl)-4,8-dioxa-1,11-undecanediol (**5c**), an amorphous solid (0.27 g, 19%); mp 164–167 °C. Kinetics of the reaction catalyzed by inositol dehydrogenase from *Bacillus subtilis* and inhibition by fluorinated substrate analogs[1]

Richard Daniellou, Hongyan Zheng, and David R.J. Palmer

Abstract: Inositol dehydrogenase (EC 1.1.1.18) from *Bacillus subtilis* catalyzes the oxidation of *myo*-inositol to *scyllo*-inosose by transfer of the equatorial hydride of the substrate to NAD^+. This is a key enzyme in the metabolism of *myo*-inositol, a primary carbon source for soil bacteria. In light of our recent discovery that the enzyme has a broad substrate spectrum while maintaining high stereoselectivity, we seek a more thorough understanding of the enzyme and its active site. We have examined the kinetics of the recombinant enzyme, and synthesized fluorinated substrate analogues as competitive inhibitors. We have evaluated all rate constants in the ordered, sequential Bi Bi mechanism. No steady-state kinetic isotope effect is observed using *myo*-[2-^{2}H]-inositol, indicating that the chemical step of the reaction is not rate-limiting. We have synthesized the substrate analogs 2-deoxy-2-fluoro-*myo*-inositol, its equatorial analog 1-deoxy-1-fluoro-*scyllo*-inositol, the *gem*-difluorinated analog 1-deoxy-1,1-difluoro-*scyllo*-inositol, and the sugar analog α-D-glucosyl fluoride. Of these, 1-deoxy-1-fluoro-*scyllo*-inositol showed no inhibition, while all others tested had K_i values comparable to the K_m values of the analogous substrates *myo*-inositol and α-D-glucose.

Key words: inositol dehydrogenase, enzyme mechanism, kinetics, competitive inhibitor, substrate analogue.

Résumé : La déshydrogénase de l'inositol (EC 1.1.1.18) du *Bacillus subtilis* catalyse l'oxydation du *myo*-inositol en *scyllo*-inosose par le transfert d'un hydrure équatorial du substrat vers la NAD^+. C'est un enzyme clé dans le métabolisme du *myo*-inositol, une source de carbone primaire pour les bactéries du sol. Compte tenu de notre découverte récente à l'effet que l'enzyme peut agir sur un large éventail de substrats tout en maintenant une stéréosélectivité élevée, une étude plus approfondie a été entreprise pour mieux comprendre cet enzyme et son site actif. À cette fin, on a étudié la cinétique de l'enzyme recombinant et on a synthétisé des analogues fluorés de substrats comme inhibiteurs compétitifs. On a évalué toutes les constantes de vitesse dans le mécanisme Bi Bi, ordonné et séquentiel. On n'a pas observé d'effet isotopique cinétique à l'état stationnaire lorsqu'on a étudié le *myo*-[2-^{2}H]-inositol; cette observation indique que l'étape chimique n'est pas cinétiquement limitante. On a aussi synthétisé les analogues de substrats 2-désoxy-2-fluoro-*myo*-inositol, son analogue équatorial 1-désoxy-1-fluoro-*scyllo*-inositol, son analogue *gem*-difluoré 1-désoxy-1,1-difluoro-*scyllo*-inositol et le sucre analogue fluorure de α-D-glucosyle. De tous ces composés, le 1-désoxy-1-fluoro-*scyllo*-inositol ne présente pas d'inhibition alors que, avec tous les autres composés évalués, les valeurs de K_i sont comparables aux valeurs de K_m des substrats analogues du *myo*-inositol et du α-D-glucose.

Mots clés : inositol, déshydrogénase, mécanisme d'enzyme, cinétique, inhibition compétitive, analogue de substrat.

Introduction

Inositol is a ubiquitous natural product that is abundant in soil. Inositol derivatives are known to occupy key roles in the biology of bacteria, fungi, plants, and animals. It has been known for many years that environmental microorganisms perform regioselective oxidation reactions on inositols and related carbohydrate derivatives (1–3). The first step in the catabolism of inositol by soil bacteria is the NAD^+-dependent oxidation of *myo*-inositol to *scyllo*-inosose by inositol dehydrogenase (IDH, EC 1.1.1.18), shown in Scheme 1. Recently, interest in IDH has increased because of links between inositol catabolism, particularly IDH activity, and the competitiveness of certain beneficial soil bacteria that can form symbiotic relationships with important crops such as peas, beans, and other legumes (4–6).

The most detailed in vitro study of IDH catalysis has used the enzyme from *Bacillus subtilis*. The native enzyme was isolated and the kinetic mechanism described by Ramaley et al. (7) more than 25 years ago. This work revealed several aspects of IDH, including some tolerance of the active site to structural variations in the substrate: α-D-glucose and α-D-xylose were also observed to be substrates. Also demon-

Scheme 1. The IDH-catalyzed oxidation of *myo*-inositol to *scyllo*-inosose and α-D-glucose to D-glucono-1,5-lactone.

Scheme 2. Cleland diagram of an ordered, sequential Bi Bi mechanism. For IDH, A is NAD^+, B is *myo*-inositol, P is *scyllo*-inosose, and Q is NADH.

strated was a sequential, ordered Bi Bi mechanism in which NAD^+ binds first and NADH is released last, as indicated in Scheme 2. However, the authors reported only the apparent Michaelis constant for *myo*-inositol at 0.5 mmol/L NAD^+ (K_m^{App} = 18 mmol/L) rather than the true K_m. No specific insight into the active-site architecture was garnered.

Our laboratory has recently subcloned and expressed recombinant IDH from *B. subtilis*. We observed that IDH can oxidize 1L-4-*O*-subtituted derivatives of *myo*-inositol, and that the substituent can be as large as a camphorsulfonyl group (8). Disaccharides could also act as substrates, but the presence of a negative charge on the substituent decreased affinity for the enzyme. This suggests a large, nonpolar pocket adjacent to the active site, allowing stereoselective recognition of these alternative substrates.

We seek a thorough understanding of this enzyme, and to that end we have evaluated rate constants for each of the steps represented in Scheme 2. In addition, we have synthesized substrate mimics in which the axial hydroxyl group of the reaction centre has been replaced with an axial and (or) equatorial fluorine atom. Fluorine can act as a hydrogen bond acceptor, but not a donor, and the ability of these compounds to act as inhibitors will indicate the role of the hydroxyl group in binding to the active site. Development of a potent inhibitor could prove very useful in determining the roles of active-site residues if a high-resolution crystal structure of inhibitor-bound enzyme can be generated.

Experimental

General

Chemical reagents, including buffers, salts, *myo*-inositol, NAD^+, and NADH, were obtained from Sigma-Aldrich Canada, Ltd. (Oakville, Ontario), or VWR CanLab (Mississauga, Ontario), and were categorized as molecular biology grade or were the highest grade available. *scyllo*-Inosose was synthesized as previously described and its spectroscopic characteristics matched those reported before (9). Inositol dehydrogenase was purified as described previously (8). UV–vis absorbance was measured using a Beckman DU-640 spectrophotometer with a circulating-water-bath-controlled temperature block. Thin layer chromatography was performed on aluminium-backed plates of Silica gel $60F_{254}$ (EM Science, Gibbstown, New Jersey) using phosphomolybdic acid – ethanol reagent, or a 10% solution of sulfuric acid in ethanol, and (or) UV at 254 nm to visualize spots. Silica gel 60 (40–63 μm) was used for flash chromatography. NMR spectra were recorded on a Bruker 500 MHz spectrometer. Chemical shifts are reported in ppm downfield from tetramethylsilane. Mass spectra were recorded with a VG 70SE mass spectrometer. NMR, mass spectrometry, and elemental analysis facilities are part of the Saskatchewan Structural Sciences Centre, University of Saskatchewan, Saskatoon, Saskatchewan.

2-Deoxy-2-fluoro-*myo*-inositol (**1**), 1-deoxy-1-fluoro-*scyllo*-inositol (**2**), 1-deoxy-1,1-difluoro-*scyllo*-inositol (**3**) (10–13), and α-D-glucosyl fluoride (**4**) (14) were synthesized according to literature methods. All spectroscopic data matched that reported previously.

myo-[2-^{2}H]-Inositol

$NaBD_4$ was added to a solution of *scyllo*-inosose (0.53 g, 3 mmol) in water (27 mL). After stirring overnight at room temperature, the reaction was quenched by the addition of acetone (5 mL). The mixture was then concentrated and the residue was peracetylated by stirring in acetic anhydride (20 mL) and pyridine (10 mL) at 100 °C for 24 h (15). Flash chromatography of the residue (hexane – ethyl acetate, 1:1), followed by deacetylation using sodium methoxide in methanol at reflux for 10 min, neutralization with Dowex 50X8 (H^+ form), filtration and concentration, gave *myo*-[2-^{2}H]-inositol isolated in 41% yield as a white solid. No *scyllo*-inositol derivative was observed. ^{1}H NMR (500 MHz, D_2O) δ: 3.15 (t, J = 9.3 Hz, 1H, H-5), 3.42 (d, J = 10.0 Hz, 2H, H-1 and H-3), 3.51 (m, 2H, H-4 and H-6). ^{13}C NMR (125 MHz, D_2O) δ: 71.44, 72.13 (t, $J_{C\text{-}D}$ = 22 Hz), 72.78, 74.73. ESI-MS : 204.06 $[M + Na]^+$, 385.13 $[2M + Na]^+$. Anal. calcd. for $C_6H_{11}DO_6$: C 39.78, H 7.23; found: C 39.99, H 6.99.

Kinetics

Forward (oxidation of *myo*-inositol) and reverse (reduction of *scyllo*-inosose) reactions were measured by continuously monitoring the appearance or the disappearance of NADH at 340 nm (ε = 6.2 $(mmol/L)^{-1}$ cm^{-1}). Initial rates were determined using various concentrations of substrates in 100 mmol/L Tris-HCl pH 9.0 at 25 °C. Kinetic constants were determined using the program Leonora (16) by nonlinear least-squares fitting of the data to eq. [1], which describes an ordered sequential Bi Bi mechanism in the absence of products,

$$[1] \qquad v = \frac{V_{max}[A][B]}{K_{iA}K_{mB} + K_{mB}[A] + K_{mA}[B] + [A][B]}$$

where [A] is the concentration of the substrate that first binds (NAD^+ or NADH), [B] is the concentration of the second substrate (*myo*-inositol or *scyllo*-inosose), K_{iA} is the dis-

© 2006 NRC Canada

sociation constant for A, K_{mA} and K_{mB} are the respective limiting Michaelis constants for the substrates A and B, and V_{max} is the maximum velocity when both substrates are in saturating condition.

The concentration of each inhibitor needed to decrease the velocity by 50% (IC_{50}) was determined at [S] = 20 mmol/L by fitting the dependence of v/v_0 on [I], where v_0 is the rate in the absence of inhibitor. The inhibition constant (K_i) was calculated using the Cheng and Prusoff equation (17).

$$[2] \qquad K_i = \frac{IC_{50}}{1 + \frac{[S]}{K^{App}}}$$

To test the validity of this method in these conditions, the inhibition constant for 1-deoxy-1-fluoro-α-D-glucose (**4**) was determined by a Dixon plot, based on eq. [3],

$$[3] \qquad v = \frac{V^{App}[S]}{K^{App}\left(1 + \frac{[I]}{K_i}\right) + [S]}$$

where S is the varied substrate, V^{App} is the maximal velocity at the concentration of the fixed substrate, K^{App} is the substrate concentration necessary for half-maximal velocity under these conditions, and K_i is the inhibition constant. The result of this analysis (66 ± 5 mmol/L) was in good agreement with the value determined using eq. [2] (58 ± 8 mmol/L).

Results and discussion

Kinetics and mechanism

The work of Ramaley et al. (7) provided the basic facts regarding the IDH mechanism, including product inhibition studies consistent with an ordered Bi Bi mechanism and a pH–rate profile, which we have confirmed in our laboratory (data not shown). To examine the details of the kinetic mechanism, the initial velocities of the enzymatic reaction at pH 9.0 were recorded at several constant concentrations of one substrate (B) while varying the concentration of the other substrate (A). When data were plotted in the form $1/v$ against 1/A, a series of straight lines was obtained for the forward and reverse enzymatic reactions. The lines intersected to the left of the ordinate axis of the double-reciprocal plot, in agreement with the ordered Bi Bi mechanism depicted in Scheme 2 (18). The families of lines are shown in Fig. 1. Our results, shown in Table 1, provide a K_m = 1.1 mmol/L for *myo*-inositol for the first time, comparable to the value of 1 mmol/L for *scyllo*-inosose and consistent with a catabolic pathway.

Some other facts become apparent from the data of Table 1. First, although we are operating at the optimal pH for oxidation of *myo*-inositol, the reverse reaction, reduction of *scyllo*-inosose, is still faster. Second, the value of K_{iq}, representing the disassociation constant of NADH binding to free IDH, is notably lower than the Michaelis constant of the substrate inositol. Product inhibition thus limits the application of IDH as a catalyst for the synthesis of inosose derivatives, but this nonproductive ternary complex would yield a wealth of information if it could be crystallized.

Fig. 1. Double reciprocal plot of the variation of rate with: (A) NAD^+ concentration at constant *myo*-inositol concentrations (2 mmol/L (●), 4 mmol/L (□), 7 mmol/L (■), 10 mmol/L (▲), 20 mmol/L (○)); and (B) inositol concentration at constant inositol concentrations (0.1 mmol/L (●), 0.2 mmol/L (○), 0.4 mmol/L (■), 1.0 mmol/L (□)).

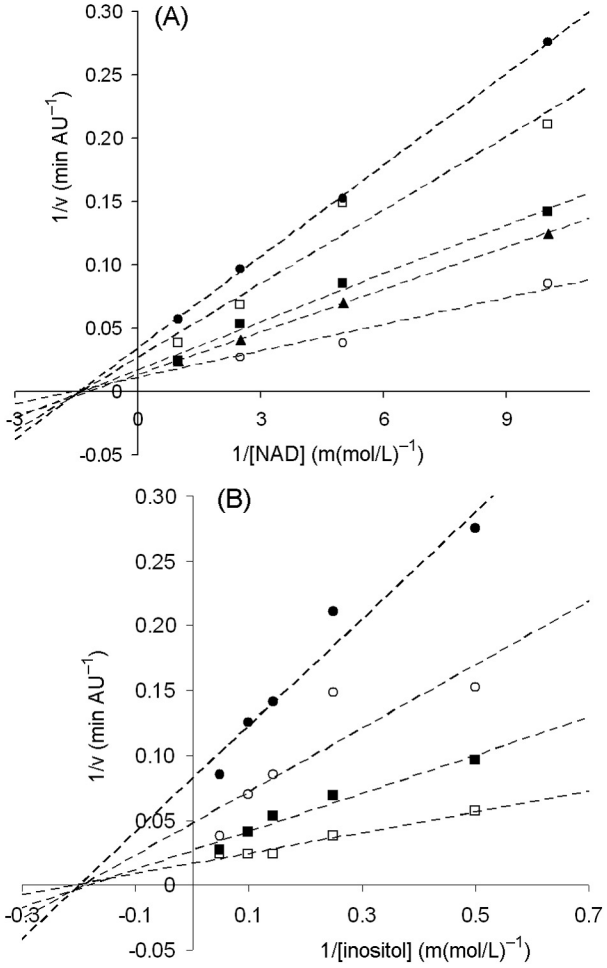

Table 1. Kinetic constants for the IDH-catalyzed reaction.

Constant	Value
K_{ia}	5±1 mmol/L
$K_{m(NAD^+)}$	0.26±0.05 mmol/L
$K_{m(inositol)}$	1.1±0.1 mmol/L
$V_{forward}$	13.5±2 μmol min^{-1} mg^{-1}
$k_{forward}$	9±1 s^{-1}
K_{iq}	50±5 μmol/L
$K_{m(NADH)}$	36±5 μmol/L
$K_{m(inosose)}$	1.0±0.1 mmol/L
$V_{reverse}$	19±2 μmol min^{-1} mg^{-1}
$k_{reverse}$	13±1 s^{-1}

Note: Conditions for the reaction were 100 mmol/L TRIS-HCl, pH 9.0, 25 °C.

Table 2. Calculated kinetic constants of IDH-catalyzed reactions.

Constant	Expression	Value
k_1	$\frac{V_{forward}}{K_{m(NAD^+)}[E_0]}$	(3.6±0.4) × 10^4 s^{-1} $(mol/L)^{-1}$
k_{-1}	$\frac{V_{forward}K_{ia}}{K_{m(NAD^+)}[E_0]}$	180±30 s^{-1}
k_2	$\frac{V_{forward}(k_{-2}+k_3)}{k_3K_{m\ (inositol)}[E_0]}$	(1.4±0.2) × 10^4 s^{-1} $(mol/L)^{-1}$
k_{-2}	$\frac{V_{forward}V_{reverse}\ K_{ia}}{[E_0](V_{forward}\ K_{ia}\ -\ V_{reverse}K_{m(NAD^+)})}$	14±1 s^{-1}
k_3	$\frac{V_{forward}V_{reverse}\ K_{iq}}{[E_0](V_{reverse}\ K_{iq}\ -\ V_{forward}K_{m(NADH)})}$	19± 1 s^{-1}
k_{-3}	$\frac{V_{reverse}(k_{-2}+k_3)}{k_{-2}K_{m\ (inositol)}[E_0]}$	(3.0±0.4) × 10^4 s^{-1} $(mol/L)^{-1}$
k_4	$\frac{V_{reverse}\ \frac{1}{K_{iq}}}{K_{m\ (NADH)}[E_0]}$	18±1 s^{-1}
k_{-4}	$\frac{V_{reverse}}{K_{m\ (NADH)}[E_0]}$	3.5±0.4 × 10^5 s^{-1} $(mol/L)^{-1}$
K_{ib}	$\frac{k_{-1}+k_{-2}}{k_2}$	14±2 mmol/L
K_{ip}	$\frac{k_{-1}+k_4}{k_1}$	5.5±0.9 mmol/L

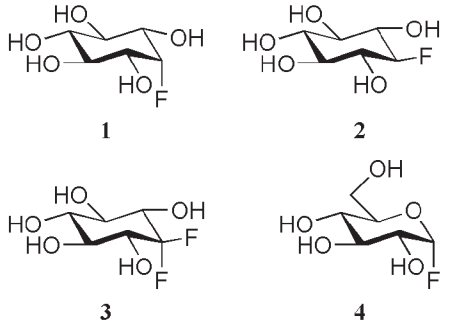
Note: Conditions for the reactions were 100 mmol/L TRIS-HCl, pH 9.0, 25 °C.

The internal consistency of the kinetic constants in Table 1 was confirmed using the Haldane relationship for an ordered Bi Bi kinetic mechanism. A value of 5.7×10^{-3} was calculated for K_{eq}. This is in good agreement with the value of 2.5×10^{-3}, which was determined experimentally at pH 9.0 and at 25 °C for the thermodynamic equilibrium constant.

$$K_{eq} = \frac{[\text{NADH}][\textit{scyllo}\text{-inosose}]}{[\text{NAD}^+][\textit{myo}\text{-inositol}]}$$

The Theorell–Chance mechanism is a special case of the ordered Bi Bi mechanism in which the concentrations of the central EAB and EPQ complexes are essentially zero. To evaluate the kinetic importance of these species and discriminate between the two mechanisms, we have calculated the ratio R, as defined by Janson and Cleland (19).

$$R = \frac{\frac{1}{V_{forward}}\left(1 - \frac{K_{m(NAD^+)}}{K_{ia}}\right) + \frac{1}{V_{reverse}}\left(1 - \frac{K_{m(NADH)}}{K_{iq}}\right)}{\frac{1}{V_{forward}} + \frac{1}{V_{reverse}}}$$



The value of R can vary between 0 and 1, where the limiting case $R = 0$ would indicate the canonical Theorell–Chance mechanism. Using our data, we calculated $R = 0.68$ for IDH under these conditions, indicating that the ternary complex has a lifetime.

By using the relationships of kinetic parameters to microscopic rate constants for an ordered Bi Bi mechanism (20), values for k_1–k_{-4} were calculated, and are summarized in Table 2. In both directions, the breakdown of the ternary complex (k_3 and k_{-2}) appears to constitute the rate-limiting step, although in the forward direction, liberation of the cofactor NADH is also slow and partially rate-limiting. This analysis does not distinguish between the chemical step, i.e., the hydride transfer, and the release of the first product.

To determine whether the chemical step or the liberation of the product is the limiting step, primary kinetic isotope effect experiments were performed. The synthesis of *myo*-[2-^{2}H]-inositol was easily effected by reaction of *scyllo*-inosose with sodium borodeuteride. One might expect a mixture of *myo*- and *scyllo*-inositol isomers, generated by hydride attack from either face of the ketone, however, only the *myo*-isomer is formed. The high stereoselectivity of this reaction, in agreement with results using related compounds (21, 22), is in accordance with the prevalence of the steric effects in reduction reactions with sodium borohydride; hydride attack occurs at the face anti to the substituents on the two adjacent carbons. A simple acetylation–deacetylation sequence was used to remove salts from the compound. For consistency, this process was also carried out using sodium borohydride to make *myo*-inositol, and this inositol was used for direct comparison with the deuterated analogue. *myo*-Inositol prepared in this manner showed no difference in behaviour from purchased *myo*-inositol. At [NAD$^+$] = 0.5 mmol/L, no kinetic isotope effect was observed on V_{max} ($V^H/V^D = 1.0$) and the isotope effect on V_{max}/K_m was only 1.1. These results lead us to the conclusion that the chemical reaction is rapid relative to liberation of product, the latter being the rate-limiting step of the enzymatic reaction.

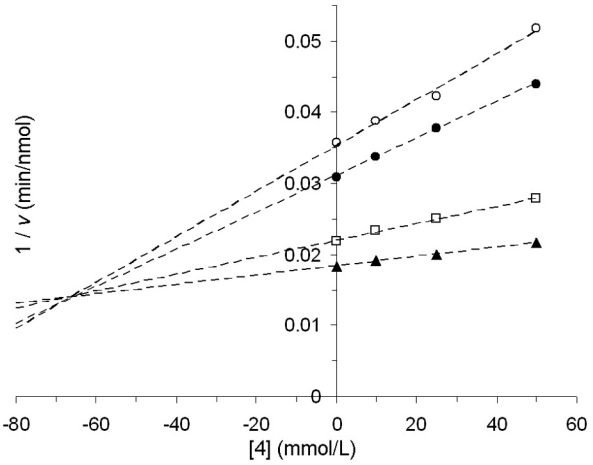
Chart 1.

Fluorine-containing analogues

Replacement of the hydroxyl group of a substrate with a fluorine atom can help one understand the mechanism of an enzyme in a number of ways (23, 24). The carbon–fluorine bond length is close to that of the carbon–oxygen bond, but fluorine is a better leaving group than hydroxyl and cannot act as a hydrogen bond donor. A substrate bearing a fluorine atom might therefore behave as a pseudosubstrate, undergoing the "normal" enzymatic chemistry, but with altered reactivity; as an inhibitor, recognized by the enzyme but undergoing no reaction, or as an inactivator, alkylating the enzyme at the active site. However, a number of studies giving unexpected results has prompted Seebach to dub fluorinated substrates "flustrates" (25).

We chose to replace the reaction centre of *myo*-inositol with a carbon bearing a fluorine substituent since the resulting molecules are approximately isosteric with the substrate, but cannot undergo the dehydrogenation reaction. The inhibitors envisioned were all accessible by published procedures. 2-Deoxy-2-fluoro-*myo*-inositol (**1**) matches the configuration of the substrate, with an axial fluorine replacing the reactive hydroxyl. 1-Deoxy-1-fluoro-*scyllo*-inositol (**2**) has all non-hydrogen substituents in the equatorial position. The all-equatorial stereoisomer of *myo*-inositol (*scyllo*-inositol) is not a substrate nor an inhibitor of IDH (7). Therefore, if we understand the recognition behaviour of the active site, **2** should show little or no inhibition. While these two inhibitors test for the requirement of an axial substituent, the *gem*-difluoro analog, 1-deoxy-1,1-difluoro-*scyllo*-inositol (**3**), tests whether the presence of an equatorial substituent is deleterious. α-D-Glucosyl fluoride (**4**) is the isosteric analog of glucose, which is also a substrate for IDH (Chart 1).



The results of the inhibition studies with **1–4** are shown in Table 3. None of these compounds could act as substrates, i.e., no reduction of NAD^+ was observed in the absence of *myo*-inositol. All experiments were performed under our standard assay conditions, where the K_m^{App} for *myo*-inositol is 18 mmol/L, and for α-D-glucose is 56 mmol/L. Solubility of the fluorinated compounds in aqueous buffer prevented very high concentrations of inhibitor from being used, but an IC_{50} value could be determined. Using the method of Cheng and Prusoff (17), a value for K_i was calculated from the IC_{50}. The Dixon plot generated for **4** shown in Fig. 2 is as expected for a competitive inhibitor. As predicted, the *myo*-inositol analog **1** inhibits IDH, while the *scyllo*-derivative **2** does not. The K_i value is about double the K_m value for *myo*-inositol under these conditions, suggesting that binding of the inhibitor to the active site is comparable, although not as favourable, as binding of substrate. Interestingly, The K_i value for **3** is very close to that for **1**, clearly indicating that the presence of an equatorial substituent is not intrinsically detrimental to binding in the active site. In this compound, a carbon–fluorine atom is taking the place of the scissile carbon–hydrogen bond (in addition to the carbon–oxygen bond), therefore, a fluorine atom can be accommodated between the carbon atom of the inositol derivative and carbon-4 of the nicotinamide ring of NAD^+. Inhibition by the glucose analog **4** suggests that binding is only slightly less favourable than substrate binding, suggesting that the fluorine atom can replace the hydroxyl group with only a small energetic penalty.

Table 3. Inhibition constants and IC_{50} values for inhibitors **1–4**.

Compound	IC_{50} (mmol/L)	K_i (mmol/L)
1	77±2	37±5
2	No inhibition	—
3	82±2	39±5
4	116±3	58±8

Note: Collected under the following conditions: 100 mmol/L TRIS-HCl, pH 9.0, 25 °C, 20 mmol/L *myo*-inositol, 0.5 mmol/L NAD^+.

Fig. 2. Dixon plot of variation of rate with varying concentrations of inhibitor **4** at constant *myo*-inositol concentrations: 10 mmol/L (○), 20 mmol/L (●), 40 mmol/L (□), 80 mmol/L (▲).

Conclusion

IDH is an enzyme that *B. subtilis* can use for catabolism of not only *myo*-inositol, but also for several monosaccharides and disaccharides (7, 8). Our results are in accord with the conclusions of Ramaley et al. (7) regarding the ordered mechanism of the enzyme, but we have now shown that the enzyme has evolved a fast hydride transfer mechanism, such that release of products limits the rate. The enzyme also regulates its production of inosose by product inhibition. The use of fluorinated analogs as inhibitors shows that an axial electronegative group is required for binding, and that fluorine can replace hydroxyl as this axial group. The presence of an equatorial carbon–fluorine bond at the reaction centre can be accommodated by the enzyme

if an axial substituent is also present. We hope that these or other inhibitors can be used to form crystals of IDH in a ternary complex, giving a clear picture of the active-site architecture during catalysis.

Pyrrolotriazine-5-carboxylate ester inhibitors of EGFR and HER2 protein tyrosine kinases and a novel one-pot synthesis of C-4 subsitituted pyrrole-2,3-dicarboxylate diesters[1]

Harold Mastalerz, Ashvinikumar V. Gavai, Brian Fink, Charles Struzynski, James Tarrant, Gregory D. Vite, Tai W. Wong, Guifen Zhang, and Dolatrai M. Vyas

Abstract: Pyrrolotriazines with an ester group at C-5 were prepared and evaluated as inhibitors of the EGFR and HER2 receptor tyrosine kinases, validated targets for cancer therapy. The C-5 ester (**15**) was at least as potent as its C-6 ester analogue (**17**), an example of a known series of pyrrolotriazine EGRF/HER2 kinase inhibitors that show good biochemical and cellular activity. The C-5 esters were synthesized from pyrrole 2,3-diesters that were made by a new, one-pot procedure. This involved reaction of readily available *N*-tosyl derivatives of α-amino acid esters or ketones with triphenylphosphine and diethyl acetylenedicarboxylate to form 3-pyrrolines via an intramolecular Wittig olefination. The 3-pyrroline intermediates were not isolated but treated directly with base to eliminate toluenesulfinic acid and generate the pyrrole 2,3-diesters in good yield.

Key words: pyrrolotriazine, EGFR, HER2, pyrrole, intramolecular Wittig reaction.

Résumé : On a préparé des pyrrolotriazines portant un groupe ester en position C-5 et on les a évalués comme inhibiteurs des kinases EGFR et HER2 du récepteur de tyrosine qui sont des cibles validées pour la thérapie du cancer. L'ester en C-5 (**15**) est au moins aussi puissant que son analogue **17**, l'ester en C-6, comme exemple d'une série connue de pyrrolotriazines qui peuvent agir comme inhibiteurs de la kinase EGRF/HER2 et qui présentent une bonne activité biochimique et cellulaire. Les esters en C-5 ont été synthétisés à partir de 2,3-diesters du pyrrole qui avaient été préparés par une nouvelle méthode monotope. Celle-ci implique la réaction des dérivés *N*-tosylés d'esters d'acides α-aminés ou de cétones avec de la triphénylphosphine et de l'acétylènedicarboxylate de diéthyle qui conduit à la formation de 3-pyrrolines par le biais d'une oléfination de Wittig intramoléculaire. Les intermédiaires 3-pyrrolines n'ont pas été isolés, mais traités directement avec une base pour éliminer l'acide toluènesulfinique et générer les 2,3-diesters du pyrrole avec de bons rendements.

Mots clés : pyrrolotriazine, EGFR, HER2, pyrrole, réaction de Wittig intramoléculaire.

[Traduit par la Rédaction]

Introduction

Receptor tyrosine kinases catalyze the phosphorylation of proteins that are involved in the signaling processes that control cell proliferation and differentiation. Since aberrant activation of this kinases results in uncontrolled cell growth, extensive drug discovery efforts have been made to find selective, small molecule inhibitors for the treatment of cancers (1). The epidermal growth factor receptor (EGFR) and HER2 are members of the ErbB family of receptor tyrosine kinases and they have been clinically validated as targets for cancer therapy (2). Their frequent coexpression in a variety of tumor types and their capacity to form heterodimers with other members of the ErbB family provides a strong rationale for simultaneous targeting of both receptors. The pyrrolo[2,1-*f*][1,2,4]triazine nucleus has been identified as a novel scaffold for ATP-competitive kinase inhibitors (3). BMS scientists have shown that pyrrolotriazine analogs (**1**) that carry an ester group at C-6 and a relatively large lipohilic amino group at C-4 can show potent inhibition of both the EGFR and the HER2 kinases (4). The C-6 ester group can be modified to further improve biochemical po-

tency and cellular activity. To explore the structure–activity relationships of these dual EGFR/HER2 pyrrolotriazine kinase inhibitors and expand the potential for further lead optimization, we prepared analogues of **1** where the C-6 ester function and the C-5 substitutent are transposed, e.g., **2** and **3**. This report describes the synthesis and the EGFR/HER2 kinase inhibition of some representative examples of these pyrrolotriazine 5-esters. It also details a convenient, one-pot synthesis of the pyrrole 2,3-diesters that are synthetic precursors of pyrrolotriazines **3**.

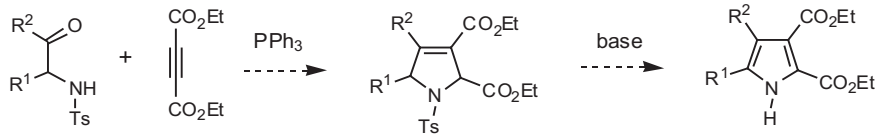
2 R = alkyl, R' = CO_2R''
3 R = alkoxy, R = CO_2R''

Results and discussion

Preparation of the 6-methyl-5-ester **15** began with the known pyrrole **4** (5) and is outlined in Scheme 1. The pyrrole was converted to its *N*-amino derivative (**6**) by treatment with sodium hydride and monochloramine (6). Cyclization of **6** in hot formamide to the pyrrolotriazine-4-one (**8**) was followed by treatment with $POCl_3$ in refluxing toluene to give the 4-chloropyrrolotriazine (**10**). The 1-(3-fluorobenzyl)-1*H*-indazol-5-amino group was chosen as the lipohilic C-4 substituent and was introduced by reaction of **10** with **13** in the presence of base. The resulting methyl ester **14** was then converted to the ethyl ester **15** to enable a direct comparison of its biological activity with that of the transposed ethyl ester analogue (**17**).



Scheme 2.

The preparation of 6-alkoxy pyrrolotriazine analogs **3** required access to pyrroles that have an alkoxy group at C-4, e.g., **5**. A novel synthesis of such pyrroles has been reported (7) and is outlined in Scheme 2. The readily available N-Boc derivatives of α-amino acid esters **18** were found to react with dimethyl acetylenedicarboxylate and triphenylphosphine to give 3-pyrrolines **20** by way of the stabilized ylide **19**. These pyrrolines were isolated and then could be oxidized to pyrroles **21** by heating with DDQ. We explored the potential one-pot version of this procedure that is outlined in Scheme 3. It was thought that the *N*-tosyl derivative of α-amino acid esters **22** would similarly react with triphenyl phosphine and an acetylenedicarboxylate to form pyrrolines **23** that could be treated directly with base to eliminate toluenesulfinic acid and give the desired pyrroles **24**. A similar base-promoted elimination of toluenesulfinic acid from a *N*-tosyl pyrroline intermediate has been reported (8) to generate the corresponding pyrrole.

Table 2. EGFR and HER2 kinase inhibition.

	IC_{50} (μmol/L)[a,b]	
Compound	EGFR	HER2
15	0.31	0.20
16	>1	>1
17	0.47	0.63

[a]Recombinant HER2 cytoplasmic sequence is expressed in Sf9 insect cells as an untagged protein and purified by ion-exchange chromatography. HER2 kinase activity is measured under the same conditions as for EGFR. See refs. 3 and 9 for assay conditions.

[b]IC_{50} values are reported as the mean of at least three determinations. Variability around the mean value was <15%.

The proposed reaction was examined with toluenesulfonamide derivatives of α-amino acid esters of glycine, alanine, phenylglycine, and α-amino butyrolactone (**22a**–**22d**, Table 1, entries 1–5) that were prepared from commercially available material by the Fischer esterification of *N*-tosyl amino acids or by treatment of the α-amino acid esters or lactone with *p*-toluenesulfonyl chloride in the presence of base. The derivatives were indeed found to react with diethyl acetylenedicarboxylate and triphenyl phosphine in refluxing dioxane to give the *N*-tosyl pyrroline intermediates **23** (confirmed by LC–MS analysis of the reaction mixture). DBU was then added and the reaction was heating at 90 °C to effect the elimination of toluenesulfinic acid. Good yields (82% to 54%) of the pyrroles **5** and **24a** to **24c** were obtained. A low yield (7%) of the fused furopyrrole **24d** was obtained. LC–MS analysis of the initial cyclization reaction mixture indicated the presence of the desired furopyrroline **23e** together with other products that were not isolated or identified. In this case, competing side reactions are most likely seen because of the additional strain that is encountered in the transition state that leads to **23e**.

To further explore the scope of this reaction, the sulfonamide derivatives of some alkyl and aryl α-aminoketones (**22f**–**22h**) were prepared and examined as substrates (Table 1, entries 6–8). Good yields (94% to 71%) of the pyrroles **24e**–**24g** were obtained in all cases.

With a convenient synthesis of 4-alkoxy pyrrole-2,3-dicarboxylic acid diesters in hand, an example of a pyrrolotriazine 5-ester with an alkoxy group at C-6 was made. The 6-methoxy pyrrolotriazine (**16**) was prepared from **5** using the same sequence of reactions that were used to make **15** (Scheme 1): N-amination of pyrrole **5**; cyclization of **7** in formamide; formation of the chloroimidate **9**; and final attachment of the 1-(3-fluorobenzyl)-1*H*-indazol-5-amino side chain. The 6-ester analogue (**17**) was made for comparison purposes from the known (4) 4-chloropyrrolotriazine intermediate (**12**).

Data for the inhibition of the EGFR and HER2 kinases by **15**–**17** is show in Table 2. The directly transposed analogue (**15**) was found to be at least as potent a dual kinase inhibitor as **17**, while the 6-ether analogue (**16**) was less potent. Since the 5-ester group in **15** is well-suited for functional group modifications that could improve biochemical potency and cellular activity, **15** became the focus of further structure activity and lead optimization studies. These results will be reported in the future.

Experimental section

Methyl 6-methyl-4-oxo-3,4-dihydropyrrolo[1,2-*f*][1,2,4]-triazine-5-carboxylate (8)

A mixture of dimethyl 4-methyl-1*H*-pyrrole-2,3-dicarboxylate (5) (**4**, 1.0 g, 5.1 mmol) and NaH (236 mg, 60% dispersion in oil, 1.3 equiv.) in dry DMF (2 mL) was stirred at room temperature for 30 min. A solution of monochloramine (6) (66 mL, 0.1 mol/L in diethyl ether, 1.3 equiv.) was added with vigorous stirring. After 2 h, the reaction was cooled in an ice-water bath and an aqueous solution of $Na_2S_2O_3$ (20 mL, 1.0 N) was added with stirring. This was diluted with water (200 mL) and extracted with EtOAc (3 × 200 mL). The combined organic extracts were washed with brine and dried (Na_2SO_4). Removal of the solvent followed by silica gel column chromatography (gradient elution with mixtures of hexane containing 0%– 50% EtOAc) afforded dimethyl 1-amino-4-methyl-1*H*-pyrrole-2,3-dicarboxylate (**6**, 845 mg, 79% yield) as an oil. ^{1}H NMR (MeOH-d_4, 500 MHz, ppm) δ: 2.08 (s, 3H), 3.78 (s, 3H), 3.82 (s, 3H), 6.69 (s, 1H). A suspension of **6** (805 mg, 3.80 mmol) in formamide (8 mL) was heated at 170 °C for 2 h under a N_2 atmosphere. After cooling to room tempera-

© 2006 NRC Canada

ture, this was poured into water (20 mL) and left stirring overnight. The product was collect by filtration, washed with water and Et_2O, and then dried (590 mg, 75%). ^{1}H NMR (MeOH-d_4, 300 MHz, ppm) δ: 2.30 (s, 3H), 3.87 (s, 3H), 7.32 (s, 1H), 7.72 (s, 1H). HPLC purity: 93%. MS (ESI) *m*/*z*: 208 (M + H).

Methyl 4-(1-(3-fluorobenzyl)-1*H*-indazol-5-ylamino)-6-methylpyrrolo[1,2-*f*][1,2,4]triazine-5-carboxylate (14)

A mixture of methyl 6-methyl-4-oxo-3,4-dihydropyrrolo-[1,2-*f*][1,2,4]triazine-5-carboxylate (**8**, 1.00 g, 4.83 mmol), $POCl_3$ (0.54 mL, 1.2 equiv.) and diisopropylethylamine (0.67 mL, 0.8 equiv.) in dry toluene (15 mL) was heated at reflux for 5 h. After cooling to room temperature, the reaction was poured into a saturated aqueous solution of $NaHCO_3$ with vigorous stirring. The organic phase was separated, washed with additional satd. aq. $NaHCO_3$ solution and dried (Na_2SO_4). Removal of the solvent followed by silica gel chromatography (elution with dichloromethane) afforded methyl 4-chloro-6-methylpyrrolo[1,2-*f*][1,2,4]-triazine-5-carboxylate (**10**, 777 mg, 72%) as a solid. ^{1}H NMR ($CDCl_3$, 500 MHz, ppm) δ: 2.45 (s, 3H), 3.95 (s, 3H), 7.68 (s, 1H), 8.26 (s, 1H). MS (ESI) *m*/*z* 226 (M + H). A mixture of **10** (1.29 g, 5.06 mmol), 1-(3-fluorobenzyl)-1*H*-indazol-5-amine (**13**, 1.46 g, 1.2 equiv.) and $NaHCO_3$ (2.13 g, 5 equiv.) in dry CH_3CN (50 mL) was left stirring at room temperature for 4 h. The product was collected by filtration, washed with water, and dried (2.06 g, 95%). ^{1}H NMR ($CDCl_3$, 300 MHz, ppm) δ: 2.43 (s, 3H), 3.97 (s, 3H), 5.59 (s, 2H), 6.95 (m, 3H), 7.34 (m, 3H) 7.65 (m, 1H), 8.06 (s, 2H), 8.40 (s, 1H). MS (ESI) *m*/*z*: 431 (M + H). HRMS (ESI) calcd. for $C_{23}H_{20}N_6O_2F$: 431.1737; found: 461.1653.

Ethyl 4-(1-(3-fluorobenzyl)-1*H*-indazol-5-ylamino)-6-methylpyrrolo[1,2-*f*][1,2,4]triazine-5-carboxylate (15)

Transesterification (EtOH, K_2CO_3) of **14** gave the product: ^{1}H NMR ($CDCl_3$, 500 MHz) (ppm) δ: 1.44 (t, *J* = 7 Hz, 3H), 4.42 (q, *J* = 7 Hz, 2H), 5.58 (s, 2H), 6.85 (m, 1H), 6.94 (m, 2H), 7.27 (m, 3H), 7.63 (m, 1H), 8.05 (s, 2H), 8.39 (s, 1H). 7.65 (m, 1H), 8.06 (s, 2H), 8.40 (s, 1H). MS (ESI) *m*/*z*: 445 (M + H). HRMS (ESI) for $C_{24}H_{22}N_6O_2F$ calcd.: 445.1788; found: 445.1778.

2-Methoxyethyl 2-(4-methylphenylsulfonamido)acetate (22b)

A mixture of 2-(4-methylphenylsulfonamido)acetic acid (5.0 g, 21.8 mmol), 2-methoxyethanol (10.0 g, 6 equiv.), and *p*-toluenesulfonic acid (0.2 g, 0.05 equiv.) in xylene (50 mL) was heated at 150 °C for 10 h. After cooling to room temperature, this was washed with satd. aq. $NaHCO_3$ solution and dried (Na_2SO_4). Removal of the solvent followed by silica gel chromatography (step gradient elution with mixtures of hexane containing 5%–30% EtOAc) afforded the product as an oil (5.3 g, 84%). ^{1}H NMR ($CDCl_3$, 300 MHz, ppm) δ: 2.37 (s, 3H), 3.28 (s, 3H), 3.47 (t, *J* = 4.5 Hz, 2H), 3.76 (d, *J* = 5.4 Hz, 2H), 4.12 (t, *J* = 4.5 Hz, 2H), 5.38 (m, 1H), 7.26 (d, *J* = 8.1 Hz, 2H), 7.70 (d, *J* = 8.1 Hz, 2H). HPLC purity: 92%. MS (ESI) *m*/*z*: 320 (M + H).

Methyl 2-(4-methylphenylsulfonamido)propanoate (22c)

Triethylamine (1.53 mL, 2 equiv.) was added dropwise to an ice-cooled mixture of DL-alanine methyl ester hydrochloride (768 mg, 5.5 mmol) and toluenesulfonyl chloride (1.05 g, 1 equiv.) in dry dichloromethane (12 mL). After 1 h, the bath was removed and after a further 2 h, the reaction was filtered. The filtrate was washed with water, dried (Na_2SO_4), and the solvent removed. This left the crude product as an oil (1.26 g). ^{1}H NMR ($CDCl_3$, 500 MHz, ppm) δ: 1.35 (d, 3H, *J* = 7 Hz), 2.39 (s, 3H), 3.51 (s, 3H), 3.96 (m, 1H), 5.33 (d, *J* = 8.5 Hz, 1H), 7.27 (d, *J* = 8.0 Hz, 2H), 7.70 (d, *J* = 8.0 Hz, 2H). HPLC purity: 93%. MS (ESI) *m*/*z*: 228 (M + H).

(*S*)-Methyl 2-(4-methylphenylsulfonamido)-2-phenylacetate (22d)

Similarly, (*S*)-(+)-phenylglycine methyl ester hydrochloride was converted to the product. ^{1}H NMR ($CDCl_3$, 500 MHz, ppm) δ: 2.38 (s, 3H), 3.56 (s, 3H), 5.05 (d, *J* = 8 Hz, 1H), 5.63 (d, *J* = 8 Hz, 1H), 7.24 (m, 7H), 7.62 (d, *J* = 8.0 Hz, 2H). HPLC purity: 92%. MS (ESI) *m*/*z*: 320 (M + H).

4-Methyl-*N*-(2-oxo-tetrahydrofuran-3-yl)benzenesulfonamide (22e)

Similarly, 3-amino-dihydrofuran-2(3*H*)-one hydrobromide was converted to the product. ^{1}H NMR ($CDCl_3$, 500 MHz, ppm) δ: 2.29 (m, 1H), 2.43 (s, 3H), 2.70 (m, 1H), 3.89 (m, 1H), 4.18 (m, 1H), 4.20 (t, *J* = 9.0 Hz, 1H), 5.15 (m, 1H), 7.32 (d, *J* = 8.5 Hz, 2H), 7.78 (d, *J*= 8.5 Hz, 2H). HPLC purity: 90%. MS (ESI) *m*/*z*: 256 (M + H).

1-(4-Methoxyphenyl)-2-(4-methylphenylsulfonamido)-ethanone (22f)

Similarly, 2-amino-1-(4-methoxyphenyl)ethanone hydrochloride was converted to the product (solid). ^{1}H NMR ($CDCl_3$, 300 MHz, ppm) δ: 2.38 (s, 3H), 3.85 (s, 3H), 4.38 (d, 2H, (d, 1H, *J* = 4.5 Hz), 5.66 (m, 1H), 6.91 (d, 2H), 7.26 (d, 2H), 7.79 (m, 4H). HPLC purity: 90%. MS (ESI) *m*/*z*: 320 (M + H).

4-Methyl-*N*-(2-oxopropyl)benzenesulfonamide (22g)

Tetrapropylammonium perruthenate (70 mg, 0.1 equiv.) was added to a stirred suspension of *N*-(2-hydroxypropyl)-4-methylbenzenesulfonamide (458 mg, 2.0 mmol), *N*-methylmorpholine *N*-oxide (35 mg, 1.5 equiv.), and powdered, dry 4 Å molecular sieves (1.6 g) in dry CH_3CN. After 20 min, the CH_3CN was removed under vacuum and the residue was dissolved in dichloromethane and filtered through a short pad of silica gel. The solvent was removed from the filtrate and the product was isolated by radial silica gel chromatography (step gradient elution with mixtures of hexane containing 0%–30% ethyl acetate) as a solid (159 mg, 35%). ^{1}H NMR ($CDCl_3$, 500 MHz, ppm) δ: 2.09 (s, 3H), 2.39 (s, 3H), 3.83 (d, *J* = 5 Hz, 2H), 5.35 (m, 1H), 7.28 (d, *J* = 8.0 Hz, 2H), 7.71 (d, *J* = 8.0 Hz, 2H). HPLC purity: 84%. MS (ESI) *m*/*z*: 228 (M + H).

Methyl 5-(4-methylphenylsulfonamido)-4-oxopentanoate (22h)

Methyl 5-amino-4-oxopentanoate hydrochloride was converted to the product as described for **22c**. ^{1}H NMR ($CDCl_3$, 500 MHz, ppm) δ: 2.41 (s, 3H), 2.60 (m, 4H), 3.62 (s, 3H), 2.89 (d, *J* = 5 Hz, 2H), 5.30 (m, 1H), 7. 28 (d, *J* = 8.0 Hz,

© 2006 NRC Canada

2H), 7.71 (d, *J* = 8.0 Hz, 2H). HPLC purity: 93%. MS (ESI) *m*/*z*: 300 (M + H).

General procedure for the preparation of 5 and 24a–24g

A mixture of the sulfonamide (**22a**–**22h**) (1.0 equiv.) and triphenylphosphine (1.25 equiv.) in dry dioxane (0.5 mol/L) under a N_2 atmosphere was cooled in an ice-water bath. Diethyl acetylenedicarboxylate (1.2 equiv.) was added dropwise over 5 min and the bath was removed. After 1 h, the reaction was brought to reflux and left heating overnight. The temperature was reduced to 90 °C and DBU (2.0 equiv.) was added. After 2 h, the solvent was removed and the product was isolated by silica gel column chromatography eluting with mixtures of hexane containing 0%–25% ethyl acetate.

Diethyl 4-methoxy-1*H*-pyrrole-2,3-dicarboxylate (5)

^{1}H NMR (300 MHz, $CDCl_3$, ppm) δ: 1.28 (m, 6H), 3.71 (m, 3H), 4.28 (m, 4H), 6.43 (d, *J* = 2.93 Hz, 1H), 9.58 (s, 1H). ^{13}C NMR (125 MHz, $CDCl_3$, ppm) δ: 164.2, 160.4, 148.5, 119.4, 109.9, 104.1, 61.1, 61.0, 58.7, 14.3. HRMS (ESI) calcd. for $C_{11}H_{14}NO_5$: 240.0872; found: 240.0875.

Diethyl 4-(2-methoxyethoxy)-1*H*-pyrrole-2,3-dicarboxylate (24a)

^{1}H NMR (500 MHz, $CDCl_3$, ppm) δ: 1.24 (t, *J* = 7.2 Hz, 3H), 1.27 (t, *J* = 7.2 Hz, 3H), 3.34 (s, 3H), 3.61 (m, 2H), 3.95 (m, 2H), 4.24 (m, 4H), 6.45 (d, *J* = 3.1 Hz, 1H), 9.69 (s, 1 H). ^{13}C NMR (125 MHz, $CDCl_3$, ppm) δ: 164.3, 160.4, 146.9, 119.1, 110.9, 106.7, 71.7, 71.1, 60.9, 60.4, 59.5, 14.2, 14.0. HRMS (ESI) calcd. for $C_{13}H_{19}NO_6$: 285.1134; found: 284.1131.

Diethyl 4-methoxy-5-methyl-1*H*-pyrrole-2,3-dicarboxylate (24b)

^{1}H NMR (500 MHz, $CDCl_3$, ppm) δ: 1.31 (t, *J* = 7.2 Hz, 3H), 1.35 (t, *J* = 7.2 Hz, 3H), 2.20 (s, 3H), 3.77 (s, 3H), 4.28 (q, *J* = 7.1 Hz, 2H), 4.33 (q, *J* = 7.2 Hz, 2H), 9.42 (s, 1H). ^{13}C NMR (125 MHz, $CDCl_3$, ppm) δ: 164.9, 161.0, 143.5, 122.8, 115.4, 114.1, 62.7, 61.0, 60.8, 14.3, 14.2, 9.5. HRMS (ESI) calcd. for $C_{12}H_{16}NO_5$: 254.1028; found: 254.1021.

Diethyl 4-methoxy-5-phenyl-1*H*-pyrrole-2,3-dicarboxylate (24c)

^{1}H NMR (500 MHz, $CDCl_3$, ppm) δ: 1.33 (t, *J* = 7.2 Hz, 3H), 1.39 (t, *J* = 7.2 Hz, 3H), 3.79 (s, 3H), 4.32 (q, *J* = 7.1 Hz, 2H), 4.39 (q, *J* = 7.0 Hz, 2H), 7.31 (t, *J* = 7.3 Hz, 1H), 7.42 (t, *J* = 7.8 Hz, 2H), 7.69 (d, *J* = 7.7 Hz, 2H), 9.18 (s, 1 H). ^{13}C NMR (125 MHz, $CDCl_3$, ppm) δ: 164.7, 160.8, 143.8, 129.8, 128.9, 127.8, 125.9, 124.7, 117.4, 115.4, 62.2, 61.3, 61.2, 14.3, 14.2. HRMS (ESI) calcd. for $C_{17}H_{18}NO_5$: 316.1185; found: 316.1179.

Diethyl 3,4-dihydro-2*H*-*furo*[3,2-*b*]pyrrole-5,6-dicarboxylate (24d)

^{1}H NMR (500 MHz, $CDCl_3$, ppm) δ: 1.35 (m, 6H), 3.12 (t, *J* = 8.4 Hz, 2H), 4.32 (m, 4H), 4.96 (t, *J* = 8.2 Hz, 2H), 9.20 (s, 1H). ^{13}C NMR (125 MHz, $CDCl_3$, ppm) δ: 162.7, 160.3, 153.3, 122.3, 121.6, 103.9, 78.4, 61.0, 60.7, 26.2, 14.4, 14.3. HRMS (ESI) calcd. for $C_{12}H_{16}NO_5$: 254.1029; found: 254.1038.

Diethyl 4-(4-methoxyphenyl)-1*H*-pyrrole-2,3-dicarboxylate (24e)

^{1}H NMR (500 MHz, $CDCl_3$, ppm) δ: 1.28 (t, *J* = 7.2 Hz, 3H), 1.34 (t, *J* = 7.2 Hz, 3H), 3.80 (s, 3H), 4.32 (m, 4H), 6.88 (m, 2H), 6.94 (d, *J* = 3.1 Hz, 1H), 7.32 (m, 2H), 9.33 (s, 1H). ^{13}C NMR (125 MHz, $CDCl_3$, ppm) δ: 166.8, 160.4, 158.8, 128.8, 126.3, 125.8, 121.3, 120.4, 120.0, 114.1, 61.4, 61.0, 55.3, 14.3, 14.2. HRMS (ESI) calcd. for $C_{17}H_{19}NO_5$: 316.1185; found: 316.1178.

Diethyl 4-methyl-1*H*-pyrrole-2,3-dicarboxylate (24f)

^{1}H NMR (500 MHz, $CDCl_3$, ppm) δ: 1.29 (t, *J* = 7.2 Hz, 3H), 1.33 (t, *J* = 7.0 Hz, 3H), 2.12 (s, 3H), 4.27 (m, 2H), 4.31 (m, 2H), 6.63 (d, *J* = 2.8 Hz, 1H), 9.55 (s, 1H). ^{13}C NMR (125 MHz, $CDCl_3$, ppm) δ: 165.8, 160.5, 122.1, 121.9, 120.7, 120.5, 60.9, 60.7, 14.3, 14.2, 10.9. HRMS (ESI) calcd. for $C_{11}H_{15}NO_4$: 224.0922; found: 224.0913.

Diethyl 4-(3-methoxy-3-oxopropyl)-1*H*-pyrrole-2,3-dicarboxylate (24g)

^{1}H NMR (500 MHz, $CDCl_3$, ppm) δ: 1.25 (t, *J* = 7.0 Hz, 3H), 1.30 (t, *J* = 7.0 Hz, 3H), 2.53 (t, *J* = 7.5 Hz, 3H), 2.83 (t, *J* = 7.63 Hz, 2H), 3.58 (s, 3H), 4.26 (m, 4H), 9.83 (s, 1H). ^{13}C NMR (125 MHz, $CDCl_3$, ppm) δ: 173.6, 165.5, 160.4, 125.1, 122.1, 120.4, 119.9, 60.9, 60.8, 51.6, 35.1, 21.2, 14.3, 14.2. HRMS (ESI) calcd. for $C_{14}H_{19}NO_6$: 298.1291; found: 298.1277.

Ethyl 6-methoxy-4-oxo-3,4-dihydropyrrolo[1,2-*f*][1,2,4]-triazine-5-carboxylate (9)

A solution of diethyl 4-methoxy-1*H*-pyrrole-2,3-dicarboxylate (**5**, 2.48 g, 10.3 mmol) in dry CH_3CN (10 mL) was added to an ice-cooled suspension of NaH (535 mg, 60% dispersion in oil, 1.3 equiv.) in dry dimethyl formamide (20 mL) over 3 min. The bath was removed and the reaction was left stirring for 1 h after which it was cooled in an ice bath. A solution of monochloramine (135 mL, 0.1 mol/L in diethyl ether, 1.3 equiv.) was added with vigorous stirring. After 30 min, the bath was removed and the reaction was left stirring for 1.5 h. It was then cooled in an ice-water bath and worked up as described for **6**. Silica gel column chromatography (gradient elution with mixtures of hexane containing 0%–25% ethyl acetate) afforded diethyl 1-amino-4-methoxy-1*H*-pyrrole-2,3-dicarboxylate (**7**) as an oil (1.53 g, 58% yield). ^{1}H NMR ($CDCl_3$, 300 MHz, ppm) δ: 1.30 (m, 6H), 3.70 (s, 3H), 4.27 (m, 4H), 5.4 (br s, 2H), 6.47 (s, 1H). MS (ESI) *m*/*z*: 257 (M + H). A suspension of **7** (880 mg, 3.44 mmol) in formamide (5 mL) was heated at 170 °C for 4 h under a N_2 atmosphere. This was worked up as described for **8** to give the product (514 mg, 63%) as a solid. ^{1}H NMR (300 MHz, DMSO-d_6, ppm) δ: 1.25 (t, *J* = 7.2 Hz, 3H), 3.76 (s, 3H), 4.20 (q, *J* = 7.2 Hz, 2H), 7.44 (s, 1H), 7.91 (s, 1H). MS (ESI) *m*/*z*: 238 (M + H). HRMS (ESI) calcd. for $C_{10}H_{12}N_3O$: 238.0828; found: 238.0824.

Ethyl 4-(1-(3-fluorobenzyl)-1*H*-indazol-5-ylamino)-6-methoxypyrrolo[1,2-*f*][1,2,4]triazine-5-carboxylate (16)

A mixture of **9** (887 mg, 3.37 mmol), $POCl_3$ (0.79 mL, 1.5 equiv.), and diisopropylethylamine (0.59 mL, 1.0 equiv.) in dry toluene (12 mL) was heated at reflux for 5 h and then worked up as described for **10**. Silica gel radial chromatography (elution with DCM) afforded ethyl 4-chloro-6-

© 2006 NRC Canada

methoxypyrrolo[1,2-*f*][1,2,4]triazine-5-carboxylate (**11**, 458 mg, 53%) as a solid. MS (ESI) *m*/*z*: 256 (M + H). HRMS (ESI) calcd. for $C_{10}H_{11}N_3O_3Cl$: 256.0489; found: 256.0496. A mixture of **11** (1.30 g, 5.10 mmol), 1-(3-fluorobenzyl)-1*H*-indazol-5-amine (**13**, 1.25 g, 1.05 equiv.), and diisopropylethylamine (1.07 mL, 1.2 equiv.) in dry CH_3CN (45 mL) was heated at 70 °C overnight. The product was collected by filtration, washed with CH_3CN, and dried (2.15 g, 92%). ^{1}H NMR (300 MHz, $CDCl_3$, ppm) δ: 1.43 (t, *J* = 6.9 Hz, 3H), 3.89 (s, 3H), 4.42 (q, *J* = 6.9 Hz, 2H), 5.57 (s, 2H), 6.84 (m, 1H), 6.94 (m, 2H), 7.14 (s, 1H), 7.26 (m, 2H) 7.60 (m, 1H), 8.04 (s, 1H), 8.08 (s, 1H), 8.38 (m, 1H). MS (ESI) *m*/*z*: 461 (M + H). HRMS (ESI) calcd. for $C_{24}H_{22}N_6O_3F$: 461.1737; found: 461.1726.

Ethyl 4-[1-(3-fluoro-benzyl)-1*H*-indazol-5-ylamino]-5-methyl-pyrrolo[2,1-*f*][1,2,4]triazine-6-carboxylate (17)

A 2 L three-neck flask was charged with ethyl 4-chloro-5-methyl-pyrrolo[2,1-*f*][1,2,4]triazine-6-carboxylate (4) (**12**, 54.0 g, 226 mmol) and acetonitrile (500 mL). To the resulting suspension was added 1-(3-fluoro-benzyl)-1*H*-indazol-5-ylamine (**13**, 54.5 g, 226 mmol) and diisopropylethyl amine (21.7 g, 214.7 mmol). The reaction was heated to 55 °C and became homogeneous after 10 min. After 18 h, it was cooled to 10 °C and filtered. The filter cake was washed with cold acetonitrile (2 × 250 mL) and dried under vacuum to afford the product as a white crystalline solid (76.3 g, 76%). ^{1}H NMR (500 MHz, $CDCl_3$, ppm) δ: 1.39 (t, *J* = 7.2 Hz, 3H), 2.93 (s, 3H), 4.35 (q, *J* = 7.2 Hz, 2H), 5.59 (s, 2H), 6.86 (d, *J* = 9.3 Hz, 1H), 6.97 (m, 2H), 7.26 (ddd, *J* = 6.04, 8.24, 14.29 Hz, 1H), 7.35 (d, 1H, *J* = 8.80 Hz), 7.42 (br s, 1H), 7.49 (dd, 1H, *J* = 1.65, 8.80 Hz), 7.91 (s, 1H), 8.00 (s, 1H), 8.07 (s, 1H), 8.09 (s, 1H). ^{13}C NMR (125 MHz, $CDCl_3$, ppm) δ: 164.5, 163.0 (d, *J* = 246 Hz), 154.9, 148.5, 139.1 (d, *J* = 5 Hz), 137.6, 133.8, 130.3, 131.2 (d, *J* = 7 Hz), 124.6, 123.5, 122.7, 121.9 (2C), 115.4, 115.3, 114.8 (d, *J* = 20 Hz), 114.1 (d, *J* = 22 Hz), 113.4, 109.7, 60.2, 52.6, 14.4, 11.9. MS (ESI) *m*/*z*: 444 $(M + H)^+$. HRMS (ESI) calcd. for $C_{24}H_{22}FN_6O_2$: 445.171; found: 445.1805. Anal calcd. for $C_{24}H_{21}FN_6O_2$: C 64.85, H 4.76, N 18.90; found: C 64.62, H 4.73, N 18.85.

Conclusion

In summary, pyrrolotriazine analogs with an ester function at C-5 were made and evaluated as dual inhibitors of EGFR and HER2 kinases. The 5-ester 6-methyl analog (**15**) showed kinase inhibition that was at least comparable to that seen for the 6-ester 5-methyl analogue (**17**). It became the focus of further structure activity and lead optimization studies and these results will be reported in the future. In addition, a general, one-pot procedure for the synthesis of C-4 substituted pyrrole-2,3-diesters from readily available *N*-tosyl derivatives of α-amino acid esters and α-amino ketones was developed.

Synthesis of 8-homocastanospermine[1]

Konrad Paśniczek, Dariusz Socha, Margarita Jurczak, Jolanta Solecka, and Marek Chmielewski

Abstract: The 1,3-dipolar cycloaddition of a five-membered cyclic nitrone derived from malic acid (**4**) and unsaturated D-*threo*-hexaldonolactone (**1**) leads to a single adduct **6**, which can be transformed into the 8-homocastanospermine (**13**) via a sequence involving rearrangement of the six-membered lactone ring into the five-membered one, removal of the terminal carbon atom from the sugar chain, cleavage of the N—O bond, and the intramolecular alkylation of the nitrogen atom. The iminosugar (**13**) does not show any interesting inhibitory activity towards α- and β-glucosidases.

Key words: iminosugars, homocastanospermine, nitrones, aldono-1,5-lactone, 1,3-dipolar cycloaddition, glucosidases.

Résumé : La cycloaddition 1,3-dipolaire d'une nitrone cyclique à cinq chaînons dérivée de l'acide malique (**4**) et de la D-*thréo*-hexaldonolactone insaturée (**1**) conduit à la formation d'un seul adduit qui peut être transformé en 8-homocastanospermine (**13**), par le biais d'une séquence impliquant le réarrangement de la lactone à six chaînons en une lactone à cinq chaînons, l'élimination de l'atome de carbone terminal de la chaîne du sucre, le clivage de la liaison N—O et d'une alkylation intramoléculaire de l'atome d'azote. L'iminosucre (**13**) ne présente pas d'activité inhibitrice intéressante vis-à-vis des α- et des β-glucosidases.

Mots clés : iminosucres, homocatanospermine, nitrones, aldono-1,5-lactone, cycloaddition 1,3-dipolaire, glucosidases.

[Traduit par la Rédaction]

Introduction

Recently, we have reported that the cycloaddition of 2,3-unsaturated aldono-1,5-lactones (**1** or **2**) and the five-membered cyclic nitrones (**3** or **4**) (Chart 1) proceeds exclusively in the exo mode and results in a high preference for the anti addition to both the acetoxymethyl group of the lactone and the 3-*tert*-butoxy group of the nitrone (1–3). In the case of mismatched pairs, the 4-acetoxy group of the lactone assumes a decisive role in the control of the stereochemical pathway of cycloaddition. The stereochemical preferences are the underlying reason that, in many cases, a single adduct or at least a high preponderance of a single adduct is observed. This observation has been well-illustrated by the exclusive formation of adducts **6** and **7** from D-*threo* 4-*O*-acetyl-lactone (**1**) and D-*erythro* 4-*O*-acetyl-lactone (**2**), respectively (Chart 2) (3).

We have shown that application of the known methodology (4) to cycloadduct **8** offers a convenient approach to the indolizidine alkaloids. This has been demonstrated by the synthesis of 7-hydroxylentiginosine (**9**) and the formal synthesis of lentiginosine (**10**) (5). The easy access to adducts **6** and **7** opens an entry to the corresponding indolizidines with an (*R*) or (*S*) configurations at the bridgehead carbon atom, which are closely related to the castanospermine (**11**) and swainsonine (**12**) (Chart 3) (6).

Both components of the cycloaddition, the nitrone and the unsaturated lactone, carry over their own substituents (protected hydroxyls) with their original configuration, whereas the configurations at C-1a, C-4a, and C-4b of the cycloadduct are established during the reaction. Adduct **6** is particularly interesting because it can be easily transformed into the compounds related to the castanospermine (**11**) and especially the 8-homocastanospermine (**13**). The castanospermine (**11**) (7) itself displays a range of interesting therapeutic properties (8), however, it is very toxic, therefore its use has a limited value. The present paper describes the synthesis of imino sugar **13** from adduct **6**.

Results and discussion

Adduct **6** (2, 3) was deacetylated with sodium methoxide in methanol to afford compound **14**. The reaction proceeds with rearrangement of the six-membered lactone ring into a five-membered one. The glycolic cleavage of the terminal diol group in **14** with $NaIO_4$ followed by the reduction of the aldehyde group with sodium triacetoxyborohydride gave compound **16** in 83% yield. The use of sodium borohydride resulted in the reduction of both carbonyl functions of the aldehyde **15**, whereas the sodium cyanoborohydride gave the desired product **16** in a low yield (Scheme 1).

The activation of the terminal hydroxymethyl group by the introduction of a halogen or sulfonyl as a leaving group, followed by the direct alkylation of the isoxazolidine nitrogen atom, led to an unattractive mixture of products. Therefore, we decided to form the indolizidine skeleton in a stepwise manner. First, the hydroxymethyl group was pro-

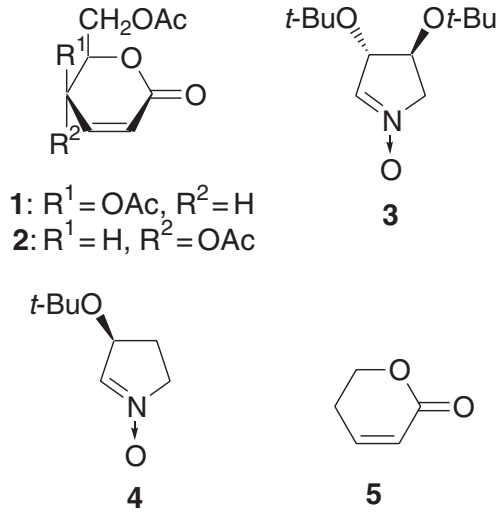

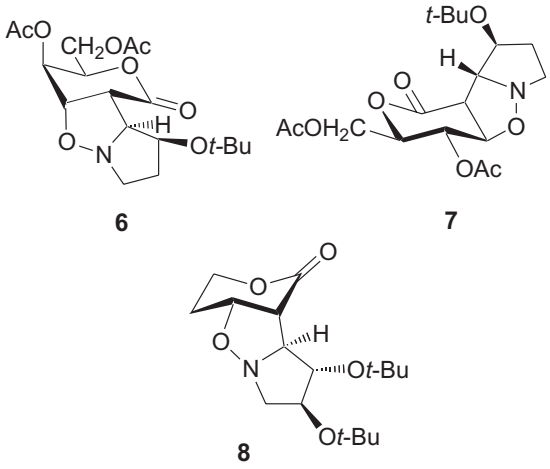

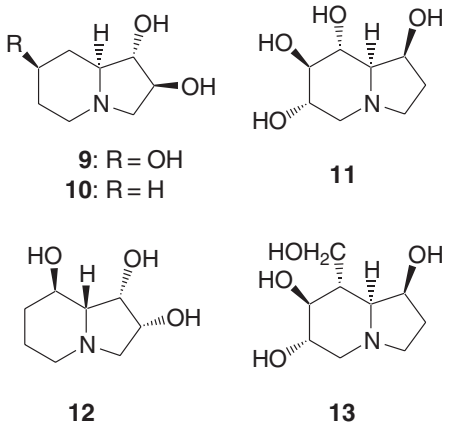

Chart 2.

tected as a *tert*-butyldiphenylsilyl derivative **17** and lactone was reduced with sodium borohydride to give diol **18**. Both hydroxy groups in **18** were masked by the formation of an isopropylidene moiety. The desilylation of **19** with tetrabutylammonium fluoride led to alcohol **20**. Due to the low stability of the isopropylidene fragment and the tendency of the terminal mesyloxymethyl group to undergo intramolecular alkylation, the next three steps were performed with only a partial purification of intermediary products. Alcohol **20** was mesylated to afford **21**, the isopropylidene protection was removed using 80% acetic acid, and the sequence was completed by the hydrogenolysis of the N—O bond over Pd/C and intramolecular alkylation of the nitrogen atom. The final product of this reaction sequence (indolizidine **22**) was acetylated and characterized as the triacetate **23**. The *tert*-butyl protection in **23** was subsequently removed with trifluoroacetic acid and the liberated hydroxy group was acetylated affording tetraacetate **24**. The complete deacetylation of **24** with ammonia in methanol furnished the **13**. Synthesis of a number of 8-hydroxymethylindolizidines using intramolecular 1,3-dipolar cycloaddition has been reported recently by Brandi's group (9).

Chart 3.

Note that the oxidation of the hydroxymethyl group in suitably protected **13** or **23** to the carboxylic function followed by an oxidative decarboxylation, for example, by the methodology recently reported by us for the other indolizidine (5), should provide **11**.

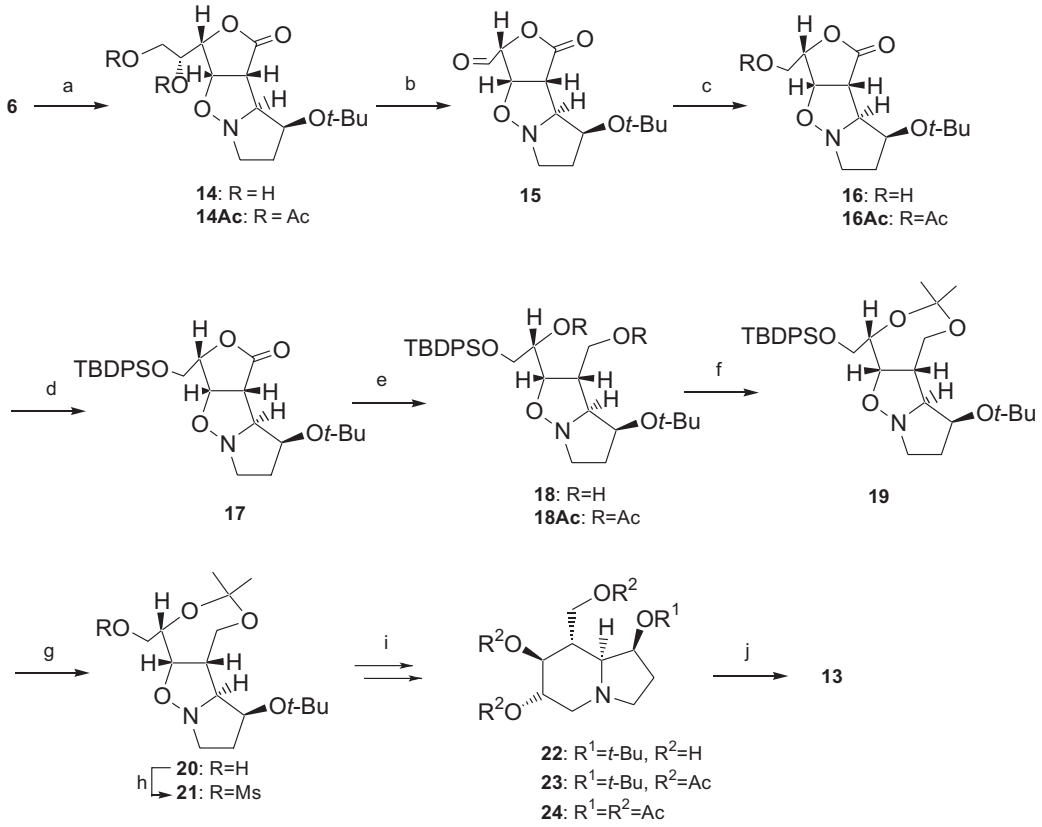
The biological activity of compound **13** toward commercially available α- and β-glucosidases was tested and compared with the corresponding data measured for commercially available **11**. Surprisingly, compound **13** showed only a trace inhibition of α-glucosidase activity in a concentration of 0.02 mol/L and no inhibition of β-glucosidase.

In summary, we have reported the simple synthesis of 8-homocastanospermine (**13**) in which a proper selection of readily available components of the 1,3-dipolar cycloaddition controls the absolute stereochemistry at all five stereogenic centers present in the target molecule. The reported synthesis demonstrated an exceptional effectiveness of the 1,3-dipolar cycloaddition of nitrones and sugar unsaturated δ-lactones, which led to formation of only one diastereomer with a fully defined configuration at all stereogenic centers.

Experimental

^{1}H NMR spectra were recorded on a Bruker DRX 500 Avance spectrometer. IR spectra were obtained on a PerkinElmer FT-IR 1600 spectrophotometer. The optical rotations were measured with a JASCO Dip-360 digital polarimeter. Mass spectra were recorded using an AMD-604 instrument and HPLC–MS were recorded with Mariner and API 356 detectors. Column chromatography was performed with E. Merck Kiesel Gel (230–400 mesh).

Adduct **6** was obtained according to the known procedure (2, 3).



Enzymes and substrates were purchased from Sigma-Aldrich: α-glucosidase from rice, type V, 63.43 U/mg, 1.34 mg/mL; β-glucosidase from almonds, 25.8 U/mg, 95.4% protein.

(1a*S*,2*R*,4a*R*,4b*S*,5*S*,1′*R*)-5-*tert*-Butoxy-2-(1′,2′-dihydroxyethyl)-4-oxo-pyrrolidino[1,2-*b*]isoxazolidino[4,5-*c*]-tetrahydrofurane (14)

Adduct **6** was dissolved in methanol, treated with 1 molar equiv. of sodium carbonate, and stirred at room temperature

Biological tests

The β-glucosidase activity of **13** was measured by the modification of the procedures described previously (10, 11). The reaction mixture consisted of 100 μL of 0.014 mol/L *p*-nitrophenyl β-D-glucopyranoside, 250 μL of 0.2 mol/L acetate buffer (pH 4.6), 50 μL of inhibitor solution (either water or methanol), and 100 μL of enzyme solution (3 μg/mL). After incubation for 15 min at 30 °C, the reaction was terminated by the addition of 1 mL of 2% sodium carbonate. The absorbance of liberated *p*-nitrophenol was measured at 405 nm.

The α-glucosidase activity of **13** was measured by modification of the procedures described previously (12, 13). The reaction mixture consisted of 25 μL of 0.0165 mol/L *p*-nitrophenyl α-D-glucopyranoside, 403 μL of 0.1 mol/L acetate buffer (pH 4.0), 50 μL of inhibitor solution (either water or methanol), and 22 μL of enzyme solution (10 times diluted). After incubation for 15 min at 37 °C, the reaction was terminated by the addition of 1 mL of 2% sodium carbonate. The absorbance of liberated *p*-nitrophenol was measured at 405 nm.

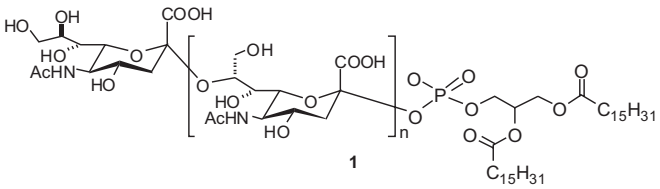
Synthesis of mono- and di-sialophospholipids via the H-phosphonate approach[1]

Hongbin Yan and Harold J. Jennings

Abstract: To overcome their inherent instability, stable modified mono- and di-sialophospholipids of the group C meningococcal polysaccharide were synthesized. Stability was achieved by introducing a spacer between the sialic acid residue and the phospholipid component, and by replacing the native ester linkages to the lipid by ether linkages. Mono- and di-hydroxylethylenesialosides were coupled to phosphoglyceroldietherlipid using H-phosphonate chemistry to give the anomerically pure sialophospholipids in good yields.

Key words: polysialic acid, glycolipid, H-phosphonate, meningococcus.



Résumé : Afin de circonvenir à leur instabilité inhérente, on a synthétisé des mono- et des di-sialophospholipides modifiés et stables du polysaccharide méningocoque du groupe C. On a atteint la stabilité en introduisant un groupe d'espacement entre le résidu d'acide sialique et le composant phospholipide et en remplaçant les liaisons esters naturelles vers le lipide par des liaisons éthers. On a réalisé le couplage des mono- et di-hydroxyéthylènesialosides au phosphoglycéroldiétherlipide en se basant sur la chimie des H-phosphonates afin d'obtenir des sialophospholipides anomériquement purs avec de bons rendements.

Mots clés : acide polysialique, glycolipide, H-phosphonate, méningocoque.

[Traduit par la Rédaction]

Introduction

Sialic acid (*N*-acetyl neuraminic acid) is a naturally occurring keto sugar that is involved in a wide range of biological processes. The capsular polysaccharides of various highly pathogenic bacteria, including those of *Escherichia coli* K1 and groups B and C *Neisseria meningitidis* are known to be homopolymers of sialic acid (1, 2), and both the group C polysaccharide and more recently, its improved protein conjugates (3, 4), have been shown to be effective human vaccines. Based on previous assays (5, 6), it was demonstrated that groups B and C *meningococcal* and *E. coli* K1 polysaccharides bear glycerol phospholipid anchors, and the proposed structure of the group C phospholipid anchor is as shown in **1** (5). Although small in size, this lipoidal group is responsible for the aggregation of the polysaccharides, and it has been proposed that it is the entity by which the polysaccharide is attached to the outer membrane of the above bacteria (5). While aggregation improves the immunogenicity of the group C *meningococcal* polysaccharide in humans (7), it has little or no effect on that of the group B *meningococcal* and *E. coli* K1 polysaccharides (8), because of the fact that their basic structure (α(2–8)-polysialic acid) mimics a human tissue antigen (9). However, highly aggregated forms of these lipidated polysaccharides do contain a protective epitope distinct from those of α(2–8) polysialic acid, but nevertheless having this latter molecule as a component (3, 10). This protective epitope is mimicked by the N-propionylated form of α(2–8) polysialic acid, which in its conjugated form is a potential human vaccine (3, 11, 12). To study the roles of α(2–8) polysialic acid and lipid anchor in the formation of this epitope, we proposed first to synthesize the truncated mono- and di-sialophospholipids, and then at a later date to use them as precursors to elongate the sialic acid chain at their nonreducing ends, using polysialyl transferases (13).

1

Results and discussion

Due to the miniscule content of phospholipid in the native lipidated polysaccharides (5) and its reported inherent instability (6), it has never been isolated. This latter property is probably also responsible for our inability to synthesize it using conventional synthetic methods (unpublished results). Therefore, we opted to synthesize more stable modified ver-

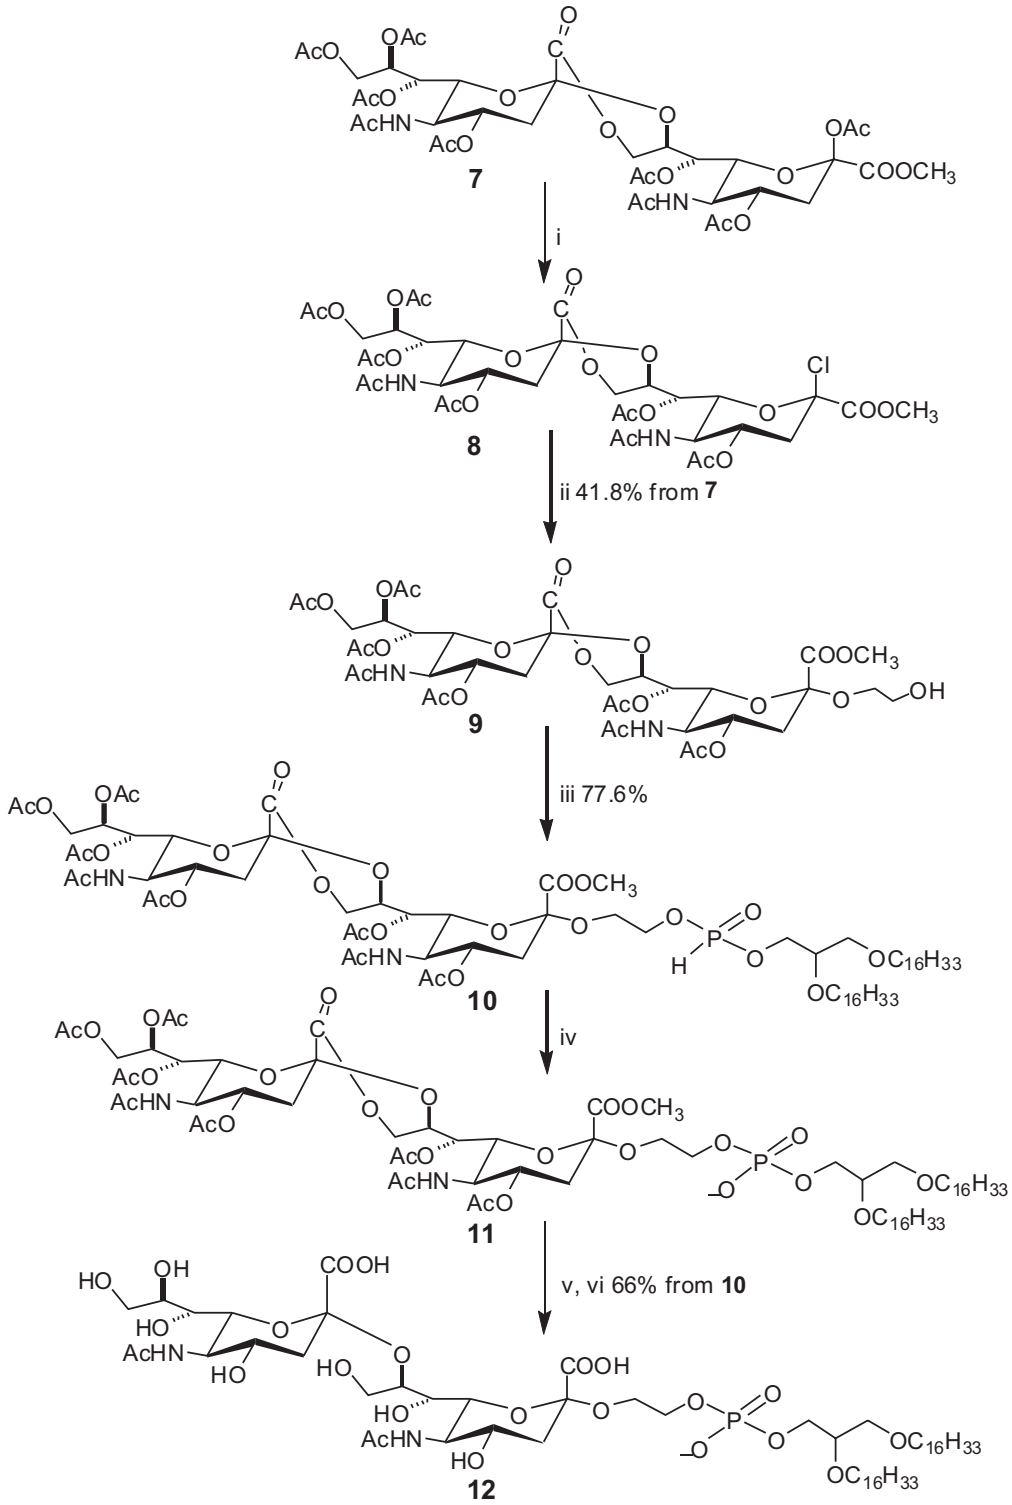
Scheme 1. Reagents and conditions: (*i*) $HOCH_2CH_2OH$, AgOTf, 2,6-di-*tert*-butylpyridine, MeCN, $CaCO_3$, –20 °C to room temp.; (*ii*) **5**, $(CH_3)_3COCl$, C_5H_5N, 0 °C, 10 min; (*iii*) I_2, C_5H_5N–H_2O, room temp.; (*iv*) Pd/C, H_2, AcOEt–MeOH, 50 psi (1 psi = 6.894 757 kPa); (*v*) MeOH, CH_2Cl_2, NaOMe.

sions of the mono- and di-sialophospholipids as model compounds. In an attempt to stabilize the lipid anchor of the monosialophospholipid, we first introduced a spacer between the sialic acid and the phospholipid as shown in **2a**. Assembly of **2a** was effected by coupling **4** (14), previously prepared from chlorosugar **3** (15), to phospholipid **5**, using H-phosphonate chemistry (see the following). However, removal of the acetyl protecting groups from **2a** in the presence of the palmitoyl esters proved to be problematic, **2b** only being isolated in very poor yields. Having also had limited success in the synthesis of an alternate donor to **3**, the fully benzylated 1-chlorodeoxy derivative of sialic acid (16), which could have possibly avoided this problem, we decided to additionally replace the palmitoyl ester groups of the glycerol moiety with ether groups (as shown in **2c**). Because the long-chain ether groups are stable under the conditions under which *O*-acetates are removed by methoxide ion, the unblocking of the fully protected sialophospholipid **2c** should furnish **2d**.



2a R_1 = Ac, R_2 = Bn, R_3 = $COC_{15}H_{31}$;
b R_1 =R_2 = H, R_3 = $COC_{15}H_{31}$;
c R_1 = Ac, R_2 = Bn, R_3 = $C_{16}H_{33}$;
d R_1 =R_2 = H, R_3 = $C_{16}H_{33}$;

To synthesize phosphoether lipid **2d** we found that H-phosphonate chemistry, which has been widely used in oligonucleotide synthesis (17), can be readily employed (Scheme 1). Thus, 1,2-dihexadecylglycerol (18) was readily phosphonylated by ammonium 4-methylphenyl H-phosphonate (19) to afford H-phosphonate **5**. Benzyl (glycolyl 5-acetamido-4,7,8,9-tetraacetyl-3,5-dideoxy-D-*glycero*-α-D-*galacto*-nonulpyranosid)onate **4** (14), which was obtained in an anomerically pure α form, was then coupled with **5** in the presence of pivaloyl chloride to yield the H-phosphonate diester **6** in good yield. Subsequent oxidation with iodine furnished phosphodiester **2c**, which on deesterification gave a good yield of the target compound (**2d**).

Synthesis of the disialophospholipid derivative (**12**), shown in Scheme 2, was achieved using similar methods to those employed in the synthesis of monosialophospholipid **2d**. The α-2,8-linked sialic acid dimer was obtained in a pure form by controlled acid hydrolysis of colominic acid, followed by fractionation of the hydrolysate on a Bio-gel P-10 column as previously described (20). More conveniently, the hydrolysate was transformed in situ (Scheme 2) to afford the peracetylated lactone disialoside methyl ester (**7**) in moderate yield (21). Thus, **7** was converted to its 2-chloro dervative (**8**) by treatment with a mixture of acetyl chloride, dichloromethane, and a trace amount of water. Glycosylation of chloride **8** with ethylene glycol was effected with silver triflate to afford α-anomer **9.** Coupling of **9** with H-phosphonate **5**, followed by oxidation of the H-phosphonate intermediate **10** gave the partially protected disialophosphate diester **11** in good yield. Subsequent deprotection of **11** with

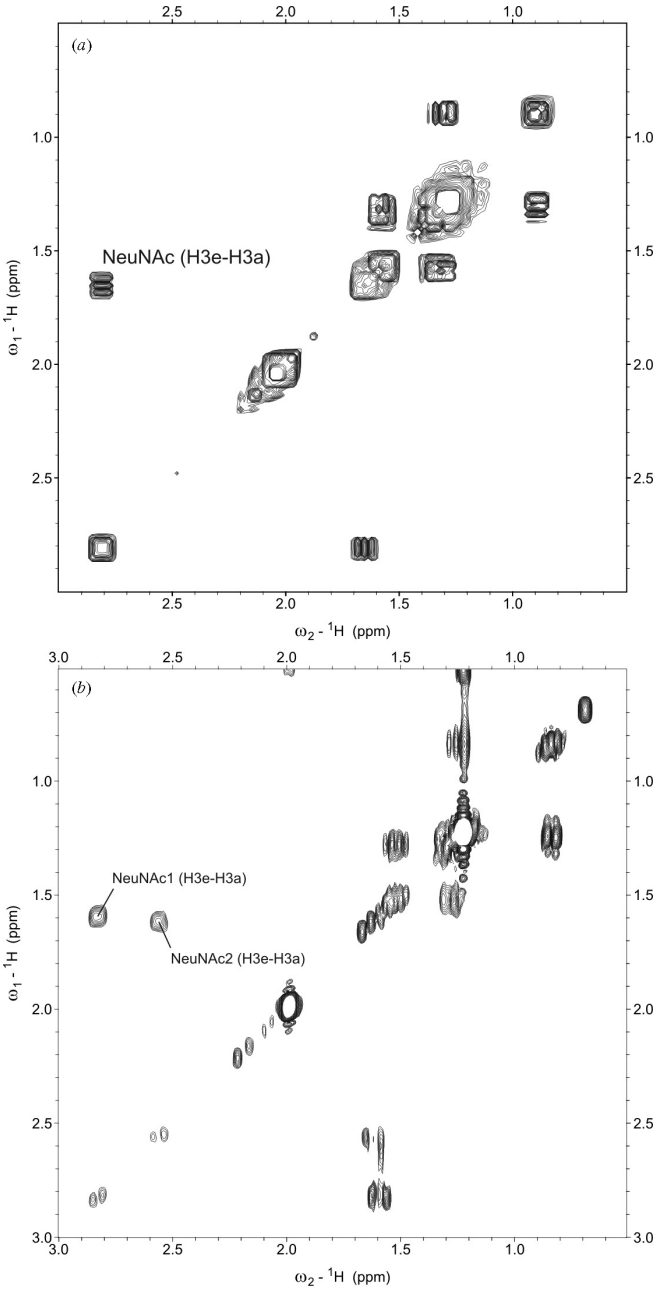
Scheme 2. Reagents and conditions: (*i*) CH_2Cl_2, CH_3COCl, H_2O; (*ii*) $HOCH_2CH_2OH$, AgOTf, 2,6-di-*tert*-butylpyridine, MeCN, $CaCO_3$, –20 °C to room temp.; (*iii*) **5**, $(CH_3)_3COCl$, C_5H_5N, 0 °C, 10 min; (*iv*) I_2, C_5H_5N–H_2O, room temp.; (*v*) MeOH, NaOMe; (*vi*) MeOH, H_2O, NaOH.



methoxide ion also gave a good yield of the target compound (**12**).

^{1}H NMR spectroscopic analysis of mono- (**2d**) and disialophospholipids (**12**) showed that they were both α-sialosides because the chemical shifts of the H_{3e} signals of their reducing end sialic acid residues were found to be 2.81 and 2.83 ppm, respectively (Fig. 1), which is indicative of α-sialosides (22). The presence of the disialic acid moiety in compound **12** is also clearly indicated by the resonances at 2.83 and 2.65 ppm, which represent the H_{3e} protons of both

the reducing and nonreducing sialic acid residues of **12**, respectively.

Experimental

^{1}H and COSY NMR spectra were measured at 400 MHz with a Varian 400 spectrometer; tetramethylsilane was used as an internal standard and *J* values are given in Hz. ^{31}P NMR spectra were measured at 80.2 MHz with a Varian 200 spectrometer spectrometer; 85% orthophosphoric acid was used as an internal standard. The FAB and ESI mass spectra were measured with a Jeol AX 505H and an Applied Biosystems Q-Star quadrupole/time-of-flight (Qq-TOF) mass spectrometer, respectively. Merck silica gel 60 F254 TLC plates were developed in solvent systems A (dichloromethane–methanol (95:5 *v*/*v*)) and B (chloroform – methanol – water – acetic acid (50:50:7:0.2 *v*/*v*)). Merck silica gel 60 Art 7729 and Art 7734-3 were used for short column chromatography and flash column chromatography, respectively. Sialic acid was purchased from Rose Scientific (Edmonton, Alberta). Colominic acid was purchased from Nacalai Tesque (Kyoto, Japan). Anhydrous dichloromethane, methanol, pyridine, and tetrahydrafuran were purchased from Sigma-Aldrich. Ethylene glycol was distilled under reduced pressure. The other chemicals were purchased from Sigma-Aldrich and were used without further purification.

Triethylammonium 1,2-dihexadecyl-glycerol-3-H-phosphonate (5)

Ammonium 4-methylphenyl H-phosphonate (19) (3.16 g, 16.71 mmol), triethylamine (5.0 mL, 35.8 mmol), and methanol (5.0 mL) were coevaporated under reduced pressure. To the residue was added (±)-1,2-dihexadecyl glycerol (18) (3.00 g, 5.566 mmol) and the mixture was azeotroped with pyridine (2 × 5 mL). The residue was redissolved in pyridine (30 mL) and cooled to –10 °C. Pivotoyl chloride (2.0 mL, 16.2 mmol) was added over a period of 5 min. After 1 h, water (5 mL) was added and the reactants were allowed to warm up to room temperature over a period of 1 h. The products were then partitioned between dichloromethane (100 mL) and saturated aqueous sodium hydrogen carbonate (2 × 80 mL). The layers were separated and the combined aqueous layers were back extracted with dichloromethane (2 × 20 mL). The combined organic layers were further extracted with triethylammonium phosphate buffer (0.5 mol/L, pH 7.0, 50 mL). The layers were separated and the aqueous layer was back extracted with dichloromethane (15 mL). The combined dried ($MgSO_4$) organic layers were concentrated under reduced pressure. The residue was fractionated by short column chromatography on silica gel. The appropriate fractions, which were eluted with dichloromethane–methanol (9:1 *v*/*v*) were pooled and concentrated under reduced pressure to give the title compound (**5**) as a colourless froth (3.53 g, 89.9%). ^{1}H NMR($CDCl_3$–CD_3OD, 1:1 *v*/*v*) include the following peaks δ_H: 0.88 (6H, t, J = 6.6 Hz), 1.20–1.32 (52H, br), 1.50–1.58 (4H, br), 5.99 (0.5H, s), 7.56 (0.5H, s). ^{31}P NMR ($CDCl_3$–CD_3OD, 1:1 *v*/*v*) δ_P: 5.66 ($^1J_{P\text{-}H}$ = 628.3 Hz). FAB$^-$-HRMS calcd. for $C_{35}H_{72}O_5P^-$: 603.51174; found: 603.5117.

[Benzyl (glycolyl-5-acetamido-4,7,8,9-*O*-tetraacetyl-3,5-dideoxy-D-*glycero*-α-D-*galacto*-2-nonulopyranosyl)]-1,2-dihexadecyl-*glycero*-3-H-phosphonate (6)

Benzyl (glycolyl-5-acetamido-4,7,8,9-tetra-*O*-acetyl-3,5-dideoxy-β-*O*-manno-2-nonulopyranosid)onate (**4**) (0.500 g, 0.818 mmol) and triethylamonnium 1,2-dihexadecyl-glycerol-3-H-phosphonate (**5**) (0.693 g, 0.981 mmol) were evaporated with dry pyridine (2 × 5 mL) and the residue was redissolved in anhydrous pyridine (10 mL) and cooled (ice-water bath). Pivaloyl chloride (0.26 mL, 2.11 mmol) was added. After a period of 10 min, the reaction was quenched by addition of water (0.5 mL). After a further period of 10 min, the products were partitioned between dichloromethane (80 mL) and saturated aqueous sodium hydrogen carbonate (2 × 50 mL). The layers were separated and the

© 2006 NRC Canada

aqueous layer was back extracted with dichloromethane (2 × 10 mL). The combined organic layers were further washed with triethylammonium phosphate buffer (0.5 mol/L, pH 7.0, 50 mL). The layers were separated and the aqueous layer was back extracted with dichloromethane (10 mL). The combined dried ($MgSO_4$) organic layers were concentrated under reduced pressure. The residue was purified by flash column chromatography on silica gel. The appropriate fractions, which were eluted with ethyl acetate, were pooled and evaporated under reduced pressure to give the title compound (**6**) as a colourless froth (0.85 g, 86.7%). R_f (system A) 0.49. ^{1}H NMR ($CDCl_3$) include the following peaks $\delta_{H:}$ 0.88 (6H, t, J = 6.6 Hz), 1.22–1.32 (52H, br), 1.50–1.58 (4H, br), 1.87 (3H, s), 2.02 (3H, s), 2.03 (3H, s), 2.04 (3H, s), 2.12 (3H, s), 2.65 (1H, dt, J = 12.8, 4.0 Hz), 5.97 (0.5H), 7.37 (5H, m), 7.76 (0.5H). ^{31}P NMR ($CDCl_3$) δ_P: 10.50, 10.36, 10.33, 10.18 ($^1J_{P\text{-}H}$ = 713.2 Hz). ESI$^+$ calcd. for $C_{63}H_{108}NO_{18}PNa^+$: 1220.7; found: 1221.0.

[Benzyl (glycolyl-5-acetamido-4,7,8,9-*O*-tetraacetyl-3,5-dideoxy-D-*glycero*-α-D-*galacto*-2-nonulopyranosyl)]-1,2-dihexadecyl-*glycero*-3-phosphate (2c)

The H-phosphonate **6** (0.800 g, 0.668 mmol) was dissolved in pyridine–water (10 mL, 4:1 *v*/*v*) followed by addition of iodine (0.100 g, 0.394 mmol) at room temperature. After 30 min, the products were poured into aqueous sodium sulfite (10 mL, 0.1 mol/L) and extracted with dichloromethane (50 mL) and triethylammonium phosphate buffer (0.5 mol/L, pH 7.0, 50 mL). The layers were separated and the aqueous layer was back extracted with dichloromethane (2 × 20 mL). The combined dried ($MgSO_4$) organic layers were concentrated under reduced pressure. The residue was fractionated by short column chromatography on silica gel. The appropriate fractions, which were eluted with dichloromethane–methanol (85:15 *v*/*v*), were combined and concentrated under reduced pressure to give the title compound **2c** as a colourless waxy solid (0.75 g, 85.3%). ^{1}H NMR ($CDCl_3$–CD_3OD–D_2O, 1:1:0.04 *v*/*v*) include the following peaks δ_H: 0.89 (6H, t, J = 7.0 Hz), 1.24–1.32 (52H, br), 1.49–1.57 (4H, br), 1.86 (3H, s), 2.03 (3H, s), 2.04 (3H, s), 2.13 (6H, s), 2.69 (1H, dd, J = 12.8, 4.4 Hz), 5.83 (5H, m). ^{31}P NMR ($CDCl_3$–CD_3OD–D_2O, 1:1:0.04 *v*/*v*) δ_P: 1.39. (Glycolyl-5-acetamido-3,5-dideoxy-D-*glycero*-α-D-*galacto*-2-nonulopyranosyl)-1,2-dihexadecyl-*glycero*-3-phosphate (2d)

Phosphate **2c** (0.65 g, 0.494 mmol) was dissolved in a mixture of ethyl acetate (15 mL) and methanol (15 mL) and was hydrogenated in hydrogen at 50 psi (1 psi = 6.894 757 kPa) at room temperature in the presence of a catalytic amount of Pd/C. After 16 h, the products were filtered. The filtrate was concentrated under reduced pressure to give a colourless froth (0.60 g). A portion of this froth (50 mg) was dissolved in methanol–dichloromethane (2 mL, 1:1 *v*/*v*), and a solution of sodium methoxide in methanol (0.4 mL, 0.2% *w*/*v*) was added. After 80 min, the products were diluted with dichloromethane (5.0 mL) and purified by short column chromatography on silica gel. The appropriate fractions, which were eluted with dichloromethane–methanol (3:1 *v*/*v*), were combined and concentrated under reduced pressure to give the title compound **2d** as a colourless powder (30 mg, 69.5%). ^{1}H NMR ($CDCl_3$–CD_3OD–D_2O, 1:1:0.04 *v*/*v*) include the following peaks δ_H: 0.89 (6H), 1.28 (52H), 1.58 (4H), 2.04 (3H), 2.81 (1H). R_f (system B): 0.52. ^{31}P NMR ($CDCl_3$–CD_3OD–D_2O, 1:1:0.04 *v*/*v*) δ_P: 4.57. FAB$^-$ calcd. for $C_{48}H_{93}NO_{15}P^-$: 954.6; found: 954.6.

Methyl [glycolyl 5-acetamido-2,4,7-*O*-triacetyl-3,5-dideoxy-8-*O*-(5-acetamido-4,7,8,9-*O*-tetraacetyl-3,5-dideoxy-D-*glycero*-α-D-*galacto*-2-nonulopyranosylono-1′,9-lactone)-D-*glycero*-D-*galacto*-2-nonulopyranosid]onate (9)

The fully protected disialo-lacton peracetate **7** (0.600 g, 0.67 mmol) (R_f (system A) 0.32) was dissolved in dichloromethane (20.0 mL) and cooled to –20 °C. Acetyl chloride (8.0 mL) and water (0.1 mL) were then added. After 2 h, the reaction mixture was warmed up to room temperature, and stirring was continued for 16 h. The products were then concentrated under reduced pressure. The residue was dissolved in dichloromethane (40 mL) and washed with ice water (15 mL). The organic layer was separated and evaporated under reduced pressure. The residue was dissolved in acetonitrile (15 mL) and cooled to –20 °C. Calcium carbonate (0.48 g, 4.8 mmol), 2,6-di-*tert*-butylpyridine (0.30 mL, 1.34 mmol), ethylene glycol (2.0 mL, 35.86 mmol), and silver triflate (0.30 g, 1.17 mmol) were added. The reaction mixture was kept at –20 °C for 2 h and then allowed to warm up to room temperature. After 18 h, dichloromethane (10 mL) was added and the products were filtered. The filtrate was evaporated under reduced pressure, and the residue was dissolved in ethyl acetate (20 mL) and extracted with saturated aqueous sodium hydrogen carbonate (15 mL). The layers were separated and the dried ($MgSO_4$) organic layer was evaporated under reduced pressure. The residue was fractionated by short column chromatography on silica gel. The appropriate fractions, which were eluted with dichloromethane–methanol (96:4 *v*/*v*), were pooled and concentrated under reduced pressure to give the title compound **9** as a colourless froth (0.25 g, 41.8%). R_f (system A) 0.22. ^{1}H NMR ($CDCl_3$) include the following peaks δ_H: 1.90 (3H, s), 1.93 (3H, s), 2.02 (3H, s), 2.04 (6H, s), 2.09 (3H, s), 2.12 (3H, s), 2.23 (3H, s), 2.45 (1H, dd, J = 13.6, 5.6 Hz), 2.67 (1H, dd, J = 13.2, 4.8 Hz). FAB$^-$ calcd. for $C_{37}H_{51}N_2O_{23}^-$: 891.3; found: 891.3.

Methyl [glycolyl 5-acetamido-2,4,7-*O*-triacetyl-3,5-dideoxy-8-*O*-(5-acetamido-4,7,8,9-*O*-tetraacetyl-3,5-dideoxy-D-*glycero*-α-D-*galacto*-2-nonulopyranosylono-1′,9-lactone)-D-*glycero*-D-*galacto*-2-nonulopyranosyl]-1,2-dihexadecyl-*glycero*-3-H-phosphonate (10)

Methyl [glycolyl 5-acetamido-2,4,7-*O*-triacetyl-3,5-dideoxy-8-*O*-(5-acetamido-4,7,8,9-*O*-tetraacetyl-3,5-dideoxy-D-*glycero*-α-D-*galacto*-2-nonulopyranosylono-1′,9-lactone)-D-*glycero*-D-*galacto*-2-nonulopyranosid]onate (**9**) (0.100 g, 0.112 mmol) and triethylamonnium 1,2-dihexa-decyl-glycerol-3-H-phosphonate (**5**) (0.103 g, 0.146 mmol) were evaporated with dry pyridine (2 × 3 mL) and the residue was redissolved in anhydrous pyridine (3 mL) and cooled (ice-water bath). Pivaloyl chloride (50 μL, 0.406 mmol) was added. After a period of 10 min, the reaction was quenched by addition of water (0.5 mL). After a further period of

10 min, the products were partitioned between dichloromethane (15 mL) and saturated aqueous sodium hydrogen carbonate (2 × 15 mL). The layers were separated and the aqueous layer was back extracted with dichloromethane (2 × 5 mL). The combined organic layers were further washed with triethylammonium phosphate buffer (0.5 mol/L, pH 7.0, 10 mL). The layers were separated and the aqueous layer was back extracted with dichloromethane (5 mL). The combined dried ($MgSO_4$) organic layers were concentrated under reduced pressure. The residue was purified by flash column chromatography on silica gel. The appropriate fractions, which were eluted with dichloromethane–methanol (98:2 *v*/*v*), were pooled and evaporated under reduced pressure to give the title compound **11** as a colourless froth (0.130 g, 77.6%). R_f (system A) 0.32. ^{1}H NMR ($CDCl_3$) include the following peaks δ_H: 0.88 (6H, t, J = 6.6 Hz), 1.22–1.32 (52H, br), 1.52–1.59 (4H, br), 2.46 (1H, dd, J = 13.6, 5.6 Hz), 2.68 (1H, dd, J = 12.8, 5.2 Hz), 6.03 (0.5H), 7.82 (0.5H). ^{31}P NMR ($CDCl_3$) δ_P: 10.50, 10.41, 10.23, 10.13 ($^1J_{P\text{-}H}$ = 720 Hz). FAB$^-$ calcd. for $C_{72}H_{122}N_2O_{27}P^-$: 1477.8; found: 1477.9.

[Glycolyl 5-acetamido-3,5-dideoxy-8-*O*-(5-acetamido-3,5-dideoxy-D-*glycero*-α-D-*galacto*-2-nonulopyranosylono)-D-*glycero*-D-*galacto*-2-nonulopyranosyl]-1,2-dihexadecyl-*glycero*-3-phosphate (12)

The H-phosphonate diester **10** (65 mg, 43.9 μmol) was dissolved in a mixture of pyridine (3.0 mL) and water (0.5 mL), followed by addition of iodine (8.0 mg). After 30 min, the products were partitioned between dichloromethane (10 mL) and aqueous sodium sulfite (0.1 mol/L, 3.0 mL). The layers were separated and the aqueous layer was back extracted with dichloromethane (5 mL). The combined organic layers were further extracted with triethylammonium phosphate buffer (50 mol/L, pH 7.0, 5 mL). The aqueous layer was back extracted with dichloromethane (5 mL). The combined organic layers were dried ($MgSO_4$) and evaporated under reduced pressure. The residue was fractionated by short column chromatography on silica gel. The appropriate fractions, which were eluted with dichloromethane–methanol (85:15 *v*/*v*), were pooled and evaporated under reduced pressure to give phosphate **11** as a colourless froth (52 mg). A portion of this froth (40 mg, 27 μmol) was dissolved in anhydrous methanol (10.0 mL) followed by addition of a solution of sodium methoxide in methanol (1.5 mol/L, 0.1 mL). After 16 h, the products were evaporated under reduced pressure. The residue was taken up in methanol (8.0 mL) followed by the addition of water (0.16 mL). After 24 h, the products were concentrated under reduced pressure and the residue was dissolved in water (3.0 mL) and passed through a Sephadex G-25 column (1.6 cm × 35 cm), eluted with water. The appropriate fractions were pooled and lyophilized to give the title compound **12** as a colourless froth (30.0 mg, 66% over two steps). R_f (system B) 0.16. ^{1}H NMR ($CDCl_3$–CD_3OD–D_2O, 1:1:0.03 *v*/*v*) include the following peaks δ_H: 0.84 (6H), 1.23 (52H), 1.52 (4H), 1.99 (3H, s), 2.00 (3H, s), 2.56 (1H), 2.83 (1H). ^{31}P NMR ($CDCl_3$–CD_3OD–D_2O, 1:1:0.03 *v*/*v*) δ_P: 4.27. FAB$^-$ calcd. for $C_{59}H_{110}N_2O_{23}P^-$: 1245.7; found: 1245.6.

Pyrolysis of 2-methoxy-5,5-dimethyl-2-methylthio-2,5-dihydro[1,3,4]oxadiazole studied with photoelectron spectroscopy and DFT calculations — He(I) photoelectron spectrum of methoxy(methylthio)carbene[1]

N.H. Werstiuk, A. Klys, and J. Warkentin

Abstract: Gas-phase pyrolysis of 2-methoxy-2-methylsulfanyl-5,5-dimethyl-2,5-dihydro[1,3,4]oxadiazole (**1**) (also known as 2-methoxy-5,5-dimethyl-2-methylthio-2,5-dihydro[1,3,4]oxadiazole and 2-methoxy-2-methylthio-5,5-dimethyl-Δ^3-l,3,4-oxadiazoline) in the source of an UV photoelectron spectrometer, by means of a CW CO_2 laser as directed heat source, gave a photoelectron (PE) spectrum that included ionization bands belonging to acetone and methoxy(methylthio)carbene (**3**). Photoelectron spectra of authentic samples of (*E*)-1,2-dimethoxy-1,2-dimethylthioethene (**4**), (*Z*)-1,2-dimethoxy-1,2-dimethylthioethene (**5**), *S*-methyl thioethanoate (**6**), and *O*-methyl ethanethioate (**7**), which can be derived by dimerization and rearrangement of the carbene, established that these compounds are not present in the pyrolysate. DFT calculations at the B3PW91/6-31+G(d,p) level and simulation of PE spectra at the B3LYP/6-31+G(d,p) level were instrumental in the interpretation of the experimental results. From the available experimental and calculated data, **3** is formed in a Sickle conformation upon pyrolysis of **1**. Transition states for the rearrangement of **3** were examined with QTAIM.

Key words: 2-methoxy-5,5-dimethyl-2-methylthio-2,5-dihydro[1,3,4]oxadiazole, pyrolysis, He(I) photoelectron spectroscopy, methoxy(methylthio)carbene, DFT calculations, QTAIM.

Résumé : La pyrolyse en phase gazeuse du 2-méthoxy-2-méthylsulfanyl-5,5-diméthyl-2,5-dihydro[1,3,4]oxadiazole (**1**) (aussi connu comme 2-méthoxy-5,5-diméthyl-2-méthylthio-2,5-dihydro[1,3,4]oxadiazole et comme 2-méthoxy-2-méthylthio-5,5-diméthyl-Δ^3-1,3,4-oxadiazoline) dans la source d'un spectromètre photoélectronique ultraviolet utilisant un laser au CO_2 à onde continue (OC) comme source focalisée de chaleur permet d'obtenir un spectre photoélectronique (PE) qui comprend des bandes d'ionisation appartenant à l'acétone ainsi qu'au méthoxy(méthylthio)carbène (**3**). Les spectres photoélectroniques d'échantillons authentiques de (*E*)-1,2-diméthoxy-1,2-diméthylthioéthène (**4**), de (*Z*)-1,2-diméthoxy-1,2-diméthylthioéthène (**5**), de thioéthanoate de *S*-méthyle et d'éthanethioate de *O*-méthyle (**7**) qui pourraient dériver d'une dimérisation et d'un réarrangement du carbène on permis d'établir que ces composés ne sont pas présents dans le produit de pyrolyse. Des calculs de la théorie de la densité fonctionnelle (TDF) au niveau B3PW91/6-31+G(d,p) et une simulation des spectres PE au niveau B3LYP/6-31+G(d,p) ont été utilisés en partie pour interpréter les résultats expérimentaux. Sur la base des données calculées et expérimentales, la pyrolyse du composé **1** conduit à la formation de l'intermédiaire **3** dans une conformation de Sickle. Les états de transition pour le réarrangement de l'intermédiaire **3** ont été étudiés par la méthode « QTAIM ».

Mots clés : 2-méthoxy-5,5,-diméthyl-2-méthylthio-2,5-dihydro[1,3,4]oxadiazole, pyrolyse, spectroscopie photoélectronique He(I), méthoxy(méthylthio)carbène, calculs selon la théorie de la densité fonctionnelle (TDF), QTAIM.

Introduction

Ultraviolet photoelectron (PE) spectroscopy, when combined with quantum chemical calculations of molecular orbital eigenvalues (energies) and eigenvectors (MOs), gives information about the electronic structure and bonding of stable as well as transient species that is provided by no other technique. PE spectra of transient carbenes are very rare (1) because of the high reactivity of these species. Special instrumentation is required. Reactive intermediates are

Scheme 1.

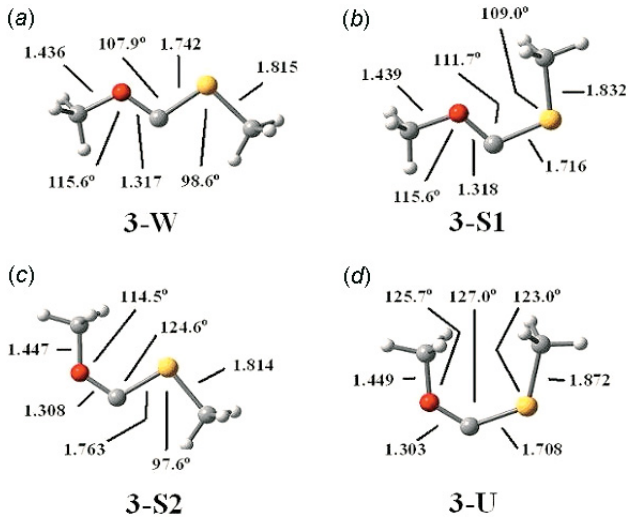
usually generated pyrolytically from labile precursors using electrically heated furnaces that are several centimeters in length (2). Yet carbenes have to be generated close to the ionization beam to minimize the incursion of reactions like rearrangement, fragmentation, or dimerization. Our unique UV PE spectrometer – CW CO_2 laser apparatus (3) allows us to use the laser as a directed heat source to produce a hot zone as short as 1 mm in length on the tip of a quartz tube positioned at about 1 cm from the point of intersection with the ionization beam. We used this setup successfully to obtain PE spectra of short-lived, reactive species such as benzazete and *o*-benzyne (3), l-(2-thiaindane)ketene and benzocyclobutene-thione (4, 5), 1,2-cyclohexadiene (6), (dimethoxy)carbene (7), and p-substituted phenylketenes (8) through pyrolysis of suitable precursors. We have also observed cycloocta-2(*Z*),4(*E*)-dien-1-one (9) and bicyclo-[3.2.0]hepta-1,3,6-triene (10) and attempted to prepare and detect *N*,*N*-dimethylcyclohepta-1(*E*),3(*Z*),5(*Z*)-trien-1-amine (11).

We decided to study the gas-phase decomposition of a series of oxadiazolines because pyrolysis of these compounds in solution (12) yields products that indicate the formation of carbenes as intermediates. In benzene, 2-methoxy-2-methylsulfanyl-5,5-dimethyl-2,5-dihydro[1,3,4]oxadiazole (**1**) gave ethenes **4** and **5** in the absence of traps; esters **6** and **7** and the products of C-H insertion (**8** and **9**) were not observed (13). We earlier prepared and studied (dimethoxy)carbene generated by pyrolysis of 2,2-dimethoxy-5,5-dimethyl-Δ^3-l,3,4-oxadiazoline (7). The particular choice of oxadiazoline **1** for this study was made because (*a*) it is a convenient source of **3**, (*b*) it gave us the additional opportunity to confirm the mode of its decomposition because on a different path **1** can yield methyl(thiomethyl)carbonate and 2-diazopropane. The latter could decompose to nitrogen and (dimethyl)carbene that would yield propene; (*c*) Its pyrolysis has been studied in solution (13), and (*d*) it is the first member in a series of similar oxadiazolines that could be used as possible precursors of O,S- and O,N-substituted carbenes in the gas phase. Possible reactions of **3** derived from ylide **2** — the possible first-formed intermediate — are summarized in Scheme 1.

Our computational study on the first adiabatic and vertical ionization potentials of carbenes (14) provided us with a calculational method (B3LYP/6-31+G(*d*) for reliably predicting these values. By applying these calculations to methoxy(methylthio)carbene (**3**) and using the program PESPEC (15) to simulate PE spectra, we expected to identify **3** through its ionization potentials if it was present in the pyrolysis spectrum of **1** and possibly establish its preferred conformation. Four conformers of carbene **3**, **3-W**, **3-S1**(Sickle1), **3-S2**(Sickle2), and **3-U** (Fig. 1), excluding the methyl rotamers, are possible.

In this paper we report the results of a He(I) PE spectroscopic study of the pyrolysis of oxadiazoline **1** along with DFT (Gaussian 98 and 03 (16, 17)) calculational data on **1**, its decomposition into ylide **2**, decomposition of **2** into methoxy(methylthio)carbene (**3**), and rearrangement of the latter to *S*-methyl thioethanoate (**6**), *O*-methyl ethanethioate (**7**), (methylthio)oxirane (**8**), and (methoxy)thiirane (**9**).

Computational details



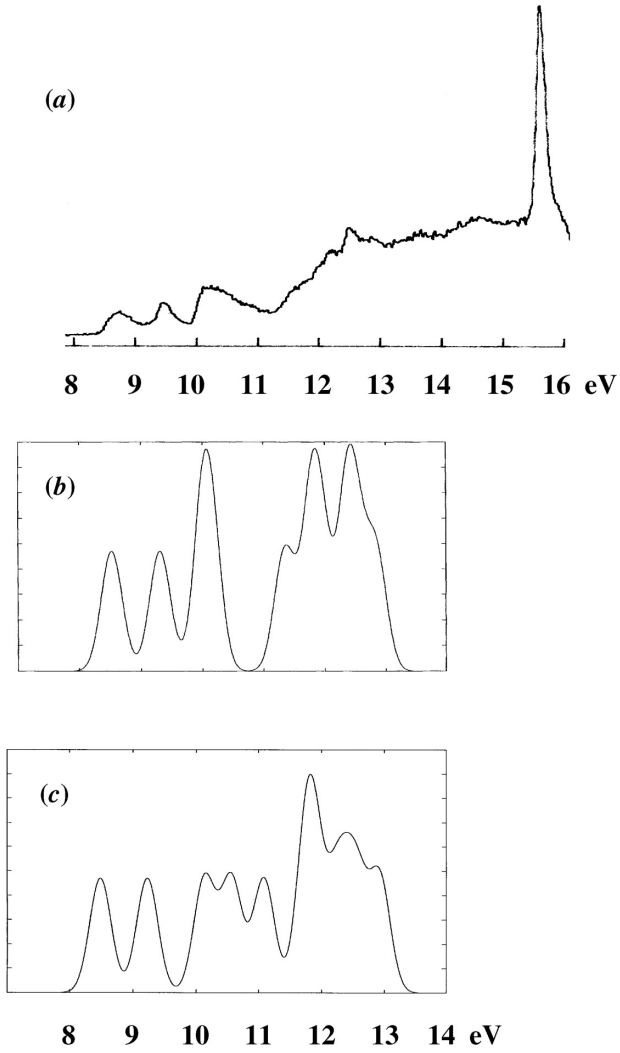
Equilibrium-optimized geometries and wave functions were obtained at the DFT level implemented in Gaussian 98 (16) and 03 (17) using the B3PW91 functional (18, 19) at the 6-31+G(d,p) level. All optimizations converged using the default convergence criteria, and vibration analyses were performed for all species to confirm that they were minima or transition states. PE spectra were simulated with the program PESPEC (15) based on calculations carried out at the B3LYP/6-31+G(d,p) level (14). Two recent publications document the procedure used to simulate spectra (9, 10). QTAIM (20) analyses were carried out with AIM 2000 (21).

Experimental details

Oxadiazoline **1** was prepared by the method described previously (13). Ethenes **4** and **5** were prepared by pyrolysis

© 2006 NRC Canada

Fig. 1. Optimized geometries of methoxy(methythio)carbene conformers and selected geometrical parameters. The red sphere is oxygen and the yellow sphere is sulfur.



of **1** in benzene in the absence of traps as described previously (13). Esters **6** and **7** were prepared with the method described by Sah (22). PE spectra were recorded with our locally built UV PE spectrometer and calibrated with the 15.6 eV IP band of N_2 that is visible in all spectra (23). Linearity of the spectral scale was checked with the lowest IP bands of methyl iodide at 9.54 and 10.16 eV prior to the experiments. Our unique UV PE spectrometer – CW CO_2 laser apparatus (6) that is fitted with a heated probe, allows us to use the laser as a directed heat source to produce a hot zone as short as 1 mm in length at the tip of a quartz tube positioned about 1 cm from the point of intersection with the ionization beam. The oxadiazoline (20–30 mg) was placed in a 5 mL flask that was attached to a probe assembly through a ground glass joint. The sample was degassed with three freeze–pump–thaw cycles at roughing vacuum and the probe was inserted into the source of the PE spectrometer while the sample was maintained at –78 °C. The temperature of the dry ice bath was gradually increased until a pressure of ~3 × 10^{-3} Torr (1 Torr = 133.322 4 Pa) could be maintained with little fluctuation. A PE spectrum of **1** was obtained and the laser beam was focused on the tip of the quartz nozzle at the end of the probe assembly in the source. The laser was tuned to a line that yielded a temperature of <500 °C as determined by calibration studies and spectra of the pyrolysate obtained. Spectra of ethenes **4** and **5** as well as esters **6** and **7** were obtained using the method described for **1**. Collected spectra — usually 20–30 — were averaged to yield the spectra reported in this paper.

Results and discussion

Experimental and computational studies

The PE spectrum of **l** is displayed as Fig. 2*a* based on the relative areas of the bands at 8.8, 9.5, and 10.2 eV (ca. 1:1:3), these bands correspond to the first five IPs. The five conformers **1a**–**1e** (Figs. 3*a*–3*e*) were minima on the oxadiazoline potential energy surface at the B3PW91/6-31+G(d,p) level. The ZPE-corrected electronic energies (E_o)

Fig. 2. (*a*) PE spectrum of 2-methoxy-2-methylthio-5,5-dimethyl-Δ^3-l,3,4-oxadiazoline (**1**); (*b*) simulated PE spectrum of 2-methoxy-2-methylthio-5,5-dimethyl-Δ^3-l,3,4-oxadiazoline conformer **1a**; and (*c*) simulated PE spectrum of 2-methoxy-2-methylthio-5,5-dimethyl-Δ^3-l,3,4 oxadiazoline conformer **1b**.

of **1a**, **1b**, **1c**, **1d**, and **1e** are –893.564 302 (0.00 kcal mol^{-1}, 1 cal = 4.184 J), –893.562 989 (+0.82), –893.561 262 (+1.91), –893.560 307 (+2.44), and –893.558 525 (+3.56) hartrees, respectively. Noteworthy is the fact that the CH_3-O- and CH_3-S- groups of **1a** and **1c** have gauche–gauche orientations in which the anomeric effect is expected to be maximal as it is in the case of the gauche–gauche conformation of dimethoxymethane (24). The relative energies indicate that conformer **1a** should be populated preferentially in the gas phase followed by **1b**. At the B3LYP/6-31+G(d,p) level, **1b** is 1.06 kcal mol^{-1} higher in energy (ΔE_o) than **1a**. To a first approximation, a sum of the simulated spectrum of **1a** (Fig. 2*b*) and a minor contribution from **1b** (Fig. 2*c*) — in keeping with the shoulder on the band centered at 9.5 eV — correlates well with the experimental spectrum. That the first three bands of **1** correspond to five IPs is seen in the simulated spectra of conformers **1a** and **1b**, displayed as Figs. 2*b* and 2*c*. The MOs corresponding to the first two bands of **1a** are displayed as Figs. 4*a* and 4*b*. It is seen that the HOMO

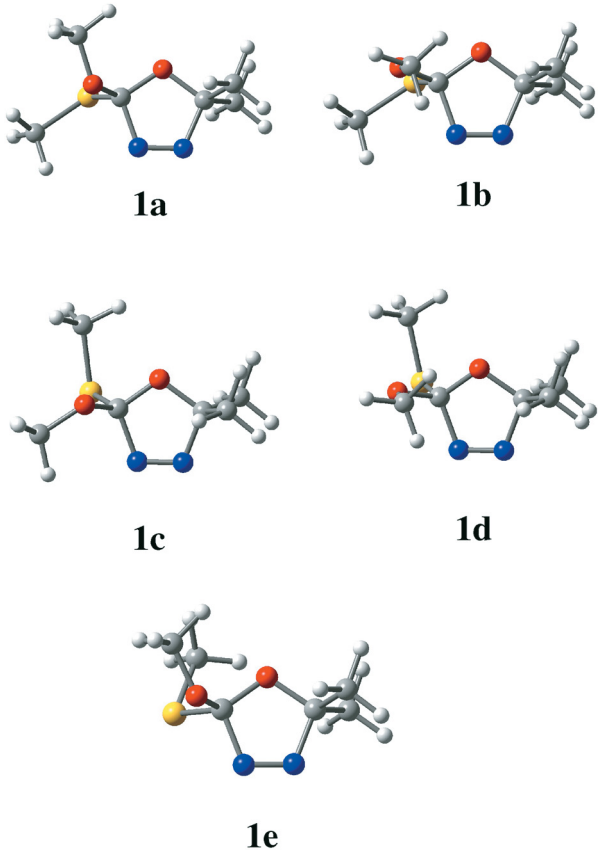
Fig. 3. Optimized geometries of 2-methoxy-2-methylthio-5,5-dimethyl-Δ^3-l,3,4-oxadiazoline conformers **1a**–**1e**. The blue sphere is nitrogen, the red sphere is oxygen, and the yellow sphere is sulfur.



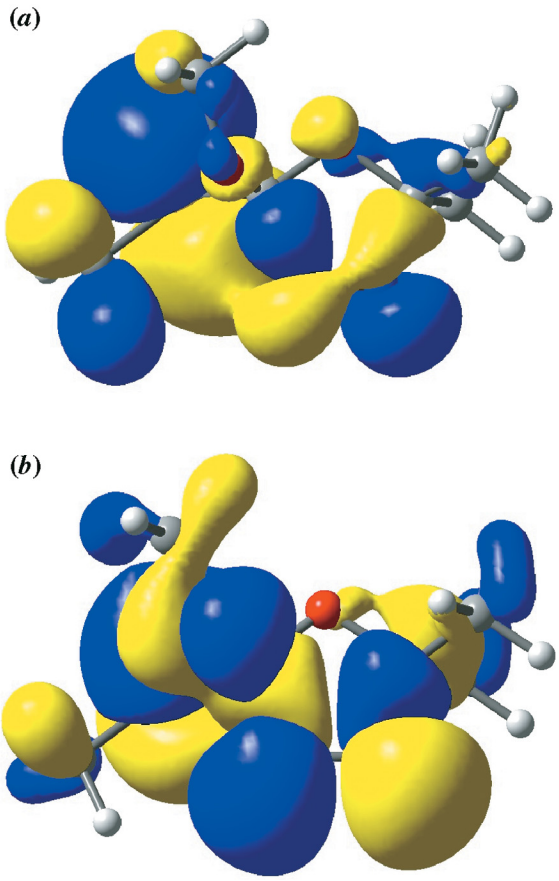


Fig. 4. Molecular orbitals of the 2-methoxy-2-methylthio-5,5-dimethyl-Δ^3-l,3,4-oxadiazoline conformer **1a** at the B3LYP/6-31+G(d,p) level. (*a*) HOMO and (*b*) HOMO–1 (contour value 0.02).

has considerable n_S character in keeping with the fact that it exhibits the lowest IP. On the other hand, HOMO–1 has significant n_N lone-pair character. The peak at 12.63 eV in Fig. 2*a* belongs to a trace of water.

The PE spectra of **1** and its pyrolysate are displayed as Figs. 5*a* and 5*b*, respectively. We take the absence of the band at 10.2 eV of **1** — labeled with a triangle (Fig. 5*a*) — in the spectrum of the pyrolysate from **1** (Fig. 5*b*) as an indication that the pyrolysis of **1** was complete. The relatively sharp feature at 9.7 eV in Fig. 5*b* is due to the lowest IP of acetone. Subtraction of a PE spectrum of acetone yielded the spectrum displayed as Fig. 5*c*.

The ZPE-corrected electronic energies and relative energies of the carbene conformers **3-W**, **3-S1**(Sickle1), **3-S2**(Sickle2), and **3-U** — the optimized structures and selected geometrical parameters are displayed in Fig. 1 — are collected in Table 1. Geometry optimizations were carried out with default convergence criteria without enforcing planarity. It is seen that **3-W** and **3-S1**(Sickle1) are close in energy and that **3-U**, the most sterically hindered conformer, is the least stable conformation of the four carbenes. It is seen that the C—O and C—S bonds to the carbenic carbon are ~0.1 Å shorter than the CH_3—O and CH_3—S bonds, a consequence of the n–π interaction between the lone pairs on the heteroatoms and the nominally vacant p orbital on the carbenic carbon. Also evident is a significant lengthening of the CH_3—O and CH_3—S bonds in the **3-S1**, **3-S2**, and **3-W** species, accountable on the basis of an anti-coplanar n–σ* interaction between the in-plane lone pair and a CH_3—X σ bond. The ZPE-corrected barrier for rearrangement of **3-W** to **3-S1** — the rotational barrier — is 18.42 kcal mol^{-1}; for the rearrangement of **3-S1** to **3-W**, it is 17.84 kcal mol^{-1}. In Fig. 6 are displayed the acetone-stripped spectrum (Fig. 6*a*) and the simulated spectra (Figs. 6*b*–6*d*) of the **3-S1**, **3-W**, and **3-S2** carbene conformers, respectively. The stripped spectrum correlates best with the simulated spectrum of carbene **3-S1**.

Transition states for extrusion of nitrogen from **1a** and **1c**, with computed barriers of 33.38 and 30.82 kcal mol^{-1}, respectively, and for the decomposition of ylide **2** are displayed in Fig. 7 along with selected geometrical parameters. Ylide **2** was derived from **TS-1c**, computed at the B3PW91/6-31+G(d,p) level (Table 2). Figure 7*a* displays **TS-1a**. There are two displays (Figs. 7*b* and 7*c*) of transition state **TS-1c**. Figure 7*c* displays **TS-1c** rotated in-plane clockwise by 90°. It is seen that the improper dihedral angle labeled as C1-C2-C3-S4 increases from 21.4° in **TS-1c** to 50.3° in ylide **2** (Fig. 2*d*) and 64.6° in **TS-2**, the transition state for the decomposition of **2** (Table 3). Ylide **2** is in a very shallow minimum (Table 2). Given the very small barrier for its decomposition to acetone and **3**, if **2** exists it must

be a very short-lived species. Figure 7*e* (**TS2**) clearly shows the putative carbene in the upper portion of the structure being formed in the **3-S1** conformation. Even in **TS-c1** (Fig. 7*b*), the putative carbene fragment is approaching the

Fig. 8. (*a*) PE spectrum of tetrasubstituted (*E*)-ethene (**4**) and (*b*) PE spectrum of tetrasubstituted (*Z*)-ethene (**5**).

Sickle1 conformation, **3-S1**. We found that the same situation — not displayed — holds for conformer **1b**. This is also the case for **TS-1a**: in forming the ylide and then the carbene, the -OCH_3 is expected to rotate to yield **3-S1**, not the high-energy conformer, **3-U**.

We isolated (*E*)- and (*Z*)-ethenes **4** and **5** from a solution-phase pyrolysis (13) and recorded their PE spectra (Figs. 8*a* and 8*b*). Given that **4** and **5** exhibit their lowest IPs below 8 eV, it is clear that **4** and **5** are not present in the pyrolysate of **1**. We also recorded PE spectra of authentic samples of esters **6** (Fig. 9*b*) and **7** (Fig. 9*c*), the potential rearrangement products of **3**. While the spectrum of **7** (Fig. 9*c*) bears some resemblance to the stripped spectrum displayed again as Fig. 9*a*, the pyrolysate certainly does not contain significant quantities of **6**.

Transition states for the formation of esters **6** and **7** from **3-W**, **3-S1**, and **3-S2** were located; **TS-3W→6** and

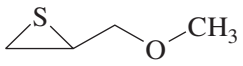
[a]See Figs. 10 and 11 (Supplementary information)[3] for displays of molecular graphs.
[b]The ZPE-corrected energies (E_o) of the methoxy(methylthio)carbene conformers are given in Table 3.
[c]The imaginary frequency in cm^{-1}.



TS-3W→7 are the molecular graphs (Figs. 10*a* and 10*b*) of the transition structures for formation of **6** and **7** from **3-W**, while **TS-3S1→6** and **TS-3S2→7** are the molecular graphs (Figs. 10*c* and 10*d*) of the transition structures for the formation of **6** and **7** from **3-S1** and **3-S2**, respectively, are included as Supplementary information.[3] Only **TS-3S2→7** exhibits a penta-coordinate carbon. The molecular graphs (Figs. 11*a* and 11*b*) of the transition states for the formation of oxirane **8** and thiirane **9** from **3-W** are **TS-3W→8** and **TS-3W→9**, respectively (Table 4). **TS-3S1→8** and **TS-3S2→9** are the molecular graphs (Figs. 11*c* and 11*d*) of the formation of **8** and **9** from **3-S1** and **3-S2**, respectively, are also included as Supplementary information.[3] The migrating hydrogen is dicoordinate in all cases. Except for the rearrangement of **3-S2** to thiirane **9**, all barriers for the formation of esters **6** and **7** from **3-W**, **3-S1**, and **3-S2** exceed 40 kcal mol^{-1}, with the barriers for formation of *S*-methyl thioethanoate (**6**) being roughly 5 kcal mol^{-1} less than the barriers of formation of *O*-methyl ethanethioate (**7**). Given that the relative intensities of the bands at 9.3 and 11.9 eV of the stripped spectrum and the spectrum of **7** differ significantly, and more importantly, our computational studies show that the rearrangement of **3** to **6** would be preferred by 5 kcal mol^{-1} over the rearrangement to **7** in the gas phase, we conclude that **6** and **7** are also not present in the pyrolysate of **1**. As regards the formation of (methylthio)oxirane (**8**) and (methoxy)thiirane (**9**), they were not detected as products in the solution-phase pyrolysis of **1** (13). While the barrier for the rearrangement of **3** into **8** (40 kcal mol^{-1}) is in the range of the barriers of the formation of esters **6** and **7** that are not observed as products, the lower barrier of the formation of **9** from **3-W** and **3-S2** suggests that it may be a possible product. A search of the literature established that **9** is an unknown compound. Its simulated PE spectrum is displayed as Fig. 9*d*. On the other hand, (methoxymethylene)thiirane (**10**) is a known compound and its spectrum has been recorded (25). Consequently, we simulated the PE spectrum of **10** and compared it with the experimental one to validate the simulation of the spectrum of **9**. The simulated spectrum of **10** is displayed in Fig. 9*e* along with vertical bars that indicate the first three experimentally determined IPs. It is seen that there is excellent agreement between the important first two calculated IPs and the experimental vertical IPs. While the predicted value for the third IP is slightly higher than the experimental one, the assignment of the third experimental vertical IP may be inexact because the third experimental band is broad. In fact, it is clear from our simulated spectrum that the fourth band is due to two overlapping bands and not one as stated in the publication (25). We take the fact that the first three vertical IPs of **10** are reproduced with very good accuracy as an indication that the PE spectrum of **9** is also simulated with good accuracy. If this is the case, then the difference in the spectra displayed as Figs. 9*a* and 9*d* in the region of 11 to 12 eV, establishes that the experimental spectrum does not correspond to thiirane **9**.

Conclusions

This study nicely illustrates the versatility of our photoelectron spectrometer in studying organic reactions and transient species in the gas phase in combination with spectrum simulation and DFT calculations. Methoxy(methylthio)carbene has been prepared and detected and its IPs have been determined.

Convenient preparation of aryl-substituted nortropanes by Suzuki–Miyaura methodology[1]

Shyamali Ghosh, William A. Kinney, Diane A. Gauthier, Edward C. Lawson, Tomas Hudlicky, and Bruce E. Maryanoff

Abstract: The synthesis of a new bicyclic vinyl boronate (**5**) was accomplished from N-Boc-nortropinone (**6**) in two steps. The Suzuki–Miyaura coupling of **5** to a variety of aryl bromides and triflates afforded 3-aryl-8-azabicyclo[3.2.1]oct-2-enes in good yields by adjusting the substrate and (or) reaction conditions. Reduction to the 3-aryl-8-azabicyclo[3.2.1]octanes was achieved by hydrogenation. Interestingly, the coupling was also successful with benzyl bromides, providing entry into another group of intermediates.

Key words: nortropane, Suzuki–Miyaura, boronate, piperidine, GPCR, benzyl bromide.

Résumé : La synthèse d'un nouveau boronate de vinyle cyclique (**5**) a été réalisée en deux étapes à partir de la N-Boc-tropinone (**6**). Le couplage du composé **5** avec des bromures et des triflates d'aryles en faisant appel à la méthode de Suzuki–Miyaura et en ajustant le substrat et les conditions réactionnelles conduit à la formation de 3-aryl-8-azabicyclo[3.2.1]oct-2-ènes avec de bons rendements. La réduction des 3-aryl-8-azabicyclo[3.2.1]octanes a été réalisée par hydrogénation. Il est intéressant de noter que la réaction de couplage a été réalisée avec succès avec des bromures de benzyle, ce qui permet d'accéder à un autre groupe d'intermédiaires.

Mots clés : nortropane, Suzuki–Miyaura, boronate, pipéridine, GPCR, bromure de benzyle.

[Traduit par la Rédaction]

Introduction

Phenyl piperidines have proven to be valuable templates for the construction of modulators of G-protein coupled receptors (GPCRs), which are the target of the largest group of marketed drugs (~50%). Of the 38 GPCR-targeted drugs on the market, listed in a recent review (1), five are aryl piperidines (Allegra, Claritin, Duragesic, Risperdal) or aryl-substituted bicyclic piperidines (Atrovent, Combivent). Several others are aryl piperazines or morphine-related polycyclic aryl piperidines. To illustrate the structural diversity of piperidine-containing GPCR ligands, some examples are illustrated in the following: μ-opioid agonist loperamide (**1**) (2), selective δ-opioid agonist **2** (3), urotensin-II receptor antagonist palosuran (**3**) (4), and nonpeptidyl growth hormone secretagogue **4** (5). These compounds demonstrate the importance of aryl piperidines and how selectivity can be altered by making changes in the aryl piperidine architecture and pendant groups. We were interested in preparing aryl-substituted 8-azabicyclo[3.2.1]octane (nortropane) systems related to **2** and **4** in pursuit of novel GPCR ligands.

We envisioned accessing aryl nortropanes by a Suzuki–Miyaura (6) coupling of bicyclic vinyl boronate (**5**) with various aryl halides (Scheme 1). This approach was useful in the preparation of a variety of 4-phenyl tetrahydropyridines from an N-Boc-piperid-3-en-4-yl boronate (7*b*). The palladium/copper(I)-catalyzed Negishi coupling of 4-piperidinylzinc iodide with aryl halides and the piperid-3-en-4-ol phosphate coupling with aryl boronic acids are also noteworthy methods to prepare 4-arylpiperidines (8, 9). Recently, a Stille coupling of a bicyclic vinyl tin reagent provided access to phenyl-substituted 8-azabicyclo[3.2.1]oct-2-enes (nortropene) and nortropanes (5). The coupling of a bicyclic vinyl boronate with aryl halides might provide a less toxic alternative to a variety of interesting nortropenes and nortropanes. Besides investigating an alternative approach, we also wanted to determine whether a greater variety of aryl and benzyl halide coupling partners could be used in combination with **5** than had been demonstrated with the Suzuki couplings of the N-Boc-piperid-3-en-4-yl boronate (7*b*).

Results and discussion

The synthesis of **5** was accomplished by the methods outlined for the preparation of other pinacolato boronates (7).

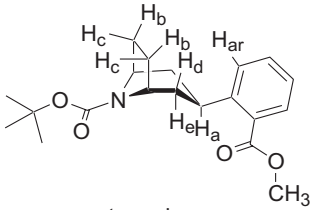
4



N-Boc-nortropinone (**6**) was deprotonated with potassium-hexamethyldisilazide at low temperature and reacted with Comins' reagent (2-(*N*,*N*-bistriflouromethanesulfonyl)amino-5-chloropyridine) to yield the vinyl triflate **7** in 92% yield. The triflate **7** was coupled with bis(pinacolato)diboron, using [1,1′-bis(diphenylphosphino)ferrocene]dichloropalladium(II) dichloromethane complex ($PdCl_2$-dppf, 2 mol%) as the catalyst, to afford bicyclic boronate (**5**) in good yield (77%–84%). This optimized yield was obtained by using only 1 equiv. of the diboron reagent and by carefully monitoring the reaction progress by ^{1}H NMR (vinyl proton of **5** vs. **7**).

The coupling of bicyclic boronate (**5**) with a variety of substituted benzene derivatives (**8**) was initially investigated (Table 1). Reaction of 1-bromo-4-methoxybenzene (**8a**) with **5** using $PdCl_2$-dppf as the catalyst (10 mol%) and potassium carbonate as the base (Method A) gave a low yield of the desired coupling. This poor result was overcome by instead utilizing triflate **8b**, which gave a quantitative yield of **9a**. In other cases the aryl bromides performed satisfactorily. For example, 1-bromo-4-methylbenzene (**8c**) and 2-bromobenzoic acid methyl ester (**8d**) gave a reasonable yield of the coupled products **9c** and **9d** (65% in each case). The example of 2-bromobenzoic acid ethyl ester (**8e**) was added to provide a direct comparison to the Stille approach, which gave a low yield (42%) of **9e** (5). In contrast, coupling of **8e** with **5** afforded **9e** more efficiently (72%). When an additional chlorine substituent was added to the aryl ring (**8f**, **8g**), the triflate (10) was a much better substrate than the bromo derivative, giving an excellent yield of **9f**. The nitro substituent in **8h** did not significantly affect the coupling yield with the arylbromide. The disubstituted nitro ester (**9h**) is a useful intermediate for adding a variety of groups at the 2- and 4-phenyl positions.

The fully reduced 3-aryl-8-azabicyclo[3.2.1]octanes (**10**, Scheme 1) could be achieved by reduction of the double bond in **9**. For example, **9d** was treated with hydrogen and 10% palladium on carbon to afford a quantitative yield of **10d** as a mixture of isomers. The same two isomers of **10d** were obtained when **9f** was reduced because of the additional reduction of the chlorine substituent. The isomers of **10d** (from **9f**) were separated by column chromatography and analyzed by 1D and 2D NMR to assign protons and distinguish the two isomers. For example, an expected NOE was observed between the H_a and H_b protons in the cis isomer (vide infra). The cis isomer is defined as having the aryl and the amine on the same side of the bicycle. Once the two isomers were distinguished, the ^{1}H NMR spectrum on the product **10d** derived from **9d** was analyzed to determine the ratio of isomers. There was a predominance of the cis isomer (cis:trans, 1.65:1), as determined by ratios of the H_a and CH_3O- integrations of the two isomers, which are clearly separated (e.g., H_a-cis δ 4.10 ppm, H_a-trans δ 3.29 ppm).

cis isomer
of **10d**

trans isomer
of **10d**

The nitrophenyl olefin (**9h**) was also efficiently (91%) reduced under the above conditions to yield the aminophenyl nortorpane (**10h**). In this case, the ratio of isomers was reversed (trans:cis, 1.27:1) based on the same comparison of H_a and CH_3O- integrations. Chlorophenyl tropane (**10f**) was available, albeit in low yield (29%, unoptimized), by a Sandmeyer reaction (11) with **10h**.

A variety of aryl and benzyl halides were evaluated as coupling partners for bicyclic boronate (**5**) (Table 1). The electron-deficient aryl bromide, 2-bromopyridine (**11**), coupled in good yield with **5** to give 2-pyridyl nortropene (**9i**). Electron-rich 3-bromoindole (**12**) did not couple efficiently under the usual conditions (Method A), but **9j** was obtained in good yield by using the same catalyst with aqueous sodium carbonate and dimethoxyethane (Method B) (12). While the reaction of benzyl bromides with aryl boronic acids has been seen in recent years (13), their reaction with vinyl boronic acids is less common (13*d*, 13*e*). Although the yield was only moderate (47%), boronate **5** coupled successfully with **13** using tetrakis(triphenylphoshine)palladium(0) as the catalyst (13*b*) to give benzyl-substituted 8-azabicyclo[3.2.1]oct-2-ene (**9k**). In the case of benzyl bromide (**14**), the coupling product **9l** and its isomer **15l** were isolated (**9l**:**15l**, 77:23) in similar yield to **9k**. The exocyclic

[a]Method A: Isolated yield using 0.1 equiv. $PdCl_2$-dppf, 3 equiv. K_2CO_3, DMF–EtOH (4:1), 100 °C, 3–16 h.
[b]Method B: Isolated yield using 0.1 equiv. $PdCl_2$-dppf, 4 equiv. 2 mol/L Na_2CO_3, DME, 100 °C, 10 h.
[c]Method C: Isolated yield using 0.1 equiv. $[Pd(PPh)_3]_4$, 2 equiv. 2 mol/L Na_2CO_3, DME, 100 °C, 16 h.

double bond product **15k** was also observed in the crude NMR spectrum of **9k** (**9k**:**15k**, 85:15), but it was not isolated.

In summary, the synthesis of new bicyclic boronate **5** was accomplished from N-Boc-nortropinone in two steps. The Suzuki–Miyaura coupling of **5** to a variety of aryl bromides and triflates afforded 3-aryl-8-azabicyclo[3.2.1]oct-2-enes in good yields by adjusting the substrate and (or) reaction conditions. Reduction to the 3-aryl-8-azabicyclo[3.2.1]octanes was achieved in good yields in cases in which the substrate had compatible functionality. Interestingly, the coupling of **5** also was successful with benzyl bromides, providing entry into another group of intermediates. The methodology described by Eastwood (7*b*) has been extended to an elaborated piperidine fragment, as well as to a greater variety of coupling partners. The chemistry demonstrated in this report should be applicable to other piperidine and bicyclic piperidine systems.

Experimental

^{1}H NMR spectra were acquired at 300 MHz on a Bruker Avance-300 spectrometer in $CDCl_3$ unless indicated otherwise, using Me_4Si as an internal standard. Normal-phase preparative chromatography was performed on an Isco Combiflash separation system Sg 100c equipped with a Redisep normal-phase disposable columns for flash chromatography containing 12 g of silica gel (optimal flow rate 30 mL/min, column volume 16.8 mL, normal-phase silica part no. 68-2203-026) with detection at 254 nm. Reverse-phase preparative chromatography was performed on a Gilson HPLC with a reversed-phase Kromasil column (10 μ, 100 Å, C18, column size 250 mm × 50 mm). Electrospray (ES) mass spectra were obtained on a Micromass platform LC single quadruple mass spectrometer in the positive mode. LC–MS analyses were performed on a Hewlett Packard series 1100 HPLC instrument eluting with a gradient of water/MeCN/CF_3COOH (10:90:0.2 to 90:10:0.2) over 6 min with a flow rate of 0.75mL/min on a Supelco ABZ + PLUS column (50 mm × 2.1 mm; 3.0 μ particle size) at 32 °C. Accurate mass measurements were performed using a Micromass (Manchester, UK) Autospec E OA-TOF high-resolution magnetic sector mass spectrometer tuned to a resolution of 6000 using the 10% valley definition. The ions were produced in a fast atom bombardment ion source at an accelerating voltage of 8 kV. Linear voltage scans at 33 Da/s were collected to include the protonated sample ion and two polyethylene glycol ions which were used as internal reference standards. The molecular mass was calculated using a linear extrapolation method. Reported mass values are averages over 100 s. Elemental analyses were determined by Quantitative Technologies, Inc., Whitehouse, New Jersey.

3-Trifluoromethanesulfonyloxy-8-azabicyclo[3.2.1]oct-2-ene-8-carboxylic acid *tert*-butyl ester (7)

A solution of N-Boc-nortropinone (**6**, 15.0 g, 67 mmol) in THF (80 mL) was added over 30 min to a cooled (–78 °C) 0.5 mol/L solution of potassium hexamethyldisilazide (162 mL, 81 mmol) in toluene under argon. More THF (20 mL) was added to the reaction mixture, which was stirred for 3.5 h and then treated with 2-(*N*,*N*-bistrifluoromethanesulfonyl)amino-5-chloropyridine (32.0 g, 81 mmol). The reaction mixture was stirred at –78 °C for 4 h and then allowed to warm to room temperature (rt) overnight (final temp: –30 °C). The reaction mixture was adsorbed onto silica gel (40 g) and purified by careful flash chromatography (elution with 10% ethyl acetate in pentane) to provide triflate **7** as a waxy solid (22 g, 92%). ^{1}H NMR ($CDCl_3$, 300 MHz) δ: 5.89 (br s, 1H), 4.25 (br m, 2H), 2.86 (br m, 1H), 2.15–1.59 (m, 5H), 1.30 (s, 9H).

3-(4,4,5,5-Tetramethyl[1,3,2]dioxaborolan-2-yl)-8-azabicyclo[3.2.1]oct-2-ene-8-carboxylic acid *tert*-butyl ester (5)

The triflate **7** (20.5 g, 57 mmol) was dissolved in dioxane (200 mL) and potassium acetate (16.8 g, 171 mmol), bis(pinacolato)diboron (15.0 g, 59 mmol), [1,1′-bis(diphenylphosphino)ferrocene]dichloropalladium(II) dichloromethane complex ($PdCl_2$-dppf, 1.0 g, 1.2 mmol), and 1,1′-bis(diphenylphosphino)ferrocene (0.7 g, mmol, 1.3 mmol) were added and the mixture was degassed with argon for 20 min. The reddish mixture was heated with stirring at 80 °C for 8–10 h, with the color turning a dark brown within the first 2 h. The product to starting material ratio was monitored by removing aliquots, evaporating the solvent, and examining the sample by ^{1}H NMR spectroscopy (ratio of vinyl H of the boronate **5** vs. the triflate **7**). The reaction mixture was cooled, filtered through Celite®, and adsorbed on silica gel (40 g). Chromatography (gradient elution with 5%–10% ethyl acetate in pentane) yielded the pure boronate **5** as a white solid (14.7 g, 77%, mp 98 °C). The fractions that showed an integration ratio of at least 10:14 (Boc-group : pinacol-group Hs) were combined to afford pure **5**. Crude boronate **5** of 41% purity (3.1 g, 7%), contaminated with diboron byproducts, was also obtained as a waxy solid. The purity of crude **5** was determined by coupling this crude material with **8b** affording a 41% yield of **9a** vs. 100% yield with pure **5** (1). ^{1}H NMR ($CDCl_3$, 300 MHz) δ: 6.71 (br s, 1H), 4.31–4.23 (m, 2H), 2.76–2.71 (m, 1H), 2.08 (m, 1H), 1.90–1.84 (m, 2H), 1.63–1.55 (m, 2H), 1.40 (s, 9H), 1.20 (s, 12H). HRMS (EI^+) *m*/*z* calcd. for $C_{18}H_{30}BNO_4$: 335.2268; found: 335.2278. Anal. calcd. for $C_{18}H_{30}BNO_4$: C 64.49, H 9.02; found: C 64.46, H 9.00.

Method A (ref. 7*b*): 3-(4-Methoxyphenyl)-8-azabicyclo-[3.2.1]oct-2-ene-8-carboxylic acid *tert*-butyl ester (9a)

To a mixture of 4-methoxy phenyl triflate (**8b**) (80 mg, 0.31 mmol), the bicyclic boronate **5** (100 mg, 0.30 mmol), [1,1′-bis(diphenylphosphino)ferrocene]dichloropalladium(II) dichloromethane complex ($PdCl_2$-dppf, 24 mg, 0.03 mmol), and K_2CO_3 (123 mg, 0.89 mmol) in a sealable tube (thick walled) was added DMF and EtOH (4:1, 2.5 mL). The mixture was stirred under argon at rt for 5–10 min and the tube was then sealed and heated at 100 °C for 3 h (3–16 h). The mixture was cooled to rt then filtered thru a pad of Celite®, washing with EtOAc. The combined organic layer was concentrated and purified by flash chromatography using a gradient system of 5%–50% ethyl acetate (0.1% TEA) in heptane. The desired product **9a** was isolated as a white solid (0.11 g, 100%). ^{1}H NMR ($CDCl_3$, 300 MHz) δ: 7.29 (d, *J* = 9 Hz, 2H), 6.85 (d, *J* = 9 Hz, 2H), 6.33 (br s, 1H), 4.6–4.4 (m, 2H), 3.80 (s, 3H), 3.1 (m, 1H), 2.3–1.6 (m, 5H), 1.45 (s, 9H). MS (ES^+, M – Boc + 1) *m*/*z*: 216.1. Anal. calcd. for $C_{19}H_{25}NO_3$: C 72.35, H 7.99, N 4.44; found: C 72.56, H 7.96, N 4.36.

3-*p*-Tolyl-8-azabicyclo[3.2.1]oct-2-ene-8-carboxylic acid *tert*-butyl ester (9c)

Aryl bromide **8c** was combined with **5** by Method A to yield **9c** as an oil (65%). ^{1}H NMR ($CDCl_3$, 300 MHz) δ: 7.25 (d, *J* = 8 Hz, 2H), 7.11 (d, *J* = 8 Hz, 2H), 6.39 (br s, 1H), 4.6–4.4 (m, 2H), 3.2–3.0 (m, 1H), 2.33 (s, 3H), 2.3–1.6 (m, 5H), 1.44 (s, 9H). MS (ES^+, M – Boc + 1) *m*/*z*: 200.1. HRMS (FAB^+) *m*/*z* calcd. for $C_{19}H_{25}NO_2$: 299.1885; found: 299.1893.

3-(2-Methoxycarbonylphenyl)-8-azabicyclo[3.2.1]oct-2-ene-8-carboxylic acid *tert*-butyl ester (9d)

Aryl bromide **8d** was combined with **5** by Method A to yield **9d** as an oil (65%). ^{1}H NMR ($CDCl_3$, 300 MHz) δ: 7.76 (d of d, *J* = 7.7, 1.3 Hz, 1H), 7.42 (m, 1H), 7.30 (m, 1H), 7.12 (d, *J* = 7.5 Hz, 1H), 5.83 (br s, 1H), 4.5–4.3 (m,

2H), 3.85 (s, 3H), 3.1–2.8 (m, 1H), 2.3–1.9 (m, 5H), 1.49 (s, 9H). MS (ES^+, M – Boc + 1) *m/z*: 244.2. HRMS (FAB^+) *m/z* calcd. for $C_{20}H_{25}NO_4$: 343.1784; found: 343.1788.

3-(2-Ethoxycarbonylphenyl)-8-azabicyclo[3.2.1]oct-2-ene-8-carboxylic acid *tert*-butyl ester (9e)

Aryl bromide **8e** was combined with **5** by Method A to yield **9e** as an oil (72%). ^1H NMR ($CDCl_3$, 300 MHz) δ: 7.74 (d, *J* = 7.6 Hz, 1H), 7.41 (m, 1H), 7.30 (m, 1H), 7.12 (d of d, *J* = 7.5, 0.8 Hz, 1H), 5.83 (br s, 1H), 4.6–4.2 (m, 4H), 3.1–2.8 (m, 1H), 2.3–1.9 (m, 5H), 1.49 (s, 9H), 1.36 (t, *J* = 7 Hz, 3H). MS (ES^+, M – Boc + 1) *m/z*: 258.1. HRMS (FAB^+) *m/z* calcd. for $C_{21}H_{27}NO_4$: 357.1940; found: 357.1935.

3-(4-Chloro-2-methoxycarbonylphenyl)-8-azabicyclo-[3.2.1]oct-2-ene-8-carboxylic acid *tert*-butyl ester (9f)

Aryl triflate **8g** (10), prepared from the corresponding phenol, was combined with **5** by Method A to yield **9f** as an oil (96%). ^1H NMR ($CDCl_3$, 300 MHz) δ: 7.75 (d, *J* = 2.2 Hz, 1H), 7.38 (d of d, *J* = 8.2, 2.2 Hz, 1H), 7.05 (d, *J* = 8.2 Hz, 1H), 5.83 (br s, 1H), 4.5–4.3 (m, 2H), 3.86 (s, 3H), 3.0–2.8 (m, 1H), 2.3–1.9 (m, 5H), 1.49 (s, 9H). MS (ES^+, M – Boc + 1) *m/z*: 278.1.

3-(2-Methoxycarbonyl-4-nitro-phenyl)-8-azabicyclo-[3.2.1]oct-2-ene-8-carboxylic acid *tert*-butyl ester (9h)

Aryl bromide **8h** was combined with **5** by Method A to yield **9h** as an oil (63%). ^1H NMR ($CDCl_3$, 300 MHz) δ: 8.63 (d, *J* = 2.4 Hz, 1H), 8.26 (d of d, *J* = 8.4, 2.4 Hz, 1H), 7.30 (d, *J* = 8.4 Hz, 1H), 5.91 (br s, 1H), 4.5–4.3 (m, 2H), 3.92 (s, 3H), 3.1–2.8 (m, 1H), 2.3–1.9 (m, 5H), 1.50 (s, 9H). MS (ES, M + Na) *m/z*: 411.1. HRMS (FAB^+) *m/z* calcd. for $C_{20}H_{24}N_2O_6$ + H: 389.1713; found: 389.1706.

3-Pyridin-2-yl-8-azabicyclo[3.2.1]oct-2-ene-8-carboxylic acid *tert*-butyl ester (9i)

2-Bromopyridine (**11**) was combined with **5** by Method A, but purified by reverse-phase HPLC (10%–90% MeCN–H_2O containing 0.2% TFA), to yield the TFA salt of **9i** as an oil (65%). ^1H NMR ($CDCl_3$, 300 MHz) δ: 8.9 (m, 1H), 8.1 (m, 1H), 7.6 (m, 2H), 7.04 (br m, 1H), 4.7–4.5 (m, 2H), 3.5–1.7 (m, 5H), 1.45 (s, 9H). MS (ES^+, M + 1) *m/z*: 287.3. HRMS (FAB^+) *m/z* calcd. for $C_{17}H_{22}N_2O_2$ + H: 287.1760; found: 287.1760.

Method B (ref. 12): 3-(8-*tert*-Butoxycarbonyl-8-azabicyclo[3.2.1]oct-2-en-3-yl)-1*H*-indole-2-carboxylic acid ethyl ester (9j)

To a mixture of the 3-bromoindole (**12**, 80 mg, 0.30 mmol), compound **5** (100 mg, 0.30 mmol), [1,1′-bis(diphenylphosphino)ferrocene]dichloropalladium(II) dichloromethane complex ($PdCl_2$-dppf, 30 mg, 0.04 mmol), and 2 mol/L aq. Na_2CO_3 (0.6 mL, 1.2 mmol) in a sealable tube (thick walled) was added DME (3 mL). After stirring under argon for 5 min, the tube was sealed and heated at 100 °C for 10 h. The reaction mixture was cooled to rt and then filtered through a pad of Celite®, washing with EtOAc. The organic layer was concentrated and purified by flash chromatography using a gradient system of 5%–50% ethyl acetate (0.1% TEA) in heptane. The desired product **9j** was isolated as a white solid (113 mg, 83%). ^1H NMR ($CDCl_3$, 300 MHz) δ: 8.78 (br s, NH), 7.61 (m, 1H), 7.4–7.2 (m, 2H), 7.13 (m, 1H), 6.09 (br s, 1H), 4.6–4.4 (m, 2H), 4.41 (q, *J* = 7 Hz, 2H), 3.6–3.4 (m, 1H), 3.2–2.9 (m, 1H), 2.4–2.0 (m, 4H), 1.50 (s, 9H), 1.42 (t, *J* = 7 Hz, 3H). MS (ES^+, M + Na) *m/z*: 419.2. Anal. calcd. for $C_{23}H_{28}N_2O_4$: C 69.67, H 7.12, N 7.07; found: C 69.86, H 7.25, N 6.90.

Method C (ref. 13*b*): 3-(3-Methoxycarbonyl-benzyl)-8-azabicyclo[3.2.1]oct-2-ene-8-carboxylic acid *tert*-butyl ester (9k)

To a mixture of benzyl bromide (**13**) (72 mg, 0.31 mmol), boronate **5** (100 mg, 0.30 mmol), tetrakis(triphenylphoshine)palladium(0) (34 mg, 0.03 mmol), and 2 mol/L Na_2CO_3 (0.30 mL, 0.60 mmol) in a sealable tube (thick walled) was added DME (3 mL). The mixture was stirred under argon for 5 min. The tube was then sealed and the reaction mixture was heated at 100 °C for 16 h. The reaction mixture was cooled to rt and then filtered through a pad of Celite®, washing with ethyl acetate. The filtrate was diluted with water and extracted with ethyl acetate. The organic layer was separated, dried (sodium sulfate), concentrated, and purified by flash chromatography using a gradient system of 5%–50% ethyl acetate (0.1% TEA) in heptane. Desired product **9k** was isolated as a white solid (53 mg, 47%). ^1H NMR ($CDCl_3$, 300 MHz) δ: 7.9–7.8 (m, 2H), 7.3 (m, 2H), 5.8 (br d, 1H), 4.4–4.1 (m, 2H), 3.91 (s, 3H), 3.24 (AB q, 2H), 2.8–1.8 (m, 4H), 1.6–1.3 (m, 2H), 1.4 (br s, 9H). MS (ES^+, M + Na) *m/z*: 380.1. HRMS (FAB^+) *m/z* calcd. for $C_{21}H_{27}NO_4$ + H: 358.2018; found: 358.2005.

3-Benzyl-8-azabicyclo[3.2.1]oct-2-ene-8-carboxylic acid *tert*-butyl ester (9l) and 3-benzylidene-8-azabicyclo-[3.2.1]octane-8-carboxylic acid *tert*-butyl ester (15l)

Benzyl bromide (**14**) was combined with **5** according to Method C to yield a mixture of **9l** and **15l** as a colorless oil (54%, **9l**:**15l**, 77:23, the exocyclic double bond isomer). ^1H NMR ($CDCl_3$, 300 MHz) δ: 7.39–7.15 (m, 5H), 6.45 (br s, 0.23H), 5.84 (br d, 0.77H), 4.4–4.1 (m, 2H), 3.5–2.5 (m, 4H), 2.2–1.5 (m, 4H), 1.40 (m, 9H). MS (ES^+, M + Na) *m/z*: 321.9. HRMS (FAB^+) *m/z* calcd. for $C_{19}H_{25}NO_2$ – H: 298.1807; found: 298.1799.

3-(2-Methoxycarbonylphenyl)-8-azabicyclo[3.2.1]octane-8-carboxylic acid *tert*-butyl ester (10d)

Compound **9d** (40 mg, 0.12 mmol), MeOH (15 mL), and 10% Pd-C (15 mg) were shaken in a Parr apparatus (40 psig of hydrogen, 3.7 atm) for 16 h. The reaction mixture was filtered through Celite® and concentrated to give **10d** as an oil (41 mg, mixture of two isomers, 100%). The ratio of isomers in the reaction mixture was determined to be 1.65:1 cis:trans. The isomers of **10d** were initially formed in the hydrogenation of **9f** and separated by flash chromatography using a gradient system of 5%–25% ethyl acetate (0.1% TEA) in heptane over 20 min (flow rate 40 mL/min) and their structures were determined. Analysis by ^1H, ^{13}C, and 2-D NMR determined that the faster eluting, major isomer was the cis isomer. Analysis of **10d** mixture from **9d**: ^1H NMR ($CDCl_3$, 300 MHz) δ: 7.78 (m, 0.62H), 7.65 (m, 0.38H), 7.44 (m, 1H), 7.34 (m, 1H), 7.24 (m, 1H), 4.4–4.2 (m, 2H), 4.10 (m, $0.62H_{a\text{-}cis}$), 3.91 (s, $1.9H_{cis}$), 3.87 (s, $1.1H_{trans}$), 3.29

(m, 0.38$H_{a\text{-}trans}$), 2.54 (m, 1H), 2.1–1.3 (m, 7H), 1.51 (s, 9H). MS (ES^+, M + Na) *m/z*: 368.0. HRMS (FAB+) *m/z* calcd. for $C_{20}H_{27}NO_4$: 345.1940; found: 345.1940.[3]

3-(4-Chloro-2-methoxycarbonylphenyl)-8-azabicyclo-[3.2.1]octane-8-carboxylic acid *tert*-butyl ester (10f)

To a stirred mixture (11) of copper(II) chloride (58 mg, 0.43 mmol) in dry acetonitrile (1.5 mL) was added *tert*-butyl nitrite (0.064 mL, 0.54 mmol) via syringe at rt under a nitrogen atmosphere. The resulting dark green suspension was then heated (65 °C) with vigorous stirring. To the warm reaction mixture was added a solution of **10h** (130 mg, 0.36 mmol) in dry acetonitrile (4 mL) via syringe (5 min). The resulting black solution was stirred at 65 °C for 1 h then allowed to cool to rt. The reaction was diluted with ether (10 mL), washed with aq. 1 N HCl (10 mL), washed with brine (10 mL), dried over anhydrous sodium sulfate, filtered, and concentrated in vacuo. The crude mixture was purified by flash chromatography using a gradient system of 5%–50% ethyl acetate (0.1% TEA) in heptane. The desired product **10f** was isolated as a clear colorless oil (40 mg, 29%) with the same mixture of isomers as **10h** (trans:cis, 1.3:1). ^{1}H NMR ($CDCl_3$, 300 MHz) δ: 7.77 (d, *J* = 2.3 Hz, 0.44H), 7.64 (d, *J* = 2.3 Hz, 0.56H), 7.38 (m, 1H), 7.3–7.2 (m, 1H), 4.4–4.2 (m, 2H), 4.09 (m, 0.44H), 3.91 (s, 1.3H), 3.88 (s, 1.7H), 3.26 (m, 0.56H), 2.5 (m, 1H), 2.1–1.3 (m, 7H), 1.51 (s, 9H), 1.36 (m, 2H). MS (ES^+, M + 1) *m/z*: 380.0.

3-(4-Amino-2-methoxycarbonylphenyl)-8-azabicyclo-[3.2.1]octane-8-carboxylic acid *tert*-butyl ester (10h)

Compound **9h** (180 mg, 0.46 mmol), MeOH (30 mL), and 10% Pd-C (60 mg) were shaken in a Parr apparatus (40 psig of hydrogen) for 16 h. The reaction mixture was filtered through Celite®, concentrated and purified by reverse-phase HPLC (20%–90% MeCN–H_2O containing 0.2% TFA). The TFA salt of compound **10h** was isolated as a white solid (200 mg, mixture of two isomers, 91%, ratio 1.27:1 of trans:cis by ^{1}H NMR) after lyophylization. ^{1}H NMR ($CDCl_3$, 300 MHz) δ: 7.39 (br s, 0.44H), 7.3–7.2 (m, 1.56H), 7.04 (m, 1H), 4.3–4.2 (m, 2H), 4.04 (m, 0.44H), 3.90 (s, 1.3H), 3.85 (s, 1.7H), 3.21 (m, 0.56H), 2.44 (m, 1H), 2.2–1.2 (m, 7H), 1.55 (s, 9H). MS (ES^+, M + 1) *m/z*: 361.2. HRMS (FAB^+) *m/z* calcd. for $C_{20}H_{29}N_2O_4$ + H: 361.2127; found: 361.2111.

Synthesis of 6-(alkoxymethyl)- and 6-(alkylsulfanylmethyl)furo[2,3-*d*]pyrimidin-2(3*H*)-one analogues[1,2]

Zlatko Janeba, Noha Maklad, and Morris J. Robins

Abstract: Treatment of 6-(hydroxymethyl)furo[2,3-*d*]pyrimidin-2(3*H*)-one (**2**) with 1-iodoalkanes and potassium carbonate resulted in predominant formation of N3 (and minor amounts of O2) alkylated regioisomers. Treatment of the 3-alkyl products (**3**) with thionyl chloride gave highly reactive 6-chloromethyl intermediates (**5**). Direct solvolysis of **5** in alcohol solutions (~50 °C) produced 3-alkyl-6-(alkoxymethyl)furopyrimidin-2(3*H*)-ones (**6**), whereas extensive decomposition of **5** occurred with added base promoters. Sonication of **5** with sodium thioacetate in acetonitrile gave the air-stable 6-(alkylsulfanylmethyl) intermediates (**7**), which were subjected to deacetylation (methanolic sodium methoxide) and in situ alkylation to give 3-alkyl-6-(alkylsulfanylmethyl)furo[2,3-*d*]pyrimidin-2(3*H*)-ones (**8**). Lipophilic derivatives of furo[2,3-*d*]pyrimidin-2(3*H*)-one are of interest as potential inhibitors of viral penetration of cells.

Key words: furo[2,3-*d*]pyrimidin-2(3*H*)-ones, alkyl, ether and thioether derivatives of furo[2,3-*d*]pyrimidin-2(3*H*)-one.

Résumé : La réaction de la 6-(hydroxyméthyl)furo[2,3-*d*]pyrimidin-2(3*H*)-one (**2**) avec des 1-iodoalcanes en présence de carbonate de potassium conduit à la formation prédominante des régioisomères alkylés en N3, avec des quantités mineures de produits alkylés en O2. Le traitement des produits 3-alkyles (**3**) avec du chlorure de thionyle fournit les intermédiaires 6-chlorométhyles (**5**) fortement réactifs. La solvolyse directe des intermédiaires **5** en solutions alcooliques, à environ ~50 °C, conduit à la production des 3-alkyl-6-(alkoxyméthyl)furopyrimidin-2(3*H*)-ones (**6**) alors qu'on observe des décompositions extensives des produits **5** lorsqu'on utilise des quantités supplémentaires de promoteurs basiques. La sonication des composés **5** avec du thioacétate de sodium dans de l'acétonitrile fournit les intermédiaires 6-(alkylsulfanylméthyl) (**7**) qui sont stables à l'air et qui ont été soumis à des désacétylation à l'aide de méthylate de sodium dans le méthanol ou d'alkylations in situ pour conduire à la formation de 3-alkyl-6-(alkylsulfanylméthyl)furo[2,3-*d*]pyrimidin-2(3*H*)-ones (**8**). Les dérivés lipophiles des furo[2,3-*d*]pyrimidin-2(3*H*)-one présentent de l'intérêt comme inhibiteurs potentiels de la pénétration virale des cellules.

Mots clés : furo[2,3-*d*]pyrimidin-2(3*H*)-ones, dérivés alkyles, éthers et thioéthers de la furo[2,3-*d*]pyrimidin-2(3*H*)-one.

[Traduit par la Rédaction]

Introduction

Certain derivatives of furo[2,3-*d*]pyrimidin-2(3*H*)-one (Fig. 1) exhibit potent antiviral activity. We have noted that Sonogashira coupling of terminal alkynes with 5-iodouracil derivatives gave the 5-(alkyn-1-yl)uracils plus variable quantities of furo[2,3-*d*]pyrimidine by-products (1). We also have reported that the latter bicyclic ring analogues could be produced in high yields by Cu(I)-catalyzed 5-endo-dig cyclization of the 5-alkynyluracil compounds (1, 2). Two decades later, Balzarini, De Clercq, McGuigan, and their co-workers described the remarkable selectivity and potency of longer-chain alkyl derivatives of such bicyclic 2′-deoxynucleosides against varicella-zoster virus (VZV) (3–5). Extensive structure–activity studies revealed that the presence of the long-chain alkyl substituents at C6 of the bicyclic ring (e.g., 6-octyl and 6-*p*-pentylphenyl) was essential for the potent anti-VZV activity. Other modifications including changing of the heteroatom at the 7 position, substituents at C6, and the sugar moiety at N3 (including acyclic analogues (6)) of the furo[2,3-*d*]pyrimidine ring did not produce compounds with more potent and selective anti-VZV activities (see refs. 7–9 for reviews).

Additional analogues that exhibited anti-human cytomegalovirus (HCMV) activity were discovered that did not require activation by nucleoside kinases. These included derivatives with an alkyl group (10) or a 2′,3′-dideoxyfuranosyl moiety at N3 (11). Interestingly, 2′-deoxynucleoside analogues with extended ether side chains at C6 showed dual anti-VZV and anti-HCMV activities (12), and interfer-

ence with viral penetration at cell surfaces might be involved. Thus, empirical SAR examination of new derivatives of this ring system is warranted.

Alkyl analogues are more readily accessible than those whose synthesis begins with expensive 2′-deoxynucleosides. We have explored routes with the potential for divergent and efficient methods for production of new series of such analogues. We (13) and others (14) have recently developed syntheses of furo[2,3-*d*]pyrimidin-2(3*H*)-ones without substituents at N3 beginning with Sonogashira coupling of 5-iodouracil (13) and derivatives (14) with 3-hydroxy-substituted 1-alkynes. These hydroxyalkyne compounds undergo efficient Cu(I)-promoted cyclization, in contrast with other 5-(alkyn-1-yl)uracils without a substituent at N3. The 6-hydroxymethylfuro[2,3-*d*]pyrimidin-2(3*H*)-one (**2**) analogue was obtained in >50% overall yield from 5-iodouracil (13). Treatment of these 6-substituted furo[2,3-*d*]pyrimidin-2(3*H*)-ones with 1-iodoalkanes gives derivatives with an alkyl substituent at N3 (plus minor 2-*O*-alkyl regioisomers). Analogues with lipophilic alkyl groups at N3 and long-chain alkoxy or alkylthio substituents at C6 can be obtained readily.

Results and discussion

Alkylation of 6-(hydroxymethyl)furo[2,3-*d*]pyrimidin-2(3*H*)-one (**2**) (Scheme 1) with 1-iodoalkanes gave the 3-alkyl-6-(hydroxymethyl)furo[2,3-*d*]pyrimidin-2(3*H*)-ones (**3**) in 28%–72% yields. The minor 2-*O*-alkyl regioisomers (**4**) (13) were not isolated. Standard procedures for conversion of the side-chain hydroxyl group of **3** into a mesylate did not give a stable product, but chlorination with $SOCl_2$–pyridine–CH_2Cl_2 at 0 °C gave the corresponding 6-chloromethyl derivates (**5**) in good yields (62%–70%). The deoxychlorination reactions appeared quantitative (TLC), but isolated yields of **5** were lower because of the high reactivity and (or) instability of such benzylic-type chlorides. Careful handling

© 2006 NRC Canada

(including reaction time and temperature, flash evaporation of volatiles at ambient temperature, fast workup, and drying) was necessary to obtain good yields of **5**. Decomposition of these chloromethyl compounds was observed upon storage (TLC), and peaks for the molecular ions were present only in the mass spectra of **5a**, **5b**, and **5e**.

When solutions of compounds **5** were heated in alcohols at ~50 °C, solvolysis occurred to give the 3-alkyl-6-(alkyloxymethyl)furo[2,3-*d*]pyrimidin-2(3*H*)-ones (**6**) in 42%–87% yields. Serious decomposition of **5a** was observed when either sodium propoxide–THF or Et_3N–PrOH was added as a base promoter.

Thioether substituents were introduced at C6 indirectly. Acetylthio intermediates (**7**) were employed to avoid odors and potential oxidative problems with alkanethiols. Sonication of the chloromethyl derivatives (**5**) and potassium thioacetate in acetonitrile for ~5 min gave the air-stable 6-(acetylsulfanylmethyl)-3-alkylfuro[2,3-*d*]pyrimidin-2(3*H*)-ones (**7**) in good yields (53%–90%). Corresponding pairs of **5** and **7** had almost identical R_f values (TLC, MeOH–CH_2Cl_2, 8:92), but they showed slightly different fluorescence properties (UV lamp, 254 nm).

The thioacetates (**7**) were added to stirred solutions of deoxygenated NaOMe–MeOH at ambient temperature. Stirring was continued for a few minutes to remove the acetyl group, and then the 1-iodoalkanes were added. The resulting 3-alkyl-6-(alkylsulfanylmethyl)furo[2,3-*d*]pyrimidin-2(3*H*)-one products (**8**) were obtained in 42%–83% yields.

Conclusions

Two new series of furo[2,3-*d*]pyrimidin-2-one derivatives were prepared from the readily available 6-(hydroxymethyl)furo[2,3-*d*]pyrimidin-2(3*H*)-one (**2**). Alkylation of **2** with 1-iodoalkanes occurred predominantly at N3 to give **3**. Deoxychlorination of the 3-alkyl-6-(hydroxymethyl)furo-[2,3-*d*]pyrimidin-2(3*H*)-ones (**3**) gave the highly reactive chloromethyl intermediates (**5**). Direct solvolysis of **5** occurred in heated alcohol solutions to give the 3-alkyl-6-(alkyloxymethyl)furo[2,3-*d*]pyrimidin-2(3*H*)-one series (**6**). Sonication of **5** with potassium thioacetate gave the air-stable 6-acetylthiomethyl intermediates (**7**), which were deacetylated in deoxygenated methanolic sodium methoxide solution and then treated in situ with 1-iodoalkanes to give the 3-alkyl-6-(alkylsulfanylmethyl)furo[2,3-*d*]pyrimidin-2(3*H*)-ones (**8**). Preliminary cytotoxicity and anti-VZV and HCMV screening of the target compounds did not reveal significant activity.

Experimental

Uncorrected melting points were determined with a hot-stage apparatus. UV spectra were determined with solutions in MeOH. ^{1}H (500 MHz) and ^{13}C (125 MHz) NMR spectra were determined with solutions in $CDCl_3$ unless otherwise indicated. "Apparent" peak shapes are in quotation marks when the first-order splitting should be more complex or when peaks were poorly resolved. High-resolution mass spectra (HRMS) were determined with FAB (thioglycerol, NaOAc) unless otherwise indicated. All reactions were performed under an atmosphere of nitrogen or argon. EtOAc, CH_2Cl_2, DMF, and MeOH were HPLC grade. 1-Propanol, 1-butanol, 1-hexanol, and 1-octanol were reagent grade. Pyridine was purified by distillation. 1-Iodobutane, 1-iodohexane, 1-iodooctane, 1-iododecane, and 1-iodododecane were used as received from Aldrich. CuI (98%) was used as received from Aldrich for all coupling/cyclization reactions.

Method 1: (**2**/K_2CO_3/1-iodoalkane/DMF) is described for **2** → **3a**; method 2: (**3**/$SOCl_2$/pyridine/CH_2Cl_2) is described for **3a** → **5a**; method 3 (**5**/alcohol/Δ) is described for **5a** → **6a**; method 4: (**5**/$KSCOCH_3$/acetonitrile/sonication) is described for **5a** → **7a**; and method 5: (**7**/MeONa/MeOH/1-iodoalkane) is described for **7a** → **8a**.

3-Butyl-6-(hydroxymethyl)furo[2,3-*d*]pyrimidin-2(3*H*)-one (3a)

Method 1

A mixture of 6-(hydroxymethyl)furo[2,3-*d*]pyrimidin-2(3*H*)-one (**2**) (1.70 g, 10.2 mmol), K_2CO_3 (1.55 g, 11.2 mmol), and 1-iodobutane (1.3 mL, 2.06 g, 11.2 mmol) in DMF (17 mL) was stirred at 50 °C for 10 h. Volatiles were evaporated under vacuum, and toluene was added and evaporated (2×). The residue was purified by flash silica gel column chromatography and recrystallized from EtOAc to give **3a** (1.63 g, 72%); mp 179–180 °C. UV max: 245, 331 nm (ε 13 800, 7 500). ^{1}H NMR (DMSO-d_6) δ: 0.89 (t, J = 7.6 Hz, 3H), 1.28 ("hext", J = 7.6 Hz, 2H), 1.64 ("quint", J = 7.6 Hz, 2H), 3.92 (t, J = 7.3 Hz, 2H), 4.42 (d, J = 6.8 Hz, 2H), 5.50 (t, J = 5.9 Hz, 1H), 6.56 (s, 1H), 8.54 (s, 1H). ^{13}C NMR (DMSO-d_6) δ: 172.0, 157.7, 155.2, 143.8, 106.3, 101.4, 56.5, 51.3, 31.2, 19.8, 14.3. HRMS *m*/*z*: 223.1071 (MH^+ [$C_{11}H_{15}N_2O_3$] = 223.1083). Anal. calcd. for $C_{11}H_{14}N_2O_3$: C 59.45, H 6.35, N 12.60; found: C 59.35, H 6.15, N 12.80.

3-Decyl-6-(hydroxymethyl)furo[2,3-*d*]pyrimidin-2(3*H*)-one (3d)

Treatment of **2** (1.7 g, 10.2 mmol), K_2CO_3 (1.55 g, 11.2 mmol), and 1-iododecane (2.4 mL, 3.00 g, 11.2 mmol) by method 1 gave **3d** (1.26 g, 40%); mp 173–175 °C. UV max: 245, 331 nm (ε 15 800, 8 800). ^{1}H NMR (DMSO-d_6) δ: 0.84 (t, J = 6.8 Hz, 3H), 1.22–1.26 (m, 14H), 1.63–1.66 (m, 2H), 3.91 (t, J = 7.3 Hz, 2H), 4.42 (d, J = 5.9 Hz, 2H), 5.50 (t, J = 5.9 Hz, 1H), 6.56 (s, 1H), 8.53 (s, 1H). ^{13}C NMR (DMSO-d_6) δ: 172.0, 157.7, 155.2, 143.8, 106.3, 101.4, 56.5, 51.6, 32.0, 29.6, 29.35, 29.31, 29.1, 26.5, 22.8, 14.6. HRMS (EI) *m*/*z*: 306.1947 (M^+ [$C_{17}H_{26}N_2O_3$] = 306.1943). Anal. calcd. for $C_{17}H_{26}N_2O_3$: C 66.64, H 8.55, N 9.14; found: C 66.85, H 8.61, N 8.97.

3-Dodecyl-6-(hydroxymethyl)furo[2,3-*d*]pyrimidin-2(3*H*)-one (3e)

Treatment of **2** (1.7 g, 10.2 mmol), K_2CO_3 (1.55 g, 11.2 mmol), and 1-iodododecane (2.8 mL, 3.32 g, 11.2 mmol) by method 1 gave **3e** (0.95 g, 28%); mp 172–174 °C. UV max: 245, 331 nm (ε 15 600, 8 200). ^{1}H NMR (DMSO-d_6) δ: 0.84 (t, J = 6.8 Hz, 3H), 1.22–1.25 (m, 18H), 1.62–1.66 (m, 2H), 3.91 (t, J = 7.3 Hz, 2H), 4.42 (d, J = 5.9 Hz, 2H), 5.50 (t, J = 5.9 Hz, 1H), 6.56 (s, 1H), 8.53 (s, 1H). ^{13} C NMR (DMSO-d_6) δ: 172.0, 157.7, 155.1, 143.7, 106.3, 101.4, 56.5, 51.6, 32.0, 29.7, 29.63, 29.55, 29.4, 29.3,

© 2006 NRC Canada

29.1, 26.5, 22.8, 14.6. HRMS *m/z*: 335.2337 (MH^+ [$C_{19}H_{31}N_2O_3$] = 335.2335). Anal. calcd. for $C_{19}H_{30}N_2O_3$: C 68.23, H 9.04, N 8.38; found: C 68.17, H 8.89, N 8.30.

3-Butyl-6-(chloromethyl)furo[2,3-*d*]pyrimidin-2(3*H*)-one (5a)

Method 2

Dried CH_2Cl_2 (40 mL) was added to **3a** (1.11 g, 5.0 mmol) in a flame-dried flask. The solution (under N_2) was cooled to 0 °C, and pyridine (0.80 mL, 0.80 g, 10.0 mmol) followed by $SOCl_2$ (0.55 mL, 0.90 g, 7.5 mmol) were added. After 40 min, the reaction mixture was diluted with CH_2Cl_2 (40 mL), and ice was added. The solution was washed with 0.01 N HCl–H_2O (~5 mL), then $NaHCO_3$–H_2O (pH ~7), and water (2×). The organic layer was dried ($MgSO_4$), the solid was filtered and washed with CH_2Cl_2, and volatiles were evaporated at ambient temperature. The solid residue was dried under vacuum at ambient temperature to give **5a** (0.84 g, 70%). UV max: 251, 332 nm (ε 12 400, 6 800). ^{1}H NMR (DMSO-d_6) δ: 0.90 (t, *J* = 7.3 Hz, 3H), 1.29 ("quint", *J* = 7.6 Hz, 2H), 1.65 ("quint", *J* = 7.6 Hz, 2H), 3.94 (t, *J* = 7.6 Hz, 2H), 4.87 (s, 2H), 6.85 (s, 1H), 8.65 (s, 1H). ^{13}C NMR (DMSO-d_6) δ: 171.9, 155.1, 152.0, 145.4, 105.8, 105.3, 51.5, 38.3, 31.1, 19.8, 14.3. HRMS *m/z*: 241.0747 (MH^+ [$C_{11}H_{14}N_2{}^{35}ClO_2$] = 241.0744).

6-(Chloromethyl)-3-hexylfuro[2,3-*d*]pyrimidin-2(3*H*)-one (5b)

Treatment of 3-hexyl-6-(hydroxymethyl)furo[2,3-*d*]pyrimidin-2(3*H*)-one (**3b**) (13) (1.25 g, 5.0 mmol) by method 2 gave **5b** (0.83 g, 62%). UV max: 251, 332 nm (ε 14 500, 7 900). ^{1}H NMR δ: 0.84 (t, *J* = 6.6 Hz, 3H), 1.30–1.37 (m, 6H), 1.81 ("quint", *J* = 7.3 Hz, 2H), 4.04 (t, *J* = 7.3 Hz, 2H), 4.55 (s, 2H), 6.55 (s, 1H), 8.02 (s, 1H). ^{13}C NMR δ: 171.8, 155.5, 152.9, 141.4, 107.0, 103.2, 52.9, 37.2, 31.6, 29.3, 26.5, 22.7, 14.2. HRMS (EI) *m/z*: 268.0977 (M^+ [$C_{13}H_{17}N_2{}^{35}ClO_2$] = 268.0979).

6-(Chloromethyl)-3-octylfuro[2,3-*d*]pyrimidin-2(3*H*)-one (5c)

Treatment of 6-(hydroxymethyl)-3-octylfuro[2,3-*d*]pyrimidin-2(3*H*)-one (**3c**) (13) (1.39 g, 5 mmol) by method 2 gave **5c** (1.20 g, 81%). UV max: 252, 332 nm (ε 14 000, 7 400). ^{1}H NMR δ: 0.87–0.90 (m, 3H), 1.27–1.34 (m, 10H), 1.82–1.83 (m, 2H), 4.00–4.04 (m, 2H), 4.55 (s, 2H), 6.49 (s, 1H), 7.91 (s, 1H). ^{13}C NMR δ: 172.0, 155.3, 152.9, 141.1, 107.2, 103.0, 52.8, 37.1, 31.9, 29.4, 26.8, 22.8, 14.3.

6-(Chloromethyl)-3-decylfuro[2,3-*d*]pyrimidin-2(3*H*)-one (5d)

Treatment of **3d** (1.53 g, 5 mmol) by method 2 gave **5d** (1.05 g, 65%). UV max: 248, 331 nm (ε 14 300, 7 900). ^{1}H NMR δ: 0.87 (t, *J* = 6.8 Hz, 3H), 1.25–1.33 (m, 14H), 1.79–1.82 (m, 2H), 4.01 (t, *J* = 7.6 Hz, 2H), 4.54 (s, 2H), 6.50 (s, 1H), 7.94 (s, 1H). ^{13}C NMR δ: 171.9, 155.3, 152.8, 141.3, 106.7, 103.1, 52.8, 37.1, 32.0, 29.67, 29.65, 29.45, 29.38, 29.33, 26.8, 22.9, 14.3.

6-(Chloromethyl)-3-dodecylfuro[2,3-*d*]pyrimidin-2(3*H*)-one (5e)

Treatment of **3e** (1.67 g, 5 mmol) by method 2 gave **5e** (1.20 g, 68%). UV max: 253, 331 nm (ε 11 500, 9 500). ^{1}H NMR (DMSO-d_6) δ: 0.84 (t, *J* = 6.6 Hz, 3H), 1.20–1.24 (m, 18H), 1.63–1.65 (m, 2H), 3.92 (t, *J* = 6.9 Hz, 2H), 4.85 (s, 2H), 6.84 (s, 1H), 8.64 (s, 1H). ^{13}C NMR δ: 172.0, 155.3, 152.9, 141.1, 106.7, 103.0, 52.8, 37.1, 32.1, 29.83, 29.76, 29.70, 29.6, 29.43, 29.37, 26.8, 22.9, 14.4. HRMS (EI) *m/z*: 352.1921 (M^+ [$C_{19}H_{29}N_2{}^{35}ClO_2$] = 352.1918).

3-Butyl-6-(octyloxymethyl)furo[2,3-*d*]pyrimidin-2(3*H*)-one (6a)

Method 3

Compound **5a** (100 mg, 0.42 mmol) was added to 1-octanol (2 mL) and the reaction was stirred overnight at 50 °C. The solution was neutralized with Et_3N, and volatiles were evaporated under *high* vacuum. The residue was purified by flash silica gel column chromatography and recrystallized from MeOH to give **6a** (76 mg, 54%); mp 155 °C. UV max: 245, 331 nm (ε 16 500, 9 100). ^{1}H NMR δ: 0.88 (t, *J* = 6.8 Hz, 3H), 0.97 (t, *J* = 7.3 Hz, 3H), 1.27–1.42 (m, 12H), 1.60–1.63 (m, 2H), 1.79–1.82 (m, 2H), 3.55 (t, *J* = 6.6 Hz, 2H), 4.02 (t, *J* = 7.6 Hz, 2H), 4.47 (s, 2H), 6.39 (s, 1H), 7.84 (s, 1H). ^{13}C NMR δ: 172.2, 155.5, 140.3, 107.1, 101.6, 71.8, 65.2, 52.4, 32.0, 31.4, 29.9, 29.6, 29.5, 26.3, 22.9, 20.0, 14.3, 13.9. HRMS (EI) *m/z*: 334.2249 (M^+ [$C_{19}H_{30}N_2O_3$] = 334.2256). Anal. calcd. for $C_{19}H_{30}N_2O_3$: C 68.23, H 9.04, N 8.38; found: C 68.12, H 8.83, N 8.12.

3-Hexyl-6-(propyloxymethyl)furo[2,3-*d*]pyrimidin-2(3*H*)-one (6b)

Treatment of **5b** (100 mg, 0.37 mmol) with 1-propanol (2 mL) by method 3 gave **6b** (68 mg, 63%); mp 165 °C. UV max: 245, 331 nm (ε 14 500, 7900). ^{1}H NMR δ: 0.86–0.96 (m, 6H), 1.31–1.32 (m, 6H), 1.64 ("quint", *J* = 7.1 Hz, 2H), 1.79–1.82 (m, 2H), 3.50–3.54 (m, 2H), 4.02 (t, *J* = 7.1 Hz, 2H), 4.47 (s, 2H), 6.44 (s, 1H), 7.91 (s, 1H). ^{13}C NMR δ: 171.6, 155.5, 155.4, 140.3, 107.3, 101.7, 73.3, 65.1, 52.7, 31.5, 29.3, 26.4, 23.0, 22.7, 14.2, 10.7. HRMS *m/z*: 293.1869 (MH^+ [$C_{16}H_{25}N_2O_3$] = 293.1865). Anal. calcd. for $C_{16}H_{24}N_2O_3$: C 65.73, H 8.27, N 9.58; found: C 65.92, H 8.12, N 9.65.

6-(Butyloxymethyl)-3-hexylfuro[2,3-*d*]pyrimidin-2(3*H*)-one (6c)

Treatment of **5b** (100 mg, 0.37 mmol) with 1-butanol (2 mL) by method 3 gave **6c** (98 mg, 87%); mp 153–155 °C. UV max: 245, 331 nm (ε 12 500, 7 000). ^{1}H NMR δ: 0.89–0.95 (m, 6H), 1.33–1.42 (m, 8H), 1.57–1.62 (m, 2H), 1.80–1.81 (m, 2H), 3.57 (t, *J* = 6.6 Hz, 2H), 4.01 (t, *J* = 7.6 Hz, 2H), 4.47 (s, 2H), 6.38 (s, 1H), 7.83 (s, 1H). ^{13}C NMR δ: 172.1, 155.5, 140.2, 107.1, 101.6, 71.5, 65.2, 52.7, 31.9, 31.6, 29.3, 26.5, 22.7, 19.5, 14.2, 14.1. HRMS *m/z:* 329.1828 (MNa^+ [$C_{17}H_{26}N_2O_3Na$] = 329.1841). Anal. calcd. for $C_{17}H_{26}N_2O_3$: C 66.64, H 8.55, N 9.14; found: C 66.73, H 8.38, N 8.99.

3-Hexyl-6-(hexyloxymethyl)furo[2,3-*d*]pyrimidin-2(3*H*)-one (6d)

Treatment of **5b** (100 mg, 0.37 mmol) with 1-hexanol (2 mL) by method 3 gave **6d** (69 mg, 56%); mp 153–155 °C. UV max: 245, 331 nm (ε 14 200, 7 700). ^{1}H NMR δ: 0.89 (t, *J* = 6.6 Hz, 6H), 1.28–1.37 (m, 12H), 1.59–1.63 (m, 2H), 1.81 ("quint", *J* = 6.8 Hz, 2H), 3.56 (t, *J* = 6.6 Hz, 2H), 4.0 (t, *J* = 7.6 Hz, 2H), 4.47 (s, 2H), 6.39 (s, 1H), 7.84 (s, 1H). ^{13}C NMR δ: 172.1, 155.5, 140.2, 107.0, 101.6, 71.8, 65.2, 52.7, 31.8, 31.6, 29.8, 29.3, 26.5, 25.9, 22.8, 22.7, 14.2. HRMS *m*/*z*: 357.2148 (MNa^+ [$C_{19}H_{30}N_2O_3Na$] = 357.2154). Anal. calcd. for $C_{19}H_{30}N_2O_3$: C 68.23, H 9.04, N 8.38; found: C 68.50, H 8.96, N 8.14.

6-(Butyloxymethyl)-3-octylfuro[2,3-*d*]pyrimidin-2(3*H*)-one (6e)

Treatment of **5c** (100mg, 0.34 mmol) with 1-butanol (2 mL) by method 3 gave **6e** (97 mg, 85%): mp 149–151 °C. UV max: 245, 331 nm (ε 16 500, 8 900). ^{1}H NMR δ: 0.87–0.89 (m, 6H), 1.18–1.42 (m, 12H), 1.58–1.62 (m, 2H), 1.75–2.49 (m, 2H), 3.56 (t, *J* = 6.6 Hz, 2H), 4.0 (t, *J* = 7.6 Hz, 2H), 4.46 (s, 2H), 6.39 (s, 1H), 7.85 (s, 1H). ^{13}C NMR δ: 172.1, 155.50, 155.46, 140.3, 107.1, 101.7, 71.5, 65.2, 52.7, 32.0, 31.9, 29.9, 29.4, 26.8, 22.8, 19.5, 14.3, 14.1. HRMS *m*/*z*: 335.2325 (MH^+ [$C_{19}H_{31}N_2O_3$] = 335.2335). Anal. calcd. for $C_{19}H_{30}N_2O_3$: C 68.23, H 9.04, N 8.38; found: C 68.35, H 8.92, N 8.45.

6-(Hexyloxymethyl)-3-octylfuro[2,3-*d*]pyrimidin-2(3*H*)-one (6f)

Treatment of **5c** (100 mg, 0.34 mmol) with 1-hexanol (2 mL) by method 3 gave **6f** (67 mg, 54%); mp 141–143 °C. UV max: 245, 331 nm (ε 12 700, 6 800). ^{1}H NMR δ: 0.87–0.89 (m, 6H), 1.26–1.38 (m, 16H), 1.62 ("quint", *J* = 7.1 Hz, 2H), 1.81 ("quint", *J* = 6.8 Hz, 2H), 3.56 (t, *J* = 6.6 Hz, 2H), 4.01 (t, *J* = 7.3 Hz, 2H), 4.47 (s, 2H), 6.39 (s, 1H), 7.83 (s, 1H). ^{13}C NMR δ: 172.1, 155.5, 140.2, 107.0, 101.6, 71.8, 65.2, 52.7, 32.0, 31.8, 29.8, 29.4, 26.8, 26.0, 22.8, 14.3. HRMS *m*/*z*: 363.2662 (MH^+ [$C_{21}H_{35}N_2O_3$] = 363.2648. Anal. calcd. for $C_{21}H_{34}N_2O_3$: C 69.58, H 9.45, N 7.73; found: C 69.61, H 9.01, N 7.63.

3-Octyl-6-(octyloxymethyl)furo[2,3-*d*]pyrimidin-2(3*H*)-one (6g)

Treatment of **5c** (100 mg, 0.34 mmol) with 1-octanol (2 mL) by method 3 gave **6g** (0.1 g, 76%); mp 139–141 °C. UV max: 245, 331 nm (ε 13 600, 7 500). ^{1}H NMR δ: 0.87–0.89 (m, 6H), 1.27–1.33 (m, 18H), 1.59–1.68 (m, 4H), 1.79–1.81 (m, 2H), 3.55 (t, *J* = 6.8 Hz, 2H), 4.01 (t, *J* = 7.3 Hz, 2H), 4.47 (s, 2H), 6.39 (s, 1H), 7.85 (s, 1H). ^{13}C NMR δ: 172.1, 155.5, 140.2, 107.1, 101.6, 71.8, 65.2, 52.7, 32.04, 31.96, 29.9, 29.6, 29.5, 29.4, 26.8, 26.3, 22.9, 22.8, 14.34, 14.31. HRMS (EI) *m*/*z*: 390.2881 (M^+ [$C_{23}H_{38}N_2O_3$] = 390.2882). Anal. calcd. for $C_{23}H_{38}N_2O_3$: C 70.73, H 9.81, N 7.17; found: C 70.69, H 9.67, N 7.17.

6-(Butyloxymethyl)-3-decylfuro[2,3-*d*]pyrimidin-2(3*H*)-one (6h)

Treatment of **5d** (100 mg, 0.31 mmol) with 1-butanol (2 mL) by method 3 gave **6h** (76 mg, 68%); mp 150–152 °C. UV max: 245, 331 nm (ε 11 200, 6 400). ^{1}H NMR δ: 0.87–0.95 (m, 6H), 1.26–1.42 (m, 16H), 1.58–1.63 (m, 2H), 1.79–1.82 (m, 2H), 3.57 (t, *J* = 6.6 Hz, 2H), 4.01 (t, *J* = 7.3 Hz, 2H), 4.47 (s, 2H), 6.39 (s, 1H), 7.84 (s, 1H). ^{13}C NMR δ: 172.2, 155.5, 140.3, 107.1, 101.6, 71.5, 65.2, 52.7, 32.1, 31.9, 30.0, 29.7, 29.5, 29.44, 29.38, 26.8, 22.9, 19.5, 14.4, 14.1. HRMS *m*/*z* 385.2462 (MNa^+ [$C_{21}H_{34}N_2O_3Na$] = 385.2467). Anal. calcd. for $C_{21}H_{34}N_2O_3$: C 69.58, H 9.45, N 7.73; found: C 69.69, H 9.46, N, 7.86.

3-Decyl-6-(hexyloxymethyl)furo[2,3-*d*]pyrimidin-2(3*H*)-one (6i)

Treatment of **5d** (100 mg, 0.31 mmol) with 1-hexanol (2 mL) by method 3 gave **6i** (74 mg, 61%); mp 141–143 °C. UV max: 245, 331 nm (ε 14 100, 7 900). ^{1}H NMR δ: 0.87–0.90 (m, 6H), 1.26–1.37 (m, 18H), 1.59–1.62 (m, 4H), 1.79–1.82 (m, 2H), 3.56 (t, *J* = 6.6 Hz, 2H), 4.01 (t, *J* = 7.3 Hz, 2H), 4.47 (s, 2H), 6.40 (s, 1H), 7.85 (s, 1H). ^{13}C NMR δ: 172.1, 155.5, 140.3, 107.1, 101.6, 71.8, 65.2, 52.7, 32.1, 31.9, 30.0, 29.8, 29.7, 29.5, 29.44, 29.38, 26.8, 26.0, 22.9, 22.8, 14.4, 14.3. HRMS *m*/*z*: 413.2796 (MNa^+ [$C_{23}H_{38}N_2O_3Na$] = 413.2780). Anal. calcd. for $C_{23}H_{38}N_2O_3$: C 70.73, H 9.81, N 7.17; found: C 70.90, H 9.66, N 7.35.

3-Decyl-6-(octyloxymethyl)furo[2,3-*d*]pyrimidin-2(3*H*)-one (6j)

Treatment of **5d** (100 mg, 0.31 mmol) with 1-octanol (2 mL) by method 3 gave **6j** (71 mg, 55%); mp 139–141 °C. UV max: 245, 331 nm (ε 10 800, 6 100). ^{1}H NMR δ: 0.89 (t, *J* = 6.6 Hz, 6H), 1.26–1.34 (m, 22H), 1.59–1.62 (m, 4H), 1.80–1.82 (m, 2H), 3.56 (t, *J* = 6.6 Hz, 2H), 4.01 (t, *J* = 7.3 Hz, 2H), 4.47 (s, 2H), 6.38 (s, 1H), 7.83 (s, 1H). ^{13}C NMR δ: 172.2, 155.5, 140.2, 107.1, 101.6, 71.8, 65.2, 52.7, 32.1, 32.0, 29.9, 29.7, 29.6, 29.5, 29.44, 29.38, 26.8, 26.3, 22.9, 14.4. HRMS *m*/*z*: 441.3099 (MNa^+ [$C_{25}H_{42}N_2O_3Na$] = 441.3093). Elemental analyses were not obtained, but NMR spectra were equally clean.

6-(Butyloxymethyl)-3-dodecylfuro[2,3-*d*]pyrimidin-2(3*H*)-one (6k)

Treatment of **5e** (100 mg, 0.28 mmol) with 1-butanol (2 mL) by method 3 gave **6k** (72 mg, 65%); mp 147–149 °C. UV max: 245, 331 nm (ε 11 800, 6 400). ^{1}H NMR δ: 0.87–0.94 (m, 6H), 1.25–1.42 (m, 20H), 1.59–1.63 (m, 2H), 1.79–1.82 (m, 2H), 3.56 (t, *J* = 6.4 Hz, 2H), 4.0 (t, *J* = 7.6 Hz, 2H), 4.46 (s, 2H), 6.38 (s, 1H), 7.84 (s, 1H). ^{13}C NMR δ: 172.1, 155.49, 155.46, 140.2, 107.0, 101.6, 71.5, 65.2, 52.7, 32.1, 31.9, 29.8, 29.73, 29.67, 29.5, 29.41, 29.36, 26.8, 22.9, 19. 4, 14.3, 14.0. HRMS (EI) *m*/*z*: 391.2976 (MH^+ [$C_{23}H_{39}N_2O_3$] = 391.2961). Anal. calcd. for $C_{23}H_{38}N_2O_3$: C 70.73, H 9.81, N 7.17; found: C 70.90, H 9.60, N 7.31.

3-Dodecyl-6-(octyloxymethyl)furo[2,3-*d*]pyrimidin-2(3*H*)-one (6l)

Treatment of **5e** (100 mg, 0.28 mmol) with 1-octanol (2 mL) by method 3 gave **6l** (74 mg, 59%); mp 136–137 °C. UV max: 245, 331 nm (ε 12 000, 6 600). ^{1}H NMR δ: 0.88 (t, *J* = 6.8 Hz, 6H), 1.25–1.33 (m, 28H), 1.61 ("quint", *J* = 6.9 Hz, 2H), 1.80 ("quint", *J* = 6.9 Hz, 2H), 3.55 (t, *J* = 6.6 Hz, 2H), 4.00 (t, *J* = 7.3 Hz, 2H), 4.46 (s, 2H), 6.39 (s, 1H), 7.87 (s, 1H). ^{13}C NMR δ: 172.1, 155.4, 140.3, 107.1, 101.6, 71.8, 65.2, 52.6, 32.1, 32.0, 29.82, 29.79, 29.72,

29.65, 29.58, 29.52, 29.4, 29.3, 26.8, 26.2, 22.9, 22.8, 14.3. HRMS *m/z*: 469.3390 (MNa^+ [$C_{27}H_{46}N_2O_3Na$] = 469.3406). Anal. calcd. for $C_{27}H_{46}N_2O_3$: C 72.60, H 10.38, N 6.27; found: C 72.83, H 10.16, N 6.34.

6-(Acetylsulfanylmethyl)-3-butylfuro[2,3-*d*]pyrimidin-2(3*H*)-one (7a)

Method 4

Dried acetonitrile (10 mL) was added to **5a** (0.24 g, 1 mmol) in a flame-dried flask, and the solution was deoxygenated (Ar) for 30 min. Potassium thioacetate (0.23 g, 2 mmol) was added, and the reaction mixture (under Ar) was sonicated for 5 min. Volatiles were evaporated and the residue was purified by silica gel column chromatography and recrystallized from EtOAc to give **7a** (0.20 g, 76%). UV max: 249, 334 nm (ε 18 500, 8 900). ^{1}H NMR δ: 0.97 (t, *J* = 7.3 Hz, 3H), 1.39 ("hext", *J* = 7.6 Hz, 2H), 1.79 ("quint", *J* = 7.6 Hz, 2H), 2.39 (s, 3H), 4.0 (t, *J* = 7.3 Hz, 2H), 4.10 (s, 2H), 6.35 (s, 1H), 7.79 (s, 1H). ^{13}C NMR δ: 194.2, 172.0, 155.4, 154.0, 140.0, 107.3, 101.6, 52.4, 31.4, 30.6, 26.2, 20.0, 13.9. HRMS *m/z:* 303.0783 (MNa^+ [$C_{13}H_{16}N_2O_3SNa$] = 303.0779).

6-(Acetylsulfanylmethyl)-3-hexylfuro[2,3-*d*]pyrimidin-2(3*H*)-one (7b)

Treatment of **5b** (0.27 g, 1 mmol) by method 4 gave **7b** (0.20 g, 71%). UV max: 251, 333 nm (ε 16 900, 6 700). ^{1}H NMR δ: 0.87 (t, *J* = 6.6 Hz, 3H), 1.29–1.31 (m, 6H), 1.75–1.79 (m, 2H), 2.37 (s, 3H), 3.99 (t, *J* = 7.1 Hz, 2H), 4.10 (s, 2H), 6.35 (s, 1H), 7.83 (s, 1H). ^{13} C NMR δ: 194.2, 171.9, 155.4, 153.9, 140.2, 107.2, 101.6, 52.6, 31.6, 30.6, 29.3, 26.4, 26.2, 22.7, 14.2. HRMS *m/z*: 331.1096 (MNa^+ [$C_{15}H_{20}N_2O_3SNa$] = 331.1092).

6-(Acetylsulfanylmethyl)-3-octylfuro[2,3-*d*]pyrimidin-2(3*H*)-one (7c)

Treatment of **5c** (0.30 g, 1 mmol) by method 4 gave **7c** (0.28 g, 83%). UV max: 250, 333 nm (ε 18 600, 9 100). ^{1}H NMR δ: 0.88 (t, *J* = 6.6 Hz, 3H), 1.26–1.32 (m, 10H), 1.78–1.80 (m, 2H), 2.38 (s, 3H), 3.99 (t, *J* = 7.3 Hz, 2H), 4.01 (s, 2H), 6.35 (s, 1H), 7.79 (s, 1H). ^{13}C NMR δ: 194.2, 171.9, 155.4, 153.9, 140.0, 107.2, 101.6, 95.0, 52.6, 31.9, 30.6, 29.4, 26.8, 26.2, 22.8, 14.3. HRMS *m/z*: 337.1577 (MH^+ [$C_{17}H_{25}N_2O_3S$] = 337.1586).

6-(Acetylsulfanylmethyl)-3-decylfuro[2,3-*d*]pyrimidin-2(3*H*)-one (7d)

Treatment of **5d** (0.32 g, 1 mmol) by method 4 gave **7d** (0.19 g, 53%). UV max: 250, 333 nm (ε 16 200, 7 800). ^{1}H NMR δ: 0.86 (t, *J* = 7.3 Hz, 3H), 1.24–1.31 (m, 14H), 1.76–1.79 (m, 2H), 2.37 (s, 3H), 3.99 (t, *J* = 7.3 Hz, 2H), 4.09 (s, 2H), 6.35 (s, 1H), 7.84 (s, 1H). ^{13}C NMR δ: 194.2, 171.9, 155.5, 153.9, 140.3, 107.3, 101.7, 52.7, 32.1, 30.6, 29.71, 29.68, 29.5, 29.43, 29.38, 26.8, 26.2, 22.9, 14.3. HRMS *m/z*: 387.1707 (MNa^+ [$C_{19}H_{28}N_2O_3SNa$] = 387.1718).

6-(Acetylsulfanylmethyl)-3-dodecylfuro[2,3-*d*]pyrimidin-2(3*H*)-one (7e)

Treatment of **5e** (0.35 g, 1 mmol) by method 4 gave **7e** (0.35 g, 90%). UV max: 250, 333 nm (ε 15 000, 7 500). ^{1}H NMR δ: 0.89 (t, *J* = 6.8 Hz, 3H), 1.25–1.33 (m, 18H), 1.78–1.80 (m, 2H), 2.38 (s, 3H), 3.99 (t, *J* = 7.3 Hz, 2H), 4.10 (s, 2H), 6.35 (s, 1H), 7.79 (s, 1H). ^{13}C NMR δ: 194.3, 172.0, 155.4, 153.9, 140.1, 107.3, 101.6, 52.7, 32.1, 30.6, 29.83, 29.77, 29.70, 29.57, 29.44, 29.39, 26.8, 26.2, 22.9, 14.4. HRMS *m/z*: 415.2029 (MNa^+ [$C_{21}H_{32}N_2O_3SNa$] = 415.2031).

3-Butyl-6-(hexylsulfanylmethyl)furo[2,3-*d*]pyrimidin-2(3*H*)-one (8a)

Method 5

Compound **7a** (200 mg, 0.71 mmol) was added to a deoxygenated solution of MeOH (5 mL) and Na metal (23 mg, 1.0 mmol). The reaction mixture was stirred at ambient temperature for 10 min, and 1-iodohexane (0.15 mL, 212 mg, 1.0 mmol) was added. Stirring was continued for 2 h, and the solution was neutralized with acetic acid. Volatiles were evaporated, and the residue was purified by silica gel column chromatography and recrystallized from MeOH to give **8a** (110 mg, 48%); mp 162 °C. UV max: 249, 334 nm (ε 16 800, 8 700). ^{1}H NMR δ: 0.88 (t, *J* = 6.6 Hz, 3H), 0.96 (t, *J* = 7.3 Hz, 3H), 1.26–1.43 (m, 8H), 1.59 ("quint", *J* = 7.3 Hz, 2H), 1.79 ("quint", *J* = 7.3 Hz, 2H), 2.61 (t, *J* = 7.3 Hz, 2H), 3.67 (s, 2H), 4.02 (t, *J* = 7.3 Hz, 2H), 6.31 (s, 1H), 7.86 (s, 1H). ^{13}C NMR δ: 172.0, 156.2, 155.4, 139.9, 107.5, 100.4, 52.3, 32.7, 31.6, 31.3, 29.3, 28.7, 22.7, 20.0, 14.2, 13.8. HRMS *m/z*: 323.1793 (MH^+ [$C_{17}H_{27}N_2O_2S$] = 323.1793). Anal. calcd. for $C_{17}H_{26}N_2O_2S$: C 63.32, H 8.13, N 8.69; found: C 63.50, H 7.89, N 8.52.

3-Butyl-6-(octylsulfanylmethyl)furo[2,3-*d*]pyrimidin-2(3*H*)-one (8b)

Treatment of **7a** (100 mg, 0.36 mmol) with 1-iodooctane (91 μL, 121 mg, 0.50 mmol) by method 5 gave **8b** (92 mg, 73%); mp 162 °C. UV max: 249, 334 nm (ε 16 800, 8 700). ^{1}H NMR δ: 0.89 (t, *J* = 6.8 Hz, 3H), 0.97 (t, *J* = 7.3 Hz, 3H), 1.27–1.42 (m, 12H), 1.60 ("quint", *J* = 7.6 Hz, 2H), 1.79 ("quint", *J* = 7.6 Hz, 2H), 2.61 (t, *J* = 7.3 Hz, 2H), 3.67 (s, 2H), 4.01 (t, *J* = 7.3 Hz, 2H), 6.29 (s, 1H), 7.79 (s, 1H). ^{13}C NMR δ: 172.1, 156.2, 155.4, 139.6, 107.4, 100.3, 52.3, 32.8, 32.0, 31.4, 29.4, 29.0, 28.7, 22.9, 20.0, 14.3, 13.9. HRMS *m/z*: 373.1938 (MNa^+ [$C_{19}H_{30}N_2O_2SNa$] = 373.1926). Anal. calcd. for $C_{19}H_{30}N_2O_2S$: C 65.10, H 8.63, N 7.99; found: C 65.32, H 8.45, N 8.05.

3-Hexyl-6-(octylsulfanylmethyl)furo[2,3-*d*]pyrimidin-2(3*H*)-one (8c)

Treatment of **7b** (100 mg, 0.32 mmol) with 1-iodooctane (73 μL, 109 mg, 0.45 mmol) by method 5 gave **8c** (82 mg, 68%); mp 158–159 °C. UV max: 249, 334 nm (ε 13 900, 7 400). ^{1}H NMR δ: 0.87–0.89 (m, 6H), 1.27–1.37 (m, 16H), 1.57–1.63 (m, 2H), 1.80 ("quint", *J* = 7.1 Hz, 2H), 2.60–2.63 (m, 2H), 3.67 (s, 2H), 4.00 (t, *J* = 7.5 Hz, 2H), 6.29 (s, 1H), 7.79 (s, 1H). ^{13}C NMR δ: 172.1, 156.3, 155.5, 139.6, 107.4, 100.4, 52.7, 32.8, 32.0, 31.6, 29.4, 29.1, 28.7, 26.5, 22.9, 22.7, 14.4, 14.2. HRMS *m/z*: 401.2244 (MNa^+ [$C_{21}H_{34}N_2O_2SNa$] = 401.2239). Elemental analyses were not obtained, but NMR spectra were equally clean.

6-(Hexylsulfanylmethyl)-3-octylfuro[2,3-*d*]pyrimidin-2(3*H*)-one (8d)

Treatment of **7c** (100 mg, 0.30 mmol) with 1-iodohexane

© 2006 NRC Canada

(61 μL, 88 mg, 0.41 mmol) by method 5 gave **8d** (75 mg, 66%); mp 155–157 °C. UV max: 249, 334 nm (ε 11 900, 6 300). ^{1}H NMR δ: 0.88–0.90 (m, 6H), 1.26–1.41 (m, 16H), 1.57–1.62 (m, 2H), 1.79–1.81 (m, 2H), 2.62 (t, *J* = 7.4 Hz, 2H), 3.67 (s, 2H), 4.0 (t, *J* = 7.5 Hz, 2H), 6.30 (s, 1H), 7.80 (s, 1H). ^{13}C NMR δ: 172.1, 156.3, 155.5, 139.6, 107.4, 100.4, 52.7, 32.8, 32.0, 31.6, 29.9, 29.41, 29.37, 28.7, 26.8, 22.84, 22.77, 14.31, 14.27. HRMS (EI) *m*/*z*: 378.2357 (M^+ [$C_{21}H_{34}N_2O_2S$] = 378.2341). Anal. calcd. for $C_{21}H_{34}N_2O_2S$: C 66.63, H 9.05, N 7.40; found: C 66.80, H 8.87, N 7.22.

3-Octyl-6-(octylsulfanylmethyl)furo[2,3-*d*]pyrimidin-2-one (8e)

Treatment of **7c** (100 mg, 0.30 mmol) with 1-iodooctane (74 μL, 98 mg, 0.41 mmol) by method 5 gave **8e** (57 mg, 47%); mp 153–155 °C. UV max: 249, 334 nm (ε 12 700, 6 700). ^{1}H NMR δ: 0.88 (t, *J* = 7.1 Hz, 6H), 1.27–1.32 (m, 20H), 1.58–1.60 (m, 2H), 1.78–1.82 (m, 2H), 2.61 (t, *J* = 7.5 Hz, 2H), 3.67 (s, 2H), 4.00 (t, *J* = 7.4 Hz, 2H), 6.30 (s, 1H), 7.79 (s, 1H). ^{13}C NMR δ: 172.1, 156.2, 155.5, 139.6, 107.4, 100.4, 52.7, 32.8, 32.03, 31.97, 30.0, 29.4, 29.1, 28.7, 26.8, 22.9, 22.8, 14.34, 14.31. Reconciling solvent effects on rotamer populations in carbohydrates — A joint MD and NMR analysis[1]

Jorge Gonzalez-Outeiriño, Karl N. Kirschner, Smita Thobhani, and Robert J. Woods

Abstract: The rotational preferences of the hydroxymethyl group in pyranosides is known to depend on the local environment, whether in solid, solution, or gas phase. By combining molecular dynamics (MD) simulations with NMR spectroscopy the rotational preferences for the ω angle in methyl 2,3-di-*O*-methyl-α-D-glucopyranoside (**3**) and methyl 2,3-di-*O*-methyl-α-D-galactopyranoside (**6**) in a variety of solvents, with polarities ranging from 80 to 2.3 D have been determined. The effects of solvent polarity on intramolecular hydrogen bonding have been identified and quantified. In water, the internal hydrogen bonding networks are disrupted by competition with hydrogen bonds to the solvent. When the internal hydrogen bonds are differentially disrupted, the rotamer populations associated with the ω angle may be altered. In the case of **3** in water, the preferential disruption of the interaction between HO6 and O4 destabilizes the *tg* rotamer, leading to the observed preference for gauche rotamers. Without the hydrogen bond enhancement offered by a low polarity environment, both **3** and **6** display rotamer populations that are consistent with expectations based on the minimization of repulsive intramolecular oxygen–oxygen interactions. In a low polarity environment, HO6 prefers to interact with O4, however, in water these interactions are markedly weakened, indicating that HO6 acts as a hydrogen bond donor to water.

Key words: carbohydrate, rotamer, molecular dynamics simulation, MD, NMR.

Résumé : Il est bien connu que les préférences rotationnelles des groupes hydroxyméthyles des pyranosides dépend de l'environnement local que ce soit à l'état solide, en solution ou en phase gazeuse. En combinant des simulations de dynamique moléculaire (DM) avec la spectroscopie RMN, on a pu déterminer les préférences rotationnelles pour l'angle ω du 2,3-di-*O*-méthyl-α-D-glucopyranoside de méthyle (**3**) 2,3-di-*O*-méthyl-α-D-galactopyranoside de méthyle (**6**), dans une variété de solvants dont les polarités s'étalent de 80 à 2,3 D. On a identifié et quantifié les effets de polarité du solvant sur la liaison hydrogène intramoléculaire. Dans l'eau, la liaison hydrogène interne est perturbée par la compétition avec les liaisons hydrogènes vers le solvant. Lorsque les liaisons hydrogènes internes sont perturbées de façons différentes, les populations de rotamères associées à l'angle ω peuvent être modifiées. Dans le cas du composé **3**, l'eau provoque une perturbation préférentielle de l'interaction entre le OH en position 6 et l'oxygène en 4 qui déstabilise le rotamère *tg*, ce qui conduit à une observation préférentielle des rotamères gauches. Lorsqu'ils ne présentent pas d'augmentation de la liaison hydrogène en raison d'un environnement de faible polarité, les populations de rotamères des composés **3** et **6** sont en accord avec ce qu'on pourrait attendre sur la base d'une minimisation des interactions répulsives oxygène–oxygène intramoléculaires. Dans une environnement de faible polarité, le OH en position 6 préfère l'interaction avec l'oxygène en 4; toutefois, dans l'eau, ces interactions sont de beaucoup affaiblies ce qui indique que le OH en position 6 agit comme donneur de liaison hydrogène pour l'eau.

Mots clés : hydrate de carbone, rotamère, simulation de dynamique moléculaire, DM, RMN.

Introduction

The importance of understanding the relationships between conformation and biological and chemical function in carbohydrates has come to the forefront of glycobiology as oligo- and poly-saccharides are increasingly implicated in both the healthy growth and functioning of organisms, as well as in a diverse range of disease states (1–3). Further, the covalent attachment of carbohydrates to proteins may affect both protein stability and structure (4–7), as well as,

Fig. 1. (A) Schematic diagram indicating glycosidic torsion angles in carbohydrates. (B) Nomenclature for the ω torsion angle (O6-C6-C5-O5). Qualitatively, the three staggered rotamers are commonly defined with respect to the O6-C6-C5-O5 and O6-C6-C5-C4 torsion angles as gauche-gauche (*gg*), gauche-trans (*gt*), and trans-gauche (*tg*).

conversely, function (8–10). The ability to correlate biological function with glycan structure can provide not only mechanistic insight (11), but is also of benefit in optimizing carbohydrate-based therapeutic agents (12).

X-ray crystallography, NMR spectroscopy, and theoretical calculations are the three techniques most commonly used in the conformational analysis of carbohydrates. X-ray crystallography has been very successful in characterizing protein–carbohydrate complexes, provided that the carbohydrate is limited in size (13, 14). However, single crystal X-ray diffraction structures of oligo- and poly-saccharides are extremely rare; a direct result of difficulties in crystallizing the generally flexible oligosaccharides (15). For solution conformational analysis, NMR spectroscopy is the preferred technique. However, the deconvolution of the observed NMR properties, such as chemical shifts, scalar *J* couplings, nuclear Overhauser effects (NOEs), and residual dipolar couplings, into the 3-D structures that are present in solution presents particular difficulties for these flexible molecules (16, 17). The challenge in deriving a mixture of physically real conformations from a spectroscopic signal that arises from the average of the conformational ensemble is generally met by introducing some aspect of theoretical modeling into the NMR data analysis. Unlike the situation with protein structure determinations by NMR, the use of NMR observables as restraints during the modeling of flexible carbohydrates can lead to the generation of nonphysical virtual conformations (18). To avoid this problem, theoretical calculations are generally employed in one of two ways, either to provide discrete models for the presumed conformations present in solution or to independently predict the conformational states. In the former application, a limited number of theoretical structures are generated, usually by some form of gas-phase energy minimization (quantum or classical mechanical energies) of initial conformations. Based on the computed NMR properties for each individual structure it may then be possible to establish the populations of the individual structures that give the best agreement with experiment. Perhaps the most significant limitation to the accuracy of this approach is the selection of the individual structures, which is often based on scientific intuition. In contrast, molecular dynamics (MD) simulations or Monte Carlo sampling may be employed to predict the ensemble of conformations that the carbohydrate populates at room temperature in the appropriate solvent, independent of investigator bias (19). The accuracy of this latter approach is limited by the choice of classical mechanical force field. Force field development remains an active research area; however, MD simulations are generally able to accurately identify the conformational states present in solution and can often predict their populations with reasonably accuracy (20–24, 19).

In solution, 3-D structures of oligosaccharides have been shown to exist as an equilibrium among several conformations, owing to the flexibility introduced in the structure by the glycosidic linkages, Φ, Ψ, and ω (see Fig. 1). The conformations of the first two torsion angles (Φ, Ψ) are dominated mainly by stereolectronic (anomeric effect) and steric effects (25, 26). As would be expected for an ether-type linkage, the ω torsion angle may adopt any of the three staggered rotamers, with populations depending heavily on the configuration at C4 and on the polarity of the local environment (27, 23).

In the solid state, an early report based on a statistical analysis of X-ray structures (28) revealed two remarkably different conformational behaviors for the ω torsion angle in carbohydrates. The glucopyranosides and mannopyranosides showed clear preferences for only the *gg* and *gt* conformations, with ratios of approximately 40:0:60 (*gt*:*tg*:*gg*), while galactopyranosides showed a significant population of the *tg* rotamer, with a ratio of approximately 58:34:8 (*gt*:*tg*:*gg*). Similar trends have been inferred from NMR data in aqueous solution for both the glucopyranosyl (50:0:53 (29), 38:4:58 (30), 44.7:3.5:51.8 (31), and 52:7:41 (32)) and galactopyranosyl series (56:32:12 (29), 61:21:18 (30), 71.6:13.9:14.5 (31), 65:21:14 (33), and 67:30:3(32)). A detailed review of the conformational properties of the ω angle has been provided by Bock and Duus (29).

In contrast to the condensed-phase experimental data, gas-phase quantum mechanical calculations fail to predict the correct rotamer populations unless the formation of internal hydrogen bonds among hydroxyl groups at C4 and C6 or between the hydroxyl group at C6 and the ring oxygen atom is prevented (34, 23, 31). A Boltzman analysis of the gas-phase quantum mechanical energies, computed at the B3LYP/6-31G(2d,2p) level has been performed for methyl α-D-glucopyranosides and galactopyranosides. A theoretical population ratio of 43:29:28 was obtained for the glucopyranoside when internal hydrogen bonding was allowed, whereas qualitative agreement with experiment (62:0:37) was only obtained when intramolecular hydrogen bonds were prevented from forming. Similarly for the galactopyranoside, ratios of 38:5:57 (with internal hydrogen bonds)

© 2006 NRC Canada

and 41:59:0 (without) were obtained (23). In neither derivative were the gas-phase calculations able to give quantitative agreement with experiment, although they suggested a role for internal hydrogen bonding. It should be noted that in all structures examined quantum mechanically, prevention of internal hydrogen bonding led to significantly higher energies relative to those of conformations in which intramolecular hydrogen bonds were present (23). Nonetheless, the observation that qualitative agreement with experiment was obtained only in the absence of intramolecular hydrogen bonds is consistent with an interpretation of rotamer populations as arising from the minimization of unfavorable 1,3-diaxial electrostatic interactions among O4, O5, and O6 (29, 23).

To obtain quantitative agreement between theoretical calculations and experiment, it was found necessary to include water explicitly in the MD simulations of the glucopyranosides and galactopyranosides (23). The mechanism whereby solvent influences ω population in methyl α-D-glucopyranoside has previously been examined experimentally in an NMR analysis of the 2,3,4,6-tetra- and 2,3,4-tri-*O*-methylated derivatives in several solvents (27). By examining the effect of solvent polarity on rotamer population of these methylated derivatives, Rockwell and Grindley (27) made two important observations, namely that permethylation removed any dependence of rotamer population on solvent polarity (maintaining approximately a ratio of 61:38:0), and, in contrast, that when O6 was unsubstituted there was a strong dependence on polarity. They inferred that polar solvents led to a decrease of intramolecular hydrogen bonding, but also that hydrogen bond donation from the hydroxymethyl group to water was not important in determining rotational preferences.

Here we extend the work of Rockwell and Grindley to derivatives of both glucopyranosides and galactopyranosides in which we elected to examine derivatives that, like the natural carbohydrates, have free hydroxyl groups at either O4 or O6. Thus, we have synthesized methyl 2,3-di-*O*-methyl-α-D-glucopyranoside (**3**) and methyl 2,3-di-*O*-methyl-α-D-galactopyranoside (**6**), and determined the rotational properties of each of their ω angles by NMR in a variety of solvents. By employing these simple models, an assessment of the importance of hydrogen bond donation from HO4 to O6 may be made, as well as of the effect of configuration at C4 on rotamer population as a function of solvent polarity. In addition, a detailed examination of the hydrogen bond properties for these glycosides and related disaccharides was undertaken by performing the longest explicitly solvated MD simulations reported to date in both water and dichloromethane. Data from the theoretical simulations is used to provide atomic level insight into the validity of the inferences made on the basis of the experimental data.

Experimental

General

^{1}H and ^{13}C NMR and 2-D correlation spectra were recorded on Varian 300 and 500 MHz spectrometers, each equipped with Sun off-line editing workstations. Chemical shifts were measured in parts per million (δ) relative to the appropriate solvent peaks and the scalar coupling constants (*J*) were measured in Hertz (Hz). Matrix assisted laser desorption ionization – time-of-flight (MALDI-TOF) mass spectra were recorded using a Hewlett Packard G2025A system with 2,5-dihydroxybenzoic acid (gentisic acid) (10 mg/mL in 50% acetonitrile) as the matrix. Melting points were recorded on a Kofler hot stage apparatus and are uncorrected.

Chemicals and reagents were purchased from Sigma-Aldrich, Fluka, or VWR and used without further purification unless otherwise stated. The reaction solvent (acetonitrile) was distilled from calcium hydride and stored over 4 Å molecular sieves prior to use. Ethanol was used without any further purification.

Synthesis

*Methyl 4,6-*O*-benzylidene-α-D-glucopyranoside (1)*

To a solution of methyl α-D-galactopyranoside (2.11 g, 10.87 mmol) in dry acetonitrile (60 mL) was added benzaldehyde dimethyl acetal (2.80 g, 18.40 mmol) and the solution acidified with camphorsulfonic acid (approx. 0.05 g, 0.22 mmol) to pH 3. After stirring at room temperature under an atmosphere of argon for 15 h, the mixture was neutralized with triethylamine and concentrated in vacuo to dryness using toluene as a cosolvent. The resulting residue was recrystallized from ethyl acetate – hexane to afford compound **1** as a white crystalline solid (2.22 g, 76%); mp 165–167 °C (lit. value (35) mp 166 to 167 °C). ^{1}H NMR (300 MHz, $CDCl_3$) δ: 7.53–7.45 (m, 2H, Ph), 7.41–7.33 (m, 3H, Ph), 5.53 (s, 1H, PhC*H*), 4.80 (d, 1H, H1), 4.30 (dd, 1H, H6a), 3.93 (t, 1H, H3), 3.85–3.77 (m, 1H, H5), 3.73 (t, 1H, H6b), 3.63 (dd, 1H, H2), 3.49 (t, 1H, H4), 3.46 (s, 3H, OCH_3). ^{13}C NMR (75 MHz, $CDCl_3$) δ: not observed (Cq, Ph), 129.2, 126.7 (5 × Ph), 101.7 (Ph*C*H), 99.2 (C1), 81.7 (C4), 72.9 (C2), 71.7 (C3), 69.2 (C6), 62.9 (C5), 55.4 (OCH_3). MALDI-TOF MS *m*/*z*: 305.2 $[M + Na]^+$.

*Methyl 4,6-*O*-benzylidene-2,3-di-*O*-methyl-α-D-glucopyranoside (2)*

Methyl 4,6-*O*-benzylidene-α-D-glucopyranoside (500 mg, 1.77 mmol) was dissolved in dry DMF (20 mL) under a nitrogen atmosphere. To this was added 60% NaH suspended in oil (260 mg, 6.50 mmol) followed by the dropwise addition of methyl iodide (340 μL, 5.46 mmol) and the reaction was left to stir for 16 h under a nitrogen atmosphere at room temperature. After this time, the reaction was quenched with water (40 mL) and the aqueous layer was washed with ethyl acetate (3 × 50 mL). The combined organic layers were then washed with satd. $NaHCO_3$ (3 × 50 mL) and water (3 × 50 mL). The combined organic layers were dried ($MgSO_4$), filtered, and the solvent removed in vacuo and the residue recrystallized from ethanol to furnish **2** as a white solid (270 mg, 49%); mp 121 to 122 °C (lit. value (36) mp 122 to 123 °C). ^{1}H NMR (300 MHz, $CDCl_3$) δ: 7.53–7.45 (m, 2H, Ph), 7.40–7.31 (m, 3H, Ph), 5.54 (s, 1H, PhC*H*), 4.85 (d, 1H, H1), 4.28 (dd, 1H, H6a), 3.88–3.78 (m, 1H, H5), 3.74 (dd, 1H, H6b), 3.69 (t, 1H, H3), 3.64 (s, 3H, OCH_3), 3.56 (s, 3H, OCH_3), 3.53 (t, 1H, H4), 3.45 (s, 3H, OCH_3), 3.30 (t, 1H, H2). ^{13}C NMR (75 MHz, $CDCl_3$) δ: not observed (Cq, Ph), 129.4, 126.9 (5 × Ph), 101.9 (Ph*C*H), 98.1 (C1), 81.9

© 2006 NRC Canada

(C2), 81.9 (C4), 80.6 (C3), 69.4 (C6), 61.9 (C5), 60.6, 59.4, 55.6 (3 × OCH_3). MALDI-TOF MS *m/z*: 332.8 $[M + Na]^+$.

*Methyl 2,3-di-*O*-methyl-α-D-glucopyranoside (3)*

To methyl 4,6-*O*-benzylidene-2,3-di-*O*-methyl-α-D-glucopyranoside (250 mg, 0.81 mmol) was added a solution of 80% acetic acid in water (15 mL) and the mixture was heated to 50 °C. After a period of 4 h, the reaction mixture was cooled, concentrated in vacuo, and then coevaporated with toluene (3 × 20 mL). The residue was recrystallized from ethyl acetate – hexane to give the desired compound **3** as a white solid (73 mg, 41%); mp 81–84 °C (lit. value (37) mp 84 °C). ^{1}H NMR (500 MHz, $CDCl_3$) δ: 4.84 (d, 1H, H1), 3.85 (dd, 1H, H6a), 3.80 (dd, 1H, H6b), 3.65–3.61 (m, 1H, H5), 3.63 (s, 3H, OCH_3), 3.49 (s, 3H, OCH_3), 3.50 (dd, 1H, H4), 3.43 (s, 3H, OCH_3), 3.46 (dd, 1H, H3), 3.21 (dd, 1H, H2). ^{13}C NMR (75 MHz, D_2O) δ: 97.3 (C1), 83.0 (C3), 80.6 (C2), 72.2 (C5) 69.8 (C4), 61.2 (C6), 60.6, 58.5, 55.4 (3 × OCH_3). MALDI TOF *m/z*: 245.2 $[M + Na]^+$.

*Methyl 4,6-*O*-benzylidene-α-D-galactopyranoside (4)*

The synthesis of methyl 4,6-*O*-benzylidene-α-D-galactopyranoside was carried out following the procedure described for the preparation of the methyl 4,6-*O*-benzylidene-α-D-glucopyranoside. Thus, methyl α-D-galactopyranoside (1.00 g, 5.15 mmol) in dry acetonitrile (160 mL) was reacted with benzaldehyde dimethyl acetal (2.20 g, 14.45 mmol) and camphorsulfonic acid (approx. 0.03 g, 0.13 mmol) to afford **4** as a white crystalline solid after recrystallization (0.73 g, 50%); mp 169–171 °C (lit. value (35) mp 168 to 169 °C). ^{1}H NMR (300 MHz, $CDCl_3$) δ: 7.52–7.35 (m, 5H, Ph), 5.55 (s, 1H, PhC*H*), 4.92 (d, 1H, H1), 4.28 (dd, 1H, H6a), 4.25 (dd, 1H, H4), 4.08 (dd, 1H, H6b), 3.93 (dd, 1H, H2), 3.89 (dd, 1H, H3), 3.69 (ddd, 1H, H5), 3.46 (s, 3H, OCH_3). ^{13}C NMR (75 MHz, $CDCl_3$) δ: not observed (Cq, Ph), 129.4, 128.2, 126.3 (5 × Ph), 101.3 (Ph*C*H), 100.0 (C1), 75.7 (C4), 70.0 (C2), 70.0 (C3), 69.4 (C6), 62.5 (C5), 55.7 (OCH_3). MALDI-TOF MS *m/z*: 305.1 $[M + Na]^+$.

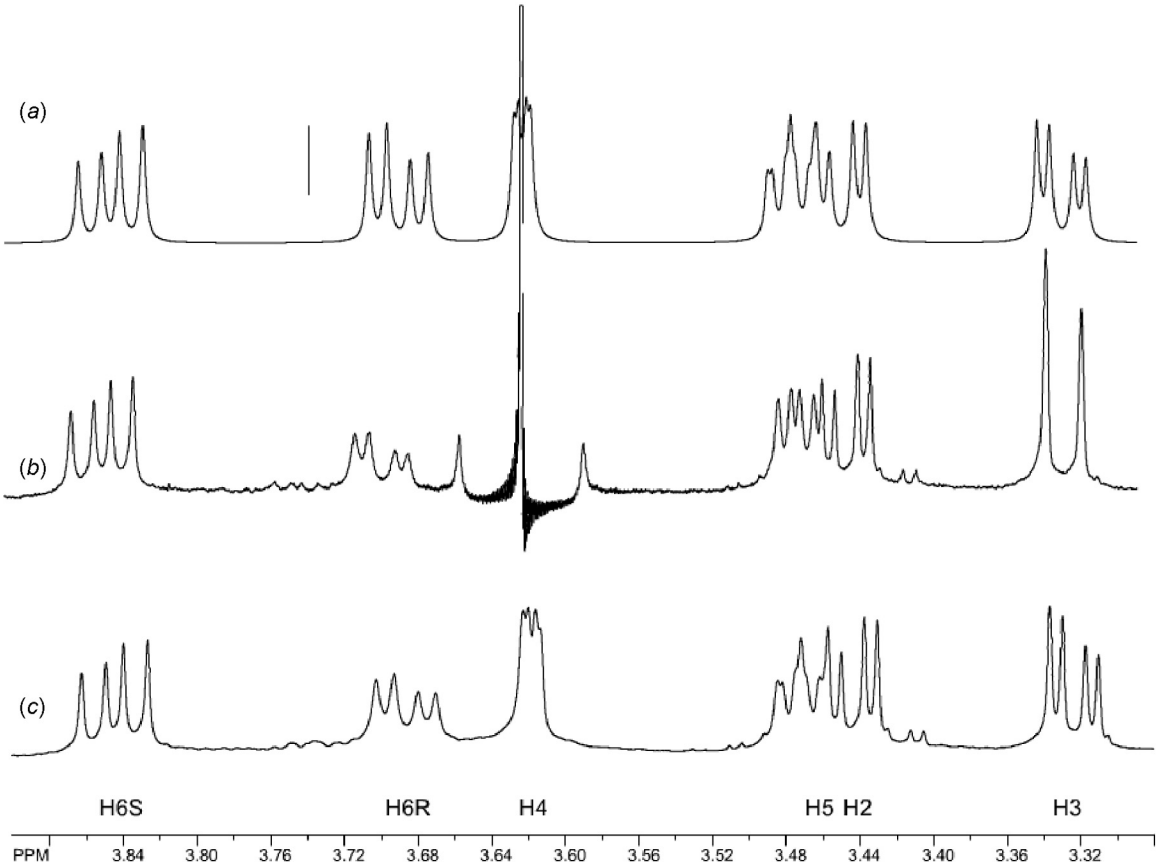
*Methyl 4,6-*O*-benzylidene-2,3-di-*O*-methyl-α-D-galactopyranoside (5)*

The synthesis of methyl 4,6-*O*-benzylidene-2,3-di-*O*-methyl-α-D-galactopyranoside was carried out following the procedure described for the preparation of the methyl 4,6-*O*-benzylidene-2,3-di-*O*-methyl-α-D-glucopyranoside. Thus, methyl 4,6-*O*-benzylidene-α-D-galactopyranoside (700 mg, 2.48 mmol) was reacted with NaH (300 mg, 7.50 mmol) and methyl iodide (900 μL, 14.46 mmol) in dry DMF (20 mL) to give **5** as a white solid after recrystallization (230 mg, 40%); mp 126 to 127 °C (lit. value (38) mp 127 to 128 °C. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 7.56–7.48 (m, 2H, Ph), 7.38–7.29 (m, 3H, Ph), 5.53 (s, 1H, PhC*H*), 4.97 (d, 1H, H1), 4.30 (d, 1H, H4), 4.22 (d, 1H, H6a), 4.03 (d, 1H, H6b), 3.77 (dd, 1H, H2), 3.66 (dd, 1H, H3), 3.57 (s, 1H, H5), 3.51 (s, 3H, OCH_3), 3.50 (s, 3H, OCH_3), 3.43 (s, 3H, OCH_3). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 137.9 (Cq, Ph), 128.9, 128.1, 126.3 (5 × Ph), 101.1 (Ph*C*H), 98.5 (C1), 77.6 (C2), 77.6 (C3), 73.7 (C4), 69.4 (C6), 62.5 (C5), 59.0, 57.8, 55.4 (3 × OCH_3). MALDI-TOF MS *m/z*: 332.8 $[M + Na]^+$.

*Methyl 2,3-di-*O*-methyl-α-D-galactopyranoside (6)*

The synthesis of methyl 2,3-di-*O*-methyl-α-D-galactopyranoside was carried out following the procedure described for the preparation of the methyl 2,3-di-*O*-methyl-α-D-glucopyranoside. Thus, methyl 4,6-*O*-benzylidene-2,3-di-*O*-methyl-α-D-galacto-pyranoside (230 mg, 0.74 mmol) was treated with 80% acetic acid (15 mL) to give the desired product **6** as a white solid after recrystallization (49 mg, 30%). ^{1}H NMR (500 MHz, $CDCl_3$) δ: 4.90 (d, 1H, H1), 4.13 (dd, 1H, H4), 3.94 (dd, 1H, H6a), 3.81 (dd, 1H, H6b), 3.76 (t, 1H, H5), 3.56 (dd, 1H, H2), 3.52 (dd, 1H, H3), 3.49 (s, 3H, OCH_3), 3.48 (s, 3H, OCH_3), 3.41 (s, 3H, OCH_3), 2.01 (s, 3H, OCH_3). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 97.7 (C1), 78.9 (C3), 77.2 (C2), 69.0 (C5), 67.4 (C4), 62.5 (C6), 58.7, 57.7, 55.1 (3 × OCH_3). MALDI-TOF MS *m/z*: 245.2 $[M + Na]^+$.

Molecular dynamics simulation



Molecular dynamics (MD) simulations were performed using the SANDER module in the AMBER5 program suite (39) with the GLYCAM (40) parameters for carbohydrates. The 1–4 electrostatic and van der Waals interactions were unscaled (SCEE = 1.0 and SCNB = 1.0), in contrast to the traditional AMBER formalism, but as demonstrated to be essential for carbohydrate simulations (23). The MD simulations were performed using an nPT ensemble with TIP3P water (41) and a dielectric constant set to unity. A long range cutoff of 8 Å was employed. For solvation in water, the carbohydrates were immersed in a theoretical box of 484 (**3**) and 473 (**6**) water molecules with approximate dimensions of 28 Å × 27 Å × 23 Å. For simulations employing dichloromethane, a cutoff of 12 Å was employed with a slightly larger theoretical box (34 Å × 32 Å × 29 Å) of 294 dichloromethane molecules (42) for both carbohydrates. The SHAKE algorithm was applied to all hydrogen-containing bonds, using the default settings. Initial conjugate-gradient energy minimization (20 000 cycles), with restrained solute coordinates, was performed on all systems studied, employing a 0.01 kcal mol^{-1} Å (1 cal = 4.184 J) convergence criterion in the energy gradient. Subsequently, energy minimization of the entire system was performed followed by a simulated annealing period for the solvent, during which the systems were heated from 5 to 300 K for a period of 50 ps, held at 300 K for 250 ps in the case of water, and 1350 ps in dichloromethane, and then the systems were cooled to 5 K over 50 ps. Lastly, the systems were heated from 5 to 300 K over 50 ps prior to the production run MD simulations. Between 100–120 ns of data were collected for each system at 300 K. In all simulations, a 2 fs time step was employed in the integration of the equations of motion. The extremely long MD simulation times were required to achieve adequate sampling of the rotational states. The post-simulation analyses were performed using the CARNAL module of the AMBER suite of programs.

NMR

Each carbohydrate (5–10 mg per sample) was dissolved in each of the different deuterated solvents (D_2O, DMSO-d_6, CD_3CN, CD_2Cl_2, $CDCl_3$, toluene-d_8, benzene-d_6) and introduced into a 5 mm NMR tube. The NMR experiments were performed on Varian 600 and 500 MHz spectrometers. One-

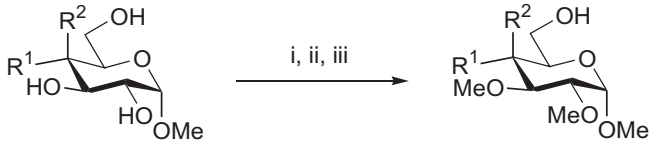
dimensional ^{1}H spectra and homodecoupled experiments with irradiation of the H4 and hydroxyl proton, OH6, were performed to obtain the initial $^3J_{\text{H5-H6(R or S)}}$ couplings (Fig. 2). Final values for the scalar couplings were obtained by iterative spectral simulation using the SPINWORKS (43) and PERCH NMR software (44).

Results and discussion



Synthesis of methyl 2,3-di-*O*-methyl-α-D-glucopyranoside and galactopyranoside

The desired 2,3-di-*O*-methylated α-D-glucopyranosides and galactopyranosides were prepared in three steps following established procedures (Scheme 1). Thus, regioselective benzylidenation of the commercially available methyl α-pyranosides at the O4 and O6 positions, followed by methylation of the hydroxyls at the C2 and C3 positions, resulted in the fully protected intermediates (**2** and **5**). The final step involved the acid-mediated cleavage of the benzylidene acetal to give the desired compounds (**3** and **6**) as white solids after recrystallization.

Calculation of $^3J_{HH}$ couplings

Due to the rapid rotational timescale for the ω angle (45, 46), the rotamer population from NMR spectroscopy may only be indirectly inferred. Any experimental measurement corresponding to a fast equilibrium with respect to the timescale of the technique can be interpreted as a weighted

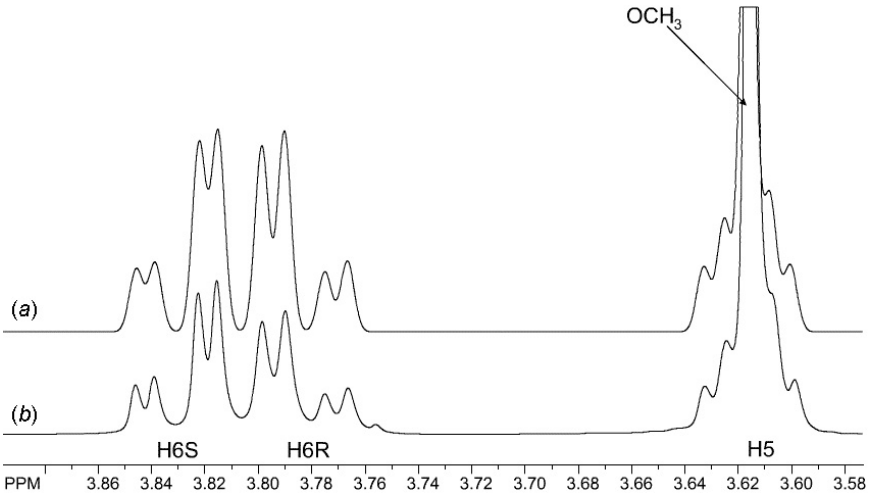
average of contributions from the individual states involved in the process. In the case of ω-angle populations, at least three conformations should be considered as being in fast equilibrium on the NMR timescale (29, 27, 47). The NMR data for the $^3J_{HH}$ couplings related to the C5-C6 rotational equilibrium are generally deconvoluted into rotamer populations using eqs. [1]–[3]:



$$[1] \quad {}^3J_{\text{H5-H6R}} = n_{gt}{}^3J_{(\text{H5-H6R},\, gt)} + n_{tg}{}^3J_{(\text{H5-H6R},\, tg)} + n_{gg}{}^3J_{(\text{H5-H6R},\, gg)}$$

$$[2] \quad {}^3J_{\text{H5-H6S}} = n_{gt}{}^3J_{(\text{H5-H6S},\, gt)} + n_{tg}{}^3J_{(\text{H5-H6S},\, tg)} + n_{gg}{}^3J_{(\text{H5-H6S},\, gg)}$$

$$[3] \quad n_{gt} + n_{tg} + n_{gg} = 1$$

in which $^3J_{H5\text{-}H6R}$ and $^3J_{H5\text{-}H6S}$ are the experimentally measured couplings between protons H5 and each of the prochiral H6 protons, and $^3J_{(H5\text{-}H6,\ ii)}$ are the limiting values of the specific coupling constants in each conformational state *ii* with population n_{ii}.

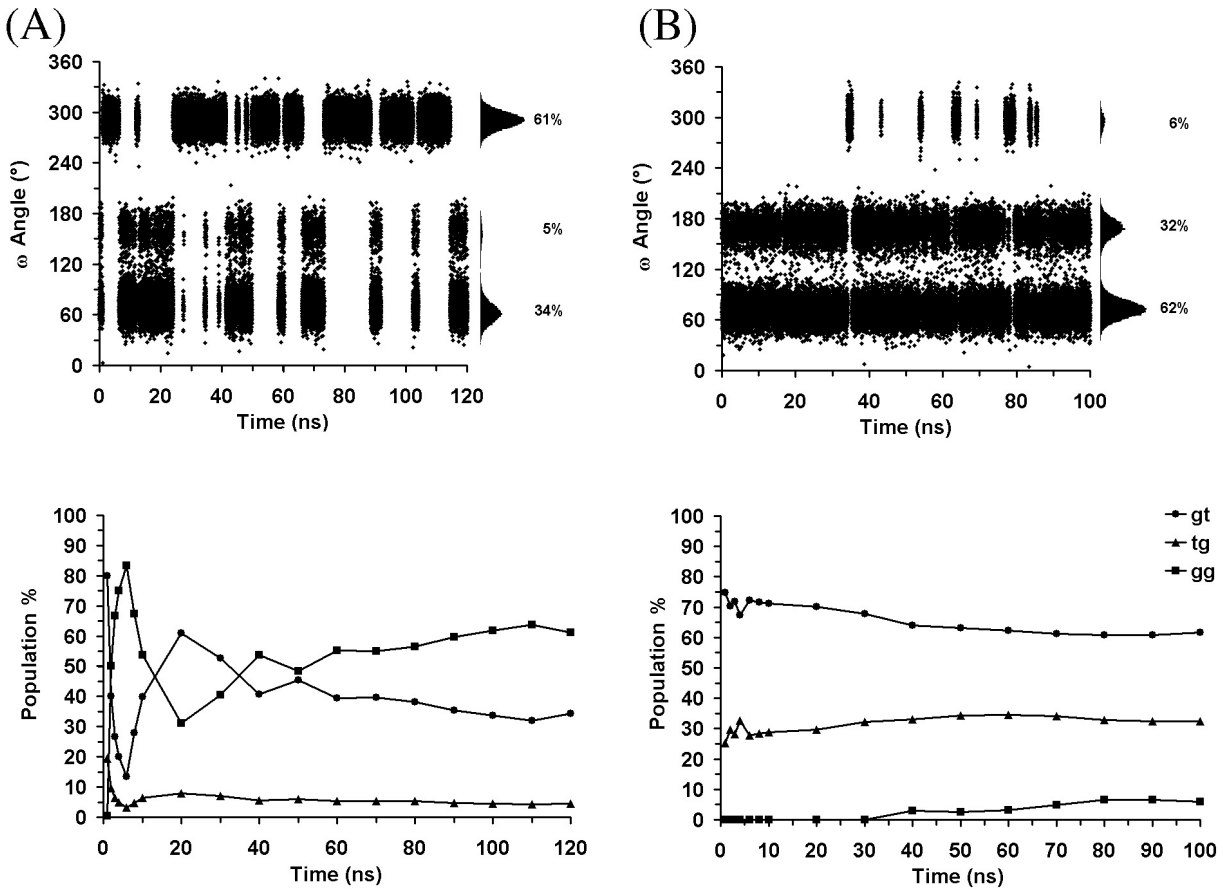
There are numerous sources of uncertainty in this approach, both in terms of the experimental measurements and in the data interpretation. Second-order effects are commonly observed in this type of spectra (Fig. 3), making the use of directly measured ^3J values inappropriate. To remove the second-order effects, the spectra were simulated via an iterative procedure in which the first-order ^3J couplings were varied, until optimal agreement between the experimental and the predicted spectra was achieved (43).

There are two further significant limitations of this method, related to the calculation of the ^3J couplings. Firstly, ^3J couplings are generally computed using a Karplus-type equation that correlates coupling constants with dihedral angles and many approaches to the parameterization of these relationships have been proposed, including empirical methods based on experimental data (48) and theoretical methods based on quantum mechanical data (32). In the case of the empirical equation reported by Haasnoot et al. (48), the equation included the effects of electronegative substituents on the $^3J_{HH}$ values, but was parameterized using rigid model compounds. A single equation was developed for computing each of the $^3J_{H5\text{-}H6R}$ and $^3J_{H5\text{-}H6S}$ values. This approach can lead to the prediction of small negative rotamer populations, particularly for dynamic systems. The equation introduced by Stenutz et al. (32) was parameterized using ^3J couplings computed from density functional theory (DFT) for a set of model compounds. By considering variations in the ω conformations, as well as in the orientation of the hydroxyl groups, Stenutz et al. arrived at a separate equation for the couplings between H5 and each of the prochiral H6 protons, reflecting both geometric and electronic variations in the pro-R and pro-S environments. A promising alternative is to compute the ^3J couplings directly from quantum mechanical calculations, without employing an empirical Karplus-type equation (49). This method has many benefits; however, its computationally intensity makes it challenging to employ when analyzing the thousands of conformations typically generated during MD simulations.

Table 1. Limiting ^3J values employed in the present analysis.

	Empirically derived (48)			Quantum derived (32)		
Coupling constant	*gt*	*tg*	*gg*	*gt*	*tg*	*gg*
$^3J_{H5\text{-}H6R}$	10.7	5	0.9	9.9	4.5	0.8
$^3J_{H5\text{-}H6S}$	3.1	10.7	2.8	1.5	10.8	1.3

Note: *J* values are in Hertz.



In the parameterization of the any given Karplus-type relationship, a set of limiting ^3J values must be derived for each rotamer. The accuracy of the limiting *J* values is critical when applying eqs. [1]–[3]. Previously, it was assumed that the ω angle would adopt idealized values of 60°, 180°, and –60° in each of the rotameric states; however, this approach often led to small unrealistic negative rotamer populations. More recently, gas-phase energy minimized geometries have been employed for each rotamer. Notably, these optimized geometries differed markedly from idealized values (29, 27). As part of this study, the extent to which the omission of solvent in the geometry optimizations biases the conformations away from those actually present in solution will be examined. Gas-phase energy minimization always leads to an excessive degree of internal hydrogen bonding (23), which is expected to introduce some level of distortion into the ω angle relative to its orientation in water. To assess the effect of the limiting *J* value on the derivation of the rotamer populations we have employed both the empirical and quantum-derived values (see Table 1).

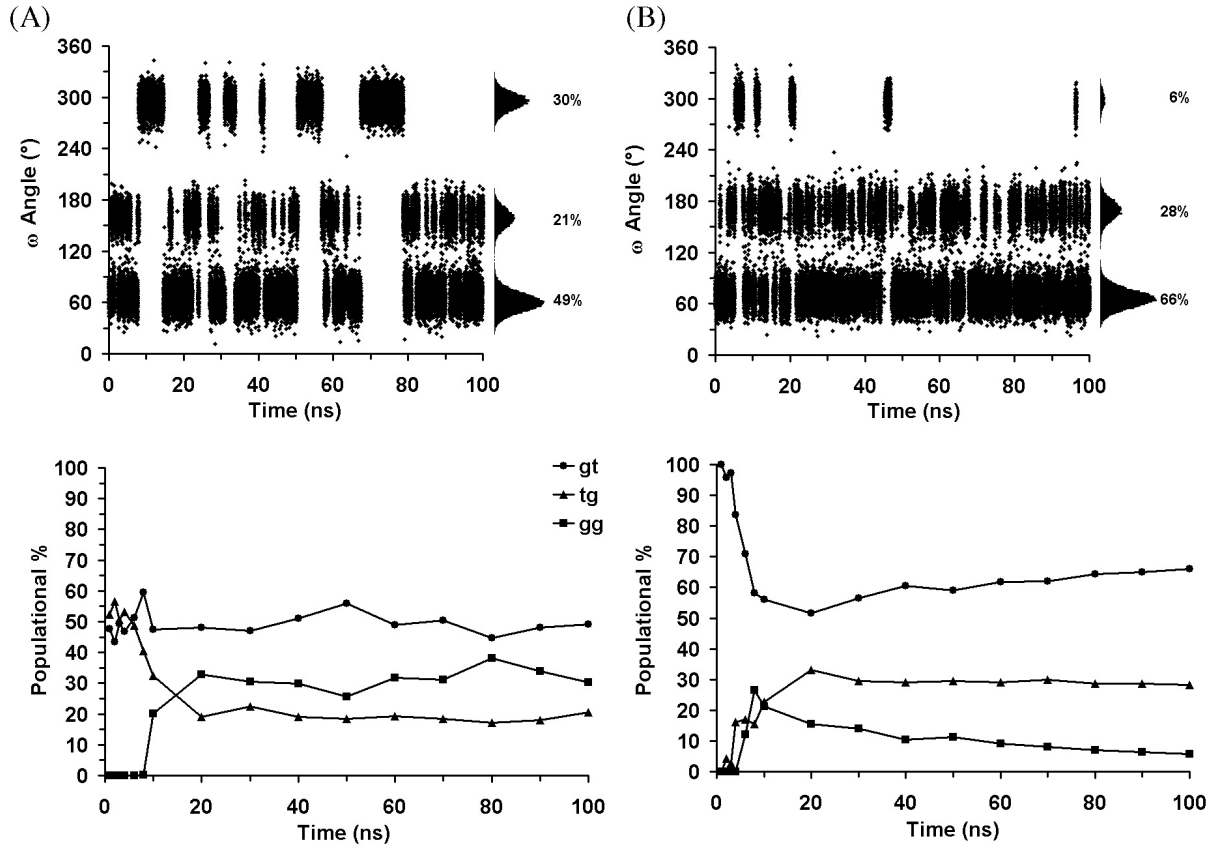
MD simulations

The rotamer populations of the ω torsion angle were predicted (Fig. 4) from explicitly solvated simulations of **3** and **6** in both water and dichloromethane (see Fig. 4). It may be seen that conformational convergence for these systems was not reached until simulation times of between 40 and 80 ns. A reoccurring question when running MD simulations is, "When has a simulation been run long enough that conclu-

© 2006 NRC Canada

Fig. 4. MD trajectories (120 and 100 ns) of the ω angle in (A) methyl 2,3-di-*O*-methyl-α-D-glucopyranoside (**3**) and (B) methyl 2,3-di-*O*-methyl-α-D-galactopyranoside (**6**) in water, with resulting histograms and population % on the right-hand side of each figure. Conformational convergence is plotted below the respective trajectories.

sions about the dynamic properties of a system can be drawn?" The amount of simulation time required to reach conformational equilibration will vary depending on the lifetime of the possible conformations, which itself is directly related to the barrier heights among the states. A molecule that has long conformational lifetimes, exhibiting infrequent conformation transitions, will require a long simulation time period to reach dynamic convergence. Conversely, a molecule that possesses short conformational lifetimes and frequent conformation transitions, will require a shorter simulation to reach convergence. In terms of the rotational states of the ω angle in **3**, there are frequent transitions between the *gt* and *tg* rotamers, and infrequent transitions to the *gg* rotamer, as seen in Fig. 4. The infrequent transitions of the *gg* rotamer, coupled with the large populations of the *gt* and *gg* rotamers, resulted in the slow convergence of the *gt* and *gg* rotamers. A relatively low energy barrier between *gt* and *tg* would explain the rapid transitions, while a higher energy barrier between *tg* and *gg* is consistent with the long lifetime for each of these rotamers. These results are in qualitative agreement with the quantum mechanical rotational energy curves computed for the rotation of the ω angle in methyl α-D-glucopyranoside (23).



A very different behavior for rotamer interconversions was observed for **6**, displaying frequent transitions between the *gt* and *tg* rotamers, and only infrequent transitions to the *gg* rotamer. In contrast to the case of **3**, the rotamer distribution in **6** reached convergence in less than 50 ns, with a rotamer ratio of 62:27:11. Again, in terms of rotational barriers, the frequency of transitions between the *gt* and *tg* states indicates a low energy barrier between these rotamers and high energy barriers around the *gg*. The rotamer convergence was achieved more rapidly than in **3** because the two rotamers with higher populations are in frequent transition with each other.

In water, the rotamer distributions for methyl 2,3-di-*O*-methyl-α-D-glucopyranosides (**3**) and methyl 2,3-di-*O*-methyl-α–D–galactopyranoside (**6**) were predicted to be 34:6:61 and 62:32:6, respectively, which are in reasonable agreement with the previously reported experimental data for the underivatized methyl glycosides (41:1:58 and 61:18:21, respectively) (30). The results from the present MD simulations are also similar to those from the 50 ns fully solvated MD simulations previously reported (23) for methyl α-D-glucopyranoside (40:6:54) and methyl α-D-galactopyranoside (64:28:8). These observations confirm that methylation of oxygens O2 and O3 does not make a remarkable impact on the rotamer population of the ω torsion angle in either **3** or **6** in water.

In an attempt to examine the ability of MD simulations to predict the effect of solvent polarity on rotamer population, MD simulations of **3** and **6** in CH_2Cl_2 were performed. It

should be noted that there are at present no force field parameters available for deuterated solvents, and simulations in nonaqueous solvents are uncommon. Thus, the solvent model for CH_2Cl_2 is relatively untested; however, the initial results are encouraging, particularly in the case of **3** (Fig. 5).

The simulation produced a population conformation ratio of 49:21:30 for **3**, which indicates a significant increase in the population of the *tg* and *gt* rotamers at the expense of the *gg* rotamer, relative to the system in water (34:6:61, *gt*:*tg*:*gg*). A negligible effect was predicted for **6** (66:28:6 in CH_2Cl_2 vs. 64:28:8 in water); however, an examination of the convergence plots indicates that even after 100 ns the populations have not fully converged.

It is interesting to note that the ω torsion angle displayed sensitivity to the solvent, as determined from the values of the average O5-C5-C6-O6 torsion angles for each rotamer extracted from each simulation (Table 2). Clearly, idealized values of 60°, 180°, and 300° are in poor agreement with our averaged solution values. Solvation appears to significantly perturb the value of the ω angle in the *tg* rotamer away from the idealized value of 180°.

NMR analysis

Presented in Tables 3 and 4 are the experimental ^3J values and the rotamer populations for **3** and **6**, respectively, predicted from these values using eqs. [1]–[3] and two sets of limiting ^3J values (32). Unlike the results from the empirically determined limiting *J* values (48), the results obtained with quantum-derived limiting *J* values (32) did not result in any nonphysical (negative) rotamer populations. In the case of **3**, regardless of the choice of the methodology, the population of the *tg* rotamer was shown to increase approximately linearly with the decreasing polarity of the small solvent molecules. This observation is consistent with expectations based on gas-phase quantum mechanical calculations of the rotational properties of the ω angle in methyl α-D-glucopyranoside (23), which implies that there would be a preferential enhancement of internal hydrogen bonding in low polarity environments, leading, in the limiting case (ε = 1), to a population ratio of approximately 43:28:28. In the larger aromatic solvents, the *tg* population is again high, but it does not follow a direct relationship with solvent polarity.

In contrast to **3**, little sensitivity to solvent polarity is displayed by **6**. This is an unexpected result in that quantum

calculations predict a decrease in polarity should lead to a significant decrease in the population of the *tg* rotamer with an increase in the *gg* (23). This change in population was predicted on the basis of the formation of strong internal hydrogen bonds in the limiting case of a purely apolar environment. However, based on the data in Table 4, it appears that an interpretation of rotamer behavior, based on the view that polar solvents disrupt the internal hydrogen bonds and therefore lead to the rotamer distribution being determined by repulsive 1,3-diaxial electrostatic interactions among O4, O5, and O6, may be correct (23). It should be noted that hydrogen bonds among conformationally restricted 1,3-diaxial hydroxyl groups appear to persist even in water (50).

Overall, the agreement with the predictions from the MD simulations both in terms of the response of the populations to polarity and in quantitative terms is notable. Thus, it is reasonable to probe the simulational results further to extract quantitative information pertaining to the level of intramolecular hydrogen bonding in each rotational state in both water and CH_2Cl_2. For each simulation the periods during which hydrogen bonds were present between O4, O5, and O6 were determined for **3** and **6** and are presented in Table 5.

Considerable insight into the sensitivity of internal hydrogen bonding to solvent polarity is provided by the MD data. Some overall trends are apparent; for example, the hydrogen bond between HO6 and O5 is consistently the most occupied (12.9%–18.0%) and the strongest, as indicated by the inter-oxygen distances. In contrast, hydroxyl group HO4 is consistently a very poor proton donor to HO6 (O4(H)···O6); displaying the lowest occupancies (2.9%–5.8%) and long internuclear distances is very weak. Similarly, the reverse interaction, that is, one in which HO6 donates a proton to HO4 (O6(H)···O4) is also weak; however, this hydrogen bond shows a strong sensitivity in both **3** and **6** to solvent polarity. In CH_2Cl_2, the O4(H)···O6 interaction was predicted to increase both in occupancy and strength. This may be understood given that as a primary alcohol, the proton at O6 is preferentially exposed to solvent and would generally be able to act as either a proton donor or acceptor with water molecules. In the low polarity environment, HO6 has little choice but to interact with either HO4 or HO5. In contrast, HO4 may continue to interact with HO3, regardless of the solvent. Similar arguments may be employed to explain the enhanced strength and occupancy in CH_2Cl_2 of the O6(H)···O5 hydrogen bond in **3** and **6**. It is notable that CH_2Cl_2 does not enhance all internal hydrogen bonding to an equal extent. When HO6 acts as a proton donor with O5, the occupancy time for this interaction is approximately doubled in both **3** and **6** in CH_2Cl_2. Notably, in the galacto-derivative **6**, the low polarity environment of the CH_2Cl_2 doubles the occupancy of the O6(H)···O4 hydrogen bond, relative to an aqueous environment, whereas for the gluco-derivative **3**, the occupancy of this hydrogen bond in CH_2Cl_2 increased nearly fourfold. Therefore, in **6**, although a low polarity environment increases the probability of interactions between O6(H) and O4 and O5, the relative strengths and occupancies of these interactions are unaffected by the solvent. On this basis, it would be predicted that the rotamer populations for **6** would not strongly influenced by solvent polarity, as confirmed by analysis of the NMR data. Since in **3** the O6(H)···O4 hydrogen bond is preferentially favored in

Table 5. Average hydrogen bond distances and occupancies for **3** and **6** from the MD data.

MD solvent	Total simulation time (ns)	Molecule	Hydrogen bond		
			O4(H)···O6	O6(H)···O4	O6(H)···O5
Water	122	**1**	3.41, 3.9	3.39, 4.8	2.98, 18.0
CH_2Cl_2	101	**1**	3.19, 2.9	3.14, 19.0	2.96, 31.4
Water	100	**2**	3.36, 5.8	3.34, 6.3	3.01, 12.9
CH_2Cl_2	114	**2**	3.36, 2.7	3.35, 12.3	3.00, 26.8

Note: Bond distances are between non-hydrogen atoms (in angstroms) and occupancies are presented as a % of total simulation time.

CH_2Cl_2, and as it can only form in the *tg* rotamer, a low polarity solvent should induce a shift in rotamer populations in favor of the *tg* state, as confirmed experimentally.

In water, the internal hydrogen bonding networks are disrupted by competition with hydrogen bonds to the solvent. When the internal hydrogen bonds are differentially disrupted, that is, when some become relatively weaker than others, the rotamer populations associated with the ω angle may be altered. In the case of **3**, in water the preferential disruption of the O6(H)···O4 interaction destabilized the *tg* rotamer, leading to the observed preference for gauche rotamers. In **6**, the O6(H)···O4 hydrogen bond forms most strongly in the *gg* orientation, an orientation in which the O6(H)···O5 hydrogen bond may also form. Thus, in the hydrogen bond strengthening environment of low polarity solvents, a higher ratio of *gg*:*gt* rotamers would be expected than in water. This trend was observed in the NMR data (see, for example, the ratios 27:57 in D_2O vs. 36:47 in $CDCl_3$). Unlike the case of **3**, the shift in rotamer populations in **6** is less profound, presumably reflecting the fact that the hydrogen bonds in **6** are approximately equally prone to disruption by water.

Conclusion

The joint NMR and MD analysis of **3** and **6** leads to the conclusion that the balance between inter- and intramolecular interactions involving HO6 plays a direct role in determining the rotational profiles for the ω angles. In a low polarity environment, internal hydrogen bonds are shown to be strengthened in both **3** and **6**, however, in **3**, such an environment disproportionately enhances the O6(H)···O4 interaction, leading to an increase in the population of the *tg* state. Without the hydrogen bond enhancement offered by a low polarity environment, both **3** and **6** display rotamer populations that are consistent with expectations based on the minimization of repulsive intramolecular oxygen–oxygen interactions. That is, when in an aqueous environment, the water disrupts stabilizing intramolecular hydrogen bonding and leads to a system whose bond rotational properties are dominated by internal electrostatic repulsions.

The results of this work are generally consistent with the conclusions reached by Rockwell and Grindley (27), to the extent that both studies illustrate that low polarity environments strengthen internal hydrogen bonds in carbohydrates. The data from the MD simulations confirm and quantify the strengthening of the intramolecular hydrogen bonds in CH_2Cl_2 inferred by the NMR analysis. A significant difference between the two studies pertains to the role of interactions between the solvent and HO6 in glucopyranosides. In this work, we find that in a low polarity environment HO6 prefers to interact with O4, but that in water these interactions are markedly weakened, indicating that HO6 acts as a hydrogen bond donor to water. That this conclusion was not supported by the studies on methyl 2,3,4-tri-*O*-methyl-α-D-glucopyranoside is perhaps related to the absence of a methyl group at O4 in the present work. It may be that the steric bulk of the methyl groups at the 2-, 3-, and 4-positions detracts from the ability of O4 to act as a hydrogen bond acceptor for HO6. The simulations performed in water have been shown to reproduce the rotamer populations to within experimental error; however, despite the long simulation times, the results from those in CH_2Cl_2 were less accurate. The MD simulations illustrate that not only are the rotamer populations sensitive to the configuration at C4 in hexopyranosides, but so are the lifetimes and pathways for transitions among the rotameric states. This latter observation indicates that MD simulations of flexible carbohydrates may require very long simulation times (>100 ns) to reach statistical convergence.

Acknowledgments

This paper is dedicated to Professor W.A. Szarek in honour of his innumerable contributions to carbohydrate chemistry and in recognition of his inspiration as a mentor. We thank the National Institutes of Health (RR05357 and GM55230) for financial support, and JG-O wishes to thank Dr. J. Glushka for helpful discussions regarding the optimization of the NMR experiments.

Synthesis and biological evaluation of 5-(alkyn-1-yl)-1-(*p*-toluenesulfonyl)uracil derivatives[1,2]

Zlatko Janeba, Jan Balzarini, Graciela Andrei, Robert Snoeck, Erik De Clercq, and Morris J. Robins

Abstract: Sonogashira coupling of 5-iodouracil (**2**) and trimethylsilylacetylene gave 5-(trimethylsilylethynyl)uracil (**3**), which was deprotected to give 5-ethynyluracil (**4**). Copper(I)-catalyzed cyclization of **4** gave furo[2,3-*d*]pyrimidin-2(3*H*)-one (**5**). Tosylation of **2** and **4** gave the 1-(*p*-toluenesulfonyl) derivatives **6** and **7**, respectively. The tosylated compound **6** and trimethylsilylacetylene did not undergo Sonogashira coupling, and copper(I)-catalyzed cyclization of **7** did not occur. Coupling of **2** with several terminal alkynes gave 5-(alkyn-1-yl)uracil derivatives (**9**), which underwent tosylation to produce the targeted 5-(alkyn-1-yl)-1-(*p*-toluenesulfonyl)uracil compounds (**11**). Copper(I)-catalyzed cyclization of **9** gave the respective furopyrimidines (**10**) in low yields. Again, cyclization did not occur with the tosyl derivatives (**11**). Activity against varicella-zoster virus (VZV) was observed with longer-chain analogues of **9** and **11**, and compound **7** showed activity against human cytomegalovirus (HCMV) at near cytotoxic levels.

Key words: antiviral screening, furo[2,3-*d*]pyrimidin-2(3*H*)-one derivatives, Sonogashira coupling, 1-(*p*-toluenesulfonyl)pyrimidine derivatives.

Résumé : Un couplage selon la méthode de Sonogashira du 5-iodouracile (**2**) avec le triméthylsilylacétylène conduit à la formation de (triméthylsilyléthynyl)uracile (**3**) qui, par déprotection, conduit au 5-éthynyluracile (**4**). La cyclisation catalysée par le cuivre(I) du composé **4** fournit la furo[2,3-*d*]pyrimidin-2(3*H*)-one (**5**). La tosylation des composés **2** et **4** fournit respectivement les dérivés 1-(*p*-toluènesulfonyle) **6** et **7**. Le composé tosylé **6** et le triméthylsilyacétylène ne réagissent pas dans les conditions de couplage de Sonogashira alors que la cyclisation catalysée par le cuivre(I) du composé **7** ne se réalise pas. Le couplage du composé **2** avec plusieurs alcynes terminaux conduit aux 5-(alcyn-1-yl)uraciles (**9**) qui peut subir une tosylation pour conduire à la formation des composés cibles 5-(alcyn-1-yl)-1-(*p*-toluènesulfony)uraciles (**11**). La cyclisation catalysée par le cuivre(I) des composés **9** fournit les furopyrimidines (**10**) correspondantes avec de faibles rendements. Encore une fois, la cyclisation des dérivés tosylés **11** ne se produit pas. On a observé une activité contre le virus varicelle-zoster avec les analogues des composés **9** et **11** à longues chaînes alors que le composé **7** présente une activité contre le cytomégalovirus humain près des niveaux cytotoxiques.

Mots clés : évaluation antivirale, dérivés de la furo[2,3-*d*]pyrimidin-2(3*H*)-one, couplage de Sonogashira, dérivés 1-(*p*-toluènesulfonyl)pyrimidine.

[Traduit par la Rédaction]

Introduction

Furo[2,3-*d*]pyrimidin-2(3*H*)-ones (derivatives of compound **5**, Fig. 1) with methyl or sugar substituents at N3 and alkyl groups at C6 were reported in 1981 by Robins and Barr (1) as fluorescent by-products (~10%) of coupling reactions of 5-iodo-1-methyluracil and 5-iodo-3′,5′-di-*O*-acetyl-2′-deoxyuridine with terminal alkynes (1, 2). Inhibition of incorporation of thymidine and 2′-deoxyuridine into primary rabbit kidney DNA was observed, but no antiviral activity was found[5] with the 6-butylfuro[2,3-*d*]pyrimidin-2(3*H*)-one 2′-deoxynucleoside (prepared in 82% yield by cyclization of 2′-deoxy-5-(hexyn-1-yl)uridine with CuI–Et_3N–MeOH (2)). Two decades later, the remarkable anti-varicella-zoster virus (VZV) selectivity and potency of such bicyclic pyrimidine nucleoside analogues (BCNAs) with longer alkyl chains at

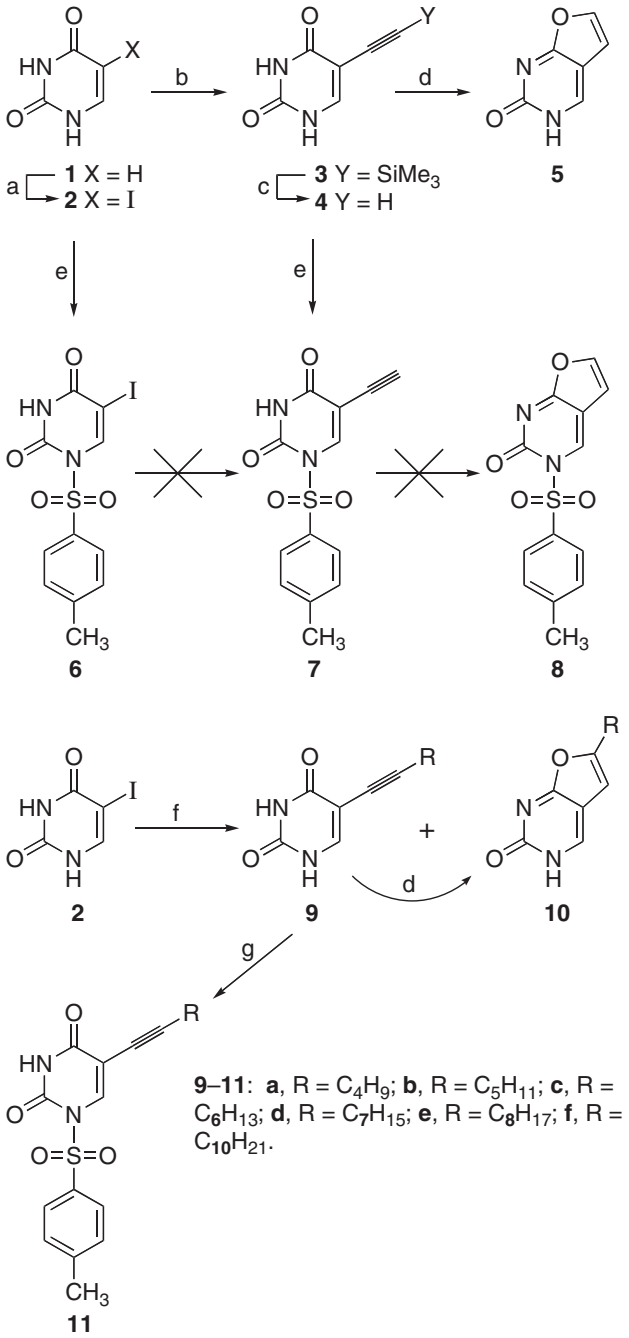
5

C6 were discovered (3). Extensive SAR studies have been pursued by McGuigan, Balzarini, De Clercq, and their coworkers (4–6).

In 2001, we observed that certain alkyl/alkynyl derivatives of **5** possess anti-human cytomegalovirus (HCMV) activity (7). It was recently reported that 2′,3′-dideoxynucleoside derivatives of **5** substituted at C6 with alkyl chains also inhibit HCMV by a "non-nucleoside" mechanism (i.e., activation by a nucleoside kinase is not required) (8). We have targeted the furo[2,3-*d*]pyrimidin-2(3*H*)-one ring system for other modifications at N3 and (or) C6 (9).

A prior synthetic approach to **5** employed cyclization of (*E*)-5-(2-bromovinyl)uracil (BVU) with potassium *tert*-butoxide (10, 11). However, the overall yield of **5** was very low for this five-stage route from uracil. The Cu(I)-promoted 5-endo-dig cyclization of 5-ethynyluracil (**4**) (Scheme 1) represented a plausible route to **5** because this type of cyclization had been shown to proceed in high yields with 1-methyl and 1-(2-deoxy-β-D-*erythro*-pentofuranosyl) derivatives of 5-(alkyn-1-yl)uracil (1, 2). However, such treatment of **4** produced **5** slowly and in limited yields (~15%). Introduction of a protecting group at N1 of **4** followed by cyclization and deprotection might provide an improved route to **5**.

Protection with a *p*-toluenesulfonyl group permits deprotection by transamidation (12). Tosylation of **4** gave 5-ethynyl-1-tosyluracil (**7**). However, **7** did not undergo cyclization with CuI–Et_3N–DMF under the usual conditions. Because **7** showed weak anti-HCMV activity, a new SAR study (13) with 5-(alkyn-1-yl)-1-tosyluracils was examined. We now describe the synthesis of such analogues with alkynyl chains of 6–10 and 12 carbon atoms and the results of evaluations against a number of viruses and tumor cell systems.



Results and discussion

Chemistry

The 5-iodouracil (**2**) starting material (Scheme 1) was conveniently prepared in >60 g scale by a modified cerium(IV)-mediated halogenation (14) of uracil (**1**). The use of acetonitrile rather than methanol as the solvent resulted in direct precipitation of the product **2**. Filtration of the reaction mixture and immediate recrystallization of the precipitated material from aqueous ethanol gave **2** (83%) of high purity.

Sonogashira coupling of **2** and trimethylsilylacetylene (TMSA) followed by removal of the TMS group from intermediate **3** with NaOH–H_2O (15) gave 5-ethynyluracil (**4**). Various reaction conditions (solvents, temperature, equivalents of CuI) were then examined. Treatment of **4** with CuI (1.1 equiv.) in DMF–Et_3N at 120 °C gave the best, although

Scheme 1. Synthesis of the test compounds. Reagents and conditions: (*a*) I_2–CAN–MeCN; (*b*) TMSA–$Pd(PPh_3)_4$–CuI–Et_3N–EtOAc; (*c*) NaOH–H_2O; (*d*) CuI–Et_3N–DMF, Δ; (*e*) TsCl–pyridine; (*f*) 1-alkyne–$Pd(PPh_3)_4$–CuI–Et_3N–DMF; (*g*) (*i*) HMDS, Δ, (*ii*) TsCl–MeCN, Δ.

limited, conversion to the cyclized ring system **5** (~15%). Tosylation of **4** under standard conditions (TsCl–pyridine) gave 5-ethynyl-1-tosyluracil (**7**) (25%). Treatment of **7** with Cu(I) did not give detected quantities of **8**. Thus, the N1-tosyl derivative **7** was more resistant to cyclization than **4** (which gave **5** slowly in ~15% yield). The strongly electron-withdrawing effect of the *p*-toluenesulfonyl group could significantly reduce electron donation from N1 into the 5,6-double bond. Such a diminished enamine contribution toward the triple bond of the alkyne substituent at C5 and (or)

© 2006 NRC Canada

the oxo group at C4 (enyne-amine and enamine-one conjugated systems, respectively) might result in sufficient retardation of complex formation with copper(I) to cause failure of the endo-dig cyclization process. Tosylation of **2** gave 5-iodo-1-tosyluracil (12) (**6**, 40%), but **6** failed to undergo Sonogashira coupling effectively with 1-hexyne or 1-octyne. Attempted coupling at ambient temperature with ethyl acetate as the solvent resulted in formation of more polar materials and recovery of starting **6** (TLC). Heating at 50 °C resulted in formation of both less and more polar materials and generation of dark coloration. Thus, withdrawal of electron density from N1 by the tosyl group apparently has significantly adverse effects on oxidative insertion of palladium into the C5–iodine bond and (or) subsequent steps in the Sonogishira cycle.

Because the Cu(I)-promoted cyclization of 5-ethynyluracil (**4**) was sluggish, we anticipated that Sonogashira couplings with 5-iodouracil (**2**) would give the desired 5-(alkyn-1-yl)uracil analogues (**9**) without significant formation of the cyclized furo[2,3-*d*]pyrimidin-2-one products (**10**). As expected, coupling of **2** with terminal alkynes–$Pd(PPh_3)_4$–CuI–Et_3N in DMF at ambient temperature gave the products **9** in moderate to good isolated yields (50%–80%), except for the highly lipophilic 1-dodecynyl derivative **9f** (~20%). Very minor amounts of the furanopyrimidine by-products (**10**) were detected as slower-migrating fluorescent spots (TLC) during these Sonogashira couplings. In several cases, we isolated the by-products in trace yields (~1%), and they were fully (**10a**, **10d**, and **10e**) or partially (**10b**) characterized. This corroborated our finding that cyclization of 5-ethynyluracil (**4**) without an N1 substituent was difficult, and is in harmony with another report of Sonogashira coupling of **2** with a terminal alkyne and cyclization to give the furanopyrimidine in low yield (16). Our treatment of purified **9d** and **9e** with CuI–Et_3N–DMF at 70 °C for 4 h resulted in complete disappearance of the starting materials, but the furanopyrimidines **10d** (34%) and **10e** (28%) were isolated in comparably low yields.

Treatment of pyrimidine bases with TsCl–pyridine and tosylation of trimethylsilylated pyrimidines have been recently employed for preparation of 1-tosylpyrimidine derivatives (12). Our treatment of 5-(decyn-1-yl)uracil (**9e**) with TsCl–pyridine at ambient temperature gave a poor yield (22%) of the 1-tosyl product **11e**, and no **11c** was detected (TLC) upon stirring 5-(octyn-1-yl)uracil (**9c**) with TsCl and K_2CO_3 in DMF for 2 days at ambient temperature. Fortunately, tosylation of the trimethylsilylated derivatives was successful. Hexamethyldisilazane (HMDS) and the 5-alkynyl compounds (**9**) were heated at reflux for 1 h, followed by evaporation of volatiles and in situ tosylation of the TMS derivatives (TsCl–MeCN, Δ). The 1-tosyl-5-(alkyn-1-yl)uracil products (**11**) (47%–75%) were isolated after ~24 h. Longer reaction times resulted in more complex reaction mixtures (TLC) with little improvement in the yields of **11**. The starting materials **9** were recovered after the 24 h treatment in 18%–28% yields by column chromatography.

Biological evaluations

Compound **6** showed weak activity against VZV (TK^+ (strain OKA) and TK^- (strain 07/1)), but no activity against HCMV or other DNA viruses such as herpes simplex viruses type 1 and type 2 and vaccinia virus (VV) (Table 1). No activity against RNA viruses such as vesicular stomatitis virus (VSV), Coxsackie B4 virus, respiratory syncytial virus (RSV), parainfluenza virus-3, reovirus-1, Sindbis virus, and Punta Toro virus, or HIV-1 and HIV-2 in cell cultures was observed (data not shown). The 5-alkynyl-substituted uracil derivatives (**9** series) and their corresponding 1-(*p*-toluenesulfonyl) derivatives (**11** series), as well as the bicyclic derivatives (**10** series), were devoid of antiviral activity at subtoxic concentrations, except for **9d**, **9e**, **11e**, and **11f** (for which weak anti-VZV activity (EC_{50}: 10–37 μmol/L) was found). The absence of significant biological activity with the **9** and **10** series compounds suggests that they do not function as substrates of thymidine phosphorylase or other cellular enzymes that convert pyrimidines to their corresponding nucleoside analogues. Attachment of the bulky tosyl group at N1 of the uracil base (for the **11** series) did not produce derivatives with significant intrinsic activity and precluded glycosyl transfer. No visible cytotoxic effects were found upon microscopic inspection of cells at compound concentrations as high as 80–400 μmol/L. These compounds were not markedly inhibitory (cytostatic) to human embryonic lung (HEL) cell proliferation (Table 1). Significant cytostatic effects were not observed with murine leukemia L1210, murine mammary carcinoma FM3A, human lymphocyte CEM, and human cervix carcinoma HeLa cells with these compounds (IC_{50}: 60 to >500 μmol/L, data not shown).

Conclusions

Sonogashira coupling of 5-iodouracil (**2**) with terminal alkynes afforded the 5-(alkyn-1-yl)uracil derivatives (**9**) in moderate to good yields. Certain 6-alkylfuro[2,3-*d*]pyrimidin-2-ones (**10**) were isolated as trace by-products. The Cu(I)-promoted cyclization of 5-ethynyluracil (**4**) gave the parent furo[2,3-*d*]pyrimidin-2(3*H*)-one (**5**) in ~15% yield, and the 6-alkyl derivatives (**10**) were obtained from the corresponding 5-(alkyn-1-yl)uracils (**9**) in yields of ~30%. In situ tosylation of trimethylsilylated derivatives of **9** gave the 5-(alkyn-1-yl)-1-tosyluracils (**11**) in moderate to good yields. Biological evaluations were performed with the 5-(alkyn-1-yl)uracils (**9**), their 1-tosyl analogues (**11**), and the 6-alkylfuro[2,3-*d*]pyrimidin-2-one derivatives (**10a**, **10d**, and **10e**). Weak anti-VZV activity was observed with **9d**, **9e**, **11e**, and **11f**, and anti-HCMV activity at near cytotoxic concentrations with **7**. No significant antiviral activity with other DNA and RNA viruses and no cytostatic activity of significance were found with other compounds in this study.

Experimental

Uncorrected melting points were determined with a hot-stage apparatus. UV spectra were measured with solutions in MeOH. ^1H (500 MHz) and ^{13}C (125 MHz) NMR spectra were determined with solutions in DMSO-d_6. "Apparent" peak shapes are in quotation marks when the first-order splitting should be more complex or when the peaks were poorly resolved. High-resolution mass spectra (HRMS) were determined by EI or FAB (thioglycerol, NaOAc). Chemicals and solvents were of reagent quality. Column chromatogra-

[a]50% Effective concentration (compound concentration required to inhibit virus-induced cytopathogenicity or plaque formation (VZV) by 50%).
[b]Minimum cytotoxic concentration (compound concentration required to cause a microscopically visible alteration of cell morphology).
[c]50% cytostatic concentration (compound concentration required to inhibit cell proliferation by 50%).

phy (silica gel, 230–400 mesh) was performed with solutions of CH_2Cl_2–MeOH.

Method 1: 5-substituted-uracil–TsCl–pyridine is described in detail for **2** → **6**. Method 2: 5-iodouracil–1-alkyne–$Pd(PPh_3)_4$–CuI–Et_3N–DMF for **2** → **9a**. Method 3: 5-(alkyn-1-yl)uracil–CuI–Et_3N–DMF for **9d** → **10d**. Method 4: (*a*) 5-(alkyn-1-yl)uracil–HMDS; (*b*) TsCl–MeCN, Δ for **9a** → **11a**.

5-Iodouracil (2) (ref. 14)

A mixture of uracil (**1**) (35.0 g, 0.31 mol), iodine (47.0 g, 0.19 mol), and CAN (85.5 g, 0.16 mol) in MeCN (750 mL) was stirred at reflux for 5 h, and precipitation of a white solid occurred. The reaction mixture was cooled to ~0 °C in a refrigerator, and the solid was filtered and washed with a small amount of cold MeCN. This material was recrystallized immediately (EtOH–H_2O, 1:1) to give **2** (61.6 g, 83%) as colorless needles; mp > 250 °C dec. (lit. value (14) mp 198 °C, 245 °C dec; lit. value (17) mp 272 °C). UV max: 280 nm (ε 7100). ^{1}H NMR δ: 7.88 (s, 1H), 11.15 (br s, 1H), 11.39 (br s, 1H). ^{13}C NMR δ: 161.5, 151.2, 146.9, 67.6. HRMS *m*/*z*: 237.9238 (M^+ $[C_4H_3IN_2O_2]$ = 237.9239).

5-Ethynyluracil (4) (ref. 15)

TMSA (14.5 mL, 10.1 g, 0.103 mol) and then Et_3N (60 mL) were added to a suspension of **2** (20.0 g, 84.0 mmol), $Pd(PPh_3)_4$ (4.9 g, 4.24 mmol), and CuI (1.3 g, 6.83 mmol) in deoxygenated EtOAc (220 mL). The reaction mixture was stirred at ambient temperature under N_2 for 3 h, and then cooled to ~0 °C. The solid TMS derivative **3** was filtered and then stirred in NaOH–H_2O (1 mol/L, 500 mL) at ambient temperature for 2 h. This mixture was diluted with H_2O (500 mL) and filtered, and the filtrate was concentrated in vacuo to half the volume (~500 mL). The pH of this solution was adjusted with AcOH (to pH ~ 5), and the suspension was cooled (~0 °C). The solid was filtered, washed (H_2O, acetone, Et_2O), and dried to give **4** (9.59 g, 83%) as a TLC-homogeneous orange powder with clean ^{1}H NMR spectra. An analytical sample was recrystallized (EtOH, 84% recovery) to give **4** as a slightly yellow powder; mp > 220 °C dec. UV max: 284, 224 nm (ε 10 000, 11 300). ^{1}H NMR δ: 4.04 (s, 1H), 7.81 (s, 1H), 11.32 (bs, 2H). ^{13}C NMR δ: 162.7, 150.5, 146.5, 96.3, 83.2, 76.6. HRMS *m*/*z*: 136.0270 (M^+ $[C_6H_4N_2O_2]$ = 136.0273). Anal. calcd. for $C_6H_4N_2O_2$: C 52.95, H 2.96, N 20.58; found: C 53.09, H 3.06, N 20.75.

Furo[2,3-*d*]pyrimidin-2(3*H*)-one (5) (refs. 10 and 11)

A suspension of **4** (680 mg, 5.0 mmol) and CuI (1 g, 5.25 mmol) in a deoxygenated mixture of Et_3N (3.5 mL) and DMF (30 mL) was heated at 120 °C for 23 h. Volatiles were evaporated in vacuo, and toluene was added to the residue and then evaporated (3 × 5 mL). The residue was chromatographed (5% MeOH – CH_2Cl_2 → 20% MeOH – CH_2Cl_2) and recrystallized (EtOH) to give slightly yellow crystals of **5** (102 mg, 14.7%); mp > 280 °C (lit. value (10) mp 260 °C; lit. value (11) mp 260–262 °C). UV max: 324, 242 nm (ε 4 800, 10 900). ^{1}H NMR δ: 6.74 (d, *J* = 2.8 Hz, 1H), 7.70 (d, *J* = 2.8 Hz, 1H), 8.34 (s, 1H), 12.15 (br s, 1H). ^{13}C NMR δ: 172.2, 156.0, 144.4, 141.3, 105.1, 104.5. HRMS *m*/*z*: 136.0279 (M^+ $[C_6H_4N_2O_2]$ = 136.0273). Anal. calcd. for $C_6H_4N_2O_2$: C 52.95, H 2.96, N 20.58; found: C 52.72, H 3.12, N 20.36.

5-Iodo-1-tosyluracil (6) (ref. 12)

Method 1

A mixture of **2** (1.0 g, 4.2 mmol) and TsCl (881 mg, 4.62 mmol) in pyridine (25 mL) was stirred at ambient temperature for 28 h. MeOH (3 mL) was added, the solution was stirred for 10 min, and volatiles were evaporated. The residue was dissolved in CH_2Cl_2 (60 mL), and the solution was washed (0.1 mol/L HCl–H_2O, satd. $NaHCO_3$–H_2O, and H_2O) and dried ($MgSO_4$). Volatiles were evaporated, and the residue was chromatographed and recrystallized (EtOAc) to give **6** (662 mg, 40%); mp 250–252 °C. UV max: 276, 231 nm (ε 9 500, 14 800). ^{1}H NMR δ: 2.43 (s, 3H), 7.49 (d, *J* = 8.3 Hz, 2H), 7.98 (d, *J* = 8.3 Hz, 2H), 8.39 (s, 1H), 12.03 (bs, 1H). ^{13}C NMR δ: 160.3, 147.0, 146.5, 141.0, 132.8, 129.8, 129.2, 73.3, 21.2. HRMS *m/z*: 391.9333 (M^+ [$C_{11}H_9N_2IO_4S$] = 391.9328). Anal. calcd. for $C_{11}H_9N_2IO_4S$: C 33.69, H 2.31, N 7.14; found: C 33.91, H 2.02, N 7.30.

5-Ethynyl-1-tosyluracil (7)

Treatment of **4** (500 mg, 3.67 mmol) by Method 1 gave **7** (263 mg, 25%); mp 206 °C. UV max: 277, 228 nm (ε 14 500, 17 100). ^{1}H NMR δ: 2.43 (s, 3H), 4.29 (s, 1H), 7.50 (d, *J* = 8.3 Hz, 2H), 7.98 (d, *J* = 8.3 Hz, 2H), 8.32 (s, 1H), 12.01 (bs, 1H). ^{13}C NMR δ: 161.2, 146.6, 146.4, 141.3, 132.7, 129.9, 129.3, 100.1, 85.2, 75.1, 21.2. HRMS *m/z*: 290.0364 (M^+ [$C_{13}H_{10}N_2O_4S$] = 290.0361). Anal. calcd. for $C_{13}H_{10}N_2O_4S$: C 53.79, H 3.47, N 9.65; found: C 53.83, H 3.60, N 9.66.

5-(Hexyn-1-yl)uracil (9a)

Method 2

A stirred suspension of **2** (2.0 g, 8.4 mmol), $(Ph_3P)_4Pd$ (490 mg, 0.42 mmol), and CuI (130 mg, 0.68 mmol) in DMF (25 mL) was purged with N_2 at room temperature. 1-Hexyne (1.26 mL, 898 mg, 10.9 mmol) was added, followed by dried Et_3N (8 mL). The reaction mixture was stirred under N_2 at ambient temperature for 40 h. Volatiles were evaporated, and toluene was added to the residue and then evaporated (2 × 8 mL). The residue was extracted with hot MeOH (100 mL), and the remaining solid was filtered and washed (MeOH). Volatiles were evaporated in vacuo from the combined MeOH extract and wash. Chromatography (5% MeOH – CH_2Cl_2) and recrystallization (MeOH) of the residue gave **9a** (980 mg, 61%); mp 248–251 °C. UV max: 289, 229 nm (ε 11 100, 13 100). ^{1}H NMR δ: 0.88 (t, *J* = 7.3 Hz, 3H), 1.37–1.44 (m, 2H), 1.46–1.48 (m, 2H), 2.34 (t, *J* = 6.8 Hz, 2H), 7.63 (s, 1H), 11.13 (s, 1H), 11.28 (s, 1H). ^{13}C NMR δ: 162.9, 150.5, 144.6, 97.7, 92.7, 73.0, 30.3, 21.4, 18.5, 13.5. HRMS *m/z*: 192.0892 (M^+ [$C_{10}H_{12}N_2O_2$] = 192.0899). Anal. calcd. for $C_{10}H_{12}N_2O_2$: C 62.49, H 6.29, N 14.57; found: C 62.56, H 6.23, N 14.72.

The fluorescent by-product was isolated from later fractions and recrystallized (EtOAc–EtOH) to give **10a** (25 mg, 1.5%); mp > 220 °C dec. UV max: 327, 244 nm (ε 4 900, 14 800). ^{1}H NMR δ: 0.90 (t, *J* = 7.6 Hz, 3H), 1.34 (dt, *J* = 7.3, 7.3 Hz, 2H), 1.59 ("quint", *J* = ~7.4 Hz, 2H), 2.63 (t, *J* = 7.3 Hz, 2H), 6.37 (s, 1H), 8.14 (s, 1H), 11.96 (bs, 1H). ^{13}C NMR (50 °C) δ: 171.9, 157.6, 155.7, 138.6, 105.9, 99.4, 28.3, 26.8, 21.3, 13.3. HRMS *m/z*: 192.0898 (M^+ [$C_{10}H_{12}N_2O_2$] = 192.0899). Anal. calcd. for $C_{10}H_{12}N_2O_2$: C 62.49, H 6.29, N 14.57; found: C 62.55, H 6.12, N 14.70.

5-(Heptyn-1-yl)uracil (9b)

Treatment of **2** (2.0 g, 8.4 mmol) by Method 2 gave **9b** (890 mg, 51%); mp 241–243 °C. UV max: 289, 230 nm (ε 11 400, 13 500). ^{1}H NMR δ: 0.86 (t, *J* = 7.3 Hz, 3H), 1.24–1.37 (m, 4H), 1.44–1.49 (m, 2H), 2.32 (t, *J* = 7.3 Hz, 2H), 7.62 (s, 1H), 11.11 (s, 1H), 11.26 (s, 1H). ^{13}C NMR δ: 162.9, 150.5, 144.6, 97.7, 92.8, 73.0, 30.5, 28.0, 21.7, 18.8, 13.9. HRMS *m/z*: 206.1052 (M^+ [$C_{11}H_{14}N_2O_2$] = 206.1055). Elemental analyses were not obtained for this compound, but NMR spectra were equally clean.

The fluorescent by-product was recrystallized to give **10b** (8 mg, 0.5%) as a white solid. ^{1}H NMR δ: 0.87 (t, *J* = 6.8 Hz, 3H), 0.88–1.32 (m, 4H), 1.59–1.62 (m, 2H), 2.62 (t, *J* = 7.3 Hz, 2H), 6.37 (s, 1H), 8.14 (s, 1H), 11.95 (bs, 1H). HRMS *m/z*: 206.1045 (M^+ [$C_{11}H_{14}N_2O_2$] = 206.1055).

5-(Octyn-1-yl)uracil (9c)

Treatment of **2** (1.0 g, 4.2 mmol) by Method 2 gave **9c** (490 mg, 53%); mp 231–235 °C. UV max: 289, 230 nm (ε 11 400, 13 500). ^{1}H NMR δ: 0.87 (t, *J* = 6.8 Hz, 3H), 1.25–1.31 (m, 4H), 1.32–1.41 (m, 2H), 1.48 ("quint", *J* = ~7.2 Hz, 2H), 2.34 (t, *J* = 6.8 Hz, 2H), 7.64 (s, 1H), 11.13 (s, 1H), 11.28 (s, 1H). ^{13}C NMR δ: 162.9, 150.5, 144.5, 97.7, 92.8, 73.0, 30.8, 28.2, 28.0, 22.1, 18.8, 13.9. HRMS *m/z*: 220.1205 (M^+ [$C_{12}H_{16}N_2O_2$] = 220.1212). Anal. calcd. for $C_{12}H_{16}N_2O_2$: C 65.43, H 7.32, N 12.72; found: C 65.27, H 7.18, N 12.58.

5-(Nonyn-1-yl)uracil (9d)

Treatment of **2** (2.0 g, 8.4 mmol) by Method 2 gave **9d** (1.19 g, 60%); mp 233–236 °C. UV max: 289, 230 nm (ε 12 500, 14 600). ^{1}H NMR δ: 0.86 (t, *J* = 6.6 Hz, 3H), 1.22–1.29 (m, 6H), 1.33–1.38 (m, 2H), 1.47 ("quint", *J* = 7.2 Hz, 2H), 2.33 (t, *J* = 7.1 Hz, 2H), 7.62 (s, 1H), 11.10 (s, 1H), 11.26 (s, 1H). ^{13}C NMR δ: 162.9, 150.5, 144.6, 97.7, 92.7, 72.9, 31.2, 28.2, 22.1, 18.8, 13.9. HRMS *m/z*: 234.1371 (M^+ [$C_{13}H_{18}N_2O_2$] = 234.1368). Anal. calcd. for $C_{13}H_{18}N_2O_2$: C 66.64, H 7.74, N 11.96; found: C 66.84, H 7.90, N 12.08.

The fluorescent by-product was recrystallized (EtOAc–EtOH) to give **10d** (19 mg, 1%), mp 265–266 °C; and identical spectral data with **10d** prepared by Method 3.

5-(Decyn-1-yl)uracil (9e)

Treatment of **2** (2.0 g, 8.4 mmol) by Method 2 gave **9e** (1.73 g, 81%); mp 210–215 °C. UV max: 289, 228 nm (ε 10 300, 12 700). ^{1}H NMR δ: 0.84 (t, *J* = 6.8 Hz, 3H), 1.22–1.26 (m, 8H), 1.35–1.37 (m, 2H), 1.46 ("quint", *J* = 7.2 Hz, 2H), 2.32 (t, *J* = 7.0 Hz, 2H), 7.61 (s, 1H), 11.11 (s, 1H), 11.27 (s, 1H). ^{13}C NMR δ: 162.9, 150.5, 144.5, 97.7, 92.8, 73.0, 31.3, 28.7, 28.6, 28.31, 28.26, 22.1, 18.8, 14.0. HRMS *m/z*: 248.1517 (M^+ [$C_{14}H_{20}N_2O_2$] = 248.1525). Anal. calcd. for $C_{14}H_{20}N_2O_2$: C 67.71, H 8.12, N 11.28; found: C 67.90, H 7.96, N 11.19.

The fluorescent by-product was recrystallized (EtOAc–EtOH) to give **10e** (15 mg, 0.7%), mp 255–256 °C; and identical spectral data with **10e** prepared by Method 3.

© 2006 NRC Canada

5-(Dodecyn-1-yl)uracil (9f)

Treatment of **2** (2.0 g, 8.4 mmol) by Method 2 gave **9f** (380 mg, 19%); mp 224–227 °C. UV max: 289, 229 nm (ε 12 500, 15 000). ^{1}H NMR δ: 0.85 (t, *J* = 6.8 Hz, 3H), 1.22–1.27 (m, 12H), 1.37–1.38 (m, 2H), 1.44–1.50 (m, 2H), 2.33 (t, *J* = 6.8 Hz, 2H), 7.61 (s, 1H), 11.10 (s, 1H), 11.25 (s, 1H). ^{13}C NMR δ: 162.8, 150.4, 144.4, 97.6, 92.7, 72.9, 31.3, 28.9, 28.7, 28.5, 28.22, 28.19, 22.1, 18.8, 13.9. HRMS *m*/*z*: 276.1838 (M^+ [$C_{16}H_{24}N_2O_2$] = 276.1838). Anal. calcd. for $C_{16}H_{24}N_2O_2$: C 69.53, H 8.75, N 10.14; found: C 69.60, H 8.59, N 10.00.

6-Heptylfuro[2,3-*d*]pyrimidin-2(3*H*)-one (10d)

Method 3

A mixture of **9d** (300 mg, 1.28 mmol), CuI (268 mg, 1.41 mmol), and Et_3N (5 mL) in deoxygenated DMF (25 mL) was stirred at 70 °C for 4 h. Volatiles were evaporated, and toluene was added and evaporated (2 × 5 mL). The residue was extracted with hot MeOH (50 mL), and the remaining solid was filtered. The filtrate was evaporated, and the residue was chromatographed (CH_2Cl_2 → 8% MeOH – CH_2Cl_2) and recrystallized (EtOAc–EtOH, 1:4) to give **10d** (103 mg, 34%); mp 267 °C. UV max: 327, 244 nm (ε 5 800, 17 000). ^{1}H NMR δ: 0.86 (t, *J* = 6.8 Hz, 3H), 1.26–1.31 (m, 8H), 1.59–1.62 (m, 2H), 2.62 (t, *J* = 7.3 Hz, 2H), 6.36 (s, 1H), 8.13 (s, 1H), 11.94 (bs, 1H). ^{13}C NMR (50 °C) δ: 171.9, 157.6, 155.7, 138.8, 105.9, 99.3, 30.9, 28.1, 28.0, 27.2, 26.2, 21.8, 13.6. HRMS (FAB) *m*/*z*: 257.1277 (MNa^+ [$C_{13}H_{18}N_2O_2Na$] = 257.1266). Anal. calcd. for $C_{13}H_{18}N_2O_2$: C 66.64, H 7.74, N 11.96; found: C 66.59, H 7.76, N 11.96.

6-Octylfuro[2,3-*d*]pyrimidin-2(3*H*)-one (10e)

Treatment of **9e** (249 mg, 1.0 mmol) by Method 3 gave **10e** (70 mg, 28%); mp 259 °C. UV max: 327, 244 nm (ε 5 500, 16 000). ^{1}H NMR δ: 0.85 (t, *J* = 6.8 Hz, 3H), 1.25–1.30 (m, 10H), 1.59–1.61 (m, 2H), 2.62 (t, *J* = 7.3 Hz, 2H), 6.36 (s, 1H), 8.13 (s, 1H), 11.92 (bs, 1H). ^{13}C NMR (50 °C) δ: 171.9, 157.6, 155.7, 138.5, 105.9, 99.3, 31.0, 28.3, 27.2, 26.2, 21.8, 13.6. HRMS *m*/*z*: 248.1535 (M^+ [$C_{14}H_{20}N_2O_2$] = 248.1525). Anal. calcd. for $C_{14}H_{20}N_2O_2$: C 67.71, H 8.12, N 11.28; found: C 67.88, H 8.15, N 11.24.

5-(Hexyn-1-yl)-1-tosyluracil (11a)

Method 4

A mixture of **9a** (500 mg, 2.60 mmol) and HMDS (15 mL) was refluxed under N_2 for 1 h. Volatiles were evaporated in vacuo with protection from moisture. The residual oil was dissolved in dried MeCN (20 mL) and TsCl (595 mg, 3.12 mmol) was added. The reaction mixture was refluxed under N_2 for 24 h. MeOH (1 mL) was added, and the mixture was stirred at ambient temperature for 10 min. Volatiles were evaporated, and the residue was chromatographed (3% MeOH in CH_2Cl_2) and recrystallized (EtOAc) to give **11a** (518 mg, 57%) as white needles; mp 196–197 °C. UV max: 284, 230 nm (ε 14 600, 22 300). ^{1}H NMR δ: 0.90 (t, *J* = 7.3 Hz, 3H), 1.40–1.44 (m, 2H), 1.50 ("quint", *J* = 7.0 Hz, 2H), 2.39–2.43 (m, 5H), 7.49 (d, *J* = 8.3 Hz, 2H), 7.98 (d, *J* = 8.3 Hz, 2H), 8.16 (s, 1H), 11.92 (s, 1H). ^{13}C NMR δ: 161.2, 146.5, 146.4, 139.2, 132.8, 129.8, 129.2, 101.3, 94.9, 71.7, 30.0, 21.3, 21.2, 18.4, 13.4. HRMS *m*/*z*: 346.0980 (M^+ [$C_{17}H_{18}N_2O_4S$] = 346.0987). Anal. calcd. for $C_{17}H_{18}N_2O_4S$: C 58.94, H 5.24, N 8.09; found: C 58.94, H 5.13, N 7.72.

Starting material **9a** (140 mg, 28%) was recovered from later chromatographic fractions.

5-(Heptyn-1-yl)-1-tosyluracil (11b)

Treatment of **9b** (250 mg, 1.21 mmol) by Method 4 gave **11b** (205 mg, 47%); mp 180 °C. UV max: 285, 230 nm (ε 13 500, 19 900). ^{1}H NMR δ: 0.88 (t, *J* = 7.3 Hz, 3H), 1.29–1.35 (m, 2H), 1.37–1.41 (m, 2H), 1.52 ("quint", *J* = 7.2 Hz, 2H), 2.40 (t, *J* = 7.1 Hz, 2H), 2.43 (s, 3H), 7.49 (d, *J* = 8.3 Hz, 2H), 7.98 (d, *J* = 8.3 Hz, 2H), 8.16 (s, 1H), 11.94 (s, 1H). ^{13}C NMR δ: 161.3, 146.5, 146.4, 139.3, 132.8, 129.8, 129.2, 101.3, 95.0, 71.7, 30.5, 27.7, 21.6, 21.2, 18.7, 13.9. HRMS (FAB) *m*/*z*: 383.1042 (M^+ [$C_{18}H_{20}N_2O_4SNa$] = 383.1041). Anal. calcd. for $C_{18}H_{20}N_2O_4S$: C 59.98, H 5.59, N 7.77; found: C 59.79, H 5.56, N 7.73.

Starting material **9b** (60 mg, 24%) was recovered from later chromatographic fractions.

5-(Octyn-1-yl)-1-tosyluracil (11c)

Treatment of **9c** (250 mg, 1.13 mmol) by Method 4 gave **11c** (320 mg, 75%); mp 168–169 °C. UV max: 284, 230 nm (ε 14 100, 21 300). ^{1}H NMR δ: 0.87 (t, *J* = 6.8 Hz, 3H), 1.27–1.28 (m, 4H), 1.39–1.40 (m, 2H), 1.51 ("quint", *J* = 7.2 Hz, 2H), 2.39 (t, *J* = 6.8 Hz, 2H), 2.42 (s, 3H), 7.48 (d, *J* = 8.3 Hz, 2H), 7.97 (d, *J* = 8.3 Hz, 2H), 8.16 (s, 1 H), 11.92 (s, 1H). ^{13}C NMR δ: 161.2, 146.5, 146.4, 139.2, 132.8, 129.8, 129.2, 101.3, 95.0, 71.7, 30.7, 27.9, 22.0, 21.2, 18.7, 13.9. HRMS (FAB) *m*/*z*: 397.1198 (MNa^+ [$C_{19}H_{22}N_2O_4SNa$] = 397.1198). Anal. calcd. for $C_{19}H_{22}N_2O_4S$: C 60.94, H 5.92, N 7.48; found: C 60.78, H 6.02, N 7.31.

Starting material **9c** (48 mg, 19%) was recovered from later chromatographic fractions.

5-(Nonyn-1-yl)-1-tosyluracil (11d)

Treatment of **9d** (250 mg, 1.07 mmol) by Method 4 gave **11d** (218 mg, 52%); mp 159 °C. UV max: 285, 230 nm (ε 13 800, 20 700). ^{1}H NMR δ: 0.86 (t, *J* = 6.8 Hz, 3H), 1.26–1.29 (m, 6H), 1.38–1.40 (m, 2H), 1.51 ("quint", *J* = 7.1 Hz, 2H), 2.39 (t, *J* = 7.0 Hz, 2H), 2.42 (s, 3H), 7.49 (d, *J* = 8.3 Hz, 2H), 7.97 (d, *J* = 8.3 Hz, 2H), 8.16 (s, 1H), 11.93 (s, 1H). ^{13}C NMR δ: 161.2, 146.5, 146.4, 139.2, 132.8, 129.8, 129.2, 101.3, 95.0, 71.7, 31.2, 28.2, 22.0, 21.2, 18.7, 13.9. HRMS (FAB) *m*/*z*: 411.1363 (MNa^+ [$C_{20}H_{24}N_2O_4SNa$] = 411.1354). Anal. calcd. for $C_{20}H_{24}N_2O_4S$: C 61.83, H 6.23, N 7.21; found: C 61.68, H 6.37, N 6.95.

Starting material **9d** (60 mg, 24%) was recovered from later chromatographic fractions.

5-(Decyn-1-yl)-1-tosyluracil (11e)

Treatment of **9e** (200 mg, 0.81 mmol) by Method 3 gave **11e** (70 mg, 22%) (as white crystals from MeOH); mp 153–154 °C. UV max: 285, 230 nm (ε 13 300, 20 000). ^{1}H NMR δ: 0.86 (t, *J* = 6.6 Hz, 3H), 1.26–1.29 (m, 8H), 1.38–1.40 (m, 2H), 1.51 ("quint", *J* = 7.1 Hz, 2H), 2.40 (t, *J* = 6.8 Hz, 2H), 2.43 (s, 3H), 7.49 (d, *J* = 8.3 Hz, 2H), 7.97 (d, *J* = 8.3 Hz, 2H), 8.16 (s, 1H), 11.93 (s, 1H). ^{13}C NMR δ: 161.2, 146.5, 146.4, 139.2, 132.8, 129.8, 129.2, 101.3, 95.0, 71.7,

31.2, 28.6, 28.5, 28.2, 27.9, 22.1, 21.2, 18.7, 13.9. HRMS (FAB) *m/z*: 425.1508 (MNa^+ $[C_{21}H_{26}N_2O_4SNa]$ = 425.1511). Anal. calcd. for $C_{21}H_{26}N_2O_4S$: C 62.66, H 6.51, N 6.96; found: C 62.80, H 6.70, N 7.04.

5-(Dodecyn-1-yl)-1-tosyluracil (11f)

Treatment of **9f** (177 mg, 0.64 mmol) by Method 4 gave **11f** (160 mg, 58%); mp 158–159 °C. UV max: 285, 229 nm (ε 12 900, 19 800). ^{1}H NMR δ: 0.85 (t, *J* = 6.6 Hz, 3H), 1.22–1.28 (m, 12H), 1.37–1.40 (m, 2H), 11.51 ("quint", *J* = 7.3 Hz, 2H), 2.39 (t, *J* = 7.1 Hz, 2H), 2.43 (s, 3H), 7.49 (d, *J* = 8.3 Hz, 2H), 7.97 (d, *J* = 8.3 Hz, 2H), 8.16 (s, 1H), 11.95 (s, 1H). ^{13}C NMR δ: 161.3, 146.5, 146.4, 139.2, 132.8, 129.8, 129.2, 101.3, 95.0, 71.7, 31.3, 28.9, 28.7, 28.5, 28.2, 27.9, 22.1, 21.2, 18.7, 14.0. HRMS (FAB) *m/z*: 453.1834 (MNa^+ $[C_{23}H_{30}N_2O_4SNa]$ = 453.1824). Anal. calcd. for $C_{23}H_{30}N_2O_4S$: C 64.16, H 7.02, N 6.51; found: C 63.96, H 7.02, N 6.36.

Starting material **9f** (32 mg, 18%) was recovered from later chromatographic fractions.

Antiviral assays

Antiviral assays, other than anti-HIV assays, were based on inhibition of virus-induced cytopathicity in either human embryonic lung (HEL) cells (herpes simplex virus type 1 (HSV-1) (KOS), HSV-2 (G), vaccinia virus, vesicular stomatitis virus, human cytomegalovirus (HCMV)), Vero (parainfluenza-3, reovirus-1, Sindbis, Coxsackie B4, Punta Toro virus), or HeLa (vesicular stomatitis virus, Coxsackie virus B4, respiratory syncytial virus) cell cultures or virus-induced plaque formation in HEL cells (varicella-zoster virus (VZV)). Confluent cell cultures in microtiter 96 well plates were inoculated with 100 $CCID_{50}$ of virus (1 $CCID_{50}$ is the virus dose required to infect 50% of the cell cultures). After a 1 h virus adsorption period, residual virus was removed and the cell cultures were incubated in the presence of varying concentrations (200, 40, 8, … μmol/L) of the test compounds. Viral cytopathicity was recorded as soon as it reached completion in the control virus-infected cell cultures that were not treated with the test compounds. The methodology for the anti-HIV assays was as follows: human CEM (~3 × 10^5 cells/cm^3) cells were infected with 100 $CCID_{50}$ HIV-1(III_B) or HIV-2(ROD)/mL and seeded in 200 μL wells of a microtiter plate containing appropriate dilutions of the test compounds. After 4 days of incubation at 37 °C, HIV-induced CEM giant cell formation was examined microscopically.

Chemoenzymatic synthesis of thio-nod factor intermediates — Enzymatic transfer of glucosamine on thiochitobiose derivatives[1]

Latino Loureiro Morais, Hideya Yuasa, Khalil Bennis, Isabelle Ripoche, and France-Isabelle Auzanneau

Abstract: The chemoenzymatic syntheses of thioanalogues of nodulation factors in which the nonreducing end glucosamine residue is available for the introduction of the fatty acid moiety at the free NH_2 group are reported. We are describing the chemical synthesis of UDP-GlcNH_2 and its use in the enzymatic transfer of GlcNH_2 by the bovine galactosyltransferase (EC 2.4.1.90) onto O-4 of the nonreducing end *N*-acetylglucosamine residues of chitobiose, thiochitobiose, and allyl thiochitobioside. The enzymatic reactions on chitobiose and thiochitobiose were followed by TLC and MALDI MS and showed about 50% conversion of the disaccharides to the desired products. However, these reducing trisaccharides could not be obtained totally free of salts and degraded on ion exchange chromatography. Thus, we investigated the enzymatic transfer on the nonreducing allyl thiochitobioside analogue. We describe here the chemical synthesis of this thiodisaccharide and the enzymatic transfer of GlcNH_2 at O-4 of its nonreducing end glucosamine residue to give the desired allyl thiotrisaccharide. This thiotrisaccharide was obtained pure in 41% yield and was characterized by ^{1}H NMR (HSQC) and HRMS.

Key words: nodulation factors, synthesis, enzymatic transfer, thiooligosaccharides, UDP-glucosamine.

Résumé : On a réalisé la synthèse chimioenzymatique de thioanalogues de facteurs de nodulation dans lesquels le résidu glucosamine de l'extrémité non réductrice est disponible pour l'introduction de portions d'acides gras au niveau du groupe NH_2. On décrit la synthèse chimique de UDP-GlcNH_2 ainsi que son utilisation dans le transfert enzymatique du GlcNH_2 par la galactosyltransférase bovine (EC 2.4.1.90) sur le O-4 des résidus *N*-acétylglucosamine non réducteurs du chitobiose, du thiochitobiose et du thiochitobioside d'allyle. Les réactions enzymatiques sur le chitobiose et le thiochitobiose ont été suivies par chromatographie sur couche mince et par spectrométrie de masse MALDI et elles montrent qu'il se produit une conversion d'environ 50 % des disaccharides en produits désirés. Toutefois, on n'a pas pu éliminer complètement le sel de ces trisaccharides réducteurs et ils se dégradent lors de la chromatographie par échange d'ions. On a donc étudié le transfert enzymatique sur l'analogue thiochitobioside d'allyle non réducteur. On décrit les synthèses chimiques de ce thiodisaccharide et le transfert enzymatique du GlcNH_2 vers le O-4 du résidu glucosamine de l'extrémité non réductrice pour obtenir le thiotrisaccharide d'allyle désiré. Ce thiotrisaccharide a été obtenu à l'état pur avec un rendement de 41 % et on l'a caractérisé par RMN du ^{1}H (HSQC) et par spectrométrie de masse à haute résolution.

Mots clés : facteurs de nodulation, synthèse, transfert enzymatique, thiooligosaccharides, UDP-glucosamine.

[Traduit par la Rédaction]

Introduction

Symbiotic association (1) of leguminous plants with soil bacteria of the genera *Rhizobium*, *Bradyrhizobium*, and *Azorhizobium* leads to the formation of nodules on the plant roots. Within these nodules the bacteria can fix and metabolize atmospheric nitrogen into ammonia and alanine and release it for use by the host plant, which in turn supplies the

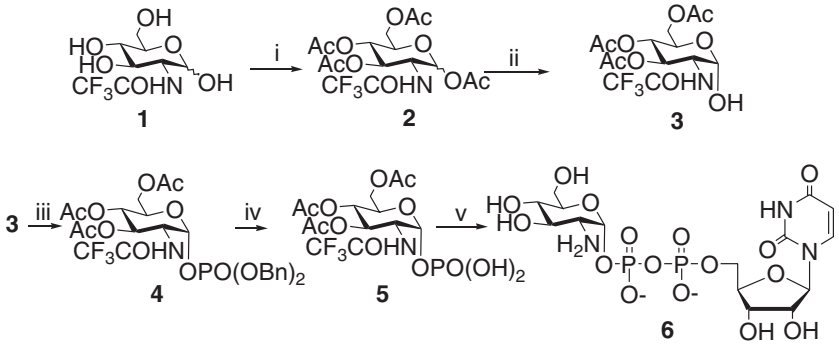
bacteria with various nutrients. Nodulation, the key step leading to this symbiotic association, is induced by the interaction with specific plant receptors of nodulation factors (Nod factors) produced by the bacteria (2). These lipooligosaccharides (3) are comprised of a tetra- or penta-oligomer of chitin with substitutions that determine the host specificity of the bacteria (Fig. 1, ref. 3). Although only very small concentrations (10^{-6} to 10^{-12} mol/L) of natural Nod factors are required to initiate nodulation, their activity is limited by the action of chitinases that cleave the glycosidic bond between the sugar units B and C (4). Therefore, we have developed a program (5) aimed at preparing thioanalogues of Nod factors in which a sulphur atom replaces one or more interglycosidic oxygen atoms, thus increasing the overall resistance of the lipooligosaccharide to chitinases (6). The synthesis of such oligosaccharide analogues with well-defined glycosidic linkages remains a challenge for carbohydrate chemists despite the advances made over the past decades. Therefore, we are investigating here the possibility of introducing a glucosamine unit at the nonreducing end of thioanalogues of Nod factors by enzymatic transfer (7). We report the use of the well-studied β-(1,4)-galactosyltransferase (7) isolated from bovine milk and involved in the biochemical synthesis of lactose and *N*-acetyllactosamine. The transfer of a glucosamine unit to the nonreducing end of chitotriose using the commercially available bovine galactosyltransferase (UDP-D-galactose:2-acetamido-2-deoxy-D-glucose 4-β-D-galactosyl tranferase; EC 2.4.1.90) has already been described (8). The work described here is, to our knowledge, the first enzymatic transfer to chitobiose derivatives that contain a sulphur atom in the glycosidic linkage and thus constitutes the first enzymatic synthesis of thiochitotriose derivatives. We describe herein the efficient chemical synthesis of UDP-glucosamine as well as the chemoenzymatic synthesis of new thiotrisaccharides precursors of thioanalogues of nodulation factors using this nucleotide donor and the bovine galactosyltranferase EC 2.4.1.90.

Results and discussion

As an alternative to the known (9) enzymatic preparation of UDP-$GlcNH_2$, the nucleotide donor **6** was synthesized chemically (Scheme 1) from the trifluoroacetamido derivative (**1**) obtained as described by Wolform and Conigliaro (10) from commercially available crystalline glucosamine hydrochloride. The synthetic strategy followed to prepare the key intermediate analogue (**5**) was similar to that employed by Sala et al. (11). Acetylation in pyridine – acetic anhydride gave the crude peracetate (**2**) as an anomeric mixture that contained the α anomer as the major compound. The crude peracetate was treated with hydrazine acetate to give the known (10, 11) α-hemiacetal (**3**) with an improved yield of 74% from **1** upon purification on silica gel. The hemiacetal **3** was treated with butyllithium to give the anomeric alkoxide that was reacted with dibenzyl phosphoryl chloride (12) in THF to give the anomeric dibenzylphosphate (**4**) in 54% yield, a yield similar to that described by Sala et al. (11) for the synthesis of the analogous anomeric diphenylphosphate (52%). The benzyl groups were removed by hydrogenolysis and the crude triacetylated anomeric phosphate (**5**) was activated with 1,1′-carbonyldiimidazole

Fig. 1. Schematic representation of nodulation factors.



in acetone and coupled with the bistrioctylammonium salt of uridine 5′-monophophate dissolved in DMF. The crude adduct was in turn treated with ammonium hydroxide in methanol to remove the *O*-acetyl and *N*-trifluoroacetyl groups and the desired UDP-$GlcNH_2$ (**6**) was isolated pure in 51% yield (from **4**) following ion exchange chromatography.

The enzymatic transfer of glucosamine by the β-1,4-galactosyltransferase isolated from bovine milk (13) was first attempted on the reducing disaccharides chitobiose (**7**) and thiochitobiose (**8**) (Scheme 2) Although the products obtained in these reactions could not be purified (see the following), these reactions were used to determine the best reaction and purification conditions for the enzymatic transfer and more importantly to establish MALDI-MS conditions that can be used to follow such transfers. While chitobiose is commercially available, the known (14) thiodisaccharide (**8**) was prepared in one step through the deacetylation of the previously reported (5*b*) peracetylated thiochitobiose. The disaccharide (**8**) obtained as an anomeric mixture could not be totally purified by conventional chromatography. However, since ^{1}H NMR (Fig. 2C and ref. 14*b*) showed a purity superior than 90% and HRMS confirmed its structure, the α,β-thiochitobiose (**8**) was submitted to enzymatic transfer. The reducing chitobiose (**7**) and thiochitobiose (**8**) were incubated with UDP-$GlcNH_2$ (**6**, 1.2 equiv.) and galactosyltransferase (5.6 U) at ambient temperature with occasional gentle mixing. TLC analysis of the reaction mixture showed in both cases the formation of a new ninhydrin positive compound that was more polar than the starting material. The formation of the trisaccharides **9** and **10** was also assessed by MALDI-MS of the reaction mixtures (Fig. 3). As can be seen in Fig. 3A, we observed for the enzymatic transfer on **7** (+Na, *m*/*z* 448 ± 1) the appearance of a signal at *m*/*z* 608 ± 1 (+Na) corresponding to the desired adduct **9**. Similarly, both the starting thiochitobiose (**8**) and the adduct **10** were observed at *m*/*z* 464 ± 1 (+Na) and *m*/*z* 625 ± 1 (+Na), respectively, by MALDI-MS for the enzymatic transfer on disaccharide **8**. After 2 weeks of incubation, the conversion evaluated by TLC had reached ~50% in both cases, and the reaction mixtures were applied to a gel permeation chromatography column of Bio-Gel eluted with a 0.25 mol/L ammonium acetate solution. While this was an efficient way to separate the unreacted disaccharides **7** and **8** from the desired trisaccharides **9** and **10**, respectively, the products could not be isolated totally free of ammonium acetate even after repeated freeze drying from water. Additional attempts to remove the excess acetate ions

by applying the impure products to ion exchange columns (AG1X-8/OH^-) resulted in the degradation or adsorption and subsequent loss of the reducing sugars. Although the products could not be obtained free of salts, NMR confirmed that the products isolated were the desired trisaccharides. ^1H NMR of **9** (Fig. 2B) clearly showed signals that could be assigned to the newly introduced glucosamine residue at 4.82 ppm for the anomeric H-1″ and at 3.06 ppm for H-2″. The ^1H NMR spectrum obtained for **10** (Fig. 2D) showed the presence of the same contaminant already observed in **8**, which we concluded was also a substrate for the galactosyltransferase. However, it also clearly demonstrated that a glucosamine unit giving typical signals at 4.83 and 3.09 ppm for H-1″ and H-2″, respectively, had been transferred onto the thiochitobiose. Finally, the structures of **9** and **10** were unambiguously confirmed by HRMS that gave protonated molecular ions at *m/z* 586.2463 for **9** (calcd. [M + H] 586.2459) and *m/z* 602.2237 for **10** (calcd. [M + H] 602.2231). Thus, these results showed that the transfer of a glucosamine residue to thiochitobiose using UDP-$GlNH_2$ and bovine β-(1,4)-galactosyltransferase can be used for the preparation of thionodulation factor intermediate trisaccharides. However, because trisaccharide **10** could not be isolated pure and free of salt without degradation, we focused our synthetic effort on the preparation of the nonreducing allyl thiochitobioside derivative (**20**) (Scheme 3).

The allyl group was chosen as a versatile aglycon that is not only easily introduced and removed at the anomeric position, but can also be used to immobilize the oligosaccharides on solid support (15) to further attempt to isolate the specific plant receptor. Nucleophilic displacement of the known (5*c*) 1,6-anhydro triflate **12** with the anomeric thiolate obtained by treatment of the thiol **11** (5*b*) with sodium hydride, afforded the thiodisaccharide **13** in excellent yield (90%). The 1,6-anhydro ring in disaccharide **13** was opened with a mixture of Ac_2O and TFA to give the anomeric mixture of **14** (α/β, 65:35) in high yield (96%). Considering the low stability of the allyl group in debenzylation conditions, we replaced the benzyl group at the C-3 hydroxyl group of the reducing end glucosamine with an acetyl group prior to introducing the allyl aglycon. Thus, the benzyl group in compound **14** was removed using iron trichloride (16) in dichloromethane and the crude intermediate alcohol was acetylated to give the peracetate **15** as an anomeric mixture (Scheme 3). The thiodisaccharide **15** was subsequently converted to the hemiacetal **16** by selective deacetylation of the anomeric hydroxyl group and the hemiacetal **16** was treated with DBU and trichloroacetonitrile to give trichloroacetimidate **17** as an anomeric mixture in favor of the α anomer (α/β, 85:15). Glycosylation of allyl alcohol with the donor **17** was performed under $BF_3{\cdot}Et_2O$ catalysis in dichloromethane and gave the desired thiodisaccharide **18**

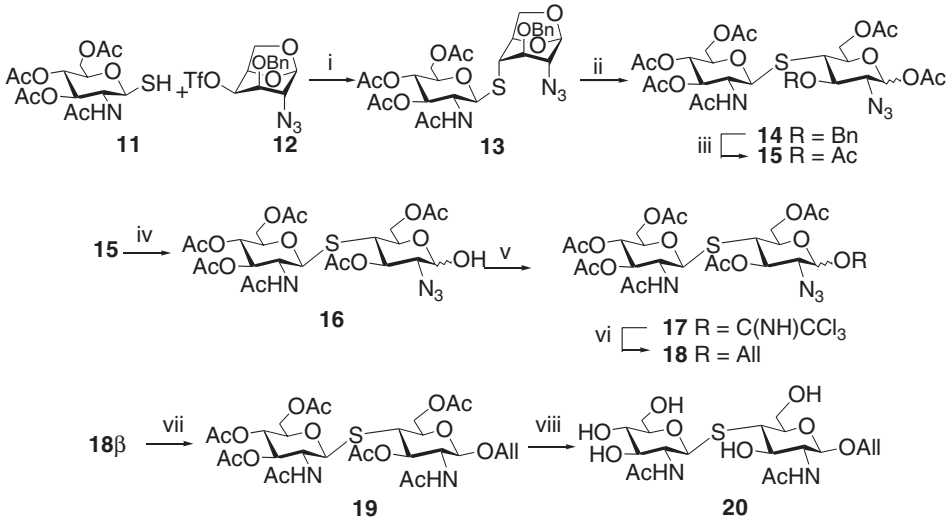
Fig. 3. MALDI-MS (accuracy *m*/*z*: ±1) of enzymatic transfer on (A) chitobiose (**7**) and (B) thiochitobiose (**8**).

in good yield (83%) and high selectivity in favor of the β anomer (α/β, 1:9). The β anomer **18**β was isolated anomerically pure by chromatography on alumina and converted to the *N*-acetate **19** in moderate yield through the reduction of the azido group (Zn-AcOH, ref. 17) followed by in situ N-acetylation. Finally, Zemplèn deacetylation of disaccharide **19** gave the acceptor **20** in good yield.

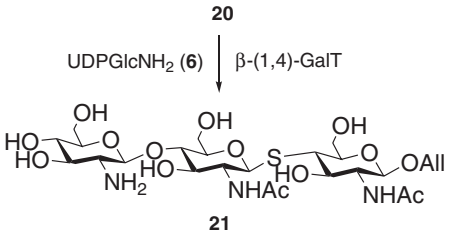
Enzymatic transfer of the glucosamine residue (Scheme 4) was accomplished using the same conditions as those described for the preparation of trisaccharides **9** and **10**. Thus, thiodisaccharide **20** was incubated for 2 weeks at ambient temperature with UDP-GlcNH$_2$ **6** (1.2 equiv.) and the bovine galactosyltransferase (5.6 U). The thiotrisaccharide **21** was obtained pure in 41% yield after chromatography on Bio-Gel P-2 ($AcONH_4$, 0.25 mol/L), followed by desalting on a small column of AG MP-1 (OH^-) eluted with water. The pure compound **21** was fully characterized by ^{1}H NMR spectroscopy, COSY, and HSQC, and its structure was confirmed by HR-ESI MS.

The results reported herein show that the transfer of a glucosamine unit to a thiochitobiose derivative by enzymatic catalysis using the well-known β-(1,4)-galactosyltransferase is applicable to the preparation of thiooligosaccharides. Further reactions on the thiotrisaccharide **21**, including the introduction of the fatty acid moiety, should provide access to a large series of thioanalogues of nodulation factors.



Experimental section

General procedure for the enzymatic reactions



The acceptors **7**, **8**, and **20** (~5 mg, ~11 μmol) and UDP-glucosamine (~9 mg, 1.2 equiv.) were dissolved in 1 mL of a pH 7.4 buffer (80 mmol/L sodium cacodylate, 5 mmol/L $MgCl_2$, 0.1 mmol/L DTT) containing β-1,4-galactosyl-

Scheme 4.

transferase (5.6 U). Solutions of $MnCl_2$ (1 mol/L, 25 μL, 5 mmol), α-lactalbumin (25 mg/mL, 45 μL), and alkaline phosphatase (1 U) were added to the mixture, which was then left at room temperature for 2 weeks. TLC monitoring of the reactions (*i*-PrOH–NH_4OH–H_2O, 7:2:1 or $CHCl_3$–MeOH–H_2O, 65:35:2) showed, in all three cases, the formation of new compounds more polar than the starting materials in ~50% yield estimated from the TLC. The reaction mixtures were then applied directly to a Bio-Gel P-2 column (100 cm × 1 cm) eluted with a 0.25 mol/L $NH_4^+AcO^-$ solution. The fractions containing the new compounds were combined and freeze dried repeatedly from MQ water. The allyl thiotrisaccharide **21** was additionally deionized on a column of AG MP-1(OH^-) eluted with H_2O.

3,4,6-Tri-*O*-acetyl-2-deoxy-2-trifluoroacetamido-α-D-glucopyranose (3)

2-Deoxy-2-trifluoroacetamido-D-glucopyranose (4.72 g, 17.1 mmol) was prepared as described by Wolform and Conigliaro (10) from commercially available crystalline D-glucosamine hydrochloride and was dissolved in pyridine (32 mL) and acetic anhydride (18 mL). The reaction mixture was kept at room temperature for 16 h and poured into ice water and stirred for 1 h. The mixture was extracted with dichloromethane and the organic layer was washed with aq. $NaHCO_3$ and dried on Na_2SO_4. The solution was concentrated to give a crude syrup (8.56 g) containing the peracetylated 2-deoxy-2-trifluoroacetamido-α/β-D-glucopyranose (**2**). ^{1}H NMR analysis showed that the α/β ratio was largely in favor of the desired α anomer (94:6). Therefore, the crude material was dissolved in DMF (50 mL) and the solution was warmed to 50 °C. Hydrazine acetate (1.74 g, 18.9 mmol, 1.05 equiv.) was added to the solution and stirring at 50 °C was maintained for 25 min. The reaction mixture was diluted with EtOAc and washed three times with brine. The organic layer was dried over $MgSO_4$ and concentrated to give a syrup (8.55 g). Chromatography on silica gel (hexane–EtOAc, 3:2) gave the title compound **3** (5.09 g, 74%) as a pure white powder. Compound **3** had characteristics in excellent agreement with those described (10, 11). $[\alpha]_D$ +21° (*c* 1.6, $CHCl_3$) (lit. value (10) +25° (*c* 1, $CHCl_3$), lit. value (11) +20° (*c* 0.5, $CHCl_3$)). ^{1}H NMR (360 MHz, $CDCl_3$) δ: 6.75 (d, 1H, $J_{NH,2}$ = 9.7 Hz, NH), 5.37 (dd, 1H, $J_{2,3}$ = 9.7 Hz, $J_{3,4}$ = 9.5 Hz, H-3), 5.37–5.34 (m, 1H, H-1), 5.27 (t, 1H, $J_{4,5}$ = 9.5 Hz, H-4), 4.32 (dt, 1H, $J_{1,2}$ = 3.5 Hz, H-2), 4.27–4.08 (m, 3H, H-5, H-6a, H-6b), 3.78 (bs, 1H, OH), 2.11, 2.06, and 2.04 (3 s, 9H, 3 × CH_3CO). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 171.4, 171.0, 169.4 (*C*OCH_3), 157.3 (q, $J_{C,F}$ = 37.4 Hz, *C*OCF_3), 115.5 (q, $J_{C\text{-}F}$ = 290 Hz, *C*F_3), 91.0 (C-1), 70.5, 67.9 (C-3, C-4, C-5), 61.9 (C-6), 52.8 (C-2), 20.8, 20.6, 20.5 (*C*H_3CO).

3,4,6-Tri-*O*-acetyl-2-deoxy-2-trifluoroacetamido-α-D-glucopyranosyl dibenzyl phosphate (4)

A solution of butyllithium (1.6 mol/L, 8.4 mL, 13.4 mmol) in hexane was added to a solution of hemiacetal **3** (5.31 g, 13.2 mmol) in THF (160 mL) stirred at –70 °C. After 2 min, a solution of dibenzyl chlorophosphate (12) (5.5 mL, 29.3 mmol) in THF (200 mL) was added slowly at –70 °C under stirring and the mixture was stirred for a further 30 min while the temperature was kept between –60 and –50 °C. Triethylamine was added to pH 8 and the solvent was evaporated. The residue was partitioned between chloroform and aqueous sodium chloride. The organic layer was dried ($MgSO_4$), concentrated, and chromatography on silica gel (hexane–EtOAc, 3:2) gave the pure dibenzylphosphate **4** (5.17 g, 59%) as a colorless glass. $[\alpha]_D$ +55° (*c* 1.2, $CHCl_3$). ^{1}H NMR (360 MHz, $CDCl_3$) δ: 8.2 (d, 1H, $J_{NH,2}$ = 9.0 Hz,

NH), 7.40–7.20 (m, 10H, H-aromatics), 5.80 (dd, 1H, $J_{1,2}$ = 3.2 Hz, $J_{1,P}$ = 6.7 Hz, H-1), 5.35 (dd, 1H, $J_{2,3}$ = 10.5 Hz, $J_{3,4}$ = 10.0 Hz, H-3), 5.16 (t, 1H, $J_{4,5}$ = 10.0 Hz, H-4), 5.28–4.98 (m, 4H, 2 × CH_2Ph), 4.41 (ddd, 1H, $J_{2,P}$ = 3.2 Hz, H-2), 4.25–3.98 (m, 3H, H-5, H-6a, H-6b), 2.03, 2.02, 1.99 (3s, 9H, 3 × CH_3CO). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 171.0, 170.5, 169.1 (*C*OCH_3), 157. 6 (q, $J_{C,F}$ = 37.7 Hz, *C*OCF_3), 135.2, 135.0, 129.0,128.8, 128.2 (C-aromatics), 115.5 (q, J_{C-F} = 286.8 Hz, *C*F_3), 95.1 (d, J_{C-P} = 5.7 Hz, C-1), 70.3, 70.2, 69.8, 67.2 (C-3, C-4, C-5, 2 × *C*H_2Ph), 61.1 (C-6), 52.6 (d, $J_{2,P}$ = 7.5 Hz, C-2), 20.6, 20.5, 20.4 (*C*H_3CO). Anal. calcd. for $C_{28}H_{31}NO_{12}PF_3$: C 50.84, H 4.72, N 2.12; found: C 50.90, H 4.67, N 1.97.

Uridine 5′-(2-amino-2-deoxy-α-D-glucopyranosyl)-diphosphate (6)

A solution of dibenzylphosphate **4** (5.17 g, 7.82 mmol) in MeOH (400 mL) containing 5% Pd/C (2.14 g) was stirred under hydrogen for 2.5 h. The catalyst was filtered off and the filtrate concentrated to dryness to give 3,4,6-tri-*O*-acetyl-2-deoxy-2-trifluoroacetamido-α-D-glucopyranosyl phosphate (**5**) as a white solid. R_f 0.28 (60:40:3, CH_2Cl_2–MeOH–H_2O). ^{1}H NMR (360 MHz, $CDCl_3$–CD_3OD, 2:1) δ: 5.64 (dd, 1H, $J_{1,2}$ = 3.0 Hz, $J_{1,P}$ = 6.0 Hz, H-1), 5.42 (dd, 1H, $J_{2,3}$ = 10.0 Hz, $J_{3,4}$ = 9.5 Hz, H-3), 5.17 (t, 1H, $J_{4,5}$ = 10.0 Hz, H-4), 4.42 (dt, 1H, $J_{2,P}$ = 3.0 Hz, H-2), 4.33–4.10 (m, 3H, H-5, H-6a, H-6b), 2.11, 2.06, 2.02 (3s, 9H, 3 × CH_3CO). Crude **5** was dissolved in acetone (130 mL) and 80% 1,1′-carbonyldiimidazole (3.3 g, 16.3 mmol) was added and the mixture was stirred for 15 h at room temperature. After completion of the reaction ($CHCl_3$–MeOH, 3:1, R_f 0.28), methanol (170 μL) was added and the mixture was stirred for another 0.5 h. The reaction mixture was concentrated and dried under reduced pressure over P_2O_5 for 6 h. While the crude imidazolate was drying, uridine 5′-monophosphate disodium salt (3.5 g, 9.51 mmol) was passed slowly through a column of Dowex 50-5X8 (H^+) resin and the column was thoroughly washed with water. The eluate was concentrated and trioctylamine (8.8 mL, 20 mmol) was added. The mixture was coevaporated three times with DMF and a solution of the aforementioned dry imidazolate in DMF (100 mL) was added. The mixture was stirred for 24 h at room temperature and the formation of the adduct was followed by TLC (CH_2Cl_2–MeOH–H_2O, 60:40:3, R_f 0.35). The solvent was evaporated and the dry residue was dissolved in methanol (150 mL) and ammonium hydroxide (60 mL). The solution was stirred at room temperature for 24 h and concentrated. The crude deacylated product was dissolved in 40 mmol/L aqueous ammonium bicarbonate and slowly passed through a Dowex 1X2-200 (HCO_2^-) column (3 cm × 30 cm). The column was kept at 23 °C and was first washed with 40 mmol/L aq. NH_4HCO_2, then it was eluted (1.6 mL/min) with a linear gradient of ammonium bicarbonate (mixing vessel 550 mL of 40 mmol/L NH_4HCO_2; reservoir 550 mL of 700 mmol/L NH_4HCO_2). The UV absorption of the eluate at 280 nm was monitored and 20 mL fractions were collected. Those fractions containing the product were pooled and concentrated and the residue dissolved in water was treated with Dowex 50-X8 (H^+) until the pH was below 7 and CO_2 gas had evolved. The resin was filtered off and the pH of the filtrate was adjusted to 8 by adding aqueous sodium hydroxide. The solution was passed through a Millex SR filter unit and the filtrate was lyophilized to give pure UDP-GlcNH_2 (**6**) as a white solid (2.43 g, 51%). ^{1}H NMR (400 MHz, D_2O) δ: 7.96 (d, 1H, $J_{5,6}$ = 8.0 Hz, H-6), 5.99 (d, 1H, $J_{1′,2′}$ = 4.4 Hz, H-1′), 5.96 (d, 1H, H-5), 5.75 (dd, 1H, $J_{1″,2″}$ = 3.3 Hz, $J_{1″\text{-}P}$ = 6.8 Hz, H-1″), 4.36 (m, 2H, H-5a′, H-5b′), 4.31–4.16 (m, 3H, H-2′, H-3′, H-4′), 3.78–3.96 (m, 4H, H-3″, H-5″, H-6a″, H-6b″), 3.53 (t, 1H, $J_{3″,4″}$ = $J_{4″,5″}$ = 9.6 Hz, H-4″), 3.16 (dd, 1H, $J_{2″,3″}$ = 10.4 Hz, $J_{2″,P}$ = 3.5 Hz, H-2″). ^{13}C NMR (75 MHz, D_2O) δ: 167.1 (C-4), 153.7 (C-2), 142.5 (C-6), 103.5 (C-5), 93.7 (d, $J_{C,P}$ = 5.3 Hz, C-1″), 89.5 (C-1′), 83.9 (d, $J_{C,P}$ = 8.7 Hz, C-4′), 74.6, 74.1, 70.8, 70.4, 69.9 (C-2′, C-3′, C-3″, C-4″, C-5″), 65.9 (d, $J_{C,P}$ = 5.3 Hz, C-5′), 60.9 (C-6″), 55.0 (d, $J_{C,P}$ = 9.3 Hz, C-2″). ^{31}P NMR (145 MHz, D_2O) δ: –10.9 (d, $J_{P,P}$ = 22.0 Hz, P-O-uridine), –13.5 (d, P-O-Glc). HRMS calcd. for $C_{15}H_{23}O_{16}N_3Na_2P_2S$ *m*/*z*: 632.0247 [M + Na]; found: 632.0245.

4-*S*-(2-Acetamido-2-deoxy-β-D-glucopyranosyl)-2-acetamido-2-deoxy-4-thio-α,β-D-glucopyranose (8)

The peracetylated thiochitobiose (5*b*) (37.2 mg, 0.040 mmol) was dissolved in anhydr. MeOH (4 mL) and a solution of sodium methoxide in MeOH (1 mol/L, 40 μL) was added. The reaction mixture was stirred for 3 days at room temperature and deionized with Amberlite® IR120 resin. The resin was filtered off, rinsed with MeOH, and the combined filtrate and washings were concentrated to dryness. The anomeric mixture of thiochitobiose (**8**) was obtained as a white precipitate (11.2 mg) from a mixture of MeOH and acetone. ^{1}H NMR was reported previously (14*b*) for the two anomers and showed the presence of less than 10% of an impurity (Fig. 2C) that could not be removed nor identified. Nevertheless, HRMS confirmed that the wanted anomeric mixture of thiochitobiose was the main product isolated. HRMS calcd. for $C_{16}H_{28}O_{10}N_2S$ *m*/*z*: 463.1362 [M + Na]; found: 463.1364.

Enzymatic transfer on chitobiose (7) and thiochitobiose (8)

MALDI-MS conditions (Kratos Kompact MALDI-TOF, external calibration on insulin): 10 μL of the reaction mixture were diluted with 90 μL of water or 0.25 mol/L $AcONH_4$ and 0.5 μL of these solutions were deposited on the target with 0.5 μL of THAP as the matrix. The trisaccharides **9** (5.7 mg) and **10** (10 mg) were isolated as amorphous white powders showing residual acetate salts by NMR (Supplementary material).[5] Compound **10** also showed the impurity seen in **8**. Nevertheless, HRMS and ^{1}H NMR showed that these compounds were the desired trisaccharides. HRMS for **9** calcd. for $C_{22}H_{39}O_{15}N_3$ *m*/*z*: 586.2459 [M + H]; found: 586.2463. HRMS for **10** calcd. for $C_{22}H_{39}O_{14}N_3S$ *m*/*z*: 602.2231 [M + H]; found: 602.2237.

4-*S*-(2-Acetamido-3,4,6-tri-*O*-acetyl-2-deoxy-β-D-glucopyranosyl)-1,6-anhydro-2-azido-3-*O*-benzyl-2-deoxy-4-thio-β-D-glucopyranose (13)

A solution of thiol **11** (5*b*) (17.6 g, 43 mmol) in DMF (300 mL) was added to a suspension of NaH (55% in oil, 2.33 g, 53 mmol, 1.2 equiv.) in DMF (10 mL) cooled to 0 °C. The mixture was stirred under Ar for 10 min at 0 °C, 10 min at 20 °C and was, in turn, added to triflate **12** (5*c*) (18.6 g, 51 mmol, 1.2 equiv.). The reaction mixture was stirred for 1 h at 20 °C and the reaction was quenched by addition of AcOH (20 mL), followed by stirring for a further 30 min at room temperature. The solvent was removed in vacuo and the residue was purified by chromatography on silica gel (1:0 to 1:4 toluene–EtOAc) to give thiodisaccharide **13** (24.5 g, 90%) as a white solid; mp 183 °C. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 7.41–7.36 (m, 5H, H-aromatics), 5.54 (d, 1H, $J_{NH,2}$ = 9.1 Hz, NH), 5.44 (s, 1H, H-1), 5.26 (t, 1H, $J_{2,3} = J_{3,4}$ = 9.9 Hz, H-3′), 5.09 (t, 1H, $J_{3',4'} = J_{4',5'}$ = 9.8 Hz, H-4′), 4.93 (d, 1H, $J_{1',2'}$ = 10.4 Hz, H-1′), 4.76–4.70 (m, 2H, C*H*Ph, H-5), 4.67 (d, 1H, *J* = 11.9 Hz, C*H*Ph), 4.27 (d, 1H, $J_{6a,6b}$ = 7.4 Hz, H-6a), 4.19 (dd, 1H, $J_{6a',6b'}$ = 12.4 Hz, $J_{5',6a'}$ = 4.7 Hz, H-6a′), 4.14 (dd, 1H, $J_{5',6b'}$ = 2.3 Hz, H-6b′), 4.00 (td, 1H, $J_{2',3'}$ = 10.4 Hz, H-2′), 3.82 (m, 1H, H-4), 3.77 (dd, 1H, $J_{5,6b}$ = 5.6 Hz, H-6b), 3.68 (m, 1H, H-5′), 3.52 (s, 1H, H-3), 3.23 (s, 1H, H-2), 2.06, 2.05, 2.03, 1.95 (4s, 12H, 4 × CH_3CO). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 170.9, 170.6, 170.2, 169.4 (*C*OCH_3), 137.5 (C-ipso), 128.6, 128.0, 127.7 (C-aromatics), 100.1 (C-1), 83.4 (C-1′), 78.6 (C-4), 76.1 (C-5′ and C-5), 73.3 (C-3′), 72.3 (*C*H_2Ph), 68.3 (C-4′), 67.8 (C-6), 62.0 (C-6′), 60.2 (C-3), 53.8 (C-2′), 44.0 (C-2), 23.3, 20.7, 20.6 (*C*H_3CO). 1,6-Di-*O*-acetyl-4-*S*-(2-acetamido-3,4,6-tri-*O*-acetyl-2-deoxy-β-D-glucopyranosyl)-2-azido-3-*O*-benzyl-2-deoxy-4-thio-α,β-D-glucopyranose (14)

Thiodisaccharide **13** (24.5 g, 39 mmol) was dissolved in Ac_2O–TFA (9:1, 166 mL), and the solution was stirred for 6.5 h at 40 °C. Solvents were evaporated under reduced pressure and residual Ac_2O was coevaporated with toluene. The residue was submitted to chromatography (3:2 to 0:1 toluene–EtOAc) to furnish compound **14** (23 g, 96%). ^{1}H NMR spectroscopy showed an α/β ratio of 65:35. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 7.50–7.30 (m, 5Hα and 5Hβ, H-aromatics), 6.29 (d, 1Hα, $J_{1,2}$ = 3.2 Hz, H-1α), 5.58 (d, 1Hα, $J_{1',2'}$ = 8.6 Hz, H-1′α), 5.47 (m, 2Hβ, H-1β and H-1′β), 5.30 (t, 1Hα and 1Hβ, $J_{2',3'+3',4'}$ = 19.7 Hz, H-3′α and H-3′β), 5.08–4.95 (m, 2Hα and 2Hβ, C*H*Phα, C*H*Phβ, H-4′α and H-4′β), 4.95–4.85 (m, 2Hα and 2Hβ, C*H*Phα, C*H*Phβ, NHα and NHβ), 4.57–4.0 (m, 2Hα and 2Hβ, H-6aα, H-6aβ, H-6bα and H-6bβ), 4.19 (dd, 1Hα, $J_{6a',6b'}$ = 12.5 Hz, $J_{5',6a'}$ = 4.9 Hz, H-6a′α), 4.11–3.96 (m, 2Hα and 2Hβ, H-5α, H-6b′α, H-6b′β and H-6a′β), 3.89–3.77 (m, 1Hα and 2Hβ, H-2′α, H-2β and H-5β), 3.73 (t, 1Hα, *J* = 10.1 Hz, H-3α), 3.69–3.63 (m, 2Hα and 1Hβ, H-5′α, H-5′β and H-2α), 3.60 (t, 1Hβ, $J_{1,2} = J_{2,3}$ = 8.9 Hz, H-2β), 3.41 (t, 1Hβ, $J_{3,4}$ = 10.0 Hz, H-3β), 2.98 (t, 1Hα, $J_{3,4} = J_{4,5}$ = 10.5 Hz, H-4α), 2.93 (t, 1Hβ, $J_{4,5}$ = 10.5 Hz, H-4β), 2.20–2.17 (2s, 3Hα and 3Hβ, $CH_3COα$ and $CH_3COβ$), 2.12 (s, 3Hα, $CH_3COα$), 2.09 (s, 3Hα, $CH_3COα$), 2.05–2.00 (m, 6Hα and 12Hβ, 2 × $CH_3COα$ and 4 × $CH_3COβ$), 1.71 (s, 3Hα, C*H*$_3$CONHα), 1.68 (s, 3Hβ, $CH_3CONHβ$). ^{13}C NMR (100 MHz, $CDCl_3$) for the α anomer δ: 170.5, 168.7 (*C*OCH_3), 128.6, 128.2, 127.6, 127.5 (C-aromatics), 90.4 (C-1), 83.6 (C-1′), 77.0 (C-3), 75.6 (*C*H_2Ph), 75.2 (C-5′), 72.8 (C-3′), 72.5 (C-5), 68.2 (C-4′), 63.9 (C-2), 63.2 (C-6), 62.1 (C-6′), 54.5 (C-2′), 46.8 (C-4), 23.1, 21.0, 20.6 (*C*H_3CO). HRMS calcd. for $C_{31}H_{40}N_4O_{14}S$ *m/z*: 747.2159 [M + Na]; found: 747.2158.

1,3,6-Tri-*O*-acetyl-4-*S*-(2-acetamido-3,4,6-tri-*O*-acetyl-2-deoxy-β-D-glucopyranosyl)-2-azido-2-deoxy-4-thio-α,β-D-glucopyranose (15)

Anhydrous $FeCl_3$ (20.4 g, 126 mmol, 4 equiv.) was added to a solution of benzyl **14** (22.7 g, 31 mmol) in freshly distilled anhydr. CH_2Cl_2 (220 mL) and the mixture was stirred for 1.5 h under Ar at 20 °C. The solvent was evaporated then pyridine (210 mL) and Ac_2O (105 mL) were added. The reaction mixture was stirred for 1.5 h at 20 °C and concd. EtOAc (350 mL) was added to the residue and the resulting solution was washed successively with 1 mol/L HCl (250 mL), satd. $NaHCO_3$ (250 mL), and brine (250 mL). The aqueous layers were reextracted with EtOAc (2 × 250 mL) and the combined organic layers were dried and concentrated. The crude product was filtered off from EtOH and further purified by chromatography on silica gel (0:1 to 9:1 EtOAc–cyclohexane) to afford acetate **15** (13.1 g, 62%) as a white powder. ^{1}H NMR spectra gave an α/β ratio of 8:2. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 6.33 (d, 1Hα, $J_{1,2}$ = 3.3 Hz, H-1α), 5.77 (d, 1Hα, $J_{NH,2}$ = 9.8 Hz, NHα), 5.69 (d, 1Hβ, $J_{NH,2}$ = 10.1 Hz, NHβ), 5.49 (d, 1Hβ, $J_{1,2}$ = 8.6 Hz, H-1β), 5.43 (t, 1Hα, $J_{2,3} = J_{3,4}$ = 10.5 Hz, H-3α), 5.11 (t, 1Hα, $J_{2',3'} = J_{3',4'}$ = 9.7 Hz, H-3′α), 5.08–4.91 (m, 1Hα and 3Hβ, H-4′α, H-4′β, H-3′β and H-3β), 4.74 (d, 1Hα and 1Hβ, $J_{1',2'}$ = 10.4 Hz, H-1′α and H-1′β), 4.60 (dd, 1Hα, $J_{6a,6b}$ = 12.5 Hz, $J_{5,6a}$ = 3.9 Hz, H-6aα), 4.55 (dd, 1Hβ, $J_{6a,6b}$ = 12.5 Hz, $J_{5,6a}$ = 4.6 Hz, H-6aβ), 4.46 (m, 1Hβ, H-6bβ), 4.40–4.29 (m, 2Hα, H-5α and H-6bα), 4.28–4.13 (m, 2Hα and 2Hβ, H-2′α, H-2′β, H-6a′α and H-6a′β), 4.10–4.00 (m, 1Hα and 1Hβ, H-6b′α and H-5β), 3.95 (dd, 1Hβ, $J_{6a',6b'}$ = 12.1 Hz, $J_{5',6b'}$ = 7.9 Hz, H-6b′β), 3.76–3.63 (m, 2Hα and 2Hβ, H-2α, H-2β, H-5′α and H-5′β), 2.95 (t, 1Hα, *J* = 11.2 Hz, H-4α), 2.86 (t, 1Hβ, $J_{3,4} = J_{4,5}$ = 10.5 Hz, H-4β), 2.22 (s, 3Hα, $CH_3COα$), 2.19 (s, 3Hα, $CH_3COα$), 2.19–2.18 (2s, 6Hβ, 2 × $CH_3COβ$), 2.13 (s, 3Hβ, $CH_3COβ$), 2.07 (s, 3Hα, $CH_3COα$), 2.06–2.01 (m, 9Hα and 9Hβ, 3 × $CH_3COα$ and 3 × $CH_3COβ$), 1.95 (s, 3Hα, $CH_3CONHα$) and 1.92 (s, 3Hβ, $CH_3CONHβ$). ^{13}C NMR (100 MHz, $CDCl_3$) for the α anomer δ: 171.3, 170.6, 170.3 (*C*OCH_3), 90.3 (C-1), 82.3 (C-1′), 75.9 (C-5′), 74.2 (C-3′), 71.1 (C-5), 68.5 (C-4′), 67.8 (C-3), 63.0, 62.9 (C-6 and C-6′), 61.8 (C-2), 51.9 (C-2′), 45.8 (C-4), 23.0, 20.9, 20.7, 20.6 (*C*H_3CO). HRMS calcd. for $C_{26}H_{36}N_4O_{15}S$ *m/z*: 699.1796 [M + Na]: found: 699.1796.

3,6-Di-*O*-acetyl-4-*S*-(2-acetamido-3,4,6-tri-*O*-acetyl-2-deoxy-β-D-glucopyranosyl)-2-azido-2-deoxy-4-thio-α,β-D-glucopyranose (16)

Hydrazine acetate (2.1 g, 23 mmol, 1.2 equiv.) was added to a solution of compound **15** (12.8 g, 19 mmol) in DMF (110 mL). The mixture was stirred for 1 h under Ar at room temperature and the solvent was removed under reduced

© 2006 NRC Canada

pressure. Residual traces of DMF were coevaporated with toluene and the residue was dissolved in EtOAc (200 mL) and washed with water (150 mL) and brine (150 mL). The aqueous layers were reextracted with EtOAc (2 × 250 mL) and the combined organic solvents were dried and concentrated. The crude product was purified by chromatography on silica gel (1:0 to 95:5 $CHCl_3$–MeOH) to yield hemiacetal **16** (8.9 g, 75%). The ^{1}H NMR spectra showed an α/β ratio of 7:3. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 5.90 (d, 1Hα, $J_{1',2'}$ = 9.9 Hz, H-1′α), 5.81 (d, 1Hβ, $J_{1',2'}$ = 9.9 Hz, H-1′β), 5.55 (t, 1Hα, $J_{2,3}$ = $J_{3,4}$ = 10.5 Hz, H-3α), 5.40 (d, 1Hα, $J_{1,2}$ = 3.1 Hz, H-1α), 5.09 (t, 1Hα, $J_{2',3'}$ = $J_{3',4'}$ = 9.5 Hz, H-3′α), 5.08–4.97 (m, 1Hα, 3Hβ, H-3′β, H-3β, H-4′α and H-4′β), 4.82 (d, 1Hα, $J_{NH,2}$ = 10.4 Hz, NHα), 4.78 (d, 1Hβ, $J_{NH,2}$ = 10.5 Hz, NHβ), 4.69 (d, 1Hβ, $J_{1,2}$ = 7.9 Hz, H-1β), 4.57 (dd, 1Hα, $J_{6a,6b}$ = 11.8 Hz, $J_{5,6a}$ = 3.7 Hz, H-6aα), 4.55 (m, 1Hα and 2Hβ, H-5α, H-6aβ and H-6bβ), 4.44 (dd, 1Hα, $J_{5,6b}$ = 1.6 Hz, H-6bα), 4.26–4.16 (m, 2Hα and 2Hβ, H-2′α, H-2′β, H-6a′α and H-6a′β), 4.01 (dd, 1Hα and 1Hβ, $J_{6a',6b'}$ = 12.3 Hz, $J_{5',6b'}$ = 6.0 Hz, H-6b′α and H-6b′β), 3.92 (m, 1Hβ, H-5β), 3.73 (m, 1Hα and 1Hβ, H-5′α and H-5′β), 3.50 (m, 1Hα and 1Hβ, H-2α and H-2β), 2.91–2.82 (m, 1Hα and 1Hβ, H-4α and H-4β), 2.17 (s, 3Hα and 3Hβ, $CH_3COα$ and $CH_3COβ$), 2.10 (s, 3Hα, $CH_3COα$), 2.09 (s, 3Hβ, $CH_3COβ$), 2.07 (s, 3Hα, $CH_3COα$), 2.06 (s, 3Hβ, $CH_3COβ$), 2.03 (s, 3Hα and 3Hβ, $CH_3COα$ and $CH_3COβ$), 2.01 (s, 3Hα and 3Hβ, $CH_3COα$ and $CH_3COβ$), 1.94 (s, 3Hα, $CH_3COα$) and 1.92 (s, 3Hβ, $CH_3COβ$). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 170.8, 170.7, 170.1, 169.4 (*C*OCH_3), 96.1 (C-1β), 91.8 (C-1α), 81.9 (C-1′α), 81.7 (C-1′β), 75.5 (C-5′α), 75.4 (C-5′β), 74.3 (C-3′α), 74.1 (C-3′β), 73.6 (C-5β), 70.1 (C-3β), 68.6 (C-5α), 68.4 (C-4′α), 68.3 (C-4′β), 67.9 (C-3α), 66.2 (C-2β), 63.5 (C-6α and C-6β), 63.2 (C-2α), 62.5 (C-6′α and C-6′β), 52.0 (C-2′α and C-2′β), 46.3 (C-4α), 46.1 (C-4β), 22.9, 21.1, 20.9, 20.7, 20.6 (*C*H_3CO). 3,6-Di-*O*-acetyl-4-*S*-(2-acetamido-3,4,6-tri-*O*-acetyl-2-deoxy-β-D-glucopyranosyl)-2-azido-3-*O*-benzyl-2-deoxy-4-thio-α,β-D-glucopyranosyl trichloroacetimidate (17)

Trichloroacetonitrile (27.5 mL, 275 mmol, 19 equiv.) and DBU (532 µL, 3.6 mmol, 0.26 equiv.) were added to a solution of hemiacetal **16** (8.74 g, 14 mmol) in anhydr. CH_2Cl_2 (130 mL). The reaction mixture was stirred under Ar at room temperature for 45 min. The reaction mixture was concentrated and the residue submitted to chromatography on silica gel (silica gel was previously washed with a 5% solution of Et_3N in EtOAc) (1:0 to 95:5 $CHCl_3$–MeOH) to give the unstable imidate **17** (10.2 g, 95%) as a glass. ^{1}H NMR spectra showed an α/β ratio of 85:15. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 8.81 (s, 1Hα, $NHCCl_3α$), 8.73 (s, 1Hβ, $NHCCl_3β$), 6.52 (d, 1Hα, $J_{1,2}$ = 3.4 Hz, H-1α), 5.78 (d, 1Hα, $J_{NH,2}$ = 9.9 Hz, NHα), 5.70 (d, 1Hβ, $J_{NH,2}$ = 10.2 Hz, NHβ), 5.66 (d, 1Hβ, $J_{1,2}$ = 8.5 Hz, H-1β), 5.52 (t, 1Hα, $J_{2,3}$ = $J_{3,4}$ = 10.5 Hz, H-3α), 5.11–5.00 (m, 2Hα and 2Hβ, H-3′α, H-3′β, H-3β and H-4′α), 4.95 (t, 1Hβ, $J_{3',4'}$ = $J_{4',5'}$ = 9.6 Hz, H-4′β), 4.78–4.68 (m, 1Hα and 1Hβ, H-1′β and H-1′α), 4.66–4.55 (m, 1Hα and 1Hβ, H-6aα and H-6aβ), 4.50–4.38 (m, 2Hα and 1Hβ, H-5α, H-6bα and H-6bβ), 4.28–4.17 (m, 1Hα and 2Hβ, H-2′α, H-2′β and H-6a′β), 4.09 (dd, 1Hα, $J_{6a',6b'}$ = 12.4 Hz, $J_{5',6a'}$ = 2.8 Hz, H-6a′α), 4.06–3.98 (m, 1Hα and 1Hβ, H-6b′α and H-5β), 3.94 (dd, 1Hβ, $J_{6a',6b'}$ = 12.0 Hz, $J_{5',6b'}$ = 8.4 Hz, H-6b′β), 3.88–3.78 (m, 1Hα and 1Hβ, H-2α and H-2β), 3.74 (m, 1Hβ, H-5′β), 3.54 (m, 1Hα, H-5′α), 3.01 (t, 1Hα, $J_{4,5}$ = 11.0 Hz, H-4α), 2.93 (t, 1Hβ, $J_{3,4}$ = $J_{4,5}$ = 11.0 Hz, H-4β), 2.20 (s, 3Hβ, $CH_3COβ$), 2.19 (s, 3Hα, $CH_3COα$), 2.14 (s, 3Hβ, $CH_3COβ$), 2.06 (s, 3Hα, $CH_3COα$), 2.05–2.03 (m, 6Hα and 6Hβ, 2 × $CH_3COα$ and 2 × $CH_3COβ$), 2.02 (s, 3Hα and 3Hβ, $CH_3COα$ and $CH_3COβ$), 1.95 (s, 3Hα, $CH_3COα$), 1.93 (s, 3Hβ, $CH_3COβ$).

Allyl 3,6-di-*O*-acetyl-4-*S*-(2-acetamido-3,4,6-tri-*O*-acetyl-2-deoxy-β-D-glucopyranosyl)-2-azido-2-deoxy-4-thio-β-D-glucopyranoside (18β)

A suspension of imidate **17** (8.87 g, 11 mmol) in anhydr. CH_2Cl_2 (140 mL) containing 4 Å activated molecular sieves (8.0 g) was stirred under Ar at room temperature for 1 h and was then cooled down to – 45 °C. Allyl alcohol (1.55 mL, 23 mmol, 2 equiv.) and $BF_3·Et_2O$ (920 µL, 3.4 mmol, 3.2 equiv.) were added to the suspension and the mixture was allowed to reach –10 °C over 2 h. Triethylamine (200 µL) was added and after additional stirring (20 min) at room temperature, the molecular sieves were filtered off. The filtrate was diluted with CH_2Cl_2 (250 mL) and washed with brine (250 mL). The aqueous layer was reextracted with CH_2Cl_2 (3 × 100 mL) and the combined organic solutions were dried and concentrated. The residue was submitted to chromatography on neutral alumina (1:2, 1:1, 3:1, 5:1, then 1:0, EtOAc–cyclohexane) to give the thiodisaccharide **18**β (5.71 g, 74%) as a white powder; mp 187 °C. ^{1}H NMR (400 MHz, $CDCl_3$) δ: 5.94 (m, 1H, $OCH_2CH_cCH_2$), 5.70 (d, 1H, $J_{NH,2}$ = 9.7 Hz, NH), 5.34 (dd, 1H, $J_{c,e}$ = 17.2 Hz, $J_{d,e}$ = 1.5 Hz, $OCH_2CHCH_dH_e$), 5.26 (dd, 1H, $J_{c,d}$ = 10.4 Hz, $OCH_2CHCH_dH_e$), 5.08–4.96 (m, 2H, H-3′ and H-4′), 4.93 (dd, 1H, $J_{2,3}$ = 9.9 Hz, $J_{3,4}$ = 11.0 Hz, H-3), 4.72 (d, 1H, $J_{1',2'}$ = 10.7 Hz, H-1′), 4.54–4.49 (m, 2H, H-6a and H-6b), 4.43–4.35 (m, 2H, H-1 and $OCH_aH_bCHCH_2$), 4.25–4.09 (m, 3H, H-2′, H-6a′ and $OCH_aH_bCHCH_2$), 4.01 (dd, 1H, $J_{6a',6b'}$ = 12.3 Hz, $J_{5',6b'}$ = 6.4 Hz, H-6b′), 3.84 (m, 1H, H-5), 3.69 (m, 1H, H-5′), 3.52 (dd, 1H, $J_{1,2}$ = 8.1 Hz, $J_{2,3}$ = 9.7 Hz, H-2), 2.83 (t, 1H, $J_{4,5}$ = 10.9 Hz, H-4), 2.17, 2.09, 2.07, 2.04, 2.02, 1.92 (6s, 6 × CH_3CO). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 171.3, 170.9, 170.5, 170.2, 169.7, 169.3 (*CO*CH_3), 133.0 ($OCH_2CH=CH_2$), 118.1 ($OCH_2CH=CH_2$), 100.8 (C-1), 81.7 (C-1′), 75.7 (C-5′), 74.1 (C-3′), 73.5 (C-5), 70.3 (C-6), 69.8 (C-3), 68.3 (C-4′), 65.0 (C-2), 63.5 ($OCH_2CH=CH_2$), 62.7 (C-6′), 51.9 (C-2′), 46.2 (C-4), 23.0, 21.1, 20.8, 20.6 (*C*H_3CO). Allyl 4-*S*-(2-acetamido-2-deoxy-β-D-glucopyranosyl)-2-acetamido-2-deoxy-4-thio-β-D-glucopyranoside (20)

MeONa (75 mg, 1.4 mmol) was added to a solution of allyl glycoside **19** (300 mg, 434 µmol) in anhydr. MeOH (3 mL). The mixture was stirred for 4 h under Ar at room temperature and then diluted with water. The pH was adjusted to 7 by adding Amberlite® IR120 resin, the resin was filtered off, and the filtrate was concentrated to dryness. The residue was precipitated from a mixture of acetone–MeOH (2:1) to afford the pure thiodisaccharide **20** (150 mg, 72%) as a white powder. ^{1}H NMR (400 MHz, D_2O) δ: 5.92 (m, 1H, $OCH_2CH_cCH_2$), 5.40–5.22 (m, 2H, $OCH_2CHCH_dH_e$ and $OCH_2CHCH_dH_e$), 4.74 (d, 1H, $J_{1',2'}$ = 10.4 Hz, H-1′), 4.55 (d, 1H, $J_{1,2}$ = 8.5 Hz, H-1), 4.35 (dd, 1H, $J_{a,b}$ = 12.9 Hz, $J_{a,c}$ = 4.5 Hz, $OCH_aH_bCHCH_2$), 4.17 (dd, 1H, $J_{b,c}$ = 6.0 Hz, $OCH_aH_bCHCH_2$), 4.09 (d, 1H, $J_{6a,6b}$ = 11.8 Hz, H-6a), 3.98–3.85 (m, 2H, H-6a′ and H-6b), 3.82–3.54 (m, 6H, H-2′, H-6b′, H-2, H-5, H-3, and H-3′), 3.54–3.40 (m, 2H, H-4′ and H-5′), 2.89 (t, 1H, $J_{3,4}$ = $J_{4,5}$ = 10.5 Hz, H-4), 2.04 (s, 6H, 2 × CH_3CO). ^{13}C NMR (100 MHz, D_2O) δ: 172.6, 172.5 ($COCH_3$), 131.3 ($OCH_2CH=CH_2$), 116.2 ($OCH_2CH=CH_2$), 97.7 (C-1), 81.8 (C-1′), 77.8 (C-4′ or C-5′), 74.4 (C-5), 72.9 (C-3′), 69.4 (C-3), 68.4 ($OCH_2CH=CH_2$), 67.6 (C-5′ or C-4′), 59.4 (C-6), 58.7 (C-6′), 54.8 (C-2), 52.9 (C-2′), 46.1 (C-4), 20.1 (CH_3CO). HRMS calcd. for $C_{19}H_{32}N_2O_{10}S$ *m/z*: 503.1675 [M + Na]; found: 503.1672.

Allyl 4-*S*-(2-acetamido-4-*O*-(2-amino-2-deoxy-β-D-glucopyranosyl)-2-deoxy-β-D-glucopyranosyl)-2-acetamido-2-deoxy-4-thio-β-D-glucopyranoside (21)

Thiodisaccharide **20** (5.45 mg, 11.35 µmol) was incubated for 14 days with UDP-$GlcNH_2$ (**6**) (8.9 mg, 13.7 µmol, 1.2 equiv.) and β-1,4-galactosyltransferase (5.6 U) as described in the general method for the enzymatic reactions. The pure trisaccharide **21** (3 mg, 41%) was isolated as a glass after freeze-drying from water. ^{1}H NMR (400 MHz, D_2O) δ: 5.88 (m, 1H, $OCH_2CH_cCH_2$), 5.35–5.19 (m, 2H, $OCH_2CHCH_dH_e$ and $OCH_2CHCH_dH_e$), 4.71 (d, 1H, $J_{1',2'}$ = 10.1 Hz, H-1′), 4.52 (d, 1H, $J_{1,2}$ = 8.4 Hz, H-1), 4.46 (d, 1H, $J_{1'',2''}$ = 8.0 Hz, H-1″), 4.30 (dd, 1H, $J_{a,b}$ = 13.1 Hz, $J_{a,c}$ = 6.3 Hz, $OCH_aH_bCHCH_2$), 4.12 (dd, 1H, $J_{b,c}$ = 6.4 Hz, $OCH_aH_bCHCH_2$), 4.05 (dd, 1H, $J_{6a,6b}$ = 12.0 Hz, $J_{6a,5}$ = 1.4 Hz, H-6a), 3.96–3.82 (m, 3H, H-6a′, H-6b and H-3′ or H-4′ or H-5′), 3.82–3.64 (m, 6H, H-2, H-2′, H-6b′, H-6a″, H-6b″ and H-3′ or H-4′ or H-5′), 3.63–3.52 (m, 3H, H-5, H-3 and H-3′ or H-4′ or H-5′), 3.46 (m, 1H, H-4″ or H-5″), 3.42–3.32 (m, 2H, H-3″ and H-4″ or H-5″), 2.85 (t, 1H, $J_{3,4}$ = $J_{4,5}$ = 10.8 Hz, H-4), 2.66 (m, 1H, H-2″), 2.03, 2.02 (2s, 2 × 3H, CH_3CO). ^{13}C NMR (D_2O, measured from HSQC at 400 MHz) δ: 132.0 ($CH_2CH=CH_2$), 117.0 ($CH_2CH=CH_2$), 102.0 (C-1″), 99.0 (C-1′), 83.0 (C-1), 78.0, 77.2, 76.1, 76.0, 75.5, 72.8, 71.0, 68.9 (not assigned), 69.0 ($CH_2CH=CH_2$), 61.0 (C-6), 59.7, 59.0, 56.5 (not assigned), 56.0 (C-2″), 54.0 (not assigned), 47.3 (C-4), 21.8 (CH_3CO). Stereoselective synthesis of dioxabicycles from 1-*C*-allyl-2-*O*-benzyl-glycosides — An intramolecular cyclization between 2-*O*-benzyl oxygen and the allyl double bond[1]

An-Tai Wu, Tian Yi, Huawu Shao, Shih-Hsiung Wu, and Wei Zou

Abstract: Addition of a proton to the double bond of 1-*C*-allyl-*O*-benzylglycosides gave a 2′-carbonium ion, which in turn reacted intramolecularly, in a regio- and diastereo-selective manner, with the nucleophilic oxygen of the 2-*O*-benzyl group to form an oxonium intermediate. Subsequent cleavage of the benzyl C—O bond led to dioxabicycles in moderate yields. Surprisingly, opposite diastereoselectivities were observed from 1-*C*-allylglycofuranosides and 1-*C*-allylglycopyranosides, which produced 2,2′-*trans*- and 2,2′-*cis*-dioxabicycles, respectively.

Key words: C-glycoside, olefin, cyclization, oxocarbonium, dioxabicycles.

Résumé : L'addition d'un proton sur la double liaison 1-*C*-allylglycosides de *O*-benzyle conduit à la formation d'un ion carbonium en 2′ qui réagit ensuite d'une façon intramoléculaire, régio- et diastéréosélective, avec l'oxygène nucléophile du groupe 2-*O*-benzyle pour conduire à la formation d'un intermédiaire oxonium. Un clivage subséquent de la liaison C—O du benzyle conduit à des dioxabicycles avec des rendements modérés. D'une façon surprenante, on a observé des diastéréosélectivités opposées les 1-*C*-allylglycofuranosides et les 1-*C*-allylglycopyranosides qui ont conduit respectivement aux 2,2′-*trans*- et 2,2′-*cis*-dioxabicycles.

Mots clés : C-glycoside, oléfine, cyclisation, oxocarbonium, dioxabicycles.

[Traduit par la Rédaction]

Introduction

The electrophile-promoted addition to an olefinic double bond is one of the most investigated reactions (1). The intermediate can be a carbonium ion or more often a bridged cation, which then reacts with a nucleophile, e.g., alcohol, acid, amine, and amide, to form an addition product. The stereoselectivity of the addition to a double bond can be achieved using selenium reagents (2), iodo complexes (3), mercury complexes (4), and Ru reagents (5). In certain cases, the stereochemistry may be guided by the asymmetric substrates (1).

Recently, during a large-scale preparation of 1-*C*-allyl-2,3,5-tri-*O*-benzyl-α-D-ribofuranoside (**2**) using ribofuranoside **1** and allyltrimethylsilane in the presence of TMSOTf, we also isolated 5-O-debenzylated **3** in 17% yield (Scheme 1), a useful intermediate obtained previously from **2** by regioselective 5-O-acetolysis followed by de-O-acetylation (6). This result prompted us to investigate if TMSOTf can selectively remove the 5-*O*-benzyl group from **2** (7). However, when compound **2** was treated with TMSOTf in acetonitrile, instead of the desired **3**, we obtained a dioxabicyclic compound as the only major product. Further studies using 1-*C*-allylglycofuranosides and 1-*C*-allylglycopyranosides as substrates revealed that the formation of dioxabicycles was both highly regioselective and diastereoselective. Here, we wish to describe this stereoselective intramolecular cyclization between 2-*O*-Bn and the allyl double bond.

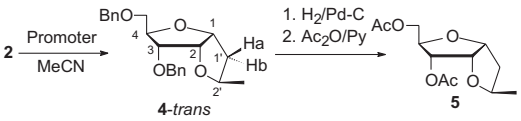
Results and discussion



The dioxabicylic compound obtained by treatment of **2** with TMSOTf (1 equiv.) in acetonitrile was characterized as **4**-*trans* (Scheme 2). The newly formed ring and the stereochemistry at C2′ were established by NMR analysis. Because of the observation of NOE between H-1 and H-3, the cyclization must have occurred at the 2-O-position. In addition, the 2,2′-trans configuration was assigned on the basis of the NOE observed between H-2′ and H-4 and the lack of NOE between H-2′ and H-2/H-1. This stereochemistry was further confirmed by NMR analysis on acetylated derivative **5**, as we observed a downfield shift of the H-3 resonance from 3.85 to 4.87 ppm owing to acetylation, and the

Promoter	*T/t*	*Isolated yield of* **4**-*trans*
TMSOTf (1equiv.)	0 °C-rt/16h	61%
TfOH (1equiv.)	0 °C/4h	41%
p-TsOH (1equiv.)	60 °C/24h	-
TfOH/p-TsOH (0.2/1 equiv.)	0 °C-rt/16h	53%

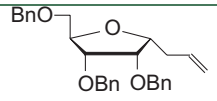
strong NOEs between H-1 and H-1′a and between H-2′ and H-1′b.

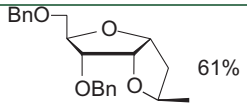
This regio- and diastereo-selective conversion of **2** to **4**-*trans* can also be promoted by TfOH (1 equiv.) at 0 °C, but with lower yield (see Scheme 2) because of the decomposition caused by nonselective de-O-benzylation. No significant transformation occurred when *p*-TsOH (1 equiv.) was used alone even at elevated temperature (60 °C, 24 h), but additional TfOH (0.2 equiv.) facilitated the formation of **4**-*trans*. Hence, this cyclization was likely acid-promoted. The proton source in the case of TMSOTf as a promoter might be the residual water from acetonitrile because when we performed the experiment under dry, but otherwise the same conditions, the reaction became very sluggish.[5] Additionally, acetonitrile as the proton source was excluded because when the reaction was performed in MeCN-d_3, no deuterium substitution on the methyl group of **4**-*trans* was detected by NMR and MS analyses.

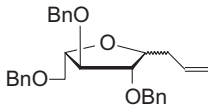
The formation of a five-membered ring indicates that the reaction proceeded through a kinetic process. We were interested to know if six-membered ring products could also be formed under certain circumstances. For instance, using 1-*C*-allyl-L-arabinofuranoside (**6**), a mixture of two anomers (α/β, 1:1) as a substrate, we expected a similar cyclization occurred in **6β** because of its 1,2-cis configuration, but we were also interested to see if the 1-*C*-allyl group in the α anomer (**6α**) would react to the 3-*O*-Bn, which is sterically possible, to form a six-membered ring. Thus, a mixture of **6α/β** was treated with TMSOTf in acetonitrile under the aforementioned conditions. TLC analysis showed the formation of a new product, but a significant amount of starting material remained. After the separation, the newly formed product with a lower R_f was characterized as dioxabicyclic **7**-*trans* (37% yield based on total starting material), produced by the cyclization between the 2-*O*-Bn and the *cis*-1-*C*-β-allyl group (Scheme 3). Again, the 2,2′-trans configuration was assigned on the basis of NOE analysis. The remaining starting material (**6α**), contaminated only with very small amount of **6β**, was recovered, which did not produce a six-membered ring product.

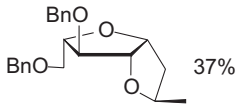
Scheme 3.

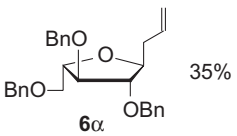
Because of the close distance between C2′ and C4 as indicated by the observation of NOE between H-2′ and H-4 in **4**-*trans*, one might speculate that the 2,2′-trans selectivity in **4**-*trans* and **7**-*trans* may have resulted from the steric hindrance exerted by 3-*O*-Bn in **2** or 5-*O*-Bn in **6**, which could prevent the methyl group at C2′ from adopting a cis configuration in the transition state. However, this argument was proven not true because 1-*C*-allyl-D-xylofuranoside (**8**), which lacks such steric effect, under the above conditions produced **9**-*trans* as the only major product (35%) and the recovery of its 1,2-trans starting material (**8β**) (42%) (see Scheme 3).

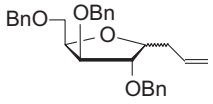


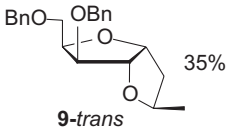


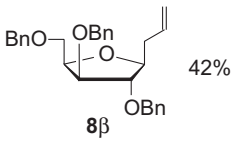


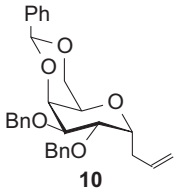


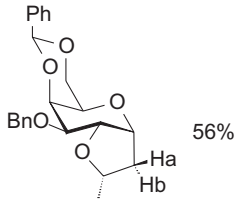


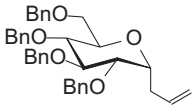


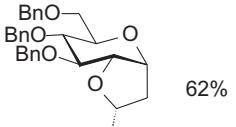


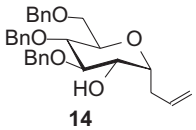


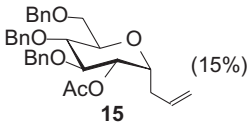












Besides the 1-*C*-allylglycofuranosides, the cyclization between the 1-*C*-allyl and the 2-*O*-Bn also occurred with 1-*C*-allylglycopyranosides under the above conditions. Remarkably, however, in contrast to the 2,2′-trans diastereoselectivity observed in 1-*C*-allylglycofuranosides, when 1-*C*-allylgalactoside (**10**) and 1-*C*-allylglucosides (**12**) were treated with TMSOTf in acetonitrile, we only obtained the respective products with the 2,2′-cis configurations, **11**-*cis* (56%) and **13**-*cis* (62%) (see Table 1). The cyclization also proceeded with 2-OH glucoside (**14**) to give **13**-*cis* (59%) as the major product and a 2-O-acetylated **15** (15%) as a minor one (8). The 2-O-acetylation resulted from the reaction between 2-OH and acetonitrile followed by hydrolysis. No cyclization occurred when **15** was used as a substrate because of the diminished 2-O-nucleophicility owing to the electron-withdrawing effect by 2-O-acetylation.

Although this acid-promoted cyclization was never reported, the iodonium-promoted cyclization between the olefin double bond and O-Bn are known. For example, Rychnovsky and Bartlett (9) prepared 2,5-cis disubstituted tetrahydrofurans by cyclizing olefinic ether in the presence of iodine and suggested that the 2,5-cis stereoselectivity was controlled by an oxonium ion intermediate with the 1,2-trans, 1,5-trans configurations. Nicotra and co-workers (10) also subjected 1-*C*-allyl-2-*O*-benzylglycoside to similar conditions to obtain a mixture of two diastereomers at C2′. The oxonium ion was also an intermediate in Fraser-Reid's glycosylation using *n*-pentenyl glycoside in which the formation of a bridged olefin halogenium ion was followed by

[5] Compound **2** and TMSOTf were separately dissolved in acetonitrile and dried over 3 Å molecular sieves. Equivalents of **2** and TMSOTf in acetonitrile were then mixed and kept at 0 °C overnight.

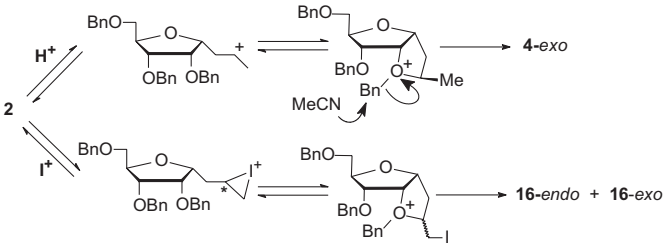
nucleophilic attack from the glycosidic oxygen leading to a glycosyl oxocarbonium ion as a glycosyl donor and the concurrent formation of a tetrahydrofuran (11).

The poor stereoselection in the iodine-promoted cyclizations contrasts with those obtained from acid-promoted cyclization. Such a difference is not substrate dependent because when **2** and **10** were treated with NIS–TMSOTf in acetonitrile a mixture of diasteromers (**16**-*trans*/*cis* and **17**-*trans*/*cis*) were also obtained, respectively, in a 1:2 to 3 trans:cis ratio (Scheme 4). The NOE between H-2′ and H-4 in **16**-*trans*, similar to **4**-*trans*, was observed, but not between H-4 and CH_2I in **16**-*cis*.[6] The chemical shifts of H-1′a (cis to H-1) and H-1′b (trans to H-1) and the pattern of proton couplings were also similar to those observed in 2′-methyl dioxabicycles (**4**-*trans*, **7**-*trans*, **9**-*trans*, **11**-*cis*, and **13**-*cis*). The double doublet H-1′b resonance in the 2,2′-trans compounds always appears downfield (2.2–2.4 ppm) from that of the H-1′a resonance (1.5–2.0 ppm), and are reversed in the 2,2′-cis compounds likely because of the change of conformation from one envelope to another.



Scheme 4. Regioselective cyclization promoted by NIS–TMSOTf.

[6] Due to the overlap of the proton signals of H-2′ and H-4, this result was obtained from a TOCSY (H-5 to H-4) – NOESY (H-4) experiment.

Scheme 5. Stereoselective cyclization.

Unlike proton-promoted electrophilic addition, which follows Markovnikov's rule leading to a carbonium ion, the addition of an iodonium ion to a double bond can result in two bridged iodonium intermediates (Scheme 5). Consequently, the subsequent S_N2 displacement by 2-*O*-Bn produced two respective diastereoisomers (2,2′-cis and 2,2′-trans) (11) (see Scheme 4). Acetonitrile likely also plays a role by facilitating the cleavage of the O—Bn bond from the oxonium intermediate by forming a benzylacetonium ion (12) because the same reaction did not occur in dichloromethane.

The opposite stereochemistry obtained from 1-*C*-allyl-glycofuranosides and -glycopyranosides suggests two distinctive transition states. It is conceivable that the parent ring structure, the chair form in the pyranosides and the envelope form in the furanosides, may play a critical role in the stabilization of the respective oxonium ion transition states. It is also possible that the stereochemistry at C2′ may simply be predetermined by the orientation of the 2-*O*-Bn, which the 2′-carbonium ion must approach from the less-hindered side to form a 1,2-trans oxonium intermediate. Unfortunately, at this moment, we have no convincible explanation for those experimental results. Molecular modeling and calculation of the minimum energies of the possible oxonium transition states may provide the information on the most likely reaction pathway.

In summary, we described an intramolecular cyclization from 1-*C*-allyl-*O*-benzylglycosides in moderate to good yields. The allyl double bond was activated by electrophiles to generate a carbonium at C2′, which reacted with nucleophilic benzyl ether giving dioxabicyclic derivatives. The cyclization is highly regioselective in favor of five-membered products. The reaction is also highly diastereoselective to form 2,2′-cis and 2,2′-trans dioxabicycles from 1-*C*-pyranosides and 1-*C*-furanosides, respectively.[7]

Experimental section

General methods

^{1}H and ^{13}C NMR spectra were recorded at 400 and 100 MHz, respectively, with a Varian instrument at 293 K. Chemical shifts are given in ppm downfield from the signal of internal TMS and are assigned on the basis of 2D COSY, TOCSY, and ^{1}H–^{13}C chemical-shift correlated experiments. High-resolution fast atom bombardment mass spectrometry (HRFABMS) was carried out on a JEOL JMS-AX505H mass spectrometer using a 6 kV xenon beam at an accelerating voltage of 3 kV. *m*-Nitrobenzyl alcohol (*m*-NBA) was used as the matrix, and polyethylene glycol (PEG) was the internal calibrant. All chemicals were purchased from the Sigma-Aldrich Chemical Co. and used without further purification.

General procedure for cyclization

To a solution of substrate (50–100 mg) in CH_3CN (2 mL) was added dropwise TMSOTf (1 equiv.) at 0 °C. The mixture was stirred and allowed to warm to room temperature overnight. The reaction was quenched by the addition of Et_3N and the solvent was removed under reduced pressure. Product purification was performed by silica gel column chromatography (hexane–EtOAc, 3:1).

1-*C*-(*R*-Propan-2′-ol)-3,5-di-*O*-benzyl-2,2′-anhydro-α-D-ribofuranoside (4-*trans*)

This compound was obtained as an oil in 61% yield. $[\alpha]_D$ +79.4° (*c* 7.0, $CHCl_3$). ^{1}H NMR ($CDCl_3$) δ: 4.80 (d, *J* = 12 Hz, 1H, $PhCH_2$), 4.77 (dd, *J* = 4.8, 4.8 Hz, 1H, H-1), 4.60 (dd, *J* = 4.8, 4.8 Hz, 1H, H-2), 4.54–4.50 (m, 3H, $PhCH_2$), 4.29 (m, 1H, H-2′), 4.00 (ddd, *J* = 8.4, 5.2, 2.4 Hz, 1H, H-7), 3.83 (dd, *J* = 8.4, 5.2 Hz, 1H, H-3), 3.66 (dd, *J* = 10.8, 2.4 Hz, 1H, H-5a), 3.45 (dd, *J* = 10.8, 5.2 Hz, 1H, H-5b), 2.23 (dd, *J* = 13.2, 4.8 Hz, 1H, H-1′b), 1.58 (ddd, *J* = 13.2, 10.4, 4.8 Hz, 1H, H-1′a), 1.30 (d, *J* = 6.0 Hz, 3H, CH_3). ^{13}C NMR ($CDCl_3$) δ: 83.6 (C-2), 80.8 (C-3), 80.5 (C-4), 79.9 (C-1), 77.0 (C-2′), 73.4 ($PhCH_2$), 72.0 ($PhCH_2$), 70.1 (C-5), 43.2 (C-1′), 20.7 (CH_3). HRFABMS calcd. for $C_{22}H_{27}O_4$ *m/z*: 355.1831 (MH^+); found: 355.2230. Starting material **2** (10 mg, 10%) was also recovered.

1-*C*-(*R*-Propan-2′-ol)-3,5-di-*O*-acetyl-2,2′-anhydro-α-D-ribofuranoside (5)

A solution of compound **4**-*trans* (120 mg, 0.33 mmol) in methanol (15 mL) was hydrogenated with 10% Pd/C (50 mg) under 50 psi (1 psi = 6.894 757 kPa) overnight. The filtrate was concentrated to a residue. To a solution of this residue in CH_2Cl_2 (10 mL) was added TEA (1 mL) and acetic anhydride (210 mg, 2.11 mmol), and the mixture was stirred overnight. Work-up and purification by chromatography gave **5** (60 mg, 68%). $[\alpha]_D$ +113.9° (*c* 1.5, $CHCl_3$). ^{1}H NMR ($CDCl_3$) δ: 4.87 (dd, 1H, *J* = 4.8, 7.6 Hz), 4.81 (dd, 1H, *J* = 4.8 Hz), 4.76 (dd, 1H, *J* = 4.8 Hz), 4.28 (dd, 1H, *J* = 11.6, 2.8 Hz), 4.20 (m, 1H), 4.14 (m, 1H), 4.05 (dd, 1H, *J* = 11.6, 5.6 Hz), 2.23 (dd, 1H, *J* = 13.2, 4.8 Hz), 2.13 (s, 3H), 2.09 (s, 3H), 1.59 (m, 1H), 1.28 (d, 3H, *J* = 6.0 Hz). ^{13}C NMR ($CDCl_3$) δ: 170.8, 170.4, 84.0, 80.6, 78.7, 77.3, 75.2, 64.0, 42.9, 20.9, 20.8, 20.6. ESMS: 259.2 (MH^+).

1-*C*-(*R*-Propan-2′-ol)-3,5-di-*O*-benzyl-2,2′-anhydro-β-L-arabinofuranoside (7-*trans*)

Under the same conditions, **7**-*trans* (37%) and **6α** (35%) were obtained from **6** (α:β, 1:1).

For **7**-*trans*: $[\alpha]_D$ –44.0° (*c* 1.12, $CHCl_3$). ^{1}H NMR ($CDCl_3$) δ: 7.37–7.24 (m, 10H), 4.72 (m, 1H), 4.71 (d, 1H, *J* = 11.6 Hz), 4.63 (dd, 1H, *J* = 4.8, 1.6 Hz), 4.56 (s, 2H),

4.52 (d, 1H, *J* = 11.6 Hz), 4.15 (m, 1H), 3.95 (dt, 1H, *J* = 3.2, 6.4 Hz), 3.78 (dd, 1H, *J* = 7.2, 2.0 Hz), 3.65 (dd, 1H, *J* = 10.4, 3.2 Hz), 3.56 (dd, 1H, *J* = 10.8, 6.4 Hz), 2.17 (dd, 1H, *J* = 13.2, 4.4 Hz), 1.42 (m, 1H), 1.27 (d, 3H, *J* = 6.0 Hz). ^{13}C NMR ($CDCl_3$) δ: 138.2, 137.8, 128.5, 128.4, 127.9, 127.7, 88.5, 85.9, 83.8, 82.6, 74.7, 73.5, 72.1, 70.2, 41.0, 19.9. ESMS: 355.3 (MH^+).

For **6α**: $[\alpha]_D$ –19.5° (*c* 1.4, $CHCl_3$). ^{1}H NMR ($CDCl_3$) δ: 7.37–7.22 (m, 15H), 5.58 (m, 1H), 5.10 (m, 2H), 4.50 (m, 6H), 4.21 (m, 1H), 4.07 (m, 1H), 4.06 (dd, 1H, *J* = 3.2 Hz), 3.87 (dd, 1H, *J* = 4.4, 2.8 Hz), 3.57 (m, 2H). ^{13}C NMR ($CDCl_3$) δ: 138.4, 138.0, 134.4, 128.5, 128.4, 128.3, 127.8, 127.7, 87.0, 85.4, 82.0, 81.6, 73.4–71.9, 70.3, 37.7. ESMS: 445.2 (MH^+).

1-*C*-(*R*-Propan-2′-ol)-3,5-di-*O*-benzyl-2,2′-anhydro-α-D-xylofuranoside (9-*trans*)

Under the same conditions, **9**-*trans* (35%) and **8β** (42%) were obtained from **8** (α:β, 1:1).

For **9**-*trans*: $[\alpha]_D$ –44.0° (*c* 1.12, $CHCl_3$). ^{1}H NMR ($CDCl_3$) δ: 7.37–7.24 (m, 10H), 4.87 (dd, 1H, *J* = 4.4 Hz), 4.67 (d, 1H, *J* = 12.0 Hz), 4.63 (d, 1H, *J* = 11.6 Hz), 4.59 (m, 1H), 4.52 (d, 1H, *J* = 6.4 Hz), 4.49 (d, 1H, *J* = 6.4 Hz), 4.18 (m, 1H), 4.12 (m,1H), 3.97 (d, 1H, *J* = 4.0 Hz), 3.68 (d, 2H, *J* = 5.6 Hz), 2.25 (dd, 1H, *J* = 13.6 Hz, 5.2 Hz), 1.50 (m, 1H), 1.24 (d, 3H, *J* = 6.4 Hz). ^{13}C NMR ($CDCl_3$) δ: 128.5, 128.4, 127.9, 127.7, 85.9, 83.8, 83.5, 81.3, 75.9, 73.6, 72.2, 68.9, 42.5, 20.6. ESIMS: 355.3 (MH^+).

For **8β**: $[\alpha]_D$ –19.5° (*c* 1.4, $CHCl_3$). ^{1}H NMR ($CDCl_3$) δ: 7.37–7.22 (m, 15H), 5.80 (m, 1H), 5.08 (m, 2H), 4.63–4.44 (m, 6H), 4.20 (dt, 1H, *J* = 1.6, 4.4 Hz), 3.96 (d, 1H, *J* = 3.6 Hz), 3.90 (dt, 1H, *J* = 3.6, 6.8 Hz), 3.79 (dd, 1H, *J* = 9.6, 5.6 Hz), 3.76 (m, 1H), 3.73 (dd, 1H, *J* = 9.6, 6.0 Hz), 2.49–2.32 (m, 2H). ^{13}C NMR ($CDCl_3$) δ: 138.4, 138.0, 134.4, 128.5, 128.4, 127.9, 127.8, 127.7, 87.0, 85.4, 82.0, 81.6, 73.4–71.9, 70.3, 37.7. ESMS: 455.3 (MH^+).

1-*C*-(*S*-Propan-2′-ol)-3-*O*-benzyl-4,6-*O*-benzylidene-2,2′-anhydro-α-D-galactopyranoside (11-*cis*)

This compound was obtained from **10** as an oil in 56% yield. $[\alpha]_D$ +44.8° (*c* 0.67, $CHCl_3$). ^{1}H NMR ($CDCl_3$) δ: 5.47 (s, 1H, PhCH), 5.07 (m, 1H, H-1), 4.87 (d, *J* = 12.4 Hz, 1H, CH_2Ph), 4.73 (d, *J* = 12.4 Hz, 1H, CH_2Ph), 4.39 (bd, *J* = 2.4 Hz, 1H, H-4), 4.33 (d, *J* = 12.4 Hz, 1H, H-6a), 4.08–4.03 (m, 2H, H-6b, H-2), 3.92 (m, 1H, H-2, 3.71 (dd, *J* = 5.6, 2.0 Hz, 1H, H-3), 3.58 (bs, 1H, H-5), 2.38 (m, 1H, H-1), 1.82 (ddd, *J* = 13.6, 8.4, 3.2 Hz, 1H, H-1), 1.34 (d, *J* = 6 Hz, 3H, CH_3). ^{13}C NMR ($CDCl_3$) δ: 100.5 (PhCH), 82.8 (C-2), 79.5 (C-3), 78.0 (C-1), 74.2 (C-2′), 73.3 (C-4), 72.6 (C-6), 71.1 ($PhCH_2$), 67.5 (C-5), 40.8 (C-1′), 21.0 (CH_3). HRFABMS calcd. for $C_{23}H_{27}O_5$ *m/z*: 383.1780 (MH^+); found: 383.2146.

1-*C*-(*S*-Propan-2′-ol)-3,4,6-tri-*O*-benzyl-2,2′-anhydro-α-D-glucopyranoside (13-*cis*)

This compound was obtained from **12** as an oil in 62% yield. $[\alpha]_D$ +76° (*c* 0.1, $CHCl_3$). ^{1}H NMR ($CDCl_3$) δ: 7.18–7.40 (m, 15H, 3 × Ph), 4.90 (d, 1H, CH_2Ph, *J* = 11.6 Hz), 4.83 (d, 1H, CH_2Ph, *J* = 11.2 Hz), 4.73 (d, 1H, CH_2Ph, *J* = 11.6 Hz), 4.59 (d, 1H, H-1), 4.53 (d, 1H, CH_2Ph, *J* = 12.4 Hz), 4.46 (d, 1H, CH_2Ph, *J* = 11.2 Hz), 4.43 (d, 1H, CH_2Ph, *J* = 12.4 Hz), 3.95 (m, 1H, H-2′), 3.77–3.85 (m, 3H, H-2, H-3, H-5), 3.55–3.67 (m, 3H, H-4, H-6, 6′), 2.25 (m, 1H, H-1′a), 1.62 (m, 1H, H-1′b), 1.34 (d, 3H, H-3′, *J* = 6.0 Hz). ^{13}C NMR ($CDCl_3$) δ: 138.9, 138.7, 138.4 (Ph), 128.6, 128.4, 127.9, 127.8, 127.6 (Ph), 83.4 (C-3), 83.3 (C-2), 76.1 (C-1), 75.5 (C-4), 75.2 (C-5), 74.7 (C-2′), 74.6 (CH_2Ph), 73.5 (CH_2Ph), 73.0 (CH_2Ph), 70.1 (C-6), 39.4 (C-1′), 21.6 (C-3′). ESMS: 475.3 (MH^+).

1-*C*-(3′-Iodo-*R/S*-propan-2′-ol)-3,5-di-*O*-benzyl-2,2′-anhydro-α-D-ribofuranoside (16-*trans* and 16-*cis*)

Compounds **16**-*trans* (19%) and **16**-*cis* (39%) obtained from **2** were separated by chromatography.

For **16**-*trans*: oil. $[\alpha]_D$ +51.7° (*c* 0.12, $CHCl_3$). ^{1}H NMR ($CDCl_3$) δ: 4.79–4.76 (m, 2H, $PhCH_2$, H-1), 4.66 (dd, *J* = 4.0, 4.0 Hz, 1H, H-2), 4.57–4.49 (m, 3H, $PhCH_2$), 4.17 (m, 1H, H-2′), 4.02 (m, 1H, H-4), 3.86 (dd, *J* = 8.0, 4.4 Hz, 1H, H-3), 3.66 (dd, *J* = 10.4, 1.6 Hz, 1H, H-5a), 3.46 (dd, *J* = 10.4, 4.8 Hz, 1H, H-5b), 3.38–3.30 (m, 2H, CH_2I), 2.37 (dd, *J* = 13.6, 5.2 Hz, 1H, H-1′b), 1.79 (ddd, *J* = 13.6, 10.0, 5.2 Hz, 1H, H-1′a). ^{13}C NMR ($CDCl_3$) δ: 83.1 (C-2), 81.9 (C-3), 80.7 (C-4), 80.1 (C-1), 79.5 (C-2′), 73.5 ($PhCH_2$), 72.2 ($PhCH_2$), 70.0 (C-5), 41.9 (C-1′), 10.2 (CH_2-I). HRFABMS calcd. for $C_{22}H_{25}IO_4$ *m/z*: 480.0797 (M^+); found: 479.0749.

For **16**-*cis*: oil. $[\alpha]_D$ +79.5° (*c* 0.2, $CHCl_3$). ^{1}H NMR ($CDCl_3$) δ: 4.79–4.73 (m, 2H, $PhCH_2$, H-1), 4.57–4.49 (m, 3H, $PhCH_2$), 4.45 (dd, *J* = 4.4, 4.4 Hz, 1H, H-2), 4.20–4.15 (m, 2H, H-2 H-4), 3.89 (dd, *J* = 8.4, 4.4 Hz, 1H, H-3), 3.67 (dd, *J* = 10.8, 1.6 Hz, 1H, H-5a), 3.50 (dd, *J* = 10.8, 4.8 Hz, 1H, H-5b), 3.41 (dd, *J* = 10.0, 5.2 Hz, 1H, CH_2I), 3.32 (dd, *J* = 9.2, 8.4 Hz, 1H, CH_2I), 2.42 (dt, *J* = 14.0, 6.8 Hz, 1H, H-1), 1.99 (ddd, *J* = 14.0, 6.8, 2.4 Hz, 1H, H-1). ^{13}C NMR ($CDCl_3$) δ: 82.9 (C-1), 82.2 (C-2), 80.8 (C-2′), 79.2 (C-3), 79.0 (C-4), 73.4 ($PhCH_2$), 72.1 ($PhCH_2$), 69.6 (C-5), 40.2 (C-1′), 8.5 (CH_2I). HRFABMS calcd. for $C_{22}H_{25}IO_4$ *m/z*: 480.0797 (M^+); found: 479.0711.

1-*C*-(3′-Iodo-*R/S*-propan-2′-ol)-3-*O*-benzyl-4,6-*O*-benzylidene-2,2′-anhydro-α-D-galactopyranoside (17-*trans* and 17-*cis*)

Compounds **17**-*trans* (20%) and **17**-*cis* (60%) obtained from **10** were separated by chromatography.

For **17**-*trans*: oil. $[\alpha]_D$ –8° (*c* 5.8, $CHCl_3$). ^{1}H NMR ($CDCl_3$) δ: 5.48 (s, 1H, PhCH), 5.20 (dd, *J* = 8.8, 4.4 Hz, 1H, H-1), 4.86 (d, *J* = 12.4 Hz, 1H, CH_2Ph), 4.73 (d, *J* = 12.8 Hz, 1H, CH_2Ph), 4.48 (dd, *J* = 9.2, 4.4 Hz, 1H, H-2), 4.40 (bs, 1H, H-4), 4.33 (d, *J* = 12.4 Hz, 1H, H-6a), 4.23 (m, 1H, H-2, 4.05 (d, *J* = 12.8 Hz, 1H, H-6b), 3.63 (d, *J* = 5.2 Hz, 1H, H-3), 3.56 (bs, 1H, H-5), 3.34–3.25 (m, 2H, CH_2I), 2.23 (dd, *J* = 13.6, 5.6 Hz, 1H, H-1), 1.82 (ddd, *J* = 13.6, 9.2, 5.6 Hz, 1H, H-1). ^{13}C NMR ($CDCl_3$) δ: 100.5 (PhCH), 84.0 (C-2), 79.2 (C-3), 78.1 (C-1), 77.7 (C-2′), 73.5 (C-4), 72.6 (C-6), 70.8 ($PhCH_2$), 67.4 (C-5), 39.8 (C-1′), 10.1 (CH_2I). HRFABMS calcd. for $C_{23}H_{25}IO_5$ *m/z*: 508.0747 (M^+); found: 507.0730.

For **17**-*cis*: oil. $[\alpha]_D$ +6.8° (*c* 9.4, $CHCl_3$). ^{1}H NMR ($CDCl_3$) δ: 5.48 (s, 1H, PhCH), 5.15 (m, 1H, H-1), 4.86 (d, *J* = 12.4 Hz, 1H, CH_2Ph), 4.73 (d, *J* = 12.4 Hz, 1H, CH_2Ph), 4.39 (bs, 1H, H-4), 4.33 (d, *J* = 12.4 Hz, 1H, OCH_2), 4.25 (dd, *J* = 9.6, 4.8 Hz, 1H, H-2), 4.23 (m, 1H, H-2′), 4.05 (d, *J* = 12.4 Hz, 1H, H-6a), 3.66 (bd, *J* = 5.2 Hz, 1H, H-3), 3.57

Quantum mechanics studies of cellobiose conformations[1]

Alfred D. French and Glenn P. Johnson

Abstract: Three regions of the conformation space that describes the relative orientations of the two glucose residues of cellobiose were analyzed with quantum mechanics. A central region, in which most crystal structures are found, was covered by a 9 × 9 grid of 20° increments of the linkage torsion angles ϕ and ψ. Besides these 81 constrained minimizations, we studied two central subregions and two regions at the edges of our maps of complete ϕ,ψ space with unconstrained minimization, for a total of 85 target geometries. HF/6-31G(d) and single-point HF/6-311+G(d) calculations were used to find the lowest energies for each geometry. B3LYP/6-31G+G(d) and single point B3LYP/6-11+G(d) calculations were also used for all unconstrained minimizations. For each target, 181 starting geometries were tried (155 for the unconstrained targets). Numerous different starting geometries resulted in the lowest energies for the various target structures. The starting geometries came from five different sets that were based on molecular mechanics energies. Although all five sets contributed to the adiabatic map, use of any single set resulted in discrepancies of 3–7 kcal/mol (1 cal = 4.184 J) with the final map. For most of the targets, the starting geometry that gave the lowest energy depended on the basis set and whether the HF or B3LYP method was used. However, each of the above four calculations gave the same overall lowest energy structure that was found previously by Strati et al. This global minimum, stabilized by highly cooperative hydrogen bonds, is in a region that is essentially not populated by crystal structures. HF/6-31G(d) energy contours of the mapped central region were compatible with the observed crystal structures. Observed structures that lacked O3···O5′ hydrogen bonds were about 1 kcal/mol above the map's minimum, and observed structures that have a pseudo twofold screw axis ranged from about 0.4 to 1.0 kcal/mol. The HF/6-311+G(d) map accommodated the observed structures nearly as well.

Key words: cellulose, carbohydrate, conformation, energy, flexibility, folding, helix, shape.

Résumé : Faisant appel à des calculs de méanique quantique, on a étudié trois régions de l'espace conformationnel qui décrit les orientations relatives de deux résidus de glucose du cellobiose. La région centrale, dans laquelle on retrouve la plupart des structures cristallines a été couverte par une grille 9 × 9 avec des augmentations de 20° des angles de torsion ϕ et ψ de la liaison. En plus de ces 81 minimisations contraintes, on a aussi étudié deux sous régions centrales et deux régions aux limites extérieures de nos cartes de l'espace ϕ,ψ avec une minimisation sans contrainte, pour un total de 85 géométries cibles. On a utilisé des calculs HF/6-31G(d) et des calculs ponctuels HF/6-311+G(d) pour trouver les énergies minimales pour chaque géométrie. On a aussi utilisé des calculs B3LYP/6-31G+G(d) et des calculs ponctuels B3LYP/6-311+G(d) pour toutes les minimisations sans contrainte. Pour chaque cible, on a essayé 181 géométries de départ (155 pour les cibles sans contrainte). Plusieurs géométries de départ différentes on conduit à des énergies minimales pour diverses structures cibles. Les géométries de départ viennent de cinq différents ensembles qui étaient basés sur des énergies de mécanique moléculaire. Même si tous ces cinq ensembles ont contribué à la carte adiabatique, l'utilisation d'un seul ensemble conduit à des divergences allant de 3–7 kcal/mol (1 cal = 4,184 J) dans la carte finale. Pour la plupart des cibles, la géométrie de départ qui donne l'énergie la plus basse dépend de l'ensemble de base et de la méthode HF ou B3LYP qui est utilisée. Toutefois, chacun des quatre calculs mentionnés plus haut à conduit à la même structure d'énergie globale la plus basse et elle correspond à celle trouvée antérieurement par Strati et al. Ce minimum global, qui est stabilisé par des liaisons hydrogènes qui offrent beaucoup de coopération, se trouve dans une région des structures cristallines qui n'est pas peuplée. Des contours d'énergie au niveau HF/6-31G(d) de la région centrale cartographie sont compatibles avec les structures cristallines observées. Les niveaux d'énergie des structures observées qui ne comportent pas de liaisons hydrogènes O3···O5′ se trouvent à environ 1 kcal/mol au-dessus du minimum de la carte et pour les structures observées qui ont un axe d'hélice pseudo-binaire les valeurs vont de 0,4 à 1,0 kcal/mol. La carte obtenue au niveau HF/6-311+G(d) accommode les structures pratiquement aussi bien.

Mots clés : cellulose, hydrate de carbone, conformation, énergie, flexibilité, repli, hélice, forme.

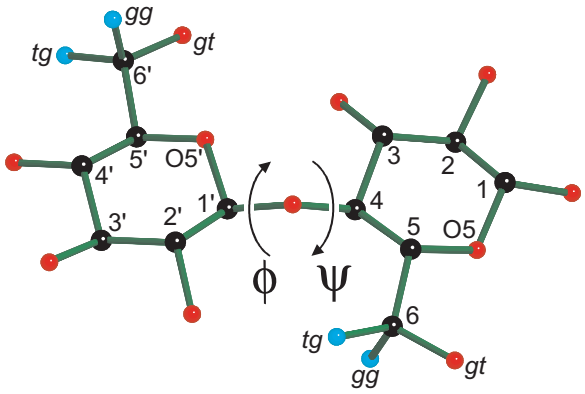
Introduction

It has not been easy to reveal the structural secrets of cellulose, the most prevalent of all biological molecules. Despite studies that began more than 90 years ago (1), detailed structures of the main crystalline forms were reported only recently (2–5). Other structures are still controversial. For example, the helix chiralities of crystalline cellulose complexes and derivatives are not known for certain. In noncrystalline environments, the shape properties are even less well understood.



Computerized molecular modeling has often been called upon, with mixed success, to gain insight on such questions. Consider two recent studies aimed at determining the conformation of hydrated cellulose fragments. One study reported that the fragments were heavily hydrated and making tight turns in water (6). The other found them to be extended and more likely to hydrogen bond with each other rather than with water (7). Because of difficulties of modeling the stereoelectronic, hydrogen bonding and solvation characteristics of carbohydrates and water, various workers have not been able to agree on one method for energy calculations or other details such as atomic charges or assumed temperature. Currently, such contradictory results are to be expected.

As a simplification, investigators of cellulose structure have often studied cellobiose (β-D-glucopyranosyl-(1→4)-D-glucopyranose) (8–14), the disaccharide that can be described as the shortest cellulose chain. Lactose (β-D-galactopyranosyl-(1→4)-D-glucopyranose) should also be a good model for cellulose linkages. The intrinsic shapes of β-cellobiose and β-lactose are so similar that their crystal structures (15, 16) are isomorphous (17), as are crystals of their methyl glycosides (18, 19). Structural results from one sugar have strong implications for the other (20), and lactose conformations have been studied by modeling as well (21–23). Studies of other β-1,4-linked sugars, such as chitobiose (24, 25), are also relevant.

The primary variables of disaccharide shape are the linkage torsion angles ϕ and ψ (Fig. 1). Contemporary conformational analysis of cellobiose involves rotating each of the glucose rings about the glycosidic (ϕ) and aglycon (ψ) bonds and calculating a minimized relative energy at each increment of rotation. Most calculated energies for these molecules have been based on empirical force fields, also called molecular mechanics (MM). After the energies are calculated, a Ramachandran contour map of energies in ϕ,ψ space is created. The lowest energy regions indicate the most likely molecular shapes. Simulation of molecular dynamics (MD) trajectories is another approach that is usually carried out with energies calculated with MM force fields. The relatively rapid MM calculations permit, with today's computers, rather thorough treatments including large numbers of possible orientations of the exo-cyclic groups in mapping studies (26). In the case of MD, explicit solvent and multinanosecond simulations can now be considered. Because of the controversial results from these various studies, development of empirical energy functions for carbohydrates has continued (27).

Electronic structure theory or quantum mechanics (QM) methods inherently account for stereoelectronic effects that occur in carbohydrates. QM has been exploited for more than 30 years to quantify these effects (28, 29). Energy values for carbohydrates from QM are often different from those from MM studies (30–32) and differences in the degree of approximations of the electronic structure also cause different results (33, 34). So, even though QM results are based on the fundamentals of molecular structure, it is important to understand their limitations. In any event, ab initio QM methods take several orders of magnitude more computer time than MM, so they have typically been applied to molecules even smaller than disaccharides. For example, numerous studies of 2-methoxy-tetrahydropyran have been carried out. A fairly complete series was reported by Tvaroška and Carver (see ref. 35 and papers cited therein). Those studies were done with the idea of providing a basis for parameterization of empirical torsional parameters that would adequately mimic stereoelectronic effects around glycosidic linkages.

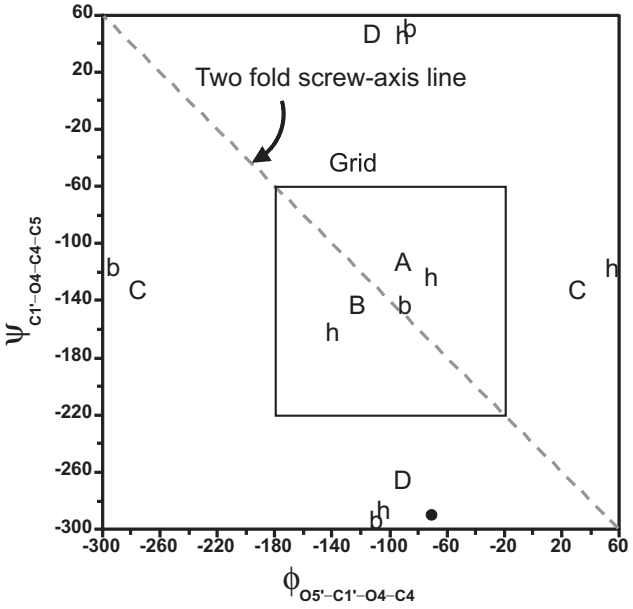
Fig. 1. Cellobiose with atom numbering, the linkage torsion angles ϕ and ψ, and the *gg*, *gt*, and *tg* O6 orientations. Hydrogen atoms are not shown. The O6 atoms shown shown in red are in the *gt* positions; and the other two staggered orientations (*gg* and *tg*) are cyan.

Additional insight on disaccharide conformations was gained with analogs of disaccharides that consisted of tetrahydropyran or cyclohexane rings standing in for glucopyranose, and tetrahydrofuran standing in for fructofuranose, linked by a "glycosidic" linkage. Semiempirical QM studies on an analog of trehalose were promising (36). With ab initio QM, only the ψ torsion was varied in initial studies (37, 38), but shortly afterwards, complete ϕ,ψ energy surfaces were published for analogs of a number of disaccharides (39). Despite the analogs' lack of hydroxyl and hydroxymethyl groups, those surfaces are remarkably predictive of linkage geometries observed in crystal structures of the disaccharides. Recently, we carried out QM studies with sterically more complete analogs of maltose and cellobiose in which all hydroxyl groups were replaced with fluorine atoms (40).

Several years ago, we devised a simple hybrid modeling method so that the electronic structure data at the glycosidic linkage could be combined with the MM results for the remainder of the molecule (41). That allowed a reasonably complete treatment of the exo-cyclic groups. Our hybrid method is better at predicting conformations of carbohydrates in crystal structures than the above QM-analog method, including the fluorinated analogs. However, even with our

© 2006 NRC Canada

hybrid method, we were not certain that we had provided an optimum rationalization for the observed structures. The experimental disaccharide conformations in the central region seemed to fall into three specific groups in ϕ,ψ space (17), but the energy surfaces suggested that there is only one central minimum. Of course, these groupings could just arise by chance or from external forces such as crystal packing effects. One way to explore whether these groups are based on intrinsic energy of the cellobiose molecule is to apply QM to the entire disaccharide. This paper conveys those results.



Besides the grouping of the crystal conformations, impetus to our efforts was provided by results from Momany and his group at our sister laboratory. That work identified 26 cellobiose structures that corresponded to local minima (42). Their structure with the lowest energy has a linkage conformation different from any of the 30 known conformations from small molecule crystal structures. With their computationally expensive B3LYP/6-311++G(d,p) calculations, this structure was 3.84 kcal/mol lower in electronic potential energy (before their zero point vibrational energy corrections) than any of the models in the region that corresponds to most experimentally observed structures. Their following work (43) showed that the low energy depended on an extensive, cooperative intramolecular hydrogen bonding system (O4′···O3′···O2′···O3···O2···O1). When the O4′ hydroxyl group was removed, the unusual ϕ,ψ conformation no longer had the lowest energy. Calculations with added water molecules have also indicated that the unusual shape is not likely in solution (F.A. Momany, private communication). Because QM energies of carbohydrates are rather dependent on the method and on the basis set, it is important to confirm their result with several types of calculation and with consideration of more possible structures. Also, a QM conformational energy surface for the isolated molecule should still be of interest.

Given the computer time required for such QM studies, it is not surprising that there are few such energy surfaces available for carbohydrates. Several types of QM calculation were used to make maps for trehalose (44), a symmetrical molecule that permitted substantial reduction in the size of the problem. QM maps for lactose have been constructed by da Silva and Nascimento (45), but the results differ somewhat from those of the present report. Preliminary results from the present study were published elsewhere (46).

Methods

To permit accurate comparison with crystal structures, we define the linkage torsion angles as ϕ = O5′-C1′-O4-C4 and ψ = C1′-O4-C4-C5 instead of the usual definitions based on H1′ and H4. To reduce the computer effort to a manageable level, we used a 9 × 9 grid of ϕ and ψ values that were spaced in increments of 20°. This grid, with ϕ = –180° to –20° and ψ = –220° to –60°, covers the central region of full ϕ,ψ maps (see Fig. 2). Some 97% of the conformations in crystal structures of molecules related to cellobiose are in this region, and polysaccharides having these ϕ,ψ conformations are extended helices (17). All variables except ϕ and ψ were optimized with HF/6-31G(d). Next, single point calculations, denoted HF/6-311+G(d)//HF/6-31G(d), were carried out on those geometries.

Fig. 2. ϕ,ψ Space with a diagonal line that represents structures having a twofold screw axis. The inset shows the restricted region of the QM energy surfaces, and the letters A–D indicate the important minimum energy regions. Lowercase letters b and h indicate the approximate locations of the minimized HF (h) and B3LYP (*b*) structures in Table 1. Also shown (●) is the location of the only small-molecule conformation (52) in the D region.

Besides the 81 target geometries and energies on the grid, four other targets were computed. Two targets were unconstrained minimizations in subregions of the central region, called A and B. The starting geometries were adjusted to have ϕ and ψ values that corresponded to minima found in our preliminary mapping studies (46). For the A region, ϕ and ψ values were –80°, –120°, and for the B region, –120°, –160°. The other two targets (C and D) correspond to the "flipped" conformations of Strati et al. (42) that are also called "folded" conformations (47) or "edge-of-the-map" structures (48). They had initial ϕ and ψ values of 60°, –120° (left and right edges) and –60°, 60° (top and bottom edges), for a total of 85 target structures for which the lowest energy was sought. Our map of the central region should allow an assessment of how predictive the vacuum electronic energies are for crystal structures, and the use of the unconstrained minimizations in the regions of the two other minima should address the relative energies of these structures.

The calculated energy of a disaccharide also depends on the orientations of the exo-cyclic groups. Because we are seeking the lowest possible energy for each target structure, it is necessary to try many combinations of the exo-cyclic group orientations (26). Because there are 10 bonds to exocyclic atoms in cellobiose about which rotation is possible, giving each group three staggered orientations would result in 3^{10} or 59 049 combinations. It is not feasible to evaluate all of these at each ϕ,ψ point, especially with QM. In this work we relied both on some structures in the literature and on our own work with MM methods to reduce the number of such combinations, or starting geometries, to a more manageable level. A conformational search procedure performed with Macromodel 7.1 (49) and its AMBER* all-atom poten-

cluster_34	–1290.649 253	HF/6-31G(d)	–141.08	–153.55	4.578	B
cluster_43	–1290.648 272	HF/6-31G(d)	–106.60	67.21	5.193	D

Note: The HF/6-311+G(d) and B3LYP/6-311+G(d) energies are for geometries optimized with HF/6-31G(d) and B3LYP/6-31+G(d), respectively.
[a]The names indicate the source of the structure, and the attached number, the particular variant. The momany structures were taken from the work of Strati et al. (42); the momany_10A and momany_15A structures were incorrect copies of the reported structures. The chem-x and cluster structures were created using Chem-X and MacroModel, respectively.

tial (50), followed by analysis with Xcluster 7.1, gave 45 conformers. Another set that we had developed earlier in an MM3 study of native and permethylated disaccharides (48) contained 58 structures. Those structures came from a rules-based conformational generator in Chem-X.[3] The 26 unique structures from the work of Strati et al. (42) were employed with three variations. As done for our cluster search and rules-based structures, all glycosidic bond angles were increased to 150°. This increase, which is quickly resolved during energy minimization, helps avoid interatomic conflicts that might otherwise arise during the rigid residue rotations to create the starting geometries for each ϕ,ψ point. Without the increase, such conflicts often cause the energy minimization to fail. Additionally, we started the grid-search minimizations (but not the unconstrained minimizations) for one set of the Strati et al. structures with the glycosidic bond angles at their as-reported angles. The third set involved alternative orientations of the hydroxyl groups based on a misinterpretation of their torsion angle descriptions for 15 of the structures. There was some redundancy within these 181 starting structures, depending on the criteria for determining a geometric difference, but the duplicates allowed internal checks on our process.

The energy of each starting geometry was minimized for all 85 target structures. Besides the HF methods mentioned above, we used B3LYP/6-31G+G(d) minimization and subsequent B3LYP/6-311+G(d) single point calculations for the unconstrained minimizations. Thus, more than 15 000 energy minimizations and an identical number of single point calculations with a larger basis set were carried out. Jaguar 5.5 (51) was used with the default convergence criteria utilizing 16 processors simultaneously on our compute farm. Because of the large number of structures evaluated, only the electronic potential energies are reported. No frequency calculations were undertaken that could have been used to determine the zero point vibrational energy or free energy.

Results and discussion

Unconstrained minimization

Figure 2 shows the complete ϕ,ψ space of cellobiose and the A–D regions. The ranges of the axes correspond to the approximate translation of ϕ,ψ if they were defined by H1′ and H4, ranging from –180° to +180°. There is an internal border for our 9 × 9 grid-point central region and the positions of the two HF minima and the B3LYP minimum within that boundary are indicated. The locations of the minimized edge-of-the-map, flipped, or folding structures are also shown. The only experimental small molecule structure (52) that does not fit into the central region is indicated in the D region. The dashed diagonal line corresponds to structures having internal twofold screw-axis (2_1) symmetry. This symmetry is reported for crystalline cellulose structures except for cellulose Iα (4), which has pseudo 2_1 symmetry. This symmetry is of interest because of controversy over potentially short contacts among the hydrogen atoms on C1′ and C4, as well as (possibly artifactual) evidence of odd-order meridional diffraction reflections that would rule out the symmetry (53). Cellobiose cannot possess actual intramolecular symmetry because the two glucose residues are chemically different, but cellulose molecules are long enough that its ends do not affect the apparent symmetry.

Table 1 shows the ϕ and ψ values and energies that were obtained during the studies of the A–D regions with the four combinations of QM method and basis set. Regarding the central region, its final minimized structures that were started with the A and B regional ϕ and ψ conformations had wide ranges of ϕ and ψ values. In the case of the HF calculations, the lowest energies were for structures that retained their regional conformations. For the B3LYP calculations, however, the lowest energy values were found for structures that were very close to the twofold symmetry line, where ϕ + ψ = –240°. This conformation is designated A/B, as it

[3]Chem-X is no longer available.

© 2006 NRC Canada

was the lowest energy structure in both the set of B3LYP minimizations started with the A conformation and the set started with the B conformation. There were minimized structures that retained the A and B regional conformations in their respective B3LYP/6-31+G(d) sets, but their energies were about 0.9 kcal/mol (1 cal = 4.184 J) higher than the nearly twofold A/B structure reported in Table 1.

The location of the D minimum depended more on the basis set than the method. Despite being single point calculations, $\phi \approx -85°$ and $\psi \approx +56°$ were preferred with the 6-311+G(d) basis set, whereas $\phi \approx -107°$ and $\psi \approx +67°$ with the smaller 6-31G(d) and 6-31+G(d) basis sets and full minimization. The (right- or left-hand edge) C minimum was essentially independent of the calculation. Five different starting geometries all minimized to give the same lowest-energy structure with both HF and B3LYP, confirmed by both single point calculations. For all combinations of method and basis set, that C-region structure has lower energy, by more than 3 kcal/mol, than structures in the other regions. This confirms the results of Strati et al. (42) with four more combinations of method and basis set, and is in agreement with da Silva and Nascimento's results (45) (minimized structure E in their Table 2). The HF/6-31G(d,p) results of Hardy et al. (47) on methyl α-cellobioside seem similar to those for our A and D regions. They found a structure in our D region (their C region) that was only 0.3 kcal/mol higher than the A region energy. Their slightly different level of theory, HF/6-31G(d,p), should give essentially the same results as our HF/6-31G(d) calculations. Their smaller energy difference may be because their A region structure (interchanged in their Fig. 1 with B) lacks an O3···O5′ hydrogen bond. They apparently did not consider structures in our C region.

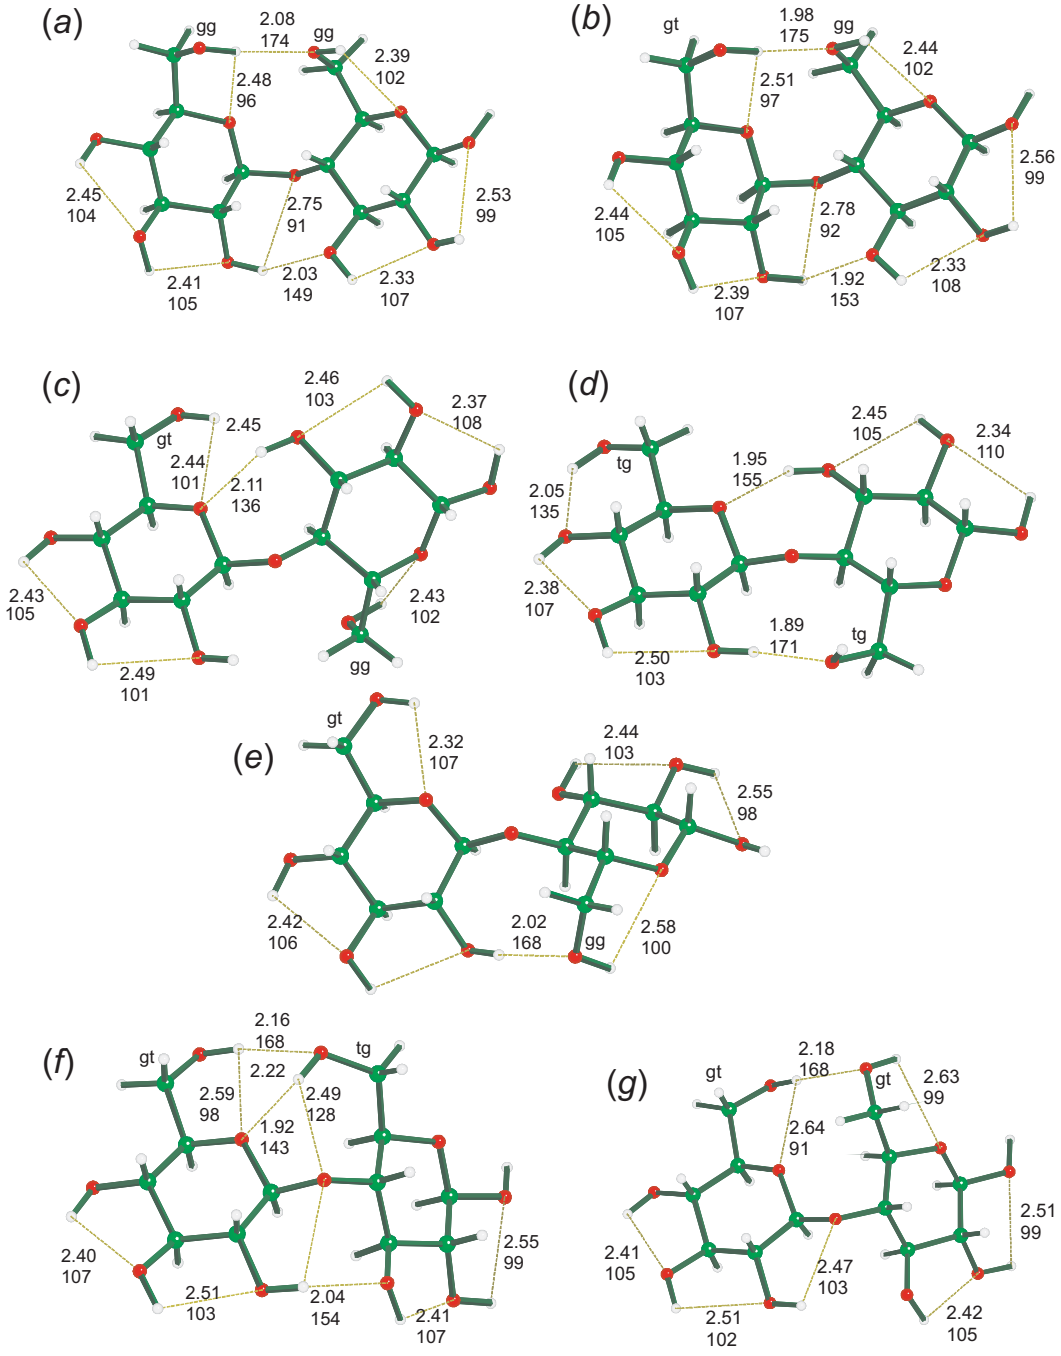
Figure 3 shows the structures for each of the minima, with hydrogen bonds shown if the H···O distance is less than 2.8 Å and the O-H···O angle is greater than 90°. The HF/6-31G(d) and B3LYP/6-31+G(d) global minimum structures (C region) are both shown (Figs. 3*a* and 3*b*) to illustrate the effect of the particular calculation on the structures. Mostly, H···O distances are longer for HF/6-31G(d), but it should be said that both methods provide distances longer than seen in crystals. Their O6 atoms are in the *gg* position, allowing strong hydrogen bonds between O6 and O6′. The overall minimum is also stabilized by a strong inter-residue hydrogen bond from O2′ to O3. These hydroxyl–hydroxyl hydrogen bonds are considered to be stronger than hydroxyl donations to the ring oxygen found in the central region for the A and A/B structures, explaining in part the preference for the C structure.

The same A-region structure was preferred in both the HF/6-31G(d) and HF/6-311+G(d) calculations. That structure (Fig. 3*c*) is surprising in that two hydroxyl hydrogen atoms are almost in contact, separated by only 2.45 Å. The O6′ and O6 atoms are *gt*,*gg*, with counterclockwise hydroxyl orientations on the nonreducing ring and clockwise orientations on the reducing ring. This is a common arrangement of O6 positions in small molecule crystals, except that in crystals, *gt* O6′ hydroxyls are turned so that O6′ can accept a bifurcated donation from O3. The hydrogen bond between O3 and O5′ is somewhat long and all of the remaining interactions are likely to contribute very little to the low energy. The values of φ and ψ, however, are likely to be nearly optimal for stabilization by the exo-anomeric effect and the external anomeric torsional effect (54). They are very similar to those of crystalline β-cellobiose ($\phi = -76°$ and $\psi = -132°$ in the crystal (15), $\phi = -71°$ and $\psi = -126°$ in the model).

The lowest energy B3LYP structure from the central region (A/B, Fig. 3*d*) has a stronger hydrogen-bonding network. Not only is the O3···O5′ hydrogen bond shorter and straighter than the HF A-region structure, but there is an even shorter and straighter O2′···O6 hydrogen bond. The O6′ to O4′ hydrogen bond also has favorable geometry. The φ and ψ torsion angles place the structure very close to the twofold screw-axis line, and the *tg* O6 orientations on both residues complete the analogy with cellulose I crystal structures. This support for a low-energy twofold structure is even more compelling because it was selected by both B3LYP calculations. Interestingly, the reducing anomeric hydroxyl groups of this and the above HF A-region structures have orientations that would not be preferred by the exo-anomeric effect, but they participate in cooperative chains ending with O5′. With HF/6-31G(d), this structure is about 1 kcal/mol higher in energy than the structure in the preceding paragraph, while that structure is about 0.9 kcal/mol higher than the present structure at the B3LYP/6-31+G(d) level.

The HF/6-31G(d) and HF/6-311+G(d) B-region structures are almost identical (the HF/6-31G(d) structure is shown in Fig. 3*e*). No structure is shown to represent the B3LYP calculations for the A or B regions, since the A/B structure was preferred. The φ and ψ values for the B region do not permit an O3···O5′ hydrogen bond, but the geometry does allow a fairly strong hydrogen bond from O2′ to O6, with O6 in the *gg* position. O6′ is in the *gt* position. No small molecule crystal structures have φ,ψ conformations in this subregion, but carbohydrate moieties in the 1ct1[4] (55), 1se3 (56), 2chb (57), and 1fbw (58) complexes with crystalline proteins are within a few degrees. Our MM and hybrid energy surfaces (46) are typically 1 or more kcal/mol higher in this region.

The D region (top or bottom of the map) contains a surprise or two. The same structure is preferred with HF/6-31G(d) and B3LYP/6-31+G(d) (Fig. 3*f*), and a different structure is preferred by both the HF/6-311+G(d) and B3LYP/6-311+G(d) single point calculations (Fig. 3*g*). The main difference between the two structures is that the reducing ring has O6 in the *tg* position for the minimized structures and in the *gt* position for the structures preferred by the single point calculations. This causes a difference in the linkage conformation. The O6′ groups are in the *gt* position. Both of the structures that were preferred with the smaller basis sets have a short distance between the O6 and O6′ protons, similar, but even shorter at 2.36 and 2.22 Å, than found for the A-region HF structures.



Energy surfaces

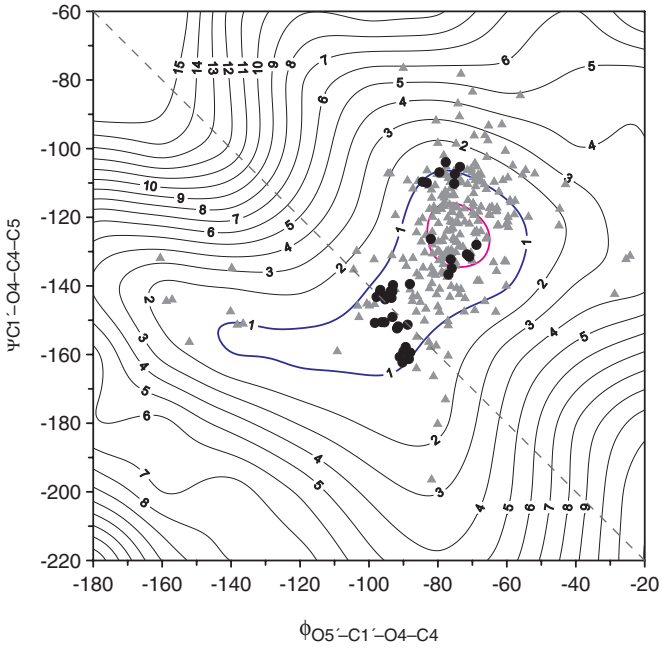
Fig. 4. HF/6-31G(d) contour map with crystal structures. The inner contour is 0.25 kcal/mol; all others are at intervals of 1.0 kcal/mol. Small-molecule structures are represented by (●). Carbohydrate conformations in complexes with proteins are shown as (▲).



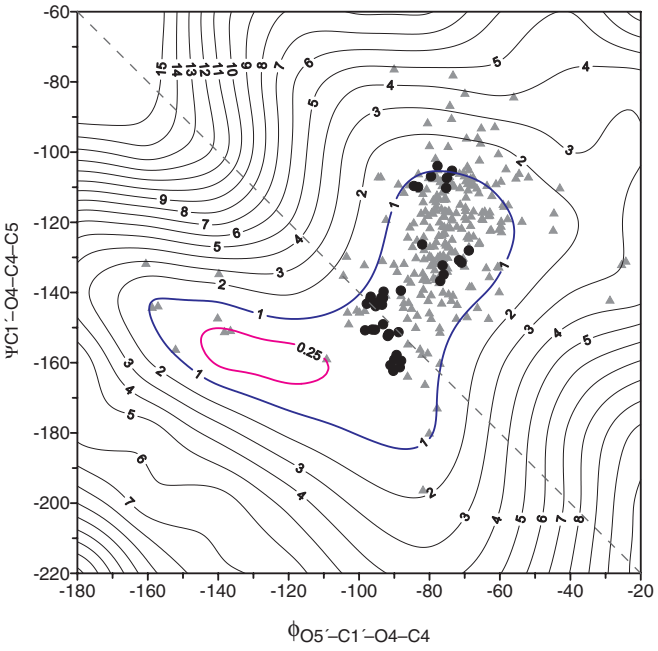


Fig. 5. HF/6-311+G(d) contour map with crystal structures, as in Fig. 4.

within, or just outside, the 1 kcal/mol contour, while a number of the protein complex structures are outside the 2 kcal/mol contour.

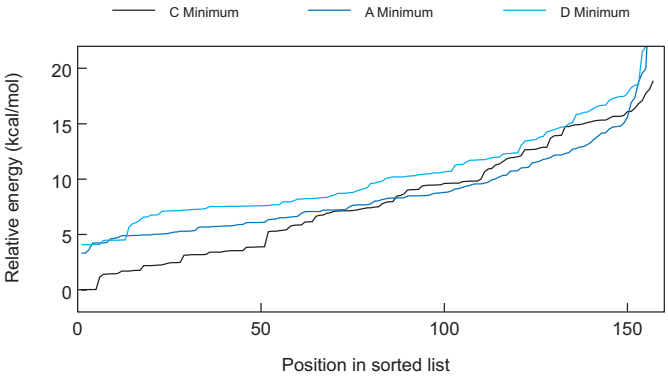
Figure 5 shows the corresponding surface for HF/6-311+G(d)//HF/6-31G(d) theory. Again, most of the experimental conformations are within the (somewhat larger) 1 kcal/mol contour. However, based on the dearth of observed structures within the 0.25 kcal/mol contour, we judge it to be less predictive than the HF/6-31G(d) surface (Fig. 4). In our study of trehalose, a seemingly similar single point calculation (HF/6-311++G(d,p)//B3LYP/6-31G(d)) yielded an energy surface that was more predictive of crystal structures than other surfaces in that work. That improved predictiveness was attributed to reduced stabilization of hydrogen-bonded structures, but the present single point calculations, based on HF/6-31G(d) geometries, do not reduce the energy of the hydrogen bonds to a similar extent. Instead, it is impressive to us that with full strength hydrogen bonding, Figs. 4 and 5 are as predictive as they are for cellobiose. This is curious because our hybrid and MM cellobiose maps demand reduction of hydrogen bond strength to be predictive (46). Fortuitous cancellation of errors may be important for these surfaces, and we cannot say that maps produced with the same approach for other disaccharides will accommodate the relevant crystal structures this well.

The biggest difference between these two QM surfaces and most of our other cellobiose energy surfaces is that structures with pseudo 2_1 symmetry now have lower relative energy. This is especially true for the preliminary HF/6-31G(d) and HF/6-311+G(d) single point surfaces, based on "only" 61 starting geometries (46). On those surfaces the diagonal symmetry line passed over a saddle point on the surface between two minima. On other surfaces in that paper, the symmetry line was tangential to the 1 kcal/mol contour. Similar, lower energies for the 2_1 structures were previously provided only by fluorinated cellobiose energy surfaces and a recent hybrid energy surface based on MM4 (40). Indication that the twofold structures may have even lower relative energy is given by the B3LYP/6-31+G(d) A/B structure that also had the lowest single point B3LYP/6-311+G(d) energy. It suggests that similar partial maps constructed with B3LYP and those basis sets might have their global minima bisected by the symmetry line.

One might have guessed that our preliminary surface based on 61 reasonably selected starting geometries would be essentially unchanged by the inclusion of more structures, but that was not the case. The individual energy surfaces provided by each of the different sets of starting geometries (see Methods) gave fairly different surfaces (not shown), except for the correct structures from the Strati et al. (42) paper, and the related set with the 150° glycosidic angle. Those two surfaces were quite similar, but the number of structures that failed to optimize (mostly because of interatomic conflicts in the starting structures) was much lower for the set with the 150° angle. Each of the sets contributed one or more points to the final map, but reliance on any single set of starting geometries resulted in discrepancies with the final composite maps of 3–7 kcal/mol.

These energy surfaces are completely different from the plot in Strati et al. (42), one that those authors had noted was not the same as conventional, grid-search plots like those prepared in the present work. Although our maps cover only the quarter of the ϕ,ψ territory where most crystal structures are found, the range of relative energies on our maps is greater than 18 kcal/mol, to which must be added the 3.7 kcal correction for the global minimum, as well as the

© 2006 NRC Canada



peaks that occur outside our central region. In the same portion of ϕ,ψ space as our limited surface covers, the Strati et al. energies have a range of about 2 kcal/mol. Unlike that flat surface, the da Silva and Nascimento surfaces (45), which were constructed with grid searches, have peaks of 85 kcal/mol and higher. Their tortuous surfaces may result, at least in part, from considering only a single starting structure for each linkage conformation. Our MM3 surfaces for cellobiose and permethylated cellobiose (48) have relative maxima of less than 30 kcal/mol, and our HF/6-31G(d) surfaces for the tetrahydropyran-based analog of cellobiose (39) have maxima of less than 20 kcal/mol.

Figure 6 shows the impact of exo-cyclic group orientation on the energies from the unconstrained minimizations. In each of the three regions of stable ϕ,ψ conformation, the energies based on exo-cyclic orientation variation have nearly continuous ranges that nearly equal the 18 kcal/mol range based on variation in ϕ and ψ. It should be kept in mind that the structures used in these calculations were preselected with the aim of providing the lowest energy, and the range based on exo-cyclic orientations would otherwise be even larger.

The conformations from the small-molecule crystals are well accounted for by Fig. 4, always bearing in mind, of course, that the global minimum is in region C, not included in the figure. The upper group of seven small-molecule structures is of interest because those crystal structures have no interresidue hydrogen bonding, yet their average energy is only about 1 kcal/mol above the map's lowest energy. There is considerably more scatter in the conformations from the protein complex structures. Those structures are not as reliably determined as the small-molecule structures, but are none-the-less interesting tests of energy surfaces. Some of these, mentioned previously when discussing the B region minimization, provide justification for the extension of the low-energy region to the lower values of the ϕ torsion angle, despite the absence of stabilization from the exo-anomeric effect. On the other hand, structures above ψ = –100° have remarkably high energies. Consider the observed point from the 1fv3 protein complex (62) with ϕ and ψ values of –72.3° and –78.2°. It lies between the 5 and 6 kcal/mol contours in Fig. 4. Rotation of the reducing ring in the 1fv3 structure to give a ψ value of –133°, a conformation essentially that of crystalline β-cellobiose, results in a O3···O5′ distance of only 2.13 Å. This indicates that the monosaccharide geometries in the 1fv3 structure are distorted considerably from those normally found, and that the structure is probably not accurately determined.

The three groups of experimental conformations from the small-molecule crystals that were mentioned in the Introduction are visible on Figs. 4 and 5. None of these surfaces have multiple minima that would account for three separated types of conformation. Instead, we can imagine that structures along the symmetry line are there because the molecules take the shape of a flat ribbon that can pack very efficiently. The remaining small-molecule structures are within a continuum of structures from the less accurately determined protein complexes. That continuum is consistent with the present energy calculations and together they imply that the groupings are not based on an intrinsic molecular energy.

Fig. 6. Sorted energies from structures started in the A, C, and D minima, calculated with B3LYP/6-31+G(d) minimization.

Conclusion

By restricting the range of ϕ and ψ to the most interesting region, we have been able to afford to construct energy surfaces for cellobiose at two levels of ab initio QM theory that involved an unusually large number of starting geometries. We also isolated the interesting minima by using the same starting geometries in unconstrained minimization. This work has confirmed that the global minimum structure for various affordable QM calculations is in a region that is not populated by any small-molecule crystal structures and is rather distant from any of the reported protein complex structures as well. The repeated finding that the same structure is the calculated global minimum, despite using several combinations of QM method and basis set, is unusual for a disaccharide. This rarity is exemplified by our finding of different structures for the other minima, or in the case of the central zone, finding a common structure with both B3LYP calculations despite starting from the A and B region conformations that had been identified with HF calculations. In support of the global minimum, its hydrogen-bonding system is arguably superior in that there are two hydroxyl–hydroxyl links between the two glucose residues instead of the weaker O3···O5′ hydrogen bonds found in the A region structures.

The large number of starting structures was important to the definition of the overall surface. Variations in energy from combinations of exo-cyclic group orientations are of a magnitude similar to those caused by variations in ϕ and ψ. The contours provided by both the HF calculations were quite predictive of the crystal structure conformations, bearing in mind that the global minimum was not included on our energy surfaces. Except for one structure that has a D conformation, the surfaces accommodated all of the experimental small-molecule structures within about 1.2 kcal of their respective minima, with the HF/6-31G(d) calculations being slightly more predictive than the single point energies that used a larger basis set. Even the experimental structure in the D region was not orphaned by these calculations. The unconstrained minimum for the D region is only 0.7 to 1.5 kcal higher than the A region, depending on the combination of method and basis set. Compared to many of our other surfaces, the experimental twofold structures corresponded to lower energy, suggesting that the strain of crystal

© 2006 NRC Canada

packing for cellulose and other small molecules near the twofold line is minimal.

Somewhat unusual structures appeared as local A and D region minima. These structures had distances between hydroxyl hydrogen atoms that are as short as 2.22 Å. That distance resulted from the better QM calculation used for minimization, B3LYP/6-31+G(d), which has been recommended for carbohydrates (63). Whether these are valid structures remains to be seen.

A great deal of progress has occurred in carbohydrate modeling. Even a decade ago, it would have been difficult to imagine that we would have been able to prepare energy surfaces such as presented herein. On the other hand, many of the problems are still present. In 1989, French and Brady (64) wrote "The biggest obstacle is the 'multiple minimum problem' which arises because energy surfaces for complex molecules have more than one local minimum." Even if this problem has been overcome in the present work by brute force, there was an important effect of the different starting geometries on the energy surface. That shows that it is important to make a thorough attempt to include all relevant structures and avoid making conclusions based on local minima. It is also clear that improved QM methods and basis sets will be useful in future calculations.

Acknowledgments

The authors dedicate this work to honor Walter Szarek, whose commitment, hard work, congeniality, and talent were inspiring during overlapping tenure with ADF on the Executive Committee of the Division of Carbohydrate Chemistry of the American Chemical Society. We thank Professors C.O. da Silva, Universidad Federal Rural do Rio de Janeiro, Brazil, and G.I. Csonka, Budapest University of Technology, Hungary, as well as Dr. K.Q. Robert of our research center for comments on a draft of this paper.

DNA and RNA enzymes with peroxidase activity — An investigation into the mechanism of action[1]

Paola Travascio, Dipankar Sen, and Andrew J. Bennet

Abstract: A DNA–hemin complex (PS2.M–hemin), and its RNA counterpart (rPS2.M–hemin), have previously been reported, in the presence of nitrogenous buffers such as HEPES, to show enhanced peroxidative activity relative to both uncomplexed hemin and a control DNA–hemin complex (Chem. Biol. **5**, 505, 1998). A kinetic analysis of these two hemin-utilizing nucleic acid enzymes provides key insights into the mechanisms for their catalyzed peroxidation reactions. First, control experiments indicate that charge on the added detergent, required for solubility reasons, has little effect on the efficiency of the nucleic-acid-catalyzed reactions. Second, the key functional impact of the two nucleic acid frameworks, either DNA or RNA, appears to be a reduction in the acidity of a water molecule coordinated to the iron atom of the hemin that is bound to the ribozyme and DNAzyme scaffolds. This effect could result from a polar environment and possibly hydrogen bond(s) at the axial position of the hemin, along with favourable hydrophobic interactions for the periphery of the porphyrin ring. Third, the basic component of the buffer enhances the activities; this likely results from a general-base-catalyzed process. Cumulatively, these data supply important clues as to how biopolymers other than a protein can complex with hemin to form productive peroxidase enzymes.

Key words: ribozyme, DNAzyme, hemin, peroxidase, mechanism, guanine quadruplex.

Résumé : Il a été rapporté antérieurement que, en présence de tampons azotés tel le HEPES, un complexe ADN–hémine (PS2.M–hémine) et sa contrepartie (rPS2.M–hémine) présentent une activité peroxydante plus élevée que celle tant de l'hémine ou un complexe ADN–hémine de contrôle (Chem. Biol. **5**, 505, 1998). Une analyse cinétique de ces deux enzymes d'acide nucléique utilisant de l'hémine fournit des éléments clés pour mieux comprendre les mécanismes de leurs réactions d'oxydation catalysées. Le premier provient des expériences de contrôle qui indiquent que la charge sur le détergent ajouté, requis pour des raisons de solubilité, n'a que peu d'effet sur l'efficacité des réactions catalysées par un acide nucléique. Le deuxième a trait au fait que l'impact fonctionnel des deux squelettes d'acides nucléiques, soit l'ADN ou l'ARN semble provenir d'une réduction de l'acidité d'une molécule d'eau liée à l'atome de fer de l'hémine qui est liée aux échafauds de ribozyme et ADNzyme. Cet effet pourrait provenir d'un environnement polaire et aussi de liaisons hydrogènes à la position axiale de l'hémine liée à des interactions hydrophobes favorables pour la périphérie du cycle porphyrine. Le troisième est lié au fait que la composante basique du tampon augmente les activités; ce qui résulte probablement d'un processus de catalyse basique générale. Dans leur ensemble, ces données fournissent des données importantes qui permettraient de comprendre comment des biopolymères autre qu'une protéine pourrait former un complexe avec l'hémine pour produire des enzymes peroxydases utiles.

Mots clés : ribozyme, ADNzyme, hémine, peroxydase, mécanisme, quadruplexe de guanine.

[Traduit par la Rédaction]

Introduction

The reaction of hydrogen peroxide with ferric porphyrins is of interest in relation to several classes of natural enzymes that use that metalloporphyrin as an essential cofactor. For instance, peroxidases catalyze the oxidation of a variety of substrates by hydrogen peroxide, whereas, catalases are enzymes that promote the disproportionation of hydrogen peroxide to give oxygen and water. Both classes of enzymes are highly efficient catalysts in which the formation of an outer-sphere porphyrin – hydrogen peroxide complex is generally the rate-determining step (1). Horseradish peroxidase (HRP), the most thoroughly studied and representative peroxidase enzyme, reacts with hydrogen peroxide, hydroperoxides, or peracids to form two distinct intermediates known as compounds I and II (2). Compound I is a green species (3) possessing two oxidizing equivalents above the Fe(III) state, and a variety of spectroscopic and kinetic studies have indicated that it is an oxo-ligated Fe(IV) porphyrin radical cation ($Fe^{IV}OP^{+\cdot}$) (4–9). Compound II is also a Fe(IV) species ($Fe^{IV}OP$), but possesses one fewer oxidizing equivalent (4–9). Extensive studies have established that the peroxidation

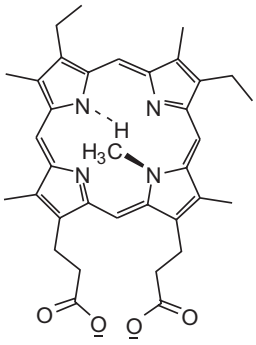
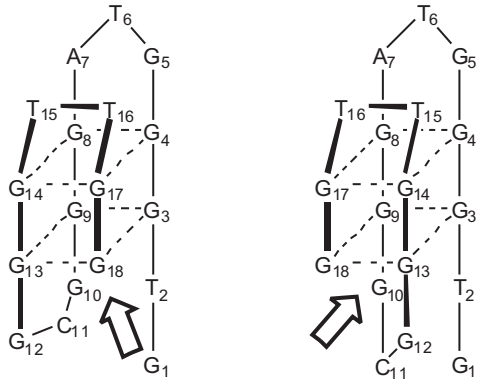
Scheme 1.



reaction catalyzed by HRP (and other peroxidases) proceeds according to the enzymatic cycle shown in Scheme 1 (4–9), where AH_2, a reducing substrate, is converted into a free radical species ($AH^{\bullet}$) by one-electron oxidation processes. A key mechanistic question concerning peroxidase catalysis is the means by which the high reaction rates for the generation of compound I are achieved. In this respect, a number of studies with peroxidase model systems have been carried out. For example, a series of articles from Traylor and coworkers (10–12) detail the oxidation reactions promoted by several ferric protoporphyrin derivatives, in methanol as solvent, using either hydrogen peroxide or a peracid as the oxidant. In comparison to hemin itself, it was reported that all derivatives possessing a covalently attached base were catalytically more active, and the observed rate accelerations upon attachment of a basic functionality were attributed to either a "proximal base effect", an intramolecular bonding interaction between the hemin and the base, or a "distal base effect", intramolecular general catalysis. Also of note, the addition of nitrogenous bases to the medium increased the reaction rate, an effect that presumably arises from intermolecular general catalysis. Other model studies on nonaggregating, water-soluble iron(III) porphyrins, which possessed meso-phenyl rings, yielded evidence for the occurrence of general catalysis by nitrogenous buffers, including 2,4,6-collidine (13).

In line with these studies on peroxidase model systems, a guanine-rich DNA oligomer and its corresponding RNA version ("PS2.M" and "rPS2.M", respectively) were found to bind hemin (**1**) with dissociation constants of 27 ± 2 nmol/L and 0.9 ± 0.2 μmol/L, respectively (14). Remarkably, PS2.M–hemin and rPS2.M–hemin complexes were found to possess high peroxidation activity, despite PS2.M being selected from a random sequence single-stranded DNA library for the specific binding of a different porphyrin, *N*-methyl mesoporphyrin IX (NMM, **2**) (14, 15).



Fe(III) protoporphyrin IX (**1**)

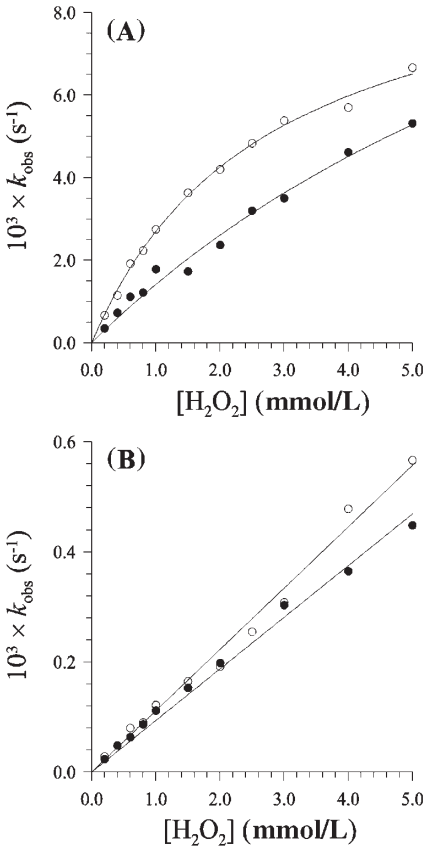
N-Methylmesoporphyrin (**2**)

Fig. 1. Two possible models for the potassium-folded PS2.M. The postulated binding sites for the hemin are shown by the arrows. The hydrogen bonding in the two guanine quartets (G_4, G_8, G_{14}, and G_{17}, and G_3, G_9, G_{13}, and G_{18}) are shown by the dashed lines.

The PS2.M–hemin and rPS2.M–hemin complexes could therefore be regarded as a new category of deoxyribozyme (DNAzyme) and ribozyme, respectively. Recently, they have found practical applications (16, 17). UV–vis and electron paramagnetic resonance (EPR) spectroscopies (14, 18) indicated that the hemin iron changed the character of its coordination upon complexation to the folded nucleic acid oligomers. Thus, the observed spectra more closely resemble those of horseradish peroxidase (HRP) and other hemoproteins rather than those associated with uncomplexed hemin.

We have recently reported a pair of models for the actively folded structure of PS2.M and these two structures are shown in Fig. 1 (19). Two loop guanines (G_{10}, G_{12}) appear to be necessary for hemin binding and one of them may serve as an axial ligand (19).

This report addresses several key questions concerning the nature of the "active" species that participate in the DNA/RNA–hemin-catalyzed peroxidation reactions. Questions include: Are the nucleotides merely acting to stabilize dissociated hemin? What is the effect of pH on the peroxidation reaction rate? Finally, what catalytic role, nucleophilic or general base, does the added buffer perform?



Results and discussion

Effect of detergents on the catalytic properties of hemin

To determine whether the contribution of the DNA moiety towards the catalytic properties of PS2.M–hemin results "trivially" from solubilization of the hemin (**1**) and surrounding it in a negatively charged environment, the catalytic activity of hemin was examined in positively, negatively, and neutrally charged micelles. Specifically, the properties of hemin solubilized by the charge neutral Triton X-100, negatively charged sodium dodecyl sulphate (SDS), and the positively charged cetyltrimethyl ammonium bromide ($CetMe_3N^+$) were studied. Hemin is solubilized by these three surfactants, however, while trying to measure the peroxidative activities of these complexes, it was observed in the case of $CetMe_3N^+$ that a precipitate formed during the peroxidation reactions, thus making it impossible to measure accurate rate constants in the positively charged micelles. Figure 2 shows the measured rate constants for hemin

Fig. 2. Plot of observed rate constant for Triton X-100–hemin-catalyzed (○) and SDS–hemin-catalyzed (●) peroxidation reactions as a function of H_2O_2 concentration. (A) HEPES buffer (200 mmol/L, pH 6.2); (B) buffer (5 mmol/L, pH 6.2).

solubilized in SDS and in Triton X-100 micelles, respectively, (in 4-(2-hydroxyethyl)piperazine–1-ethanesulfonic acid (HEPES) buffer (200 mmol/L and 5 mmol/L), and as a function of hydrogen peroxide concentration). The characteristics of the two plots are very similar, most notably under conditions of low buffer concentration.

Given that the peroxidative activity of hemin was not markedly different in neutral (Triton X-100) or anionic surfactant (SDS) micelles, it was possible to conclude that measured catalytic efficiency of the PS2.M– and rPS2.M–hemin complexes (14, 15) does not originate from solubilization of hemin in a negatively charged environment, thus suggesting that the polyanionic character of the phosphate backbone in the PS2.M– and rPS2.M–hemin complexes is not the primary reason for the observed peroxidation catalysis.

The "alkaline transition" of hemin complexes

It has been known for many years that acid–base transitions occur for many ferric hemoproteins, and that they are linked to the ionization of a water molecule coordinated to the sixth (axial) position of the hemin iron (20, 21). Therefore, the acid–base titrations for the nucleotide–hemin complexes were followed by monitoring the absorption curve at various pH values. The measured spectra showed sharp changes and clean isosbestic points, indicating that the

Fig. 3. Spectrophotometric titration to determine the pK_a of the water molecule ligated to the PS2.M–hemin complex from the ratio of absorptions at 404 and 360 nm. The symbols (○) are experimental values, and the curve is the best nonlinear fit to a standard titration equation.

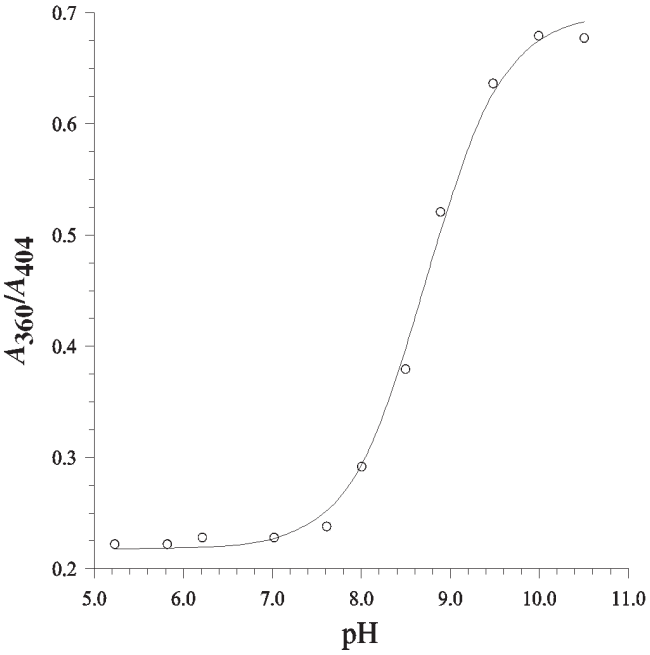

Table 1. Derived pK_a values for the acid–alkaline transitions of various hemin complexes.

Enzyme (hemin complex)	pK_a
PS2.M	8.70±0.03
rPS2.M	8.60±0.10
Triton X-100	3.4±0.2
$CetMe_3NBr$	3.0±0.1
SDS	4.0±0.5
OXY4	5.9±0.3
MetMyo[a]	8.93±0.03
MetHem[a]	8.33±0.02
HRP[b]	10.9±0.4

[a]Quoted values are from ref. 21.
[b]Quoted values are from ref. 36.

hemin complexes underwent a clean interconversion among two species. The pK_a values for these transitions were calculated from the ratio of the measured absorbances at 360 and 404 nm (Fig. 3 shows the data for PS2.M–hemin). The corresponding pK_a values were also calculated for the pH-dependent ionizations in the rPS2.M–hemin complex, the OXY4–hemin complex (OXY4 was a noncatalytic control guanine-rich DNA, 5′-d[T_4G_4]$_4$-3′), known to fold into a guanine quadruplex, but whose complex with hemin gave only a modest peroxidase activity (1), and the various hemin–detergent complexes. These measured pK_a values are compiled in Table 1.

By analogy to previous reports (20), it appears likely that the acidic species in the DNA–hemin complexes, such as PS2.M–hemin, rPS2.M–hemin, and OXY4–hemin, corre-

© 2006 NRC Canada

spond to a high-spin aquo iron(III) species, while the deprotonated form is likely a low-spin, hydroxide-coordinated iron moiety. Clearly, the pK_a values associated with the PS2.M–hemin and rPS2.M–hemin complexes are significantly different from that of the OXY4–hemin complex as well as of hemin in the presence of the three detergents. Of note, complexation of hemin to both PS2.M and rPS2.M considerably reduces the acidity of the iron-bound water molecule, and the pK_a values associated with these complexes are comparable to those of metmyoglobin and methemoglobin (ferric myoglobin and hemoglobin) (21–23), heme proteins with demonstrated peroxidase activities.

The large difference in pK_a values between Triton X-100 solubilized hemin and the PS2.M–hemin and rPS2.M–hemin complexes is almost certainly one of the major sources for the enhanced catalytic activity of the ribozyme– and DNAzyme–hemin complexes. That is, at pH values between 6.0 and 8.0, the transition-state structures for the respective HEPES-catalyzed peroxidations contain, in addition to the oxidant (H_2O_2) and the basic component of the buffer, either the acid form of the ribozyme– and DNAzyme–hemin complex or the conjugate base of a hemin molecule. In other words, the obligatory coordination of the peroxide to the iron centre by displacement of one of the axially bound ligands is likely to be a much slower process when a hydroxide group occupies one of these sites instead of a water molecule, with the concomitant result that, in the absence of the nucleotide, the hemin reactivity towards H_2O_2 is low. This notion is supported by data from studies on HRP, a hemin-containing enzyme that was shown to have a significantly reduced activity upon deprotonation in basic solutions (2, 24).

The pK_a of the hemin-bound water in the catalytically poorly active OXY4 aptamer is lower than for PS2.M (ca. 2.7 pH units), but higher than the values found for detergents. This suggests that, although the environment presented by OXY4 guanine quadruplex might be as polar as that for PS2.M, the distance and (or) the position of key functional group(s) with respect to the hemin (and vice versa) might be different between the folded PS2.M and OXY4 molecules. Likewise, the low pK_a values associated with hemin in the micellar systems suggested that a hydrophobic environment increases the acidity of one of the axial water protons (25). Finally, the high value for the pK_a of HRP compared with the other hemin complexes has been attributed to an acid–alkaline transition different from those found in the other complexes. It has been reported that HRP is converted from a high-spin five-coordinate species, with no water in the sixth position, to a six-coordinate low-spin heme at high alkaline pH (26).

The effect of HEPES buffer

Previous investigations on PS2.M–hemin-catalyzed peroxidations suggested that buffer catalysis was an important component to these biological reaction mimics (14). Indeed, HEPES was found to be a particularly good catalyst, and therefore the effect of HEPES concentration (between 0 and 200 mmol/L) on the rate of the peroxidation reactions catalyzed by both Triton-solubilized hemin and PS2.M–hemin were measured at four different pH values (6.2, 7.0, 7.7, and 8.0). Figure 4 shows the dependence of the observed rate constant (k_{obs}) of PS2.M–hemin- and hemin-catalyzed peroxidation reactions on HEPES concentrations (at pH values of 6.2 and 7.0).

Fig. 4. Plot of the measured pseudo-first-order rate constants for the PS2.M–hemin-cataylzed (pH 6.2, ■ and pH 7.0, ●) and hemin-catalyzed (pH 6.2, □ and pH 7.0, ○) peroxidation reactions as a function of the total HEPES concentration ([H_2O_2] = 600 μmol/L). The straight lines shown are the best linear fits of the rate constant data for [HEPES] ≤ 0.05 mol/L.

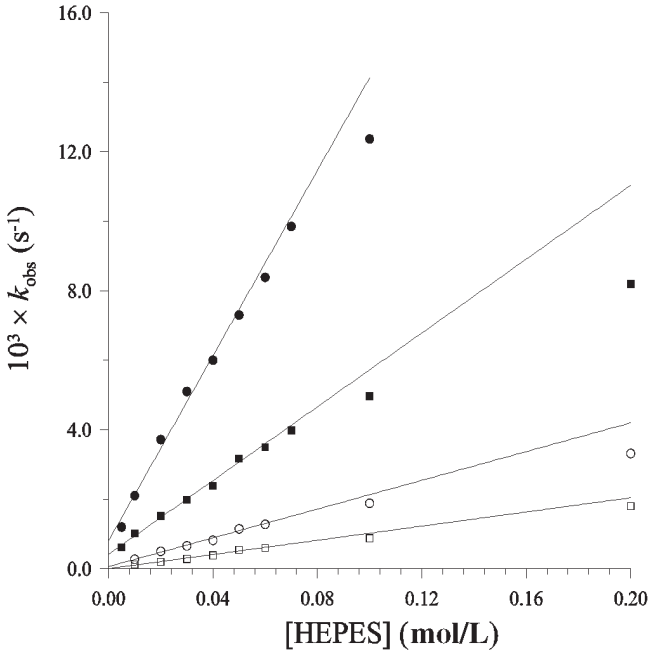

Table 2. Variation of k_3 ((mol/L)$^{-2}$ s^{-1}) with the mole fraction of free HEPES for the PS2.M–hemin-, rPS2.M–hemin-, and hemin-catalyzed peroxidation reactions.

f_B	PS2.M–hemin	rPS2.M–hemin	Hemin
0.043	0.53×10^6	0.53×10^6	0.089×10^6
0.220	1.54×10^6	1.71×10^6	0.157×10^6
0.585	4.34×10^6	4.00×10^6	0.073×10^6
0.738	3.90×10^6	3.90×10^6	0.070×10^6
0.081	—	—	0.105×10^6

Note: Estimated errors, 5%.

Linear fits of the above rate constant data, at the low buffer concentration yielded, after correction for the concentration of catalyst, pseudo-third-order rate constants. A listing of these calculated rate constants (k_3) as functions of the fraction of the basic component of the buffer (f_B) is given in Table 2.

A striking feature of the pseudo-third-order rate constants on oxidant concentration is a discontinuity in each dependence (Table 2). The decrease in activity for both nucleotide–hemin complexes at high pH likely results from the increasing concentration of the iron hydroxide form of the respective complexes. In contrast, in the hemin case the protonation state of the iron's ligands does not change at the pH values used in these experiment, and it is not clear as to the origin of the discontinuity evident in the rate constant data listed in Table 2.

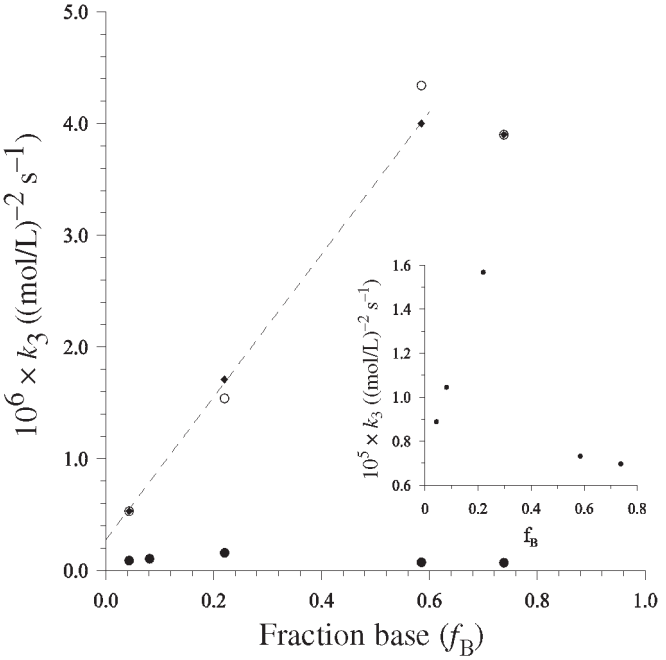
Fig. 5. Plot of observed pseudo-first-order rate constants as functions of H_2O_2 at [HEPES] = 200 mmol/L (pH 6.2). The insert is the kinetic data at a HEPES concentration of 5 mmol/L (pH 6.2).



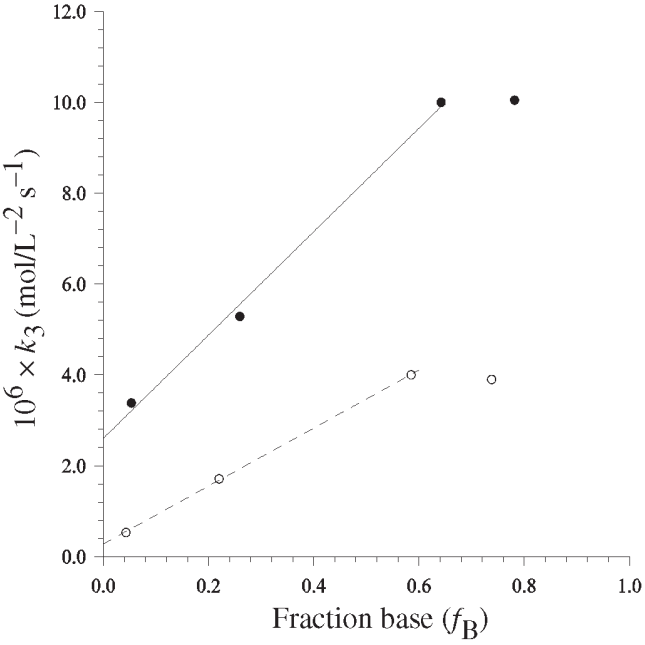


Fig. 6. Comparison of the variation of k_3 with the mole fraction of free base for collidine (●) and HEPES (○) buffers in the PS2.M–hemin-catalyzed peroxidation reactions.

In addition, to probe how the activity of the nucleotide–hemin complexes is affected by the concentration of oxidant, the pseudo-first-order rate constants (k_{obs}) for both PS2.M–hemin and rPS2.M–hemin-catalyzed peroxidations were measured as a function of the oxidant concentration ([H_2O_2]) at high and low HEPES concentrations (200 and 5 mmol/L, respectively). The so-derived rate constants are shown in Fig. 5.

It is clear that both PS2.M–hemin and rPS2.M–hemin display similar rate constants for their respective peroxidation reactions at high HEPES concentration, and that the rPS2.M–hemin complex is a much more active catalyst at low buffer concentrations. These observations are consistent with cleavage of the oxygen–oxygen bond not being rate-determining at high buffer concentration and that the RNA–hemin complex has a higher intrinsic activity than the DNA–hemin combination. PS2.M was isolated from a selection experiment designed to generate tight DNA binders of NMM (**2**), a nonplanar hemin analogue. Given that, it is remarkable that the corresponding RNA sequence (rPS2.M) also binds hemin and NMM, although this complexation is less strong and presumably less optimal. However, it is this complex (rPS2.M–hemin) that shows the greater catalytic efficiency.

Effect of collidine buffer

To investigate whether catalysis by the buffer results from coordination of the buffer to the ferric iron (27) or via a base-catalyzed pathway, the peroxidation reactions were monitored in a collidine/collidine-H^+ buffer, in place of the HEPES–NH_4OH buffer (14). Of note, the conjugate acid of collidine has a pK_a value similar to that of HEPES (p$K_a \approx$ 7.55); however, it is a sterically hindered base, which has been shown not to bind iron even at high concentrations (10). Figure 6 shows the results of peroxidation experiments with the PS2.M–hemin complex in collidine-buffered solutions. Of note, the observed rate constants in collidine-buffered solutions are higher than those measured in HEPES buffers. Also of note, it is evident that the conjugate acid of collidine also catalyzes the peroxidation by the PS2.M–hemin complex, albeit less efficiently than its basic form.

It can be concluded that the acceleration of the PS2.M–hemin- and rPS2.M–hemin-catalyzed peroxidations caused by both HEPES and collidine results from general base catalysis. Also, it is likely that the greater activity of collidine results from either its likely greater affinity for the Triton X-100 micelles or from a favourable π-stacking interaction with the nucleotide–hemin complex.

Conclusions

The PS2.M DNAzyme originally resulted from an in vitro selection for a reaction (porphyrin metallation) very different from peroxidation (28–30). In analyzing the mechanism of that quite distinct catalytic activity, it was found that the catalysis by PS2.M originated from its ability to enhance the basicity of the bound porphyrin substrate (30). Intriguingly, our conclusion in this paper is that PS2.M likewise reduces the acidity (or enhances the basicity) of the bound metalloporphyrin (hemin) cofactor in the incarnation of PS2.M as a peroxidase enzyme. The intial strangeness of a DNA enzyme selected for porphyrin metallation also proving capable of catalyzing peroxidation now appears both comprehensible and mechanistically reasonable.

The ribozyme (rPS2.M–hemin) is a better catalyst than the DNAzyme (PS2.M–hemin), in spite of hemin being bound approximately 10^3-fold more strongly to PS2.M than to rPS2.M (15). It is likely that the strongly bound PS2.M–hemin complex is structurally more rigid than rPS2.M–

© 2006 NRC Canada

hemin, which impacts negatively on its catalytic activity relative to that of rPS2.M–hemin.

The discovery of DNA– and RNA–hemin complexes capable of catalysis of peroxidation is of significant interest to the "RNA World" hypothesis for the origin of primordial life (31–34). According to this hypothesis, modern RNA-DNA-protein based life-forms were preceded by RNA molecules capable of self-replication and the catalysis of metabolic reactions. In modern primary metabolism, reduction–oxidation (redox) reactions comprise nearly one-quarter of the total number of classified enzymatic reactions (35). It is conceivable that in an RNA World, ribozymes (and DNAzymes) catalyzing metabolically important redox reactions might have recruited hemin or hemin-like molecules as cofactors.

Materials and methods

All chemicals were of the highest purity available and they were used without further purification. Sodium dodecyl sulfate (SDS), Triton X-100 (T X-100), cetyltrimethyl ammonium bromide ($CetMe_3N^+$), ammonium hydroxide (NH_4OH), nitric acid (HNO_3), cesium nitrate ($CsNO_3$), 2,2′-azinobis(3-ethylbenzothioazoline)-6-sulfonic acid (ABTS), 2,4,6-collidine, and HEPES buffer were purchased from Sigma-Aldrich. Hydrogen peroxide (3%, *w*/*v* stabilized form) was purchased from VWR Canlab.

PS2.M, a guanine-rich aptamer of DNA (deoxyribonucleic acid, 5′-GTG GGT AGG GCG GGT TGG-3′), PS2.M–hemin, DNA–aptamer–hemin complex, rPS2.M, the corresponding RNA (ribonucleic acid) version of PS2.M, were made using standard automated methods.

Titration and catalysis of hemin in the presence of various detergents

Standardized solutions of hemin were prepared as described previously (14, 15). All solutions used for spectral or kinetic measurements contained 0.2 mol/L caesium nitrate. 0.5–0.8 μmol/L hemin solutions (diluted from a 500 μmol/L stock solution in DMSO) were individually prepared in 2-[*N*-morpholino]ethanesulfonic acid (MES) – tris[hydroxymethyl]aminomethane (Tris) buffer (100 mmol/L MES, pH 6.2, 50 mmol/L Tris, DMSO 1%) containing different concentrations of either SDS, TX-100, or $CetMe_3N^+$. These solutions were scanned spectroscopically over the wavelength range of 300–700 nm to determine the detergent concentrations at which hemin aggregation became insignificant (yielding saturated absorption profiles). The so-derived saturating concentrations of each detergent obtained in this way were then used for the kinetic assays, which were carried out in *N*-[2-hydroxyethyl]piperazine-*N*-[2-ethanesulfonic acid] (HEPES)–NH_4OH buffer solutions with HEPES concentrations of 5 and 200 mmol/L and 0.1 μmol/L of hemin. Reactions were initiated by the addition of H_2O_2 and followed by monitoring the appearance of the ABTS radical cation ($ABTS^{+\cdot}$), which absorbs at 414 nm. Spectroscopic and kinetic data were measured using a dual-beam multicell holder Cary 3E spectrophotometer with thermostat controller, at 20 °C

Acid–alkaline transition for hemin complexes

The various buffers used were: pH 2.0–4.0 (glycine–HNO_3), pH 4.6–7.0 (MES–Tris), pH 5.8–8.0 (HPO_4^{2-}–$H_2PO_4^-$), pH 7.0–8.9 (Tris–HNO_3), and pH 8.5–10.5 (glycine–OH^-). The electronic absorption curves of various hemin complexes were found to be consistent at given pH values, although different buffers were used in regions of overlapping pH. All buffer solutions contained 0.1 mol/L caesium nitrate, and 20 mmol/L KCl to ensure proper DNA and RNA folding. KCl was omitted from the solutions containing SDS because even low potassium concentrations caused SDS precipitation. The concentrations of the various hemin complexes were made up to 0.5–0.8 μmol/L hemin with sufficient concentrations of the various detergents, RNA, or DNA oligomers to ensure saturation of the hemin binding.

Buffer catalysis by HEPES and collidine

The kinetics of the reaction of H_2O_2 with hemin and various hemin complexes were determined by following the increase in absorbance of $ABTS^{+\cdot}$ at 414 nm and 20 °C. Buffers were prepared by mixing appropriate amounts of the acid and base species at a fixed pH. Each individual sample was prepared by adding 500 μL of a 2× buffer (also containing 40 mmol/L KCl for proper DNA and RNA folding, and 0.2 mol/L caesium nitrate) to a 500 μL of 2× stock solution (final concentrations: 0.05% T X-100, 1% DMSO, 5 mmol/L ABTS). The final concentrations of hemin and of hemin complexes were ~0.1 μmol/L. Kinetic runs were typically carried out by mixing ~1.4 μL of a 0.44 mol/L solution of H_2O_2 (final 600 μL) to the previously prepared DNA or RNA solutions (1 mL), in a quartz cuvette with 10 mm path length. The experimental curves of A_{414} vs. time were digitized and computer-fitted (GraphPad Prism™ 2.0 software) to obtain pseudo-first-order rate constants (k_{obs}).

Lanthanum-catalyzed aqueous acylation of monosaccharides by benzoyl methyl phosphate[1]

Ian James Gray, Rui Ren, Bernhard Westermann, and Ronald Kluger

Abstract: It was previously reported that diols dissolved in water (pH 8, EPPS buffer) react with benzoyl methyl phosphate (BMP) in the presence of lanthanide ions to form monobenzoyl esters. We have investigated the possibility of extending this process to include formation of esters of monosaccharides in water from lanthanide-catalyzed reactions with BMP. The combination of methyl-α-D-glucopyranoside and BMP in the presence of lanthanum trichloride gave selective monoacylation of the 2- and 6-hydroxyl groups in a ratio of 2:1. The likely mechanism involves preferential bisbidentate coordination of BMP and the diol to lanthanide ion (which explains how an ester forms when water is in enormous excess) followed by base-catalyzed intramolecular acyl transfer. The method should be generally applicable where a selective acylation reaction in water as solvent is desirable.

Key words: benzoyl methyl phosphate, lanthanide, catalysis, water, monoacylation, selective.

Résumé : Il a été rapporté antérieurement que les diols dissous dans l'eau (pH de 8 et tampon « EPPS ») réagissent avec le phosphate de benzoyle et de méthyle (PBM), en présence d'ions de lanthanide, pour conduire à la formation d'esters monobenzoylés. On a examiné la possibilité d'étendre cette méthode de façon à inclure la formation d'esters de monosaccharides, par des réactions en milieu aqueux avec du PBM et catalysées par des lanthanides. La combinaison de l'α-D-glucopyranoside de méthyle et du PBM, en présence de trichlorure de lanthane, conduit à la monoacétylation sélective des groupes hydroxyles en positions 2 et 6, dans un rapport de 2 : 1. Le mécanisme probable implique la coordination bisbidentate préférentielle du PBM et du diol à l'ion lanthanide (qui explique comme un ester peut se former en présence d'un énorme excès d'eau), qui est suivie d'un transfert de groupe acyle intramoléculaire catalysé par la base. La méthode devrait être applicable d'une façon générale quand il est désirable d'effectuer une réaction d'acétylation sélective en utilisant l'eau comme solvant.

Mots clés : phosphate de benzoyle et de méthyle, lanthanide, catalyse, eau, monoacétylation, sélective.

Introduction

We are reporting our work in conjunction with the production of an issue of the *Canadian Journal of Chemistry* honoring Walter Szarek, whose work in the field of biological carbohydrate chemistry exemplifies his insight, perspective, and creativity. In addition, Walter's outstanding personal qualities match his science.

Reactions that accomplish selective monoacylation of carbohydrates take advantage of differences in the inherent reactivity of individual hydroxyl groups (1, 2). For example, monobenzoates result from reactions of *N*-benzoyl imidazole and benzoyl cyanide with protected monosaccharides, provided that the combination of regioselection and product stability is sufficient (3). Subtle differences in the reactivity of hydroxyls and the catalysis of group migration add to the complexity of possible outcomes (4).

Benzoyl methyl phosphate (BMP) is an acyl phosphate monoester, a class of materials that resists hydrolysis and is inherently unreactive toward alcohols (5). Yet, acyl phosphates are anhydrides that have a high chemical potential for acyl transfer and are utilized in diverse biochemical acylation, including the formation of aminoacyl tRNAs. It was recently reported that BMP can form monobenozyl esters from diols in water in the presence of lanthanide ions (6). It is likely that bidentate coordination is the key to the selective acylation reaction since under similar conditions there is only a modest acceleration of base-catalyzed hydrolysis and formation of methyl esters (in methanol–water mixtures) (7). The likely mechanism is consistent with Clarke et al.'s (8) observations of lanthanide-promoted monoacetylation of diols in nonhydroxylic solvents. They reported NMR data that characterized an intermediate bisbidentate-coordinated complex of the lanthanide with a diol and an anhydride. Ionization of a coordinated hydroxyl in such an intermediate leads to Lewis acid promoted intramolecular attack on the adjacent carbonyl of the coordinated anhydride to form the ester (7).

Based on this background, we have been interested in extending the utility of BMP as a water-stable benzoylating agent whose inherent specificity would be associated with

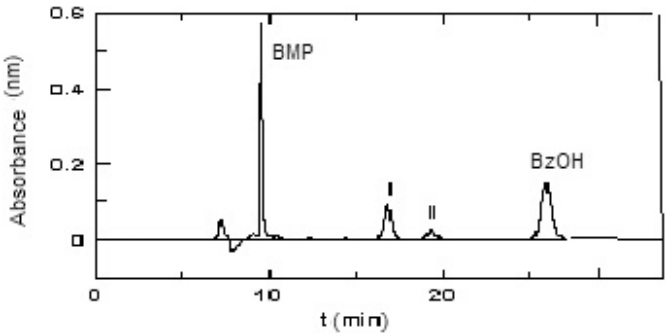
the formation of lanthanide chelates from adjacent hydroxyls of the reactant, a description that could find useful applications in the carbohydrate field. Applications of lanthanide catalysis of reactions by acyl phosphate monoesters would be expected to provide for selection among hydroxyl groups based on the properties of their lanthanide chelates, rather than on the inherent differences of reactivity among the hydroxyl groups of the substrate. We have now investigated the reactions of typical monosaccharides with BMP and lanthanide ions and find that this combination can introduce chelation-based selectivity in monobenzoylation reactions conducted in water.

Experimental

Reagent grade chemicals were used as received. High-resolution mass spectrometry was performed at the QStar Chemistry Mass Spectral Facility, University of Toronto. HPLC analysis and preparation were performed with C18 reversed-phase analytical columns (Waters μBondapak™ C18 3.9 mm × 300 mm) and preparative columns (Waters μBondapak™ C18 7.8 mm × 300 mm). Samples were eluted with purified water and HPLC grade acetonitrile. Benzoyl methyl phosphate (BMP) was prepared by the previously reported procedure (6, 9). Acylation of the carbohydrates was followed by HPLC, detected at 230 nm on a C18 reverse-phase analytical column, and eluted with 75:25 (*v*/*v*) water–acetonitrile containing 0.1% trifluoroacetic acid (TFA). The flow rate was 1.5 mL/min. Solvents were filtered and degassed before use. The ratio of acylation and hydrolysis from BMP was determined from the relative molar amounts of reactants (carbohydrate:water) to their corresponding products (ester:acid), according to eq. [1]. The ratio of products was obtained from the areas of the HPLC peaks for the resulting esters and benzoic acid.

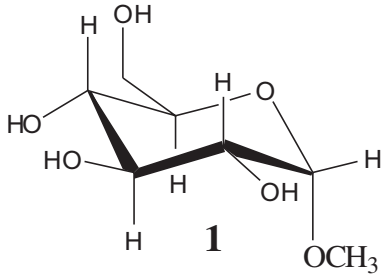
$$[1] \qquad k_{rel} = (\text{Area}_{ester}/\text{Area}_{acid}) \times ([H_2O]/[\text{carbohydrate}])$$



Separation of the ester products by was performed by HPLC. The effluent was continuously monitored at UV 230 nm on a C18 reverse-phase preparative column. The material in each product peak was freeze-dried and stored at –20 °C. The general structure was ascertained from the mass spectrum and refined by NMR analysis.

Methyl 4,6-*O*-benzylidene-α-D-glucopyranoside was obtained commercially. Methyl 4,6-*O*-benzylidene-α-D-mannopyranoside was prepared by the published method (10, 11).

Benzoylation of methyl-α-D-glucopyranoside (1) using BMP



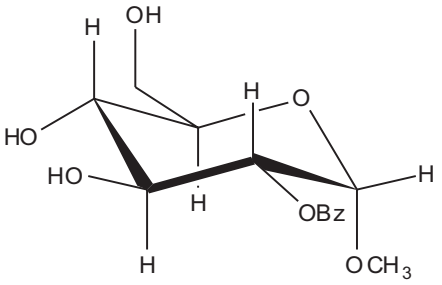
One equivalent of **1** and 2 equiv. of lanthanum trichloride were dissolved in 100 mmol/Lof EPPS buffer at pH 8. Freshly prepared BMP (1 equiv.) was added to this solution and stirred at room temperature. The reaction was monitored by HPLC (quenched with buffer (pH 8) containing EDTA at time points) and was complete within about 2 h. The disappearance of the BMP peak signified its conversion into benzoic acid and benzoyl ester products. Relative yields were calculated using internal standards.

Fig. 1. HPLC output for lanthanum-promoted reaction of BMP and **1**.

Results and discussion

Our initial studies focused on the monobenzoylation of methyl-α-D-glucopyranoside (**1**) with the intention of establishing a general procedure that extends to the monobenzoylation of other monosaccharides.

As expected, combining **1** with BMP in 100 mmol/L of EPPS (pH 8) without added lanthanum ion produces no reaction. Under the same conditions with added lanthanum, three new HPLC peaks are observed within 1 min (Fig. 1). We optimized reaction conditions by varying the concentration and found that 2 equiv. of lanthanum trichloride and 1 equiv. each of BMP and carbohydrate in 100 mmol/L of EPPS buffer at pH 8, produced a 33% conversion to the product esters within 2 h, while the remaining substrate could be recovered and BMP was hydrolyzed.



Each product was separated by preparative HPLC. ESI-MS analysis revealed two of the peaks to be monobenzoyl esters of **1**, while the third was that of benzoic acid from the hydrolysis of BMP.

The stability of the esters in the reaction solution was observed over several days in the reaction solution. Product ratios were invariant, indicating that the hydrolysis of the benzoate esters is not promoted by the metal ions in the solution under these conditions. We have noted that lanthanum ions promote formation of monoesters from cis-diols by BMP in water (6). In **1**, the geometry of adjacent diols is constrained by the ring and this will affect coordination as well as the reactions of the coordinated species. The primary hydroxyl (6-position) and equatorial hydroxyl groups at positions 2, 3, and 4 are all potential candidates for benzoylation. Each of the products peaks was isolated to determine the pattern of the reaction.

Ester B	99.59	71.62	73.18	70.15	69.59	**64.33**

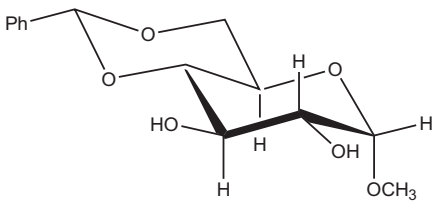
Ester A

Ester B

Table 2. Relative rates of acylation and hydrolysis in EPPS buffer (pH 8) with 50 mmol/L of lanthanum trichloride, 25 mmol/L of BMP, and 25 mmol/L of carbohydrate.

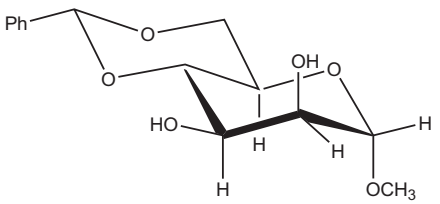
Carbohydrate	Time (min)	k_{rel} (25 °C)	k_{rel} (0 °C)
Methyl-α-D-mannopyranoside	60	50	100
Methyl-α-D-glucopyranoside	60	370	730
Methyl-β-D-galactopyranoside	60	800	1 310
D-Ribose	60	8800	11 330

Analysis of the ^{13}C NMR spectra of the products (Table 1) indicate that reaction occurs at 2-OH and 6-OH preferentially.



Due to competition with water, used as a solvent for the reaction, it is inevitable that BMP hydrolysis accompanies the monoacylation reaction. We found that hydrolysis was significantly less competitive at low temperatures (Table 2). The same carbohydrate reaction preferences hold at the lower temperatures, with ester formation being the major process.

In order for the reaction with BMP with the monosaccharide to compete with hydrolysis, the possibility of bidentate coordination must overwhelm the effect of overwhelmingly large excess of reaction sites in the water that serves as the solvent. To test this further, we proposed that no reaction would occur if the 6-hydroxyl is blocked, which would prevent the possibility of bidentate coordination. We used methyl-4,6-*O*-benzylidene-α-D-glucopyranoside and methyl-4,6-*O*-benzylidene-α-D-mannopyranoside. No ester formation occurs after 5 days with BMP and lanthanum trichloride under conditions where **1** reacts rapidly. This result supports the NMR-based analysis for reaction of **1**. More detailed product studies are in progress.



We have also done a preliminary survey of the reaction patterns of BMP and lanthanum trichloride with other monosaccharides (Table 3). From these results we see that the monobenzoylation process is applicable to a variety of species with varying efficacy: D-ribose > methyl-β-D-galactopyranoside > methyl-α-D-glucopyranoside > methyl-α-D-mannopyranoside.

For the reactants in Table 3, D-ribose gives the highest overall yield of ester products. However, we have not yet identified the individual monobenzoylated materials (there are three in all). The reaction of 2-deoxyribose leads to only two products, suggesting that one of the chelates involves the 2-OH. Two monobenzoylated esters were produced from uridine. There was no reaction with 2-deoxyuridine, as would be expected if 2,3-chelation is the major mode of reaction. The other aldohexose methyl pyranosides reacted similarly to the glucoside, giving two monobenzoylated products.

A probable mechanism, illustrated with methyl-α-D-glucopyranoside, is shown in Scheme 1. This involves internal addition from the conjugate base of the bisbidentate chelate of the lanthanide and the two reactants (7, 8), as has been shown in reactions of diol substrates.

[a]Relative yields were calculated from HPLC analysis.

Scheme 1. Proposed mechanism for the monobenzoylation of **1**.

Conclusions

We have for the first time shown that lanthanide-promoted monoesterification reactions of monosaccharides in water can be achieved by the reaction of an acyl phosphate monoester with lanthanum chloride. Products form from both hexoses and pentoses. NMR analysis indicated that the methyl-α-D-glucopyranoside (**1**) was benzoylated at the 2-oxygen and 6-oxygen in a ratio of 2:1. Since the 6-position is primary and the 2-position is secondary, it is clear that steric effects do not control the site of the reaction and that the geometry of the transition state is controlled by the coordination of the reacting complex. We intend to determine in further detail the scope, selectivity, and optimal conditions for this interesting new process. This approach should also be amenable to detection of species in complex mixtures and differential recognition, as well as for general synthetic applications.

Stereoselective synthesis of chiral piperidine derivatives employing arabinopyranosylamine as the carbohydrate auxiliary[1]

Birgit Kranke and Horst Kunz

Abstract: Stereoselective synthesis of 2-substituted dehydropiperidinones and their further transformation to variously disubstituted piperidine derivatives was achieved employing D-arabinopyranosylamine as the stereodifferentiating carbohydrate auxiliary. A domino Mannich–Michael reaction of 1-methoxy-3-(trimethylsiloxy)butadiene (Danishefsky's diene) with O-pivaloylated arbinosylaldimines furnished *N*-arabinosyl dehydropiperidinones in high diastereoselectivity. Subsequent conjugate cuprate addition gave 2,6-cis-substituted piperidinones, while enolate alkylation furnished 2,3-trans-substituted dehydropiperidinones. Electrophilic substitution at the enamine structure afforded 5-nitro- and 5-halogen dehydropiperidinones of which the latter were applied in palladium-catalyzed coupling reactions. The absolute configuration of the obtained products was proven by NMR and X-ray structure analysis as well as by syntheses of the alkaloids (+)-coniine and (+)-dihydropinidine.

Key words: piperidine alkaloids, carbohydrate auxiliary, domino Mannich–Michael reaction, conjugate cuprate and hydride addition, electrophilic substitution of enamines.

Résumé : On a réalisé la synthèse stéréosélective de déhydropipéridones substituées en position 2 et leur transformation subséquente en divers dérivés disubstitués de la pipéridine en utilisant de la D-arabinopyranosylamine comme hydrate de carbone auxiliaire permettant de faire une stéréodifférenciation. Une réaction de Mannich–Michael en domino du 1-méthoxy-3-(triméthylsiloxy)butadiène (réactif de Danishefsky) avec de *O*-pivaloyl-arbinosylaldimines conduit à la formation de *N*-arabinosyl déhydropipéridinones avec une grande diastéréosélectivité. Une addition subséquente conjuguée de cuprate fournit les pipéridinones 2,6-cis-substituées alors qu'une alkylation de l'énolate conduit déhydropipéridinones aux 2,3-trans-substituées. Une substitution électrophile de la structure énamine conduit aux 5-nitro- et 5-halogéno-déhydropipéridinones; ces dernières ont par la suite été utilisées dans des réactions de couplage catalysées par le palladiium. La configuration absolue des produits obtenus a été démontrée par RMN et par diffraction des rayons X ainsi que par synthèse des alcaloïdes (+)-coniine et (+)-dihydropinidine.

Introduction

Due to their great diversity in biological and pharmacological activities (1), piperidine alkaloids and synthetic piperidines containing various substitution patterns are considered interesting target structures for drug development. Therefore, these heterocyclic structures are the subject of numerous synthetic, often stereoselective approaches (2).

During the past years, we have developed a strategy for the enantioselective synthesis of piperidine alkaloids using glycosylamines as chiral auxiliaries (3, 4). In this approach, steric, stereoelectronic, and complexing effects of carbohydrates are exploited for diastereofacial differentiation of nucleophilic additions to *N*-glycosyl aldimines. It is a special feature that this methodology offers the possibility of synthesizing both enantiomeric series of chiral piperidines by varying the carbohydrate auxiliary, e.g., employing the (pseudo-)enantiomeric carbohydrates, D-galactosylamine (3) and D-arabinosylamine (4), respectively. Herein, we report full experimental details for the application of D-arabinosylamine **1** in the stereoselective synthesis of 2-substituted *N*-arabinosyl dehydropiperidinones **4** and their subsequent regioselective and stereoselective modification in the preparation of variously substituted piperidines.

talysis furnished *N*-arabinopyranosylimines **2**. These aldimines reacted with 1-methoxy-3-(trimethylsiloxy)butadiene (Danishefsky's diene, **3**) in a domino Mannich–Michael reaction promoted by zinc chloride to give *N*-(2,3,4-tri-*O*-pivaloyl-α-D-arabinopyranosyl)-5,6-didehydropiperidin-4-ones (**4**) in high yields and high diastereoselectivity (Scheme 1, Table 1).

The stereochemical course of the reaction and hence the configuration of the nitrogen heterocycle in **4** was controlled by the sterically demanding pivaloyl group at C-2 of the carbohydrate auxiliary, which effectively shields the si side of aldimine **2**. Thus, the initial step in the domino Mannich–Michael reaction consists of the nucleophilic addition of Danishefsky's diene **3** at the re side of glycosyl imine **2**.

In contrast, in galactosyl imines **5** reported earlier (3) the re side is efficiently blocked by the C-2 pivaloyl group, leading to *N*-galactosyl dehydropiperidinones **6** bearing the opposite configuration at position 2 of the nitrogen heterocycle (Scheme 2). This is due to the fact that although arabinosylamine belongs to the D series of carbohydrates, it displays almost the mirror image of D-galactosylamine. Thus, by using either D-galactosylamine or its pseudoenantiomer, D-arabinosylamine, enantiomeric dehydropiperidinones are accessible offering the possibility of synthesizing both enantiomers of piperidines by choosing the appropriate auxiliary.

The absolute configuration of the *N*-arabinosyl dehydropiperidinones was proven by X-ray analysis showing **4f** to have (*S*)-configuration (Fig. 1). This compound preferably adopts a conformation in which the planes of the nitrogen heterocycle and the carbohydrate are almost perpendicular to each other allowing optimal overlap of the nonbonding orbital of the nitrogen and the σ* orbital of the C—O bond within the carbohydrate ring (exo-anomeric effect).

Conversion of *N*-arabinosyl dehydropiperidinone **4f** into the well-known alkaloid (*S*)-coniine **10** gave rise to further evidence of the absolute configuration of the nitrogen heterocycle in **4f**, and in addition, demonstrated the applicability of the shown reaction strategy for the stereoselective preparation of chiral 2-substituted piperidine alkaloids. Coniine is a highly toxic alkaloid leading to central respiratory paralysis and was the first alkaloid synthesized chemically (Ladenburg, 1886). In our auxiliary-mediated synthesis, the double bond of *N*-arabinosyl-2-propyl-5,6-

Scheme 3. Synthesis of enantiomerically pure (+)-(6*R*)-coniine hydrochloride.

Derivatization of *N*-arabinosyl dehydropiperidinones

N-Arabinosyl dehydropiperidinones **4** represent versatile precursors for the synthesis of variously substituted nitrogen heterocycles, e.g., the regioselective and stereoselective preparation of 2,6-, 2,5-, and 2,3-disubstituted piperidines.

2,6-cis-Disubstituted piperidines

N-Arabinosyl dehydropiperidinones **4** are α,β-unsaturated carbonyl compounds. Their reactivity as Michael acceptors is reduced because of the vinylogous amide structure. However, cuprate addition was accomplished by activation with hard electrophiles. For example, reaction of Yamamoto cuprates (6) activated by boron trifluoride diethyletherate ($RCu{\cdot}BF_3$) or of Gilman cuprates (8) (R_2CuLi) in combination with chlorotrimethylsilane (7) resulted in the formation of 2,6-cis-disubstituted piperidinones **11** with high diastereoselectivity (Scheme 4, Table 2).

The cis configuration was confirmed by X-ray analysis of **11a** (Fig. 2). The nitrogen heterocycle adopts a twisted conformation with the smaller substituent in axial position, the larger substituent in equatorial position, and a pyramidally configured nitrogen atom. The alignment of the two heterocycles is stabilized by the exo-anomeric effect (compare, Fig. 1).

The observed cis stereoselectivity of the 1,4-addition can be explained by stereoelectronic effects using the X-ray structure of **4f**. Two rotamers A and B, stabilized by the exo-anomeric effect, are expected for *N*-arabinosyl dehydropiperidinones **4** (Scheme 5). Compared with rotamer A, rotamer B benefits from a smaller steric hindrance between the substituent in position 2 of the nitrogen heterocycle and the pivaloyl group at C-2 of the carbohydrate. Thus, the backside of the nitrogen heterocycle is shielded by this pivaloyl group, and the front-side attack of the cuprate results in the favoured cis-substitution pattern.

Enantiomerically pure (+)-dihydropinidine was synthesized to demonstrate the applicability of *N*-arabinosyl dehydropiperidinones **4** in the stereoselective synthesis of cis-2,6-disubstituted piperidine alkaloids. For this purpose, piperidinone derivative **11e** was converted into dithiolane **13** and subsequently treated with Raney nickel to form *N*-arabinosyl piperidine **14**. The enantiomerically pure alkaloid

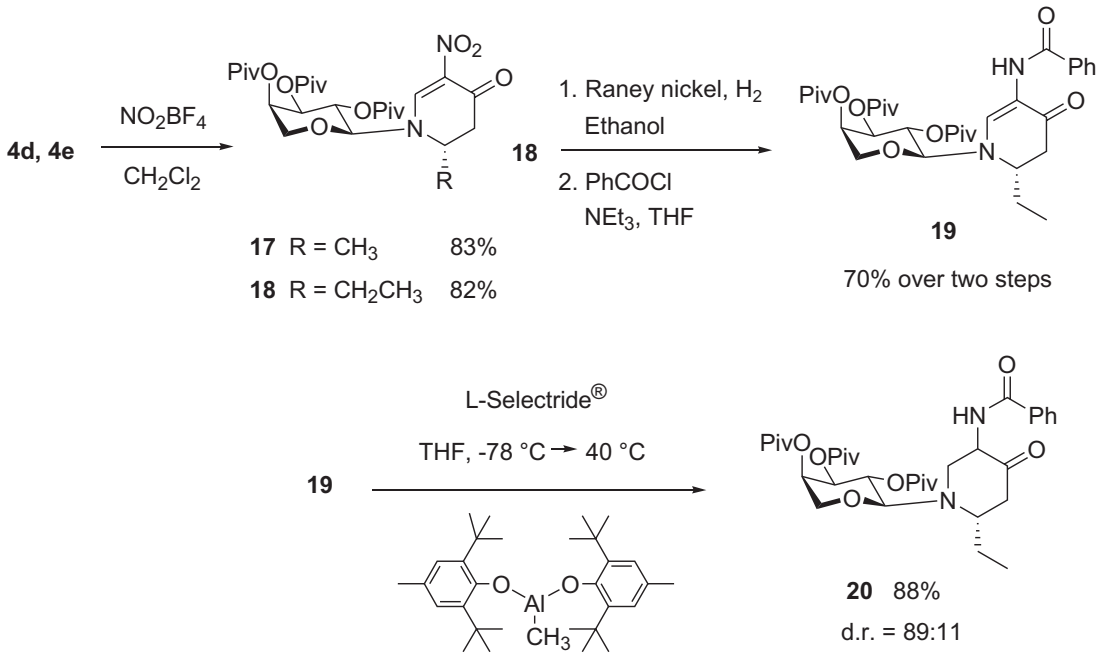
hydrochloride **15** was released from the carbohydrate by mild acidolysis with dilute HCl in methanol (Scheme 6). The optical rotation value was in agreement with literature data (9) and confirmed the absolute configuration.

2,5-Disubstituted piperidines

Due to their enamine structure, *N*-arabinosyl dehydropiperidinones **4** are capable of adding electrophiles. Regeneration of the stable conjugated enaminone π system by abstraction of a proton subsequently leads to 2,5-disubstituted dehydropiperidinones **16** (Scheme 7).



In terms of this electrophilic substitution, nitration of **4d** and **4e** was achieved in high yields using nitronium tetrafluoroborate applied as a solution in sulfolane allowing convenient handling of this air sensitive reagent (Scheme 8). Sulfolane can easily be separated from products **17** and **18**, respectively, by washing with water.

Reduction of the nitro group furnished an aminoketone, whose functionality is known to serve as precursor for syntheses of pharmacological important patterns like heterocycles, carbamates, or amides. Successful hydrogenation was achieved with Raney nickel, whereas reduction conditions such as zinc in hydrochloric acid or hydrogen and palladium on charcoal could not be applied. Immediate reaction of the sensitive amine with benzoyl chloride and triethylamine in ethanol gave the *N*-acyl compound **19** (Scheme 8).

N-Arabinosyl dehydropiperidinones that bear no substituent at C-5 of the nitrogen heterocycle, such as **4**, can be completely transformed into the corresponding piperidinones using L-Selectride®. This hydride reagent selectively reduces the double bond of the α,β-unsaturated carbonyl function in terms of a 1,4-addition without affecting the keto function in terms of a 1,2-addition. Using these reaction conditions for the hydrogenation of dehydropiperidinone **19**, a conversion of only 50% of the starting material was observed. Addition of further equivalents of L-Selectride® did not improve the conversion, but reduced already formed piperidin-4-one **20** to the 4-hydroxypiperidine. In contrast, complete chemoselective addition of the hydride was achieved applying an excess L-Selectride® in the presence of the sterically demanding Lewis acid methylaluminum bis(2,6-di-*tert*-butyl-4-methylphenoxide) (MAD). This reagent has been shown to induce 1,4-addition of organolithiums to α,β-unsaturated ketones (10) and to enable the chemoselective reduction of the double bond of polymer-bound galactosyl dehydropiperidinones (11). The oxygenophilic Lewis acid effectively shields the keto function and, thus, favours the selective hy-

Scheme 8. Nitration of *N*-arabinosyl dehydropiperidinones and subsequent reduction of the obtained products.

dride addition at the β-position even by application of an excess of L-Selectride® for complete conversion of the starting material (Scheme 8).

N-Bromo succinimide and *N*-iodo succinimide were used in electrophilic substitution reactions at the enamine structure of *N*-arabinosyl dehydropiperidinones **4** to furnish halogenated compounds **21** in high yields (Scheme 9, Table 3).

Halogenated dehydropiperidinones **21** constitute vinyl halides capable of reacting in metal-catalyzed coupling reactions. In this way, piperidine derivatives with functionalized aryl substituents at C-5 were accessible. It turned out that iododehydropiperidinones **21** were more suitable in palladium-catalyzed syntheses than the bromo-substituted derivatives. Thus, in Stille reactions (12) applying bromodehydropiperidinone **21g** and phenyltributyl tin, 68% conversion of the starting material was observed after 24 h, while iododehydropiperidinone **21a** reacted faster and was completely consumed under these conditions, although product **22** was isolated in only moderate yield (Scheme 9).

Since boronic acids benefit from a much lower toxicity and an insensitivity to water compared with the tin reagents used in Stille-type reactions, Suzuki–Miyaura coupling conditions (13) were also applied for the synthesis of 5-aryl piperidine derivatives. Reaction of dehydropiperidinone **21c** with *p*-methoxybenzene boronic acid under palladium catalysis resulted in the formation of **23**. The reaction conditions have not yet been optimized (Scheme 9).

Even though the reaction conditions require further optimization, it appears that palladium-catalyzed reactions at C-5 of *N*-arabinosyl dehydropiperidinones **21** suffer from the sterically demanding auxiliary hampering the palladium complex from reaching the reaction site. However, the presented method provides access to 2,5-disubstituted piperidine derivatives containing pharmacologically valuable functionalized aryl substituents.

2,3-trans-Disubstituted N-*arabinosyl dehydropiperidinones*

Functionalization of *N*-arabinosyl dehydropiperidinones **4** at C-3 was achieved by deprotonation with strong bases and subsequent reaction with electrophiles. For this purpose, **4** was treated with lithium bis(trimethylsilyl)amide (LiHMDS), and the intermediate enolate was reacted with alkylhalides to afford 2,3-trans-disubstituted *N*-arabinosyl dehydropiperidinones **24** in high yields (Scheme 10, Table 4).

The coupling constant of product **24a** ($J_{H\text{-}2,H\text{-}3}$ = 11.7 Hz) determined by ^{1}H NMR spectroscopy indicated that these two protons are positioned in an antiperiplanar alignment, while the methyl group, as well as the aryl substituent, are arranged trans to each other and in an equatorial position. The stereoselectivity of the reaction can be explained by assuming that deprotonation of **4** forms a 6π-electron system resulting in an additional flattening of the dehydropiperidinone. The axial position of the substituent at C-2 induces a diastereofacial differentiation of the enolate favouring an attack of the electrophile from the sterically less-hindered side, i.e., trans to the first substituent resulting in the formation of the 2,3-trans-disubstituted compounds **24**.

Conclusions

The described results show that chiral piperidine derivatives of varying substitution patterns, valuable as building blocks for the construction of drugs and natural products, can stereoselectively be synthesized using α-D-arabinopyranosylamine (**1**) as the chiral auxiliary. Imines **2** of **1** undergo domino Mannich–Michael reaction sequences to furnish 2-substituted 5,6-dihydropiperidinones **4** with excellent diastereoselectivity. These compounds are substrates to a versatile modification of the piperidine structure (*i*) by conjugate addition of cuprates to give 2,6-cis-disubstituted piperidinones **11** with high stereoselectivity, (*ii*) to 5-

[a]Determined by ^1H NMR.

Experimental

General methods

^1H NMR and ^{13}C NMR spectra were recorded on Bruker AC-200, AC-300, or AM-400 spectrometers. Mass spectra were recorded on a Navigator-1 ESI mass spectrometer (ThermoQuest) and a Finnigan MAT 95 spectrometer. Optical rotation values were measured on a PerkinElmer 241 polarimeter. Analytical HPLC were performed with a Phenomenex Luna C18 (2) column (5 μ, 250 mm × 4.6 mm).

Materials

THF was distilled over potassium benzophenone ketyl and CH_2Cl_2 over calcium hydride. 2,3,4-Tri-*O*-pivaloyl-α-D-arabinosylamine (**1**) was synthesized according to the literature procedure (5). Aldehydes used for imine formation were distilled prior to use. A solution of zinc chloride in THF was prepared by melting $ZnCl_2$ under high vacuum and dissolving it in dry THF after recooling. Diene **3** was prepared from 4-methoxybut-3-ene-2-one by the silylation procedure given by Danishefsky and Kitahara (14) followed by repeated careful distillation at moderate temperature (oil bath temperature has to be kept below 70 °C). TLC was performed on

Merck silica gel 60 F_{254} aluminum sheets. Flash chromatography was carried out with ICN Biomedicals silica gel (40–63 μm mesh).

General procedure for the synthesis of *N*-arabinosyl imines 2

Method A (aromatic aldehydes)

The aromatic aldehyde (12 mmol) and acetic acid (12 drops) were added to a solution of amine **1** (10 mmol) in isopropanol (20 mL) and heated to 80 °C for 3 h. The mixture was cooled and kept at 4 °C overnight. The crystallized product was filtered and washed with ice-cold isopropanol. Concentration of the mother liquor provided further amounts of product. The combined samples were, if necessary, recrystallized from *n*-heptane. Characterization was carried out upon the *N*-arabinosyl dehydropiperidinones **4**.

Method B (aliphatic aldehydes)

The aliphatic aldehyde (12 mmol) was added dropwise to a mixture of amine **1** (10 mmol), *n*-pentane (60 mL), and dried molecular sieves (6 g, 4 Å) and stirred for 36 h at room temperature. Filtration through Hyflo® and removal of the solvent in vacuo yielded an amorphous solid, which was used without further purification. Characterization was carried out upon the *N*-arabinosyl dehydropiperidinones **4**.

General procedure for the synthesis of *N*-arabinosyl dehydropiperidinones 4

A solution of $ZnCl_2$ in dry THF (1 mol/L, 11 mL) was added to a solution of imine **2** (10.0 mmol) in dry THF (50 mL) at –78 °C and stirred for 10 min. Danishefsky's diene **3** (2.5 mL, 12.5 mmol) was added. After stirring for 30 min, the solution was allowed to warm to –20 °C. After complete consumption of the starting material (1 to 2 days), the reaction was terminated by addition of 1 N aq. HCl (10 mL). THF was evaporated in vacuo, the residue was dissolved in diethyl ether, and the layers were separated. The organic layer was washed with satd. aq. $NaHCO_3$ (3 × 50 mL), 10% aq. Titriplex III® (2 × 50 mL) and brine, dried over $MgSO_4$, and concentrated.

ESI-MS for $C_8H_{18}ClN$ *m/z*: 128.1 [M – Cl]$^+$, 291.2 [2M(^{35}Cl) – Cl]$^+$, 293.1 [M(^{37}Cl) – Cl]$^+$.

General procedure for the addition of R′Cu·BF_3 complexes to enaminones

The solution of the corresponding Grignard reagent in THF or diethyl ether was added to a suspension of copper salt (1 mmol) in dry THF (5–10 mL) at the temperature given for the corresponding cuprate (given in the following) and stirred until the cuprate was formed (time and change in colour for each compound is given in the following). Subsequently, the cuprate was cooled to –78 °C, $BF_3{\cdot}OEt_2$ (1 mmol) was added and the mixture stirred for 15 min. Dehydropiperidinone **4** in dry THF (20 mL per mmol piperidinone) was added dropwise, and the mixture was stirred for 15 h. In general, a slow increase of temperature was required for complete consumption of the starting material. The reaction was terminated by addition of concd. NH_4OH – satd. NH_4Cl (1:1 *v*/*v*). The mixture was warmed to room temperature (r.t.), diluted with diethyl ether (20 mL), and the layers were seperated. The organic layer was washed with concd. NH_4OH – satd. NH_4Cl (1:1 *v*/*v*), washed with brine and dried over $MgSO_4$. The solvent was removed in vacuo, and the residue was purified by flash chromatography.

*(2*R*,6*S*)*-*N*-*(2′,3′,4′-Tri*-O-*pivaloyl-*α*-*D*-*arabinopyranosyl)-2-(*p*-*chlorophenyl)-6-phenylpiperidin-4-one (11a)*

Piperidinone **11a** was prepared from **4a** (592 mg, 1.0 mmol) according to the general procedure. For the formation of the beige cuprate solution, CuI (952 mg, 5 mmol) and phenylmagnesium bromide (1 mol/L in THF, 5 mL) were treated in THF (30 mL) at –78 °C for 1 h. Purification of **11a** was achieved by flash chromatography (petroleum ether – ethyl acetate, 14:1 → 10:1). Yield: 484 mg (0.7 mmol, 72%); colourless solid; mp 179 °C. X-ray analysis: space group, *P*1 (triklin); lattice parameters: a = 10.1869(6) Å, b = 13.1017(12) Å, c = 15.5126(12) Å, V = 1901.1(3) Å^3, Z = 2, F(000) = 716; diffractometer, CAD4 Enraf Nonius; irradiation, Cu K_α graphite monochromator.[3] R_f 0.55 (petroleum ether – ethyl acetate, 3:1). $[\alpha]^{25}_D$ –35.44° (*c* 1, $CHCl_3$); d.r.: 99:1 (HPLC: 80% CH_3CN, 20% H_2O → 100% CH_3CN, 20 min). ^{1}H NMR (200 MHz, $CDCl_3$, ppm) δ: 7.50–7.15 (m, 9H, aryl), 5.36 (t, 1H, $J_{H\text{-}2',H\text{-}1'}$ = 9.5 Hz, $J_{H\text{-}2',H\text{-}3'}$ = 9.5 Hz, H-2′), 5.15–5.00 (m, 2H, H-4′, aryl-C*H*-N), 4.90–4.50 (m, 2H, H-3′, aryl-C*H*-N), 4.24 (d, 1H, $J_{H\text{-}1',H\text{-}2'}$ = 9.3 Hz, H-1′), 3.97 (dd, 1H, $J_{H\text{-}5'a,H\text{-}5'b}$ = 12.9 Hz, $J_{H\text{-}5'a,H\text{-}4'}$ = 2.2 Hz, H-5′a), 3.51–3.25 (m, 2H, H-5′, CH_2C=O), 2.86 (dd, 1H, $J_{gem.}$ = 16.1 Hz, $J_{vic.}$ = 2.4 Hz, CH_2C=O), 2.61 (dd, $J_{gem.}$ = 18.1 Hz, $J_{vic.}$ = 12.7 Hz, CH_2C=O), 2.41 (dd, 1H, $J_{gem.}$ = 18.3 Hz, $J_{vic.}$ = 3.7 Hz, CH_2C=O), 1.26, 1.08, 1.01 (3s, 27H, piv-CH_3). ^{13}C NMR (50.3 MHz, $CDCl_3$, ppm) δ: 208.0 (C-4), 177.5, 177.2, 175.3 (pivC=O), 144.1, 140.5, 133.8, 129.1, 128.6, 127.1, 126.3 (Aryl), 90.3 (C-1′), 72.9, 68.7, 66.3 (C-2′, C-3′, C-4′), 65.2 (C-5′), 58.3, 53.4 (C-2, C-6), 47.5, 46.4 (C-3, C-5), 39.0, 38.7, 38.6 (pivC$_{quart.}$), 27.2, 27.0 (piv-CH_3). *(2**R**,6**S**)-**N**-(2′,3′,4′-Tri-**O**-pivaloyl-α-D-arabinopyranosyl)-2-methyl-6-**n**-propylpiperidin-4-one (11e)*

A solution of methyllithium in diethyl ether (1.6 mol/L, 9.6 mL, 15.4 mmol) was added dropwise to a cold (–35 °C) suspension of CuI (1.50 g, 8.0 mmol) in dry THF (40 mL). The mixture was warmed to –25 °C in 2 h. During this time, the initially yellow solid was dissolved upon formation of a colourless solution, which was then cooled to –78 °C. Piperidinone **4f** (2.51 g, 4.8 mmol) and TMSCl (3 mL) in dry THF (80 mL) were added and the colour changed to yellow and finally to orange. The reaction mixture was allowed to warm to r.t. within 14 h. The reaction was terminated by addition of concd. NH_4OH – satd. NH_4Cl (1:1 *v/v*) (72 mL), and the mixture was diluted with diethyl ether (250 mL). The organic layer was washed with brine, dried over $MgSO_4$, and concentrated in vacuo to yield silylenol ether **12** as an amorphous solid. It was dissolved in THF (48 mL) and a solution of tetrabutylammonia fluoride in THF (1 mol/L, 7.2 mL, 7.2 mmol) was added and the mixture was stirred until **12** was consumed. The solvent was removed in vacuo, the residue was dissolved in diethyl ether (240 mL), washed with water (100 mL) and brine (100 mL), and dried over $MgSO_4$. The solvent was evaporated in vacuo and the residue was purified by flash chromatography (petroleum ether – ethyl acetate, 5:1) to yield **11e** as a colourless crystalline solid (2.28 g, 4.2 mmol, 88%); mp 162 °C. R_f 0.46 (petroleum ether – ethyl acetate, 3:1). $[\alpha]^{25}_D$ –6.11° (*c* 1, $CHCl_3$); d.r.: 91:9 (HPLC of the crude product), HPLC: 80% CH_3CN, 20% H_2O → 100% CH_3CN, 20 min). ^{1}H NMR (200 MHz, $CDCl_3$, ppm) δ: 5.48 (t, 1H, $J_{H\text{-}2',H\text{-}1'}$ = 9.5 Hz, $J_{H\text{-}2',H\text{-}3'}$ = 9.5 Hz, H-2′), 5.20–5.10 (m, 1H, H-4′), 5.06 (dd, 1H, $J_{H\text{-}3',H\text{-}2'}$ = 9.8 Hz, $J_{H\text{-}3',H\text{-}4'}$ = 3.4 Hz, H-3′), 4.23 (d, 1H, $J_{H\text{-}1',H\text{-}2'}$ = 9.3 Hz, H-1′), 3.93 (dd, $J_{H\text{-}5'b,H\text{-}5'a}$ = 13.2 Hz, $J_{H\text{-}5'b,H\text{-}4'}$ = 2.0 Hz, H-5′b), 3.85–3.70, 3.45–3.25 (2m, each 1H, H-2, H-6), 3.55 (d, 1H, $J_{H\text{-}5'a,H\text{-}5'b}$ = 12.7 Hz, H-5′a), 2.78 (dd, 1H, $J_{H\text{-}3a,H\text{-}3b}$ = 15.1 Hz, $J_{H\text{-}3a,H\text{-}2}$ = 6.8 Hz, H-3a), 2.62 (dd, 1H, $J_{H\text{-}3b,H\text{-}3a}$ = 15.1 Hz, $J_{H\text{-}3b,H\text{-}2}$ = 5.9 Hz, H-3b), 2.27 (dd, 1H, J_{gem} = 15.6 Hz, $J_{vic.}$ = 6.8 Hz, H-5a), 2.25–2.10 (m, 1H, H-5b), 1.70–1.50 (m, 1H, propyl-CH_2), 1.50–1.00 (m, 33H, piv-CH_3, CH_3, propyl-CH_2), 0.86 (t, 3H, J = 7.1 Hz, propyl-CH_3). ^{13}C NMR (50.3 MHz, $CDCl_3$, ppm) δ: 210.7 (C-4), 177.4, 177.2, 176.8 (pivC=O), 94.7 (C-1′), 72.2, 68.7, 66.4 (C-2′, C-3′, C-4′), 65.2 (C-5′), 58.7, 48.9 (C-2, C-6), 47.3, 44.3 (C-3, C-5), 40.3 (propyl-CH_2), 38.9, 38.7 (pivC$_{quart.}$), 27.2, 27.1, 27.1 (piv-CH_3), 24.5 (CH_3), 19.8 (propyl-CH_2), 14.0 (propyl-CH_3). N-*(2′,3′,4′-Tri*-O-*pivaloyl-*α-*D-arabinopyranosyl)-5-benzamido-2-ethylpiperidin-4-one (20)*

(a) Preparation of the aluminum complex MAD

At r.t., trimethylaluminium (2 mol/L in toluene, 0.1 mL) was added to a solution of 2,6-di-*tert*-butyl-4-methylphenol (86 mg, 0.39 mmol) in toluene (3 mL) and stirred until the methane evolution ceased (30 min).

(b) Conjugate hydride addition

The clear solution preapared under (*a*) was cooled to –78 °C and a solution of **19** (25 mg, 0.04 mmol) in THF (2 mL) was added dropwise. After 15 min, L-Selectride® (1 mol/L in THF, 0.08 mL) was added at the same temperature, and the mixture was then allowed to warm to –40 °C within 3 h. The reaction was terminated by addition of acetic acid (0.05 mL), and the solvent was evaporated in vacuo. The residue was dissolved in diethyl ether (50 mL), washed with 1 N HCl (20 mL) and water (20 mL), and dried over $MgSO_4$. Evaporation of the solvent in vacuo afforded the crude product, which was purified by flash chromatography (cyclohexane – ethyl acetate, 5:1) to yield **20** as a colourless amorphous solid (22 mg, 0.035 mmol, 88%). R_f 0.40 (toluene – ethyl acetate, 3:1). $[\alpha]^{22}_D$ +4.90° (*c* 1, $CHCl_3$); d.r.: 89:11 (HPLC: 80% CH_3CH, 20% H_2O → 100% CH_3CN, 30 min); recrystallization from ether afforded the pure major diastereomer. ^{1}H NMR (400 MHz, $CDCl_3$, ppm) δ: 7.80–7.75 (m, 2H, phenyl), 7.50–7.45 (m, 1H, phenyl), 7.44–7.37 (m, 2H, phenyl), 7.01 (d, 1H, $J_{NH,H\text{-}5}$ = 5.8 Hz, NH), 5.52 (t, 1H, $J_{H\text{-}2',H\text{-}1'}$ = 9.6 Hz, $J_{H\text{-}2',H\text{-}3'}$ = 9.6 Hz, H-2′), 5.26–5.22 (m, 1H, H-4′), 5.15 (dd, 1H, $J_{H\text{-}3',H\text{-}2'}$ = 9.8 Hz, $J_{H\text{-}3',H\text{-}4'}$ = 3.5 Hz, H-3′), 4.90–4.80 (m, 1H, H-5), 4.29 (d, 1H, $J_{H\text{-}1',H\text{-}2'}$ = 9.0 Hz, H-1′), 4.04 (dd, 1H, $J_{H\text{-}6a,H\text{-}6b}$ = 12.7 Hz, $J_{H\text{-}6a,H\text{-}5}$ = 7.6 Hz, H-6a), 3.98 (dd, 1H, $J_{H\text{-}5'a,H\text{-}5'b}$ = 13.1 Hz, $J_{H\text{-}5'a,H\text{-}4'}$ = 2.1 Hz, H-5′a), 3.61 (d, 1H, $J_{H\text{-}5'b,H\text{-}5'a}$ = 12.9 Hz, H-5′b), 3.44–3.35 (m, 1H, H-2), 2.87 (dd, 1H, $J_{H\text{-}3a,H\text{-}3b}$ = 12.9 Hz, $J_{H\text{-}3a,H\text{-}2}$ = 6.3 Hz, H-3a), 2.79 (dd, 1H, $J_{H\text{-}6b,H\text{-}6a}$ = 13.3 Hz, $J_{H\text{-}6b,H\text{-}5}$ = 10.2, H-6b), 2.47 (dd, $J_{H\text{-}3b,H\text{-}3a}$ = 12.9 Hz, $J_{H\text{-}3b,H\text{-}2}$ = 1.6 Hz, H-3b), 1.63–1.51 (m, 1H, CH_2), 1.43–1.31 (m, 1H, CH_2), 1.30, 1.15, 1.13 (3s, 27H, piv-CH_3), 0.85 (t, 3H, *J* = 7.4 Hz, CH_3). ^{13}C NMR (75.4 MHz, $CDCl_3$, ppm) δ: 206.6 (C-4), 177.7, 177.4, 177.1 (pivC=O), 166.6 (NH-C=O), 134.1 (ipso-aryl), 131.5, 128.5, 127.1 (aryl), 95.7 (C-1′), 71.9, 68.3, 66.2, 65.4 (C-2′, C-3′, C-4′, C-5′), 62.7 (C-5), 58.1 (C-2), 49.2 (C-6), 45.1 (C-3), 39.0, 38.8 ($piv_{quart.}$), 27.3, 27.2, 27.1 (piv-CH_3), 25.1 (CH_2), 11.3 (CH_3). General procedure for the halogenation of dehydropiperidinones 4

To a solution of *N*-arabinosyl dehydropiperidinone **4** (1 mmol) in dry THF (20 mL) were added several equivalents (see for each compound) of solid *N*-bromosuccinimide or *N*-iodosuccinimide at –78 °C and stirred until complete consumption of the starting material. The solution was diluted with diethyl ether (100 mL), washed with 10% aq. $Na_2S_2O_3$ (3 × 20 mL), and the resulting aqueous layers were extracted with diethyl ether (3 × 20 mL). The combined organic layers were washed with brine, dried over $MgSO_4$, and concentrated in vacuo. The crude product was purified by flash chromatography.

(2R)-N-*(2′,3′,4′-Tri*-O-*pivaloyl-*α-*D-arabinopyranosyl)-2-(*p*-chlorophenyl)-5-iodo-5,6-dehydropiperidin-4-one (21a)*

Iododehydropiperidinone **21a** was synthesized according to the general procedure using **4a** (1.18 g, 2 mmol) and *N*-iodosuccinimide (1.35, 6 mmol). Purification was carried out by flash chromatography (petroleum ether – ethyl acetate, 6:1) to yield **21a** (1.33 g, 1.9 mmol, 93%) as a colourless solid. Chemical and chemoenzymatic synthesis of a trisaccharide fragment of *Tsukamurella paurometabola* lipoarabinomannan[1]

Karen M. Ridgway, Wei Shi, Shuang-Jun Lin, Monica M. Palcic, and Todd L. Lowary

Abstract: The synthesis of a trisaccharide fragment (**1**) of the lipoarabinomannan from *Tsukamurella paurometabola* is reported. Two approaches were investigated for the synthesis of the target. One was purely chemical, while the other involved the addition of one of the monosaccharide residues via a mannosyltransferase-catalyzed reaction. Both approaches produced the target in good overall yields. Thus, this chemoenzymatic approach appears to be a useful addition to the arsenal of methods for the synthesis of lipoarabinomannan-derived oligosaccharides.

Key words: lipoarabinomannan, oligosaccharide, mannosyltransferase, enzymatic synthesis.

Résumé : On a réalisé la synthèse d'un fragment trisaccharide (**1**) du lipoarabinomannane extrait du *Tsukamurella paurometabola*. On a étudié deux approches pour la synthèse de ce produit cible. L'une est purement chimique alors que l'autre implique l'addition des résidus monosaccharides par le biais d'une réaction catalysée par la mannosyltransférase. Les deux approches ont permis d'arriver à la cible avec de bons rendements globaux. L'approche chimioenzymatique semble donc être une addition utile à l'arsenal des méthodes de synthèse des oligosaccharides dérivés du lipoarabinomannane.

Mots clés : lipoarabinomannane, oligosaccharide, mannosyltransférase, synthèse enzymatique.

[Traduit par la Rédaction]

Introduction

The human pathogen *Mycobacterium tuberculosis* produces an immunomodulatory lipidated polysaccharide, lipoarabinomannan (LAM), which plays a critical role in the progression of tuberculosis (1, 2). This disease, and those caused by other pathogenic mycobacteria (e.g., *M. leprae* and *M. avium*), are of increasing interest because of their resurgence in the industrialized world, the emergence of drug-resistant strains, and the susceptibility of immunocompromised individuals to these infections (3, 4). It is now well-appreciated that the immunomodulatory properties of mycobacterial LAM depend on structural motifs within the glycan (1, 2). For example, LAM from *M. tuberculosis* has been shown to inhibit the production of the proinflammatory cytokines including TNF-α (5). In contrast, LAM from the nonpathogenic *M. smegmatis*, which differs only slightly in structure from *M. tuberculosis* LAM, induces the release of these same cytokines (6). These observations have sparked interest in determining the structure of LAM molecules not only from mycobacterial strains, but also from other actinomycetes and a number of such investigations have been carried out, revealing an impressive range of structural diversity (7–17).

A general model for how LAMs influence the immune response has been proposed (10); however, there is relatively little detailed information on the role of various structural motifs within these glycans. A systematic structure function analysis of the activation or suppression of the immune response by fragments of LAM should open up new strategies for the treatment of mycobacterial disease. Among them are the design of biosynthetic inhibitors of the immunosuppressive glycans or the preparation of novel vaccines that generate antibodies capable of masking these epitopes. The fundamental biochemical studies that must precede achieving such a goal require access to discrete oligosaccharide fragments of a range of LAM motifs, which are most efficiently obtained via chemical synthesis. Previously, we synthesized fragments of LAM from *M. tuberculosis* (18, 19) and *Rhodococcus ruber* (20). Reported here is the synthesis of a fragment of LAM from *Tsukamurella paurometabola* (10) (TpaLAM). Human infections by this actinomycete,

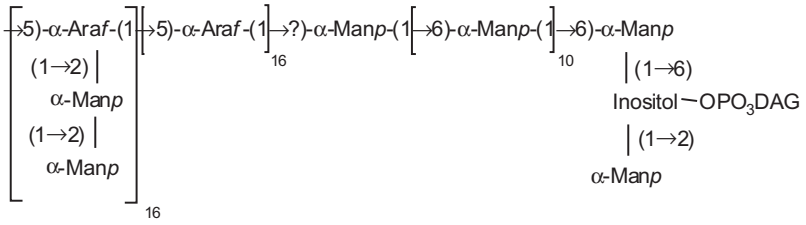
Fig. 1. Proposed structure of the LAM from *Tsukamurella pauroametabola* (TpaLAM) (10). Diacylglycerol (DAG). All monosaccharide residues are in the D-form.



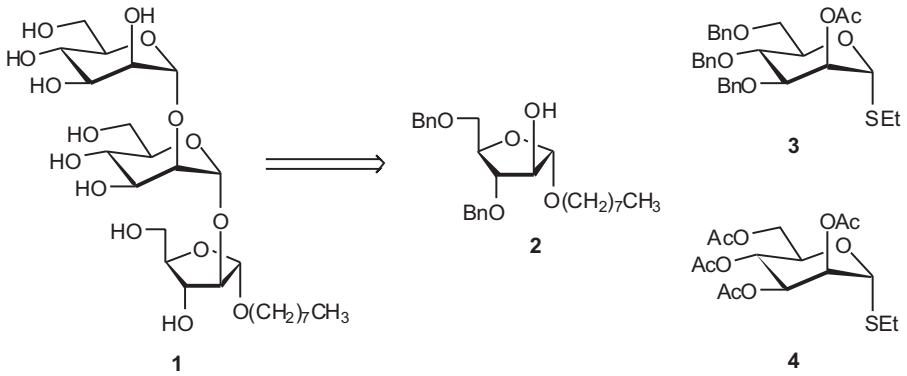


Fig. 2. Target oligosaccharide (**1**) and the building blocks chosen for its synthesis (**2**–**4**).

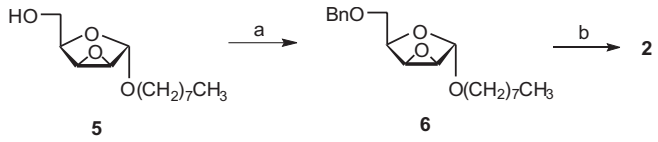
although rare, are occasionally found in immunocompromised patients (21).



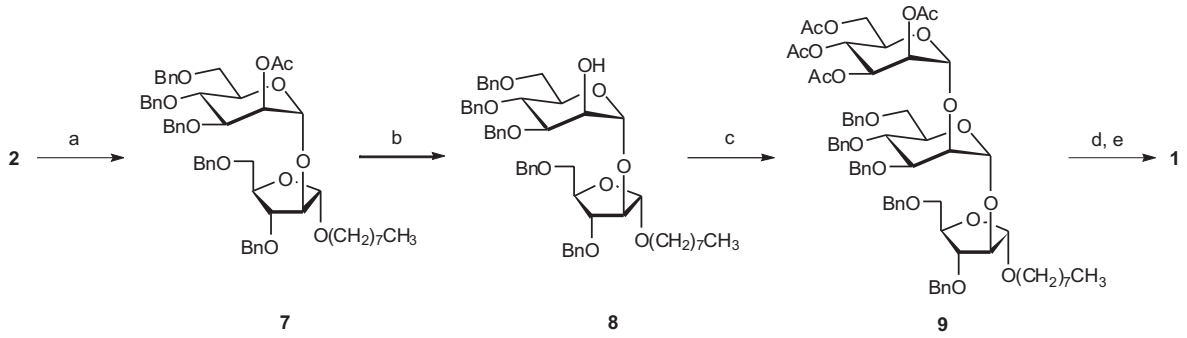
Results and discussion

The proposed structure of TpaLAM is shown in Fig. 1 (10). Similar to other glycoconjugates of this class, the glycan has at its core a mannosylated phosphatidylinositol moiety, to which is attached a chain of α-(1→6)-linked D-mannopyranose (Man*p*) residues. This mannan domain is devoid of branching Man*p* units, which is a common feature of all mycobacterial LAM structures reported to date (1, 2). The mannan is further elaborated by a linear arabinan, consisting of α-(1→5)-linked D-arabinofuranose (Ara*f*) residues. In contrast to the mycobacterial variant (1, 2), there is no branching within the arabinan; however, approximately half of the Ara*f* residues are further glycosylated on O-2 by an α-(1→2)-linked Man*p* disaccharide.

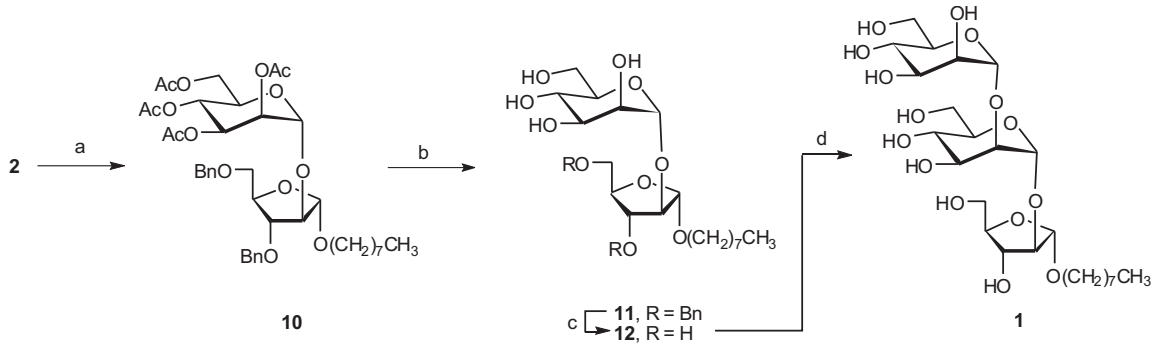
With this in mind, we chose to synthesize a trisaccharide fragment corresponding to the substituted Ara*f* residue present in the arabinan domain. The target thus chosen was **1** (Fig. 2), which we envisioned could be synthesized from three monosaccharide building blocks (**2**–**4**). Thioglycosides **3** and **4** were prepared as previously described (22, 23); the protected octyl glycoside **2** was straightforwardly synthesized as outlined in the following paragraph.

Access to **2** was achieved starting from the known epoxy glycoside **5** (24), first by benzylation of the hydroxyl group under standard conditions. The reaction proceeded to give **6** in 79% yield (Scheme 1). Octyl glycoside **2** was then obtained by heating **6** in a solution of benzyl alcohol and sodium benzylate at 100 °C overnight. The reaction proceeded with the expected high degree of regioselectivity (25), affording **2** in 88% yield. Given the relatively sluggish nature of this reaction, we also evaluated the use of microwave irradiation to effect the conversion of **6** into **2**. After optimization of the reaction conditions, we were able to carry out this reaction in only 30 min by microwave irradiation of a solution of **2** and sodium benzylate in benzyl alcohol at 170 °C. Under these conditions, an 82% yield of the product was obtained.

Scheme 1. (*a*) BnBr, NaH, THF, 0 °C → rt, 79%; (*b*) NaOBn, BnOH, 100 °C, 88%.



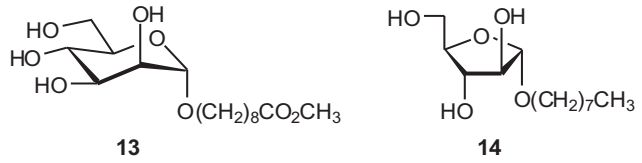
Once **2**–**4** were prepared, the target was synthesized without difficulty as illustrated in Scheme 2. Coupling of thioglycoside **3** with alcohol **2** was carried out under the promotion of *N*-iodosuccinimide and silver triflate (26), which afforded disaccharide **7** in 84% yield. The acetate protecting group in **7** was then cleaved giving a 97% yield of alcohol **8**. The final monosaccharide residue was introduced by reaction of **8** with **4**, again promoted by *N*-iodosuccinimde and silver triflate. The expected trisaccharide product (**9**) was obtained in 61% yield. Deprotection of **9** was achieved first by removal of the acetate esters by transesterification and then hydrogenation of the benzyl ethers, yielding a quantitative overall yield of **1**.



Having in place a route to **1** via a purely chemical approach, we explored an alternate method, which involved the introduction of the "nonreducing" mannopyranose unit via an enzymatic reaction. To test the feasibility of this route, we synthesized a fully deprotected disaccharide (**12**, Scheme 3), which is a potential substrate for an α-(1→2)-mannosyltransferase (α-(1→2)-ManT) from *Saccharomyces cerevisiae* that has been used in chemoenzymatic syntheses

© 2006 NRC Canada

Scheme 2. (*a*) **3**, NIS, AgOTf, CH_2Cl_2, –40 °C → rt, 84%; (*b*) $NaOCH_3$, CH_3OH, rt, 97%; (*c*) **4**, NIS, AgOTf, CH_2Cl_2, rt, 61%; (*d*) K_2CO_3, CH_3OH, rt, quantitative; (*e*) H_2, $Pd(OH)_2$/C, CH_3OH, rt, quantitative.



Scheme 3. (*a*) **4**, NIS, AgOTf, CH_2Cl_2, –50 °C → rt, 45%; (*b*) $NaOCH_3$, CH_3OH, rt, 83%; (*c*) H_2, $Pd(OH)_2$, CH_3OH, rt, 83%; (*d*) GDP-Man, ManT, rt, 90%.

of oligosaccharides (27–30). Thus, disaccharide **12** was synthesized by first reacting **2** with **4**, which gave **10** in 87% yield. Deprotection of **10** in two steps (transesterification and hydrogenation) gave **12** via **11**, in 69% overall yield.

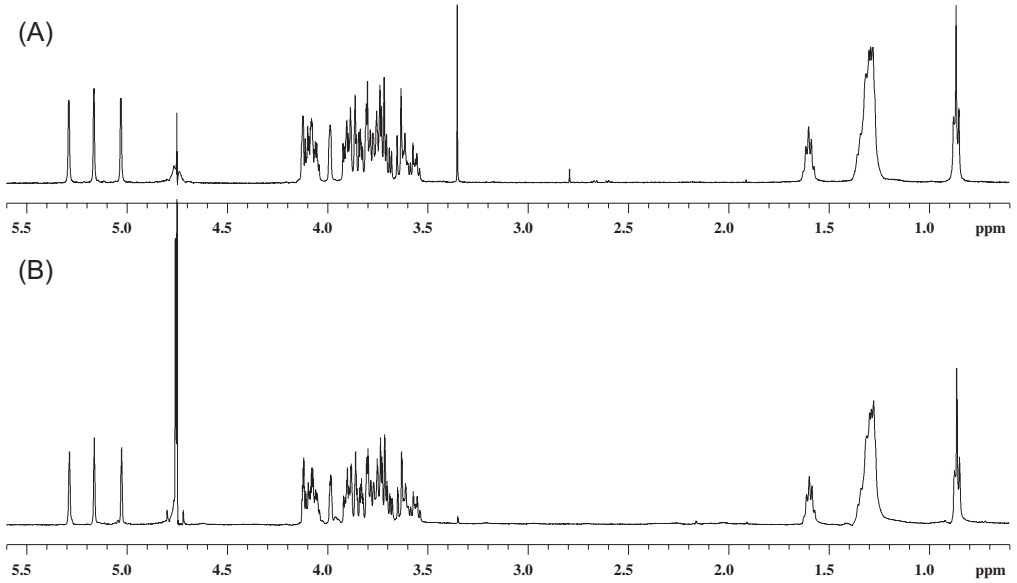
With **12** in hand, we first tested its ability to serve as a substrate for this α-(1→2)-ManT by incubating it with radiolabelled guanosine diphosphate mannose ([^{3}H]-GDP-Man) in the presence of the enzyme and then quantitation by scintillation counting. Using this assay, the amount of radioactivity transferred to **12** was approximately 15% of that transferred to 8-methoxy(carbonyloctyl) α-D-mannopyranoside (**13**, Fig. 3), a substrate for this enzyme. Encouraged by this result, we then carried out a larger-scale incubation of **12** with GDP-Man and the α-(1→2)-ManT. After shaking the mixture for 25 h at room temperature (rt), the reaction was complete and purification of the product gave a 90% yield of **1**. The ^{1}H NMR spectrum for this trisaccharide was identical to that of **1** obtained from chemical synthesis (Fig. 4). In addition, the mass spectrum of the enzymatically formed product also showed a peak at *m/z* 609.6, which corresponds to the sodium adduct of the expected trisaccharide. Given the success in the synthesis of the trisaccharide by this chemoenzymatic approach, we also explored the synthesis of disaccharide **12** by the α-(1→2)-ManT catalyzed coupling of GDP-Man with octyl α-D-arabinofuranoside (**14**, Fig. 3). To explore this possibility, **14** was incubated with [^{3}H]-GDP-Man and the α-(1→2)-ManT. However, no transfer of radioactivity to the monosaccharide was observed,

Fig. 3. Positive and negative substrate controls for the α-(1→2)-ManT.

thus demonstrating that this simple furanoside is not a substrate for the enzyme, and therefore the synthesis of **12** from **14** via the action of this enzyme is not feasible.

In summary, a trisaccharide fragment of the LAM from *T. paurometabola*, has been synthesized using chemical and chemoenzymatic approaches. Both routes proceeded efficiently to give the target compound. To the best of our knowledge, this is the first example of a chemoenzymatic synthesis of an oligosaccharide substructure of LAM. The success of this approach suggests that similar strategies may facilitate the synthesis of more complicated fragments of these structurally diverse glycoconjugates.[3]

Experimental



General methods

Reactions were carried out in oven-dried glassware. Reaction solvents were distilled from appropriate drying agents before use. Unless stated otherwise, all reactions were car-

Fig. 4. ^{1}H NMR spectra for trisaccharide **1** (recorded in D_2O). (A) Product obtained via chemical synthesis; (B) product obtained via chemoenzymatic synthesis. The peak at ~3.35 ppm is a methanol impurity.

ried out with stirring at rt under a positive pressure of argon and were monitored by TLC on silica gel 60 F_{254} (0.25 mm, E. Merck). Spots were detected under UV light or by charring with acidified *p*-anisaldehyde solution in EtOH. In the processing of reaction mixtures, solutions of organic solvents were washed with equal amounts of aqueous solutions. Organic solutions were concentrated under vacuum at <40 °C. All column chromatography was performed on silica gel (40–60 μmol/L) or Iatrobeads, which refers to a beaded silica gel 6RS-8060, manufactured by Iatron Laboratories (Tokyo). In all cases, the ratio between adsorbent and crude product ranged from 100 to 50:1 (*w*/*w*). Optical rotations were measured at 22 ± 2 °C and in units of degrees mL/g dm. ^{1}H NMR spectra were recorded at 400, 500, or 600 MHz, and chemical shifts were referenced to internal $CHCl_3$ (7.26 ppm, $CDCl_3$), CHD_2OD (3.30 ppm, CD_3OD), or external acetone (2.23 ppm, D_2O). ^{13}C NMR spectra were recorded at 100 or 125 MHz, and ^{13}C chemical shifts were referenced to internal $CDCl_3$ (77.23 ppm, $CDCl_3$) or CD_3OD (49.0 ppm, CD_3OD). ^{1}H NMR data are reported as though they were first order. Electrospray mass spectra were recorded on samples suspended in CH_3OH. The recombinant *S. cerevisiae* α-(1→2)-ManT used in the enzymatic reactions was produced as previously reported (31).

Octyl 2-*O*-[2-*O*-(α-D-mannopyranosyl)-α-D-mannopyranosyl]-α-D-arabinofuranoside (1)

Trisaccharide **9** (30.0 mg, 0.025 mmol) and K_2CO_3 (2.7 mg, 0.020 mmol) were stirred in CH_3OH (2.0 mL) at rt overnight. The solution was concentrated and the residue was purified by column chromatography (CH_2Cl_2–CH_3OH, 20:1) to give a partially deprotected intermediate (25.7 mg, 100%). To a solution of this intermediate (25.7 mg, 0.025 mmol) in methanol (5 mL) was added $Pd(OH)_2$/C (30 mg). The mixture was stirred overnight under an H_2 atmosphere and the catalyst was separated by filtration through Celite and then washed with CH_3OH (10 mL). Concentration of the filtrate gave **1** (14.5 mg, 100%) as a white solid. R_f 0.23 (CH_2Cl_2–CH_3OH, 2:1). $[\alpha]_D$ +93.9° (*c* 1.4, CH_3OH). ^{1}H NMR (500 MHz, CD_3OD) δ_H: 5.28 (d, 1H, $J_{1',2'}$ = 1.7 Hz, H-1′), 4.98 (d, 1H, $J_{1,2}$ = 1.6 Hz, H-1), 4.97 (d, 1H, $J_{1'',2''}$ = 1.7 Hz, H-1″), 4.08 (dd, 1H, $J_{1,2}$ = 1.6 Hz, $J_{2,3}$ = 3.8 Hz, H-2), 3.95–3.99 (m, 2H, H-3, H-2″), 3.88–3.91 (m, 1H, H-4), 3.78–3.88 (m, 4H, H-2′, H-6a′, H-6a″, H-6b″), 3.64–3.78 (m, 7H, H-5a, H-6b′, H-3′, H-3″, H-4′, H-5″, octyl OCH_2), 3.62 (dd, 1H, $J_{4,5b}$ = 5.6 Hz, $J_{5a,5b}$ = 12.2 Hz, H-5b), 3.57 (dd, 1H, $J_{3'',4''}$ = 9.5 Hz, $J_{4'',5''}$ = 9.5 Hz, H-4″), 3.53 (ddd, 1H, $J_{4',5'}$ = 9.6, $J_{5',6a'}$ = 2.4 Hz, $J_{5',6b'}$ = 5.3 Hz, H-5′), 3.42 (dt, 1H, *J* = 9.5, 6.6 Hz, octyl OCH_2), 1.53–1.61 (m, 2H, octyl CH_2), 1.26–1.38 (m, 10H, octyl CH_2), 0.87 (t, 3H, *J* = 6.9 Hz, octyl CH_3). ^{13}C NMR (125 MHz, CD_3OD) δ_C: 107.6 (C-1), 104.2 (C-1″, $^1J_{C\text{-}1'',H\text{-}1''}$ = 168.8 Hz), 99.5 (C-1′, $^1J_{C\text{-}1',H\text{-}1'}$ = 168.8 Hz), 88.9 (C-2), 84.5 (C-4), 80.3 (C-2′), 77.2 (C-2″), 75.1 (C-5), 75.0 (C-5″), 72.4 (C-3′), 71.9(2) (C-3″), 71.8(6) (C-3), 68.8(3) (C-4′), 68.8(2) (octyl OCH_2), 68.7(6) (C-4″), 63.2 (C-6′), 62.8 (C-6″), 62.7 (C-5), 33.0 (octyl CH_2), 30.8 (octyl CH_2), 30.5 (octyl CH_2), 30.4 (octyl CH_2), 27.3 (octyl CH_2), 23.7 (octyl CH_2), 14.4 (octyl CH_3). HRMS (ESI) calcd. for $C_{25}H_{46}O_{15}$: 609.2729 (M + Na); found: 609.2729.

Octyl 3,5-di-*O*-benzyl-α-D-arabinofuranoside (2)

Thermal method

Compound **6** (199 mg, 0.60 mmol) was dissolved in benzyl alcohol (10 mL). Sodium benzylate (1 mol/L, 7 mL, 7 mmol) was added and the reaction was stirred at 100 °C overnight. After cooling, a few drops of acetic acid were added to neutralize the reaction mixture. The solution was then concentrated to remove all but traces of the benzyl alcohol and the resulting residue was purified by column chromatography (hexanes–EtOAc, 6:1) to give **2** (231 mg, 88%) as a yellow syrup. R_f 0.19 (hexanes–EtOAc 6:1). $[\alpha]_D$ +81.1° (*c* 1.3, CH_2Cl_2). ^{1}H NMR (400 MHz, $CDCl_3$) δ_H: 7.27–7.38 (m, 10H, Ph), 5.01 (s, 1H, H-1), 4.68 (d, 1H, *J* = 12.1 Hz,

Microwave method

Sodium benzylate (1 mol/L, 0.126 mL, 0.126 mmol) was added to **6** (21.2 mg, 0.063 mmol) in benzyl alcohol (0.37 mL). The mixture was heated, with stirring, in a CEM Discover/Explorer microwave system at 300 W and 170 °C for 0.5 h. After cooling, acetic acid was added dropwise until the mixture was neutralized. The solution was filtered through cotton, concentrated, and the resulting residue was purified by chromatography (hexanes–EtOAc, 6:1) to give **2** (22.9 mg, 82%) as a yellow syrup.

Octyl 2,3-anhydro-5-*O*-benzyl-α-D-lyxofuranoside (6)

To a solution of **5** (24) (2.71 g, 11.1 mmol) in THF (20 mL) at 0 °C, a mixture of NaH (60% in mineral oil, 0.89 g, 22.2 mmol) in THF (20 mL) was added dropwise. After 10 min, BnBr (1.7 mL, 14.3 mmol) was added dropwise. The reaction mixture was stirred for 2 h while warming to rt before water was added. The aqueous layer was extracted with CH_2Cl_2 and the organic extract was washed with brine, dried (Na_2SO_4), filtered, and concentrated. The crude product was purified by chromatography (hexanes–EtOAc (20:1) → hexanes–EtOAc (8:1)) to give **6** (2.94 g, 79%) as a pale yellow syrup. R_f 0.53 (hexanes–EtOAc, 8:1). $[\alpha]_D$ +13.5° (*c* 1.2, CH_2Cl_2). ^{1}H NMR (400 MHz, $CDCl_3$) δ_H: 7.27–7.38 (m, 5H, Ph), 5.05 (s, 1H, H-1), 4.63 (d, 1H, J = 12.0 Hz, PhCH_2), 4.58 (d, 1H, J = 12.0 Hz, PhCH_2), 4.21 (dd, 1H, $J_{4,5a}$ = $J_{4,5b}$ = 6.4 Hz, H-4), 3.77 (d, 1H, $J_{2,3}$ = 2.9 Hz, H-3), 3.75 (dt, 1H, J = 9.5, 6.7 Hz, octyl OCH_2), 3.66 (d, 2H, $J_{4,5}$ = 6.4 Hz, H-5), 3.65 (d, 1H, $J_{2,3}$ = 2.9 Hz, H-2), 3.46 (dt, 1H, J = 9.5, 6.7 Hz, octyl OCH_2), 1.53–1.62 (m, 2H, octyl CH_2), 1.23–1.38 (m, 10H, octyl CH_2), 0.89 (t, 3H, J = 6.8 Hz, octyl CH_3). ^{13}C NMR (125 MHz, $CDCl_3$) δ_C: 138.0 (Ph), 128.4 (Ph), 128.4 (Ph), 127.8 (Ph), 127.7 (Ph), 127.7 (Ph), 101.2 (C-1), 75.0 (C-4), 73.6 (Ph*C*H_2), 68.6 (C-5), 68.6 (octyl OCH_2), 56.3 (C-2), 54.5 (C-3), 31.8 (octyl CH_2), 29.6 (octyl CH_2), 29.3 (octyl CH_2), 29.2 (octyl CH_2), 26.1 (octyl CH_2), 22.6 (octyl CH_2), 14.1 (octyl CH_3). Octyl 2-*O*-(2,3,4,6-tetra-*O*-acetyl-α-D-mannopyranosyl)-3,5-di-*O*-benzyl-α-D-arabinofuranoside (10)

Alcohol **2** (22.7 mg, 0.051 mmol) and thioglycoside **4** (23) (46.4 mg, 0.102 mmol) were dissolved in CH_2Cl_2 (5 mL). To this solution were added 4 Å molecular sieves (50 mg). After stirring at rt for 15 min, the reaction mixture was cooled to 0 °C and stirred for another 15 min. NIS (25.3 mg, 0.112 mmol) was added, followed by AgOTf (4.0 mg, 0.016 mmol). The reaction was monitored by TLC and after the disappearance of **4**, 3 drops of Et_3N were added. The reaction mixture was filtered through Celite. The filtrate was concentrated and the resulting crude product was purified by column chromatography (hexanes–EtOAc, 3:1) to give **11** (33.8 mg, 87%). R_f 0.27 (hexanes–EtOAc, 3:1). $[\alpha]_D$ +66.0° (*c* 3.4, CH_2Cl_2). ^{1}H NMR (400 MHz, $CDCl_3$) δ_H: 7.23–7.33 (m, 10H, Ph), 5.22–5.31 (m, 2H, H-4′, H-3′), 5.16 (dd, 1H, $J_{1,2}$ = 1.9 Hz, $J_{2,3}$ = 2.9 Hz, H-2′), 5.06 (s, 1H, H-1), 4.85 (d, 1H, $J_{1,2}$ = 1.8 Hz, H-1′), 4.46–4.60 (m, 4H, PhCH_2), 4.24 (dd, 1H, $J_{5,6a'}$ = 5.4 Hz, $J_{6a',6b'}$ = 12.2 Hz, H-6a′), 4.12–4.18 (m, 2H, H-2, H-4), 4.07 (dd, 1H, $J_{5,6b'}$ = 2.3, $J_{6a',6b'}$ = 12.2 Hz, H-6b′), 3.97–4.03 (m, 1H, H-5′), 3.88 (dd, 1H, *J* = 3.0 Hz, *J* = 6.7 Hz, H-3), 3.68 (dt, 1H, *J* = 9.5, 7.0 Hz, octyl OCH_2), 3.61 (dd, 1H, $J_{4,5a}$ = 3.7 Hz, $J_{5a,5b}$ = 10.8 Hz, H-5a), 3.56 (dd, 1H, $J_{4,5b}$ = 5.1 Hz, $J_{5a,5b}$ = 10.8 Hz, H-5b), 3.39 (dt, 1H, *J* = 9.5, 7.0 Hz, octyl OCH_2), 2.14 (s, 3H, C(O)CH_3), 2.06 (s, 3H, C(O)CH_3), 2.01 (s, 3H, C(O)CH_3), 1.97 (s, 3H, C(O)CH_3), 1.51–1.59 (m, 2H, octyl CH_2), 1.20–1.33 (m, 10H, octyl CH_2), 0.85 (t, 3H, *J* = 6.9 Hz, octyl CH_3). ^{13}C NMR (100 MHz, $CDCl_3$) δ_C: 170.5 (C=O), 169.9 (C=O), 169.8 (C=O), 169.7 (C=O), 138.0 (Ph), 137.6 (Ph), 128.3(9) (2C, Ph), 128.3(6) (2C, Ph), 127.8 (4C, Ph), 127.6 (2C, Ph), 105.6 (C-1), 97.2 (C-1′), 87.4 (C-4), 83.4 (C-3), 80.5 (C-2), 73.4 (Ph*C*H_2), 72.4 (Ph*C*H_2), 69.6 (C-3′), 69.5 (C-5), 69.1 (C-2′), 68.8 (C-5′), 67.8 (octyl OCH_2), 66.0 (C-4′), 62.3 (C-6′), 31.8 (octyl CH_2), 29.6 (octyl CH_2), 29.4 (octyl CH_2), 29.2 (octyl CH_2), 26.1 (octyl CH_2), 22.6 (octyl CH_2), 20.9 (C(O)*C*H_3), 20.6(9) (C(O)*C*H_3), 20.6(6) (2C, C(O)*C*H_3), 14.1 (octyl CH_3). HRMS (ESI) calcd. for $C_{41}H_{54}O_{14}$: 795.3568 (M + Na); found: 795.3562. Anal. calcd. for $C_{41}H_{54}O_{14}$: C 63.72, H 7.30; found: C 63.73, H 7.35.

Octyl 2-*O*-(α-D-mannopyranosyl)-α-D-arabinofuranoside (12)

Disaccharide **10** (41.1 mg, 0.054 mmol) and K_2CO_3 (4.1 mg, 0.030 mmol) were stirred together in CH_3OH (2 mL) at rt overnight. The solution was then concentrated and the residue purified by chromatography (CH_2Cl_2–CH_3OH, 10:1) to give **11** (26.8 mg, 83%). R_f 0.44 (CH_2Cl_2–CH_3OH, 10:1). ^{1}H NMR (500 MHz, CD_3OD) δ_H: 7.24–7.34 (m, 10H, Ph), 5.08 (s, 1H, H-1), 4.84 (d, 1H, *J* = 1.6 Hz, H-1′), 4.61 (d, 1H, *J* = 12.0 Hz, PhCH_2), 4.53 (s, 2H, PhCH_2), 4.51 (d, 1H, *J* = 12.0 Hz, PhCH_2), 4.17 (d, 1H, $J_{2,3}$ = 2.2 Hz, H-2), 4.14 (ddd 1H, $J_{3,4}$ = $J_{4,5a}$ = $J_{4,5b}$ = 5.4 Hz, H-4), 3.83

(dd, 1H, $J_{2,3}$ = 2.2 Hz, $J_{3,4}$ = 5.4 Hz, H-3), 3.81 (dd, 1H, $J_{5',6a'}$ = 2.2 Hz, $J_{6a',6b'}$ = 11.9 Hz, H-6a′), 3.54–3.73 (m, 7H, H-5a, H-5b, H-6b′, H-2′, H-3′, H-4′, octyl OCH_2), 3.50–3.54 (m, 1H, H-5′), 3.42 (dt, 1H, J = 9.5, 6.3 Hz, octyl OCH_2), 1.53–1.60 (m, 2H, octyl CH_2), 1.22–1.40 (m, 10H, octyl CH_2), 0.87 (t, 3H, J = 6.4 Hz, octyl CH_3). ^{13}C NMR (125 MHz, CD_3OD) δ_C: 139.5 (Ph), 139.3 (Ph), 129.4 (4C, Ph), 128.9(9) (2C, Ph), 128.9(5) (2C, Ph), 128.8(5) (Ph), 128.8 (Ph), 107.8 (C-1), 101.3 (C-1′), 87.1 (C-4), 85.0 (C-2), 82.5 (C-3), 75.3 (C-4′), 74.4 (Ph*C*H_2), 73.1 (Ph*C*H_2), 72.4 (C-2′), 72.3 (C-3′), 71.0 (C-5), 68.5 (octyl OCH_2), 68.4 (C-5′), 62.7 (C-6′), 33.0 (octyl CH_2), 30.7 (octyl CH_2), 30.5(2) (octyl CH_2), 30.4(6) (octyl CH_2), 27.3 (octyl CH_2), 23.7 (octyl CH_2), 14.5 (octyl CH_3).

Disaccharide **11** (26.8 mg, 0.045 mmol) was dissolved in CH_3OH (3 mL) and $Pd(OH)_2$/C (10.6 mg) was added. A balloon containing hydrogen was placed over the reaction flask. The solution stirred overnight at rt until the reaction was complete, as shown by TLC. The catalyst was removed by filtration through Celite. After washing the filtered catalyst with CH_3OH, the combined filtrates were concentrated, the residue dissolved in H_2O, and the resulting solution was then loaded onto a C18 Sep-Pak cartridge, which had been preequilibrated with CH_3OH (10 mL) and then water (10 mL). The cartridge was then washed with water (10 mL) and the product was eluted with CH_3OH (2 × 5 mL). The eluants were concentrated, the residue redissolved in water, and the solution filtered through a 0.22 μm Millex-GV filter. Freeze-drying of the filtered solution gave **12** (15.6 mg, 83%) as a white solid. R_f 0.55 (CH_2Cl_2–CH_3OH, 3:1. $[\alpha]_D$ +52.2° (*c* 1.1, CH_3OH). ^{1}H NMR (600 MHz, CD_3OD) δ_H: 4.99 (d, 1H, $J_{1',2'}$ = 1.2 Hz, H-1′), 4.98 (d, 1H, $J_{1,2}$ = 1.8 Hz, H-1), 4.08 (dd, 1H, $J_{1,2}$ = 1.8 Hz, $J_{2,3}$ = 4.2 Hz, H-2), 3.94 (dd, 1H, $J_{2,3}$ = 4.2 Hz, $J_{3,4}$ = 7.2 Hz, H-3), 3.88 (ddd, 1H, J = 3.0 Hz, J = 5.4 Hz, $J_{3,4}$ = 7.2 Hz, H-4), 3.77–3.81 (m, 2H, H-2′, H-6a′), 3.63–3.75 (m, 5H, H-5a, H-3′, H-4′, H-6b′, octyl OCH_2), 3.60 (dd, 1H, J = 4.8, 12.0 Hz, H-5b), 3.51–3.55 (m, 1H, H-5′), 3.40 (dt, 1H, J = 9.6, 6.6 Hz, octyl OCH_2), 1.53–1.59 (m, 2H, octyl CH_2), 1.26–1.37 (m, 10H, octyl CH_2), 0.87–0.92 (m, 3H, octyl CH_3). ^{13}C NMR (100 MHz, $CDCl_3$) δ_C: 107.4 (C-1), 101.2 (C-1′), 89.0 (C-2), 84.4 (C-4), 77.1 (C-3), 75.0 (C-5′), 72.4 (C-3′), 72.2 (C-2′), 68.4 (C-4′), 68.8 (octyl OCH_2), 62.7 (C-5), 62.6 (C-6′), 33.0 (octyl CH_2), 30.7 (octyl CH_2), 30.5 (octyl CH_2), 30.4 (octyl CH_2), 27.3 (octyl CH_2), 23.7 (octyl CH_2), 14.4 (octyl CH_3). HRMS (ESI) calcd. for $C_{19}H_{36}O_{10}$: 447.2206 (M + Na); found: 447.2201.

α-(1→2)-ManT assay for determining relative substrate activity of 12–14

Reaction mixtures for assessing the incorporation of [^{3}H]-Man into **12–14** consisted of 50 mmol/L MOPS (pH 7.5), 10 mmol/L $MgCl_2$, 0.5 mmol/L GDP-Man, 1.0 mmol/L potential acceptor substrate, the α-(1→2)-ManT (0.0134 mU for **12**, 0.0027 mU for **13**, 0.134 mU for **14**) (32), 0.1% Triton X-100, 1 mg/mL of BSA, guanosine diphosphate mannose (American Radiolabeled Chemicals, Inc., 8.9 Ci/mmol, 0.6 μL) in a total reaction volume of 30 μL. The mixture was incubated at 37 °C for 30 min. Control assays without acceptor were also performed. Radiolabeled products were isolated by reverse-phase chromatography on SepPak C18 cartridges (Waters) (32) and quantified by liquid scintillation counting on a Beckman LS6500 scintillation counter. Under these conditions, [^{3}H]-Man transfer to **12** was 15% of that of **13**, whereas the radioactivity transferred to **14** was at background levels. Modification of the assay with the use of 2.0 mmol/L GDP-Man, 4.0 mmol/L **14**, and increased α-(1→2)-ManT did not lead to greater levels of radioactivity transfer, thus demonstrating that this monosaccharide is not a substrate for the enzyme.

Enzymatic synthesis of 1 from 12

Disaccharide **12** (2.1 mg, 4.95 μmol) and GDP-mannose disodium salt (4.32 mg, μmol) were reacted with the α-(1→2)-ManT (200 mU) in 50 mmol/L MOPS buffer at pH 7.5, containing 0.1% Triton X-100, 10 mmol/L $MnCl_2$, 1 mg/mL BSA, 2 mmol/L DTT, and alkaline phosphatase (3 U). The total reaction volume was 600 μL. The reaction mixture was incubated on an end-to-end shaker at rt for 25 h and reaction progress was monitored by TLC ($CHCl_3$–CH_3OH–water, 70:35:2, R_f 0.5). When TLC showed the complete disappearance of **12**, cold water (~600 μL) was added and the incubation mixture was centrifuged to remove precipitates. The supernatent was loaded onto a C18 Sep-Pak cartridge, which had been preequilibrated with CH_3OH (50 mL) and then water (50 mL). The cartridge was then washed with water (50 mL) and the product was eluted with 50% CH_3OH–H_2O (2 × 20 mL). The eluants were concentrated to remove the CH_3OH and the resulting aqueous solution was filtered through a 0.22 μm Millex-GV filter. The filtrate was lyophilized to yield **1** as a white powder (2.6 mg, 90%). The ^{1}H NMR spectrum (500 MHz, D_2O) obtained on this product was identical to that obtained from **1** produced by chemical synthesis. Analysis of the product by ESI-MS showed a signal and *m/z* 609.6 corresponding to the $[M + Na]^+$ peak of the trisaccharide.

Cyclodextrin derivatives with cyanohydrin and carboxylate groups as artificial glycosidases[1]

Fernando Ortega-Caballero and Mikael Bols

Abstract: Two cyclodextrin derivatives (**1** and **2**) were prepared in an attempt to create glycosidase mimics with a general acid catalyst and a nucleophilic carboxylate group. The catalysts **1** and **2** were found to catalyse the hydrolysis of 4-nitrophenyl β-D-glucopyranoside at pH 8.0, but rapidly underwent decomposition with loss of hydrogen cyanide to convert the cyanohydrin to the corresponding aldehyde. The initial rate of the catalysis shows that the cyanohydrin group in these molecules functions as a good catalyst, but that the carboxylate has no positive effect. The decomposition product aldehydes display little or no catalysis. A mechanism for the decomposition is suggested.

Key words: biomimicry, enzyme model, kinetics, intramolecular reaction.

Résumé : On a préparé deux dérivés de la cyclodextrine (**1** et **2**) dans le but de créer des imitations de glycosidase avec un catalyseur acide général et un groupe carboxylate nucléophile. On a trouvé que les catalyseurs **1** et **2** catalysent bien l'hydrolyse β-D-glucopyranoside de 4-nitrophényle, à un pH de 8,0, mais qu'ils subissent rapidement une décomposition avec perte de cyanure d'hydrogène qui transforme en aldéhyde correspondant. La vitesse initiale de la catalyse montre que le groupe cyanohydrine des ces molécules fonctionne comme un bon catalyseur, mais que le carboxylate n'a pas d'effet positif. Les aldéhydes obtenus comme produits de décomposition ne présentent pas, ou peu, d'activité catalytique. On propose un mécanisme pour la décomposition.

Mots clés : bio-imitation, modèle d'enzyme, cinétique, réaction intramoléculaire.

[Traduit par la Rédaction]

Introduction

Supramolecular chemistry is a science that attempts to understand and use chemistry beyond the molecule (1). A fascinating research area is aimed at using supramolecular chemistry to achieve catalysis thereby creating what is *de-facto* artificial enzymes (2).

We have recently reported some of the first examples of artificial glycosidases (3). The most effective type discovered was cyclodextrin derivatives, such as **A** (Fig. 1), containing a cyanohydrin group at the primary rim (4). For these catalysts, a k_{cat}/k_{uncat} of up to 8000 was obtained for the hydrolysis of aryl glycosides (5). Based on structure–activity analysis of a series of derivatives, it was found that both the cyano group and the cyanohydrin OH were essential for catalysis, indicating that the acidity of this group was essential. It is therefore suggested that **A** works by acid catalysis as shown in Fig. 1.

A second type of cyclodextrin, such as **B**, having two carboxylate or sulphate groups at the primary rim was also found to catalyse aryl glycoside cleavage. While these catalysts were found relatively inefficient (with k_{cat}/k_{uncat} of up to 10–50), at normal conditions (6), increasing the phosphate concentration led to k_{cat}/k_{uncat} values of up to 1000 (7). Since this type of artificial enzyme has both functional groups negatively charged, the catalysis was believed to be mainly electrostatic.

The observation, in this latter case, that increasing the phosphate concentration increased the catalytic rate, was taken as evidence for the involvement of nucleophilic substitution with phosphate and suggested that the catalysis could be increased by the presence of a nucleophile. Indeed, the catalysis by the better catalyst **A** is also boosted by phosphate, but not in a linear fashion. It was therefore proposed to incorporate a nucleophilic group into a cyanohydrin-containing cyclodextrin with the goal of achieving general acid catalysis and nucleophilic catalysis in the same molecule. It was decided to attempt to use a carboxylate as the nucleophile so that the desired catalyst essentially would become a hybrid on **A** and **B**. In this paper we report the synthesis of two such molecules (**1** and **2**), each having a cyanohydrin and a carboxylate group at the primary rim, only differing in the chain length between carboxylate and cyclodextrin (Fig. 1). Both compounds were found to be catalytic, but undergo rapid decomposition of the cyanohydrin group under the reaction conditions.

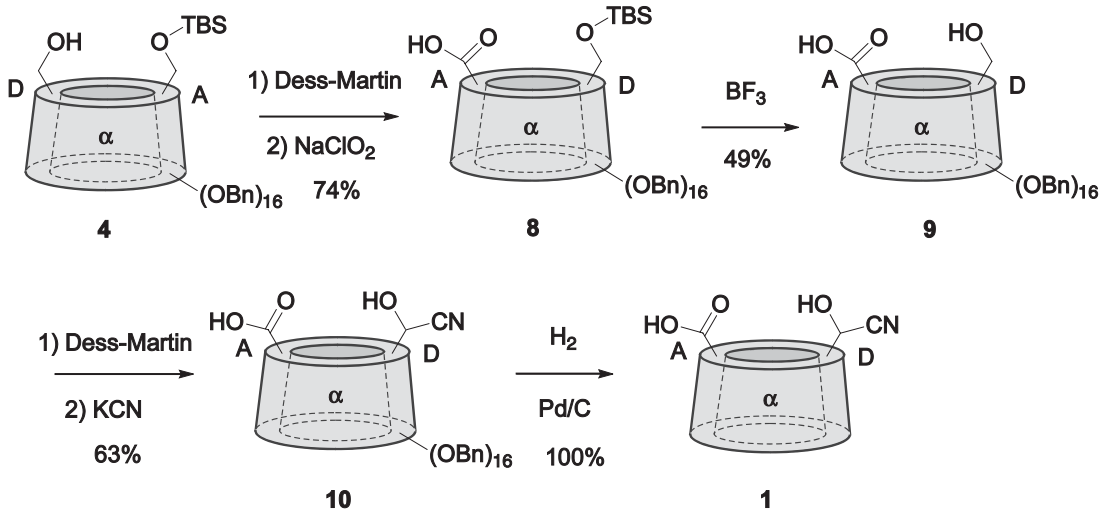
Fig. 1. Proposed mode of catalysis of cyclodextrin cyanohydrins (**A**) and cyclodextrin diacids (**B**).

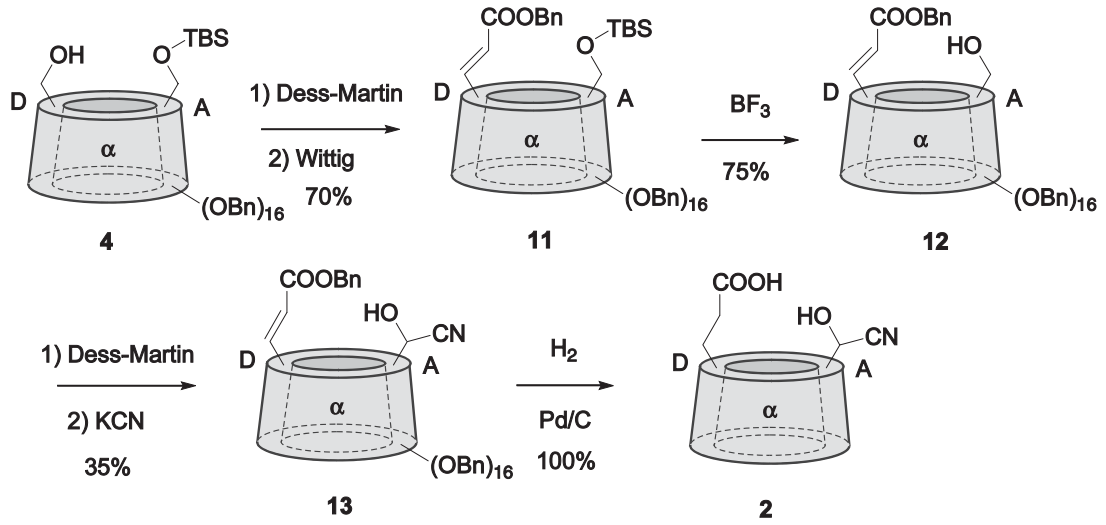
Scheme 1. Synthesis of silylated derivatives **4**–**7**.

Results and discussion



Synthesis

The synthesis of **1** and **2** was carried out from the hexadecabenzylated diol **3** readily available from α-cyclodextrin in two steps (Scheme 1) (8). Monosilylation of the diol **3** with TBSCl–imidazol was, however, not very selective, leading to a mixture of the mono- and di-silylated products (**4** and **5**), which could be separated by column chromatography to obtain them in 46% and 19% yield, respectively.



In an attempt to obtain **4** in a higher yield, a two-step synthesis procedure was attempted involving synthesis of silicon-bridged molecules **6** and **7** and subsequent attack on silicon with a *tert*-butyl organometalic reagent. The synthesis of the silicon diethers proceeded reasonably well; reaction of **3** with 1 equiv. of Me_2SiCl_2–pyridine gave **6** in 64% yield (Scheme 2). Similar reaction of **3** with *i*-Pr_2SiCl_2–

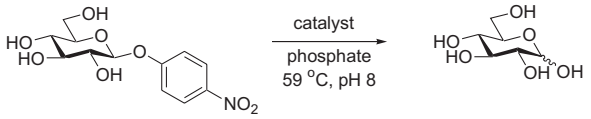
Scheme 2. Synthesis of **1**.

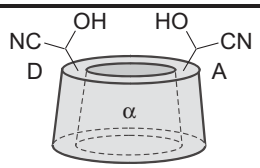
Scheme 3. Synthesis of **2**.

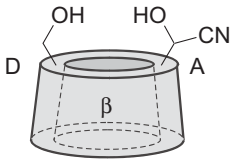
pyridine gave **7** in 30% yield. However, reaction of either **6** or **7** with a selection of organometalic reagents, such as methyl or *tert*-butyl magnesium chloride or butyllithium, gave neither a reaction nor loss of the protection group. Therefore, we had to satisfy ourselves with the relatively modest yield of **4**, obtained by direct silylation of **3**.

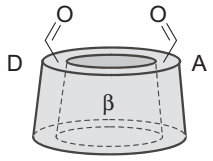
Oxidation of **4** to the aldehyde with Dess–Martin's periodinane, followed by subsequent oxidation to the carboxylic acid with $NaClO_2$, gave the acid **8** in 74% yield (Scheme 2). Removal of the TBS group with BF_3 afforded **9** in 49% yield. Oxidation of the remaining primary alcohol of **9** with Dess–Martin's periodinane and reaction of the resulting aldehyde with KCN then gave us **10** in 63% yield. Finally, hydrogenolysis of the benzyl groups gave target **1** in quantitative yield.

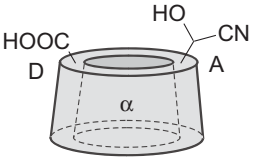


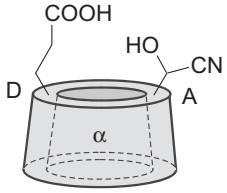
A related procedure was used to obtain **2**. Oxidation of **4** to the aldehyde was followed by Wittig reaction with benzyl 2-triphenylphosphonium acetate, which led to Wittig adduct **11** in 70% yield (Scheme 3). Deprotection of the silyl group with BF_3 gave structure **12**. As **12** was subjected to oxidation and reaction with KCN, the aldehyde was converted to the cyanohydrin **13**, albeit in a rather low yield of 35%. Hydrogenolysis eventually gave saturation of the double bond and removal of all protection groups affording a quantitative yield of target **2**.











Catalysis

The glycosidase activity of **1** and **2** was investigated by monitoring their influence on the hydrolysis of 4-nitrophenyl-β-D-glucopyranoside at pH 8 and 59 °C (Table 1). These reactions were monitored by following the increase in absorption at 400 nm. Similarly to previously investigated cyclodextrin cyanohydrins (4, 5), both **1** and **2** were found to be catalytic. However, in contrast, the catalysis was found to decline rapidly as a function of time. As shown in Figs. 2 and 3, the progress curves were initiated by a boost of a rapid reaction, which in 1 to 2 h declined to become a steady-state rate that was identical or slightly higher than the background reaction rate. Since over the time period only a small amount of substrate was converted, the phenomenon cannot be caused by substrate depletion. Furthermore, since the change in rate, depending on the condi-

[a]Initial catalytic rate.
[b]End catalytic rate.
[c]No catalysis.

tions, was complete before even one turnover occurred, it is extremely unlikely that product inhibition or covalent reaction between substrate and catalyst is the reason for the decline in the hydrolysis rate. As a control, the catalyst (**1** or **2**) was incubated for 2 h in buffer at 59 °C before being added to the substrate, and under these conditions the rapid reaction onset disappears and the initial rate is identical to the end rate. It is therefore safe to conclude that the catalyst undergoes a chemical reaction – decomposition reaction under the reaction conditions.

By fitting a line either to the progress curve over the first 0.5 h or after 3 h, it was possible to determine an initial rate of reaction and an end reaction rate (Table 1). For **2**, the end rate is identical to the background rate, i.e., there is no catalysis. For the other cases, a catalytic rate is obtained by subtracting the background rates, giving catalysed rates. These catalysed rates follow, both for the initial rate and the end rate, Michaelis–Menten kinetics,giving the K_M and k_{cat} values as shown in Table 1. The k_{cat} is used together with the uncatalysed rate to calculate a k_{cat}/k_{uncat} value.

As demonstrated, the values for k_{cat}/k_{uncat} for the initial reaction is 1102 and 567 for **1** and **2**, respectively. This is very similar to the rate accelerations obtained with other cyclodextrin cyanohydrins. Thus, the α-cyclodextrin dicyanohydrin gave a k_{cat}/k_{uncat} of 2688 under these conditions, while β-cyclodextrin monocyanohydrin gave k_{cat}/k_{uncat} = 1067 (Table 1) (5). It is therefore probable that **1** and **2** are able to initially function with the cyanohydrin in-

Scheme 4. Two possible mechanisms for the decomposition of **1**.

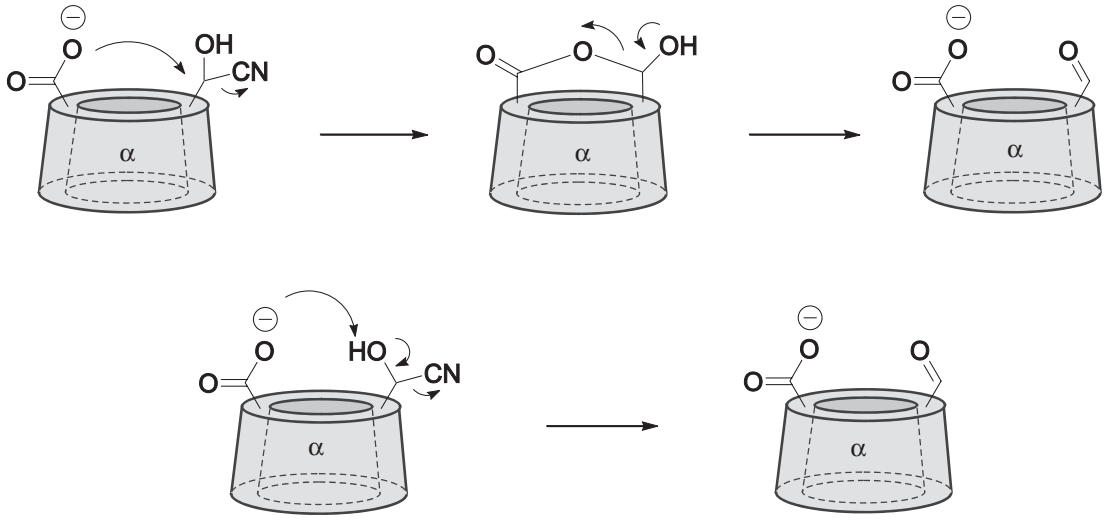

Fig. 2. Progress curve for the hydrolysis of 4-nitrophenyl β-D-glucopyranoside (pH 8, T = 59 °C, 50 mmol/L of phosphate buffer) in the presence of **1** or nothing (background).

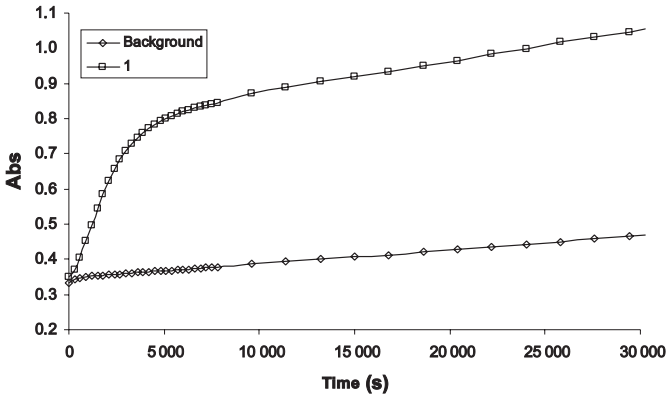

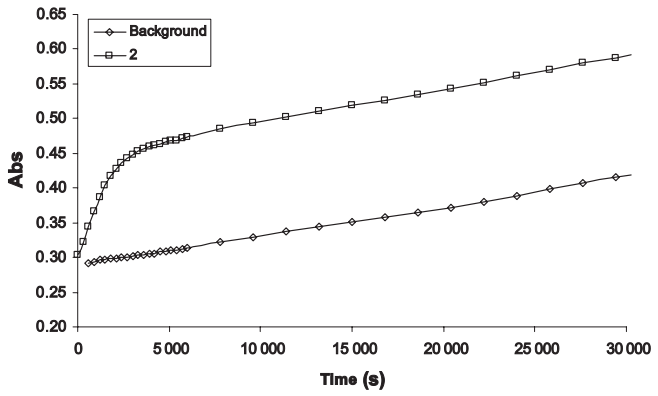

Fig. 3. Progress curve for the hydrolysis of 4-nitrophenyl β-D-glucopyranoside (pH 8, T = 59 °C, 50 mmol/L of phosphate buffer) in the presence of **2** or nothing (background).

tact and having the intended catalytic role. However, it was also observed that this initial catalysis was not higher than that of the previous catalysts, indicating that there is none of the intended cooperative catalysis between carboxylate and cyanohydrin.

The end k_{cat}/k_{uncat}, on the other hand, is 43 and no catalysis occurred for **1** and **2**, respectively (Table 1). This in likelihood means that the cyanohydrin has been blocked or destroyed. There are two reasonable possibilities of how this might occur. Either the free carboxylic acid might form an ester, a lactone, with the cyanohydrin hydroxyl group or another alcohol, which either blocks the catalytic group or the cavity to an extent that the substrate cannot enter. Alternatively, the carboxylate may function as an internal nucleophile and perform nucleophilic catalysis, not as intended on the substrate, but on the cyanohydrin, making it undergo hydrolysis to the aldehyde and cyanide. This latter explanation makes more chemical sense: lactonization of hydroxy acids is normally not thermodynamically favorable at pH 8, so it is not very plausible that a lactone would be the major form of **1** or **2** at pH 8. Further, the relatively weak catalysis obtained from decomposed **1** does indeed suggest that the compound has been converted to an aldehyde, since we have previously found that β-cyclodextrin dialdehyde is a weak catalyst (Table 1).

To support either hypothesis, the decomposition of **1** in buffer was followed by MS spectroscopy at different intervals, and the initial peak corresponding to M + Na of **1** was over time converted to new peak corresponding to M + Na of the corresponding cyclodextrin acidaldehyde. It is therefore clear that the rapidly declining catalytic activity of **1** and **2** is due to rapid decomposition of the cyanohydrin into the aldehyde, and we propose the intramolecular mechanisms outlined in Scheme 4 for this conversion. Thus, either attack of carboxylate ion on the cyanohydrin leads to substitution of this group and formation of a lactone hemiacetal that subsequently cleaves readily. Alternatively, the carboxylate acts as a general base catalyst, assisting the spontaneous decomposition of the cyanohydrin. At present these mechanisms are indistinguishable. It is remarkable that both **1** and **2** undergo this cleavage with ease despite the fact that the carboxylate is placed at rather different positions, though it is also clear that **2** undergoes decomposition faster. Nevertheless, the observation that **1** undergoes this reaction at all suggests that a considerable flexibility is present in the cyclodextrin.

In summary, we have prepared two new cyclodextrin derivatives that contain a cyanohydrin and a carboxylate group on the primary face of the cyclodextrin. Both compounds are able to catalyse the hydrolysis of glycosides with a rate that is equivalent to the rate previously seen with other cyclodextrin cyanohydrins, but rapidly lose activity. This decomposition was found to occur as the cyanohydrin cleaved into the corresponding aldehyde and cyanide, and the carboxylate group is believed to catalyse this process.

Experimental

All reagents were used as purchased without further purification. TLC was performed on Merck silica gel 60 F_{254} plates with detection by charring with cerium sulphate and ammonium heptamolybdat, and by UV light when applicable. Flash column chromatography was performed on Fluka silica gel (230–400 mesh) as the stationary phase. Optical rotations were recorded on a PerkinElmer 241 polarimeter at room temperature. IR spectra were recorded on a PerkinElmer FT-IR Paragon 1000. ^{1}H and ^{13}C NMR spectra were recorded on a Varian Mercury 400 MHz spectrometer. Chemical shifts are given in ppm and referenced to internal $SiMe_4$ (δ_H, δ_C 0.00). *J* values are given in Hz. MALDI-TOF mass spectra were recorded on a Bruker Daltonics mass spectrometer (Bruker) using an α-cyano-4-hydroxy-cinnamic acid (HCCA) matrix.

Procedure for determining the rate of hydrolysis

Each assay was performed on 2 mL samples prepared from 1 mL aqueous solutions of the appropriate aryl glycoside at different concentrations mixed with 1 mL of phosphate or other buffer containing either cyclodextrin derivative (0.5 mg/mL) or nothing as the control. The reactions were followed continuously at 59 °C using UV absorption at 400 nm. The reactions were monitored for 3–18 h. Velocities were determined as the slope of the progress curve of each reaction. Uncatalysed velocities were obtained directly from the control samples. Catalyzed velocities were calculated by subtracting the uncatalysed velocity from the velocity of the appropriate cyclodextrin-containing sample. The catalysed velocities were used to construct a Hanes plot ([S]/*V* vs. [S]) from which K_m and V_{max} were determined. k_{cat} was calculated as V_{max}/[cyclodextrin]. k_{uncat} was determined as the slope from a plot of V_{uncat} vs. [S].

From enolates to anthraquinones[1]

David Bailey, Jeffrey N. Murphy, and Vance E. Williams

Abstract: A series of highly reactive cyclopentadienones were prepared in situ from the corresponding hydroxycyclopent-2-enones and trapped with a variety of quinones. Reaction of 1,4-naphthoquinone with 4-hydroxy-3,4-diphenyl-cyclopent-2-enone afforded 2,3-diphenylanthraquinone, whereas reaction of benzoquinone with this same cyclopentadienone precursor yielded a mixture of 6,7-diphenyl-1,4-naphthoquinone and 2,3,6,7-tetraphenylanthraquinone. A number of other 2,3-diarylanthraquinones were likewise prepared in moderate yields from the reaction of 1,4-naphthoquinone with the appropriate 4-hydroxy-3,4-diarylcyclopent-2-enones. This method appears to be generally applicable to the synthesis of anthraquinone derivatives substituted at the 2- and 3-positions from inexpensive starting materials.

Key words: anthraquinone, Diels–Alder, cyclopentadienone, in situ.

Résumé : On a préparé in situ une série de cyclopentadiénones très réactives à partir des hydroxycyclopent-2-énones correspondantes et on les a piégées à l'aide d'une variété de quinones. La réaction de la 1,4-naphtoquinone avec la 4-hydroxy-3,4-diphénylcyclopent-2-énone conduit à la formation de 2,3-diphénylanthraquinone alors que la réaction de la benzoquinone avec la même cyclopentadiénone conduit à un mélange de 6,7-diphényl-1,4-naphtoquinone et de 2,3,6,7-tétraphénylanthraquinone. On a préparé un certain nombre d'autres 2,3-diarylanthraquinones avec des rendements modérés par réaction de la 1,4-naphtoquinone avec des 4-hydroxy-3,4-diarylcyclopent-2-énones appropriées. Le domaine d'application de cette méthode semble général pour la synthèse de dérivés de l'anthraquinone substitués dans les positions 2 et 3, à partir de produits de départs peu coûteux.

Mots clés : anthraquinone, Diels–Alder, cyclopentadiénone, in situ.

Introduction

> *If you learn nothing else from this class, I want you to remember: "Enolates are nucleophiles."* — Walter Szarek, speaking to his 3rd year organic chemistry class in 1991.

Anthraquinones are a versatile class of compounds that have been exploited as dyes (1), chemical sensors (2), organogelators (3), liquid crystals (4–8), anticancer agents (9), DNA photooxidants (10), and as precursors to substituted anthracenes. Our own interest in the synthesis of anthraquinone derivatives arose out of investigations into the [4+4]-photocycloaddition reactions of peripherally substituted chromophores such as 2,3,6,7-tetraphenylanthracene (11), the logical precursor of which is the anthraquinone (**1**). This quinone could be prepared in a one-pot reaction between 3,4-diphenylthiophene-1,1-dioxide (**2**) and benzoquinone (Scheme 1). Likewise, treatment of compound **2** with 1,4-naphthoquinone afforded 2,3-diphenylanthraquinone (**3**) in 70% yield (12). Although these sulfones are relatively stable and can be prepared from readily accessible thiophenes, the large-scale synthesis of these molecules has, in our hands, proven unreliable. For this reason, we decided to investigate the use of in situ generated cyclopentadienones as synthetic equivalents of sulfones in the construction of anthraquinones.

Cyclopentadienones condense with alkynes to form Diels–Alder adducts, which, upon loss of carbon monoxide, afford highly substituted benzene derivatives (13–16). These cyclones therefore behave in a similar manner to thiophene-1,1-dioxides, although the former tend to be much more reactive than the latter. Unlike sulfones, cyclopentadienones are highly unstable unless substituted at the 2- and 5-positions, and derivatives that lack bulky groups at these sites generally must be generated in situ from precursors such as the corresponding hydroxycyclopent-2-enones (15, 17, 18). Perhaps for this reason, cyclopentadienones have rarely been employed in the synthesis of anthraquinones (15, 19, 20), and only relatively stable derivatives of this type have been used for this purpose. Indeed, while there is some precedent for in situ generated cyclones being used in Diels–Alder reactions with alkynes (15, 19), we are aware of no examples of these compounds being trapped with quinone dienophiles to afford either anthraquinones or naphthoquinones. We therefore wished to explore whether the use of

hydroxycyclopent-2-enones in the synthesis of anthraquinones was a viable strategy or would merely result in a fiasco.

Experimental

Materials and methods

^{1}H NMR (400 MHz) and ^{13}C NMR (100 MHz) were carried out on a Bruker AMX-400 400 MHz spectrometer; FT-IR spectroscopy was performed on a Thermo Nicolet Nexus 670 FT-IR ESP spectrometer, using KBr pellets. Microanalyses (C, H, N) were performed at Simon Fraser University, Burnaby, British Columbia, by Mr. Miki Yang. Low-resolution EI (70 eV) mass spectrometry was carried out on a Hewlett Packard 5985 mass spectrometer. Melting points were performed on either an Olympus BX50 polarizing microscope with a Linkam 94 heating stage or a MelTempII melting point apparatus and are uncorrected. MALDI-TOF mass spectra were obtained on a Perspective Voyager-DE STR from PE Applied Biosystems with a nitrogen laser (337 nm) and using 2,5-dihydroxybenzoic acid as the matrix.

1,4-Benzoquinone and *p*-toluenesulfonic acid were purchased from the Fisher Scientific Company. 1,4-Napthoquinone was obtained from Eastman Organic Chemicals. Copper sulfate, tetrakis(triphenylphosphine)palladium, copper(I) iodide, diisopropylamine, potassium iodide, benzaldehyde, *p*-anisaldehyde, 2-naphthaldehyde, 4-bromobenzaldehyde, 4-iodoanisole, and phenylacetylene were purchased from the Sigma-Aldrich Chemical Company Inc. The *o*-tolualdehyde was purchased from Matheson, Coleman, and Bell. Silica gel (230–400 mesh ASTM) was purchased from EMD Chemicals Inc. 1,4-Benzoquinone and 1,4-naphthoquinone were sublimed prior to use. Tetrahydrofuran was dried over sodium using benzophenone as an indicator. Benzaldehyde was distilled at reduced pressure. All other reagents were used as received.

Note that in the case of compounds **1**, **3**, **8**, **9**, **11**, **12**, and **24**, fewer peaks were observed in the ^{13}C NMR spectra than were predicted. This is probably due to inadequate peak resolution arising from the similarity in the chemical environments of many of the carbon nuclei. Attempts to resolve these peaks using d_6-benzene as the solvent were unsuccessful.

Synthesis

2,3,6,7-Tetraphenylanthraquinone (1) and 6,7-diphenyl-1,4-naphthaquinone (7)

To a solution of 1,4-benzoquinone (0.71 g, 6.6 mmol) in 180 mL acetic acid was added 0.84 g (3.3 mmol) of 4-hydroxy-3,4-diphenylcyclopent-2-enone (**4**) and 0.065 g (0.38 mmol) of *p*-toluenesulfonic acid. This mixture was refluxed for 49 h, then cooled to room temperature, poured over water (150 mL), and extracted with CH_2Cl_2 (3 × 100 mL). The combined organic extracts were dried over $MgSO_4$ and the solvent was removed in vacuo. The crude product was purified by column chromatography using silica gel with toluene as the eluent. 2,3,6,7-Tetraphenylanthraquinone (**1**) was eluted from the column first, followed by 6,7-diphenylnaphthoquinone (**7**).

*2,3,6,7-Tetraphenylanthraquinone (**1**)*

2,3,6,7-Tetraphenylanthraquinone (**1**) was recrystallized from ethanol to afford 0.22 g (0.46 mmol) of a yellow solid; mp: 323 to 324 °C. IR (cm^{-1}): 1672 (C=O stretch). ^{1}H NMR (ppm, acetone-d_6) δ: 8.39 (s, 4H), 7.22–7.29 (m, 20H). ^{13}C NMR (ppm, $CDCl_3$) δ: 182.8, 146.4, 139.6, 132.4, 129.7, 128.2, 127.7 (eight peaks predicted, seven observed). MS (EI) *m*/*z*: 512. HRMS calcd. for $C_{38}H_{24}O_2$: 512.1776; found: 512.1774.

*6,7-Diphenyl-1,4-naphthoquinone (**7**)*

6,7-Diphenyl-1,4-naphthoquinone (**7**) was recrystallized from ethanol to afford 150 mg (0.48 mmol) of a yellow solid; mp: 123–125 °C. IR (cm^{-1}): 1668 (C=O stretch). ^{1}H NMR (ppm, CD_2Cl_2) δ: 8.11 (s, 2H), 7.17–7.29 (m, 10H), 7.00 (s, 2H). ^{13}C NMR (ppm, $CDCl_3$) δ: 184.9, 146.2, 139.5, 138.8, 130.6, 129.6 128.8, 128.2, 127.7. MS (EI) *m*/*z*: 310 [M$^+$]. HRMS calcd. for $C_{22}H_{14}O_2$: 310.0994; found: 310.0996.

2,3-Diphenylanthraquinone (3)

To a solution of 1,4-naphthoquinone (0.81 g, 5.2 mmol) in 130 mL acetic acid was added 0.64 g (2.6 mmol) of 4-hydroxy-3,4-diphenylcyclopent-2-enone and 0.090 g (0.52 mmol) of *p*-toluenesulfonic acid. This mixture was then refluxed for 39 h. The solution was then cooled to room temperature, poured over water (150 mL), and then extracted with CH_2Cl_2 (3 × 100 mL). The combined organic extracts were dried over $MgSO_4$ and the solvent removed in vacuo. The crude product was purified by column chromatography on silica gel with toluene as the eluent and then recrystallized from ethanol to afford 0.39 g (1.1 mmol, 42%) of **3**; mp: 203–206 °C (lit. value (21) mp 211 to 212 °C). IR (cm^{-1}): 1676 (C=O stretch). ^{1}H NMR (ppm, $CDCl_3$) δ: 8.36 (s, 2H), 8.35 (dd, 2H, *J* = 3.36, 5.80 Hz), 7.82 (dd, 2H, *J* =

© 2006 NRC Canada

3.36, 5.80 Hz), 7.30–7.20 (m, 10H). ^{13}C NMR (ppm, $CDCl_3$) δ: 183.0, 146.4, 139.6, 134.1, 132.2, 129.7, 128.3, 127.7, 127.3 (11 peaks predicted, 9 observed). MS (EI) *m/z*: 360 [M^+].

2,3-Di(naphthalen-2-yl)anthraquinone (8)

2,3-Di(naphthalen-2-yl)anthraquinone (**8**) was prepared from 4-hydroxy-3,4-di(naphthalen-2-yl)cyclopent-2-enone (**16**) according to the method described previously. The crude product was eluted through silica gel with a 1:1 mixture of hexanes–toluene, and then recrystallized from ethanol to afford 0.055 g (0.13 mmol, 18%) of **8** as a yellow solid; mp: 238 °C. ^{1}H NMR (ppm, $CDCl_3$) δ: 8.53 (s, 2H), 8.38 (dd, 2H, *J* = 3.3, 5.8 Hz), 7.96 (s, 2H), 7.85 (dd, 2H, *J* = 3.3, 5.8 Hz), 7.81 (dd, 2H, *J* = 3.4, 6.0 Hz), 7.76 (dd, 2H, *J* = 3.4, 6.0 Hz), 7.59 (d, 2H, *J* = 8.6 Hz), 7.48 (dd, 4H, *J* = 3.2, 6.2 Hz), 7.17 (dd, 4H, *J* = 1.7, 8.5 Hz). ^{13}C NMR (ppm, $CDCl_3$) δ: 183.0, 146.4, 137.3, 134.2, 133.8, 133.3, 132.6, 132.4, 130.1, 128.9, 128.3, 127.7, 127.4, 127.3, 126.5, 126.3 (17 peaks predicted, 16 observed). MALDI-TOF *m/z*: 462 [M + 2, 100]. Elemental anal. calcd. for $C_{34}H_{20}O_2$: C 88.67, H 4.38; found: C 88.51, H 4.58.

2,3-Di(o-tolyl)anthraquinone (9)

2,3-Di(*o*-tolyl)anthraquinone (**9**) was prepared from 4-hydroxy-3,4-di(*o*-tolyl)cyclopent-2-enone (**17**) according to the method described previously. The crude product was eluted through silica gel with toluene and recrystallized from ethanol to yield 0.090 g (0.23 mmol, 17%) of **9** as an off-white solid; mp 247 °C. ^{1}H NMR (ppm, $CDCl_3$) δ: 8.34 (dd, 2H, *J* = 3.3, 5.7 Hz), 8.28 (s, 2H), 7.82 (dd, 2H, *J* = 3.3, 5.7 Hz), 7.13–6.91 (broad m, 8H), 2.11 (s, 6H). ^{13}C NMR (ppm, $CDCl_3$) δ: 183.1, 147.3 (broad), 139.1 (broad), 135.3, 134.1, 133.8, 131.9, 130.2, 129.8, 127.8, 127.2, 125.2, 20.2 (broad) (14 peaks predicted, 13 observed). MS (EI) *m/z*: 388.1 [M^+, 100]. Elemental anal. calcd. for $C_{28}H_{20}O_2$: C 86.57, H 5.19; found: C 86.38, H 5.27.

2,3-Bis(4-methoxyphenyl)anthraquinone (10)

2,3-Bis(4-methoxyphenyl)anthraquinone (**10**) was prepared from 4-hydroxy-3,4-bis(4-methoxyphenyl)cyclopent-2-enone (**18**) according to the method described previously. The crude product was eluted through silica gel with a 4:1 mixture of hexanes – ethyl acetate as the eluent. The resulting product was recrystallized from ethanol to afford 0.04 g (0.09 mmol, 7%) of **10** as a brown solid; mp 168 °C. ^{1}H NMR (ppm, $CDCl_3$) δ: 8.34 (dd, 2H, *J* = 3.3, 5.8 Hz), 8.31 (s, 2H), 7.81 (dd, 2H, *J* = 3.3, 5.8 Hz), 7.16 (d, 4H, *J* = 8.7 Hz), 6.82 (d, 4H, *J* = 8.7 Hz), 3.82 (s, 6H). ^{13}C NMR (ppm, $CDCl_3$) δ: 183.0, 159.2, 145.9, 134.0, 133.8, 132.1, 131.9, 130.9, 129.5, 127.2, 113.8, 55.2. MS (CI) *m/z*: 421.2, 422.1 [M + 1, 100] (29%). Elemental anal. calcd. for $C_{28}H_{20}O_4$: C 79.98, H 4.97; found: C 80.13, H 4.90.

2-(4-Methoxyphenyl)-3-phenylanthraquinone (11)

2-(4-Methoxyphenyl)-3-phenylanthraquinone (**11**) was prepared from a mixture of **21a** and **21b** according to the method described previously. The crude product was eluted through a silica gel column using toluene. Recrystallization from ethanol afforded 0.087 g (0.22 mmol, 18%) of **11** as a yellow solid; mp 89–91 °C. ^{1}H NMR (ppm, $CDCl_3$) δ: 8.36–8.34 (m, 4H), 7.82 (dd, 2H, *J* = 3.3, 5.8 Hz), 7.30–7.29 (m, 3H), 7.23 (dd, 2H, *J* = 3.0, 6.7 Hz), 7.14 (d, 2H, *J* = 8.7 Hz), 6.80 (d, 2H, *J* = 8.7 Hz), 3.80 (s, 3H). ^{13}C NMR (ppm, $CDCl_3$) δ: 183.3, 183.2, 159.5, 146.5, 146.3, 140.1, 134.3, 134.3, 134.0, 133.9, 132.5, 132.1, 131.1, 130.0, 129.8, 129.7, 128.5, 127.8, 127.5, 113.9, 55.5 (23 peaks predicted, 21 observed). MS (EI) *m/z*: 390.4 [$C_{27}H_{18}O_3^+$, 100]. Elemental anal. calcd. for $C_{27}H_{18}O_3$: C 83.06, H 4.65; found: C 82.80, H 4.89.

2-(4-Bromophenyl)-3-(4-methoxyphenyl)anthraquinone (12)

2-(4-Bromophenyl)-3-(4-methoxyphenyl)anthraquinone (**12**) was prepared from 3-(4-bromophenyl)-4-hydroxy-4-(4-methoxyphenyl)cyclopent-2-enone/4-(4-bromophenyl)-4-hydroxy-3-(4-methoxyphenyl)cyclopent-2-enone (**23**) according to the method described previously. The product was eluted through silica gel with toluene, then recrystallized from ethanol to afford 0.120 g (0.26 mmol, 21%) of **12** as an orange solid; mp 215 to 216 °C. ^{1}H NMR (ppm, $CDCl_3$) δ: 8.34 (dd, 2H, *J* = 3.1, 5.4 Hz), 8.33 (s, 1H), 8.30 (s, 1H), 7.83 (dd, 2H, *J* = 3.3, 5.8 Hz), 7.43 (d, 2H, *J* = 8.4 Hz), 7.14–7.09 (m, 4H), 6.83 (d, 2H, *J* = 8.7 Hz), 3.82 (s, 3H). ^{13}C NMR (ppm, $CDCl_3$) δ: 183.2, 183.1, 159.6, 146.3, 145.1, 139.0, 134.4, 134.4, 133.9, 132.7, 132.2, 131.8, 131.7, 131.4, 131.1, 129.8, 129.7, 127.5, 122.3, 114.1, 55.5 (23 peaks predicted, 21 observed). MS (CI) *m/z* (relative intensity): 468.2 (80%), 469.2 (60%), 470.2 (100%), 471.2 (58%), 472 (13%). Elemental anal. calcd. for $C_{27}H_{17}BrO_3$: C 69.10, H 3.65; found: C 69.27, H 3.72.

2-(4-Methoxyphenyl)-3,6,7-triphenylanthraquinone (24)

2-(4-Methoxyphenyl)-3,6,7-triphenylanthraquinone (**24**) was prepared from 6,7-diphenyl-1,4-naphthoquinone and a mixture of **21a** and **21b**. The crude product was purified through silica gel with toluene as the eluent. Recrystallization of this product from ethanol afforded 0.14 g (0.26 mmol, 26%) of **24** as an orange solid; mp 230 °C. ^{1}H NMR (ppm, $CDCl_3$) δ: 8.40 (s, 2H), 8.38 (d, 2H, *J* = 2.9 Hz), 7.31–7.23 (m, 15H), 7.17 (d, 2H, *J* = 8.8 Hz), 6.82 (d, 2H, *J* = 8.8 Hz), 3.81 (s, 3H). ^{13}C NMR (ppm, $CDCl_3$) δ: 183.1, 183.0, 159.5, 146.6, 146.6, 146.4, 146.3, 140.1, 139.9, 132.7, 136.7, 132.3, 132.1, 131.2, 130.0, 129.9, 129.8, 129.7, 128.5, 128.4, 127.9, 127.8, 113.9, 55.5 (31 peaks predicted, 24 observed). MALDI-TOF *m/z*: 543 [M^+, 100]. Elemental anal. calcd. for $C_{39}H_{26}O_3$: C 86.32, H 4.83; found: C 85.97, H 5.03.

2,3-Bis(4-methoxyphenyl)-6,7-diphenylanthraquinone (25)

2,3-Bis(4-methoxyphenyl)-6,7-diphenylanthraquinone (**25**) was prepared from 6,7-diphenyl-1,4-napthoquinone (**7**) and 4-hydroxy-3,4-bis(4-methoxyphenyl)cyclopent-2-enone (**18**) according to the method described previously. This mixture of products was then purified through silica gel with a 4:1 mixture of hexanes – ethyl acetate as the eluent. The resulting solid was recrystallized from ethanol to afford 0.050 g (0.09 mmol, 7%) of **25** as an orange solid; mp 235 °C. ^{1}H NMR (ppm, $CDCl_3$) δ: 8.39 (s, 2H), 8.35 (s, 2H), 7.30–7.22 (m, 10H), 7.18 (d, 4H, *J* = 8.8 Hz), 6.83 (d, 4H, *J* = 8.7 Hz), 3.82 (s, 6H). ^{13}C NMR (ppm, $CDCl_3$) δ: 183.1, 159.4, 146.6, 146.1, 139.9, 132.7, 132.4, 132.3, 131.1, 129.9, 129.9, 129.8, 128.4, 127.9, 114.0, 55.5. General method for the preparation of ethane diones

The aldehyde (32 mmol) and potassium cyanide (1.3 g, 20 mmol) were dissolved in 20 mL of ethanol and 10 mL of water. After refluxing for 24 h, the solution was poured over water and extracted with dichloromethane, yielding the coupled α-hydroxyketone. This product was then dissolved in 25 mL pyridine and 15 mL water, and 5.0 g $CuSO_4$ (35 mmol) was added. This solution was refluxed for 16 h, then cooled to room temperature and extracted with dichloromethane. The combined organic extracts were washed water and the solvent removed to afford the 1,2-dione.

1,2-Di(o-tolyl)ethane-1,2-dione (14)

1,2-Di(*o*-tolyl)ethane-1,2-dione (**14**) was prepared in the manner described in the previous paragraph and was isolated as a pale yellow solid (66% yield); mp 88 to 89 °C (lit. value (22) mp 92 °C). ^{1}H NMR (ppm, $CDCl_3$) δ: 7.66 (d, 2H, *J* = 7.8 Hz), 7.49 (t, 2H, *J* = 7.5 Hz), 7.35 (d, 2H, *J* = 7.6 Hz), 7.28 (m, 2H), 2.71 (s, 6H).

1,2-Bis(4-methoxyphenyl)ethane-1,2-dione (15)

1,2-Bis(4-methoxyphenyl)ethane-1,2-dione (**15**) was prepared in the manner described previously and was isolated as a yellow solid (32% yield); mp obs. 131 °C (lit. value (23) mp 133 °C). ^{1}H NMR (ppm, DCl_3) δ: 7.95 (d, 4H, *J* = 8.8 Hz), 6.97 (d, 4H, *J* = 8.9 Hz), 3.89 (s, 6H).

1,2-Di(naphthalen-2-yl)ethane-1,2-dione (16)

1,2-Di(naphthalen-2-yl)ethane-1,2-dione (**16**) was prepared in the manner described previously, except NaCN was used in place of KCN, and the benzoin condensation was only allowed to proceed for 1.5 h instead of 24 h. Compound **16** was isolated in 64% yield as an off-white solid; mp 155 °C (lit. value (24) mp 155 to 156 °C). ^{1}H NMR (ppm, $CDCl_3$) δ: 8.45 (s, 2H), 8.15 (dd, 2H, *J* = 1.6 8.6 Hz), 7.99 (d, 2H, *J* = 8.7 Hz), 7.90 (d, 4H, *J* = 8.8 Hz), 7.64 (t, 2H, *J* = 7.6 Hz), 7.55 (t, 2H, *J* = 7.6 Hz). ^{13}C NMR (ppm, $CDCl_3$) δ: 194.8, 136.4, 133.6, 132.4, 130.5, 130.0, 129.6, 129.2, 128.0, 127.2, 123.8.

1-(4-Methoxyphenyl)-2-phenylethane-1,2-dione (20)

1-(4-Methoxyphenyl)-2-phenylethane-1,2-dione (**20**) was prepared in the manner described previously and was purified by column chromatography (silica gel, toluene) as a pale yellow solid (22% yield); mp 58.5–60 °C (lit. value (25) mp 61 °C). ^{1}H NMR (ppm, $CDCl_3$) δ: 7.96 (m, 4H), 7.65 (t, 1H, *J* = 7.4 Hz), 7.51 (t, 2H, *J* = 7.8 Hz), 6.98 (d, 2H, *J* = 8.9 Hz), 3.89 (s, 1H).

1-(4-Bromophenyl)-2-(4-methoxyphenyl)ethane-1,2-dione (22)

1-(4-Bromophenyl)-2-(4-methoxyphenyl)ethane-1,2-dione (**22**) was prepared in the manner described previously and was isolated as a yellow solid (46% yield); mp 135 °C (lit. value (26) mp 136 to 137 °C). ^{1}H NMR (ppm, $CDCl_3$) δ: 7.93 (d, 2H, *J* = 8.9 Hz), 7.84 (d, 2H, *J* = 8.6 Hz), 7.65 (d, 2H, *J* = 8.6 Hz), 6.98 (d, 2H, *J* = 8.9 Hz), 3.89 (s, 3H).

Alternate synthesis of 1-(4-methoxyphenyl)-2-phenylethane-1,2-dione (20)

To a dried Schlenk flask was added 4-iodoanisole (3.2 g, 13.8 mmol), tetrakis(triphenylphosphine)palladium (0.059 g, 0.05 mmol), and copper(I) iodide (0.815 g, 4.3 mmol) under nitrogen. To this mixture was added via syringe phenylacetylene (1.75 mL, 16 mmol), 50 mL of dry tetrahydrofuran, and 10 mL of dry diisopropylamine. The resulting mixture was refluxed under nitrogen for 45 h, at which time it was cooled to room temperature and eluted through a short plug of silica gel with dichloromethane. After removing the solvent in vacuo, the crude product was oxidized by treating it with iodine (3.94 g, 15.6 mmol) in dimethylsulfoxide (50 mL) at 145 °C for 44 h. This solution was cooled to room temperature, poured into water, and the resulting mixture was extracted with dichloromethane. The combined organic extracts were washed with brine, then with a saturated aqueous potassium iodide solution, dried ($MgSO_4$), and the solvent removed under reduced pressure. The product was then recrystallized from a methanol–water mixture to **20** as a pale yellow solid (1.7 g, 8.2 mmol, 59% yield).

General method for the preparation of 4-hydroxy-3,4-diarylcyclopent-2-enones

Ethane-1,2-dione (10 mmol) was stirred for 1 week at room temperature in an ethanolic solution of potassium hydroxide (0.56 g, 10 mmol) and acetone (12 mL, 160 mmol). This solution was then poured over water and extracted with dichloromethane, yielding the desired product. Since these compounds proved difficult to purify, they were used directly in the condensation reactions with quinones.

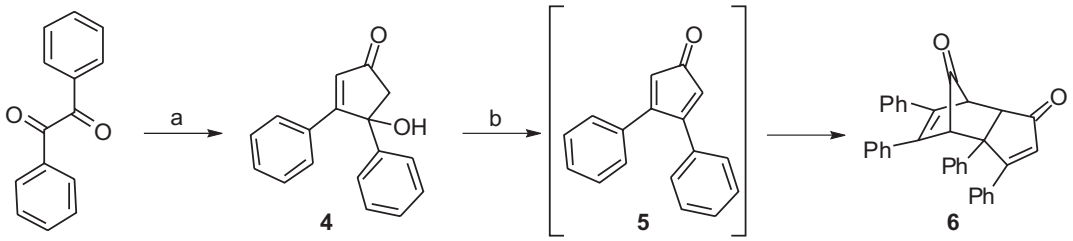
4-Hydroxy-3,4-diphenylcyclopent-2-enone (4)

4-Hydroxy-3,4-diphenylcyclopent-2-enone (**4**) was prepared in the manner described in the previous paragraph as a pale yellow solid (96% yield). ^{1}H NMR (ppm, $CDCl_3$) δ: 7.52–7.50 (m, 2H), 7.47–7.44 (m, 2H), 7.37–7.27 (m, 6H), 6.71 (s, 1H), 3.02 (d, 1H, *J* = 18.5 Hz), 2.90 (d, 1H, *J* = 18.5 Hz).

4-Hydroxy-3,4-di(naphthalene-2-yl)cyclopent-2-enone (16)

4-Hydroxy-3,4-di(naphthalene-2-yl)cyclopent-2-enone **(16)** was prepared in the manner described previously as a brown solid. ^{1}H NMR (ppm, $CDCl_3$) δ: 8.19 (d, 2H, *J* = 11.5 Hz), 7.85–7.40 (m, 12H), 6.90 (s, 1H), 3.13 (d, 1H, *J* = 18.6 Hz), 3.02 (d, 1H, *J* = 18.6 Hz).

4-Hydroxy-3,4-di(o-tolyl)cyclopent-2-enone (17)



4-Hydroxy-3,4-di(*o*-tolyl)cyclopent-2-enone (**17**) was prepared in the manner described previously as a brown solid. ^{1}H NMR (ppm, $CDCl_3$) δ: 7.55–7.53 (m, 2H), 7.20–7.14 (m, 4H). 6.99–6.97 (m, 2H), 6.40 (s, 1H), 3.07 (d, 2H, *J* = 18.6 Hz), 2.98 (d, 2H, *J* = 18.6 Hz), 2.41 (s, 3H), 2.31 (s, 3H).

4-Hydroxy-3,4-bis(4-methoxyphenyl)cyclopent-2-enone (18)

4-Hydroxy-3,4-bis(4-methoxyphenyl)cyclopent-2-enone (**18**) was prepared in the manner described previously as a brown solid. ^{1}H NMR (ppm, $CDCl_3$) δ: 7.52 (d, 2H, *J* = 9.0 Hz), 7.34 (d, 2H, *J* = 8.8 Hz), 6.83 (dd, 4H, *J* = 8.9, 20.5 Hz),

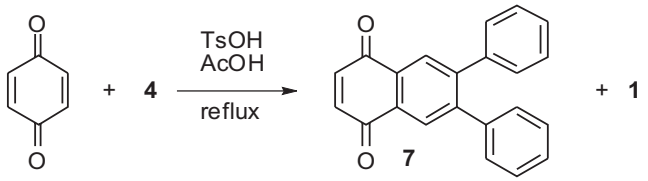
6.60 (s, 1H), 3.79 (s, 3H), 3.78 (s, 3H), 2.98 (d, 2H, *J* = 18.5 Hz), 2.85 (d, 2H, *J* = 18.5 Hz).

4-Hydroxy-3-(4-methoxyphenyl)-4-phenylcyclopent-2-enone (21a)

4-Hydroxy-3-(4-methoxyphenyl)-4-phenylcyclopent-2-enone (**21a**) was prepared in the manner described previously and isolated via column chromatography (silica, toluene–EtOAc, 9:1 as eluent) as a white solid. ^{1}H NMR (ppm, $CDCl_3$) δ: 7.51 (dt, 2H, *J* = 9.0, 2.1 Hz), 7.45 (dt, 2H, *J* = 7.3, 1.6 Hz), 7.35 (td, 2H, *J* = 7.6, 1.8 Hz), 7.28–7.25 (m, 1H), 2.88 (d, 1H, *J* = 18.4 Hz), 2.53 (br, 1H).

4-Hydroxy-4-(p-methoxyphenyl)-3-phenylcyclopent-2-enone (21b)

4-Hydroxy-4-(*p*-methoxyphenyl)-3-phenylcyclopent-2-enone (**21b**) was prepared in the manner described previously and isolated via column chromatography (silica, toluene–EtOAc, 7:3 as eluent) as a yellow solid. ^{1}H NMR (ppm, $CDCl_3$) δ: 7.52 (dt, 2H, *J* = 7.1, 1.3 Hz), 7.37–7.35 (m, 3H), 7.30 (td, 2H, *J* = 7.4, 1.5 Hz), 6.87 (dt, 2H *J* = 8.8, 2.5 Hz), 6.66 (s, 1H), 3.79 (s, 3H), 3.00 (d, 1H, *J* = 18.5 Hz), 2.88 (d, 1H, *J* = 18.5 Hz), 2.65 (br, 1H).



3-(4-Bromophenyl)-4-hydroxy-4-(4-methoxyphenyl)cyclopent-2-enone and 4-(4-bromophenyl)-4-hydroxy-3-(4-methoxyphenyl)cyclopent-2-enone (23)

3-(4-Bromophenyl)-4-hydroxy-4-(4-methoxyphenyl)cyclopent-2-enone and 4-(4-bromophenyl)-4-hydroxy-3-(4-methoxyphenyl)cyclopent-2-enone (**23**) were prepared in the manner described previously as a yellow solid. No attempt was made to separate these isomers. ^{1}H NMR (ppm, $CDCl_3$) δ: 7.52–7.43 (m, 4H), 7.34–7.32 (m, 2H), 6.86 (d, 2H, *J* = 9.0 Hz), 6.82 (d, 2H, *J* = 8.9 Hz), 6.66 (s, 1H), 6.64 (s, 1H), 3.79 (s, 3H), 2.97 (d, 1H, *J* = 18.6 Hz), 2.83 (d, 1H, *J* = 18.5 Hz).

Results and discussion

Our initial studies focused on the construction of 2,3-diphenylanthraquinone (**3**) starting from benzil, which has the advantage of being an inexpensive, commercially available starting material. 4-Hydroxy-3,4-diphenylcyclopent-2-enone (**4**) was synthesized in 96% yield by the condensation of benzil and acetone in the presence of catalytic potassium hydroxide (27). Heating **4** in refluxing acetic acid for 48 h caused no appreciable decomposition of this compound. When this reaction was carried out in the presence of catalytic *p*-toluenesulfonic acid, however, compound **6** was obtained almost quantitatively. The formation of this product, which arises from the dimerization of the highly reactive intermediate **5** (17, 18), demonstrates that this cyclone was indeed being generated under these conditions (Scheme 2).

Scheme 3. Condensation of compound **4** with benzoquinone.

We next turned our attention to trapping this in situ generated cyclone with 1,4-naphthoquinone. When cyclopentadienone **5** was generated in the presence of excess quinone, compound **3** was formed as the major product in 42% yield. Significantly, only trace quantities (<5%) of the dimer **6** were observed under these conditions. More generally, this side product did not arise to an appreciable extent in any subsequent reactions of **4** with quinones, indicating that the dimerization of **5** does not pose a significant problem in these syntheses.

The condensation of **4** with 1,4-benzoquinone was next investigated. This reaction affords two major products: the anthraquinone derivative **1** and the naphthoquinone **7** in an approximately 1:1 ratio (Scheme 3). That significant quantities of the anthraquinone were formed even in the presence of a twofold excess of benzoquinone — conditions that should strongly promote formation of the naphthoquinone **7** — suggests that compound **7** or one of its precursors is a much more reactive dienophile than benzoquinone itself, thus favouring the rapid reaction with a second equivalent of the cyclone. This tendency for benzoquinone to form bisadducts in acetic acid has previously been observed in its reaction with anthracene (28) and 1,1-thiophene dioxides (12).

Far from being an unwanted side product, the naphthoquinone **7** is desirable as a potential dienophile for the subsequent preparation of unsymmetrical anthraquinones. In an attempt to bias the reaction towards the formation of this compound, the condensation of **4** with benzoquinone was carried out in refluxing toluene, which has previously been found to favor formation of monoadducts (12, 28). Once again, catalytic *p*-toluenesulfonic acid was added to activate **4** towards dehydration. Under these conditions, the formation of the cyclopentadienone intermediate **5** is considerably slower than when the reaction was carried out in acetic acid. After 2 days, no appreciable reaction of the starting materials was observed. Allowing this reaction to proceed for 6 days led to only 25% of compound **4** being consumed, although it was gratifying to note that the ratio of naphthoquinone to anthraquinone obtained had increased to 20:1. Addition of a small amount of acetic acid to this reaction

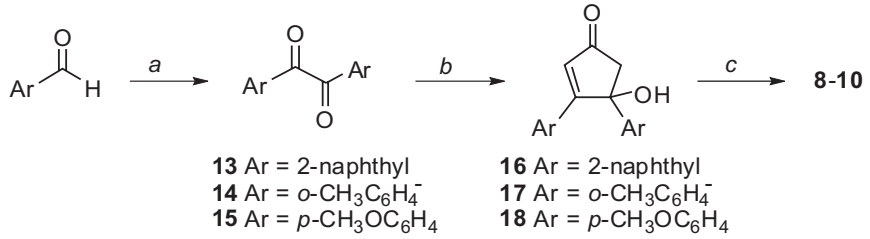
Scheme 4. Reagents and conditions: (*a*) NaCN or KCN, EtOH–H_2O, reflux; (*b*) acetone, KOH, RT, 1 week; (*c*) 1,4-naphthoquinone, AcOH, TsOH, reflux 48 h.



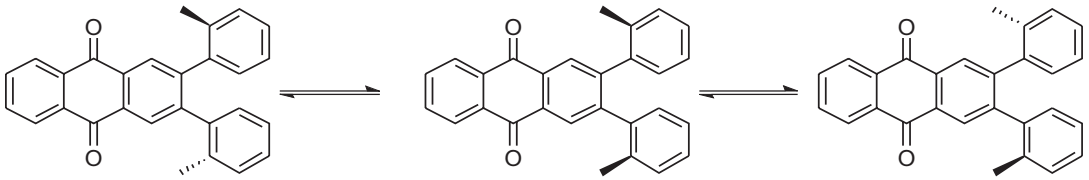


Fig. 1. syn–anti Isomerization of compound **10**.

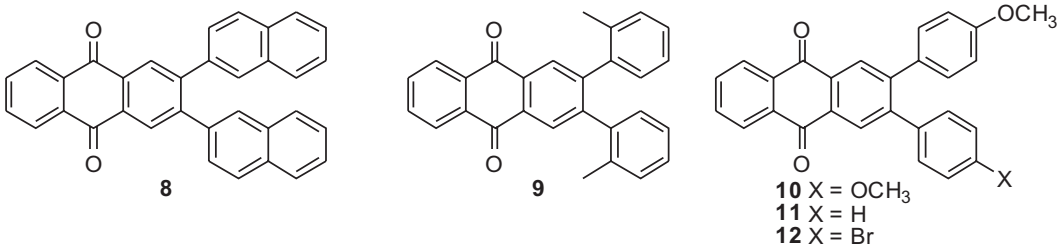
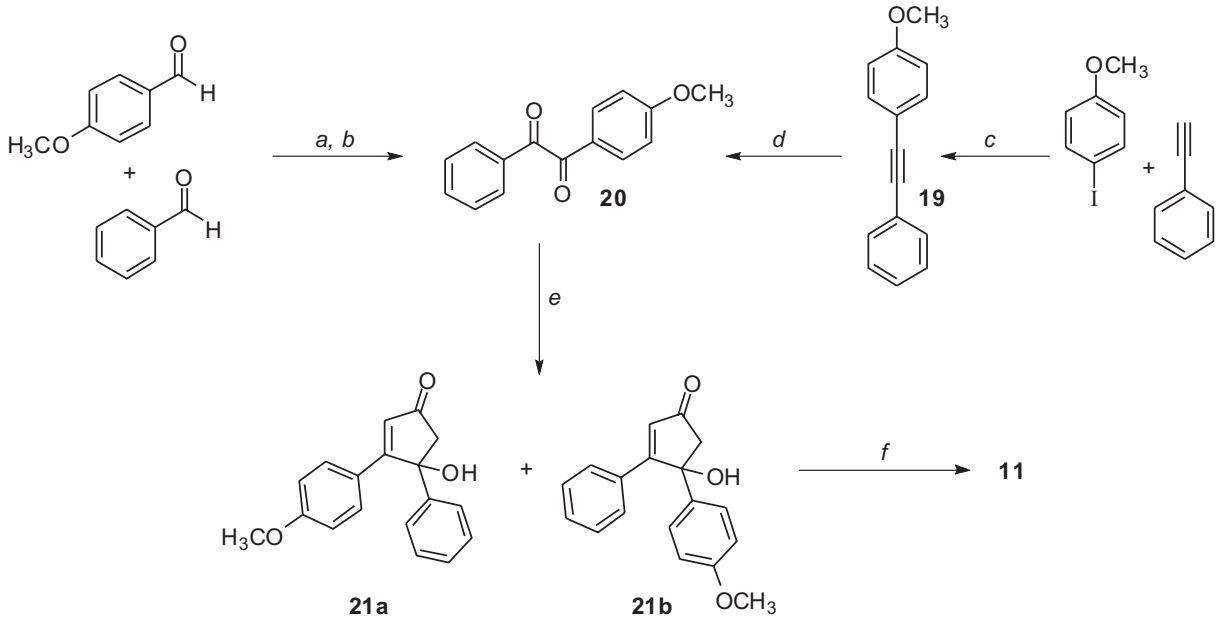


mixture greatly increased the rate; under these conditions, 40% of **4** had reacted after 2 days, but the ratio of naphthoquinone–anthraquinone dropped to 5:1.

The success of the approach described above prompted us to attempt the preparation of other 2,3-disubstituted anthraquinones. Since electronic and steric effects play important roles in the photochemistry of anthracene derivatives (11, 29), we were interested in synthesizing a range of anthraquinones with different pendant aromatic rings. The naphthyl- and *o*-tolyl-substituted derivatives **8** and **9** were therefore targeted as more sterically congested analogs of **3**. On the other hand, the introduction of para-substituents onto the peripheral aromatic rings in compounds **10**–**12** should not appreciably alter lateral bulk of the phenyl rings, but will change electronic properties of these groups. More specifically, methoxy- and bromo-substituents were chosen because they also provide useful points of attachment for the eventual incorporation of these compounds into polymers or other structures.

The symmetrical 1,2-diaryl-1,2-ethanediones (**13**–**15**) were synthesized from 2-naphthaldehyde, *o*-tolualdehyde, and *p*-anisaldehyde, respectively, using slightly modified literature procedures (22–24). Like benzil, these compounds are readily converted to the corresponding hydroxycyclopent-2-enones (**16**–**18**). These hydroxy compounds in general proved difficult to purify and were therefore used as obtained in subsequent reactions. Condensation of these compounds with 1,4-naphthoquinone afforded the desired products **8**–**10** in isolated yields that varied from 7%–18% (Scheme 4). It is unclear at this time why the reactions involving these substituted derivatives were much lower than for **4**, although both electronic and steric effects may have been in part responsible.



In the course of characterizing the tolyl derivative **9**, it was noted that several peaks in both the ^1H and ^{13}C NMR spectra of this compound were appreciably broadened. The affected peaks were identified as those associated with the pendant tolyl groups, suggesting that these rings are undergoing conformational syn-/anti-isomerism on the NMR timescale (Fig. 1). This is consistent with the observation that a similar molecule (2,2′-dimethyl-*o*-terphenyl) has a barrier to isomerization of 62 kJ/mol, with an NMR coalescence temperature of 9 °C (30). Although quantitative variable-temperature NMR experiments have not yet been carried out on **9**, the tolyl peaks were observed to sharpen at elevated temperatures, as expected.

This general synthetic approach can also be employed in the preparation of lower symmetry anthraquinones such as **11** and **12**, which were derived from the corresponding unsymmetrical benzils **20** and **22**, respectively (Schemes 5 and 6). Two routes were explored for the preparation of benzil **20**. This compound can be obtained via the cross-benzoin condensation of benzaldehyde and anisaldehyde (31). Although this synthesis has the advantage of employing relatively inexpensive starting materials, it does yield a mixture of benzil and compound **20** in an approximately 1:3 ratio, with **20** being isolated in only a 22% yield. A more systematic synthesis of this compound proceeds via the oxidation of the diphenylacetylene derivative (**19**), which is easily prepared from phenylacetylene and *p*-iodoanisole using standard Hagihara–Sonagashira conditions. Conversion of this compound to **20** has previously been reported using catalytic

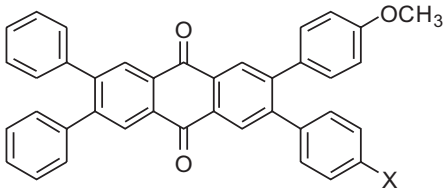
Scheme 6. Reagents and conditions: (*a*) NaCN or KCN, EtOH–H_2O, reflux; (*b*) $CuSO_4$, pyridine–H_2O; (*c*) I_2, DMSO, 145 °C; (*d*) acetone, KOH, RT, 1 week; (*e*) 1,4-naphthoquinone, AcOH, TsOH, reflux 48 h.

palladium chloride in DMSO (32). We have found that, contrary to this previous report, **19** was also cleanly oxidized to **20** in the presence of I_2/DMSO. The overall yields for this alkyne route are considerably higher (59% vs. 22%) than for the cross-benzoin method, although the use of more costly reagents is required.



Condensation of the unsymmetrical benzil **20** with acetone yields two products that were formed in a 5:2 ratio. These products were readily separated by column chromatography and were identified as the two regioisomers of the hydroxycyclopent-2-enones **21a** and **21b**. To positively identify the two isomers, NOESY spectra were obtained for both compounds. The spectrum of the major product showed a strong NOE between the protons on the anisole ring and the vinylic proton on the cyclopentene ring, which led to the identification of this compound as **21a**. Conversely, a significant cross peak was observed between the phenyl ring and the vinylic proton in the NOESY spectrum of the minor product, confirming the identity of this compound as the second regioisomer **21b**. The formation of **21a** as the major product is consistent with the stabilization of the incipient positive charge on the cyclopentane ring by the electron-donating *p*-methoxy group during the elimination of water. From a practical standpoint, the formation of two isomers is not problematic, since both **21a** and **21b** yield the same cyclopentiadienone upon loss of water. These isomeric hydroxycyclopent-2-enones were therefore not separated prior to carrying out Diels–Alder reactions with naphthoquinone derivatives in subsequent experiments. Condensation of a mixture of these intermediates with 1,4-naphthoquinone afforded **11** in 18% yield.

In a similar manner, the brominated anthraquinone (**12**) was prepared from *p*-bromobenzaldehyde and anisaldehyde (Scheme 6). The two isomers of the cyclone precursor, collectively denoted as **23**, were not separated from one another prior to condensation with 1,4-naphthoquinone.

It is also possible to use these hydroxycyclopent-2-enone intermediates in the synthesis of 2,3,6,7-tetraarylanthraquinones bearing different aromatic rings at one or more of the sites. To demonstrate the feasibility of this approach, we condensed 6,7-diphenyl-1,4-naphthoquione (**7**) with both **21a**, **21b**, and **18**. In this manner, we were able to prepare compounds **24** and **25** in yields of 26% and 7%, respectively.

In conclusion, we have developed a new strategy for synthesizing highly substituted anthraquinone derivatives from in situ generated cyclopentadienones. This approach is complementary to other methods that have commonly been used to prepare anthraquinones, such as the Friedel–Crafts con-

densation of phthalic anhydrides with benzene derivatives, an approach that is incompatible with functional groups such as pendant aromatic rings. Although the yields of the condensation reactions reported herein were generally low, our approach nonetheless offers several advantages. These compounds were prepared in only four steps from inexpensive starting materials such as acetone, 1,4-naphthoquinone, and commercially available aldehydes. Significantly, these syntheses are also amenable to working at larger scales. The hydroxycyclopent-2-enone precursors reported herein are readily prepared in multigram quantities, and gram-scale reactions of naphthoquinone with these compounds have been routinely carried out in our laboratory. In contrast, the sulfone **2** is synthesized using much more expensive starting materials and catalysts and could not, in our hands, be prepared on large scales. Moreover, the use of cyclopentadienones lends itself to the formation of lower-symmetry derivatives, such as **10**–**12**, **24**, and **25**, which would be more difficult to prepare from the corresponding sulfones. This approach is also tolerant of functional groups such as aryl bromides, which are incompatible with the chemistry used to prepare diarylsulfone analogues of **2**. These cyclopentadienones are therefore viable precursors for the large-scale preparation of anthraquinones that are not otherwise readily accessible. Further work is being carried out in our laboratory in an ongoing attempt to optimize these reactions.

Iodosulfonation of alkenes with benzenesulfinic acid – *N*-iodosuccinimide — Facile preparation of α,β-unsaturated sulfones[1]

Russell R. Wolff, Vikram Basava, Robert M. Giuliano, Walter J. Boyko, and J. Herman Schauble

Abstract: Reaction of alkenes and alkenols with *N*-iodosuccinimide (NIS) and benzenesulfinic acid in dichloromethane at room temperature affords *vic*-iodophenylsulfonyl adducts in good to high yields. Treatment of the iodosulfones with neutral alumina in dichloromethane at room temperature results in dehydroiodination to give the corresponding vinyl sulfones in high yield and purity by this convenient two-step procedure. Application of the iodosulfonation–dehydroiodination sequence to allylic alcohols and silyl ethers gave γ-oxygenated, α,β-unsaturated phenylsulfones, while the attempted iodosulfonation of glycals, as intermediates to vinyl sulfones, resulted in addition of benzenesulfinic acid with double bond shift (Ferrier rearrangement).

Key words: iodosulfonation, vinyl sulfones, benzenesulfinic acid, *N*-iodosuccinimide, dehydroiodination.

Résumé : La réaction d'alcènes et d'alcénols avec du *N*-iodosuccinimide (NIS) et de l'acide benzènesulfinique dans le dichlorométhane à la température ambiante conduit à la formation d'adduits *vic*-iodophénylsulfonyles avec des rendements allant de bons à élevés. Le traitement des iodosulfones avec de l'alumine neutre dans le dichlorométhane à la température ambiante provoque une déshydroiodation qui fournit les vinylsulfones correspondantes avec un rendement et une pureté élevés et qui complète cette méthode de synthèse pratique en deux étapes. L'application de la séquence de réactions iodosulfonation–déshydroiodation à des alcools allyliques et à des éthers silylés conduit à la formation de phénylsulfones γ-oxygénées et α,β-insaturées alors que les essais d'iodosulfonation de glycals, pour conduire à des intermédiaires de vinyl sulfones, conduisent à une addition de l'acide benzènesulfinique avec un déplacement de la double liaison (réarrangement de Ferrier).

Mots clés : iodosulfonation, vinyl sulfones, acide benzènesulfinique, *N*-iodosuccinimide, déshydroiodation.

[Traduit par la Rédaction]

Introduction

The two-step halosulfonation–dehydrohalogenation sequence is a useful method for conversion of alkenes to α,β-unsaturated sulfones. The first step of this process has generally been carried out by the reaction of an alkene with an arylsulfonyl halide to give a *vic*-halo(arylsulfonyl)alkane (1). Such reactions with sulfonyl chlorides or bromides occur via a radical-chain process, and require initiators such Cu(I, II) (2–5) or Ru(II) (6) salts, peroxides (7–9), or UV irradiation (5, 8, 10, 11).

Arylsulfonyl iodides are considerably more susceptible to homolysis than the chlorides, typically undergoing slow addition to alkenes in the dark (12, 13), although being accelerated by ambient or applied visible light (12–16), Cu(II) salts (17), or other radical initiators (12). Arylsulfonyl iodides are unstable reagents that are prepared from iodine and sodium arylsulfinate. Direct iodosulfonation can also be carried out with iodine and sodium arylsulfinate; however, a catalyst, such as a Cu(II) or Hg(II) salt, is usually included (18–20).

Herein we describe an alternate synthesis of iodo(arylsulfonyl)alkanes by the reaction of alkenes with *N*-iodosuccinimide (NIS) and benzenesulfinic acid in dichloromethane at room temperature. The free sulfinic acid is soluble in organic solvents, and is stable for extended periods when stored at 0 °C. Iodophenylsulfonyl adducts are obtained regioselectively in good yields. We also report that treatment of the iodosulfones with neutral alumina at room temperature results in facile elimination of HI, to give synthetically useful vinyl sulfones in high yield and purity.

Results and discussion

Iodosulfonation products obtained from reaction of various alkenes and alkenols with NIS and benzenesulfinic acid are listed in Table 1. Reactions of cyclopentene, cyclohexene, 1-methylcyclohexene, and norbornylene all gave high

yields of single *vic*-iodosulfones having the trans configuration. 1-Methylcyclohexene gave only *trans*-1-iodo-1-methyl-2-(phenylsulfonyl)cyclohexane, having the anti-Markovnikov regiochemistry, consistent with free radical, rather than ionic addition. The same regiochemistry, previously observed for reaction of alkenes with iodine and sodium arylsulfonates, was rationalized as being due to the steric bulk of the sulfinate anion, favoring rearside attack on the intermediate three-membered ring iodonium intermediates at the less-hindered position (18). However, an ionic pathway for such iodosulfonation reactions appears unlikely, since we observe that reaction of benzenesulfinic acid with NIS in dichloromethane-d_2 at room temperature gives benzenesulfonyl iodide at a rate similar to that for iodosulfonation of alkenes. A radical pathway is further supported by our observation that methyl vinyl ketone and the corresponding alcohol (3-buten-2-ol) undergo iodosulfonylation with NIS – benzenesulfinic acid at similar rates. Additionally, Yus and coworkers (21) have shown that reaction of α,β-unsaturated carbonyl compounds with sodium *p*-toluenesulfinate and iodine gives α-iodo-β-sulfonyl adducts, as expected for free radical addition.

Iodosulfonylation of *E*-4-octene gave a mixture of *threo*- and *erythro*-4-iodo-5-phenylsulfonyl octanes (**9a**, **9b**). This result is of interest in light of a report by Skell and McNamara (14) on reaction of phenylsulfonyl iodide with *cis*- or *trans*-2-butene, both of which gave identical mixtures of *threo*- and *erythro*-iodosulfones. The latter apparently formed via a 3-phenylsulfonyl-2-butyl radical, which undergoes conformational exchange at a rate competitive with that for iodine abstraction from phenylsulfonyl iodide to give the iodosulfonation product. No isomerization of starting butenes was observed (as occurred for chlorosulfonation with sulfonyl chlorides) (22), since iodine abstraction occurs faster than reversion of the phenylsulfonyl-2-butyl radical to alkene.

The mixture of *erythro*- and *threo*-4-iodo-5-(phenylsulfonyl)octanes (**9a**, **9b**) was inseparable by TLC. Although ^{1}H NMR revealed the isomers to be present in 71:29 molar ratio, their spectra were too similar to distinguish them. However, dehydroiodination on neutral alumina (vide infra) gave *E*- and *Z*-4-(phenylsulfonyl)octenes (**10a**, **10b**) in 67:32 molar ratio. Providing that elimination occurs by an E2 process, the major E isomer **10a** derives from the *erythro*-iodosulfone (**9a**) while the Z isomer **10b** forms via the *threo*-iodosulfone (**9b**).

Iodosulfonation of norbornylene gave a mixture of 2-*endo*-iodo-3-*exo*-(phenylsulfonyl)norbornane (**7a**) and a second compound, tentatively identified as the 2-*exo*-iodo-3-*endo*-phenylsulfonyl isomer **7b** in approximately equimolar ratio. Formation of **7a** is consistent with the intermediacy of the 3-*exo*-(phenylsulfonyl)-2-norbornyl radical, which would be trapped by iodine transfer from benzenesulfonyl iodide to the endo face. In contrast, **7b** apparently forms via the 2,3-*exo*-iodonium intermediate resulting from iodonium (I^+) transfer from NIS to norbornylene, followed by endo attack by the benzenesulfinate ion. It thus appears that iodosulfone formation via iodonium intermediates may be expected in cases involving more nucleophilic alkenes such as norbornylene.

1,3-Cyclohexadiene gave a mixture of *cis*/*trans*-3-iodo-6-(phenylsulfonyl)cyclohexene (**11a**, **11b**) in approximately equimolar ratio, determined from the integrated intensities for the CHI and $CHSO_2Ph$ peaks in the ^{1}H NMR spectrum. Vicinal coupling for H_6 indicated the sulfonyl group to be pseudoequatorial for the major isomer and pseudoaxial for the minor one; however, since J_{vic} values for H_3 could not be determined; it was not possible to distinguish the two isomers by NMR.

Dehydroiodination of α-iodo-β-alkylsulfonyl or arylsulfonyl compounds has previously been carried out using pyridine in benzene under reflux (14), or triethylamine in various solvents at room temperature, or with heating (12, 17–21, 23). In the present work, it was found that flash chromatography of *trans*-1-iodo-2-(phenylsulfonyl)cyclohexane (**3**) on neutral alumina resulted in partial conversion to 1-(phenylsulfonyl)cyclohexene (**4**). This led to the observation that dehydroiodination could be carried out preparatively, simply by stirring neutral alumina slurries of the iodosulfones in dichloromethane at room temperature to yield the corresponding α,β-unsaturated sulfones, generally in very good to excellent yields (Table 1). This procedure avoids the use of amine bases that may be incompatible with some functional groups. However, dehydroiodination of the iodosulfone TMBDS ethers **19**, **21**, and **23** (vide infra) did not occur on alumina. In these cases, we found that the elimination could be carried out using 1,4-diazabicyclo[2.2.2]octane (DABCO).

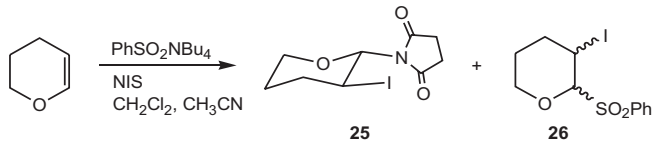
We were also interested in application of the iodophenylsulfonation–dehydroiodination sequence to the synthesis of γ-oxygenated, α,β-unsaturated phenylsulfones by using allylic alcohols or their derivatives as substrates. Products derived from allylic alcohols could thus serve as precursors to phenylsulfonyl-substituted, α,β-unsaturated ketones, which are established heterodienes in Diels–Alder reactions (24), as well as other synthetic applications involving conjugate additions (25). γ-Alkoxy-α,β-unsaturated phenylsulfones are useful as substrates in [3+2] cycloadditions, via π-allyl palladium complexes, as a method for cyclopentenone annulation (26), and also in six-membered ring annulations by a conjugate addition–alkylation sequence (27).

Examples of the allylic alcohols used as substrates in the iodophenylsulfonation–elimination sequence are shown in Table 1. Treatment of allyl alcohol with benzensulfinic acid and NIS in dry dichloromethane overnight gave a 54% yield of iodophenylsulfone **13**. The NMR spectrum indicated a single regioisomer, resulting from addition of the phenylsulfonyl group to the less-substituted carbon, consistent with our results for other unsymmetrically substituted alkenes. Treatment of the iodophenylsulfone with neutral alumina gave a nearly quantitative yield of the γ-hydroxy-α,β-unsaturated sulfone **14**, the structure of which was confirmed by comparison of physical data with reported values for this compound prepared by either microwave- or ultrasound-assisted alkylation of sodium benzenesulfinate by Villemin and Aloum (28).

Similarly, treatment of 3-butene-2-ol with benzenesulfinic acid and NIS gave iodophenylsulfone **15** as a mixture of diastereomers. Again, a single regiochemistry of addition was observed. Elimination w ith alumina occurred smoothly to give the known (29) γ-hydroxy-α,β-unsaturated sulfone **16**. An isomeric vinyl sulfone, 3-(phenylsulfonyl)-3-buten-2-ol, was previously prepared by the addition of phenyl vinyl

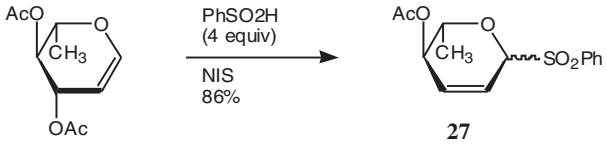
© 2006 NRC Canada

sulfone to acetaldehyde. Oxidation gave 3-(benzenesulfonyl)-3-buten-2-one, which was shown to undergo hetero-Diels–Alder reactions with vinyl ethers in high yield at or below room temperature (24). It is anticipated that the ketone derived by oxidation of **16** would also be useful as a heterodiene. Similarly, (*E*)-1-(phenylsulfonyl)-hex-1-en-3-ol (**18**) (30) was prepared from 1-hexen-3-ol in good overall yield by regioselective iodosulfonation–elimination.



Both 2-cyclohexen-1-ol and 2-methyl-2-cyclohexen-1-ol were unsuitable as substrates for the synthesis of vinyl sulfones using the iodophenylsulfonation–elimination sequence because of side reactions. Better results were obtained using the *tert*-butyldimethylsilyl (TBDMS) ethers of these cyclic allylic alcohols. The attempted synthesis of 3-(*tert*-butyldimethylsiloxy)-1-(phenylsulfonyl)cyclohexene (**21**) from 2-cyclohexen-1-ol by this method resulted in a mixture of vinyl sulfones **21** and **22** because of a lack of regioselectivity in the initial addition step. Treatment of the TBDMS ether of 2-methyl-2-cyclohexen-1-ol gave diastereomeric 2-iodo-3-phenylsulfonyl derivatives (**23**), which were converted to vinyl sulfone **24**, albeit in lower overall yield than was observed for the other cases. Vinyl sulfone **21** was used in the synthesis of annulated cyclopentenones by Trost et al. (26).

Ley and co-workers (31) have developed synthetically useful alkylation reactions of anions derived from 2-benzensulfonyl tetrahydropyran. We decided to attempt the application of our iodophenylsulfonation reaction to dihydropyran and to glycals. The only products obtained from dihydropyran upon treatment with NIS – benzenesulfinic acid, were those resulting from addition of benzenesulfinic acid, suggesting that protonation of the double bond occurs faster than iodination, or alternatively, hydrogen atom abstraction by the adduct of DHP and benzenesulfonyl radical is again faster than iodination. We also attempted iodophenylsulfonation of dihydropyran using NIS and tetra-*N*-butylammonium benzenesulfinate and observed a significant amount of adduct **25** (apparently resulting from trapping of dihydropyran iodonium ion by succinimide), along with iodophenylsulfone **26** and other products that were not identified (Scheme 1).



Iodophenylsulfonation of glycals was also attempted using NIS and benzenesulfinic acid in an effort to prepare carbohydrate vinyl sulfones. Ley and co-workers (31*a*) had observed that benzenesulfinic acid adds to tri-*O*-acetyl-L-glucal with double bond migration (Ferrier rearrangement). This same result was also observed in our study for the reaction of either tri-*O*-acetyl-D-glucal or di-*O*-acetyl-L-rhamnal, when treated with benzenesulfinic acid in the presence or absence of *N*-iodosuccinimide. In both cases, the Ferrier rearrangment product was obtained, with no evidence of iodophenylsulfone formation. Di-*O*-acetyl-L-rhamnal gave an 86% yield of the anomeric phenylsulfone adducts **27** when treated with excess benzenesulfinic acid at room temperature (Scheme 2).

In summary, a convenient two-step synthesis of α,β-unsaturated sulfones has been developed using iodophenylsulfonation of alkenes or alkenols with NIS – benzenesulfinic acid, followed by dehydroiodination on neutral alumina at room temperature. The overall process is highly regioselective for unsymmetrical alkenes, giving vinyl sulfones that can be used for a variety of synthetic applications.

Scheme 1.

Scheme 2.

Experimental

Preparation of benzenesulfinic acid

A stirred solution of sodium benzene sufinate (10.0 g, 61.0 mmol) in distilled water (25 mL) under nitrogen at 0 °C was slowly acidified to pH 1 by dropwise addition of 12 mol/L HCl. The white crystalline benzenesulfinic acid was filtered and air dried on a Büchner funnel, then stored at 0 °C (7.35 g, (85% yield); mp 82–86 °C (lit. value (32) mp 77 to 78 °C; (33) mp 82–84 °C).

General procedure for iodophenylsulfonation of alkenes using NIS – benzenesulfinic acid

To a stirred solution of NIS (225 mg, 1.0 mmol) in CH_2Cl_2 (50 mL) was added benzenesulfinic acid (142 mg, 1.0 mmol) and stirring continued for ~5 min to effect solution. The alkene (1.0 mmol) was added, and the reaction mixture was stirred for 30 min to 2 h at room temperature (monitored by TLC on silica gel using hexane – ethyl acetate, 1:1 *v*/*v* as eluent), then extracted with satd. aq. $NaHCO_3$ and $NaHSO_3$ (50 mL, each), dried ($MgSO_4$), and filtered. Flash chromatography on silica gel (60–200 mesh) using hexane – ethyl acetate (1:1) as eluent gave the oily liquid iodosulfones. No dehydroiodination products were detected, except in the case of iodosulfone **5**, which was accompanied by ~10% of 1-methyl-2-(phenylsulfonyl)cyclohexene (**6**).

trans-1-Iodo-2-(phenylsulfonyl)cyclopentane (1)

Yield: 322 mg (96%). ^{1}H NMR (300 MHz, $CDCl_3$) δ: 7.98 (m, 2H, Ph-H), 7.71 (m, 1H, Ph-H), 7.65 (m, 2H, Ph-H), 4.64 (ddd, 1H, H_1, $J_{1,2}$ = 4.2 Hz, $J_{1,5a}$ = 3.2 Hz, $J_{1,5b}$ = 3.0 Hz), 3.94 (ddd, 1H, H_2, $J_{1,2}$ = 4.2 Hz, $J_{2,3a}$ = 3.1 Hz, $J_{2,3b}$ = 3.0 Hz), 2.5–1.8 (cms, 6H, H_{3-5}) ^{13}C NMR (75.4 MHz, $CDCl_3$) δ: 138.8, 134.4, 129.8, 128.8 (Ph), 75.2 (C_2), 40.87 (C_5), 26.36, 25.41, 20.48 ($C_{1,3,4}$). The cyclopentane ring ^{1}H shifts are consistent with literature values for the corresponding 1-iodo-2-p-toluenesulfone (17).

trans-1-Iodo-2-(phenylsulfonyl)cyclohexane (3)

Yield: 238 mg (86%). ^{1}H NMR (300 MHz, $CDCl_3$) δ: 8.10–7.92 (m, 2H, Ph-H), 7.77–7.69 (m, 1H, Ph-H), 7.69–7.60 (m, 2H, Ph-H), 5.14 (bs, 1H, H_1), 3.41 (bs, 1H, H_2), 1.95–0.82 (cms, 8H, H_{3-6}). ^{13}C NMR (75.4 MHz, $CDCl_3$) δ: 138.2 (C_i), 134.3 (C_p), 129.7 (C_o), 128.8 (C_m), 67.86 (C_2),

© 2006 NRC Canada

34.0 (C_6); 25.9, 23.6, 22.6, 21.5 (C_1, $C_{3–5}$). The ^{1}H NMR shifts are consistent with published data (17).

***trans*-1-Iodo-1-methyl-2-(phenylsulfonyl)cyclohexane (5)**

Yield: 328 mg (90%). IR (KBr, cm^{-1}) ν_{max}: 1300 (SO_2, ν_{asym}), 1130 (SO_2, ν_{sym}). ^{1}H NMR (300 MHz, $CDCl_3$) δ: 7.92 (m, 2H, Ph-H), 7.64 (m, 1H, Ph-H), 7.55 (m, 1H, Ph-H), 3.70 (bs, 1H, H_2), 2.01 (s, 3H, CH_3), 2.2–1.1 (cms, 8H, $H_{3–6}$). The cyclohexyl ^{1}H shifts agree with those reported for *trans*-1-iodo-1-methyl-2-tosylcyclohexane (17). In addition to the iodosulfone **5**, column chromatography also gave 1-methyl-2-(phenylsulfonyl)cyclohexene (**6**, 24 mg, 10%) identified by comparison of the ^{1}H NMR spectrum with literature data (17).

2-Iodo-3-(phenylsulfonyl)norbornanes (7a, 7b)

Yield: 307 mg (85% combined yield; ~1:1 molar ratio by ^{1}H NMR). ^{1}H NMR (300 MHz, $CDCl_3$) for the 2-*endo*-iodo-3-*exo*-(phenylsulfonyl) isomer **7a** δ: 7.99 (m, 2H, Ph-H), 7.77 (m, 1H, Ph-H), 7.68 (m, 2H, Ph-H), 4.38 (cm, 1H, H_{2x}, $J_{2x,3n}$ = 5.9 Hz, $J_{1,2x}$= 3.7 Hz, $J_{2x,6x}$ = 1.7 Hz, $J_{2x,7s}$ = ~0 Hz; no COSY cross peak). A cross peak was observed for H_1-H_{2x}, aiding confirmation of H_{3n}, H_{2x}), 3.05 (dd, 1H, H_{3n}, $J_{2x,3n}$ = 5.9 Hz, $J_{3n,7a}$ = 1.7 Hz, $J_{3n,4}$ = ~0 Hz), 2.81 (m, 1H, H_4), 2.52 (m, 1H, H_1), 2.08 (m, 1H, H_{7s}), 1.67 (cms, 2H, H_{5x}, H_{6x}) 1.34 (m, 1H, H_{7a}), 1.27 (m,1H, H_{5n}), 1.08 (m, 1H, H_{6n}). ^{13}C NMR (75.4 MHz, $CDCl_3$) phenyl δ: 138.5 (C_i), 133.9 (C_p), 129.4 (C_m), 128.7 (C_o); norbornyl δ: 76.11 (C_3), 45.31 (C_1), 38.44 (C_4), 34.64 (C_7), 29.22 (C_5), 27.46 (C_6), 26.36 (C_1).

For 2-*exo*-iodo-3-*endo*-(phenylsulfonyl)norbornane (**7b**): ^{1}H NMR (300 MHz, $CDCl_3$) δ: 4.11 (dd, 1H, H_{2n}), 3.27 (dd, 1H, H_{3x}), 2.89 (bs, 1H, H_4), 2.50 (bs, 1H, H_1), 2.41 (d, 1H, H_{7s}), ~1.7–1.0 (ms, 5H, $H_{5,6}$, H_{7a}).

4-Iodo-5-(phenylsulfonyl)octane (9a, 9b)

Yield: 316 mg (83% combined yield); single component by TLC on silica gel (hexane – ethylacetate (1:1 *v*/*v* as eluent); however, ^{1}H NMR revealed the formation of **9a** and **9b** in 67:33 molar ratio. For the major isomer **9a**: ^{1}H NMR (300 MHz, $CDCl_3$) δ: 7.88 (m, 2H, Ph-H), 7.62 (m, 1H, Ph-H), 7.59 (m, 2H, Ph-H), 4.61 (ddd, 1H, H_4, $J_{3a,4}$ = 10.8 Hz, $J_{3b,4}$ = 3.3 Hz, $J_{4,5}$ = 2.4 Hz), 3.54 (ddd, 1H, H_5, $J_{5,6a}$ = 7.7 Hz, $J_{5,6b}$ = 3.7 Hz, $J_{4,5}$ = 2.4 Hz), 2.11, 1.99 (ms, 2H, $H_{6a,6b}$), 1.77, 1.67 (ms, 2H, $H_{3a,3b}$), 1.41 (m, 2H, H_7), 1.55, 1.25 (ms, 2H, $H_{2a,2b}$), 0.91 (t, 3H, H_1, $J_{1,2}$ = 7.3 Hz), 0.88 (t, 3H, H_8, $J_{7,8}$ = 7.3 Hz); $J_{2,3}$ and $J_{6,7}$ were not determined. ^{13}C NMR (75.4 MHz, $CDCl_3$) δ: 139.3 (s, C_i), 134.4 (d, C_p), 129.8 (d, C_m) 128.7 (d, C_o), 72.53 (d, C_5), 36.52 (t, C_3), 31.84 (d, C_4), 28.21 (t, C_6), 23.89 (t, C_2), 22.46 (t, C_7), 14.18 (q, C_8), 13.23 (q, C_1). Anal. calcd. for $C_{14}H_{21}SO_2I$ (%): C 44.08, H 5.55, S 8.41; found (mixture of **9a** and **9b**): C 44.24, H 5.29, S 8.01.

For the minor isomer **9b**: ^{1}H NMR δ: 7.94 (m, 2H, Ph), 7.62 (m, 1H, Ph), 7.59 (m, 2H, Ph), 4.51 (ddd, 1H, H_4, $J_{3a,4}$ = 9.2 Hz, $J_{3b,4}$ = 5.4 Hz, $J_{4,5}$ = 2.2 Hz), 2.70 (ddd, 1H, H_5, $J_{5,6a}$ = 5.9 Hz, $J_{5,6b}$ = 5.2 Hz, $J_{4,5}$ = 2.2 Hz), 2.02, 1.73 (ms, 2H $H_{6a,6b}$), 1.99, 1.70 (ms, 2H, $H_{3a,3b}$), 1.43 (m, 2H, H_7), 1.50, 1.39 (ms, 2H, $H_{2a,2b}$), 0.88 (t, 3H, H_1, $J_{1,2}$ = 7.1 Hz), 0.875 (t, 3H, H_8, $J_{7,8}$ = 7.3 Hz). ^{1}H shifts for **9a** and **9b** were determined using COSY, HETCOR, and 1D decoupling; $J_{2,3}$ and $J_{6,7}$ were not determined. ^{13}C NMR (75.4 MHz, $CDCl_3$) for **9b** δ: 138.47 (s, C_i), 134.33 (d, C_p), 129.53 (d, C_m and C_o), 68.66 (d, C_5), 42.34 (t, C_3), 33.27 (t, C_6), 30.62 (d, C_4), 23.04 (t, C_2), 21.63 (t, C_7), 14.30 (q, C_8), 13.16 (q, C_1).

***cis*/*trans*-3-Iodo-6-(phenylsulfonyl)cyclohexene (11a, 11b)**

Yield: 319 mg (92% combined yield); single component by TLC on silica gel; ~1:1 molar ratio determined by ^{1}H NMR. Configurations at C_3 could not be assigned since vicinal couplings for H_3 were unobtainable owing to peak overlap. For **11a**: ^{1}H NMR (300 MHz, $CDCl_3$) δ: 7.88 (m, 2H, Ph-H), 7.68 (m, 2H, Ph-H), 7.58 (m, 1H, Ph-H), 6.37 (dd, 1H, H_2, $J_{1,2}$ = 9.9 Hz, $J_{2,3}$ = 4.9 Hz), 5.61 (dd, 1H, H_1, $J_{1,2}$ = 9.9 Hz, $J_{1,6}$ = 4.4 Hz), 4.98 (m, 1H, H_3, $J_{2,3}$ = 4.9 Hz, $J_{3,6}$ = 1.0 Hz, $J_{1,3}$ = 1.0 Hz; $J_{3,4a}$ and $J_{3,4b}$ could not be determined), 3.95 (m, 1H, H_6, $J_{5,6a}$ = 5.6 Hz, $J_{5,6b}$ = 3.5 Hz, $J_{1,6}$ = 4.4 Hz, $J_{3,6}$ = 1.0 Hz), 2.17 (m, 2H, H_5), 2.08, 1.96 (ms, 2H, H_4). ^{13}C NMR (75.4 MHz, $CDCl_3$) δ: 138.04 (C_2), 118.32 (C_1), 59.06 (C_6), 26.14 (C_4), 24.22 (C_3), 19.39 (C_5); Ph absorptions for **11a** and **11b**: 136.87, 135.72 (C_i), 128.92, 128.78 (C_m), 128.8, 128.42 (C_o), 133.71 (C_p, both isomers). For **11b**: ^{1}H NMR δ: 6.19 (dd, 1H, H_2, $J_{1,2}$ = 10.0 Hz, $J_{2,3}$ = 5.1 Hz), 5.84 (dd, 1H, H_1, $J_{1,2}$ = 10.0 Hz, $J_{1,6}$ = 2.6 Hz, $J_{1,3}$ = 1.3 Hz), 4.87 (m, 1H, H_3, $J_{2,3}$ = 5.1 Hz, $J_{3,6}$ = 1.8 Hz, $J_{1,3}$ = 1.3 Hz; $J_{3,4a}$ and $J_{3,4b}$ could not be determined), 4.22 (m, 1H, H_6, $J_{5,6a}$ = 10.7 Hz, $J_{5,6b}$ = 6.2 Hz, $J_{1,6}$ = 2.6 Hz, $J_{3,6}$ = 1.8 Hz), 2.11, 2.02 (ms, 2H, H_5), 2.11, 1.69 (ms, 2H, H_4). Ph absorptions overlapped those for **11a**. ^{13}C NMR (75.4 MHz, $CDCl_3$) δ: 136.81 (C_2), 119.30 (C_1), 61.65 (C_6), 30.96 (C_4), 23.68 (C_3), 20.00 (C_5). Anal. calcd. for $C_{12}H_{13}SO_2I$ (%): C 41.25, H 3.75, S 9.18; found for **11a** and **11b**: C 40.83, H 3.68, S 8.66.

A mixture of *cis*/*trans*-3-iodo-6-*p*-tosylcyclohexenes was previously obtained from reaction of 1,3-cyclohexadiene wth iodine/sodium *p*-toluenesulfinate (20).

General procedure for dehydroiodination of iodo(phenylsulfonyl) compounds 1, 3, 5, 7, 9, and 11

To a solution of the iodosulfonyl compound (1.0 mmol) in CH_2Cl_2 (50 mL) under nitrogen, neutral alumina (60–200 mesh, 100 cc) was added, and the resulting slurry was stirred for 1 day at rt, filtered, and the alumina was extracted with CH_2Cl_2 (50 mL). The combined extract was evaporated to give the crude α,β-unsaturated sulfone, which was purified by flash column chromatography on silica gel (toluene eluent, unless noted otherwise). Products were oily liquids, unless noted otherwise.

1-(Phenylsulfonyl)cyclopentene (2)

Flash chromatography on silica gel with hexane – ethyl acetate (1:1 *v*/*v*) as eluent (192 mg, 92%); mp 20–25 °C. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 7.9 (m, 2H, Ph), 7.6 (m, 3H, Ph), 6.81 (dd, 1H, H_2, $J_{2,3a}$ = 3.8 Hz, $J_{2,3b}$ = 3.1 Hz) 3.1 (m, 4H, H_3, H_5), 2.1 (m, 2H, H_4); the ^{1}H shifts are consistent with literature (34) data. ^{13}C NMR (75.4 MHz, $CDCl_3$) phenyl δ: 140.1 (C_i), 133.65 (C_p), 129.46 (C_m), 128.21 (C_o); cyclopentenyl δ: 145.52, 140.51, 33.29, 31.19, 23.97.

© 2006 NRC Canada

1-(Phenylsulfonyl)cyclohexene (4)

Yield: 198 mg (95%); mp 39–43 °C. IR (KBr, cm^{-1}) ν_{max}: 1620 (C=C), 1300 (SO_2, ν_{asym}), 1140, (SO_2, ν_{sym}). ^1H NMR (300 MHz, $CDCl_3$) δ: 7.11 (dd, 1H, H_2, $J_{2,3a}$ = 4.3 Hz, $J_{2,3b}$ = 3.1 Hz), 2.35 (m, 2H, H_3, H_6), 1.8–1.5 (m, 4H, H_4, H_5); the shifts and splitting pattern for Ph were similar to those for **2**. The ^1H shifts are consistent with published (17, 34) values.

2-(Phenylsulfonyl)norbornene (8) (ref. 34)

Yield: 209 mg (89%). ^1H NMR (300 MHz, $CDCl_3$) δ: 6.93 (d, 1H, H_3, $J_{3,4}$ = 3.8 Hz), 3.14 (cm, 1H, H_1), 3.01 (cm, 1H, H_4), 1.79 (cm, 1H, $H_{6\text{-exo}}$), 1.67 (cm, 1H, $H_{5\text{-exo}}$), 1.52 (m, 1H, $H_{7\text{-syn}}$), 1.24 (m, 1H, $H_{7\text{-anti}}$), 1.10 (cm, 1H, $H_{6\text{-endo}}$), 0.96 (cm, 1H, $H_{5\text{-endo}}$); the Ph shifts and splitting patterns were similar to those for **7**. ^{13}C NMR (75.4 MHz, $CDCl_3$) phenyl δ: 140.22 (C_i), 133,59 (C_p), 129.50 (C_m), 128.09 (C_o); norbornenyl δ: 147.80 (C_2), 146.39 (C_3), 49.73 (C_7), 44.03 (C_4), 43.38 (C_1), 25.18 (C_5), 25.07 (C_6). Anal. calcd. for $C_{13}H_{14}SO_2$ (%): C 66.63, H 6.02, S 13.68; found: C 66.50, H 6.29, S 13.58.

(*Z*,*E*)-4-(Phenylsulfonyl)-4-octene (10a, 10b)

Flash chromatography (hexane – ethyl acetate, 1:1 *v*/*v*), 187 mg (80% combined yield); E:Z = 67:33 determined by ^1H NMR. For the Z isomer (**10a**): ^1H NMR (300 MHz, $CDCl_3$) δ: 7.884 (m, 2H, C_o), 7.60 (m, 1H, H_p), 7.53 (m, 2H, H_m), 6.008 (dd, 1H, H_5, $J_{5,6}$ = 7.9 Hz, $J_{3,5}$ = 1.2 Hz), 2.604 (m, 2H, H_6, $J_{5,6}$ = 7.9 Hz, $J_{6,7}$ = 7.4 Hz, $J_{3,6}$ = 1.2 Hz), 2.284 (ddd, 2H, H_3, $J_{2,3}$ = 7.5 Hz, $J_{3,5}$ = 1.2 Hz, $J_{3,6}$ = 1.2 Hz), 1.522 (m, 2H, H_2, $J_{2,3}$ = 7.5 Hz, $J_{1,2}$ = 7.4 Hz), 1.393 (m, 2H, H_7, $J_{6,7}$ = 7.4 Hz, $J_{7,8}$ = 7.4 Hz), 0.889 (t, 3H, H_8, $J_{7,8}$ = 7.4 Hz) 0.877 (t, 3H, H_1, $J_{1,2}$ = 7.4 Hz); the ^1H shifts are consistent with literature (35) data. ^{13}C NMR (75.4 MHz, $CDCl_3$) phenyl δ: 141.53 (s, C_i), 132.82 (d, C_p), 128.78 (d, C_m), 126.90 (d, C_o); octene chain δ: 142.99 (d, C_5), 140.20 (s, C_4), 34.80 (t, C_3), 30.21 (t, C_6), 22.19 (t, C_7), 22.10 (t, C_2), 13.39 (q, C_1), 13.11 (q, C_8). For the E isomer (**10b**): ^1H NMR δ: 7.857 (m, 2H, C_o), 7.60 (m, 1H, H_p), 7.53 (m, 2H, H_m), 6.927 (dd, 1H, H_5, $J_{5,6}$ = 7.5 Hz, $J_{3,5}$ = 0.5 Hz), 2.185 (m, 2H, H_6, $J_{5,6}$ = 7.5 Hz, $J_{6,7}$ = 7.5 Hz; $J_{3,6}$ could not be determined), 2.189 (m, 2H, H_3, $J_{2,3}$ = 6.5 Hz, $J_{3,5}$ = 0.5 Hz), 1.522 (m, 2H, H_7, $J_{6,7}$ = 7.5 Hz, $J_{7,8}$ = 7.5 Hz), 1.359 (m, 2H, H_2, $J_{1,2}$ = 7.5 Hz, $J_{2,3}$ = 6.5 Hz), 0.947 (t, 3H, H_8, $J_{7,8}$ = 7.5 Hz) 0.826 (t, 3H, H_1, $J_{1,2}$ = 7.5 Hz); the ^1H shifts agree with published (35) data. ^{13}C NMR phenyl δ: 140.83 (s, C_i), 132.79 (d, C_p), 128.80 (d, C_m), 127.65 (d, C_o); octene chain δ: 142.06 (d, C_5), 139.89 (s, C_4), 30.08 (t, C_3), 28.22 (t, C_6), 21.54 (t, C_7), 22.10 (t, C_2), 13.71 (q, C_1), 13.51 (q, C_8). The chemical shift and coupling assignments for **10a** and **10b** were made using a combination of correlated COSY, HETCOR, and 1-D decoupling. Anal. calcd. for $C_{14}H_{20}SO_2$ (%): C 66.33, H 7.99, S 12.71; found (**10a** and **10b**): C 65.92, H 7.81, S 12.35.

1-(Phenylsulfonyl)-1,3-cyclohexadiene (12) (refs. 3*a*, 34)

Yield: 203 mg (92%). ^1H NMR (300 MHz, $CDCl_3$) δ: 7.9 (m, 2H, Ph-H), 7.5 (m, 2H, Ph-H), 7.04 (dd, 1H, H_2, $J_{2,3}$ = 4.5 Hz, $J_{2,4}$ = 2.0 Hz), 7.61 (m, 1H, Ph-H), 6.11 (dd, 1H, H_3, $J_{3,4}$ = 9.4 Hz, $J_{2,3}$ = 4.5 Hz) Hz, 6.07 (cm, 1H, H_4) 2.35 (cm, 2H, H_6), and 2.27 (cm, 2H, H_5). ^{13}C NMR (75.4 MHz, $CDCl_3$) phenyl δ: 139.50 (C_i), 133.08 (C_p), 129.01 (C_m), 127.67 (C_o); cyclohexadiene δ: 136.05 (C_1), 133.21 (C_4),131.59 (C_2),122.5 (C_3), 22.9 (C_5), 19.9 (C_6). The ^1H shifts are similar to published (34) data.

General procedure for the synthesis of γ-oxygenated, α,β-unsaturated sulfones

Allylic alcohols or their *tert*-butyldimethylsilyl ethers were treated with 1 equiv. each of benzensulfinic acid and *N*-iodosuccinimide in anhydrous dichloromethane at room termperature. Progress of reactions was monitored by TLC using mixtures of ethyl acetate – hexanes as noted with each example shown in the following. The reaction mixture was diluted with dichloromethane (10 mL), then washed with 5% aqueous sodium thiosulfate solution, water, and brine, dried (sodium sulfate), and concentrated. Crude iodophenylsulfones were redissolved in dichloromethane and stirred overnight at room temperature with neutral alumina (10× excess by weight). The reaction mixture was filtered, solids were washed with ethyl acetate, and the filtrate was concentrated to give the vinyl sulfones that were purified further in some cases as noted. In the case of iodophenylsulfones **19**, **20**, and **23**, elimination was carried out by stirring overnight in carbon tetrachloride containing 1.3 equiv. of DABCO.

(*E*)-3-Phenylsulfonyl-2-propen-1-ol (14)

Allyl alcohol was converted to the iodophenylsulfonyl derivative **13** in 60% yield as described in the previous paragraph. R_f 0.17 (40% ethyl acetate – hexanes). IR (ATR, cm^{-1}) ν_{max}: 3495 (OH), 3064, 2934, 1447, 1300 (S=O), 1142 (S=O), 1082. ^1H NMR ($CDCl_3$) δ: 7.9 (m, 2H, PhH), 7.7 (m, 3H, PhH), 4.57 (sextet, 1H, *J* = 4.5 Hz, CHI), 4.04 (dd, 1H, *J* = 4.5, 12.6 Hz, CHOH), 3.93 (dd, 1H, *J* = 4.5, 12.6 Hz, CHOH), 3.93 (dd, 1H, *J* = 9.6 Hz, $PhSO_2CH_2$), 3.67 (dd, 1H, *J* = 4.5 Hz, $PhSO_2CH_2$), 2.43 (bs, 1H, OH). ^{13}C NMR ($CDCl_3$) δ: 139.0, 134.6, 129.8, 128.2, 67.4 (CHOH), 62.3 (CH_2SO_2Ph), 22.0 (CHI). HRMS calcd. for $C_9H_{12}O_3SI$: 325.9552 (M + H); found: 325.9561.

Elimination as described in the general procedure gave crystalline vinyl sulfone **14** (202 mg, 95%); mp 134–136 °C (lit. value (27) mp 139 to 140 °C). R_f 0.18 (ethyl acetate – hexanes, 1:1). ^1H NMR ($CDCl_3$) δ: 7.9 (m, 2H, PhH), 7.6 (m, 3H, PhH), 7.06 (m, 1H, *J* = 18 Hz, C=CH), 6.66 (m, 1H, *J* = 18 Hz, C=CH), 4.42 (m, 2H, CH_2OH), 1.6, (bs, 1H, OH). The ^1H NMR spectrum of **14** reported in the literature lists the vinylic hydrogens as a multiplet at δ 7.1–6.6, the CH_2OH methylene hydrogens as a multiplet at δ 5.55–4.20, and the hydroxyl proton resonance as a broad singlet at δ 3.90 (28).

(*E*)-4-Phenylsulfonyl-3-buten-2-ol (16)

3-Butene-2-ol (72 mg, 1 mmol) was converted to diastereomeric 3-iodo-4-phenylsulfonyl-2-butanols (**15**). Yield: 216 mg (63%). R_f 0.23 (40% ethyl acetate – hexanes). IR (ATR, cm^{-1}) ν_{max}: 3531 (OH), 2960, 1447, 1280 (S=O), 1142 (S=O), 1082. ^1H NMR δ: 7.90 (m, 2H, PhH), 7.62 (m, 3H, PhH), 4.60 (ddd, 1H, *J* = 9.8, 4.2, 2.0 Hz, CHI), 4.53 (td, 1H, *J* = 6.6, 4.2 Hz, CHI), 4.06 (dd, 1H, *J* = 14.2, 9.8 Hz, $PhSO_2CH$), 3.74 (d, 2H, *J* = 6.6 Hz, $PhSO_2CH_2$), 3.70 (dd, 1H, *J* = 14.2, 4.4 Hz, $PhSO_2CH$), 3.62, (bs or dq if OH is decoupled, 1H, *J* = 4.2, 6.1 Hz, CHOH), 3.43 (bs or dq if OH is decoupled, 1H, *J* = 5.9, 2.0 Hz, CHOH), 2.20

© 2006 NRC Canada

(bs, OH), 1.29 (d, 3H, J = 6.1 Hz, CH_3), 1.27 (d, 3H, J = 5.9 Hz, CH_3). ^{13}C NMR ($CDCl_3$) δ: 134.1, 134.0, 128.4, 128.4, 128.0, 127.7, 69.7 (CHOH), 67.7 (CHOH), 62.5 ($PhSO_2CH_2$), 62.0 ($PhSO_2CH_2$), 32.6 (CHI), 30.7 (CHI), 25.0 (CH_3), 20.9 (CH_3). HRMS calcd. for $C_{10}H_{14}O_3SI$: 340.9708 (M + H); found: 340.9705.

Treatment with alumina (2.1 g) gave 122 mg (92%) of vinyl sulfone **16**; mp 74 to 75 °C (lit. value (29) mp 64–66 °C. R_f 0.19 (40% ethyl acetate – hexanes). The ^{1}H NMR spectrum of **16** matched that reported (29).

(*E*)-1-(Phenylsulfonyl)hex-1-en-3-ol (18)

1-Hexen-3-ol (100 mg, 1 mmol) was converted to diastereomeric 2-iodo-1-(phenylsulfonyl)hex-1-en-3-ols (**17**). Yield: 305 mg (83%). R_f 0.36 (40% ethyl acetate – hexanes). IR (ATR, cm^{-1}) ν_{max}: 3497, 2959, 2933, 1447, 1304 (S=O), 1142 (S=O) 1083. ^{1}H NMR δ: 7.90 (m, 2H, PhH), 7.60 (m, 3H, PhH), 4.62 (ddd, 1H, J = 10.0, 4.3, 2.0 Hz, CHI), 4.49 (td, 1H, J = 6.9, 6.3, 4.1 Hz, CHI), 4.09 (dd, 1H, J = 14.2, 10.0 Hz, $PhSO_2CH$), 3.79 (dd, 1H, J = 15.4, 6.3 Hz, $PhSO_2CH_2$), 3.71 (dd, 1, J = 15.4, 6.9 Hz, $PhSO_2CH$), 3.70 (dd, 1, J = 14.2, 4.3 Hz, $PhSO_2CH$), 3.54 (cm, 1H, J = 4.1 Hz, CHOH), 3.11 (cm, 1H, J = 2.0 Hz, CHOH), 2.10 (bs, OH), 1.64–1.32 (m, 2 × 4H, CH_2), 0.96 (m, 3H, J = 6.9 Hz, CH_3), 0.94 (m, 3H, J = 6.7 Hz, CH_3). ^{13}C NMR ($CDCl_3$) δ: 138.7, 138.5, 134.0, 134.0, 129.4, 129.3, 129.3, 128.0, 127.7, 74.3 (CHOH), 71.0 (CHOH), 62.6 ($PhSO_2CH_2$), 61.5 ($PhSO_2CH_2$), 41.3, 36.5, 31.6, 28.6, 18.7, 18.5, 13.9, 13.9. HRMS calcd. for $C_{12}H_{18}O_3SI$: 369.0021 (M + H); found: 369.0021.

Treatment with alumina (3 g) gave 211 mg (88%) of vinyl sulfone **18**; mp 54–57 °C (lit. value (30) mp 56–58 °C). R_f 0.25 (40% ethyl acetate – hexanes). The ^{1}H and ^{13}C NMR spectra of **18** matched those reported (30).

3-(*tert*-Butyldimethylsiloxy)-1-(phenylsulfonyl)cyclohexene (21) and 3-(*tert*-butyldimethylsiloxy)-2-(phenylsulfonyl)cyclohexene (22)

Iodophenylsulfonation of the TBDMS ether of cyclohexenol gave a mixture of regioisomeric 2-iodo-1-phenylsulfonyl and 1-iodo-2-phenylsulfonyl derivatives (**19**, **20**); from 214 mg (1 mmol) of alkene there was obtained 371 mg (77%) of iodophenylsulfonyl adducts as an oil. R_f 0.36 (10% ethyl acetate – hexanes). ^{1}H NMR δ: 7.90 (m, 2H, PhH), 7.60 (m, 3H, PhH), 5.15 (m, 1H), 4.90 (m, 1H), 4.40 (m, 1H), 3.61 (m, 1H), 3.51 (m, 1H), 3.19 (m, 1H), 2.14–1.90 (m, 4H), 1.66–1.48 (m, 2H), 0.90 (s, *t*-Bu), 0.82 (s, *t*-Bu), 0.06 (s, CH_3), 0.04 (s, CH_3).

The crude mixture was taken up in carbon tetrachloride (3 mL), DABCO was added (112 mg, 1.3 equiv.), and the mixture was stirred overnight at room temperature. The mixture was diluted with dichloromethane, extracted with water and brine, dried (Na_2SO_4), and concentrated to give 262 mg (92%) of a mixture of vinyl sulfone **21** and its regioisomer **22**, which were not separated. R_f 0.27 (10% ethyl acetate – hexanes). The ^{1}H NMR spectrum of the mixture of vinyl sulfones showed a 2.2:1 ratio of vinyl sulfone **21** (the resonances of which matched those reported in the literature, ref. 27) and another product, assigned as the regioisomeric vinyl sulfone **22**, which showed peaks at δ 7.17 (C=CH) and 4.66 (CHOSi). HRMS calcd. for $C_{18}H_{29}O_3SiS$: 353.1607 (M + H); found: 353.1612.

3-(*tert*-Butyldimethylsiloxy)-2-methyl-1-(phenylsulfonyl)-cyclohexene (24)

The TBDMS ether of 2-methylcyclohexenol gave diastereomeric 2-iodo-3-phenylsulfonyl derivatives (**23**) and a small amount of a side product that was not identified; from 266 mg (1.18 mmol) of alkene there was obtained 334 mg (57%) of iodophenylsulfonyl adducts as an oil. R_f 0.30 (10% ethyl acetate – hexanes). ^{1}H NMR δ: 7.89 (m, 2H, PhH), 7.51 (m, 3H, PhH), 3.83 (m, 1H), 3.12 (m, 1H), 2.75 (m, 1H), 2.47–1.41 (m, 6H), 1.29 (s, 3H, CH_3), 1.26 (s, 3H, CH_3), 0.85 (s, *t*-Bu), 0.83 (s, *t*-Bu), 0.06 (s, CH_3), 0.04 (s, CH_3).

The crude mixture was taken up in carbon tetrachloride (3 mL), DABCO was added (88 mg, 1.3 equiv.), and the mixture was stirred overnight at room temperature. The mixture was diluted with dichloromethane, extracted with water and brine, dried (Na_2SO_4), and concentrated to give 196 mg of a mixture of products that was purified using a Waters vacuum manifold with a 20 Sep-Pak silica gel cartridge and 5%–20% ethyl acetate – hexanes as eluant to give 95 mg (38%) of vinyl sulfone **24** as an oil. R_f 028 (10% ethyl acetate – hexanes). ^{1}H NMR δ: 7.86 (m, 2H, PhH), 7.60 (m, 3H, PhH), 3.87 (m, 1H, CHOSi), 3.12 (m, 1H), 2.45 (s, 3H, CH_3), 2.36–1.24 (m, 6H), 1.29 (s, CH_3), 0.93 (s, *t*-Bu), 0.13 (s, CH_3), 0.12 (s, CH_3). HRMS calcd. for $C_{19}H_{31}O_3SiS$: 366.1763 (M + H); found: 366.1772

Phenylsulfonyl 4-*O*-acetyl-2,3,6-trideoxy-α,β-L-*threo*-hex-2-enopyranoside (27)

Benzenesulfinic acid (560 mg, 4 equiv.) was added to a stirring solution of 3,4-di-*O*-acetyl-6-deoxy-L-glucal (214 mg, 1 mmol) in 5 mL of anhydrous dichloromethane at 0 °C. The reaction was allowed to warm to room temperature and stirred for 1 h, after which TLC (20% ethyl acetate – hexane) showed that starting material was consumed. The mixture was then diluted with 40 mL of dichloromethane and washed with 10% $NaHCO_3$ (40 mL) and brine (40 mL), dried (Na_2SO_4), and concentrated to an oil that was purified on a Waters vacuum manifold using a 20 cc Sep-Pak silica gel cartridge and 20% ethyl acetate – hexane as eluant to give a 3:1 mixture of α and β anomers that were not separated. Yield: 255 mg (86%). R_f 0.4 (40% ethyl acetate – hexanes). ^{1}H NMR (300 MHz, $CDCl_3$): see Table 2. ^{13}C NMR (75.4 MHz, $CDCl_3$) δ: 169.8, 169.4, 136.6, 134.0, 133.7 (C_2/C_3), 132.9 (C_2/C_3), 129.6, 128.7, 128.6, 128.1, 120.9 (C_2/C_3), 119.0 (C_2/C_3), 89.3 (C_1, α), 88.1 (C_1, β), 72.4, 68.7, 68.4, 20.7, 20.6, 17.8, 17.5. Analytical MW calcd. for $C_{14}H_{16}O_5S$: 296; found by ESIMS: 314.3 (38%) $(M + NH_4)^+$, 155.3 (100%). HRMS calcd. for $C_{14}H_{17}O_5S$: 296.0797 (M + H); found: 297.0787.

Iodophenylsulfonation of dihydropyran

Dihydropyran (252 mg, 3 mmol) was dissolved in a mixture of 3 mL each of anhydrous acetonitrile and anhydrous dichloromethane. Tetra-*N*-butylammonium benzenesulfinate (36) (3 mmol, 1.15 g) and 4 Å molecular sieves (100 mg) were added and the reaction mixture was stirred for 30 min, then *N*-iodosuccinimide (675 mg, 3 mmol) was added and

[a]H_2 and H_3 shifts, including related coupling constants, may need to be exchanged.
[b]Broadened dt multiplet.
[c]Shifts determined with the help of COSY.
[d]The coupling constants could not be determined because of the small $\Delta\delta$ between H_2 and H_3, generating high order multiplets.

the reaction was allowed to stir for 8 h at –78 °C. The reaction was diluted with dichloromethane (50 mL), washed with 10% $NaHSO_3$ (50 mL), water (50 mL), and brine (50 mL), dried over Na_2SO_4, and concentrated to give a yellow oily product that was then purified by flash chromatography over silica gel using 40% ethyl acetate in hexanes as the eluant. One of the products separated as a waxy solid (101 mg, 11%) was determined to be the *trans*-3-iodo-2-succinimide adduct of dihydropyran. The other fractions contained a mixture (211 mg) of the 3-iodo-2-phenylsulfonyl adducts and other side products that were not identified. The *trans*-3-iodo-2-succinimide **26** adduct had: R_f 0.28 (40% ethyl acetate – hexane). IR (film, cm^{-1}) ν_{max}: 2950, 1716, 1371. ^1H NMR δ: 5.24 (d, 1H, J = 11.2 Hz, CHN), 5.16 (ddd, 1H, J = 2.8, 11.2 Hz, CHI), 4.15 (m, 1H), 3.68 (m, 1H), 2.74 (s, 4H, CH_2CH_2), 2.60 (m, 1H), 2.13 (m, 1H), 1.78 (m, 1H), 1.40 (m, 1H). ^{13}C NMR δ: 178.2, 86.2, 71.6, 39.9, 31.2, 30.4, 26.7. HRMS calcd. for $C_9H_{13}NO_3I$: 309.9940; found: 309.9942.

The 3-iodo-2-phenylsulfonyl adducts **27** had: R_f 0.5 (40% ethyl acetate – hexane). IR (film, (cm^{-1}) ν_{max}: 2950, 1625, 1439, 1320 (S=O), 1139 (S=O). ^1H NMR δ: 5.01 (d, 1H, J = 5.6 Hz, CHS) 4.86 (d, 1H, J = 6.7 Hz, CHS), 4.21–3.98 (m, 2H), 3.72 (m, 1H), 3.62 (m, 1H), 2.2–1.6 (m, 10H). HRMS calcd. for $C_{11}H_{12}O_3SI$: 350.9548 (M – H); found: 350.9582.

Acknowledgments

The authors thank Dr. John Wojcik for conducting experiments that revealed the formation of benzenesulfonyl iodide from benzenesulfinic acid and *N*-iodosuccinimide. We also thank Villanova University for financial support of this research.

HR-MAS NMR studies of ^{15}N-labeled cells confirm the structure of the *O*-methyl phosphoramidate CPS modification in *Campylobacter jejuni* and provide insight into its biosynthesis[1]

David J. McNally, Marc Lamoureux, Jianjun Li, John Kelly, Jean-Robert Brisson, Christine M. Szymanski, and Harold C. Jarrell

Abstract: Because *Campylobacter jejuni* is the leading cause of bacterial food-borne gastroenteritis throughout the world, there is intense effort to determine the mechanisms of infectivity associated with this bacterium. Capsular polysaccharide (CPS) has been shown to be an important virulence factor for *C. jejuni* and a recent study that examined the 11168V26 strain identified several phase-variable CPS modifications including an unusual *O*-methyl phosphoramidate (MeO*P*N) group on C-3 of the Gal*f*NAc residue. In this study, we examined the MeO*P*N group using homo- and hetero-nuclear high-resolution magic angle spinning (HR-MAS) NMR experiments of whole bacterial cells grown on $^{15}NH_4Cl$-enriched media. ^{1}H–^{31}P HSQC NMR experiments showed that the level of ^{15}N labeling within the MeO*P*N reached 80%, and a large $^{1}J(^{15}N$–$^{31}P)$ scalar coupling provided direct evidence that confirmed the structure of the MeO*P*N as $CH_3OP(O)(NH_2)(OR)$. Because ^{15}N was also detected within the major outer membrane protein as well as the NAc and NGro groups of CPS, ammonium was concluded to be an important building block used in the synthesis of amino acids and glycan structures in *C. jejuni*. HR-MAS NMR studies of ^{15}N-labeled cells revealed an unanticipated level of complexity as multiple MeO*P*N signals were observed within ^{1}H-^{31}P HSQC spectra for the 11168V26 and 11168H strains. While some signals originated from the MeO*P*N at C-3 of Gal*f*NAc, others were attributed to a novel MeO*P*N located on D-*glycero*-α-L-*gluco*-heptopyranose. Together, these HR-MAS NMR findings shed light on nitrogen metabolism in *C. jejuni*, confirm the chemical structure of the MeO*P*N, and demonstrate that the modification occurs on both furanose and pyranose CPS sugars for this bacterium.

Key words: Campylobacter jejuni, capsular polysaccharide, HR-MAS NMR, isotope labeling, phosphoramidate.

Résumé : Compte tenu du fait que le *Campylobacter jejuni* est la cause principale des gastroentérites reliées à l'alimentation dans le monde, un effort intense est développé pour déterminer les mécanismes d'infection associés à cette bactérie. Il a été démontré que le polysaccharide capsulaire (PSC) est un facteur important de virulence du *C. jejuni* et une étude récente qui a examiné la souche 11168V26 a permis d'identifier plusieurs modifications du PSC de phase variable, dont une comportant le groupement inhabituel phosphoramidate de *O*-méthyle (MeO*P*N) en position C-3 du résidu Gal*f*NAc. Dans cette étude, le groupe MeO*P*N a été examiné par des expériences de RMN homo- et hétéronucléaires à haute résolution, à l'angle magique de rotation (« HR-MAS ») sur des cellules complètes de bactéries cultivées dans un milieu enrichi en $^{15}NH_4Cl$. Des expériences de RMN « HSQC » ^{1}H–^{31}P ont permis de montrer que le niveau de marquage au ^{15}N dans le MeO*P*N atteint 80 % et le grand couplage scalaire $^{1}J(^{15}N$–$^{31}P)$ a fourni une preuve directe pour confirmer que la structure du MeO*P*N est $CH_3OP(O)(NH_2)(OR)$. Compte tenu du fait qu'on peut aussi détecter la présence de ^{15}N dans la protéine principale de la membrane extérieure de la cellule sous la forme de groupes NAc et NGro du PSC, on en conclut que l'ammonium est un produit important dans la synthèse des acides aminés et les structures des glycanes du *C. jejuni*. Les études de RMN à haute résolution, à l'angle magique de rotation, des cellules marquées au ^{15}N ont permis de montrer l'existence d'un degré inattendu de complexité alors qu'on a observé de multiples signaux de MeO*P*N dans les spectres HSQC ^{1}H–^{31}P des souches 11168V26 et 11168H. Alors que quelques signaux trouvent leur origine dans le MeO*P*N en position C-3 du Gal*f*NAc, d'autres peuvent être attribués à un nouveau MeO*P*N situé sur le D-*glycéro*-α-L-*gluco*-heptopyranose. Prises dans leur ensemble, ces données obtenues par des études RMN HR-MAS, permettent de jeter de la lumière sur le métabolisme de l'azote dans le *C. jejuni*,

Introduction

The Gram-negative, spiral-shaped bacterium *Campylobacter jejuni* is the leading cause of bacterial gastroenteritis worldwide and a significant cause of child morbidity in underdeveloped countries (1). In addition, there is convincing evidence linking *C. jejuni* infections to the development of Miller Fisher and Guillain-Barré neuropathies, the latter being the primary cause of neuroparalysis since the eradication of polio (1, 2). As a result, there is intense effort to elucidate the virulence factors and mechanisms of infectivity associated with this mucosal pathogen.

Capsular polysaccharides (CPSs) are found on the surface of a large number of bacterial species and play a key role in survival in the environment and often contribute to pathogenesis (3). By mimicking host cell antigens and through structural variation, CPSs also convey evasion from host immune responses and are therefore considered important virulence factors. Based on its role in ferret disease, chicken colonization, maintenance of cell surface hydrophilicity, diarrhoeal disease, adherence and invasion of human epithelial cells, and serum resistance, CPS has been established as an important virulence factor in *C. jejuni* (4, 5).

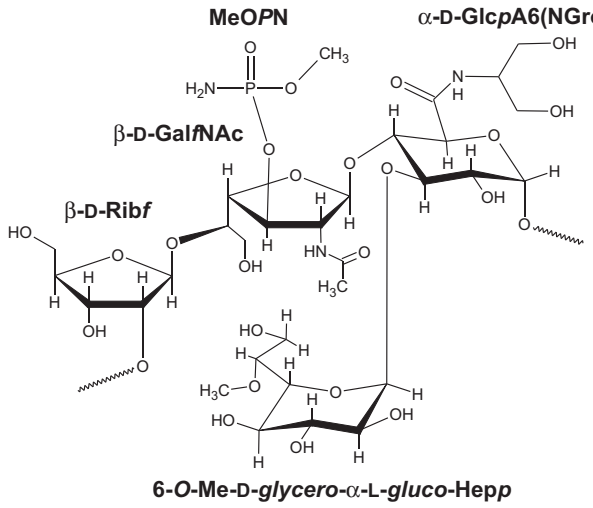
The CPSs produced by *C. jejuni* are structurally diverse and highly variable. For instance, there are presently more than 60 serostrains described for this bacterium, excluding nontypeable strains, representing different CPS structures (6). Genetic mechanisms for this structural variability were partially uncovered when examining the genome of *C. jejuni* NCTC11168 (HS:2) where hypervariable sequences were shown to be a prominent feature of genes encoding the biosynthesis or modification of glycan surface structures (7). By comparing the CPS biosynthetic regions for several strains of *C. jejuni* to the genome of NCTC11168, a recent study demonstrated multiple mechanisms of structural variation including exchange of CPS genes and entire clusters by horizontal transfer, gene duplication, deletion, and fusion, as well as gene variation (6). Direct evidence for structural mechanisms of variation was provided by a study that used high-resolution magic angle spinning (HR-MAS) NMR to examine CPS from growth of individual bacterial colonies of the 11168V26 strain (8). This study identified several phase-variable CPS modifications such as methyl, ethanolamine, and aminoglycerol groups and provided the first report of a variable *O*-methyl phosphoramidate, $CH_3OP(O)(NH_2)(OR)$ (MeO*P*N), on the CPS located at C-3 of the Gal*f*NAc residue (Fig. 1) (8). The structure of the MeO*P*N residue was deduced from mass spectrometric and NMR chemical shift data (8). Since these studies, the MeO*P*N CPS modification was detected on two other strains of *C. jejuni* including NCTC12517 (HS:19) and G1 (HS:1), suggesting it may be common to the species (6). Examination of CPS in the HS:1 serostrain (ATCC 43429, designation MK5-S7630) showed that it has a structurally heterogeneous, teichoic acidlike CPS with a [-4)-α-D-Gal*p*-(1-2)-(*R*)-Gro-(1-*P*]$_n$ repeating unit and two fructofuranose branches substituted at C-3 with MeO*P*N groups (9). By examining purified and cell-bound CPS on the surface of bacterial cells using HR-MAS NMR, this study demonstrated that structural heterogeneity was due to nonstoichiometric fructosylation of Gal and variable MeO*P*N groups. Based on these findings, it was postulated that structural heterogeneity of CPS may represent a mechanism of host evasion or increased fitness in the HS:1 strain (9).

Phosphoramidates are extremely labile structures with large standard free energies of hydrolysis (10, 11), likely explaining why the MeO*P*N was overlooked by previous studies examining CPSs in *C. jejuni*. Although there is little information available regarding the biochemistry or role of phosphoramidates in nature, there is convincing evidence for their involvement in two-component and phosphorelay signal transduction pathways in bacteria that mediate responses such as sporulation, chemotaxis, mucoidy, and flagellar movement (12–18). For *C. jejuni*, there is presently a lack of structural and biochemical information for this MeO*P*N CPS modification. Definitive evidence for the N—P bond would be provided by biosynthetically incorporating ^{15}N into the CPS MeO*P*N residues and demonstrating a $^1J(^{15}N–^{31}P)$ scalar coupling.

In this study, we have developed a method of labeling the MeO*P*N with ^{15}N by growing *C. jejuni* on $^{15}NH_4Cl$-enriched media. The amount of ^{15}N incorporation within the MeO*P*N and its structure were determined directly on the surface of bacterial cells using homo- and hetero-nuclear HR-MAS NMR experiments. Since nitrogen metabolism in campylobacters is largely uncharacterized, CE-ESI/MS and nanoLC–MS/MS were used to analyze the extent of ^{15}N labeling within select proteins and glycan structures. Herein, we show that ammonium is an important source of nitrogen for *C. jejuni*, provide conclusive NMR evidence confirming the structure of the MeO*P*N, and demonstrate the complexity of its distribution on the surface of *C. jejuni* cells.

Experimental

Solvents and reagents



Unless otherwise stated, solvents and reagents were purchased from Sigma Biochemicals and Reagents (Oakville, Ontario).

Bacterial strains, media, and growth conditions

Both *C. jejuni* 11168 isolates, 11168V26 (HS:2) (8, 19) and 11168H (HS:2) (20), were routinely maintained on Mueller Hinton (MH) (Difco, Kansas City, Missouri) plates under microaerophilic conditions (10% CO_2, 5% O_2, and 85% N_2) at 37 °C. ^{14}N- and ^{15}N-labeled MH plates were prepared by combining filter sterilized (0.22 μm, Millipore,

Billerica, Massachusetts) aqueous solutions of $^{14}NH_4Cl$ (Sigma) or $^{15}NH_4Cl$ (Cambridge Isotopes Laboratories Inc., Andover, Maryland) with autoclaved MH agar to a final volume of 20 mL. To obtain ^{14}N- and ^{15}N-labeled bacterial cells, strains were grown for a total of 48 h under microaerophilic conditions on ^{14}N- or ^{15}N-labeled plates, with transfer onto fresh plates after 24 h.

HR-MAS NMR spectroscopy

For HR-MAS NMR analysis, bacterial cells were prepared as previously described before being loaded into a 40 μL nano-NMR tube (Varian, Palo Alto, California) (8, 9). HR-MAS experiments were performed using a Varian Inova 500 MHz spectrometer equipped with a Varian 4 mm indirect detection gradient nano-NMR probe with a broadband decoupling coil. Spectra from 40 μL cell samples were spun at 3 kHz and recorded at ambient temperature (23 °C), and all experiments were performed with suppression of the HOD signal by presaturation as previously described (8). ^1H NMR spectra of bacterial cells were acquired using the Carr–Purcell–Meiboom–Gill (CPMG) pulse sequence (90 – $(\tau - 180 - \tau)_n$ acquisition) to remove broad signals originating from lipids and solidlike materials (21). The total duration of the CPMG pulse ($n2\tau$) was 10 ms with τ set to (1/MAS spin rate). ^1H NMR spectra for cell-bound CPS on the surface of bacterial cells were typically obtained using 256 transients (11 min). 1D and 2D ^1H–^{31}P HSQC spectra were acquired with the standard Varian HSQC pulse sequence with 1D spectra representing the first increment of the standard HSQC experiment. Unless otherwise specified, 1D ^1H–^{31}P HSQC spectra were obtained with 600 scans and $^3J_{H,P}$ = 10 Hz (20 min), while 2D ^1H–^{31}P HSQC spectra were obtained using 128 scans, 64 increments, and $^3J_{H,P}$ = 10 Hz (8 h) with proton decoupling to remove $J_{H,P}$ scalar couplings. ^1H NMR spectra were referenced to an internal TSP (3-(trimethylsilyl)propionic-2,2,3,3-d_4 acid sodium salt, Sigma) standard (δ_H 0.00 ppm), and ^1H–^{31}P HSQC NMR spectra were referenced to the major MeO*P*N signal at δ_P 13.6 ppm (8).

Mass spectrometric analysis of ^{15}N labeling within CPS

For mass spectrometric analysis of ^{14}N- and ^{15}N-labeled CPS, *C. jejuni* 11168V26 cells were grown on four MH plates enriched with 100 mmol/L of $^{14}NH_4Cl$ or $^{15}NH_4Cl$ for 48 h as described in the previous section. Cells were harvested and blended in 90% phenol at 96 °C for 15 min to extract CPS, allowed to cool for 30 min, and then dialyzed (MWCO 12 kDa, Sigma) against running water for 72 h to eliminate traces of phenol. Cells were then ultracentrifuged (140 000 × *g*, 15 °C) for 2 h and the supernatant, which contained crude CPS, was lyophilized to dryness. Due to the high molecular weight of CPS, samples were mass-analyzed using in-source, collision-induced dissociation CE-ESI/MS (22) with a Crystal model 310 Capillary electrophoresis instrument (ATI Unicam, Boston, Massachusetts) coupled to an API 3000 mass spectrometer (Applied Biosystems/Sciex, Concord, Ontario) via a microion spray interface. A sheath solution (isopropanol–methanol, 2:1) was delivered at a flow rate of 1 μL min^{-1}. Separations were achieved on approximately 90 cm of bare fused-silica capillary (190 μm o.d. × 50 μm i.d., Polymicro Technologies, Phoenix, Arizona) using 15 mmol/L ammonium acetate – ammonium hydroxide in deionized water (pH 9.0) containing 5% MeOH as separation buffer. A voltage of 20 kV was typically applied during CE separation and +5 kV was used as the electrospray voltage. Mass spectra were acquired with dwell times of 3.0 ms per step of 0.1 m/z^{-1} unit in full-mass scan mode. Fragment ions formed by collision activation of selected precursor ions with nitrogen in the RF-only quadrupole collision cell were mass analyzed by scanning the third quadrupole. All samples were analyzed in positive ion mode using an orifice voltage of +200 V.

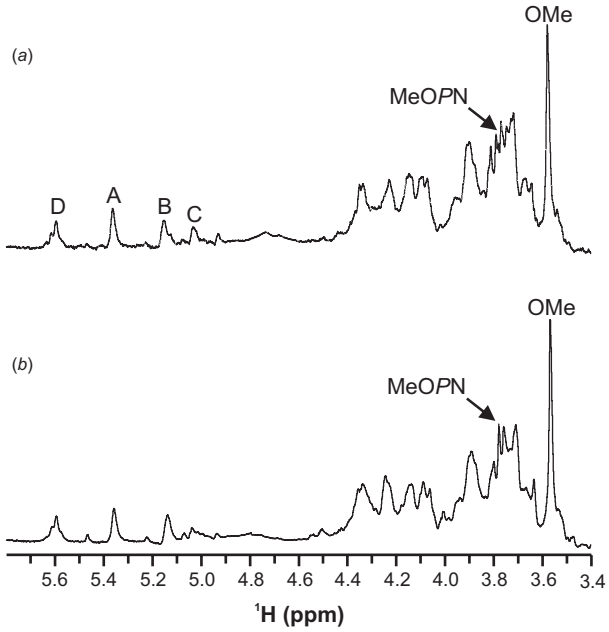
Mass spectrometric analysis of ^{15}N labeling within proteins

For mass spectrometric analysis of ^{14}N- and ^{15}N-labeling in proteins, *C. jejuni* 11168V26 cells were grown on two MH plates enriched with 100 mmol/L of $^{14}NH_4Cl$ or $^{15}NH_4Cl$ for 48 h as described in the previous section. Cells were harvested and proteins were extracted for 20 min with 500 μL of cold glycine (0.2 mol/L, pH 9.2). Extracts were then centrifuged (8900 × *g* for 2 min) to pellet cells and the supernatant was retained. A 2X SDS PAGE sample buffer (10 mL 1.5 mol/L Tris pH 6.8, 6 mL 20% SDS, 30 mL glycerol, 15 mL β-mercaptoethanol, 1.8 mg bromophenol blue, 40 mL H_2O) was then added to the extracts (buffer–supernatant, 3:1 *v/v* ratio) prior to heating at 100 °C for 15 min. To purify proteins, 20 μL of crude protein extract was loaded onto a 10% acrylamide gel (30% acrylamide–Bis solution, 37:1, BioRad, Mississauga, Ontario) and separation of proteins was achieved over 45 min (200 V, 0.04 A). Protein bands were visualized by staining with colloidal coomassie blue for 45 min (Biosafe Coomassie, G250 stain, BioRad) and pure protein bands were manually excised from the gel. Proteins were then destained with a 1:1 ratio of 30 mmol/L potassium ferricyanide and 100 mmol/L sodium thiosulphate, digested with Promega modified trypsin (Madison, Wisconsin) overnight in 50 mmol/L NH_4HCO_3 and peptides

© 2006 NRC Canada

were extracted with 5% HOAc – 50% aqueous MeOH as previously described (23). Peptide fragments were then analyzed by nanoLC–MS/MS using a Q-TOF2 mass spectrometer (Micromass, Waters, Milford, Massachusetts) in automated mode as previously reported (23).

Results



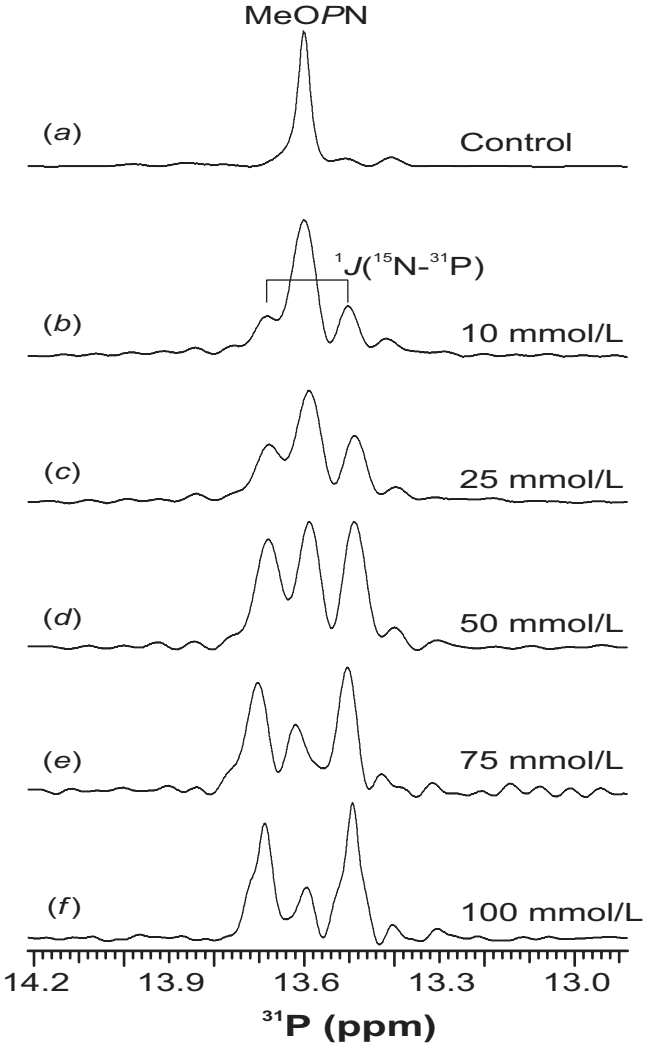
Bacterial growth on $^{15}NH_4Cl$-enriched media

To establish unambiguously the structure of the MeO*P*N residue, we sought to demonstrate a $^1J(^{15}N–^{31}P)$ scalar coupling in the $^1H–^{31}P$ HSQC spectra of CPS biosynthetically labeled with ^{15}N. To label the MeO*P*N with ^{15}N, *C. jejuni* 11168V26 cells were grown on six different concentrations of $^{15}NH_4Cl$ (0, 10, 25, 50, 75, and 100 mmol/L) for 48 h and then examined with HR-MAS NMR. Although bacteria exhibited moderately reduced growth at 75 and 100 mmol/L NH_4Cl (not shown), the HR-MAS ^1H NMR spectrum for cells grown on 100 mmol/L of $^{15}NH_4Cl$ had identical spectral features compared to control cells grown on unlabeled MH plates (Fig. 2*a* vs. 2*b*). Furthermore, the proton chemical shifts for the CPS anomeric resonances of cells grown on labeled and unlabelled media were nearly identical to those reported for this strain by our previous study (8). Because the expression of sensitive phase-variable CPS modifications such as OMe and MeO*P*N groups was not affected and since the chemical shifts of CPS anomeric resonances were not altered, it was concluded that growth on $^{15}NH_4Cl$-enriched media did not introduce obvious structural artifacts within the CPS.

HR-MAS NMR spectroscopy of ^{15}N labeling within the MeO*P*N

To quantify the levels of ^{15}N labeling within the MeO*P*N modification, *C. jejuni* 11168V26 cells grown on different concentrations of $^{15}NH_4Cl$ were examined using $^1H–^{31}P$ HSQC HR-MAS NMR (Fig. 3). Because of the low natural abundance of ^{15}N, $^1J(^{15}N–^{31}P)$ scalar couplings were not observed for the MeO*P*N residue in the spectra of control cells grown on unlabeled MH plates resulting in one phosphorous signal at 13.6 ppm, as expected (Fig. 3*a*). Upon the addition of 10 mmol/L $^{15}NH_4Cl$ to the media, however, additional phosphorous signals were observed as a result of a $^1J(^{15}N–^{31}P)$ scalar coupling (Fig. 3*b*). The magnitude of the $^1J(^{15}N–^{31}P)$ scalar coupling observed for the MeO*P*N at 39 (±2) Hz was consistent with values reported for $^1J(^{15}N–^{31}P)$ scalar couplings in the literature, where they were shown to range from approximately 28 to 43 Hz (24). Integration of these new signals revealed that the addition of 10 mmol/L of $^{15}NH_4Cl$ to the media resulted in approximately 35% ^{15}N labeling within the MeO*P*N. Increasing concentrations of $^{15}NH_4Cl$ within the media resulted in higher levels of ^{15}N incorporation within the MeO*P*N. For instance, bacteria grown on 25, 50, and 75 mmol/L of $^{15}NH_4Cl$ exhibited 50%, 65%, and 75% ^{15}N labeling, respectively, within their MeO*P*N modifications (Figs. 3*c*–3*e*). Bacteria grown on 100 mmol/L of $^{15}NH_4Cl$ exhibited the highest incorporation of ^{15}N within the MeO*P*N at 80% (Fig. 3*f*).

Fig. 2. HR-MAS NMR spectra showing the effects of adding $^{15}NH_4Cl$ to growth media in *Campylobactor jejuni*. (*a*) HR-MAS ^1H NMR spectrum of *C. jejuni* 11168V26 cells grown on media enriched with 100 mmol/L $^{15}NH_4Cl$. (*b*) HR-MAS ^1H NMR spectrum of *C. jejuni* 11168V26 cells grown on unlabelled media (control). Abbreviations: β-D-Rib*f* (A), α-D-Glc*p*A6(NGro) (B), β-D-Gal*f*NAc (C), D-*glycero*-α-L-*gluco*-heptopyranose (D), 6-*O*-methyl group of D-*glycero*-α-L-*gluco*-heptopyranose (OMe), *O*-methyl phosphoramidate (MeO*P*N).



Mass spectrometric analysis of ^{15}N labeling within CPS

To confirm ^{15}N incorporation within the MeO*P*N and determine if the NGro and NAc CPS groups were being labeled, CPS was partially purified from 11168V26 cells grown on 100 mmol/L of $^{15}NH_4Cl$ or $^{14}NH_4Cl$ and analyzed with in-source, collision-induced dissociation CE-ESI/MS (22). Approximately 289 mg of cells (wet pellet mass) was harvested from four $^{15}NH_4Cl$ enriched plates that yielded 16 mg of crude CPS. A comparable amount of cells (281 mg) and crude CPS (12 mg) was recovered from four plates enriched with $^{14}NH_4Cl$. Due to the presence of contaminating ions originating from proteins, nucleic acids, and lipids, precursor ion scans for D-*glycero*-α-L-*gluco*-heptopyranose (*m*/*z* 250) were used to mass analyze both CPS samples (Figs. 4*a* and 4*b*). CE-ESI/MS analysis of CPS prepared from cells grown on $^{14}NH_4Cl$-labeled media showed the mass of one CPS repeat to be *m*/*z* 884.5 $[M + H]^+$, and was consistent with what has been reported for *C. jejuni* 11168V26 (8) (Fig. 4*a*). An intense ion at *m*/*z* 791.0, representing one CPS repeat minus the MeO*P*N $[M + H – 93]^+$, showed that the dominant isotope of nitrogen within the MeO*P*N for these cells was ^{14}N. Because only one sharp signal was observed for *m*/*z* 884.5, it was concluded that the amount of ^{15}N labeling for the NGro and NAc CPS groups was negligible, as expected. In contrast, three distinct ions at *m*/*z* 885.5, 886.5, and 887.5 observed for CPS prepared from cells grown on $^{15}NH_4Cl$ media confirmed that the MeO*P*N, NAc and NGro CPS groups were labeled with ^{15}N (Fig. 4*a*

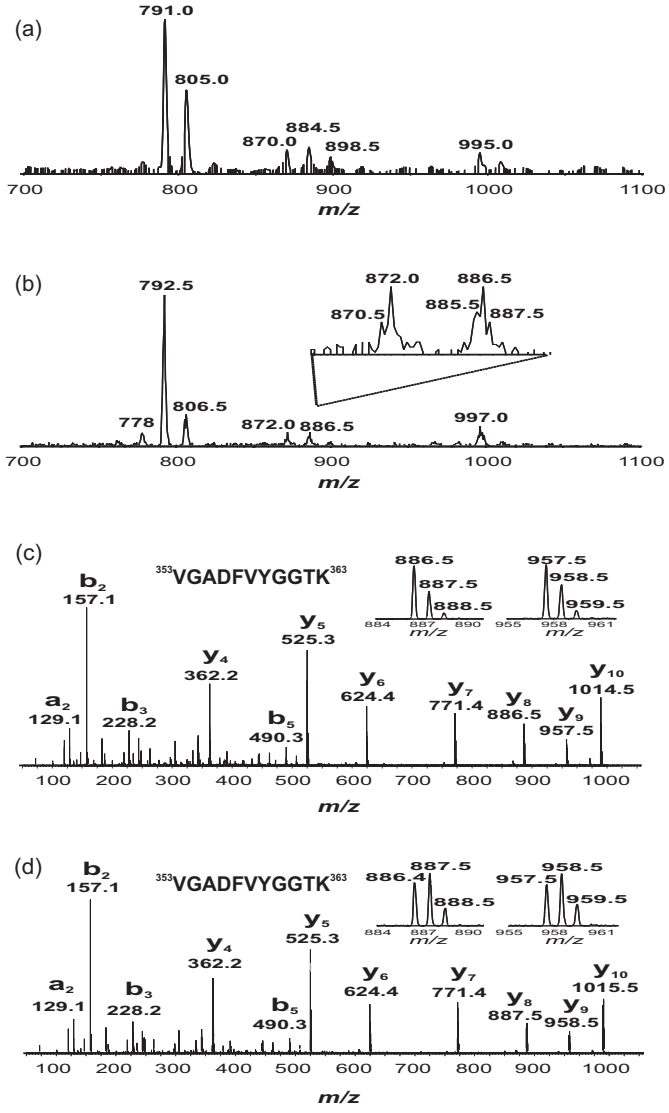
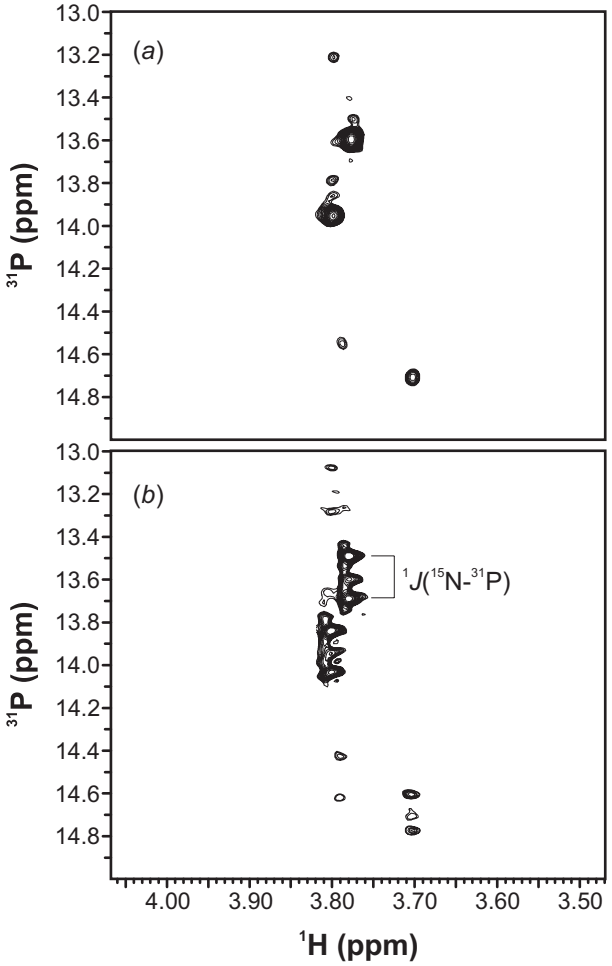
Fig. 3. HR-MAS ^{1}H–^{31}P HSQC NMR spectra showing ^{15}N labeling within the MeO*P*N for *Campylobactor jejuni* 11168V26 cells. Spectra are shown as traces of the ^{31}P dimension centered on the same MeO*P*N modification. (*a*) Control cells grown on unlabelled media. (*b–f*) Cells grown on media enriched with 10, 25, 50, 75, and 100 mmol/L of $^{15}NH_4Cl$, respectively. For cells grown on $^{15}NH_4Cl$-labeled media, a doublet generated by a $^{1}J(^{15}N–^{31}P)$ of 39 (±2) Hz is evident. Abbreviations: *O*-methyl phosphoramidate (MeO*P*N).



vs. 4*b*). Moreover, an ion at *m/z* 792.5, representing one CPS repeat minus the MeO*P*N $[M + H - 94]^{+}$, indicated that ^{15}N was the dominant isotope of nitrogen within the MeO*P*N for these cells.

Mass spectrometric analysis of ^{15}N labeling within proteins



To characterize the amount of ^{15}N labeling within proteins, glycine extracts prepared from *C. jejuni* 11168V26 cells grown on MH plates enriched with 100 mmol/L of $^{14}NH_4Cl$ or $^{15}NH_4Cl$ were separated using SDS PAGE. A strong protein band at 47 kDa was identified as the major outer membrane protein (MOMP) using in-gel tryptic digestion and nanoLC–MS/MS. To analyze ^{15}N incorporation within this protein, the isotope profiles of the tryptic peptides from ^{14}N- and ^{15}N-labeled MOMP as well as their MS/MS fragment ions were compared. As an example, the MS/MS spectra obtained for the ^{14}N- and ^{15}N-labeled tryptic peptide, ^{353}VGADFVYGGTK^{363}, are presented in Figs. 4*c* and 4*d*, respectively. The y_8 (*m/z* 886.5) and y_9 (*m/z* 957.5)

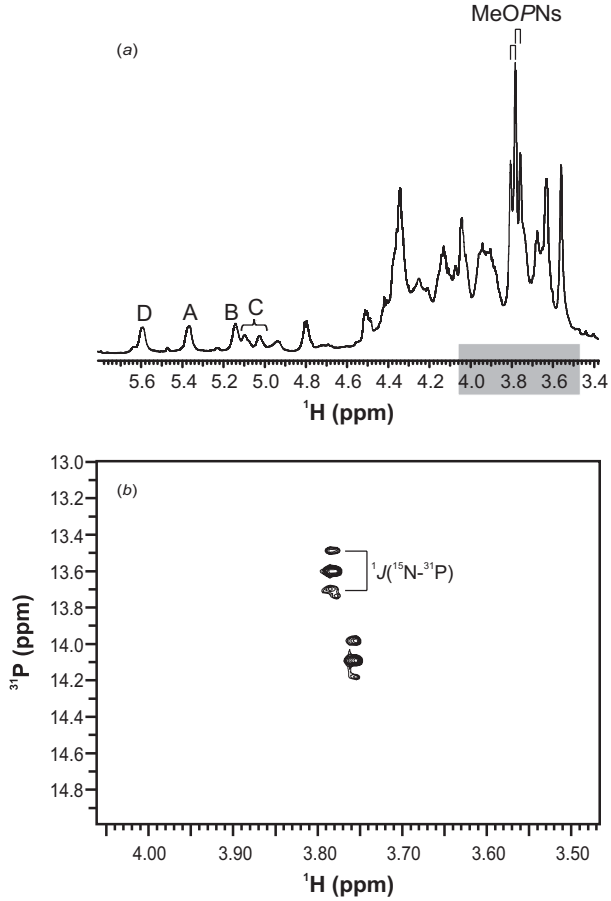
Fig. 5. HR-MAS NMR analysis of the MeO*P*N CPS modification on the surface of *Campylobacter jejuni* 11168V26 cells. (*a*) Proton decoupled $^{1}H–^{31}P$ HSQC NMR spectrum showing five distinct signals originating from MeO*P*Ns on the surface of cells grown on media enriched with 100 mmol/L of $^{14}NH_4Cl$; and (*b*) the same NMR experiment for cells grown on media enriched with 100 mmol/L of $^{15}NH_4Cl$. For cells grown on $^{15}NH_4Cl$ media, $^{1}J(^{15}N–^{31}P)$ scalar couplings observed for MeO*P*Ns range from 32 to 40 (±2) Hz.

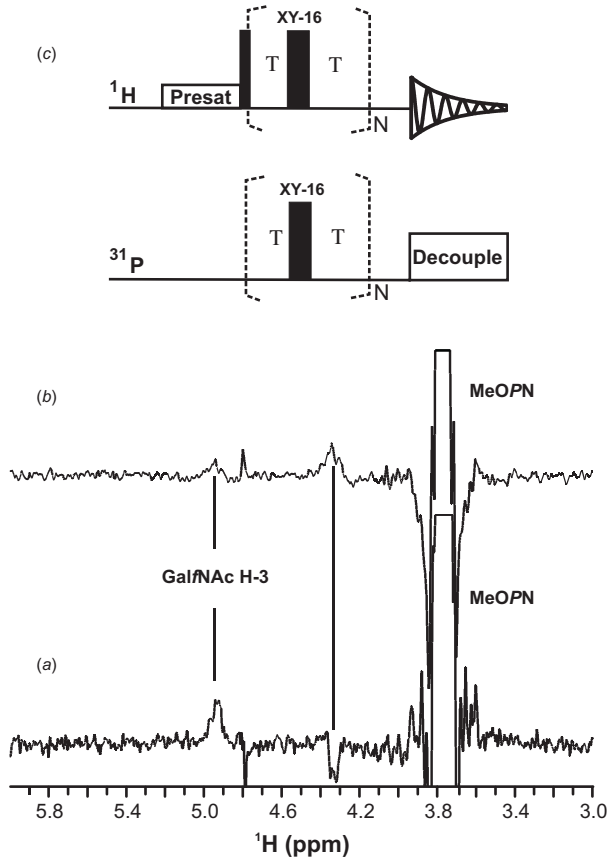


fragment ions are presented in the insets. Based on their isotope profiles, we calculated that approximately 40% of the nitrogen atoms in the ^{15}N-labeled ions have been substituted with ^{15}N. This result was in general agreement with the calculations performed for other peptides that were derived from proteins extracted from *C. jejuni* cells grown on the $^{15}NH_4Cl$ media.

HR-MAS NMR spectroscopy of ^{15}N-labeled 11168V26 and 11168H cells

To characterize the distribution of MeO*P*N on the surface of bacterial cells, *C. jejuni* 11168V26 and 11168H cells were grown on media enriched with 100 mmol/L $^{14}NH_4Cl$ or $^{15}NH_4Cl$ and examined with HR-MAS NMR (Figs. 5 and 6). The $^{1}H–^{31}P$ HSQC spectrum of ^{14}N-labeled 11168V26 cells revealed five distinct signals with chemical shifts characteristic of phosphoramidates between δ_P 13.2 and 13.8 ppm (25–27) (Fig. 5*a*). The $^{1}H–^{31}P$ HSQC spectrum of ^{15}N-

Fig. 6. HR-MAS NMR analysis of *Campylobacter jejuni* 11168H cells. (*a*) HR-MAS ^{1}H NMR spectrum for cells grown on unlabeled media showing two distinct MeO*P*Ns as overlapping doublets at 3.78 and 3.76 ppm ($^{3}J_{H,P}$ = 12 Hz). Two anomeric signals were observed for residue C (β-D-Gal*f*NAc) representing different forms of the sugar; one form where the MeO*P*N is present at C-3 of the sugar (5.10 ppm) and another where the MeO*P*N is absent (5.02 ppm). (*b*) Proton decoupled $^{1}H–^{31}P$ HSQC NMR spectrum for cells grown on media enriched with 100 mmol/L of $^{15}NH_4Cl$ showing an expanded view of the shaded region in (*a*). Two MeO*P*Ns are evident with $^{1}J(^{15}N–^{31}P)$ scalar couplings of approximately 40 (±2) Hz. Abbreviations: β-D-Rib*f* (A), α-D-Glc*p*A6(NGro) (B), B-D-Gal*f*NAc (C), 6-*O*-Me-D-*glycero*-α-L-*gluco*-heptopyranose (D), *O*-methyl phosphoramidate (MeO*P*N).



labeled cells confirmed that these signals originated from MeO*P*Ns as they exhibited $^{1}J(^{15}N–^{31}P)$ scalar couplings between 32 and 40 (±2) Hz (24) (Fig. 5*b*). Two MeO*P*N signals were observed within the HR-MAS ^{1}H NMR spectrum for *C. jejuni* 11168H cells as overlapping doublets at 3.78 and 3.76 ppm ($^{3}J_{P,H}$ = 12 Hz) (Fig. 6*a*). The $^{1}H–^{31}P$ HSQC spectrum of ^{15}N-labeled 11168H cells showed that these two signals at δ_P 13.6 and 14.1 ppm had $^{1}J(^{15}N–^{31}P)$ scalar couplings of approximately 40 (±2) Hz, and therefore confirmed that they originated from MeO*P*Ns (Fig. 6*b*).

That several MeO*P*N signals were detected for C. *jejuni* 11168V26 and 11168H cells is suggestive of environmental heterogeneity on the cell surface resulting in multiple signals

© 2006 NRC Canada

Fig. 7. (*a*) 1D ^{1}H–^{31}P HSQC HR-MAS spectrum of *Campylobactor jejuni* 11168H cells showing proton resonances for CPS carbohydrates linked to MeO*P*N residues. The peak at 4.94 ppm corresponds to the Gal*f*NAc H-3 MeO*P*N (2048 scans, $^{3}J_{H,P}$ = 15 Hz). (*b*) ^{1}H–^{31}P correlation difference spectrum showing proton resonances of CPS carbohydrates linked to MeO*P*N residues. The spectrum was acquired using the pulse sequence shown in (*c*) (4096 scans, $^{3}J_{H,P}$ = 12 Hz). (*c*) Pulse sequence used to obtain the ^{1}H–^{31}P correlation difference spectrum. Narrow and thick bars represent 90° and 180° RF pulses, respectively. The 90° pulse durations were 4.5 μs (^{1}H) and 23 μs (^{31}P). The 180° pulse durations for the CPMG pulse train were 27 μs (γB_1 = 9.26 kHz) and 102 μs (γB_1 = 2.45 kHz) for ^{1}H and ^{31}P, respectively. The ^{31}P pulses were on-resonance for the MeO*P*N residue during odd scans, and off-resonance (28 kHz) for even scans. The receiver phase was alternated between x and –x. Pulse phases in the XY-16 are: [x,y,x,y,y,x,y,x,–x,–y,–x,–y,–y,–x,–y,–x]. The number of cycles (*N*) and the *T* interval (~150 μs) were calculated so that the duration of *N* consecutive XY-16 cycles corresponded to 0.5 $J_{H,P}$ (12 Hz). Abbreviations: *O*-methyl phosphoramidate (MeO*P*N), presaturation (Presat).

for the MeO*P*N at C-3 of Gal*f*NAc, or that there are other MeO*P*N(s) substituted elsewhere. To investigate these possibilities, a 1D HR-MAS ^{1}H–^{31}P HSQC spectrum was acquired ($^{3}J_{H,P}$ = 15 Hz, Fig. 7), since MeO*P*N cross peaks to carbohydrate residues are not typically observed for the 2D ^{1}H–^{31}P HSQC experiment. In addition to the expected MeO*P*N methyl resonances and Gal*f*NAc H-3 resonance at 4.94 ppm, a novel signal at 4.34 ppm was detected for 11168H cells (Fig. 7*a*). Inversion of this novel resonance at 4.34 ppm relative to the one at 4.94 ppm was most likely the result of ^{1}H homonuclear couplings during the 1/2*J* period that had magnitudes approaching the heteronuclear coupling (6–8 Hz) (28), which suggested that the ^{31}P was scalar coupled to a geminal proton or a proton attached to a pyranose ring with a gluco configuration.

To establish that the signal at 4.34 ppm was not an artifact, a 1D difference spectrum was acquired using the pulse sequence shown in Fig. 7c. During odd acquisitions, a CPMG pulse train was simultaneously applied to ^{1}H and ^{31}P during the 1/2*J* coherence transfer step to maintain in-phase ^{1}H magnetization similar to the CPMG–INEPT transfer (28, 29). During even acquisitions, ^{31}P π pulses were applied off-resonance (28 kHz) and subtracted. After an evolution time of 1/2*J* (*J* = 12–15 Hz), the heteronuclear single quantum coherence (I_xS_z) is present, but does not evolve into a detectable signal during acquisition when ^{31}P is decoupled. Subtraction of the spectrum acquired without ^{31}P π pulses produces a difference spectrum in which only those protons scalar coupled to ^{31}P are visible. This is similar to a heteronuclear spin-echo difference spectrum, however; with this experiment, the evolution time is reduced by a factor of two, thereby reducing T_2 attenuation of the signal. The resulting spectrum for 11168H cells exhibited peaks at 4.94 and 4.34 ppm that were in-phase (Fig. 7*b*). Because both peaks were in phase, it was concluded that the resonance at 4.34 ppm was not an artifact since the ^{1}H CPMG-pulse train of this difference experiment selectively suppresses the evolution of homonuclear couplings ($J_{H,H}$).

Based on previous studies showing that substitution with the MeO*P*N causes a localized downfield shift of 0.6–0.8 ppm (8, 9), we propose that the signal at 4.34 ppm originates from a novel MeO*P*N located at the 3-O or 4-O position of the D-*glycero*-α-L-*gluco*-heptopyranose CPS residue. For example, addition of the MeO*P*N to the Gal*f*NAc 3-O position in 11168V26 was shown to cause a downfield shift of H-2 (0.2 ppm), H-3 (0.64 ppm), and H-4 (0.24 ppm) relative to that of the unsubstituted Gal*f*NAc (8). Similarly, addition of MeO*P*N to the 3-O position of Fru in the CPS of the HS:1 serostrain lead to a downfield shift of H-3 (0.74 ppm) and H-4 (0.7 ppm) compared with Fru without MeO*P*N (9). Inspection of the chemical shifts reported for the unsubstituted CPS of 11168V26 (30) reveals that the 3-O (3.72 ppm) and 4-O (3.52 ppm) positions of D-*glycero*-α-L-*gluco*-heptopyranose are both candidates for the MeO*P*N at 4.34 ppm, since this would correspond to downfield shifts of 0.62 and 0.82 ppm, respectively, at these locations.

Discussion

In this study, we used HR-MAS NMR of cells grown on $^{15}NH_4Cl$-enriched media to confirm the chemical structure of the MeO*P*N CPS modification. By doing so, we also present new findings on nitrogen metabolism in *C. jejuni*, the complexity of MeO*P*N distribution on the cell surface, and the biosynthetic pathway responsible for MeO*P*N production.

HR-MAS NMR is well-suited for the study of the MeO*P*N modification in *C. jejuni* since it is a highly labile surface structure that is readily hydrolyzed by chemical reagents used to purify CPS from bacteria (8, 9). By examin-

© 2006 NRC Canada

ing proton chemical shifts for the anomeric resonances of CPS sugars and the expression of phase-variable CPS modifications such as the OMe and MeO*P*N groups with ^{1}H HR-MAS NMR, we determined that the concentrations of NH_4Cl used during this study did not affect the structure of the CPS. These phase-variable CPS groups in *C. jejuni* are useful biomarkers since their expression is highly variable (8). A large $^{1}J(^{15}N–^{31}P)$ coupling of 39 (±2) Hz observed in the $^{1}H–^{31}P$ HSQC spectra for cells grown on $^{15}NH_4Cl$-enriched media provided, for the first time, direct evidence confirming the N—P bond for the MeO*P*N. This is an important result since phosphoramidates are rare in nature and prior to this study, the structure of the MeO*P*N in *C. jejuni* was proposed based on mass spectrometric and NMR chemical shift data (8, 9). That the amount of ^{15}N labeling within the MeO*P*N reached 80% and was directly correlated to the amount of $^{15}NH_4Cl$ in the media indicates that ammonium can be a primary source of nitrogen used for MeO*P*N biosynthesis in *C. jejuni*.

Because of phylogenetic similarities, it was previously thought that metabolism in *C. jejuni* closely resembled *Helicobacter pylori*, however, the genome sequence for *C. jejuni* NCTC11168 showed that only 55.4% of *C. jejuni* genes have orthologues in *H. pylori* (7). Consequently, the factors that contribute to the metabolic versatility of *C. jejuni* allowing it to adapt its metabolism to many environments within and outside its hosts are still poorly understood (31–46). That ^{15}N was detected within the major outer membrane protein, as well as the NAc and NGro groups of the CPS, shows that *C. jejuni* can exploit exogenous sources of inorganic nitrogen to make amino acids and glycan structures. This result suggests that growth on $^{15}NH_4Cl$-enriched media could potentially be used to label proteins, sugars, and phase-variable modifications in *C. jejuni* for NMR analysis.

It is interesting that two MeO*P*Ns were identified for the 11168H strain differing by $\Delta\delta_H$ 0.2 ppm; one at C-3 of Gal*f*NAc and a novel MeO*P*N most likely located at C-3 or C-4 of D-*glycero*-α-L-*gluco*-heptopyranose. Inspection of the ^{1}H-^{31}P HSQC spectra for 11168V26 cells shows that four of the five MeO*P*N signals can be grouped into two general populations that also differ by $\Delta\delta_H$ 0.2 ppm, suggesting that a novel heptose-associated MeO*P*N is present for this 11168 isolate as well (Fig. 5). Definitive location of the novel MeO*P*N in 11168 will require detailed NMR studies of the purified CPS. The diverse range of phosphorous chemical shifts exhibited by these different MeO*P*Ns is possibly due to structural heterogeneity for cell-bound CPS or moderately different pH environments, since the chemical shifts of phosphoramidates were shown to vary considerably with slight changes in pH (27). That a weak MeO*P*N signal at δ_H 3.70 ppm and δ_p 14.7 ppm was observed for 11168V26 cells is suggestive of another MeO*P*N at an unknown location. It is conceivable that MeO*P*N could be located on glycan structures other than CPS. For example, the harsh chemical treatments used to purify LOS would likely hydrolyze the MeO*P*N, resulting in it being overlooked by previous studies examining these structures in *C. jejuni*.

This is the first evidence suggesting that the MeO*P*N CPS modification in *C. jejuni* can be found on CPS sugars with a pyranose ring configuration, since it was shown to be substituted on furanose sugars for *C. jejuni* 11168V26 (C-3 of Gal*f*NAc) and the HS:1 serostrain (C-3 of Fru*f*) (8, 9). That MeO*P*Ns are found on both pyranose and furanose sugars in 11168 suggests that transfer of the MeO*P*N to CPS carbohydrates is possibly regulated by more than one gene. This hypothesis supports the genetic findings for the HS:23 serostrain, where *HS:23.07* and *HS:23.20* were speculated to be involved in adding MeO*P*N to CPS sugars (6). Interestingly, these genes were shown to have high sequence similarity with *cj1422c*, the putative glycosyltransferase from 11168 (6). Examination of the *cps* gene cluster from 11168 demonstrated that there exists a second gene (*cj1421c*) with similarity to *cj1422c*, which may also be involved in transferring MeO*P*N to CPS sugars (6).

In the case of 11168H, this study has shown that the phosphoramidate modification occurs at predominantly two sites in the CPS with approximately equal frequency. This raises the question as to whether each repeating unit in the CPS has two sites that are simultaneously decorated with the MeO*P*N modification, or only one MeO*P*N with equal frequency throughout the CPS. For the latter situation, two additional structures potentially exist, since repeats with only one MeO*P*N could be homogeneously or randomly distributed within the CPS. These structures present largely different CPS epitopes and have interesting implications regarding the details of CPS assembly from subunits containing the MeO*P*N modification. While the basic CPS structure of 11168 has been established (8, 30), it will be important to examine the structure of the purified CPS with respect to the topology of phosphoramidation.

Ab initio DFT calculations of the configurational and conformational preferences of 2-phenylsulfinylcyclohexanones — Evidence for "exo-anomeric" interactions[1]

Melissa L. Trapp, John F. Wojcik, Walter W. Zajac, Jr., and B. Mario Pinto

Abstract: The conformational analysis of 2-phenylsulfinylcyclohexanone by ab initio density functional calculations is described. Six conformations corresponding to axial/equatorial isomers and rotation about the exocyclic C2—S bond in each of the RR or RS diastereomers were calculated and the results were examined in terms of relative energies, electrostatic interactions, orbital interactions, and geometrical variations. The global minimum conformation was the RS isomer that positioned the phenylsulfinyl moiety in an equatorial orientation and the sulfinyl oxygen in an anti orientation with respect to the carbonyl carbon atom. Of the other three low energy conformations, only one had a gauche arrangement of these atoms, and only in one of the four lower energy conformations was evidence found for a S-O(–)···C(+)-O electrostatic interaction. In contrast, the results were consistent with the operation of $n_S \rightarrow \pi^*_{C=O}$ stabilizing orbital interactions. Further support for this hypothesis was obtained from the increased C=O bond lengths in these four conformations relative to the other conformations, and by the torsional angle distortion away from ideal geometry, presumably to maximize the stabilizing orbital interaction. We propose that this conformational preference is a manifestation of a generalized exo-anomeric effect. The longer C2—S bond in the axial isomers was also interpreted in terms of a stabilizing $\pi_{C=O} \rightarrow \sigma^*_{C-S}$ interaction, analogous to an endo-anomeric interaction. Comparison of the computational results to available experimental data on the conformational equilibrium of each diastereomer in solution suggests which conformers are present in each of the equilibria. The available data for the solid state indicate that the RR and RS isomers both crystallize in high energy conformations, stabilized by intermolecular interactions.

Key words: 2-phenylsulfinylcyclohexanones, configurational isomers, conformational preferences, DFT calculations, exo-anomeric effect.

Résumé : On a fait appel à des calculs ab initio de densité fonctionnelle pour faire l'analyse conformationnelle de la 2-phénylsulfinylcyclohexanone. On a fait des calculs sur six conformations qui correspondent aux isomères axial/équatorial et de rotation autour de la liaison C2—S pour chacun des diastéréoisomères RR et RS et on a examiné les résultats en fonction des énergies relatives, des interactions électrostatiques, des interactions d'orbitales et des variations de géométrie. La conformation d'énergie globale minimale est celle de l'isomère RS portant le substituant phénylsulfinyle en position équatoriale avec l'oxygène du sulfinyle dans une orientation anti par rapport à l'atome de carbone du carbonyle. Des trois autres conformations de faible énergie, une seule comporte un arrangement gauche de ces atomes et on n'a trouvé des données suggérant l'existence d'une interaction électrostatique S-O(–)···C(+)-O que pour une seule des quatre conformations de basse énergie. Par ailleurs, les résultats sont en accord avec l'opération d'interactions d'orbitales stabilisantes $n_S \rightarrow \pi^*_{C=O}$. On a obtenu une confirmation supplémentaire pour cette hypothèse dans l'augmentation des longueurs de liaison C=O dans ces quatre conformations par rapport aux longueurs dans les autres conformations ainsi que dans la distorsion de l'angle de torsion par rapport à la géométrie idéale, probablement afin de maximiser l'interaction orbitalaire stabilisante. On propose que cette préférence conformationnelle est une manifestation d'un effet généralisé exo-anomère. On interprète aussi la longueur plus grande de la liaison C2—S des isomères axiaux par une interaction stabilisante $\pi_{C=O} \rightarrow \sigma^*_{C-S}$ semblable à celle d'une interaction endo-anomère. Une comparaison des résultats des calculs théoriques avec les résultats expérimentaux disponibles pour l'équilibre conformationnel de chaque diastéroisomère en solution suggère quels sont les conformères qui sont présents dans chacun des équilibres. Fig. 1. Molecular orbital (left) and equivalent valence bond (right) descriptions of stabilizing orbital interactions in 2-substituted cyclohexanones.

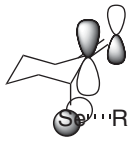
Introduction

We have been intrigued by the conformational effects operating in 2-substituted cyclohexanones (e.g., Scheme 1), particularly when the substituents contain chalcogen atoms (1, 2). It had been suggested that the increased axial preference for the heavier chalcogen substituents was due to the increased nonbonded repulsion with the carbonyl group in the equatorial conformer (3, 4). However, the possibility of the role of $\sigma_{C\text{-}X} \rightarrow \pi^*_{C=O}$ and $n_X \rightarrow \pi^*_{C=O}$ stabilizing orbital interactions as contributors to the conformational preferences was also recognized (Fig. 1) (5, 6).

Recently, in a systematic study of 2-[4-R-substituted-phenyl)seleno]cyclohexanones, we provided evidence for the

Fig. 2. Stabilizing $n_{Se} \rightarrow \pi^*_{C=O}$ orbital interaction associated with the generalized exo-anomeric effect in 2-arylselenocyclohexanones.



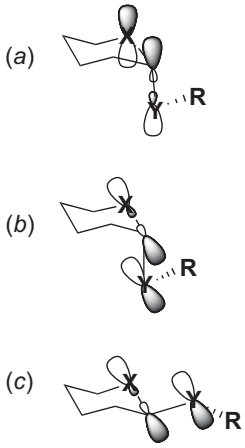


Fig. 3. Stabilizing $n \rightarrow \sigma^*$ orbital interactions associated with the (*a*) endo-anomeric effect and (*b*) and (*c*) exo-anomeric effect in 2-substituted heterocyclohexanes.

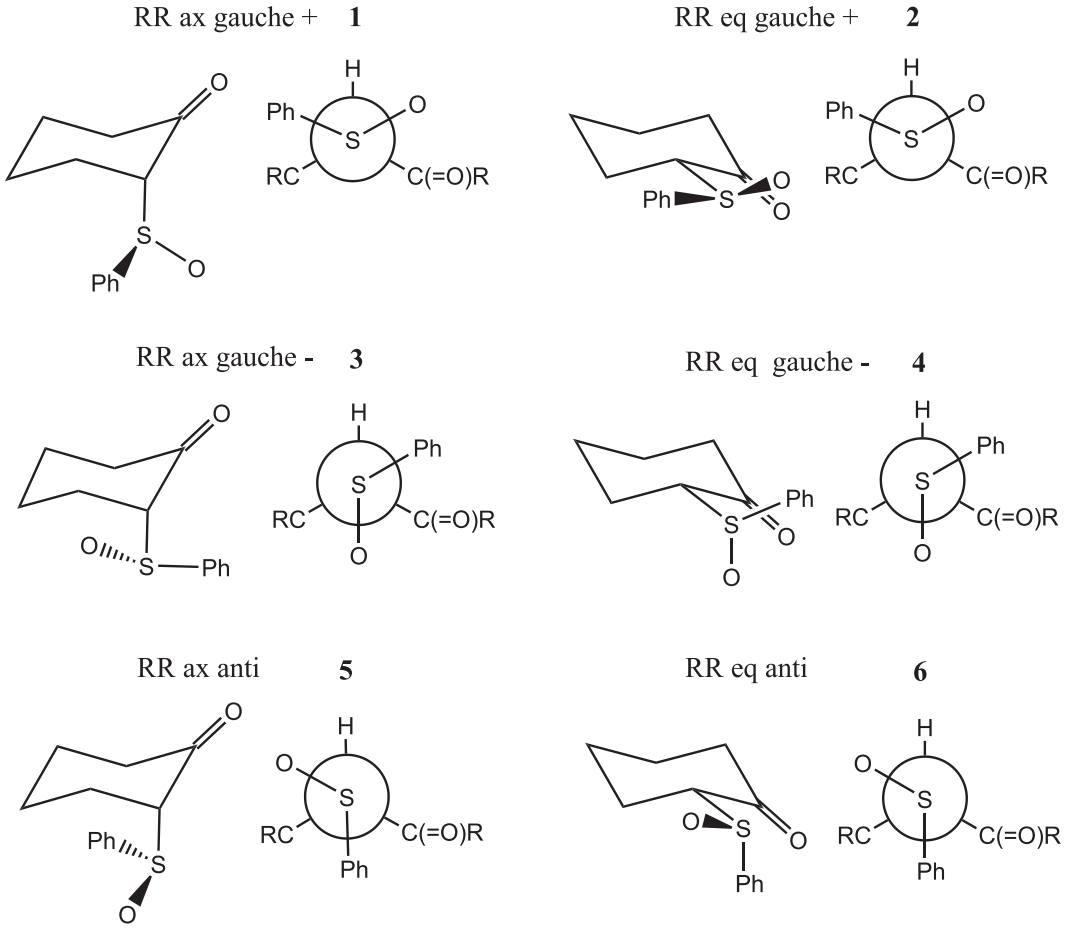
dominance of $n_{Se} \rightarrow \pi^*_{C=O}$ interactions in influencing the conformational equilibrium (2) by stabilizing the axial conformer (Fig. 2).

We further suggested that this interaction was akin to that proposed by R.U. Lemieux to account for the exo-anomeric effect in carbohydrates, which is the preference for the gauche conformation around the C_1-aglyconic carbon bond of glycopyranosides that permits expression of an $n_Y \rightarrow \sigma^*_{C\text{-}X}$ stabilizing orbital interaction (Fig. 3) (7), and that the $n_{Se} \rightarrow \pi^*_{C=O}$ interactions expressed in the 2-arylselenocyclohexanones are a manifestation of a generalized anomeric effect.



An additional possible interaction in these systems is a $\pi_{C=O} \rightarrow \sigma^*_{C\text{-}X}$ orbital interaction (Fig. 1*c*) that is only possible in the axial conformation, and is analogous to the $n_X \rightarrow \sigma^*_{C\text{-}Y}$ orbital interactions (Fig. 3) proposed to account for the endo-anomeric effect in carbohydrate derivatives (8–11).

Seemingly anomalous results obtained in the experimental evaluation of the conformational preferences of 2-phenylsulfinylcyclohexanone (1), (12)[4], (13)[5], prompted us to perform a detailed analysis of the configurational and

Fig. 4. Conformations around the C2—S bond in the RR isomer of 2-phenylsulfinylcyclohexanone. Only the enantiomer ($2R,S_R$) is shown for convenience. Two different chair conformations for each pair are also shown to reflect the axial–equatorial interconversion.

conformational preferences of this compound by molecular orbital DFT calculations. The computations were intended to provide insight into the experimental observations. We note that Faria et al. (14) have recently reported a similar study at a lower level of computation, namely the PM3 semiempirical level. We report herein that the energy preferences and geometrical differences between configurational and conformational isomers can be rationalized in terms of a generalized "exo-anomeric" interaction between the sulfur lone pair and the $\pi^*_{C=O}$ fragment orbital. The conclusions differ somewhat from those of Faria et al. (14), who concluded that electrostatic interactions dominate.

Results and discussion

2-Phenylsulfinylcyclohexanone can exist as two enantiomeric pairs of diastereomers, dictated by the configuration at C2 of the cyclohexanone ring and at the stereogenic sulfur atom. For convenience, in this discussion only one enantiomer in each set will be shown. Thus, the diastereomers will be designated as RR or RS, where the first descriptor refers to the configuration at C2 and the second descriptor to the configuration at sulfur. The conformations of these compounds can be designated in terms of the axial or equatorial orientation of the phenylsulfinyl moiety, and the dihedral angle ϕ about the C—S bond, defined as +gauche, –gauche, or anti with respect to the C(carbonyl)-C2-S-O unit (Scheme 1). The conformations are shown in Figs. 4 and 5, but for simplicity, each conformer has been assigned a number to facilitate discussion. The structures were arranged in pairs as axial and equatorial conformers representing the two chair conformations.

To determine which basis set would be most appropriate for yielding accurate energy values within reasonable times for these twelve conformers, preliminary calculations were performed on conformers (**3**) and (**5**). The results are summarized in Table 1. It was found that the B3LYP/6-31+G* basis set was sufficient to obtain optimized energies for the purposes of this study. A summary of the ab initio energy values and dipole moments for the twelve conformers is given in Table 2. The optimized bond angles and bond lengths are listed in Table 3.

It is instructive to examine the orbital interactions and electrostatic interactions in the lower energy conformations (**3**, **6**, **11**, and **12**) of 2-phenylsulfinylcyclohexanone. Conformation **3**, with a relative energy of 0.21 kcal mol^{-1} (1 cal = 4.184 J), presents the S-O and C-O dipoles in a mutually perpendicular orientation and also aligns the sulfur lone pair for interaction with the $\pi^*_{C=O}$ fragment orbital, as indicated in Fig. 6*a*. This conformation also permits an attractive electrostatic interaction between the O of the sulfinyl moiety and the C of the CO moiety, an S-O (–)···C(+)-O interaction, as suggested by Faria et al. (14). In conformation **12**, the global minimum, the S-O and C-O dipoles are mutually perpendic-

Fig. 5. Conformations about the C—S bond in the RS isomer of 2-phenylsulfinylcyclohexanone. Only the enantiomer (2R,S_S) is shown for convenience. Two different chair conformations for each pair are also shown to reflect the axial–equatorial interconversion.

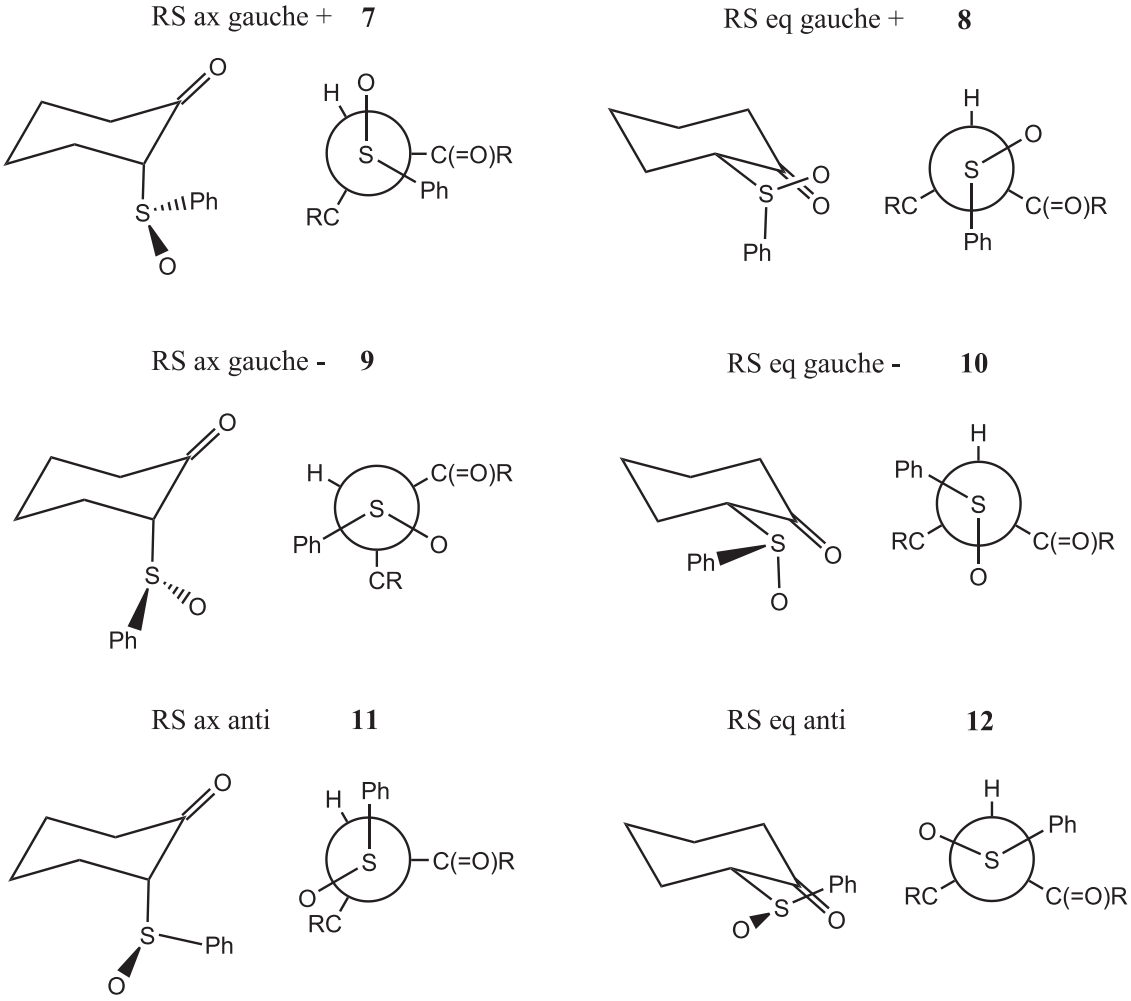

Table 1. Dependence on basis set of energies of the diastereomeric 2-phenylsulfinylcyclohexanones.

	Conformer **3**		Conformer **5**	
B3LYP basis set	Energy (a.u.)	Dipole moment (D)	Energy (a.u.)	Dipole moment (D)
6-31G*	–1014.299 387	1.7705	–1014.296 644	3.9054
6-31+G*	–1014.324 748	2.0108	–1014.321 723	4.0820
6-31+G**	–1014.344 949	1.8968	–1014.342 086	4.0912

ular, and the sulfur lone pair is in the same plane as the $\pi^*_{C=O}$ fragment orbital, and therefore, optimally aligned for interaction (Fig. 6*b*). The electrostatic interaction postulated by Faria et al. (14) is absent in this conformation. Conformation **11** (relative energy 0.57 kcal mol^{-1}) has anti-parallel dipoles and also has the orbitals suitably aligned for an $n_S \rightarrow \pi^*_{C=O}$ exo-anomeric interaction (Fig. 6*c*). Finally, in conformation **6** (relative energy 0.72 kcal mol^{-1}), the S-O and C-O dipoles are orthogonal, and an $n_S \rightarrow \pi^*_{C=O}$ exo-anomeric interaction is again possible (Fig. 6*d*). In the latter two cases, the electrostatic interaction postulated by Faria et al. (14) is again absent. We note that of the low energy conformations (**3**, **6**, **11**, and **12**), only **3** is in a gauche conformation, and the global minimum has the phenylsulfinyl group in an equatorial orientation, contrary to the earlier study (14).

As further evidence for the operation of exo-anomeric interactions, we note that the C—O bond lengths in **3**, **6**, **11**, and **12** are generally longer than in the other conformers, and that the C1-C2-S-O torsion angle (–50° in **3**, 172° in **6**, –157° in **11**, and –172° in **12**) is distorted from ideal geometry in these conformers relative to their counterparts, presumably to optimize the orbital interaction (Table 3). It is also of significance that the C—O bond lengths in **5**, **7**, and **9** are of similar magnitude to those in **3**, **6**, **11**, and **12**; we suggest that this feature results because an $n_S \rightarrow \pi^*_{C=O}$ exo-anomeric interaction is again possible in the former set of conformations. It should also be noted that **12** must be stabilized by some interaction that counteracts the high dipole moment in this conformation (Table 2). The dipole moments increase in the order **11** < **3** < **12** < **6**.

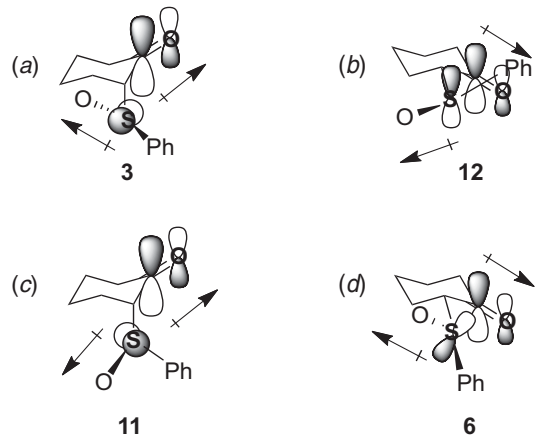
Further examination of the geometrical variations in Table 3 indicates that C2—S bond lengths in the axial isomers are consistently longer than in their equatorial counterparts, suggesting the operation of a $\pi_{C=O} \rightarrow \sigma^*_{C\text{-}S}$ interaction, analogous to an endo-anomeric interaction (11) (Figs. 1*c*, 3*a*). The simultaneous operation of endo- and exo-anomeric interactions and the resulting net stabilization is reminiscent of these effects in axially oriented carbohydrate acetals and hemiacetals (10, 11). Accompanying this geometrical change, the S—C (aryl) bond is shorter and the C6-C1-C2 bond angle is larger in the axial conformers.

As a final point of interest, we compare our computational results with the available experimental data. Analysis of the ^{1}H NMR data in $CDCl_3$ for a diastereomeric mixture of 2-phenylsulfinylcyclohexanone (**A** + **B**) had indicated the presence of two H-2 resonances at 3.31 and 3.55 ppm (12)[4]. Comparison of line widths with those of anancomeric, conformationally biased derivatives indicated that the isomer **A**, whose chemical shift was 3.31 ppm, existed as a 3:2 mixture of axial:equatorial conformers, whereas **B**, whose chemical shift was 3.55 ppm, existed as a 2:1 mixture of equatorial:axial conformers. Thus, energetically, there is no strong conformational bias in the equilibria of **A** and **B**. Fractional crystallization had also afforded separate diastereomers whose X-ray crystal structures were determined (13)[5]. It became clear that isomer **A** was the RS isomer and **B** was the RR isomer. Interestingly, both isomers adopted a conformation in which the phenylsulfinyl substituent was equatorially oriented. In addition, isomer **A** adopted a conformation about the C—S bond that corresponded to **10**, whose relative energy was calculated in the present work to be 1.28 kcal mol^{-1} higher than the global minimum. We suggest from our results that the RS isomer **A** exists predominantly as an equilibrium mixture of ax **11** and eq **12**, and that it crystallizes in the higher energy form **10**. Isomer **B** adopted a conformation about the C—S bond that corresponded to **2**, whose relative energy was calculated in the present work to be 3.33 kcal mol^{-1} higher than the global minimum. We suggest from our results that the RR isomer **B** exists as an equilibrium mixture of ax **3** and eq **6**, and that it too crystallizes in a high energy form.

The experimentally observed solvent effects on the axial–equatorial conformational equilibria for the RS (**A**) and RR (**B**) diastereomers are consistent with our interpretation. Thus, changing the solvent from $CDCl_3$ to CD_3CN results in a greater proportion of the equatorial isomer in the case of both **A** and **B** (12)[4], (13)[5]. One would predict from our data (Table 2) that in the equilibrium of ax **11** (dipole moment 1.139) with eq **12** (dipole moment 4.442), the isomer with the higher dipole moment, i.e., **12**, would be more favoured in the more polar solvent CD_3CN than in $CDCl_3$. Similarly, in the equilibrium of ax **3** (dipole moment 2.011) with eq **6** (dipole moment 4.696), the isomer with the higher dipole moment, i.e., **6**, would be more favoured in the polar solvent. Finally, we note that both **2** and **10** have high dipole moments and thus, the solid-state behaviour is not likely to reflect the behaviour in solution.

The conformational preferences in 2-phenylsulfinylcyclohexanone and its analogues are of interest in their own right but might also have implications in stereoselective aldol reactions such as those with lithium ester enolates (15).

Experimental section



Ab initio calculations were performed with Gaussian 98 (16), using as input structures that were modeled on Insight II and initially optimized using force field calculations using Discover. The molecules were optimized in the gas phase with a full population analysis using the B3LYP version of density functional theory (17) and the Gaussian basis set 6-31G, 6-31+G*, or 6-31+G** (see text). Following optimization, a frequency calculation was performed, which provided the bending and stretching modes of the molecule and ensured that a stable minimum was found. With the exception of **7**, the frequencies found were real, and therefore, every structure is considered as a reliable geometrical minimum. Conformer **7**, which contained one nonreal frequency, represented a transition state in which the phenyl group was nearly eclipsed with the cyclohexanone ring. However, conformer **11** in which the sulfinyl moiety was eclipsed with C2 of the cyclohexanone ring was a stable minimum energy structure. The optimized output yielded the absolute ener-

Component analysis of the X-C-Y anomeric effect (X = O, S; Y = F, OMe, NHMe) by DFT molecular orbital calculations and natural bond orbital analysis[1]

Melissa L. Trapp, Jonathan K. Watts, Noham Weinberg, and B. Mario Pinto

Abstract: Six 2-Y-substituted oxacyclohexane and thiacyclohexane heterocycles (Y = F, OMe, NHMe) were examined using DFT molecular orbital calculations. Natural bond orbital (NBO) analysis of the total energy behaviour yielded the orbital-interaction factors contributing to the conformational equilibria. The dipole moments of the optimized systems were used to estimate the electrostatic contributions to the anomeric effect. The primary determinant of the X-C-Y anomeric effect was found to be the orbital interaction components associated with the combined endo- and exo-anomeric effects acting in concert in the axial conformers. Electrostatic interactions made a contribution to the observed conformer stabilization in all cases, but did not account for the relative magnitudes of the energy differences among conformers of homologous molecules. In the case of the methylamino substituent, accentuated steric interactions in the axial conformer precluded stabilization by the exo-anomeric interaction and consequently, the net endo/exo anomeric stabilization did not dominate the conformational equilibria.

Key words: anomeric effect, component analysis, natural bond orbital analysis, electrostatic, steric, and orbital interaction effects.

Résumé : Six oxacyclohexane et thiacyclohexane hétérocycles (substitués en position 2 par F, OMe, NHMe) ont été examinés par des calculs DFT des orbitales moléculaires. Des analyses des orbitales naturelles des liens (« NBO ») du comportement global de l'énergie a donné les contributions des interactions des orbitales aux équilibres conformationnels. Les moments dipolaires des systèmes optimizés ont été utilizés pour estimer les contributions électrostatiques à l'effet anomère. La cause déterminante primaire de l'effet anomère X-C-Y s'est montré les éléments d'interactions orbitalaires associés aux effets anomères endo et exo, qui agissent ensemble dans les conformères axiaux. Les interactions électrostatiques ont contribué à la stabilization du conformère observé dans tous les cas, mais n'ont pas pu expliquer les magnitudes relatives des différences de l'énergie entre les conformères des molécules homologues. Dans le cas du substituant methylamino, des interactions stériques accentuées dans le conformère axial ont interdit la stabilization par l'interaction anomère exo et par conséquent, la stabilization anomère endo/exo net n'a pas dominé les équilibres conformationnels.

Mots clés : effet anomère, analyse des composants, analyse des orbitales naturelles des liens, effets électrostatiques, effets stériques, effets des interactions orbitalaires.

Introduction

The anomeric effect (1, 2) has challenged the imagination and provoked the actions of both experimental and theoretical chemists alike (3). This effect, in its generalized form, refers to the gauche preferences of substituents about X—A and A—Y bonds in RX-A-YR′ or RX-A-Y structures (3, 4). With respect to substituted five- and six-membered heterocyclic rings, this effect is generally manifested as a preference of a 2-substituent for the axial orientation over and above that predicted on the basis of steric grounds. Several explanations have been advanced to account for the origin of this effect, including the favourable orientation of dipoles in the gauche conformations (1), stabilizing electrostatic inter-

actions (2), and stabilizing molecular orbital interactions (5–7). The explanation for the axial preference in terms of electrostatic interactions derives from the observation that the favoured axial conformer has a lower dipole moment than the equatorial conformer, arising from fragment molecular dipoles whose directional Cartesian coordinates undergo vector subtraction. The orbital interaction component in carbohydrate derivatives has been further classified in terms of an endo-anomeric effect (8), or preference for an axial substituent that derives from an $n_X \rightarrow \sigma^*_{C\text{-}Y}$ stabilizing orbital interaction (Fig. 1), and an exo-anomeric effect (9), or preference for the gauche conformation around the C_1 – aglyconic carbon bond of glycopyranosides that permits expression of an $n_Y \rightarrow \sigma^*_{C\text{-}X}$ stabilizing orbital interaction (Fig. 1). What is still uncertain, however, is why the operation of both the endo- and exo-anomeric interactions, acting in concert in the axial conformers, and claimed to be in competition (8), should be net stabilizing.

Justification for the role of orbital interactions in influencing the conformational preferences in systems containing RX-A-YR′ fragments has been provided by the geometrical variations among the different conformations of these units (3, 10). The endo-anomeric interaction is predicted to lead to a lengthening of the C—Y bond and a shortening of the C—X bond (3, 10). Conversely, the exo-anomeric interaction would lead to the opposite trend in bond lengths, namely a shortening of the C—Y bond and a lengthening of the C—X bond. In the axial conformers, if both endo- and exo-anomeric interactions are active, a bond of intermediate length is observed; in the equatorial conformers, in which only the exo-anomeric effect can operate, the bond length changes described above ensue.

However, it is clear that electrostatic and steric effects do play a role, although their individual assessment is often problematic. We have previously attempted an evaluation of the individual components by estimation of the steric and electrostatic effects through molecular mechanics calculations, and by attribution of the orbital interaction component to the difference between the experimental conformational free energy and the calculated combined steric/electrostatic effects (11). This approximation, although informative at the time, is far from satisfactory. We now report the use of DFT molecular orbital calculations to determine the conformational preferences in three analogous pairs of 2-substituted heterocycles: 2-fluorooxacyclohexane (**1**) and 2-fluorothiacyclohexane (**2**), 2-methoxyoxacyclohexane (**3**) and 2-methoxythiacyclohexane (**4**), and 2-methylaminooxacyclohexane (**5**) and 2-methylaminothiacyclohexane (**6**) (Fig. 2). The magnitudes of the energy differences of axial and equatorial isomers in oxygen-containing and sulfur-containing rings were compared, and a quantitative analysis of the orbital interaction term was facilitated by means of a natural

bond orbital (NBO) analysis of the total energy behaviour. The dipole moments of the optimized systems were used to estimate the electrostatic contributions to the anomeric effect. The results indicate that the orbital interaction component dominates the conformational equilibria, and can therefore be taken as the origin of the anomeric effect.

Computational

DFT calculations were carried out with Gaussian 98 (12), using as input unoptimized Cartesian coordinates from the WebLab program (Accelrys Inc.). The molecules were optimized in the gas phase in the $^4C_1$ chair conformation with a full population analysis using the B3LYP hybrid DFT method (13) at the 6-31++G** level. Following optimization, a frequency calculation was performed, which calculated the bending and stretching modes of the molecule and ensured that a stable minimum was found. In every calculation, the frequencies found were of the real number system, and therefore, every structure is considered as a reliable geometrical minimum.

A NBO analysis was performed on the optimized geometry, using NBO version 3.1 (14) in Gaussian 98. NBOs arise from an occupancy-weighted symmetric orthogonalization (OWSO) procedure in which delocalized molecular orbitals are mathematically transformed into a minimal basis set to represent localized electron pairs (15). The categorized NBOs correspond to the natural Lewis structure of core orbitals, bonding orbitals, and lone-pair orbitals, as well as the antibonding and Rydberg orbitals that do not correspond to Lewis representations (15). Rydberg orbitals are weakly occupied, extra valence shell functions that arise from the extended basis set used for the calculation (16).

A second-order perturbation theory analysis was performed on the NBOs to estimate the stabilization energy of donor–acceptor orbital interactions. In this way, the perturbative origin of the anomeric effect was analyzed and a quantitative measure of the energy associated with orbital interactions was estimated. The perturbative surface is approximated by a quadratic function and therefore contains some uncertainty, but the technique is nonetheless useful for understanding the relative magnitudes of orbital interactions.

Destabilizing interactions were calculated as the orthogonalization energy of the NBOs. The Pauli exclusion principle requires that spatially overlapping orbitals be mutually

orthogonal. The resulting compression and formation of orthogonalization tails is often considered to be the source of destabilizing "steric" interactions (17). In the context of NBO analysis, this destabilization can be calculated as the difference in energy between preorthogonal NBOs and their orthogonal counterparts (18, 19). To quantitate the energy of steric interactions in a pairwise fashion, all orbitals were first orthogonalized and the orbitals of interest were subsequently partially reconverted to their preorthogonal forms with respect to each other; this allowed the calculation to take place in the context of the nodal and electronic structure corresponding as closely as possible to the real system, making this approximation reasonably accurate in the weak overlap limit (18). A further improvement was obtained by using natural localized molecular orbitals (NLMOs) and their preorthogonal counterparts instead of NBOs because of the associated incorporation of the delocalization tails of the NLMOs (20). The calculations were carried out using the Steric feature of the GENNBO 5.0 program (21). We focused our attention on the large $n \rightarrow \sigma$ interactions that parallel the endo- and exo-anomeric orbital interactions.

Molecular orbital diagrams were prepared with the NBOView program (22), using plot files prepared with GENNBO 5.0 (21). The overlap matrix element in the preorthogonal NBO (PNBO) basis is proportional to the NBO orbital overlap (23), and is, therefore, ideally suited to visualize orbital overlap in interactions such as the anomeric effect. PNBOs also have the most intuitive orbital shapes; thus, all diagrams were constructed using the PNBO basis. The apparent orbital size was reduced from the default setting by increasing the first contour value to 0.06 and the contour step size to 0.10 (approximately doubled from their default values). This process allowed the most meaningful visualization of the structure of the PNBO orbitals.

To investigate the contribution of dipole–dipole interactions to the anomeric effect, we sought to represent the cyclic molecules by a series of fragments with their individual dipole moments and polarizabilities. For example, 2-fluorothiacyclohexane was represented by three fragments: propane, 2-fluoropropane, and dimethylsulfide. However, after optimization of the acyclic fragments, it was determined that the methyl groups in the fragments did not accurately represent the electrostatic environment in the cyclic molecule. Therefore, the dipole moment of the propane, 2-fluoropropane, and dimethylsulfide fragments could not be used to mimic the fragment dipoles of the cyclic system. Thus, the dipole moments of the optimized cyclic systems themselves were used to estimate the electrostatic contributions to the anomeric effect.

Results

Table 1 summarizes the optimized parameters found for the 2-substituted oxacyclohexanes and thiacyclohexanes. Table 2 compares the energies, dipole moments, bond lengths, and valence bond angles for the axial and equatorial conformers. NBO perturbation theory analysis was used to identify specific orbital interactions corresponding to the endo- and exo-anomeric effects (Table 3). The values of the interactions were determined independently of each other, so the numbers associated with each particular interaction cannot be compared directly to the overall energies, nor to the energy differences between axial and equatorial conformers. Orbital interactions are favoured by a low energy difference between the donor (d) and acceptor (a) orbitals and (or) a high off-diagonal NBO Fock matrix element, F(d,a), which is proportional to orbital overlap, as shown in eq. [1] (24). These two elements were examined as part of the perturbation theory analysis, and the resulting energy differences and Fock matrix elements are given in Table 3.

$$[1] \qquad E = \frac{F(\mathrm{d},\mathrm{a})^2}{e_\mathrm{a} - e_\mathrm{d}}$$

The salient features of each system are discussed in the following section.

Dipolar interactions

In every case in which a particular conformer was energetically preferred, that structure also had a lower dipole moment. However, in comparison of the 2-fluoro- and 2-methoxy-oxacyclohexanes with the corresponding thiacyclohexanes, the analogue that showed the greatest differ-

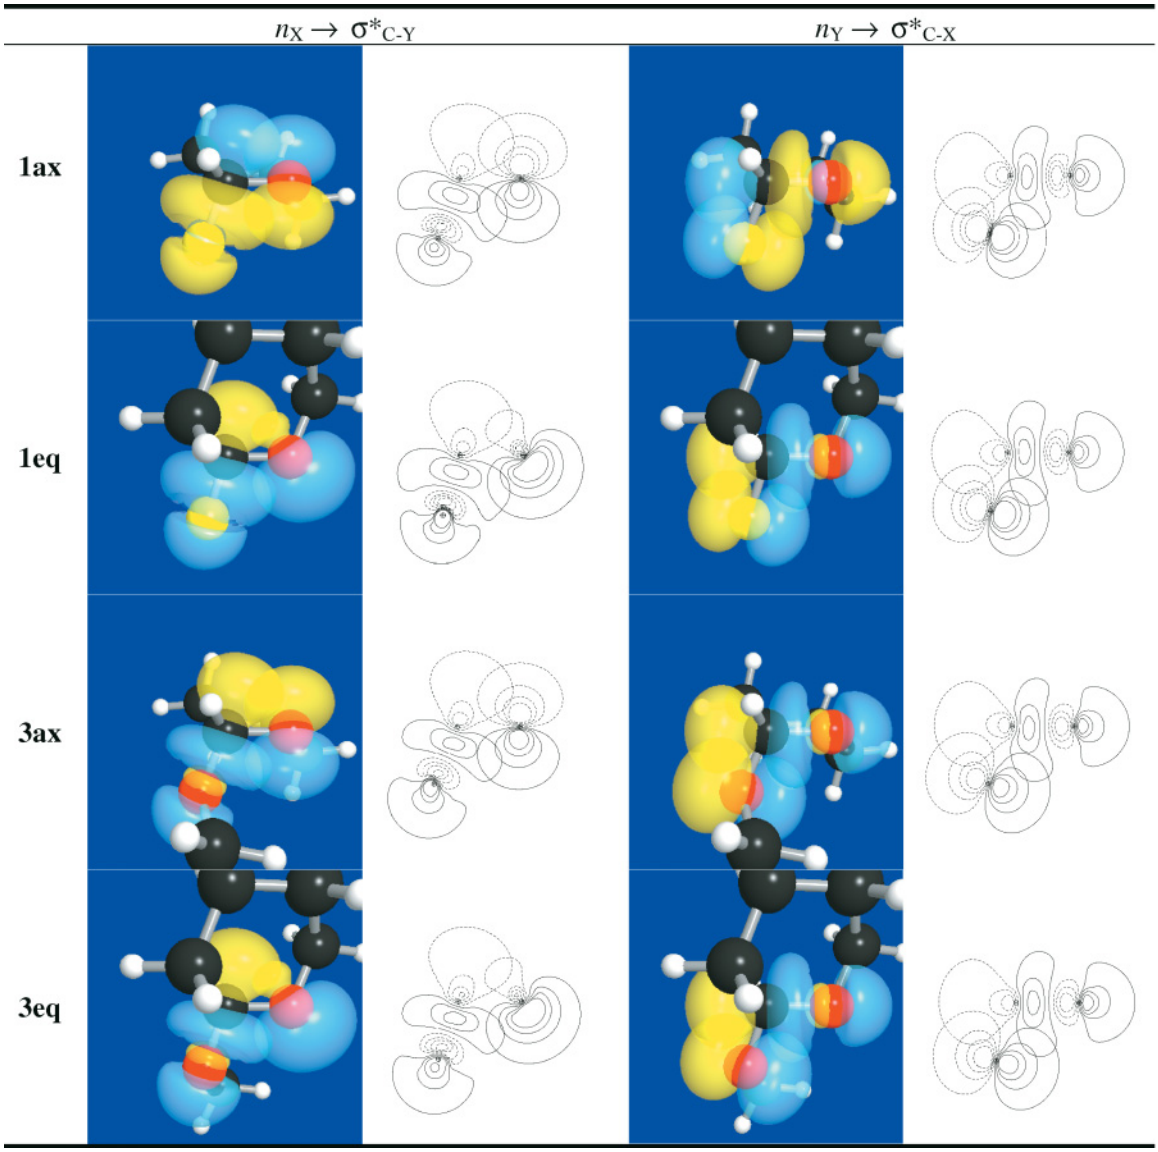
[d]Not observed; interactions below 0.5 kcal mol^{-1} are not listed.

ence in energy between axial and equatorial conformers also had the smallest change in dipole moment. Thus, 2-methoxythiacyclohexane (**4**) had a greater Δ*E* value among conformers than 2-methoxy-oxacyclohexane (**3**), but the latter (**3**) had a greater Δμ value among conformers. A similar relationship was observed for the 2-fluoro derivatives **1** and **2**, although in this case, it was the oxygen congener **1** that had a smaller Δ*E* value and a higher Δμ value. Since a larger difference in dipole moment among axial/equatorial pairs was not manifested in a greater energy difference among conformers, it follows that dipole–dipole interactions are not the primary determinants of the net stabilization.

Orbital interactions



2-Fluorooxacyclohexane (1) and 2-fluorothiacyclohexane (2)

In 2-fluorooxacyclohexane (**1**), the axial conformer is preferred over the equatorial by 2.89 kcal mol^{-1} (1 cal = 4.184 J). NBO analysis (Table 3) indicated that in the axial conformer, the orbital interactions with the highest stabilization energy were the endo-anomeric ($n_O \rightarrow \sigma^*_{C\text{-}F}$) interaction of 20.9 kcal mol^{-1} and the exo-anomeric ($n_F \rightarrow \sigma^*_{C\text{-}O}$) interaction of 10.5 kcal mol^{-1}. In the equatorial conformer, the greatest orbital interaction is the exo-anomeric ($n_F \rightarrow \sigma^*_{C\text{-}O}$) interaction of 11.6 kcal mol^{-1}. In addition, there is an endo-anomeric orbital interaction of 5.1 kcal mol^{-1} that derives from interaction of the subjacent sp lone-pair fragment orbital on oxygen with the $\sigma^*_{C\text{-}F}$ fragment orbital. These interactions are shown in Fig. 3. It is clear that the large difference in the endo-anomeric interactions leads to the strong preference for the axial conformer. The consequences of these orbital interactions are reflected in the bond lengths and valence bond angles shown in Table 2: the C—O bond was shorter, the C—F bond was longer, and the O-C-F angle was greater in the axial conformer than in the equatorial conformer (10). The magnitudes of the axial vs. equatorial stabilizing interactions shown in Table 3 do not correspond directly to the energy difference between the conformers (Table 1) because of the steric effects that destabilize the axial isomer.

In 2-fluorothiacyclohexane (**2**), the axial conformer was preferred over the equatorial by 2.56 kcal mol^{-1}). From the NBO perturbation theory analysis, in the axial conformer, the two greatest orbital interactions were the $n_S \rightarrow \sigma^*_{C\text{-}F}$ endo-anomeric effect of 13.0 kcal mol^{-1} and the $n_F \rightarrow \sigma^*_{C\text{-}S}$ exo-anomeric effect of 8.5 kcal mol^{-1}. These interactions result in a shortened C—S bond length of 1.818 Å and lengthened C—F bond of 1.416 Å in the axial structure. In the equatorial conformer, the greatest interaction was the $n_F \rightarrow \sigma^*_{C\text{-}S}$ exo-anomeric effect of 8.1 kcal mol^{-1}, of similar magnitude to the exo-anomeric orbital interaction in the axial conformer. It can be concluded that the appreciable endo-

Fig. 3. Fragment molecular orbital interactions in the axial and equatorial conformers of **1** and **3**, illustrating the endo- and exo-anomeric orbital interactions. In the equatorial conformers, the $n_X \rightarrow \sigma^*_{C\text{-}Y}$ interaction is from the subjacent sp-type orbital on the ring oxygen atom. The preorthogonalized NBOs were generated with the NBOView program (21). Figures showing the orbital interactions of compounds **2**, **4**, **5**, and **6** are given in the Supplementary data.[3]

anomeric orbital interaction in the axial conformer controls its energetic preference. The interactions are shown in the Supplementary information.[3] In this case, the endo-anomeric orbital interaction that derives from interaction of the subjacent sp lone-pair fragment orbital on sulfur with the $\sigma^*_{C\text{-}F}$ fragment orbital is small (0.68 kcal mol^{-1}), in contrast to the oxygen congener.

Further comparison of the results for 2-fluorooxacyclohexane (**1**) and 2-fluorothiacyclohexane (**2**) indicated that the energy difference between axial and equatorial conformers was only slightly greater for the oxygen congener (**1**). This result is due to the much lesser steric effect in the axial isomer of the thiacyclohexane derivative, but still correlates with the sum of the exo and endo interactions for the two conformers, which gave a smaller energy difference for the 2-fluorothiacyclohexane (**2**). It is noteworthy that the difference in the combined destabilizing $n_X \rightarrow \sigma_{C\text{-}F}$ and $n_F \rightarrow \sigma_{C\text{-}X}$ interactions between axial and equatorial conformers is of much lesser magnitude than the stabilizing endo and exo interactions in the axial conformers (Table 3).

2-Methoxyoxacyclohexane (3) and 2-methoxythiacyclohexane (4)

In 2-methoxyoxacyclohexane (**3**), the axial conformer was

© 2006 NRC Canada

preferred by 0.78 kcal mol^{-1}. NBO perturbation analysis indicated that the orbital interactions with the largest stabilization energies in the axial conformer were the exo-anomeric orbital interaction of 13.9 kcal mol^{-1} and the endo-anomeric orbital interaction of 13.6 kcal mol^{-1}. These values were similar due to the approximate equivalence of the $n_O \rightarrow \sigma^*_{C\text{-}O}$ interactions. In the equatorial conformer, the largest stabilizing orbital interaction was the exo-anomeric orbital interaction of 14.5 kcal mol^{-1}. The interactions are shown in Fig. 3. In addition, an endo-anomeric orbital interaction of the subjacent sp lone-pair fragment orbital on the ring oxygen atom with the $\sigma^*_{C\text{-}O}$ orbital of energy 3.8 kcal mol^{-1} was present. Thus, the presence of the endo-anomeric orbital interaction dictates the axial preference.

In 2-methoxythiacyclohexane (**4**), the axial conformer was favoured by 1.99 kcal mol^{-1}. In the axial conformation, NBO perturbation theory analysis indicated that the greatest stabilizing orbital interactions were the exo-anomeric ($n_O \rightarrow \sigma^*_{C\text{-}S}$) interaction of 13.2 kcal mol^{-1} and the endo-anomeric ($n_S \rightarrow \sigma^*_{C\text{-}O}$) interaction of 8.4 kcal mol^{-1}. It is noteworthy that the exo-anomeric orbital interaction was greater than the endo-anomeric orbital interaction in the axial conformer, although the C—O (1.412 Å) and C—S (1.860 Å) bond lengths relative to the equatorial conformer reflect the balance of the endo- and exo-anomeric effects. The interactions are shown in the Supplementary information.[3]

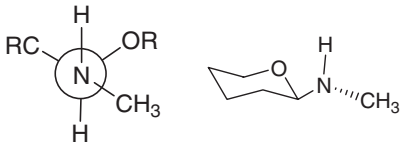
It is of direct relevance to the present work that Wolfe and Shi (25), in an examination of methyl thiomethyl ether by electron momentum spectroscopy and photoelectron spectroscopy, have shown that although the p-type lone pair on sulfur is the HOMO of the molecule, the dominant orbital interactions are of the $n_O \rightarrow \sigma^*_{C\text{-}S}$ type, with some contribution from the destabilizing $n_O \rightarrow \sigma_{C\text{-}S}$ interaction. Thus, the lone pair on oxygen dominates the anomeric interactions in an RS-CH_2-OR′ fragment.

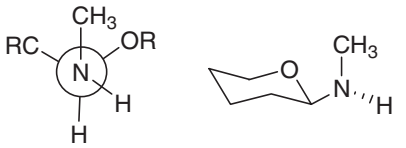
NBO perturbation theory analysis of the equatorial conformer of 2-methoxythiacyclohexane (**4**) indicated that the greatest stabilizing orbital interaction was the exo-anomeric ($n_O \rightarrow \sigma^*_{C\text{-}S}$) interaction of 12.8 kcal mol^{-1}. This result was consistent with the optimized parameters in which the C—S bond was lengthened (1.875 Å) and the C—O bond was shortened (1.402 Å) when compared with the axial conformer. In this case, the endo-anomeric orbital interaction of the subjacent sp lone-pair fragment orbital on the ring sulfur atom with the $\sigma^*_{C\text{-}O}$ orbital was negligible.

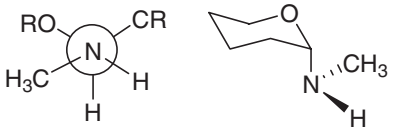
Comparison of the results of 2-methoxyoxacyclohexane (**3**) and 2-methoxythiacyclohexane (**4**) indicated that the energy difference between axial and equatorial conformers was greater in the sulfur congener. This trend is in contrast to compounds **1** and **2** where the energy difference was greater for the oxygen congener. The discrepancy may be attributed to the dominant role of the combined endo and exo interactions in stabilizing the axial conformer. This result verifies the conclusions from our previous work (11) that showed the preferential stabilization of the axial conformers in 2-alkoxythiacyclohexanes relative to their oxygen counterparts. If dipole–dipole interactions had dominated, one would have predicted the opposite trend. As was the case for **1** and **2**, the difference in the combined destabilizing $n_X \rightarrow \sigma_{C\text{-}O}$ and $n_O \rightarrow \sigma_{C\text{-}X}$ interactions between axial and equatorial conformers is of much lesser magnitude than the stabilizing endo and exo interactions in the axial conformers (Table 3).

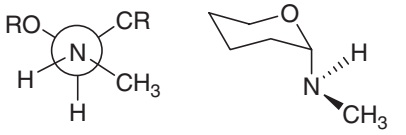
2-Methylaminooxacyclohexane (5) and 2-methylaminothiacyclohexane (6)

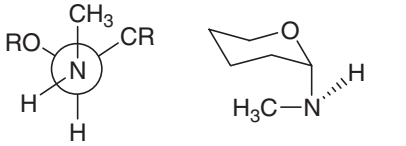
Both 2-methylaminooxacyclohexane **(5)** and 2-methylaminothiacyclohexane **(6)** preferred the equatorial conformers despite the fact that the C—X and C—Y bond length differences (Table 2) and perturbation analysis (Table 3) showed evidence of increased endo-anomeric orbital interactions in the axial conformers. We turn, therefore, to a detailed discussion of the rotamers shown in Tables 4 and 5.











In 2-methylaminooxacyclohexane (**5**) (Table 4), the most stable equatorial conformer was favoured over the most stable axial conformer by 2.98 kcal mol^{-1}. In fact, two equatorial conformers of 2-methylaminooxacyclohexane (**5**) were more stable than the axial conformers. As argued previously (11, 26), the axial conformers cannot enjoy the stabilization by the exo-anomeric effect because the required rotamer would necessarily place one of the substituents on nitrogen under the six-membered ring, resulting in a dramatic steric destabilization. The contention is supported by the observation that of the axial structures, those with the nitrogen lone pair projected under the ring were more stable, in spite of their less favourable orbital interactions. The steric penalty of placing a methyl group under the ring (structure **E**) overwhelms the $n_N \rightarrow \sigma^*_{C\text{-}O}$ orbital interaction. In contrast, the equatorial conformer features a large exo-anomeric orbital interaction (>16 kcal mol^{-1}), and the stabilizing endo-anomeric orbital interaction of 9 to 10 kcal mol^{-1}, available in the axial conformer, is not sufficient to outweigh the former interaction (see Supplementary information).[3] Thus, as predicted previously (7*c*, 25), the $n_N \rightarrow \sigma^*_{C\text{-}O}$ orbital interaction outweighs the $n_O \rightarrow \sigma^*_{C\text{-}N}$ orbital interaction. Both of the low-energy equatorial structures (**A** and **B**), shown in Table 3, were stabilized by exo-anomeric interactions. Steric effects determine which of the two is more stable, as structure **A** features only one gauche interaction and structure **B** has two (see Newman projections, Fig. 3). In this case, the endo-anomeric orbital interaction of the subjacent sp lone-pair fragment orbital on the ring sulfur atom with the $\sigma^*_{C\text{-}N}$ orbital was 2.2 kcal mol^{-1}.

It is of interest to also comment on the dominant destabilizing interactions in the rotamers of **5** (Table 4). In rotamers **5A**, **5B**, and **5E**, the nitrogen lone-pair orbital is properly aligned to interact with the $\sigma_{C\text{-}O}$ orbital. This $n_N \rightarrow \sigma_{C\text{-}O}$ interaction is worth 13.41, 13.29, and 10.56 kcal mol^{-1} in **5A**, **5B**, and **5E**, respectively. In rotamers **5C** and **5D**, the dominant destabilizing interaction is the $n_O \rightarrow \sigma_{C\text{-}N}$ interaction, worth 8.92 and 10.17 kcal mol^{-1}, respectively. These interactions are significant, but it is the stabilizing exo interaction in the equatorial conformer **5A** that dictates its stabilization relative to the most stable axial conformer, **5C**.

In 2-methylaminothiacyclohexane **6** (Table 5), the most stable equatorial conformer was energetically preferred by 1.83 kcal mol^{-1} over the axial conformer. Once again, structure **A** was favoured over structure **B** because of the fewer number of gauche interactions. Of the four axial structures, those with the nitrogen lone pair beneath the ring (structures **C** and **D**) were more stable than those with a substituent beneath the ring (structures **E** and **F**). In this case, the endo-

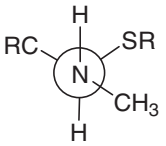
Rotamer of **5**		Relative E (kcal mol^{-1})	$n_O \rightarrow \sigma^*_{C\text{-}N}$ (kcal mol^{-1})	$n_N \rightarrow \sigma^*_{C\text{-}O}$ (kcal mol^{-1})	$n_O/\sigma_{C\text{-}N}$ (kcal mol^{-1})	$n_N/\sigma_{C\text{-}O}$ (kcal mol^{-1})
A		0.00	2.2	16.2	2.87[a]	13.41
B		1.73	2.2	16.1	2.92[a]	13.29
C		2.98	9.1	5.4	8.92[b]	1.90
D		4.11	9.1	1.3	10.17[b]	*n/o*[c]
E		7.29	10.6	17.8	8.42	10.56

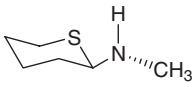
[a]Interaction was with the sp-type (n_{sp}) orbital.
[b]A small destabilizing interaction with n_{sp} (not shown) was also observed.
[c]Not observed; interactions below 0.5 kcal mol^{-1} are not listed.

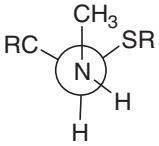
anomeric orbital interaction of the subjacent sp lone-pair fragment orbital on the ring sulfur atom with the $\sigma^*_{C\text{-}N}$ orbital was negligible.

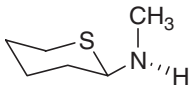
The axial structures all displayed an endo-anomeric orbital interaction, while differing in the extent of an exo-anomeric orbital interaction. Once again, as predicted (7*c*, 25), the $n_N \rightarrow \sigma^*_{C\text{-}S}$ orbital interaction outweighs the $n_S \rightarrow \sigma^*_{C\text{-}N}$ orbital interaction. Structure **C**, a stereoisomer of **D**, was found to be the most stable axial structure overall. The appropriate orientation of the methyl group allowed an exo-anomeric orbital interaction of 3.26 kcal mol^{-1} in addition to an endo-anomeric orbital interaction of 5.72 kcal mol^{-1}. Increasing the exo-anomeric interaction would necessitate placing one of the nitrogen substituents under the ring. The most stable rotamers **(C** and **D)** thus lacked the exo-anomeric orbital interaction, but also the accentuated steric interaction (see Supplementary information)[3] (11, 26).

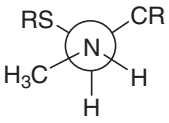
A comparison of rotamers **E** and **F** illustrates the influence of orbital interactions in overcoming a significant steric penalty. Thus, rotamer **E** is destabilized by the placement of a methyl group directly under the ring, but features a highly stabilizing exo-anomeric interaction of nearly 17 kcal mol^{-1}. In contrast, structure **F** does not have an exo-anomeric interaction and only places the smaller substituent (H) under the ring; yet rotamer **E** is favoured over **F** by 0.75 kcal mol^{-1}.

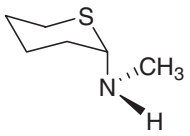


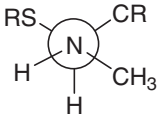


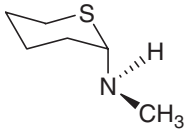


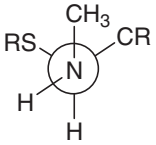


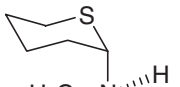


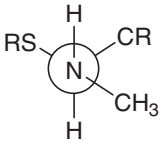


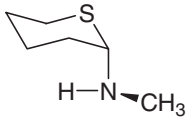












Once again, we also comment on the dominant destabilizing interactions in the rotamers of **6** (Table 4). In each of rotamers **6A, 6B**, and **6E**, the nitrogen lone-pair orbital is properly aligned to interact with the $\sigma_{C\text{-}S}$ orbital. This $n_N \rightarrow \sigma_{C\text{-}S}$ interaction is worth 13.75, 13.68, and 12.29 kcal mol^{-1} in **6A**, **6B**, and **6E**, respectively. In rotamer **6C**, the $n_S \rightarrow \sigma_{C\text{-}N}$ and $n_N \rightarrow \sigma_{C\text{-}S}$ destabilizing interactions of 5.29 and 2.77 kcal mol^{-1}, respectively, were observed. These interactions are significant, but are smaller than the stabilizing exo interaction in the equatorial conformer **6A** that dictates its stabilization relative to the most stable axial conformer, **6C**.

Discussion

Comparison of the endo-anomeric orbital interactions in

[a]Not observed; interactions below 0.5 kcal mol^{-1} are not listed.
[b]Interaction was via the sp-type (n_{sp}) orbital.

the oxygen vs. the sulfur series (Table 3) indicates that they are greater in the former series than in the latter, as previously suggested for first-row vs. second-row anomeric interactions (27). In the thiacyclohexane compounds, the energy difference between orbitals (ΔE) was less than that of the corresponding oxacyclohexane compounds for the endo interactions. However, the F(d,a) term was consistently greater in the substituted oxacyclohexanes, indicating that the orbital overlap is greater in the oxygen series because of the shorter C—O vs. C—S bond, and dominates the orbital interaction, as suggested by Wolfe and Shi (25). Thus, irrespective of the exocyclic substituent and the exo-anomeric contribution, the endo-anomeric effect is greater for O vs. S. Interestingly, for the exo-anomeric interaction, one also observes a greater interaction in the oxygen series, irrespective of the exocyclic substituent, because of a lesser energy difference between interacting orbitals and greater overlap between the interacting orbitals. Presumably, the greater overall overlap is due to the greater electronegativity of oxygen, which leads, in turn, to the increased size of the σ* orbital lobe on C and thus, to better overlap with the exocyclic donor orbital. A noticeable $n_X \rightarrow \sigma^*_{C\text{-}Y}$ interaction (endo-anomeric interaction) from the subjacent sp lone pair orbital on the ring heteroatom was observed in the *equatorial* conformers of the substituted oxacyclohexanes, but this was small (Y = F) or negligible (Y = OCH_3, $NHCH_3$) for the thiacyclohexanes. Again, this difference is related to the larger Fock matrix element (better orbital overlap) in the oxygen series, and not the relative energy levels.

It would appear that although dipolar interactions play

© 2006 NRC Canada

some role in the stabilization of the axial conformers in this series of compounds, they are not the dominant force in controlling the conformational preferences. It is the combined endo- and exo-anomeric orbital interactions that dominate.

It is important to note that the exo- and endo-anomeric orbital interactions do not compete energetically, as the sets of orbitals involved are orthogonal to each other. A valence bond interpretation might suggest otherwise (8). By way of example, in 2-fluorothiacyclohexane (**2**), the axial conformer has an endo-anomeric interaction of 13.0 kcal mol^{-1} and an exo-anomeric interaction of 8.5 kcal mol^{-1}. If these were in competition, a net endo-anomeric interaction of 4.5 kcal mol^{-1} would result and would be disfavoured relative to the net exo-anomeric interaction of 8.1 kcal mol^{-1} available in the equatorial conformer. That the axial conformer is preferred suggests that the endo- and exo-anomeric orbital interactions do not compete energetically.

Finally, we reiterate (11, 26) that in 2-methylaminoheterocyclohexanes, the stabilization provided by the exo-anomeric interaction in the axial conformers does not ensue because it would force an accentuated steric interaction. Consequently, the equatorial conformer, which does exhibit an exo-anomeric effect, is favoured since, as predicted previously (7*c*, 25), the $n_N \rightarrow \sigma^*_{C\text{-}X}$ exo-orbital interaction outweighs the $n_X \rightarrow \sigma^*_{C\text{-}N}$ endo-orbital interaction.

Complexation of diazinon, an organophosphorus pesticide, with α-, β-, and γ-cyclodextrin — NMR and computational studies[1,2]

Doreen Churchill, Jason Chiu Fung Cheung, Yong Sung Park, Vedene H. Smith, Gary vanLoon, and Erwin Buncel

Abstract: Complexation of the organophosphorus pesticide, diazinon, with α-, β- and γ- cyclodextrin has been investigated through NMR and computational methodologies. Binding constants (K_b) determined by ^{1}H and ^{31}P NMR follow the order γ-CD > α-CD = β-CD, in contrast with reported K_b data for other pesticides and thus indicative of steric encumbrance by the isopropyl group in diazinon being an important factor influencing binding constants. The interaction of diazinon with the CDs has also been investigated through computational studies via molecular dynamics – molecular mechanics (MD–MM2) and density functional theory (DFT), B3LYP/6-31G*. It is shown that the most favorable orientation in binding corresponds to the hydrophobic heterocyclic residue of diazinon being pulled deepest into the CD cavity, in agreement with the experimentally determined order of binding constants. Moreover, the computations show that it is only with γ-CD that the heterocyclic residue of diazinon and the phosphoryl residue are both largely encrypted in the CD cavity, marking a clear differentiation with α-CD and β-CD where the phosphoryl residue is located largely outside the cavity. Thus, the computational results are in essential agreement with the experimental binding constants where γ-CD stands out with the highest K_b value. Our work could point to the potential usefulness of computational studies to be undertaken in tandem with experimental work in environmental situations such as soil remediation.

Key words: organophosphorus pesticides, diazinon complexation, cyclodextrins, computational studies, molecular mechanics.

Résumé : Faisant appel à la RMN et à des calculs théoriques, on a étudié la complexation du diazinon, un pesticide organophosphoré, avec les α-, β- et γ-cyclodextrines. Faisant appel à la RMN du ^{1}H et du ^{31}P, on a déterminé que les constantes de fixation (K_b) sont dans l'ordre γ-CD > α-CD = β-CD, ce qui contraste avec les valeurs de K_b rapportées pour d'autres pesticides; ces différences pourraient suggérer que l'encombrement stérique provoqué par le groupe isopropyle du diazinon est un facteur qui présente une influence importante dans les constantes de fixation. L'interaction du diazinon avec les cyclodextrines a été examinée d'une façon théorique en faisant appel à la théorie de la dynamique moléculaire – mécanique moléculaire (DM–MM2) et à la théorie de la densité fonctionnelle (TDF), B3LYP/6-31G*. On a montré que l'orientation la plus favorable lors de la fixation correspond à celle où le résidu hétérocyclique hydrophobe du diazinon est inséré au point le plus profond de la cavité de la cyclodextrine, ce qui correspond à l'ordre déterminé d'une façon expérimentale par les constantes de fixation. De plus, les calculs montrent le résidu hétérocyclique du diazinon et le résidu phosphoryle ne sont bien insérés que dans la cavité de la γ-CD, ce qui la différencie clairement de l'α-CD et de la β-CD avec lesquelles le résidu phosphoryle se trouve largement à l'extérieur de la cavité. Les résultats théoriques sont donc, pour l'essentiel, en accord avec les constantes de fixations expérimentales alors que la valeur pour la γ-CD est la plus élevée. Ce travail pourrait démontrer l'utilité potentielle d'études théoriques pour étudier, en tandem, avec des expérimentales, des situations environnementales, telles que la récupération des sols.

Mots clés : pesticides organophosphorés, complexation du diazinon, cyclodextrines, études théoriques, mécanique moléculaire.

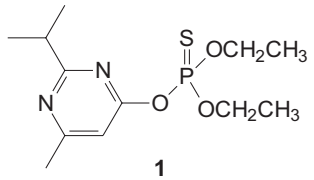
Fig. 1. Chemical structure of α-CD, β-CD, and γ-CD consisting of six, seven, and eight glucose units, respectively.



α-cyclodextrin β-cyclodextrin γ-cyclodextrin

Introduction

The wide usage of pesticides in modern agriculture, coupled with the known toxicity of pesticide residues to humans and other nontarget organisms, calls for fresh research into methods for the facile degradation of such residues under environmentally benign conditions and without generating further toxic materials (metabolites) in the process. Our own approach toward that goal is through the tools of structure–reactivity relationships in physical organic chemistry and environmental science. Several papers have been published from our laboratories concerning the degradation of various pesticides and other hydrophobic organic compounds (1–7).

In the present work we have explored, through computational and NMR methodology, the interaction of the organophosphorus pesticide, diazinon (**1**), with several cyclodextrin (CD) molecules.

1

The CDs being investigated are α-, β-, and γ-CD, containing six, seven, and eight glucose moieties, respectively, in the cyclic structure (Fig. 1). The CDs may be shown by the torus ("bucket") representation in which the secondary hydroxyls are situated on the upper, wider rim, and the primary hydroxyls on the lower rim (see figures in the Computational studies section).

The important characteristic of the CD-type glucose oligosaccharide structure is a hydrophilic exterior imparted by the CD hydroxyl groups and an interior lined by H-C-O linkages that impart hydrophobic character (8, 9). The hydrophobic interior is then capable of encapsulating a hydrophobic or low polarity molecule, for example, a typical pesticide containing an aromatic or heteroaromatic moiety, resulting in the formation of a host–guest complex. The driving force for CD host–guest complex formation is presumed to have as its origin the combination of the following factors: (1) release of "high-energy" H_2O molecules from the CD cavity; (2) relief of strain in the CD molecule upon complexation of the guest (important for the small α-CD); (3) hydrophobic and van der Waals interactions; (4) hydrogen bonding between host and guest; (5) compatability between guest size and dimensions of the host cavity; (6) orientation of the guest molecule in the cavity. The computer modeling and NMR studies reported in this paper bring insight into some of these factors.

CDs have a potentially uniquely important role in the removal of pesticide residues from contaminated soils, for example, from localized industrial sites. In such a situation, the leaching of the pesticide through rainwater, along with other hydrophobic compounds, causes these to localize below the ground water table where they accumulate as DNPLs (dense nonaqueous phase liquids); there they remain virtually immune to degradation through bacterial action over several decades or longer (10). Now, if a CD solution is pumped from the surface into the DNPL, it complexes the hydrophobic material, which once solubilized, can be carried downstream. From there it can be pumped up to the surface where it is separated into its constituents and degraded, while the CD solution is recycled upstream. This process is similar to the traditional "pump-and-treat" procedure using surfactants (11).

Measurement of binding constants between a given pesticide and available CDs enables one to quantify and optimize this methodology. Different methods for the determination of binding constants have been developed (8, 9, 12), including NMR spectroscopy (13, 14). In the case of diazinon, both ^1H and ^{31}P NMR become particularly convenient.

Experimental

Materials

Diazinon was synthesized based on the method of Gysin and Margot (15). The dried sodium salt of 2-isopropyl-6-methylpyrimidin-4-ol was heated for 2 days under nitrogen with diethyl chlorothiophosphate in dry acetone at 35 °C. After cooling and filtering to remove KCl, then removal of solvent under vacuo, the residue was chromatographed with methylene chloride as eluent. Further purification was effected by dissolving in hexanes and extracting with water. The hexane layer was dried ($MgSO_4$), and after filtering was first concentrated and then dried in vacuo to yield pure diazinon. Purity was checked by ^1H, ^{13}C (proton-decoupled),

© 2006 NRC Canada

and ^{31}P (proton-decoupled) NMR. Spectra were run on a 300 MHz Bruker Avance spectrophotometer using $CDCl_3$ as solvent. All spectra were consistent with diazinon and contained no impurity peaks. ^{1}H NMR (ppm) δ: 6.64 (s, 1H), 4.33 (d of q, $J_{H\text{-}H}$ = 7.1 Hz, $J_{H\text{-}P}$ = 11.2 Hz, 4H), 3.10 (sept, $J_{H\text{-}H}$ = 6.9 Hz, 1H), 2.47 (s, 3H), 1.37 (t, $J_{H\text{-}H}$ = 7.1 Hz, 6H), 1.30 (d, $J_{H\text{-}H}$ = 6.9 Hz, 6H). ^{13}C NMR (ppm) δ: 176 (s), 170(s), 165 (d, $J_{C\text{-}P}$ = 4.6 Hz), 107 (d, $J_{C\text{-}P}$ = 6.4 Hz), 65.6 (d, $J_{C\text{-}P}$ = 5.1 Hz), 37.7 (s), 24.5 (s), 21.8 (s), 16.2 (d, $J_{C\text{-}P}$ = 8.0 Hz). ^{31}P NMR (ppm) δ: 61 (s).

α-, β-, and γ-CDs were a generous gift from Cerestar USA and were used without further treatment. DMSO-d_6 and D_2O were purchased from Cambridge Isotopes and used as received.

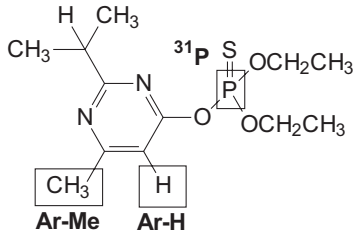
NMR determination of binding constants

Sample preparation

To determine each binding constant, 10 samples were prepared in NMR tubes; the first with diazinon (plus DMSO cosolvent, 0.2% *v*/*v*) in D_2O, and the following containing successively more CD. First, a 0.99 mol/L stock solution of diazinon was prepared in DMSO-d_6, then a 0.006–0.06 mol/L stock solution of CD in 2.5 mL D_2O. Ten NMR tubes were filled with various amounts of the CD solution and D_2O to give a range of CD concentrations from zero (D_2O only) to that of the pure CD stock solution (no added D_2O). To each tube was added 2.5 μL of the diazinon stock solution, giving a final diazinon concentration of 4.93×10^{-3} mol/L in each. The NMR spectra were recorded using a 400 or 500 MHz Bruker Avance spectrophotometer.

K_b *determination by* ^{1}*H NMR*

^{1}H NMR spectra were run on all 10 tubes using a water presat to remove the HOD peak from the spectra. Two proton signals were examined, the aromatic proton (Ar-H) on the pyrimidinol ring and the CH_3 protons (Ar-Me) located on the pyrimidinol ring, as illustrated in Fig. 2. Both singlets appear in an area of the spectrum with no interference from CD signals. The change in chemical shift (Δδ) for the Ar-Me and Ar-H peaks of diazinon with increasing CD concentration, when plotted against [CD], yielded a curved binding isotherm. The curve-fitting program GraphPad Prism® was used to determine K_b according to eq. [1]



$$[1] \qquad \Delta = \frac{\Delta_b K_b [CD]}{1 + [CD] K_b}$$

where Δ is the observed change in chemical shift, Δ_b is the maximum change in chemical shift for 100% bound substrate, and K_b is the binding constant. K_b values were also obtained by the Benesi–Hildebrand eq. [2], the linear double reciprocal plot of the binding isotherm equation.

$$[2] \qquad \frac{1}{\Delta} = \frac{1}{\Delta_b K_b [CD]} + \frac{1}{\Delta_b}$$

On plotting 1/Δ vs. 1/[CD], K_b was found by dividing the intercept by the slope, as determined by linear regression using Microsoft Excel®. Each determination was made at least twice by each method, and all of the values acquired were averaged to obtain the reported K_b value.

Fig. 2. Structure of diazinon illustrating the portions studied by NMR to determine the binding constant (K_b) with cyclodextrins.

K_b *determination by* ^{31}*P NMR*

Proton-decoupled ^{31}P NMR spectra were recorded for each tube (see the general Sample preparation section), as singlets, no other peaks being observed. The change in chemical shift (Δδ) with increasing CD concentration gave a curved binding isotherm. Plotting Δδ vs. [CD] and using the curve-fitting program GraphPad Prism® yielded K_b according to eq. [1]. K_b was again evaluated using the Benesi–Hildebrand eq. [2]. Each determination was made at least twice by each method, and all of the acquired values were averaged to obtain the reported K_b value.

Results and discussion

CD–diazinon binding constants

K_b *from* ^{1}*H NMR*

The change in chemical shift of the Ar-H and Ar-Me peaks in the NMR spectra of diazinon on increasing the CD concentration was followed for α-, β-, and γ-CD. The change in chemical shift was downfield, except for the Ar-H peak in γ-CD, where it shifted upfield with increasing [CD]. The data were used to produce binding isotherms that fit a 1:1 binding model for all three CDs. Figure 3 shows results for α-CD. Figure 3*a* gives the binding isotherm generated for the Ar-H peak, which yields K_b = 183 $(mol/L)^{-1}$, while Fig. 3*b* provides the plot according to the Benesi–Hildebrand treatment, yielding K_b = 221 $(mol/L)^{-1}$. Plots for β-CD and γ-CD are qualitatively similar.

K_b *from* ^{31}*P NMR*

Downfield changes in the ^{31}P NMR chemical shift for diazinon were observed on increasing the CD concentration for α-, β-, and γ-CD. Figure 4*a* shows the binding isotherm for α-CD, while Fig. 4*b* gives the Benesi–Hildebrand plot of the data. β-CD and γ-CD yield similar plots.

Structure–stability relationships

The overall average K_b values obtained from the ^{1}H (Ar-H and Ar-Me) and ^{31}P NMR data are given in Table 1. Clearly, the largest K_b value is found for γ-CD, around 400 $(mol/L)^{-1}$, while the values for α-CD and β-CD are not significantly different, at around 200 $(mol/L)^{-1}$.

A partial summary of existing literature K_b data for pesticides is given in Table 2. The values generally vary from 100 to 600 $(mol/L)^{-1}$. Thus, the present results for diazinon (Table 1) fall within the range of existing data for other pesticides (Table 2). Data for all three CDs are available for parathion (**2**), methyl parathion (**3**), and paraoxon (**4**), all three organophosphorus pesticides with an aromatic moiety

in place of the heteroaromatic moiety in diazinon, but otherwise similar structures.

2

3

4

A major difference between our results and earlier ones now becomes apparent in that K_b values in Table 2 are lowest for γ-CD, while in our study (Table 1), γ-CD has the highest K_b. A plausible explanation for this variance lies with the sterically demanding isopropyl group in diazinon, which together with the Ar-methyl cannot easily be accommodated in the α-CD or β-CD cavity, but can be readily accommodated in the γ-CD cavity. The computational study that follows sheds further light on this aspect.

Computational studies

The manifold applications of computational chemistry have made enormous impact in the field of cyclodextrin chemistry, including modeling studies of the host–guest type. The article by Kenny Lipkowitz on this subject, which appeared in 1998 in a special issue of *Chemical Reviews* featuring cyclodextrin chemistry, provides an excellent overview of this area up to that time; it lists 214 references (24), while many have appeared since then. In this study we present results of two approaches in computational chemistry as applicable to the present system: molecular mechanics (MM) and ab initio, density functional theory (DFT).

B3LYP energy optimized structures

Figure 5 presents the B3LYP/6-31G** minimized structure of diazinon in the form of the space-filling model and as ball-and-stick representation. These are used in visualizing the orientations of diazinon bound in the α-, β-, and γ-CD cavities presented in the following.

Binding orientations of diazinon into α-, β-, and γ-CDs

The dimensions of the diazinon – CD bound complex have been evaluated using MD–MM2 and the results are

Fig. 6. α-CD–, β-CD–, and γ-CD–diazinon binding orientation, energy optimized with MD–MM2. Top row shows the diazinon in the ball-and-stick model and the α-CD, β-CD, and γ-CD in the wire-frame model; bottom row shows the torus representation of α-CD, β-CD, and γ-CD.

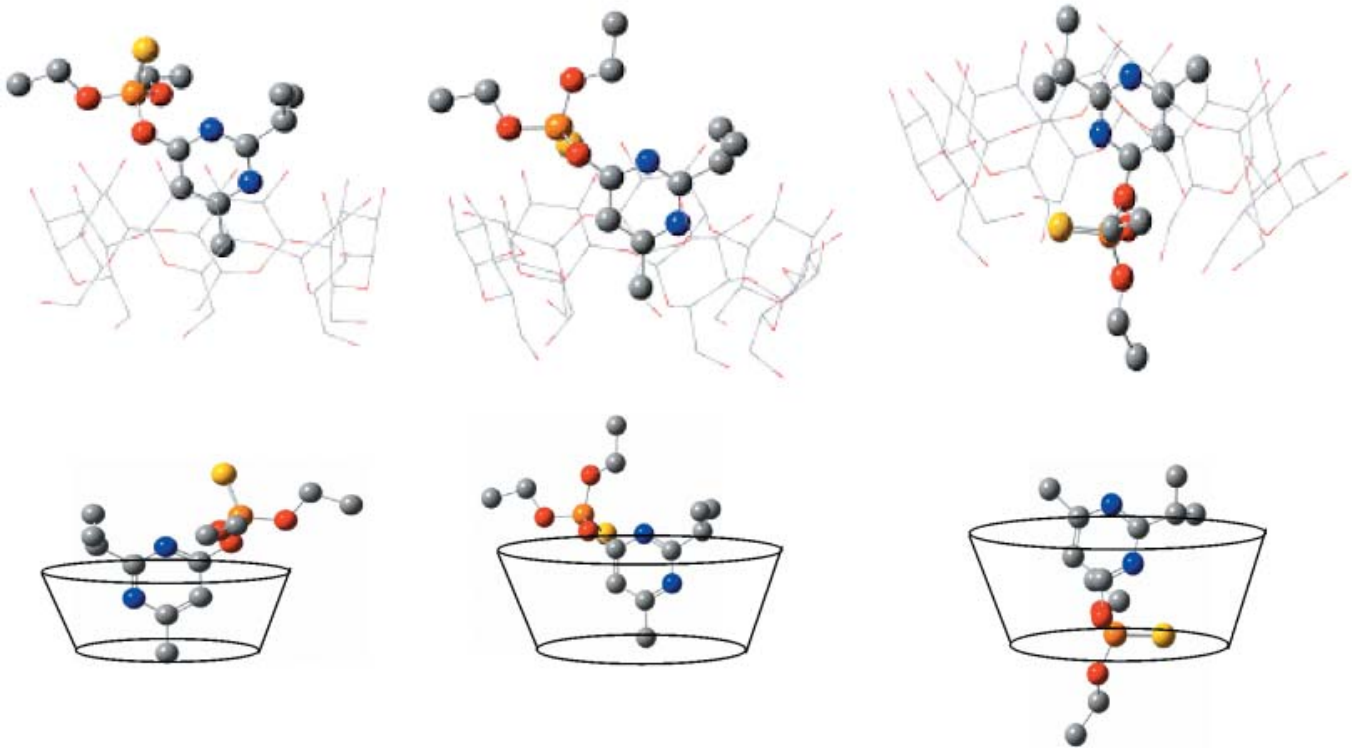

Table 3. Primary OH rim radius, secondary OH rim radius, and height of the diazinon–CD complexes, with errors, optimized with MD–MM2.

	Primary OH rim radius (Å)	Error in primary rim radius (Å)	Secondary OH rim radius (Å)	Error in secondary radius (Å)	Height (Å)	Error in height (Å)
α-CD + diazinon	4.97	1.25	5.13	1.00	5.24	0.41
β-CD + diazinon	5.77	1.62	6.25	0.85	5.40	0.47
γ-CD + diazinon	5.57	1.45	6.76	1.31	5.86	0.39

given in Table 3 as the primary OH rim and secondary OH rim radii, and the height of the complexed CDs. The diazinon-complexed γ-CD is found to have the largest secondary OH rim radius, as expected. Interestingly however, the primary OH rim radius in the complexed CD is about equal for β- and γ-CD.

We have also calculated (using MM2) the distance from the phosphorus atom of diazinon to the secondary OH rim, as the average distance to the three nearest secondary oxygen neighbours. This gives a measure of the depth of the diazinon molecule inside the CD cavity. The results given in Table 4 clearly show that this distance is greatest with γ-CD, i.e., diazinon is found deepest in the CD cavity with γ-CD.

Figure 6 shows the different orientations for the binding of diazinon in α-, β-, and γ-CD optimized with MD–MM2. The illustrations given are for both ball-and-stick models showing diazinon inside the wire-frame CD and the corresponding CD torus representation (Fig. 6), and also space-filling models (Fig. 7).

Table 4. Calculation of average distance from the phosphorus atom to the secondary oxygen plane optimized with MM2 with three nearest oxygen neighbours.

	Distance (Å)
α-CD + diazinon	2.52
β-CD + diazinon	0.55
γ-CD + diazinon	6.37

Note: Alternatively one can indicate distance measurements above the rim as + and below the rim as –, giving the values for α-CD (+2.52), β-CD (+0.55), γ-CD (–6.37).

Several important observations follow on visual examination of these models. (1) The heterocyclic residue of diazinon appears inside the cavity for all three CDs. (2) The methyl substituent is inside the cavity and points downwards for α- and β-CD, while for γ-CD it is situated largely out-

© 2006 NRC Canada

Fig. 7. Space-filling model of diazinon with α-, β-, and γ-cyclodextrins complex optimized with MD–MM2.

side, pointing upwards. (3) The isopropyl substituent is largely outside pointing upwards for α- and β-CD, while being situated on the secondary rim with γ-CD (4). The main contrast comes with the phosphoryl residue that is essentially outside the cavity for α- and β-CD, while with γ-CD it is inside the cavity, with the exception of one ethoxy substituent that protrudes from the lower rim.

Thus, the computations reveal a clear contrast in the three computed orientations. In the case of γ-CD, the bulk of the hydrophobic diazinon molecule, i.e., both the heterocyclic residue and the phosphoryl residue, are situated inside the CD cavity, whereas with α- and β-CD only the heterocyclic residue is present inside the cavity. This, then, provides a rationale for the experimental observation of γ-CD having the greatest binding constant compared with α-CD and β-CD, which possess much smaller and virtually equal K_b values. Any attempts at environmental remediation of pesticides, e.g., from soils, must be cognizant of these findings.

Concluding comments

Binding of the organophosphorus pesticide, diazinon, to α-, β-, and γ-cyclodextrin has been investigated through NMR and computational methodologies. The largest K_b value (400 $(mol/L)^{-1}$) was observed for γ-CD (^1H and ^{31}P NMR). This was corroborated computationally (MD–MM2 and B3LYP/6-31**), which have revealed the deepest location for the hydrophobic diazinon molecule within γ-CD. The direct correspondence and mutually supporting nature of the experimental and computational results, suggests a promising role for computational methodology in environmental remediation of pesticides.

Photochemical reactions of thiols with organic nitrates — Oxygen atom transfer via a thionitrate[1]

Jennifer L. Clarke, Irida Kastrati, Linda J. Johnston, and Gregory R.J. Thatcher

Abstract: Nitroglycerin is an organic nitrate that has been used in the clinical treatment of angina for 130 years, yet important details of its mechanism of action remain unanswered. The biological activity of nitrates suggests that they are bioactivated to NO via a three-electron reduction. The involvement of free or bound protein thiols in this reduction has often been proposed. To examine the involvement of thiyl radicals in such a process, the photochemical generation of benzenethiyl radical from thiol and disulfide precursors was studied in the presence of isopropyl nitrate. Analysis of reaction products and kinetics led to the conclusion that photolysis of the nitrate to NO_2 dominated the observed photochemistry. Formation of sulfonothioate and NO as products, and trapping of NO_2 by 4-chlorophenol, indicated a mechanism involving oxygen atom transfer from N to S via a thionitrate intermediate. The results of the study did not indicate a rapid reaction between thiyl radical and organic nitrate. Despite weak nitrate absorption of light >300 nm and a relatively high BDE for homolysis to give NO_2, the photochemistry under thiyl-generating conditions was driven by nitrate photolysis to NO_2. A novel nitrate, containing a phenyl disulfanyl group linked to nitrate groups, did not undergo photolysis to NO_2 or generate sulfonothioate, but did yield NO. These observations suggest that reaction between thiyl radicals and nitrates leading to NO release is a viable pathway, but it is subservient to other competing reactions, such as photolysis, in the case of IPN, and reaction with thiolate, in the case of the novel nitrate.

Key words: nitrate, photolysis, thiyl radical, nitrogen dioxide, nitric oxide.

Résumé : Même si la nitroglycérine est un nitrate organique qui a été utilisé depuis 130 ans dans le traitement de l'angine, beaucoup de détails importants de son mode d'action restent sans réponse. L'activité biologique des nitrates suggère qu'ils sont biologiquement activés en NO par le biais d'une réduction à trois électrons. L'implication de groupes thiols de protéines libres ou liées dans cette réduction a été souvent proposée. Afin d'examiner l'implication des radicaux thiyles dans ce processus, on a étudié la génération photochimique du radical benzènethiyle à partir de précurseurs thiols et disulfures, en présence de nitrate d'isopropyle. L'analyse de la cinétique et des produits de la réaction conduit à la conclusion que la photolyse du nitrate en NO_2 domine la photochimie observée. La formation de sulfonothioate et de NO comme produits et le piégeage du NO_2 par du 4-chlorophénol suggèrent un mécanisme impliquant le transfert d'un atome d'oxygène du N vers le S par le biais d'un intermédiaire thionitrate. Les résultats de cette étude indiquent qu'il n'y a pas de réaction rapide entre le radical thiyle et le nitrate organique. Malgré la faible absorption de la lumière par le nitrate à des valeurs supérieures à 300 nm et une valeur relativement élevée du « BDE » pour l'homolyse conduisant au NO_2, la photochimie dans les conditions conduisant à la formation de thiyle est dominée par la photolyse du nitrate en NO_2. Un nouveau nitrate contenant du groupe phényl disulfanyle lié à des groupes nitrates conduit à du NO, mais ne donne pas lieu à une photolyse conduisant au NO_2 ou à la génération d'un sulfonothionate. Ces observations suggèrent que la réaction entre les radicaux thiyles et les nitrates est une voie viable pour la production de NO, mais elle est soumise à d'autres réactions de compétition, dont la photolyse dans le cas du nitrate d'isopropyle et d'une réaction avec le thiolate dans le cas du nouveau nitrate.

Mots clés : nitrate, photolyse, radical thiyl, bioxyde d'azote, oxyde nitrique.

Introduction

The synthesis of nitroglycerin (glyceryl trinitrate, GTN) was first reported in 1846. In 1878, it was demonstrated that small doses of GTN taken sublingually provided rapid and remarkable relief from the pain of angina. This led to clinical use of GTN in the treatment of angina pectoris that has continued to this day (1, 2). GTN is now applied in controlled hypotension during cardiac surgery and in congestive heart failure, whereas other organic nitrate vasodilators, including isosorbide dinitrate (ISDN), are used in the treatment of angina pectoris. ISDN, in a combination therapy, is entering the clinic for prevention of heart failure (3). Hybrid nitrates that conjugate a nitrate group to an established drug via a labile linker have been the subject of numerous preclinical and clinical studies (4), and novel nitrates are being explored beyond traditional cardiovascular applications (5). However, despite the historical and growing importance of nitrates in disease therapy, their mechanism of action is not well understood. One prevailing theory is that nitrates function as NO prodrugs, requiring bioactivation (or mechanism-based biotransformation) of the nitrate moiety ($RONO_2$) to NO (6, 7).

Nitrate esters (or organic nitrates) contain the nitrooxy functional group (-ONO_2); conversion of the nitrooxy group to NO is a three-electron reduction that must involve oxygen atom transfer. To date, no purified protein system has been demonstrated to mediate the direct reduction of nitrates to yield relevant quantities of NO, although this is widely held to be the biologically active product of nitrate bioactivation (8, 9). The biotransformation of GTN yields the dinitrate metabolites, glyceryl-1,2-dinitrate (1,2-GDN) and glyceryl-1,3-dinitrate (1,3-GDN), as products. Several proteins have been identified that are capable of mediating the denitration of GTN, yielding GDN and NO_2^- as products, including hemoglobin, myoglobin, xanthine oxidoreductase, old yellow enzyme, glutathione *S*-transferase (GST), cytochrome P450 oxidase, and cytochrome P450 reductase (10–17). More recently, it was confirmed that ALDH2 (aldehyde dehydrogenase) was capable of mediating denitration of classical nitrates (18–20).

The vascular effects of nitrates are believed to be mediated primarily via activation of soluble guanylyl cyclase (sGC), which converts GTP to the secondary messenger, cGMP. sGC is activated by binding of NO to its ferrous-heme centre, inducing a conformational change that triggers activation (21, 22). However, in the context of nitrates and GTN, there is a disparity between sGC activity in intact tissue vs. both broken cell preparations and purified protein: only in intact tissue is GTN a potent sGC activator. In contrast, GTN and simple organic nitrates are incapable of activating sGC above basal levels, in vitro, in the absence of thiol adjuvants (23–25). GTN does react with cysteine in simple aqueous buffer to release NO, but the reaction is slow and does not yield a large flux of NO (26). Nevertheless, the reaction of an organic nitrate with a thiol, whether a free thiol or protein thiol such as in GST or ALDH2, does provide the simplest reaction leading to nitrate bioactivation. Study of the reaction of nitrates with thiols, and their oxidation and reduction products, is therefore important for understanding the mechanism of nitrate biotransformation and bioactivation.

The putative bioactivation of organic nitrate to NO is a three-electron reduction. If bioactivation is mediated by a thiol, of the three potential reducing agents, thiol, thiolate, and disulfide radical anion, the latter is clearly the best candidate simply based on reduction potentials (27).

$$[1a] \quad RS^{\cdot} + e^- \rightarrow RS^- \qquad E^\circ = 0.78 \text{ V}$$

$$[1b] \quad RS^{\cdot} + e^- + H^+ \rightarrow RSH \qquad E^\circ = 1.35 \text{ V}$$

$$[1c] \quad RSSR + e^- \rightarrow (RSSR)^{\cdot -} \qquad E^\circ = -1.42 \text{ V}$$

The reactions of nitrates with disulfide radical anions are worthy of study in this respect. Disulfide radical anions can be formed by the reversible combination of thiyl radical with thiolate (eq. [2]) and by reduction of disulfides (eq. [1*c*]).

$$[2] \quad RS^{\cdot} + RS^- \underset{k_{-f}}{\overset{k_f}{\rightleftharpoons}} (RSSR)^{\cdot -}$$

It is apparent that thiyl radicals are likely to be present in any system designed to generate a disulfide radical anion. It is also possible to draw a mechanism of reaction for nitrate with thiyl leading to NO.

$$[3] \quad R'S^{\cdot} + RONO_2 \rightarrow [RON(O)OSR']^{\cdot} \rightarrow R'SO^{\cdot} + RONO$$

$$[4] \quad RONO + 1e^- + H^+ \rightarrow ROH + NO$$

Therefore, it is essential to explore the reactivity of thiyl radicals themselves with nitrates. However, the clean generation of thiyl radicals (and disulfide radical anions) presents a challenge since there is no ready thermal source as has been described for other biological radicals, such as superoxide (28). Conversely, a number of photochemical systems for thiyl radical generation have been described. In this paper, thiyl radicals generated from disulfide and thiol photochemical precursors are studied in the presence of nitrates.

Experimental section

All reagents were supplied by Sigma-Aldrich (Oakville, Ontario), with the exception of GTN and GT-130 that were synthesized by literature methods (29). All solvents used were HPLC grade. NO was supplied by Praxair Products Inc. (Mississauga, Ontario) and was used with a NO specific regulator. Phosphate buffer (PB) (0.1 mol/L, pH 7.4) was adjusted to pH and microfiltered before use.

All ^{1}H NMR analyses were done on a Bruker Avance-400 (400 MHz) spectrometer. A Varian Cary 3 UV–vis diode array spectrometer was used, with 1 cm × 1 cm quartz cells. Kinetic measurements were performed on a HP 8452A diode array spectrophotometer at 40 °C. Chemiluminescence measurements were made using a SIEVERS 270B NO chemiluminescence analyzer and a SIEVERS 207B nitric oxide analyzer (Boulder, Colorado). The UV light sources used were 300, 350, and mixed 300/350 nm Rayonet reactors equipped with lamps from the Southern New England Ultraviolet Company (Brantford, Connecticut).

The lasers used in the laser flash photolysis experiments were an EX-530 Excimer-500 (Lumonics, Inc.), an UV-24 N_2 laser (Laser Photonics), and a HY 750 ytrium–aluminum–garnet (YAG) laser (Lumonics, Inc.). The detec-

© 2006 NRC Canada

tor consisted of a Digikrom 240 monochromator (CVI Instruments) with a six dynode photomultiplier tube. The oscilloscope used was a Tektronix 7912 AD programmable digitizer and the delay generator was a DG535 four-channel digital delay/pulse generator (Stanford Research Systems).

All gas chromatography (GC) work was done on a Hewlett Packard 5890 series II gas chromatograph with flame ionization detection. The column used was a HP-1 with dimensions 25 m × 0.2 mm × 0.33 μm, column pressure 20 psi He (1 psi = 6.894 757 kPa), and splitflow 30 cc/min. One microliter injection volumes were made by an autoinjector using a 10 μL syringe that was cleaned with acetonitrile (MeCN). The GC–MS used was a HP 5890 gas chromatograph with a HP 5970 series mass selective detector. The MS library used was the Wiley138 database. One microliter manual injections were made. The column used was a HP-5 with dimensions 25 m × 0.2 mm × 0.33 μm, column pressure 10 psi He, and splitflow 30 cc/min. The optimal GC method for analyzing the thiol-nitrate samples used an injection port temperature of 200 °C, a detector temperature of 300 °C, and an initial oven temperature of 50 °C with a gradient of 10 °C/min to a final temperature of 250 °C. This temperature was maintained for an additional 9 min.

All high-pressure liquid chromatography (HPLC) analyses were done at room temperature on Hewlett Packard series II 1090 liquid chromatographs using diode array spectrophotometers (HPIB 15). An autosampler was used with 25 μL injections. Both C8 and C18 reverse-phase columns were used. The C8 column was a Waters Nova-Pak HPLC column, with a 4 μm diameter and dimensions of 3.9 mm × 150 mm. The C18 column was a Waters Spherisorb ODS2 column with a diameter of 5 μm and dimensions of 4.6 mm × 250 mm. For all experiments, the eluant was a mixture of methanol (MeOH) and Millipore-filtered water, with a flow rate of 1 mL/min. Three HPLC methods were used, where A is H_2O and B is MeOH. Method 1 used a gradient from 35% to 95% B over 16 min, followed by a plateau at 95% B for 6 min and gradient to 35% B over 2 min. Method 2 used a gradient from 35% to 95% B over 30 min, followed by a 5 min plateau. Products from the PhSH/IPN photoreaction were detected using HPLC Method 2 and the C18 column. HPLC Method 2 and the C8 column were used for the GT-130 photochemical and thermal product analysis. Detection of GDNs from GTN electron capture was done using Method 1 with the C18 column.

Benzenethiyl radical was generated by irradiation of benzenethiol (1) (PhSH, 10 mmol/L), diphenyl disulfide (PhSSPh, 4 or 1 mmol/L), or GT-130 (1 mmol/L) in the presence of 100 mmol/L 2,3-dimethyl-1,3-butadiene in oxygen- or nitrogen-saturated acetonitrile (MeCN/N_2) using either a 300 nm Rayonet reactor (arrangement of UV lamps) or a laser flash photolysis setup, respectively. Decane (3 mmol/L, anhydr.) was used as a standard for GC-FID analysis of the Rayonet reactions. GC–MS was first used to identify the 1,4- and 1,2-addition products, the identity of which was further confirmed by ^{1}H NMR analysis and quantified by GC-FID.

Benzenethiyl radical was also generated in the presence of isopropyl nitrate (IPN, 100 mmol/L or 1.0 mol/L) by irradiating PhSH (10 mmol/L or 100 mmol/L) or PhSSPh (5 mmol/L) in nitrogen-saturated acetonitrile (MeCN–N_2) using 300 and 350 nm Rayonets, respectively. All experiments were done in duplicate. Reactions were analyzed by GC-FID using 3 mmol/L anhydrous decane as standard. Relative peak areas from the GC traces were calibrated and converted to concentration plots using GC calibration curves. These calibration curves were obtained using authentic PhSH, PhSSPh, and $PhSO_2SPh$. For $PhSO_2SPh$, a photodegradation calibration was necessary because it is photolabile and breaks down during the course of the experiment. The use of a photodegradation calibration run under identical conditions to the experiment provided an estimated correction. The calibrated concentrations were transformed to molar "% conversion" relative to the starting concentration of PhSH.

IPN (0.5 mol/L) with and without PhSH (10 mmol/L) in MeCN–N_2, GTN (5 mmol/L), and GT-130 (5 mmol/L) in MeCN–PB–N_2 (40:60), were each irradiated using Rayonets with 300 and (or) 350 nm lamps, and NO release was quantified using a NO chemiluminescence (CL) detector. CL was calibrated by the use of the diazeniumdiolate NO donor, SPE–NO: initial rates data were collected for NO release over 10 min and calibrated by comparison to the first-order rate constant obtained by spectrophotometric analysis of SPE–NO decay.

Solutions of 10 mmol/L PhSH, 1.0 mol/L IPN, and varying concentrations of 0–100 mmol/L 4-chlorophenol in MeCN–N_2 were irradiated for 0 and 10 min in a 300 nm Rayonet reactor. To determine the extent of photolysis at longer wavelength, solutions of 5 mmol/L PhSSPh, 1.0 mol/L IPN, and 0–100 mmol/L *p*-chlorophenol were deoxygenated with nitrogen and irradiated for 0 and 45 min in a 350 nm Rayonet reactor. Anhydrous decane was used as a standard in both experiments and product analysis was done by GC-FID.

Nitric oxide gas was purified according to the method of Bostrup et al. (30). Using this purification setup, three 25 mL portions of MeCN were each saturated with argon. One was flushed with purified NO for 25 min (until saturated) and another with unpurified NO. A stock solution was made with 20 mmol/L PhSH and 20 mmol/L decane standard. One milliliter of this solution was saturated with nitrogen and diluted with 1 mL of either (*i*) argon-saturated, (*ii*) purified NO-saturated, or (*iii*) unpurified NO-saturated MeCN, giving final concentrations of 10 mmol/L PhSH and 10 mmol/L decane. Another stock solution was made with 60 mmol/L *p*-chlorophenol and 20 mmol/L decane. This solution was deoxygenated with nitrogen and diluted with the satd. MeCN solutions similar to the above method. The resulting concentrations were 30 mmol/L and 10 mmol/L *p*-chlorophenol and decane, respectively. All samples were analyzed by GC-FID with decane as a standard.

Theoretical methods

Geometry optimizations were performed with density functional theory using the (U)B3LYP function (31) with the 6-311++G(d,p) basis set implemented in the Gaussian 03 suite of programs (32). Calculation of structure and energy of the excited state of IPN was carried out in Spartan 04 (Wavefunction, Inc.) using TDDFT at the B3LYP/6-31G* level. For calculation of the thermodynamics of homolysis, minima were fully optimized and characterized by harmonic

© 2006 NRC Canada

vibrational frequency analysis, followed by further optimization and energy evaluation using the complete basis set (CBS-QB3) methodology, known to provide thermochemical estimates approaching experimental accuracy. Energy minimum structures were confirmed to have adequate convergence and zero imaginary vibrational frequencies. For the radical species, spin determinant calculations were evaluated to check for spin contamination.

Results

The photochemical sources of thiyl radicals used were photolysis of the RS—H bond (eq. [5]) and photolysis of the S—S bond (eq. [6]) of the corresponding disulfide (33). Hydrogen abstraction from RSH by photochemically generated *tert*-butoxyl radicals (*t*-BuO$^{\cdot}$) is an alternative route (eq. [7]) that is complicated by the potential side reactions of the alkoxyl radical in solutions containing nitrates.

[5] $$RSH \xrightarrow{h\nu} RS^{\cdot} + {}^{\cdot}H$$

[6] $$RSSR \xrightarrow{h\nu} 2RS^{\cdot}$$

[7] $$t\text{-BuO–O-}t\text{-Bu} \xrightarrow{h\nu} t\text{-BuO}^{\cdot} \xrightarrow{RSH} RS^{\cdot} + t\text{-BuOH}$$

A restriction to these methods is the chromophore of the source, which is often weak. Alkyl thiyl radicals typically absorb at 330 nm, which is similar to the optical spectra of their sources, and have low extinction coefficients ($\varepsilon \sim 500$ (mol/L)$^{-1}$ cm^{-1}) (27). They are therefore difficult to detect and monitor using photochemical techniques (27, 34). Generation of aryl thiyl radicals is more facile owing to higher wavelength chromophores with higher extinction coefficients ($\varepsilon \sim 2500$ at 460 nm and 10 000 (mol/L)$^{-1}$ cm^{-1} at 295 nm) (27). Consequently, aryl thiols and aryl disulfides are preferred as thiyl radical sources. A relatively clean method of generating thiyl radicals was found by irradiation in MeCN using a YAG laser ($\lambda = 355$ nm). Benzenethiyl radical (PhS$^{\cdot}$) was generated from the disulfide or thiol precursor and characterized by laser flash photolysis (LFP). The PhS$^{\cdot}$ spectrum obtained displayed the well-characterized absorbance maxima at 490 and 450 nm.

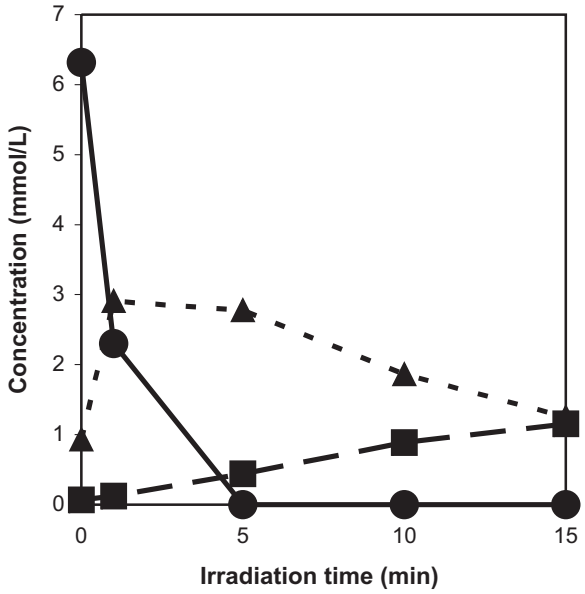
The thiyl radical was further characterized by measuring the kinetics of conjugate addition to 2,3-dimethyl-1,3-butadiene (DMB). Under anaerobic conditions, thiyl is known to add to olefinic bonds in anti-Markovnikov fashion (27), where the 1,4-adduct is expected to be the major product in the case of DMB (35). LFP was used to measure the addition rates of PhS$^{\cdot}$ to DMB in the presence and absence of oxygen. The rate constants thus derived for the addition of PhS$^{\cdot}$ to DMB under aerobic and anaerobic conditions were found to be 1.3×10^8 and 0.83×10^8 (mol/L)$^{-1}$ s^{-1}, respectively. These experiments validate and quantify the formation of thiyl radical, the rate of addition to the diene, and the utility of the diene trap in measuring thiyl formation.

Generation of PhS$^{\cdot}$ in the presence of IPN — An intermolecular model

To facilitate product monitoring, photolysis of PhSH in the presence of DMB was carried out using a Rayonet photoreactor fitted with 300 nm lamps. In the absence of DMB, the only product observed by GC-FID analysis was disulfide. However, with excess quantities of DMB present, the yield of disulfide was reduced and both the 1,4- and 1,2-adducts were observed by GC-FID and ^{1}H NMR analysis, with the major product being that of conjugate addition. Thermal generation of benzenethiyl at 95 °C and subsequent addition to DMB has previously been investigated, where the yield of the 1,4-adduct was found to be 98% (35). DMB is therefore an effective thiyl trap as predicted by the rate constants determined by LFP analysis. Addition of IPN to this reaction system led to a decrease in the yield of addition product in a concentration dependent manner (data not shown), suggesting that IPN inhibited reaction of thiyl radical with the conjugated diene.

To examine whether a reaction between benzenethiyl and IPN was responsible for the observed reduction in formation of the 1,4-DMB adduct, PhSH (10 mmol/L) was irradiated in the presence of IPN (1.0 mol/L) alone. A new product was observed in the GC-FID chromatogram, which was identified as a sulfonothioate (*S*-phenyl benzenesulfonothioate; $RS(O)_2SR$, R = Ph) by GC–MS and by comparison to an authentic sample. Formation of this product increased with irradiation time (Fig. 1); however, the sulfonothioate is a photolabile compound and its quantity is therefore underestimated by this assessment, especially at longer irradiation times. As a result, the sulfonothioate product stability was measured by GC-FID analysis as a function of irradiation time under the reaction conditions. This enabled construction of a corrected calibration curve that was used to more accurately estimate sulfonothioate formation (Fig. 1).

It is evident from Fig. 1 that in addition to a decrease in PhSH with irradiation time, a decrease in the disulfide product is also observed. The disulfide absorbs light at 300 nm and is cleaved into thiyl radicals, though requiring longer irradiation times than the corresponding thiol. This is compatible with the increase in sulfonothioate product observed at irradiation times where the PhSH source has been depleted. The sulfonate product therefore results from reaction of PhS$^{\cdot}$ formed from photolysis of both the thiol and the disulfide.



PhS$^{\cdot}$ was also generated from 5 mmol/L PhSSPh using LFP. A second-order fit to the decay trace (monitored at 460 nm) gave a rate constant for radical recombination of 2×10^7 (mol/L)$^{-1}$ s^{-1}. Addition of IPN had no effect on the decay rate of the radical, even when 80% IPN – 20% MeCN was used as the solvent, indicating that any reaction with IPN cannot compete with radical recombination. This effect was consistent under aerobic and anaerobic conditions, and questions the viability of a direct and rapid reaction between thiyl radical and nitrate.

Sulfonothioate as a product of NO_2 reaction

The sulfonothioate product could potentially result from direct reaction between benzenethiyl radical and NO_2, since NO_2 is the expected product of IPN photolysis. Smaller amounts of sulfonothioate were observed in photochemical experiments where longer wavelength irradiation was used: reaction of PhS$^{\cdot}$ with IPN was performed using a 350 nm lamp and PhSSPh as the thiyl precursor. As shown in Fig. 2, much smaller amounts of sulfonothioate were detected, in comparison to the irradiation of PhSH and IPN at 300 nm. It should be noted that at $\lambda = 300$ nm, the relative molar

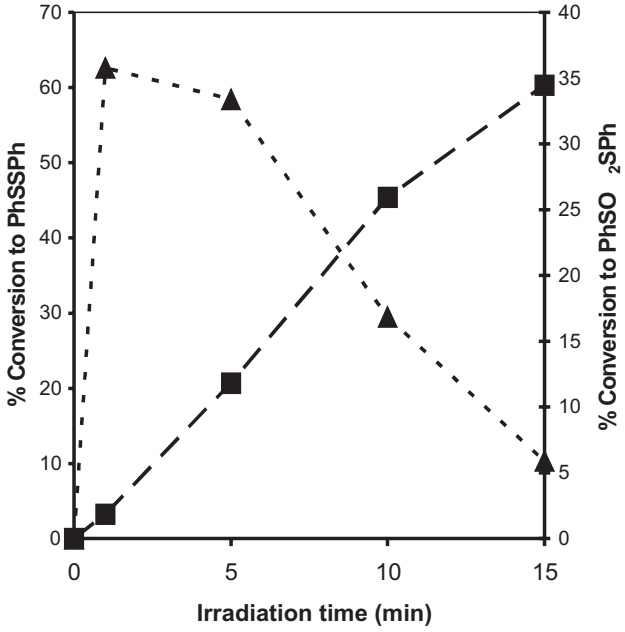
Fig. 1. Left: Decay of reactant (●) and growth of products (thiosulfonate (■) and disulfide (▲)) from irradiation of PhSH (10 mmol/L) in the presence of IPN (1.0 mol/L) in MeCN–N_2 using a 300 nm lamp, as assayed by GC-FID calibrated using authentic samples (average of two trials). Right: Identical reactant and product data incorporating a correction for the photochemical decomposition of the products under the reaction conditions.



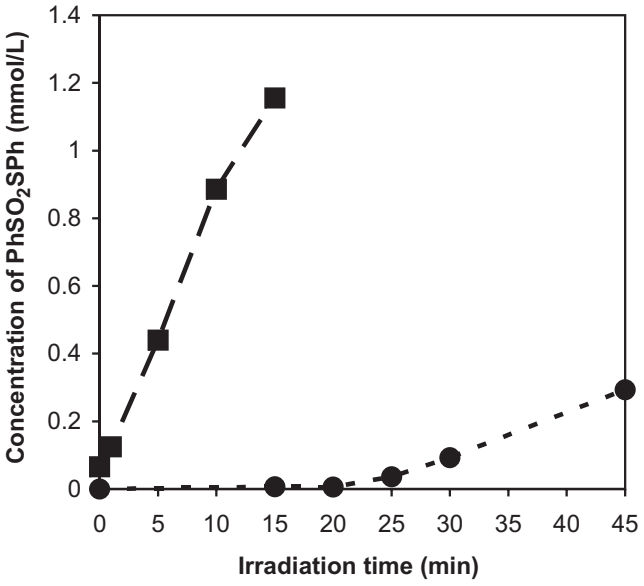


Fig. 2. Comparison of $PhS(O)_2SPh$ yield from IPN (1.0 mol/L) in MeCN–N_2. Irradiation of PhSH (10 mmol/L) at 300 nm (■); irradiation of PhSSPh (5 mmol/L) at 350 nm (●). Average of two trials.

absorbance of PhSH to IPN is approximately 10:1, whereas at 350 nm, the absorbance of IPN is lower by a factor of 40. Thus, it is expected that less NO_2, and consequently less sulfonate, would be generated at 350 nm as a result of decreased light absorption and photolysis of the nitrate. Evidence for thermal decomposition of IPN to NO_2 was seen in careful inspection of Fig. 1, which shows sulfonothioate product present at time zero. Sulfonothioate was formed owing to thermolysis in the high-temperature GC injection port (200 °C). To examine the photolysis of IPN, a NO_2 trapping experiment was designed using 4-chlorophenol. Photonitration of arenes has been known for many years and recent work has been published reporting the formation of 2- and 4-nitrophenol resulting from irradiation of nitrate or nitrite ion in the presence of phenol in aqueous solution (36, 37). The ortho-nitration of tyrosine is a well-known reaction (38), and the use of 4-chlorophenol has the advantage of limiting nitration to one isomeric product. Generation of 4-chloro-2-nitrophenol was shown to result from irradiation of 1.0 mol/L IPN in the presence of 10 mmol/L *p*-chlorophenol, where the product identity was confirmed by GC–MS analysis.

Increasing concentrations of 4-chlorophenol were added to irradiated solutions of IPN with PhSH or PhSSPh to compete with $PhS^{\cdot}$ for any NO_2 generated by nitrate photolysis (Fig. 3). The decrease in relative peak area of 4-chlorophenol was the same as the increase observed in the relative peak area of 4-chloro-2-nitrophenol (data not shown), indicating that nitration was efficient and was the only reaction occurring with 4-chlorophenol. The observation of 4-chloro-2-nitrophenol formation confirmed the generation of NO_2 on irradiation, while nonirradiated solutions gave no nitration products. Clearly, NO_2 is generated by irradiation of 1.0 mol/L IPN at 300 nm and to a lesser extent at 350 nm. It also appears from Fig. 3 that the amount of 4-chloro-2-nitrophenol formed reaches a plateau. A simple rationale would be the lower yield of $PhS^{\cdot}$ and of NO_2 owing to competitive absorbance by 4-chlorophenol and 2-nitro-4-chlorophenol in the reaction solution. At 100 mmol/L 4-chlorophenol, A(300 nm) = 2.4 and A(350 nm) = 0.079; whereas for PhSH (10 mmol/L), A(300 nm) = 0.85; for PhSSPh (5 mmol/L), A(350 nm) = 0.75; and for IPN (1.0 mmol/L), A(300 nm) = 3.4 and A(350 nm) = 0.087.

Both the nitration of 4-chlorophenol and the formation of sulfonothioate appeared to result from the photolysis of IPN to NO_2. Commercial gaseous NO provides a further means

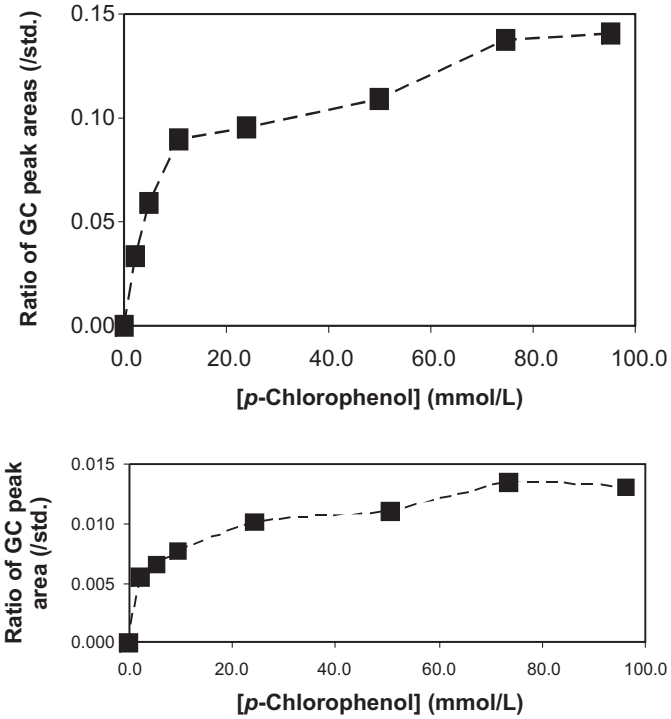

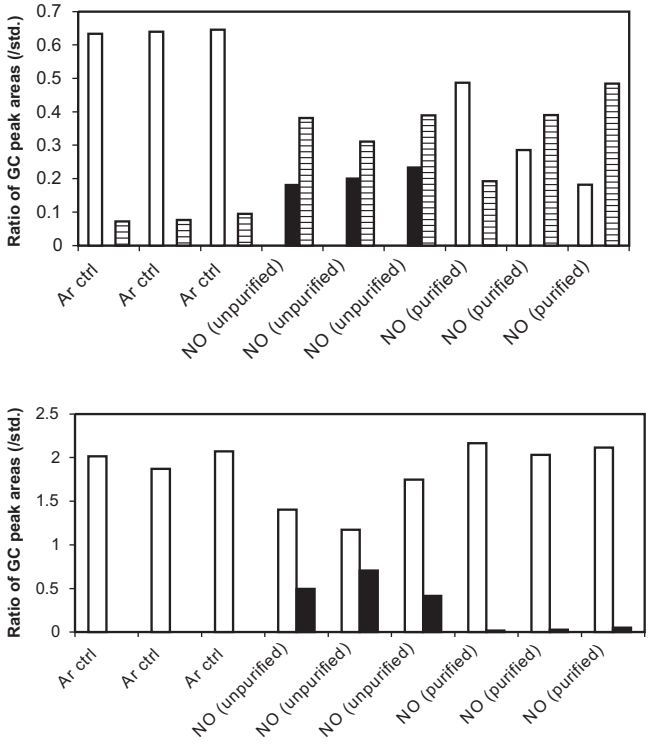

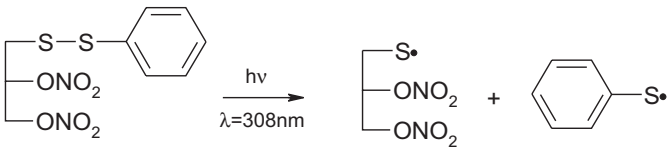

Fig. 4. Quantitation of products from reaction of NO gas with PhSH (10 mmol/L) in MeCN–N_2 by GC-FID. Argon, unpurified NO–NO_2 gas, or purified NO gas passed through alkaline scrubbers was bubbled through the reaction solution at comparable rates. Top: reactant PhSH (open bar), $PhS(O)_2SPh$ (solid bar), and PhSSPh (hashed bar) were measured. Bottom: the same reactions were carried out in the presence of 4-chlorophenol (open bar) and product 4-chloro-2-nitrophenol (solid bar) was measured. Triplicate reactions shown.

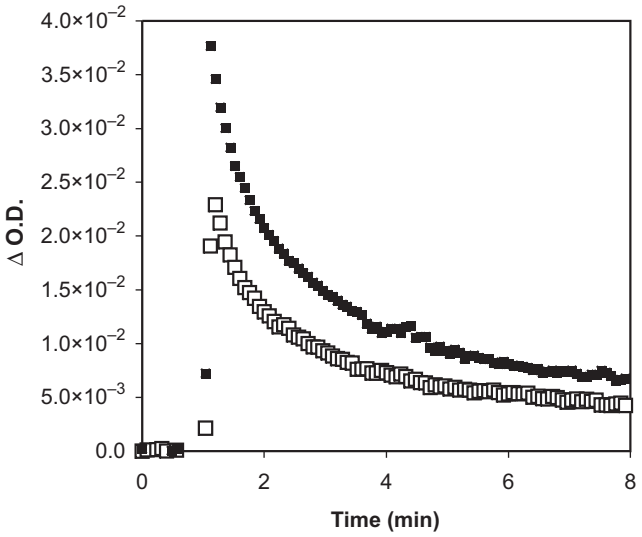
to test this hypothesis because the unscrubbed gas contains NO_2 as the major impurity. Nitration of 4-chlorophenol was measured in solutions of PhSH in MeCN–N_2 treated with gas streams of either argon, the unpurified NO–NO_2, or NO purified by passage through alkaline scrubbers (Fig. 4, bottom). Only in the samples treated with NO–NO_2 was significant nitration observed, indicating that this system is useful for studying reactions of NO_2 in the presence of other nitrogen oxide species and that 4-chlorophenol is an effective NO_2 trap. In parallel experiments, unreacted thiol, disulfide, and sulfonothioate were measured by GC-FID analysis in solutions of PhSH in MeCN–N_2 treated with gas streams of either argon, unpurified NO–NO_2, or purified NO. Treatment with purified NO resulted in significant oxidation of thiol to disulfide, but no sulfonothioate formation. In contrast, treatment with NO–NO_2 gas led to complete depletion of thiol, yielding both disulfide and sulfonothioate (Fig. 4, top). The nitration of 4-chlorophenol in PhSH solution flushed with NO–NO_2 was also monitored in a UV–vis spectrometer at 350 nm in which 4-chloro-2-nitrophenol was observed to form immediately upon flushing with the gas (data not shown).

An intramolecular model for thiyl-nitrate interactions — GT-130



The phenyldisulfanyl dinitrate (GT-130) contains both disulfide and nitrate moieties, and is therefore a suitable candidate for studying the likelihood of thiyl radical reactivity with nitrates owing to the proximity of the two reactive groups. In the presence of DMB and under identical conditions to those used for the study of PhSH–IPN, irradiation of GT-130 resulted in formation of the same 1,4-thiyl-DMB adduct, verifying that $PhS^{\bullet}$ was produced and therefore confirming photolysis of the S—S bond.

Using an Excimer laser (308 nm) to excite GT-130, $PhS^{\bullet}$ was again identified by LFP analysis of its characteristic spectrum and shown to be a product of GT-130 photolysis. The decay curves of $PhS^{\bullet}$ generated by photolysis of GT-130 and Ph_2S_2 at equal concentrations are shown in Fig. 5. As expected, the change in optical density from Ph_2S_2 photolysis was approximately twice that from GT-130 photolysis, since twice as many $PhS^{\bullet}$ radicals would result from photolysis of the S—S bond. The decay rate constants measured for each curve were second order and were found to be similar, indicating that the recombination pathway for the GT-130 radicals has similar kinetics to the radical–radi-

Fig. 5. Decay curves of $PhS^{\cdot}$ monitored at 450 nm by LFP. Formed by irradiation of 1 mmol/L GT-130 (□) or 1 mmol/L PhSSPh (■) in MeCN–N_2 using an Excimer laser (308 nm).

cal recombination of $PhS^{\cdot}$ forming PhSSPh. This suggests that the $PhS^{\cdot}$ radical formed via photolysis undergoes recombination to GT-130 with a rate similar to that of self-combination to PhSSPh.

To explore possible nitrate photolysis of GT-130, irradiation was performed at 300 nm in the presence of the 4-chlorophenol trap. Nitration was not observed (data not shown), indicating that NO_2 either was not formed or was trapped more rapidly by another species. A reasonable explanation is the low absorbance associated with the nitrate groups in GT-130 (5 mmol/L), which is substantially less than in experiments with IPN (1.0 mol/L). Disulfide cleavage is therefore the dominant route of photolysis upon irradiation of GT-130 at 5 mmol/L.

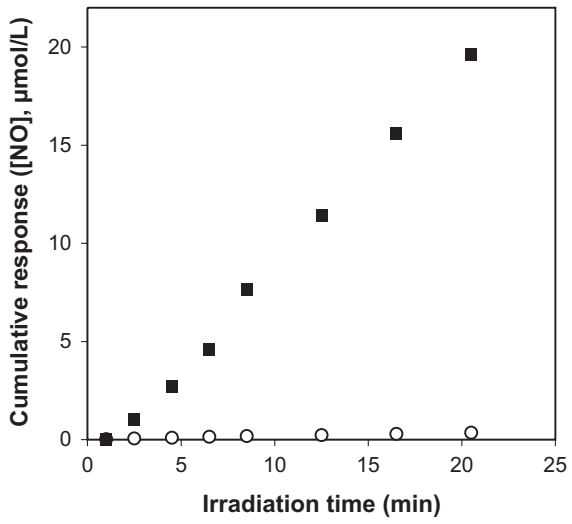
NO release from reaction of GT-130

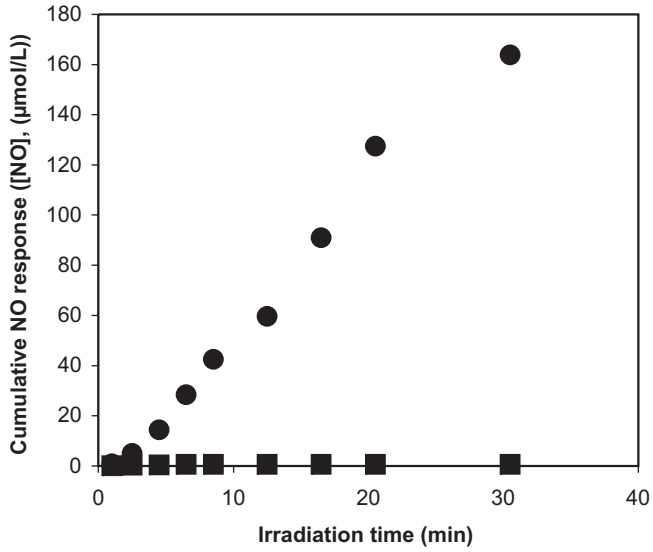
The thermal reaction of GT-130 with thiols has been reported to result in production of NO (29). The photolysis of GT-130 was compared with that of GTN by chemiluminescence detection of NO in headspace gas of the reaction mixtures (Fig. 6). Small, submicromolar quantities of NO were observed from GTN photolysis, but GT-130 photolysis generated more than 20 μmol/L NO after 20 min irradiation. However, comparison of NO release from thermal reaction of GT-130 with cysteine vs. photochemical reaction of GT-130 showed that the thermal reaction is more efficient in generating NO (29). Irradiation of GT-130 under aerobic or anaerobic conditions exhibited no change in the NO response (data not shown).

Interestingly, irradiated solutions of PhSH–IPN in MeCN–N_2 also generated NO, with a linear rate of NO release for at least the first 20 min of reaction (Fig. 7). As shown, photolysis of IPN alone did not produce NO within the detection limits.

Once it was established that irradiation of GT-130 resulted in efficient S—S bond cleavage, the nature of the resulting organic products was investigated. The products resulting from thermal reaction of GT-130 with PhSH in neutral aqueous solution were analyzed by HPLC with UV detection and

Fig. 6. Comparison of cumulative NO response. Irradiation of 5 mmol/L GTN (○) and 5 mmol/L GT-130 (■) in MeCN–PB–N_2 (40:60) using mixed 300 and 350 nm lamps (average of three trials).





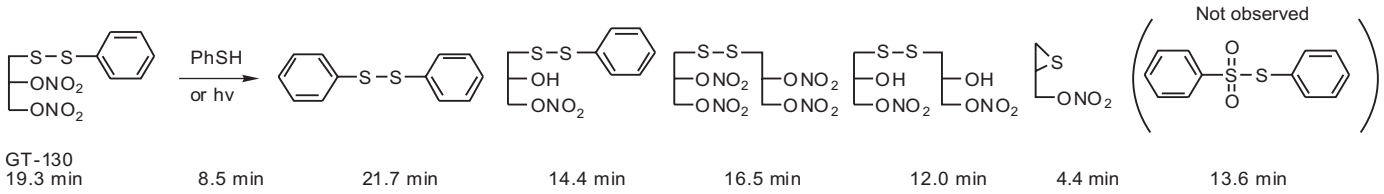


Fig. 7. Comparison of NO response. Irradiation of 10 mmol/L PhSH + 0.5 mol/L IPN (●) vs. irradiation of 0.5 mol/L IPN (■) in MeCN–N_2 (average of three trials).

have been reported previously (29). The major products were identified by comparison of HPLC chromatograms with authentic samples, and were found to be PhSSPh and 2-denitro-GT-130, with an equal amount of unreacted GT-130 present (Scheme 1). Of numerous minor products, the cyclic thiirane was the most abundant and the symmetrical disulfide 1,2-di(3-nitrooxy-2-hydroxypropyl)disulfane was also identified (Scheme 1). The products identified in the photolysis of GT-130 (excluding the starting material) were, in order of abundance, diphenyldisulfide > 2-denitro-GT-130 > 1,2-di(2,3-dinitrooxypropyl)disulfane > 3-nitrooxypropylthiirane > 1,2-di(3-nitrooxy-2-hydroxypropyl)disulfane (Scheme 1). In the context of this work, it is important to note that no $PhS(O)_2SPh$ was detected in either the thermochemical or photochemical reactions of GT-130. In

Scheme 1. HPLC retention times are annotated under the conditions described in the text.

contrast, HPLC analysis of reaction mixtures of PhSH and IPN did reveal sulfonothioate after irradiation.

Irradiation of GT-130 for 20 min at 300 nm was sufficient to identify the photoproducts. Further experiments revealed no change in photochemical products from nitrogen-deoxygenated to air-equilibrated solutions. It can therefore be confirmed that oxygen has no effect on the photochemical reaction of GT-130 leading to the products shown.

Discussion

The release of NO from organic nitrates in complex biological systems can often be observed using a variety of different methods. In human plasma, NO release was observed from solutions of nitrates and thiosalicylic acid using amperometric detection (39). In plasma, the series of 1,2-dinitrooxy propane derivatives including GTN were all observed to release NO in the presence of TSA with an initial rate of ~4–80 nmol/L s^{-1} at 0.25–0.5 mmol/L nitrate concentration. At physiological pH, the reactivity of free thiols towards nitrates is dependent on thiol pK_a and is too slow to account for the rapid bioactivation of GTN; for example, only 10% reaction of GTN (1 mmol/L) with cysteine (2 mmol/L) is observed in aqueous solution at pH 7.4, 37 °C, after 1 h (26). Using earlier electrochemical devices, this reaction was not found to produce NO within the detection limits, while chemiluminescence was able to detect the low levels of NO produced in these mixtures (26, 40). Nevertheless, catalysis of the reaction between cysteine thiol and nitrate at an enzyme active site or at other protein sites containing reactive thiols, such as thioredoxin folds, may lead to acceleration of reaction and an increased flux of NO (6). The most popular, contemporary theory for GTN bioactivation invokes ALDH2, which contains three cysteines at the active site (41, 42). ALDH2 and several other proteins are capable of accelerating reductive denitration of nitrates to inorganic nitrite (eq. [8]), however, conversion to NO requires further reduction.

[8] $RONO_2 + 2e^- + 2H^+ \rightarrow ROH + NO_2^-$

[9] $NO_2^- + e^- + H^+ \rightarrow HO^- + NO$

A chemical mechanism that identified an organic thionitrate ($RSNO_2$) as the common intermediate in a mechanism leading to either NO_2^- or NO from the reaction of thiol with nitrate was first described by Yeates (43). Later computational and experimental approaches to this reaction yielded a cohesive thionitrate rearrangement pathway for a thiol-nitrate reaction leading to NO release (eqs. [10]–[13]) (44, 45). In an investigation of the aqueous decomposition of *tert*-butyl thionitrate, the only organic products observed were sulfonothioate and sulfinothioate, which were proposed to result from radical combination based on computational studies (eqs. [14] and [15]). The lack of disulfide product formed from reaction of pure samples of thionitrate indicated that rxns. [16]–[18] (and thiyl radical recombination) were not competitive under the reaction conditions.

[10] $RSH + R'ONO_2 \rightarrow RSNO_2 + R'OH$

[11] $RSNO_2 \rightarrow [RS^{\cdot}NO_2^{\cdot}]$

[12] $[RS^{\cdot}NO_2^{\cdot}] \rightarrow RSONO$ or $RS(O)NO$

[13] $RSONO \rightarrow RSO^{\cdot} + NO$

[14] $2RSO^{\cdot} \rightarrow RS(O)_2SR$

[15] $RSO^{\cdot} + RS^{\cdot} \rightarrow RS(O)SR$

[16] $[RS^{\cdot}NO_2^{\cdot}] \rightarrow RS^{\cdot} + NO_2^{\cdot}$

[17] $RS^- + NO_2^{\cdot} \rightarrow RS^{\cdot} + NO_2^-$

[18] $RS^- + RSNO_2 \rightarrow RSSR + NO_2^-$

GT-150 (2,3-dinitrooxypropane-1-thiol) contains a thiol group *vicinal* to a nitrate group. This compound was shown to spontaneously generate NO in neutral aqueous solution, as was the related disulfanyl nitrate GT-130 on addition of thiol (Scheme 1) (29), with no evidence being obtained for sulfonyl or sulfinyl products (S=O containing). Reaction of the disulfanylnitrates was unaffected by O_2, and other reductants studied did not facilitate NO release. The simplest mechanism, compatible with these observations was proposed to be a thiol-disulfide exchange.

[19] $RSSCH_2CHRONO_2 + R'S^- \rightarrow RSSR' + {}^-SCH_2CHRONO_2$

[20] ${}^-SCH_2CHRONO_2 \rightarrow \rightarrow NO$

A sequence of reactions postulated to account for NO production in the absence of S=O containing products proceeds via a sulfenate (RSO^-) and a nitrosothiol (RSNO) intermediate (eqs. [21]–[24]). The spontaneous release of NO from nitrosothiols in the presence of thiol is a well-studied phenomenon (46, 47).

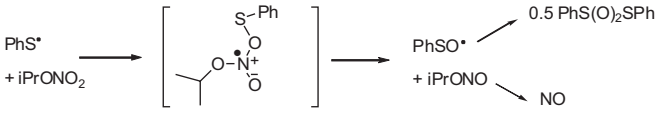
[21] $RS^- + R'ONO_2 \rightarrow RSO^- + R'ONO$

[22] $RSO^- + RSH + H^+ \rightarrow RSSR + H_2O$

[23] $R'ONO + RSH \rightarrow RSNO + R'OH$

[24] $RSNO \rightarrow RS^{\cdot} + NO$

Alternative mechanisms were considered, including an inner-sphere electron-transfer process via an intermediate in thiol-disulfide exchange or a disulfide radical anion. Since



© 2006 NRC Canada

the overall reaction is a $3e^-$ reduction, radicals in addition to NO must be involved or released at some stage of the reaction. In many such reaction mechanisms a thiyl radical is a by-product.

To initiate studies into the reactivity of S-centred radicals with nitrates, thiyl radical, the simplest of such radicals, was studied using photochemical systems to generate the radical in the presence of a simple aliphatic nitrate (IPN). The $PhS^{\bullet}$ radical was generated by photolysis of benzene thiol or the disulfide and characterized by LFP analysis of its characteristic spectrum and decay rates in the presence of DMB. The conjugate addition of the thiyl radical to the DMB diene was also used as a measure of the ability of the nitrate to react with thiyl radical and inhibit the addition reaction. Significant inhibition of the formation of addition product from reaction of $PhS^{\bullet}$ with DMB was only observed at high concentrations of the nitrate ([IPN] = 1.0 mol/L). The reaction of the benzene thiyl radical with IPN at this high concentration was studied by identifying the reaction products and quantifying formation as a function of irradiation time. In addition to the expected disulfide product of thiyl radical combination, the sulfonothioate ($PhS(O)_2SPh$), was observed. The observation of this product under the anaerobic reaction conditions demonstrated that the photochemical reaction of thiyl with nitrate involved O atom transfer from nitrogen to sulfur.

Direct reaction of the electrophilic thiyl radical with the HOMO of the nitrate (localized on the nonbonding orbitals of the terminal oxygens) would yield a radical intermediate leading to O atom transfer (eq. [25]). Homolysis of this intermediate yields sulfinyl radical and organic nitrite, with subsequent sulfinyl radical combination leading to the observed sulfonothioate product. An important feature of this mechanism is that the organic nitrite product is a known source of NO (48).

[25]

However, a sulfonothioate is also the major product of the thermal decomposition of *tert*-butyl thionitrate (*t*-$BuSNO_2$) in neutral aqueous solution at room temperature (44), hinting at the formation of $PhSNO_2$ as an intermediate in the photochemical reaction of $PhS^{\bullet}$ with IPN. The simplest route to thionitrate is by the rapid radical combination of NO_2 with thiyl radical.

[26] $PhS^{\bullet} + NO_2^{\bullet} \rightarrow PhSNO_2$

[27] $PhSNO_2 \rightarrow PhSONO \rightarrow PhSO + NO$

[28] $2PhSO \rightarrow 0.5PhS(O)_2SPh$

Evidence against the direct reaction of thiyl with nitrate was seen in the photochemical generation of $PhS^{\bullet}$ from irradiation of PhSSPh at 350 nm in which sulfonothioate formation was greatly reduced from the 35% yield observed on irradiation of PhSH at 300 nm. This observation is compatible with thionitrate formation from NO_2 formed by the initial photolysis of IPN, which would be greatly reduced owing to the negligible absorbance of organic nitrates at 350 nm compared with 300 nm.

Nitration of 4-chlorophenol was used to confirm the nitrate photolysis pathway. The nitration of phenols by NO_2, involving oxidation and radical addition, is a well-known reaction that leads to tyrosine nitration in vivo. 4-Chlorophenol was used as a NO_2 trap, where formation of 4-chloro-2-nitrophenol revealed release of NO_2 upon irradiation of PhSH–IPN at 300 nm. In contrast, significantly less NO_2 was observed from irradiation of PhSSPh–IPN at 350 nm, compatible with the very weak absorbance of nitrates at higher wavelength.

The use of the 4-chlorophenol trap was validated by observation of nitration by unpurified NO gas containing NO_2 impurity, whereas purified NO gave almost no nitration product. Treatment of a PhSH solution with NO–NO_2 gave substantial formation of $PhS(O)_2SPh$, which was not observed with purified NO gas, supporting photolysis of IPN to NO_2 as the source of sulfonothioate. The thermal experiments with the gaseous NO–NO_2 source confirm that reaction of NO_2 with thiyl radical (eq. [26]) competes both with thiol oxidation and with radical combination with NO (eqs. [29]–[31]), which is in accord with literature rate data.

[29] $RSH + NO_2 \rightarrow RS^{\bullet} + HNO_2$

[30] $RS^{\bullet} + NO_2 \rightarrow RSNO_2$

[31] $NO + NO_2 \rightarrow N_2O_3$

In addition to photolysis to NO_2, the irradiation of PhSH–IPN solutions generated a reasonable flux of NO, with the presence of thiol being a requirement. This novel observation is entirely compatible with the rearrangement of the thionitrate intermediate to yield NO (eq. [27]), which we have previously reported in the context of the thermal decomposition of a thionitrate (44).

A large part of the early work on organic nitrate reactivity, including photochemistry, is part of the impressive ouevre of Canadian carbohydrate chemists, and published in this journal (49, 50). From these and other studies, it is seen that various benzyl nitrates are photolabile, whereas simple aliphatic nitrates require extended reaction times to observe photolysis products (51, 52). Work by Csizmadia and Hayward investigating the photolysis of hydrobenzoin and acenaphthenediol dinitrates in benzene found the predominant process to be photolysis to NO_2 (49, 50). This was validated by the detection of NO_2 as a reaction product using ESR spectroscopy (49). There is no evidence for direct photolysis leading to NO.

Calculation of the thermodynamics for homolysis of IPN reveals the BDE and ΔG of reaction to be 43.7 and 31.6 kcal/mol, respectively, (1 cal = 4.184 J) employing CBS-QB3//B3LYP methodology. The structure of the first excited state was calculated and the energy shown to be 54 kcal/mol above the ground state (Table 1). The calculated BDE for a nitrate is substantially larger than that for homolysis of the S—N bond of a nitrosothiol as shown by comparison of the thermochemical data calculated for $MeONO_2$ and MeSNO, which reveals a BDE for the nitrate greater by 11 kcal/mol. Nitrosothiols are well-known to be labile to photolysis to NO. Nitrosothiol photolysis is facili-

tated by significant absorbance and a λ_{max} above 300 nm, in contrast to nitrates.

The disulfanyl dinitrate (GT-130) might be anticipated to undergo competitive photolysis to yield either PhS$^{\cdot}$ or NO_2. Good evidence for efficient thiyl radical formation was obtained, but no evidence for formation of NO_2 was found. This novel nitrate, containing a phenyl disulfanyl group linked to an organic nitrate, introduces the possibility of an intramolecular reaction between thiyl radical and the nitrate functionality. Photolysis of GT-130 (5 mmol/L) was observed to give a reasonable rate of NO flux, but the rate was lower than from the thermal reaction of GT-130 with thiol.

Taken together, the results of this study provide no support for a rapid reaction between thiyl radical and organic nitrate. Despite weak absorption of light >300 nm and a relatively high BDE for homolysis, the dominant photochemistry under conditions required to generate thiyl radical was driven by nitrate photolysis to NO_2. The observation of both sulfonothioate and NO as products of reaction is readily explained by the formation of a thionitrate intermediate and provides further evidence that thionitrates are a source of NO. A novel nitrate containing a phenyl disulfanyl group did not undergo photolysis to NO_2, nor generate sulfonothioate, but did yield NO. The observations with the novel nitrate suggest that reaction between thiyl radicals and nitrates leading to NO release is a viable pathway, but is subservient to other competing reactions, such as photolysis in the case of IPN and reaction with thiolate in the case of the novel nitrate.

Sulfonated-polydimethylsiloxane (PDMS) microdevices with enhanced electroosmotic pumping and stability[1]

Bin Wang, J. Hugh Horton, and Richard D. Oleschuk

Abstract: Polydimethylsiloxane (PDMS) microfluidic devices offer several advantages in terms of cost and ease of fabrication compared with those fabricated from both glass and silicon materials. PDMS, however, has some potential disadvantages compared with other materials including high hydrophobicity, which makes filling the micron-sized channels difficult, and minimal surface charge resulting in reduced electroosmotic flow (EOF). Here, we describe the oxidation of the PDMS surface to form silanol groups using both air plasma and a discharge from a Tesla coil, and subsequent modification to form sulfonated-PDMS surfaces. The flow performance of freshly prepared and aged sulfonated-PDMS chips was determined at pH 5 and compared with those of unmodified and oxidized PDMS chips. The electroosmotic mobility (μ_{eo}) for a sulfonated-PDMS microdevice was determined at various pH values (pH 3~8) and compared with that for an oxidized PDMS chip. The lower pK_a of a sulfonic acid modified surface compared with a silanol modified surface generated a stronger EOF over the entire pH range studied. Chemical force titrations were used to characterize the changes in functional groups present on the surface of freshly prepared and aged sulfonated-PDMS surfaces. These experiments show that the sulfonated-PDMS is a superior material for use in microfluidic applications because (*i*) it supports EOF over a much wider range of pH than similar polymer materials and (*ii*) is less susceptible to degradation of its EOF rate owing to air aging effects and surface reorganization.

Key words: polydimethylsiloxane (PDMS), sulfonated surface modification, electroosmotic flow (EOF), aging effect, chemical force titrations.

Résumé : Les dispositifs en polydiméthylsiloxane (PDMS) microfluide offrent de nombreux avantages en termes de coût et de facilité de fabrication par comparaison à ceux fabriqués de matériaux tant en verre qu'en silicone. Toutefois le PDMS possèdent quelques désavantages par rapport aux autres matériaux, dont son caractère hydrophobe élevé qui rend difficile le remplissage de canaux de la taille du micron et une charge superficielle minimale qui réduit l'écoulement électroosmotique (EEO). On a effectué une oxydation de la surface du PDMS en faisant appel à un plasma d'air ainsi qu'une décharge à partir d'une bobine de Tesla qui a conduit à la formation de groupes silanols qui ont été par la suite modifiés pour former des surfaces de PDMS sulfoné. Opérant à un pH de 5, on a déterminé la performance d'écoulement de copeaux de PDMS sulfoné fraîchement préparé et vieilli et on l'a comparée à celles de copeaux de PDMS non modifié et de copeaux de PDMS oxydé. On a déterminé la mobilité électroosmotique (μ_{eo}) d'un microdispositif en PDMS sulfoné sur une plage de pH allant de 3~8 et on l'a comparée à celle d'un copeau de PDMS oxydé. Le fait que le pK_a est plus bas pour une surface modifié avec de l'acide sulfonique que celui d'une surface modifiée en silanol fait que le EEO est plus élevé sur toute la plage de pH étudiés. On a utilisé des titrages de la force chimique pour caractériser les changements dans les groupes fonctionnels présents sur les surfaces de PDMS sulfoné fraîchement préparé et vieilli. Ces expériences montrent que le PDMS sulfoné est un matériau dont l'usage est avantageux dans les applications microfluides en raison (*i*) du fait qu'il supporte un EEO sur une plage plus grande de pH que les matériaux polymères similaires et (*ii*) du fait qu'il est moins susceptible de subir une réorganisation de sa surface ou de voir son taux de EEO dégradé en raison d'effets de vieillissement par l'air.

Mots clés : polydiméthylsiloxane (PDMS), modification de la surface par sulfonation, écoulement électroosmotique, EEO, effet de vieillissement, titrages de la force chimique.

Introduction

Recently, polymeric micro-total analysis system (μ-TAS) devices have been developed as an alternative to expensive glass- and silicon-based devices. Many polymer types have been investigated for their use as substrate materials including polydimethylsiloxane (PDMS) (1–4), polymethylmethacrylate (PMMA)(5, 6), polycarbonate (PC) (6), polyethylene (PE) (4), and polystyrene (4), amongst others. The composition of polymer materials can be readily adapted to suit a particular application or the polymer can be surface modified to alter its characteristics. Different surface functionalities, such as carboxyl groups and amine groups, can be generated during the modification process to appropriately alter the surface chemistry and may also be used to further functionalize the surface with biochemical reagents such as proteins and antibodies (4, 7–9). PDMS has been widely investigated as a material for constructing microfluidic devices because of the relative ease with which devices can be fabricated using micromolding (1, 2). PDMS, however, has some potential disadvantages compared with other materials, including high hydrophobicity, which makes filling the micron-sized channels difficult, and minimal surface charge resulting in reduced electroosmotic flow (EOF). A plasma oxidation method has been used to form silanol groups on PDMS surfaces to increase the surface charge and make the surface hydrophilic (10, 11). As a result, the Si-CH_3 groups on the PDMS surface can be modified through oxidation to Si-OH, which increases the microchannel EOF rate owing to an increase in the surface ζ potential arising from deprotonation to form SiO^- sites. One significant drawback of this surface modification is that it is only temporary. Following oxidation, the PDMS begins to revert back to its original surface properties, which has been ascribed to the diffusion of low molecular weight polymer from the bulk to cover SiO_x sites on the surface (12–14). Other groups have covalently attached a variety of functional groups to PDMS surfaces to augment microfluidic device performance (15–18). In particular, Hu et al. (16) have used UV light to graft a series of acrylate monomers onto PDMS surfaces and measured the electroosmotic flow characteristics of resulting devices. Slentz et al. (18) have utilized a metal-catalyzed radical polymerization reaction to graft sulfonic acid containing moieties on the surface of PDMS microdevices. Although these coupling strategies yielded PDMS surfaces with different functionalization, the grafting process is more complicated than that described here. Chemical derivatization methods have also been used to extend the effective lifetime of the surface-modified PDMS (16, 18–20). In our previous work, we described a facile two-stage surface modification process for PDMS, consisting of an oxidation step followed by chemical derivatization with aminopropyltriethoxysilane (APTES) to form amine groups on the PDMS surface (19, 20). The APTES group enhanced the stability of the surface modification considerably. However, the surface ζ potential also changed sign: at low pH values (≈3.0), the flow within the microfluidic device could be reversed (anodic EOF) compared with native PDMS (cathodic EOF) through the protonation of the amino group on the PDMS surface.

Oxidized PDMS microchips show excellent flow performance at high pH values. However, the EOF rate in oxidized microchannels is reduced at pH values near the pK_a of the SiOH (≈4 to 5) because of protonation of the SiO^- sites and a consequent decrease in ζ potential. To increase the pH range over which strong cathodic EOF can be maintained, a chemical derivatization method was employed using 2-(4-chlorosulfonylphenyl)ethyltrimethoxysilane (SUFTMS) as the surface modification reagent. This compound has been previously used to terminate oxidized silicon wafers with sulfonic acid groups (21). In this paper, we describe the oxidation of the PDMS surface to form silanol groups using both air plasma and a discharge from a Tesla coil, with subsequent modification to form sulfonated-PDMS surfaces that have a lower surface pK_a than the unmodified silanol. The flow performance of freshly prepared and aged sulfonated-PDMS microchips is compared with that of unmodified and oxidized PDMS chips. Chemical force titrations (22, 23) are used to characterize changes in functional groups present on the surface of freshly prepared and aged sulfonated-PDMS surfaces. AFM imaging is also used to follow changes in surface morphology and patterning effects on the PDMS and showed that the stability of sulfonated-PDMS surfaces is significantly improved (in other words, the aging effect is reduced) and is comparable to that of the amine-modified PDMS surfaces. This report discusses devices that have been aged in air. This represents a worst-case scenario for aging as others have shown that contacting a modified PDMS surface with a solvent of higher surface free energy results in a greatly reduced aging effect (13, 14). The surface modification protocol described in this paper is facile, extends the application of polymer-based materials in microfluidic devices to lower pH, and aids in maintaining the surface and electrokinetic pumping characteristics of PDMS devices.

Experimental section

Chemical reagents

Sylgard 184 silicone elastomer and curing agent were purchased from Dow Corning Corporation (Midland, Michigan). Cy5™ monocarboxyl dye was purchased from Amersham Pharmacia Biotech UK (Amersham, UK). 2-(4-Chlorosulfonylphenyl)ethyltrimethoxysilane (SUFTMS), acetic acid, sodium salt (anhydrous reagent ACS), and pyridine (reagent ACS) were obtained from ACROS Organics (New Jersey). Potassium phosphate, sodium hydroxide, and methylene chloride (dichloromethane) were purchased from Fisher Scientific (Fair Lawn, New Jersey), while acetic acid (glacial), phosphoric acid, and hydrochloric acid were acquired from Fisher Scientific (Nepean, Ontario). Toluene was obtained from Anachemia Canada (Montréal, Quebec).

Fabrication of PDMS microchips and surface modification

Fabrication protocols for PDMS microchips based on a Sylgard 184 PDMS formulation have been described in detail elsewhere (19) and will only be briefly outlined here. Sylgard 184 PDMS prepolymer was mixed thoroughly in a 10:1 mass ratio of silicone elastomer to curing agent and poured onto a glass substrate (Twin-T, Micralyne, Edmonton, Alberta) containing six identical electrophoretic devices (as shown in Table 1) that acted as a negative master. The PDMS was polymerized at 65 °C for 4 h and peeled from

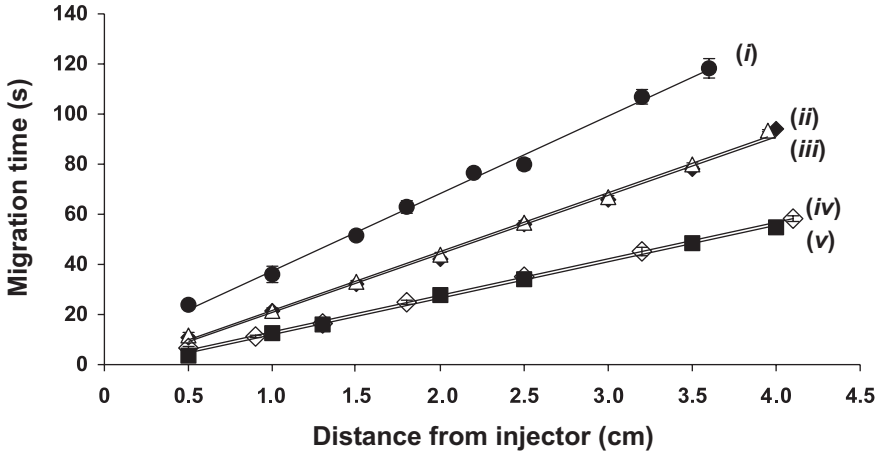
the substrate and then used in a second PDMS molding step to yield the microfluidic substrate. Following this, one of two surface oxidation methods was used. A Tesla coil was used to oxidize the resulting PDMS substrate and an unpatterned cover plate for about 10 min. Alternatively, the PDMS substrate and the unpatterned cover were placed in an air plasma (Harrick Scientific Corporation, Ossining, New York) for 2 min (10 MHz RF level at 70 mTorr, 1 Torr = 133.322 4 Pa). The sulfonated-PDMS devices were produced by immersing the freshly oxidized PDMS substrate and cover into a 20 mmol/L SUFTMS in pyridine solution for approximately 4 h. The PDMS substrate and cover were then immersed in Milli-Q deionized water (resistivity 18.2 MΩ cm at 25 °C) for about 0.5 h to hydrolyze the chlorosulfonate groups. After modification was completed, the PDMS substrate and cover were dried in a stream of dry nitrogen gas. They were then laid on top of one another, forming a reversible air- and water-tight seal.

The SUFTMS compound is commercially available as a 50% solution in dichloromethane. Initial attempts to prepare sulfonic acid terminated PDMS surfaces used this solution diluted to a 20 mmol/L concentration in either dichloromethane or toluene. Immersion in such solutions, even for short times, resulted in a cloudy, etched polymer. This was ascribed to acid etching of the PDMS by sulfonic acid produced by hydrolysis of SUFTMS from trace amounts of water in solution. Using the weakly basic pyridine as a solvent eliminated this problem.

Migration time measurements and electroosmotic mobility (μ_{eo}) measurements

A microfluidic tool kit (Micralyne, Edmonton, Alberta) was used to determine the migration rates of fluorescent samples of Cy5™ (1.4 μmol/L) in the different substrate materials. The kit consists of a high-voltage (HV) power supply coupled with a laser-induced fluorescence (LIF) detection system (635 nm diode laser with a 670 nm band pass filter for detection of Cy5™ fluorescence). The detector was moved manually from the intersection of the injection channel and separation channel along the length of the separation channel to measure the migration time at each detector distance for each substrate material. An identical voltage program for injection and separation was used for all migration time experiments at pH 5.0, as shown in Table 1*a*. These two-step programs were repeated six times for replicate injection and migration measurements.

The measurement of electroosmotic mobility (μ_{eo}) in the microchannels was performed using current monitoring (3). The microchannels were first filled with a low ionic strength buffer (5 mmol/L). Subsequently, the buffer reservoir (as shown in Table 1) was emptied and filled with a higher ionic strength buffer (10 mmol/L). The electrodes were then placed in the two wells (buffer reservoir and buffer waste reservoir) and the current monitored as a function of time. The current increases owing to filling of the microchannel with the higher ionic strength buffer. The EOF was measured at various pH values using either phosphate (pH 3, 6.2, 7, and 8) or acetate (pH 4 and 5) buffer solutions.



As a result of using two methods to determine the flow performance of PDMS devices, we need to compare the consistency of these two methods. In the EOF rate measurements, the rate of migration (apparent mobility, μ_{app}) for the charged fluorescent marker is a combination of the electrophoretic mobility (μ_{ep}) of negatively charged Cy5™ dye and electroosmotic mobility (μ_{eo}) where:

$$[1] \qquad \mu_{app} = \mu_{ep} + \mu_{eo}$$

Using the data for oxidized PDMS at a pH of 8, the migration rate of oxidized PDMS (20) is (10.4 ± 0.2) × 10^{-2} cm/s, which is (2.6 ± 0.2) × 10^{-4} cm^2/V s (μ_{app}).

© 2006 NRC Canada

Fig. 1. Migration times of a Cy5™ marker in a PDMS microfluidic device, whose flow channels had undergone various surface modifications. All flow measurements were performed at a pH of 5.0, immediately following surface modification. (*i*) Unmodified PDMS (●); (*ii*) PDMS oxidized using the Tesla coil method (Δ); (*iii*) PDMS oxidized using the air plasma method (◆); (*iv*) PDMS oxidized using the Tesla coil and subsequently modified with sulfonic acid (◇); (*v*) PDMS oxidized using the air plasma method and subsequently modified with sulfonic acid (■).

The μ_{ep} of negatively charged Cy5™ is $(-1.7 \pm 0.2) \times 10^{-4}$ cm^2/V s (20). Therefore, μ_{eo} for oxidized PDMS is $(4.3 \pm 0.2) \times 10^{-4}$ cm^2/V s. In comparison, current monitoring showed the EOF of oxidized PDMS at pH 8 to be $(4.5 \pm 0.2) \times 10^{-4}$ cm^2/V s. The results show that these two flow performance measurement methods are comparable and can be used interchangably.

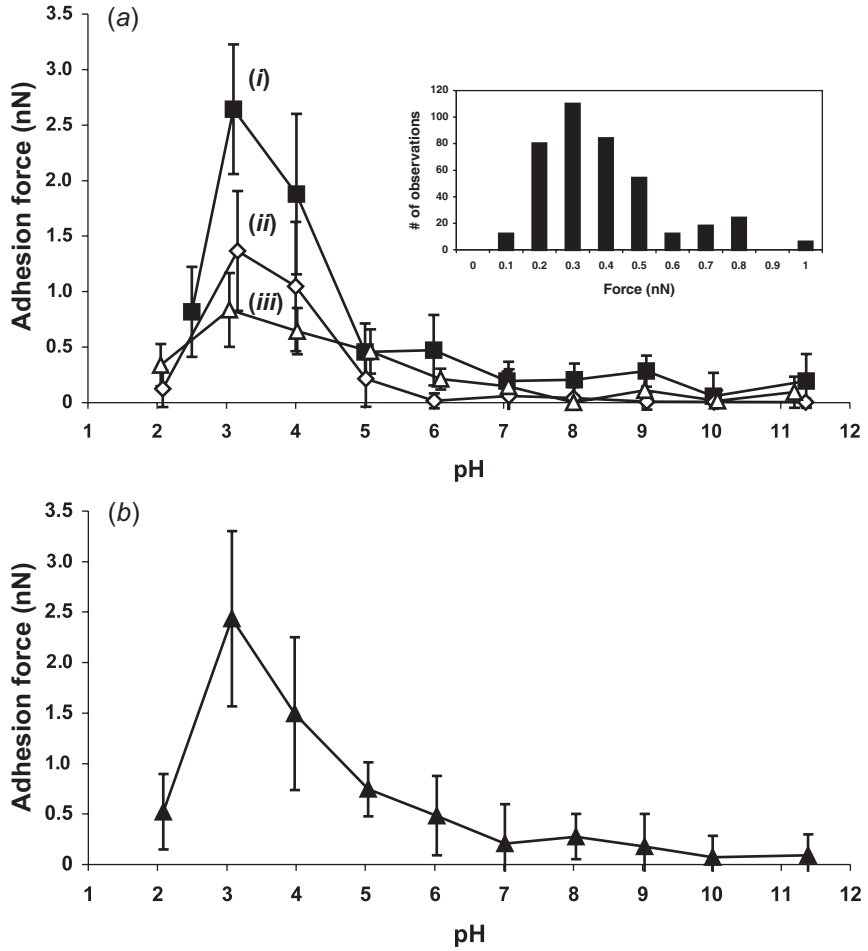
Surface characterization using AFM

All AFM image data shown were acquired using a PicoSPM (Molecular Imaging, Tempe, Arizona) and a Nanoscope IIE controller (Digital Instruments, Santa Barbara, California). Images were acquired in air, using intermittent contact mode, while chemical force measurements were carried out in solution. All CFM data was acquired on a PDMS film cast in a similar manner to the cover plates used in microfluidic chip manufacture. The PDMS film underwent exactly the same synthesis and surface modification procedures as cover plates used in the manufacture of the microfluidic chips. The cantilevers used for image acquisition were terminated with standard Si_3N_4 tips (40–100 nm) and had a resonance frequency of ~100 kHz. Height and phase shift data were recorded simultaneously, although only the height mode images are shown here. Images were recorded at scan rates of 1 to 2 Hz using a 30 μm × 30 μm scanner.

Chemical force titration data were obtained using the same apparatus (23, 24). Force–distance curves were acquired using freshly prepared unbuffered NaOH or HCl solutions of pH ranging from 2–12. Unbuffered solutions were chosen to avoid potential interference of buffer ions in solution on the probe–substrate interactions. Solutions were checked after each experiment to ensure that their pH had not changed significantly. Experiments were carried out at low ionic strength conditions (0.01 mol/L), i.e., the only ions in solution were those introduced by pH adjustment with NaOH and HCl. Some 300–500 force–distance curves were obtained for each sample. The reported values of the adhesive interaction are an average of all the force curves obtained, while the reported errors reflect the standard deviation of the data. The AFM tips used in the chemical force titration measurements were silicon oxide sharpened silicon nitride tips. The tips were functionalized with sulfonic acid end groups by immersion in a 20 mmol/L pyridine solution of SUFTMS for 24 h, then immersed in Milli-Q deionized water for about 0.5 h, finally drying in a stream of nitrogen gas. The force constants of the cantilevers ranged from 0.08 to 0.4 N m^{-1} as determined by the method of Hutter and Bechhoefer (25).

Results

The flow characteristics of devices constructed from unmodified PDMS and PDMS, which had undergone various oxidation and sulfonic acid modification treatments, are shown in Fig. 1. Migration rates were determined at different distances from the injector to enhance measurement accuracy. The graph shows the time taken for the fluorescent Cy5™ marker to migrate down the channel, as a function of the distance from the injector at which the detector is placed. In Fig. 1, a steep slope corresponds to a long migration time and thus a low electroosmotic flow velocity (v_{EOF}), while a shallow slope corresponds to a high v_{EOF}. All flow measurements shown in Fig. 1 were performed at a pH of 5.0. From the graph we may observe that devices constructed from oxidized PDMS exhibit similar flow rates regardless of whether the Tesla coil (curve *ii*) or plasma method (curve *iii*) is used. Devices constructed from sulfonated-PDMS (curve *iv* and *v*) exhibit larger v_{EOF}, but again the initial oxidation method seems to have little effect.



The migration rates, determined using the data in Fig. 1, for modified PDMS surfaces are summarized in Table 2. These measurements were carried out within 1 h of the sample treatment process ("freshly prepared"). We may note that devices from freshly prepared oxidized PDMS exhibit a migration rate that is 35% faster than that of unmodified PDMS at pH 5. Devices made from freshly prepared

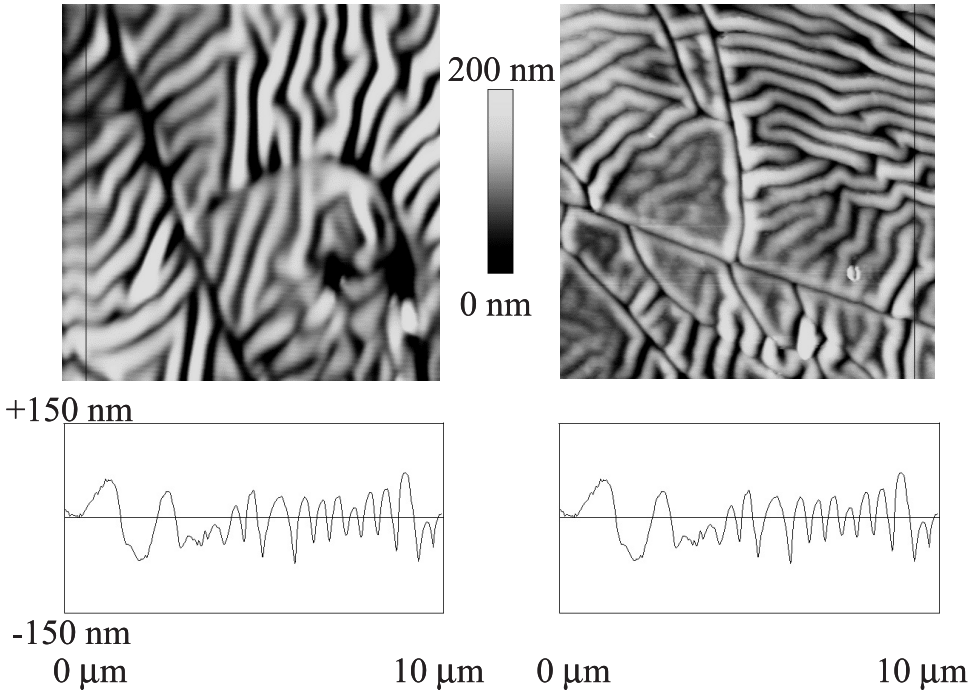
Table 2. Migration rates for modified PDMS surfaces.

Chip surface treatment	Aging time	Migration rate ($\times 10^{-2}$ cm/s)
Unmodified PDMS	Freshly prepared	3.2±0.1
Oxidized PDMS (Tesla coil)	Freshly prepared	4.2±0.1
Oxidized PDMS (air plasma)	Freshly prepared	4.3±0.1
Sulfonic acid modified PDMS (Tesla coil oxidized)	Freshly prepared	6.8±0.1
Sulfonic acid modified PDMS (air plasma oxidized)	Freshly prepared	6.8±0.1
	24 h	6.5±0.1
	10 Days	5.1±0.1

Fig. 2. Chemical force titration curves showing the adhesive force between an AFM tip terminated with sulfonic acid and various substrates as a function of solution pH. The error bars represent the standard deviation in the adhesion force as measured from the average of 300–500 force-distance curves. (*a*): (*i*) PDMS substrate oxidized using the air plasma method and subsequently modified with sulfonic acid, freshly prepared (■); (*ii*) a 24 h aged PDMS substrate oxidized using the air plasma method and subsequently modified with sulfonic acid (◇); (*iii*) a 10 day aged PDMS substrate oxidized using the air plasma method and subsequently modified with sulfonic acid (Δ). The inset shows a typical adhesion force histogram, in this case obtained for the 10 day aged PDMS sample oxidized using air plasma and subsequently modified with sulfonic acid at pH 2.05. (*b*) A PDMS substrate oxidized using the Tesla coil and subsequently modified with sulfonic acid, freshly prepared (▲).



sulfonated-PDMS exhibit a migration rate that is 112% faster than that of unmodified PDMS. Migration times are about 60% faster than those PDMS devices that had only undergone the oxidation step.

Flow rate experiments were also carried out on sulfonic acid modified PDMS 24 h and 10 days after the surface modification process had been carried out ("aged" samples). They are also shown in Table 2. From the table we may observe that the freshly prepared sulfonated-PDMS exhibits the fastest v_{EOF}, while the 24 h aged sulfonated-PDMS exhibits a similar but somewhat slower (4%) migration rate in comparison. The 10 day aged sulfonated-PDMS is 25% slower than that of freshly prepared sulfonated-PDMS.

The aging flow results should be considered in conjunction with Fig. 2*a*, which shows the results of the chemical force measurements for freshly prepared, 24 h aged and

Fig. 3. AFM images (scale 10 μm) of sulfonic acid modified PDMS formed by exposure of air plasma oxidized PDMS to a solution of SUFTMS. The left image shows the surface within 2 h of forming the sulfonic acid modified surface, while the right one shows the same sample 10 days later. Image scales are noted in the figure. Cross sections of the images appear directly below the relevant image, and the cross section is indicated with a black line on the image.

10 day aged sulfonic acid modified air plasma oxidized PDMS surfaces. In all cases, measurements were carried out using a silicon oxide sharpened Si_3N_4 tip derivatized with SUFTMS and then rinsed with Milli-Q deionized water, to form a sulfonic acid terminated layer on the tip. The same tip was used to acquire all three curves. In Fig. 2*a*, the adhesive force observed between the AFM tip and the sample surface is plotted as a function of the solution pH. This is referred to as a force titration curve. The freshly prepared sulfonic acid modified PDMS (curve *i*) has an adhesive interaction of 2.7 nN, with a maximum peak near a pH of 3. The 24 h aged sulfonic acid modified PDMS (curve *ii*) also exhibits a maximum at a pH of 3 but which has been reduced in magnitude to 1.4 nN. The 10 days aged sulfonic acid-modified PDMS (curve iii) shows weaker force interaction of 0.8 nN, but the maximum still remains at pH 3. The inset depicted in Fig. 2*a* represents a typical force histogram comprised of 300–500 individual measurements that are translated into an average tip/sample adhesive force.

Figure 2*b* shows the result of the chemical force measurements for freshly prepared sulfonic acid modified Tesla coil oxidized PDMS surfaces. We may observe that the adhesive force between the sulfonic acid terminated Si_3N_4 tip and the sample surface is about 2.5 nN, with a maximum peak near a pH of 3. The magnitude and position of the peak are all similar with that of freshly prepared sulfonic acid modified air plasma oxidized PDMS surfaces, as shown in Fig. 2*a*.

In Fig. 3, we show two AFM images of a PDMS substrate, which had been oxidized by air plasma and subsequently exposed to the 20 mmol/L pyridine solution of SUFTMS to form a sulfonic acid terminated surface. The left image, at the 10 μm scale, taken within 2 h following the sulfonation process, shows undulating surface features. Such features are not observed on the original unmodified or solvent exposed (blank) PDMS samples (19). The right image, taken at the same scale as the left one, shows that after 10 days the structures remain essentially intact on the surface. Cross sections of the freshly prepared and aged surfaces shown in the figure demonstrate that the height and width of the features remain essentially unchanged after 10 days.

The EOF profiles of freshly prepared sulfonic acid modified air plasma oxidized PDMS and freshly prepared air plasma oxidized PDMS as a function of pH are shown in Fig. 4. Electroosmotic mobility measured in sulfonated-PDMS microchannels (curve *ii*) showed significantly higher values at all pH values studied when compared with the oxidized PDMS (curve *i*). Figure 5 and Table 3 show the electrophorograms and corresponding efficiencies obtained by injection and separation of a Cy5™ sample plug with differently modified substrate materials.

Discussion

The results of the flow experiments shown in Table 2 may be interpreted by considering that during electroosmosis in the microfluidic device, the flow velocity is directly proportional to the potential gradient (E) along the microchannel (26):

$$[2] \qquad \nu_{EOF} = \frac{\varepsilon_0 \varepsilon_r \zeta E}{\eta}$$

Table 3. The efficiencies obtained by injection and separation of a Cy5™ sample plug with differently modified substrate materials.

PDMS surface modification	Efficiency (plates/m)	t_R (RSD %) n = 50
Unmodified	58 000	3.1
Oxidized	108 000	2.3
Sulfonic acid	83 000	1.4

where ζ is the potential of the surface (i.e., the potential at the boundary between bound and free solvent and (or) electrolyte at the surface), ε_0 is the vacuum permittivity, ε_r is the relative permittivity of the solution, and η is the dynamic viscosity of the solution. Since both the buffer and potential gradient used in each case are identical within the set of experiments, the relative values of the measured ν_{EOF} are a direct measure of the relative ζ potential, and hence the fixed charge density on the surface of the PDMS.

The results in Fig. 1 demonstrate that the unmodified PDMS surface shows the slowest flow rate, and hence the smallest ζ potential. This might be initially considered surprising, as native PDMS should contain no surface ionizable sites under these conditions, and we would hence expect no EOF at all. Using X-ray photoelectron spectroscopy (XPS), it has been shown that the surface elemental composition of the Sylgard 184 PDMS formulation used here is enriched in oxygen and depleted in carbon by about 5% relative to the expected stoichiometric ratio (27, 28). The higher content of oxygen was attributed to the contribution from the silica filler, even though previous studies suggested that silica filler is rarely observed in the depth range probed by XPS (~7–10 nm) (29, 30). This may explain the small EOF observed in native PDMS microchannels as being due to residual SiOH sites being exposed on the surface.

Following oxidation using either the Tesla coil or air plasma method, the flow rate and hence the ζ potential increases, demonstrating that sites have been formed on the

© 2006 NRC Canada

surface that are ionizable under the pH 5 conditions of the flow experiments. Previously published (19, 20) chemical force titration measurements showed that the average surface pK_a of oxidized PDMS (Si-OH) is between 4 and 5. Therefore, there are ionizable Si-O$^-$ sites on the oxidized PDMS surface at pH 5.

We and others (12, 14, 16, 20) have observed that oxidized PDMS surfaces rapidly lose their efficacy in supporting electroosmotic flow through an "aging effect". This effect has been attributed to the rapid diffusion of surface hydroxyl sites into the bulk (surface reorganization), reducing the availability of ionizable groups at the surface. Such diffusion is aided by the fact that the oxidation process results in breaking of the polymer chain in the surface region, with the concomitant production of shorter chain oligomers that can undergo much more rapid diffusion. While the oxidized surfaces indeed effectively support electroosmotic flow, the aging effect means that they are not useful as a means of permanently augmenting flow in PDMS microfluidic devices. Instead, we considered the possibility of further surface modification to form ionizable groups that are more stable. In this study, we terminate the PDMS surface with sulfonic acid functional groups by means of SUFTMS treatment of the oxidized PDMS.

We may observe from Fig. 1 that sulfonated-PDMS microchips exhibit a ν_{EOF} that is double that of unmodified PDMS. The higher flow rate demonstrates that the surface negative charge density is increased dramatically. Chemical force titration measurements (Fig. 2*a*, curve *i*) on freshly prepared sulfonated-PDMS surfaces oxidized using the air plasma shows a maximum peak at a pH of 3. Previous workers have shown that, under low ionic strength conditions, the maxima in chemical force titration plots occur at pH values that are at the surface pK_a of the ionizable group (23, 31). At the surface pK_a, exactly half of the sites are ionized on both the tip and the sample. This allows for maximum ionic hydrogen bonding taking place, leading to a maximum adhesive interaction. Since the tip and sample site in this study contain the same functional group, the maximum should appear at the average surface pK_a of sulfonic acid. Figure 2 indicates that the pK_a of the sulfonated-PDMS surface is about 3.0. This value is higher than the typical pK_a of a sulfonic acid group in solution. Such a result is typically observed and may be attributed to two effects: intermolecular H-bonding taking place among neighboring SO_3H groups on the surface and the absence of charge screening among neighboring SO_3^- sites on the sample surface.

With the lower surface pK_a, there are many ionized SO_3^- sites on the sulfonated-PDMS surface at the pH 5 conditions under which the flow measurements were carried out. The ν_{EOF} in sulfonated-PDMS microchannels is 60% faster than that of oxidized PDMS.

In this study, we compared two surface oxidation methods: Tesla coil and air plasma oxidation. According to the migration rates shown in Fig. 1 and Table 2, it is apparent that these two methods can achieve the same oxidizing effects. Sulfonating derivatization following either oxidation method results in modified PDMS devices that exhibit the same flow performance ($(6.8 \pm 0.1) \times 10^{-2}$ cm/s). Chemical force titration results (Figs. 2*a* and 2*b*) show that freshly prepared sulfonated-PDMS substrates that have undergone oxidation with either air plasma or Tesla coil exhibit a maximum peak at the same position (pH 3) and similar magnitude (2.5~2.7 nN). Chemical force titration results confirm the conclusion that Tesla coil and air plasma oxidation are comparable oxidizing methods and can be used interchangably.

The flow characteristics of freshly prepared, 24 h and 10 day aged sulfonated-PDMS devices at pH 5 are also shown in Table 2. From the table, we observe that the freshly prepared sulfonic acid modified PDMS exhibits the fastest ν_{EOF}, while the 24 h aged sulfonic acid modified PDMS exhibits similar but somewhat slower (4%) ν_{EOF} in comparison. After 10 days, the migration rate is $(5.1 \pm 0.1) \times 10^{-2}$ cm/s, which is 75% of that of freshly prepared sulfonated-PDMS. We may observe that after exposure in air for 10 days, the ν_{EOF} of aged sulfonated-PDMS is still higher than that of freshly prepared oxidized and unmodified PDMS under the pH 5 conditions. The sulfonated PDMS surface shows similar stability to mixed monomer grafted PDMS over a 24 h period (16), however, comparing stability beyond 24 h is not possible as the previous study did not monitor aging effects for longer than 24 h in air. Also, a long term stability experiment was performed by Slentz et al. (18) that showed the sulfonic acid coating was stable for greater than 1 month. However, the details of device storage were not given so a direct comparison of the relative stabilities of the grafting and derivatization methodologies is not possible.

In previously published work, we found the changes in ν_{EOF} owing to aging of PDMS modified with an amine group was of effectively the same magnitude (20), although we cannot compare the absolute ν_{EOF} values of amine modified and sulfonic acid modified PDMS since they have opposite surface charges. In effect then, whatever the mechanism of the aging process, it results in a loss of a similar relative number of ionizable sites on the surface, regardless of which species — amine or sulfonic acid — has been grafted onto it.

The force titration curves shown in Fig. 2*a* are consistent with the flow performance results. As the sulfonic acid terminated surface ages over a period of 24 h and then 10 days, we can see from curves *ii* and *iii* that the extent of the force interaction between tip and sample diminishes. This indicates that the SO_3H sites are diffusing away or being covered up from the surface layer. Unlike the oxidized case (20), however, even after 10 days enough sulfonic acid sites remain on the surface to produce a recognizable force titration curve. This is consistent with the SUFTMS forming a denser cross-linked surface layer that would inhibit oligomer migration into the surface region. The AFM images of the aged surface in Fig. 3 are also consistent with this: the undulations remain intact and the surface morphology does not change dramatically after 10 days of aging. Only some finer structures disappear suggesting that the surface layer undergoes a slow reorganization, leading to fewer sulfonic acid sites exposed on the surface.

Finally, we used the current monitoring method to measure EOF mobility in modified PDMS microchannels at various pH values. The electroosmotic mobility (μ_{eo}) is obtained by eq. [3]:

$$[3] \qquad \mu_{eo} = L/(tE)$$

© 2006 NRC Canada

where L is the effective length from buffer reservoir to buffer waster reservoir, t the time to reach the current plateau, and E the applied field strength (3, 32).

With a lower surface pK_a of 3, the sulfonic acid terminated PDMS should be more appropriate for use in microfluidic devices operating under low pH conditions owing to its ability to support higher negative charge density below pH 5. We compared the EOF in sulfonated-PDMS and oxidized PDMS microchannels at various pH values from 3 to 8, as shown in Fig. 4. Under the pH 3 conditions, according to the definition of pK_a, half of the sulfonic acid groups present on the surface should be deprotonated to form -SO_3^-. The experimentally measured EOF is $(2.44 \pm 0.04) \times 10^{-4}$ cm^2/V s, higher than the measured EOF of oxidized PDMS at pH 5 ($(2.22 \pm 0.02) \times 10^{-4}$ cm^2/V s), which is above the surface pK_a value of Si-OH. Indeed, we observe from Fig. 4 that sulfonated-PDMS shows higher EOF at all pH values when compared with that of oxidized PDMS.

Previous workers (6) have compared the EOFs for sulfonated-polycarbonate and unmodified polycarbonate at pH values from 4 to 10. They found that EOFs measured in sulfonated-PC microchannels showed significantly higher values at pH below 8 when compared with the unmodified PC. However, the EOFs of both PC surfaces were similar from pH 8 to 10, thus indicating that the surface charge density was comparable at those pH (6). In our case, under the pH 8 condition, the EOFs of two modified PDMS surfaces were not comparable. From Fig. 4, we may also observe that curve *i* and curve *ii* show similar shapes. This may be related to the property of PDMS from which the devices are constructed and the inflection point (pH ≈5.5) has been interpreted to correspond to acidic groups in the PDMS support (3). These results demonstrate that sulfonated-PDMS is a superior material for generating improved EOF and stability at all pH values, compared with oxidized PDMS.

The relative separation efficiencies produced by the unmodified and modified PDMS substrates are quite different (Fig. 5 and Table 3). The oxidized PDMS substrate produced the highest efficiencies (≈108 000 plates/m), followed by the sulfonic acid modified (≈83 000 plates/m), and unmodified (≈58 000 plates/m). These efficiencies are similar to those reported for grafting of mixed monomer (17) onto PDMS, but are generally lower than those shown for PDMS grafted with sulfonic acid moieties (18). Slentz et al. (18) have, however, proposed that the separation involved both electrophoretic and chromatographic separation mechanisms, which may explain the increased efficiencies.

Conclusions

The surface modification of sulfonic acid terminated PDMS and the subsequent aging effects on this modified surface have been studied using EOF measurements in microfluidic devices in addition to atomic force and chemical force microscopy.

The sulfonic acid modified PDMS microdevices showed excellent flow performance at various pH values from 3 to 8, compared with oxidized PDMS devices. The sulfonic acid modified surface also showed aging effects; however, the change in EOF was significantly reduced compared with the oxidized surface where flow enhancements resulting from the surface modification disappear in a matter of hours. After 24 h of aging, the migration rate (under pH 5 conditions) in a sulfonic acid modified PDMS chip had dropped by only 4%; after 10 days it was still at 75% of its initial value. Chemical force titrations and AFM imaging demonstrated that there were still reasonable concentrations of sulfonic acid groups present on these aged surfaces. The aging experiment conditions were chosen to represent a worst case scenario, and when modified surfaces are contacted with a higher energy medium, it is expected that the stability of the surface modification will be considerably enhanced.

The results demonstrate that facile sulfonic acid modification can significantly decrease the rate of the surface aging effect and generate a surface with significant ζ potential. Therefore, a sulfonic acid based chemical derivatization is an effective means of improving the flow performance and durability of surface modifications for microfluidic devices made from PDMS. As a result, sulfonated-PDMS is a superior material for use in microfluidic applications because it can support high EOF over a wide range of pH and is less susceptible to degradation of its EOF rate owing to aging effects.

Conformational analysis in aqueous solution and estimation of the persistence length of exopolysaccharides produced by *Lactobacillus helveticus* Lh59 and *Streptococcus macedonicus* Sc136[1]

J. Albert van Kuik, Sébastien J.F. Vincent, Bas R. Leeflang, Loes M.J. Kroon-Batenburg, and Johannis P. Kamerling

Abstract: The conformations of two exopolysaccharides, one produced by *Lactobacillus helveticus* Lh59 and one by *Streptococcus macedonicus* Sc136, were investigated by molecular modelling to get insight into their physical properties. In particular, the influence of side chains and glycosidic linkage types on the overall shapes and persistence lengths of the polysaccharides were studied. It appeared that the side chains had only minor effects on the persistence lengths of the polysaccharides, with the exception of the monosaccharide residue directly attached to the backbone. The extensiveness of the backbone is enhanced by β-D-Hex*p*-(1→4) structural elements, whereas α-D-Hex*p*-(1→3) and α-D-Hex*p*-(1→4) elements create structural variability by introducing bends. The occurrence of either (1→5)- or (1→6)-linked monosaccharides, resulting in one extra bond between monosaccharide units, causes the overall flexibility of the polysaccharide chain to be enhanced and extensiveness to be reduced. The presence of such flexible linkages in the backbone leads to a shorter persistence length than when present in the side chain: a value of only 4.5 nm was found for the *L. helveticus* Lh59 EPS with a (1→5) linkage in the backbone, and a value of 8.5 nm for the *S. macedonicus* Sc136 EPS with two (1→6) linkages in the side chain.

Key words: conformational analysis, exopolysaccharide, *Lactobacillus helveticus*, molecular modelling, persistence length, *Streptococcus macedonicus*.

Résumé : Faisant appel à la modélisation moléculaire, on a étudié les conformations de deux exopolysaccharides, l'un produit par *Lactobacillus helveticus* Lh59 et l'autre par le *Streptococcus macedonicus* Sc136, dans le but de mieux comprendre leurs propriétés physiques. On a étudié particulièrement l'influence des chaînes latérales et les types de liaisons glycosidiques sur les formes globales et sur la longuer de persistance des polysaccharides. Il semble que les chaînes latérales n'ont que des effets mineurs sur la longuer de persistance des chaînes des polysaccharides, à l'exception du résidu monosaccharide attaché directement au squelette. L'étendue du squelette est augmentée par les éléments structuraux β-D-Hex*p*-(1→4) alors que les éléments α-D-Hex*p*(1→3) et α-D-Hex*p*(1→4) créent de la variabilité structurale en introduisant des courbures. La présence de monosaccharides liés soit en (1→5)- ou (1→6)-, qui conduit à la présence d'une liaison supplémentaire entre les unités de monosaccharides, provoque une augmentation de la flexibilité globale de la chaîne polysaccharide et à une diminution de l'étendue du squelette. La présence de telles liaisons flexibles dans le squelette conduit à une longuer de persistance moins longue que celle observée lorsqu'on les retrouve dans les chaînes latérales. La valeur de l'« EPS » pour le *L. helveticus* Lh59 comportant une liaison (1→5) dans le squelette n'est que de 4,5 nm alors que pour le *S. macedonicus* Sc136 comportant deux liaisons (1→6) dans la chaîne latérale, cette valeur est de 8,5 nm.

Mots clés : analyse conformationnelle, exopolysaccharide, *Lactobacillus helveticus*, modélisation moléculaire, longueur de persistance, *Streptococcus macedonicus*.

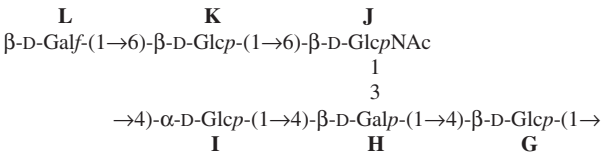
Introduction

In recent years, the interest in exopolysaccharides (EPSs) from lactic acid bacteria (LAB) has increased remarkably in the food industry, mainly because of the thickening capacities of EPSs in dairy products and the GRAS (Generally Recognized As Safe) status of the associated microorganisms (1–3). In the context of getting insight into the physical and (or) rheological properties of EPSs, conformational analysis of these biopolymers in aqueous solution is of the utmost importance. To explore this area, in an earlier investigation we have presented a method for constructing conformational models in water of heteropolysaccharides built up from repeating units, and applied this methodology to the exopolysaccharide produced by *Lactobacillus helveticus* 766 (4). Polysaccharide models were formed from oligosaccharide fragment models that were obtained from molecular dynamics (MD) simulations. The fragments were incorporated in the backbone in a ratio dictated by the population distribution of the glycosidic linkages. These were determined by the method of adaptive umbrella sampling (AUS) of the potential of mean force (PMF) (5).



When cultured in skimmed milk, *L. helveticus* Lh59, one of the attractive alternatives to replace currently used thickeners, produces a high-molecular-mass EPS ($\geq 2 \times 10^6$ Da) with a branched hexasaccharide repeating unit (Scheme 1A) (6). *Streptococcus macedonicus* Sc136, being part of the starter flora present in Greek sheep and used in goat cheese production, produces an EPS with a different branched hexasaccharide repeating unit (Scheme 1B) (7), having a large molecular-mass distribution ranging from 1×10^5 to $\geq 2 \times 10^6$ Da and highly texturizing properties. The viscosity of the growth medium was shown to be significantly reduced by alteration of the EPS side chain (7).

In the present study, the conformational properties of the EPSs of the *L. helveticus* Lh59 and *S. macedonicus* Sc136 strains were investigated. Because the presence and structure of a side chain within the repeating unit of a polysaccharide is a key element for its texturizing properties, specific attention was paid to the relation between the polysaccharide conformation in solution and the side-chain structure as well as to the persistence length of the EPSs.

Scheme 1.

(A) *Lactobacillus helveticus* Lh59 EPS

(B) *Streptococcus macedonicus* Sc136 EPS

Experimental

Nomenclature

For the three staggered conformations of the C5—C6 bonds in hexopyranoses and the C4—C5 bonds in hexofuranoses, the notation *tg*, *gt*, and *gg* was used. In this nomenclature, *g* and *t* are abbreviations of gauche (±60°) and trans (180°), respectively, indicating qualitatively the value of a dihedral angle. The angle of the O_n-C_n-C_{n-1}-O_{n-1} moiety is indicated by the first character and the angle of the O_n-C_n-C_{n-1}-C_{n-2} moiety by the second.

Isoenergy (φ, ψ) maps

Minimum energy calculations were performed using the TINKER modelling package (8). TINKER has the ability to use various common force fields such as AMBER or CHARMm. In this study we provided TINKER with the force field parameters of CHEAT (9, 10), a CHARMm-based force field where special atom types and related parameters are introduced for hydroxyl groups. In CHEAT, hydroxyl groups are represented by extended atoms to prevent the formation of intramolecular hydrogen bonds, and whereby energies are independent of the hydroxyl group orientation. Isoenergy contour maps were generated by incrementing the interglycosidic torsion angles of disaccharides in steps of 10°, producing a 36 × 36 grid. For the (1→5) and (1→6) linkage, a three-dimensional energy map was generated at a 20 × 20 × 20 resolution. Three dihedral angles per sugar ring and both interglycosidic angles were kept fixed by setting constraints during a first minimization at each grid point. For a second minimization, all constraints inside the ring were removed and the molecule was minimized again. Contour levels were plotted in steps of 1 kcal/mol (1 cal = 4.184 J), starting at the global minimum.

Molecular dynamics calculations

Molecular dynamics simulations were performed using the GROMOS-87 program package (11) and the improved force field for carbohydrates (12), on Linux computers. Each molecule was surrounded by SPC/E water molecules (13) and placed in a truncated octahedral periodic box. All bond lengths were kept fixed using the SHAKE procedure (14). Nonbonded interactions were calculated using a cutoff radius of 0.8 nm, and a time step of 2 fs. Simulations were performed with loose coupling to a pressure bath at 1 atm (1 atm = 101.325 kPa) and a temperature bath at 300 K (15) with time constants of 0.5 and 0.1 ps, respectively. A hydrogen bond is considered to be present if O-H···O < 2.5 Å, and if O-H···O angle >120°. Interglycosidic torsion angles are defined as φ (O_{ring}-$C_{1'}$-O_n-C_n), ψ ($C_{1'}$-O_n-C_n-C_{n-1}), and ω (O_n-C_n-C_{n-1}-C_{n-2}) according to IUPAC convention (16).

PMF calculations

To calculate the free energy differences of the disaccharide conformers in relation to one dihedral angle of the glycosidic linkage, PMF calculations were performed with the AUS method (5) and the GROMOS force field. All simulations were divided into jobs of 10 ps. Dihedral angle values were partitioned into 72 classes, each having a width of 5°. The derivatives of the PMF were fitted to a 12 term Fourier series. The first 0.2 ps of each job were discarded. Each system was simulated between 5 and 10 ns for

© 2006 NRC Canada

disaccharides, and up to 35 ns for the tetrasaccharide, and the final PMF was used to obtain the rotamer population distribution of the sampled dihedral angle.

Persistence length calculations

The persistence lengths of the polysaccharides were calculated similarly as has been done for cellulose (17). For cellulose, disaccharide conformational data have been used that had been selected from appropriate conformational regions of the MD simulations. For the exopolysaccharides, extended repeating units were used instead of disaccharides. For each persistence length calculation, extended repeating unit frames were selected at regular intervals from suitable MD runs, and used to randomly create 1000 polymer chains consisting of 100 repeating units each. For these compact molecules, steric hindrance can not be neglected, as could be done for cellulose. Interaction among nonbonded segments is taken into account by putting together polysaccharide models that still contain all atoms, instead of using a simplified model with vectors derived from the disaccharide building blocks. During the construction of the polysaccharide a new unit is added only after it has been checked for occupied space violations with the already existing part of the polysaccharide. The persistence length was determined by fitting the angular correlation function

$$C(j) = < \cos \vartheta_{i,i+j} >_i = \frac{< \vec{r}_i \cdot \vec{r}_{i+j} >_i}{|\vec{r}_i| \cdot |\vec{r}_{i+j}|}$$

Results and discussion

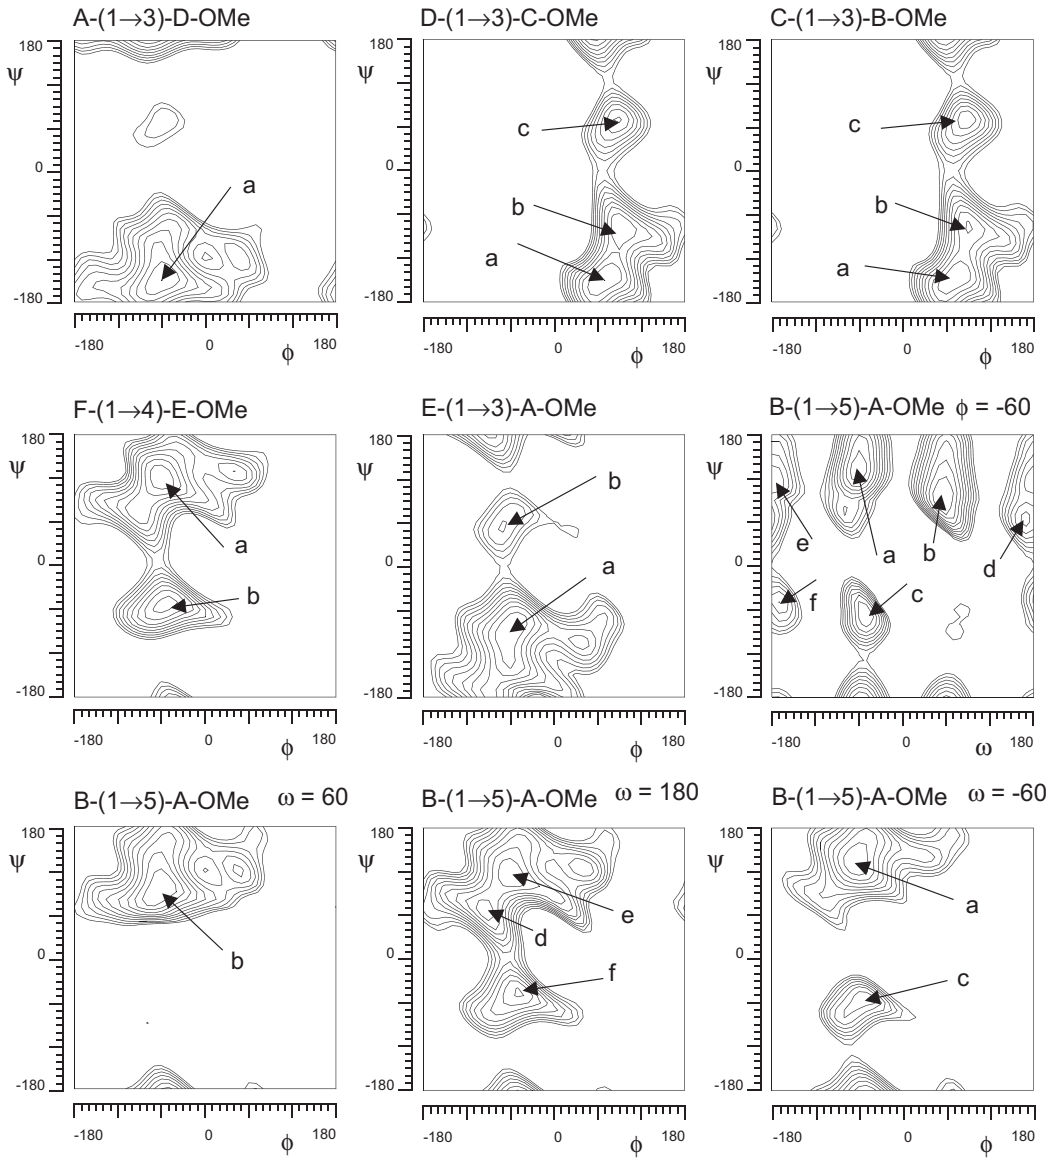
General

The *L. helveticus* Lh59 EPS is composed of a hexasaccharide repeating unit built up from a four-residue backbone, including a galactofuranose branching point, and a lactosyl side chain (Scheme 1A) (6). For this EPS the influence of the (**F**→**E**→) lactosyl side chain on the polysaccharide conformation has been evaluated through constructing polysaccharide models from MD simulations. The *S. macedonicus* Sc136 EPS is composed of a hexasaccharide repeating unit built up from three backbone residues and a trimeric side chain (Scheme 1B) (7). For this EPS separate MD simulations have been performed for repeating units with different numbers of side-chain residues attached. In fact, the influence of the (**L**→**K**→**J**→) side chain was evaluated through a conformational analysis performed on polysaccharide models consisting of (*i*) only the backbone (**I**→**H**→**G**), (*ii*) the backbone with a side chain composed of one residue attached to the branching **H** unit (**I**→[**J**→]**H**→**G**), (*iii*) the backbone with a side chain composed of two residues attached to the branching **H** unit (**I**→[**K**→**J**→]**H**→**G**), or (*iv*) the backbone with the complete side chain of three residues attached to the branching **H** unit (**I**→[**L**→**K**→**J**→]**H**→**G**). For both EPSs, specific attention has been paid to linkages with three bonds, the (1→6) linkages for hexopyranoses and the (1→5) linkages for hexofuranoses, since these linkages, when present in the backbone, induce flexibility in the polysaccharide.

Minimum energy calculations

To explore the conformational space of both EPSs, first the global and local energy minima of the glycosidic dihedral angles of the constituting disaccharide fragments in vacuo were investigated. Relaxed energy contour maps for the φ and ψ glycosidic dihedral angles were created by means of the CHEAT force field at 10° resolution. For each map generated for the (1→3) and (1→4) linkages, the energy minima differed only in ψ and have φ essentially at one position, either 60° or –60° (Fig. 1, Lh59 EPS and Fig. 2, Sc136 EPS). The (1→5) linkages for internal furanoses and the (1→6) linkages for internal pyranoses involve one extra dihedral angle (ω) and therefore three-dimensional (3D) maps were created at 18° resolution. It appeared from the 3D maps that the low energy conformations have φ essentially at –60°, with ψ either near –60° or 120° for (1→5) linkages, or near 180°, 60°, or –60° for (1→6) linkages. The angles ω were found to be near 180°, 60°, or –60°. Hence, for all (1→5) and (1→6) linkages, three (φ, ψ) maps were generated at 10° resolution, with ω at 180°, 60°, and –60°, respectively, reflecting the gauche–trans (*gt*), gauche–gauche (*gg*), and trans–gauche (*tg*) orientations of the ω angle. Moreover, one (ψ, ω) map with φ set at –60° was calculated. The results are depicted in Fig. 1 (Lh59 EPS) and Fig. 2 (Sc136 EPS). For all minimum energy positions in the maps, conformations were minimized without constraints. For each map, the obtained glycosidic dihedral angles and the relative energies of the minima are listed in Table 1.

Adaptive umbrella sampling of the PMF



The low-energy conformations in vacuo were obtained from the calculation of energy minima. Then, the population distributions of these energy minima in aqueous solution were obtained from the PMF calculated for each low energy conformer (5). Hydrogen bonds are known to play a key role in carbohydrates (18). By explicitly including water, the influence of hydrogen bonds is modelled properly. For each set of (1→3) and (1→4) linkages, only the ψ angle spanned multiple conformational regions, while the φ angle was found to be essentially constant. Therefore, the PMF was only calculated for the ψ angles. For all AUS simulations, disaccharides were used with simulation times from 5 to 10 ns.

Lactobacillus helveticus Lh59 EPS

From the PMF calculations, the population distribution can be calculated. It turned out that the (1→3) and (1→4) linkages each adopt one single dominant conformation (Table 2). From the energy maps of the (1→5) linkage, it emerged that low energy conformations have a φ angle at –60°, and a ψ angle of 140° and sometimes –60°, whereas ω takes values of 180°, –60°, or 60°. To get the population distribution for ω, an AUS run was performed for ω with φ and ψ initially set to –60° and 140°, respectively. The calculations were performed on the tetrasaccharide fragment **B**→[**E**→]**A**→**D** to incorporate the influence of long range interactions as much as possible. The result is a population distribution for the ω angle of 180°/–60°/60° = 31/67/2 (Fig. 3A). The φ and ψ dihedral angles remained close to –70° and 140°, respectively, during a 17 ns calculation. Subsequently, a 35 ns AUS run for the ψ dihedral angle was performed, again with φ initially set at –60°. This demonstrated

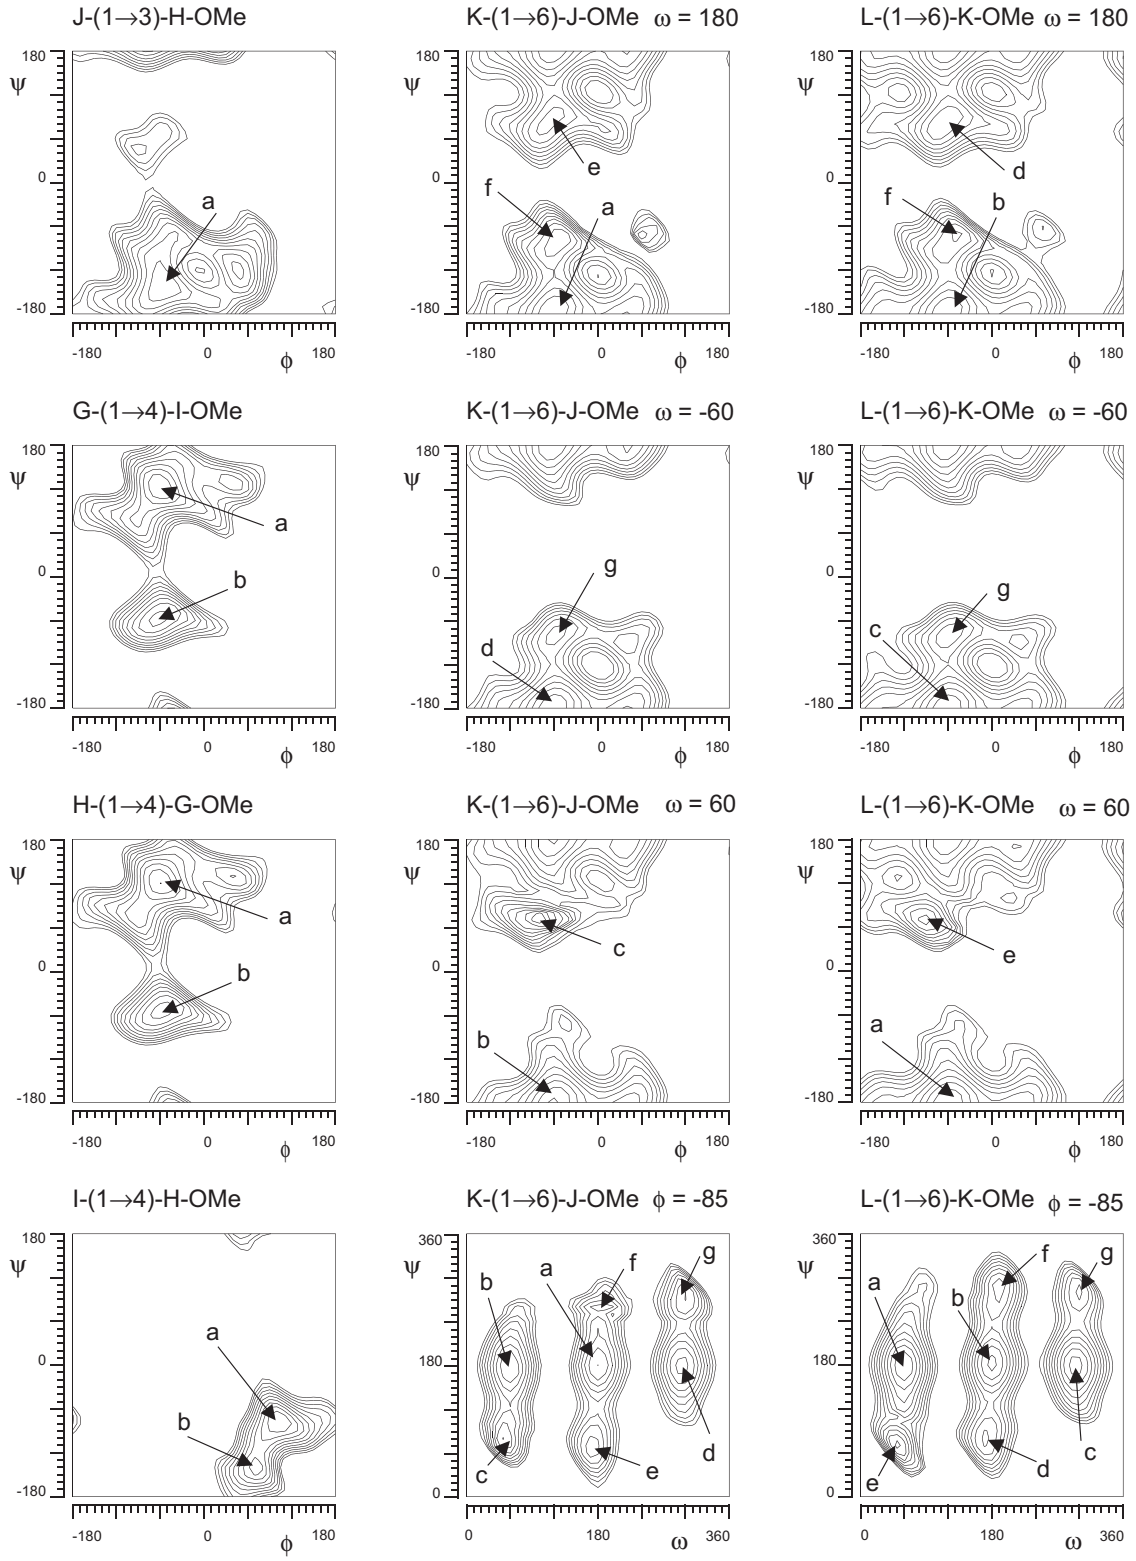
that the ψ dihedral angle has a marked preference for values around 140° (Fig. 3B). During this run, ω visited all low-energy positions that were discovered in the energy contour maps (Fig. 4B). This was in accordance with the results of the AUS run for ω, and indicates that ψ has been adequately sampled. Note that during the AUS run of dihedral ω, the ψ dihedral angle varied between 180° and 60°, and did not sample all low-energy positions that were discovered in the energy contour maps (Fig. 4A). However, this is in agreement with the population distribution of the ψ dihedral angle.



Streptococcus macedonicus Sc136 EPS

The population distributions of the (1→4) and (1→3) linkages (**G→I**, **I→H**, **H→G**, and **J→H**) showed essentially one conformational region (Table 2). From the energy maps of the (1→6) linkages, it emerged that low-energy conformations have a φ angle at –85°, a ψ angle predominantly at 180°, and ω with values of 180°, –60°, or 60°. The population distribution for ω was again obtained from AUS runs performed for the ω angle with φ and ψ initially set to –85° and 180°, respectively. The (1→6) linkages (**K→J** and **L→K**) both displayed two main conformational regions for ω of 180° and 60° (Table 2, Figs. 3C and 3D). Similarly to the (1→5) linkage in the EPS of *L. helveticus* Lh59, the ψ dihedral angle has a preference for values around 180°. Figures 4C and 4D show that ψ visited all low-energy positions during the sampling of the ω dihedral angles. The population distribution of both ω dihedral angles (Table 2) reveals that the flexibility of this polysaccharide is located mainly in the side chains.

Note that the low-energy positions and the relative energies obtained from the energy maps might deviate slightly from those resulting from the AUS method. For **B→A** (Lh59 EPS) and **L→K** (Sc136 EPS), this resulted even in different global minima.

Molecular dynamics calculations

MD simulations were performed on polysaccharide fragments. The results of the AUS simulations were used to identify the most probable conformations for each fragment, which would then be used to start the MD simulations. The ω dihedral angle of the (1→5) and (1→6) linkages spanned

multiple low-energy regions, making an adequate sampling during the MD calculations unlikely. Therefore, three separate simulations were started for these linkages with the most stable conformations taking ω initially set to 180°, –60°, and 60°.

Lactobacillus helveticus Lh59 EPS

All glycosidic φ and ψ dihedral angles were set at their global energy minima. The polysaccharide fragment was composed of a repeating unit (six monosaccharides) and three supplementary backbone monosaccharides (**D′→C′→B′**). These extra monosaccharides were connected to galactofuranose residue **A**, thus resulting in fragment **D→C→B→[F→E→]A→D′→C′→B′**. This was done to ensure that the branching residue **A**, likely to be a very flexible position in the backbone, might allow the sampling of conformations with long-range interactions between the side chain and the backbone of the polysaccharide. Three starting conformations were established with varying **B**-(1→5)-**A** ω angles of 180°, –60°, and 60°, respectively. For each of the starting conformations of this fragment, a 5 ns MD simulation was performed (data not shown). The MD trajectories were inspected to determine the transitions of the various dihedral angles, the formation of hydrogen bonds, and the general shape of the molecule. Trajectory-averaged dihedral angles of the MD simulations are given in Table 3. During the 5 ns

[c]Transition: –100° → 60° after 4.5 ns.

simulation time, transitions observed for the ω angle were in the simulations started from conformations with ω either at 180° or –60°. For a short period of 200 ps, ω changed from 180° to –60° before returning to 180° again in the first MD simulation. Similarly, in the second MD simulation, ω changed from –60° to 180° for a short period of 300 ps and then switched back to –60°. In the third MD simulation, the glycosidic ψ angle of the disaccharide **E**→**A** showed a transition from –100° to 60° after 4.5 ns. Otherwise, it was found that the other trajectory-averaged dihedral angles were essentially the same for all MD simulations. The trajectory-averaged dihedral angles of the polysaccharide fragment were found to be similar to those calculated during the AUS simulations of the disaccharides or of the tetrasaccharide **B**→[**E**→]**A**→**D**. No major long-range hydrogen bond formation was detected in any of the MD runs. The hydrogen bonds detected for more than 7% of the simulation time were usually between neighbouring monosaccharide residues. The only exception was a hydrogen bond between **E** OH-6 and **B** OH-2 for the simulation with ω = 60°, which was observed for 50% of the simulation time. This hydrogen bond might be a stabilizing factor for this conformation. Because the conformation with ω = 60° only contributes at a level of 2% to the conformation of the polysaccharide, this was not further investigated. Conformations with ω = 180° or –60° induced a curved backbone, while ω = 60° yielded an almost straight backbone (Figs. 5A–5C).

Streptococcus macedonicus Sc136 EPS

To study the influence of the side chains on the conformational behaviour of the polysaccharide, 5 ns MD simulations were performed on polysaccharide units containing zero to three side-chain residues. The simulated molecules were relatively large fragments consisting of three repeating units. A first MD simulation was performed with a polysaccharide fragment representing the bare backbone and only consists of three times the **I**→**H**→**G** backbone unit (*i*), resulting in a fragment of nine monosaccharide residues. As expected from the energy contour maps and the AUS calculations of the PMF, all linkages were found almost exclusively in one conformational region (Table 4). This clearly showed that the backbone of the Sc136 EPS is more rigid than that of the Lh59 EPS. The second MD simulation (*ii*) was made with the fragment in (*i*) extended with one

Fig. 5. The three most probable conformations of a repeating unit of *L. helveticus* Lh59 EPS, (A) $B_{180}\rightarrow$**A**, (B) $\mathbf{B}_{-60}\rightarrow$**A**, and (C) $\mathbf{B}_{60}\rightarrow$**A**. The four most probable conformations of a repeating unit of *S. macedonicus* Sc136 EPS, (D) $\mathbf{L}_{180}\rightarrow\mathbf{K}_{180}\rightarrow$**J**, (E) $\mathbf{L}_{60}\rightarrow\mathbf{K}_{180}\rightarrow$**J**, (F) $\mathbf{L}_{180}\rightarrow\mathbf{K}_{60}\rightarrow$**J**, and (G) $\mathbf{L}_{60}\rightarrow\mathbf{K}_{60}\rightarrow$**J**. A ribbon is drawn to visualize the backbone of the polysaccharides. Monosaccharide residues belonging to one repeating unit are drawn in bold.

side chain monosaccharide **J** for each repeating unit, resulting in a fragment composed of three **I**→[**J**→]**H**→**G** units. Again, each linkage was confined to its most stable conformation. For the following two MD simulations, the fragment in (*ii*) was further extended with monosaccharide **K** on each repeating unit, defining a fragment consisting of three **I**→[**K**→**J**→]**H**→**G** units. The MD simulations were performed with (*iii*) $\mathbf{I}\rightarrow[\mathbf{K}_{180}\rightarrow\mathbf{J}\rightarrow]\mathbf{H}\rightarrow\mathbf{G}$ (ω_{KJ} = 180°) and (*iv*) $\mathbf{I}\rightarrow[\mathbf{K}_{60}\rightarrow\mathbf{J}\rightarrow]\mathbf{H}\rightarrow\mathbf{G}$ (ω_{KJ} = 60°). A simulation with ω_{KJ} = –60° was not considered because of the low probability (2%) of the associated conformation. The conformations of the two "external" repeating units (numbered 1 and 3) were chosen to be the same as the central unit (numbered 2). Only during the first MD simulation (*iii*) a transition did occur. The ω_{KJ} angle (middle unit) switched from 180° to –60° and back to 180° after 400 ps. In the last series of MD simulations monosaccharide **L** was added, completing the repeating unit **I**→[**L**→**K**→**J**→]**H**→**G**. Four different MD simulations were performed with (*v*) $\mathbf{I}\rightarrow[\mathbf{L}_{180}\rightarrow\mathbf{K}_{180}\rightarrow\mathbf{J}\rightarrow]\mathbf{H}\rightarrow\mathbf{G}$ (ω_{LK} = 180°, ω_{KJ} = 180°), (*vi*) $\mathbf{I}\rightarrow[\mathbf{L}_{60}\rightarrow\mathbf{K}_{180}\rightarrow\mathbf{J}\rightarrow]\mathbf{H}\rightarrow\mathbf{G}$ (ω_{LK} = 60°, ω_{KJ} = 180°), (*vii*) $\mathbf{I}\rightarrow[\mathbf{L}_{180}\rightarrow\mathbf{K}_{60}\rightarrow\mathbf{J}\rightarrow]\mathbf{H}\rightarrow\mathbf{G}$ (ω_{LK} = 180°, ω_{KJ} = 60°), and (*viii*) $\mathbf{I}\rightarrow[\mathbf{L}_{60}\rightarrow\mathbf{K}_{60}\rightarrow\mathbf{J}\rightarrow]\mathbf{H}\rightarrow\mathbf{G}$ (ω_{LK} = 60°, ω_{KJ} = 60°). The four different conformations for each repeating unit are shown in Figs. 5D–5G. In MD simulation (*v*), the ω_{KJ} angle (middle unit) went from 180° to –100° and back to 180° after 3 ns. In the same simulation, the ω_{LK} (first unit) went from 180° to 60° after 2 ns, while ω_{LK} (middle unit) went from 180° to 60° after 3 ns. During MD simulation (*vi*), all ω dihedral angles kept the initial conformation during the simulation. In MD simulation (*vii*), the ω_{KJ} angle (first unit) went from 60° to 180° after 500 ps. A simulation (*viii*) with ω_{LK} = 60° and ω_{KJ} = 60° was started three times, but within a few ps, ω_{LK} or ω_{KJ} (in the middle unit) jumped from 60° to 180°. It seems that ω = 60° for

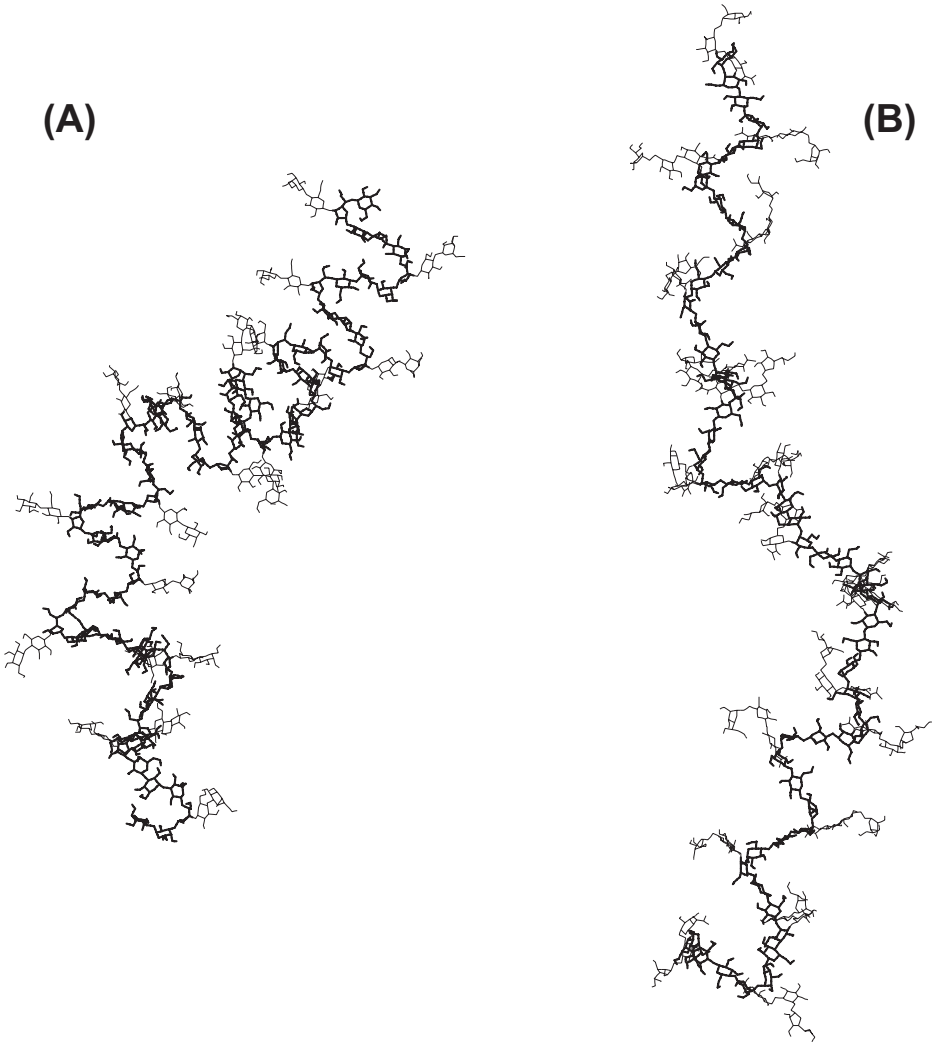
both (1→6) linkages does not result in a stable conformation. Therefore, this conformation is not used in the rest of the work. Figure 5 shows that the **H→G** and **G→I** segments have a linear conformation, while the **I→H** segment introduces a turn in the backbone. The **J→H** segment points away from the backbone into the solution.

Constructing polysaccharide models

The data generated by the MD simulations were used to construct a number of polysaccharide models with lengths between 10 and 500 repeating units. To this end, configurations were selected randomly from the MD runs choosing suitable conformations based on their statistical representation in the runs. The chosen repeating unit was then attached to the "growing" chain by a homemade polysaccharide-building program, which checked for space-filling constraints and prevented van der Waals clashes. Although the polysaccharide models themselves are grown in vacuo, the models do represent polysaccharides in aqueous solution because the applied building blocks are directly transferred from MD simulations in the presence of water. Since the interaction between water and the saccharides is very dynamic — no "sticky" water molecules have been observed during the MD simulations — no persistent influence is expected on the spatial arrangement of the building blocks.

Lactobacillus helveticus Lh59 EPS



Configurations were selected randomly from the MD runs of **D→C→B→[F→E→]A→D′→C′→B′** with ω = 180°/–60°/60° in a ratio of 31:67:2. Connections were made by the attachment of residue **C′** of one configuration to residue **B** of the next configuration, in addition to the removal of redundant residues (**B′**, **D**, and **C**). The newly attached fragments were checked for steric overlap with the already present part of the polysaccharide and, if needed, replaced with other fragments until no overlap occurred. Visual inspection showed a flexible structure with a secondary conformation presenting zigzags and a random coil tertiary conformation for *L. helveticus* Lh59 EPS. The galactofuranose units induced a twist in the backbone and all lactosyl side chains were extended into the solvent. A model that demonstrates the general shape of the polysaccharide is depicted in Fig. 6A.

Streptococcus macedonicus Sc136 EPS

Configurations were again selected randomly from appropriate MD runs. Connections were made by attaching residue **G** of one configuration to residue **I** of the next configuration, and removing the redundant first and last repeating units. Again, newly attached fragments were checked for steric overlap with the already present part of the polysaccharide and, if needed, replaced with other fragments until no overlap occurred. Visual inspection shows a secondary conformation that consisted of a stretched β-D-Gal*p*-(1→4)-β-D-Glc*p*-(1→4)-α-D-Glc*p* part, and then a curve where α-D-Glc*p* connects to β-D-Gal*p*. This leads to an overall "random coil" spatial conformation. The side chains were found to be very flexible, but did not seem to influence the secondary conformation. Therefore, the shape of *S. mace-*

donicus EPS is mainly determined by the rigid backbone. A model that demonstrates the general shape of the polysaccharide is depicted in Fig. 6B.

Persistence length calculations

Finally, the stiffness of the polysaccharides was estimated by calculating the persistence length L_p (17), which was statistically derived from 1000 generated polysaccharide structures with a length of 100 repeating units each. The results are compiled in Table 5.

The persistence length is a measure for the "extensiveness" of a polysaccharide. The occurrence of disaccharide linkages with multiple (and populated) glycosidic conformations has enormous lowering effects on the L_p. This almost always applies to (1–6) linkages. Similar effects are observable for variations in the carbohydrate ring structure as is most prominent for furanose rings. Smaller effects are caused by the natural variation between snapshots of a "single" conformation. Here the width of the glycosidic potential energy wells plays a role. The presence of steric effects (e.g., induced by side chains) will narrow these potential energy wells resulting in an increased persistence length.

Lactobacillus helveticus Lh59 EPS

Calculation of the L_p yielded a value of 4.5 nm. The EPS turned out to be flexible and compact. By comparison, the L_p of the very stiff polysaccharide cellulose was estimated to be 14 nm (17). Steric interactions were also shown to have a considerable influence on the L_p value as demonstrated by calculations of the L_p without checking for steric overlap: a value of 2.2 nm was found, being a reduction of the L_p value by a factor of two. In addition, L_p calculations were performed on polysaccharides where the side chain had been either shortened or removed. Note that this was done with configurations from the MD simulations of the intact side chain. The side chain was only been trimmed prior to the building process. Thus, the effect on the L_p only reflects the steric hindrance during the construction of the polysaccharides. Nevertheless, as the side chains did not show many interactions with the backbone during the MD simulations, even for "long" side chains, the assumption was made that this approximation was in essence valid.

Streptococcus macedonicus Sc136 EPS

Table 5. Persistence length (L_p) and average length of the repeating unit (l) of *L. helveticus* Lh59 EPS and *S. macedonicus* Sc139 EPS that were built from tri-, tetra-, penta-, and hexa-meric repeating units from MD simulations in water.

Repeating unit	L_p (nm)	l (nm)
Lh59		
D→C→B→[F→E→]A	4.5	1.05
D→C→B→[E→]A	4.2	1.05
D→C→B→A	3.7	1.05
D→C→B→[F→E→]A[a]	2.2	1.04
Sc136		
I→H→G	6.5	1.00
I→[J→]H→G	8.9	1.13
I→[K_{180}→J→]H→G	10.5	1.08
I→[K_{60}→J→]H→G	9.5	0.97
I→[K→J→]H→G	8.7	1.06
I→[L_{180}→K_{180}→J]H→G	10.1	1.19
I→[L_{60}→K_{180}→J→]H→G	8.1	1.12
I→[L_{180}→K_{60}→J→]H→G	9.3	1.07
I→[L→K→J→]H→G	8.5	1.14

Note: When an exclusive conformational region is used for the **K**-(1→6)-**J** and **L**-(1→6)-**K** glycosidic linkages, this is indicated by 180 or 60.

[a]No excluded volume effects were taken into account.

showed a similar L_p of ~8.7 nm. For **I→[J→]H→G**, **I→[K→J→]H→G**, and **I→[L→K→J→]H→G**, the persistence lengths were found to be 8.9, 8.7, and 8.5 nm, respectively. The bare backbone (**I→H→G**) yielded an L_p of 6.5 nm, thereby indicating a higher flexibility. From these results it can be deduced that only the first side-chain residue (**J**) influences the L_p of the polysaccharide in such a way as to strech the polysaccharide, a finding that can be explained by the position of **J** in close contact with the **I→H→G** backbone.

Conclusions

The conformational analysis method used in this paper allowed one to explicitly include the key influence of water solvation. The secondary structures of both polysaccharides studied showed a twisted backbone with side chains extending in the solvent. The main flexibility was found to be located in the intrinsically flexible (1→5) or (1→6) linkages, as well as in the furanose ring form. For *L. helveticus* Lh59 EPS, this flexibility is located in the backbone, resulting in a more compact overall shape. Analysis of the polysaccharide models showed no interactions between side chains and backbone except for the linkage point, and generally no long-range interaction among backbone units. Therefore, for the polysaccharides studied, the conclusion is that the extrapolation of small oligosaccharide fragments to polysaccharides was well-justified.

The general shape of the polysaccharides was found to be compact. This was expressed by the values obtained for the calculated persistence length. In this study, we have taken into account only the most probable conformations of the glycosidic linkages. Neglecting the less-occurring conformations may have had some influence on the calculated persistence length, since some of those minor conformations could introduce sharp bends in the backbone of the polysaccharide. Nevertheless, the dominant conformations used for the construction of the polysaccharide models and the sizes of the fragments used were large enough to include all intermonomer interactions.

The conformation of the side chains was shown to have only a small influence on the flexibility and the persistence length of the polysaccharide. Only the first residue of the side chain, linked directly to the backbone, had a clear influence. It reduced the flexibility of the backbone and made the chain stiffer. The backbone glycosidic linkages largely determined the overall shapes of the polysaccharides. The fully stretched parts were stemming from the β-D-Hex*p*-(1→4) elements, similarly as is the case for the β-D-Glc*p*-(1→4) elements in cellulose. The structural elements, α-D-Hex*p*-(1→4) and α-D-Hex*p*-(1→3), introduced bends in the backbone, thereby reducing the calculated persistence length. As the distance O4—O1 in a 4-substituted monosaccharide is longer than the distance O3—O1 in a 3-substituted monosaccharide, (1→4) linkages usually produce a longer residue length (l) than (1→3) linkages. Backbone three-bond linkages (φ, ψ, and ω) gave rise to a large variation in conformations, enhancing the flexibility and giving shorter persistence lengths.

A concise synthesis of α-D-ribofuranosyl alkylphosphonates — Putative substrate intermediates for the carbon–phosphorous lyase system[1]

Yan Luo and David L. Zechel

Abstract: Carbon–phosphorous lyase is a multienzyme system found in many species of bacteria that is distinguished by its ability to hydrolyze a broad array of unactivated alkylphosphonates. α-D-Ribofuranosyl alkylphosphonates are potential metabolic intermediates generated by the carbon–phosphorous lyase pathway. Here we describe a facile synthesis of α-D-ribofuranosyl alkylphosphonates using β-D-ribofuranosyl trichloracetimidate as a glycosyl donor.

Key words: carbon–phosphorous lyase, *phn* operon, phnN, phosphonates, glycosyl trichloroacetimidate donor, α-D-ribofuranosyl ethylphosphonate.

Résumé : La lyase carbone–phosphore est un système multienzyme qu'on retrouve dans plusieurs espèces et qui se distingue par sa facilité à hydrolyser une grande variété d'alkylphosphonates qui ne sont pas activés. Les alkylphosphonates de α-D-ribofuranosyle sont des intermédiaires métaboliques potentiels générés par la voie réactionnelle de la lyase carbone–phosphore. Dans ce travail, on décrit une méthode facile de synthèse d'alkylphosphonates de α-D-ribofuranosyle utilizant le trichloroacétimidate de β-D-ribofuranosyle comme donneur de glycosyle.

Mots clés : lyase carbone–phosphore, *phn* opéron, phnN, phosphonates, trichloroacétimidate de glycosyle comme donneur, éthylphosphonate de α-D-ribofuranosyle.

Introduction

Phosphate is a fundamental functional group in biology as exemplified by its many structural, signalling, and energy storage roles. Organophosphonates are characterized by a highly stable carbon–phosphorous (CP) bond that is comparable in energy to a carbon–carbon bond (1). In addition to other reduced forms of phosphate such as phosphite and hypophosphite, organophosphonates are significant contributors to the global phosphate pool. They may well have served as the original source of water soluble phosphorous for the assembly of biological precursors on prebiotic earth, as inorganic phosphate would have been largely inaccessible as the mineral apatite (2). Although anthropogenic generation of organophosphonates is considerable (1), natural production is also substantial. The biosynthesis of the majority of organophosphonate natural products begins with the rearrangement of phosphenolpyruvate to phosphonopyruvate by phosphoenolpyruvate mutase (3). From this precursor, *Streptomyces* species biosynthesize a number of bioactive phosphonates, including the antibiotic fosfomycin and the herbicide bialaphos (4). 2-Amino-3-phosphonopropionic acid and 2-aminoethylphosphonic acid are the most widely distributed biogenic organophosphonates, occurring as constituents of lipids, proteins, and polysaccharides in virtually all organisms, including man (5). Due to the global abundance of organophosphonates, bacteria have also evolved a number of strategies to cleave the CP bond to produce inorganic phosphate when the latter is scarce in the environment (1, 6). At present, four distinct CP bond-cleaving activities are known. Three of these activities, comprised of phosphonoacetaldehyde hydrolase (7), phosphonopyruvate hydrolase, (8) and phosphonoacetate hydrolase (9), share a β-carbonyl group as a feature of their respective substrates (**1** in Scheme 1). A mechanism for the cleavage of the CP bond in these substrates can be envisioned as direct nucleophilic attack by water or an enzyme residue on phosphorous, displacing a carbanion to form an enzyme stabilized enolate. In the case of phosphonoacetaldehyde hydrolase, the substrate β-carbonyl is activated as a Schiff base (**2**) followed by attack of a carboxylate nucleophile to form an acyl phosphate intermediate (**3**); hydrolysis forms acetaldehyde (**4**) and inorganic phosphate (7).

Unlike phosphonoacetaldehyde hydrolase, CP-lyase is a multienzyme system that is distinguished by its ability to cleave a broad array of "unactivated" alkylphosphonates (**5**) yielding alkanes (**7**) and inorganic phosphate as products (Scheme 2) (10). In *Escherichia coli*, the *phn* operon encoding CP-lyase consists of 14 genes (*phnCDEFGHIJKLMNOP*) (11, 12); mutational and sequence analysis of the *phn* operon in whole cell metabolic studies has shown that *phnCDE* encodes a phosphonate transport system and *phnG–phnP* en-

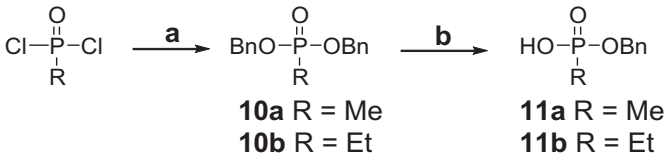
Scheme 1. Cleavage of an "activated" carbon–phosphorous bond by phosphonoacetaldehyde hydrolase (7).

Scheme 2. A hypothetical reaction pathway depicting the cleavage of "unactivated" alkylphosphonates by CP-lyase utilizing **6** as an intermediate. The subsequent phosphorylation reaction by phnN produces a precursor (**9**) for NADH biosynthesis (14).

codes enzymes that are required for CP bond cleavage and transcription regulation (13). The sequences of several of these enzymes are unique, yielding no insight via homology into their possible function. An in vitro reconstruction of CP-lyase activity has not yet been achieved, further hampering functional assignments. This is primarily due to the difficulty in expressing several of these enzymes, some of which appear to be associated with the membrane of bacterial cells (13). The only in vitro reaction assigned to a *phn* protein is that of phnN, which was recently shown to be an ATP-dependent kinase, phosphorylating 5-phospho-α-D-ribofuranosyl phosphate (**8**) to yield 5-phospho-α-D-ribofuranosyl diphosphate (PRPP, **9**), a precursor in the biosynthesis of the essential cofactor NAD (14). Intriguingly, α-D-ribofuranosyl ethylphosphonate (**6**) was observed to reach significant concentrations in the culture medium when *E. coli* with a mutated, yet partly functional *phn* operon subsisted on ethylphosphonate. Free phosphate was not produced. By contrast, a mutant strain of *E. coli* with an inoperative *phn* operon did not produce **6** when fed ethylphosphonate, indicating that the some of the CP-lyase enzymes were likely involved in its biosynthesis (15). The substrate specificity of phnN and the biosynthesis of **6** by CP-lyase enzymes strongly suggest that a *phn* enzyme can cleave the CP bond of **6** (or a derivative) and in doing so support NAD biosynthesis. The chemical mechanism of CP-lyase is of great interest, not only for its ability to cleave the remarkably stable carbon–phosphorous bond, but also for the development of environmental remediation catalysts that will degrade phosphonates, such as nerve agents and herbicides. As part of our current program in characterizing the functions and reactions of individual CP-lyase enzymes, we have synthesized **6** and other phosphonate analogues as putative CP-lyase substrate intermediates.



Results and discussion

A major challenge facing the stereoselective synthesis of α-D-ribofuranosyl phosphates is the reactivity and 1,2-cis arrangement of the glycosidic linkage (the product itself is a glycosyl donor (16)). The diphosphate **8** has been synthesized enzymatically (17) by direct condensation of the per-O-acetylated sugar with phosphoric acid (18, 19) or by reaction of the ribofuranosyl bromide with dibenzyl phosphate (20, 21). A synthetically useful enzymatic route to **6** is not yet possible, and the current synthetic methods suffer from low yields or the use of toxic and difficult to handle reagents (e.g., HBr gas). We report that β-D-ribofuranosyl trichloroacetimidate serves as a high yielding and stereoselective donor for the synthesis of **6**.

The required glycosyl acceptors (**11a** and **11b**) were conveniently prepared in two steps (Scheme 3). The corresponding phosphonochloridates were reacted with benzyl alcohol to yield dibenzyl methylphosphonate (**10a**) and dibenzyl ethylphosphonate (**10b**) (22). Refluxing with DABCO in anhydrous toluene afforded mono-protected **11a** and **11b** quan-

Scheme 3. Reagents and conditions: (*a*) BnOH, toluene–pyridine, 0 °C to RT, 5 h; (*b*) DABCO, toluene, reflux, 3 h.

titatively (23). The trichloroacetimidate glycosyl donor **12** was prepared from methyl 2,3,5-tri-*O*-benzyl-α-D-ribofuranoside after solvolysis in 5% aq. HCl – dioxane and treatment of the free anomeric hydroxyl with trichloroacetonitrile and potassium carbonate in dry dichloromethane (Scheme 4). Phosphonic acids **11a** and **11b** were reacted with the donor **12** in dry dichloromethane in the presence of 4 Å molecular sieves to produce a 2:1 α/β mixture of the ribofuranosyl alkylphosphonates **14** and **15** in 60% yield. Reaction with dibenzyl phosphoric acid produced a similar mixture of the corresponding ribofuranosyl phosphate (**13**). An attempt to increase the α/β ratio by reducing the reaction temperature to –20 °C was unsuccessful. However, the β anomers readily isomerized to the thermodynamically stable α anomer in the presence of $BF_3{\cdot}Et_2O$ and 2-chloropyridine. The β anomer was notably unstable, as we observed that **13**β decomposed overnight at room temperature. The stereochemistry of the α anomer was assigned based on NOESY experiments: the signal corresponding to H-1 (δ 6.09) exhibits an NOE with both H-2 and H-3, indicating that H-1, H-2, and H-3 are on the same side of the ribofuranose ring. Compounds **13**α, **14**α, and **15**α were deprotected by catalytic hydrogenolysis to afford the desired α-D-ribofuranosyl phosphate (**16**) and alkylphosphonates (**17** and **18**) in quantitative yield. These were subsequently converted to the triethylammonium salts.

The putative substrate intermediates (**17** and **18**) are very likely to be crucial for assigning the functions of CP-lyase proteins as they are all, or in part, produced in a soluble form suitable for in vitro studies. The stereoselective and high yielding synthetic route described here is considerably more facile than previously reported methods. We can now readily synthesize a wide array of putative CP-lyase intermediates that can also include radiolabels, chromaphores, or fluorophores. Of particular interest is the substrate specificity of the CP-lyase enzyme that ultimately cleaves the CP bond: Does this enzyme cleave simple alkylphosphonates or only glycosylated derivatives like **6** or both? Likewise, which CP-lyase enzyme is responsible for forming **6**? As the ultimate CP bond cleaving mechanism is suspected to be radical based (10), we can also readily incorporate radical stabilizing functionalities (thio, allyl, etc.) into **17** and **18** to serve as radical probes. Our current success in producing soluble CP-lyase proteins will benefit from access to these substrates and will be the topic of future reports.

Experimental

General

Solvents were distilled under dry nitrogen by standard methods (THF from Na/benzophenone and CH_2Cl_2 from CaH_2) prior to use. All commercially available reagents were used without further purification. All reactions were performed under a dry nitrogen atmosphere. ^{1}H NMR spectra was recorded on a 400 MHz Bruker spectrometer using $CDCl_3$ (δ 7.26 ppm), MeOD (δ 3.35 ppm), and D_2O (δ 4.81 ppm) as internal references. ^{13}C NMR and ^{31}P NMR spectra were recorded at 100.6 and 162.0 MHz, respectively. ^{31}P NMR spectra are reported relative to phosphate. Mass spectra were determined by electrospray ionization (ESI) or fast atom bombardment (FAB) mass spectroscopy. Analytical TLC was perfomed on Silicycle F_{254} silica gel plates. Visualization was performed under UV light or by staining with ceric ammonium molybdate. Flash chromatography was performed using Silicycle (40–63 μm) silica gel.

Synthesis

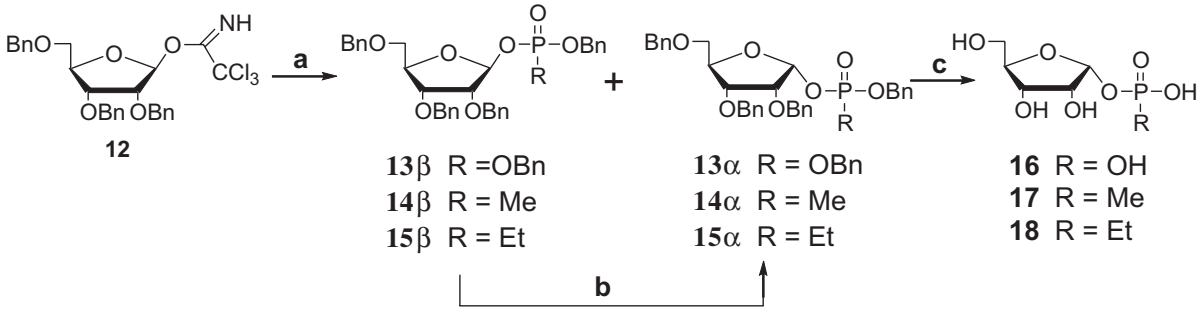
Dibenzyl ethylphosphonate (10b)

A suspension of ethylphosphonylchloridate (1 mL, 9.4 mmol) was stirred rapidly in dry toluene (5 mL) at 0 °C. A mixture of dry benzyl alcohol (2 mL, 18.8 mmol) and dry pyridine (1.5 mL, 18.8 mmol) was added over 90 min while the temperature was maintained. After the addition was complete, the reaction was allowed to reach room temperature and stirred for a further 3 h. The solid product, dibenzyl ethylphosphonate (**10b**), was removed by filtration and washed with toluene, 2 mol/L NaOH, water, then dried over Na_2SO_4 and concentrated in vacuo. Crude **10b** was used in the next reaction without further purification. Data for **10b**: ^{1}H NMR (400 MHz, $CDCl_3$) δ: 7.4–7.3 (m, 10H, aromatic), 5.08 (m, 2H, OCH_2Ph), 4.98 (m, 2H, OCH_2Ph), 1.76 (m, 2H, CH_2), 1.22 (m, 3H, CH_3). ^{31}P NMR ($CDCl_3$) δ: 35, 37.

Benzyl ethylphosphonic acid (11b)

To a stirred solution of crude **10b** (3.0 g, 10 mmol) in dry toluene (20 mL) was added DABCO (1.12 g, 10 mmol) under a nitrogen atmosphere. The reaction mixture was refluxed for 3 h before the solvent was removed in vacuo and the residue was redissolved in 5% aq. HCl. The aqueous layer was extracted with ethyl acetate, dried over Na_2SO_4, then evaporated under reduced pressure to yield benzyl ethylphosphonic acid (**11b**) (1.87 g, 99% calcd. from ethylphosphonylchloridate). Data for **11b**: ^{1}H NMR (400 MHz, $CDCl_3$) δ: 5.07 (m, 2H, OCH_2Ph), 1.8 (m, 2H, CH_2), 1.2 (m, 3H, CH_3). ^{31}P NMR ($CDCl_3$) δ: 36.

Dibenzyl methylphosphonate (10a)



The procedure for the preparation of **10b** was followed. Data for **10a**: ^{1}H NMR (400 MHz, $CDCl_3$) δ: 7.4–7.3 (m, 10H, aromatic), 5.08 (m, 2H, OCH_2Ph), 4.98 (m, 2H, OCH_2Ph), 1.5 (d, J = 17.6 Hz, 3H, CH_3). ^{13}C NMR ($CDCl_3$) δ: 67.16 (OCH_2Ph), 67.09 (OCH_2Ph), 12.42, 10.99 (CH_3). ^{31}P NMR ($CDCl_3$) δ: 31.

Benzyl methylphosphonic acid (11a)

The procedure for the preparation of **11b** was followed. Data for **11a**: ^{1}H NMR (400 MHz, $CDCl_3$) δ: 7.3–7.4 (m, 5H, aromatic), 5.07 (m, 2H, OCH_2Ph), 1.55 (d, J = 17.9 Hz, 3H, CH_3). ^{13}C NMR ($CDCl_3$) δ: 66.59 (OCH_2Ph), 12.39, 11.14 (CH_3).

Scheme 4. Reagents and conditions: (*a*) phosphonic acid, dichloromethane, 0 °C to RT, 3 h; (*b*) $BF_3{\cdot}Et_2O$, 2-chloropyridine, RT, 2 h; (*c*) Pd/C (10%), H_2, 12 h.

*2,3,5-Tri-*O*-benzyl-*D*-ribofuranosyl benzyl ethylphosphonate (15)*

A solution of 2,3,5-tri-*O*-benzyl-D-ribofuranose (1 g, 2.5 mmol), potassium carbonate (396 mg, 2.87 mmol), and trichloroacetonitrile (4 mL, 40 mmol) in anhydrous dichloromethane (20 mL) was stirred overnight at room temperature. The mixture was filtered through Celite and concentrated in vacuo. Flash chromatography using ethyl acetate – hexanes (1:2) yielded pure 2,3,5-tri-*O*-benzyl-β-D-ribofuranosyl trichloracetimidate (**12**). Data for **12**: ^{1}H NMR (400 MHz, $CDCl_3$) δ: 8.5 (s, 1H, NH), 7.4–7.3 (m, 15H, aromatic), 6.35 (s, 1H, H1), 4.8–4.4 (m, 7H, OCH_2Ph, H2), 4.15 (m, 2H, H3, H4), 3.7 (dd, 2H, H5a, H5b). ^{13}C NMR ($CDCl_3$) δ: 160.77 (C=NH), 103.43 (C1), 82.15 (C4), 78.48 (C2), 77.22 (C3), 73.25, 72.54, 72.18 (CH_2Ph), 70.19 (C5). To an ice-cold solution of **12** (698 mg, 1.24 mmol) in anhydrous dichloromethane was added **11b** (527 mg, 2.6 mmol) in the presence of 4 Å molecular sieves. The mixture was stirred for 3 h whereupon TLC indicated complete conversion of **12**. The mixture was filtered through Celite and concentrated in vacuo to yield an anomeric mixture of **15** (450 mg, 60%, α/β = 2:1). The anomers were resolved by flash chromatography (ethyl acetate – hexanes, 1:3 to 1:1). The β anomer **15**β (100 mg, 0.17 mmol) was subsequently dissolved in anhydrous dichloromethane (5 mL) followed by $BF_3{\cdot}Et_2O$ (10 μL, 0.087 mmol) and 2-chloropyridine (16 μL, 0.174 mmol). The mixture was stirred at room temperature for 1.5 h then neutralized with triethylamine and evaporated in vacuo. The crude product was purified by flash chromatography (ethyl acetate – hexane, 1:1) to yield the α anomer **15**α (75 mg, 75%). Data for **15**α: ^{1}H NMR (400 MHz, $CDCl_3$) δ: 7.1–7.4 (m, 20H, aromatic), 6.09 (dd, $J_{1,2}$ = 4.4 Hz, $J_{1,P}$ = 4.6 Hz, 1H, H1), 5.0–5.1 (m, 2H, $POCH_2Ph$), 4.8–4.4 (m, 6H, OCH_2Ph), 4.38 (m, 1H, H4), 3.9 (d, 2H, H2, H3), 3.5 (dd, 2H, H5), 1.9 (m, 2H, CH_2), 1.2 (m, 3H, CH_3). ^{13}C NMR ($CDCl_3$) δ: 97 (C1), 84.3 (C4), 78.97 (C2), 75.54 (C3), 73.53, 72.56, 72.63 (OCH_2Ph), 69.92 (C5), 66.20 ($POCH_2Ph$), 18.89 (CH_2), 6.44 (CH_3). ^{31}P NMR ($CDCl_3$) δ: 34. ESI-MS *m*/*z*: 603.22 (50%, $[M + H]^+$), 295.12 (100%, $[M - C_{16}H_{20}O_4P - H]^+$). HR-MS *m*/*z* calcd. for $C_{35}H_{40}O_7P$ $[M + H]^+$: 603.25116; found: 603.21992. Data for **15**β: ^{1}H NMR (400 MHz, $CDCl_3$) δ: 7.1–7.4 (m, 20H, aromatic), 5.88 (dd, $J_{1,2}$ = 5.9 Hz, $J_{1,P}$ = 6.1 Hz, 1H, H1), 4.9–5.1 (m, 2H, $POCH_2Ph$), 4.5–4.7 (m, 6H, OCH_2Ph), 4.4 (m, 1H, H4), 4.15 (m, 1H, H3), 3.9 (m, 1H, H2), 3.7 (dd, 1H, H5a), 3.55 (dd, 1H, H5b), 1.9 (m, 2H, CH_2), 1.2 (m, 3H, CH_3). ^{13}C NMR ($CDCl_3$) δ: 100.63 (C1), 81.54 (C4), 80.01 (C2), 77.03 (C3), 73.16, 72.54, 72.27 (OCH_2Ph), 72.19 (C5), 66.8 ($POCH_2Ph$). ^{31}P NMR ($CDCl_3$) δ: 34.

*2,3,5-Tri-*O*-benzyl-*D*-ribofuranosyl dibenzylphosphate (13)*

The procedure for **15** was followed. Data for **13**α: ^{1}H NMR (400 MHz, $CDCl_3$) δ: 7.34–7.2 (m, 25H, aromatic), 6.1 (t, $J_{1,2}$ = 1.5 Hz, $J_{1,P}$ = 2.1 Hz, 1H, H1), 5.08 (m, 4H, $P(OCH_2Ph)_2$), 4.7 (m, 2H, OCH_2Ph), 4.5–4.6 (m, 4H, OCH_2Ph), 4.4 (m, 1H, H4), 4.02 (d, 2H, H2,H3), 3.5 (d, 2H, H5). ^{13}C NMR ($CDCl_3$) δ: 99.1, 99.06 (C1), 8.4.64 (C4), 79.05 (C2), 75.44 (C3), 73.55, 72.68, 72.63 (OCH_2Ph), 69.79 (C5), 69.31, 69.25 ($P(OCH_2Ph)_2$). ^{31}P NMR ($CDCl_3$) δ: –2.51. Data for **13**β: ^{1}H NMR (400 MHz, $CDCl_3$) δ: 7.34–7.2 (m, 25H, aromatic), 5.86 (d, *J* = 4.9 Hz, 1H, H1), 5.0–5.1 (m, 4H, $P(OCH_2Ph)_2$), 4.7–4.5 (m, 6H, OCH_2Ph), 4.4 (m, 1H, H4), 4.1 (m, 1H, H3), 3.9 (m, 1H, H2), 3.6–3.7 (dd, 2H, H5). ^{13}C NMR ($CDCl_3$) δ: 102.65 (C1), 81.08 (C4), 79.13 (C2), 77.71 (C3), 73.18, 72.58, 72.32 (OCH_2Ph), 70.4 (C5), 69.33, 69.29 ($P(OCH_2Ph)_2$). ^{31}P NMR ($CDCl_3$) δ: –3.1.

*2,3,5-Tri-*O*-benzyl-*D*-ribofuranosyl benzyl methylphosphonate (14)*

The procedure for **15** was followed. Data for **14**α: ^{1}H NMR (400 MHz, $CDCl_3$) δ: 7.4–7.3 (m, 20H, aromatic), 6.09 (dd, 1H, $J_{1,2}$ = 1.6 Hz, $J_{1,P}$ = 3.8 Hz, H1), 4.9–5.1 (m, 2H, $POCH_2Ph$), 4.7 (d, 2H, OCH_2Ph), 4.6 (m, 2H, OCH_2Ph), 4.5 (d, 2H, OCH_2Ph), 4.3 (m, 1H, H4), 3.9 (m, 2H, H2, H3), 3.4 (m, 2H, H5). ^{13}C NMR ($CDCl_3$) δ: 97.37 (C1), 84.13 (C4), 78.63 (C2), 75.27 (C3), 73.52 (OCH_2Ph), 72.73 (OCH_2Ph), 72.49 (OCH_2Ph), 69.81 (C5), 67.15 ($POCH_2Ph$). ^{31}P NMR ($CDCl_3$) δ: 32, 31. Data for **14**β: ^{1}H NMR (400 MHz, $CDCl_3$) δ: 7.4–7.3 (m, 20H, aromatic), 5.87 (d, 1H, *J* = 5.8 Hz, H1), 5.0 (m, 2H, $POCH_2Ph$), 4.7 (d, 2H, OCH_2Ph), 4.6 (d, 2H, OCH_2Ph), 4.5 (m, 2H, OCH_2Ph), 4.1 (m, 1H, H4), 3.9 (m, 2H, H2, H3), 3.59 (m, 2H, H5). ^{13}C NMR ($CDCl_3$) δ: 100.75 (C1), 80.07 (C4), 79.99 (C2), 76.65 (C3), 73.17 (OCH_2Ph), 72.58 (OCH_2Ph), 72.26 (OCH_2Ph), 69.84 (C5), 66.95 ($POCH_2Ph$). ^{31}P NMR ($CDCl_3$) δ: 30, 31.

α-D-Ribofuranosyl ethylphosphonate (18)

To a solution of compound **15**α (200 mg, 0.33 mmol) in MeOH (10 mL) was added 10% Pd/C. The reaction mixture was stirred under H_2 overnight, filtered through Celite, and concentrated to afford **18** (82 mg, 100%). The crude product was purified through an Amberlite IR-120 ion exchange column, titrated with triethylamine, then dried in vacuo to obtain the triethylammonium salt. Data for **18**: ^{1}H NMR

Enantiomeric synthesis of carbocyclic analogs of D- and L-6-azapyrimidine ribonucleosides[1]

Peng Liu and Chung K. Chu

Abstract: An effective and practical synthesis of carbocyclic D- and L-6-azapyrimidine nucleosides (**3**–**8**) was described. Starting from D-ribose, a new efficient methodology for the synthesis of L-2,3-*O*-cyclohexylidene-4-cyclopentenone (**23**) was developed via a ring-closing metathesis, which was applied for the synthesis of L-cyclopentyl-6-azapyrimidine nucleosides (**6**–**8**). The regiospecific introduction of 6-azauracil on the carbocyclic moiety (**9** and **25**) was also achieved by masking its N_3 position with a 4-methylthio group.

Key words: carbocyclic nucleosides, 6-azapyrimidine nucleosides, enantiomeric synthesis.

Résumé : On décrit une méthode efficace et pratique de synthèse des nucléosides des D- et L-6-azapyrimidines carbocycliques (**3**–**8**). Utilisant le D-ribose comme produit de départ, on a développé une nouvelle méthodologie efficace pour la synthèse de la L-2,3-*O*-cyclohexylidène-4-cyclopenténone (**23**) qui fait appel à une réaction de métathèse conduisant à une fermeture de cycle et on l'a appliquée à la synthèse de nucléosides de la L-cyclopentyl-6-azapyrimidine (**6**–**8**). L'introduction régiospécifique du 6-azauracile sur la portion carbocyclique (**9** et **25**) a été réalisée en masquant sa position N_3 à l'aide d'un groupe 4-méthylthio.

Mots clés : nucléosides carbocycliques, nucléosides de 6-azapyrimidine, synthèse énantiomérique.

[Traduit par la Rédaction]

Introduction

Nucleosides are the building blocks of nucleic acids and therefore of fundamental importance in all living systems (1, 2). They have been playing a major role in fighting tumors and viruses, either as selective inhibitors of certain necessary enzymes for cancer or viral reproduction (3) or as nucleic acid chain terminators that interrupt the replication of cancer cells or a virus (4, 5). Currently, 8 out of 21 FDA approved anti-HIV agents are nucleoside analogues, and more than 10 other nucleosides are available for the treatment of other viral infections (2, 6). However, the toxicities (7), enzymatic degradation (8), as well as the emergence of resistant viral strains (9), prompted the search for novel nucleoside analogues. Consequently, extensive modifications on both the sugar and the heterocyclic moiety of the nucleosides have been carried out. Carbocyclic nucleosides, where the furanose ring is replaced with a cyclopentyl ring, have attracted much attention because of their increased metabolic stability as well as interesting biological activities (10, 11). Two milestones in carbocyclic nucleosides are the approval of abacavir (12) and entecavir (13) by the FDA as anti-HIV and anti-HBV agents, respectively (Fig. 1).

Azapyrimidine nucleosides are an interesting class of nucleosides, which are derived from the replacement of the carbon atom of a pyrimidine ring by a nitrogen. For example, D-6-azacytidine (**1**) is an antimetabolite with a wide spectrum of therapeutic activities (14). D-6-Azauridine (**2**) exhibited antitumor activity both experimentally and clinically (15). More recently, 6-azauridine **2** was identified to be significantly effective against West Nile Virus (WNV) in vitro (16). Therefore, as a part of our ongoing antiviral drug discovery program, herein we report an enantiomeric synthesis of carbocyclic analogues of D- and L-6-azapyrimidine ribonucleoside (**3**–**8**) as analogues of 6-azauridine.

Results and discussion

In preliminary studies, we have reported the synthesis of carbocyclic D-6-azauridine **4** and found that the 6-azauracil moiety is a more reactive base in comparison to uracil for Mitsunobu reaction with cyclopentanol **9** because of the introduction of the third nitrogen atom (17). However, the competition among N_1-, N_3-, and O-substitutions caused difficulties in separating the desired N_1 product and gave a poor yield of **10** (Table 1), thus limiting the application of this methodology for the preparation of other carbocyclic 6-azapyrimidine nucleosides. Therefore, finding the suitable N_3-blocked 6-azapyrimidines, which can be condensed with D-cyclopentanol **9** under the standard Mitsunobu conditions, was crucial for the current project.

4-Methylthiotriazinone (**14**) (18) can be regarded as a precursor of 6-azacytosine or 6-azauracil as it can be readily converted to 6-azacytosine upon treatment with saturated methanolic ammonia (19) or to 6-azauracil by hydrolysis (20, 21). In addition, it possesses the structural feature of a N_3-blocked analog, which makes it a N_1-regioselective building block to couple with the sugar moiety **9**. To our sur-

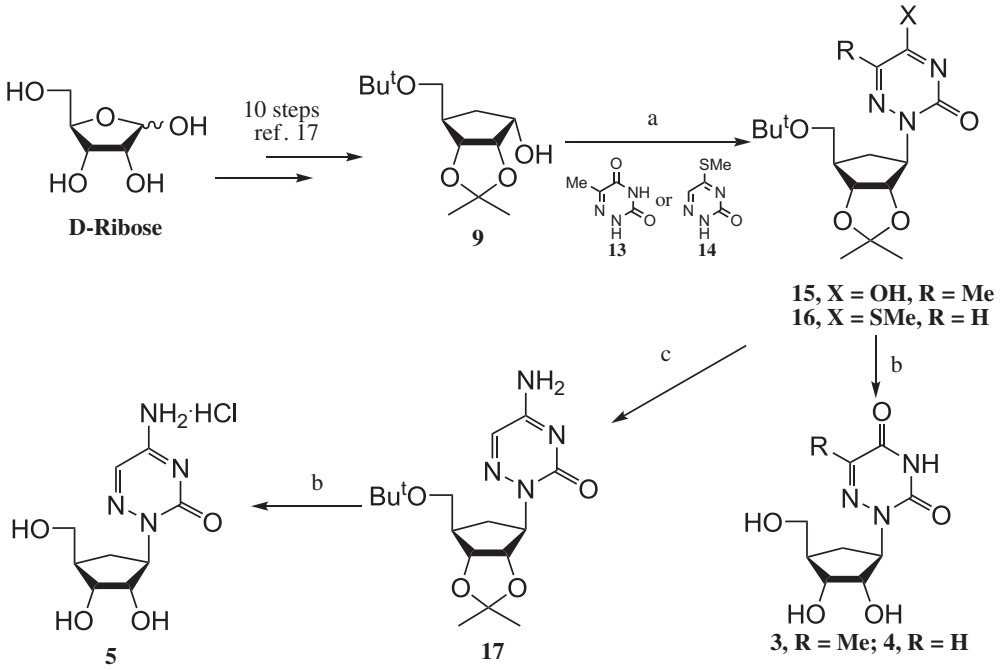
Table 1. Direct coupling of free 6-azauracil and 6-azathymine with D-α-cyclopentanol (**9**).

			Regioisomer ratio			
R	Reaction time	Temperature	**10**	**11**	**12**	Overall yield (%)
H	5 Days	rt	4	1.7	1	83
H	5 h	50–60 °C	Trace	Trace	1	—
Me	11 Days	rt	2	1	2	75

prise, the coupling reaction between **14** and D-cyclopentanol (**9**) took place in a regiospecific manner under the standard Mitsunobu conditions (Scheme 1). Using **14** is the convenient way to avoid the undesired N_3 isomer. The coupled product (**16**) was isolated as a mixture of the desired nucleoside along with reduced DIAD as a by-product. After amination of crude **16** with saturated methanolic ammonia at room temperature for 24 h, compound **17** was obtained in two steps in 89% overall yield. Preparation of the final carbocyclic D-6-azacytidine (**5**) was accomplished by deprotection of **17** with HCl–MeOH (1:3) in quantitative yield. Carbocyclic D-6-azauridine (**4**) was also obtained by hydrolysis of **16** in 3 N HCl in methanol in 92% yield.

For the synthesis of L-6-azapyrimidine analogues **6**–**8**, we utilized the intermediate, 2,3-*O*-cyclohexylidene protected L-cyclopentenone (**23**, Scheme 2) owing to reasons described below.



Jeong and co-workers (22) have reported a short route to isopropylidene-protected L-cyclopentenone (**30**) from intermediate **29** (Scheme 3). However, it was found that the handling of vinyl aldehyde **29** was quite inconvenient and often lead to irreproducible yield because of its high volatility (22, 23). This difficulty prompted us to seek an alternative and practical method for the synthesis of L-enone (**23**). Starting from D-ribose, the cyclohexylidene-protected product **18** was prepared with cyclohexanone in the presence of *p*-toluenesulfonic acid as the catalyst in 92% yield (Scheme 2). By using triphenylphosphonium methylidene in THF, a Wittig reaction of **18** was carried out to give the diol **19**, which underwent an oxidative cleavage with sodium periodate to furnish the vinyl aldehyde **20** in two steps in 65% yield. The aldehyde **20** is a nonvolatile oil that can be conveniently purified by column chromatography and thoroughly dried in vacuum. Treatment of **20** with vinylmagnesium bromide in anhydr. THF gave the diene **21** as a mixture of two diastereoisomers in 85% yield. The metathesis ring-closing reaction of **21** was carried out in the presence of 1 mol% of Grubbs catalyst in CH_2Cl_2 at room temperature for 24 h, followed by PDC oxidation in one pot gave the cyclopentenone **23** in two steps in 80% yield. The key intermediate L-α-cyclopentanol (**25**) was prepared in two steps from **23** using the same procedure as for **9**. The Mitsunobu reaction was used to couple the alcohol **25** with 6-azathymine (**13**) and 4-methylthiotriazinone (**14**) to yield compounds **26** and **27**, respectively. The final compounds, L-6-azapyrimidine carbanucleosides (**6**–**8**), were prepared using the same procedure for carbocyclic D-6-azapyrimidine nucleosides (**3**–**5**) (Scheme 1).

The antiviral activities of **3**–**8** were evaluated against SARS, Yellow Fever, West Nile, VEE, and Punta Toro A viruses; however, no significant antiviral activity against these viruses was detected.

In summary, we have developed an efficient and practical synthetic methodology for D- and L-cyclopentenones as the key intermediates in the preparation of various carbocyclic nucleosides. By choosing 4-methylthiotriazinone (**14**) as the N_3-blocked base, we achieved the N_1-regiospecific coupling

Scheme 1. Synthesis of D-cyclopentyl-6-azapyrimidine analogues. Reagents and conditions: (*a*) DIAD, Ph_3P, base **13** or **14**, THF, –78 °C to rt, 3–11 days; (*b*) 3 N HCl–MeOH, rt, 6–8 h; (*c*) NH_3–MeOH, rt, 24 h.

of 6-azapyrimidine base with D- and L-α-cyclopentanols (**9** and **25**) under Mitsunobu conditions.

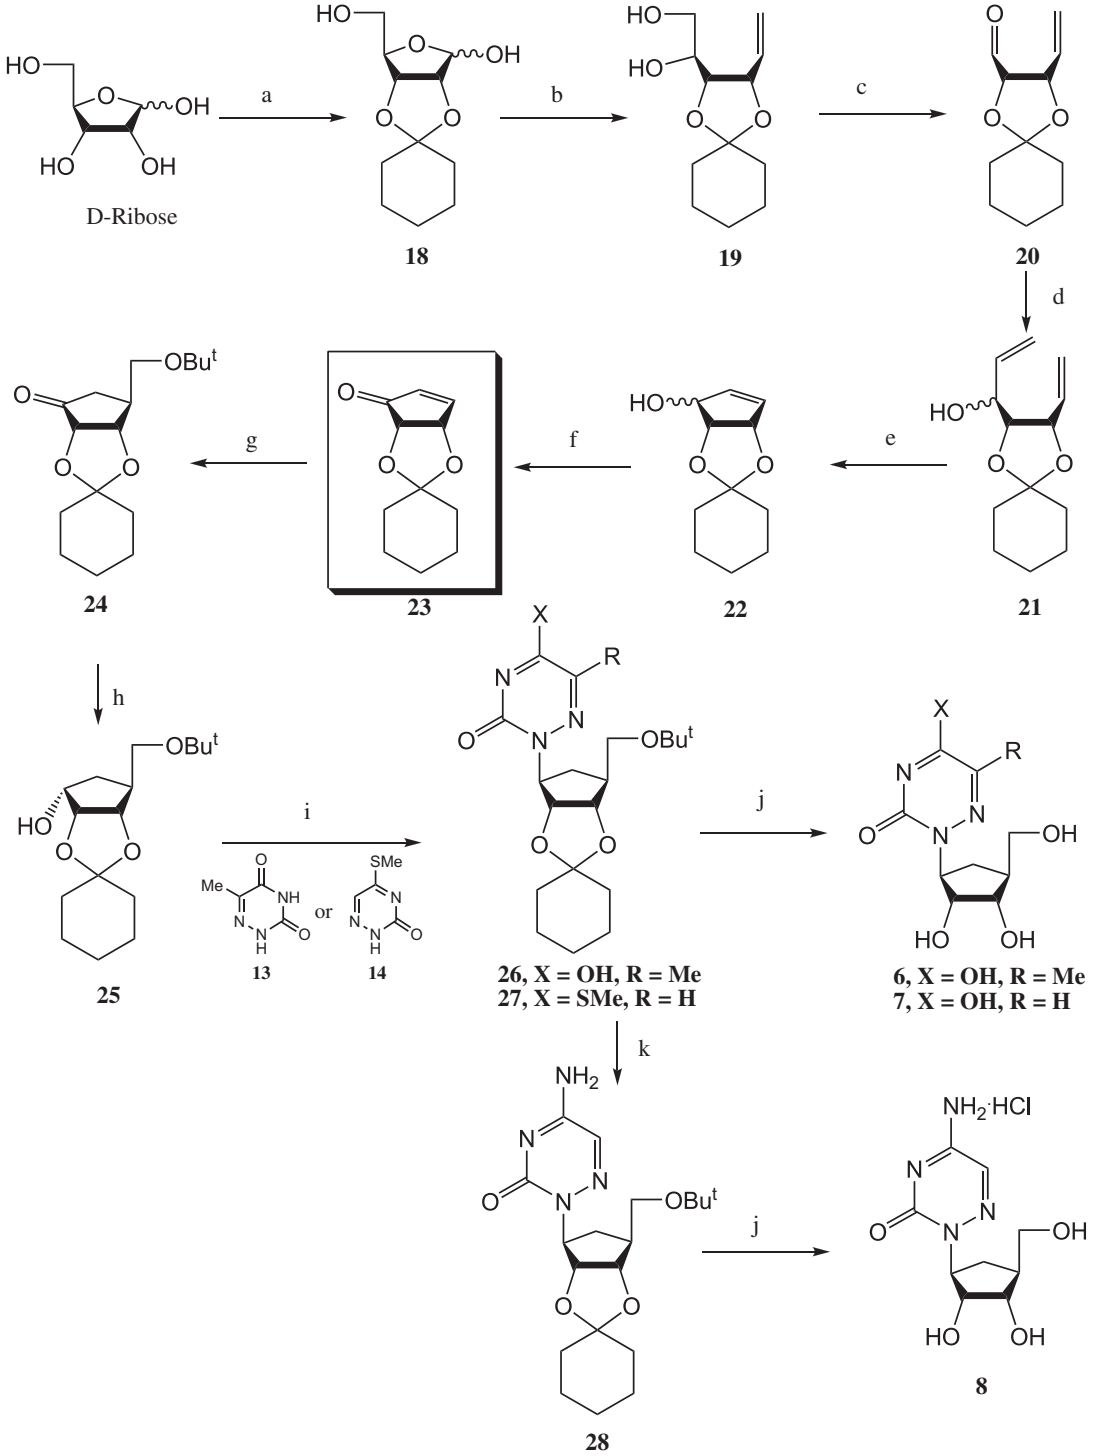
Experimental section

Melting points were determined on a Mel-Temp II laboratory device and are uncorrected. NMR spectra were recorded on a Varian 500 spectrometer at 500 MHz (^{1}H) and 100 MHz (^{13}C) in the indicated solvents with TMS as the internal standard. UV spectra were obtained on a Beckman DU-650 spectrophotometer. Optical rotations were measured on a JASCO DIP-370 digital polarimeter. Mass spectra were recorded on a Micromass Autospec high-resolution mass spectrometer in ESI mode. Elementary analyses were performed by Atlantic Microlab, Inc., (Atlanta, Georgia).

(1′*R*,2′*S*,3′*R*,4′*R*)-1-[2,3-Dihydroxy-4-(hydroxymethyl)cyclopent-1-yl]-6-azathymine (3)

Diisopropyl azodicarboxylate (DIAD, 0.41 mL, 2.1 mmol) was added dropwise to the solution of triphenylphosphine (550 mg, 2.1 mmol) in THF (15 mL) at 0 °C. After the formation of DIAD–Ph_3P complex, the slurry was stirred for 10 min and transferred to a solution of 6-azathymine (200 mg, 1.57 mmol) and **9** (17) (245 mg, 1.05 mmol) in anhydr. THF (10 mL) at –78 °C. The reaction mixture was stirred for additional 1 h at –78 °C and then warmed up to room temperature (rt). After the suspension was kept stirring at rt for 11 days, the resulting clear amber solution was concentrated and the residue was purified by flash column chromatography on silica gel (hexanes–EtOAc, 10:1) to yield **15**. Compound **15** was contaminated with reduced DIAD and was used for the next reaction without further purification.

The crude product (**15**) was dissolved in a 3:1 mixture of MeOH with 37% hydrochloric acid (15 mL), and the mixture was stirred at rt for 6 h. The solvent was removed under reduced pressure and the residue was purified by flash column chromatography on silica gel (CH_2Cl_2–MeOH, 20:1 to 10:1) to yield compound **3** (82 mg, 31%) as a white solid; mp 186–188 °C. $[\alpha]^{26}_D$ 1.46° (*c* 0.64, CH_3OH). UV (H_2O, nm) λ_{max}: 259.0 (4934, pH 2), 259.0 (4909, pH 7), 300.0 (5538, pH 11). ^{1}H NMR (CD_3OD) δ: 5.15–5.11 (m, 1H), 4.58 (t, *J* = 6.0 Hz, 1H), 4.05 (t, *J* = 6.0 Hz, 1H), 3.75–3.72 (m, 1H), 3.58–3.54 (m, 1H), 2.15–2.14 (m, 1H), 2.14 (s, 3H), 2.04 1.98 (m, 1H), 1.89 1.84 (m, 1H). ^{13}C NMR (CD_3OD) δ: 157.50, 150.45, 143.13, 72.59, 72.20, 63.66, 57.55, 45.95, 25.71, 15.70. MS (ESI) *m*/*z*: 258 (M^+ + H), 280 (M^+ + Na). Anal. calcd. for $C_{10}H_{15}N_3O_5 \cdot 0.6H_2O$: C 44.81, H 6.09, N 15.68; found: C 44.96, H 6.10, N 15.48.



(1′*R*,2′*S*,3′*R*,4′*R*)-1-[4-(*tert*-Butoxymethyl)-2,3-(isopropylidenedioxy)cyclopent-1-yl]-6-azacytosine (17)

DIAD (0.58 mL, 2.92 mmol) was added dropwise to a solution of Ph_3P (840 mg, 3.2 mmol) in THF (30 mL) at 0 °C. The resulting slurry was stirred for 10 min and added to a solution of **14** (313 mg, 2.19 mmol) and **9** (16) (360 mg, 1.46 mmol) in THF (15 mL) at –78 °C. The reaction mixture was stirred for an additional hour at –78 °C and allowed to warm up to rt. After the suspension had been stirred for 4 days, the clear amber solution was evaporated and the residue was purified by column chromatography on silica gel (hexanes–EtOAc, 10:1) to yield **16** and used for the next reaction without further purification.

The crude product (**16**) was dissolved in saturated methanolic ammonia (20 mL) and stirred at rt for 24 h. The mixture was concentrated under reduced pressure, and the residue was purified by flash column chromatography on silica gel (CH_2Cl_2–MeOH, 50:1 to 20:1) to give compound **17** (362 mg, 89%) as a white solid; mp 236 to 237 °C. $[\alpha]^{27}_D$ –95.45° (*c* 1.31, $CHCl_3$). UV ($CHCl_3$, nm) λ_{max}: 261, 289.

D-Ribose **29** **30**

(1′*R*,2′*S*,3′*R*,4′*R*)-1-[2,3-Dihydroxy-4-(hydroxymethyl)cyclopent-1-yl]-6-azauracil (4)

The crude product (**16**) (195 mg, 0.48 mmol) was dissolved in a 3:1 mixture of methanol with 37% hydrochloric acid (15 mL), and the mixture was stirred at rt for 12 h. The solvent was evaporated under vacuum and the residue was chromatographed on silica gel (CH_2Cl_2–MeOH, 20:1 to 10:1) to obtain compound **4** (98 mg, 84%) as a white solid; mp 278 to 279 °C. $[\alpha]^{25}_D$ –3.26° (*c* 0.61, CH_3OH). UV (H_2O, nm) λ_{max}: 257.5 (3459, pH 2), 257.5 (4548, pH 7), 300 (3110, pH 11). ^{1}H NMR (CD_3OD) δ: 7.34 (s, 1H), 5.14–5.09 (m, 1H), 4.58 (t, *J* = 6.0 Hz, 1H), 4.04 (t, *J* = 6.0 Hz, 1H), 3.74–3.71 (m, 1H), 3.76–3.54 (m, 1H), 2.15–2.12 (m, 1H), 2.04–1.99 (m, 1H), 1.89–1.82 (m, 1H). ^{13}C NMR (CD_3OD) δ: 157.40, 149.83, 135.11, 72.54, 72.14, 63.62, 57.39, 45.92, 25.62. MS (ESI) *m*/*z*: 242 (M^+ + H), 266 (M^+ + Na), 282 (M^+ + K). Anal. calcd. for $C_9H_{13}N_3O_5$: C 44.44, H 5.39, N 17.28; found: C 44.56, H 5.54, N 17.18.

(1′*R*,2′*S*,3′*R*,4′*R*)-1-[2,3-Dihydroxy-4-(hydroxymethyl)cyclopent-1-yl]-6-azacytosine hydrochloride (5)

Compound **17** (630mg, 1.86 mmol) was dissolved in a 1:3 mixture of 37% hydrochloric acid with methanol (15 mL), and the mixture was stirred at rt for 6 h. The solvent was evaporated under vacuum and the residue was dissolved in distilled water (5 mL). The resulting aqueous solution was extracted with IPA–$CHCl_3$ (1:4, 3 × 10 mL). The aqueous phase was freeze-dried, and the crude product (**5**) was recrystalized from methanol – ethyl ether to obtain **5** as a white solid in quantitative yield; mp > 300 °C (dec.). $[\alpha]^{26}_D$ –72.85° (*c* 0.82, CH_3OH). UV (H_2O, nm) λ_{max}: 281.5 (7689, pH 2), 284 (7760, pH 7), 280 (7728, pH 11). ^{1}H NMR (CD_3OD) δ: 7.65 (s, 1H), 5.11–5.08 (m, 1H), 4.21 (dd, J_1 = 9.0 Hz, J_2 = 5.5 Hz, 1H), 3.93–3.91 (m, 1H), 3.63–3.54 (m, 2H), 2.13–2.15 (m, 2H), 1.53–1.48 (m, 1H). ^{13}C NMR (CD_3OD) δ: 159.19, 156.11, 127.87, 74.90, 72.60, 63.53, 63.00, 45.41, 28.13. MS (ESI) *m*/*z*: 243 (M^+ + H), 485 (M_2H^+). Anal. calcd. for $C_9H_{15}ClN_4O_4{\cdot}0.5H_2O$: C 37.57, H 5.61, N 19.47; found: C 37.56, H 5.77, N 19.57.

(1*R*)-1-((2*R*,3*S*)-3-Vinyl-1,4-dioxaspiro[4.5]dec-2-yl)-ethane-1,2-diol (19)

To a suspension of methyltriphenylphosphonium bromide (45.1 g, 125 mmol) in THF (350 mL) was added potassium *tert*-butoxide (18.5 g, 143.4 mmol) at 0 °C. The reaction mixture was stirred at 0 °C for 15 min and then at room temperature for 1 h. The reaction mixture was cooled to 0 °C again, compound **18** (24) (10.32 g, 44.8 mmol) dissolved in THF (100 mL) was added, and the resulting mixture was stirred at rt overnight. The reaction was quenched carefully by adding water (200 mL) at 0 °C, and extracted with ethyl acetate (3 × 300 mL). The combined organic phases were washed with brine (2 × 100 mL), dried (Na_2SO_4), filtered, and concentrated. The resulting yellow syrup was purified by vacuum chromatography (hexanes–EtOAc, 2:1) to give crude compound **19** (14.5 g) along with triphenylphosphine oxide. ^{1}H NMR ($CDCl_3$) δ: 5.97–6.01 (m, 1H), 5.47 (dd, J_1 = 18 Hz, J_2 = 1.5 Hz, 1H), 5.32 (dd, J_1 = 11.5 Hz, J_2 = 1.5 Hz, 1H), 4.70 (t, *J* = 6 Hz, 1H), 4.07 (t, *J* = 7.5 Hz, 1H), 3.81–3.83 (m, 1H), 3.71–3.74 (m, 1H), 1.54–1.69 (m, 8H), 1.38–1.42 (m, 2H). ^{13}C NMR ($CDCl_3$) δ: 134.02, 118.53, 109.73, 78.22, 77.84, 69.91, 64.49, 37.64, 34.77, 25.10, 24.08, 23.75. HR-ESI MS calcd. for $C_{12}H_{20}O_4$: 229.1362 (M^+ + H); found: 229.1402.

(2*S*,3*S*)-3-Vinyl-1,4-dioxaspiro[4.5]decane-2-carbaldehyde (20)

To a solution of crude product **19** (14.5 g) in CH_2Cl_2 (200 mL) was added a solution of $NaIO_4$ (14.24 g, 66 mmol) in water (100 mL) at rt and the reaction mixture was stirred for 30 min. The mixture was filtered through a short pad of Celite and the aqueous filtrate was separated and extracted with CH_2Cl_2 (2 × 200 mL). The combined organic layers were dried (Na_2SO_4) and concentrated. The residue was chromatographed on silica gel (hexanes–EtOAc, 10:1) to give **20** as a colorless oil. ^{1}H NMR ($CDCl_3$) δ: 9.56 (d, *J* = 3.0 Hz, 1H), 5.72–5.79 (m, 1H), 5.47 (dd, J_1 = 17.5 Hz, J_2 = 1.5 Hz, 1H), 5.32 (dd, J_1 = 9.0 Hz, J_2 = 1.5 Hz, 1H), 4.85 (t, *J* = 7.5 Hz, 1H), 4.40–4.42 (m, 1H), 1.59–1.84 (m, 8H), 1.42–1.47 (m, 2H). ^{13}C NMR ($CDCl_3$) δ: 201.08, 131.53, 119.64, 112.09, 81.94, 78.74, 37.20, 34.81, 25.01, 24.01, 23.73.

(1*R*)- and (1*S*)-1-((2*R*,3*S*)-3-Vinyl-1,4-dioxaspiro[4.5]dec-2-yl)prop-2-en-1-ol (21)

To a solution of **20** (400 mg, 2.04 mmol) in THF (5 mL) was added vinylmagnesium bromide solution (1 mol/L, 3 mL, 3 mmol) at 0 °C over 10 min. The mixture was stirred at rt for 1 h and satd. aq. NH_4Cl (5 mL) was added to quench the reaction. The aqueous layer was extracted with ethyl acetate (3 × 10 mL). The combined organic layers were dried (Na_2SO_4), filtered, and concentrated in vacuo. The residue was purified by column chromatography on silica gel (hexanes–EtOAc, 30:1) to give **21** as two diastereoisomers (**21a** and **21b**, dr 1:1) in 85% overall yield. **21a**: $[\alpha]^{26}_D$ 4.81° (*c* 0.85, $CHCl_3$). ^{1}H NMR ($CDCl_3$) δ: 5.96–6.03 (m, 1H), 5.81–5.88 (m, 1H), 5.21–5.40 (m, 4H), 4.58–4.63 (m, 1H), 4.05–4.13 (m, 2H), 2.47 (d, *J* = 13 Hz, 1H), 1.58–1.76 (m, 8H), 1.39–1.44 (m, 2H). ^{13}C NMR ($CDCl_3$) δ: 136.68, 134.17, 119.29, 117.15, 109.47, 80.29, 78.55, 70.70, 37.30, 34.50, 25.13, 24.07, 23.70. **21b**: $[\alpha]^{26}_D$ 24.15 (*c* 0.9, $CHCl_3$). ^{1}H NMR ($CDCl_3$) δ: 6.01–6.09 (m, 2H), 5.22–5.46 (m, 4H), 4.68 (t, *J* = 7.0 Hz, 1H), 4.18 (s, 1H), 4.00–4.03 (m, 1H), 2.04 (s, 1H), 1.56–1.70 (m, 8H), 1.38–1.41 (m, 2H). ^{13}C NMR ($CDCl_3$) δ: 137.80, 134.38, 118.24, 116.17, 109.51,

80.16, 78.38, 71.02, 37.53, 34.79, 25.15, 24.05, 23.73. Anal. calcd. for $C_{13}H_{20}O_3$: C 69.61, H 8.99; found: C 69.85, H 9.08.

(2*S*,3*S*)-2,3-(Cyclohexylidenedioxy)-4-cyclopentenone (23)

Grubbs catalyst (13 mg, 0.01 mmol) was added to a solution of **21** (153 mg, 0.68 mmol) in anhydr. CH_2Cl_2 (5 mL) and the resulting dark brown solution was stirred at rt for 24 h. PDC (293 mg, 1.36 mmol) and 4 Å molecular sieves (150 mg) were added to the reaction mixture, and the suspension was stirred at rt for 4 h. The reaction mixture was filtered through a short pad of silica gel and thoroughly washed with acetone. The filtrate was concentrated under reduced pressure and the residue was purified by column chromatography (hexanes–EtOAc, 10:1) to yield **23** (105 mg, 80%) as a white solid; mp 86–88 °C (lit. value (25) mp 87 °C). $[\alpha]^{27}_D$ 74.33° (*c* 1.11, $CHCl_3$). ^{1}H NMR ($CDCl_3$) δ: 7.61–7.62 (m, 1H), 6.20 (d, *J* = 6 Hz, 1H), 5.26–5.27 (m, 1H), 4.46 (d, *J* = 5.5 Hz, 1H), 1.54–1.67 (m, 8H), 1.38–1.39 (m, 2H).

(2*S*,3*S*,4*S*)-4-(*tert*-Butoxymethyl)-2,3-(cyclohexylidenedioxy)-1-cyclopentanone (24)

Compound **23** (1.57g, 8.1 mmol) was converted to **24** (1.97 g, 86%) according to the reported procedure (26). $[\alpha]^{25}_D$ 139.45° (*c* 0.61, $CHCl_3$). The melting point and ^{1}H NMR data were identical to that described in ref. 26.

(1*R*,2*R*,3*S*,4*S*)-4-(*tert*-Butoxymethyl)-2,3-(cyclohexylidenedioxy)-1-cyclopentanol (25)

To a solution of **24** (1.97 g, 7.0 mmol) in methanol (30 mL) was added cerium(III) chloride heptahydrate (1.82 g, 4.9 mmol) at –30 °C. After stirring at this temperature for 15 min, sodium borohydride (532 mg, 14.0 mmol) was added portionwise. The reaction mixture was gradually warmed up to rt and stirred for 30 min. Hexane – ethyl acetate (1:1, 30 mL) was added, and the resulting precipitated mixture was filtered through a pad of silica gel. The filtrate was concentrated and the residue was chromatographed on silica gel (hexanes–EtOAc, 50:1) to afford **25** as a colorless oil (1.87 g, 94%). $[\alpha]^{27}_D$ 0.04 (*c* 0.67, $CHCl_3$). ^{1}H NMR ($CDCl_3$) δ: 4.43–4.45 (m, 2H), 4.22–4.25 (m, 1H), 3.31–3.33 (m, 1H), 3.19–3.22 (m, 1H), 2.52 (d, *J* = 9.0 Hz, 1H), 2.21 (s, br, 1H), 1.82–1.85 (m, 2H), 1.55–1.68 (m, 8H), 1.40 (s, 2H), 1.13 (s, 9H). ^{13}C NMR ($CDCl_3$) δ: 111.34, 83.18, 79.18, 72.59, 72.10, 63.10, 42.21, 36.16, 36.00, 33.79, 27.42, 25.21, 24.09, 23.65. Anal. calcd. for $C_{16}H_{19}O_4$: C 67.57, H 9.92; found: C 67.59, H 10.03.

(1′*S*,2′*R*,3′*S*,4′*S*)-1-[2,3-Dihydroxy-4-(hydroxymethyl)cyclopent-1-yl]-6-azathymine (6)

Compound **6** was prepared from **25** on a 1.72 mmol scale following the same procedure used for compound **3**. Purification on silica gel using 5% MeOH in CH_2Cl_2 as eluent gave 154 mg of **6** (35%) as a white solid. $[\alpha]^{26}_D$ –1.13° (*c* 0.79, CH_3OH). ^{1}H NMR (CD_3OD) δ: 5.15–5.20 (m, 1H), 4.63 (t, *J* = 6.0 Hz, 1H), 4.10 (t, *J* = 6.0 Hz, 1H), 3.77 (q, J_1 = 10.5 Hz, J_2 = 6.5 Hz, 1H), 3.60 (q, J_1 = 10.5 Hz, J_2 = 6.5 Hz, 1H), 3.34–3.35 (m, 1H), 2.19 (s, 3H), 2.04–2.08 (m, 1H), 1.87–1.93 (m, 1H). ^{13}C NMR (CD_3OD) δ: 157.30, 150.27, 142.98, 72.49, 72.06, 63.42, 57.39, 45.73, 25.49, 15.51. MS (ESI) *m*/*z*: 258 (M^+ + H), 280 (M^+ + Na). Anal. calcd. for $C_{10}H_{15}N_3O_5$·0.3MeOH: C 46.36, H 6.12, N 15.75; found: C 46.50, H 6.05, N 15.51.

(1′*S*,2′*R*,3′*S*,4′*S*)-1-[4-(*tert*-Butoxymethyl)-2,3-(cyclohexylidenedioxy)cyclopent-1-yl]-6-azacytosine (28)

Using the same procedure as described for compound **17**, compound **25** (330 mg, 1.17 mmol) was coupled with **14** under Mitsunobu conditions to give **27**. The crude product (**27**) was treated with saturated methanolic ammonia at rt to afford compound **28** (400 mg, 90%) as a white solid after flash column chromatography on silica gel (CH_2Cl_2–MeOH, 50: 1 to 20:1); mp 258 to 259 °C. $[\alpha]^{27}_D$ 78.91° (*c* 0.60, $CHCl_3$). UV (CH_3OH, nm) λ_{max}: 277. ^{1}H NMR ($CDCl_3$) δ: 8.20 (s, br, 1H), 7.60 (s, 1H), 6.60 (s, br, 1H), 5.15–5.18 (m, 1H), 4.82–4.84 (m, 1H), 4.41–4.43 (m, 1H), 3.48–3.51 (m, 1H), 3.32–3.36 (m, 1H), 2.29–2.33 (m, 2H), 1.50–1.82 (m, 9H), 1.35–1.36 (m, 2H), 1.17 (s, 9H). ^{13}C NMR ($CDCl_3$) δ: 158.98, 154.41, 127.37, 113.53, 82.68, 81.07, 72.68, 64.11, 62.75, 44.76, 37.52, 34.84, 33.70, 27.56, 25.17, 24.07, 23.60. HR-ESI MS calcd. for $C_{19}H_{30}N_4O_4$: 379.2267 (M^+ + H); found: 379.2297.

(1′*S*,2′*R*,3′*S*,4′*S*)-1-[2,3-Dihydroxy-4-(hydroxymethyl)cyclopent-1-yl]-6-azauracil (7)

Compound **27** (105 mg, 0.26 mmol) was converted to **7** (57 mg, 92%) according to the same procedure for **4**; mp 278–280 °C. $[\alpha]^{27}_D$ 2.96 (*c* 0.68, MeOH). ^{1}H NMR (CD_3OD) δ: 7.37 (s, 1H), 5.14–5.16 (m, 1H), 4.61 (t, *J* = 6.0 Hz, 1H), 4.07 (t, *J* = 6.0 Hz, 1H), 3.74–3.78 (m, 1H), 3.58–3.62 (m, 1H), 2.08–2.18 (m, 1H), 2.02–2.08 (m, 1H), 1.88–1.93 (m, 1H). ^{13}C NMR (CD_3OD) δ: 157.20, 149.67, 135.02, 73.03, 72.38, 63.16, 57.32, 45.71, 25.39. MS (ESI) *m*/*z*: 242 (M^+ – 1), 266 (M^+ + Na). Anal. calcd. for $C_9H_{13}N_3O_5$·0.5CH_3OH: C 44.01, H 5.83, N 16.21; found: C 44.04, H 5.66, N 16.04.

(1′*S*,2′*R*,3′*S*,4′*S*)-1-[2,3-Dihydroxy-4-(hydroxymethyl)-cyclopent-1-yl]-6-azacytosine hydrochloride (8)

Compound **28** (630 mg, 1.66 mmol) was converted to **8** (448 mg, 97%) according to the same procedure as for **5**; mp 235–238 °C (dec.). $[\alpha]^{26}_D$ 74.37 (*c* 0.91, CH_3OH). ^{1}H NMR (CD_3OD) δ: 7.79 (s, 1H), 5.17–5.13 (m, 1H), 4.23 (dd, J_1 = 9.0 Hz, J_2 = 5.5 Hz, 1H), 3.95 (dd, J_1 = 5.5 Hz, J_2 = 4.0 Hz, 1H), 3.66–3.58 (m, 2H), 2.28–2.19 (m, 2H), 1.61–1.55 (m, 1H). ^{13}C NMR (CD_3OD) δ: 153.68, 147.03, 135.38, 127.78, 74.52, 72.11, 63.14, 45.14, 27.46. MS (ESI) *m*/*z*: 243 (M^+ + H), 485 (M_2^+ + H). Anal. calcd. for $C_9H_{15}ClN_4O_4$·0.5H_2O: C 37.57, H 5.61, N 19.47; found: C 37.56, H 5.77, N 19.57.

TRIBUTE / HOMMAGE

"How bittersweet it is"

Walter Szarek was born on 19 April 1938 in St. Catharines, Ontario. He received his B.Sc. in Honours Chemistry in 1960 from McMaster University, Hamilton, Ontario. During the summer months of 1956–1958 he was employed at the Ontario Paper Co. in Thorold, Ontario where he studied the alkaline oxidation of lignin, an experience that first exposed him to industrial chemistry and research. Walter received a M.Sc. degree in 1962 from McMaster University, having studied with Professor David B. MacLean in the area of alkaloid chemistry. His thesis research was concerned with the structural elucidation of annotine, a member of the *Lycopodium* alkaloids. This class of alkaloids had attracted the attention of several of the internationally renowned stars of natural products chemistry in Canada. For example, annotine itself was first isolated from *L. annotinium* of Canadian origin by the legendary Canadian alkaloid duo, R.H.F. Manske and L. Marion. In addition to Dave MacLean and Ian Spenser at McMaster, other Canadian researchers in the field who studied the elucidation and subsequent synthesis of the fascinating *Lycopodium* structures included K. Wiesner, Z. Valenta, W.A. Ayer, and F.A.L. Anet. Walter was well-advanced towards the completion of his Ph.D. program at McMaster when a certain restlessness had set in and he began contemplating a change of venue and a change of research interests. Thus, in 1962 he began studies towards the Ph.D. degree with Professor J.K.N. Jones at Queen's University in Kingston, Ontario. He completed his studies in 1964 in the area of carbohydrate chemistry.

Having worked with both alkaloids and carbohydrates, Walter has been tempted to say that his career has been "bittersweet". His thesis research at Queen's was concerned with the replacement of the ring oxygen of sugars by nitrogen. Among the accomplishments, the first example of a sugar having nitrogen in a five-membered ring (methyl 4-acetamido-4-deoxy-L-erythrofuranoside) was synthesized, and the hindered internal rotation of such sugars was demonstrated by NMR spectroscopy. This area of the replacement of the ring oxygen by other hetero atoms remained dormant for several years, but the discovery of the so-called azasugars in Nature and the recognition that some of them are inhibitors of glycosidases and possess other biological activities of potential therapeutic value stimulated tremendous chemical and biological interest in this class of compounds and in related analogs in which the ring oxygen has been replaced by sulfur or selenium. Thus, originating with some of Walter's work, this activity continues to this day.

Carbohydrate chemistry was to become the field to which Walter would make the greatest contributions. Upon completion of his Ph.D. studies in 1964, he went on to do postdoctoral work with Professor Melville L. Wolfrom at The Ohio State University, Columbus, Ohio. Professor Wolfrom had developed the outstanding School of Carbohydrate Chemistry that attracted hundreds of students and postdoctoral fellows from many countries; in the Canadian context, Professor Raymond Lemieux had been a postdoctoral fellow and Professor Steve Hanessian had been a graduate student with Professor Wolfrom. Professor Wolfrom had a very large group and Walter, during his time at Ohio State, served as a cosupervisor in the old laboratories known as "Sugar Alley". This experience was truly excellent training for his own future career in academia. Within a year he was offered the position of Assistant Professor of Biochemistry in the Department of Physiology and Biochemistry at Rutgers University in New Jersey. Walter was successfully developing his research programs, but he yearned to be back in a chemistry department. In 1967 he returned to Queen's as Assistant Professor of Chemistry where he remains to this day. He was promoted to Associate Professor in 1971 and to Full Professor in 1976. During the period 1976–1985 he was also Director of the Carbohydrate Research Institute at Queen's. In 2003 he became Professor Emeritus, and continues to be very active in research.

In addition to serving on many committees, both at Queen's and outside of Queen's, he has had a distinguished teaching career at both the undergraduate and graduate levels, having won four teaching awards including the Queen's University Arts and Science Undergraduate Teaching Excellence Award in 1989, as well as a distinguished research career. To date 18 M.Sc. (degree conferred), 29 Ph.D. (degree conferred) students, and ~85 Postdoctoral Fellows have studied under his supervision. His caring mentorship both in chemistry and in the trials and tribulations of life are much appreciated by his students and postdoctoral fellows. To date, Walter is the author of over 250 peer-reviewed papers, over 30 issued patents, 11 book chapters, and is the editor of 2 books. His research accomplishments in carbohydrate chemistry have been recognized by the receipt of the American Chemical Society Claude S. Hudson Award in Carbohydrate Chemistry in 1989 and the Melville L. Wolfrom Award of the Division of Carbohydrate Chemistry of the American Chemical Society in 1992.

Walter's interest in carbohydrates has been truly comprehensive. His publications cover almost every aspect of carbohydrates. He has published on the structure and synthesis of carbohydrates and carbohydrate-containing antibiotics, design of biologically active nucleosides, including carbocyclic analogs, biochemical aspects, conformational and mechanistic studies of carbohydrate reactions, photochemistry of carbohydrates, heterocyclic conformational analysis, synthesis of radiopharmaceuticals for use in positron emission reconstruction tomography, chemistry and novel applications of vitamin C, microbiological oxidation of sugars and their derivatives, chemical modification of polysaccharides, design and synthesis of carbohydrate sweeteners, theory of sweetness, carbohydrate derivatives in the enantioselective synthesis of biologically active compounds, targeted delivery of drugs, studies on *Pseudomonas aeruginosa* A-Band lipopolysaccharide: a common antigen, vaccine development, oligomeric carbohydrates in parenteral nutrition, and inhibitors of glycosidases and glycosyltransferases.

Throughout his career, Walter has had great interest in medicinal chemistry and in drug development, and it is in these areas that his potentially longest-lasting and most significant contributions reside. In the mid-1980s, Walter began collaborating with Dr. Bob Kisilevsky of the Department of Pathology at Queen's University. Bob had developed an interest in amyloid as a result of an association with Dr. Michael Axelrad of the Department of Pathology. Dr. Axelrad began the work on amyloid at Queen's because he was suffering from and eventually succumbed to a form of amyloid disease himself. When Bob Kisilevsky and Walter started collaborating, there was growing interest that a carbohydrate polymer, known generally as a glycosaminoglycan, was implicated in amyloid deposition.

© 2006 NRC Canada

The research collaboration was highly successful, and in late 1993, Neurochem, Inc. was founded at Queen's, together with Dr. Don Weaver, who is now at Dalhousie University. Neurochem is now a public biopharmaceutical company currently located in Laval, Quebec. Its clinical milestones include Fibrillex™ for the treatment of amyloid A (AA) amyloidosis, Alzhemed™ for the treatment of Alzheimer's Disease, and Cerebril™ for the treatment of hemorrhagic stroke owing to cerebral amyloid angiopathy. The drug candidates for all of these indications were synthesized in Walter's laboratory in old Gordon Hall at Queen's University. In addition to these developments in the amyloid area, Walter and his collaborators have discovered some new exciting lead candidates showing high potency against malaria, a program that Walter characteristically continues to pursue. His current interests are focused on the applications of chemistry to problems of medical interest.

Walter has always been known as the Godfather of the carbohydrate family and the Prince of hospitality. He has served as a mentor to many young scientists, giving freely of his time to provide valuable advice in his unassuming way. He is truly a "great colleague next door" to many in the chemistry department at Queen's. This issue is dedicated to Walter for his many contributions to Canadian Chemistry. It is evidence of his profound influence on the next generations of chemists, and clearly demonstrates that the situation is not always "a fiasco", one of his favorite expressions. Indeed, one might venture to describe Walter's achievements with the expression, "How sweet it is".

« Une carrière aigre-douce »

Walter Szarek est né le 19 avril 1938 à St. Catharines (Ontario). En 1960, il obtient un baccalauréat spécialisé en chimie de l'Université McMaster, à Hamilton (Ontario). Au cours des étés de 1956 à 1958, il fait ses premières armes en chimie industrielle et en recherche à la société Ontario Paper, de Thorold (Ontario), où il examine l'oxydation alcaline de la lignine. Il étudie la chimie des alcaloïdes auprès du professeur David B. MacLean et obtient une maîtrise ès sciences de l'Université McMaster en 1962. Son mémoire de maîtrise porte alors sur l'élucidation des structures de l'annotine, de la famille des alcaloïdes du Lycopodium, catégorie d'alcaloïdes qui capte alors l'attention de bon nombre de sommités mondiales dans le domaine de la chimie des produits naturels au Canada. Ainsi, le célèbre « tandem des alcaloïdes », soit R.H.F. Manske et L. Marion, isolait pour la première fois l'annotine proprement dite à partir du Lycopodium annotinum du Canada. Outre Dave MacLean et Ian Spenser de l'Université McMaster, d'autres chercheurs ont étudié l'élucidation et la synthèse des étonnantes structures du Lycopodium, notamment K. Wiesner, Z. Valenta, W.A. Ayer et F.A.L. Anet. Walter Szarek, progressant pourtant à pas de géant dans son programme de doctorat, est soudain pris d'une certaine inquiétude qui le conduit à envisager une nouvelle orientation et d'autres sujets de recherche. C'est ainsi qu'en 1962, il entreprend un doctorat en chimie des glucides avec le professeur J.K.N. Jones, à l'Université Queen's de Kingston, en Ontario, qu'il achève en 1964.

Comme il a travaillé à la fois sur les alcaloïdes et sur les glucides, Walter Szarek se plaît à dire qu'il a connu une carrière « aigre-douce ». Sa thèse de doctorat à Queen's portait sur le remplacement de l'oxygène du cycle des glucides par l'azote. Parmi ses réalisations, notons le premier exemple de synthèse des glucides contenant un cycle à cinq atomes (4-acétamide-4-déoxy-L-erythrofuranoside de méthyle) et la rotation interne empêchée de tels glucides, démontrée par spectroscopie RMN. Ce domaine du remplacement de l'oxygène du cycle par d'autres structures hétérocycliques est demeuré dans l'ombre pendant de nombreuses années. Toutefois, la découverte de ce qu'il convient d'appeler des aza-sucres naturels – et le fait que certains de ces aza-sucres sont inhibiteurs de glycosidase et exercent d'autres activités biologiques d'intérêt thérapeutique potentiel – a suscité un immense intérêt, tant sur le plan chimique que biologique, pour ce type de composé chimique et pour d'autres analogues issus du remplacement de l'oxygène du cycle par du soufre ou du sélénium. C'est donc dire que certaines recherches stimulées par Walter Szarek se poursuivent encore aujourd'hui.

Walter Szarek allait devenir un acteur de premier plan dans le domaine de la glycobiologie. Aussitôt son doctorat terminé en 1964, il entreprend des travaux postdoctoraux auprès du professeur Melville L. Wolfrom, à l'Université d'État d'Ohio, à Columbus. Le professeur Wolfrom a mis sur pied la célèbre School of Carbohydrate Chemistry qui a accueilli des centaines d'étudiants et de détenteurs d'une bourse de perfectionnement postdoctoral provenant de nombreux pays. Le Canada n'étant pas en reste, les professeurs Raymond Lemieux, détenteur d'une bourse de perfectionnement postdoctoral, et Steve Hanessian, étudiant de troisième cycle, ont étudié avec le professeur Wolfrom. Eu égard à la taille importante du groupe d'étudiants du professeur Wolfrom, Walter Szarek a assumé la codirection des vieux laboratoires appelés « Sugar Alley » lors de son séjour en Ohio. Cette expérience s'est avérée des plus bénéfiques pour sa future carrière universitaire. En effet, moins d'un an plus tard, on lui offre le poste de chargé d'enseignement en biochimie au département de physiologie et de biochimie de l'Université Rutgers, au New Jersey. Bien qu'élaborant avec brio ses programmes de recherche, Walter Szarek aspire à un retour dans un département de chimie. En 1967, il retourne assumer une charge d'enseignement de la chimie à l'Université Queen's, où il enseigne toujours aujourd'hui. Il est promu professeur agrégé en 1971, puis professeur titulaire en 1976. De 1976 à 1985, il dirige également le Carbohydrate Research Institute de l'Université Queen's. Il est nommé professeur émérite en 2003 et demeure très actif dans le domaine de la recherche.

Non content de siéger auprès de maints comités, tant à l'Université Queen's qu'ailleurs, il mène une prestigieuse carrière d'enseignant au premier cycle comme aux cycles supérieurs. Lauréat de quatre prix en enseignement, dont le prix d'excellence de l'Université Queen's pour l'enseignement des arts et des sciences au premier cycle, en 1989, il mène parallèlement une brillante carrière de chercheur. À ce jour, 18 étudiants à la maîtrise ès science (diplôme obtenu), 29 étudiants au doctorat (diplôme obtenu) et quelque 85 détenteurs d'une bourse de perfectionnement postdoctoral ont étudié sous sa gouverne. Ses étudiants et les détenteurs de bourse de perfectionnement ne tarissent pas d'éloges pour son encadrement attentionné, tant dans le domaine de la chimie que devant les épreuves et tribulations de la vie quotidienne. À ce jour, on doit à Walter Szarek plus de 250 publications avérées, plus de 30 brevets délivrés et 11 chapitres de livre. Il a en outre dirigé la rédaction de deux ouvrages. En reconnaissance de ses réalisations dans le domaine de la recherche en glycobiologie, la Division of Carbohydrate Chemistry de l'American Chemical Society lui a décerné le prix Claude S. Hudson, en 1989, et le prix Melville L. Wolfrom, en 1992.

Walter Szarek affiche un intérêt des plus vastes pour les glucides. Ses publications en touchent pratiquement tous les aspects, dont la structure et la synthèse des glucides et des antibiotiques contenant des glucides, la conception des nucléosides biologiquement actifs, notamment les analogues carbocycliques, les aspects biochimiques, l'étude conformationnelle et mécaniste des réactions des glucides, la photochimie des glucides, l'analyse conformationnelle hétérocyclique, la synthèse des produits radiopharmaceutiques utilisés en tomographie par émission de positons, la chimie et les nouvelles applications de la vitamine C, l'oxydation microbiologique des glucides et de leurs produits dérivés, la transformation chimique des polysaccharides, la conception et la synthèse des glucides utilisés comme édulcorants, la théorie du goût sucré, les produits dérivés des glucides dans la synthèse énantiosélective de composés chimiques biologiquement actifs, la libération ciblée de médicaments, l'étude du lipopolysaccharide de bande A du Pseudomonas aeruginosa (un antigène commun), la mise au point de vaccins, les glucides oligomériques dans la nutrition parentérale et les inhibiteurs des glycosidases et des glycosyltransférases.

Tout au long de sa carrière, Walter Szarek s'est intéressé de près à la chimie médicale et à la mise au point de médicaments, des domaines auxquels il a apporté une contribution

© 2006 NRC Canada

d'envergure et durable. Au milieu des années 1980, il entreprend une collaboration avec Bob Kisilevsky, du département d'anatomie pathologique de l'Université Queen's, qui s'était intéressé aux produits amyloïdes dans la foulée d'une collaboration avec Michael Axelrad, du même département. M. Axelrad, lui-même atteint d'une amylose qui finit par l'emporter, avait entrepris des travaux sur les produits amyloïdes. Messieurs Kisilevsky et Szarek commencent à collaborer à un moment où le polymère glucidique glycosaminoglycan suscite de plus en plus d'intérêt du fait qu'il serait lié au dépôt d'amyloïde. À la fin de 1993, au terme d'une collaboration fructueuse, les deux collègues fondent Neurochem inc. à l'Université Queen's, en compagnie de Don Weaver, qui œuvre aujourd'hui à l'Université Dalhousie. Neurochem, société biopharmaceutique ouverte, a actuellement pignon sur rue à Laval (Québec). Ses jalons cliniques importants comprennent la mise au point de Fibrillex™ pour le traitement de l'amylose amyloïde, Alzhemed™ pour le traitement de la maladie d'Alzheimer et Cerebril™ pour le traitement des accidents vasculaires cérébraux hémorragiques causés par l'angiopathie amyloïde cérébrale. Dans tous les cas, les candidats-médicaments à l'essai ont été synthétisés dans le laboratoire de Walter Szarek, à l'immeuble Gordon Hall de l'Université Queen's. Parallèlement à leurs percées dans le domaine des produits amyloïdes, Walter Szarek et ses collaborateurs ont découvert de puissants candidats-médicaments très prometteurs contre la malaria, et ce, dans le cadre d'un programme que Szarek poursuit toujours, faut-il s'en étonner. Aujourd'hui, Walter Szarek s'intéresse plus particulièrement aux applications de la chimie à des problèmes qui présentent un intérêt sur le plan médical.

Walter Szarek a toujours été le parrain de la famille des glucides et le prince de l'hospitalité. Il a été pour bon nombre de jeunes scientifiques un mentor, donnant généreusement de son temps et prodiguant de précieux conseils, sans prétention aucune. Il représente pour de nombreux spécialistes du département de l'Université Queen's le collègue idéal. Nous rendons hommage à Walter Szarek pour son importante contribution à l'avancement de la chimie au pays. Les prochaines générations de chimistes pourront lui être grandement reconnaissantes, ce qui démontre hors de tout doute que tout ne se termine pas toujours en « fiasco », pour emprunter une expression qui lui est chère. S'il faut qualifier ses réalisations, oserons-nous affirmer qu'il a mené une carrière beaucoup moins « aigre » que « douce »!

B. Mario Pinto

Titanium pyridyl-phosphinimide complexes — Synthesis, structure, and ethylene polymerization catalysis

Chad Beddie, Pingrong Wei, and Douglas W. Stephan

Abstract: A series of Ti–pyridyl-phosphinimide complexes of the form $Cp'TiX_2[NPR_2(2\text{-}CH_2Py)]$ (Cp' = Cp, Cp*, R = *i*-Pr, *t*-Bu, X = Cl, Me) have been prepared and characterized. These complexes generate ethylene polymerization catalysts upon activation with MAO or $B(C_6F_5)_3$. The resulting polymers exhibit broad molecular weight distributions. The role of the pyridyl group is discussed in light of stoichiometric reactions of $CpTiCl_2[NPR_2(2\text{-}CH_2Py)]$ with $B(C_6F_5)_3$.

Key words: phosphinimide complexes, pyridyl-phosphinimides, olefin polymerization.

Résumé : On a préparé et caractérisé une série de complexes Ti–pyridyl-phosphinimide de la forme $Cp'TiX_2[NPR_2(2\text{-}CH_2Py)]$ (Cp' = Cp, Cp*, R = *i*-Pr, *t*-Bu, X = Cl, Me). Par activation avec du MAO ou du $B(C_6F_5)_3$, ces complexes peuvent générer des catalyseurs pour la polymérisation de l'éthylène. Les polymères ainsi obtenus présentent de larges distributions de poids moléculaires. On discute du rôle du groupe pyridyle à la lumière des réactions stoechiométriques du $CpTiCl_2[NPR_2(2\text{-}CH_2Py)]$ avec le $B(C_6F_5)_3$.

Mots clés : complexe du phosphimide, pyridyl-phosphimides, polymérisation d'oléfines.

[Traduit par la Rédaction]

Introduction

The quest for new and effective homogeneous olefin polymerization catalysts have prompted much interest in early transition metal chemistry over the last two decades. Studies of non-metallocene systems have probed a wide variety of novel ancillary ligands (1–3). In our own work we have described titanium catalysts that contain bulky-phosphinimide ligands. This family of compounds of the form $CpTi(NPR_3)Cl_2$ yield active ethylene polymerization catalysts upon activation by MAO (4–10), while activation of the species $Ti(t\text{-}Bu_3PN)_2Me_2$ by $B(C_6F_5)_3$ or $Ph_3C[B(C_6F_5)_4]$ provides a remarkably active catalyst, producing polyethylene of narrow polydispersity and relatively high molecular weight (7). Single-site or living polymerization catalysts typically afford narrow polydispersities (1.0–2.0), however, in practical terms such resins prove difficult to process (11, 12). Thus, while single-site polymerization offers access to unique polymers, such materials prompt other problems. A number of methods can be employed to alter both the molecular weight and the molecular weight distributions of resulting polymers. In some cases, controlled hydrogenolysis (13, 14) can be utilitzed to broaden the molecular weight distributions. Alternatively, sequential catalysts can be employed to produce bimodal resins (15–29). In attempting to address this issue, we are examining potential single-site catalyst precursors that offer the possibility of generating several single-site catalysts upon activation. To this end, we report the synthesis and evaluation of Ti–phosphinimide complexes that incorporate pendant pyridyl substituents. The notion here is that these substituents may interact with the Lewis acid activators in a reversible manner and thus afford the possibility of two or more catalysts in solution. In this, our first report employing this strategy, we describe the synthesis and characterization of such compounds and evaluate such species in ethylene polymerization catalysis. The effect of the pyridyl group on the polymer molecular weight distributions is considered and discussed.

Experimental

General data

All preparations were done under an atmosphere of dry, O_2-free N_2 employing both Schlenk line techniques and a MBraun inert atmosphere glovebox. Solvents were purified employing a Grubbs' type solvent purification system manufactured by Innovative Technology. All organic reagents were purified by conventional methods. ^1H, $^{31}P\{^1H\}$, and $^{13}C\{^1H\}$ NMR spectra were recorded on Bruker Avance-300 and -500 spectrometers. All spectra were recorded in C_6D_6 at 25 °C unless otherwise noted. All chemical shifts are reported in ppm. Trace amounts of protonated solvents were used as references and chemical shifts are reported relative to $SiMe_4$. $^{31}P\{^1H\}$ NMR spectra were referenced to external 85% H_3PO_4. Combustion analyses were done in-house employing a PerkinElmer CHN analyzer. The compounds $PR_2(2\text{-}CH_2Py)$ (R = *i*-Pr (**1**), *t*-Bu (**2**)) (30, 31), and $Me_3SiNP(i\text{-}Pr)_2(2\text{-}CH_2Py)$ (**3**) (32)) were prepared by literature methods. $CpTiCl_3$, Cp^*TiCl_3 ($Cp^* = Me_5Cp$), and

 doi:10.1139/V06-071 © 2006 NRC Canada

Me_3SiN_3 were purchased from Strem Chemical Co. and Sigma-Aldrich Chemical Co., respectively, and employed without further purification. MAO and Al(*i*-Bu)$_3$, as well as GPC analysis service, were generously provided by NOVA Chemicals Corp.

Synthesis of Me_3SiNP-*t*-Bu_2(2-CH_2Py) (4)

To a solution of **2** (1.99 g, 8.38 mmol) in toluene (30 mL) was added Me_3SiN_3 (2.24 mL, 16.9 mmol). The resulting solution was heated at refluxing temperature for 48 h. The volume of the solution was reduced to ca. 5 mL, and the solution was filtered through Celite. The remaining solvent and excess Me_3SiN_3 were removed under vacuum, resulting in a pale yellow oil. Yield: 2.06 g, 6.36 mmol, 76%. ^{1}H NMR δ: 8.41 (d, 1H, $^3J_{H-H}$ = 4 Hz, Py), 7.44 (m, 1H, Py), 7.17 (m, 1H, Py), 6.65 (m, 1H, Py), 3.14 (d, 2H, $^2J_{P-H}$ = 11 Hz, CH_2), 1.04 (d, 18H, $^3J_{P-H}$ = 14 Hz, *t*-Bu), 0.30 (s, 9H, $SiMe_3$). ^{13}C{^{1}H} NMR δ: 157.0 (d, $^2J_{P-C}$ = 7 Hz, Py, (ipso-C)), 149.4 (s, Py), 135.3 (s, Py), 126.1 (s, Py), 121.6 (s, Py), 37.5 (d, $^1J_{P-C}$ = 61 Hz, *t*-Bu), 34.8 (d, $^1J_{P-C}$ = 53 Hz, CH_2), 27.8 (s, *t*-Bu), 5.3 (s, $SiMe_3$). ^{31}P{^{1}H} NMR δ: 25.9 (s).

Syntheses of Cp′$TiCl_2$[NPR_2(2-CH_2Py)] (Cp′ = Cp, *i*-Pr (5), *t*-Bu (6), Cp′ = Cp*, R = *i*-Pr (7), *t*-Bu (8))

These complexes were prepared in similar fashions and thus only one preparation is detailed. To a yellow slurry of $CpTiCl_3$ (0.370 g, 1.69 mmol) in toluene (40 mL) was added a solution of **3** (0.501 g, 1.69 mmol) in toluene (10 mL). The resulting solution was stirred for 12 h at room temperature. The solvent and volatile products were removed under vacuum to cause the formation of a yellow crystalline solid, which was washed with hexanes and dried under vacuum. Yield: 0.641 g, 1.57 mmol, 93%. **5**: ^{1}H NMR δ: 8.25 (br, 1H, Py), 7.40 (m, 1H, Py), 7.15 (m, 1H, Py), 6.58 (m, 1H, Py), 6.34 (s, 5H, Cp), 2.97 (d, 2H, $^2J_{P-H}$ = 13 Hz, CH_2), 1.68 (d(sept), 2H, $^3J_{P-H}$ = 10 Hz, $^3J_{H-H}$ = 7 Hz, CH), 0.94 (dd, 6H, $^3J_{P-H}$ = 16 Hz, $^3J_{H-H}$ = 7 Hz, Me) 0.86 (dd, 6H, $^3J_{P-H}$ = 17 Hz, $^3J_{H-H}$ = 7 Hz, Me). ^{13}C{^{1}H} NMR δ: 153.1 (d, $^2J_{P-C}$ = 7 Hz, Py (ipso-C)), 149.7 (s, Py), 135.6 (s, Py), 126.6 (s, Py), 122.6 (s, Py), 115.5 (s, Cp), 33.8 (d, $^1J_{P-C}$ = 51 Hz, CH_2), 27.3 (d, $^1J_{P-C}$ = 59 Hz, CH), 16.1 (d, $^2J_{P-C}$ = 6 Hz, Me). ^{31}P{^{1}H} NMR δ: 31.7 (s). Elemental anal. calcd.: C 50.15, H 6.19, N 6.88; found: C 49.95, H 6.41, N 6.76. Syntheses of $CpTiCl_2$[NPR_2(2-CH_2Py)]·$B(C_6F_5)_3$ (R = *i*-Pr (9), *t*-Bu (10))

These complexes were prepared in similar fashions and thus only one preparation is detailed. To a yellow solution of $CpTiCl_2$[NP(*i*-Pr)$_2$(2-CH_2Py)] (**5**) (0.020 g, 0.49 mmol) in benzene (2 mL) was added a solution of $B(C_6F_5)_3$ (0.025 g, 0.049 mmol) in benzene (2 mL). The resulting clear yellow solution was stirred for 5 min. The solvent was removed under vacuum to produce a yellow solid. Yield: 0.044 g, 0.48 mmol, 98%. **9**: ^{1}H NMR δ: 9.46 (d, 1H, $^3J_{H-H}$ = 8 Hz, Py), 8.35 (m, 1H, Py), 7.53 (m, 1H, Py), 6.35 (m, 1H, Py), 6.24 (s, 5H, Cp), 3.43 (dd, 1H, $^2J_{P-H}$ = 12 Hz, $^3J_{H-H}$ = 16 Hz, CH_2), 3.13 (dd, 1H, $^2J_{P-H}$ = 12 Hz, $^3J_{H-H}$ = 16 Hz, CH_2), 1.69 (d(sept), 1H, $^2J_{P-H}$ = 9 Hz, $^3J_{H-H}$ = 7 Hz, CH), 0.94 (m, 1H, CH), 0.76 (dd, 3H, $^3J_{P-H}$ = 17 Hz, $^3J_{H-H}$ = 7 Hz, Me), 0.74 (dd, 3H, $^3J_{P-H}$ = 17 Hz, $^3J_{H-H}$ = 7 Hz, Me), 0.69 (dd, 3H, $^3J_{P-H}$ = 17 Hz, $^3J_{H-H}$ = 7 Hz, Me), 0.29 (dd, 3H, $^3J_{P-H}$ = 17 Hz, $^3J_{H-H}$ = 7 Hz, Me). ^{13}C{^{1}H} NMR (partial, some resonances in the C_6F_5 rings could not be observed) δ: 153.4 (s, Py (ipso-C)), 148.9 (s, Py), 148.2 (br d, $^1J_{C-F}$ ~ 240 Hz, C_6F_5), 143.8 (s, Py), 138.1 (br d, $^1J_{C-F}$ ~ 230 Hz, C_6F_5), 131.6 (s, Py), 124.2 (s, Py), 116.3 (s, Cp), 28.3 (d, $^1J_{P-C}$ = 51 Hz, CH_2), 28.2 (d, $^1J_{P-C}$ = 60 Hz, CH), 28.1 (d, $^1J_{P-C}$ = 59 Hz, CH), 16.2 (s, Me), 15.8 (d, $^2J_{P-C}$ = 3 Hz, Me), 15.3 (s, Me), 15.2 (d, $^2J_{P-C}$ = 3 Hz, Me). ^{11}B{^{1}H} NMR δ: –3.4 (s). ^{19}F NMR δ: –126.4 (dd, 1F, $^3J_{F-F}$ = 25 Hz, $^3J_{F-F}$ = 25 Hz), –127.0 (br, 1F), –130.4 (d, 1F, $^3J_{F-F}$ = 23 Hz), –132.6 (br, 2F), –135.2 (dd, 1F, $^3J_{F-F}$ = 25 Hz, $^3J_{F-F}$ = 25 Hz), –153.7 (dd, 1F, $^3J_{F-F}$ = 21 Hz, $^3J_{F-F}$ = 21 Hz), –154.1 (dd, 1F, $^3J_{F-F}$ = 21 Hz, $^3J_{F-F}$ = 21 Hz), –155.8 (dd, 1F, $^3J_{F-F}$ = 21 Hz, $^3J_{F-F}$ = 21 Hz), –160.8 (m, 1F), –162.0 (m, 1F), –162.1 (m, 1F), –162.6 (m, 1F), –163.3 (m, 1F), –164.0 (m, 1F). ^{31}P{^{1}H} NMR δ: 30.2 (s). Synthesis of $Cp^*TiMe_2[NP\text{-}t\text{-}Bu_2(2\text{-}CH_2Py)]$ (11)

To a yellow suspension of **8** (0.306 g, 0.605 mmol) in a mixture of diethyl ether (30 mL) and toluene (50 mL) cooled to –78 °C was added 3.0 mol/L MeMgCl in THF (0.38 mL, 1.14 mmol). The resulting yellow suspension was stirred at –78 °C for ~20 min and then was slowly warmed to room temperature over a period of 1.5 h. The solvent was removed under vacuum, and the crude residue was extracted with hexanes. The suspension was filtered through Celite and the solvent was removed under vacuum to yield a crude brown solid. Subsequent recrystallization attempts from hexanes produced a yellow solid that was 95% pure by NMR analysis. Yield: 0.155 g, 0.336 mmol, 59%. ^1H NMR δ: 8.39 (d, 1H, $^3J_{H-H}$ = 4 Hz, Py), 7.61 (d, 1H, $^3J_{H-H}$ = 6 Hz, Py), 7.16 (m, 1H, Py), 6.63 (m, 1H, Py), 3.35 (d, 2H, $^2J_{P-H}$ = 12 Hz, CH_2), 2.04 (s, 15H, Cp*), 1.21 (d, 18H, $^3J_{P-H}$ = 14 Hz, *t*-Bu), 0.41 (s, 6H, $TiMe_2$). $^{13}C\{^1H\}$ NMR δ: 156.2 (d, $^2J_{P-C}$ = 6 Hz, Py, (ipso-C)), 149.6 (s, Py), 135.9 (s, Py), 127.1 (s, Py), 122.0 (s, Py), 118.8 (s, Cp*), 44.5 (s, $TiMe_2$, 39.4 (d, $^1J_{P-C}$ = 54 Hz, *t*-Bu), 36.1 (d, $^1J_{P-C}$ = 45 Hz, CH_2), 28.2 (s, *t*-Bu), 12.6 (s, Cp*). $^{31}P\{^1H\}$ NMR δ: 22.9 (s). Elemental anal. calcd.: C 67.23, H 9.76, N 6.03; found: C 66.16, H 9.97, N 6.25.

Polymerization protocol

Polymerization experiments were performed using a glass Büchi polymerization reactor. Toluene (600 mL) was transferred into the reactor, heated to 30 °C ± 2 °C, and presaturated with ethylene prior to injection of catalyst and cocatalyst. The solution was stirred at 1000 rpm for the duration of the polymerization experiment. At the end of the experiments, the polymer was collected and treated as previously described (9). For the catalyst precursors (**5**–**10**), polymerization experiments were conducted for 30 min employing MAO as the cocatalyst. In these polymerizations, 500 equiv. of MAO was injected into the reactor and the solution was stirred for 5 min prior to injecting a toluene solution of the precatalyst. Catalyst concentrations of 100 μmol/L were employed, thus 0.060 mmol of catalyst in 8 mL of toluene was injected. In the case of **11**, 1, 2, and 10 equiv. of $B(C_6F_5)_3$ were used as the cocatalyst, while 20 equiv. of $Al(i\text{-}Bu)_3$ was used as a scavenger. Catalyst concentrations of 20 μmol/L were employed, thus 0.012 mmol of catalyst in 4 mL of toluene was injected. These polymerization experiments were conducted for 10 min.

X-ray data collection and reduction

Crystals were manipulated and mounted in capillaries in a glovebox, thus maintaining a dry, O_2-free environment for each crystal. Diffraction experiments were performed on a Siemens SMART System CCD diffractometer. The data were collected in a hemisphere of data in 1329 frames with 10 s exposure times. The observed extinctions were consistent with the space groups in each case. The data sets were collected ($4.5° < 2\theta < 45–50.0°$). A measure of decay was obtained by recollecting the first 50 frames of each data set. The intensities of reflections within these frames showed no statistically significant change over the duration of the data collections. The data were processed using the SAINT and XPREP processing packages. An empirical absorption correction based on redundant data was applied to each data set. Subsequent solution and refinement was performed using the SHELXTL solution package operating on a Pentium computer.

Structure solution and refinement

Non-hydrogen atomic scattering factors were taken from the literature tabulations (33). The heavy atom positions were determined using direct methods employing the SHELXTL direct-methods routine. The remaining non-hydrogen atoms were located from successive difference Fourier map calculations. The refinements were carried out by using full-matrix least-squares techniques on *F*, minimizing the function $\omega(|F_o| - |F_c|)^2$, where the weight (ω) is defined as $4F_o^2/2\sigma(F_o^2)$ and F_o and F_c are the observed and calculated structure factor amplitudes, respectively. In the final cycles of each refinement, all non-hydrogen atoms were assigned anisotropic temperature factors in the absence of disorder or insufficient data. In the latter cases, atoms were treated isotropically. C-H atom positions were calculated and allowed to ride on the carbon to which they are bonded, assuming a C—H bond length of 0.95 Å. H-atom temperature factors were fixed at 1.10 times the isotropic temperature factor of the C-atom to which they are bonded. The H-atom contributions were calculated, but not refined. The locations of the largest peaks in the final difference Fourier map calculation, as well as the magnitude of the residual electron densities in each case, were of no chemical significance. Additional details are provided in the supplementary data.[2]

Results and discussion

The phosphinimine ligands, $Me_3SiNPR_2(2\text{-}CH_2Py)$ (R = *i*-Pr (**3**) (32), *t*-Bu (**4**)), were prepared in conventional fashion

from reaction of the precursor phosphines (30) with Me_3SiN_3 in toluene at refluxing temperatures. These products were characterized by ^1H, $^{31}P\{^1H\}$, and $^{13}C\{^1H\}$ NMR spectroscopy, and all data were consistent with the proposed formulation. The corresponding Ti complexes, Cp′$TiCl_2[NPR_2(2\text{-}CH_2Py)]$ (Cp′ = Cp, R = *i*-Pr (**5**), *t*-Bu (**6**); Cp′ = Cp*, R = *i*-Pr (**7**), *t*-Bu (**8**)), were prepared via reaction of the phosphinimine ligands, $Me_3SiNPR_2(2\text{-}CH_2Py)$ (R = *i*-Pr (**3**) (32), R = *t*-Bu (**4**)), with the precursors $CpTiCl_3$ and Cp*$TiCl_3$, respectively (Scheme 1). Similar preparative methods for species of the form Cp′$Ti(NPR_3)Cl_2$ have been previously described (9). Spectroscopic data for **5**–**8** were as expected and elemental analyses were consistent with the formulations. Single crystal X-ray data were also obtained for these complexes (Table 1) (Fig. 1). All of these complexes are monomeric as expected, with pseudo-tetrahedral geometries at Ti with the coordination sphere comprised of a η^5-bound Cp or Cp* ligand, an N-bound phosphinimide, and

Fig. 1. ORTEP diagrams (30% probability ellipsoids) of (*a*) **5**, (*b*) **6**, (*c*) **7**, (*d*) **8**. Hydrogen atoms have been omitted for clarity.

two chloride ligands. Metric parameters (Table 2) are similar to those reported for related compounds (4, 9, 34–37). The P-N-Ti bond angles for complexes **5**–**8** are approximately linear at 173.8(1)°, 170.9(2)°, 165.0(3)°, and 166.5(2)°, respectively, and are within the range of 158.7(1)° to 178.38(11)° for related titanium phosphinimide compounds (34, 37). The smaller P-N-Ti angles for **7** and **8** are attributable to the greater electron donation and steric demand of the Cp* ligand. This view is also consistent with the longer Ti—N distances for complexes **7** and **8** (1.775(4) and 1.792(2) Å) compared with those in **5** and **6** (1.768(2) and 1.761(2) Å). Similarly, the P—N bond lengths for compounds **5** and **6** (1.607(2) and 1.609(2) Å) are longer than those for **7** and **8** (1.600(4) and 1.597(2) Å). The orientation of the pyridyl substituent of the phosphinimide ligands varies. In **5** and **6**, this substituent is oriented in the general direction of the Cp ligand, while in **7** and **8**, it projects away from the Cp* ligand. This is presumably a steric effect. No preferred orientation of the nitrogen atom of the pyridyl group is observed and there is no intra- or inter-molecular interactions of this donor atom with the Lewis acidic Ti center.

Table 2. Metric parameters (bond lengths and angles) for **5**–**8**.

	5	**6**	**7**	**8**

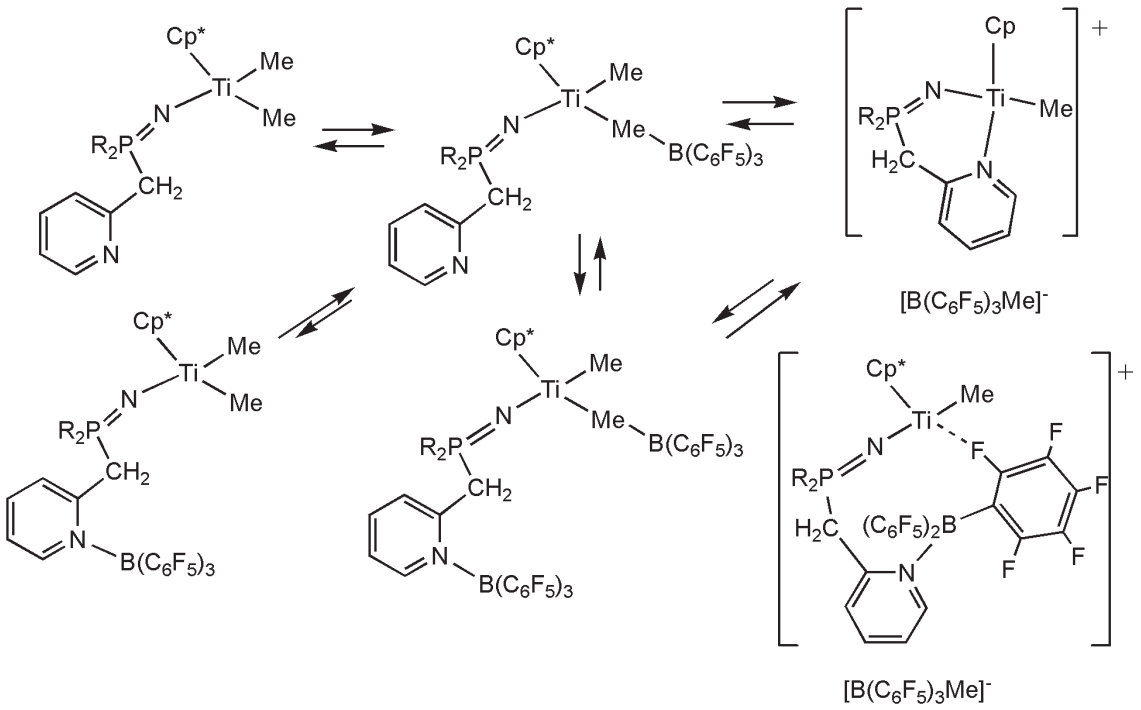
10	67 000	534 800	8	2



Note: Conditions for polymerization: ethylene pressure = 2 atm, T = 30 °C, toluene, [catalyst] = 100 µmol/L, 500 equiv. MAO.

Polymerization

The complexes **5**–**8** were tested as ethylene polymerization precatalysts using a Büchi polymerization reactor at 30 °C for 30 min in toluene, under an atmosphere of 2 atm of ethylene (1 atm = 101.325 kPa). A precatalyst concentration of 100 µmol/L was used and 500 equiv. of MAO was used as cocatalyst (Table 3). The resulting polymers have molecular weight (M_w) ranges from approximately 200 000 to 600 000 g/mol with polydispersity indices (PDI) varying from 4 to 26. These relatively high molecular weights together with high PDIs suggest that there may be several active catalyst species generated in solution. Certainly, these species do not behave as single site catalysts, nonetheless, such systems are of interest as they may provide polymers with desirable processability. In terms of activities, complex **5** displayed moderate activity (18 g mmol^{-1} h^{-1} atm^{-1}), while complexes **6**–**8** showed low activity. These results stand in contrast to previous results that demonstrated a high activity catalyst was derived from $CpTiCl_2(NP\text{-}t\text{-}Bu_3)$ under similar conditions (4, 9). These data also contrast the polymerization activity observed for $Cp^*TiCl_2[NP(t\text{-}Bu)_2(CH_2Ph)]$ under similar conditions (142 g mmol^{-1} h^{-1} atm^{-1}) (38). Clearly,

Scheme 2.

the only structural difference between **8** and $Cp^*TiCl_2[NP(t\text{-}Bu)_2(CH_2Ph)]$ is the N atom of the pyridine ring, and thus efforts to query the role of this atom were undertaken.

$B(C_6F_5)_3$ adducts

In an attempt to sequester any potential interference of the pyridyl group in the polymerization process, the complexes **5** and **6** were treated with $B(C_6F_5)_3$ producing donor–acceptor complexes of the general formula, $CpTiCl_2[NPR_2(2\text{-}CH_2Py)]\cdot B(C_6F_5)_3$ (R = *i*-Pr (**9**), *t*-Bu (**10**) (Scheme 1). $^{31}P\{^1H\}$, ^1H, ^{19}F, and $^{13}C\{^1H\}$ NMR data were consistent with the formulation. In particular, the $^{19}F\{^1H\}$ NMR spectra revealed 15 resonances for both **9** and **10**, indicating complexation and the inequivalence of all F atoms in the $B(C_6F_5)_3$ fragment. The downfield ^1H NMR shifts of the protons ortho to N in **5** and **6** upon reaction with the borane were greater than 1 ppm, consistent with B—N donor–acceptor bond formation. It is a noteworthy comparison that no reaction is observed between $CpTiCl_2(NP\text{-}t\text{-}Bu_3)$ and $B(C_6F_5)_3$ at 25 °C (39). The proposed structures of **9** and **10** were not confirmed crystallographically, despite numerous attempts to acquire suitable crystals.

The species **9** and **10** were evaluated as precatalysts for ethylene polymerization activity. Aliquots of the freshly prepared solutions were employed. The polymerization experiments were conducted in an identical fashion to those described previously (Table 3). The resulting activities of the catalysts derived from **9** and **10** were significantly lower than those derived from **5** and **6**, respectively. However, the causes of these observations remain unclear. It is likely that MAO competes with $B(C_6F_5)_3$ for coordination to the pyridyl N. Thus, the notion that one might use of coordination of borane to the pyridyl group to provide a sterically crowded phosphinimide ligand in situ is clearly simplistic.

Table 4. Ethylene polymerization data and $B(C_6F_5)_3$ activation.

Precat.	$B(C_6F_5)_3$ (equiv.)	Activity (g $mmol^{-1}$ h^{-1} atm^{-1})
11	1	47
11	2	120
11	10	75

Note: Conditions for polymerization: ethylene pressure = 2 atm, T = 30 °C, toluene, [catalyst] = 20 μmol/L, [TiBAl] = 400 μmol/L, 10 min.

Reaction of MeMgX with **5**–**7** resulted in mixtures of products that could not be separated despite exhaustive attempts to effect extraction, selective precipitation, or crystallization. These difficulties are thought to arise from the known acidity of the methylene protons of the pyridyl-phosphinimide ligand. For example, it is known that reaction of *n*-BuLi with **3** results in the formation of $Li(THF)_2[Me_3SiNP(i\text{-}Pr)_2(2\text{-}CHPy)]$ (32). Nonetheless, the species $Cp^*TiMe_2[NP(t\text{-}Bu)_2(2\text{-}CH_2Py)]$ (**11**) (Scheme 1) was successfully produced from reaction of MeMgCl with **8**, although multiple extractions with hexanes and subsequent reprecipitations were required to effect adequate purification.

Ethylene polymerization catalysis were examined using **11** and 1, 2, and 10 equiv. of $B(C_6F_5)_3$ as a cocatalyst (Table 4). These data reveal that **11**–$B(C_6F_5)_3$ is a much more active catalyst system than those derived from **8**–MAO. Interestingly, increasing the amount of borane from 1 to 2 equiv. prompted an increase in the polymerization activity from 47 to 120 g $mmol^{-1}$ h^{-1} atm^{-1}. In the presence of a larger excess of $B(C_6F_5)_3$, i.e., 10 equiv., a polymerization activity of 75 g $mmol^{-1}$ h^{-1} atm^{-1} was observed. Molecular weight distributions (GPC analysis) in these polymerizations were precluded by solubility problems, presumably a result of polymer molecular weights exceeding the limit of the instrumentation (i.e., >1 000 000 g mol^{-1}). It is noteworthy

© 2006 NRC Canada

that use of $B(C_6F_5)_3$ to activate Ti–phosphinimide catalysts has previously been shown to give rise to high molecular weight polymers in comparison to the similar systems in which MAO was employed as the activator (4–10).

The above polymerization data show that increasing from 1 to 2 equiv. of borane appears to increase the concentration of the active catalyst, while further increases in cocatalyst concentration reduce the observed activity. This suggests the involvement of several equilibria governing the concentration of the active catalyst(s). While the precise nature of these species involved remains unclear, it is tempting to speculate that such species could involve interaction of $B(C_6F_5)_3$ with the Ti-bound alkyl groups or the pyridyl group, chelation of the pyridyl fragment to Ti, or interaction of the Ti center with the pyridyl-bound $B(C_6F_5)_3$ (Scheme 2).

In conclusion, a series of Ti–pyridyl-phosphinimide complexes generate ethylene polymerization catalysts upon activation with MAO or $B(C_6F_5)_3$. While these catalysts do not exhibit the exceptional activity of previously reported Ti–phosphinimides, the presence of the pyridyl substituents appears to result in polymers with broadened molecular weight distributions. While the cause of this effect is the subject of speculation, the potential of a substituent modification approach to the alteration of the polydispersity remains a subject of on-going study.

Indium(I) iodide promoted cleavage of dialkyl disulfides — Application of the Michael addition of thiolate anions to conjugated carbonyl compounds and regioselective ring opening of epoxides

Brindaban C. Ranu and Tanmay Mandal

Abstract: Indium(I) iodide promotes cleavage of dialkyl disulfides generating thiolate anions that then undergo facile addition to α,β-unsaturated ketones, aldehydes, carboxylic esters, and nitriles under neutral conditions producing corresponding β-ketosulfides or β-cyanosulfides. This strategy has also been used for the regioselective nucleophilic ring opening of epoxides by thiolate anions in presence of indium(III) chloride producing corresponding β-hydroxyphenyl sulfides. The reactions are in general, very clean, high yielding, and reasonably fast. Thus, simple and convenient procedures for the synthesis of β-ketosulfides or β-cyanosulfides and β-hydroxyalkyl sulfides have been developed using this cleavage reaction.

Key words: indium(I) iodide, Michael addition, β-ketosulfide, β-cyanosulfide, epoxide, β-hydroxy sulfide.

Résumé : L'iodure d'indium(I) facilite le clivage des disulfures d'alkyles et génère la formation d'anions thiolates qui peuvent ensuite s'additionner facilement sur des cétones, des aldéhydes, des esters carboxyliques et des nitriles α,β-insaturés, dans des conditions neutres, pour conduire à la formation des β-céto ou β-cyanosulfures correspondants. On a aussi utilisé cette stratégie pour l'ouverture de cycle nucléophile et régiosélective d'époxydes par des anions thiolates en présence de chlorure d'indium(III) qui conduisent à la formation des sulfures de β-hydroxyphényle. Les réactions sont, en général, très propres et elles donnent des rendements élevés rapidement. Des méthodes simples et faciles utilisant cette réaction de clivage permettent donc de synthétiser des β-cétosulfures ou des β-cyanosulfures ainsi que des sulfures de β-hydroxyalkyles.

Mots clés : iodure d'indium(I), addition de Michael, β-cétosulfure, β-cyanosulfure, époxyde, β-hydroxysulfure.

[Traduit par la Rédaction]

Introduction

The importance of indium reagents in organic synthesis has been well-demonstrated through novel protocols for carbon–carbon bond formation, rearrangements, and a variety of other useful transformations over past few years (1) and increasing interest in this area is continuing (2). As a part of our activities in indium-mediated reactions (3), we are constantly looking for new indium reagents and we reported the application of indium(I) iodide (4) for the cleavage of diphenyl diselenide and disulfide followed by in situ condensation with alkyl halide (4*a*, 4*b*). We also communicated the cleavage of dialkyl disulfides promoted by InI followed by subsequent Michael addition of thiolate anions to conjugated carbonyl compounds (4*c*). We have now discovered another application of this protocol for regioselective ring opening of epoxides by thiolate anions in presence of indium(III) chloride to provide β-hydroxy sulfides. We wish to report here the results of our earlier communication (4*c*) in detail together with this new observation (Scheme 1).

The β-oxy- and β-hydroxy-sulfides are very useful molecules as they constitute a common structural component in a vast group of natural products (5). Some of the synthetic molecules are found to have biological and pharmaceutical activities (6). These molecules are also very useful intermediates in organic synthesis (7). Many methods are available in the literature for the synthesis of β-oxy- (8) and β-hydroxy-sulfides (9) and these are primarily based on reaction with thiols under base or acid catalysis. However, many of them suffer from disadvantages of harsh reaction conditions, poor regioselectivity, unsatisfactory yields, long reaction times, and are associated with undesirable side reactions owing to the oxidation of thiol or rearrangement of epoxides. Since β-oxy- and β-hydroxy-sulfides have become increasingly useful and important in organic synthesis, development of simple, efficient, and mild procedures for their

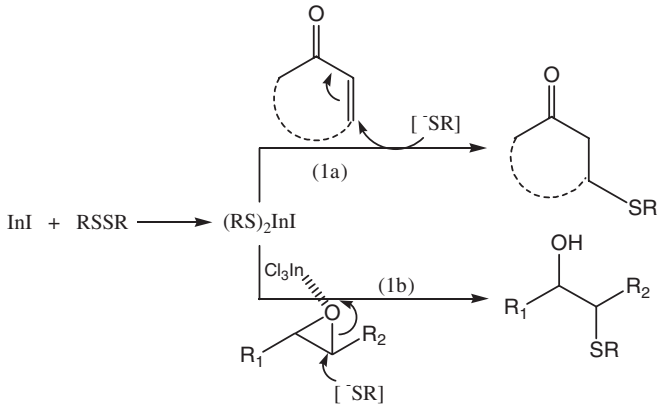
Scheme 1.

synthesis are highly desirable. Thus, we sought an alternative approach replacing thiol by a more stable sulphur reagent and we found that dialkyl disulfide can do this job more efficiently (Scheme 1).



Results and discussion

The experimental procedures for both of these reactions are very simple and convenient. A solution of dialkyl disulfide and activated alkene in THF was heated under reflux in the presence of indium(I) iodide and the Michael adduct was isolated by the usual workup. On the other hand, a stirred solution of indium(I) iodide, dialkyl disulfide, and epoxide in dry THF was heated under reflux in the presence of a catalytic amount of indium trichloride (5 mol%) (TLC) and quenched with a few drops of water. Extraction with ether and the usual workup produced a pure product.

Several α,β-unsaturated ketones, aldehydes, and carboxylic esters underwent facile Michael additions to dithiolate anions generated by the cleavage of disulfides by this procedure to provide the corresponding adducts in high yields. Conjugated nitriles were also found to react with the thiolate anions, although the yields are relatively low compared with those with carbonyl compounds. The results are summarized in Table 1. Aliphatic as well as aromatic disulfides are found to undergo cleavage and subsequent reaction. On the other hand, both cyclic and acyclic conjugated carbonyl compounds participate in this reaction as Michael acceptors.

A wide range of structurally diverse epoxides underwent cleavages by reaction with dialkyl or diaryl disulfides by this procedure to provide the corresponding β-hydroxysulfides in high yields. The results are summarized in Table 2. The cleavages are highly regio- and stereo-selective. As expected, attack of thiolate anion occurred at the less-hindered carbon atom of the terminal alkyl-substituted epoxides (Table 2, entries 1–5). However, an aryl-substituted epoxide (Table 2, entry 6) attack occurs at the benzylic carbon atom. The cyclic epoxides (Table 2, entries 7–12) produced stereospecifically trans-diequatorial β-hydroxysulfides. In case of open-chain, α-keto aryl epoxides (Table 2, entries 13–15) thiolate anion also stitched at the benzylic carbon producing the corresponding γ-keto-β-hydroxysulfides. In all cases, the syn orientation of hydroxy and thiophenyl were observed as revealed by their coupling constants in ^{1}H NMR. The nonaromatic cyclic α-keto epoxides (Table 2, entries 16–18) underwent the attack of thiolate anion to the epoxycarbon atom α to the carbonyl group and simultaneous dehydration

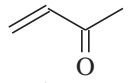
Scheme 2.

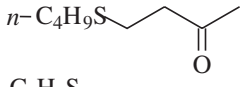
occurred under the reaction process to produce the corresponding α-thiophenyl α,β-unsaturated ketones, although in β-methyl epoxyketone (Table 2, entry 18), a minor product (20%) from the β attack was isolated. However, in the case of α-methyl-α,β-epoxyketone (Table 2, entry 19) α-methyl-α-thiophenyl-β-hydroxyketone was obtained, as dehydration is not feasible.

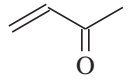
In general, the reactions are considerably fast, clean, and high yielding. Presumably, these reactions are going through the intermediacy of bis(phenylthiophenyl)iodoindium(III), formed readily by the oxidative insertion of equimolar quantities of InI to diphenyl disulfide, which then releases thiolate anion to trigger the Michael addition and epoxide cleavage under the catalysis of $InCl_3$ (Scheme 2). It has also been observed that the epoxide cleavage reactions did not proceed at all without the presence of $InCl_3$.

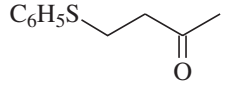
In conclusion, this one-pot procedure for the synthesis of β-oxy- and β-hydroxyalkyl sulfides has been developed involving indium(I) iodide mediated cleavage of diorganyl disulfides and subsequent reaction with conjugated carbonyl compounds and epoxides. The significant advantages offered by this method are operational simplicity, relatively fast reaction, neutral and mild reaction conditions, general applicability, high regio- and stereo-selectivity, and good yields. Thus, it provides a better and practical alternative to the existing procedures (8, 9). Moreover, this constitutes a novel approach demonstrating the synthetic potential of indium(I) iodide, and further useful applications of this reagent are in progress.

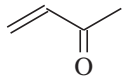
Experimental

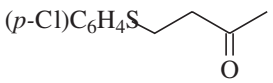


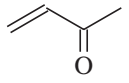


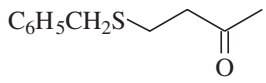


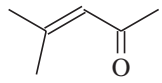


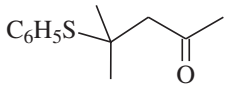


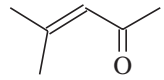


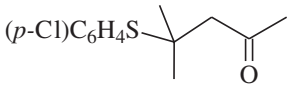


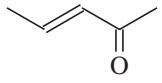


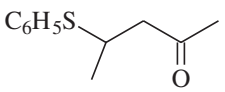


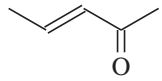


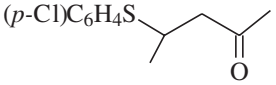


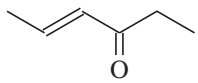


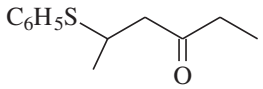


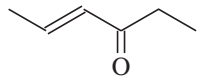


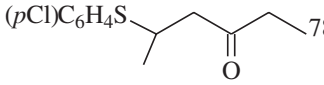


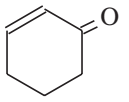


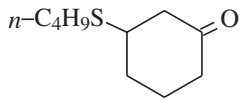


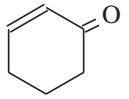


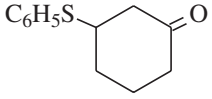


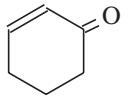


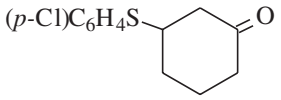


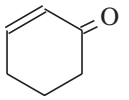


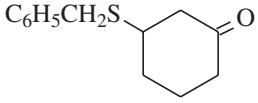












General experimental procedure

Representative procedure for the cleavage of diphenyl disulfide and subsequent reaction with methyl vinyl ketone (Table 1, entry 2)

Indium(I) iodide (121 mg, 0.5 mmol) was added to a solution of diphenyl disulfide (109 mg, 0.5 mmol) in freshly distilled tetrahydrofuran (2.5 mL) under an argon atmosphere followed by the addition of methyl vinyl ketone (70 mg, 1 mmol). The reaction mixture was heated under reflux for 2.5 h (TLC). THF was then evaporated off and the residue was quenched with water and extracted with diethyl ether (3 × 10 mL). The ether extract was washed with water and

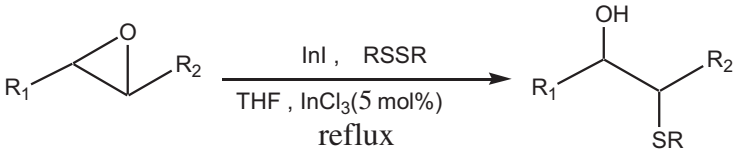
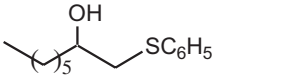
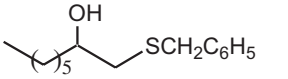
[a]Yields refer to those of pure isolated products characterized by spectroscopic data (IR and ^{1}H and ^{13}C NMR).
[b]Ratio of diastereoisomers as determined by ^{1}H NMR.

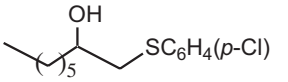
4-(4-Chlorophenylsulfanylbutan-2-one (Table 1, entry 3)

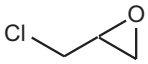


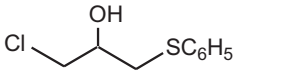
Colourless liquid. IR (neat, cm^{-1}) ν: 1438, 1477, 1578, 1716. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 2.14 (s, 3H), 2.73 (t, *J* = 7.2 Hz, 2H), 3.10 (t, *J* = 7.2 Hz, 2H), 7.25 (s, 4H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 28.1, 30.5, 43.3, 129.5 (2C), 131.2 (2C), 132.8, 134.7, 206.7. Anal. calcd. for $C_{10}H_{11}ClOS$: C 55.94, H 5.16; found: C 55.81, H 5.09.

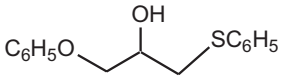


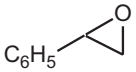


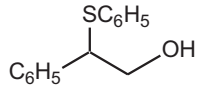


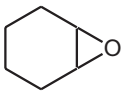


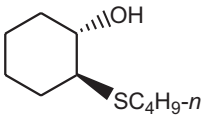


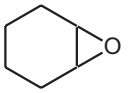


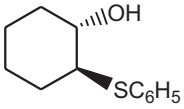


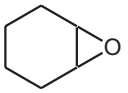


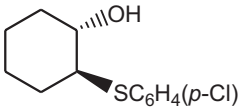


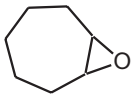


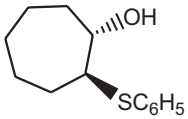


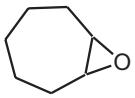


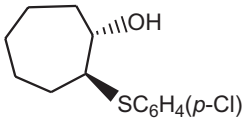


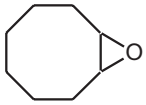


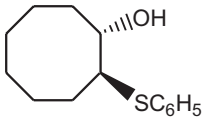












4-(4-Chlorophenylsulfanyl)-4-methyl-pentan-2-one (Table 1, entry 6)

Colourless liquid. IR (neat, cm^{-1}) ν: 1438, 1473, 1573, 1715. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 1.36 (s, 6H), 2.11 (s, 3H), 2.62 (s, 2H), 7.28 (d, *J* = 8.4 Hz, 2H), 7.41 (d, *J* = 8.4 Hz, 2H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 28.1 (2C), 32.0, 47.2, 54.2, 128.8 (2C), 129.8, 136.9, 138.7 (2C), 206.2.

[a]Yields refer to pure isolated products characterized by spectroscopic data (IR and ^{1}H and ^{13}C NMR).
[b]The ratio was determined by ^{1}H NMR spectroscopic data.
[c]Corresponds to compound 18a.

4-(4-Chlorophenylsulfanyl)pentan-2-one (Table 1, entry 8)

Colourless liquid. IR (neat, cm^{-1}) ν: 1475, 1716. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 1.27 (d, J = 6.5 Hz, 3H), 2.12 (s, 3H), 2.55 (dd, J_1 = 8.3 Hz, J_2 = 17.2 Hz, 1H), 2.72 (dd, J_1 = 5.3 Hz, J_2 = 17.2 Hz, 1H), 3.65 (m, 1H), 7.26 (d, J = 8.6 Hz, 2H), 7.33 (d, J = 8.6 Hz, 2H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 20.9, 30.5, 38.4, 50.0, 129.0 (2C), 132.5, 133.4, 133.6 (2C), 206.2. Anal. calcd. for $C_{11}H_{13}ClOS$: C 57.76, H 5.73; found: C 57.84, H 5.81.

5-Phenylsulfanyl-hexan-3-one (Table 1, entry 9)

Colourless liquid. IR (neat, cm^{-1}) ν: 1477, 1712. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 1.03 (t, J = 7.3 Hz, 3H), 1.27 (d, J = 6.7 Hz, 3H), 2.39 (q, J = 14.8 Hz, 2H), 2.53 (dd, J = 8.5 Hz, 16.9 Hz, 1H), 2.73 (dd, J = 5.3 Hz, 16.9 Hz, 1H), 3.71 (m, 1H), 7.23–7.32 (m, 3H), 7.38–7.42 (m, 2H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 7.5, 20.9, 36.6, 38.2, 48.9, 124.5, 127.1 (2C), 132.2 (2C), 134.2, 209.2. Anal. calcd. for $C_{12}H_{16}OS$: C 69.19, H 7.74; found: C 68.93, H 7.60.

5-(4-Chlorophenylsulfanyl)hexan-3-one (Table 1, entry 10)

Colourless liquid. IR (neat, cm^{-1}) ν: 1475, 1714. ^1H NMR (300 MHz, $CDCl_3$) δ: 1.03 (t, *J* = 7.3 Hz, 3H), 1.26 (d, *J* = 6.7 Hz, 3H), 2.39 (q, *J* = 14.3 Hz, 2H), 2.52 (dd, *J* = 8.3 Hz, 16.4 Hz, 1H), 2.69 (dd, *J* = 5.5 Hz, 16.3 Hz, 1H), 3.68 (m, 1H), 7.25 (d, *J* = 8.5 Hz, 2H), 7.33 (d, *J* = 8.5 Hz, 2H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 7.5, 20.9, 36.6, 38.5, 48.8, 128.9 (2C), 132.8, 132.9, 133.3 (2C), 208.9. Anal. calcd. for $C_{12}H_{15}ClOS$: C 59.37, H 6.23; found: C 59.21, H 6.07.

3-(4-Chlorophenylsulfanyl)butanal (Table 1, entry 16)

Colourless liquid. IR (neat, cm^{-1}) ν: 1437, 1475, 1724. ^1H NMR (300 MHz, $CDCl_3$) δ: 1.34 (d, *J* = 6.6 Hz, 3H), 2.54–2.73 (m, 2H), 3.63–3.69 (m, 1H), 7.23–7.37 (m, 4H), 9.74 (t, *J* = 1.5 Hz, 1H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 21.5, 38.2, 50.4, 128.1, 129.6 (2C), 132.3, 134.7 (2C), 200.5. Anal. calcd. for $C_{10}H_{11}ClOS$: C 55.94, H 5.16; found: C 55.73, H 5.07.

3-Benzylsulfanyl-butanal (Table 1, entry 17)

IR (neat, cm^{-1}) ν: 1477, 1724. ^1H NMR (300 MHz, $CDCl_3$) δ: 1.33 (d, *J* = 6.8 Hz, 3H), 2.55–2.61 (m, 2H), 3.13–3.19 (m, 1H), 3.78 (s, 2H), 7.24–7.33 (m, 5H), 9.66 (s, 1H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 21.3, 33.6, 35.2, 50.1, 127.1, 128.5 (2C), 128.7 (2C), 137.9, 200.5. Anal. calcd. for $C_{11}H_{14}OS$: C 68.0, H 7.26; found: C 68.09, H 7.17.

2-Methyl-3-phenylsulfanyl-pentanal (Table 1, entry 19)

Obtained as a mixture of diastereoisomers (61:39). IR (neat, cm^{-1}) ν: 1447, 1722, 2721. ^1H NMR (300 MHz, $CDCl_3$) δ: 1.08 (t, *J* = 7.2 Hz, 3H), 1.20 (d, *J* = 7.2 Hz, 3H), 1.54–1.67 (m, 2H), 2.55–2.59 (m, 1H), 3.39–3.45 (m, 1H), 7.22–7.33 (m, 3H), 7.41–7.44 (m, 2H), 9.68 (d, *J* = 1.6 Hz, 1H major), 9.69 (d, *J* = 1.0 Hz, 1H, minor). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 9.7 (minor), 10.1 (major), 11.8 (major), 12.1 (minor), 24.2 (major), 26.2 (minor), 49.1 (minor), 49.7 (major), 51.3 (major), 52.7 (minor), 127.2, 128.9 (2C), 132.3 (2C), 133.2, 203.5. Anal. calcd. for $C_{12}H_{16}OS$: C 69.19, H 7.74; found: C 69.03, H 7.60.

3-(4-Chlorophenylsulfanyl)-2-methyl-pentanal (Table 1, entry 20)

Colourless liquid obtained as a mixture of diastereoisomers (59:41). IR (neat, cm^{-1}) ν: 1475, 1724, 2721. ^1H NMR (300 MHz, $CDCl_3$) δ: 1.04 (t, *J* = 7.2 Hz, 3H), 1.20 (d, *J* = 7.21 Hz, 3H), 1.62–1.73 (m, 2H), 2.63–2.67 (m, 1H), 3.34–3.40 (m, 1H), 7.26 (d, *J* = 8.3 Hz, 2H), 7.37 (d, *J* = 8.3 Hz, 2H), 9.67 (d, *J* = 1.6 Hz, 1H, minor), 9.68 (d, *J* = 1.0 Hz, 1H, major). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 9.7 (major), 10.2 (minor), 11.8 (minor), 12.1 (major), 24.2 (minor), 26.2 (major), 48.9 (major), 49.6 (minor), 51.7 (minor), 52.9 (major), 129.1 (2C), 133.4, 133.5 (2C), 133.6, 203.2. Anal. calcd. for $C_{12}H_{15}ClOS$: C 59.37, H 6.23; found: C 59.41, H 6.17.

2-Ethyl-3-phenylsulfanyl-hexanal (Table 1, entry 21)

Colourless liquid obtained as a mixture of diastereoisomers (53:47). IR (neat, cm^{-1}) ν: 1479, 1720, 2715. ^1H NMR (300 MHz, $CDCl_3$) δ: 0.88–0.96 (m, 6H), 1.51–1.71 (m, 6H), 2.33–2.37 (m, 1H), 3.35–3.43 (m, 1H), 7.21–7.32 (m, 3H), 7.38–7.43 (m, 2H), 9.66 (d, *J* = 2.7 Hz, 1H, major), 9.75 (d, *J* = 2.3 Hz, 1H, minor). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 11.9 (major), 12.0 (minor), 13.6 (major), 13.7 (minor), 19.3 (major), 19.3 (minor), 20.2 (major), 20.5 (minor), 34.1 (minor), 34.6 (major), 49.2 (major), 49.8 (minor), 56.5 (minor), 56.9 (major), 127.2, 128.9 (2C), 132.3 (2C), 134.8, 203.5 (major), 204.1 (minor). Anal. calcd. for $C_{14}H_{20}OS$: C 71.14, H 8.53; found: C 70.93, H 8.39.

3-(4-Chlorophenylsulfanyl)-2-ethyl-hexanal (Table 1, entry 22)

Colourless liquid obtained as a mixture of diastereoisomers (51:49). IR (neat, cm^{-1}) ν: 1475, 1722, 2719. ^1H NMR (300 MHz, $CDCl_3$) δ: 0.88, 0.94 (m, 6H), 1.49–1.84 (m, 6H), 2.32–2.36 (m, 1H), 3.31–3.37 (m, 1H), 7.28 (d, *J* = 7.8 Hz, 2H), 7.34 (d, *J* = 7.8 Hz, 2H), 9.66 (d, *J* = 2.7 Hz, 1H, minor), 9.73 (d, *J* = 2.2 Hz, 1H, major). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 11.9 (major), 12.0 (minor), 13.6 (major), 13.6 (minor), 19.2 (major), 19.3 (minor), 20.2 (major), 20.5 (minor), 34.0 (major), 34.6 (minor), 49.6 (major), 50.2 (minor), 56.8 (major), 56.4 (minor), 129.1 (2C), 133.3, 133.4, 133.6 (2C), 203.3 (major), 203.6 (minor). Anal. calcd. for $C_{14}H_{19}ClOS$: C 62.09, H 7.07; found: C 61.89, H 6.94.

3-(4-Chlorophenylsulfanyl)propionic acid methyl ester (Table 1, entry 24)

Colourless liquid. IR (neat, cm^{-1}) ν: 1477, 1737. ^1H NMR (300 MHz, $CDCl_3$) δ: 2.59 (t, *J* = 7.5 Hz, 2H), 3.13 (t, *J* = 7.5 Hz, 2H), 3.67 (s, 3H), 7.19–7.29 (m, 4H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 29.7, 34.4, 52.3, 129.5 (2C), 131.8 (2C), 134.1, 134.2, 172.4. Anal. calcd. for $C_{10}H_{11}ClO_2S$: C 52.06, H 4.77; found: C 52.11, H 4.71.

3-(4-Chlorophenylsulfanyl)propionitrile (Table 1, entry 27)

Pale yellow gummy liquid. IR (neat, cm^{-1}) ν: 1431, 1477, 2243. ^1H NMR (300 MHz, $CDCl_3$) δ: 2.55–2.61 (m, 2H), 3.07–3.13 (m, 2H), 7.25–7.37 (m, 4H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 18.1, 30.4, 117.6, 129.5 (2C), 131.6, 132.7 (2C), 133.9. Anal. calcd. for C_9H_8ClNS: C 54.68, H 4.08, N 7.09; found: C 54.49, H 4.01, N 7.02.

2-Methyl-3-phenylsulfanyl-propionitrile (Table 1, entry 28)

Pale yellow liquid. IR (neat, cm^{-1}) ν: 1438, 1481, 1583, 2241. ^1H NMR (300 MHz, $CDCl_3$) δ: 1.40 (d, *J* = 6.9 Hz, 3H), 2.71–2.78 (m, 1H), 2.93–3.02 (m, 1H), 3.12–3.28 (m, 1H), 7.23–7.35 (m, 3H), 7.38–7.43 (m, 2H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 17.1, 26.0, 38.2, 121.4, 127.4, 129.3 (2C), 131.1 (2C), 137.0. Anal. calcd. for $C_{10}H_{11}NS$: C 67.75, H 6.25, N 7.90; found: C 75.43, H 6.16, N 7.81.

General procedure for the synthesis of β-hydroxyalkyl/aryl sulfides

Representative procedure for 1-phenylsulfanyloctan-2-ol (Table 2, entry 1)

To a stirred solution of indium(I) iodide (121 mg, 0.5 mmol) and diphenyldisulphide (109 mg, 0.5 mmol) in dry THF (2.5 mL) was added 1-octene oxide (128 mg, 1 mmol) and indium trichloride (11.05 mg, 5 mol%) under nitrogen. The reaction mixture was heated under reflux for 3 h (TLC) and quenched with a few drops of water. THF was then evaporated off and the residual mixture was then extracted with ether (3 × 20 mL). The combined ether ex-

© 2006 NRC Canada

tract was washed with brine and dried (Na_2SO_4). Evaporation of the solvent left the crude product, which was purified by column chromatography over silica gel (hexane–ether, 85:15) to furnish the pure product, 1-thiophenyloctan-2-ol as a colourless oil (233 mg, 98%). The product was identified by comparison of its spectroscopic data (IR and ^{1}H and ^{13}C NMR) with the reported values (8*g*).

This procedure was followed for all the reactions listed in Table 2. All the products are adequately characterized by their spectroscopic data (IR and ^{1}H and ^{13}C NMR). The values for the known compounds are in good agreement with those reported (Table 2). The spectroscopic data and elemental analysis for new compounds that are not available in the literature are provided here.

1-(4-Chlorophenylsulfanyl)octan-2-ol (Table 2, entry 3)

Colourless liquid. IR (neat, cm^{-1}) ν: 1439, 1479, 1580, 3467. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 0.87 (t, *J* = 6.36 Hz, 3H), 1.26–1.41 (m, 7H), 1.42–1.53 (m, 3H), 2.36 (bs, 1H), 2.84 (dd, *J* = 8.49, 13.56 Hz, 1H), 3.08 (dd, *J* = 3.39 Hz, 13.56 Hz, 1H), 3.62–3.70 (m, 1H), 7.23–7.32 (m, 4H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 14.4, 22.9, 25.9, 29.6, 32.1, 36.5, 42.7, 69.9, 129.5 (2C), 131.6 (2C), 132.9, 134.5. Anal. calcd. for $C_{14}H_{21}ClOS$: C 61.63, H 7.76; found: C 61.50, H 7.61.

2-(4-Chlorophenylsulfanyl)cyclohexanal (Table 2, entry 9)

Colourless liquid. IR (neat, cm^{-1}) ν: 1446, 1477, 1581, 3398. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 1.17–1.38 (m, 4H), 1.67–1.79 (m, 2H), 2.03–2.12 (m, 2H), 2.70–2.77 (m, 1H), 2.80 (s, 1H), 3.30 (ddd, *J* = 4.20, 9.86, 10.01 Hz, 1H), 7.23–7.26 (m, 2H), 7.35–7.39 (m, 2H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 24.6, 26.4, 32.9, 34.3, 56.9, 72.4, 129.4 (2C), 131.7, 134.3, 135.3 (2C). Anal. calcd. for $C_{12}H_{15}ClOS$: C 59.37, H 6.23; found: C 59.21, H 6.11.

2-(4-Chlorophenylsulfanyl)cycloheptanol (Table 2, entry 11)

Colourless liquid. IR (neat, cm^{-1}) ν: 1438, 1478, 1582, 3473. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 1.46–1.61 (m, 4H), 1.69–1.77 (m, 2H), 1.99–2.25 (m, 2H), 2.27–2.40 (m, 2H), 2.41 (s, 1H), 3.64 (ddd, *J* = 3.21, 8.73, 9.87 Hz, 1H), 4.02–4.09 (m, 1H), 7.24–7.38 (m, 4H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 22.0, 25.0, 26.9, 32.6, 35.3, 66.1, 79.2, 126.4, 127.7, 129.5 (2C), 133.5 (2C). Anal. calcd. for $C_{13}H_{17}ClOS$: C 60.80, H 6.67; found: C 60.62, H 6.51.

3-Hydroxy-1,3-diphenyl-2-phenylsulfanyl-propan-1-one (Table 2, entry 13)

Yellow oil. IR (neat, cm^{-1}) ν: 1438, 1477, 1597, 1683, 3460. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 2.94 (bs, 1H), 4.64 (d, *J* = 2.58 Hz, 1H), 5.48 (d, *J* = 2.58 Hz, 1H), 7.10–7.13 (m, 2H), 7.20–7.24 (m, 6H), 7.45–7.62 (m, 4H), 7.62–7.68 (m, 3H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 58.0, 75.1, 128.2, 128.5 (2C), 128.6, 128.7 (2C), 129.0 (2C), 129.2 (2C), 129.3 (2C), 129.4, 129.5, 133.3 (2C), 134.5, 135.9, 198.9. Anal. calcd. for $C_{21}H_{18}O_2S$: C 75.42, H 5.42; found: C 75.31, H 5.33.

2-Hydroxy-3-(4-methoxy-phenyl)-1-phenyl-3-phenylsulfanyl-propan-1-one (as a mixture of diastereomers, 52:48) (Table 2, entry 14)

Yellowish, low-melting solid; mp 40–43 °C. IR (neat, cm^{-1}) ν: 1438, 1477, 1581, 1682, 3465. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 3.74 (s, 3H, major), 3.78 (s, 3H, minor), 4.57 (d, *J* = 2.64 Hz, 1H, minor), 4.64 (d, *J* = 2.58 Hz, 1H, major), 5.42 (d, *J* = 2.64 Hz, 1H, minor), 5.45 (d, *J* = 2.58 Hz, 1H, major), 6.74 (d, *J* = 7.32 Hz, 2H, minor), 6.86 (d, *J* = 8.70 Hz, 2H, major), 7.04–7.07 (m, 4H, (2H for major and 2H for minor)), 7.29–7.32 (m, 4H (2H for major and 2H for minor)), 7.41–7.50 (m, 8H (4H for major and 4H for minor)), 7.62–7.64 (m, 4H (2H for major and 2H for minor)), 7.66 (d, *J* = 8.70 Hz, 2H, major), 7.84 (d, *J* = 7.32 Hz, 2H, minor). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 55.5 (major), 55.6 (minor), 57.3 (minor), 58.4 (major), 75.2 (minor), 77.1 (major), 113.9 (minor, 2C), 114.3 (major, 2C), 127.6 (minor), 127.8 (major), 128.1 (minor), 128.2 (major), 128.8 (major, 2C), 128.9 (minor, 2C), 129.1 (major, 2C), 129.2 (minor, 2C), 129.4 (major, 2C), 129.5 (minor, 2C), 129.9 (minor, 2C), 130.1 (minor), 130.4 (major, 2C), 130.5 (major), 132.8 (minor, 2C), 133.3 (major, 2C), 134.2 (minor), 134.5 (major), 134.7 (minor), 135.1 (major), 159.5 (minor), 159.7 (major), 199.1 (minor), 199.7 (major). Anal. calcd. for $C_{22}H_{20}O_3S$: C 72.50, H 5.53; found: C 72.41, H 5.43.

2-Hydroxy-3-phenyl-3-phenylsulfanyl propionic acid ethyl ester (Table 2, entry 15)

Colourless liquid. IR (neat, cm^{-1}) ν: 1439, 1479, 1583, 1732, 3484. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 1.07 (t, *J* = 7.20 Hz, 3H), 2.88 (bs, 1H), 3.99 (q, *J* = 7.20 Hz, 2H), 4.49 (d, *J* = 3.69 Hz, 1H), 4.52 (d, *J* = 3.69 Hz, 1H), 7.11–7.18 (m, 6H), 7.28–7.33 (m, 4H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 13.9, 56.5, 61.8, 72.6, 127.4, 127.9, 128.2 (2C), 128.3 (2C), 128.7 (2C), 132.1 (2C), 134.2, 136.4, 171.8. Anal. calcd. for $C_{17}H_{18}O_3S$: C 67.52, H 6.00; found: C 67.45, H 5.91.

1-Phenylsulfanyl-4,4a,5,6,7,8-hexahydro-3*H*-naphthalen-2-one (Table 2, entry 16)

Yellowish liquid. IR (neat, cm^{-1}) ν: 1439, 1477, 1582, 1674, 3477. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 0.97–1.51 (m, 4H), 1.52–2.13 (m, 5H), 2.44–2.83 (m, 3H), 3.59–3.69 (m, 1H), 7.07–7.44 (m, 5H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 25.3, 27.2, 28.2, 34.6, 35.2, 37.0, 41.0, 125.3, 127.2 (2C), 128.9 (2C), 137.2, 137.4, 174.0, 195.1. Anal. calcd. for $C_{16}H_{18}OS$: C 74.38, H 7.02; found: C 74.25, H 6.92.

2-Hydroxy-3,5,5-trimethyl-3-phenylsufanyl-cyclohexanone (Table 2, entry 18b)

Colourless liquid. IR (neat, cm^{-1}) ν: 1439, 1477, 1582, 1740. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 1.15 (s, 3H), 1.27 (s, 3H), 1.42 (s, 3H), 1.81–1.86 (m, 1H), 2.25–2.34 (m, 2H), 2.53–2.59 (m, 1H), 4.44 (s, 1H), 7.15–7.26 (m, 5H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 26.3, 30.7, 31.1, 32.9, 47.1, 54.7, 56.8, 71.3, 128.0, 129.0 (2C), 133.2, 133.8, 134.2, 220.7. Anal. calcd. for $C_{15}H_{20}O_2S$: C 68.14, H 7.62; found: C 67.95, H 7.48.

3-Hydroxy-5-isopropenyl-2-methyl-2-phenylsulfanyl-cyclohexanone (Table 2, entry 19)

Colourless liquid. IR (neat, cm^{-1}) ν: 1439, 1474, 1646, 1696, 3464. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 1.18 (s, 3H), 1.76 (s, 3H), 1.89–1.97 (m, 1H), 2.32–2.42 (m, 2H), 2.57 (bs, 1H), 2.84–2.94 (m, 1H), 3.30–3.41 (m, 1H), 4.18–4.20 (m, 1H), 4.79 (d, *J* = 0.75 Hz, 2H), 7.24–7.35 (m, 5H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 18.8, 20.4, 33.4, 39.2, 41.7, 59.9,

Ab initio charge density analysis of $(B_6C)^{2-}$ and B_4C_3 species — How to describe the bonding pattern?

Cina Foroutan-Nejad, Gholam Hossein Shafiee, Abdolreza Sadjadi, and Shant Shahbazian

Abstract: In this study, a detailed topological charge density analysis based on the quantum theory of atoms in molecules (QTAIM) developed by Bader and co-workers, has been accomplished (using the B3LYP method) on the CB_6^{2-} anion and three planar isomers of the C_3B_4 species, which had been first proposed by Exner and Schleyer as examples of molecules containing hexacoordinate carbon atoms. The analysis uncovers the strong (covalent) interactions of boron atoms as well as the "nondirectional" interaction of central carbon atom with those peripheral atoms. On the other hand, instabilities have been found in the topological networks of $(B_6C)^{2-}$ and B_4C_3(para) species. A detailed investigation of these instabilities demonstrates that the topology of charge density has a floppy nature near the equilibrium geometries of the species under study. Thus, these species seems to be best described as complexes of a relatively concrete ring containing boron or carbon atoms and a central carbon atom that is confined in the plane of the molecule, but with nondirectional interactions with the surrounding atoms.

Key words: hypervalency, hexacoordinate carbon, quantum theory of atoms in molecules, charge density analysis, ab initio methods.

Résumé : Faisant appel à la méthode B3LYP et en se basant sur la théorie quantique des atomes dans les molécules développée par Bader et ses collaborateurs, on a fait une analyse détaillée de la densité de charge topologique de l'anion CB_6^{2-} et de trois isomères plans de l'espèce C_3B_4 qui ont été originalement proposées par Exner et Schleyer comme exemples de molécules contenant des atomes de carbone hexacoordinés. L'analyse met en évidence les fortes interactions covalentes des atomes de bore ainsi que l'interaction sans direction de l'atome centre de carbone avec les atomes périphériques. On a par ailleurs mis en évidence des instabilités dans les réseaux topologiques des espèces $(B_6C)^{2-}$ et B_4C_3(para). Une étude détaillée de ces instabilités démontre que la topologie de la densité de charge est de nature souple près des géométries d'équilibre des espèces étudiées. Il semble donc que la meilleure façon de décrire ces espèces soit de les assimiler à des complexes d'un noyau relativement concret contenant du bore ou des atomes de carbone et un atome de carbone central qui est confiné dans le plan de la molécule mais qui a des interactions non directionnelles avec les atomes qui l'entourent.

Mots clés : hypervalence, carbone hexacoordiné, théorie quantique des atomes dans les molécules, analyse de la densité de charge, méthodes ab initio.

[Traduit par la Rédaction]

Introduction

During the last two decades of the previous millennium, a real revolution took place in theoretical chemistry. Due to advances in both computational implementation (software) of reliable quantum chemical methods and hardware facilities, the role of theoretical chemistry has been changed from an almost descriptive tool to a powerful predictive mean. Nowadays, it is a routine procedure to investigate the properties of molecules prior to synthesis by employing high level ab initio quantum chemical methods. So, this unprecedented opportunity in combination with a chemist's imagination makes it possible to designate novel molecules before any experiments. On the other hand, by modeling a single molecule in a computer, it is possible to investigate species that in usual laboratory conditions have no thermodynamic stability. Therefore intermediates, transient and unstable species, and even transition states could be studied with much less effort (rather than using experimental procedures) using current theoretical methods.

In this regard, strange carbon compounds (strange in comparison to traditional ideas in classical organic chemistry) have always been the central attention of predators of odd

molecules. Historically, the pioneering work done by Schleyer and co-workers (1–3) almost 20 years ago may be viewed as the first systematic research (using ab initio quantum chemical methods) in this field. Since then, a wealth of studies has been conducted to investigate novel, unprecedented hypervalent carbon compounds. In 1997, Olah and Rasul (4) reviewed different previous calculations on penta- to hepta-coordinate carbon-containing species. In the same period, reports on new experimental data confirmed that odd carbon compounds are not hypothetical entities imagined by theoretical chemists, but real molecules, some even with bulk stability (5–7).

In such an atmosphere, Exner and Schleyer (8) proposed a new class of boron–carbon compounds, which they believed to be the first examples of planar hexacoordinate carbon compounds. Since that pioneering work, new theoretical studies have been conducted to dig more into the nature of these and related similar compounds (9–11). Not only in these studies has a special attention been paid on the bonding pattern of cited compounds, but the bonding mode of these species is also the main concern of our study.

Although these and related studies (for an up-to-date review of the relevant literature, see ref. 11) confirm the great power of theoretical approaches that are unprecedented during the whole history of chemistry, but such an approach brings delicate technical problems regarding the connection of the theoretical quantum chemical calculations with the usual chemical concepts. Questions regarding the mode of bonding in these odd molecules can be used as the best examples of these approaches. How can we propose or classify the bonding patterns in these molecules? How is it possible to make a relationship with the experimentally known species? And more importantly: Could traditional approaches in common bonding models (based and developed on well-known species) be successfully extended to embed these odd species?

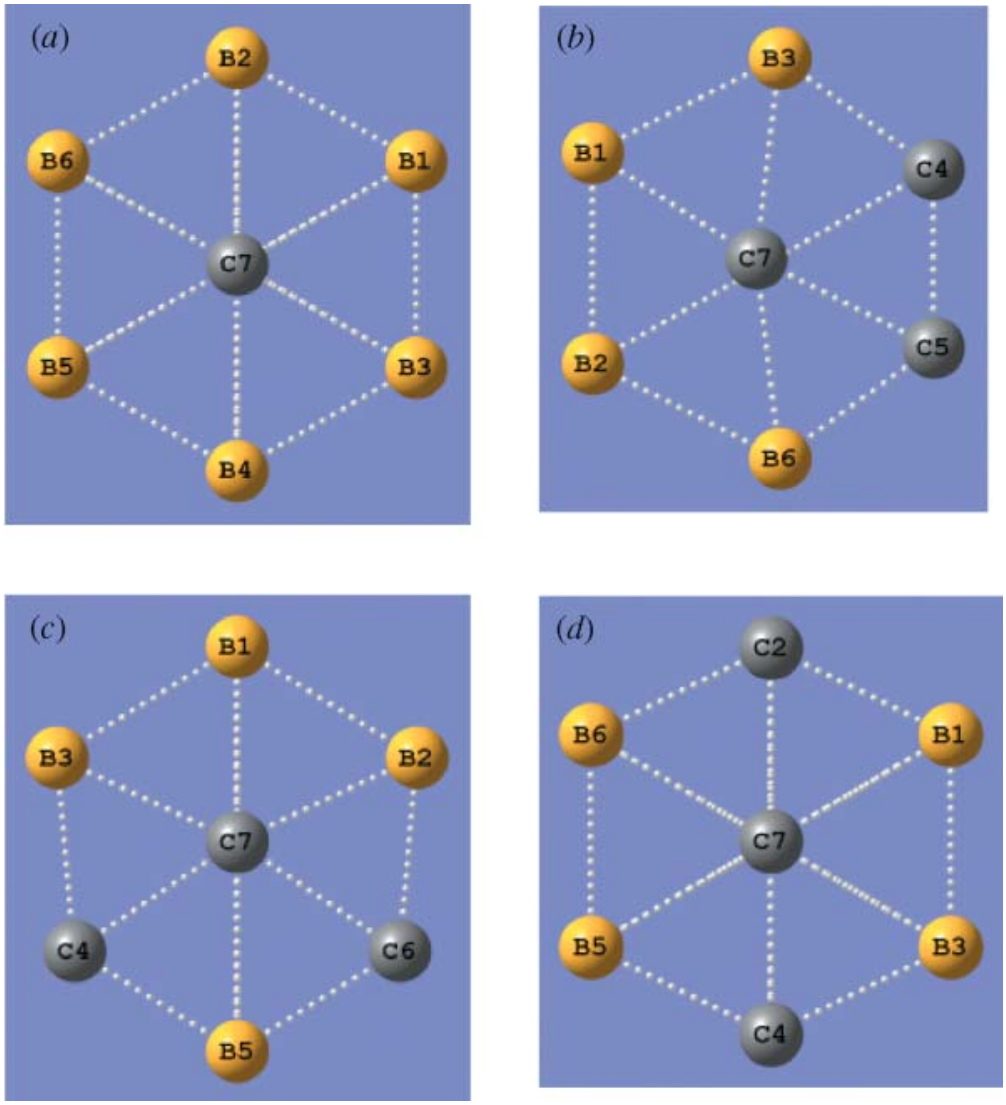
Traditionally, and indeed in the great part of the history of chemistry, chemists have developed the bonding patterns for experimentally known compounds to construct a model that connects the different aspects of the chemical and physical properties of the molecule under study in a logical manner. So, in most cases (but not all), bonding models have been developed to "describe" experimental facts. Consequently, it seems that the bonding models have been employed more for "classification" of the known facts rather than predictive tools in chemistry. In a more detailed view, it is reasonable to claim that the "molecular structure hypothesis" along with the "bonding scheme" of the constituent atoms or functional groups of the target molecule, "coded" the chemical and even some physical information in a compact form. So, a question naturally arises: What does one really ask of a theory of bonding model using only the facts that are obtained from the computed expectation values of quantum mechanical operators? It seems to us that this and similar related questions are crucial in the extension of chemical bonding models to extreme domains as exemplified above.

Therefore, our concern in this paper is the role of the rigorous quantum theory of atoms in molecules (QTAIM) developed by Bader and co-workers (12) in the description of the bonding pattern of the species under study. Since charge density and related functions are the main inputs of QTAIM, in this study we will concentrate on charge densities and relevant topological features of the four species described in the original study (8), namely CB_6^{2-} and three isomers of C_3B_4 (see Fig. 1), and leave other aspects of QTAIM study to another paper. Although these species are intrinsically interesting, our main motivation in this study is not solely confined to these species and they serve as prototypes for applying the general strategy of QTAIM to give answers to some of methodological questions mentioned previously.

Computational details

Density functional calculations have been performed on $(B_6C)^{2-}$, *ortho*-B_4C3, *meta*-B_4C_3, and *para*-B_4C_3 species (see Fig. 1) at the B3LYP/6-311+G(d) level (the same computational level was used in the original study (8)), without any spatial symmetry constraints. In the first step, the equilibrium geometries were located and then frequency calculations were done to establish the local minima. To compare the C—C, B—B, and B—C bonded interactions in the cited species with those in the known chemical species, the molecules C_2H_6, C_2H_4, B_2H_4 (D_{2d}), B_2H_2 (linear), BH_2CH_3 (bisected), and $BHCH_2$ were chosen and their local minimum geometries were obtained at the same level of calculations. Then QTAIM's 3D partitioning scheme of charge densities was performed using the wave function of each molecule. All DFT calculations were carried out using PC GAMESS (version 6.4) (13, 14) and QTAIM calculations with MORPHY99 (15–20). The useful utilities implemented in the ChemCraft (version 1.4 beta) program (21) were optimized for handling the outputs of GAMESS.

Results and discussion



Although the optimized geometries of the species under study were reported in the original account (8) using another computational package a reoptimization was carried out to check the consistency. The results of the geometry optimizations are offered in Table 1 (the numbering scheme from Fig. 1 is used). With no exceptions, the internuclear distances of all the species under study coincide with the original study within 0.001 Å. The internuclear distances are important since they are usually employed to decide whether certain atoms are "bonded" or not (8). As will be discussed (vide infra), this is not the approach followed in this study.

The corresponding state functions of the optimized geometries have been used to construct electronic charge densities. The results of the topological analysis of charge densities are qualitatively depicted in Fig. 2, with the usual emphasis on general topological characters and the corresponding quantitative results are in Table 2. The standard topological analysis and nomenclature were employed in this study, therefore, the details of the analysis have not been discussed in this paper and only some primary descriptions are made in following paragraphs (for details and a comprehensive discussion of relevant analysis, see ref. 12).

According to QTAIM, the bonded atoms are determined by duo-gradient paths of charge density function, which originate from a bond critical point (a point where the gradient of charge density vanishes and the Hessian matrix of charge density has two negative and one positive eigenvalues) and terminate on corresponding atomic nuclei. As

Fig. 1. Spatial orientation of nuclei and their labels for optimized geometries at B3LYP/6-311+G* level. (*a*) $(B_6C)^{2-}$; (*b*) *o*-B_4C_3; (*c*) *m*-B_4C_3; (*d*) *p*-B_4C_3.

has been discussed by Bader in detail (12, 22), these gradient paths, which at equilibrium geometry are called "bond paths", must be regarded as the "universal indicators of bonded interactions" even when this contradicts descriptions based on classical physics or chemical intuition. The details of methodological problems and controversies regarding this choice have been discussed elsewhere (23). So, in this paper we follow the standard QTAIM proposal and admit the bond paths as a necessary and sufficient condition for the two atoms so-linked to be bonded to one another (22).

Even a brief look at Figs. 1 and 2 clearly denotes that there are differences in the overall bond path networks in the four species under study. Particularly, the number of bonded atoms to the central carbon atom vary. On the other hand, a detailed inspection of Fig. 2 demonstrates that, in the case of $(B_6C)^{-2}$ and *para*-B_4C_3 species, we are faced with unusual molecular graphs (we will use the phrase "molecular graph" to distinguish the topological networks (graphs) at equilibrium geometry with those corresponding to nonequilibrium geometries). Before discussing the detailed topological analysis of the individual members of the molecular set selected in this paper, this point necessitates special attention and further elaboration.

Stable vs. unstable molecular graphs

As has been discussed fully elsewhere (12), the stable topological networks are invariant under some finite geometrical changes of nuclei (the nuclear excursions). So, for a finite domain of nuclear geometrical changes, the "equivalent" topological network is retained. The word equivalent means that in the two topological networks corresponding to two neighboring nuclear geometries, the number and type of critical points and also the gradient paths that originate or terminate from these critical points remains the same. In the technical literature, this topological equivalence is termed homomorphism. On the other hand, under sufficiently steep deformations of nuclear geometry, new topological networks will appear. According to catastrophe theory, as implemented in the dynamical theory of charge density evolution relative to nuclear geometrical variations, the two networks interconverted abruptly (for details and a comprehensive discussion see ref. 12). Accordingly, there is a certain nuclear

geometry for which the topological network does not belong to either of the two networks mentioned previously. This topological network may be imagined as a borderline between the two stable topological domains. By implementation of a mathematical theorem on structural stability as first derived by Palis and Smale (24) (and then implemented on the topological evolution of charge density relative to changes of nuclear geometry (12)), the borderline unstable topological networks may be classified systematically. Without going into detail, this classification leads to two distinct groups of unstable topological networks. In the first class, one encounters topological networks with degenerate critical points (critical points with ranks lower than three) and the other class contains networks with critical points whose connection causes the "nontransverse" intersect of stable and unstable manifolds (for details, see ref. 12). The first type of unstable topological network (with degenerate critical points) has been named bifurcation points, whereas the second type has been named conflict structures. The nuclear geometries corresponding to these two types of topological networks may be viewed as a natural borderline between the two topologically stable domains. So, with a small perturbation of nuclear geometry corresponds to an unstable topological network, this network will disappear and a new topological structure with a finite domain of stability will appear. In this regard, Fig. 2 vividly depicts the conflict topological networks at equilibrium geometries of the $(B_6C)^{2-}$ and *para*-B_4C_3 species. In the case of the molecular graph of $(B_6C)^{2-}$, the bond paths that originated from bond critical points (3,4,5,8,9,11), from one end have been terminated (normally) in the nucleus of central carbon atom, but from the other end have been terminated in another group of bond critical points (2,1,6,7,10,12), respectively. Similarly, in the case of the topological network of *para*-B_4C_3, the bond paths that originated from the bond critical points (3,4), from one end have been terminated in the nucleus of the central carbon atom, but from the other end have been terminated to another group of bond critical points (2,10), respectively. Both cases exemplify conflict structures. These topological instabilities have delicate effects on the bonding description of associated species and will be considered in detail in this paper.

Topological analysis

Table 2 offers the quantitative information regarding the

Fig. 2. The complete molecular graphs (MG) for (*a*) $(B_6C)^{2-}$, (*b*) *o*-B_4C_3, (*c*) *m*-B_4C_3, and (*d*) *p*-B_4C_3 at B3LYP/6-311+G* optimized geometries. Small black squares are BCPs and small black triangles are RCPs.

amount of charge density, the values of the Laplacian of charge density ($\nabla^2\rho$), the ellipticities ($\varepsilon = (\lambda_1/\lambda_2) - 1$), and the corresponding λ_1 and λ_2 values at bond critical points (BCPs) of all four species (λ_1 and λ_2 are the two negative eigenvalues of the Hessian matrix of charge density. By convention, λ_2 is the smaller curvature. Ellipticity provides a measure of the extent to which charge is preferentially accumulated in a given plane. For details, see ref. 12 and refs. cited therein). Table 3 has also been constructed to compare the results of Table 2 with a standard set. Table 3 contains some geometrical as well as topological characters (like those offered in Table 2) for the set of molecules C_2H_6, C_2H_4, B_2H_4 (D_{2d}), B_2H_2 (linear), BH_2CH_3 (bisected), and $BHCH_2$. This set has been selected as a prototype standard reference for C—C, B—C, and B—B single and double bonds (of course, single and double bonds in a classical context). Although such selection and corresponding comparison is inevitably arbitrary and since this is a common strategy in similar considerations, we also adapted this strategy in our study. Accordingly, with this standard set and the information available from Table 2 and Fig. 2, it is now possible to make a detailed analysis of the charge density of the species under study.

The $(B_6C)^{2-}$ anion

A detailed inspection of Tables 2 and 3, as well as Fig. 2, demonstrates some interesting patterns regarding the bonding mode of $(B_6C)^{2-}$. The amount of charge density in BCPs connecting boron atoms to each other is only 0.150 au, which is a bit lower than those in the B_2H_4 and B_2H_2 species. On the other hand, the ellipticity is 0.583, which is between the ellipticity of the B—B bonded interaction in the B_2H_4 and B_2H_2 species. Also, the sign of the Laplacian of electronic charge density is negative like those for the B_2H_4 and B_2H_2 molecules. These negative values are indicator of a "shared" interaction, which is usually interpreted as presence of a "covalent" bond (12). As is evident from Fig. 2, there are no direct bonded interactions between boron atoms and

the central carbon atom. The topological characters of other BCPs, as well as ring critical points (RCPs), may be used to investigate the instability of the topological network of $(B_6C)^{2-}$.

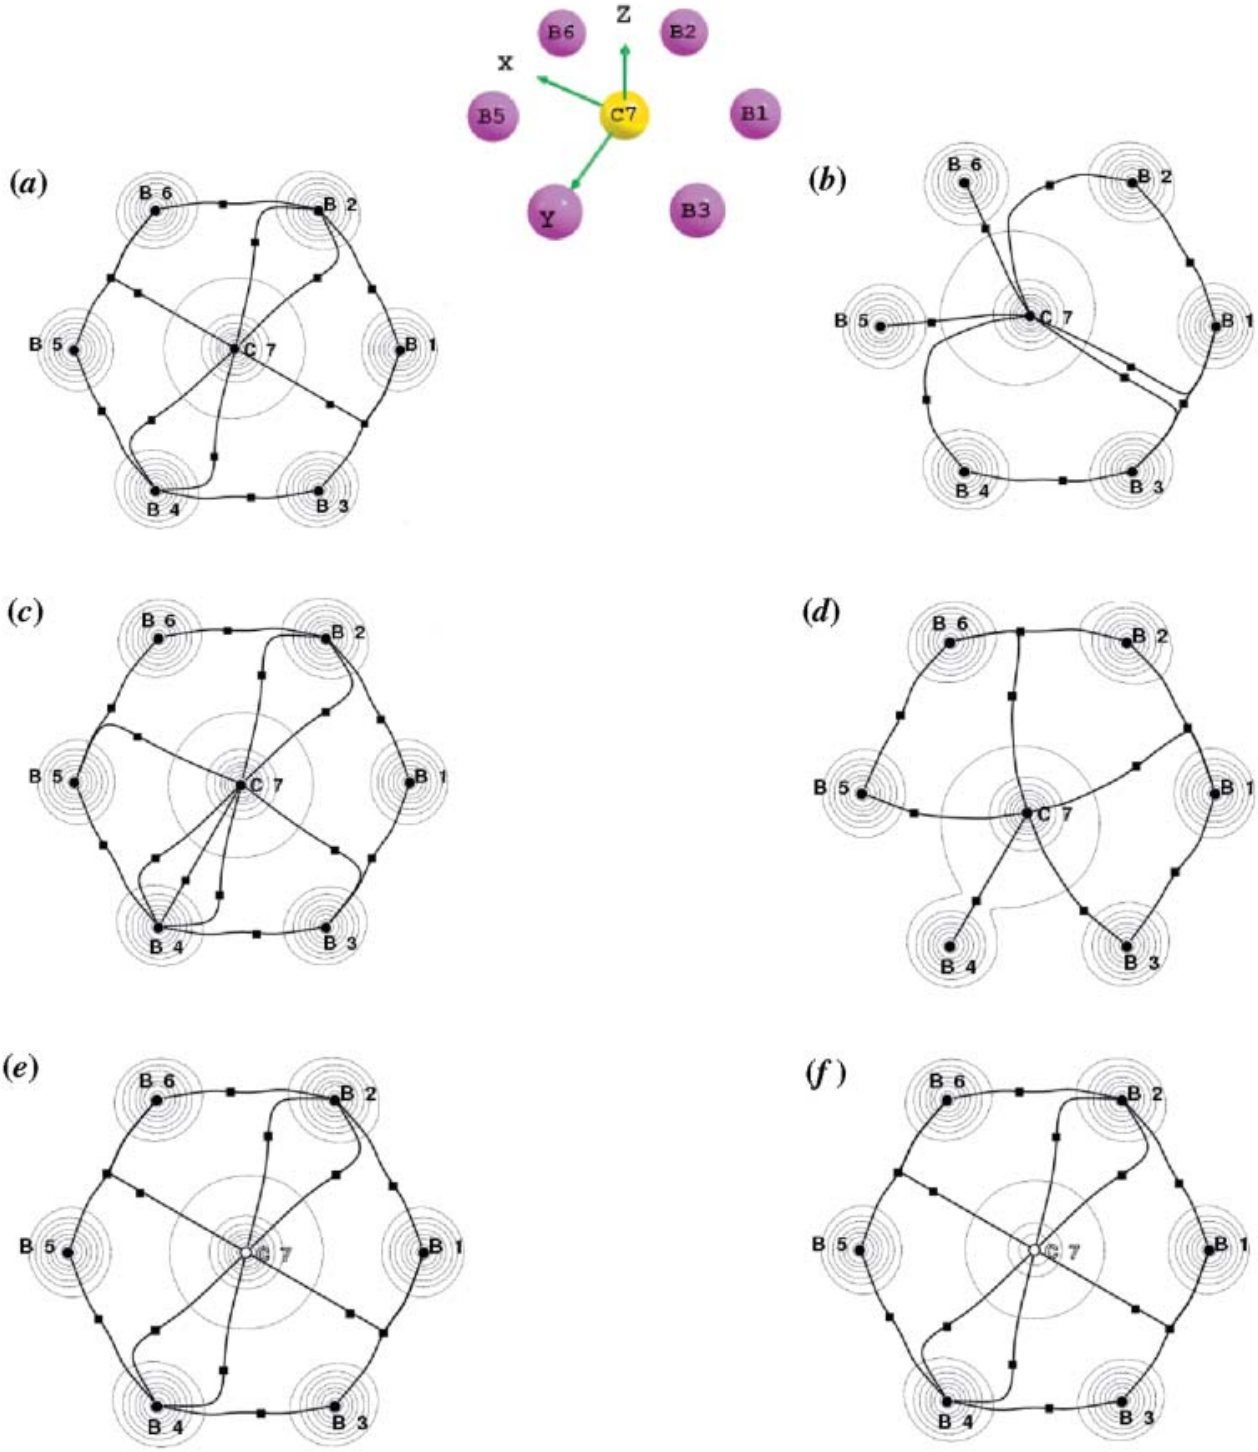
In the case of the topological network of $(B_6C)^{2-}$ at equilibrium geometry, we encountered a conflict structure as discussed previously. The data in Table 2, also confirm the unstable nature of this topological network. The comparison of the amounts of charge density of BCPs (3,4,5,8,9,11) and RCPs reveals small differences (less than 0.01 au), so the overall charge density is relatively flat in a hypothetical ring imagined around the central carbon nucleus. This flatness of charge density may be interpreted as an indication of the ease of change in topological structure (12). On the other hand, the large ellipticities that are associated with BCPs (3,4,5,8,9,11) also confirm this conclusion. The large ellipti-

© 2006 NRC Canada

cities are another indicator of the readiness of topological changes (12). Indeed, a more detailed inspection of the corresponding negative eigenvalues of the Hessian matrix of charge density (λ_1 and λ_2) from Table 2 demonstrates the near vanishing of the negative curvature of the BCPs (λ_2 = –0.001) along an axes in the plane of the ring and perpendicular to the bond path, and the same near vanishing of the correspondingly directed positive curvature at the RCPs (λ_2 = 0.005). To establish these changes unequivocally, small arbitrary perturbations of geometrical parameters have been made to demonstrate the abrupt onset of topological changes in the molecular graph of $(B_6C)^{2-}$.

Figure 3 depicts the topological networks of this molecule after some small, arbitrary shifting in nuclear geometrical parameters. In the first step, with a small 0.02 Å shift of the central carbon (C7) nucleus toward a line bisecting a hypothetical line going through B—B (X direction), the molecular graph of $(B_6C)^{2-}$ has been changed dramatically and a new topological network has emerged. Accordingly, from this new graph (shown in Fig. 3*a*), it is evident that there are two BCPs, which are connected from one side to the nucleus of the central carbon and from the other side to another BCP, so, this molecular graph is also a new conflict structure (must be distinguished from the original conflict structure). In a second step, a 0.2 Å shift of the central carbon nucleus in the same direction was performed and as is evident from Fig. 3*b*, this new topological structure is now a stable topological network. The same procedure (shifting of central carbon nucleus) was accomplished for two other directions, namely one directly toward one of the boron nuclei of the peripheral ring (Y direction) and the other in a perpendicular, out-of-plane shifting (Z direction). Figures 3*c*–3*f* depict the resultant topological networks. In all cases, dramatic changes of molecular graphs have taken place following the applied geometrical changes. Except for Fig. 3*c*, all other topological networks are conflict structures (with the same criterion described previously). What is more interesting in considering these graphs, is that there are two or even three "distinct gradient paths" connecting the central carbon nucleus and one of the boron nuclei of the peripheral ring, as is evident from Fig. 3. This is an unusual and possibly a novel trait regarding the common topological networks considered previously (12). Although these are only a selected set of possible graphs (with a constraint search in selected directions of geometrical parameters space), even with this set and taking into account the nuclear excursion during the vibrations, it is evident that $(B_6C)^{2-}$ does not have a "unique" topological structure around its equilibrium geometry.

On the other hand, with external energy pumping into the vibrational degrees of freedom (vibrationally "hot" molecules), not only the low-lying vibrational states, but also the higher (excited) vibrational levels, may also gain considerable population. So, the high amplitude vibrations may take place and as previous analysis has demonstrated (with controlled shifting of the central carbon from 0.02 to 0.2 Å) new topological regimes will be available to the molecule (since explicit consideration of nuclear motion has not yet been incorporated in QTAIM, this is an ad hoc, but reasonable assumption). The other interesting feature of the topological networks of Fig. 3 is the bonded pattern of corresponding atoms. By changing the mode of geometrical perturbations of the central carbon, bonded interactions have been created and annihilated according to the amount and also the direction of the corresponding geometrical shift. For instance, whereas B5—B6 internuclear distances are the same in Figs. 3*a* and 3*b*, in Fig. 3*a* there is a bonded interaction between them, whereas the same bonded interaction has been ruptured in the topological network that is depicted in Fig. 3*b*. The same feature may be traced in the other topological networks, which are depicted in Fig. 3. Since the molecular vibrations are usually considered using normal mode analysis (25) (from nuclear dynamics analysis in the context of Born–Oppenheimer approximation) and this implies complex relative motions of nuclei, therefore, with the mixture of different normal modes and possible contributions of excited vibrational states with corresponding normal modes, it seems hard (if not impossible) to attribute a single or even a well-defined set of molecular graphs to the $(B_6C)^{2-}$ anion. So, it seems that $(B_6C)^{2-}$ anion must be viewed topologically as a "floppy" molecule.



The three isomers of B_4C_3

In the case of B_4C_3, we are faced with numerous possible isomers, but this study is confined to the three isomers that were considered in the original study (8) and are depicted in Fig. 1. They have been named according to the relative position of the two carbon atoms in the peripheral ring of atoms around the central carbon atom, applying the usual classical nomenclature, namely *ortho*-B_4C_3, *meta*-B_4C_3, and *para*-B_4C_3. As noted previously and as is evident from Fig. 2, the molecular graphs of these three species differ remarkably. These differences, as well as the similarities, will be considered separately.

In the case of the *ortho*-B_4C_3 molecule, we are faced with a stable molecular graph. The central carbon atom is bonded from one side to the two carbon atoms, whereas from the other side, there are two other bonded interactions with boron atoms. So, all three types of bonding couples, namely B—B, C—C, and B—C, coexist in this molecule. The comparison of topological characters from Tables 2 and 3 reveals some interesting patterns. In all cases, except the C4—C5 bonded interaction, the amount of charge density at BCPs are smaller than those in reference double and even single bond BCPs, although, with no exception, they are all in the range of shared interactions. On the other hand, the Laplacians of charge density at BCPs of C—C and B—B bonded interactions are negative, also indicating shared interactions, whereas the same quantity is positive at BCPs of B—C bonded interactions. This positive value of the Laplacian of charge density seems to be in contradiction with the shared interaction proposed according to the charge density of corresponding BCPs. But, it must keep in mind that the internuclear distance of B—C (1.46 and 1.50 Å) in this molecule is shorter than the internuclear distance of B—C in BH_2CH_3 (1.55 Å), and so it is probable that the shortening of B—C bonds in the *ortho*-B_4C_3 molecule causes a transition to the "internal" regime of the positive Laplacian of charge density (see ref. 26 and refs. cited therein). As considered in detail by Costales et al. (26), the lengthening and shortening of internuclear distances will motivate some universal changes of charge density distributions. One of these characteristics is the appearance of a positive

Fig. 3. The molecular graphs of the $(B_6C)^{2-}$ ion when the C7 nucleus is moved in the X, Y, and Z directions of the molecular axis (shown at the top). (*a*, *b*) 0.02 and 0.2 Å displacements in the X direction. (*c*, *d*) 0.02 and 0.2 Å displacements in the Y direction. (*e*, *f*) 0.02 and 0.2 Å displacements in the Z direction. The hollow circle shows the out-of-plane nucleus.

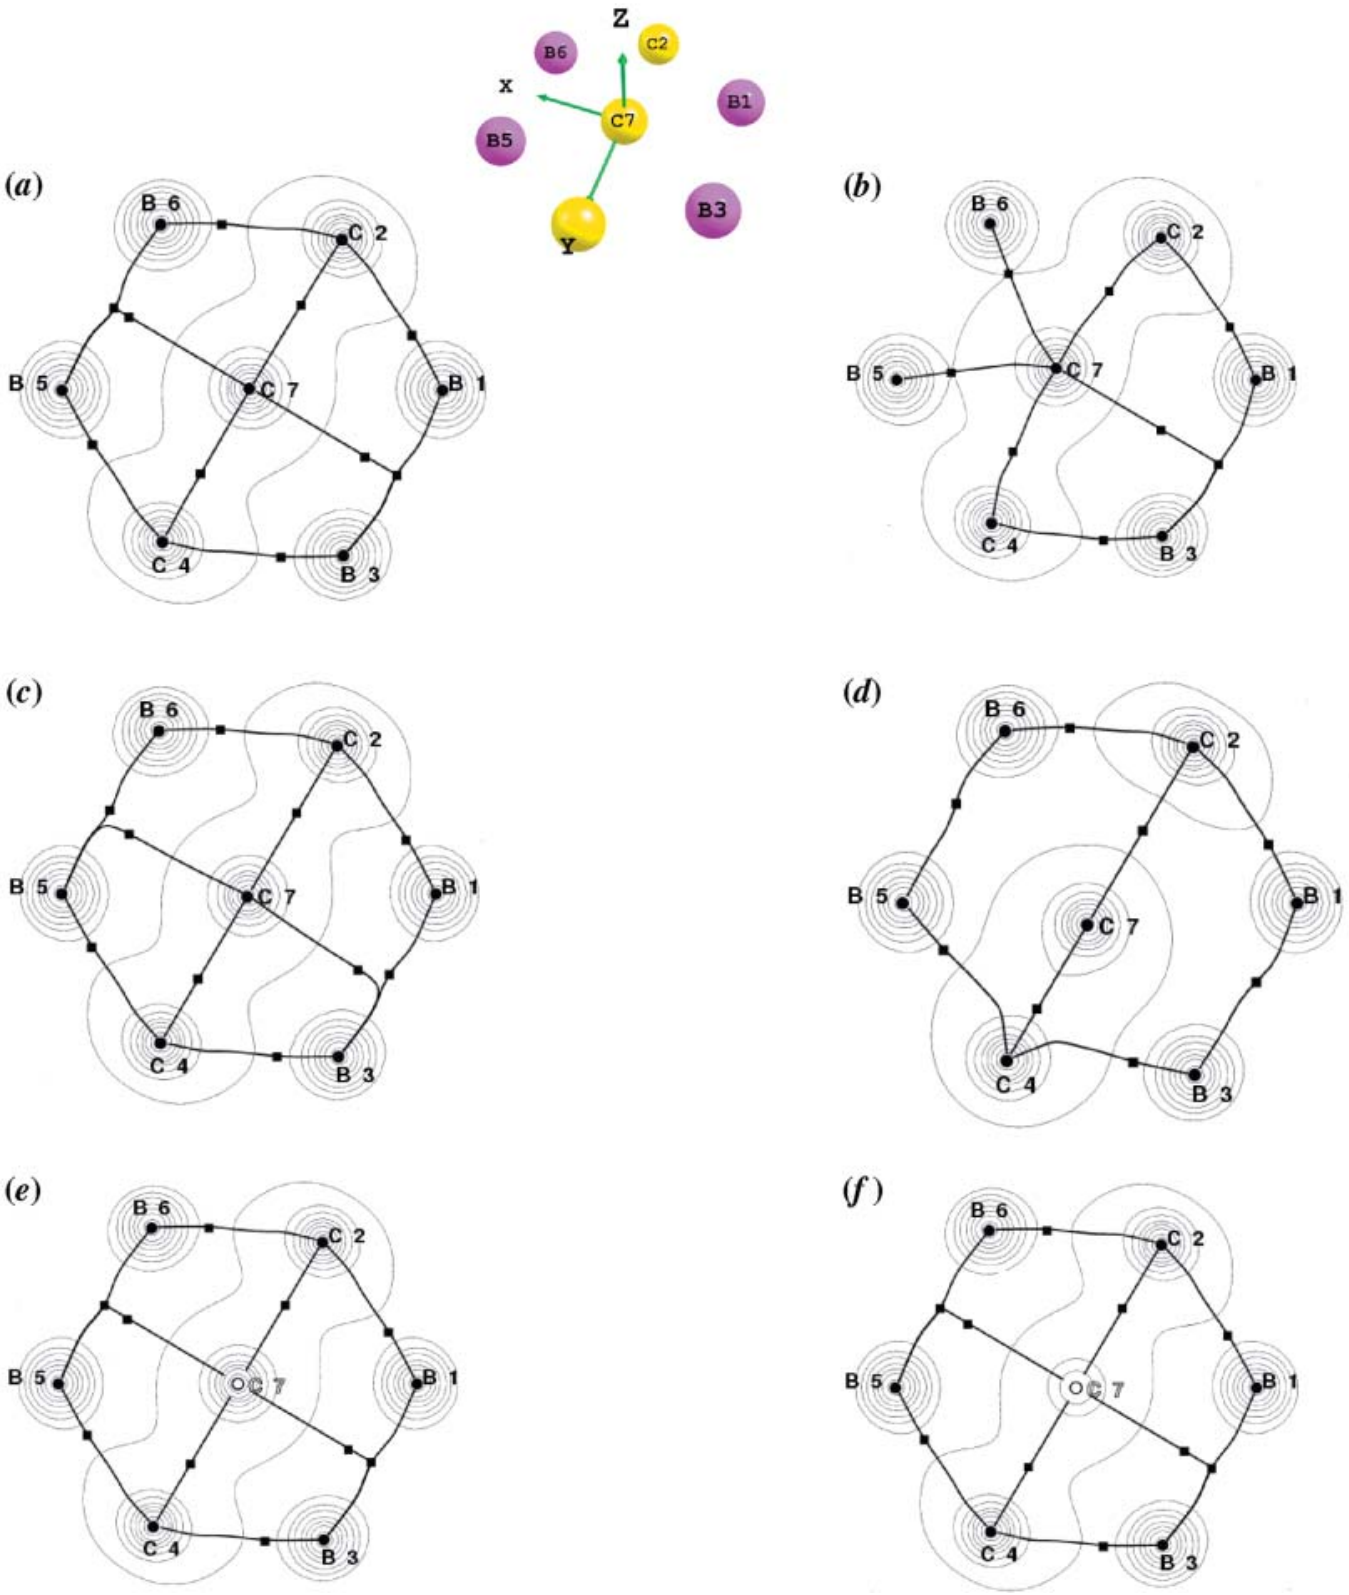
Laplacian of charge density at BCPs (indicator of closed shared interactions) in molecules, where there is no doubt on their shared interaction (like the N_2 molecule). These positive values appear at large and small internuclear distances (usually out of the range of normal equilibrium internuclear distances), whereas at intermediate distances the usual negative value is retained. So, it is reasonable to assume that if the equilibrium internuclear distance of certain nuclei decreases considerably (like the B—C in *ortho*-B_4C_3 molecule), then a positive value of the Laplacian of charge density at BCP is not unexpected. The values of ellipticities are also worth mentioning in this analysis. In spite of small ellipticities in C4—C5 and B—C bonded interactions, large, unusual ellipticites (in comparison to those in Table 3) were

© 2006 NRC Canada

observed at other BCPs. As mentioned in the case of the $(B_6C)^{2-}$ anion, the large unusual value of ellipticity is an indicator of the proximity of a topological instability. Also, in this case one may find the near vanishing of the negative curvature of the BCPs ($\lambda_2 < -0.09$) along an axes in the plane of the ring and perpendicular to the bond path and the same near vanishing of the correspondingly directed positive curvature at the RCPs ($\lambda_2 < 0.08$). Accordingly, the comparison of the charge density values at BCPs, which possess the large of ellipticity values, with the charge density values at RCPs, confirms the proximity of topological instability. The difference between the amounts of charge density at BCPs (1,4,2,6,3,5) with neighboring RCPs (1,3,2) is between 0.002 and 0.012 au, which reveals the relative flatness of charge density around the central carbon nucleus. This feature is reminiscent of the charge density distribution of the $(B_6C)^{2-}$ anion as discussed previously. So, the presence of a multiple of topological networks regarding the nuclear excursion in a vibrational normal mode analysis is not unexpected.

Some of these topological characteristics of *ortho*-B_4C_3 seem to be shared with the two other isomers. In the case of the *meta*-B_4C_3 isomer, the amounts of charge density at BCPs are comparable with those in the *ortho*-B_4C_3 isomer. The sign of the Laplacian of charge density is also like those in the *ortho*-B_4C_3 isomer, although the sign of this function at the two BCPs of the B—C bonded interactions (B2—C7 and B3—C7) are slightly negative. As is evident from Fig. 2*c*, this may be due to a large deformation of corresponding bond paths from a straight line. On the other hand, large ellipticities have been observed again, particularly at the BCPs of the B2—C7 and B3—C7 bonded interactions. The proximity of the RCPs (1, 3) to the BCPs (1, 2) reveals the origin of these large ellipticities. One may also observe the near vanishing of the negative curvature of the BCPs ($\lambda_2 = -0.024$) along an axes in the plane of the ring and perpendicular to the bond path and the same near vanishing of the correspondingly directed positive curvature at the RCPs ($\lambda_2 = 0.019$). Comparison of the amounts of charge density at these RCPs and BCPs confirms that the difference is even smaller than 0.001 au, and so we are near to an unstable topological network with a "degenerate critical point", which may be created from the coalescence of a RCP and a BCP (see ref. 12 and refs. cited therein). So, this topological graph is also on the edge of the stability–instability regime. In the case of *para*-B_4C_3, in contrast to the two other isomers, a conflict structure exists at equilibrium geometry like those in the $(B_6C)^-$ anion. However, in the case of bonded interactions, namely B—B, B—C, and C—C, the amounts of charge density at the corresponding critical points is almost similar to those found in *ortho*-B_4C_3, *meta*-B_4C_3, and $(B_6C)^{2-}$ species. In all species considered, with the minor exception of B2—C7 and B3–C7 in *meta*-B_4C_3, the sign of the Laplacian of charge density at BCPs corresponding to all C—C and B—B bonded interactions are negative and those belonging to B—C bonded interactions are positive. The large ellipticity values of the BCPs (3,4) also confirm the topological instability of the molecular graph. Again, the difference between the amounts of the charge density of BCPs (3,4) and neighboring RCPs (1,2,3,4) is only 0.004 au, and combined with the near vanishing of the negative curvature of the BCPs ($\lambda_2 = -0.010$) along an axes in the plane of the ring and perpendicular to the bond path and the same near vanishing of the correspondingly directed positive curvature at the RCPs ($\lambda_2 = 0.027$), may be interpreted as the possibility of coalescence of BCPs and RCPs and creation of degenerate critical points is probable. Like the $(B_6C)^{2-}$ anion, some selected deformations have been applied to the equilibrium geometry of this molecule and the corresponding topological networks are depicted in Fig. 4. Again, dramatic changes have taken place in the topological networks. Some of these structures, such as Figs. 4*a*, 4*b*, 4*e*, and 4*f*, are also unstable conflict structures. So, according to the reasoning that has been offered in the case of the $(B_6C)^{2-}$ anion, the vibrational dynamics of nuclei prevent the attribution of a single definite molecular graph to the *para*-B_4C_3 molecule around equilibrium geometry, another example of a topologically floppy molecule.

Conclusion and remarks



This study reveals some of the interesting features of the topological characters of the charge density in the species under consideration and clearly indicates that a nontrivial, possibly floppy topological pattern exists in this series of molecules because of the extraordinary sensitivity of the topological characters of these species relative to the small changes in their geometries. In this regard, it is worth mentioning that such a topological floppiness is not unique and has been reported previously in other sets of molecules (27–29). So, what can be said about their bonding pattern?

In a recent paper entitled "Where to draw the line in defining a molecular structure", Bader et al. (30) discussed in detail an interesting case, namely bonding between Mn, Si, and H atoms in the adduct resulting from the reaction between $HSiCl_3$ and $Cp(CO)_2Mn$ molecules. Since there were conflicting opinions regarding the most appropriate bonding pattern of this adduct (31, 32), the QTAIM clear-cut answer regarding the associated bonding pattern based solely on quantum mechanics of proper open systems seems a remarkable achievement. So, at least if one may neglect (with or without reasonable physical justification) the nuclear motion and hence just describe the topology of the charge density of a certain point in geometrical space or corresponding PES, QTAIM could offer unambiguous results. Unfortunately, this study did not encounter such a well-defined case. Left alone, the conflict structures of $(B_6C)^{2-}$ and *para*-B_4C_3 molecules, which are inherently topologically unstable structures, and even in the case of *ortho*-B_4C_3 and *meta*-B_4C_3 molecules with stable topological structure, there are clues that nuclear excursions may cause geometrical deformations that make available new topological domains different from those corresponding to the equilibrium geometry. So, it seems to us that explicit consideration of the nuclear motion in the framework of QTAIM could be helpful for a better understanding of the bonding pattern of these molecules. Although this possibility for a general extension of QTAIM is under study,[2] even the analysis accomplished in this paper reveals certain points that are worth mentioning.

Fig. 4. The complete molecular graphs of p-B_4C_3 when the C7 nucleus is moved in the X, Y, and Z directions of the molecular axis (shown at the top). (*a*, b) 0.02 and 0.2 Å in the X direction. (*c*, *d*) 0.02 and 0.2 Å in the Y direction.

Intuitionally, one expects that in such hexacoordinate species, the nucleus of the central carbon atom should be connected to the nuclei of peripheral atoms with six distinct bond paths, but Figs. 2–4 clearly demonstrate that none of the topological networks corresponding to the species under study have a central carbon atom with six or more bond

© 2006 NRC Canada

paths connecting them to all six atoms in the peripheral ring. It is interesting to note that the same topological analysis that has been done on the other celebrated hexacoordinate molecule, namely CLi_6, came to another conclusion and confirmed that the central carbon atom, which is confined in an octahedral structure, has indeed six bond paths connecting the carbon atom to six lithium atoms (33). (The same molecular graph was retained using more extended basis sets and even taking into account the correlation effects by employing sophisticated DFT methods).[3] So, it seems to us that we are faced with unusual, "possibly" hexacoordinate species in this study.

On the other hand, the topological characteristics of the BCPs of the $(B_6C)^{2-}$ anion unequivocally established the shared interaction between boron atoms and also the flat charge density around the nucleus of the central carbon. This seems to indicate that no firm "directional interaction" takes place between the central carbon and the boron atoms. Although the free rotation of a single atom is not of physical significance, if the charge density distribution of the other extended planar boron rings encompassing the small molecular clusters resembles the $(B_6C)^{2-}$ anion, then a nearly free rotation of the central cluster must be expected. Although according to the best of our knowledge no study of the topological characters of charge density distributions have been yet performed on such extended boron–carbon clusters, the ab initio calculations (11) have been conducted on such species and indeed have been estimated to have a very low barrier for the rotation of the central carbon clusters encompassing the ring of boron atoms. The future direct examination of the topological features of the charge density of these species will establish the possible common trait among them. This study has been restricted only to the detailed analysis of charge density distributions and corresponding topological networks. The evaluation of atomic expectation values, as well as analysis of localization/delocalization indices, will be done in a subsequent paper.

Acknowledgments

Special thanks to Professor Kirk A. Peterson from Washington State University for his very useful comments and Dr. Paul Lode Albert Popelier from the University of Manchester Institute of Science and Technology, Manchester, UK (UMIST) for helping us to access the MORPHY99 software and sending the related materials. We are also grateful to Professor R.F.W Bader and two other reviewers for their useful technical comments and to the respected editor, since his final comments on the linguistic aspects of this paper helped us to improve the manuscript.

Living biomembrane bitemplate route for simultaneous synthesis of different morphologies of CdSe and ZnSe nanomaterials

Li Li, Qing-Sheng Wu, and Ya-Ping Ding

Abstract: In this paper, CdSe (nanotubes, nanorods) and ZnSe (nanorods, nanoslats) were simultaneously synthesized through a biomineralization process through biomembrane bitemplates of mungbean sprouts at room temperature. The XRD patterns indicated that these nanocrystals were crystallized in the hexagonal structure and cubic structure with lattice constants a = 0.423 and c = 0.701 nm (CdSe) and a = 0.567 nm (ZnSe), respectively. The possible formation mechanism was investigated in the paper.

Key words: CdSe, ZnSe, nanotubes, nanorods, nanoslats, living biomembrane, bitemplates.

Résumé : On a synthétisé simultanément du CdSe (nanotubes, nanotiges) et du ZnSe (nanotiges, nanolamelles) dans le cadre d'un processus de biominéralisation à la température ambiante, à travers une biomembrane à double gabarit de germe de haricot mungo. Les patrons de diffraction des rayons X indiquent que ces nanocristaux appartiennent respectivement à des structures hexagonale et cubique avec des constantes a = 0,423 et c = 0,701 nm (CdSe) et a = 0,567 nm (ZnSe) respectivement. On a étudié le mécanisme possible de formation.

Mots clés : CdSe, ZnSe, nanotubes, nanotiges, nanolamelles, biomembrane vivante, double gabarit.

[Traduit par la Rédaction]

Teeth, bones, and shells are known as the products of biological mineralization by cells (1, 2). They are nanodimensional materials synthesized by organism itself. Biomembranes, formed by orderly arrangements of cells, are highly regular and controllable. Some difficult functions such as high penetrability and selectivity that haven't been achieved can be obtained by biomembranes with powerful transmission capacities and ideal separation efficiencies. Recently, monomolecular membranes (3) and multimolecular membranes (LB membranes) (4, 5) have been utilized as a simplified model for biomembranes that are used to simulate the transportation of ions and the transfer of information and energy in the biomembranes. Now membrane research is at the molecule level. In recent years, it has attracted many researchers' interest in using biomembranes as templates for the synthesis of nanomaterials (6–8). But no one has been trying to utilize bitemplates, and only a few 1-D nanomaterials have been produced. No reports about the method of manipulating the nucleation and the growth of the molecule to simultaneously synthesize different morphologies of nanomaterials by means of biomembrane bitemplates with dense structure, orderly arrangement, and different inner and outer structures have been made.

The nanoscale II–VI semiconductor compounds, such as the direct band gap materials ZnSe and CdSe, have been thoroughly investigated and widely used (9–13). These wide-gap II–VI semiconductors are efficient emitters in the blue to ultraviolet spectral region, and excitons in these compounds are much more stable than those in conventional III–V semiconductors that are widely used in optoelectronic applications such as blue laser diodes, light-emitting diodes, and photodetectors (14, 15).

The mung bean radicle is a kind of simple and available living biomembrane material that is able to live in solution. There are many well-distributed grooves on its stem surface and many conduits in the stem (Fig. 1). The structures of the inner and outer membranes of the stem are very different. Because the membrane controls the entrance and exit of inorganic ions and affects mineralization, therefore, the mung bean radicle is an ideal material for use as a living biomembrane bitemplate for the synthesis of allomorphic nanomaterials. By using biological mineralization, 1-D selenides, such as ZnSe and CdSe semiconductor nanomaterials, were simultaneously synthesized by induction of these living biological bitemplates.

Experimental section

Materials

Selenium (99.95%), KBH_4 (94%), $CdCl_2$, $ZnSO_4$, and absolute ethanol (A.R.) were all purchased from the Shanghai

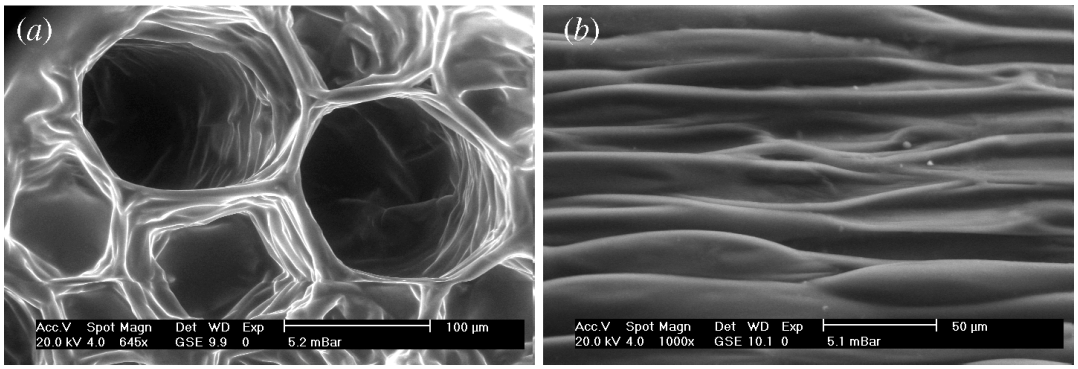

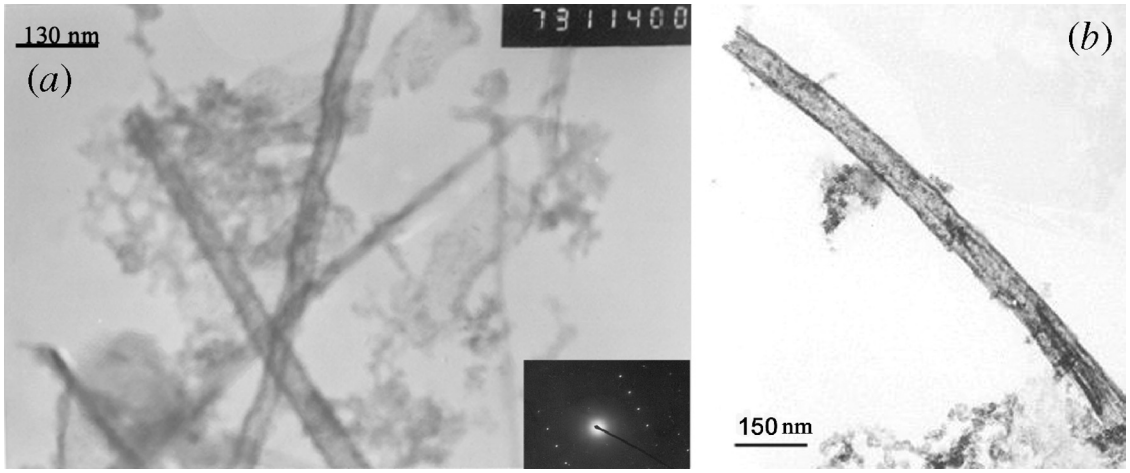

Fig. 2. (*a*) TEM image of as-prepared CdSe nanotubes (external products) and SAED. (*b*) TEM image of a single CdSe nanotube.

Chemical Reagent Factory, China. Mung bean sprouts were fresh and purchased from the market.

Instrumentation

TEM images and electron diffraction spectra were generated on a Hitachi model-800 transmission electron microscope. Powder X-ray diffraction (XRD) patterns of the samples were measured on a Phillips 1710 X-ray diffractometer with Cu Kα radiation (λ = 1.5406 Å). ESEM images were obtained on a Phillips XL-30E environmental scanning electron microscope. Absorption spectra were recorded on an Aligent 8453 UV–vis spectrophotometer. Photoluminescence (PL) spectra were obtained on a PerkinElmer LS-55 luminescence spectrophotometer (Boston, Massachusetts).

Procedure

One-dimensional semiconductor ZnSe nanomaterials were prepared according to the following procedure: mung bean sprouts (except for laminae) were immersed in a solution of 0.1 mol/L aq. $ZnSO_4$ at room temperature for 6 h before they were taken out and rinsed under deionized water. After immersion in a solution of 0.1 mol/L aq. KHSe (KBH_4–Se in 20 mL deionized water) for 3 h (10), the mung bean sprouts were rinsed under deionized water and anhydrous ethanol successively. The brown solid on the surface of the mung bean sprouts was scraped off with a glass rod and transferred into a beaker. Then these mung bean sprouts were silted, and the inner product was scraped off with a glass rod and transferred into another beaker. Ten milliliters of carbon tetrachloride was added to the beakers, and the suspensions were agitated with an ultrasonator for 30 min followed by centrifugalization. The solids were kept in absolute ethanol.

When $CdCl_2$ was used in this procedure in place of $ZnSO_4$, ZnSe nanomaterials were prepared.

Characterization method

The crystal structures of the products were examined by XRD. The morphology and size of the synthesized products were observed by TEM. The PL spectra of the products were obtained using a PerkinElmer luminescence spectrophotometer (LS-55). The UV spectra of the products were obtained using an UV–vis spectrophotometer (Aligent 8453).

Results

Morphology and structure

Figure 2*a* and the inset display a CdSe TEM image of the external products and their selected area electron diffraction (SAED) patterns, suggesting that they are nanotubes and

single crystals. The outside diameter of these nanotubes is 65–70 nm, the inner diameter is 60–65 nm, and the lengths are up to 800–1000 nm. Observation (Figs. 3*a* and 3*b*) of the inside products shows that they are nanorods with a diameter of about 50 nm and a length longer than 3000 nm. The nanorods are smooth and straight. Figure 3*b* shows the typical electron diffraction pattern of nanorods, which indicates that they are single crystals.

Figure 4*a* shows the ZnSe TEM micrographs and SAED patterns of the external products. The diameter of the nanorod is about 80 nm, and the average length is about 3.5 μm. The SAED pattern inserted in Fig. 4*a* shows that the nanorods synthesized in the experiment are single crystals. Figure 4*b* and the inset display a TEM image of the interior products and their SAED pattern, suggesting that they are regular nanoslats and they are single crystals. Their diameter is in the range of 150 nm, their length about 1100–1250 nm, and their thickness in the range of about 50 nm.

Figures 5*a* and 5*b* show the XRD patterns of the ZnSe and CdSe samples prepared using the living biomembrane. In Fig. 5*a*, the peaks can be indexed as cubic zinc-blende phase ZnSe with a lattice parameter of $a = 0.567$ nm, which is consistent with The Joint Committee on Powder Diffraction Standards (JCPDS) card No. 5-0522. The XRD pattern of CdSe is shown in Fig. 5*b* and all of the peaks were indexed as the hexagonal phase of CdSe (JCPDS card No. 8-459). The broadness of the XRD peaks corresponded to their small grain size.

Experimental conditions

We have tried the synthesis of CdSe or ZnSe materials without the templates of the mung bean sprouts. The morphologies and structures of these materials are quite different from the products produced using the templates. The TEM images of the CdSe or ZnSe material (Fig. 6), which were synthesized without the templates of the mung bean sprouts, suggest that they were all amorphous crystals.

When the concentration was at 0.1–0.2 mol/L, a range of 1-D nanomaterials were commonly observed. When the concentration was less than 0.1 mol/L, the nanoparticles gradually increased. When the concentration was more than 0.2 mol/L, it was not a suitable environment for mung bean sprouts to live. There were two reasons for our selection of KBH_4 as the reductant: one was the possible existence of active H^- in KBH_4, which activated the reaction between Se and $Cd^{2+}(Zn^{2+})$ (16); another was the existence of K^+ ions in KBH_4, which "eliminated the toxicity of the single salt" caused by the $Cd^{2+}(Zn^{2+})$ ions.

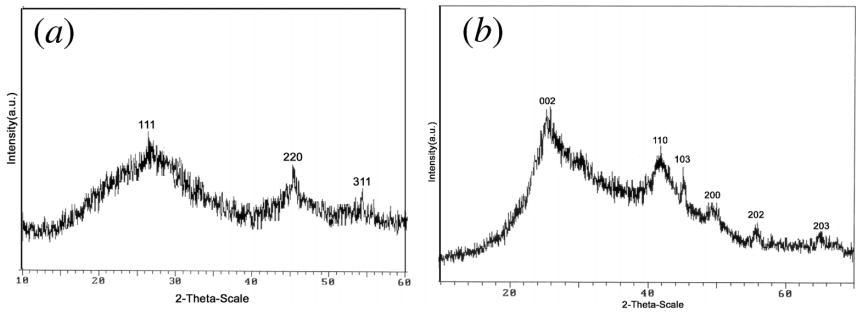

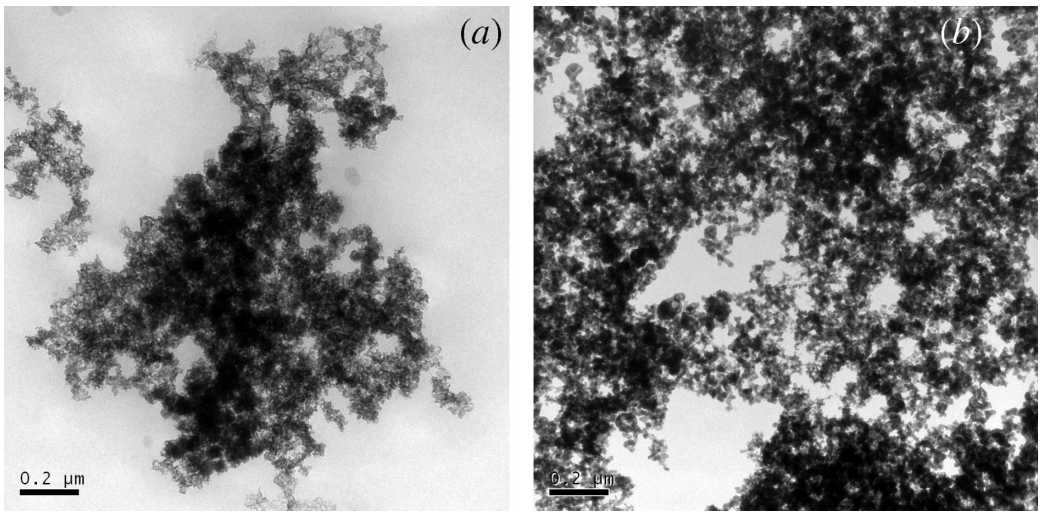

Fig. 6. (*a*) TEM image of as-prepared ZnSe materials (*without* using the mung bean sprout). (*b*) TEM image of as-prepared CdSe materials (*without* using the mung bean sprout).

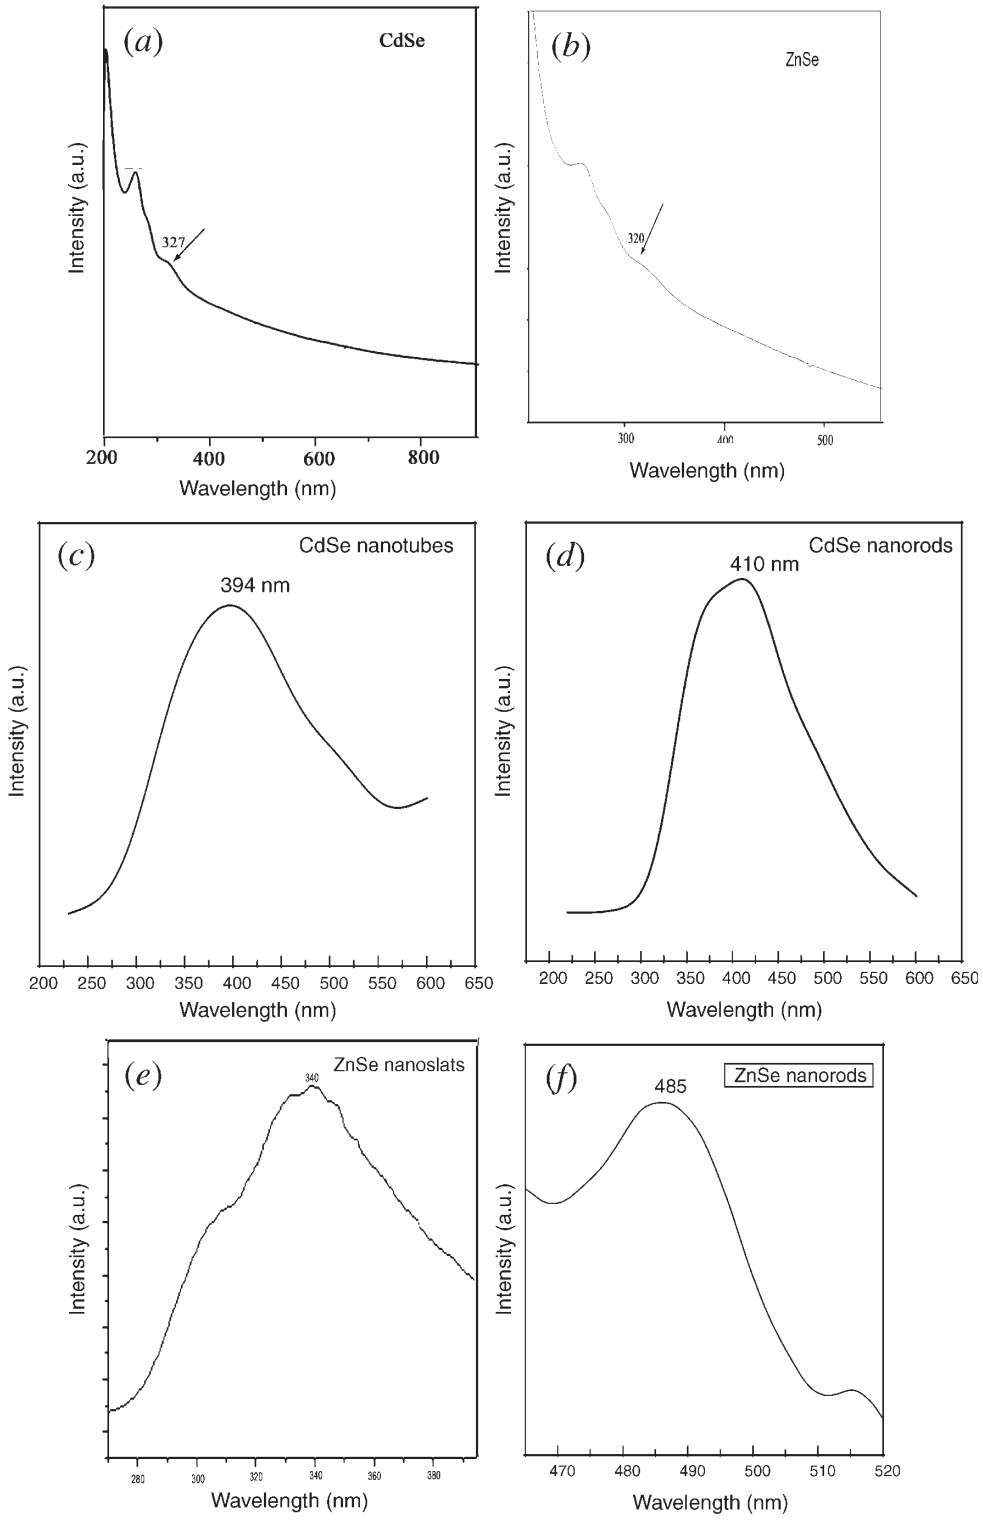
Optical properties

Until now, a few reports of ZnSe or CdSe preparation referred to the luminescence properties, largely for their unique semiconductor properties. Here, we examined the UV spectra and PL spectra of the as-prepared nanomaterials at room temperature and our result shows it as a potential application in optical devices. Figure 7*a* shows the UV–vis absorption spectrum at 327 nm for the CdSe nanomaterials and an obvious blue shift was observed when compared with the bulk CdSe at 712 nm (1.74 eV) owing to quantum confinement. The PL of the CdSe nanostructure was characterized with an excitation wavelength of 230 nm. As compared with the PL spectrum acquired from the source CdSe powders, whose luminescence peak is located at 735 nm, the CdSe nanomaterials showed a peak at 394 nm (nanotubes) and 410 nm (nanorods) (Figs. 7*c* and 7*d*), shifted toward blue, possibly because of the small diameters of the CdSe nanomaterials.

UV–vis absorption spectra (Fig. 7*b*) of ZnSe quasi-nanospheres showed a strong absorption peak at about 320 nm (4.84 eV) and an obvious blue shift was observed when compared with bulk ZnSe at 480 nm (2.6 eV) owing to quantum confinement. The absorption peak for the products shifted about 160 nm, which is consistent with those ZnSe nanomaterials synthesized by other methods (17, 18). Figures 7*e* and 7*f* show the PL spectrra of an ethanol solution containing ZnSe nanomaterials. The PL spectrum of the ZnSe shows a broad emission band peaked at ca. 340 nm (nanoslats) and 485 nm (nanorods), using a 230 nm excitation wavelength. The characteristic blue shift of the PL spectrum of nanomaterials is attributed to their small diameter and larger aspect ratio.



Conclusions

In summary, different morphologies of CdSe and ZnSe 1-D nanomaterials have been synthesized under the control of living bitemplates using fresh mung bean sprouts.[2] This method is mild, convenient, and "green" because of the absence of surfactant and organic solvent (19, 20). This approach can be extended to synthesize other nanostructured materials. We could use other living biomembranes instead of mung bean sprouts. The synthesis mechanism, especially the organism changes, the process of action, and the trans-

Interaction of peroxynitrite with myoglobin and hemoglobin

Shivashankar Kalinga

Abstract: Peroxynitrite, a biological toxin produced in vivo by the nearly diffusion-controlled reaction of nitrogen monoxide with superoxide, can nitrate and oxidize various biomolecules. Modifications caused by peroxynitrite have been linked to many human diseases, in particular, increased levels of free or protein-bound 3-nitrotyrosine, a biomarker for peroxynitrite in vivo, have been detected in a variety of pulmonary and cardiovascular diseases as well as in neurodegenerative and chronic inflammatory disorders. These observations have led to the search for a drug that can scavenge this powerful nitrating and oxidizing agent. Heme proteins, in particular myoglobin and hemoglobin, present in large amounts in muscles and red blood cells, respectively, have been proposed to serve as sinks for peroxynitrite in these cells. This report reviews the current knowledge of the reactions of different forms of myoglobin and hemoglobin with peroxynitrite and discusses their physiological role on the basis of measured rate constants.

Key words: myoglobin, hemoglobin, peroxynitrite, tyrosine nitration, iron(III) peroxynitrite complex.

Résumé : Le peroxynitrite est une toxine biologique qui est produite in vivo par la réaction dont la vitesse est pratiquement contrôlée par la diffusion du monoxyde d'azote avec le superoxyde et qui peut conduire à la nitration et à l'oxydation de diverses biomolécules. Des modifications provoquées par le peroxynitrite ont été liées à diverses pathologies humaines, en particulier, des niveaux accrus de 3-nitrotyrosine libre ou liée à une protéine, un biomarqueur du peroxynitrite in vivo, ont été détectés dans une variété de maladies pulmonaires ou cardiovasculaires ainsi que dans des désordres neurodégénératifs et des inflammations chroniques. Ces observations ont orienté des recherches vers le développement d'un médicament qui pourrait capter ce puissant agent de nitration et d'oxydation. Les héme protéines, en particulier la myoglobine et l'hémoglobine, qui sont présentes en grandes quantités respectivement dans les muscles et les cellules rouges du sang ont été proposées pour servir de piège pour le peroxynitrite présent dans ces cellules. Le présent travail passe en revue les connaissances actuelles des réactions des diverses formes de la myoglobine et de l'hémoglobine avec le peroxynitrite et discute de leur rôle physiologique sur la base de constantes de vitesse mesurées.

Mots clés : myoglobine, hémoglobine, peroxynitrite, nitration de la tyrosine, complexe du fer(III) et du peroxynitrite.

[Traduit par la Rédaction]

Introduction

In humans, the endothelial, neuronal, and inducible nitric oxide synthases produce nitrogen monoxide in nanomolar concentration from arginine with the aid of dioxygen and nicotinamide adenine dinucleotide phosphate (reduced form, NADPH) (1). Under physiological levels, nitrogen monoxide plays an important role in regulating blood pressure, as a defensive cytotoxin of the immune system, and as a neurotransmitter (1). However, overproduction of nitrogen monoxide is known to be involved in the pathogenesis of several inflammatory diseases (2). For example, overproduction of nitrogen monoxide in blood vessels of a septic organism leads to sustained, often lethal hypotension (3). Importantly, the extravascular half-life of nitrogen monoxide ranges from 0.09 to ~2 s; it can readily diffuse across cellular membranes and react with molecules such as dioxygen and superoxide radicals (4). Nitrogen monoxide reacts with dioxygen to give nitrogen dioxide and the rate constant for this ternary reaction in aqueous solution is 2×10^6 $(mol/L)^{-2}$ s^{-1} at 25 °C (5). However, this reaction proceeds slowly under physiological conditions. Nitrogen monoxide reacts rapidly with superoxide to form peroxynitrite, which is a far more reactive molecule than its precursors (eqs. [1] and [2]) (6).

$$[1] \quad NO^{\cdot} + O_2^{\cdot -} \xrightarrow{1.6 \times 10^{10}\ (mol/L)^{-1}\ s^{-1}} ONOO^- \overset{H^+}{\rightleftharpoons} ONOOH$$

$$[2] \quad 2O_2^{\cdot -} + 2H^+ \xrightarrow[SOD]{2 \times 10^9\ (mol/L)^{-1}\ s^{-1}} O_2 + H_2O_2$$

Peroxynitrite, a reactive transient species with a biological half-life of 10–20 ms, is a potent oxidant with the ability to destroy critical cellular components (6, 7). It may oxidize thiols (8) and (or) nitrates of all major types of biomolecules including DNA (9, 10), proteins (11, 12), and lipids (13). Koppenol and co-workers (14, 15) pointed out that the second-order rate constant for the reaction of nitrogen monoxide with superoxide is $(1.6 \pm 0.3) \times 10^{10}$ $(mol/L)^{-1}$ s^{-1} (eq. [1]), a value that is larger than that for the reaction of

superoxide with superoxide dismutase (2×10^9 (mol/L)$^{-1}$ s^{-1}, ref. 16) (eq. [2]). Thus, peroxynitrite may be formed even in the presence of physiological concentrations of superoxide dismutase, especially if the nitrogen monoxide concentration is in the micromolar range. The normal intracellular concentration of nitrogen monoxide is ca. 10 nmol/L and that of superoxide dismutase is 10 μmol/L (17). However, during inflammation, the extracellular concentration of nitrogen monoxide is expected to rise to ~2 μmol/L (17). Under these conditions, nitrogen monoxide can out compete superoxide dismutase and react with superoxide to form peroxynitrite.

The reactivity of peroxynitrite is complex and highly pH-dependent (18). Kissner et al. (14) reported that the pK_a of peroxynitrous acid is about 6.8 in 50 mmol/L phosphate buffer, but can increase up to 8, depending on the buffer composition and concentration. The term peroxynitrite refers to the sum of peroxynitrite anion ($ONOO^-$) and its conjugate acid, peroxynitrous acid (ONOOH). Peroxynitrite can directly perform one- or two-electron oxidation reactions with electrode potentials (E″ (ONOOH, $H^+/NO_2^{\cdot}$, H_2O) = 1.6 ± 0.1 V) or (E″ (ONOOH, H^+/NO_2^-, H_2O) = 1.3 ± 0.1 V), respectively (19). The peroxynitrite anion is rather stable in alkaline solutions, slowly decomposing to nitrite and dioxygen (20). However, peroxynitrous acid is unstable and isomerizes to give nitrate or decomposes into a reactive intermediate, though the final outcome is still under debate.

The first proposed pathway is the decomposition of peroxynitrous acid to give nitrogen dioxide and hydroxyl radicals (18). This proposed homolytic cleavage leads to a pair of radicals formed in a cage surrounded by water molecules. These caged radicals can recombine to reform peroxynitrous acid, diffuse apart to give nitrogen dioxide and hydroxyl radicals, or recombine to form nitrate (eq. [3]). The yield of nitrogen dioxide and hydroxyl radicals was estimated to be 30% (21, 22). However, the rate of homolysis (0.6 to 10^{-4} s^{-1}) of peroxynitrous acid is slower than the rate of isomerization (1.2 s^{-1}), and thus homolysis is highly unlikely (23).

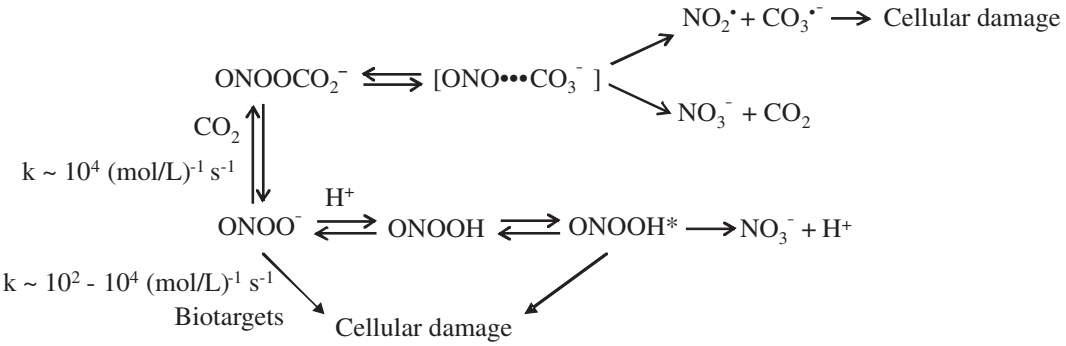
$$[3]\quad ONOOH \underset{\text{Cage}}{\overset{\text{Homolysis}}{\rightleftharpoons}} [NO_2^{\cdot}\bullet\bullet\bullet OH^{\cdot}] \begin{cases} \xrightarrow{70\%} NO_3^- + H^+ \\ \xrightarrow{30\%} NO_2^{\cdot} + OH^{\cdot} \end{cases}$$

Koppenol et al. (23) proposed an alternative pathway for the decomposition of ONOOH that involves an as yet undefined metastable species of peroxynitrous acid, HOONO* (eq. [4]). This intermediate can rapidly isomerize to nitrate (eq. [4]). As the half-life of peroxynitrous acid is less than a second, it is difficult to directly study this metastable intermediate. However, theoretical studies support the existence of such a metastable species (24).

$$[4]\quad ONOOH \rightleftharpoons [ONOOH^*] \xrightarrow{\text{Isomerization}} NO_3^- + H^+$$

$$[5]\quad ONOOH + ONOO^- \rightleftharpoons \underset{\text{adduct}}{ONOOHONOO^-} \longrightarrow 2NO_2^- + O_2 + H^+$$

In recent work, no direct evidence was found for the formation of hydroxyl radicals (14, 18, 19, 23). In contrast, several studies reported results that are not in agreement with the following hypothesis: (*i*) when the concentration of peroxynitrite exceeds 100 μmol/L, its disappearance is delayed because of the formation of an adduct between peroxynitrite anion and peroxynitrous acid (14). This adduct ($ONOOHONOO^-$) decomposes to give nitrite and dioxygen (eq. [5]). Thus, the yields of nitrite and nitrate depend on the peroxynitrite concentration and the pH. For instance, at pH 7.0, 2.5 mmol/L peroxynitrite gives less than 10% nitrite, whereas at pH 10, up to 80% nitrite is formed (25). (*ii*) The decay of peroxynitrous acid in the presence of [^{15}N]nitrite involves initial formation of an adduct between nitrite and peroxynitrite to give [^{15}N]nitrate. However, according to the homolysis hypothesis, the yields of [^{15}N]nitrate predicted for low [^{15}N]nitrite concentrations are much larger than those obtained experimentally (26). (*iii*) The reaction of peroxynitrous acid with monohydroascorbate gives nitrate via an intermediate adduct without formation of ascorbyl radicals (27). (*iv*) The isomerization of peroxynitrite has a small entropy of activation of 3 ± 2 eu (24) and a volume of activation of 6.9 ± 0.9 cm^3 mol^{-1} (28), two values that are not fully compatible with homolysis. In general, activation volumes for homolysis reactions are close to 10 cm^3 mol^{-1}, however, values found for the isomerization of peroxynitrous acid (6–10 cm^3 mol^{-1}) do not reveal a mechanism of conversion. In conclusion, the above results support the notion put forth by Kissner and Koppenol (25) for the isomerization of peroxynitrite: "a radical-free mechanism rather than a free-radical mechanism."



In all peroxynitrite study, it is important to minimize the contamination of nitrite and nitrate in the peroxynitrite salt and to accurately measure these nitrogen oxo anion products formed during the decomposition of peroxynitrite. Equally important is to test the degree of dioxygen retention during the isomerization of peroxynitrite. By using isotopic labeling studies, it has been demonstrated that only a small fraction of the product nitrate contained isotopic dioxygen when peroxynitrous acid was allowed to decompose in dioxygen-labeled water ($^{18}OH_2$) (29). The amount of peroxynitrous acid that isomerizes does so with exchange of the dioxygen with the solvent. However, a major fraction (83%) of the nitrate product had complete retention of its dioxygen atoms from the isomerization of peroxynitrite (29).

Numerous studies have been reported on the cytotoxicity of peroxynitrite (6–13), however, one of the main targets of peroxynitrite in human tissues is carbon dioxide, present at mmol/L concentration. Peroxynitrite reacts rapidly with carbon dioxide to form the adduct 1-carboxylato-2-nitrosodioxidane ($ONOOCO_2^-$), which rapidly produces carbon dioxide and nitrate, possibly via the formation of nitrogen dioxide and trioxidocarbonate (·1–). At 37 °C, the second-order rate constant for the reaction is 5.7×10^4 (mol/L)$^{-1}$ s^{-1} (30) (eq. [6]). Since the intracellular and extracellular carbon dioxide concentrations are about 1 to 2 mmol/L, this reaction

$$[6]\quad ONOO^- + CO_2 \underset{}{\overset{5.7\times10^4\ (\text{mol/L})^{-1}\ \text{s}^{-1}}{\rightleftharpoons}} ONOOCO_2^- \longrightarrow \text{Products}$$

[7]

represents one of the major routes for peroxynitrite reactivity in vivo (30). Therefore, reactions of peroxynitrite in vivo are more likely to be mediated by $ONOOCO_2^-$ and by the products derived from its decomposition than by peroxynitrite itself (31, 32). While the adduct $ONOOCO_2^-$ has not yet been directly detected, an observed delay before the combined carbon dioxide – peroxynitrite begins to decay is consistent with the formation of $ONOOCO_2^-$ (31–35). The amount of radicals generated from the decay of $ONOOCO_2^-$ is still under investigation. It is assumed that 70% of the radicals formed recombine inside the solvent cage to give nitrate and carbon dioxide, while the remaining 30% are able to react with target molecules (33, 34). In contrast, it has been shown that upon mixing peroxynitrite with carbon dioxide in the presence of nitrogen monoxide, the extent of nitrogen dioxide and trioxidocarbonate (·1–) formed is less than 4% (35). Nitrogen monoxide is known to react with nitrogen dioxide and trioxidocarbonate (·1–) to give carbon dioxide and nitrite, but does not react with peroxynitrite anion. Trioxidocarbonate (·1–) is a strong oxidant, and nitrogen dioxide is both an oxidizing and a nitrating agent. The electrode potential of the couple $CO_3^{\bullet-}/CO_3^{2-}$ is 1.58 V (35) and that of $NO_2^{\bullet}/NO_2^-$ pair is 0.99 V (19).

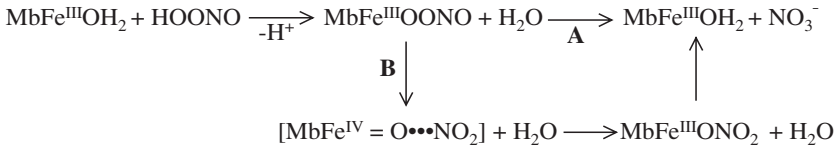
Although, peroxynitrite can oxidize many substrates in biological systems either directly or by producing secondary oxidants (eq. [7]), most of the peroxynitrite in vivo will be consumed by direct reactions, mainly with thiols, ascorbate, uric acid, transition metal centers, and carbon dioxide.

Myoglobin and hemoglobin

The idea that myoglobin and hemoglobin, apart from dioxygen storage and transport, may function as scavengers of nitrogen monoxide and (or) peroxynitrite in the blood vessels and in the cardiac and skeletal muscles is currently a subject of great interest. It has been shown that myoglobin efficiently scavenges nitrogen monoxide generated by induced nitric oxide synthase (iNOS), leading to an attenuation of heart disease, especially cardiac arrest (36). This study used double transgenic mice with high levels of cardiac specific over expression of iNOS (tg-$iNOS^+$) combined with myoglobin deficiency (myo^-) that ultimately developed signs of heart disease (37). However, mice with tg-$iNOS^+$ and functional myoglobin (myo^+) demonstrated normal cardiac function (37). Thus, it is reasonable to propose globin proteins like myoglobin and hemoglobin, present in high concentrations in cardiac and skeletal muscle and in blood vessels, respectively, may act as scavengers of nitrogen monoxide and (or) peroxynitrite.

Despite the presence of 1.2 mmol/L carbon dioxide in the blood (30), peroxynitrite is able to diffuse across the red blood cell membrane and react with oxyhemoglobin. Thus, the reaction of peroxynitrite with oxyhemoglobin (and oxymyoglobin) to yield methemoglobin (and metmyoglobin) has been considered pathophysiologically relevant. This reaction proceeds in two steps via a ferryl intermediate. The second-order rate constants for the peroxynitrite-mediated oxidation of oxymyoglobin and oxyhemoglobin are on the order of 10^4 $(mol/L)^{-1}$ s^{-1} at pH 7.0 and 20 °C (eq. [8]) (38). However, in the presence of physiological amounts of carbon dioxide (1.2 mmol/L), the first reaction step proceeds faster with a second-order rate constant of 10^5 $(mol/L)^{-1}$ s^{-1} (39).

[8] $$HbFe^{II}O_2 \xrightarrow[ONOOH]{5.4\times10^4\ (mol/L)^{-1}\ s^{-1}} HbFeI^{V}{=}O$$



$$HbFeI^{V}{=}O \xrightarrow[ONOOH]{2.2\times10^4\ (mol/L)^{-1}\ s^{-1}} HbFe^{III}OH_2$$

[9] $$MbFe^{III}OH_2 \xrightarrow[ONOOH]{2.9\times10^4\ (mol/L)^{-1}\ s^{-1}} MbFe^{III}OH_2 + NO_3^- + H^+$$

The met forms of horse heart myoglobin and human hemoglobin have been shown to catalyze the isomerization of peroxynitrite to nitrate (40). The catalytic rate constants determined at pH 7.0 and 20 °C are $(1.2 \pm 0.1) \times 10^4$ and $(2.9 \pm 0.1) \times 10^4$ $(mol/L)^{-1}$ s^{-1}, for methemoglobin and metmyoglobin, respectively, at pH 7.5 and 20 °C (eq. [9]) (40). In contrast to the oxyhemoglobin and oxymyoglobin, no intermediate ferryl species could be detected when the met forms of hemoglobin and myoglobin were allowed to react with peroxynitrite in the absence or presence of 1.2 mmol/L carbon dioxide. However, to explain the catalytic isomerization of peroxynitrite to nitrate, it has been proposed that this reaction proceeds as shown in Scheme 1. In the first step, the coordinated water is replaced by peroxynitrite, and thus an intermediate iron(III) peroxynitrite complex ($MbFe^{III}OONO$) is generated. Since this complex could not be detected, it probably decays to nitrate and metmyoglobin at a very fast rate (40). Hence, binding of peroxynitrite to metmyoglobin must be the rate-determining step. The decay of the intermediate $MbFe^{III}OONO$ can proceed according to two possible mechanisms (pathways A and B) as shown in Scheme 1. The same $MbFe^{III}OONO$ or $HbFe^{III}OONO$ complexes have been characterized by UV–

Scheme 1. Possible mechanisms for the metMb-catalyzed isomerization of peroxynitrite.

vis and EPR spectroscopies as intermediates of the reaction of nitrogen monoxide with oxymyoglobin or with oxyhemoglobin at alkaline pH (41–43). The $MbFe^{III}OONO$ decays to give nitrate and metmyoglobin, and the rate constant reported is 205 ± 5 s^{-1} at pH 9.5 and 20 °C (eq. [10]) (42).

[10] $MbFe^{II}O_2 + NO^{\cdot} \longrightarrow MbFe^{III}ONOO \xrightarrow{k \sim 205\ s^{-1}} MbFe^{III}OH_2 + NO_3^-$

[11] $MbFe^{IV}{=}O + NO_2^{\cdot} \longrightarrow [MbFe^{IV}{=}O\cdots NO_2] \longrightarrow MbFe^{III}ONO_2 \xrightarrow{k \sim 35\ s^{-1}} MbFe^{III}OH_2 + NO_3^-$

In another experiment, $MbFe^{III}ONO_2$, generated by pulse radiolysis from the reaction between ferrylmyoglobin and nitrogen dioxide, has been reported to decay to give nitrate and metmyoglobin at a rate of 35 s^{-1} (eq. [11]) (42). Recent reinvestigation of this reaction showed that this value is probably incorrect and indeed, the values of the nitrate dissociation rate constants measured by Herold et al. (42) in a series of preliminary experiments were not reproducible, but they were always significantly lower than 205 s^{-1}. Taken together, these dissociation constants suggest that the decay of $MbFe^{III}OONO$ to nitrate and metmyoglobin cannot occur via the formation of the corresponding nitrato complex (pathway B in Scheme 1). Thus, based on these observations, it is proposed that the intermediate formed from the reaction between peroxynitrite and metmyoglobin decays to give nitrate and metmyoglobin via pathway A (Scheme 1).

Very recently, Goldstein et al. (44) remeasured the rate of dissociation of nitrate from $MbFe^{III}ONO_2$ (also generated by pulse radiolysis from the reaction between ferrylmyoglobin and nitrogen dioxide) and obtained a value of 190 ± 20 s^{-1} (at pH 9.7 and 20 °C). Under slightly different experimental conditions, the value obtained for the observed rate constant was reproducible. Additionally, by considering the calculated lifetime of alkyl peroxynitrites to nearly 1 μs, they suggested that the $MbFe^{III}OONO$ complex should rapidly convert to $MbFe^{III}ONO_2$ via ferryl myoglobin and nitrogen dioxide (44). Thus, they concluded that $MbFe^{III}OONO$ cannot be detected and that the intermediate characterized under alkaline conditions is $MbFe^{III}ONO_2$. However, the UV–vis spectrum of the hemoglobin peroxynitrite complex ($HbFe^{III}OONO$) is different from that of the nitrato complex ($HbFe^{III}ONO_2$) (42). In conclusion, based on the new value reported for the rate constant of the decay of $MbFe^{III}ONO_2$, which is essentially identical to that of the decay of $MbFe^{III}OONO$, it is reasonable to suggest that both pathways (Scheme 1) are possible for the metmyoglobin-catalyzed isomerization of peroxynitrite.

Groves and co-workers (45) also studied the metmyoglobin-catalyzed isomerization of peroxynitrite and proposed a mechanism similar to pathway B in Scheme 1. They suggested that part of the nitrogen dioxide eludes the reaction with ferrylmyoglobin and undergoes hydrolysis to nitrite and nitrate. Their conclusion is based on the observation that a constant level of approximately 10% nitrite was produced from the decay of peroxynitrite in the presence of 100–200 μmol/L of metmyoglobin (45). However, it is reported that in the presence of higher concentrations of metmyoglobin (750 μmol/L) peroxynitrite is converted quantitatively to nitrate (40). If large amounts of nitrogen dioxide escape recombination, one might expect ferrylmyoglobin to be observed, but no intermediate was detected (45). Thus, if the decomposition of peroxynitrite to nitrate proceeds via pathway B (Scheme 1), nitrogen dioxide and ferryl myoglobin react quantitatively to $MbFe^{III}ONO_2$.

Furthermore, studies with distal histidine sperm whale myoglobin mutants have shown that when His64 is replaced with alanine or aspartic acid, very low concentrations (5 μmol/L) of these proteins were needed to achieve 100% isomerization of peroxynitrite to nitrate (46). The efficiency of these proteins to catalyze the isomerization of peroxynitrite is consistent with the larger value of k_{cat} (see the following). These data indicate that, in contrast to the hypothesis of Groves and co-workers (45), in the presence of efficient catalysts (H64A or H64D), the decomposition of peroxynitrite does not lead to nitrite formation. This supports the above-mentioned mechanism for the decay of the $MbFe^{III}OONO$ complex: if the reaction proceeds via pathway B (Scheme 1), the reaction between ferryl myoglobin and nitrogen dioxide must be quantitative.

The catalytic rate constants reported for the decay of peroxynitrite in the presence of the iron(III) forms of myoglobin and hemoglobin is lower compared with that of water-soluble iron(III)-porphyrin complexes such as iron(III) 5,10,15,20-tetrakis(*N*-methyl-4′-pyridyl) porphyrin (Fe(III)-TM-2-PyP) and iron(III) 5,10,15,20-tetrakis(2,4,6-trimethyl-3,5-sulfonatophenyl) porphyrin (Fe(III)-TMPS) (47). These complexes react rapidly with peroxynitrite and therefore, are proposed to be promising drug candidates against peroxynitrite toxicity. However, to explain the difference in catalytic rate constants, we hypothesized that the reactivity of peroxynitrite with the iron(III) center of the proteins is most likely regulated by the distal histidine, which is strongly hydrogen bonded to the water molecule coordinated to the iron(III) center (40). Indeed, mechanistic studies by using mutants of sperm whale metmyoglobin in which the distal histidine was substituted with amino acid residues that cannot undergo a hydrogen bond with the coordinated water, react faster with peroxynitrite and catalyze its isomerization to nitrate more efficiently (46). The catalytic rate constants for the decay of peroxynitrite are (5.8 ± 0.1) × 10^6 and (4.8 ± 0.1) × 10^6 $(mol/L)^{-1}$ s^{-1}, (at pH 7.5 and 20 °C) for H64A-metMb and H64D-metMb, respectively (46). These values are comparable to those of the most efficient iron(III)-porphyrin catalysts such as Fe(III)-TM-2-PyP (k_{cat} = 2.2 ×

© 2006 NRC Canada

10^6 (mol/L)$^{-1}$ s^{-1}, at pH 7.4 and 37 °C) and Fe(III)-TMPS (k_{cat} = 6.4 × 10^5 (mol/L)$^{-1}$ s^{-1}, at pH 7.4 and 37 °C) (47).

Apart from its reaction with the heme center, in principle peroxynitrite could induce nitration of aromatic residues in these proteins (1). However, to be an efficient scavenger, myoglobin or hemoglobin should not be damaged in the course of its reaction with peroxynitrite. The tyrosine residues of the oxy- and met-forms of hemoglobin and myoglobin are nitrated to less than 1% upon addition of 1 equiv. of peroxynitrite (48). These nitration yields are physiologically irrelevant since the concentration of peroxynitrite in vivo will never be as high as that of myoglobin and hemoglobin. Indeed, no nitrated tyrosine residues were found in the hemoglobin of aged red blood cells (49). The mechanistic studies showed relatively larger nitration yields of tyrosine and tryptophan residues in apomyoglobin or in the cyanide-bound form of iron(III) myoglobin (metMbCN) treated with peroxynitrite (48). This suggests that the iron center in the oxy- and met-forms of the proteins plays a role in inhibiting peroxynitrite-mediated nitrotyrosine formation. Furthermore, experiments with different forms of myoglobin and hemoglobin showed that oxymyoglobin is the species that most efficiently prevents peroxynitrite-mediated nitration of added free tyrosine (40, 48). Significantly larger nitration yields of free tyrosine were observed by addition of peroxynitrite in the presence of apomyoglobin or metMbCN. Taken together, these results strongly indicate that the heme center in the oxy- and met-forms of myoglobin and hemoglobin acts as an efficient scavenger of peroxynitrite and thus may prevent peroxynitrite-mediated nitration, not only of the tyrosine and tryptophan residues of the globins, but also those of other proteins.

Under physiological conditions, hemoglobin and myoglobin are mostly found in the oxygenated form with only 1%–5% present in the oxidized iron(III) form of the corresponding proteins. Since the second-order rate constants of the reactions of peroxynitrite with oxymyoglobin and oxyhemoglobin (10^4 (mol/L)$^{-1}$ s^{-1}) are on the same order of magnitude as the catalytic rate constants for the metmyoglobin- and methemoglobin-catalyzed isomerization of peroxynitrite, oxyhemoglobin and oxymyoglobin are primarily involved in the scavenging of peroxynitrite in vivo (38). Moreover, the deoxygenated forms of myoglobin and hemoglobin have been shown to react with peroxynitrite at a rate of 2 orders of magnitude larger (10^6 (mol/L)$^{-1}$ s^{-1}) than that for the reaction with the corresponding oxygenated proteins (38). Thus, under hypoxic conditions, the reaction of the deoxygenated forms of the protein with peroxynitrite may be biologically relevant.

Under ischemic conditions such as low dioxygen tension, one can argue whether or not there is formation of nitrogen monoxide and (or) peroxynitrite in venous blood. Two different enzymes may produce nitrogen monoxide or superoxide under different conditions (50). When there is sufficient supply of L-arginine and dioxygen, nitric oxide synthase makes nitrogen monoxide (1), whereas the same enzyme may generate considerable amounts of superoxide when the concentrations of arginine and cofactors are limited (50). Xanthine oxidase generates superoxide, for example, during reperfusion after ischemia (51), whereas nitrite reduction to nitrogen monoxide occurs preferentially during hypoxia (52). Moreover, nitrite can react with deoxyhemoglobin to generate nitrosylated hemoglobin ($HbFe^{II}NO$) (53–55). Cosby et al. (56) have shown that intra-arterial infusion of nitrite at physiological levels caused vasodilation in healthy humans, thus demonstrating that nitrogen monoxide can be liberated from nitrosylated hemoglobin in vivo. Thus, there is an efficient pathway to also make nitrogen monoxide and peroxynitrite under hypoxic conditions. Deoxymyoglobin and deoxyhemoglobin may play a role as peroxynitrite scavengers. Indeed, these proteins are present in high concentrations and are among the species that react with the highest rate constants with peroxynitrite (38, 39).

Conclusion

In conclusion, the concentrations of myoglobin and hemoglobin in cardiac and skeletal muscle and in the blood vessels, respectively, are significantly larger than that of peroxynitrite (which is often generated continuously in nmol/L range). Under physiological conditions, these proteins may trap most peroxynitrite by its reaction with the heme center and prevent damage to the surrounding biomolecules.

A novel and green version of the Passerini reaction in an ionic liquid ([bmim][BF_4])

Xuesen Fan, Yanzhen Li, Xinying Zhang, Guirong Qu, and Jianji Wang

Abstract: The Passerini three-component condensation among a carboxylic acid (**1**), an aldehyde or ketone (**2**), and an isocyanide (**3**) was carried out for the first time in an ionic liquid, [bmim][BF_4], and a series of acyloxycarboxamides were obtained through this reaction. The method presented herein has the advantages of high efficiency, a greener nature, and a simple operational procedure. Moreover, the ionic liquid can be easily recovered and reused for several runs without obvious loss of efficiency.

Key words: Passerini reaction, acyloxycarboxamides, ionic liquid, green synthesis.

Résumé : La condensation de Passerini à trois composants d'un acide carboxylique (**1**), d'un aldéhyde ou d'une cétone (**2**) et d'un isocyanure (**3**) a été réalisée pour la première fois dans un liquide ionique [bmim][BF_4] et on a en obtenu une série d'acyloxycarboxamides. La méthode décrite présente les avantages d'une grande efficacité, de sa nature écologique et de la simplicité d'opération. De plus, le liquide ionique peut facilement être récupéré et réutilisé plusieurs fois sans perte apparente de son efficacité.

Mots clés : réaction de Passerini, acyloxycarboxamides, liquide ionique, synthèse écologique.

[Traduit par la Rédaction]

Introduction

Multicomponent reactions (MCRs) are special types of synthetically useful organic reactions in which three or more reactants come together in a single reaction vessel to form a new product containing portions of all the components. They hold a privileged position among the synthetic strategies in terms of efficiency, particularly regarding the preparation of a library of molecules or in diversity-oriented synthesis (1). Among the MCRs, those with isocyanides, such as the Passerini and Ugi reactions, have developed into popular organic reactions in the pharmaceutical industry for the preparation of compound libraries of low-molecular druglike compounds (2). The Passerini reaction, also called the 3-CC reaction, which consists of the reaction of a carboxylic acid, a carbonyl compound, and an isocyanide providing an α-acyloxycarboxamide in a single step, was first discovered by Passerini more than 80 years ago (3). This reaction was often used as a key step in the total synthesis of natural products (4) and the α-acyloxycarboxamide group is also a frequently recurring motif in biologically active compounds, for example, in the pharmacologically interesting depsipeptides (5).

Usually, the Passerini reaction was carried out in volatile organic solvents, such as CH_2Cl_2. Reaction times from 12 h to several days are often prescribed and the yields of the products still have room to be improved (6). Therefore, developing a more efficient and environmentally friendly methodology for the Passerini reaction is highly desirable. In recent years, room-temperature ionic liquids have attracted considerable interest as greener reaction media in organic synthesis because of their unique properties such as nonvolatility, nonflammability, excellent chemical and thermal stability, and recyclability (7). Many chemical transformations have been carried out successfully by employing ionic liquids as "green" substitutes for traditional organic solvents (8). In view of the rapidly increasing importance of imidazolium-based ionic liquids as novel reaction media, we have been exploring the use of 1-butyl-3-methylimidazolium tetrafluoroborate ([bmim][BF_4]) as a recyclable solvent and promoter for greener organic synthesis (9). As a continuation of our research in this area, herein we would like to report the results of our investigation of the Passerini reaction in [bmim][BF_4] for the first time (Scheme 1).

Results and discussion

Initially, the reaction among benzoic acid (**1a**, 0.55 mmol), *m*-nitrobenzaldehyde (**2a**, 0.50 mmol), and cyclohexyl isocyanide (**3a**, 0.50 mmol) in 1 mL of [bmim][BF_4] was studied under various conditions (Scheme 2, Table 1). It turned out that this three-component reaction can be carried out smoothly in [bmim][BF_4]. The results listed in Table 1 also show that the process of this reaction is significantly subject to the reaction temperature. While this process needs as long as 2 days to be completed at ambient temperature (Table 1, entry 2), it results in full conversion of the starting material and good yield of the product in only several hours at 60 °C (Table 1, entry 4). It

[a]Isolated yields.

was also observed that as the reaction proceeded, the initially clear solution became heterogeneous because the product formed was poorly soluble in [bmim][BF_4]. At completion, the product was readily collected with high purity upon suction, featuring an easy isolation process of the final product.

The mild reaction conditions, good yield, and simple operational process encouraged us to examine the scope and generality of the present method. In this regard, structurally diversified carbonyl compounds, various carboxylic acids, and two isocyanides were screened and the results are listed in Table 2.

Firstly, it turned out that a variety of substituted aromatic (Table 2, entries 1–13) and aliphatic (Table 2, entries 14–16) carboxylic acids underwent the reaction and produced the corresponding products in high purity with good yield. For the carbonyl component, aromatic aldehydes bearing either electron-donating or electron-withdrawing substituents on the aromatic ring could be introduced effectively. Two aliphatic aldehydes were also tried (Table 2, entries 17 and 18). Unlike their aromatic counterparts, reactions involving aliphatic aldehydes seemed to be complicated and several unidentified substances were formed together with the desired α-(acyloxy)carboxamide products according to TLC analysis. Furthermore, the α-(acyloxy)carboxamides could only be obtained with high purity through column chromatography separation, in contrast with the simple suction collection as experienced with the aromatic aldehydes. In the case of ketones, cyclohexanone (**2k**) was found to be successfully included into this 3-CC process and gave the corresponding product in reasonable yield (Scheme 3, Table 2, entry 19). However, attempts to use acetophenone as the carbonyl substrate failed and acetophenone was found intact after being stirred with benzoic acid and isocyanocyclohexane at 60 °C for 8 h. Though no mechanistic studies were made on this result, it may be reasonable to attribute the inactivity of acetophenone in this reaction to the steric effect of the relatively bulky phenyl group. Actually, a steric congestion effect was also manifested with other substrates. For example, with aromatic carboxylic acids or aldehydes substituted on the *o*-position of the aromatic ring, the reactions gave lower yields compared with those unsubstituted or substituted on the *p*- or *m*-position (Table 2, entries 1–3, entries 4–6, respectively). Finally, in terms of isocyanides, both cyclohexyl isocyanide (**3a**) and *tert*-butyl (**3b**) isocyanide have proved to be good components. Therefore, variations in all three components have been accommodated comfortably.

On the other hand, the recovery and reuse of solvent and (or) catalyst are highly preferable in terms of a green synthetic process. We continued our research in this regard by studying the reusage of [bmim][BF_4], and **1a**, **2a**, and **3a** were used as model substrates. Upon completion of the condensation process, precipitated products were collected by suction and rinsed with water and cold ethanol. The filtrate was concentrated under reduced pressure, washed with ethyl ether (2 × 5 mL) and then dried at 100 °C for several hours. The recovered [bmim][BF_4] was then checked by ^{1}H NMR and no obvious difference in the NMR spectrum was observed compared to that of the original ionic liquid. Further studies also showed that the recovered [bmim][BF_4] could be successively recycled in subsequent reactions without obvious loss in its efficiency (Table 3). It should also be noted that even in the fifth round, reuse of [bmim][BF_4] recovered from the fourth round still produced the corresponding product with good yield (Table 3, entry 5).

It has been reported that, in many cases, compared with classical organic solvents, ionic liquids not only possess a green nature, but also demonstrate the advantages of offering

a simple operational process and (or) actually accelerating the reaction rate and increasing the yields. To compare [bmim][BF_4] with conventional organic solvents with regard to their efficiency and practicality, four conventional organic solvents (dichloromethane, methanol, THF, and toluene) were also studied as reaction media. The results of this investigation using **1a**, **2a**, and **3b** as the model substrates are listed in Table 4 and we conclude that the reaction run in [bmim][BF_4] is more efficient over dichloromethane, toluene, and methanol in terms of yield and reaction time. Though a higher yield can be obtained with THF, the product is dissolved in solution, as in the cases of dichloromethane, toluene, and methanol, and it has to be separated from the impurities by column chromatography instead of suction collection, as experienced with [bmim][BF_4].

In conclusion, a greener procedure for the synthesis of acyloxycarboxamides through a Passerini three-component condensation reaction was described in this paper. The work demonstrated the scope and limitations of this reaction by using an ionic liquid ([bmim][BF_4]) as a greener reaction medium and resulted in a library of 19 numbered α-(acyloxy)carboxamides. To the best of our knowledge, this is the first example in which an ionic liquid was used as a greener reaction medium for the Passerini reaction. The method presented here has the advantages of high efficiency, a green nature, a simple operation, and ease of recovery and reuse of the reaction medium. Moreover, the insolubility of the products in ionic liquid makes the isolation procedure especially convenient. Further studies on other MCRs in ionic liquids are currently in progress.

Experimental

Melting points were measured by a Kofler micromelting point apparatus and are uncorrected. Infrared spectra were recorded on a FTS-40G spectrometer in KBr with absorption in cm^{-1}. ^1H NMR spectra were determined on a Bruker AC 400 spectrometer as $CDCl_3$ solutions. Chemical shifts (δ) are expressed in ppm downfield from the internal standard tetramethylsilane and coupling constants (*J*) are given in Hz. Mass spectra were obtained by a HP-5989B mass spectrometer. Elemental analyses were performed on an EA-1110 instrument.

The ionic liquid, [bmim][BF_4], was prepared and purified according to literature procedure (10). Other reagents were of reagent grade and were used without further purification.

General procedure for the Passerini reaction in ionic liquid

A mixture of a carboxylic acid (**1**, 0.55 mmol), an aromatic aldehyde (**2**, 0.50 mmol), and an isocyanide (**3**, 0.50 mmol) in 1 mL of [bmim][BF_4] was stirred at 60 °C for a certain period of time (shown in Table 2). Upon completion, the reaction mixture was allowed to cool to room temperature and 2 mL of water was then added. The precipitate was collected by suction, subsequently rinsed with water and cyclohexane, and then dried to give product **4** with high purity. The filtrate was concentrated under reduced pressure and dried at 100 °C for several hours to recover the ionic liquid for subsequent reuse.

(Cyclohexylcarbamoyl)(3-nitrophenyl)methyl benzoate (4a)

Melting point: 201 to 202 °C. IR (KBr, cm^{-1}) ν: 3282, 1728, 1660, 1531, 1345, 1250. ^1H NMR ($CDCl_3$, 400 MHz) δ: 1.16–1.96 (m, 10H, $5CH_2$), 3.81–3.88 (m, 1H, N-CH), 6.23 (br, 1H, NH), 6.41 (s, 1H, CH), 7.55 (t, 2H, *J* = 8.0 Hz, ArH), 7.61 (t, 1H, *J* = 8.0 Hz, ArH), 7.69 (t, 1H, *J* = 8.0 Hz, ArH), 7.94 (d, 1H, *J* = 8.0 Hz, ArH), 8.13 (d, 2H, *J* = 8.0 Hz, ArH), 8.25 (d, 1H, *J* = 8.0 Hz, ArH), 8.41 (s, 1H, ArH). MS *m/z*: 382 (M^+), 256, 207, 135, 105 (100%), 83, 77, 55, 28. Anal. calcd. for $C_{21}H_{22}N_2O_5$: C 65.96, H 5.80, N 7.33; found: C 65.80, H 5.92, N 7.42.

(Cyclohexylcarbamoyl)(4-nitrophenyl)methyl benzoate (4b)

Melting point: 210–212 °C. IR (KBr, cm^{-1}) ν: 3290, 1730, 1658, 1535, 1341, 1240. ^1H NMR ($CDCl_3$, 400 MHz) δ: 1.12–1.94 (m, 10H, $5CH_2$), 3.77–3.86 (m, 1H, N-CH), 6.16 (br, 1H, NH), 7.26 (s, 1H, CH), 7.53 (t, 2H, *J* = 8.0 Hz, ArH), 7.67 (t, 1H, *J* = 8.0 Hz, ArH), 7.72 (d, 2H, *J* = 8.0 Hz, ArH), 8.10 (d, 2H, *J* = 8.0 Hz, ArH), 8.24 (d, 2H, *J* = 8.0 Hz, ArH). (*tert*-Butylcarbamoyl)(4-methylphenyl)methyl benzoate (4h)

Melting point: 151–153 °C. IR (KBr, cm^{-1}) ν: 3280, 1718, 1664, 1531, 1257. ^1H NMR ($CDCl_3$, 400 MHz) δ: 1.36 (s, 9H, $3CH_3$), 2.35 (s, 3H, CH_3), 5.95 (br s, 1H, NH), 6.18 (s, 1H, CH), 7.20 (d, 2H, *J* = 8.0 Hz, ArH), 7.40 (d, 2H, *J* = 8.0 Hz, ArH), 7.47 (t, 2H, *J* = 8.0 Hz, ArH), 7.60 (t, 1H, *J* = 8.0 Hz, ArH), 8.08 (d, 2H, *J* = 8.0 Hz, ArH). MS *m/z*: 325 (M^+), 226, 105 (100%), 77, 57, 15. Anal. calcd. for $C_{20}H_{23}NO_3$: C 73.82, H 7.12, N 4.30; found: C 73.72, H 7.33, N 4.22.

(*tert*-Butylcarbamoyl)(4-bromophenyl)methyl benzoate (4i)

Melting point: 194–196 °C. IR (KBr, cm^{-1}) ν: 3313, 1738, 1665, 1548, 1260. ^1H NMR ($CDCl_3$, 400 MHz) δ: 1.37 (s, 9H, $3CH_3$), 6.03 (br s, 1H, NH), 6.16 (s, 1H, CH), 7.40 (d, 2H, *J* = 8.0 Hz, ArH), 7.48 (d, 2H, *J* = 8.0 Hz, ArH), 7.51 (t, 2H, *J* = 8.0 Hz, ArH), 7.62 (t, 1H, *J* = 8.0 Hz, ArH), 8.07 (d, 2H, *J* = 8.0 Hz, ArH). MS *m/z*: 389 (M^+), 211, 131, 105 (100%), 77, 57. Anal. calcd. for $C_{19}H_{20}BrNO_3$: C 58.47, H 5.17, N 3.59; found: C 58.61, H 5.01, N 3.66.

(*tert*-Butylcarbamoyl)(2-bromophenyl)methyl benzoate (4j)

Melting point: 158–160 °C. IR (KBr, cm^{-1}) ν: 3302, 1726, 1667, 1559, 1262. ^1H NMR ($CDCl_3$, 400 MHz) δ: 1.37 (s, 9H, $3CH_3$), 6.03 (br s, 1H, NH), 6.50 (s, 1H, CH), 7.23 (t, 1H, *J* = 8.0 Hz, ArH), 7.37 (t, 1H, *J* = 8.0 Hz, ArH), 7.47 (t, 2H, *J* = 8.0 Hz, ArH), 7.60 (t, 1H, *J* = 8.0 Hz, ArH), 7.65 (d, 2H, *J* = 8.0 Hz, ArH), 8.11 (d, 2H, *J* = 8.0 Hz, ArH). MS *m/z*: 389 (M^+), 211, 105 (100%), 77, 57. Anal. calcd. for $C_{19}H_{20}BrNO_3$: C 58.47, H 5.17, N 3.59; found: C 58.43, H 5.03, N 3.70.

(*tert*-Butylcarbamoyl)(3-nitrophenyl)methyl benzoate (4k)

Melting point: 163–165 °C. IR (KBr, cm^{-1}) ν: 3298, 1728, 1661, 1542, 1350, 1258. ^1H NMR ($CDCl_3$, 400 MHz) δ: 1.39 (s, 9H, $3CH_3$), 6.20 (br s, 1H, NH), 6.31 (s, 1H, CH), 7.52 (t, 2H, *J* = 8.0 Hz, ArH), 7.58 (t, 1H, *J* = 8.0 Hz, ArH), 7.66 (t, 1H, *J* = 8.0 Hz, ArH), 7.90 (d, 1H, *J* = 8.0 Hz, ArH), 8.10 (d, 2H, *J* = 8.0 Hz, ArH), 8.22 (d, 1H, *J* = 8.0 Hz, ArH), 8.37 (s, 1H, ArH). MS *m/z*: 356 (M^+), 257, 105 (100%), 77, 57. Anal. calcd. for $C_{19}H_{20}N_2O_5$: C 64.04, H 5.66, N 7.86; found: C 64.21, H 5.41, N 7.82.

(Cyclohexylcarbamoyl)(4-chlorophenyl)methyl 4-methoxybenzoate (4l)

Melting point: 184–186 °C. IR (KBr, cm^{-1}) ν: 3280, 1732, 1664, 1532, 1262. ^1H NMR ($CDCl_3$, 400 MHz) δ: 1.09–1.94 (m, 10H, $5CH_2$), 3.78–3.85 (m, 1H, N-CH), 3.88 (s, 3H, OCH_3), 6.06 (br, 1H, NH), 6.25 (s, 1H, CH), 6.96 (d, 2H, *J* = 8.8 Hz, ArH), 7.35 (d, 2H, *J* = 8.4 Hz, ArH), 7.46 (d, 2H, *J* = 8.4 Hz, ArH), 8.03 (d, 2H, *J* = 8.8 Hz, ArH). MS *m/z*: 401 (M^+), 370, 124, 104 (100%), 55. Anal. calcd. for $C_{22}H_{24}ClNO_4$: C 65.75, H 6.02, N 3.49; found: C 65.61, H 5.89, N 3.42.

(Cyclohexylcarbamoyl)(4-nitrophenyl)methyl 4-methoxybenzoate (4m)

Melting point: 199–201 °C. IR (KBr, cm^{-1}) ν: 3301, 1745, 1661, 1531, 1350, 1255. ^1H NMR ($CDCl_3$, 400 MHz) δ: 1.12–1.93 (m, 10H, $5CH_2$), 3.77–3.84 (m, 1H, N-CH), 3.90 (s, 3H, OCH_3), 6.17 (br, 1H, NH), 6.36 (s, 1H, CH), 6.99 (d, 2H, *J* = 8.8 Hz, ArH), 7.71 (d, 2H, *J* = 8.8 Hz, ArH), 8.05 (d, 2H, *J* = 8.8 Hz, ArH), 8.23 (d, 2H, *J* = 8.8 Hz, ArH). MS *m/z*: 412 (M^+), 381, 135, 104 (100%), 55. Anal. calcd. for $C_{22}H_{24}N_2O_6$: C 64.07, H 5.87, N 6.79; found: C 64.21, H 5.68, N 6.91.

(Cyclohexylcarbamoyl)(3-nitrophenyl)methyl 2-phenoxyacetate (4n)

Melting point: 137–139 °C. IR (KBr, cm^{-1}) ν: 3281, 2926, 1766, 1656, 1533, 1352, 1194. ^1H NMR ($CDCl_3$, 400 MHz) δ: 0.93–1.80 (m, 10H, $5CH_2$), 3.64–3.73 (m, 1H, N-CH), 4.80 (s, 2H, OCH_2), 6.02 (br, 1H, NH), 6.17 (s, 1H, CH), 6.93 (d, 2H, *J* = 8.0 Hz, ArH), 7.06 (t, 1H, *J* = 8.0 Hz, ArH), 7.34 (t, 2H, *J* = 8.0 Hz, ArH), 7.53 (t, 1H, *J* = 8.0 Hz, ArH), 7.74 (d, 1H, *J* = 8.0 Hz, ArH), 8.20 (d, 1H, *J* = 8.0 Hz, ArH), 8.22 (s, 1H, ArH). MS *m/z*: 412 (M^+), 135 (100%), 94, 55, 42, 28. Anal. calcd. for $C_{22}H_{24}N_2O_6$: C 64.07, H 5.87, N 6.79; found: C 64.12, H 5.70, N 6.88.

(Cyclohexylcarbamoyl)(3-nitrophenyl)methyl acetate (4o)

Melting point: 146–148 °C. IR (KBr, cm^{-1}) ν: 3288, 2939, 1748, 1656, 1533, 1349, 1232. ^1H NMR ($CDCl_3$, 400 MHz) δ: 1.19–1.94 (m, 10H, $5CH_2$), 2.24 (s, 3H, CH_3), 3.74–3.83 (m, 1H, N-CH), 6.11 (s, 1H, CH), 6.16 (br, 1H, NH), 7.56 (t, 1H, *J* = 8.0 Hz, ArH), 7.82 (d, 1H, *J* = 8.0 Hz, ArH), 8.20 (d, 1H, *J* = 8.0 Hz, ArH), 8.26 (s, 1H, ArH). MS *m/z*: 320 (M^+), 207, 135 (100%), 105, 83, 55, 43, 28. Anal. calcd. for $C_{16}H_{20}N_2O_5$: C 59.99, H 6.29, N 8.74; found: C 60.12, H 6.43, N 8.68.

(*tert*-Butylcarbamoyl)(3-nitrophenyl)methyl butyrate (4p)

Melting point: 96–98 °C. IR (KBr, cm^{-1}) ν: 3331, 1754, 1666, 1529, 1350, 1166. ^1H NMR ($CDCl_3$, 400 MHz) δ: 0.98 (t, 3H, *J* = 8.0 Hz, CH_3), 1.37 (s, 9H, $3CH_3$), 1.72 (m, 2H, CH_2), 2.46 (t, 2H, *J* = 8.0 Hz, CH_2), 6.05 (s, 1H, CH), 6.12 (br, 1H, NH), 7.55 (t, 1H, *J* = 8.0 Hz, ArH), 7.81 (d, 1H, *J* = 8.0 Hz, ArH), 8.20 (d, 1H, *J* = 8.0 Hz, ArH), 8.25 (s, 1H, ArH). MS *m/z*: 322 (M^+), 135 (100%), 105, 71, 57, 43, 28. Anal. calcd. for $C_{16}H_{22}N_2O_5$: C 59.61, H 6.88, N 8.69; found: C 59.52, H 6.66, N 8.85.

A simple, highly regioselective and efficient reaction of indole with epoxides under solvent-free conditions

Najmedin Azizi, Shokopheh Mehrazma, and Mohammad R. Saidi

Abstract: Lithium perchlorate has been found to be an inexpensive and efficient catalyst for the ring opening of epoxides by indole and *N*-methylindole, which provides an environmentally friendly method for the synthesis of substituted indoles. A complete regioselectivity in favor of nucleophilic attack at the benzylic carbon atom of aromatic epoxides, such as styrene oxide, is observed. However, aliphatic unsymmetrical alkene oxides undergo selective nucleophilic attack at the sterically less-hindered carbon atom. This catalyst offers several advantages, such as short reaction time, high yields, lower catalytic loading, simple experimental procedure, and easy isolation of the products, under solvent-free conditions.

Key words: indole, epoxide, regioselectivity, solvent-free.

Résumé : On a observé que le perchlorate de lithium est un catalyseur peu dispendieux et efficace pour l'ouverture des cycles époxydes par l'indole et le *N*-méthylindole et la synthèse dans un environnement écologique d'indoles substitués. Les réactions sont complètement régiosélectives en faveur d'une attaque nucléophile au niveau de l'atome de carbone benzylique d'époxydes aromatiques tels que l'oxyde de styrène. Toutefois, avec les oxydes d'alcènes aliphatiques non symétriques, l'attaque nucléophile se fait sélectivement au niveau de l'atome de carbone le moins encombré. Ce catalyseur présente plusieurs avantages, tel son court temps de réaction, des rendements élevés, une quantité plus faible de catalyseur, une procédure expérimentale simple et une méthode facile d'isoler les produits dans des conditions sans solvant.

Mots clés : indole, époxyde, régiosélectivité, sans solvant.

[Traduit par la Rédaction]

Introduction

Epoxides have been recognized as important and versatile synthetic intermediates in organic synthesis (1) because they are susceptible to attack by several nucleophiles and readily accessible in pure form (2). Therefore, there is a significant current interest in the ring opening of epoxides with a large variety of reagents such as electrophiles, nucleophiles, acids, bases, reducing agents, and some oxidizing agents. However, the epoxide ring-opening reaction with certain nucleophiles is generally performed with acid or base catalysis, with a large excess of nucleophiles at elevated temperature, and often fails when poor nucleophiles such as indole and hindered epoxides are used. Few procedures for the ring-opening reaction of epoxides with indole are reported in the literature by using high pressure or SiO_2 (3), $InCl_3$ (4), and $InBr_3$ (5) as catalysts. While the employment of high pressure requires the use of special equipment, for a catalyst such as SiO_2, although simple, several days were necessary to obtain good yields of products. Indium salts are expensive and indoles were only reactive toward vinyl epoxides. Furthermore, all of these reactions have been extensively investigated in toxic organic solvents, and to the best of our knowledge, reactions of indole with epoxides under solvent-free conditions have not been reported. Thus, there is a need to develop a convenient and efficient protocol for the regioselective ring opening of epoxides with indole to produce 3-alkylindole derivatives of biological importance.

Results and discussion

As part of our research on organic synthesis under solvent-free conditions (6), in this paper we describe a simple and practical method for the synthesis of indole derivatives using a catalytic amount of lithium perchlorate. To find out the best reaction conditions for the ring opening of epoxide with indole in the presence of $LiClO_4$, styrene oxide was reacted with 1-methylindole in a common organic solvent and under solvent-free conditions with a different amount of solid lithium perchlorate. A series of experiments carried out on epoxide and indole indicated that the best yields were obtained in the presence of 20 mol% anhydr. $LiClO_4$ and 1.0 equiv. of epoxide at 60 °C under neat conditions (Table 1). In the absence of lithium perchlorate, only the starting material was obtained after prolonged reaction times. As was expected, conducting the same reaction with 20 mol% of anhydrous lithium perchlorate in common organic solvents such as THF, diethyl ether, petroleum ether, dichloro-

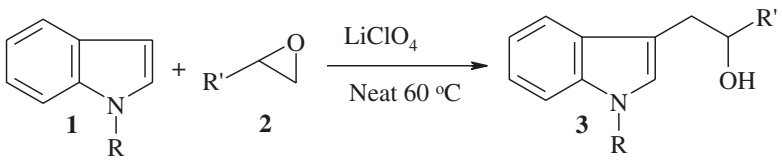
methane, acetonitrile, methanol, and water resulted, for the most part, in the recovery of the starting materials.

This shows that the solvent-free conditions play an essential role in facilitating the desired epoxide ring-opening reaction in the presence of anhydr. $LiClO_4$. On the other hand, our study shows that by increasing the amount of lithium perchlorate to 200 mol% in diethyl ether (5 mol/L solution of lithium perchlorate in diethyl ether, LPDE), the direct nucleophilic addition of indole to styrene oxide is faster than the rearrangement of the epoxide to the corresponding carbonyl compounds (Scheme 1). It also indicates that the solvent-free condition is a superior method owing to low loading of catalyst.

Lithium perchlorate is an extraordinarily efficient catalyst for the highly regioselective ring-opening reaction of epoxides. To show the generality and scope of the $LiClO_4$-promoted ring opening of epoxide with indole, the reaction was examined with various structurally diverse epoxides. The data in Table 2 clearly show that all reactions proceed smoothly under these reaction conditions to afford the desired indolyl alcohols in good yields with high regioselectivity. This method is also effective with aliphatic oxiranes. No precaution is needed to exclude moisture from the reaction media. The regioselectivity in the reaction for unsymmetrical epoxides is governed by both steric and electronic effects. The regioselectivity was determined by ^1H NMR and by comparison with the known samples. Aliphatic oxiranes underwent cleavage by indole and *N*-methylindole with the preferential attack at the less-substituted carbon atom. On the other hand, in the case of styrene oxide and other aromatic oxiranes, the reaction likely proceeds partly through an attack by the indole on the more stabilized "carbocation" with participation of phenyl groups. The role of $LiClO_4$ in catalyzing the opening of epoxide rings with indole may be realized through the coordination of Li^+ with epoxide oxygen and rendering the epoxide more susceptible to nucleophilic attack by indole, followed by hydrogen transfer to form the indolyl alcohols. The comparison of the present methods with respect to the amount of the catalyst used, reaction time and requirement of solvent, products yield and regioselectivity with those reported in the literature, reveals that this newly developed method is superior to the previous procedures.



Reaction of 2-methylindole with 2,3-epoxypropyl phenyl ether proceeds efficiently at 60 °C in the presence of 20 mol% of anhydr. $LiClO_4$ under neat conditions and gave the corresponding 3-substituted 2-methylindole (**4**) in 60% yield after 1.5 h.

In summary, we have described a new direct protocol for the preparation of indolyl alcohol derivatives by ring-opening reactions of epoxides with indole and *N*-methylindole in the presence of 20 mol% of anhydr. $LiClO_4$. The notable features of this procedure are the mild reaction conditions, high conversions, short reaction times, economic viability of the reagents, simple experimental procedure, and product isolation. Although lithium perchlorate is normally responsible for the rearrangement of aromatic epoxides to the corresponding carbonyls, the mild reaction conditions allowed the isolation of the desired compounds in high yields and without rearrangement, when a 5 mol/L solution of LPDE was used.

Experimental

General procedure for the preparation of tryptophol derivatives

To a mixture of indole (4 mmol) and epoxide (4 mmol), anhydrous lithium perchlorate (0.1 mmol) was added and stirred at 60 °C for 1–4 h. When the reaction was completed, as indicated by TLC or GC, the reaction mixture was diluted with diethyl ether or ethyl acetate and purified by flash column chromatography (Et_2O–hexanes, 30:70) to give the desired products. All compounds were characterized on the basis of NMR spectroscopic data.

A topological analysis of the interion interactions of tetraphenylphosphonium squarate

David Wolstenholme, Manuel A.S. Aquino, T. Stanley Cameron, Joseph D. Ferrara, and Katherine N. Robertson

Abstract: The tetraphenylphosphonium squarate salt crystallizes with a number of diverse interactions, which all have the potential to be classified as hydrogen bonds. The squarate anions are found as dimers linked by O-H···O interactions. The multipole refinement of the tetraphenylphosphonium squarate was performed using the Hansen–Coppens model followed by topological analysis of its intermolecular interactions. A total of 28 interactions were found among the symmetry related molecules, which include a number of C-H···C_π, C-H···O, and C-H···H-C interactions, along with the O-H···O interaction. With the criteria for hydrogen bonding proposed by Popelier and Koch, it is possible to determine which of these interactions are hydrogen bonds and which are van der Waals interactions. Both linear and exponentially dependent correlations can be seen for the properties of the bond critical points involving the intermolecular interactions that fulfill these criteria. All this leads to a better understanding of the role that hydrogen bonds play in the formation of small organic compounds.

Key words: electron density, multiple refinement, hydrogen bonds.

Résumé : Le squarate de tétraphénylphosphonium cristallise avec un certain nombre d'interactions qui pourraient éventuellement toutes être considérées comme des liaisons hydrogènes. On retrouve les anions squarate sous la forme de dimères liés par des interactions O-H···O. On a effectué un affinement multipôle du squarate de tétraphénylphosphonium en utilisant le modèle Hansen–Coppens suivi d'une analyse topologique de ses interactions intermoléculaires. On a trouvé un total de 28 interactions entre les molécules reliées par de la symétrie, y compris un certain nombre d'interactions C-H···C_π, C-H···O et C-H···H-C en plus de l'interaction O-H···O. Avec le critère d'une liaison hydrogène proposé par Popelier et Koch, il est possible de déterminer lesquelles de ces interactions sont des liaisons hydrogènes et lesquelles sont des interactions de van der Waals. On peut déceler des corrélations qui dépendent tant linéairement qu'exponentiellement pour les propriétés des points critiques de liaison impliquant les interactions intermoléculaires qui répondent à ces critères. Toutes ces observations conduisent à une meilleure compréhension du rôle que les liaisons hydrogènes jouent dans la formation de petits composés organiques.

Mots clés : densité électronique, affinement multiple, liaisons hydrogènes.

Introduction

The experimental measurement and analysis of the charge density in a variety of molecular crystals has been achieved through the use of high-resolution X-ray diffraction data at low temperatures (1, 2). The charge density of a compound is evaluated through the interpretation of its electron density. There are several different ways of obtaining the electron density, but the most common method is the multipole expansion, which incorporates the Hansen–Coppens (3) model, and can be expressed by the following equation:

$$[1]\quad \rho(r) = P_c\rho_{core}(r) + P_v\kappa^3\rho_{valence}(\kappa r) + \sum_{l=0}^{l_{max}}\kappa'^3 R_l(\kappa' r)\sum_{m=0}^{1} P_{lm\pm} d_{lm\pm}(\theta,\phi)$$

where ρ_{core} and $\rho_{valence}$ are spherically averaged Hartree–Fock core and valence densities, $d_{lm\pm}$ represents spherical harmonic angular functions, R_l is the radial function, κ and κ' are the expansion–contraction parameters, and P_v and $P_{lm\pm}$ represent the population parameters.

The theory of atoms in molecules (AIM) can then be used to evaluate the experimental electron density as determined from the above model through topological means. It is this methodology that allows for the identification of a bond between any two atoms in a molecule (2). This involves locating critical points obtained from the Hessian matrix of the electron density and in particular {3,–1} critical points, also referred to as bond critical points. The bond critical point is not the only topological component of importance; the line of maximum electron density (the bond path) is also essential for identifying a bond from its topology. Another important AIM property obtained from the electron density is the

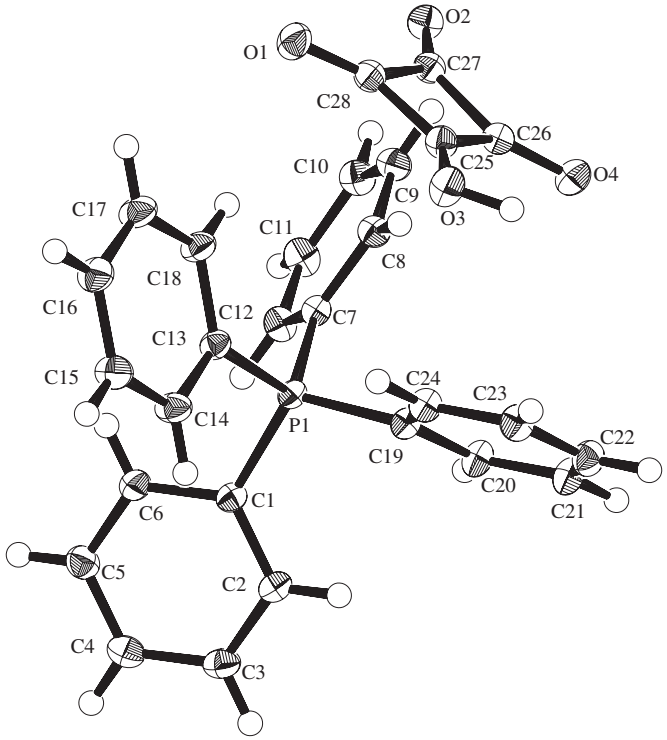
Laplacian, which can be defined as the sum of the eigenvalues of the Hessian matrix ($\nabla^2\rho(r) = \lambda_1 + \lambda_2 + \lambda_3$). A wealth of knowledge can be obtained from interpreting the Laplacian; when $\nabla^2\rho(r) < 0$, the density is locally concentrated, which is typical of a shared interaction, and when $\nabla^2\rho(r) > 0$, the density is locally depleted, such as a closed shell interaction. Another topological component of the charge density distribution is the interaction length (R_{ij}). This is the length of the bond path between a pair of noncovalently bonded atoms.

It is simply not enough to specify that a bond is occurring between two atoms. What is of greater importance is to determine the type of bonding that is involved in the molecule, in particular, hydrogen bonding. This can be achieved both experimentally and theoretically by evaluating the properties of the bond critical points. Koch and Popelier (4, 5) have proposed eight criteria to distinguish a hydrogen bond from a van der Waals interaction. All eight criteria must be fulfilled in order for the bond to be classified as a hydrogen bond and not a van der Waals interaction. The first four criteria involve the properties of the bond critical points, such as the presence of charge density at the critical point and a positive value of the Laplacian. The fourth criterion, considered necessary and sufficient for hydrogen bonding, involves the mutual penetration of the hydrogen and acceptor atoms (2, 4). The last four criteria involve the integration over the atomic basin of the hydrogen atoms of interest. This will result in the loss of charge, energetic destabilization, decrease of dipolar polarization, and a decrease in volume of the hydrogen atoms (4, 5).



Espinosa et al. (6–11) have shown that there are many correlations between the topological and energetic properties of the electron density distributions in hydrogen-bonded systems. In closed shell interactions, they found a linear fit between the local kinetic and potential energy densities and the Hessian eigenvalues (7). Mallinson et al. (12) have also evaluated both intra- and inter-molecular interactions in terms of the first four criteria (2). For example, they demonstrated that the length of the interaction line is correlated to many of the topological properties, showing a general trend on going from weak hydrogen bonds to strong hydrogen bonds (12). These types of analyses will be applied to the tetraphenylphosphonium squarate compound.

We chose the tetraphenylphosphonium squarate (Fig. 1) compound to analyze because of the number and variety of interactions that were possible in its crystalline state. Evaluation of the experimental charge density resulted in the following four types of interactions being found: C-H···H-C, C-H···Cπ, C-H···O, and O-H···O. These types of interactions are important because they have been shown to influence the packing motif of this type of molecule (13, 14). This article will focus on the characterization of all four of these types of interactions according to the first four criteria proposed by Koch and Popelier (5).

Experimental

The synthesis of the compound tetraphenylphosphonium squarate involved squaric acid (0.074 g, 0.65 mmol) being dissolved in 10 mL of triply deionized water. The solution was then adjusted to pH 4 using NaOH. Tetraphenylphosphonium bromide (0.271 g, 0.65 mmol) was then dissolved in 15 mL of triply deionized water, gravity filtered and added, with stirring, to the squaric acid solution. The reaction mixture was stirred in a sealed Erlenmeyer flask for 2 h at room temperature, filtered, placed into a beaker, and allowed to slowly evaporate at room temperature. After about 2 weeks, large colourless crystals had formed with a yield of 90%.

Fig. 1. ORTEP diagram with labels for atoms of tetraphenylphosphonium squarate at 93 K with 50% ellipsoid probability.

A colorless prism crystal of $C_{28}H_{21}O_4P$ having approximate dimensions of 0.20 mm × 0.20 mm × 0.20 mm was mounted on a glass fiber. All measurements were made on a Rigaku Raxis rapid imaging plate area detector with graphite-monochromated Mo Kα radiation. The crystal data of the X-ray diffraction experiment can be found in Table 1. The data were collected with eight scans, each containing 36 images with an exposure time of 36 s/°, and slices of ω between 20 and 200 in increments of 5° (χ = 0° and 45° and ϕ = 0°, 90°, 180°, and 270°). The data collection was monitored and reduced with the HKL2000 (15) software, while the sorting, scaling, and merging of the intensities were performed with Sortav (16) as included in the WinGX (17) package. The structure was solved by direct methods and expanded using Fourier techniques through the CrystalStructure™ software (18). The non-hydrogen atoms were refined anisotropically and the hydrogen atoms were refined isotropically. The final cycle of full-matrix least-squares refinement on F^2 was based on 12 107 observed reflections and 303 variable parameters. All calculations were performed using the CrystalStructure™ (18) crystallographic software package except for the refinement, which was per-

formed using a SHELXL-97 interface (19). All of the molecular thermal ellipsoid plots were generated using the ORTEP-3 program (20). The CIF has been deposited.[2]

Multipole refinement

The refinements were carried out with the module XDLSM incorporated in the software package XD (21). The residual bonding density not modeled in the conventional spherical refinement was taken into account in the multipole refinement (2). The scattering factors used in the multipole refinement were those derived by Su, Macchi, and Coppens' wave functions for all atoms (22, 23). The function minimized in the least-squares refinement is $\Sigma w(|F_0|^2 - K|F_c|^2)^2$ for all reflections with $I > 3\sigma(I)$ (2). For the carbon and oxygen atoms, the multipole expansion was applied up to the octapole level (l_{max} = 3), for the phosphorus up to the hexadecapole (l_{max} = 4), and for the hydrogen atoms up to the dipole level (l_{max} = 1). Separate κ and κ′ parameters were employed for each oxygen atom, as well as each type of carbon (squarate, tetraphenylphosphonium), and for the phosphorus atom. The expansion–contraction parameters of the hydrogen atoms were left fixed at the default XDLSM value of 1.2. It has been shown on several occasions that the default values of n_l and ξ used by XDLSM are not sufficient for multipole refinement of four-coordinate phosphorus atoms (13, 24). The n_l and ξ parameters were therefore chosen based on previous work on triphenylphosphonium benzylide (n_l = 6,6,6,7,7 and ξ = 3.6 b^{-1} (13)). To determine accurate positional and thermal parameters for the non-hydrogen atoms, a high-order (sin θ/λ ≥ 0.6 Å) refinement was performed. A low-order (sin θ/λ ≤ 0.6 Å) refinement was then performed to obtain accurate positional and thermal parameters of all the hydrogen atoms. The positions of the hydrogen atoms were then set to the reported neutron diffraction distance for the rest of the multipole refinement ($C_{ar/sq}$-H = 1.083, O-H = 1.03) (2, 25, 26). The charge neutrality constraint was applied throughout the multiple refinement to achieve an overall neutral molecule. The multipole refinement strategy used was as follows: (*a*) scale factor, (*b*) P_v and κ, (*c*) P_v and P_{lm}, (*d*) P_{lm} and κ, (*e*) P_{lm} and the thermal and positional parameters of all non-hydrogen atoms, and finally, (*f*) κ′. A secondary extinction of type 1 was also applied throughout all the steps and the procedure was cycled through until convergence. Difference mean square displacement amplitudes (DMSDA) for all the bonds where within the Hirshfeld limits. The good quality of the final model is also indicated by Fig. 2, which shows the residual density of the squarate and the C-P-C plane of the tetraphenylphosphonium. The accumulation of residual charge density in the vicinity of the phosphorus atom is most likely due to the

possible nature of polarization and the deficiencies in the multipole model to account for the overall density at that particular site (2). The XDPROP program incorporated into the XD (21) package was used to determine the total electron density, $\rho(r)$, the Laplacian, and the ellipticity at all the bond critical points that were observed for the tetraphenylphosphonium squarate compound. All static, residual, dynamic, and deformation maps were produced using the XDGRAPH option in the XD (21) package. The final atomic coordinates, thermal parameters, and bond lengths of the tetraphenylphosphonium squarate are provided as Supporting information.[2]

Results and discussion

The asymmetric unit of the compound of interest contains one squarate anion and one tetraphenylphosphonium cation. The squarate anions exist as symmetric dimers bonded by hydrogen bonds around a centre of symmetry in the crystalline state. Thus, five atoms (O4-C25-C26-O3-H25) from one squarate ion form a 10-membered ring involving two hydrogen bonds with the equivalent atoms from another squarate ion. The four oxygen atoms and the two hydrogen atoms are very close to planar; the hydrogen atom, H(25), is +0.036(18) Å from the least-squares best plane through the O(3)-H(25)···O(4)/O(4)′···H(25)′-O(3)′ system. The two carbon atoms at each end of the ring are puckered in opposite directions; C(25) and C(26) are –0.250(1) and –0.260(1) Å, respectively, from this plane. With the least-squares best plane through all 10 atoms, the largest deviation from planarity occurs at O(4) (0.1132(5) Å), with C(25) and C(26) –0.0774(6) Å and –0.0813(5) Å, respectively from this 10-atom plane. The squarate dimer and its interactions with different tetraphenylphosphonium cations in the unit cell play a significant role in how the crystal is formed. The carbonyl oxygens each form several interactions to the tetraphenylphosphonium phenyl hydrogens with varying interaction lengths (Table 2). The most significant of these interactions are those of O(1) to X2_H(11) and $X4^1$_H(20), as well as O(2) to X1_H(5), X2_H(6), and H(9), all of which have short interaction lengths ranging from 2.13 to 2.54 Å. The anionic squarate oxygen, O(4), also forms several strong interactions with other phenyl hydrogens, in particular X1_H(4) and X4_H(16), which have interaction lengths of 2.54 and 2.61 Å, respectively. The *xyz* and translations of the symmetry related molecules used throughout the text can be found at the end of Table 2. Some of the tetraphenylphosphonium carbons and hydrogens also play significant roles in the way the crystal is formed. The most significant of these are the interactions between C(3) with X3_H(11) and $X3^1$_H(23), C(9) with X2_H(6), C(21) with $X3^1$_H(15), C(22) with $X3^1$_H(14), and H(3) with $X2^2$_H(21). Their interaction lengths are all short (2.91, 2.75, 2.97, 2.89, 3.00, and 2.17 Å, respectively) and are characteristic of hydrogen bonds; this will be investigated in more detail in the following paragraphs.

The main objectives of the present study are to characterize the intermolecular interactions involving C-H···O, C-H···C_π, C-H···H-C, and O-H···O for the tetraphenylphosphonium squarate molecule and to evaluate them based on the first four criteria proposed by Koch and Popelier (5).

Criteria 1–4

Consistent bond paths (BP) and bond critical points (BCP) were found for 28 intermolecular interactions; these can be divided into 13 C-H···O, 11 C-H···C_π, 3 C-H···H-C, and 1 O-H···O interactions (Fig. 3). The electron density (ρ_{cp}) at the BCPs for hydrogen bonds generally falls within a certain range of values, typically between 0.013 and 0.5 e Å^{-3}, as determined by a number of independent studies (2, 5). The experimental electron density for the BCPs of the C-H···O interactions in tetraphenylphosphonium squarate lie within the range 0.01 to 0.1 e Å^{-3}. The C-H···C interactions are within the range 0.01 to 0.05 e Å^{-3}. The C-H···H-C interactions are within the range 0.01 to 0.05 e Å^{-3}, and the O-H···O interaction has a ρ_{cp} value of 0.493 e Å^{-3}. This means that all 28 interactions have ρ_{cp} values consistent with hydrogen bonding. The experimental topological parameters used to characterize these interactions are given in Table 2. All of the tetraphenylphosphonium squarate interactions follow an exponential dependence for ρ_{cp} vs. R_{ij}, although different types of interactions tend to occupy particular subranges of R_{ij}. This dependence is analogous to Pauling's relation between bond order and internuclear distances (12). If we now look at the correlations between the electron density at the BCP and R_{ij}, which generally has values ranging from 1.5 to 3.6 Å, several regions of separation are observed and can be used to help classify the strengths of the hydrogen bonds (Fig. 4). It can be seen that as the values of the electron density at the BCPs increase, the interaction lengths decrease, and this is directly proportional to the strength of the hydrogen bonds. A region of overlap has previously been determined to offer a possible distance limit for hydrogen bonding (2). This region has been used here to separate the C-H···C_π interactions (classically referred to as van der Waals interactions) and C-H···O interactions.

The local potential energy density, $V(r_{cp})$, at the BCPs represents a quantity proportional to the hydrogen bond energy (4). It generally ranges from –4 to –300 KJ mol^{-1} b^{-3} for hydrogen bonds. Again, a region of separation and overlap can be distinguished through the correlation of the interaction lengths and the local potential energy densities (Fig. 5). As in the case of the correlation between the electron density and interaction lengths, the local potential energy density decreases as the interaction length decreases allowing for a separation of the hydrogen bond strengths into one of two categories: strong and weak hydrogen bonds. The region of overlap can again be used to determine which C-H···C and C-H···O interactions are hydrogen bonds.

The characteristic hydrogen bond values of the Laplacian ($\nabla^2\rho$) generally fall within the range of 0.35 to 4.0 e Å^{-5} as proposed by Koch and Popelier (5). The experimental values of the Laplacian for the C-H···O interactions of tetraphenylphosphonium squarate lie within the range 0.18 to 1.85 e Å^{-5}; the C-H···C interactions are within the range 0.185–0.64 e Å^{-5}; the C-H···H-C interactions are within the range 0.16 to 0.74 e Å^{-5} and the O-H···O interaction has a value of 5.4 e Å^{-5}. This means that 25 of the observed interactions in tetraphenylphosphonium squarate satisfy the Laplacian criterion. The correlation of the Laplacian and the interaction

length shows that as the Laplacian decreases, the interaction length increases (Fig. 6). Again the region of overlap shows a range of R_{ij} values that includes both C-H···C_π and C-H···O interactions that can be classified as hydrogen bonds.

The most important of the four Popelier criteria involves the mutual penetration of the hydrogen and the acceptor atoms. This is measured by looking at the $\Delta r_H + \Delta r_B$ values, where Δr_X is simply the non-bonding radius of the acceptor or donor atom minus its bonding radius. The nonbonding radius is taken to be equivalent to the gas-phase van der Waals radius for any particular atom. In this work, the nonbonding radius for carbon is taken as 1.85 Å, oxygen as 1.54 Å, and hydrogen as 1.2 Å (21, 27, 28). The bonding radius is taken as the distance from the nucleus to the BCP. For an interaction to be classified as a hydrogen bond, the penetration

tions resulted in eight C-H···O, nine C-H···C, two C-H···H-C, and one O-H···O interactions that satisfy this criterion. Another important factor in the mutual penetration of the hydrogen and acceptor atoms is the amount by which the critical point penetrates the donor's van der Waals sphere in comparison to that of the acceptor atom. This is measured by looking at $\Delta r_H - \Delta r_B$, where Δr_X is the same as in the above example, and should still be positive. The tetraphenylphosphonium squarate possesses five C-H···O, two C-H···C, one C-H···H-C, and the O-H···O interactions that completely satisfy this portion of the fourth criterion. Of the 28 interactions found in this compound, only nine show full penetration of both the hydrogen atom and the acceptor atom and thus fully satisfy this criterion. Full penetration implies that both the acceptor and donor atoms have Δr values that are positive, meaning that both atoms are being penetrated along the bond axis. It is also apparent that there is a strong linear correlation between $\Delta r_H + \Delta r_B$ and R_{ij} (Fig. 7). As expected, this shows that the penetrations of the two atoms are quite dependent on the distance between them (12).

The C-H···H-C interactions observed for the tetraphenylphosphonium squarate, unlike the other three types of interactions, can be classified as either simple van der Waals interactions or as hydrogen–hydrogen bonds, but not as hydrogen bonds. This means that of the nine interactions mentioned previously, all of which satisfy the first four criteria of hydrogen bonding proposed by Popelier, only eight of them can in fact be considered as hydrogen bonds. The final interaction involves a C-H···H-C type interaction and is better classified as a hydrogen–hydrogen bond. This is due to the fact that both hydrogen atoms carry a small positive charge, whereas dihydrogen bonds possess both a positively charged (donor) and a negatively charged (acceptor) hydrogen (29). Supplementary data tables that summarize the refinement are available.[2]

Conclusion

Experimental charge density calculations on the tetraphenylphosphonium squarate molecule have shown that 8 of the 28 intermolecular interactions can be classified as hydrogen bonds according to the first four criteria proposed by Koch and Popelier. One of the C-H···H-C interactions can be classified as a hydrogen–hydrogen bond even though it seems to fulfill all of the first four criteria for hydrogen bonding, and the remainder of the interactions can be classified as weak van der Waals interactions. Using the correlations between the properties of the bond critical point and the interaction lengths can lead to several subsets of hydrogen bonding according to their relative bond strengths (12). The correlations also show a region of overlap, which can be used as a good approximation for a borderline between hydrogen bonding and van der Waals interactions (2). This region of overlap must be carefully interpreted because of the fact that not all interactions, at least, of the tetraphenylphosphonium squarate will fall within the hydrogen bond region even though they completely fulfill all of the first four criteria. These interactions are of importance because they are clearly used to hold the crystalline form of the molecule together.

Solvent-free and selective tosylation of alcohols and phenols with *p*-toluenesulfonyl chloride by heteropolyacids as highly efficient catalysts

Razieh Fazaeli, Shahram Tangestaninejad, and Hamid Aliyan

Abstract: Tosylation of some alcohols and phenols has been directly carried out with *p*-toluenesulfonyl chloride using heterodoxy acids ($H_3PW_{12}O_{40}$, $H_3PMo_{12}O_{40}$, $AlPW_{12}O_{40}$, and $AlPMo_{12}O_{40}$) as catalysts in the absence of solvent. We found that heteropoly acids $AlPW_{12}O_{40}$ and $AlPMo_{12}O_{40}$ were effective catalysts for the tosylation of alcohols and phenols. In the case of aliphatic alcohols, secondary alcohols undergo tosylation chemoselectively in the presence of primary hydroxyl groups. This new method consistently has the advantage of excellent yields and short reaction time.

Key words: tosylation, *p*-TsCl, Keggin-type polyoxometalate, solvent-free reaction.

Résumé : La réaction de tosylation de quelques alcools et phénols a été réalisée directement par réaction avec du chlorure de *p*-toluènesulfonyle en utilisant des acides hétérodoxes ($H_3PW_{12}O_{40}$, $H_3PMo_{12}O_{40}$, $AlPW_{12}O_{40}$ et $AlPMo_{12}O_{40}$) comme catalyseurs, en l'absence de solvants. On a trouvé que les hétéropolyacides $AlPW_{12}O_{40}$ et $AlPMo_{12}O_{40}$ sont des catalyseurs efficaces pour la tosylation des alcools et des phénols. Dans le cas des alcools aliphatiques, les alcools secondaires subissent une tosylation chimiosélective lorsqu'ils sont en présence de groupes hydroxyles primaires. Cette nouvelle méthode présente les avantages d'excellents rendements et de temps de réaction courts.

Mots clés : tosylation, chlorure de *p*-tosyle, polyoxométallate de type Keggin, réaction sans solvant.

[Traduit par la Rédaction]

Introduction

Tosylation of alcohols is an important transformation in organic synthesis (1, 2). The most widely used reagents, *p*-toluenesulfonyl chloride (*p*-TsCl) or anhydride, are reactive in comparison with *p*-toluenesulfonic acid (3). Preparation of sulfonates generally relies on the use of the corresponding sulfonyl chloride or anhydride in the presence of pyridine (3*b*, 4), triethylamine (3*a*, 3*c*), 1,4-diazabicyclo[2.2.2]octane (DABCO) (3*d*), or an aqueous base.

p-Toluenesulfonic acid (*p*-TsOH) has also been used (5) as a tosylating agent, but in this case, expensive reagents such as trialkyl orthoformates, alkylethers, esters, or 2-alkoxybenzothiazolium salt are also necessary. Organic base adducts of sulfonyls such as aryl sulfonyl methylimidazolium salts, 1-phenylsulfonyl benzotriazole, and 1-(benzenesulfonyl)- and 1-(*p*-toluenesulfonyl)-3-methylimidazolium triflates have also been employed for sulfonate synthesis (6). The formation of the side products using these reagents in the presence of a base is also a problem (1, 3*b*, 5).

Fe^{3+}-montmorillonite clay has been reported to catalyze the tosylation of alcohols with *p*-TsOH (7). This catalyst is effective for tosylation of aliphatic alcohols, but aromatic alcohols give rearranged or polymeric products. Also, in this case, primary and secondary alcohols behaved very similarly. $CoCl_2 \cdot 6H_2O$ (8), silica chloride (9), and $ZrCl_4$ (10) have also been used to catalyze the tosylation of both aliphatic and aromatic alcohols with *p*-TsOH. In these methods, tosylation of long-chain alcohols required longer reaction times and the yields were poor.

Selective tosylation of a primary hydroxyl group in a molecule containing primary and secondary hydroxyl groups is often required. The resulting sulfonates are the precursors for epoxides enroute to the synthesis of a number of natural products and drugs (11). It is important to realize a high regioselectivity in the initial sulfonylation step to obtain epoxides with high purity via cyclization of the product hydroxyl sulfonates. Thus, there are a limited number of suitable direct tosylation methods for alcohols with *p*-TsOH and there is still a need to develop efficient protocols for this purpose.

Herein, we wish to report a suitable method for direct tosylation of alcohols with *p*-TsCl catalyzed by polyoxometalates as Lewis acid catalysts (Scheme 1).

Polyoxometalates belong to a large class of nanosized metal–oxygen cluster anions. The chemistry of polyoxometalates (heteropolyacids and heteropolysalts), started by Berzelius back in 1826, has now reached maturity. But it is still a rapidly developing field interconnected with many disciplines (12).

The applications of polyoxometalates (POMs, especially polyoxotungstates) for environmental protection and remediation have attracted much attention in recent years (13–19). The majority of POMs have structures composed of molyb-

Scheme 1.

denum and tungsten polyhedrons. Other elements occur in small amounts in these structures. Polyoxotungstates and polyoxomolybdates decompose in alkaline media to form simple tungstate and molybdate ions, and therefore, they can be determined in these forms (20).

The relative activity of Keggin heteropolyacids primarily depends on their acid strength. Other properties, such as the oxidation potential as well as the thermal and hydrolytic stability, are also important.

Tungsten heteropolyacids are usually the catalysts of choice because of their stronger acidity, higher thermal stability, and lower oxidation potential compared with molybdenum acids. Generally, if the reaction rate is controlled by the catalyst acid strength, $H_3PW_{12}O_{40}$ shows the highest catalytic activity in the Keggin series. The acids $H_3PW_{12}O_{40}$, (HTP) and $H_3PMo_{12}O_{40}$, (HMP) are readily available and most frequently used as catalysts. These acids have relatively high thermal stabilities and decompose at 465 and 375 °C, respectively (12).

Preparation of aluminum dodecatungstophosphate ($AlPW_{12}O_{40}$) was reported in 1982 by Ono (21) from the reaction of aluminum nitrate and dodecatungstophosphoric acid in a quantitative yield. We have also prepared aluminum dodecatungstophosphate ($AlPW_{12}O_{40}$ or AlTP) and aluminum dodecamolybdophosphate ($AlPMo_{12}O_{40}$ or AlMP) by the addition of aluminum nitrate or aluminum carbonate to the aqueous solution of tungstophosphoric acid or molybdatophosphoric acid, respectively, which on complete evaporation of water gave the desired compound as white (AlTP) and yellow (AlMP) powders in quantitative yield. AlTP prepared by both protocols gave satisfactory analytical results within the range of the experimental error. This salt is a water stable and nonhygroscopic compound (21–23).

Experimental

Tungstophosphoric acid and dodecamolybdophosphoric acid (HTP and HMP), which are cheap, reusable, heterogeneous, and easily available catalysts, were purchased from Merck and were purified by extraction with Et_2O from the aqueous solution of the acids. After evacuation at 150–300 °C for 1 to 2 h under reduced pressure, pure HTP and HMP were obtained (24). AlTP can be prepared from cheap and commercially available chemicals in a quantitative yield in aqueous media. In contrast to many other Lewis acids, storage of this compound does not need special precautions, e.g., it can be stored on a bench top for months without losing its catalytic activity. In addition, as a nonhygroscopic, noncorrosive, and water stable compound, handling of AlTP is easy, which makes it a suitable catalyst for large-scale operations.

All solvents were reagent grade. All reaction mixtures were stirred magnetically and were monitored by TLC. IR spectra were recorded on a PerkinElmer FT-IR Impact 400D spectrophotometer with KBr. ^{1}H and ^{13}C NMR spectra were recorded on a Bruker AW 500 MHz spectrometer.

General procedure for tosylation

The solvent-free method has an operationally simple procedure. An alcohol or phenol (1 mmol) and POM ($AlPW_{12}O_{40}$, $AlPMo_{12}O_{40}$, $H_3PW_{12}O_{40}$, or $H_3PMo_{12}O_{40}$, 0.03 mmol) and *p*-TsCl (1.2 mmol) were ground together in a mortar and pestle at room temperature for several minutes to form the tosylates. In cases when the mixture stuck to the walls of the mortar, it was taken off the walls with a spatula and grounding was redone. The progress of the reaction was monitored by GC and TLC. After complete disappearance of the starting material, the mixture was poured into a satd. $NaHCO_3$ solution, extracted with CH_2Cl_2 (3 × 20 mL), and the organic phase was dried over Na_2SO_4. The residue was subjected to column chromatography over silica gel using EtOAc–hexane (1:4) as eluent to produce pure tosylate. The structures of the products were established from their spectral (^{1}H and ^{13}C NMR, IR, and MS) data.

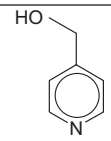
Selected spectroscopic data

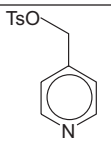
Cyclopentyl* p-*toluenesulfonate (Table 1, n)

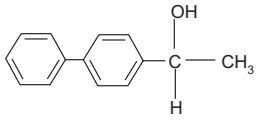
Thick oil. IR (film, cm^{-1}): 1172, 1354. ^{1}H NMR (200 MHz, $CDCl_3$) δ: 1.54–1.78 (8H, m, -$[CH_2]_4$-), 2.43 (3H, s, CH_3), 4.49 (1H, m, CHO-), 7.32 (2H, d, *m*-H, J = 8.1 Hz), 7.78 (2H, d, *o*-H, J = 8.1Hz). MS (EI) *m/z*: 240 (M^+, 2), 172 (61), 107 (33), 91 (100), 65 (34).

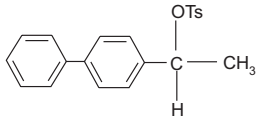
Cyclohexyl* p-*toluenesulfonate (Table 1, m)

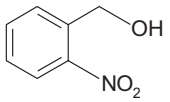
Thick oil. IR (film, cm^{-1}): 1170, 1351. ^{1}H NMR (200 MHz, $CDCl_3$) δ: 1.30–1.78 (10H, m, -$[CH_2]_5$-), 2.44 (3H, s, CH_3), 4.49 (1H, m, CHO-), 7.32 (2H, d, *m*-H, J = 8.8 Hz), 7.79 (2H, d, *o*-H, J = 8.8 Hz). ^{13}C NMR (200 MHz, $CDCl_3$) δ: 143.99, 134.32, 129.38, 127.11 (Ar carbons), 81.12 (CHO), 31.90, 24.46, 22.92, 21.11 (alkane). MS (EI) *m/z*: 254 (M^+, 2), 173 (100), 155 (46), 91 (31), 82 (31), 67 (22), 65 (7).

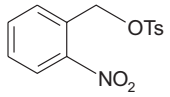


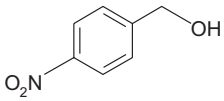


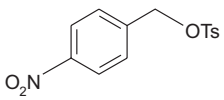


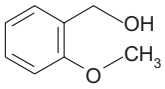


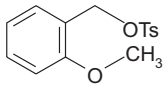


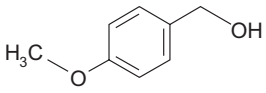


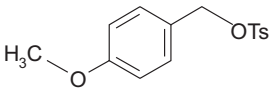


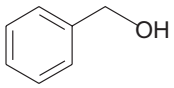


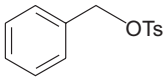


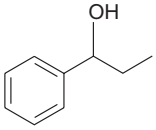


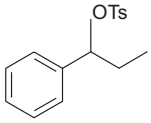


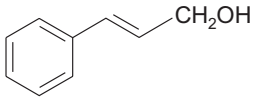


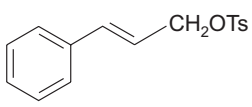


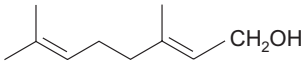


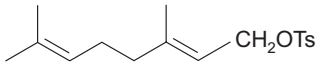


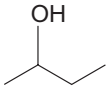


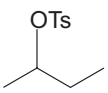












Results and discussion

At first, to investigate the catalytic ability of heteropolyacids ($H_3PW_{12}O_{40}$, $H_3PMo_{12}O_{40}$, $AlPW_{12}O_{40}$, $AlPMo_{12}O_{40}$) to act as catalysts on the tosylation of alcohols and phenols, different alcohols and phenols were mixed with *p*-TsCl in the presence of POMs to form the tosylates under solvent-free conditions. The results showed that $AlPW_{12}O_{40}$ and $AlPMo_{12}O_{40}$ show higher catalytic activity than the acid forms in our experimental conditions (Tables 1 and 2). The catalytic activities are as follows: $AlPW_{12}O_{40}$ ~ $AlPMo_{12}O_{40}$ ≥ $H_3PW_{12}O_{40}$ > $H_3PMo_{12}O_{40}$. The blank experiments, in the absence of catalysts, showed that *p*-TsCl is much less efficient in producing the tosylated products.

As shown in Tables 1 and 2, by using $AlPW_{12}O_{40}$ or $AlPMo_{12}O_{40}$ as catalyst, primary, secondary, benzylic, and allylic alcohols gave tosylated products in good yields. Benzylic alcohols, such as benzyl, 2-nitrobenzyl, 4-

nitrobenzyl, 3-methoxybenzyl, 4-methoxybenzyl, and 1-phenylpropyl alcohol, were converted to the corresponding tosylates in 78%–100% yields (Table 1, entries b–h). Similarly, allylic alcohols, such as cinnamyl and geraniol alcohol, underwent tosylation to afford the corresponding tosylates in 90%–98% yields (Table 1, entries i and j). Aliphatic alcohols were more easily tosylated than aromatic alcohols. However, long-chain alcohols, in the presence of $AlPW_{12}O_{40}$ or $AlPW_{12}O_{40}$ as catalyst, were converted to the desired products in moderate yields (Table 1, entries q–t, 73%–80%). Cholesterol (Table 1, entry o), which is a more complex secondary alcohol, produced the tosylated product

in high yield (90%–96%). Some phenols (Table 2) and tertiary alcohols (Table 1, entries u and v) undergo tosylation under the same experimental conditions. For aromatic alcohols, no rearranged or polymeric products were observed. In the case of diols, under the same reaction conditions, no tosylate product was detected in the reaction mixture and both hydroxyl groups remained intact in the presence of *p*-TsCl (Table 1, entries w–z).

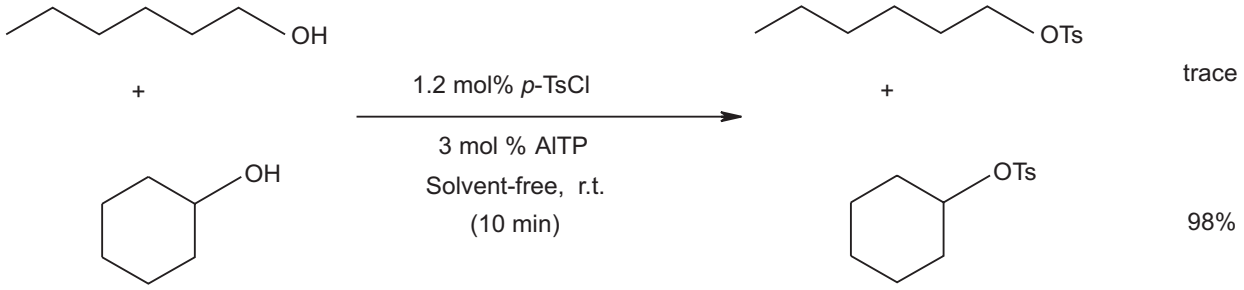
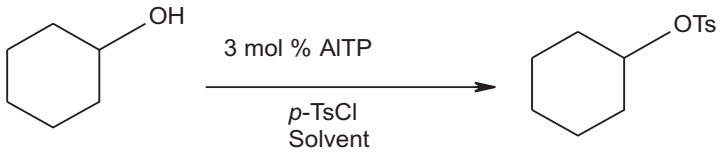
Scheme 2.





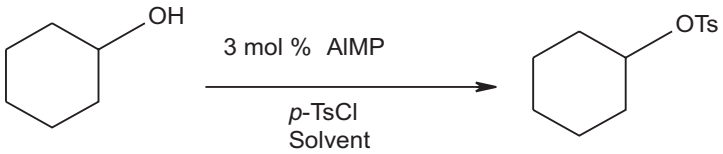


Table 3. Tosylation of cyclohexanol with *p*-TsCl in the presence of $AlPW_{12}O_{40}$ in various solvents.

Entry	Solvent	GC yield (%) after 6 min	GC yield (%) after 30 min
1	$CHCl_3$	20	50
2	CH_3CN	35	65
3	CH_2Cl_2	10	35
4	Acetone	25	50
5	EtOH	15	35

Note: Reaction conditions: cyclohexanol (1 mmol), *p*-TsCl (1.2 mmol), $AlPW_{12}O_{40}$ (3 mol%), and reflux.

Table 4. Tosylation of cyclohexanol with *p*-TsCl in the presence of $AlPMo_{12}O_{40}$ in various solvents.

Entry	Solvent	GC yield (%) after 9 min	GC yield (%) after 30 min
1	$CHCl_3$	20	30
2	CH_3CN	35	50
3	CH_2Cl_2	10	35
4	Acetone	15	35
5	EtOH	20	35

Note: Reaction conditions: cyclohexanol (1 mmol), *p*-TsCl (1.2 mmol), $AlPMo_{12}O_{40}$ (3 mol%), and reflux.

In the case of the aliphatic alcohols, secondary alcohols were tosylated much faster compared with primary hydroxyl groups (Table 1, entries k–t). Thus, a secondary alcohol can be tosylated chemoselectively in the presence of a primary alcohol, as previously reported in the case of $CoCl_2{\cdot}6H_2O$ (8) and silica chloride (9).

The difference in reaction rates between primary and secondary alcohols, which is observed in Table 1, prompted us to examine the chemoselective tosylation of alcohols. For example, when a mixture of *n*-hexanol and cyclohexanol was allowed to react with 0.5 equiv. *p*-TsCl in the presence of these catalysts for 10 min, cyclohexanol underwent tosylation chemoselectively in 98% yield and only a trace amount of *n*-hexyl tosylate was detected (Scheme 2). These studies clearly reveal that this methodology can be applied for the chemoselective direct tosylation of aliphatic secondary alcohols in the presence of primary hydroxyl groups.

Effect of solvent

The tosylation of cyclohexanol was also conducted in different solvents (chloroform, acetonitrile, dichloromethane, acetone, and ethanol). The results show that the yield of the reaction in solutions is much less than those observed under solvent-free conditions (Tables 3 and 4).

Effect of the catalyst

Amongst the catalysts used ($H_3PW_{12}O_{40}$, $H_3PMo_{12}O_{40}$, $AlPW_{12}O_{40}$, and $AlPMo_{12}O_{40}$) in the tosylation of alcohols

© 2006 NRC Canada

and phenols, it was found that both $AlPW_{12}O_{40}$ and $AlPMo_{12}O_{40}$ were effective catalysts for the tosylation of alcohols and phenols. The results showed that in the absence of the catalysts, the tosylation reaction did not proceed after 30 min at room temperature, but in the presence of two heteropolyacids ($AlPW_{12}O_{40}$ and $AlPMo_{12}O_{40}$), the conversion proceeded efficiently in a few minutes under similar reaction conditions (Tables 1 and 2). Therefore, we chose $AlPW_{12}O_{40}$ and $AlPMo_{12}O_{40}$ which are heterogeneous and environmentally benign compounds, as catalysts for further tosylation studies. Furthermore, the use of just 3 mol% POM is sufficient to promote the reaction and no other additives are required for this conversion. No improvements were observed in the reaction yields by increasing the amount of POM from 3 to 5 mol%.

Conclusions

In this study, we have introduced aluminum dodecatungstophosphate ($AlPW_{12}O_{40}$) and aluminium dodecamolybdophosphate ($AlPMo_{12}O_{40}$) as new, highly effective, nonhygroscopic, noncorrosive, heterogeneous, and environmentally benign catalysts for the efficient tosylation of a variety of alcohols and phenols in high yields. Phenols and primary, secondary, benzylic, and allylic alcohols gave tosylated products in good yields. In the case of aliphatic alcohols, secondary alcohols are transformed to the corresponding tosylates chemoselectively in the presence of the primaryhydroxy groups. The advantages of the present methods may be summarized as: high stereoselectivities, good yields of the desired products, short reaction times, mild and solvent-free conditions, and simple experimental procedure and product isolation. The only disadvantage of this system is the release of HCl as a by-product. We feel our protocol is an attractive alternative to the existing procedures for tosylation of alcohols and phenols.

Microwave-assisted regioselective synthesis of acyclic nucleosides through an alkylating reaction with 2-oxa-1,4-butanediol diacetate

Guirong Qu, Suhui Han, Zhiguang Zhang, Mingwei Geng, and Feng Xue

Abstract: An efficient and green procedure for the synthesis of purine acyclic nucleosides through microwave-assisted alkylation of various purine nucleobases with 2-oxa-1,4-butanediol diacetate in the absence of solvent and catalyst is described. The advantages of using this method include its environmental friendliness, simple manipulation, short reaction time, high regioselectivity, and good yields.

Key words: acyclic nucleosides, microwave irradiation, regioselectivity, alkylation, 2-oxa-1,4-butanediol diacetate.

Résumé : On a mis au point une méthode efficace et verte pour la synthèse de nucléosides acyclique de l'acide qui fait appel à une alkylation à l'aide de micro-onde de nucléobases purines avec le diacétate du 2-oxa-1,4-butanediol en absence de solvant et de catalyseur. Les avantages de cette méthode reposent sur son caractère écologique, sa facilité de manipulation, sa faible durée de réaction, sur sa grande régiosélectivité et sur ses bons rendements.

Mots clés : nucléosides acycliques, irradiation micro-onde, régiosélectivité, alkylation, diacétate du 2-oxa-1,4-butanediol.

[Traduit par la Rédaction]

Introduction

In the past two decades, considerable efforts have been invested to develop an efficient treatment against human immunodeficiency virus (HIV) infection. The use of acyclic nucleosides as therapeutic agents, such as acyclovir (**1**), ganciclovir (**2**), and penciclovir (**3**) (Fig. 1), leads to promising results in the treatment of patients with devastating infections by viruses such as varicella zoster virus (VZV), human cytomegalovirus (HCMV), Epstein–Barr virus (EBV), and herpes viruses (1). While versatile methods for the synthesis of acyclic nucleosides have been developed (2), many of them suffer from harsh reaction conditions, the use of expensive alkylating reagents and catalysts, long reaction time, and low selectivity and yields. Thus, simple and efficient protocols for the synthesis of acyclic nucleosides with excellent bioactivities are still in demand.

As one of the most frequently used pathways to prepare purine acyclic nucleosides, the alkylating reaction involves the condensation of purine nucleobases with a haloalkyl ether, trimethylsilyalkyl ether, or polyfunctional open-chain riboside analogues having a reactive α-methylene group (3). This classical process is usually carried out by freezing a DMF solution of reactants at temperatures ranging from –78 to –50 °C in the presence of strong bases or Lewis acids to produce corresponding functionalized 9-(2-acetoxyethoxymethyl) derivatives of purines with moderate yields. Unfortunately, the obtained acyclic nucleosides often were N^9/N^7 isomeric mixtures that were difficult to separate (4). Subsequent studies showed the problems resulting from the classical alkylating procedures can be overcome either by heating the mixture of N^2,N^9-diacetylguanine and 2-oxa-1,4-butanediol diacetate at 105 °C for 80 h to generate the desired N^2-acetyl-9-(2-acetoxyethoxymethyl)guanine in high yield (5). However, these methods still have some drawbacks, notably requiring the use of an oil bath that can maintain the reaction mixture at 105 °C for 80 h, thus making these methods unsuitable for scale up in an environmentally benign and economical way.

Microwave irradiation as a nonconventional energy source has been a very popular and useful technique in organic chemistry (6). The combination of microwave irradiation and solvent-free reaction conditions leads to significantly reduced reaction time, enhanced conversions, and sometimes, higher selectivity, with several advantages for the eco-friendly approach, termed green chemistry. The synthesis of acyclic nucleosides accelerated by this technique is scarce (7). In line with our research program of using microwave irradiation to synthesize a series of nucleoside compounds (8), we wish to report here a facile and efficient procedure for the synthesis of 9-(2-acetoxyethoxymethyl) derivatives of purines through a solvent-free alkylating reaction of purine

nucleobases with 2-oxa-1,4-butanediol diacetate in a neutral alumina bath using silica gel as the supporting material under microwave irradiation (Scheme 1).

Results and discussion

We set out to optimize the alkylating reaction conditions under microwave irradiation, using 6-chloropurine (Scheme 2, **4a**) and 2-oxa-1,4-butanediol diacetate (**5**) as the starting materials.

Firstly, the mixture of **4a** and **5** (10 equiv.) in a 25 mL round-bottomed flask was irradiated directly at 400 W for 10 min, two obvious new spots both showing higher R_f than **4a** on TLC. After purification by column chromatography, the compound with the higher R_f was proved to be the N^9 isomer by HMBC with 34% isolated yield, and the one with the lower R_f was the N^7 isomer with a similar yield, which showed the regioselectivity was very low (Table 1, entry 1). To reduce the ratio of the N^7 isomer, we shortened the equivalents of **5** to 3 and added an appropriate amount of neutral alumina as the supporting material to overcome the possible agglomeration because of the decrease of the fluid **5**. After being crushed vigorously with neutral alumina, the mixture was irradiated in a small beaker at 400 W for 5 min. To our delight, the desired N^9 isomer was predominant for the part facing the irradiation source, which was almost

[a]Isolated yields for **6a–6o** purified by silica gel column chromatography.

molted to yellow; the part opposite of the irradiation source remained white and no obvious reaction took place as indicated by TLC. The integrated yield of this method is low (Table 1, entry 2). Under the same conditions, no new spot was observed using silica gel instead of neutral alumina as the supporting material (Table 1, entry 3). Considering the different absorption capacities of neutral alumina and silica gel to microwave, we chose neutral alumina as the bath and silica gel as the supporting material. Fortunately, the expected product **6a** was obtained with high yield when the bath system was irradiated at 400 W for 4 min (Table 1, entry 4). Further studies showed that the yields could not be improved when *p*-toluenesulfonic acid (PTSA), $ZnBr_2$-doped natural phosphate (NP–$ZnBr_2$) (9), or K10 montmorillonite (K10 mont.) were used as catalysts (Table 1, entries 5–7), or when the microwave irradiation time and power were increased (Table 1, entries 8–10). So we chose 400 W and 4 min as irradiation conditions and no catalyst was used.

As for the possible mechanism of this reaction, we believe that the microwave energy was accumulated quickly by the alumina bath and dramatically accelerated the molecule activity of the mixture in a very short time and made the reaction easily occur at position 9 and not 7 because of the electronic origin (10–12).

Based on the above results, this process was then extended to other purine substrates to investigate its scope and generality (Table 2). It can be seen that under microwave irradiation, a wide range of purine nucleobases can be alkylated easily with **5** to give 9-(2-acetoxyethoxymethyl) purine analogs in a short time and with very high yields (Table 2, entries 1–3). When 6-substituted aminopurines (**4f–4n**) were used as the substrates, the desired N^9 products (**6f–6n**) can be obtained with good yields (Table 2, entries 6–14). In the structures of **4f–4n**, the unmatched electrons on the nitrogen atom can spread effectively to the aromatic ring, which decreased the possibility of an electron density increase at position 7. In addition, the use of silica gel acting as the supporting agent also eases the work-up manipulation, which can permit direct purification by silica gel column chromatography.

Table 3. A comparative synthesis of compounds **6a** and **6b** using the conventional protocol of Robins and Hatfield (2*b*) vs. the solvent-free, microwave-assisted method.

Product	Time (h)[a]	Yield (%)[a]	Time (min)[b]	Yield (%)[b]
6a	6	81	4	93
6b	6	87	4	91

[a]Conventional protocol of Robins and Hatfield (2*b*).
[b]Solvent-free, microwave-assisted method.

To demonstrate the advantage of our method, we synthesized compounds **6a** and **6b** following the conventional protocol of Robins and Hatfield (2*b*) and compared the results with the microwave irradiation method (Table 3). As Table 3 indicates, an acceleration of the reaction rate on the order of a 90-fold increase is observed when the microwave was used. Higher yields of **6a** and **6b** were reached at 4–6 min with microwave heating than those obtained at 6 h using the classical method.

In conclusion, the solvent-free, microwave-assisted alkylating reaction was proved to be a useful and facile protocol to synthesize a series of 9-(2-acetoxyethoxymethyl) derivatives of purines with high regioselectivity. The system of alumina as bath and silica gel as supporting agent was found to be efficient for the quick absorption of microwave energy and for the dramatic and homogeneous acceleration of the reactions. The simple experimental and product isolation procedures are expected to contribute to the development of greener and waste-free chemical processes for the preparation of other acyclic nucleosides. Further studies to develop other new uses for microwave irradiation in the synthesis of nucleoside compounds are now in progress in our laboratory.

Experimental

Melting points were determined with an XRC-1 micro melting point apparatus and are uncorrected. ^{1}H and ^{13}C NMR spectra were recorded in $CDCl_3$ and DMSO-d_6 solutions on a Bruker DPX-400 spectrometer (at 400 and 100 MHz, respectively) using TMS as internal standard. Chemical shifts (δ) are expressed in ppm and coupling constants (*J*) are given in Hz. IR spectra were recorded for KBr tablets on a Bruker Vector 22 spectrometer with absorptions expressed in cm^{-1}. Mass spectra (ESI) were recorded on an Agilent 1100 (LC–MSD-Tarp-SL) mass spectrometer. Elemental analyses were performed on an EA-1110 (CE Instruments) instrument.

The starting substrates **4a**–**4e** and **5** were achieved from Xinxiang Tuoxin Biochemical Technology and Science Co. Ltd, P.R. China. **4f**–**4o** were synthesized by the amination of **4a**, **4b**, and 2-amino-6-chloropurine with the corresponding amines (our unpublished work). All reagents were reagent grade and used without any further purification. The progress of reaction was followed by TLC analysis using silica gel plates (Merck, silica gel 60F$_{254}$). Column chromatography was performed on silica gel (Merck, 200–300 mesh). All the reactions were carried out in a SANYO EM-202MSI microwave oven.

General procedure for the synthesis of 9-[(2-acetoxyethoxy)methyl]-6-chloropurine (6a)

In a mortar, a mixture of 6-chloropurine **4a** (0.308 g, 2 mmol) and 2-oxa-1,4-butanediol diacetate (**5**) (0.94 mL, 6 mmol) was crushed vigorously to give a homogeneous mass, an appropriate amount of silica gel (Merck, 200–300 mesh) was added as supporting agent and mixed carefully with a small spatula to give a fluent mixture. Subsequently, the mixture was transferred to a small beaker (5 mL), which was placed in an alumina bath (60 g neutral alumina (>70 mesh) was placed in a big beaker (100 mL)). The system was irradiated at 400 W for 4 min at several time intervals. At each irradiation time interval (1 min), the microwave was stopped and then the reaction mixture was stirred with a small spatula to homogenize the reaction mixture. After the reaction was completed (monitored by TLC), the reaction mixture was purified directly by silica gel column chromatography ($CHCl_3$–CH_3OH, 95:5 *v*/*v*) to give **6a** (0.503 g, 93% yield). Compounds **6b**–**6o** were synthesized from the corresponding starting materials **4b**–**4o** under similar procedure. The spectra data of **6a**–**6e** were identified by using the available literature (2*b*, 3*d*, 13, 14). The melting point of **6e** was not available and compounds **6f**–**6o** were unknown. All new compounds were fully characterized by IR, ^{1}H NMR, ^{13}C NMR, MS, and elemental analysis.

9-[(2-Acetoxyethoxy)methyl]hypoxanthine (6e)

Melting point 170–172 °C. ^{1}H NMR (400 MHz, DMSO-d_6) δ: 1.94 (s, 3H, CH_3CO), 3.70 (t, *J* = 4.4 Hz, 2H, $AcOCH_2CH_2$), 4.07 (t, *J* = 4.4 Hz, 2H, $AcOCH_2CH_2$), 5.56 (s, 2H, NCH_2O), 8.08 (s, 1H, H-2), 8.23 (s, 1H, H-8).

9-[(2-Acetoxyethoxy)methyl]-6-cyclohexylaminopurine (6f)

Organosulfur oxoacids. Part 1. Synthesis, structure, and reactivity of dimethylaminoiminomethanesulfinic acid (DMAIMSA)

Jonathan F. Ojo, Jeffrey L. Petersen, Adenike Otoikhian, and Reuben H. Simoyi

Abstract: One of the major metabolites of dimethylthiourea, dimethylaminoiminomethanesulfinic acid (DMAIMSA), was synthesized by controlled oxidation of dimethylthiourea using hydrogen peroxide. The crystal structure was determined by X-ray crystallography. It is a zwitterionic species in its solid form, with a positive charge delocalized around an sp^2-hybridized carbon center and two nitrogen atoms. It crystallizes in the triclinic $P\bar{1}$ space group. The C—S bond, at 1.880(2) Å, is much longer than a typical C—S single bond length of 1.79 Å. It is also longer than the one observed in thiourea trioxide, a comparable sulfonic acid. This C—S bond is stable in acidic conditions and is easily cleaved in basic conditions or in the presence of suitable nucleophiles that can attack the positively disposed carbon center. DMAIMSA is highly reactive and easily decomposes in basic conditions to yield dithionite in the presence of oxygen, whereas in strictly anaerobic conditions it gives a mixture of sulfite and sulfide. The precursor to dithionite, $SO_2^{\cdot-}$, is formed from the one-electron oxidation of the sulfoxylate anion, SO_2^{2-}, which results from an initial heterolytic cleavage of the C—S bond in DMAIMSA. The sulfur center is oxidized, even by mild oxidants such as aqueous iodine, to sulfate.

Key words: thiourea metabolites, synthesis, structure, reactivity.

Résumé : On a réalisé la synthèse de l'acide diméthylaminoiminométhanesulfinique (ADMAIMS), un des métabolites principaux de la diméthylthiourée, en procédant à l'oxydation contrôlée de la diméthylthiourée à l'aide de peroxyde d'hydrogène. On en a déterminé la structure cristalline par diffraction des rayons X. Dans sa forme solide, il s'agit d'une espèce zwitterionique comportant une charge positive délocalisée autour d'un atome de carbone à hybridisation sp^2 et de deux atomes d'azote. Cet acide cristallise dans le groupe d'espace triclinique $P\bar{1}$. La longueur de la liaison C—S, à 1,880(2) Å, est beaucoup plus longue qu'une liaison C—S simple de longueur typique 1,79 Å. Elle est aussi beaucoup plus longue que celle observée dans le trioxyde de thiourée, un acide sulfonique comparable. Cette liaison C—S est stable dans des conditions acides et elle peut facilement être clivée dans des conditions basiques ou en présence de nucléophiles appropriés qui peuvent attaquer le centre carboné à disposition positive. L'ADMAIMS est fortement réactif et se décompose facilement dans des conditions basiques pour fournir du dithionite en présence d'oxygène alors que, dans des conditions strictement aérobiques, il conduit à la formation du sulfite et du sulfure. Le précurseur dans la formation du dithionite, le $SO_2^{\cdot-}$, se forme à partir d'une oxydation impliquant un électron qui conduit à l'anion sulfoxylate, SO_2^{2-}, qui résulte d'un clivage hétérolytique initial de la liaison C—S de l'acide ADMAIMS. Le centre sulfuré est oxydé en sulfate sous l'influence d'oxydants, même doux, tel que l'iode aqueux.

Mots clés : métabolites de la thiourée, synthèse, structure, réactivité.

[Traduit par la Rédaction]

Introduction

N,*N*′-Dimethylthiourea (DMTU), a thiocarbamide, is a small diffusive molecule that efficiently scavenges toxic oxygen metabolites in vitro and reduces oxidative injury in many biological systems (1). DMTU is one of the most efficient scavengers known for hydrogen peroxide, hydroxyl radical, and hypochlorous acid (2). In this respect, DMTU should act as a powerful antioxidant in vivo. The known effects of DMTU on human health, however, have been contradictory (3). For example, the DMTU treatment resulted in decreases in blood glutathione (GSH) levels in humans (4). GSH can limit damage caused by toxic oxygen metabolites, and the loss of GSH might partially offset some of the

oxygen-metabolite-scavenging benefits of DMTU. Ultimately, the occurrence of increased stomach size, lethargy, and other behavioral changes in rats provides support to the premise that DMTU is toxic (4). This formally unrecognized toxicity of DMTU provides a possible explanation for the apparently conflicting reports regarding the efficacy of DMTU in cytoprotectivity.

Closely related thiocarbamides cause severe pulmonary edema and large pleural effusions that appear to reflect highly specific damage to the pulmonary capillary endothelium (5, 6). This creates a seemingly intractable problem: while lung injury from thioureas can be reduced by OH scavengers like DMTU, this therapy brings its own toxicity. A pertinent question is whether DMTU toxicity is mediated by intact DMTU molecules or by metabolic products of DMTU. The answer lies in a mechanistic evaluation of the metabolic pathways of ingested organosulfur compounds. The nucleophilic nature of the sulfur center and its low oxidation state of –2 would suggest that the pathway to metabolic activation of nearly all organosulfur atoms is oxidative (7). The use of labeled sulfur atoms in phenylthiourea fed to rats showed that all the sulfur atoms in phenylthiourea ended up as sulfate in the urine. Several studies, including ours, have suggested that the active forms of organosulfur compounds in the physiological environment must be the reactive sulfur oxoacids generated in the S-oxidation of thiocarbamides, such as thiourea and thioacetamide (8).

While these oxoacids have been postulated, few have been isolated and studied to examine their possible role in the physiological environment. Not much is known about the structure and reactivities of these possible metabolic intermediates. One major reason for this lack of knowledge is the instability of the first metabolite that is formed in the stepwise oxidation of thiocarbamides: the sulfenic acid (9). Very few sulfenic acids have been isolated as free acids, and those that have been isolated, such as 1-anthraquinonesulfenic acid, are stabilized by extensive hydrogen bonding and steric hindrance (10).

We report on the synthesis, characterization, and structure of the sulfinic acid of DMTU, dimethylaminoiminomethanesulfinic acid (DMAIMSA). The isolation of the intermediate of a bioactive thiocarbamide is essential in deriving a possible mechanism for the observed physiological effects of this thiocarbamide.

Experimental

DMTU, hydrogen peroxide, and acetonitrile (Sigma-Aldrich) were purchased and used without any further purification. Some batches of DMTU were damp and oily and could not form DMAIMSA according to the following method. Instead, the product formed slowly, and turned yellow upon exposure to the atmosphere and at ambient temperatures. The consistency of the DMTU batches was extremely important for the generation of high and consistent yields of DMAIMSA. Aqueous iodine solutions were prepared by dissolving iodine crystals (Sigma-Aldrich) in distilled water, followed by filtration and storage in the dark. Standard solutions of sodium hydroxide were purchased from Fisher Scientific.

Synthesis of DMAIMSA

N,*N*′-Dimethylaminoiminomethanesulfinic acid was prepared according to the synthetic procedure given in the literature (11), which was followed with some modification. DMTU (10.42 g, 0.10 mol) was dissolved in 80 mL of a 50% acetonitrile solution, which was chilled in an acetone–CO_2 ice bath at –59 °C. To this ice-cold solution, 2 equiv. (0.2 mol) of hydrogen peroxide, which were measured as a 20.41 mL aliquot of a 30% concentrated solution, were added dropwise with the rate of addition maintained such that temperature of the reaction mixture did not exceed –39 °C. The 2:1 ratio of hydrogen peroxide to DMTU had to be strictly maintained to avoid the production of mixtures of oxoacids. The frozen mixture was allowed to sit until it melted out and was then stirred at room temperature for 2 h. The resulting long, colorless needlelike crystals were filtered and washed twice with 50% acetonitrile solution and deionized water and then dried in a dessicator. Typical yields were approximately 80%. Further recrystallization and purification was still performed using the same strength acetonitrile solution. Thus, most of the product was lost during the washing, giving much lower yields.

Methods

UV–vis spectra were taken on a PerkinElmer Lambda 2S spectrophotometer equipped with a thermostatable compartment. Most experiments were performed at 25 ± 0.5 °C. Distilled and deionized water were utilized to prepare all standard solutions used in these experiments. The reaction between DMAIMSA and iodine was followed by the use of the iodine–triiodide isosbestic point, which had been experimentally determined as 465 nm in this work and other previous studies from our laboratory using the same spectrophotometer (12). Only freshly prepared iodine solutions were utilized. A Hi-Tech Scientific SF-DX2 (Wiltshire, UK) stopped-flow spectrophotometer was used to follow the oxidation of DMAIMSA by aqueous iodine. KinetAsyst 2.1 software (Hi-Tech, 1998) was used for data acquisition and analysis. Temperature control was maintained with a NesLab RTE-101 thermostat bath. Some reaction solutions were degassed with argon and tightly capped to reduce the effects of dissolved oxygen.

Structure determination

Well-defined needlelike crystals used for X-ray analysis were first recrystallized from a trifluoroacetic acid – water solution and vacuum dried overnight. A colorless crystal of $SO_2C(NHMe)_2$ was covered in the perfluoropolyether PFO-XR75 (Lancaster, UK), and sealed under nitrogen in a glass capillary. The crystal was optically aligned on the four-circle of a Siemens P4 diffractometer equipped with a graphite monochromatic crystal, a MoKα radiation source (λ = 0.710 73 Å), and a SMART CCD detector held at 5.084 cm from the crystal.

Structure solution and refinement

The crystal structure was solved by a combination of direct methods and Fourier methods with the use of SHELXTL6.1 (13). Idealized positions for the hydrogen atoms were included as fixed contributions using a riding model with isotropic temperature factors set at 1.2 (amine

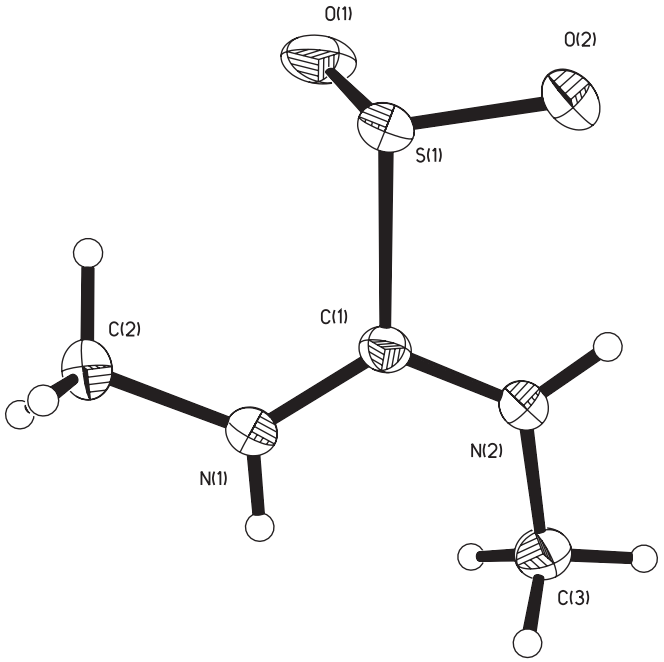
Results and discussion

Description of the molecular structure of DMAIMSA ($SO_2C(NHMe)_2$)



The molecular structure of DMAIMSA was determined by X-ray crystallography.[2] The perspective view is shown in Fig. 1. It is a zwitterionic species with a delocalized negative charge over the O(1)-S-O(2) framework. Whereas the geometry about the S atom is pyramidal, the geometry about the carbon is strictly planar with the sum of angles about C(1) being exactly 360°. The molecular structure of DMAIMSA is highlighted by a three-center four-electron π-interaction of two filled nitrogen p_π orbitals and a vacant carbon p_π orbital at the formally cationic carbon center. This helps to account for the very short C—N bonds observed for C(1)—N(1) (1.303(3) Å) and C(1)—N(2) (1.304(3) Å). In contrast, the corresponding N—C(methyl) bond lengths of 1.457(3) Å are typical of a single C—N bond. The orientation of the methyl groups with respect to the sulfinic acid group does not conform to either a "U" or "W" configuration. The methyl groups, however, are oriented to minimize intramolecular repulsion.

The C—S bond length of 1.880(2) Å is nearly 0.1 Å longer than a typical C—S bond length of 1.79 Å (15) based upon the sum of the covalent radii. This can be compared with the values observed for the unsubstituted thiourea dioxide ($(NH_2)_2CSO_2$) with 1.867(7) Å (16), thiourea trioxide ($(NH_2)_2CSO_3$) with 1.815(2) Å, and the sulfonic acid analogue of DMAIMSA ($(MeHN)_2CSO_3$) with a bond length of 1.820(3) Å (17). The bond lengthening is likely due to antibonding interaction between the sulfur lone pair and the filled π orbitals in the CN_2 central unit.

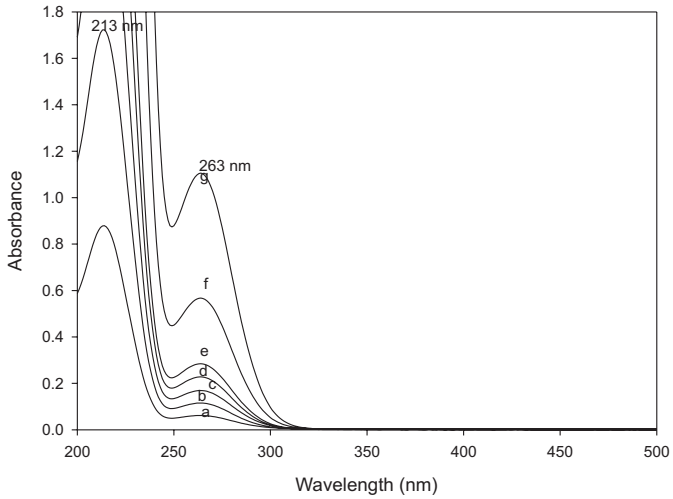
Fig. 1. The perspective view of the molecular structure of DMAIMSA ($SO_2C(NHMe)_2$) with the atom labeling scheme. Thermal ellipsoids are scaled to enclose 30% probability.

Recent experimental results from this laboratory have shown that thiourea dioxides are much more reactive than their trioxides (18). The longer C—S bonds in the dioxides clearly suggests that this reactivity is based on the cleavage of the C—S bond to yield the highly reducing sulfoxylate anion (HSO_2^-) (19). This theory was tested by stability analysis experiments (pH stability and reaction with mild oxidants). The two S—O bonds are nearly equivalent at 1.479(2) and 1.476(2) Å. They are shorter than the unique S—O bonds in unsubstituted thiourea dioxide (1.496(3) Å) and are much longer than those that range from 1.431 to 1.446 Å in thiourea trioxide. The density of DMAIMSA (1.496 g cm^{-3}) is much lower than that recorded for thiourea trioxide (1.948 g cm^{-3}) (17), which is probably a consequence of the absence of extensive H-bonding in DMAIMSA (17).



The UV–vis spectrum of DMAIMSA in aqueous solutions is shown in Fig. 2. It shows two peaks in the UV region centered at 213 and 263 nm. No other peaks are visible after the 263 nm peak. The absorptivity coefficient of DMAIMSA at 213 nm is 8695 $(mol/L)^{-1}$ cm^{-1} and at 263 nm is 573 $(mol/L)^{-1}$ cm^{-1}.

Reactivity and stability of DMAIMSA in aqueous solutions

Effect of pH

Figure 3*a* shows a series of experiments carried out at varying pH conditions to evaluate the stability of DMAIMSA. Carefully weighed out samples of DMAIMSA were dissolved in aqueous solutions at specific pH conditions. These solutions were capped in a spectrophotometric cuvette and the rate of disappearance of the 263 nm peak was observed. DMAIMSA is very stable in acidic and slightly basic conditions as traces a to e in Fig. 3*a* show. Although unstable in slightly basic conditions, the decomposition is very slow in pH conditions lower than pH 11.0. Full decomposition of DMAIMSA at pH 11.0 could be effected after an incubation of several days. At pH 12.0 (NaOH, 0.01 mol/L), the decomposition was very fast and could be complete in less than 5 min.

Fig. 2. The UV–vis spectrum of DMAIMSA in aqueous solutions and neutral pH. Only two peaks are visible at 213 and 263 nm. The peak at 263 nm was used to monitor the rate of decomposition of DMAIMSA. The concentrations of DMAIMSA were: (a) 0.0001, (b) 0.0002, (c) 0.0003, (d) 0.0004, (e) 0.0005, (f) 0.001, (g) 0.002 mol/L.

Decomposition products

A decomposing solution of DMAIMSA (see Fig. 3*b*) was subjected to several periodic spectral scans between 200 and 400 nm. These spectral scans showed the decay of peaks at 213 and 263 nm with a concomitant increase in a peak at 315 nm after some time delay (induction period). From an examination of spectrum k (Fig. 3*b*), which is the final product spectrum obtained, one of the products of this decomposition was deduced to be dithionite ($S_2O_4^{2-}$). Dimethylurea, which would be the product organic moiety, does not have any absorption peaks at $\lambda > 280$ nm. Figure 4*a* shows the formation of dithionite in solutions of varying DMAIMSA concentrations. These traces, as expected (20), are characterized by an induction period followed by a slow formation of dithionite. The induction period is virtually eliminated in high concentrations of DMAIMSA. Some solutions were first degassed with argon, immediately capped, and absorbance at 315 nm monitored (see Fig. 4*b*). Degassing greatly reduced the induction period and also decreased the amount of dithionite formed.

The precursor to the formation of dithionite is the sulfoxyl anion radical ($SO_2^{\cdot-}$) (21):

$$[1] \qquad 2SO_2^{\cdot-} \rightleftharpoons S_2O_4^{2-}$$

This would suggest that the cleavage of the C—S bond could occur in DMAIMSA by the nucleophilic attack of the hydroxyl ion on the carbon atom, followed by the elimination of the sulfoxylate anion (SO_2^{2-}):

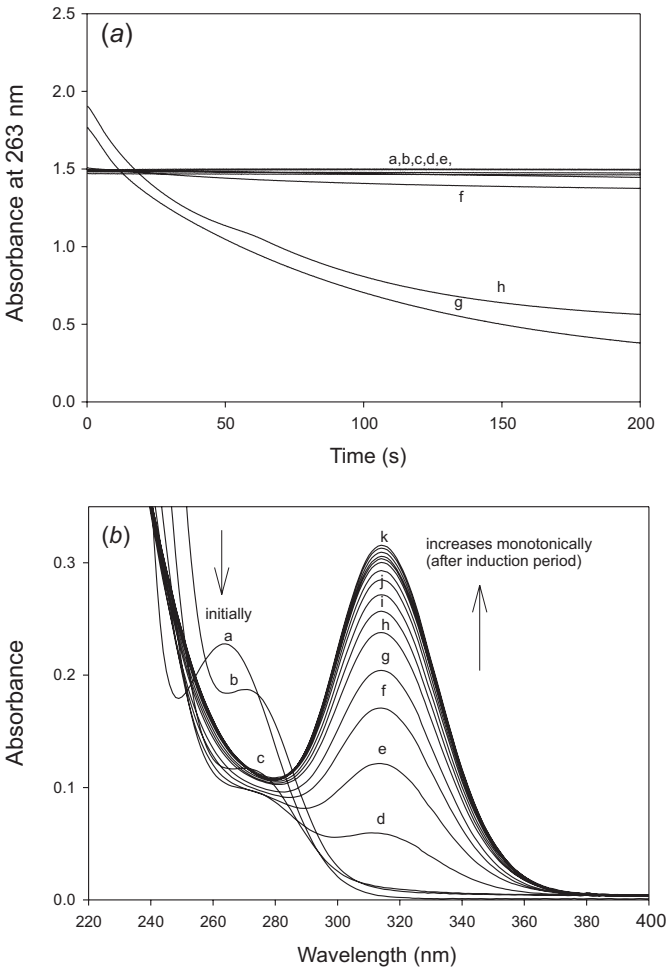
Fig. 3. (*a*) The decomposition of DMAIMSA at various pH conditions monitored at 263 nm. Its decomposition is slow to negligible in acidic conditions. Decomposition products include dithionite, bisulfite, sulfide, and a urea residue. For all experiments, the concentration of DMAMSA used was 0.0052 mol/L. The pH conditions used were: (a) 0.0, (b) 2.0, (c) 3.0, (d) 8.0, (e) 9.0, (f) 11.0, (g) 12.0, (h) 13.0. (*b*) Spectral scans taken every 60 s between wavelengths of 200 and 400 nm, showing all the active regions during the decomposition of DMAIMSA. Initially, the peak at 263 nm goes down without any activity at 315 nm. The absorbance at 315 nm next grows to a maximum value that is determined by the amount of oxygen present in solution. $[DMAIMSA]_0$ = 0.0004 mol/L, $[NaOH]_0$ = 0.50 mol/L.



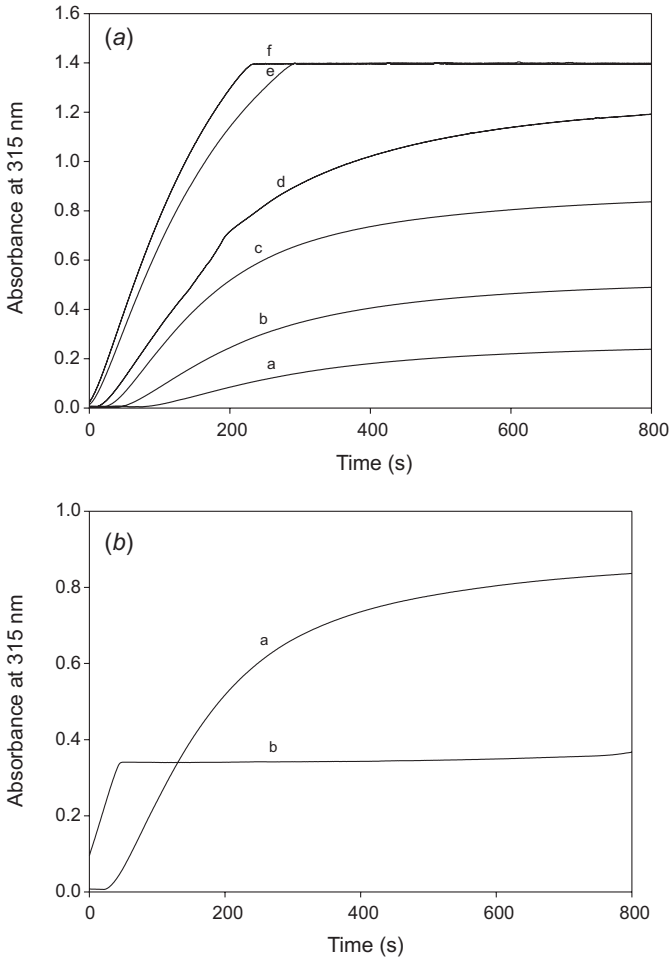


Fig. 4. (*a*) The decomposition of DMAIMSA in high pH conditions and in aerobic environments showing the formation of dithionite after a short induction period. The presence of oxygen is a prerequisite for the formation of dithionite. $[NaOH]_0$ = 0.50 mol/L; $[DMAIMSA]_0$ = (a) 0.0004, (b) 0.0005, (c) 0.0006, (d) 0.0007, (e) 0.00095, (f) 0.001 mol/L. (*b*) Comparison of the traces obtained from an air-saturated solution and an argon-purged solution. The induction period and amount of dithionite formed is greatly reduced in reduced-oxygen environments. Trace a is obtained from air-saturated solutions and trace b is from solutions degassed by bubbling argon into the reaction mixture for 7 min. $[NaOH]_0$ = 0.50 mol/L, $[DMAIMSA]_0$ = 0.0006 mol/L.

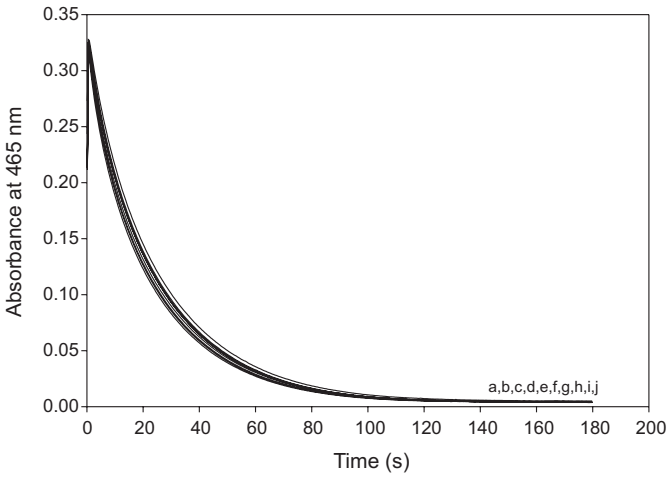
[2] $MeHN(MeN=)C\text{-}SO_2^- + OH^- \rightarrow (MeHN)_2C{=}O + SO_2^{2-}$

The hydroxide ion can be regenerated:

[3] $SO_2^{2-} + H_2O \rightarrow HSO_2^- + OH^-$



The sulfoxylate anion is known to have a strong affinity for oxygen, with which it reacts at a diffusion-controlled rate to produce the sulfoxyl anion radical (22):

[4] $SO_2^{2-} + O_2(aq) \rightarrow SO_2^{\cdot -} + O_2^-$

The sulfoxyl anion radical can react according to rxn. [1] to produce dithionite. The superoxide ion can then subsequently decompose into oxygen and hydrogen peroxide (23). The reaction solutions that were not degassed had the standard concentrations of 2.0×10^{-4} mol/L in dissolved oxygen, while degassed solutions, though not completely depleted in oxygen, had concentrations that were much lower than 2.0×10^{-4} mol/L. Previous experiments from this laboratory on the decomposition of thiourea dioxide did not form dithionite in strictly anaerobic conditions (20). The induction period is the time taken for reactions of type [4] to mop up all the oxygen in the solution. This explains why higher DMAIMSA concentrations delivered shorter induction periods. The final amount of dithionite is also controlled by the

Fig. 5. The direct oxidation of DMAIMSA by aqueous iodine under pseudo-first-order kinetics. The age of the DMAIMSA solutions does not have any effect on the rate of reaction. $[I_2]_0 = 5.1 \times 10^{-4}$ mol/L, $[DMAIMSA]_0 = 0.00679$ mol/L. The solutions were aged for: (a) 3, (b) 10, (c) 20, (d) 38, (e) 60, (f) 90, (g) 116, (h) 165, (i) 186, (j) 214 min.

amount of oxygen initially present in solution. Figure 4*a* also shows that higher DMAIMSA concentrations quickly attain saturation with respect to the amount of dithionite formed.

Reaction with iodine

The ease of oxidation of any organosulfur compound can be tested by the use of the mild oxidant, iodine. Figure 5 shows a series of experiments in which the DMAIMSA aqueous solutions were first allowed to age before being used to reduce iodine. The reaction of iodine and DMAIMSA is moderately fast, but not as fast as the reaction between thiourea dioxide and iodine (18). The reaction also does not display the classic autoinhibition that characterizes most iodine oxidations. Previous experiments with other sulfinic and sulfonic acids have suggested that in aqueous solutions these oxoacids slowly degenerate (see Figs. 3*a* and 3*b*) until there is mixture of urea, bisulfite, and sulfide (19):

[5] $$MeHN(MeN=)C\text{-}SO_2H + H_2O \rightarrow (MeHN)_2C=O + HSO_2^- + H^+$$

[6] $$3HSO_2^- \rightleftharpoons 2HSO_3^- + HS^-$$

The bisulfite and sulfide formed in rxn. [6] are much easier to oxidize, so if rxn. [5] is rate-determining in the oxidation of the sulfinic acid, then aged solutions should react much faster. Data in Fig. 5 shows that there is no real distinction in the reaction rates of aged and unaged solutions. This would suggest that rxn. [5] is rapid enough to not influence the rate of oxidation of DMAIMSA.

Conclusion

We have managed to synthesize, isolate, and characterize the most important metabolite of the physiologically active radical scavenger, DMTU. DMAIMSA is also extremely reactive, much more reactive than either the parent compound (DMTU) or the sulfonic acid analogue. This reactivity could be attributed to the very long C—S bond, which is easily cleaved to yield the highly reducing sulfoxylate anion and which upon oxidation by molecular oxygen, should yield a dithionite precursor.

Synthesis and characterization of a series of 3-methyl-3-{3-[1-methyl-3-aryl-2-triazenyl]propyl}-1-aryl-1-triazenes and related compounds

Jeff D. Clarke, Shasta L. Moser, and Keith Vaughan

Abstract: A series of diazonium salts has been coupled to both secondary nitrogen atoms of the bis-secondary amine, *N*,*N*′-dimethyl-1,3-propanediamine ($MeNHCH_2CH_2CH_2NHMe$), to afford the new bistriazene series, the 3-methyl-3-{3-[1-methyl-3-aryl-2-triazenyl]propyl}-1-aryl-1-triazenes (**9**). These compounds have been fully characterized by IR and NMR spectroscopy, with supporting data from elemental analysis and high-resolution mass spectrometry. A limited number of model compounds in the *N*,*N*-dimethyl-*N*-{3-[1-methyl-3-aryl-2-triazenyl]propyl}amine series (**10**) have been synthesized to aid in the interpretation of the NMR spectra of the bistriazenes (**9**). A series of related compounds, the 3-ethyl-3-{(*E*)-4-[1-ethyl-3-aryl-2-triazenyl]-2-butenyl}-1-aryl-1-triazenes (**11**), have been synthesized by diazonium coupling with the bis-secondary amine *N*,*N*′-diethyl-2-butene-1,4-diamine (**15**), and the diazonium coupling reaction with *trans-N*,*N*′-dimethycyclohexane-1,2-diamine (**19**) has been used to prepare another related series of bistriazenes, the 3-methyl-3-{2-[1-methyl-3-aryl-2-triazenyl]cyclohexyl}-1-aryl-1-triazenes (**12**). The ^{1}H NMR spectra of these compounds are complex because of the presence of two chiral centres in the cyclohexanediamine moiety; the diastereotopic protons of the methylene groups in the cyclohexane ring are clearly distinguished in the 500 MHz spectra of these compounds.

Key words: triazene, bistriazene, synthesis, nuclear magnetic resonance, propanediamine, 1,4-diamino-2-butene, cyclohexanediamine.

Résumé : Le couplage d'une série de sels de diazonium à chacun des deux atomes d'azote secondaire de l'amine bis-secondaire, *N*,*N*′-diméthyl-1,3-propanediamine ($MeNHCH_2CH_2CH_2NHMe$), conduit à la formation d'une série de nouveaux bistriazène, les 3-méthyl-3-{3-[1-méthyl-3-aryl-2-triazényl]propyl}-1-aryl-1-triazènes (**9**). On a effectué une caractérisation complète de ces composés par analyse élémentaire, spectroscopies IR et RMN et spectrométrie de masse. Afin de pouvoir faire une interprétation des spectres RMN des bistriazènes (**9**), on a synthétisé un nombre limité de composés modèles de la série *N*,*N*-diméthyl-*N*-{3-[1-méthyl-3-aryl-2-triazényl]propyl}amine (**10**). On a aussi synthétisé une série de composés apparentés, les 3-éthyl-3-{(*E*)-4-[1-éthyl-3-aryl-2-triazényl]-2-buténYl}-1-aryl-1-triazènes (**11**), par couplage de sels de diazonium avec l'amine bis-secondaire *N*,*N*′-diéthyl-2-butène-1,4-diamine (**15**) alors qu'on a fait appel à une réaction de couplage de diazonium avec le *trans-N*,*N*′-diméthylcyclohexane-1,2-diamine (**19**) pour préparer une autre série de bistriazènes apparentés, les 3-méthyl-3-{2-[1-méthyl-3-aryl-2-triazényl]cyclohexyl}-1-aryl-1-triazènes (**12**). Les spectres RMN de ces composés sont complexes en raison de la présence de deux centres chiraux dans la portion cyclohexanediamine; les protons diastéréotopes des groupes méthylènes du noyau cyclohexane peuvent facilement être distingués dans les spectres à 500 MHz de ces composés.

Mots clés : triazène, bistriazène, synthèse, résonance magnétique nucléaire, propanediamine, 1,4-diamino-2-butène, cyclohexanediamine.

[Traduit par la Rédaction]

Introduction

The term "bistriazene" has been coined to describe any molecule that contains two triazene units in the same molecule, with a link or spacer between the triazene moieties. Recent progress in the synthesis of bistriazenes has been reviewed (1) and the variety of known bistriazenes can be described by the general structures **1** and **2**. In bistriazenes of type **1** the triazenes are linked at N-3 of each triazene unit through the spacer (2, 3) whereas in bistriazenes of type **2** the spacer is attached at N-1 of each triazene unit (4). Mixed bistriazenes of type **3**, where a triazene is linked at N-1 via a spacer to N-3 of a second triazene, are at present unknown.

Bistriazenes have been investigated for their chemical and biological properties by several groups. The antitumor properties of certain bistriazenes of type **1** have been investigated, with the conclusion that these triazenes may be potential prodrugs for the cytotoxic monomethyltriazene (5). This was followed up with a study of bistriazenes of type **4** as multifunctional alkylating agents (6); triazenes of type **5** were found to interact with DNA forming a highly reactive species capable of multistrand breaks and interstrand cross

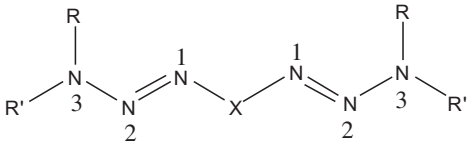
links (7). A synthetic application of bistriazenes is the reported (8) thermal cleavage reaction of a series of *N*,*N*′-bis(arylazo)piperazines to afford the related substituted biphenyl derivatives. Indeed, triazenes have been recognised as being versatile tools in organic synthesis (9) and multifunctional triazene linkers have found application in the efficient solid-phase synthesis of heterocyclic libraries (10). Bistriazenes have been used as one of many functional groups required for characterization of polyarylene compositions with enhanced modulus profiles (11). A recent report (12) describes a neutral 1,2-bis(phenyltriazenido)benzene complex of platinum(II), the first example of a π fragment of platinum(II) stabilized by two symmetrical triazenido chains.

An earlier documented molecule of the bistriazene type is bis(3-phenyltriazen-1-yl)ethane (**5**), obtained by Pochinok et al. (13) by the addition of phenylmagnesium bromide to 1,2-diazidoethane. A similar method was used more recently by Blumenstein and Michejda (6) to prepare the series of 1,2-bis(alkyltriazeno)ethanes (**4**). A serendipitous development in bistriazene chemistry came about during studies of the diazonium coupling reaction with formaldehyde–methylamine mixtures (14). The by-product of these reactions was found to be the *N*,*N*′-bis(1-aryl-3-methyltriazen-3-ylmethyl)methylamine (**6**) (15, 16). A further development in this area of research was the study of the reaction of diazonium salts with ammonia–formaldehyde mixtures, which affords the cagelike bistriazenes, the 3,7-bis(arylazo)-1,3,5,7-tetraazabicyclo[3.3.1]nonanes (**7**) (17). The molecule of type **7** is structurally derived from **6** by the insertion of an extra nitrogen atom to link the carbon atoms of the three *N*-methyl groups.

A more predictable reaction was observed when the diazonium salt was coupled with a *N*,*N*′-dialkylethylenediamine, which affords the 1,2-bis(1-aryl-3-alkyltriazen-3-yl)ethanes (**8**) (2). These bistriazenes were studied extensively by NMR spectroscopy and the bistriazene connectivity was established by X-ray crystallography (18). More recently (19), this work was extended to include the bis(3-pyridyl) derivative (**8**, Ar = 3-pyridyl). In this paper, we wish to report a logical extension of the previous work (2), in which the diazonium salt has been coupled to both secondary nitrogen atoms of the bis-secondary amine, *N*,*N*′-dimethyl-1,3-propanediamine ($MeNHCH_2CH_2CH_2NHMe$), to afford the new bistriazene series, the 3-methyl-3-{3-[1-methyl-3-aryl-2-triazenyl]propyl}-1-aryl-1-triazenes (**9**).



These compounds have been fully characterized by IR and NMR spectroscopy, with supporting data from elemental analysis or high-resolution mass spectrometry. A limited number of model compounds in the *N*,*N*-dimethyl-*N*-{3-[1-methyl-3-aryl-2-triazenyl]propyl}amine series (**10**) have

been synthesized to aid in the interpretation of the NMR spectra of the bistriazenes (**9**). A series of related compounds, the 3-ethyl-3-{(*E*)-4-[1-ethyl-3-aryl-2-triazenyl]-2-butenyl}-1-aryl-1-triazenes (**11**), have been synthesized by diazonium coupling with the bis-secondary amine *N*,*N*′-diethyl-2-butene-1,4-diamine, and the diazonium coupling reaction with *trans*-*N*,*N*′-dimethycyclohexane-1,2-diamine has been used to prepare another related series of bistriazenes, the 3-methyl-3-{2-[1-methyl-3-aryl-2-triazenyl]cyclohexyl}-1-aryl-1-triazenes (**12**). The structural connection between these seemingly different series (**8**, **9**, **11** and **12**) is that these molecules are composed of two (1-aryl-3-alkyltriazen-3-yl-)methyl groups linked by different spacers. It is noteworthy that the compounds of series **11** and **12** are isomeric.

Experimental

All reagents were reagent grade materials purchased from Sigma-Aldrich Canada Ltd., Oakville, Ontario, and were used without further purification. Melting points were determined on a Fisher-Johns melting point apparatus and are uncorrected. Infrared spectra were obtained using Nujol mulls on a Bruker Vector 22 spectrometer. ^{1}H and ^{13}C NMR spectra were obtained with either (*i*) the Bruker 500 MHz spectrometer at the Atlantic Regional Magnetic Resonance Center at Dalhousie University or (*ii*) the ANASAZI 60 MHz EFT spectrometer at St. Mary's University (SMU). Chemical shifts were recorded in $CDCl_3$ solutions at 300 K (unless specified otherwise) and are relative to TMS as internal standard. Elemental analyses were performed by the Canadian Microanalytical Service Ltd., Delta, British Columbia. Accurate mass measurements were made on a CEC 21-110B mass spectrometer operated at a mass resolution of 8000 (10% valley) by computer-controlled peak matching to appropriate PFK reference ions. Spectra were obtained using electron ionization at 70 V and a source temperature of 175 °C, with samples being introduced by means of a heatable quartz probe. The standard deviation of mass measurement is ±0.0008 amu, which is an average of 3.6 ppm over the mass range 100 to 300 amu.

3-Methyl-3-{3-[1-methyl-3-aryl-2-triazenyl]propyl}-1-aryl-1-triazenes (9a–9n)

General procedure

The aromatic primary amine (0.01 mol) was dissolved in 10 mL of 3 mol/L hydrochloric acid, with the aid of heat if necessary, and the resulting solution was cooled in an ice–salt bath to 0 °C. The solution was diazotized with a solution of sodium nitrite (0.76 g) in deionized water (3.0 mL) while maintaining the temperature below 5 °C, and then stirred for a further 0.5 h in the cold. The resulting diazonium salt solution was cold-filtered if necessary. A separate solution of *N*,*N*′-dimethy-1,3-propanediamine (0.005 mol) in deionized water (5 mL) was prepared and this solution was added slowly to the diazonium salt solution. After stirring in the cold for 0.5 h, the resulting mixture was then neutralized with saturated sodium bicarbonate solution. The mixture was then left to stir until precipitation was deemed to be complete (0.5–3 h). The solid product was filtered under suction, dried, and recrystallized from an appropriate solvent. Products that separated as oils were extracted into dichloromethane, dried over anhydrous magnesium sulfate, and isolated by evaporation under vacuum. Physical data of the products, i.e., yield, mp, recrystallization solvent, and IR data, are listed in Table 1. Table 2 is a list of ^{1}H NMR chemical shift data, with appropriate assignments, and selected ^{13}C NMR data are listed in Table 3. The elemental analysis and high-resolution mass spectral data of selected compounds of series **9** are reported in Tables 4 and 5, respectively.

N,*N*-Dimethyl-*N*-{3-[1-methyl-3-aryl-2-triazenyl]propyl}amines (10)

4-Aminobenzonitrile (0.311 g) was dissolved in 3.0 mL of 3 mol/L hydrochloric acid, with the aid of heat if necessary, and the resulting solution was cooled in an ice–salt bath to 0 °C. The solution was diazotized with sodium nitrite (0.21 g) in water (2.0 mL) while maintaining the temperature below 5 °C, and then stirred for a further 0.5 h in the cold. A solution of *N*,*N*,*N*′-trimethyl-1,3-propanediamine (0.32 g) in water (2.0 mL) was added to the cold diazonium salt solution and the resulting mixture stirred in the cold for a further 0.5 h. The mixture was then neutralized with saturated aqueous sodium bicarbonate, and the product was either filtered and dried under suction or extracted into dichloromethane, dried with anhydrous magnesium sulfate, and isolated by evaporation under vacuum to give the following products.

3-Ethyl-3-{(*E*)-4-[1-ethyl-3-aryl-2-triazenyl]-2-butenyl}-1-aryl-1-triazenes (11)

General procedure

The aromatic primary amine (0.00 703 mol) was dissolved in 7.1 mL of 3 mol/L hydrochloric acid, with the aid of heat if necessary, and the resulting solution was cooled in an ice–salt bath to 0 °C. The solution was diazotized with a solution of sodium nitrite (0.518 g) in deionized water (2.0 mL) while maintaining the temperature below 5 °C, and then stirred for a further 0.5 h in the cold. The resulting diazonium salt solution was cold-filtered if necessary. A separate solution of *N*,*N*′-diethyl-2-butene-1,4-diamine (0.0035 mol, 0.505 g) in deionized water (2.0 mL) was prepared and this solution was added slowly to the diazonium salt solution. After stirring in the cold for 0.5 h, the resulting mixture was then neutralized with saturated sodium bicarbonate solution. The mixture was then left to stir for 1 h. The solid product was filtered under suction, dried, and recrystallized from an appropriate solvent. The following products were obtained.

*3-Ethyl-3-{(***E***)-4-[1-ethyl-3-(***p***-cyanophenyl)-2-triazenyl]-2-butenyl}-1-(***p***-cyanophenyl)-1-triazene (11a)*

X = *p*-CN; 88% yield, tan-colored powder, mp 115.5–117.5 °C (hexanes). IR (cm^{-1}) ν_{max}: 2221 (CN), 842 (OOP). ^1H NMR (500 MHz, $CDCl_3$, ppm) δ: 1.30 (6H, br, 2 × CH_3), 3.79 (4H, br, 2 × N-CH_2), 4.39 (4H, br, 2 × N-CH_2 allylic), 5.74 (2H, br, =CH-), 7.46 (4H, d, J = 8.6 Hz, arom.), 7.59 (4H, d, J = 8.5 Hz, arom.). 3-Methyl-3-{2-[1-methyl-3-aryl-2-triazenyl]cyclohexyl}-1-aryl-1-triazenes (12)

General procedure

The aromatic primary amine (0.015 mol) was dissolved in 15 mL of 3 mol/L hydrochloric acid, with the aid of heat if necessary, and the resulting solution was cooled in an ice–salt bath to 0 °C. The solution was diazotized with a solution of sodium nitrite (1.1 g, 0.016 mol) in deionized water (3.0 mL) while maintaining the temperature below 5 °C, and then stirred for a further 0.5 h in the cold. The resulting diazonium salt solution was cold-filtered if necessary. A separate solution of *trans-N,N′*-dimethycyclohexane-1,2-diamine (0.005 mol, 0.715 g) in deionized water (2.0 mL) was prepared and this solution was added slowly to the diazonium salt solution. After stirring in the cold for 0.5 h, the resulting mixture was then neutralized with saturated sodium bicarbonate solution. The mixture was then left to stir until precipitation was deemed to be complete (~1.75 h). The solid product was filtered under suction, dried, and recrystallized from an appropriate solvent. Products that separated as oils were extracted into dichloromethane, dried over anhydrous magnesium sulfate, and isolated by evaporation under vacuum. The following products were obtained.

3-Methyl-3-{2-[1-methyl-3-(p-cyanophenyl)-2-triazenyl]cyclohexyl}-1-(p-cyanophenyl)-1-triazene (12a)

X = *p*-CN; 96% yield, fine pale yellow plates, mp 147 to 148 °C (aqueous ethanol). IR (cm^{-1}) ν_{max}: 2220 (CN), 840 (OOP). ^{1}H NMR(500 MHz, $CDCl_3$, ppm) δ: 1.48 (2H, quintet, J = 9.8 Hz, H_e or H_d), 1.83 (2H, dq, J = 2.8, 9.2 Hz, H_e or H_d), 1.97 (2H, br d, J = 8.1 Hz, H_b or H_c), 2.18 (2H, d, J = 13.5 Hz, H_b or H_c), 3.13 (6H, s, 2 × N-CH_3), 4.16 (2H, d (J = 9.6 Hz) + dt (J = 3.7, 13.6 Hz), H_a), 7.37 (4H, d, J = 8.5 Hz, arom.), 7.55 (4H, d, J = 8.4 Hz, arom.). Results and discussion

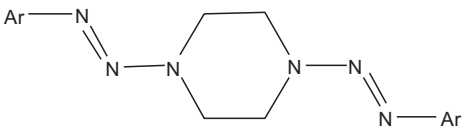
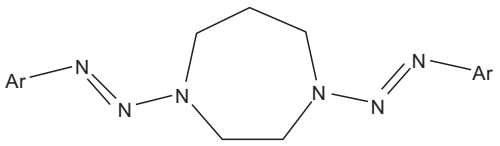
The reaction of a diazonium salt with a secondary alkylamine is the traditional way of synthesizing a simple triazene (20) (eq.[1]).



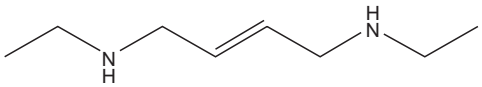
A logical extension of this approach is to couple the diazonium salt with an alkanediamine to afford a bistriazene (1) and this approach was used successfully to prepare the bistriazene series **8** (2). More recent work in this laboratory has developed this approach to the synthesis of a series of *N*,*N*′-bis(aryldiazenyl)piperazines (**13**) (21) by diazonium coupling with piperazine. Further development with the heterocyclic homologue, homopiperazine (*diazepane*), led to the synthesis of the novel bistriazene series **14** (22). The main thrust of the present work is to investigate the synthesis of the new bistriazenes series, the 3-methyl-3-{3-[1-methyl-3-aryl-2-triazenyl]propyl}-1-aryl-1-triazenes (**9**), which are the homolgues of series **8**, and are also of interest as being the acyclic analogues of the known bis(aryldiazenyl)diazepines (**14**).

The synthesis of the new series **9** was undertaken by reaction of 2 equiv. of the diazonium salt (ArN_2^+) with 1 equiv. of *N*,*N*′-dimethyl-1,3-propanediamine ($MeNHCH_2CH_2CH_2NHMe$). The yields and physical data of the products are reported in Table 1. The yields are mostly moderate to excellent. The compounds of type **9** with electron-withdrawing aryl substituents are crystalline solids, whereas others are oils. The IR spectra of the series **9a**–**9n** are consistent with the nature of the aryl substituent and with the position of substitution in the aromatic ring. The elemental composition of all but two of the compounds in this series has been determined by either high-resolution mass spectrometry (EI) or by elemental analysis. Further structure elucidation of series **9** is supported by the results of ^{1}H NMR analysis, which is reported in Table 2.

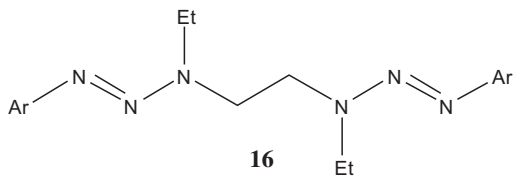


In the ^{1}H NMR spectra, the *N*-methyl proton resonance is observed as a six-proton singlet in the range 2.9–3.3 ppm. The protons of the methylene groups in the propane spacer appear as a four-proton triplet at ca. 3.4–3.9 ppm and a two-proton quintet at ca. 1.7–2.2 ppm. The coupling constant between the methylene groups is in the range 6.6–6.9 Hz. The protons present in the aryl substituent (X) are observed as expected, as are the AA′BB′ signal patterns in the p-substituted derivatives **9a**–**9j**. The results of ^{13}C NMR analysis of some of the compounds in series **9** are reported in Table 3. ^{13}C NMR analysis of the compounds in this series was limited by the severe broadening of the signals of the *N*-alkyl carbon atoms owing to the restricted rotation about the N—N bond of the triazene moiety (23), which results in weak carbon signals being undetectable at ambient temperature. The results reported in Table 3 are those for which a complete set of ^{13}C signals is observed. The *N*-methyl carbon resonates at ca. 36 ppm; the central methylene carbon of the spacer is observed at ca. 27 ppm and the *N*-methylene carbon of the spacer resonates at ca. 52 ppm.

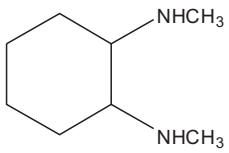
Comparison of these observations with previous NMR studies with compounds of series **8** (2) is very favourable. The N-Me resonance in **8** is ca. 3.2–3.3 ppm, compared to 2.9–3.3 ppm in series **9**. The *N*-methylene signal in **8** occurs at ca. 4.0–4.1 ppm, compared to 3.4–3.9 ppm in **9**. The *N*-methyl carbon signal in series **8** arises at ca. 35 ppm, compared to 35 to 36 ppm in **9**, and the *N*-methylene carbon in **8** resonates at ca. 54 ppm, compared to 52 to 53 ppm in **9**.



The synthesis of the model compounds (**10**) was achieved by diazonium coupling with *N*,*N*,*N*′-trimethyl-1,3-propanediamine ($Me_2NCH_2CH_2CH_2NHMe$). The triazenes of series **10** proved to be somewhat troublesome; many of the prod-



13



14

15

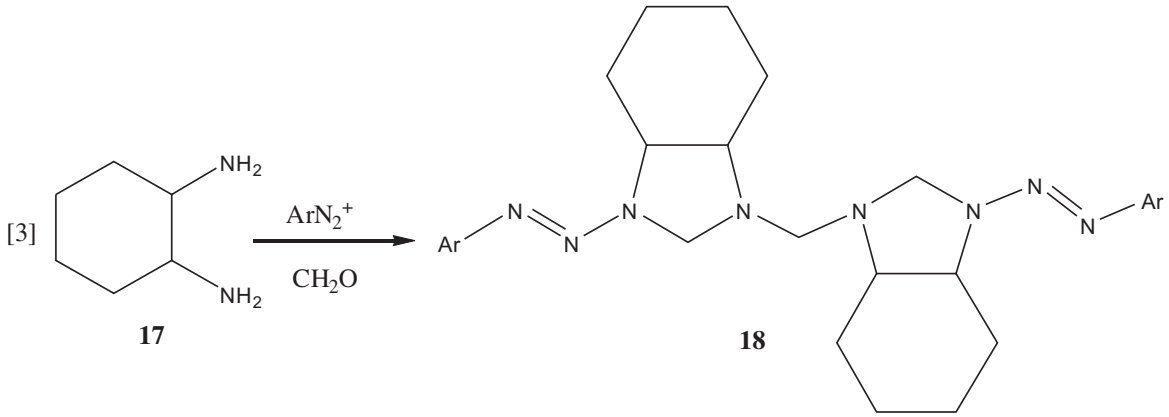
ucts were found to be intractable solids or viscous oils. Successful characterization was achieved with triazenes of type **10** with electron-withdrawing aryl substituents (i.e., X = CN, CO_2Me, COMe, and Br). Comparison of the NMR spectra of compounds of series **9** and **10** shows that the *N*-methyl resonance occurs at ca. 3.2–3.4 ppm in the model compounds **10**, compared with 2.9–3.3 ppm in **9**. The *N*-methylene protons adjacent to the triazene moiety in **10** resonates at ca. 3.6–3.8 ppm compared with 3.4–3.9 ppm in **9**. The *N*-methyl carbon signals occur at ca. 35 ppm in both series and the *N*-methylene carbons are found at ca. 52 ppm in both.

The bistriazenes of series **9** have a three-carbon spacer connecting the N-3 nitrogen atoms, compared with the two-carbon spacer in series **8** previously reported (2). The target molecules of structure **11** are relevant to this study because of the natural extension to the four-carbon spacer. The compounds of series **11** were prepared by reaction of 2 equiv. of the diazonium salt with 1 equiv. of *N*,*N*′-diethyl-2-butene-1,4-diamine (**15**), which is a commercially available starting material. The products are crystalline solids and are obtained in excellent yields (76%–90%), with the exception of the *p*-tolyl derivative (**11d**). The bistriazenes of series **11** have been characterized by IR and NMR spectroscopy and the elemental composition has been verified by high-resolution mass sapectrometry (EI) in all cases.

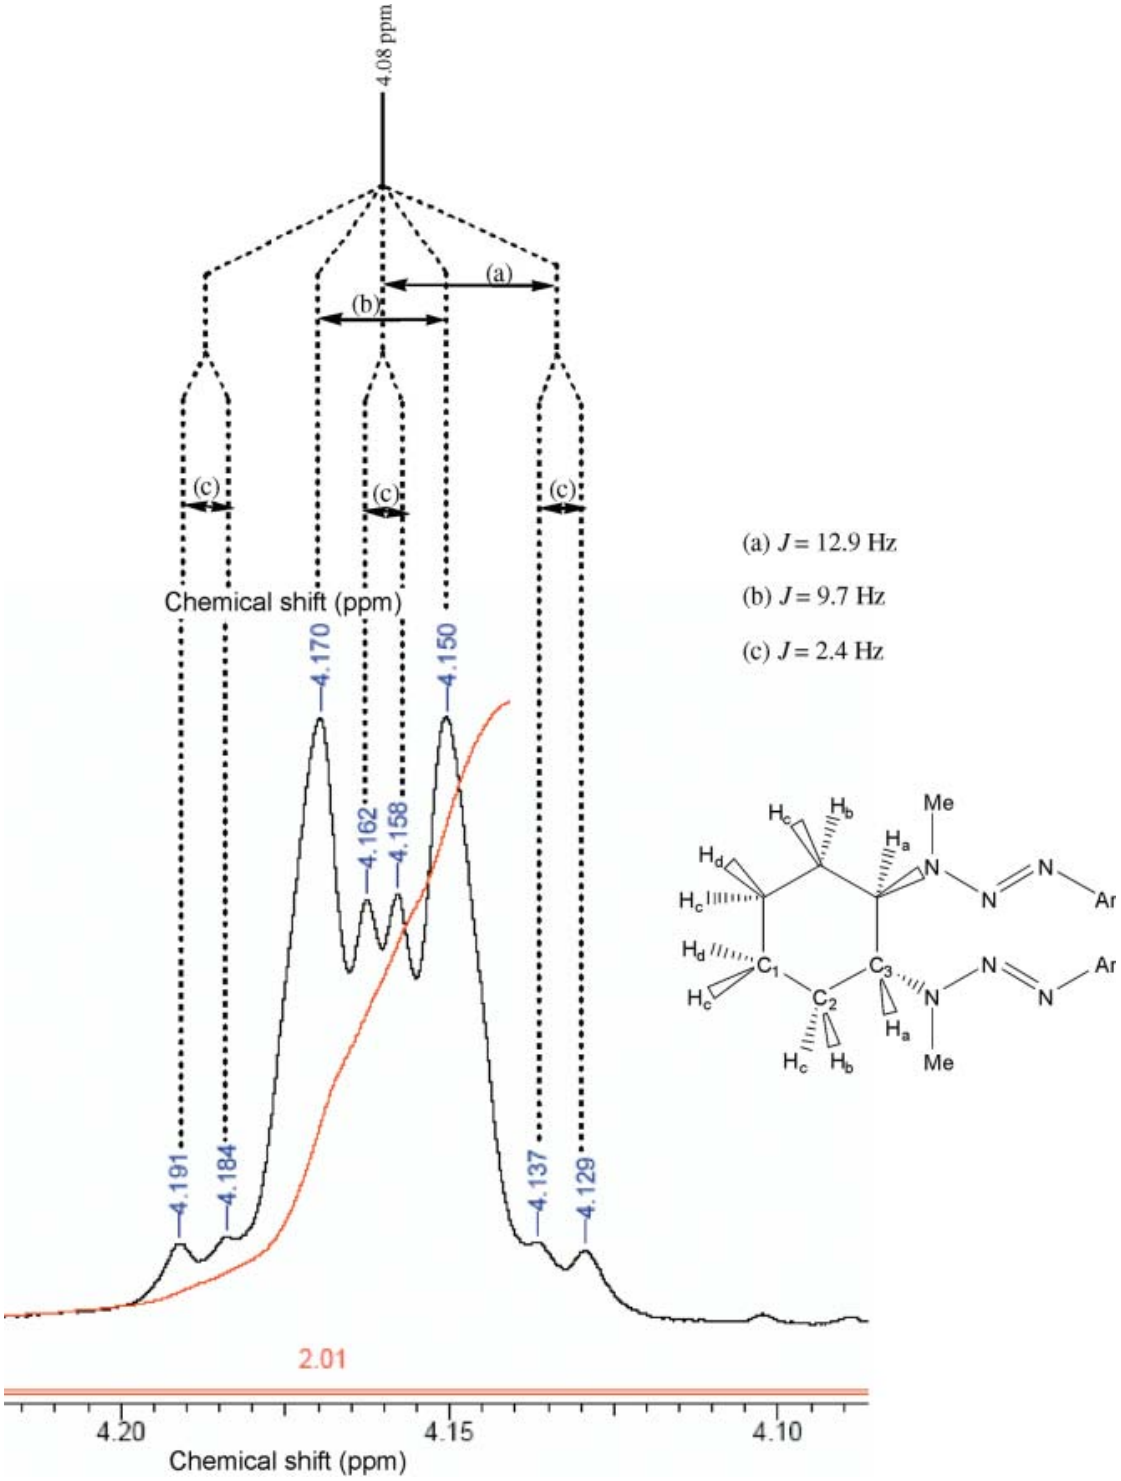
Although the ^{1}H NMR spectra of products **11a**–**11f** are fully consistent with the assigned structures, the complete interpretation of the splitting patterns in the spectra proved difficult owing to extreme broadening of the NMR signals. Line broadening in the NMR spectra of triazenes is a common occurrence owing to the restricted rotation around the N2—N3 single bond alluded to earlier in this paper (23) (eq. [2]).



[2] 

The restriction to the rotation around N2—N3 is enhanced by the ubiquitous resonance phenomenon present in triazenes. Such resonance is enhanced by the presence of electron-withdrawing groups in the aryl substituent (X); significantly, most of the compounds of series **11** have an electron-withdrawing substituent (X = CN, NO_2, CO_2Me, Br, or Cl), and equally significantly, the NMR spectrum of the tolyl derivative (**11d**) is the one that provides the most information about the splitting patterns.

Thus, the ^{1}H NMR spectrum of **11d** shows the predicted resonances of the AA′BB′ aromatic system at 7.12 and 7.30 ppm, and also displays the tolyl Me groups as a six-proton singlet at 2.33 ppm. The *N*-ethyl protons show up as a six-proton triplet methyl signal at 1.22 ppm and a four-proton methylene quartet at 3.72 ppm. The *N*-methylene group of the butenyl spacer is a four-proton doublet at 4.31 ppm and the vinylic proton resonates at 5.74 ppm with the expected triplet multiplicity. The chemical shifts observed in the other bistriazenes of series **11** are analogous to those assigned in the spectrum of **11d**. The *N*-ethyl protons are in the range 1.22–1.34 ppm and 3.72–3.83 ppm; the allylic *N*-methylene protons resonate in the range 4.31–4.42 ppm and the vinylic protons are observed at 5.73–5.77 ppm. The resonances of the *N*-ethyl protons compare favourably with the published data (2) for the bistriazene series (**16**), which display signals in the range 1.24–1.36 ppm and 3.74–3.84 ppm.



The final variation on the bistriazene theme in this paper is series **12**, which have a cyclohexane moiety as the spacer group between the N-3 nitrogens of the triazene units. Cyclohexanediamine chemistry has a rather oblique but significant connection to another aspect of the research being pursued in this laboratory, which is the general study of diazonium coupling reactions with primary alkanediamines mixed with formaldehyde (3, 24). When 1,2-diaminocyclohexane (**17**) is mixed with formaldehyde and the mixture is treated with a diazonium salt solution, the resulting product is the 1-[2-aryl-1-diazenyl]-3-({3-[2-aryl-1-diazenyl]perhydrobenzo[*d*]imidazol-1-yl}methyl)perhydrobenzo[*d*]imidazole (**18**) (25, 26).

Thus, we undertook the study of the diazonium coupling reaction with *trans*-*N*,*N*′-dimethylcyclohexane-1,2-diamine (**19**), a commercially available bis-secondary amine, which affords the series of 3-methyl-3-{2-[1-methyl-3-aryl-2-triazenyl]cyclohexyl}-1-aryl-1-triazenes (**12**). The yields of these products are excellent and, with one exception, they are crystalline solids. The IR spectra of the bistriazenes of series **12** are consistent with the functional groups present and the elemental composition was verified by high-resolution mass spectrometry (EI). The ^{1}H NMR spectra of these compounds are complex because of the presence of two chiral centres in the cyclohexanediamine moiety. The diastereotopic protons of the methylene groups (H_b/H_c and

Fig. 1. Detail of the ^{1}H NMR spectrum of 3-methyl-3-{2-[1-methyl-3-(*p*-tolyl)-2-triazenyl]cyclohexyl}-1-(*p*-tolyl)-1-triazene (**12d**) at 273 K in $CDCl_3$ showing the H_a proton signals.

H_d/H_e, see Fig. 1 for the proton key), are clearly distinguished in the 500 MHz spectra of these compounds.

The protons furthest away from the triazene units in **12** give rise to the high field signals at 1.40–1.48 ppm and 1.76–1.83 ppm, which are assigned to protons H_d and H_e. The multiplicity of these two signals is different; one signal is a quintet, the other is a doublet of quartets (when resolved). Either of these multiplicities is consistent with a given proton, e.g., H_e, having four nonequivalent neighbours, i.e., geminal H_d, vicinal H_d, and vicinal H_b/H_c. The reason why H_d and H_e are slightly different in this respect is not clear. However, H_b and H_c are also observed as diastereotopic protons at 1.87–1.97 ppm and 2.08–2.18 ppm. These signals are unequivocally broad doublets and we

attribute the doublet splitting to coupling with the vicinal methane proton (H_a). The signal of the methine proton itself (H_a) is found in the range 4.08–4.18 ppm, but the multiplicity of this two-proton signal is a very intriguing combination of a broad doublet and a doublet of triplets, both centered at the same frequency. This pattern is consistent for all substituents; Fig. 1 shows a detail of this multiplet taken from the spectrum of the *p*-tolyl derivative (**12d**). The precise origin of this doublet – doublet of triplets combination is not immediately clear, but the most likely explanation is that it is connected to the dynamic equilibrium of the N2—N3 rotamers. This hypothesis is supported by the result of a VT NMR experiment with **12d**, illustrated in Fig. 2. The H_a signal becomes a broad hump when the temperature of a solution of **12d** is raised to 313 K. The triazene *N*-methyl signal at 3.06 ppm also shows significant broadening at higher temperature, whereas the signal of the tolyl methyl group, which is far removed from the rotameric center in the triazene moiety, does not appear to change. Likewise, the signals in the range 1.3–2.1 ppm, those from the cyclohexane methylene groups (H_b, H_c, H_d, and H_e), change little with an increase in temperature.

Conclusion

A fitting conclusion to this paper is to take a broad view of the NMR characteristics of the new compounds reported here in comparison to the known NMR data of previously reported compounds. This comparison is shown in Table 6. There is consistency in the ^{1}H chemical shift data of *N*-methyl groups attached to N-3 of the triazene and also of the spacer *N*-methylene groups linking the N-3 atoms of two triazene units. The ^{13}C NMR data are also consistent. One final point of comparison is to take up the suggestion made earlier that the new compounds of series **9** are the acyclic analogues of the diazepane series (**14**). Since there are no *N*-

© 2006 NRC Canada

methyl groups in **14**, the valid comparison is to compare the NMR characteristics of the propane spacer, which is common to both. In series **9**, the *N*-methylene proton signal is observed in the range 3.44–3.94 ppm compared with 3.76–4.25 ppm in **14**; the central methylene of the three-carbon spacer is observed at 1.75–2.20 ppm in **9**, compared to 1.75–2.41 ppm in **14**.

Novel synthesis of 2-naphthol Mannich bases and their NMR behaviour

Amitabh Jha, Nawal K. Paul, Smriti Trikha, and T. Stanley Cameron

Abstract: A novel two-step procedure involving the formation of 1-arylidene-2-tetralones from 2-tetralone and subsequent Michael addition of a cyclic secondary amine on the alkenone followed by in situ aerial oxidation was developed to produce 2-naphthol Mannich bases. A simple microwave-assisted one-pot synthesis of 2-naphthol Mannich bases was also carried out under solvent-free conditions from 2-naphthol and corresponding aldehydes and amines in the presence of *p*-toluenesulfonic acid. The compounds of this series displayed interesting NMR behaviour. Extensive variable-temperature NMR investigations, including HSQC experiments, are herein reported. NMR results on the conformation in solution phase were found to be consistent with the X-ray crystal structure in the solid state.

Key words: Mannich bases, microwave-assisted Mannich reaction, temperature-variable NMR spectroscopy, NMR dynamics, X-ray crystallography.

Résumé : On a mis au point une nouvelle méthode en deux étapes qui permet de produire des bases de Mannich du 2-naphtol et qui implique la formation de 1-arylidène-2-tétralones à partir de la 2-tétralone, puis une addition subséquente de Michael d'une amine secondaire cyclique sur l'alcénone, suivie d'une oxydation in situ par de l'air. On a aussi réalisé une synthèse des bases de Mannich du 2-naphtol par une simple réaction monotope du 2-naphtol, des aldéhydes et des amines correspondants en présence d'acide *p*-toluènesulfonique, sous l'effet de micro-ondes, dans des conditions sans solvant. Les composés de cette série présentent des comportements RMN intéressants. On a effectué de nombreuses études RMN à température variable, y compris des expériences de « HSQC ». On a trouvé que les résultats de la RMN sur la conformation en solution sont en accord avec la structure cristalline déterminée par diffraction des rayons X, à l'état solide.

Mots clés : bases de Mannich, réaction de Mannich assistée par les micro-ondes, spectroscopie RMN à température variable, dynamique RMN, cristallographie par diffraction des rayons X.

[Traduit par la Rédaction]

Introduction

Numerous chiral aminomethyl phenols have been reported as excellent chelating agents in metal-catalyzed asymmetric induction in a variety of reactions (1–10). Chiral Mannich bases of 2-naphthol are particularly popular in metal-mediated and ligand-accelerated catalysis of enantioselective carbon–carbon bond formation (11–17). Many of these carbon–carbon bond formation reactions involve the use of organozinc compounds as alkylating agents, which are relatively unreactive if uncoordinated (11). These ligands may be used in catalytic amounts. The first synthesis of racemic Mannich bases of 2-naphthol was achieved by Betti (18–22) at the turn of the 20th century. Thereafter, numerous modifications of this reaction surfaced (23–27) and optically pure Betti base analogs were prepared either by resolution or by the induction of chirality by the use of optically active amines (11–17, 28, 29).

In addition, potent oxytocic activity of compounds of this type is reported in the literature (30). Since these compounds have multiple centres for chelation with metal ions, they are likely to be potent inhibitors of metalloenzymes containing Fe, Cu, Zn, Co, etc., ions as cofactors (31–34). Also, these compounds have the potential to be used as scavengers in cases of heavy metal (Pd, Hg, Cd, As, Sb, etc.) poisoning (35, 36).

We herein report a novel synthetic route to this class of compounds (**1**–**4**, Fig. 1) involving two steps starting from 2-tetralones. Also, additional analogs (**5**–**11**, Fig. 1) were obtained in moderate to excellent yields with improved reaction time by modifying a reported microwave-assisted procedure (26). While characterizing the compounds using the usual spectroscopic means, we observed anomalous and interesting NMR behaviour of heterocyclic rings. NMR experiments to study the solution phase dynamics as well as

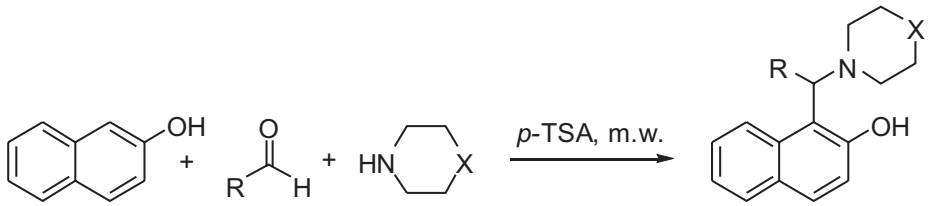
solid-state X-ray crystal structure of representative compounds are also reported here.

Experimental

General

All chemicals were obtained from the Sigma-Aldrich Chemical Company, Inc. Column chromatographic purifications were undertaken using silica gel (230–400 mesh) obtained from Silicycle. ^{1}H and ^{13}C NMR were recorded on Bruker AV500 and AV300 NMR spectrometers. HSQC spectra were obtained on a Bruker AV500 spectrometer using 256 increments and a sweep width of 20 kHz in the indirect (carbon) dimension. Coherence selection was achieved using gradients and phase-sensitive HSQC data were obtained using the echo-antiecho method. All 180° pulses in the sequence were replaced with adiabatic shapes for improved broadband inversion and refocussing over the entire carbon frequency range. EI-MS and HR-MS spectra were obtained on a CEC 21-110B Sector instrument. Melting points were recorded on an electrothermal apparatus and are uncorrected. UV–vis and IR spectra were recorded on LKB Biochrom Ultraspec Plus 4054 and Nicolet Avatar 330 FT-IR spectrophotometers, respectively. A domestic microwave oven manufactured by Kenmore was used for the microwave-assisted reactions at highest power (900 W) and 2450 MHz operating frequency.

Synthesis of substituted 1-arylidene-2-tetralones (A)



Palladium-catalyzed Knoevenagel-type condensation (37) from 2-tetralone and appropriate aldehydes resulted in 1-arylidene-2-tetralones. To a mixture of 2-tetralone (20 mmol), appropriate aromatic aldehyde (22 mmol), 10% Pd/C (2 mol %), and DMF (30 mL) was added TMSCl (22 mmol) in dropwise fashion at room temperature. After 30 min, the reaction was warmed to 75 °C and stirred for 5 h. DMF was rotary evaporated and the residue was chromatographed with 2% EtOAc in hexanes. The resulting products were characterized as 1-arylidene-2-tetralones (**A**) by comparison of their physical and spectral data with those reported in the literature (38). The melting points (°C) and percentage yields of the compounds in this series were as follows: **A** (R = phenyl): 116 to 117, 76; **A** (R = 4-tolyl): 103 to 104, 73; **A** (R = 4-NO_2-phenyl): 153 to 154, 82; **A** (R = 2-NO_2-phenyl): 122 to 123, 71.

Synthesis of 1-(arylpiperidin-1-yl methyl)naphthalen-2-ols (1–11)

Procedure A (Schemes 1 and 2): Appropriate 1-arylidene-2-tetralones (**A**, 10 mmol) reacted with excess piperidine at room temperature to produce the compounds (**1**–**4**) over a period of 7 days. No reaction progress was observed by TLC after 24 h. The resulting compounds were purified using silica gel column chromatography with 3% ethyl acetate in hexanes as the eluent. Unreacted starting materials (**A**) were also recovered.

© 2006 NRC Canada

Scheme 3. Synthethic route for the microwave-assisted reactions of compounds **1**–**12**.

1-12

Procedure B (Scheme 3): A mixture of 2-naphthol (10 mmol), appropriate aromatic aldehyde (12 mmol), *p*-TSA (50 mg, cat.), and appropriate secondary amine (12 mmol) was irradiated using the microwave for 1 min (30 s × 2, to avoid overheating). The reaction mixture was cooled and methanol was added to it. Several products, viz. compounds **1**, **3**, **5**, **6**, and **8**, were purified by digestion in methanol as follows. The reaction mixture was stirred in hot methanol (20 mL) for 1 h and kept at room temperature overnight for crystallization and precipitation. The solid product was filtered, washed with cold methanol (2 × 5 mL), and dried under vacuum. The rest of the derivatives were purified by column chromatography using silica gel. The desired product eluted with 2% ethyl acetate in hexanes. The products thus obtained were further purified by crystallization.

1-(Phenylpiperidin-1-ylmethyl)naphthalen-2-ol (1)

^{1}H and ^{13}C NMR were identical to those reported in the literature (27). UV–vis (MeOH, nm) λ_{max}: 244, 280, 336. IR (KBr disc, cm^{-1}) ν: 3443, 3050, 2971, 1621, 1599, 1455, 1268, 1238, 702. EI-MS (70 eV) *m*/*z* (% int.): 317 (M$^+$, 11), 231 (100), 200 (2), 84 (41). HR-MS calcd. for $C_{22}H_{23}NO$: 317.1780; found: 317.1785.

1-(4-Methylphenyl)piperidin-1-ylmethyl)naphthalen-2-ol (2)

UV–vis (MeOH, nm) λ_{max}: 244, 291, 336. IR (KBr disc, cm^{-1}) ν: 3439, 3060, 2963, 1621, 1595, 1384, 1359, 1261, 1231, 821. ^{1}H NMR (300 MHz, 273 K, $CDCl_3$) δ: 1.41 (1H, bs, CH), 1.50–1.91 (5H, m, 5 × CH), 2.27–2.46 (4H, m, Ar-CH_3, NCH), 2.92 (1H, bs, NCH), 3.23 (1H, bs, NCH), 3.53 (1H, bs, NCH), 5.23 (1H, s, Ar-CH-Ar′), 7.01–7.08 (1H, m, Ar-H), 7.22–7.28 (2H, m, Ar-H), 7.37–7.42 (3H, m, Ar-H), 7.49–7.52 (2H, m, Ar-H), 7.68–7.73 (1H, m, Ar-H), 7.81–7.84 (1H, m, Ar-H), 13.32 (1H, bs, OH). ^{13}C NMR (75 MHz, 273 K, $CDCl_3$) δ: 21.63, 24.03, 25.72, 26.00, 52.10, 55.20, 64.90, 109.00, 117.82, 120.33, 121.24, 123.06, 126.22, 127.10, 129.11, 129.47, 130.25, 130.87, 134.88, 155.36. EI-MS (70 eV) *m*/*z* (% int.): 331 (M$^+$, 14), 247 (10), 231 (100). HR-MS calcd. for $C_{23}H_{25}NO$: 331.1936; found: 331.1930.

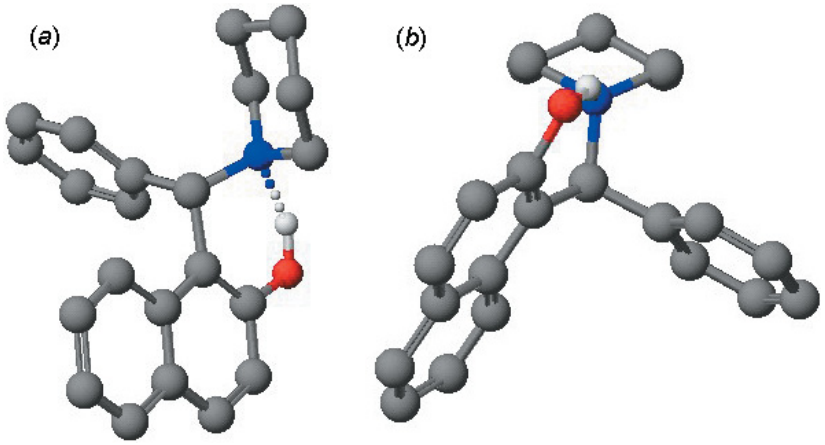
1-(4-Nitrophenyl)piperidin-1-ylmethyl)naphthalen-2-ol (3)

UV–vis (MeOH, nm) λ_{max}: 244, 295, 335. IR (KBr disc, cm^{-1}) ν: 3439, 3080, 3060, 2926, 1621, 1514, 1441, 1414, 1346, 1265, 1231, 830. ^{1}H NMR (300 MHz, 273 K, $CDCl_3$) δ: 1.28 (1H, bs, CH), 1.58–1.73 (5H, m, 5 × CH), 2.02 (1H, bs, -NCH), 2.15 (1H, bs, -NCH), 2.65 (1H, bs, -NCH), 3.37 (1H, bs, -NCH), 5.23 (1H, s, Ar-CH-Ar′), 7.18–7.31 (2H, m, Ar-H), 7.42 (1H, t, *J*= 7.5 Hz, Ar-H), 7.70–7.81 (5H, m, Ar-H), 8.13–8.16 (2H, m, Ar-H), 13.78 (1H, bs, OH). ^{13}C NMR (75 MHz, 273 K, $CDCl_3$) δ: 24.32, 26.10, 26.40, 52.78, 55.03, 71.45, 115.26, 120.48, 120.83, 123.22, 124.61, 127.26, 129.06, 129.61, 130.21, 130.62, 132.33, 147.61, 147.73, 155.74. EI-MS (70 eV) *m*/*z* (% int.): 362 (M$^+$, 14), 279 (9), 260 (61), 231 (39), 230 (100), 85 (54), 58 (14). HR-MS calcd. for $C_{22}H_{22}N_2O_3$: 362.1630; found: 362.1634.

1-(2-Nitrophenyl)piperidin-1-ylmethyl)naphthalen-2-ol (4)

UV–vis (MeOH, nm) λ_{max}: 241, 335. IR (KBr disc, cm^{-1}) ν: 3439, 3052, 2926, 1621, 1595, 1514, 1316, 1265, 1231, 830. ^{1}H NMR (500 MHz, 273 K, $CDCl_3$) δ: 1.25–1.32 (1H, m, CH), 1.67–1.77 (5H, m, 5 × CH), 2.35–2.38 (2H, m, 2 × NCH), 2.58 (1H, d, *J* = 9.5 Hz, NCH), 3.30 (1H, d, *J* = 11.5 Hz, NCH), 6.08 (1H, s, Ar-CH-Ar′), 7.15 (1H, d, *J* = 9.0 Hz, Ar-H), 7.21–7.26 (1H, m, Ar-H), 7.31–7.45 (3H, m, Ar-H), 7.65–7.71 (3H, m, Ar-H), 7.81–7.85 (2H, m, Ar-H), 14.54 (1H, bs, OH). ^{13}C NMR (125 MHz, 273 K, $CDCl_3$) δ: 23.90, 25.93, 26.52, 49.92, 54.62, 64.02, 115.07, 120.20, 120.64, 122.69, 124.29, 126.97, 128.58, 128.86, 128.93, 130.09, 131.55, 132.61, 133.65, 133.70, 150.22, 156.94. EI-MS (70 eV) *m*/*z* (% int.): 362 (M$^+$, 2), 231 (100), 232 (47), 85 (3). HR-MS calcd. for $C_{23}H_{23}NO_3$: 362.1630; found: 362.1633.

1-(4-Chlorophenyl)piperidin-1-ylmethyl)naphthalen-2-ol (5)



UV–vis (MeOH, nm) λ_{max}: 242, 291, 336. IR (KBr disc, cm^{-1}) ν: 3440, 3080, 2951, 1620, 1519, 1474, 1384, 1104, 742, 515. ^{1}H NMR (300 MHz, 273 K, $CDCl_3$) δ: 1.27 (1H, bs, CH), 1.62–1.70 (5H, bs, 5 × CH), 1.97 (1H, bs, NCH), 2.03 (1H, bs, NCH), 2.73 (1H, bs, NCH), 3.36 (1H, bs, NCH), 5.07 (1H, s, Ar-CH-Ar′), 7.19–7.41 (4H, m, Ar-H), 7.43–7.46 (1H, m, Ar-H), 7.54–7.68 (2H, m, Ar-H), 7.71–7.81 (3H, m, Ar-H), 3.12 (1H, bs, OH). ^{13}C NMR (75 MHz, 273 K, $CDCl_3$) δ: 24.35, 26.10, 26.30, 52.41, 55.14, 71.49, 117.13, 120.45, 121.20, 123.06, 127.08, 129.51, 129.77, 130.22 130.94, 131.16, 132.50, 134.21, 138.33, 156.12. EI-MS (70 eV) *m*/*z* (% int.): 353 (M + 2, 0.7), 350 (M$^+$, 2), 266 (2), 264 (2), 231 (6), 84 (100). HR-MS calcd. for $C_{22}H_{22}ClNO$: 351.1390; found: 351.1387.

1-(Piperidin-1-yl-pyridin-4-ylmethyl)naphthalen-2-ol (6)

UV–vis (MeOH, nm) λ_{max}: 241, 298. IR (KBr disc, cm^{-1}) ν: 3442, 3044, 2944, 1621, 1598, 1451, 1384, 1267, 1236, 816. ^{1}H NMR (300 MHz, 273 K, $CDCl_3$) δ: 1.61 (1H, bs, CH), 1.72–1.88 (5H, bs, 5 × CH), 2.10 (1H, bs, -NCH), 2.71 (1H, bs, -NCH), 3.16 (1H, bs, -NCH), 3.35 (1H, bs, -NCH),
