MINIREVIEW / MINISYNTHÈSE

Recent development in functionalized ionic liquids as reaction media and promoters

Wing-Leung Wong and Kwok-Yin Wong

Abstract: The recent development in the use of functionalized ionic liquids as both reaction media and promoters is reviewed. Ionic liquids designed with special functionality can enhance the reaction rate, selectivity, and productivity in various chemical reactions. In this context, some important chemical reactions involving C–C, C–O, C–N, and C–S bond formation in functionalized ionic liquids are discussed. These functionalized ionic liquids were found to provide distinct advantages over conventional organic solvents in these catalytic reactions.

Key words: ionic liquids, homogeneous catalysis, organocatalysis, green chemistry.

Résumé : On passe en revue les développements récents dans le domaine de l'utilisation des liquides ioniques fonctionnalisés tant comme milieux réactionnels que comme catalyseurs. Les liquides ioniques préparés avec des fonctionnalités spéciales peuvent augmenter la vitesse de réaction, la sélectivité et la productivité dans diverses réactions chimiques. Dans ce contexte, on discute de quelques réactions chimiques importantes impliquant la formation de liaisons C–C, C–O, C–N et C–S dans des liquides ioniques fonctionnalisés. On a trouvé que, dans ces réactions catalytiques, ces liquides ioniques fonctionnalisés présentent des avantages distincts par rapport aux solvants organiques conventionnels.

Mots-clés : liquides ioniques, catalyse homogène, catalyse organique, chimie écologique.

Introduction

Research into ionic liquids has experienced tremendous growth during the past 10 years. There were over 10 000 research articles published with ionic liquid as the keyword in this period. The most important driving force of the booming research on ionic liquids is their potential in substituting for volatile organic solvents in chemical synthesis because they are generally nonvolatile.[1–4] The use of ionic liquids to replace conventional solvents as the medium for industrial chemical processes could partially eliminate the emission of volatile organic compounds, which are a major source of environmental pollution, although the concept of using ionic liquids as "greener" replacements may need to be further validated because organic solvents are often used in the synthesis of ionic liquids. For the production of high-value chemicals, such as fine chemicals and pharmaceuticals, the replacement of a conventional process by a process based on ionic liquid is still attractive if the ionic liquid permits a high degree of reusability, high yields, and easy separation of products. In recent years, scientists have realized that not all ionic liquids are intrinsically green solvents as some are extremely toxic.[4,5] However, there is no doubt that chemists are able to tune the properties of ionic liquids via molecular design, and ionic liquids, if used properly, can contribute to the sustainability of our Earth.

The importance of ionic liquids can be deduced from their applications in a wide range of areas, which include organic synthesis and catalysis,[6–11] separations,[12,13] lubrication,[14] and materials science.[15,16] Ionic liquids are readily synthesized from a number of classes of cations, typically including those based on imidazolium, pyrrolidinium, ammonium, phosphonium, guanidinium, and pyridinium. An immense number of ionic liquids can be made by combining these cations with a variety of anions. Nowadays, ionic liquids are not only utilized as solvents but integrated with functionalities for specific purposes. During the past decade, reviews on the use of functionalized ionic liquids in specific applications rather than simply as solvents have appeared. The latest developments for ionic liquids, for example, in inorganic material synthesis (ionic liquids as templates and precursors),[17] supported ionic liquid-phase catalysis (ionic liquids as supports or ionic tags for immobilization of molecular catalysts),[18–22] asymmetric organocatalysis,[23] and biocatalytic transformations,[24–26]

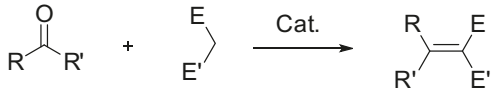
have been reviewed. In this review, only recent (2000–2011) and special contributions of functional ionic liquids that serve as both promoters and reaction media will be discussed. Other systems in which the ionic liquids were used just as alternative solvents and (or) media for chemical reactions are not included as they are outside the scope of this review.

Applications in C–C bond formation reactions

Knoevenagel condensation



The Knoevenagel condensation reaction is one of the most useful reactions for carbon–carbon bond formation in organic syntheses. It involves the nucleophilic addition of an active methylene compound to a carbonyl group (aldehyde or ketone) to give electrophilic alkenes with a base or an acid as the catalyst (Scheme 1). More recently, a zeolite imidazolate framework[27] (ZIF-8) has been demonstrated to be an efficient heterogeneous catalyst for Knoevenagel reaction.

A simple ionic liquid system for Knoevenagel condensation, in which ethylammonium nitrate (an ionic liquid) was used as both solvent and promoter for the condensation of 4-oxo-(4*H*)-1-benzopyran-3-carbaldehydes with 3-methyl-1-phenylpyrazolin-5-(4*H*)-one at room temperature and was reported by Shingare and co-workers.[28] In this ionic liquid system, the water produced during the reaction was absorbed by the ionic liquid and thus the reaction was able to proceed well. The reaction gave high yields (70%–92%) in a very short reaction time (20–30 min) compared with conventional methods in organic solvents.

A cyclic guanidinium lactate ionic liquid (**IL1**) reported by Lin and co-workers[29] was also investigated in the Knoevenagel condensation (Scheme 2). It was found that the aromatic aldehydes were able to react with a number of active methylene compounds in **IL1** at room temperature and a high yield of products (over 90%) were obtained in just 1–7 min. The work-up procedure for the ionic liquid system was very simple and the products did not need to be purified further. The ionic liquid could be reused six times without a loss in catalytic activity. Another alkylammonium-based ionic liquid (**IL2**, 2-hydroxyethylammonium formate) reported by Alizadeh et al.[30,31] is able to act as a task-specific ionic liquid for promoting Knoevenagel condensation reactions. Nitroalkanes were reacted with various aldehydes in **IL2** at room temperature to produce β-nitrostyrenes in high yields. This reaction does not involve any hazardous organic solvent or toxic catalyst. **IL2** is also recoverable and recyclable by simple separation procedures. A mechanism involving the ambiphilic dual activation by **IL2**, which bears a hydroxyl group, an ammonium acidic moiety, and a formate anion, was proposed.[30]

The imidazolium-based ionic liquids such as **IL3** and **IL4** were also investigated for the Knoevenagel condensation. **IL3** as reported by Ranu and Jana[32] is able to catalyze a wide range of aliphatic and aromatic aldehydes and ketones to undergo condensations with a variety of active methylene compounds including diethyl malonate, ethyl cyanoacetate, malononitrile, malonic acid, and ethyl acetoacetate. **IL3** was found to promote the reaction of aliphatic aldehydes with diethyl malonate effectively. When its OH^- counteranion was replaced by BF_4^- or Br^-, however, the reaction did not proceed. The results indicated that the hydroxyl counterion played a vital role in the condensation reaction. **IL4** with

E, E' = electron withdrawing groups

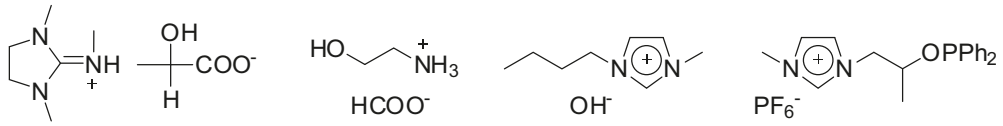
PF_6^- as the counteranion was demonstrated by Valizadeh and Gholipour[33] to be a reusable reaction promoter and a solvent for the synthesis of *E*-acrylates via the Knoevenagel condensation reaction. The success of **IL4** in the catalysis may arise from its phosphinite-functionalized pendant, which shows weak Lewis base characters.

Michael addition

Michael addition is the nucleophilic addition of a carbanion or another nucleophile to an α,β-unsaturated carbonyl compound (Scheme 3). It is one of the most frequently used C–C bond formation reactions in organic synthesis. The reaction is catalyzed by various basic catalysts. For example, NaOH and KOH salts are commonly used in Michael addition reactions.

The use of basic ionic liquids as reaction promoters and media in Michael addition reactions has been demonstrated by a number of research groups in recent years. Ranu et al. reported a task-specific ionic liquid (**IL3**) system for the reaction.[34,35] Interestingly, **IL3** always drives the reaction of nitriles and 1,3-dicarbonyl compounds with α,β-unsaturated esters to produce bis-adducts exclusively in a one-pot process. These results are difficult to achieve by one-step preparation via conventional methods, which demonstrates the dramatic influence of ionic liquids in Michael additions.

The Michael addition of malonodinitrile to chalcone was also found to proceed well in some ionic liquids (**IL5**–**IL8**) without the addition of other catalysts (Scheme 4). Mečiarová and Toma[36] explicated the effects of ionic liquids on the proton dissociation constants of the C–H bond of some active methylene compounds such as malonodinitrile ($CH_2(CN)_2$). In addition, they concluded that ionic liquids exert special effects on the Michael addition of malonodinitrile to chalcone because the nucleophility of the malonodinitrile anion after the dissociation of a C–H acid is significantly enhanced in the ionic liquid medium.



A chiral pool of functionalized ammonium-, imidazolium-, and pyridinium-based ionic liquids, which are derived from (–)-ephedrine, were developed by Truong and Vo-Thanh[37] (Scheme 5). These chiral ionic liquids (**IL9**–**IL11**) were used as both chiral reaction media and promoters (with 6 mol% of KOH as a co-catalyst) for the asymmetric Michael addition of diethyl acetylaminomalonate to chalcone derivatives. Moderate to good yields (up to 80%) and enantioselectivities (up to 70% ee) were obtained under microwave activation conditions. The ionic liquids could be recycled and reused three times. Similar activity and stereoselectivity were maintained in the recycling. However, loss of activity was observed in the fourth cycle.

Diels–Alder reaction

The Diels–Alder reaction is a very important tool for carbon–carbon bond formation reactions in organic synthesis. It is an

addition reaction of a conjugated diene to a dienophile (usually an alkene) to produce a six-membered carbocycle in one concerted step (Scheme 6). Many investigations have been devoted to both the mechanisms and reaction rates of this reaction. In addition, there are a number of reports on Diels–Alder reactions using various ionic liquids as reaction media.[38–45] The efficiency and selectivity of the reaction are also known to be influenced by the acidity of the ionic liquid medium.[46]

The use of functionalized ionic liquids as solvents and promoters for the Diels–Alder reaction is rarely reported in the literature. Some protic imidazolium ionic liquids (**IL12**–**IL13**) developed by Pernak and co-workers[47] were demonstrated to be effective reaction media and promoters in Diels–Alder reactions (Scheme 7). In the reaction of cyclopentadiene with two dienophiles (dimethyl maleate and methyl acrylate), good conversions and endo/exo selectivities were achieved. It is believed that the dienophile was activated by the formation of hydrogen bonds with protic imidazolium ionic liquids. In addition, the ionic liquids could be recycled and no alterations in both yield and selectivity of the process were observed after 10 reaction cycles.

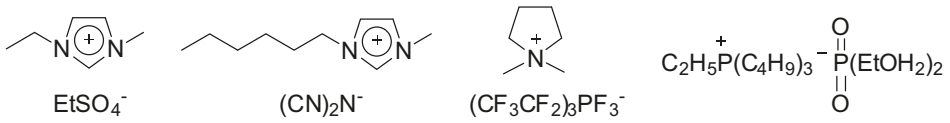
Friedel–Crafts reaction

The Friedel–Crafts reaction is an attractive synthetic approach for C–C bond formation in aromatic rings. The reaction usually involves the alkylation of an aromatic ring with an alkyl halide using a strong Lewis acid as the catalyst. Diphenylmethane and its derivatives, for example, are important pharmaceutical intermediates and are produced industrially via the Friedel–Crafts reaction of benzene with benzyl chloride using acid catalysts such as $AlCl_3$, $FeCl_3$, or H_2SO_4 (Scheme 8). It is also known that organochloroaluminate ionic liquids, which are prepared by a mixture of a quaternary ammonium chloride salts (typically 1,3-dialkylimidazolium chloride) with aluminum chloride, are effective catalysts for this reaction.[48–51]

Friedel–Crafts alkylation of nitrogen heterocycles, such as indoles and pyrroles, can be carried out in ionic liquids under mild conditions. A study using **IL14a**–**IL14d** as the reaction media for the alkylation of various indoles with styrene oxide under ambient conditions was reported by Kantam et al.[52] The investigation indicated that **IL14a** gave better catalytic reactivity than other ionic liquids (**IL14b**–**IL14d**), whereas **IL14d** did not catalyze the alkylation reaction. When the reaction was carried out in CH_2Cl_2 instead of ionic liquid, no product was formed even after a prolonged reaction time. The strong Lewis acid character of **IL14a** may account for its high reactivity in the reaction (Scheme 9).

The pyrrolidinium-based ionic liquid (**IL15**) with fluorine-containing anions developed by Xiao and co-workers[53] is a highly fluidic liquid even below room temperature. **IL15** was used as a recyclable solvent and an efficient Brønsted acid promoter for Friedel–Crafts alkylations of indoles with nitroalkenes. The reaction may proceed via an ionic liquid – nitroalkene complex that involves the formation of intermolecular double hydrogen bonds between the protons on the nitrogen of the cation and the oxygens of the nitro group. However, when **IL15** was replaced by DMSO for the addition of indole to *trans*-β-nitrostyrene, no product was formed even when the reaction was allowed to proceed for 2 days. This ionic liquid was also recyclable after extraction and drying under vacuum. The recycled **IL15** was directly reused in the catalysis and showed no significant decrease in catalytic performance.

Pyridinium-based ionic liquids **IL16a**–**IL16b** reported by Xiao and Malhotra[54] were also investigated in the Friedel–Crafts acylations of some aromatic compounds with acetic anhydride. It was found that a significant amount of products (51%–81% conversion) was obtained simply using the ionic liquid as the reaction medium (without any metal catalyst) under relatively mild conditions (at 50–75 °C for 4 h). The ionic liquids could be recycled and reused in Friedel–Crafts acylations. In addition, an excellent solvent–catalyst system for the reaction was obtained by adding $FeCl_3$ as a co-catalyst in **IL16b**. High conversions were achieved at a relatively low temperature (50 °C). As compared with **IL16a**, ionic liquid **IL16b** exhibited better performance in the acylation reaction with $FeCl_3$ as the co-catalyst.



Prins reaction

The Prins reaction is an important C–C bond forming reaction and is a powerful synthetic route for the construction of six-membered tetrahydropyran derivatives, which are commonly found in a number of natural products, for example, avermectins, aplysiatoxins, oscillatoxins, latrunculins, talaromycins, and acutiphycins. The typical Prins reaction usually involves the use of strong Brønsted acids, for example, sulfuric acid, hydrochloric acid, and *p*-toluenesulfonic acid, as the catalyst to catalyze the reaction of olefins with aldehydes to produce tetrahydropyran derivatives (Scheme 10).

Some Brønsted acid ionic liquids have been utilized as effective and recyclable promoters for Prins reactions (Scheme 11) in recent years.[55,56] However, reports on investigations with ionic liquids as both promoters and solvents for Prins reactions are relatively rare. The use of ionic liquid **IL17** (1-*n*-butyl-3-methylimidazolium chloroaluminate) in Prins cyclizations to produce 4-chlorotetrahydropyran derivatives was reported by Yadav et al.[57] The reaction took place in **IL17**,

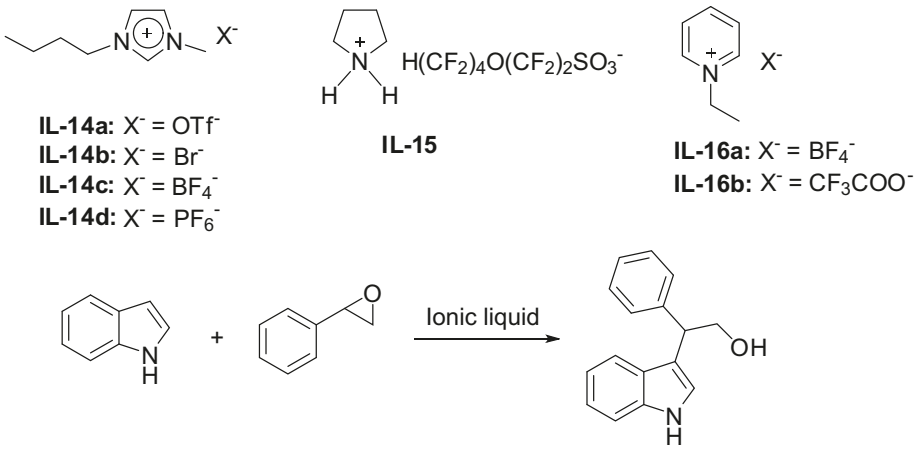
which played a dual role as a promoter and a solvent, to give excellent yields of chlorotetrahydropyrans in short reaction times (5–15 min) at room temperature. The Lewis acid species in this ionic liquid system was recognized to be $Al_2Cl_7^-$, and its concentration in the 1-*n*-butyl-3-methylimidazolium chloride ionic liquid depended on the amount of $AlCl_3$ present. The reaction rate was enhanced by increasing the molar fraction of $AlCl_3$ in the ionic liquid. However, no reaction was observed under both basic and neutral conditions.

The cyclization of homoallylic alcohols with various aldehydes was investigated by Fuchigami and co-workers[58] in some ionic liquids. The alkylammonium ionic liquids containing hydrogen fluoride played roles as reaction medium, promoter, and the fluorine source simultaneously in the Prins reaction. Whereas $Et_3N{\cdot}3HF$ (molar ratio = 1:3) and $Et_3N{\cdot}4HF$ did not promote the cyclization reaction, the reaction in **IL18**·5HF afforded the corresponding 4-fluorinated tetrahydropyrans in excellent yields with very high stereoselectivity (cis isomers exclusively). For benzaldehydes with an electron-donating group (OCH_3 or OH) at the para position, no stereoselectivity was observed (a mixture of cis and trans isomers was obtained in an almost 1:1 ratio).

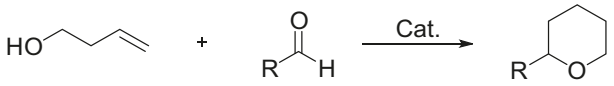
Applications in C–O bond formation reactions

Esterification



Organic esters, including aliphatic, arylic, and heterocyclic esters, are valuable intermediates in both chemical and pharmaceutical industries. The typical methodology employs Brønsted acids as the catalysts for esterification of carboxylic acids and alcohols. The main difficulty usually encountered in acid-catalyzed esterification arises from its reversible reactions (Scheme 12). To shift the equilibrium to favor ester production, it is necessary that one of the reactants is in excess and (or) the produced ester or water is removed constantly during the reaction.

In the past 10 years, Lewis acid or base ionic liquids have been synthesized and used as both reaction media and promoters in the esterification process. 1-Butylpyridinium chloroaluminate ionic liquid (**IL19**) developed by Deng et al.[59] was able to promote the esterifiation of acetic acid with equal equivalents of alcohols (isopropyl, isopentyl, isooctanol, benzyl alcohol, and glycerol) at 30–110 °C for 2 h. The study demonstrated that the aluminium chloride-based ionic liquid is stable enough to resist degradation by water if the molar ratio of aluminium chloride – butylpyridine chloride is 1:2. Comparison studies on the catalytic performance between **IL19** and concentrated sulfuric acid indicated that the ionic liquid gave better results under the same reaction conditions because the esters produced were not soluble in the reaction medium (ionic liquid). **IL19** was recycled three times and comparable yields and selectivity of esters were obtained in the reactions.



Another ionic liquid system prepared by choline chloride and $ZnCl_2$ was reported by Prasad and co-workers.[60] The Lewis acid ionic liquid (**IL20**) was used in the synthesis of wax esters using equal molar quantities of long-chain carboxylic acids and long-chain alcohols at 110 °C for 4–24 h. This liquid–liquid biphasic method shows several advantages in wax ester preparation. **IL20** is water insensitive, so there is no need to remove the water produced during the reaction. It can be reused for at least six cycles without pretreatment or significant loss of activity, and the liquid esters being a separate phase can be readily decanted from the ionic liquid phase after reaction. Thus, the use of volatile organic solvents for extraction can be avoided (Scheme 13).

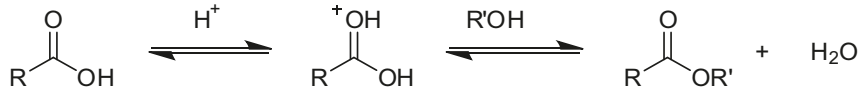
Scheme 10. A typical Prins reaction.

Scheme 11. Some ionic liquids used in Prins reactions.

The strong Brønsted acid ionic liquids (**IL21**–**IL22**), which bear an appended sulfonic acid group (SO_3H), were reported by Forbes and co-workers[61,62] (Scheme 14). **IL21a** showed no observable loss of triflic acid (CF_3SO_3H, bp = 162 °C at 760 torr; 1 torr = 133.3224 Pa) even under vacuum (10 torr) at 150 °C. For **IL22**, no free *p*-toluene sulfonic acid was found in the extracts after washing with toluene or diethyl ether. The application of these ionic liquids as dual solvent catalysts was demonstrated in the Fisher esterification. With an equal mole ratio of acetic acid and ethanol, both **IL21a** and **IL22** were able to promote the formation of ethylacetate in 82%–96% yields at 22–175 °C for 0.75–48 h. **IL22** was also successfully reused for five cycles in the esterification. Other acid-promoted organic reactions such as alcohol dehydrodimerization and pinacol–benzopinacole rearrangement were also explored for **IL22**.

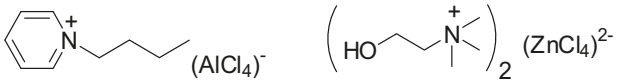
A number of other sulfonic acid-functionalized imidazolium ionic liquids, which are analogues of **IL21a** with different *n*-alkyl chain lengths, were reported by Deng and co-workers.[63] The addition reactions of aliphatic acids and olefins to give the corresponding esters were also investigated. The esters were simply isolated by decantation, and the ionic liquids were reused continuously after drying in a vacuum (5–12 mm Hg; 1 mm Hg = 122.3224 Pa) at 80 °C.

More recently, Fradet and co-workers[64] developed a new method for the synthesis of polyesters using a Brønsted acid ionic liquid. It was found that the polyesterification of 12-hydroxydodecanoic acid in **IL21b** yielded high molar mass poly(12-hydroxydodecanoic acid) at low to moderate temperatures (90–130 °C) in short reaction times (30–60 min) under atmospheric pressure. Another similar ionic liquid reported by Dai and co-workers[65] was also employed as a promoter and medium in the alcoholysis of acetonitrile to ester. The results showed that the Brønsted acid ionic liquid bearing an appended sulfonic acid group and with HSO_4^- as a counteranion gave better catalytic performance than other counteranions such as BF_4^- and $H_2PO_4^-$. However, the ionic liquid system encounters a solubility problem for the cyclic or long-chained alcohols because these substrates are relatively nonpolar. The highest yield of 85% was achieved for *n*-butyl alcohol. *n*-Octyl alcohol is almost insoluble in the ionic liquid medium and a poor yield of octyl acetate was obtained.



The pyridinium- and tetraalkylammonium-based ionic liquids functionalized with an appended sulfonic acid group were also investigated for ester synthesis. The Brønsted acids **IL23** and **IL24** with hydrogen sulfate as counterions were reported by Sun and co-workers[66] (Scheme 15). It was found that the esterification of ethanol and acetic acid (in 1:1 molar ratio) in these ionic liquid media gave both good conversion and high selectivity. Moreover, the liquid esters formed a separate phase that was readily decanted from the ionic liquid after reaction. The ionic liquids could be reused after removal of water under vacuum.

Li and co-workers[67] also reported a pyridinium-based ionic liquid that is similar to **IL23** (with a shorter alkyl chain) and demonstrated its activity in esterification of salicylic acid with a number of alcohols under microwave irradiation conditions. The results indicated that the sulfonic acid-functionalized ionic liquid with HSO_4^- as the counteranoin exhibited high catalytic activity and the esters were obtained in 92%–94% yield. The ionic liquid can be readily used after the separation of esters by decantation. The activity of the ionic liquids in esterification reactions is generally dependent on their Brønsted acidity.



Some other sulfonic acid-functionalized ionic liquids based on the tetraalkylammonium cation (structurally similar to **IL24** with either HSO_4^- or $H_2PO_4^-$ as the counteranions) were developed by Yu and co-workers.[68] In the investigation of the esterification of α-pinene and acetic acid, the ionic liquids functionalized with an alkyl sulfonic acid showed much better catalytic activity than those simply using H_2SO_4

IL23 **IL24**

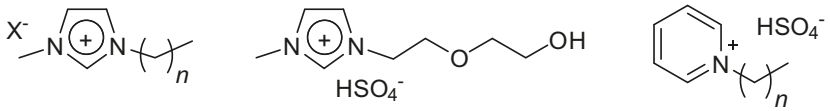
or H_3PO_4 as the catalyst in organic solvents. Moreover, the ionic liquid with HSO_4^- as the counteranion exhibited better catalytic performance (in terms of conversion and selectivity of esters) than the one with the $H_2PO_4^-$ anion. The difference in the selectivity of esters was attributed to the HSO_4^- anion, which possessed better stabilization ability than $H_2PO_4^-$ for the unstable carbonium intermediate during the esterification reaction.

Ionic liquids with acidic counteranions were also developed for esterification. For example, **IL25a**–**IL25b**, **IL26**, and **IL27** reported by Bazureau and co-workers[69,70] were used as the recyclable task-specific ionic liquids in the synthesis of lipophilic esters (Scheme 16). Experimental results showed that the increase of Brønsted acidity of the counteranion (**IL25a** and **IL25b**) could increase the reaction rate in the esterification reactions. In addition, the performance of an ionic liquid in the reaction is dependent on the character of the side chain of the cation (low lipophilic character of **IL25a** and high polarity of **IL26**). The immiscibility of the produced esters with the ionic liquid medium also facilitates the reaction equilibrium to shift to the product side. Along with the four ionic liquids examined in the esterification, **IL27** gave the best performance because of its low lipophilic characters. **IL25c** with dicyanamide as the couteranion was reported by Biswas et al.[71] This ionic liquid showed high solubility for maltodextrin and was demonstrated to be a good promoter and (or) medium for the reaction between maltodextrin and vinyl stearate or stearic acid at 75 °C.

Some simple alkylammonium salts including triethylammonium hydrogen sulfate, triethylammonium dihydrogen phosphate, and triethylammonium tetrafluoroborate were reported by Ganeshpure et al.[72,73] for the esterification of carboxylic acids with primary alcohols. The ionic liquids **IL28a**–**IL28d** utilized as the Brønsted acid promoter and reaction media in esterifications were prepared directly by the reaction of tertiary alkylamines with inorganic acids (Scheme 17). Among the various anions used, HSO_4^- gave the best activity because it provided strong Brønsted acidity for the catalysis. The ionic liquids with p-$CH_3C_6H_4SO_3^-$, $H_2PO_4^-$, or BF_4^- anions are relatively weaker acids and thus they show lower activity in the esterification reactions. For a given anion, however, the yield of esters was found to increase as the size of the ionic liquid cation became smaller. The better solvation of water by the smaller cations is probably responsible for their high activity. The ionic liquids also show phase separation properties in the esterification process. When the reaction was complete, the ester product did not dissolve in and readily separated from the ionic liquid medium. The separation and recycling process are therefore simple and convenient.

Ionic liquid **IL29** was synthesized by the reaction of *N*-alkylimidazoles with inorganic acids such as tetrafluoroboric acid. Tang and He and co-workers[74] reported the use of **IL29** in the esterification of a variety of carboxylic acids with some common alcohols (methanol, ethanol, 1-butanol, and 1-octanol) at 110 °C. The esters produced were easily separated as they are immiscible with the ionic liquid medium. No volatile organic solvent is required in the work up and recycling processes for the ester synthesis in **IL29**. Continuous removal of water or using an excess of reactant was also not necessary.

Later on, a similar ionic liquid system based on **IL29** for the esterification of alcohols with acetic acids was reported by Halligudi and co-workers.[75] A comparison study of **IL29** and **IL25d** on the catalytic activity for the esterification was also conducted. **IL29** was found to exhibit superior performance in the reaction, probably because of its stronger Brønsted acidity than that of **IL25d**.



Paal–Knorr furan synthesis

The Paal–Knorr synthesis is an important reaction in organic chemistry because it is the most widely used approach to generate furans, pyrroles, or thiophenes from 1,4-diketones. The substituted furans and pyrroles are the common structural components of many pharmaceutical and natural products. The reaction can proceed under neutral or slightly acidic conditions (Scheme 18). In general, the addition of a weak acid such as acetic acid accelerates the cyclization reaction. The use of amine or ammonium hydrochloride salts as the catalyst or by controlling the reaction pH at <3 lead to furans as the main products.

In recent years, many methods have been developed for the conversion of 1,4-dicarbonyl compounds to furan derivatives via acid-mediated dehydrative cyclization. The use of ionic liquids in the Paal–Knorr furan synthesis is relatively unexplored. There are only a few reports in the literature. A

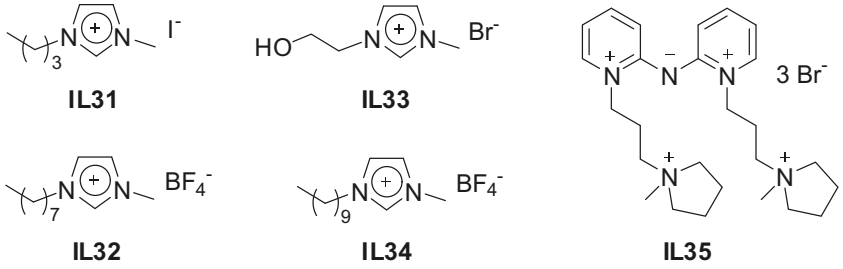
Scheme 20. The reaction of CO_2 with oxiranes to produce cyclic carbonates.

Brønsted acid ionic liquid (**IL30**) was reported independently by two research groups for furan synthesis (Scheme 19).[76,77] Wang and co-workers[77] demonstrated that **IL30** was able to promote the synthesis of 9-aryl-3,4,5,6,7,9-hexahydro-1*H*-xanthene-1,8-(2*H*)-dione. In the reaction, **IL30** offered remarkable improvement over existing methods with organic solvents. Excellent yields (85%–94%) of products were achieved in the ionic liquid system. The ionic liquid was recycled and reused without showing loss of activity. In addition, the nature of the anion and cation of ionic liquids showed strong influence on the catalytic performance in the Paal–Knorr reaction.

The Paal–Knorr reaction of the ester-substituted 1,4-diketones in **IL30** was first reported by He and co-workers.[76] In this ionic liquid system, a wide range of aliphatic and aromatic 1,4-diketones were able to undergo cyclization to form furan derivatives in high yields. A mechanism for the conversion of 1,4-diketones into furans in ionic liquid was also proposed. It was suggested that **IL30** acted as a Brønsted acidic promoter and provided protons to catalyze the reaction.

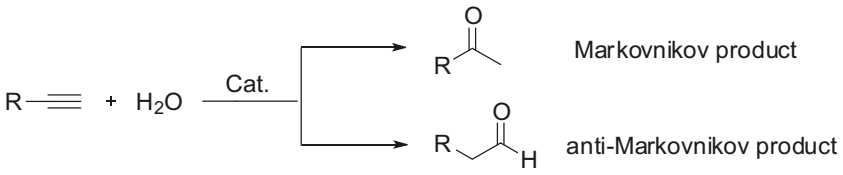
Chemical fixation of carbon dioxide

The reaction of CO_2 with oxiranes to form organic cyclic carbonates is readily catalyzed by a number of onium halide salts such as tetraethyl ammonium bromide (Scheme 20). The reaction also proceeds in the presence of a wide range of catalysts, including metal halides or transition-metal complexes in ionic liquid medium.[78–80] The utilization of ionic liquids as both reaction promoters and media in the transformation of CO_2 to cyclic carbonate under metal-free conditions has attracted increasing attention in recent years. Among the developed ionic liquid systems based on imidazolium, pyrridinium, and quaternary ammonium salts, halides such as Br^- and I^- are commonly used as the counteranions. It is probably because halides, particularly Br^- and I^- anions, are able to assist the ring-opening process of terminal epoxides.[81]



Tetrabutylammonium halides, such as bromide or iodide salts, have been reported to serve as solvents and promoters in cyclic carbonate synthesis from CO_2 and various epoxides. Caló et al.[82] reported that epoxides dissolved in tetrabutylammonium bromide (TBAB) reacted with CO_2 at atmospheric pressure to give good yields of cyclic carbonates. The cyclic carbonate was then isolated by vacuum distillation or by extraction with ethyl acetate. This procedure allowed the recycling of tetrabutylammonium salts. The possible role exerted by different cations such as imidazolium and pyridinium on the CO_2 fixation reaction was also investigated. It was found that the halide salts of imidazolium and pyridinium were unstable and readily decomposed under the high reaction temperature conditions. The stability of ionic liquids observed in this study is in accordance with a recent report.[83]

Another example of using TBAB in cyclic carbonate synthesis was demonstrated by Arai and co-workers.[84] In this system, two sequential reactions of epoxidation and cycloaddition were coupled into a one-pot process. Styrene carbonate was synthesized in ionic liquid medium by a direct oxidative carboxylation of styrene with *tert*-butyl hydroperoxide as the oxidant. It was found that both the structure of ionic liquids and the nucleophilicity of anions (nucleophilic tendency decreases in the order: $I^- > Br^- > Cl^-$) strongly affected the production of styrene carbonate. TBAB was identified to be the most effective promoter in the reaction.



IL31 reported by Kim and Cheong[85] is also an efficient promoter and reaction medium in the coupling reaction of CO_2 with propylene oxide (Scheme 21). Under mild reaction conditions (50 °C, 1 h), propylene carbonates were obtained in 87% yields. When ZnI_2 was added as a co-catalyst in the ionic liquid system, significant improvements on both yield and reaction rate were observed. Interestingly, when DMF was used as the solvent for the reaction, less than 4% yields

Scheme 22. Hydration of terminal alkynes.

Scheme 23. An ionic liquid for hydration of terminal alkynes.

of carbonates were obtained even when using ZnI_2 as the catalyst in the reaction.

A rapid and effective ionic liquid – supercritical CO_2 system for the synthesis of propylene carbonate was developed by Kawanami et al.[86] The reactions conducted in **IL32** (1-octyl-3-methylimidazolium tetrafluoroborate) were able to achieve 99% yield and 100% selectivity of propylene carbonate within 5 min at 100 °C under supercritical conditions (operation pressure at 14 MPa). The TOF value (516 h^{-1}) achieved in the study was 77 times larger than another system (operation pressure at 4 MPa, at 110 °C, TOF = 6.7 h^{-1}) that employed a similar ionic liquid (1-*n*-butyl-3-methylimidazolium tetrafluoroborate, **IL14c**) for the reaction.[87] This may be due to the increase in the solubility of both CO_2 and propylene oxide in **IL32** as its *n*-alkyl chain is lengthened. Under supercritical conditions, the effects of counterions (NO_3^-, $CF_3SO_3^-$, BF_4^-, and PF_6^-) of the 1-ethyl-3-methylimidazolium ionic liquid were also investigated. BF_4^- was found to be most effective for promoting the chemical fixation of CO_2.

The hydroxyl-functionalized ionic liquid (**IL33**) developed by Zhang and co-workers[88] was also an effective medium for the synthesis of cyclic carbonate in the absence of co-catalyst and co-solvents. The OH group of **IL33** was demonstrated to be essential for the reaction to proceed smoothly because it facilitates in the ring opening of epoxides. The reaction of propylene oxide and CO_2 in **IL33** under 125 °C and 2.0 MPa for 1 h gave 99% conversion of propylene oxide and 99.8% selectivity of propylene carbonates. More recently, a similar system in which the ionic liquid was functionalized with one or more carboxylic acid groups (COOH) was reported as an efficient acid–base bifunctional catalyst for the fixation of CO_2 with epoxides under metal and solvent-free conditions.[89]

IL34 reported by Deng and co-workers[90] was also an effective promoter and reaction medium for the carbonylation of amines with propargylic alcohol using CO_2 as the carbonyl source to yield N-substituted 4-methylene-2-oxazolidinones under mild conditions. Comparison studies using dimethyl sulfoxide and toluene as solvents without additional catalysts under the same reaction conditions indicated that the CO_2 fixation reaction between cyclohexyl amine and 2-methyl-3-butyn-2-ol did not proceed readily. It was thus suggested that the ionic liquid took some crucial effects in the reaction. In addition, the nature of the cation and anion of **IL34** exhibited a strong influence on the formation of N-substituted 4-methylene-2-oxazolidinone derivatives.

A robust ionic liquid (**IL35**) that integrated with both pyrrolidinium and pyridinium moieties was developed by Wong et al.[91] for chemical fixation of CO_2. **IL35** designed with polycationic sites was demonstrated to be an efficient promoter and reaction medium in the synthesis of cyclic carbonates from CO_2 and epoxides. The ionic liquid system without other metal salts as co-catalysts showed excellent reactivity and selectivity of cyclic carbonates under the conditions of mild reaction temperature (80 °C) and low operation pressure (0.5 MPa). Also, the ionic liquid could be recycled and reused without significant loss in its catalytic activity. However, **IL35**, similar to many ionic liquid-based catalytic systems reported in literature, encountered difficulties for nonpolar epoxides. For the long-chain aliphatic epoxides such as 2-butyloxirane, the yield of isolated product was found to be 58% under relatively harsh reaction conditions (80 °C, 3 MPa, 3 h). The reduced productivity in the reaction was presumably caused by the lower solubility of the long-chain aliphatic epoxides in the highly polar ionic liquid medium.

Hydration of alkynes to ketones

Hydration of alkynes to carbonyl compounds is one of the most important and fundamental functional group transformations. The addition of water to alkynes requires a strong acid, usually sulfuric acid, and is facilitated by mercuric sulfate (Scheme 22). In general, the addition of water to alkynes gives ketones as the product (except for acetylene, which yields acetaldehyde) in the mercuric–sulfuric acid system. In recent years, alternative transition-metal complexes have also been successfully developed for hydration of alkynes. Some

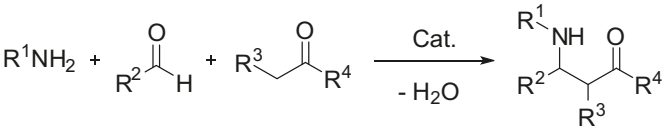
of these metal-catalyzed systems are able to produce aldehydes selectively (anti-Markovnikov product) from terminal alkynes.[92]

The use of functionalized ionic liquids for the transformation of alkynes to ketones or aldehydes is relatively unexplored. In addition, most methodologies reported in the literature for this chemical process are usually carried out in organic solvents. Recently, a nonmetallic protocol based on **IL36** with a small amount of sulfuric acid for rapid conversion of alkynes to ketones has been reported by Wong et al.[93] In the ionic liquid system, various alkynes were efficiently converted to ketones under mild conditions (40 °C, 0.5 h). Moreover, the system exhibited excellent reactivity and stability over multiple cycles. The good efficiency of the system is attributed to the high chemical activity of protons in the ionic liquid medium. A larger scale hydration of phenylacetylene (up to 70 mmol) was also demonstrated with good yield and selectivity. The product could be isolated in high yields by vacuum distillation. Both the ionic liquid medium and H_2SO_4 can be constantly recycled and promoted the transformation of terminal alkynes to ketones without losing its catalytic reactivity (Scheme 23).

Applications in C–N bond formation reactions



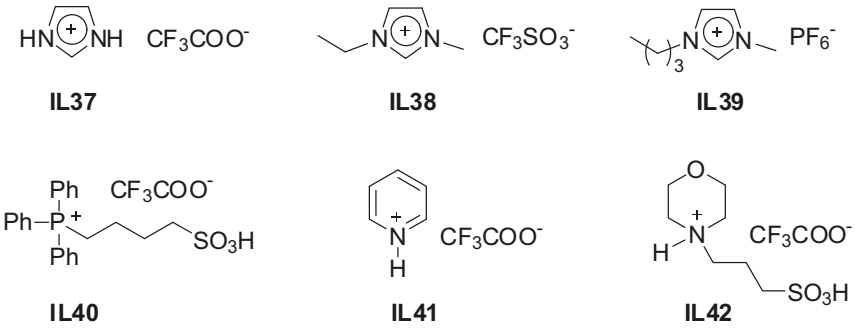
Mannich reaction

The Mannich reaction is a one-pot three-component reaction, which consists of an amino alkylation of an α-methylene carbonyl compound (an acidic proton placed next to a carbonyl functional group) with an aldehyde and ammonia or any primary and (or) secondary amine (Scheme 24). The final product is a β-aminocarbonyl compound, which is also known as Mannich base. The β-aminocarbonyl compounds are the key intermediates for the synthesis of natural products and pharmaceutically valuable compounds. During the past decade, Lewis acids or bases, Brønsted acids, and rare earth metal salts have been used as active catalysts in Mannich-type reactions.

In recent years, the use of ionic liquid for Mannich reactions has attracted considerable attention. Brønsted acid ionic liquids, including l-butyl-3-methylimidazolium hydrogen sulfate, l-butyl-3-methylimidazolium dihydrogen phosphate, 1-methylimidazolium *p*-toluenesulfonic acid and 1-methylimidazolium trifluoroacetic acid developed by Jiang and co-workers,[94] were demonstrated to be effective solvents and promoters for the three-component Mannich reaction of aldehdyes, amines, and ketones at 25 °C. **IL37** was able to catalyze the reaction efficiently and exhibited the highest catalytic activity among the ionic liquids examined in the investigation. Increasing the amount of **IL37** in the reaction could also improve the Mannich base formation. In addition, as indicated by the results of control experiments, Mannich reactions taking place in ionic liquids could in general produce higher yields than traditional systems conducted in organic solvents such as ethanol.

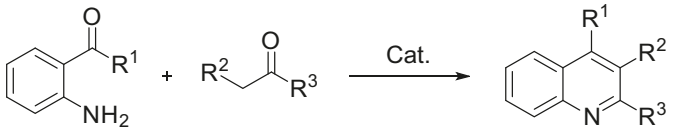
A Lewis acid ionic liquid **IL38** (1-ethyl-3-methylimidazolium triflate) was reported by Akiyama et al.[95] to effectively promote the Mannich-type reaction of silyl enolates with aldimines. The reaction simply employed **IL38** as the solvent without the addition of extra activator, and excellent yields of β-aminocarbonyl compounds were obtained under room-temperature conditions. The ionic liquid could be recycled as least 5 times before a significant decrease in the yield was observed. Another imidazolium-based ionic liquid (**IL39**) was developed by Xu and co-workers[96] for the synthesis of 2,2-dimethyl-6-substituted 4-piperidones via the Mannich reaction. When compared with the results in organic solvents such as ethanol or ethylene glycol, the Mannich reactions taking place in **IL39** usually gave a better performance in chemoselectivity (up to 78%). It was speculated that **IL39** might favor the formation of imine and, consequently, resulted in a preferential occurrence of Mannich reaction over aldol reaction. The different chemoselectivities obtained in various ionic liquid media may be attributed to the different viscosity of the ionic liquids or ammonia solubility. However, the addition of L-proline (20 mol%) as the co-catalyst in **IL37** resulted in a chemoselectivity up to 93% (Scheme 25).

Scheme 24. A typical Mannich reaction.



The ionic liquid **IL40** reported by Joseph and co-workers[97] was Brønsted acidic and was able to catalyze the Mannich reaction smoothly to afford β-aminocarbonyl compounds in excellent yields with short reaction times at 25 °C. In the reaction, benzaldehyde, aniline, and acetophenone were in equal molar ratios. It was found that the system suffered from poor miscibility and therefore a low yield of products was obtained. However, simply adding a small amount of water into the ionic liquid medium could improve the productivity effectively. The ionic liquid could be separated by water extraction from the reaction mixture and was recycled 4 times without any loss in activity. The structure of the ionic liquid was confirmed by NMR and remained unchanged after recycling.

An acidic pyridinium trifluoroacetate (**IL41**) synthesized by Yue et al.[98] was also investigated in the Mannich reaction of various aromatic aldehydes, aromatic ketones, and aromatic amines. The corresponding β-aminocarbonyl compounds were obtained in reasonable yields (50%–90%) at room temperature. As the molar ratio of benzaldehyde, acetophenone, and aniline was 1:1:1, the yield of product was increased with an increasing amount of **IL41** (130 mol% of a reactant). **IL41** was believed to provide protons to catalyze the Mannich reaction. The ionic liquid was reused 4 times without significant loss of activity. The morpholinium-based ionic liquid **IL42**, which is functionalized with an alkane sulfonic acid group, was utilized for the Mannich reactions with a number of aromatic aldehydes, acetophenone, and aromatic amines under mild reaction conditions.[99] In this ionic liquid system, the addition of a small amount of water could also improve the yield of Mannich products. However, in the case of using HSO_4^- as the counteranion, no Mannich product was obtained under the same reaction conditions because the strong acidic ionic liquid readily reacted with aniline.



Friedländer synthesis

The Friedländer synthesis is a convenient method for the preparation of quinoline derivatives. This class of compounds

shows a broad range of biological activities such as antibacterial and antihypersensitive activities. The synthesis typically involves the condensation reaction of a 2-aminoaryl ketone and a carbonyl compound with a reactive α-methylene group and is usually catalyzed by strong acids or bases (Scheme 26).

Recently, Friedländer reactions have also been investigated in ionic liquids.[100,101] Some simple acidic ionic liquids, for example, the Lewis acidic choline chloride – $ZnCl_2$,[102] 1-butyl-3-methylimidazolium chloride – $ZnCl_2$,[103] and ethyl-ammonium nitrate[104], were recognized as excellent solvents and promoters for green synthesis of quinolines via Friedländer reactions under mild conditions.

Srinivasan and co-workers[105,106] evaluated a number of 1-butylimidazolium ionic liquids with varying anions in the preparation of substituted quinolines and fused polycyclic quinolines through Friedländer heteroannulation reactions (Scheme 27). **IL43** was found to be the best ionic liquid for this synthesis. The efficiency of the ionic liquid for promoting the heterocyclization reaction increased progressively with the increase of Brønsted acidity of ionic liquids in the reaction. This correlation became more obvious in a comparison study that used **IL44** (less acidic than **IL43**) as the reaction medium under similar conditions. However, the ionic liquid system based on **IL43** suffered some drawbacks from its reaction conditions. For example, the reaction of *o*-aminoacetophenone with cyclopentanone in **IL43** at 90 °C for 24 h only gave a conversion of less than 30%. On other hand, when the temperature was increased to 130 °C, **IL43** decomposed during the reaction.

aza-Michael addition

The aza-Michael addition is an important reaction for the synthesis of C–N heterocyclic compounds with a β-aminocarbonyl functional moiety (Scheme 28). This class of compound serves as essential intermediates in the synthesis of a number of biologically active compounds, such as β-amino ketones, β-amino acids, and β-lactam antibiotics. The aza-Michael reactions are generally promoted by harsh bases or strong acids.

Recently, some room-temperature ionic liquids such as 1-butyl-3-methylimidazolium salts (with BF_4^- or PF_6^- as counterions) have been found to be efficient promoters for the conjugate addition reaction of azides to α,β-unsaturated carbonyl compounds. The use of azides as the Michael donor is a new synthetic procedure in aza-Michael addition reactions.[107] A basic ionic liquid (1-butyl-3-methylimidazolium hydroxide) developed by Lin and co-workers,[108–110] was used as both promoter and reaction medium in aza-Michael addition reactions for various amines and α,β-unsaturated carbonyl compounds. Control experiments in the addition reaction of piperidine and methyl acrylate, taking place in organic solvents such as THF and DMSO without adding 1-butyl-3-methylimidazolium hydroxide, gave yields of only less than 30% after 48 h reaction. These results indicated the ionic liquid played the role of promoter while serving as the reaction medium.

1-Butyl-3-methylimidazolium thiocyanate ionic liquid (**IL45**) developed by Yadav et al.[111] was also investigated in the aza-Michael addition of diethyl *N*-arylphosphoramidates to chalcones. The excellent reactivity and high diastereoselectivity achieved in **IL45** was probably induced by the NCS^- anions of the ionic liquid. Adding KSCN salt to 1-butyl-3-methylimidazolium tetrafluoroborate ionic liquid instead of using **IL45**, however, gave a significantly lower yield of product. This indicates that the nucleophilicity of NCS^- anion was considerably higher in **IL45** compared with that of KSCN (Scheme 29).

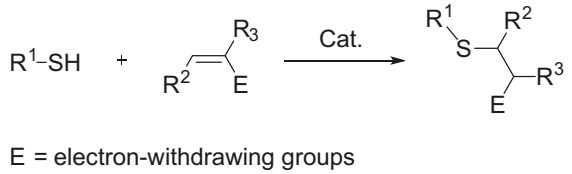
The use of a DBU-derived ionic liquid as a promoter in aza-Michael addition was reported by Chen and co-workers.[112] The basic ionic liquid **IL46** was found suitable for the conjugate addition of various aliphatic or aromatic amines to various electron-deficient alkenes under room-temperature conditions. It was demonstrated that the protocol could be scaled up to 100 mmol. **IL46** was recovered by drying under vacuum at 60 °C for 5 h after the reaction and was reused for 6 times without significant loss of catalytic activity.

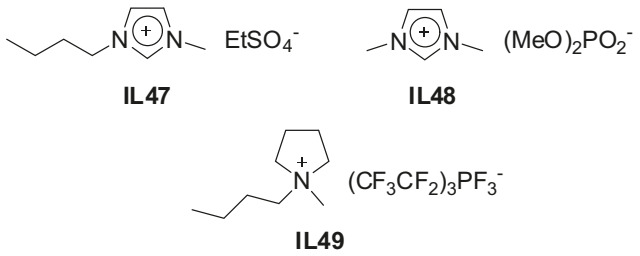
Applications in C–S bond formation reactions

Thia-Michael addition



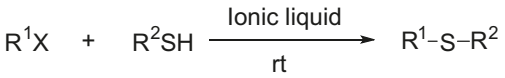
The conjugate addition of thiols to α,β-unsaturated carbonyl or nitrile compounds by Michael reaction to form carbon–sulfur bond constituents is an important reaction in both biosynthetic processes and organic synthesis. A large number of methods have been developed for the 1,4-addition of thiols to electron-deficient olefins through the activation of thiols (sulfur nucleophiles as the Michael donors) by using bases or acids as catalysts (Scheme 30).

α,β-Unsaturated ketones undergo rapid conjugate addition with thiols in a hydrophobic ionic liquid, such as 1-butyl-3-methylimidazolium hexafluorophosphate (with water as a co-solvent), without the use of any acid catalyst to afford the corresponding Michael adducts in high to quantitative yields. This ionic liquid system developed by Yadav et al.[113] exhibits excellent 1,4-selectivity under mild and neutral conditions. The ionic liquid plays the dual role of solvent and promoter in the Michael addition reactions. The reactivity of enones can be enhanced in ionic liquid medium and thus the reaction time was reduced and the yield was improved. The recovered ionic liquid was reused 4–5 times with consistent activity. In addition, Ranu and Dey[114] reported the use of 1-pentyl-3-methylimidazolium bromide in the Michael addition of aliphatic and aromatic thiols with a variety of acyclic- and cyclic-conjugated alkenes at room temperature. The role of the ionic liquid in the catalytic system was also investigated. It was postulated that the bromide ion forms a hydrogen bond to the thiol and then increases the nucleophilicity of the sulfur atom. The thiolate anion is thus a better Michael donor for the addition reaction of conjugated alkenes.



Sharma and Degani[115] reported the use of 2-hydroxyethylammonium formate as a cost-effective ionic liquid for the thia-Michael addition reaction. This ionic liquid system was effective in the addition of various aromatic sulfur nucleophiles to the activated olefins and could be recycled without significant loss in activity. The activity of this ionic liquid was comparable to ethyl-tri-*n*-butylphosphonium tosylate ionic liquid,[116] but showed better catalytic activity than 1-pentyl-3-methylimidazolium bromide.

The use of a phosphonium-based ionic liquid such as tetradecyl-trihexylphosphonium chloride in the thia-Michael addition of aromatic thiols to chalcones was reported by Pawar and co-workers.[117] This ionic liquid was highly basic and thermally more stable than ammonium salts. However, it exhibited higher viscosities than the ammonium ionic liquids at room temperature. The viscosity can be reduced by raising the temperature to 70–100 °C. In addition, tetraalkylphosphonium ionic liquid is chemically more stable compared with the imidazolium cations because it does not have acidic protons or aromatic rings.



Scheme 30. A typical C–S bond formation via Michael addition.

Scheme 31. Some ionic liquids used in thia-Michael addition reactions.

Scheme 32. The conversion of thiols to thioether in ionic liquid.

Organocatalyzed addition of thiophenols to chalcones in ionic liquids was also reported by Toma and co-workers.[118] The reactions carried out in ionic liquids **IL47**–**IL49** without any additional catalysts gave excellent yields. Comparison studies showed that the addition reactions conducted in ionic liquid media generally proceeded faster than those in organic solvents. Also, the reaction rate was strongly dependent on the structure of the ionic liquids. **IL48** showed a much higher reaction rate (2 min, 94%) than **IL47** (15 min, 94%) and **IL49** (3 h, 91%) under the same conditions. A possible explanation for the high reactivity of thiophenol in ionic liquids, particularly in **IL48**, could be that the dissociation constant of thiophenol is higher in ionic liquids than in organic solvents. Furthermore, **IL48** is slightly basic in nature, whereas **IL47** and **IL49** are neutral. It thus facilitates the formation of PhS^- anions from PhSH. Consequently, the reaction rate was effectively enhanced in **IL48** (Scheme 31).

Thioether and thioester synthesis

Thioethers and thioesters are very useful building blocks for the preparation of various organosulfur compounds. A number of synthetic methods have been reported in the literature. The convenient and direct conversion of thiols to thioethers or thioesters usually involves the reaction of thiolate anions with organic halides. A room-temperature ionic liquid (1-pentyl-3-methylimidazolium bromide) used for this chemical process was reported by Ranu and Jana.[119] The ionic liquid was able to promote the reaction of alkyl halides or acyl halides with thiols to give thioethers or thioesters in high yields at room temperature (Scheme 32). This ionic liquid system was also extended for the synthesis of dithianes and *trans*-thioetherification. The products were isolated by direct distillation from the reaction mixture under reduced

Can. J. Chem. Downloaded from www.nrcresearchpress.com by Renmin University of China on 09/02/12

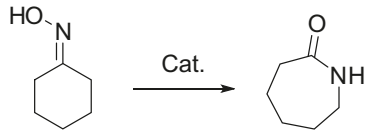
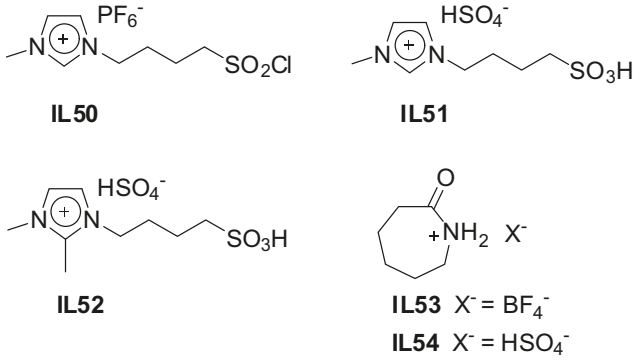
pressure and therefore the ionic liquid could be readily recovered and recycled.

Applications in other chemical reactions



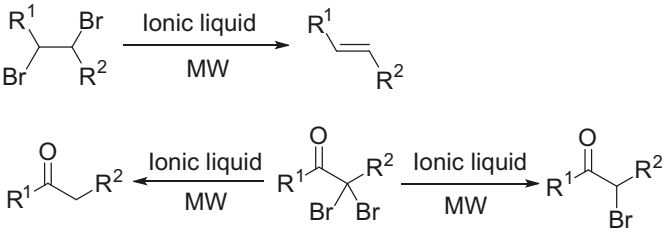
Beckmann rearrangement

The Beckmann rearrangement is an important synthetic method for the preparation of various N-substituted amides, which are valuable intermediates for the synthesis of various natural products and medicinal drugs and materials, through the conversion of ketoximes to amides. ε-Caprolactam, for example, has been synthesized industrially through the Beckmann rearrangement of cyclohexanone oxime (Scheme 33). The reaction is usually conducted with stoichiometic or excess amounts of strong Brønsted or Lewis acids under high-temperature (130 °C) conditions. Over the past years, ionic liquid systems with catalytic amounts of acidic catalysts, such as PCl_5,[120,121] P_2O_5,[122] H_2SO_4,[123] metaboric acid,[124] cyanuric chloride,[125] and $ZnCl_2$[126] have been developed for this chemical process.

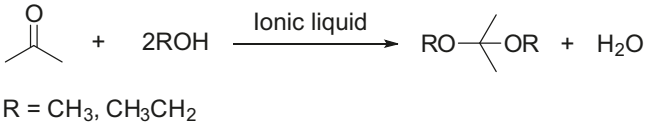


An imidazolium-based ionic liquid functionalized with a sulfonyl chloride group was developed by Sun and co-workers[127] and was demonstrated to be a stable and highly active reaction medium for Beckmann rearrangement of ketoximes under mild conditions. **IL50** was found particularly effective for the conversion of cyclohexanone oxime to ε-caprolactam (Scheme 34). For a reaction taking place at 80 °C for 2 h, 98% conversion and 98% selectivity of ε-caprolactam were achieved. The ionic liquid is immiscible with water, whereas ε-caprolactam has good solubility. The products were easily separated from **IL50** by water extraction. **IL51** and **IL52** (both functionalized with a sulfonic acid group) also showed good performance for the preparation of ε-caprolactam via the Beckmann rearrangement. Lévêque and co-workers[128] revealed that the good activity of these ionic liquid systems was essentially a result of the acidity of the sulfonic acid group on the ionic liquid. However, the ionic liquids also suffered from their high viscosity when they were used as a reaction medium. The drawbacks could be overcome at higher reaction temperatures. Moreover, it was concluded that a combination of the hydrogen sulfate anion and the sulfonic acid group of an ionic liquid was needed to obtain the rearrangement product rapidly under mild conditions.

Caprolactam-based Brønsted acidic ionic liquids were also developed as effective promoters and (or) media for the Beckmann rearrangement of cyclohexanone oxime to afford caprolactam. **IL53** reported by Deng and co-workers[129] was able to achieve high conversion (93%) and good selectivity (89%) at 100 °C. The occurrence of the Beckmann rearrangement of cyclohexanone oxime in **IL53** was confirmed by in situ FT-Raman spectroscopy. Later on, Horváth and co-workers[130] also reported the use of **IL54** for this reaction. The mechanism for the conversion of cyclohexanone oxime into caprolactam in **IL54** was established using NMR spectroscopy. The results indicated that the cyclohexanone oxime was first protonated (either on the oxygen or the nitrogen atom), followed by the elimination of water to form a cationic species, which was identified as a key intermediate in the Beckmann rearrangement. The study also pointed out that the mixture (or oleum) of caprolactam and sulfuric acid should be considered as an ionic liquid. In addition, the mixture (**IL54**) was able to hold SO_3 very strongly up to 140 °C and therefore provided a safe environment for a very exothermic reaction.



Scheme 33. A typical Beckmann rearrangement reaction of cyclohexanone oxime.



Scheme 34. Some ionic liquids developed for Beckmann rearrangement reactions.

Scheme 35. Debromination reactions in ionic liquid.

Scheme 36. The preparation of dialkoxypropanes in ionic liquid.

R = CH_3, CH_3CH_2

Debromination reaction

A debromination reaction is usually carried out in organic solvents under refluxing conditions with a reactive metal, such as Sm, In, Mg, and Zn, as the reducing agent. Ranu and Jana[131] developed a simple ionic liquid system for this process without using metals. The investigation demonstrated that the stereoselective debromination of a variety of structurally diverse vicinal-dibromides to the corresponding *E*-alkenes could be achieved in ionic liquid medium (1-methyl-3-pentylimidazolium fluoroborate) under microwave irradiation for 2–5 min (Scheme 35). The reaction did not occur without the ionic liquid and did not proceed effectively in 1-methyl-3-pentylimidazolium bromide under similar reaction conditions. It was therefore proposed that the BF_4^- anion of the ionic liquid plays a vital role in the debromination process under microwave irradiation conditions. The ionic liquid also promoted the selective debromination of α-bromoketones

Can. J. Chem. Downloaded from www.nrcresearchpress.com by Renmin University of China on 09/02/12
For personal use only.

under microwave irradiation.[132] *gem*-α-Dibromoketones were selectively debrominated to either monobromoketone or debromoketones as the final product by controlling the reaction time of the process.

Dialkoxypropane synthesis

Dialkoxypropanes are a class of valuable fine chemicals widely used in polymer preparation, surfactants, and natural product extraction. They are also important intermediates in pharmaceutical and medicinal industry for the synthesis of clarithromycin, β-ionone, vitamin A, and vitamin E. The formation of dialkoxypropanes from ketones and alcohols with acid catalysts is one of the most practical methods.

Li and co-workers[133] reported the use of some simple ammonium ionic liquids as reaction promoters and media for the preparation of a dialkoxypropane (2,2-dimerthoxypropane) from acetone and methanol or ethanol (Scheme 36). These air- and water-stable ammonium ionic liquids were easily synthesized from the reaction of acids and various alkylamines, such as diethylamine, ethylamine, triethylamine, *n*-tripropylamine, isopropylamine, *n*-tributylamine, and *n*-butylamine. The study demonstrated that the catalytic activity of the ionic liquids was strongly influenced by their anions. The best results were obtained using ionic liquids with hydrogen sulfate counteranions, for example, $[Et_3NH]^+[HSO_4]^-$, probably because of their high acidity. The ammonium cations showed only a small influence on catalytic performance. Nonetheless, the immiscibility of the dialkoxypropanes produced with the ionic liquid medium shifted the reaction equilibrium in favor of dialkoxypropane formation.

Conclusions and outlook

This review summarizes some successful examples of using functionalized ionic liquids as both reaction media and promoters in a number of important chemical reactions including C–C, C–O, C–N, and C–S bond formation. Ionic liquids designed with special functionality are generally found to enhance the reaction rate, selectivity, and productivity in various chemical reactions.

The recent developments of ionic liquids in catalysis as well as in other research fields indicates that ionic liquids are no longer just "green solvents" for the replacement of organic solvents. Numerous excellent papers published in recent years also demonstrate the novel applications of ionic liquids with specific functionalities in chemical reactions, catalysis, separation, and material science.

There is no doubt that ionic liquids can provide advantages over conventional solvents in the development of green technologies through molecular design and synthesis of new ionic liquids with different functionalities. Nevertheless, with respect to the literature reviewed in this article, imidazolium-based ionic liquids are still dominant in ionic liquid design over other analogues such as pyrrolidinium and alkylammonium, although the later two classes of cations are chemically more stable. As a matter of fact, ionic liquids used as solvents or catalysts in organic synthesis are not totally inert under the reaction conditions. In some cases, they provide unexpected reactivity and are advantageous to the reaction, whereas in others they may lead to problems. It is thus imperative that properly selecting or preparing an ionic liquid for a particular application is essential, and more attention should be paid to its compatibility with the reaction conditions. However, only a few reports addressed the stability issues of ionic liquids in organic reactions and catalysis.[82,83,105,106]

It can be foreseen that new utilizations of ionic liquids will appear over time. Large-scale applications of ionic liquid however remain a challenge which is of great importance for industrial processes. We expect that more and more exciting discoveries and news will emerge in the coming decade.

REVIEW / SYNTHÈSE

Discovery of green tea polyphenol-based proteasome inhibitors — A successful collaboration with Tak-Hang (Bill) Chan

Kristin Landis-Piwowar, Saeed Bazzi, and Q. Ping Dou

Abstract: This article is written to commemorate the contributions of Professor Tak-Hang (Bill) Chan to the field of chemistry and his collaborative efforts that have lead to insights pertaining to cancer cell biology and the development of potential cancer therapeutic agents. This article reviews the chronological scientific findings that evolved from a partnership between Bill Chan and Q. Ping Dou, spanning more than 10 years. While many compounds have been chemically synthesized by the Chan group and biologically scrutinized by the Dou group, the outcomes presented here will focus on green tea polyphenols as tumor proteasome inhibitors and anticancer agents. Furthermore, the biochemical alterations that increase or decrease the therapeutic potential of the polyphenol compounds in human cancer cells will also be discussed.

Key words: proteasome, anticancer agents, (–)-epigallocatechin-3-gallate (EGCG), structure–activity relationships.

Résumé : Cet article a été rédigé pour commémorer les contributions du professeur Tak-Hang (Bill) Chan au domaine de la chimie et les efforts de collaboration qui ont conduit à une meilleure compréhension de la biologie cellulaire du cancer et au développement d'agents thérapeutiques potentiels pour le cancer. Cet article présente une revue chronologique des découvertes scientifiques découlant des travaux effectués en partenariat entre Bill Chan et Q. Ping Dou sur une période s'étalant sur plus de 10 ans. Même si plusieurs composés ont été obtenus par synthèse chimique par le groupe de Chan et que ceux-ci ont été étudiés d'un point de vue biologique par le groupe de Dou, les résultats présentés ici sont focalisés sur les possibilités d'utiliser les polyphénols du thé vert comme inhibiteurs de protéasome de tumeurs et comme agents anticancéreux. Des plus, on discute aussi des modifications biochimiques qui augmentent ou qui diminuent le potentiel thérapeutique des composés polyphénols dans les cancéreuses humaines.

Mots-clés : protéasome, agents anticancéreux, gallate d'épigallocatéchine (GEGC), relations structure activité.

[Traduit par la Rédaction]

Introduction

This year is the 10th anniversary of our collaboration with Professor Tak-Hang (Bill) Chan. Our collaboration has focused on discovering novel green tea polyphenol-based proteasome inhibitors for cancer treatment and prevention. Chan's contributions, both intellectually and chemically, have been vital to the success of understanding the manner in which green tea polyphenols inhibit proteasome activity in cancer cells. Chan's group has been instrumental in conceptualizing and generating compounds that impart proteasome inhibition and ultimately anticancer effects in numerous cell culture and animal models. The compounds developed by his group have proven to be potentially used as alternatives to some of the more traditional cancer therapeutics.

The proteasome is the heart of ubiquitin-mediated protein degradation and is responsible for the vast majority of regulated proteolysis in eukaryotic cells. Proteasome function is crucial for biological homeostasis and the regulation of numerous cellular processes in both normal and cancer cells. For this reason, understanding the anticancer effects of molecules that inhibit proteasome activity persists. While it may seem disastrous to alter the activity of this crucial protein degradation system, proteasome inhibition has been well established as a rational strategy for multiple myeloma,[1,2] non-Hodgkin lymphoma,[3] and some solid tumors.[4]

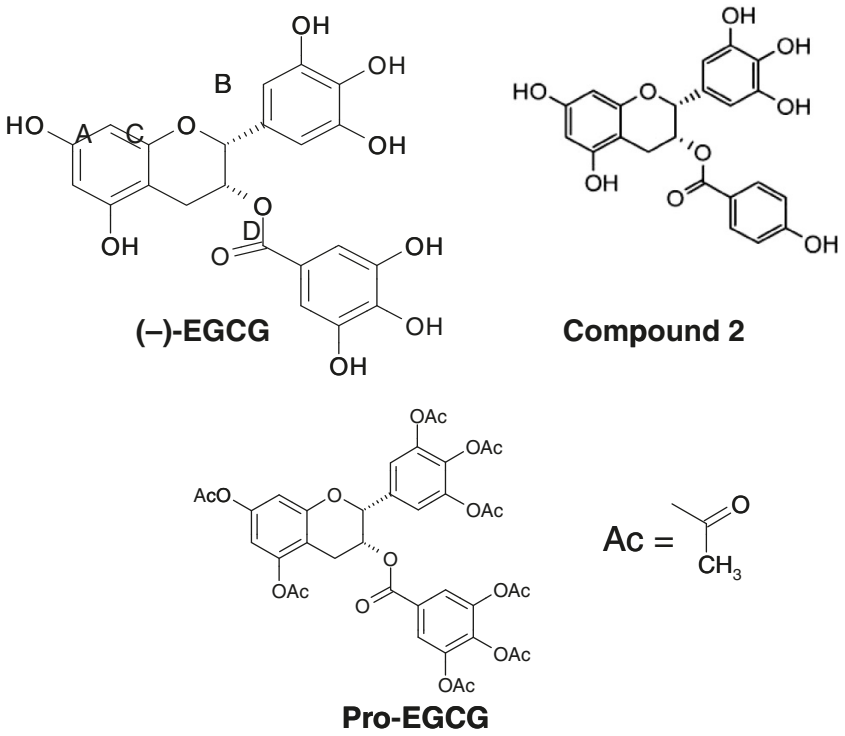
Bortezomib (Velcade, PS-341) was the first proteasome inhibitor to receive approval from the US Food and Drug Administration for the treatment of multiple myeloma and mantle cell lymphoma. Clinical trials have indicated that bortezomib has remarkable efficacy against hematological malignancies, in both single and combination regimens. However, bortezomib has failed to show significant efficacy for the treatment of solid tumors. The toxicity of bortezomib was also observed in clinical trials, which warrants continued examination of new compounds that exhibit safe, nontoxic proteasome inhibition. Bill Chan has been pivotal in chemically synthesizing numerous compounds, such as green tea polyphenol derivatives, as reviewed in this article, that have been investigated for their proteasome-inhibitory activities. Significantly, green tea polyphenols, as well as several other flavonoids (e.g., curcumin, genistein, and resveratrol), have been shown to not only act as anticancer agents alone, but have also demonstrated chemosensitizing properties in prostate, breast, hepatic, and lung tumors.[5]

Because proteasome inhibition was well established as a mechanism to induce tumor cell growth arrest or cell death and because consumption of green tea has been associated with cancer prevention, our group began investigating the green tea compound (–)-epigallocatechin-3-gallate or EGCG (Fig. 1) for its potential as a proteasome inhibitor. Our group first described that ester bond-containing tea polyphenols, such as EGCG, potently and specifically inhibited the chymotrypsin-like (CT-like) activity of the proteasome, but not trypsin-like activity, in vitro (IC_{50} = 86–194 nmol/L) and in vivo (1–10 μmol/L), at the concentrations found in the serum of green tea drinkers. Among the tea polyphenols examined, EGCG showed the strongest inhibitory activity against purified 20S proteasome, 26S proteasome of tumor cell extracts, and 26S proteasome in intact tumor cells. Atomic orbital energy analyses and high performance liquid chromatography (HPLC) indicated that the carbonyl carbon of EGCG is essential for proteasome inhibition and resulted in accumulation of the natural proteasome substrates, p27 and IκB-α. Furthermore, normal human fibroblasts were found to be resistant to EGCG-mediated proteasome inhibition compared with a simian virus-transformed fibroblast counterpart. These early studies suggested that the proteasome is a cancer-related molecular target of tea polyphenols and its inhibition by ester bond-containing polyphenols may contribute to the cancer-preventative effect of tea.[6]

While our group investigated the biological effects of EGCG, Chan's group began the enantioselective synthesis of EGCG. Their work was critical for subsequent studies that required a pure compound without the laborious extraction of EGCG from the leaves of the *Camillia sinensis* plant. Until then, green tea polyphenols had been extracted or purified from green tea leaves for preclinical and clinical studies. At the time, EGCG was isolated from green tea extract, and the yield was highly dependent upon the processing and source of the tea. With the advancement of EGCG chemical synthesis, mechanistic studies for the cellular action of EGCG could be evaluated. A synthetic approach for the generation of EGCG and its analogs was thus developed to provide sufficient quantities of the biochemicals for examination as anticancer agents.[7]

In 2001, while working at the Moffitt Cancer Institute, Tampa, Florida, Dr. Dou read Chan's aforementioned paper and was impressed by his novel synthetic route for EGCG. Dr. Dou then approached him by e-mail to ask if he was willing to do a collaboration to study the effect of his synthetic EGCG analogs on tumor proteasomes. Dr. Chan was pleased to accept this invitation after reading our manuscript.[6] Our 10-year collaboration started from there. While the collaboration continued, in 2003, Dr. Dou moved to his current position (Karmanos Cancer Institute, Wayne State University, Detroit, Michigan), which is much closer to McGill University in Montreal, Quebec, and the proximity brought us several fruitful visits.

Chemical and biological analysis of natural product synthetic analogs



The novel synthesis of green tea polyphenols as proteasome inhibitors

Over the last 10 years, we have studied proteasome activity and apoptosis induction in cells that have been exposed to naturally occurring and chemically synthesized derivatives of green tea. We identified that ester bond-containing tea polyphenols, such as EGCG, inhibited CT-like proteasome activity in vitro and in vivo. However, EGCG had also been shown to be relatively unstable under neutral or alkaline conditions and could be rapidly degraded via deprotonation of hydroxyl (–OH) groups on the phenol rings.[8] Furthermore, these –OH groups could be modified through major biotransformation reactions, including methylation, glucuronidation, and sulfonation, resulting in reduced biological activities of EGCG in vivo.[9–11]

In a joint *Molecular Medicine* paper published in 2002,[12] our collaborative efforts resulted in the first description of enantioselective synthesis of EGCG analogs, followed by validation with multiple biological assays. This landmark publication detailed findings that novel synthetic tea chemicals could be developed as unique proteasome inhibitors. The paper described the biological evaluation of synthetic green tea polyphenols and showed that these compounds exhibited proteasome-inhibitory activity in vitro and in vivo. Chan's group generated a benzyl-protected compound (Bn-EGCG), which lacked –OH groups for hydrogen binding and showed no proteasome-inhibitory activity, serving as one of the first clues to the great importance of hydroxylated EGCG. Not surprisingly, the hydroxylated synthetic green tea polyphenols acted as anticancer agents by inhibiting cell proliferation, inducing apoptosis, and suppressing the transforming activity of human cancer cells. The findings suggested that hydrogen bonding to some or all of the –OH groups surrounding EGCG are vital for proteasome inhibition.[12]

The previous study established that naturally occurring ester bond-containing green tea polyphenols (EGCG, GCG, and ECG) possess proteasome-inhibitory activity in vitro and in vivo and that green tea polyphenols without the gallate ester (EGC, GC, and EC) were not proteasome inhibitors. To validate the model, the syntheses of the natural (+)-CG and (–)-ECG as well as their enantiomers were conducted and the compounds were examined for biological proteasome inhibition. The green tea polyphenol catechin-3-gallate (CG) and epicatechin-3-gallate (ECG) were synthesized enantioselectively via a

Fig. 1. The natural (–)-epigallocatechin-3-gallate (EGCG) and synthetic (compound **2** and protected EGCG (pro-EGCG)) green tea polyphenols are depicted.

Sharpless hydroxylation reaction followed by a diastereoselective cyclization. Their abilities to inhibit proteasome activity were measured. The unnatural enantiomers were found to be as equally potent as the natural compounds.[13]

The novel synthesis of EGCG analogs as proteasome inhibitors

Structure–activity relationships (SARs) of synthetically derived green tea polyphenols

In the earliest studies, the molecular mechanisms of proteasome inhibition by tea polyphenols were not well understood. To elucidate the interaction of green tea polyphenols and proteasome active site interaction, our group considered the importance of acylation of the proteasome β5-subunit's catalytic N-terminal threonine (Thr 1). In silico docking experiments were used to aid in the understanding of the binding of EGCG to induce proteasome inhibition. On the basis of these docking experiments, we proposed that EGCG could bind the CT site in an orientation and conformation suitable for a nucleophilic attack by Thr 1. In fact, the distance from the electrophilic carbonyl carbon of EGCG to the hydroxyl group of Thr 1 was measured as 3.18 Å. Furthermore, the A ring of EGCG (Fig. 1) was found to act as a tyrosine mimic, binding to the hydrophobic S1 pocket of the β5 subunit and the EGCG scissile bond appeared to become strained, lowering the activation energy for attack by the hydroxyl group of Thr 1. The model was validated by comparison of predicted and actual activities of several EGCG analogs, either naturally occurring or previously synthesized by Chan's group.[14]

EGCG analogs of the A and C rings

Analysis of various EGCG analogs continued to dominate our search for the most effective proteasome inhibitors and anticancer agents. EGCG amides and five simple analogs were prepared by enantioselective synthesis. Proteasome inhibition, in vitro, was measured by fluorogenic substrate assay and in vivo by accumulation of proteasome target proteins (p27, IκB-α, and Bax). Inhibition of tumor cell proliferation and (or) induction of cell death were determined by G_1 arrest, DNA fragmentation, and colony formation inhibition. EGCG analogs with modifications in the A ring, C ring, or ester bond were found to inhibit the CT-like activity of a purified 20S proteasome with altered potencies, while they were able to potently inhibit proteasome activity in tumor cells. Furthermore, colony formation of prostate cancer LNCaP cells was suppressed and some compounds induced G_1 arrest and DNA fragmentation in leukemia Jurkat T cells. However, these EGCG analogs caused no or little proteasome inhibition in normal or nontransformed cells. From these studies, it was well established that the A ring and gallate ester and amide bond are essential for the proteasome-inhibitory function of (–)-EGCG.[15]

EGCG analogs of the A and B rings

In the next set of studies, the SAR of EGCG analogs possessing changes to the A and B rings (Fig. 1) were examined. An analysis of the importance of the various –OH groups in the B ring (Fig. 1) as well as the effect of a hydrophobic substituent in the A ring was conducted in regard to biological activity against the proteasome. Four unnatural green tea catechin analogs and two benzyl compounds were prepared and their biological activities were compared with compounds from previous studies. It was found that a decrease in the number of –OH groups in the B ring led to a decreased potency, whereas the introduction of a hydrophobic benzyl

Can. J. Chem. Downloaded from www.nrcresearchpress.com by Renmin University of China on 09/02/12
For personal use only.

group into the A ring did not significantly affect the proteasome-inhibitory potency.[16]

Peracetate-protected EGCG analogs as prodrugs of proteasome inhibitors

EGCG analogs of the B and D rings and peracetate protection

In an effort to discover still more stable polyphenol proteasome inhibitors, Chan's group next synthesized several novel EGCG analogs with –OH groups eliminated from the B and (or) D rings. In an attempt to increase the stability of green tea catechins in vivo, a group of putative prodrugs with –OH groups protected by peracetate were also synthesized. These prodrugs can be converted to an active form by removal of the peracetate groups by cellular cytosolic esterases. The SAR of the unprotected and protected compounds was examined for their proteasome-inhibitory potentials. It was determined that decreasing –OH groups from either the B or D ring led to diminished proteasome-inhibitory activity in vitro. However, in cultured tumor cells only the protected analogs were capable of potently inhibiting the proteasome activity. Furthermore, these protected analogs induced apoptotic cell death in a tumor cell-specific manner. The superior efficacy of the protected (–)-EGCG analogs indicated the formation of an entirely new compound(s) in intact tumor cells and that peracetate protection could be developed into novel anticancer and cancer-preventive agents.[17]

Because the –OH groups of the EGCG D ring were found to form hydrogen bonds with Gly47 or Ser131 of the proteasome by in silico analysis, a D-ring analog, compound **2** (Fig. 1) (peracetate protected and unprotected) was synthesized by Chan's group and examined for its proteasome-inhibitory activity. Compound **2** contains only one *p*-hydroxyl group on the D ring and was found to be a much weaker proteasome inhibitor than EGCG, confirming the importance of D-ring –OH groups. Since an amino group is capable of forming hydrogen bonds both as a donor and an acceptor, Chan's group also synthesized a compound that replaced the hydroxyl group in the D ring with an amino group in an attempt to increase the potency of compound **2**. The *para*-amino substituent on the D ring of compound **2** exhibited proteasome-inhibitory activity with a potency similar to that of EGCG. Furthermore, the *O*-acetylated amino – green tea polyphenol analogs appeared to behave as prodrugs and the mechanism of action involves targeting the proteasome in tumor cells, thereby inducing cell death. The presence of the *para*-amino substituent could increase the bioavailability of these compounds by limiting biotransformation reactions to the hydroxyls, such as glucuronidation, sulfonation, and methylation. Since the *p*-aminobenzoic acid moiety is a normal constituent of folic acid and generally presumed to be innocuous, the study of these *para*-amino substituted green tea polyphenols may offer the possibility of discovering novel anticancer drugs.[18]

Peracetate protection of EGCG and EGCG analogs

We began to more heavily investigate the effect of peracetate protection on green tea catechins and especially on EGCG to enhance its in vivo stability. Chan's group synthesized fully protected EGCG (later named pro-EGCG, Fig. 1). HPLC analysis revealed that the protected EGCG analog was six times more stable than natural, unprotected EGCG under slightly alkaline conditions. A series of bioassays showed that protected EGCG was not inhibitory against a purified 20S proteasome in vitro, but exhibited increased proteasome-inhibitory activity in intact leukemic cells over natural (–)-EGCG, indicating an intercellular conversion. Furthermore, inhibition of cellular proteasome activity by protected EGCG was associated with the induction of cell death. Therefore, our results indicated that the protected EGCG analog functioned as a prodrug of the proteasome inhibitor, EGCG.[19]

Chan's group next synthesized several (–)-EGCG analogs with peracetate protection on the –OH groups. The acetylated synthetic tea analogs inhibited proteasome activity in cultured tumor cells more potently than natural EGCG and exhibited higher potency to inhibit proliferation and transforming activity and to induce apoptosis in human leukemic, prostate, breast, and simian virus 40-transformed cells. Additionally, the protected analogs were relatively benign to normal and nontransformed human cells.[20]

We next assessed the activity of fully protected EGCG (pro-EGCG) in breast cancer culture and animal models. It became clear that when cultured human breast cancer MDA-MB-231 cells were treated with pro-EGCG, EGCG was not only converted but also accumulated in those cells, accompanied by enhanced levels of proteasome inhibition, growth suppression, and apoptosis induction, compared with cells treated with natural EGCG. In fact, HPLC analysis confirmed conversion of pro-EGCG to EGCG in cultured human leukemic Jurkat T cells.[21] We investigated the potential use of pro-EGCG as a novel prodrug that converts to a cellular proteasome inhibitor and anticancer agent in vivo by inducing MDA-MB-231 tumors in nude mice, followed by treatment with pro-EGCG or EGCG for 31 days. A significant inhibition of breast tumor growth by pro-EGCG (greater than that of EGCG) was associated with increased proteasome inhibition and apoptosis induction in tumor tissues. Pro-EGCG was confirmed to increase the bioavailability, stability, and proteasome-inhibitory and anticancer activities of EGCG in human breast cancer cells and tumors, more strongly suggesting its potential use for cancer prevention and treatment.[22]

Methylation as a biotransforming event on EGCG

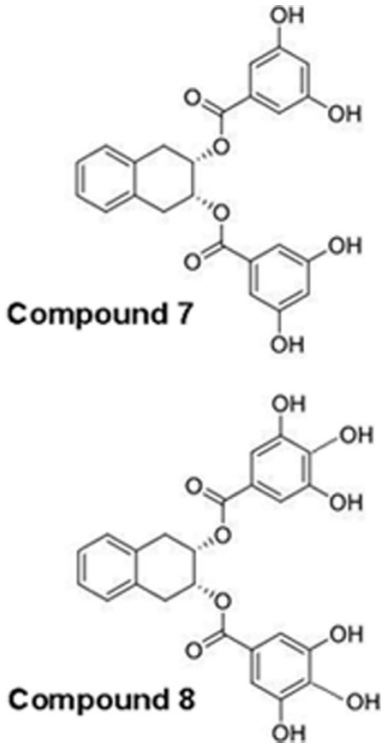
SARs of methylated EGCG analogs

Biological and in silico docking experiments revealed that EGCG binds the CT site in an orientation and conformation that is suitable for a nucleophilic attack by Thr 1 of the proteasomal β5 subunit. In addition, our in silico docking study suggested that a particular pose of EGCG could lead to potential covalent modification of Thr 1. Because biotransformation reactions, such as methylation, could result in reduced biological activity of EGCG in vivo, we hypothesized that methylation reduces binding of EGCG to the β5 subunit of the proteasome and, therefore, decreases its proteasomal chymotrypsin-like-inhibitory potency. We examined the potential effects of methylated EGCG analogs in an in silico model and determined that methylation had no effect on nucleophilic susceptibility of EGCG and ECG. However, it appeared to disrupt the ability of these polyphenols to

Can. J. Chem. Downloaded from www.nrcresearchpress.com by Renmin University of China on 09/02/12
For personal use only.

interact with Thr 1 of the proteasome β5 subunit by moving the ester carbon away from, or entirely blocking, Thr 1. Additionally, methylation impaired the ability of EGCG and ECG to dock in a consistent low energy pose. We determined that methylation disrupts the ability of EGCG and ECG to bind to the proteasome β5 subunit, which was likely responsible for their diminished proteasomal inhibitory and, therefore, other biological activities.[23]

Biological activities and HPLC analysis of methylated EGCG analogs



We next tested whether methylated green tea polyphenols (GTPs) decreased proteasome-inhibitory abilities in cultured cells. Methylated EGCG and ECG analogs, which are known to be found in vivo, were synthesized and studied for their SARs using a purified 20S proteasome. The addition of a single methyl group on EGCG or ECG led to decreased proteasome inhibition and as the number of methyl groups increased, the inhibitory potencies further decreased. Furthermore, peracetate-protected forms of methylated GTPs were added to intact Jurkat T cells to observe the intracellular effects of methylation. Peracetate-protected, monomethylated EGCG induced greater cellular proteasome inhibition and apoptosis than did peracetate-protected, trimethylated EGCG, which is consistent with the potencies of the parent methylated analogs against a purified 20S proteasome. Therefore, methylation on GTPs, under physiological conditions, could decrease their proteasome-inhibitory activity, contributing to decreased cancer-preventive effects of tea consumption.[21]

Catechol-O-methyltransferase activity in human breast cancer cells

Because EGCG was known to be unstable under physiological conditions and methylation of EGCG by catechol-*O*-methyltransferase (COMT) reduces the biological activity of EGCG, we hypothesized that COMT suppression in human breast cancer cells could increase the proteasome-inhibitory potency of EGCG and, therefore, enhance its tumor cell growth-inhibitory activity. We determined the COMT genotype and basal levels of COMT activity in various human breast cancer cell lines. When breast cancer MDA-MB-231 cells containing high COMT activity were tested, the diminished COMT activity appeared to increase the effectiveness of EGCG via augmented proteasome inhibition and apoptosis induction. The findings supplemented our previous conclusions that methylated EGCG is less bioactive and supported the notion that COMT inhibition may increase the anticancer properties of tea polyphenols. Furthermore, the combination of COMT inhibition and EGCG administration may serve as a novel approach or supplemental treatment for breast cancer chemotherapy.[24]

Toward the goal of targeting the problem of EGCG biological methylation in vivo, a novel EGCG analog devoid of the *O*-catechol structure (compound **7**, Fig. 2) that should not be a substrate of COMT was examined. While the proteasome-inhibitory activity of this EGCG analog (**7**) was not affected by the addition of the COMT inhibitor dinitrocatechol (DNC), proteasome inhibition by compound **8** (Fig. 2), as well as EGCG, was enhanced. Similarly, the addition of DNC potently enhanced the antiproliferative activities of acetate protected EGCG, but not the acetate-protected form of this novel synthetic compound (**7**) in MDA-MB-231 breast cancer cells expressing high COMT activity.[25]

Fig. 2. The synthetic compounds **7** and **8** are shown. Compound **7** is resistant to methylation by the enzyme catechol-*O*-methyltransferase.

Although compound **7**, presumably resistant to COMT-mediated methylation and inactivation in cells, was able to inhibit the activity of purified 20S proteasome and cellular 26S proteasome, the involved molecular mechanism is unknown. Most recently, we applied a computational solution to understand the possible interaction between compound **7** and the proteasome β5 subunit. We found that the ester carbonyls at the C2 and C3 atoms may be targets for nucleophilic attack in both compounds **7** and **8**. The metadiol structure in presumably COMT-resistant compound **7** gives a more stable conformation and lower docked free energy than other EGCG analogs.[26] These studies suggest that COMT is a critical factor in mediating the antiproliferative activities of EGCG and EGCG analogs, especially in cells expressing high COMT activity, such as MDA-MB-231 breast cancer cells.

Conclusion

Throughout the 10 years of collaborative efforts with Bill Chan and members of his laboratory, we have developed numerous green tea polyphenol-based proteasome inhibitors as potential anticancer drugs and chemosensitizers for cancer treatment and prevention. Of these compounds, EGCG and EGCG derivates have proven to be most effect in both in vitro and in vivo models. From conception to generation, the Chan group have provided the insight to generate innocuous compounds that impart proteasome inhibition and ultimately anticancer effects in various cell culture and animal systems. These compounds should have great potential to be used as preventive agents and even as cancer therapeutics. Our

biological findings would not have been possible without Bill's invaluable contributions.

Acknowledgements

Because of space limitation and the special focus of this review article, we mainly cited our joint publications with Chan's group and we therefore sincerely apologize to those colleagues whose work has not been cited in this succinct review article. We would like to extend a special thanks to Elizabeth DeWitt for critical reading of this manuscript. Her attention to detail and thoughtful analysis of this work was invaluable to its completion.

Abstract: Antioxidants have potential for the treatment of stroke and neurodegeneration, and chimeric compounds that combine a flavon-3-ol head group related to myricetin and a lipophilic decyl tail are known to protect membranes from oxidative damage at least as well as vitamin E. New flavon-3-ols that are highly hydroxylated in the B ring in ways not found in natural flavon-3-ols and bearing a lipophilic decyl tail have been prepared from trimethoxy- and tetramethoxybenzoic acids accessed by lithiation–carboxylation reactions. Direct enolate acylation was preferred over Baker–Venkataraman rearrangement when there were methoxy groups at both the 2- and the 6-position of the benzoic acid derivatives.

Key words: flavonol, antioxidant, synthesis, polyphenols, tocopherol.

Résumé : Les antioxydants pourraient potentiellement être utilisés dans le traitement des défaillances cardiovasculaires et des processus neurodégénératifs et il est connu que des produis chimériques qui combinent un groupe de tête flavon-3-ol apparenté à la myricétine et un groupe de queue lipophile décyle protègent les membranes des dommages oxydants, au moins aussi bien que la vitamine E. Utilisant comme produits de départs des acides triméthoxy- et tétraméthoxybenzoïques obtenus par des réactions de lithiation/carboxylation, on a préparé de nouveaux flavon-3-ols hautement hydroxylés dans le noyau B, qui diffèrent ainsi des flavon-3-ols naturels et qui portent un groupe de queue lipophile décyle. Dans les cas où on retrouve des groupes méthoxy à la fois dans les positions 2- et 6- des dérivés de l'acide benzoïque, on a préféré l'acylation directe de l'énolate par rapport au réarrangement de Baker–Venkataramn.

Mots-clés : flavonol, antioxydant, synthèse, polyphénols, tocophérol.

[Traduit par la Rédaction]

Introduction

Flavonoids (Fig. 1) are polyphenolic compounds produced as secondary metabolites by plants. They have attracted a great deal of attention over the years because they are found in a range of fruit, vegetables, and beverages, including wine, chocolate and green tea, and so are a common component of the human diet.[1] The consumption of foods rich in these compounds has been associated with a plethora of health benefits. Although feeding studies[2–5] using isotopically labelled flavonoids[6,7] have shown that such compounds are highly metabolized and the dietary benefits are probably due to smaller phenolic compounds,[1] the original interest has led to flavonols being tested in a wide range of assays. These tests have revealed that flavonols have promising properties including as antioxidants, antivirals, antibacterials, and anticancer agents.[8] Indeed, flavopiridol (Alvocidib), a flavonoid analogue of the natural product rohitukine, is a powerful inhibitor of cyclin-dependent kinases and is undergoing clinical trails for the treatment of hematologic malignancies.[9] Different flavonoids have been shown to have different modes of action even when the same therapeutic effect is sought, and inhibition of the proteasome has been investigated as a mode for the anticancer activity for the flavonoids in green tea and their analogues.[10–12] Consequently, the chromone core of flavonoids has been regarded as a scaffold for the construction of potential drug candidates,[13,14] and is considered a privileged substructure for drug discovery.[15]

We were interested in the potential of flavon-3-ols as therapeutic antioxidants, in particular for the treatment of stroke[16] and neurodegeneration.[17,18] Flavon-3-ols that are capable of forming orthoquinones or extended paraquinones[19] have been shown to react very rapidly with oxygen-centred radicals.[20] Myricetin **1** in particular was found to react nearly 28 times as fast as vitamin E with galvinoxyl radicals and to destroy twice as many radicals, and this is believed to be related to its ability to form orthoquinone **2** and extended paraquinone **3** (Scheme 1).[20] However, myricetin itself does not protect membranes well from oxidative assault because of its poor solubility in lipids.[21,22] We prepared chimeric compounds[23,24] with a head based on myricetin **1** and a tail

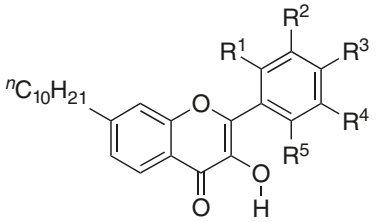
similar to that of *d*-α-tocopherol **4** (the main component of vitamin E,[25] Fig. 2). Varying the tail length and position indicated that the chain length and orientation were of primary importance and compounds **5** and **6**, which matched the overall length of *d*-α-tocopherol best, protected vitamin E-deficient microsomes from oxidation most effectively. Optimal alkyl chain lengths rather than simple relationships to lipophilicity have been observed for other polar antioxidants bearing lipophilic tails and appear to be associated with location of the antioxidant at the water–lipid interface.[26] Chimeric molecules based on flavones have also been reported for other medicinal applications.[27,28]

We have now investigated the preparation of analogues **7a**–**7g** (Fig. 3) of compounds **5** and **6**. These fall into two categories: those with a trihydroxylated B ring (**7a**–**7c**) but different substitution patterns and those with a tetrahydroxylated B ring (**7d**–**7g**). Flavon-3-ols bearing hydroxyl groups in these substitution patterns on the B ring are not naturally occurring, although there are synthetic examples with the 2′,3′,4′-trihydroxy and 2′,3′,4′,5′-tetrahydroxy substi-

Fig. 2. Comparison of *d*-α-tocopherol **4** and chimeric antioxidants **5** and **6**.



tution patterns.[29–31] The decyl chain was chosen because it was the optimum chain length in the related compounds **5** and **6**, and for the flavonoids trihydroxylated on the B ring (**7a**–**7c**), the hydrophilicity–lipophilicity balance[26] would be very similar. The routes demonstrated could, in theory, be applied to a wide range of chain lengths.

Results and discussion

We previously prepared 7-decyl-flavonoid **6** from the B-ring fragment, 2,4,5-trimethoxybenzoic acid, by a sequence involving esterification, Baker–Venkataraman rearrangement, cyclization, and deprotection. Benzoic acid derivatives **8a**–**8g** (Fig. 4) were required to follow the same route. Carboxylic acids **8a** and **8d** were commercially available, whereas the remaining carboxylic acids were synthesized by combining various literature methods. Following the method of Dorn et al.[32] (later used by Cortez et al.[33]) vanillin **9** was brominated, and Dakin oxidation of the resulting aldehyde **10** then gave phenol **11** (Scheme 2). Methylation using methyl iodide (rather than dimethyl sulfate[32,33]) gave aryl bromide **12**. Lithiation–carboxylation of aryl bromide **12** then gave carboxylic acid **8b**.[33,34] Ortholithiation–carboxylation of trimethyl ether **13** gave carboxylic acid **8c** in low yield (Scheme 3).[35,36] Acid **8e** was prepared by bromination of carboxylic acid **14** followed by substitution with methoxide according to the method of Meyers et al.[37] (Scheme 4). Carboxylic acid **8f** was prepared in a similar way to acid **8b**, Baeyer–Villiger oxidation of aldehyde **15** and saponification of the resulting formate ester gave phenol **16** (Scheme 5).[38] Methylation of phenol **16** yielded ether **17**[39] and ortholithiation–carboxylation gave acid **8f**.[40] Reduction of quinone **18** followed by methylation of the resulting tetra-ol by modification of the method of Keegstra et al.[41] gave tetramethyl ether **19** (Scheme 6). In our hands palladium on carbon proved to be superior to platinum oxide. Alternatively, tetramethyl ether **19** was accessed by Baeyer–Villiger oxidation of aldehyde **20** followed by hydroylsis to give phenol **21** and then methylation gave **19** in 51% yield over two steps.[42] Although acid **8g** has been accessed directly from tetramethyl ether **19** by ortholithiation–carboxylation,[43] in our hands only the diacid was obtained. Fortunately, formylation by the method of Poigny et al.[44]

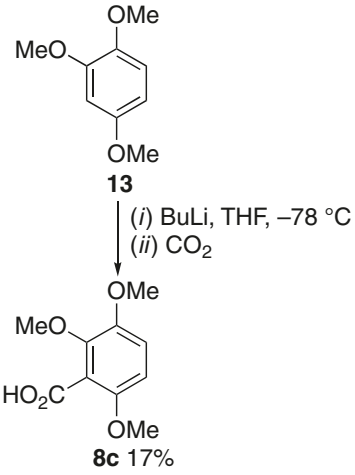
followed by oxidation[45] of the aldehyde **22** proved more successful.



Phenol **23** was prepared as we described previously,[23] and was esterified by reaction with carboxylic acids **8a**, **8b**, **8d**, and **8e** using the water-soluble coupling reagent *N*-(3-dimethylaminopropyl)-*N*′-ethylcarbodiimide hydrochloride (EDCI) to give esters **24a**, **24b**, **24d**, and **24e**, respectively, in poor to good yield (Scheme 7). The esterification typically proceeded smoothly with the exception of the reaction using acid **8d**, which failed to couple completely even after extended reaction times, presumably because of steric hindrance by the 2- and 6-methoxy groups, whereas ester **24b** appeared to be unstable to column chromatography on silica gel. Baker–Venkataraman rearrangement of esters **24a**, **24b**, **24d**, and **24e** to give diketones **25a**, **25b**, **25d**, and **25e** was then achieved using lithium bis(trimethylsilyl)amide

Scheme 5. Synthesis of 2,3,4,6-tetramethoxybenzoic acid **8f**.

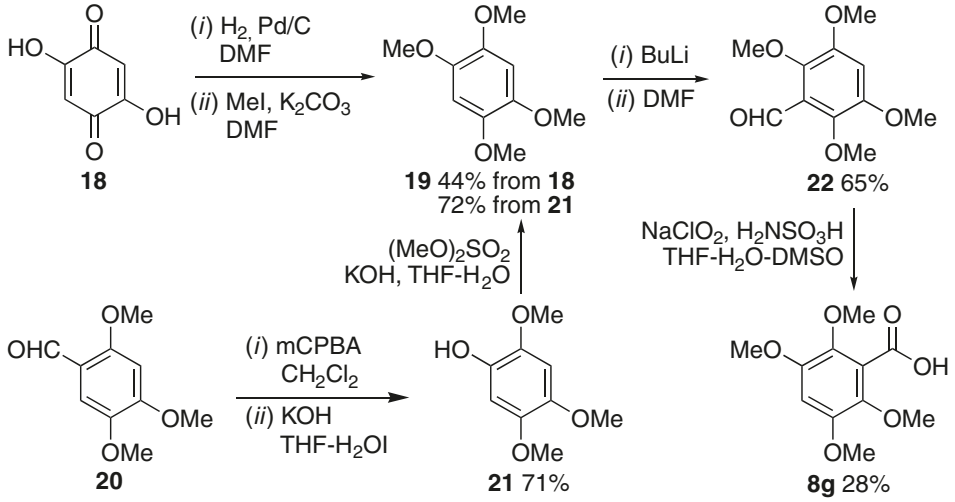
(LiHMDS) in THF at low temperature. To overcome the problem of poor esterification owing to steric hindrance when there are methoxy groups at both the 2 and 6 position of the benzoic acid derivative, carboxylic acids **8c**, **8f**, and **8g** were converted into the corresponding acid chlorides **26c**, **26f**, and **26g** by reaction with thionyl chloride and then reacted with the enolate generated by double deprotonation of phenol–ketone **23** (Scheme 8). This direct C acylation of the acetophenone **23** was more successful and diketones **25c** and **25g** were obtained in good yield, although the yield of diketone **25f** remained rather poor. Cyclisation of the diketones **25a**–**25g** using trimethylsilyl triflate gave protected flavonols **27a**–**27g** in moderate to excellent yield. Interestingly, a highly methoxylated flavone from *Struthiola argentea* is a potent antiparasitic lead compound for livestock health.[46] Boron tribromide deprotection of the methoxy protecting groups gave flavonols **7a**–**7e** again in excellent yield (Scheme 9). Unfortuantely, although demethylation appeared to be successful, it was not possible to obtain pure samples of flavonols **7f** and **7g**, presumably because of oxidative processes.

In summary, we report the preparation of five new chimeric compounds that combine flavon-3-ol head groups having B rings that are more highly hydroxylated or differently substituted from natural flavonols with the lipophilic decyl tail. The new head groups are potentially potent antioxidants having arrangements that would allow the formation of quinones and (or) extended quinones,[19,20,47] whereas the lipophilic tail has been shown previously to be optimal for the membrane protective properties of myricetin analogues.[23,24]

Experimental

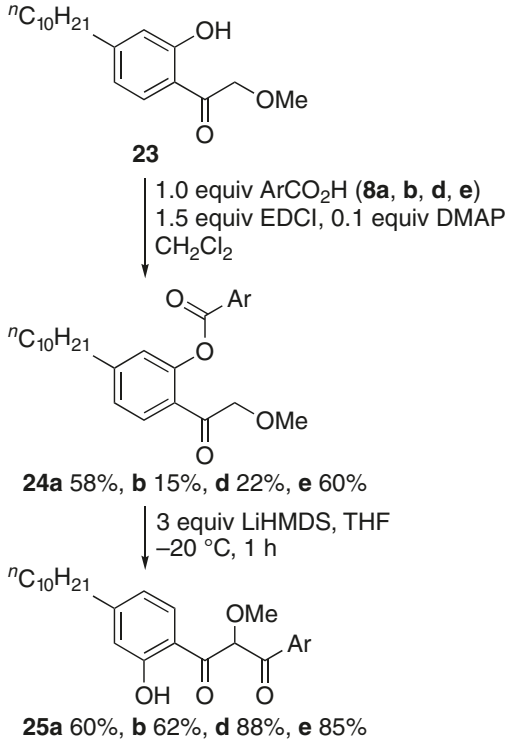
The synthesis of carboxylic acids **8a**–**8g** were carried out by the methods described in the papers cited in the text.[32–45] Reactions carried out under argon used oven-dried or flame-dried glassware. Solutions were added via syringe. Reagents and solvents were obtained from commercial suppliers and used without further purification. Where dry solvents were used, THF was freshly distilled from sodium–benzophenone and dichloromethane (DCM) was distilled from CaH_2. Purification by column chromatography was carried out using silica gel (mesh size 35–70 μm) as the stationary phase. Melting points are uncorrected. IR spectra were obtained on a Nicolet Impact 410 FTIR, JASCO FTIR, or Shimadzu FTIR-8400S spectrometer. In some cases an attachment that allows attenuated total reflectance (ATR) was used so that the IR spectrum of the compound (solid or liquid) could be directly detected (thin layer) without any sample preparation. NMR spectra were recorded using a Bruker DPX-400. All NMR *J* values are given in Hz. DEPT was used to assign the signals in the ^{13}C NMR spectra as C, CH, CH_2, or CH_3. Mass spectra were recorded on a JEOL JMS700 spectrometer.

General procedure 1 — Esterification



A solution of phenol **23** (0.3 mol/L), benzoic acid **8a**, **8b**, **8d**, or **8e** (1.0 equiv), EDCI (1.5 equiv), and DMAP (0.1 equiv) in dry DCM was stirred at room temperature (RT) under argon for 24 h. The solution was then diluted with DCM and washed with water. The aqueous washings were re-extracted with DCM. The combined organics were washed with brine, dried over magnesium sulfate, and concentrated under vacuum to give the ester, which was purified as described in the following.

4′-Decyl-2-methoxy-2′-(2″,3″,4″-trimethoxybenzoyloxy) acetophenone (24a)



Ester **24a** (927 mg, 58%) was obtained as an oil following general procedure 1 on a 3.18 mmol scale, followed by column chromatography (SiO_2, EtOAc–hexane (1:1)). R_f (SiO_2, EtOAc–hexane (1:1)) 0.30. IR υ_{max} (thin film, cm^{-1}): 2927 (CH_2), 1743 (C=O), 1702 (C=O). δ_H (400 MHz, $CDCl_3$): 0.88 (3H, t, J 6.8 Hz, CH_2CH_3), 1.25–1.31 (14H, m, 7 × CH_2), 1.60–1.68 (2H, m, $ArCH_2CH_2$), 2.67 (2H, t, J = 7.6 Hz, $ArCH_2CH_2$), 3.39 (3H, s, OCH_3), 3.91 (3H, s, OCH_3), 3.95 (3H, s, OCH_3), 3.98 (3H, s, OCH_3), 4.55 (2H, s, OCH_2), 6.78 (1H, d, J = 8.8 Hz, H-5″), 7.07 (1H, d, J = 1.2 Hz, H-3′), 7.16 (1H, dd, J = 1.2 and 8.0 Hz, H-5′), 7.77 (1H, d, J = 8.0 Hz, H-6′), 7.88 (1H, d, J = 8.8 Hz, H-6″). δ_C (100 MHz, $CDCl_3$): 14.03 (CH_3), 22.59 (CH_2), 29.18 (CH_2), 29.23 (CH_2), 29.34 (CH_2), 29.45 (CH_2), 29.50 (CH_2), 30.70 (CH_2), 31.81 (CH_2), 35.70 (CH_2), 56.10 (CH_3), 59.17 (CH_3), 60.98 (CH_3), 61.84 (CH_3), 76.87 (CH_2), 107.06 (CH), 116.46 (C), 123.76 (CH), 126.03 (CH), 126.39 (C), 127.83 (CH), 129.62 (CH), 143.06 (C), 149.61 (C), 149.92 (C), 155.50 (C), 158.00 (C), 163.25 (C), 196.00 (C). *m/z* (EI): 500 (M^+, 5%),

Scheme 9. Completion of the synthesis of 7-decyl-flavonoids.

4′-Decyl-2-methoxy-2′-(2″,4″,6″-trimethoxybenzoyloxy) acetophenone (24d)

Ester **24d** (295 mg, 22%) was obtained as a pale yellow oil following general procedure 1 on a 2.70 mmol scale except the reaction time was extended to 3 days, followed by column chromatography (SiO_2, EtOAc–hexane (1:1)). R_f (SiO_2, EtOAc–hexane (1:1)) 0.38. IR υ_{max} (thin film, cm^{-1}): 2913 (CH_2), 1751 (C=O), 1695 (C=O). δ_H (400 MHz, $CDCl_3$): 0.88 (3H, t, J = 6.8 Hz, CH_2CH_3), 1.26–1.31 (14H, m, 7 × CH_2), 1.60–1.67 (2H, m, $ArCH_2CH_2$), 2.66 (2H, t, J = 7.6 Hz, $ArCH_2CH_2$), 3.42 (3H, s, OCH_3), 3.85 (3H, s, OCH_3), 3.87 (6H, s, 2 × OCH_3), 4.65 (2H, s, OCH_2), 6.15 (2H, s, H-3″ + H-5″), 7.12–7.15 (2H, m, H-3′ + H-5′), 7.85 (1H, d, J = 8.0 Hz, H-6′). δ_C (100 MHz, $CDCl_3$): 14.04 (CH_3), 22.61 (CH_2), 29.15 (CH_2), 29.24 (CH_2), 29.38 (CH_2), 29.48 (CH_2), 29.53 (CH_2), 30.71 (CH_2), 31.82 (CH_2), 35.68 (CH_2), 55.49 (CH_3), 55.96 (CH_3), 59.17 (CH_3), 77.93 (CH_2), 90.52 (CH), 104.58 (C), 123.08 (CH), 126.22 (CH), 126.66 (C), 129.94 (CH), 149.67 (C), 150.08 (C), 158.94 (C), 163.30 (C), 164.51 (C), 196.22 (C). *m/z* (CI): 501 [$(M + H)^+$, 5%], 471 (10), 307 (100), 195 (100). HRMS calcd for $C_{29}H_{41}O_7$: $(M + H)^+$ 501.2853; found: 501.2851.

4′-Decyl-2-methoxy-2′-(2″,3″,4″,5″-tetramethoxybenzoyloxy) acetophenone (24e)

Ester **24e** (896 mg, 60%) was obtained as a pale yellow oil following general procedure 1 on a 2.82 mmol scale, followed by column chromatography (SiO_2, EtOAc–hexane (1:2)). R_f (SiO_2, EtOAc–hexane (1:2)) 0.30. IR υ_{max} (thin film, cm^{-1}): 2927 (CH_2), 1749 (C=O), 1698 (C=O). δ_H (400 MHz, $CDCl_3$): 0.88 (3H, t, J = 6.8 Hz, CH_2CH_3), 1.19–1.31 (14H, m, 7 × CH_2), 1.60–1.68 (2H, m, $ArCH_2CH_2$), 2.67 (2H, t, J = 7.6 Hz, $ArCH_2CH_2$), 3.40 (3H, s, OCH_3), 3.91 (3H, s, OCH_3), 3.92 (3H, s, OCH_3), 3.94 (3H, s, OCH_3), 4.00 (3H, s, OCH_3), 4.56 (2H, s, OCH_2), 7.08 (1H, d, J = 1.4 Hz, H-3′), 7.16 (1H, dd, J = 1.5 and 8.0 Hz, H-5′), 7.38 (1H, s, H-6″), 7.76 (1H, d, J 8.0 Hz, H-6′). δ_C (100 MHz, $CDCl_3$): 14.07 (CH_3), 22.63 (CH_2), 29.22 (CH_2), 29.27 (CH_2), 29.38 (CH_2), 29.49 (CH_2), 29.55 (CH_2), 30.74 (CH_2), 31.85 (CH_2), 35.75 (CH_2), 56.25 (CH_3), 59.24 (CH_3), 61.23 (CH_3), 61.37 (CH_3), 62.04 (CH_3), 77.72 (CH_2), 108.94 (CH), 117.81 (C), 123.78 (CH), 126.16 (CH), 126.26 (C), 129.62 (CH), 147.75 (C), 147.78 (C), 149.10 (C), 149.52 (C), 149.89 (C), 150.09 (C), 163.52, (C), 196.06 (C). *m/z* (EI): 530 (M^+, 15%), 261 (10), 225 (100). HRMS calcd for $C_{30}H_{42}O_8$: (M^+) 530.2879; found: 530.2880.

General procedure 2 — The Baker–Venkataraman rearrangement

LiHMDS (3.0 equiv, 1.0 mol/L solution in THF) was added to a stirred solution of ester **24a**, **24b**, **24d**, or **24e** (0.3 mol/L) in dry THF at –20 °C under argon. After 1 h the reaction was quenched with aqueous HCl (1 mol/L) and the mixture extracted with EtOAc (2×). The combined organics where washed with water and brine and then dried over magnesium sulfate. The diketones **25** were purified as described in the following.

1-(4′-Decyl-2′-hydroxyphenyl)-2-methoxy-3-(2″,3″,4″-trimethoxyphenyl)propan-1,3-dione (25a)

Diketone **25a** (387 mg, 60%) was obtained as a bright yellow solid following general procedure 2 on a 1.28 mmol scale, followed by column chromatography (SiO_2, EtOAc–hexane (1:2)). R_f (SiO_2, EtOAc–hexane (1:2)) 0.29; mp 60–62 °C. IR υ_{max} (thin film, cm^{-1}): 3409 (OH), 2927 (CH_2), 1685 (C=O), 1637 (C=O). δ_H (400 MHz, $CDCl_3$): 0.88 (3H, t, J = 6.8 Hz, CH_2CH_3), 1.26–1.31 (14H, m, 7 × CH_2), 1.58–1.63 (2H, m, $ArCH_2CH_2$), 2.60 (2H, t, J = 7.5 Hz, $ArCH_2CH_2$), 3.57 (3H, s, OCH_3), 3.79 (3H, s, OCH_3), 3.80 (3H, s, OCH_3), 3.91 (3H, s, OCH_3), 5.78 (1H, s, H-2), 6.73 (1H, d, J = 8.8 Hz, H-5″), 6.76 (1H, dd, J = 1.6 and 8.4 Hz, H-5′), 6.80 (1H, d, J = 1.6 Hz, H-3′), 7.66 (1H, d, J = 8.8 Hz, H-6″), 7.81 (1H, d, J = 8.4 Hz, H-6′), 11.72 (1H, s, OH). δ_C (100 MHz, $CDCl_3$): 14.08 (CH_3), 22.65 (CH_2), 29.24 (CH_2), 29.29 (CH_2), 29.41 (CH_2), 29.51 (CH_2), 29.56 (CH_2), 30.50 (CH_2), 31.86 (CH_2), 36.28 (CH_2), 56.13 (CH_3), 58.77 (CH_3), 60.80 (CH_3), 61.01 (CH_3), 88.19 (CH), 107.14 (CH), 116.20 (C), 117.76 (CH), 119.90 (CH), 123.04 (C), 126.21 (CH), 130.79 (CH), 141.29 (C), 153.59 (C), 153.66 (C), 158.36 (C), 163.28 (C), 193.54 (C), 198.84 (C). *m/z* (EI): 500 (M^+, 1%), 261 (5), 195 (100). HRMS calcd for $C_{29}H_{40}O_7$: (M^+) 500.2774; found: 500.2773.

1-(4′-Decyl-2′-hydroxyphenyl)-2-methoxy-3-(2″,3″,5″-trimethoxyphenyl)propan-1,3-dione (25b)

Diketone **25b** was obtained as a yellow oil (144 mg, 62%) and as a complex mixture with cyclic diastereomers and keto–enol forms following general procedure 2 on a 0.46 mmol scale and then column chromatography (SiO_2, EtOAc–hexane (1:2)). The mixture was used in the next step without further purification.

General procedure 3 — C-acylation

Thionyl chloride was added to benzoic acid **8c**, **8f**, or **8g** under argon to give a 1.0 mol/L solution and the mixture was then heated under reflux for 2 h. After cooling, the excess thionyl chloride was removed under vacuum to give acid chloride **26c**, **26f**, or **26g**, which was then used in the next reaction without further purification. LiHMDS (3.0 equiv, 1.0 mol/L solution in THF) was added to a stirred solution of phenol **23** in dry THF (0.3 mol/L solution) at –78 °C under an atmosphere of argon. The solution was stirred at –78 °C for 30 min. After this time a solution of the freshly prepared acid chloride in THF was added. After stirring at –78 °C for a further 5 min, the solution was immediately warmed to RT and stirred for 1 h. The reaction mixture was then quenched with aqueous HCl (1 mol/L) and extracted with EtOAc (2×). The combined organics were washed with water, then brine, and then were dried over magnesium sulfate and concentrated under vacuum. The diketones **25** were purified as described in the following.

1-(4′-Decyl-2′-hydroxyphenyl)-2-methoxy-3-(2″,3″,6″-trimethoxyphenyl)propan-1,3-dione (25c)

Diketone **25c** (536 mg, 95%) was obtained as a golden yellow oil and as a complex mixture of cyclic diastereomers, diketone, and keto–enol forms following general procedure 3 on a 1.13 mmol scale and was used in the next step without further purification. Using general procedure 3, diketone **25c** was synthesized on a 1.13 mmol scale. The diketone, obtained as a golden yellow oil, was used without further purification in the next step.

1-(4′-Decyl-2′-hydroxyphenyl)-2-methoxy-3-(2″,3″,4″,6″-tetramethoxyphenyl)propan-1,3-dione (25f)

Diketone **25f** (148 mg, 19%) was obtained as a golden yellow oil following general procedure 3 on a 1.48 mmol scale, followed by column chromatography (SiO_2, EtOAc–hexane (1:2)). R_f (SiO_2, EtOAc–hexane (1:2)) 0.22. In $CDCl_3$ the product existed as a 6:1 ratio of diketone and keto–enol forms. NMR data given is for the diketone form **25f**. IR υ_{max} (thin film, cm^{-1}): 3488 (OH), 2927 (CH_2), 1722 (C=O), 1633 (C=O). δ_H (400 MHz, $CDCl_3$): 0.88 (3H, t, J = 6.6 Hz, CH_2CH_3), 1.24–1.30 (14H, m, 7 × CH_2), 1.57–1.61 (2H, m, $ArCH_2CH_2$), 2.56 (2H, t, J = 7.8 Hz, $ArCH_2CH_2$), 3.61 (3H, s, OCH_3), 3.68 (3H, s, OCH_3), 3.77 (3H, s, OCH_3), 3.78 (3H, s, OCH_3), 3.86 (3H, s, OCH_3), 5.31 (1H, s, H-2), 6.17 (1H, s, H-5″), 6.68 (1H, dd, J = 1.6 and 8.3 Hz, H-5′), 6.75 (1H, d, J = 1.6 Hz, H-3″), 7.95 (1H, d, J = 8.3 Hz, H-6″), 11.81 (1H, s, OH). δ_C (100 MHz, $CDCl_3$): 14.00 (CH_3), 22.57 (CH_2), 29.14 (CH_2), 29.20 (CH_2), 29.33 (CH_2), 29.43 (CH_2), 29.48 (CH_2), 30.47 (CH_2), 31.77 (CH_2), 36.18 (CH_2), 56.66 (CH_3), 55.98 (CH_3), 58.66 (CH_3), 60.88 (CH_3), 61.49 (CH_3), 91.67 (CH), 93.45 (CH), 113.93 (C), 116.20 (C), 117.14 (CH), 119.47 (CH), 131.80 (CH), 135.63 (C), 151.55 (C), 153.01 (C), 153.33 (C), 155.96 (C), 163.03 (C), 195.90 (C), 198.52 (C). *m/z* (EI): 530 (M^+, 1%), 499.3 (1), 225.1 (100), 195 (6). HRMS calcd for $C_{30}H_{42}O_8$: (M^+) 530.2880; found: 530.2882.

1-(4′-Decyl-2′-hydroxyphenyl)-2-methoxy-3-(2″,3″,5″,6″-tetramethoxyphenyl)propan-1,3-dione (25g)

Diketone **25g** (538 mg, 64%) was obtained as a golden yellow oil following general procedure 3 on a 1.82 mmol scale, followed by column chromatography (SiO_2, EtOAc–hexane (1:2)). R_f (SiO_2, EtOAc–hexane (1:2)) 0.25. In $CDCl_3$ the product existed as a 4:1 ratio of diketone and keto–enol forms. NMR data given is for the diketone form **25g**. υ_{max} (thin film, cm^{-1}): 3469 (OH), 2927 (CH_2), 1720 (C=O), 1633 (C=O). δ_H (400 MHz, $CDCl_3$): 0.88 (3H, t, J = 6.6 Hz, CH_2CH_3), 1.24–1.30 (14H, m, 7 × CH_2), 1.57–1.61 (2H, m, $ArCH_2CH_2$), 2.56 (2H, t, J = 7.8 Hz, $ArCH_2CH_2$), 3.50 (3H, s, OCH_3), 3.66 (6H, s, 2 × OCH_3), 3.83 (6H, s, 2 × OCH_3), 5.27 (1H, s, H-2), 6.58 (1H, s, H-4″), 6.69 (1H, dd, J = 1.6 and 8.2 Hz, H-5′), 6.76 (1H, d, J = 1.6 Hz, H-3″), 7.98 (1H, d, J = 8.3 Hz, H-6′), 11.78 (1H, s, OH). δ_C (100 MHz, $CDCl_3$): 13.98 (CH_3), 22.55

General procedure 4 — Cyclization

TMSOTf (1.1 equiv) was added to a stirred solution of the diketone **25a**–**25g** (0.3 mol/L) in dry DCM at RT under argon. After stirring at RT for 1 h, the reaction mixture was diluted with DCM and quenched with saturated aqueous $NaHCO_3$. The layers were separated and the aqueous layer extracted with DCM. The combined organics were washed with brine, dried over magnesium sulfate, and concentrated under vacuum. The flavone derivatives **27** were purified further where necessary as described in the following.

7-Decyl-3,2′,3′,4′-tetramethoxyflavone (27a)

Flavone **27a** (251 mg, 87%) was obtained as a viscous yellow oil following general procedure 4 on a 0.59 mmol scale. IR υ_{max} (thin film, cm^{-1}): 2929 (CH_2), 1621 (C=O). δ_H (400 MHz, $CDCl_3$): 0.88 (3H, t, J = 6.8 Hz, CH_2CH_3), 1.26–1.31 (14H, m, 7 × CH_2), 1.62–1.70 (2H, m, $ArCH_2CH_2$), 2.72 (2H, t, J = 7.5 Hz, $ArCH_2CH_2$), 3.80 (3H, s, OCH_3), 3.93 (3H, s, OCH_3), 3.94 (3H, s, OCH_3), 3.95 (3H, s, OCH_3), 6.78 (1H, d, J = 8.7 Hz, H-5′), 7.19–7.25 (3H, m, H-6, 8 and 6′), 8.18 (1H, d, J = 8.2 Hz, H-5). δ_C (100 MHz, $CDCl_3$): 14.06 (CH_3), 22.63 (CH_2), 29.15 (CH_2), 29.39 (CH_2), 29.49 (CH_2), 29.54 (CH_2), 29.54 (CH_2), 30.89 (CH_2), 31.84 (CH_2), 35.99 (CH_2), 56.07 (CH_3), 60.40 (CH_3), 60.88 (CH_3), 61.48 (CH_3), 107.00 (CH), 117.03 (CH), 118.04 (C), 122.47 (C), 125.40 (CH), 125.46 (CH), 125.60 (CH), 141.69 (C), 142.37 (C), 149.55 (C), 152.36 (C), 155.61 (C), 155.75 (C), 155.78 (C), 174.76 (C). *m/z* (EI): 482 (M^+, 60%), 467 (75), 451 (100). HRMS calcd for $C_{29}H_{38}O_6$: (M^+) 482.2669; found: 482.2666.

7-Decyl-3,2′,3′,5′-tetramethoxyflavone (27b)

Flavone **27b** (102 mg, 77%) was obtained as a viscous yellow oil following general procedure 4 on a 0.27 mmol scale. IR υ_{max} (thin film, cm^{-1}): 2925 (CH_2), 1619 (C=O). δ_H (400 MHz, $CDCl_3$): 0.88 (3H, t, J = 6.8 Hz, CH_2CH_3), 1.24–1.32 (14H, m, 7 × CH_2), 1.62–1.70 (2H, m, $ArCH_2CH_2$), 2.72 (2H, t, J = 7.5 Hz, $ArCH_2CH_2$), 3.81 (6H, s, 2 × OCH_3), 3.82 (3H, s, OCH_3), 3.91 (3H, s, OCH_3), 6.65 (1H, d, J = 2.9 Hz, H-4′), 6.66 (1H, d, J = 2.9 Hz, H-6′), 7.22–7.25 (2H, m, H-6 and H-8), 8.19 (1H, d, J = 8.1 Hz, H-5). δ_C (100 MHz, $CDCl_3$): 14.08 (CH_3), 22.64 (CH_2), 29.16 (CH_2), 29.27 (CH_2), 29.40 (CH_2), 29.50 (CH_2), 29.55 (CH_2), 30.87 (CH_2), 31.85 (CH_2), 36.01 (CH_2), 55.72 (CH_3), 55.90 (CH_3), 60.56 (CH_3), 61.50 (CH_3), 102.68 (CH), 104.60 (CH), 117.08 (CH), 125.38 (C), 125.60 (CH), 125.65 (CH), 141.60 (C), 141.72 (C), 149.74 (C), 153.69 (C), 155.79 (C), 174.75 (C). *m/z* (EI): 482 (M^+, 55%), 467 (70), 451 (100). HRMS calcd for $C_{29}H_{38}O_6$: (M^+) 482.2669; found: 482.2666.

7-Decyl-3,2′,3′,6′-tetramethoxyflavone (27c)

Flavone **27c** (77 mg, 75%) was obtained as a viscous yellow oil following general procedure 4 on a 0.23 mmol scale, followed by column chromatography (SiO_2, EtOAc–hexane (1:2)). R_f (SiO_2, EtOAc–hexane (1:2)) 0.21. IR υ_{max} (thin film, cm^{-1}): 2927 (CH_2), 1623 (C=O). δ_H (400 MHz, $CDCl_3$): 0.87 (3H, t, J = 6.8 Hz, CH_2CH_3), 1.22–1.31 (14H, m, 7 × CH_2), 1.62–1.69 (2H, m, $ArCH_2CH_2$), 2.71 (2H, t, J = 7.5 Hz, $ArCH_2CH_2$), 3.75 (3H, s, OCH_3), 3.81 (3H, s, OCH_3), 3.83 (3H, s, OCH_3), 3.86 (3H, s, OCH_3), 6.69 (1H, d, J = 9.1 Hz, H-4′), 7.02 (1H, d, J = 9.1 Hz, H-3′), 7.21–7.24 (2H, m, H-6 and H-8), 8.21 (1H, d, J = 8.1 Hz, H-5). δ_C (100 MHz, $CDCl_3$): 14.06 (CH_3), 22.63 (CH_2), 29.17 (CH_2), 29.26 (CH_2), 29.39 (CH_2), 29.48 (CH_2), 29.53 (CH_2), 30.84 (CH_2), 31.83 (CH_2), 35.98 (CH_2), 56.08 (CH_3), 56.47 (CH_3), 60.21 (CH_3), 61.29 (CH_3), 105.91 (CH), 115.09 (CH), 115.57 (C), 117.208 (CH), 122.61 (C), 125.41 (CH), 125.58 (CH), 142.65 (C), 146.65 (C), 148.41 (C), 149.40 (C), 151.70 (C), 153.09 (C), 156.19 (C), 174.68 (C). *m/z* (EI): 482 (M^+, 15%), 451 (100). HRMS calcd for $C_{29}H_{38}O_6$: (M^+) 482.2669; found: 482.2668.

7-Decyl-3,2′,4′,6′-tetramethoxyflavone (27d)

Flavone **27d** (77 mg, 37%) was obtained as a viscous oil following general procedure 4 on a 0.43 mmol scale, followed by column chromatography (SiO_2, EtOAc–hexane (1:2)). R_f (SiO_2, EtOAc–hexane (1:2)) 0.15. δ_H (400 MHz, $CDCl_3$): 0.87 (3H, t, J = 6.7 Hz, CH_2CH_3), 1.26–1.31 (14H, m, 7 × CH_2), 1.61–1.69 (2H, m, $ArCH_2CH_2$), 2.70 (2H, t, J = 7.5 Hz, $ArCH_2CH_2$), 3.76 (6H, s, 2 × OCH_3), 3.79 (3H, s, OCH_3), 3.87 (3H, s, OCH_3), 6.21 (2H, s, H-3′and H-5′), 7.19 (1H, dd, J = 1.4 and 8.2 Hz, H-6), 7.24 (1H, s, H-8), 8.18 (1H, d, J = 8.2 Hz, H-5). δ_C (100 MHz, $CDCl_3$): 14.02 (CH_3), 22.58 (CH_2), 29.13 (CH_2), 29.22 (CH_2), 29.35 (CH_2), 29.44 (CH_2), 29.49 (CH_2), 30.80 (CH_2), 31.79 (CH_2), 35.91 (CH_2), 55.37 (CH_3), 55.77 (CH_3), 60.01 (CH_3), 90.58 (CH), 102.19 (C), 117.22 (CH), 122.65 (C), 125.08 (CH), 125.45 (CH), 142.98 (C), 148.98 (C), 153.42 (C), 156.29 (C), 159.31 (C), 163.20 (C), 174.68 (C). *m/z* (EI): 482 (M^+, 10%), 451 (100). HRMS calcd for $C_{29}H_{38}O_6$: (M^+) 482.2669; found: 482.2666.

7-Decyl-3,2′,3′,4′,5′-pentamethoxyflavone (27e)

Flavone **27e** (305 mg, 48%) was obtained as a viscous yellow oil following general procedure 4 on a 1.23 mmol scale, followed by column chromatography (SiO_2, EtOAc–hexane (1:2)). R_f (SiO_2, EtOAc–hexane (1:2)) 0.24. IR υ_{max} (thin film, cm^{-1}): 2927 (CH_2), 1646 (C=O). δ_H (400 MHz, $CDCl_3$): 0.88 (3H, t, J = 6.8 Hz, CH_2CH_3), 1.24–1.32 (14H, m, 7 × CH_2), 1.63–1.71 (2H, m, $ArCH_2CH_2$), 2.73 (2H, t, J = 7.6 Hz, $ArCH_2CH_2$), 3.84 (3H, s, OCH_3), 3.86 (3H, s, OCH_3), 3.89 (3H, s, OCH_3), 3.99 (6H, s, 2 × OCH_3), 6.77 (1H, s, H-6′), 7.23 (1H, dd, J = 1.3 and 8.2 Hz, H-6), 7.26 (1H, s, H-8), 8.19 (1H, d, J = 8.2 Hz, H-5). δ_C (100 MHz, $CDCl_3$): 14.01 (CH_3), 22.58 (CH_2), 29.10 (CH_2), 29.20 (CH_2), 29.33 (CH_2), 29.44 (CH_2), 29.48 (CH_2), 30.82 (CH_2), 31.78 (CH_2), 35.94 (CH_2), 56.23 (CH_3), 60.42 (CH_3), 61.14 (2 × CH_3), 61.65 (CH_3), 107.86 (CH), 116.98 (CH), 119.33 (C), 122.40 (C), 125.51 (CH), 125.57 (CH), 141.59 (C), 144.97 (C), 146.25 (C), 147.24 (C), 149.18 (C), 149.62 (C), 155.37 (C), 155.69 (C), 174.66 (C). *m/z* (EI): 512 (M^+, 50%), 497 (80), 481 (100), 280 (70), 91 (55). HRMS calcd for $C_{30}H_{40}O_7$: (M^+) 512.2774; found: 512.2772.

7-Decyl-3,2′,3′,4′,6′-pentamethoxyflavone (27f)

Flavone **27f** (40 mg, 41%) was obtained as a yellow oil following general procedure 4 on a 0.19 mmol scale, followed by column chromatography (SiO_2, EtOAc–hexane (1:2)). R_f (SiO_2, EtOAc–hexane (1:2)) 0.13. IR υ_{max} (thin film, cm^{-1}): 2927 (CH_2), 1625 (C=O). δ_H (400 MHz, $CDCl_3$): 0.87 (3H, t, J = 6.8 Hz, CH_2CH_3), 1.24–1.31 (14H, m, 7 × CH_2), 1.62–1.69 (2H, m, $ArCH_2CH_2$), 2.71 (2H, t, J = 7.6 Hz, $ArCH_2CH_2$), 3.77 (3H, s, OCH_3), 3.83 (3H, s, OCH_3), 3.85 (3H, s, OCH_3), 3.88 (3H, s, OCH_3), 3.95 (3H, s, OCH_3), 6.37 (1H, s, H-5′), 7.21 (1H, dd, J = 1.3 and 8.2 Hz, H-6), 7.24 (1H, s, H-8), 8.20 (1H, d, J = 8.2 Hz, H-5). δ_C (100 MHz, $CDCl_3$): 14.15 (CH_3), 22.63 (CH_2), 29.18 (CH_2), 29.26 (CH_2), 29.39 (CH_2), 29.49 (CH_2), 29.54 (CH_2), 30.86 (CH_2), 31.84 (CH_2), 35.98 (CH_2), 56.07 (CH_3), 56.11 (CH_3), 60.14 (CH_3), 61.04 (CH_3), 61.48 (CH_3), 92.10 (CH), 107.14 (C), 117.18 (CH), 122.67 (C), 125.29 (CH), 125.57 (CH), 136.10 (C), 142.91 (C), 149.24 (C), 152.75 (C), 152.95 (C), 153.93(C), 155.74 (C), 156.17 (C), 174.69 (C). m/z (EI): 512 (M^+, 25%), 481 (100). HRMS calcd for $C_{30}H_{40}O_7$: (M^+) 512.2774; found: 512.2773.

7-Decyl-3,2′,3′,5′,6′-pentamethoxyflavone (27g)

Flavone **27g** (244 mg, 44%) was obtained as a yellow solid following general procedure 4 on a 1.09 mmol scale, followed by column chromatography (SiO_2, EtOAc–hexane (1:1)). R_f (SiO_2, EtOAc–hexane (1:1)) 0.31; mp 93–96 °C. IR υ_{max} (ATR, cm^{-1}): 2921 (CH_2), 1619 (C=O). δ_H (400 MHz, $CDCl_3$): 0.87 (3H, t, J = 6.8 Hz, CH_2CH_3), 1.21–1.31 (14H, m, 7 × CH_2), 1.62–1.70 (2H, m, $ArCH_2CH_2$), 2.71 (2H, t, J = 7.5 Hz, $ArCH_2CH_2$), 3.76 (6H, s, 2 × OCH_3), 3.83 (3H, s, OCH_3), 3.93 (6H, s, 2 × OCH_3), 6.72 (1H, s, H-4′), 7.23–7.25 (2H, m, H-6 and H-8), 8.21 (1H, d, J = 8.6 Hz, H-5). δ_C (100 MHz, $CDCl_3$): 14.06 (CH_3), 22.63 (CH_2), 29.18 (CH_2), 29.26 (CH_2), 29.38 (CH_2), 29.48 (CH_2), 29.54 (CH_2), 30.84 (CH_2), 31.84 (CH_2), 35.98 (CH_2), 56.56 (CH_3), 60.34 (CH_3), 61.48 (CH_3), 101.53 (CH), 117.09 (CH), 120.89 (C), 122.68 (C), 125.48 (CH), 125.64 (CH), 140.78 (C), 142.57 (C), 148.91 (C), 149.48 (C), 152.76 (C), 156.02 (C), 174.61 (C). m/z (EI): 512 (M^+, 55%), 481 (100). HRMS calcd for $C_{30}H_{40}O_7$: (M^+) 512.2774; found: 512.2772.

General procedure 5 — Deprotection

Boron tribromide (1.0 mol/L in DCM, 1.25 equiv per OMe to be removed) was added to a stirred solution of the flavone **27** in DCM (0.3 mol/L) at RT under argon. The solution was stirred overnight at RT. After this time MeOH was added slowly (0.5 mL per 1.0 mL of BBr_3 solution used). Once gas evolution had ceased, the reaction mixture was heated under reflux for 30 min and then concentrated under vacuum. Water (5.0 mL per mmol of starting material) was added and the resulting suspension placed in a sonic bath for 15 min. The solid was filtered off, washed with water, and then dried under vacuum over P_2O_5 to give the flavonol **7**.

7-Decyl-3,2′,3′,4′-tetrahydroxyflavone (7a)

Flavonol **7a** was obtained as a greeny brown amorphous solid (188 mg, 98%) following general procedure 5 on a 0.45 mmol scale. mp decomp >90 °C. IR υ_{max} (ATR, cm^{-1}): 3203 (OH), 2915 (CH_2), 1594 (C=O). δ_H (400 MHz, D_6-DMSO): 0.84 (3H, t, J = 6.8 Hz, CH_2CH_3), 1.22–1.28 (14H, m, 7 × CH_2), 1.60–1.74 (2H, m, $ArCH_2CH_2$), 2.72 (2H, t, J = 7.4 Hz, $ArCH_2CH_2$), 6.44 (1H, d, J = 8.5 Hz, H-5′), 6.81 (1H, d, J = 8.5 Hz, H-6′), 7.28 (1H, d, J = 8.2 Hz, H-6), 7.39 (1H, s, H-8), 8.01 (1H, d, J 8.2 Hz, H-5). δ_C (100 MHz, D_6-DMSO): 14.28 (CH_3), 22.43 (CH_2), 28.91 (CH_2), 29.02 (CH_2), 29.14 (CH_2), 29.29 (CH_2), 29.30 (CH_2), 30.70 (CH_2), 31.62 (CH_2), 35.37 (CH_2), 107.53 (CH), 111.00 (C), 117.50 (CH), 120.26 (C), 120.69 (CH), 124.95 (CH), 125.39 (CH), 133.84 (C), 138.27 (C), 145.32 (C), 148.14 (C), 148.31 (C), 149.06 (C), 155.50 (C), 172.66 (C). m/z (FAB): 427 [$(M + H)^+$, 100%]. HRMS calcd for $C_{25}H_{31}O_6$: [$(M + H)^+$] 427.2120; found: 427.2121.

7-Decyl-3,2′,3′,5′-tetrahydroxyflavone (7b)

Flavonol **7b** was obtained as a red-brown amorphous solid (64 mg, 77%) following general procedure 5 on a 0.20 mmol scale. mp decomp >90 °C. IR υ_{max} (ATR, cm^{-1}): 3210 (OH), 2919 (CH_2), 1589 (C=O). δ_H (400 MHz, D_6-DMSO): 0.83 (3H, m, CH_2CH_3), 1.22–1.28 (14H, m, 7 × CH_2), 1.60–1.64 (2H, m, $ArCH_2CH_2$), 2.72 (2H, t, J = 7.5 Hz, $ArCH_2CH_2$), 6.31 (1H, d, J = 2.5 Hz, H-4′), 6.43 (1H, d, J = 2.5 Hz, H-6′), 7.28 (1H, d, J = 7.9 Hz, H-6), 7.41 (1H, s, H-8), 8.00 (1H, d, J = 8.2 Hz, H-5). δ_C (100 MHz, D_6-DMSO): 14.30 (CH_3), 22.44 (CH_2), 28.92 (CH_2), 29.02 (CH_2), 29.14 (CH_2), 29.30 (CH_2), 29.31 (CH_2), 30.71 (CH_2), 31.63 (CH_2), 35.38 (CH_2), 105.56 (CH), 106.15 (CH), 117.53 (CH), 119.35 (C), 120.26 (C), 124.99 (CH), 125.51 (CH), 136.67 (C), 138.62 (C), 147.08 (C), 147.64 (C), 149.27 (C), 150.01 (C), 155.52 (C), 172.84 (C). m/z (FAB): 427 [$(M + H)^+$, 75%], 261 (80), 86 (100). HRMS calcd for $C_{25}H_{31}O_6$: [$(M + H)^+$] 427.2120; found: 427.2120.

7-Decyl-3,2′,3′,6′-tetrahydroxyflavone (7c)

Flavonol **7c** was obtained as a red-brown amorphous solid (136 mg, 68%) following general procedure 5 on a 0.46 mmol scale. mp decomp >90 °C. IR υ_{max} (ATR, cm^{-1}): 3355 (OH), 2919 (CH_2), 1589 (C=O). δ_H (400 MHz, D_6-DMSO): 0.85 (3H, t, J 6.8 Hz, CH_2CH_3), 1.22–1.28 (14H, m, 7 × CH_2), 1.61–63 (2H, m, $ArCH_2CH_2$), 2.72 (2H, t, J = 7.2 Hz, $ArCH_2CH_2$), 6.21 (1H, d, J = 8.8 Hz, H-5′), 6.71 (1H, d, J = 8.4 Hz, H-4′), 7.29 (1H, d, J = 8.2 Hz, H-6), 7.40 (1H, s, H-8), 8.03 (1H, d, J = 8.2 Hz, H-5), 8.53 (1H, s, OH), 8.57 (1H, s, OH), 8.69 (1H, s, OH), 8.85 (1H, s, OH). δ_C (100 MHz, D_6-DMSO): 13.93 (CH_3), 22.07 (CH_2), 28.58 (CH_2), 28.66 (CH_2), 28.80 (CH_2), 28.95 (CH_2), 28.96 (CH_2), 30.41 (CH_2), 31.25 (CH_2), 35.00 (CH_2), 104.86 (CH), 107.65 (C), 117.10 (CH), 117.18 (CH), 120.11 (C), 124.61 (CH), 124.90 (CH), 137.38 (C), 139.95 (C), 144.60 (C), 145.10 (C), 148.51 (C), 148.75 (C), 155.53 (C), 172.54 (C). m/z (FAB): 427 [$(M + H)^+$, 25%], 261 (15), 169 (20), 86 (100). HRMS calcd for $C_{25}H_{31}O_6$: [$(M + H)^+$] 427.2121; found: 427.2120.

7-Decyl-3,2′,4′,6′-tetrahydroxyflavone (7d)

Flavonol **7d** was obtained as a pale green amorphous solid (45 mg, 79%) following general procedure 5 on a 0.13 mmol scale. mp decomp >90 °C. IR υ_{max} (ATR, cm^{-1}): 3207 (OH), 2917 (CH_2), 1614 (C=O). δ_H (400 MHz, D_6-DMSO): 0.85 (3H, t, J = 6.7 Hz, CH_2CH_3), 1.22–1.28 (14H, m, 7 × CH_2), 1.60–1.64 (2H, m, $ArCH_2CH_2$), 2.71 (2H, t, J = 7.7 Hz,

Abstract: In this research, NMR, ESI-MS, and circular dichroism (CD) spectroscopies were used to investigate the formation and recognition of G-quadruplex by a G-rich sequence that has been demonstrated to be relevant for pilin variation in *Neisseria gonorrhoeae*. The NMR spectra provided strong evidence that the G-quadruplex structure was formed from this G-rich sequence, and this result was confirmed by CD spectroscopy. In addition, two small-molecule natural products (jatrorrhizine hydrochloride (**J**) and dehydrocorydaline (**D**)) were found to bind to this G-quadruplex over the corresponding duplex DNA with high selectivity by ESI-MS.

Key words: formation, recognition, G-quadruplex, pilin antigenic variation, *Neisseria gonorrhoeae*.

Résumé : Dans ce travail, on a fait appel à la résonance magnétique nucléaire (RMN), la spectrométrie de masse avec ionisation par électronébulisation (SM-IEN) et le dichroïsme circulaire (DC) pour étudier la formation et la reconnaissance d'un quadruplex G par une séquence riche en G qui serait pertinente pour la variation antigénique de la piline dans *Neisseria gonorrhoeae*. Les spectres RMN ont fourni de solides résultats qui permettent d'affirmer que la structure du quadruplex G se forme à partir de la séquence riche en G et cette conclusion a été confirmée par la spectroscopie de DC. De plus, faisant appel à la SM-IEN, on a trouvé que deux petites molécules de produits naturels, le chlorhydrate de jatrorrhizine (**J**) et la déhydrocorydaline (**D**) se lient avec une grande sélectivité à ce quadruplex G sur le duplexe d'ADN correspondant.

Mots-clés : formation, reconnaissance, quadruplex G, variation antigénique de la piline, *Neisseria gonorrhoeae*.

[Traduit par la Rédaction]

Introduction

G-quadruplex is a specific secondary structure of DNA that consists of π-stacked G-quartets, where four guanines are linked by eight hydrogen bonds.[1,2] G-quadruplex structures have been found to be formed in the regions of human telomeres, oncogene promoters, and other regions of the human genome.[1–4] Their biological significance has been demonstrated by numerous in vitro and in vivo studies.[3–8]

Gonorrhea is an infectious disease caused by *Neisseria gonorrhoeae*, which can use DNA recombination to prompt pilin antigenic variation (Av) to avoid immune surveillance[9] and this has impeded vaccine development. Recently, Cahoon and Seifert[10] found that a G-rich sequence is required for the pilin antigenic variation and this G-rich sequence can form a G-quadruplex structure. Therefore, the selective recognition and binding of the G-quadruplex is important for suppressing the pilin antigenic variation using small molecules.

ESI-MS, NMR, and circular dichroism (CD) spectroscopies have been used widely to analyze G-quadruplex structure and its interactions with small molecules. In this research, NMR and CD spectroscopies were used to investigate the formation of the pilin G-quadruplex and the recognition selectivity and stoichiometry of small-molecule natural products to the pilin G-quadruplex were probed by electrospray ionization mass spectrometry (ESI-MS). It was found that two small molecule natural products (jatrorrhizine hydrochloride and dehydrocorydaline) recognize and bind to the pilin G-quadruplex over the corresponding duplex DNA with high selectivity.

Results and discussion

The wild-type G-rich sequence relevant to the pilin antigenic variation contains three GGG tracts and one GGGG tract (Fig. 1A). According to the typical G-quadruplex topology reported in the literature,[11,12] the four G-tracts will form four separate strands of G-quadruplex and all the guanines in the three GGG tracts will be involved in G-tetrad formation. However, there are two options for the four guanines in the GGGG tract to be involved in G-tetrad formation: G15 to G17 or, alternatively, G16 to G18. In this research, a single G was mutated into T at G15 (15T mutant) and G18 (18T

Fig. 1. (A) DNA sequences. (B) Imino region of 1D ^{1}H NMR. (C) Circular dichroism (CD) spectra of the three DNA sequences in potassium solution. DNA concentration for NMR and CD are 0.2 mmol/L and 10 μmol/L, respectively, in a solution of 25 mmol/L K-PO_4 and 70 mmol/L KCl at pH 7.0.

mutant), respectively (Fig. 1A) to help characterize the G-quadruplex structure formed by the wild-type sequence.

G-quadruplex formation by a wild-type pilin Av sequence and two mutants

The formation of G-quadruplex structures of the wild-type pilin Av sequence and the two mutants in potassium solution were probed by ^{1}H NMR spectroscopy. The ^{1}H NMR spectra in Fig. 1B show that there is a cluster of imino H peaks at 10.50–12.10 ppm. These are the characteristic peaks of the G-quadruplex structure. The intense cluster peak corresponding to 12 protons indicated the formation of a dominant G-quadruplex, whereas the small peaks labeled with a star in the downfield region suggested the presence of a minor G-quadruplex in the solution. In the case of the two mutants, four peaks at the same downfield region can also be detected. This suggests that they form a similar structure to the wild-type minor G-quadruplex.

G-quadruplex formation by the three sequences is confirmed by their CD spectra. The three G-rich sequences shown similar profiles in potassium ion solution with a major positive peak at 265 nm, a negative peak at 245 nm, and a minor positive peak at 295 nm (Fig. 1C). These peaks are consistent with the character of a typical G-quadruplex reported in the literature.[13,14] The results from the CD spectra indicate that the three G-rich sequences adopt relatively similar conformations in G-quadruplex formation because their CD spectra almost overlap.

Small molecule recognition of the G-quadruplex

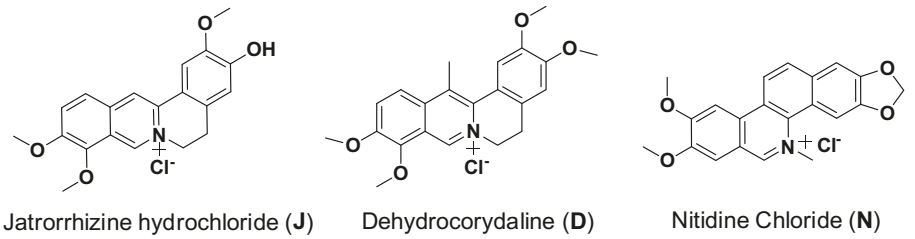
Small molecules that can selectively recognize pilin G-quadruplex might have the potential to inhibit pilin Av. Here, the interaction of small molecule natural products and the pilin G-quadruplex were studied by ESI-MS. It was found that three natural small molecules (Fig. 2), jatrorrhizine hydrochloride (**J**), dehydrocorydaline (**D**), and nitidine chloride (**N**), have good binding properties to the G-quadruplex. Figure 3 shows the mass spectra of the G-quadruplex and small molecules in molar ratios of 1:1 and 1:2 ([G] denotes G-quadruplex ion, [G + nP] denotes a 1:n complex ion of G-quadruplex (G) and a small molecule (P) (P = **J**, **N**, or **D**)). After an equal amount of **J** was added, the complex ion ($[G + \mathbf{J}]^{4-}$) at *m/z* 1605.5 became the base peak (100%), while the abundance of the G-quadruplex peak ($[G]^{4-}$) at *m/z* 1521.4 decreased to about 70% (Fig. 3A). When the concentration ratio of **J** to DNA was increased to 2.0, the abundance of complex ion ($[G + 2\mathbf{J}]^{4-}$) at *m/z* 1689.1 was 100%, whereas the peak of the G-quadruplex almost disappeared (Fig. 3B). The complex ion at *m/z* 1689.1 ($[G + 2\mathbf{J}]^{4-}$) suggested that two small molecules (**J**) stack on the two ends of the G-tetrad. For **D**, the ESI mass spectra show that the complex ions of $[G + \mathbf{D}]^{4-}$ at *m/z* 1612 were also the base peak (100%) at G:**D** = 1:1 and 1:2 (Figs. 3C and 3D). As for **N** in Fig. 3F, the relative abundance of the 1:1 complex ion ($[G + \mathbf{N}]^{4-}$) at *m/z* 1608.0 was 100% at G:**N** = 1:2. These results indicate that the three small molecules bind strongly to the G-quadruplex.

Here, a parameter (BA, binding affinity) was used to compare the binding affinity of the three small molecules with the pilin G-quadruplex.[15,16] The BAs are shown in Table 1 and the maximum value of BA is 1. If the BA value is greater, the BA of the small molecule to the pilin G-quadruplex is greater. From the data in Table 1, the order of the BAs is **J** > **D** > **N**.

Small molecules selectively binding to G-quadruplex over duplex DNA

To evaluate selective recognition for the G-quadruplex, the mixed solutions of the pilin G-quadruplex, the corresponding duplex DNA, and the small molecules were analyzed by ESI-MS (Fig. 4). For **J** and **D**, 1:1 complex ions with G-quadruplex at *m/z* 1607 and 1614 were base peaks (100%), respectively, and no complex ion of the small molecule with the duplex

Fig. 2. Structures of the three small molecules.



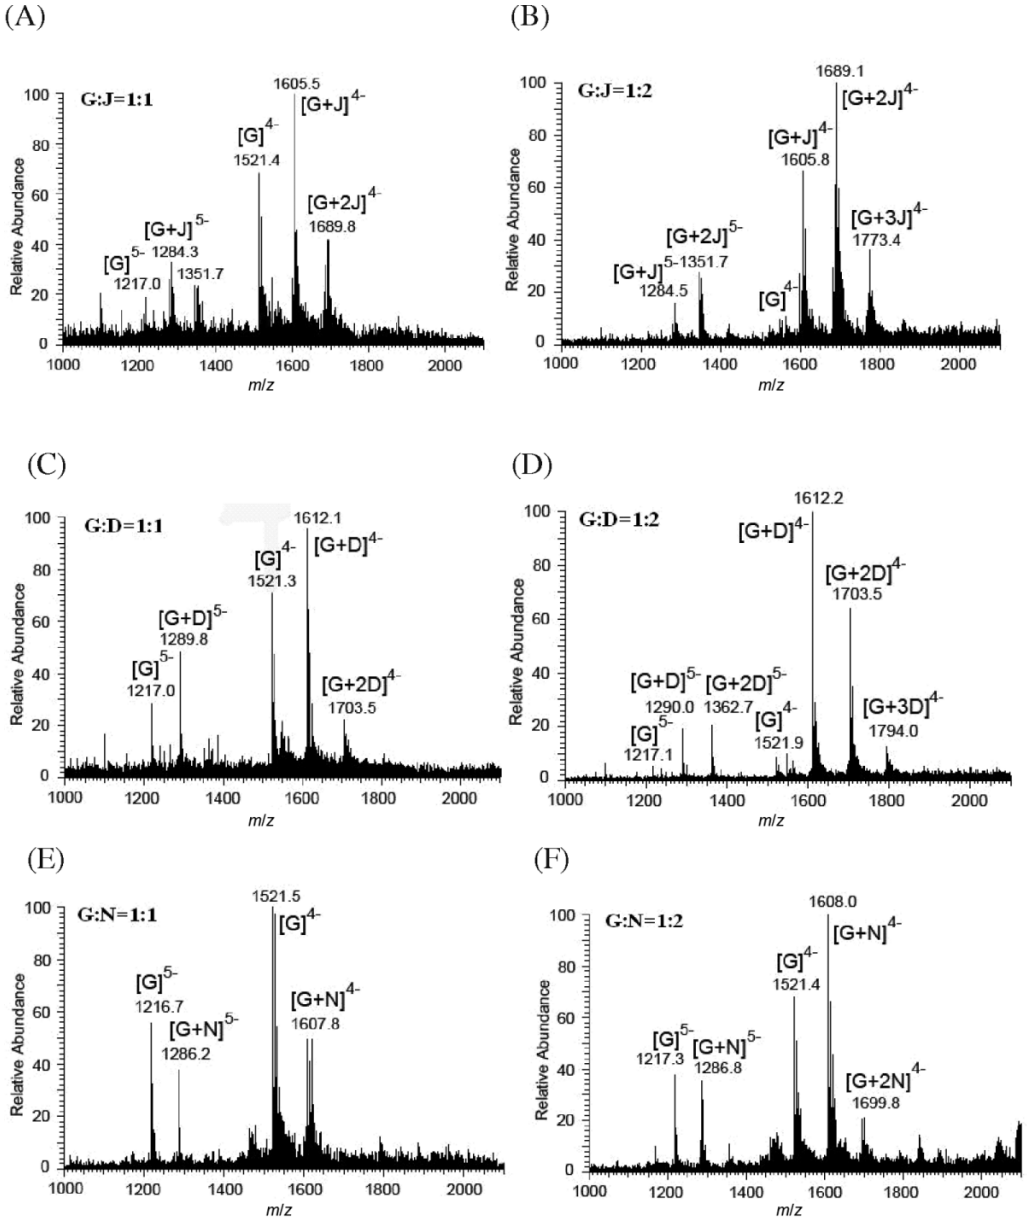


Fig. 3. Mass spectra of the complexes of the G-quadruplex with small molecules. (A) G:**J** = 1:1, (B) G:**J** = 1:2, (C) G:**D** = 1:1, (D) G:**D** = 1:2, (E) G:**N** = 1:1, and (F) G:**N** = 1:2. **J**, jatrorrhizine hydrochloride, **D**, dehydrocorydaline, and **N**, nitidine chloride.

DNA was observed (Figs. 4A and 4B). **N** showed a lower binding capacity (Fig. 4C) with the G-quadruplex DNA than **J** or **D**. These results indicate that **J** and **D** have very high binding selectivities to the G-quadruplex over the duplex DNA.

Conclusion

G-quadruplex formation by a G-rich sequence that is relevant for the pilin Av in *Neisseria gonorrhoeae* was demonstrated using NMR and CD spectroscopy. Two small molecule natural

Fig. 4. ESI-MS spectra of mixed solutions of G-quadruplex – duplex – small molecules = 1:1:2. $[G + 2NH_4^+ - 7H^+]^{5-}$ and $[G + 2NH_4^+ - 6H^+]^{4-}$ are denoted as $[G]^{5-}$ and $[G]^{4-}$, respectively. Duplex DNA is denoted as "D". The concentration of the G-quadruplex or the duplex DNA is 5 μmol/L in 50 mmol/L NH_4Ac solution.

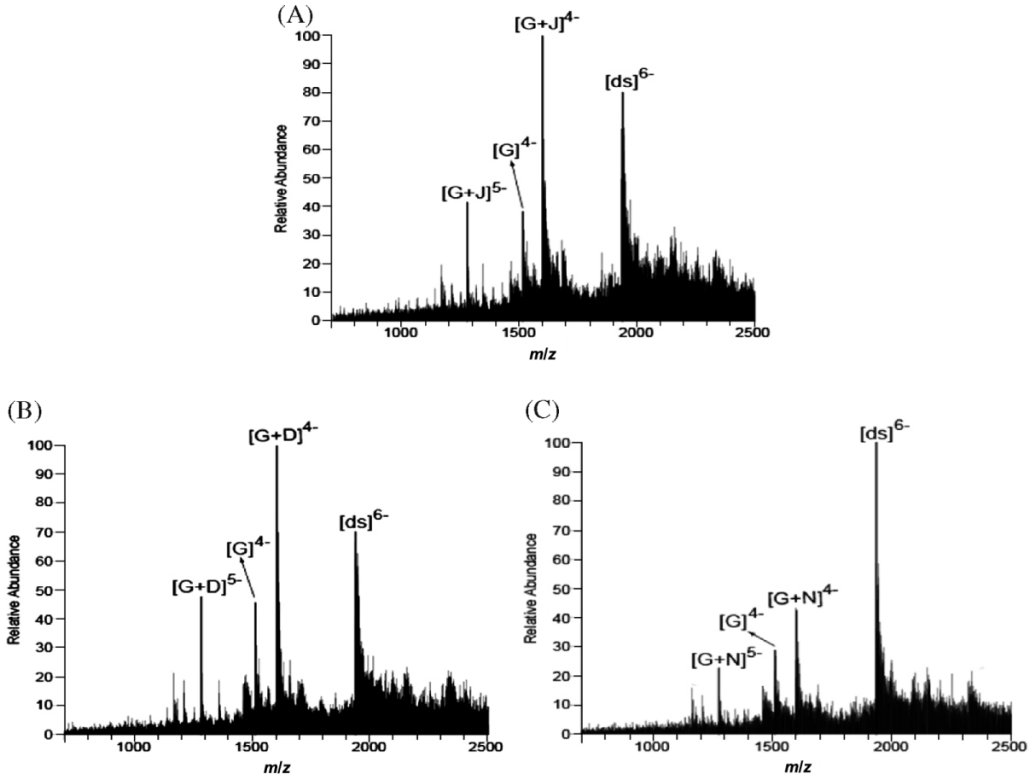

Table 1. The binding affinities (BAs) of the small molecules.

	BA	
	Concentration ratio	
Small molecule	1:1	1:2
Jatrorrhizine hydrochloride	0.68	0.97
Dehydrocorydaline	0.63	0.93
Nitidine chloride	0.35	0.60

products (dehydrocorydaline and jatrorrhizine hydrochloride) were found to bind preferably to the pilin G-quadruplex over the corresponding duplex DNA by ESI-MS. Jatrorrhizine hydrochloride and dehydrocorydaline can be used to probe the biological function of the G-quadruplex in vivo.

Materials and methods

Oligonucleotides

The wild-type G-rich sequence relevant to pilin Av and two single G to T mutants were purchased from Sangon Biotech Co., Ltd., Shanghai (Fig. 1A). The oligonucleotides were dissolved in ultra-purified water at a concentration of 1 mmol/L as a stock. Samples for NMR were prepared by dilution to a solution of 90%:10% H_2O:D_2O. The final NMR samples contained 0.2 mmol/L oligonucleotides in a buffer of 25 mmol/L K-PO_4 and 70 mmol/L KCl at pH 7.0. Samples for CD measurement were prepared with 25 mmol/L K-PO_4 and 70 mmol/L KCl solution to a DNA concentration of 10 μmol/L. Samples for ESI-MS were prepared by dilution with an ammonium acetate buffer (100 mmol/L) to a DNA concentration of 5–10 μmol/L.

Small molecules

Small molecules for ESI-MS screening were obtained from the Chinese National Institute for the Control of Pharmaceutical and Biological Products, Beijing. A 10 mmol/L stock solution in distilled water was prepared and stored at –20 °C.

NMR analysis

NMR experiments were performed on a 600 MHz Bruker spectrometer equipped with a 5 mm Penta probe. The *Jump and Return* program was used for solvent signal suppression with maximum sensitivity.

CD spectrometry

CD spectra of the oligonucleotides were recorded on a Jasco J-810 spectropolarimeter (Jasco, Japan). A 1 mm quartz cell was used with a scanning speed of 100 nm/min between 200 and 400 nm at room temperature. Spectra were baseline-corrected and the signal contributions of the buffer were subtracted.

Mass spectrometry

ESI-MS spectra were obtained using a Finnigan LCQ Deca XP Plus mass spectrometer (San Jose, California). The direct infusion flow rate was 2.0 μL/min, the electrospray voltage was 2.7 kV, and the capillary temperature was 120 °C.

Abstract: The biocatalytic performance of a cloned cyclohexylamine oxidase derived from *Brevibacterium oxydans* IH-35A towards structurally different amines was investigated. Cycloalkyl primary amines, alkyl aryl amines, and α-carbon-substituted aliphatic amines were identified as suitable substrates for the biocatalyst based on an activity assay. Kinetic resolutions of several amines by either recombinant whole cells or crude enzyme extracts prepared therefrom gave enantiomerically pure (*R*)-amines besides the corresponding ketones. When cyclohexylamine oxidase in combination with a borane–ammonia complex as reducing agent was applied to the deracemization of several substrates, excellent enantiomeric ratios (>99:1) and good isolated yields (62%–75%) of the corresponding (*R*)-amines were obtained.

Key words: biocatalysis, cyclohexylamine oxidase, chiral amines, kinetic resolution, deracemization.

Résumé : On a étudié la performance biocatalytique d'un clone de l'oxydase de la cyclohexylamine dérivé du *Brevibacterium oxydans* IH-35A vis-à-vis des amines de structures diverses. Sur la base d'un essai d'activité, il a été possible d'identifier les cycloalkylamines primaires, les alkylarylamines primaires et les amines aliphatiques portant un substituant sur le carbone en α comme des substrats appropriés pour le biocatalyseur. Les résolutions cinétiques de plusieurs amines par des cellules recombinantes complètes ou des extraits bruts d'enzyme préparés à partir de celles-ci conduisent à des amines (*R*) énantiomériquement pures aux côtés des cétones correspondantes. On a utilisé l'oxydase de la cyclohexylamine en combinaison avec un complexe de borane–ammoniac comme agent réducteur pour effectuer la déracémisation de plusieurs substrats, avec d'excellents rapports énantiomériques (>99/1) et de bons rendements en produits isolés (72 % à 75 %) des amines (*R*) correspondantes.

Mots-clés : biocatalyseur, oxydase de la cyclohexylamine, amines chirales, résolution cinétique, déracémisation.

[Traduit par la Rédaction]

Introduction

The importance of enantiomerically pure amines as starting materials for pharmaceuticals and agrochemicals, as chiral auxiliaries, and as resolving agents is beyond question.[1] Despite the wide applications of chiral amines in chemistry, medicine, and biology, their synthesis remains challenging. Chemical protocols include the resolution of racemic amines as their diasteriomeric salts, enantioselective enamide and imine reduction, reductive amination, olefin hydroamination, and enantioselective carbanion addition to imines.[2] Alternative to the chemical method biocatalytic routes have been developed as promising strategies.[3] Most notably are the applicatons of ω-transaminases, which can be either used for the kinetic resolution of racemic amines and amino acids or for the asymmetric synthesis of amines from ketones.[4]

In addition, the ability of flavoproteins to oxidize amines to imines has been exploited for the synthesis of chiral amines (Scheme 1).[5] Initial experiments by Hafner and Weller[6] using D-amino acid oxidase in combination with sodium borohydride led to the preparation of L-amino acids from the corresponding *R*-enantiomers. Applying the same concept, Soda and co-workers[7] demonstrated the deracemization of racemic amino acids. Synthetically useful protocols, which allowed for the synthesis of enantiopure amino acids

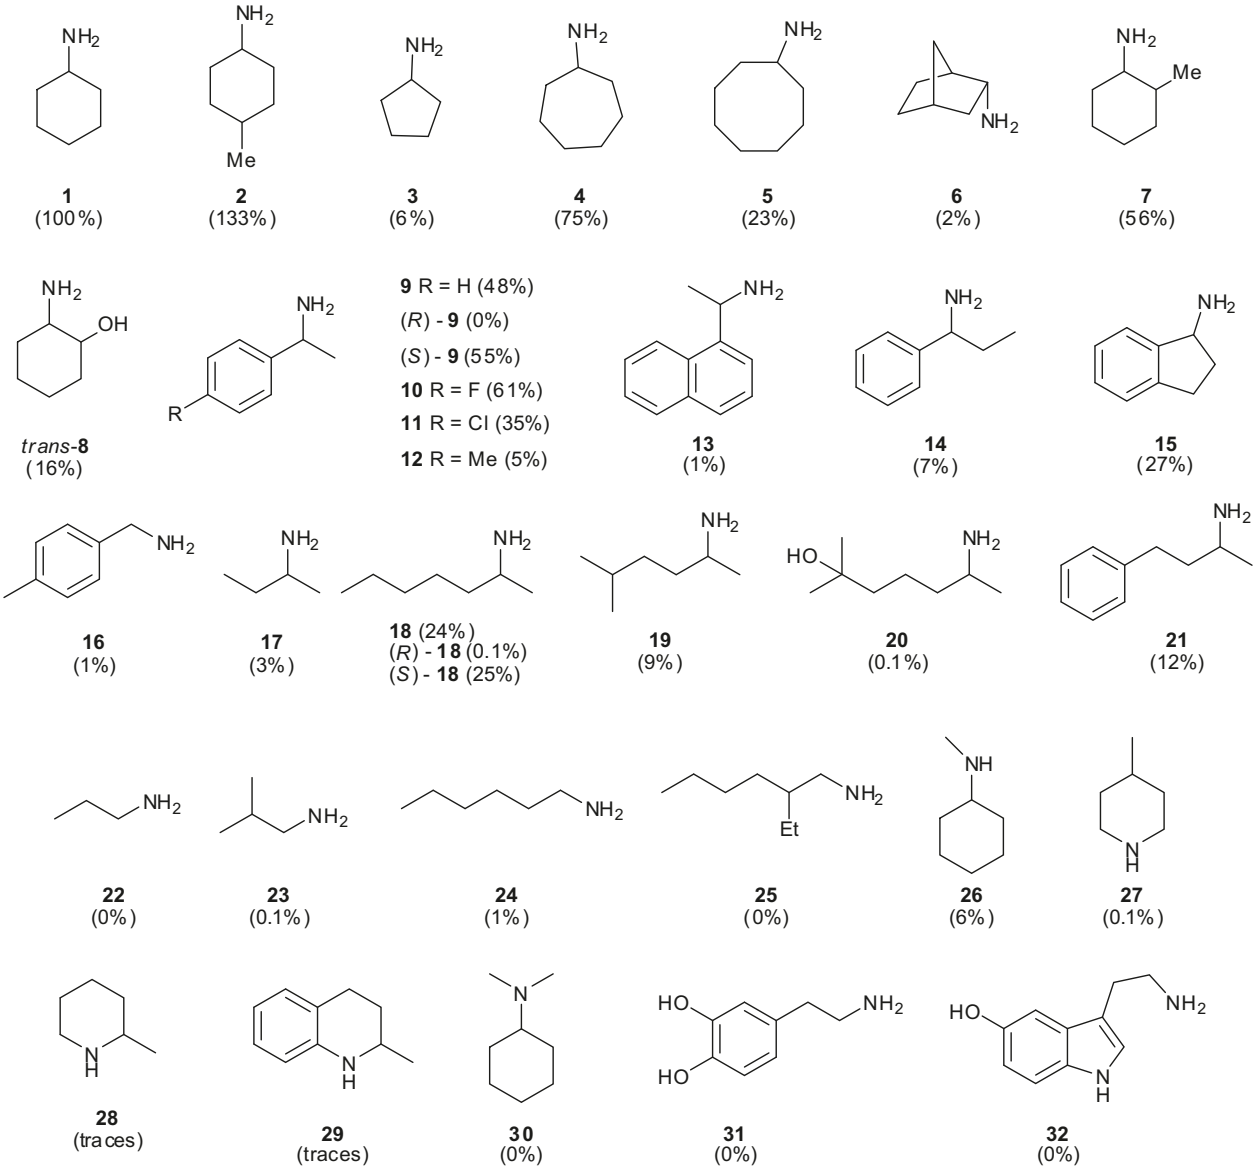
in excellent yields from racemic starting materials, were developed by Turner and co-workers[8] using porcine D-amino acid oxidase. Subsequently, the application of recombinant monoamine oxidase from *Aspergillus niger*[9] and mutants obtained by directed evolution led to the development of biocatalytic protocols for the deracemization of primary,[10] secondary,[11] and tertiary amines,[12] desymmetrization of substituted pyrrolidines,[13] enantioselective oxidation of hydroxylamines,[14] and the design of tandem biocatalysis multicomponent reactions.[15]

Prompted by the wide-ranging applications and excellent enantioselectivity of monoamine oxidase and its mutants from *A. niger*, we were interested in the exploitation of a bacterial amine oxidase as an alternative or complementary biocatalyst. As a result, cyclohexylamine oxidase (CHAO), a 50 kDa flavoprotein responsible for the oxidation of cyclohexylamine to cyclohexanone in *Brevibacterium oxydans* IH-35A,[16] was investigated and this new biocatalytic potential is reported herein.



Results and discussion

To gain access to sufficient amounts of CHAO, the CHAO-encoding gene was cloned in a conventional isopropyl-β-D-thiogalactopyranoside (IPTG)-inducible expression vector (pSD80), and the recombinant plasmid was produced in *Escherichia coli* strain BL 21.[17] Crude cell extracts, prepared from a Luria Bertani medium grown and with IPTG-induced cells, were assayed for their rate of oxidation of structurally diverse amines (Fig. 1). CHAO was found to exhibit activity towards a wide range of amines with cycloalkyl primary amine derivatives **1**–**8** showing the highest activity. The specific activity for cyclohexylamine was determined to be 10.7 U per mg crude enzyme preparation. Given the fact that a nonoptimized 1 L Terrific Broth medium fermentation experiment produced 650 mg of crude CHAO enzyme preparation (6955 U/L), this amount of biocatalyst produced would be capable of transforming 40 g of cyclohexylamine per h. Interestingly, 4-methyl cyclohexylamine (**2**) was oxidized 1.3 times faster than cyclohexylamine (**1**). Additionally, α-alkyl aryl derivatives **9**–**15** and α-carbon-substituted aliphatic amines **17**–**21** were acceptable substrates, whereas compounds of the structure R–CH_2–NH_2 (**22**–**25**) and straight-chain and cyclic secondary and tertiary amines showed very limited activity. Amino acids and monoamine neurotransmitters such as dopamine (**31**) or serotonin (**32**) were not oxidized by CHAO. With respect to enantioselectivity of CHAO we tested the oxidation rates of enantiomerically pure (*R*)- and (*S*)-α-methyl benzylamine (**9**) and 2-heptylamine (**18**). In both cases, CHAO displayed virtually no detectable activity for the (*S*)-enantiomers, indicating a highly enantioselective biocatalyst.

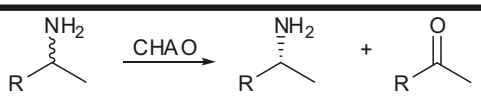
To demonstrate the practicality of CHAO in the syntheses of chiral amines, we tested either whole cells overexpressing CHAO or crude enzyme extracts for the kinetic resolution of racemic amines (Table 1). α-Alkyl aryl derivatives **9**–**12**, **14**, and **15** were resolved in excellent enantioselectivities and CHAO selectively oxidized the (*S*)-enantiomer of the aryl amine derivative to the corresponding ketone, whrereas the (*R*)-enantiomer remained unreacted even after complete consumption of the (*S*)-enantiomer. Preparative scale experiments led to the isolation of enantiopure (*R*)-α-methyl benzylamine (**9**) with recombinant whole cells in 38% and with crude enzyme extracts in 42% isolated yield after simple acid–base extraction. In contrast, the kinetic resolution of 2-heptylamine (**18**) had to be stopped after approximately 50% conversion, since after complete consumption of the (*S*)-enantiomer the less reactive (*R*)-enantiomer (Fig. 1) was oxidized by CHAO at a considerable rate. Interestingly, CHAO oxidized both enantiomers of 2-phenylbutylamine (**21**) at the same rate and only racemic **21** was detected by GC analysis.

Since the kinetic resolution of a racemate only produced a maximum yield of 50% of enantiopure amine, we examined

Fig. 1. Relative rates of the oxidation of amines using crude enzyme extracts of cyclohexylamine oxidase (CHAO). Activities are relative to the oxidation of cyclohexylamine (**1**).

CHAO for the deracemization of amines. Based on the existing deracemization protocols developed by Turner and co-workers,[8,10–12] we investigated the deracemization of α-methyl benzylamine (**9**) under varying reaction conditions (Table 2). Initial experiments using 20 equiv of borane–ammonia complex as the reducing reagent led to the formation of (*R*)-**9** in 79% as determined by GC, confirming the concept of deracemization.

In addition, we observed the formation of 21% phenylethanol, most likely derived from hydrolyzed imine, which was further reduced. The use of sodium cyanoborohydride or sodium borohydride as alternative and more reactive reducing agents led to either decreased yields of amines or insufficient reaction rates. The use of increased equivalents of borane–ammonia complex led to the formation of higher amounts of amine and (*R*)-**9** was isolated in 69% yield after workup. The use of whole cells gave a slightly lower yield. In addition, CHAO in combination with borane–ammonia complex was applied successfully to the deracemization of phenylpropan-1-amine (**14**) and 1-indanamine (**15**).



The great potential of CHAO as a biocatalyst for the deracemization of amines is reflected by the fact that both phenylpropan-1-amine (**14**) and 1-indanamine (**15**) were isolated in higher yield than α-methylbenzylamine (**9**), although the relative activities toward both compounds were much lower than that of compound **9**. This underscores the fact that even compounds with relatively low activity can be used for this powerful biocatalytic application.

Although relative oxidation rates of secondary amines were very low as determined by colorimetric assay, we applied the same protocol to the deracemization of 2-methylpiperidine (**28**) and tetrahydroquinaldine (**29**). As expected, we observed only a slight enrichment of one enantiomer of tetrahydroquinaldine, and 2-methylpiperidine was recovered in racemic form.

Conclusion

We demonstrated for the first time the application of a bacterial amine oxidase to the synthesis of chiral amines. Recombinant CHAO from *B. oxydans* IH-35A displays high activity towards a wide range of structurally different amines, a substrate spectrum that is different from that of the fungal monoamine oxidase.[13] In addition, we demonstrated that CHAO can be applied to the synthesis of primary (*R*)-amines by either kinetic resolution or deracemization protocols. Currently, we are working on the preparation of CHAO mutants with increased activities towards secondary and tertiary amines and their application to biocatalysis.

Experimental

All chemicals and reagents, including amines **1**–**30**, chiral amines (*R*)-**9**–**12**, (*R*)-**14**, (*R*)-**15**, and (*R*)-**18**, (*S*)-**9**, (*S*)-**18**, and the corresponding ketones derived from **9**–**12**, **14**, **15**, and **18** were purchased from Sigma-Aldrich (Mississauga, Ontario), Alfar Aesar (USA), TCI America (USA), and Thermo Fisher Scientific (USA) and were used without further purification.

For the determination of the conversion of amines by GC, appropriate calibration curves and response factors for product/substrate mixtures were prepared.[18] The enantiomeric ratio of α-methylbenzylamine (**9**) was determined after reaction with propionyl chloride (4 equiv) in the presence of triethylamine (8 equiv) in DCM; for all other amines (**10**–**12**, **14**, **15**, **18**, and **28**) acetamides were prepared using acetylchloride (4 equiv) and triethylamine (8 equiv) in DCM. Enantiomers of **29** were separated by chiral GC without derivatization. Co-injection with samples of acetamides prepared from commercial (chiral) standards allowed for the determination of the absolute configuration. The structure of acetamides were confirmed by GC–MS analysis, and the structures of isolated amines were confirmed by ^{1}H nuclear magnetic resonance (NMR) analysis performed on a Bruker (500 MHz) spectrometer.

GC analysis of products and reaction mixtures

GC analysis of reaction mixtures, acetamides, and racemic and chiral standards was carried out on a Hewlett-Packard 6890 Series gas chromatograph with a Hewlett-Packard 6890 Series autosampler equipped with a flame ionization detector. One microlitre was injected under pulse split (1:5) conditions on a Varian Chirasil-Dex CB column (25 m × 0.25 mm × 0.25 μm) with 8 mL/min helium flow. The following temperature program was used: 75 °C for 5 min; 2.5 °C/min to 175 °C, 10 min at 175 °C, 10 °C/min to 200 °C, 2.5 min at 200 °C. Table 3 illustrates retention times for the ketones and acetamides.

GC–MS analysis of acetamides

Analysis of acetamides derived from compounds **10**, **11**, **12**, **14**, and **15** was performed on an Agilent Technologies 7890A GC coupled to a 5975C quadrupole MS and a CTC Analytics Combipal autosampler. One microlitre was injected under pulse split (1:10) conditions on a 30 m × 0.25 mm × 0.25 μm HP-5MS capillary column (Agilent). The temperature program was as follows: 70 °C for 1.5 min; 65 °C/min to 135 °C, 5 °C/min to 280 °C, and 15 min at 280 °C. Helium was used as the carrier gas. The injector and the detector were adjusted to 250 and 280 °C, respectively. The MSD detector was run in the EI (70 eV) scan mode between 45 and 500 amu.

Analysis of propionate amide derived from **9** and acetamide from **18** was performed on a Hewlett-Packard 6890 GC coupled to a 5973 quadrupole MS and a 7683 autosampler. One microlitre was injected under pulse splitless conditions on a 50 m × 0.2 mm × 0.25 μm HP-5MS capillary column (Agilent). The temperature program was as follows: 70 °C for 1.5 min; 65 °C/min to 135 °C, 5 °C/min to 280 °C, and 15 min at 280 °C. Helium was used as the carrier gas. The injector and the detector were adjusted to 250 and 280 °C, respectively. The MSD detector was run in the EI (70 eV) scan mode between 45 and 500 amu.

Preparation of bacterial cells and the crude enzyme extract of CHAO

Escherichia coli BL21 harboring the CHAO-containing plasmid was maintained on LB medium containing glycerol (50%, v/v) at –80 °C. For biotransformation experiments, a fresh LB agar plate (1.5% agar) containing ampicillin (100 μg/mL) was prepared from the stock culture, and one colony was transferred to a preculture (10 mL) containing LB medium supplemented with ampicillin (100 μg/mL) and grown at 30 °C at 200 rpm on an orbital shaker overnight. In a 2 L DASGIP bioreactor system (Germany) an aliquot of the suspension (10 mL) was used to inoculate 1 L of TB medium. The temperature was set to 30 °C and the pH was controlled at 7.0 by the addition of concentrated ammonium hydroxide. The cell broth was aerated at 1.0 vvm and stirred at 400–1000 rpm to maintain 30% dissolved oxygen. If necessary, the airflow was supplemented with oxygen. At an OD_{600} of 10 (~7 h), protein expression was induced by the addition of IPTG (final concentration 1 mmol/L) and glucose (33% w/w aqueous solution) was fed at an initial rate of 3 mL/h and gradually increased to 7 mL/h. The cells were harvested by centrifugation (6300*g*, 4 °C, 20 min) 16 h after induction and washed with 20 mmol/L sodium phosphate buffer (pH 7), followed by centrifugation. Whole cells (could be stored at 4 °C up to 3 days without loss of activity) were resuspended in the appropriate amount of 100 mmol/L phosphate buffer (pH 7) to give a final OD_{600} of 5 and used for the biotransformations.

Alternatively, the centrifuged and washed cells were resuspended in 20 mmol/L sodium phosphate buffer (OD_{600} ~ 70) and broken using a French press cell operating at 20 000 psi (1 psi = 6.894757 kPa). The crude extract was obtained by centrifugation (20 000*g*, 45 min), followed by sterile filtration using a 0.22 μm membrane. Protein concentration was determined by Bradford assay[19] and the activity was determined as described below. A 1 L fermentation yielded ~650 mg of crude CHAO.

Activity assay

Cyclohexylamine oxidase activity was determined by a modified procedure of Braun et al.[20]

The formation of a dye (ε = 29.4 mmol/L^{-1} cm^{-1}) produced by the action of horseradish peroxidase with liberated hydrogen peroxide from the reaction of the amine (5 mmol/L) and CHAO, 4-aminoantipyrine, and 2,4,6-tribromo-3-hydroxybenzoic acid was monitored at 510 nm using a Beckman spectrophotometer (model DU 640). The standard assay mixture (1 mL total volume) contained: 965 μL of 50 mmol/L phosphate buffer (pH 7), 10 μL of a 2,4,6-tribromo-3-hydroxybenzoic acid stock solution (20 mg/ mL in DMSO), 0.15 mg of 4-aminoantipyrine, 5 μL of an amine stock solution (1 mol/L in DMSO), and 10 μL of a horse radish peroxidase stock solution (5 mg/mL). The reaction (1 mL) was started by the addition of 10 μL of an appropriate amount of enzyme at room temperature. Enzymatic assays were performed in triplicate with the appropriate control experiments. One enzyme unit (U) was defined as the amount of enzyme that produced 1 μmol of hydrogen peroxide from

Table 3. Retention times of ketones and alcohols and response factors for amines and ketones.

Compound	Retention time (min) (*R*)-Enantiomer acetamide	(*S*)-Enantiomer acetamide	Ketone	Alcohol[a]	Amine:ketone response factor
9[b]	38.97	38.66	18.69	25.59 and 26.32	1:1.48
10	38.22	37.54	18.59	na	1:1.51
11	45.41	45.95	27.54	na	1:1.63
12	40.69	40.13	23.50	na	1.02:1[c]
14	38.84	38.29	22.47	29.56 and 29.94	1:1.68
15	45.14	44.52	29.06	32.18 and 32.39	1:1.81
18	44.27	43.88	26.83	na	1:1.25
21	28.70	27.65	8.76	na	1:2.57
28	29.66	29.26	na	na	na
29[e]	32.34	32.73	na	na	na

Note: na, not applicable.

[a]Two enantiomers.

[b]Propionate amides were prepared.

[d]Response factor based on acetamide and ketone.

[e]Absolute configuration was not determined; (*R*)- and (*S*)- based on enrichment by CHAO.

cyclohexylamine (**1**) per min. Relative activities (%) were calculated by dividing the activity of the amine tested by the activity of cyclohexylamine (**1**).

Kinetic resolution of racemic amines using either whole cells or crude enzyme extract

Screening scale

The amine (0.2 mmol) dissolved in DMSO (0.2 mL) was added to either a solution of CHAO (final concentration 1.2 U/mL) in 100 mmol/L phosphate buffer (pH 7, 20 mL) or a suspension of whole cells overexpressing CHAO (OD_{600} 5) resuspended in 100 mmol/L phosphate buffer (pH 7, 20 mL). The mixture was shaken at 200 rpm at 30 °C on an orbital shaker for 18 h, before the pH of the reaction mixture was adjusted to 2 with 2 mol/L HCl. The suspension was centrifuged (6300*g*, 20 min) and the supernatant was basified to pH 9 with 5 mol/L NaOH. The aqueous layer was extracted 3 times with DCM and the organic layers were combined, washed with brine, dried over anhydrous sodium sulphate, and filtered. An aliquot (1 mL) was analyzed for the conversion of amine to ketone. For determination of the enantiomeric ratio the organic solvent was concentrated to 1 mL, cooled to 0 °C, and triethylamine (81 mg, 0.8 mmol) was added followed by the dropwise addition of acetylchloride (31 mg, 0.4 mmol). Then the reaction mixture was allowed to react at room temperature for 1 h. An aliquot of the reaction mixture (20 µL) was added to a mixture of DCM–MeOH, 8:2 (1 mL) and analyzed by chiral GC and GC–MS.

Preparative scale

α-Methylbenzylamine (**9**) (121 mg, 1 mmol) dissolved in DMSO (0.5 mL) was added to either a solution of CHAO (final concentration 1.2 U/mL) in 100 mmol/L phosphate buffer (pH 7, 100 mL) or a suspension of whole cells overexpressing CHAO (OD_{600} 5) resuspended in 100 mmol/L phosphate buffer (pH 7, 100 mL). The mixture was shaken at 200 rpm at 30 °C on an orbital shaker for 18 h, before the pH of the reaction mixture was adjusted to 2 with 2 mol/L HCl. The suspension was centrifuged (6300*g*, 20 min) and the supernatant was basified to pH 9 with 5 mol/L NaOH. For the crude enzyme extracts the centrifugation step could be omitted. The aqueous layer was extracted 3 times with DCM and the organic layers were combined. An aliquot (1 mL) was analyzed for the conversion by GC analysis. The organic solvent was concentrated (25 mL) and extracted 3 times with 1 mol/L HCl. The aqueous layers were combined, basified to pH 9 with 5 mol/L NaOH, and extracted 3 times with DCM. The organic layers were combined, washed with brine, dried over anhydrous sodium sulphate, and filtered. Evaporation of the solvent gave enantiopure (*R*)-α-methylbenzylamine (**9**) in 38% yield (46 mg) with whole cell transformations and in 42% yield (51 mg) with the crude enzyme extract experiment. The enantiomeric ratio of the obtained products was determined as described before.

Deracemization of racemic amines using either whole cells or crude enzyme extract

Screening scale

The amine (0.2 mmol) dissolved in DMSO (0.2 mL) was either added to a solution of CHAO (final concentration 1.2 U/mL) and borane–ammonia complex (123 mg, 4.0 mmol) in 100 mmol/L phosphate buffer (pH 7, 20 mL) or to a suspension of whole cells overexpressing CHAO (OD_{600} 5) resuspended in 100 mmol/L phosphate buffer (pH 7, 20 mL) and borane–ammonia complex (123 mg, 4.0 mmol). The mixture was shaken at 200 rpm at 30 °C on an orbital shaker for 18 h, before the pH of the reaction mixture was carefully adjusted to 2 with 2 mol/L HCl. The suspension was centrifuged (6300*g*, 20 min) and the supernatant was basified to pH 9 with 5 mol/L NaOH. The aqueous layer was extracted 3 times with DCM and the organic layers were combined, washed with brine, dried over anhydrous sodium sulphate, and filtered. An aliquot (1 mL) was analyzed for the content of amine, the corresponding ketone, and alcohol derivatives. For determination of the enantiomeric ratio the organic solvent was concentrated to 1 mL, treated with acetylchloride, and analyzed by chiral GC as described before.

Preparative scale

The amine (1 mmol) dissolved in DMSO (0.5 mL) was either added to a solution of CHAO (final concentration 1.2 U/mL) and borane–ammonia complex (617 mg, 20.0 mmol; for the deracemization of **9**, 926 mg, 30 mmol) in 100 mmol/L phosphate buffer (pH 7, 20 mL) or to a suspension of whole cells overexpressing CHAO (OD_{600} 5) resuspended in 100 mmol/L phosphate buffer (pH 7, 20 mL) and borane–ammonia complex (617 mg, 20.0 mmol). The mixture was shaken at 200 rpm at 30 °C on an orbital shaker for 18 h, before the pH of the reaction mixture was carefully adjusted to 2 with 2 mol/L HCl. The suspension was centrifuged (6300*g*, 20 min) and the supernatant was basified to pH 9 with 5 mol/L NaOH. The aqueous layer was extracted 3 times with DCM, the organic layers were combined, and an aliquot (1 mL) was analyzed for the content of amine and the corresponding ketone and alcohol. The organic solvent was concentrated (25 mL) and extracted 3 times with 1 mol/L HCl. The aqueous layers were combined, basified to pH 9 with 5 mol/L NaOH, and extracted 3 times with DCM. The organic layers were combined, washed with brine, dried over anhydrous sodium sulphate, and filtered.

Evaporation of the solvent gave 83 mg (69% yield) of (*R*)-**9** using crude enzyme extracts, 75 mg (62% yield) of (*R*)-**9** using whole cells, 101 mg (75% yield) of (*R*)-**14** using crude enzyme extracts, and 92 mg (69% yield) of (*R*)-**14** using crude enzyme extracts. The enantiomeric ratio of the obtained products was determined after derivatization of an aliquot of the product as described before.

The role of solvent in organometallic chemistry — Oxidative addition with dichloromethane or chloroform

Anwar Abo-Amer, Matthew S. McCready, Fenbao Zhang, and Richard J. Puddephatt

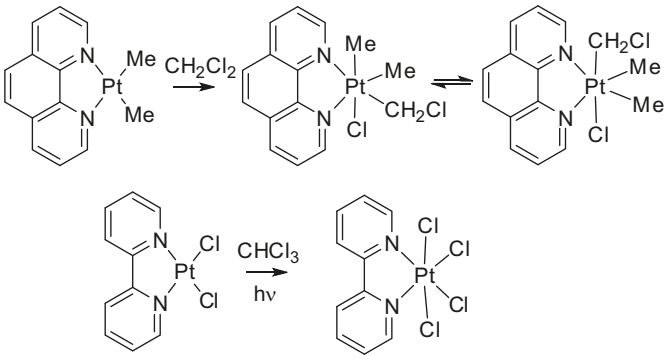
Can. J. Chem. Downloaded from www.nrcresearchpress.com by Renmin University of China on 09/02/12
For personal use only.

Abstract: Dimethylplatinum(II) complexes [$PtMe_2$(NN)], with NN = diimine ligand, can react with dichloromethane or chloroform solvent to give the corresponding organoplatinum(IV) complexes [$PtClMe_2(CH_2Cl)$(NN)] or [$PtClMe_2(CHCl_2)$(NN)], respectively. The products can exist in isomeric forms, corresponding to products of cis or trans oxidative addition. The structures of three dichloromethane adducts and one chloroform adduct are reported.

Key words: platinum, dichloromethane, chloroform, oxidative addition.

Résumé : Les complexes du diméthylplatine(II) [$PtMe_2$(NN)] dans lesquels NN correspond à un ligand diimine peuvent réagir avec les solvants dichlorométhane et chloroforme pour conduire respectivement aux complexes organoplatine(IV) correspondants [$PtClMe_2(CH_2Cl)$(NN)] ou [$PtClMe_2(CHCl_2)$(NN)]. Les produits peuvent exister sous des formes isomères qui correspondent à des produits d'addition oxydante cis ou trans. On a déterminé et on rapporte les caractéristiques des structures de trois adduits du dichlorométhane et d'un adduit du chloroforme.

Mots-clés : platine, dichlorométhane, chloroforme, addition oxydante.



[Traduit par la Rédaction]

Introduction

One of the challenges in the application of organometallic compounds is that there are limits on the range of solvents that can be used. For example, the development of organometallic chemistry in "greener" solvents, such as water or ionic liquids, has presented unusual challenges and opportunities.[1,2] Metal–alkyl bonds are often cleaved by protic solvents, whereas halogen-containing solvents can react to form metal halides.[1,2] Chlorinated solvents such as dichloromethane and chloroform may react with transition-metal complexes in low oxidation states by oxidative addition of one or more of the C–Cl bonds, and examples are known with several late-transition metals including rhenium,[3,4] ruthenium,[5] cobalt,[6,7] rhodium,[8–22] iridium,[23] palladium,[24–27] platinum,[28–37] and gold.[38] In previous studies of electron-rich dimethylplatinum(II) complexes, it has been noted that reactions with chlorinated solvents can occur to give oxidative addition of a C–Cl bond or to give chlorine atom abstraction or a mixture of these reactions (Scheme 1).[31–37,39,40]

This paper describes new examples of these reactions including the first examples with unsymmetrical supporting ligands, leading to a greater range of isomeric organoplatinum(IV) products, and the first structure determinations on

Scheme 1. Oxidative addition and chlorine abstraction reactions.[33,40]

chloromethyl and dichloromethyl derivatives of platinum(IV). This allows a comparison of the structures of the platinum(IV) complexes with known platinum(II) complexes, which have been prepared either by oxidative addition to Pt(0) or by methylene insertion reactions.[27,28,41–43]

Results

The complex [$PtMe_2$(2,2′-bipyridine)] is already known to react with dichloromethane by oxidative addition of a C–Cl

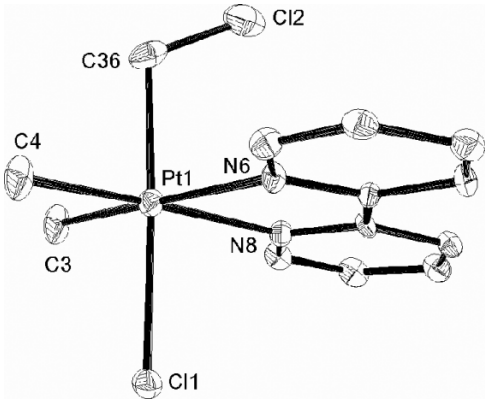
							4.89	91

Scheme 2. Complexes with 2,2′-bipyridine.



bond (Scheme 2).[32,37] The thermodynamically more stable product is **2a**, but the kinetic product is mostly **2b**, formed by cis-oxidative addition. At equilibrium, the ratio of isomers **2a**:**2b** in roughly 5:2. Complexes **2a** and **2b** have effective C_s and C_1 symmetry, respectively, so, in the ^{1}H NMR spectrum, **2a** gives a single methylplatinum resonance and a single $PtCH_2Cl$ resonance, whereas **2b** gives two methylplatinum resonances and two resonances for the $PtCH^aH^bCl$ protons (Table 1). The equatorial and axial PtMe and $PtCH_2Cl$ groups (defined with respect to the Pt–bipy plane) are readily identified by the characteristic differences in chemical shifts (Table 1). For example, in **2b** the equatorial $PtMe^a$ and $PtMe^c$ resonances occur at δ(^{1}H) = 1.39 and 0.65, respectively, and the equatorial and axial $PtCH_2Cl$ resonances in **2b** and **2a**, respectively, occur at δ(^{1}H) = 4.34 and 4.67 and at δ(^{1}H) = 3.33 (Table 1).

Recrystallization of the mixture of isomeric compounds **2a** and **2b** gave single crystals of **2a**, but crystals of **2b** could not be obtained. The structure of complex **2a** is shown in Fig. 1. It confirms that the chloromethyl group and chloride ligand are mutually trans in the octahedral platinum(IV) complex. The chloromethyl group is oriented such that the chlorine atom lies towards one of the pyridyl nitrogen atoms of the 2,2′-bipyridine ligand, with the torsion angle N(8)–Pt(1)–C(36)–Cl(2) = –3.5°. The angle Pt(1)–C(36)–Cl(2) of 115.2(7)° is larger than the tetrahedral angle, perhaps to reduce steric interactions. There is minor unresolved disorder in the position of the chloromethyl group.

The reactions of dichloromethane solvent with two unsymmetrical dimethylplatinum(II) complexes were studied, as shown in Scheme 3. In these cases, there are three possible isomeric products of oxidative addition and all three were observed. In the slow reaction of the dimethylplatinum(II) complex **3**, with the 3,6-di-2-pyridylpyridazine derivative (dppd) as the supporting ligand,[44,45] the reaction with CD_2Cl_2 gave a mixture of **4a**:**4b**:**4c** in the ratio 3:2:1 after 2 h reaction, but 5:1:1 after 24 or 48 h, as determined by monitoring using ^{1}H NMR. In this case, the oxidative addition was slow and was only about 20% complete after 2 h, but complete after 24 h, and it seems that the rate of isomerization is competitive with the rate of oxidative addition. Complex **4b** is formed in a higher proportion early in the reaction, so it can be considered as the kinetically preferred product, but the selectivity cannot be determined accurately. The reaction of dimethylplatinum(II) complex **5** with the 2,5-di-2-pyridyl-1,3,4-oxadiazole supporting ligand dpox[46,47] occurred in a similar way to give **6a**:**6b**:**6c** in a final ratio of 9:1:1.

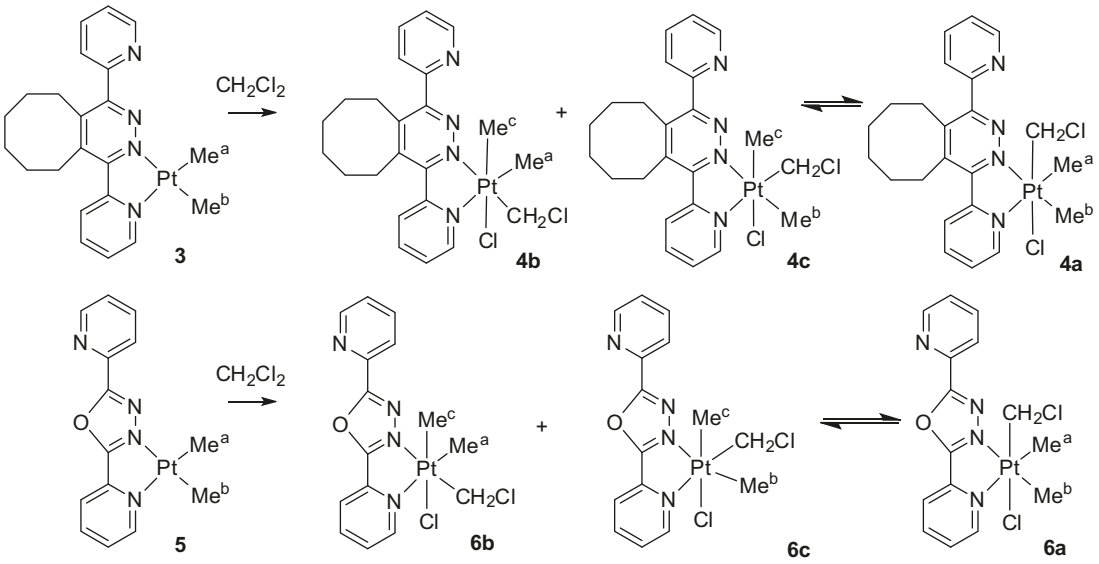


Fig. 1. A view of the structure of complex **2a**. Selected dimensions: Pt(1)–C(3) 2.079(12) Å, Pt(1)–C(4) 2.115(16) Å, Pt(1)–C(36) 2.076(14) Å, Pt(1)–N(6) 2.167(8) Å, Pt(1)–N(8) 2.177(10) Å, Pt(1)–Cl(1) 2.435(3) Å, Cl(2)–C(36) 1.74(2) Å; Pt(1)–C(36)–Cl(2) 115.2(7)°.

The isomers were identified by their ^{1}H NMR spectra, as illustrated here for the mixture **4a**, **4b**, and **4c**. The major isomer **4a** was readily identified by the presence of two equatorial methylplatinum chemical shifts and the typical chemical shift values for an axial $PtCH_2Cl$ group (Table 1, compare with **2a** and **2b**). Distinguishing between the isomers **4b** and

Can. J. Chem. Downloaded from www.nrcresearchpress.com by Renmin University of China on 09/02/12
For personal use only.

Scheme 3. The unsymmetrical dichloromethane adducts.

4c was more difficult and relied on information from COSY and NOESY NMR spectra to identify whether the methyl or CH_2Cl group was adjacent to the *ortho*-pyridyl proton for a given isomer. It can be seen from the data in Table 1 that the equatorial methylplatinum group $PtMe^b$ consistently had a higher chemical shift than for the other equatorial methylplatinum group $PtMe^a$.[48,49] The isomers **6a**, **6b**, and **6c** were identified in a similar way.

The structure of complex **4a** is shown in Fig. 2. The structure is similar to that of **2a**. In **4a** the chlorine atom of the chloromethyl group lies above the nitrogen atom of the coordinated pyridyl group, with a torsion angle of N(4)–Pt(1)–C(21)–Cl(1) = 5° and with the angle Pt(1)–C(21)–Cl(1) = 116.2(4)°. The presence of the cyclooctene ring in **4a** causes steric hindrance, and the pyridyl and pyridazine rings are skewed by 17° to reduce the steric congestion. In contrast, the two pyridyl rings in **2a** are skewed by only 1°. The uncoordinated pyridyl group is skewed with respect to the pyridazine ring by 49°; this distortion is presumably again to reduce steric hindrance, since potential conjugation would favour the planar structure.

The structure of complex **6a**·H_2O is shown in Fig. 3. There are similarities and some differences when compared with the structures of **2a** and **4a**. In **6a**, as observed in **4a**, the chlorine atom of the chloromethyl group lies roughly above the nitrogen atom of the coordinated pyridyl group, with a torsion angle N(1)–Pt(1)–C(2)–Cl(1) = –15° and with the angle Pt(1)–C(21)–Cl(1) = 116.2(4)°. In contrast to **4a**, the coordinated pyridyl and oxadiazole rings are skewed by only 2°, and the free pyridyl ring and the oxadiazole ring are skewed by only 3°. These differences clearly arise as a result of the much lower steric hindrance in **6a** compared with **4a**. The nitrogen atom of the free pyridyl group and the oxygen atom of the oxadiazole group are mutually syn, and they are involved in hydrogen bonding to one hydrogen atom of a water solvate molecule (Fig. 3, O(1)···O(2B) = 2.98 Å and N(5)···O(2B) = 3.03 Å). The second hydrogen atom of the water molecule hydrogen bonds to the PtCl chlorine atom of a neighbouring molecule, and this hydrogen bonding forms racemic dimer units in which the two

Fig. 2. A view of the structure of complex **4a**. Selected parameters: Pt(1)–C(21) 2.027(8) Å, Pt(1)–C(22) 2.046(7) Å, Pt(1)–C(23) 2.052 (8) Å, Pt(1)–N(4) 2.133(6) Å, Pt(1)–N(1) 2.136(5) Å, Pt(1)–Cl(2) 2.4371(18) Å Cl(1)–C(21) 1.767(9) Å, Cl(1)–C(21)–Pt(1) 116.2(4)°.

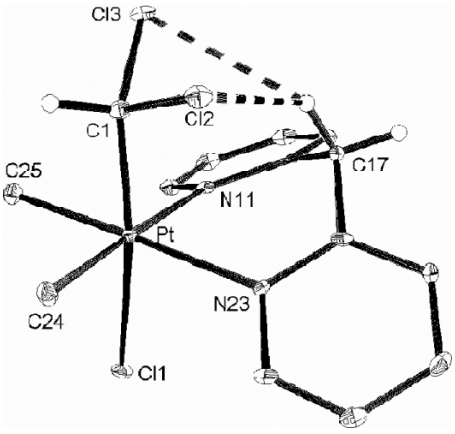
Scheme 4. Oxidative addition of chloroform.



chiral molecules of **6a** are related by an inversion centre (Fig. 3; Cl(2)···O(2A) = 3.23 Å).

The oxidative addition of chloroform to dimethylplatinum (II) complexes often gives intractable mixtures of products,[32,35] but the reaction with [$PtMe_2$(dpm)] (dpm = di-2-pyridylmethane)[48] occurred to give complex **8a** as the major product according to Scheme 4. The complex **8b** was not confidently detected, but there was evidence for formation of complex **9**, the product of chlorine atom abstraction, when the reaction was monitored in $CDCl_3$.[35,39]

The structure of complex **8a** is shown in Fig. 4 and confirms the trans orientation of the $CHCl_2$ and Cl groups. The dichloromethyl group adopts a conformation with the chlorine atoms roughly above each coordinated nitrogen atom of the dpm ligand, with torsion angles N(11)–PtC(1)–Cl(3) = 20.3° and N(23)–PtC(1)–Cl(2) = –18°. The dpm ligand adopts a bowed conformation (angle between the planes of the pyridyl groups = 47°) with the CH_2 group oriented towards the dichloromethyl group. In this conformation, one of the hydrogens is in a position to form a weak CH···Cl hydrogen bond to both of the $CHCl_2$ chlorine atoms with C(17)···Cl(2) = 3.43 Å and C(17)···Cl(3) = 3.49 Å (Fig. 4).

Fig. 4. A view of the structure of complex **8a**. Selected bond parameters: Pt–C(1) 2.040(7) Å, Pt–C(25) 2.051(7) Å, Pt–C(24) 2.062(7) Å, Pt–N(23) 2.163(5) Å, Pt–N(11) 2.171(5)Å, Pt–Cl(1) 2.406(2) Å, C(1)–Cl(2) 1.796(7) Å, C(1)–-Cl(3) 1.806(7) Å; selected angle parameters: Cl(2)–C(1)–Cl(3) 108.2(4)°, Cl(2)–C(1)–Pt 114.7(4)°, Cl(3)–C(1)–Pt 114.2(3)°.

Discussion

The structure determination of both chloromethyl (**2a**, **4a**, and **6a**) and dichloromethyl (**8a**) complexes of platinum(IV) allows a comparison of the bond parameters, and selected data are given in Table 2.[50,51] The Pt–Cl distance is slightly shorter in **8a** than in the chloromethyl complexes, indicating that the more electronegative dichloromethyl group in **8a** has a slightly lower trans influence than the chloromethyl group. The Pt–Cl distances are all in the range expected for a Pt–Cl bond trans to an alkyl group, but the data indicate the trans-influence series $CH_3 > CH_2Cl > CHCl_2$.[52–54]

In the parent chlorocarbons, the C–Cl distance decreases slightly in the sequence $CH_3Cl > CH_2Cl_2 > CHCl_3$ (Table 2),[50] but the limited data suggest that the trend is reversed in the platinum complexes with *d*(C–Cl) for **8a** > **6a**. This could be interpreted in terms of carbene character from resonance forms $[Pt{=}CHCl]^+Cl^-$, but the other bond parameters, such as the value of *d*(Pt–C) = 2.040(7) Å, do not support this interpretation. Instead the parameters suggest a more polar group $Pt^{\delta+}$–$CHCl_2^{\delta-}$, but without significant carbene character. We note that the differences in C–Cl distances (excluding the disordered **2a**) are just statistically significant, so further comment is not warranted.

A second feature of interest is the kinetic preference for cis-oxidative addition in the reactions of dichloromethane to form **2**, **4**, and **6** (Schemes 2 and 3), and this will be considered in terms of the simplest example with the 2,2′-bipyridine ligand. Three possible mechanisms are shown in Scheme 5. Dichloromethane can undergo nucleophilic substitution,[51] and this could lead to oxidative addition by the polar mechanism involving an initial intermediate $[PtMe_2(CH_2Cl)(bipy)]^+Cl^-$ (***A***), which would need to isomerize to a second intermediate ***B*** before coordination of chloride occurs to form the cis product **2b** (Scheme 5).[55–57] Subsequent isomerization of **2b** to **2a** would require reversal of this step, to proceed through intermediates ***B*** and ***A*** (Scheme 5). There is evidence that the reactions with dichloromethane can be accelerated by photolysis or by radical initiators and retarded by radical scavengers, indicating that at least part of the oxidative addition occurs through a radical chain mechanism.[33,34,58,59] The initial radical, formed by attack of the chain-carrying radical $CH_2Cl\cdot$ would be ***C*** and this would need to isomerize to ***D*** prior to chlorine-atom abstraction from solvent to form **2b** as the kinetic product (Scheme 5). The subsequent isomerization of **2b** to **2a** would occur through intermediates ***B*** and ***A***, as in the polar mechanism (Scheme 5).[55–57] A third mechanism might involve a free radical nonchain mechanism, involving a radical pair formed by chlorine-atom abstraction to give ***E***, but there is no easy way to form isomer **2b** in this case, since isomerization of ***E*** to ***F*** followed by recombination would give the unobserved isomer ***G*** (Scheme 5). Therefore, this mechanism can probably be eliminated. The activation energy for the chlorine-atom abstraction step to give $[PtClMe_2(bipy)]\cdot + CH_2Cl\cdot$ is calculated to be 193 kJ mol^{-1} and this represents the initiation step for the free radical chain reaction. The chain reaction is expected to be fast (Fig. 5), but thermal initiation is slow.

Some further insight into the mechanism was obtained by carrying out DFT calculations. First, it was calculated that **2a** is more stable than **2b** by only 2 kJ mol^{-1}, consistent with the

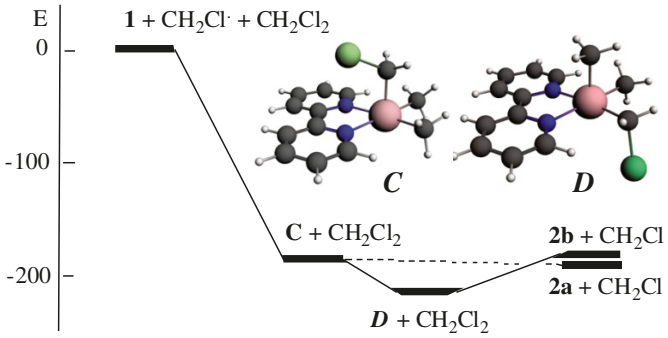
8a	2.406(2)	2.040(7)	1.796(7), 1.806(7)	114.7(4), 114.2(3)	108.2(4)



Scheme 5. Three possible mechanisms of reaction.

observed equilibrium constant K = [**2a**]/[**2b**] = 2.5, corresponding to ΔG(293K) = –2.2 kJ mol^{-1}. However, for the radical intermediates (Fig. 5), it was calculated that ***D*** is more stable than ***C*** by 37 kJ mol^{-1}, so the required isomerization step in Scheme 5 should be favoured. Chlorine-atom abstraction by ***D*** would then give **2b** as the kinetic isomer.

Fig. 5. Calculated energies (kJ mol^{-1}) and structures of intermediates ***C*** and ***D*** in the radical chain mechanism of oxidative addition of dichloromethane.

There are two factors that appear to favour the isomerization of ***C*** to ***D***. First, there is a steric factor because the chloromethyl group in ***D*** can adopt a conformation with the larger chlorine atom towards the open coordination site (Fig. 5) and so it is favourable to have the bulkier alkyl group in an equatorial position in the 5-coordinate compound, whereas in the octahedral complex, it is favourable to have the chloromethyl group in the axial position in **2a**, where the chlorine substituent can lie above the flat 2,2′-bipyridine ligand (Fig. 1). Second, there is an electronic effect because the methyl group has a slightly greater trans influence than the chloromethyl group and the vacant site tends to be in the position across from the ligand with highest trans influence, and perhaps also because of more favourable delocalization of the radical onto the chloromethyl group (Fig. 6). The angle Pt–C–Cl is calculated to be 107°, compared with 117° in **2b**, but the associated distance Pt···Cl = 3.28 Å is still too long for there to be a significant bonding interaction. Figure 6 indicates that the radical is also delocalized over the π-system of the bipy ligand. A similar trend in relative energies is calculated for the possible cationic intermediates, with ***B*** calculated to be more stable than ***A*** by 20 kJ mol^{-1}. Hence, the stereochemistry of the oxidative addition reaction can be rationalized in terms of either the polar S_N2 mechanism or the free radical chain mechanism, but not by the free radical nonchain mechanism (Scheme 5). The experimental data indicate that the free radical chain reaction is the dominant mechanism.

For oxidative addition of chloroform, the S_N2 mechanism is precluded because of steric effects in the transition state and so the free radical chain mechanism is most likely. The DFT calculations indicate a greater overall driving force for oxidative addition (–239 vs –197 kJ mol^{-1} for the reaction of **1** with chloroform vs dichloromethane; Figs. 5 and 7). There is less preference (25 vs 37 kJ mol^{-1}) for the radical *cis*-[$PtMe_2(CHCl_2)$(bipy]· (***H***) over the isomer *trans*-[$PtMe_2(CHCl_2)$(bipy]· (***I***), but higher preference (25 vs 2 kJ mol^{-1}) for the product *trans*-[$PtClMe_2(CHCl_2)$(bipy] (***J***) over *cis*-[$PtMe_2(CHCl_2)$(bipy] (***K***), when compared with the dichloromethane reaction. The formation of only isomer **8a** in the reaction of **7** with chloroform is therefore not surprising.

Experimental section

^{1}H NMR spectra were recorded using a Varian Mercury 400 or a Varian Inova 400 NMR spectrometer. The ligands

and the complexes [$PtMe_2$(NN)] (NN = bipy, **1**; dppn, **3**; dpox, **5**; dpm, **7**) were prepared using the literature methods.[45,46,48,49,60,61] The DFT calculations were carried out by DFT calculations, using the Amsterdam Density Functional program based on the Becke–Perdew functional, with first-order scalar relativistic corrections.[62] Data for the X-ray structure determinations were collected using a Bruker diffractometer. The frames were integrated with the Bruker SAINT software package using a narrow-frame algorithm. Data were corrected for absorption effects using the multi-scan method (SADABS). The structures were solved by direct methods and refined using the Bruker SHELXTL software package. Details are given in Table 3. For complex **6a**, the hydrogen atoms of the water molecule could not be located or positions calculated using the riding atom procedure, so the water molecule was treated as an oxygen atom only. For **2a**, there was evidence for minor disorder of the chloromethyl group, but the disorder could not be resolved; the positions of the CH_2Cl atoms are therefore poorly defined.

[PtClMe$_2$(CH$_2$Cl)(bipy)] (2a and 2b)

A solution of [PtMe$_2$(bipy)] (60 mg, 0.16 mmol) in CH_2Cl_2 (15 mL) was stirred at room temperature for 24 h. The red solution became pale yellow. The solvent was removed under vacuum and the resulting pale yellow solid was washed with diethyl ether. Crystals of **2a** were grown from CH_2Cl_2/pentane by slow diffusion. Yield: 90%, as isomeric mixture. NMR in CD_2Cl_2 **2a**: δ(^{1}H) = 1.29 (s, 6H, ^2J(PtH) = 69 Hz, PtMe), 3.55 (s, 2H, ^2J(PtH) = 52 Hz, PtCH_2Cl), 7.64 (m, 2H, bipy), 8.10 (m, 2H, bipy), 8.26 (m, 2H, bipy), 8.84 (m, 2H, bipy); **2b**: δ(^{1}H) = 0.65 (s, 3H, ^2J(PtH) = 74 Hz, PtMe^c *trans* to Cl), 1.39 (s, 3H, ^2J(PtH) = 69 Hz, PtMe^a *trans* to N), 4.34 (m, 1H, ^2J(HH) = 8 Hz, ^2J(PtH) = 46 Hz, PtCH_2Cl), 4.67 (m, 1H, ^2J(HH) = 8 Hz, ^2J(PtH) = 88 Hz, PtCH_2Cl); bipy resonances partly obscured in the range δ(^{1}H) = 7.6 – 9.3. Anal. calcd for $C_{13}H_{16}C_{l2}N_2Pt$ (%): C 33.49, H 3.46, N 6.01; found: C 33.02, H 3.11, N 5.95.

[PtClMe$_2$(CH$_2$Cl)(dppn)] (4a–4c)

A solution of [PtMe$_2$(6-dppn)] (25 mg) in CH_2Cl_2 (5 mL) was allowed to stand overnight. The solvent was then removed under vacuum and the product was washed with pentane (2 × 5 mL). The resultant yellow solid was recrystallized from acetone/pentane. The crystal of **4a** was obtained from acetone/pentane by slow diffusion. Yield: 84% as isomeric mixture. NMR in acetone-d^6) **4a**: δ(^{1}H) = 1.26 (s, 3H, ^2J(PtH) = 70 Hz, Pt–Me^a trans to N), 1.41 (s, 3H, ^2J(PtH) = 70 Hz, Pt–Me^b trans to N), 1.54–1.75 (m, 4H, 2 × ring CH_2), 2.01 (m, 2H, ring CH_2), 2.13 (m, 2H, ring CH_2), 3.25 (m, 2H, ring CH_2), 3.49 (m, 2H, ring CH_2), 3.53 (d, 1H, ^2J(H^{a}H^b) = 7 Hz, ^2J(PtH^b) = 48 Hz, Pt–CH^a*H^b*Cl), 3.54 (d, 1H, ^2J(H^{a}H^b) = 7 Hz, ^2J(PtH^a) = 58 Hz, Pt–C*H^a*H^{b}Cl), 7.61 (m, 1H, $H_5{}^1$), 7.95 (t, 1H, H_5), 8.11 (m, 2H, $H_3{}^2$/$H_4{}^2$), 8.41 (t, 1H, $H_4{}^1$), 8.60 (d, 1H, $H_3{}^1$), 8.79 (d, 1H, $H_6{}^1$), 9.06 (d, 1H, H_6, ^3J(PtH) = 19 Hz); **4b**: δ(^{1}H) = 0.61 (s, 3H, ^2J(PtH) = 74 Hz, Pt–Me^c trans to Cl), 1.44 (s, 3H, ^2J(PtH) = 70 Hz, Pt–Me^a trans to N), 1.55–3.50 (12H, 6 × ring CH_2), 4.72 (d, 1H, ^2J(H^a*H^b*) = 6 Hz, ^2J(PtH) = 78 Hz, PtCH_2Cl), 4.89 (d, 1H, ^2J(*H^a*H^b) = 6 Hz, ^2J(PtH) = 86 Hz, PtCH_2Cl), 7.55–9.55 (8H, pyridyl); **4c**: δ(^{1}H) = 0.66 (s, 3H, ^2J(PtH) = 74 Hz, Pt–Me^c trans to Cl), 1.55 (s, 3H, ^2J(PtH) = 70 Hz, Pt–Me^b trans to N), 1.55–3.50 (12H, 6 × ring CH_2), 4.26 (d, 1H, ^2J(H^a*H^b*) = 8 Hz, ^2J(PtH) = 44 Hz, PtCH_2Cl), 4.74 (d, 1H, ^2J(*H^a*H^b) = 8 Hz, ^2J(PtH) = 92 Hz, PtCH_2Cl), 7.55–9.55 (8H, 8 × py CH). Anal. calcd for $C_{23}H_{28}Cl_2N_4Pt$ (%): C 44.10, H 4.50, N 8.94; found: C 43.83, H 4.58, N 8.67.

[PtMe$_2$Cl(CH$_2$Cl)(dpox)] (6a–6c)

A solution of [PtMe$_2$(dpox)] (**5**, 20 mg) in dichloromethane (5 mL) was stirred at room temperature for 24 h. The red solution turned pale yellow. The solvent was removed under vacuum and the resulting pale yellow solid was washed with diethyl ether. The crystal of **6a** was obtained from CH_2Cl_2/pentane by slow diffusion. Yield: 80%. ^{1}H NMR in CD_2Cl_2 **6a**: δ(^{1}H) = 1.46 (s, 3H, ^2J(PtH) = 74 Hz, PtMe^a), 1.60 (s, 3H, ^2J(PtH) = 74 Hz, PtMe^b), 3.62 (d, 1H, ^2J(HH) = 7 Hz, ^2J(PtH) = 44 Hz, PtCH_2Cl), 3.83 (d, 1H, ^2J(HH) = 7 Hz, ^2J(PtH) = 57 Hz, PtCH_2Cl), 7.63 (m, 1H, py), 7.88 (m, 1H), 8.04 (m, 1H), 8.27 (m, 1H), 8.37 (m, 1H), 8.43 (m, 1H), 8.86 (m, 1H), 8.94 (m, 1H); **6b**: δ(^{1}H) = 0.92 (s, 3H, ^2J(PtH) = 73 Hz, PtMe^c), 1.45 (s, 3H, ^2J(PtH) = 73 Hz, PtMe^a), 4.27 (d, 1H, ^2J(HH) = 7 Hz, ^2J(PtH) = 43 Hz, PtCH_2Cl), 4.84 (d, 1H, ^2J(HH) = 7 Hz, ^2J(PtH) = 89 Hz, PtCH_2Cl; aromatic peaks partly obscured in region δ(^{1}H) = 7.5–9.6; **6c**: δ(^{1}H) = 0.93 (s, 3H, ^2J(PtH) = 73 Hz, PtMe^c), 1.69 (s, 3H, ^2J(PtH) = 73 Hz, PtMe^b), 4.22 (d, 1H, ^2J(HH) = 7 Hz, ^2J(PtH) = 43 Hz, PtCH_2Cl), 4.89 (d, 1H, ^2J(HH) = 7 Hz, ^2J(PtH) = 91 Hz, PtCH_2Cl); aromatic peaks partly obscured in region δ(^{1}H) = 7.5–9.6.

[PtClMe$_2$(CHCl$_2$)(dpm)] (8a)

A solution of [PtMe$_2$(dpm)] (0.10 g) in $CHCl_3$ (2 mL) was allowed to stand at room temperature for 1 day. The pale

yellow crystals that precipitated were separated by filtration, washed with ether, and dried under vacuum. Yield: 87%. NMR in $CDCl_3$: $\delta(^1H)$ = 1.50 (s, 6H, ^2J(PtH) = 67 Hz, PtMe), 4.24, 5.49 (each d, 1H, ^2J(HH) = 16 Hz, CH_2), 5.83 (s, 1H, ^2J(PtH) = 45 Hz, $PtCHCl_2$), 7.34 (t, 2H, ^3J(HH) = 7 Hz, py H^5), 7.52 (d, 2H, ^3J(HH) = 7 Hz, py H^3), 7.81 (t, 2H, ^3J(HH) = 7 Hz, py H^4), 8.81 (d, 2H, ^3J(HH) = 7 Hz, ^3J(PtH) = 13 Hz, py H^6). Anal. calcd for $C_{14}H_{17}Cl_3N_2Pt$ (%): C 32.67, H 3.33, N 5.44; found: C 32.48, H 3.47, N 5.39.

Abstract: In this study, electrospray ionization mass spectrometry (ESI-MS) and circular dichroism (CD) spectroscopy were used to investigate selective recognition of G-quadruplex in the vascular endothelial growth factor (*VEGF*) gene with 12 small-molecule natural products. We found that kaempferol, a natural flavonol, shows the highest binding affinity among the 12 natural molecules. The results from ESI-MS and CD spectra indicated that kaempferol could enhance the thermal stability of the *VEGF*–G-quadruplex and showed selective recognition for the G-quadruplex in a solution consisting of the G-quadruplex and the corresponding duplex DNA.

Key words: VEGF gene, natural products, DNA recognition, ESI mass spectrometry, CD spectroscopy.

Résumé : Dans ce travail, on a utilisé la spectrométrie de masse avec ionisation par électronébulisation (SM-IEN) et la spectroscopie de dichroïsme circulaire (DC) pour étudier la reconnaissance sélective d'un quadruplex G dans le gène du facteur de croissance endothélial vasculaire (*FCEV*) par 12 petites molécules de produits naturels. On a trouvé que le kaempférol, un flavonol naturel, possède l'affinité de fixation la plus élevée parmi ces 12 molécules naturelles. Les résultats des spectres de SM-IEN et de DC indiquent que le kaempférol pourrait augmenter la stabilité thermique du *FCEV*–quadruplex G et qu'il présente une reconnaissance sélective pour le quadruplex G dans une solution formée du quadruplex G et du duplex correspondant de l'ADN.

Mots-clés : gène du facteur de croissance endothélial vasculaire (*FCEV*), produits naturels, reconnaissance de l'ADN, spectrométrie de masse avec ionisation par électronébulisation (IEN), spectroscopie de dichroïsme circulaire (DC).

[Traduit par la Rédaction]

Introduction

Targeting G-guadruplex with chemical small molecules is a useful strategy for gene therapy of cancers.[1–4] Thus, the development of novel small-molecule ligands has attracted the interest of many scientists.[5–7]

The human vascular endothelial growth factor (*VEGF*) gene has an important function in the spread of cancers, and the overexpression of *VEGF* is found in some human tumors.[8,9] The d(GGGGCGGGCCGGGGGCGGGG) sequence located at –85 to –66 bp upstream of the *VEGF* promoter can form the G-quadruplex structure, which is essential for the regulation of *VEGF* expression in cancer cells.[10–13] In our previous study,[11] a synthetic molecule, perylene derivative, showed good binding affinity to the G-quadruplex. Because of the structural diversity of natural products and their lower toxicity compared with synthetic compounds,[14,15] 12 small-molecule natural products were selected to study the selective recognition for the human *VEGF*–G-quadruplex structure (Fig. 1).

Electrospray ionization mass spectrometry (ESI-MS) with high sensitivity and rapid speed is a powerful tool for investigation of noncovalent interactions between small molecules and DNA[16–19] and it is easy to get the information about the stoichiometry of the complexes and the binding affinities. Circular dichroism (CD) spectroscopy can obtain the DNA conformation information and is also widely used to study interactions of DNA and small molecules.[7,20–22] In this research, ESI-MS coupled with CD spectroscopy was used to probe the selective recognition of small-molecule natural products to *VEGF*–G-quadruplex. The results indicate that

kaempferol, a natural flavonol isolated from tea, is a potential G-quadruplex binding agent with selective recognition.

Results and discussion

Noncovalent interactions between small molecules and *VEGF*–G-quadruplex

It has been confirmed that NH_4Ac can induce the *VEGF* G-rich sequence (S1) to adopt intramolecular parallel/antiparallel G-quadruplex structure.[11] In this study, 12 natural-product molecules were selected to probe the noncovalent interactions with human *VEGF*–G-quadruplex by ESI-MS. The mass spectra of *VEGF*–G-quadruplex and four small-molecule natural products in a molar ratio of 1:4 as examples are shown in Fig. 2. In the ESI mass spectra,[11] $[G]^{5-}$ and $[G]^{4-}$ denote the G-quadruplex ions with –5 and –4 charge, respectively, $[G + nP]^{5-}$ and $[G + nP]^{4-}$ denote the 1:*n* complex ion of G-quadruplex and a small molecule with –5 and –4 charge, respectively. The mass spectrum (Fig. 2A) shows that the 1:1 complex ion ($[G + P]^{5-}$ at *m*/*z* 1335.3) of the G-quadruplex (G) with kaempferol (P1) was the base peak (100%) and the 1:2 complex ion ($[G + 2P]^{5-}$ at *m*/*z* 1392.4) was nearly 50%, whereas the intensity of the G-quadruplex peak ($[G]^{5-}$ at *m*/*z* 1278.0) was only 70%. The results from ESI-MS indicate that kaempferol is a good binding molecule to the *VEGF*–G-quadruplex. For the other molecules, such as P6, the intensity of the 1:1 complex ion ($[G + P]^{5-}$ at *m*/*z* 1361.6) was about 80%, but the G-quadruplex peak ($[G]^{5-}$ at *m*/*z* 1278.0) remained the base peak (Fig. 2B). And the ESI mass spectra of P7 and P12 with the *VEGF*–G-quadruplex also exhibited the stronger peaks of the complex ions (Figs. 2C and 2D), respectively.

To estimate the binding properties of small molecules, the parameter IR, is introduced to compare the binding affinities of different small molecule natural products with the *VEGF*–G-quadruplex.[11] IR[G + P] and IR[G + 2P] denote the ability of G-quadruplex to bind with one or two small molecules, respectively, IRa is a ratio of the total intensity of the complex ion to the total intensity of the G-quadruplex ion and denotes the relative binding affinity of the small molecule to the G-quadruplex.

$$[1] \qquad \mathrm{IR}[\mathrm{G}+n\mathrm{P}] = \frac{\sum I_r(\mathrm{G}+n\mathrm{P})}{\sum I_r(\mathrm{G})} \qquad (n = 1 \text{ or } 2)$$

$$[2] \qquad \mathrm{IRa} = \frac{\sum I_r(\mathrm{G}+\mathrm{P}) + \sum I_r(\mathrm{G}+2\mathrm{P})}{\sum I_r(\mathrm{G})}$$

where $\sum I_r$ (G) and $\sum I_r$ (G + *n*P) (*n* = 1 or 2) are the total intensities of the G-quadruplexes and the 1:1 and 1:2

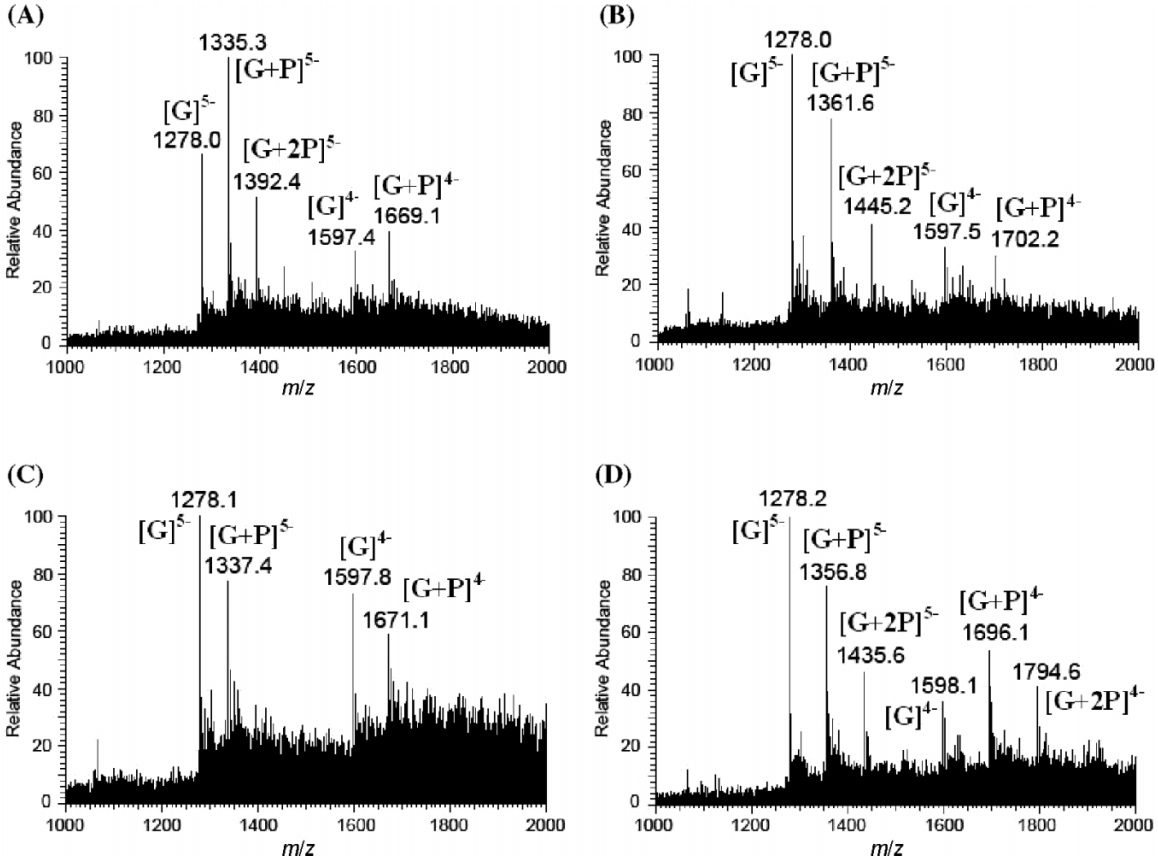
Fig. 2. Electrospray ionization (ESI) mass spectra of 5 μmol/L G-quadruplex DNA (G) with 20 μmol/L small molecules (P). (A) P1, (B) P6, (C) P7, and (D) P12.



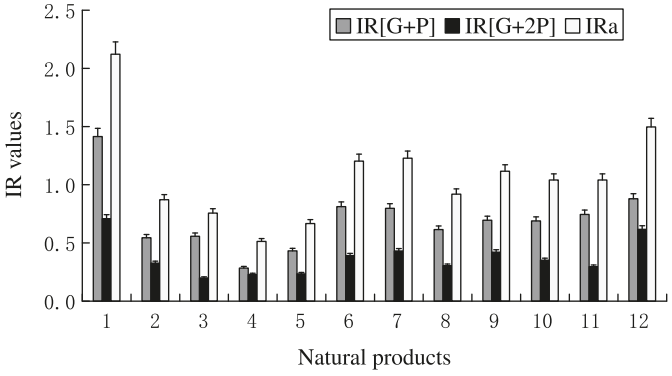


Fig. 3. IR values of 12 small molecules with *VEGF*–G-quadruplex. The error bar is the standard deviation of three independent measurements.

complex ions, respectively, and P represents the small-molecule natural product.

All the IR values of the 12 small molecules with *VEGF*–G-quadruplex were calculated by this formula and are shown in Fig. 3. If the IRa value of the small molecule to the G-quadruplex is greater, the binding affinity of the small molecule is also greater. It obviously shows that P1 has the best binding affinity among the 12 small-molecule natural products and the relative binding affinity order is P1 > P12 > P7 > P6 > P9 > P10~P11 > P8 > P2 > P3 > P5 > P4. Furthermore, P1–P4 are all flavonols with similar structure, but they show different binding affinities to *VEGF*–G-quadruplex. Comparing the structures of P1–P4, the aromaticity and the phenolic hydroxyl group were important for G-quadruplex recognition.

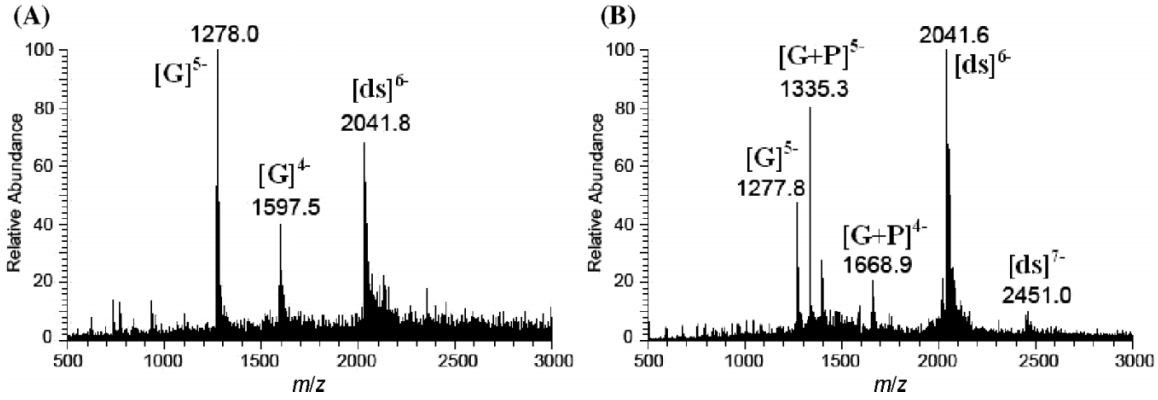
Selective recognition of *VEGF*–G-quadruplex by P1

Besides the binding affinity of the ligands, the selectivity of the recognition is also important. So the selective recognition of P1 to the G-quadruplex structures and corresponding duplex DNA was probed in a solution consisting of the duplex DNA and the G-quadruplex. The mass spectrum of the *VEGF* duplex and the G-quadruplex solution is shown in Fig. 4A. The $[G]^{5-}$ peak at *m/z* 1278.0 was the base peak because of a better ESI efficiency of the G-quadruplex and the intensity of the duplex peak ($[ds]^{6-}$) at *m/z* 2041.8 was nearly 70%. After P1 was added to the duplex DNA / G-quadruplex solution, the ESI mass spectrum showed that the intensity of the complex ion of P1 and the *VEGF*–G-quadruplex ($[G + P]^{5-}$ at *m/z* 1335.3) was 80%, whereas the complex ion of P1 and the duplex DNA is not observed (Fig. 4B). It shows that P1 could bind selectively with *VEGF*–G-quadruplex in a solution consisting of the G-quadruplex and the corresponding duplex DNA.

P1-enhanced *VEGF*–G-quadruplex thermal stability

The *VEGF* G-rich sequence (S1) (Fig. 5A) showed a positive peak at 264 nm and a shoulder peak at 290 nm that are the characteristics of the parallel/antiparallel G-quadruplex structure. After P1 was added to this DNA solution, the CD spectrum still showed the 264 nm positive peak and the

Fig. 4. Mass spectra of (A) 5 μmol/L vascular endothelial growth factor (*VEGF*) – G-quadruplex and duplex DNA solution and (B) the DNA solution adding 20 μmol/L kaempferol.



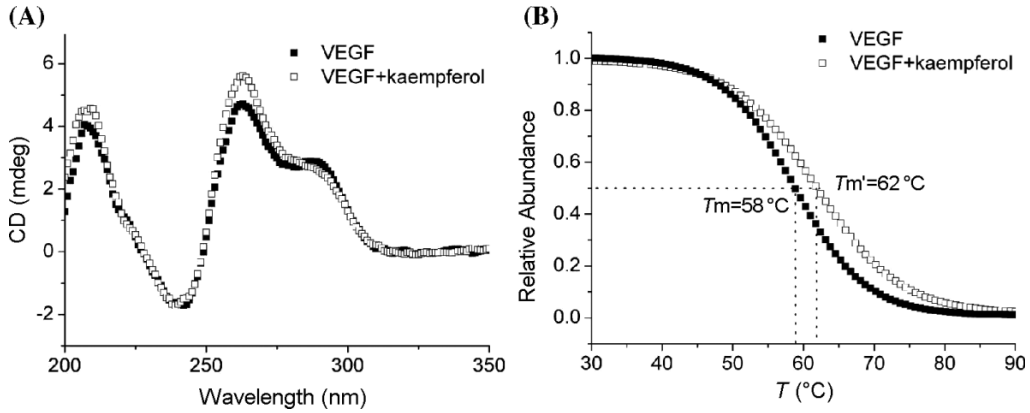


Fig. 5. (A) Circular dichroism (CD) spectra and (B) CD melting curves of 10 μmol/L vascular endothelial growth factor (*VEGF*) – G-quadruplex in the absence or presence of 40 μmol/L kaempferol (P1).

shoulder peak at 290 nm. These results indicated that the structure of the G-quadruplex was maintained after binding with P1. The thermal stability of the *VEGF*–G-quadruplex and the complex was evaluated using CD spectroscopy by the melting experiment. The CD melting experiment revealed that the *T*m (melting temperature) value of the *VEGF*–G-quadruplex was 58 °C and the *T*m value of the complex of *VEGF*–G-quadruplex with P1 was increased to 62 °C. These results indicate that P1 can stabilize the *VEGF*–G-quadruplex.

In this work, the selective recognitions of 12 small-molecule natural products with human *VEGF*–G-quadruplex were studied. P1 was found to have the highest binding affinity among these molecules. More importantly, P1 was then proven to bind *VEGF*–G-quadruplex selectively compared with *VEGF* – duplex DNA. And the results of the CD experiments revealed that P1 could enhance the thermal stability of *VEGF*–G-quadruplex. In conclusion, P1 selectively recognizes the *VEGF*–G-quadruplex and could be a potential *VEGF*–G-quadruplex binding agent.

Experimental

Chemicals

Single-strand oligonucleotides (S1 = d (GGGGCGGGC-CGGGGGCGGGG), *m/z* 6359.1; S2 = d (CCCCGCCCC-CGGCCCGCCCC), *m/z* 5879.0) were purchased from the Sangon Company (Shanghai, China). The obtained oligonucleotides were dissolved in deionized water and the concentrations were determined by a Nanodrop 2000 spectrophotometer (Thermo Scientific). For duplex DNA (S1/S2), two complementary single-strand oligonucleotides were mixed with equal molar quantities in buffers, then annealed at 90 °C for 10 min and then slowly cooled to room temperature (over 4 h) . The duplex and G-quadruplex mixed solution for ESI study was obtained by mixing the same molar of ds DNA and G-quadruplex DNA.

The natural product molecules used in this study were purchased from the China National Institute for the Control of Pharmaceutical and Biological Products (NICPBP), Beijing, P. R. China.

Mass spectrometry

ESI-MS spectra were obtained with a Finnigan LCQ Deca XP Plus ion trap mass spectrometer (Thermo Finnigan, San Jose, California), and all the experiments were carried out in the negative-ion mode. The DNA solution was directly injected into the mass spectrometer at a flow rate of 2 μL/min. The ESI conditions were optimized to observe the noncovalent complexes. The electrospray source conditions were 2.7 kV spray voltage and 120 °C capillary temperature.

Circular dichroism

The CD spectra were obtained using a JASCO J-815 spectropolarimeter equipped with a Peltier junction temperature-

controlled cell holder. CD experiments were carried out on samples at a concentration of 10 μmol/L DNA (10 mmol/L Tris–HCl and 50 mmol/L NH_4Ac, pH 7.40). Melting experiments were measured at 290 nm, and the *T*m values were calculated from the normalized CD melting curves according to the methods described previously.[23,24]

Abstract: Ionic ligands derived from a salen ligand containing two proximal 1,3-disubstituted imidazolium ionic liquid cores form cobalt(III) complexes capable of selectively oxidizing veratryl alcohol, a lignin model compound, to veratraldehyde using air as the source of oxygen. These complexes are easy to prepare, inexpensive, water stable, and soluble in ionic liquids, making them viable candidates for use as oxidation catalysts.

Key words: task-specific ionic liquid (TSIL), oxidation, IL–salen–Co complex, catalysis, veratryl alcohol.

Résumé : Les ligands ioniques dérivés d'un ligand salène comportant deux noyaux proximaux de liquides ioniques d'imidazolium 1,3-disubstitué forment des complexes avec le cobalt(III) qui peuvent oxyder d'une façon sélective le vératrol, un composé modèle de la lignine, en vératraldéhyde en utilisant de l'air comme source d'oxygène. Ces complexes, qui peuvent être préparés facilement et qui ne sont pas coûteux, sont stables dans l'eau et sont solubles dans les liquides ioniques ce qui en fait des candidats intéressants comme catalyseurs de réactions d'oxydation.

Mots-clés : liquide ionique (ILTS) à tâche spécifique, oxydation, complexe IL–salène–Co, catalyse, vératrol.

Introduction

As one of the 12 principles of green chemistry,[1] the use of alternative solvents in chemical applications has become an increasingly important and highly studied area of interest over the last decade. The advent of green chemistry in the 1990s was due in no small part to the earlier work of chemists such as Trost who coined the term, "Atom Economy",[2] and Chan who reported pioneering work in which organometallic reagents were used in aqueous systems.[3] Although water is the most obvious solvent of choice in terms of its environmental friendliness and its ubiquitous nature and acceptance as the "universal solvent" as described in many undergraduate textbooks, there are a number of other potential alternative solvents that warrant investigation. Hence, the work of Chan has provided inspiration for the study of a number of materials that have emerged as viable alternatives to conventional solvents. These include supercritical fluids, polymeric liquids, fluorous solvents, and ionic liquids (ILs).

ILs are now well-established in the chemical literature and are now enjoying growing utility in industrial applications. Among the current industrial applications are ILs for acid scavenging in the BASIL process developed by BASF, performance additives in paints developed by Degussa, cleaning fluids by Iolotec–Wandres, as well as a number of other processes at the pilot scale.[4] Hence, it is obvious that these liquids are now being investigated for their utility in several applications in addition to being used merely as reaction media. These include applications such as lubricants,[5] extractants,[6] electrolytes,[7] surfactants,[8] and biomass processing.[9] These applications arose because of the unique set of properties attributed to ILs that make them interesting not only from a green chemistry point of view but also from a more purely chemical point of view. Such properties include a general lack of volatility and flammability, polarity and (or) ionic nature, and the ability to dissolve a wide array of organic and inorganic materials. Pertinent to this report is the ability to tune these properties through careful manipulation of the structural features of the IL under investigation. The coordinating ability, viscosity, thermal stability, and biodegradability can all be easily tuned by adopting a modular approach to the synthesis of ILs. Simple variation of the cationic core, the counterion, and substituents on either, or both, of these can have profound effects on these properties. The incorporation of functionality into an IL to control its properties and to impart the ability to perform a predetermined function gives rise to task-specific ionic liquids (TSILs).[10]

We recently reported the preparation of TSILs **1a**–**1d**, capable of forming octahedral complexes with copper, cobalt, and nickel (Scheme 1).[11] Replacement of a methyl group on these complexes with an *n*-decyl group imparted sufficient hydrophobicity on the complex to enable it to spontaneously separate from aqueous solution upon its formation. These TSILs were shown to be useful in the removal of copper

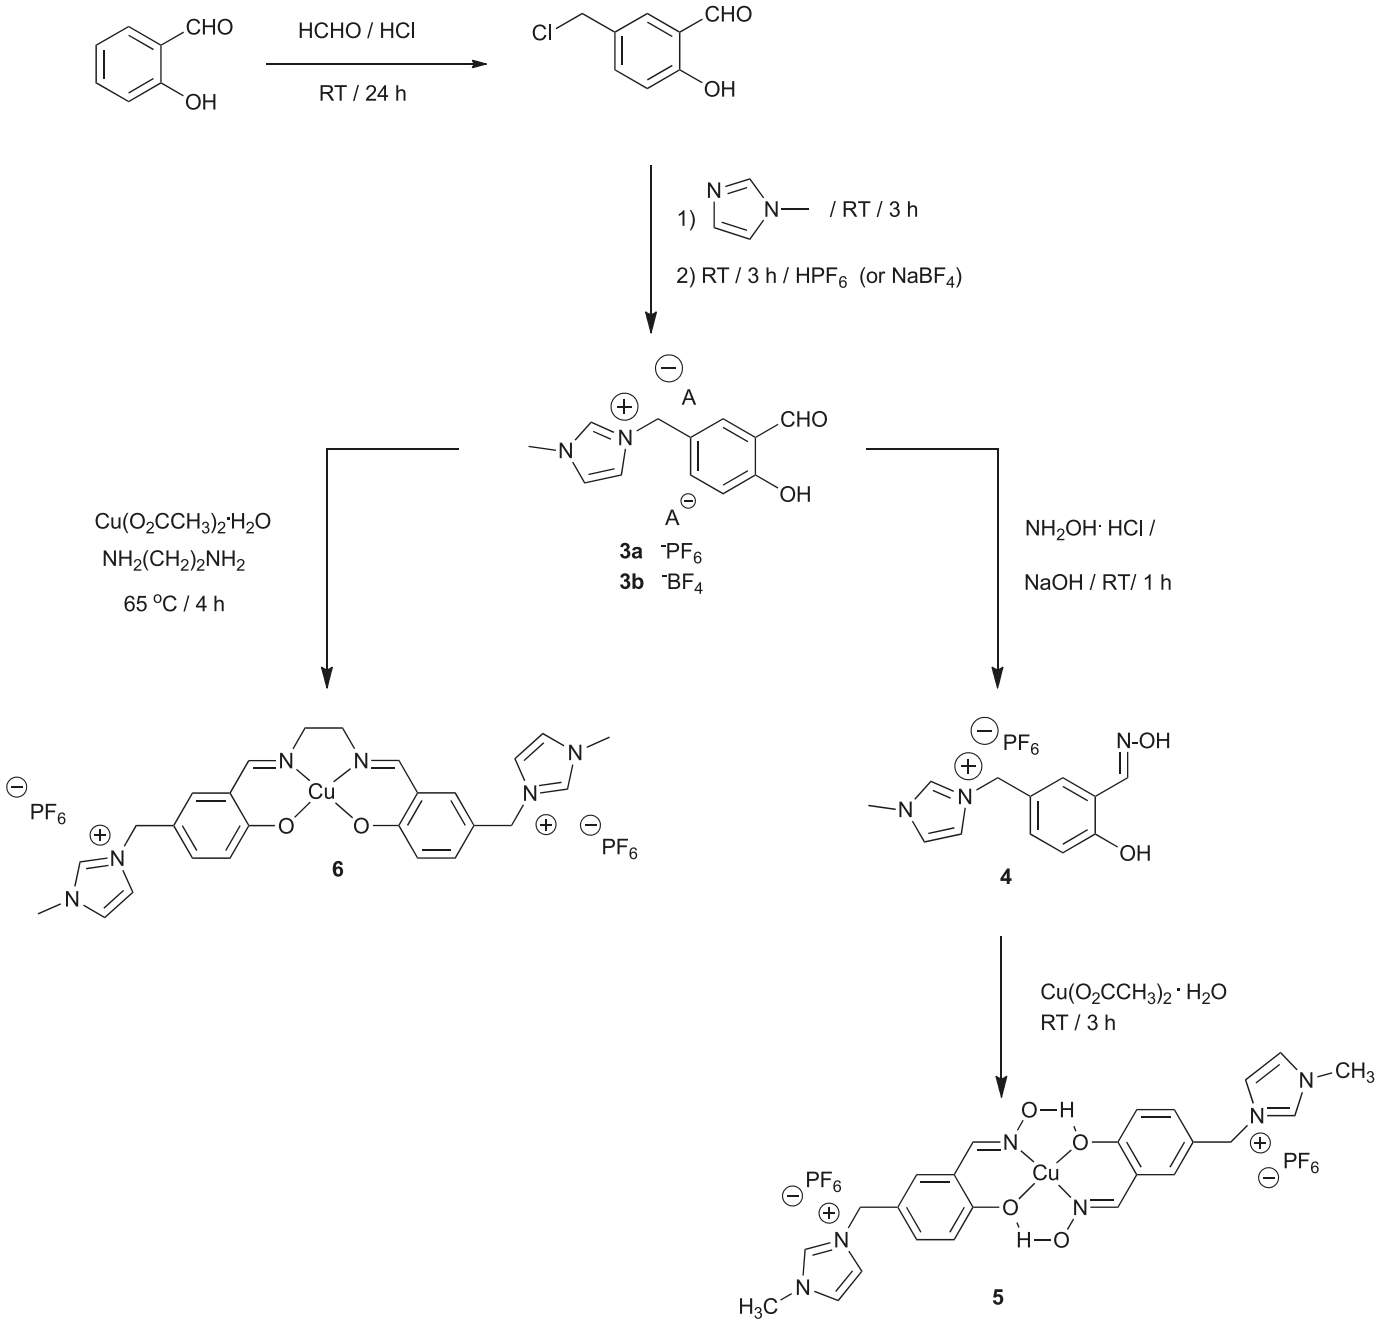
Scheme 1. Copper chelation using a task-specific ionic liquid (TSIL).[11]

from an aqueous solution indicating potential use in hydrometallurgical applications.

A subsequent study reported by our research group demonstrated the modular approach to preparing TSILs capable of metal chelation. Incorporation of a salicylaldehyde moiety into an imidazolium-based IL allowed the chelating moiety in the resulting TSILs to be easily altered (Scheme 2).[12] A common precursor to a series of TSILs is easily prepared through the chloromethylation of salicylaldehyde followed by quaternization of 1-methylimidazole to afford compound **3a** after metathesis of the chloride salt to the hexafluorophosphate analogue. Reaction of compound **3a** with hydroxylamine hydrochloride resulted in the formation of an imidazolium salt containing a salicylaldoxime moiety, **4**. The salicylaldoxime moiety is a well-established chelator of copper and this TSIL, not surprisingly, easily formed an isolable complex with copper (**5**). The same precursor (**3a**) was also reacted with copper(II) acetate and 1,2-diaminoethane in situ to afford an IL–salen–Cu^{II} complex (**6**). Incorporation of a manganese(III) atom into a complex using this same ligand resulted in a complex capable of catalyzing the epoxidation of alkenes. Hence, this study demonstrated the ability of such TSILs to be used both in metal separations and in the preparation of ionic complexes for use in catalysis.

It has been demonstrated that catalytic species derived from TSILs, or ion-tagged ligands, provide the ability to more efficiently entrain the resulting catalytic ionic complex in an IL of similar structure.[13] If the IL used to entrain the TSIL-derived catalyst is water immiscible then the IL/catalyst phase may be more easily separated from aqueous- or organic-phase reaction mixtures containing substrates and products. Hence, not only is product isolation facilitated but catalyst recycling becomes possible. Furthermore, the advantages of both a heterogeneous catalyst and a homogenous catalyst may be exploited.

The catalytic abilities of a number of salen–Co complexes have been reported in the literature.[14] Among these are the Co–salen complexes (**7a** and **7b**, Scheme 3), which have been reported to catalyze the oxidation of benzylic alcohols to aldehydes without over oxidation to the corresponding carboxylic acids. These reactions have been reported to proceed via a superoxo- or a bridging μ-peroxo complex formed from the Co–salen complex reacting with dioxygen.[15] The nature of the actual catalytic species present in solution has been shown to be dependent upon reaction conditions such as temperature, pH, the nature of added base, and the reaction time.[14] Of particular significance is the Co–salen-catalyzed oxidation of veratryl alcohol (3,4-dimethoxybenzyl alcohol) a lignin model compound, to veratraldehyde (3,4-dimethoxybenzaldehyde). The ability to selectively perform such a reaction without further oxidation to the carboxylic acid (3,4-dimethoxybenzoic acid) provides a potential commercially viable route to value-added products based on lignin degradation products such as veratryl alcohol.



It became clear that if the ligand contained in the IL–salen–Cu^{II} (**6**) complex could be isolated in the absence of a chelated metal, the opportunity to coordinate it to a wider variety of metals would be presented. The catalytic ability of such IL–salen–metal complexes and the ability to entrain them in other ILs could then be investigated. Hence, we report herein our investigations in which the IL–salen ligand used in **6** was prepared and characterized. We also report the chelation of cobalt(III) using this ligand to afford an octahedral complex containing two axial ammine ligands as well as the catalytic activity of this complex in the oxidation of veratryl alcohol using air as the source of oxygen.

Results and discussion

The key precursors to the imidazolium-tagged ligands containing the salen-chelating ligand were prepared according to a previous procedure used in our laboratory starting with the reaction of salicylaldehyde with formaldehyde in the presence of HCl at room temperature over 1 day to afford 5-chloromethyl-2-hydroxybenzaldehyde.[12] Quaternization of 1-methylmidazole using this chloromethylated salicylaldehyde as an alkylating agent afforded the chloride salt, which was then metathesized to either the hexafluorophosphate salt (**3a**) or the tetrafluoroborate salt (**3b**) using aqueous hexafluorophosphoric acid (HPF_6(aq)) or sodium tetrafluoroborate as appropriate. The salicylaldehyde-functionalized imidazolium salts **3a** and **3b** could then be reacted with ethylene diamine to afford the IL–salen ligands **8a** and **8b** (Scheme 4 and Fig. 1). Recrystallization of **8a** from the slow evaporation of an acetone solution afforded a 64% yield of crystals appropriate for X-ray diffraction. This salen ligand is a dication owing to the presence of two proximal 1,3-disubstituted imidazolium substituents at either end of the salen moiety. Two poorly coordinating hexafluorophosphate ions act as the counterions as demonstrated by their remote locations relative to any positive charges or lone pairs of electrons on the complex as seen in its crystal structure (Fig. 1).

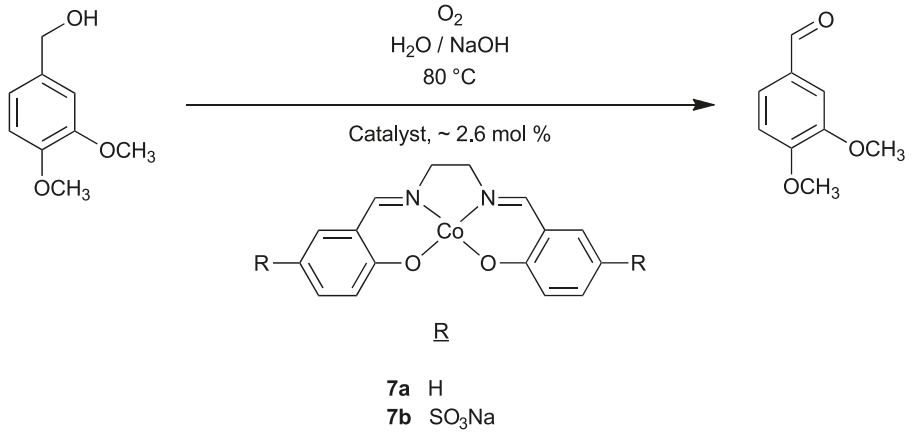
Scheme 2. Synthesis of ionic liquid (IL) – salen – Cu (**6**) and bis(salicylaldoxime)Cu (**5**) complexes from task-specific ionic liquids (TSILs).[12]



The cobalt chelate complex **9a** was easily prepared through reaction of the ligand **8a** and cobalt(II) acetate under basic conditions and reflux for 10 h, after which the complex precipitated out of solution. Recrystallization from a 9:1 *v*/*v* mixture of acetone and methanol afforded a 58% yield of crystals appropriate for X-ray diffraction.

The structure of **9a** shows an octahedral geometry about the cobalt atom with two axial ammine ligands. These ligands originate from the ammonium hydroxide solution used to basify the solution to ensure the phenoxide oxygen atoms were deprotonated and hence be available for coordination to the metal centre. Interestingly, the structure shows the presence of three hexafluophosphate ions in the asymmetric unit indicating a cobalt(III) metal centre. It appears the cobalt(II) metal centre contained in the cobalt(II) acetate reactant was oxidized under the aerobic conditions under which complex formation occurred. Hence, three hexafluorophosphate ions are required to balance the charge on the ionic complex. The stoichiometry of the reaction, in which ligand **8a** is the limiting reactant, then dictates that one-third of the IL–salen ligand will be uncomplexed and is removed during the ethanol wash of the product or during recrystallization. The two tethered, proximal 3-methylimidazolium cores of this complex provide for the potential exploitation of enhanced solubility in typical ILs such as 1-butyl-3-methylimidazolium hexafluorophosphate ([bmim]PF_6). The use of such enhanced solubility is a topic of a subsequent paper focusing on the use of entrained catalysts of this type in ILs. The present study

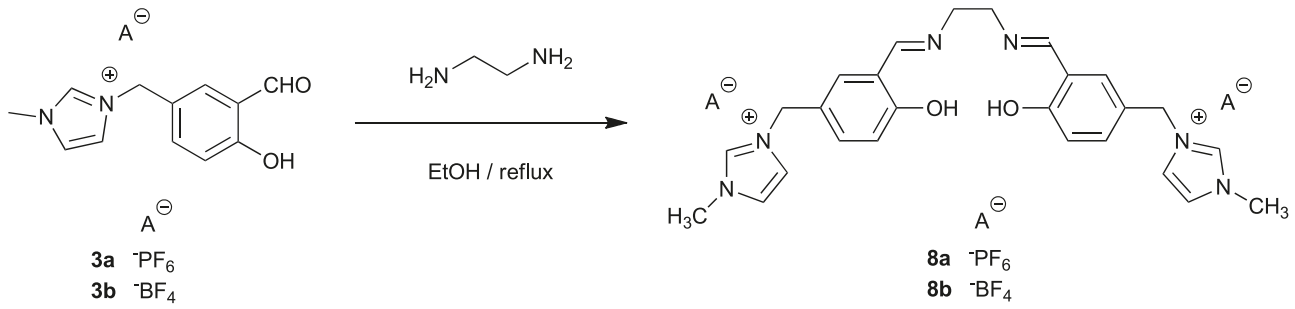
Scheme 3. Oxidation of veratryl alcohol with salen–Co catalysts.[14]

Scheme 4. Synthesis of ionic liquid (IL) – salen ligands **8a** and **8b**.



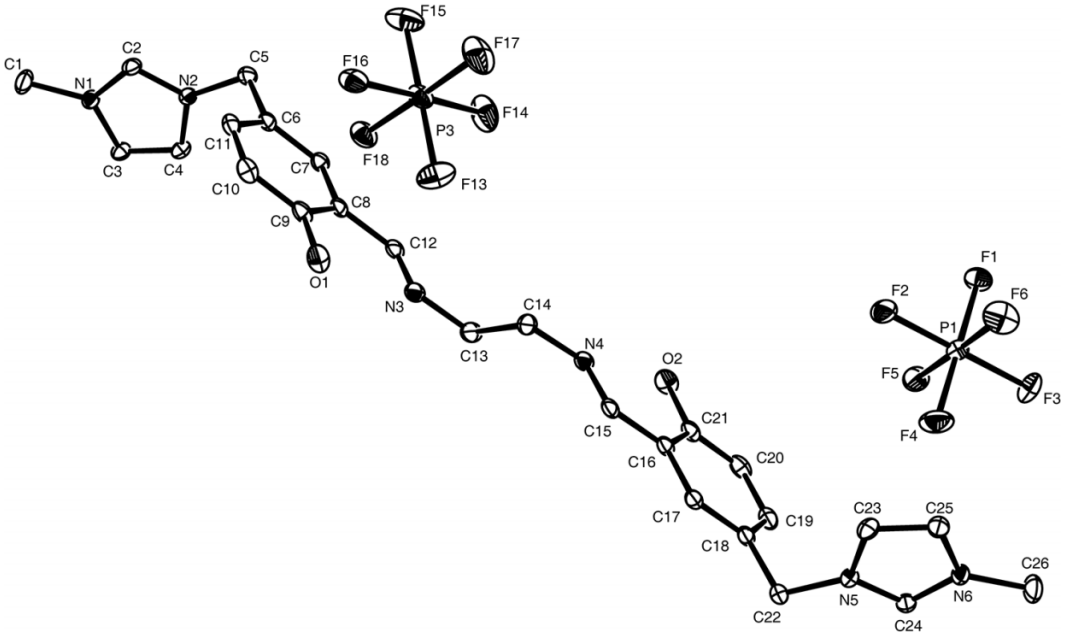


Fig. 1. Crystal structure of ionic liquid (IL) – salen task-specific ionic liquid (TSIL) **8a**. Thermal ellipsoids are drawn at 30% probability.

has focused on establishing the presence of any catalytic activity of this complex in oxidations in aqueous systems.

An isostructural tetrafluoroborate complex (**9b**) was isolated in an identical fashion through the reaction of the IL–salen ligand **8b**, again under basic conditions using NH_4OH (aq) as the base. The octahedral cobalt centre in this case also displays two axial ammine ligands and three tetrafluoroborate counterions. Once again there is a cobalt(III) metal centre required to account for the overall neutral charge on the complex and the presence of three tetrafluoroborate anions in the asymmetric unit.

With the IL–salen–Co complexes **9a** and **9b** in hand, we sought to determine whether they possessed any catalytic activity in the oxidation of veratryl alcohol to veratraldehyde. Veratryl alcohol was chosen as the substrate for this study, since, as alluded to above, it is a typical lignin model

Can. J. Chem. Downloaded from www.nrcresearchpress.com by Renmin University of China on 09/02/12
For personal use only.

compound and is often used in studies of enzymatic lignin degradation.[16] It had been shown in a previous study by Repo and co-workers[14] that the optimum pH for these reactions was ca. pH 12.5 and that the optimum temperature was above 60 °C. These reported reactions were typically run at 80 °C; hence, we used these reaction conditions to conduct our oxidation reactions of veratryl alcohol catalyzed by IL–salen–Co complexes **9a** and **9b**.

Initial reactions in which IL–salen–Co complex **9a** was used as the catalyst utilized pure oxygen as the oxidant. Whereas these reactions generally gave very high yields of veratraldehyde, as determined by gas chromatographic analysis and were consistent with other catalysts that have been used using oxygen as the oxidant, we opted to use air as our source of oxygen. We regarded this as a much safer, cheaper, and therefore a green advantage of our approach.

A series of reactions using IL–salen–Co complex **9a** as the catalyst in which the base used to adjust the pH to ca. 12.5 was varied, gave moderate yields of veratraldehyde. Essentially no difference in the yield of the aldehyde product was observed when the base was changed from potassium hydroxide to sodium hydroxide (Table 1, entries 1 and 2). A noticeable decrease in yield occurred when NH_4OH(aq) was used. However, use of sodium carbonate resulted in an increase in yield even in the absence of pyridine (Table 1, entries 3–5). Switching the catalyst to IL–salen–Co complex **9b** with a tetrafluoroborate counterion gave slightly lower yield of the aldehyde product (Table 1, entry 7). IL–salen–Co complex **9a** could be dissolved in the water immiscible IL [bmim]PF_6, giving a biphasic catalytic system when used with water. Using air as the source of oxygen, this system afforded a comparable, yet moderate, yield of veratraldehyde (Table 1, entry 6). This biphasic system facilitated separation of the catalytic layer from the product and unreacted starting material. Further investigation into the utility of this, and other similar biphasic systems in which catalysts are entrained in IL phases, are the topics of current studies ongoing in our laboratory.

Noteworthy is the experiment in which no IL–salen–Co catalysts **9a** or **9b** were added. Not surprisingly, only a trace amount of aldehyde product was detected in this reaction where all other reaction conditions were maintained except for the exclusion of the catalytic complex (Table 1, entry 8). This confirms the role of the cobalt complexes **9a** and **9b** as active catalysts for the selective oxidation of veratryl alcohol to veratraldehyde.

Conclusions

The synthesis and isolation of two new IL–salen ligands (**8a** and **8b**) containing proximal 1,3-disubstituted imidazolium IL moieties, from cheap and readily available starting materials, further demonstrates the effectiveness of the modular approach we have developed for the preparation of TSILs capable of chelating metals. Theses complexes are easy to prepare, water stable, and soluble in ILs. The potential of the ionic metal complexes described herein as catalysts has been established through the selective oxidation of veratryl alcohol, using air as the source of oxygen, to afford moderate yields of veratraldehyde. No evidence of further oxidation to the carboxylic acid was detected. Although yields using air as the oxygen source are generally lower than those when pure oxygen is used, the method does offer a safer and less expensive methodology. Future studies in which these and other related catalysts useful for the oxidation of lignin model compounds are entrained in other ILs are ongoing and will be the topic of future publications. Such immobilization of the catalysts in these systems may enable ready recycling of the catalyst while also facilitating product isolation and yield, hence enhancing the overall greenness of this methodology.

Experimental

General procedures

Veratryl alcohol (96%) and all other commercial reagents were purchased from Sigma-Aldrich and used without further purification. Thin layer chromatography (TLC) was performed on silica gel plates and visualization was done by UV light. Column chromatography was performed using 230–400 mesh silica gel. IR spectra were acquired on a Bruker Vertex-70 IR using a KBr disc. ^{1}H, ^{13}C, and ^{31}P NMR spectra were acquired on a Bruker AV Sspectrometer (^{1}H, 500 MHz; ^{13}C, 126 MHz; and ^{31}P, 202 MHz) or on a Bruker/Tecmag AC spectrometer (^{1}H, 250 MHz; ^{13}C, 62 MHz); ^{19}F NMR spectra (235 MHz) were also acquired using the Bruker/Tecmag spectrometer. When DMSO-d_6 was used as a solvent, the chemical shifts are reported in ppm relative to TMS as an internal standard (0.00 ppm for ^{1}H and ^{13}C) or DMSO-d_6 (2.50 ppm for ^{1}H and 39.52 ppm for ^{13}C). The chemical shifts in ^{31}P NMR spectra are reported in ppm with respect to aq 85% H_3PO_3 as the external standard (0.00 ppm for ^{31}P) and in ^{19}F NMR spectra with respect to 0.5% $CF_3C_6H_5$ in $CDCl_3$ as the external standard (63.72 ppm for ^{19}F). Multiplicities are indicated by singlet (s), doublet (d), and triplet (t). Coupling constants (*J*) are reported in Hz. ESI-MS data were acquired in positive and negative modes on an Agilent 1100 LC equipped with an MSD trap. High-resolution mass spectra were acquired in positive mode on a Bruker microTof Focus orthogonal ESI-TOF.

Single crystals were placed in Paratone-N oil, mounted in a nylon loop, and cooled to 150 K (**8a**), to 100 K (**9a**), or to 130 K (**9b**) using an Oxford Cryostream cooling system. The data were collected using the Bruker APEX2 software package[17,18] on a Siemens diffractometer equipped with an APEXII CCD detector, a graphite monochromator, and Mo Kα radiation (λ = 0.71073 Å). A hemisphere of data was collected in 1664 frames. Data processing and absorption corrections were applied using the APEX2 software package.[17,18] The structure was solved (direct methods) and all non-H atoms were refined anisotropically. Hydrogen atoms were placed in calculated positions using an appropriate riding model and coupled isotropic temperature factors. ORTEP-3[19] renderings are provided in Figs. 1–3. Selected crystallographic data are included in Tables 2–4 and are also included in the Supplementary data for this manuscript.

All spectra of known compounds agreed with those reported in the literature. For new compounds (i.e., **8a** and **8b** and **9a** and **9b**), the ^{1}H and ^{13}C NMR of the purified compounds and the HRMS (in addition to other spectral data) are provided in lieu of combustion analysis, since these compounds are characteristically resistant to combustion.

Preparation of 5-chloromethyl-2-hydroxybenzaldehyde

To a well stirred mixture of concd hydrochloric acid (150 mL) and formaldehyde (10.8 mL; 37 wt% in H_2O) was added salicylaldehyde (15.0 mL, 141.4 mmol). The reaction was stirred at room temperature for 24 h. The solid that separated out was filtered, dissolved in diethyl ether, and reisolated through evaporation of the solvent. Recrystallization from *n*-hexane afforded a white solid. Yield: 51.5%; mp 84–85 °C. ^{1}H NMR (250 MHz, DMSO-d_6) δ: 4.74 (s, 2H, Cl–CH_2), 7.00 (d, 1H, J = 8.5 Hz, Ar–H), 7.57 (dd, 1H, J = 2.3, 6.3 Hz, Ar–H), 7.70 (d, 1H, J = 2 Hz, Ar–H), 10.26 (s, 1H, CHO), 10.92 (s, 1H, OH). ^{13}C NMR (62 MHz, DMSO-d_6) δ: 45.71, 117.73, 122.15, 128.78, 129.08, 136.97, 160.74, 190.66.

Preparation of 1-(3-formyl-4-hydroxybenzyl)-3-methylimidazolium chloride

To a solution of 1-methylimidazole (14.0 mL, 140.3 mmol) in toluene (30 mL) at room temperature was added 5-chloromethyl-2-hydroxybenzaldehyde (20.0 g, 117 mmol) under a nitrogen atmosphere. The resulting solution was stirred at room temperature for 3 h. The solid that separated out was washed with ether (3 × 20 mL) and dried to give a pale yellow solid. Yield: 97.0%; mp 185–187 °C. IR (KBr, cm^{-1}): 1562 (C=C), 1611 (C=N), 1675 (C=O), 3459 (O–H). ^{1}H NMR (500 MHz, DMSO-d_6) δ: 3.86 (s, 3H, N–CH_3), 5.39 (s, 2H, $^+$N–CH_2), 7.21 (d, 1H, J = 8.5 Hz, Ar–H), 7.63 (dd, 1H, J = 2.5, 6.0 Hz, Ar–H), 7.73 (t, 1H, J = 1.5, 2.0 Hz, Ar–H), 7.76 (d, 1H, J = 2.5 Hz, Ar–H), 7.83 (t, 1H, J = 1.5 Hz, Ar–H), 9.33 (s, 1H, Ar–H), 10.31 (s, 1H, CHO), 11.31 (s, 1H, OH). ^{13}C NMR (126 MHz, DMSO-d_6) δ: 35.85, 51.03, 118.20, 122.14, 122.54, 123.96, 125.59, 128.47, 136.50, 136.53, 161.43, 190.06. MS ESI(+): 217.1, 135.0, 120.8, 99.4, 83.1.

1-(3-Formyl-4-hydroxybenzyl)-3-methylimidazolium hexafluorophosphate (3a)

To a solution of 1-(3-formyl-4-hydroxybenzyl)-3-methylimidazolium chloride (14.80 g, 58.70 mmol) in water (100 mL) at room temperature was added an aqueous solution of hexafluorophosphate (12.8 mL, 88.1 mmol) while cooling in an ice bath over 1 h. The resulting solution was stirred at room temperature for 3 h. The solid that separated out was washed with water and then with diethyl ether (3 × 20 mL) and dried to give a solid white product. Yield:

Preparation of IL–salen–Co tetrafluoroborate complex (9b)

To a solution of tetrafluoroborate ligand (3.00 g, 4.75 mmol, **8b**) in dry ethanol (30 mL) was added ammonium hydroxide to bring the pH to 8–9. This solution was stirred for 15 min after which cobalt(II) acetate (1.30 g, 5.22 mmol) was added at room temperature. The resulting solution was stirred at reflux temperature for 10 hafter which a solid separated out. This solid was washed with ethanol (3 × 5 mL) and dried to give a brown solid product. The product was recrystallized from an acetone–methanol mixture (9:1 *v*/*v*) to give crystals suitable for X-ray crystallographic analysis. Yield: 2.58 g (67% based upon the ligand, **8b**). IR (KBr, cm^{-1}): 1573 (C=C), 1646 (C=N), 3618 (N–H). ^{1}H NMR (500 MHz, DMSO-d_6) δ: 2.76 (s, 6H, 2 × N–CH_3), 3.86 (s, 6H, 2 × N–CH_3), 3.88 (s, 4H, 2 × =N–CH_2), 5.27 (s, 4H, 2 × $^+$N–CH_2), 7.02 (d, 2H, J = 9.0 Hz, Ar–H), 7.33 (dd, 2H, J = 2.0, 6.5 Hz, Ar–H), 7.41 (d, 2H, J = 2.0 Hz, Ar–H), 7.69 (d, 2H, J = 1.5 Hz, Ar–H), 7.73 (d, 2H, J = 1.5 Hz, Ar–H), 8.08 (s, 2H, N=C–H), 9.20 (s, 2H, Ar–H). ^{13}C NMR (126 MHz, DMSO-d_6) δ: 35.87, 51.35, 57.86, 118.35, 119.94, 121.98, 122.80, 124.04, 134.23, 134.88, 136.19, 166.08, 167.61. ^{19}F NMR (235 MHz, DMSO-d_6) δ: –144.3. MS (ESI+) *m*/*z*: 723.0; ESI(–) *m*/*z*: 86.9. HRMS (ESI) ESI^+ calcd for $C_{26}H_{34}B_2CoF_8N_8O_2^+$: 723.2195; found: 723.2176.

Typical procedure for the oxidation of veratryl alcohol using IL–salen–Co catalysts 9a and **9b**

In a 50 mL two-necked flask IL–salen–Co complex (**9a** or **9b**, 10 mol%) and pyridine (10 mol%) were added to 10 mL of distilled water and stirred for about 15 min. Base, as indicated in Table 1, was then added to adjust the pH to about 12.5, followed by the slow addition of veratryl alcohol. At this point, the pH of the solution was monitored to ensure a basic pH. The reaction mixture was heated at 80 °C with constant air bubbling. The reaction was allowed to proceed for the desired time. The reaction was stopped by cooling to room temperature. The pH of the reaction mixture was adjusted to 6–7 with 2 mol/L HCl. The product (veratraldehyde) was extracted by dichloromethane, and the combined organic extracts were dried over magnesium sulfate followed by solvent removal in vacuo to afford a white solid; mp 41–43 °C. ^{1}H NMR (250 MHz, DMSO-d_6) δ: 3.8 (s, 3H, O–CH_3), 3.9 (s, 3H, O–CH_3), 7.1 (dd, 1H, Ar–H), 7.2 (s, 1H, Ar–H), 7.5 (d, 1H, Ar–H), 9.8 (s, 1H, CHO). ^{13}C NMR (62 MHz, DMSO-d_6) δ: 55.4, 55.8, 109.3, 111.2, 126.1, 129.6, 149.2, 154.2, 191.4. MS *m*/*z*: 166.

Supplementary data

Supplementary data are available with the article through the journal Web site (http://nrcresearchpress.com/doi/suppl/10.1139/v11-106). CCDC 822063–822065 contain the X-ray data in CIF format (for compounds **8a**, **9a**, and **9b**) for this manuscript. These data can be obtained, free of charge, via http://www.ccdc.cam.ac.uk/cgi-bin/catreq.cgi (Or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1Ez, UK; fax +44 1223 336033; or deposit @ccdc.cam.ac.uk).

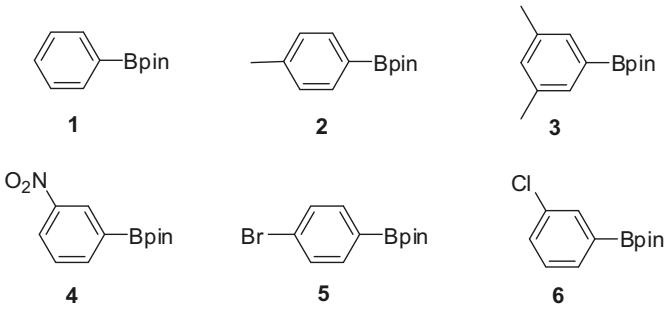
Abstract: Arylboronates are important compounds widely used in cross-coupling reactions. By analyzing the NMR spectra data of a variety of pinacol arylboronates, we have determined the increments for ^{1}H and ^{13}C NMR chemical shifts caused by a pinacol boronate substituent in the benzene ring. These data can be used in the estimation of chemical shifts of aromatic pinacol boronates.

Key words: ^{1}H NMR, ^{13}C NMR, pinacol boronates, chemical shift increments.

Résumé : Les esters arylboronates sont des composés importants fréquemment utilisés dans des réactions de couplages croisés. Sur la base d'une analyse de données spectrales de RMN pour une variétés d'arylboronates du pinacol, il a été possible de déterminer les incréments dans les déplacements chimiques de RMN du ^{1}H et du ^{13}C provoqués par un substituant présent dans le noyau aromatique d'un boronate du pinacol. Ces données peuvent être utilisées pour évaluer les déplacements chimiques de boronates aromatiques du pinacol.

Mots-clés : RMN du ^{1}H, RMN du ^{13}C, boronates du pinacol, incréments dans les déplacements chimiques.



[Traduit par la Rédaction]

Introduction

Functionalized arylboronic acid and arylboronates have attracted much attention in the organic chemistry community in recent years because of their extensive applications in organic synthesis as well as in other fields.[1,2] Particularly, the Pd-catalyzed reaction of aromatic boron compounds, namely Suzuki–Miyaura cross-coupling reactions, have proved to be powerful tools for the construction of Csp^2–Csp^2 bond formations. The widespread use of aromatic boron compounds has stimulated the development of methods for the synthesis of these valuable chemicals. Pinacol boronic esters can be easily prepared from the corresponding boronic acids. They can also be synthesized by using Pd-catalyzed coupling of bis(pinacolato)diboron with aromatic halides (Miyaura borylation) or by rhodium- or iridium-catalyzed direct C–H bond activation.[1f,3] Because of the importance of aromatic boron compounds, it is highly desirable to develop methods that can conveniently and rapidly determine the structure of aromatic boronates.[4] In this context, Voss and co-workers[5] developed a formula to show the increments for ^{1}H and ^{13}C NMR chemical shifts of arylboronic acids. Since pinacol arylboronates are also widely used in organic synthesis, it would be helpful to develop methods that can be used for rapid structure elucidation. To the best of our knowledge, the corresponding NMR chemical-shift increments for pinacol arylboronates have not been reported in the literature. As a continuation of our recent interest in the chemistry of aromatic pinacol esters,[6] we have investigated the increments for ^{1}H and ^{13}C NMR chemical shifts caused by the pinacol boronate group in the benzene rings.

Results and discussion

We used the pinacol arylboronates **1**–**6** shown below as the reference compounds to calculate the NMR increments. $CDCl_3$ is used as the NMR solvent and the spectra were all measured with a Bruker 400 MHz NMR spectrometer.

Increments I^{H}_{B} for the ^{1}H chemical-shift differences caused by the pinacol boronate group (Bpin) are calculated from the $\delta(^{1}H)$ of the pinacol arylboronates **1**–**6** by using eq. [1] (7.34 is the ^{1}H NMR chemical shift of benzene in $CDCl_3$). The results are summarized in Table 1. The increments for I^{H}s are taken from the literature (for methyl, meta = –0.12 and para = –0.22; for nitro, meta = 0.26; for bromo, para = –0.04; and for chloro, meta = –0.02).[7]

Table 1. ^{1}H chemical shifts (δ, ppm) and increments for the ^{1}H chemical-shift differences (I^H_B) caused by the pinacol boronate group for the pinacol arylboronates.

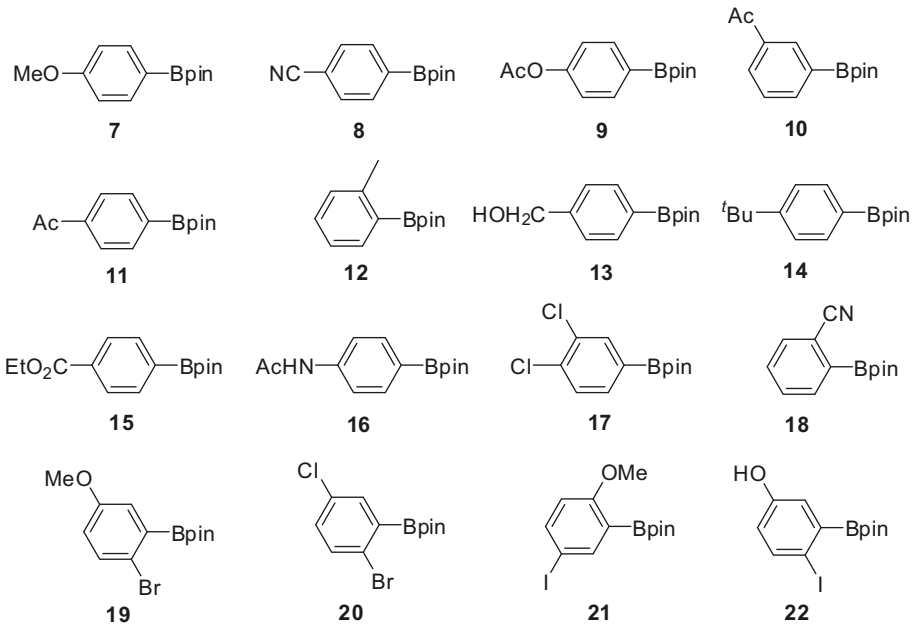
	Pinacol arylboronate											
	1		**2**		**3**		**4**		**5**		**6**	
Position	δ	I^H_B	δ	I^H_B	δ	I^H_B	δ	I^H_B	δ	I^H_B	δ	I^H_B
ortho-H	7.81	0.47	7.70	0.48	7.44	0.49	8.64	0.42	7.66	0.46	7.78	0.41
	7.81	0.47	7.70	0.48	7.44	0.49	8.10	0.39	7.66	0.46	7.66	0.37
meta-H	7.36	0.02	7.18	0.04	—	—	7.54	–0.01	7.50	0.03	7.30	0.01
	7.36	0.02	7.18	0.04	—	—	—	—	7.50	0.03	—	—
para-H	7.45	0.11	—	—	7.10	0.14	8.30	0.08	—	—	7.42	0.05

[1] $$I^H_B = \delta(^1H) - (7.34 + \Sigma I^H s)$$

From the results shown in Table 1, the mean I^H_Bs and the standard deviation can be calculated as follows:

$$I^H_B(\text{ortho}) = 0.44 \pm 0.04$$
$$I^H_B(\text{meta}) = 0.02 \pm 0.02$$
$$I^H_B(\text{para}) = 0.10 \pm 0.04$$

Compared with the chemical-shift increments caused by the boronic acid group (I^H_B(ortho) = 1.02 ± 0.03, I^H_B(meta) = 0.25 ± 0.04, I^H_B(para) = 0.34 ± 0.04),[5] I^H_B values for the pinacol boronate substituent clearly indicate that it is less electron withdrawing when compared with boronic acid.[8] They are comparable to the values of a cyano or a trifluoromethyl substituent, whereas the corresponding values for the boronic acid substituent are comparable to those of a nitro substituent. However, the factors that are related to the NMR chemical shift of boronic acids are more complicated because of reversible anhydride formation and possible dimerization through hydrogen bonding.



Similarly, the corresponding ^{13}C chemical-shift increments (I^C_B) caused by the pinacol boronate substituent can be calculated from the δ(^{13}C) of the pinacol arylboronates **1**–**6** by using eq. [2] (128.32 is the ^{13}C NMR chemical shift of benzene in $CDCl_3$). The results are summarized in Table 2. The increments for I^Cs are taken from the literature for methyl, ipso = 9.3, ortho = 0.6, meta = 0.0, and para = –3.1; for nitro, ipso = 19.6, ortho = –5.3, meta = 0.8, and para = 6.0; for bromo, ipso = –5.4, ortho = 3.3, meta = 2.2, and para = –1.0).[7]

[2] $$I^C_B = \delta(^{13}C) - (128.32 + \Sigma I^C s)$$

From the results shown in Table 2, the average increments and the standard deviation can be calculated as follows:

$$I^C_B(\text{ortho}) = 6.2 \pm 0.2$$
$$I^C_B(\text{meta}) = -0.5 \pm 0.2$$
$$I^C_B(\text{para}) = 3.1 \pm 0.5$$

With the I^H_B and the I^C_B data in hand, we subsequently verified the efficacy of these data in the estimation of chemical shifts of aromatic pinacol boronates by using the compounds **7**–**22**.

22	7.01	7.02	7.63	7.64	6.67	6.60

The calculated ^{1}H and ^{13}C chemical shifts of pinacol arylboronates found by using eqs. [1] and [2] and the corresponding measured chemical shifts are summarized in Tables 3 and 4 (see the Supplementary data for more information). The measured data were all recorded by a Bruker-400 NMR spectrometer. The increments of other functional groups are taken from the literature.[7]

From the data collected in Tables 3 and 4, the standard deviations for the estimated and measured chemical shifts were obtained.

$$d^{H}_{B}(\text{ortho}) = 0.06 \pm 0.04$$
$$d^{H}_{B}(\text{meta}) = 0.02 \pm 0.02$$
$$d^{H}_{B}(\text{para}) = 0.07 \pm 0.06$$

$$d^{C}_{B}(\text{ortho}) = 0.9 \pm 1.3$$
$$d^{C}_{B}(\text{meta}) = 0.8 \pm 0.9$$
$$d^{C}_{B}(\text{para}) = 0.8 \pm 0.5$$

The data compiled in Tables 3 and 4 demonstrate satisfactory agreement of the calculated and measured ^{1}H and ^{13}C NMR chemical shifts. However, when there are multiple substituents in the aromatic ring, relatively larger deviations of the ^{13}C chemical shifts are observed, as shown by compounds **19–22**.

Conclusion

In conclusion, we have obtained the increments for ^{1}H and ^{13}C NMR chemical shifts caused by the existence of a pinacol boronate substituent in the aromatic rings. These data could be widely used in the estimation of the NMR chemical shifts of aromatic pinacol boronates.[9]

Supplementary data

Abstract: 1,3-Dimethyl-2-nitrobenzene was converted to the key intramolecular Friedel–Crafts intermediate **24** in ten steps. Treatment of **24** with $TiCl_4$ produced tricyclic enone **25** in 61%–75% yield, having the requisite trans relationship of the two angular methyl groups and many of the salient features of the dolastane diterpenes. The structure of enone **25** was verified by X-ray crystallography analysis. Cyclization product **25** permitted the facile synthesis of (±)-14-*epi*-hydroxydolasta-1(15),7,9-triene and (±)-7-*epi*-acetoxy-14-*epi*-hydroxydolasta-1(15),8-diene, which are detailed in this article.

Key words: dolastanes, cyclialkylation, intramolecular Friedel–Crafts reactions, conformational biasing, regiospecific reductions.

Résumé : On a effectué la transformation en dix étapes du 1,3-diméthyl-3-nitrobenzène en composé **24**, l'intermédiaire clé d'une réaction de Friedel–Crafts intramoléculaire. Le traitement du produit **24** par du $TiCl_4$ à conduit avec un rendement de 61 à 75 % à formation de l'énone tricyclique **25** comportant la relation trans requise entre les deux groupes méthyles angulaires ainsi que plusieurs des caractéristiques principales des diterpènes du dolastane. La structure de l'énone **25** par diffraction des rayons-X. La cyclisation du produit **25** a permis de réaliser facilement la synthèse du (±)-14-*épi*-hydroxydolasta-1(15),7,9-triène et du (±)-7-*épi*-acétoxy-14-*épi*-hydroxydolasta-1(15),8-diène. Veuillez noter la cyclialkylation dans le texte.

Mots-clés : dolastanes, cycloalkylation, réactions de Friedel–Crafts intramoléculaires, biais conformationnel, réductions régiospécifiques.

[Traduit par la Rédaction]

Introduction

Fifty years ago, the diterpenoids were rare components of the marine environment. However, there are now more than 1900 diterpenoids known,[1] including twenty-five dolastanes. Dolatriol (**1**), the first dolastane isolated, was obtained from extracts of the digestive gland of the poisonous Indian Ocean sea hare *Dolabella auricularia* (Scheme 1)[2–5] and was very cytotoxic. Further work, however, established that dolatriol was actually produced by a brown algae genus *Dictyota* and only concentrated by *Dolabella auricularia* through its diet. All dolastanes have a distinctive 5,7,6-linear fused tricyclic framework. Their structural diversity rests on the following features: (*i*) the number and the position(s) of the hydroxyl group and double bond(s) (cf. **3**); (*ii*) the trans configuration of the two angular methyl groups at C-5 and C-12; (*iii*) the BC-ring system is usually trans fused; and (*iv*) many of the relative stereochemical configurations have been assigned based on X-ray crystal structure analysis or NMR studies. Finally, isoamijiol (**2**) has antimicrobial activity against *Mucor mucedo* and *Staphylococcus aureus*, and several dolastanes exhibit promising biological activity.[6]

The research groups of Pattenden,[7] Piers,[8] Mehta,[9] Paquette,[10] Williams,[11] and Majetich[12] have completed total syntheses of various dolastanes. The first dolastane synthesized was (±)-amijiol (**2**) by Pattenden and co-workers in 1986.[7] Their strategy for introducing the trans angular methyl groups is shown in Chart 1. The alkylation of hydroazulenone **5**, produced in seven steps from cyclopentanone, gave exclusively the α–epimer **6** because of the steric influence of the C-16 angular methyl group. The C-ring was formed with the requisite C-14 stereochemistry, using an intramolecular reductive coupling of ketone **6** with the alkyne; an allylic oxidation of alkene **7** introduced the C-2 hydroxyl group, albeit in low yield. In their synthesis of **3** from ketone **8**, Piers and Friesen used a similar alkylation strategy to introduce the C-12 and C-5 chirality (cf. **9** → **10**).[8] Vinylstannane **10** was converted into a Grignard reagent, which added to the C-14 carbonyl group to complete the synthesis. In 1987 Mehta and Krishnamurthy used a similar A+B→AB+C→ABC strategy to prepare **10**, using Pattenden's strategy, to install the C–14 hydroxyl group and create the C-ring.[9] The synthesis of the non-natural (±)-4aβ,10β-doladiol acetate (**4**) was achieved by Paquette et. al.[10] Instead of using the C-12

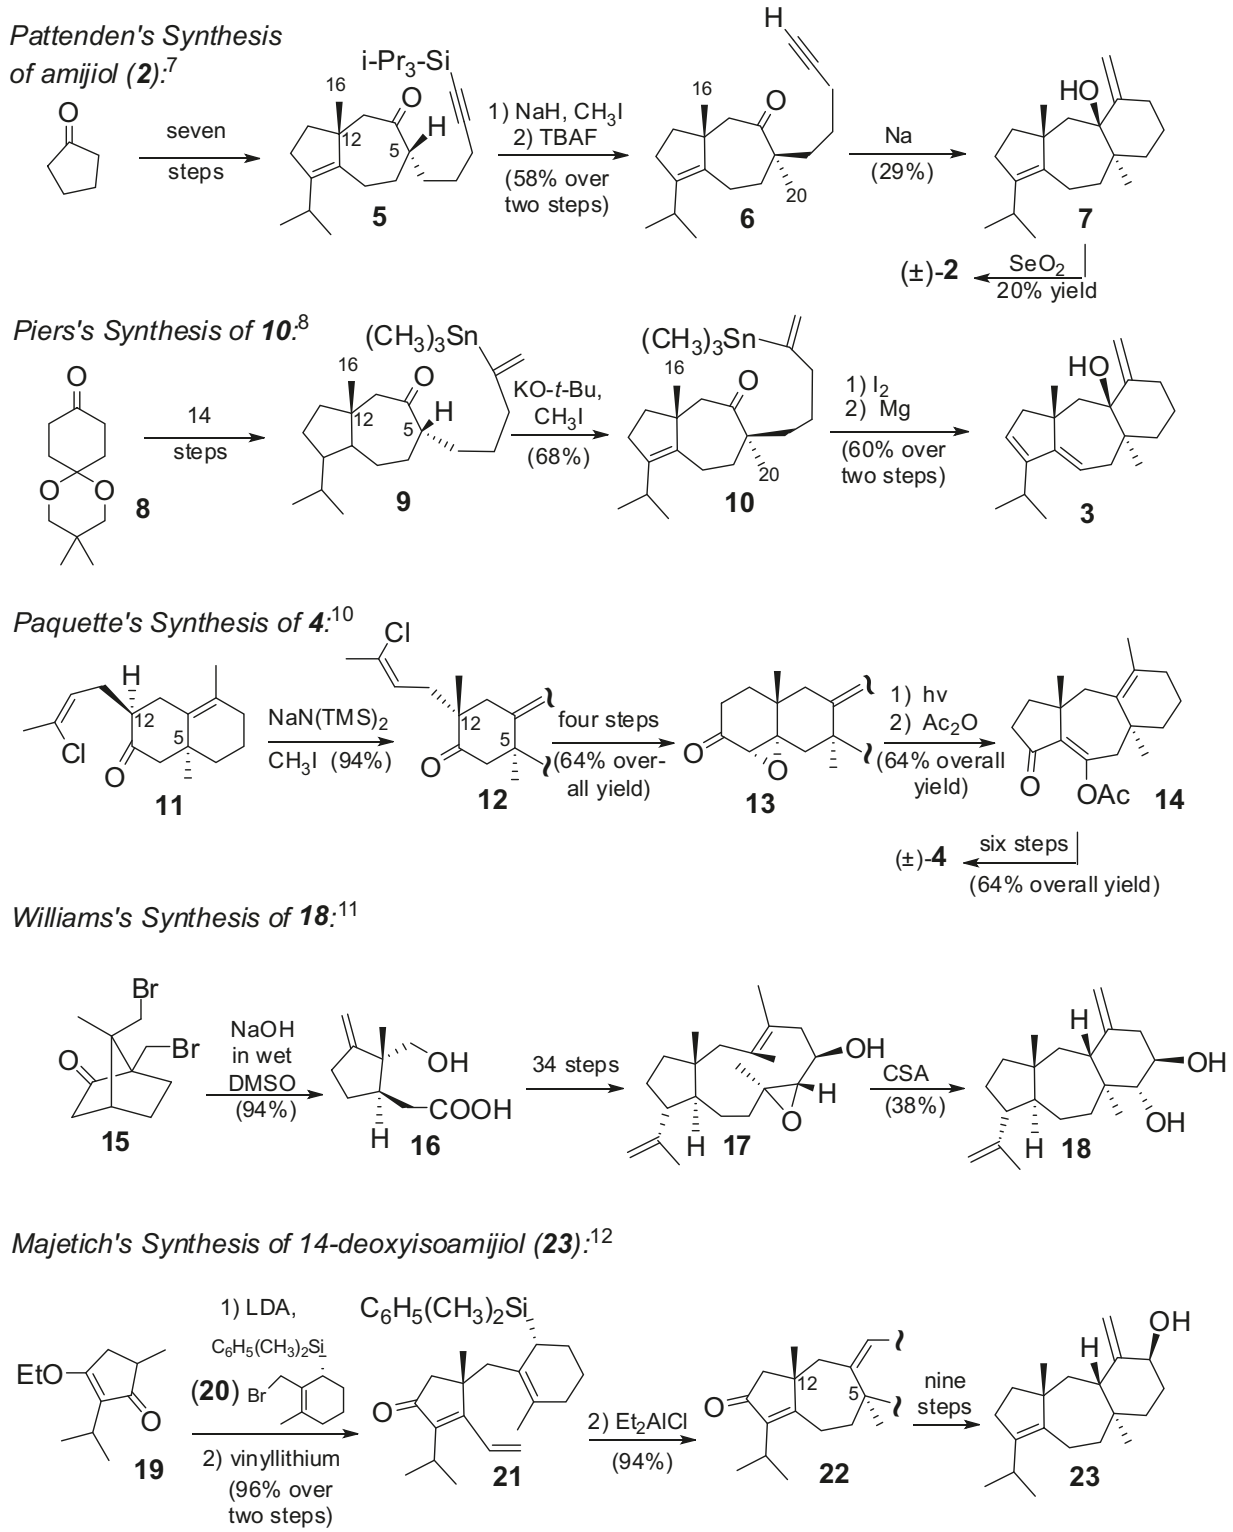
methyl group to create the C-5 stereocenter, the alkylation of decalenone **11** produced alkylated product **12**, using the C-5 angular methyl group to create the C-12 stereochemistry. This synthesis featured a photochemical rearrangement to isomerize the 6,6,6-tricyclic α,β-epoxy ketone **13** into a 5,7,6-tricyclic dolastane skeleton. Six additional steps were needed to convert enone **14** into the 7,14-epimers of natural dolastane **4**. Williams and co-workers synthesized (–)-clavulara-1(15),17-dien-3,4-diol (**18**) from (+)-9,10-dibromocamphor **15**, which fragmented to form acid **16** upon exposure to NaOH.[11] Thirty-four transformations were required to transform **16** into macrocyclic epoxide **17**. An acid-catalyzed transannular epoxide opening of **17** created the C-ring with the required C-5 stereogenic center in 38% yield. In contrast to these strategies, Majetich and co-workers used an A +C→AC→ABC strategy to synthesize natural (±)-1(15),8-dolastadien-2-ol (±)-**23** (also called 14-deoxyisoamijiol).[12] In this synthesis, a functionalized A-ring (cf. **19**) was coupled with a C-ring containing an allylsilane (cf. **20**), followed by the addition of vinyllithium to the C-8 carbonyl group to produce dienone **21**. An intramolecular 1,6-addition of the allylsilane to the dienone **21** produced the dolastane skeleton with the trans relationship of the C-5 and C-12 angular methyl groups (cf. **22**). Nine steps were needed to introduce the C-1,C-15 double bond and the β-oriented C-2 hydroxyl group of **23**.

We have found that intramolecular Friedel–Crafts reactions, or cyclialkylations,[13] of conjugated dienones represent a powerful strategy to assemble various tricyclic frameworks.[14] We speculated that conformational biasing prior to ring formation would also create stereogenic centers (Scheme 2). However, the examination of a Dreiding model of **24** suggests that steric interactions between the C-16 and C-20 methyl groups in conformer **i**, and the steric interactions between the C-16 and C-15 methyl groups in conformer **ii** are comparable. We have observed that when the ortho and para positions are both substituted with identical groups (H, CH_3, or Cl), cyclization occurs at the para position relative to the electron donating substitutent (cf. **ii**). Thus, ring closure via conformer **ii** would produce the central cyclohexane ring and a trans relationship between the C-12 and C-5 angular methyl groups. If so, the functionality present in the A- and C-rings of enone **25** makes it an attractive precursor for the synthesis of several dolastanes. Herein, we report the synthesis of tricyclic enone **25** and its conversion into (±)-14-*epi*-hydroxydolasta-1(15),7,9-triene (**3**) and (±)-7-*epi*-acetoxy-14-*epi*-hydroxydolasta-1(15),8-diene (**4**).

Our study began with the preparation of the A- and C-rings. The A-ring was synthesized from 4-methylpentan-2-one (**26**), using our published procedure (Scheme 3);[12] commercially available 1,3-dimethyl-2-nitrobenzene (**29**) was our starting material for the C-ring synthesis (Scheme 4).

Monobromination of **29** followed by nucleophilic aromatic substitution gave anisole derivative **30** in 83% yield.[15] Zinc metal reduction of the nitro group provided aniline compound **31**.[16] The next step, a Sandmeyer reaction,[17] gave an inseparable mixture of mono- and di-bromination products **32** and **35**, respectively. Fortunately, the reaction of the organolithium reagents derived from **32** and **35** with DMF produced aldehyde **33** and dialdehyde **36**, which were easily separated. Reduction of aldehyde **33** to an alcohol with LAH was followed by the conversion of the benzylic alcohol to the corresponding benzyl bromide **34** by treatment with PBr_3.

With the A- and C-rings in hand, we set out to prepare dienone **24**, the key cyclization precursor. Coupling of **19** with **34** gave adduct **37** in excellent yield (Scheme 5). Addition of vinyllithium to ketone **37**, followed by acidic work-up, gave dienone **24** in high yield. There are two facial-selective products possible from the cyclization of dienone **24** (cf. **25** and **25a**) and two possible regioisomers (cf. **25b** and **25c**). In each case, cyclialkylation would produce a C-ring dienone, since the newly created quaternary carbon center (either at C-5 or at C-1) precludes re-aromatization. In a related cyclialkylation,[18] we found that under Lewis acid catalysis, dienone **38** produces tricycle **39** having an angularly fused quaternary carbon center (Scheme 6). We were pleased to find that treatment of dienone **24** with $TiCl_4$ at –60 °C for 30 min produced only enone **25**, albeit the isolated yield varied between 61% and 75%. An X-ray crystal structure analysis of **25** verified the trans configuration of the two angular methyl groups.



Several of the dolastanes have a β-hydroxyl group at C-2 and a C-1, C-15 exocyclic double bond, or a C-14 β-hydroxyl group, or a hydroxyl group or an acetate at C-4 (Scheme 7). To achieve a synthesis of (±)-7,14-*epi*-1(15),8-dolastadiene-7,14-diol 7-acetate (**4**), we needed to selectively reduce the C-2 and C-10 carbonyl groups and the C-3,C-4 double bond of enone **25**, as well as selectively introduce an acetate at C-7 and an α-oriented hydroxyl group at C-14 (cf. **4**). We were confident that the A-ring enone moiety would permit the introduction of the C-7,C-9 diene (cf. **40**) thereby facilitating a synthesis of **10**.

The C-2 carbonyl group, which is conjugated to two double bonds, has more resonance contributors with a negative charge on oxygen, thereby making it less reactive than the C-10 carbonyl group (Scheme 8). Indeed, treatment of enone

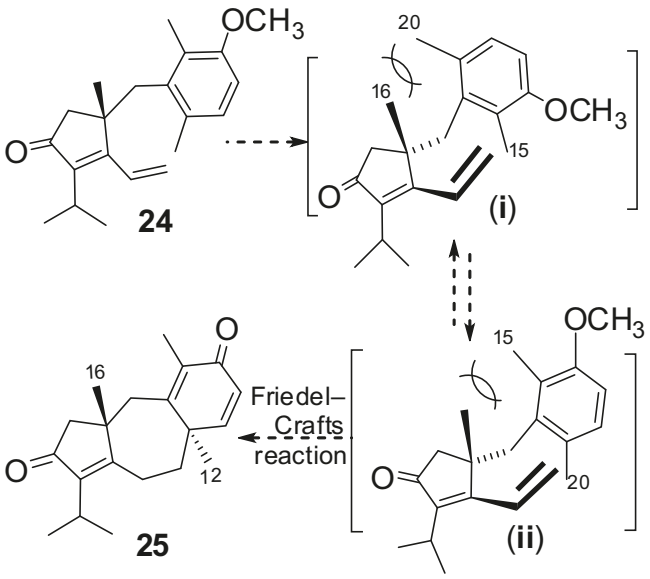
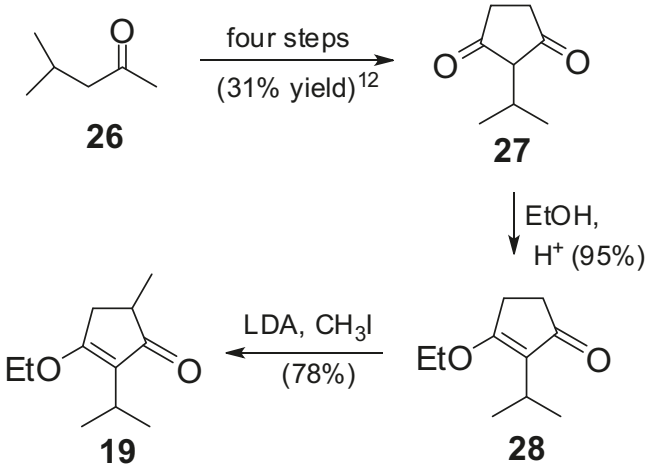
Chart 1.



25 with sodium borohydride in the presence of TFA in dichloromethane selectivity reduced the C-10 carbonyl group to a methylene unit.[19] If, however, we first reduced the C-3, C-4 double bond (cf. **42**), the C-2 carbonyl group was found to be more reactive, presumably a result of the steric hindrance by the isopropyl group. Note that under the reaction conditions, enone **43** is rapidly reduced to produce diene **44**.



In their synthesis of **4**, Paquette et al. found that singlet oxygen migrated the C-1,C-14 double bond to the C-1,C-15 position and introduced an α-oriented alcohol at C-14.[10a] Reaction of enone **43** with singlet oxygen, followed by reduction of the intermediate allylic peroxide, introduced an alcohol from the α-face because of the steric effect of the C-16 methyl, which added in Michael fashion to the A-ring enone

Can. J. Chem. Downloaded from www.nrcresearchpress.com by Renmin University of China on 09/02/12

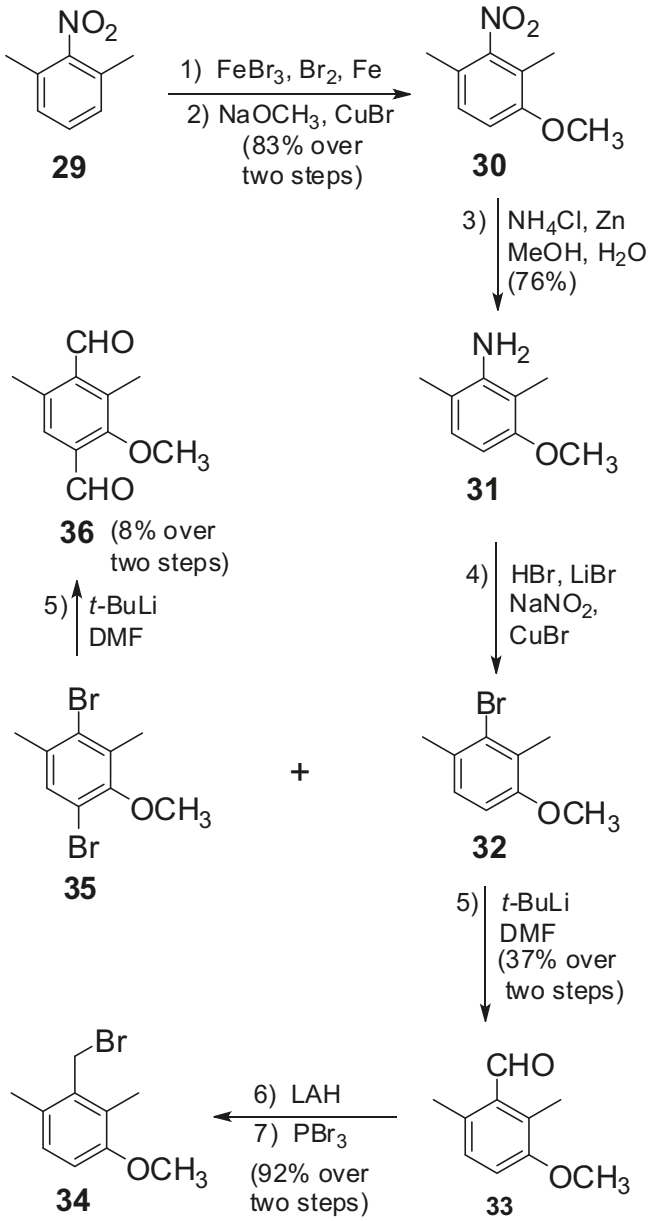
Scheme 2.

Scheme 3.

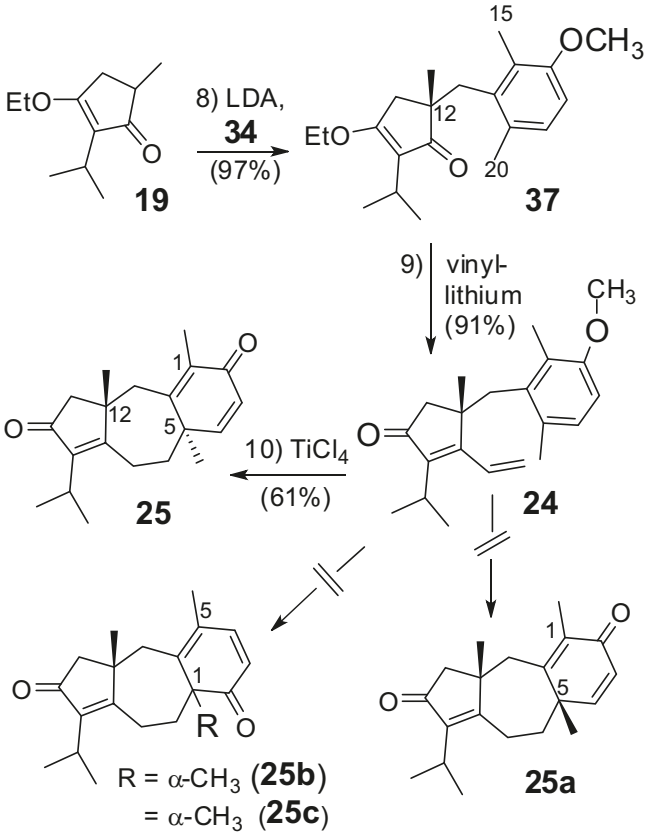


to form tetrahydrofuran **45** in 92% yield. This result indicated that the C-10 carbonyl group had to be removed, or protected, before the C-14 α-hydroxyl group is introduced.

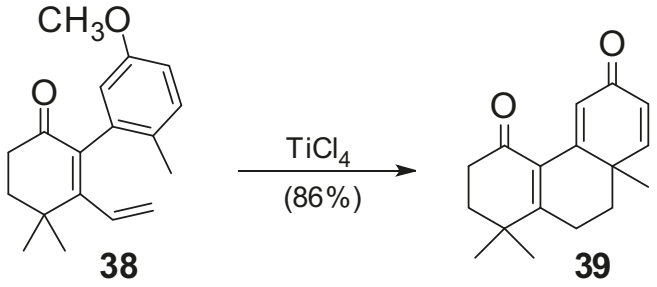
Another way to introduce the C-14 α-allylic alcohol was by opening a C-1,C-14 α-epoxide. However, because of the steric influence of the C-16 methyl group, the epoxidation of **43** gave only epoxide **46** (Scheme 9). The reduction of the C-10 carbonyl group with LAH gave an allylic alcohol, which rapidly dehydrated to form diene **47**. Treatment of **47** with LDA at 50 °C overnight gave alcohol **48** in 93% yield; this compound is epimeric at C-14 to natural dolastane **10**. A traditional way to prepare an epimeric epoxide is to make the bromohydrin from the alkene and then treat it with base. Since the C-16 methyl blocks the β-face of the C-1,C-14 double bond, bromonium ion formation must occur from the α-face so that the addition of water to the bromonium ion generated in situ must add from the β-face to provide the β-epoxide. However, when **43** was treated with NBS in wet acetone, allylic oxidation at C-2 produced dienone **42** in 71% yield.

Scheme 10 presents a formal synthesis of **4** from diene **44**. Longer reaction time in the reduction of enone **42** produced

Scheme 4.



diene **44** in 73% yield. The reaction of diene **44** with selenium dioxide and *t*-butylhydroperoxide produced alcohol **49** in 45% yield and triene **50** in 40% yield; all efforts to prevent the in situ dehydration of **49** failed. Allylic alcohol **49** was oxidized using freshly activated MnO_2 to enone **51**, which Paquette and co-workers converted to **4** using the three transformations shown in 64% overall yield.[10c]



In summary, 1,3-dimethyl-2-nitrobenzene was converted in ten steps into tricyclic dienone **25.** In the key reaction, diene **24** was cyclized to produce the central seven-membered ring and created the required stereochemistry of the C-5 and C-12 quaternary carbon atoms. Changing the oxidation states at C-3, C-4, C-10, C-14, and C-15 required six transformations and produced (±)-14-*epi*-hydroxydolasta-1(15),7,9-triene (**48**), which is epimeric at C-14 to the natural dolastane. Diene **44**, at first an unwanted side product in the reduction of dienone **42**, was optimized and then converted in two steps into enone **51**, an intermediate in Paquette's synthesis of

(±)-7-*epi*-acetoxy-14-*epi*-hydroxydolasta-1(15),8-diene (**4**). We are confident that dienone **25,**, or a derivative thereof, will permit the efficient synthesis of the more oxygenated naturally occurring dolastanes.

Experimental section

General procedures

All reactions were run under a nitrogen atmosphere and monitored by TLC analysis. Unless otherwise indicated, all ethereal work-ups consisted of the following procedure. The

Scheme 10.

reaction was quenched at RT (RT) with water. The organic solvent was removed under reduced pressure on a rotary evaporator, and the residue was extracted with diethyl ether twice. The combined organic layer was washed with water, brine, and dried over anhydrous magnesium sulfate. Filtration, followed by concentration at reduced pressure on a rotary evaporator and at 1 torr (1 torr = 133.322 4 Pa) to constant weight, afforded a crude residue that was purified by flash chromatography using silica gel 60 (230–400 mesh ASTM) eluted with distilled reagent grade petroleum ether and diethyl ether. Melting points were recorded on a Laboratory Devices Mel–Temp 3.0. ^{1}H and ^{13}C NMR spectra were recorded on Bruker AVB–400 and DRX–500 MHz spectrometers with ^{13}C operating frequencies of 100 and 125 MHz, respectively. ^{1}H NMR spectra were obtained in $CDCl_3$ and were calibrated using trace $CHCl_3$ present (δ 7.27) as an internal reference. ^{13}C NMR spectra were obtained in $CDCl_3$ and were calibrated using trace $CHCl_3$ present (δ 77.23) as an internal reference. The IR spectra were obtained using an Avatar 360FT-IR spectrophotometer and are reported in frequency of absorption (cm^{-1}). Only selected IR absorbances are reported. High-resolution MS spectra were taken using a LCT Premier mass spectrometer from Waters.

1-Methoxy-2,4-dimethyl-3-nitrobenzene (30)

To a solution of 1,3-dimethyl-2-nitrobenzene (**29**) (50.0 g, 331 mmol) in freshly distilled DCM (150 mL) was added $FeBr_3$ (2.0 g, 6.8 mmol) and Fe (5.0 g, 89 mmol). Molecular bromine (18.6 mL, 361 mmol) was added dropwise, and 100 mL of DCM was added to the mixture. The reaction mixture was refluxed for 8 h. The reaction mixture was cooled to RT, followed by standard ethereal work-up. The organic layer was dried over anhydrous $MgSO_4$, filtered, and then concentrated under vacuum using rotary evaporator to give 74.3 g (98.0%) of the bromide as a crude red oil. IR (film): λ_{max}: 2927, 1517, 1370, 815 cm^{-1}. ^{1}H (400 MHz) δ: 7.55 (d, J = 4.8 Hz, 1H), 7.02 (d, J = 4.8 Hz, 1H), 2.35 (s, 3H), 2.26 (s, 3H). ^{13}C NMR (100 MHz) δ: 134.0 (d), 129.9 (d), 129.6 (s), 128.7 (s), 123.2 (s), 18.3 (q), 17.3 (q) ppm. HR-MS: $[M]^+_{obs}$ = 228.9738, $[M]^+_{calcd}$ = 228.9738. This crude bromide was used in the next reaction without purification.

A solution of sodium methoxide was prepared by adding small pieces of sodium metal (21.0 g, 0.913 mol) to anhydrous methanol (300 mL). After the complete consumption of the sodium, a solution of the above bromide (70.0 g, 304 mmol) in anhydrous DMF (300 mL) was added, followed by the addition of CuBr (4.0, 28.0 mmol). The reaction mixture was heated at 110 °C for 12 h, then cooled to RT, and water (100 mL) was added dropwise to quench the reaction. Standard ethereal work-up gave 46.8 g (85%) of nitrobenzene **30** as a crude red solid, which was recrystallized (benzene) to give white crystals. Mp 48.7–49.0 °C. IR (film) λ_{max}: 2930, 1524, 1263, 810 cm^{-1}. ^{1}H (400 MHz) δ: 7.06 (d, J = 8.8 Hz, 1H), 6.84 (d, J = 8.8 Hz, 1H), 3.85 (s, 3H), 2.23 (s, 3H), 2.14 (s, 3H). ^{13}C NMR (100 MHz) δ: 181.1 (s), 156.4 (s), 128.9 (d), 120.6 (s), 118.7 (s), 111.8 (d), 56.2 (q), 16.7 (q), 10.9 (q) ppm. HR-MS: $[M]^+_{obs}$ = 181.0741, $[M]^+_{calcd}$ = 181.0739.

3-Methoxy-2,6-dimethylaniline (31)

To a solution of anisole **30** (30.0 g, 166 mmol) in MeOH (270 mL) and H_2O (30 mL) was added NH_4Cl (26.0 g, 486 mmol), followed by Zn powder (110 g, 1.68 mol) in small portions. The reaction mixture was stirred at RT for 2 h, followed by standard ethereal work-up, to give 19.0 g (76.0%) of aniline **31** as a crude red oil which was used in the next step without purification. IR (film) λ_{max}: 3393, 2910, 1626, 1496, 1262, 791 cm^{-1}. ^{1}H (400 MHz) δ: 6.89 (d, J = 8.4 Hz, 1H), 6.32 (d, J = 8.4 Hz, 1H), 3.80 (s, 3H), 2.15 (s, 3H), 2.09 (s, 3H). ^{13}C NMR (100 MHz) δ: 156.7 (s), 143.8 (s), 127.6 (d), 115.1 (s), 110.9 (s), 101.0 (d), 55.9 (q), 17.4 (q), 9.4 (q) ppm. HR-MS: $[M]^+_{obs}$ = 152.1074, $[M]^+_{calcd}$ = 152.1075.

2-Bromo-4-methoxy-1,3-dimethylbenzene (32) and 1,4-dibromo-2-methoxy-3,5-dimethylbenzene (35)

A round bottom flask at 0 °C was charged with HBr (4.67 g, 27.7 mmol), THF (60 mL), LiBr (1.14 g, 13.1 mmol), $NaNO_2$ (1.0 g, 14.5 mmol), and CuBr (2.26 g, 15.8 mmol). The ice bath was removed, and aniline **31** (3.0 g, 2.00 mmol) in THF (15 mL) was added dropwise. The reaction mixture was stirred at RT for an additional 1 h, followed by standard ethereal work-up, to give 3.43 g of a black oil which was predominantly bromide **32** along with dibromide **35**, which could not be separated. Albeit a mixture, the following data is for bromide **32**, the major component. ^{1}H (400 MHz) δ: 7.08 (d, J = 8.3 Hz, 1H), 6.75 (d, J = 8.3 Hz, 1H), 3.80 (s, 3H), 2.20 (s, 3H), 2.18 (s, 3H).

3-Methoxy-2,6-dimethylbenzaldehyde (33) and 2-methoxy-3,5-dimethylterephthalaldehyde (36)

To a solution of **32** and **35** (34 g) in THF (250 mL) at –78 °C was slowly added *t*-BuLi (180 mL, 306 mmol). This mixture was stirred at –78 °C for 2 h, followed by the addition of DMF (40 mL). The reaction mixture was warmed to RT and stirred overnight. Water (10 mL) was added slowly to quench the reaction, followed by standard ethereal work-up. Column chromatography (elution with pet. ether/EtOAc, 10:1) gave 1.22 g (37% over two steps) of aldehyde **33** (hexane/EtOAc, 4:1, R_f **33** = 0.66) as a

white solid. IR (film) λ_{max}: 2939, 1691, 1262 cm^{-1}. ^{1}H (400 MHz) δ: 10.6 (s, 1H), 7.03 (d, J = 8.4 Hz, 1H), 6.93 (d, J = 8.4 Hz, 1H), 3.83 (s, 3H), 2.51 (s, 3H), 2.46 (s, 3H). ^{13}C NMR (125 MHz) δ: 194.5 (d), 156.4 (s), 133.8 (s), 132.1 (s), 129.8 (s), 129.6 (d), 115.0 (d), 56.1 (q), 20.1 (q), 11.5 (q) ppm. HR-MS: $[M]^+_{obs}$ = 164.0840, $[M]^+_{calcd}$ = 164.0837. Further elution gave 0.31 g (8.1% over two steps) of *bis*-aldehyde **36** as a white solid (hexane/EtOAc, 4:1, R_f **36** = 0.45). Mp = 82.0–82.3 °C. IR (film) λ_{max}: 2930, 1691, 1409, 1232 cm^{-1}. ^{1}H (400 MHz) δ: 10.6 (s, 1H), 10.4 (s, 1H), 7.54 (s, 1H), 3.85 (s, 3H), 2.55 (s, 3H), 2.52 (s, 3H). ^{13}C NMR (100 MHz) δ: 193.7 (d), 190.1 (d), 160.4 (s), 138.8 (s), 136.2 (s), 134.9 (s), 131.4 (s), 128.9 (d), 63.8 (q), 19.9 (q), 11.8 (q) ppm. HR-MS: $[M]^+_{obs}$ = 192.0790, $[M]^+_{calcd}$ = 192.0786.

2-(Bromomethyl)-4-methoxy-1,3-dimethylbenzene (34)

A solution of aldehyde **33** (10.0 g, 61.0 mol) in Et_2O (150 mL) was cooled to 0 °C and LAH (2.55 g, 67.1 mmol) was added portion-wise. The ice bath was removed and the solution was stirred at RT for 1 h. The solution was poured into a 2 L Erlenmeyer flask containing Na_2SO_4 (20 g) and EtOAc (300 mL). Water was added slowly until the heterogeneous mixture turned to white. Standard ethereal work-up, followed by column chromatography (elution with pet ether/EtOAc = 4:1), afforded 9.60 g (95%) (3-methoxy-2,6-dimethylphenyl)methanol as a white solid (hexane/EtOAc, 4:1, R_f alcohol = 0.25). IR (film) λ_{max}: 3396, 2957, 1464, 1258 cm^{-1}. ^{1}H (400 MHz) δ: 7.02 (d, J = 8.8 Hz, 1H), 6.75 (d, J = 8.0 Hz, 1H), 4.75 (s, 2H), 3.82 (s, 3H), 2.38 (s, 3H), 2.31 (s, 3H). ^{13}C NMR (125 MHz) δ: 156.4 (s), 137.8 (s), 129.2 (s), 128.4 (d), 126.4 (s), 110.4 (d), 59.8 (t), 55.9 (q), 19.2 (q), 11.6 (q) ppm. HR-MS: $[M]^+_{obs}$ = 166.0999, $[M]^+_{calcd}$ = 166.0994.

A solution of the above alcohol (5.00 g, 30.1 mmol) in Et_2O (150 mL) was cooled to 0 °C and PBr_3 (3.1 mL, 33.1 mmol) was added dropwise. The resulting solution was removed from the ice bath and stirred at RT for 1 h. The resulting solution was cooled to 0 °C, and brine (30 mL) was added slowly. The aqueous phase was removed and the organic layer was dried over anhydrous magnesium sulfate. Filtration, followed by concentration at reduced pressure, and column chromatography (elution with pet ether/EtOAc, 15:1) afforded 6.69 g (97%) of bromide **34** as a white solid (hexane/EtOAc, 4:1, R_f **34** = 0.80). Mp = 62.3–62.5 °C. IR (film) λ_{max}: 3000, 2833, 1486, 1261 cm^{-1}. ^{1}H (400 MHz) δ: 7.03 (d, J = 8.4 Hz, 1H), 6.77 (d, J = 8.8 Hz, 1H), 4.60 (s, 2H), 3.83 (s, 3H), 2.40 (s, 3H), 2.33 (s, 3H). ^{13}C NMR (125 MHz) δ: 156.4 (s), 135.3 (s), 129.3 (s), 128.4 (d), 126.5 (s), 111.0 (d), 55.9 (q), 29.9 (t), 19.0 (q), 11.4 (q) ppm. HR-MS: $[M+H]^+_{obs}$ = 228.0140, $[M+H]^+_{calcd}$ = 228.0150.

3-Ethoxy-2-isopropyl-5-(3-methoxy-2,6-dimethylbenzyl)-5-methylcyclopent-2-en-1-one (37)

To a solution of diisopropylamine (2.40 mL, 17 mmol) in THF (20 mL) at –78 °C was added *n*-butyllithium (6.30 mL, 16 mmol) over a 5 min period. The resulting mixture was stirred at RT for 10 min then cooled to –78 °C. A solution of enone **19** (2.60 g, 14.3 mmol) and HMPA (2.60 g, 14.3 mmol) in THF (10 mL) was cannulated over a 5 min period. The resulting solution was stirred for 1 h at –78 °C then raised to –63 °C. A solution of bromide **34** (2.94 g, 17.2 mmol) in THF (10 mL) was cannulated into the reaction mixture over a 2 min period, and the resulting mixture was stirred overnight. Standard ethereal work-up, followed by column chromatography (elution with pet ether/EtOAc, 10:1), afforded 4.2 g (97%) of adduct **37** as a light yellow oil (hexane/EtOAc, 4:1, R_f **37** = 0.47). IR (film) λ_{max}: 2981, 1622, 1342, 1253 cm^{-1}. ^{1}H (400 MHz) δ: 6.94 (d, J = 8.4 Hz, 1H), 6.64 (d, J = 8.4 Hz, 1H), 3.99 (m, 1H), 3.87 (m, 1H), 3.79 (s, 3H), 3.28 (d, J = 14.8 Hz, 1H), 3.74 (d, J = 14.8 Hz, 1H), 2.71 (septet, J = 7.2 Hz, 1H), 2.38 (d, J = 17.2 Hz, 1H), 2.18 (s, 3H), 2.16 (d, J = 17.2 Hz, 1H), 2.10 (s, 3H), 1.28 (s, 3H), 1.19 (t, J = 7.2 Hz, 3H), 1.10 (d, J = 6.8 Hz, 3H), 1.08 (d, J = 7.2 Hz, 3H). ^{13}C NMR (100 MHz) δ: 209.3 (s), 181.9 (s), 156.3 (s), 137.9 (s), 129.7 (s), 128.0 (d), 126.4 (s), 122.9 (s), 108.5 (d), 64.9 (t), 55.8 (q), 46.9 (s), 36.8 (t), 36.4 (t), 27.9 (q), 23.0 (d), 21.0 (q), 20.3 (q), 20.3 (q), 15.1 (q), 13.5 (q) ppm. HR-MS: $[M+H]^+_{obs}$ = 331.2266, $[M+H]^+_{calcd}$ = 331.2273.

2-Isopropyl-4-(3-methoxy-2,6-dimethylbenzyl)-4-methyl-3-vinylcyclopent-2-en-1-one (24)

To a solution of vinyl bromide (3.2 mL, 45 mmol) in freshly distilled Et_2O (60 mL) at –78 °C, *t*-butyllithium (54 mL, 1.7 mol/L, 91 mmol) was added over a 15 min period. After stirring 2.5 h at RT, the vinyllithium mixture was cannulated into **37** (2.00 g, 6.1 mmol) in THF (60 mL) solution at –78 °C. The resulting mixture was warmed to RT and stirred for an additional 8 h. Hydrochloric acid (20.0 mL, 1.0 mol/L) was added dropwise at 0 °C, and the resulting mixture was stirred for 30 min. Standard ethereal work-up, followed by column chromatography (elution with pet ether/EtOAc, 8:1), gave 1.76 g (91%) of conjugated dienone **24** as a light yellow oil (hexane/EtOAc, 2:1, R_f **24** = 0.75). IR (film) λ_{max}: 2960, 1693, 1258, 1102 cm^{-1}. ^{1}H (400 MHz) δ: 6.96 (d, J = 8.0 Hz, 1H), 6.90 (dd, *J1* = 11.2 Hz, *J2* = 17.6 Hz, 1H), 6.66 (d, J = 8.4 Hz, 1H), 5.63 (d, J = 17.6 Hz, 1H), 5.47 (d, J = 11.2 Hz, 1H), 3.79 (s, 3H), 3.43 (m, 1H), 3.08 (dd, *J1* = 6.4 Hz, *J2* = 14.0 Hz, 1H), 2.93 (septet, J = 7.2 Hz, 1H), 2.57 (dd, *J1* = 10.0 Hz, *J2* = 14.0 Hz, 1H), 2.28 (m, 1H), 2.25 (s, 3H), 2.20 (s, 3H), 1.28 (s, 3H), 1.26 (d, J = 6.8 Hz, 1H), 1.22 (d, J = 6.8 Hz, 1H). ^{13}C NMR (125 MHz) δ: 208.3 (s), 166.9 (s), 156.4 (s), 145.0 (s), 138.1 (s), 130.4 (d), 128.4 (s), 128.3 (d), 125.2 (), 121.5 (t), 108.4 (d), 55.5 (q), 41.1 (t), 36.8 (d), 35.8 (t), 20.9 (q), 20.6 (q), 20.5 (q), 15.1 (q), 12.8 (q) ppm.

(3a*S*,8a*R*)-1-Isopropyl-3a,5,8a-trimethyl-3a,4,9,10-tetrahydrobenzo[*f*]azulene-2,6(3*H*,8a*H*)-dione (25)

To a solution of conjugated dienone **24** (200 mg, 0.641 mmol) in fresh distilled DCM (2 mL) at –78 °C was added $TiCl_4$ (10 μL, 0.91 mmol). The resulting mixture was stirred at –78 °C for 1 h, and the temperature was raised to –60 °C, then stirred for an additional 0.5 h. Water (5 mL) was added dropwise to quench the reaction, followed by standard ethereal work-up. Column chromatography (elution with pet ether/EtOAc, 4:1) afforded 115 mg (61%) of tricyclic enone **25** as a white solid (hexane/EtOAc, 2:1, R_f **25** = 0.41). IR (film) λ_{max}: 2963, 1738, 1693, 1658, 1627, 1379 cm^{-1}. ^{1}H (500 MHz) δ: 6.81 (d, J = 9.5 Hz, 1H), 6.31 (d, J = 9.5 Hz, 1H), 3.03 (d, J = 13.5 Hz, 1H),

2.74 (m, 1H), 2.67 (septet, J = 7.0 Hz, 1H), 2.35 (m, 3H), 2.17 (m, 1H), 1.96 (s, 3H), 1.71 (m, 1H), 1.59 (m, 1H), 1.22 (s, 3H), 1.13 (m, 6H), 1.09 (s, 3H). ^{13}C NMR (125 MHz) δ: 207.4 (s), 186.2 (s), 179.3 (s), 158.0 (s), 157.7 (d), 140.9 (s), 136.0 (s), 128.2 (d), 52.0 (t), 45.6 (t), 45.1 (s), 40.0 (t), 38.4 (t), 29.9 (q), 25.7 (q), 24.7 (d), 23.9 (t), 20.8 (q), 20.7 (q), 13.8 (q) ppm. HR-MS: $[M+H]^+_{obs}$ = 299.2010, $[M+H]^+_{calcd}$ = 299.2011.

(3a*R*,8a*R*)-1-Isopropyl-3a,5,8a-trimethyl-2,3,3a,4,9,10-hexahydrobenzo[*f*]azulen-6(8a*H*)-one (41)

To a solution of tricycle **25** (100 mg, 0.336 mmol) in freshly distilled DCM (10 mL) was added 10% TFA in DCM solution (5 mL), followed by $NaBH_4$ (64 mg, 1.7 mmol). The resulting mixture was stirred for 0.5 h. Water (5 mL) was added to quench the reaction, followed by standard ethereal work-up. Column chromatography (elution with pet ether/EtOAc, 10:1) gave 64 mg (67%) of dienone **41** as a light yellow oil (hexane/EtOAc, 4:1, R_f **41** = 0.55). IR (film) λ_{max}: 2963, 1658, 1462, 1151 cm^{-1}. ^{1}H (500 MHz) δ: 6.81 (d, J = 9.5 Hz, 1H), 6.31 (d, J = 9.5 Hz, 1H), 2.67 (septet, J = 7.0 Hz, 1H), 2.15–1.5 (m, 11H), 1.96 (s, 3H), 1.22 (s, 3H), 1.13 (m, 6H), 1.09 (s, 3H). HR-MS: $[M+H]^+_{obs}$ = 285.2222, $[M+H]^+_{calcd}$ = 285.2218.

(3a*R*,8a*R*)-1-Isopropyl-3a,5,8a-trimethyl-2,3,3a,4,8,8a,9,10-octahydrobenzo[*f*]azulen-6(7*H*)-one (42)

To a dry 20-mL round-bottomed flask was added tricycle **25** (100 mg, 0.336 mmol) under nitrogen atmosphere, followed by addition of anhydrous EtOAc (5 mL) and 5% of Pd/C (10 mg, 10% in weight). The nitrogen in the reaction flask was removed by bubbling H_2 into the reaction medium for a 5 min period. A balloon filled with H_2 was connected to the round-bottomed flask and the resulting mixture was stirred under H_2 for 2 h. The H_2 balloon was disconnected and the residue H_2 gas was removed by bubbling N_2 into the reaction mixture, followed by filtration through a short pad of silica gel to remove the catalyst. Standard ethereal work-up, followed by column chromatography (elution with pet ether/EtOAc, 4:1), gave 100 mg (99%) of *bis*-enone **42** as a white solid (hexane/EtOAc, 2:1, R_f **42** = 0.40). Mp = 147.0–147.2 °C. IR (film) λ_{max}: 3376, 2959, 1697, 1460, 1379, 1118 cm^{-1}. ^{1}H (400 MHz) δ: 2.87 (d, J = 13.2 Hz, 1H), 2.52–2.79 (m, 4H), 2.39 (d, J = 18.0 Hz, 1H), 2.30 (d, J = 18.8 Hz, 1H), 2.21 (m, 2H), 2.04 (m, 1H), 1.85 (s, 3H), 1.79 (m, 1H), 1.58 (m, 2H), 1.17 (m, 9H), 1.13 (s, 3H). ^{13}C NMR (100 MHz) δ: 207.3 (s), 198.5 (s), 179.5 (s), 160.6 (s), 140.6 (s), 135.3 (s), 52.0 (t), 44.5 (s), 41.0 (t), 40.1 (t), 34.9 (t), 34.4 (t), 26.6 (q), 25.5 (q), 24.7 (d), 22.5 (t), 20.9 (q), 20.8 (q), 13.7 (q) ppm. HR-MS: $[M+H]^+_{obs}$ = 301.2167, $[M+H]^+_{calcd}$ = 301.2168.

(3a*S*,8a*S*)-1-Isopropyl-3a,5,8a-trimethyl-3a,4,6,7,8,8a,9,10-octahydrobenzo[*f*]azulen-2(3*H*)-one (43) and (3a*R*,8a*S*)-1-isopropyl-3a,5,8a-trimethyl-2,3,3a,4,6,7,8,8a,9,10-decahydrobenzo[*f*]azulene (44)

To a solution of *bis*-enone **42** (153 mg, 0.510 mmol) in fresh distilled DCM (15 mL) was added 10% TFA in DCM solution (10 mL), followed by $NaBH_4$ (97 mg, 2.6 mmol). The resulting mixture was stirred for 0.5 h at RT. Water (5 mL) was added to quench the reaction, followed by standard ethereal work-up. Column chromatography (elution with pet ether/EtOAc, 10:1) gave 44 mg (30%) of diene **44** as a light yellow oil (hexane/EtOAc, 4:1, R_f **44** = 0.90). IR (film) λ_{max}: 2933, 1464, 1372 cm^{-1}. ^{1}H (400 MHz) δ: 1.70–2.35 (m, 17H), 1.67 (s, 3H), 1.13–1.19 (m, 6H), 1.10 (s, 3H), 0.98 (s, 3H). ^{13}C NMR (100 MHz) δ: 208.6 (s), 182.5 (s), 139.7 (s), 132.9 (s), 131.9 (s), 52.0 (t), 44.9 (s), 41.7 (t), 38.3 (s), 37.9 (t), 37.2 (t), 32.3 (t), 28.4 (q), 25.7 (q), 24.6 (d), 22.9 (t), 21.8 (q), 20.9 (q), 19.3 (t) ppm. HR-MS: $[M]^+_{obs}$ = 286.2295, $[M]^+_{calcd}$ = 286.2297. Further elution gave 76 mg (55%) of enone **43** as a light yellow oil (hexane/EtOAc, 4:1, R_f **43** = 0.55). ^{1}H (400 MHz) δ: 2.58–2.74 (m, 3H), 2.30 (d, J = 18.4 Hz, 1H), 2.20 (d, J = 18.0 Hz, 1H), 2.12 (m, 1H), 1.95 (m, 3H), 1.68–1.84 (m, 3H), 1.67 (s, 3H), 1.25–1.44 (m, 3H), 1.15 (m, 6H), 1.10 (s, 3H), 0.98 (s, 3H). ^{13}C NMR (100 MHz) δ: 208.6 (s), 182.5 (s), 139.7 (s), 132.9 (s), 131.9 (s), 52.0 (t), 44.9 (s), 41.7 (t), 38.3 (s), 37.9 (t), 37.2 (t), 32.3 (t), 28.4 (q), 25.7 (q), 24.6 (d), 22.9 (t), 21.8 (q), 20.9 (q), 19.3 (t) ppm. HR-MS: $[M+H]^+_{obs}$ = 287.2376, $[M+H]^+_{calcd}$ = 287.2375. Note: Allowing the reduction to proceed overnight (12 h) gave diene **44** in 73% yield.

(1*S*,3a*S*,8a*S*)-1-Isopropyl-3a,8a-dimethyl-5-methylenedecahydro-4a,10a-epoxybenzo[*f*]azulen-2(1H)-one (45)

A solution of **43** (10 mg, 0.034 mmol) and rose bengal (2.0 mg) in 5 mL of a solution of methanol/dichloromethane (1:9) was irradiated at –5 °C with a 500 W tungsten lamp, while oxygen was bubbled through the reaction mixture. After 40 min, the reaction mixture was treated with triethyl phosphite (0.3 mL) at RT for 1 h with vigorous stirring. After concentration, standard ethereal work-up provided a crude residue, which was purified by column chromatography (elution with pet ether: EtOAc, 10:1) and gave 9.9 mg (92%) of furan **45** (hexane: EtOAc, 4:1, R_f **45** = 0.45) as a colorless oil. IR (film) λ_{max}: 2933, 1740, 1075, 895 cm^{-1}. ^{1}H (400 MHz) δ: 4.76 (s, 1H), 4.66 (s, 1H), 2.93 (d, J = 17.6 Hz, 1H), 2.61–2.74 (m, 2H), 2.08–2.41 (m, 6H), 1.72–1.80 (m, 1H), 1.58–1.69 (m, 4H), 1.25–1.40 (m, 2H), 1.20 (m, 6H), 1.12 (s, 3H), 0.83 (s, 3H). ^{13}C NMR (100 MHz) δ: 217.0 (s), 148.7 (s), 103.1 (t), 90.9 (s), 86.6 (s), 59.2 (d), 54.6 (t), 46.6 (t), 44.9 (q), 36.2 (s), 35.8 (t), 32.8 (t), 31.4 (t), 25.7 (d), 24.4 (t), 21.9 (q), 21.2 (t), 19.9 (q), 18.8 (q), 18.1 (q) ppm. HR-MS: $[M+H]^+_{obs}$ = 303.2316, $[M+H]^+_{calcd}$ = 303.2324.

(1a*R*,4a*S*,9a*S*,10a*S*)-7-Isopropyl-1a,4a,9a-trimethyl-2,3,4,4a,5,6,9a,10-octahydro-1aH-azuleno[5′,6′:1,6]benzo[1,2-*b*]oxiren-8(9*H*)-one (46)

To a solution of diene **43** (35 mg, 0.12 mmol) in freshly distilled DCM (4 mL) under nitrogen atmosphere was added *m*-CPBA (77%, 33 mg, 0.15 mmol, 1.2 equiv.). The resulting mixture was stirred at RT for 1 h. Standard ethereal work-up, followed by column chromatography (elution with pet ether/EtOAc, 5:1), afforded 35.0 mg (95%) of epoxide **46** as a white foam (hexane/EtOAc, 2:1, R_f **46** = 0.49). IR (film) λ_{max}: 3006, 2918, 1717, 1364, 1224 cm^{-1}. ^{1}H (400 MHz) δ: 2.87 (m, 1H), 2.73 (septet, J = 7.2 Hz, 1H), 2.42 (m, 1H), 2.22 (d, J = 8.8 Hz, 2H), 1.90–2.12 (m, 3H), 1.64–1.83 (m, 3H), 1.39–1.52 (m, 3H), 1.37 (s, 3H), 1.29 (s, 3H), 1.20–

1.25 (m, 1H), 1.18 (s, 3H), 1.16 (s, 3H) 0.97 (s, 3H). ^{13}C NMR (100 MHz) δ: 207.3 (s), 179.4 (s), 141.2 (s), 68.6 (s), 65.3 (s), 53.3 (t), 42.8 (s), 42.2 (t), 37.7 (s), 36.8 (t), 36.7 (t), 31.4 (t), 25.9 (q), 24.8 (d), 24.2 t), 23.4 (q), 23.0 (q), 20.4 (q), 20.3 (q), 16.6 (q) ppm. HR-MS: $[M]^+_{obs}$ = 302.2243, $[M]^+_{calcd}$ = 302.2246.

(1a*R*,4a*S*,9a*R*,10a*S*)-7-Isopropyl-1a,4a,9a-trimethyl-2,3,4,4a,5,9,9a,10-octahydro-1a*H*-azuleno[5′,6′:1,6]benzo[1,2-*b*]oxirene (47)

To a solution of enone **46** (60 mg, 0.20 mmol) in freshly distilled Et_2O (10 mL) at 0 °C under nitrogen atmosphere was added LAH (7.6 mg, 0.20 mmol). The resulting reaction mixture was stirred for 1 h at RT. Water (4 mL) was slowly added to quench the reaction, followed by standard ethereal work-up. Concentration of the filtered organic phase afforded yellow oil. Silica gel was added to the bottle, and the resulting mixture was allowed to sit on the bench overnight. Column chromatography (elution with pet ether/EtOAc, 15:1) afforded 45.5 mg (80%) of diene **47** (hexane/EtOAc, 8:1, R_f **47** = 0.50) as a colorless oil. IR (film) λ_{max}: 3247, 2952, 1660, 1359, 1010 cm^{-1}. ^{1}H (500 MHz) δ: 5.60 (s, 1H), 5.45 (m, 1H), 2.90 (d, *J* = 15.0 Hz, 1H), 2.41 (m, 1H), 2.14–2.33 (m, 3H), 1.70–1.98 (m, 4H), 0.80–1.62 (m, 4H), 1.39 (s, 3H), 1.18 (s, 3H), 1.07–1.13 (m, 6H), 1.03 (s, 3H). ^{13}C NMR 154.5 (s), 149.5 (s), 125.6 (d), 113.6 (d), 70.4 (s), 65.8 (s), 49.6 (t), 43.5 (s), 39.2 (t), 37.9 (s), 37.2 (t), 34.8 (t), 30.1 (t), 25.7 (d), 24.0 (q), 23.7 (q), 23.3 (q), 22.3 (q), 22.3 (q), 16.7 (t) ppm. HR-MS: $[M]^+_{obs}$ = 286.2297, $[M]^+_{calcd}$ = 286.2297.

(3a*R*,4a*R*,8a*S*)-1-Isopropyl-3a,8a-dimethyl-5-methylene-3,3a,4,4a,5,6,7,8,8a,9-decahydrobenzo[*f*]azulen-4a-ol (48)

To a solution of diisopropylamine (0.70 mL, 5.0 mmol) in freshly distilled Et_2O (10 mL) at 0 °C was added *n*-butyllithium (2 mL, 5 mmol). The resulting mixture was stirred at RT for 10 min. Epoxide **47** (8.0 mg, 0.028 mmol) was transferred into a sealed tube, and 2 mL of the above LDA solution was added. The reaction vessel was closed, and it was heated to 50 °C and kept at this temperature for 36 h. Water (2 mL) was added to quench the reaction followed by standard ethereal work-up. Column chromatography (elution with pet ether/EtOAc, 15:1) afforded 7.4 mg (93%) of allylic alcohol **48** (hexane/EtOAc, 8:1, R_f **48** = 0.81) as a colorless oil. IR (film) λ_{max}: 3556, 2923, 1466, 1115 cm^{-1}. ^{1}H (500 MHz) δ: 5.74 (t, *J* = 7.0 Hz, 1H), 5.70 (s, 1H), 5.02 (s, 1H), 4.69 (s, 1H), 3.01 (s, 1H), 2.61 (d, *J* = 17.0 Hz, 1H), 2.44 (septet, *J* = 7.0 Hz, 1H), 2.36 (m, 2H), 2.27 (m, 1H), 2.12 (dd, *J*1 = 3.0 Hz, *J*2 = 16.5 Hz, 1H), 2.03 (dt, *J*1 = 12.5 Hz, *J*2 = 5 Hz, 1H), 1.83 (m, 2H), 1.40–1.62 (m, 3H), 1.44 (s, 3H), 1.13 (d, *J* = 7.0 Hz, 3H), 1.11 (s, 3H), 1.04 (d, *J* = 7.0 Hz, 3H), 0.96 (s, 3H). ^{13}C NMR (125 MHz) δ: 157.5 (s), 153.6 (s), 148.6 (s), 128.3 (d), 125.8 (d), 107.1 (t), 79.2 (s), 50.5 (t), 45.4 (t), 44.4 (s), 41.7 (t), 39.0 (t), 34.7 (t), 30.6 (q), 28.4 (q), 25.9 (d), 23.6 (t), 79.2 (s), 50.5 (t), 45.4 (t), 44.4 (s), 41.7 (t), 39.0 (t), 34.7 (t), 30.6 (q), 28.4 (q), 25.9 (d), 23.6 (t), 22.2 (q), 21.7 (q), 21.3 (q) ppm. HR-MS: $[M]^+_{obs}$ = 286.2300, $[M]^+_{calcd}$ = 286.2297.

(3a*S*,8a*R*)-1-Isopropyl-3a,5,8a-trimethyl-3a,4,8,8a,9,10-hexahydrobenzo[*f*]azulene-2,6(3*H*,7*H*)-dione (42) from enone (43)

To a solution of enone **43** (10 mg, 0.035 mmol) in acetone (2 mL) and H_2O (1 mL) was added *N*-bromosuccinimide (8.1 mg, 0.046 mmol, 1.3 equiv.) in one portion. The resulting mixture was stirred at RT for 5 min and was quenched with water (2 mL). Acetone was removed under vacuum using a rotary evaporator, followed by standard ethereal work-up. Column chromatographic purification (elution with pet ether/EtOAc, 4:1) gave 7.4 mg (71%) of *bis*-enone **42** (hexane/EtOAc, 2:1, R_f **42** = 0.40) as a white solid, which was identical to that previously characterized (i.e., the reduction of **25** to give **42**).

(3a*R*,8a*S*,10*S*)-1-Isopropyl-3a,5,8a-trimethyl-2,3,3a,4,6,7,8,8a,9,10-decahydrobenzo[*f*]azulen-10-ol (49)

To a solution of SeO_2 (9.1 mg, 0.089 mmol) in freshly distilled DCM (0.50 mL) was added *t*-BuOOH (37 μL, 0.36 mmol). The resulting mixture was stirred for 25 min at RT. Diene **44** (48 mg, 0.18 mmol) in DCM (0.50 mL) was added dropwise. The resulting mixture was stirred at RT for 8 h, followed by standard ethereal work-up. Column chromatography (elution with pet ether/EtOAc, 10:1) afforded 19 mg (40%) of triene **50** as a light yellow oil (hexane/EtOAc, 4:1, R_f **50** = 0.95). Further elution gave 23 mg (45%) of allylic alcohol **49** as a light yellow oil (hexane/EtOAc, 4:1, R_f **49** = 0.39).

(3a*R*,8a*S*)-1-Isopropyl-3a,5,8a-trimethyl-2,3,3a,4,7,8,8a,9-octahydrobenzo[*f*]azulen-10(6*H*)-one (51)

To a solution of allylic alcohol **49** (5.2 mg, 0.018 mmol) in CCl_4 (0.5 mL) was added MnO_2 (16 mg, 0.18 mmol). The resulting mixture was heated at 60 °C for 6 h. Standard ethereal work-up, followed by column chromatography (elution with pet ether/EtOAc, 12:1), gave 3.4 mg (65%) of enone **51** as a light yellow oil (hexane/EtOAc, 4:1, R_f **51** = 0.75). ^{1}H (400 MHz) δ: 3.34 (heptet, *J* = 7.2 Hz, 1H), 2.85 (d, *J* = 14.8 Hz, 1H), 2.57 (d, *J* = 14.0 Hz, 1H), 2.40 (t, *J* = 7.2 Hz, 2H), 2.22 (d, *J* = 14.8 Hz, 1H), 2.16 (d, *J* = 14.0 Hz, 1H), 2.01 (bs, 2H), 1.67 (s, 3H), 1.46–1.75 (m, 6H), 1.08 (s, 3H), 0.98–1.04 (m, 9H). ^{13}C NMR (125 MHz) δ: 202.7, 161.7, 142.9, 133.7, 129.0, 58.0, 48.7, 42.0, 40.8, 39.6, 36.1, 33.4, 29.1, 27.9, 25.6, 23.0, 20.9, 20.7, 20.7, 19.1 ppm.

Supplementary data

Supplementary data for this article are available on the journal Web site (www.nrcresearchpress.com/doi/suppl/10.1139/v11-116). The X-ray data for key intermediate **25**, CCDC 835868, has also been deposited with the Cambridge Crystallographic Data Centre. These data can be obtained, free of charge, via www.ccdc.cam.ac.uk/cgi-bin/catreq.cgi (or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1Ez, UK; fax +44 1223 336033; or e-mail deposit@ccdc.cam.ac.uk).

Abstract: The tandem reaction of Morita–Baylis–Hillman (MBH) alcohols **1a**–**1l** derived from acrylic nitrile with 2-aminobenzimidazole (**2**) in ionic iquid (IL) [BMIM]Cl/H_2O without additional catalyst was developed for the efficient synthesis of benzimidazol[1,2-*a*]pyrimidin-7(8*H*)-imine compounds. The tandem reaction included aza-Michael addition and intramolecular addition of an amino group to the cyano group in one pot. The combination of ionic liquid and water was found to be the best reaction medium, which played a role for accelerating the tandem reaction.

Key words: Morita–Baylis–Hillman, ionic liquids, catalyst-free, aza-Michael addition.

Résumé : Comme méthode de synthèse efficace des dérivés de la benzimidazo[1,2-*a*]pyrimidine-7(8*H*)-imine, on a mis au point une réaction en tandem de Morita–Baylis–Hillman (MBH) d'alcools **1a**–**1l** dérivés de l'acrylonitrile avec du 2-aminobenzimidazole (**2**) dans un liquide ionique (LI) formé de chlorure de 1-butyl-3-méthylimidazolium (BMIM) et d'eau, sans addition de catalyseur. La réaction en tandem comporte une addition d'aza-Michael et une addition intramoléculaire du groupe amino sur le groupe cyano dans une réaction monotope. On a trouvé que la combinaison du liquide ionique et de l'eau est le meilleur milieu réactionnel qui joue un rôle d'accélérateur dans la réaction en tandem.

Mots-clés : Morita–Baylis–Hillman, liquides ioniques, sans catalyseur, addition d'aza-Michael.

[Traduit par la Rédaction]

Introduction

The Morita–Baylis–Hillman (MBH) reactions have proved to be one of the most successful methods for C–C bond-forming reactions. Since three functionalized groups, the hydroxyl group, the double bond, and the carbonyl (cyano) group, lie closely in one molecule, the MBH adducts are suitable precursors for the synthesis of many heterocycles and biologically active molecules.[1] Particularly, the Michael addition of the amine to the double bond of an MBH adduct's molecule and the subsequent functionalization have been employed in the synthesis of many aza-heterocycles.[2]

Imidazo[1,2-*a*]pyrimidines are very important intermediates and are widely used in the pharmaceutical chemistry, such as for the synthesis of the antianxiety drug divaplon (**A**) (Fig. 1).[3] Among them, several 7-amino-imidazo[1,2-*a*]pyrimidine derivatives also exhibited interesting biological activities including as $GABA_A$ receptors (**B**) (Fig. 1).[4] Recently, we reported the efficient synthesis of benzimidazo[1,2-*a*]pyrimidinone via a catalyst-free tandem reaction of MBH adducts bearing an ester unit with 2-aminobenzimidazole.[5] In general, the reaction containing the nitrile compound as a substrate is one of the most efficient approaches for introducing an amino group into a molecule. We envisioned that the tandem reaction of MBH alcohols derived from acrylic nitrile with 2-aminobenzoimidazole should be very interesting for the development of an efficient protocol accessible to the novel fused aza-heterocyclic compounds.

On the other hand, in recent years, ionic liquids (ILs) have attracted considerable attention as an alternative solvent in organic reactions because of their tunable physical properties, such as their almost nonvolatile nature, high thermal stability, strong solvating ability to a great number of organics, inorganics and polymers, reusability, and recyclability. Several ILs have been successfully used as solvents and promoters in a lot of chemical transformations.[6]

Herein, we will report a tandem reaction of MBH alcohols derived from acrylic nitrile and aldehydes with 2-aminobenzimidazole[7] in ILs with a small amount of water without any additional catalyst to produce novel fused aza-heterocyclic compounds.

Results and discussion

Initially, under the condition that is similar to the reaction of MBH alcohol derived from acrylic ester with 2-aminobenzimidazole (**2**),[5] the reaction of MBH alcohol **1h** derived from benzaldehyde and acrylic nitrile with **2** was carried

A, Divaplon **B**

out in dioxane at 80 °C (Table 1, entry 1). However, the yield of the product **3h** was very low. Although various organic solvents were used, the yields of **3h** were unsatisfactory either (Table 1, entries 2–6), even in the presence of K_2CO_3 as a catalyst (Table 1, entry 7). But the reaction of **1h** with **2** could proceed smoothly in water (Table 1, entry 8). Unfortunately, when the aqueous condition was employed to other substrates, such as **1a**, the reaction with **2** became sluggish and the products were complicated (Table 2, entries 1 and 2). This is probably attributed to the poor solubility and stability of the MBH alcohol **1a** in water at high temperature. To improve the solubility of the MBH alcohols and **2**, the ionic liquids were selected to be reaction media. If ionic liquid [BMIM]Cl was used as a medium for the reaction of **1a** with **2** at 100 °C, a homogeneous solution was formed and the product, 6-(4-chlorophenylhydroxylmethyl)-5,6-dihydro-benzimidazo-[1,2-*a*]pyrimidin-7(8*H*)-imine (**3a**), was obtained in 53% yield (Table 2, entry 3). To our delight, the addition of a small amount of water to the medium ([BMIM]Cl/H_2O = 11:1) led the yield of **3a** to increase (Table 2, entries 4 and 5). It was probably that the small amount of water could promote this reaction.[8] The tandem reaction did not need any additional catalyst for the high yield of the final product **3a**. However, when the water percentage in the reaction medium was increased to 4:1 ([BMIM]Cl/H_2O), the yield of **3a** was decreased sharply to 6%. It is proposed that the substrate **1a** decomposed under the conditions with such a large amount of water (Table 2, entry 6).

Based on these results, various ILs (Fig. 2) were employed in the reaction of **1a** with **2** as reaction media containing a small amount of water (IL/water = 11:1). As shown in Table 2 for the same cation ($[BMIM]^+$), the anions of the ILs used strongly influnced the yields of the product **3a** (Table 2, entry 5 vs entries 7–9). Moreover, with the same anion (BF_4^-) the molecular structure of the ammonium ion also has a strong effect on the reaction. It was found that $[EMIM]^+$ bearing an *N*-ethyl group and $[OMIM]^+$ bearing an *N*-octyl group provided poor yields of **3a** (Table 2, entries 10 and 11, respectively), but for $[BMIM]^+$ bearing an *N*-butyl group a 74% yield of **3a** was obtained (Table 2, entry 9). In comparison with $[BMIM]^+$, the change of the N′-substituent from a methyl to a vinyl group ($[BEIM]^+$) and introduction of a second methyl group ($[BDMIM]^+$) provided a complicated product mixture and very poor yield of **3a** (Table 2, entries 12 and 13) despite having the same core structure of imidazole. The employment of the pyridine unit ($[NBPD]^+$) as a cation part did not improve the yield of **3a** at all (Table 2, entry 14). Interestingly, the use of organic solvents with a small amount of water (Sol/H_2O = 11:1) also afforded a complicated mixture of the products (Table 2, entries 15 and 16). In summary, the IL [BMIM]Cl/water was determined to be the most efficient reaction medium for this tandem reaction.

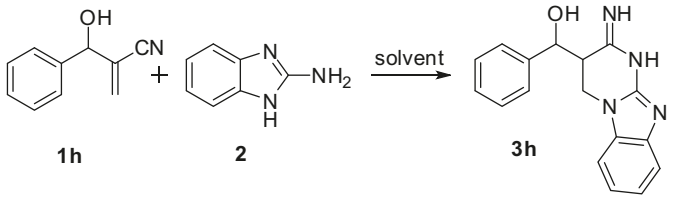
With optimized conditions in hand, we examined the scope of the MBH alcohols derived from acrylic nitrile[9] with **2** in IL [BMIM]Cl/H_2O (11:1) at 100 °C in the absence of any additional catalyst (Scheme 1). The results are summarized in Table 3. As shown in Table 3, the reactions of various MBH alcohols (**1a**–**1l**) derived from acrylic nitrile proceeded smoothly in a period of 6 h to form the corresponding products **3a**–**3l** in good yields. The electronic properties of the substituents of MBH alcohols had no effect on the reaction. The MBH alcohol **1k** bearing the steric group also generated the product **3k** in 89% yield (Table 3, entries 11). Although much a longer reaction time (48 h) was needed, alkyl-substituted MBH alcohol **1l** could also give the expected product **3l** in good yield (75%) (Table 3, entry 12).

In terms of a plausible mechanism for the nucleophilic reaction with imidazole,[7b] the route of the reaction of MBH alcohols **1** derived from acrylic nitrile with 2-aminobenzimidazole (**2**) was proposed as shown in Scheme 2. In the first step, the nitrogen atom at the 3 position of 2-aminobenzimidazole attacked at the α,β-unsaturated carbon atom of the MBH alcohol in a Michael-addition manner to generate an intermediate **I** (path A). In this step, ILs, especially [BMIM]Cl containing a small amount of water, played the roles of both reaction medium and accelerator.[8] It was noteworthy that since the MBH alcohols **1** derived from acrylic nitrile were unstable to water and could be decomposed through retro-MBH reaction at high temperature, the water percentage in the IL was confined to a small range: H_2O:IL = 1:11 ~ <1:4. In the second step (path B), the intermediate **I** underwent an intramolecular addition reaction of an amino group to the cyano group, giving cyclization product **3**. In general, for the addition reaction of an amino group to the cyano group a suitable catalyst or a relatively higher reaction temperature were required. Thus, in a catalyst-free system a high reaction temperature (100 °C) had to be employed unavoidably.

Conclusion

In conclusion, we have developed an efficient method for the synthesis of fused aza-heterocyclic compounds, benzimidazo[1,2-*a*]pyrimi-din-7(8*H*)-imine derivatives in good to excellent yields via a tandem reaction of BMH alcohols (**1a**–**1l**) with 2-aminobenzoimidazole in IL/H_2O. The developed protocol was simple and catalyst free. The reaction underwent the Michael addition reaction, followed by intramolecular cyclization in a one-pot process. The produced fused heterocyclic compounds provided an opportunity to enhance the diversity of benzimidazo[1,2-*a*]pyrimidine compounds by further derivation.

Experimental



Typical procedure for the reaction of MBH alcohol (1) with 2-aminobenzimidazole (2)

To a solution of MBH alcohol **1a** (97 mg, 0.5 mmol) and **2** (100 mg, 0.75 mmol) in 0.5 mL of IL [BMIM]Cl was added water (40 μL, 2.5 mmol). The resulting mixture was heated at 100 °C until completion as indicated by TLC. Then the reaction mixture was extracted by ethyl acetate and

Abstract: Isoindolinone derivatives are important pharmaceutical building blocks in medicinal chemistry. Isoindolo[2,1-*a*]quinolines are a class of interesting compounds that possess protective effects against N_2-induced hypoxia and inhibitory activities against human topoisomerase II and bacterial DNA-gyrase. The conventional methods for synthesizing these compounds are unsatisfactory because of their harsh reaction conditions, complex starting materials, and multistaged purification procedures. This synthesis of the propargyl-isoindolinone core features an aldehyde–alkyne–amine (A^3) coupling-based tandem strategy using methyl 2-formylbenzoate, primary aryl amine, and terminal alkyne under $Cu(OTf)_2$ catalysis.

Key words: aldehyde–alkyne–amine (A^3) coupling, propargyl-isoindolinone, isoindolo[2,1-*a*]quinoline, copper(II) catalysis, tandem reaction.

Résumé : Les dérivés de l'isoindolinone sont d'importants synthons en chimie médicinale. Les isoindolo[2,1-*a*]quinoléines font partie d'une classe intéressante de composés qui possèdent effets protecteurs contre l'hypoxie induite par N_2 et des activités inhibitrices contre la topoisomérase II humaine et la gyrase d'ADN bactérienne. Les méthodes de synthèse conventionnelles de ces composés ne sont pas satisfaisantes en raison de la sévérité de leurs conditions réactionnelles, de la nature complexes de leurs produits de départ et des méthodes de purification en plusieurs étapes. Cette synthèse du synthon propargyl-isoindolinone comporte un couplage d'aldéhyde, d'alcyne et d'amine (A^3) à base d'une stratégie en tandem impliquant du 2-formylbenzoate de méthyle, une amine aromatique primaire et un alcyne terminal sous l'influence d'un catalyseur de $Cu(OTf)_2$.

Mots-clés : couplage d'aldéhyde, d'alcyne et d'amine (A^3), propargyl-isoindolinone, isoindolo[2,1-*a*]quinoléine, catalyse par le cuivre(II), réaction en tandem.

[Traduit par la Rédaction]

Introduction

A tandem reaction, also called a cascade or domino reaction, is defined as a consecutive series of reactions that usually proceed via highly reactive intermediates; the product of each reaction acts as the substrate of subsequent reactions.[1] These reactions possess high synthetic value in the sense that they not only allow efficient construction of complex structures from simple precursors but also display overall reduced operations and better step economy, which translates into reduced labor time, energy input, and waste; therefore, they have been the subject of extensive investigations in recent years.[2]

Isoindoline derivatives are important pharmaceutical building blocks that possess unique medicinal properties. For instance, the diuretic activity of sulfonamide-functionalized isoindoline in Fig. 1 is 100 times more than for chlorothiazide.[3] Furthermore, isoindolylalkylphosphonium salts possess antitumour activities and have displayed substantial activity in the P-388 lymphocytic leukemia screen.[4] In some recent reports, these salts have been demonstrated to possess herbicidal activity[5] and to act as antagonists of the 5-hydroxytryptamine 2C ($5\text{-}HT_{2C}$) receptor,[6] as well as being candidates to treat various cancers.[7] There have also been some recent studies in applying isoindoline derivatives in pigments.[8]

One of the most common isoindoline derivatives is isoindolinone, which has also attracted much research interest owing to its substantial biological activities. N-Substituted isoindolinones of general structure **1** possess anxiolytic activity and are commonly applied as sedatives, hypnotics, and muscle relaxants.[9] Some examples, such as anxiolytics pazinaclone, pagoclone (Sanofi-Aventis and Pfizer, phase III

clinical trials), and the anticonvulsant zopiclone, are shown in Fig. 2.[10]

Conventional synthetic methods adopted in approaching polysubstituted isoindolinone derivatives are usually unsatisfactory because of their harsh reaction conditions, complex starting materials, and lengthy synthetic sequence.[11] In recent years, more and more cascade reactions have been devoted to the construction of the isoindolinone skeletons. For example, an elegant palladium(0)-catalyzed three-component carbonylation – amination – Michael addition was used by Grigg and et al.[9a] in 2005 in their synthesis of various isoindolinones. Nevertheless, the applications of cascade reactions are still quite limited.

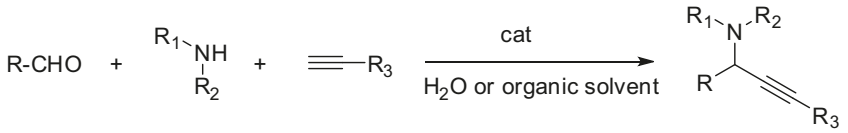
While working on the aldehyde–alkyne–amine (A^3) methodology (A^3 coupling; Scheme 1) for the synthesis of monopropargyl amines,[12] we envisioned that the secondary amine formed in the product could also be utilized as a nucleophile to perform consecutive reactions. Under proper conditions, this nucleophilic nitrogen can be treated as the building block for a lactam ready to access various isoindolinone derivatives.

Results and discussion

Li and co-workers[13] developed the first copper-catalyzed addition as well as asymmetric addition of acetylenes to various imine and acylimines. This discovery has attracted much attention and also triggered intensive research in this area[14] because the final products are synthetically versatile building blocks for the preparation of many nitrogen-containing compounds that possess valuable biological activities. It has been proven that the A^3 coupling can be catalyzed by various types of transition-metal catalysts, including Cu(I), Cu(II), Ag(I), Au(I), and Au(III) salts and Cu/Ru bimetallic systems, etc.[12] Depending on the nature of the substrates, the reaction can proceed in organic solvent, water, or neat. We rationalized that from simple commercially available starting materials **5**, **6**, and **7**, under transition-metal catalysis, the A^3-coupling product **8** would quickly form in situ, and upon intramolecular cyclization, the isoindolinone core **9** would be constructed in one step (Scheme 2).

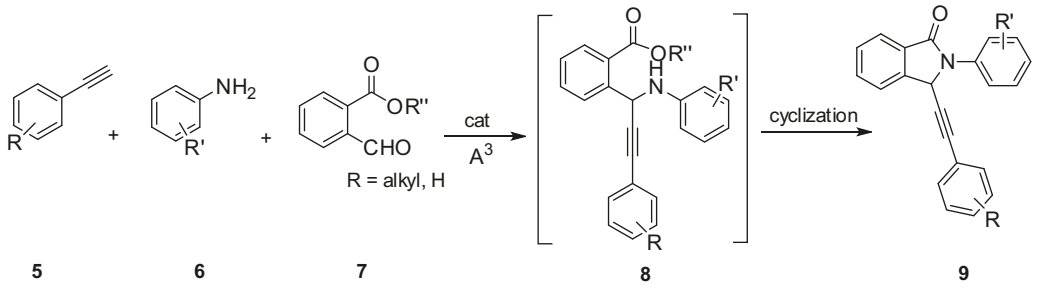
Our initial examination started by using 2-carboxybenzaldehyde, aniline, and phenyl acetylene as the starting materials, all of which are inexpensive readily available commercial substrates. Unfortunately, no desired product was obtained. ^{1}H NMR studies showed that 2-carboxybenzaldehyde mainly exists in its fused bicyclic form (Scheme 3). We believe that this form obstructs the formation of imine and thus prevents A^3 coupling from occurring. Another factor possibly responsible for the failure of the reaction is that the substrate does not contain a good leaving group to facilitate the cyclization of the amido ring.

To render a good leaving group into the substrate as well as converting it into its "open" form, we decided to use its methyl ester, "methyl 2-formylbenzoate", and re-subject it to the same sets of conditions examined previously; in this case, all metal catalysts offered the desired product in different yields, among which $Cu(OTf)_2$ had the highest product:impurities ratio. Upon systematic screening, the optimized conditions were determined to be 15 mol % of $Cu(OTf)_2$ at 100 °C for 12 h in toluene. One noteworthy fact is that the solvent is an essential component of the reaction, without which the conditions provided would be too harsh for the substrates used, and in most cases the phenylacetylene would be converted into acetophenone.



Various types of aniline derivatives were examined. Experimental results (Table 1) indicated that any ortho substituent on the aniline ring (**9g–9m**) impedes the formation of the desired product with no reaction observed, most likely because of steric hindrance. The presence of electron-withdrawing groups on the meta or para position (**9b–9f**) can reduce the yield compared with electron-donating groups.

Screening of the acetylene substrates proved to be challenging using this methodology. The results for the reactions tend to vary upon repetitions; thus, each yield reported in Table 2 is the averaged isolated yield among a few trials. Similar to the results of anilines, ortho-substitution patterns in aryl acetylenes (**9u** and **9z**) do not favour formation of desired products; most importantly, electronic characters of the aryl cycles do not seem to play a crucial role in the yield, despite the fact that in the para-substituted cases, electron-donating groups seem to offer a better yield than electron-withdrawing groups. Alkyl acetylenes (**9v** and **9w**) always provide higher yields than aryl acetylenes (**9n–9t**).



Two special situations have been observed. Firstly, when the aryl acetylene contains a nitrogen heterocycle, the yield diminishes to nearly zero. Based on the colour of the catalyst and the amount of starting materials recovered, we can clearly conclude that the catalyst is not turning over. We suspect that this is caused by the strong coordination and

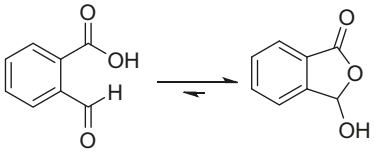


Scheme 1. Three-component coupling of aldehyde, alkyne, and amine (A^3 coupling).

Scheme 2. Proposed isoindoline synthesis via the A^3-coupling strategy.

Scheme 3. Equilibrium of 2-carboxybenzaldehyde.

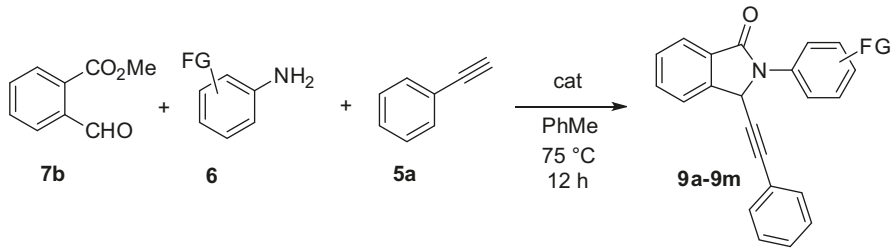
complexation between the heterocyclic nitrogen and copper(II), which prevents the formation of copper acetylide. An elevated temperature or the addition of a catalytic amount of acid does not solve this problem. Secondly, when using propiolate as the alkyne, the desired isoindolinone core does not form; in this case, the mechanistic pathway is altered and the reaction exclusively yields the 1,4-dihydropyridine system (>90% isolated yield), as shown in Scheme 4. Initially, we were quite impressed by this outcome because previously known synthesis of 1,4-dihydropyridines either requires a microwave apparatus[15] or preformation of the imine with a rare earth metal catalyst (RE triflates, RE = Sc, Y, La, Ce, Pr, Nd, Sm, or Yb).[16] Unfortunately, upon careful review of the synthetic literature, we concluded that this methodology is not the greenest approach to date; as with our studies, Mai et al.[17] in 2009 used Brønsted acid as the catalyst and completed the same transformation in a one-pot tandem manner in the absence of any transition metal.

Conclusion

In summary, we have demonstrated a one-pot synthesis of the pharmaceutically interesting propargyl-isoindolinone core (**9**) based on the tandem A^3-coupling methodology, starting from methyl 2-formylbenzoate, aniline derivative, and alkynes as the precursors. Such methodology provides a simple and efficient access to a variety of isoindolinone building blocks from inexpensive starting materials readily. Within the scope of this reaction, two exceptions were observed: (*i*) using propiolates as the acetylene source provides 1,4-dihydropyridine as the only product and (*ii*) heterocyclic amines do not favour the formation of the desired product. For future work, chiral ligands shall be introduced into the reaction to generate enantio- or diastereo-selectivity. the isoindolinone core (**9**) can also be transformed into a series of biologically active compounds.

Experimental

All glassware used for moisture-sensitive reactions was flame-dried under vacuum and subsequently purged with nitrogen. All reagents were commercially available materials and were used without further purification unless specified. Standard column chromatography was performed on 20–60 μm silica gel (obtained from Silicycle Inc.) or on Sorbent silica gel (30–60 μm) using standard flash column chromatography techniques. Infrared analyses were recorded as a thin film on NaCl plates and solid compounds as KBr pellets. ^{1}H and ^{13}C NMR spectra were recorded on a Varian 400 MHz or 300 MHz spectrometer. Chemical shifts for ^{1}H NMR spectra were reported in parts per million (ppm) from tetramethylsilane with the solvent resonance as the internal standard (deuterated chloroform: δ 7.26 ppm, DMSO: δ 2.50 ppm). Chemical shifts for ^{13}C NMR spectra were reported in ppm from tetramethylsilane with the solvent resonance as the internal standard (deuterated chloroform: δ 77.0 ppm). Mass spectrometry (MS) data were obtained by using a Kratos MS25RFA mass spectrometer. High-resolution mass spectrometry electrospray ionization (HR-MS-ESI) measurements were performed at the McGill University MS Laboratory.



General procedure for the synthesis of isoindolinones

Under an argon atmosphere, acetylene (0.36 mmol), aniline (0.36 mmol), methyl 2-formylbenzoate (0.30 mmol), Cu $(OTf)_2$ (15 mol %), and anhydrous toluene (1 mL) were added into a tube and stirred at 75 °C for 12 h. After the reaction, 15 mL of ethyl acetate was added into the tube and the entire reaction mixture was filtered through a short plug of silica. The filtrate was concentrated in vacuo and then subjected to liquid column chromatography (hexane/EtOAc = 7:1 to 5:1 gradient elution). The solvent of the combined fractions was removed under reduced pressure to afford the desired isoindolinone compound as a viscous light yellow oil or semisolid.

Abstract: Two MOFs were reported based on Zn(II) with 1,2-bis(4-pyridyl)hydrazine (**L1**); a two-dimensional interpenetrating MOF **I** of formula $[Zn_2(\mathbf{L1})_2(\mathbf{L2})_2]_\infty$ was formed with terephthalic acid (**L2**) as an additional linker. A three-dimensional MOF **II** of formula $[Zn_2(\mathbf{L1})_2(\mathbf{L3})_2]_\infty$, was formed with the use of a larger spacer 2,6-naphthalenedicarboxylic acid (**L3**). MOF **II** consists of large porosity with a total volume of 3746 Å^3 that occupies 34.1% of the unit cell.

Key words: metal organic framework, coordination polymer, 1,2-bis(4-pyridyl)hydrazine, interpenetrating polymer, microporous, hydrogen bond.

Résumé : On rapporte les propriétés de deux charpentes organométalliques (COM) à base de Zn(II) et de 1,2-bis(4-pyridyl)hydrazine (**L1**); un COM bidimensionnelle imbriquée (**I**) de formule $[Zn_2(\mathbf{L1})_2(\mathbf{L2})_2]_\infty$ formé à l'aide d'acide téréphtalique (**L2**) utilisé comme coupleur additionnel. Il se forme aussi une COM tridimensionnelle (**II**) de formule $[Zn_2(\mathbf{L1})_2(\mathbf{L3})_2]_\infty$ lorsqu'on utilise l'acide naphtalène-2,6-dicarboxylique (**L3**) comme coupleur plus long. La charpente organométallique **II** possède une grande porosité, avec un volume total de 3746 A^3 qui occupe 34,1 % de la maille élémentaire.

Mots-clés : charpente organométallique, polymère de coordination, 1,2-bis(4-pyridyl)hydrazine, polymère imbriqué, microporeux, liaison hydrogène.

[Traduit par la Rédaction]

Introduction

Metal-organic frameworks (MOFs) have attracted much attention in the past decade because of their well-organized three-dimensional forms with permanent porosity, as well as their potential applications in adsorption, separation, and ion exchange processes,[1,2] catalysis,[3] and drug delivery.[4] Their specific chemical and physical properties are mainly dependent on the frameworks, which can be achieved by introducing different bridging ligands with geometrically predetermined metal centres. However, obtaining MOFs with desired topologies and functionalities is still a challenging task.

Organic linkers with C, N, O and S atoms or groups provide great opportunities to create functionalized porous frameworks with these heteroatoms exposed inside the pore space; this in turn can lead to materials tailor-made for specific applications. Among different linkers, nitrogen-containing linkers are of particular interest, with azo-ligand being one example.[5] Azo-ligand has shown good thermal stability and unique optical properties, which make it suitable for optical data storage and electro-optical devices.[5a,5b] Moreover, because of cis–trans isomerization of the N=N bond, azo-ligand is able to perform various kinds of molecular motions upon external stimuli.[5c–5e] By incorporating the azo functional groups into MOF, it may be possible to introduce interesting photochemical and physical properties in the product. Meanwhile, Zn has been demonstrated to be a versatile metal for the construction of MOFs. A recent example of a Zn MOF showed second-order nonlinear optical effects and a ferro-electric feature.[5g] Therefore, our initial attempt was to develop a Zn MOF with azo-linkers by performing reactions of $ZnCl_2$, 4,4′-azopyridine and terephthalic acid (**L2**) under (solvo)thermal conditions. Crystals suitable for X-ray single crystal characterization were obtained, and they showed a two-dimensional polymeric network. In the polymer $[Zn_2(\mathbf{L1})_2(\mathbf{L2})_2]_\infty$ (**I**), 1,2-bis(4-pyridyl)hydrazine (**L1**), which resulted from hydrogenation of 4,4′-azopyridines, was surprisingly observed. A similar reduction reaction in the presence of Ru ions was also reported.[6] Contrary to 4,4′-azopyridine, **L1** may provide excellent flexibility and functionality in the MOF structure. The single N–N bond of **L1** allows the flexibility to adopt various kinds of

conformation when **L1** coordinates to metal ions. In contrast to the non-polar C–C bond, hydrazine units provide free basic centers to further interact with (*i*) metals in various coordination modes[7] or (*ii*) polar molecules through strong noncovalent interactions (e.g., hydrogen bonds).[8] The latter, having been found ubiquitously in biological systems, is considered one of the strong directional interactions for constructing coordination polymer with predictable features (molecular tectonics).[9] However, studies on hydrazine-containing MOFs are rare.[10] Moreover, to the best of our knowledge, there is no report on the development of **L1** for two- or three-dimensional network construction. We are interested in developing MOFs based on **L1**. Using the same synthetic strategy, a reaction of $ZnCl_2$, 4,4′-azopyridine, and a longer spacer, and 2,6-naphthalenedicarboxylic acids (**L3**) was attempted. Crystals were obtained, and the crystal structure showed a three-dimensional network, with formula $[Zn_2(\mathbf{L1})_2(\mathbf{L3})_2]_\infty$ (**II**).

Experimental

General

NMR spectra in solution were recorded on a Bruker Ultrashield 400 Plus MHz instrument, and the chemical shifts were referenced internally to residual solvent peaks in parts per million (ppm). Thermal gravimetric analysis data were recorded on a PerkinElmer Thermogravimetric Analyzer (TGA7) with a heating rate of 5 °C/min in an N_2 atmosphere. Infrared spectra were recorded on a Nicolet Nexus 470 FTIR spectrometer in the range 4000–400 cm^{-1}, by using dry KBr pellets containing about 1%–2% of the sample. Elemental analyses were recorded on a Vario EL elemental analyzer. Positive ion mass spectra were taken by Waters Quattro Ultima equipped with triple quadruple in electrospray mode.

X-ray crystallography

Measurements for crystal data were carried out on a Bruker Smart 1000 system equipped with an APEX II CCD device for **I** and **II**, with graphite monochromated Mo Kα radiation at room temperature. Multi-scan absorption correction was applied by SADABS program,[11] and the SAINT program was utilized for integration of the diffraction profiles.[12] The structures were solved by direct method and was refined by a full matrix least-squares treatment on F^2, using the SHELXTL programme system.[13,14] Finally, SQUEEZE–PLATON was used to remove the heavily disordered lattice solvents from refinement in **II**.[15] Crystal data, as well as details of data collection and refinement, for **I** and **II** are summarized in Table 1.

Synthesis and characterizations of MOF I, $[Zn_2(L1)_2(L2)_2]_\infty$

MOF **I** was synthesized by mixing 4,4′-azopyridine (13.8 mg, 0.075 mmol), terephthalic acid (**L2**) (8.3 mg, 0.05 mmol), and $Zn(NO_3)_2{\cdot}6H_2O$ (14.9 mg, 0.05 mmol) in DMF (4 mL) in an oven at 120 °C for 72 h, followed by slow cooling to room temperature at a rate of 10 °C h^{-1}. A mixture of solids and crystals resulted. Light-red crystals suitable for X-ray characterization and found to be MOF **I** were obtained. Yield: 15 mg (36%) on the basis of $Zn(NO_3)_2{\cdot}6H_2O$. The compound was characterized by single crystal X-ray

Synthesis and characterizations of MOF II, $[Zn_2(L1)_2(L3)_2]_\infty$

MOF **II** was synthesized by mixing 4,4′-azopyridine (13.8 mg, 0.075 mmol), 2,6-naphthalenedicarboxylic acid (**L3**) (10.8 mg, 0.05 mmol), and $Zn(NO_3)_2{\cdot}6H_2O$ (14.9 mg, 0.05 mmol) in DMF (4 mL) in an oven at 120 °C for 72 h, followed by slow cooling to room temperature at a rate of 10 °C h^{-1}. A mixture of solids and crystals resulted. Light-red crystals suitable for X-ray characterization and found to be MOF **II** were obtained. Yield: 13 mg (31%) on the basis of $Zn(NO_3)_2{\cdot}6H_2O$. The compound was characterized by single crystal X-ray diffraction, powder X-ray diffraction (PXRD), thermogravimetric analysis (TGA), elemental analysis, and IR spectroscopy. IR (KBr pellet, ν, cm^{-1}): 3457.9 w, 3247.7 m, 1618.3 s, 1577.6 s, 1407.9 s, 1357.7 s, 1214.9 m, 1020.2 m, 790.7 m. Elemental analysis (in wt%): calcd. for $Zn_2(\mathbf{L1})_2(\mathbf{L3})_2{\cdot}2H_2O{\cdot}4DMF$: C 53.55, H 4.78, N 13.39; found: C 53.70, H 4.85, N 13.00.

Isolation and characterizations of L1 after MOF synthesis

A crude mixture of **I** was treated with 6N HCl (5 mL) for 2 h. The aqueous layer was extracted with Et_2O (20 mL) three times. The aqueous layer was then neutralized by 2M NaOH (15 mL) and further extracted with CH_2Cl_2 (20 mL) three times. The organic layer was obtained and dried with $MgSO_4$. The solvent was removed under reduced pressure. **L1** was isolated (yield: 30%) and characterized by ^1H NMR and ESI-MS. A similar procedure was applied to crude mixture

Results and discussion

Hydrogenation of 4,4′-azopyridine to form 1,2-bis(4-pyridyl)hydrazine

In the literature there are a variety of methods for the reduction of azo compounds to hydrazo compounds, commonly by metal-mediated reduction.[16] Conventional reduction of 4,4′-azopyridine to 1,2-bis(4-pyridyl)hydrazine required metal catalysts (e.g., Pd,[16a] Ni,[16b] Zn,[17] etc.) and in the presence of hydrogen donors such as formic acid,[18] ammonium formate,[19] and hydrazine.[20] Recently, an example of in situ formation of hydrazine ligands during MOF preparation by Zn-catalyzed hydration process was proposed.[10a] In our studies, 4,4′-azopyridines can be reduced to 1,2-bis(4-

pyridyl)hydrazines in the presence of Zn salts and organic acids under solvothermal conditions. In an attempt to understand the hydrogenation process from the azo group to hydrazine, control experiments were carried out. Firstly the reaction was carried out in the absence of Zn salt or organic acid, and secondly the reaction was carried out using all reactants at 120 °C under atmospheric pressure. The hydrazine product (**L1**) cannot be obtained in all these control reactions. Although the mechanism for the reduction and the role of Zn salts are not clear at this stage, these experiments indicated the importance of high pressure during hydrogenation process and suggested the source of hydrogen donors from carboxylic acids (**L2** or **L3**).

Structure of I

The single crystal X-ray diffraction study reveals that **I** crystallizes in the monoclinic space group *Pc*. The asymmetric unit (Fig. 1) consists of two zinc centers, both of them have a distorted tetrahedral geometry (average bond angles of 108.8° and 108.7°, respectively), and each coordinates with two pyridyl nitrogen atoms and two oxygen atoms from the monodentate carboxylate groups. Zn–E (E = N, O) bond lengths within the structure are found to be in agreement with literature values (1.940–2.043Å).[21]

As mentioned previously, 4,4′-azopyridine was found to have been hydrogenated to form **L1**. Initially, the presence of the amino protons could only be speculated through indirect evidence, as designation of proton purely based on residue peaks is often difficult. One such evidence is the largely twisted geometry of the whole ligand itself, with dihedral angles of 91.7° (between N(11) and N(21) pyridine rings) and 101.0° (between N(31) and N(41) pyridine rings), respectively. Furthermore, the extended N–N bonds (1.380 and 1.388 Å, compared with a typical N=N bond length of 1.25 Å)[22] also point to the hydrogenation of the azo group (Fig. 1*b*). Another subtle clue to the presence of the amino protons comes in the form of the C–O bond lengths found within the carboxylate groups. In a monodentate system, a difference in bond length between the two C–O bonds would normally be expected. However, while there is a minor difference between the bond length in general (1.212–1.306 Å), the bonds are still far shorter than the typical C–O bond length of 1.43 Å.[22] Thus the negative charge is still considered to be largely delocalized across the whole carboxylate group. Under this situation, the uncoordinated oxygen cannot

Fig. 7. A packing diagram of **II** showing the large volume of voids. The majority of hydrogen atoms are omitted for clarity.

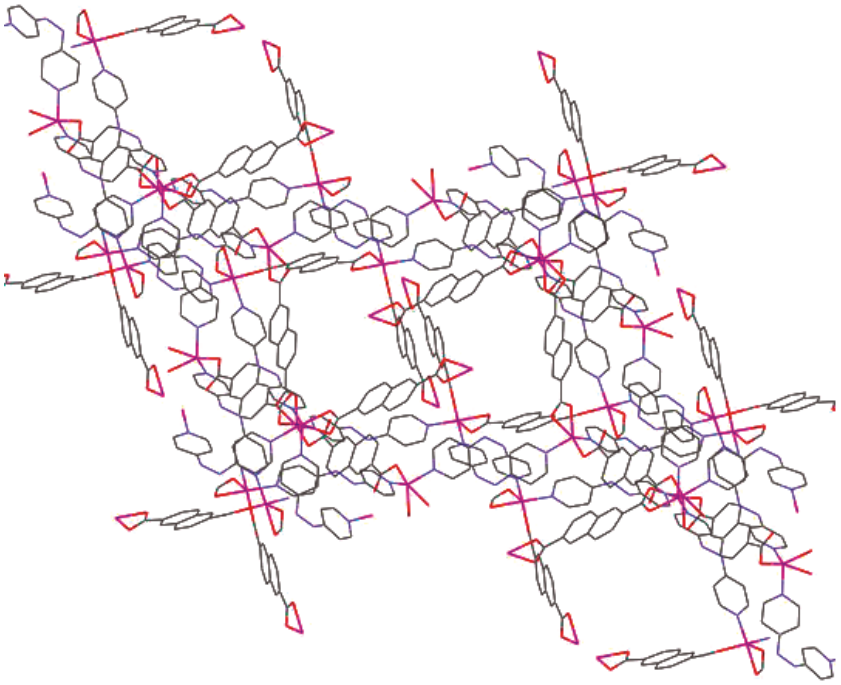

Fig. 8. Thermogravimetric curve of MOF (*a*) **I** and (*b*) **II**.

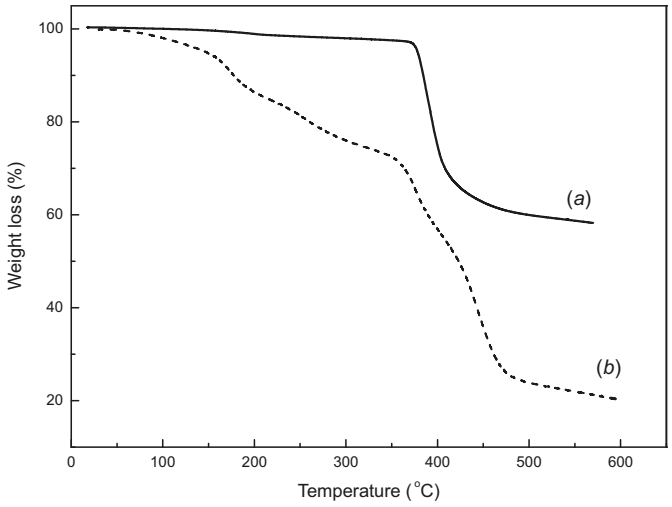

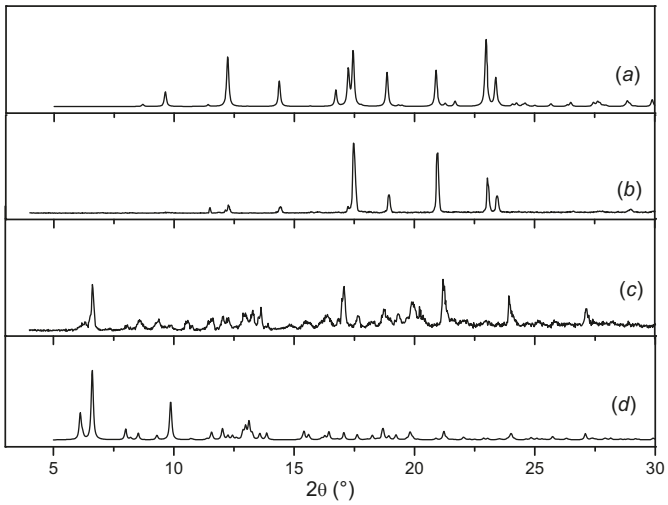

Fig. 9. Powder X-ray diffraction patterns of (*a*) simulation from a single crystal of MOF **I**, (*b*) crystals of MOF **I**, (*c*) crystals of MOF **II**, and (*d*) simulation from a single crystal of MOF **II**.

be truly unattached, and the amino proton is found to be within suitable distant and geometry to provide the necessary interaction through hydrogen bonding (Fig. 2). As **L1** is known to form a strong hydrogen bond,[8] the presence of the amino proton-oxygen hydrogen bonding is also potentially important to the way the carboxylate group is coordinated to the zinc center and in turn to the entire formation of the coordination polymer itself.

In the extended lattice, **L2** bridges over two crystallographically different zinc centers (i.e., between Zn(1) and Zn (2), and vice versa), whereas **L1** bridges across symmetrically equivalent zinc atoms (i.e., between neighboring Zn(1) atoms or neighboring Zn(2) atoms). The result is a ring with four bridges (two each of **L1** and **L2**), linking up four zinc metal centers as vertexes. This can then be seen to extend indefinitely, forming a 2D net. Because of the largely tetrahedral nature of the metal centers, a layer of the net has a distinctive zig-zag shape, this shape in turn allows for two sets of net to interpenetrate each other (Fig. 3). The aforementioned hydrogen bonding interactions are formed between these interpenetrating layers to provide stabilization. The interpenetrating arrangement means that no solvent accessible void can be found within any given layers; in fact, no lattice solvent could be located from the crystallographic data. The lack of lattice solvent would become one of the major differences between structure of **I** and **II**.

The structural analysis of **II** was severely hampered by the decomposition of the crystal during data collection. The solution could only be obtained after a number of attempts. **II** was found to crystallize in the centrosymmetric space group

For personal use only.

of *C*2/*c*. Many features found in **I** can also be found in the analogous **II**. For example, the severely twisted nature of **L1** after the azo group was hydrogenated during the synthesis (dihedral angle of 72.6° and 99.0° between corresponding pyridine rings, respectively) (Fig. 4*a*), and hydrogen bonds between the amino proton and the uncoordinated oxygen on the carboxylate group can be observed too (Fig. 5). A comparison of hydrogen bonds in **I** and **II** is summarized in Table 2.

Unlike **I**, **L3** is seen to be bridging across symmetrically identical zinc atoms (i.e., Zn(1) to Zn(1) or Zn(2) to Zn(2)), whereas **L1** links together zinc centers of different environments (i.e., Zn(1) to Zn(2) and vice versa). More pertinently, the two types of zinc centers do have different coordination environments, as opposed to **I** whose two zinc centers have the same coordination mode. Zn(2) is four-coordinated, while Zn(1) is five-coordinated (Fig. 6).[23] Zn(2) is coordinated with two pyridyl N atoms and two O atoms from two carboxylate groups and takes up a distorted tetrahedral geometry (average bond angle of 108.9°), similar to the zinc centers found in **I**. The penta-coordinated Zn(1), on the other hand, arises from coordination with two pyridyl nitrogen atoms and three carboxylate oxygen atoms. One of the carboxylate groups is found to chelate to the zinc atom; as a result, the geometry at the zinc centre resembles an approximate trigonal bipyrimid. Steric hindrance is an issue surrounding chelation to the zinc center, as evident from the longer than typical O(81)–Zn(1) and O(82)–Zn(1) bond (2.142 and 2.268 Å, respectively), and perhaps unsurprisingly, no hydrogen bonding is observed for either oxygen atoms.

The larger **L3** ligand compared with **L2** and the difference in coordination environments allow for the formation of a 3D network as opposed to the 2D net seen in structure **I**. The basic motif is formed with eight zinc centers and eight bridges (four each of the **L1** and **L3** ligands). This motif extends throughout the lattice, where rings can be seen interpenetrating each other, making the overall structure rather complex (Fig. 7). Solvent accessible cavities can be found within the lattice, and these cavities occupy 33.9% of one unit cell volume (3746.1 $Å^3$ out of 11044.8 $Å^3$).[24] The crystal data show that solvent molecules such as DMF and water can be found inside the cavities, however, the heavily disordered nature made it difficult to determine the precise amount of each solvent present. The only satisfactory solution was obtained through the use of SQUEEZE (PLATON),[24] where the solvents were discounted from the lattice.

Thermal stabilities and powder XRD studies of I and II

To study the thermal stabilities of **I**, thermogravimetric analyses (TGAs) were performed on their polycrystalline samples (Fig. 8*a*). For MOF **I**, no weight loss was observed up to 385 °C. A significant weight loss was then observed at ca. 385–550 °C, indicating the framework decomposition of **I**. MOF **I** shows high thermal stability (>250 °C), and the lack of solvent capacity is consistent with its interpenetrating arrangement found in the crystal structure. The structural homogeneity of bulk powder samples of **I** was examined through comparison of experimental and simulated powder XRD patterns (Figs. 9*a* and 9*b*). The experimental pattern is in agreement with that of the simulated one generated from single-crystal X-ray diffraction data, which indicates the homogenous phase of final products.

However, during the sample preparation of **II** for TGA and powder XRD analysis, the compound lost its crystallinity gradually upon solvent removal and appeared to be decomposed slowly over a few hours. The TGA spectrum of **II** showed two major steps in the weight loss (Fig. 8*b*). The first obvious weight loss includes the release of water (2.75%) and DMF (23.10%) molecules at ca. 50–130 and 165–340 °C. The total weight loss of guest molecules is about 25.85% and closely matches the solvent amount calculated from the formula $[Zn_2(\mathbf{L1})_2(\mathbf{L3})_2]\cdot 2H_2O\cdot 4DMF$ (26.06%), which is based on the elemental analysis. A second obvious weight loss happened at ca. 360–470 °C, which shows decomposition of the solid-state framework. The powder XRD spectrum of **II** also showed the lost in crystalline nature and decomposition of the compound during the experiment (Figs. 9*c* and 9*d*), as it showed a difference in peak positions and intensities compared with the spectrum simulated from its single crystal.

Conclusion

We have demonstrated the use of flexible **L1** in the formation of two novel Zn metal-organic polymers. The use of larger **L3** over **L2**, as well as the coordination environment around the Zn ions, induces a significant change in the dimensions of the polymers, from 2D interpenetrating in **I** to 3D highly porous network in **II**. Moreover, extensive hydrogen bonds are observed between amino protons of **L1** and oxygens of carboxylate linkers in both polymers. This may play a prominent role in the formation of the two final solid-state organizations, and it opens up new strategy for well-defined supramolecular motif with porous architectures. Although the solid-state structures of MOF **II** are not stable enough for further application, the free basic centers in the structure have great potential to serve as the adsorption sites for guest molecules (e.g., metal ions and gases). We are extending the synthetic strategy to prepare other porous MOFs with the combination of **L1** and other carboxylate derivatives.

Supplementary data

Supplementary data for this article are available on the journal Web site (www.nrcresearchpress.com/doi/suppl/10.1139/v11-132). Crystallographic data CCDC 809663 and 809662 have also been deposited with the Cambridge Crystallographic Data Centre. These data can be obtained, free of charge, via www.ccdc.cam.ac.uk/cgi-bin/catreq.cgi (or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1Ez, UK; fax +44 1223 336033; or e-mail deposit@ccdc.cam.ac.uk).

Abstract: Late transition-metal complexes bearing linked cyclopentadienyl/indenyl–carboranyl ligands were synthesized and their reactivities were examined. Reaction of $Li_2[Me_2C(L)(C_2B_{10}H_{10})]$ (L = C_5H_4, C_9H_6, $Me_2NCH_2CH_2C_5H_3$) with $MCl_2(PPh_3)_2$ in Et_2O afforded $[\eta^5{:}\sigma\text{-}Me_2C(C_5H_4)(C_2B_{10}H_{10})]M(PPh_3)$ (M = Co (**4**), Ni (**5**)), $[\eta^5{:}\sigma\text{-}Me_2C(C_9H_6)(C_2B_{10}H_{10})]M(PPh_3)$ (M = Co (**6**), Ni (**7**)), and $[\eta^5{:}\sigma\text{-}Me_2C(Me_2NCH_2CH_2C_5H_3)(C_2B_{10}H_{10})]Ni(PPh_3)$ (**8**). Treatment of **4** or **5** with 2,6-dimethylphenylisocyanide, N-heterocyclic carbene (NHC), PCy_3, or 1,2-bis(diphenylphosphino)ethane (dppe) gave the corresponding PPh_3 displacement complexes $[\eta^5{:}\sigma\text{-}Me_2C(C_5H_4)(C_2B_{10}H_{10})]M(2,6\text{-}Me_2C_6H_3NC)$ (M = Co (**9**), Ni (**10**)), $[\eta^5{:}\sigma\text{-}Me_2C(C_5H_4)(C_2B_{10}H_{10})]M[1,3\text{-}(2,6\text{-}i\text{-}Pr_2C_6H_3)_2C_3N_2H_2]$ (M = Co (**11**), Ni (**12**)), $[\eta^5{:}\sigma\text{-}Me_2C(C_5H_4)(C_2B_{10}H_{10})]Ni(PCy_3)$ (**13**), or $\{[\eta^5{:}\sigma\text{-}Me_2C(C_5H_4)(C_2B_{10}H_{10})]Co\}_2(dppe)$ (**14**), respectively. These complexes were characterized by various spectroscopic techniques and elemental analyses. The molecular structures of **4**–**14** were further confirmed by single-crystal X-ray analyses.

Key words: carborane, cyclopentadienyl, cobalt complexes, nickel complexes, substitution reaction.

Résumé : On a effectué la synthèse de complexes de métaux de transition portant des ligands liés cyclopentadiényl/indényl-carboranyles et on en a examiné les réactivités. La réaction du $Li_2[Me_2C(L)(C_2B_{10}H_{10})]$ (L = C_5H_4, C_9H_6, $Me_2NCH_2CH_2C_5H_3$) avec le $MCl_2(PPh_3)_2$, dans l'éther, conduit à la formation des $[\eta^5{:}\sigma\text{-}Me_2C(C_5H_4)(C_2B_{10}H_{10})]M(PPh_3)$ (M = Co (**4**); Ni (**5**)), $[\eta^5{:}\sigma\text{-}Me_2C(C_9H_6)(C_2B_{10}H_{10})]M(PPh_3)$ (M = Co (**6**); Ni (**7**)) et $[\eta^5{:}\sigma\text{-}Me_2C(Me_2NCH_2CH_2CH_2C_5H_3)(C_2B_{10}H_{10})]Ni(PPh_3)$ (**8**). Le traitement des composés 4 et 5 avec de l'isocyanure de 2,6-diméthylphényle, des carbènes N-hétérocycliques (NHC), du PCy_3 ou du 1,2-bis(diphénylphosphino)éthane (dppe), conduit aux complexes correspondants avec remplacement du PPh_3, soit respectivement les $[\eta^5{:}\sigma\text{-}Me_2C(C_5H_4)(C_2B_{10}H_{10})]M(2,6\text{-}Me_2\text{-}C_6H_3NC)$ (M = Co (**9**); Ni (**10**)), $[\eta^5{:}\sigma\text{-}Me_2C(C_9H_6)(C_2B_{10}H_{10})]M[1,3\text{-}(2,6\text{-}i\text{-}Pr_2C_6H_3NC)_2(C_3N_2H_2]$ (M = Co (**11**); Ni (**12**)) $[\eta^5{:}\sigma\text{-}Me_2C(C_5H_4)(C_2B_{10}H_{10})]Ni(PCy_3)$ (**13**) ou $\{[\eta^5{:}\sigma\text{-}Me_2C(Me_2C_5H_4)(C_2B_{10}H_{10})]Co\}_2(dppe)$ (**14**). Ces complexes ont été caractérisés par diverses techniques spectroscopiques et par des analyses élémentaires. Les structures moléculaires des composés **4**–**14** ont de plus été confirmées par des diffractions de rayons-X sur des cristaux uniques.

Mots-clés : carborane, cyclopentadiényle, complexes du cobalt, complexes du nickel, réaction de substitution.

[Traduit par la Rédaction]

Introduction

Linked cyclopentadienyl/indenyl/fluorenyl–carboranyl ligands have been widely used for the synthesis of constrained-geometry transition-metal complexes,[1–3] in which the non-traditional metal–carbon(cage) (M–C_{cage}) bonds are generally inert toward electrophiles because of steric reasons.[1e,1f] On the other hand, they can offer transition-metal complexes unique features.[4] For example, the constrained-geometry ruthenium complexes, $[\eta^5{:}\sigma\text{-}Me_2C(C_5H_4)(C_2B_{10}H_{10})]Ru(L_2)$ (L = NHR_2, CH_3CN) can react with alkynes to produce Ru–carbene, –diene, and –bisvinylidene complexes bearing the $[Me_2C(C_5H_4)(C_2B_{10}H_{10})]^{2-}$ ligand.[4] In addition, $[\eta^5{:}\sigma\text{-}Me_2C(C_5H_4)(C_2B_{10}H_{10})]Ru(CH_3CN)_2$ can also react with 3 equiv of terminal alkynes ArC≡CH to form the unexpected tricyclic compounds with the activation of the incorporated C_5H_4 ring.[4f]

It has been documented that the Co and Ni complexes show some common features with the Ru ones in [2+2+2] cyclotrimerization of alkynes and C–C coupling reactions.[5] Connected to this and to understand the similarities and differences among late transition-metal complexes with linked cyclopentadienyl–carboranyl ligands, we extended our research to include cobalt and nickel metals. We report herein the synthesis, structure, and reactivity of Co and Ni complexes

Scheme 1. Synthesis of cobalt and nickel complexes.

bearing carbon-linked cyclopentadienyl/indenyl–carboranyl ligands.

Results and discussion

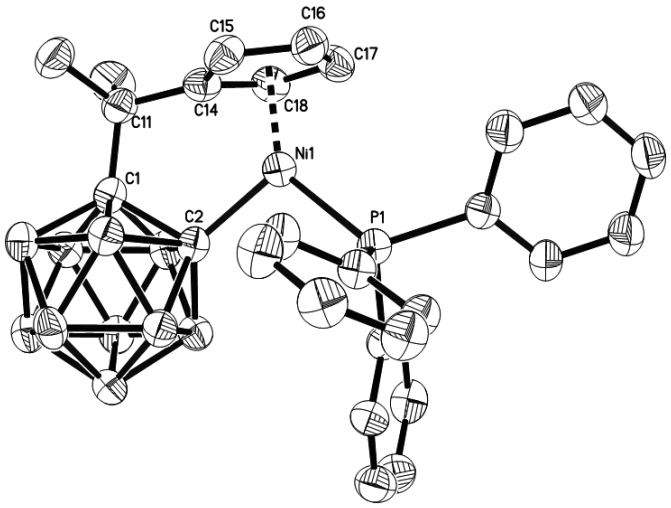
Synthesis and structure

Treatment of $Li_2[Me_2C(C_5H_4)(C_2B_{10}H_{10})]$[2d] with 1 equiv of $MCl_2(PPh_3)_2$ (M = Co, Ni) in THF at room temperature afforded, after recrystallization from Et_2O, constrained-geometry transition-metal complexes $[\eta^5{:}\sigma\text{-}Me_2C(C_5H_4)(C_2B_{10}H_{10})]M(PPh_3)$ (M = Co (**4**) or Ni (**5**)) in ~90% isolated yields (Scheme 1). In a similar manner, complexes $[\eta^5{:}\sigma\text{-}Me_2C(C_9H_6)(C_2B_{10}H_{10})]M(PPh_3)$ (M = Co (**6**) or Ni (**7**)) and $[\eta^5{:}\sigma\text{-}Me_2C(Me_2NCH_2CH_2C_5H_3)(C_2B_{10}H_{10})]Ni(PPh_3)$ (**8**) were also synthesized from the interaction of $Li_2[Me_2C(C_9H_6)(C_2B_{10}H_{10})]$[2e] or $Li_2[Me_2C(Me_2NCH_2CH_2C_5H_3)(C_2B_{10}H_{10})]$ with 1 equiv of $MCl_2(PPh_3)_2$ in 63%–79% isolated yields, respectively (Scheme 1).

Complexes **4** and **6** were paramagnetic species, which did not provide useful NMR information. For complexes **5**, **7**, and **8**, the ^1H and ^{13}C NMR spectra showed the presence of the ligand and coordinated PPh_3 with an 1:1 molar ratio. Their ^{11}B NMR spectra exhibited the same 2:3:5 pattern. The ^{31}P NMR spectra displayed a singlet at 47.3 ppm for **5**, 33.8 ppm for **7**, and 36.5 ppm for **8**, respectively. The compositions of complexes **4**–**8** were confirmed by elemental analyses.

The solid-state structures of **4**–**8** as revealed by single-crystal X-ray analyses show that the metal atoms are η^5-bound to the cyclopentadienyl ligand (in **4**, **5**, and **8**) or indenyl ligand (in **6** and **7**), σ-bound to one cage carbon atom, and coordinated to a triphenylphosphine in a trigonal planar geometry, leading to the formation of 17 e^- cobalt and 18 e^- nickel complexes. The representative structures of **5**, **7**, and **8** are shown in Figs. 1–3, respectively. The selected bond

Fig. 1. Molecular structure of $[\eta^5{:}\sigma\text{-}Me_2C(C_5H_4)(C_2B_{10}H_{10})]NiPPh_3$ (**5**).



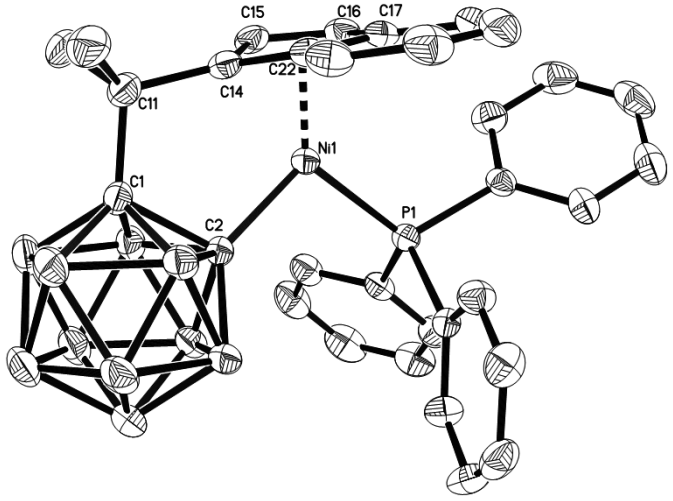


Fig. 2. Molecular structure of $[\eta^5{:}\sigma\text{-}Me_2C(C_9H_6)(C_2B_{10}H_{10})]NiPPh_3$ (**7**).

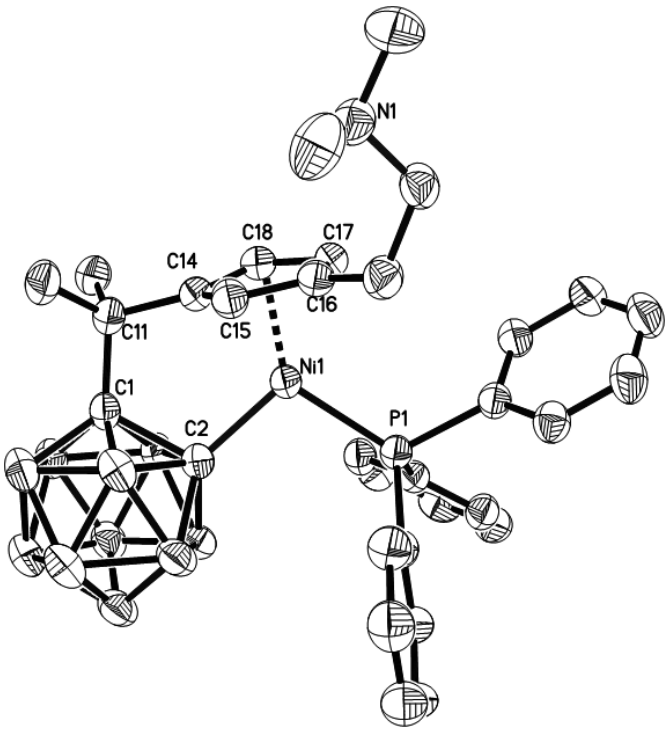

distances and angles around the metal atoms are listed in Table 1 for comparison. It is noted that the appended N atom in **8** does not substitute the P atom to form the intramolecular coordination to the Ni atom as the N atom is a harder base than the P atom.

The distances between the Co atom and the five-membered ring atoms ($Co–C_{ring}$) range from 2.028(3) to 2.126(3) Å in **4** and from 2.044(4) to 2.259(4) Å in **6**. These values are comparable to the 2.102(2) Å in $(\eta^5\text{-}C_5H_5)Co(PPh_3)[\eta^1(N)\text{-}N(O)Me]$,[6] to the 2.06(5) Å in $(\eta^5\text{-}C_5H_5)Co(S_2C_2B_{10}H_{10})$,[7] and to the 2.154(9) Å in $(\eta^5\text{-}C_9H_6)(C_3H_7)(PMe_3)_2CoI$.[8] The average $Ni–C_{ring}$ distances of 2.145(6) Å in **5**, 2.17 ± 0.01 Å in **7**, and 2.131(3) Å in **8** are very close to each other. They are also similar to the 2.102(6) Å in $[Ni(\eta^5\text{-}C_5H_5)(PPh_3)C{\equiv}CCHO]$,[9] to the 2.182(3) Å in $[(\eta^5\text{-}1\text{-}TMS\text{-}C_9H_5)NiCl(PPh_3)]$,[10] to the 2.114(7) Å in $(\eta^5{:}\eta^1\text{-}C_5H_4CH_2CH_2NMe_2)Ni(C_{12}H_8N)$,[11] and to the 2.098(9) Å in $[(\eta^5\text{-}C_5H_4CH_2CH_2NMe_2)Ni(dmpe)][PF_6]$.[12]

The metal – cage carbon distances ($M–C_{cage}$) between 1.95 and 2.01 Å for **4**–**8** are comparable to the 1.998(9)–2.013(9) Å in $[Ni\{(C_2B_{10}H_{10})_2\}_2]^{2-}$,[13] to the 2.051(12)–2.070(12) Å

Fig. 3. Molecular structure of [η^5:σ-$Me_2C(Me_2NCH_2CH_2C_5H_3)(C_2B_{10}H_{10})$]$NiPPh_3$ (**8**).

in $[Co\{(C_2B_{10}H_{10})_2\}_2]^{2-}$,[13] and to the 1.972(5) Å in $[\eta$:σ-$(2\text{-}C_5H_4NCH_2C_2B_{10}H_{10})]_2Ni$.[14]

The metal–phosphorus distances (M–P) in **4**–**8** fall in the range 2.19–2.25 Å. They are comparable to the 2.184(1) Å in (η^5-C_5H_5)$Co(PPh_3)[\eta^1(N)$-N(O)Me],[6] to the 2.146(1) Å in (η^5-C_9H_6)$Co(CO)(PPh_3)$,[15] to the 2.29(1)/2.20(1) Å in $(PPh_3)_2Ni(C_2B_{10}H_{10})$,[16] to the 2.211(2)/2.214(2) Å in $\{(PPh_3)_2Ni[\mu\text{-}(\eta^5\text{-}C_5H_4)CMe_2(\eta^5\text{-}C_5H_4)]Ni(PPh_3)_2\}\{PF_6\}_2$,[17] and to the 2.134(1) Å in $Cp^*Ni(PPh_3)(CH_2CO$*t*-Bu).[18]

Reactivity

The substitution reactions of **4** and **5** with various Lewis bases were examined to gain information on the lability of the PPh_3 ligand. The results showed that the PPh_3 in **4** and **5** were easily replaced by isocyanide, N-heterocyclic carbene (NHC), and other phosphines.

Treatment of **4** or **5** with 1 equiv of 2,6-dimethylphenylisocyanide at room temperature in toluene afforded, after recrystallization from Et_2O, the PPh_3 displacement products, [η^5:σ-$Me_2C(C_5H_4)(C_2B_{10}H_{10})$]$M(CNC_6H_3Me_2\text{-}2,6)$ (M = Co (**9**) or Ni (**10**)) in 77% and 59% isolated yield, respectively (Scheme 2). The reactions were monitored by ^{31}P NMR spectra. Complex **10** showed a distinct NMR spectrum from its parent complex **5**. Except for the resonances corresponding to the protons of the bridging ligand, signals in the range 6.66–6.51 ppm assignable to the aromatic protons and one singlet at 2.11 ppm attributable to the methyl protons on the phenyl ring were observed in the ^1H NMR spectrum. The characteristic resonance of the N=*C* at 162.8 ppm was observed in the ^{13}C NMR spectrum. The ^{11}B NMR spectrum showed a 1:2:3:4 pattern.

The structures of both **9** and **10** were confirmed by single-crystal X-ray analyses. They are isomorphous and isostructural with a trigonal planar geometry. The representative structure of **9** is shown in Fig. 4. The average $M–C_{ring}$ bond distances of 2.074(3)/2.099(4) Å in Co (**9**)/Ni (**10**) are comparable to those of 2.085(3)/2.145(6) Å observed in **4/5**, and the $M–C_{cage}$ bond distances of 1.922(3)/1.898(3) Å in **9/10** are slightly shorter than those of 1.989(3)/1.975(5) Å found in **4/5**. The M–C bond distances of 1.838(3)/1.790(3) Å in **9/10** compare to those of 1.87(1)/1.89(1) Å in $[Co(L_{C=O}:N_2(SO)_2)(CN$*t*-$Bu)_2]^-$,[19] to 1.772(18)/1.963(18) Å in $CoBr(PhCOCH)(CNC_6H_3Me_2\text{-}2,6)_6$,[20] to 1.787(3) Å in $Ni(triphos)(CNC_6H_3Me_2\text{-}2,6)$,[21] to 1.820(4) Å in $Ni\{S_2P(O)(OEt)\}(CNC_6H_3Me_2\text{-}2,6)(PCy_3)$,[22] and to 1.789(9)/1.789(8) Å in $[Ni(\mu\text{-}t\text{-}Bu_2As)(p\text{-tol-NC})_2]_2$.[23]

Reaction of **4** or **5** with 1 equiv of NHC (1,3-bis(2,6-diisopropylphenyl)-1,3-dihydro-2*H*-imidazol-2-ylidene) in toluene at room temperature afforded [η^5:σ-$Me_2C(C_5H_4)(C_2B_{10}H_{10})$]$M[C(2,6\text{-}i\text{-}Pr_2C_6H_3\text{–}NCH)_2]$ (M = Co (**11**) or Ni (**12**)) in 51% and 60% isolated yield, respectively (Scheme 2). The characteristic ^{13}C resonance at 163.1 ppm corresponding to the NHC carbene carbon was observed in the ^{13}C NMR spectrum of **12**. Its ^{11}B NMR spectrum showed a 2:3:5 pattern.

The structures of complexes **11** and **12** were confirmed by single-crystal X-ray analyses. They are isomorphous and isostructural. The metal atom is η^5-bound to the Cp ring, σ-bound to the cage carbon atom, and coordinated to the carbene atom in a trigonal planar geometry. The representative structure of **11** is shown in Fig. 5. The average $M–C_{ring}$/$M–C_{cage}$ bond distances of 2.143(3)/2.152(4) Å in **11** and 2.003(3)/1.945(3) Å in **12** are comparable to the corresponding values observed in **4** and **5**, respectively. The $Co–C_{NHC}$ bond distance of 2.011(2) Å in **11** is similar to that of 2.043(2)/2.019(2) Å in $[(TIMEN^{xyl})Co][BPh_4]_2$ (TIMEN = tris[2-(3-arylimidazol-2-ylidene)ethyl]amine; xyl = 2,6-dimethylphenyl))[24] and to 1.914(2) Å in (η^5-C_5H_4)$Co[C(2,6\text{-}i\text{-}Pr_2C_6H_3\text{–}NCH)_2]Me_2$.[25] The $Ni–C_{NHC}$ bond distance of 1.934(2) Å in **12** is somewhat longer than the 1.882(4) Å in $Cp[(\eta^2\text{:}\eta^2\text{-}CH_2{=}CHCH_2NCHCHNMe)]C]Ni$,[26] than the 1.886(3) Å in $(C_9H_7)[(i\text{-}PrNCH)_2C]NiCl$,[27] than the 1.888(4) Å in $(C_9H_7)[(i\text{-}PrNCH)_2C]NiBr$,[27] and than the 1.901(3) Å in $[(m\text{-}MeOC_6H_4CH_2NCHCHNCH_2CH_2PPh_2)C]_2NiCl_2$.[28]

Interaction of **5** with 1 equiv of PCy_3 (Cy = cyclohexyl) in refluxing toluene afforded [η^5:σ-$Me_2C(C_5H_4)(C_2B_{10}H_{10})$]$Ni(PCy_3)$ (**13**) in 57% isolated yield. The room-temperature reaction was very slow. An equimolar reaction of **4** with 0.5 equiv of dppe (1,2-bis(diphenylphosphino)ethane) gave $\{[\eta^5$:σ-$Me_2C(C_5H_4)(C_2B_{10}H_{10})]Co\}_2$(dppe) (**14**) in 62% isolated yield (Scheme 2). The substitution of PPh_3 in **5** by PCy_3 was confirmed by ^1H and ^{31}P NMR spectra. In addition to the resonances assignable to the protons of the bridging ligand, multiplets in the region 2.11–1.07 ppm corresponding to the cyclohexyl protons were observed in the ^1H NMR spectrum. Its ^{31}P NMR spectrum showed a singlet at 44.4 ppm compared with the 47.3 ppm in **5**.

The molecular structure of **13** is shown in Fig. 6. The Ni atom is η^5-bound to the cyclopentadienyl ring, σ-bound to one cage carbon atom, and coordinated to the P atom of the tricyclohexylphosphine in a trigonal planar geometry. The average $Ni–C_{ring}$/$Ni–C_{cage}$/Ni–P bond distances of 2.140(5)/1.949(5)/2.226(1) Å are very close to those of 2.145(6)/1.975(5)/2.210(1) Å in **5**. On the other hand, as revealed by

14	1.951(3)	2.084(4)	1.697	2.216(1) (X = P)	123.4	114.3(2)

[a]Cent: the centroid of the five-membered ring.

Scheme 2. Reactivity of cobalt and nickel complexes.

single-crystal X-ray analyses, **14** is a dinuclear complex (shown in Fig. 7), in which two trigonal planar [η^5:σ-$Me_2C(C_5H_4)(C_2B_{10}H_{10})$]Co moieties are connected by a $Ph_2PCH_2CH_2PPh_2$ linkage resulting in the formation of a 17 e^- complex for each Co atom. The average Co–C_{ring}/Co–C_{cage}/Co–P bond distances of 2.084(4)/1.951(3)/2.216(1) Å are very similar to the 2.085(3)/1.989(3)/2.207(1) Å observed in **4**.

The aforementioned results show that the coordinated PPh_3 in complexes **4** and **5** is labile and can be replaced by Lewis bases. However, they are inert toward alkynes, nitriles, and H_2. Complexes **9** and **10** are also very thermally stable. The inertness of the M–C_{cage} σ bonds in these late transition-metal complexes can be ascribed to the steric hindrance of the icosahedral carborane cage.[1e,1f]

Conclusion

A series of cobalt and nickel complexes bearing carbon-bridged cyclopentadienyl/indenyl/$C_5H_3CH_2CH_2NMe_2$–carboranyl

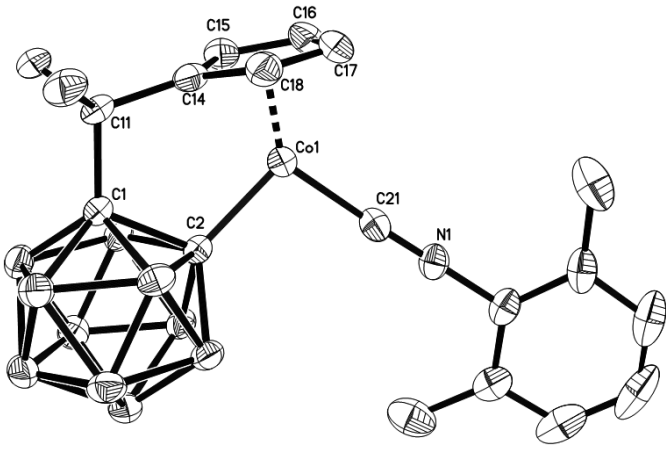
Fig. 4. Molecular structure of $[\eta^5{:}\sigma\text{-}Me_2C(C_5H_4)(C_2B_{10}H_{10})]Co(CNC_6H_3Me_2\text{-}2,6)$ (**9**).



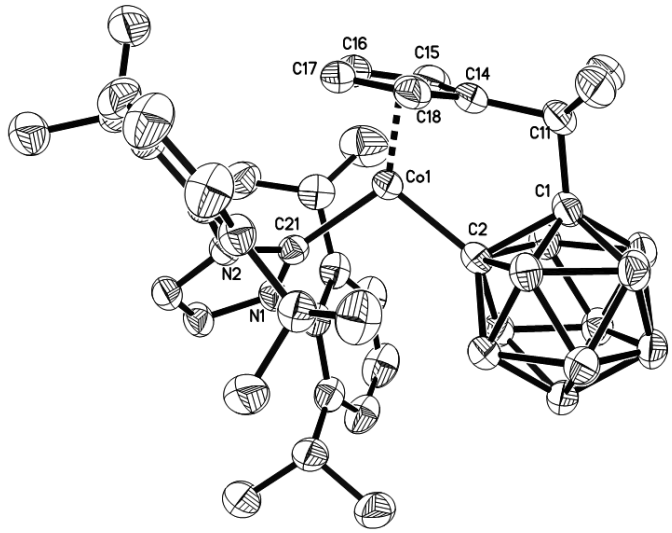


Fig. 5. Molecular structure of $[\eta^5{:}\sigma\text{-}Me_2C(C_5H_4)(C_2B_{10}H_{10})]Co[1,3\text{-}(2,6\text{-}i\text{-}Pr_2C_6H_3)_2C_3N_2H_2]$ (**11**).

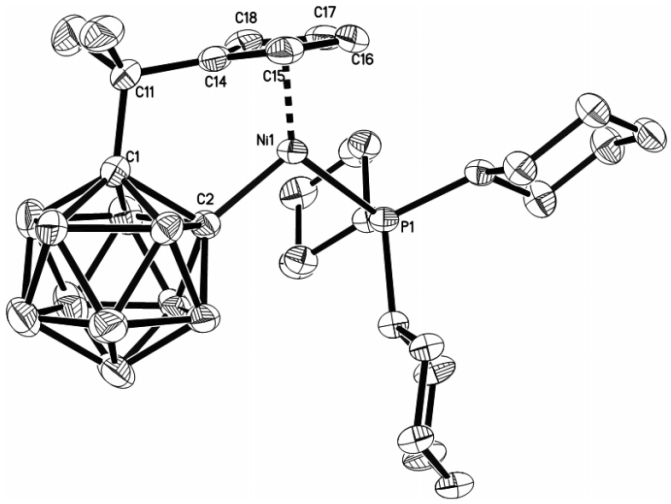
ligands were synthesized via salt metathesis reactions between the dilithium salts of these ligands and metal halides. They adopt a trigonal planar geometry, leading to a 17 e– cobalt and a 18 e– nickel complex, respectively. The phosphines in $[\eta^5{:}\sigma\text{-}Me_2C(C_5H_4)(C_2B_{10}H_{10})]M(PPh_3)$ are labile and can be displaced by other Lewis bases. However, the $M–C_{cage}$ bonds in these complexes are inert toward electrophiles such as alkynes, nitriles, isonitriles, and H_2 because of the steric hindrance of the carboranyl ligand.

Experimental section

General procedures

All experiments were performed under an atmosphere of dry dinitrogen with the rigid exclusion of air and moisture using standard Schlenk or cannula techniques or in a glovebox. All organic solvents were refluxed over sodium benzophenone ketyl for several days and freshly distilled prior to use. All chemicals were purchased from either Sigma-Aldrich or Acros Chemical Co. and used as received unless otherwise noted. $Me_2NCH_2CH_2Cl$,[29] $Me_2NCH_2CH_2C_5H_3CMe_2$,[30] $Me_2C(C_5H_5)(C_2B_{10}H_{11})$,[2d] $Me_2C(C_9H_7)(C_2B_{10}H_{11})$,[2e]

Fig. 6. Molecular structure of $[\eta^5{:}\sigma\text{-}Me_2C(C_5H_4)(C_2B_{10}H_{10})]NiPCy_3$ (**13**).



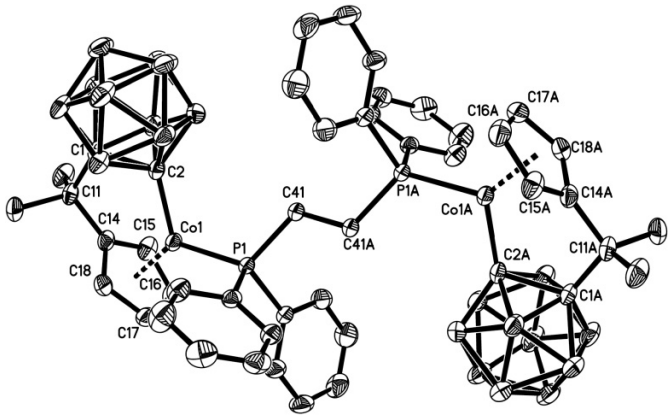


Fig. 7. Molecular structure of $\{[\eta^5{:}\sigma\text{-}Me_2C(C_5H_4)(C_2B_{10}H_{10})]Co\}_2(dppe)$ (**14**).

$NiCl_2(PPh_3)_2$,[31] and $CoCl_2(PPh_3)_2$[32] were prepared according to literature methods. Infrared spectra were obtained from KBr pellets prepared in the glovebox on a PerkinElmer 1600 Fourier transform spectrometer. ^1H and ^{13}C NMR spectra were recorded on a Bruker DPX 300 spectrometer at 300 and 75.5 MHz, respectively. ^{11}B and ^{31}P NMR spectra were recorded on a Varian Inova 400 spectrometer at 128 and 162 MHz, respectively. All chemical shifts were reported in δ units with references to the residual protons of the deuterated solvents for proton and carbon chemical shifts, to external $BF_3{\cdot}OEt_2$ (0.00 ppm) for boron chemical shifts, and to external 85% H_3PO_4 (0.00 ppm) for phosphorus chemical shifts. Elemental analyses were performed by the Shanghai Institute of Organic Chemistry, Chinese Academy of Sciences, China.

Preparation of $Me_2C(Me_2NCH_2CH_2C_5H_4)(C_2B_{10}H_{11})$ (3)

To a toluene/Et_2O (2:1) solution (15 mL) of $o\text{-}C_2B_{10}H_{12}$ (1.44 g, 10.0 mmol) was added a 1.60 mol/L solution of *n*-BuLi in hexane (12.6 mL, 20.2 mmol) at 0 °C, and the reaction mixture was warmed to room temperature and stirred for 2 h. The resulting $Li_2C_2B_{10}H_{10}$ solution was then cooled to 0 °C, to which was slowly added a solution

Can. J. Chem. Downloaded from www.nrcresearchpress.com by Renmin University of China on 09/02/12
For personal use only.

of dimethyl(dimethylaminoethyl)fulvene (2.12 g, 12.0 mmol) in a toluene/Et_2O (2:1) mixture (9 mL). The reaction mixture was maintained at 0 °C for 1 h, slowly warmed to room temperature, and then refluxed overnight. After removal of the solvent, Et_2O was added. The solution was quenched with a saturated NH_4Cl solution. The organic layer was separated and washed with water and then dried with anhydrous $MgSO_4$. After removal of the solvent by rotary evaporation, the residue was subjected to column chromatography on silica gel to give **3** as a yellow oil (2.66 g, 83%). IR (KBr, cm^{-1}) ν_{BH}: 2521 (vs). ^1H NMR ($CDCl_3$) δ: 6.25–5.70 (m, 3H) (vinylic *H*), 3.32 + 3.15 (s, 1H) (cage C*H*), 2.97 + 2.93 (s, 1H) (methylene *H* on Cp), 2.53 (m, 2H) ($CH_2CH_2N(CH_3)_2$), 2.43 (m, 2H) ($CH_2CH_2N(CH_3)_2$), 2.28 + 2.25 (s, 6H) ($CH_2CH_2N(CH_3)_2$), 1.58 + 1.50 (s, 6H) ($C(CH_3)_2$). $^{13}C\{^1H\}$ NMR ($CDCl_3$) δ: 150.1, 149.2, 133.2, 130.9, 127.1, 126.9, 126.3, 126.1 (vinylic *C*), 84.8 (cage *C*), 63.9, 63.4 ($N(CH_3)_2$), 59.5, 58.8 ($CH_2CH_2N(CH_3)_2$), 45.5, 42.9 ($CH_2CH_2N(CH_3)_2$), 44.3, 42.1 (methylene *C* on Cp), 42.1, 40.4 ($C(CH_3)_2$), 31.5, 30.8, 29.0, 28.3 ($C(CH_3)_2$). $^{11}B\{^1H\}$ NMR ($CDCl_3$): δ –3.9 (2B), –8.9 (2B), –11.3 (2B), –13.5 (4B). The ^1H and ^{13}C NMR data suggested that **3** was a mixture of isomers with the $Me_2NCH_2CH_2$ group bound to either the sp^2 or sp^3 carbon of the Cp ring.[2d]

Preparation of [η⁵:σ-Me₂C(C₅H₄)(C₂B₁₀H₁₀)]Co(PPh₃) (4)

An *n*-BuLi solution in *n*-hexane (1.60 mol/L, 1.25 mL, 2.0 mmol) was slowly added to a THF (10 mL) solution of $Me_2C(C_5H_5)(C_2B_{10}H_{11})$ (0.25 g, 1.0 mmol) at –78 °C and the mixture was warmed up to room temperature and then stirred for 3 h. The resulting solution was slowly added to a THF suspension (10 mL) of $CoCl_2(PPh_3)_2$ (0.65 g, 1.0 mmol) at room temperature, and the reaction mixture was stirred overnight. After removal of the solvent, the residue was extracted with Et_2O (2 × 25 mL). The Et_2O solution was concentrated to ~10 mL. Complex **4** was isolated as brown crystals after this solution stood at room temperature for 2 days (0.50 g, 87%). IR (KBr, cm^{-1}) ν_{BH}: 2579 (vs). Anal. calcd for $C_{28}H_{35}B_{10}CoP$ (**4**): C 59.04, H 6.19; found: C 59.08, H 6.61.

Preparation of [η⁵:σ-Me₂C(C₅H₄)(C₂B₁₀H₁₀)]Ni(PPh₃) (5)

This complex was prepared as green crystals from $Me_2C(C_5H_5)(C_2B_{10}H_{11})$ (0.25 g, 1.0 mmol), *n*-BuLi (1.60 mol/L, 1.25 mL, 2.0 mmol), and $NiCl_2(PPh_3)_2$ (0.65 g, 1.0 mmol) in THF (20 mL) using the same procedure as reported for **4**; yield: 0.53 g (93%). IR (KBr, cm^{-1}) ν_{BH}: 2581 (vs). ^1H NMR (C_6D_6) δ: 7.62 (m, 6H), 7.01 (m, 9H) (C_6H_5), 5.96 (br, 2H), 3.70 (br, 2H) (C_5H_4), 1.39 (s, 6H) ($(CH_3)_2C$). $^{13}C\{^1H\}$ NMR (C_6D_6) δ: 134.8, 134.7, 131.0, 128.9 (C_6H_5), 99.6, 88.2 (C_5H_4), 66.3 (cage *C*), 41.3 ($(CH_3)_2C$), 32.3 ($(CH_3)_2C$). $^{11}B\{^1H\}$ NMR (C_6D_6) δ: –3.5 (2B), –7.0 (3B), –9.8 (5B). $^{31}P\{^1H\}$ NMR (C_6D_6) δ: 47.3. Anal. calcd for $C_{28}H_{35}B_{10}NiP$ (**5**): C 59.07, H 6.20; found: C 58.51, H 6.25.

Preparation of [η⁵:σ-Me₂C(C₉H₆)(C₂B₁₀H₁₀)]Co(PPh₃) (6)

This complex was prepared as brown crystals from $Me_2C(C_9H_7)(C_2B_{10}H_{11})$ (0.30 g, 1.0 mmol), *n*-BuLi (1.60 mol/L, 1.25 mL, 2.0 mmol), and $CoCl_2(PPh_3)_2$ (0.65 g, 1.0 mmol) in THF (20 mL) using the same procedure as reported for **4**; yield: 0.49 g (79%). IR (KBr, cm^{-1}) ν_{BH}: 2593 (vs). Anal. calcd for $C_{32}H_{37}B_{10}CoP$ (**6**): C 62.03, H 6.02; found: C 62.30, H 6.17.

Preparation of [η⁵:σ-Me₂C(C₉H₆)(C₂B₁₀H₁₀)]Ni(PPh₃) (7)

This complex was prepared as green crystals from $Me_2C(C_9H_7)(C_2B_{10}H_{11})$ (0.30 g, 1.0 mmol), *n*-BuLi (1.60 mol/L, 1.25 mL, 2.0 mmol), and $NiCl_2(PPh_3)_2$ (0.65 g, 1.0 mmol) in THF (20 mL) using the same procedure as reported for **4**; yield: 0.43 g (69%). IR (KBr, cm^{-1}) ν_{BH}: 2581 (vs). ^1H NMR (C_6D_6) δ: 7.75 (d, J = 8.0 Hz, 1H), 6.78 (t, J = 8.0 Hz, 2H), 6.45 (d, J = 3.6 Hz, 1H), 5.13 (d, J = 8.0 Hz, 1H), 3.88 (t, J = 3.6 Hz, 1H) (C_9H_6), 7.32 (m, 6H), 6.99 (m, 9H) (C_6H_5), 1.60 (s, 3H), 1.54 (s, 3H) ($(CH_3)_2C$). $^{13}C\{^1H\}$ NMR (C_6D_6) δ: 135.0, 135.8, 134.4, 132.8, 132.7, 131.9, 130.9, 129.6, 126.6, 125.3, 123.8, 121.9, 117.3, 106.5 (C_9H_6 + C_6H_5), 64.5 (cage *C*), 44.1 ($(CH_3)_2C$), 32.3, 31.3 ($(CH_3)_2C$). $^{11}B\{^1H\}$ NMR (C_6D_6) δ: –3.2 (2B), –6.4 (3B), –9.3 (5B). $^{31}P\{^1H\}$ NMR (C_6D_6) δ: 33.8. Anal. calcd for $C_{32}H_{37}B_{10}NiP$ (**7**): C 62.05, H 6.02; found: C 62.07, H 5.80.

Preparation of [η⁵:σ-Me₂C(C₅H₃CH₂CH₂NMe₂)(C₂B₁₀H₁₀)]Ni(PPh₃) (8)

This complex was prepared as green crystals from $Me_2C(C_5H_4CH_2CH_2NMe_2)(C_2B_{10}H_{11})$ (0.32 g, 1.0 mmol), *n*-BuLi (1.60 mol/L, 1.25 mL, 2.0 mmol), and $NiCl_2(PPh_3)_2$ (0.65 g, 1.0 mmol) in THF (20 mL) using the same procedure as reported for **4**; yield: 0.40 g (63%). IR (KBr, cm^{-1}) ν_{BH}: 2587 (vs). ^1H NMR (C_6D_6) δ: 7.69 (m, 6H), 7.02 (m, 9H) (C_6H_5), 6.07 (d, J = 1.5 Hz, 1H), 5.87 (s, 1H), 3.76 (d, J = 2.4 Hz, 1H) (C_5H_3), 2.11 (m, 2H) ($CH_2CH_2NMe_2$), 1.90 (m, 2H) ($CH_2CH_2NMe_2$), 1.86 (s, 6H) ($N(CH_3)_2$), 1.45 (s, 3H), 1.40 (s, 3H) ($(CH_3)_2C$). $^{13}C\{^1H\}$ NMR (C_6D_6) δ: 135.5, 135.4, 134.8, 132.5, 132.1, 131.1, 109.8, 99.4, 97.7 (C_6H_5 + C_5H_3), 88.0 (cage *C*), 66.5 ($CH_2CH_2NMe_2$), 45.9 ($N(CH_3)_2$), 41.5 ($CH_2CH_2NMe_2$), 32.5 ($C(CH_3)_2$), 31.3, 30.7 ($C(CH_3)_2$). $^{11}B\{^1H\}$ NMR (C_6D_6) δ: –3.6 (2B), –6.8 (3B), –9.5 (5B). $^{31}P\{^1H\}$ NMR (C_6D_6) δ: 36.5. Anal. calcd for $C_{32}H_{44}B_{10}NNiP$ (**8**): C 60.01, H 6.92, N 2.19; found: C 60.35, H 6.83, N 2.06.

Preparation of [η⁵:σ-Me₂C(C₅H₄)(C₂B₁₀H₁₀)]Co(2,6-Me₂C₆H₃NC) (9)

To a toluene (5 mL) solution of [η⁵:σ-$Me_2C(C_5H_4)(C_2B_{10}H_{10})$]$Co(PPh_3)$ (**4**; 0.29 g, 0.50 mmol) was added 2,6-$Me_2C_6H_3NC$ (0.07 g, 0.50 mmol) at room temperature. The reaction mixture was stirred at room temperature overnight. After removal of the solvent, the residue was extracted with Et_2O (10 mL × 2). The combined Et_2O solutions were concentrated to ~5 mL. Complex **9** was isolated as brown crystals after this solution stood at room temperature for 1 day (0.17 g, 77%). IR (KBr, cm^{-1}) ν_{BH}: 2575 (vs). Anal. calcd for $C_{19}H_{29}B_{10}CoN$ (**9**): C 52.05, H 6.67, N 3.19; found: C 52.26, H 6.70, N 3.42.

Preparation of [η⁵:σ-Me₂C(C₅H₄)(C₂B₁₀H₁₀)]Ni(2,6-Me₂C₆H₃NC) (10)

This complex was prepared as green crystals from [η⁵:σ-$Me_2C(C_5H_4)(C_2B_{10}H_{10})$]$Ni(PPh_3)$ (**5**; 0.29 g, 0.50 mmol) and 2,6-$Me_2C_6H_3NC$ (0.07 g, 0.50 mmol) in toluene (5 mL)

$^{11}B\{^1H\}$ NMR (C_6D_6) δ: –2.4 (5B), –6.0 (2B), –8.9 (3B). $^{31}P\{^1H\}$ NMR (C_6D_6) δ: 44.4. Anal. calcd for $C_{30}H_{58}B_{10}NiO_{0.5}P$ (**13** + $0.5Et_2O$): C 57.69, H 9.36; found: C 58.09, H 9.11.

Preparation of {[η⁵:σ-Me₂C(C₅H₄)(C₂B₁₀H₁₀)]Co}₂(dppe) (14)

This complex was prepared as brown crystals from [η⁵:σ-$Me_2C(C_5H_4)(C_2B_{10}H_{10})$]Co($PPh_3$) (**4**; 0.29 g, 0.50 mmol) and dppe (0.10 g, 0.25 mmol) in toluene (5 mL) using the same procedure as reported for **13**; yield: 0.19 g (62%). IR (KBr, cm^{-1}) ν_{BH}: 2573 (vs). Anal. calcd for $C_{46}H_{64}B_{20}Co_2P_2$ (**14** + $2Et_2O$): C 54.54, H 6.37; found: C 54.24, H 6.25.

X-ray structure determination

All single crystals were immersed in Paraton-N oil and sealed under N_2 in thin-walled glass capillaries. Data were collected at 293 K on a Bruker SMART 1000 CCD diffractometer using Mo Kα radiation. An empirical absorption correction was applied using the SADABS program.[33] All structures were solved by direct methods and subsequent Fourier difference techniques and refined anisotropically for all non-hydrogen atoms by full-matrix least-squares calculations on F^2 using the SHELXTL program package.[34] All hydrogen atoms were geometrically fixed using the riding model. Molecular structures of **13** and **14** showed the solvation of half and two Et_2O molecules, respectively. For the noncentrosymmetric structures **9** and **10**, the appropriate enantiomorph of **9** was chosen by refining Flack's parameter χ toward zero;[35] however, the appropriate enantiomorph of **10** was unable to be chosen as its $\chi \approx 0.5$ after refinement. Crystal data and details of data collection and structure refinements were given in Tables 2 and 3 (X-ray data can be found in the Supplementary data).

Supplementary data

Supplementary data are available for this article through the journal Web site at http://nrcresearchpress.com/doi/suppl/10.1139/v11-115. CCDC 823250–823260 contain the X-ray data in CIF format for this manuscript (compounds **4**–**14**). These data can be obtained, free of charge, via http://www.ccdc.cam.ac.uk/cgi-bin/catreq.cgi (Or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1Ez, UK; fax +44 1223 336033; or e-mail deposit@ccdc.cam.ac.uk).

Acknowledgment

The work described in this article was supported by grants from the Research Grants Council of the Hong Kong Special Administration Region (Project No. 404609) and Direct Grant (Project No. 2060407).

Abstract: Low-temperature (293–60 K) Raman spectra have been recorded in the 3500–50 cm^{-1} region for the crystalline *tert*-butylisocyanide (CNBu-t) complexes, $Cr(CO)_5$(CNBu-*t*) (**I**) and *cis*-$Cr(CO)_4$(CNBu-*t*)$_2$ (**II**). Several of the factor group splittings that are predicted for the ν_{CO}, ν_{CN}, ν_{CrC}, ν_{CrCN} and δ_{CrCO} modes on the basis of the $P2_1/a$ (C_{2h}^5) (**I**) and *Pccn* (D_{2h}^{10}) (**II**) crystallographic symmetries can be detected at very low temperatures. No phase transitions are observed for either complex throughout the temperature range investigated.

Key words: low-temperature Raman spectra, *tert*-butylisocyanide complexes, factor group analysis.

Résumé : Opérant à basse température (293–60 K), on a mesuré les spectres Raman dans la région de 3500–50 cm^{-1} de complexes cristallins de l'isocyanure *tert*-butyle (CNBu-*t*), soit le $Cr(CO)_5$(CNBu-*t*) (**I**) et le *cis*-$Cr(CO)_4$(CNBu-*t*)$_2$ (**II**). À des températures très basses, il est possible de détecter des dédoublements de facteur de groupe qui sont prédits sur la base des symétries cristallographiques $P2_1/a$ (C_{2h}^5) (**I**) et *Pccn* (D_{2h}^{10}) (**II**) pour les modes ν_{CO}, ν_{CN}, ν_{CrC}, ν_{CrCN} et δ_{CrCO}. Pour toute la plage de températures étudiée, il n'a pas été possible de détecter des transitions de phases pour l'un ou l'autre des complexes.

Mots-clés : spectres Raman à basse température. complexes de l'isocyanure de *tert*-butyle, analyse du facteur de groupe.

[Traduit par la Rédaction]

Introduction

Isocyanide ligands, CNR (R = alkyl or aryl), have attracted the attention of organometallic chemists for many years because of the close similarity of their bonding properties to those of the CO ligand. The pioneers in this organometallic field were Bigorgne and Bouquet,[2] whose initial isocyanide work with nickel and iron carbonyls was reported in the first volume of the *Journal of Organometallic Chemistry* in 1963. Isocyanides are considered to be better σ-donors but poorer π-acceptors than is CO, this conclusion being reached on the basis of molecular spectroscopic measurements on complexes such as the mixed carbonyl-isocyanide complexes, $Re_2(CO)_{10-n}(CNR)_n$ ($n = 1$–4)[3] and $M(CO)_{6-n}$(CNBu-*t*)$_n$ (M = Cr, Mo, W; Bu = *tert*-butyl; n = 1–3), at ambient temperature[4,5] and also under high external pressures.[6] There are now well-established procedures for the synthesis of these types of mixed carbonyl-isocyanide complexes.[7] In the cases of $Cr(CO)_5$(CNBu-*t*) (**I**) and *cis*-$Cr(CO)_4$(CNBu-*t*)$_2$ (**II**), evidence has been presented for pressure-induced, structural phase transitions occurring at about 11 and 6 kbar, respectively.[6] Since the unit cells of crystalline solids are known to contract dramatically upon compression and also with decreasing temperature, we decided it would be worthwhile investigating the low-temperature Raman spectra of these two complexes to see whether or not any related structural phase transitions would occur as the temperature was lowered. A further interest was to see if any factor group splittings could be detected in the spectra, and, if so, could these splittings be correlated to the known crystallographic space groups of the crystalline materials, i.e., complex **I** (monoclinic $P2_1/a$, C_{2h}^5)[8] and complex **II** (orthorhombic *Pccn*, D_{2h}^{10}).[9]

Experimental

Complexes **I** and **II** were prepared and purified by the literature methods.[5] All the solvents used in the syntheses were of reagent grade quality. Raman spectra were recorded at 1 cm^{-1} resolution on an Instruments S.A. U-1000 spectrometer. The 514.5 nm green line of a Spectra-Physics model 164 5-W argon-ion laser was used to excite the spectra; the power levels used were typically about 100 mW to avoid sample burning. The organometallic samples were sealed in glass capillary tubes and mounted onto the cold finger of a Displex closed-cycle helium cryostat fitted with a DE-202 expander and coupled to a HC-2D compressor for the low-temperature measurements. The temperature of the cryostat was measured and maintained with the aid of a 9650 Digital temperature

indicator–controller. Raman spectra were measured at about every 20 K in both the cooling and heating directions.

Results and discussion

The low-temperature Raman spectra of complexes **I** and **II** showed no evidence of any phase transitions down to 60 K. For the spectroscopic C_{2h}^5 space group of complex **I**,[8] the correlation between the local C_{4v} molecular, C_1 site and C_{2h} factor group symmetries indicates that the original Raman-active a_1 and b_1 modes would be expected to split into doublets, while the doubly degenerate *e* modes should give rise to quartets in the spectra. In the ν_{CN} and ν_{CO} region (2200–1800 cm^{-1}), none of the modes is split further, even at 60 K. There is one peak, however, which initially appears at 2008 cm^{-1} at ca. 220 K that gains intensity as the temperature is decreased. A similar peak appeared in the high-pressure Raman spectra at ca. 5 kbar.[6] This new peak is attributed to a combination of the a_1 ν_{CO} mode at 1917 cm^{-1} and the *e* δ_{CCrC} mode at 95 cm^{-1}. The temperature dependence of the intensity of the combination mode suggests that it is in Fermi resonance with the nearby *e* ν_{CO} fundamental at 1953 cm^{-1}.

On the basis of normal coordinate calculations for the closely related $M(CO)_6$ and $[M(CN)_6]^{3-}$ species,[10] the δ_{CrCO}, δ_{CrCN}, $\nu_{Cr\text{-}CO}$, and $\nu_{Cr\text{-}CN}$ modes of the mixed carbonyl–*tert*-butylisocyanide complexes should appear in the 700–300 cm^{-1} region. Specific vibrational assignments for this type of mixed ligand derivative are difficult because of the significant vibrational coupling that occurs. The Cr-CO and Cr-CN stretching modes are expected at lower wavenumbers than are the linear δ_{CrCO} and δ_{CrCN} bending modes. Moreover, since the Cr-CO force constants are larger than are those of Cr-CN, the δ_{CrCO} and $\nu_{Cr\text{-}CO}$ modes should appear at higher wavenumbers than do the δ_{CrCN} and $\nu_{Cr\text{-}CN}$ modes. Because of the vibrational coupling, however, substantial band overlap is almost certainly expected.

In the case of the low-energy Raman spectrum of complex **I**, the spectroscopic predictions are four $\nu_{Cr\text{-}CO}$, six δ_{CrCO}, one $\nu_{Cr\text{-}CN}$, and one δ_{CrCN} mode. A factor group analysis reveals that ten $\nu_{Cr\text{-}C(O\ and\ N)}$ and eighteen $\delta_{CrC(O\ and\ N)}$ modes would be expected in total. Twelve Raman-active bands are actually detected in the low-temperature Raman spectra of complex I. According to Farona et al.,[11] coupling between the $\nu_{Cr\text{-}CO}$, δ_{CrCO}, $\nu_{Cr\text{-}CN}$, and δ_{CrCN} vibrational modes leads to markedly reduced intensities for the $\nu_{Cr\text{-}CN}$ and δ_{CrCN} modes. The Raman pattern for complex **I** closely resembles those of the pentacarbonyl complexes, $Cr(CO)_5(CS)$ and $Mn(CO)_5X$ (X = Cl, Br, I). The four δ_{CrCO} modes are weak. In addition, two very weak peaks at ca. 372 and 438 cm^{-1}, which can only be seen clearly in the low-temperature spectra, are assigned to $\nu_{Cr\text{-}CN}$ and δ_{CrCN}, respectively. The strong b_1 $\nu_{Cr\text{-}CO}$ peak at 394 cm^{-1}, evidenced a shoulder initially at ca. 200 K, which gradually separated into a single peak at 403 cm^{-1}. This new band is attributed to a $\nu_{Cr\text{-}CO}$ mode. The two very strong bands at 96 and 107 cm^{-1} in the room temperature Raman spectrum are associated with the *e* and a_1 δ_{CCrC} modes, respectively. Another δ_{CCrC} mode (a_1) at 137 cm^{-1} is clearly resolved at 180 K, at which temperature the strong δ_{CCrC} band at 107 cm^{-1} has sharpened considerably. This latter mode is appreciably more temperature sensitive and shifts to much higher wavenumbers at lower temperatures than does the δ_{CCrC} mode at 95 cm^{-1}. At 150 K the 107 cm^{-1} mode has shifted to 113 cm^{-1}, while at 130 K it is split into two components at 111 and 115 cm^{-1}. Finally, three lattice modes become detectable at low temperatures at 82, 62 and 51 cm^{-1}, since the Rayleigh line has become much sharper (Fig. 1).

In the case of complex **II,** the observed vibrational bands obey the selection rules for C_{2v} local molecular symmetry very well in the ν_{CO} and ν_{CN} region (2200–1800 cm^{-1}). According to a factor group analysis for C_{2v} local symmetry, C_1 site symmetry, and C_{2h} crystal symmetry, each of the Raman-active ν_{CO}, $\nu_{Cr\text{-}CO}$, ν_{CN}, and $\nu_{Cr\text{-}CN}$ modes with a_1, b_1, and b_2 symmetry should split into doublets in the solid-state spectra. At ambient temperature, there is some splitting detected in the ν_{CO} bands, but none is observed for the ν_{CN} modes (Fig. 2). In the 2200–1800 cm^{-1} region, the a_1 and b_2 ν_{CN} modes begin to split into doublets at ca. 200 K, while all the ν_{CO} modes exhibit additional splitting upon lowering the temperature further. It is probable that the ν_{CN} modes do not exhibit any significant factor group splitting at ambient

conditions because of the large thermal motions of the *tert*-butyl groups. Methyl groups in molecular crystals are well-known to have large rotational motions even at ca. 100 K.[12] When the temperature of complex **II** is lowered or when external pressure is applied, however, the thermal motions of the *tert*-butyl group presumably become more restricted, thus obliterating the expected factor group splittings. The ν_{CN} modes are much more temperature sensitive than are the ν_{CO} modes — larger shifts to higher wavenumbers are observed upon decreasing the temperature. In the earlier high-pressure work, the ν_{CN} modes displayed much higher pressure dependences than did the ν_{CO} modes.[6] These observations reflect the changes in electron density distribution between the Cr atom and the ligands at low temperatures and high pressures.

Most vibrational modes in molecular crystals shift to higher wavenumbers when the crystal lattices and molecular bond distances shrink at lower temperatures. In our case, therefore, the CO, CN, Cr-CO, and Cr-CN force constants would be expected to increase as the temperature is lowered. However, as originally pointed out by the Adams group,[13,14] decreasing the M–CO bond distance in a metal carbonyl complex results in increased π-backbonding between the metal M and the π*-orbitals of the CO ligands. Any increase in the extent of π-backbonding will lead to a reduction in the force constants of the CO bonds. Consequently, the observed ν_{CO} band shifts are the net result of two opposing effects. In our case, the CNBu-*t* ligand is considered to be a weaker π-acceptor than is CO, so there should be less π-backbonding in the Cr–CN bonds than in the Cr–CO bonds when the Cr-ligand distances are reduced by either low temperatures or increasing pressure. The CN bond will not be weakened as much as the CO bonds. In addition, the electron-donating *tert*-butyl group, $-C(CH_3)_3$, should donate more electron density through its σ-framework to the CN ligand when the Cr–CN bond distance is being decreased as the result of the low-temperature or high-pressure effects.

In the low-energy region, two strong $\nu_{Cr\text{-}CO}$ bands at 400 and 478 cm^{-1} and a δ_{CrCO} band at 660 cm^{-1} are split into two components. Many other weak peaks, which could be assigned as ν_{CrCN} or δ_{CrCN} and modes, are clearly observed as the temperature is lowered. One strong δ_{CCrC} mode at 103 cm^{-1} also exhibits distinct components at low temperature.

In conclusion, (*i*) the low-temperature Raman spectra of complexes **I** and **II** do exhibit some of the splittings consistent with those predicted from the factor group analyses, and (*ii*) there are no phase transitions detected down to about 60 K.

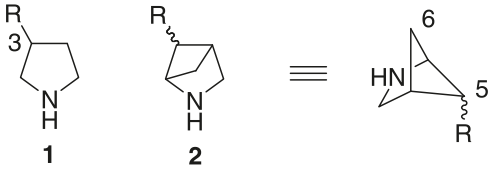
Abstract: Oxidation of the title bromoalcohol provided the strained ketone, 5-bromo-6-oxo-2-azabicyclo[2.1.1]hexane. Additions of nucleophiles to either this or the debrominated ketone have been used to introduce 5(6)-*syn*-alkyl and aryl groups, 5(6)-alkylidene linkages, and 5(6)-*anti*-alkyl and acyl substituents. Facial selectivity is for additions to the 6-bromo-5-ketone and 5-alkylidene azabicycles to occur from the face syn to the nitrogen atom. The bromine atom of the title alcohol has also been replaced by a 6-*anti*-(1-hydroxyethyl) substituent using a directed radical addition process. The stereoselective functionalization reactions expand the range of available methano-bridged pyrrolidines.

Key words: methanopyrrolidine, 6-oxo-2-azabicyclo[2.1.1]hexane, directed radical addition, facial selectivity and nucleophilic addition, strained ketone.



Résumé : L'oxydation du bromoalcool mentionné dans le titre conduit à une cétone tendue, le 5-bromo-6-oxo-2-azabicyclo [2.1.1]hexane. L'addition de nucléophiles aussi bien à ce produit qu'à la cétone débromée a été utilisée pour introduire des groupes 5(6)-*syn*-alkyles ou aryles, des liaisons 5(6)-alkylidènes et des substituants 5(6)-*anti*-alkyles ou acyles. La sélectivité faciale conduit à des additions sur les azabicycles avec des substituants 6-bromo et 5-cétone ou une chaîne 5-alkylidène qui se produisent par la face syn par rapport à l'atome d'azote. On a aussi remplacé l'atome de brome de l'alcool mentionné dans le titre par un substituant 6-*anti*-(1-hydroxyéthyle) en faisant appel à un processus d'addition radicalaire orienté. Les réactions de fonctionnalisations sélectives étendent la plage de pyrrolidines à pont méthano disponibles.

Mots-clés : méthanopyrrolidine, 6-oxo-2-azabicyclo[2.1.1]hexane, addition radicalaire orientée, sélectivité faciale, addition nucléophile, cétone tendue.

[Traduit par la Rédaction]

Introduction

Pyrrolidines **1** substituted with alkyl,[1,2] aryl,[3] or acyl[4] substituents at the 3-position, β to the nitrogen, are found in a number of molecules with interesting biological or structural properties. A 5-substituted 2-azabicyclo[2.1.1]hexane ring system (**2**) is a mimic of a pyrrolidine that has been constrained to exist in a single conformation in which a 2,4-methylene bridge forces the substituted C^{β} atom to be puckered out of the plane described by the other four atoms of its pyrrolidine ring. As part of a strategy to incorporate key pharmacophoric units into inflexible structures,[5] practical methods to introduce substituents in defined spatial orientations at one or both positions $C_{5(6)}$ of azabicycles such as **2** are of interest. Such molecules may prove to be valuable scaffolds for drug discovery and for incorporation into novel β-amino acids.[6]

2-Azabicyclo[2.1.1]hexanes **2** with alkyl, acyl, or aryl side chains attached at $C_{5(6)}$ are known, but effective syntheses for 5(6)-syn orientation of these groups predominate. Examples where only the C_5 bridge and the nitrogen atom have substituents are shown as follows.[7] The synthetic approaches to introduce alkyl groups include skeletal rearrangement (R = 6-*syn*-methyl, with heteroatoms in the other methylene bridge);[8] ring closure and subsequent manipulation (R = 5-*syn*-CH_2OH **3a** and R = 6-*syn*-CH_2NH_2, with a heteroatom in the 5-bridge).[9] There are photochemical cycloaddition

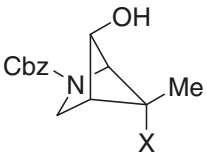
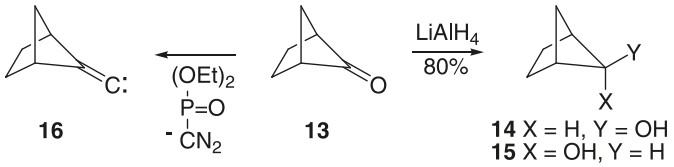
routes that introduce R/H = Me_2, along with a 1-aryl group;[10] R = $C(OR)_3$ or CH_2SiMe_3 along with acyl in the other methylene bridge;[11,12] and *R* = syn- or anti-oriented cyclohexane rings fused from C_5 to C_4 or cyclohexanone rings fused from C_5 to C_1.[13] Recently, alkylester **4b**, accompanied by some extended chain addition products, was prepared by methyl acrylate addition to radicals generated at C_5 from either a 5-*syn*-acid (**5b**) or 5-iodo-2-azabicyclo[2.1.1]hexane.[14] Phenyl substitution (R = 6-*syn*-Ph along with a 5-*anti*-heteroatom) was effected via a rearrangement route,[8] and also a 6:1 *syn*/*anti*-Ph mixture of **6b** and **7** were synthesized using a lead tetraacetate-initiated decarboxylative radical arylation of acid **5b**.[14] For 5-*syn*/*anti*-carbonyl substitution several photochemical syntheses introduced a 5-acetyl group[11,12,15] or 1,5-fused cyclohexanone ring systems.[16] Three routes to 5-carboxy azabicycles have been described. One somewhat lengthy route to the R = 5-*syn*-acid **5a** involves ring closure and subsequent modification of substituents.[9] A 6-acetyl-5-ester, of undefined stereochemistry, has been prepared from an azabicycle with an R = 5-*syn*-orthoester and a 6-*syn*-acetyl substituent using a photochemical ring closure sequence and subsequent synthetic modification of the orthoester.[11] We have described[17] a shorter approach to the preparation of R = 5-*syn*-**5b** and 5-*anti*-carboxy-2-azabicyclo[2.1.1]hexane (**8b**), useful for multigram quantities of the 5-*syn*-acid **5b**, from readily prepared and separable (9:1) 5-*syn*/*anti*-acetyl-2-azabicyclo[2.1.1]hexanes **9b/10** first described by Kwak and Winkler.[15] There remains a need for stereoselective synthetic routes that introduce 5-*anti*-alkyl and 5-*anti*-carboxy substituents onto 2-azabicyclo[2.1.1]hexanes.

A second synthetic challenge is the preparation of 2-azabicyclo[2.1.1]hexanes with functional groups and substituents on the same methylene bridge. There are two examples of such structures. These are the 6-*syn*-fluoro-6-*anti*-methyl-5-*anti*-alcohol **11** and the 6-*syn*-hydroxy-6-*anti*-methyl-5-*anti*-alcohol **12**.[8] There are no similar structures reported with the reversed stereochemistry at the tertiary carbon.



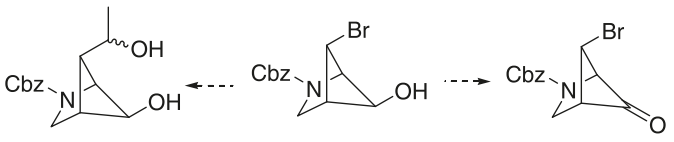
a Z = Cbz
b Z = BOC



3 R = CH_2OH
4 R = $CH_2CH_2CO_2Me$
5 R = COOH
6 R = Ph
9 R = $COCH_3$

7 R = Ph
8 R = COOH
10 R = $COCH_3$

11 X = F
12 X = OH

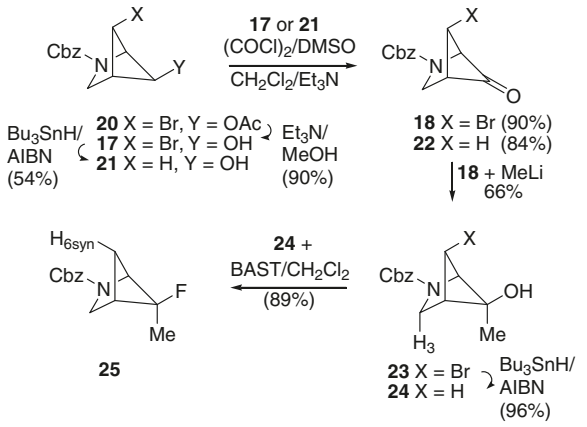


A disconnection of tertiary alcohol **12** suggested that an azabicyclic ketone might be a useful synthon for introduction of substituents at the C_5 position, although the stereochemistry of the addition to the ketone is an issue.[5a] The corresponding carbocycle (bicyclo[2.1.1]hexan-5-one **13**) has been synthesized[18] in an optimized 54% yield by alcohol oxidation,[18c] but only two nucleophilic addition reactions have been reported. Reduction of **13** gives and 82:18 exo/endo mixture of alcohols **14/15** in which the major product derives from hydride attack on the side of the ethylene bridge.[18a,18b] The only carbon nucleophile reported for reaction with ketone **13** was diethyl(diazomethyl)phosphonate; the transient alkylidene carbene **16** from this reaction does not retain evidence for the initial facial selectivity of nucleophilic attack.[19]

16 **13**

14 X = H, Y = OH
15 X = OH, Y = H

In this paper we show how a readily available pyridine-derived alcohol **17** can be oxidized to ketone **18**, and how subsequent carbonyl addition reactions provide solutions to the stereochemical problems outlined previously.[20] Stereocontrolled syntheses of tertiary alcohols with 5-*syn*-alkyl or 5-*syn*-aryl substituents, 5-*anti*-alkyl and 5-*anti*-carboxy compounds, as well as 5-*exo*-alkylidenes will be described. Additionally, we show how the bromoalcohol **17** can be used to incorporate a 6-*anti*-alkyl group onto the 2-azabicyclo [2.1.1]hexane skeleton to give diol **19** using a radical trapping process. Since 5(6)-substituents in these azabicycles are often compatible with subsequent introduction of substituents at the C_1 and C_3 positions, the functional group modifications described herein should prove useful in the preparation of more highly functionalized 5-substituted 2-azabicyclo[2.1.1]hexanes.[21]



19 **17** **18**

Results and discussion

Hydrolysis of the bromoacetate **20**, prepared in three steps from pyridine,[20] afforded bromoalcohol **17** (90%), which was oxidized using Swern conditions (oxalyl chloride / DMSO / CH_2Cl_2 / Et_3N) to give the bromoketone **18** in 90% yield.[22] The ketone showed an IR carbonyl band at 1818 cm^{-1}. Debromination of bromoalcohol **17** using tributyltin hydride[23] gave alcohol **21** that was also oxidized to ketone **22** using the Swern procedure. The ketone **22** has an IR carbonyl stretch band at 1809 cm^{-1}. The parent carbocycle **13** has its carbonyl band at 1799 cm^{-1}.[18a]

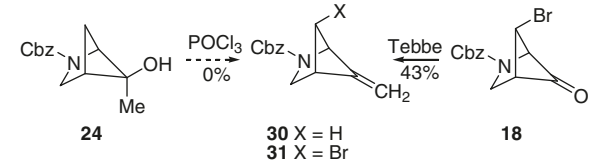
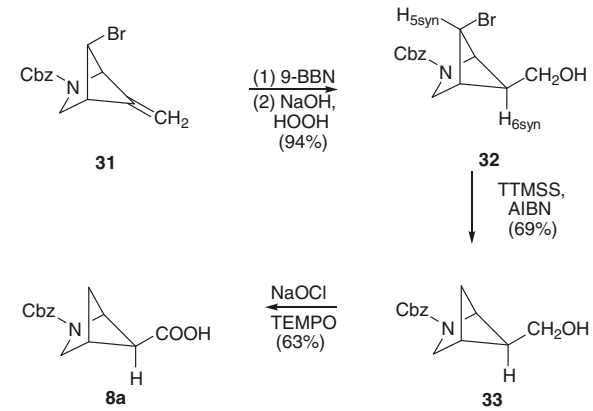
[1]

Addition of MeLi to ketone **18** afforded a single adduct **23** that was shown to have 6-*syn*-Me stereochemistry by NOE interaction of the methyl and an H_3 proton. Reductive removal of the bromine of **23** using tributyltin hydride[23] gave the alcohol **24**. Notably, the 5-*syn*-methyl and 5-*anti*-hydroxyl groups in **23** and **24** have complementary (inverted) stereochemistry relative to the tertiary alcohol **12** formed by a rearrangement pathway. The alcohol **24** was converted to the fluoride **25** by reaction with bis(2-methoxylethyl)aminosulfur trifluoride (BAST).[24] The absence of W-coupling between the 5-*anti*-fluorine atom and H_{6syn} enabled a stereochemical assignment for fluoride **25** that is consistent with precedent for retention of stereochemistry for an *anti*-alcohol displacement in this azabicyclic ring system.[25]



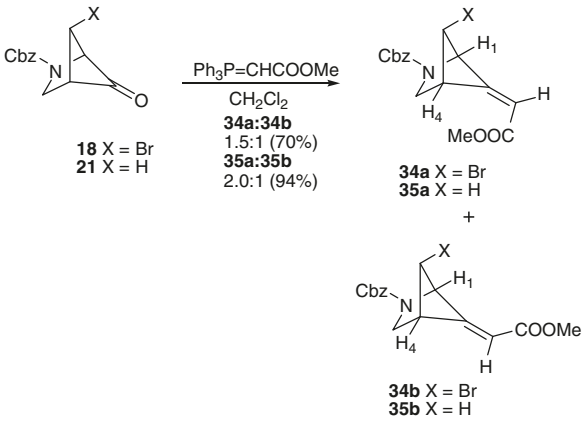
Addition of phenylmagnesium bromide or 2-chloro-pyridyl-5-lithium[26] to bromoketone **18** provided the arylalcohols **26** or **27**, respectively. The stereochemical assignment for both **26** and **27** were shown to be 6-*syn*-aryl by NOE interaction between H_2 of the respective aryl and pyridyl rings and H_3. The bromine atoms of **26** and **27** were reductively removed to give alcohols **28** and **29**; in the latter case with retention of the pyridyl chlorine atom. The syn relationship of the nitrogen atom in the attached chloropyridyl group at C_6 and the β-amino group embedded in the bicyclic ring is found also in epibatidine.[5a]

[2]



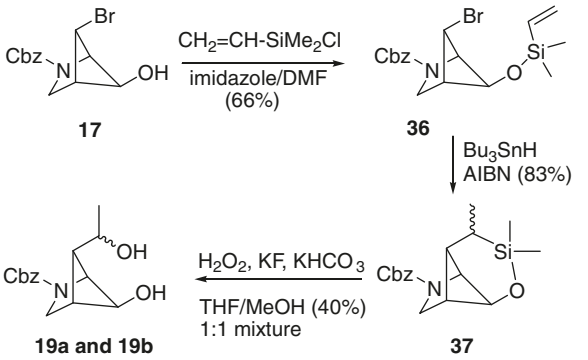
As part of an effort to prepare β-amino acids based on conformationally constrained pyrrolidines,[6] we desired a stereocontrolled synthetic route to the 5-*anti*-carboxylic acid **8b**. Toward this end, we attempted, unsuccessfully, to prepare 5-*exo*-methylene derivative **30** by dehydration of alcohol **24** using $POCl_3$/pyridine. Successful preparation of 5-*anti*-bromo-6-*exo*-methylene derivative **31** was achieved by reacting bromoketone **18** with the Tebbe reagent (48 h).[27] The Wittig reaction of bromoketone **18** with triphenylphosphonium methylide was unsuccessful as a route to 6-*exo*-methylene **31**.

[3]



Alkene **31** was best converted to bromoalcohol **32** (94%) with 9-BBN at room temperature for 7 h, followed by basic hydrogen peroxide.[28] The 5-anti-6-anti- stereochemistry for **32** was shown by a W-plan coupling (J = 7.2 Hz) between H_{5syn} and H_{6syn}. Debromination of **32** with tris(trimethylsilyl) silane (TTMSS) gave alcohol **33** (69%)[29]; subsequent oxidation with NaOCl/TEMPO afforded the desired 5-*anti*-acid **8a**.[30]

[4]



The difficulty in isolating useful product from the reaction of bromoketone **18** with $Ph_3P{=}CH_2$ was noted previously (see eq. [3]). Surprisingly, ketones **18** and **21** reacted with the conjugated ylide methyl(triphenylphosphoranylidene)acetate in CH_2Cl_2 to give mixtures of stereoisomeric esters **34a**–**34b** and **35a**–**35b**, respectively (eq. [5]).[31] This stable ylide generally reacts poorly, if at all, with ketones. The major isomers in both cases have the ester oriented toward C_4 (*E*-ester) as indicated by NOE experiments in which the vinylidene hydrogen interacts with H_1. In the minor isomer **34b**, NOE experiments indicate the vinylidene hydrogen is closer to H_4, whereas in the minor isomer **35b**, the *Z*-ester stereochemistry could not be confirmed by NOE experiments because of the overlap between H_1 and the vinylidene hydrogen.

[5]

The 5-anti-6-anti- substituents in bromoalcohol **17** are ideally situated to take advantage of an intramolecular cyclization approach to introduce a functionalized 5-*syn*-alkyl substituent by use of a silicon-containing tether.[32] Accordingly, alcohol **17** was reacted with dimethylvinylchlorosilane to afford the vinylsilyl ether **36**. The radical generated by abstraction of the bromine of **36** with tributyltin hydride (1.5 equiv) at reflux afforded tethered silyl ether **37** formed by 5-exo-cyclization (83%). Tamao oxidation of **37** gave a 1:1 mixture of alcohols **19a**–**19b** (40%), epimeric at the side-chain hydroxyl position.[33]

[6]

Conclusion

Addition reactions with bromoketone **18** and ketone **22** have been shown to extend the stereochemical diversity of alkyl-, acyl-, and aryl-substituted 2-azabicyclo[2.1.1]hexanes. It is now possible to access 2-azabicyclo[2.1.1]hexanes with 5(6)-*anti*-carboxy (or alkyl) groups and also 5(6)-*syn*-alkyl (or aryl) tertiary alcohols. Organolithium and organomagnesium carbonyl additions, as well as 9-BBN addition and catalytic hydrogenation of *exo*-alkylidines, have been shown to be stereoselective for attack from the face syn to the nitrogen-containing bridge.[34] In separate experiments the usefulness of the bromine substituent of bromoalcohol **17** for the introduction of 5-*anti*-alkyl groups by a tethering process has been demonstrated. The 5-bromine substituents in products derived from ketone **18** should prove useful in further synthetic manipulations of this azabicyclic ring system.[5a,35] The results have implications for development of bridged pyrrolidine-based pharmaceuticals and the preparation of β-amino acid oligomers with useful functionalities.

Experimental section

General procedures

Thin layer chromatography (TLC) was performed on precoated plates of silica gel GF 250–1000 μm. Column chromatography was performed on silica gel Merck grade 60 (230–400 mesh). Reagent chemicals were obtained from commercial suppliers, and reagent grade solvents were used without further purification. Both the ^{1}H and ^{13}C NMR spectra (see Supplementary data) are often complicated by the presence of carbamate conformers, and resonances are often presented as pairs. Chemical shifts are expressed in ppm relative to internal TMS (^{1}H) or solvent $CDCl_3$ (^{13}C). High-resolution mass spectra were performed at Merck Research Laboratories (West Point, Pennsylvania) using FAB ionization methods.

N-Benzyloxycarbonyl-6-*anti*-bromo-5-*anti*-hydroxy-2-azabicyclo[2.1.1]hexane (17)[20]

Triethylamine (20 mL) was added to the known[20] bromoacetate **20** (2.0 g, 5.6 mmol) in MeOH (10 mL) at room temperature (RT). The resulting mixture was stirred for 12 h. The solvent was removed, and purification of the resulting crude oil by column chromatography gave the known alcohol **17** (1.57 g, 90%) at R_f = 0.35 (2:1 hexanes/ether). ^{1}H NMR δ: 7.26 (s, 5H), 5.07 (s, 2H), 4.37 (d, J = 5.4 Hz, 1H), 4.19 (d, J = 7 Hz, 1H), 4.01 (d, J = 7.5 Hz, 1H), 3.53 (d, J = 8.8 Hz, 1H), 3.47 (d, J = 8.8 Hz, 1H), 3.5–3.4 (br, 1H), 2.92 (d, J = 7 Hz, 1H). ^{13}C NMR δ: 155.7, 136.5, 129.0, 128.7, 128.5, 85.4, 67.8, 66.4, 65.9, 52.4, 50.4, 49.7.

N-Benzyloxycarbonyl-5-*anti*-bromo-6-oxo-2-azabicyclo [2.1.1]hexane (18) — General procedure

Oxalyl chloride (360 mg, 2.76 mmol) dissolved in CH_2Cl_2 (10 mL) was placed in a 50 mL flask. The contents of the flask were cooled to –78 °C and DMSO (452 mg, 5.25 mmol) in CH_2Cl_2 (3 mL) was added dropwise over 5 min. Stirring was continued at –78 °C for 10 min followed by addition of the alcohol **17** (730 mg, 2.3 mmol) in CH_2Cl_2 (3 mL) over 10 min. The reaction mixture was stirred for 30 min, and triethylamine (1.16 g, 11.5 mmol) was added in over 10 min with stirring at –78 °C for 1 h. The cooling bath was removed and the reaction was stirred for an additional 3 h. Water (20 mL) was added at RT. After 10 min of stirring, the organic layer was separated. The aqueous layer was extracted with CH_2Cl_2 (3 × 20 mL), and the combined organic extracts were washed with brine, dried over $MgSO_4$, and filtered. The solvent was removed in vacuo. Column chromatography gave pure ketone **18** (642 mg, 90%) at R_f = 0.32 (1:1 hexanes / diethyl ether). ^{1}H NMR (500 MHz, $CDCl_3$) δ: 7.36 (m, 5H), 5.16 (s, 2H), 4.76 (d, J = 6.6 Hz, 1H, H_1), 3.90 (s, 1H, H_5), 3.77 (dd, J = 9.1, 1.4 Hz, 1H, H_3), 3.61 (dd, J = 9.0, 0.9 Hz, 1H, H_3), 3.49 (dbr, J = 6.6 Hz, 1H, H_4). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 189.2 (C_6), 154.9 (C=O), 136.1, 129.1, 128.9, 128.7, 75.3 (C_1), 68.2 (CH_2Ph), 64.9 (C_4), 47.5 (C_5), 40.8 (C_3). HRMS m/z found: 310.0074; calcd for $C_{13}H_{13}{}^{79}BrNO_3$ (M + H)

310.0078; *m/z* found: 312.0053; calcd for $C_{13}H_{13}{}^{81}BrNO_3$ (M + H): 312.0058.

N-Benzyloxycarbonyl-6-*anti*-hydroxy-2-azabicyclo[2.1.1] hexane (21) — General procedure

Bromoalcohol **17** (300 mg, 0.96 mmol) dissolved in toluene (17 mL) was degassed for 30 min with argon. AIBN (16 mg, 0.96 mmol) and tristrimethylsilylsilane (0.59 mL, 1.92 mmol) were added and the reaction was heated to 100 °C for 2 h under argon.[23] The reaction was allowed to come to RT and the solvent was removed in vacuo. The resultant oil was purified by preparative silica gel TLC to yield alcohol **21** (150 mg, 67%) at $R_f = 0.38$ (1:1 ethyl acetate / hexanes). ^{1}H NMR (300 MHz, $CDCl_3$) δ: 7.39 (m, 5H), 5.19 (s, 2H), 4.26, 4.26 (2 d, J = 7.2, 7.5 Hz, 1H, H_1), 4.12 (d, J = 7.2 Hz, 1H, H_6), 3.45 (s, 2H, $2H_3$), 3.08 (br, 1H, OH), 2.97 (2 br, 1H, H_4), 2.72, 2.71 (2 d, J = 7.2, 7.2 Hz, 2H, H_{5x}), 1.68 (dd, J = 7.2, 7.2 Hz, H_{5n}). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 156.2, 137.1, 128.9, 128.4, 128.2, 81.5 (C_6), 67.2 (CH_2Ph), 63.9 (C_1), 48.7 (C_3), 44.3 (C_4), 37.3 (C_6). HRMS *m/z* found: 256.0946: calcd for $C_{13}H_{15}NO_3Na$ (M + Na) *m/z*: 256.0950.

N-Benzyloxycarbonyl-5-oxo-2-azabicyclo[2.1.1]hexane (22)

According to the general procedure, oxalyl chloride (0.055 mL, 0.63 mmol) in dry CH_2Cl_2 (2 mL) was cooled to –78 °C. DMSO (0.09 mL, 1.26 mmol) was added by syringe, then stirred for 15 min. To this the alcohol **21** (74 mg, 0.32 mmol) dissolved in CH_2Cl_2 (1 mL) was added slowly over 15 min, followed by NEt_3 (0.18 mL, 1.26 mmol) over 10 min. After 15 min at –78 °C, the mixture was allowed to stir in a 0 °C bath for 2 h. The reaction was diluted with CH_2Cl_2 (6 mL) and washed with dilute HCl (3 × 3 mL, 0.1 N). Workup afforded ketone **22** as a pale yellow oil (64 mg, 84%) that remained at the origin when eluted with ether on a silica gel TLC plate. ^{1}H NMR (500 MHz, $CDCl_3$) δ: 7.37–7.30 (m, 5H), 5.16–5.14 (m, 2H, benzyl CH_2), 4.67 (d, J = 6.3 Hz, 1H, H_1), 3.62 (m, 2H, H_3), 3.30 (dd, J = 6.5, 3.2 Hz, 1H, H_4), 1.97 (dm, 1H, J = 8.9 Hz, H_{6anti}), 1.79 (bd, 1H, J = 8.9 Hz, H_{6syn}). ^{13}C NMR (126 MHz, $CDCl_3$) δ: 189.3, 155.2, 136.1, 128.5, 128.0, 69.6, 67.2, 55.8, 46.4, 29.6. HRMS *m/z* found: 232.0971; calcd for $C_{13}H_{14}NO_3$ (M + H) *m/z*: 232.0968.

N-Benzyloxycarbonyl-6-*anti*-bromo-5-*anti*-hydroxy-5-*syn*-methyl-2-azabicyclo[2.1.1]hexane (23)

MeLi (10.6 mg, 0.48 mmol) was added to cooled ether (5 mL, dry) at 0 °C with argon protection. After stirring for 5 min, bromoketone **18** (100 mg, 0.32 mmol) dissolved in ether (5 mL) was added dropwise over 10 min. Stirring was continued for 2 h. The cooling bath was removed and concd NH_4Cl (10 mL) was added at RT. The reaction mixture was stirred for an additional 5 min. The organic layer was separated, and the aqueous layer was extracted with ether (3 × 10 mL). The combined organic extracts were washed with brine, dried over $MgSO_4$, and filtered. The solvent was removed in vacuo and chromatography of the residue gave alcohol **23** (69 mg, 66%) at $R_f = 0.31$ (1:2 hexanes / diethyl ether). ^{1}H NMR (400 MHz, $CDCl_3$) δ: 7.26 (m, 5H), 5.16 (m, 2H), 4.36, 4.31 (2 d, J = 6.8 Hz, 1H, H_1), 4.01 (s, 1H, H_5), 3.62, 3.61 (2 s, 1H, OH), 3.53 (d, J = 9.2 Hz, 1H, H_3), 3.48 (d, J = 9.2 Hz, 1H, H_3), 2.83 (d, J = 6.8 Hz, 1H, H_4), 1.24, 1,21 (2 s, 3H, CH_3). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 155.7, 136.4, 128.8, 128.5, 128.4, 128.2, 127.9, 86.9, 86.7 (C_6), 68.0, 67.8 (C_1), 67.4, 67.2 (CH_2Ph), 52.3 (C_3), 50.6, 50.3 (C_4), 49.2, 49.0 (C_5), 20.3 (CH_3). HRMS *m/z* found: 348.0203; calcd for $C_{14}H_{16}{}^{79}BrNNaO_3$ (M + Na): 348.0211; *m/z* found: 350.0185; calcd for $C_{14}H_{16}{}^{81}BrNNaO_3$ (M + Na): 350.0191. The stereochemistry at C_6 was confirmed by an NOE experiment that showed a Me/H_3 interaction.

N-Benzyloxycarbonyl-5-*anti*-hydroxy-5-*syn*-methyl-2-azabicyclo[2.1.1]hexane (24)

Following the general procedure, AIBN (12 mg, 0.07 mmol) was added to the bromoalcohol **23** (480 mg, 1.47 mmol) in benzene (20 mL) with argon protection. The resulting mixture was refluxed for 5 min, and Bu_3SnH (595 μL, 2.20 mmol) was added by syringe. The reaction was refluxed for an additional 10 h. The solvent was removed in vacuo and column chromatography of the residue gave alcohol **24** (350 mg, 96%) at $R_f = 0.18$ (1:2 hexanes / diethyl ether). ^{1}H NMR (400 MHz, $CDCl_3$) δ: 7.36 (m, 5H), 5.16 (s, 2H), 4.18, 4.15 (2 d, J = 6.8 Hz, 1H, H_1), 3.37 (d, J = 9.2 Hz, 1H, H_3), 3.34 (d, J = 9.2 Hz, 1H, H_3), 2.85 (d, J = 7.2 Hz, 1H, H_6), 2.55 (br, 1H, H_4), 2.42 (br, 1H, OH), 1.43 (d, J = 7.2 Hz, 1H, H_6), 1.17 (s, 3H, Me). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 156.5, 155.9 (C=O), 137.0, 128.6, 128.1, 128.0, 83.8, 83.5 (C_5), 67.0, 66.9 (CH_2Ph), 65.9, 65.4 (C_1), 48.5 (C_3), 46.5 (C_4), 36.2, 36.0 (C_6), 19.1. HRMS *m/z* found: 248.1285; calcd for $C_{14}H_{18}NO_3$ (M + H): 248.1281; *m/z* found: 270.1090; calcd for $C_{14}H_{17}NNaO_3$ (M + Na): 270.1100.

N-Benzyloxycarbonyl-5-*anti*-fluoro-5-*syn*-methyl-2-azabicyclo[2.1.1]hexane (25)

A 50 wt % BAST solution in THF (299 μL, 0.8 mmol) was added dropwise to a solution of tertiary alcohol **24** (100 mg, 0.4 mmol) in CH_2Cl_2 (20 mL) at RT. The solution was stirred for 16 h. The solvent was removed in vacuo and column chromatography of the residue gave the fluoride **25** (90 mg, 89%) at $R_f = 0.44$ (1:1 hexanes / diethyl ether). ^{1}H NMR (300 MHz, $CDCl_3$) δ: 7.34 (m, 5H), 5.17 (s, 2H), 4.34. 4.30 (2 d, J = 7.2 Hz, 1H, H_1), 3.42 (d, J = 9.3 Hz, 1H, H_3), 3.34 (d, J = 9.3 Hz, 1H, H_3), 2.77 (br, 2H, H_4 and H_6), 1.56, 1.53 (2 d, J = 7.8 Hz, 1H, H_6), 1.30, 1.28 (2 d, J = 22.2 Hz, 3H, Me). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 156.6, 156.0 (C=O), 137.1, 128.9, 128.8, 128.7, 128.6, 128.5, 128.3, 105.4, 103.4 (C_5), 67.4 (CH_2Ph), 64.8, 64.5, 64.2, 64.0 (C_1), 48.3 (C_3), 46.3, 46.2, 46.0 (C_4), 35.7, 35.6 (C_6), 15.9, 15.6 (CH_3). HRMS *m/z* found: 250.1233; calcd for $C_{14}H_{17}FNO_2$ (M + H): 250.1238.

N-Benzyloxycarbonyl-5-*anti*-bromo-6-*anti*-hydroxy-6-*syn*-phenyl-2-azabicyclo-[2.1.1]hexane (26)

Anhydrous diethyl ether (3 mL, dry) was added to bromoketone **18** (100 mg, 0.32 mmol) at 0 °C with argon protection. PhMgBr (87 mg, 0.48 mmol) was added to the mixture over 5 min. After stirring for 1 h, the cooling bath was removed and concd NH_4Cl (5 mL) was added at RT. The organic layer was separated, and the aqueous layer was extracted with diethyl ether (3 × 10 mL). The combined ether layers were dried over $MgSO_4$ and then filtered. Solvent

removal in vacuo and column chromatography of the residue gave pure bromide **26** (90 mg, 72%) at R_f = 0.45 (1:2 hexanes / diethyl ether). ^{1}H NMR (400 MHz, $CDCl_3$) δ: 7.33~6.96 (m, 10H, H on Ph), 5.09, 4.94, 4.93, 4.84 (4 d, J = 12.4, 12.4, 12.8, 12.8 Hz, 2H, CH_2Ph), 4.78, 4.74 (2 d, J = 7.2 Hz, 1H, H_1), 4.07, 4.05 (2 s, 1H, H_5), 3.40, 3.38 (2 br, 1H, OH), 3.33 (d, J = 9.2 Hz, 1H, H_3), 3.22, 3.21 (2 d, J = 7.2 Hz, 1H, H_4), 2.98 (d, J = 9.2 Hz, 1H, H_3). ^{1}H NMR (400 MHz, $CDCl_3$, 60 °C) δ: 7.21 (m, 5H), 5.11~4.86 (m, 2H), 4.78, 4.74 (2 d, J = 7.0, 7.1 Hz, 1H, H_1), 4.09 (s, 1H, H_5), 3.44, 3.42 (2 br, 1H, OH), 3.38 (d, J = 9.0 Hz, 1H, H_3), 3.24, 3.22 (2 d, J = 7.2 Hz, 1H, H_4), 3.03 (d, J = 9.0 Hz, 1H, H_3). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 154.5, 154.4 (C=O), 140.1, 140.0, 136.6, 136.5, 129.2, 129.0, 128.7, 128.6, 128.5, 128.4, 128.2, 127.7, 125.9, 125.7 (C on Ph), 89.7, 89.5 (C_6), 67.6, 67.0 (CH_2Ph), 66.6, 65.9 (C_1), 51.7, 51.4 (C_4), 49.2, 49.0 (C_5), 48.9, 48.7 (C_3). HRMS *m/z* found: 388.0565; calcd for $C_{19}H_{19}{}^{79}BrNO_3$ (M + H): 388.0543.

N-Benzyloxycarbonyl-5-*anti*-bromo-6-*syn*-(6-chloro-3-pyridyl)-6-*anti*-hydroxy-2-azabicyclo[2.1.1]hexane (27)

At –78 °C, *n*-butyllithium in hexane (1.6 mol/L) (0.40 mL, 0.65 mmol) was added dropwise to a solution of 2-chloro-5-iodopyridine (0.155 g, 0.65 mmol) in dry THF (10 mL). The reaction was stirred for 30 min at –78 °C, whereupon the ketone **18** (0.200 g, 0.65 mmol) in dry THF (10 mL) was added slowly. The reaction was stirred at –78 °C for 0.5 h followed by 2 h at RT. The reaction was quenched with sat. aq ammonium chloride (10 mL), diluted with water (10 mL), and extracted with EtOAc (3 × 30 mL). The combined organic layers were washed with water, dried, and solvent was evaporated in vacuo to give the crude product. Column chromatography on silica gel, eluting with 1:1 hexanes / diethyl ether, gave the alcohol **27** (160 mg, 59%) at R_f = 0.27 (1:2 hexanes / diethyl ether). ^{1}H NMR (400 MHz, $CDCl_3$) δ: 8.11, 8.08 (2 br, 1H, H_2'), 7.30 (m, 5H), 7.04 (m, 2H, H_4' and H_5'), 4.95 (3 d, J = 12.0, 12.4, 12.8 Hz, 2H, CH_2Ph), 4.76 (br, 1H, H_1), 4.29 (br, 1H, OH), 4.08 (s, 1H, H_5), 3.40 (d, J = 9.2 Hz, 1H, H_{3n}), 3.25 (br, 1H, H_4), 2.88 (d, J = 9.2 Hz, 1H, H_{3x}). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 154.6 (C=O), 151.4, 148.1, 137.2, 136.9, 136.3, 134.7, 129.2, 129.0, 128.7, 128.2, 125.9, 124.8, 87.6 (C_6), 68.1, 67.6 (CH_2Ph), 66.6, 65.9 (C_1), 52.0, 51.7 (C_4), 49.2 (C_3), 49.1, 48.7 (C_5). HRMS *m/z* found: 423.0105; calcd for $C_{18}H_{17}{}^{79}Br{}^{35}ClN_2O_3$ (MH): 423.0106.

N-Benzyloxycarbonyl-5-*anti*-hydroxy-5-*syn*-phenyl-2-azabicyclo[2.1.1]hexane (28)

Following the general procedure, AIBN (18 mg, 0.05 equiv) was added to the bromoalcohol **26** (0.84 g, 2.16 mmol) in benzene (25 mL) with argon protection. The resulting mixture was refluxed for 5 min and Bu_3SnH (0.87 mL, 1.5 equiv) was added. The reaction was refluxed for an additional 10 h. Workup and column chromatography gave the alcohol **28** (400 mg, 60%) at R_f = 0.32 (1:2 hexanes / diethyl ether). ^{1}H NMR (400 MHz, $CDCl_3$) δ: = 7.27~6.91 (m, 10H), 5.00, 4.87, 4.86, 4.74 (4 d, J = 12.8 Hz, 2H, CH_2Ph), 4.51 (multiple d, J = 7.2 Hz, 1H, H_1), 3.19 (br, 1H, OH), 3.13, 3.10 (2 d, J = 8.8 Hz, 1H, H_3), 2.89~2.80 (m, 3H, H_3, H_4, and H_6), 1.43 (d, J = 7.2 Hz, 1H, H_6). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 155.4, 155.3 (C=O), 140.1, 137.3, 137.2, 129.1, 128.9, 128.7, 128.5, 128.4, 128.3, 128.0, 127.6, 126.5, 126.3, 87.3, 87.1 (C_6), 67.1, 66.5 (CH_2Ph), 64.4, 63.8 (C_1), 48.3, 48.1 (C_3), 46.1, 45.8 (C_4), 35.5, 35.3 (C_5). HRMS *m/z* found: 332.1251; calcd for $C_{19}H_{19}NNaO_3$ (M + Na): 332.1257.

N-Benzyloxycarbonyl-5-*syn*-(6-chloro-3-pyridyl)-5-*anti*-hydroxy-2-azabicyclo[2.1.1]hexane (29)

Following the general procedure, AIBN (2 mg, 0.05 equiv) was added to bromoalcohol **27** (0.130 g, 0.31 mmol) in 15 mL benzene with argon protection and Bu_3SnH (0.124 mL, 0.46 mmol) was added. After 10 h reflux, workup and column chromatography gave the alcohol **29** (60 mg, 60%) at R_f = 0.13 (1:2 hexanes / diethyl ether). ^{1}H NMR (400 MHz, $CDCl_3$) δ: 8.03, 7.99 (2 s, 1H, H_2'), 7.29 (m, 5H), 7.02 (m, 2H, H_4' and H_5'), 5.02, 4.95, 4.82 (3 d, J = 12.0, 12.0, 12.8 Hz, 2H, CH_2Ph), 4.58, 4.56 (2 d, J = 7.2 Hz, 1H, H_1), 3.60~3.00 (br, 1H, OH), 3.25, 3.24 (2 d, J = 9.2 Hz, 1H, H_{3n}), 2.98 (m, 2H, H_4 and H_6), 2.76 (d, J = 9.2 Hz, 1H, H_{3x}), 1.55 (d, J = 7.2 Hz, 1H, H_6). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 155.3 (C=O), 151.2, 148.3, 148.1, 137.6, 137.4, 136.9, 134.8, 129.0, 128.6, 128.4, 127.9, 124.7, 84.8, 84.7 (C_5), 67.4, 66.9 (CH_2Ph), 64.4, 63.7 (C_1), 48.1, 47.9 (C_3), 46.4, 46.0 (C_4), 36.1, 35.8 (C_6). HRMS *m/z* found: 345.0989; calcd for $C_{18}H_{18}{}^{35}ClN_2O_3$ (MH): 345.1001. The stereochemistry on C_5 was confirmed by NOE. When $H_{2'}$ was irradiated, the signals of H_1, H_4, and H_{3x} were increased.

Attempted dehydration of alcohol 24 to give olefin 30

The tertiary alcohol **24** (200 mg, 0.6 mmol) in pyridine (5 mL) was placed in a 50 mL flask. To this stirred solution, phosphorus oxychloride (270 μL) was added at 0–5 °C, and the mixture was stirred for 14 h at RT. The reaction mixture was diluted with diethyl ether (10 mL) and slowly quenched with water (10 mL) to hydrolyze the excess phosphorus oxychloride. The layers were separated and the aqueous layer was extracted with diethyl ether (3 × 10 mL). The combined organic layers were washed with brine, dried over $MgSO_4$, and filtered. Solvent removal gave only 10 mg of crude oil that did not contain the desired alkene **30**.

N-Benzyloxycarbonyl-5-*anti*-bromo-6-methylene-2-azabicyclo[2.1.1]hexane (31)

To a solution of ketone **18** (1.26 mmol, 390 mg) in dry THF (15 mL) at 0 °C was added a toluene solution of the Tebbe reagent (2.52 mL of 0.5 mol/L solution, 1.26 mmol).[27] The mixture was allowed to warm to RT and stirred for 2 days, whereupon Et_2O (20 mL) was added followed slowly followed by 5 drops of aq NaOH (0.1 mol/L). After gas evolution ceased, the mixture was dried (Na_2SO_4) and filtered using a Celite pad. The solvent was removed in vacuo and purification of the residue by chromatography on silica gel (4:1 hexanes / diethyl ether) gave the bromoalkene **31** (165 mg, 43%) at R_f = 0.41 (1:1 hexanes / diethyl ether). ^{1}H NMR (400 MHz, $CDCl_3$) δ: 7.27 (m, 5H), 5.08 (s, 2H), 4.87 (br, 1H, $=CH_2$), 4.81 (s, 1H, $=CH_2$), 4.57 (br, 1H, H_1), 3.85 (s, 1H, H_5), 3.53 (d, J = 8.5 Hz, 1H, H_3), 3.42 (d, J = 8.5 Hz, 1H, H_3), 3.19 (d, J = 6.4 Hz, 1H, H_4). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 155.7 (C=O), 148.5 (C_6), 136.7,

128.9, 128.8, 128.7, 128.5, 128.4 (Ph), 100.9 (=CH_2), 69.4 (C_1), 67.6, 67.4 (CH_2Ph), 54.5 (C_4), 50.2 (C_6), 49.6 (C_3). HRMS *m/z* found: 330.0094 (^{79}Br), 332.0070 (^{81}Br); calcd for $C_{14}H_{14}BrNO_2Na$ (MNa): 330.0100 (^{79}Br), 332.0080 (^{81}Br).

Wittig reaction of ketone 18 — Attempted synthesis of alkene 31

To a suspension of $CH_3{}^+PPh_3Br^-$ (77 mg, 0.22 mmol) in dry THF (1.1 mL) at –78 °C was added *n*-BuLi (135 μL, 0.215 mmol, 1.6 mol/L) by syringe, resulting in the appearance of a bright yellow color. After 30 min at –78 °C, ketone **18** (63 mg, 0.20 mmol) in dry THF (1.01 mL) was added slowly and allowed to rise to RT overnight. The reaction was quenched with water, and the solvent was removed in vacuo. The mixture was taken up in CH_2Cl_2 (6 mL) and washed with water (3 × 2 mL) and once with brine (1 × 2 mL). The solvent was removed in vacuo, and the resultant oil was purified by preparative TLC (4:1 hexanes/ether). Eight UV active bands were collected as fractions (63 mg total). No fraction corresponded to either starting material or the desired alkene **31**.

***N*-Benzyloxycarbonyl-5-*anti*-bromo-6-*anti*-(hydroxymethyl)-2-azabicyclo[2.1.1]-hexane (32)**

To a stirred solution of olefin **31** (150 mg, 0.49 mmol) in THF (10 mL) at 0 °C under an argon atmosphere was added 9-BBN (2.94 mL, 1.47 mmol, 0.5 mol/L solution in hexane). After the solution was stirred at RT for 7 h, 6 mol/L NaOH (1.3 mL) and 30% H_2O_2 (1.3 mL) were added at 0 °C. After stirring at RT overnight, the reaction mixture was diluted with water and extracted with diethyl ether (3 × 15 mL). The organic phase was washed with water, dried over Na_2SO_4, and concentrated under reduced pressure. Column chromatography of the residue (2:3 hexanes / diethyl ether) gave the alcohol **32** (150 mg, 94%) at R_f = 0.27 (1:1 hexanes / ethyl acetate). ^{1}H NMR (400 MHz, $CDCl_3$) δ: 7.36 (m, 5H), 5.16 (s, 2H), 4.54 (d, *J* = 7.2 Hz, 1H, H_1), 4,51 (d, *J* = 7.2 Hz, 2H, OCH_2), 3.96 (d, *J* = 7.2 Hz, 1H, H_{5syn}), 3.61 (d, *J* = 8.8 Hz, 1H, H_3), 3.54 (d, *J* = 8.8 Hz, 1H, H_3), 3.06 (d, *J* = 7.2 Hz, 1H, H_4), 2.44 (td, *J* = 7.2, 7.2 Hz, 1H, H_{6syn}), 2.00 (2 br, 1H, OH). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 155.6 (C=O), 136.7, 128.9, 128.7, 128.5, 128.3, 67.5 (OCH_2), 65.3, 64.8 (C_1), 61.4 (CH_2Ph), 58.8 (C_3), 53.5 (C_5), 52.3 (C_4), 47.0 (C_6). HRMS *m/z* found: 326.0382; calcd for $C_{14}H_{17}{}^{79}BrNO_3$ (M + H): 326.0387.

***N*-Benzyloxycarbonyl-5-*anti*-(hydroxymethyl)-2-azabicyclo [2.1.1]hexane-2-carboxylate (33)**

To a toluene (15 mL) solution of bromide **32** (250 mg, 0.77 mmol) was added TTMSS (1.18 mL, 3.83 mmol) and a catalytic amount of AIBN. The resulting solution was refluxed under argon for 12 h until no starting material remained. The solvent was removed and purification of the residue by silica gel flash column chromatography gave alcohol **33** (130 mg, 69%) at R_f = 0.13 (1:1 hexanes / ethyl acetate). ^{1}H NMR (400 MHz, $CDCl_3$) δ: 7.34 (m, 5H), 5.16 (s, 2H, CH_2Ph), 4.35 (d, *J* = 7.2 Hz, 1H, H_1), 3.89 (d, *J* = 7.6 Hz, 2H, OCH_2), 3.46 (d, *J* = 8.4 Hz, 1H, H_3), 3.42 (d, *J* = 8.4 Hz, 1H, H_3), 2.74, 2.73 (2 d, *J* = 7.2 Hz, 1H, H_4), 2.41 (d, *J* = 8.0 Hz, 1H, H_6), 2.15 (td, *J* = 7.6, 7.6 Hz, H_5), 1.73 (br, 1H, OH), 1.51 (dd, *J* = 8.0, 7.6 Hz, 1H, H_6). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 156.1, 137.1, 128.7, 128.5, 128.3, 128.1, 127.9, 66.9 (OCH_2), 61.7, 61.2 (C_1), 61.0 (CH_2Ph), 56.6 (C_3), 50.9 (C_5), 39.7 (C4), 38.0 (C_6). HRMS *m/z* found: 248.1274; calcd for $C_{14}H_{18}NO_3$ (M + H): 248.1281.

***N*-Benzyloxycarbonyl-5-*anti*-carboxy-2-azabicyclo[2.1.1] hexane (8a)**

To a stirred solution of alcohol **33** (60 mg, 0.24 mmol) in CH_2Cl_2 (3 mL) containing TEMPO (1 mg) was added $NaHCO_3$ (aq) (0.74 mL) containing KBr (3.0 mg) and Bu_4NCl (4.0 mg). The mixture was cooled to 0 °C and a solution of NaOCl (0.60 mL), $NaHCO_3$ (0.51 mL), and brine (0.55 mL) was added dropwise. After 1 h, the layers were separated. The organic layer was extracted with water (4 × 5 mL). The combined aqueous solution was acidified with 10% HCl. The resulting solution was extracted with EtOAc (4 × 10 mL). The combined organic solution was dried over Na_2SO_4. Removal of solvent and purification of the residue by column chromatography gave acid **8a** (40 mg, 63%) at R_f = 0.32 (90:10:1 CH_2Cl_2/MeOH/TFA). ^{1}H NMR (300 MHz, CD_3OD) δ: 7.41 (m, 5H), 5.20 (s, 2H), 4.58 (br, 1H, H_1), 3.48 (br, 2H, $2H_3$), 3.08, 3.06 (2 br, 1H, H_4), 2.61 (br, 2H, H_{6x} and H_5), 2.32 (t, *J* = 7.8 Hz, 1H, H_{6n}). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 177.6 (COOH), 156.1 (C=O), 137.3, 137.0, 128.8, 128.6, 128.3, 128.1 (C on Ph), 67.1 (CH_2Ph), 63.3 (C_1), 58.7 (C_5), 50.8 (C_3), 42.3 (C_4), 39.4 (C_6). HRMS *m/z* found: 284.0898; calcd for $C_{14}H_{15}NO_4Na$ (M + Na): 284.0893. ^{1}H COSY showed couplings between H_1 and H_4 and H_{6x} and H_{6n}.

***N*-Benzyloxycarbonyl-5-[(methoxycarbonyl)methylene]-6-*anti*-bromo-2-azabicyclo[2.1.1]hexane (stereoisomers *E*-34a and *Z*-34b)**

Methyl(triphenylphosphoranylidene)acetate (582 mg, 1.74 mmol) was added to a solution of ketone **18** (360 mg, 1.16 mmol) in 20 mL CH_2Cl_2 at RT. The reaction mixture was stirred for 2 days. The solvent was removed in vacuo and purification of the residue by column chromatography on silica gel (4:1 hexanes / diethyl ether) provided stereoisomer **34a** (110 mg, 27%), stereioisomer **34b** (170 mg, 42%), and starting material (20 mg). Analytical data for product **34a** at R_f = 0.37 (1:1 hexanes / diethyl ether): ^{1}H NMR (400 MHz, $CDCl_3$) δ: 7.24 (m, 5H), 5.72 (s, 1H, =CH), 5.08 (s, 2H), 4.68 (br, 1H, H_1), 3.96 (d, *J* = 6.8 Hz, 1H, H_4), 3.94 (s, 1H, H_5), 3.67 (s, 3H, CH_3), 3.60 (d, *J* = 8.4 Hz, 1H, H_3), 3.50 (d, *J* = 8.4 Hz, 1H, H_3). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 167.2, 159.7 (C_6), 155.5 (CO_2Bn), 136.5, 129.0, 128.8, 128.7, 128.6, 128.5, 108.4 (=CH), 68.9 (C_1), 67.8 (CH_2Ph), 55.2 (C_4), 52.0 (CH_3), 49.2 (C_3), 48.8 (C_5). HRMS *m/z* found: 388.0152; calcd for $C_{16}H_{16}{}^{79}BrNO_4Na$ (M + Na): 388.0155; *m/z* found: 390.0132; calcd for $C_{16}H_{16}{}^{81}BrNO_4Na$ (M + Na): 390.0134. Analytical data for product **34b** at R_f = 0.29 (1:1 hexanes / diethyl ether): ^{1}H NMR (400 MHz, $CDCl_3$) δ: 7.27 (m, 5H), 5.64 (s, 1H, =CH), 5.28 (d, 1H, *J* = 6.8 Hz, H_1), 5.09 (m, 2H, CH_2Ph), 3.93 (s, 1H, H_5), 3.61 (s, 3H, CH_3), 3.60 (d, *J* = 8.8 Hz, 1H, H_3), 3.59 (d, *J* = 8.8 Hz, 1H, H_3), 3.33 (d, *J* = 6.4 Hz, 1H, H_4). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 165.8, 157.8 (C_6), 155.5 (CO_2Bn), 136.6, 128.9, 128.8, 128.7, 128.6, 128.3, 108.3 (=CH),

68.9 (C_1), 67.7, 67.6 (CH_2Ph), 54.7 (C_4), 52.0 (CH_3), 49.4 (C_3), 48.6 (C_5). HRMS *m/z* found: 388.0145; calcd for $C_{16}H_{16}{}^{79}BrNO_4Na$ (M + Na): 388.0155; *m/z* found: 390.0124; calcd for $C_{16}H_{16}{}^{81}BrNO_4Na$ (M + Na): 390.0134.

N-Benzyloxycarbonyl-5-[(methoxycarbonyl)methylene]-2-azabicyclo[2.1.1]hexane (stereoisomers *E*-35a and *Z*-35b)

According to the preceding procedure, methyl(triphenylphosphoranylidene)acetate (430 mg, 1.29 mmol) was added to a solution of ketone **21** (210 mg, 0.86 mmol) in CH_2Cl_2 (20 mL) at RT. After 36 h, workup and column chromatography on silica gel (3:1 hexanes / diethyl ether) provided alkene **35a** (155 mg, 62%) and alkene **35b** (80 mg, 32%). Analytical data for product **35a** at R_f = 0.34 (1:1 hexanes / diethyl ether): ^{1}H NMR (400 MHz, $CDCl_3$) δ: 7.25 (m, 5H), 5.38 (br, 1H, =CH), 5.07 (s, 2H), 4.66 (br, 1H, H_1), 3.89, 3.88 (2 d, J = 6.4, 6.8 Hz, 1H, H_4), 3.63 (s, 3H, CH_3), 3.45 (d, J = 8.0 Hz, 1H, H_3), 3.41 (d, J = 8.0 Hz, 1H, H_3). 1.89, 1.88 (2 d, J = 7.6 Hz, 1H, H_6), 1.68, 1.67 (2 d, J = 7.6 Hz, 1H, H_6). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 167.2, 159.7 (C_5), 156.2, 137.0, 129.0, 128.9, 128.7, 128.6, 128.4, 128.3, 101.5 (=CH), 67.3 (CH_2Ph), 64.3 (C_1), 51.7 (CH_3), 49.2 (C_3), 47.3 (C_4), 36.9 (C_6). HRMS *m/z* found: 288.1229; calcd for $C_{16}H_{17}NO_4Na$ (M + Na): 288.1231. Analytical data for product **35b** at R_f = 0.27 (1:1 hexanes / diethyl ether): ^{1}H NMR (400 MHz, $CDCl_3$) δ: 7.26 (m, 5H), 5.29 (m, 2H, =CH and H_1), 5.09 (m, 2H, CH_2Ph), 3.60 (br, 3H, CH_3), 3.44 (d, J = 8.4 Hz, 1H, H_3), 3.36 (d, J = 8.4 Hz, 1H, H_3), 3.24 (2 d, J = 6.6 Hz, 1H, H_4), 1.89, 1.88 (2 d, J = 7.2 Hz, 1H, H_5), 1.68 (d, J = 7.2 Hz, 1H, H_5). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 166.5, 158.9 (C_5), 156.2 (CO_2Bn), 137.1, 128.8, 128.6, 128.4, 128.3, 128.2 (C on Ph), 101.4 (=CH), 67.2 (CH_2Ph), 64.4 (C_1), 51.7 (CH_3), 49.2 (C_3), 46.8 (C_4), 36.9 (C_6). HRMS *m/z* found: 288.1230; calcd for $C_{16}H_{17}NO_4Na$ (M + Na): 288.1231.

N-Benzyloxycarbonyl-5-*anti*-bromo-6-*anti*-[dimethyl(vinyl) silyloxy]-2-azabicyclo[2.1.1]hexane (36)

Dimethylvinylchlorosilane (0.77 g, 6.4 mmol) was added to bromoalcohol **17** (2.0 g, 6.4 mmol) in DMF (1 mL) at RT followed by addition of imidazole (0.44 g, 6.4 mmol). The resulting mixture was stirred for 2 days. Diethyl ether (20 mL) and distilled water (20 mL) were added. The organic layer was separated and the aqueous layer was extracted with ether (3 × 20 mL). The combined organic extracts were washed with brine and then dried over $MgSO_4$. After filtration, the solvent was removed in vacuo and purification of the residue by column chromatography gave vinylsilane **36** (1.68 g, 66%) at R_f = 0.29 (4:1 hexanes / diethyl ether). ^{1}H NMR (400 MHz, $CDCl_3$) δ: 7.35 (m, 5H), 6.16 (dd, J = 20.0, 14.8 Hz, 1H, =CH), 6.05, 6.04 (2 d, J = 14.8, 14.4 Hz, 1H, $=CH_{2cis}$), 5.82, 5.81 (2 d, J = 20.0, 20.4 Hz, 1H, $=CH_{2trans}$), 5.14 (m, 2H, CH_2Ph), 4.36 (br, 1H, H_6), 4.27 (d, J = 6.4 Hz, 1H, H_1), 4.04 (d, J = 7.2 Hz, 1H, H_5), 3.53, 3.52 (2 d, J = 9.2, 8.8 Hz, 1H, H_3), 3.47 (d, J = 8.8 Hz, 1H, H_3), 2.90 (d, J = 6.4 Hz, 1H, H_4), 0.25 (s, 6H). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 155.7, 155.2 (C=O), 137.0, 136.6 (=CH), 134.4 ($=CH_2$), 128.9, 128.5, 128.3, 83.7 (C_6), 67.5 (CH_2Ph), 66.4, 65.7 (C_1), 50.7 (C_4), 50.0 (C_5), 49.3 (C_3), –1.26, –1.55 ($2CH_3$). HRMS *m/z* found: 418.0436; calcd for $C_{17}H_{22}{}^{79}BrNaNO_3Si$ (M + Na): 418.0451; *m/z* found: 420.0423; calcd for $C_{17}H_{22}{}^{81}BrNO_3SiNa$ (M + Na): 420.0430.

N-Benzyloxycarbonyl-5-*anti*-oxy-6-*anti*-(1-ethyl)-2-azabicyclo[2.1.1]hexyl-dimethylsilane (37) (a 2,2,3-trimethyl-1,2-oxasilepane)

AIBN (3.0 mg, 0.02 mmol) was added to a solution of compound **36** (150 mg, 0.38 mmol) in benzene (20 mL) under argon. The resulting mixture was refluxed for 5 min and tributyltin hydride (165 mg, 0.57 mmol) was added immediately. The mixture was refluxed for an additional 5 h. The solvent was removed in vacuo to give a residue that after column chromatography gave tethered silane **37** (100 mg, 83%) at R_f = 0.32 (2:1 hexanes / diethyl ether). ^{1}H NMR (400 MHz, $CDCl_3$) δ: 7.30 (m, 5H), 5.11 (s, 2H), 4.15, 4.13 (2 d, J = 7.6, 7.2 Hz, 1H, H_6), 4.15, 4.08 (2 br, 1H, H_1), 3.40 (m, 2H, $2H_3$), 2.55 (br, 1H, H_5), 2.32, 2.30 (2 d, J = 7.6 Hz, 1H, H_4), 1.46 (m, 1H, CHSi), 1.05, 1.03 (2 d, J = 8.4, 7.6 Hz, 3H, CH_3), 0.20, 0.17, 0.16, 0.15 (4 s, 6H, $2CH_3$). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 156.0 (C=O), 137.2, 128.9, 128.4, 128.2, 127.9, 84.5, 84.3 (C_6), 67.1 (CH_2Ph), 66.3, 65.7, 63.2, 62.6 (C_1), 57.9 (C_3), 49.5, 49.4 (C_4), 48.7, 48.2, 44.8, 44.5 (C_5), 19.6, 18.7 (SiCH), 15.8, 15.3 (CH_3), 1.87, 1.42 (CH_3), –1.12, –1.29 (CH_3). HRMS *m/z* found: 340.1344; calcd for $C_{17}H_{23}NO_3SiNa$ (M + Na): 340.1345.

N-Benzyloxycarbonyl-5-*anti*-hydroxy-6-*anti*-(1-hydroxyethyl)-2-azabicyclo[2.1.1]hexane stereoisomers (19)

Route A: To silylether **37** (30 mg, 0.095 mmol) in 1:1 THF/MeOH (0.2 mL) was added $KHCO_3$ (10 mg, 0.10 mmol) and KF (12 mg, 0.21 mmol). To this stirred suspension was added 30% H_2O_2 (50 mL, 0.45 mmol).[33] The suspension was stirred at RT open to the air for 28 h. Because of the small reaction volume, two additional portions of 1:1 THF/MeOH were added as the reaction solvent evaporated. The reaction was quenched by addition of 50% NaS_2O_3 (0.5 mL), and the solution (0.7 mL) was applied to a preparative silica gel TLC plate that was allowed to dry. Elution with 1:1 hexanes/Et_2O gave 6 mg (20%) of unreacted **37** (R_f = 0.5, 1:1 hexanes/Et_2O). A second elution with 2:1 EtOAc/hexanes yielded 17 mg (65%) of diols **19a** + **19b** at R_f = 0.3 (2:1 EtOAc/hexanes) taken as one fraction. The ratio of isomers was 45:55 by ^{1}H NMR based on integrations of unique peaks at δ 2.81 and 2.60. Route B: To a solution of compound **37** (520 mg, 1.64 mmol) in THF/MeOH (1:1, 15 mL), $KHCO_3$ (492 mg, 4.92 mmol), KF (190 mg, 3.28 mmol), and 90% H_2O_2 (0.78 mL, 39.36 mmol) were successively added. The resulting solution was stirred at RT for 20 h and then diluted with Et_2O. The solvent was filtered over Celite and concentrated in vacuo. Column chromatography gave diol **19a** (90 mg, 20% at R_f = 0.17, 2:1 ethyl acetate / hexanes) and diol **19b** (90 mg, 20% at R_f = 0.12, 2:1 ethyl acetate / hexanes). Spectral data for **19a**: ^{1}H NMR (400 MHz, $CDCl_3$) δ: 7.35 (br, 5H), 5.10 (br, 2H, CH_2Ph), 4.96, 4.84 (2 br, 1H, H_6), 4.34 (d, J = 7.2 Hz, 1H, H_1), 4.12 (d, J = 7.2 Hz, 1H, OCH), 3.85, 3.10 (2 br, 1H, OH), 3.49 (d, J = 8.8 Hz, 1H, H_3), 3.44 (d, J = 8.8 Hz, 1H, H_3), 2.60 (d, J = 7.2 Hz, 1H, H_4), 2.24 (br, 1H, OH), 2.14 (m, 1H,

H_5), 1.24 (d, J = 5.6 Hz, 3H, CH_3). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 156.0, 137.0, 128.9, 128.4, 128.2, 83.3 (C_6), 67.3 (C_1), 66.5 (OCH), 63.7 (CH_2Ph), 63.0 (C_3), 50.8 (C_4), 46.0 (C_5), 23.2 (CH_3). HRMS *m/z* found: 300.1196; calcd for $C_{15}H_{19}NaNO_4$ (M + Na): 300.1206. Spectral data for **19b**: ^1H NMR (400 MHz, $CDCl_3$) δ: 7.34 (br, 5H), 5.14 (s, 2H), 4.79 (br, 1H, OCH), 4.14 (2 d, J = 7.2 Hz, H_1 and H_6), 3.53 (d, J = 8.8 Hz, 1H, H_3), 3.45 (d, J = 8.8 Hz, 1H, H_3), 3.00 (br, 1H, OH), 2.83 (d, J = 7.2 Hz, 1H, H_4), 2.16 (m, 1H, H_5), 1.82 (br, 1H, OH), 1.26 (d, J = 6.0 Hz, 3H, CH_3). ^{13}C NMR (100 MHz, $CDCl_3$) δ: 156.0, 137.0, 128.8, 128.6, 128.4, 128.2, 83.4 (C_6), 67.2 (OCH), 65.9 (C_1), 64.5 (CH_2Ph), 62.5 (C_3), 50.7 (C_4), 44.9 (C_5), 23.9 (CH_3). HRMS *m/z* found: 300.1217; calcd for $C_{15}H_{19}NaNO_4$ (M + Na): 300.1206.

Supplementary data

Supplementary data (copies of reported ^1H NMR and ^{13}C NMR spectra for all new compounds) are available with this article through the journal Web site at http://nrcresearchpress.com/doi/suppl/10.1139/v11-112.

Abstract: Polymeric microspheres responsive to pH and temperature changes have been prepared by a two-step surfactant-free emulsion polymerization with a polystyrene core and a hydrogel shell. The double sensitivity is achieved by the copolymerization in the shell layer of acrylic acid and *N*-isopropylacrylamide, which are pH- and thermo-responsive, respectively. Above a certain critical concentration, these microspheres are able to self-assemble into crystalline colloidal arrays, causing intense visible light diffraction. The behavior of these structures has been studied and correlated to the properties of the microspheres. The packing of these microspheres results in stimuli-sensitive colloidal crystals, with a behavior directly linked to the interactions between the particles and the surrounding media.

Key words: core-shell microspheres, surfactant-free emulsion polymerization, pH and thermo-sensitivity, crystalline colloidal arrays.

Résumé : Des microsphères doublement sensibles et composées d'un coeur de polystyrène entouré d'une couche d'hydrogel ont été synthétisées par polymérisation en émulsion sans tensioactif. La double sensibilité a été obtenue grâce à la copolymérisation de l'acide acrylique et du *N*-isopropylacrylamide, tous deux connus pour être sensibles respectivement au pH et à la température. Au dessus d'une concentration critique, ces microsphères sont capables de s'auto-assembler pour former des cristaux colloïdaux et affichent des couleurs intenses dues à la diffraction de la lumière visible. Le comportement de ces structures a été étudié en rapport avec les propriétés des particules. L'empilement de ces microsphères donne des cristaux colloïdaux sensibles à leur environnement, propriété qui semble être liée à la nature des interactions entre les particules.

Mots-clés : microsphères coeur-coquille, polymérisation en émulsion sans tensioactif, sensibilité au pH et à la température, cristaux colloïdaux.

Introduction

Polymer microspheres have been the subject of intense research interests for biosensor-related applications because of their high surface area, hence fast response and easy functionalization.[1] Stimuli-responsive microgels have proven to be particularly interesting because of their ability to swell or shrink, depending on their environment[2,3] or their interaction with an analyte, such as the complexation with a biological molecule.[4–6] Crystalline colloidal arrays (CCAs) may be formed through the self-assembly of these particles, and the stimuli-responsiveness combined to their visible light diffraction make these structures interesting and useful. CCAs may be used as photonic gap materials[7,8] and biosensors,[9,10] mainly in the form of polymerized crystalline colloidal arrays, where the self-assembled hard spheres are fixed inside a crosslinked hydrogel matrix, which is responsive toward the external stimulus. With this system, Asher and co-workers developed sensors for a large range of analytes from glucose to metal ions.[11,12]

For a direct response of the particles, stimuli sensitivity can be introduced into the particles. Lyon and co-workers have studied thermo-responsive poly(*N*-isopropylacrylamide) (PNIPAM) microgels, containing a very small fraction of acrylic acid monomers, and investigated the effect of temperature on their self-assembly,[13–15] noticing a loss of order above the lower critical solution temperature (LCST) of PNIPAM. The demand for more advanced properties also led to the development of particles with core-shell structures, often with a rigid core and a soft hydrophilic shell. Two kinds of stimuli-responsive core-shell particles have been synthesized, either with one responsive component[16–19] or even two or more components, forming multi-responsive systems.[20–22] The stimuli sensitivity can be introduced into the particles by adding a soft and responsive shell made of a hydrogel. Meng et al. showed the importance of the hydrophilic shell in the packing mechanism of core-shell particles with a polystyrene core.[17] They also showed the pH response of CCAs with a shell made of poly(acrylic acid). Li et al. investigated

the response to temperature using a poly(*N*-isopropylacrylamide) shell and noticed a shift of the diffraction peak.[18]

In this work, microspheres were synthesized by surfactant-free emulsion polymerization with a polystyrene core and a hydrogel shell. The shell was made of poly(acrylic acid) for pH-sensitivity and of a copolymer of acrylic acid and *N*-isopropylacrylamide for double sensitivity to both pH and temperature. These particles easily self-assemble into CCAs and display visible light diffraction. The packing mechanism and the properties of the CCAs in response to both pH and temperature changes have been studied and compared. The preliminary results indicate that the response is closely related to the kind of interactions that exist among the microspheres.

Experimental

Materials and synthesis of core-shell particles

Styrene, acrylic acid (AA), *N*-isopropylacrylamide (NIPAM), and potassium persulfate (KPS) were purchased from Sigma-Aldrich. Styrene and AA were distilled under reduced pressure. NIPAM was recrystallized from hexanes. The initiator KPS was used as received.

The core-shell microspheres were synthesized by a two-step surfactant-free emulsion polymerization in an aqueous medium following a procedure reported by Xiao et al.[23] and Meng et al.[17] In a 250 mL three-neck flask, equipped with a reflux condenser, 2.3 g of styrene and 0.2 g of hydrophilic monomers, either AA or a 1:1 mixture (weight ratio) of AA and NIPAM, were dissolved in 130 mL of milli-Q water. The system was degassed with nitrogen for 30 min while stirring with a mechanical stirrer at a speed of 300 rpm. The initiator KPS was then added with 20 mL of water, and the flask was heated to 70 °C in an oil bath. After 2 h of stirring, 1 g of the hydrophilic monomer or the mixture of hydrophilic monomers was added. The temperature and the stirring were maintained for an additional 22 h. The water–particle mixture was centrifuged, and the supernatant was removed and replaced by milli-Q water. The particles were redispersed by the use of a vortex and a sonicator. The centrifugation procedure was repeated three times, followed by dialysis against distilled water for one week at room temperature (RT) in a cellulose sack (MW cut off at 3200).

Characterization of the particles and the CCAs

The microsphere sizes were measured by dynamic light scattering on a Brookhaven BI-200SM instrument with a 532 nm green laser. The samples concentration was 0.02 wt %. For each sample, three measurements were taken. Our samples are composed of only one population of particles with a narrow distribution, the method of cumulants with a third-order fit was used to obtain the average size from the normalized autocorrelation function. The pH of the samples were adjusted by adding $HCl_{(aq)}$ or $NaOH_{(aq)}$ for the study of pH sensitivity. The temperature was controlled with a water bath, and the samples were allowed to equilibrate for 30 min before taking the measurements.

The particle packing was obtained with simple centrifugation before being studied by visible light diffraction, which was measured by the use of a home-assembled spectrophotometer (USB2000, Ocean Optics) equipped with a tungsten-halogen source (400–1000 nm), a backscattering probe (R200–7 VIS/NIR, Ocean Optics), and a cuvette holder with water circulation for temperature control. For pH studies, 5 samples of the same particle concentration but with different pH values were prepared with solutions of $HCl_{(aq)}$ or $NaOH_{(aq)}$.

Transmission electron microscopy (TEM) images of the particles were obtained with a Philips CM200 instrument at an acceleration voltage of 200 kV. TEM samples were prepared by depositing a 20 μL drop of particles solution of 0.1 wt% on a carbon-coated copper grid for 2 min before absorbing the excess with precision paper. The grids were then dried at RT overnight.

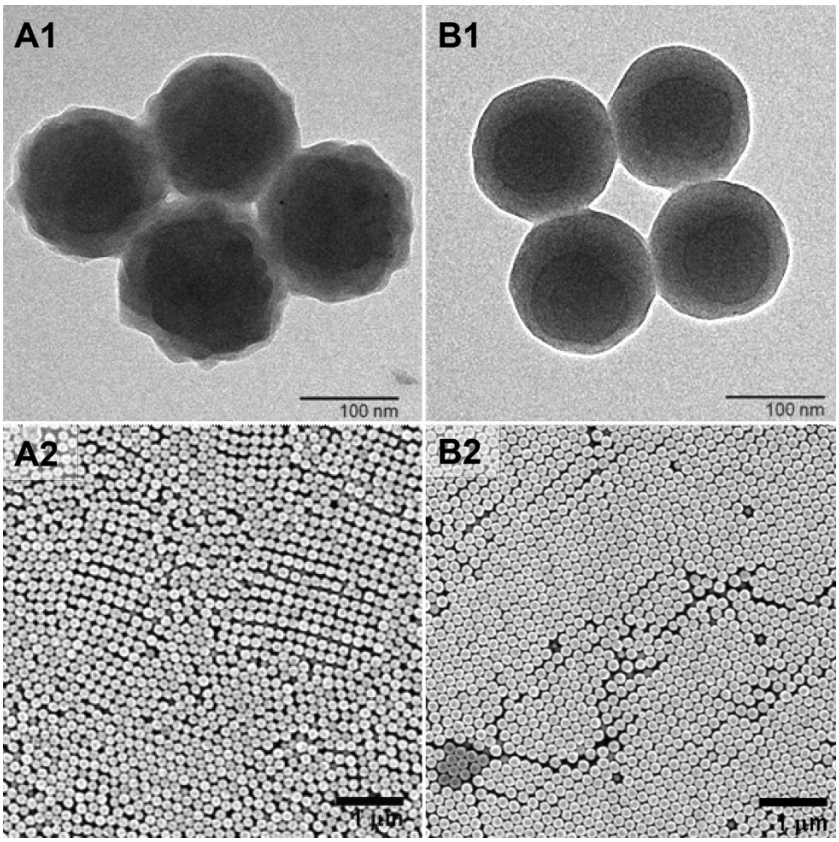
For scanning electron microscopy (SEM) of the CCAs, a concentrated solution of particles was drop-casted and dried at RT. The samples were coated with a layer of Pd–Au of 20 nm thickness and observed on a FE-SEM (Hitachi S-4700) with an accelerating voltage of 2 kV.

Results and discussion

Preparation and morphology of the polymer spheres

The two-step synthesis of the core-shell particles can be described as a surfactant-free emulsion polymerization followed by a seed polymerization. The first step is the synthesis of the microsphere core: the hydrophilic monomers start to polymerize in the aqueous medium, initiated by the water-soluble KPS. As more styrene units are incorporated, the oligomers become less water-soluble and start to form the core. The second step is the shell formation onto the cores, which serve as seed particles.

It has been shown that even one-step synthesis with a hydrophobic monomer and a hydrophilic one can yield core-shell structures to minimize unfavorable interactions between the hydrophobic units and water.[24] However, it has also been shown that the use of a second step gives better uniformity and a thicker shell.[19,23] The use of a more hydrophilic monomer in the first step helps stabilize the surface, leading to more particles smaller in size. However, larger amounts of hydrophilic monomers in the reaction medium can result in their polymerization in the solvent rather than their participation in the particles.



TEM images in Fig. 1 confirm that the core-shell structures of the particles and their uniformity in both size and shape. The surface of the P(S-AA-NIPAM) particles is smooth but the P(S-AA) particles are less regular, which is probably due to the solubility difference of the polymers in the shell at the temperature of preparation.

Double sensitivity toward pH and temperature

Figure 2A shows the pH effect on both kinds of microspheres. As expected, the P(S-AA) particles show a pH-induced transition characterized by a decrease in size at lower pH values, as the protonation facilitates hydrogen bonding between the carboxylic acid groups and thus the expulsion of water from the shell. The stimuli responsiveness of the hydrogel particles can be manifested by a volume phase transition (VPT), analogous to the cloud points of linear polymers. The VPT happens here between pH 6 and 7. The pK_a of the monomer is 4.3, but it is known that the polymerization, the chains entanglements, and the presence of hydrophobic units all may affect the value of

Fig. 1. TEM images (top) of (A) P(S-AA) and (B) P(S-AA-NIPAM) microspheres, showing the spherical and core-shell structures and SEM images (bottom) of the dried films showing the self-assembly of the particles into crystalline colloidal arrays.

the effective pK_a.[25,26] In this case, it may be shifted to a higher value. The P(S-AA-NIPAM) particles show a similar behavior versus pH with a decrease in size at acidic pH. The transition for the P(S-AA-NIPAM) microspheres versus pH at RT occurs over the same range of pH, but the change in size is less significant because of the smaller amount of AA in the shell in comparison to the P(S-AA) particles. At 46 °C, above the LCST of PNIPAM, the polymer becomes more hydrophobic and shrinks, causing a decrease in size. As a result, the particles are less pH-responsive with a broader transition and a smaller change in size than at lower temperatures.

In addition to the pH responsiveness, the P(S-AA-NIPAM) microspheres clearly demonstrate a temperature sensitivity, as shown in Fig. 2B. At pH 9, all the acrylic acid units are deprotonated, making the shell highly hydrophilic. There is a sharp VPT at ca. 30 °C, slightly under the known LCST of linear PNIPAM (32 °C), probably because the hydrophobic polystyrene core may lower the apparent hydrophilicity. The VPT at pH 3.5 (lower than the pK_a) is more gradual and spread over a temperature range of over 20 °C with a smaller change in size. Under this condition, PAA is protonated and less swollen, decreasing the hydrophilicity and making the particles less responsive to temperature. Matsuoka et al. showed that the addition of some ionic groups in PNIPAM particles sharpens the VPT compared with PNIPAM alone and attributed it to the presence of electrorepulsive force decreasing entanglements and interactions between the PNIPAM chains.[27]

Crystalline colloidal arrays

When the concentration is sufficiently high, both P(S-AA) and P(S-AA-NIPAM) microsphere samples can self-assemble into CCAs and exhibit intense color, which varies with the angle of the incident light, as a result of visible light diffraction. The diffraction of light by the CCAs formed by the microspheres follows Bragg's law:

$$[1] \qquad m\lambda = 2nd_{hkl}\sin\theta$$

where m is the order of diffraction, λ the wavelength of the diffracted light, n the refractive index of the CCAs, d_{hkl} the interplanar spacing for the lattice plane defined by the Miller indices (hkl), and θ the angle between the incident light and the diffracting lattice plane. The refractive index of a mixture, such as a solution of polymer in water, is regarded as additive and thus can be estimated from eq. [2]:

$$[2] \qquad n = n_{\mathrm{p}}\varphi_{\mathrm{p}} + n_{\mathrm{w}}(1 - \varphi_{\mathrm{p}})$$

where φ_{p} is the volume fraction of the particles and n_p and n_{w} are the refractive indices of the particles and water, respectively. The refractive index of the polymeric particles is estimated according to eq. [2] from the refractive indices of the corresponding homopolymers found in the literature[28–30] and the volume fractions of the core and shell as determined from TEM images. In the case of P(S-AA-NIPAM), the PAA/PNIPAM ratio in the shell is assumed to be identical to the feed ratio.

Light diffraction is observed over a wide range of particle concentrations, as shown in Figs. 3A and 3B, with the

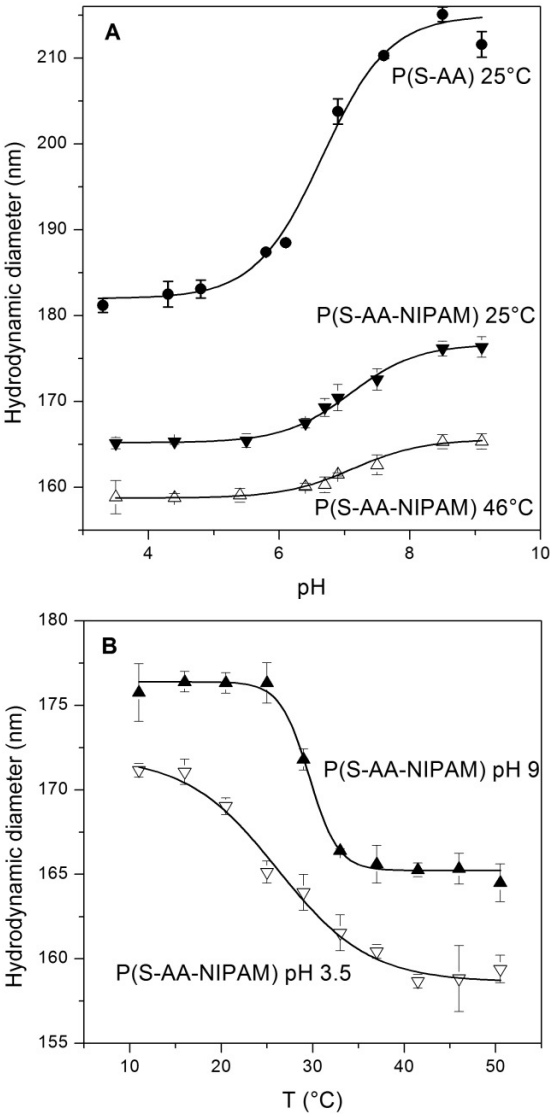
Fig. 2. (A) Hydrodynamic diameters of P(S-AA) and P(S-AA-NIPAM) as a function of pH, and (B) hydrodynamic diameters of P(S-AA-NIPAM) as a function of temperature showing its double sensitivity.



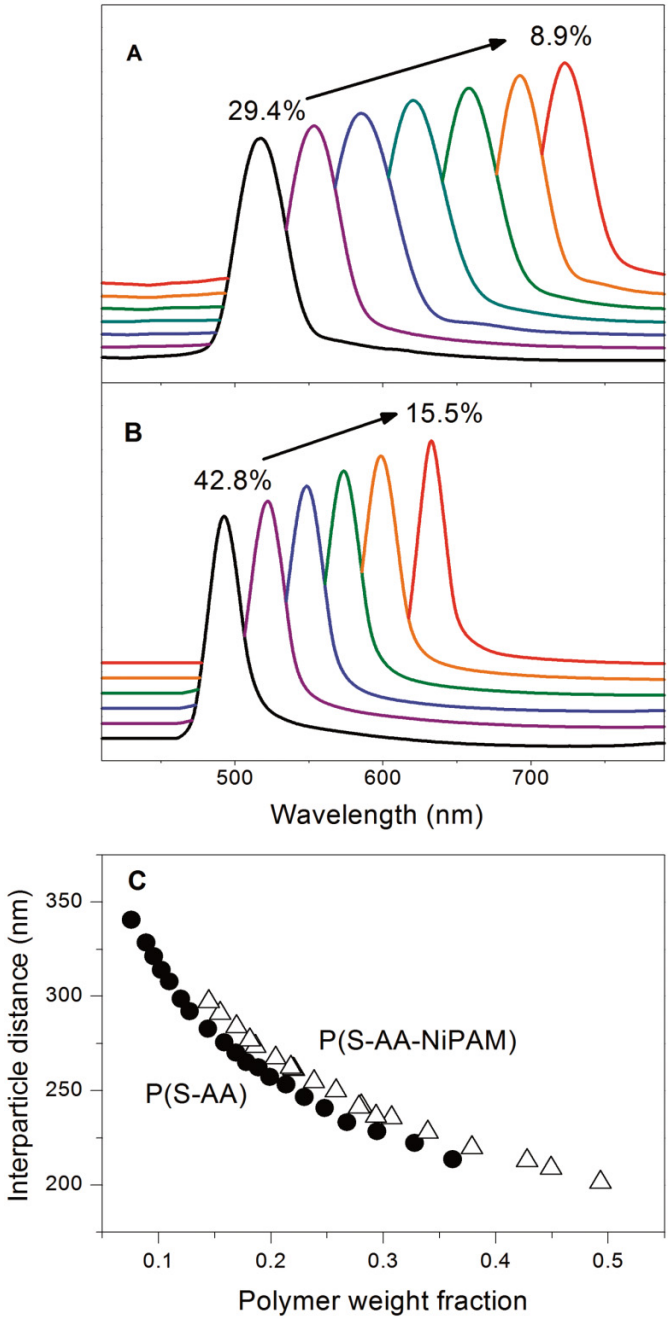


Fig. 3. Evolution of the diffraction spectra upon dilution of the CCAs of (A) P(S-AA) and (B) P(S-AA-NIPAM) particles. (C) The evolution of the estimated interparticle distance versus the polymer weight fraction. Spectra are normalized to the same intensity for the highest peak for better comparison. Weight percentages of particles in water are indicated in A and B.

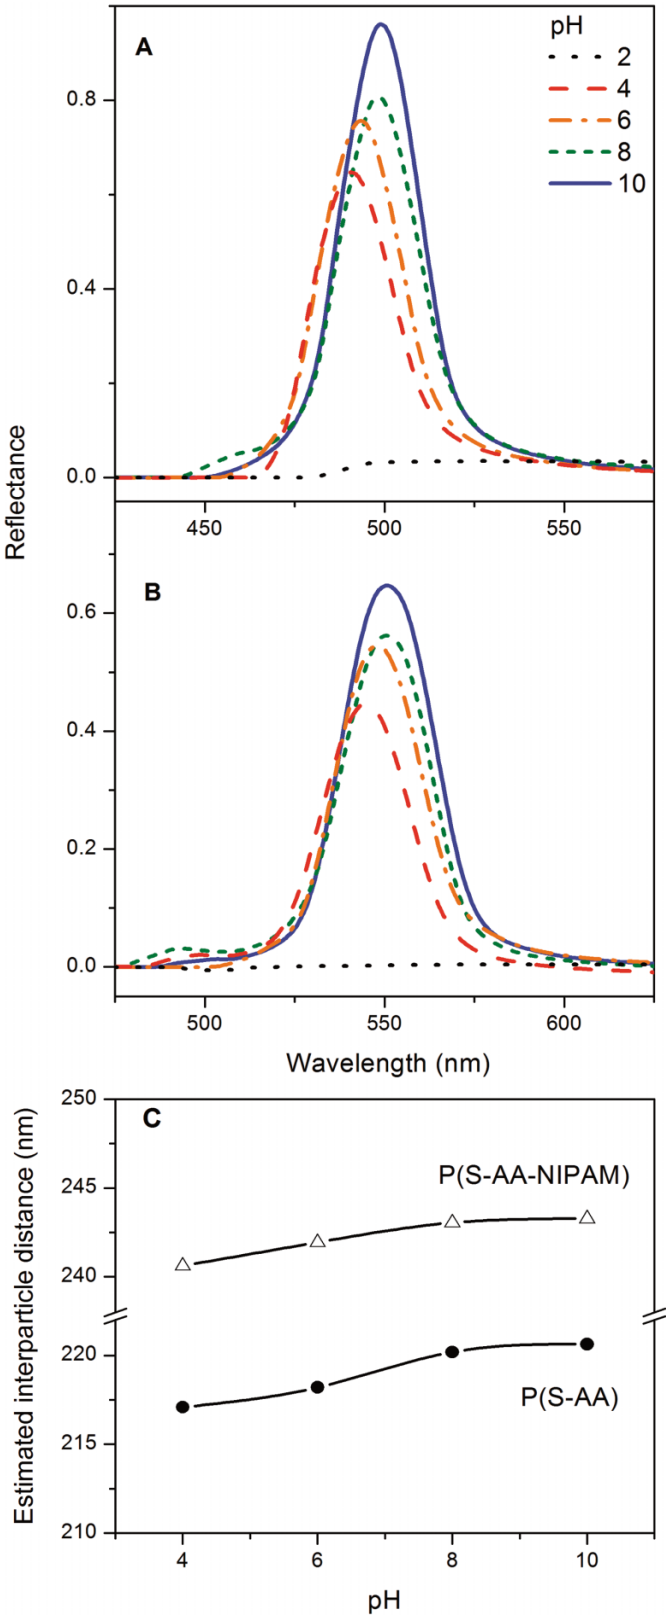
diffraction peaks red-shifting upon dilution. Figure 3C shows the estimated interparticle distance versus the particle weight fraction. The interparticle distance was obtained through the lattice space given by Bragg's law (eq. [1]) by using the estimated values of refractive index (eq. [2]). It is interesting to compare the smallest interparticle distance, corresponding to the highest concentration obtained, to the microsphere size. The estimated interparticle distance for P(S-AA) CCAs at 36 wt% is 214 nm for a value of refractive index of 1.40. For P(S-AA-NIPAM) CCAs at 49 wt%, the estimated interparticle distance is 201 nm for a refractive index of 1.43. For both kinds of CCAs, these values are higher than the hydrodynamic diameters of the particles, 203 and 170 nm for P(S-AA) and P(S-AA-NIPAM), respectively. This may be an indicator that the CCAs are not close-packed, even at the highest concentrations obtained.

Figure 3C shows the same decreasing trend of the interparticle distances with the particle concentration for both kinds of particles. As the sample is diluted, the particles move further away from each other while maintaining the crystalline structure, leading to a larger interparticle distance and thus a higher wavelength of diffracted light. At some point of dilution (7 and 14 wt% for P(S-AA) and P(S-AA-NIPAM), respectively), the order is disrupted, highlighted by the disappearance of the diffraction peak. At this distance (estimated to be ca. 350 and 300 nm for P(S-AA) and P(S-AA-NIPAM), respectively) the electrostatic repulsion between

Can. J. Chem. Downloaded from www.nrcresearchpress.com by Renmin University of China on 09/02/12
For personal use only.

particles is not strong enough and is overcome by the Brownian motion, leading to a disordered suspension. As expected, with similar sizes, the P(S-AA) particles remain crystalline until 7 wt%, compared with only 14 wt% for the P(S-AA-NIPAM) particles: fewer charges mean weaker electrostatic interactions that are effective over shorter distances.

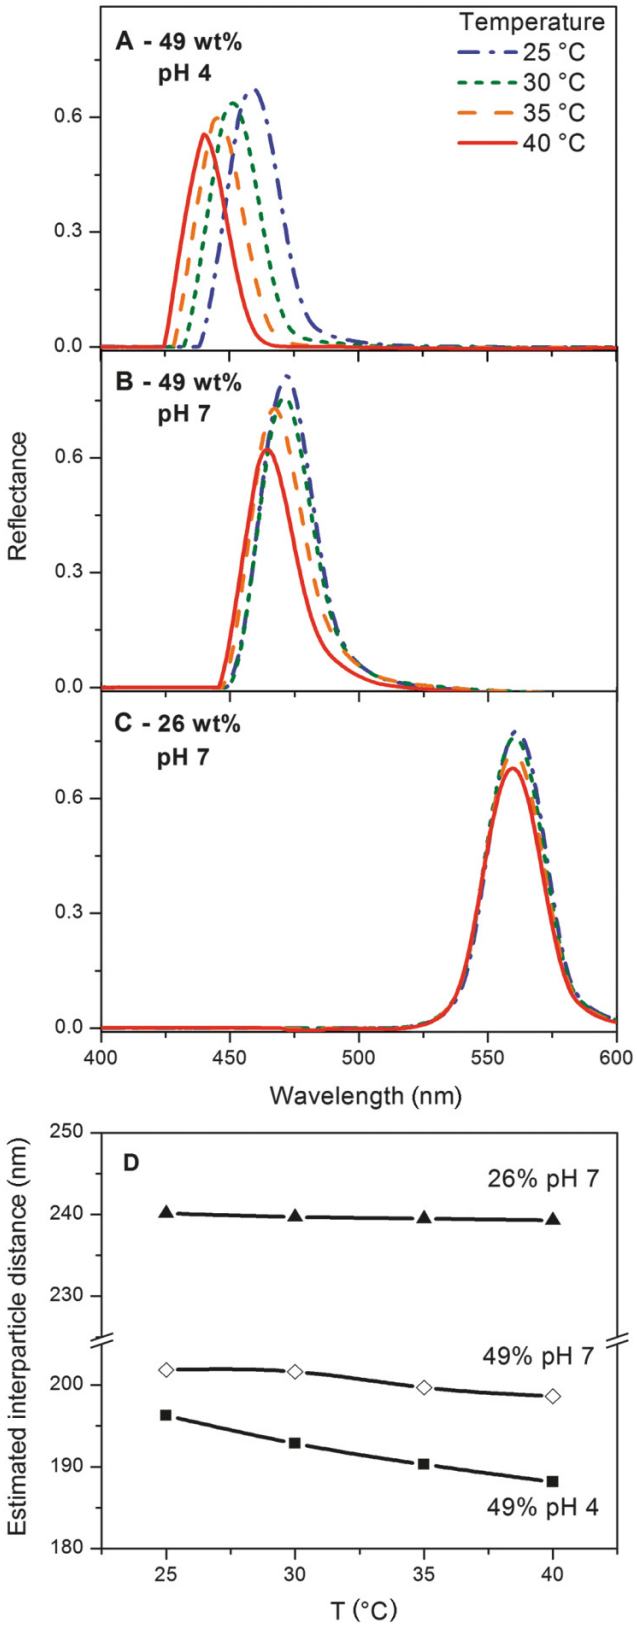
The P(S-AA-NIPAM) microspheres in dilute suspensions clearly demonstrate double sensitivity through their change in size. There is a greater complexity for more concentrated samples as the particles are packed into CCAs.



In Fig. 4, the effect of pH on CCA diffraction is shown. Both kinds of particles show the same trend. At pH 2, the acrylic acid residues chains are fully protonated decreasing the surface charge density. In addition, compared with pH 4, the aqueous medium at pH 2 has a higher ionic strength because of the $HCl_{(aq)}$ added to adjust the pH. The higher ionic strength results in weaker electrostatic interactions.[31,32] According to the DLS experiments, this happens for all pH values lower than 3, leading to the aggregation of particles in dilute suspensions. For the CCAs, the electrostatic repulsion is not strong enough to stabilize the system, causing a total loss of order. Between pH 4 and 10, the microspheres are organized into CCAs as shown by the presence of the diffraction peaks. At pH 10, the diffraction peaks are intense, while the PAA chains are fully deprotonated. As the pH decreases, the peaks become less intense and start to shift towards shorter wavelengths, indicating that the particles are closer to each other with a certain loss of order. Figure 4C summarizes the variation of the estimated interparticle distance as a function of pH. The same tendency is observed for both kinds of particles, but the changes seem to be larger for the P(S-AA) particles for which the variation of the surface charge density is more significant.

The thermo-responsiveness was also studied for the CCAs of P(S-AA-NIPAM), as shown in Fig. 5. First, a very concentrated sample at 49 wt% of the particles was studied at pH 7 (Fig. 5B). The increase in temperature causes a blue shift of the diffraction with a decrease of intensity, similar to the effect of pH. However, contrary to pH, the change in temperature does not affect the electrostatic repulsion but does affect the van der Waals interactions through the Hamaker constant, which increases from the swollen to the collapsed states of PNIPAM. At pH 4 (Fig. 5A), the shift is more significant, probably due to weaker electrostatic interactions, which make the system more sensitive to the van der Waals interactions. This proposed origin for the diffraction peak shift is further confirmed by the results obtained with a less concentrated sample (Fig. 5C). At this concentration (26 wt %), the particles are further away from each other and the van der Waals interactions are weaker between them, despite the increase of the Hamaker constant. As a result, the increase in temperature does not affect the interparticle distance to any significant extent, only a small decrease of the diffraction peak intensity due to the faster Brownian motion.

Conclusion



Core-shell microspheres with double sensitivity have been made via a simple two-step emulsion polymerization. The copolymerization of NIPAM and AA in the shell makes the particles responsive to changes in both pH and temperature.

Fig. 4. Diffraction spectra of the CCAs of (A) P(S-AA) and (B) P(S-AA-NIPAM) particles at different pH values with a particle concentration of 28 wt% at 25 °C. (C) The variation of the estimated interparticle distance as a function of pH.

Fig. 5. Diffraction spectra (A, B and C) of the CCAs of P(S-AA-NIPAM) particles at different temperatures under the specified conditions. (D) The variation of the estimated interparticle distance as a function of temperature. Notice the blue shift (towards shorter wavelengths) for the more concentrated samples.

It appears that the best sensitivity to temperature is obtained at high pH values, while the highest pH sensitivity is observed at low temperatures: the VPT is more intense and sharper when the shell is more hydrophilic. The CCAs obtained from these particles exhibit a good stability over a wide range of concentrations and also responsiveness to both temperature and pH stimuli. The increase of temperature and the decrease of pH both cause a decrease of the interparticle distance and a reduced order of the CCAs. These behaviors appear to be related to the nature and evolution of the interactions between particles rather than the change of particles size at the VPTs. The understanding of the self-assembly of the core-shell particles and the response of the CCAs toward the external stimuli is essential to their applications, especially in the design of biosensors by the use of such materials.

Abstract: A palladium pincer catalyst grafted onto the surface of magnetic nanoparticles (MNPs) has been developed. This material effectively catalyzes the reductive homocoupling of various aryl halide substrates, with the MNP support acting as the reducing agent. The catalyst can be recycled up to five times in the absence of additional reducing agent to give almost quantitative yields of biaryl homocoupling products. After the reducing power of the MNP has been depleted, the supported Pd complex remains an effective catalyst for Suzuki–Miyaura cross-coupling.

Key words: magnetic nanoparticles, reducing agent, supported Pd catalyst, reductive homocoupling, aryl halides.

Résumé : On a développé un catalyseur à tenaille à base de palladium greffé sur la surface de nanoparticules magnétiques (NPM). Ce matériau catalyse d'une façon efficace l'homocouplage réducteur de divers substrats d'halogénures d'aryle et les nanoparticules magnétiques agissent alors comme agent réducteur. Le catalyseur peut aussi être recyclé jusqu'à cinq fois, sans addition de nouvel agent réducteur, pour conduire à des rendements pratiquement quantitatifs de produits biaryles d'homocouplage. Une fois que le pouvoir réducteur des nanoparticules magnétiques a disparu, le complexe de palladium présent sur le support continue à être un catalyseur efficace pour la réaction de couplage croisé de Suzuki–Miyaura.

Mots-clés : nanoparticules, agent réducteur, catalyseur de palladium, réducteur, homocouplage.

[Traduit par la Rédaction]

Introduction

Palladium-catalyzed coupling reactions are among the most useful synthetic methods for the formation of carbon–carbon and carbon–heteroatom bonds and are widely utilized to assemble a vast range of important molecules in pharmaceutical, agricultural, natural product, and material sciences.[1] Using homogeneous palladium catalysis, a high reaction rate, turnover number (TON), selectivity, and yield are often possible after addition of the appropriate ligand.[2] However, the main drawback of homogeneous catalysis is associated with the separation and recycling of the catalyst. This aspect leads to a loss of expensive metal (and ligands), as well as to the presence of metal impurities in the products. The complete removal of residual metals is a major problem especially for pharmaceutical products, where carryover of metal impurities may cause serious problems in the production of many formulations.[3]

Recently, magnetic nanoparticles (MNPs)[4] have emerged as new catalyst supports because of their facile separation from the reaction mixture with the aid of an external magnet.[4] In this regard, we initiated a systematic program to develop novel types of grafted metal–catalysts on MNP,[5] and to apply them in metal-catalyzed reactions, as such types of catalysts not only can perform with superior catalytic activities compared with their corresponding bulk metals,[6] but also provide increased loading capacity. Herein, we report our new MNP-supported Pd pincer complex, which can catalyze the reductive homocoupling of aryl halides in high yields and can be recycled up to five times *in the absence of added reducing agents* without loss of activity. We show that Pd leaching is not responsible for the subsequent loss of activity for reductive homocoupling as the supported catalyst remains active for Suzuki–Miyaura cross-coupling catalysis.

Results and discussion

The MNPs utilized for immobilizing the Pd–catalyst were synthesized via a thermal decomposition approach according to the procedure reported by Cai and Wan.[7] Thus, the reaction of $Fe(acac)_3$ in triethylene glycol leads to the MNP. The formed MNPs were characterized by transmission electron microscopy (TEM), and the TEM image (Fig. 1) shows that they are relatively uniform with an average size of 6 ± 1 nm.

The synthesis of the NCN pincer ligand commenced as outlined in Scheme 1.

The commercially available 5-aminoisophthalic acid **1** was first converted to its diethyl ester **2**,[8] followed by $LiAlH_4$

reduction to afford diol **3** in 75% overall yield in two steps. An efficient acylation–chlorination sequence subsequently elaborated **3** into bis(chloromethyl)aniline **4** in 63% overall yield.[9] Compound **4** then underwent nucleophilic substitution of pyrazole, followed by hydrolysis to give bispyrazol-substituted aniline **5** in 79% yield (two steps). The substituted aniline **5** was then coupled with succinic anhydride in the presence of Et_3N to give amide **6** in 93% yield. Amide **6** was coupled to the MNP under standard conditions[7] to deliver **7**, which was then treated with $Pd(PhCN)_2Cl_2$ in refluxing toluene to afford the desired MNP-supported Pd–catalyst **8** as a black powder. The Pd loading level of the catalyst is 0.020 mmol/g, determined by elemental analysis.

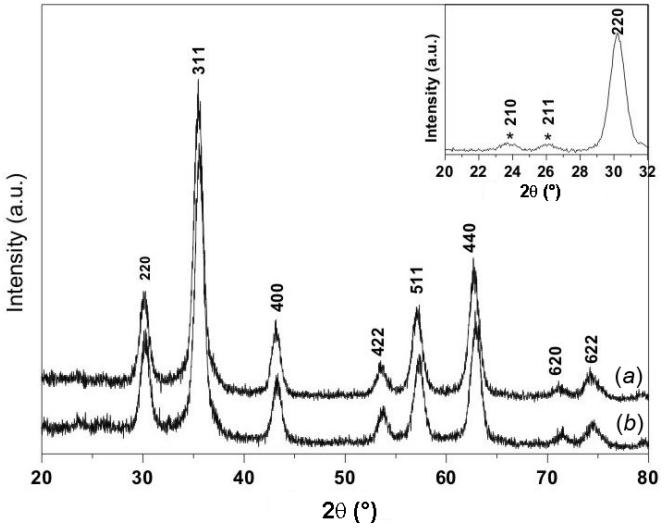
[a]Determined by ^{1}H NMR.

To test the efficiency and reactivity of the newly generated magnetic catalyst **8** in Pd-catalyzed coupling reactions, we first selected the Suzuki–Miyaura reaction because of its importance in the synthesis of unsymmetrical biaryls.[10]

Thus, when aryl iodide **9** was reacted with phenyl boronic acid **10** under typical Suzuki–Miyaura coupling conditions in the presence of catalyst **8**, the expected product **11** was obtained in 70% yield, together with the formation of 15% of the symmetrical biaryl product **12**, derived, surprisingly, from the reductive homocoupling of the aryliodide.

Symmetric biaryls Ar–Ar generated from oxidative homocoupling of the arylboronic acid $ArB(OH)_2$ are typically observed in Suzuki–Miyaura reactions, as they result from the process that reduces Pd(II) catalyst precursors to Pd(0) active catalysts.[10] However, the reductive homocoupling product derived from the aryl halide is seldom reported in Suzuki–Miyaura reactions.[11]

We attributed the formation of the homocoupling product **12** to the grafted magnetite nanocatalyst **8**. We also envisaged that the MNP derived from Fe_3O_4 might play the role of the reducing agent. We therefore decided to explore the feasibility of carring out the useful reductive homocoupling of aryl halides without the addition of any other reducing agents.



Thus, **13** was selected as the substrate, and the reaction was carried out in DMF for 12 h at 110 °C in the presence of K_2CO_3 and catalyst **8** (2.0 mol %). To our delight, the expected symmetric biaryl product **14** was obtained in quantitative yield (Table 1). It is noteworthy that the same catalyst could be recycled five times without loss of catalytic activity.

However, when the catalyst was continually applied to this reaction more than five times, the reductive homocoupling yield was decreased dramatically, indicating that the reducing capability of the MNPs had diminished. We also noticed that the color of the nanoparticles changed from black to red-brown after the homocoupling reaction, which suggested that Fe_3O_4 might be undergoing oxidation to Fe_2O_3. To prove our hypothesis, we characterized the nanoparticles by X-ray diffraction.

As shown in Fig. 2, the diffraction peaks indicate that the magnetite particles have been oxidized to maghemite after

Fig. 2. X-ray diffraction patterns. (*a*) The magnetic nanoparticles before catalytic reactions. (*b*) The magnetic nanoparticles after five catalytic cycles. The inset shows a magnification of the region 2θ = 20°–32° of curve (*b*).

five catalytic cycles, as evidenced by the observation of the enhancement of characteristic (210) and (211) diffraction peaks of maghemite in the XRD patterns of the nanoparticles after the coupling reaction.[12]

After the homocoupling reaction, catalyst **8** was simply attracted to the side of the vial by an external magnet (Fig. 3), the reaction mixture was transferred out of the flask, and the remaining catalyst was washed three times with CH_2Cl_2 before recharging with the substrate and the solvent.

To verify the role of MNP-grafted catalyst **8** in this coupling reaction, we then carried out comparison reactions. Thus, catalyst **8** was replaced with NCN pincer ligand and $Pd(PhCN)_2Cl_2$, respectively, to carry out the same reaction as depicted in Table 1. As a result, no coupling product **14** was observed, indicating that neither the NCN pincer ligand nor $Pd(PhCN)_2Cl_2$ can catalyze the observed homocoupling individually.

To clarify further if the leached Pd species is the active catalyst, we carried out the following reaction. Accordingly, the coupling reaction was carried out under the conditions listed in Table 1. After one catalytic cycle, the MNP-grafted catalyst **8** was removed with a magnet. The remaining solution was analyzed by GC–MS, and the result indicated that the conversion of the homocoupling reaction is 99%. To this solution were added the same amounts of **13** and K_2CO_3, and the formed mixture first underwent GC–MS analysis and then was heated at 110 °C for 12 h. The analytical results indicated that no homocoupling reaction proceeded by comparison of their GC–MS spectra before and after the reaction (Figs. 4–6). Thus, Pd species leached from the MNP-grafted catalyst **8** as an active catalyst could be precluded.

To profile the substrate scope, we selected nine additional substrates (**15**–**23**) for the homocoupling reactions under the conditions listed in Table 2. To our delight, all of the substrates gave essentially quantitative yields of the coupling products[13] (Table 2).

To evaluate whether the MNP plays a critical role in this reductive homocoupling process, we carried out the coupling

Scheme 2. Syntheses of compounds **11** and **12**.

reaction of **13** by replacing catalyst **8** with a combination of amino-MNP **6** and $PdCl_2(PhCN)_2$. The expected homocoupling indeed took place; however, considerable palladium aggregation was observed, and the catalyst system could not be recycled. Next, we also carried out the Suzuki–Miyaura reaction depicted in Scheme 2 with deactivated catalyst **8** (i.e., after five cycles in the homocoupling reaction). In this case, the coupling reaction between substrates **9** and **10** was catalyzed with deactivated catalyst **8** in the presence of DMF, K_2CO_3, and distilled water, the normal Suzuki–Miyaura product **12** was formed, and the previously observed homocoupling product **13** was not observed, indicating that (*i*) the MNPs in **8** serve as both the catalyst support and the reducing agent and (*ii*) Pd leaching is not responsible for the deactivation of the catalyst for the reductive homocoupling process.

Fig. 4. GC–MS spectra for the homocoupling reaction with or without magnetic nanoparticle (MNP) - grafted Pd–complex **8**. (Top) Spectra of the homocoupling product 4,4'-dinitrobiphenyl after one cycle with MNP-grafted Pd–complex **8** as catalyst. (Center) Spectra after removal of MNPs from the reaction mixture and addition of 1-iodo-4-nitrobenzene (0.3 mmol). The mixture was analyzed by GC–MS. (Bottom) After addition of K_2CO_3 (0.36 mmol) to the reaction mixture and the reaction was stirred at 110 °C for another 12 h. The mixture was analyzed by GC–MS.

Mechanistically, the formation of homocoupling products from aryl iodides might proceed through a process of sequential oxidative additions of aryl iodide to a MNP-grafted Pd–complex, accompanying by the in situ MNP-mediated reduction of the formed aryl palladium halide, and the generated MNP-grafted $PdAr_2$ species could undergo reductive elimination to give a reduced MNP-grafted Pd species and the biaryl, Ar–Ar. It is not useful at this time to speculate further on the nature of the Pd intermediates, as it is not clear whether a Pd(0)–Pd(II) or Pd(II)–Pd(IV) cycle is operating.

In summary, the Pd–pincer complex grafted onto MNP **8** exhibited good catalytic activity for the homocoupling of aryl halides to give symmetric biaryl compounds in the absence of additional reducing agents. This catalyst can be recycled up to five times without loss of catalytic activity. Our studies should stimulate further research in heterogeneous catalysis using MNP-grafted catalysts.

Experimental section

Materials and general procedure

All reactions were carried out under a nitrogen atmosphere with dry solvents under anhydrous conditions unless otherwise noted. All chemicals were commercially available and used without further purification. Solvents used in all the reactions were dried by standard procedures.

Reactions were monitored by thin-layer chromatography (TLC) carried out on 0.25 mm Tsingdao silica gel plates (60F-254) using UV light as the visualizing agent. Tsingdao silica gel (60, particle size 0.040–0.063 mm) was used for flash column chromatography.

Reagents were purchased at the highest commercial quality and used without further purification, unless otherwise stated. NMR spectra were recorded on a Brüker Avance 300 (^{1}H, 300 MHz; ^{13}C, 75.5 MHz) or a Brüker Avance 500 (^{1}H, 500 MHz; ^{13}C, 125 MHz). XRD was carried out on a D/max 2500PC X-ray diffractometer at room temperature.

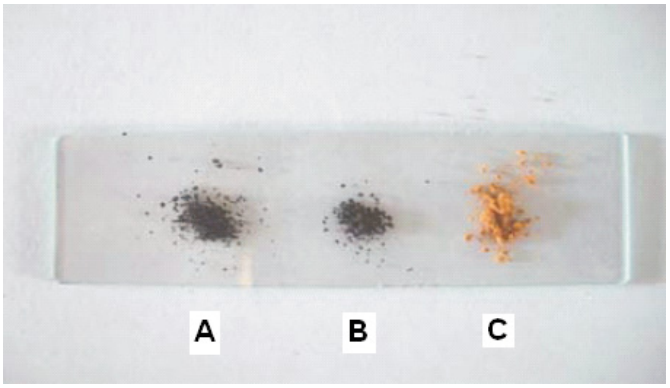
Experimental procedures



Synthesis of diethyl-5-(amino)isophthaloate (2)

To a stirred solution of 5-(amino)isophthalic acid **1** (5.0 g, 27.5 mmol) in absolute ethanol (100 mL) was added thionyl chloride (6.0 mL, 82.5 mmol) dropwise at 0 °C, and the formed mixture was stirred at reflux for 5 h. The solvent was removed in vacuum, the crude residue was dissolved in ethyl acetate, and the organic layer was washed with a saturated aqueous solution of sodium carbonate and then dried over sodium sulfate. The solvent was removed under vacuum to give diester **2** as a white solid in 97% yield. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 8.07 (t, J = 1.2 Hz, 1H), 7.53 (d, J = 1.2 Hz, 2H), 4.39 (q, J = 7.2 Hz, 4H), 3.94 (bs, 2H), 1.41 (t, J = 7.2 Hz, 6H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 166.02, 146.58, 131.72, 120.50, 119.59, 61.14, 14.24. HRMS (*m/z*) calcd for $C_{12}H_{16}NO_4$ [M + H$^+$]: 238.1079; found: 238.1074.

(*b*) MNP-grafted Pd–complex **8** heated to 110 °C in DMF for 60 h without color change (black color). (*c*) After the homocoupling reaction for five cycles, the color of MNP-grafted Pd–complex **8** was brownish.

Synthesis of 3,5-bis(hydroxymethyl)aniline (3)

To a slurry of $LiAlH_4$ (2.39 g, 63 mmol) in THF (200 mL), a solution of diethyl-5-(amino)isophthaloate (5.0 g, 21 mmol) in dry THF (100 mL) was added slowly at 0 °C with vigorous stirring. After this addition, the mixture was stirred initially at the same temperature for an additional 30 min and then at room temperature for 6 h. The reaction was quenched by the slow addition of ethyl acetate (20 mL) with vigorous stirring to consume the excess $LiAlH_4$. After stirring at the room temperature for 2 h, a saturated NH_4Cl solution (50 mL) was then added to hydrolyze the aluminum salt. After stirring for another 1 h, the resulting slurry was filtered through a pad of silica gel, and the pad was washed with ethyl acetate (3 × 100 mL). The filtrate was concentrated, and the residue was purified by flash chromatography on silica gel to give compound **3** (2.41 g) in 75% yield. ^{1}H NMR (300 MHz, DMSO-d_6) δ: 6.40 (s, 3H), 4.95 (t, J = 5.4 Hz, 4H,), 4.34 (br, 2H), 4.32 (br, 2H). ^{13}C NMR (75 MHz, DMSO-d_6) δ: 148.62, 143.21, 112.85, 111.01, 63.68. HRMS (*m*/*z*) calcd for $C_{12}H_{12}NO_2$ [M + H$^+$]: 154.0868; found: 154.0867.

Synthesis of* N*-acetyl-3,5-bis(chloromethyl)anilide (4)

To a solution of **3** (1.90 g, 12.4 mmol) in THF (100 mL) was sequentially added Et_3N (1.8 mol, 12.4 mmol) and acetic anhydride (1.2 mL, 12.4 mmol) at room temperature, and the mixture was stirred for 1 h. The reaction mixture was filtered, and the solid was washed with THF. The combined filtrates were concentrated and purified by flash chromatography on silica gel to give the amide (2.01 g) in 83% yield as a white solid. ^{1}H NMR (300 MHz, DMSO-d_6) δ: 9.85 (s, 1H), 7.41 (s, 2H), 6.92 (s, 1H), 5.15 (t, J = 5.7 Hz, 2H), 4.43 (d, J = 5.7 Hz, 4H), 2.02 (s, 3H). ^{13}C NMR (75 MHz, DMSO-d_6) δ: 168.51, 143.19, 139.43, 119.51, 115.84, 63.34, 24.40. HRMS (*m*/*z*) calcd for $C_{10}H_{14}NO_3$ [M + H$^+$]: 196.0974; found: 196.0964.

To a solution of the amide prepared above (1.84 g, 9.4 mmol) and pyridine (1.7 mL, 21 mmol) in CH_2Cl_2 (50 mL) was added thionyl chloride (1.5 mL, 21 mmol) in a dropwise manner at 0 °C, and the mixture was stirred at room temperature for 5 h. The reaction was quenched by the addition of water (30 mol), and the organic phase was then sequentially washed with water (2 × 30 mL), 1 N HCl (2 × 10 mL), and brine (2 × 10 mL), and the organic phase was finally dried over Na_2SO_4. The solvent was removed in vacuum, and the residue was purified by flash chromatography on silica gel to give **4** (1.66 g) in 76% yield. ^{1}H NMR (300 MHz, DMSO-d_6) δ: 7.53 (s, 2H), 7.16 (s, 1H), 4.54 (s, 4H), 2.19 (s, 3H). ^{13}C NMR (75 MHz, DMSO-d_6) δ: 168.51, 138.85, 138.54, 124.24, 119.65, 45.51, 24.53. HRMS (*m*/*z*) calcd for $C_{10}H_{12}Cl_2NO$ [M + H$^+$]: 232.0296; found: 232.0293.

Synthesis of 3,5-bis[(1*H*-pyrazol-1-yl)methyl]aniline (5)

To a solution of **4** (1.16 g, 5 mmol) in CH_3CN (30 mL) was added potassium carbonate (1.73 g, 12.5 mmol) and pyrazole (0.68 g, 10 mmol), and the mixture was refluxed for 24 h. The reaction mixture was filtered, and the solid was washed with CH_3CN (3 × 10 mL). The filtrate was concentrated in vacuum, and the residue was purified by flash chromatography on silica gel to give the intermediate dipyrazole (1.27 g) in 86% yield. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 8.60 (s, 1H), 7.48–7.47 (m, 2H), 7.39–7.38 (m, 2H), 7.16 (s, 2H), 6.65 (s, 1H), 6.26–6.25 (m, 2H), 5.15 (s, 4H), 2.00 (s, 3H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 168.85, 139.67, 139.37, 137.97, 129.78, 121.47, 117.98, 106.05, 55.32, 24.18. HRMS (*m*/*z*) calcd for $C_{16}H_{18}N_5O$ [M + H$^+$]: 296.1511; found: 296.1511.

To a solution of the dipyrazole prepared above (1.18 g, 4 mmol) in 95% ethanol (50 mL) was added KOH (2.24 g, 40 mmol), and the mixture was refluxed for 20 h. The reaction mixture was neutralized by addition of a concentrated solution of HCl. The solvent was removed in vacuum, and the residue was extracted with CH_2Cl_2 (3 × 30 mL). The combined extracts were washed with a saturated solution of Na_2CO_3 (3 × 50 mL) and then dried over Na_2SO_4. The solvent was removed in vacuum, and the residue was purified by flash chromatography on silica gel to give **5** (0.93 g) in 92% yield. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 7.54–7.53 (m, 2H), 7.38–7.37 (m, 2H), 6.46 (s, 1H), 6.38 (s, 2H), 6.28–6.27 (m, 2H), 5.19 (s, 4H), 3.69 (s, 2H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 147.34, 139.44, 138.43, 129.27, 116.61, 113.50, 105.88. 55.60. HRMS (*m*/*z*) calcd for $C_{14}H_{16}N_5$ [M + H$^+$]: 254.1406; found: 254.1403.

Synthesis of 4-{3,5-bis[(1*H*-pyrazol-1-yl)methyl] phenylamino}-4-oxobutanoic acid (6)

To a solution of **5** (0.76 g, 3 mmol) in dry THF (15 mL) was added triethylamine (0.5 mL, 3.5 mmol) and succinic anhydride (0.3 g, 3 mmol), and the mixture was refluxed for 36 h. A saturated solution of NH_4Cl (10 mL) was added, and the mixture was extracted with EtOAc (3 × 20 mL). The filtrate was concentrated in vacuum, and the residue was purified by flash chromatography on silica gel to give acid **6** (0.98 g) in 93% yield. ^{1}H NMR (500 MHz, DMSO-d_6) δ: 9.95 (s, 1H) 7.75–7.74 (m, 2H), 7.44–7.43 (m, 2H), 7.33 (s, 2H), 6.78 (s, 1H), 6.25–6.24 (m, 2H), 5.24 (s, 4H), 2.49–2.48 (m, 4H). ^{13}C NMR (125 MHz, DMSO-d_6) δ: 174.28, 170.74, 140.25, 139.56, 138.99, 130.69, 121.85, 117.84, 106.04, 55.20, 31.56, 29.35. HRMS (*m*/*z*) calcd for $C_{18}H_{20}N_5O_3$ [M + H$^+$]: 354.1566; found: 354.1561.

Synthesis of iron oxide nanocrystals

A typical procedure for the synthesis of MNPs was as follows: $Fe(acac)_3$ (7.1 g, 20 mmol) and triethylene glycol (250 mL) were directly added to a three-necked round-bottomed flask equipped with a condenser, mechanical stirrer, thermograph, and heating mantle, and the mixture was stirred under argon. The mixture was slowly heated to 180 °C first and kept at that temperature for 30 min and then quickly heated to reflux (~280 °C) and kept at reflux for another 30 min. After cooling to room temperature, a black homogeneous colloid (magnetite nanoparticles) was formed. To this solution was added ethyl acetate (500 mL), and the formed flocculation was separated from the solution with a magnet. The black precipitate was first redispersed in ethanol and then precipitated with ethyl acetate. This washing procedure was repeated twice to remove excess triethylene glycol and by-products completely, and the resulting MNPs were obtained by drying the precipitate in vacuum.

Synthesis of amino-functionalized iron oxide nanocrystals

Iron oxide nanocrystals (1.0 g) were refluxed with 3-aminopropyltrimethoxysilane (4.0 mL, 0.023 mmol) in dry toluene (6.0 mL) for 1 day, and the solids were separated by applying an external magnetic field and washed with dry acetone (6 × 30 mL). The resulting product was dried in vacuum for 1 h.

General procedure for the synthesis of MNP-supported palladium catalyst

To a solution of ligand **6** (0.043 g, 0.12 mmol) in DMF (4.0 mL) was added dicyclohexylcarbodimide (0.027 g, 0.13 mmol), and the resulting solution was stirred at room temperature for 1 h. To this solution was added the amine-terminated MNP (0.3 g), and the mixture was stirred at room temperature for 24 h. After the reaction, the solid was separated by applying an external magnetic field and washed with dry dichloromethane (6 × 10 mL). The residue was dispersed in dry toluene (10 mL), followed by addition of $Pd(PhCN)_2Cl_2$ (0.013 g, 0.017 mmol), and the resulting mixture was stirred at reflux for 24 h. The formed MNP-supported catalyst **8** was magnetically separated and washed with dry dichloromethane (6 × 10 mL).

Procedure for using the MNP-supported palladium catalyst in homocoupling reactions

To a solution of the aryl halide (0.3 mmol) and K_2CO_3 (50 mg, 0.36 mmol) in DMF (3 mL) was added catalyst **8** (0.300 g), and the mixture was heated at 110 °C for 12 or 24 h under a nitrogen atmosphere. After the reaction, a magnet was used to separate the catalyst, which was then washed with dry CH_2Cl_2 (10 mL). The combined organic phases were washed with water, dried with Na_2SO_4 and then evaporated. All of the coupling products have been previously reported.[13]

Synthesis of 4,4'-diacetylbiphenyl (12)

^{1}H NMR (300 MHz, $CDCl_3$) δ: 8.09 (d, 4H, J = 8.3 Hz), 7.75 (d, 4H, J = 8.3 Hz), 2.66 (s, 6H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 196.5, 143.3, 135.5, 127.9, 126.3, 25.6.[14]

Synthesis of 4,4'-dinitrobiphenyl (14)

^{1}H NMR (300 MHz, $CDCl_3$) δ: 8.37 (d, J = 8.1 Hz, 4H), 7.79 (d, J = 8.1 Hz, 4H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 148.00, 144.95, 128.31, 124.37.

Synthesis of 4,4'-diethylcarboxylatebiphenyl (15)

^{1}H NMR (300 MHz, $CDCl_3$) δ: 8.15–8.12 (m, 4H), 7.70–7.67 (m, 4H), 4.41 (q, J = 7.2 Hz, 4H), 1.42 (t, J = 7.2 Hz, 6H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 166.3, 144.2, 130.1, 129.9, 127.1, 61.0, 14.3. HRMS (*m*/*z*) calcd for $C_{18}H_{19}O_4$ [M^+]: 299.12834; found: 299.12738.

Synthesis 4,4'-dimethylcarboxylatebiphenyl (16)[14]

^{1}H NMR (300 MHz, $CDCl_3$) δ: 8.14–8.11 (m, 4H), 7.70–7.67 (m, 4H), 3.94 (s, 6H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 166.81, 144.29, 130.13, 129.64, 127.18, 52.15. HRMS (*m*/*z*) calcd for $C_{16}H_{15}O_4$ [M^+]: 271.09704; found: 271.09627.

Synthesis of 4,4'-ditrifluoromethylbiphenyl (17)[14]

^{1}H NMR (300 MHz, $CDCl_3$) δ: 7.74 (d, J = 8.3 Hz, 4H), 7.70 (d, J = 8.3 Hz, 4H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 143.2, 130.2 (q, J = 32.2 Hz), 127.5, 125.9 (q, J = 3.7 Hz), 122.2 (q, J = 272 Hz).

Synthesis of 4,4'-difluorobiphenyl (18)[14]

^{1}H NMR (300 MHz, $CDCl_3$) δ: 7.51 (m, 4H), 7.14 (t, 4H, J = 8.7 Hz). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 164.00 (d, J = 246.4 Hz), 136.35 (d, J = 3.3 Hz), 128.5 (d, J = 8.1 Hz), 115.61 (d, J = 21.4 Hz).

Synthesis of biphenyl (19)[14]

^{1}H NMR (300 MHz, $CDCl_3$) δ: 7.85 (d, 4H, J = 7.5 Hz), 7.72 (t, 4H, J = 7.5 Hz), 7.52 (t, 2H, J = 7.3 Hz). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 141.2, 128.7, 127.2, 127.1.

Synthesis of 4,4'-dimethylbiphenyl (20)[14]

^{1}H NMR (300 MHz, $CDCl_3$) δ: 7.47 (d, J = 8.1 Hz, 4H), 7.23 (d, 4H, J = 8.1 Hz), 2.38 (s, 6H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 138.22, 136.62, 129.36, 126.73, 20.99. HRMS (*m*/*z*) calcd for $C_{14}H_{13}$ (–): 181.10212; found: 181.10043.

Synthesis of 4,4'-dimethoxylbiphenyl (21)[14]

^{1}H NMR (300 MHz, $CDCl_3$) δ: 7.51 (d, 4H, J = 8.8 Hz), 6.97 (d, 4H, J = 8.8 Hz), 3.85 (s, 6H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 158.7, 133.5, 127.7, 114.1, 55.3.

Synthesis of 4,4'-diformylbiphenyl (23)

^{1}H NMR (300 MHz, $CDCl_3$) δ: 10.10 (s, 2H), 8.00 (d, J = 8.4 Hz, 4H), 7.81 (d, J = 8.4 Hz, 4H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 191.6, 145.5, 135.9, 130.3, 127.9. HRMS (*m*/*z*) calcd for $C_{14}H_{11}O_2$ ($M + H^+$): 211.07591; found: 211.07479.

Supplementary data

Supplementary data (experimental procedures and ^{1}H NMR and ^{13}C NMR spectra) are available with the article through the Journal Web site at http://nrcresearchpress.com/doi/suppl/10.1139/v11-133.

Rational size control of gold nanoparticles employing an organometallic precursor [Au-C≡C- *t*-Bu]$_4$ and tunable thiolate-functionalized ionic liquids in organic medium

Kylie L. Luska and Audrey Moores

Can. J. Chem. Downloaded from www.nrcresearchpress.com by Renmin University of China on 09/02/12
For personal use only.

Abstract: Gold nanoparticles (Au NPs) stabilized with six different thiolate-functionalized ionic liquids (TFILs) were synthesized in an organic solvent. The size and optical properties of the TFIL-stabilized Au NPs can be rationally controlled by altering the *N*-alkyl chain length and (or) the counteranion of the TFIL-stabilizing ligand. Au NPs were prepared from the reduction of a gold precursor ($HAuCl_4$ or [Au-C≡C-*t*-Bu]$_4$) employing $NaBH_4$ in the presence of the different disulfide precursors. A model, based on Israelachvili theory, is proposed to account for the dependence of NP size on the *N*-alkyl chain length and the counteranion of the surfactantlike TFIL stabilizers.

Key words: gold nanoparticles, functionalized ionic liquids, gold(I) complexes, surface plasmon band, imidazolium salts.

Résumé : Des nanoparticules d'or (NPAu) stabilisées par six ioniques liquides fonctionnalisés par un thiolate (ILFT) ont été synthétisées dans un solvant organique. La taille et les propriétés optiques de ces NPAu stabilisées par des ILFT peuvent être contrôlées rationnellement en modifiant la longueur de la chaine *N*-alkyle et (ou) le contre-anion du ILFT. Les NPAu ont été préparées par réduction d'un précurseur d'or, $HAuCl_4$ ou [Au-C≡C-*t*-Bu]$_4$, à l'aide de $NaBH_4$, en présence de chacun des six précurseurs de disulfure. Un modèle, basé sur la théorie de Israelachvili, est avancé pour rendre compte de la relation entre la taille des NPAu et la longueur de la chaine *N*-alkyle et la taille du contre-anion du ILFT, qui agit comme stabilisant de la NP et surfactant.

Mots-clés : nanoparticules d'or, liquides ioniques fonctionnels, complexe d'or(I), bande plasmon de surface, sels d'imidazolium.

Introduction

Gold nanoparticles (Au NPs) are subject to intensive research because of their application in optical sensing,[1] surface-enhanced Raman spectroscopy,[2] and catalysis.[3,4] Optical[1] and catalytic[4] properties are governed by various factors including, among others, the size and shape of the NPs and the nature of the stabilizing ligand. Correlations between NP size and the properties of NPs are challenging to establish as different ligands are most often employed to achieve variance in the NP size,[5] which alter not only the size but also the electronics of the metal core. To establish such a relationship, it would be desirable to develop a family of stabilizing ligands, employed under identical reaction conditions,[6,7] that can control particle size. To reach this goal, we synthesized Au NPs of tunable size using the same class of ligand, thiolate-functionalized ionic liquids (TFILs), based on an imidazolium structure. This class of Au NP ligand was first proposed by Itoh et al.[8] and used for anion sensing. They were chosen here as (*i*) TFILs provide both electrostatic and covalent stabilization to metal NPs increasing their long-term stability[9–11] and (*ii*) alterations to the TFIL structure can be accomplished that do not involve changing the metal-binding moiety (i.e., *N*-alkyl chain length or counteranion), and thus preserve the electronic nature of the NP. Kim et al.[12] previously employed TFILs in the synthesis of Au and Pt NPs and demonstrated that the position and number of thiol moieties present in either the cation or anion of the TFIL ligands impacted the size of the Au and Pt NPs. Such ligand alterations dramatically influence both the electronic properties of the metal core and the organization of the ligand sphere, parameters that are proposed to remain constant in this study. Recent reports on Au NP synthesis have featured novel gold precursors (e.g., AuX (for X = Cl or Br),[13] $[AuN(SiMe_3)_2]_4$,[14] and $[NMe_4][Au(CF_3)_2]$[15]) in an effort to complement the well-established methodologies based on $HAuCl_4$[16] and to provide insight into the Au NP formation mechanism.[17] $[AuN(SiMe_3)_2]_4$ and $[NMe_4][Au(CF_3)_2]$ are interesting precursors as they eliminate the presence of halides in the reaction mixture, which have been shown to affect the properties of NPs.[18] For instance, a recent DFT study by Janiak and coworkers[19] demonstrated that the interaction between chloride anions and Au clusters possesses a large binding energy and thus Cl^- will play a role in stabilizing Au NPs if present in

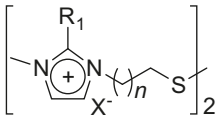
the synthetic mixture. Furthermore, in the context of IL chemistry, it was even more important to select a metal precursor that does not produce any ionic by-products that can undergo ion exchange with either of the IL ions.

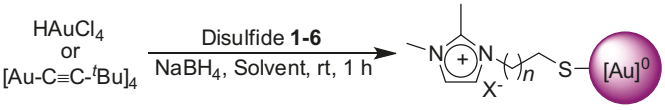
Recently, the groups of Roucoux,[20] Hou,[21] and Dyson[22] studied the influence of various structural parameters of functionalized ionic liquid (FIL)-stabilized Rh and Pd NPs. Specifically, the concept of "supramolecular" arrangement of FILs at the surface of stabilized NPs was explored and evoked to rationalize such NP properties as catalytic activity.



Herein, we propose the use of a family of disulfide TFIL precursors **1**–**6** (Scheme 1) in the formation of stable Au NPs with control of the NP size (Scheme 2) by reduction of gold precursors using $NaBH_4$. The TFILs act as surfactants, which stabilize the NPs through the anchoring of the thiol moiety to the metal surface. We also introduce a model to rationalize this control and study the impact of the ligands **1**–**6** onto the optical properties of the synthesized Au NPs. We also introduced a novel organometallic Au NP precursor, $[Au\text{-}C{\equiv}C\text{-}t\text{-}Bu]_4$,[23] to avoid the presence of halides during the NP synthesis and compared its performance with the more commonly used halide-based precursor, $HAuCl_4$. $[Au\text{-}C{\equiv}C\text{-}t\text{-}Bu]_4$ is expected to decompose under reducing conditions into Au(0) and volatile organic by-products, thus leaving the NP surface and the IL free of unwanted contaminants. Overall, our study suggests that FILs can act as surfactants to stabilize metal NPs and exert some level of size control over the final NP size.

Results and discussion

Synthesis of TFILs



Compounds **1**–**6** are characterized by four parameters: (1) a thiolate function that binds to the Au particle, (2) an imidazolium unit, (3) an alkyl chain playing the role of spacer between the metal binding and imidazolium moiety, and (4) a counteranion (Scheme 2). In this study we altered both components (3) and (4) to impact the size of the particle while preserving (1) and (2) to have constant electronic and molecular structure, respectively. The procedure employed for the synthesis of **1**–**6** was adapted from that reported by Itoh et al.[8] (R_1 = H, n = 5, and X = Cl^-; Scheme 1) to prepare a series of TFIL precursors having differing *N*-alkyl chains (n = 5, 8, and 10) and counteranions (X^- = ^-OTf and $^-NTf_2$) (Scheme 3). Synthesis of the disulfide precursors **1**–**6** was achieved through the quaternization of ω-bromodisulfides with 1,2-dimethylimidazole, followed by an ion exchange of Br^- with either ^-OTf or $^-NTf_2$. 1,2-Dimethylimidazole was selected here instead of 1-methylimidazole, to ensure the stabilization of the NPs was provided solely by the TFILs **1**–**6**. NPs stabilized by 1-alkyl-3-methylimidazolium ILs may involve the formation of *N*-heterocyclic carbenes, which primarily occur at the C2 position on the imidazolium ring.[24–26] Thus, TFILs based on the 1-alkyl-2,3-dimethylimidazolium moiety were employed in this study to restrict the formation of carbene stabilizing species. Furthermore, ion exchange of Br^- to form disulfides **1**–**6** prior to NP synthesis allows for a better control of the properties of both the TFIL stabilizers and the resulting Au NPs. This contrasts with the work of Itoh et al.[8] as anion exchange was performed directly on the Au NPs. Their technique led to the development of a useful anion sensor; however, the extent of the full counteranion replacement within the NP ligand sphere, as well as the anion's impact during the synthesis of the NPs, was not determined. The present work used TFIL precursors composed of a known counterion and explored their influence on the properties of the resulting Au NPs.

R_1 = H; X = Cl^-; n = 5 (Itoh et al. precursor)
R_1 = CH_3; X = $^-OSO_2CF_3$ (^-OTf); n = 5 (**1**), n = 8 (**2**), n = 10 (**3**)
R_1 = CH_3; X = $^-N(SO_2CF_3)_2$ ($^-NTf_2$); n = 5 (**4**), n = 8 (**5**), n = 10 (**6**)

Scheme 2. Synthesis of thiolate-stabilized gold nanoparticles.

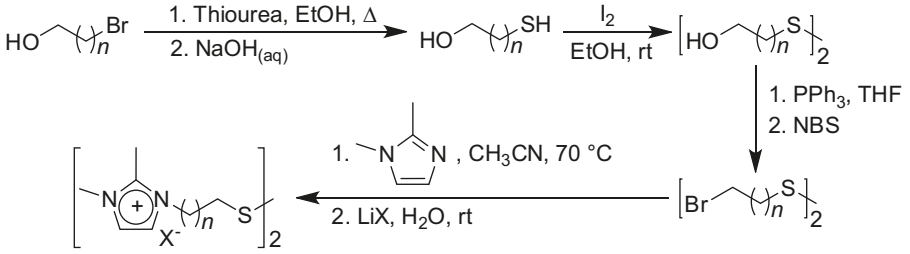
Nanoparticle synthesis and characterization

Synthesis of Au NPs was achieved by combining an organic solution of an Au precursor ($HAuCl_4$ or $[Au\text{-}C{\equiv}C\text{-}t\text{-}Bu]_4$, 0.100 and 0.025 mmol, respectively) with a methanol solution of one of disulfides **1**–**6** (0.20 mmol) and reducing the mixture with $NaBH_4$ (Scheme 2). The solution instantly changed colour from pale yellow to purple, indicating the formation of Au NPs. TEM analysis of the reaction mixtures showed the presence of well-dispersed Au NPs having mean diameters ranging from 3.0 to 4.3 nm depending on n and X^- (Fig. 1 and Table 1; see the Supplementary data for size and distribution data, Figs. S1 and S2). X-ray photoelectron spectrometry (XPS) analysis of the Au NPs (for $HAuCl_4$ and disulfide **1**) indicated the presence of gold, sulfur, carbon, nitrogen, oxygen, and fluorine, which signified the TFIL stabilization of the NPs (Supplementary data Figs. S3–S7). The $S2p_{(3/2)}$ binding energies (BEs) for disulfide **1** and the corresponding stabilized Au NPs are 163.7 and 162.3 eV respectively; a shift (–1.4 eV) that was in agreement with the binding of the thiolate functionality to the surface of the Au NPs.[27] Additional evidence for the presence of an Au–S bond was provided by the BEs of Au ($4f_{(7/2)}$ = 84.0 eV and $4f_{(5/2)}$ = 87.7 eV).[27,28] The Au:disulfide ratio was optimal at 1:2, affording small and well-dispersed NPs, whereas a smaller ratio (1:1) formed large Au aggregates and a larger ratio (1:4) produced clusters of small Au NPs that were not monodispersed. This ratio (1:2) was kept constant in all of the subsequent studies.

Size analysis and supporting model

The nature of the disulfide precursor, in terms of n and X^-, was found to influence the size of the Au NPs synthesized from $[Au\text{-}C{\equiv}C\text{-}t\text{-}Bu]_4$ (Table 1, entries 1–6). These results showed an increase in the NP size with an increase in the length of the *N*-alkyl chain (n) and a decrease in the NP size with an increase in the molecular volume of the counteranion

Scheme 3. Synthetic pathway for the preparation of disulfide ionic liquids **1–6** (for n = 5, 8, and 10 and X^- = $^-$OTf and $^-NTf_2$).



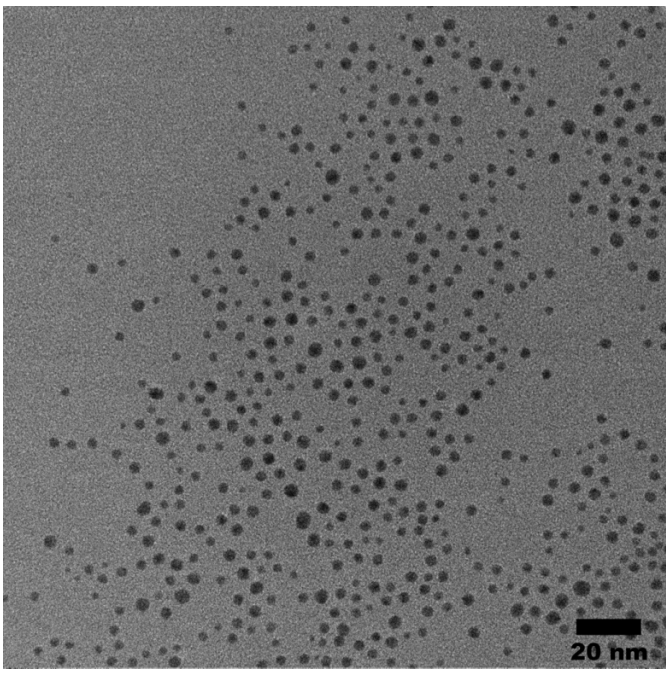


Fig. 1. Transmission electron micrograph of thiolate-stabilized gold nanoparticles, employing [Au-C≡C-*t*-Bu]$_4$ and disulfide **6**.

(X^-). The dependence of n and X^- on the size of the Au NPs can be justified by adapting the geometric theory proposed by Israelachvili[29] for the formation of spherical micelles (Scheme 4). This theory was adapted because of the intrinsic surfactant nature of the TFILs and their ability to bind strongly to the Au surface through their thiolate functionality. For a conventional micelle, (Scheme 4A) the radius (R) of a spherical micelle is dependent on the properties of the surfactant molecule such that $R = 3v/a_0$, where v is the volume of the hydrocarbon chain and a_0 is the area of the headgroup. This relationship can be extended to the formation of spherical NPs stabilized by TFILs **1–6** such that $R \propto v/a_0$, where R is now the radius of the structure containing the particle and the ligand shell, v is the volume of the hydrocarbon chain, including the thiolate moiety, and a_0 is the area of the imidazolium headgroup, including both the cation and the anion (Scheme 4B). According to this relationship, an increase in n would increase v, thus increase R, and ultimately the NP size. The TEM data obtained for Au NPs stabilized by thiolate ligands **1–6** (Table 1, entries 1–6) showed an increase in NP size when comparing n = 5, 8, and 10. In terms of the influence of X^-, this relationship predicts that an increase in a_0 would decrease the diameter of the NP. The molecular volume of the counteranions employed here are 0.131 and 0.232 nm^3 for $^-$OTf and $^-NTf_2$, respectively.[30] Therefore, the larger $^-NTf_2$ anion would increase a_0 and thus decrease the NP size. A comparison of the TEM data for thiolate-stabilized NPs with $^-$OTf (Table 1, entries 1–3) and $^-NTf_2$ (Table 1, entries 4–6) counteranions showed a consistently smaller size for the $^-NTf_2$ species.

The relationship between NP size and the TFIL counteranion was investigated already by Janiak and co-workers[30–32] in metal NPs synthesized directly in IL solvents. In their system, the relationship is opposite to what we observe, with an increase in NP diameter when the molecular volume of the anion was increased. Their results provided evidence that the NPs were stabilized by a classical electric double layer where anionic species stabilize the metal surface and thus govern the size of the NPs.[30] For our system, the size variation trends observed and the XPS measurements are both consistent with a covalent binding of the thiolate to the metal surface (as suggested by Itoh et al.[8] and shown in Scheme 2) and a global arrangement where the IL anion and cation pair are localized at the periphery of the ligand shell. These results, and especially the compliance to the Israelachvili model, suggest that there is a high level of organisation in the ligand shell resulting from the surfactant nature of the TFIL stabilizers. This is in accordance to what is expected from both imidazolium moieties[33] through electrostatic interactions and the *N*-alkyl chains through van der Waals interactions; the later being a similar phenomenon to that observed in the formation of self-assembled monolayers (SAMs) of long-chain alkanethiol on Au NPs.[34]

Influence of the gold precursor

Au NPs synthesized from [Au-C≡C-*t*-Bu]$_4$ were compared with NPs prepared employing $HAuCl_4$. [Au-C≡C-*t*-Bu]$_4$[23] is expected to decompose under reducing conditions to Au(0) and volatile organic by-products. TEM analysis of the thiolate-stabilized Au NPs showed well-dispersed NPs for the syntheses with either precursor, although slightly larger NPs were obtained from $HAuCl_4$ (Table 1, entries 7–12) compared with those from [Au-C≡C-*t*-Bu]$_4$ (Table 1, entries 1–6). This difference was attributed to the presence of Cl^- ions in the Au precursor, which may exchange with the counteranion of the TFIL stabilizer. According to our proposed model (Scheme 3), exchange of either $^-$OTf or $^-NTf_2$ with the smaller Cl^- species would decrease a_0 and increase the size of the resulting Au NPs. It was also observed that the trend between NP size and the properties of the disulfide ligand (n and X^-) were not as clear for particles synthesized from $HAuCl_4$. This discrepancy was most pronounced when

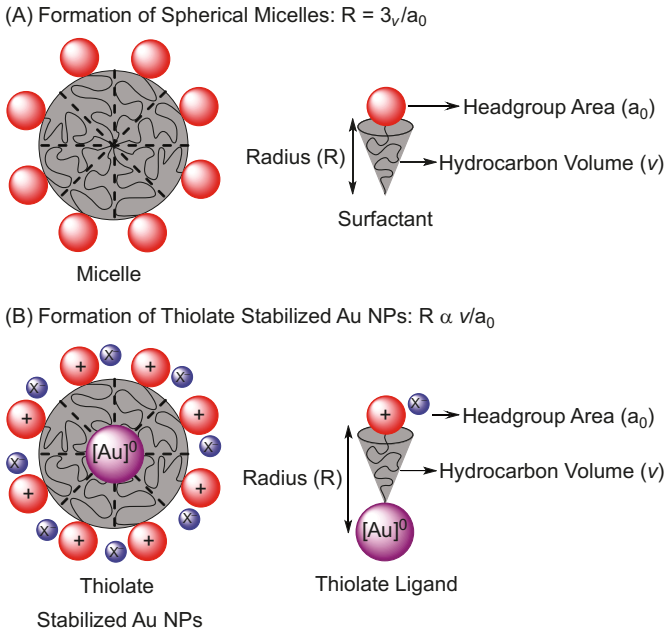
Table 1. Influence of the gold and disulfide precursors on the size and size distribution of thiolate-stabilized gold nanoparticles (Au NPs).

		Stabilizing ligand			
Entry	Au precursor	Disulfide	n	X^-	Au NP size (nm) (standard deviation σ)[a]
1	[Au-C≡C-*t*-Bu]$_4$	**1**	5	$^-$OTf	2.9(±0.6)
2		**2**	8	$^-$OTf	3.2(±0.6)
3		**3**	10	$^-$OTf	3.3(±0.6)
4		**4**	5	$^-$NTf$_2$	2.7(±0.5)
5		**5**	8	$^-$NTf$_2$	2.9(±0.4)
6		**6**	10	$^-$NTf$_2$	3.2(±0.6)
7	HAuCl$_4$	**1**	5	$^-$OTf	3.3(±0.6)
8		**2**	8	$^-$OTf	4.2(±0.7)
9		**3**	10	$^-$OTf	4.3(±0.7)
10		**4**	5	$^-$NTf$_2$	3.0(±0.4)
11		**5**	8	$^-$NTf$_2$	3.0(±0.3)
12		**6**	10	$^-$NTf$_2$	3.1(±0.5)

Note: Reaction conditions: [Au] = 0.1 mmol, disulfide = 0.2 mmol (2 equiv), $NaBH_4$ = 1.0 mmol (10 equiv), solvent = CH_3OH (for $HAuCl_4$), CH_3OH–CH_2Cl_2 (3:2, for [Au-C≡C-*t*-Bu]$_4$).



[a]Determined by TEM, measurement of >200 spherical particles.

comparing disulfides **2** (4.2 nm) to **3** (4.3 nm) (Table 1, entries 8 and 9) and **4** (3.0 nm) to **5** (3.0 nm) (Table 1, entries 10 and 11) as very little difference in size was observed for these NPs. The lack of correlation within the $HAuCl_4$ data was again accredited to anion exchange of the TFIL anion and thus emphasizes the importance of having well-defined systems in the synthesis of nanomaterials, including the use of halide-free metal precursors such as [Au-C≡C-*t*-Bu]$_4$.

Optical properties analysis

The optical properties of the synthesized Au NPs were analyzed using UV–vis spectroscopy. A surface plasmon band (SPB) was observed for Au NPs stabilized by TFILs **1**–**6** (λ_{max}(MeOH) = 535–650 nm) and was dependent on the nature of the thiolate employed (Fig. 2). The length of the alkyl chain was observed to influence the SPB as the longer chain thiolates, n = 8 and 10 (Fig. 2, curves b, c, e, and f), showed λ_{max} = 535 nm, whereas Au NPs synthesized from the shorter chain disulfides, n = 5 (Fig. 2, curves a and d), caused the λ_{max} to red shift to >535 nm. For TFIL **1** and **4** (n = 5) stabilized NPs, the distance between the particle surface and the IL environment is smaller than in the case of the longer chain TFIL-stabilized NPs. This shorter distance resulted in the NP perceiving a more polar environment and thus a globally higher dielectric medium at its surrounding. The theory predicts that the position of the SPB shifts toward the lower energy region as the surrounding medium refractive index increases,[1,35] which is consistent with the observed trend. A shorter chain disulfide (n = 2) was desired to further test this hypothesis; however, the synthesis of this disulfide could not be achieved. Aggregation of the NPs in solution could also be envisaged as the cause of this shift, in which case a red-shift is expected when the mean distance between particles decreases;[1,36] however, the TEM images obtained for all NPs are not consistent with significant aggregation in solution (Supplementary data Figs. S1 and S3). These results

Scheme 4. Schematic representation of (A) the size dependence of micelles on surfactant properties and (B) the size dependence of gold nanoparticles (Au NPs) on thiolate-functionalized ionic liquids (TFIL) properties.[29]

are supporting the idea that TFILs organize around the particle. Indeed, in the case of the longest alkyl spacers (n = 8 and 10), the respective blue-shift observed proves that the alkyl portion of the TFIL resides close to the surface of the particle, whereas the imidazolium cation and anion are maintained at the periphery of the ligand sphere. Moreover, the results obtained for n = 8 and 10 are virtually identical. This can be explained by the fact that changes happening far from the surface will not impact the perceived dielectric medium of the particle significantly. When the alkyl spacer is short (n = 5), the dielectric medium perceived by the Au NP is altered by the presence of the imidazolium cation and anion.

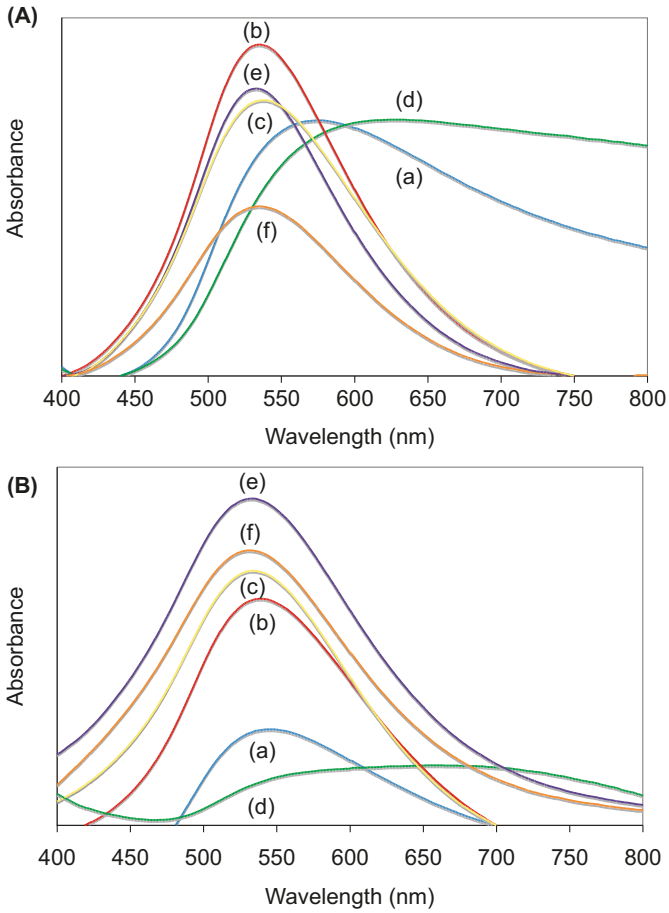
Conclusions

In conclusion, this report has outlined the synthesis of stable, well-dispersed Au NPs employing an organometallic Au precursor [Au-C≡C-*t*-Bu]$_4$ and TFIL stabilizers in a molecular solvent. This halogen-free Au complex allowed for the recognition of a relationship between the properties of the Au NPs, in terms of NP size and SPB, and two properties of the thiolate-stabilizing ligand, namely the length of the *N*-alkyl chain and the counteranion. A model, based on Israelachvili theory, was employed to explain the correlation between the size of Au NPs and the properties of the thiolate ligands. This model and XPS data evidenced a high level of organization inside these NPs where the TFILs interact with the particle surface through their thiolate functionalities. Functionalized ionic liquids act as surfactants for the synthesis of metal NPs with controlled properties leading to a novel bottom-up approach to the design of functional nanomaterials, as well as models to measure the influence of small size changes on the properties of NPs. Furthermore, [Au-C≡C-*t*-Bu]$_4$ has been shown to be an effective precursor in the synthesis of NPs featuring increased compositional purity and opens new opportunities for gaining an understanding in the role various stabilizing ligands play in the formation of Au NPs.

Experimental section

General remarks

All syntheses of ILs and NPs were carried out under an argon atmosphere employing Schlenk techniques. 6-Mercapto-1-hexanol,[37,38] 9-mercapto-1-nonanol,[37,39,40] 11-mercapto-1-undecanol,[37,41,42] bis(6-hydroxyhexyl)disulfide,[41] bis(11-hydroxyundecyl)disulfide,[37,41] bis(6-bromohexyl)disulfide,[42,43] and [Au-C≡C-*t*-Bu]$_4$[23,44] were prepared following known literature procedures. Tetrahydrofuran (distillation over Na and benzophenone) and acetonitrile (dried over 4 Å molecular sieves) were purified prior to use. All other chemicals and solvents were purchased from commercial sources and used without further purification. Melting points (mp) were determined on a Gallenkamp melting point apparatus and are uncorrected. Nuclear magnetic resonance (NMR) spectra were recorded on a 300 MHz Varian Mercury spectrometer. Mass spectra (MS) were recorded in positive electrospray mode with an IonSpec 7.0 tesla FTMS (IonSpec Corp., Lake Forest, California). TEM was performed on a Phillips CM 200 microscope. UV–vis spectra were recorded on a Jasco V-660 spectrophotometer. XPS was performed on a VG ESCALAB 3 MKII spectrometer (VG, Thermo Electron Corporation, UK) equipped with an Mg Kα source.



Synthesis of TFILs

The synthesis of disulfide ILs **1**–**6** followed a similar pathway to that reported by Itoh et al. (Scheme 1).[8] The synthesis and characterization data for all novel compounds are reported.

Bis(9-hydroxynonyl)disulfide

9-Mercapto-1-nonanol (7.81 g, 58.2 mmol) was dissolved in 12 mL MeOH and titrated with 0.5 mol/L methanolic iodine until the reaction turned from colourless to a persistent yellow colour. The mixture was allowed to stir at room temperature (rt) for 1 h. The reaction was quenched with 10% NaHSO$_3$(aq) and extracted with CH_2Cl_2 (3 × 50 mL). The organic phase was washed with 10% NaHSO$_3$(aq) and H_2O and dried over $MgSO_4$. The solvent was removed and the product was dried in vacuo to yield a white solid. Yield: 7.09 g (92%); mp 65–66 °C. ^{1}H NMR (300 MHz, $CDCl_3$, ppm) δ: 3.61(t, J = 6.2 Hz, 4H), 2.65 (t, J = 7.3 Hz, 4H), 1.64–1.28 (m, 30H). ^{13}C NMR (75.5 MHz, $CDCl_3$, ppm) δ: 63.2, 39.4, 33.0, 29.7, 29.6, 29.4, 29.4, 28.7, 25.9. MS (ESI$^+$) *m/z*: 351.2386 ($M^+ = [C_{18}H_{39}O_2S_2]^+$ requires 351.2385).

Fig. 2. UV–vis spectra of λ_{max}(MeOH) for gold nanoparticles (Au NPs) synthesized employing (A) $HAuCl_4$ and (B) [Au-C≡C-*t*-Bu]$_4$ as gold precursors stabilized by thiolates (a) n = 5, X^- = $^-$OTf; (b) n = 8, X^- = $^-$OTf; (c) n = 10, X^- = $^-$OTf; (d) n = 5, X^- = $^-$NTf$_2$; (e) n = 8, X^- = $^-$NTf$_2$; and (f) n = 10, X^- = $^-$NTf$_2$.

Bis(9-bromononyl)disulfide

Bis(9-hydroxynonyl)disulfide (3.55 g, 10.1 mmol) and PPh_3 (5.56 g, 21.2 mmol) were dissolved in 100 mL of distilled THF under an argon atmosphere. NBS (4.50 g, 25.3 mmol) was added in portions over 30 min. The mixture was stirred at rt for 1 h then heated to 50 °C for 18 h. The solvent volume was reduced, EtO_2 was added, and the mixture was cooled for 30 min to cause the precipitation of white solids. Upon filtration and solvent evaporation, the crude mixture was purified on silica employing EtOAc–hexanes. Bis(9-bromononyl)disulfide was obtained as a colourless liquid. Yield: 3.56 g (74%). ^{1}H NMR (300 MHz, $CDCl_3$, ppm) δ: 3.38 (t, J = 6.8 Hz, 4H), 2.65 (t, J = 7.4 Hz, 4H), 1.82 (pentet, J = 7.4 Hz, 4H), 1.64 (pentet, J = 7.1 Hz, 4H),

1.46–1.22 (m, 20H). ^{13}C NMR (75.5 MHz, $CDCl_3$, ppm) δ: 39.3, 34.2, 33.0, 29.7, 29.3, 29.3, 28.9, 28.6, 28.3.

Bis(11-bromoundecyl)disulfide

Bis(11-bromoundecyl)disulfide was obtained as a white solid. Yield: 2.93 g (52%). ^{1}H NMR (300 MHz, $CDCl_3$, ppm) δ: 3.39 (t, J = 6.9 Hz, 4H), 2.66 (t, J = 7.5 Hz, 4H), 1.83 (pentet, J = 7.2 Hz, 4H), 1.65 (pentet, J = 7.2 Hz, 4H), 1.45–1.21 (m, 28H). ^{13}C NMR (75.5 MHz, $CDCl_3$, ppm) δ: 39.4, 34.3, 33.0, 29.7, 29.7, 29.6, 29.4, 29.4, 29.0, 28.7, 28.4.

Disulfide 1

1,2-Dimethylimidazole (1.37 g, 14.3 mmol) was dissolved in 10 mL of MeCN. Bis(6-bromohexyl)disulfide (2.74 g, 6.99 mmol) was added and the mixture was stirred at 70 °C for 48 h. The solvent was removed in vacuo and the residual solid was washed with Et_2O (3 × 20 mL). Lithium trifluoromethanesulfonate (2.23 g, 14.3 mmol) was added in small portions to a solution of the crude product in 15 mL of H_2O. The mixture was stirred at rt for 1 h and 25 mL of CH_2Cl_2 was added. The organic phase was washed with H_2O and dried over $MgSO_4$. The solvent was removed and the product was dried in vacuo to yield a white solid. Yield: 3.63 g (72%); mp 104–106 °C. ^{1}H NMR (300 MHz, $(CD_3)_2CO$, ppm) δ: 7.65 (d, J = 2.0 Hz, 2H), 7.60 (d, J = 2.0 Hz, 2H), 4.28 (t, J = 7.5 Hz, 4H), 3.93 (s, 6H), 2.77 (s, 6H), 2.70 (t, J = 7.5 Hz, 4H), 1.88 (pentet, J = 7.5 Hz, 4H), 1.68 (pentet, J = 7.5 Hz, 4H), 1.52–1.28 (m, 8H). ^{13}C NMR (75.5 MHz, $(CD_3)_2CO$, ppm) δ: 145.6, 123.4, 122.3 (q, J_{CF} = 322.1 Hz), 122.0, 49.0, 38.9, 35.5, 30.4, 29.6, 28.5, 26.4, 9.8. MS (ESI$^+$) m/z: 212.1342 (M^{2+} = $[C_{22}H_{40}N_4S_2]^{2+}$ requires 212.1344).

Disulfide 2

The product was obtained as an amber oil. Yield: 3.19 g (80%). ^{1}H NMR (300 MHz, $(CD_3)_2CO$, ppm) δ: 7.65 (d, J = 2.0 Hz, 2H), 7.60 (d, J = 2.1 Hz, 2H), 4.27 (t, J = 7.5 Hz, 4H), 3.92 (s, 6H), 2.76 (s, 6H), 2.70 (t, J = 7.5 Hz, 4H), 1.86 (pentet, J = 7.5 Hz, 4H), 1.66 (pentet, J = 7.5 Hz, 4H), 1.48–1.25 (m, 20H). ^{13}C NMR (75.5 MHz, $(CD_3)_2CO$, ppm) δ: 145.6, 123.4, 122.3 (q, J_{CF} = 322.1 Hz), 121.9, 49.0, 39.3, 35.5, 30.5, 30.0, 29.8, 29.8, 29.7, 29.0, 26.8, 9.8. MS (ESI$^+$) m/z: 254.1811 (M^{2+} = $[C_{28}H_{52}N_4S_2]^{2+}$ requires 254.1809).

Disulfide 3

The product was obtained as an amber oil. Yield: 2.20 g (79%). ^{1}H NMR (300 MHz, $(CD_3)_2CO$, ppm) δ: 7.64 (d, J = 2.0 Hz, 2H), 7.61 (d, J = 2.0 Hz, 2H), 4.28 (t, J = 7.5 Hz, 4H), 3.93 (s, 6H), 2.77 (s, 6H), 2.71 (t, J = 7.5 Hz, 4H), 1.87 (pentet, J = 7.2 Hz, 4H), 1.67 (pentet, J = 7.2 Hz, 4H), 1.45–1.25 (m, 28H). ^{13}C NMR (75.5 MHz, $(CD_3)_2CO$, ppm) δ: 145.6, 123.4, 122.3 (q, J_{CF} = 322.1 Hz), 121.9, 49.1, 39.3, 35.5, 30.5, 30.2, 30.2, 30.2, 30.2, 29.8, 29.8, 29.1, 26.9, 9.8. MS (ESI$^+$) m/z: 282.2124 (M^{2+} = $[C_{32}H_{60}N_4S_2]^{2+}$ requires 282.2128).

Disulfide 4

The product was obtained as an amber oil. Yield: 2.91 g (90%). ^{1}H NMR (300 MHz, $(CD_3)_2CO$, ppm) δ: 7.60 (d, J = 2.1 Hz, 2H), 7.56 (d, J = 2.1 Hz, 2H), 4.27 (t, J = 7.5 Hz, 4H), 3.92 (s, 6H), 2.76 (s, 6H), 2.70 (t, J = 7.2 Hz, 4H), 1.89 (pentet, J = 7.4 Hz, 4H), 1.68 (pentet, J = 7.1 Hz, 4H), 1.54–1.30 (m, 8H). ^{13}C NMR (75.5 MHz, $(CD_3)_2CO$, ppm) δ: 145.5, 123.3, 121.8, 120.9 (q, J_{CF} = 321.6 Hz), 49.1, 38.8, 35.5, 30.3, 29.5, 28.5, 26.4, 9.7. MS (ESI$^+$) m/z: 212.1342 (M^{2+} = $[C_{22}H_{40}N_4S_2]^{2+}$ requires 212.1345).

Disulfide 5

The product was obtained as an amber oil. Yield: 3.90 g (79%). ^{1}H NMR (300 MHz, $(CD_3)_2CO$, ppm) δ: 7.62 (d, J = 2.1 Hz, 2H), 7.58 (d, J = 2.1 Hz, 2H), 4.27 (t, J = 7.5 Hz, 4H), 3.93 (s, 6H), 2.77 (s, 6H), 2.70 (t, J = 7.2 Hz, 4H), 1.83 (pentet, J = 7.4 Hz, 4H), 1.66 (pentet, J = 7.2 Hz, 4H), 1.50–1.24 (m, 20H). ^{13}C NMR (75.5 MHz, $(CD_3)_2CO$, ppm) δ: 145.6, 123.4, 121.9, 121.0 (q, J_{CF} = 321.4 Hz), 49.1, 39.2, 35.5, 30.5, 30.0, 29.8, 29.8, 29.7, 29.1, 26.9, 9.8. MS (ESI$^+$) m/z: 254.1811 (M^{2+} = $[C_{28}H_{52}N_4S_2]^{2+}$ requires 254.1813).

Disulfide 6

The product was obtained as a pale yellow oil. Yield: 3.39 g (58%). ^{1}H NMR (300 MHz, $(CD_3)_2CO$, ppm) δ: 7.62 (d, J = 2.1 Hz, 2H), 7.58 (d, J = 2.1 Hz, 2H), 4.27 (t, J = 7.5 Hz, 4H), 3.93 (s, 6H), 2.77 (s, 6H), 2.71 (t, J = 7.5 Hz, 4H), 1.88 (pentet, J = 7.2 Hz, 4H), 1.67 (pentet, J = 7.2 Hz, 4H), 1.45–1.25 (m, 28H). ^{13}C NMR (75.5 MHz, $(CD_3)_2CO$, ppm) δ: 145.6, 123.4, 121.9, 121.0 (q, J_{CF} = 321.6 Hz), 49.1, 39.3, 35.5, 30.5, 30.2, 30.2, 30.2, 30.2, 29.8, 29.8, 29.1, 26.9, 9.8. MS (ESI$^+$) m/z: 282.2124 (M^{2+} = $[C_{32}H_{60}N_4S_2]^{2+}$ requires 282.2128).

Synthesis of gold nanoparticles

From [Au-C≡C-t-Bu]$_4$

$[Au\text{-}C{\equiv}C\text{-}t\text{-}Bu]_4$ (27 mg, 0.025 mmol) was dissolved in 10 mL of degassed CH_2Cl_2 and the disulfide IL (0.20 mmol) was dissolved in 10 mL of degassed MeOH. Upon addition of the disulfide solution, the mixture was stirred for 30 min to form a light yellow solution. $NaBH_4$ (38 mg, 1.0 mmol) in 5 mL MeOH was added dropwise and stirred for 1 h. The precipitate was isolated via centrifugation (7500 rpm for 10 min), washed with acetone–pentane (2:1) (3 × 10 mL), and dried in vacuo. The crude mixture was employed for UV–vis and TEM analyses, while purified NPs were used for XPS.

From HAuCl$_4$

$HAuCl_4{\cdot}3H_2O$ (34 mg, 0.10 mmol) and the disulfide IL (0.20 mmol) were separately dissolved in 10 mL of degassed MeOH. Upon addition of the disulfide, the mixture was stirred for 30 min to form a light yellow solution. $NaBH_4$ (38 mg, 1.0 mmol) in 5 mL MeOH was added dropwise and stirred for 1 h. The precipitate was isolated via centrifugation (7500 rpm for 10 min), washed with acetone–pentane (2:1) (3 × 10 mL), and dried in vacuo. The crude mixture was employed for UV–vis and TEM analyses, while purified NPs were used for XPS.

Transmission electron microscopy

TEM of Au NPs was obtained on a Phillips CM 200 microscope operating at an accelerating voltage of 200 kV with a point resolution of 0.24 nm. Sample preparation included dilution of 10 drops of the Au NP solution in 20 drops of

i-PrOH, followed by deposition on a carbon-coated copper grid (400 mesh) at rt. The NP size distribution was determined from the measurement of >200 spherical particles chosen in arbitrary areas of enlarged micrographs.

UV–vis spectroscopy

Spectra were recorded on a Jasco V-660 spectrophotometer. Sample preparation included the dilution of 0.1 mL of the crude Au NP solution in 4.0 mL of MeOH. A correction of the raw data was employed to normalize the background.

Abstract: Silicone elastomer surfaces that are rough at the nanometer to micron scales could be useful for biomaterials, but there are few efficient routes for their preparation. Silicones undergo depolymerization under equilibrating conditions. We demonstrate that surface roughness can be induced by depolymerizing silicone elastomers using triflic acid, tetrabutylammonium fluoride or KOH as catalysts. The efficiency of depolymerization, however, is decoupled from the roughness that develops. When the catalysts are dissolved in solvents that do not effectively swell silicones, the etching reaction can be mostly directed to the elastomer surface. Acid catalysis leads to slow, nearly homogenous surface erosion with surface roughnesses only increasing from 15 to about 125 nm root mean squared roughness. By contrast, once KOH partitions into the elastomer, the rate of erosion is more efficient than return of the catalyst to the solvent, leading to deep channels and roughnesses of up to ~850 nm. The use of fluoride requires good solvents for silicone, and leads to surfaces of intermediate roughness. Thus, judicious choice of catalyst and solvent permits independent control over depolymerization and the induction of surface roughness.

Key words: silicone, redistribution/equilibration, surface roughness.

Résumé : Des surfaces élastomères de silicone qui seraient dures aux échelles allant du nanomètre au micron pourraient être utiles comme biomatériaux, mais on ne connaît que peu de méthodes pour les préparer. Les silicones peuvent donner lieu à une dépolymérisation dans des conditions équilibrantes. Dans ce travail, on démontre que la rugosité de la surface peut être induite par une dépolarisation d'élastomères de silicone en utilisant de l'acide triflique, du fluorure de tétrabutylammonium ou du KOH comme catalyseurs. Toutefois, l'efficacité de la dépolymérisation est découplée de la rugosité qui se développe. Quand les catalyseurs sont dissous dans des solvants qui ne gonflent pas les silicones d'une façon efficace, la réaction d'attaque chimique peut être orientée principalement vers la surface de l'élastomère. La catalyse acide conduit à une érosion lente et pratiquement homogène de la surface qui ne fait passer la rugosité quadratique moyenne que d'environ 15 à 125 nm. À l'autre bout du spectre, une fois que le KOH a commencé la partition de l'élastomère, la vitesse d'érosion est beaucoup plus efficace que le retour du catalyseur dans le solvant et il en résulte qu'il y a formation de canaux et des rugosités allant jusqu'à environ 850 nm. L'utilisation du fluorure exige l'utilisation de bons solvants pour la silicone et conduit à des surfaces de rugosités intermédiaires. En peu en conclure qu'un choix judicieux de catalyseur et de solvant peut permettre d'avoir un contrôle indépendant sur la dépolarisation et l'induction d'une rugosité de surface.

Mots-clés : silicone, redistribution/équilibration, rugosité de surface.

Introduction

Silicone elastomers are widely used in a variety of biomaterials applications. The utility of such materials depends on the ability of the desired biological entities to populate the synthetic polymer surface. Various parameters affect the interactions between the silicone and local biology,[1] including the elastomer modulus, hydrophobicity, and surface roughness,[2] among others. Although the relationship between surface physical chemistry and cell adhesion and growth is not yet completely clear, polymer surface texture clearly affects cell adhesion, shape, proliferation, and function.[3,4] Some cell types prefer to adhere to rougher surfaces,[5–7] including on

This article is part of a Special Issue dedicated to Professor Tak-Hang Chan. It is a tremendous pleasure to dedicate this paper to (Tak Hang) Bill Chan. I made lots of silicone polymers as undesired by-products while doing my Ph.D. in his lab. There is thus a certain irony in using this opportunity to report on degradation products when most of Bill's career has rather been associated with controlled synthesis. The subject was purposefully chosen, however. The element of surface control we attempt to describe in this paper was unexpected. Bill taught me to try and be a careful observer, to capture unexpected results, and to creatively (in his case) move them in new directions. I am extraordinarily grateful for his role as mentor.

low-energy silicone surfaces,[8] although this trend is not universally followed.[9]

Surface roughness in silicone elastomers can be induced at various length scales. Silicones are very adept at accommodating details in complex molds and this serves as one strategy to make rough surfaces, for example, as stamps for microcontact printing.[10,11] However, we were interested in developing simple strategies that would randomly induce surface roughness at length scales ranging from ~10 nm to ~1 μm. These surfaces of pure dimethylsilicone could then be tested for their ability to facilitate cell adhesion and proliferation.

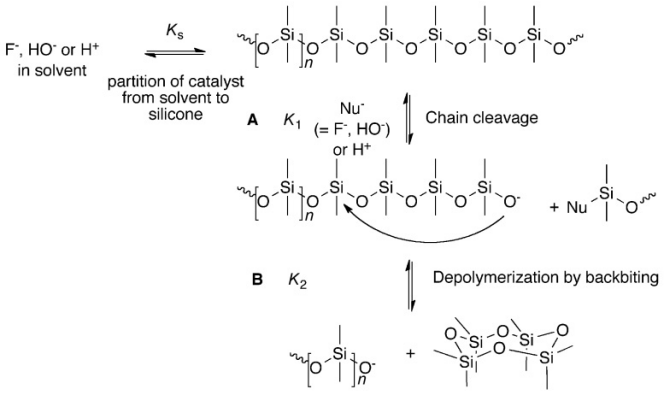
Silicones are known for their resistance to thermal and oxidative conditions. However, at pHs away from neutrality, silicones readily undergo chain scission in hydroxylic solvents.[12] Fluoride ion is similarly able to cleave Si–O bonds.[13] Once reactive chain ends form, reduction of the silicone polymer chain length occurs by backbiting, with concomitant ring formation. Both chain scission and backbiting lead to loss of molecular weight (Figs. 1A and 1B).

The equilibrium constant K_2 between chains and rings (Fig. 1B) is ~1 and is reduced by any factor that reduces the concentration of monomers in chains,[14] such as dilution by solvents or even by the presence of more voluminous side chains on the silicone backbone. One of the by-products of equilibration is D_4 $(Me_2SiO)_4$, which readily evaporates at room temperature and can further push the equilibrium towards depolymerization.[15]

The complete depolymerization of silicones by equilibration has previously been used to create porous media. For example, the silicone portion of block copolymers of silicone and polyisoprene leads to nanoporous foams[16] following erosion by tetrabutylammonium fluoride trihydrate (TBAF).[17]

The generation of rough surfaces on a silicone elastomer requires asymmetric depolymerization along the exposed surface. We report that random roughness between about 20 and 1000 nm can be readily induced in silicone elastomer surfaces by controlled depolymerization in an appropriate solvent using acid, base,[18] or fluoride catalysts, respectively: the three catalysts engender roughness quite differently.

Experimental section



Materials

TBAF, KOH, and triflic acid (F_3CSO_3H, 98%) were purchased from Sigma-Aldrich and SylGard 184 (silicone elastomer kit) and poly(methylhydrosiloxane)($(MeHSiO)_n$, DC1107) were purchased from Dow Corning. The compounds and solvents (Caledon) 2-propanol (IPA), THF, hexanes, diethylene glycol dimethyl ether (diglyme), methanol, acetone, and dimethylformamide (DMF) were used as received.

Surface characterization

FTIR spectra (16 scans at 4 cm^{-1} resolution) of the surfaces prepared as described in the following were obtained using a Bio-Rad (Cambridge, MA) FTS-40 FTIR spectrometer with a fixed 45° angle attenuated total reflectance (ATR, ZnSe) cell attachment under N_2 purge. Thus, the samples were placed on an ATR cell and the FTIR scans were obtained; background runs were subtracted from the sample spectrum. The imaging data were analyzed with WinIR Pro software (Bio-Rad) and Excel software.

Fig. 1. Silicone equilibration.

The surface textures of both unmodified and modified elastomers were characterized by an optical profilometer and scanning electron microscopy (SEM). A Veeco WYKO NT1100 optical profiler (mode: VSI, objective 50×, FOV 2.0×), was used with Vision32 software. Three traces/images were recorded for each specimen in different locations to give an image of the profile and the root mean squared roughness (Rq) in nanometers. The images shown (Fig. 2) represent surfaces of approximately 225 μm × 300 μm.

PDMS discs were gold coated (25 nm) using a Gatan precision etching coating system (PECS), model 682, and then SEM images were taken with a Jeol 7000F microscope at different magnifications.

Silicone elastomers

Silicone elastomers were prepared following manufacturer's directions (two parts mixed in a 1:10 ratio of curing agent:base and allowed to cure at ambient temperature for 2 days in a Petri dish. Silicone elastomer slabs were punched into small circular discs of ~1.0 cm diameter × 0.3 cm thick using a coring tool.

Etching protocols

Surface-etching solutions were prepared by dissolving fixed weight fractions of the catalyst (TBAF, KOH, or triflic acid) into methanol, THF, or mixtures of these solvents with water (Table 1). The PDMS disks were placed into a vial normally containing 0.5–2 mL of the etching solution and shaken for various time periods at room temperature. Experiments were run in triplicate.

After etching, the elastomer discs were removed from the vials and washed extensively to remove any physically adhering materials. In a typical washing cycle, the rubber slabs were washed with acetone, THF, acetone, hexanes, acetone, water, acetone, and finally flushed with nitrogen and then placed in a vacuum chamber at room temperature overnight.

Preparation of Si–H surfaces

The reversibility of the etching process at the silicone interface was demonstrated by etching in the presence of a second silicone polymer. To a vial containing 5 mL absolute methanol and 3 mL poly(methylhydrosiloxane) (DC1107) was

added 1–30 PDMS discs and 50 μL trifluoromethanesulfonic acid (TfOH). After being vigorously shaken at room temperature, the discs were rinsed thoroughly with dry methanol and hexane to remove TfOH and unreacted DC1107 and then promptly blown dry with nitrogen followed by further drying under vacuum for 2 h. The presence of the SiH at the interface was shown by FTIR (cm^{-1}, neat: 2167 (Si–H)). IPA was an alternative solvent used for making the Si–H surface and led to a much more intense Si–H peak in the IR. However, the discs became brittle and a little bit cloudy after the process. Therefore, all the studies of Si–H materials described in the following were based on the recipe using methanol as the solvent.

The effect of reaction time on the roughness of the Si–H surface was investigated by varying the reaction duration from 1 to 35 min (1, 5, 10, 15, 20, 25, 30, and 35 min). Different concentrations of TfOH (5, 25, 50, and 125 μL in 8 mL of methanol and DC1107 mixture) were also used to study rates of surface modification.

Results

Silicone elastomers were prepared from a commercial kit: platinum-catalyzed addition cure was initiated simply by mixing the base and cross-linker. After mixing, the mobile mixture was placed in a Petri dish where it flowed before curing to give smooth elastomer films of ~3 mm thickness, which was completely cured over ~2 days at room temperature. These cured films exhibited a Rq[19] of ~15 nm as determined using a surface profilometer. We note that this technique is particularly convenient and rapid. However, it is often accompanied by large variations: it provides excellent resolution in the *Z* direction, but much less in the *X*–*Y* plane. In addition, error bars increase when nonregular features are present (e.g., the large cracks shown in Fig. 2D). Small cylindrical coupons of 1 cm diameter were cut from the cured films and used as substrates for surface modification. Etching and depolymerization were simultaneously performed by immersing one or more coupons in single or mixed solvents with one of three different catalyst types: the silicon-specific nucleophile (fluoride in TBAF), acid (triflic acid), or base (KOH) (Table 1).

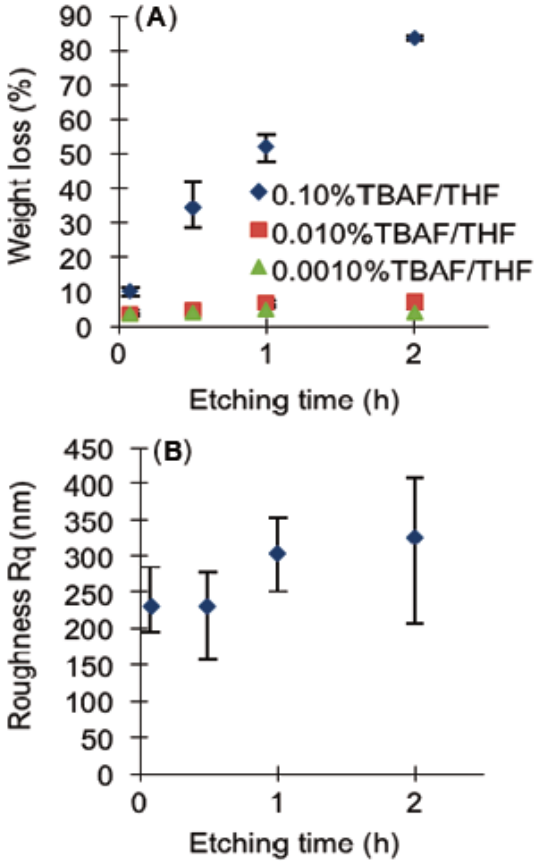
Effect of solvent

Two classes of solvents were used to perform etching experiments. "Good" solvents that efficiently swell silicone elastomers include THF, diglyme, IPA, hexanes, and, to a lesser extent, DMF and acetone. Such solvents were required when fluoride was used as a depolymerization catalyst. However, these solvents were problematic when acid- or base-catalyzed depolymerization was examined because depolymerization was extremely efficient and difficult to control. After the exposure of elastomers to these conditions, degradation was easily observed as the formation of cracks along grain boundaries (Fig. 2D) and, ultimately, brittle structures. Controlled modification of the elastomer surface alone with these catalysts in good solvents was not generally possible in our hands. Therefore, poor or nonsolvents

Can. J. Chem. Downloaded from www.nrcresearchpress.com by Renmin University of China on 09/02/12
For personal use only.

for silicones, including water and methanol, were used for surface modification by acids or bases (for degrees of swelling of the elastomer in various solvents, see Fig. 9). The low solubility of the solvents and catalysts in silicones constrained reactions mostly to the external interface of the elastomer coupon.

Fluoride (TBAF) etch



TBAF (Bu_4NF) is widely used as a source of organic-soluble fluoride ion to remove silyl ether protecting groups. While fluoride is a weak base, it is a powerful nucleophile for silicon both because of its small size (little steric barrier to attack at silicon) and the very high strength of the Si–F bond.[20] Fluoride can also facilitate the equilibration of silicone polymers under mild conditions.[21]

Attempts to modify the surface of silicone elastomers using TBAF in dry methanol, diglyme, or acetone were unsuccessful; even after reaction for 24 h at room temperature there was no change in surface roughness and significant weight loss was not observed. The fluoride was simply not an effective catalyst with these solvents. By contrast, etching in THF was efficient under these conditions, as shown by the efficient weight loss of the elastomer over time (Fig. 3A). Over longer etching times, the PDMS disc first became thinner then completely disappeared after etching for 3 h in 2.00 mL 0.10% TBAF/THF. Surprisingly, however, there was little concomitant change in surface roughness during this process. Following a rapid increase in Rq from ~15 to 230 nm, there was little further change over time as the elastomer decomposed (Fig. 3B). Profilometer and SEM images suggest that roughness is a result of asymmetric depolymerization along the surface in channels normal to the external surface (Figs. 2C and 2E).

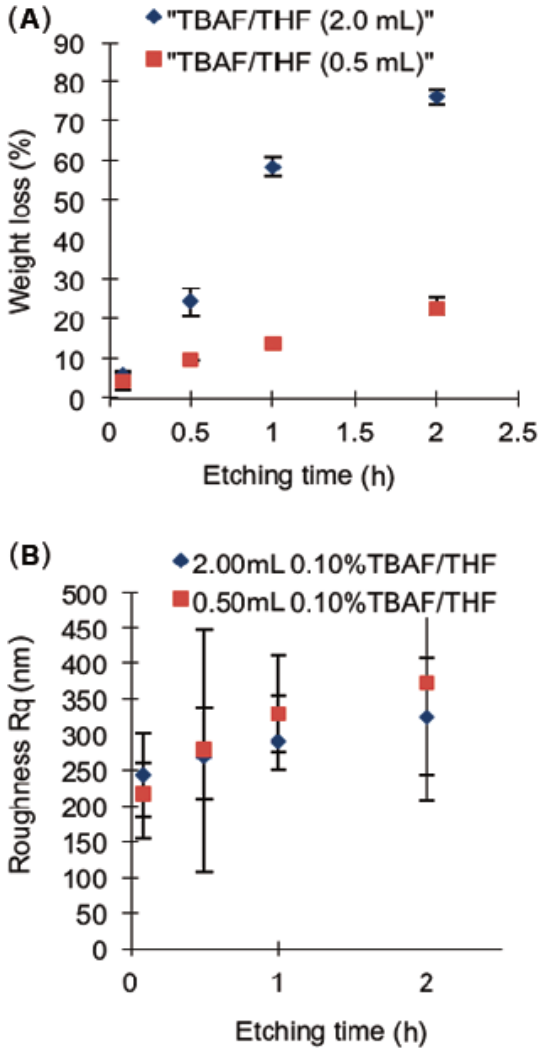
The rate of degradation was also affected by the total volume of the TBAF/THF etching solution, not simply the concentration of the solution. For example, the use of 0.5 or 2 mL of the same 0.10% TBAF in THF solution, led to very different changes in the surface chemistry occurring on the elastomer surface. Higher volumes, thus more net fluoride and THF available to the elastomer, led to more profound changes in the surface roughness. This observation is consistent with a reaction mechanism in which, in addition to the rate of attack of the fluoride nucleophile at silicon, bond breaking is related to the rates of absorption of fluoride and (or) of swelling of the elastomer (see the following). The data in Fig. 4 further suggests that depolymerization of the silicone is decoupled from the induced surface roughness.

The efficiency of surface etching was also shown to depend strongly on the amount of water present in the reaction medium (Fig. 5). It is exceptionally difficult to completely dehydrate TBAF: most commercial samples are sold as a hydrate (we used the trihydrate). However, as the amount of water was increased from this low level, both the efficiency of depolymerization and resulting roughness were significantly reduced even in the presence of the good solvent, THF (Fig. 5). This suggests that water outcompetes silicone for the available fluoride, and no depolymerization of the silicone can result once the moisture content reaches a threshold value of ~4%.

Fig. 3. (A) Elastomer weight loss as a function of tetrabutylammonium fluoride trihydrate (TBAF) concentration. (B) Surface roughness as a function of etching time in 0.1% TBAF/THF (2.00 mL).

Acid-catalyzed etching

Triflic acid, which is commonly used to equilibrate silicones (particularly those containing Si–H groups that are degraded by basic conditions),[5] was added in various concentrations to methanol. Silicone elastomers exposed to acidic solutions for various periods of time changed very little from the starting roughness of ~15 nm Rq, as determined using profilometry (Fig. 6).



We were initially concerned that essentially no silicone reactions were taking place under these conditions. Therefore, a series of redistribution reactions between a silicone fluid and the silicone elastomer (rather the simple depolymerization, Fig. 7) was attempted using either the poor solvent methanol or the good solvent IPA.

Initially, the dimethylsilicone-based elastomer was exposed to a homogenous solution of DC1107 poly(methylhydrosiloxane) silicone oil and TfOH in IPA. This led rapidly to a silicone elastomer surface rich in Si–H groups as shown by a huge Si–H band at 2167 cm^{-1} (Fig. 7A). The visibly swollen elastomer rapidly developed cracks and then became brittle. This outcome at least demonstrated that reactions were occurring at the surface and internally in the presence of the acid in a good solvent for silicones (Fig. 10).

A dispersion of TfOH and DC1107 in the poorer solvent methanol was then used to modify the elastomer. Over a short period of time the surface became enriched with SiH groups, demonstrating that the silicone polymer was undergoing

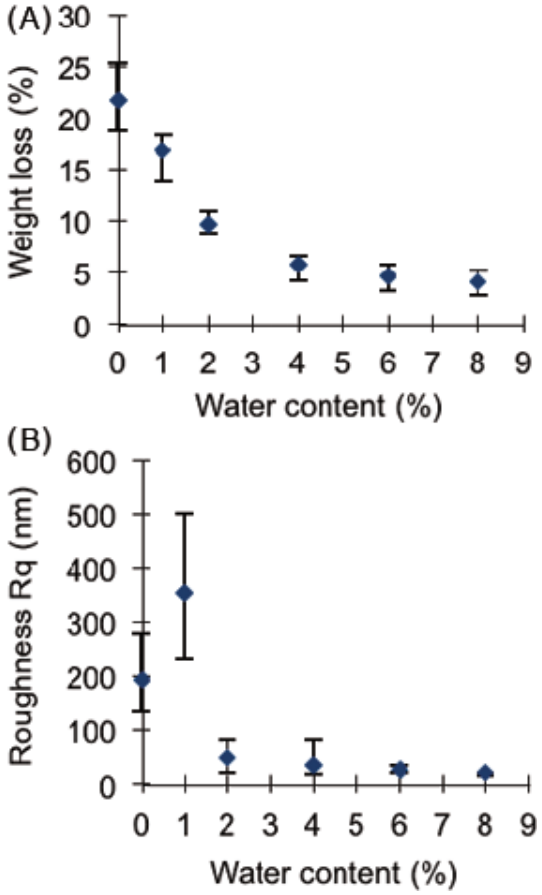
Fig. 4. Effect of available tetrabutylammonium fluoride trihydrate (TBAF) on (A) weight loss and (B) roughness when etching silicone elastomers.



depolymerization/repolymerization at the interface leading to growth of new layers and (or) exchange of MeHSiO monomers with the Me_2SiO monomers of the silicone elastomer (Fig. 7B). The rate of surface enrichment in SiH groups also increased with the concentrations of TfOH (data not shown).[22] During these reactions, there was a gradual increase in surface roughness over time (Fig. 2B) that was accelerated with higher TfOH concentrations (Fig. 7C). The profilometer images suggest that more or less uniform etching of the surface is occurring, with the exception of some islands that resist degradation. That is, the surface roughness does not change a great deal during the etching process. An alternative explanation for smooth islands is the presence of adsorbed or absorbed silicone oil. This was discounted after extensive washing showed no change in the surface roughness.

Base-catalyzed etching

KOH is an effective catalyst for silicone equilibration.[22] In good solvents for silicone, degradation led to the rapid formation and propagation of cracks and very rough surfaces

Fig. 5. Effect of water concentration on (A) the rate of silicone degradation in THF and (B) resulting surface roughness.

(Fig. 2D). Surprisingly, even in solvent systems that were mostly water, a nonsolvent for silicones, very rough surfaces (Fig. 2C) rapidly evolved provided that even low concentrations of good solvents, such as acetone and particularly THF, were also present. The poor solvent methanol, to which water was added, was therefore used to preferentially direct reaction to the outer surface of the elastomer.

Unlike degradation catalyzed by fluoride or acid, almost no weight loss of PDMS was observed after etching for 5 h in 1.0% KOH/(MeOH + 10%H_2O), although a surface roughness of Rq 200 nm was obtained; further etching to 48 h did lead to further increases in surface roughness, although weight loss continued in a nearly linear fashion. Much higher roughness required higher catalyst loadings.

As with the case with fluoride, the eroded surface of the elastomer was comprised of pits (Fig. 2F). These pitted surfaces formed very early in the process, long before significant weight loss had occurred from the elastomer. At much later points during erosion, cracking processes and eventually complete degradation occurred.

Discussion

In solution, in the presence of any of the three catalysts examined, silicone polymers undergo random chain cleavage with concomitant reduction in the average molecular weight. This is the reverse process of the condensation process that leads to their formation (Fig. 1A). In the elastomeric structures

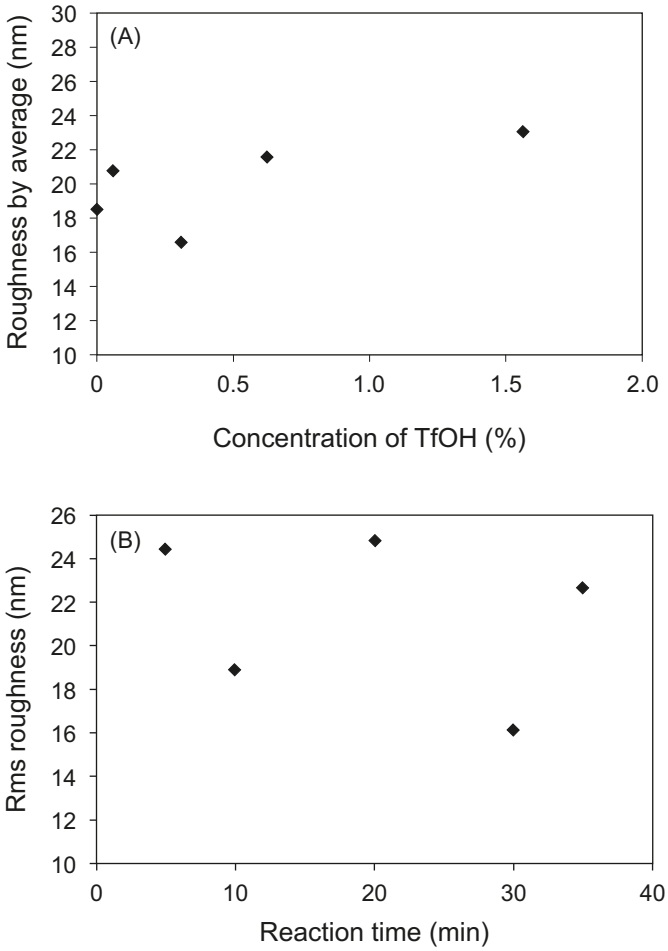

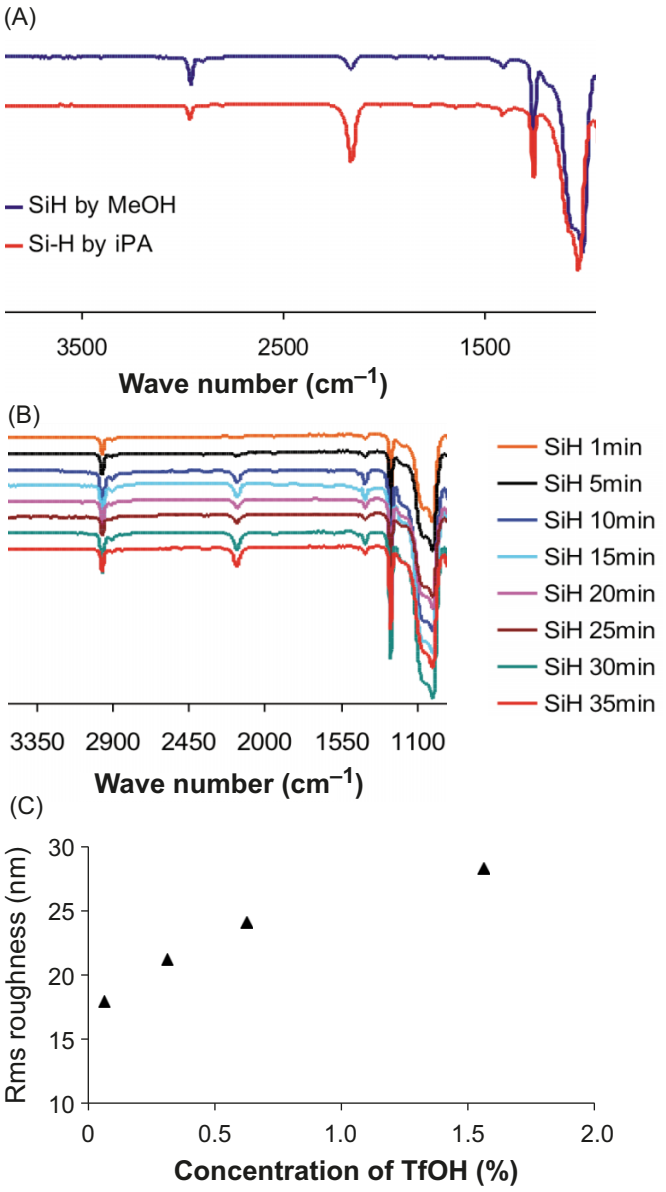

Fig. 7. Introduction of SiH groups (as shown by the IR band at 2167 cm^{-1}) on the PDMS elastomer surface with 0.6 wt % trifluoromethanesulfonic acid (TfOH) for 30 min (A) in alcohol and (B) in methanol over time. (C) Effect of TfOH concentration on induced roughness.

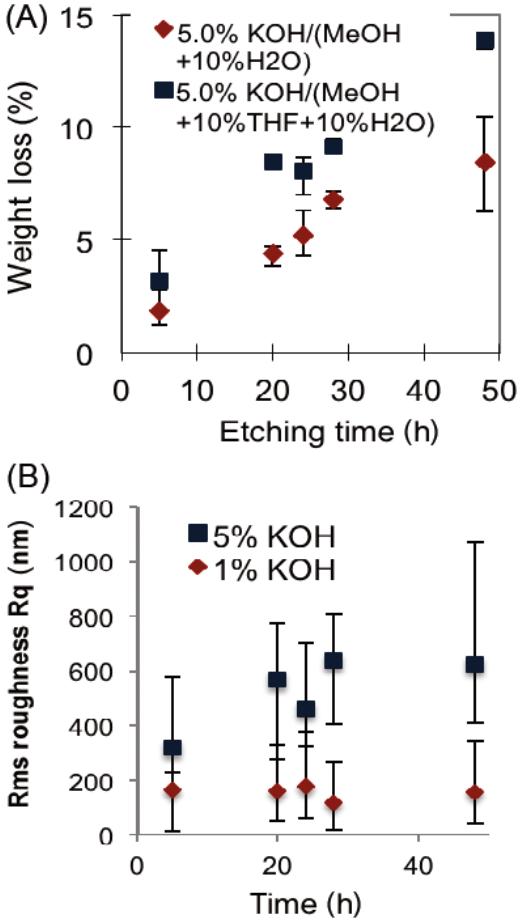
examined here, these processes cleave siloxane chains between cross-links. Chain cleavage is later accompanied by a depolymerization (unzipping) process through backbiting with concomitant loss of silicone cyclics (Fig. 1B).



There is thus a temporal change in the cross-link density of the silicone elastomer. At the early stage of the degradative process, cleavage reduces the cross-link density, initially leading to softer elastomers. As depolymerization sets in, the loss of silicone monomers will increase the ratio of cross-links to chains leading to higher cross-link densities in the elastomer body. Cracking of the elastomer can result and, in the limit, low molecular weight linear and cyclic silicones and highly cross-linked resins are produced.

If the degradation processes were to occur uniformly across the elastomer surface (or uniformly within the silicone elastomer), loss of silicones from the elastomer would occur with little or no change in the surface roughness. That is, the elastomer would lose weight during degradation, but the surface roughness remains essentially unchanged. Such a situation was observed in the case of the acid catalyst in poor solvents for silicone. Aside from some "islands" that formed (Fig. 2B) — possibly because of pre-existing zones of higher cross-link density — slow and homogenous erosion from the outer surface was observed. Thus, the ability of the catalyst to facilitate degradation of the elastomer did not correlate with induced roughness.

The acid etch was performed in a poor solvent for silicones. In addition to the rates at which the decomposition equilibria are established in a given medium, the catalyst must partition between the solution and the silicone elastomer (K_s, Fig. 1), which exists as a distinct phase. The solvation equilibrium clearly favours the presence of the acid in solution rather than in the silicone. That is, the acid moves from solution to silicone, facilitates a small amount of silicone degradation, and then preferentially migrates back into solution. The process is then repeated at a different position on the surface such that more or less homogenous decomposition/depolymerization across the elastomer surface occurs with little change in surface roughness.

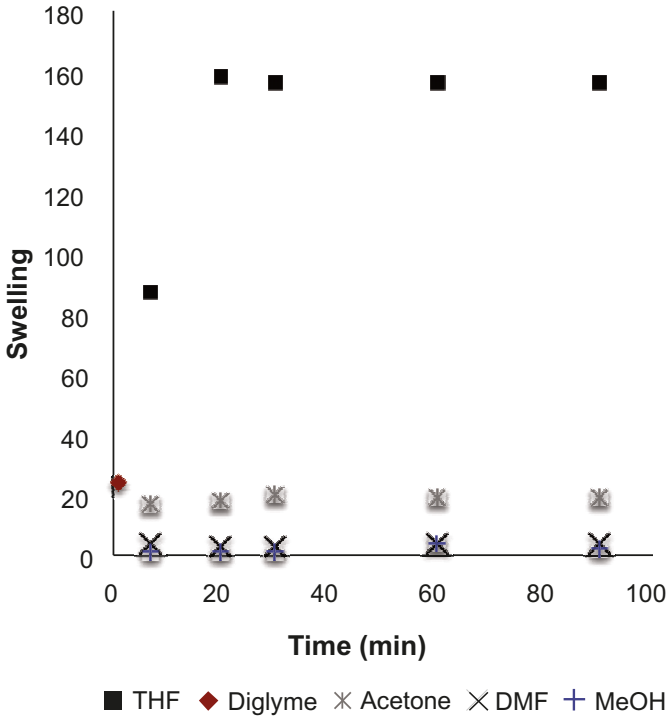
Fig. 8. Elastomers exposed to KOH in water/MeOH (optionally THF). (A) Weight loss. (B) Surface roughness.

The equilibration process under these conditions is inefficient. However, the ability to show that it is occurring was demonstrated by the redistribution of silicones in solution (hydrosilicones) with dimethylsilicones on the elastomer surface. Over time, the quantity of (grafted) SiH groups on the elastomer surface gradually increases as shown by IR spectroscopy (Fig. 7).

Etching with fluoride was not effective in poor solvents for silicones, suggesting that the fluoride does not efficiently leave solution to enter the silicone phase under these conditions. With a highly THF swollen silicone elastomer, by contrast, the fluoride enters the silicone phase and efficiently causes depolymerization of silicone. Very rapid decomposition was observed under these conditions, but not in a homogenous manner. Instead, the etching led to the formation of porous channels within the silicone (Fig. 2E). This observation is consistent with a process in which, once the fluoride has migrated into the silicone phase from THF, it remains there for a considerable period of time ($K_s > 1$, Fig. 1) causing "pockets" of degradation before returning to solution. If solvent conditions are such that the partition of catalyst into the silicone is disfavoured, it is possible to suppress degradation entirely: the efficiency of the catalyst drops dramatically with water content (Fig. 5), as has previously been observed.[23] Once the silicone degradation process is established, a rough surface is generated at a comparable rate to surface erosion such that the net surface roughness does not change (Fig. 3B), even if higher concentrations of catalyst are used (Fig. 4).

Fig. 9. Degree of swelling of the silicone elastomer in different solvents (DMF–MeOH and acetone–diglyme).



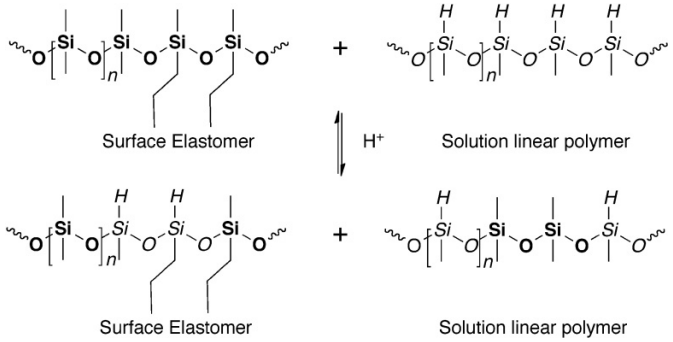


Fig. 10. Acid-catalyzed equilibration reaction between linear poly(methylhydrosiloxane) and elastomer polydimethylsiloxane.

KOH is promiscuous with regard to silicone degradation. Irrespective of solvent, efficient degradation of the elastomer body occurred. The erosion process was facilitated by the presence of even small quantities of good solvents for silicone, such as THF, even when diluted into water in small quantities (Figs. 2C and 2D).

As with fluoride, KOH leads to asymmetric degradation of the silicone elastomer such that as the silicone degrades, the surface becomes rougher. Once KOH partitions from solution into the elastomer body ($K_s >> 1$, Fig. 1), it remains there for extended periods of time "burrowing" (Fig. 2F) into the silicone leading to highly rough surfaces, prior to returning to the solution. With KOH, the relative amount of erosion to give rough surfaces, versus overall erosion, was highly concentration-dependent. Higher catalyst concentrations led to rougher surfaces.

The simple technology described previously allows silicone elastomer surfaces from ~15 to 1000 nm roughness to be generated with random features. Such a process would not be useful for creating fine patterns on a silicone elastomer surface. By contrast, it is an efficacious, simple, and reasonablly controllable method to manipulate large surfaces, as are found with stents, catheters, and other implantable silicone devices. With such materials in hand, it will be possible to establish optimum surface structures for proliferation of different cell types such that surfaces can be engineered for different biomaterials applications, which will be the subject of future reports.

Conclusion

Silicone elastomers are readily etched by catalysts that facilitate silicone redistribution. However, the catalysts examined (TfOH, TBAF, and KOH) exhibited different propensities to induce the formation of rough surfaces that were solvent-dependent. Fluoride required good solvents for silicone to induce significant changes in surface roughness at all. Under these conditions where silicones were swollen, degradation processes competed effectively with migration of the catalyst out of the silicone phase leading to significant losses of material in addition to induction of surface roughness. Otherwise, poor solvents for silicone were generally needed to limit reaction primarily to the elastomer surface. Acid slowly eroded the surface homogenously leading to only small changes in surface roughness over time because the catalyst preferentially resided in solution. By contrast, once KOH entered the silicone body, it continued to catalyze degradation burrowing into the silicone leading to large changes in roughness, but only relatively low losses of weight of the elastomer body. Thus, asymmetry in the elastomer surface can be controlled by the use of catalysts that preferentially partition from solution into silicone.

Abstract: The dynamical properties of the product CaBr for the reaction Ca + CF_3Br were studied with the quasi-classical trajectory method based on the extended London–Eyring–Polanyi–Sato potential energy surface. In this paper, the results, such as vibrational distribution, reaction cross section, and rotational alignment of the product CaBr, were calculated and the reaction mechanism has been discussed. The peak value of the vibrational distribution is located at around $v = 3$ when the collision energy equals 0.55 eV. The result obtained in this paper agrees well with the experimental vibrational result. The reaction cross section and the product rotational alignment all decrease with the increasing collision energy, which changes from 0.1 to 1.0 eV.

Key words: QCT method, LEPS PES, Ca + CF_3Br reaction, dynamics property, reaction mechanism.

Résumé : Les propriétés dynamiques du produit CaBr résultant de la réaction Ca + CF_3Br ont été étudiées par la méthode de la trajectoire semi-classique à base de la surface d'énergie potentielle étendue de London–Eyring–Polanyi–Sato. Dans ce travail, on rapporte les résultats de calculs, telle la distribution vibrationnelle, la section droite de la réaction et l'alignement rotationnel du produit, et on discute du mécanisme réactionnel. La valeur maximale pour la distribution vibrationnelle se situe à environ $v = 3$, quand l'énergie de collision est égale à 0,55 eV. Les résultats obtenus dans ce travail sont en bon accord avec les valeurs vibrationnelles expérimentales. La section droite de la réaction et l'alignement rotationnel du produit diminuent tous avec une augmentation de l'énergie de collision qui passe de 0,1 à 1,0 eV.

Mots-clés : méthode de la trajectoire quasi-classique (TQC), surface d'énergie potentielle étendue de London–Eyring–Polanyi–Sato (SEP LEPS), réaction Ca + CF_3Br, propriété dynamique, mécanisme réactionnel.

Introduction

With the rapid development in experimental technology and theoretical studies, more and more people have studied the field of molecular reaction dynamics in recent decades, and the results obtained from the reaction are more exact than before. Especially, the reactions between alkaline earth metal atoms and halogenated methane have been widely studied in both experiment and theory.[1–15]

The main experimental technologies that have been used to measure the property of reaction is chemiluminescence (CL), laser-induced fluorescence (LIF), and cross molecular beam.[1,2] By means of these methods, distributions of the internal energy state, the velocity, and the space angle of the product can be detected.

In 1984, Munakata and Kasuya[3] measured the product-state distributions of reaction system Ba + CF_3Br by means of the LIF method in a crossed-beam configuration of the supersonic CF_3Br beam and the effusive Ba beam. They mainly studied the nascent vibrational distribution of the product BaBr and found that the vibrational distribution had a bimodal feature. They explained this phenomenon as that the reaction Ba + CF_3Br proceeded along two pathways. And later in 1993, Han et al.[4] measured the CL spectra, the collision cross sections, and the CL cross sections of reactions Ca(^{3}P) + CF_3I and Ca(^{3}P) + CH_3I in a beam-gas arrangement. They found that the vibrational excitation probability of product CaI ($A^2\prod$,$B^2\sum^+$) obtained from reaction Ca(^{3}P) + CF_3I was larger than that from reaction Ca(^{3}P) + CH_3I. Three years later, Stolte and co-workers[5] measured the continuous-wave LIF spectra of nascent products SrBr, SrI, and CaBr, which were formed in reactions of Sr with CH_3X and CF_3X (X = Br or I) and Ca with CH_3Br and CF_3Br. They obtained the vibrational distribution $P(v)$ and the rotational distribution $P_v(J)$ at a specific v value from the spectral simulations and found that the vibrational energy released into the monohalide product for reactions with CF_3X (X = Br or I) was larger than that for the corresponding reactions with CH_3X, and a detailed explanation was also given in their paper.[5] In the same year, Lendvay and co-workers[6] investigated the reactive properties of the O(^{1}D) + CF_3Br system via experimental and theoretical studies using the crossed molecular beam scattering measurement and the quasi-classical trajectory (QCT) method. They obtained the energy and angular distributions of the product OBr from the experiment. And from the theoretical study, they estimated the rate coefficients and scattering properties through classical trajectory calculations on a

potential energy surface (PES) that was derived from spectroscopic and ab initio data. Later in 1999, Hou and co-workers[7] studied the same reaction as Lendvay.[6] The reaction in Hou's study was induced by photolysis of the CF_3Br–O_3 system under UV irradiation at 253.7 nm.

At the same time, from the theoretical study, the QCT, the semi-classical, and the quantum theory methods were the main methods that were used to study the molecular reaction dynamics. As we know, the molecular reaction dynamics had been studied by means of the QCT method during the 1930s[8] for the first time, which has undergone development since the 1960s.[9] Until now, the experimental result could be simulated, and the reaction mechanism could be further discussed and explained by means of the QCT method. Therefore, we can say that the QCT method is the most widely used now.

In 1996, van der Avoird and co-workers[10] investigated the energy dependence of the steric effect for reactions $Ca(^1D) + CH_3X$ (j,k,m = 1,1,1) with X = F, Cl, or Br by means of the semi-classical method and knew that products CaX were in the excited states $A^2\prod$, $B^2\sum^+$, and $A'^2\Delta$, respectively. Recently, Yao and co-workers,[11] using the QCT method, studied the dynamical properties of the product CaBr, which was formed in the reaction Ca + CH_3Br. They reported the results of vibrational distribution, rotational distribution, reaction cross section, and product rotational alignment for this reaction. And there were some other studies for reactions between alkaline earth metal atoms and halogenated methane that were related to the reaction Ca + CF_3Br; for example, Ba + CF_3Cl,[12] Sr + CF_3Cl,[13] and $O(^1D)$ + CF_3Cl.[14,15]

However, as we know up until now, no one has carried out a theoretical study on the reaction Ca + $CF_3Br \rightarrow$ CaBr + CF_3 by means of the QCT method. So, we will construct the extended London–Eyring–Polanyi–Sato (LEPS) PES for the reaction Ca + CF_3Br for the first time and apply the QCT method to calculate the vibrational distribution, reaction cross section, and product rotational alignment of the reaction in this paper, as well as analyze the reaction mechanism.

Theory

PES

The PES is the basis of the study and of the analysis of the reaction. Because of the absence of an accurate ab initio PES for the reaction Ca + CF_3Br, the LEPS PES is extended in this work to describe the reaction.

As for the reaction system A + BC → AB + C, the extended LEPS PES mentioned above can be interpreted for the ground state as follows.[16–18]

$$[1]\quad V(r_1, r_2, r_3) = Q_1 + Q_2 + Q_3 - (J_1^2 + J_2^2 + J_3^2 - J_1J_2 - J_2J_3 - J_1J_3)^{1/2}$$

where

$$[2]\quad Q_i = ({}^1E_i + {}^3E_i)/2$$

$$[3]\quad J_i = ({}^1E_i - {}^3E_i)/2$$

where ${}^1E_i$ is defined as the diatomic Morse potential function and ${}^3E_i$ stands for the anti-Morse function.

$$[4]\quad {}^1E_i = D_i\Big(\{1 - \exp[-\beta_i(r - r_0)]\}^2 - 1\Big)$$

$$[5]\quad {}^3E_i = {}^3D_i\Big(\{1 + \exp[-\beta_i(r - r_0)]\}^2 - 1\Big)$$

where

$$[6]\quad {}^3D_i = D_i(1 - S_i)/[2(1 + S_i)]$$

where S_i is an adjustable parameter (so-called Sato parameter) that has been used to achieve more reasonable LEPS PES. D_e, β_i, and R_i^0 are the Morse parameters of a diatomic molecule representing the classical dissociation energy, the spectrum constant, and the equilibrium bond length, respectively. Subscripts i = 1, 2, and 3 indicate Ca–Br, CF_3–Br, and Ca–CF_3, respectively, for the reaction Ca + CF_3Br. By means of these Morse parameters and through adjusting the Sato parameters S_i (i = 1, 2, or 3), whose values change from –1.0 to 1.0, the LEPS PES of the title reaction can be constructed to simulate the experimental results.[5]

The values of the Morse parameters can be obtained from eqs. [7]–[9] according to the data from the Gaussian 03 program on the MP2/6–311++G** level.[19] The configurations used in the calculations are all in the most stable states after being optimized. The optimizations of Ca–Br, CF_3–Br, and Ca–CF_3 were carried out and the energies were obtained. Then the frequency calculations of the three configurations were also given corresponding to stretching vibrational modes. After the data above was obtained, eqs. [7]–[9] were used to dispose these data to obtain the initial data used in the QCT calculation. In the calculation, group CF_3 is treated as a rigid group or an atom whose internal configuration almost does not change during the reaction, according to the Gaussian calculations, and the energy (E_{MP2}), equilibrium bond length (R_i^0), and force constant (Frc) were obtained.

$$[7]\quad D_e(\mathrm{AB}) = 27.2116[E_{MP2}(\mathrm{A}) + E_{MP2}(\mathrm{B}) - E_{MP2}(\mathrm{AB})]$$

$$[8]\quad K_e = 6.192\mathrm{Frc}$$

$$[9]\quad \beta_i = \sqrt{\frac{K_e}{2D_e}}$$

Here, D_e is in eV and E_{MP2} is in hartrees. In eq. [7], A stands for atom Ca and B stands for atom Br. Frc is in eV/Å^2. K_e is the vibrational force constant in mdyn/Å.

To study all of the collisions of an atom, the value of the maximum impact parameter (b_{max}) has to be found, although the calculation and only the calculation that has been carried out under the condition of $b \le b_{max}$ can ensure the accuracy of the result. All the results for the reaction Ca + CF_3Br can be given with the parameters presented in Tables 1 and 2.

Quasi-classical trajectory calculation

Hamilton's classical equations are numerically integrated for motion in three dimensions.[20] Since the arithmetical solutions of Hamilton's equations are difficult to obtain and the previous theoretical studies have already proved that the QCT method is good enough for the study of chemical reactions, the QCT method has been used to study the reaction in

this paper, and the details are the same as the descriptions in refs. 21–24.

From simulation and comparison with the experimental results of the product state distributions for the reaction Ca + CF_3Br, the same initial conditions with the experiment (collision energy (E_{col}) = 0.55 eV) were chosen in this paper. A batch of 100 000 trajectories in the calculations was run for each of the collision energies for the reaction Ca + CF_3Br and the integration step size was chosen to be 0.1 fs, which would ensure the conservation of total energy and angular momentum. Trajectories were initiated at a Ca–CF_3Br internuclear separation of 15 Å and for the CF_3Br molecule at $v = 0$ and $j = 0$ levels.

Product rotational alignment

For a chemical reaction, the distribution of the product rotational angular momentum ($\mathbf{J}'$) relative to the reactant relative velocity vector ($\mathbf{K}$) can be described by the product rotational alignment ($\langle P_2(\mathbf{J}' \cdot \mathbf{K})\rangle$), and the computational method used in this paper was developed by Han et al.[16] and Costen et al.[25] Herein a brief description is shown.

During a reactive encounter, the total angular momentum is conserved ($\mathbf{J} + \mathbf{L} = \mathbf{J}' + \mathbf{L}'$), where $\mathbf{L}$ and $\mathbf{L}'$ are the reagent and product orbital momenta, respectively, and $\mathbf{J}$ is the reagent rotational angular momentum. When $\mathbf{J}$ is small (as is common), the product rotation can only result from $\mathbf{L}$. $\mathbf{J}'$ can be described by a function $f(\theta)$, where θ is the angle between $\mathbf{J}'$ and $\mathbf{K}$. $f(\theta)$ can be expanded in a set of Legendre polynomials.[16,26]

$$[10] \qquad f(\theta) = \sum a_l P_l(\cos\theta)$$

where

$$[11] \qquad a_l = \frac{2l+1}{l}\int_{-1}^{+1} P_l(\cos\theta) f(\cos\theta)\mathrm{d}\theta$$

The coefficients a_0, a_1, and a_2 are used to represent the isotropic distribution, product rotational orientation, and product rotational alignment, respectively.

$$[12] \qquad a_2 = 5\langle P_2(\cos\theta)\rangle = 5\langle P_2(\mathbf{J}' \cdot \mathbf{K})\rangle$$

and

$$[13] \qquad \langle P_2(\mathbf{J}' \cdot \mathbf{K})\rangle = \left\langle \frac{3\cos^2\theta - 1}{2} \right\rangle$$

Here P_2 denotes the second Legendre polynomial, $\langle \cos^2\theta \rangle$ can be obtained by averaging all the directions and parameters of collision, and the angular brackets indicate an average over the distribution of $\mathbf{J}'$ about $\mathbf{K}$.[26]

Apparently, the rotational alignment is determined by the average value of $P_2(\mathbf{J}'\cdot\mathbf{K})$ and the expected value is between 0.0 (randomly aligned) and –0.5 (completely aligned). The maximum product rotational alignment usually occurs when the conditions $|\mathbf{L}| >> |\mathbf{J}|$ and $|\mathbf{L}'| >> |\mathbf{J}'|$ are satisfied. The first condition is satisfied for reactions with large cross sections, whereas the typical Heavy + Heavy–Light (HHL) mass configuration leads to the second condition.[27] In other words, the phenomenon that product rotation is strongly aligned with the relative velocity of the reagent is mainly caused by the HHL mass combination, and the value of $\langle P_2(\mathbf{J}' \cdot \mathbf{K})\rangle$ should be equal to –0.5.

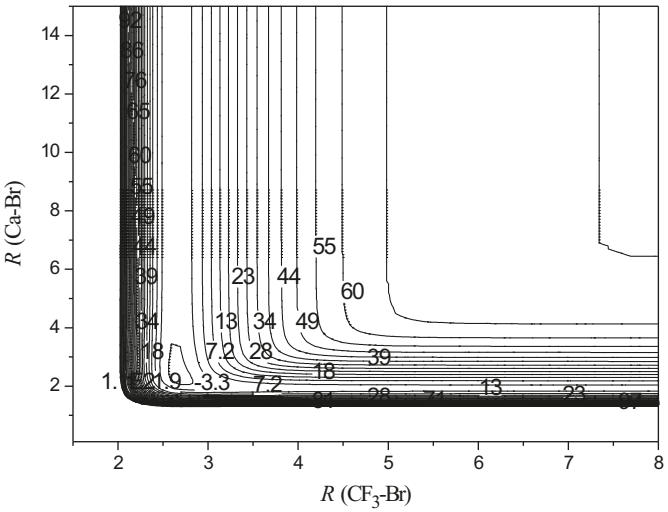
Results and discussions

PES

The construction of LEPS PES for the reaction Ca + CF_3Br is a precondition to obtain the dynamical properties of the reaction and study the reaction mechanism. The PES can be divided into two types according to the different types of energy released in the reaction A + BC → AB + C. One is attractive PES (energy is released in the process when atom A approaches molecule BC), and the other is repulsive PES (energy is released in the process when atom C is dissociated from molecule AB). The PES constructed in this paper belongs to the attractive PES. The specific method used to construct the LEPS PES is described in the second part of this paper and the parameters are given in Tables 1 and 2.

Figure 1 shows the contour plot of the LEPS PES for the reaction Ca + CF_3Br. Based on this extended LEPS PES, the dynamical properties, for example vibrational distribution, reaction cross section, and the product rotational alignment, were calculated by means of the QCT method and the results are shown in the following figures. The range of R is from 1.5 to 8.0 Å, as there are no significant barriers and wells in the entrance channel and exit channel at R from 0 to 1.5 Å and from 8.0 to 15.0 Å in Fig. 1. As can be seen from Fig. 1, the potential energy gradually decreases from the entrance ($R_{Ca,CF_3Br} = \infty$, corresponding to the reactants) to the exit ($R_{CaBr,CF_3} = \infty$, corresponding to the products). There is no reaction barrier involved in Fig. 1, whereas a shallow well exists in the entrance path of the LEPS PES. The position of the potential well on the LEPS PES is (2.7 Å, 2.3 Å) and the depth of the potential well is –10.45 erg × 10^{16}. The existence of this shallow well leads to the result that the reaction cross section decreases with the increasing collision energy.

Vibrational distribution



The vibrational distribution of product CaBr, which was obtained through the QCT calculations, is shown in Fig. 2 and it can be described as a function of vibrational quantum number. The vibrational distribution of the experiment is also shown in Fig. 2 for comparison and it is derived from Fig. 11 in ref. 5. To guarantee this comparison, an E_{col} of 0.55 eV was chosen according to the experiment, and the initial internal energy state of the reactant was set to be the ground state ($v = 0$, $j = 0$). As for the reaction Ca + CF_3Br, the QCT

Table 2. The values of the maximum impact parameter (b_{max}) for the reaction Ca + CF_3Br.

	E_{col} (eV)										
	0.1	0.2	0.3	0.4	0.5	0.55	0.6	0.7	0.8	0.9	1.0
b_{max}	5.70	5.40	5.25	5.15	5.00	5.00	5.00	4.90	4.80	4.70	4.70

The values of b_{max} for the reaction Ca + CF_3Br were calculated when the collision energy (E_{col}) changed.

Fig. 1. The plot of the London–Eyring–Polanyi–Sato potential energy surface (LEPS PES) for the reaction Ca + CF_3Br. The unit of R is Å and the unit of energy is erg × 10^{16} (1 erg = 1.4393 × 10^{13} kcal/mol; 1 cal = 4.184 J).

calculated product vibrational distribution of the CaBr shows a bell shape when the vibrational quantum number changes from 0 to 15. It can be seen from Fig. 2 that the vibrational distribution result rapidly increases to its maximum value and then decreases with the increasing v, with the condition that E_{col} = 0.55 eV. Both the experimental and theoretical product vibrational distributions reach peak values at around v = 3 for the product CaBr in Fig. 2. Obviously, the variational tendencies of the two vibrational distributions are similar with each other, and the QCT result obtained in this study is in good agreement with the experimental one.

The reactions between alkaline earth metal atoms (M) and halogenated alkanes have two pathways, which are the abstraction reaction and the insertion reaction. The collision energy cannot conquer the repellant when atom Ca attacks CF_3Br in the repulsive area, which closes to group CF_3, and then atom Ca shifts to the attractive area, which closes to atom Br. Under the conditions mentioned above, the insertion reaction occurs and the vibrational excitation of product CaBr is strong. When the collision energy is large enough, atom Ca and molecule CF_3Br can rapidly get close to each other and the C–Br bond fractures to form the product CaBr. This is the abstraction reaction that results in the weakness in vibrational excitation. The vibrational distribution is concentrated for the reactions between alkaline earth metal atoms (M) and halogenated alkanes. It mainly concentrates on the maximum value of the distribution. The vibrational distribution of the product has a strong dependence on the relative position of the halogen atom in the reactant and the direction from which the alkaline earth metal atom (M) approaches the halogenated alkane.

Unavoidably, there exist some differences between the experimental result and the theoretical one at high vibrational quantum numbers that are >4, since the theoretical simulation simplified the complex processing of the real world. The differences were caused by the single collision energy used in this work, by only considering the ground state in the QCT calculations, and by the single-particle approximation used for group CF_3. Although some of the differences can be seen in Fig. 2, we cannot neglect the merits of the QCT method, which are simple, illustrative, and accurate. It can deal with a big reaction system that cannot be treated by the quantum mechanics method and can obtain the dynamical results that were not given by Stolte and co-workers.[5]

Reaction cross section

The reaction cross section can be obtained with the QCT method and its equation can be written as follows.[28–30]

$$[14] \qquad \sigma_r = \pi b_{max}^2 (N_r/N)$$

where N is the number of total trajectories in the calculation and N_r is the number of reactive trajectories under the $b \leq b_{max}$ condition.

In this paper, the values of N, N_r, and b_{max} are obtained through the QCT calculations, and the results of reaction cross section versus collision energy are obtained by eq. [14] for the reaction Ca + CF_3Br and are shown in Fig. 3. As can be seen from Fig. 3, the reaction cross section regularly decreases from a maximum value of 27.466 Å^2 to a minimum value of 17.916 Å^2 when collision energy increases from 0.1 to 1.0 eV. This phenomenon indicates a kind of inverse relation that high reaction probabilities appear at low energies, whereas low reaction probabilities appear at high energies in the calculated results in Fig. 3.

The result that the reaction cross section decreases with the increasing collision energy agrees with the general behavior of chemical reactions that a potential well exists on the LEPS PES. This phenomenon is characteristic of the concurrent contraction of the capture radius with the increasing energy for systems with purely attractive PES.[31] In this study, the LEPS PES belongs to the attractive PES type and a shallow well can be seen on the LEPS PES in Fig. 1. The reaction cross section obtained in this paper can give a good description of the reaction Ca + CF_3Br.

Product rotational alignment

The product rotational alignment of the reaction Ca + CF_3Br versus collision energy has been calculated by means of the QCT method and the results are shown in Fig. 4. The values of the product rotational alignment $\langle P_2(\mathbf{J}' \cdot \mathbf{K})\rangle$ calculated in this paper have deviated overall from the kinematic limit (–0.5), and as the collision energy increases from 0.1 to 1.0 eV, the product rotational alignment steadily decreases

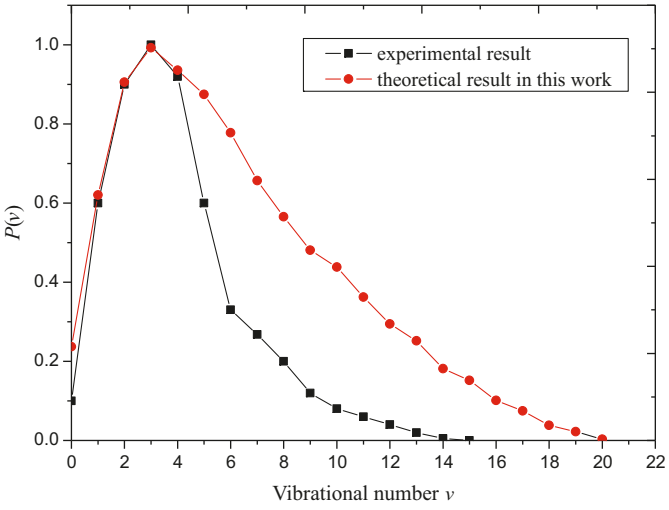
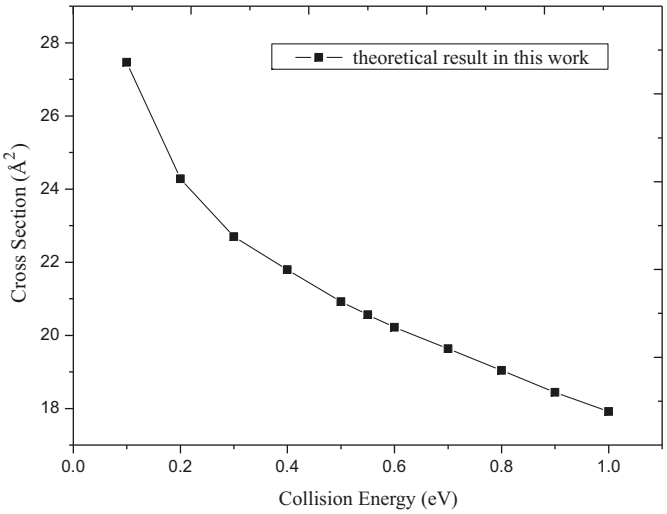
Fig. 2. Vibrational distribution of product CaBr obtained from the reaction Ca + CF_3Br when collision energy equals 0.55 eV. The experimental result was obtained from Fig. 11 in ref. 5.





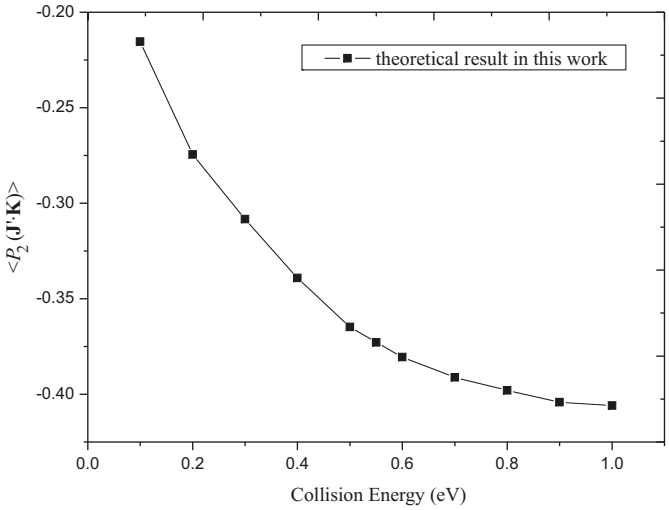


Fig. 3. The reaction cross section result versus collision energy for the reaction Ca + CF_3Br.

from –0.2154 to –0.4059. The result presents a falling trend and the alignment effect becomes strong.

The product rotational alignment is almost independent of the characters of PES, but can be influenced by the type of mass combination. The reaction Ca + CF_3Br studied in this paper belongs to the type of Light + Light–Light (LLL) mass combination and it can be found that the product rotational alignment shown in Fig. 4 is similar to the result of Fig. 4 in ref. 16. The LLL mass combination is similar to the HHH (Heavy + Heavy–Heavy) mass combination. The so-called LLL mass combination only refers to the mass ratio of three atoms and is approximately 1:1:1 and it does not mean that these three atoms are light atoms. The atomic mass of Ca is 40.08, the atomic mass of Br is 79.904, the atomic mass summation of the group CF_3 is 69.005 and the mass factor $\cos^2\beta$ ($\cos^2\beta = \frac{M_{Ca}M_{CF_3}}{M_{CaBr}M_{CaCF_3}}$, where M_{Ca} is the atomic mass of Ca, M_{CF_3} is the atomic mass summation of the group CF_3, M_{CaBr} is the mass of the product CaBr, and

Fig. 4. The product rotational alignment result versus collision energy for the reaction Ca + CF_3Br.

M_{CaCF_3} is the atomic mass summation of the group $CaCF_3$ of the reaction system and is 0.211. Here, the main consideration is the approximate mass proportion. Even so, for the $\langle P_2(\mathbf{J}' \cdot \mathbf{K})\rangle$ values of these two figures, there are some slight differences. The product rotational alignment of the reaction Ca + CF_3Br is smaller than the value of Fig. 4 at high collision energy, and the alignment effect is stronger than the low collision energy. The main reason for this phenomenon is that the mass proportion of this reaction slightly deviates from the LLL mass configuration.

Conclusions

In this paper, theoretical studies have been performed on the LEPS PES at different collision energies by means of the QCT method for the reaction Ca + CF_3Br. Some dynamical results such as the vibrational distribution, reaction cross section, and product rotational alignment were obtained.

The LEPS PES constructed for the reaction Ca + CF_3Br in this paper has a potential well in the entrance portion. The vibrational distribution first increases and then decreases with the increasing vibrational quantum number in both the experimental and theoretical results. The maximum value of the vibrational distribution appears at around $v = 3$ when the collision energy equals 0.55 eV. At the same time, the reaction cross section and the product rotational alignment were calculated for the title reaction when collision energy changes from 0.1 to 1.0 eV. The value of the reaction cross section decreases with the increasing collision energy and this phenomenon is due to the existence of a potential well on the LEPS PES. The result of product rotational alignment shows that the value decreases with the increasing collision energy and the relationship between the product rotational alignment and collision energy mainly depends on the mass combination. The reaction mechanism has been discussed in this paper through analyzing these calculated results.

As mentioned previously, from the related distributions of the reaction Ca + CF_3Br, it can be concluded that the theoretical results obtained by means of the QCT method are consistent with the experimental data and a reasonable interpretation is given for the experimental results.

Abstract: A catalytic amount (2 mol %) of phosphotungstic acid (PTA) is sufficient to synthesize homoallylic alcohol in excellent yields from aldehyde with allyltributylstannane upon grinding under solvent-free reaction conditions. Easy handling, very short reaction time, solvent-free reaction conditions, and aqueous workup free isolation protocol may make our method very useful for synthetic chemists.

Key words: aldehyde, allyltributylstannane, homoallylic alcohol, phosphotungstic acid, grinding.

Résumé : Une quantité catalytique (2 mol %) d'acide phosphotungstique (APT) est suffisante pour effectuer la synthèse d'alcools homoallyliques, avec d'excellents rendements, par broyage d'un aldéhyde avec de l'allyltributylstannane dans des conditions réactionnelles sans solvant. La facilité de la manipulation, son temps de réaction très court, les conditions réactionnelles sans solvant et le protocole d'extraction en milieu aqueux pourrait en faire une méthode très précieuse pour les chimistes de synthèse.

Mots-clés : aldéhyde, allyltributylstannane, alcool homoallylique, acide phosphotungstique, broyage.

[Traduit par la Rédaction]

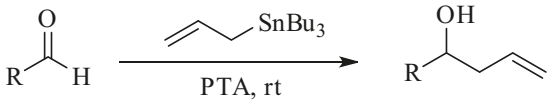
Introduction

In recent years, organic synthesis under solvent-free conditions has been considered to be one of the most important features for designing environmentally benign reaction protocols.[1,2] The solvent-free reactions can eliminate a commonly encountered solubility problem associated with reactivity and make the work-up process very easy by eliminating tedious aqueous workup and subsequent removal of solvents. Ironically, solvent accounts for the high *E* factor[3] of a reaction, which is a measure of the total waste generated during a reaction process. In recent years, phosphotungstic acid ($H_3PW_{12}O_{40}$) has found a lot of attention for being an environmentally benign and commercially available solid compound. Being a pseudoliquid,[4] phosphotungstic acid (PTA) is considered to be a better catalyst for organic transformations[5–9] than conventional inorganic and organic acids.

Homoallylic alcohols are considered as one of the most ubiquitous building blocks in organic synthesis and their applications in the field of organic total synthesis and pharmaceutical research[10–12] are well documented. With the advent of the ring-closing metathesis (RCM) approach,[13] homoallylic alcohols and amines are finding new impetus in the synthesis of bioactive natural products.[14–16] Acid-catalyzed reaction of aldehydes with allyltributylsatannanes is one of the most frequently exercised protocols for generation of homoallylic alcohols at room temperature. Among the Lewis acids,[17–28] $BF_3{\cdot}Et_2O$, $SnCl_4$, $TiCl_4$, etc., are highly moisture sensitive and hence require strictly anhydrous conditions, whereas transition-metal complexes such as AgOTf, $ReBr(CO)_5$, and $Sc(OTf)_3$ are very expensive, although water-tolerant. Although palladium and platinum complexes were also used as catalysts,[29–31] they are highly expensive and require high temperatures and long reaction times. The use of solid-supported reagents, such as polymer-bound sulfonamide,[32] silica–$Bi(OTf)_2$,[33] Ln–resins,[34] pincer bis(oxazolinyl)phenyl ligands on solid support,[35] and titanium-exchanged ZSM-5 catalyst[36] have also been reported, but those methods require catalyst preparation before use. Therefore, introduction of a new catalyst system that can address these drawbacks, as well as being efficient, selective, high yielding, and environmentally friendly, cannot be overlooked. As most of these reactions have considerably long reaction times and use hazardous organic solvents, we were looking for a catalyst to reduce the reaction time for this conversion and that could work in the absence of any solvent. Here, we wish to report PTA as an effective catalyst for the synthesis of homoallylic alcohol from aldehyde with allyltributylstannane.

Experimental

General remarks



All reagents were commercially available and used without further purification. Most of the aldehydes were purchased from Sigma-Aldrich. The IR spectra were recorded on a PerkinElmer 983 spectrophotometer. For column chromatography, we employed Merck silica gel 60–120 mesh. ^1H NMR (400 MHz) and ^{13}C NMR (100 MHz) spectra were recorded

on an AMX-400 MHz spectrometer using $CDCl_3$ as solvent and TMS as internal standard, unless otherwise stated. Mass spectra were obtained from a Waters ZQ 4000 mass spectrometer by the ESI method and the elemental analyses of the complexes were performed on a PerkinElmer-2400 CHN/S analyzer. Please see the Supplementary data for procedures and spectra.

Catalyst preparation

Phosphotungstic acid

Analytical grade $H_3PW_{12}O_{40}{\cdot}nH_2O$ was obtained commercially and used as a catalyst for the reaction.

Phosphotungstic acid/SiO_2

To a solution of $H_3PW_{12}O_{40}.nH_2O$ (0.5 g, 0.5 equiv by weight) in methanol (25 mL) was added silica gel (60–120 mesh, 4.5 g, 0.9 equiv by weight) and the mixture was stirred at room temperature for 6 h. Evaporation of methanol under reduced pressure gave a dry white powder. The catalyst was stored in a container for further use.

General procedure for phosphotungstic acid-catalyzed synthesis of homoallylic alcohol

A mixture of the aldehyde (1 mmol), allyltributylstannane (1.2 mmol), and phosphotungstic acid (0.02 mmol) was ground with a pestle in a mortar for the specified time (see Table 1). After complete conversion of the starting material, the crude mixture was dissolved in dichloromethane and directly loaded into a chromatography column charged with silica gel 60–120 mesh and eluted with a petroleum ether / ethyl acetate mixture as eluent in the appropriate ratio to obtain the pure product.

Results and discussion

Catalyst testing

In pursuance of our recent interests in PTA-catalyzed reactions,[37,38] we sought to use it for the allylation of aldehyde with allyltributylstannane. To achieve the stated objective, we stirred a mixture of *p*-nitrobenzaldehyde (1 mmol) with allyltributylstannane (1.2 equiv) in acetonitrile in the presence of 5 mol % of PTA. Upon constant monitoring by TLC, it was observed that the reaction was completed within 5 h to give 92% yield of the desired product.

As the surface area of PTA is smaller in comparison with its polyoxometalates, we wanted to know whether silica-supported PTA could reduce the reaction time. While using a PTA/SiO_2 reagent system, we initially opted to carry out the reaction in acetonitrile to mix the reacting species properly and found that the reaction was completed in 5 h to give 83% isolated yield of the desired product. Since the solvent is one of the most important contributors to the reaction rate, we wanted to use solvent-free conditions solely for carrying out the reaction.[39] When *p*-nitrobenzaldehyde (1 mmol) and allyltributylstannane (1.2 equiv) were stirred with the PTA/SiO_2 reagent system without using any solvent, complete conversion of the starting aldehyde took ~5 h. As these observations did not warrant any improvement over solution-phase stirring with PTA itself, we wanted to see the effect of grinding a mixture of aldehyde and allyltributylstannane with 5 mol % of the catalyst. To that effect, a mixture of *p*-nitrobenzaldehyde (1 mmol) and allyltributylstannane (1.2 equiv) was ground with a pestle in a mortar in the presence of 5 mol % of PTA. To our surprise, the reaction was completed within 5 min to give almost quantitative yield (Scheme 1).

Scheme 1. Synthesis of homoallylic alcohols.

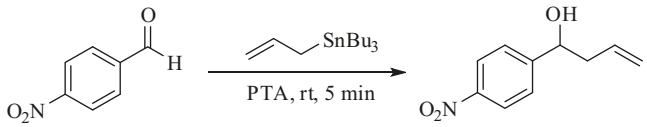

Table 2. Optimization of catalyst for the allylation of aldehyde.

Entry	Catalyst (mol %)	*p*-Nitrobenzaldehyde time (min)[a]	Hexanal time (min)[a]
1	1.0	120	300
2	1.5	15	25
3	2.0	5	10
4	4.0	5	9
5	5.0	5	9

Note: Aldehyde–allyltributylstannane, 1:1.2.
[a]The time for complete conversion.

Correlation of the catalyst ratio and reaction time

The fact that reaction proceeded slowly in the solution phase in the presence of PTA and silica-supported PTA suggests that the collision among the reactants upon grinding of the reaction mixture with PTA might have contributed to the shorter reaction time. It was observed that the reaction does not occur at room temperature, when a mixture of *p*-nitrobenzaldehyde and allyltributylstannane is ground in the absence of the catalyst. This established that there is no catalytic effect produced by the mortar and the pestle that might have contributed towards the shorter reaction time for completion. When complete conversion of the starting aldehyde was studied for the same reaction under catalytic conditions by varying the catalyst ratio, we found that 2 mol % of the catalyst is sufficient to complete the reaction within 5 min (Table 2). It was also observed that an amount of catalyst <2 mol % leads to increased reaction time for complete conversion, whereas an increased concentration of the catalyst up to 5 mol % could not reduce the reaction time significantly. We also tried to evaluate the reactivity pattern of aliphatic aldehyde by reacting a mixture of hexanal and allyltributylstannane in the presence of a catalytic amount of PTA (2 mol %) and found that the reaction takes a comparatively longer time.

Recovery of the catalyst

Since catalyst recovery is one of the most crucial components in catalytic reactions in general, we studied the reusability of the catalyst for successive batches for the reaction of *p*-nitrobenzaldehyde and allyltributylstannane using our reaction protocol. After completion of the reaction, diethyl ether was added to dissolve the product mixture and filtered to get the solid PTA residue. The PTA residue was washed thoroughly with diethyl ether and dried in an oven at 100 °C for 1 h and then cooled to room temperature. The recovered PTA catalyst obtained as mentioned was used for second, third, and fourth batches of the same reactants under similar reaction conditions without loss of appreciable activity in terms of reaction time and yield.

Generalization of the method

Having standardized the reaction parameters, such as the catalyst and the process, we set out to explore the general applicability of our method for both aromatic as well as aliphatic aldehydes[14] and its compatibility towards acid-sensitive functional groups (Table 1). It was observed that reaction worked exceedingly well for aromatic aldehydes having either +M or –M effect on the phenyl rings. The presence of phenolic an –OMe group in the para position of the aldehyde group did not have any noticable effect on the yield of the product, which is evident from the excellent yields of the products (Table 1, entry 3). Ironically, the vanillin (Table 1, entry 10) did not react despite the addition of 10 mol % of the catalyst under similar reaction conditions. It might be due to the poor electrophilicity of the aldehyde group resulting from the presence of the *p*-OH and *m*-OMe groups having +M effect on the phenyl ring. Several functional groups such as OTHP, methylenedioxy, etc., were hardly affected by the reaction conditions, as reflected by their excellent yields. From its excellent yield, we concluded that the OTBS (Table 1, entry 12) group is very stable under our reaction conditions. We did not observe any significant differences in reactivity for *m*- and *p*-nitrobenzaldehydes (Table 1, entries 7 and 8), as they took almost a similar reaction time for complete conversion. It is interesting to note that the aliphatic aldehydes (Table 1, entries 13–15) also gave excellent yields of their corresponding homoallylic alcohols upon grinding with allyltributylstannane in the presence of PTA. Excellent yield of homoallylic alcohol from cinnamaldehyde (Table 1, entry 16) shows that 1,2-addition is prefered in α,β-unsaturated aldehydes. *N*-Boc-pyrrolidine-2-carbaldehyde also generated its corresponding homoallylic alcohol (Table 1, entry 17) in good yield to verify the fact that the amide group, α to the aldehyde functionality, hardly has any negative impact on the efficiency of the reaction system.

Conclusion

This report introduces PTA as one of the most efficient catalysts for the allylation of aldehyde with allyltributylstannane. It has also established the fact that the catalytic activity increases manifold, resulting in a sharp reduction of reaction time, upon grinding the aldehyde and allyltributylstannane with PTA. Easy handling, very short reaction time, solvent-free reaction conditions, excellent yields, and a simple purification process devoid of aqueous workup may make our protocol very useful to synthetic chemists.

Abstract: Thioglycolic acid (TGA)-capped CdTe nanoparticles (NPs) were synthesized in aqueous medium, and their application as fluorescence probes in the detection of adenine and guanine was studied. The TGA-capped CdTe NPs were characterized by transmission electron microscopy, X–ray diffraction spectrometry, spectrofluorometry, Fourier transform infrared, and ultraviolet-visible spectrometry. Based on the significant enhancement of fluorescence emission of these CdTe fluorescence probes in the presence of adenine or guanine, a quantitative analysis method for these purines was proposed. Experimental conditions that govern the extent of fluorescence enhancement were optimized. Under the optimal conditions, the relative fluorescence intensity versus adenine or guanine concentrations gave a linear response, permitting the dynamic range of 7.0×10^{-7}–1.0×10^{-4} mol/L and 6.0×10^{-7}–9.0×10^{-5} mol/L for adenine and guanine, respectively. The method has also been applied successfully to the detection of adenine and guanine in synthetic samples with satisfactory results.

Key words: CdTe nanoparticles, fluorescence probe, adenine, guanine.

Résumé : Opérant dans un milieu aqueux, on a effectué la synthèse de nanoparticules (NP) de CdTe coiffées par d'acide thioglycolique (ATG) et on a étudié la possibilité de les utiliser comme sondes de fluorescence pour la détection de l'adénine et de la guanine. On a caractérisé ces nanoparticules de CdTd coiffées par d'acide thioglycolique (ATG) par microscopie électronique de transmission, par spectrométrie de diffraction des rayons-X, par spectrofluorométrie, par spectrométrie infrarouge à transformation de Fourier et par spectrométrie ultraviolette-visible. Sur la base de l'augmentation significative de l'émission de fluorescence de ces sondes de fluorescence à base de CdTe en présence d'adénine ou de guanine, on a proposé une méthode d'analyse quantitative pour ces purines. On a optimisé les conditions expérimentales qui favorisent une augmentation de la fluorescence. Dans les conditions optimales, on observe une corrélation linéaire entre l'intensité relative de la fluorescence en fonction des concentrations d'adénine ou de guanine et ceci établit que les plages dynamiques sont respectivement de $7{,}0 \times 10^{-7}$à $1{,}0 \times 10^{-4}$ mol/L et de $6{,}0 \times 10^{-7}$ à $9{,}0 \times 10^{-5}$ mol/L pour l'adénine et la guanine. La méthode a été appliquée avec succès à la détection de l'adénine et de la guanine dans des échantillons de synthèse.

Mots-clés : nanoparticules de CdTe, sonde de fluorescence, adénine, guanine.

1. Introduction

Semiconductor nanoparticles (NPs) are nanostructured materials,[1] also known as zero-dimensional materials or nanocrystallites.[2] These smart NPs are composed of atoms from groups II–VI, III–V or IV–VI elements in the periodic table.[3] Because of their quantum confinement of charge carriers in tiny spaces, NPs show some unique and fascinating optical properties, which are not available from either isolated molecules or bulk materials,[4,5] such as broad excitation wavelength range, narrow and symmetrical emission spectrum, size-tunable emission peak, longer fluorescence lifetime than organic fluorophores, high photobleaching threshold, and high resistance to optical and chemical degradation.[6–9] As the optical properties of NPs strongly depend on the nature of the surface, the interactions between specific analytes and the surface of the NPs can result in dramatic changes in their optical properties.[10] In addition, the high quantum yield makes them appealing for direct detection applications, removing the need for sample enrichment and amplification, making the prescribed technique more versatile and accessible.[11] Hence, functionalized NPs have been widely exploited for tracing biorecognition events or biocatalytic transformations,[12,13] and for biomolecule sensing strategies.[14]

Adenine and guanine are building blocks of both DNA and RNA that play a crucial role in protein biosynthesis and the storage of genetic information.[15] Adenine has important effects on physiological processes of human body. It controls blood flow, prevents cardiac arrhythmias, inhibits neurotransmitter release, affects cerebral circulation, and modulates activity of adenylate cyclase.[16] Guanine is believed to play a

key role in the oxidation of DNA by various types of oxidants and free radicals.[17] Thus, it can be used to predetermine physical and chemical mechanisms responsible for the degree, localization, and chemical impact of oxidative damage to DNA.[17,18] The importance of such a determination stems from the fact that abnormal concentrations of these purines in cells may reflect alterations in the activity of catabolic, anabolic, interconversion of enzymes, and the presence of various diseases.[19] Hence, quantitative analysis of adenine and guanine is very essential to bioscience and clinical diagnosis.

To date, various methods have been available for the determination of adenine and guanine. These include high performance liquid chromatography,[20] electrophoresis with spectroscopic and electrochemical detection,[21] electrochemical analysis,[22] liquid chromatography tandem mass spectroscopy,[23] flow injection chemiluminescence,[24] and surface-enhanced Raman spectroscopy.[25] However, each approach exhibits certain disadvantages. For example, chromatographic methods often require the isolation of matrix components, as well as derivatization steps,[26] while the electrochemical technique tends to suffer from irreversible adsorption on the electrode surface thus hampering the estimation.[19,27] In contrast, the fluorescence probe method appears to be a simple and fast experimental process, with

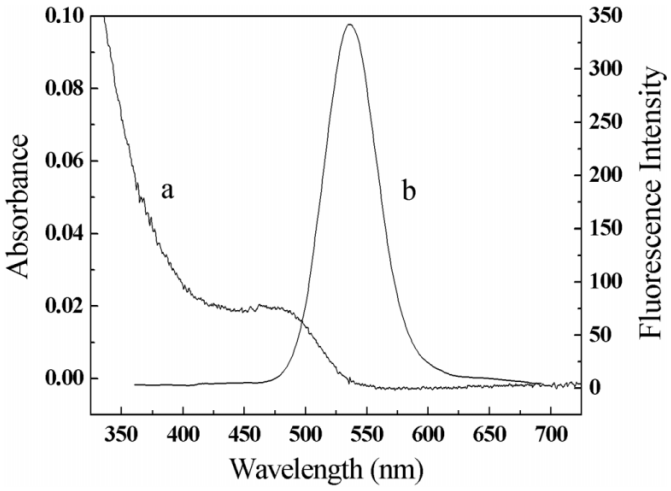

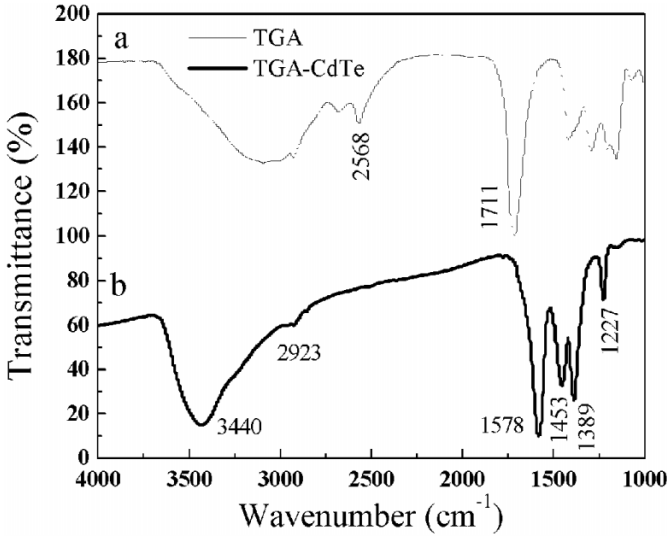

Fig. 3. (*a*) FTIR spectra of TGA and (*b*) TGA capped CdTe NPs.

high sensitivity for different fluorescent emission wavelengths corresponding to different molecular structures.[28]

In this paper, we present a simple, convenient and sensitive fluorescence emission method for the quantitative determination of adenine and guanine based on the interaction of CdTe NPs with adenine or guanine. The CdTe NPs were prepared in aqueous solution through a straightforward process by using safe inorganic salts as precursors and low-cost thioglycollic acid as the stabilizer. Under optimum conditions, the fluorescence of functionalized CdTe NPs was enhanced through binding with adenine or guanine, wherein the extent of the fluorescence intensity enhancement was proportional to the concentrations of the analytes. Interference tests using several metal ions and some small biomolecules demonstrated little impact on determination of the two purines.

2. Experimental

2.1 Reagents and materials

The chemicals used in the experiments included $CdCl_2 \cdot 2.5H_2O$ (analytical purity), sodium borohydride (96%),

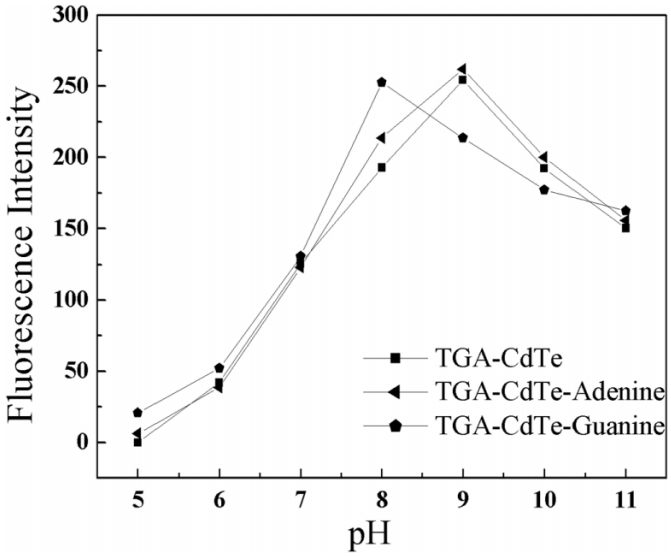
Fig. 4. Effect of pH on the fluorescence intensity of TGA–CdTe system in the absence and presence of adenine or guanine.



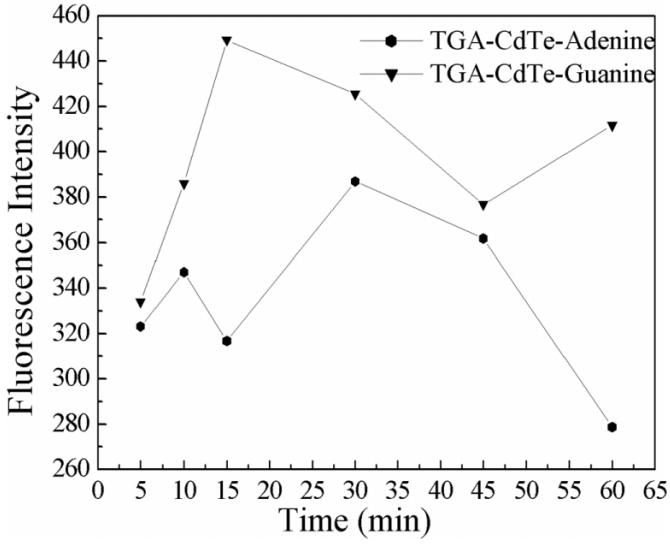


Fig. 5. Effect of reaction time on the fluorescence intensity of TGA–CdTe–adenine and TGA–CdTe–guanine systems.

tellurium powder (99.999%), adenine (biology reagent), guanine (biology reagent), and thioglycolic acid (TGA, purity). All chemicals were purchased from Shanghai Sinopharm Chemical Reagent Co. Ltd. (China) and used without further purification. Doubly distilled water (DDW) was used throughout. Stock solutions of adenine and guanine were prepared in 0.1 mol/L HCl at a concentration of 5 mmol/L and were further diluted with DDW whenever necessary. The phosphoric buffer solution (PBS) was prepared by adjusting 0.1 mol/L K_2HPO_4, KH_2PO_4, H_3PO_4, or NaOH accordingly.

2.2 Apparatus

Transmission electron microscopy (TEM) images were obtained using JEOL 200 CX transmission electron microscope. X–ray powder diffraction (XRD) spectra were taken on a Rigaku D/max 2550 X–ray diffractometer with Cu Kα radiation (λ = 0.15418 nm). The fluorescence emission spectra were measured by using a RF-5301PC spectrofluorometer with a 1 cm quartz cell. Absorption spectra were recorded on a UV-2501PC spectrometer. Infrared spectra were recorded by using an AVATAR 370 Fourier transform infrared (FTIR) spectrophotometer. The pH measurements were made with a pHS-3C pH meter. All optical measurements were carried out at room temperature under ambient conditions.

2.3 Synthesis of NaHTe

NaHTe solution was prepared using a modified literature procedure by treatment of Te powder with excess $NaBH_4$ at a molar ratio of 1:20.[29] To a small flask was loaded 151 mg (4 mmol) of $NaBH_4$ followed by the addition of 5 mL of DDW and 25.5 mg (0.2 mmol) of Te powder. The mixture was stirred under a N_2 atmosphere in ice-cooled water bath. During the course of the reaction, a small outlet connected to the flask was kept open to discharge the pressure from the N_2 and the resulting H_2. The NaHTe solution was obtained when the color of the solution changed from black to white.

2.4 Aqueous synthesis of TGA-capped CdTe nanoparticles

The synthesis of the colloidal CdTe NPs was carried out in a three-necked round-bottomed flask. Typically, 0.4 mmol of $CdCl_2{\cdot}2.5H_2O$ was dissolved in 100 mL DDW, and 0.96 mmol of TGA was added under stirring, followed by adjusting the pH to 11.2 by the addition of 1.0 mol/L NaOH solution dropwise. The resulted solution was degassed by N_2 bubbling for 30 min. Under vigorous stirring, 0.2 mmol of freshly prepared oxygen-free NaHTe was injected into the above solution. The molar ratio of Cd^{2+}/Te^{2-}/TGA was 2:1:4.8 in our experiments. The reaction between Cd^{2+} and NaHTe took place immediately upon the injection of NaHTe solution. The colorless solution changed to golden yellow. After being refluxed for 1 h at 95 °C, TGA-stabilized CdTe NPs exhibiting green fluorescence were obtained.

2.5 Determination of adenine and guanine with TGA–CdTe fluorescence probe

To determine the concentrations of adenine and guanine, a series of solutions prepared as follows were used to monitor the change of emission fluorescence intensity by means of spectrofluorometer. To a set of dry 25 mL calibrated flasks were added 400 μL of as-prepared TGA–CdTe solution and a series of known volumes of adenine or guanine standard solutions. The resulting solutions were diluted to the volume with PBS and mixed thoroughly. The mixtures were kept for a while in the dark prior to making the fluorescence measurements at room temperature. For emission measurements, the excitation wavelength was fixed at 351 nm, where neither adenine nor guanine possesses absorption. The fluorescence intensity was measured at 535 nm for adenine and 538 nm for guanine, respectively. Both slit widths of excitation and emission were 5 nm. The scanning bound was from 361 to 692 nm.

3. Results and discussion

3.1 Characterization of the prepared TGA–CdTe nanoparticles

The morphology of the prepared TGA–CdTe NPs was visualized by transmission electron microscopy. The typical TEM image (Fig. 1*a*) of TGA–CdTe NPs illustrates that

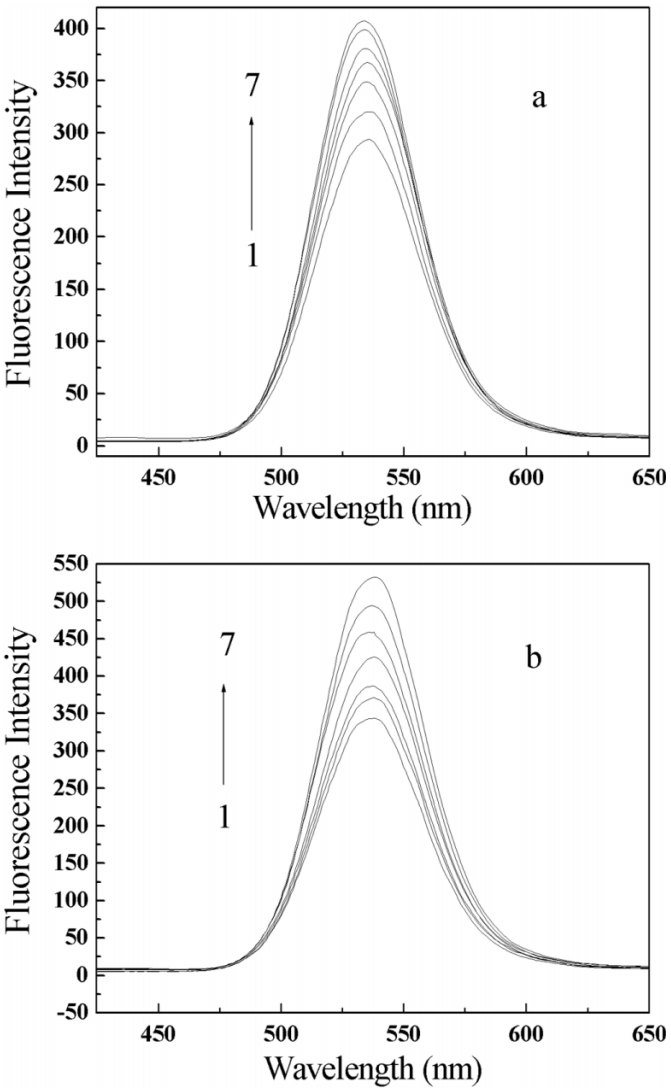

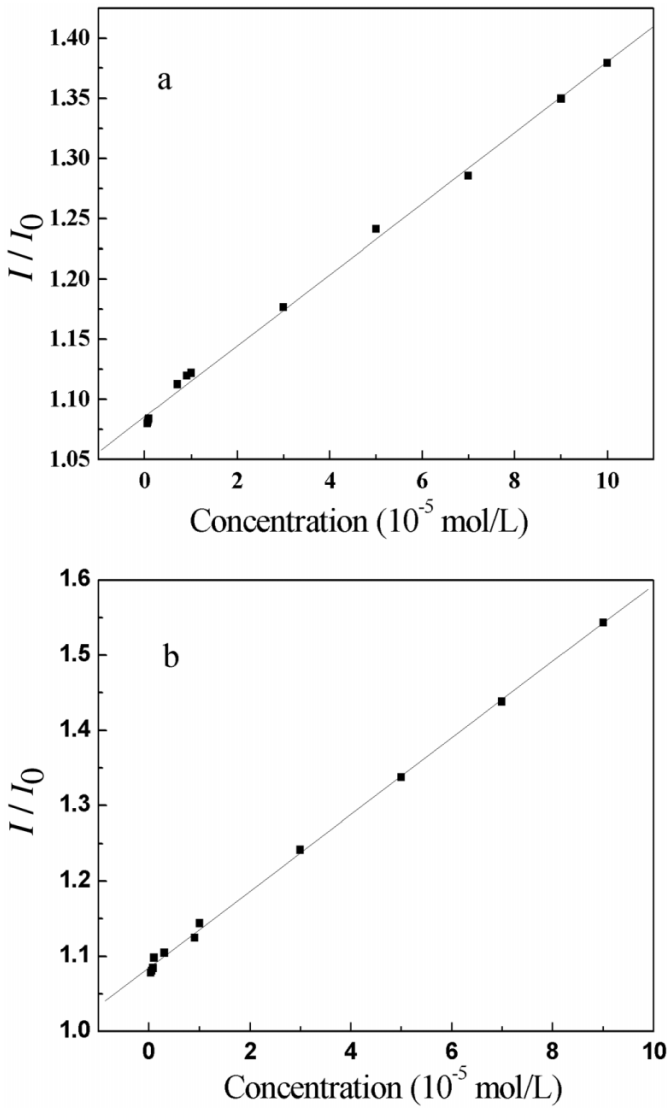

Fig. 7. Linear graph of the relative fluorescence intensity (I/I_0) versus the concentrations (C) of (*a*) adenine and (*b*) guanine.

these NPs are monodispersed, and the shape of them is close to regular spherical NPs with average diameters of approximately 30 nm. The XRD pattern (Fig. 1*b*) was obtained from TGA–CdTe powders precipitated from an aqueous solution of CdTe NPs with excess isopropanol. The XRD spectrum shows two main peaks at 25.3° and 41.7°, corresponding to the crystal planes 101 and 103, confirming that it has a hexagonal wurtzite crystalline structure. According to the Debye–Scherrer equation, $D = 0.89\lambda/\beta\cos\theta$, the average size of TGA–CdTe NPs is 30.8579 nm, which is in good agreement with the particle size estimated from the TEM image.

The optical properties of TGA–CdTe NPs were also characterized by using UV–vis absorption and fluorescence spectroscopy (Fig. 2). The absorption spectrum indicates that TGA–CdTe NPs have a wide range of absorption, and the excitonic absorption peak is at 475 nm. The emission spectrum displays an emission peak at 537 nm, and this spectrum is characterized by good symmetry and relatively narrow spectral width.

To demonstrate whether TGA has been capped onto CdTe NPs, FTIR studies were used to characterize the structure of TGA (Fig. 3*a*) and the TGA-modified CdTe NPs (Fig. 3*b*). Figure 3*b* clearly shows that the infrared absorption bands occur at 3440 cm^{-1} (OH stretching vibration), 2923 cm^{-1} (CH_2 symmetric stretching vibration), 1578 cm^{-1} (COO^- asymmetric stretching vibration), 1453 cm^{-1} (CH_2 scissoring vibration), 1389 cm^{-1} (COO^- symmetric stretching vibration), and 1227 cm^{-1} (CO stretching vibration).[30] It is noteworthy that the characteristic S–H vibrations in TGA at around 2568 cm^{-1} disappeared completely in the spectrum of TGA–CdTe NPs. Hence, it could be concluded that the S–Cd bonds were formed between TGA and CdTe core.[31] Besides, the asymmetric stretching vibration of the carboxyl group in TGA shifted from 1711 to 1578 cm^{-1}, indicating that TGA was absorbed onto Cd^{2+} as carboxylate after deprotonation.[32]

3.2 Optimization of the general procedure

The fluorescence emission spectra of many matters are sensitive to their surrounding environment. To develop a sensitive and rapid spectrophotometric method for the determination of adenine and guanine, the test conditions were optimized by studying the effects of various factors such as pH value, incubation time, and temperature.

The effect of pH in a range between 4.0 and 11.0 was studied. PBS (0.1 mol/L) was used as the buffer to adjust the acidity of the aqueous medium. As shown in Fig. 4, pH influences the fluorescence intensity of NPs in the absence and presence of adenine or guanine. It can be seen clearly from Fig. 4 that the maximum fluorescence intensity of the TGA–CdTe–adenine system occurs at pH 9.0, whereas the optimal pH is 8.0 for the TGA–CdTe–guanine system. Therefore, pH of 9.0 and 8.0 was chosen to run the two systems, respectively.

The influence of reaction time on the fluorescence enhancement intensity was also studied. Fluorescence spectrum was recorded at different time intervals after the addition of adenine or guanine into the NPs solution. The results (in Fig. 5) show that the maximum fluorescence intensity is obtained when the reaction time is 30 min for adenine and 15 min for guanine. It was noted that temperature, as expected, had an effect on the fluorescence intensity of the TGA-capped CdTe NPs. Therefore, all analytical studies were conducted at room temperature (25 °C).

3.3 Spectral characteristics of fluorescence

A series of different concentrations of adenine or guanine were added to the TGA–CdTe NPs system. It was observed that the fluorescence intensity increased on the addition of adenine or guanine with no obvious spectra shift. Changes of the fluorescence emission spectra are given in Fig. 6. The

Can. J. Chem. Downloaded from www.nrcresearchpress.com by Renmin University of China on 09/02/12
For personal use only.

observed fluorescence band centers are at 535 nm (excitation 351 nm) for adenine and 538 nm (excitation 351 nm) for guanine. The possible mechanism of the interaction between TGA–CdTe NPs and the two purines is a hydrogen bond in nature.[33,34] The significant enhancement of fluorescence intensity offered the possibility of developing a sensitive method for quantitative assay of adenine and guanine based on spectrofluorometry.

3.4 Standard curve and detection limit

Under optimal experimental conditions, the enhancement effect of adenine or guanine on the fluorescence emission of TGA-capped CdTe NPs was concentration-dependent, which was best demonstrated in Fig. 7. There are good linear relationships between the relative fluorescence intensity ($\Delta I = I/I_0$) and the concentrations (C) of adenine and guanine, where I_0 and I are the fluorescence intensities at λ_{em} when excited at λ_{ex} in the absence and presence of purine solutions, respectively. The dynamic range of adenine is 7.0×10^{-7}–1.0×10^{-4} mol/L with a correlation coefficient (r) of 0.9985, and the dynamic range of guanine is 6.0×10^{-7}–9.0×10^{-5} mol/L with a correlation coefficient (r) of 0.9993. The calibration curve established the following equation, $\Delta I = 1.085 + 0.02949\ C$ (C, 10^{-5} mol/L) for adenine and $\Delta I = 1.084 + 0.05094\ C$ (C, 10^{-5} mol/L) for guanine. The detection limit was 1.4×10^{-7} mol/L for adenine and 8.0×10^{-8} mol/L for guanine. These analytical parameters are comparable or better than results reported for adenine or guanine detection (Table 1), which signifies that this method is sensitive.

3.5 Tolerance of foreign substances

Under the optimized conditions of assay, the effects of foreign substances on the fluorescence signals of CdTe NPs were investigated to evaluate the selectivity of this proposed method. Each foreign substance, of various concentrations, was mixed with 1.0×10^{-5} mol/L adenine or guanine prior to the detection. The tolerance limit was defined as the maximum concentration of the foreign substance that produced a determination error of less than 5% (Table 2). The results show that most of the substances examined have no obvious interference in determination, indicating that this method is selective and amenable to the detection of adenine and guanine in human or animal body fluid samples.

3.6 Analytical performance

The present method was applied to quantify adenine and guanine in three synthetic samples containing adenine or guanine and foreign substances whose concentrations were below the tolerance of coexisting species listed in Table 2. The average recovery (R) is defined by the equation $R = [(C_T - C_A)/C] \times 100\%$,[38] where C is the amount of purines (adenine or guanine) from synthetic samples, C_A is the added amount of standard solution of purines, and C_T is the amount of purines after the addition of standard solution of purines, which is obtained from the regression equation. The determination results and recovery tests are shown in Table 3. It can be seen that values acquired from the three samples are identical with the expected values. Moreover, the relative standard deviations (R.S.D.) are lower than 3%, showing good precision of this method. The average recovery ranges from 97.22% to 101.46%, which meets the requirement of micro-analysis. This indicates that our method is accurate, sensitive, and reproducible.

4. Conclusions

In this study, a novel fluorescence probe method based on TGA-capped CdTe NPs has been developed for the quantitative analysis of adenine and guanine. The TGA-capped CdTe NPs with excellent fluorescence properties were synthesized in aqueous solution through a straightforward process. The fluorescence intensity of the functionalized nanoparticles displayed a positive linear correlation with the concentrations of adenine or guanine. The use of TGA–CdTe NPs as fluorescence probes offered a particularly inexpensive, simple, and sensitive assay for adenine and guanine. These studies should provide valuable information in the design of fluorescence probes for the detection of other biomolecules. Finally, the CdTe nanoparticles may find more extensive applications in analytical biochemistry.

Abstract: A new approach for the simultaneous determination of ephedrine, methylephedrine, and pseudoephedrine is developed, using capillary electrophoresis coupled with electrochemiluminescence detection with internal standard method. Separation efficiency and sensitivity were improved by use of an ionic liquid. Parameters affecting separation and detection were investigated in detail. Under optimum conditions, the three ephedra alkaloids were well separated and detected. The limits of detection (S/N = 3) of ephedrine, methylephedrine and pseudoephedrine are 4.0×10^{-8}, 6.5×10^{-8}, and 4.6×10^{-8} mol/L, respectively. The limits of quantitation (S/N = 10) in human urine are 5.3×10^{-7} mol/L for ephedrine, 9.1×10^{-7} mol/L for methylephedrine, and 6.9×10^{-7} mol/L for pseudoephedrine, respectively. The precision (RSD%) of the peak area and the migration time were from 2.2% to 2.5% and from 0.1% to 0.2% within a day and from 2.7% to 3.9% and from 0.4% to 0.8% in three days. The proposed method was successfully applied to the determination of three analytes in traditional Chinese medicine and human urine, and the monitoring of pharmacokinetics of pseudoephedrine in human body.

Key words: capillary electrophoresis, electrochemiluminescence, ephedra alkaloids, pharmacokinetics, traditional chinese medicine.

Résumé : On a développé une nouvelle méthode de détermination simultanée de l'éphédrine, de la méthyléphédrine et de la pseudoéphédrine par électrophorèse capillaire couplée à un détecteur à électrochimiluminescence, utilisant un standard interne. On a amélioré l'efficacité et la sensibilité de la séparation en utilisant un liquide ionique. On a étudié en détail les paramètres qui peuvent affecter la séparation et la détection. Dans des conditions optimales, les alcaloïdes de l'éphédra sont bien séparés et bien détectés. Les limites de détection (signal/bruit > 3) de l'éphédrine, de la méthyléphédrine et de la pseudoéphédrine sont respectivement de $4{,}0 \times 1^{-8}$, $6{,}5 \times 1^{-8}$ et $4{,}6 \times 1^{-8}$ mol/L. Les limites de quantification (signal/bruit > 10) dans l'urine humaine sont pour l'éphédrine, la méthyléphédrine et la pseudoéphédrine sont respectivement de $5{,}3 \times 10^{-7}$, $9{,}1 \times 10^{-7}$ et $6{,}9 \times 10^{-7}$ mol/L. Les précisions, écarts types relatifs (ETR%), de la surface sous les pics et des temps de migration varient de 2,2 % à 2,5 % et de 0,1 % à 0,2 % au cours d'une journée et de 2, 7 % à 3,9 % et de 0,4 % à 0,8 % en trois jours. La méthode proposée a été appliquée avec succès à la détermination des trois analytes dans des médicaments chinois traditionnels, dans l'urine humaine et au suivi pharmacocinétique de la pseudoéphédrine dans le corps humain.

Mots-clés : électrolyse capillaire, électrochimiluminescence, alcaloïdes de l'éphédra, pharmacocinétique, médicaments chinois traditionnels.

[Traduit par la Rédaction]

Introduction

Ephedrine (E), methylephedrine (ME), and pseudoephedrine (PE) are sympathomimetic amines with central nervous system stimulating properties.[1,2] These substances are ingredients of Ma Huang, which is a traditional Chinese medicine (TCM) derived from ephedrae herba that is used as a stimulant, diaphoretic, and anti-asthmatic.[3] They are also ingredients of many pharmaceuticals commonly used in the treatment of flu, rhinitis, colds, and allergy.[4] The International Olympic Committee[5] and most international sports federations have put the ephedrines on their list of prohibited doping substances and have adopted urinary threshold concentrations, above which an athlete is regarded as positive. Therefore, a fast, simple, and reliable method is needed for the simultaneous quantification of these substances. However, the simultaneous separation and detection of E, ME, and PE is difficult because of their similar chemical structure. Increasing concern on the part of both consumers and regulatory agencies of the safety of ephedra alkaloids has led to the development of a variety of analytical methods to measure these important drug ephedra alkaloids, such as gas chromatography (GC)[6,7] and liquid chromatography (LC).[8–10]

Capillary electrophoresis (CE) has been widely applied to the analysis of pharmaceutical compounds because of its high resolution, short analysis time, low reagent consumption, and easy automation.[11,12] Phinney et al.[13] reported a CE-UV method for the determination of E and PE enantiomers based on the cyclodextrin as additive. Li et al.[14] separated E and PE by CE, modified with a Cu (II)-L-lysine complex utilizing UV detection. Xie et al.[15] and Dong et al.[16] determined E and PE after derivatization by CE-LIF. Electrochemiluminescence (ECL) has become an attractive and powerful detection tool because of its advantages, such as high sensitivity, good selectivity, wide linear range, and low equipment cost.[17,18] Tris(2,2′-bipyridyl)ruthenium(II) ($Ru(bpy)_3^{2+}$) is the most efficient and widely used ECL reagent, because of its high luminescence efficiency and stability in aqueous media. Recently, CE coupled with ECL using $Ru(bpy)_3^{2+}$, has been proven to be a sensitive and efficient analytical technique and was successfully demonstrated in analyses of proteins,[19,20] amino acids,[21] and drugs.[22–24]

Ionic liquids (ILs) are new advanced materials consisting of entirely ionic species at ambient temperatures. They have some unique properties, compared with conventional organic solvents, such as nonvolatility, high chemical and thermal stability, a wide electrochemical window, good conductivity, and high viscosity.[25,26] ILs have played an important role as separation media in past decades in advancing research in GC,[27] LC,[28,29] and CE.[30,31] The wetting ability and the viscosity of ILs make them an ideal coating in stationary phases in GC. The addition of ILs as new mobile phase additives or chemical modifiers in LC could eliminate band broadening and tailing and improve resolution. ILs have been recognized as suitable background electrolytes in CE. Similar to LC, their use in CE has been shown to enhance resolution, peak efficiency, and peak symmetry.[32,33]

In this work, a sensitive CE-ECL method was developed for the simultaneous determination of E, ME, and PE with IL. To improve precision and obtain more accurate results, the internal standard method was adopted. The conditions for separation and detection were investigated in detail. The applicability of the proposed method was illustrated in the qualitative and quantitative analysis of three ephedra alkaloids in traditional Chinese medicine. The method was also applied to the determination of E, ME, and PE in human urine samples and the monitoring of pharmacokinetics for PE in the human body.

Experimental

Materials and reagents

E, ME, and PE were purchased from the National Institute for the Control of Pharmaceutical and Biological Products (Beijing, China). Tripropylamine (TPA) was obtained from Sigma-Aldrich Chemicals (Milwaukee, Wis., USA). PE sustained release capsules were acquired from Zhongmei Tianjin Shike Pharmaceutical Co. Ltd. (Tianjin, China). Xiao'er Qingre Zhike Koufuye (a kind of TCM for the treatment of colds, containing E, ME, and PE) was acquired from Hebei Sunstone Pharma (Tangshan, China). Tris(2,2′-bipyridyl) ruthenium(II) chloride hexahydrate was purchased from Alfa Aesar (A Johnson Matthey Company, Ward Hill, Mass., USA). 1-Butyl-3-methylimidazolium tetrafluoroborate ($BMIMBF_4$) was purchased from Wako Pure Chemical Industries (Japan). All chemicals and reagents were of analytical grade and used without further purification.

An amount of 5 mmol/L stock solutions of E, ME, PE, and TPA were prepared by dissolving each standard substance in pure water (18.2 MΩ cm) and processed with an Ultrapure Water System (Kangning Water Treatment Solution Provider, China). A series of working standard solutions were prepared by diluting the stock solution with pure water for calibration. All solutions were stored in a refrigerator at 4 °C and filtered through 0.22 μm cellulose acetate filters (Shanghai Xingya Purification Material Factory, China) prior to use.

CE-ECL apparatus

The CE-ECL experiments were performed on a model MPI-A CE ECL system (Xi'an Remax Electronic Science-Tech, Xi'an, China). The system provided a programmable high-voltage power supply (0–20 kV), an electrochemical potentiostat, a multifunction chemiluminescence detector, and a multichannel data collection analyzer. Output ECL intensity was amplified and recorded in a computer using the MPI-A software.

The end-column ECL detection cell was composed of a 500 μm Pt disk working electrode, an Ag/AgCl reference electrode (KCl saturated), and a Pt wire counter electrode. The surface of the working electrode was polished sequentially with 0.3 and 0.05 μm α-Al_2O_3 on a piece of polishing cloth until a mirror smooth surface appeared, and it was then sonicated for 10 min in water. The electrode was subjected to repeated cycling in the potential region of 0.2–1.25 V (versus Ag/AgCl) to obtain a reproducible cyclic voltammogram before the first use of every day. About 300 μL of 5 mmol/L $Ru(bpy)_3^{2+}$ with 50 mmol/L PBS solution at pH 8.5 was added into the cell before analysis and replaced every 6 h to eliminate depletion effects.

Procedure

All separations were performed in a 50 cm long fused-silica capillary, with 50 μm i.d. and 375 μm o.d. (Yongnian Reafine Chromatography, Hebei, China). The new capillary was rinsed sequentially with 2.0 mol/L CH_3OH-NaOH (2 g NaOH dissolved in 25 mL (4:1, *v*/*v*) CH_3OH/H_2O solution), 1.0 mol/L NaOH, 1.0 mol/L HCl, H_2O, and electrophoretic buffer for 30 min. At the beginning of each day, the capillary was flushed with 0.1 mol/L NaOH, HCl, H_2O, and equilibrated with the electrophoretic buffer for 5 min successively to maintain an active and reproducible inner surface. The capillary was rinsed sequentially with 0.1 mol/L NaOH, 0.1 mol/L HCl, H_2O, and electrophoretic buffer for 2 min after every five runs. The voltage of the photomultiplier tube (type CR105, Beijing Binsong Photonics, China) used to collect the ECL signal was set at –850 V during detection. The detection potential applied at the working electrode was fixed at 1.20 V. Electrokinetic injections were performed at 10 kV for 10 s. The inlet end of the capillary was held at a positive potential, and the outlet end was maintained at ground. Five mmol/L of $Ru(bpy)_3^{2+}$, prepared in 50 mmol/L phosphate buffer solution (PBS), was added to the detection cell. The peak area was used for the analysis.

Results and discussion

$Ru(bpy)_3^{2+}$ generated ECL with ME

ME was used as a model analyte to study the ECL performances of the ephedra alkaloids in this work. The results of CV of $Ru(bpy)_3^{2+}$ and ME showed that the CV wave of the ECL reaction of $Ru(bpy)_3^{2+}$ was observed with a peak voltage of 1.20 V. In presence of ME, the rise in the anodic current, a marker of the catalytic effect of $Ru(bpy)_3^{2+}$, were observed as the potential was scanned from 0.2 to 1.25 V. The possible mechanism for the enhanced ECL emission might occur as follows[18]:

[1] $$Ru(bpy)_3^{2+} - e^- \rightarrow Ru(bpy)_3^{3+}$$

[2] $$ME - e^- \rightarrow ME^{\bullet +}$$

[3] $$ME^{\bullet +} \rightarrow ME^{\bullet} + H^+$$

[4] $$Ru(bpy)_3^{3+} + ME^{\bullet} \rightarrow Ru(bpy)_3^{2+*} + \text{product}$$

[5] $$Ru(bpy)_3^{2+*} \rightarrow Ru(bpy)_3^{2+} + h\nu$$

Effect of electrophoretic buffer type

In CE, electrophoretic buffer has great influence on separation and detection. Four kinds of buffer, Tris-HCl, $Na_2B_4O_7$, PBS, and phosphate containing borax with the same concentration ($Na_2B_4O_7$-PBS), were examined separately and the results were shown in Fig. 1. It can be seen from Fig. 1 that the use of $Na_2B_4O_7$-PBS buffer can obtain good resolution (Rs) and high sensitivity.

Orthogonal experimental design for the electrophoretic buffer

Traditionally, separation conditions are optimized by a univariate study. This method can achieve certain satisfying performance. However, the best combination of every experimental parameter cannot be obtained when the interaction between some factors occurs. Combination investigation of all possible factors needs a large number of experiments.[34] To reduce the experiment number and gain the desired experimental results, orthogonal experimental design (OAD) can very efficiently and quickly generate useful information on key variables by arranging different factors for effective optimization of experimental conditions. In this work, the three main factors for electrophoretic buffer are pH, concentration of electrophoretic buffer, and percentage of IL ($BMIMBF_4$). The preliminary experiments showed that the addition of $BMIMBF_4$ as an additive to the electrophoretic buffer could improve the separation and detection sensitivity of the three drugs. The improvement in resolution and sensitivity is attributed to the interaction with analytes or by changing the conductivity, viscosity, and ionic strength of the background electrolytes.[35] Each factor in this OAD was evaluated at three levels, including pH at 9.0, 9.5, or 10, buffer concentration at 15, 20, or 25 mmol/L, and $BMIMBF_4$ at 0%, 0.2%, or 0.4% (*v*/*v*). The OAD results for the separation of E, ME, PE and TPA used as internal standard substance (IS) are shown in Fig. 2. Figure 2*e* shows that the Rs of E, ME, and PE mixtures were markedly improved, and ECL intensities of

Fig. 1. Effect of electrophoretic buffer type on resolution and sensitivity. Peaks are denoterd by, 1: E, 2: ME, 3: PE. Labels are denoted by, a: Tris-HCl, b: $Na_2B_4O_7$, c: PBS; d: $Na_2B_4O_7$-PBS. Conditions: detection potential, 1.2 V; electrophoretic buffer, 20 mmol/L $Na_2B_4O_7$-PBS at pH 9.5; electrokinetic injection, 10 kV × 10 s; separation voltage, 10 kV; ECL detection solution, 5 mmol/L $Ru(bpy)_3^{2+}$ with 50 mmol/L PBS at pH 8.5.

Table 1. The performance characteristics of the proposed method.

Analytes	Liner range (μmol/L)	Calibration curves				
		Slope	Intercept	*r*	LOD (mol/L)	LOQ (mol/L) in urine
E	0.2–100	11 338	16 981	0.9992	4.0×10^{-8}	5.3×10^{-7}
ME	0.5–150	10 502	–3 326	0.9994	6.5×10^{-8}	9.1×10^{-7}
PE	0.2–100	10 266	12 185	0.9994	4.6×10^{-8}	6.9×10^{-7}

Table 2. Study of the precision of the proposed method.

Analytes	RSD% for migration time of intraday ($n = 5$)		RSD % for area of intraday ($n = 5$)		RSD % for migration time of interday ($n = 15$)		RSD % for area of interday ($n = 15$)	
	External standard	Internal standard	External standard	Internal standard	External standard	Internal standard	External standard	Internal standard
E	0.6	0.1	3.5	2.2	1.3	0.4	4.9	2.7
ME	0.5	0.2	3.0	2.5	1.4	0.8	4.5	3.9
PE	0.8	0.2	3.1	2.4	1.3	0.6	5.4	3.7

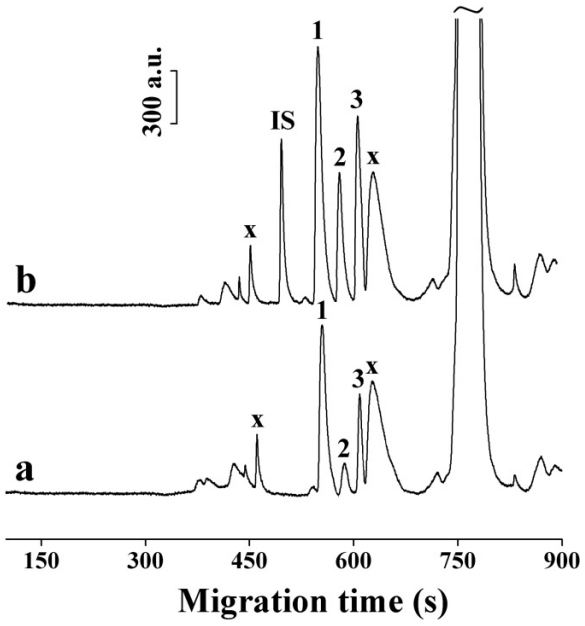
three ephedra alkaloids were also increased (~3-fold) when 0.4% $BMIMBF_4$ was used in 20 mmol/L $Na_2B_4O_7$-PBS at pH 9.5. Under the optimum conditions, complete baseline separation within 10 min at a separation voltage of 10 kV could be obtained.

Effect of detection potential

ECL intensity is dependent on the rate of the light-emitting chemical reaction, which is in turn dependent on the potential applied to the electrode. The effect of the working potential on ECL responses in a potential range from 1.05 to 1.30 V was tested. The results showed that the ECL intensity for E, ME, and PE increased and reached maximum values at 1.20 V, and then decreased with the increasing detection potential from 1.05 to 1.30 V. Therefore, the optimum detection potential should be fixed at 1.20 V.

Effect of buffer pH in detection cell

The pH of buffer in detection cell also has a significant effect on the ECL response. The buffer pH range from 7.6 to 9.1 was examined. The results showed that the ECL intensity of the three analytes increased with the pH from 7.6 to 8.5, and then decreased. Thus, pH 8.5 was selected.



Effect of separation voltage

A study of the influence of the separation voltage on ECL intensity and Rs was carried out using the range 8 to 13 kV. ECL intensity increased as the separation voltage increased to 10 kV, and then decreased. Rs1 (E and ME) and Rs2 (ME and PE) decreased with increased the separation voltage, and Rs2 < 1.5 when the separation voltage was higher than 10 kV. Therefore, 10 kV was chosen.

Performance characteristics of the method

Under the optimized conditions, E, ME, PE and TPA used as IS were well separated. The typical electropherogram is shown in Fig. 2*e*. To evaluate the linearity of the established method, calibration curves were made by plotting peak area values against the analyte concentrations. The results obtained are listed in Table 1. It can be seen that the regression coefficients of the calibration curves are greater than 0.9992.

Fig. 3. Electropherograms of (*a*) TCM and (*b*) TCM spiked with 4.0×10^{-5} mol/L of E, 6.0×10^{-5} mol/L of ME, 5.0×10^{-5} mol/L of PE. Peaks are denoted by, 1: E, 2: ME, 3: PE, X: unknown compounds. Other conditions are the same as in Fig. 2*e*.

The limits of detection (LOD) in standard solution and the limits of quantitation (LOQ) in real samples were considered the minimum analyte concentrations yielding an S/N ratio equal to 3 and S/N ratio equal to 10, respectively. To reduce the irreproducibility associated with a complex sample matrix, sample injection volume, temperature, the properties of buffer and other factors, TPA was used as IS in this work. The ratios of the analyte peak (or migration time) to IS peak (or migration time) were used in the analysis.

The precision of the proposed method was evaluated in terms of repeatability and intermediate precision for the internal standard method and external standard method. The results are listed in Table 2. The repeatability was assessed on the same day by using five repetitive injections of a mixture standard solution of 5.0×10^{-7} mol/L of TPA, 4.0×10^{-6}

80	78.3	97.9	2.5	0.4	4.3	1.5

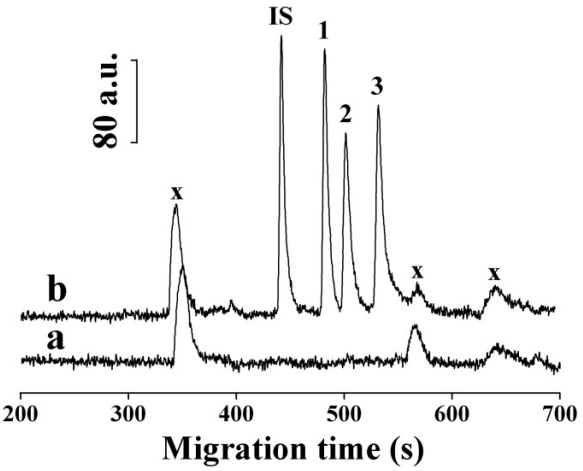
mol/L of E, 7.0×10^{-6} mol/L of ME, and 5.0×10^{-6} mol/L of PE. Intermediate precision was evaluated on three consecutive days with a similar procedure for repeatability evaluation. It can be seen in Table 2 that the precision of the internal standard method was better than that of external standard method.

Applications

The proposed CE-ECL method was applied to the determination of E, ME, and PE in a TCM, Xiao'er Qingre Zhike Koufuye. The preliminary experiments showed that satisfactory separation and detection can be achieved when samples were diluted 8-fold with pure water. The typical electropherograms of TCM, and TCM spiked with 1.0×10^{-5} mol/L of TPA, 4.0×10^{-5} mol/L of E, 6.0×10^{-5} mol/L of ME, and 5.0×10^{-5} mol/L of PE are illustrated in Figs. 3*a* and 3*b*, respectively. The content of the three ephedrines in TCM were determined to be 1.2×10^{-3} mol/L for E, 4.1×10^{-5} mol/L for ME, and 4.5×10^{-4} mol/L for PE. The recoveries of the three ephedrines in drugs were determined at three different spiked concentration levels, and the results are listed in Table 3. The RSDs for the measurement of peak areas were evaluated by the repeatability and intermediate precision for the internal standard method and the external standard method (also listed in Table 3).

The applicability was also examined by analyzing the three ephedrines in human urine. The urine was filtered through 0.22 μm cellulose acetate filters and then diluted 5-fold with pure water before CE-ECL analysis. The typical electropherograms of a blank urine sample from a healthy female person and also spiked with 2.0×10^{-6} mol/L of TPA, 1.0×10^{-5} mol/L of E, 1.2×10^{-5} mol/L of ME, and 1.0×10^{-5} mol/L of PE are illustrated in Figs. 4*a* and 4*b*, respectively. E, ME, PE, and TPA are not endogenous compounds, so they are not detected in the urine of healthy person and could be well separated and detected in spiked urine. Comparing with the published results in urine applications,[2,6] this CE-ECL method can realize good separation and sensitive detection for E, ME, and PE in human urine. The recoveries at three different spiked concentration levels (20, 200, and 400 μmol/L) were 101.5%–104.3% for E, 88.2%–101.3% for ME, and 97.6%–100.0% for PE, respectively. The RSDs of the peak area were less than 3.6%. The LOQs of E, ME, and PE in human

Fig. 4. Electropherograms of the (*a*) heathy human urine and (*b*) also spiked with 1.0×10^{-5} mol/L of E, 1.2×10^{-5} mol/L of ME, 1.0×10^{-5} mol/L of PE. Peaks are denoted by, 1: E, 2: ME, 3: PE, X: unknown compounds. Other conditions are the same as in Fig. 2*e*.



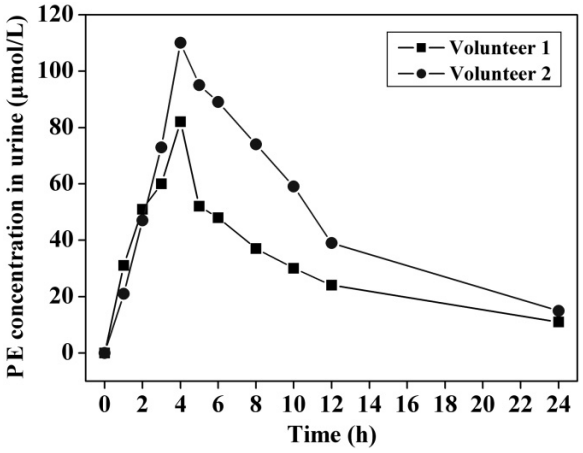


Fig. 5. PE concentration change in urine samples 0, 1, 2, 3, 4, 6, 8, 12, and 24 h after the ingestion of 90 mg of PE sustained release capsules to the volunteers. Other conditions are the same as in Fig. 2*e*.

urine were 5.3×10^{-7}, 9.1×10^{-7}, and 6.9×10^{-7} mol/L, respectively. These results indicated that the proposed method is accurate and reliable.

In the study of PE pharmacokinetics, two healthy female volunteers received an oral administration of 90 mg of PE sustained release capsules and were asked to drink sufficient and comparable amounts of water through the collection period. The urine samples were collected and analyzed immediately before the oral dose and again at 1, 2, 3, 4, 6, 8, 12 and 24 h after the oral dose. The results of the two volunteers are presented in the concentration time profile of Fig. 5. It can be seen that the maximal contents of PE in the urine samples from the two volunteers were achieved at about 4 h after receiving the oral dose and then subsequently decreased. The results also show that there is a difference in the content of PE in the urine of the two volunteers, which might be caused by metabolizability diversity between individuals.

Conclusions

This work proposes a simple, rapid, and sensitive method for the simultaneous determination of E, ME, and PE in TCM and human urine and the monitoring of pharmacokinetics for PE in the human body. Both separation efficiency and sensitivity can be improved by utilization of $BMIMBF_4$ as an additive in electrophoretic buffer. The use of TPA as IS improves the precision. The developed method has advantages of high separation efficiency, short analysis time, low sample consumption, simple operation, and high sensitivity. This method could be developed into a practical and valuable technique for the determination of ephedra alkaloids in clinical and biochemical analysis and pharmacokinetics study.

Abstract: The rate constant of the unimolecular decomposition reaction of the CF_3CCl_2O radical was calculated by using the method proposed by Yao and Lin (YL method). Two important channels of decomposition occurring via C–C and C–Cl bond scission were investigated. The results show that C–Cl bond scission is the dominant channel during the decomposition of the CF_3CCl_2O radical. Especially, the reasonable anharmonic effect on the decomposition reaction was investigated. The results show that the harmonic rate constants are higher than those of the anharmonic case in both microcanonical and canonical systems. The anharmonic effect is more evident with increasing energy.

Key words: anharmonic effect, unimolecular reaction, rate constant, YL method.

Résumé : Faisant appel à la méthode proposée par Yao et Lin (méthode YL), on a calculé la constante de vitesse de la réaction de décomposition unimoléculaire du radical CF_3CCl_2O. On a étudié deux voies importantes de décomposition se produisant par le biais de scissions des liaisons C–C et C–Cl. Les résultats montrent que la scission de la liaison C–Cl est la voie dominante durant la décomposition du radical CF_3CCl_2O. On a étudié particulièrement l'effet anharmonique raisonnable sur la réaction de décomposition. Les résultats montrent que les constantes de vitesse harmoniques sont plus élevées que celles du cas anharmonique tant dans le système microcanonique que dans le système canonique. L'effet anharmonique est plus évident avec une augmentation de l'énergie.

Mots-clés : effet anharmonique, réaction unimoléculaire, constante de réaction, méthode Yao et Lin (méthode YL).

Introduction

Many studies have indicated that the chemical and physical properties of chlorofluorocarbons (CFCs) along with their thermodynamic and transport properties made them suited for several industrial applications, but the stability of fully halogenated CFCs made them dangerous to the stratospheric ozone layer. As early as 1974, many scientists recognized that the release of CFCs into the stratosphere through a series of catalytic reactions leads to ozone-layer depletion, increasing global warming.[1–4] In 1987, with the threat of CFCs becoming more and more serious, the Montreal Protocol was developed to prohibit the production and use of CFCs. At the same time, there was an urgent need to develop acceptable substitutes that had similar properties to CFCs except for the environmental behaviors such as depletion of the ozone layer and global warming. After that, hydrofluorocarbons (HFCs) and hydrochlorofluorocarbons (HCFCs) were found to be substitutes for CFCs in refrigeration and air-conditioning systems.[5,6] Unlike CFCs, HFCs and HCFCs break down readily and react with the OH radical in the lower atmosphere, resulting in much shorter atmospheric lifetimes and a reduced potential to contribute to ozone depletion and to global warming in comparison with the CFCs.[7] One of the most widely used HCFCs is 2,2-dichloro-1,1,1-trifluoroethane (HCFC-123). It is not only used as a gaseous fire extinguisher but also as a metal and electronics cleaning agent. Although HCFC-123 contains chlorine, which is dangerous to the stratospheric ozone layer, its hydrogen-containing molecule decomposes primarily in the lower atmosphere before it can reach the ozone layer. Because the chlorine is dissipated at a lower altitude, HCFC-123 has relatively short atmospheric lifetimes and much lower ozone depletion potentials than CFCs. Thus, the haloalkoxy radicals formed by HCFC-123 in the atmosphere play an important role in the degradation mechanism of organic vapors in the troposphere.[8,9] Recently, considerable theoretical studies have been performed on similar haloalkoxy radicals.[10–14] Singh et al.[15] calculated the harmonic rate constant for C–C and C–Cl bond scission in CF_3CCl_2O decomposition for the canonical case at 298 K and 1 atm (1 atm = 101.325 kPa) pressure, obtaining the values $k_{C–C} = 6.7 \times 10^6$ s^{-1} and $k_{C–C} = 1.1 \times 10^8$ s^{-1}. The theoretical work suggested that C–Cl bond scission was favorable for the CF_3CCl_2O radical decomposition.[15] A literature survey indicated that there is no experimental data available on the CF_3CCl_2O radical.

On the other hand, many chemists had observed that the anharmonic effect played an important role in molecular systems, especially in those of molecules and clusters with highly flexible transition states.[16] In 1962, Schlag and Sandsmark[17]

discovered that anharmonicity corrections may be significant in practice. Then, Haarhoff[18] considered the anharmonic corrections about the density of vibrational energy levels for a system of simple Morse oscillators. At present, many chemists have also observed that anharmonic effects are quite significant in the dissociation of clusters and molecular systems.[19–23] It is well-known that the characteristic features of the anharmonic effect contain an increase in the bond length and in the distance of bond dissociation and a decrease in vibrational bond-stretching frequencies. Several authors laid stress on the requirement for the anharmonic correction to previous reaction rate theories.[24–26] For this reason, using experimental thermodynamic data, Troe[27] presented a simple empirical method for generating anharmonic vibrational densities of states. Recently, a new method (Yao and Lin, YL method) that could carry out the first principle calculations about the rate constants of molecular reactions within the framework of transition-state theory has been proposed.[28] With this method, the anharmonic effect that is on the dissociation of molecular reaction was examined. The results mentioned above suggested that the YL method was appropriate for calculating rate constants of the unimolecular reaction and for investigating the anharmonic effect of the rate constant.

The purpose of this paper is to calculate the harmonic rate constants for the unimolecular decomposition of the CF_3CCl_2O radical and to investigate the anharmonic effect on this reaction. Therefore, we applied the YL method to examine the anharmonic effect on the unimolecular decomposition of the CF_3CCl_2O radical. The computational methods are described in detail in the Computational methods section. The Results and discussion section provides numerical results and detailed discussions. Finally, concluding remarks and a summary of this work are presented in the Conclusions.

Computational methods

Ab initio calculations

The two unimolecular decomposition channels of the CF_3CCl_2O radical are investigated (C–C and C–Cl bond scission) as given as follows:

$$CF_3CCl_2O \rightarrow CF_3 + C(O)Cl_2 \qquad (C-C \text{ bond scission})$$

Table 2. Parameters used in the rate constant calculations obtained from B3LYP/6–311++G** calculations.

Parameter	CF_3CCl_2O	TS1	TS2
Zero-point energy (B3LYP) (Hartree)	0.02418	0.02275	0.02347
Imaginary frequency	—	328.6*i*	350.3*i*
Energy (B3LYP) (Hartree)	–1371.47009	–1371.46055	–1371.46749
Single-point energy (CCSD(T)) (Hartree)	–1369.40440	–1369.38739	–1369.39834
Barrier (kcal/mol)		10.67	3.83

Note: TS1 and TS2 are the transition states corresponding to channels 1 and 2, respectively. The barriers are calculated at the CCSD(T)/6–311++G** level. 1 cal = 4.184 J).

$$CF_3CCl_2O \rightarrow CF_3C(O)Cl + Cl \qquad (C-Cl \text{ bond scission})$$

In the two reactions, the geometries of the reactant and transition states have been optimized using the B3LYP method with the 6–311++G** basis set. The vibrational harmonic and anharmonic frequencies, which were calculated at the same level, are used for characterization of stationary points, zero-point-energy (ZPE) corrections, and for the calculations of reaction rate constants using transition-state and Rice–Ramsperger–Kassel–Marcus (RRKM) theory. To obtain more accurate and reliable data, the single-point energies were recalculated by employing the CCSD(T) method with the 6–311++G** basis set. To confirm that the transition state connected smoothly to the reactant and the products, the transition state was subjected to an intrinsic reaction coordinate (IRC) with the same level of theory at which the optimization and frequency calculations were performed. The frequencies, energies of reactant, and transition-state (TS) structures in this paper were all calculated at 298 K and 1 atm pressure (room temperature). The Gaussian 03 program[29] was applied for all ab initio calculations.

RRKM theory

According to the RRKM theory, for the microcanonical system, the rate constant $k(E)$ for the unimolecular reaction can be expressed as[30]

$$[1] \qquad k(E) = \frac{\sigma}{h}\frac{W^{\neq}(E-E^{\neq})}{\rho(E)}$$

where σ is the symmetry factor (here we set $\sigma = 1$), h is Planck's constant, $\rho(E)$ represents the density of the state of the reactant, $W^{\neq}(E)$ stands for the total number of states for the transition state, and E and $E^{\neq}$ are the total energy and the activation energy in the microcanonical case, respectively.

In general, the definition of $W(E)$ and $\rho(E)$ can be expressed as[31–33]

$$[2] \qquad W(E) = \sum_i H(E-E_i)$$

$$[3] \qquad \rho(E) = \frac{\mathrm{d}W(E)}{\mathrm{d}E}$$

where $H(E - E_i)$ denotes Heaviside function and E_i are energy levels. $W(E)$ can be obtained by direct counting of those states that are less than or equal to E. The CF_3CCl_2O radical has 18 vibrational modes ($3N - 6$, N is the number of atoms in the reaction) for the reactants and 17 vibrational modes for TSs. The imaginary frequencies are excluded. The anharmonic effect was added in all the vibrational modes in the anharmonic calculations. The Laplace transformation was utilized for $W(E)$ and $\rho(E)$:[31–33]

$$[4] \qquad \int_0^{\infty} \mathrm{d}E e^{-\beta E} W(E) = \frac{Q(\beta)}{\beta} = L[W(E)]$$

$$[5] \qquad \int_0^{\infty} \mathrm{d}E e^{-\beta E} \rho(E) = Q(\beta) = L[\rho(E)]$$

where $\beta = 1/kT$, k is Boltzmann's constant, T is the temperature of the system, and $Q(\beta)$ is the partition function of the system. That is, when $Q(\beta)$ is obtained, $W(E)$ and $\rho(E)$ can be determined by eqs. [4] and [5] by applying the inverse Laplace transformation. The details can be found in ref. 28.

For a canonical system, the rate constant $k(T)$ for a unimolecular reaction is given by[31,33–35]

$$[6] \qquad k(T) = \frac{kT}{h}\frac{Q^{\neq}(T)}{Q(T)}e^{-\frac{E^{\neq}}{kT}}$$

where $Q(T)$ and $Q^{\neq}(T)$ are the partition functions of the reactant and the activated complex, respectively. In this case, we obtain

$$[7] \qquad Q^{\neq}(T) = \prod_i^{N-1} q_i^{\neq}(T)$$

$$[8] \qquad Q(T) = \prod_i^{N} q_i(T)$$

where N is the number of vibrational modes of the reactant and $q_i^{\neq}(T)$ and $q_i(T)$ represent the vibrational partition functions of the activated complex and the reactant, respectively.

According to the above discussion, we ascertain that the partition function plays a very important role in calculating the total number of states, the density of states, and the rate constant. To calculate the partition function of both microcanonical and canonical cases and to investigate the anharmonic effect on an unimolecular reaction, the Morse oscillator (MO) is taken as a simple form. For the MO we have

$$[9] \qquad E_{n_i} = (n_i + 1/2)\hbar\omega_i - x_i(n_i + 1/2)\hbar\omega_i$$

where n_i is the vibrational quantum number of the vibrational mode and ω_i is the frequency of the ith vibrational mode. Actually, the Morse and harmonic models give similar results at low energy, just like the equilibrium position of the stretching

Fig. 2. The canonical rate constants for the C–C scission. The rate constant unit is s^{-1}.

bond. We can use the Morse model to simulate all the degrees of freedom, including nonstretching and stretching bonds of this reaction. x_i is the MO parameter, which is a measure of the deviation of the potential from the harmonic case. It is related to the dissociation energy and the energy of the fundamental transition. For $x_i = 0$, the anharmonic potential is reduced to the harmonic case. It can be expressed as $x_i = \hbar\omega_i/4D_{ie}$, where D_{ie} is the well depth of the MO, and the maximum of n_i is given by $n_i(m) = \frac{1}{2x_i} - \frac{1}{2}$. In this case, it is known that the anharmonic effect has two features: one is that the energy spacings are not equal and the other is that there is a maximum quantum number ($n_i(m)$) in the MO. In this paper, we shall discuss the anharmonic effect of the dissociation rate constant for the unimolecular decomposition reaction of the CF_3CCl_2O radical.

Results and discussion

For the unimolecular decomposition reaction of the CF_3CCl_2O radical, the optimized structure of the reactants, transition states, and products are illustrated in Fig. 1. Corresponding to Fig. 1, the geometric parameters are recorded in Table 1, from which it can be seen that the elongation of the C–C bond is found to be changed from 1.567 to 1.967 Å, together with a decrease in C–O bond distance from 1.309 to 1.210 Å. Similarly, the elongation of the C–Cl bond is found to be from 1.841 to 2.084 Å, together with a decrease in C–O bond distance from 1.309 to 1.247 Å. The information is obtained by way of employing the ab initio calculation of Gaussian 03 at the B3LYP/6–311++G** level. The energetic parameters of the reactant and the transition states calculated are shown in Table 2. From Table 2, the barrier height of the title reaction for channels 1 and 2 are 5.09 and 1.19 kcal/mol (1 cal = 4.184 J), respectively, with ZPE corrected. To obtain higher accuracy and reliability, we recomputed the single-point energies at the CCSD(T)/6–311++G** level, then got the values of the energy barriers as 10.67 and 3.83 kcal/mol. The results are different from the values given in ref. 15 because the optimized geometries of the reactants, transition states, and products used a different method and levels in ref. 15.

Fig. 3. The microcanonical rate constants for the C–C scission. The rate constant unit is s^{-1}.

C–C bond scission

For the canonical system, the harmonic and anharmonic rate constants calculated by the YL method are presented in Table 3, with temperatures ranging from 200 to 2000 K. Corresponding to Table 3, the rate constants are also plotted in Fig. 2. From Table 3, the calculated harmonic rate constant is 1.36×10^5 s^{-1} at the 298 K. The result is different from the value given in ref. 15 because of the energy barrier we obtained differed from that given in ref. 15 In our work, the reactants, TSs, and products of the title reaction were optimized using the B3LYP method with the 6–311++G** basis set, and the single-point energies were recalculated by employing the CCSD(T) method with the 6–311++G** basis set with ZPE (calculated at the B3LYP/6–311++G** level) corrected. In Singh et al.'s[15] theoretical work, the reactants, TSs, and products of the CF_3CCl_2O radical decomposition were optimized at the B3LYP/6–311G(d,p) level, and the energy barrier was calculated using the G2M(CC,MP2) method. Therefore, we obtained the energy barrier of 10.67kcal/mol, whereas the value given in ref. 15 was 8.6 kcal/mol. On the other hand, it is clear that both the harmonic and anharmonic rate constants increase with increasing temperature. With the temperature increasing from 200 to 2000 K, the harmonic rate constant increased from 12.87×10^{12} to 1.93×10^{12} s^{-1}, whereas the anharmonic rate constant was in the range of 12.41×10^{12} to 1.02×10^{12} s^{-1}. The harmonic rate constants are higher than the anharmonic ones at all temperatures. When the temperature is 298 K, the anharmonic rate constant (1.24×10^5 s^{-1}) is 8.8% lower than the harmonic rate constant (1.36×10^5 s^{-1}), whereas the anharmonic rate constant (1.02×10^{12} s^{-1}) is 47.2% lower than the harmonic rate constant (1.93×10^{12} s^{-1}) at 2000 K. We can draw the conclusion that with increasing temperature the difference between the two cases is significant. In other words, the anharmonic effect becomes more significant with increasing temperature in the canonical system. It is worth noting in Table 3 that the first four energies are all lower than the calculated activation energy of 10.67 kcal/mol in this work. Hence, we had to calculate the rate constant in the microcanonical system at higher energy.

Note: 1 cal = 4.184 J.

Fig. 4. The canonical rate constants for the C–Cl scission. The rate constant unit is s^{-1}.

To calculate the energy corresponding to the temperatures listed in Table 3, we employed the relation between the total energy of a microcanonical system and the temperature of a canonical system by

$$[10] \qquad E = -\left(\frac{\partial \ln Q}{\partial \beta}\right)$$

The energy in the microcanonical system can be obtained with eq. [10].

The total energies are 3 809, 4 862, 6 016, 7 075, 8 223, 9 384, 10 811, 11 748, 12 944, and 14 144 cm^{-1}, corresponding to the temperatures of 600, 700, 800, 900, 1000, 1100, 1200, 1300, 1400, and 1500 K. Table 4 shows the harmonic and anharmonic total number of states, density of states, and rate constants for channel 1. The rate constants with respect to the microcanonical total energies are also illustrated in Fig. 3.

From Table 4 and Fig. 3, we can see that for the microcanonical system the harmonic and anharmonic rate constants increase with increasing total energy. With the energy increasing from 3 809 to 14 144 cm^{-1}, the harmonic rate constant increases from 2.91×10^6 to 5.67×10^{11} s^{-1}, whereas the anharmonic rate constant is in the range of 1.12×10^6 to 2.09×10^{11} s^{-1}. The harmonic rate constants are higher than the anharmonic ones at all ranges of energy. When the total energy is 3809 cm^{-1}, the anharmonic rate constant (1.12×10^6 s^{-1}) is 61.5% lower than the harmonic rate constant (2.91×10^6 s^{-1}), whereas the anharmonic rate constant (2.09×10^{11} s^{-1}) is 65.0% lower than the harmonic rate constant (5.67×10^{11} s^{-1}) at a total energy of 14 144 cm^{-1}. It can be seen that, although the anharmonic effect is weak at low energy, it is obvious at higher energies. That is to say, with the increment of total energy, the anharmonic effect becomes more significant in the microcanonical system. Moreover, as seen from Tables 3 and 4, when the total energy is 14 144 cm^{-1}, the anharmonic rate constant (2.09×10^{11} s^{-1}) is 65.0% lower than the harmonic rate constant (5.67×10^{11} s^{-1}) for the microcanonical case, whereas the anharmonic rate constant (3.97×10^{11} s^{-1}) is 45.8% lower than the harmonic rate constant (7.33×10^{11} s^{-1}) for the canonical case. Thus,

Fig. 5. The microcanonical rate constants for the C–Cl scission. The rate constant unit is s^{-1}.

we can conclude that the rate constant is sensitive to the microcanonical system, but insensitive to the canonical system. That is, compared with the canonical case, the anharmonic effect in the microcanonical case is more obvious.

C–Cl bond scission

Similarly, for channel 2, the harmonic and anharmonic rate constants calculated for the canonical system using the YL method are all presented in Table 5, with the temperature ranging from 200 to 2000 K. Corresponding to Table 5, the rate constants are also plotted in Fig. 4. It is worth mentioning that from Table 5, when the temperature is lower than 298 K, the energies are all lower than the calculated activation energy of 3.83 kcal/mol. Hence, we have to calculate the rate constant in the microcanonical system at higher energy. Table 6 shows the the harmonic and anharmonic rate constants for the microcanonical case. Corresponding to Table 6, these data are illustrated in Fig. 5.

For the C–Cl bond scission reaction, from the results of Table 5 and at 298 K, the corresponding harmonic rate constant is 9.89×10^{9} s^{-1}. The result is different from the value given in ref. 15, the main reason being that the energy barrier we obtain differs from that given in ref. 15 In our work, the reactants, TSs, and products of the title reaction are optimized at the B3LYP/6–311++G** level, while in Singh et al.'s[15] theoretical work, the B3LYP method with the 6–311G(d,p) basis set was used. Therefore, we obtain an energy barrier of 3.83 kcal/mol, whereas the value given in ref. 15 is 6.5 kcal/mol. On the other hand, from Table 5 it is clear that the harmonic and anharmonic rate constants all increase with increasing temperature. With the temperature increasing from 200 to 2000 K, the harmonic rate constant is in the range of 2.99×10^{8} to 4.95×10^{12} s^{-1}, whereas the anharmonic rate constant increases from 2.50×10^{8} to 2.62×10^{12} s^{-1}. The anharmonic rate constants are lower than the harmonic ones at all ranges of temperature. When the temperature is 298 K, the anharmonic rate constant (7.29×10^{9} s^{-1}) is 26.3% lower than the harmonic rate constant (9.89×10^{9} s^{-1}), whereas the anharmonic rate constant (2.62×10^{12} s^{-1}) is 47.1% lower than the harmonic rate

Can. J. Chem. Downloaded from www.nrcresearchpress.com by Renmin University of China on 09/02/12
For personal use only.

constant (4.95×10^{12} s^{-1}) at 2000 K. Therefore, we can draw the conclusion that with increasing temperature the difference between the two cases becomes larger. That is to say, the anharmonic effect becomes more significant with increasing temperature in the canonical system. The results of Table 6 indicate that the rate constants basically increase with the increment of energy. With the energy increasing from 3 809 to 14 144 cm^{-1}, the harmonic rate constant increases from 3.13×10^{11} to 3.53×10^{12} s^{-1}, whereas the anharmonic rate constant is in the range of 1.64×10^{11} to 1.59×10^{12} s^{-1}. The harmonic rate constants are higher than the anharmonic ones at all ranges of temperature. When the total energy is 3809 cm^{-1}, the anharmonic rate constant (1.64×10^{11} s^{-1}) is 47.6% lower than the harmonic rate constant (3.13×10^{11} s^{-1}), whereas the anharmonic rate constant (1.59×10^{12} s^{-1}) is 55.0% lower than the harmonic rate constant (3.53×10^{12} s^{-1}) at a total energy of 14 144 cm^{-1}. Thus, we can see that, for microcanonical case, although the harmonic and anharmonic rate constants yield similar results at lower energy, the difference becomes increasingly obvious at higher energy. That is, with the increment of total energy the anharmonic effect becomes more and more obvious in the microcanonical system. Moreover, as can be seen from Tables 5 and 6, when the total energy is 14 144 cm^{-1}, the anharmonic rate constant (1.59×10^{12} s^{-1}) is 55.0% lower than the harmonic rate constant (3.53×10^{12} s^{-1}) for the microcanonical case, whereas the anharmonic rate constant (1.69×10^{12} s^{-1}) is 50.9% lower than the harmonic rate constant (3.44×10^{12} s^{-1}) for the canonical case. It can be seen that the rate constant is insensitive to the canonical case, but sensitive to the microcanonical case. In other words, compared with the canonical case, the anharmonic effect in the microcanonical system is more obvious.

From Figs. 2–5 and Tables 3–6, we can see that the rate constants for the C–Cl bond scission are all larger than those for the C–C bond scission. This means that the C–Cl bond scission is the predominant decomposition channel. The result is in reasonable agreement with that of Singh et al.'s[15] theoretical work. However, with increasing temperature and energy, the difference in the rate constants between the C–C and C–Cl bond scissions becomes smaller. In the canonical system, when the temperature is 2000 K, the differences in the harmonic and anharmonic rate constants between the C–C and C–Cl bond scissions decrease to 61.0% and 61.1%, respectively. In the microcanonical system, when the energy is 14 144 cm^{-1}, the difference in the harmonic and anharmonic rate constants between the C–C and C–Cl bond scissions decrease to 98.3% and 98.4%, respectively. Within both the C–C and C–Cl bond scissions, the difference between the harmonic and the anharmonic rate constants is rather small at lower energy and temperature, but it becomes large at a higher energy and temperature for both the canonical and microcanonical cases. For the C–C bond scission, the difference between the harmonic and the anharmonic rate constants for the canonical case increases from 3.6% to 47.2% and, for the microcanonical case, it increases from 61.5% to 65.0%. For the C–Cl bond scission, the difference between the harmonic and the anharmonic rate constants for the canonical case increases from 16.4% to 47.1% and from 47.6% to 55.0% for the microcanonical case. This indicates that the difference between the harmonic and the anharmonic rate constants increases with a total energy increase for either the C–C bond or C–Cl bond scission. Thus, we draw the conclusion that with an increment of temperature or total energy the anharmonic effect becomes more and more significant in both canonical and microcanonical systems. It is worth mentioning that the harmonic rate constants are all larger than the anharmonic ones for both the microcanonial and canonical systems.

Conclusions

In this paper, we calculated the harmonic and anharmonic rate constants of the unimolecular decomposition reaction of the CF_3CCl_2O radical using the YL method. We have only considered two unimolecular dissociation channels of the CF_3CCl_2O radical, i.e., C–C and the C–Cl bond scissions. Especially, we have investigated the anharmonic effect of the rate constant through comparing the anharmonic rate constants at different situations.

For the C–C bond scission, the calculated rate constant is 1.36×10^5 s^{-1} at 298 K for the harmonic case. Whereas for the C–Cl bond scission, the harmonic rate constants is 9.89×10^9 s^{-1} at 298 K. Our results differ from the values given in ref. 15 because of the values of the energy barriers for the two cases are different. There is no experimental data available in the literature for comparison. The rate constants of the C–Cl bond scission are all larger than those of the C–C bond scission. This indicates that the C–Cl bond scission is the dominating decomposition channel. The result is in reasonable agreement with that of Singh et al.'s[15] theoretical work.

Within both the C–C and C–Cl bond scissions, although the difference between the harmonic and the anharmonic rate constants is rather small at a lower energy and temperature, it becomes large at a higher energy and temperature for both the canonical case and microcanonical cases. This indicates that the difference between the harmonic and the anharmonic rate constants increases with increasing total energy. Thus, we can draw a conclusion that the anharmonic effect becomes more significant with increasing temperature or total energy for both the canonical and microcanonical cases.

In both canonical and microcanonical cases for two unimolecular decomposition channels, on one hand, the rate constants all basically increase with increasing total energy, but on the other hand, the harmonic and anharmonic rate constants give similar results when the temperature and energy are low. However, the difference between the two kinds of rate constants is quite large at a higher energy and temperature. Furthermore, the difference increases with increasing total energy. Therefore, we can conclude that the anharmonic effect becomes more significant with increasing total energy. Moreover, the results show that the difference between the harmonic rate constants and the anharmonic ones is rather small for the canonical case, whereas it is quite significant for the microcanonical case. That is to say, compared with the canonical case, the anharmonic effect in the microcanonical case is more obvious. The harmonic rate constants are all larger than the anharmonic ones in both canonical and microcanonical systems.

The present results indicate that within both microcanonical and canonical cases, the YL method works for investigating the rate constants of this type unimolecular decomposition.

Furthermore, the anharmonic effect of the title reaction, the unimolecular decomposition reaction of the CF_3CCl_2O radical, cannot be neglected.

Highly efficient one-pot synthesis of trisubstituted imidazoles under catalyst-free conditions

Najmadin Azizi, Nairreh Dado, and Alireza Khajeh Amiri

Abstract: Operationally simple, atom economical, and scalable synthesis of 2,4,5-trisubstituted imidazoles from benzil, aldehydes, and ammonium acetate is shown to proceed readily in methanol with high yield. The scope of the reaction is quite broad; a variety of aromatic and aliphatic activated and unactivated aldehydes have all been shown to be viable substrates for this reaction. Excellent yields and purity were obtained by washing the products with hot ethanol.

Key words: aldehyde, benzil, imidazole, atom economic, solvent effect, catalyst free.

Résumé : On a montré qu'un procédé simple, économique d'un point de vue atomique et d'échelle variable peut être appliqué à la synthèse, avec un rendement élevé, dans le méthanol, d'imidazoles 2,4,5-trisubstitués à partir du benzile, d'aldéhydes et d'acétate d'ammonium. Le domaine d'application de la réaction est étendu; on a en effet montré qu'une variété d'aldéhydes aromatiques et aliphatiques, activés et non activés, peuvent être utilisés comme substrats pour la réaction. On a obtenu rendements élevés et une pureté excellente en lavant les produits avec de l'éthanol bouillant.

Mots-clés : aldéhyde, benzile, imidazole, économique d'un point de vue atomique, effet de solvant, sans catalyseur.

Introduction

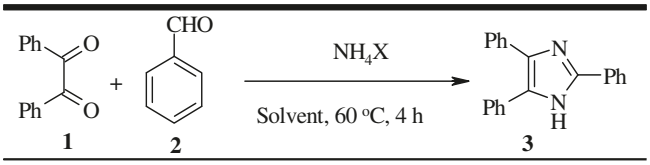
Imidazole derivatives play an important role in chemical and biological systems.[1] Many of the substituted imidazoles are known as inhibitors of fungicides and herbicides, plant growth regulators, and therapeutic agents.[2] Recent advances in green chemistry have extended the boundary of imidazoles as ionic liquids that can be used as electrolytes or green solvents because of their low vapor pressure and wide chemical stability.[3] Furthermore, imidazolylidene carbenes have been used in coordination chemistry, as ligands in transition-metal and metal-free catalysts for organic synthesis.[4,5]

Owing to the wide applicability of imidazoles, preparative methodologies for this class of compounds have been intensively developed in the literature.[6] Conventional methods for imidazole core synthesis usually involve the reaction of α-diketones and α-haloketones with formamide (Bredereck synthesis),[7] the base-promoted reaction of tosylmethyl isocyanides and aldimines or imidoyl chlorides,[8] and catalytic multicomponent coupling reactions in the presence of a Lewis acid[9] and an organocatalyst.[10]

However, the use of high temperatures, expensive instruments such as microwaves, and corrosive reagents limit these methods, and there are few reports on practical methods for preparing them, and no method is catalyst-free. Thus, highly efficient and flexible protocols for the synthesis of imidazoles are still in need as there is a scope for further improvement towards milder reaction conditions, development of simple workup, inexpensive reagents, convenient procedures, and higher product yields. In this article, a simple, rapid, and catalyst-free imidazole formation with excellent yield has been developed.

Results and discussion

Recently, we were interested in performing organic reactions in water, and we have shown that the aqueous medium can strongly favor the reactivity and selectivity, even when they are carried out under heterogeneous conditions.[11] Herein, we wish to report the simple synthesis of new imidazole derivatives with the reaction of 1,2-diketones and variety of aldehydes performed in methanol with excellent yields and without using any catalyst.



First, we embarked upon a series of experiments to establish the optimum conditions. The one-pot three-component reaction of benzaldehyde **2**, benzil **1**, and ammonium salts were studied (Table 1). First findings indicated that the presence of ammonium acetate in methanol was an excellent solvent without using any catalyst or promoter and 2,4,6-triphenyimidazole **3** crystals were obtained in 97% yield by reacting equimolar amounts of **1** and **2** at 60 °C for 4 h. Other ammonium salts such as fluoride, chloride, nitrate, and hydrogen sulfate and ammonia solution (32%) give low yields of desired products for these reaction conditions. We also investigated the effects of common organic solvents and the influence of different solvents on the rate and the course of these reactions. In dichloromethane, cyclohexane, and THF the reaction did not take place and the starting materials were recovered and low yield of the product was observed in acetonitrile, water, ethanol, and solvent-free conditions (Table 1).

Note: Reaction conditions: benzil (1 mmol), benzaldehyde (1 mmol), ammonium salts (3 mmol), and solvent (1 mL), 4 h.

With optimal conditions in hand, the reaction of benzil with different aldehydes was examined to explore the scope of the reaction. First, ammonium actate and benzil were used as model substrates (Table 2), and the results indicated that all commercially available aldehydes were good substrates for this system. Aromatic aldehydes bearing such functional groups as fluoro, chloro, bromo, methyl, or methoxy were able to effect the imidazole synthesis. We also observed that electronic effect on the aldehydes had little influence on the yield and the reaction conditions; that is, aryl aldehydes with electron-withdrawing groups reacted rapidly, whereas the substitution of electron-rich groups on the benzene ring did not decreased the reactivity. Moreover, a good yield for 3,5-dimethoxy benzaldehyde (Table 2, entry 24), the substrate with a strong electron-donating group, was observed. In addition, the 2-furaldehyde, (Table 2, entry 29), thiophenaldehyde (Table 2, entry 30), 2-naphthaldehyde (Table 2, entry 25), and 1-naphthaldehyde (Table 2, entry 26) also gave good yields of products. On the other hand, for the first time we have shown that fluorene-9-carbaldehyde (Table 2, entry 27), indole-3-carboxaldehyde (Table 2, entry 28), terephthaldehyde (Table 2, entry 31), isophthaldehyde (Table 2, entry 32), ferrocene carbaldehyde, (Table 2, entry 33), and aliphatic aldehydes still displayed high reactivity and clean reactions under these standard conditions.

It is noteworthy that the present method is very simple and that the process became even more attractive for large-scale applications when we found that it could be run at large scales without decreased yields and with the use of ethanol as the organic solvent in the workup without tedious column chromatography.

In summary, we have described a simple, highly efficient, and facile procedure for one-pot three-component synthesis of imidazole derivatives from readily available starting materials. To the best of our knowledge, this is the first report of the catalyst-free synthesis of imidazoles under very mild conditions. The procedure offers a simple experimental procedure and a short reaction time, is catalyst-free, is low cost, and provides efficient yields, which makes this method a useful and attractive strategy in view of economic and environmental advantages.

Experimental section

Instrumentation, analyses, and starting material

NMR spectra were recorded on a Bruker ACF 500 (^{1}H NMR at 500 MHz and ^{13}C NMR at 125 MHz) spectrometer in pure deuterated solvents with tetramethylsilane (Supplementary data). Melting points were determined in open capillary tubes in a Buchi-535 melting-point apparatus. All reagents, unless otherwise stated, were used as received from suppliers. Solvents were distilled before use.

General procedure for the synthesis of imidazole derivatives in methanol

To a well-stirred mixture of benzaldehyde (0.1 cm^3, 1 mmol) and benzil (0.21 g, 1 mmol) in methanol (1 cm^3) ammonium acetate was added (0.23 g, 3 mmol) and the reaction mixture was heated at 60 °C for 4–8 h. The reaction was allowed to cool and the resulting precipitates were recrystallized from ethanol to give pure imidazole derivatives.

Abstract: As part of our continuing effort to discover new potential anti-inflammatory agents, four new triterpenoids, chisopanins L-O (**1**–**4**), were isolated from the twigs of *Chisocheton paniculatus*. Their structures were established on the basis of detailed analysis of spectroscopic data, including IR, NMR (1D and 2D NMR), and HR-ESI-MS. Their inhibitory effects against nitric oxide (NO) production were evaluated in an in vitro model of lipopolysaccharide (LPS)-stimulated RAW264.7 macrophages. Compounds **1**, **3**, and **4** were found to exhibit moderate activity with IC_{50} values less than 10 μmol/L.

Key words: Chisocheton paniculatus, triterpenoids, anti-inflammatory activity.

Résumé : Dans le cadre de nos travaux effectués dans le but de découvrir de nouveaux agents potentiellement anti-inflammatoires, on a isolé quatre nouveaux triterpénoïdes, les chisopanines L-O (**1**–**4**) des brindilles de *Chisocheton paniculatus*. On a déterminé leurs structures en se basant sur une analyse détaillée de données spectroscopiques, dont l'infrarouge, la résonance magnétique nucléaire uni- (RMN 1D) et bi-dimensionnelle (RMN 2D) et la spectrométrie de masse avec ionisation par électronébulisation et à haute résolution (SM-IEN-HR). On a évalué leurs effets d'inhibition contre la production d'oxyde nitrique (NO) dans un modèle in vitro de macrophages RAW264,7 stimulés par un lipopolysaccharide (LPS). Les composés **1**, **3** et **4** présentent une activité modérée avec des valeurs de IC_{50} inférieures à 10 μmol/L.

Mots-clés : Chisocheton paniculatus, triterpénoïdes, activité anti-inflammatoire.

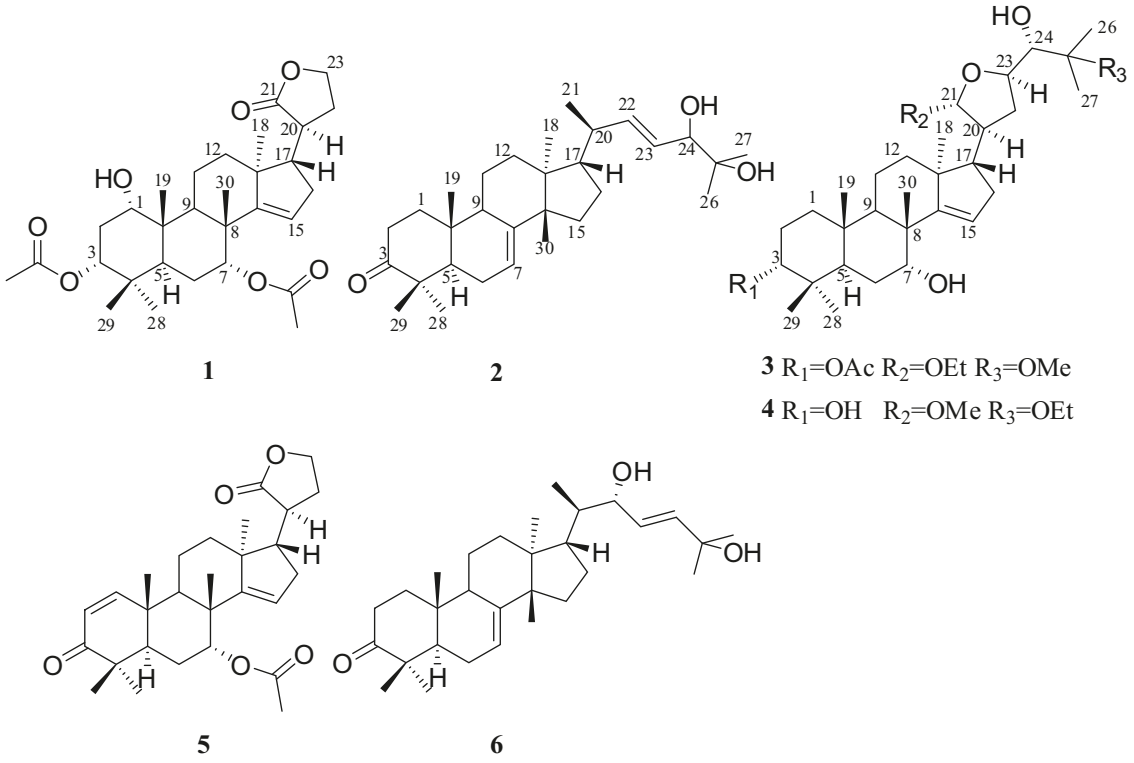
[Traduit par la Rédaction]

Introduction

Chisocheton paniculatus Hiern (Meliaceae) is a rich source of protolimonoids and simple limonoids.[1,2] Several new C-*seco*-type tetranortriterpenoids and protolimonoids were isolated from this plant, showing significant anti-inflammatory activity in our previous reports.[3,4] Further investigation on fractions that exhibited anti-inflammatory activity led to the isolation of four new triterpenoids, chisopanins L-O (**1**–**4**). In this study, we describe the isolation and structural elucidation of these new compounds as well as their inhibitory activities against lipopolysaccharide (LPS)-induced NO production in RAW264.7 macrophages.

Results and discussion

The $CHCl_3$ extract of twigs of *C. paniculatus* was subjected to a silica gel column to yield several fractions, which was separated by repeated chromatography over MCI gel and silica gel columns, and finally by preparative HPLC to afford chisopanins L-O (**1**–**4**) (Fig. 1). The structures of these isolates were elucidated by analysis of their spectroscopic data, including IR, NMR (1D and 2D NMR), and HR-ESI-MS.



Chisopanin L (**1**) was isolated as a white amorphous powder. The $[M+Na]^+$ peak at *m/z* 534.3411 (calcd. for $C_{30}H_{44}O_7Na$, 534.3425) in the HR-ESI-MS indicated the molecular formula of $C_{30}H_{44}O_7$. Bands at 3579, 1784, and 1722 cm^{-1} in the IR spectrum revealed the existence of hydroxyl and carbonyl groups, respectively. The ^1H NMR spectrum (Table 1) showed the presence of 5 tertiary methyl groups (δ_H 0.80, 0.91, 0.92, 1.12, and 1.07, each 3H, s), two acetoxyl groups (δ_H 1.98, 2.11, each 3H, s), 5 oxygenated protons (δ_H 3.49, 3.90, 4.46, 4.94, and 5.18), and one olefinic proton (δ_H 5.26, t, 3.5 Hz). Except for the two acetoxyl groups, its ^{13}C NMR spectrum (Table 2) exhibited 26 carbons, including 5 methyls, 7 methylenes, 8 methines, and 6 quaternary carbons, featuring a tetranortriterpenoid skeleton. Similar to the known compound **5** (Fig. 1), the resonance of carbonyl signal at δ_C 176.7 in the ^{13}C NMR spectrum, along with the methylene proton signals at δ_H 4.46 and 3.90 (t, 8.5 Hz) in the ^1H NMR spectrum, indicated a γ-lactone nature of ring E, rather than a furan ring.[5] The observed HMBC correlations (Fig. 2) from H-23 (δ_H 3.90 and 4.46) to C-21 (δ_C 176.7), C-22 (δ_C 33.9), and C-17 (δ_C 58.1), from H-22a (δ_H 2.50) to C-21 (δ_C 176.7), and C-23 (δ_C 72.6), and from H-22b (δ_H 2.05) to C-17 (δ_C 58.1), C-20 (δ_C 37.6), and C-21 (δ_C 176.7), unambiguously confirmed the existence of a γ-lactone ring E. Further comparison with **5** revealed the absence of the characteristic α,β-unsaturated carbonyl moiety [δ_H 7.12 (d, 10 Hz), and 5.84 (d, 10 Hz); δ_C 204.3, 157.8, and 125.5] in **1**,[5] and instead, the appearance of two oxygen-

ated protons at C-1 and C-3 (δ_H 3.49 and 4.94),[6] which was confirmed by the HMBC correlations from H-19 (δ_H 0.92) and H-3 (δ_H 4.94) to C-1 (δ_C 71.3), and from H-28 (δ_H 0.80) and H-29 (δ_H 0.91) to C-3 (δ_C 78.7). Furthermore, the HMBC spectrum located the two acetoxyl groups at C-3 and C-7 by the cross peaks between the acetoxyl carbonyl signals (δ_C 169.4 and 170.2), and H-3 (δ_H 4.94), and H-7 (δ_H 5.18), respectively. The relative configuration of compound **1** was assigned by ROESY experiment (Fig. 3). In particular, the ROESY cross-peaks of Me-19/H-1, Me-30/H-7, and Me-29/H-3, as well as the small coupling constants, indicated the β-orientation for H-1, H-3, and H-7. Strong ROESY cross-peak between H-20 and Me-18 also revealed the α-orientation for H-20. Complete assignments of the proton and carbon resonances in **1** were made by the combined application of 1D and 2D NMR techniques, including HSQC, HMBC, and ROESY. Thus, the structure of **1** was determined to be as shown in Fig. 1.

Chisopanin M (**2**), a white amorphous powder, gave a $[M+Na]^+$ peak at *m*/*z* 479.3492 (calcd. for $C_{30}H_{48}O_3Na$, 479.3496) in the HR-ESI-MS, corresponding to the molecular formula of $C_{30}H_{48}O_3$. IR peaks at 3453 and 1699 cm^{-1} revealed the presence of hydroxyl and carbonyl groups. Seven tertiary and one secondary methyl groups in the ^1H NMR spectrum, in addition to 30 exhibited carbons in ^{13}C NMR, revealed a tirucallane skeleton of **2**. Further analysis suggested that compound **2** was an analogue of a known tirucallane triterpene **6**.[7] Both of them had one keto group at C-3 and one alkenyl at C-7, but differed in the side chain. The HMBC cross-peaks (Fig. 2) from H-22 (δ_H 5.61) to C-20 (δ_C 40.3), C-21 (δ_C 20.1), C-23 (δ_C 126.1), and C-24 (δ_C 79.7), together with the large coupling constant of H-22 (J = 15.3 Hz), revealed the existence of a trans-double bond between C-22 and C-23. The HMBC correlations from H-24 (δ_H 3.84) to C-23 (δ_C 126.1), C-25 (δ_C 72.9), C-26 (δ_C 26.4), and C-27 (δ_C 23.8) placed a hydroxyl group at C-24. The relative configuration of the tetracyclic core in **2** was assigned by a ROESY experiment and was identical to that of **6**. Despite the possible rotation at C-20, the observed NOE correlations of Me-18/H-20 and H-12β/Me-21 could still be used to suggest a preferred H-20α (C-20*S*) configuration and thus to confirm the tirucallane triterpene nature of **2**.[8,9] Thus, the structure of **2** was determined to be as shown in Fig. 1.

Chisopanin N (**3**) revealed a $[M+Na]^+$ peak at *m*/*z* 613.4057 (calcd. for $C_{35}H_{58}O_7Na$, 613.4075) in the HR-ESI-MS, corresponding to a molecular formula of $C_{35}H_{58}O_7$. All NMR data (Tables 1 and 2) were generally close to those of *apo*-tirucallol protolimonoids with a tetrahydrofuran ring E and an acetal group at C-21.[3] The ^1H NMR spectrum of **1** showed the presence of seven tertiary methyl groups (δ_H 0.86, 0.90, 0.91, 1.06, 1.11, 1.14, and 1.24, each 3H, s), one ethoxyl [δ_H 1.22 (3H, t, 7.1 Hz), 3.74 and 3.44 (each 1H, m)], one acetoxyl (δ_H 2.07, 3H, s), one methoxyl (δ_H 3.23, 3H, s), and one olefinic proton (δ_H 5.45, t, 2.0 Hz). The ^{13}C NMR spectrum indicated the presence of 10 methyls, 8 methylenes, 10 methines, and 7 quaternary carbons. Analysis of the HMBC spectrum positioned the ethoxyl at C-21 and the methoxyl at C-25. The location of the acetoxyl group was shown to be at C-3 by the HMBC cross peak between H-3 (δ_H 4.65) and the acetyl carbonyl at δ_C 171.0. The stereochemistry of **3** was determined on the basis of ROESY experiments. The observed ROESY correlations of H-21/H-17, Me-18/H-20, Me-18/H-21, Me-18/OEt-21, H-20/OEt-21, and

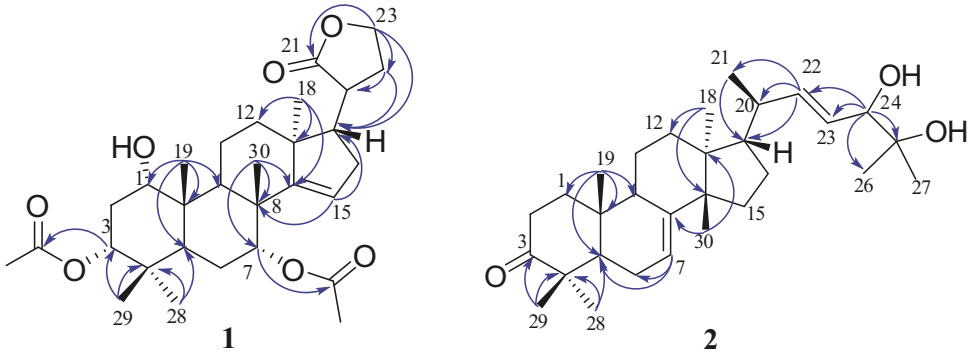
H-23/OEt-21 were only possible in case of 20*S*, 21*R*, and 23*R* configuration.[3,10,11] The ROESY cross peaks of H-24/H-22 and H-24/H-23 and the small coupling constant ($J_{23,24}$ = 2.6 Hz) revealed a 24*R* configuration. From these observations, the structure of **3** was established as shown in Fig. 1.

Chisopanin O (**4**) exhibited a $[M+Na]^+$ peak at *m*/*z* 571.3988 (calcd. for $C_{33}H_{56}O_6Na$, 571.3969) in the HR-ESI-MS, corresponding to the molecular formula of $C_{33}H_{56}O_6$. Its NMR spectra were closely related to those of **3**, except for the absence of an acetoxyl group at C-3 in **4**, in accordance with having 42 mass units less than **3** in MS. The ethoxyl and methoxyl in **3** were confirmed to swap their positions in **4** by the observed HMBC cross-peaks from the ethoxylic methylene protons to C-25, and from the methoxyl protons to C-21. The configuration of **4** was also determined by a ROESY experiment to be identical to that of **3**. Thus, the structure of **4** was established as shown in Fig. 1.

Nitric oxide (NO) plays an important role in regulation of inflammatory processes, and compounds that inhibited NO release are thought to be potential anti-inflammatory agents.[12,13] Considering the exhibited anti-inflammatory activity of *C. paniculatus*,[3] these four triterpenoids were evaluated in vitro for their abilities to inhibit the NO release in LPS-stimulated mouse macrophages RAW 264.7. As shown in Table 3, compounds **1**, **3**, and **4** showed better inhibitory effects with IC_{50} values less than 10 μmol/L, as compared with other reported natural products,[14–16] most of which had effects that were several-fold higher. The NO release inhibitory effects of compounds **3** and **4**, together with previously reported other protolimonoids that excelled in this regards,[3] favored the investigation of this title plant for the discovery of lead compounds for new anti-inflammatory agent development.

Experimental

General



Optical rotations were carried out on a JASCO P-1020 polarimeter. IR (KBr disks) spectra were measured using a Bruker Tensor-27 spectrophotometer. NMR spectra were recorded on Bruker ACF-500 instrument (^{1}H: 500 MHz, ^{13}C: 125 MHz) using standard Bruker pulse programs. Chemical

Extraction and isolation

The air-dried twigs of *C. paniculatus* (30 kg) were crushed into pieces (2 mm thick, QYD100II slicer, Shanghai TCM Machine) and extracted with 95% EtOH under reflux for 3 × 3 h. After concentration of the solution, the crude extract (1.5 kg) was suspended in water and then partitioned with $CHCl_3$ (6 × 2 L) and EtOAc (6 × 2 L) to afford a $CHCl_3$ layer (300 g) and an EtOAc layer (205 g). The $CHCl_3$ extract was chromatographed on a silica gel column eluted with gradient PE/EtOAc (100:0 to 1:1) to yield 10 fractions (CS1–CS10). Fraction CS2 (11 g) was chromatographed on a silica gel column eluted with PE/EtOAc (100:1 to 2:1) to mainly give three fractions, 2A–2C. Further purification of the fraction 2C by repeated preparative HPLC (MeCN/H_2O, 80:20) led to the isolation of **3** (3 mg). Fraction CS3 (9 g) was separated on a silica gel column with PE/EtOAc (50:1 to 2:1) to afford four fractions (3A–3D). Purification of the fraction 3B by MCI gel with MeOH/H_2O (70:30 to 100:0) and further preparation by HPLC (MeCN/H_2O, 85:15) afforded **2** (3 mg) and **4** (4 mg). Fraction CS8 (26 g) was subjected to chromatography over MCI gel (MeOH /H_2O, 30:70 to 100:0) and silica gel column ($CHCl_3$/MeOH, 100:0 to 50:1) to afford fractions 8A–8D. By repeated preparative HPLC (MeCN/H_2O, 45:55 and (or) MeOH/H_2O, 50:50), **1** (6 mg) were obtained from fraction 8A.

Measurement of NO production

This assay was performed as previously described.[3] Briefly, RAW 264.7 macrophages were cultured at 37 °C in 5% CO_2 in an RPMI 1640 medium, supplemented with 10% heated-deactivated fetal bovine serum (FBS), penicillin (100 U/mL), and streptomycin (15 μmol/L). The cells were incubated in 24-well cell culture plates at an initial density of 1×10^5 with 500 μL culture medium for 24 h and then pretreated with different compounds and lipopolysaccharide (LPS) (2 μg/mL) for 18 h. The amount of NO was assessed by determining the nitrite concentration in the cultured RAW 264.7 macrophage supernatants with Griess reagent (1% sulfanilamide and 0.1% naphthyl ethylene diamine dihydrochloride in 5% H_3PO_4). The absorbance at 540 nm was measured using a microplate reader.

Abstract: Polymer electrolyte membranes made of sulfonated poly(ether ether)ketone (SPEEK) and polysulfone (PSf) (2–10 wt %) were prepared by a solution casting method. The characteristic properties of the SPEEK/PSf polymer blend membranes were investigated using thermogravimetric analysis (TGA), scanning electron microscopy (SEM), and the AC impedance method. The SPEEK/PSf blend membranes showed good thermal and mechanical properties and appreciable ionic conductivity. It was revealed that the addition of PSf into the SPEEK matrix could markedly improve the electrochemical properties of the resulting membranes, which can be accomplished by a simple blend method. As a result, the SPEEK/PSf blends appear to be good candidates for the proton exchange membrane fuel cell (PEMFC) and direct methanol fuel cell (DMFC) applications. These blend membranes, having various amounts of PSf (2–10 wt %), were investigated in PEMFC and DMFC. The power densities were about 400 and 50 mW/cm^2 for PEMFC and DMFC, respectively. This makes PSf-based DMFC and PEMFC suitable for application in portable devices and transportation, respectively.

Key words: SPEEK, polysulfone, blend membranes, proton conductivity, polymer electrolyte.

Résumé : On a préparé des membranes de polymère électrolyte de poly(éther éther)cétone sulfonée (PEECS) et de polysulfone (PSf) (2 à 10 wt %) en procédant par la méthode de coulée à partir d'une solution. On a étudié les propriétés caractéristiques des membranes de polymères mixtes PEECS/PSf en faisant appel à l'analyse thermogravimétrique (ATG), la microscopie électronique à balayage (MEB) et la méthode d'impédance à courant alternatif. Les membranes de polymères mixtes PEECS/PSf présentent de bonnes propriétés thermiques et mécaniques ainsi qu'une conductivité appréciable. Leurs propriétés ont permis de montrer que l'addition de PSf dans la matrice de PEECS permet d'améliorer d'une façon marquée les propriétés électrochimiques des membranes qui en résultent et ceci peut être réalisé par une simple opération de mélange. On peut donc en conclure que les mélanges de PEECS de PSf pourraient être de bons candidats pour des applications dans une pile à combustible à membrane échangeuse de protons (PCAEP) et une pile à combustible à méthanol direct (PCMD). On a examiné les propriétés des membranes mixtes comportant diverses quantités de PSf (2 à 10 wt %) dans des systèmes de PCAEP et de PCMD. Les densités de puissance sont respectivement de 400 et de 50 mW/cm^2 pour la PCAEP et la PCMD. Ces caractéristiques suggèrent que les puissances des polymères mixtes, à base de PSf, dans des systèmes de PCAEP et de PCMD, pourraient respectivement être utilisables dans des dispositifs portables et pour le transport.

Mots-clés : polymère électrolyte de poly(éther éther)cétone sulfonée (PEECS), polysulfone, membranes mixtes, conductivité du proton, polymère électrolyte.

Introduction

In the past two decades, fuel cells have emerged as a feasible alternative to conventional hydrocarbon-based power sources because of their high power density and overall low emission levels.[1] The direct methanol fuel cell (DMFC) has been under development for applications over a broad range of power outputs in different operating environments. One of the key components that determines the efficiency of the fuel cell is the proton exchange membrane (PEM), which not only acts as a medium for the transportation of protons but also as a barrier that prevents mixing of the fuel gases (hydrogen and oxygen). The current fuel cell technology is based on perfluorosulfonic acid membranes as electrolytes such as Nafion,[2–4] which exhibits many attractive properties like excellent proton conductivity and high thermal and mechanical stabilities.

Among the diverse fuel cells, the proton exchange membrane fuel cells (PEMFCs) offer the advantages of high power density, low operating temperatures (60–100 °C) with consequent rapid start up, and dynamic response. However, the major barriers of PEM fuel cells using hydrogen as a fuel includes production, distribution, storage, humidification, etc. Also, the very low flash point of hydrogen (–423 F; 1 degree Fahrenheit = 5/9 K) causes increasing concerns about

For personal use only.

the safety issues of hydrogen. All these limitations enabled researchers to think of other fuels that can be easily oxidized. Direct oxidation fuel cells using liquid methanol as a fuel has already attracted intensive research.[5–8]

The commercialization of the Nafion membrane was severely affected because of drawbacks such as (*i*) high cost; (*ii*) non eco-friendly nature; (*iii*) high crossover of methanol, especially in the case of the DMFC; (*iv*) dependence on relative humidity in maintaining proton conductivity; and (*v*) loss of proton conductivity at elevated temperatures, etc. To overcome these shortcomings associated with the Nafion and other similar perfluorinated membranes, several hydrocarbon-based aromatic polymers were considered for the synthesis of PEM. It includes sulfonated poly(ether ether)ketone (SPEEK),[9–11] sulfonated polyphenylene oxide (SPPO),[12,13] and sulfonated polybenzimidazole.[14–16] In all of these cases, the ionic conductivity at higher temperatures (>100 °C) must be improved, which implies that better water retention at higher temperatures is an absolute requirement. In this context, to enhance the water-retention property of the polymer electrolyte membranes and also to improve the stability of such membranes, various inorganic fillers such as silica, titania, zeolites, and montmorillonite (MMT) have been added into the polymer systems.[17–24] Among the various aromatic hydrocarbon-based polymers, SPEEK has been demonstrated to exhibit a stable performance that is comparable to Nafion in a fuel cell at 50 °C for more than 4300 h. To enhance the proton conductivity of SPEEK, the incorporation of several inorganic heteropolyacids was considered.[25–27]

In our current investigation, we tried to evaluate the performance of SPEEK membranes incorporated with various amounts of polysulfone (PSf). The ion-exchange capacity (IEC) was found to be appreciable. However, there is a decrease in the IEC values when the content of PSf was increased from 2% to 10%. Durability studies were performed and the membranes were stable for more than 6 h. All blend membranes were stable up to 200 °C for successful application as PEM in the PEMFC and the DMFC. The mechanical properties were found tincrease with increasing PSf content. The proton conductivity was found to be in the range of 10^{-3} S/cm, which is appreciable for the PEMFC and the DMFC.

Experimental

Materials and chemicals

PEEK was procured from Victrex, UK, and was dried overnight at 100 °C before use. PSf was kindly supplied by Sigma-Aldrich, USA. Sulfuric acid, *N*-methyl pyrollidone (NMP), and methanol were obtained from SRL Chemicals, India. Pt and Pt/Ru catalysts were procured from Arora Matthey, India.

Sulfonation of PEEK

The process of sulfonation is considered to be the most important stage during the synthesis of the polymer electrolyte. It not only provides the exchangeable protons to make the polymer capable of exchanging ions, especially protons, but also increases the hydrophilicity of the polymer electrolyte. An increase in the hydrophilic character is highly appreciable as it increases the water uptake capacity that in turn increases the proton conduction, the most characteristic property for the polymer electrolyte to be used in fuel cells.

The quantity of sulfuric acid for the desirable degree of sulfonation (40%) was calculated by carrying out the sulfonation reaction of PEEK with different amounts of sulfuric acid. The optimum amount was found to be 20 mL for 1 g of PEEK. In a typical process, ~10 g of dry PEEK was taken in a three-necked round-bottomed flask and 200 mL of sulfuric acid was added and the contents of the flask were vigorously stirred at room temperature. After the desired time, the contents of the flask were poured onto a large excess of crushed ice. The innumerable number of fibres that were formed was recovered by filtration. It was then washed several times with deionised water until the pH of the wash water fell between 6.5 and 7.0. It was then dried in an oven at 90 °C for 10 h. The resulting product was the sulfonated form of SPEEK.

Preparation of the blend membrane

To prepare the blend membranes, desired amounts of SPEEK and PSf were dissolved separately in NMP. After complete dissolution, the PSf solution was added slowly to the SPEEK solution. It was then kept under stirring for 6 h and degassed by ultrasonication. The solution was poured onto a clean Petri dish. The solution was kept in a hot air oven at 90 °C for 12 h. The blend membrane was obtained in the form of a clear, pale brown, transparent membrane. It was peeled off from the Petri dish and was stored for further investigation. The variations in the composition of the different blends are given in Table 1.

Characterization

The IEC indicates the number of mequiv of ions in 1 g of the dry polymer. It was determined by the titration method. The membrane in its acid form was weighed and then soaked in an aqueous solution containing a large excess of KCl to extract all the protons from the membrane. The electrolyte solution was then neutralized using a very dilute Na_2CO_3 solution of known concentration (0.01 N). The equivalent weight (EW) values were calculated from the dry weight of the membrane divided by the volume and the normality of the Na_2CO_3 solution. The IEC values were expressed as the number of milliequivalents of sulfonic groups per gram of dry polymer.

The amount of solvent intake by the membranes was studied. The dried membranes were weighed and soaked in water and methanol separately and allowed to get equilibrated at room temperature for 24 h, above which the weight was constant. The swollen membranes were then quickly weighed after blotting the surface water and the values noted. The swelling degree was determined using the formula

$$\mathrm{SW} = \frac{M_{\mathrm{wet}} - M_{\mathrm{dry}}}{M_{\mathrm{dry}}} 100$$

where M_{wet} = weight of the wet membrane and M_{dry} = weight of the dry membrane.

The measurements of proton conductivity (σ, S/cm) of the membranes were carried out using an Autolab potentiostat galvanostat impedance analyser. Membranes with the required dimensions were cut and pretreated with 0.01 N sulphuric

acid and kept in water for 100% hydration. Then they were placed between two silver electrodes with an area of 1.33 cm^2 with a uniform pressure applied to hold the system. The cell set-up was Ag/SPEEK + PSf/Ag. The resistance offered by the membrane was calculated and then converted to conductivity values using the formula

$$\sigma = L/(RA)$$

where R is the resistance offered by the membrane in Ω, L is the thickness of the membrane in cm, and A is the area of the membrane in cm^2.

The methanol permeability is a serious factor that reduces the efficiency of the fuel cell particularly in the case of DMFCs. The permeation not only allows the methanol fuel to the cathodic compartment, but also the mixing of the fuel with the incoming gas at the cathode. This drastically reduces the performance of the fuel cell. The methanol permeabilities of the blend membranes were analyzed using a diaphragm diffusion cell, consisting of two glass bottles that can be interconnected with a capacity of 50 cm^3. The membrane can be clamped between the two compartments. Initially, 25 mL of deionised water was taken in compartment A and 25 mL of 20% *v*/*v* methanol in water was taken in compartment B. As a result of the concentration difference between the two compartments, methanol flux arose across the membrane. The increase in the methanol concentration with respect to time in compartment A was followed using a PAL II digital refractometer.

NMR spectra were obtained with Bruker NMR spectrometer using deuterated dimethylsulfoxide as the solvent. The presence of the sulfonic acid group was confirmed from the NMR spectra.

The surface morphology of the blend membranes was investigated using a scanning electron microscope (SEM, JEOL 6360). A piece of membrane was vacuum sputtered with a thin layer of gold prior to SEM examination. The nature of the pores and the level of dispersion of PSf were examined.

For checking the durability of the blend membranes, the following procedure was adopted. Initially, a 4 ppm ferrous ammonium sulfate in 3% H_2O_2 solution was freshly prepared and the temperature of the solution was maintained at 80 °C. A 0.5 cm^2 membrane was cut and soaked in the solution. The time required for the physical disintegration of the blend membrane was carefully noted down and reported. The reaction was expected to occur by a free radical mechanism and the probable mechanism is shown in Scheme 1.

Thermogravimetric analysis (TGA) is mainly carried out to determine the thermal stability of the blend membranes. The change in weight of the membrane with an increase in temperature at a heating rate of 20 °C/min in a temperature range between 30 and 800 °C was followed using a SDT Q600 US analyser.

The mechanical properties were obtained from a Hounsfield universal testing machine. The sample size used was 5 mm × 50 mm as reported by Jung et al.[28] The cross-head speed was set at a constant speed of 10 mm/min. For each testing reported, at least three measurements were taken and the average value was reported.

The IR spectra (450–4000 cm^{-1}) for the dried membranes were recorded with a PerkinElmer FTIR spectrometer at 25 ± 2 °C. The samples were dried at 100 °C for 1 h before recording the spectrum.

X-ray diffraction (XRD) measurements were performed using an X'Pert Pro diffractometer. The dried samples were mounted on an aluminium sample holder. The scanning angle ranged from 1° to 80° with a scanning rate of 2°/min. All the spectra were taken at ambient temperature (25 ± 2 °C).

Membrane electrode assembly preparation

Membrane electrode assembly (MEA) was obtained by sandwiching the SPEEK/PSf blend membrane between the anode and cathode. For the PEMFC, the electrocatalyst used was 20 wt % Pt on Vulcan XC-72 for both the anode (loading 0.25 mg/cm^2) and cathode (loading 0.5 mg/cm^2) sides. For the DMFC, the electrocatalysts used were 40 wt % Pt:Ru (2:1) on Vulcan XC-72 and 20 wt % Pt on Vulcan XC-72 in the anode (loading 2.5 mg/cm^2) and in the cathode (loading 0.5 mg/cm^2), respectively. The catalyst layer was obtained by mixing the catalyst, isopropyl alcohol (IPA), deionised water, and Nafion solution as the binder and was coated on the carbon cloth. The electrode dimensions were 5 cm × 5 cm (total area, 25 cm^2). The MEA was fabricated uniaxially by hot pressing the anode and cathode onto the membrane at 95 °C and 150 kg/cm^2 for 3 min.

Single cell test

Performance of the fabricated membranes was measured via the PEMFC and DMFC test stations. A single cell with a 25 cm^2 active area was used in both the PEMFC and DMFC experiments. The external load was applied by means of an electronic load that was manually controlled. The fabricated MEA was placed in the test cell and the bolts were tightened with an equal torque on each bolt. In the PEMFC, the H_2 and O_2 flow rates were maintained at 40 mL/min in the anode and cathode, respectively, whereas ifor the DMFC, 2 mol/L methanol with a flow rate of 20 mL/min was fed into the anode side and O_2 with a flow rate of 40 mL/min was fed into the cathode side.

Results and discussion

The IEC values of the various blend membranes are given in Table 2. Although the IEC values were found to be decreasing with the content of PSf, all the membranes exhibit an IEC value better than Nafion 117, which was reported to

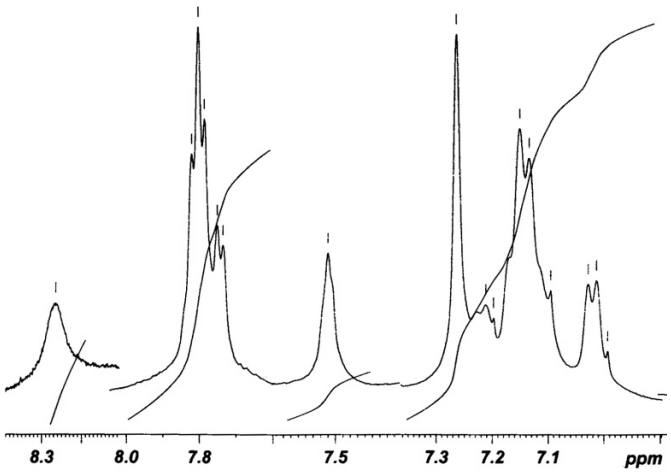
be 0.91 mequiv/g.[29] Actually, the protons that are available in the sulfonic acid groupings of SPEEK were responsible for the exchange of ions. When the concentration of PSf is increased, the concentration of SPEEK decreases and, in other words, the effective concentrations of the sulfonic acid groupings decrease. This obviously accounts for the decreasing trend in IEC values.



The water/alcohol absorption results are given in Table 2. The water uptake of Nafion 117 was reported to be 28.51%[30] and, in the case of the blend membranes, the water absorption was found to be decreasing with increasing content of PSf. The methanol absorption was also found to follow a similar trend like water absorption. This may be due to the reduction in the number of hydrophilic sulfonic acid groupings as the content of PSf is increased. The decreased methanol absorption content revealed that the blend membranes could be uitable candidates for use in DMFCs, when methanol is used as the fuel.

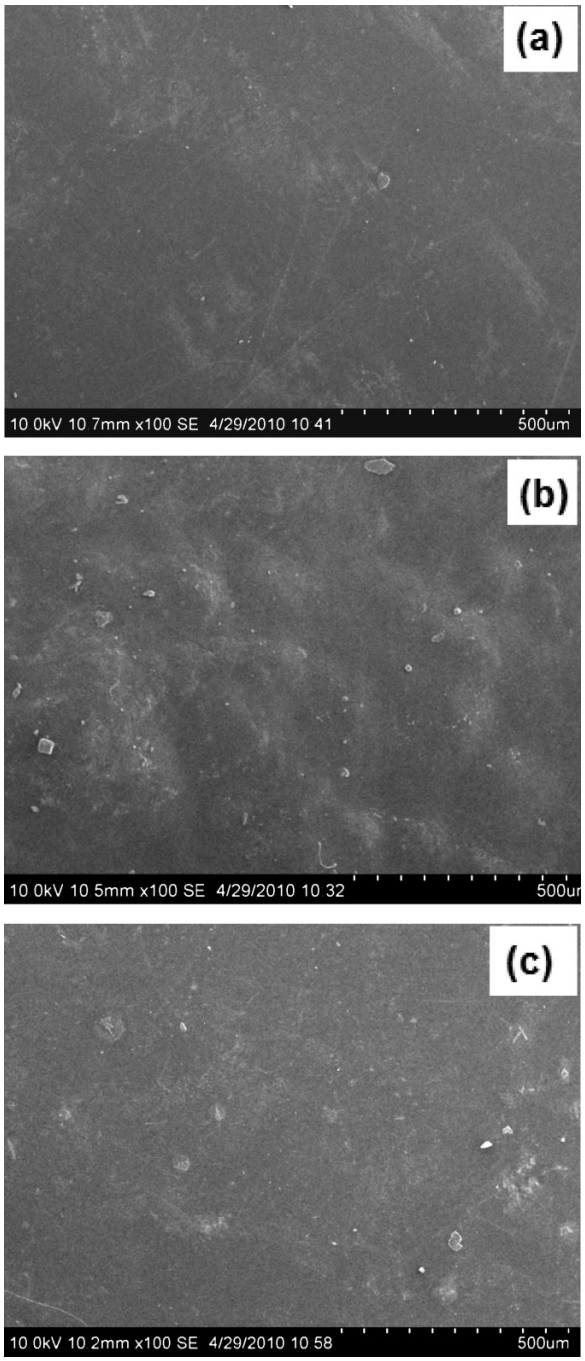
The results of the proton conductivity are given in Table 2. The proton conductivity of Nafion 117 was reported to be 2.95×10^{-2} S/cm. The proton conductivity of SPEEK tends to decrease with the addition of PSf. Water uptake plays an essential role in ionomer membrane properties. A possible reason that could be attributed to the reduction in the proton conductivity is that, as the content of PSf is increased in the blend, the effective concentration of SPEEK and hence the SO_3H groupings decreases. The protons of the sulfonic acid groupings are mainly responsible for the proton conductivity.

Methanol permeability plays a vital role in DMFCs. With an increase in the PSf loading, the methanol permeability decreases and the results are shown in Table 3. This may be due to the hydrophobic nature of PSf that prevents methanol from transferring through the membrane. The decrease in the methanol permeability makes these electrolyte blend membranes possible low cost alternatives to Nafion 117 for applications in DMFCs.

The ^{1}H NMR spectra of the SPEEK sample is shown in Fig. 1 and the numbering of various protons is shown in Scheme 2. In the spectra, the $H_{C'}$ of the unsubstituted hydroquinone ring of the PEEK repeat unit appears as a characteristic singlet at 7.26.[31] The presence of a sulfonic acid group causes a new peak at 7.51 that can be assigned to H_E and two doublets at 7.20 and 7.14 that may be assigned to the H_C and H_B protons in the sulfonated hydroquinone ring, respectively.

Fig. 1. ^{1}H NMR spectra of sulfonated poly(ether ether)ketone (SPEEK).

The SEM images of SPEEK and two representative blend membranes are given in Fig. 2. The SEM image looks dense, clear, and homogenous indicating a very good compatibility between the constituent polymers. Even at higher magnifications, the blend membranes showed no fissures, which may be due to the high boiling solvent used for the casting purpose. The evaporation of NMP solvent (boiling point 203 °C) was performed at 90 °C, indicating a very slow process of evaporation. On the other hand, if the evaporation was done at a faster rate or if a low boiling solvent was used, fissures could be observed.[32] The blend membranes appear to be pore-free even at higher magnification.



In the durability study, the time taken for the physical disintegration of the various blends was studied and the results are shown in Table 4. It is evident from the table that there is a gradual increase in the withstanding ability of the blends with increasing PSf content. An increase in the durability of the blend membranes indicates that the individual constituent polymeric materials in the blends are compatible with each other.

The TGA spectra of the blend membranes are given in Fig. 3. A three-stage degradation was observed. The initial loss up to 175 °C may be attributed to the loss of physically and chemically bound water along with a trace amount of residual solvent. The weight loss that occurs between 200 and

375 °C may be due to the loss of sulfonic acid groupings. The third weight loss from 450 to 600 °C may be correlated to the main chain degradation.

The tensile strength and percentage elongation at the breaks of the various blend membranes are given in Table 4. There is an increase in the tensile strength with an increase in the content of PSf. One possible reason for this kind of behaviour in the mechanical properties may be due to the very good compatibility among the constituents, thus making the membrane stiffer. As a result, an increase in the tensile property was observed.

Table 4. Durability and mechanical properties.

Membrane code (SPX)	Durability (h)	Tensile strength (MPa)	Percentage elongation (%)

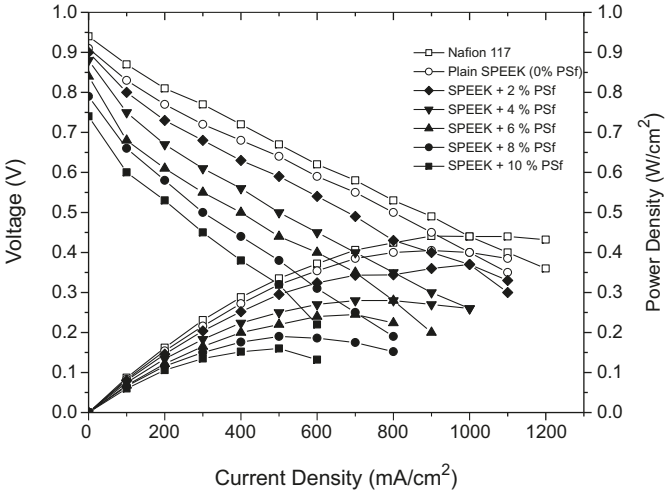

Fig. 5. X-ray diffraction (XRD) spectra of sulfonated poly(ether ether)ketone (SPEEK) with (*a*) 2% polysulfone (PSf), (*b*) 4% PSf, (*c*) 6% PSf, (*d*) 8% PSf, and (*e*) 10% PSf.

1640 cm^{-1}. Generally, this vibration occurs close to 1750 cm^{-1}, but because of the conjugation with the adjacent aromatic ring and phenolic oxygen, it is shifted to a very low value. The asymmetric O=S=O stretch of the sulfonic acid occurs close to 1260 cm^{-1}. There is a band at 1025 cm^{-1} that is due to the symmetric O=S=O stretch.

The XRD spectra of the blends are given in Fig. 5. In the case of the blend with 2% PSf, a broad envelope is observed between $2\theta = 10°–30°$. When the concentration of PSf was increased in the blend, the crystalline peak became broader and slowly disappeared when the concentration of PSf was elevated to 10%. Overall, the amorphous nature is enhanced with an increasing concentration of PSf, which could result in better mechanical properties, especially the tensile strength.

Fig. 6. Polarization curves of sulfonated poly(ether ether)ketone (SPEEK) with 2%–10% polysulfone (PSf) for proton exchange membrane fuel cells (PEMFCs).

Single cell performance in the PEMFC and the DMFC

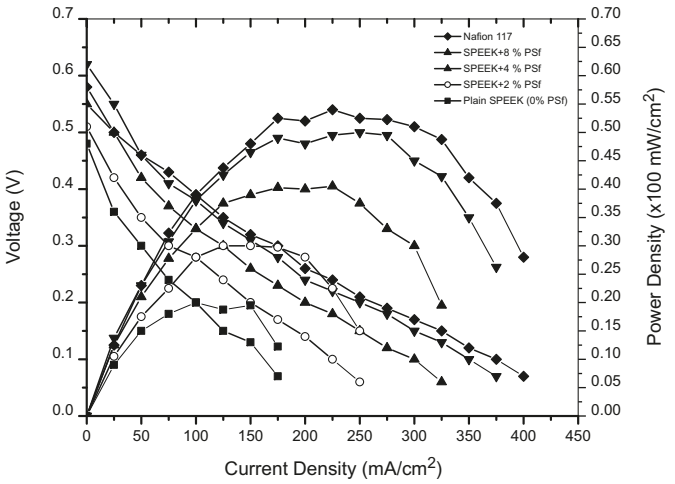

Figure 6 compares the polarization curves of the SPEEK/PSf blend membranes (2–10 wt %) with those of plain SPEEK and Nafion 117 membranes at room temperature in the PEMFC. For example, the SPEEK/PSf blend membranes show OCV values around 0.9 V, which is in comparison to that of plain SPEEK and Nafion 117 membranes. The maximum powers reached for the cell constructed with SPEEK/PSf membranes are 410, 340, 280, 224, 152, and 135 mW/cm^2 for the membranes with PSf loading of 0% (plain SPEEK), 2%, 4%, 6%, 8%, and 10%, respectively. The current density of the plain SPEEK membrane was 800 mA/cm^2 at 0.55 V, whereas that of SPEEK + 10% PSf blend was 220 mA/cm^2 under the same conditions. The reduction in the current density may be attributed to the resistance offered by the presence of PSf in the blend.

Figure 7 compares the polarization curves of SPEEK/PSf blend membranes (2–10 wt %) with those of plain SPEEK and Nafion 117 membranes at room temperature in the DMFC. The blend membranes show better performance in the DMFC than the plain SPEEK membrane because of low methanol crossover. The lower methanol crossover suppresses the catalyst poisoning and lowers the mixed potential at the cathode, resulting in an increase in the OCV under steady state conditions. The lower methanol crossover in the blend membrane could not only help lead to better long-term stability and performance but also to lower the Pt catalyst loading at the cathode. At 0.3 V, the maximum powesr reached for the cells constructed with SPEEK/PSf membranes are 51 and 37.5 mW/cm^2 for the membranes with a PSf loading of 8% and 4%, respectively, whereas under the same operating conditions, the maximum power densities offered by Nafion 117 and SPEEK (0% PSf) membranes are 46.5 and 16 mW/cm^2, respectively, at room temperature with a 2 mol/L methanol solution.

Conclusion

In the present study, blend membranes with SPEEK and PSf were synthesized. The blends were found to be mechanically

Fig. 7. Polarization curves of sulfonated poly(ether ether)ketone (SPEEK) with 2%–8% polysulfone (PSf) for the direct methanol fuel cell (DMFC).

stable. The SEM images revealed good compatibility between the constituents of the blend. The prepared membranes were found to be thermally stable upto 225 °C, which is highly suitable for the DMFC applications. The water retention capacity as well as the proton conductivity of the blend membranes was decreased due to the introduction of PSf. However, the proton conductivity was in the order of 10^{-3} S/cm. The presence of PSf has also influenced the durability of the membrane and it was found to be increasing. There was a very good reduction in the methanol permeability of the blends when compared to virgin SPEEK indicating a possible alternate for Nafion in the DMFC.

In the PEMFC, SPEEK/polysulphone blend membranes give the same results with that of Nafion 117 and exhibited OCV values around 0.9 V and the maximum power density obtained was around 400 mW/cm^2 and possesses excellent stability and performance. In the DMFC, the assistance of polysulphone enhances the resistivity to methanol crossover. The lower methanol crossover suppresses the catalyst poisoning and lowers the mixed potential at the cathode resulting in an increase in the OCV at steady state. The lower methanol crossover in the blend membrane could not only help lead to a better long-term stability and performance but also to lower the Pt catalyst loading at the cathode. The maximum power reached for the DMFC constructed with SPEEK/PSf membranes are around 50 mW/ cm^2, which is found to be most promising for the DMFC applications.

Abstract: A facile synthesis of polysubstituted pyrroles from tosylmethyl isocyanide (TOSMIC) and readily synthesized vinyl azides was developed. The reaction proceeded under mild conditions in the presence of base. 2-Tosyl-substituted pyrroles were obtained in moderate to good isolated yields. Additionally, a base-initiated one-pot pyrrole synthesis also was developed using carboxaldehydes, ethyl 2-azidoacetate, and TOSMIC.

Key words: vinyl azides, 2,3,4-trisubstituted pyrroles, cyclization reaction, nucleophilic reaction, multicomponent reaction.

Résumé : On a développé une méthode facile de synthèse de pyrroles polysubstitués à partir de l'isocyanure de tosylméthyle (ICTOSM) et d'azotures de vinyles facilement accessibles. La réaction s'effectue dans des conditions douces, en présence d'une base. On a obtenu des 2-tosylpyrroles substitués avec des rendements en produits isolés allant de modérés à bons. De plus, on a mis au point une synthèse monotope de pyrroles initiée par une base et impliquant des carboxaldéhydes, du 2-azidoacétate d'éthyle et de l'isocyanure de tosylméthyle.

Mots-clés : azotures de vinyle, pyrroles 2,3,4-trisubstitués, réaction de cyclisation, réaction nucléophile, réaction à plusieurs composants.

[Traduit par la Rédaction]

Introduction

Substituted pyrroles are important heterocycles that are present as the core scaffolds in many natural products[1] and are reported to contribute to a wide spectrum of biological activities.[2] Thus, pyrroles are interesting synthetic targets for obtaining biologically active compounds. Over the past decades, a number of classical and new multicomponent reactions (MCRs) have been reported for the preparation of pyrroles, including the Hantzsch reaction,[3] the Paal–Knorr cyclization reaction of 1,4-dicarbonyl compounds and amines,[4] transition-metal-based strategies,[5] the Van Leusen cyclization,[6] and other cyclizations.[7–11] Despite the numerous approaches for the synthesis of pyrroles that have been developed so far, it is still challenging to prepare structurally diverse pyrroles from readily available building blocks.

Vinyl azide is a pivotal three-atom synthon for the formation of nitrogen-containing heterocycles (azaheterocycles). Especially, it has been reported that vinyl azide was employed with various transition metals in pyrrole synthesis.[9] Recently, we studied the base initial synthesis of polysubstituted pyrrolo[1,2-α]pyrazine using vinyl azides as the starting material.[12] As part of our ongoing studies on synthetic applications of vinyl azides, we present a facile and general synthesis from tosylmethyl isocyanide (TOSMIC) and vinyl azides, furnishing 2,3,4-trisubstituted pyrroles in the presence of base. In the previous studies, the azide group of vinyl azides lost nitrogen and incorporated the nitrogen atom into a newly formed molecule. In this report, however, the azide group of vinyl azides serves as a leaving group, which is crucial for the final aromatization of the intermediate to the final products. Meanwhile, in the Van Leusen synthesis, pyrroles are formed via elimination of sulfinic acid from the intermediate cycloadducts. Therefore, the present work would be a good addition to the synthetic application of Van Leusen's reagent. Moreover, previous reports on the use of vinyl azides as reaction partners for the preparation of 2-tosyl-substituted pyrroles are rare.

Results and discussion

The reaction of vinyl azide **1a**, derived from benzaldehyde, with TOSMIC was selected as a prototype reaction (Table 1) for the identification of the optimal reaction conditions for this synthesis. No reaction was observed when base was absent (Table 1, entry 1), but the transformation occurred in the presence of a variety of bases at room temperature to form **3a** as the major product (Table 1). Screening of the bases revealed

[a]Isolated yield.

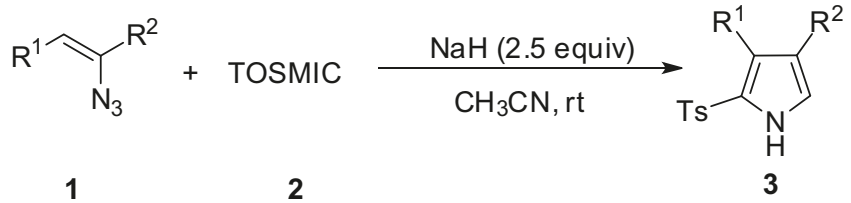
that NaH was the most efficient base (Table 1, entries 2–11). When 1,8-diazabicyclo[5.4.0]undec-7-ene (DBU), a strong base, was employed, the desired product **3a** was obtained with a yield of 24% (Table 1, entry 2). When the base was changed to Cs_2CO_3, the yield of **3a** was 46% (Table 1, entry 4). Other inorganic bases, such as *t*-BuOK and K_2CO_3 gave the product in low yields (Table 1, entries 3 and 5). Optimization of the solvent showed that acetonitrile (Table 1, entry 6) was superior to other solvents (Table 1, entries 6–10). This reaction was also tested at a higher temperature, but with a decrease in the yield (Table 1, entry 11). Based on this initial study, the optimal conditions were obtained in acetonitrile at room temperature when NaH was employed as a base (51%; Table 1, entry 6).

With the optimized reaction condition in hand, this methodology was evaluated using different substituted vinyl azides (**1**) with TOSMIC (**2**; Table 2). The vinyl azides (Table 2, entries 1–10) were readily prepared from the corresponding aromatic carboxaldehydes with ethyl 2-azidoacetate via a Knoevenagel condensation.[9] Additional vinyl azides (Table 2, entries 11–14) were prepared from the corresponding olefins by successive reaction with bromine then with sodium azide.[13]

As presented in Table 2, various substituted vinyl azides with TOSMIC worked well to provide the corresponding pyrroles in moderate to good isolated yields. The reaction could tolerate an array of R_1 substituents in the vinyl azides such as aryl, H, and the furyl moiety (Table 2). Vinyl azides bearing an electron-withdrawing group on the aryl ring gave good yields (62%–86%; Table 2, entries 4–9). The case is illustrated in Table 2, entry 8, where the vinyl azide with a NO_2 substituent at the aryl group gave a good isolated yield (86%). The influence of R_2 substituents in this reaction is also illustrated in Table 2 (entries 11–14). When an arylcarbonyl group occurred at the α-position of the vinyl azide, it lead to a sharp decrease in the yield (<45%; Table 2, entries 11–14), compared with entry 4 (75%; Table 2). The α-*N*-morpholinylcarbonyl-substituted vinyl azide greatly favored this process, providing the corresponding product in higher yield (94%; Table 2, entry 12).

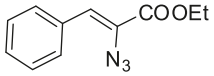
α-Azidostyrene (Table 2, entry 11) was detrimental to the desired transformation, most probably because of its relatively low electron-withdrawing properties.

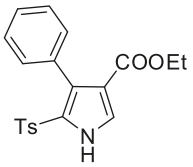
On the basis of the results presented above, we propose the following possible mechanism for this reaction, as shown in Scheme 1. First, it is expected to involve a Michael addition of TOSMIC **2** to the vinyl azides **1**, followed by an intramolecular cyclization reaction. The desired product **3** is generated via intramolecular proton transfer and the elimination of the N_3^- group.

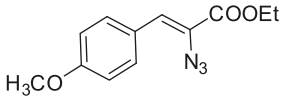


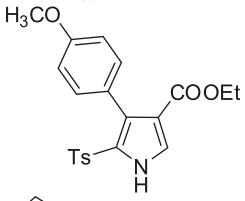
Multicomponent reactions have a couple of distinct advantages.[14] In this report, a one-pot three-component process was also investigated, where a mixture of 3-nitrobenzaldehyde and ethyl 2-azidoacetate was stirred under the Knoevenagel condensation conditions using NaH as the base for 2 h at –15 °C, followed by addition of TOSMIC. The reaction mixture was then stirred at room temperature (rt) for 24 h to give the desired product **3h** (Scheme 2) with a total yield of 54%.

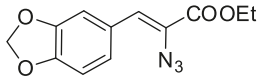
Conclusions

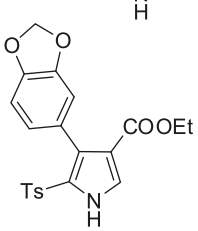


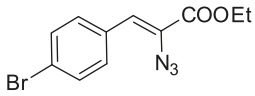


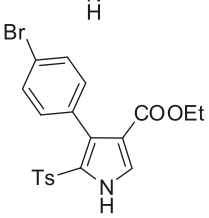


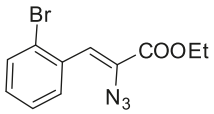


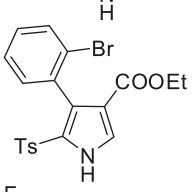


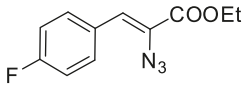


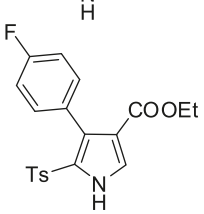


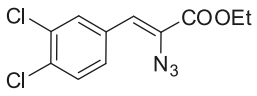


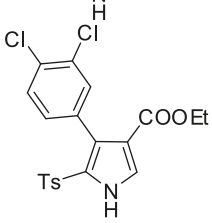












In conclusion, we have developed an efficient approach for the generation of 2,3,4-trisubstituted pyrroles in moderate to good yields. This reaction was realized through a domino process from TOSMIC and readily available vinyl azides. Expansion of the method to a one-pot, three-component protocol to generate pyrrole **3h** from commercially available aromatic carboxaldehyde, ethyl 2-azidoacetate, and TOSMIC

also was accomplished. The domino process includes a Knoevenagel condensation, a Michael addition, and intramolecular cycloaddition.

Experimental section

General methods

All solvents were purified according to standard methods prior to use. Reactions were run under an atmosphere of nitrogen unless mentioned otherwise. Purifications of the reaction products were carried out by chromatography using silica gel (200–300 mesh). Melting points were recorded on a BÜCHI B-540 melting point apparatus. Infrared spectra were recorded on an FTIR spectrophotometer. NMR spectra were recorded for ^{1}H NMR at 500 MHz and for ^{13}C NMR at 125 MHz. For ^{1}H NMR, tetramethylsilane (TMS) served as the internal standard ($\delta = 0$) and data are reported as follows: chemical shift, integration, multiplicity (s = singlet, d = doublet, t = triplet, q = quartet, and m = multiplet), and coupling constant(s) in Hz. For ^{13}C NMR, TMS ($\delta = 0$) or $CDCl_3$ ($\delta = 77.26$) was used as the internal standard and spectra were obtained with complete proton decoupling. LC–MS and HRMS data were obtained using ESI ionization.

General procedure A for the synthesis of 3

A mixture of vinyl azide **1** (1.0 mmol), TOSMIC **2** (2.0 mmol), and NaH (2.5 mmol) was stirred in anhydrous CH_3CN (2 mL) at rt under nitrogen for 24 h. The reaction mixture was quenched with water (10 mL) and then extracted three times with EtOAc (3 × 10 mL). The combined organic extracts were washed with brine (10 mL), dried over $MgSO_4$, and concentrated. The crude product was purified by chromatography (silica gel; petroleum ether:ethyl acetate = 3:1) to afford **3** and was crystallized from a mixture of EtOAc with hexanes.

General procedure B for the one-pot synthesis of 3h

A mixture of 3-nitrobenzaldehyde (1.0 mmol), ethyl 2-azidoacetate (5.0 mmol), and NaH (5.0 mmol) was stirred in anhydrous CH_3CN (5 mL) at –15 °C under nitrogen for 2 h. A solution of TOSMIC (3.0 mmol) and NaH (3.0 mmol) in anhydrous CH_3CN was then added into this mixture. The reaction was stirred at –15 °C to rt for 24 h. After the completion of the reaction, the resulting solution was quenched with saturated NH_4Cl solution (10 mL) and then extracted three times with EtOAc (3 × 10 mL). The combined organic extracts were washed with brine (10 mL), dried over $MgSO_4$,

and concentrated. The crude product was purified by chromatography (silica gel; petroleum ether:ethyl acetate = 3:1) to afford **3h** and was crystallized from a mixture of EtOAc with hexanes.

Ethyl 4-phenyl-5-tosyl-1*H*-pyrrole-3-carboxylate (3a)

Treatment of **1a** (217 mg, 1.0 mmol) with **2** (390 mg, 2.0 mmol) by General procedure A gave **3a** (188 mg, 51%) as a pale yellow solid (EtOAc/hexane); mp 168–170 °C. IR (KBr, cm^{-1}) ν: 3451, 3234, 2986, 1684, 770, 698, 661. ^{1}H NMR (500 MHz, $CDCl_3$) δ: 1.07 (3H, t, J = 7.0 Hz), 2.34 (3H, s), 4.08 (2H, q, J = 7.0 Hz), 7.07 (2H, d, J = 8.0 Hz), 7.14 (2H, d, J = 7.5 Hz), 7.25 (2H, d, J = 8.0 Hz), 7.30 (2H, t, J = 7.5 Hz), 7.34 (1H, d, J = 7.0 Hz), 7.58 (1H, d, J = 2.0 Hz), 10.07 (1H, brs). ^{13}C NMR (125 MHz, $CDCl_3$) δ: 14.1, 21.7, 60.2, 117.9, 126.4, 127.4, 127.7, 128.0, 130.0, 130.7, 130.8, 131.5, 138.2, 144.4, 163.5. LC–MS (ESI) m/z $[M + H]^+$: 370.3. HRMS (EI) m/z calcd for $C_{20}H_{19}NO_4S$ $(M)^+$: 369.1035; found: 369.1033.

Ethyl 4-(4-methoxyphenyl)-5-tosyl-1*H*-pyrrole-3-carboxylate (3b)

Treatment of **1b** (247 mg, 1.0 mmol) with **2** (390 mg, 2.0 mmol) by General procedure A gave **3b** (168 mg, 42%) as a pale yellow solid (EtOAc/hexane); mp 140–142 °C. IR (KBr, cm^{-1}) ν: 3451, 3236, 2987, 1674, 807, 768. ^{1}H NMR (500 MHz, $CDCl_3$) δ: 1.12 (3H, t, J = 7.0 Hz), 2.35 (3H, s), 3.86 (3H, s), 4.10 (2H, q, J = 7.0 Hz), 6.86 (2H, d, J = 8.5 Hz), 7.08–7.11 (4H, m), 7.28 (2H, d, J = 8.5 Hz), 7.56 (1H, d, J = 3 Hz), 10.13 (1H, brs). ^{13}C NMR (125 MHz, $CDCl_3$) δ: 14.1, 21.5, 55.3, 59.9, 112.8, 117.6, 123.4, 126.4, 127.2, 127.4, 129.4, 130.7, 131.8, 138.1, 144.2, 159.3, 163.4. LC–MS (ESI) m/z $[M + H]^+$: 400.4. HRMS (EI) m/z calcd for $C_{21}H_{21}NO_5S$ $(M)^+$: 399.1140; found: 399.1137.

Ethyl 4-(benzo[*d*][1,3]dioxol-5-yl)-5-tosyl-1*H*-pyrrole-3-carboxylate (3c)

Treatment of **1c** (261 mg, 1.0 mmol) with **2** (390 mg, 2.0 mmol) by General procedure A gave **3c** (207 mg, 50%) as a pale yellow solid (EtOAc/hexane); mp 173–175 °C. IR (KBr, cm^{-1}) ν: 3450, 3270, 2924, 1692, 810, 771. ^{1}H NMR (500 MHz, $CDCl_3$) δ: 1.14 (3H, t, J = 7.0 Hz), 2.37 (3H, s), 4.11 (2H, q, J = 7.0 Hz), 5.98 (2H, s), 6.57 (1H, d, J = 1.5 Hz), 6.62 (1H, dd, J_1 = 1.5 Hz, J_2 = 8.0 Hz), 6.76 (1H, d, J = 8.0 Hz), 7.13 (2H, d, J = 8.5 Hz), 7.36 (2H, d, J = 8.5 Hz), 7.56 (d, 1H, J = 3.5 Hz), 10.11 (1H, brs). ^{13}C NMR (125 MHz, $CDCl_3$) δ: 14.3, 21.8, 60.2, 101.2, 107.5, 111.3, 117.9, 124.4, 124.9, 126.5, 127.5, 127.8, 129.6, 130.4, 138.2, 144.6, 146.9, 147.4, 163.4. LC–MS (ESI) m/z $[M + H]^+$: 414.3. HRMS (EI) m/z calcd for $C_{21}H_{19}NO_6S$ $(M)^+$: 413.0933; found: 413.0935.

Ethyl 4-(4-bromophenyl)-5-tosyl-1*H*-pyrrole-3-carboxylate (3d)

Treatment of **1d** (296 mg, 1.0 mmol) with **2** (390 mg, 2.0 mmol) by General procedure A gave **3d** (336 mg, 75%) as a pale yellow solid (EtOAc/hexane); mp 185–187 °C. IR (KBr, cm^{-1}) ν: 3450, 3223, 2924, 1685, 818, 778. ^{1}H NMR (500 MHz, $CDCl_3$) δ: 1.11 (3H, t, J = 7.0 Hz), 2.37 (3H, s), 4.09 (2H, q, J = 7.0 Hz), 7.02 (2H, d, J = 8.5 Hz), 7.12 (2H, d, J = 8.5 Hz), 7.28 (2H, d, J = 8.5 Hz), 7.44 (2H, d, J = 8.5 Hz), 7.59 (1H, s), 9.87 (1H, brs). ^{13}C NMR (125 MHz, $CDCl_3$) δ: 14.2, 21.8, 60.3, 118.0, 122.4, 126.3, 127.5, 128.0, 129.3, 129.7, 130.5, 130.7, 132.5, 138.0, 144.8, 163.3. LC–MS (ESI) m/z $[M + H]^+$: 448.2. HRMS (EI) m/z calcd for $C_{20}H_{18}NO_4SBr$ $(M)^+$: 447.0140; found: 447.0147.

Ethyl 4-(2-bromophenyl)-5-tosyl-1*H*-pyrrole-3-carboxylate (3e)

Treatment of **1e** (296 mg, 1.0 mmol) with **2** (390 mg, 2.0 mmol) by General procedure A gave **3e** (350 mg, 78%) as an off-white solid (EtOAc/hexane); mp 179–181 °C. IR (KBr, cm^{-1}) ν: 3450, 3219, 2982, 1690, 763. ^{1}H NMR (500 MHz, $CDCl_3$) δ: 1.01 (3H, t, J = 7.0 Hz), 2.38 (3H, s), 4.00–4.11 (2H, m), 7.11 (2H, d, J = 8.5 Hz), 7.21–7.24 (1H, m), 7.28–7.32 (3H, m), 7.34–7.37 (1H, m), 7.45 (1H, d, J = 7.0 Hz), 7.61 (1H, d, J = 3.5 Hz), 9.92 (1H, brs). ^{13}C NMR (125 MHz, $CDCl_3$) δ: 14.0, 21.8, 60.2, 118.8, 125.3, 125.9, 126.7, 127.7, 128.7, 129.6, 129.7, 131.9, 132.8, 133.1, 137.4, 144.7, 163.3. LC–MS (ESI) m/z $[M + H]^+$: 448.2. HRMS (EI) m/z calcd for $C_{20}H_{18}NO_4SBr$ $(M)^+$: 447.0140; found: 447.0139.

Ethyl 4-(4-fluorophenyl)-5-tosyl-1*H*-pyrrole-3-carboxylate (3f)

Treatment of **1f** (235 mg, 1.0 mmol) with **2** (390 mg, 2.0 mmol) by General procedure A gave **3f** (248 mg, 64%) as a pale yellow solid (EtOAc/hexane); mp 183–185 °C. IR (KBr, cm^{-1}) ν: 3451, 3220, 2986, 1686, 808, 781. ^{1}H NMR (500 MHz, $CDCl_3$) δ: 1.10 (3H, t, J = 7.0 Hz), 2.36 (3H, s), 4.09 (2H, q, J = 7.0 Hz), 6.98–7.02 (2H, m), 7.10–7.14 (4H, m), 7.26–7.29 (2H, m), 7.59 (1H, s), 10.08 (1H, brs). ^{13}C NMR (125 MHz, $CDCl_3$) δ: 14.2, 21.8, 60.3, 114.5 (d, J = 21 Hz), 118.0, 126.5, 127.4, 127.9, 129.6, 129.7, 132.8 (d, J = 8 Hz), 138.1, 144.7, 162.8 (d, J = 245 Hz), 163.4. LC–MS (ESI) m/z $[M + H]^+$: 388.3. HRMS (EI) m/z calcd for $C_{20}H_{18}NO_4FS$ $(M)^+$: 387.0941; found: 387.0938.

Ethyl 4-(3, 4-dichlorophenyl)-5-tosyl-1*H*-pyrrole-3-carboxylate (3g)

Treatment of **1g** (286 mg, 1.0 mmol) with **2** (390 mg, 2.0 mmol) by General procedure A gave **3g** (272 mg, 62%) as a pale yellow solid (EtOAc/hexane); mp 191–193 °C. IR (KBr, cm^{-1}) ν: 3451, 3237, 2924, 1686, 770, 672. ^{1}H NMR (500 MHz, $CDCl_3$) δ: 1.11 (3H, t, J = 7.0 Hz), 2.39 (3H, s), 4.10 (2H, q, J = 7.0 Hz), 7.03 (1H, s), 7.07 (1H, d, J = 8.0 Hz), 7.16 (2H, d, J = 8.0 Hz), 7.33 (2H, d, J = 8.0 Hz), 7.40 (1H, d, J = 8.0 Hz), 7.60 (1H, s). ^{13}C NMR (125 MHz, $CDCl_3$) δ: 14.2, 21.8, 60.4, 118.0, 126.3, 127.6, 128.5, 129.5, 129.8, 130.3, 131.5, 131.6, 132.3, 132.4, 137.8, 145.1, 163.1. LC–MS (ESI) m/z $[M + H]^+$: 438.2. HRMS (EI) m/z calcd for $C_{20}H_{17}NO_4SCl_2$ $(M)^+$: 437.0255; found: 437.0258.

Ethyl 4-(3-nitrophenyl)-5-tosyl-1*H*-pyrrole-3-carboxylate (3h)

Treatment of **1h** (262 mg, 1.0 mmol) with **2** (390 mg, 2.0 mmol) by General procedure B gave **3h** (356 mg, 86%) as a pale yellow solid (EtOAc/hexane); mp 161–163 °C. IR (KBr, cm^{-1}) ν: 3451, 3250, 2984, 1689, 810, 737. ^{1}H NMR (500 MHz, $CDCl_3$) δ: 1.07 (3H, t, J = 7.0 Hz), 2.36 (3H, s), 4.08 (2H, q, J = 7.0 Hz), 7.13 (2H, d, J = 8.0 Hz), 7.32 (2H, d, J = 8 Hz), 7.54 (1H, t, J = 8.0 Hz), 7.62–7.64 (2H, m),

For personal use only.

7.78 (1H, s), 8.22 (1H, d, J = 8.0 Hz). ^{13}C NMR (125 MHz, $CDCl_3$) δ: 14.2, 21.7, 60.5, 118.0, 122.9, 125.6, 126.7, 127.4, 127.7, 128.5, 129.9, 133.5, 137.2, 137.9, 145.3, 147.5, 163.1. LC–MS (ESI) m/z $[M + H]^+$: 415.3. HRMS (EI) m/z calcd for $C_{20}H_{18}N_2O_6S$ $(M)^+$: 414.0886; found: 414.0889.

Ethyl 4-(4-(methylsulfonyl)phenyl)-5-tosyl-1*H*-pyrrole-3-carboxylate (3i)

Treatment of **1i** (295 mg, 1.0 mmol) with **2** (390 mg, 2.0 mmol) by General procedure A gave **3i** (322 mg, 72%) as a pale yellow solid (EtOAc/hexane); mp 180–182 °C. IR (KBr, cm^{-1}) ν: 3452, 3266, 2986, 1684, 771. ^{1}H NMR (500 MHz, $CDCl_3$) δ: 1.11 (3H, t, J = 7.0 Hz), 2.36 (3H, s), 3.12 (3H, s), 4.10 (2H, q, J = 7.0 Hz), 7.11 (2H, d, J = 8.0 Hz), 7.27–7.28 (2H, m), 7.38 (2H, d, J = 8.0 Hz), 7.64 (1H, s), 7.88 (2H, d, J = 8.5 Hz). ^{13}C NMR (125 MHz, $CDCl_3$) δ: 14.2, 21.8, 44.8, 60.5, 117.8, 126.4, 126.5, 127.4, 128.3, 128.5, 129.8, 131.9, 137.8, 140.0, 145.1, 163.1. LC–MS (ESI) m/z $[M + H]^+$: 448.3. HRMS (EI) m/z calcd for $C_{21}H_{21}NO_6S_2$ $(M)^+$: 447.0810; found: m/z: 447.0815.

Ethyl 4-(furan-2-yl)-5-tosyl-1*H*-pyrrole-3-carboxylate (3j)

Treatment of **1j** (207 mg, 1.0 mmol) with **2** (390 mg, 2.0 mmol) by General procedure A gave **3j** (165 mg, 46%) as a yellow solid (EtOAc/hexane); mp 209–211 °C. IR (KBr, cm^{-1}) ν: 3451, 3225, 2988, 1685. ^{1}H NMR (500 MHz, $CDCl_3$) δ: 1.10 (3H, t, J = 7.0 Hz), 2.36 (3H, s), 4.09 (2H, q, J = 7.0 Hz), 6.99–7.02 (2H, m), 7.10 (2H, d, J = 8.0 Hz), 7.12–7.14 (1H, m), 7.26 (2H, d, J = 8.0 Hz), 7.59 (1H, s), 9.80 (1H, brs). ^{13}C NMR (125 MHz, $CDCl_3$) δ: 14.2, 21.8, 60.3, 114.4, 114.6, 118.1, 126.2, 127.5, 128.1, 129.6, 132.5, 132.6, 138.1, 144.7, 163.4. LC–MS (ESI) m/z $[M + H]^+$: 360.2. HRMS (EI) m/z calcd for $C_{18}H_{17}NO_5S$ $(M)^+$: 359.0827; found: 359.0826.

Morpholino(5-tosyl-1*H*-pyrrol-3-yl)methanone (3l)

Treatment of **1l** (182 mg, 1.0 mmol) with **2** (390 mg, 2.0 mmol) by General procedure A gave **3l** (314 mg, 94%) as an off-white solid (EtOAc/hexane); mp 202–204 °C. IR (KBr, cm^{-1}) ν: 3451, 3238, 2998, 1625. ^{1}H NMR (500 MHz, DMSO-d_6) δ: 2.37 (3H, s), 3.57 (8H, m), 6.96 (1H, d, J = 1.0 Hz), 7.41–7.43 (3H, m), 7.83 (2H, d, J = 8.5 Hz), 12.77 (1H, brs). ^{13}C NMR (125 MHz, DMSO-d_6) δ: 21.5, 66.7, 115.6, 119.7, 127.2, 127.3, 129.3, 130.5, 139.5, 144.5, 164.2. LC–MS (ESI) m/z $[M + H]^+$: 335.3. HRMS (EI) m/z calcd for $C_{16}H_{18}N_2O_4S$ $(M)^+$: 334.0987; found: 334.0978.

(4-(4-Bromophenyl)-5-tosyl-1*H*-pyrrol-3-yl)(4-chlorophenyl)methanone (3m)

Treatment of **1m** (363 mg, 1.0 mmol) with **2** (390 mg, 2.0 mmol) by General procedure A gave **3m** (232 mg, 45%) as an off-white solid (EtOAc/hexane); mp 225–227 °C. IR (KBr, cm^{-1}) ν: 3451, 1650. ^{1}H NMR (500 MHz, $CDCl_3$) δ: 2.36 (3H, s), 7.03–7.04 (2H, m), 7.11 (2H, d, J = 8.0 Hz), 7.29–7.30 (2H, m), 7.30–7.32 (4H, m), 7.36–7.37 (3H, m), 7.60–7.62 (2H, m). ^{13}C NMR (125 MHz, $CDCl_3$) δ: 21.8, 122.6, 125.2, 126.9, 127.4, 128.5, 128.8, 129.3, 129.8, 130.3, 130.9, 131.0, 132.4, 136.9, 137.8, 139.0, 145.0, 189.3. LC–MS (ESI) m/z $[M + H]^+$: 514.2. HRMS (EI) m/z calcd for $C_{24}H_{17}NO_3SClBr$ $(M)^+$: 512.9801; found: 512.9807.

(4-(4-Bromophenyl)-5-tosyl-1*H*-pyrrol-3-yl)(*p*-tolyl)methanone (3n)

Treatment of **1n** (342 mg, 1.0 mmol) with **2** (390 mg, 2.0 mmol) by General procedure A gave **3n** (178 mg, 36%) as a yellow solid (EtOAc/hexane); mp 180–182 °C. IR (KBr, cm^{-1}) ν: 3451, 1645. ^{1}H NMR (500 MHz, $CDCl_3$) δ: 2.35 (3H, s), 2.36 (3H, s), 7.05 (2H, d, J = 8.5 Hz), 7.10–7.14 (4H, m), 7.31 (2H, d, J = 8.5 Hz), 7.35–7.36 (3H, m), 7.58 (2H, d, J = 8.0 Hz), 10.05 (1H, brs). ^{13}C NMR (125 MHz, $CDCl_3$) δ: 21.8, 122.4, 125.7, 126.7, 127.4, 128.0, 129.1, 129.4, 129.7, 130.5, 130.9, 132.5, 135.9, 138.0, 143.5, 144.8, 190.3. LC–MS (ESI) m/z $[M + H]^+$: 494.3. HRMS (EI) m/z calcd for $C_{25}H_{20}NO_3SBr$ $(M)^+$: 493.0347; found: 493.0343.

Supplementary data

Supplementary data (including experimental procedures, characterization data, and copies of ^{1}H and ^{13}C NMR spectra for all products) are available with the article through the journal Web site at http://nrcresearchpress.com/doi/suppl/10.1139/v11-150.

Synthesis and intramolecular hydrogen bonding of *syn*-9-hydroxy-18-substituted [3.3]metacyclophanes

Kazuya Tazoe, Xing Feng, Bigyan Sharma, Shinpei Miyamoto, and Takehiko Yamato

Can. J. Chem. Downloaded from www.nrcresearchpress.com by Renmin University of China on 09/02/12
For personal use only.

Abstract: Various *anti*-9-methoxy[3.3]metacyclophane-2,11-diones are exclusively obtained by the coupling reaction of the corresponding 1,3-bis(bromomethyl)benzenes and 2,6-bis[2-isocyano-2-(tolylsulfonyl)ethyl]-4-*tert*-butylanisole in dimethylformamide (DMF) with an excess of sodium hydride, from which the corresponding *syn*-[3.3]metacyclophanes (MCPs) are synthesized via anti/syn-isomerization during the Wolff–Kishner reduction. Demethylation of *syn*-9-methoxy[3.3]MCPs with BBr_3 afforded the corresponding *syn*-9-hydroxy[3.3]MCPs in good yields. The existence of the strong intramolecular hydrogen bonding between the 9-hydroxy group and the 18-substituents, such as F, OH, and OMe groups at the opposing aromatic rings, are observed in solution and in the solid state. A distinct low-field shift of the phenolic OH proton was observed in the ^{1}H NMR spectrum compared with that of the 18-unsubstituted analog. Furthermore, O–H···F through-space coupling was observed.

Key words: metacyclophanes, conformation, anti/syn-isomerization, intramolecular hydrogen bonding, through-space coupling.

Résumé : Diverses *anti*-9-méthoxy[3,3]métacyclophane-2,11-diones peuvent être préparées à l'état pur par une réaction de couplage des 1,3-bis(bromométhyl)benzènes et du 2,6-bis[2-isocyano-2-(tolylsulfonyl)éthyl]-4-*tert*-butylanisole, dans le diméthylformamide (DMF), en présence d'un excès d'hydrure de sodium; ces dicétones, soumises à une réaction de Wolff–Kishner, conduisent aux *syn*[3,3]métacyclophanes (MCPs), par le biais d'une isomérisation anti/syn au cours de cette réduction. La déméthylation des *syn*-9-méthoxy[3,3]MCPs, à l'aide de BBr_3, conduit à la formation de *syn*-9-hydroxy[3,3]MCPs, avec de bons rendements. Il a été possible d'observer, tant en solution qu'à l'état solide, l'existence de fortes liaisons hydrogènes intramoléculaires entre le groupe hydroxyle en position 9 et les substituants en position 18, tels le F ou les groupes OH et OMe attachés aux noyaux aromatiques opposés. En RMN du ^{1}H, par comparaison avec l'analogue non substitué en position 18, on a observé un déplacement caractéristique à bas champ pour le proton du OH phénolique. De plus, on a observé un couplage O–H···F à travers l'espace.

Mots-clés : métacyclophanes, conformation, isomérisation anti/syn, liaison hydrogène intramoléculaire, couplage à travers l'espace.

[Traduit par la Rédaction]

Introduction

The synthesis and stereochemical aspects of conformationally mobile [3.3]MCPs (MCP = metacyclophane) have been of interest until now with particular attention[1–4] paid to dithia[3.3]MCPs, which possess an anti-stepped conformation. The pioneering work of the conformational investigation of 2,11-dithia[3.3]MCPs was reported by Vögtle and Schunder.[5] Shinmyozu et al.[6] reported the first preparation and conformational behavior in the carbocyclic [3.3]MCPs and their analogues (Fig. 1). [3.3]MCP exists in the syn geometry with a chair–chair arrangement of the trimethylene chains in the crystal state.[7–9] The preferred geometry of [3.3]MCP in solution is also a syn on the basis of the ^{1}H NMR spectrum, in which [3.3]MCP shows a strong temperature-dependent phenomenon at low temperature.[10–14]

Shinmyozu et al.[6] prepared [3.3]MCP using (*p*-tolylsulfonyl)methyl isocyanide (TosMIC) as the cyclization reagent, followed by Wolff–Kishner reduction. They made studies of syn/anti conversions in other [3.3]MCPs, especially in relation to the size of substituents such as halogens.[15] Like the parent compound, 9-halo[3.3]MCPs prefer the syn conformation, but the corresponding 2,11-diones favour the anti arrangement. Even one internal halogen substituent is sufficient to allow the isolation of a discrete syn- or anti-isomer. Although the effect on the ratio of syn- and anti-conformers of [3.3]MCPs was reported, it is still not clear what the effects are, not only properties of the internal substituents, but also having unsymmetrically substituted benzene rings arising from charge-transfer-type interactions between two benzene rings, as well as steric effects of substituents at the 6- and 15-positions.

Interestingly, all of the previously synthesized [3.3]MCPs are internally unsubstituted [3.3]MCP-2,11-diones and it is surprising that there are very few reports[16,17] on the preparation

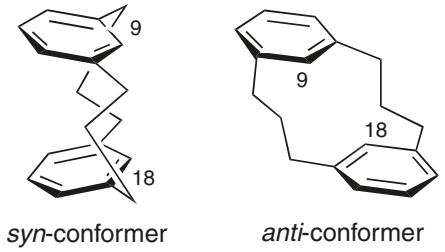
Fig. 1. syn- and anti-Conformers of [3.3]metacyclophane (MCP).



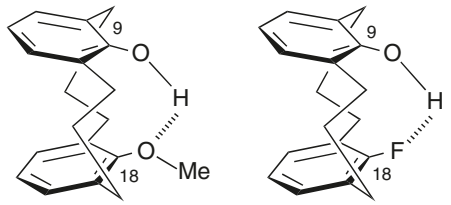


Fig. 2. Proposed intramolecular hydrogen bonding of *syn*-9-hydroxy-18-methoxy[3.3]MCP and *syn*-9-hydroxy-18-fluoro[3.3]MCP (MCP = metacyclophane).

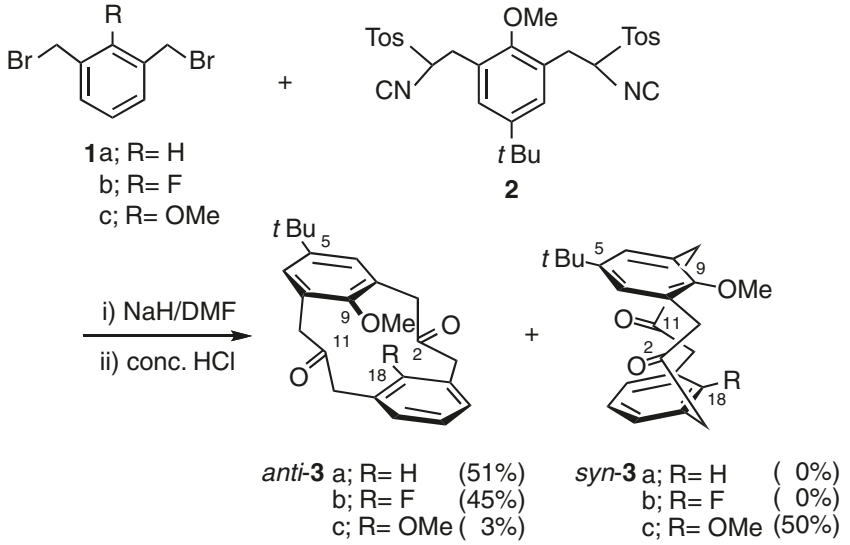
of 9-methyl- or 9-methoxy analogues despite the fact that the chemical shift of the internal substituents, such as methyl and methoxy groups, provides a convenient probe for ^{1}H NMR studies of any possible conformational changes.

On the other hand, the cyclophane skeleton is suitable for realizing the ideal C–X (X = O, F)···H–O distance, angles, and evaluating the intramolecular hydrogen bond (Fig. 2). Especially, the C–F···H–O hydrogen bond is a new type of hydrogen bond, which was first proposed by Glusker and co-workers[18] in 1983. Following their work, research studies and discussions have been continued by many researchers who are still making efforts to confirm the hydrogen bonds using a variety of methods. Based on this speculation, we employed the cyclophane skeleton for investigating the C–F···H–O hydrogen bond. Phenol and fluorobenzene units in *syn*-9-hydroxy-18-fluoro[3.3]MCP could be fixed and close to each other. Here, we report the synthesis and stereochemical assignments of 9-methoxy-18-substituted [3.3]MCP-2,11-diones and their conversion to the corresponding 9-hydroxy-18-substituted [3.3]MCPs by Wolff–Kishner reduction followed by demethylation with BBr_3. The intramolecular hydrogen bonding between the 9-hydroxyl group and 18-substituents is also discussed.

Results and discussion



Vögtle and co-workers[19–21] reported the preparation of carbocyclic [3$_n$]MCPs using TosMIC[22,23] as the cyclization reagent, which was applied in a new cyclization procedure without phase-transfer conditions.[24–28] This strategy can be employed for the preparation of [3.3]MCP containing two benzene rings. However, the preparation of [3.3]MCPs using the TosMIC method is difficult because of its low yield as well as the difficulty of product separation from the other macrocyclic oligoketones, i.e., trimers and tetramers. Therefore, it has been very difficult to obtain sufficient amounts of the above compounds to investigate their chemical behavior.

Therefore, we selected the stepwise synthetic route, i.e., the preparation of the TosMIC adduct **2** first and then the cyclization of **2** with 1,3-bis(bromomethyl)-1-substituted benzenes **1** to prepare the desired cyclic dimer **3**. The preparation of 1,3-bis(bromomethyl)-1-substituted benzenes **1** are carried out by the treatment of 1,3-dimethyl-1-substituted benzenes with *N*-bromosuccinimide by the reported procedure.[29–31] The starting compound (2,6-bis(bromomethyl)-4-*tert*-butylanisole) was easily prepared by bromomethylation of 4-*tert*-butylanisole[32,33] using the *tert*-butyl group as a positional protecting group on the aromatic ring.[29–35] Although TosMIC adduct **2** was obtained in 78% yield by the reaction of 2,6-bis(bromomethyl)-4-*tert*-butylanisole with TosMIC as a mixture of two isomers, i.e., meso and dl, the attempted pure separation of these isomers of **2** failed. The cyclic diketones **3** were synthesized by coupling the 1,3-bis(bromomethyl)-1-substituted benzenes **1** with TosMIC adduct **2** under highly diluted conditions in DMF with an excess of sodium hydride as shown in Scheme 1. We have improved the addition procedure in Vögtle and co-workers' method.[19–21] Thus, to a suspension of NaH in DMF was dropped a solution of **1** and TosMIC adducts **2** in DMF at room temperature. This not only improves the yield of the desired ketones but also makes the handling of the base (solid NaH) easier. The ^{1}H NMR spectrum of **3** shows methoxy protons as a singlet except for diketone **3c**, which shows two kinds of methoxy protons, each as a singlet. By careful column chromatography (silica gel, Wako C-300), two conformers, *anti*-**3c** and *syn*-**3c**, were separated. They are thermally stable and do not interconvert at 150 °C in DMSO solution nor at 400 °C in the solid state.

The structures of **3** were elucidated by elemental analyses and spectral data. For instance, the mass spectral data for *anti*-**3a** (M^+ = 350) strongly supports a cyclic structure. The IR spectrum of *anti*-**3a** shows the absorption of the carbonyl stretching vibration around 1697 cm^{-1}. The ^{1}H NMR spectrum (in $CDCl_3$) of *anti*-**3a** exhibits two sets of doublets at δ 3.32 and 3.74 ppm (J = 14.2 Hz) and δ 3.33 and 3.48 ppm (J = 12.2 Hz) for the Ar*CH*$_2$CO*CH*$_2$Ar methylene protons and a singlet for the internal methoxy group at an upfield shift δ 3.33 ppm from anisole (δ 3.75 ppm) owing to the ring current of the opposing aromatic ring.[1,2,29,30,36–40] Similarly, the internal aromatic proton at the 18-position was observed at higher field, δ 5.39 ppm compared with that of the **1a** at δ 7.28 ppm. These observations strongly suggest that *anti*-**3a** adopts the anti-conformation. Similarly, the assignments of structures for other anti-conformers in *anti*-**3b** and *anti*-**3c** were readily apparent from their ^{1}H NMR spectra. Thus, upfield shifts of methoxy protons were observed at δ 3.13 ppm for *anti*-**3b** and δ 3.16 ppm for *anti*-**3c**. In contrast, the methoxy protons of *syn*-**3c** were observed at δ 3.55 and 3.56 ppm. Further, the aryl hydrogens at the 5,7-positions can clearly be seen to be shielded at δ 6.66 ppm by the adjacent ring, a common consequence of a face-to-face benzene ring.[36–45] Also the *tert*-butyl protons were observed at higher field, δ 1.12 ppm, compared with that of the *anti*-**3c** at δ 1.32 ppm owing to the strong shielding effect of the benzene ring. These observations strongly suggest that compound *syn*-**3c** adopts a syn-conformation.

Thus, the 9-methoxy analogue is exclusively formed as the anti-conformer independent of substituents R of 1,3-bis(bromomethyl)-1-substituted benzenes **1**, but the 9,18-dimethoxy

Scheme 1. Synthesis of *anti*-6-*tert*-butyl-9-methoxy-18-substituted [3.3]metacyclophane-2,11-diones **3**.

analogue **3c** is formed as a mixture of syn- and anti-conformers. Although the detailed reaction pathway of the formation of *syn*-**3c** is still not clear from the present results, one might propose the through-space interaction between the nonbonding electron pairs of the oxygen atom of both methoxy groups at the 9- and 18-positions and the opposite aromatic π-electrons, which may disfavour the formation of the anti-conformer.

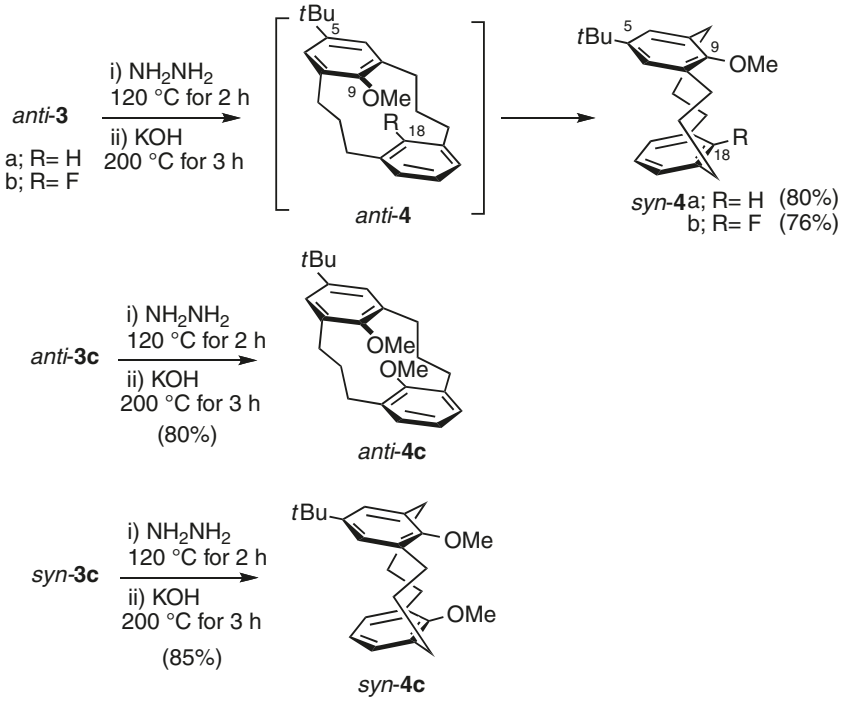
The Wolff–Kishner reduction of *syn*- and *anti*-diketone **3c** afforded the desired *syn*- and *anti*-6-*tert*-butyl-9,18-dimethoxy[3.3]MCPs (**4c**) in 80% and 85% yields, respectively. No syn/anti-isomerization was observed under the reaction conditions used (Scheme 2).

In contrast, the attempted Wolff–Kishner reduction of *anti*-diketone *syn*-**3a**, carried out under the same reaction conditions as **3c**, led to *syn*-6-*tert*-butyl-9-methoxy[3.3]MCP (*syn*-**4a**) in 80% yield. No formation of the corresponding anti-conformer was observed under the reaction conditions used.

The structure of *syn*-**4a** has been elucidated by elemental analyses and spectral data. The ^{1}H NMR spectrum (in $CDCl_3$) of *syn*-**4a** exhibits a singlet at δ 3.67 ppm for the methoxy protons. Further, a singlet of the intra-annular proton H_{18} was observed at δ 7.18 ppm in addition to the resonances at δ 6.55 ppm for the 5,7-protons and at δ 6.54 and 6.73 ppm for the other three protons of the opposing aromatic rings, which clearly can be seen to be shielded by the adjacent ring, a common consequence of a face-to-face benzene ring.[36–45] Also, the *tert*-butyl protons were observed at higher field (δ 1.09 ppm) compared with that of the *anti*-**3a** at δ 1.35 ppm owing to the strong shielding effect of the benzene ring. These observations strongly suggest that compound *syn*-**4a** adopts a syn-conformation.

Interestingly, a similar result was obtained for the reduction of *anti*-**3b** to afford *syn*-6-*tert*-butyl-18-fluoro-9-methoxy[3.3]MCP (*syn*-**4b**) carried out under the same reaction conditions. anti/syn-Isomerization was observed under the reaction conditions used (Scheme 2). These findings strongly suggest that the ring inversion to the thermodynamically more stable syn-conformation is possible in the 9-methoxy[3.3]MCPs **4a** and **4b**.

On the other hand, as mentioned previously, we reported that *syn*-**3c** and *anti*-**3c** are thermally stable and do not interconvert at 150 °C in DMSO solution nor at 400 °C in the solid state. Although the detailed mechanistic conclusion to rationalize the present observation of anti-to-syn conversion is not clear, one might assume the similar behaviour that the [3.3]MCP exists in the syn geometry with a chair–chair arrangement of the trimethylene chains.[10]



Demethylation of *syn*-9-methoxy[3.3]MCPs *syn*-**4a** and *syn*-**4b** with BBr_3 in dichloromethane affords the corresponding *syn*-9-hydroxy[3.3]MCPs *syn*-**5a** and *syn*-**5b** in 80% and 75% yields, respectively (Scheme 3). No formation of the corresponding anti-conformer was observed under the reaction conditions used. This finding suggests that the ring inversion to the thermodynamically stable anti-conformation is not possible in the 9-hydroxy[3.3]MCPs, which seem to have sufficient space for the conformational flipping as demonstrated by the molecular models. The same treatment of *syn*-9,18-dimethoxy[3.3]MCP *syn*-**4c** gives the corresponding *syn*-9,18-dihydroxy[3.3]MCP *syn*-**5c** in 85% yield.

The conformations of hydroxy[3.3]MCPs *syn*-**5** in solution, which have been prepared in the present work, are rigid and the signals of the methylene bridge do not coalesce below 130 °C in $CDBr_3$, the energy barriers to flipping being above 25 kcal mol^{-1} (1 cal = 4.184 J). The ^{1}H NMR spectrum (in $CDCl_3$) exhibits the signals for hydroxyl groups at around δ 4.61 ppm for *syn*-**5a** and at δ 4.81 ppm for *syn*-**5b**. The latter appeared as a doublet ($J_{H–F}$ = 6.6 Hz) that is coupled with the fluorine atom at the 18-position. These data show the existence of the intramolecular hydrogen bonding between two hydroxy groups among the opposing aromatic rings. The chemical shifts of the phenolic OH proton of *syn*-**5b** in $CDCl_3$ at concentrations of 1.0×10^{-1}, 1.0×10^{-2}, and 1.0×10^{-3} mol/L were the same within experimental error (δ_{OH} (*syn*-**5b**) = 4.81 ppm). Therefore, the C–F···H–O hydrogen bond is obvious in the ^{1}H NMR spectra. Moreover, specific phenomena were seen in the spectrum of *syn*-**5b**, viz., the OH signal appeared as a doublet ($J_{H–F}$ = 6.6 Hz), which shows the through-space coupling with the fluorine atom. By irradiation of the F atom, the coupling

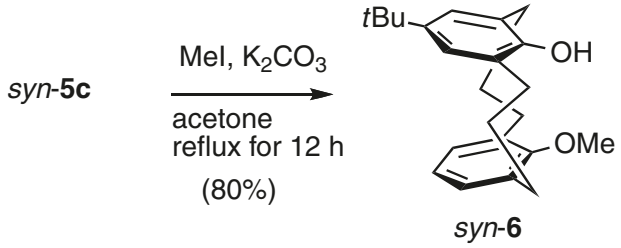
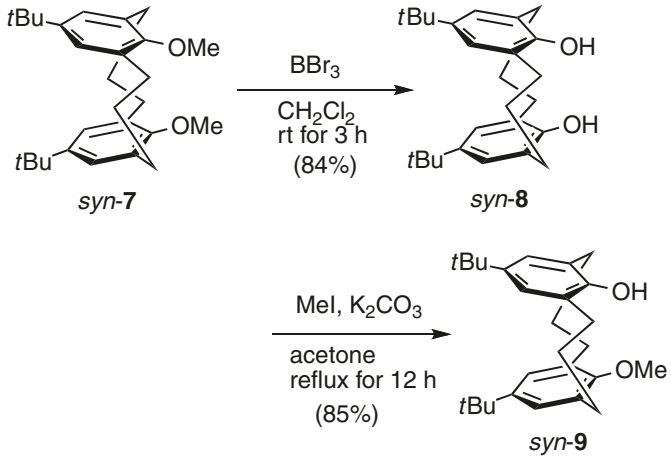


Scheme 2. Synthesis of *syn*- and *anti*-6-*tert*-butyl-9-methoxy-18-substituted [3.3]metacyclophanes **4**.

Scheme 3. Demethylation of *syn*-9-methoxy[3.3]metacyclophanes (*syn*-**4**) with BBr_3.

Scheme 4. O-Methylation of *syn*-6-*tert*-butyl-9,18-dihydroxy[3.3] metacyclophane (*syn*-**5c**).

disappeared and the doublet became a singlet. Furthermore, in a donating solvent such as [D_6]DMSO, the signal appeared as a singlet. This is further evidence of an O–H···F interaction.



On the other hand for *syn*-9,18-dihydroxy[3.3]MCP (*syn*-**5c**), the signals of the OH protons were not observed clearly in $CDCl_3$ nor in benzene-d_6, different from those of *syn*-**5a** and *syn*-**5b**. This phenomena seems to be due to the faster exchange of intramolecular hydrogen bonding between unsymmetrical hydroxyl groups than NMR time scale. To studythe intramolecular hydrogen bonding of *syn*-**5c** in more detail, we attempted introduction of a methyl group to the one of the hydroxyl groups of *syn*-**5c**. Thus, reaction of *syn*-**5c** with methyl iodide was carried out in the presence of potassium carbonate in acetone reflux for 12 h. We succeeded in the preparation of the mono-O-methylation product *syn*-**6** in 80% yield (Scheme 4). The chemical shift of the phenolic OH proton of *syn*-**6** in $CDCl_3$ was observed at a lower magnetic field at δ 6.81 ppm owing to the intramolecular hydrogen bonding between 18-methoxy groups.

We have also carried out a similar partial O-methylation of the corresponding *syn*-6,15-di-*tert*-butyl-9,18-dihydroxy[3.3]MCP (*syn*-**8**; Scheme 5), which was prepared by demethylation of *syn*-6,15-di-*tert*-butyl-9,18-dimethoxy[3.3]MCP (*syn*-**7**)[46] with BBr_3, to afford the compound *syn*-**9** in 85% yield. Similarly, a distinct low-field shift of the phenolic OH proton was observed in the ^{1}H NMR spectrum of *syn*-**9** (δ 7.04 ppm) compared to that of the OMe-free analog *syn*-**5a** (δ 4.61 ppm).

Conclusions

Various anti-9-substituted [3.3]MCP-2,11-diones were exclusively obtained by the coupling reaction of the corresponding 1,3-bis(bromomethyl)-1-substituted benzenes **1** and 2,6-bis[2-isocyano-2-(tolylsulfonyl)ethyl]-4-*tert*-butylanisole **2** in DMF with an excess of sodium hydride. In the case of the coupling reaction of 1,3-bis(bromomethyl)anisole **1c** with **2**, a mixture of *anti*-**3c** and *syn*-**3c** was obtained owing to the repulsive interaction between the unshared electrons of the methoxy groups at the 9- and 18-positions and the opposite aromatic π-electrons, which may disfavour the formation of *anti*-**3c**. The corresponding *syn*-[3.3]MCPs *syn*-**4** were synthesized via anti/syn-isomerization by the Wolff–Kishner reduction. Demethylation of *syn*-9-methoxy[3.3]MCPs *syn*-**4** with BBr_3 afforded the corresponding *syn*-hydroxy[3.3]MCPs *syn*-**5** in good yields. The existence of

Scheme 5. O-Methylation of *syn*-6,15-di-*tert*-butyl-9,18-dihydroxy [3.3]metacyclophane (*syn*-**8**).

the strong intramolecular hydrogen bonding between the 9-hydroxy group and the 18-substituents at the opposing aromatic rings, such as the F atom and the OMe group, were observed in solution and in the solid state. Actually, evidence for the C–F···H–O hydrogen bond was obtained from the results of the crystallographic analysis. In the ^{1}H NMR spectrum, the O–H bond signal of *syn*-**5b** appears at a lower field than that of the fluorine-free analog *syn*-**5a**. Furthermore, through-space coupling between the F atom and the OH proton is observed. Similarly, a distinct lowfield shift of the phenolic OH proton was observed in the ^{1}H NMR spectrum of *syn*-**9** compared with that of the OMe-free analog *syn*-**5a**. Further studies on the chemical properties of *syn*-9-hydroxy-18-substituted [3.3]MCPs *syn*-**5**, *syn*-**6**, and *syn*-**9** are now in progress.

Experimental

All melting points are uncorrected. ^{1}H NMR spectra were recorded on a Nippon Denshi JEOL FT-300 spectrometer. Chemical shifts are reported as δ values (ppm) relative to internal Me_4Si. Mass spectra were obtained on a Nippon Denshi JIR-AQ2OM mass spectrometer at an ionization energy of 70 eV using a direct-inlet system through GLC; the *m*/*z* values reported include the parent ion peak. IR spectra were obtained on a Nippon Denshi JIR-AQ2OM spectrophotometer as KBr disks. Elemental analyses were performed by Yanaco MT-5. GLC analyses were performed on a Shimadzu GC (GC-14A); silicone OV-1, 2 m; programmed temperature rise, 12 °C min^{-1}; carrier gas nitrogen, 25 mL min^{-1}.

Materials

2,6-Bis(bromomethyl)-4-*tert*-butylanisole was prepared using the reported procedure.[32,33] The preparations of 1,3-bis(bromomethyl)-1-substituted benzenes (**1a**–**1c**) have been previously described.[47,48] *syn*-6,15-Di-*tert*-butyl-9,18-dimethoxy[3.3]metacyclophane (*syn*-**7**) was prepared using the reported procedure.[46]

Preparation of the TosMIC adduct 2 — Typical procedure

To a mixture of 20% aqueous NaOH (40 mL) and CH_2Cl_2 (50 mL) was added *n*-Bu_4NI (700 mg, 1.9 mmol) followed by a solution of TosMIC (8 g, 41 mmol) in CH_2Cl_2 (50 mL). After the reaction, the mixture was stirred at room temperature for 30 min and then a solution of 2,6-bis(bromomethyl)-4-*tert*-butylanisole (4.0 g, 11 mmol) in CH_2Cl_2 (50 mL) was added. The reaction mixture was stirred at room temperature for 2 h, quenched with water (100 mL), and was extracted with CH_2Cl_2 (3 × 100 mL). It was washed with water (100 mL), dried with Na_2SO_4, and concentrated in vacuo to leave a residue. To this residue methanol (100 mL) was added and the mixture was left overnight in the refrigerator to give 4.97 g (78%) of 2,6-bis[2-isocyano-2-(tolylsulfonyl)ethyl]-4-*tert*-butylanisole (**2**) as pale brown prisms (hexane), mp 150–151 °C. ν_{max} (KBr, cm^{-1}): 2134 (CN). δ_H ($CDCl_3$): 1.26, 1.27 (9H, each s, *t*-Bu), 2.49, 2.50 (6H, each s, *Me*), 2.87, 2.99 (2H, each dd, J = 11.7, 13.7 Hz, *CH*$_2$), 3.66, 3.77 (2H, each dd, J = 2.9, 13.7 Hz, *CH*$_2$), 3.76, 3.80 (3H, each s, *OMe*), 4.73, 4.83 (2H, each dd, J = 2.9, 11.7 Hz, *CH*), 7.19, 7.20 (2H, each s, Ar-*H*), 7.44, 7.46 (4H, d, J = 8.3 Hz, Ar-*H*), 7.87, 7.93 (4H, d, J = 8.3 Hz, Ar-*H*). *m*/*z*: 578 (M^+). Anal. calcd for $C_{31}H_{34}N_2O_5S_2$ (578.75): C 64.34, H, 5.92, N 4.84); found: C 64.56, H 5.87, N 4.73.

Stepwise cyclization of TosMIC adduct 2 and dibromide 1a

To a suspension of NaH (2.1 g, 51 mmol) in DMF (150 mL) a solution of **2** (4.7 g, 8.5 mmol) and **1a** (5.0 g, 8.5 mmol) in DMF (35 mL) was added dropwise over a period of 6 h. After the suspension was stirred for an additional 5 h at room temperature, it was quenched with ice water (300 mL). The reaction mixture was extracted with CH_2Cl_2 (3 × 100 mL), washed with water (200 mL), dried with Na_2SO_4, and concentrated in vacuo to 15 mL. Concentrated HCl (15 mL) was added and the solution was stirred for 15 min. The organic layer was again extracted with CH_2Cl_2 (3 × 100 mL), washed with water (2 × 100 mL), dried with Na_2SO_4, and concentrated and condensed under reduced pressure. The residue was chromatographed on silica gel using $CHCl_3$ as eluent to give crude *anti*-**3a** as a pale yellow solid. Recrystallization from methanol afforded *anti*-6-*tert*-butyl-9-methoxy[3.3]metacyclophane-2,11-dione (*anti*-**3a**, 1.52 g, 51%) as colourless prisms (MeOH), mp 110–111 °C. ν_{max} (KBr, cm^{-1}): 1698 (C=O). δ_H ($CDCl_3$): 1.35 (9H, s, *t*-Bu), 3.32 (2H, d, J = 14.2 Hz, *CH*$_2$), 3.33 (3H, s, O*Me*), 3.33 (2H, d, J = 12.2 Hz, *CH*$_2$), 3.48 (2H, d, J = 12.2 Hz, *CH*$_2$), 3.74 (2H, d, J = 14.2 Hz, *CH*$_2$), 5.55 (1H, s, Ar-*H*), 7.05–7.10 (3H, m, Ar-*H*), 7.25 (2H, s, Ar-*H*). *m*/*z*: 350 (M^+). Anal. calcd for $C_{23}H_{26}O_3$ (350.46): C 78.83, H 7.48; found: C 78.71, H 7.48.

Similarly, compound *anti*-**3b** was obtained in 45% yield.

anti-6-*tert*-Butyl-9-furuoro-18-methoxy[3.3]metacyclophane-2,11-dione (*anti*-**3b**) was obtained as colourless prisms (MeOH), mp 109–111 °C. ν_{max} (KBr, cm^{-1}): 1697 (C=O). δ_H ($CDCl_3$): 1.25 (9H, s, *t*-Bu), 3.13 (3H, s, OMe), 3.20 (4H, d, J = 14.9 Hz, *CH*$_2$), 3.67 (4H, d, J = 14.9 Hz, *CH*$_2$), 6.89 (1H, t, J = 6.0 Hz, Ar-*H*), 7.06 (2H, t, J = 7.2 Hz, Ar-*H*), 7.12 (2H, s, Ar-*H*). *m*/*z*: 368 (M^+). Anal. calcd. for $C_{23}H_{25}FO_3$ (368.44): C 74.98, H 6.84; found: C 74.64, H 7.00.

Stepwise cyclization of TosMIC adduct 2 and dibromide 1c

To a suspension of NaH (2.1 g, 51 mmol) in DMF (150 mL) a solution of **2** (4.7 g, 8.5 mmol) and **1c** (5.0 g, 8.5 mmol) in DMF (35 mL) was added dropwise over a

period of 6 h. After the suspension was stirred for an additional 5 h at room temperature, it was quenched with ice water (300 mL). The reaction mixture was extracted with CH_2Cl_2 (3 × 100 mL), washed with water (200 mL), dried with Na_2SO_4, and concentrated in vacuo to 15 mL. Concentrated HCl (15 mL) was added, and the solution was stirred for 15 min. The organic layer was extracted again with CH_2Cl_2 (3 × 100 mL), washed with water (2 × 100 mL), dried with Na_2SO_4, and concentrated and condensed under reduced pressure. The residue was chromatographed on silica gel using $CHCl_3$ as the eluent to give crude *anti*-**3c** as a pale yellow solid. The anti:syn ratio was determined as 5:95 by the ^{1}H NMR spectrum. The residue was chromatographed on silica gel using $CHCl_3$ as the eluent to give crude *anti*-**3c** and *syn*-**3c** as a pale yellow solid and a pale yellow oil, respectively. Recrystallization from hexane afforded *anti*-**3c** (96 mg, 3%). Crude *syn*-**3c** was again chromatographed on silica gel using $CHCl_3$ as the eluent to afford 1.62 g (50%) of *syn*-**3c** as a pale yellow oil.

anti-6-*tert*-Butyl-9,18-dimethoxy[3.3]metacyclophane-2,11-dione (*anti*-**3c**) was obtained as colourless prisms (hexane), mp 198–199 °C. ν_{max} (KBr, cm^{-1}): 1685 (C=O). δ_H ($CDCl_3$): 1.32 (9H, s, *t*-Bu), 3.16 (6H, s, O*Me*), 3.23 (4H, d, J = 14.6 Hz, CH_2), 3.60 (2H, d, J = 14.6 Hz, CH_2), 3.63 (2H, d, J = 14.6 Hz, CH_2), 6.93–6.99 (1H, m, Ar-*H*), 7.17 (2H, s, Ar-*H*) and 7.16–7.18 (2H, m, Ar-*H*). *m*/*z*: 380 (M$^+$). Anal. calcd for $C_{24}H_{28}O_4$ (380.49): C 75.75, H 7.42; found: C 75.56, H 7.54.

syn-6-*tert*-Butyl-9,18-dimethoxy[3.3]metacyclophane-2,11-dione (*syn*-**3c**) was obtained as a pale yellow oil. ν_{max} (NaCl, cm^{-1}): 1688 (C=O). δ_H ($CDCl_3$): 1.12 (9H, s, *t*-Bu), 3.32 (4H, d, J = 12.7 Hz, CH_2), 3.55 (3H, s, O*Me*), 3.56 (3H, s, O*Me*), 4.30 (4H, d, J = 12.7 Hz, CH_2), 6.48–6.54 (1H, m, Ar-*H*), 6.66 (2H, s, Ar-*H*), 6.65–6.68 (2H, m, Ar-*H*). *m*/*z*: 380 (M$^+$). Anal. calcd for $C_{24}H_{28}O_4$ (380.49): C 75.76, H 7.42; found: C 75.62, H 7.35.

Wolff–Kishner reduction of anti-*3a*

A mixture of *anti*-**3a** (1.20 g, 3.42 mmol), KOH (1.28 g, 23.0 mmol), 100% hydrazine hydrate (0.35 mL, 6.2 mmol), and triethylene glycol (3 × 50 mL) was heated at 120 °C for 2 h and then at 220 °C for 3 h. The cooled mixture was poured into water (50 mL), acidified with diluted HCl, extracted with CH_2Cl_2 (3 × 50 mL), washed with water (2 × 20 mL), dried with Na_2SO_4, and concentrated under reduced pressure. The residue was chromatographed on silica gel using hexane/benzene (1:1) as the eluent to give crude *syn*-**4a** as a colourless solid. Recrystallization from MeOH afforded *syn*-6-*tert*-butyl-9-methoxy[3.3]metacyclophane (*syn*-**4a**), which was obtained as colourless prisms (882 mg, 80%), mp 112–114 °C. δ_H ($CDCl_3$): 1.09 (9H, s, *t*-Bu), 1.70–1.82 (2H, m, CH_2), 2.30–2.37 (2H, m, CH_2), 2.47–2.76 (6H, m, CH_2), 3.00–3.09 (2H, m, CH_2), 3.67 (3H, s, O*Me*), 6.54 (2H, d, J = 7.0 Hz, Ar-*H*), 6.55 (2H, s, Ar-*H*), 6.73 (1H, t, J = 7.0 Hz, Ar-*H*), 7.18 (1H, s, Ar-*H*). *m*/*z*: 322 (M$^+$). Anal. calcd for $C_{23}H_{30}O$ (322.49): C 85.66, H 9.38; found: C 85.65, H 9.39.

Compounds *syn*-**4b** and *syn*-**4c** were similarly prepared in 76% and 85% yield, respectively.

syn-6-*tert*-Butyl-9-furuoro-18-methoxy[3.3]metacyclophane (*syn*-**4b**) was obtained as colourless prisms (MeOH), mp 146–148 °C. δ_H ($CDCl_3$): 1.06 (9H, s, *t*-Bu), 1.69–1.82 (2H, m, CH_2), 2.25–2.53 (6H, m, CH_2), 2.88–3.12 (4H, m, CH_2), 3.47 (6H, s, O*Me*), 6.41–6.50 (5H, m, Ar-*H*). *m*/*z*: 340 (M$^+$). Anal. calcd for $C_{23}H_{29}FO$ (340.49): C 81.14, H 8.59; found: C 81.21, H 8.70.

syn-6-*tert*-Butyl-9,18-dimethoxy[3.3]metacyclophane (*syn*-**4c**) was obtained as colourless prisms (hexane), mp 82–84 °C. δ_H ($CDCl_3$): 1.15 (9H, s, *t*-Bu), 1.81–1.89 (2H, m, CH_2), 2.45–2.52 (6H, m, CH_2), 3.03–3.13 (4H, m, CH_2), 3.48 (3H, s, O*Me*), 3.49 (3H, s, O*Me*), 6.48–6.56 (5H, m, Ar-*H*). *m*/*z*: 352 (M$^+$). Anal. calcd for $C_{24}H_{32}O_2$ (352.52): C 81.77, H 9.15; found: C 81.58, H 9.11.

Wolff–Kishner reduction of anti-*3c*

A mixture of *anti*-**3c** (1.20 g, 3.3 mmol), KOH (1.28 g, 23.0 mmol), 100% hydrazine hydrate (0.35 mL, 6.2 mmol), and triethylene glycol (3 × 50 mL) was heated at 120 °C for 2 h and then at 220 °C for 3 h. The cooled mixture was poured into water (50 mL), acidified with diluted HCl, extracted with CH_2Cl_2 (3 × 50 mL), washed with water (2 × 20 mL), dried with Na_2SO_4, and concentrated under reduced pressure. The residue was chromatographed on silica gel using hexane/benzene (1:1) as the eluent to give crude *anti*-**4c** as a colourless solid. Recrystallization from hexane afforded *anti*-6-*tert*-butyl-9,18-dimethoxy[3.3]metacyclophane (*anti*-**4c**) was obtained as colourless prisms (930 mg, 80%), mp 220–222 °C. δ_H ($CDCl_3$): 1.34 (9H, s, *t*-Bu), 2.05–2.15 (4H, m, CH_2), 2.31–2.42 (4H, m, CH_2), 2.57–2.69 (4H, m, CH_2), 3.10 (3H, s, O*Me*), 3.15 (3H, s, O*Me*), 6.85–6.88 (1H, m, Ar-*H*), 6.95–6.87 (4H, m, Ar-*H*). *m*/*z*: 352 (M$^+$). Anal. calcd for $C_{24}H_{32}O_2$ (352.52): C 81.77, H 9.15; found: C 81.69, H 9.04.

Reaction of syn-*4a with* BBr_3

To a solution of *syn*-**4a** (60 mg, 0.186 mmol) in CH_2Cl_2 (6 mL) at 0 °C was gradually added a solution of BBr_3 (0.087 mL, 0.922 mmol) in CH_2Cl_2 (0.1 mL). After the reaction mixture had been stirred at room temperature for 3 h, it was poured into ice water (10 mL) and then extracted with CH_2Cl_2 (10 mL × 3). The combined extracts were washed with water (2 × 10 mL), dried over Na_2SO_4, and concentrated in vacuo to leave a residue. The residue was chromatographed over silica gel (Wako C-300, 100 g) with hexane/$CHCl_3$ (4:1) as the eluent to give crude *syn*-**5a** as a colourless solid. Recrystallization from MeOH afforded *syn*-6-*tert*-butyl-9-hydroxy[3.3]metacyclophane (*syn*-**5a**) was obtained as a brown oil (46 mg, 80%). ν_{max} (NaCl, cm^{-1}): 3424 (OH). δ_H ($CDCl_3$): 1.03 (9H, s, *t*-Bu), 1.72–1.81 (2H, m, CH_2), 2.25–2.32 (2H, m, CH_2), 2.42–2.52 (2H, m, CH_2), 2.54–2.56 (2H, m, CH_2), 2.59–2.68 (2H, m, CH_2), 2.81–2.90 (2H, m, CH_2), 4.61 (1H, s, *OH*), 6.46 (2H, s, Ar-*H*), 6.48 (2H, d, J = 6.0 Hz, Ar-*H*), 6.72 (1H, t, J = 6.0 Hz, Ar-*H*). *m*/*z*: 308 (M$^+$). Anal. calcd for $C_{22}H_{28}O$ (308.46): C 85.66, H 9.15; found: C 85.56, H 9.31.

Compounds *syn*-**5b** and *syn*-**5c** were similarly prepared in 75% and 85% yield, respectively.

syn-6-*tert*-Butyl-18-furuoro-9-hydroxy[3.3]metacyclophane (*syn*-**5b**) was obtained as a pale yellow oil. ν_{max} (NaCl, cm^{-1}): 3354 (OH). δ_H ($CDCl_3$): 1.13 (9H, s, *t*-Bu), 1.80–1.92 (2H, m, CH_2), 2.33–2.43 (2H, m, CH_2), 2.52–2.65 (2H, m, CH_2), 2.52–2.65 (2H, m, CH_2), 2.95–3.01 (4H, m, CH_2), 4.81 (1H,

d, J = 6.6 Hz, *OH*), 6.49–6.98 (5H, m, Ar-*H*). *m/z*: 326 (M^+). Anal. calcd for $C_{22}H_{27}FO$ (326.46): C 80.94, H 8.34; found: C 80.76, H 8.35.

syn-6-*tert*-Butyl-9,18-dihydroxy[3.3]metacyclophane (*syn*-**5c**) was obtained as colourless prisms (hexane), mp 80–82 °C. ν_{max} (KBr, cm^{-1}): 3210 (OH). δ_H ($CDCl_3$): 1.15 (9H, s, *t*-Bu), 1.81–1.89 (2H, m, CH_2), 2.45–2.52 (6H, m, CH_2), 3.03–3.13 (4H, m, CH_2), 6.48–6.56 (5H, m, Ar-*H*). *m/z*: 324 (M^+). Anal. calcd $C_{22}H_{28}O_2$ (324.47): C 81.44, H 8.7; found: C 81.58, H 8.9.

O-Methylation of syn-*6-*tert-*butyl-9,18-dihydroxy[3.3] metacyclophane (*syn-*5c) in the presence of potassium carbonate*

A mixture of *syn*-**5c** (81 mg, 0.25 mmol) and potassium carbonate (86.4 mg, 1.25 mmol) in dry acetone (16 mL) was heated at reflux for 1.5 h under nitrogen. Then methyl iodide (0.16 mL, 2.5 mmol) was added and the mixture was heated at reflux for 6 h. After cooling of the reaction mixture to room temperature, it was filtered. The filtrate was concentrated to give a colourless oil, which was then chromatographed over silica gel (Wako, C-300; 100 g) with hexane/benzene (1:1) as the eluent to give a colourless solid, which was recrystallized from MeOH to afford *syn*-6-*tert*-butyl-9-hydroxy-18-methoxy[3.3]metacyclophane (*syn*-**6**) as colourless prisms (76 mg, 80%), mp 44–46 °C. ν_{max} (KBr, cm^{-1}): 3354 (OH). δ_H ($CDCl_3$): 1.11 (9H, s, *t*-Bu), 2.21–2.28 (4H, m, CH_2), 2.58–2.65 (4H, m, CH_2), 2.86–2.97 (4H, m, CH_2), 6.40–6.53 (3H, m, Ar-*H*), 6.60 (2H, s, Ar-*H*), 6.81 (1H, s, *OH*). *m/z*: 338 (M^+). Anal. calcd for $C_{23}H_{30}O_2$ (338.49): C 81.61 H 8.93; found: C 81.43, H 8.81.

Demethylation of syn-*6,15-di-*tert-*butyl-9,18-dimethoxy[3.3] metacyclophane (*syn-*7) with BBr_3*

To a solution of *anti*-**7**[46] (200 mg, 0.49 mmol) in CH_2Cl_2 (10 mL) at 0 °C was gradually added a solution of BBr_3 (1.0 mL, 10.6 mmol) in CH_2Cl_2 (1 mL). After the reaction mixture had been stirred at room temperature for 3 h, it was poured into ice water (20 mL), extracted with CH_2Cl_2 (2 × 10 mL), washed with water (2 × 10 mL), dried with Na_2SO_4, and concentrated in vacuo to give crude *syn*-**8** as a colourless solid. Recrystallization from methanol afforded 156 mg (84%) of *syn*-6,15-di-*tert*-butyl-9,18-dihydroxy[3.3] metacyclophane (*syn*-**8**). *syn*-**8** was obtained as colourless prisms (MeOH), mp 166–167 °C. ν_{max} (KBr, cm^{-1}): 3439 (OH). δ_H ($CDCl_3$): 1.11 (18H, s), 2.21–2.28 (4H, m), 2.58–2.65 (4H, m), 2.86–2.97 (4H, m), 5.30 (2H, s, OH), 6.62 (4H, s). *m/z*: 380 (M^+). Anal calcd for $C_{26}H_{36}O_2$ (380.58): C 82.06, H 9.53; found: C 82.33, H 9.51.

Compounds *syn*-**9** was similarly prepared in 85% yield by O-methylation of *syn*-**8** in the presence of potassium carbonate under the same conditions as *syn*-**5c**.

syn-6,15-Di-*tert*-butyl-9-hydroxy-18-methoxy[3.3]metacyclophane (*syn*-**9**) was obtained as colourless prisms (MeOH/$CHCl_3$, 1:1), mp 170–171 °C. ν_{max} (KBr, cm^{-1}): 3345 (OH). δ_H ($CDCl_3$): 1.11 (18H, s, *t*-Bu), 2.23–2.31 (4H, m, CH_2), 2.50–2.64 (4H, m, CH_2), 2.98–3.28 (4H, m, CH_2), 3.65 (3H, s, O*Me*), 6.54 (2H, s, Ar-*H*), 6.63 (2H, s, Ar-*H*), 7.04 (1H, s, *OH*). *m/z*: 394 (M^+). Anal calcd for $C_{27}H_{38}O_2$ (394.6): C 82.18, H 9.71; found: C 82.45, H 9.50.

Abstract: In this work, we employed the quasi-classical trajectory (QCT) method to study the vector correlations and the influence of the reagent initial rotational quantum number j for the reaction He + T_2^+ ($v = 0$, $j = 0$–3) → HeT^+ + T on a new potential energy surface (PES). The PES was improved by Aquilanti co-workers (Chem. Phys. Lett. 2009. **469:** 26–30). The polarization-dependent differential cross sections (PDDCSs) and the distributions of $P(\theta_r)$, $P(\phi_r)$, and $P(\theta_r, \phi_r)$ are presented in this work. The plots of the PDDCSs provide us with abundant information about the distribution of the product angular momentum polarization. The $P(\theta_r)$ is used to describe the correlation between **k** (the relative velocity of the reagent) and **j′** (the product rotational angular momentum). The distribution of dihedral angle $P(\phi_r)$ shows the **k**–**k′**–**j′** (**k′** refers to the relative velocity of the product) correlation. The PDDCS calculations illustrate that the product of this reaction is mainly backward scatter and it has the strongest polarization in the backward and sideways scattering directions. At the same time, the results of the $P(\phi_r)$ demonstrate that the product HeT^+ tends to be oriented along the positive direction of the y axis and it tends to rotate right-handedly in planes parallel to the scattering plane. Moreover, the distribution of the $P(\theta_r)$ manifests that the product angular momentum is aligned along different directions relative to **k**. The direction of the product alignment may be perpendicular, opposite, or parallel to **k**. Moreover, our calculations are independent of the initial rotational quantum number.

Key words: quasi-classical trajectory, vector correlations, steorodynamics, polarization-dependent differential cross sections (PDDCSs).

Résumé : Dans ce travail, on a utilisé la méthode de la trajectoire quasi-classiqe (TQC) pour étudier les corrélations des vecteurs ainsi que l'influence du nombre quantique initial du réactif, j, de la réaction He + T_2^+ ($v = 0$; $j = 0$–3) → HeT^+ + T sur une nouvelle surface d'énergie potentielle (SEP) . La surface d'énergie potentielle correspond à celle améliorée par Aquilanti et collègues (Chem. Phys. Lett. 2009. **469:** 26–30). Dans ce travail, on rapporte les valeurs de la différentielle des sections droites qui dépendent de la polarisation (DSDDP) ainsi que les distributions de $P(\theta_r)$, $P(\phi_r)$ et $P(\theta_r, \phi_r)$. Les courbes des valeurs de la DSDDP fournissent une information abondante concernant la distribution de la polarisation du moment angulaire du produit. On utilise le $P(\theta_r)$ pour décrire la corrélation entre **k** (la vitesse relative du réactif) et **j′** (le moment angulaire rotationnel du produit). La distribution du $P(\phi_r)$ dièdre permet de démontrer la corrélation **k**–**k′**–**j** (dans laquelle **k′** se réfère à la vitesse relative du réactif). Les calculs des valeurs de la DSDDP permettent d'illustrer que le produit de cette réaction donne principalement lieu à une rétrodiffusion et qu'elle est polarisée le plus fortement dans des directions de rétrodiffusion et de diffusion latérale. Parallèlement, les résultats obtenus pour les valeurs de $P(\phi_r)$ démontrent que le produit de HeT^+ tend à être orienté le long de la direction positive de l'axe y et que sa rotation tend vers la droite dans les plans parallèles au plan de diffusion. De plus, la distribution des valeurs de $P(\theta_r)$ démontre que l'alignement du produit peut être perpendiculaire, opposé ou parallèle à **k**. De plus, ces calculs sont indépendants de nombre quantique rotationnel initial.

Mots-clés : trajectoire quasi-classique, corrélations de vecteurs, stéréodynamique, différentielle des sections droites qui dépendent de la polarisation (DSDDP).

Introduction

During the development of ion–molecule reaction dynamics, the reaction He + H_2^+ and the isotopic reactions owing to its typical characteristics, have attracted more and more people to the study of the systems for dynamical progress. The experimental investigations have received considerable attention, as has theoretical study.[1–11] Being typical ion–molecule reactions, the reactions are regarded as the prototype systems for the testing of the quality of new theories and experiments. Therefore, it is necessary to obtain the dynamical

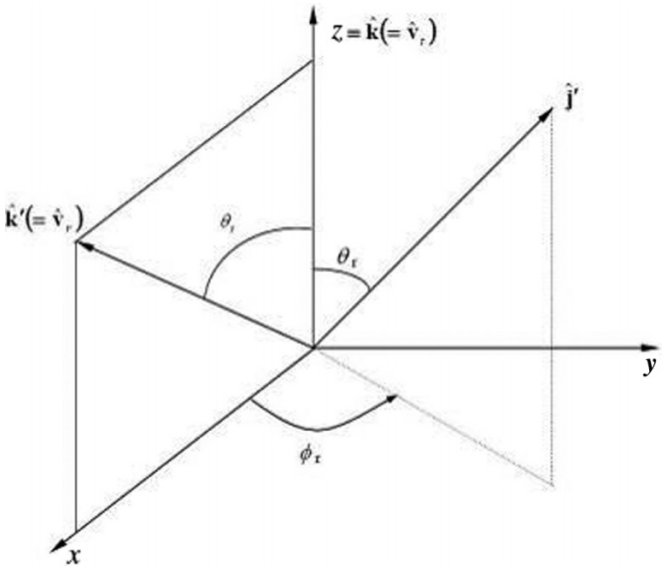
information of the reactions. In 1994, the ab initio calculations for the He + H_2^+ → HeH^+ + H was performed by Costen et al.[12] for the scattering energies near the threshold (21.91–26.52 kcal/mol; 1 cal = 4.184 J) at the MRCI level and the "exact" integral quantum reactive cross sections. Palmieri et al.[8] constructed the accurate potential energy surface, and the effect of the reagent vibration on the He + H_2^+ (v = 0–2, j = 0) → HeH^+ + H reaction was studied. The results implied that different vibrational quantum numbers made great differences on the reaction probability at the same collision energy and that the reaction cross sections generally increased as the vibrational number increased. Chu et al.[1] studied the He + H_2^+ reaction using the time-dependent quantum wave packet method, but this method was different from the former time-dependent quantum wave packet theory. Coriolis coupling was considered in this method. The conclusions regarding the reaction probability and reaction cross sections fundamentally agreed with the experimental results. Tiwari et al.[13] discussed the effect of reagent rotation on isotopic branching for the reaction He + HD^+ and the results showed that the branch ratios depended sensitively on the reagent rotation. Later, Tang et al.[9] investigated the reaction He + HD^+ (v = 0–3, j = 1) using time-dependent quantum wave packet method calculations, and the results were in excellent accordance with the experiments. Xu et al.[5,14] calculated the total integral reaction cross section as a function of the collision energy in the range of 0–46.12 kcal/mol and the isotope effect of He + H_2^+/D_2^+/T_2^+ on the stereodynamics at a collision energy of 50 kcal/mol by use of the quasi-classical trajectory (QCT) calculation. It should be mentioned that Aquilanti and co-workers[15] constructed a new potential energy surface (PES) of the He + H_2^+ → HeH^+ + H reaction. The stereodynamics and vector correlation information of the He + H_2^+ → HeH^+ + H reaction on the new PES have been less reported on. In addition, sufficient systematic reports have not been reported on the reaction He + T_2^+ → HeT^+ + T.

In recent years, the QCT method has played a key role in the study of molecule dynamics because of its precision and simplicity, especially the stereodynamics information.[11,16–31] As a consequence, we theoretically studied the He + T_2^+ → HeT^+ + T reaction using the QCT method.



In this work, we will discuss the vector correlations of the reaction and the influence of reagent rotation states on the reaction by use of the QCT method on a new PES.[15] In our calculations, we set the reagent initial vibrational number (v) as 0, and the rotational quantum number (j) as 0–3. A collision energy of 3 eV was chosen. Apart from these, a batch of 10 000 trajectories was run and the integration step was chosen to be 0.1 fs.

Theoretical and computational method

The center-of-mass (CM) frame was chosen, in which the z axis was parallel to the reagent relative velocity **k** and the y axis was perpendicular to the x–z plane containing **k** and **k′**.

The fully correlated CM angular distribution is written as the sum[32–34]

Fig. 1. The center-of-mass coordinate system used to describe the **k**–**k′**–**j′** correlation.

$$[1]\qquad P(\cos\theta, \cos\theta_r, \phi_r) = \frac{1}{4\pi}\sum_{k=0}^{\infty}\sum_{q=-k}^{k}(2k+1) \times \frac{2\pi}{\sigma}\frac{d\sigma_{kq}}{d\omega}C_{kq}(\theta_r, \phi_r)$$

where $\omega = \theta$, ϕ and $\omega_r = \theta_r$, ϕ_r refer to the coordinates of the unit vectors **k′** and **j′** along the direction of the product relative velocity and rotational angular momentum vectors in the CM frame, respectively, and $C_{kq}(\theta_r, \phi_r)$ are modified spherical harmonics. $\frac{1}{\sigma}\frac{d\sigma_{kq}}{d\omega}$ represents the generalized polarization-dependent differential cross sections (PDDCSs).[32,35–40]

The PDDCSs are written as follows:

$$\frac{2\pi}{\sigma}\frac{d\sigma_{k0}}{d\omega} = 0$$

when k is odd,

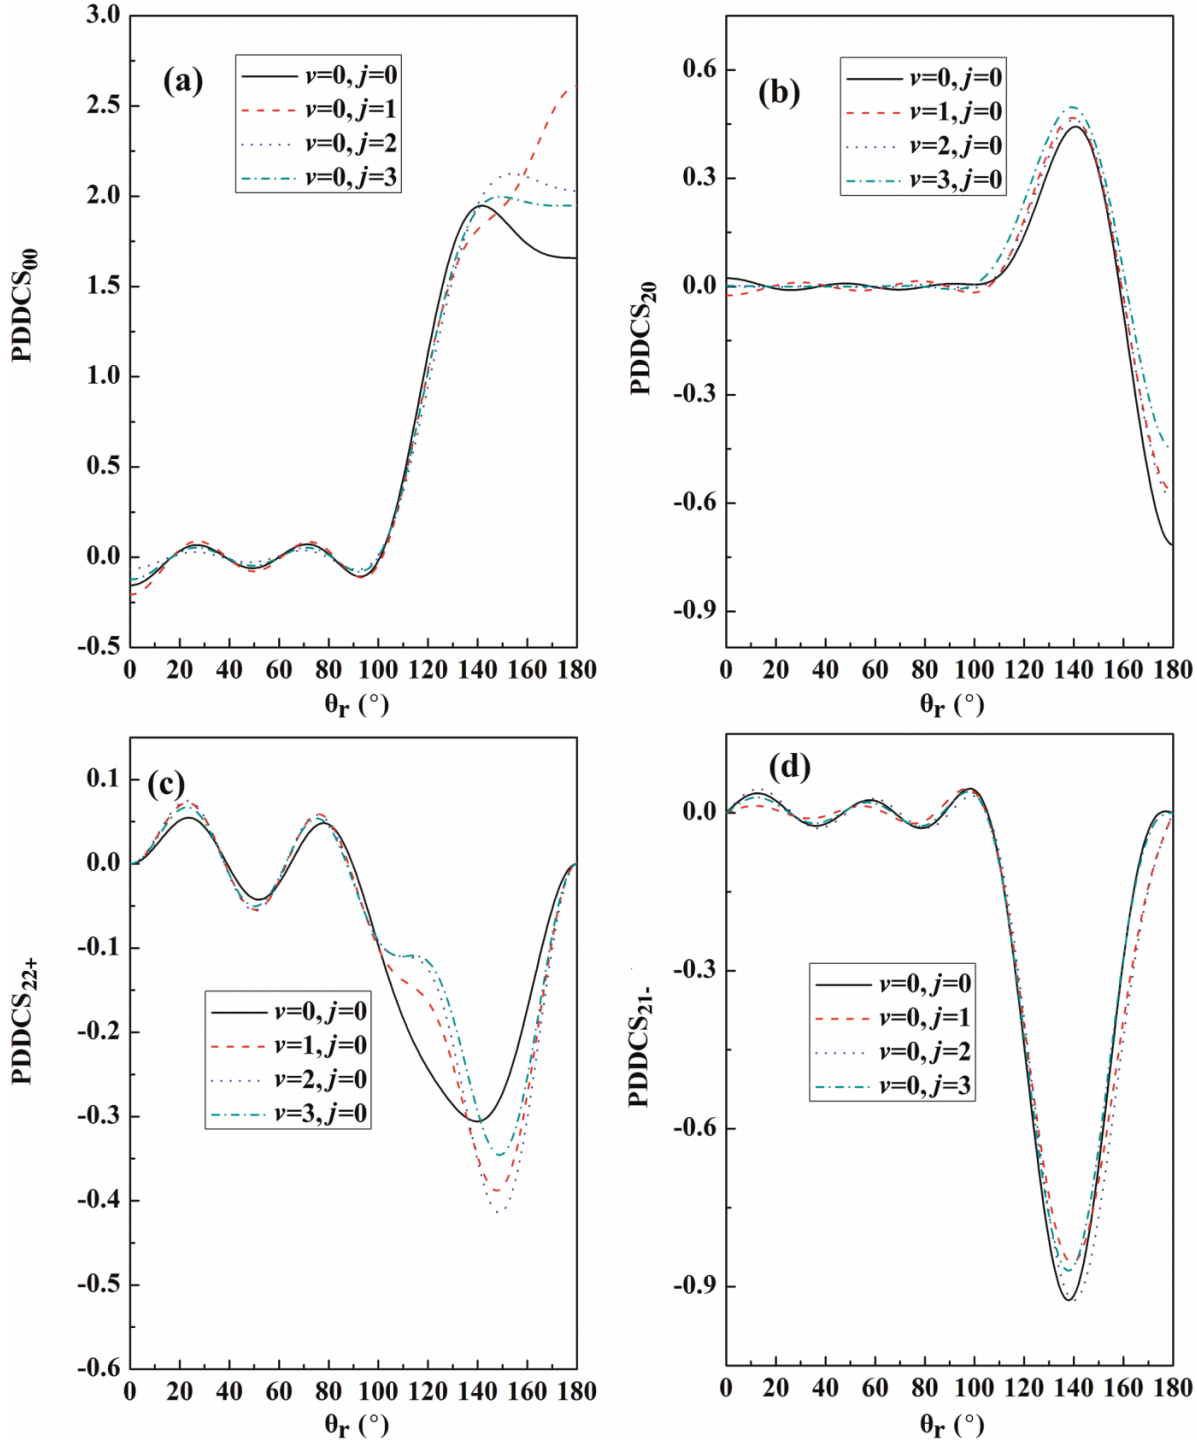
$$\frac{2\pi}{\sigma}\frac{d\sigma_{kq+}}{d\omega} = \frac{2\pi}{\sigma}\frac{d\sigma_{kq}}{d\omega} = \frac{2\pi}{\sigma}\frac{d\sigma_{k-q}}{d\omega} = 0$$

when k is even, q is odd or k is odd q is even, and

$$\frac{2\pi}{\sigma}\frac{d\sigma_{kq-}}{d\omega} = \frac{2\pi}{\sigma}\frac{d\sigma_{kq}}{d\omega} - \frac{2\pi}{\sigma}\frac{d\sigma_{k-q}}{d\omega} = 0$$

when k and q are even or k and q are odd. We also can summarize it as[1,37,40,41–48]

$$[2]\qquad \frac{2\pi}{\sigma}\frac{d\sigma_{kq\pm}}{d\omega} = \sum_{k_1}\frac{[k_1]}{4\pi}S^{k_1}_{kq\pm}C_{k_1-q}(\theta, 0)$$



where $[k_1] = 2k_1 + 1$ and $S^{k_1}_{q\pm}$ can be expressed as

$$[3]\qquad S^{k_1}_{kq\pm} = \langle c_{k_1q}(\theta, 0)c_{kq}(\theta_r, 0)[(-1)^q e^{iq\phi_r} \pm e^{-iq\phi_r}]\rangle$$

Two vector correlations (**k**–**j′**, **k**–**k′**, or **k′**–**j′**) can be expanded into a series of Legendre polynomials (Fig. 1).[49–52] The $P(\theta_r)$ distribution corresponding to the **k**–**j′** correlation is written as

Fig. 2. Calculated polarization-dependent differential cross sections (PDDCSs) of the He + T_2^+ reaction at different initial states. (*a*) Indicating the $PDDCS_{00}$ of different rotational quantum numbers (from 0 to 3) at vibrational number 0. (*b*) Indicating the $PDDCS_{20}$ of different rotational quantum numbers (from 0 to 3) at vibrational number 0. (*c*) Indicating the $PDDCS_{22+}$ of different rotational quantum numbers (from 0 to 3) at vibrational number 0. (*d*) Indicating the $PDDCS_{21-}$ of different rotational quantum numbers (from 0 to 3) at vibrational number 0.

$$[4] \qquad P(\theta_r) = 1/2\sum_k [k] a_0^k P_k(\cos\theta_r)$$

The a_0^k coefficients (polarization parameters) are given by

$$a_0^k = P_k(\cos\theta_r)$$

The brackets represent an average over all the reactive trajectories. The dihedral angle distribution of the **k**–**k**′–**j**′ three-vector correlation is characterized by the angle $P(\theta_r)$. The distribution of the dihedral angle $P(\phi_r)$ could be expanded as a Fourier series

Can. J. Chem. Downloaded from www.nrcresearchpress.com by Renmin University of China on 09/02/12
For personal use only.

$$[5] \quad P(\phi_r) = \frac{1}{2\pi}\left(1 + \sum_{n\geq 2}^{\text{even}} a_n \cos n\phi_r + \sum_{n\geq 1}^{\text{odd}} b_n \sin\phi_r\right)$$

with a_n and b_n given by

$$a_n = 2\langle \cos n\phi_r \rangle$$

$$b_n = 2\langle \sin n\phi_r \rangle$$

In this work, convergence results were obtained when $P(\phi_r)$ was expended up to $n = 24$.

The joint of probability density function of angles θ_r and ϕ_r, which define the direction of $\mathbf{j}'$, can be written as

$$[6] \quad P(\theta_r, \phi_r) = \frac{1}{4\pi}\sum_{kq}[k]a_q^k C_{kq}(\theta_r, \phi_r)^* = \frac{1}{4\pi}\sum_k\sum_{q\geq 0}[a_{q\pm}^k \cos q\phi_r - a_{q\mp}^k i \sin q\phi_r]C_{kq}(\theta_r, 0)$$

The parameter a_q^k is evaluated as

$$[7] \quad a_{q\pm}^k = 2\langle C_{k|q|}(\theta_r, 0)\cos q\phi_r \rangle \quad k \text{ is even}$$

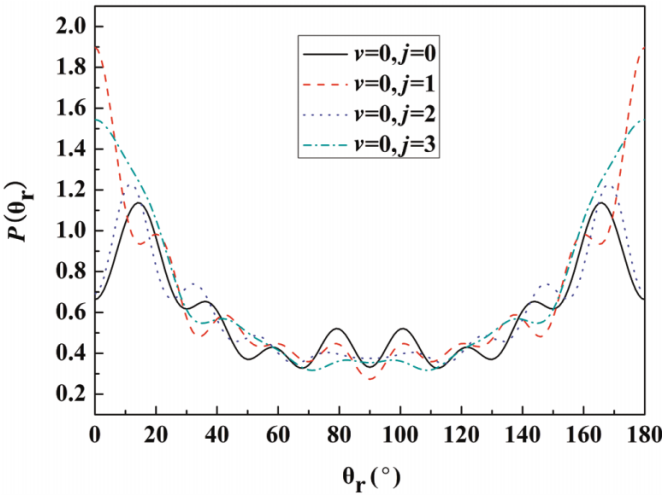
$$[8] \quad a_{q\pm}^k = 2i\langle C_{k|q|}(\theta_r, 0)\sin q\phi_r \rangle \quad k \text{ is odd}$$

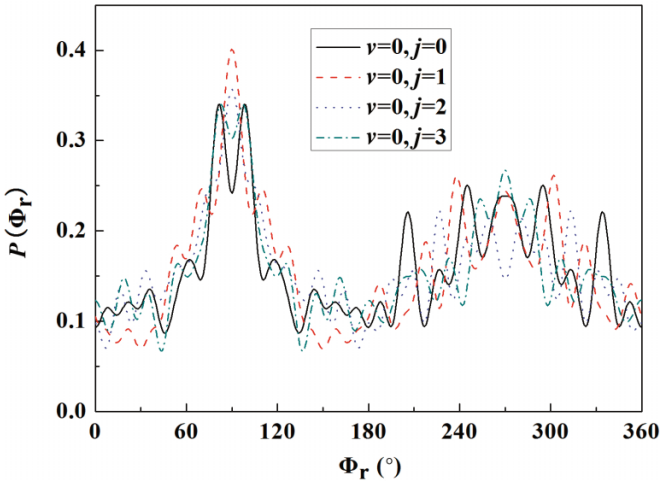
During the calculation, $P(\theta_r, \phi_r)$ was expanded up to $k = 7$, which was sufficient for good convergence.

Results and discussion

Figure 2*a* presents the PDDCS ($(2\pi/\sigma)(d\sigma_{00}/d\omega_t)$), which is proportional to the general differential cross section (DCS). The PDDCS is not involved in the orientation and alignment effect of product angular momentum, however, it can give us the scattering direction of the product in this reaction or we can say that it describes the correlation of **k**–**k**′. From Fig. 2*a*, we can draw the conclusion that the product of this reaction is dominated by backward and sideways scattering. Comparing the different $PDDCSs_{00}$ of various j values, the forward and sideways scattering directions of the product are nearly unrelated to the rotational quantum numbers, whereas the backward scattering shows slight changes when the rotational quantum number increases. The PDDCS $(2\pi/\sigma)(d\sigma_{20}/d\omega_t)$ is shown in Fig. 2*b*, which represents the expectation value of the second Legendre moment $\langle P_2(\cos\theta)\rangle$. In addition, the $PDDCS_{20}$ is not opposite to the distribution of $PDDCS_{00}$, but it can tell us that the product angular momentum is strongly polarized in backward and sideways scattering directions. This phenomenon is different from the reaction He + H_2^+.[5] What has caused this difference remains to be further discussed, but we may also ascribe it to the mass factors according to ref. 22 or the properties of the new PES. It indicates that $\mathbf{j}'$ is preferentially polarized along the direction perpendicular to **k** at $\theta_t = 180°$ (θ_t is the angle between **k** and **k**′). It can be seen from Figs. 2*c* and 2*d* that all PDDCSs with $q \neq 0$ equal 0 at $\theta_t = 0°$ and 180°, and the PDDCSs

Fig. 3. Comparisons of the calculated angular distribution of $P(\theta_r)$ at different initial quantum states. The vibrational number is equal to 0 and the rotational quantum numbers range from 0 to 3.





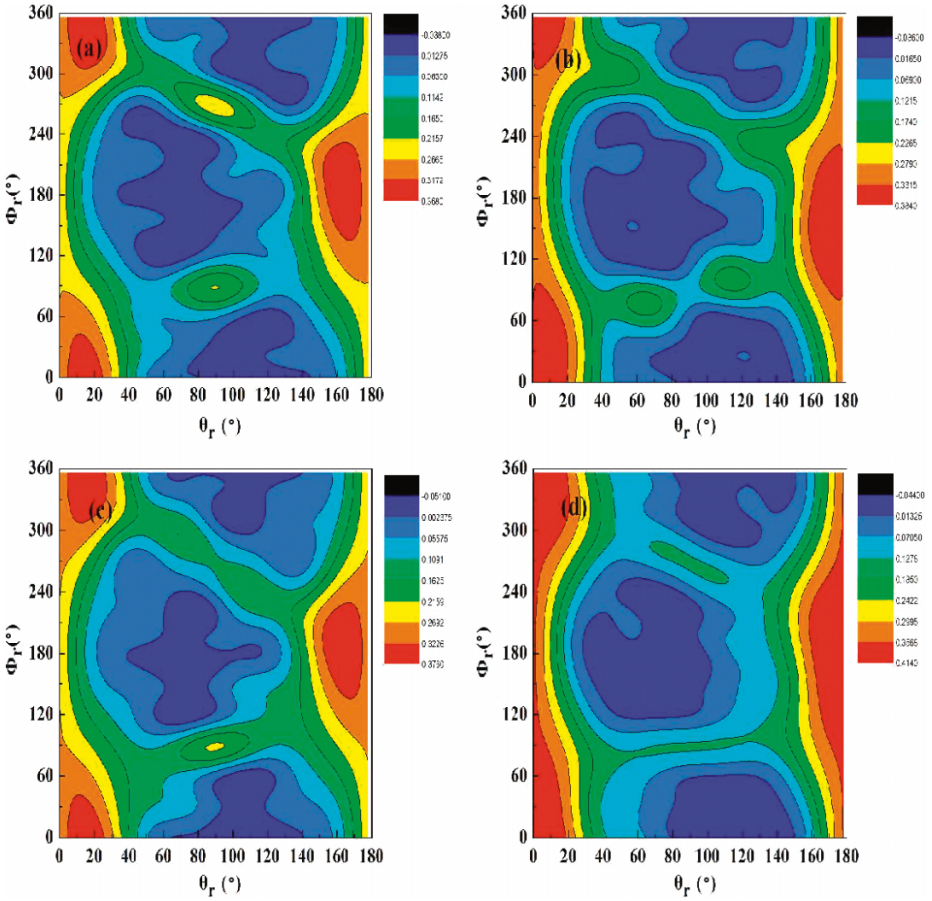


Fig. 4. The dihedral angle distribution of product rotational momentum $\mathbf{j}'$ regarding the **k**–**k**′ plane at different states of different rotational quantum numbers when the vibrational number equals 0, reflecting the correlations of **k**–**k**′–$\mathbf{j}'$.

$(2\pi/\sigma)(d\sigma_{22+}/d\omega_t)$ are nonzero at other majority portions of the scattering angles. However, the PDDCSs $(2\pi/\sigma)(d\sigma_{21-}/d\omega_t)$, which are related to $\langle \cos\theta_r \sin\theta_r \sin\phi_r \rangle$, are close to 0 when θ_t <100° and θ_t >170°. We can see that the $PDDCS_{22+}$ and $PDDCS_{21-}$ are both peaking at about θ_t = 140°. Moreover, as can be seen from (Fig. 2*d*), the polarization trends of the reaction in different initial states is displayed consistently. In addition, the distributions of the PDDCSs exhibit a trend of independence of the variation of j. What is interesting is that the PDDCSs ($q \neq 1$) are all different from the ones of the He + H_2^+/HD^+ reactions and presents different dynamical behaviors. The product of the former reaction is mainly backward and sideways scattered, however, the latter is mainly forward scattered[5] and the product angular momentum is strongly polarized in the backward and sideways scattering directions, whereas the product angular momentums of the latter reactions are forward scattered.

Fig. 5. Polar plots of the $P(\theta_r,\phi_r)$ distribution averaged over all scattering angles at each initial state. (*a*) Expression of the initial state $v = 0$, $j = 0$. (*b*) Expression of the initial state $v = 0$, $j = 1$. (*c*) Expression of the initial state $v = 0$, $j = 2$. (*d*) Expression of the initial state $v = 0$, $j = 3$.

For the reaction He + T_2^+, we also plot the $P(\theta_r)$ distribution in Fig. 3. Figure 3 clearly illustrates that the $P(\theta_r)$ distribution is symmetric with respect to 90° owing to the planar symmetry of this system. However, the peaks are not at the same angle. The peaks of the distribution $P(\theta_r)$ ($v = 0$, $j = 0$, 2) are at approximately 10° and 170°, whereas the peaks of the distribution $P(\theta_r)$ ($v = 0$, $j = 1$, 3) are both at 0° and 180°. The distributions $P(\theta_r)$, which represent the **k**–**j′** correlation, suggest that the product angular momentum vector is aligned along different directions relative to **k**. When the rotational quantum number is 0 or 2, the product rotational angular momentum is not aligned along a stationary direction, but could be aligned along the perpendicular, parallel, or opposite direction to **k**. Nonetheless, for the $v = 0$, $j = 1$, 3 states, the peaks at 0° and 180° demonstrate that the product rotational angular strongly aligns along the direction parallel and opposite to **k**.

Figure 4 shows the distributions of $P(\phi_r)$ in different quantum states. In this figure, a common feature exists for the $P(\phi_r)$ distributions in that they are prone to being asymmetric with respect to about $\phi_r = 180°$ (the scattering **k**–**k′** plane), with two distinct peaks emerging at $\phi_r = 90°$ and 270°. The peaks at 90° and 270° provide us with the information that the product tends to align along the direction of the *y* axis, which is perpendicular to the scattering plane. However, the differences between the peaks at 90° and 270° can be seen. Since the peaks at 90° are apparently stronger than the peaks at 270°, a conclusion can be mapped out that the products of the reaction of different *j* and $v = 0$ are not only aligned, but also oriented along the positive direction of the *y* axis. As well, the peak at 270° implies a preference for left-handed product rotation in planes parallel to the scattering plane; certainly, the peak at 90° indicates a preference for the right-handed product rotation. According to ref. 17, we will use the term "in-plane" to refer to this preference of the product rotating in the planes parallel to the scattering direction and the term "out-of-plane" to refer to the preference of the product rotating in planes parallel to the scattering plane simultaneously. With increasing *j*, no apparent variations were observed. That is to say, the product of the reaction He + T_2^+ ($v = 0$, $j = 0$–3) tends to right-hand rotate in planes parallel to the scattering plane.

The fact that the distribution $P(\phi_r)$ remains unchanged implies that the stereodynamic properties of this reaction at $v = 0$ are nearly independent of the rotational quantum number *j*. Figure 5 depicts the product angular momentum polarization in the form of polar plots θ_r and ϕ_r, which corresponds to the spatial distribution of the product rotational angular momentum. The spatial distribution is expressed by $P(\theta_r, \phi_r)$ distribution averaged over all scattering angles. What can we see from Fig. 5 is that, in regard to the reaction He + T_2^+ ($v = 0$, $j = 0$), the distribution of the $P(\theta_r,\phi_r)$ peaks is not only at

(90°, 90°), but also at (90°, 270°). They are in good agreement with the distributions of $P(\theta_r)$ and $P(\phi_r)$ of the products. However, Figs. 5*b* and 5*c* have a obvious distribution at around (90°, 90°) and a weak distribution at around (90°, 270°), and Fig. 4*d* has a relatively obvious distribution at around (90°, 270°) with a weak one at around (90°, 90°). They are also in good accordance with disributions of $P(\phi_r)$ and $P(\theta_r)$ of the products.

Conclusion

In this paper, the reaction He + T_2^+ (v = 0, j = 0–3) → HeT^+ + T has been theoretically calculated by use of the QCT method on a new PES at a collision energy of 3 eV. We have plotted the distribution curves of $P(\theta_r)$, $P(\phi_r)$, and $P(\theta_r, \phi_r)$. By investigating the angular distributions and comparing the changes with respect to j, we find that they are insensitive to the rotational quantum number j. The product rotational angular momentum is not aligned along a stationary direction. This is in agreement with the ref. 14, in which the effect of the HeT^+ product alignment along the direction perpendicular to k becomes weaker. The distribution of $P(\phi_r)$ reveals that the product rotational angular momentum vector is preferentially oriented along the positive direction of the y axis. Furthermore, the PDDCSs are calculated at the same time and compared among different j values. They demonstrate that the product of this reaction is dominated by backward and sideways scattering. In addition, they also perform an independent behavior on the initial rotational quantum number.

Abstract: In this study we report on the preparation of Ni(II), Pd(II), Co(II), and Cu(II) complexes with H2cdsalen (methyl-2{*N*-[2-(2′-hydroxyphenyl)methylidenenitrilo]ethyl}amino-1-cyclopentenedithiocarboxylate)salicylaldehyde. The products were characterized using 1D NMR (^{1}H and ^{13}C) and 2D NMR (COSY, NOESY, and ROESY) techniques. The conformational studies of the complexes with Ni and Pd in solution have been performed with help of the nuclear Overhauser effect (NOE) and 2D ROESY experiments.

Key words: ROESY, conformational, H2cdsalen.

Résumé : On a effectué la préparation de complexes du Ni(II), Pd(II), Co(II) et Cu(II) avec le (méthyl-2-{*N*-[2-(2′-hydroxyphényl)méthylidènenitrilo]éthyl}amino-2-cyclopentènedithiocarboxylate)salicaldéhyde, H2cdsalen. Les produits ont été caractérisés par des techniques de RMN 1D du ^{1}H et du ^{13}C et de RMN 2D (« COSY », « NOESY », « ROESY »). On a réalisé des études conformationnelles des complexes du Ni et du Pd en solution en faisant appel à des mesures de l'effet Overhauser nucléaire (EON) et du « ROESY » 2D.

Mots-clés : ROESY, conformationnelle, H2cdsalen.

Introduction

The coordination compounds of transition metals have had great impact on numerous branches of science, from catalysis,[1–5] medicine,[6–10] or analytical chemistry[11–14] to the design and construction of materials with new properties (structural composites and metalloproteins).[15–18]

Recently, these synthetic and structural properties, in particular those of 2-amino 1-cyclopentene 1-carboxylic acid (ACDA) and its coordination derivatives, were studied.[19–21] In particular, the metal complexes of N- or S-alkylated ACDA derivatives have attracted considerable attention because of the specific bonding formed, which depends on the nature of the metallic core. The ACDA complexes with different transition metals have exhibited remarkable diversity in their coordination.[22] The steric orientation of the functional groups in the ACDA allows the formation of six-membered ring chelates with the metal, which is perhaps responsible for biological activity such as the antifungal action that is demonstrated by ACDA.[23] Because of its structure and chelating behavior, the ACDA molecule has been applied in vast domains for the determination of the ultra traces of the concentrations for metals such as copper, cadmium, nickel, and cobalt in water solutions of different origins, via flocculation or spectrophotometric analysis.[24–27] Thus, coordination compounds derived from ACDA play an important role, both biological and chemical, and it becomes interesting to study the influence of changing their binders and (or) coordination metals.

In this framework, our research group has studied the synthesis and conformational studies of metallic complexes from ACDA derivatives, mainly with the help of NMR.

Results and discussions

The ACDA (**2**) was prepared from cyclopentanone (**1**) through the methodology previously reported by Takeshima et al.[28] and purified by the Nag procedure.[29] The methylation of the obtained ACDA derivatives (**2**) using dimethyl sulfate under basic conditions yielded compound **3**, which immediately

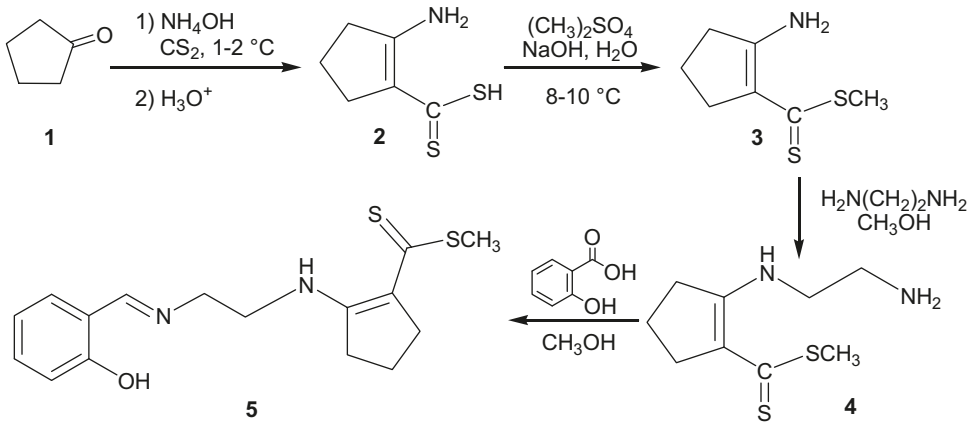
Scheme 1. Methodology for obtaining the H2cdsalen (methyl-2{*N*-[2-(2′-hydroxyphenyl)methylidenenitrilo]ethyl}amino-1-cyclopentene-dithiocarboxylate) (**5**).



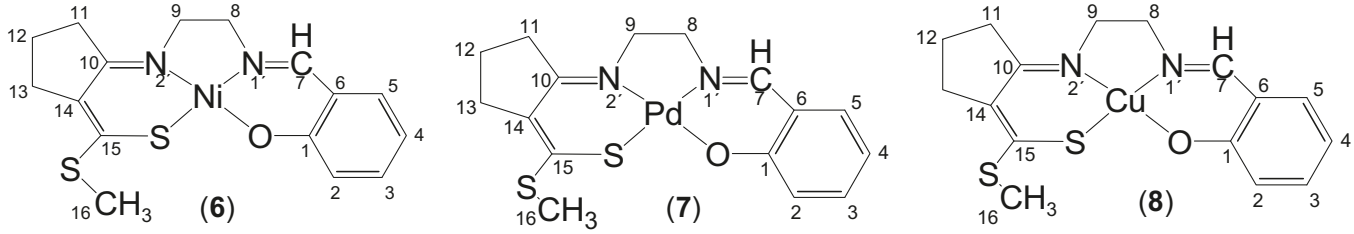


Fig. 1. Conformation proposed for complexes **6**–**8**.

reacted with diethylamine to produce the derivate **4**. Finally, the ligand **5** (H2cdsalen) was obtained through the reaction of amine **4** with salicylic acid (Scheme 1).

The synthesis of complexes **6**–**8** (Fig. 1) was realized using the Pereira methodology[30] with minor (Scheme 2) variations in the reaction conditions such as temperature and reaction time (see Experimental).

According to the literature,[31–33] it was possible to assume a square plane conformation for all four compounds synthesized, like the one shown in Fig. 1. The final conformations of the compounds as identified by the NMR ROESY experiments are consistent and fully agreed with a square-planar geometry.

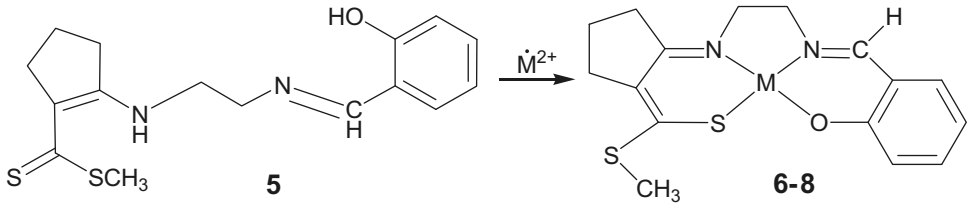
Conformational studies

Since the derivatives **6**–**8** (Fig. 1) may be of some synthetic and structural interest, detailed studies of the structural properties, through the central metal and the peripheral moieties occurring in such compounds, was necessary.

To obtain more information on these structures, we performed conformational studies of the Ni(II), Pd(II), and Cu (II) complexes with H2cdsalen (methyl-2{*N*-[2-(2′-hydroxyphenyl)methylidenenitrilo]ethyl}amino-1-cyclopentenedithiocarboxylate derivatives, through the 2D NMR experiments (NOESY and ROESY).

First, Hcdsalen **5** and the molecules **6**–**8** were carefully identified using the usual high-resolution 1D and 2D NMR and techniques, which are shown in the Experimental section. Although these assignments are rather consistent and unambiguous, they will be briefly commented upon.

The high-resolution ^{1}H NMR spectrum ($CDCl_3$, 500 MHz) of H2cdsalen **5** (Supplementary data) showed the hydrogen on the methylene cyclopentane's C11, C12, and C13 at δ 1.84, 2.70, and 2.75 ppm, respectively, the singlet at δ 2.57 ppm was assigned to the hydrogen from the methyl dithioate moiety; the hydrogen from the methylene's C8 and C9 attached at the nitrogen atom appear at δ 3.71 and 3.84 ppm. In addition, we observed the aromatic protons from phenol at δ 6.85 (1H;C4), δ 6.95 (1H;C2), and 7.25 (1H;C5); a sharp singlet at δ 8.39 was assigned to the hydrogen's imine and two broad singlets at δ 12.38 and 12.85 ppm was assigned to the amine and alcohol moieties, respectively.



The high-resolution ^{1}H NMR spectrum ($CDCl_3$, 500 MHz) for complex **6** (see Fig. 1) shows a sextuple signal at δ 1.84 ppm for the methylene C12, a triple signal for the methylenes on C11 and C13 at δ 2.49 and 2.63 ppm, respectively. A singlet signal at δ 2.68 was assigned to the methyl dithioate. The signals for the methylenes on C8 and C9, both joined to a nitrogen atom, were assigned to δ 3.25 and 3.53 ppm, respectively. The aromatic protons of the phenol were designated in a multiple signal at δ 6.49 ppm (1H, C4), a double signal at δ 6.81ppm (1H, C2), a triple signal at δ 7.06 ppm (H1, C5), and a double from double signal at δ 7.13 ppm (1H, C3). Finally, the hydrogen from the imine was a single signal at δ 7.7 ppm.

Besides a few reports on the synthesis of these complexes (**6**–**8**),[24–30] there are not many studies related to their spatial behavior. For this very reason, we decided to perform a 2D NMR conformational study for these molecules, for example, the dipolar interactions between key protons through the space, using phase-sensitive NOESY and ROESY experiments.

Initially, a larger chemical shift difference between the protons of the imine in the H2cdsalen (**5**) and the imine in the compound **6** (δ 1.26) was observed, suggesting that the

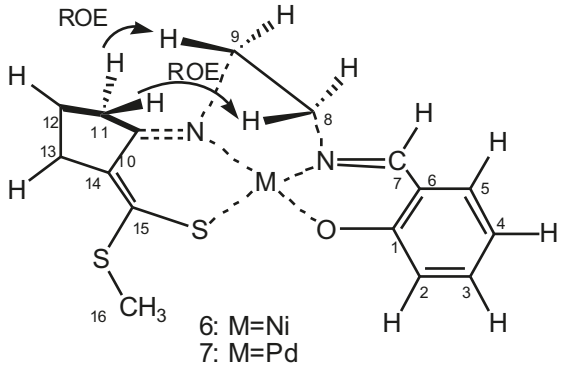
Scheme 2. Complex formation. M: Ni, Pd, and Cu.

proton in **6** at δ 7.13 suffered diamagnetic shielding owing to the formation of a complex between the nickel and the ligand H2cdsalen (**5**). In addition, the signals for the hydrogens in the phenyl ring are shown at high frequency, this spectroscopic behavior is in accordance with the formation of complex **6**. The spectroscopic behavior for complex **7**, through the NMR spectroscopy, was similar.



The conformational behavior of the derivatives **6–8** was then studied with help of the ROESY experiment. An interesting observation about the conformational study by the 2D NMR ROESY is the interaction between the methylene hydrogen from the cyclopentane and the methylene hydrogen in the lateral chain for the nickel and palladium compounds (Fig. 2). Unfortunately, it was not possible to obtain similar good quality 2D NMR ROESY spectra for the complex with copper. Nevertheless, it was possible to identify compound **8** through a crystal structure, showing a planar square conformation (see the Supplementary data).

For **6** in particular, the ROESY experiment (Fig. 3) shows two different interactions in space between the methylene hydrogen on C11 from the cyclopentane and the methylene hydrogen in the lateral chain on C8 and C9. This interaction is only possible if the methylene on C11 from the cyclopentane is placed out of the plane formed by the carbons C10–C14 in the same cyclopentane (see Fig. 3). In other words, the preferred conformation of this molecule is in an envelope, which is observed in some cyclopentane derivates. In addition, Bereman and co-workers[34,35] reported a distortion in the square-planar conformation for complexes containing Ni(II). This observation could be explained by the proximity of the hydrogen in the methylenes C8 and C9 and the hydrogen on C11 from the cyclopentane.

The shift for the methylene C11 with respect to methylene in the ligand is observed at 0.24 ppm high frequency, which supposes that the positive diamagnetic term increases because of its proximity to the methylenes C8 and C9. These methylenes (C11, C8, and C9) are the cornerstone of the conformational study of the metal–H2cdsalen (**5**) complexes, as its interaction in the ROESY experiment are the tools for understanding their behavior in solution.

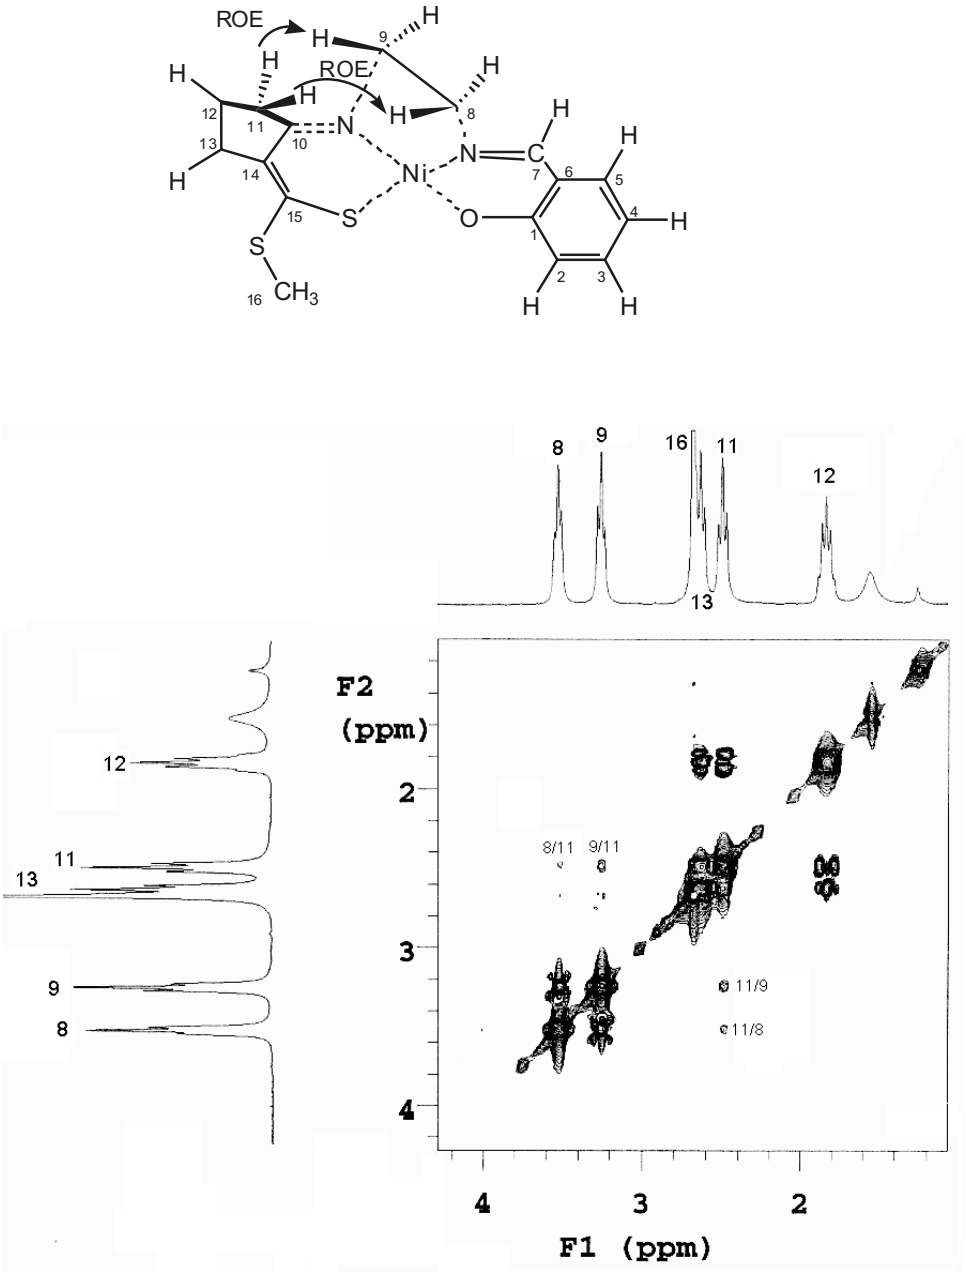
For derivative **7**, its ROESY spectra experiment resembled the one observed for compound **6** (Fig. 4). The dipolar correlation between protons on C11/ C9, as well as the one observed for C11/C8, again suggested an envelope conformation for the cyclopentane moiety of these molecules. In other words, the carbons C10, C12, C13, and C14 are in a plane; whereas the hydrogen on carbon C11 is out-of-plane. According to the Bereman observations and interactions in the ROESY experiment, it is possible to propose a behavior for this family of metal complexes with H2cdsalen (**5**).

Fig. 2. Conformational behavior of Ni(II) and Pd(II) complexes with methyl-2{*N*-[2-(2′-hydroxyphenyl)methylidenenitrilo]ethyl}amino-1-cyclopentenedithiocarboxylate.

Conclusions

We were able to establish from a complete conformational behavior study of the Ni(II) and Pd(II) complexes with H2cdsalen (**5**) that their preferred conformation is an envelope for the cyclopentane moiety. The spatial proximity between the hydrogen on the methylene, carbons C8 and C9, with the hydrogen on the methylene C11 from the cyclopentane confirmed this observation.

Finally, the 2D NMR ROESY is a useful tool and important in the conformational study of small molecules. The information obtained from this experiment about the deviation from the fully planar conformation of these molecules enabled us to better understand the behavior of these complexes, which is important for determining their biological role and possible applications.



Experimental

Materials and physical measurements

All compounds used for the synthesis of the ligand and the complexes were purchased from Sigma-Aldrich and used without further purification. The ACDA,[13] Hcden,[5] and H_2cdsalen (**5**)[14] were synthesized by methods reported in the literature. Infrared spectra were recorded in the range 4000 to 400 cm^{-1} on a Nicolet FT-IR 510 spectrometer as KBr powder. The ^1H and ^{13}C spectra were recorded on a Varian Unity 10 for routine experiments and Varian Unity 500 spectrometers for 2D experiments (COSY, NOESY, and ROESY). The ^1H and ^{13}C chemical shifts (δ) are given in ppm relative to TMS as the internal standard (0.00 ppm). The mass spectra were recorded on a JEOL JMS-AX505HA via the EI/PI mode (70 eV; 200 °C direct probe for ligands) and fast atom bombardment ionization (FAB PI) was used for the complexes. Only molecular or protonated molecular ions (*m*/*z*) values are reported.

Abstract: Employing a stochastic model, both Planck and Fokker proposed almost a century ago that stoichiometric chemical reactions proceed by a chain mechanism involving discrete reaction steps. To determine whether such a chain mechanism was in fact a valid mechanism for chemical reactions was the subject of a recent study (Garfinkle, M. 2002. *J. Phys. Chem.* **106A:** 490). Using a thermodynamic–probabilistic algorithm the stochastic reaction paths were found to be in excellent agreement with the observed reaction paths plotted from experimental data. This study was then extended to test the conclusions of Ehrenfest and Prigogine that a chain mechanism dictates that the number of discrete reaction steps required for a chemical reaction to attain equilibrium must be finite. The stochastic and empirical reaction paths were compared using experimental data for first-, second-, and third-order reactions as well as fractional order reactions. The empirical verification was excellent.

Key words: chemical thermodynamics, irreversible thermodynamics, reaction kinetics, mass action, natural path.

Résumé : En se basant sur un modèle stochastique, Plank et Fokker ont tous les deux proposé indépendamment, il y a pratiquement un siècle, que les réactions chimiques stoechiométriques se produisent par un mécanisme en chaîne impliquant des étapes réactionnelles distinctes. Un travail récent (Garfinkle, M. 2002. *J. Phys. Chem.* **106A:** 490) a été réalisé pour déterminer si un tel mécanisme en chaîne est un mécanisme valide pour les réactions chimiques. Sur la base d'un algorithme thermodynamique–probabilistique, on a trouvé que les voies réactionnelles stochastiques sont en excellent accord avec les voies réactionnelles observées sur la base de graphiques obtenus à partir de données expérimentales. Cette étude a alors été étendue pour vérifier la véracité des conclusions de Ehrenfest et Prigogine à l'effet qu'un mécanisme en chaîne impose un nombre déterminé d'étapes réactionnelles distinctes nécessaires pour qu'une réaction chimique atteigne un équilibre. On a comparé les voies réactionnelles stochastiques et empiriques à l'aide de données expérimentales pour des réactions d'ordre un, deux et trois ainsi que pour des réactions d'ordres fractionnaires. La vérification empirique est excellente.

Mots-clés : thermodynamique chimique, thermodynamique irréversible, cinétique réactionnelle, action de masse, voie naturelle.

[Traduit par la Rédaction]

Introduction

Classically, the progress of chemical reactions have been described by the empirical rate equations, first elucidated by Guldberg and Waage (see ref. 1) a century and a half ago. Their approach was strictly deterministic and depended on chemical concentrations. Its great success is testimony to its power to describe the reaction mechanisms involved in complex chemical reactions. The present study involves a parallel approach in which the chemical affinity, rather than the chemical concentrations, is used in describing the progress of chemical reactions. It is this thermodynamic–probabilistic approach that is described herein.

This study is a sequel to a work[2] describing the reaction path of homogeneous chemical reactions by a thermodynamic–probabilistic analysis. The agreement between the probabilistic and empirical reaction paths was excellent and is evident from the reaction plots of first-, second-, and third-order reactions as well as fractional order reactions including a 2/3 order free-radical chain mechanism.

The original analysis was then extended to elucidate the expected time to attain chemical equilibrium. Whether in fact this expected time required to attain equilibrium is quantifiable for chemical processes has been a subject of intense discussion for well over a century. Planck and Fokker (see refs. 3 and 4) concluded that the expected time was quantifiable. In contrast, chemical kineticists generally assert that the expected time to reach chemical equilibrium is infinite in accordance with the empirical rate equations first formulated by Guldberg and Waage,[1] a conclusion contrary to that arrived at by other investigators, including Prigogine et al.[5] and Ehrenfest and Ehrenfest.[6]

Equilibrium can be defined as a state whose microscopic properties are time-invariant, but this definition does not preclude microscopic fluctuations about the mean value of these properties. Boltzmann[7] argued that the energy probability

distribution in an isolated system is itself an almost periodic function of time that never repeats itself. Hence, some displacement must always be present between a system approaching equilibrium and a state defined as equilibrium by virtue of its canonical distribution. In contrast, Prigogine et al.[5] argued that as long as the system has a finite volume encompassing a finite number of particles then the energy distribution must in time attain the canonical form. This would be in agreement with the statistical model of chain processes developed by Planck and Fokker (see refs. 3 and 4) and extended by Ehrenfest and Ehrenfest.[6]

From either of these arguments equilibrium is a special state that can be reached in either a finite time or not at all, depending on the investigator's proclivities. It is this view of equilibrium that is disputed in this study. Equilibrium can be viewed as just one discrete state in a succession of discrete states originating with reaction initiation and ending with reaction completion. This equilibrium state is distinguishable only probabilistically from other discrete states. This view is substantiated from a comprehensive empirical analysis.

Chemical reactions classically have been perceived as systems of discrete reacting particles. In this regard consider the homogeneous stoichiometric chemical reaction

$$[1] \qquad \sum [\nu_m M_m]_{T,V} = 0$$

proceeding in a closed system at fixed temperature T and volume V from reaction initiation towards reaction equilibrium along a specific reaction path, wherein ν_m is the stoichiometric coefficient and M_m is the molecular weight of reacting component m, with $\nu_m < 0$ for reactants. The process proceeds in discrete reaction steps wherein a set of reactant particles transforms to a set of product particles in strict accordance with reaction stoichiometry.

Deterministic approach

According to the classical approach, chemical kinetics as a formal study began with the empirical rate equations a century and a half ago using the kinetic mass action law.[1] The great utility of this approach has developed over the years, particularly with our understanding of molecular dynamics.[8] According to this mechanistic–deterministic approach reaction mechanisms can be elucidated, revealing the reaction rates of the specific steps that comprise the overall reaction. According to this deterministic approach, the reaction rate or velocity $v = [\delta c_m/\delta t]_{T,V}$ is equated to some function of the component concentration (c_m) depending on reaction mechanism.

The transformation rate for each chemical species is expressed as concentration change per unit time with the rate dependent on the concentration of each particular species c_m in the reaction volume. According to this formalism the forward reaction rate (v_f) decreases from its initial ($t = 0$) value of $v_f = v_0$ as the reaction proceeds according to

$$[2a] \qquad v_f = k_f \Pi [c_r]^{\nu_m}$$

In contrast the reverse reaction rate (v_r) increases from its initial ($t = 0$) value of $v_r = 0$ as the reaction proceeds according to

$$[2b] \qquad v_r = k_r \Pi [c_p]^{\nu_m}$$

where k_f and k_r are the forward and reverse reaction rate constants, respectively, and c_r and c_p designate the concentration of reactants and products, respectively. The overall reaction rate (v) is simply the difference $v = v_f - v_r$ and equilibrium is defined as the state at which $v_f = v_r$.

Upon summation of eqs. [2*a*] and [2*b*] and integration of the resultant concentration terms, c_r and c_p always appear as a logarithmic function directly proportional to the elapsed time. By inserting the equilibrium values of the concentrations of reactants and products (c_{eq}) into the integrated equation the expected time to attain equilibrium t_K is determined and is always found to be infinite according to this logarithmic formulation: $t_K = \infty$. The mechanistic–deterministic equilibrium is thus a static state for which overall $v = 0$: a direct outcome of its logarithmic formulation.

Probabilistic approach

The great utility of this thermodynamic–probabilistic analysis is its ability to elucidate the overall energetics of homogeneous stoichiometric chemical reactions independent of reaction mechanism. In this regard, the present comprehensive probabilistic analysis was conducted to (*i*) confirm the viability of this probabilistic description of stoichiometric chemical reactions, (*ii*) verify the probabilistic results by a comprehensive empirical analysis, and (*iii*) examine the approach to chemical equilibrium in relation to this empirical analysis.

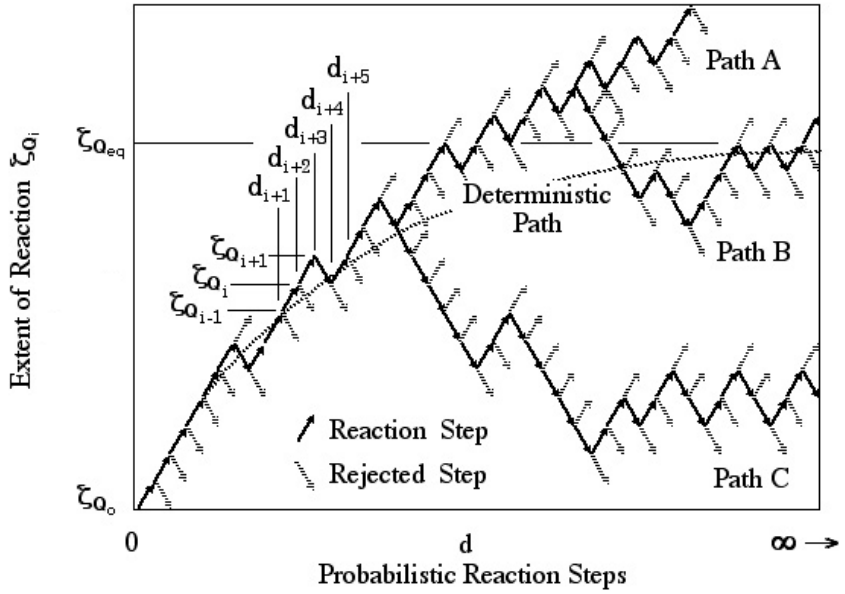
Recapitulating the previous analysis[2] wherein the description and detail of the terms used are found, consider a chemical reaction in which the activity ratio Q_i at any state i between reaction initiation and equilibrium is classically defined as

$$[3a] \qquad Q_i = \Pi [r_m]^{\nu_m} [p_m]^{-\nu_m}$$

The same formalism is used to describe the equilibrium constant K by Guldberg and Waage (see ref. 1) as

$$[3b] \qquad K = \Pi [r_m]_{eq}^{\nu_m} [p_m]_{eq}^{-\nu_m}$$

Taking the ratio of eq. [3*a*] to eq. [3*b*] establishes an extent-of-reaction term as $\zeta_{Q_i} \equiv Q_i/K$, where $0 \leq \zeta_{Q_i} \leq 1$, indicating reaction initiation at one extreme ($\zeta_{Q_i} = 0$) and equilibrium at the other ($\zeta_{Q_i} = 1$).[9,10]



With the extent-of-reaction term (ζ_{Q_i}) defined we can now consider a probabilistic approach to the expected time to attain equilibrium for a finite chain mechanism for a chemical reaction between discrete particles. This probabilistic analysis requires that certain conditions be met:

1. The isothermal, isochoric reacting system is homogeneous in that all reacting species are uniformly distributed in a single fluid phase.
2. The reacting system is closed in that there is no mass transfer between the reacting system and its surroundings.
3. The reacting system involves a transformation between reactants and products in a strictly fixed stoichiometric ratio.

These are in fact a formal expression of the ordinary conditions under which stoichiometric chemical reactions are

Fig. 1. Chain mechanism depicting transformations along several possible reaction paths.

generally observed. Consider now the approach to equilibrium.[11] The thermodynamic–probabilistic approach is based on the linear assumption

$$[4] \qquad p_{i,i\pm1} \propto \zeta_{Q_i}$$

between the probability for reaction $p_{i,i\pm1}$ from the present state (ζ_{Q_i}) to either the following states (ζ_{Q_i+1}) or the previous state (ζ_{Q_i-1}).[2]

The specific linear equations describing a probabilistic reaction path can be derived from the following boundary conditions. At reaction initiation ($\zeta_{Q_i} = 0$) for the forward reaction step, $p_{0,0+1} = 1$, and for the reverse reaction step, $p_{0,0-1} = 0$. At equilibrium ($\zeta_{Q_{eq}} = 1$) for both the forward and reverse reaction steps, $p_{eq,eq\pm1} = 1/2$.

Using these boundary conditions for the reaction steps, the forward reaction expression takes the form

$$[5a] \qquad p_{i,i+1} = 1 - 1/2\zeta_{Q_i}$$

and the reverse reaction expression takes the form

$$[5b] \qquad p_{i,i-1} = 1/2\zeta_{Q_i}$$

and, consequently, $p_{i,i+1} + p_{i,i-1} = 1$, as would be expected.[2]

The determination of the validity of eqs. [5*a*] and [5*b*] required empirical verification. To place the probability data in a form amenable to empirical analysis, the chemical affinity A_i — a function of state introduced by De Donder[12] to quantify the driving force for a chemical reaction — can be readily calculated from both the calculated and experimental extent-of-reaction data.

$$[6] \qquad A_i = -RT \ln \zeta_{Q_i}$$

Almost 100 stoichiometric chemical reactions were examined, the kinetic data having been obtained from literature compilations or directly from kineticists, and from which each of the required (A_i:t_i) coordinate pairs were determined, where reaction initiation is defined as the state at which ∞:0 and equilibrium at which 0:t_K. These reactions included those with highly complex mechanisms in gaseous as well as aqueous and nonaqueous solutions. The agreement between the probabilistic and empirical reaction paths were excellent and it is evident from the published reaction plots of first-, second-, and third-order reactions as well as fractional order reactions (including a 2/3 order free-radical chain mechanism in addition to halogen exchange reactions), cyanohydrin formation reactions, and third-order tris(dipyridyl) ion reactions; pretty much covering the whole gamut of stoichiometric reaction mechanisms.[2]

With the validity of eqs. [5*a*] and [5*b*] established, the expected time to attain equilibrium can now be addressed using this thermodynamic–probabilistic approach. Immediately, we confront a basic departure from the classical mechanistic–deterministic approach wherein equilibrium is described as an invariant or static state at which $v = 0$. This classical approach, however, harbors a major inconsistency. Although it is generally agreed that chemical reactions are discrete particulate processes, the empirical rate equations themselves are continuous functions with their derivation involving integration. This discrepancy renders extreme extrapolation ($v_f - v_r \rightarrow 0$) uncertain.

The probabilistic approach, in contrast to the deterministic approach, describes a purely discontinuous or stepwise process. According to this stochastic model, equilibrium is simply the state at which $\zeta_{Q_i} = 1$ and therefore $p_{eq,eq-1} \rightarrow p_{eq,eq+1}$; a probabilistic or dynamic state is represented by $p_{eq,eq-1} - p_{eq,eq+1} = 0$. Using this approach, the expected time to attain equilibrium can now be considered.

Statistical analysis

Because the extent-of-reaction ζ_{Q_i} is directly proportional to the probabilities, the extent-of-reaction will be referred to for the remainder of this analysis. For stoichiometric chemical reactions to be amenable to this probabilistic analysis requires that the reaction path to be followed conforms to certain conditions:

Can. J. Chem. Downloaded from www.nrcresearchpress.com by Renmin University of China on 09/02/12
For personal use only.

1. The process must be discontinuous in that it proceeds in discrete steps between specific states ζ_{Q_i} and $\zeta_{Q_i\pm1}$.
2. The process must be periodic in that the number of reaction steps ($\Delta_{i,i+n}$) between point d_i and d_{i+n} required to return to any state ζ_{Q_i} from any other state $\zeta_{Q_i\pm n}$ is a multiple of some positive integer.
    1. The process must be irreducible in that the probabilities $p_{i,i\pm1}$ associated with the transformation of any present (t_i) state ζ_{Q_i} to any future (t_{i+1}) state ζ_{Q_i+1} must be independent of any past (t_{i-1}) state ζ_{Q_i-1}.

These conditions are really a natural consequence of a discrete kinetic formalism, specifically, a Markov[13] chain mechanism: a discrete form of a generalized Markov process.[14] Such a process is illustrated schematically in Fig. 1. For comparison, the deterministic path is shown, which gradually approaches, but never quite reaches, a static equilibrium state at $\zeta_{Q_{eq}}$.

The probability of a reaction step occurring is always greater than a rejected step except at equilibrium, where the probabilities are equal. The number of steps along any of the three probabilistic paths A, B, or C shown required to return to any specified prior state are the same and, consequently, the chain is periodic. For example, several reaction steps are designated d_{i+1}, d_{i+2}, d_{i+3}, d_{i+4}, d_{i+5}, and so forth, for any arbitrary state *i*. Various possible paths are shown by which the reaction can pass from state ζ_{Q_i-1} through state ζ_{Q_i} to state ζ_{Q_i+1}. This chain is irreducible if the probabilities associated with reaching either of the successive states ζ_{Q_i-1} or ζ_{Q_i+1} are independent of the path traversed to reach the present state ζ_{Q_i}.

Each reaction state shown in Fig. 1 can be specified by the coordinates (ζ_{Q_i},d_i). In the sequence of steps from d_{i+1} to d_{i+5} the extent-of-reaction term ζ_{Q_i} alternates from ζ_{Q_i-1} to ζ_{Q_i} then to ζ_{Q_i+1} then backwards to ζ_{Q_i} and then forwards to ζ_{Q_i+1}. This sequence of steps is periodic because any path chosen between steps (ζ_{Q_i-1},d_{i+1}) and (ζ_{Q_i+1},d_{i+5}) will always have the same number of transformations (in this example, four).

As the reaction progresses forward from state ζ_{Q_0} along path B the forward-reaction probability $p_{i,i+1}$ diminishes from 1 to 1/2 from step d_0 to the approach to equilibrium according to eq. [5*a*] for $\zeta_{Q_i} \rightarrow 1$. Accordingly, at each state ζ_{Q_i} the probability for transition to a state closer to equilibrium (ζ_{Q_i+1}) is always greater than the probability for a transition further from equilibrium (ζ_{Q_i-1}), regardless of which side of equilibrium the present state (ζ_{Q_i}) is on. Hence, path B is simply the expected path. However, inasmuch as the model is probabilistic, the reaction need never reach equilibrium as is evident from the possible path C. The reaction can cycle between several states indefinitely, although such an occurrence is highly unlikely. Alternatively, the reaction path can deviate progressively further from equilibrium toward completion as shown in path A, but again such an occurrence is highly unlikely. It is only the expected path with which we are concerned.

The classical kinetic model of equilibrium is essentially steady state with opposite reaction velocities equal. Instead, according to this probabilistic approach, the equilibrium state is not static, but a state in which the opposite reaction *probabilities* are equal and, consequently, in a continuing state of transformation, as is any other state. The reaction deviates from equilibrium according to local probability with the equilibrium state as the only expected state. Rarely, if ever, is the system precisely in its equilibrium state and even then it is a passing occurrence.

The use of stoichastic methods to examine the behavior of particulate processes is decidedly not recent. In 1907, Ehrenfest and Ehrenfest[6] developed a statistical model of atomic diffusion using chains that was shown to be in accordance with experimental evidence. The development of chain processes to account for physical behavior was due to Planck and Fokker (see refs. 3 and 4) In all of these cases the expected time to attain equilibrium was finite ($t_K < \infty$). This being the case, the next requirement is to determine the expected number of transformations needed to attain equilibrium.

Dynamic equilibrium

A principal requirement in describing a probabilistic reaction path for a chemical reaction is to determine the expected number of transformations ($\Delta_{i,j}$) required for the reaction to transition from any step d_i for a ζ_{Q_i} to any other step d_j for a ζ_{Q_j}, where $\Delta_{i,j} = d_j - d_i$. We are particularly interested in the expected number of transformations ($\Delta_{i,eq}$) required to attain the equilibrium step d_{eq} from any previous step d_i.

If one knows the expected number of transformations to reach equilibrium from a given step d_i, then, by induction, the number of steps required to reach equilibrium from the previous step d_{i-1} depends on the probability that the previous step will reach the given state ζ_{Q_i}.

If $\Delta_{i,j}$ represents the expected number of transformations required to reach state ζ_{Q_j} from any state ζ_{Q_i}, then $\Delta_{i,eq}$ represents the expected number of transformations required to reach equilibrium step d_{eq} from any step d_i. Similarly, $\Delta_{i-1,eq}$ is the expected number of transformations required to reach equilibrium from step d_{i-1}, which can be defined recursively in terms of the probability of state transformation as

$$[7] \qquad \Delta_{i-1,eq} = 1 + p_{i-1,i}\Delta_{i,eq} + p_{i-1,i-2}\Delta_{i-2,eq}$$

where obviously

$$[8] \qquad \Delta_{eq,eq} = 0$$

Similarly, it is clear that for the initial condition

$$[9] \qquad \Delta_{1,eq} = 1 + \Delta_{0,eq}$$

and that for the final condition

$$[10] \qquad \Delta_{i,eq} = 1 + \Delta_{i-1,eq}$$

It is now necessary to simultaneously solve eqs. [7]–[10] for $\Delta_{i,eq}$ to determine the number of transformations to the equilibrium step d_{eq} from step d_i. The usual and most convenient method for the solution of these multiple simultaneous linear equations is through matrix algebra.[15] By combining these linear recursive relationships, the system of simultaneous equations can be rewritten as the stochastic matrix expression

$$[11] \qquad \mathbf{Md} = \mathbf{c}$$

In this form **M** is a square matrix that represents the coefficients of the simultaneous linear system of relationships

given by eqs. [7]–[10], with **d** representing the column vector of $\Delta_{i,\mathrm{eq}}$ (the expected number of transformations required to achieve equilibrium d_{eq} from state d_i) and **c** is the column vector of constants. However, to solve for **d** requires that matrix **M** be represented in Jordan canonical form[4] and therefore invertible ($\mathbf{M} \neq 0$). The Jordan canonical form (also called the classical canonical form) is a special type of a square matrix comprised of discrete Jordan blocks.[16] For a reaction capable of achieving $n + 1$ states d_0 through d_n, these stochastic matrices can be fully expressed as

$$[12] \quad \mathbf{M} = \begin{bmatrix} 1 & -1 & 0 & \dots & 0 & 0 & 0 & \dots & 0 & 0 & 0 \\ -p_{2,1} & 1 & -p_{2,3} & \dots & 0 & 0 & 0 & \dots & 0 & 0 & 0 \\ 0 & -p_{3,2} & 1 & \dots & 0 & 0 & 0 & \dots & 0 & 0 & 0 \\ \dots & \dots & \dots & \dots & \dots & \dots & \dots & \dots & \dots & \dots & \dots \\ 0 & 0 & 0 & \dots & 1 & -p_{\mathrm{eq}-1,\mathrm{eq}} & 0 & \dots & 0 & 0 & 0 \\ 0 & 0 & 0 & \dots & 0 & 1 & 0 & \dots & 0 & 0 & 0 \\ 0 & 0 & 0 & \dots & 0 & -p_{\mathrm{eq}+1,\mathrm{eq}} & 1 & \dots & 0 & 0 & 0 \\ \dots & \dots & \dots & \dots & \dots & \dots & \dots & \dots & \dots & \dots & \dots \\ 0 & 0 & 0 & \dots & 0 & 0 & 0 & \dots & 1 & -p_{n-2,n-1} & 0 \\ 0 & 0 & 0 & \dots & 0 & 0 & 0 & \dots & -p_{n-1,n-2} & 1 & -p_{n-1,n} \\ 0 & 0 & 0 & \dots & 0 & 0 & 0 & \dots & 0 & -1 & 1 \end{bmatrix}$$

and

$$[13] \quad \mathbf{d} = \begin{bmatrix} d_{1,\mathrm{eq}} \\ d_{2,\mathrm{eq}} \\ d_{3,\mathrm{eq}} \\ \dots \\ d_{\mathrm{eq}-1,\mathrm{eq}} \\ d_{\mathrm{eq},\mathrm{eq}} \\ d_{\mathrm{eq}+1,\mathrm{eq}} \\ \dots \\ d_{n-2,\mathrm{eq}} \\ d_{n-1,\mathrm{eq}} \\ d_{n,\mathrm{eq}} \end{bmatrix} \quad \mathbf{c} = \begin{bmatrix} 1 \\ 1 \\ 1 \\ \dots \\ 1 \\ 0 \\ 1 \\ \dots \\ 1 \\ 1 \\ 1 \end{bmatrix}$$

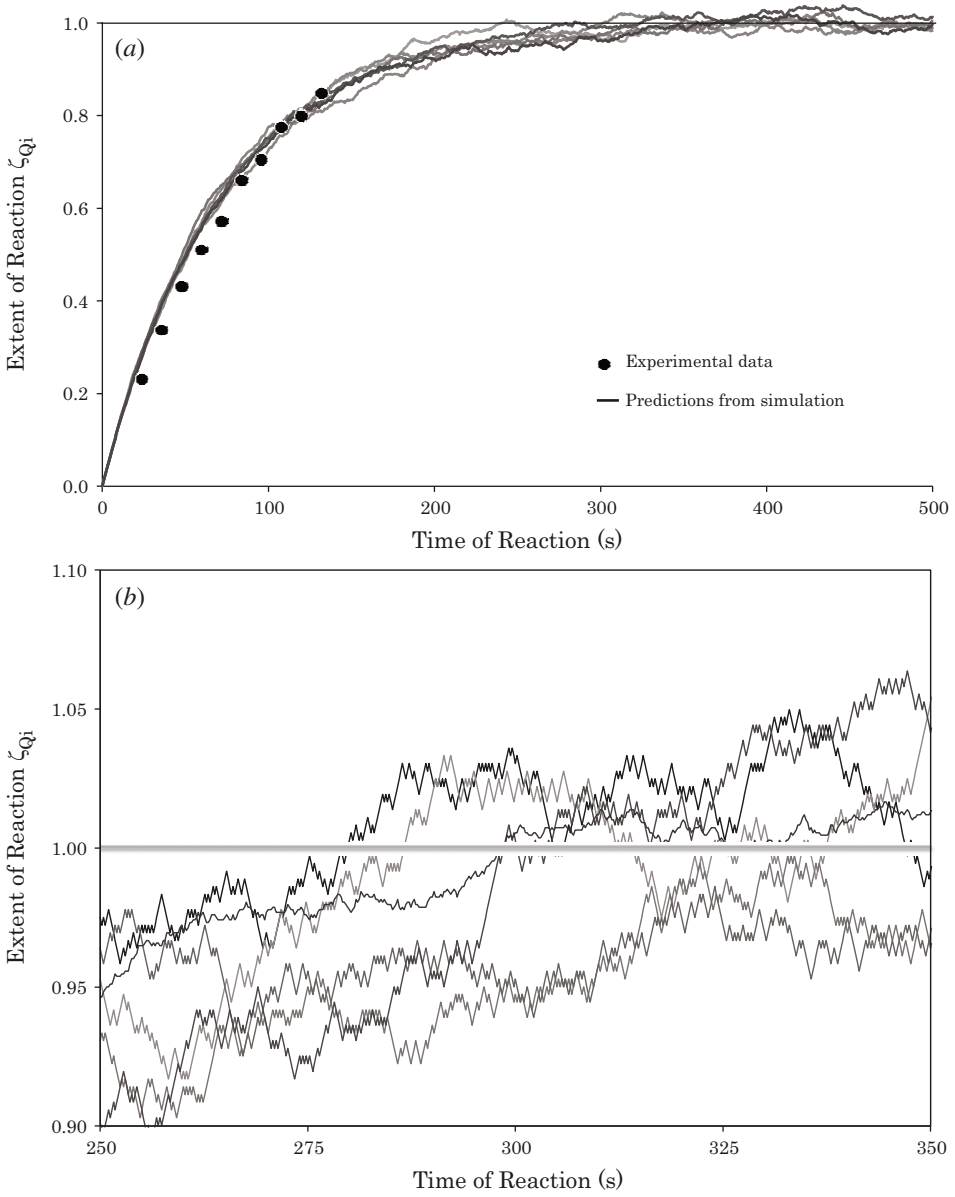
Thus

$$[14] \quad \mathbf{d} = \mathbf{M}^{-1}\mathbf{c}$$

Equation [14] is solvable because only a matrix with coefficients in an algebraically closed field can be represented in Jordan canonical form. Obviously **M** is in this form. The matrix is thus nonsingular and, therefore, the stochastic matrix **M** is in fact invertible ($\mathbf{M} \neq 0$). Consequently, of the well-defined solutions for $\Delta_{i,\mathrm{eq}}$, all indicate without exception that the expected number of transformations required for rxn. [1] at any state ζ_{Q_i} to attain the equilibrium state $\zeta_{Q_{\mathrm{eq}}}$ cannot be infinite. Thus

$$[15] \quad 0 < \Delta_{i,\mathrm{eq}} < \infty$$

Accordingly, for a system of discrete reacting particles the expected number of transformations($\Delta_{0,\mathrm{eq}}$) required for rxn. [1] to reach its equilibrium step d_{eq} from its initial step d_0 must be finite.



Elapsed time

Having established that the number of transformation steps required to attain equilibrium is finite, the expected time to attain equilibrium can now be considered. Because $\Delta_{0,\mathrm{eq}} < \infty$, the temporal progress of rxn. [1] can be expressed as a ratio $\Delta_{0,i}{:}\Delta_{0,\mathrm{eq}}$ between the number of steps required to reach any state i and the number required to reach the equilibrium state, where $\Delta_{0,i} < \Delta_{0,\mathrm{eq}}$. This ratio will now be related to the ratio of the elapsed time required to reach any state of the system (ζ_{Q_i}) to the expected time ($t_{0,\mathrm{eq}}$) required to attain equilibrium ($\zeta_{Q_{\mathrm{eq}}}$). Kineticists generally examine stoichiometric chemical reactions as interactions between chemical components as measured by concentration terms, but more precisely reaction rates are dependent on the chemical activities of the components rather than their concentrations. To circumvent this problem reactions are ordinarily observed under conditions of high dilution wherein partial pressures and concentrations closely approximate activities. Under these conditions of high dilution the relative number of collisions between reacting species in the reaction volume is insignificant compared with the total number of elastic collisions between all species present (diluent and reactant), and hence does not effect the overall collision rate. The accepted interpretation is that the Maxwell–Boltzmann energy distribution is not significantly disturbed by the meager number of reaction collisions.[17,18] Accordingly, because the overall collision rate is invariant at constant temperature, so must be the number of reaction collisions $\Delta_{i,i+n}$ per unit time from any step d_i to step d_{i+n}. Consequently, the elapsed time ($\mathrm{t}_{i,i+n}$) between each collision must be equally constant. Hence,

$$[16a] \quad t_{0,n} \propto \Delta_{0,n}$$

Inasmuch as the number of steps to attain equilibrium is finite, so must be the expected time to attain equilibrium, denoted $t_{0,eq}$. Because the overall collision rate is constant, then from eq. [16*a*]

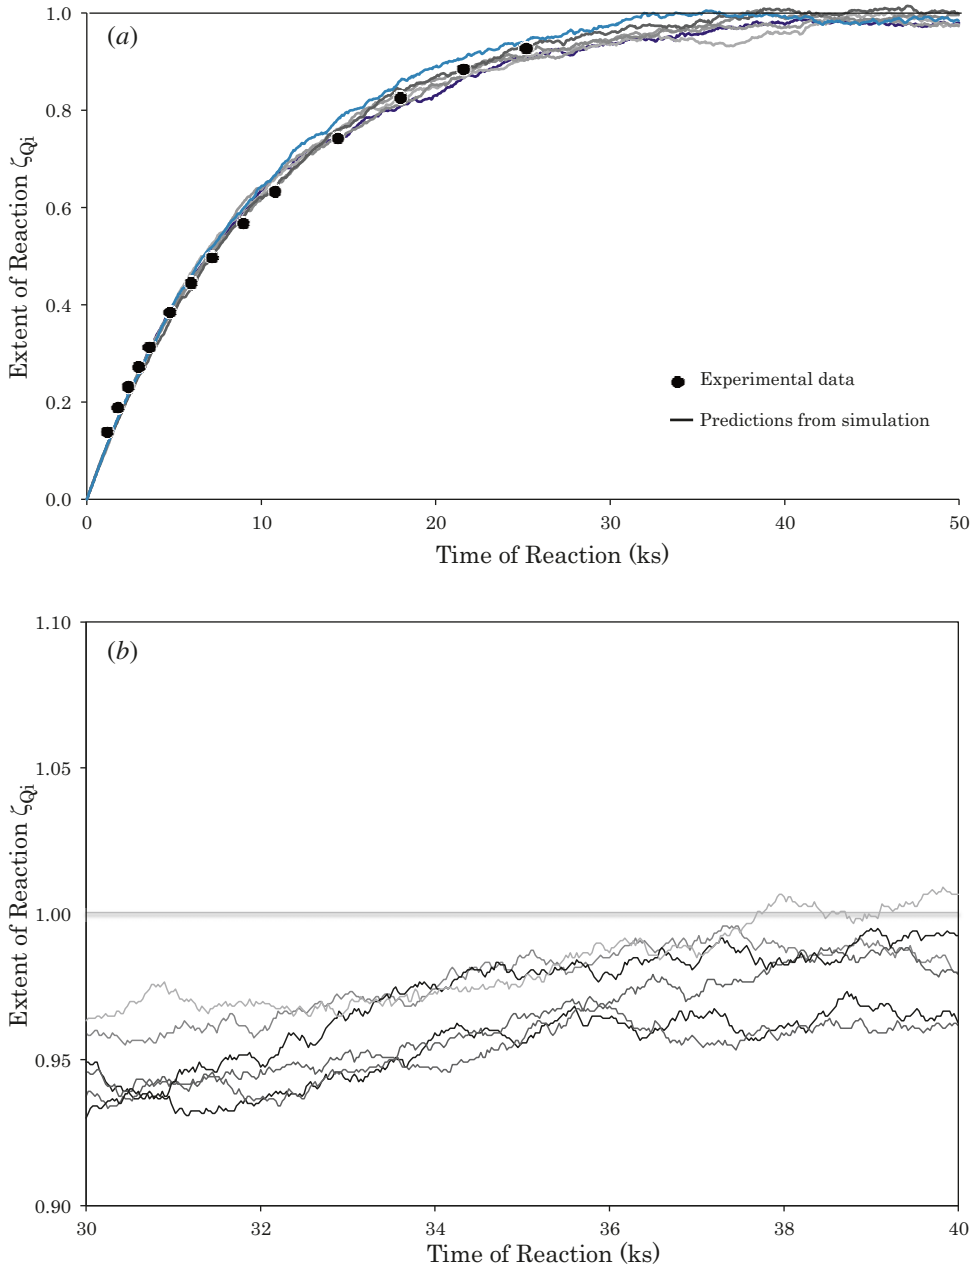
$$[16b] \qquad t_{0,eq} \propto \Delta_{0,eq}$$

Taking the ratio of eq. [16*a*] to eq. [16*b*], where $t \equiv t_{0,n}$ and $t_K \equiv t_{0,eq}$, yields

$$[17] \qquad t/t_K = \Delta_{0,n}/\Delta_{0,eq}$$

Only if $t_K < \infty$ would the ratio of the transformations $\Delta_{0,n}/\Delta_{0,eq}$ be meaningful.

Empirical validation



Although it is evident from this analysis that the expected time to attain equilibrium must be finite, the expected values of that elapse time must be probabilistic: it probably extends over an indeterminate, but finite range. To illustrate, consider the following empirical reaction data correlated by this probabilistic analysis according to eqs. [5*a*] and [5*b*] on approach to equilibrium. The probabilistic reaction paths were generated by an algorithm described in detail by Garfinkle[2] using a Microsoft Excel spreadsheet with an internal random-number generator. Thirty-six reaction plots were generated for each of the reactions cited and these were grouped into the six paths illustrated.

The reaction of styrene with iodine in carbon tetrachloride at 295 K is a highly complex process.[19]

$$[18] \qquad C_6H_5{-}CH{-}CH_2 + I_2 \rightarrow C_6H_5{-}CHI{-}CH_2I$$

The formation of styrene diiodide apparently involves both a free-radical chain mechanism that has a first-order dependency on iodine concentration and a 3/2 order dependency

Fig. 3. (*a*) Dehydrogenation of isobutane by iodine at 525 K. (*b*) Approach to equilibrium for the dehydrogenation of isobutane by iodine at 525 K.

on styrene concentration. The six reaction paths are illustrated in Fig. 2*a* with the empirical data points.

Figure 2*a* details the extrapolated reaction paths on approach to equilibrium, illustrating their probabilistic nature.

Apparently the time to attain equilibrium is >250 s. Probabilistically, however, equilibrium could be attained at any shorter time, but that time would not be the expected time.

The dehydrogenation of isobutane by iodine vapor at 525 K is exceedingly complex.

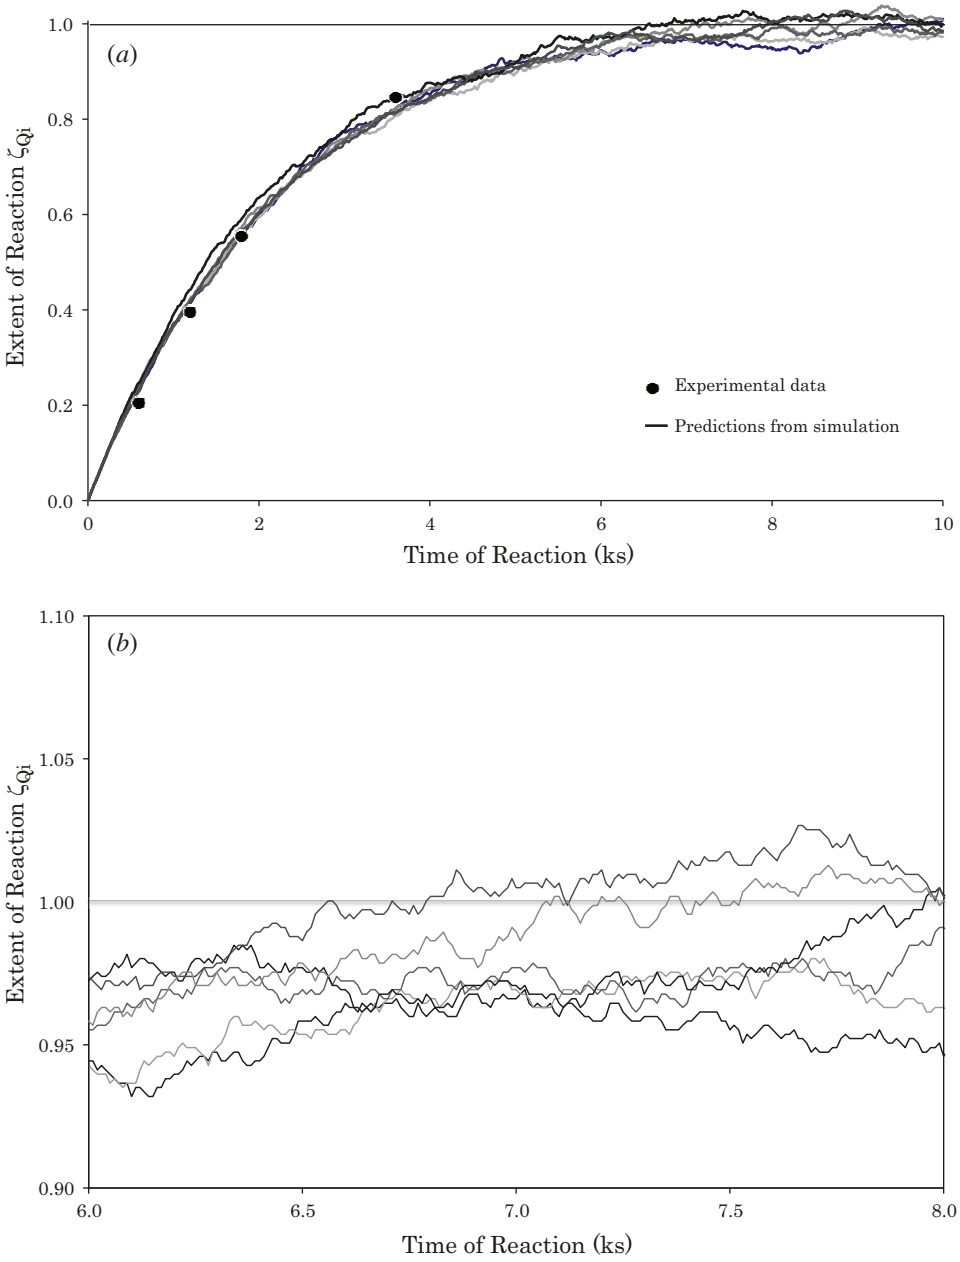
[19] $i\text{-}CH_6 + I_2 \rightarrow i\text{-}CH_4 + 2HI$

The reaction mechanism involves a free-radical chain reaction, with the postulated reaction rate depending on the equilibrium constant for iodine, where M is any molecule present.[20]

[20*a*] $I_2 + M \leftrightarrow 2I + M$

[20*b*] $i\text{-}BuH + I \rightarrow t\text{-}Bu + HI$

[20*c*] $t\text{-}Bu + I_2 \rightarrow t\text{-}BuI + I$



terminating in

[20*d*] $t\text{-}BuI \rightarrow i\text{-}Butene + HI$

It is immediately evident that the overall reaction rate depends on the concentrations of I_2 and HI molecules. The six

reaction paths are illustrated in Fig. 3*a* with the empirical data points.

Figure 3*b* details these six reaction paths on approach to equilibrium. Compare with Fig. 1.

The bromination of platinic ammonia chloride ion in KCl solution at 308 K is probably an elementary substitution reaction wherein

[21] $Pt(NH_3)Cl^+ + Br^- \rightarrow Pt(NH_3)Br^+ + Cl^-$

although an activated intermediate species is possibly involved.[21]

[22*a*] $Pt(NH_3)Cl^+ + Br^- \leftrightarrow Pt(NH_3)BrCl$

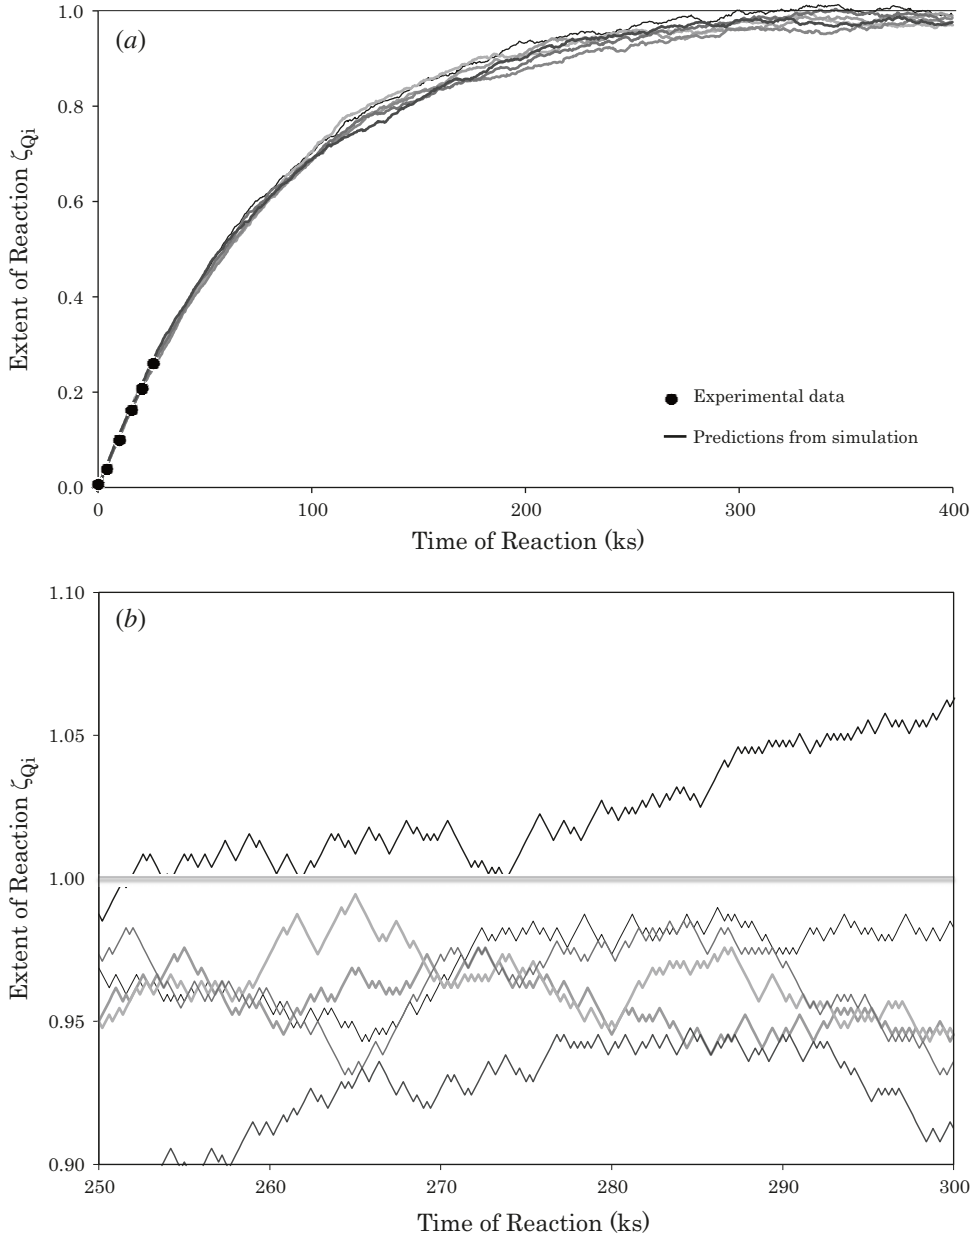
followed by

[22*b*] $Pt(NH_3)BrCl^{\ddagger} \rightarrow Pt(NH_3)Br^+ + Cl^-$

The six reaction paths are illustrated in Fig. 4*a* with the empirical data points. Figure 4*b* details these six reaction paths on approach to equilibrium.

Unexpectedly, the formation of acetone cyanohydrin in aqueous solution does not involve catalysis, as does many other such cyanohydrin formation processes.[22]

[23] $CH_3COCH_3 + HCN \rightarrow (CH_3)_2C(OH)CN$



Instead, the formation reaction is a two-step process following ionization of HCN

[24*a*] $HCN \leftrightarrow H^+ + CN^-$

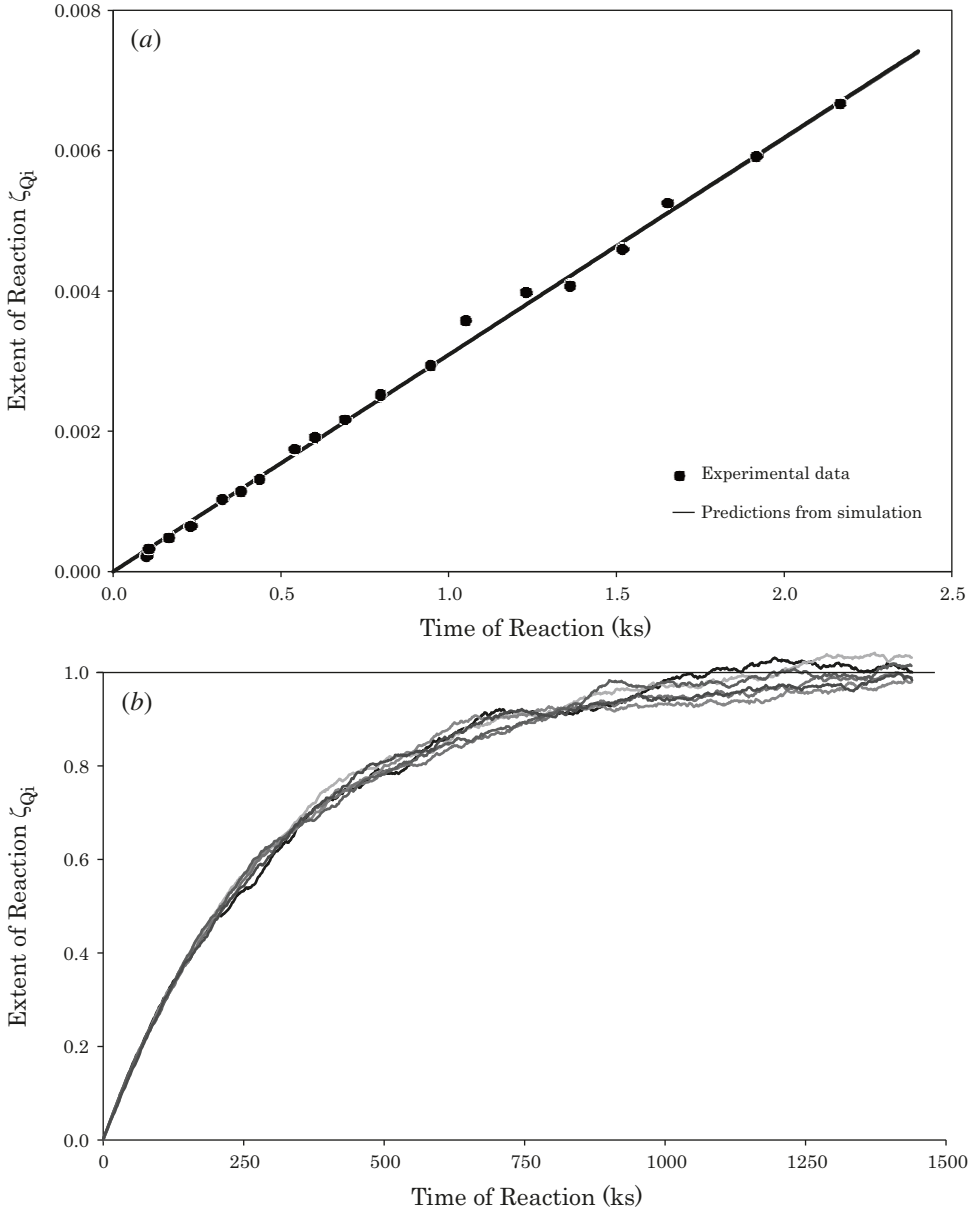
Fig. 5. (*a*) Formation of acetone cyanohydrin at 298 K. (*b*) Approach to equilibrium for the formation of acetone cyanohydrin at 298 K.

[24*b*] $CH_3COCH_3 + CN^- \rightarrow (CH_3)_3COCN^-$

[24*c*] $(CH_3)_3COCN^- + H^+ \rightarrow (CH_3)_3C(OH)CN$

with the slower reaction (eq. [24*b*]) controlling the overall reaction rate. The six reaction paths are illustrated in Fig. 5*a* with the empirical data points. Figure 5*b* details these six reaction paths on approach to equilibrium.

Discussion



The multiple reactions paths plotted for the various reactions considered are in accordance with the schematic paths shown in Fig. 1 that illustrate a Markov[13] chain mechanism. A chain mechanism dictates that the expected time to attain equilibrium or any other state will be finite, which is in agreement with the matrix-algebra analysis. It is evident from these data correlations that given sufficient time the extent-of-reaction ζ_{Q_i} will attain some equilibrium value in a finite time as a passing occurrence. To quantify that expected time is considerably more difficult inasmuch as it involves a range of values. The expanded plots show the reaction paths as $\zeta_{Q_i} \rightarrow 1$. Accordingly, the only conclusion that has any validity is that $t_K < \infty$, in agreement with the stochastic argument.

For example, consider the formation of nitrosyl chloride at 333 K, which ostensibly depends on ternary collisions that are estimated to be about 100 times as rare as binary collisions.[23]

[25] $2NO + Cl_2 \rightarrow 2NOCl$

Can. J. Chem. Downloaded from www.nrcresearchpress.com by Renmin University of China on 09/02/12
For personal use only.

Fig. 6. (*a*) Time dependency of the extent-of-reaction for the formation of nitrosyl chloride at 333 K. (*b*) Time dependency of the extent-of-reaction for the formation of nitrosyl chloride at 333 K.

However, the reaction can be explained by a two-stage bimolecular process.[24]

[26*a*] $NO + Cl_2 \rightarrow NOCl + Cl\cdot$

[26*b*] $NO + Cl\cdot \rightarrow NOCl$

The six reaction paths for the formation of NOCl are illustrated in Fig. 6*a*.

On extrapolation using eq. [5*a*], the expected time to attain equilibrium was just under 10^5 s as shown in Fig. 6*b* (just over a quarter of a day: a relatively short period).

Now consider the quasi-unimolecular decomposition of nitrous oxide at 858 K.[25]

[27] $2N_2O \rightarrow 2N_2 + O_2$

This process probably involves an activated molecule

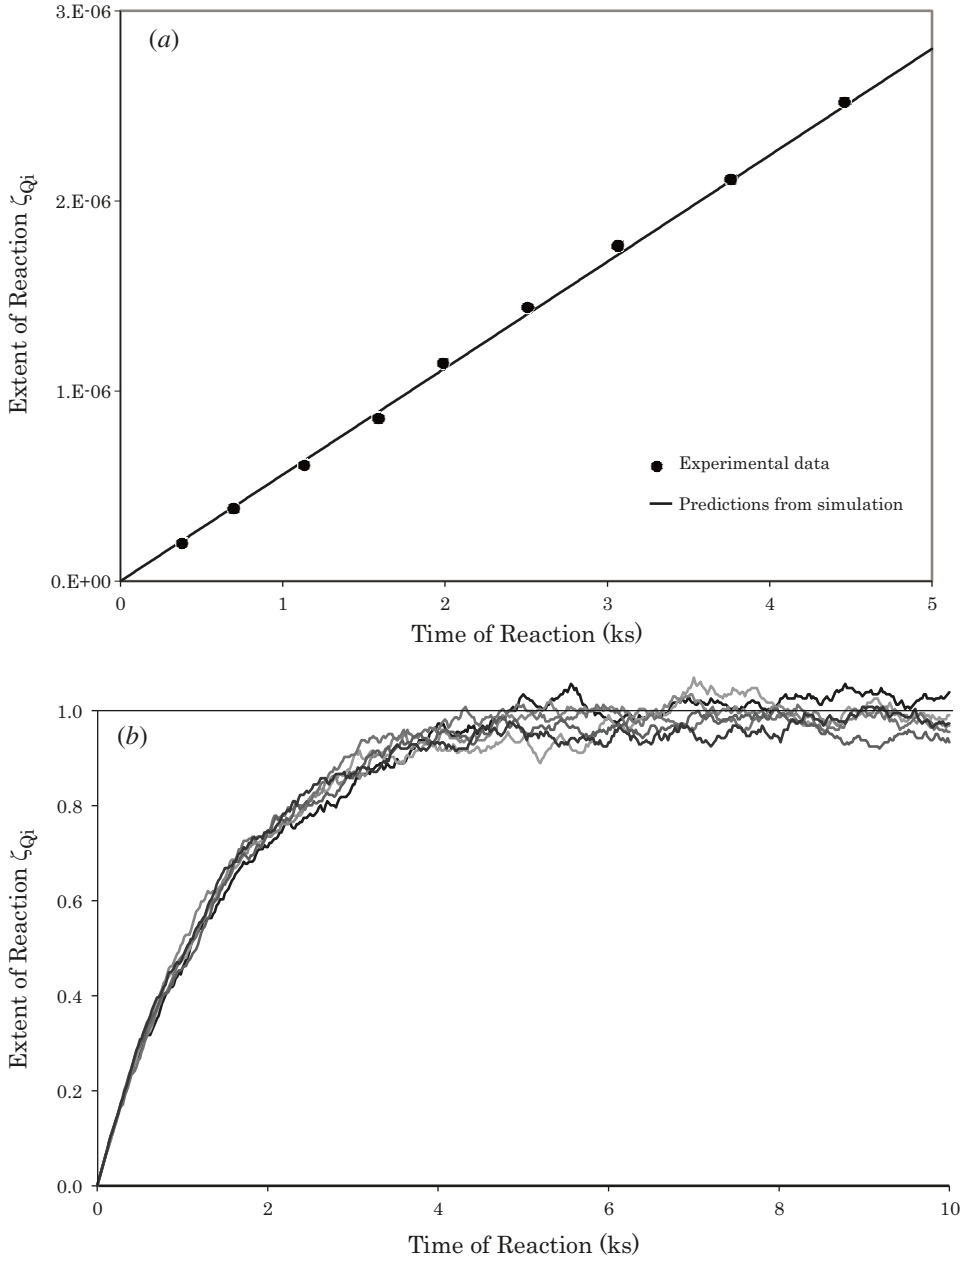
[28] $N_2O + M \rightarrow NO + N\cdot + M$

where M indicates collision activation. After activation, the probable sequence of steps is as follows:

[29*a*] $N\cdot + N_2O \rightarrow N_2 + NO$

The NO molecule then essentially drives the reaction

[29*b*] $NO + N_2O \rightarrow N_2 + O_2 + N\cdot$



that terminates as

[29*c*] $N\cdot + NO \rightarrow N_2O$

The six reaction paths with data points are shown in Fig. 7*a*.

Can. J. Chem. Downloaded from www.nrcresearchpress.com by Renmin University of China on 09/02/12
For personal use only.

Fig. 7. (*a*) Decomposition of nitrous oxide at 858 K. (*b*) Approach to equilibrium for the decomposition of nitrous oxide at 858 K.

On extrapolation using eq. [5*a*], the expected time to attain equilibrium was roughly 10^9 s, just over a century as shown in Fig. 7*b*: well over an average lifetime, but still well short of infinity.

Of course, for most of the almost 100 reactions examined[10] the expected time to attain equilibrium was far beyond any practical observation time, and in fact beyond many lifetimes. For example, consider the oxidation of Fe(II) by Co(III) in perchloric acid solution at 298 K.[26]

[30] $\mathrm{Fe(II) + Co(III) \rightarrow Fe(III) + Co(II)}$

The ostensibly simple mechanism is really quite complex and probably involves the initial reaction

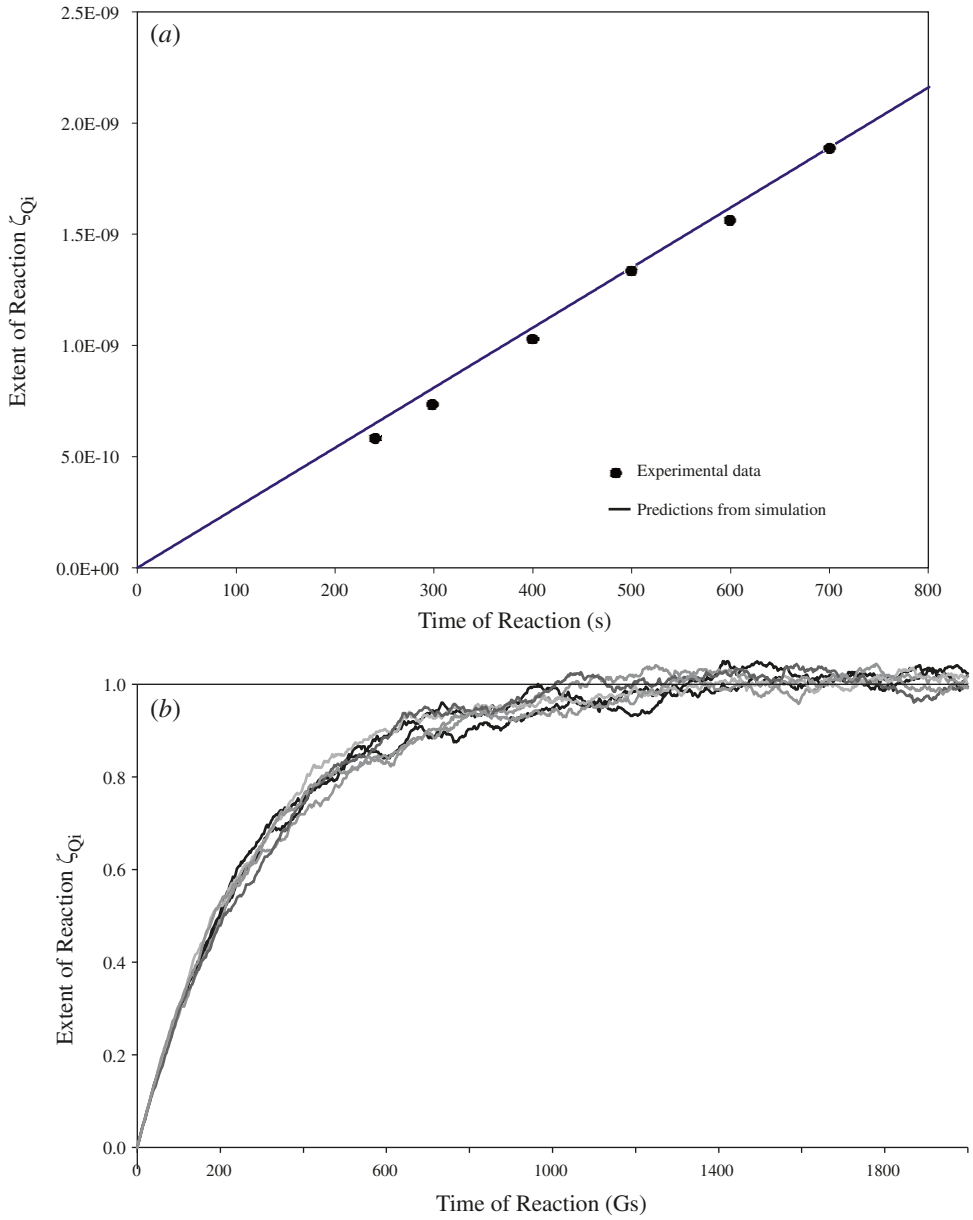
[31*a*] $\mathrm{Co^{3+} + OH^- \leftrightarrow CoOH^{2+}}$

followed by the hydroxyl transfer reaction

[31*b*] $\mathrm{Fe^{2+} + CoOH^{2+} \rightarrow FeOH^{2+} + Co^{2+}}$

and terminating in

[31*c*] $\mathrm{FeOH^{2+} \rightarrow Fe^{3+} + OH^-}$



The reaction path is shown in Fig. 8*a*.

On extrapolation using eq. [5*a*], the expected time to attain equilibrium is well over 10^{11} s. This duration is roughly 5000 years; while a significant duration, nevertheless a value still considerably shy of infinity.

Conclusion

This thermodynamic–probabilistic parallels the approach of Guldberg and Waage, but this thermodynamic approach

Fig. 8. (*a*) Time dependency of the extent-of-reaction for the oxidation of Fe(II) by Co(III) at 298 K. (*b*) Time dependency of the extent-of-reaction for the oxidation of Fe(II) by Co(III) at 298 K.

depends on a discrete algorithm in contrast with the deterministic approach of the emprical rate equations. Whereas the probabilistic approach has been successfully applied to physical processes, it has now been shown by this study that it is equally valid for chemical reactions. This approach demonstrates that stoichiometric chemical reactions proceed by a Markov chain mechanism towards equilibrium as formulated by Planck and Fokker and that the expected number of discrete reaction steps is finite as predicted by Ehrenfest and Prigogine. Because the elapsed time to attain equilibrium is directly proportional to the number of reaction steps, the elapsed time must be also finite.

Stereodynamics study of the $O^+ + D_2$ ($v = 0, j = 0–2$) → $OD^+ + D$ reaction

Jiawu Chen, Xinguo Liu, and Qinggang Zhang

Can. J. Chem. Downloaded from www.nrcresearchpress.com by Renmin University of China on 09/02/12
For personal use only.

Abstract: The vector correlations between products and reagents for the ion–molecule reaction $O^+ + D_2 \rightarrow OD^+ + D$ with different rotational quantum numbers ($j = 0$, 1, or 2) were explored theoretically using the quasi-classical trajectory method (QCT) on a Martìnez–Millán–González (MMG) surface. The three angular distributions $P(\theta_r)$, $P(\phi_r)$, and $P(\theta_r,\phi_r)$, as well as four polarization-dependent differential cross sections (PDDCSs) were calculated. The results indicate that a reagent's rotational excitation greatly influences both the vector correlations of **k**–**k**′, **k**–**j**′, and **k**–**k**′–**j**′ and the PDDCSs of the title reaction, which means the reactivity is very sensitive to the rotational quantum number.

Key words: vector correlation, quasi-classical trajectory (QCT), stereodynamics, rotational excitation, polarization-dependent differential cross sections.

Résumé : On a fait appel à la méthode de la trajectoire quasi-classique (TQC) sur une surface MMG pour étudier d'une façon théorique la corrélation des vecteurs entre les produits et les réactifs pour la réaction ion–molécule $O^+ + D_2 \rightarrow OH^+ + D$ avec différents nombres quantiques rotationnels ($j = 0$, 1, ou 2). On a calculé respectivement les trois distributions angulaires $P(\theta_r)$, $P(\phi_r)$ et $P(\theta_r,\phi_r)$ ainsi que les quatre sections droites différentielles qui dépendent de la polarisation (SDDDP). Les résultats indiquent que l'excitation rotationnelle du réactif influence grandement la corrélation des vecteurs de **k**–**k**, **k**–**j**′ et **k**–**k**′–**j**′ ainsi que les sections droites différentielles qui dépendent de la polarisation (SDDDP) de la réaction mentionnée dans le titre, ce qui signifie que la réactivité est très sensible au nombre quantique rotationnel.

Mots-clés : corrélation des vecteurs, trajectoire quasi-classique (TQC), stéréodynamique, excitation rotationnelle, sections droites différentielles qui dépendent de la polarisation (SDDDP).

[Traduit par la Rédaction]

Introduction

Ion–molecule reactions are important processes that occur in many interesting situations, such as electric discharges, planetary ionospheres, interstellar space, and so on.[1–3] Being a very important ion–molecule reaction, the $O^+ + H_2 \rightarrow OH^+ + H$ system plays a key role in H_2-rich interstellar chemistry and in the Earth's ionosphere. As an isotopic variant reactivity of $O^+ + H_2 \rightarrow OH^+ + H$, the reaction

$$O^+ + D_2 \rightarrow OD^+ + D$$

can be regarded as a prototypical three-atom reaction system in the field of ion–molecule reaction dynamics and has received considerable attention both experimentally and theoretically. One of the most fascinating aspects of the reaction is that it is a moderately exothermic ion–molecule reaction. The reaction $O^+ + H_2 \rightarrow OH^+ + H$ is particularly important in dense interstellar clouds, where subsequent reactions of OH^+ with H_2 lead to the formation of H_2O^+ and H_3O^+ molecular ions, which are very important substances.[4]

In 2004, Rodrigo et al.[5] constructed a most accurate potential energy surface (PES) for $O^+ + H_2 \rightarrow OH^+ + H$. Subsequently, there have been many theoretical and experimental studies for $O^+ + H_2 \rightarrow OH^+ + H$ and its isotopic variants. Using the quasi-classical trajectory method (QCT), Rodrigo et al.[5] studied many scalar properties of the above reaction, such as the cross section, maximum impact parameter, and the reaction probability of $O^+ + H_2 \rightarrow OH^+ + H$. The results of QCT are in excellent agreement with the experimental results taken from Burley et al.[6] Recently, Sun et al.[7] studied the isotope effect of stereodynamics at collision energies of 1.0, 1.5, 2.0, and 2.5 eV. Besides the theoretical studies mentioned above, many experimental techniques, such as polarization-resolved chemiluminescence and polarized laser-induced fluorescence, have been used to measure the vector correlations between reagents and products.[8–10]

As mentioned, the reaction of $O^+ + H_2$ and its isotopic variants has been under considerable investigation, which, however, basically have dealt with scalar properties such as the rate constant, integral cross section, reaction probability, etc. Actually, it is at least equally important to study the vector properties if we want to fully understand the dynamics of the $O^+ + H_2$ system. Only by understanding both the scalar and vector properties can we have the fullest picture of the scattering dynamics.[11–17] As far as we know, although there have been several studies on the $O^+ + D_2 \rightarrow OD^+ + D$ reaction, the effects of different rotational quantum numbers on vector properties, which practically deserve further investigation,

have not been explored yet. That is why we carried out this theoretical calculation and feel that we have obtained some valuable results.

Theory

Product rotational polarization

For an atom–diatom reaction, a centre-of-mass (CM) frame is utilized in which the z axis lies in the direction of the reagent relative velocity (**k**). The reagent and product relative velocities are defined in terms of the reagent and product CM velocities as $\mathbf{k} = v_A - v_{BC}$, where v_A is the CM velocity of the reagent atom A and v_{BC} is the CM velocity of reagent diatom BC, and $\mathbf{k}' = v_{AB} - v_C$, where v_{AB} is the CM velocity of the product diatom AB and v_C is the CM velocity of the product atom C. We can see from Fig. 1 that **k** is parallel to the z axis and the x–z plane is the scattering plane that contains the initial and final relative velocity vectors. θ is the angle between the reagent and product relative velocity. θ_r and ϕ_r are the polar and azimuthal angles of the final rotational angular momentum **j**′.

Since the deduction process for the following formulae can be found in ref. 18, we will just summarize the formulae here.

The distribution function $P(\theta_r)$ describing the **k**–**j**′ correlation can be expanded into a series of Legendre polynomials[19–24]

$$[1] \qquad P(\theta_r) = \frac{1}{2}\sum_k (2k+1)a_0^{(k)}P_k(\cos\theta_r)$$

where

$$[2] \qquad a_0^{(k)} = \int_0^{\pi} P(\theta_r)P_k(\cos\theta_r)\sin\theta_r d\theta_r = \langle P_k(\cos\theta_r)\rangle$$

where k is the coefficient of the Legendre polynomials and P_k is part of the expression of the Legendre polynomials. The angular brackets represent an average over all trajectories. The expanding coefficients $a_0^{(k)}$ are called orientation (k is odd) and alignment (k is even) parameters.

Table 1. The product rotational alignment parameter $\langle P_2(\mathbf{j}'\cdot\mathbf{k})\rangle$ calculated with $j = 0$–2.

	Initial rotational No. (j)		
	0	1	2
$\langle P_2(\mathbf{j}'\cdot\mathbf{k})\rangle$	–0.410	–0.348	–0.245

Note: j, rotational quantum number; **j**′, product rotational angular momentum vector; **k**, relative velocity direction.

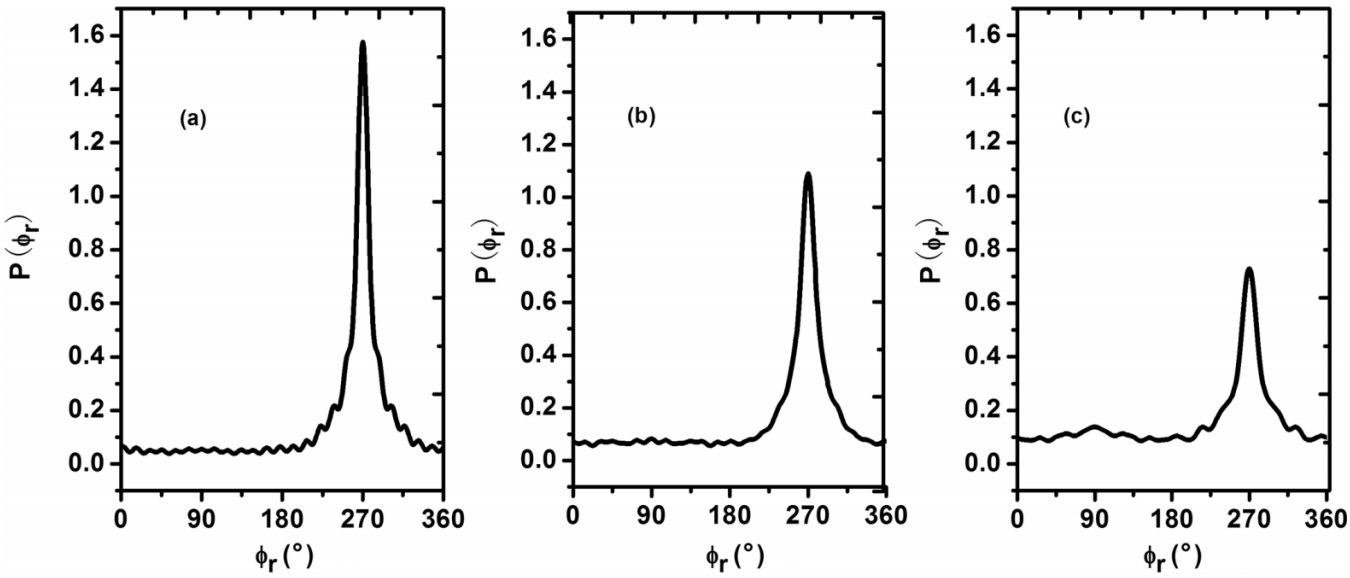
The angle distribution function $P(\theta_r)$ describing the **k**–**k**′–**j**′ correlation can be expanded into a Fourier series

$$[3] \qquad P(\phi_r) = \frac{1}{2\pi}\left(1 + \sum_{n\geq 2}^{\text{even}} a_n \cos n\phi_r + \sum_{n\geq 1}^{\text{odd}} b_n \sin\phi_r\right)$$

where n is the coefficient of the Fourier series.

$$[4] \qquad a_n = 2\langle\cos n\phi_r\rangle$$

$$[5] \qquad b_n = 2\langle\sin n\phi_r\rangle$$



The angular brackets represent an average over all trajectories. In this calculation, $P(\phi_r)$ shows good convergence when it is expanded up to $n = 24$. The joint probability density function of angles θ_r and ϕ_r defining the direction of **j**′ can be written as

$$[6] \qquad P(\theta_r, \phi_r) = \frac{1}{4\pi}\sum_{kq}[k]a_q^k C_{kq}(\theta_r, \phi_r)^* = \frac{1}{4\pi}\sum_k\sum_{q\geq 0}[a_{q\pm}^k \cos q\phi_r - a_{q\mp}^k i\sin q\phi_r] \times C_{kq}(\theta_r, 0)$$

where q is the coefficient of the modified spherical harmonics and $C_{kq}(\theta_r, \phi_r) = \sqrt{4\pi/(2k+1)}Y_{kq}(\theta_r, \phi_r)$ (modified spherical harmonics), where Y_{kq} is the spherical harmonics. The polarization parameter is evaluated as

Fig. 3. The dihedral angle distribution of $\mathbf{j}'$ with respect to the $\mathbf{k}$–$\mathbf{k}'$ plane. Panels (*a*)–(*c*) describe the distributions with $j = 0$, 1, and 2, respectively.

$$[7] \qquad a^{k}_{q\pm} = 2\langle C_{k|q|}(\theta_r, 0)\cos q\phi_r\rangle \qquad (k \text{ is even})$$

$$[8] \qquad a_{q\mp} = 2i\langle C_{k|q|}(\theta_r, 0)\sin q\phi_r\rangle \qquad (k \text{ is odd})$$

In this calculation, $P(\theta_r,\phi_r)$ shows good convergence when it is expanded up to $k = 7$.

Polarization-dependent differential cross section (PDDCS)

The full three-dimensional angular distribution associated with $\mathbf{k}$–$\mathbf{k}'$–$\mathbf{j}'$ can be represented by a set of generalized PDDCSs in the CM frame. The fully correlated CM angular distribution is written as

$$[9] \qquad P(\omega_t, \omega_r) = \sum_{kq} \frac{[k]}{4\pi}\frac{1}{\sigma}\frac{d\sigma_{kq}}{d\omega_t}C_{kq}(\theta_r, \phi_r)^*$$

where ω_t is the coordinate of the unit vector $\mathbf{k}'$ along the direction of the product relative velocity, ω_r is the coordinate of the unit vector $\mathbf{j}'$ along the direction of the rotational angular momentum, and $\frac{1}{\sigma}\frac{d\sigma_{kq}}{d\omega_t}$ is a generalized PDDCS and $\frac{1}{\sigma}\frac{d\sigma_{kq}}{d\omega_t}$ yields

$$[10] \qquad \frac{1}{\sigma}\frac{d\sigma_{k0}}{d\omega_t} = 0 \qquad (k \text{ is odd})$$

$$[11] \qquad \frac{1}{\sigma}\frac{d\sigma_{kq+}}{d\omega_t} = \frac{1}{\sigma}\frac{d\sigma_{kq}}{d\omega_t} + \frac{1}{\sigma}\frac{d\sigma_{k-q}}{d\omega_t} = 0$$
$$(k \text{ is even and } q \text{ is odd or } k \text{ is odd and } q \text{ is even})$$

$$[12] \qquad \frac{1}{\sigma}\frac{d\sigma_{kq-}}{d\omega_t} = \frac{1}{\sigma}\frac{d\sigma_{kq}}{d\omega_t} - \frac{1}{\sigma}\frac{d\sigma_{k-q}}{d\omega_t} = 0$$
$$(k \text{ is even and } q \text{ is even or } k \text{ is odd and } q \text{ is odd})$$

The PDDCS may be written in a more compact form

$$[13] \qquad \frac{1}{\sigma}\frac{d\sigma_{kq\pm}}{d\omega_t} = \sum_{k_1}\frac{k_1}{4\pi}S^{k_1}_{kq\pm}C_{k_1q}(\theta_t, 0)$$

where the $S^{k_1}_{kq\pm}$ can be evaluated using the expected value expression

$$[14] \qquad S^{k_1}_{kq\pm} = \langle C_{k_1q}(\theta_t, 0)C_{kq}(\theta_r, 0)[(-1)^q e^{iq\phi_r} \pm e^{-iq\phi_r}]\rangle$$

where the angular brackets represent an average over all angles. With $q = 0$, the PDDCS can be represented as

$$[15] \qquad \frac{1}{\sigma}\frac{d\sigma_{k0}}{d\omega_t} = \frac{1}{4\pi}\sum_{k_1}[k_1]S^{k_1}_{k0}P_{k_1}(\cos\theta_t)$$

where $S^{k_1}_{k0}$ may be evaluated by the expected value expression

$$[16] \qquad S^{k_1}_{k0} = \langle P_{k_1}(\cos\theta_t)P_k(\cos\theta_r)\rangle$$

Many photon-initiated bimolecular reaction experiments are just sensitive to the polarization moments with $k = 0$ and $k = 2$. Therefore, we calculated the four PDDCSs: $(2\pi/\sigma)(d\sigma_{00}/d\omega_t)$, $(2\pi/\sigma)(d\sigma_{20}/d\omega_t)$, $(2\pi/\sigma)(d\sigma_{22}/d\omega_t)$, and $(2\pi/\sigma)(d\sigma_{21}/d\omega_t)$. In these calculations, the PDDCSs are expanded up to $k = 7$, which can show good convergence.

The distribution of the angular momentum $\mathbf{j}'$of the product molecule is described by a function $f(\theta_r)$, where θ_r is the angle between $\mathbf{j}'$ and $\mathbf{k}'$. $f(\theta_r)$ can be represented by the Legendre polynomial

$$[17] \qquad f(\theta_r) = \sum a_n P_n(\cos\theta_r)$$

with $n = 1$ indicating the product rotational alignment.

$$[18] \qquad \langle P_1(\mathbf{j}'\cdot\mathbf{k})\rangle = \langle\cos\theta_r\rangle$$

with $n = 2$ indicating the product rotational alignment.

$$[19] \qquad \langle P_2(\mathbf{j}'\cdot\mathbf{k})\rangle = \frac{1}{2}\langle 3\cos^2\theta_r - 1\rangle$$

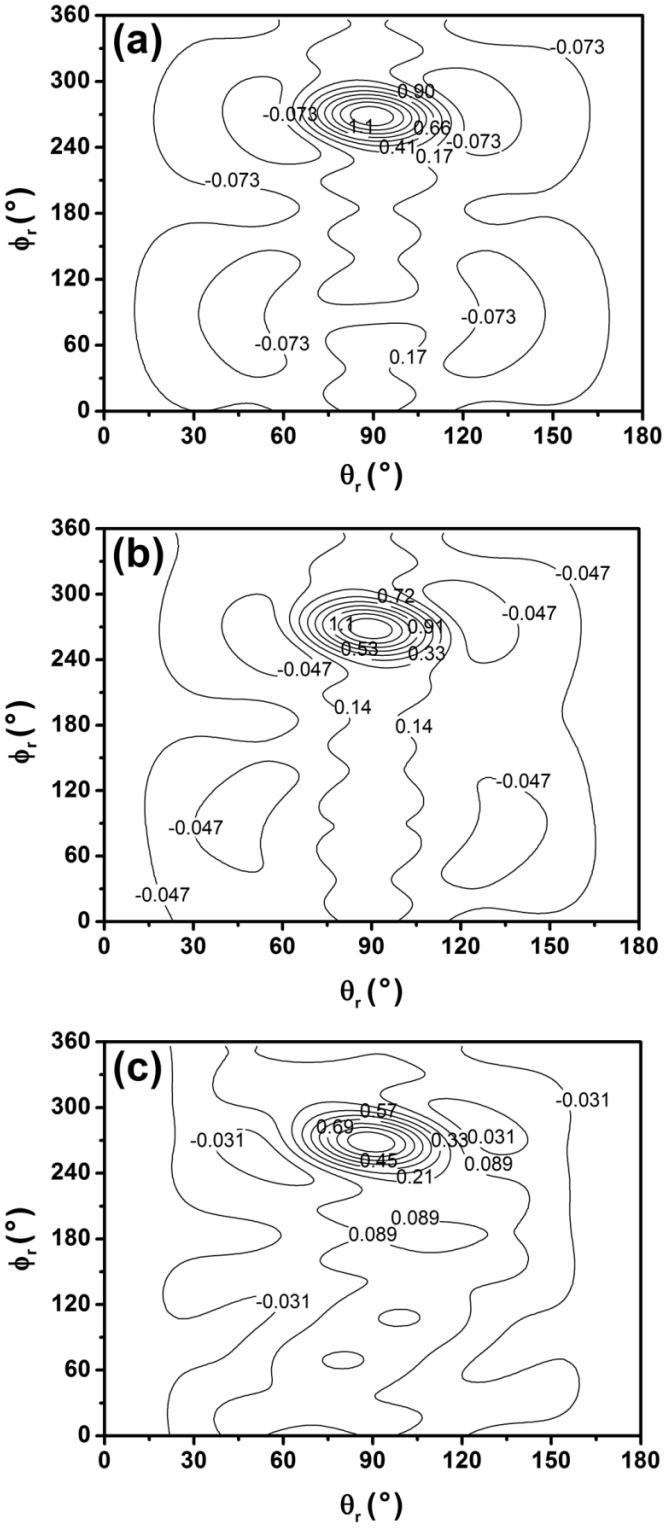
PES

The PES used in this article was the Martìnez–Millán–González (MMG) surface.[5] The obtained analytical representation for the PES was employed by a many body expansion. The fitted values of the dissociation energy (D_e) for OH^+ and H_2 are 5.1268 and 4.7621 eV, respectively, which are in good agreement with the experimental results. It can be found that a barrier and two wells are observed with a decrease of the OHH angle. The height of the barrier becomes bigger and the energy of the wells decreases when the OHH angle decreases.

QCT calculations



The QCT method was carried out to study the stereodynamics of the $O^+ + D_2 \rightarrow OD^+ + D$ reaction at a collision energy of 2.0 eV on the MMG surface.[5] The QCT calculation method we use here is the same as that found in refs. 17–20 and 25–27. The initial azimuthal orientation angle and polar angle of the reagent molecule internuclear axis are randomly sampled using the Monte Carlo method, and the ranges of the angles θ_r and ϕ_r are from 0° to 180° and from 0° to 360°, respectively. In the calculation, batches of 50 000 trajectories were run for each reaction and a 0.1 fs integration step size was chosen. All trajectories were started at an initial distance of 12.0 Å between the O^+ and the CM of the diatomic molecule. The impact parameter (b_{max}) for $j = 0$, 1, and 2 are 1.83, 1.85, and 1.88 Å, respectively.

Results and discussion

The $P(\theta_r)$ describing the $\mathbf{k}$–$\mathbf{j}'$ correlation is associated with the rotational quantum number and the calculated distributions of $P(\theta_r)$ for the $O^+ + D_2$ ($\upsilon = 0$, $j = 0$–2) reactivity are shown in Fig. 2, showing that the peak of $P(\theta_r)$ at $\theta_r = 90°$ is symmetric with respect to 90°, which means that $\mathbf{j}'$ is both strongly polarized and aligned along a direction perpendicular to $\mathbf{k}$. Clearly, Fig. 2 demonstrates that the peak of $P(\theta_r)$ becomes broader and lower as the rotational quantum number increases, which implies that the product rotational alignment effect becomes weaker with an increase of the rotational quantum number. From this discussion, it can be concluded that the rotational excitation of the reagent molecule D_2 has a great effect on the product rotational alignment. The CM frame alignment parameter $<P_2(\mathbf{j}'\cdot\mathbf{k})>$ is usually used to express the degree of product rotational polarization. The results presented in Table 1 agree well with the distribution of $P(\theta_r)$, namely, the smaller the expected value of $<P_2(\mathbf{j}'\cdot\mathbf{k})>$, the stronger the rotational alignment. It proves once again that the product rotational alignment is sensitive to the rotational quantum number.

A comparison of the $P(\theta_r)$ of the $O^+ + D_2 \rightarrow OD^+ + D$ reaction with $j = 0$, 1, and 2 is presented in Fig. 3, which clearly shows that the distributions of $P(\phi_r)$ tend to be asymmetric with respect to $\phi_r = 180°$, directly reflecting the strong polarization of the angular momentum for the three reactions. The $P(\phi_r)$ peaks appearing at both $\phi_r = 90°$ and 270° show that the rotational angular momentum vectors of the product of this reaction with $j = 0$, 1, and 2 are mainly aligned along the direction of y axis in the CM frame. Since the peak at $\phi_r = 90°$ is far lower than the one at $\phi_r = 270°$, we conclude that $\mathbf{j}'$ is not only aligned, but also oriented

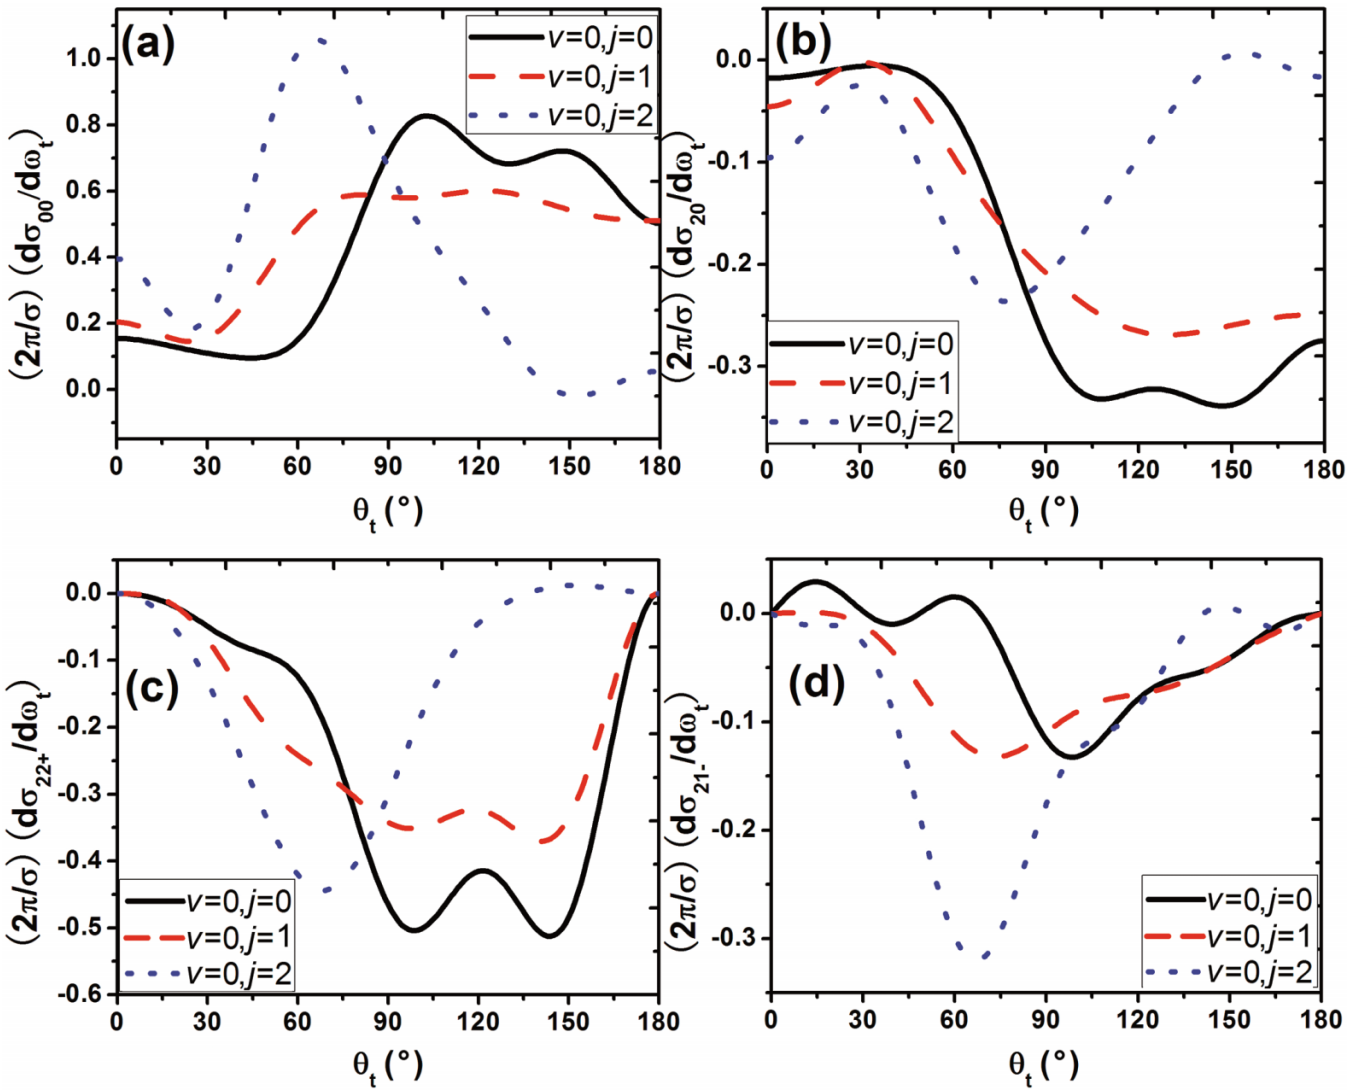


Fig. 4. Polar plots of the $P(\theta_r,\phi_r)$ distribution averaged over all scattering angles. Panels (*a*)–(*c*) describe the distributions with $j = 0$, 1, and 2, respectively.

along the opposite direction of the y axis. The results agree well with ref. 10, i.e., when the PES is repulsive for a heavy–light–light (HLL) system, $P(\phi_r)$ distributions usually show only one strong peak. It can also be found that the $P(\phi_r)$ peak for this reaction with $j = 0$ is the highest and the peak

Fig. 5. The polarization-dependent generalized differential cross sections for the reaction $O^+ + D_2$ ($v = 0$, $j = 0$–2). (*a*) $(2\pi/\sigma)(d\sigma_{00}/d\omega_t)$. (*b*) $(2\pi/\sigma)(d\sigma_{20}/d\omega_t)$. (*c*) $(2\pi/\sigma)(d\sigma_{22+}/d\omega_t)$. (*d*) $(2\pi/\sigma)(d\sigma_{21-}/d\omega_t)$.

with $j = 2$ is the lowest at $\phi_r = 270°$, and, to the contrary, the $P(\phi_r)$ peak for this reaction with $j = 0$ is the lowest and that with $j = 2$ is the highest at $\phi_r = 90°$, indicating that the distribution of $P(\phi_r)$ is very sensitive to j. The fact that the peaks $\phi_r = 270°$ of the three reactions are all strongly higher than those at $\phi_r = 90°$ implies that $\mathbf{j}'$ is preferentially oriented along the direction of the opposite direction of the y axis. Based on previous instantaneous collision theoretical studies[23,28] on the three-atom reaction, we have $\mathbf{j}' = \mathbf{L}\sin^2\beta + \mathbf{j}\cos^2\beta + \mathbf{J_1}m_B/m_{AB}$, where $\mathbf{L}$ is the reagent orbital angular momentum, m_B is the mass of atom B, m_{AB} is the total mass of atoms A and B, and $\mathbf{J_1} = \sqrt{\mu_{BC}R}(\mathbf{r}_{AB} \times \mathbf{r}_{CB})$, where $\mathbf{r}_{AB}$ and $\mathbf{r}_{CB}$ are unit vectors where B points to A and B points to C, respectively, μ_{BC} is the reduced mass of the BC molecule, and R is the repulsive energy. During the process of chemical bond formation and breakage for this reaction, the term $\mathbf{L}\sin^2\beta + \mathbf{j}\cos^2\beta$ in the equation is symmetric, whereas the left term of $\mathbf{j}'$ ($\mathbf{J_1}m_B/m_{AB}$) shows an appulsive direction as a result of the repulsive energy, which leads to the orientation of the product OD^+.

To get more valid stereodynamic information, the angular momentum polarizations in the form of polar plots are shown in Fig. 4. The three graphs show that the $P(\theta_r,\phi_r)$ distributions have a strong peak at (90°,270°) and a very weak peak at (90°,90°), which is in good agreement with the distributions of $P(\theta_r)$ and $P(\phi_r)$. The strong peak at (90°,270°) might result because the PES is a repulsive potential.

The PDDCS is used to describe the $\mathbf{k}$–$\mathbf{k}'$–$\mathbf{j}'$ correlation and the scattering direction of the product molecule. The calculated results for the $O^+ + D_2 \rightarrow OD^+ + D$ reaction with a chosen collision energy of 2.0 eV are presented in Fig. 5. The PDDCS $(2\pi/\sigma)(d\sigma_{00}/d\omega_t)$ is simply called the differential cross section (DCS), which is just used to describe the $\mathbf{k}$–$\mathbf{k}'$ correlation or the scattering direction of the product and is not related to the orientation and alignment of $\mathbf{j}'$. Clearly, Fig. 5*a* shows that the rotational quantum number has a great effect on the distribution of the PDDCS $(2\pi/\sigma)(d\sigma_{00}/d\omega_t)$, which indicates the intensity of the product molecule becomes stronger with an increase of the rotational quantum number when θ_t is <90°. To the contrary, it becomes weaker with an increase of the rotational quantum number when θ_t is

Can. J. Chem. Downloaded from www.nrcresearchpress.com by Renmin University of China on 09/02/12
For personal use only.

>90°. Furthermore, the product is sideways and backward scattering for $j = 0$ and 1 and totally forward scattering for $j = 2$. As ref. 10 indicates for a HLL combination reaction, the product mainly shows sideways and backward scattering when the PES is a repulsive surface; however, for $j = 2$, the product is totally forward scattering, from which we can deduce that a bigger rotational quantum number has a greater effect than the PES. The PDDCS $(2\pi/\sigma)(d\sigma_{20}/d\omega_t)$ is the expected value of the second Legendre moment, which is plotted in Fig. 5*b*. The tendency of $(2\pi/\sigma)(d\sigma_{20}/d\omega_t)$ is obviously opposite to that of $(2\pi/\sigma)(d\sigma_{00}/d\omega_t)$, indicating that $\mathbf{j}'$ is strongly aligned perpendicular to $\mathbf{k}$. In addition, the rotational quantum number has a strong influence on the angular distribution of PDDCSs with $q \neq 0$. In Fig. 5*c* the value of $(2\pi/\sigma)(d\sigma_{22+}/d\omega_t)$ is negative for all scattering angles, implying that the product is strongly aligned along the y axis. All PDDCSs with $q \neq 0$ equal to zero at the extremities of forward and backward scattering, which is determined by the fact that the average value of $\langle C_{k_1q}(\theta_t, 0)\rangle$ is 0 in eq. [14]. The strongest polarizations of the product of the three rotational quantum numbers ($j = 0$, 1, and 2) are at around 142°, 140°, and 70°, respectively. The distribution of $(2\pi/\sigma)(d\sigma_{21-}/d\omega_t)$ is shown in Fig. 5*d*. The polarization tendency is almost consistent with that of $(2\pi/\sigma)(d\sigma_{22+}/d\omega_t)$ with a small discrepancy. The strongest polarizations of the products of $j = 0$, 1, and 2 are at about 100°, 70°, and 65°, respectively.

Conclusions

In this paper we investigated the vector correlations for the chemical reaction $O^+ + D_2$ ($\upsilon = 0$, $j = 0$–2) using a QCT method on a MMG PES. The results demonstrate that the rotational polarization of the product shows diverse characteristics for different rotational quantum numbers. The $P(\theta_r)$ peak describing the $\mathbf{k}$–$\mathbf{j}'$ correlation becomes lower at 90° as the rotational quantum number increases, which indicates that the product rotational alignment effect becomes weaker with an increase of the rotational quantum number, and that the rotational excitation of the reagent molecule D_2 has a great effect on the product rotational alignment. The product rotational angular momentum vectors $\mathbf{j}'$ are not only aligned, but also preferentially oriented along the opposite direction of the y axis. The degree of orientation becomes lower with an increase of the rotational quantum number. In addition, at the same collision energy, the PDDCSs present distinct characteristics for different rotational quantum numbers, implying that the product rotational polarization is very sensitive to the rotational excitation of the reagent molecule.

Abstract: The benzoin condensation that involves the umpolung coupling of two aldehyde groups has been applied to the formation of functionalized silicon and silicon oxide surfaces using thiamine and other N-heterocyclic carbene (NHC) catalysis in water. This bioorthogonal conjugation of an aldehyde to a modified silicon or silicon oxide surface has been monitored and characterized using X-ray photoelectron spectroscopy and IR spectroscopy. NHC catalysis was found to be efficient in water mediating full conversion of the aldehyde functionalized silicon oxide surfaces at the interface.

Key words: "click" chemistry, benzoin condensation, silicon, surface functionalization.

Résumé : Dans le but de préparer des surfaces de silicium et d'oxydes de silicium fonctionnalisées, on a fait appel à une réaction de condensation de type benzoïne impliquant un couplage avec inversion de polarité de deux groupes aldéhydes, effectuée en solution aqueuse en présence de thiamine et d'autres carbènes N-hétérocycliques (CNH) utilisés comme catalyseurs. On a contrôlé la conjugaison bioorthogonale d'un aldéhyde à une surface de silicium ou d'oxyde de silicium modifiée et on l'a caractérisée en faisant appel à la spectroscopie photoélectronique des rayons-X et à la spectroscopie infrarouge. On a observé que la catalyse par des carbènes N-hétérocycliques est efficace dans l'eau pour conduire à une conversion complète des surfaces d'oxyde de silicium fonctionnalisées par un aldéhyde à l'interface.

Mots-clés : « chimie à clic », condensation de type benzoïne, silicium, fonctionnalisation d'une surface.

[Traduit par la Rédaction]

The development of organic reactions on silicon and silicon oxide surfaces is a highly active area of research because of the potential impact of the resulting new materials on applications in molecular electronics, biosensor development, and microarray technologies.[1] Considerable effort has been invested into building functional substrates onto silicon oxide surfaces at the nanoscale, leading to the development of several silicon oxide-bound systems for use on both particles and chips.[1,2] The most common techniques for the formation of monolayers on hydrogen-terminated silicon include: UV irradiation of alcohols and aldehydes, radical reactions of olefins using a radical initiator, or reactions with acylchlorides, which can then be further functionalized.[3] Silanes have been used for many years as a means to attach organic molecules to silicon oxide or glass and remain an important reagent in the fabrication of modified surfaces.[2] Currently, the techniques available to functionalize surfaces with biomolecules such as proteins are limited. Thus, there is a need to develop reactions that work well under aqueous conditions and that can be adapted to silicon surfaces.

Current strategies include physical, bioaffinity, and covalent immobilization.[4] Covalent immobilization, where a biomolecule such as a protein is directly attached to the surface via a newly formed covalent bond, offers advantages over other immobilization strategies. In particular, it allows for specific orientation of molecules at the surface and thus the generation of a homogenous surface. Also, unlike bioaffinity immobilization, the coupling partners employed in covalent immobilization can be relatively small, thus minimizing the chance that they will affect the structure and activity of the molecule being attached to the surface.

Covalent immobilization approaches for biomolecule attachment to silicon surfaces typically make use of highly specific bioorthogonal chemical reactions where functional groups not found in biology are used to specifically label and immobilize biomolecules.[4] While this approach offers many advantages, there exists only a handful of reactions that can be employed in a bioorthogonal manner.[4] The benzoin condensation, originally published in 1832 by Wöhler and Liebig,[5] represents a possible alternative for covalent coupling reactions onto silicon surfaces. The benzoin condensation involves the coupling of two aromatic aldehydes to form an α-hydroxy ketone via activation by cyanide.[5] The mechanism for this transformation was later elucidated by

Fig. 1. Catalytic cycle for thiamine-catalyzed benzoin condensation.

Lapworth in 1903.[6] Thiamine (vitamin B_1) is a naturally occurring water soluble compound that is also an effective catalyst for the benzoin reaction and was studied extensively by Breslow.[7] A reaction mechanism for the benzoin condensation catalyzed by thiamine is shown in Fig. 1. N-Heterocyclic carbenes (NHC) can also catalyze the benzoin reaction.[8–10]

Current research into benzoin-type reactions has shown that many NHCs similar to thiamine can also catalyze the reaction in polar protic solvents.[8,11,12] Moreover, recent advances have helped to make these transformations both asymmetric and also chemoselective for cross-coupled products.[9,10,13–17] Thiamine itself was also used to efficiently cross-couple different aldehydes as an enzyme complex with enzymes benzaldehyde lyase (BAL) and benzoylformate decarboxylase (BFD).[18] These findings suggest that the benzoin condensation may be a good candidate for further development as a reaction for covalent immobilization onto surfaces, since the catalysts are nontoxic, biocompatible, and aromatic aldehydes are functional groups not frequently found in commonly used model biological systems and offer an alternative to other click reactions.[19–37] A key nontrivial challenge is to determine the conditions under which the cross-coupling products are favoured in aqueous solution. We were interested in exploring conditions specifically for conjugating molecules to surfaces that have potential for future applications in biosensor and microarray functionalization. Herein, we describe the development of methodology using thiamine and NHC-catalyzed cross-coupling of aromatic aldehydes onto both hydrogen-terminated silicon and silicon oxide surfaces.

Results

Thiamine-catalyzed benzoin condensations were conducted on silicon oxide surfaces to determine the reactivity at the solid–liquid interface. Para-substituted benzaldehydes were used to test the electronic properties of the aldehydes for

Can. J. Chem. Downloaded from www.nrcresearchpress.com by Renmin University of China on 09/02/12

rapid functionalization of the silicon surfaces. Benzaldehyde, 4-nitrobenzaldehyde, and 4-methoxybenzaldehyde were used in thiamine-catalyzed benzoin condensations on silicon oxide surfaces according to the sequence in Fig. 2 and are described in detail in the Experimental section. The optimal coupling involved reactions with 4-methoxybenzaldehyde by FTIR. No reactions were observed in the absense of catalyst or of 4-methoxybenzaldehyde.

FTIR analysis of samples

Thiamine was used to couple 4-methoxybenzaldehyde to the model surfaces of silicon oxide attenuated total reflection (ATR) chips to facilitate the measurement of changes in IR vibrational fequencies during the chemical reactions by FTIR. An ATR chip was prepared to afford the aldehyde surfaces shown in Fig. 2. Peaks in the FTIR spectrum (Fig. 3) of this surface agreed with the proposed bonding pattern with the peak at 1645 cm^{-1} corresponding to the imine C=N stretching mode,[38–40] the small peak observed at 1606 cm^{-1} associated with a vibrational mode of the phenyl ring, and the peak at 1703 cm^{-1} corresponding to the C=O stretching of the substituted benzaldheyde.[40] The ATR chip was then subjected to the benzoin condensation using the optimized reaction conditions with thiamine and 4-methoxybenzaldehyde and the reaction progress was monitored by FTIR (Fig. 3). After 4 h, the aldehyde peak at 1703 cm^{-1} was considerably reduced and, after 24 h, the aldehyde peak was no longer visible, whereas the peak at 1606 cm^{-1} had grown considerably, which is to be expected for the additional phenyl ring in the benzoin product. The carbonyl stretching vibration for the benzoin product[38,39] was masked by the imine peak of the linker. Control experiments were carried out where an imine-linker aldehyde surface ATR chip was immersed in benzoin reaction conditions including 4-methoxybenzaldehyde and TEA in water, but without the thiamine catalyst and separately without aldehyde. After 4 h under these conditions, the IR spectrum was unchanged, indicating that the changes in the IR spectra in Fig. 3 are the result of the benzoin condensation. The native oxide surface was exposed to the same reaction conditions to rule out nonspecific absorption. Again no new peaks were observed in the FTIR spectrum.

To test whether a bulkier group would be tolerated at the para position, a tether bearing electron-rich benzaldehyde 4-[2-(2-hydroxyethoxy)ethylamino]benzaldehyde was synthesized to mimic the electronics of the 4-methoxybenzaldehyde and to be a potential tether in future experiments. Thiamine was then used to catalyze the coupling of 4-[2-(2-hydroxyethoxy)ethylamino]benzaldehyde to the aldehyde-terminated ATR chip surface prepared according to Fig. 2. The reaction proceeded at a similar rate to that with 4-methoxybenzaldehyde. Again, the aldehyde carbonyl peak at 1703 cm^{-1} was greatly reduced after 4 h and no longer visible after 24 h (Fig. 4). A peak at 1605 cm^{-1} corresponding to the phenyl group was also present, as observed previously.

4-Fluorobenzaldehyde was also coupled to an aldehyde-terminated surface of an ATR chip using thiamine as a catalyst to test whether an electron-deficient aldehyde would affect the rate of the reaction. The reaction proceeded more slowly (Fig. 5), which was surprising given that it is more electrophilic. The reaction took approximately 6 times longer to reach completion. After 24 h the aldehyde carbonyl peak was no longer visible, and the remaining spectral features were consistent with those observed for the analogous reaction with 4-methoxybenzaldehyde.

A total of 11 NHCs,[3,7,41–46] all of which were already known catalysts of benzoin-type reactions in organic media, were tested in solution-based experiments towards the coupling of 4-methoxybenzaldehyde to the model surface. Of those tested, 1,3-bis(2,4,6-trimethylphenyl)imidazolium chloride (Fig. 6) was found to be the most efficient and was tested with the aldehyde surface in Fig. 2. Reaction conditions were adjusted to use only 1 equiv of base to fully deprotonate this NHC as opposed to the 2 equiv required with thiamine hydrochloride. After 4 h, the FTIR spectrum showed the reaction to be complete, since the aldehyde carbonyl peak at 1703 cm^{-1} was no longer visible and the phenyl peak at 1606 cm^{-1} had increased in intensity, corresponding to the increase of the second phenyl ring. The 1,3-bis(2,4,6-trimethylphenyl)imidazolium chloride catalyst appeared to be a better catalyst than thiamine for the cross-coupling of aldehydes at the solid–liquid interface.

X-ray photoelectron spectroscopy characterization of thiamine-catalyzed coupling reactions

The condensation of 4-fluorobenzaldehyde onto the surface was also monitored by using X-ray photoelectron spectroscopy (XPS). After 24 h under thiamine-catalyzed reaction conditions with 4-fluorobenzaldehyde, XPS scans of the imine-linker aldehyde surface (Fig. 5) showed the appearance of an F 1s signal at ~688 eV that is absent in scans of the surface prior to the reaction. A control experiment, where the surface was exposed to reaction conditions without thiamine, was carried out and detected fluorine at near background levels. To determine the amount of benzoin product formed on the surface, the N/F ratio of the final surface was determined. To calculate this ratio, sensitivity factors relative to carbon for both nitrogen (1.68) and fluorine (4) had to be considered.[47] The ratios were obtained by multiplying the observed intensity ratio from high-resolution scans by the inverse ratio of the sensitivity factors. The N/F ratio was found to be 4.7 for the benzoin-coated wafer (where the theoretical ratio should be 1) and 10.0 for the control wafer. The high N/F ratio indicates that not all of the terminal aldehydes reacted to form a benzoin product.

To enhance the fluorine reporter signal, 4-(trifluoromethyl) benzaldehyde was used in place of 4-fluorobenzaldehyde. In the survey scan of the reacted surface (Fig. 7), the F 1s signal at 688 eV was much larger than previously observed with 4-fluorobenzaldehyde. A high-resolution scan of the F 1s region showed that the reacted surface had a fourfold increase of fluorine emission over the control. The N/F ratio for the final functionalized surface was calculated to be 1.4 (the theoretical ratio should be 0.33) compared with 2.5 for the control wafer. Additionally, a high-resolution scan of the C 1s region showed an additional signal at 294 binding eV, which can be associated to a CF_3 carbon. An F/C_{CF_3} ratio of 3 was calculated (using sensitivity factors of 4 and 1 for F and C, respectively) which agrees with the theoretical value. Using the entire C 1s region between 282 and 295 binding eV, the calculated C/F ratio was 11.5 compared with a theoretical ratio of 6.3 for the benzoin product.

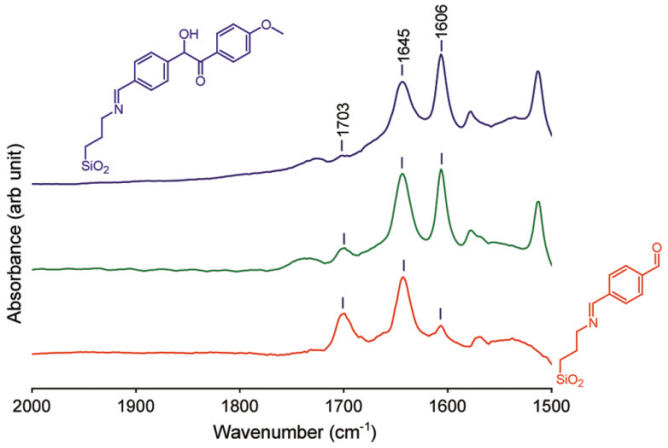

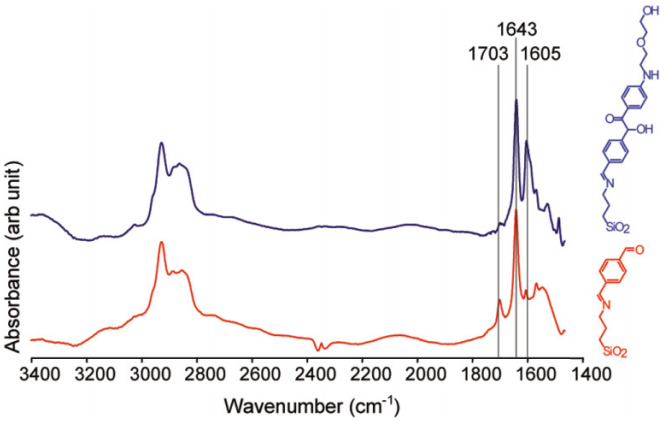

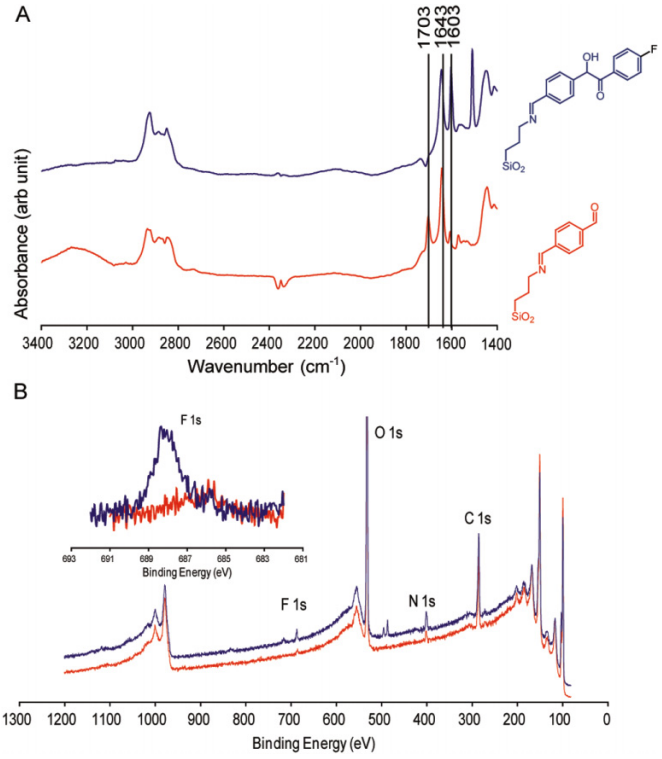

Fig. 4. FTIR characterization of thiamine-catalyzed coupling of 4-[2-(2-hydroxyethoxy)ethylamino]benzaldehyde to a model surface. Reaction progression at 4 h is shown.

Si(111) functionalization

Other surfaces were also tested to see whether the benzoin condensation reaction would be suitable for use in other applications where the use of glass or SiO_2 was not appropriate. A hydrogen-terminated (H-terminated) Si(111) ATR chip was prepared to provide the ether-linked aldehyde surface as in Fig. 8. Terephthaldialdehyde was directly attached to the H-terminated surface to yield the directly attached aldehyde to the Si(111) surface. The initial aldehyde-terminated surface provided a clean IR spectrum, with a peak at 1707 cm^{-1} corresponding to the C=O stretching of the benzaldehyde and a peak at 1612 cm^{-1} assigned to the phenyl. The directly attached

aldehyde surface was submitted to the same reaction conditions that were used to couple 4-methoxybenzaldehyde to silicon oxide surfaces using thiamine catalysis and monitored by FTIR (Fig. 8). After 4 h, the aldehyde carbonyl peak at 1707 cm^{-1} was significantly reduced and a new peak at 1655 cm^{-1} appeared, which was assigned to the C=O stretching of the benzoin carbonyl group. After 24 h, the aldehyde peak was no longer visible and only peaks assigned to the benzoin product remained.

Discussion

The thiamine-catalyzed benzoin condensation reaction was used to attach model aldehydes to surfaces. The reactions were generally observed to be faster and more chemoselective than those in solution. We hypothesize that the solid–liquid interface concentrates the organic reactants and acts similar to phase-transfer catalysis.[48–50] SiO_2 was chosen as the base substrate, since it is a common substrate in microarrays and has been extensively studied in such applications. Also, aldehyde coupling reactions provide new methods for bioconjugation given that a number of new methods exist for incorporating unnatural aldehyde groups into peptides and proteins.[51–54] Another advantage for performing methodology development on SiO_2 is that the surface also lends itself well to many spectroscopic techniques, including FTIR and XPS that were used extensively to characterize our modified surfaces.

Fig. 8. FTIR characterization of thiamine-catalyzed coupling of 4-methoxybenzaldehyde to hydrogen-terminated Si(111) surfaces. Directly attached aldehyde surface and reaction progression at 0 h (bottom trace) and 24 h (top trace).

Interestingly, we observed reactivity patterns that were different from those observed for NHC-catalyzed aldehyde cross-coupling reactions in solution. Usually electron-withdrawing substituents are favored for cross-coupling of benzaldehyde derivatives.[9,10,13–17] However, there are examples of analogous thiamine catalyzing cross-coupling reactions in water with methoxy-substituted benzaldehydes, where the thiamine catalyst is bound as a co-factor to an enzyme.[18] Interesting donor–acceptor relationships were established under these reaction conditions.[18] Others have postulated that differences between thiamine-dependent enzymatic catalysis and enzyme-free thiamine catalysis in solution may be due to desolvation and orientation of the thiamine co-factor on the enzyme.[55] A similar phenomenon may be happening for the catalysis on silicon surfaces where aromatic aldehydes are oriented with respect to the plane of the surface and where solvent behaviour is quite different from bulk solution.

(3-Aminopropyl)triethoxysilane (APTES) was chosen as the attachment molecule as it is a commonly used aminosilane for such purposes.[56,57] Although it is commonly used, it also has a complex reactivity profile because of its three reactive ethoxy groups. It can undergo the desired reaction of

Can. J. Chem. Downloaded from www.nrcresearchpress.com by Renmin University of China on 09/02/12
For personal use only.

covalent attachment with the surface through one, two, or three of the ethoxy groups; however, either vertical or horizontal polymerization are also possibilities with this substrate.[58] The latter, horizontal polymerization, can still be useful in surface functionalization, since it is possible that there is one ethoxy group still present and able to react with the SiO_2 even once it is polymerized and anchor the preassembled layer to the surface. APTES can also form hydrogen bonds to orient itself in several different arrangements on the surface.[58] This complex reactivity results in a nonhomogeneous surface and monolayers of APTES on SiO_2 that are difficult to consistently reproduce.

It has been previously shown that APTES quickly reacts with the surface at ambient temperature and pressure, without the need for any additional reagents or solvents.[59] An advantage to using ambient temperature and pressure vapour deposition is that we did not have to worry about excess water in the solvent causing uncontrollable polymerization of APTES. Reaction of the surface with APTES resulted in an amine-terminated surface. The terminal aromatic aldehyde was then installed by reacting the surface with an aqueous solution of terephthaldialdehyde as previously reported.[40] This provided an efficient means of reaching the terminal aldehyde without excess reagents, and the peak for the aldehyde (at ~1703 cm^{-1}) was clearly visible in the resulting IR spectrum of the surface.

The reaction progress between the aldehyde surface described in Fig. 3 and 4-methoxybenzaldehyde was followed by monitoring of the intensity of peaks of important functional groups in the FTIR spectrum. The shrinking of the aldehyde carbonyl peak at 1703 cm^{-1} was used to report on the consumption of the initial aldehyde-functionalized surface. The peak at 1606 cm^{-1} (a ring vibrational mode) was present in the initial aldehyde, but its intensity increased considerably upon formation of the benzoin product with the addition of a second phenyl ring on the surface. The peak at 1643 cm^{-1} (C=N stretching mode of the imine) remained unchanged after the benzoin reaction, evidence that the imine-linker was still intact. This suggests that the benzoin product was indeed being formed on the surface and giving rise to the observed changes in the IR spectrum.

It is interesting to note that, whereas the carbonyl peak for the benzoin products was not visible for the silicon oxide surfaces, the 4-methoxybenzoin surface derived from Si(111) did include a peak at ~1660 cm^{-1} that was assigned to the benzoin carbonyl peak. This suggests that the carbonyl peak of the benzoins on the model silicon oxide surfaces was in fact masked by the imine signal at 1643 cm^{-1}.

When 4-[2-(2-hydroxyethoxy)ethylamino]benzaldehyde was used, the reaction proceeded on the same time scale as the initial experiment; however, when 1,3-bis(2,4,6-trimethylphenyl)imidazolium chloride was used in place of thiamine, the 1703 cm^{-1} peak was no longer detectable after only 4 h (compared with 24 h with thiamine). This may be due to the increased stability and reactivity of the carbene formed after the deprotonation of the C_2 hydrogen. The presence of a phenyl ring on both heteroatoms as compared with only one with thiamine provide additional electron density to the C_2 site, stabilizing the resulting carbene.[12] The same system was also tested using an electron-poor aldehyde, 4-fluorobenzaldehyde. Fortuitously, we did see a reduction of the 1701 cm^{-1} peak and the emergence of a peak at 1603 cm^{-1}, which was assigned to the additional phenyl ring; however, this change in the spectrum was only apparent after 24 h. This observation does support our initial hypothesis that the electronics of the benzaldehydes play a role in determining the speed at which the reaction progresses. More evidence that the activated aldehyde species is forming with the electron-rich aldehyde is that when the imine-linked aldehyde-terminated surface is reacted with only catalyst and base, there is little change in the surface spectrum, where the 1703 cm^{-1} is only slightly decreased, but no additional peaks are observed.

The XPS data obtained from reactions involving aldehydes with fluorine substituents (4-fluorobenzaldehyde and 4-(trifluoromethyl)benzaldehyde) suggests that the main pathway for the incorporation of the fluoro signal at 688 eV is from the formation of the benzoin product on the surface. With reactions involving 4-fluorobenzaldehyde, the observed N/F ratio of 4.7 shows that under the reaction conditions, approximately one in five amines carried a benzoin product. The presence of a small F peak in the control can be attributed to either cross contamination or to 4-fluorobenzaldehyde reacting with free amines from unreacted APTES. With 4-(trifluoromethyl)benzaldehyde, the observed N/F ratio of 1.4 corresponds to approximately one in four amines carrying a benzoin product, which was very similar to the results in the previous system. The additional signal at 294 eV corresponding to the carbon of the CF_3 group and the observed F/C_{CF_3} ratio of 3 confirms that the entire F signal is associated with the incorporation of 4-(trifluoromethyl)benzaldehyde onto the surface. When considering the entire carbon region, the observed C/F ratio of 11.5 was much higher than the theoretical ratio of 6.3 for the benzoin product and much higher than the ratio of 3.7 for imine formation between unreacted APTES at the surface and 4-(trifluoromethyl)benzaldehyde. Since unreacted terminal aldehyde will increase the carbon content, this could indicate that only about 50% of the terminal aldehydes undergo benzoin condensation. The higher C/F ratio also indicated that the direct coupling of unreacted APTES at the surface and 4-(trifluoromethyl)benzaldehyde must be a negligible reaction pathway.

Conclusions

The benzoin condensation is an effective bioconjugation reaction to functionalize silicon and silicon oxide surfaces that proceeds using thiamine and NHC catalysts in water. Although we were able to demonstrate the condensation reactions using APTES-functionalized silicon oxide surfaces, more stable surfaces will be required to fully exploit this chemistry. Surfaces such as those generated by the reaction of terephthalaldehyde on H-terminated silicon surfaces, where the aromatic aldehyde is attached directly to the silicon surface through an Si–O–C bond, are stable and easily functionalized by the benzoin condensation. This method provides a new entry into the chemistry for functionalizing surfaces with biomolecules and has the potential to be exploited in the development of bioassays and in other applications.

Experimental

Materials and methods

Thiamine chloride hydrochloride, 1,3-bis(2,4,6-trimethylphenyl)imidazolium chloride, triethylamine, solvents, inorganic salts, and all benzaldehydes were used as received from Sigma-Aldrich unless otherwise stated in the text. Nuclear magnetic resonance spectra were recorded on a Bruker DRX-400 using a frequency of 400.13 MHz for ^{1}H and 100.61 MHz for ^{13}C and using a broadband direct detection probe. High-pressure liquid chromatography – mass spectrometry/mass spectrometry (HPLC–MS/MS) were carried out on a Waters system consisting of a Waters 996 photodiode array Ddetector, an Alliance HT – Waters 2795 separations module, and a Waters Micromass Z_{Q2000} unit equipped with a pneumatically assisted electrospray ionization source. Samples were run on a Waters Sunfire C18 (100 × 2.10 mm, 3.5 μm) column with a gradient of 10%–95% acetonitrile / 0.1% formic acid in H_2O / 0.1% formic acid over 15 min with a flow rate of 0.2 mL/min. MS data were collected in single-ion recording mode and processed using Masslynx. Attenuated total reflection Fourier transform IR (ATR-FTIR) spectra were recorded using a Nicolet MAGNA-IR 860 spectrometer at 4 cm^{-1} resolution. The ATR crystals were mounted in a purged sample chamber with the light focused normal to one of the 45° bevels. Background spectra were obtained using a blank surface (oxide surface or H-terminated surface depending on the experiment). XPS was performed on a PHI 5500 instrument using monochromated Al KR (1486 eV) radiation with detection on the surface normal. Spectra were fitted with Gaussian profiles using standard procedures. The positions of all peaks were normalized to C 1s at 285.0 eV. Experimental details for the benzoin compounds and the surface design are given in the Experimental section.

Silicon oxide elements

ATR elements were cleaned with piranha solution at 120 °C for 20 min and then rinsed with deionized water. To form the imine-linker aldehyde surface, the ATR element was exposed to APTES vapour for 10 min at room temperature. Once the free amine layer was formed, the ATR element was washed by sonicating in ethanol for 10 s, followed by rinsing with ethanol and then placement in a 1 mmol/L solution of terephthalaldehyde in water for 30 min at room temperature. The ATR element was then removed from the terephthalaldehyde solution and washed by sonicating in ethanol for 10 s, followed by rinsing with ethanol.

Silicon elements (H-terminated)

ATR elements were cleaned with piranha solution (96% H_2SO_4 and 30% H_2O_2, 3:1) at 120 °C for 20 min and then rinsed with deionized water. Samples were H-terminated by etching in degassed ammonium fluoride for 15 min, followed by a brief rinse in degassed water. To form the directly attached aldehyde surface, a 0.2 mol/L solution of terephthalaldehyde in toluene was degassed by bubbling with argon in a glass Schlenk tube for 10 min, followed by addition of the ATR element and heating of the solution at 90 °C for 1 h. The solution was cooled to room temperature and the ATR element removed and washed with 1,1,2-trichloroethane (TCE) in a Soxhlet extractor for 15–20 min and then further reacted as previously described.

Benzoin condensation on surfaces

Typically, 0.1 mmol of catalyst was dissolved in 1 mL of distilled water. To this, triethylamine (TEA) (27 μL, 0.2 mmol (with thiamine) or 18 μL, 0.1 mmol (with imidazolium catalyst)) was added. Para-substituted benzaldehyde (0.1 mmol) was added, and the solution was thoroughly mixed to form an emulsion. The reactions proceeded more slowly at lower catalyst concentrations and did not proceed at all in the absence of catalyst. The aromatic aldehyde-terminated ATR element was immersed in the solution and gently shaken. The reaction progression was monitored by ATR-FTIR. Gentle to vigorous washing was used as needed before scans to remove any noncovalently bound material.

Methoxybenzoins

Distributed among four 1.5 mL eppendorf vials, thiamine chloride hydrochloride (328 mg, 0.984 mmol) was dissolved in distilled water (2.4 mL) along with TEA (280 μL, 1.968 mmol). 4-Methoxybenzaldehye (160 μL, 0.984 mmol) and benzaldehyde (120 μL, 0.984 mmol) were added to the solution and the solution was shaken vigorously to form an emulsion. The vials were then placed in a centrifuge and spun for 3 days at 1400 rpm. The reactions were combined and 10 mL of water and 10 mL of ethyl acetate were added. The organic phase was isolated and the aqueous phase extracted 2 times with 10 mL of ethyl acetate. The organic fractions were combined, dried with magnesium sulfate, filtered, and concentrated. The resulting oil was purified by silica gel chromatography (4:1, hexanes – ethyl acetate, R_f = 0.32) to isolate the desired benzoin product as a mixture of regioisomers (3:1 based on NMR). The isomers were then separated by preparative HPLC (NovaPak C18 19 × 300 mm, iso 30% MeCN in H_2O, 20 min) in 41% total isolated yield.

2-Hydroxy-1-(4-methoxyphenyl)-2-phenylethanone[38]

Yield: 20 mg (33%). ^{1}H NMR (400 MHz, $CDCl_3$, ppm) δ: 7.93 (2H, d, J = 9.0 Hz), 7.39–7.25 (5H, m), 6.88 (2H, d, J = 9.0 Hz), 5.91 (1H, d, J = 5.8 Hz), 4.67 (1H, d, J = 6.0 Hz), 3.84 (3H, s). MS (positive ESI, M + 1) m/z 243.

2-Hydroxy-2-(4-methoxyphenyl)-1-phenylethanone

Prepared as previously described.[38] Yield: 8 mg (8%). ^{1}H NMR (400 MHz, $CDCl_3$, ppm) δ: 8.00–7.86 (2H, m), 7.54 (1H, dd, J = 4.3, 10.5 Hz), 7.42 (2H, t, J = 7.7 Hz), 7.30–7.24 (3H, m), 6.87 (2H, d, J = 8.7 Hz), 5.93 (1H, d, J = 6.0 Hz), 4.50 (1H, d, J = 6.0 Hz), 3.78 (3H, s). MS (positive ESI, M + 1) m/z 243.

4-[2-(2-Hydroxyethoxy)ethylamino]benzaldehyde

Prepared as previously described.[60] A mixture of 4-bromobenzaldehyde (925 mg, 5 mmol), 2-(2-aminoethoxy)ethanol (725 μL, 7.5 mmol), K_2CO_3 (1.38 g, 10 mmol), CuI (95 mg, 0.5 mmol), and L-proline (23 mg, 1 mmol) in 3 mL of DMF (dry) was heated to 80 °C for 48 h in a sealed flask under Ar. The cooled mixture was diluted with ethyl acetate and water. The organic layer was separated, and the aqueous layer was extracted with ethyl acetate. The combined organic layers were washed with brine, dried over Na_2SO_4, filtered, and con-

centrated. The residual oil was loaded on a silica gel column and eluted with ethyl acetate to afford 200 mg of the corresponding aniline (19% yield). ^{1}H NMR (400 MHz, $CDCl_3$, ppm) δ: 9.75 (1H, s), 7.72 (2H, d, J = 8.7 Hz), 6.66 (2H, d, J = 8.7 Hz), 4.80 (1H, s), 3.80 (2H, s), 3.78–3.72 (2H, m), 3.69–3.57 (2H, m), 3.44 (2H, q, J = 5.3 Hz), 2.01 (1H, s). ^{13}C NMR (100 MHz, $CDCl_3$, ppm) δ: 190.56 (CH), 153.45 (C), 132.54 (CH), 126.90 (C), 112.19 (CH), 72.49 (CH_2), 69.44 (CH_2), 62.01 (CH_2), 43.04 (CH_2). MS (positive ESI, M + 1) *m*/*z* 210.3; (negative ESI, M – 1) *m*/*z* 208.3.

4-Formyl-N-*[2-(2-hydroxyethoxy)ethyl]benzamide*

4-Carboxybenzaldehyde (1.015 g, 6.76 mmol) was dissolved in 16 mL of toluene. Once the aldehyde was dissolved, *p*-toluenesulfonic acid (38 mg, 0.20 mmol) and ethylene glycol (415 μL, 7.44 mmol) was added. The reaction was refluxed with a Dean–Stark apparatus overnight. Once the reaction was complete, the toluene was evaporated and the residual oil was dissolved in ethyl acetate (30 mL) and washed once with water (30 mL) and once with brine solution (30 mL). The organic phase was collected, dried over Na_2SO_4, and concentrated. The protected acid was recrystallized from hexanes – ethyl acetate to afford 1.22 g of 4-[1,3]dioxolan-2-yl-benzoic acid (92% yield). ^{1}H NMR (400 MHz, $CDCl_3$, ppm) δ: 8.02 (2H, d, J = 8.0 Hz), 7.49 (2H, d, J = 8.4 Hz), 5.78 (1H, s), 3.99 (4H, m). 4-[1,3]Dioxolan-2-yl-benzoic acid (123 mg, 0.633 mmol) was dissolved in 5 mL of DMF. Once the acid was dissolved, 2-(2-aminoethoxy)ethanol (7 μL, 0.697 mmol) was added along with DCC (196 mg, 0.950 mmol) and HOBt (128 mg, 0.950 mmol) and the reaction was allowed to stir at room temperature overnight. Once the reaction was complete, the mixture was dissolved in 10% sulfuric acid (5 mL) and left to stir at room temperature for 2 h to deprotect the aldehyde. Once the reaction was complete, the product was purified by flash chromatography (5%–10% methanol in dichloromethane) to afford 64 mg of the aldehyde (43% yield). ^{1}H NMR (400 MHz, $CDCl_3$, ppm) δ: 10.05 (1H, s), 7.92 (4H, s), 3.76 (2H, m), 3.69 (4H, m), 3.62 (2H, m). MS (positive ESI, M + 1) *m*/*z* 238.3; (negative ESI, M – 1) *m*/*z* 236.1.

Abstract: In this study, a simple and direct biosensor was proposed, which was based on biotin immobilized onto a conducting polymer-coated electrode, for the determination of avidin, a highly stable glycoprotein found in egg whites. Biotin was immobilized onto the electrode by covalent coupling to the primary amine group on poly-3′-(2-methoxy-5-amino-β-styryl)-(2,2′:5′,2″-terthiophene) (PMAST), and the biotin–avidin interaction was monitored by square-wave voltammetry. Incubation of the PMAST/biotin-modified coated electrode with avidin in a phosphate-buffered saline solution caused a significant change to its square-wave voltammogram, which was explained by the binding of avidin by biotin, and resulted in restricted ion transfer to and from the conducting polymer. This change was then utilized to determine avidin. Importantly, we found a linear relationship for the avidin sensor in the range of 4×10^{-14} to 3×10^{-4} mol/L, and the detection limit was determined to be approximately 10^{-14} mol/L.

Key words: avidin, biosensor, electronic conducting polymer, cyclic voltammetry, electrode surface modification, square-wave voltammetry, biological functionalization.

Résumé : Dans cette étude, on propose l'utilisation d'un biosenseur simple et direct, qui est basé sur de la biotine immobilisée sur une électrode recouverte de polymère conducteur, pour la détermination de l'avidine, une glycoprotéine très stable qu'on retrouve dans les blancs d'oeufs. La biotine a été immobilisée sur l'électrode par un couplage covalent à un groupe amine primaire du poly-3′-(2-méthoxy-5-amino-β-styryl)-(2,2′:5′,2″-terthiophène (PMAST) et l'interaction biotine–avidine a été mesurée par voltampérométrie à onde carrée. Une incubation de l'électrode modifiée par une couche de PMAST / biotine avec de l'avidine, dans une solution saline tamponnée au phosphate, provoque un changement important dans le voltampérogramme qui est expliqué par une fixation de l'avidine par la biotine qui provoque une restriction dans le transfert d'ion vers et à partir du polymère conducteur. Ce changement a ensuite été utilisé pour déterminer l'avidine. De plus, on a trouvé qu'il existe une relation linéaire pour le senseur d'avidine dans la plage de concentrations allant de 4×10^{-14} à 3×10^{-4} mol/L et on a déterminé que la limite de détection est d'environ 10^{-14} mol/L.

Mots-clés : avidine, biosenseur, polymère conducteur d'électron, voltampérométrie cyclique, électrode à surface modifiée, voltampérométrie à onde carrée, fonctionnalisation biologique.

[Traduit par la Rédaction]

Introduction

Two types of biosensor formats (direct and indirect) were used and were based on the electrochemical techniques for the detection of proteins.[1] However, most indirect methods, where a sensitive and detectable label is combined with a protein of interest, are time-consuming and involve several steps. In contrast, direct electrochemical techniques are based on the measurement of potential, capacitance, and conductivity changes that are caused by specifically fixing the protein onto the surface of an electrode. Vital advantages of direct biosensors include the ability to perform single-stage reagentless analyses and the achievement of molecular recognition by sensing a specific bioreceptor–biomolecule interaction on the electrode surface. A successful electrochemical biosensor must be able to selectively recognize the desired biomolecule and produce a measurable electrochemical signal.[2] The conducting polymers, which are prepared from terthiophene, are known for their simple functionalization and relatively good stability in air in both neutral and oxidized states.[3,4] Consequently, oligo- and poly-thiophenes have been functionalized as advanced materials for electrode surface modifications, allowing for the development of biosensor devices. Indeed, DNA electrochemical sensors[5–7] and glucose sensors[8,9] have been recently developed. However, the development of protein biosensors has not been explored fully, but interesting works have been carried out to construct sensors for the avidin[10–12] and vitellogenin proteins.[13] In these two examples, a functionalized polyterthiophene was used as an electronic transducer by covalent immobilization of the bioreceptors

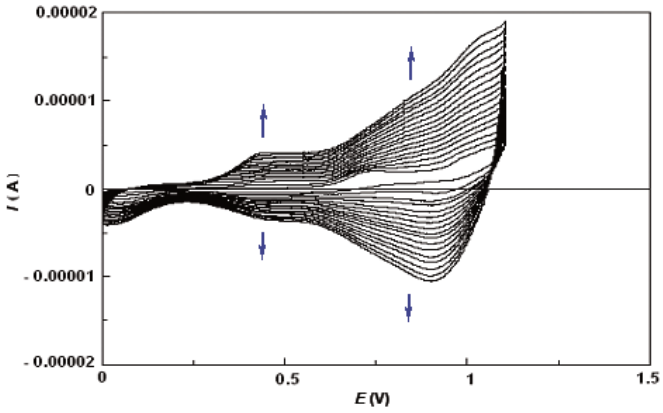
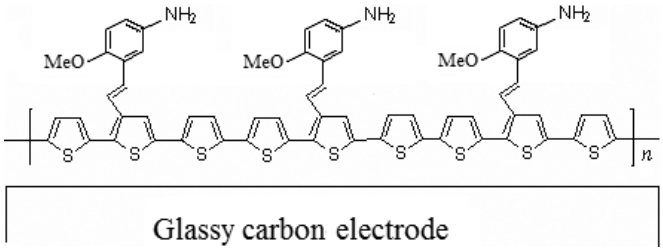
(either biotin for the avidin electrode or an antibody to vitellogenin for the vitellogenin electrode) on a polyterthiophene-coated electrode. For the avidin sensor, functionalization of terthiophene by biotin was carried out by directly binding biotin to the central thiophene ring in the 3′ position by chemical synthesis. However, using chemical synthesis to biologically functionalize polythiophene was inconvenient because it limited the electrode to only a single target biomolecule. A second inconvenience was that the polythiophene redox signal was situated at a high potential, ~1 V vs Ag/AgCl, which usually led to biotin degradation. For the vitelloginin sensor, terthiophene was functionalized by adding a carboxylic acid group (–COOH) to the 3′ position of the central thiophene ring, resulting in terthiophene 3′-carboxylic acid (TCA). An advantage of biosensor systems that are based on poly(TCA) films is that they are not restricted to a single target biomolecule because various bioreceptors could be immobilized through an interaction with the free carboxylic acid groups present on the poly(TCA) film surface. However, the inconvenience of this biosensor system is that, again, the polythiophene backbone redox signal is situated at a high potential, which may cause the degradation of the immobilized bioreceptor on its surface.



Herein, we report a simple and direct biosensor for the determination of avidin using square-wave voltammetry. This sensor was fabricated by covalent immobilization of biotin onto a conducting polymer-coated glassy carbon electrode, which was based on the 3′-(2-methoxy-5-amino-β-styryl)-(2,2′:5′,2″-terthiophene) (MAST) monomer.



The MAST monomer

We investigated the possibility of using amino β-styryl-functionalized poly(terthiophene) in biosensor devices. For these types of sensors, the redox signal of the aminophenyl moiety was used as a transduction mechanism instead of the polyterthiophene redox signal. In this case, measurements at high oxidation potential were avoided, which could damage the biofunctionalization of the electrode at its surface, and polyterthiophene was used as a means of immobilization onto the electrode surface by electrodeposition. As the biotin–avidin interaction is known for this highly specific interaction, we began with the detection of avidin as a proof-of-concept experiment. Our group has recently described the preparation and characterization of the CAST monomer.[14] Among the principal advantages of this conducting polymer was the ability to change the nature of the immobilized bio-

Fig. 1. Growth of poly(3′-(2-methoxy-5-amino-β-styryl)-(2,2′:5′,2″-terthiophene)) (MAST) by repetitive scan cyclic voltammetry on a 7.068 mm^2 glassy carbon electrode between 0.0 and 1.1 V. Auxiliary electrode: Pt wire, reference electrode, Ag/AgCl; scan rate, 10 mV s^{-1}; 5 mmol/L MAST monomer; and 0.1 mol/L tetrabutylammonium perchlorate (TBAP) – dichloromethane (DCM). *E*, energy; *I*, current.

receptor through the formation of a covalent bond with the free primary amine groups on the polymer surface; hence, this polymer could be used as a biosensor for various biomolecule targets. Moreover, it was possible to observe the redox signal (oxidation peak) of the aminophenyl moiety in the square-wave voltammograms of the polymer MAST (PMAST) in organic medium.[14] We used the relative current measured at this oxidation peak, which is related to the concentration of avidin in a buffered medium, as the signal that is modified by the specific interaction of biotin–avidin on the surface electrode. Avidin is a highly stable glycoprotein (molecular mass ~68 000) found in egg whites. Avidin has been isolated as a tetramer, with each subunit containing a binding site for biotin that forms an exceedingly strong complex through noncovalent interactions ($K_a = 10^{15}$ $(mol/L)^{-1}$).[15,16]

Experimental

Reagents

The MAST monomer was synthesized according to our previous work.[14] The following chemicals were used: ethyl-3-(3-dimethylaminopropyl) carbodiimide (EDC), biotin, and tetrabutylammonium perchlorate (TBAP, electrochemical grade) from Sigma-Aldrich (Canada) and dichloromethane (DCM, HPLC grade), avidin from egg whites, and phosphate-

buffered saline (PBS, 0.1 mol/L, pH 7.4 at 25 °C) from Fisher Scientific (Canada). All experimental solutions were prepared in double-distilled water obtained from a Milli-Q water system (18 MΩ cm^{-1}).

Modification of the electrode surface

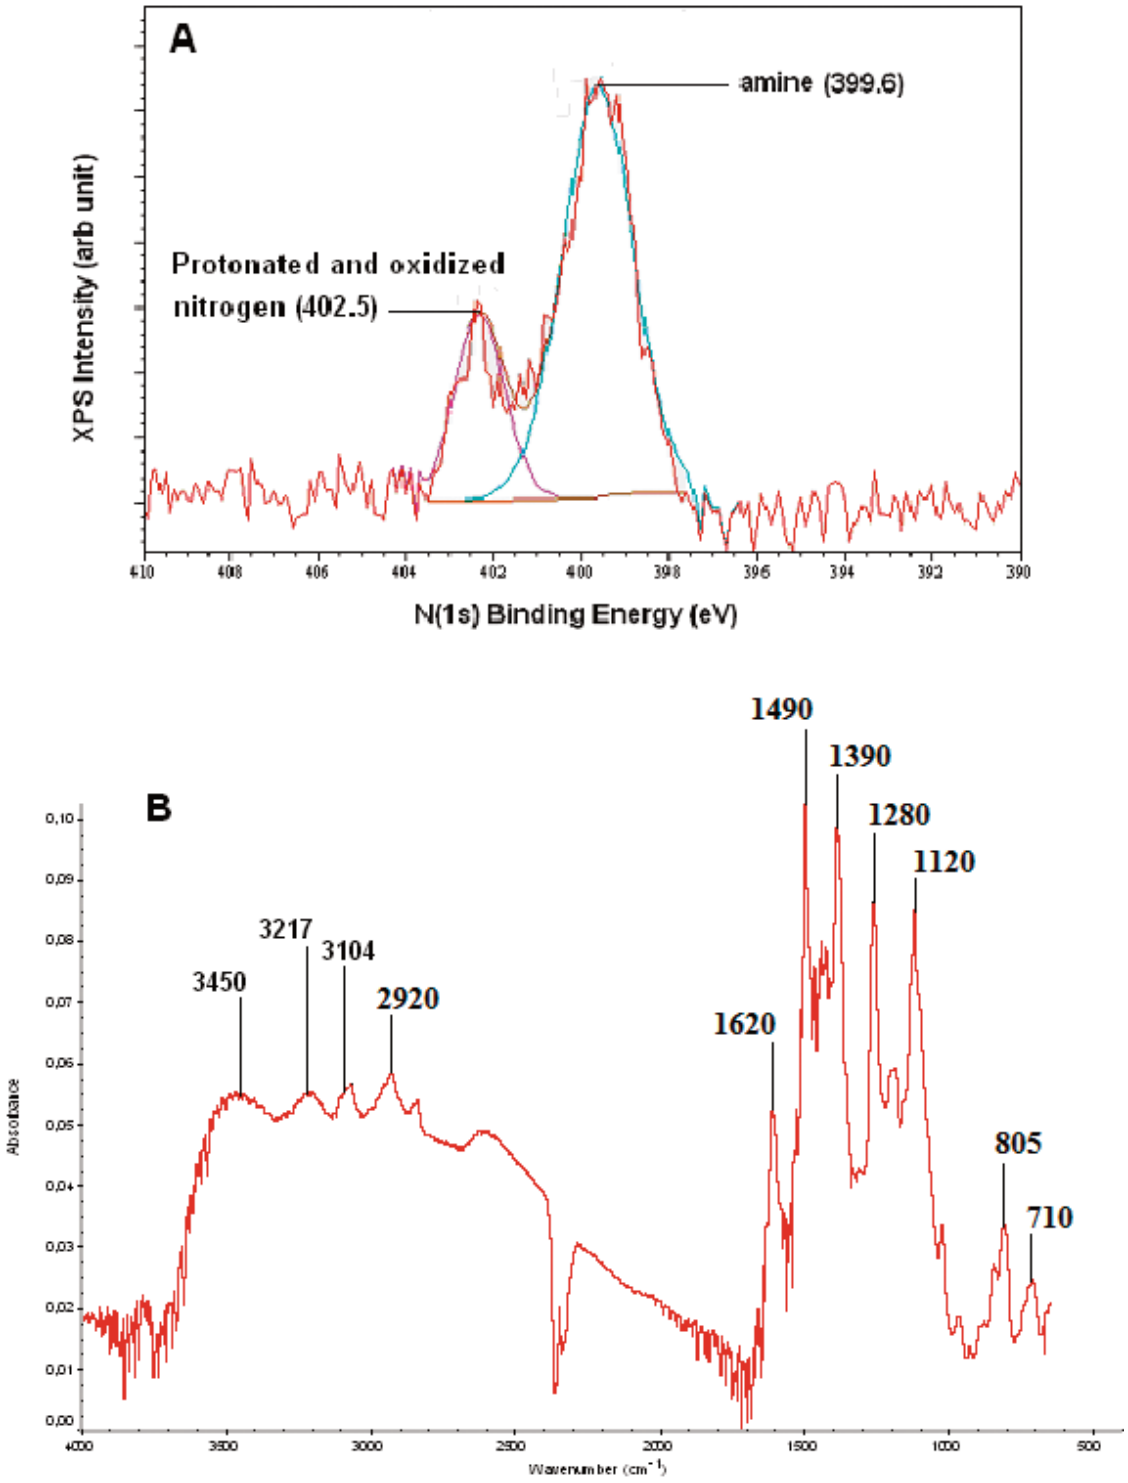
The conducting polymer film on the polished glassy carbon electrode (area = 7.068 mm^2) was prepared by electropolymerization of 5 mmol/L of the MAST monomer in a 0.1 mol/L TBAP/CH_2Cl_2 solution by potential cycling between 0.0 and 1.1 V (vs Ag/AgCl) several times at 10 mV s^{-1}. After polymerization, the electrode surface was rinsed with CH_2Cl_2 to remove any excess monomers from the electrode surface. The poly-MAST (PMAST)-coated electrode was then immersed in a 0.1 mol/L PBS solution (pH 8) containing 0.05 mol/L EDC and 0.05 mol/L biotin for 24 h at 40 °C. Individual biotin molecules were then immobilized onto the PMAST film through the formation of a covalent bond with a free primary amine group on the polymer surface. The electrode was then rinsed thoroughly with the same buffer to remove any biotin that was not immobilized, and cyclic voltammograms (CVs) and square-wave voltammograms (SWVs) were recorded. Finally, the PMAST/biotin-modified electrode was incubated in a 0.1 mol/L PBS solution (pH 7.4) containing a known amount of avidin for 15 min at room temperature to block the active sites of avidin through a specific interaction with biotin. The electrode was then removed, rinsed with the same buffer to remove any avidin that had not reacted with biotin, and allowed to dry. CVs and SWVs were then recorded.

Instruments and electrochemical techniques

The measuring setup for all electrochemical experiments consisted of a three-electrode system, in which a glassy carbon electrode, an Ag/AgCl (saturated KCl) electrode, and a platinum foil (dimension, 1 cm × 1 cm; 0.025 mm^2 thickness) were used as the working, the reference, and the auxiliary electrodes, respectively. The CVs and the SWVs were recorded by employing a potentiostat/galvanostat (model EG & G, Princeton Applied Research, 273 A). All of the measurements were carried out in a 0.1 mol/L TBAP–DCM solution at room temperature.

Characterization techniques

The neutral PMAST and PMAST/biotin-modified sensors were characterized using a reflectance Fourier transform infrared (FT-IR) experiment and by X-ray photoelectron spectroscopy (XPS). FT-IR spectra of PMAST films on gold-coated glass electrodes were recorded on a NEXUS 670 FT-IR over the range 600–4000 cm^{-1}. XPS examination was carried out on the PMAST films grown on indium–tin–oxide (ITO)-coated glass electrodes using an Escalab 220i XL spectrometer (Vacuum Generator).



Results and discussion

Electrochemical polymerization of the MAST monomer and CVs and SWVs

Figure 1 shows the repetitive scan CVs for the formation of a PMAST film on a glassy carbon electrode. The CVs show the expected increase in current with increasing number of potential cycles, indicating the growth of an electronic conducting polymer (ECP). A robust and adherent black uniform polymer film was electrodeposited successfully onto the electrode surface. However, it was necessary to grow a thick polymer film to ensure that the polymer remained adherent during the transfers between aqueous and nonaqueous media; therefore, we made a film from 10 repetitive scans.

Scheme 1 shows the structure of the PMAST that was electrodeposited onto a glassy carbon electrode, and Fig. 2 shows the CVs and SWVs of PMAST on the glassy carbon working electrode. The CVs and SWVs clearly showed two redox couples, which can be assigned to the aminophenyl moiety redox potentials (labeled a and b, Fig. 2) at 0.5 V vs Ag/AgCl and the polythiophene backbone redox potentials (labeled c and d, Fig. 2) at 0.9 V vs Ag/AgCl. Indeed, we were able to determine the origin of the redox couples (a/b and c/d) by comparing the CVs and SWVs of a polyterthiophene

Fig. 3. X-ray photoelectron spectroscopy (XPS) (A) and Fourier transform infrared (FT-IR) (B) spectra of the poly-3′-(3-methoxy-4-amino-β-styryl)-(2,2′:5′,2″-terthiophene) (PMAST) film that had been grown on indium–tin–oxide (ITO)-coated glass and gold-coated glass, respectively, at room temperature.

film prepared under the same conditions and using the results from previously published studies that had analyzed polyterthiophene.[17] We found that the polaronic oxidation peak was situated toward 1.05 V vs SCE (corresponding to 1.09 V vs Ag/AgCl), and the anodic peak (a, Fig. 2) corresponded to the oxidation of the aminophenyl moiety. It has been reported that the aminophenyl moiety could be oxidized to give a radical cation.[18] This oxidation removes an electron from the free electron doublet of the nitrogen in its neutral state (NH_2), resulting in a radical nitrogen cation ($NH_2^{\cdot+}$).

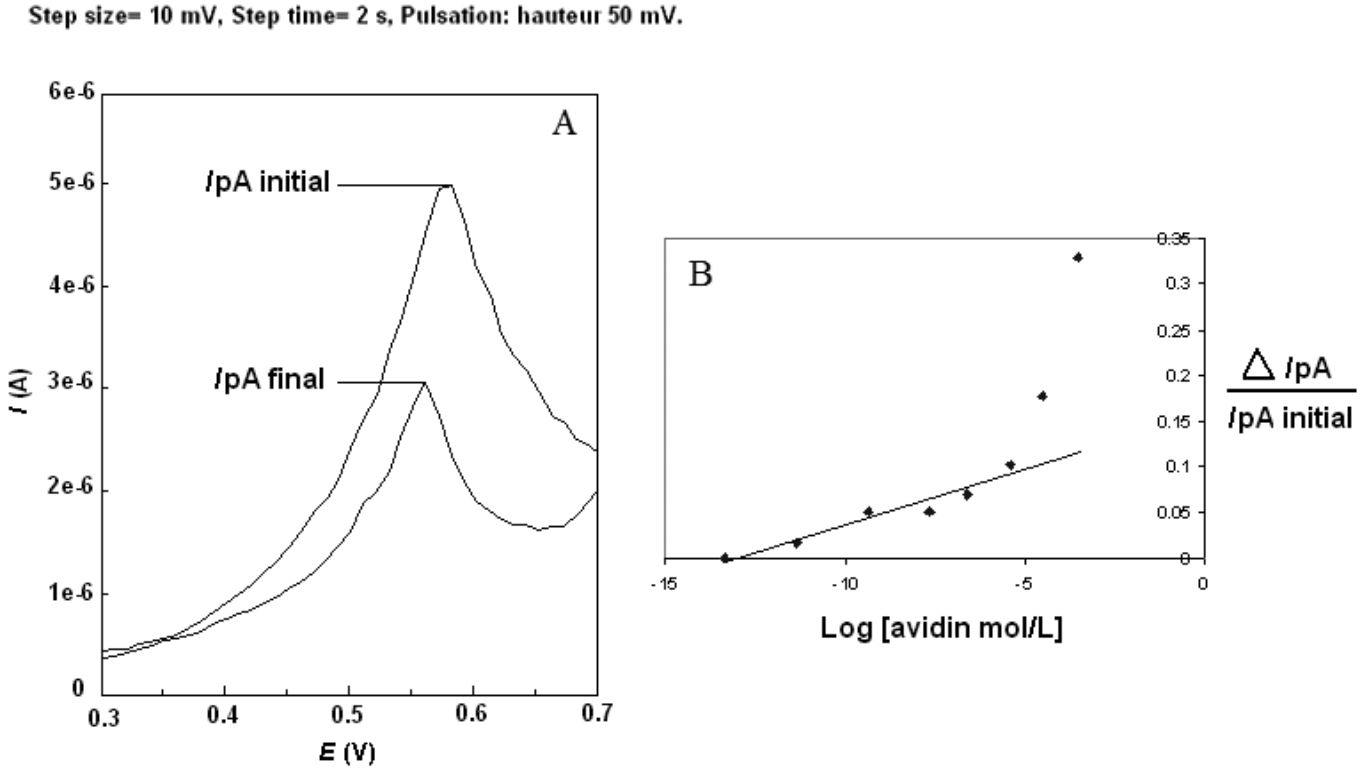
(B) Subtraction spectrum of the PMAST/biotin-modified and the PMAST polymers.

Characterization by the XPS and FT-IR techniques



Studies of the PMAST film using the FT-IR and XPS techniques clearly showed the presence of free primary amine groups on the polymer film surface, and these groups were used in the next step of biofunctionalization of the PMAST surface. The XPS and the FT-IR spectra of the PMAST film are shown in Fig. 3. The XPS spectrum showed the deconvoluted N 1s spectrum for the surface of the PMAST film grown on an ITO-coated glass electrode. The two features seen at 402.5 and 399.6 eV were ascribed to a cationic nitrogen species (NH_3^+ and $NH_2^{\cdot+}$) and an amine I species (NH_2), respectively.[19,20] The FT-IR spectrum of the PMAST film grown on gold-coated glass showed two absorbance peaks at 3450 and 3217 cm^{-1} (amine I band, N–H stretching vibration),[21] which corresponded to the primary amine groups on the aminophenyl moiety. In addition, a C–H stretching vibration of the aromatic ring[22] was observed at 3104 cm^{-1}. Regarding the polythiophene backbone, the FT-IR spectrum showed a C–H stretching vibration band at 2920 cm^{-1}, a C=C stretching band at 1390–1620 cm^{-1}, a C–H plane-bending band at 1120 cm^{-1}, and a C–S bending band at 710 cm^{-1}.[23]

Surface modification with biotin

The step used to link biotin to the surface of the PMAST-coated electrode is summarized in Fig. 4. This procedure has the advantage of being performed under simple conditions and forms a covalent bond between the moieties.

A neutral PMAST film was grown on a gold-coated glass working electrode. Figure 5 shows the FT-IR spectra of the PMAST film before and after modification by biotin. Figure 5B clearly shows a new medium shoulder at 1660 cm^{-1} (amide II band, C=O stretching vibration) in the spectrum (b) after modification with biotin. The subtraction spectra of the PMAST/biotin-modified film (b) and PMAST film (a) clearly show an amide II band at 1669 cm^{-1} (C=O stretching vibration), which results from the amide II bond between biotin and the free primary amine groups on the PMAST film surface. It has been reported that the C=O stretching vibration

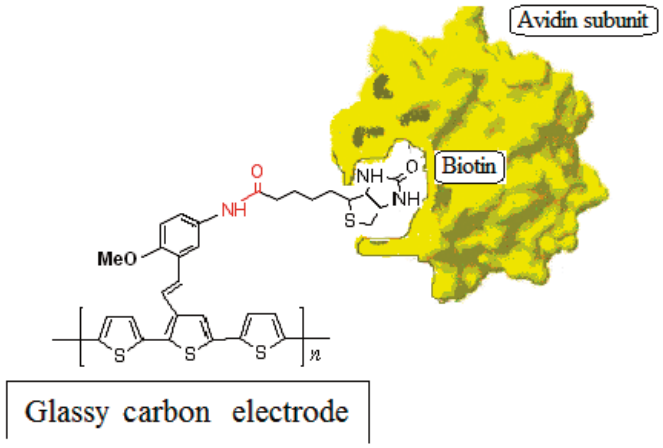


Fig. 6. (A) Square-wave voltammograms of the poly-3′-(3-methoxy-4-amino-β-styryl)-(2,2′:5′,2″-terthiophene) (PMAST) / biotin-modified coated glassy carbon working electrode, before (*I*pA initial) and after (*I*pA final) exposure to a solution of avidin (3×10^{-4} mol/L) in phosphate-buffered saline (PBS, 0.1 mol/L) for 15 min. Auxiliary electrode: Pt foil; reference electrode: Ag/AgCl; in 0.1 mol/L tetrabutylammonium perchlorate (TBAP) / dichloromethane (DCM). (B) Δ*I*pA / *I*pA initial as a function of log(avidin concentration in mol/L). *I*, current.

of an amide II in the solid phase is situated between 1680 and 1630 cm^{-1}.[24]

We also observed by cyclic and square-wave voltammetry that biotin immobilization on the PMAST/biotin-modified coated glassy carbon electrode caused a shift of the anodic peak toward a higher potential (from 0.5 to 0.575 V vs Ag/AgCl), which was initially attributed to the oxidation of the aminophenyl moiety. After biotin immobilization, the anodic peak corresponded to the oxidation of the amidophenyl on the polymer film surface. Indeed, it has been reported[25] that an amidophenyl moiety had a higher oxidation peak than its corresponding aminophenyl moiety. For example, a report[24] has stated that the acetoamidophenyl anodic peak was situated at +1.24 V vs Ag/AgCl, whereas the aminophenyl anodic peak was located at +0.98 V vs Ag/AgCl.

Scheme 2. Illustration of the direct electrochemical avidin sensor.

Effect of avidin exposure on the square-wave response of the PMAST/biotin-modified coated electrode and the linear relationship of the avidin sensor

The SWVs of the PMAST/biotin-modified coated working electrode, before and after exposure to a solution of 3×10^{-4} mol/L avidin in PBS (0.1 mol/L) for 15 min, are shown in Fig. 6A. We observed that exposure of the PMAST/biotin-modified coated working electrode to the avidin solution had a diminishing effect upon its electrochemical response, which caused a significant decrease in the oxidation current that was measured for the anodic peak (*I*pA). The current variation (Δ*I*pA) caused by avidin exposure corresponded to *I*pA initial – *I*pA final (Scheme 2).

In contrast, we observed no significant change when the PMAST/nonmodified coated working electrode was exposed to the avidin solution; thus, the electrochemistry of the PMAST/nonmodified film was unaffected by exposure to avidin. Therefore, avidin interacted specifically with the biotin moieties in the PMAST/biotin-modified film. This unusual voltammetry response after avidin exposure was consistent with the presence of avidin covering the polymer film surface, thus decreasing the number of amidophenyl moieties able to be oxidized during electrooxidation of the polymer film.

A plot of the relative variation of the current (ΔIpA / IpA initial) measured at the anodic peak potential (EpA) for the PMAST/biotin-modified film vs logavidin concentration) is shown in Fig. 6B to illustrate the possibility of constructing an avidin sensor using this system. We used various concentrations within the range of 4×10^{-14} to 3×10^{-4} mol/L, and the time of incubation was 15 min at room temperature. We observed a linear correlation of 0.97 between the concentrations of avidin from 4×10^{-6} to 4×10^{-4} mol/L. In contrast, there was a loss of this linear correlation at concentrations above 4×10^{-6} mol/L, which could be explained by the presence of an interaction between avidin and the modified surface electrode (other than the specific biotin–avidin interaction) caused by increasing avidin concentrations.

The plot is represented by the linear equation ΔIpA / IpA initial = 0.154 + 0.012 log(concentration). Finally, the minimum detectable concentration of avidin by this biosensor system was approximately 10^{-14} mol/L. Scheme 1 shows an illustration of the direct electrochemical avidin sensor that is based on the poly(methoxyamino-β-styryl terthiophene)-coated glassy carbon electrode.

Conclusion and prospects

In this study, we investigated the feasibility of a direct assay for avidin in a PBS solution. We have also illustrated the advantage of a simple procedure of biotin immobilization by covalent coupling to a primary amino group in a conducting polymer of a MAST-modified electrode, which did not hinder the specific biotin–avidin interaction. In principle, an avidin sensor could be constructed by electrogenerating a PMAST/biotin-modified coated glassy carbon working electrode. The biotin–avidin interaction was monitored by square-wave voltammetry, and a linear relationship for avidin for this sensor in the range of 4×10^{-14} to 3×10^{-4} mol/L was determined. Additionally, the detection limit was determined to be approximately 10^{-14} mol/L. Future work to investigate the possibility of using these PMAST films to target various biomolecules will focus on the biofunctionalization of its surface with various bioreceptors.

Abstract: A series of new dendritic platinum bisferrocenylacetylide complexes have been synthesized utilizing the coupling reaction of *trans*-Pt complexes with C–H bonds in alkynes as key steps. These new bimetallic dendrimers were fully characterized by multinuclear NMR (^{1}H, ^{13}C, and ^{31}P) and mass spectrometry (MALDI-TOF-MS and CSI-TOF-MS). Electrochemical studies of these complexes were carried out and revealed that all of the redox moieties are stable, independent, and electrochemically active. In addition, all metallodendrimers show one-electron reaction responses, and the increased sizes of these complexes did not exhibit a dramatic influence on the diffusion coefficient.

Key words: metallodendrimer, platinum biferrocenylacetylide complex, electrochemistry.

Résumé : On a réalisé la synthèse d'une série de nouveaux complexes dendritiques du bisferrocénylacétylure de platine en utilisant comme étapes clés une réaction de couplage de complexes *trans* du platine avec les liaisons C–H d'alcynes. Ces nouveaux dendrimères bimétalliques ont été complètement caractérisés par RMN multinucléaire (^{1}H, ^{13}C et ^{31}P) et par spectrométrie de masse en temps de vol (SM-TDV) avec ionisation par désorption au laser d'une matrice (« MALDI ») ou avec ionisation par nébulisation à froid (INF). On a effectué des études électrochimiques de ces complexes qui révèlent que toutes les portions redox sont stables, indépendantes et électrochimiquement actives. De plus, tous les métallodendrimères donnent des réponses avec des réactions un électron et l'augmentation de la taille de ces complexes n'influence pas d'une façon dramatique le coefficient de diffusion.

Mots-clés : métallodendrimère, complexe de bisferrocénylacétylure de platine, électrochimie.

[Traduit par la Rédaction]

Introduction

Dendrimers[1] are globular, highly branched macromolecules with a "well-defined" three-dimensional shape, size, and molecular weight. Usually, these branched macromolecules are comprised of several dendritic wedges extending outward from an internal core via interactive or stepwise procedures. In the past two decades, the design and synthesis of diverse dendrimers has received increasing attention,[2] not only because of their aesthetically pleasing structures but also as a result of their various applications in host–guest chemistry,[3] material science,[4] and membrane chemistry.[5] Since the pioneering work by Newkome et al.[6] and Balzani and co-workers[7] in the early 1990s, metallodendrimers[8,9] have evolved to be one of the most attractive fields within supramolecular chemistry. The incorporation of metal ions to the dendritic framework usually gives rise to new properties for the corresponding metallodendritic architectures, such as novel physical, optical, electrochemical, photochemical, biological, and catalytic properties.[10,11] Thus, numerous efforts have been taken to construct new metallodendrimers. For example, we reported the fabrication of a new family of metallodendrimers possessing well-defined and controllable cavities as cores via coordination-driven self-assembly.[12] Recently, our research interests have turned to the fabrication of heterometallic dendrimers connected by unsaturated carbon-rich bridges.

The carbon-rich organometallic complexes containing rigid π-conjugated chains have attracted considerable attention in the past few decades.[13] By taking advantage of the linear geometry of the alkynyl unit and its π-unsaturated character, the metal alkynyls have been extensively explored to prepare molecular wires and polymeric organometallic materials, which may possess interesting properties such as optical nonlinearity, luminescence, liquid crystallinity, and electrical conductivity.[14] In particular, the complexes with mixed-valence bimetallic skeletons have evolved to be important design targets for investigations into molecular electronic devices and chemical-sensing applications because of the possible charge delocalization along the entire conjugated backbone.[15,16]

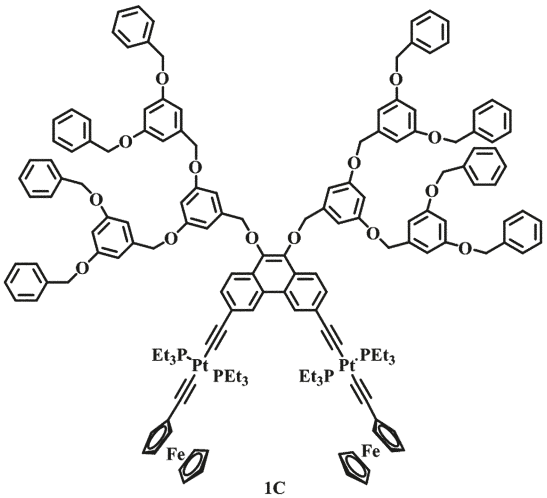
Ferrocene, as a stable and readily oxidizable organometallic complex, has been widely utilized in multifunctional compounds because of its potential to be used in electroluminescence, information storage, and photochemical devices.[17,18] With their importance to material chemistry, there is increasing interest in the construction of novel ferrocenyl bimetallic oligomers or polymers.[19] For example, in the early 1990s, the synthesis and oxidation of Pt(II)–, Ru(II)–, Os (II)–, and Mn(I)–ferrocenylacetylide complexes were reported by the groups of Sato, Werner, Wong,[20] and Wolf.[21] After that the possibility of nonlinear optical response and the important role of the mixed-valence states in these complexes have been extensively investigated. For instance, Wolf and co-workers[21] synthesized a series of novel ruthenium(II) bisferrocenylacetylide complexes and investigated the effect of ancillaryl ligands on electronic delocalization.

In the past decade, the design and construction of platinum–acetylide dendrimers has attracted a great deal of attention because of their potential to provide new nano-sized organometallic materials.[18] For instance, Takahashi and coworkers[22a] reported the preparation of a new family of platinum–acetylide dendrimers possessing a porphyrin core. These novel dendrimers exhibited intramolecular energy transfer from platinum–acetylide moieties to the porphyrin core. Inspired in part by our successful results on the synthesis of platinum–acetylide building blocks,[12d,23b–23e] we envisioned that the synthesis of new platinum–bisferrocenylacetylide dendrimers with different spatial orientations would be realized by the proper choice of precursors with predefined angles and symmetry. It is noted that bimetallic metallodendrimers are of interest because of a variety of materials and synthetic applications.[22a,22b,23g] In addition, the possibility of fine-tuning the size and spatial orientation of the metallodendrimers would help provide enhanced understanding of the geometrical influence on the photo- and electro-chemical properties. Herein, we designed and synthesized two series of platinum–bisferrocenylacetylide dendrimers with different spatial orientations (60° and 120°) (Chart 1). The structures of all complexes were characterized by multinuclear NMR (^{1}H, ^{13}C, and ^{31}P) and mass spectrometry (MALDI-TOF-MS and CSI-TOF-MS), and their electrochemical behavior was investigated.

Results and discussion

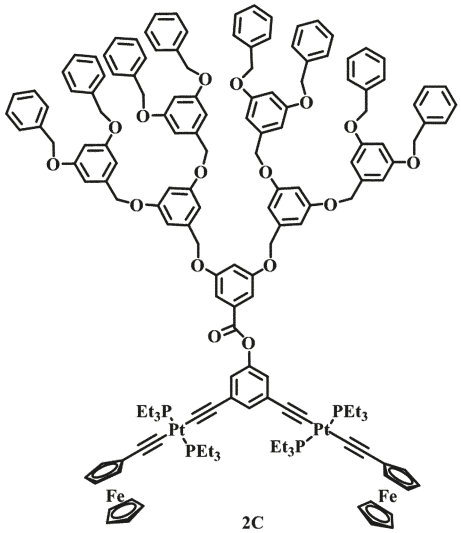
Synthesis of dendritic platinum–bisferrocenylacetylide complexes

The acidity of C–H bonds in alkynes induced by transition metals has received considerable attention in organometallic chemistry.[23] Herein, we utilized the coupling reaction of *trans*-Pt complexes with C–H bonds in alkynes as key steps to the synthesis of all dendritic bimetallic complexes. Complexes **1a**–**1c** were easily prepared in five steps as indicated in Scheme 1. Fréchet-type dendrons were introduced by an etherification reaction of **3** with corresponding dendritic bromides. From dendritic 3,6-dibromophenanthrene derivatives **4a**–**4c**, dendritic 3,6-diethynylphenanthrenes **6a**–**6c** were obtained by the coupling reaction with (trimethylsilyl)acetylene, followed by deprotection with K_2CO_3 in a mixture of methanol and THF. Compounds **6a**–**6c** were then reacted with 4 equiv of *trans*-$PtI_2(PEt_3)_2$ to give diiodometal complexes **7a**–**7c**, by using similar procedures to those reported in previous studies.[22d,23d] Subsequent coupling reactions of **7a**–**7c** with ferrocenylacetylene resulted in the target Pt–Fe bimetallic dendrimers with a 60° orientation. Another series of 120° dendritic platinum–bisferrocenylacetylide complexes were obtained through similar procedures from known dendritic diiodometal complexes **8a**–**8c**[12d] as outlined in Scheme 2. In all cases, the desired complexes were purified by column chromatography on silica gel using dichloromethane as eluent and were obtained as yellow glassy solids with high purities. They exhibited good solubility in common organic solvents such as CH_2Cl_2 and $CHCl_3$. Moreover, these newly designed metallodendrimers are air- and humidity-stable at room temperature.



Structure characterization

Multinuclear NMR (^{1}H, ^{13}C, and ^{31}P) analysis of all bimetallic acetylide complexes revealed the formation of discrete highly symmetric species. The room-temperature ^{31}P NMR spectra of dendritic complexes **1a**–**1c** and **2a**–**2c** displayed a sharp singlet (ca. δ = 11.5 ppm) accompanied by platinum satellites (ca. $J_{Pt\text{-}P}$ = 2380 Hz), which is consistent with the trans configuration around the Pt(II) atom. It should be noted that the singlet in the ^{31}P NMR spectra of **1a**–**1c** and **2a**–**2c** exhibited a small downfield shift from the diiodometal precursors by ~2.3 ppm (Fig. 1). This change, as well as the increase in coupling of the flanking ^{195}Pt satellites (ca. ΔJ = +60 Hz), might be caused by the electron-withdrawing effect of the large π-conjugate bridges. Moreover, with the increase in the generation of dendrimers, ^{31}P NMR spectra of complexes do not display obvious changes. The ^{1}H NMR spectra of **1a**–**1c** exhibited characteristic phenanthrene proton resonances in the aromatic area, one singlet and two doublets. Compared with the diPt(II) precursors **7a**–**7c**, the ^{1}H NMR spectra of **1a**–**1c** show that some proton resonances in the phenanthrene ring displayed slight downfield shifts owing to the electron-withdrawing effect of the large π-conjugate bridges. For example, the singlet (δ 8.51 ppm) of **1c** showed an ~0.03 ppm downfield shift from 8.48 ppm in the spectrum of **7c**. Likewise, the analysis of the ^{1}H NMR spectra of **2a**–**2c** agrees well with the characterization of 120° bimetallic acetylide dendrimers.



Usually MALDI-TOF-MS studies allow the complexes to remain intact during the analysis process and provide the high resolution required for the unambiguous determination of their absolute molecular weight and molecularity. MALDI-TOF-MS investigation of bimetallic acytelide dendrimers **1a**–**1c** and **2a**–**2c** were carried out first. Because of high molecular weights and complex isotope splitting of such multimetallic dendrimers, it is difficult to get strong mass signals even under the MALDI-TOF-MS conditions. With considerable effort, satisfactory high-resolution MALDI-TOF-MS results of **1a** and **2a** and **2b** were found, confirming the structure of such bimetallic complexes. To obtain the higher resolution of mass spectrometric studies for the other complexes, CSI-TOF-MS studies of **1b**, **1c**, and **2c** were performed. In the CSI-TOF-MS spectrum of **1b**, the peak at m/z = 2124.0, corresponding to the charge state $[M + H]^+$, was observed, and its isotopic resolution is in excellent agreement with the theoretical distribution (see Supplementary data). Moreover, the peaks at m/z = 1495.2 for

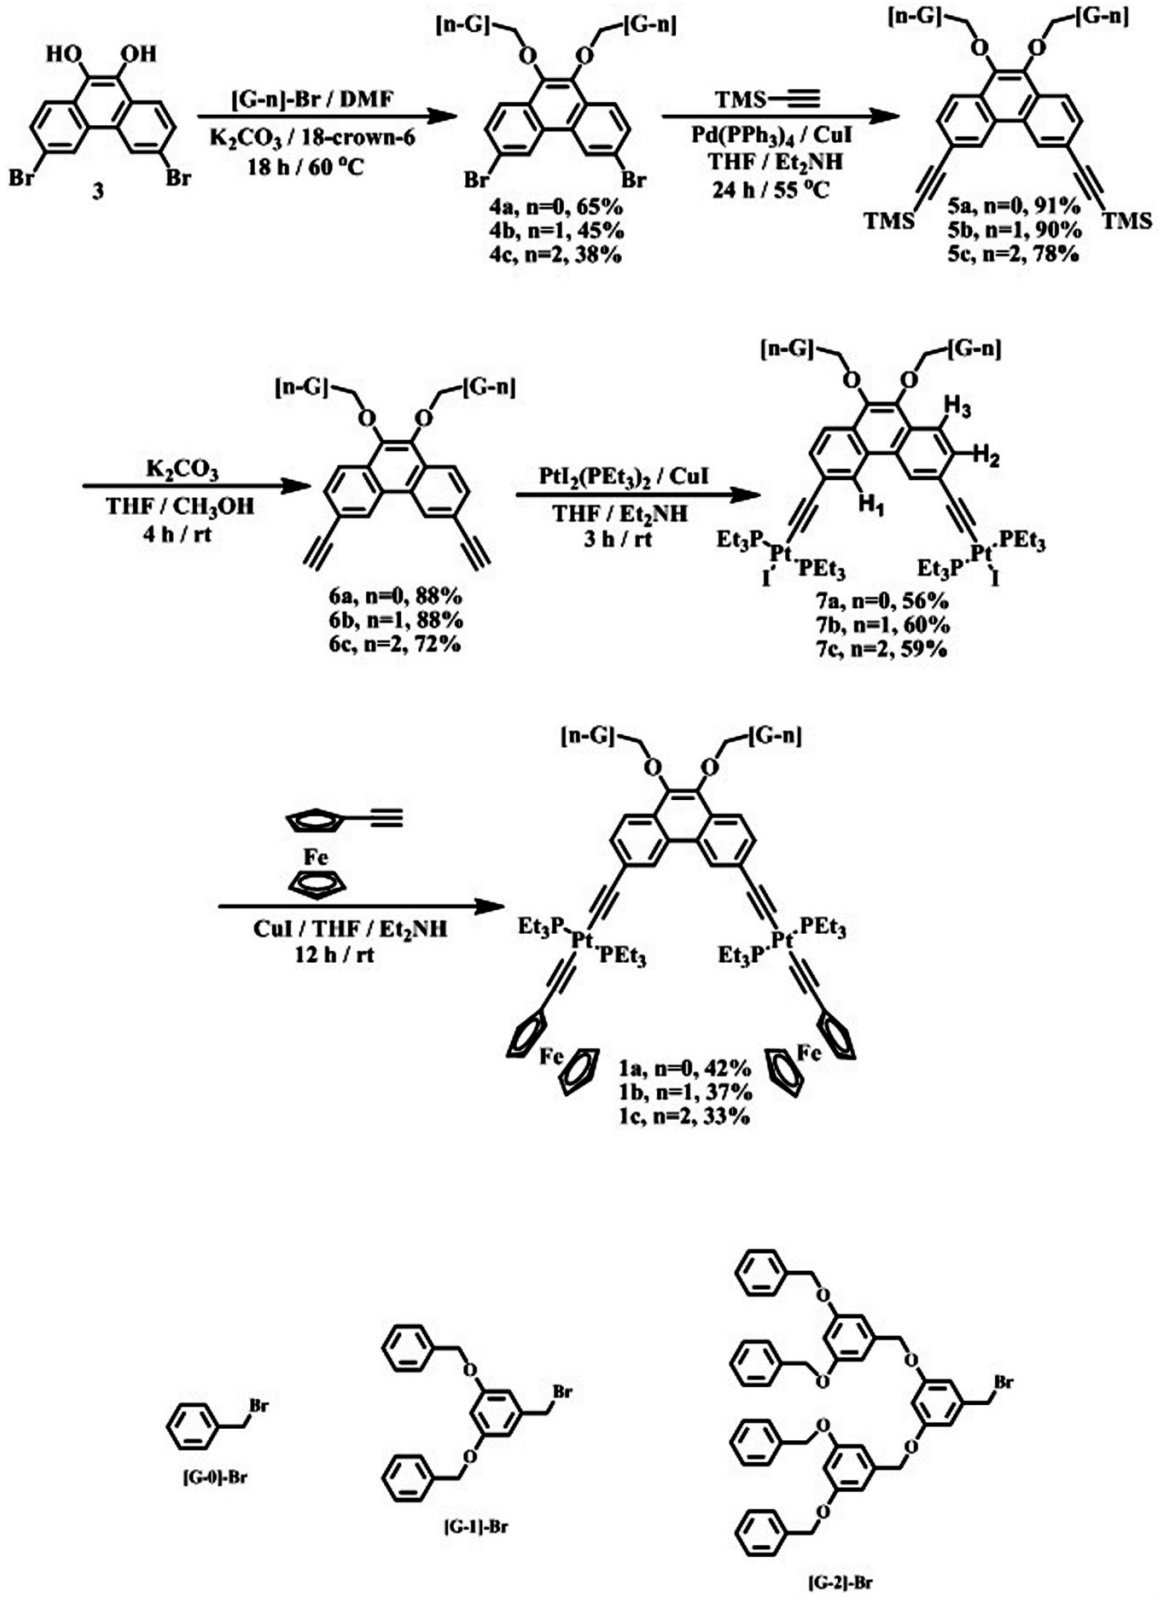
2C

1c and m/z = 1505.3 for **2c** were found in the CSI-TOF-MS spectra of [G-3] bimetallic acetylide dendrimers, which corresponds to the $[M + 2H]^{2+}$ charge state. These peaks were isotopically resolved and agree well with their theoretical distribution (Fig. 2).

Simulated molecular models

Flexible high-generation dendrimers often prove difficult to crystallize. All attempts to grow X-ray quality single crystals of dendritic bimetallic complexes **1a**–**1c** and **2a**–**2c** have proven to be unsuccessful to date. Thus, PM6 semiempirical molecular orbital method was employed to optimize the geometry of all dendritic platinum–bisferrocenylacetylide complexes. In the optimized structures of all bimetallic complexes, the ferrocene moieties and phenyl acetylides are σ-bonded to platinum in a trans configuration with 60° and 120° spatial orientations, respectively, whereas the dendrons position on the other side. Coordination around the platinum atoms is square-planar, with slight tetrahedral distortions. Moreover, the distance between two Fe atoms is about 1.7 nm for **1a**–**1c** and 2.4 nm for **2a**–**2c** (Fig. 3; also see Supplementary data).

Absorption and emission properties



The absorption and emission properties of this series of platinum–acetylide biferrocenyl dendrimers were studied in dilute dichloromethane solution (ca. 10^{-5} mol/L) and the data are collected in Table 1. The electronic absorption spectra of metallodedrimers **1a**–**1c** displayed absorption bands in the range of 264–336 and 357–381 nm. Likewise, the absorption spectra of **2a**–**2c** were dominated by intense relatively broad bands in the near-UV region with strong transitions at higher energy. The dominant absorption band was described as metal-to-ligand charge transfer (MLCT) transitions according to a similar previous report.[24] Upon photo excitation, all metallodendrimers show weak luminescence in dichloromethane solution at room temperature. For example, upon being excited at 362 nm, **1a**–**1c** feature a band with a maximum at 406–409 nm in dilute dichloromethane solution (ca. 10^{-5} mol/L). Furthermore, in the emission spectrum of each compound, the approximate mirror symmetry with the respect to the lowest energy absorption bands was observed, which indicated that the same optical transition was involved in both absorption and emission processes. In addition, a small Stokes shift was found in each fluorescence spectrum, indicating that the emission emanates from the lowest singlet state. It should be noted that the emission bands are only slightly influenced by the increase of dendritic generations.

Electrochemistry properties

The electrochemical behavior of these platinum–acetylide biferrocenyl dendrimers has been investigated via cyclic voltammetry (CV) (Table 2). The study was performed in a dichloromethane solution of **1a**–**1c** and **2a**–**2c** containing 0.2 mol/L n-Bu_4NPF_6 as the supporting electrolyte at a ~7.0 mm^2 glassy carbon electrode. The cyclic voltammograms corresponding to the one-electron oxidation of the ferrocene groups yielded anodic to cathodic peak current ratios of $i_a/i_c \approx 1$ (Fig. 4; also see Supplementary data). Moreover, it was found that the oxidation of the ferrocene moieties in each complex was reversible, which was indicated by the nearly identical cathodic and anodic peak currents, as well as nearly scan-rate-independent peak potentials. The difference between the anodic and cathodic peak potentials (ΔE_p) measured at different scan rates was found to be larger than the theoretical value of 59 mV expected for a reversible one-electron redox reaction, a consequence of the solution ohmic resistance.

With the aim of obtaining the effects of dendron subunits in the electrochemical properties of ferrocenes, the further cyclic voltammetry of these complexes was carried out to gain the diffusion coefficients (D). Different from our previous reports,[12] the D values did not change dramatically with an increase in the molecular weight and molecular size in this study. These results indicate that the dendron moieties are located far from the electrochemical active centers and do not influence the electrochemical activity of ferrocenyl groups, which has been supported by the optimized structures.

Experimental section

General comments

Materials and reagents

Toluene and THF was distilled from sodium and diethylamine was dried over potassium hydroxide. All solvents were degassed under N_2 for 30 min before use. NMR solvents ($CDCl_3$) and all other reagents were purchased and used without further purification.

Physical measurements and instrumentation

^1H, ^{13}C, and ^{31}P NMR spectra were recorded on a Bruker 300 MHz spectrometer (^1H: 300 MHz; ^{13}C: 75 MHz; and ^{31}P: 121.4 MHz) at 298 K or a 400 MHz spectrometer (^1H: 400 MHz; ^{13}C: 100 MHz; and ^{31}P: 162 MHz) at 298 K. The ^1H and ^{13}C NMR chemical shifts are reported relative to residual solvent signals, and ^{31}P NMR resonances are referenced to an internal standard sample of 85% H_3PO_4 (δ 0.0). Coupling constants (*J*) are in Hz and chemical shifts (δ) are in ppm. Multiplicities are denoted as follows: s = singlet, d = doublet, m = multiplet, and t = triplet. ESI-MS and EI -MS were recorded on an Agilent 5973N mass spectrometer using electrospray or electron ionization. MALDI-HRMS was recorded on a Waters GCT Premier mass spectrometer. CSI-TOF-MS was recorded on a JMS-T100LC mass spectrometer using electrospray ionization.

Spectroscopic measurements

UV–vis spectra were recorded on a Cary 50 Bio UV–vis spectrophotometer. Emission spectra were measured on a Cary Eclipse luminescence spectrometer. Samples for absorption and emission measurements were contained in 1 cm quartz cuvettes. CV was performed using a three-electrode cell and a RST electrochemical work station. The working electrode was a glassy carbon disk with a surface area of ~7.0 mm^2. A SCE electrode was used as reference electrode and a Pt wire as the counter electrode.

4.83 mmol; for G2, 3.9 g, 4.83 mmol), and K_2CO_3 (2.9 g, 21.0 mmol) were dissolved in DMF (25 mL). The mixture was heated at reflux for 18 h and then cooled to room temperature. Solvent was distilled and the resulting mixture was poured into water and extracted with methylene chloride (3 × 15 mL). The methylene chloride solution was washed with water, dried over anhydrous magnesium sulfate, and filtered. The crude products were purified by column chromatography on silica gel (dichloromethane / petroleum ether, ~1:1) to give compounds **4a**–**4c**.

4a

Yield (white solid): 0.58 g, 65%; mp 192 °C. R_f 0.74 (dichloromethane / petroleum ether, 1;1). ^{1}H NMR ($CDCl_3$, 300 MHz) δ: 8.66 (s, H_1, 2H), 8.10 (d, H_2, J = 8.7 Hz, 2H), 7.69 (d, H_3, J = 6.3 Hz, 2H), 7.52–7.49 (m, Ph*H*, 4H), 7.43–7.36 (m, Ph*H*, 6H), 5.27 (s, PhCH_2O, 4H). ^{13}C NMR ($CDCl_3$, 75 MHz) δ: 143.2, 136.9, 130.6, 129.0, 128.6, 128.4, 125.4, 124.3, 120.6, 75.5. MALDI-HRMS for **4a** *m*/*z* calcd for $C_{28}H_{20}Br_2O_2Na$ ([M + Na]$^+$): 568.97; found: 569.00.

4b

Yield (white glassy solid): 0.92 g, 45%; mp 152 °C. R_f 0.50 (dichloromethane / petroleum ether, 3:1). ^{1}H NMR ($CDCl_3$, 300 MHz) δ: 8.67 (d, H_1, J = 1.5 Hz, 2H), 8.08 (d, H_2, J = 8.7 Hz, 2H), 7.69 (d, H_3, J = 9.0 Hz, 2H), 7.37–7.29 (m, Ph*H*, 20H), 6.74 (d, Ph*H*, J = 2.1 Hz, 4H), 6.57 (t, Ph*H*, J = 2.1 Hz, 2H), 5.18 (s, PhCH_2O, 4H), 4.93 (s, PhCH_2O, 8H). ^{13}C NMR ($CDCl_3$, 75 MHz) δ: 160.1, 143.1, 139.3, 136.7, 130.7, 129.1, 128.6, 128.3, 128.0, 127.5, 125.5, 124.3, 120.7, 106.9, 101.9, 75.3, 70.1. MALDI-HRMS of **4b** *m*/*z* calcd for $C_{56}H_{44}Br_2O_6Na$ ([M + Na]$^+$): 993.14; found: 993.20.

4c

Yield (white glassy solid): 1.45 g, 38%; mp: 46 °C. R_f 0.36 (dichloromethane / petroleum ether, 4:1). ^{1}H NMR ($CDCl_3$, 400 MHz) δ: 8.65 (s, H_1, 2H), 8.09 (d, H_2, J = 8.8 Hz, 2H), 7.69 (d, H_3, J = 6.3 Hz, 2H), 7.34–7.28 (m, Ph*H*, 40H), 6.72 (s, Ph*H*, 4H), 6.62 (s, Ph*H*, 8H), 6.51 (s, Ph*H*, 6H), 5.15 (s, PhCH_2O, 4H), 4.93 (s, PhCH_2O, 16H), 4.82 (s, PhCH_2O, 8H). ^{13}C NMR ($CDCl_3$, 100 MHz) δ: 160.1, 160.0, 143.2, 139.4, 139.2, 136.7, 130.7, 129.1, 128.5, 128.3, 127.9, 127.5, 124.3, 120.8, 106.8, 106.4, 102.0, 101.6, 70.0, 69.9. MALDI-HRMS of **4c** *m*/*z* calcd for $C_{112}H_{92}Br_2O_{14}Na$ ([M + Na]$^+$): 1841.48; found: 1841.60.

Synthesis of 5a–5c

To a 50 mL round-bottomed Schlenk flask were added **4a**–**4c** (**4a**, 200 mg, 0.36 mmol; **4b**, 250 mg, 0.26 mmol; and **4c**, 300 mg, 0.16 mmol), trimethylsilylethyne (for G1, 0.41 mL, 2.88 mmol; for G2, 0.30 mL, 2.08 mmol; and for G3, 0.19 mL, 1.28 mmol), $Pd(PPh_3)_4$ (for G1, 42 mg; for G2, 30 mg; and for G3, 19 mg), and CuI (for G1, 7.0 mg; for G2, 5.0 mg; and for G3, 3.0 mg). Then a mixture of tetrahydrofuran (for G1, 4.0 mL; for G2, 3.0 mL; and for G3, 2.0 mL) and dry diethylamine (for G1, 4.0 mL; for G2, 3.0 mL; and for G3, 2.0 mL) was added under nitrogen. The solution was stirred at 66 °C for 24 h. The solvent was removed under vacuum and the resulting yellow residue was purified via column chromatography on silica gel (dichloromethane / petroleum ether, ~1:2) to provide compounds **5a**–**5c** (yields: G1, 91%; G2, 90%; and G3, 78%).

Synthesis of 6a–6c

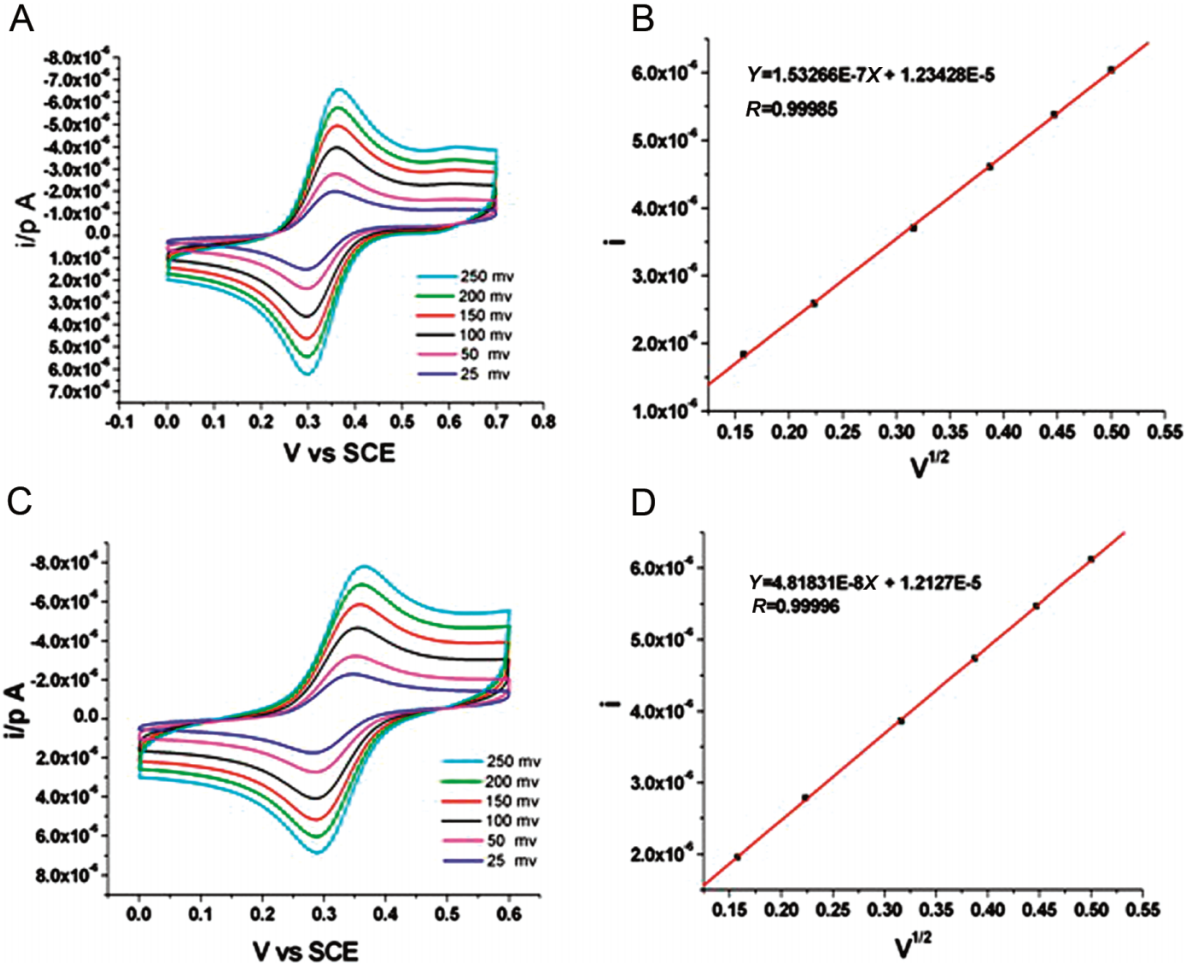
Desilylation of **5a**–**5c** (**5a**, 105 mg, 0.18 mmol; **5b**, 182 mg, 0.18 mmol; and **5c**, 335 mg, 0.18 mmol) was achieved by stirring the compounds in a K_2CO_3 suspending solution of methanol–THF (100 mg in 20 mL methanol and 20 mL THF) for 4 h. The solution was carefully diluted with 30 mL of water and organic product was extracted with diethyl ether. Drying the ether phase over magnesium sulfate and subsequent filtration resulted in slightly yellow oil after removal of the solvent. Compounds **6a**–**6c** were obtained by column chromatography on silica gel (dichloromethane / petroleum ether, ~1:1).

6a

Yield (pale yellow solid): 92 mg, 88%; mp 138 °C. R_f 0.31 (dichloromethane / petroleum ether, 1:3). ^{1}H NMR ($CDCl_3$, 400 MHz) δ: 8.76 (s, H_1, 2H), 8.19 (d, H_2, J = 8.0 Hz, 2H), 7.68 (d, H_3, J = 8.8 Hz, 2H), 7.53–7.51 (m, H_3 and Ph*H*, 4H), 7.41–7.39 (m, Ph*H*, 6H), 5.28 (s, PhCH_2O, 4H), 3.22 (s, C≡C*H*, 2H). ^{13}C NMR ($CDCl_3$, 100 MHz) δ: 144.0, 137.1, 130.2, 129.5, 128.6, 128.4, 128.3, 127.8, 126.9, 122.7 119.8, 84.0, 77.9, 75.6. EI HRMS of **6a** *m*/*z* calcd for $C_{32}H_{22}O_2$: 438.1620 (M$^+$); found: 438.1623.

6b

Yield (pale yellow solid): 160 mg, 88%; mp 104 °C. R_f 0.31 (dichloromethane / petroleum ether, 1:1). ^{1}H NMR ($CDCl_3$, 400 MHz) δ: 8.77 (s, H_1, 2H), 8.17 (d, H_2, J = 8.4 Hz, 2H), 7.68 (d, H_3, J = 8.4 Hz, 2H), 7.36–7.33 (m, Ph*H*, 20H), 6.76 (s, Ph*H*, 4H), 6.56 (s, Ph*H*, 2H), 5.20 (s, PhCH_2O, 4H), 4.92 (s, PhCH_2O, 8H), 3.23 (s, C≡C*H*, 2H). ^{13}C NMR ($CDCl_3$, 100 MHz) δ: 160.1, 143.9, 139.4, 136.7, 130.3, 129.4, 128.6, 128.0, 127.5, 127.0, 122.6, 119.9, 106.9, 101.9, 84.0, 78.0, 75.3, 70.1. ESI HRMS of **6b** *m*/*z* calcd for $C_{60}H_{46}NaO_6$ ([M + Na]$^+$): 885.3187; found: 885.3175.



6c

Yield (pale yellow solid): 241 mg, 72%; mp 42 °C. R_f 0.38 (dichloromethane / petroleum ether, 3:1). ^{1}H NMR ($CDCl_3$, 400 MHz) δ: 8.76 (s, H_1, 2H), 8.19 (d, H_2, J = 6.8 Hz, 2H), 7.69 (d, H_3, J = 6.4 Hz, 2H), 7.34–7.30 (m, Ph*H*, 40H), 6.73 (s, Ph*H*, 4H), 6.63 (s, Ph*H*, 8H), 6.51 (s, Ph*H*, 6H), 5.17 (s, PhCH_2O, 4H), 4.93 (s, PhCH_2O, 16H), 4.82 (s, PhCH_2O, 8H), 3.20 (s, C≡C*H*, 2H). ^{13}C NMR ($CDCl_3$, 100 MHz) δ:

400 MHz) δ: 8.48 (s, H_1, 2H), 8.12 (d, H_2, J = 8.4 Hz, 2H), 7.53 (d, H_3, J = 7.6 Hz, 2H), 7.34–7.29 (m, Ph*H*, 40H), 6.78 (s, Ph*H*, 4H), 6.63 (s, Ph*H*, 8H), 6.51 (s, Ph*H*, 6H), 5.16 (s, PhCH_2O, 4H), 4.93 (s, PhCH_2O, 16H), 4.82 (s, PhCH_2O, 8H), 2.27 (br, PhCH_2CH_3, 24H), 1.26–1.17 (m, PhCH$_2CH_3$, 36H). ^{13}C NMR ($CDCl_3$, 100 MHz) δ: 160.1, 143.1, 140.0, 139.2, 136.8, 129.9, 128.5, 128.3, 127.9, 127.5, 127.0, 122.0, 106.7, 106.5, 101.8, 101.6, 75.2, 70.0, 69.9, 16.9, 16.8, 16.6, 8.4. ^{31}P NMR ($CDCl_3$, 161.9 Hz) δ: 9.24 (s, $^1J_{Pt-P}$ = 2321.6 Hz).

Synthesis of 1a–1c

One of complexes **7a**–**7c** (**7a**, 93 mg, 0.06 mmol; **7b**, 119 mg, 0.06 mmol; or **7c**, 170 mg, 0.06 mmol) and ethynylferrocene (50 mg, 0.24 mmol) were dissolved in a mixture of THF (10 mL) and diethylamine (5 mL). CuI (2.0 mg) was added to this reaction mixture as a catalyst. The yellowish brown mixture was then stirred at room temperature for 12 h, and the solvent was removed under reduced pressure. The greenish yellow gummy residue was then purified by column chromatography on silica gel with dichloromethane as the eluent to afford a brownish yellow glassy solid of either **1a**, **1b**, or **1c**.

1a

Yield (brownish yellow glassy solid): 39 mg, 42%; mp 47 °C. R_f 0.58 (dichloromethane). ^{1}H NMR ($CDCl_3$, 400 MHz) δ: 8.48 (s, H_1, 2H), 8.08 (d, H_2, J = 8.0 Hz, 2H), 7.56–7.50 (m, Ph*H*, 6H), 7.41–7.36 (m, Ph*H*, 6H), 5.23 (s, PhCH_2O, 4H), 4.25 (s, Fc–*H,* 4H), 4.15 (s, Fc–*H*, 10H), 4.07 (s, Fc–*H*, 4H), 2.25–2.23 (m, PhCH_2CH_3, 24H), 1.33–1.27 (m, PhCH$_2CH_3$, 36H). ^{13}C NMR ($CDCl_3$, 100 MHz) δ: 167.7, 143.0, 137.6, 132.3, 130.9, 130.0, 128.8, 128.5, 128.3, 128.0, 126.8, 124.4, 121.8, 75.4, 70.3, 70.0, 69.4, 67.0, 65.5, 16.6, 16.5, 16.3, 8.5. ^{31}P NMR ($CDCl_3$, 161.9 Hz) δ: 11.5 (s, $^1J_{Pt-P}$ = 2381.5 Hz). MALDI-HRMS of **1a** m/z calcd for $C_{80}H_{99}Fe_2O_2P_4Pt_2$ ([M + H]$^+$): 1717.46; found: 1721.60.

1b

Yield (brownish yellow glassy solid): 48 mg, 37%; mp 49 °C. R_f 0.51 (dichloromethane). ^{1}H NMR ($CDCl_3$, 400 MHz) δ: 8.51 (s, H_1, 2H), 8.09 (d, H_2, J = 7.6 Hz, 2H), 7.54 (d, H_3, J = 8.0 Hz, 2H), 7.39–7.32 (m, Ph*H*, 20H), 6.82 (s, Ph*H*, 4H), 6.58 (s, Ph*H*, 2H), 5.20 (s, PhCH_2O, 4H), 4.94 (s, PhCH_2O, 8H), 4.27 (s, Fc–*H*, 4H), 4.17 (s, Fc–*H*, 10H), 4.09 (s, Fc–*H*, 4H), 2.27–2.26 (m, PhCH_2CH_3, 24H), 1.40–1.29 (m, PhCH$_2CH_3$, 36H). ^{13}C NMR ($CDCl_3$, 100 MHz) δ: 160.1, 140.1, 136.8, 130.2, 128.5, 128.4, 127.9, 127.6, 124.4, 121.8, 106.8, 101.8, 75.1, 70.3, 69.4, 67.0, 16.6, 16.5, 16.3, 8.5. ^{31}P NMR ($CDCl_3$, 161.9 Hz) δ: 11.5 (s, $^1J_{Pt-P}$ = 2379.9 Hz). CSI-TOF-MS of **1b** m/z calcd for $C_{108}H_{123}Fe_2O_6P_4Pt_2$ ([M + H]$^+$): 2141.63; found: 2142.00.

1c

Yield (brownish yellow glassy solid): 56 mg, 33%; mp: 50 °C. R_f 0.45(dichloromethane). ^{1}H NMR ($CDCl_3$, 400 MHz) δ: 8.51 (s, H_1, 2H), 8.11 (d, H_2, J = 8.4 Hz, 2H), 7.55 (d, H_3, J = 8.0 Hz, 2H), 7.35–7.30 (m, Ph*H*, 40H), 6.80 (s, Ph*H*, 4H), 6.65 (s, Ph*H*, 8H), 6.52 (s, Ph*H*, 6H), 5.17 (s, PhCH_2O, 4H), 4.94 (s, PhCH_2O, 16H), 4.82 (s, PhCH_2O, 8H), 4.26 (s, Fc–*H*, 4H), 4.16 (s, Fc–*H*, 10H), 4.08 (s, Fc–*H*, 4H), 2.35–2.33 (m, PhCH_2CH_3, 24H), 1.39–1.27 (m, PhCH$_2CH_3$, 36H). ^{13}C NMR ($CDCl_3$, 100 MHz) δ: 160.1, 160.0, 140.1, 139.2, 136.8, 128.5, 127.9, 127.5, 106.7, 106.5, 101.6, 70.3, 70.0, 69.9, 69.4, 67.0, 16.6, 16.4, 16.3, 8.5. ^{31}P NMR ($CDCl_3$, 161.9 Hz) δ: 11.4 (s, $^1J_{Pt-P}$ = 2379.9 Hz). CSI-TOF-MS of **1c** m/z calcd for $C_{164}H_{172}Fe_2O_{14}P_4Pt_2$ ([M + 2H]$^{2+}$): 1495.00; found: 1495.20.

Synthesis of 2a–2c

The synthetic procedure of **2a**–**2c** was similar to that for **1a**–**1c** except that 120° [G-1]–[G-3] dendritic precursors **8a**–**8c** were used and the brownish yellow glassy solids were obtained as desired products with moderate yields (G1, 76%; G2, 68%; and G3, 66%).

2a

Yield (brownish yellow glassy solid): 101 mg, 76%; mp: 49 °C. R_f 0.23 (dichloromethane / petroleum ether, 3:1). ^{1}H NMR ($CDCl_3$, 400 MHz) δ: 7.46–7.35 (m, Ph*H*, 12H), 7.12 (s, H_1, 1H), 6.87–6.85 (m, H_2 and Ph*H*, 3H), 5.11 (s, PhCH_2O, 4H), 4.23 (s, Fc–*H*, 4H), 4.14 (s, Fc–*H*, 10H), 4.06 (s, Fc–*H*, 4H), 2.17–2.18 (m, PhCH_2CH_3, 24H), 1.27–1.21 (m, PhCH$_2CH_3$, 36H). ^{13}C NMR ($CDCl_3$, 100 MHz) δ: 164.7, 159.9, 150.3, 136.4, 131.8, 131.2, 129.6, 128.6, 128.1, 127.5, 120.6, 109.0, 108.7, 108.5, 107.7, 105.1, 102.3, 72.8, 70.4, 70.2, 69.3, 66.9, 16.6, 16.4, 16.2, 14.1, 8.4. ^{31}P NMR ($CDCl_3$, 162 Hz) δ: 11.4 (s, $^1J_{Pt-P}$ = 2386.4 Hz). MALDI-HRMS of **2a** m/z calcd for $C_{79}H_{99}Fe_2O_4P_4Pt_2$ ([M + H]$^+$): 1737.45; found: 1736.50.

2b

Yield (brownish yellow glassy solid): 86 mg, 68%; mp 53 °C. R_f 0.67 (dichloromethane / ethyl acetate, 1:20). ^{1}H NMR ($CDCl_3$, 400 MHz) δ: 7.43–7.30 (m, Ph*H*, 22H), 7.11 (s, H_1, 1H), 6.84–6.82 (m, H_2 and Ph*H*, 3H), 6.69 (s, Ph*H*, 4H), 6.58 (s, Ph*H*, 2H), 5.04 (s, PhCH_2O, 12H), 4.22 (s, Fc–*H*, 4H), 4.18 (s, Fc–*H*, 10H), 4.05 (s, Fc–*H*, 4H), 2.16 (br, PhCH_2CH_3, 24H), 1.24–1.18 (m, PhCH$_2CH_3$, 36H). ^{13}C NMR ($CDCl_3$, 100 MHz) δ: 160.2, 159.8, 138.8, 136.8, 128.6, 128.0, 127.5, 109.0, 106.4, 101.8, 70.2, 69.4, 67.0, 16.6, 16.4, 16.2, 8.4. ^{31}P NMR ($CDCl_3$, 161.9 Hz) δ: 11.5 (s, $^1J_{Pt-P}$ = 2379.9 Hz). MALDI-HRMS of **2b** m/z calcd for $C_{107}H_{123}Fe_2O_8P_4Pt_2$ ([M + H]$^+$): 2161.62; found: 2161.60.

2c

Yield (brownish yellow glassy solid): 117 mg, 66%; mp 55 °C. R_f 0.67 (dichloromethane). ^{1}H NMR ($CDCl_3$, 400 MHz) δ: 7.44 (s, Ph*H*, 1H), 7.40–7.30 (m, Ph*H*, 42H), 7.10 (s, H_1, 1H), 6.84 (s, H_2 and Ph*H*, 3H), 6.67 (s, Ph*H*, 12H), 6.56 (s, Ph*H*, 6H), 5.01–4.95 (m, PhCH_2O, 28), 4.22 (s, Fc–*H*, 4H), 4.13 (s, Fc–*H*, 10H), 4.05 (s, Fc–*H*, 4H), 2.14 (br, Fc–*H*, 24H), 1.28–1.17 (m, Fc–*H*, 36H). ^{13}C NMR ($CDCl_3$, 100 MHz) δ: 160.2, 160.1, 159.8, 139.2, 136.8, 128.6, 128.0, 127.5, 106.5, 106.4, 106.7, 70.2, 70.1, 70.0, 69.4, 66.9, 16.6, 16.4, 16.2, 8.4. ^{31}P NMR ($CDCl_3$, 162 Hz) δ: 11.4 (s, $^1J_{Pt-P}$ = 2379.9 Hz). CSI-TOF-MS of **2c** m/z calcd for $C_{163}H_{172}Fe_2O_{16}P_4Pt_2$ ([M + 2H]$^{2+}$): 1505.00; found: 1505.30.

Conclusion

By employing the coupling reaction of *trans*-Pt complexes with C–H bonds in alkynes as key steps, we have successfully prepared a new family of dendritic platinum–bisferrocenylacetylide complexes from simple starting materials in satisfactory yields. Multinuclear NMR (^{1}H, ^{13}C, and ^{31}P) analysis of all metallodendrimers displayed very similar characteristics that are indicative of the generation of the desired species. The sharp NMR signals in both ^{31}P {^{1}H} and ^{1}H NMR spectra, along with the solubility of these species, ruled out the formation of oligomers. Moreover, mass spectrometric studies, including MALDI-TOF-MS and CSI-TOF-MS, provided further evidence for the unambiguous determination of their absolute molecular weight and molecularity. All bimetallic metallodendrimers exhibit remarkable solubility in common organic solvents, such as dichloromethane and chloroform. Furthermore, these newly designed metallodendrimers are air- and humidity-stable at room temperature. Electrochemical studies reveal that all of the redox moieties are stable, independent, and electrochemically active. In addition, all metallodendrimers show one-electron reaction responses and the increased size of the assemblies do not influence *D*. To the best of our knowledge, this is the first report on the synthesis of platinum–bisferrocenylacetylide dendrimers, which obviously enriches the library of heterometallic dendrimers connected by unsaturated carbon-rich bridges.

Supplementary data

Abstract: A novel ionic-liquid-supported 1,5,7-triazabicyclo[4.4.0]dec-5-ene (IL–TBD) was synthesized and investigated for its ability to act as an active organocatalyst in the Michael addition of active methylene compounds and thiophenols to chalcones under solvent-free conditions. The IL–TBD afforded Michael addition products in excellent yields (82%–94%) at room temperature, and it was simply recycled and reused at least five times without significant loss of catalytic activity.

Key words: ionic liquid, supported catalysis, organocatalyst, Michael addition, α,β-unsaturated ketones.

Résumé : On a réalisé la synthèse d'un liquide ionique supporté par du 1,5,7-triazabicyclo[4.4.0]déc-5-ène (LI–TBD) et on a étudié ses capacités d'agir comme organocatalyseur dans l'addition de Michael de composés comportant des méthylènes actifs et des thiophénols à des chalcones, dans des conditions sans solvant. Le LI–TBD permet d'obtenir des produits d'addition de Michael avec d'excellents rendements (82 % à 94 %), à la température ambiante; il peut être recyclé facilement et réutilisé jusqu'à cinq fois sans perte significative de son activité catalytique.

Mots-clés : liquide ionique, catalyseur sur un support, organocatalyseur, addition de Michael, cétones α,β-insaturées.

[Traduit par la Rédaction]

Introduction

Organocatalyses have emerged as new and powerful tools in organic synthesis.[1–4] Lower cost, operational simplicity, easy availability, efficiency, and less toxicity make organocatalysts attractive alternatives to organometallic catalysts in organic synthesis. The major problems associated with most homogeneous organocatalyst systems are high organocatalyst loadings to afford efficient synthesis, long and tedious preparation steps, and separation and recycling of these catalysts. To overcome these difficulties catalysts have been immobilized on various solid supports. However, reaction rates are lower with solid-supported reagents and require longer validation times.

Ionic liquids (ILs) are fascinating materials for chemists as they offer new chemical and physical properties such as high thermal stability, very low to negligible vapor pressure, good solvating ability, a noncoordinating nature, and ease of recyclability.[5–10] In recent years, functionalized ionic liquids (FILs) synthesized with properties for specific desired chemical tasks have attracted the attention of chemists.[11,12] Several ILs functionalized with catalytically active groups have been developed and used effectively as recyclable organocatalysts for various organic transformations.[13–22] Imidazolium ILs functionalized with basic organic molecules such as proline[23–25] and pyrrolidine[26–32] have been extensively studied for Michael additions. FILs not only overcome the problems of lower reaction rate and longer validation reaction time but also provide reagents with tuneable properties and "green" credentials.

1,5,7-Triazabicyclo[4,4.0]dec-5-ene (TBD) is a versatile bicyclic guanidine with nucleophilic and basic properties that render this compound an extremely useful catalyst for many organic transformations.[33–37] Several methods have been reported for the preparation of heterogeneous basic catalysts in which TBD is covalently attached with polymer support or silica.[38–40] The solid-supported TBDs have efficiently promoted some fundamental base-catalyzed organic transformations such as the Nef reaction,[41] alkylation,[42] 1,2-epoxide ring opening,[43] aldol-type condensation,[43] Knoevenagel condensation,[43,44] Michael addition,[44] synthesis of thioureas,[45] aryl ether synthesis,[46] synthesis of benzofuran[47] and thiazoles,[48] and transesterification of soybean oil.[49] However, heterogeneous TBD usually suffers from the disadvantage of being only slightly recyclable, requires a compatible solvent for swelling, and has prolonged reaction times. In continuation of our effort to develop IL-based catalysts,[50] herein, we report the synthesis of a novel IL-functionalized TBD (IL–TBD)

Scheme 1. Michael addition of active methylene compounds and thiophenols to chalcones. EWG, electron-withdrawing group.

and its use as an organocatalyst for the Michael addition of active methylene compounds and thiophenols to chalcones (Scheme 1).

Results and discussion

Synthesis of IL–TBD was achieved following the reaction sequences shown in Scheme 2. Initially, the reaction of 1-methylimidazole (**1**) with 1-bromo-4-chlorobutane (**2**) at room temperature afforded (4′-chlorobutyl)-3-methylimidazolium bromide (**3**). Subsequent reaction of **3** with 1.5 equiv of TBD (**4**) at 100 °C for 6 h gave IL–TBD **5** with bromide as the anion. The excess TBD was removed by washing with dichloromethane, and the IL–TBD was purified by column chromatography on silica gel. The structure of **5** was confirmed by ^{1}H NMR, ^{13}C NMR, and high-resolution mass spectrometry. The ^{1}H NMR spectrum showed multiplets in the range of 3.24 to 3.04, representing the methylene protons of TBD adjacent to nitrogens. In ^{13}C NMR, six carbons appeared in the aliphatic region in addition to methyl and methylene carbons of the IL, which corresponds to the methylene carbon of TBD. In HRMS peaks appeared at 356.1260 $[M]^+$, 358.1257 $[M + 2]^+$, and 276.1889 $[M - Br]^+$, which confirmed the structure of **5**.

The catalytic activity of IL–TBD as an organocatalyst was evaluated for the Michael addition of malononitrile to chalcones. The reaction conditions were optimized by taking the reaction of 3-(2-fluorophenyl)-1-(4-methoxyphenyl)prop-2-en-1-one with malononitrile to give **7** as model reaction (Table 1). Loading studies using different concentrations of catalyst showed the requirement of 50 mol % of IL–TBD to catalyze the reaction to maximum yields (Table 1, entries 1–4). The yield of Michael addition product was higher under solvent-free conditions (87%; Table 1, entry 3) as compared with the reaction in different organic solvents (58%–85%; Table 1, entries 5–9). The aqueous medium served as a poor system for this reaction giving no product over the period under similar reaction conditions (Table 1, entry 11). This may be due to the insolubility of both chalcone and the catalyst in water. The product yield was low (17%–20%) when the reaction was performed in ILs ([bmim]Br, [bmim]BF_4, and [bmim]PF_6) as solvents. The low yield in these ILs may

probably be due to the slight acidic nature of the IL and the poor solubility of the reactant at room temperature in [bmim]Br. The role of IL–TBD as catalyst is confirmed by the fact that no product was formed in the absence of this catalyst. The reaction seems to proceed with a general base-catalyzed pathway. A plausible mechanism is shown in Scheme 3.

Furthermore, the catalyst was evaluated for its general application in Michael addition reactions by performing the reaction with different chalcones having electron-releasing and electron-withdrawing groups on either side as Michael acceptors and malononitrile and ethyl cyanoacetate as Michael donors (Table 2). It was observed that chalcones with both electron-withdrawing and electron-releasing groups resulted in high yields of Michael products. The presence of electron-withdrawing or electron-releasing groups had a negligible effect on the yield of the product. Malononitrile was found to be a better donor (Table 2, entries 1 and 8) when compared with ethyl cyanoacetate (Table 2, entries 9 and 10). The structure of the synthesized compound was confirmed by ^{1}H NMR and ^{13}C NMR.

The catalytic scope of the IL–TBD was also assessed for the thia-Michael addition to chalcones. As expected, thia-Michael addition of thiophenols to chalcones was extraordinarily fast with thiols in the presence of IL–TBD (10 mol %) and gave high yields with short reaction times (3–5 min) at room temperature (Table 3). Although the reaction also proceeded in [bmim][PF_6] alone to give **7** in 10% yield, the yield of product was greater (87%) and it required a shorter reaction time in the presence of a catalytic amount of IL–TBD under solvent-free conditions.

Finally, the recyclability of catalyst **5** was investigated in the model reaction. Addition of malononitrile to chalcone (3-(2-fluorophenyl)-1-(4-methoxyphenyl)prop-2-en-1-one) afforded **7**. After extracting **7**, the recovered **5** was again used for the model reaction and it was found that catalyst **5** can be efficiently reused for up to five cycles without much loss in the yield of **7** (Fig. 1).

Conclusion

We have described the synthesis of a novel IL–TBD and its ability to act as an active organocatalyst in the Michael addition of active methylene compounds and thiophenols to chalcones under solvent-free conditions. The IL–TBD afforded Michael addition products in excellent yields (82%–94%) at room temperature, and it was easily recycled and reused at least five times without significant loss of catalytic activity. This is the first example of an IL–TBD and its use in organic synthesis. The present study shows that high catalytic efficacy can be achieved by functionalizing ILs with organocatalysts under greener reaction conditions.

Experimental section

General

1-Methylimidazole, 1-bromo-4-chlorobutane, and TBD were purchased from Sigma-Aldrich, India. All other reagents and solvents were purchased from S. D. Fine, India, and used without further purification unless otherwise specified. Column chromatography was carried out over silica gel (60–120 mesh, S. D. Fine, India). NMR spectra were recorded on Brucker Heaven Avance 11 400 and Varian (500 MHz) spectrometers using $CDCl_3$ and DMSO-d_6 as solvents, and the chemical shifts are expressed in ppm. Mass spectra were recorded on a QSTAR ELITE LX/MS/MS mass spectrometer from Applied Biosystems. The purity of the products was determined on silica-coated aluminum plates (Merck).

Synthesis of 1-methyl-3-(4′-TBD-butyl)imidazolium bromide (IL–TBD) (5)

1-Bromo-4-chlorobutane (**2**, 2.09 g, 12 mmol) was added dropwise to 1-methylimidazole (**1**, 1.0 g, 12 mmol) at room temperature, and the reaction mixture was stirred for 4 h. The mixture turned viscous over this time. After completion of the reaction as indicated by thin-layer chromatography (TLC), the reaction mixture was extracted with ethyl acetate (3 × 10 mL) to remove unreacted starting materials. The trapped ethyl acetate was removed on a rotatory evaporator under reduced pressure to obtain the product **3** in 2.7 g (89% yield). IL **3** (2.7 g, 10.7 mmol) was added to TBD (**4**, 3.71 g 17.7 mmol) and the mixture was heated at 100 °C for 6 h. After completion of the reaction, the reaction mixture was cooled to room temperature and washed with DCM (5 × 15 mL) to remove unreacted TBD and TBD salt. The resulting IL was dried under reduced pressure to form a thick light yellow liquid, which was purified by column chromatography on silica gel to give **5**. Viscous liquid. Yield: 3.48 g (92%). ^{1}HNMR (500 MHz, DMSO-d_6) δ: 9.30 (s, 1H), 7.73 (s, 1H), 7.62 (s, 1H), 4.06 (t, J = 6.8 Hz, 2H), 3.69 (s, 3H), 3.24–3.19 (m, 2H), 3.13–3.04 (m, 6H), 3.00 (s, 2H), 1.74–1.56 (m, 6H), 1.32–1.23 (m, 2H). ^{13}C NMR (126 MHz, DMSO-d_6) δ: 150.2, 137.0, 123.9, 122.7, 48.9, 48.7, 47.7, 47.2, 46.1, 38.5, 36.2, 26.5, 23.6, 20.9, 20.7. HRMS calcd for $C_{15}H_{26}N_5Br$: 356.14; found: 356.1260 $[M]^+$, 358.1257 $[M + 2]^+$, 276.1889 $[M - Br]^+$.

General procedure for the Michael addition of active methylene compounds and thiophenols to chalcones

Malononitrile / ethyl 2-cyanoacetate / thiophenol (1.0 mmol) was added to a solution of chalcone (1.0 mmol) and **5** (0.5 mmol or 0.1 mmol for thiophenols). The reaction mixture was stirred vigorously until reaction completions (see Tables 2 and 3 for reaction times). The progress of the reaction was monitored by TLC. After completion of the reaction, the product was extracted from the catalyst by ethyl acetate (2 × 5 mL), leaving the IL–TBD catalyst in the flask. The ethyl acetate layer was evaporated and washed with diethyl ether to afford the pure product.

2-(1-(2-Fluorophenyl)-3-(4-methoxyphenyl)-3-oxopropyl) malononitrile (7)

^{1}H NMR (400 MHz, DMSO) δ: 7.87 (d, J = 7.4 Hz, 2H), 7.68–6.68 (m, 6H), 5.32 (d, J = 6.3 Hz, 1H), 4.58–4.19 (m, 1H), 3.80 (s, 3H), 3.71–3.57 (m, 1H). ^{13}C NMR (101 MHz, DMSO) δ: 194.81, 163.96, 161.93, 159.54, 130.92, 129.29, 125.24, 116.17, 116.00, 114.39, 113.63, 113.44, 56.00, 39.98, 33.72, 28.92. HRMS calcd for $C_{19}H_{15}FN_2O_2$: 322.1118; found: 323.1016 $[M]^+$.

Scheme 3. Plausible mechanism for the catalytic activity of ionic-liquid-supported 1,5,7-triazabicyclo[4.4.0]dec-5-ene (IL–TBD).

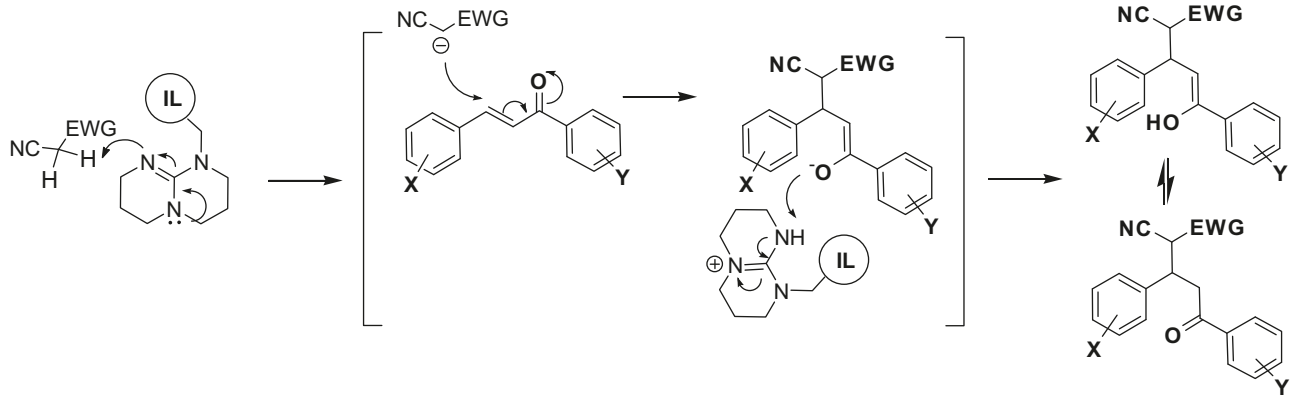

Table 2. Michael addition of active methylene compounds to chalcones catalyzed by **5**.

Product	X	Y	EWG	Time (h)	Yield (%)[a,b]
7	4-OCH_3	2-F	CN	4	87
8	4-Cl	2-F	CN	1.5	90
9	4-Cl	3-NO_2	CN	2	87
10	4-Cl	4-NO_2	CN	2	87
11	4-Cl	H	CN	2	92
12	4-OCH_3	4-NO_2	CN	4	86
13	4-OCH_3	4-OCH_3	CN	3	86
14	H	4-OCH_3	CN	3	85
15	4-Cl	H	CO_2Et	3	87
16	4-OCH_3	2-F	CO_2Et	6	82

Note: EWG, electron-withdrawing group.
[a]All the compounds showed satisfactory ^{1}H NMR and ^{13}C NMR.
[b]Isolated yield.

Table 3. Michael addition of thiophenols to chalcones catalyzed by **5**.

Product	X	Y	Ar	Time (min)	Yield (%)[a,b]
17	4-Cl	2-F	Ph	2	93
18	4-OCH_3	2-F	Ph	2	92

32	4-Cl	H	4-CH_3OPh	4	90

[a]All the compounds showed satisfactory ^{1}H NMR and ^{13}C NMR.
[b]Isolated yield.

2-(3-(4-Chlorophenyl)-1-(2-fluorophenyl)-3-oxopropyl) malononitrile (8)

^{1}H NMR (500 MHz, DMSO) δ: 7.98 (d, J = 7.28 Hz, 2H), 7.60–7.58 (m, 3H), 7.40–7.35 (m, 1H), 7.26–7.20 (m, 2H), 5.25 (d, J = 6.5 Hz, 1H), 4.36–4.32 (m, 1H), 3.90 (dd, J = 18.3, 8.65 Hz, 1H), 3.69 (dd, J = 18.3, 5.4 Hz, 1H). ^{13}C NMR (126 MHz, DMSO) δ: 195.66, 139.03, 135.00, 130.76, 130.70, 130.45, 129.33, 125.25, 116.16, 115.98, 113.55, 113.35, 40.48, 33.60, 28.85. HRMS calcd for $C_{18}H_{12}ClFN_2O$: 326.0622; found: 327.0006 $[M]^+$.

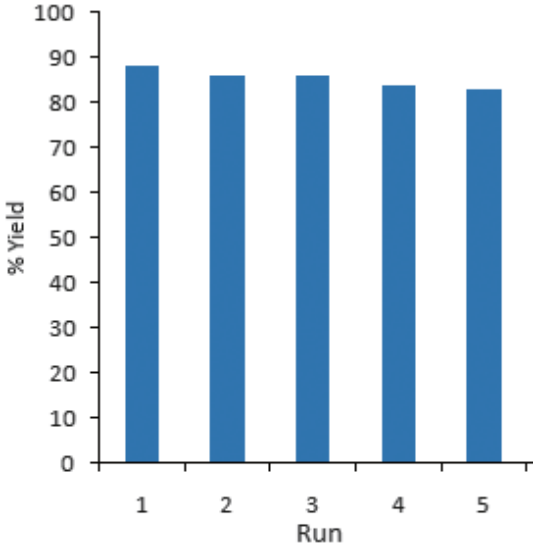
2-(3-(4-Chlorophenyl)-1-(3-nitrophenyl)-3-oxopropyl) malononitrile (9)

^{1}H NMR (400 MHz, DMSO) δ: 8.00 (d, J = 6.8 Hz, 2H), 7.65–7.61 (m, 3H), 7.42–7.38 (m, 1H), 7.26 (d, J = 6.68 Hz, 2H), 5.26 (d, J = 6.5 Hz, 1H), 4.41–4.32 (m, 1H), 3.95–3.89 (m, 1H), 3.73–3.68 (m, 1H). ^{13}C NMR (101 MHz, DMSO) δ: 195.73, 139.09, 135.01, 130.84, 130.74, 130.54, 129.37, 125.29, 116.23, 115.98, 113.66, 113.43, 40.93, 33.52, 28.93. HRMS calcd for $C_{18}H_{12}ClN_3O_3$: 353.0567; found: 375.0487 $[M - H + Na]^+$.

2-(3-(4-Chlorophenyl)-1-(4-nitrophenyl)-3-oxopropyl) malononitrile (10)

^{1}H NMR (400 MHz, DMSO) δ: 8.26 (d, J = 7.27 Hz, 2H), 8.01 (d, J = 7.3 Hz, 2H), 7.82 (d, J = 7.3 Hz, 2H), 7.61 (d, J = 7.3 Hz, 2H), 5.32 (d, J = 6.3 Hz, 1H), 4.32–4.26 (m, 1H), 4.06–3.96 (m, 1H), 3.81–3.69 (m, 1H). ^{13}C NMR (101 MHz, DMSO) δ: 195.68, 147.86, 145.87, 139.15, 134.99, 130.57, 130.36, 129.39, 124.17, 113.60, 113.36, 40.47, 40.16, 29.30. HRMS calcd for $C_{18}H_{12}ClN_3O_3$: 353.0567; found: 375.0484 $[M - H + Na]^+$.

2-(3-(4-Chlorophenyl)-3-oxo-1-phenylpropyl)malononitrile (11)



^{1}H NMR (400 MHz, DMSO) δ: 8.02–7.98 (m, 2H), 7.64–7.54 (m, 3H), 7.53–7.41 (m, 2H), 7.39–7.35 (m, 2H), 5.25–5.20 (m, 1H), 4.07–4.03 (m, 1H), 3.88–3.84 (m, 1H), 3.68–3.64 (m, 1H). ^{13}C NMR (101 MHz, DMSO) δ: 196.02, 139.07, 138.20, 135.18, 130.54, 129.37, 129.11, 128.74, 113.93, 113.65, 40.67, 40.50, 29.77. HRMS calcd for $C_{18}H_{13}ClN_2O$: 308.0716; found: 309.0701 $[M]^+$.

2-(3-(4-Methoxyphenyl)-1-(4-nitrophenyl)-3-oxopropyl) malononitrile (12)

^{1}H NMR (400 MHz, DMSO) δ: 8.22 (d, J = 7.12 Hz, 2H), 7.84 (d, J = 6.9 Hz, 2H), 7.43 (d, J = 6.9 Hz, 2H), 6.89 (d,

J = 7.1 Hz, 2H), 5.23 (d, J = 6.5 Hz, 1H), 4.43–4.36 (m, 1H), 4.01–3.96 (m, 1H), 3.83–3.72 (m, 1H), 3.78 (s, 3H). ^{13}C NMR (101 MHz, DMSO) δ: 195.78, 144.87, 143.97, 139.25, 135.69, 130.64, 130.23, 128.59, 128.23, 114.64, 113.86, 55.53, 40.87, 41.26, 29.45. HRMS calcd for $C_{19}H_{15}N_3O_4$: 349.1063; found: 371.0978 [M – H + Na]$^+$.

2-(1,3-Bis(4-methoxyphenyl)-3-oxopropyl)malononitrile (13)

^{1}H NMR (400 MHz, DMSO) δ: 8.01–7.96 (m, 2H), 7.45–7.37 (m, 2H), 7.04–7.02 (m, 2H), 7.01–6.98 (m, 2H), 5.21 (d, J = 6.5 Hz, 1H), 4.03–3.98 (m, 1H), 3.82 (s, 3H), 3.77–3.73 (m, 1H), 3.72 (s, 3H), 3.55–3.53 (m, 1H). ^{13}C NMR (101 MHz, DMSO) δ: 195.22, 163.92, 159.50, 130.95, 130.12, 129.88, 129.53, 114.41, 114.11, 113.80, 56.03, 55.50, 40.34, 40.31, 29.99. HRMS calcd for $C_{20}H_{18}N_2O_3$: 334.1317; found: 335.1187 [M]$^+$.

2-(1-(4-Methoxyphenyl)-3-oxo-3-phenylpropyl)malononitrile (14)

^{1}H NMR (400 MHz, DMSO) δ: 7.99 (d, J = 7.3 Hz, 2H), 7.71–7.62 (m, 1H), 7.60–7.49 (m, 2H), 7.45–7.36 (m, 2H), 7.03–6.89 (m, 2H), 5.24–5.05 (m, 1H), 4.06–3.98 (m, 1H), 3.82–3.78 (m, 1H), 3.73 (s, 3H), 3.63–3.57 (m, 1H). ^{13}C NMR (101 MHz, DMSO) δ: 196.95, 159.51, 136.54, 134.12, 130.06, 129.89, 129.28, 128.58, 114.43, 114.08, 113.76, 55.54, 40.78, 40.58, 29.98. HRMS calcd for $C_{19}H_{16}N_2O_2$: 304.1212; found: 333.1114 [M – H + K]$^+$.

Ethyl 5-(4-chlorophenyl)-2-cyano-5-oxo-3-phenylpentanoate (15)

^{1}H NMR (400 MHz, DMSO) δ: 8.01 (d, J = 7.5 Hz, 2H), 7.59 (d, J = 7.1 Hz, 2H), 7.35–7.26 (m, 5H), 4.69–4.46 (m, 1H), 4.08–3.97 (m, 3H), 3.72–3.65 (m, 2H), 1.08 (t, J = 7.1 Hz, 3H). ^{13}C NMR (101 MHz, DMSO) δ: 196.24, 165.75, 138.93, 135.39, 130.48, 129.39, 128.93, 128.57, 128.42, 128.20, 62.58, 44.11, 41.75, 40.86, 14.22. HRMS calcd for $C_{20}H_{18}ClNO_3$: 355.0975; found: 356.0798 [M]$^+$.

Ethyl 2-cyano-3-(2-fluorophenyl)-5-(4-methoxyphenyl)-5-oxopentanoate (16)

^{1}H NMR (400 MHz, DMSO) δ: 7.99 (d, J = 5.9, Hz, 2H), 7.62–7.58 (m, 2H), 7.53–7.45 (m, 1H), 7.35–7.30 (m, 1H), 7.18 (d, J = 6.6 Hz, 2H), 4.60 (d, J = 4.5 Hz, 1H), 4.37–4.28 (m, 1H), 4.11–4.04 (m, 2H), 3.88–3.57 (m, 2H), 1.01 (t, J = 6.7 Hz, 3H). ^{13}C NMR (101 MHz, DMSO) δ: 196.23, 165.85, 139.25, 135.49, 132.83, 130.46, 130.06, 129.50, 129.39, 125.22, 116.71, 115.94, 62.80, 43.49, 43.16, 41.60, 32.61, 14.09. HRMS calcd for $C_{21}H_{20}FNO_4$: 369.1376; found: 370.1288 [M]$^+$.

1-(4-Chlorophenyl)-3-(2-fluorophenyl)-3-(phenylthio) propan-1-one (17)

^{1}H NMR (400 MHz, DMSO) δ: 8.21–8. 13 (m, 1H), 7.97 (d, J = 6.9 Hz, 2H), 7.57–7.09 (m, 10H), 5.18–4.98 (m, 1H), 3.90–3.81 (m, 1H), 3.79–3.72 (m, 1H). ^{13}C NMR (101 MHz, DMSO) δ: 196.32, 138.93, 135.32, 133.89, 133.39, 132.49, 131.02, 130.48, 129.56, 129.35, 128.76, 125.43, 124.91, 116.09, 115.59, 43.36, 40.83. HRMS calcd for $C_{21}H_{16}ClFOS$: 370.0594; found: 392.0561 [M – H + Na]$^+$.

3-(2-Fluorophenyl)-1-(4-methoxyphenyl)-3-(phenylthio) propan-1-one (18)

^{1}H NMR (400 MHz, DMSO) δ: 7.95 (d, J = 6.87 Hz, 2H), 7.54–7.46 (m, 1H), 7.36–7.18 (m, 6H), 7.15–7.05 (m, 2H), 7.01 (d, J = 6.85 Hz, 2H), 5.21–5.08 (m, 1H), 3.83 (s, 3H), 3.83–3.78 (m, 1H), 3.72–3.58 (m, 1H). ^{13}C NMR (101 MHz, DMSO) δ: 195.48, 163.83, 161.33, 158.89, 134.17, 132.36, 130.92, 129.67, 129.55, 129.46, 129.04, 128.91, 128.07, 124.90, 115.82, 115.60, 114.40, 56.03, 42.87, 40.96. HRMS calcd for $C_{22}H_{19}FO_2S$: 366.1090; found: 367.1062 [M]$^+$.

3-(4-Chlorophenyl)-1-phenyl-3-(phenylthio)propan-1-one (19)

^{1}H NMR (400 MHz, $CDCl_3$) δ: 7.89 (d, J = 7.3 Hz, 2H), 7.59–7.55 (m, 1H), 7.46 (d, J = 7.5, 2H), 7.38–7.16 (m, 9H), 4.94–4.90 (m, 1H), 3.67–3.55 (m, 2H). ^{13}C NMR (101 MHz, $CDCl_3$) δ: 196.50, 139.62, 136.31, 133.47, 133.24, 132.78, 128.97, 128.77, 128.49, 128.38, 127.85, 127.63, 47.41, 44.27. HRMS calcd for $C_{21}H_{17}ClOS$: 352.0689; found: 353.0597 [M]$^+$.

3-Phenyl-3-(phenylthio)-1-*p*-tolylpropan-1-one (20)

^{1}H NMR (400 MHz, $CDCl_3$) δ: 7.79 (d, J = 7.4, 2H), 7.33–7.22 (m, 12H), 4.95 (t, J = 7.0 Hz, 1H), 3.63–3.50 (m, 2H), 2.39 (s, 3H). ^{13}C NMR (101 MHz, $CDCl_3$) δ: 195.63, 132.50, 129.09, 128.63, 128.23, 128.00, 127.60, 127.28, 127.13, 48.01, 44.27, 21.46. HRMS calcd for $C_{22}H_{20}OS$: 332.1235; found: 333.1187 [M]$^+$.

1-(4-Methoxyphenyl)-3-(3-nitrophenyl)-3-(phenylthio) propan-1-one (21)

^{1}H NMR (400 MHz, $CDCl_3$) δ: 8.18 (s, 1H), 8.04 (d, J = 6.5 Hz, 1H), 7.88 (d, J = 7.5 Hz, 2H), 7.62 (d, J = 6.7 Hz, 1H), 7.48–7.35 (m, 1H), 7.31–7.23 (m, 5H), 6.93 (d, J = 7.5 Hz, 2H), 5.01 (t, J = 6.0 Hz, 1H), 3.86 (s, 3H), 3.63 (d, J = 6.8 Hz, 2H). ^{13}C NMR (101 MHz, $CDCl_3$) δ: 194.46, 163.68, 143.64, 134.13, 133.19, 130.20, 129.14, 129.01,

3-(4-Methoxyphenyl)-3-(phenylthio)-1-*p*-tolylpropan-1-one (25)

^{1}H NMR (400 MHz, $CDCl_3$) δ: 7.79 (d, J = 8.1 Hz, 2H), 7.33–7.22 (m, 9H), 6.79 (d, J = 8.6 Hz, 2H), 4.94 (dd, J = 5.6, 8.4 Hz, 1H), 3.76 (s, 3H), 3.65–3.49 (m, 2H), 2.40 (s, 3H). ^{13}C NMR (101 MHz, $CDCl_3$) δ: 196.61, 158.48, 143.90, 134.06, 132.94, 132.41, 129.08, 128.67, 128.64, 128.00, 127.20, 113.59, 55.00, 47.45, 44.42, 21.46. HRMS calcd for $C_{23}H_{22}O_2S$: 362.1341; found: 363.1274 $[M]^+$.

1,3-Bis(4-methoxyphenyl)-3-(phenylthio)propan-1-one (26)

^{1}H NMR (400 MHz, $CDCl_3$) δ: 7.87 (d, J = 8.0 Hz, 2H), 7.32–7.13 (m, 7H), 6.90 (d, J = 7.9 Hz, 2H), 6.79 (d, J = 6.4 Hz, 2H), 4.94 (m, 1H), 3.85 (s, 3H), 3.75 (s, 3H), 3.63–3.50 (m, 2H). ^{13}C NMR (101 MHz, $CDCl_3$) δ: 195.49, 176.44, 163.37, 158.47, 132.98, 132.36, 130.19, 128.66, 127.17, 113.58, 113.52, 55.28, 55.00, 47.52, 44.16. HRMS calcd for $C_{23}H_{22}O_3S$: 378.129; found: 390.1205 $[M - H + Na]^+$.

1-(4-Chlorophenyl)-3-phenyl-3-(phenylthio)propan-1-one (27)

^{1}H NMR (400 MHz, $CDCl_3$) δ: 7.82 (d, J = 7.6 Hz, 2H), 7.42–2.24 (m, 12H), 4.94 (t, J = 7.8 Hz, 1H), 3.66–3.52 (m, 2H). ^{13}C NMR (101 MHz, $CDCl_3$) δ: 195.69, 140.77, 139.55, 134.78, 133.86, 132.60, 129.29, 128.74, 128.71, 128.32, 127.57, 127.44, 127.28, 48.02, 44.44. HRMS calcd for $C_{21}H_{17}ClOS$: 352.0689; found: 353.0582 $[M]^+$.

1-(4-Nitrophenyl)-3-phenyl-3-(phenylthio)propan-1-one (28)

^{1}H NMR (400 MHz, $CDCl_3$) δ: 8.26 (d, J = 8.80, 2H), 8.00 (d, J = 8.74 Hz, 2H), 7.37–7.17 (m, 10H), 4.90 (dd, J = 7.6, 6.0 Hz, 1H), 3.70–3.57 (m, 2H). ^{13}C NMR (101 MHz, $CDCl_3$) δ: 195.45 141.18, 139.45, 134.96, 133.98, 132.60, 129.64, 128.84, 128.61, 128.46, 127.12, 127.44, 127.28, 48.10, 44.42. HRMS calcd for $C_{21}H_{17}NO_3S$: 363.0929; found: 385.0879 $[M - H + Na]^+$.

1-(4-Methoxyphenyl)-3-phenyl-3-(phenylthio)propan-1-one (29)

^{1}H NMR (400 MHz, $CDCl_3$) δ: 8.00–7.79 (m, 2H), 7.34–7.24 (m, 10H), 6.98–6.84 (m, 2H), 4.97 (m, 1H), 3.85 (s, 3H), 3.61–3.51 (m, 2H). ^{13}C NMR (101 MHz, $CDCl_3$) δ: 195.32, 163.40, 141.08, 132.45, 130.20, 129.60, 128.64, 128.24, 127.61, 127.26, 127.12, 113.54, 55.29, 48.10, 44.02. HRMS calcd for $C_{22}H_{20}O_2S$: 348.1184; found: 349.1079 $[M]^+$.

3-(3-Nitrophenyl)-3-(phenylthio)-1-*p*-tolylpropan-1-one (30)

^{1}H NMR (400 MHz, $CDCl_3$) δ: 8.18 (s, 1H), 8.04 (d, J = 6.1 Hz, 1H), 7.90–7.74 (m, 2H), 7.62 (d, J = 6.3 Hz, 1H), 7.42–7.35 (m, 1H), 7.32–7.25 (m, 7H), 5.09–4.90 (m, 1H), 3.67–3.56 (m, 2H), 2.41 (s, 3H). ^{13}C NMR (101 MHz, $CDCl_3$) δ: 195.62, 147.98, 144.42, 143.59, 134.11, 133.59, 133.22, 132.65, 129.24, 129.02, 128.89, 128.07, 127.99, 122.44, 122.11, 47.58, 43.72, 21.49. HRMS calcd for $C_{22}H_{19}NO_3S$: 377.1086; found: 378.1023 $[M]^+$.

3-(3-Nitrophenyl)-1-phenyl-3-(phenylthio)propan-1-one (31)

^{1}H NMR (400 MHz, $CDCl_3$) δ: 8.18 (s, 1H), 8.05 (d, J = 7.1 Hz, H), 7.91 (d, J = 7.0 Hz, 2H), 7.71–7.54 (m, 2H), 7.54–7.36 (m, 3H), 7.36–7.17 (m, 5H), 5.01 (t, J = 6.7 Hz, 1H), 3.69 (d, J = 6.7 Hz, 2H). ^{13}C NMR (101 MHz, $CDCl_3$) δ: 196.00, 143.51, 136.03, 134.10, 133.46, 133.26, 129.05, 128.91, 128.58, 128.12, 127.86, 122.44, 122.15, 47.51, 43.90. HRMS calcd for $C_{21}H_{17}NO_3S$: 363.0929; found: 364.00875 $[M]^+$.

3-(4-Methoxyphenylthio)-1-(4-chlorophenyl)-3-phenylpropan-1-one (32)

^{1}H NMR (400 MHz, $CDCl_3$) δ: 7.79 (d, J = 8.6 Hz, 2H), 7.38 (d, J = 8.6 Hz, 2H), 7.29–7.17 (m, 7H), 6.74 (d, J = 8.7 Hz, 2H), 4.70 (m, 1H), 3.75 (s, 3H), 3.53–3.57 (m, 2H). ^{13}C NMR (101 MHz, $CDCl_3$) δ: 195.99, 159.92, 141.19, 139.69, 136.28, 135.11, 129.50, 128.93, 128.43, 127.80, 127.35, 124.06, 123.51, 121.93, 114.41, 55.29, 49.40, 44.26. HRMS calcd for $C_{22}H_{19}ClO_2S$: 382.0794; found: 404.0703 $[M - H + Na]^+$.

General procedure for recycling the catalyst

Malononitrile (1.0 mmol) was added to the solution of 3-(2-fluorophenyl)-1-(4-methoxyphenyl)prop-2-en-1-one and

IL–TBD (**5**) (0.5 mmol). The reaction mixture was stirred vigorously until reaction completion. The product was then extracted from the catalyst by ethyl acetate (2 × 5 mL) leaving the IL–TBD catalyst in the flask. The IL–TBD was washed with diethyl ether and dried under reduced pressure. The recovered IL was again used as a catalyst for a fresh batch of chalcone and malononitrile (1.0 mmol) under the same experimental conditions. The process was repeated five times without much loss in catalytic activity.

Abstract: ZnO nanostructures of various morphologies and crystallinities were fabricated by thermal evaporation from Zn powder in a tube furnace in the presence of oxygen. It was found that the morphology of ZnO nanostructures was affected by synthesis parameters, such as growth temperature, carrier gas flow, and the presence of catalyst on the surface of the substrate. Representative ZnO nanostructures were studied by X-ray excited optical luminescence (XEOL) and cathodoluminescence (CL) methods. The luminescence from these samples exhibits a morphology dependence of the branching ratio of the near band gap (NBG) emission in the UV and defect emission in the green (GE). The appearance of the optical emission also depends on the excitation method. X-ray absorption near-edge structures (XANES) at the O K-edge and Zn L-edge are also presented and their implications discussed.

Key words: ZnO nanostructures, XEOL, XANES, cathodoluminescence.

Résumé : Faisant appel à une méthode d'évaporation thermique d'une poudre de Zn dans un four électrique à tube en présence d'oxygène, on a fabriqué des nanostructures de ZnO de morphologies et de cristallinités diverses. On a trouvé que la morphologie des nanostructures de ZnO est affectée par divers paramètres de la synthèse, telle la température de croissance, la vitesse d'écoulement du gaz et la présence de catalyseur sur la surface du substrat. On a étudié les structures de nanostructures de ZnO représentatives en faisant appel aux méthodes de luminescence optique excitée par rayons-X (LOEX) et de cathodoluminescence (CL). La luminescence dans ces échantillons présente, dans l'UV, une relation entre la morphologie sur le rapport de ramification et l'émission de la bande interdite rapprochée (BIR) et l'émission de défaut dans le vert (EV). L'apparition d'une émission optique dépend aussi de la méthode d'excitation. On a aussi déterminé les structures d'absorption des rayons-X près du seuil (« XANES ») au seuil K de l'oxygène et au seuil L du zinc et on discute de leurs implications.

Mots-clés : nanostructures du ZnO, luminescence optique excitée par rayons X (LOEX), structures d'absorption des rayons X près du seuil (« XANES »), cathodoluminescence.

Introduction

Zinc oxide, a versatile technological material for light emitting and photonic applications (e.g., solid-state lasers and LEDs), is a semiconductor with a wide band gap (~3.37 eV) and large free exciton energy (~60 meV). Its unique properties, availability in nature, and relatively low cost make it an attractive candidate for optoelectronic, lasing, and piezoelectronic as well as gas-sensing applications among other semiconducting materials with similar parameters.[1–3]

Previous studies have shown that the luminescence properties of ZnO nanostructures exhibit strong size and shape dependence.[4–10] Optical emission spectra of ZnO nanostructures usually show a sharp near-band-gap peak owing to excitonic transitions and a wide visible emission peak, which is usually ascribed to defect states within the band gap. Oxygen vacancies are commonly assigned as the origin of green emission in undoped ZnO crystals. The intensity of optical emission, branching ratio of the peaks, and position of the emission peaks (especially defect emission peaks) are affected by the morphology of ZnO nanostructures.[4–10]

On a nanoscale, as a rule, crystalline nanostructures tend to have superior crystal quality in terms of a lack of defects compared with bulk material. In nanostructures, defects tend to collect on the surface or in the near-surface region, which help reduce the strain in the crystal. As was shown in a cathodoluminescence (CL) study of ZnO nanostructures,[9] the

green emission is from defects. With the reduction of size and the increase of the surface-to-volume ratio, the surface and near-surface regions begin to play a prominent role in determining the optical properties of nanostructures.

Among other considerations, the optical spectra of nanostructures can be significantly affected by the nature of the excitation. For example, Liao et al.[11] observed a shift of the emission peaks and a difference in their branching ratio when probing emission properties of a ZnO nanostructure sample using CL and photoluminescence methods.

Here, we present a comparative study of the optical properties of ZnO nanostructures with different morphologies using two excitation methods: CL and X-ray excited optical luminescence (XEOL). The latter was conducted using synchrotron radiation with excitation energy tuned from below to above the O K- and Zn $L_{3,2}$-edges, providing site specificity by preferentially exciting the core levels of the O and Zn sites of the nanostructure, respectively. This provision was not available using CL and a laboratory laser or a UV lamp light source. We also present X-ray absorption near-edge structure (XANES) spectra obtained at the two absorption edges.

Experimental methods

ZnO nanostructure samples were synthesized from Zn powder by the chemical vapour deposition (CVD) method in a tube furnace in the presence of oxygen as described previously.[9] Morphology of the final product in this CVD process is strongly affected by synthesis parameters such as temperature, starting materials, carrier gas flow, nature of substrate, and the presence of catalyst. In this work, ZnO nanostructures were grown on a clean Si(100) slab substrate placed along the tube furnace, of which half of the substrate along the tube was covered with an Au catalyst.

XEOL and XANES spectra of ZnO samples were collected at the spherical grating monochromator (SGM) beam line of the Canadian Light Source (CLS), Saskatoon, Saskatchewan.[12] CL spectra were recorded using a Reliotron microscope stage-mounted CL instrument and spectrometer at the Department of Earth Sciences, The University of Western Ontario, London, Ontario.

CLS is a 2.9 GeV third-generation synchrotron light source. It produces a highly collimated and bright X-ray beam that can be finely tuned over a wide energy range (from IR to hard X-rays). The SGM beam line is equiped with an undulator providing soft X-ray photons in the energy range 250–2000 eV. Synchrotron-based spectroscopic methods such as XANES and XEOL were utilized in this experiment because they are especially suitable for probing the optical properties of nanostructured samples because of the tunability, brightness, and time structure of synchrotron radiation.

XEOL is an X-ray photon-in / optical photon-out method, converting the X-ray energy absorbed by the specimen into optical emission. Excitation of a specimen with X-ray photon energy tuned across the absorption edge of a particular element makes XEOL an element-, site-, and absorption-edge-specific technique under favourable conditions, since the absorption coefficient at an absorption edge of an element changes abruptly in favour of the element; this can provide more noticeable changes in the branching ratio. With the CL method, there is no such selectivity. The electron beam used for CL excites all of the possible emission channels via core excitation and secondary processes. CL results depend on the parameters of the electron beam such as the accelerating voltage and the beam current.[11,13] Thus, accelerating voltage determines the size of the excited volume inside the sample. Changes in the accelerating voltage lead to variation of the penetration depth of electrons. In general, the higher the energy (voltage) of the incident electron, the more penetrating the electron and the more energetic the secondary process, the longer the thermalization track for the secondary electrons and holes, which can recombined radiatively. As noted above, the near band-gap (exciton) and visible (defect) emission are relatively fast and slow processes, respectively, depending on the size and the crystallinity of the specimen.[9,10] They can also originate from various depth of the specimen, especially in nanostructures where the thermalization track may be truncated owing to the small size; therefore, the branching ratio of the peaks in the CL-induced optical spectrum of ZnO should depend somewhat on the accelerating voltage.[13]

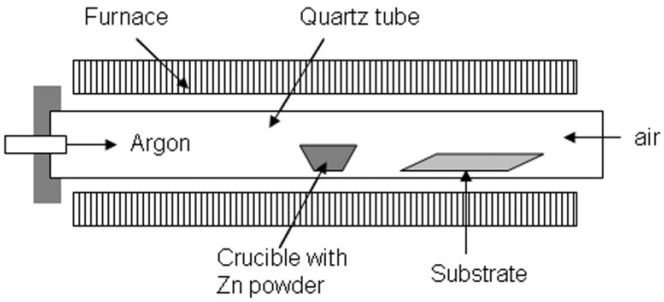

Fig. 1. Schematic for the fabrication process.

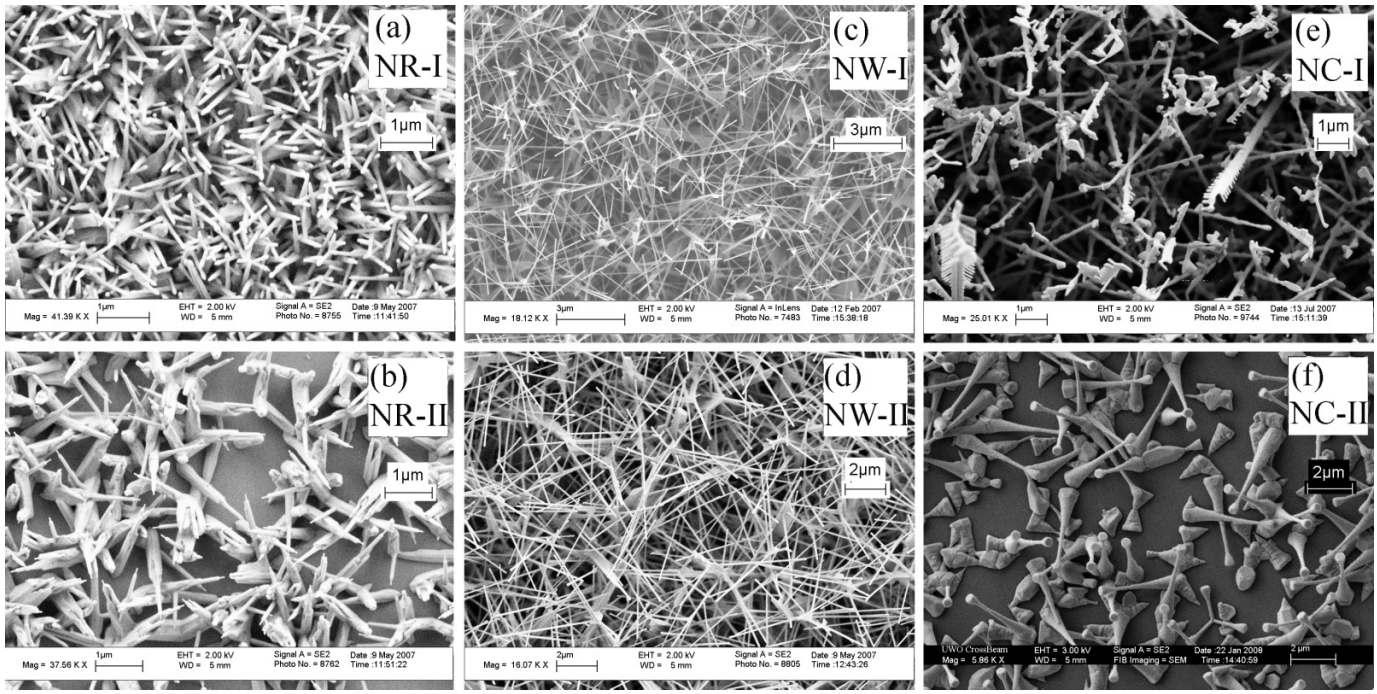

Synthesis of ZnO nanostructures

ZnO nanostructures were fabricated in a tube furnace from Zn powder (99.99%, Alfa Aesar) in the presence of oxygen. An alumina boat with starting material was placed in the centre of the quartz tube mounted into the furnace. The temperature in the furnace was increased at a rate of 10 °C/min to 550–570 °C and then kept constant for 45–60 min. At one end of the tube, a carrier gas (argon) was introduced into the system at a flow rate of 80 sccm. A silicon substrate (~0.5 in. wide (1 in. = 25.4 mm), 3 in. long slab of an Si(100) wafer) was placed downstream from the boat containing the starting material. The other end of the quartz tube was opened to ambient air (Fig. 1). At the synthesis temperature, Zn evaporated and reacted with ambient oxygen to form ZnO_x clusters ($x \leq 1$). The carrier gas transported Zn vapour and ZnO_x clusters toward the substrate where the nanostructures were formed.[13]

The Si wafer substrate was prewashed in acetone, alcohol, and distilled water. Half of the Si slab was covered along the length with colloidal gold (colloidal solution of thiol-capped gold nanoparticles), so that we could compare nanostructures grown with and without a catalyst. At an elevated temperature in the furnace the gold nanoparticles agglomerated into Au islands, which serve as catalysts for the subsequent growth of ZnO nanostructures by the vapour–liquid–solid (VLS) mechanism. On the clean part of the Si wafer, ZnO nanostructures were formed by the vapour–solid (VS) process.

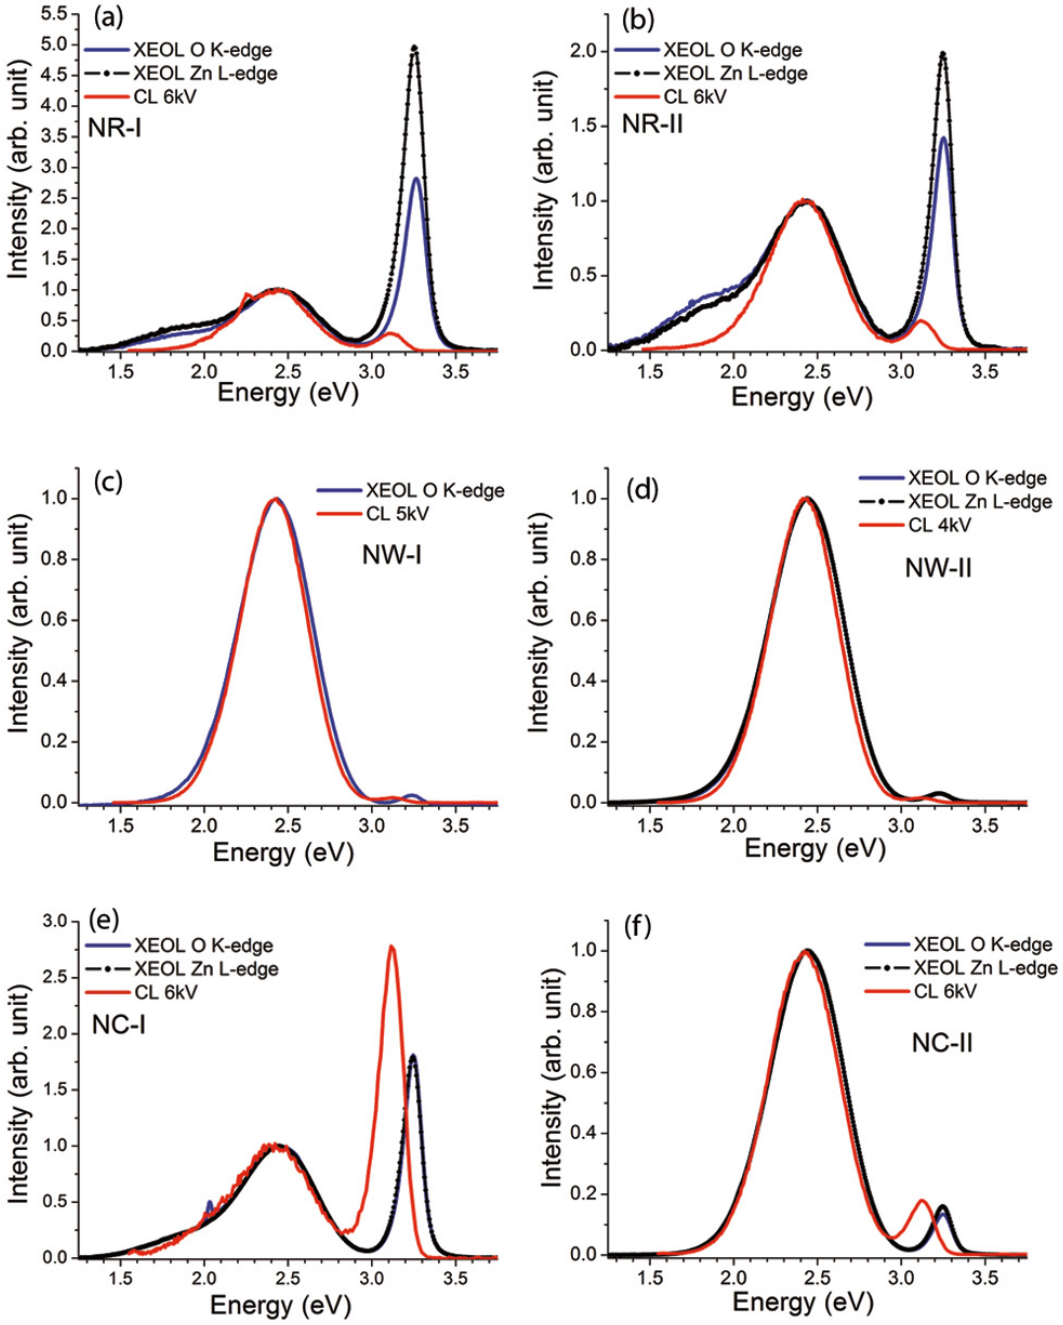
Fig. 2. Scanning electron microscopy (SEM) of ZnO nanostructures: (*a*) and (*b*) nanorod samples NR-I and NR-II, respectively; (*c*) and (*d*) nanowire samples NW-I and NW-II, respectively; (*e*) and (*f*) nanocombs NC-I and nanocones NC-II, respectively. Upper row: nanostructures were grown on an Si wafer with Au catalyst; lower row: nanostructures were grown without catalyst on a clean Si wafer.

Although the presence of a catalyst is not a necessary condition for forming ZnO nanostructures, it affects the resulting morphology. The ZnO nanostructures thus formed appear as a grayish-white film on the surface of the Si wafer. When excited with an UV lamp the samples produced green light.

Several ZnO nanosamples with distinctly different morphologies along the substrate slab were chosen for characterization. Images of the selected samples were taken using a LEO 1530 scanning electron microscope (SEM) in the Nanofab Lab at The University of Western Ontario, London, Ontario.

Nanorod samples NR-I (Fig. 2*a*) and NR-II (Fig. 2*b*) were formed on Si wafer substrates with and without an Au catalyst, respectively, under the following synthesis conditions: temperature at the centre of the furnace, 550 °C; and Ar flow rate, 80 sccm. Sample NR-I contained ~350 nm nanorods with tips of ~70 nm in diameter, and sample NR-II was composed of ~300 nm nanorods with ~90 nm tips, terminating with even smaller spikes (~30 nm). Since the samples were collected at the same distance from the furnace centre, the experimental parameters, the growth temperature and the amount of Zn vapour, in the growth region can be considered identical. The influence of the Au catalyst led to the formation of nanorod structures with different dimensions, which is evident in the SEM images (Figs. 2*a* and 2*b*). When grown with the catalyst, ZnO formed a denser coverage on the substrate (sample NR-I, Fig. 2*a*), whereas the sample grown without a catalyst displayed bare Si wafer underneath the ZnO nanorods (sample NR-II, Fig. 2*b*).



Nanowire samples NW-I (Fig. 2*c*) and NW-II (Fig. 2*d*) were fabricated using the same procedures at a temperature of 570 °C and at 75 sccm Ar flow with and without the Au catalyst, respectively. Sample NW-I was composed of nanowires ~50 nm in diameter, whereas sample NW-II was comprised of ~90 nm nanowires. Apparently, in this case, the concentration of Zn vapour was high enough to create a dense coverage of ZnO nanowires independent of the presence of catalyst.

The next two samples (nanocomb NC-I and nanocone NC-II) were fabricated using slightly a different growth scheme, i.e., the downstream end of the quartz tube was closed off to the atmosphere. The synthesis was performed at a temperature of 750 °C with a mixture of argon and oxygen (Ar (50 sccm) + O_2 (10 sccm)) as the carrier gas. This alteration of the synthetic procedure led to the formation of nanostructures with a very different morphology. Sample NC-I was grown on Si substrate with an Au catalyst. It consisted of a mixture of thinner nanowires, ~140 nm in diameter, and thicker rods, ~350 nm in diameter, with nanocombs formed on the ends (Fig. 2*e*). The nanocomb needlelike spikes are ~50–70 nm in diameter. Sample NC-II, which was grown on a clean Si surface, was composed of relatively large nanocones with a thick end of ~800–850 nm, a top of ~400–450 nm, and a neck measuring ~160 nm (Fig. 2*f*). Again the presence of the catalyst on the substrate led to denser growth of nanomaterials.

Results and discussion

Emission spectra of the aforementioned ZnO nanostructures were studied by XEOL and CL methods. XEOL spectra were excited with photon energy selected at just above the O K-edge (539 eV) and the Zn L-edge (1026 eV). The X-ray photon excitation energy was chosen in both cases so that a considerable fraction of photon flux was absorbed by the element of interest compared with situations just below the

edge. It should be noted that XEOL was done below and above the relevant absorption edges in many measurements we conducted previously on ZnO nanostructures.[9,10,12] There was no strong variation in the branching ratio for a given specimen, but the overall intensity varies because of an abrupt change of penetration depth that depends somewhat on the sample thickness, morphology, and degree of imperfection. In most cases, when the sample is thick compared with the one absorption length, the total luminescence yield with excitation across the O K-edge decreases, whereas at the Zn L-edge, the total luminescence yield increases; this is largely due to an interplay of penetration depth and the effective energy transfer of the Auger and secondary electrons to the optical channel. If Auger electrons are emitted in the surface region, they can escape the surface without contributing to the secondary process and, in turn, the luminescence. For most of the presented CL spectra we used an accelerating voltage of 6 kV. In the case of nanowire samples NW I and NW II, which produced very intense green emissions, the accelerating voltage was lowered (shown in the graph legend of Fig. 2). All the presented spectra are normalized to the intensity of the green emission peak for comparison.

XEOL and CL spectra of the nanorod sample NR-I are shown in Fig. 3*a*. XEOL collected at the O K-edge and at

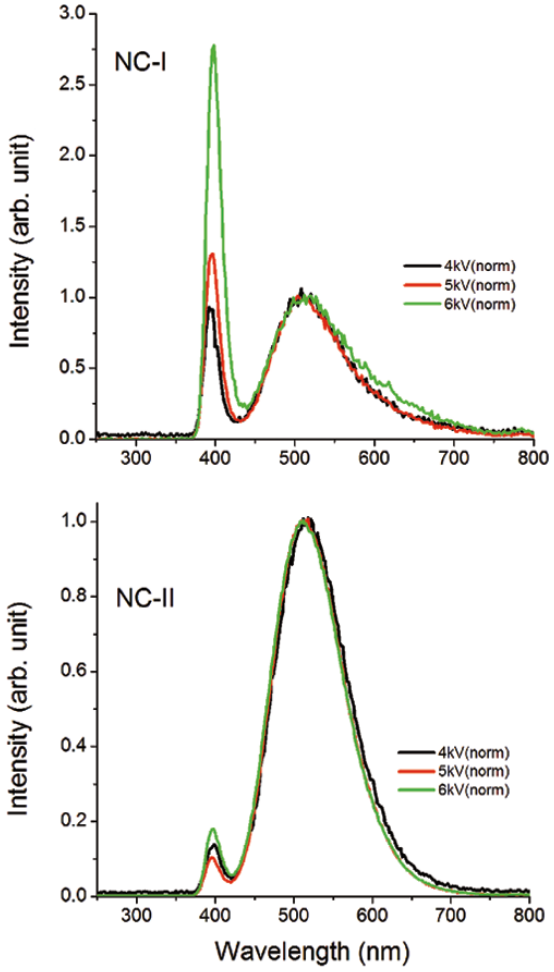
Fig. 4. Cathodoluminescence (CL) of nanocomb (NC-I) and nanocone (NC-II) ZnO nanostructures excited with different electron energies (4–6 kV). The CL is normalized to the intensity of the green emission.



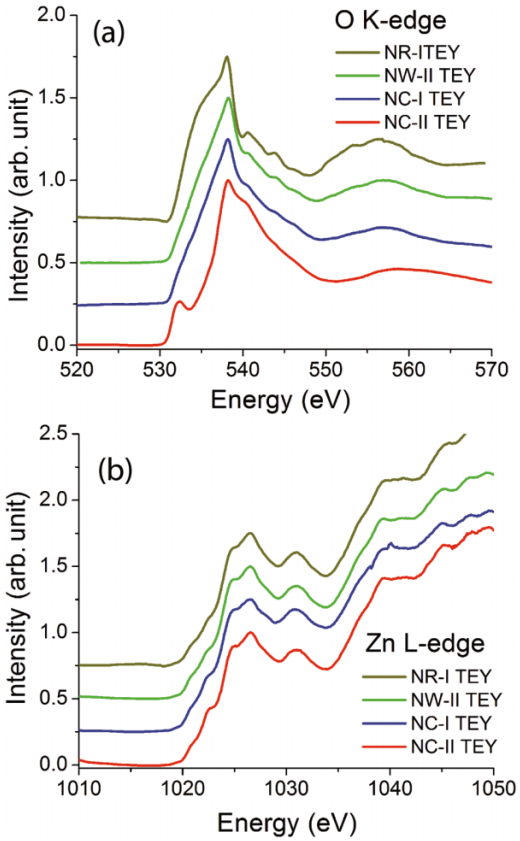


Fig. 5. X-ray absorption near-edge structure (XANES) total electron yield (TEY) of ZnO nanorod, nanowire, nanocomb, and nanocone samples. (*a*) O K-edge. (*b*) Zn L-edge.

the Zn L-edge show a sharp near-band-gap emission (NBG) peak at ~3.25 eV (381 nm), a broad green emission (GE) band at ~2.44 eV (508 nm) owing to defect states in the core, and a red shoulder at ~1.75 eV (710 nm) attributable to surface states. It has been shown that the branching ratio of the NBG and GE emission bands in XEOL is strongly dependent on the crystallinity and morphology of the nanostructure. Time-resolved experiments showed that, in general, the NBG is a very fast decay and can be dominant if the nanocrystal is near perfect (few defects).[9,10] The defect emission in the green is slow and is associated with defect concentration and the dynamics of the secondary processes in which energetic electrons thermalize in the solid. The observation of an intense NBG relative to GE indicates that NR-I is most crystalline among all samples investigated.[9,10] The branching ratio of the NBG peak is more intense for the XEOL spectrum recorded at the Zn L-edge (~1000 eV) than the spectrum at the O K-edge (~500 eV), although the overall behaviour of both curves is similar. This difference in NBG vs GE intensity is attributable to a relatively deeper probing depth in the Zn L-edge and a more effective truncation of the thermalization track of the secondary electrons and hole that are primarily responsible for the defect luminescence, so that the more energetic secondary electrons (e.g., associated with Zn $L_{3,2}$-edge decay) can escape the nanostructure effectively without contributing to the green emission. This argument applies to all situations with the same morphology.

The CL spectrum of sample NR-I has a weak NBG emission peak at ~3.11 eV (398 nm) and a more intensive broad green emission at ~2.44 eV (508 nm) (Fig. 3). This 3.11 eV peak is significantly lower in energy than the band gap and can be due to a self-trapped exciton with shallow electron traps that competes effectively with the NBG emission. It can also be due to band gap shrinkage from high excitation density resulting from irradiation of the high-energy electron beam, merging the shallow trapped states with the conduction band.[14] The spike at 2.25 eV is probably due to an electronic glitch or an impurity emission. As can be seen, the green emission peak is dominant and is more symmetric in the CL spectra than in the XEOL spectra. There is no red shoulder in the CL spectrum. As noted above, the NBG peak in the CL spectrum is red-shifted compared with the XEOL spectra. This appears to be a common feature for all our samples, and will be discussed further, whereas the green emission peaks are in good agreement with assignments in the literature and with the XEOL results. This confirms the general notion that the usually slow oxygen vacancy green emission is due to energy transfer via a secondary process independent of the excitation.

Optical emission spectra (XEOL and CL) of sample NR-II are shown in Fig. 3*b*. As in the previous case, the XEOL spectra have a NBG peak at ~3.25 eV, a GE peak at ~2.44 eV, and a red shoulder at ~1.75 eV. The CL spectrum displays a NBG peak at ~3.12 eV (397 nm), with an intensity lower than the corresponding XEOL peak, and a GE peak at ~2.43 eV (510 nm). Overall, the CL and XEOL spectra of NR-II have an appearance similar to that of sample NR-I, although the branching ratio of the two main peaks is slightly different: sample NR-II exhibits more intense defect (green) emissions for both XEOL and CL, indicating that it has a higher defect concentration than NR-I, although it is still highly crystalline. Again, the Zn L-edge excitation produces a higher branching ratio for the NBG emission, as expected for the same reason as discussed in the case of NR-I.

The emission spectra of the two nanowire samples (NW-I and NW-II) are in close agreement with each other (Figs. 3*c* and 3*d*, respectively). For both samples, the XEOL and CL emission curves exhibit very similar behaviour, but they are significantly different from those of NR-I and NR-II in that the green emission dominates with a relatively weak NBG emission. For sample NW-I (NWs of ~50 nm diameter), the XEOL collected at the O K-edge displays a weak NBG peak at ~3.23 eV (383 nm) and a very intensive GE peak at ~2.43 eV (510 nm) (Fig. 3*c*). In the CL spectrum, which was recorded at an accelerating voltage of 5 kV, the NBG peak is even weaker and red-shifted (~3.12 eV) as was the case for NR-I and NR-II. The green emission peak in the CL spectrum is at 2.43 eV, which is in agreement with the corresponding XEOL peak. These results suggest that these NW specimens have high defect concentrations enhancing an effective energy transfer to these sites at the expense of the NBG emission. These results are also in excellent agreement with previous findings that nanowires tend to have more defects than highly crystalline nanoneedles, nanorods, and nanoparticles and therefore emit in the green intensely.[9]

For sample NW-II (NWs of ~90 nm diameter), the normalized XEOL spectra excited at the O K-edge and the Zn L-edge practically coincide with each other: both have a very weak NBG peak at ~3.23 eV and an intensive GE peak at ~2.44 eV (Fig. 3*d*). CL collected at an accelerating voltage of 4 kV produces the same appearance as the XEOL spectra with a green peak at ~2.43 eV. The NBG peak is almost negligible (~3.12 eV), indicating that this is a defect abundant specimen and the excitonic energy transfers effectively to the defects.

The XEOL spectra of nanocomb sample NC-I exhibits a sharp NBG peak at ~3.25 eV and a weaker green emission peak at ~2.44 eV (Fig. 3*e*). It also displays a shoulder on the red side at ~1.75 eV, although it is not as prominent as the shoulder observed in the spectra of the nanorod samples. The CL spectrum of NC-I has an even higher branching ratio for the NBG peak compared with XEOL: the NBG peak is at 3.12 eV, again shifted to the red compared with the XEOL results, and the green emission peak is at 2.42 eV (512 nm). This result can be understood in terms of the more complex morphology of the sample. Close examination of the electron micrograph (Fig. 2*e*) reveals a mixed morphology situation with the presence of nanowires and nanorods (needles). The nanorods (needles) must be near perfect crystals, whereas the nanowires dominate the defect emission. The more intense and red-shifted NBG peak can result from band gap narrowing owing to high excitation (hence carrier) density when the sample is excited with a high-energy electron beam in contrast to quantum confinement where the band gap widens when the size decreases. This notion can be tested by varying the energy of the electrons in CL. One expects to see a more intense NBG emission if one lowers the excitation energy (decreasing the penetration depth). The results of such a test on the nanorod samples are shown in Fig. 4, where the NBG emission shifts to the red and the branching ratio of the NBG emission increases with increasing excitation energy.

For ZnO nanocones (sample NC-II), the green emission is more intense than the NBG emission in both the XEOL and CL spectra (Fig. 3*f*). In XEOL, the NBG peak is at ~3.25 eV and the GE peak is at ~2.44 eV. As observed for other samples, the NBG peak (~3.12 eV) on the CL spectrum of sample NC-II is red-shifted compared with that of XEOL at ~3.25 eV. The green peak is at ~2.42 eV in CL.

Based on these results, there are three types of emission bands: NBG emission, green emission, and red shoulder, corresponding to near band gap, bulk, and surface defects, respectively. Their relative intensities correlate with size, morphology, and crystallinity as described previously.[15–17] It appears that, for all ZnO samples except the thin nanowires, the XEOL spectra excited at the Zn L-edge have higher branching ratios for the NBG peak than the XEOL spectra at the O K-edge. For thin nanowires, the XEOL spectra excited at both absorption edges after being normalized are practically identical to each other, and the NBG emission is nearly quenched by the defects via energy transfer to the longer wavelength radiative channel. Several features are apparent for all samples examined: (*i*) in CL spectra, the NBG emission peak is red-shifted compared with the XEOL spectra; (*ii*) the defect emission in XEOL and CL spectra have almost the same energy position and profile; and (*iii*) the red shoulder, displayed in the XEOL spectra of nanorods (samples NR-I and NR-II) and nanocombs (sample NC-I), is not observed in the CL spectra, and the CL defect emission peak is more symmetric.

These results indicate that the variation in the excitation and energy-transfer mechanisms led to the different appearance of the XEOL and CL spectra, which depends on the crystallinity and morphology of the nanostructure. The probing depth was generally comparable for both methods because the size of the nanostructures is generally comparable to the probing depth of the excitation source. Most CL spectra were excited by an electron beam with an accelerating voltage of 4–6 kV. A rough estimate gives a value of 200–250 nm[19] for depth (inelastic scattering mean free path of electrons with a given energy) of the excited volume at these voltages. As for the XEOL spectra, the attenuation length of X-rays in ZnO is in the range of ~200–350 nm in the vicinity of the O K-edge and ~200–850 nm in the vicinity of the Zn L-edge.[20] For the samples examined, the X-ray attenuation length was greater than the diameter of the nanostructures (or at least comparable to it). The most important difference is that X-rays preferentially excite core electrons with site selectivity, whereas CL excites mostly valence and shallow core electrons with relatively little site selectivity. It should also be noted that the relatively poor vacuum conditiond in the CL measurements (mtorr) is most likely the reason for the

Can. J. Chem. Downloaded from www.nrcresearchpress.com by Renmin University of China on 09/02/12
For personal use only.

quenching of the red surface emission observed in XEOL, where the vacuum was about 10^{-8} torr (1 torr = 133.3224 Pa). What remains somewhat puzzling is the systematic red shift of the NBG peak in the CL spectra relative to the XEOL spectra, which was observed in all cases. We propose that in XEOL, the excitation of a core hole facilitates the formation of a more localized exciton that can decay rapidly, whereas in CL, the exciton becomes less localized in the absence of the core hole and the presence of shallow electron traps and high-density excitation. This notion needs to be confirmed with further investigations.

We have also tracked the structure and electronic behaviour of these materials by measuring their O K-edge and Zn $L_{3,2}$-edge XANES. Figure 5 shows some representative spectra at these edges.

Figure 5 displays the XANES collected in total electron yield (TEY) for four samples with distinctly different morphologies: nanorod (sample NR-I), nanowire (sample NW-II), nanocomb (sample NC-I), and nanocone (sample NC-II). At the O K-edge (Fig. 5*a*), all four samples have conformed TEY curves with the main absorption peak at 538 eV. The pre-edge peak in the TEY of sample NC-II can be assigned to silicon oxide on the surface of substrate. The SEM image (Fig. 2*f*) of the ZnO nanocones shows low packing density, and the surface of the Si wafer is clearly exposed. Comparison of the TEY curves of the four samples reveals that NR-I produces the most prominent and sharpest resonances on the TEY spectrum, whereas the TEY of the other samples are rather smooth. The sharpness of the resonance is associated with little disorder, while increasing broadening of these features can mean increasing disorder owing to increasing imperfection (disorder and defects, etc.) of the crystal as well as chemical inhomogeniety. The result suggests that the nanorod (sample NR-I) has a higher crystal quality than the other samples, and that crystal quality in the remaining samples decreases in thin nanowires (NW-II). Nanocombs (NC-I) and nanocones (NC-II) have mixed morphology, resulting in static disorder (inhomogeniety). The relative intensity of the NBG emission peak also supports this observation. The Zn $L_{3,2}$-edge XANES, however, do not exhibit significant changes, indicating that defects associated with oxygen play a more important role in the optical properties of these materials (Fig. 5*b*).

Summary

The emission properties of ZnO nanostructures with different morphologies were studied using XEOL and CL methods. XEOL spectra were obtained at the O K-edge and at the Zn L-edge.

Our results demonstrate that the optical emissions of ZnO nanostructures are dependent on their morphology and crystallinity. All samples had a sharp NBG (exciton) peak and a broad green (defect) emission peak, although the former is very sensitive to the presence of defects. The relative intensity (branching ratio) of the two emission peaks was very sensitive to nanostructures of different morphologies. Thus, ZnO nanowires have a very intense green emission peak compared with the NBG peak, suggesting that it has the most imperfect crystal structure, whereas the XEOL spectra of nanorods exhibits the most intense NBG emission owing to its near-perfect crystal structure, and finally the nanocombs and nanocombs with mixed morphology display both of the features shown for the nanowires and nanorods. In addition to the green emission, ZnO nanorods and nanocombs exhibit a red shoulder in the XEOL spectra and these are attributed to surface defects of a near-perfect crystal. If the nanostructure is defect abundant in the bulk, these surface features will be quenched because of the energy transfer to the bulk defects.

The appearance of the optical spectra also depends on the excitation method. For most samples, the green emission dominates in the CL spectra, presumably because of the high excitation density, which narrows the band gap and facilitates energy transfer to the defects, except for the nanocombs, which produce a more intense NBG peak and this can be attributed to the presence of highly crystalline nanorods (needles). Finally, no red emission shoulder was registered in the CL of the ZnO samples studied. Although the reason for this is not entirely clear, surface adsorption quenching could be one of the reasons for this difference.

XANES spectra at the O K-edge evidently reflect the difference in the morphology of the nanostructures and the local disorder (defect). The results suggest that ZnO nanorods have superior crystalline structures compared with the other samples. XANES spectra of the different nanosamples at the Zn L-edge are practically the same, indicating that oxygen plays a more significant role in the optical properties of these nanostructures.

Abstract: The preparation of 2-substituted benzoxazoles was achieved through a sequential aerobic oxidation – enolization – oxidative cyclization reaction of N-substituted 2-aminophenols catalyzed by platinum nanoclusters supported on a polymer / carbon black composite material.

Key words: nanoparticles, platinum, oxidation, polymers, supported catalysis.

Résumé : La synthèse de benzoxazoles substitués en position 2 a été réalisée à partir de 2-aminophénols N-substitués à l'aide d'une séquence réactionnelle oxydation aérobie – énolisation – cyclisation oxydante catalysée par des nanoclusters de platine supportés sur un matériau composite polymère / noir de charbon.

Mots-clés : nanoparticules, platine, oxydation, polymères, catalyse supportée.

Introduction

The development of novel strategies for the efficient synthesis of compounds of high molecular complexity in an expedient manner is of great interest to the synthetic organic community. The utilization of catalysts for sequential reactions circumvents the necessary drain of resources caused by the act of isolation and purification of intermediates faced by traditional iterative synthetic methods.[1] Furthermore, the ability to perform one-pot tandem reactions would allow for the formation and use of highly reactive and (or) unstable intermediates in organic synthetic schemes. Whereas most sequential reactions are performed with homogenous catalysts, the use of heterogeneous catalysts would improve the synthetic utility of cascade reactions by facilitating its recovery and subsequent reuse. In addition to the ease of separation from the reaction mixture, heterogeneous systems for multicatalytic sequential reactions would allow for the use of mutually incompatible catalysts to coexist because of the site isolation of the catalytic species caused by the heterogeneous support.[2]

With our ongoing interest in the preparation of highly active immobilized metal catalysts, we have reported an efficient method for the immobilization of metal catalysts with styrene-based co-polymers through a process known as the polymer-incarcerated (PI) method.[3] We have demonstrated that various gold, platinum, and gold–bimetallic nanoclusters could be stabilized and immobilized by the polymer support and act as highly active heterogeneous catalysts for the aerobic oxidation of alcohols[4] and hydroquinones[5] under ambient pressure and temperature. Furthermore, these PI metal nanoclusters were utilized as catalysts for tandem reactions such as the oxidative esterification of alcohols[6] and sequential allylic oxidation – Michael addition reactions between 1,3-dicarbonyl compounds and allylic alcohols.[7]

As part of our continuing effort into developing aerobic oxidative reactions catalyzed by PI metal nanoclusters, we recently reported the use of platinum nanoclusters immobilized on a polymer / carbon black composite material (PI/CB–Pt) as an effective catalyst for the oxidative cyclization of phenolic and thiophenolic imines **1** to 2-substituted benzoxazoles and benzothiazoles **2** under ambient conditions (Scheme 1, eq. [1]).[8]

During the course of the aerobic oxidative cyclization reaction, we found trace amounts of *ortho*-quinones in the crude reaction mixture and believed these species to arise from the hydrolysis of *ortho*-quinone/thioquinone imines derived from the aerobic oxidation of 2-aminophenols/thiophenols. In a related work, Jiang et al.[9] described a *tert*-butyl hydroperoxide (TBHP) / I_2-mediated domino oxidative cyclization reaction with alkenes **3** and benzyl amines **4** to prepare polysubstituted oxazoles **5** (Scheme 1, eq. [2]). In their proposed mechanism, α-keto imine intermediate **6** was believed to enolize to **7** and was subsequently transformed to their desired oxazole **5** via cyclization and oxidation reactions. Inspired by the work of Jiang et al., we envisioned a similar mechanistic scenario in which N-substituted aminophenols **8** could be oxidatively converted to 2-substituted benzoxazoles **9** (Scheme 1, eq. [3]). Assuming that the PI/CB–Pt catalyst could oxidize **8** to *ortho*-quinone imine **10**, the enolization to phenolic

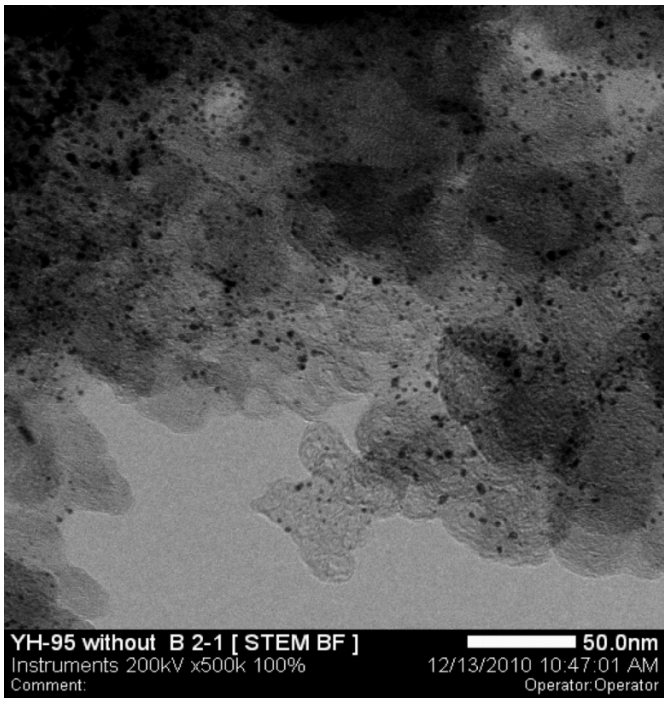
imine **11** should be highly favorable because of the rearomatization of the benzene ring.

In this paper, we report the preparation of benzoxazoles **9** from N-substituted 2-aminophenols **8** under mild aerobic oxidative conditions through a tandem reaction consisting of an aerobic oxidation – enolization – oxidative cyclization sequence catalyzed by polymer-supported platinum nanoclusters.

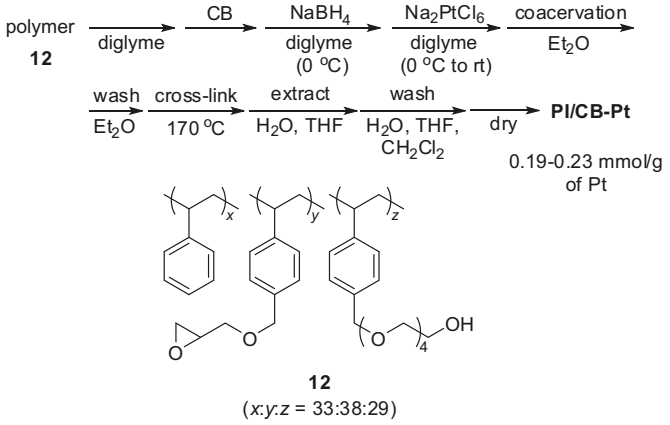
Results and discussion

We began our studies by preparing PI/CB–Pt catalyst (Pt particle size = 2.1 ± 0.7 nm; Fig. 1) following our previously reported procedure (Scheme 2) and attempted to perform the sequential oxidative transformation of aminophenol **8a** to 2-substituted benzoxazole **9a** (Table 1).



However, our initial attempts to synthesize benzoxazole **9a** by applying our previous conditions for the oxidative cyclization reaction failed, and only trace amounts of the desired product **9a** was observed (Table 1, entry 1). Since **8a** was fully converted and *ortho*-quinone was observed in the crude reaction mixture, we attributed this disappointing result to the relative instability of the reactive *ortho*-quinone imine intermediate. Thus, by introducing a substituent group to the aromatic ring of the aminophenol (**8b**) to stabilize the intermediate, 2-substituted benzoxazole **9b** was obtained with a poor yield (Table 1, entry 2). We found that, by diluting the reaction mixture (Table 1, entry 3) and reducing the amount of water (Table 1, entry 4), a modest improvement for the sequential oxidative transformation of **8b** was provided. However, it should be noted that water plays an important role and excluding water from the system reduces the ability of PI/CB–Pt to catalyze the aerobic oxidation reactions (Table 1, entry 5).

Next, we examined the scope of the tandem oxidative transformation reaction of N-substituted 2-aminophenols **8b**–**8l** (Table 2).



We initially examined the effect of the substituents on the aromatic ring of the 2-aminophenols and found that, by adjusting the position of the methyl group to be para to the

amine (**8c**), an improvement of the yield for benzoxazole **9c** (Table 2, entry 2) resulted, whereas the introduction of a more stabilizing group (*t*-Bu) lead to the quantitative conversion of **8d** to benzoxazole **9d** (Table 2, entry 3). Various 2-aryl benzoxazoles **9e**–**9h** bearing electron-rich and -poor substituents were prepared through the sequential oxidative transformation of N-substituted 2-aminophenols **8e**–**8h** with excellent yields (Table 2, entries 4–7). The synthesis of benzoxazoles with alkenyl (**9i**) and alkynyl (**9j**) substituents was achieved in moderate yields, but required a stoichiometric amount of base (Table 2, entries 8 and 9). Finally, benzoxazoles that possessed a primary aliphatic substituent at the 2-position (**9k** and **9l**) were prepared under our optimized reaction conditions with good results (Table 2, entries 10 and 11).

A tentative mechanism for the sequential oxidative transformation of N-substituted 2-aminophenols **8** to benzoxazoles **9** is shown in Scheme 3.

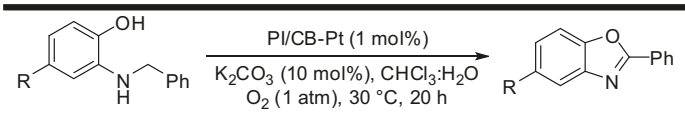
Based on our previous observations of the conversion of 2-aminophenols to *ortho*-quinones, we envisioned a reaction pathway in which N-substituted 2-aminophenol **8** would be oxidized to the corresponding *ortho*-quinone imine **10**, catalyzed by PI/CB–Pt. The facile enolization of **10** to phenolic imine **11** would restore aromaticity to the system and, after oxidative cyclization, would provide the desired benzoxazole **9**. Although the direct oxidation of **8** to **11** is a distinct possibility, this reaction pathway was discounted, since aerobic oxidation of amines to imines with metal nanoclusters is relatively difficult and requires high reaction temperatures.[10]

We also examined the possibility of an aerobic oxidation of **8** in the absence of the platinum catalyst. We performed control studies in which aminophenol **8d** was subjected to our optimized reaction conditions in the absence of PI/CB–Pt and also with our hybrid polymer / carbon black support material without platinum nanoclusters. In both cases, only trace amounts of **10** and **11** were detected by ^{1}H NMR of the crude reaction mixture.

Finally, we examined the possibility of recovery and reuse of our PI/CB–Pt catalyst for the sequential oxidative transformation of **8d**, and found that the catalyst could be reused for five cycles without noticeable loss of catalytic activity (Scheme 4).

Conclusion

In summary, we have developed a sequential aerobic oxidation – enolization – oxidative cyclization reaction of N-substituted 2-aminophenols to 2-substituted benzoxazoles catalyzed by platinum nanoclusters supported on a polymer / carbon black composite material. The reaction was shown to be remarkably mild and could be utilized to prepare 2-substiuted benzoxazoles with aryl, alkenyl, alkynyl, and aliphatic groups. Further investigations into improving the substrate scope and exploring additional oxidative methods towards the preparation of aromatic heterocycles are now in progress.



Experimental

Preparation method for PI/CB–Pt

Ketjen black (0.3751 g) was added to a solution of polymer **12** (0.3751 g) in diglyme (25 mL). After stirring the heterogeneous solution for 15 min, a solution of $NaBH_4$ (95.3 mg, 2.52 mmol) in diglyme (5.4 mL) was added dropwise, then a solution of $Na_2PtCl_6{\cdot}6H_2O$ (117.8 mg, 0.21 mmol) in diglyme (15 mL) was added dropwise at 0 °C. After stirring for 4 h at room temperature, Et_2O (200 mL) was added dropwise. The polymer-coated carbon black was washed several times with Et_2O and dried at room temperature. After light grinding with a motor and pestle, the recovered solid powder was heated at 170 °C for 4 h under a balloon of argon. After cooling to room temperature, the cross-linked polymer-coated carbon black was stirred in a THF–H_2O (1:1, 40 mL) mixture overnight. After being filtered and then washed with H_2O, tetrahydrofuran (THF), and dichloromethane (DCM), the recovered solid was dried

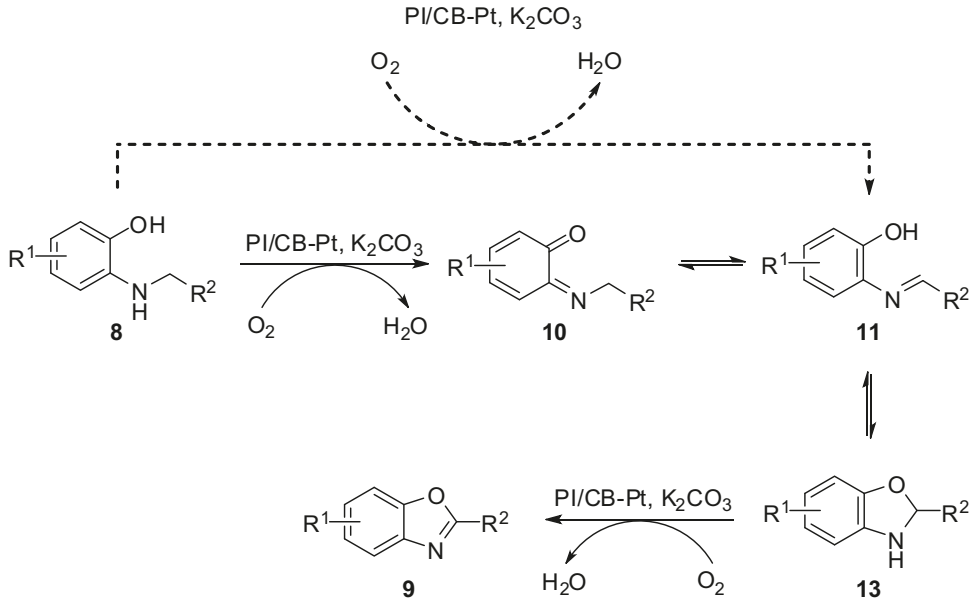
under vacuum to provide the desired heterogeneous catalyst (PI/CB–Pt, 0.83 g; Pt loading, 0.2090 mmol/g).



General experimental procedure for the preparation of N-substituted 2-aminophenols via reductive amination

Benzaldehyde (305 µL, 3.00 mmol) was added to a solution of 2-amino-4-*tert*-butylphenol (0.4857 g, 2.940 mmol) in EtOH (15 mL), and the reaction mixture was stirred for 4 h at room temperature. Then, $NaBH_4$ (0.1135 g, 3.00 mmol) was added portionwise and was allowed to stir for 1 h. After the reaction was completed, the reaction was quenched with H_2O (20 mL), extracted with CH_2Cl_2, and the combined organic layers were washed with a saturated brine solution. The extracted crude product was dried over $MgSO_4$, filtered, concentrated under reduced pressure, and then purified by column chromatography (EtOAc:hexane = 1:4) to provide the desired product **8d** (0.6130 g, 2.40 mmol, 82%) as a white solid.

5-Methyl-2-((3-phenylpropyl)amino)phenol (8l)

mp 69–71 °C. IR (KBr, cm^{-1}): 3412 (w), 3285 (m), 2955 (s), 2852 (s), 2663 (s), 1901 (w), 1818 (w), 1746 (w), 1585 (s), 1478 (s), 1445 (s), 1371 (s), 1180 (s), 1084 (m). ^{1}H NMR ($CDCl_3$, 600 MHz) δ: 7.35–7.22 (m, 5H), 6.96 (t, J = 7.6 Hz, 1H), 6.80 (d, J = 8.2 Hz, 1H), 6.71 (d, J = 7.6 Hz), 2.92 (t, J = 6.8 Hz, 2H), 2.76 (t, J = 7.6 Hz, 2H), 2.29 (s, 3H), 2.00–1.94 (m, 2H). ^{13}C NMR ($CDCl_3$, 150 MHz) δ: 152.2, 141.5, 133.5, 132.8, 128.4, 128.3, 125.9, 125.4, 121.6, 111.8, 48.7, 33.4, 32.3, 17.3. DART-HRMS (*m/z*) calcd for $C_{16}H_{20}N_1O_1$ [$(M + H)^+$]: 242.15449; found: 242.15469.

Experimental procedure for the preparation of 4-(*tert*-butyl)-2-((3-phenylpropyl)amino)phenol (8k)

1-Bromo-3-phenylpropane (3.0 mL, 20 mmol) was added to a heterogeneous mixture of 2-amino-4-*tert*-butylphenol (6.573 g, 39.78 mmol) and $KHCO_3$ (8.763 g, 87.52 mmol) in DMF (10 mL), and the reaction mixture was stirred overnight at room temperature. The reaction mixture was diluted with EtOAc (30 mL) and H_2O (30 mL), extracted with EtOAc, and the combined organic layers were washed with a saturated brine solution. The extracted crude product was dried over $MgSO_4$, filtered, concentrated under reduced pressure, and then purified by column chromatography (EtOAc:hexane = 1:5) to provide the desired product **8k** (5.617 g, 19.82 mmol, 95%) as a white solid, mp 107–108 °C. IR (KBr, cm^{-1}): 3414 (s), 3330 (s), 3235 (s), 2959 (s), 2863 (s), 1940 (w), 1870 (w), 1806 (w), 1598 (s), 1522 (s), 1475 (s), 1417 (s), 1312 (m), 1208 (s), 1106 (m). ^{1}H NMR ($CDCl_3$, 600 MHz) δ: 7.34–7.21 (m, 6H), 6.74 (s, 2H), 2.77 (s, 2H), 2.00 (s, 2H), 1.31 (s, 9H). ^{13}C NMR ($CDCl_3$, 150 MHz) δ: 141.7, 128.4, 125.9, 33.3, 31.6. DART-HRMS (*m/z*) calcd for $C_{19}H_{26}N_1O_1$ [$(M + H)^+$]: 284.20144; found: 284.20186.

General experimental procedure for the sequential oxidative transformations of N-substituted 2-aminophenols

In a screw cap glass test tube, PI/CB–Pt (0.0210 g, 0.0025 mmol, 1 mol%), **8d** (0.0638 g, 0.250 mmol), and K_2CO_3 (0.0025 g, 0.025 mmol) were added and then partially dissolved in $CHCl_3$ (4.75 mL) and H_2O (0.25 mL). The reaction mixture was allowed to stir for 20 h at 30 °C under an O_2 balloon. After the completion of the reaction, the heterogeneous catalyst was removed by filtration and washed with CH_2Cl_2. $MgSO_4$ (0.02 g) was added to the resulting filtrate, and the dried crude reaction mixture was filtered again and then concentrated under reduced pressure. The crude product was purified by preparative thin-layer chromatography (EtOAc:hexane = 1:9) to provide **9d** (0.0626 g, 0.249 mmol, 100%) as a white solid.

5-Methyl-2-phenylbenzooxazole (9b)

^{1}H NMR ($CDCl_3$, 600 MHz) δ: 8.24–8.22 (m, 2H), 7.54–7.50 (m, 4H), 7.44 (d, J = 8.2 Hz, 1H), 7.14 (d, J = 8.2 Hz, 1H), 2.47 (s, 3H). ^{13}C NMR ($CDCl_3$, 150 MHz) δ 163.1, 149.0, 142.2, 134.4, 131.4, 128.9, 127.5, 127.3, 126.2, 119.9, 109.9, 21.5. This is a known compound and the spectral data are identical to those reported in the literature.[11]

6-Methyl-2-phenylbenzooxazole (9c)

^{1}H NMR ($CDCl_3$, 600 MHz) δ: 8.16 (s, 2H), 7.57 (d, J = 7.6 Hz, 1H), 7.45 (s, 1H), 7.09 (d, J = 8.2 Hz, 1H), 2.43 (s, 3H). ^{13}C NMR ($CDCl_3$, 150 MHz) δ: 162.5, 151.0, 139.8, 135.5, 131.3, 128.8, 127.4, 127.3, 125.8, 119.3, 110.7, 21.8. This is a known compound and the spectral data are identical to those reported in the literature.[12]

5-(*tert-*Butyl)-2-phenylbenzooxazole (9d)

^{1}H NMR ($CDCl_3$, 600 MHz) δ: 8.25–8.22 (m, 2H), 7.79 (d, J = 2 Hz, 1H), 7.52–7.47 (m, 4H), 7.41–7.39 (dd, J = 2 Hz, 1H), 1.38 (s, 3H). ^{13}C NMR ($CDCl_3$, 150 MHz) δ: 163.1, 148.7, 148.1, 142.0, 131.3, 128.9, 127.5, 127.3, 122.8, 116.5, 109.7, 34.9, 31.7. This is a known compound and the spectral data are identical to those reported in the literature.[13]

2-(4-Methylphenyl)-5-*tert-*butylbenzooxazole (9e)

^{1}H NMR ($CDCl_3$, 600 MHz) δ: 8.12 (d, J = 8.2 Hz, 2H), 7.78 (d, J = 1.4 Hz, 1H), 7.45 (d, J = 8.2 Hz, 1H), 7.39–7.36 (dd, J = 2 Hz, 1H), 7.29 (d, J = 8.3 Hz, 2H), 2.41 (s, 3H), 1.38 (s, 9H). ^{13}C NMR ($CDCl_3$, 150 MHz) δ: 163.4, 148.7, 148.0, 142.0, 141.8, 129.6, 127.4, 124.6, 122.5, 116.3, 109.5, 34.9, 31.7, 21.6. This is a known compound and the spectral data are identical to those reported in the literature.[14]

Abstract: Interaction of 1-butanol (BuOH) with a cationic surfactant, cetyltrimethylammonium bromide (CTAB) aggregate, in water and salt solution has been studied by viscometry, small-angle neutron scattering (SANS), and 2D-NMR techniques. The experimental results are interpreted in terms of a possible micellar growth occurring in the presence of added alcohol and salt. It was observed that the addition of BuOH strongly influences the viscosity of the CTAB/salt micellar system, reaching a peak viscosity at about 0.5% *w/v* of BuOH over a range of salt concentrations. Scattering measurements support the idea of a structural transformation by the observation of a spectral shift (broadening) as the total concentration of surfactant varies, indicating a decrease in the intermicellar distance and narrow size distribution. The chemical shift from ^{1}H NMR measurements gave complementary data on the solubilization of BuOH in CTAB micelles, whereas the expected locus (site) of the additive added to the surfactant including the dynamics of the molecules in micellar aggregates were successfully correlated by significant and positive cross peaks obtained from two-dimensional nuclear Overhauser effect spectroscopy (2D-NOESY).

Key words: micellar growth, solubilization, viscosity, SANS, 2D-NOESY.

Résumé : On a fait appel à des techniques de viscosimétrie, de diffraction de neutrons aux petits angles (DNPA) et de RMN bidimensionnelles pour étudier l'interaction entre le butan-1-ol (BuOH) et un agent de surface cationique, le bromure de cétyltriméthylammonium (BCTA) sous la forme d'agrégats dans l'eau et dans une solution de sel. On interprète les résultats expérimentaux en fonction d'une croissance micellaire potentielle qui se produirait en raison de la présence de l'alcool et du sel ajoutés. On a observé que l'addition de BuOH influence fortement la viscosité du système micellaire BCTA/sel alors que la viscosité atteint un maximum à environ 0.5 % p/V de BuOH sur une grande plage de concentrations de sel. En se basant sur le fait qu'on observe un élargissement du spectre avec une augmentation de la concentration totale de l'agent de surface, indiquant qu'il se produit une diminution dans la distance intermicellaire et une diminution de la distribution de la taille, les mesures de diffraction apportent un support à l'idée qu'il se produit une transformation de structure. Le déplacement chimique des mesures RMN du ^{1}H fournissent des données complémentaires sur la solubilization du BuOH dans des micelles de BCTA alors qu'on a établi une bonne corrélation avec les sites attendus de fixation de l'additif ajouté à l'agent de surface, y compris la dynamique des molécules dans les agrégats micellaires, grâce à des pics croisés significatifs et positifs obtenus par le biais de la spectroscopie de l'effet Overhauser nucléaire bidimensionnel (« 2D-NOESY »).

Mots-clés : croissance micellaire, solubilization, viscosité, diffraction de neutrons aux petits angles (DNPA), 2D-NOESY.

[Traduit par la Rédaction]

Introduction

Aqueous micellar solutions of cationic surfactants are well known to solubilize water insoluble or slightly soluble organic compounds. Such micellar systems have a wide range of applications, e.g., in the formation of microemulsions in tertiary oil recovery, as germicides in detergency, cosmetic preparations, dyeing operations, in the synthesis of mesoporous materials, in micellar catalysis, and as templates for the fabrication of nanostructures.[1–5]

Alcohols are either considered as cosurfactants (cosolutes) and (or) cosolvents. Depending on the chain length of the added alcohol, their amphipathic nature anchors them either in the surface region of aggregates or in the surrounding solution, altering the surfactant/solvent interfacial properties. The characteristics of surfactant/alcohol mixtures are dependent on the structure, length, and concentration of the alcohol chain. The addition of electrolytes to such surfactant/alcohol systems has been found to alter the existing micellar structures.[5] A number of reports can be found in the literature

where the influence of added alcohol on the various fundamental micellar properties, including the critical micelle concentrations (the CMC value), aggregation number, the micellar charge, and the structure of aggregates composed of alkyltrimethylammonium bromide surfactants in aqueous solutions have been determined.[6–10]

The location and distribution of the alcohol between the aqueous and micellar pseudophases and its degree of solubilization are of both practical and academic interest. The addition of organic additives (electrolytes or polar compounds) influences the energy required for the transfer of the surfactant ion from the bulk solution to the micelle because of the screening effect on the micellar charge. It also alters the micellar morphology, depending upon the extent of their penetration and (or) intercalation into the micelles.[10,11] Alcohols that are partially miscible in water decrease the CMC for both ionic and nonionic surfactants, while completely miscible alcohols cause an increase of the CMC.[12–14] The literature also reports that, in concentrated micellar systems, morphological transformations of isotropically spherical micelles to more asymmetric shapes, such as ellipsoids (oblate or prolate) and even rods, results[13–19] in many cases, leading to viscoelastic effects in these systems. The occurrence of viscoelasticity over a certain range of either the surfactant or additive concentration is critically dependent on packing parameter considerations. Packing constraints are dependent on a number of factors in these systems, including the ionic strength, structure of the surfactant head group, the structure of counterions bound to the micelle, the degree of binding, and the location of these counterions in the aggregates, as well as the manner in which hydrophobic additives are solubilized.[10,13,14,19–21]

Although a number of studies dealing with the morphology of concentrated surfactant solutions have appeared in the literature,[8–17,22] a number of fundamental questions regarding the interactions that cause the transitions from spherical to wormlike or rodlike micelles remain. Systematic studies of the growth of micelles in the presence of additives could help understand the kinetics of micellar and mesophase growth. Recently, mesophasic structures have been identified as excellent templating agents for microspheres and nanoparticles of various types. Given the importance of mesophases in these applications, and the importance of the flow properties of surfactant solutions in a number of commercial products, we have embarked on a systematic and detailed investigation of the properties and the microstructure of a cationic micellar solution as a function of salt and alcohol concentration and temperature. In the present research paper, we obtained the viscosities of cetyltrimethylammonium bromide (CTAB) / salt solutions as a function of added 1-butanol (BuOH) and temperature. The micellar dimensions of CTAB aggregates as a function of alcohol and salt concentration were obtained from scattering techniques. 2D ^{1}H NMR (NOESY) spectra provided detailed information on the sites of alcohol encapsulation in the aggregates. These experiments give sensitive details about the molecular packing of the surfactants and the alcohol inside the aggregates. All these results provide important new insights in terms of the molecular interactions that lead to micellar growth and subsequent rheological behavior exhibited by these systems.

Experimental section

Materials and methods

Cationic surfactant CTAB was obtained from Sigma-Aldrich (USA). BuOH (Fluka) with a minimum 99.5% purity was used. Inorganic salts (NaBr or KBr) of AR grade were used in this study. Triple-distilled water was used for solution preparation. Deuterium oxide (D_2O) with 99.9% purity (Sigma-Aldrich) was used for small-angle neutron scattering (SANS) and ^{1}H NMR.

Viscosity experiments

Viscosity measurements were performed using an Ubbelohde suspended level capillary viscometer. This viscometer was cleaned and dried thoroughly before and after each measurement and was always suspended vertically in a thermostat with a temperature stability of ±0.1 °C in the investigated region. The flow time for a constant volume of solution through the capillary was measured with a calibrated stopwatch.[21]

SANS analysis

SANS measurements were conducted at the Neutron Scattering Laboratory (NSL) BATAN in Serpong, Indonesia, using a 36 m SANS spectrometer (SMARTer).[23] Each sample was measured at two detector distances (1.5 and 4 m) to cover a momentum transfer Q range of 0.025 to 0.3 Å^{-1}, with a neutron wavelength (λ) of 3.9 Å ($\Delta\lambda/\lambda$ = 13%). (We could not get the oscillation at high Q range because of the polydispersity of the micelles and the low resolution of the instrument; hence, all the SANS plots presented in this paper are plotted in a range of 0.02 to 0.14 Å^{-1}, as they appear more clear and distinct. SANS plots in the full Q range of 0.025 to 0.3 Å^{-1} are provided in the Supplementary data). All samples were dissolved in D_2O; the samples were then poured into 5 mm thick quartz cells and exposed to the neutron beam for a period of 30 min. For the concentration-dependent experiments, each sample was held at 30 °C to avoid any Krafft point issues. Scattering intensities of the samples were corrected for background noise, scattering by the solvent and quartz cell, and the sample's transmission using Graphical reduction and analysis SANS program (GRASP).[24] The corrected scattering intensity data at high Q range were normalized at the same level of the incoherent background. Then they were combined with the data at low Q range to cover the whole Q range of the experimental setup and then fitted using the SANS NIST data analysis program.[25]

The intensity $I(Q)$ of small-angle scattering as a function of momentum transfer Q for a homogeneous monodisperse interacting spherical micelle system can be expressed as

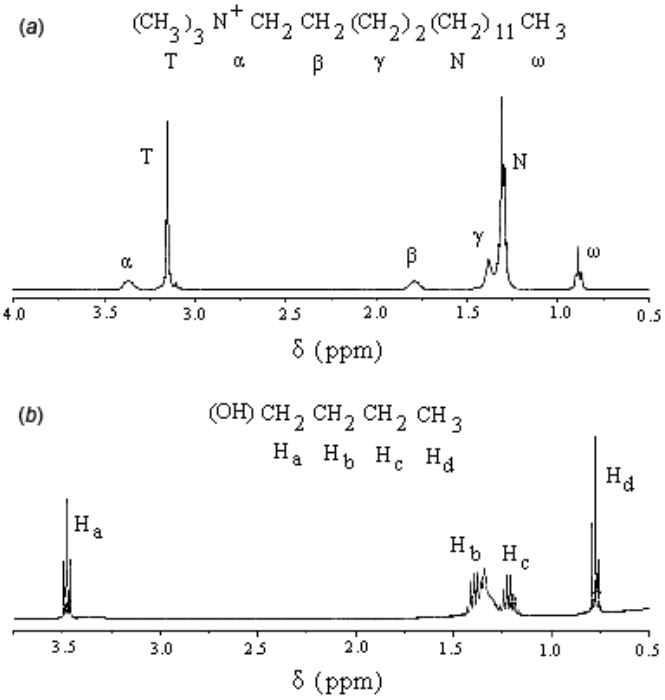
$$[1] \qquad I(Q) = n(\rho_m - \rho_s)^2 V^2 P(Q) S(Q)$$

where n denotes the number density of micelles and ρ_m and ρ_s are the scattering length densities of the micelle and the solvent, respectively. The term ($\rho_m - \rho_s$) is called contrast, V is the volume of a micelle, which is calculated by $V = 4\pi R(a)R(b)^2/3$, where $R(a)$ and $R(b)$ are the minor and major semi-axes, respectively. Equation [1] is used as an approximation for nonspherical and nonmonodisperse micelles. The form factor $P(Q)$ (also known as the intraparticle

Can. J. Chem. Downloaded from www.nrcresearchpress.com by Renmin University of China on 09/02/12
For personal use only.

structure factor) depends on the shape (cylinder, ellipsoid, or sphere) and the size of the micelles, and $S(Q)$ is the interparticle structure factor, which depends on the interaction potential and the number density. The expression derived by Hayter and Penfold was used.[26]

For an isotropic system, $S(Q)$ can be written as



$$[2] \qquad S(Q) = 1 + 4\pi n \int [g(r) - 1] \frac{\sin Qr}{Qr} r^2 \mathrm{d}r$$

where $g(r)$ is the radial distribution function (the probability of finding another particle at a distance r from a reference particle centered at the origin).

^{1}H NMR and two-dimensional nuclear Overhauser effect spectroscopy (2D-NOESY)

1D and 2D NMR experiments (^{1}H, gradient COSY, and NOESY with and without solvent suppression) were performed with a Bruker AVANCE-II 400 MHz spectrometer at St. Francis Xavier University, Antigonish, Nova Scotia. The mixing and the delay times for the NOESY experiments were estimated from the spin-lattice relaxation time of a 5.0 wt % solution of BuOH in CTAB separately. To obtain 2D-NOESY spectra, acquisition delays of $\approx 3 \times T$ and mixing times of $\approx 1 \times T$ were used. Here, T is the acquisition time during which the signal is recorded. For the COSY experiments, the data were zero-filled once and multiplied by a sine-bell window in both dimensions prior to the 2DFT. In the gradient NOESY experiments, 256 transients of either 2 or 4 scans over 512 complex data points were acquired. All acquisitions were done in phase-sensitive mode, with and without the saturation of the water resonance at ~4.65 ppm. The data were zero-filled twice in dimension 1 and multiplied by a squared sine function in both dimensions before 2DFT.[20,27] Solutions were prepared directly in small sample vials, and these were dispensed into the NMR tubes with a volumetric pipette. Labeled ^{1}H spectra for CTAB and BuOH are given in Scheme 1.

Results and discussion

Effect of additive concentration

According to the literature, the viscosities of certain cationic surfactant solutions are substantially altered when a medium chain length alcohol is added to the cationic micellar system in the presence of salt.[11,13,14] Figure 1 presents the viscosity measurements of a solution containing 0.10 mol/L CTAB mixed with varying amounts of NaBr as a function of the BuOH concentration.

It should be noted from Fig. 1 that there is very little change in the solution viscosity in the CTAB solution containing small amounts of NaBr over the range of alcohol concentrations investigated. This indicates that, in these systems, no significant aggregate growth was observed, indicating that these structures are essentially spherical micelles over the alcohol concentration range investigated. However, further additions of NaBr substantially influences the viscosity of the system, indicating significant growth in the aggregate size investigated at the higher salt concentrations. It is well-known in the literature that ionic surfactants tend to endure uniaxial growth upon the addition of salt,[8–17,22] leading to a wide array of aggregate morphologies ranging from oblate, prolate, or rodlike micelles, or even multiconnected wormlike micelles. An unusual highly viscoelastic solution was observed to form in the range of 0.2% to 2% *w/v* of added BuOH, indicating a significant structural transformation is occurring in this concentration range, which is attributed to the strong screening effect of the salt on the micellar charge and the partitioning of alcohol into the cationic micelles; the combination of these two factors leads to a substantial reduction in the aggregate charge density and, hence, reduced electrostatic repulsions. On further addition of salt, the viscosity decreases rapidly, which is likely due to the sliding over of cross-links or multiconnected networks.[10] Although the viscosity measurements provide a reasonable indication of structural changes occurring in the solution as a function of additive concentration, detailed information on the aggregate dimensions as a function of alcohol and salt concentration was obtained from a thorough quantitative analysis of the scattering data obtained from the SANS measurements.

SANS studies revealed the intensity dependence of the scattered neutrons on the additive concentration.[28,29] The scattering data were analyzed and fitted using a data analysis program for different micellar structures. The solid lines in the SANS plots represent the calculated scattering patterns as the best fits of the experimental data. Dimensional parameters such as semi-minor axis $R(a)$ and semi-major axis $R(b)$ were used as fitting variables. The correlation peak usually occurs at $Q_{max} = 2\pi/d$, where d is taken as the average distance between the micelles and Q_{max} is the value of Q at the peak position. Figures 2 and 3 explain the concentration-dependent study of 0.1 mol/L CTAB in D_2O solution as a function of BuOH and KBr concentration. The calculated distributions give peak positions that agree well with the

experimentally determined values for all the studied concentrations.

Figure 2 illustrates the scattering intensity of 0.10 mol/L CTAB solutions to which increasing amounts of BuOH are added. The shifts in the maximum of the scattering profile indicate changing concentrations of BuOH lead to the changes in the aggregate structure. It is well-known that, as alcohols solubilize inside micelles, the nonpolar hydroxyl group is interspersed amongst the charged surfactant headgroups and has a significant influence on the surface charge density of the aggregate. In micellar systems, this is manifested in changes in both the degrees of counterion binding as well as the surfactant aggregation number, i.e., both of

Fig. 3. Small-angle neutron scattering (SANS) plot of 0.1 mol/L cetyltrimethylammonium bromide (CTAB) solution in a fixed salt concentration (0.1 mol/L) as a function of 1-butanol (BuOH) concentration (*%w/v*) at 30 °C.

these parameters are known to substantially decrease as the amount of alcohol in the mixed solvent is increased in the dilute concentration range. At higher alcohol concentrations, micellar growth possible transitions owing to the modification of the electrostatic interactions between the micelles by the large amounts of alcohol incorporation into the aggregates. In the absence of additives, the scattering spectrum of the 0.10 mol/L CTAB solution shows a characteristic correlation peak owing to the repulsive intermicellar interactions between the positively charged CTAB micelles, signifying the presence of dense micelles in the system. We note that in the absence of salt (and with the increase in alcohol concentration of >2% *w/v*), the interparticle distances decrease and the peak shifts to higher *Q* values, indicating the change in micellar shape and size from a higher morphology structure to the lower ones.

Figure 3 shows the influence of changing both salt and BuOH concentrations on the mesophasic nature of CTAB solution. These results are consistent with the fact that for the self-assembly of the alcohol/surfactant system investigated here, the environment surrounding the cationic headgroups of CTAB is sensitive to the charge density of the aggregates and the "hardness" of the counterion. A number of studies recently have discussed the specific interactions that exist between charged headgroups of aggregating amphiphiles (i.e., forming micelles and vesicles) in terms of a lyotropic (Hofmeister) series: $OH^- < F^- < Cl^- < Br^-$. These ions are small in size and possess a high charge density and greatly influence the aggregation process depending on their location in the series.[19] In the present study, the formation of large stable aggregates in the cationic surfactant / alcohol / salt system was observed.

It was observed that with the addition of a fixed concentration of KBr (0.10 mol/L) to 0.10 mol/L CTAB in varying concentrations of BuOH, noticeable aggregate growth occurred (0.5% *w/v*) as the hydration shell of the Br^- ions was found to be more perturbed. We expect that the Debye

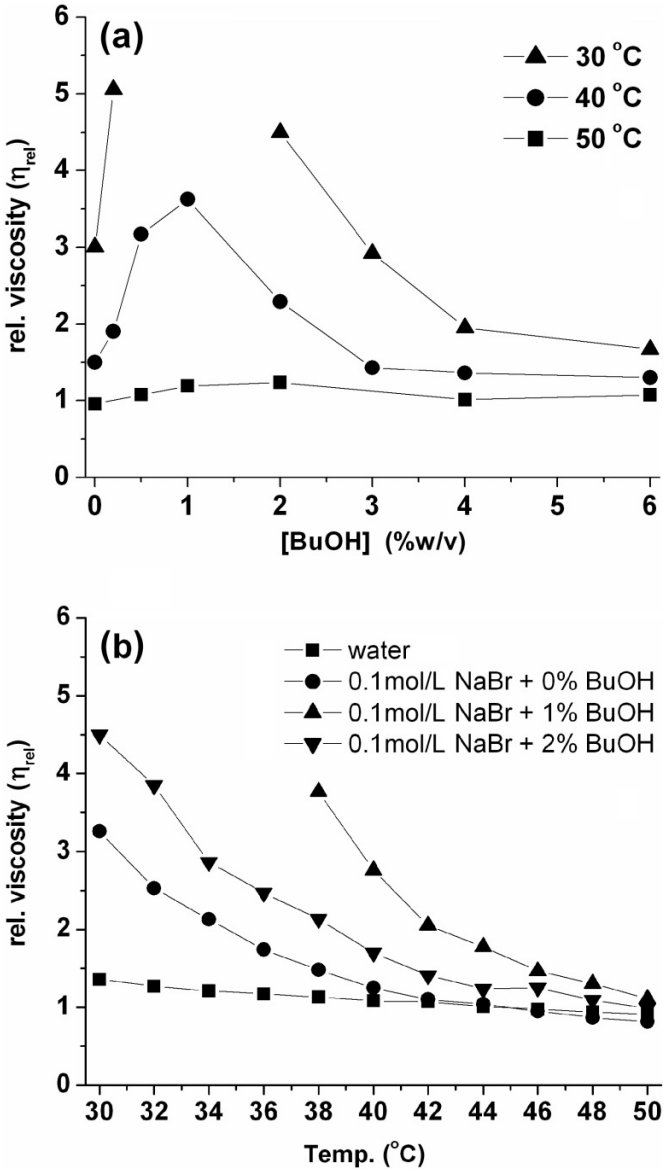
Note: *R*(*a*) = semi-minor axis; *R*(*b*) = semi-major axis.

screening length decreases in this region because of an increase in the ionic strength of the medium by the addition of KBr. The correlation peak broadens and, as well, the Q_{max} shifts to lower Q values. Such a broadening of the correlation peak at a constant volume fraction of cationic aggregates indicates a significant decrease in the magnitude and the range of electrostatic interactions. The SANS scattering data are well described after fitting to the spherical model with a narrow particle size distribution for the investigated system. The parameters obtained from the fitting of the scattering profiles are shown in Table 1.



Effect of temperature

The effect of temperature on the relative viscosity of 0.10 mol/L CTAB solution in the presence of varying additive concentrations is shown in Fig. 4. It was found that, at lower temperature, the influence of salt and alcohol is more pronounced as the micellar growth is more inductive to higher dimensionality, leading to the formation of networks.[10,30]

When we examine Fig. 4, we can clearly infer the promotion of the volume fraction of CTAB micelles at 30 °C, which is attributed to the incorporation of alcohol in the interfacial region of aggregates, presumably with its –OH group in the Stern layer. It then reaches a maximum (~0.5% *w/v* BuOH) where shear thinning is observed at higher shear rates, indicating that these systems may be highly viscoelastic. Such behavior is characteristic of long rodlike or wormlike micelles.[10] As well, on increasing the alcohol content, we expect that the BuOH molecules will solubilize in the palisade region of the CTAB micelles and, with an increase in temperature, the viscosity of the system would decrease, which could be explained by the shear alignment of micelles as well as the thermal breakdown of the entangled micellar networks.

This interpretation of the relative viscosity results is found to be consistent with the SANS data as shown in Fig. 5. Here, the intensity of the scattered neutrons and aggregate length was found to decrease with increasing temperature, as they break down into smaller structures because of an increase in the degree of the dissociation of counterions, resulting in stronger repulsions between the charged head groups. Consequently, the effective head group area per surfactant molecule increases and causes the packing parameter to decrease, which affects the intermicellar separation and shifts the peak to larger Q values.[10] Table 2 provides a quantitative estimate of the micellar parameters obtained after model fitting.

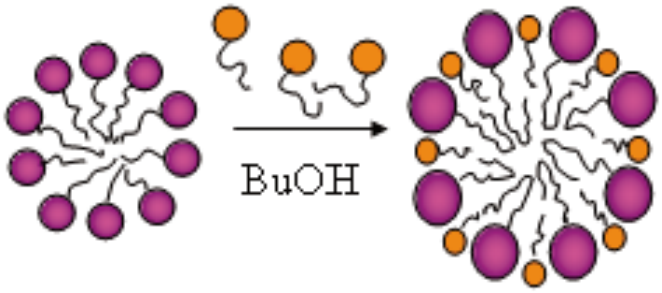
Location of BuOH in the micelle

2D-NOESY experiments provide excellent insight into the fundamental nature of the self-assembly process in a wide array of self-assembled systems. Cross peaks observed in the 2D-NOESY spectra signify the spatial proximity (within 5 Å) of protons in the self-assembled aggregates. By measuring the cross-peak amplitudes, significant information on the encapsulation and location of the alcohol molecule in the surfactant micelle can be readily obtained.[20,27,31]

On examining the NOESY spectra of the CTAB/BuOH mixed system, a few similarities in the nature of the cross peaks were observed for these systems as well as for dodecyltrimethylammonium bromide (DTAB) / BuOH and sodium dodecylsulfate (SDS) / BuOH.[20] Figure 6 exhibits stronger cross peaks in the headgroup region of the CTAB/BuOH system, indicating a preferential solubilization of the alcohol near the palisade layer in the large cationic micelles. Additional cross peaks were also observed between the terminal $-CH_3$ group of CTAB and BuOH, consistent with the spatial proximity of these sets of protons. We also observed strong correlations between the β protons of CTAB with the H_a protons of BuOH (δ ~ 1.4 ppm) and the β and γ protons of CTAB with the H_b and H_c protons of BuOH. The $N-CH_3$ protons also had very strong interactions with the H_b and the H_c protons of BuOH. Some intramolecular

Fig. 6. Contour plot of the 2D-NOESY spectrum of 0.1 mol/L cetyltrimethylammonium bromide (CTAB) in 5%*w/v* 1-butanol (BuOH).



interactions between the H_b and H_c protons of the BuOH are consistent with some folding of the alcohol occurring in the palisade region of the micelle. These types of strong intramolecular interactions owing to the folding of surfactants in micelles have been discussed previously.[32]

We also observed a strong correlation between the $-CH_3$ protons of the alcohol-surfactant (δ ~ 0.9 ppm) and the first few chain protons of CTAB, as well as a number of other correlations in the region around 1–1.2 ppm that represent cross peaks between the ω-CH_3 peak of the cationic surfactant and the H_d alcohol peak. These cross peaks may be due to the folding of the carbon chains of CTA^+ cations in the interior of the micelles. This is consistent with the alcohol being located in the micelle palisade layer with its headgroup in intimate contact with CTAB headgroups located near the shell (hydration layer) or the palisade boundary, and its hydrocarbon chain pointed inwards towards the center of the aggregates. In the case of the higher alcohol concentrations investigated here, there is possibly some folding of the alcohol found in the headgroup region that may lead to the swelling of the aggregates in aqueous solution, consistent with the presence of the larger aggregates observed above. A probable encapsulation of BuOH occurring in the CTAB micelle from the analysis of the cross-peak locations and magnitudes is represented in Fig. 7.

Conclusions

Significant aggregate growth in a surfactant/alcohol/salt system has been verified through a combination of viscosity, SANS, and NMR NOESY experiments. Viscosity results appear to indicate a large change in the aggregate morphology in certain alcohol-rich regimes. SANS experiments also indicated that the interaggregate associations and significant surfactant incorporation into growing micelles, owing to favorable electrostatic and hydrophobic interactions, lead to significant viscosity enhancement in certain surfactant/salt/

Fig. 7. Encapsulation of 1-butanol (BuOH) in cetyltrimethylammonium bromide (CTAB) micelles.

alcohol concentrations. NMR NOESY experiments, being sensitive to molecular details, yielded important information on the location of the alcohol in the mixed aggregates and, hence, provided some indication of the folding and (or) encapsulation of the alcohol molecules in the micelles. All these results indicate that, in certain concentration ranges, organic additives like alcohols can serve as a partial substitute for salt with respect to the ability to thicken the surfactant solutions in aqueous medium.

Abstract: Peroxyacetals **2a**–**2j** were prepared by $TiCl_4$-promoted nucleophilic addition of both *tert*-butyl hydroperoxide (TBHP) and an alcohol to the corresponding aldehyde. The reaction works well with a variety of aldehydes, but not with ketones. The magnitude of the equilibrium constant for hemiacetal formation plays an important role; a large constant enables high conversion to peroxyacetal.

Key words: peroxyaceta , aldehyde, titanium chloride, peroxide.

Résumé : On a préparé les peroxyacétals **2a**–**2j** par addition nucléophile catalysée par le $TiCl_4$ simultanée de l'hydroperoxyde de *tert*-butyle et d'un alcool sur l'aldéhyde correspondant. La réaction fonctionne bien avec un grand nombre d'aldéhydes, mais elle ne donne pas de bons résultats avec les cétones. La valeur de la constante d'équilibre de formation de l'hémiacétal joue un rôle important; avec une constante dont la valeur est élevée, on obtient un degré élevé de conversion en peroxyacétal.

Mots-clés : peroxyacétal, aldéhyde, chlorure de titane, peroxyde.

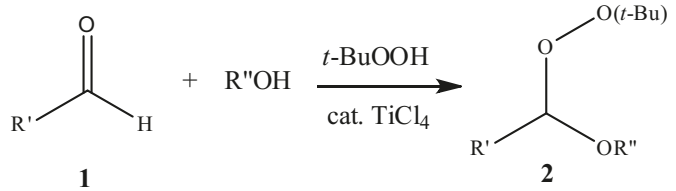
[Traduit par la Rédaction]

Introduction

The number of reported peroxide natural products continues to increase and some organic peroxides have been discovered to have antimalarial properties,[1] therefore, peroxide synthesis has been studied for a long time and is of continuing interest for chemists.[2–4,5,6] In last two decades, peroxyacetals have been used as substrates in the development of new methodology for peroxide synthesis. For example, neighboring iodo, alkoxy, acetoxy, and silyl groups impart useful levels of diastereoselection in the Lewis acid-mediated allylation of peroxyacetals, generating chiral peroxides.[2] Peroxyacetals undergo reaction with allyltrimethylsilane, silyl enol ethers, and silyl ketene acetals in the presence of Lewis acids, such as $TiCl_4$, $SnCl_4$, and trimethylsilyl triflate, to afford homoallyl peroxides, 3-peroxyketones, and 3-peroxyalkanoates, respectively.[3] Acid hydrolysis of peroxyacetals may generate alkyl hydroperoxides.[4] Hence, the synthesis of peroxyacetals has become interesting as well.

The major synthetic route to monoperoxyacetals or bisperoxyacetals is through the ozonolysis of alkenes or enol ethers, followed by alkylation or silylation of the resulting hydroperoxyacetals.[1c,4,7] The drawback of this general synthetic method is that the selectivity of ozonolysis is poor and cannot be used for substrates containing ozone-sensitive groups. Bisperoxyacetals and (or) ketals can be synthesized by another method, which involves the reaction of acetals or ketals with H_2O_2 in the presence of protic or Lewis acids, such as $BF_3{\cdot}OEt_2$, HCl, AcOH, and tungstic acid, followed by alkylation or silylation of the resulting dihydroperoxyacetals.[8] Bisperoxyacetals or ketals can also be directly synthesized by the reaction of acetals or ketals with alkyl hydroperoxides in the presence of protic or Lewis acids ($BF_3{\cdot}OEt_2$).[5] Recently, a newly developed methodology for monoperoxyacetals or bisperoxyacetals used iodine as a catalyst to peroxidize carbonyl compounds and, in this method, both ketones and aldehydes have the possibility of being converted into bisperoxyacetals or ketals or monoperoxyacetals or ketals.[6] In this paper, we will introduce a novel synthetic method that uses $TiCl_4$ as a catalyst and selectively converts an aldehyde into monoperoxyacetals. For this methodology, it is unnecessary to convert aldehydes into acetals or vinyl ethers before the preparation of peroxyacetals. In addition, this method for peroxyacetal synthesis works only for aldehydes, not for ketones, and that is quite different from ketal synthesis. To figure out what causes the difference, we propose a reaction mechanism for the $TiCl_4$-promoted peroxyacetal synthesis. A detailed analysis will lead us to the answer.

Results and discussion



In this paper, we found that reaction of an aldehyde with 1 equiv of alcohol and 1.7 equiv of TBHP in the presence of a catalytic amount of $TiCl_4$ (0.1 equiv) in $CDCl_3$ solvent generated a peroxyacetal. To understand the scope of this reaction, we tested various aldehydes and alcohols for this type of reaction, and the results are shown in Table 1. First, we used an aromatic aldehyde (benzaldehyde) as an aldehyde substrate to react with a primary alcohol (*n*-BuOH), secondary alcohol (*i*-PrOH), benzyl alcohol, or tertiary alcohol (*t*-BuOH) for the peroxyacetal synthesis. What we found was that they

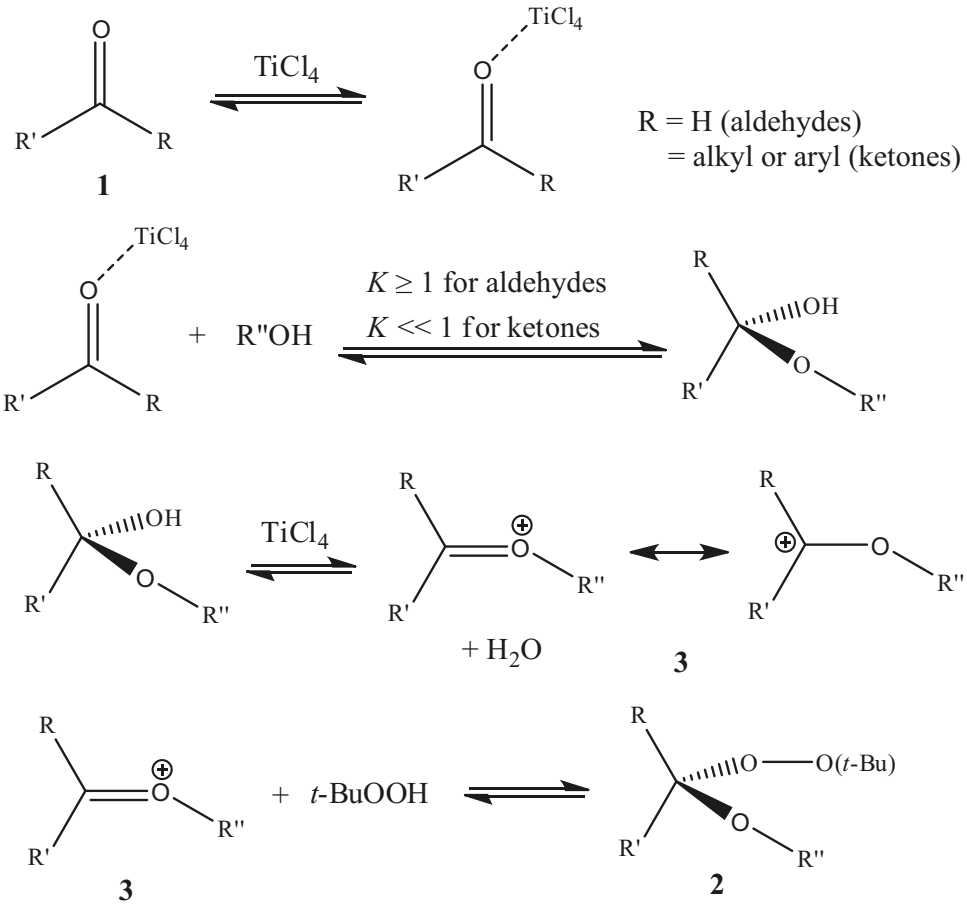
all generated the desired product in good yield, but a sterically hindered alcohol such as *t*-BuOH may result in a lower yield.

Afterwards, we used a primary alcohol ($Ph(CH_2)_3OH$) as a nucleophile to react with two types of aliphatic aldehydes (**1e** and **1f**). These two aliphatic aldehydes have different degrees of steric hindrance adjacent to their respective carbonyl groups, but they both worked well and similarly in the peroxyacetal synthesis.

We further explored electronic effects on this peroxyacetal synthesis. We used various substituted benzaldehydes as an aldehyde substrate to react with *n*-BuOH. The substituent includes *p*-NO_2, *m*-NO_2, *p*-Cl, and *p*-MeO, ranging from highly electron-withdrawing to highly electron-donating. What we found was that benzaldehyde with a highly electron-withdrawing substituent gave the peroxyacetal very easily and in high yield. Just like the synthesis of the other peroxyacetals mentioned above, they worked very well without using a dehydrating agent such as 4 Å molecular sieves. However, when we carried out the peroxyacetal synthesis for an aromatic aldehyde substrate with a strong electron-donating substituent such as *p*-MeO, conversion to the peroxyacetal was very low (<10%). This low conversion was significantly improved by using a very dry solvent and activated 4 Å molecular sieves.

In the $TiCl_4$-promoted nucleophilic addition of both TBHP and an alcohol to an aldehyde, we usually had acetal and bisperoxyacetal as by-products. When the ratio of the quantities for aldehyde, alcohol, and TBHP was 1:1:1 in the peroxyacetal synthesis, we obtained little of the acetal by-product. When the ratio was 1:1:2, we obtained little of the bisperoxyacetal. The best ratio for these substances was 1:1:1.7, where the major product was peroxyacetal with negligible acetal and bisperoxyacetal by-products.



The limitation for the $TiCl_4$-promoted peroxyacetal synthesis is that the substrate cannot be a ketone. The ketone substrates we tried included acetone, acetaphenone, benzophenone, and benzil. This methodology did not work out for all the ketones even under very dry conditions and with a dehydration agent. This is quite different from ketal synthesis and that inspired us to analyze the reaction mechanism for the $TiCl_4$-promoted peroxyacetal synthesis.

Advantages of the $TiCl_4$-promoted peroxyacetal synthesis are as follows: (*i*) The method can be carried out at room temperature; (*ii*) Most peroxyacetal syntheses do not need a dehydrating agent and still achieve high yields, except for aldehyde substrates with highly electron-donating substituents. For aldehyde substrates with highly electron-donating substituents, one can still obtain peroxyacetals in high yield as long as a dried solvent and dehydrating agent are used; (*iii*) The peroxyacetal synthesis is selective for aldehyde substrates in the presence of ketone groups; (*iv*) It is unnecessary to convert aldehydes into acetals or vinyl ethers before preparation of peroxyacetals.

The mechanism for the $TiCl_4$-promoted peroxyacetal synthesis from an aldehyde substrate is assumed to be similar to that for acid-catalyzed acetal synthesis from an aldehyde substrate. Acid-catalyzed acetal synthesis from an aldehyde substrate usually involves two parts: (*i*) formation of hemiacetal from aldehyde and (*ii*) formation of acetal from hemiacetal. Then, the mechanism for the $TiCl_4$-promoted peroxyacetal synthesis from an aldehyde substrate is assumed to involve the same two parts (shown in Scheme 1). Chemists paid more attention to each of the two parts of the mechanism separately rather than the whole integrated mechanism.[9] In this paper, we will not only investigate each part of the mechanism, but also analyze the integrated mechanism as a whole.

For the second part of the mechanism, a hemiacetal intermediate may eliminate the OH group with the assistance of $TiCl_4$ activation,[10] forming a trigonal carbon and stabilized carbocation **3**. This ion will react very fast with an alcohol or TBHP to yield an acetal or ketal. The carbocation **3** is better stabilized by alkyl or aryl group than by H. If the formation of carbocation **3** is rate-limiting in the $TiCl_4$-promoted peroxyacetal synthesis, the activation energy for the formation of peroxyketal is supposed to be smaller than that for the formation of peroxyacetal. Therefore, we should have been

Scheme 1. Proposed mechanism for $TiCl_4$-promoted peroxyacetal synthesis.

able to prepare peroxyketal with this method, but we could not. This indicates that the second part of the mechanism (formation of acetal from hemiacetal) does not play the most important role in the $TiCl_4$-promoted peroxyacetal synthesis, but the first part of the mechanism (formation of hemiacetal from aldehyde) does.

The first part of the mechanism (formation of the hemiacetal or hemiketal) is similar to that for aldehyde or ketone hydration. Aldehyde hydration is usually thermodynamically favorable with an equilibrium constant close to or greater than 1, but ketone hydration is thermodynamically unfavorable with an equilibrium constant much smaller than 1. There are two pieces of evidence that support that the first part of the mechanism (formation of hemiacetal from aldehyde) plays the most important role in the $TiCl_4$-promoted peroxyacetal synthesis. The first piece of evidence is that peroxyketals cannot be prepared by this method. The possible explanation is that the thermodynamically unfavorable formation of hemiketal makes the formation of peroxyketal impossible in the $TiCl_4$-promoted peroxyacetal synthesis. The second piece of evidence is that the conversion to **2j** in the absence of a drying agent is much lower than the conversion to **2g** or **2h** under the same conditions. The possible explanation is that a strong electron-donating group (*p*-MeO) on **1j** and **2j** makes the formation of hemiacetal less thermodynamically favorable than a strong electron-withdrawing group (NO_2) and this causes the formation of peroxyacetal at low conversion levels. We solved the low-conversion problem by removing the water by-product with 4 Å molecular sieves, shifting the equilibrium position to the peroxyacetal product. This is usually found in the acetal synthesis, where azeotropic distillation is usually used as a way to remove the water by-product. However, azeotropic distillation is not a suitable way to remove water in the peroxyacetal synthesis because heat may further degrade the peroxyacetal product. Hence, the reason why the peroxyacetal synthesis does not work with ketones is that the formation constants from the ketones to the corresponding hemiketals in the first part of the reaction are too small to generate a large enough concentration of hemiketals for the second part of the reaction.

Conclusion

$TiCl_4$-promoted nucleophilic addition of both TBHP and an alcohol to an aldehyde generated a peroxyacetal. This methodology works selectively for aldehydes, but not for ketones. Various alcohols and aldehydes can be used in this peroxyacetal synthesis. To reduce the acetal and bisperoxyacetal by-products to a negligible amount, the best ratio of the quantities for aldehyde, alcohol, and TBHP in the peroxyacetal synthesis is 1:1:1.7. The equilibrium constant for the formation of hemiacetal plays the most important role in the $TiCl_4$-promoted peroxyacetal synthesis. The larger the formation constant of hemiacetal, the better conversion the peroxyacetal synthesis can reach.

Experimental section

General procedure for synthesis of peroxyacetals (2)

To aldehyde (1 mmol) and 4 Å molecular sieves (0.5 g) in $CHCl_3$ or $CDCl_3$ (2 mL) at room temperature was added $TiCl_4$ (0.1 mmol, 10% in $CHCl_3$ or $CDCl_3$). The mixture was stirred at room temperature for 1 h. Toluene solutions of TBHP (1.7 mmol) and alcohol (1 mmol) were added into the mixture, followed by stirring at room temperature for around 1–2 days. The reaction was monitored by ^{1}H NMR spectrometry until the reaction was complete. The product **2** was purified by column chromatography with silica gel as a stationary phase and hexane/EtOAc as a mobile phase.

(*tert*-Butylperoxybutoxymethyl)benzene (2a)

Colorless oil. ^{1}H NMR (300 MHz, $CDCl_3$) δ: 7.37–7.49 (m, 5H), 5.84 (s, 1H), 3.99 (dt, J = 9.6, 6.5 Hz, 1H), 3.67 (dt, J = 9.6, 6.7 Hz, 1H), 1.66 (m, 2H), 1.42 (m, 2H), 1.30 (s, 9H), 0.93 (t, J = 7.3 Hz, 3H). ^{13}C NMR (75 MHz, $CDCl_3$) δ: 136.9, 128.7, 128.1, 126.9, 106.0, 80.7, 69.3, 32.0, 26.5, 19.3, 13.8. The NMR data were in agreement with those previously reported for this compound (ref. 11). Anal. calcd for $C_{15}H_{24}O_3$: C 71.38, H 9.59; found: C 71.41, H 9.57.

Abstract: The presence of aluminium in natural waters is of major concern at present because of the potential threat for the health of a number of species, including humans. In natural water, aluminium exists in different forms depending on the concentrations of various other species, organic matter, the types of minerals, the pH, etc. The aluminium species in the natural water – gibbsite system is considered in this work. The main approaches for estimating of the individual concentrations of the aluminium species involve the use of reliable thermodynamic data, together with experimental measurements of free or total concentrations of major components. The new type of diagrams based on graphical and computerized methods, which quantitatively describe the distribution of soluble and insoluble, inorganic, and organic, and monomeric and polymeric aluminium species in heterogeneous aquatic systems is presented. This approach utilizes thermodynamic relationships coupled with original mass balance constraints, where the mineral phases are explicitly expressed. The factors influencing the distribution of soluble and insoluble aluminium species in aquatic systems were analyzed. The new type of developed diagrams may be used to interpret data obtained within the framework of water-quality monitoring programs.

Key words: gibbsite, diagram of distribution, heterogeneous system, thermodynamic stability.

Résumé : La présence d'aluminium dans les eaux naturelles est maintenant une préoccupation majeure en raison des dangers potentiels que ce métal présente pour la santé d'un certain nombre d'espèces, dont les humains. Dans les eaux naturelles, l'aluminium existe sous diverses formes suivant, entre autres, les concentrations des diverses autres espèces, des matières organiques, des types de minéraux et du pH. Dans le présent travail, on considère la gibbsite comme l'espèce d'aluminium qui existe dans le système d'eau naturelle. Les principales approches utilisées pour évaluer les concentrations individuelles des espèces d'aluminium impliquent l'utilisation de données thermodynamiques fiables en relation avec des mesures expérimentales des concentrations libres ou totales des composants principaux. On a mis au point un nouveau type de diagrammes, basés sur des méthodes graphiques et des ordinateurs, qui permet de décrire d'une façon quantitative la distribution des espèces d'aluminium solubles et insolubles, inorganiques ou organiques, monomères ou polymères, dans des systèmes aquatiques hétérogènes. Cette approche utilise des relations thermodynamiques liées aux contraintes originales de balance des masses, dans lesquelles les phases minérales sont exprimées d'une façon explicite. On a analysé les facteurs qui influencent la distribution des espèces aluminium solubles et insolubles dans les systèmes aquatiques. Le nouveau type de diagramme qui a été mis au point peut être utilisé pour interpréter des données obtenues dans le cadre de programmes de surveillance de la qualité de l'eau.

Mots-clés : gibbsite, diagramme de distribution, système hétérogène, stabilité thermodynamique.

[Traduit par la Rédaction]

Introduction

Chemical forms of aluminium occurrence in natural waters are quite various, as Al^{3+} forms complexes with OH^-, SO_4^{2-}, F^-, and organic compounds. It is known that different chemical forms of aluminium possess different degrees of toxicity for live organisms in natural waters.[1–12] Furthermore, aluminium can play a toxic role in severe illnesses.[4–6] The identification and quantitative determination of the chemical forms of aluminium in situ, without any effect on chemical equilibrium of the system would be a crucial step. There are two general ways for fulfillment of the given problem: (*i*) experimental determination of individual chemical forms on the basis of their reactions with certain reagents with known physical and chemical properties or (*ii*) calculation of their distribution on the basis of the thermodynamic analysis and measurement of the total or equilibrium concentrations of metal and the most important ligands. Chemical modeling represents a unique method for the prediction of aluminium behavior in aqueous systems. Nevertheless, the majority of computer models include only inorganic mononuclear chemical forms (species) of aluminium, neglecting the formation of polynuclear and organic ones.[2] The equilibria and specification of individual chemical forms (species) of aluminium are represented in the form of various diagrams, basically diagrams of distribution or predominance.[5,8,13] Natural waters are in equilibrium with minerals, e.g., gibbsite, which affect the concentration of aluminium within certain limits.

Consequently, it is necessary to consider natural waters in concert with solid phases.

The main objective of the present paper consists of the thermodynamic analysis and graphical representation of the distribution of various chemical forms of aluminium both in saturated aqueous solutions and solid phases. Initially, some assumptions similar to ref. 2, are made, including (*i*) the studied systems were considered in a stable state of chemical equilibrium, (*ii*) natural waters were analyzed as diluted solutions with a low ionic strength, (*iii*) the natural water was in balance with the mineral phase gibbsite, (*iv*) equilibrium reactions with the participation of Fe and Mn were not included in this model, (*v*) two chemical forms of aluminium – organic matter were considered (AlOrg and $AlHOrg^+$), (*vi*) the adsorption of anions (F^- and SO_4^{2-}) was not included in the model, (*vii*) Al phosphate complexes could be presented in the form of $AlH_2PO_4^{2+}$ and Al silicate complexes might be neglected. From the third assumption, the equilibrium concentration of aluminium ion [Al^{3+}] can be estimated as a function of pH using the following relations, where K_S is the equilibrium constant (solubility product).

$$[1] \qquad Al(OH)_3(s) + 3H^+ \Leftrightarrow Al^{3+} + 3H_2O, \qquad [Al^{3+}] = K_S[H^+]^3$$

The technical execution of the diagrams that explicitly specify the area of the loss of solid phases has been considered by the author.[5] However, such diagrams have a mainly qualitative character and are poorly suitable for some quantitative assessments. In this work, the new type of diagrams for the graphical representation of equilibrium in natural waters containing a mineral-phase gibbsite has been developed. Their construction is based on mass balance equations (MB) within the framework of the method of residual concentrations (RC)[14,15] and the thermodynamic delimitation of the stability of the solid phases.[16–19] Systems of liquid and solid phases, in which a series of chemical reactions proceeds concomitantly, shall be defined as heterogeneous and the constructed diagrams as diagrams of heterogeneous chemical equilibrium (DHCE). Outwardly, such diagrams are similar to the diagrams of distribution for homogeneous systems;[13] however, the principle of their construction differs radically from the last ones.

Theoretical

Besides the process of gibbsite dissolution (eq. [1]), a set of possible (probable) equilibria in the mineral phase – natural water system, presented in the Appendix (Table A1) is taken into account. The MB conditions in this system may be formulated on the basis of the method of residual concentrations (RC; see Appendix Table A2, eqs. [A1] and [A7]).[14,15] Quantities C_i^0 and C_i^r in eqs. [A1]–[A7] (Table A2) represent, respectively, the analytical and residual concentrations of the component *i* in the considered heterogeneous system.[14] In eq. [A7], C_H^0 denotes the excess of H^+ ions in relation to hydroxyl ions in a two-phase mixture $C_H^0 = -C_{OH}^0$.[14] From the stoichiometric composition of gibbsite $Al(OH)_3(s)$, the following ratio is obtained:

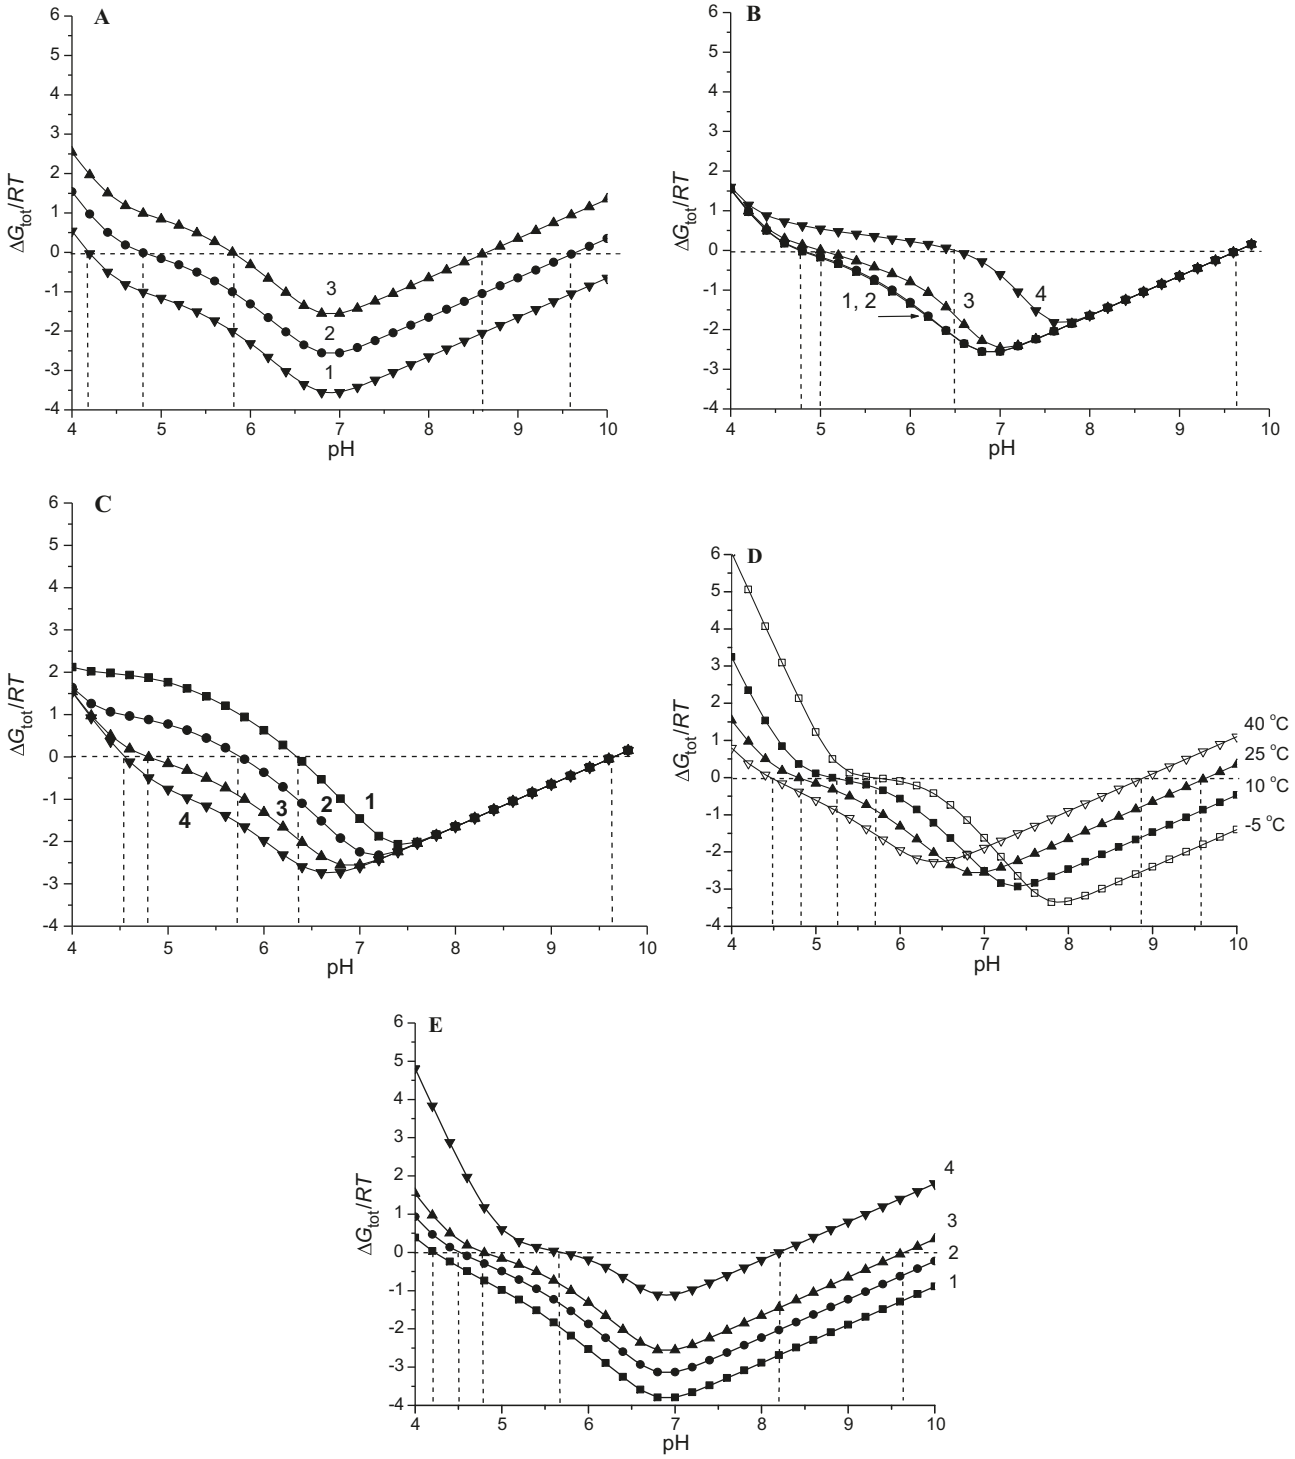
$$[2] \qquad 3 = \Delta C_{OH}/\Delta C_{Al}$$

Besides, within the RC method, the relations $\Delta C_{OH} = -\Delta C_H$ and $C_{OH}^r = -C_H^r$ are appropriate, and eq. [A7] (Table A2) becomes

$$[3] \qquad C_H^0 = -3\Delta C_{Al} + C_H^r$$

The equilibrium concentration of the Al^{3+} ion is determined from the equilibrium constant K_S (eq. [1]). From the equations of the conditions of mass balance (eqs. [A1]–[A7]) for a given pH and taking into account the relation in eq. [2]) and the equations of the law of mass action (LMA), a system of five equations with five unknown quantities [F], [Org], [SO_4], [PO_4], and ΔC_{Al} is derived, which may be easily solved numerically (eqs. [A1]–[A7], Table A2). Using the combined equations of LMA and MB, it is possible to calculate the diagrams of distribution of aluminium ion both in solid and liquid phases (species in aqueous solution), i.e., the diagrams of heterogeneous chemical equilibrium.

The following equations for calculation of the partial molar fractions of species γ_i in a heterogeneous system, where the reactions presented in Table A1 proceed concomitantly, can be written:



$$[4] \qquad \gamma_S = \frac{\Delta C_{Al}}{C_{Al}^0}, \gamma_{tot} = \frac{C_{Al}^r}{C_{Al}^0}, \gamma_{Al} = \frac{[Al]}{C_{Al}^0}, \quad \gamma_{i,j} = \frac{i[Al_i(OH)_j]}{C_{Al}^0}, \gamma_{f,j} = \frac{[AlF_j]}{C_{Al}^0}, \quad \gamma_{O1} = \frac{[AlOrg]}{C_{Al}^0}, \gamma_{O2} = \frac{[AlHOrg]}{C_{Al}^0}, \quad \gamma_{S1} = \frac{[AlSO_4]}{C_{Al}^0}, \gamma_{S2} = \frac{[Al(SO_4)_2]}{C_{Al}^0}, \quad \gamma_{PO_4} = \frac{[AlH_2PO_4]}{C_{Al}^0}$$

The index "tot" means the sum of the partial molar fractions of all the soluble particles. By comparing eq. [4] with eqs. [A1]–[7A] (Table A2), the following equation is valid.

$$[5] \qquad \gamma_S + \gamma_{tot} = \gamma_S + \gamma_{Al} + \sum_{i=1}\sum_{j=1}\gamma_{i,j} + \sum_{j=1}\gamma_{f,j} + \gamma_{O1} + \gamma_{O2} + \gamma_{S1} + \gamma_{S2} + \gamma_{PO_4}$$

The diagrams of the DHCE, outwardly, are similar to diagrams of species distribution in the homogeneous systems. The latter usually are fitted with the coordinates γ_i(pH), as in the absence of polynuclear complexes the partial molar fractions of species γ_i in aqueous solution (more frequently, notated as *f* or α) are functions only of the solution pH and do not depend on the initial concentrations of components. In the case of heterogeneous equilibria, the partial molar fractions of species also depend on the initial composition of the mixture and, for a given pH, are functions of five variables $\gamma_i = f(C_{Al}^0, C_F^0, C_{SO_4}^0, C_{Org}^0, C_{PO_4}^0)$. In this case, it is reasonable to fit diagrams with the coordinates (γ_i, pH) while the values of other quantities are constant.

The procedure for the construction of the DHCE includes following necessary stages:

i. Thermodynamic calculation of the gibbsite stability area. For this purpose, the Gibbs energy values for this complex process, where the reactions presented in Table A1 proceed concomitantly, are determined by the following equations:[16–19]

$$[6a] \qquad \Delta G_{\text{tot}} = -RT \ln \frac{C^r_{\text{Al}}}{C^0_{\text{Al}}} = -RT \ln \gamma_{\text{tot}} \qquad \text{or}$$

$$[6b] \qquad \Delta G_{\text{tot}} = -RT \ln (1 - \gamma_{\text{S}})$$

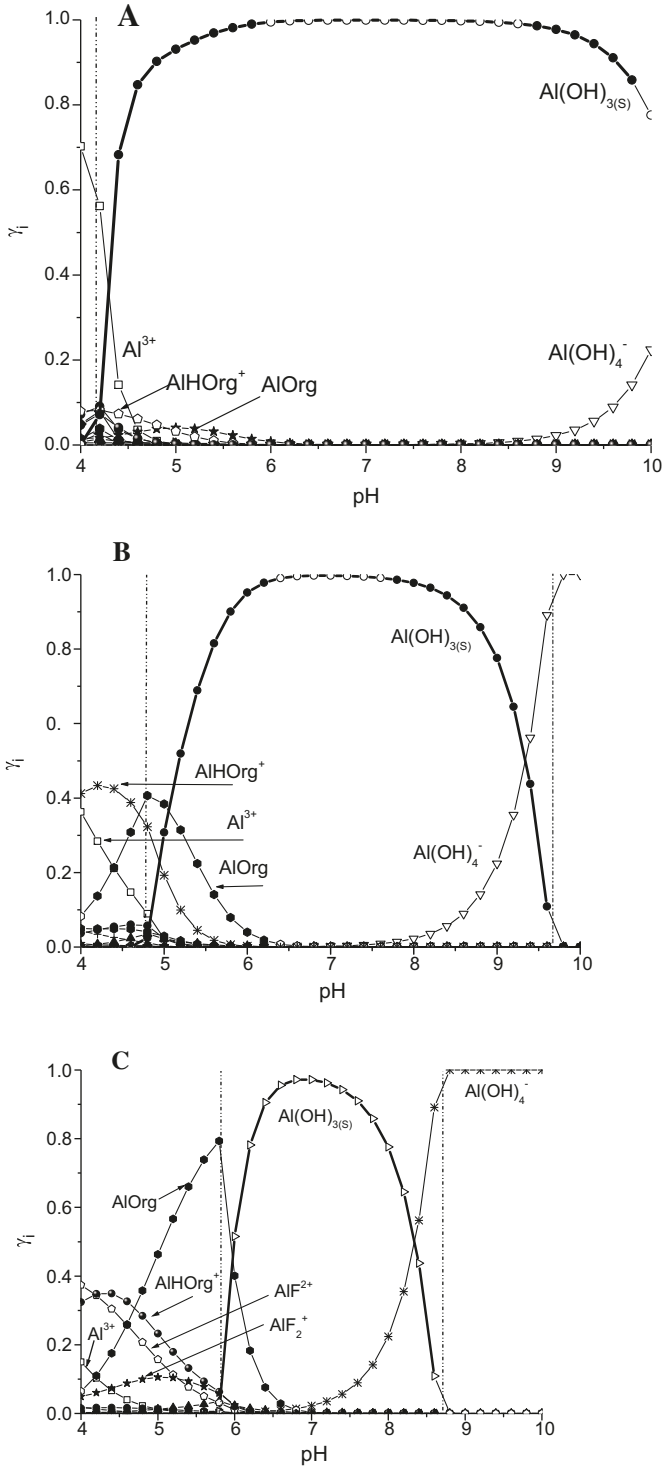
The solid-phase $Al(OH)_3(s)$ is stable if $\Delta G_{\text{tot}} > 0$. The condition $\Delta G_{\text{tot}} = 0$ corresponds to the beginning of its dissolution and (or) sedimentation.

i. Calculation of the partial molar fractions (γ_i) of all the chemical forms containing aluminium ion by eq. [4] for the gibbsite stability area established at previous stage.

ii. For completeness outside of this region, i.e., for a homogeneous aqueous solution, the partial molar fractions are computed by the usual equations used for the construction of distribution diagrams.[13] In this case, under conditions of only mononuclear complex species formation, the γ values do not depend on the initial concentration of the components.

It is worth mentioning that, by means of the partial molar fraction γ_S of the solid phase, it is possible to calculate the amount of the formed solid phase for a given initial concentration C^0_{Al} of the aluminium ion.

$$[7] \qquad \Delta C_{\text{Al}} = \gamma_{\text{S}} C^0_{\text{Al}}$$



Results and discussion

It is well-known that pH value of saturated solutions is one of the major factors (master variable) influencing the distribution of insoluble aluminium hydroxide as well as its inorganic and organic forms. Figures 1A–1C show the variation in Gibbs energy depending on the pH in the system "saturated aqueous solution – gibbsite" for different concentrations of individual components of the investigated natural waters (NW). The diagrams for ΔG_{tot} (pH) allow for the easy definition of the gibbsite stability area.

The analysis of data presented in Fig. 1A shows that the thermodynamic stability area of gibbsite becomes considerably larger with an increase in the total (analytical) concentration of aluminium ion (C^0_{Al}). The presence of significant amounts of inorganic ligand, fluoride ion F^- (Fig. 1B), and organic ligand Org^{3-} (Fig. 1C) also significantly affects the solubility of gibbsite.

The DHCE for the investigated system at various concentrations of aluminium ion are represented in Fig. 1D. Such diagrams clearly reflect the distribution of various aluminium chemical forms both in the solid phase and saturated solutions. Partial molar fractions of soluble aluminium forms are changing strongly at the pH value of dissolution – formation of the solid phase. For a given total concentration of aluminium (C^0_{Al}) in acidic and neutral solutions the equilibrium concentrations of mononuclear hydroxo complexes are small (Figs. 2A–2C). Concomitantly, our calculations prove that the fraction of polynuclear hydroxocomplexes is negligible under the studied conditions. The partial molar fraction of free alu-

minium ions increases in a narrowed region of pH values as the total (analytical) concentration C^0_{Al} in saturated solution rises.

Moreover, the area of stability of the anionic hydroxo complex $Al(OH)_4^-$ gets narrower and, in alkalescent or alkaline media of heterogeneous systems, such species become the prevailing form. For concentrations $C^0_{Al} < 1 \times 10^{-3}$ mol/L in acescent or acidic media among soluble forms, the AlOrg and $AlHOrg^+$ species prevail.

At $[C^0_{Al}] = 1 \times 10^{-5}$ mol/L, an appreciable contribution is introduced by the complexes AlF^{2+} and AlF_2^+. The DHCE presented here differ significantly from the diagrams presented by Bi[2] as the latter considered the distribution of inorganic and organic forms only in aqueous solution.

Our calculations prove that aluminium complexes with sulfate and phosphate ions are formed in irrelevant quantities for the given composition of NWs, and this conclusion is in concordance with the work done by Bi.[2]

The effect of temperature on Gibbs energy variation is represented in Fig. 2. The equilibrium constants for different temperatures have been estimated on the basis of van't Hoff equation.

$$[8] \qquad \log K_2 = \log K_1 + (1/T_1 - 1/T_2)\Delta H/2.303R$$

The appropriate values of the enthalpies ΔH are listed in Table A1. Value T_1 has been chosen equal to 298 K ≡ 25 °C. It is supposed that the temperature insignificantly influences the ΔH values within the investigated temperature interval. The analysis of the curves proves that, in acidic media, the ΔG_{tot} value decreases with decreasing temperature and increases in alkaline media; however, in both media the area of maximal values of ΔG_{tot}, i.e., the area of maximal stability of the solid phase, is displaced by reducing the temperature towards higher values of pH.

One of the basic tasks concerning the calculations of chemical equilibria refers to the correct choice of equilibrium constants, i.e., their reliability and accuracy, from which the final results completely depend. As an example, the effect of accuracy of equilibrium constant values (K_S) on the functions ΔG_{tot}(pH) was considered. For various modifications of gibbsite, a series of values for K_S is known, e.g., 8.11, used for synthetic gibbsite; 8.77, used for natural gibbsite; 9.35, used for monocrystalline gibbsite; and 10.80, used for amorphous gibbsite.[2,3] As seen in Fig. 1E, the selection of an equilibrium constant for rxn. [1] has considerable effect on the gibbsite thermodynamic stability. By increasing the $\log K_S$ value, the range of pH values for the solid-phase thermodynamic stability becomes considerably narrower, with a concomitantly decrease in the ΔG_{tot} value.

Conclusions

A new type of diagram based on the thermodynamic analysis of the stability of natural mineral and original conditions of mass balance in the heterogeneous system saturated aqueous solution – gibbsite has been presented. Conditions of mass balance take into consideration all the chemical forms present in aqueous and solid phases, including inorganic and organic mononuclear and polynuclear forms. The effect of major factors influencing the distribution and concentration of soluble and insoluble species of aluminium in aquatic systems was analyzed. Our data regarding the factors influencing Al speciation, based on the constructed DHCE diagrams, are in good agreement with the previous results,[2,3] but they are more specific, taking explicitly into account the heterogeneous character of NWs.

Abstract: Complete basis set CBS-QB3, hybrid-density functional theory (B3LYP/Def2-TZVPP) based methods and NBO interpretation were used to investigate the impacts of the stereoelectronic effects and electrostatic and steric interactions on the conformational properties of halocarbonyl isocyanates (halo = F (**1**), Cl (**2**), and Br (**3**)), halothiocarbonyl isocyanates (halo = F (**4**), Cl (**5**), and Br (**6**)), and haloselenocarbonyl isocyanates(halo = F (**7**), Cl (**8**), and Br (**9**)). Both methods showed that the Z-conformations of compounds **1**, **4**, and **7** are more stable than their corresponding E conformations, but the stability of the E conformations, when compared with the corresponding Z conformations, increases from compound **1** to compound **3**, compound **4** to compound **6**, and also from compound **7** to compound **9**. The NBO analysis showed that the generalized anomeric effect (GAE) is in favor of the Z conformations of compounds **1**, **4**, and **7**. The GAE values calculated (i.e., GAE_E–GAE_Z) increase from compound **1** to compound **3**, compound **4** to compound **6**, and also from compound **7** to compound **9**. On the other hand, there are none of the same trends between the calculated total dipole moment and the Gibbs free energy difference values between the E and Z conformations (i.e., $\Delta\mu_{E-Z}$ and ΔG_{E-Z}) of compounds **1**–**3**, **4**–**6**, and **7**–**9**. Accordingly, the GAE succeeds in accounting for the increase of the E conformation stability from compound **1** to compound **3**, compound **4** to compound **6**, and also from compound **7** to compound **9**. Therefore, the GAE associated with the electron delocalization, not the total dipole moment changes (i.e., $\Delta\mu_{E-Z}$), is a reasonable indicator of the total energy difference in compounds **1**–**3**, **4**–**6**, and **7**–**9**. There is a direct correlation between the calculated GAE and $\Delta[r_{2-6}(E) - r_{2-6}(Z)]$ parameters. Importantly, there are interesting through-space electron delocalizations ($LP_2X_6 \rightarrow \pi^*_{C4-O5}$) that justify the increase of the E conformation stability from compound **1** to compound **3**, compound **4** to compound **6**, and also from compound **7** to compound **9**, when compared with their corresponding Z conformations. The correlations between the GAE, bond orders, total steric exchange energies (TSEE), ΔG_{Z-E}, $\Delta\mu_{E-Z}$, structural parameters, and conformational behaviors of compounds **1**–**9** were investigated.

Key words: halocarbonyl isocyanates, stereoelectronic effect, molecular modeling, ab initio, NBO.

Résumé : On a fait appel à l'ensemble de base complet CBS-QB3, aux méthodes basées sur la théorie de la fonctionnelle de la densité hybride (B3LYP/Def2-TZVPP) et à une interprétation par les orbitales de liaison naturelle (OLN) pour étudier les impacts des effets stéréoélectroniques et des interactions électrostatiques et stériques sur les propriétés conformationnelles des isocyanates d'halogénocarbonyles (halogéno = F (**1**), Cl (**2**) et Br (**3**)), des isocyanates d'halogénothiocarbonyles (halogéno = F (**4**), Cl (**5**) et Br (**6**)) et des isocyanates d'halogénosélénocarbonyles (halogéno = F (**7**), Cl (**8**) et Br (**9**)). Les deux méthodes ont permis de montrer que les conformations Z des composés **1**, **4** et **7** sont plus stables que les conformations E, mais que la stabilité des conformations E, comparée celle des conformations Z, augmente du composé **1** au composé **3**, du composé **4** au composé **6** ainsi que du composé **7** au composé **9**. L'interprétation par les orbitales de liaison naturelle (OLN) montre que l'effet anomère généralisé (EAG) favorise les conformations Z des composés **1**, **4** et **7**. Les valeurs calculées pour l'effet anomère généralisé (EAG) (c'est-à-dire EAG_E–EAG_Z) augmente du composé **1** au composé **3**, du composé **4** au composé **6** ainsi que du composé **7** au composé **9**. Par ailleurs, il ne semble pas y avoir de tendances semblables pour les valeurs calculées pour les moments dipolaires totaux ou les différences d'énergie libre de Gibbs entre les conformations E et Z (c'est-à-dire $\Delta\mu_{E-Z}$ et ΔG_{E-Z}) pour les composés **1**–**3**, **4**–**6** et **7**–**9**. En conséquence, l'effet anomère généralisé (EAG) permet d'expliquer l'augmentation de stabilité de la conformation E du composé **1** au composé **3**, du composé **4** au composé **6** ainsi que du composé **7** au composé **9**. Il en ressort donc que l'effet anomère généralisé (EAG) associé à la délocalisation d'électron, et non pas les changements dans les moments dipolaires totaux (c'est-à-dire $\Delta\mu_{E-Z}$), est

un indicateur raisonnable de la différence d'énergie totale dans les composés **1**–**3**, **4**–**6** et **7**–**9**. Il existe une corrélation directe entre l'effet anomère généralisé (EAG) et les paramètres $\Delta[r_{2\text{–}6}(E) - r_{2\text{–}6}(Z)]$. Il est aussi important de réaliser qu'il existe des délocalisations d'électrons intéressantes à travers l'espace ($LP_2X_6 \rightarrow \pi^*_{C4\text{–}O5}$) qui permet de justifier l'augmentation de la stabilité des conformations E du composé **1** au composé **3**, du composé **4** au composé **6** ainsi que du composé **7** au composé **9**, par comparaison avec les conformations Z correspondantes. On a aussi étudié les corrélations entre l'effet anomère généralisé (EAG), les ordres de liaison, les énergies d'échange stérique totales (EEST), $\Delta G_{E\text{–}Z}$, $\Delta\mu_{E\text{–}Z}$, paramètres structuraux et les comportements conformationnels des composés **1**–**9**.

Mots-clés : isocyanates d'halogénocarbonyles, effet stéréoélectronique, modelage moléculaire, ab initio, orbitales de liaison naturelle (OLN).

Introduction

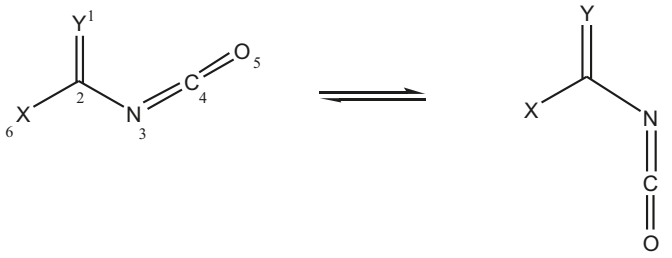
The conformations of organic molecules can be determined by the electron delocalization from donor to acceptor and it is then referred to as stereoelectronic effects. The conformational behavior of molecules may be used to predict or explain the chemical reactivity of molecules on the basis of electronic activation or deactivation.[1,2] Esters of carboxylic acids, which have been the subject of extensive experimental and theoretical studies,[3,4] adopt a planar conformation, with a strong preference for the conformation in which the alkyl group attached to the ether oxygen is syn to the carbonyl oxygen. This planarity is predicted by overlapping between a nonbonding electron pair on the ether oxygen and the antibonding σ* orbital of the antiperiplanar C–O bond.[5] The internal rotation of the acetyl group around the C–C bond in chloroacetyl isocyanates in the condensed phase has been investigated using IR spectra.[6] The chemical reactivity and higher stability of the Z forms of acetyl isoicyanate and trichloroacetyl isocyanate have been examined using MO calculations.[7] Microwave[8] and electron diffraction[9] studies have showed that acetyl isocyanate only occurs in its Z form in the gas phase. UV, IR, and ^{13}C NMR techniques have been used to assign the Z and E forms of a large series of carbonyl and acyl isocyanates.[10]

In 1989, Mack et al.[11] used the gas electron diffraction (GED) approach to study the conformational properties of chlorocarbonyl isocyanate (**2**). The results from the GED study showed a mixture of E and Z isomers in a ratio of ~3:1 (ΔG = 0.7(3) kcal mol^{-1}, 1 cal = 4.184 J), which confirmed the interpretation of the vibrational spectra. Although the ab initio calculations (HF, MP2, and MP4(SDTQ) with different basis sets (4–31G*, 6–31G*, and D95*)) reproduced the experimental trans structure reasonably well, the relative stability of the two isomers is at variance with the experiment.

In 1991, Nguyen et al.[12] employed the MP2/6–31G(d,p) level of theory to investigate the conformations of chlorocarbonyl isocyanate (**2**). Their results showed that ab initio molecular orbital (MO) calculations at the MP2/6–31G** level of theory are reliable in determining the Z and E conformation differences of compound **2**. The results obtained at the MP2/6–31G** level of theory showed that the E conformer was prefered in compound **2** when compared with its Z conformation, which is in agreement with experiment. They stressed that the failure of the calculations by Mack et al.[11] to reproduce the Z and E conformation separation gap might be due to the geometrical parameters employed in their work. In addition, the MP2/6–31G(2d)//MP2/6–31G(d), MP2/6–311++G** results showed the E conformation of chlorocarbonyl isocyanate (**2**) is lower in energy than the Z isomer.[13,14] The results obtained at these levels of theory are in excellent agreement with experimental results obtained by gas-phase IR and electron-diffraction experiments. The importance of adding a sufficient number of polarization functions is emphasized.

In 1994, Durig et al.[15] used Raman and IR techniques for the study of the conformational preference of chlorocarbonyl isocyanate (**1**) in the gas and solid phases. They pointed out that the observed bands are assigned on the basis of the more stable Z conformation in the fluid states, but only the E conformation remains in the annealed solid.

In the same year, Klapstein and Nau[16] performed a variable-temperature approach for the study of the IR spectrum of chlorocarbonyl isocyanate (**2**) in the gas phase. They stressed that the higher stability of the E conformations for chloro- and bromo-carbonyl isocyanates are attributed to the high polarizabilities of the halogen atoms and explained as an electrostatic interaction between the heavy halides and the isocyanato carbon atom in the E conformation.



There is experimental and theoretical data for the conformational properties of some halocarbonyl isocyanate compounds,[6–19] but there is no published experimental and theoretical information about the donor–acceptor delocalization effects on the conformational properties of compounds **1**–**9** (see Scheme 1).

It should be noted that there is a stereoelectronic preference for conformations in which the best donor lone pair is antiperiplanar to the best acceptor bond.[20–34] Based on this argument, we could stress that the generalized anomeric effect (GAE), observable in acyclic compounds (such as dimethoxymethanes),[34] must be considered as the difference between the GAE of the E and Z conformations:

$$[1] \qquad GAE = GAE_E - GAE_Z$$

One of the goals of this work is the exploration of the argument stressed by Klapstein and Nau[16] about the higher stability of the E conformation for compounds **2** and **3** and also to give an answer to this question: Which factor has the most impact on the conformational behavior in compounds **1**–**9**? In this work, the stereoelectronic interactions associated with the GAE and also the conformational and structural properties of compounds **1**–**9** are investigated computationally

Scheme 1. Schematic representation of the conformations of compounds **1**–**9**.

Z-conformation *E*-conformation

[Numbering used for compounds **1**-**9** [Y=O, X=F (**1**), Cl (**2**), Br (**3**); Y=S, X=F (**4**), Cl (**5**), Br (**6**); Y=Se, X=F (**7**), Cl (**8**), Br (**9**)]

using the complete basis set - quadratic Becke3 composite method (CBS-QB3), hybrid - density functional theory (DFT) based methods, and natural bond orbital (NBO) analysis (see Scheme 1).[35–48]

The stabilization energies (E_2) associated with $LPN_3 \rightarrow \sigma^*_{C2-Y1}$, $LP_1Y_1 \rightarrow \sigma^*_{C2-N3}$, $LP_2Y_1 \rightarrow \sigma^*_{C2-N3}$, $LP_1X_6 \rightarrow \sigma^*_{C2-Y1}$, $LP_2X_6 \rightarrow \sigma^*_{C2-Y1}$, $LP_3X_6 \rightarrow \pi^*_{C2-Y1}$, $LP_2X_6 \rightarrow \pi^*_{C4-O5}$, $LP_1X_6 \rightarrow \sigma^*_{C2-N3}$, $LP_2X_6 \rightarrow \sigma^*_{C2-N3}$, and $LPN_3 \rightarrow \sigma^*_{C2-X6}$ electron delocalizations (see Fig. 1) and their influences on the conformational properties of compounds **1**–**9** were quantitatively investigated by NBO analysis. The stabilization energies associated with LP→σ* electron delocalizations are proportional to $S^2/\Delta E$ where S is the orbital overlap integral and ΔE is the energy differences between the LP and σ* orbitals.[49,50]

In addition, the E_2 associated with $i \rightarrow j$ delocalization is explicitly estimated by the following equation:

$$[2] \qquad E_2 = q_i \frac{F^2(i,j)}{\varepsilon_j - \varepsilon_i}$$

where q_i is the ith donor orbital occupancy, ε_i and ε_j are diagonal elements (orbital energies), and $F(i,j)$ represents off-diagonal elements associated with the NBO Fock matrix. Therefore, there is a direct relationship between $F(i,j)$ and S. It is known that the NBO analysis is a efficient approach for the investigation of the impacts of stereoelctronic interactions on the reactivity and dynamic behaviors of chemical compounds.[51,52]

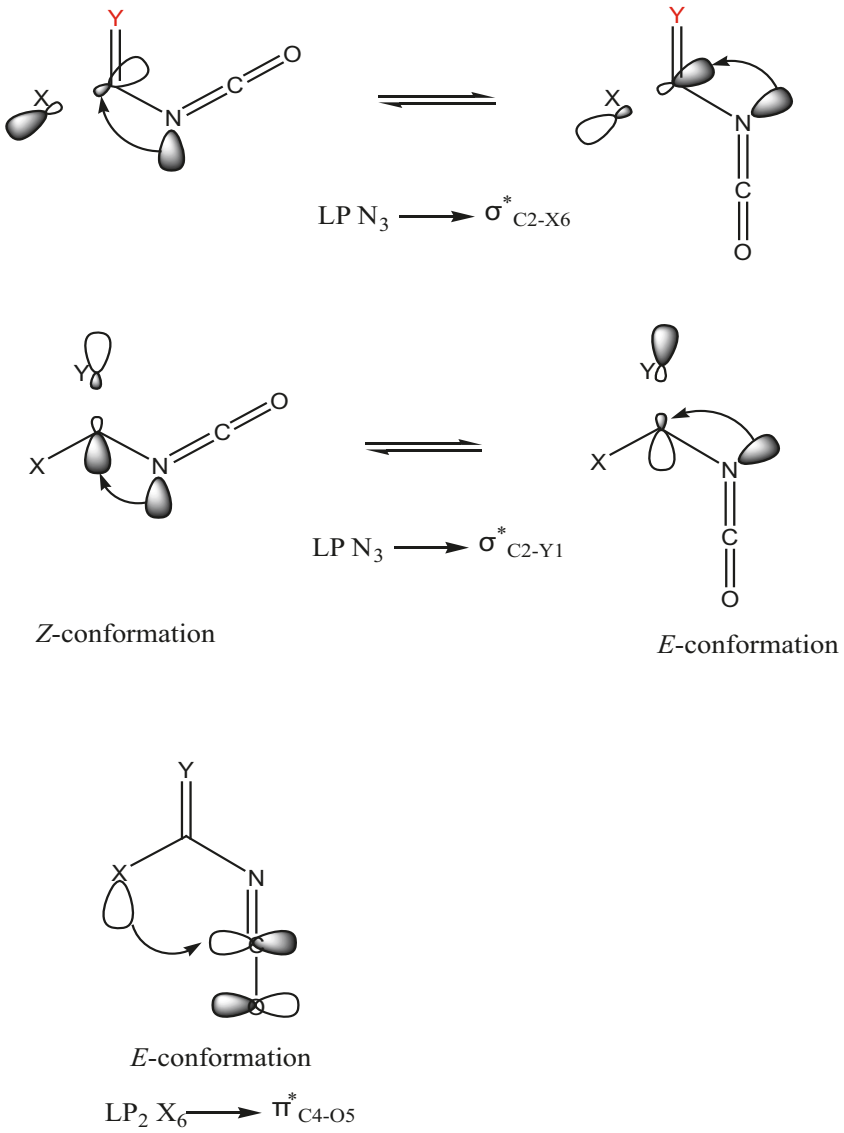
Computational details

Composite complete basis set (CBS)[42–47] and hybrid-DFT calculations were carried out using the CBS-4 and B3LYP/Def2-TZVPP[35–41] levels of theory with the GAUSSIAN 03 package of programs.[35] The CBS models are compound methods that extrapolate to the CBS limit by using the $N - 1$ asymptotic convergence of MP2 pair energies calculated from pair natural orbital expansions.[42–47] The five-step CBS-QB3 series of calculations starts with a geometry optimization at the B3LYP[35–39] level, followed by a frequency calculation to obtain thermal corrections, zero-point vibrational energy, and entropic information. The next three computations are single-point calculations at the CCSD(T), MP4SDQ, and MP2 levels. It also corrects for spin contamination. The CBS extrapolation then computes the final energies.[46]

To quantitatively estimate the magnitude of the plausible donor–acceptor hyperconjugative interactions in Z and E conformations of compounds **1**–**9**, the NBO analysis was performed at the B3LYP/Def2-TZVPP level of theory by the NBO 5.G program contained in the PC-GAMESS interface.[48] The bonding and antibonding orbital occupancies in the Z and E conformations of compounds **1**–**9** and the stabilization energies associated with donor–acceptor electron delocalization were calculated using NBO analysis.

In the NBO analysis, the electronic wave functions are interpreted in terms of a set of occupied Lewis and a set of unoccupied non-Lewis localized orbitals. The delocalization effects (or donor–acceptor charge transfers) can be estimated from the presence of off-diagonal elements of the Fock matrix in the NBO basis. The NBO program searches for an optimal natural Lewis structure, which has the maximum occupancy of its occupied NBOs, and in general agrees with the pattern of bonds and lone pairs of the standard structural Lewis formula. Therefore, the new orbitals are more stable than pure Lewis orbitals, stabilizing the wave function and giving a set of molecular orbitals equivalent to canonical molecular orbitals.

Results and discussion



Conformation preference

The Gibbs free energy, enthalpy, and entropy differences (i.e., ΔG, ΔH, and ΔS) for the Z and E conformations of compounds **1**–**9**, as calculated at the B3LYP/Def2-TZVPP and CBS-QB3 levels of theory, are given in Table 1. It has to be noted that the absolute values of the thermodynamic properties certainly cannot be calculated at the accuracy level shown in Table 1. However, the quantities of interest here are the relative values of the thermodynamic functions for the Z and E conformations of the same molecule. Effectively, we expect that the errors in such differences will be very small and that even the corresponding errors between the different closely related compounds will be minimal. Accordingly, the smooth variation among the calculated values supports this expectation.

According to the B3LYP/Def2-TZVPP and CBS-QB3 results, the stability of the E conformation, when compared with the corresponding Z conformation, increases from compound **1** to compound **3**. The B3LYP/Def2-TZVPP method showed that the Z conformation of compound **1** is more

Fig. 1. Schematic representation of electron delocalizations between nonbonding and antibonding orbitals in the Z and E conformations of compounds **1**–**9**.

stable than its corresponding E conformation, while there is opposite trend for compound **3**. It has to be noted that there is no significant difference between the E and Z conformations of compound **2** (as calculated at the B3LYP/Def2-TZVPP level of theory). Except for compound **2**, the differences between the results of the CBS-QB3 method and B3LYP/Def2-TZVPP method are well within the uncertainty of CBS-QB3 as determined by tests of a group of standard molecules.[24] For compound **2**, CBS-QB3 shows an E conformation preference of 0.18 kcal mol^{-1} (1 cal = 4.184 J) in ΔG, whereas the B3LYP/Def2-TZVPP method has a 0.02 kcal mol^{-1} preference for the Z form. It has to be noted that the GED[11] results for compound **2** showed an E conformation preference of 0.7 kcal mol^{-1} in ΔG; therefore, the results of the CBS-QB3 method are is good agreement with the reported experimental data.

Similar to the trend observed for compounds **1**–**3**, the stability of the E conformation, when compared with the corresponding E conformation, increases from compound **4** to compound **6** and also from compound **7** to compound **9** (see Table 1). Klapstein and Nau[16] pointed out that the higher stability of the E conformations for chloro- and bromocarbonyl isocyanates are attributed to the electrostatic interaction between the heavy halides and the isocyanato carbon atom in the E conformation. It has to be noted that the negative charges of the halogen atoms decrease from the E conformations of compound **1** to compound **3** and also there are no significant differences between the positive charges of the isocyanato carbon atoms in these forms. Therefore, the electrostatic interaction associated with the attractive interactions between the negative charges of the halogen atoms and the isocyanato carbon atom in the E conformation is not responsible for the increase of the E conformation stability from compound **1** to compound **3**. The increasing polarizabilities of the halogen atoms may increase the attractive interaction between the halogen atoms and the isocyanato carbon atoms.

Stabilization energies and GAE

The NBO analysis shows that the E and Z conformations of compounds **1**–**9** benefit from the stabilization energies associated with the donor–acceptor electron delocalizations. Based on the optimized ground-state geometries using the B3LYP method, the NBO analysis of donor–acceptor (bond–antibond) interactions showed that the stabilization energies associated with $LPN_3 \rightarrow \sigma^*_{C2-Y1}$ electron delocalization for the Z conformations of compounds **1**–**3** are 8.81, 9.21, and 9.15 kcal mol^{-1}, respectively. Also, the stabilization energies associated with $LPN_3 \rightarrow \sigma^*_{C2-Y1}$ electron delocalization for the E conformations of compounds **1**–**3** are 1.97, 2.91, and 2.94 kcal mol^{-1}, respectively (see Table 2). Based on the results obtained, there are no significant differences between the stabilization energies associated with $LPN_3 \rightarrow \sigma^*_{C2-Y1}$ electron delocalization for the Z and E conformations of compounds **1**–**3**. Therefore, the stabilization energies associated with $LPN_3 \rightarrow \sigma^*_{C2-Y1}$ electron delocalizations cannot explain the increase of the E conformation stability from compound **1** to compound **3**. This fact can be seen in compounds **4**–**6** and **7**–**9** (see Tables 1 and 2).

Interestingly, the stabilization energy associated with $LPN_3 \rightarrow \sigma^*_{C2-X6}$ electron delocalization increases from the E conformation of compound **1** to compound **3**, compound **4**

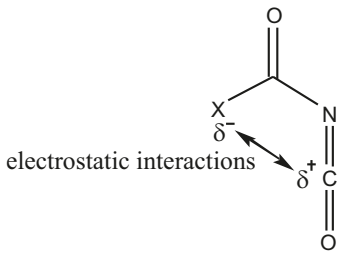
to compound **6**, and also from compound **7** to compound **9**. This follows the same trend with the increase of the stability of the E conformation, when compared with the corresponding Z conformation, from compound **1** to compound **3**, compound **4** to compound **6**, and also from compound **7** to compound **9**.

More interestingly, there is an intriguing through-space electron delocalization ($LP_2X_6 \rightarrow \pi^*_{C4-O5}$) in the E conformations of compounds **1**–**9** that justifies the increase of the stability of the E conformations, when compared with their corresponding Z conformations (see Fig. 1). The stabilization energies associated with $LP_2X_6 \rightarrow \pi^*_{C4-O5}$ electron delocalization for the E confrmations of compounds **1**–**3** are 0.52, 01.04, and 1.24 kcal mol^{-1}, respectively. Also, the NBO results show that the natural negative charges of the halogen atoms of the E conformations decrease on going from fluorine to bromine atoms (see Table 2). This fact can be attributed to the decrease of the electronegativity of the halogen atoms on going from fluorine to bromine atoms. Consequently, there are no increasing electrostatic stabilization interactions associated with the attractive interactions between the negative charges of the halogen atoms and the isocyanato carbon atom in the E conformations of compounds **1**–**3** (see Scheme 2).[11]



Based on eq. [2], the GAE values calculated (i.e., GAE_E–GAE_Z) associated with $LPN_3 \rightarrow \sigma^*_{C2-Y1}$, $LP_1Y_1 \rightarrow \sigma^*_{C2-N3}$, $LP_2Y_1 \rightarrow \sigma^*_{C2-N3}$, $LP_1X_6 \rightarrow \sigma^*_{C2-Y1}$, $LP_2X_6 \rightarrow \sigma^*_{C2-Y1}$, $LP_3X_6 \rightarrow \pi^*_{C2-Y1}$, $LP_2X_6 \rightarrow \pi^*_{C4-Y5}$, $LP_1X_6 \rightarrow \sigma^*_{C2-N3}$, $LP_2X_6 \rightarrow \sigma^*_{C2-N3}$, and $LPN_3 \rightarrow \sigma^*_{C2-X6}$ electronic delocalization for compounds **1**–**3** are –4.86, 1.82, and 4.96 kcal mol^{-1}, respectively (see Table 2). The GAE decreases from compound **1** to compound **3**. The stability of the E conformation, when compared with its corresponding Z conformation, increases from compound **1** to compound **3**, the rationalization of the conformational preference being accounted for solely in terms of the GAE. Similar to the trend observed for compounds **1**–**3**, the GAE succeeds in qualitatively accounting for the increase of the E conformation preferences from compound **4** to compound **6** and also from compound **7** to compound **9**.

Both methods revealed that the Z conformation preference in compounds **1**, **4**, and **7** increases from compound **1** to

off-diagonal elements ($F(i,j)$, in atomic units), orbital energies (in atomic units), orbital occupancies, bond orders (Wiberg bond index, B3LYP/Def2-TZVPP level of theory, for the conformations of compounds **1**–**9** (1 cal = 4.184 J).

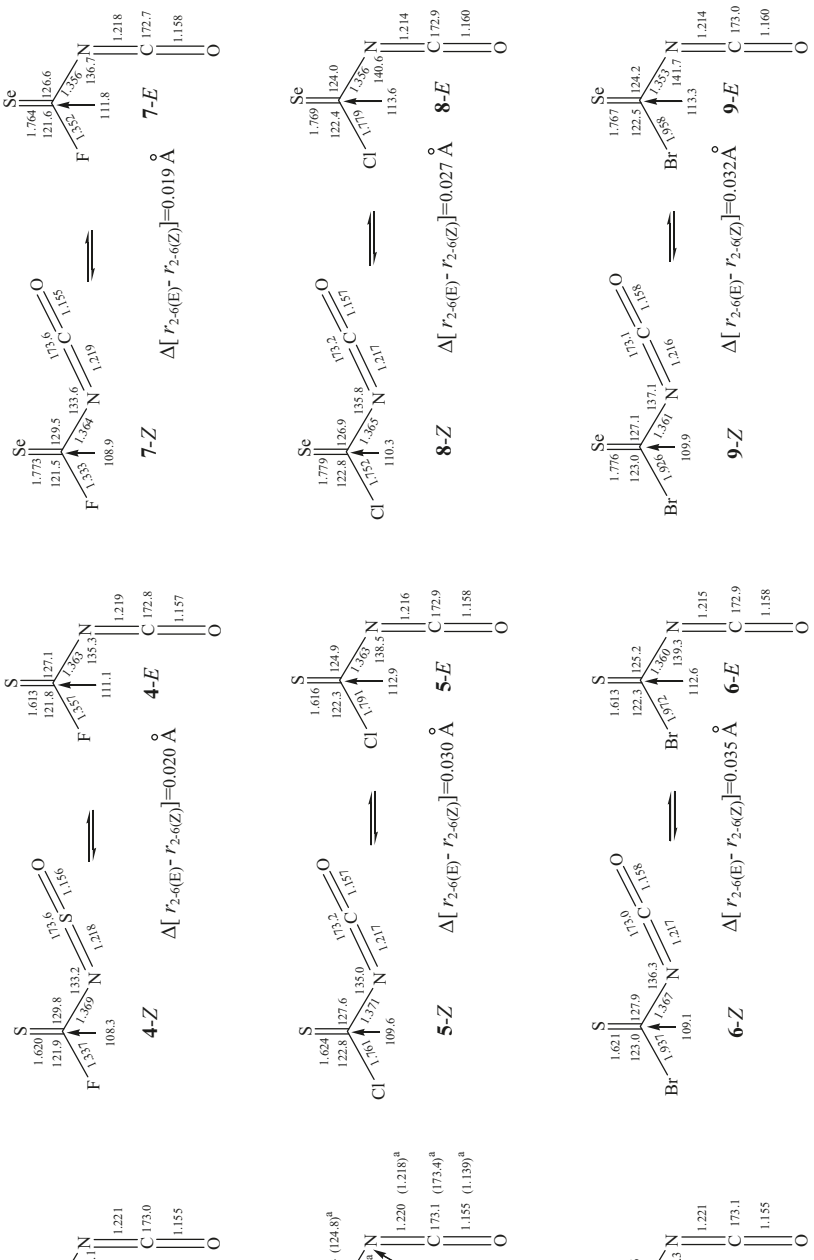
Scheme 2. Schematic representation of the electrostatic interactions between the halides and the isocyanato carbon atom in the E conformations

compound **7**. The CBS-QB3 calculated ΔG_{E-Z} values for compounds **1**, **4**, and **7** are 0.65, 1.37, and 1.74 kcal mol^{-1}, respectively. The B3LYP/Def2/TZVPP calculated ΔG_{E-Z} values for compounds **1**, **4**, and **7** are in agreement with the CBS-QB3 results (see Table 1). This fact can be attributed to an increase of the total GAE from compound **1** to compound **7**. The calculated GAE for compounds **1**, **4**, and **7** are –4.86, –7.50, and –7.52 kcal mol^{-1}, respectively.

Orbital occupancies



The orbital occupancies of the most effective electron delocalization that have the most impact on the GAE of the E conformations of compounds **1**–**9** (i.e., $LPN_3 \rightarrow \sigma^*_{C2-X6}$) have been investigated. The NBO results showed that the LPN_3 nonbonding orbital occupancies in the E conformations of compounds **1**–**3** are 1.677, 1.667, and 1.664, respectively. Also, the σ^*_{C2-X6} antibonding orbital occupancies in the E conformations of compounds **1**–**3** are 0.158, 0.188, and 0.214, respectively.

Similar to the trend observed for compounds **1**–**3**, the LPN_3 nonbonding orbital occupancies in the E conformations decreased from compound **4** to compound **6** and from compound **7** to compound **9**, and the σ^*_{C2-X6} antibonding orbital occupancies increased (see Table 2). This fact could be justified by the increase of the $LPN_3 \rightarrow \sigma^*_{C2-X6}$ electron delocalization from the E conformations of compound **1** to

compound **3**, compound **4** to compound **6**, and also from compound **7** to compound **9**.

Orbital energies and off-diagonal elements

It has to be noted that the stabilization energies associated with electron delocalization are proportional to $F_{i,j}^2/\Delta E_{ij}$ where $F_{i,j}$ is the orbital overlap integral (or off-diagonal elements of the secular determinant) and $\Delta E_{i,j}$ is the energy difference between the donor bonding (or nonbonding) and σ* (or π*) antibonding orbitals. The stereoelectronic orbital interactions are anticipated to be more effective for the anti rather than the syn or gauche arrangement between the donor and acceptor orbitals. Also, the stabilization (resonance) energy associated with the electron delocalization may increase as the acceptor orbital energy decreases and the donor orbital energy increases.

The energy differences between donor (E_{LPN_3}) and acceptor ($E\sigma^*_{C2-X6}$) orbitals (i.e., $\Delta(E\sigma^*_{C2-X6} - E_{LPN_3})$) for the E conformations of compounds **1–3** are 0.59098, 0.44045 and 0.38571, respectively, as calculated by the NBO analysis. The energy differences between LPN_3 (donor) nonbonding and σ^*_{C2-X6} (acceptor) antibonding orbitals (i.e., $\Delta(E\sigma^*_{C2-X6} - E_{LPaxM1})$) decrease from the E conformations of compound **1** to compound **3** (see Table 2). The strong acceptor antibonding orbital of the E conformation of compound **3** ($E\sigma^*_{C2-X6} = -0.01428$ atomic unit), when compared with those in compounds **2** and **1** (0.4144 and 0.18537 atomic unit, respectively), gives rise to strong $LPN_3 \rightarrow \sigma^*_{C2-X6}$ electron delocalization. On the other hand, the decrease of the *orbital overlap integral* (S) (i.e., off-diagonal elements ($F_{i,j}$)) values could reduce the $LPN_3 \rightarrow \sigma^*_{C2-X6}$ electron delocalization (see Table 2). NBO calculated $F_{i,j}$ values for the $LPN_3 \rightarrow \sigma^*_{C2-X6}$ electron delocalization for the E conformations of compounds **1–3** are 0.080, 0.077, and 0.076 atomic unit, respectively. The decrease of $F_{i,j}$ values could be justified by the increase of the X atom radius from compound **1** to compound **3**. Consequently, it seems that in the E conformations of compounds **1–3** the $\Delta(E\sigma^*_{C2-X6} - E_{LPaxM1})$ values could affect and control the order of the stabilization energies associated with $LPN_3 \rightarrow \sigma^*_{C2-X6}$ electron delocalizations. This conclusion can be generalized for compounds **4–6** and **7–9**.

Dipole moments

In the gas phase it is generally found that the conformation with the larger electrostatic energy (i.e., the larger dipole moment) has an increased overall energy.[53]

Liu and co-workers[54,55] pointed out that the total dipole moment change is a reasonable descriptor of the total energy difference; however, these correlations are not strong enough. It seems using any of the electron delocalization and electrostatic interactions alone is not adequately convincing to explain the general validity of the anomeric effect. Also, they stressed another explanation in terms of exchange–correlation and electrostatic interactions.

In this work, we have examined the contribution of the electrostatic interactions (by the calculation of the total dipole moment values)[53–56] on the total energy differences between the E and Z conformations of compounds **1–3**, **4–6**, and **7–9**. The calculated dipole moments for the E and Z conformations of compounds **1–3**, **4–6**, and **7–9** are given in Table 2. Using the dipole moments obtained, a "Δ" parameter could be found as $\Delta\mu_{E-Z}$. The corresponding $\Delta\mu_{E-Z}$ value increases from compound **1** to compound **2**, but decreases slightly from compound **2** to compound **3**. On the other hand, the calculated $\Delta\mu_{E-Z}$ value decreases from compound **4** to compound **6**. Interestingly, the calculated $\Delta\mu_{E-Z}$ value decreases from compound **7** to compound **8**, but increases from compound **8** to compound **9**. Therefore, the variations of the the calculated $\Delta\mu_{E-Z}$ value are not the same trend observed for the corresponding ΔG_{E-Z} values (i.e., the total energy differences). It seems the calculated $\Delta\mu_{E-Z}$ values fail to account for the increase of the calculated ΔG_{E-Z} values from compound **1** to compound **3**, compound **4** to compound **6**, and also from compound **7** to compound **9**. Therefore, the electrostatic interactions are not solely responsible for the total energy differences between the E and Z conformations of compounds **1–9** and it seems the GAE associated with the electron delocalization is a reasonable descriptor of the total energy differences between the E and Z conformations of compounds **1–9**.

Bond orders

The $LPN_3 \rightarrow \sigma^*_{C2-X6}$ electron delocalizations can affect the bond orders (e.g., Wiberg bond index, WBI: the sum of squares of off-diagonal density matrix elements between atoms, as formulated in terms of the natural atomic orbital (NAO) basis set) of C_2–X_6 bonds. In this regard, the differences between the WBI of C_2–X_6 bonds in the Z and E conformations (i.e., $\Delta(WBI(C_2-X_6)_{Z-E})$) increase from compound **1** to compound **3**, compound **4** to compound **6**, and also from compound **7** to compound **9** (see Table 2). The variation of the calculated $\Delta(WBI(C_2-X_6)_{Z-E})$ parameters are in accordance with the increase of the calculated GAE from compound **1** to compound **3**, compound **4** to compound **6**, and also from compound **7** to compound **9** (see Table 2).

Total steric exchange energies (TSEEs)

NBO analysis was used to calculate the steric exchange contributions in the Z and E conformations of compounds **1–9**. Contrary to the increase of the halogen atom radii from compounds **1→3**, **4→6**, and **7→9**, the differences between the calculated TSEE values for the Z and E conformations, $\Delta(TSEE_{Z-E})$, increase (see Table 2). The increase of the calculated $\Delta(TSEE_{Z-E})$ values can be justified by the increase of the C–X bond length from compounds **1→3**, **4→6**, and **7→9**. Therefore, the increase of the calculated $\Delta(TSEE_{Z-E})$ values

Can. J. Chem. Downloaded from www.nrcresearchpress.com by Renmin University of China on 09/02/12
For personal use only.

from compounds **1**→**3**, **4**→**6**, and **7**→**9** increases the relative stabilities of the E conformations compared with their corresponding Z conformations. Consequently, the variation of the calculated $\Delta(TSEE_{Z-E})$ values is in the same trend observed for the variation of the GAE values (see Table 2).

Structural parameters

Representative structural parameters for the E and Z conformations of compounds **1**–**9**, as calculated at the B3LYP/Def2-TZVPP level of theory, are shown in Fig. 2. Although it is not expected, in principle, to obtain exactly the experimental values because of the differences in the definition of bond length values, it is possible to carry out theoretical calculations, from which many properties and structures can be obtained with an accuracy that is competitive with experiment.

Importantly, the B3LYP/Def2-TZVPP results show that the C_2–X_6 bond lengths in the E conformations of compounds **1**–**9** are significantly longer than those of their corresponding Z conformations (see Fig. 2). In addition, the $\theta_{X6-C2-N3}$ bond angles of the Z conformations are smaller than those in the E conformations. This can be explained by the large $LPN_3 \rightarrow \sigma^*_{C2-X6}$ electron delocalization in the E conformations by increasing π-bond character of the N_3–C_2 bonds (see Scheme 3).

Using the structural parameters obtained, Δ parameters could be found as $\Delta[r_{2-6}(E) - r_{2-6}(Z)]$. The results obtained show that with the increase of the stabilization energies associated with $LPN_3 \rightarrow \sigma^*_{C2-X6}$ electron delocalizations in the E conformations of compounds **1**–**3**, **4**–**6**, and **7**–**9**, the calculated $\Delta[r_{2-6}(E) - r_{2-6}(Z)]$ parameter values increase from compound **1** to compound **3**, compound **4** to compound **6**, and also from compound **7** to compound **9** (see Table 2 and Fig. 2).

There is a direct correlation between the stabilization energies associated with $LPN_3 \rightarrow \sigma^*_{C2-X6}$ electron delocalizations and the calculated GAE values in compounds **1**–**9**. Consequently, the calculated $\Delta[r_{2-6}(E) - r_{2-6}(Z)]$ parameter could be proposed as a criterion for the evaluation of the GAE values in compounds **1**–**9**.

Conclusion

The CBS-QB3 and B3LYP/Def2-TZVPP calculations reported above and the NBO analysis provided a reasonable picture from structural, energetic, bonding, and stereoelectronic points of view for the conformational behavior in compounds **1**–**9**. Effectively, CBS-QB3 and B3LYP/Def2-TZVPP results revealed that the calculated ΔG_{E-Z} values increase from compound **1** to compound **3**, compound **4** to compound **6**, and also from compound **7** to compound **9**. A similar trend was observed for the calculated GAE (i.e., $GAE_E - GAE_Z$) and the differences between the calculated TSEE values for the Z and E conformations, $\Delta(TSEE_{Z-E})$. Accordingly, the correlations between the GAE, $\Delta(TSEE_{Z-E})$, and the calculated ΔG_{E-Z} values are strong enough. Consequently, the rationalization of the conformational preference in terms of the GAE and $\Delta(TSEE_{Z-E})$ succeeds in accounting for the increase of the E conformation stability from compound **1** to compound **3**, compound **4** to compound **6**, and also from compound **7** to compound **9**.

Importantly, the variations of the calculated $\Delta\mu_{E-Z}$ values from compound **1** to compound **3**, compound **4** to compound **6**, and also from compound **7** to compound **9** are not the same trend observed for the corresponding ΔG_{E-Z} values. Therefore, a reasonable correlation between the dipole moment differences and total energy differences was not found.

The longer C_2–X_6 bond lengths in the E conformations compared with those of their corresponding Z conformations can be explained by the large $LPN_3 \rightarrow \sigma^*_{C2-X6}$ electron delocalization in the E conformations by decreasing σ-bond character of the C_2–X_6 bonds. Importantly, the calculated $\Delta[r_{2-6}(E) - r_{2-6}(Z)]$ parameter could be proposed as a criterion for the evaluation of the GAE values in the E and Z conformations of compounds **1**–**9**.

Abstract: In this paper, the dynamical properties of the product SrI, which is formed in the reaction Sr + CF_3I, were studied by means of the quasi-classical trajectory method based on the extended London–Eyring–Polanyi–Sato potential energy surface. The vibrational distribution, rotational distribution, reaction cross section, and rotational alignment of the product SrI were calculated, and the mechanism of the title reaction has also been discussed. The calculated vibrational and rotational distributions show that their peak values are located at $v = 23$ and $J = 110$ at a collision energy of $E_{col} =$ 0.83 eV. These results are in good agreement with the results in Stolte's experiment. And the results obtained in this paper also indicate that the reaction cross section increases with increasing collision energy (from 0.5 to 1.5 eV), whereas the product rotational alignment decreases.

Key words: QCT method, LEPS PES, Sr + CF_3I reaction, dynamical property, reaction mechanism.

Résumé : Faisant appel à la méthode de la trajectoire quasi-classique basée sur la surface d'énergie potentielle étendue de London–Eyring–Polanyi–Sato, on a étudié les propriétés dynamiques du produit SrI qui se forme par la réaction Sr + CF_3I. On a calculé la distribution vibrationnelle, la distribution rotationnelle, la section droite de la réaction et l'alignement rotationnel du produit SrI et on discute aussi du mécanisme de la réaction mentionnée dans le titre. Les distributions vibrationnelle et rotationnelle montrent que leurs valeurs maximales se situent à $v = 23$ et $J = 110$, à une énergie de collision $E_{col} =$ 0,83 eV. Ces résultats sont en bon accord avec ceux obtenus dans l'expérience de Stolte. Et les résultats obtenus dans le présent travail indiquent aussi que la section droite de la réaction augmente avec une augmentation de l'énergie de collision de 0,5 à 1,5 eV, alors que l'alignement rotationnel du produit diminue.

Mots-clés : méthode de la trajectoire quasi-classique (TQC), surface d'énergie potentielle (SEP) étendue de London–Eyring–Polanyi–Sato (LEPS), réaction Sr + CF_3I, propriété dynamique, mécanisme de réaction.

Introduction

The CF_3I molecule is an important intermediate with fluoride that can introduce methyl fluoride into organic synthesis. Because of its strong reactivity, the CF_3I molecule can be dissociated easily in the lower atmosphere and usually does not reach the ozone layer. Therefore, its ozone depression potential (ODP) is zero and its global warming potential (GWP) is low.[1,2]

In recent years, the CF_3I molecule has been considered as a new type of environmentally friendly fire-extinguishing agent that can substitute for halon. As a result of the good oil soluble and material compatibility of the CF_3I molecule, it has been also considered as a latent substitute for refrigerants. At the same time, the CF_3I molecule has been widely applied to organic synthesis, biochemistry, surface active agents, dyes, and so on.[3] The electronic structure, the bonding properties, and the reactive property of the CF_3I molecule have become the focal point in experimental and theoretical studies.[4–11] Arai and co-workers[12] successfully developed a novel vapor-phase production process for CF_3I, which was obtained from the reaction of $CHF_3 + I_2$ with a unique catalyst in 2004. They found that the most effective catalyst for this reaction was alkali metal salt on an activated carbon carrier.[12]

The "dual-mode" mechanism was first postulated by Brooks et al.[13] in the study of the reaction K + $CF_3I \rightarrow$ KI + CF_3, which corresponded to the title reaction of this paper. A bimodal vibrational distribution of the product BaBr for the reaction Ba + CF_3Br was obtained by means of the laser-induced fluorescence (LIF) method by Munakata et al.[14] The reaction mechanism was also explained by the dual-mode mechanism, which has an analogy with the reaction K + CF_3I. The reaction between ground-state Sr and CF_3Cl was in tandem studied by Solarz and Johnson[15] in 1979 and Schifino and co-workers in 1993.[16] For the reaction Ba + CF_3I, Zare and co-workers[17,18] reported an analysis of the vibrational states of the product BaI using the LIF method. Lin et al.[19] deduced the recoil energy distributions and angular distributions for the reactions Ba + CH_3I, Ca + CH_3I, and Ba + CF_3I using a molecular beam apparatus.

Lou and co-workers[20,21] studied the reactions Ca + CH_3I and Ca + CF_3I and Ca(^{3}P) + CH_3I and Ca(^{3}P) + CF_3I in

1988 and 1993. Energy partitioning, vibrational state distributions, and recoil momentum distributions of the product CaI were obtained from the studies of Ca + CH_3I and Ca + CF_3I.[20] The chemiluminescence (CL) spectra, collision cross sections, and CL cross sections of the reactions Ca(^{3}P) + CH_3I and Ca(^{3}P) + CF_3I were measured in a beam-gas arrangement.[21] Lou and co-workers[20,21] discovered that the sequence of the values of the cross sections for the reactions Ca(^{3}P) + CH_3I and Ca(^{3}P) + CF_3I was contrary to the results of the reactions Ca + CH_3I and Ca + CF_3I. Subsequently, the reaction of OH with CF_3I was investigated by Marshall and co-workers[22] via experimental and computational studies. The most correlative experiment with this work was the investigations of the reactions of Ca or Sr with CH_3X or CF_3X (X = Br or I) by Stolte and co-workers[23,24] With the LIF method, the experimental and simulated spectra and the vibrational and rotational distributions of nascent SrBr, SrI, and CaBr were measured.[23]

Recently, the exothermic reaction Sr + CH_3I was studied by means of the quasi-classical trajectory (QCT) method by Zhao and Li[25] They calculated the relationship of product energy disposal and product rotational alignment, respectively, with collision energy. The results for the reaction cross section and product vibrational distribution were also obtained in their work.[25]

As mentioned, there are a lot of experimental studies corresponding to the reaction Sr + CF_3I. In the previous papers,[26–28] some investigations for the reactions of alkaline earth metal atoms with halogenated methane were done by using the QCT method. However, there are no studies about the title reaction that have been carried out theoretically. Therefore, the QCT method based on an extended London–Eyring–Polanyi–Sato (LEPS) potential energy surface (PES) will be applied to study the dynamical properties of the reaction Sr + CF_3I in this paper.

Theory

Potential energy surface (PES)

Since constructing an accurate ab initio PES for the reaction Sr + CF_3I is difficult, an extended LEPS PES is employed in this work. In the QCT calculation, the LEPS PES is considered as a basis and can be described as follows:[29–31]

$$[1]\quad V(r_1, r_2, r_2) = Q_1 + Q_2 + Q_3 - (J_1^2 + J_2^2 + J_3^2 - J_1J_2 - J_2J_3 - J_1J_3)^{1/2}$$

where

$$[2]\quad Q_i = ({}^1E_i + {}^3E_i)/2$$

$$[3]\quad J_i = ({}^1E_i - {}^3E_i)/2$$

where ${}^1E_i$ is defined as the diatomic Morse potential function and ${}^3E_i$ stands for the anti-Morse function.

$$[4]\quad {}^1E_i = D_i\Big(\{1 - \exp[-\beta_i(r - r_0)]\}^2 - 1\Big)$$

$$[5]\quad {}^3E_i = {}^3D_i\Big(\{1 + \exp[-\beta_i(r - r_0)]\}^2 - 1\Big)$$

where

$$[6]\quad {}^3D_i = D_i(1 - S_i)/[2(1 + S_i)]$$

where S_i is an adjustable parameter (the so-called Sato parameter), whose value changes from –1.0 to 1.0. To achieve an exact LEPS PES, the Sato parameters have to be adjusted. First, they were adjusted to simulate the experimental result of the vibrational distribution in ref. 23. Once the theoretical result agreed with the experimental one, the obtained Sato parameters were used to calculate the other dynamical results of the reaction Sr + CF_3I. D_i, β_i, and R_i^0 are the Morse parameters of a semidiatomic molecule representing the classical dissociation energy, the spectrum constant, and the equilibrium nuclear separation, respectively. Subscripts i = 1, 2, and 3 indicate Sr–I, CF_3–I, and Sr–CF_3, respectively, for the title reaction.

In this paper, by means of these Morse parameters and Sato parameters, the LEPS PES of the title reaction can be constructed. Only the Morse parameters of Sr–I can be obtained from ref. 25, whereas the values of the other Morse parameters were not given in the corresponding literature.[1–25] Therefore, the Gaussian 03 program[32] was employed to calculate the Morse parameters of CF_3–I and Sr–CF_3 in this work.

The initial data in eqs. [7]–[9] were obtained by means of the Gaussian 03 program on the B3LYP/lanl2dz level.[32] The most stable configurations of CF_3–I and Sr–CF_3 can be found at the minimum energy level after the optimization. At the same time, the energy E_{HF} and equilibrium bond length R_i^0 can be obtained in the output files. Then from the frequency calculations of these configurations, the force constant (Frc) that corresponds to the stretching vibrational mode can be obtained in the output file. The Frc is a very important parameter that reflects the interactivity among atoms in a molecule (i.e., bond). The Frc is the second derivative of energy. It determines whether energy is becoming large or small. In other words, this can be described as uphill or downhill. Uphill indicates that the second derivative is negative, and downhill indicates that the second derivative is positive. Therefore, Frc has a relationship with molecular energy. In these calculations, the CF_3 group is treated as a rigid group because its internal configuration usually does not change during the reaction (checked by the Gaussian 03 program). After that, eqs. [7]–[9] were used to dispose of these initial data and obtain the Morse parameters.

$$[7]\quad D_i(\mathrm{AB}) = 27.2116[E_{\mathrm{HF}}(\mathrm{A}) + E_{\mathrm{HF}}(\mathrm{B}) - E_{\mathrm{HF}}(\mathrm{AB})]$$

$$[8]\quad K_e = 6.192\mathrm{Frc}$$

$$[9]\quad \beta_i = \sqrt{\frac{K_e}{2D_i}}$$

where K_e is the vibrational force constant.

For the reaction A + BC → AB + C, A stands for the Sr atom, B stands for the I atom, and C stands for the CF_3 group in this paper. In eq. [7], D_i is in eV and the single-point Hartree–Fock energy (E_{HF}) is in hartrees. In eq. [8], Frc is in mdyn/Å and K_e is in eV/Å^2. To use international units, the Gaussian system of units (mdyn/Å) has been

changed into kcal/mol/Å^2 (1 cal = 4.184 J). Because the unit of energy used in this paper is eV, the unit kcal/mol/Å^2 has been changed into eV/Å^2 (1 mdyn/Å = 144 × 4.3363 × 10^{-2} eV/Å^2 = 6.192 eV/Å^2).

To study all of the atomic collisions for the reaction Sr + CF_3I, the value of the maximum impact parameter (b_{max}) has to be determined during the calculation. The Morses and the Sato parameters of the reaction Sr + CF_3I are presented in Table 1. The values of b_{max} are listed in Table 2. All of the results of the reaction Sr + CF_3I can be obtained with these parameters.

Quasi-classical trajectory calculation

Hamilton's classical equations are numerically integrated by means of the conventional quasi-classical algorithm.[33,34] Previous theoretical studies[35–39] have already proven that the QCT method is good enough for the study of chemical reactions and has been chosen for this paper.

From a simulation and a comparison with the experimental results, the same collision energy with the experiment (0.83 eV) was chosen for use in this paper. In the calculations, a batch of 100 000 trajectories was sampled for each of the collision energies for the title reaction. The integration step size was chosen to be 0.1 fs for the conservation of total energy and angular momentum. Trajectories were initiated at an internuclear separation of 15 Å and for the CF_3I molecule at the ground-state level ($v = 0$, $j = 0$).

Product rotational alignment

In the study of a chemical reaction, the vector property also has to be considered. In this paper, the product rotational alignment of the reaction Sr + CF_3I was calculated with the method developed by Han and co-workers[29,40] A brief description is shown as follows.

During a reactive encounter, according to the conservation of the total angular momentum

$$[10] \qquad \mathbf{J} + \mathbf{L} = \mathbf{J}' + \mathbf{L}'$$

where $\mathbf{L}$ and $\mathbf{L}'$ are the reagent and product orbital momenta, respectively, and $\mathbf{J}$ and $\mathbf{J}'$ are the reagent and product rotational angular momenta, respectively. When $\mathbf{J}$ is small (as is common), the product rotation can only result from $\mathbf{L}$. $\mathbf{J}'$ can be described by a function $f(\theta)$, where θ is the angle between $\mathbf{J}'$ and the relative velocity vector $\mathbf{K}$. $f(\theta)$ can be expanded in a set of Legendre polynomials.[29,41]

$$[11] \qquad f(\theta) = \sum a_l P_l(\cos\theta)$$

where

$$[12] \qquad a_l = \frac{2l+1}{2}\int_{-1}^{+1} P_l(\cos\theta) f(\cos\theta) \mathrm{d}\theta$$

The coefficients a_0, a_1, and a_2 are used to represent the isotropic distribution, product rotational orientation, and product rotational alignment, respectively.

$$[13] \qquad a_2 = 5\langle P_2(\cos\theta)\rangle = 5\langle P_2(\mathbf{J}'\cdot\mathbf{K})\rangle$$

and

$$[14] \qquad \langle P_2(\mathbf{J}'\cdot\mathbf{K})\rangle = \left\langle \frac{3\cos^2\theta - 1}{2} \right\rangle$$

Here P_2 denotes the second item of the Legendre polynomial. The angular brackets in eq. [14] indicate an average over the distribution of $\mathbf{J}'$ about $\mathbf{K}$.[41]

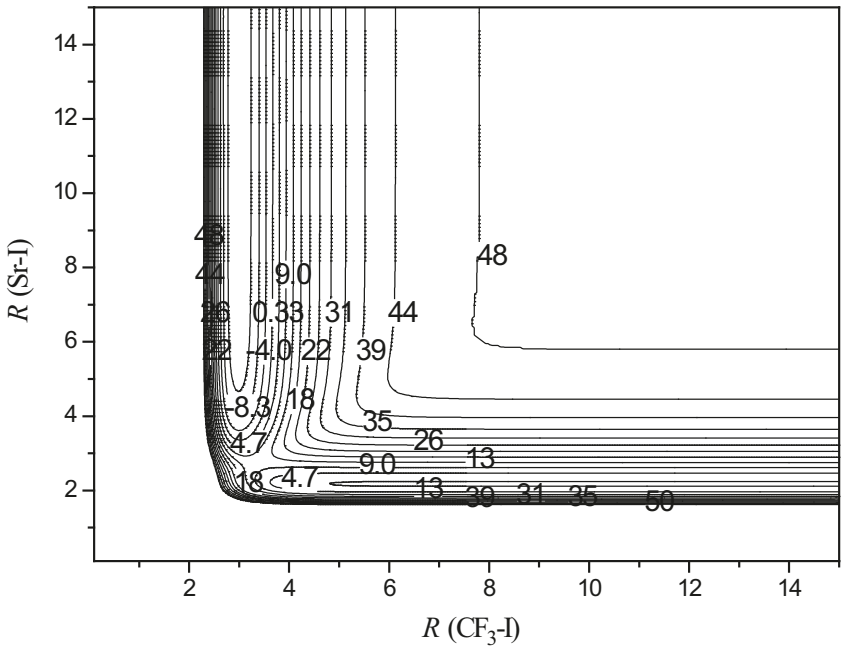
The expected value of $\langle P_2(\mathbf{J}'\cdot\mathbf{K})\rangle$ is between 0.0 (randomly aligned) and –0.5 (completely aligned).[42] The maximum product rotational alignment usually occurs when the conditions $|\mathbf{L}| >> |\mathbf{J}|$ and $|\mathbf{L}'| >> |\mathbf{J}'|$ are satisfied. The first condition is satisfied for reactions with large cross sections, whereas the typical heavy + heavy–light (HHL) mass configuration leads to the second condition.[42] In other words, for the HHL mass combination, the product rotation is strongly aligned with the relative velocity of the reagent and the value of $\langle P_2(\mathbf{J}'\cdot\mathbf{K})\rangle$ should be equal to –0.5.[29]

Results and discussion

PES

The features of the LEPS PES constructed for the reaction Sr + CF_3I are the most basic conditions to obtain more precise results of the dynamical properties and study the reaction mechanism. Since the energy is released at different

Fig. 1. The plot of the London–Eyring–Polanyi–Sato (LEPS) potential energy surface (PES) for the reaction Sr + CF_3I. *R* is in Å and energy is in erg × 10^{16} (1 erg = 6.2415 × 10^{11} eV).



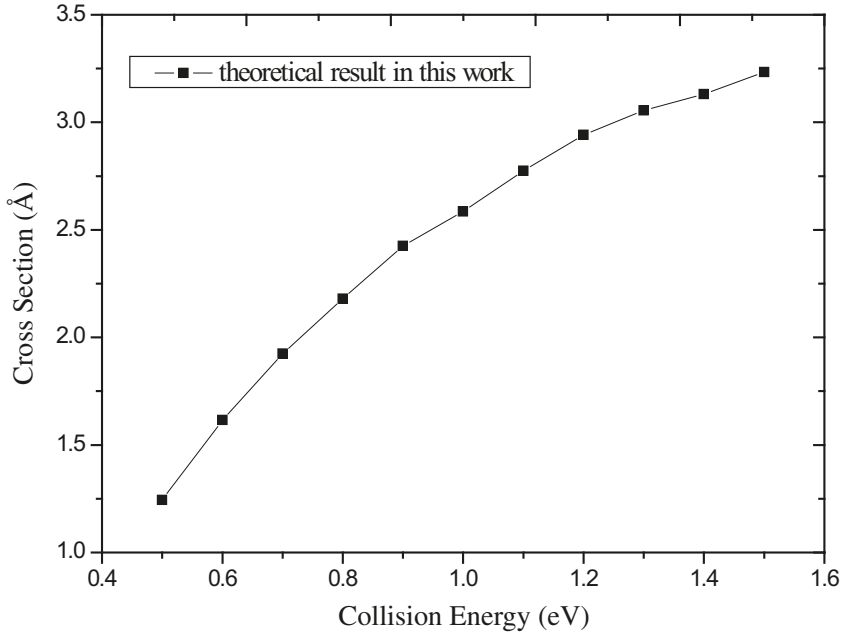


Fig. 2. The result of reaction cross section versus collision energy for the reaction Sr + CF_3I.

times in the reaction A + BC → AB + C, the PES can be divided into two types: attractive and repulsive PES. Energy is released when atom A approaches molecule BC for the attractive PES, and the potential energy is decreasing at the entrance valley of the reaction path. However, energy is released when atom C is dissociated from molecule AB for the repulsive PES, and the potential energy is decreasing at the exit valley. The LEPS PES of the title reaction was constructed using the method that is described in the theoretical part of this paper. The relevant parameters listed in Table 1 were obtained from ref. 25 and the Gaussian 03 program.

In this paper, the constructed PES is a repulsive PES and the contour plot of this extended LEPS PES is shown in Fig. 1. Based on it, the dynamical properties, just like the vibrational distribution, the rotational distribution, the reaction cross section, and the product rotational alignment, were calculated and the results are shown in the following section.

From Fig. 1, it can be seen that the potential energy gradually decreases along the minimum energy path, which is from the entrance ($R_{Sr,CF_3I} = \infty$, corresponding to the reactants) to the exit ($R_{SrI,CF_3} = \infty$, corresponding to the products). There is no potential well, but there is a reaction

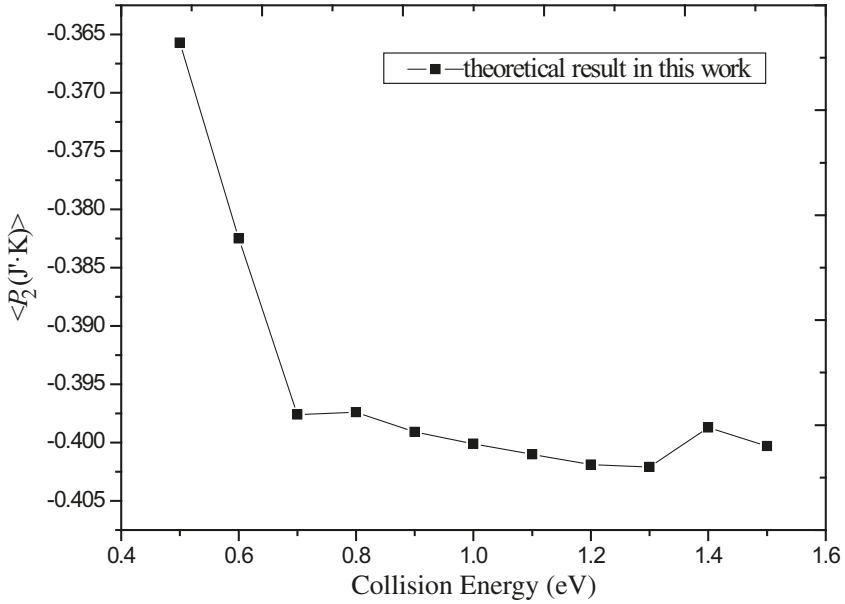
barrier with a value of 11.446 erg × 10^{16} (7.144 × 10^{-4} eV) existing in the entrance path of the LEPS PES in Fig. 1. This reaction barrier leads to the result that the reaction cross section increases with increasing collision energy, which is shown in Fig. 2.

Vibrational distribution



The theoretical result of the vibrational distribution for the reaction Sr + CF_3I is presented in Fig. 3 and it is compared with that of the experiment that is directly derived from Fig. 8 in ref. 23. The distribution can be described as a function of vibration quantum number. For the exactness of this comparison, the QCT calculation was carried out when the collision energy was equal to 0.83 eV and the trajectories were initiated at the ground state ($v = 0$, $j = 0$).

As for the title reaction, the QCT-calculated vibrational distribution of the product SrI is similar to a bell shape for the whole range of vibration quantum numbers $v = 0 \sim 60$. It can be seen from Fig. 3 that the value of the vibrational distribution changes from a regular increase to a decrease

Fig. 5. The result of product rotational alignment versus collision energy for the reaction Sr + CF_3I.

with increasing v. The peak values in the experimental and calculated results both appear when the value of v is equal to 23.

There are two pathways in the reactions of alkaline earth metal atoms (M) and halogenated alkanes, namely the abstraction reaction and the insertion reaction. If the repellant cannot be conquered by the collision energy in the process of the Sr atom attacking CF_3I in the repulsive area, which closes in on group CF_3, the insertion reaction will occur and thenthe Sr atom will shift to the attractive area, which closes in on atom I. But if the value of collision energy is large enough, the Sr atom and the CF_3I molecule can rapidly get close to each other and the C–I bond will fracture to form the product. This is the abstraction reaction. The vibrational distribution result strongly depends on the relative position of the halogen in the reactant and the direction of the M atom approaching the halogenated alkane.

It is necessary to draw a comparison between the theoretical result of the vibrational distribution and the experimental one. Unavoidably, some differences existing in the region around $v = 30 \sim 60$ are found in Fig. 3. Otherwise, the vibrational distribution of the product SrI calculated in this work agrees with the experimental result in ref. 23. These small differences in Fig. 3 are probably because the QCT calculation is taken at a single collision energy, only the ground state of reactants is considered, and the single-particle approximation for group CF_3 is used in this work. In other words, the complex process in the real reaction has been simplified in the theoretical simulation. Even so, the merits of the QCT method, which are simple, illustrative, and accurate, cannot be neglected by us. We often use the QCT method to treat some complex reaction systems instead of the quantum mechanics method. Generally speaking, the variational tendencies of these two results are similar to each other. The theoretical calculation in this work is still good for simulating the experimental result.

Rotational distribution

Figure 4 shows the experimental and the calculated rotational distributions of the product SrI formed in the reaction Sr + CF_3I by means of the QCT method when the collision energy is 0.83 eV. The corresponding experimental result is obtained from Fig. 8 in ref. 23. Stolte and co-workers[23] obtained the rotational distribution $P_v(J)$ at a specific v value from the spectrum simulation. In this paper, Fig. 4 is drawn for $v = 17$. From Fig. 4, it can be seen that when the rotational quantum number J increases, $P_v(J)$ first increases to its peak value and then decreases. In both the experimental and theoretical results, the peak values of $P_v(J)$ appear at around $J = 110$. However, the calculated rotational distribution of the product SrI has some differences in its "tail" when compared with the result in the experiment. The differences are caused by the same reasons for those of the vibrational distribution given in this paper. In summary, the shape of the theoretical result is nearly the same with that of the experimental result of Stolte and co-workers.[23]

Reaction cross section

The relative cross section can be obtained from the experiment,[23] whereas in the theoretical calculation, the absolute cross section can be obtained. In this paper, the reaction cross section is obtained from the following equation:[43]

$$[15] \qquad \sigma_r = \pi b_{max}^2 (N_r/N)$$

where N is the number of total trajectories in the calculation and N_r is the number of reactive trajectories under the $b \leq b_{max}$ condition. The values of these parameters can all be obtained in the output file of the QCT calculation.

The curve of the reaction cross section versus collision energy for the reaction Sr + CF_3I is depicted in Fig. 2 from which it can be seen that the reaction cross section shows a steady increase from a minimum value of 1.2439 Å^2 to a maximum value of 3.2329 Å^2 when the collision energy

Can. J. Chem. Downloaded from www.nrcresearchpress.com by Renmin University of China on 09/02/12
For personal use only.

changes between 0.5 and 1.5 eV. The relationship of the reaction cross section and the collision energy is considered directly proportional. The phenomenon that low reaction probabilities appear at low energies and high probabilities at high energies can be observed in the calculated results of this reaction cross section.

This indicates that a reaction barrier exists on the LEPS PES of the reaction Sr + CF_3I, which results in the reaction cross section increasing with increasing collision energy. The LEPS PES constructed for the title reaction belongs to the repulsive PES type, and the reaction barrier can be found in Fig. 1. It is clear that the results of the reaction cross section obtained here describe the reaction Sr + CF_3I well.

Product rotational alignment

The rotational alignment of the product SrI has been calculated versus a series of collision energies by means of the QCT method. Figure 5 shows the result of the reaction Sr + CF_3I. From the calculated product rotational alignment values, it can be seen that, overall, they have deviated slightly from –0.5, which is the kinematic limit value, and change from –0.3657 to –0.4003 versus the collision energy in the range of 0.5 to 1.5 eV. This result presents a falling trend: the product rotational alignment steadily decreases with increasing collision energy along which the alignment effect becomes strong.

Han et al. obtained the conclusion that the product rotational alignment is independent of the PES properties, but can be influenced by the type of mass combination.[29] According to the approximate mass ratio of the reactants, the Sr + CF_3I reaction can generally be regarded as an HHL mass combination. The result shown in Fig. 5 is similar to that of Fig. 2 in ref. 29. Since the product rotational angular momentum completely comes from the initial orbital angular momentum, the product rotation is strongly aligned about the relative velocity of the reactant and its value should be equal to –0.5.[29] However, the disposal of angular momentum into product orbital motion ($\mathbf{L} \rightarrow \mathbf{J}' + \mathbf{L}'$), particularly at lower collision energies, decreases the value of the product rotational alignment.[29] Therefore, it deviates from –0.5 and decreases with increasing collision energy for this mass combination. For $\langle P_2(\mathbf{J}' \cdot \mathbf{K}) \rangle$, it can be seen that the calculated result of the reaction Sr + CF_3I is bigger than the value of the product rotational alignment of the HHL mass combination shown in ref. 29. From the mass proportion of this reaction, it can be determined that the atomic mass of Sr is 87.62, the atomic mass of I is 126.905, and the atomic mass summation of the CF_3 group is 69.005. The mass ratio of this title reaction deviates slightly from the HHL mass configuration and between the HHL and the light + heavy–light (LHL) mass configurations. This is considered as the main reason for the phenomenon mentioned above.

Conclusions

In this paper, studies of the relationships of the vibrational distribution, rotational distribution, reaction cross section, and product rotational alignment with the collision energy for the reaction Sr + CF_3I have been carried out by means of the QCT method based on an extended LEPS PES.

There is a reaction barrier in the entrance part of the LEPS PES that is constructed for the title reaction. The result of the vibrational distribution shows that it first increases and then decreases in both the experimental and theoretical studies when the vibration quantum number continuously increases. Its maximum value appears at around $v = 23$ at a collision energy of 0.83 eV. In both the experimental and theoretical results of $P_v(J)$, their peak values all appear at around $J = 110$ and their changing tendencies basically agree. With increasing collision energy, the reaction cross section increases and this is caused by the reaction barrier on the LEPS PES. The product rotational alignment decreases with increasing collision energy and its value depends on the type of the mass combination of this reaction. The reaction mechanism has been discussed based on these conclusions and a reasonable interpretation is given. In summary, it can be concluded that the results in this paper are consistent with the experimental data for the exothermic reaction Sr + CF_3I.

Abstract: In the atmosphere, linalool ozonolysis will generate a series of oxidation products and then form particles through nucleation. In this study, the linalool ozonolysis mechanisms were studied and some of the main products detected from experiment are verified. The Rice–Ramsperger–Kassel–Marcus (RRKM) theory and the canonical variational transition state theory (CVT) with small curvature tunneling effect (SCT) are used to calculate rate constants over the temperature range of 200~800 K. The total rate constant for the reaction of ozone with linalool is 4.50×10^{-16} cm^3 molecule^{-1} s^{-1}, and the addition of ozone to $(CH_3)_2C{=}CH{-}$ is the main ozone addition position. Furthermore, the Arrhenius formulas are fitted and the lifetimes of reaction species in the troposphere are discussed for the first time. The total atmospheric lifetime of linalool relative to O_3 is 2.30 h. The O_3-initiated atmospheric lifetimes of P1, P3, and P6 are 2.64 months, 16.67 days, and 15.5 h, respectively.

Key words: linalool, ozonolysis reaction, rate constants, atmospheric lifetime.

Résumé : Dans l'atmosphère, l'ozololyse du linalol conduit à la formation d'une série de produits d'oxydation qui, par nucléation, provoqueront la formation de particules. Dans cette étude, on a étudié les mécanismes d'ozonolyse du linalol et on a vérifié la nature de quelques-uns des produits principaux formés au cours de ces expériences. On a fait appel à la théorie de Rice–Rampsperger–Kassel–Marcus (RRKM) et la théorie de l'état de transition à variation canonique (TVC) modifiée par un léger effet tunnel de courbure (ETC) pour calculer les constantes de vitesse dans la plage de températures allant de 200 à 800 K. La constante de vitesse de réaction totale de l'ozone avec le linalol est de $4{,}50 \times 10^{-16}$ cm^3 molécule^{-1} s^{-1} et l'addition de l'ozone sur le linalol se fait principalement sur la portion $(CH_3)_2C{=}CH{-}$. De plus, pour la première fois, on a ajusté les formules d'Arrhenius et on discute des temps de vie des espèces réactives dans la troposphère. Le temps de vie total du linalol dans l'atmosphère, relatif à celui du O_3, est de 2,30 jours. Les temps de vie atmosphériques initiés par le O_3 des produits P1, P3 et P6 sont respectivement de 2,64 mois, 16,67 jours et 15,5 h.

Mots-clés : réaction d'ozonolyse du linalol, constantes de vitesse, temps de vie atmosphérique.

[Traduit par la Rédaction]

Introduction

Linalool ($(CH_3)_2C{=}CHCH_2CH_2C(CH_3)(OH)CH{=}CH_2$), a monoterpene compound with a floral scent, is released into the atmosphere from certain types of vegetation,[1–3] including tea, oranges, grapes, mangos, lemons, tomatos, basil, and lavender.[4] Linalool is used as a scent in 60%–80% of perfumed hygiene products and cleaning agents including soaps, detergents, shampoos, and lotions.

Linalool has a stereogenic center at C_3 that results in two stereoisomers: (*S*)- and (*R*)-linalool. There are different scents in these two stereoisomers, which contribute to the aroma of many common plants. (*S*)-Linalool has a scent associated with flowers and (or) orange, whereas (*R*)-linalool has a lavender scent and is typically found in lavender and basil. Since (*S*)- and (*R*)-linalool are equally stable,[5] the (*S*)-linalool (abbreviated to linalool) was choosen as an example.

In the troposphere it is easy for linalool to react with OH, NO_3, or O_3 to generate a series of oxidation products that lead to ambient secondary organic aerosol (SOA)[6]. SOA will have a great influence on atmospheric environment and human health. Thus, the studies on the mechanism for atmospheric oxidation of linalool are very important to reduce the formation of SOA. Among all of the atmospheric linalool oxidations, the ozonolysis reaction is particularly important. Many studies on linalool ozonolysis have been reported.[6–9] The products of linalool reacting with O_3 were investigated in ~6500–7900 L Teflon chambers using gas chromatography with mass spectrometry (GC–MS) and GC with Fourier transform infrared absorption spectroscopy (GC–FTIR) detection by Shu et al.[6] Acetone, formaldehyde, 4-hydroxy-4-methyl-5-hexenal, and 5-ethenyldihydro-5-ethyl-2(3*H*)-furanone are the main products, but the subsequent reactions of these products with ozone were not considered. Meera[8] studied linalool ozone reactions and analyzed the consequent reactive oxygen species using two chamber systems. At the same time, the rate constant for the linalool ozonolysis was found to be 3.49×10^{-16} cm^3 molecule^{-1} s^{-1}. Chen et al.[9]

used a dynamic system to study the SOA formation by linalool ozonolysis at room temperature. They only certified that linalool is less efficient in potential SOA formation yields compared with other terpene species like α-pinene, which has one endocyclic unsaturated carbon bond. However, the reaction mechanism of the linalool ozonolysis has still been neglected.

Our group has reported the reaction mechanism of linalool with ozone in the atmosphere using density functional theory (DFT).[10] The intermediates with H_2O were also discussed in detail. It was the first computational study to obtain a mechanistic understanding of how the detected products are generated, but the reaction rate of every elementary reaction was not calculated.

In this study, the geometrical parameters were optimized at the MPWB1K/6–31+G(d,p) level instead of at B3LYP/6–31G(d), with the calculation precision considered. It is well known that the B3LYP method underestimates barrier heights systematically. Furthermore, previous study has shown that the MPWB1K is an excellent method for the prediction of transition-state geometries.[11] On the basis of the quantum chemical information, the rate constants were calculated using the multichannel Rice–Ramsperger–Kassel–Marcus (RRKM) theory,[12] the transition-state theory (TST), and the canonical variational transition-state theory (CVT) with small-curvature tunneling (SCT) or zero-curvatue tunneling correction (ZCT)[13–15] over a wide temperature range of 200∼800 K.

Computational methods

Geometry optimization

The unrestricted MPWB1K method is used to treat systems with an even number of electrons but partial open-shell character, such as ozone or the criegee biradicals.[16,17] The geometrical parameters of stationary points are optimized at the MPWB1K/6–31+G(d,p) level. The vibrational frequencies were calculated at the same level to determine the nature of the stationary points. Each transition state was verified for their connection to the designated reactants and products by performing an intrinsic reaction coordinate (IRC) analysis.[18] A more flexible basis set, 6–311+G(3df,2p), was employed to calculate the single-point energies of various species. All quantum chemical calculations were performed with the Gaussian 03 programs.[19]

Kinetic calculations

The initial information obtained from ab initio calculations allowed us to calculate the rate constants including the tunneling effects. The kinetic calculations were carried out using RRKM theory and the CVT with SCT correction.

RRKM theory was used to calculate the rate constants of the bimolecular reaction. The kinetic program that had considered the pressure effect was supported by Hou et al.[12] The CVT with SCT correction is an effective method for the calculation of rate constants, but it fails to take the pressure change into consideration. In this paper, the CVT/SCT method was used to calculate the rate constants of the monomolecular isomerization over a suitable temperature range. Along the minimum energy path, approximately 40 points were selected. For each point, the frequency was calculated to obtain information on cartesian coordinates, gradients, and Hessian matrices. The kinetic calculations were carried out using the Polyrate 9.7 program.[20]

Results and discussion

The main reaction paths for linalool with O_3 are drawn in Fig. 1. The profiles of the potential energy surfaces are shownn in Figs. 2 and 3. The rate constants for the TST, CVT, CVT/ZCT, and CVT/SCT methods are presented in Fig. 4. Table 1 lists the rate constants of the elementary reaction at 200∼800 K (in s^{-1} and cm^3 $molecule^{-1}$ s^{-1} for unimolecular and bimolecular reactions, respectively). The Arrhenius formulas for elementary reactions over the temperature range are listed in Table 2. Table 3 presents the lifetimes of the reactant species in the atmosphere according to the rate constants.

Reaction mechanism

Linalool ozone reactions proceed through two possible routes because of the presence of the two double bonds in its chemical structure. The potential barriers of the initial addition of ozone to $(CH_3)_2C{=}CH$ and the addition of ozone to $CH_2{=}CH–$ are 0.27 and 2.36 kcal/mol (1 cal = 4.184 J), respectively. It agrees with the experiment study in which the ozone attacks $(CH_3)_2C{=}CH–$ more easily than it attacks $CH_2{=}CH–$.[6,9]

The primary ozonide is expected to undergo rapid decomposition into Criegee biradicals. The addition of ozone to $(CH_3)_2C{=}CH–$ (labeled as IM2) is used to explain the next part of the reaction mechanism. IM2 can decompose into 4-hydroxy-4-methyl-5-hexenal (P1) and $(CH_3)_2COO$ via TS2 with a barrier of 24.12 kcal/mol and also can produce biradical $CH_2{=}CHC(OH)(CH_3)CH_2CH_2C(H)OO$ (IM4) and acetone via TS5 with a barrier of 28.63 kcal/mol. P1 is more favored than IM4 by comparison. P1 will be cyclized and be named as 2-ethenyl-2-methyl-5-hydroxyterahydrofuran (P8). After IM4 reacts with H_2O, IM5 is produced and acid $CH_2{=}CHC(OH)(CH_3)CH_2CH_2COOH$ (P3) is obtained with the loss of a water molecule. Owing to the presence of the second double bond, P1 and P3 can further react with O_3 to give rise to secondary Criegee biradicals as suggested by Shu et al.,[6] Atkinson et al.,[21] and Calogirou et al.[22] It should be noted that P1 and P8 are the major products, which are in agreement with the previous study by Shu et al.[6] The primarily generated Criegee biradicals have seven carbon atoms and are expected to react with stable intermediates and then undergo nucleation and form particles.[9] These nucleate particles can be condensed and absorb volatile organics in the surroundings and grow in size, which will be the important constituents of SOA. The further attack of ozone on the second unsaturated carbon bond will lead to further fragmentation of carbon backbones, which yields products with even fewer carbon atoms, and therefore will be less likely to contribute to SOA formation and growth. Figure 1 shows the reaction sequence of the oxidation of linalool with ozone.

Rate constants

The RRKM, TST, and the CVT with SCT correction methods are used to calculate the rate constants. Given that the temperature ranges from –56 to 15 °C in the troposphere, a

Fig. 4. The rate constants of the elementary reaction 2 with TST and canonical variational transition-state theory (CVT) methods.

wider range of 200~800 K was chosen to study the relationship between temperature and rate constants. The reaction pressure was adopted at atmospheric pressure.

The RRKM method was used to calculate the rate constants in elementary reactions that have no barriers or very low barriers, such as elementary rxns. [1], [3], [6], [8], [10], [13], and [15]. The results are listed in Table 1.

For the primary ozonization, the rate constant for the ozonolysis reaction of $(CH_3)_2C{=}CH–$ (elementary rxn. [1]) is 3.83×10^{-16} cm^3 molecule^{-1} s^{-1} at 298.15 K, higher than that of the ozonization reaction of $CH_2{=}CH–$ (elementary rxn. [10]), 6.67×10^{-17} cm^3 molecule^{-1} s^{-1}. This result can be interpreted as that the preponderant ozone addition position is $(CH_3)_2C{=}CH–$. According to the rate constants of the addition reaction of ozone to $(CH_3)_2C{=}CH–$ and $CH_2{=}CH–$, the total rate constants for the ozonolysis reaction of linalool is 4.50×10^{-16} cm^3 molecule^{-1} s^{-1}, which is similar to 4.3×10^{-16} cm^3 molecule^{-1} s^{-1} found by Atkinson et al.[21] and 3.49×10^{-16} cm^3 molecule^{-1} s^{-1} found by Meera.[8]

For the secondary ozonization, such as elementary rxns. [3], [8], and [15], the rate constants at 298.15 K are 5.45×10^{-19}, 2.59×10^{-18}, and 6.39×10^{-16} cm^3 molecule^{-1} s^{-1}, respectively. It can be seen that the ozonization reactivity of P1 and P3 is lower than that of linalool, while the ozonization reactivity of P6 is higher than that of linalool. These rate constants range from 10^{-18} to 10^{-16} cm^3 molecule^{-1} s^{-1}. The calculated results are reasonable and acceptable.

As for the reactions involving water molecules, such as the elementary rxns. [6] and [13], the rate constants at 298.15 K are 1.83×10^{-20} and 3.15×10^{-22} cm^3 molecule^{-1} s^{-1}, respectively. Obviously, the rate constants are lower than those of the ozonolysis reaction.

The rate constants of TST share the same variation trend as that of CVT for the whole temperature range of 200~800 K studied, i.e., the higher the temperature, the larger the rate constant. The rate constants of elementary rxn. [2] are taken as an example.

In particular, the rate constant of the TST method is about 3.77 and 8.80 times of those of the CVT method at 200 K (TST, 7.02×10^{-15} s^{-1}; CVT, 1.86×10^{-15} s^{-1}) and at 800 K (TST, 5.87×10^{7}; CVT, 6.67×10^{6}), which suggests that the variational effect cannot be neglected in this reaction. Meanwhile, we can find that the higher the temprature, the greater the variational effect.

The tunneling effect is also taken into account in the computation of the rate constants. The CVT rate constants are larger than the CVT/ZCT and CVT/SCT ones over the temperature range of 200~800 K. For example, at 298.15 K, the CVT rate constant is 5.28×10^{-6} s^{-1}, whereas the CVT/ZCT and CVT/SCT rate constants are 1.72×10^{-6} and 1.73×10^{-6} s^{-1}, respectively. The former is 3.07 times the latter. The higher the temperature is, the less the ratio is, which suggests that the tunneling effect plays a more important role at low temperature than at high temperature for the calculation of the rate constants. As for TST and CVT/ZCT, the same trend is found. Another phenomenon that was observed was that the CVT/SCT rate constants come closer to the rate constants of TST and CVT in the higher temperature range. According to previous studies,[23,24] the CVT/SCT rate constants are in good agreement with experimental values in a large temperature range. Therefore, the results of the CVT/SCT method are reported for the other elementary reactions, which are also listed in Table 1.

Owing to the low barriers, elementary rxns. [4] and [16] occur easily. But the elementary rxns. [7] and [14] have barriers high above 60 kcal/mol and the rate constants are very low. The rate constants of elementary rxns. [2], [5], and [9] have similar orders of magnitudes with the expermental particle wall loss rate constants.[25–27] Elementary rxns. [12], [13], [17], [18], and [19] have the lower rate constants.

To be used more effectively, the calculated rate constants are fitted, and Arrhenius formulas $k(T) = a \times 10^b \exp(\Delta E/RT)$ for the crucial elementary reactions over the temperature

[a] O_3 concentration is ~2.688×10^{11} molecule/cm^3 (1.0×10^{-8} O_3 in the atmosphere).

[b] Water concentration is ~5.375×10^{17} molecule/cm^3 (2% H_2O in the atmosphere).

range of 200~800 K are listed in Table 2. The pre-exponential factor, the activation energy, and the rate constants can be obtained from these formulas. These formulas can provide helpful information for the atmospheric model study on the formation of SOA.

Atmospheric lifetimes

According to the rate constants of the elementary reactions, the atmospheric lifetimes of the reactants can be calculated. For the first-order reaction, the lifetime τ is the reciprocal of the rate constant k, that is, $\tau = \frac{1}{k}$. For the pseudo-first-order reaction, the lifetime is calculated according to $\tau = \frac{1}{k[x]_{const}}$, where the $[x]_{const}$ term is one of the reactant concentrations that can be taken as a constant in the troposphere. For the parallel reaction, the reciprocal of the total lifetime equals the sum of the reciprocal of the sublifetime, that is, $\frac{1}{\tau_{total}} = \sum_{i=1}^{m} \frac{1}{\tau_i}$. The m term is the number of parallel reactions. Then, the lifetime of the reactants in the 19 elementary rxns. can be obtained over the range of 200~800 K and

are listed in Table 3. The lifetimes at room temprature are taken as an example.

For the bimolecular reactions, such as elementary rxns. [1], [3], [6], [8], [10], [13], and [15], the atmospheric lifetimes can be calculated according to the pseudo-first-order reaction, since the concentrations of O_3 and H_2O can be taken as constant in atmosphere. Therefore, the total atmospheric lifetime of linalool relative to O_3 is 2.30 h. The O_3-initiated atmospheric lifetimes of P1, P3, and P6 are 2.64 months, 16.67 days, and 15.5 h, respectively. The atmospheric lifetimes of IM4 and IM8 relative to H_2O are 1.7 min and 1.64 h, respectively. For the pseudo-first-order reaction, the higher the constant concentration, the shorter the lifetime. In this case, high humidity can promote elementary rxns. [6] and [13].

For the monomolecular decomposition or isomerization reactions, the atmospheric lifetimes of the intermediate species vary greatly from seconds to years, such as IM2 (6.69 days), IM3 (2.92 min), IM6 (2.49 months), and IM11 (1.25 h). As for IM5 and IM9, the dehydration reactions from IM5 to P3 and IM9 to P6 have difficulty taking place as the barriers are very high. Therefore, the atmospheric lifetimes of IM5 and

Table 3. Arrhenius formulas for elementary reactions over the temperature range of 200–800 K.

Reaction	Arrhenius formula
R+O_3→TS1→IM2	$k(T) = 7.92\times10^{-13}$ exp(–2233.81/T)
IM2→TS2→P1+$C_3H_6O_2$	$k(T) = 3.93\times10^{13}$ exp(–13271.34/T)

P1→TS17→P8	$k(T) = 8.41\times10^{11}$ exp(–1549272/T)
P2→TS18→P9	$k(T) = 8.83\times10^{11}$ exp(–16931.43/T)
P7→TS19→P10	$k(T) = 9.28\times10^{11}$ exp(–18827.26/T)

Note: Units are s^{-1} and cm^3 $molecule^{-1}$ s^{-1} for the unimolecular and bimolecular reactions, respectively.

IM9 are very long. As for the other species, IM7, P1, P2, and P7 also have long atmospheric lifetimes.

In the atmosphere, linalool ozonolysis will generate a series of oxidation products to form particles through nucleation. These nucleate particles can be condensed and absorb volatile organics to contribute to the formation of SOA. The longer the atmospheric lifetime, the more important the contribution to the SOA formation.

Abstract: The structures of two one-dimensional coordination complexes, $[M^{II}(3\text{-}Bzpy)_2(N(CN)_2)_2]$ (M = Mn (**1**) and Co (**2**) and 3-Bzpy = 3-benzoylpyridine), have been determined in this work. The two structures are isomorphous, crystallize in a monoclinic $P2_1/c$ space group, and show almost the same crystal structure. The magnetic measurements of the two compounds (2–300 K) indicate that antiferromagnetic exchanges exist between the metal ions of the two compounds.

Key words: dicyanamide, 1-D, structure, magnetic property.

Résumé : Dans ce travail, on a déterminé les structures de deux complexes de coordination unidimensionnels, $[M^{II}(3\text{-}Bzpy)_2(N(CN)_2)_2]$ (M = Mn (**1**) et Co (**2**) et 3-Bzpy = 3-benzoylpyridine). Les deux structures sont isomorphes, elles cristallisent dans le groupe d'espace monoclinique $P2_1/c$ et elles se présentent sous des formes cristallines pratiquement semblables. Des mesures magnétiques effectuées sur les deux composés (2–300 K) indiquent qu'il se produit des échanges antiferromagnétiques entre les ions métalliques des deux composés.

Mots-clés : dicyanamide, 1-D, structure, propriété magnétique.

[Traduit par la Rédaction]

Introduction

In the last 10 years, 1-D coordination polymers have been frequently investigated because of their magnetic characteristics.[1–3] The dicyanamide ligand $[N(CN)_2]^-$ is extremely popular as a building block in constructing coordination polymers, since it can act in a mono-, bi-, or tri-dentate coordination manner[4,5] and act as a molecular-based magnet precursor with several first-row transition ions such as Cu(II), Ni(II), Co(II), Mn(II), and Cr(II).[6–9] The introduction of N-based bridging and a terminal ligand into the metal $[N(CN)_2]^-$ system has led to many different structures with interesting magnetic properties. For example, when the metal/dca ratio is 1:2 and the metal is hexacoordinated, the dca ligand often acts as a tridentate ligand with the three nitrogen atoms and forms neutral three-dimensional compounds. If the metal is tetrachordinate, the dca ligand then acts as an end-to-end $\mu_{1,5}$ bidentate ligand.[10–13] It is interesting that the formation of the compounds in this family follow a strategy that their structural formulas can be expressed by $[ML_2(dca)_2]$, in which L may be two monodentate ligands or one bidentate ligand, and afford compounds with bidentate dca ligands.[11] Many such compounds have been reported, such as 1-D for $[M^{II}(pyr)_2(N(CN)_2)_2]$ (M = Mn (**1**) and Co (**2**) and pyr = 2-pyrrolidone)[14] and $Mn[N(CN)_2]_2(2,4'\text{-bpy})_2$ (2,4′-bpy = 2,4-bipyridine),[15] 2-D for $[M^{II}(N(CN)_2)_2(H_2O)]$phz (M = Co or Ni and phz = phenazine),[16] $Zn[N(CN)_2]_2$,[17] and 3-D for $M^{II}[N(CN)_2]_2$ (M = Cu, Co, Ni, or Mn)[6,18] and $M(dca)_2$(apym) (M = Co or Ni and apym = 2-aminopyrimidine).[19] In our previous work, we successfully introduced 3-benzoylpyridine as ancillary ligand of the dicyanamide system and obtained an interesting structure, $[Zn^{II}(3\text{-}Bzpy)_2(N(CN)_2)_2]$ (3-Bzpy = 3-benzoylpyridine).[20] Enlightened by this success, we report the structure and magnetic properties of two new 1-D coordination compounds of this family here, in which M is manganese(II) and cobalt(II) and the L_2 is two 3-benzoylpyridines with the formula $[M^{II}(3\text{-}Bzpy)_2(N(CN)_2)_2]$ (M = Mn (**1**) and Co (**2**)), where the dicyanamide anion bridged the metal ions in an end-to-end $\mu_{1,5}$ model as expected. The magnetic measurements indicate weak antiferromagnetic coupling with $J = -0.16$ for compound (**1**). It seems that weak antiferromagnetic coupling is the common gender of the manganese(II) complex in the double $\mu_{1,5}$-dicyanamide family,[21] but the magnetic properties of complex **2** are special from others in this family, and it shows significant orbital contribution at room temperature and obvious orbital angular momentum at lower temperatures.

Note: $R_1 = \Sigma|F_o - F_c|/\Sigma F_o$ and $wR_2 = [\Sigma w(F_o - F_c)^2/\Sigma wF_o^2]^{1/2}$, where $w = 1/[\sigma^2(F_o^2) + (0.0808P)^2 + 0.17P]$ and $P = (\text{Max}(F_o^2, 0) + 2F_c^2)/3$ or $w = 1/[\sigma^2(F_o^2) + (0.0163P)^2 + 0.63P]$ and $P = (\text{Max}(F_o^2, 0) + 2F_c^2)/3$.

The crystal structure of compound **1** is very similar with the reported crystal structure: *trans*-$[Mn(4\text{-}Bzpy)_2(N(CN)_2)]$ (4-Bzpy = 4-benzoylpyridine),[21] which consists of chains with double $\mu_{1,5}$-dicyanamide bridges between neighboring manganese(II) atoms and shows weak antiferromagnetic coupling with $J = -0.3$. The differences of ancillary ligand L and magnetic behaviour between them indicate that any disparities of the ancillary ligand can lead to differences in the dicyanamide system both in topology structure and properties.

Experimental

Materials

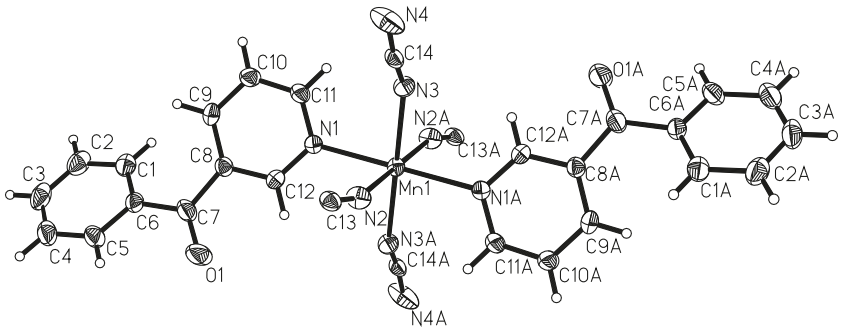
All chemicals used (reagent grade) were commercially available. $Na[N(CN)_2]_2$ was purchased from the ACROS Company. Elemental analyses (C, H, and N) were carried out by using a Elementar Analysensysteme GmbH Vario EL instrument. The IR spectrum was recorded on a AThermo-Nicolet AVATAR FT-IR 360 spectrometer as KBr pellets in the 4000 ± 400 cm^{-1} region. The temperature-dependent magnetizations (M vs H) at 2.5 K of complexes **1** and **2** were measured by using a Quantum Design vibrating sample magnetometer (VSM) in the Physical property measurement system (PPMS).

Preparation of $[M^{II}(3\text{-}Bzpy)_2(N(CN)_2)_2]$ (M = Mn (1) and Co (2))

Complex (**1**) was prepared as follows: 3-Bzpy (21.96 mg, 0.12 mmol) was added slowly with stirring in an aqueous solution (5 mL) of $Mn(CH_3COO)_2{\cdot}4H_2O$ (30.00 mg, 0.12 mmol) and then sodium dicyanamide (21.36 mg, 0.24 mmol) in a methanol–water solution (5 mL) was added slowly. The resulting solution was continuously stirred for about 30 min at room temperature and then filtered. The filtrate was slowly evaporated at room temperature over several days, and yellowish needles crystals suitable for X-ray analysis were obtained. The yield was 80%. IR (KBr, cm^{-1}): 2308, 2229, 2171, 1650, 1596, 1450, 1425, 1371, 780, 703, 690, 650. Anal. calcd for $C_{28}H_{18}MnN_8O_2$ (%): C 60.77, N 20.25, H 3.28; found: C 61.23, N 20.12, H 3.34.

Compound **2** was synthesized exactly as for **1** but from $Co(Ac)_2{\cdot}4H_2O$. The crystal appeared as pink needles and the yield was 85%. IR (KBr, cm^{-1}): 2306, 2237, 2179, 1650, 1596, 1444, 1410, 1365, 780, 690, 703, 650. Anal. calcd for $C_{28}H_{18}CoN_8O_2$ (%): C 60.33, N 20.10, H 3.25; found: C 60.46, N 20.17, H 3.29.

Crystal data collection and refinement



The structures of two compounds **1** and **2** were studied at the Sun B.W. Lab of Southeast University, Nanjing, P.R. China. Data were collected on a Rigaku Scxmini 1 K CCD area detector diffractometer with graphite-monochromated Mo Kα radiation (λ = 0.710 73 Å). The structural analyses show that they are isomorphous. Crystal data are summarized in Table 1. All the data were collected, processed, and corrected for Lorentz and polarization effects using the Bruker

Fig. 1. Structure of complex **1** ($[Mn(3\text{-}Bzpy)_2(N(CN)_2)_2]$; 3-Bzpy = 3-benzoylpyridine) with thermal ellipsoids drawn at the 50% probability level (hydrogen atoms are omitted for clarity).

SADABS program with the multiscan method. The structures were solved by direct methods and refined by a full-matrix least-squares technique based on F_2 using the SHELXL 97 program.[14] All non-hydrogen atoms were refined anisotropically, and hydrogen atoms were placed by calculation positions and refined isotropically.

Results and discussion

Crystallographic data for $[Mn(3\text{-}Bzpy)_2(N(CN)_2)_2]$ (**1**) and $[Co(3\text{-}Bzpy)_2(N(CN)_2)_2]$ (**2**), are listed in Table 1. Selected bond distances (Å) and angles (°) for complexes **1** and **2** are also listed in Table 2. Compounds **1** and **2** are one-dimensional coordination complexes. The structures of the two complexes are isomorphous and are exemplified by $[Mn(3\text{-}Bzpy)_2(N(CN)_2)_2]$ (see the Supplementary data).

A perspective view of the metal coordination environment in the crystals of complex **1** is presented in Fig. 1. It shows that the compound crystallizes in a monoclinic $P2_1/c$ space group. The Mn(II) ion, which lies on the inversion centre, is in an octahedral geometry with the four N atoms of different $[N(CN)_2]^-$ ligands in the equatorial plane. The another two N atoms of different 3-Bzpy ligands occupy the axial positions, since the bond angles of N1–Mn1–N1A, N2–Mn1–N2B, and N3–Mn1–N3B are all 180°, whereas, in the crystal structure of *trans*-$[Mn(4\text{-}Bzpy)_2(N(CN)_2)]$, the same bond angles are only 102.1(2)°.[13] This means that the disparity of the ancillary ligand can have a great affect on the topology structure of the dicyanamide system.

In the crystal structure, the Mn(II) atoms are bridged to form a 1-D chain by dicyanamide ligands (Fig. 2), which act

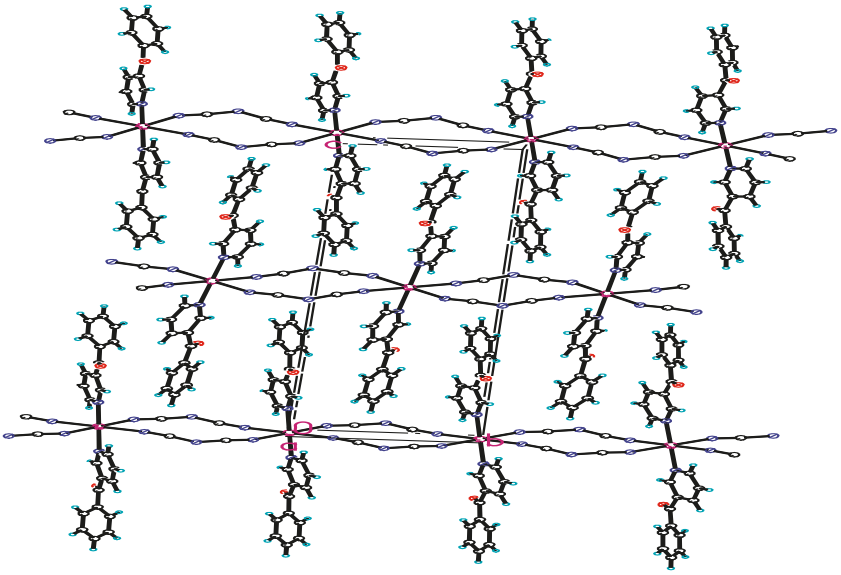
Fig. 2. A packing diagram of complex **1** ([Mn(3-Bzpy)$_2$(N(CN)$_2$)$_2$]) looking down the *b* axis showing how discrete 1-D Mn(3-Bzpy)$_2$(N(CN)$_2$)$_2$ coordination polymers are further extended into interesting 2-D supramolecular arrays through π-π stacking interactions (3-Bzpy = 3-benzoylpyridine). Displacement ellipsoids are drawn at the 50%, probability level and hydrogen atoms are omitted for clarity.



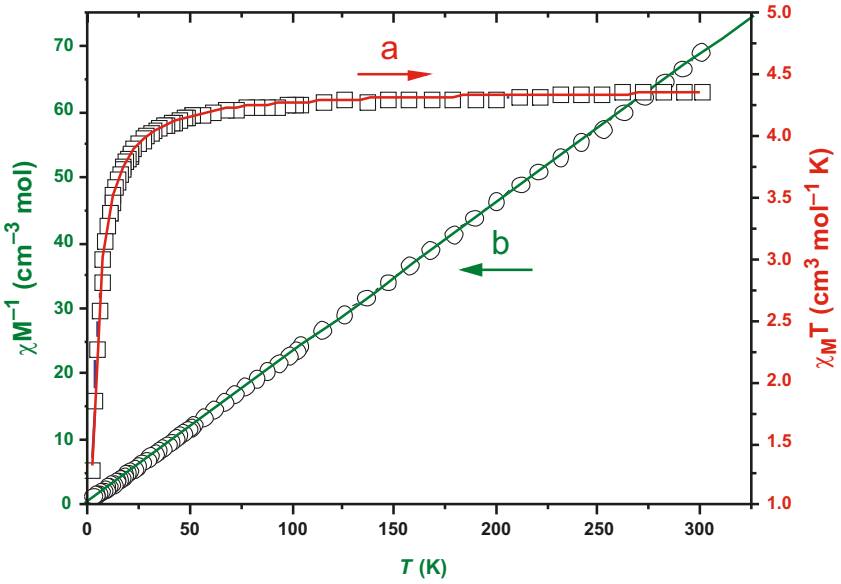


Fig. 3. Plots of the dependence of (*a*) $\chi_M T$ and (*b*) χ_M^{-1} on temperature for complex **1**([Mn(3-Bzpy)$_2$(N(CN)$_2$)$_2$]; 3-Bzpy = 3-benzoylpyridine). Circles and squares represent the experimental values and the solid lines represent the best calculated curves. χ_M is the molar magnetic susceptibility.

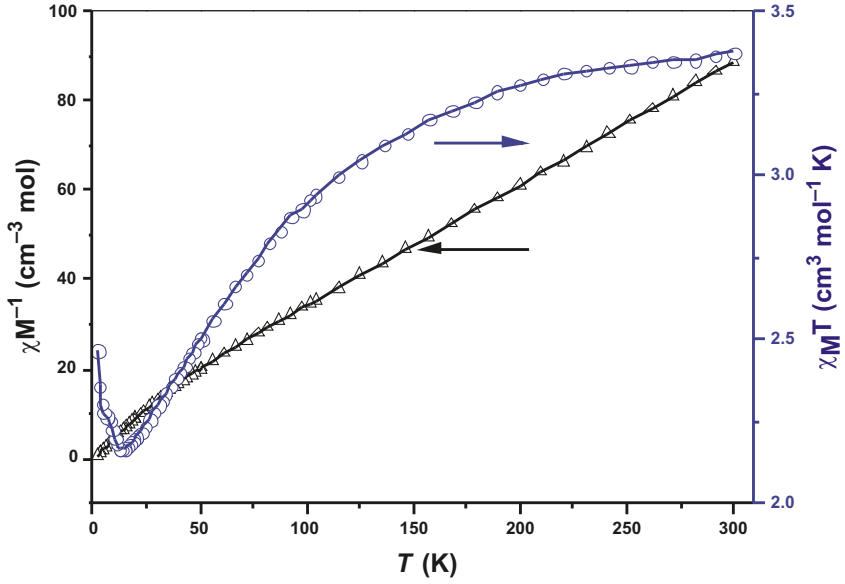

as bidentate bridging ligands by coordinating to adjacent Mn (II) centres through their two terminal nitrile N atoms. In addition, the shortest centroid-to-centriod distances between 3-Bzpy of adjacent chains are 4.000 and 4.118 Å, implying there are π–π stacking interactions among neighboring polymeric 1-D chains, which force the 1-D chains into interesting 2-D supramolecular arrays. Polymeric 1-D chains are generated parallel to the *b* axis, with adjacent chains staggered along the *b* axis and there are chains of metal ions bridged by the N atoms of the $[N(CN)_2]^-$ ligands, with Mn···Mn distances of 6.3943(13) Å. The Mn···Mn distance is shorter than that of [Mn(4-Bzpy)$_2$(N(CN)$_2$)] (7.584 Å)[13] and [Mn(pyr)$_2$(N(CN)$_2$)$_2$] (7.538 Å), since the bond angle of C13–N4–C14 is bigger than that in [Mn(pyr)$_2$(N(CN)$_2$)$_2$].[5]

The structure of **2** is very similar to that of [Mn(3-Bzpy)$_2$(N(CN)$_2$)$_2$], and it is necessary to note that the shortest intrachain distance between Co···Co was found as 7.4490(16) Å, and the shortest centroid-to-centroid distances between 3-Bzpy of adjacent chains are 3.969 and 4.105 Å.

Magnetochemistry

The temperature dependence of the molar magnetic susceptibility (χ_M) for complexes **1** and **2** was measured in the

Fig. 4. Plots of the dependence of (*a*) $\chi_M T$ and (*b* χ_M^{-1}) on temperature for complex **2** ([Co(3-Bzpy)$_2$(N(CN)$_2$)$_2$]). Circles and squares represent the experimental values and the solid lines represent the best calculated curves. χ_M is the molar magnetic susceptibility.

2–300 K temperature range, as shown in Figs. 3 and 4, in the forms of $\chi_M^{-1}$and $\chi_M T$ vs T. From the figures, we can see the two complexes both imply antiferromagnetic exchanges between the metal ions. According to the χ_M^{-1}–T line, the magnetic behaviors of **1** and **2** follow the Curie–Weiss law $\chi_M = C/(T - \theta)$ with Curie constant (C) values of 4.40 and 3.45 cm^3 mol^{-1} K and Weiss temperatures θ of –3.10 and –12.34 K. The value of $\chi_M T$ of **1** at 300 K is 4.371 cm^3 mol^{-1} K, and is perfectly agreement with the spin-only value expected for uncoupled high-spin $S = 5/2$ ions (4.37 cm^3 mol^{-1} K), so we can see the interactions between Mn^{2+} ions are very weak as expected. The magnetic susceptibility data were quantitatively analyzed by eq. [1], which is deduced from the Hamiltonian model with $H = -2JS_{Mn}S_{Mn}$ and derived from the Heisenberg infinite linear chain model.[22]

$$[1] \qquad \chi_M = \frac{Ng^2\mu_B{}^2S(S+1)}{3k_BT}\cdot\frac{1+u(K)}{1-u(K)}$$

where N is Avogadro's number, μ_B is the Bohr magneton, k_B is the Boltzman constant ($k_B = 0.695$), and J is the intrachain coupling constant of Mn^{2+} ions. From this, $N\beta^2/3k_B = 0.125$, $K = 2 \times J \times 2.5 \times 3.5/0.695/T$, where $u(K)$ and K are defined as

$$[2] \qquad u(K) = \coth K - \frac{1}{K}$$

$$[3] \qquad K = \frac{2JS(S+1)}{k_BT}$$

In eq. [2], coth K is expressed as

$$[4] \qquad \coth K = \frac{[\exp(K) + \exp(-K)]}{[\exp(K) - \exp(-K)]}$$

The values from eqs. [1]–[4] can be used to deduce the definite expression for χ_M.

$$[5] \qquad \chi_M = 1.1g^2 \times \frac{1 + [\exp(25.18J/T) + \exp(-25.18J/T) - T/25.18J]}{1 - [\exp(25.18J/T) - \exp(-25.18J/T)] + T/25.18J}$$

The best-fit parameters of the experimental data to the theoretical model were found to be $J = -0.16$ cm^{-1} and $g = 2.00$. The solid line in Fig. 3 represents the best-fit result. According to the single-crystal structure of complex **1**, the distance between Mn···Mn is 6.3943(13) Å and the pathway through a bridge of five atoms. This is one of the important reasons for the weak magnetic exchange interactions between the paramagnetic centres in the chains. Another reason for this phenomenon was proved by Mealli and Proserpio[23] based on MO calculation and confirms that the $\mu_{1,5}$-dicyanamide bridge should be assumed to be a very poor superexchange mediator. As for *trans*-[Mn(4-Bzpy)$_2$(N(CN)$_2$)], it shows the same magnetic profiles as **1** with a $\chi_M T$ of 4.20 cm^3 mol^{-1} K at 300 K.

Fig. 4 presents the $\chi_M T$–T curve of complex **2**. The $\chi_M T$ value gradually decreases from 3.38 to 2.20 cm^3 mol^{-1} K from 300 to 20 K because of antiferromagnetic exchange,but at lower temperature it increases more steeply to reach 2.47 cm^3 mol^{-1} K at 2 K, which is attributed to the orbital angular momentum of the Co atoms. The value of $\chi_M T$ per Co(II) ion at room temperature is greater than calculated for the spin-only case (1.87 cm^3 mol^{-1} K), revealing that a significant orbital contribution occurs.

Bonding topology, hydrogen bond strength, and vibrational chemical shifts on hetero-ring hydrogen-bonded complexes — Theoretical insights revisited

Boaz G. Oliveira and Regiane C. M. U. Araújo

Can. J. Chem. Downloaded from www.nrcresearchpress.com by Renmin University of China on 09/02/12
For personal use only.

Abstract: This work presents a theoretical study about the interaction strength of the hydrogen-bonded complexes $C_2H_4O\cdots HF$, $C_3H_6O\cdots HF$, $C_2H_4O\cdots HCF_3$, and $C_3H_6O\cdots HCF_3$ at the B3LYP/6–311++G(d,p) level. The structures, hydrogen bond energies, charge transfers, and dipole moments of these complexes were analyzed in accordance with routine spectroscopy events, such as the red- and blue-shifts on the stretch frequencies of the proton donors (HF and HCF_3). The ChelpG atomic charges were used to quantify the charge-transfer fluxes from electron donor (O) towards to acceptors (HF or HCF_3). Moreover, the topological calculations on the basis of the quantum theory of atoms in molecules (QTAIM) approach were also used to unveil the hydrogen bond strength (O···H), mainly in the determination of their electronic densities and Laplacian shapes.

Key words: vibrational spectrum, oxirane, oxetane, ChelpG, QTAIM.

Résumé : Dans ce travail, on présente les résultats d'une étude théorique, effectuée au niveau B3LYP/6–311++G(d,p), sur la force des interactions dans les complexes comportant des liaisons hydrogènes, $C_2H_4O\cdots HF$, $C_3H_6O\cdots HF$, $C_2H_4O\cdots HCF_3$ et $C_3H_6O\cdots HCF_3$. On a analysé les structures, les énergies des liaisons hydrogènes, les transferts de charge et les moments dipolaires de ces complexes en relation avec des événements spectroscopiques de routine, tels les déplacements vers le bleu ou vers le rouge des fréquences d'élongation des donneurs de proton (HF et HCF_3). On a utilisé les valeurs des charges atomiques ChelpG pour quantifier les flux de transfert de charge du donneur d'électron (O) vers les accepteurs (HF et HCF_3). Des plus, on a aussi utilisé des calculs topologiques sur la base de l'approche de la théorie quantique des atomes dans les molécules (TQADM) pour déterminer la force des liaisons hydrogènes (O···H), particulièrement dans la détermination de leurs densités électroniques et des forces de leurs laplaciens.

Mots-clés : spectre vibrationnel, oxirane, oxétane, ChelpG, TQADM.

[Traduit par la Rédaction]

Introduction

It is well-known that many chemical, physical, and biological systems are formed by noncovalent interactions, of which the hydrogen bond is currently dominant.[1–3] Nowadays, the hydrogen bond has attained a high importance level owing to the immensity of phenomena originated from the contact between a proton donor and a center containing high charge density.[4] This statement can be verified in many studies, such as identification of intermediaries in reaction mechanisms,[5] determination of functionality of molecules into the bioorganic active sites,[6] and design of new compounds pharmacologically more potent.[7,8]

From the viewpoint of theoretical chemistry, the hydrogen bond can be analyzed in conformity with the contributions of the electrostatic potential, polarizability, exchange potential, dispersion forces, and charge transfer.[9] It should be kept in mind that the relative contributions of these parameters, which are quantified for each system albeit the redundant ratio of the electrostatic potential, is practically uncontestable.[10–12] Also, other studies have shown that the charge transfer is decisive for determination of the molecular stability,[13] and in some cases, the charge transfer is the greatest amount rather than electrostatic effects.[14]

In a historical background of the theoretical approaches implemented to study intermolecular systems, from the proposition of the energy and charge distribution decomposition (ECDD)[15] until symmetry-adapted perturbation theory (SAPT)[16], several works have been published with the persistent emphasis upon the formation of the hydrogen bonds for discovering the dominant term.[17] To shed light on this still unsolved question, it is quite recognized that the charge transfer drastically affects the proton donors, where the enhancement of their bond lengths is one of the most important

characteristics.[18,19] In spectroscopy, these structural changes are titled bathochromic events or red-shift effects because the stretch frequencies of the proton donors are dislocated to downward values followed by increases on their absorption intensities.[20]

In the past, Pinchas[21] and Sandorfy and co-workers[22] were some of the pioneers in spectroscopy studies of intermolecular complexes. More recently, Hobza et al.[23] certified a novel interaction named as "opposite hydrogen bond" or "anti hydrogen bond", motivated by the detection of a blue-shift effect on the stretch frequency of the proton donor.[24–26] On the contrary to the hydrogen bonds with red-shift effects, systems with blue-shifts present a shortening of the bond lengths of the proton donors, and thereby their stretch frequencies are moved to upward values in the IR spectrum.[27,28] A classic example of a blue-shifting hydrogen bond is found in the heterocyclic system $C_2H_4O\cdots HCF_3$, whose spectroscopic properties have been well-defined by means of sophisticated ab initio calculations.[29] On the other hand, heterocyclic complexes formed by the association between oxirane (C_2H_4O) and oxetane (C_3H_6O) with monoprotic acids H–X (X = Cl, F, CN, NC, and CCH) have been exhaustively studied, and because of spectroscopic formalism, their red-shift effects were theoretically identified at the level of the density functional theory (DFT).[30,31]

To propose a theoretical interpretation to the IR chemical shifts in intermolecular complexes, Hermansson[32] showed the influence of the electric field (proton acceptors) on the dipole moment of proton donors, and, of course, this phenomenon affects the formation of the hydrogen bonds as well as their stretch frequencies. Therefore, it was noticed that blue-shifts are manifested when long hydrogen bonds are formed, in these cases where the derivative of the induced dipole moment is negative.[33] In total conformity with this scenario, it was also verified that unsaturated hydrocarbons are useful proton acceptors, yielding the formation of long and short hydrogen bond distances when blue- and red-shift effects were observed, respectively.[34,35] Although the electric field analysis has been widely used, it has not been established which parameter is the most adequate for the interpretation the hydrogen bond strength and its main vibrational characteristic, red- or blue-shifts, as commented above. In this context, the main goal of this work is focused on a theoretical study of hydrogen-bonded complexes formed by $C_nH_mO\cdots HX$ (for oxirane, $n = 2$ and $m = 4$; for oxetane, $n = 3$ and $m = 6$; for hydrofluoric acid, X = F; and for fluoroform, X = CF_3).[36–40]

Theoretical methods and level of analysis

The molecular properties and structures of hydrogen-bonded complexes have been the target of examination in a large number of theoretical works, and many of these examinations were performed through the application of hybrid functionals of exchange correlation.[41] However, the capability of B3LYP in investigations of the electronic structures of many system types has been shown over the years, mainly those formed via hydrogen bonds.[42] Because of this B3LYP functionality, we elected to use it in our investigation. Nevertheless, the formation of hydrogen complexes is conceived by means of the interaction between the HOMO and LUMO frontier orbitals, which represent the Lewis definitions of base (proton acceptors) and acid (proton donors), respectively. Although several atomic-charge approaches are available, such as Mulliken population analysis,[43] natural bond orbitals (NBO),[44] generalized polar atomic tensors (GAPT),[45] as well as the charges based on the Gasteiger[46] and Löwdin[47] methods, the evaluation of the charge transfer between the frontier orbitals is vital. By this context, it becomes necessary to keep in mind some criteria to choose a method with (*i*) satisfactory prediction of the charge transfer; (*ii*) low computational effort; and, if possible, (*iii*) a slight dependence from the ab initio basis sets. By taking into account these recommendations, ChelpG (charges derived from the electrostatic potential grid)[48] is the most appropriate method. In practice, the ChelpG charges have been widely used in studies of hydrogen complexes with quantification of the charge transfer[49] and prediction of the red- and blue-shift effects.[25–29,50]

Topological contribution

The works written by Koch and Popelier[51] Mosquera and co-workers,[52] Grabowski and Małecka,[53] Tang and Cui,[54] and others[55–59] show us that hydrogen bonds and their properties can be carefully predicted through the quantum theory of atoms in molecules (QTAIM).[60] Recently, Bader[61] revisited some QTAIM concepts, mainly the way in which the quantum basis can be adapted to describe the topological electronic density and the atomic behavior within the molecular environment.[62,63] By analyzing the QTAIM geneses, the construction of bond paths (BP)[64,65] and bond critical points (BCP)[66] model the chemical bonds and, in addition, these two topological descriptors try to explain an old unsolved question in chemistry: "Where is the atomic frontier localized into a chemical bond?" However, although Bader has warned that "bond paths are not chemical bonds",[67] the information obtained by means of topographic calculations developed at both the BCP and BP levels has aided in the interpretation of the chemical bonds and intermolecular interactions, such as hydrogen bonds and others.[40,68,69] The identification of the maxima and minima of the electronic density emerging from each BCP is performed when the zero flux is known.[70] In an overview, high and low charge density concentration can be interpreted through the Laplacian of the electronic density ($\nabla^2\rho$), whose profile can assume $\nabla^2\rho > 0$ to depression (intermolecular interactions) or $\nabla^2\rho < 0$ to accumulation (covalent bonds). By the fact that QTAIM is well-applied to heterocyclic structures,[68] we elected to use it on the $C_2H_4O\cdots HF$, $C_3H_6O\cdots HF$, $C_2H_4O\cdots HCF_3$, and $C_3H_6O\cdots HCF_3$ hydrogen-bonded complexes with the purpose of elucidating their hydrogen bond strengths (O···H), as well as the interpretation of the red- and blue-shifts on the proton donors HF and HCF_3.

Computational procedure

The optimized geometries of the hydrogen-bonded complexes $C_2H_4O\cdots HF$, $C_3H_6O\cdots HF$, $C_2H_4O\cdots HCF_3$, and $C_3H_6O\cdots HCF_3$ were obtained through the B3LYP/6–311++G(d,p) theoretical level. The calculations were carried out by GAUSSIAN software version 98W.[71] The ChelpG charges and QTAIM calculations were executed by GAUSSIAN 98W, although it should be highlighted that additional topological calculations were also executed by the AIM2000 1.0[72] program. The values of the hydrogen bond energies (ΔE) were determined

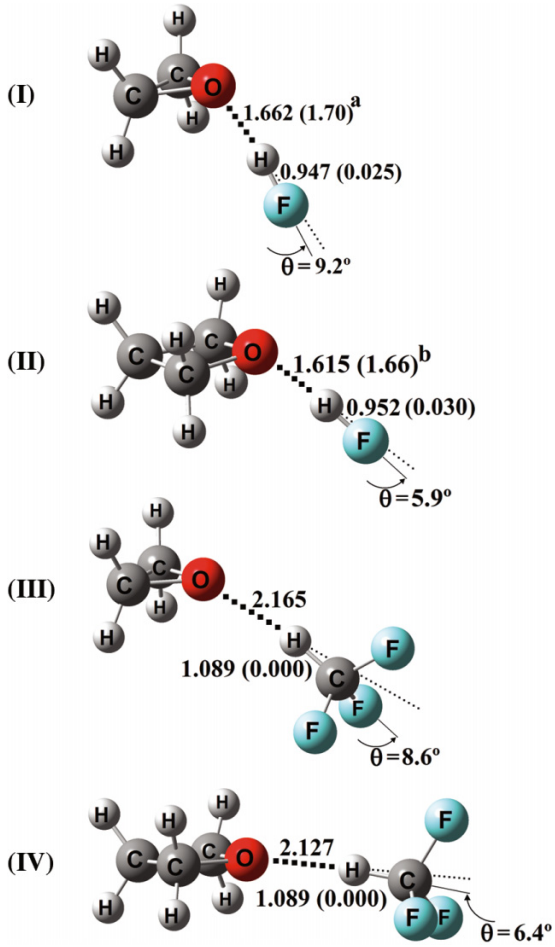
Can. J. Chem. Downloaded from www.nrcresearchpress.com by Renmin University of China on 09/02/12
For personal use only.

in conformity with the supermolecule approach.[9] The ΔE values were corrected through the results of the zero-point energy (ZPE)[73] and basis sets superposition error (BSSE).[74]

Results

Geometry

Figure 1 illustrates the optimized geometries of the $C_2H_4O\cdots HF$ (**I**), $C_3H_6O\cdots HF$ (**II**), $C_2H_4O\cdots HCF_3$ (**III**), and $C_3H_6O\cdots HCF_3$ (**IV**) hydrogen-bonded complexes. The small amount of data available for these systems from the little experimental research that has been done is still very useful for confirming the quality of our work. Actually, the experimental hydrogen bond distances of 1.70[75] and 1.66 Å[76] for **I** and **II**, respectively, are in good agreement with our theoretical results of 1.662 and 1.615 Å, respectively, obtained by means of the B3LYP/6–311++G(d,p) level. With regards to the $C_2H_4O\cdots HX$ complexes with X = F, Cl, CN, and CCH,[77] nonlinearities (θ) on their hydrogen bonds (O···H) are observed.[78] This structural distortion is manifested because of the secondary interactions between the electronegative centers (lone-electron pairs or π-electrons) of the proton donors and the axial hydrogen atoms of the hetero ring.[79] Not only theoretical, but experimental assays also prove the existence of this secondary interaction,[80–82] although at this time, we are not interested in this specific phenomenon. In fact, our objective is concentrated in the structural or vibrational deformations that occur upon the formation of the **I**, **II**, **III**, and **IV** complexes.[83]



In a detailed analysis of the results pictured in Fig. 1, it can be easily perceived that **I** and **II** are the shortest bound systems, which is due to the high polarity of the hydrofluoric acid, as observed in other studies.[57] Regarding the H–F and H–C bond lengths of the proton donors, it can be emphasized that the enhanced results of 0.025 and 0.030 Å, respectively, corroborate the results of the hydrogen bond distances, i.e., the more stronger or shorter bound the complexes are, the more impressive the structural changes on the proton donors are observed. Note that the H–C changes slightly, which was already predicted by Hobza and Havlas,[29] by means of slight variations, in the range of 10^{-3}, when fluoroform binds with oxirane, and thereby the blue-shift on the stretch frequency is manifested.

IR spectrum analysis

Of course, incisive explanations about red- and blue-shift effects on the proton donors HF and HCF_3 can be formulated only after a circumstantial examination of their stretch frequencies,[84] whose values are listed in Table 1. This agrees with Alabugin et al.,[85] who stated that strong and weak bound complexes are vibrationaly identified by the emergence of red- and blue-shifts, respectively. As expected, the values of the red-shift effects are –535.2 and –654.7 cm^{-1} in **I** and **II**, respectively, whereas blue-shifts of +15.7 and +3.1 cm^{-1} are attributed to **III** and **IV**, respectively. We can see a systematic trend in the values of the absorption intensities listed in Table 1, in which increases and reductions of absorption ratios were found in the red- and blue-shift complexes,[86–88] respectively.

However, the hydrogen bond strength cannot be justly analyzed based only on the intermolecular distances and chemical shifts, but the values of the new vibrational modes listed in Table 1 are also considered great spectroscopy arguments in this regard.[89] By furnishing excellent agreement with all results discussed in this work, the spectroscopy criteria indicate that blue-shift complexes **III** and **IV** are weakly bound, either by the new vibrational modes of 94.1 and 82.3 cm^{-1}, respectively, or by the absorption intensities of 5.3 and 2.3 km mol^{-1}, respectively. In opposition to this, the $\upsilon^{Str}_{(O\cdots H-X)}$ values of 254.3 and 258 cm^{-1}, respectively, and $I^{Str}_{(O\cdots H-X)}$ values of 23.3 and 19.3 km mol^{-1}, respectively, are indications that red-shift complexes **I** and **II** are the strongest bonded.

Fig. 1. Optimized geometries of the $C_2H_4O\cdots HF$ (**I**), $C_3H_6O\cdots HF$ (**II**), $C_2H_4O\cdots HCF_3$ (**III**), and $C_3H_6O\cdots HCF_3$ (**IV**) complexes obtained from B3LYP/6–311++G(d,p) calculations.

Hydrogen bond energy and dipole moment

Through B3LYP/6–311++G(d,p) calculations, Table 2 lists the values of the total electronic energies (E), uncorrected results of the hydrogen bond energies (ΔE) and those with correction (ΔE^C), as well as the values of ΔZPE and BSSE for complexes **I**, **II**, **III**, and **IV**. The discovery of the most appropriate calculation level to reproduce or predict molecular properties is considered one of the most important objectives in theoretical chemistry,[90,91] although an old question still was not answered: "'Which is the most efficient method, between B3LYP and MP2, to be used in intermolecular studies?" This is not our focus at this time, but once

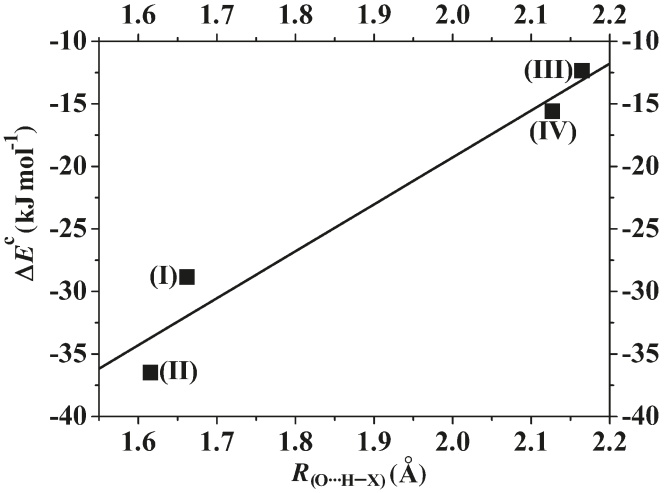
Note: Values of E, ΔE, ΔE^C, ΔZPE, and BSSE are given in kJ mol^{-1}. Values of Δq^T and Δq^P are given in electrostatic units (esu). Values of $\Delta\mu$ are given in Debye (D).

Fig. 2. The relationship (ΔE^C = 37.5 R – 94.3 ; R^2 = 0.97) between the values of the corrected hydrogen bond energies and the hydrogen bond distances. All values were computed at the B3LYP/6–311++G(d,p) level of theory.



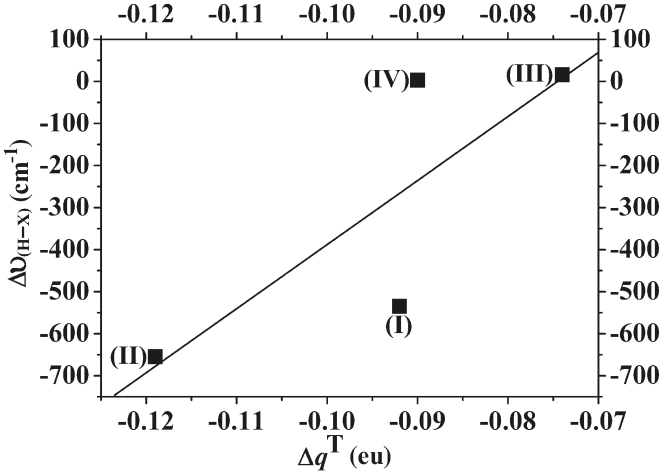


Fig. 3. The relationship ($\Delta\upsilon^{Str}_{(H–X)}$ = 15 234.5Δq^T + 1135.4; R^2 = 0.80) between the values of the red- and blue-shifts and the ChelpG charge transfer. All values were computed at the B3LYP/6–311++G(d,p) level of theory.

there are a large number of published works about this question, this could become a focus of our group.[30,92] However, by examining the values of the total electronic energies computed at the B3LYP/6–311++G(d,p) level, our result of –254.3348532 H for **I** is significantly more stable than the value of –253.77688 divulged by Chandra and Nguyen,[93] who used MP2/6–311++G(d,p) as their standard calculation method. Through the analysis of the hydrogen bond energies, Fig. 2 plots a close relationship between the ΔE^C values and the respective distances, $R_{(O\cdots H–X)}$. As noted in some works that energetic and structural parameters serve as the basis for predicting the interaction strength,[94,95] the amount of the hydrogen bond strength can be reliably observed by means of the relationship featured in Fig. 2, i.e., the computation of the higher ΔE^C energies and shorter

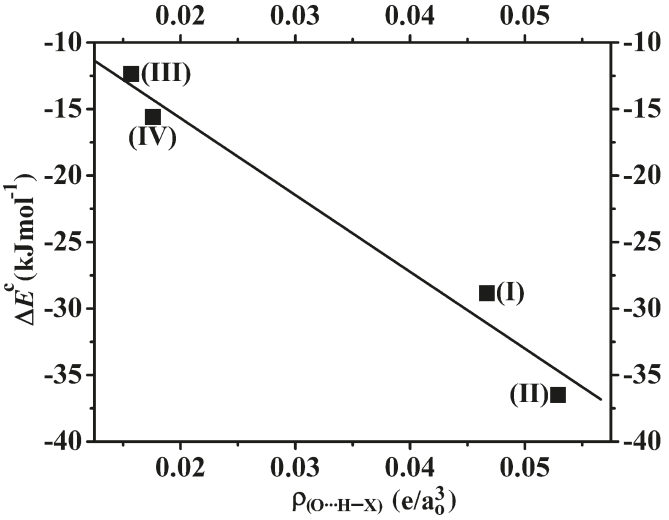
Table 3. Values of the electronic density (ρ) and the Laplacians ($\nabla^2\rho$) of the hydrogen bonds (O···H–X) and proton-donor bonds H–F and H–C.

	Hetero-ring hydrogen-bonded complex			
Parameter	**I**	**II**	**III**	**IV**
$\rho_{(O\cdots H-X)}$	0.047	0.053	0.015	0.017
$\nabla^2\rho_{(O\cdots H-X)}$	0.149	0.160	0.056	0.063
$\rho_{(H-X)}$	0.334	0.327	0.305	0.304
$\nabla^2\rho_{(H-X)}$	–2.43	–2.34	–1.116	–1.165

Note: Values of ρ and $\nabla^2\rho$ are given in e/a_0^3 and e/a_0^5, respectively. Values of ρ related to H–F (hydrofluoric acid monomer) and H–C (fluoroform monomer) bonds are 0.369 and 0.302 e/a_o^3, respectively. Values of $\Delta\rho_{(H-X)}$ computed for **I**, **II**, **III**, and **IV** are –0.035, –0.042, 0.003, and 0.002 e/a_0^3, respectively.

Fig. 4. The relationship ($\Delta E^C = -576.6\ \rho_{(O\cdots H-X)} - 4.17$; $R^2 = -0.98$) between the corrected hydrogen bond energies and the electronic density amounts.



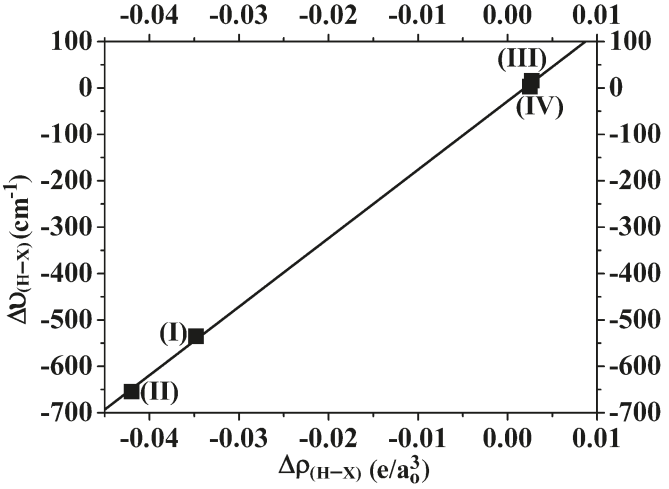


Fig. 5. The relationship ($\Delta\upsilon^{Str}_{(H-X)} = 14\,765\Delta\rho_{(H-X)} - 28.4$; $R^2 = 0.99$) between the values of the red- and blue-shifts versus the variations of the electronic densities of the H–X bonds.

$R_{(O\cdots H-X)}$ distances led us to affirm that blue-shift complexes are weakly bound in comparison with red-shift ones.

Analyzing Table 2, it can be seen that the values of the dipole moment enhancements (Δμ) are in good agreement with the hydrogen bond energies ΔE^C, i.e., ΔE^C (**II**) > ΔE^C (**I**) and Δμ (**II**) > Δμ (**I**), as well as ΔE^C (**IV**) > ΔE^C (**III**) and Δμ (**IV**) > Δμ (**III**). From the literature, Δμ is a measurement of the molecular distortion. Thus, it can be also used to interpret the interaction strength even indirectly, and indeed, the extension of the dipole moment enhancement is closely related with the charge transfer, as recently demonstrated by Stone and Misquita.[96] With this insight, it should be observed that charge transfer amounts from either Δq^T or Δq^P are in a good relationship with Δμ.

Charge transfer

It is well-known that the hydrogen bond energy is governed by the charge transfer between the molecular frontier orbitals, wherein the HOMO and LUMO are ascribed to the acceptor and donor of protons, respectively.[97] Here, it must be emphasized that the charge transference mechanism presents distinct profiles in both red- and blue-shift complexes. The charge fluxes in **I** and **II** are concentrated between hydrogen and fluorine on the hydrofluoric acid, whereas the charge transferred is dispersed among the carbon, hydrogen, and fluorine of the fluoroform in **III** and **IV**. To analyze these charge transference amounts, we decided that two measures should be done: (*i*) full charge transfer (Δq^T) along the proton donor molecule and (*ii*) partial charge transfer (Δq^P) on the hydrogen atom of the proton donors. Thus, we expect a clear justification about the formation of the red- and blue-shift effects, since the direct relationship between charge transfer and chemical shifts is well-known.[17,18,58,98] The Δq^T and Δq^P values are presented in Table 2. Throughout this work, it has been demonstrated that **I** and **II** are the stronger bound systems, which was also observed by means of the Δq^T values of –0.092 and –0.119 esu. Figure 3 demonstrates, however, that a satisfactory relationship between Δq^T and red- and blue-shifts could not be obtained.

However, if the charge transfer was partial (Δq^P), a good relationship could not be verified. For instance, the charge transfer values of –0.065 and –0.071 esu, respectively, are not in agreement with the respective blue-shift values of +15.7 and +3.1 cm^{-1}, respectively, in the **III** and **IV** systems. Furthermore, by comparing the Δq^P values of –0.057 and –0.065 esu, respectively, with the results for ΔE^C of –28.85 and –12.36 kJ mol^{-1}, respectively, once again, no direct relationship was obtained. It would be expected that the more stronger bonded the intermolecular system, the more intense the charge transfer should be, but this was not observed. In this context, it is necessary to use an alternative approach that can be efficiently used to validate the formation of the red- and blue-shifts of the hydrogen-bonded complexes **I**, **II**, **III**, and **IV**.

Bonding topology

When the QTAIM content and its applicability in studies of electronic structure was revisited,[99,100] the great capability of this theoretical method to evaluate the chemical bond and the electronic dynamism related to atomic interaction, either

Can. J. Chem. Downloaded from www.nrcresearchpress.com by Renmin University of China on 09/02/12
For personal use only.

in classical chemical bonds such as covalent or unsaturated ones,[101] and, of course, in the unusual intermolecular interactions, could be perceived.[102–105] The values in Table 3 demonstrate that low amounts of electronic density, in the range of 0.015–0.053 e/a_0^3, are associated with positive Laplacian values. These are two topological arguments of the QTAIM formalism used to characterize the hydrogen bonds O···H–F and O···H–C. As mentioned, the charge concentration on the H–F and H–C bonds is evidenced by the negative Laplacian values accompanied by high charge density, which also can be seen in Table 3. Nevertheless, a question still must be answered here: Owing to the failure of the ChelpG charge transfer in the interpretation of the red- and blue-shift effects, is it possible that another analysis yields more efficient results? From the values listed in Table 3, a reduction of the electronic density in the H–F bonds, with variations from 0.369 (hydrofluoric acid monomer) to 0.334 and 0.327 e/a_o^3 upon the formation of the red-shifted complexes **I** and **II**, can be observed. On the other hand, the electronic density of 0.302 e/a_0^3 of the H–C of the fluoroform monomer is constant, with values for **III** and **IV** of 0.305 and 0.304 e/a_0^3, respectively.

In this work, it has been demonstrated that stronger and weaker hydrogen bonds are characterized by the appearance of red- and blue-shift effects, although a new relationship was formulated between the hydrogen bond energies and electronic density amounts computed using the QTAIM. By this insight and the results plotted in Fig. 4, it is assumed that the alterations of the charge density of the H–F and H–C bonds are caused by the hydrogen bond strength.

Ideally, it can be perceived that weak hydrogen bonds cannot provoke significant changes in the electronic densities of the proton donors and vice-versa. In this context, the results illustrated in Fig. 5 show the relationship between the values of the red-shift and blue-shift and the variations in the electronic densities of the H–F and H–C bonds when **I**, **II**, **III**, and **IV** are formed.

As can be easily noted, an excellent relationship between ΔE^C and $\Delta\rho_{(H-X)}$ was obtained. In opposition to traditional studies of intermolecular systems, this result indicates that the charge transfer analysis does not always produce good results to validate the inherent phenomena of the hydrogen bonds, but the QTAIM electronic density behaves as a trusted parameter to this type of investigation, as already reported in recent work.[106]

Conclusions

In this work, a theoretical study of the molecular parameters of hydrogen-bonded complexes was presented. The structures $C_2H_4O\cdots HF$, $C_3H_6O\cdots HF$, $C_2H_4O\cdots HCF_3$, and $C_3H_6O\cdots HCF_3$ were conceived with prominence to the generation of the red- and blue-shifts on the stretch frequencies of the proton donors. Because of this, our discussion was dedicated to the inefficiency of the ChelpG in the evaluation of the charge transfer to be used in the interpretation of these chemical shifts. In conformity with traditional intermolecular systems studies, this is unusual as ChelpG is well-recognized as one of the most efficient approaches used in punctual charge calculations, but here we found that we had to apply an alternative procedure to this analysis type: the QTAIM topology. The structural and electronic analysis showed that the hydrogen bond strength can be interpreted through the direct relationship between distances and the corrected binding energies.

By taking into account the vibrational parameters, it was observed that red- and blue-shifts are closely related with stronger and weaker bound systems. Topologically, drastic and slight electronic density variations in the H–F and H–C bonds of the proton donors correlate with high and low binding energies, which is also correlated with red- and blue-shifted complexes. In this context, it a justification was proposed to the red- and blue-shifts based on the electronic density analysis. Henceforth, we expect that our results can be useful in further spectroscopy studies, mainly those composed of weak intermolecular systems with nontrivial vibrational characterization.

Abstract: The organophosphorous compound tabun is highly neurotoxic because of its irreversible inhibition on acetylcholinesterase (AChE). It is wildly used as a warfare agent in the military. In this work, the aging and reactivation mechanism of tabun-inhibited AChE were studied by using the quantum mechanical / molecular mechanical (QM/MM) method. Geometry optimization of the stationary points were performed at the B3LYP/6–31G(d) level. Single-point energies were computed at the B3LYP/6–311++G(d,p) level. On the basis of the QM/MM results, a conclusion that the C–O bond scission is caused by water attack on the ethoxy group in the aging mechanism can be drawn. The reactivation process initialed by the antidotes CH_2NO^- or HLÖ-7 consists of three elemental steps, the nucleophilic attack on the P atom by the antidote, the dephosphorylation process, and the decomposition of the antidote–tabun complex. The highest energy barriers of the aging reaction, CH_2NO^--induced reactivation, and HLÖ-7-induced reactivation are 19.9, 20.0, and 14.8 kcal/mol (1 cal = 4.184 J), respectively. The relative lower overall energy barrier of HLÖ-7-induced reactivation compared with that of the aging reaction indicates that HLÖ-7 is able to reactivate tabun-inhibited AChE. In addition, whether a newly designed antidote is able to reactivate tabun-inhibited AChE can be examined by the inequation $X < 19.9$ kcal/mol,where X means the highest energy barrier of the reactivation reaction of the newly designed antidote.

Key words: tabun, aging mechanism, reactivation mechanism, QM/MM method.

Résumé : Le tabun, un composé organophosphoré, est extrêmement neurotoxique en raison de son inhibition irréversible de l'acétylcholinestérase (AChE). Il a été utilisé comme arme chimique. Dans ce travail, faisant appel à la méthode de mécanique quantique / mécanique moléculaire (MQ/MM), on a étudié le vieillissement et le mécanisme de réactivation de de l'AChE inhibée par le tabun. On a effectué l'optimisation de la géométrie des points stationnaires au niveau B3LYP/6–31G(d) de la théorie. On a calculé les énergies des points uniques au niveau B3LYP/6–3111++G(d,p) de la théorie. Sur la base des résultats de méthode de MQ/MM, il est possible d'arriver à une conclusion à l'effet que, dans le mécanisme de vieillissement, la scission de la liaison C–O est causée par l'attaque d'une molécule d'eau sur le groupe éthoxy. Le processus de réactivation initié par les antidotes CH_2NO^- ou HLÖ-7 comporte trois étapes élémentaires, l'attaque nucléophile sur l'atome de phosphore par l'antidote, le processus de déphosphorylation et la décomposition du complexe antidote-tabun. La barrière d'énergie la plus élevée de la réaction de vieillissement, la réactivation induite par le CH_2NO^- et la réactivation induite par le HLÖ-7 sont respectivement de 19,9, 20,0 et 14,8 kcal/mol (1 cal = 4.184 J). Le niveau relativement plus bas de l'énergie d'activation globale pour la réactivation induite par le HLÖ-7 comparée à celle de la réaction de vieillissement indique que le HLÖ-7 peut réactiver l'AChE inhibée par le tabun. De plus, la possibilité qu'un nouvel antidote puisse réactiver l'AChE inhibée par le tabun a été examinée par l'inéquation $X < 19{,}9$ kcal/mol dans laquelle X correspond à la barrière d'énergie la plus élevée de la réaction de réactivation du nouvel antidote mis au point.

Mots-clés : tabun, mécanisme de vieillissement, mécanisme de réactivation, méthode MQ/MM.

Introduction

Organophosphorus (OP) compounds, such as paraoxon, methamidophos, VX, and tabun, have been used as insecticides in modern agriculture or as chemical warfare agents in the military. The broad distribution of OP compounds causes huge numbers of intoxications and thousands of deaths each year.[1,2] In addition, the OP chemical warfare agents are still widely used in the globalization and escalation of terrorist attacks as well as in other military conflicts since the 1990s. Tabun is the earliest synthesized chemical warfare agent and its output reached 10 000 – 12 000 tons during 1936–1944.[3,4] Because of its simple 3D structure, tabun can be a perfect model and representation for OP compounds in theoretical

study. Tabun can firmly combine with acetylcholinesterase (AChE; EC 3.1.1.7) and hinder its hydrolysis function towards the neurotransmitter acetylcholine (ACh). For example, Ser203, which is a critical amino acid in the active site of AChE, can be inhibited by tabun through nucleophillic attack. This inhibiting progress is also called "phosphonylation reaction". The inhibited AChE may spontaneously change into the "aged" state through an "aging reaction", making AChE irreversibly inactive. Successive accumulation of acetylcholine will paralyze neurotransmission and eventually lead to muscle fasciculation and respiratory failure. Without injecting the proper antidote immediately, people may die soon after the poisoning.[5] Actually, the inhibited AChE can be reactivated if a nucleophile attacks the P atom of tabun and removes it from the active site before the aging reaction.

There are two hypotheses about the aging mechanism of tabun-inhibited AChE: one suggests that the P–N bond breaks in the aging progress[6] and the other suggests that the aging reaction proceeds via O-dealkylation.[7] Both of the hypotheses are based on mass spectrometry studies. Kinetic analysis[8] and mechanisms[9] of reactivation and aging pathways by different phosphoramidates have also been reported. However, the aging and reactivate mechanisms of tabun-inhibited AChE have not been fully understood, and many details should be elucidated, such as the exact location of the antidotes, the structure information of the intermediates and transition states, and the movement and function of the critical amino acids in the active site. In the present work, the quantum mechanical / molecular mechanical (QM/MM) calculations were performed to clarify these issues. CH_2NO^- and HLÖ-7 were selected as the models. Some useful guidance in designing more efficient antidotes is also provided based on the computational results.

Computational methods

The QM/MM calculations were performed with the ChemShell package[10] integrating Turbomole[11] and DL-POLY programs.[12] The QM calculations were carried out by Turbomole with the aid of density functional theory (DFT).[13–15] The QM part was treated at the B3LYP/6–31G(d) level, and the single-point energies of the intermediates and transition states were calculated at the B3LYP/6–311++G(d,p) level, while the MM region was considered by the CHARMM22[16] force field. The QM and MM energies are considered complementary in our QM/MM calculations. The energy equation is as follows (E = entire, I = inner, O= outer, L = link, and Corr = corrections):[17]

$$E^{E}_{QM/MM} = E^{O}_{MM} + E^{I,L}_{QM} + E^{I,O}_{QM-MM} - E^{I,L}_{Corr}$$

An electronic embedding scheme[18] incorporating the MM charges into the one-electron Hamiltonian of the QM treatment and hydrogen link atoms with a charge shift model[19,20] were adopted for the QM/MM boundary. The default convergence criteria have been adopted in the QM/MM calculations with HDLC optimizers[21] for the reactant, intermediates, and product. The potential energy surface scan from reactant to product was employed in searching the transition state. Various potential energy surface (PES) scans (for example, P–O bond formation in the nucleophilic attack progress) were performed by constraining the relevant internal coordinates. The corresponding structure of the highest energy point during the PES was extracted and optimized before we confirmed its transition-state characteristics. All the structures were viewed through the VMD program.[22]

Refinement of the crystal structure

The simulation system was prepared on the basis of the crystal structure of mouse AChE (PDB code: 3DL7) obtained from the Protein Data Bank (http://www.pdb.org). According to the protein information in the file 3DL7.pdb, 11 residues are missing in the ChainA. The MODELLER[23] program was employed to replenish ChainA. The missing hydrogen atoms were added using the HBUILD facility in the CHARMM package.[24] CH_2NO^- was docked into the AChE enzyme using Accelrys Discovery Studio 2.1 (Accelrys Software Inc.). In fact, the crystal structure of the tabun–HLÖ-7–AChE complex (PDB code: 2JEZ) has been reported,[25] however, to make the results comparable, HLÖ-7 was extracted from 2JEZ and then docked with 3DL7 using Accelrys Discovery Studio 2.1. Together with the crystal water molecules, the antidote–AChE complex was initially placed in a cubic box with 42 875 water molecules. The cubic box was then modified to a sphere with a radius of 42 Å. The molecular dynamic simulation was done by the CHARMM program with the CHARMM22 force field for protein and the TIP3P model[26] for water. The force field for the antidote (CH_2NO^- and HLÖ-7) was built on the basis of the CHARMM General Force Field.[27] The system was then neutralized by nine sodium ions at random positions. The antidote was kept fixed while the others were allowed to move freely, then the constraints were removed. The system was first gradually heated from absolute zero to 298.15 K by 50 000 steps, then it was equilibrated thermally for 500 000 steps to reach the equilibration state, and then the canonical (NVT) ensemble was employed in the 2 ns simulation dynamics. The QM/MM calculation started with the last snapshot of the simulation dynamics. The analysis results (equilibration tendency of total energy and system stability) of the 2 ns simulation dynamics are shown in the Supplementary data (Figs. S1–S6).

Determination of the QM and movable MM regions

In the aging reaction, the QM subsystem is composed of key parts of residues Gly121, Gly122, Glu202, Sun203 (combination of Ser203 and tabun), Glu334, His447, and a water molecule with 77 atoms. It is labeled blue in Fig. 1A. In the reactivation reaction induced by CH_2NO^-, the QM subsystem, which is labeled blue in Fig. 1B, consists of 72 atoms. The MM region is selected within 6 Å of residues Gly121, Gly122, Sun203, Glu334, His44,7 and CH_2NO^-, with 1898 movable atoms. In the reactivation reaction induced by HLÖ-7, the QM subsystem consists of 106 atoms. All of the atoms within 20 Å of the P atom were selected to be the movable MM region, which contains 3993 atoms.

In the aging reaction, atoms within 6, 8, and 10 Å of residues Gly121, Gly122, Sun203, Glu334, and His447 were selected to be the movable MM region to test its contribution to the energy value of the optimizations. There are 1783, 2941, and 4684 movable atoms in the MM region, respectively. The results show that different scales for the MM region merely change the energy barrier of the reaction. Thus, although the movable atom number of the MM region is

Labeled figures are key distances of the reaction center. The colour version of this figure can be viewed with the article on the journal Web site.

different, the results obtained from the aging reaction and CH_2NO^-- or HLÖ-7-induced reactivation are comparable.

Results and discussion

Aging reaction initiated by a water molecule

A water molecule shown in Fig. 2 is involved in the aging reaction. This water molecule is supposed to be not far from the ethoxy moiety. Thus, it can easily attack the carbon atom of the ethoxy moiety. However, the crystal structure (PDB code: 3DL7) fails to provide the precise position of the water molecule because of low resolution or other unknown factors. We found the precise position of the water molecule by MD simulation using the CHARMM22 force field. An earlier study focused on the phosphonylation mechanism of tabun-inhibited AChE[28] and indicated that His447 should be at the protonated state and share a hydrogen bond with Sun203. Our optimized structure indicates that His447 is too far away from the water molecule to abstract an H atom from it. However, it can facilitate the aging reaction by gradually moving to the oxygen atom of the ethoxy moiety and attracting the electrons of the C–O bond, making it easier to break. On the other hand, Glu202 abstracts a hydrogen atom from the water molecule and promotes the nucleophilic attack on the carbon atom of the ethoxy moiety. The QM/MM results show that the aging reaction can occur easily (energy barrier 19.9 kcal/mol). This is consistent with the widely accepted idea that the aging reaction of tabun-inhibited AChE is spontaneous.

CH_2NO^--induced reactivation

Oximes are used as potential reactivators for OP-inhibited AChE. The simplest oxime, formaldehyde oximate anion (CH_2NO^-), was chosen as one model. In the present study, we mark the model that contains th eamino acid Glu334 in

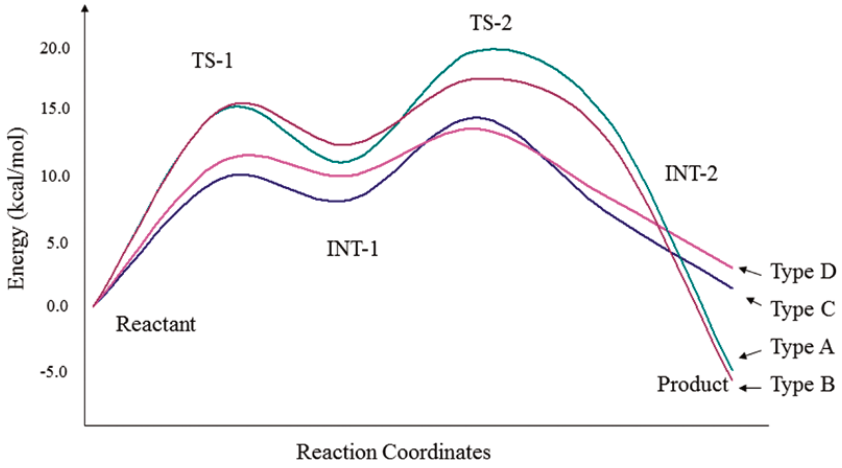
D	173.3	118.0	112.6	128.8

the QM subsystem as type A. The location of this oximate anion can be determined by MD simulation using the CHARMM force field together with the geometry optimization of the AChE–tabun–oximeate anion complex. The MD results show that the anion is stabilized by three surrounding water molecules.

The first step of the reactivate mechanism is the nucleophilic attack on the P atom by CH_2NO^-. This process should overcome an energy barrier of 15.3 kcal/mol. From Table 1, we find that the lengths of the O^{α}–P bond, O^{γ}–P bond, N^{ω}–P, and O^{δ}–P bond slightly increase during the nucleophilic attack. The angles of O^{β}–P–O^{γ}, O^{α}–P–N^{ω}, N^{ω}–P–O^{γ}, and O^{γ}–P–O^{α} are 170.1°, 114.5°, 118.6°, and 125.9°, respectively. The structure of intermediate 1 (INT-1) clearly shows the trigonal bipyramidal characteristic (Supplementary data Fig. S7). The second step is known as the dephosphorylation. His447 may steadily approach and donate a proton to the O^{δ} atom, which causes the H–O^{δ} bond formation and the P–O^{δ} bond scission. This process needs to overcome a barrier of 8.7 kcal/mol, which is lower than the first step. Comparing some key distances of the reactant with transition state 1 (TS-1), INT-1, TS-2, and INT-2, we find that distance 7 (D7), D8, and D9 change gradually while D1, D2, D3, D5, and D6 stay stable (Table 1; Supplementary data Figs. S7 and S8). The last step is the decomposition of the CH_2NO^-–tabun complex from the catalytic center of AChE. As a whole, the nucleophilic attack step is the rate-determining step (the energy barrier is 15.3 kcal/mol).

We mark the QM subsystem without Glu334 as type B. Type B is used to compare with type A to test the influence of the residue GLU334 on the reactivation reaction, especially on the energy barriers. This strategy has been adopted and explained in a former article.[29] In type B, the energy barrier of the nucleophilic attack step is 15.4 kcal/mol, which is almost the same as type A (15.3 kcal/mol). This indicates that including or not including Glu334 in the QM part has little impact on the nucleophilic attack step. However, the energy barrier of the dephosphorylation reaction is 5.2 kcal/mol in type B, which is 3.5 kcal/mol lower than that of type A.

Fig. 3. Energy profiles of reactivation reaction types A, B, C, and D. These reactions were determined by the B3LYP/6–311++G**: CHARMM quantum mechanical / molecular mechanical (QM/MM) method.



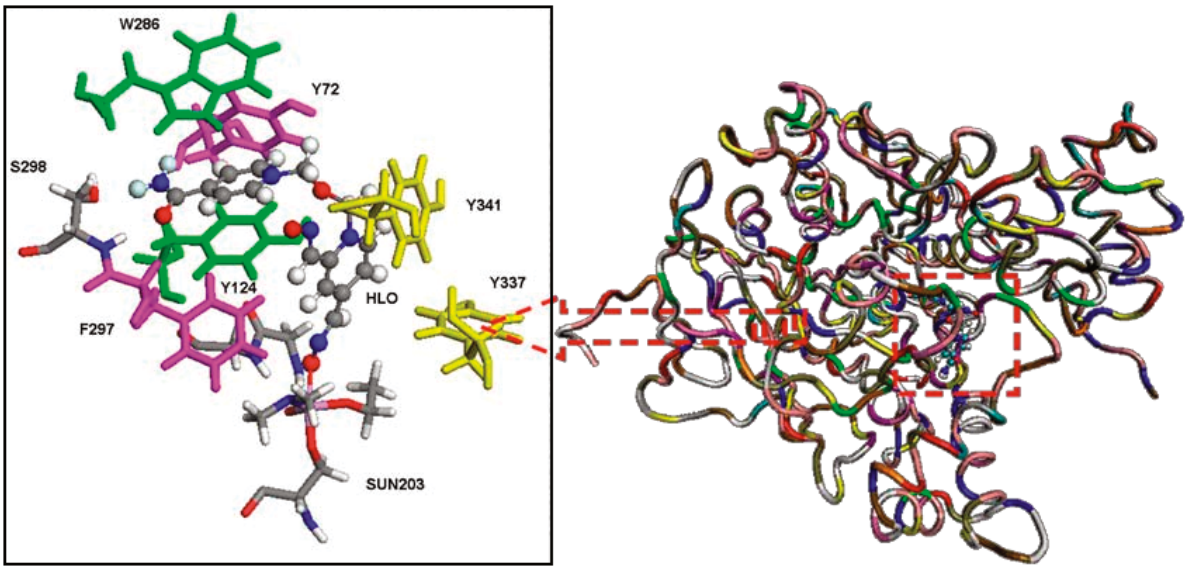


Fig. 4. The surrounding amino acids of HLÖ-7 and its location in acetylcholinesterase (AChE).

This means Glu334 does hinder the P–O$^{\delta}$ bond scission. Glu334 stabilizes INT-1 more than TS-2, consistent with the previous study; therefore, this glutamic acid facilitates the phosphonylation reaction.[30] The changes in D10 shown in Table 1 provide the information that Glu334 gradually leaves His447 without proton transfer. Energy profiles of reactivation reaction types A and B are shown in Fig. 3. The optimized structures are provided in the Supplementary data (Figs. S7 and S8). The computed single-point energies of each optimized structure along the reaction paths are shown in Table 2.

HLÖ-7-induced reactivation

One of the rings of HLÖ-7 is located near the ring of Trp286 and of Tyr124 by π-stacking interaction. Three hydrogen bonds are formed separately with Ser298, Phe297, and the amide group. The other ring is aligned by Tyr124, Tyr341, and Tyr337, shown in Fig. 4. In the study of HLÖ-7-induced reactivation, two models were built: one with Glu334 in the QM subsystem is defined as type C, the one without Glu334 in the QM subsystem is defined as type D. The INT-1 angles shown in Table 3 demonstrate its trigonal bipyramidal characteristics, which is in accordance with the results by da Silva Gonçalves et al.[20] Figure 5 shows the optimized structure information of the nucleophilic attack step of type C. In type C, the barrier of the reaction INT-1 → INT-2 is 6.5 kcal/mol, whereas it is 3.7 kcal/mol in type D. This reconfirms the conclusion above that Glu334 stabilizes INT-1 more than TS-2 in the dephosphorylation reaction. As shown in Fig. 3, the highest barriers of the HLÖ-7- and CH_2NO^--induced reactivation reactions are 14.8 and 20.0 kcal/mol, respectively. This distinctness may be caused by the structure difference of the two antidotes. The optimized structure information of the rest of the two steps are shown in Fig. 6.

The comparison of the aging reaction, CH_2NO^-- and HLÖ-7-induced reactivation

The CH_2NO^-- and HLÖ-7-induced reactivation mechanisms share two main common points: (*i*) They both consist of three steps: nucleophilic attack on the P atom, the dephosphorylation process, and the decomposition of the antidote–tabun

complex from the active site; and (*ii*) They both have an intermediate with the trigonal bipyramidal characteristics.

One main difference is that the highest energy barrier of the CH_2NO^--induced reactivation reaction is 5.2 kcal/mol

Can. J. Chem. Downloaded from www.nrcresearchpress.com by Renmin University of China on 09/02/12
For personal use only.

higher than that of the HLÖ-7-induced reactivation reaction. An inequation can be drawn: $X < 19.9$ kcal/mol, where X means the overall energy barrier of the reactivation reaction by any antidotes, such as CH_2NO^-, HLÖ-7, pralidoxime, obidoxime, TMB-4, or HI-6.[31] The energy barrier of the aging reaction is 19.9 kcal/mol. If X is greater than 19.9 kcal/mol, the antidote will not be able to reactivate tabun-inhibited AChE. In addition, our results showed that the overall reactivation reaction by HLÖ-7 is endothermic, which indicates the reaction is reversible to some extent. Although the energy barrier is lower than 19.9 kcal/mol, it still seems that it is not a highly efficient oxime. The computational results are in accordance with the experiment data where maximum reactivation of tabun-inhibited AChE by HLÖ-7 is around 45%.[8] Thus, a second criterion of exothermicity is also useful for forecasting the reactivate efficacy of the newly designed antidote.

Conclusion

The aging mechanism and the reactivate mechanism were studied and elucidated in this work. HLÖ-7 was proved to be able to reactivate tabun-inhibited AChE by a QM/MM study. We provided an inequation ($X < 19.9$ kcal/mol) by two antidotes: CH_2NO^- and HLÖ-7. Besides this inequation, a second criterion of exothermicity is also introduced in forecasting the reactivate efficacy of the newly designed antidote. Of course, other already known useful antidotes should be tested using the same method to check the accuracy of the inequation.

Abstract: Volatile organic compounds (VOCs) are emitted as pollutants into the atmosphere from many natural and artificial sources. The oxidation of VOCs by atmospheric species plays a key role in the degradation of VOCs. In the present investigation, the atmospheric degradation of a cyclic organosulfur compound, 1,4-thioxane, by an $NO_3^\bullet$ radical is studied. Pathways for the reaction of 1,4-thioxane with the $NO_3^\bullet$ radical were modeled through electronic structure calculations using density functional theory methods B3LYP, M06-2X, and MP2 with the 6–31G(d,p) basis set. The $NO_3^\bullet$-initiated reaction of 1,4-thioxane was found to proceed in three ways: by single-hydrogen atom abstraction, by direct transfer of the O atom of $NO_3^\bullet$ to the S atom moiety of 1,4-thioxane, or by two-hydrogen atom transfer reactions leading to the formation of a peroxy radical intermediate, which further undergoes secondary reactions with other atmospheric species. Structures, energies, and vibrational frequencies obtained from M06-2X/6–31G(d,p) electronic structure calculations were subsequently used to perform canonical variational transition-state theory calculations to determine the rate constants over the temperature range of 278–350 K and to study the lifetime of 1,4-thioxane in the atmosphere. The rate constant calculated for the reaction of 1,4-thioxane with the $NO_3^\bullet$ radical is in good agreement with the available experimental data.

Key words: 1,4-thioxane, atmospheric reactions, NO_3 radical, energy barrier, rate constant.

Résumé : Les composés organiques volatils (COVs) peuvent être émis dans l'atmosphère comme polluants émis par des sources naturelles et artificielles. L'oxydation de COVs par des espèces atmosphériques joue un rôle clé dans la dégradation des COVs. Dans le présent travail, on a étudié la dégradation atmosphérique d'un composé organosulfuré, le 1,4-thioxane, par le radical $NO_3^\bullet$. On a effectué une modélisation des voies possibles pour la réaction du 1,4-thioxane avec le radical $NO_3^\bullet$ et, à cette fin, on a fait appel à diverses méthodes de la théorie de la fonctionnelle de la densité, B3LYP, M06-2X et MP2 avec un ensemble de base 6–31G(d,p). On a trouvé que la réaction du 1,4-thioxane initiée par le $NO_3^\bullet$ pour s'effectuer suivant trois voies réactionnelles, par enlèvement d'un seul atome d'hydrogène, par transfert direct d'un atome d'oxygène du NO_3 à la portion sulfuré du 1,4-thoxane ou par des réactions de transfert de deux atomes d'hydrogène conduisant à la formation d'une intermédiaire radicalaire peroxy qui subit par la suite des réactions secondaires par réaction avec d'autres espèces atmosphériques. Les structures, les énergies et les fréquences vibrationnelles obtenues par calculs de structure électronique M06-2X/6–31G(d,p) ont subséquemment été utilisées pour effectuer des calculs selon la théorie de l'état de transition variationnel canonique dans le but de déterminer les constantes de vitesse pour la plage de température allant de 278 à 350 K et pour étudier le temps de vie du 1,4-thioxane dans l'atmosphère. La constante de vitesse calculée pour la réaction du 1,4-thioxane avec le radical $NO_3^\bullet$ est en bon accord avec les données expérimentales disponibles.

Mots-clés : 1,4-thioxane, réactions atmosphériques, radical NO_3, barrière d'énergie, constante de vitesse.

[Traduit par la Rédaction]

Introduction

Volatile organic compounds (VOCs) are emitted as pollutants into the atmosphere from anthropogenic and biogenic sources.[1–5] These compounds undergo a series of chemical reactions, leading to their removal from the troposphere or transformation into other compounds. The possible degradation process for these VOCs is their reactions with $OH^\bullet$ and $NO_3^\bullet$ radicals present in the atmosphere. The reactions of VOCs with these radicals can also lead to the formation of ozone, which is the major constituent of photochemical smog.[6] The $NO_3^\bullet$ radical is a common constituent of the atmosphere in the nighttime, and its maximum concentration is typically 10∼100 ppt.[7] The reaction of the $NO_3^\bullet$ radical with VOCs takes place during nighttime because $NO_3^\bullet$ rapidly photolyzes during the day time.[8] $NO_3^\bullet$ has been detected in both polluted and remote regions[9] of the atmosphere and thus the reaction of $NO_3^\bullet$ with VOCs acts as a driving force for the degradation of the VOCs. These reactions lead to the formation of products that are either harmless, do less harm, or are even hazardous to life on earth. Hence, it is very important to study the reaction between VOCs and the $NO_3^\bullet$

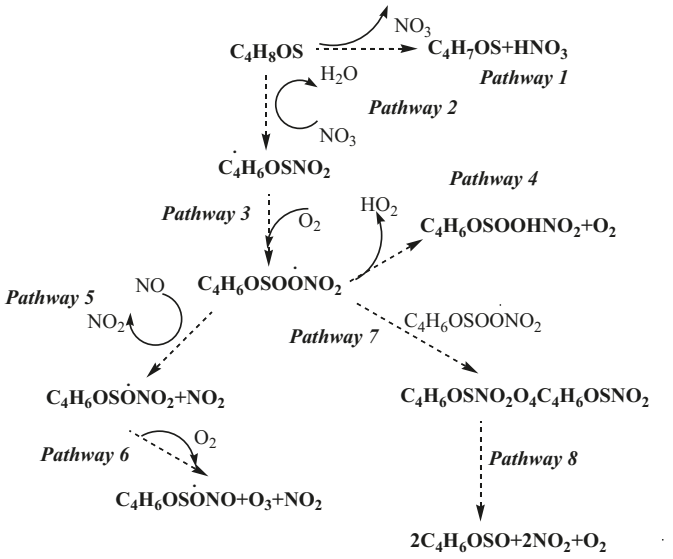
radical to know about the different degradation pathways. Also, the kinetics of the reactions are essential for finding the lifetimes of the VOCs emitted into the atmosphere and to understand the environmental implications.

The reaction kinetics of sulfur-containing VOCs have been studied and were reported on in various articles.[6,10–13] The cyclic organosulfur compound 1,4-thioxane is a breakdown product of a chemical weapon agent called mustard gas when it is disposed in the sea.[14,15] These organosulfur compounds are released into the atmosphere as a result of fossil fuel refining and combustion.[6] Recently, the kinetics of the reaction of 1,4-thioxane with NO_3• was evaluated experimentally by Aschmann et al.[16] The measured rate constant for the reaction of 1,4-thioxane with the NO_3• radical at room temperature is 5.9×10^{-14} cm^3 $molecule^{-1}$ s^{-1}. Except for this kinetic data, the reaction mechanism for the oxidation of 1,4-thioxane by the NO_3• radical and the reactions subsequent to the principal oxidation step have not been studied. As shown in previous studies, the formation of ozone is expected in the secondary reactions of the NO_3•-initiated reaction of VOCs.[1,8] Hence, the experimental study by Aschmann et al.[16] merits a theoretical study to analyze the reaction mechanism for 1,4-thioxane degradation by NO_3•.

In the present work, the interaction of the NO_3• radical with 1,4-thioxane was studied at two different C-atom sites, one at the C atom nearer to the O atom of 1,4-thioxane and the other at the C-atom site nearer to the S-atom of 1,4-thioxane. Previous studies[17–19] on the reactions of VOCs with the NO_3• radical have shown that the reactions involve two key intermediates, a peroxy radical and an alkoxy radical. In the present work, three possible reaction mechanisms are proposed for the NO_3•-initiated reactions of 1,4-thioxane. One of the mechanisms involves the abstraction of a single H atom from the CH_2 group of 1,4-thioxane by NO_3•, and the second mechanism involves the abstraction of two H atoms from the CH_2 group by NO_3•. The latter mechanism is characterized by an interesting proton-coupled electron transfer process. As shown in Figs. 1 and 2, the alkyl radical is formed through the abstraction of the hydrogen atoms of the CH_2 group in 1,4-thioxane. Furthermore, the alkyl radical reacts with O_2 to form alkyl peroxy radical as the first key intermediate. This alkyl peroxy radical interacts with NO and produces NO_2 and an alkoxy radical, which is the second key intermediate. The alkoxy radical further reacts with O_2 in the atmosphere and leads to the formation of ozone. Furthermore, a variety of potential secondary reaction paths are possible owing to the reaction between atmospheric species and the alkoxy radical. An important characteristic of the alkyl peroxy radical is its capability to undergo a self reaction.[20,21] The third reaction mechanism proceeds via the direct transfer of the O atom of NO_3 to the S-atom moiety of 1,4-thioxane.

To the best of our knowledge, the details of the reaction mechanisms of organosulfur compounds with the NO_3• radical are very limited. Except for the initial hydrogen atom abstraction step,[16] the reaction mechanisms and kinetics of secondary reactions for 1,4-thioxane with the NO_3• radical have not been studied. To determine the degradation pathways, a complete knowledge of the reaction mechanism is very essential. In view of the above-mentioned exposures, the aim of this work is to model the different reaction pathways for the degradation of 1,4-thioxane by the NO_3• radical using quantum chemical methods, and to determine the kinetics of the most favorable reactions using variational transition-state theory.[22]

Fig. 1. Reaction scheme for the interaction of NO_3• radical at the C-atom site adjacent to the O atom of 1,4-thioxane.



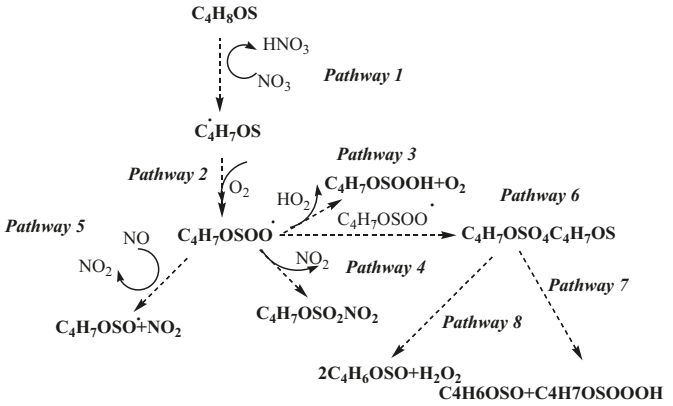


Fig. 2. Reaction scheme for the interaction of NO_3• radical at the C-atom site adjacent to the S atom of 1,4-thioxane.

Computational methods

The geometry of the minima and first-order saddle points on the potential energy surface of the reaction of 1,4-thioxane with the NO_3• radical were optimized using hybrid density functional theory methods, B3LYP[23,24] and M06-2X[25] with the 6–31G(d,p) basis set. Selected stationary points on the potential energy surface of the reaction system also were optimized at the MP2[26–28] level of theory with the 6–31G(d,p) basis set. At these levels of theory, the harmonic vibrational frequencies were calculated for all the optimized geometries to verify the nature of the stationary points. All minima were confirmed with positive frequencies and each transition state had one imaginary frequency confirming their location as maxima in one reaction coordinate. The connection of transition-state structure between designated reactant and product was confirmed in each case by intrinsic reaction coordinate

(IRC) calculations using the B3LYP and M06-2X methods using the second-order algorithm of Gonzalez and Schlegel.[29,30] The energy derivatives including gradients and hessians at stationary points along the minimum energy path (MEP) were also obtained. The enthalpy of a reaction and barrier height were calculated by including thermodynamic correction to the potential energy surface at a temperature of 298.15 K and 1 atm (1 atm = 101.325 kPa) pressure. All the electronic structure calculations were performed using the Gaussian09 program package.[31]

The theoretical rate constants for the most favorable reactions of 1,4-thioxane with the NO_3• radical were calculated using canonical variational transition-state theory (CVT).[32–34] The quantum effect correction for the CVT rate constant was made by small curvature tunneling (SCT) calculations.[35,36] The potential energy surface, gradients, and hessians obtained from M06-2X/6–31G(d,p) level electronic structure calculations were directly used to calculate the rate constants. Through CVT, the rate constant at temperature T is given by

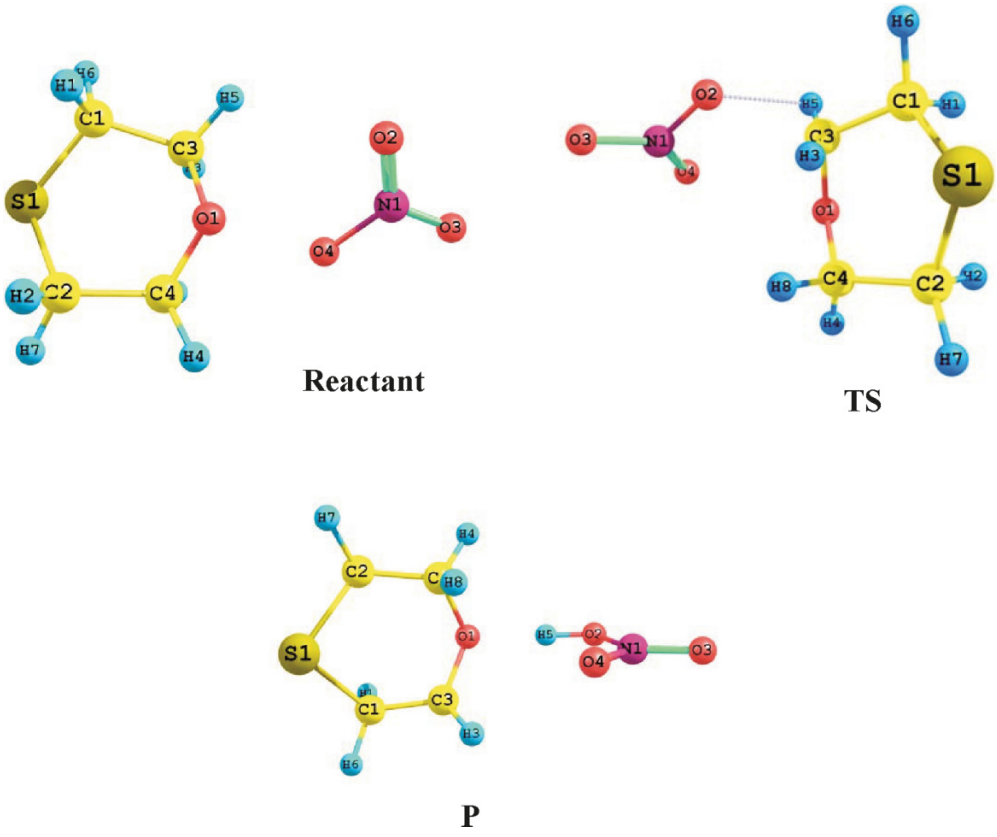
$$[1] \qquad k^{\mathrm{CVT}}(T) = \min_s k^{\mathrm{GT}}(T, s)$$

where

$$[2] \qquad k^{\mathrm{GT}}(T, s) = \frac{\sigma k_{\mathrm{B}} T Q^{\mathrm{GT}}(T, s)}{h \quad \phi^{\mathrm{R}}(T)} e^{-V_{\mathrm{MEP}}(s)/k_{\mathrm{B}}T}$$

where $k^{\mathrm{GT}}(T,s)$ is the generalized transition-state theory rate constant at the dividing surface s, σ is the symmetry factor accounting for the possibility of more than one symmetry related reaction path, k_{B} is the Boltzmann constant, h is Planck's constant, $\phi^{\mathrm{R}}(T)$ is the reactant partition function per unit volume, $V_{\mathrm{MEP}}(s)$ is the classical potential energy at point s on the minimum energy path, and $Q^{\mathrm{GT}}(T,s)$ is the partition function of a generalized transition state at s. The partition functions for most of the vibrational modes were evaluated by treating them as quantum mechanically separable harmonic oscillators and the lowest vibrational mode was evaluated by hinder-rotor approximation.[37,38] The rate constant calculations were performed by using the GAUSSRATE 2009A[39] program, which is an interface between the Gaussian09 and POLYRATE 2010A[40] programs.

Results and discussion



The NO_3•-initiated reaction of 1,4-thioxane proceeds in three different ways, a single H-atom abstraction from the CH_2 group of 1,4-thioxane by NO_3•, direct O-atom transfer to the S atom of 1,4-thioxane, or transfer of two hydrogen atoms from the CH_2 group of 1,4-thioxane to the O atom of NO_3•. It has been reported in various articles that the reaction of VOCs with NO_3• proceed mainly via single H-atom abstraction.[1,41,42] In this study, the pathway involving two-proton transfer and substitution of NO_2 as the initial step for NO_3• reactions with VOCs is reported for the first time. The interaction between the NO_3• radical and 1,4-thioxane was studied at two different C-atom sites, one at the C atom nearer to the O atom and the other at the C atom nearer to the S atom of 1,4-thioxane. The energy barrier for the reaction of single H-atom abstraction at the C atom adjacent to the O atom of 1,4-thioxane is 4.3 kcal/mol (1 cal = 4.184 J) and that at the C atom adjacent to the S atom of 1,4-thioxane is 13.1 kcal/mol, and the energy barrier for the two H-atom abstraction reaction is 22.51 kcal/mol. The calculated bond dissociation energy of the C–H bond adjacent to the O atom is 17.06 kcal/mol and that adjacent to the S atom is 39.64 kcal/mol. The dissociation energy of the C–H bond adjacent to the O atom is less when compared with that of the C–H bond adjacent to the S atom. This is due to the resonance of the C-radical site with the O atom. The direct transfer of the O atom from NO_3• to the S-atom moiety of 1,4-thioxane involves an energy barrier of 36 kcal/mol, which is quite large compared with the abstraction reactions. Hence, the subsequent reaction pathways corresponding to the initial H-atom abstraction reactions are studied in detail. The intermediates, transition states, and products are labeled as I, TS, and P, respectively, followed by a number.

Reaction mechanism and reaction pathways corresponding to the interaction of NO_3• radical at the C site nearer to the O atom of 1,4-thioxane

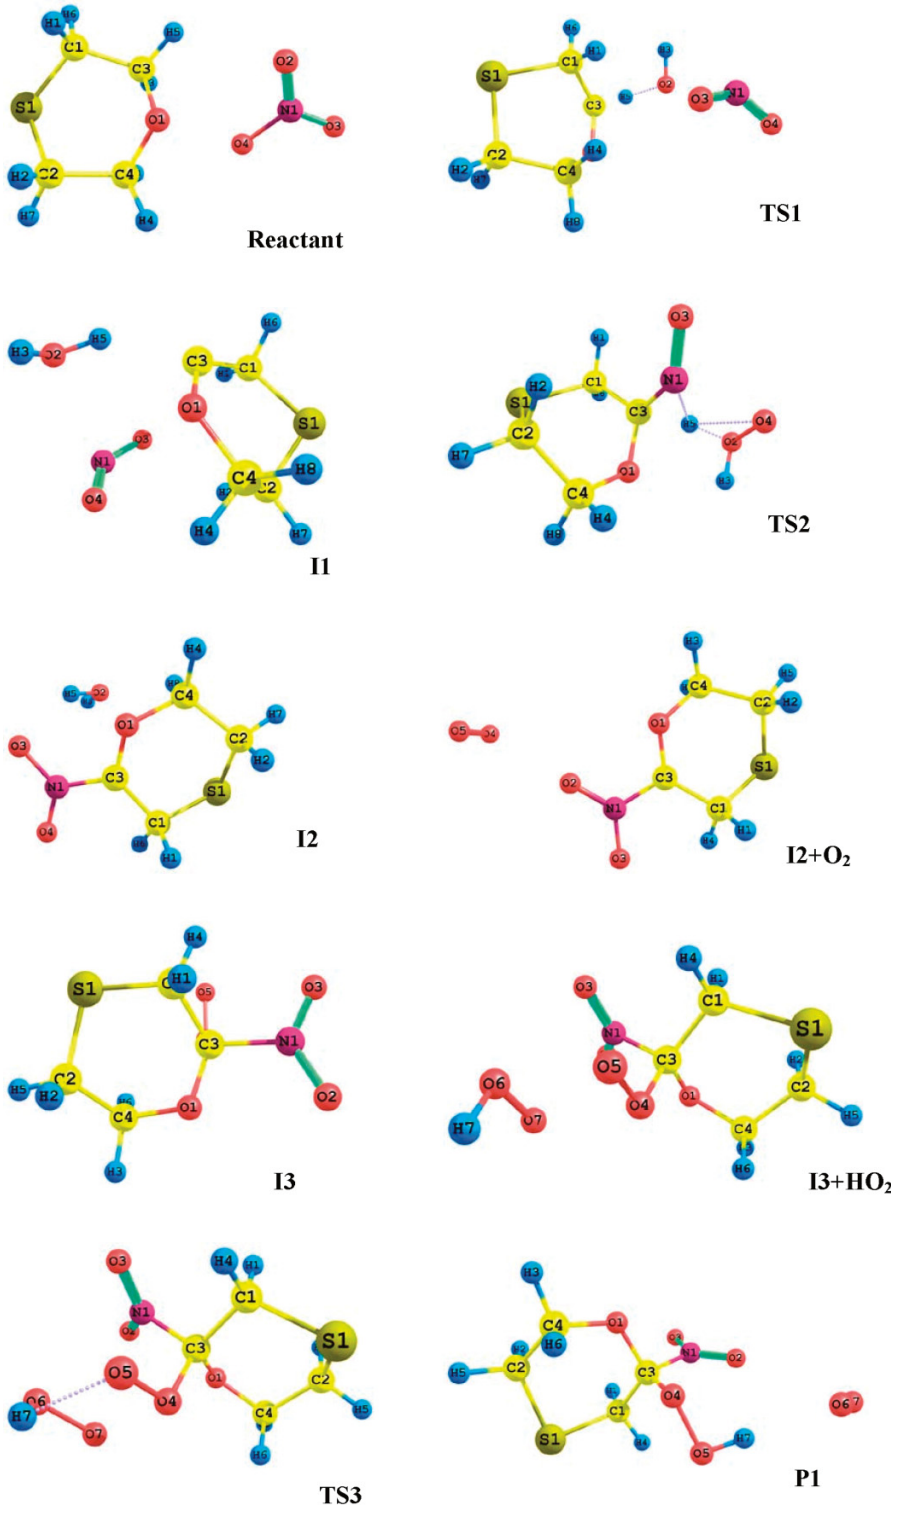
The reaction scheme corresponding to the reaction pathways involved in the reaction of the NO_3• radical with the C atom nearer to the O atom of 1,4-thioxane is illustrated in Fig. 1. The optimized structure of the reactive species corresponding to single H-atom abstraction reaction is given in Fig. 3. The structure of the stationary points optimized at M06-2X/6–31G(d,p) level of theory corresponding to the most favorable reaction pathway from the two H-atom abstraction reaction is illustrated in Fig. 4. The structure of the stationary points of the other reaction pathways is given in Fig. S1 of the Supplementary data. The energy profile corresponding to the favorable reaction pathway is illustrated in Fig. 5, and the energy profile for the other pathways is illustrated in Fig. S2 of the Supplementary data. The energy barrier (ΔE), enthalpy of the reaction (ΔH), and Gibb's free energy (ΔG) of the reactions calculated at the M06-2X/6–31G(d,p) level of theory are summarized in Table 1. The energetics obtained at the B3LYP/6–31G(d,p) level of theory are summarized in Table S1 of the Supplementary data. The structural parameters of the reactive species obtained from the two DFT methods and the MP2 method do not significantly differ from each other. For instance, the average root mean square deviation (rmsd) between the internal coordinates obtained at the above two exchange correlation functionals for the initial single H-atom abstraction reaction is 0.2 Å for the reactants, 0.07 Å for the transition state, and 0.1 Å for the product. The rmsd obtained with the MP2 and M06-2X methods are 0.1, 0.2, and 0.05 Å for the reactant, transition state, and product, respectively. Note that these rmsd values include both bonding and nonbonding interactions.

The single H-atom abstraction reaction results in the formation of nitric acid and thiooxonium radical (P) as products (pathway 1 in Fig. 1). This reaction proceeds through a TS with an energy barrier of 3.77, 4.3, and 7.2 kcal/mol, respectively, at the B3LYP, M06-2X, and MP2 level of theories. As expected, the B3LYP method underestimates the energy barrier for the single H-atom abstraction reaction. As shown in Fig. 3, in the TS, a weak hydrogen bonding exists between the H atom to be abstracted and the O atom of NO_3. The single H-atom abstraction reaction is exothermic by –16.61 kcal/mol

Fig. 3. The optimized structure of the reactive species corresponding to single H-atom abstraction at the C-atom site adjacent to the O atom of 1,4-thioxane.

and the reaction is exoergic by –16.98 kcal/mol at the M06-2X/6–31G(d,p) level of theory.

The reaction mechanism and reaction pathways corresponding to the two H-atom abstraction reaction was studied using the B3LYP and M06-2X functionals with the 6–31G(d,p) basis set. Several attempts were made to study these reactions using the MP2/6–31G(d,p) level of theory, but for many cases the optimization of the reactive species did not converge. Hence, the reactions corresponding to the two H-atom abstraction were studied and discussed using the results obtained from the M06-2X and B3LYP methods. The selected geometrical parameters of the reactive species corresponding to the most favorable reaction pathway from the two H-atom abstraction reaction obtained using DFT methods are summarized in Table S2 of the Supplementary data. The rmsd between the internal coordinates obtained at the B3LYP/6–31G(d,p) and M06-2X/6–31G(d,p) levels for the most favorable reaction pathway is 0.05 Å for the reactants, 0.1 Å for the TS, and 0.08 Å for the P. The structure and energetics obtained using the M06-2X functional with the 6–31G(d,p) basis set are discussed in detail and are used in further kinetic calculations.



This second reaction mechanism involves the formation of an intermediate (I1) in which two H atoms of 1,4-thioxane are transferred to the O atom of NO_3 and thus a water molecule is eliminated (pathway 2 in Fig. 1). This initial reaction proceeds via TS1 with an energy barrier of 22.51 kcal/mol. TS1 shows a conserved character of the CH_2 and NO_3 groups with the distance between the O atom of NO_3 and the C atom of CH_2 reduced by 0.8 Å from that of the reactants (see Fig. 4). The reaction is exothermic by –1.3 kcal/mol and exoergic by –4.25 kcal/mol. In the next step, the NO_2 group binds with the carbon atom of the radical site of I1 and thus nitroso-thiooxonium radical I2 is formed through TS2. Thus, this reaction is a stepwise proton-coupled electron-transfer process. The barrier associated with TS2 is 50.83 kcal/mol. As reported in Table 1, the reaction is exothermic and exoergic by –46.36 and –43.24 kcal/mol, respectively.

As shown in Fig. 1 (pathway 3), the radical I2 reacts with O_2 to form nitroso-1,4-thioxane peroxy radical intermediate, I3. The oxygen molecule binds with the C atom of radical I2 in a barrierless reaction with a reaction enthalpy of –24.18 kcal/mol and a free energy of –18.8 kcal/mol. In the atmosphere, the I3 reacts with other atmospheric constituents and with itself and leads to multiple reaction pathways. The mechanisms of the reaction pathways to several dissociation products are discussed below.

The intermediate I3 further reacts with HO_2 in the atmosphere leading to the formation of 2-nitroso-1,4-thioxane-2-yl-hydroperoxide, P1, as a product (pathway 4 in Fig. 1). This product is formed because of the cleavage of the H–O bond of HO_2 and the cleaved H atom binds with the terminal O of the peroxy radical and O_2 is formed. This product formation is characterized by TS3 with a barrier of 1.92 kcal/mol. In TS3, the breaking O–H bond length is 1 Å and the newly formed H–O bond length in the product is 1.7 Å. As given in Table 1, this product formation is exothermic and exoergic with a ΔH of –35.02 kcal/mol and a ΔG of –38.4 kcal/mol.

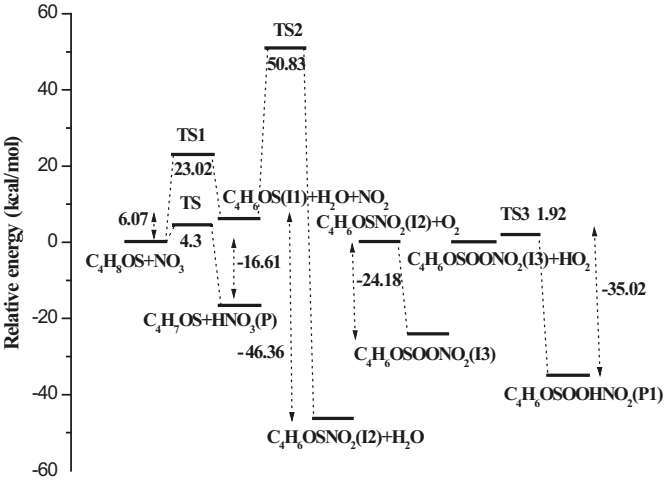
Fig. 4. The optimized structures of the reactive species corresponding to the most favorable reaction pathway from the two H-atom abstraction reaction.



This pathway is energetically favorable because of the small barrier height.

As illustrated in Fig. 1, the intermediate I2 can oxidize NO and a nitro-alkoxy radical, I4, is formed as another intermediate (pathway 5). This intermediate is formed in a barrierless reaction with an exothermicity of –26.36 kcal/mol and the formation is exoergic with ΔG = –25.51 kcal/mol. As discussed before, the reaction of the $NO_3^{\bullet}$ radical with 1,4-thioxane is an important source for the formation of ozone (P2). The intermediate I3 along with NO_2 react with O_2 to form ozone (pathway 6 in Fig. 1). This reaction is characterized by TS4 with a barrier of 75.87 kcal/mol. In TS4, the N–O

Fig. 5. Relative energy profile for the most favorable reaction pathway from the two H-atom abstraction reaction.

bond of I3 is cleaved and the oxygen atom binds with O_2 to form a triangular structure, and the distance between the terminal O atoms of the triangular structure was found to be 0.2 Å greater than that of the product (see Fig. S1 of the Supplementary data). From TS4, O_3 is formed along with NO_2 and a coproduct. Here, the coproduct is a radical in which the N–O bond possesses a double bond character. This product channel is the most endothermic and endoergic with ΔH = 43.38 kcal/mol and ΔG = 44.02 kcal/mol. The repulsive interaction between the O atom of O_2 and that of I4 strengthens the endothermicity of the reaction.

The next most significant pathways are due to the self-reactions of hydroxyl-1,4-thioxane peroxy radicals. As illustrated in Fig. 1, the self reactions of peroxy radicals are characterized by the formation of a tetraoxide intermediate (pathway 7) and the geometry of this intermediate determines the pathway.[21] In the present case, the self reactions involved the formation of a linear tetraoxide intermediate, I5. I5 is formed in an endothermic reaction without any barrier and an enthalpy of 20.71 kcal/mol. This pathway is endoergic with a ΔG of 23.36 kcal/mol. I5 can further decompose into different products.

As shown in Fig. 1 (pathway 8), the self-reactions of nitroso peroxy radicals lead to the formation of neutral products 1,4-thioxane-2-one, O_2, and NO_2 (P3). This pathway involves TS5 with a barrier of 4.85 kcal/mol. In TS5, the oxygen molecule is cleaved and an increase in C–N bond length by 0.5 Å is observed over that of I5. The neutral products are formed when the C–N bond is cleaved and the C–O bond acquires double bond character. The reaction is exothermic and exergonic with a ΔH of –24.09 kcal/mol and a ΔG of –25.88 kcal/mol.

Thus, three different product channels were identified for the reactions of 1,4-thioxane with the NO_3• radical. Of all the pathways studied for the two H-atom transfer reaction, the reaction pathway leading to the formation of 2-nitroso-1,4-thioxane-2-yl-hydroperoxide (pathway 4, P1) was found to be the most favorable.

Kinetics

The reaction mechanisms and pathways corresponding to the interaction of NO_3• with the C-atom site nearer to the O atom of 1,4-thioxane discussed in the previous section show that the NO_3•-initiated reaction of 1,4-thioxane proceeds favorably in two ways as single H-atom abstraction from CH_2 group of 1,4-thioxane and also by a two H-atom transfer along with substitution reaction. The subsequent reactions studied for the two H-atom transfer reaction show that the formation of nitroso-1,4-thioxane peroxy radical intermediate (I33) is the key step in the reaction mechanism. Also, the formation of 2-nitroso-1,4-thioxane-2-yl-hydroperoxide along with O_2 (P1) is the most favorable reaction pathway. Hence, the rate constants are calculated for the formation of nitric acid and thiooxonium (P) product channels resulting from single H-atom abstraction reaction, and the intermediate channels (I1 and I2) of the two H-atom transfer reaction, the formation of nitroso-1,4-thioxane peroxy radical intermediate (I3) channel, and the formation of hydroperoxide along with the O_2 (P1) product channel of two H-atom abstraction reaction. The rate constants were calculated using CVT with SCT in a temperature range from 278 to 350 K with zero-point energy (ZPE)-corrected energies, gradients, and hessians calculated at the M06-2X/6–31G(d,p) level of theory. The rate constants for the single hydrogen abstraction channel (P), the formation of intermediate I1 and I2 channels, the formation of the peroxy radical intermediate channel (I3), and the product channel (P1) are designated as k_P, k_{I1}, k_{I2}, k_{I3} and k_{P1}, respectively, and are summarized in Table 2.

The calculated k_P for the single H-atom abstraction reaction at 298 K is 2.33×10^{-13} cm^3 molecule^{-1} s^{-1}. This value is comparable to the experimental value of 5.9×10^{-14} cm^3 molecule^{-1} s^{-1} by Aschmann et al.[16] The calculated rate constant agrees well with those obtained in previous studies.[41] The tunneling factor for this initial reaction is negligible because of the broad energy barrier as noted from the small imaginary vibrational frequency of the TS (–103 cm^{-1}). The rate constant k_{I1} for the two H-atom transfer reaction as the initial step is 4.71×10^{-18} cm^3 molecule^{-1} s^{-1} at 298 K. The calculated k_{I2} at 298 K for the intermediate I2 formation is 2.58×10^{-51} cm^3 molecule^{-1} s^{-1}. The small rate constant calculated for the formation of I2 shows that this reaction is not feasible in atmospheric chemistry. However, as observed in Table 2, k_{I2} shows positive temperature dependence and thus this reaction is important in the lower layer of the troposphere. The tunneling effect for this reaction is appreciable because of the high energy barrier (50.83 kcal/mol). That is, the formation of I2 is the rate-determining step for the whole reaction mechanism. Since I3 is formed without a potential barrier, the rate constant for this channel is obtained by variationally moving the reference position along the minimum energy path. The rate constant calculated for I3 at 298 K is 1.04×10^{-11} cm^3 molecule^{-1} s^{-1}. The rate constant k_{P1} calculated at 298 K for the formation of 2-nitroso-1,4-thioxane-2-yl-hydroperoxide along with the O_2 in product channel P1 is 2.16×10^{-16} cm^3 molecule^{-1} s^{-1}, and this is comparable to the estimated value based on the reported rate constants for $RO_2 + HO_2$ reactions.[43]

Reaction mechanism and reaction pathways corresponding to the interaction of NO_3• radical at the C site nearer to the S atom of 1,4-thioxane

The reaction scheme for the interaction of NO_3• at the C atom nearer to the S atom of 1,4-thioxane and the

Table 1. Energy barrier ΔE (in kcal/mol), enthalpy ΔH (in kcal/mol), and Gibb's free energy ΔG (in kcal/mol) for the proposed reactions of the interaction of $NO_3^\bullet$ radical at the C-atom site nearer to the O atom of 1,4-thioxane.

corresponding pathways are given in Fig. 2. The reaction mechanism and reaction pathways corresponding to the interaction of the $NO_3^\bullet$ radical at the C-atom site adjacent to the S atom of 1,4-thioxane were studied using the B3LYP, M06-2X, and MP2 level of theories with the 6–31G(d,p) basis set. The structures of the stationary points optimized at the M06-2X/6–31G(d,p) level of theory corresponding to the most favorable pathway are shown in Fig. 6. The structure of the reactive species of the other pathways is given in Fig. S3 of the Supplementary data. The relative energy profile corresponding to the favorable reaction pathway calculated at the M06-2X level of theory is illustrated in Fig. 7. The energy profile of the other reaction pathways is shown in Fig. S4 of the Supplementary data. The energy barrier (ΔE), ΔH of the reaction, and ΔG of the reactive species calculated at the M06-2X level of theory are summarized in Table 3. The energetics obtained using the B3LYP and MP2 methods are summarized in Table S3 of the Supplementary data. The selected geometrical parameters of the reactive species corresponding to the most favorable reaction pathway calculated using the three methods are tabulated in Table S4 of the Supplementary data. The average rmsds between the internal coordinates obtained at the B3LYP and M06-2X functionals for the most favorable reaction pathway are 0.06, 0.4, and 0.1 Å for the reactants, transition state, and product, respectively. The rmsds obtained at the M06-2X and MP2 level of theories for the most favorable reaction pathway are 0.07 Å for the reactant, 0.1 Å for the transition state, and 0.09 Å for the products. The energy barriers calculated for the favorable reaction path are 4.09, 11.0, and 8.66 kcal/mol at the B3LYP, M06-2X, and MP2 level of theories, respectively. As expected, for a few cases, the energy barrier calculated from the DFT methods differed significantly from the results of the MP2 method. While comparing the results obtained for various reaction paths, it was observed that the relative importance of the studied reaction paths does not change with respect to the methods of calculation. For instance, both the DFT and MP2 methods predict that the reaction corresponding to the formation of 1,4-thioxane-2-yl nitroperoxoate is the favorable path. The structure and energetics obtained using the M06-2X functional with the 6–31G(d,p) basis set are discussed in detail and are used in further kinetic calculations.

The H-atom abstraction by the $NO_3^\bullet$ radical from the CH_2 group nearer to the S atom of 1,4-thioxane results in the formation of I1 and HNO_3 (pathway 1 in Fig. 2). This reaction occurs through transition state TS1 with an energy barrier of 13.1 kcal/mol. As given in Table 3, this reaction channel is formed with a small exothermicity of –0.93 kcal/mol in a mild exoergic reaction with ΔG = –3.0 kcal/mol. As explained for the previous reaction, the thiooxonium radical further reacts with O_2 in the atmosphere leading to the formation of I2 (pathway 2 in Fig. 2). This peroxy radical formation occurs in a barrierless reaction with a small reaction enthalpy of –1.58 kcal/mol and the reaction is exoergic

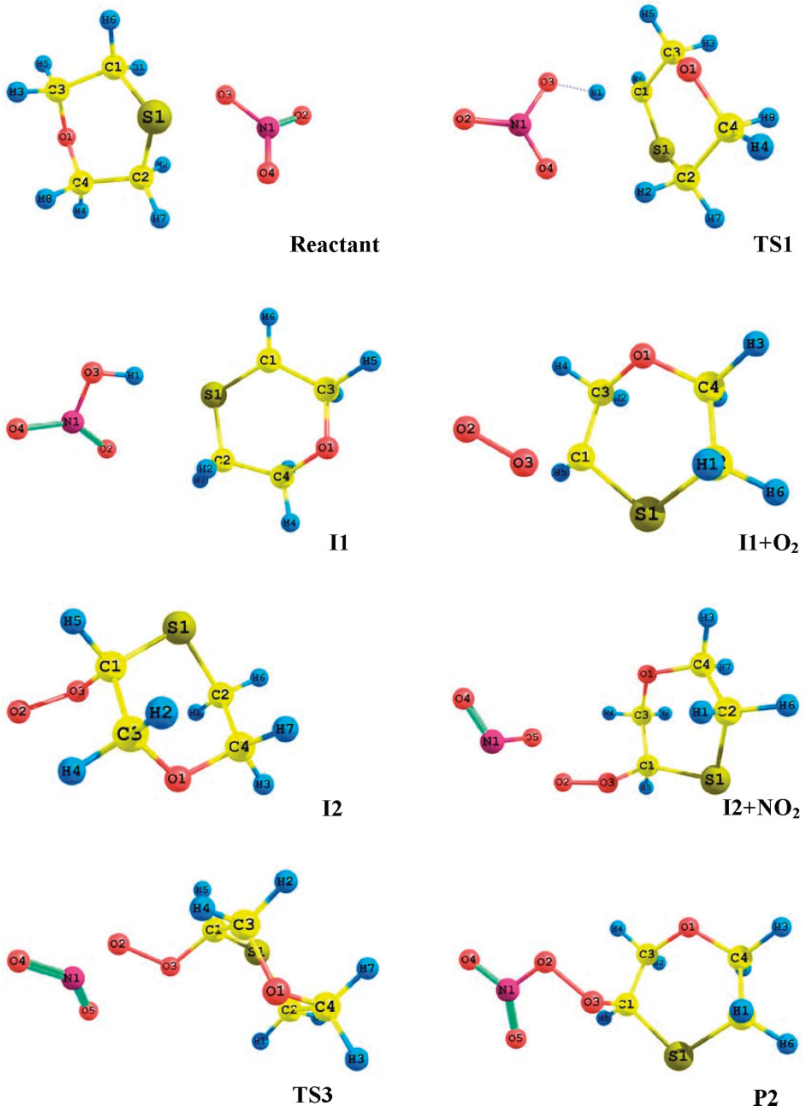
Fig. 6. The optimized structures of the reactive species corresponding to the most favorable reaction pathway from the single H-atom abstraction reaction.



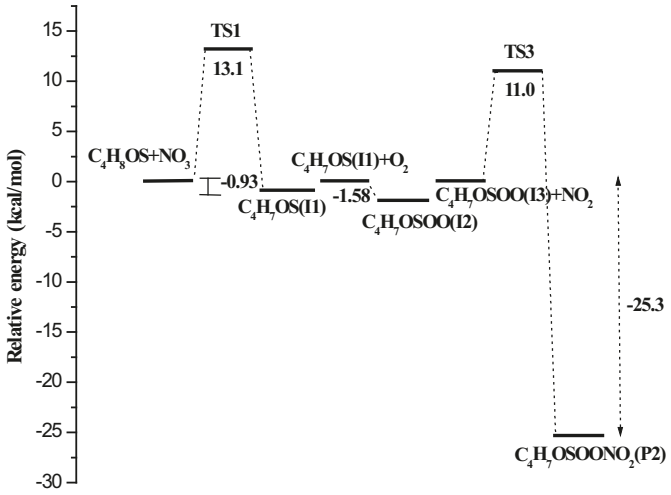


Fig. 7. Relative energy profile for the most favorable reaction pathway from the single H-atom abstraction reaction.

with $\Delta G = -1.0$ kcal/mol. As shown in Fig. 2, this peroxy radical can react in a variety of ways.

The peroxy radical reacts with HO_2 in the atmosphere leading to the formation of 2-hydroperoxy-1,4-thioxane (P1) and O_2 (pathway 3 in Fig. 2). These products are formed via TS2 with a large energy barrier of 47.78 kcal/mol, and the reaction is endothermic with a reaction enthalpy of 5.64 kcal/mol and a free energy of 4.12 kcal/mol. This reaction is not as feasible under atmospheric conditions because of the pronounced energy barrier of TS2.

The next pathway studied was the reaction of I2 with NO_2 in the atmosphere (pathway 4 in Fig. 2). This reaction is an important process during the oxidation of 1,4-thioxane because traces of nitrogen oxides are often present in the atmosphere, which may then be consumed in several atmospheric processes. This reaction may terminate the radical chain reactions and produce alkyl nitrates, where peroxy radicals act as NO_x reservoir compounds. In this reaction, the nitrogen atom of NO_2 is directly bonded with the oxygen atom of the peroxy radical (see Fig. 6) to form 1,4-thioxane-2-yl

Table 3. Energy barriers (ΔE in kcal/mol), enthalpy (ΔH in kcal/mol), and Gibb's free energy (ΔG in kcal/mol) for the proposed reactions of the interaction of the $NO_3^\bullet$ radical at the C-atom site nearer to the S atom of 1,4-thioxane.

	Parameter

nitroperoxoate (P2). This reaction is characterized by TS3 with an energy barrier of 11 kcal/mol. In the transition-state structure, the distance between the terminal O atom of the peroxy radical and the N atom of NO_2 was reduced by 1.2 Å from that of the reactants. This reaction is exothermic and exoergic by $\Delta H = –25.3$ kcal/mol and $\Delta G = –24.1$ kcal/mol, respectively. This reaction is kinetically favorable because of the small energy barrier.

The peroxy radical I2 can be reduced by NO under atmospheric conditions (pathway 5 in Fig. 2). This reaction results in the formation of alkoxy radical I3 in a barrierless reaction with a reaction enthalpy of 2.28 kcal/mol and with an endoergicity of 2.6 kcal/mol. The self-reaction of the peroxy radical involves the formation of a linear tetraoxide intermediate (I4) as observed in the previous case (pathway 6 in Fig. 2). As given in Table 3, this intermediate is formed without any barrier and the reaction is exothermic by –31.72 kcal/mol and exoergic by –31.17 kcal/mol. As shown in Fig. 2 (pathway 7), this intermediate further dissociates into 1,4-thioxane-2-one and an hydroperoxy compound (P3) through TS4. In the transition-state structure, the tetraoxide bond is broken and the two O atoms in the tetraoxide intermediate weakly bind with the O atom of one of the self reactants, and the C–O bond length of the other self-reactant is 1.3 Å (see Fig. S3 of the Supplementary data). This pathway is exothermic by –57.05 kcal/mol and it passes through a barrier of 20.25 kcal/mol with an exoergicity of –59.05 kcal/mol.

Another important dissociation channel from I4 leads to the formation of hydroperoxide and two carbonyl compounds (P4) (pathway 8 in Fig. 2). This reaction occurs via TS5 with an energy barrier of 11.42 kcal/mol. As shown in Fig. S3 of the Supplementary data, in TS5 the tetraoxide bond is broken and two H atoms from the self-reactants are abstracted by the O atoms and weak hydrogen bonding exists between the H atoms and the O atoms. From this structure, the hydroperoxide is removed and two carbonyl products are formed. This reaction is very exothermic with a reaction enthalpy of –110.07 kcal/mol and is very exoergic with a free energy of –114.86 kcal/mol. This reaction is the lowest energy pathway and is kinetically favorable.

Thus, four different product channels were identified for the interaction of the $NO_3^\bullet$ radical at the C-atom site nearer to the S atom of 1,4-thioxane. Among the reaction pathways studied, the reaction of the peroxy radical with NO_2 leading to the formation of 1,4-thioxane-2-yl nitroperoxoate (P2) is the most favorable reaction.

Kinetics

The reaction mechanism for the interaction of the $NO_3^\bullet$ radical at the C-atom site nearer to the S atom of 1,4-thioxane

Can. J. Chem. Downloaded from www.nrcresearchpress.com by Renmin University of China on 09/02/12

shows that the formation of P2 through I2 followed from the initial H-atom abstraction step (I1) is the most favorable reaction. Hence, the rate constants were calculated for the reaction channels involved in the formation of the product channel (P2). The rate constants k_{I1}, k_{I2}, and k_{P2} calculated in the temperature range of 278–350 K are summarized in Table 4. The rate constant k_{I1} calculated at 298 K is 8.65×10^{-19} cm^3 molecule^{-1} s^{-1}. The tunneling factor is negligible for this initial reaction channel. As observed in Table 4, the rate constant k_{I2} calculated for I2 formation remains the same for the whole temperature range studied with a value of 1.28×10^{-11} cm^3 molecule^{-1} s^{-1} at 298 K. The product channel (P2) is formed with a k_{P2} of 7.35×10^{-12} cm^3 molecule^{-1} s^{-1} at 298 K. The calculated rate constant k_{P2} does not show any significant variation with temperature. This value agrees well with the rate constant value calculated for the formation of nitroperoxoate in previous studies.[1]

Conclusions

The potential energy surface and the thermochemical and kinetic data for the atmospheric oxidation of 1,4-thioxane by the NO_3• radical were explored using quantum chemical methods and variational transition state theory. The results reveal several important aspects of organosulfur compounds in atmospheric chemistry. The following main conclusions were obtained.

1. The interaction of the NO_3• radical with 1,4-thioxane was studied at two different C-atom sites, one at the C atom nearer to the O atom and the other at the C atom nearer to the S atom of 1,4-thioxane. There are two possible ways favorable for the reaction between 1,4-thioxane and NO_3•, a single H-atom abstraction from the CH_2 group of 1,4-thioxane or a two H-atom transfer from CH_2 to NO_3• and subsequent binding of NO_2 with the thiooxonium radical.
2. The single H-atom abstraction reaction results in the formation of nitric acid and thiooxonium radical, whereas the two H-atom transfer reaction leads to the formation of a nitroso-thiooxonium radical and a water molecule.
3. The energy barrier for the single H-atom abstraction reaction from the C atom nearer to the O atom is 4.3 kcal/mol and the energy barrier for this abstraction from the C atom nearer to the S atom is 13.1 kcal/mol. This shows that the interaction of the NO_3• radical at the C-atom site nearer to the O atom is more favorable.
4. For two H-atom transfer reaction, the subsequent reaction pathways were studied and it was determined that the formation of the nitroso-1,4-thioxane peroxy radical is the major intermediate in the reaction pathways, and the most favorable secondary reaction pathway is the formation of 2-nitroso-1,4-thioxane-2-yl-hydroperoxide along with O_2.
5. The favorable reaction pathway from the single H-atom abstraction for the C atom adjacent to the S atom of 1,4-thioxane is the formation of 1,4-thioxane-2-yl nitroperoxoate (P2) with an energy barrier of 11 kcal/mol.
6. The rate constant for the single H-atom abstraction reaction from the C atom adjacent to the O atom is 2.33×10^{-13} cm^3 molecule^{-1} s^{-1} at 298 K and the rate constant for the two H-atom transfer reaction is 4.71×10^{-18} cm^3 molecule^{-1} s^{-1}. The rate constant calculated at 298 K for initial H-atom abstraction from the C-atom site adjacent to the S atom of 1,4-thioxane is 8.65×10^{-19} cm^3 molecule^{-1} s^{-1}. This result shows that the H-atom abstraction by the NO_3• radical from the C atom adjacent to the O atom of 1,4-thioxane is thermodynamically favored. The kinetic analysis carried out in this work agrees well with the available experimental results.

Supplementary data

Supplementary data are available with the article through the journal Web site http://nrcresearchpress.com/doi/suppl/10.1139/v2012-010. The energy barriers (ΔE), enthalpies (ΔH), and Gibbs free energies (ΔG) of the reactive species corresponding to the reaction pathways from the two H-atom abstraction reactions calculated at the B3LYP/6–31G(d,p) level of theory are summarized in Table S1. The selected structural parameters of the reactive species of the most favorable reaction pathway of this reaction system are summarized in Table S2. The optimized structures of the reactive species involved in this reaction mechanism are illustrated in Fig. S1 and the relative energy profile of the reaction pathways is shown in Fig. S2. The energy barriers (ΔE), enthalpies (ΔH), and Gibbs free energies (ΔG) of the reactive species corresponding to the reaction pathways from the single H-atom abstraction reactions calculated at the B3LYP/6–31G(d,p) and MP2/6–31G(d,p) levels of theory are summarized in Table S3. The selected structural parameters of the reactive species of the most favorable reaction pathway of this reaction system are summarized in Table S4. The optimized structures of the reactive species involved in this reaction mechanism are illustrated in Fig. S3 and the relative energy profile of the reaction pathways is shown in Fig. S4.

Abstract: A novel ion–molecular buffer approach for estimating buffer capacities for natural water – mineral equilibria has been developed. Using this approach, the buffer capacity for any component of the heterogeneous system can be assessed. A proportional relation between different capacities in relation to ions of the compound distributed between two phases has been found. The influence of major thermodynamic parameters, such as temperature, pH, and the main chemical component concentrations of natural waters upon system buffer capacities has been investigated. It is expected that this type of approach will help to predict long-term diminishing effects in natural waters as a remediation alternative. The obtained results are intended to provide users with a compulsory tool to set reliable limits of ion (including metal) levels in environmental systems.

Key words: buffer capacity, chemical equilibria, minerals, natural water, heterogeneous system.

Résumé : On a mis au point une nouvelle approche par tampon ion–moléculaire pour l'évaluation des capacités comme tampon de l'équilibre eau naturelle minérale. Utilisant cette approche, il est possible d'évaluer la capacité comme tampon par rapport à tout composant d'un système hétérogène. On a mis en évidence l'existence d'une relation proportionnelle entre les capacités différentes en relations avec les ions du composé distribué entre deux phases. On a étudié l'influence des paramètres thermodynamiques principaux, telle la température, le pH et les concentrations des principaux composants chimiques des eaux naturelles sur les capacités comme tampon du système. On peut s'attendre à ce qu'une telle approche pourra probablement être utile, comme alternative de réhabilitation, pour prédire les effets à long terme de diminution dans les eaux naturelles. Les résultats obtenus sont détaillés afin de fournir aux utilisateurs un outil obligatoire pour fixer des limites fiables pour les niveaux ioniques (y compris les métaux) dans les systèmes environnementaux.

Mots-clés : capacité comme tampon, équilibre chimique, minéraux, eau naturelle, système hétérogène.

[Traduit par la Rédaction]

Introduction

Under natural conditions the chemical composition of waters is regulated by natural processes, which preserve the chemical balance between the entry of chemical components into water and their elimination from it. The complexity of natural water (NW) composition, containing mineral phases and a huge set of chemical combinations, stimulates the capability of simultaneous occurring different chemical reactions and the capacity of mineral solid phases to be constant to a certain level in the aqueous solution composition. The property of a heterogeneous system to resist composition change, i.e., to maintain its chemical status at an invariable level at the flow outcome of chemical compounds of natural or anthropogenic character is called buffer action. Under real conditions, the buffer action of NW heterogeneous systems is expressed by the fact that, at the consumption of any element from solution, a partial dissolution of solid phases takes place and the solution composition is restored. If some excessive quantities of compounds come down from the outside in NW, the solid phase of the minerals bond such substances, again maintaining constant water composition. Therefore, the natural buffer action of natural systems is stipulated by a number of chemical reactions simultaneously taking place between aqueous solution and solid particles of minerals. Some of the basic physicochemical factors defining the stability of water systems under changing environmental conditions or at anthropogenic activity are (*i*) chemical composition and physicochemical properties of environmental objects, (*ii*) buffer action of waters and minerals, (*iii*) the water system acid-reduction function. Thus, NW in equilibrium with mineral phases not only geochemically accumulates geochemically the components of pollution, but also acts as a natural buffer that controls element and compound transfer and possesses the capacity to reduce negative effects of contaminants on vegetative and animal organisms. Such NW properties may be characterized by the concept of ion–molecular buffer action that is similar to acid–base buffering. Therefore, the concept of buffer capacity (or buffer intensity) can be expanded and used for the prediction of water system stability towards any other ions or neutral (molecular) compounds. In other words, the NWs are buffered not only towards the hydrogen ion (proton) concentration, but also in relation to the concentration of other NW-dissolved components. The processes of

[a]The — specifies the absence of experimental data.

dissolution and ionic exchange and complex formation, as well as biological activity, have their ion–molecular buffer action. Many slightly soluble components of NW systems, such as minerals, clay, and magmatic materials, contribute significantly to the buffer action of the given systems towards pH and other pX (where X is any ion, pX = –log[X]).

The buffer action of heterogeneous system mineral-saturated solutions depends on the chemical composition of the water solutions, as well as on the composition and properties of the mineral phases. We will examine a concrete real system (gibbsite-saturated solution), although the approach developed here can be applied for any other. As aluminium occurs in many minerals and materials, it is mostly present in all superficial waters. The average concentration of aluminium in river waters is 8.9×10^{-7} mol L^{-1} with a range from 3.7×10^{-7} up to 9.3×10^{-5} mol L^{-1}.[1] With an increase of the acidity of waters (up to a critical threshold of water biota survival; for example, for mollusks this threshold is pH 6.0 and for perches it is pH 4.5), the content of aluminium increases rapidly because of the interaction of aluminium hydroxide of natural materials with acid.

$$[1] \qquad Al(OH)_3(s) + 3H^+ \Leftrightarrow Al^{3+} + 3H_2O, \qquad K_S = [Al^{3+}][H^+]^{-3}$$

In eq. [1] K_S denotes the constant of equilibrium (solubility product). Even small concentrations of aluminium ions can be lethal to fishes. At the same time, phosphates provided by the evolution of phytoplankton and other water vegetation, combining with aluminium, become inaccessible to these organisms. In spite of the fact that the concept of buffer capacity towards all the components of solid phase has evident significance for the assessment of the NW composition stability in the presence of mineral phases, at present there is a limited number of works dedicated to this question.[2–8] In the literature, a few attempts of theoretical background development for the buffer action of heterogeneous systems towards the proton as the master variable can be found. For example, Bi and Yin[2] deduced the equation of buffer capacity towards the proton on the basis of classical systems of mass balance and electroneutrality equations. The latter equations in essence do not allow one to obtain the general expression of the buffer capacity (β_i^S; the superscript index S specifies the presence of the solid phase) for a wide range of considered heterogeneous systems. Besides, a number of limiting assumptions had been made by Bi and Yin[2] for their determination of the mathematical expressions.

Theory

As a criterion for the quantitative assessment of the intensity of buffer action of the studied multicomponent heterogeneous systems, the value of the buffer capacity deduced by us (β_i^S), which can be defined as a partial derivative,[4] was used

$$[2] \qquad \beta_i^S = \left(\frac{\partial C_i^0}{\partial \ln[i]}\right)_{C_j^0(j\neq i)}$$

where C_i^0 and $[i]$ are the initial concentration in heterogeneous mixture and the equilibrium concentration in solution

Can. J. Chem. Downloaded from www.nrcresearchpress.com by Renmin University of China on 09/02/12
For personal use only.

of the i component of solid phases, respectively; the subscript index C_j^0 shows that the initial concentrations of other components in the mixture remain constant.

Besides the process of gibbsite dissolution (eq. [1]), a set of possible equilibria in the system mineral phase – natural water, listed in Table 1,[2] has been taken into account.

The mass balance conditions in the heterogeneous system can be formulated on the basis of the method of residual concentrations:[6,7,9]

$$[3]\quad C^0_{Al} = C^r_{Al} + \Delta C_{Al} = \sum_{i=0}\sum_{j=1} i[Al_i(OH)_j] + \sum_{j=1}[AlF_j] + [AlSO_4] + [Al(SO_4)_2] + [AlOrg] + [AlHOrg] + [AlH_2PO_4] + \Delta C_{Al}$$

$$[4]\quad C^0_F = [F] + [HF] + \sum_{j=1} j[AlF_j]$$

$$[5]\quad C^0_{SO_4} = [SO_4] + [AlSO_4] + 2[Al(SO_4)_2]$$

$$[6]\quad C^0_{Org} = \sum_{m=0}[H_mOrg] + [AlHOrg] + [AlOrg]$$

where Org refers to organic ligand.

$$[7]\quad C^0_{CO_3} = [CO_3] + [HCO_3] + [H_2CO_3]$$

$$[8]\quad C^0_{PO_4} = \sum_{l=0}[H_lPO_4] + [AlH_2PO_4]$$

$$[9]\quad C^0_H = C^r_H + \Delta C_H = [H] - [OH] - \sum_{i=1}\sum_{j=1} j[Al_i(OH)_j] + [AlHOrg] + 2[AlH_2PO_4] + [HF] + \sum_{m=1} m[H_mOrg] - 3\Delta C_{Al} + [HCO_3] + 2[H_2CO_3] + \sum_{l=1} l[H_lPO_4]$$

For convenience, the charges of the species are omitted. The values C_i^0 and C_i^r in eqs. [3]–[8] are, respectively, the analytical and residual concentrations of a component i in the considered heterogeneous system.[6] In eq. [9], $C_H{}^0$ is the excess of H^+ ions in relation to hydroxyl ions in the two-phase mixture, $C_H{}^0 = -C_{OH}{}^0$.[6] Equation [9] also takes into account the stoichiometric composition of the solid phase.

$$3\Delta C_{Al} = \Delta C_{OH} = -\Delta C_H$$

The deduction of the expression for the buffer capacity towards the proton (or the proton buffer capacity) is presented in the Appendix. In the absence of polynuclear complexes, i.e., $i = 1$, the $\tilde{m}$ value coincides with the analytical concentration of aluminium in aqueous solution.

Taking into account the relation (eq. [A10], see the Appendix) one can obtain

$$[10]\quad \frac{\partial \Delta C_H}{\partial \ln[H]} = 9\tilde{m} + 3\tilde{i} + 3\sum_{j=1} j[AlF_j]\frac{\partial \ln[F]}{\partial \ln[H]} + 3([AlSO_4] + 2[Al(SO_4)_2])\frac{\partial \ln[SO_4]}{\partial \ln[H]} + 3([AlOrg] + [AlHOrg])\frac{\partial \ln[Org]}{\partial \ln[H]} + 3[AlH_2PO_4]\frac{\partial \ln[PO_4]}{\partial \ln[H]}$$

Substituting eq. [10] into the expression eq. [A1], taking into account the derivative (eqs. [A4]–[A8]), one can finally get

$$[11]\quad \beta^S_H = \tilde{h} + 6\tilde{i} + 9\tilde{m} - \frac{\left(\sum_{l=1} l[H_lPO_4] + 5[AlH_2PO_4]\right)^2}{C^0_{PO_4}} - \frac{([HCO_3] + 2[H_2CO_3])^2}{C^0_{CO_3}} - \frac{\left(\sum_{m=1} m[H_mOrg] + 3[AlOrg] + 4[AlHOrg]\right)^2}{C^0_{Org}} - \frac{9([AlSO_4] + 2[Al(SO_4)_2])^2}{[SO_4] + [AlSO_4] + 4[Al(SO_4)_2]} - \frac{\left([HF] + 3\sum_{j=1} j[AlF_j]\right)^2}{[F] + [HF] + \sum_{j=1} j^2[AlF_j]}$$

Similarly, it is possible to prove that, for the buffer capacity towards aluminium, the following expression is valid.

$$[12]\quad \beta^S_{Al} \equiv \left(\frac{\partial C^0_{Al}}{\partial \ln[Al]}\right)_{C_j^0} = \frac{1}{9}\tilde{h} + \frac{2}{3}\tilde{i} + \tilde{m} - \frac{\left(\frac{1}{3}\sum_{l=1} l[H_lPO_4] + \frac{5}{3}[AlH_2PO_4]\right)^2}{C^0_{PO_4}} - \frac{([HCO_3] + 2[H_2CO_3])^2}{9C^0_{CO_3}} - \frac{\left(\frac{1}{3}\sum_{m=1} m[H_mOrg] + [AlOrg] + \frac{4}{3}[AlHOrg]\right)^2}{C^0_{Org}} - \frac{\left([AlSO_4] + 2[Al(SO_4)_2]\right)^2}{[SO_4] + [AlSO_4] + 4[Al(SO_4)_2]} - \frac{\left(\frac{1}{3}[HF] + \sum_{j=1} j[AlF_j]\right)^2}{[F] + [HF] + \sum_{j=1} j^2[AlF_j]}$$

Comparing eqs. [11] and [12], an important interrelation between the buffer capacities of the heterogeneous saturated aqueous solution – gibbsite $Al(OH)_3(s)$ system can be identified.

$$[13] \qquad \beta_H^S = 9\beta_{Al}^S$$

In the case of the formation of the slightly soluble hydroxide $M(OH)_n(s)$, eq. [13] can be generalized.[6, 9]

$$[14] \qquad \beta_H^S = n^2\beta_M^S$$

Thus, the studied system containing the solid-phase gibbsite exhibits buffer properties towards both its components and, from eqs. [13] and [14], the buffer capacities are mutually proportional. Equations [11] and [12] allow the evaluation of the buffer action of the heterogeneous system in relation to components of the solid phase on the basis of equilibrium constants. It is worthy to mention that the obtained relations are only valid in the presence of the solid phase. The stability area of the latter is determined on the basis of the thermodynamic analysis of equilibriums in the studied systems.[6,7]

The proportionality of buffer capacities towards all the ions of the compound distributed between two phases is a general feature for heterogeneous systems. Similar relations were deduced for the liquid–liquid extraction systems.[10–13]

Results and discussion

The results of the calculations of the buffer capacities β_H^S as a function of pH for different compositions of the heterogeneous mixture are shown in Figs. 1–3. Obviously, an increase of the total concentration C_{Al}^0 (Fig. 1) augments the area of the buffer action because of the extension of the pH interval of the thermodynamic stability of the solid phase.

The curves of buffer capacities for separate components of the heterogeneous mixture, shown in Fig. 2, are calculated by the equations

$$[15] \qquad \beta_H^{Al} = \widetilde{h}_{Al} + 6\widetilde{i}_{Al} + 9\widetilde{m}_{Al}$$

where $\widetilde{h}_{Al} = \sum_{i=1}\sum_{j=1} j^2[Al_i(OH)_j]$, $\widetilde{i}_{Al} = -\sum_{i=1}\sum_{j=1} ij[Al_i(OH)_j]$, and $\widetilde{m}_{Al} = \sum_{i=0}\sum_{j=1} i^2[Al_i(OH)_j]$.

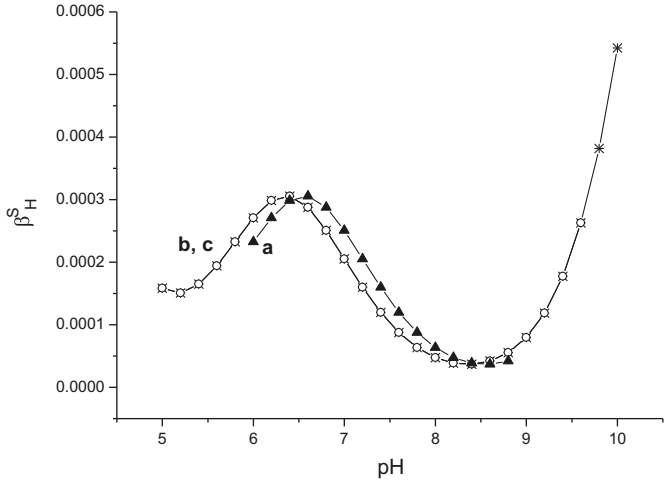
$$[16] \qquad \beta_H^F = \widetilde{h}_F + 9\widetilde{m}_F - \frac{\left([HF] + 3\sum_{j=1} j[AlF_j]\right)^2}{[F] + [HF] + \sum_{j=1} j^2[AlF_j]}$$

where $\widetilde{h}_F = [HF]$ and $\widetilde{m}_F = \sum_{j=1}[AlF_j]$.

$$[17] \qquad \beta_H^{Org} = \widetilde{h}_{Org} + 6\widetilde{i}_{Org} + 9\widetilde{m}_{Org} - \frac{\left(\sum_{m=1} m[H_mOrg] + 3[AlOrg] + 4[AlHOrg]\right)^2}{C_{Org}^0}$$

Here, $\widetilde{h}_{Org} = \sum_{m=1} m^2[H_mOrg] + [AlHOrg]$, $\widetilde{i}_{Org} = [AlHOrg]$, and $\widetilde{m}_{Org} = [AlOrg] + [AlHOrg]$.

Fig. 1. Buffer capacity β_H^S vs pH for the "saturated aqueous solution – gibbsite" system. Concentrations (mol/dm^3): C_{Org}^0, C_{PO4}^0, and $C_{SO4}^0 = 1 \times 10^{-4}$; $C_F^0 = 5 \times 10^{-6}$; $C_{CO3}^0 = 1 \times 10^{-3}$; C_{Al}^0: (*a*) 1×10^{-3}, (*b*) 1×10^{-4}, and (*c*) 1×10^{-5}. Org, organic ligand.



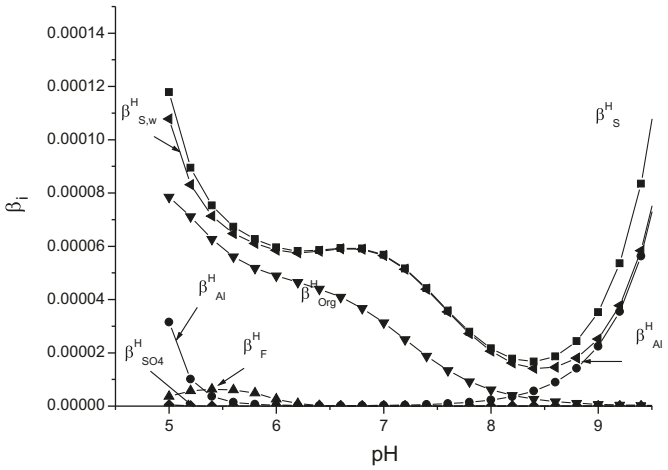


Fig. 2. The contribution of separate components of the heterogeneous mixture β_i (the composition is specified in the text) to the total buffer capacity β_H^S. $\beta_{H,W}^S$ value is the buffer capacity β_H^S disregarding the contribution of $[H^+]$ and $[OH^-]$.

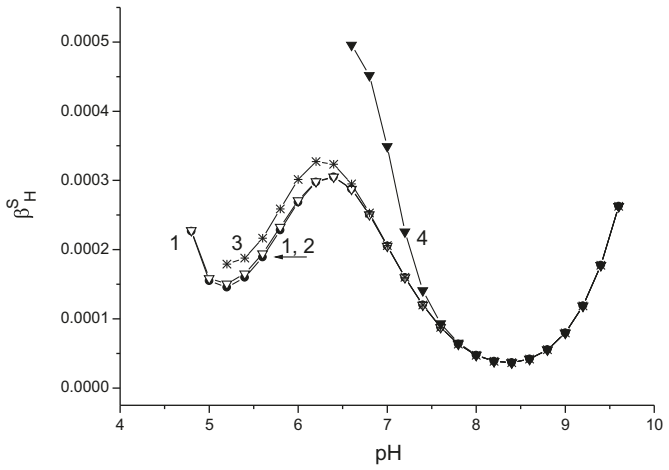
$$[18] \qquad \beta_H^{SO_4} = 9\widetilde{m}_{SO_4} - \frac{9([AlSO_4] + 2[Al(SO_4)_2])^2}{[SO_4] + [AlSO_4] + 4[Al(SO_4)_2]}$$



$$\widetilde{m}_{SO_4} = [AlSO_4] + [Al(SO_4)_2]$$

The following composition of the heterogeneous system has been used for the calculations: $C_{Al}^0 = 1 \times 10^{-4}$ mol/dm^3, $C_F^0 = 5 \times 10^{-6}$ mol/dm^3, $C_{Org}^0 = 1 \times 10^{-4}$ mol/dm^3, $C_{PO4}^0 = 1 \times 10^{-4}$ mol/dm^3, $C_{SO4}^0 = 1 \times 10^{-4}$ mol/dm^3, and $C_{CO3}^0 = 1 \times 10^{-5}$ mol/dm^3. One can state that the influence of H^+ in the studied pH interval may be neglected, and the OH^- ions exercise influence on β_H^S only at pH > 8.5. The aluminium ions and their hydroxocomplexes make a significant contribution in acid solutions up to pH 5.5 and at pH > 8 because of the predominance of the stable anionic hydroxocomplex $Al(OH)_4^-$.

The β_H^F value has a certain contribution within the pH range from 5 to 6, whereas the β_H^{SO4} value can be neglected in the whole interval of pH values. A quite significant contribution

Fig. 3. Buffer capacity $\beta_H{}^S$ vs pH for the "saturated aqueous solution – gibbsite" system. Concentrations (mol/dm^3): $C_{Al}{}^0$, $C_{Org}{}^0$, $C_{PO4}{}^0$, and $C_{SO4}{}^0 = 1 \times 10^{-4}$; $C_{CO3}{}^0 = 1 \times 10^{-3}$; $C_F{}^0$: (1) 5×10^{-7}, (2) 5×10^{-6}, (3) 5×10^{-5}, and (4) 5×10^{-4}. Org, organic ligand.

to the total buffer capacity $\beta_H{}^S$ has the value of $\beta_H{}^{Org}$ up to pH 8. At concentrations of fluoride ($C_F{}^0$) > 5×10^{-4} mol/dm^3, the $\beta_H{}^S$ value increases sharply in the range of pH values of the gibbsite dissolution–formation with a simultaneous narrowing of the total pH range of the buffer action (Fig. 3). As one can see from Fig. 4, the same effect is recorded with an increase of the $C_{Org}{}^0$ value, whereas the buffer capacity can increase many times.

The dependences of $\beta_H{}^S$ (pH) for different concentrations of carbonate ion are presented in Fig. 5. By taking into account the contribution of equilibria including carbonate ion in the total buffer capacity $\beta_H{}^S$, the $\beta_H{}^{CO3}$ value was calculated separately. In this case, the expression for $\tilde{h}$ (eq. [A2], see the Appendix) is simplified considerably.

$$[19] \qquad \tilde{h}_{CO_3} = [H] + [OH] + [HCO_3] + 4[H_2CO_3]$$

and

$$[20] \qquad \beta_H^{CO_3} = \tilde{h}_{CO_3} - \frac{([HCO_3] + 2[H_2CO_3])^2}{C^0_{CO_3}}$$

A comparison of the curves calculated by eqs. [A10] and [20] shows that equilibria with $CO_3{}^{2-}$ participation have a substantial contributionto $\beta_H{}^S$ at a $C_{CO3}{}^0 > 1 \times 10^{-4}$ mol/dm^3 (Figs. 6*a* and 6*b*). The contribution of the separate chemical species can be assessed from the diagrams of heterogeneous chemical equilibriums discussed in ref. 7.

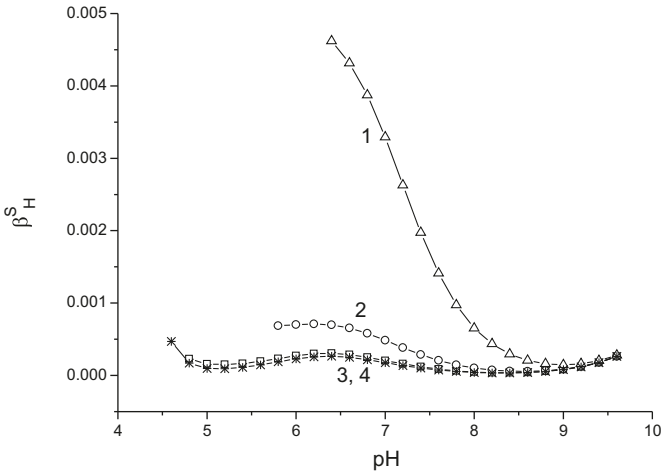
The analysis of the obtained data presented in Figs. 1–5, taking into account eq. [13] allows us to conclude that the investigated heterogeneous system has a considerable buffer capacity towards to aluminium as well.

The influence of temperature on the value of the buffer capacity was also studied. The results of the calculations are presented in Fig. 7. The equilibrium constants for different temperatures have been estimated by the van't Hoff equation.

$$\log K_2 = \log K_1 + (1/T_1 - 1/T_2)\Delta H/2.303R$$

The necessary values of enthalpies (ΔH) are listed in Table 1. T_1 was set to 298 K = 25 °C. It was assumed that the

Concentrations (mol/dm^3): $C_{Al}{}^0$, $C_{PO4}{}^0$, and $C_{SO4}{}^0 = 1 \times 10^{-4}$; $C_F{}^0 = 5 \times 10^{-6}$; $C_{CO3}{}^0 = 1 \times 10^{-3}$; $C_{Org}{}^0$: (1) 1×10^{-2}, (2) 1×10^{-3}, (3) 1×10^{-4}, and (4) 1×10^{-5}. Org, organic ligand.



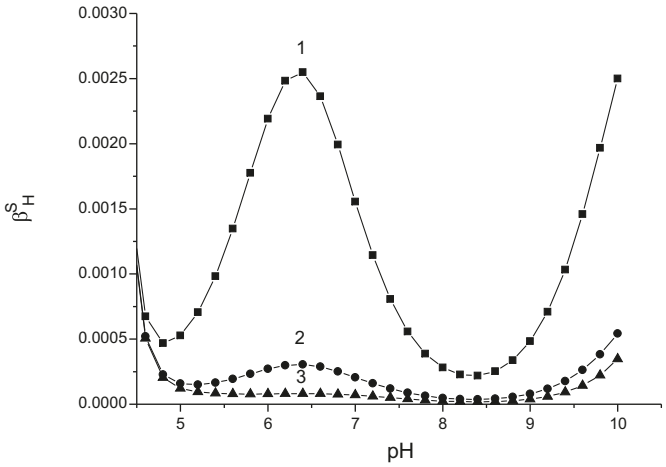


Fig. 5. Buffer capacity $\beta_H{}^S$ vs pH for the "saturated aqueous solution – gibbsite" system. Concentrations (mol/dm^3): $C_{Al}{}^0$, $C_{PO4}{}^0$, $C_{SO4}{}^0$, and $C_{Org}{}^0 = 1 \times 10^{-4}$; $C_F{}^0 = 5 \times 10^{-6}$; $C_{CO3}{}^0$: (1) 1×10^{-2}, (2) 1×10^{-3}, and (3) 1×10^{-4}. Org, organic ligand.

temperature insignificantly influences the ΔH values inside the investigated temperature range. AN analysis of the curves in Fig. 7 shows that the buffer capacity increases with a temperature decrease, whereas the pH interval of 5.5–7.0 of the maximum values of the buffer capacity displaces slightly.

Comparing the results of the calculation of ΔG_r with the $\beta_i{}^S$ calculation, one can see that the buffer capacity increases with an increase of the solubility of solid phase, i.e., the residual concentrations of ions in solution. Povar[6] remarked that at the pH of the total dissolution of the precipitate the buffer capacity changes sharply. Our obtained data correlate well with the experimental values of the buffer capacity $\beta_i{}^S$ presented in ref. 2, but their direct comparison is impossible because of the lack of experimental pH values in this reference. Thus, NW in equilibrium with mineral phases has a considerable potential reserve, by means of which the

equilibrium is regulated and one of its parameters is maintained constant.

Conclusions

On the basis of the method of residual concentrations, the original mathematical expressions for the quantitative calculation of buffer capacities towards both components of the mineral phase were deduced. The influence of different factors (temperature, pH, and concentrations of the main NW components) on the values of buffer capacities of the investigated heterogeneous systems was studied. It was established that NW in equilibrium with gibbsite has a certain potential reserve, by means of which the equilibrium is adjusted and one of its parameters is maintained constant. The presence of ligands that form stable complexes with ions of the solid phase promotes the amplification of the buffer actions of the heterogeneous systems. The presented approach can be used for research of the buffer action in the case of formation of one or several other solid phases in natural waters.

expressions for slightly soluble salts of composition $M_mA_n(s)$ was elucidated in ref. A1).

[A1] $$\beta_H^S = \left(\frac{\partial C_H^0}{\partial \ln[H]}\right)_{C_j^0} = \widetilde{h} + 3\widetilde{i} + \frac{\partial \Delta C_H}{\partial \ln[H]} + ([AlHOrg] + \sum_{m=1} m[H_mOrg])\frac{\partial \ln[Org]}{\partial \ln[H]} + \left(2[AlH_2PO_4] + \sum_{l=1} l[H_lPO_4]\right)\frac{\partial \ln[PO_4]}{\partial \ln[H]} + [HF]\frac{\partial \ln[F]}{\partial \ln[H]} + ([HCO_3] + 2[H_2CO_3])\frac{\partial \ln[CO_3]}{\partial \ln[H]}$$

where

[A2] $$\widetilde{h} = [H] + [OH] + \sum_{i=1}\sum_{j=1} j^2[Al_i(OH)_j] + [AlHOrg] + 4[AlH_2PO_4] + [HF] + \sum_{m=1} m^2[H_mOrg] + [HCO_3] + 4[H_2CO_3] + \sum_{l=1} l^2[H_lPO_4]$$

[A3] $$\widetilde{i} = -\sum_{i=1}\sum_{j=1} ij[Al_i(OH)_j] + [AlHOrg] + 2[AlH_2PO_4]$$

For the deduction of the eq. [A1] the following relationships have been taken into account:

$$\frac{\partial [H]}{\partial \ln[H]} = [H]\frac{\partial \ln[H]}{\partial \ln[H]} = [H]$$

$$\frac{\partial [OH]}{\partial \ln[H]} = [OH]\frac{\partial \ln(K_W[H]^{-1})}{\partial \ln[H]} = -[OH]$$

$$\frac{\partial \ln[Al]}{\partial \ln[H]} = \frac{\partial \ln(K_S[H]^3)}{\partial \ln[H]} = 3$$

as

$$\frac{\partial \ln K_S}{\partial \ln[H]} = 0$$

For the determination of partial derivatives $\frac{\partial \ln[Org]}{\partial \ln[H]}$, $\frac{\partial \ln[PO_4]}{\partial \ln[H]}$, $\frac{\partial \ln[F]}{\partial \ln[H]}$, and $\frac{\partial \ln[CO_3]}{\partial \ln[H]}$, eqs. [4]–[8] (see text) are differentiated on ln[H], taking into account that the corresponding analytical concentrations of i components in the examined heterogeneous system do not depend on pH.

$$\left(\frac{\partial C_F^0}{\partial \ln[H]}\right)_{C_H^0, C_{Al}^0} = 0 = \left([F] + [HF] + \sum_{j=1} j^2[AlF_j]\right)\frac{\partial \ln[F]}{\partial \ln[H]} + [HF] + 3\sum_{j=1} j[AlF_j]$$

Hence,

[A4] $$\frac{\partial \ln[F]}{\partial \ln[H]} = -\frac{[HF] + 3\sum_{j=1} j[AlF_j]}{[F] + [HF] + \sum_{j=1} j^2[AlF_j]}$$

$$\left(\frac{\partial C_{SO_4}^0}{\partial \ln[H]}\right)_{C_{Al}^0} = 0 = \left([SO_4] + [AlSO_4] + 4[Al(SO_4)_2]\right) \times \frac{\partial \ln[SO_4]}{\partial \ln[H]} + 3\left([AlSO_4] + 2[Al(SO_4)_2]\right)$$

[A5] $$\frac{\partial \ln[SO_4]}{\partial \ln[H]} = -\frac{3([AlSO_4] + 2[Al(SO_4)_2])}{[SO_4] + [AlSO_4] + 4[Al(SO_4)_2]}$$

$$\left(\frac{\partial C_{Org}^0}{\partial \ln[H]}\right)_{C_{Al}^0, C_H^0} = 0 = C_{Org}^0\frac{\partial \ln[Org]}{\partial \ln[H]} + \sum_{m=1} m[H_mOrg] + [AlHOrg] + 3([AlOrg] + [AlHOrg])$$

[A6] $$\frac{\partial \ln[Org]}{\partial \ln[H]} = -\frac{\sum_{m=1} m[H_mOrg] + 3[AlOrg] + 4[AlHOrg]}{C_{Org}^0}$$

$$\left(\frac{\partial C_{CO_3}^0}{\partial \ln[H]}\right)_{C_H^0} = 0 = [HCO_3] + 2[H_2CO_3] + C_{CO_3}^0\frac{\partial \ln[CO_3]}{\partial \ln[H]}$$

[A7] $$\frac{\partial \ln[CO_3]}{\partial \ln[H]} = -\frac{[HCO_3] + 2[H_2CO_3]}{C_{CO_3}^0}$$

$$\left(\frac{\partial C_{PO_4}^0}{\partial \ln[H]}\right)_{C_{Al}^0, C_H^0} = 0 = C_{PO_4}^0\frac{\partial \ln[PO_4]}{\partial \ln[H]} + \sum_{l=1} l[H_lPO_4] + 2[AlH_2PO_4] + 3[AlH_2PO_4]$$

[A8] $$\frac{\partial \ln[PO_4]}{\partial \ln[H]} = -\frac{\sum_{l=1} l[H_lPO_4] + 5[AlH_2PO_4]}{C_{PO_4}^0}$$

The transformation of eq. [3] (see the text) and determination of the partial derivative $\frac{\partial \Delta C_H}{\partial \ln[H]}$ in eq. [A1] yields

[A9] $$C_{Al}^0 = \sum_{i=0}\sum_{j=1} i[Al_i(OH)_j] + \sum_{j=1}[AlF_j] + \sum_{k=1}[Al(SO_4)_k] + [AlHOrg] + [AlOrg] + [AlH_2PO_4] - \frac{1}{3}\Delta C_H$$

$$[A10]\quad \left(\frac{\partial C^0_{Al}}{\partial \ln[H]}\right)_{C^0_j} = 0 = 3\widetilde{m} + \widetilde{i} + \sum_{j=1} j[AlF_j]\frac{\partial \ln[F]}{\partial \ln[H]} + ([SO_4] + [AlSO_4] + 2[Al(SO_4)_2])\frac{\partial \ln[SO_4]}{\partial \ln[H]} + ([AlOrg] + [AlHOrg])\frac{\partial \ln[Org]}{\partial \ln[H]} + [AlH_2PO_4]\frac{\partial \ln[PO_4]}{\partial \ln[H]} - \frac{1\partial \Delta C_H}{3\partial \ln[H]}$$

where through $\widetilde{m}$ the following expression is noted.

$$[A11]\quad \widetilde{m} = \sum_{i=0}\sum_{j=1} i^2[Al_i(OH)_j] + \sum_{j=1}[AlF_j] + [AlSO_4] + [Al(SO_4)_2] + [AlOrg] + [AlHOrg] + [AlH_2PO_4]$$

Abstract: The geometries of the reactant, products, and transition states involved in the decomposition pathways of the $CH_3OCF_2O^{\bullet}$ radical formed during the photooxidation of CH_3OCHF_2 (HFE-152a) have been optimized and characterized at the DFT-B3LYP level of theory using the 6–311G(d,p) basis set. Single-point energy calculations have been made at the G2M (CC,MP2) level of theory. Out of the four prominent decomposition channels considered, the β-C–O bond scission is found to be the dominant path involving a barrier height of 9.78 kcal mol^{-1} (1 cal = 4.184 J). The thermal rate constant for the above decomposition pathway is evaluated using canonical transition state theory (CTST) and was found to be 5.27×10^4 s^{-1} at 298 K and 1 atm (1 atm = 101.325 kPa).

Key words: HFE-152a, decomposition of HFE, potential energy surface, canonical transition state theory.

Résumé : Les géométries du réactif, du produit et des états de transition impliqués dans les voies de décomposition du radical $CH_3OCF_2O^{\bullet}$ qui se forme lors de la photooxydation du CH_3OCHF_2 (HFE-152a) ont été optimisées et caractérisées au niveau B3LYP de la théorie de la fonctionnelle de densité (TFD) en faisant appel à un ensemble de base 6–311G(d,p). On a aussi fait des calculs de points uniques au niveau G2M (CC,MP2) de la théorie. Des quatre voies principales de décomposition qui ont été considérées, on a trouvé que la scission de la liaison β-C–O est la voie dominante avec une barrière de 9,78 kcal mol^{-1} (1 cal = 4.184 J). Faisant appel à la théorie de l'état de transition canonique (TETC), on a évalué la constante thermique de vitesse pour cette voie de décomposition et on a trouvé qu'elle s'établit à $5,27 \times 10^4$ s^{-1}, à 298 K et 1 atm (1 atm = 101.325 kPa).

Mots-clés : HFE-152a, décomposition du HFE, surface d'énergie potentielle, théorie de l'état de transition canonique.

Introduction

Concern over the global environmental consequences of fully halogenated chlorofluorocarbons (CFCs) has created a need to determine the potential impact of other halogenated organic compounds on stratospheric ozone. The absence of an H-atom in the CFCs does not allow them to be oxidized or photolyzed in the troposphere. Thus, such compounds are transported into the stratosphere and their subsequent decomposition can lead to chlorine-catalyzed ozone depletion.[1–4] Because of the critical role played by CFCs in stratospheric ozone depletion, continuous efforts are being made to find replacement compounds. Hydrochlorofluorocarbons (HCFCs) and hydrofluorocarbons (HFCs) have been found to be an alternative and have gained wide industrial applications.[5,6] However, the release of HCFCs in the atmosphere has been attributed as leading to global warming because they possess significant absorbing potential for the IR radiation reflected from the Earth's surface and are thus called green house gases.[7,8] The physicochemical, environmental, and toxicological properties of HFCs are similar to CFCs and HCFCs and have been used as interim replacements for them. However, there are some environmental hazards and health risks involved in using HFCs[9,10] too. Studies performed with many of the HFCs and HCFCs have shown that these are not a viable solution for the protection of the ozone layer because they possess significant global warming potential (GWP).[11,12] Recently, attention has been paid to hydrofluoroethers (HFEs) for use as third-generation replacements to CFCs and which may find a place in the industry to be used as cleaning agents for electronic equipment, heat-transfer agents in refrigeration systems, and as carrier fluids for lubricant deposition.[13–15] One of the principal advantages of the HFEs is their shorter atmospheric lifetimes in comparison with HFCs.[16] The shorter lifetimes of these HFEs lead to lower GWPs.[17] The absence of chlorine atoms in HFEs would lead us to believe that such compounds would have little impact on stratospheric ozone and that they would possess a negligible ozone-depleting potential (ODP).[18,19] On the other hand, the presence of C–F and C–O bonds in HFEs may enhance the absorption features in the atmospheric IR region (800–1400 cm^{-1}) and could play a significant role as green house gases.[20] Therefore, it is pertinent to perform experimental and theoretical studies on the decomposition of HFEs to ascertain their suitability as replacement compounds

Fig. 1. Tropospheric degradation mechanism of HFE-152a.

for HCFCs and HFCs.[21–24] A general mechanism of tropospheric degradation of HFE-152a is shown in Fig. 1, which is based on the fact that initial attack of the $OH^{\bullet}$ radical on HFE-152a leads to the formation of the haloalkyl radical ($CH_3OCF_2^{\bullet}$). The latter reacts with atmospheric O_2 to produce peroxy radicals ($CH_3OCF_2O_2^{\bullet}$). In a polluted atmosphere, the peroxy radicals thus formed may further react with other oxidizing species such as NO_2 and NO that ultimately lead to the formation of the haloalkoxy radical. On the other hand, the haloalkoxy radical may also be generated through another intermediate, the hydroperoxide ($CH_3OCF_2O_2H$) formed by the reaction of $CH_3OCF_2O_2$ and HO_2. The haloalkoxy radicals thus formed play a critical role in removing a variety of organic vapours present in the troposphere.[25] Several theoretical and experimental studies performed with a few HFEs such as CHF_2OCHF_2 (HFE-134), CF_3OCH_3 (HFE-143a), $CF_3CF_2OCH_3$ (HFE-245cb2), and $CF_3CF_2CF_2OCH_3$ (HFE-347mcc3) have shown that these HFEs possess favorable physical and chemical properties as that of CFCs, HCFCs, and HFCs.[26,27] The low ODP and shorter atmospheric life time (1.5 years) of difluoromethyl methyl ether CH_3OCHF_2 (HFE-152a) make it the most suitable replacement for CH_3CF_2Cl (HCFC-142b) as a refrigerant.[27] Christensen et al.[28] studied the degradation pathways of a similar hydrofluoroether, CF_3OCH_3 (HFE-143a), using a smog chamber / FTIR technique and concluded that the haloalkoxy radical, $CF_3OCH_2O^{\bullet}$ produced from HFE-143a, degraded primarily by reaction with O_2 in the atmosphere. In another study, Good et al.[29] also investigated the atmospheric oxidation mechanism of HFE-143a, HFE-134, and HFE-125 using experimental and ab initio methods and proposed that the H-atom abstraction reaction caused by photochemically produced hydroxyl radicals was the dominant path for removing these compounds from the troposphere. The studies performed by these groups[28,29] reflect the position that the F-atom on different carbon atoms in the HFEs changed the dominant pathways of decomposition.

Thus, studying the fate of haloalkoxy radicals formed from HFE-152a is important from the viewpoint of understanding its role in atmospheric chemistry. The literature survey reveals that no experimental or theoretical studies have been performed on HFE-152a with regards to its decomposition kinetics. There are four potential pathways of decomposition of $CH_3OCF_2O^{\bullet}$ produced from HFE-152a that involve bond scission and isomerization processes. These are represented as follows:

[1] $CH_3OCF_2O^{\bullet} \rightarrow CH_3O + CF_2O$

[2] $CH_3OCF_2O^{\bullet} \rightarrow CH_2O + CF_2O + H$

[3] $CH_3OCF_2O^{\bullet} \rightarrow CH_3OC(O)F + F$

[4] $CH_3OCF_2O^{\bullet} \rightarrow CH_2OCF_2OH$

In the present investigation, density functional theory (DFT) calculations on the decomposition pathways of the $CH_3OCF_2O^{\bullet}$ radical given by rxns. [1]–[4] were performed. Energetic calculations were performed using the modified G2 method, G2M(CC,MP2), and thermodynamic properties such as reaction enthalpies and free energies were calculated. Canonical transition state theory (CTST) was utilized to predict the rate constants for the above decomposition channels (rxns.[1]–[4]). Attempts were made to search and characterize transition states for the corresponding potential energy surfaces and energy barriers to decomposition were evaluated. The intrinsic reaction coordinate (IRC) calculation was also

Can. J. Chem. Downloaded from www.nrcresearchpress.com by Renmin University of China on 09/02/12
For personal use only.

performed to confirm the smooth transition from reactant to products through the respective transition states.

Computational method

Ab initio quantum mechanical calculations were performed with the Gaussian03 suite of programs.[30] Geometry optimizations of the reactant, products, and transition states were made using DFT employing Becke's three-parameter hybrid functional (B3LYP)[31,32] with the 6–311G (d,p) basis set. To determine the nature of different stationary points on the potential energy surface, vibrational frequencies were determined using the same level of theory at which the optimization was made. All the stationary points were identified to correspond to the minima with no imaginary frequency (NIMAG = 0), and the transition states were characterized by the presence of only one imaginary frequency (NIMAG = 1). To ascertain that the identified transition states connect reactant and products smoothly, IRC calculations[33] were performed at the UB3LYP/6–311G(d,p) level. To refine the energy values for various species involved in rxns. [1]–[4], a variant of the G-2 compound method,[34] G2M(CC,MP2), was utilized during the present study. Mebel et al.[35] suggested that the G2M(CC,MP2) method yielded accurate values of energy for the systems containing six to seven heavy atoms. According to the proposed scheme, geometry optimizations and frequency calculations were performed at the UB3LYP/6–311G (d,p) level and single-point energy calculations were completed at the MP2 and MP4 levels. CCSD(T)/6–311G(d,p) was substituted for the QCISD(T)/6–311G(d,p) calculation in the original G2 method. The G2M(CC,MP2) method yielded a composite energy value as described in the following:

$$E[\mathrm{G2M(CC,\,MP2)}] = E_{\mathrm{base}} + \Delta E(\mathrm{3df,2p}) + \Delta E(\mathrm{CC}) + \mathrm{HLC} + \mathrm{ZPE}$$

where

$$E_{\mathrm{base}} = E[\mathrm{MP4/6-311G(d,p)}]$$

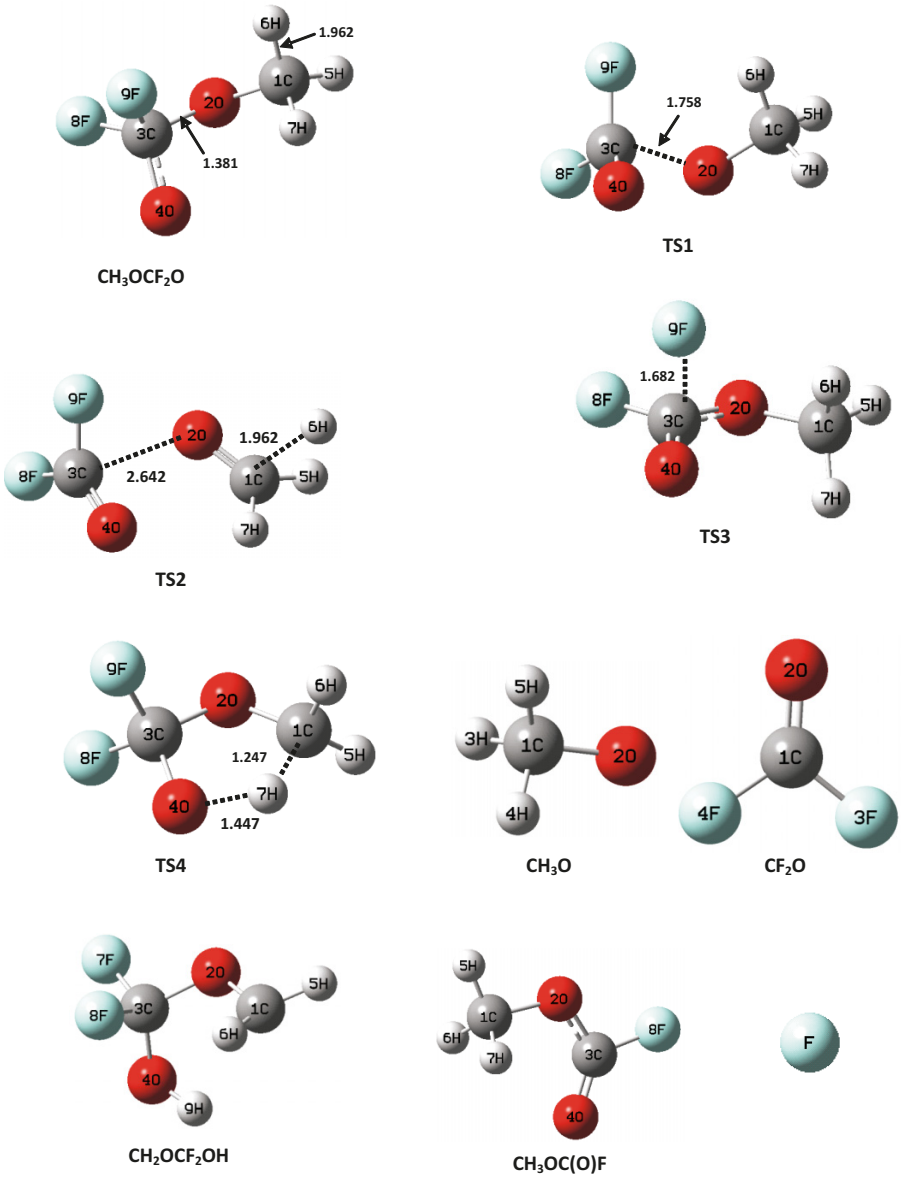
$$\Delta E(\mathrm{3df,2p}) = E[\mathrm{MP2/6-311+G(3df,2p)}] - E[\mathrm{MP2/6-311G(d,p)}]$$

$$\Delta E(\mathrm{CC}) = E[\mathrm{CCSD(T)/6-311G(d,p)}] - E[\mathrm{MP4/6-311G(d,p)}]$$

HLC (high level correction) = $-0.00525n_\beta - 0.00019n_\alpha$ (n_α and n_β are the number of α and β valence electrons with $n_\alpha \geq n_\beta$), and ZPE = zero-point energy, obtained from the vibrational frequency calculation performed at UB3LYP/6–311G(d,p) level.

Results and discussion

The fate of haloalkoxy radical ($CH_3OCF_2O^\bullet$) during its thermal decomposition in the atmosphere is envisaged to occur via rxns. [1]–[4]. The detailed thermodynamic calculations for the decomposition channels (rxns. [1]–[4]) were performed at the UB3LYP/6–311G(d,p) level and the results obtained for the associated reaction enthalpies and free energies are listed in Table 1. Results show that the endothermicity of rxn. [3] is 10.03 kcal mol^{-1} (1 cal = 4.184 J) and it proceeds with a positive free energy change ($_r\Delta G^0(298)$ = 12.49 kcal mol^{-1}). This shows that rxn. [3] would be less probable in comparison with rxns. [1], [2], and [4]. Optimized geometries of the reactant, products, and transition states obtained at the UB3LYP/6–311G(d,p) level of theory are shown in Fig. 2, with the relevant bond lengths superimposed for the transition states. The detailed optimized structural parameters of the reactant, products, and transition states are given in Supplementary data Table S1. Transition states were searched on the potential energy surfaces of rxns. [1]–[4] and characterized as TS1, TS2, TS3, and TS4, respectively. The search was made along the minimum energy path on a relaxed potential energy surface, and the transition states were characterized by the presence of only one imaginary frequency. In the optimized structure of TS1, the elongation of the β-C–O bond is found to be from 1.381 to 1.758 Å (about a 27% increase) with a simultaneous shrinkage of the C–O• (C3–O4) bond by almost 9% (1.320–1.211 Å). The cleavage of the C–H bond (channel 2) leads to atomic hydrogen, CH_2O, and CF_2O. The corresponding transition state (TS2) shows larger structural changes than TS1, i.e., a substantial elongation (~45%) of the C–H (C1–H6) bond and a shortening (~16%) of the C–O bond (C1–O2). A similar analysis made on the optimized structure of TS3 reveals the elongation of the C–F (C3–F9) bond length from 1.365 to 1.862 Å, resulting in an increase of about 36% accompanied by a shrinkage of the β-C–O bond (C3–O2) from 1.381 to 1.304 Å (~6%). The only possible rearrangement pathway through a four-membered ring-type transition state (TS4) leads to the formation of CH_2OCF_2OH. The main structural characteristic in TS4 is the elongation of the C–H (C1–H7) bond by 14% and a decrease of the O(2)–C(1)–H(7) angle from 110.7 Å in CH_3OCF_2O to 97.9 Å in TS4, reflecting the migration of H(7) from C(1) to O(4).



Results obtained during frequency calculations for the reactant, products, and transition states involved in rxns. [1]–[4] are recorded in Supplementary data Table S2. These results show that the reactant and products have stable minima on their potential energy surfaces characterized by the occurrence of only real and positive vibrational frequencies. The results recorded in Table S2 further show that the transition states are characterized by the occurrence of only one imaginary frequency obtained at 530, 610, 371, and 1543 cm^{-1} for TS1, TS2, TS3, and TS4, respectively. These frequencies were analyzed using the GaussView[36] visualization program, which revealed the smooth transition from reactant to products through the corresponding transition state. The existence of a transition state on the potential energy surface is ascertained by the IRC calculation performed at the same level of theory at which geometry optimization was made and performed using the Gonzalez–Schlegel steepest descent path[33] in the most weighted Cartesian coordinates, with a step size of 0.05 ($amu^{1/2}$-bohr). Force constants at 31 selected points (15 points in the reactant channel and 15 points in the product channel) were calculated, and the geometries were optimized at each point along the minimum energy path.

Single-point energy calculations of various species involved in the decomposition pathways were determined using

Table 1. Thermochemical data for the decomposition channels of $CH_3OCF_2O^{\bullet}$ calculated at the B3LYP/6–311G(d,p) level of theory.

Reaction channel	$_rΔH^0$ (298 K; kcal mol^{-1})	$_rΔG^0$ (298 K; kcal mol^{-1})
$CH_3OCF_2O^{\bullet} \rightarrow CH_3O + CF_2O$	–19.52	–25.45
$CH_3OCF_2O^{\bullet} \rightarrow CH_2O + CF_2O + H$	–5.42	–17.33
$CH_3OCF_2O^{\bullet} \rightarrow CH_3OC(O)F + F$	10.03	12.49
$CH_3OCF_2O^{\bullet} \rightarrow CH_2OCF_2OH$	–9.13	–9.24

the MP2, MP4, and CCSD(T) level of theories at the B3LYP/6–311G(d,p) optimized geometries and corrected for ZPE. The ZPE was calculated using B3LYP/6–311G(d,p) and corrected with a scale factor of 0.96 to partly eliminate the systematic errors.[37] To refine the energy values, these calculations were also performed using larger basis sets incorporating polarized and diffused basis functions. Zero-point-corrected total energies using standard and extended basis sets for various species and transition states involved are listed in Supplementary data Table S3. The data listed in Table S3 were used to calculate the energy barrier for β-C–O bond scission and the results are recorded in Table 2. The results show that the energy barrier for β-C–O bond scission falls in the range of 9–11 kcal mol^{-1}, whereas for F-elimination it is in the range of 22–27 kcal mol^{-1} depending on the level of theories involved during the calculations. No experimental

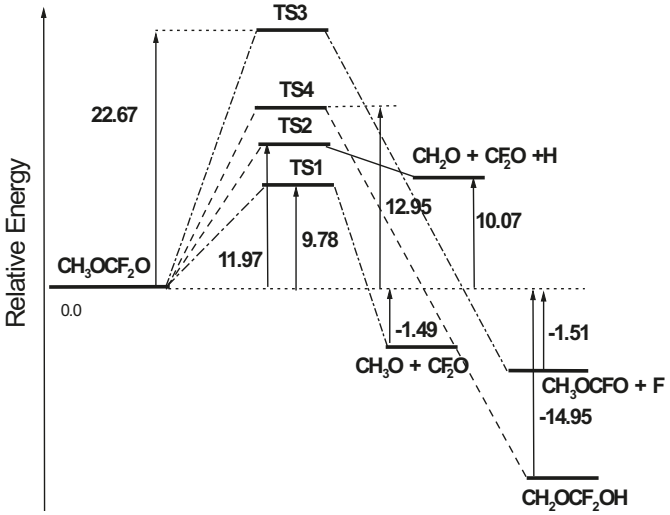
Table 2. Calculated energy barriers in kcal mol^{-1}.

	Transition state			
Method	TS1	TS2	TS3	TS4
MP2/6–311G(d,p)	10.80	14.77	25.43	15.67
MP2/6–311+G(3df,2p)	10.92	15.20	26.52	14.27
MP4/6–311G(d,p)	10.39	18.29	23.76	15.80
CCSD(T)/6–311G(d,p)	11.33	19.20	22.18	16.08
G2M(CC,MP2)	9.78	11.97	22.67	12.95

or theoretical data are available in the literature for comparison of the energy barriers associated with the decomposition channels of $CH_3OCF_2O^\bullet$ that were considered during the present investigation. However, to ascertain the reliability of the calculated values, a comparison was made with the energy values calculated at B3LYP/6–311+G(2d,2p)// B3LYP/6–31G(d) by Good et al.[29] for structurally similar compounds CF_3OCF_2O (HFE-125) and CHF_2OCF_2O (HFE-134), yielding the energy barriers for β-C–O bond scission of 9.4 and 10.30 kcal mol^{-1}, respectively, whereas the corresponding values for the F-elimination process were found to be 22.8 and 25.8 kcal mol^{-1}. The results obtained during the course of the present investigation for β-C–O bond scission and F-elimination (9.78 and 22.67 kcal mol^{-1} for $CH_3OCF_2O^\bullet$ radical decomposition using the G2M(CC, MP2) method) show a good agreement with the data obtained by Good et al.[29] for structurally similar hydrofluoroethers HFE-125 and HFE-134. This validates the use of the single-point energy calculation data obtained using the G2M(CC,MP2) method on the geometries optimized at the B3LYP/6–311G(d,p) level to construct a potential energy diagram for the decomposition channels of $CH_3OCF_2O^\bullet$ considered during the present study. The zero-point corrected total energies of various species obtained at G2M(CC,MP2) as listed in Table S3 were used relative to the ground-state energy of $CH_3OCF_2O^\bullet$ taken as zero. This energy diagram is shown in Fig. 3 and demonstrates that the barrier height of 9.78 kcal mol^{-1} for β-C–O bond scission is considerably lower than that for other decomposition pathways, and the dominance of the β-C–O bond scission in the decomposition of this haloalkoxy radical in the atmosphere is thus envisioned. Spin contamination was not important for the $CH_3OCF_2O^\bullet$ radical because $<S^2>$ was 0.76 before annihilation, which is only slightly larger than the expected value of $<S^2> = 0.75$ for doublets.



Rate constants

The rate constants for the decomposition channels shown by rxns. [1]–[4] of the $CH_3OCF_2O^\bullet$ radical were calculated using CTST[38] using the following expression:

$$[5] \qquad k = \Gamma(T)\frac{k_B T Q^{\ddagger}_{TS}}{h \quad Q_R}\exp\frac{-\Delta E}{RT}$$

where $\Gamma(T)$ is the tunneling correction factor at temperature T; $Q^{\ddagger}_{TS}$ and Q_R are the total partition functions for the transition state and reactant, respectively; ΔE is the barrier height including zero-point energy; k_B is the Boltzmann constant; and h is Planck's constant. Calculations for $\Gamma(T)$ were made using the expression of Wigner[39] as given by the following:

Fig. 3. Energy profile for $CH_3OCF_2O^\bullet$ unimolecular decomposition and isomerization at the G2M(CC,MP2) level. Energy values are given in kcal mol^{-1}.

$$[6] \qquad \Gamma(T) = 1 + \frac{1}{24}\left(\frac{h\nu^{\#}}{k_B T}\right)^2$$

where $\nu^{\#}$ is the imaginary frequency at the saddle point. However, $\Gamma(T)$ should be negligible for heavier atoms or groups as in the reactions studied. The partition functions for the respective transition state and reactant at 298 K are obtained from the vibrational frequency calculation made at the B3LYP/6–311G(d,p) level. The rate constant for β-C–O bond scission in $CH_3OCF_2O^\bullet$ decomposition occurring via rxn. [1] was calculated to be 5.27×10^4 s^{-1} at 298 K and 1 atm (1 atm = 101.325 kPa). A computational study performed by Henon et al.[40] on a structurally similar alkoxy radical ($CH_3OCH_2O^\bullet$) yielded a rate constant for β-C–O bond scission of 5.2×10^4 s^{-1}, which is in good agreement with the value of 5.27×10^4 s^{-1} calculated during the present investigation. Our modeling calculations for the A-factor for β-C–O bond scission in $CH_3OCF_2O^\bullet$ show it to be 0.78×10^{13} s^{-1}, which is also in good agreement with the value of 1×10^{13} to 2×10^{13} s^{-1} obtained by Good and Francisco[41] for β-C–O bond scission in the $CH_3OCH_2O^\bullet$ radical. The rate constants calculated during the present study for decomposition channels [2] and [4] were found to be 9.84×10^3 and 0.08×10^2 s^{-1}, respectively. Similar calculations performed to determine the rate constant for F-elimination occurring via rxn. [3] involving TS3 as the transition state yielded a value of 1.31×10^{-5} s^{-1} at 298 K and 1 atm with an associated A-factor of 5.59×10^{12} s^{-1}.

Conclusion

The most important stationary points on the potential energy surface for the thermal decomposition of the $CH_3OCF_2O^\bullet$ radical were investigated at the B3LYP/6–311G(d,p) level of theory. Energetic calculations performed at G2M (CC,MP2) revealed that the most dominant decomposition pathway for $CH_3OCF_2O^\bullet$ is the β-C–O bond scission that occurs with a barrier height of 9.78 kcal mol^{-1}. The other reaction pathways considered during the present investigation, such as H- and F-elimination and 1,5 H-transfer, occur with a barrier height in the range of 11.97–22.67 kcal mol^{-1}. Thus, the dominance of β-C–O bond scission in $CH_3OCF_2O^\bullet$ was established during the present investigation, and the thermal rate constants evaluated using conventional transition-state theory for this scission was estimated to be 5.27×10^4 s^{-1} with a corresponding A-factor of 0.78×10^{13} s^{-1} at 298 K and 1 atm pressure.

Supplementary data

Supplementary data for the geometrical parameters of the optimized geometries of the reactant, products, and transition states, and single-point energy data for various species involved in the decomposition channels (rxns. [1]–[4]) are listed in Tables S1–S3 and are available with this article through the journal Web site http://nrcresearchpress.com/doi/suppl/10.1139/v2012-005.

Abstract: The pulsed-field-gradient (PFG) ^{31}P NMR diffusion spectra were measured under varied sample conditions to characterize the low-affinity binding of adenosine 5′-triphosphate (ATP) on human serum albumin (HSA) or bovine serum albumin (BSA). The NMR diffusion constants of ATP, ATP–HSA, or ATP–BSA were illustrated as function of ATP concentrations. The binding curves of ATP–HSA and ATP–BSA were identical but strikingly different from the ATP curve. Using a "Scatchard plot", the apparent binding constant (K) and number of ATP binding sites (n) on serum albumin were evaluated as $K = 75.25$ (mol/L)$^{-1}$ and $n = 10$, respectively. At a pH < 5.0 and a pH > 9.0 or a temperature > 45 °C, the diffusion data of ATP–HSA were found to increase remarkably, suggesting that the dissociation of ATP from HSA was largely enhanced, probably because of pH- or heat-induced protein structural change, degradation, or aggregation. In addition, our data indicated that ADP was strongly competitive with ATP for the low-affinity binding to HSA, but heptanone and Cl^- were essentially noncompetitive. These results are important for further elucidating the interaction of ATP with serum albumin and its possible effect on related bioprocesses. The method can be well applied to study the binding of other nucleotides/nucleosides on proteins.

Key words: NMR, ^{31}P, ATP, serum albumin, affinity, diffusion.

Résumé : Opérant des diverses conditions de l'échantillon, on a mesuré les spectres de diffusion de RMN du ^{31}P par la méthode du gradient de champ pulsé (GCP) dans le but de caractériser la faible affinité de fixation du 5′-triphosphate d'adénosine (TPA) sur de l'albumine sérique humaine (ASH) ou de l'albumine sérique bovine (ASB). Les constantes de diffusion de RMN du TPA et des agrégats TPA–ASH et TPA–ASB sont illustrées en fonction des concentrations du TPA. Les courbes de fixation des agrégats TPA–ASH et TPA–ASB sont identiques, mais ils diffèrent beaucoup de la courbe du TPA. Faisant appel à la « courbe de Scatchard », on a déterminé que la constante apparente de fixation (K) et le nombre des sites de fixation (n) du TPA sur l'albumine sérique sont respectivement de $K = 75{,}25$ (mol/L)$^{-1}$ et $n = 10$. À un pH < 5,0 et à un pH > 9,0 ou une température > 45 °C, on a observé que les données de diffusion pour de l'agrégat TPA–ASH augmentent d'une façon remarquable, ce qui suggère que la dissociation du TPA de l'ASH est fortement augmentée, probablement en raison de dégradations, d'agrégations ou changements structuraux dans la protéine induits par le pH ou la chaleur. De plus, nos données suggèrent que le diphosphate d'adénosine (DPA) offre une grande compétition au TPA pour la fixation de faible affinité avec l'ASH, mais que l'heptanone et l'ion Cl^- ne sont pas en compétition. Ces résultats sont importants pour une élucidation ultérieure de l'interaction du TPA avec l'albumine sérique et des ses effets potentiels sur les bioprocessus apparentés. La méthode peut facilement être appliquée à l'étude de la fixation d'autres nucléotides/nucléosides sur des protéines.

Mots-clés : RMN, ^{31}P, TPA, albumine sérique, affinité, diffusion.

[Traduit par la Rédaction]

Introduction

Human serum albumin (HSA) is a most abundant protein in blood plasma. It serves as a storage and transport protein for a variety of substances, such as drugs, hormones, fatty acids, metal ions, and flavor compounds.[1] The binding capacities of serum albumin are important for regulating the delivery, redistribution, and activities of its bound ligands.[1–5]

There are two major types of binding sites on serum albumin, i.e., the high- and low-affinity sites.[6] The high-affinity sites are also classified into three categories according to their ligand selectivity.[7–9] In general, the high-affinity sites may have relatively lower binding capacity for a specific ligand because the number of these sites is often small, whereas the low-affinity sites can have a higher binding capacity because of a larger number of the total sites. If the ligand concentration is sufficiently high, a ligand species may bind to both high- and low-affinity sites on serum albumin.[10]

Ligand binding to serum albumin has been widely studied using a variety of techniques, such as ultrafiltration,[9,11] HPLC,[12] electrophoresis,[13] optical spectroscopy,[14–23] ESR,[24–26]

and NMR.[10,27–35] Among these methods, NMR pulsed-field-gradient (PFG) diffusion is particularly useful for characterizing low-affinity binding, in which the weakly bound ligands undergo rapid exchange with the free ligands on the NMR chemical shift timescale, i.e., the exchange is fast relative to chemical shift differences between the free and bound species, thus, the observed ligand signals represent a weighted average for signals of free and bound ligands.[27,36] In contrast, if ligands are tightly bound to the high-affinity sites on protein, the NMR signals of bound ligands are often difficult to analyze because of much lowered spectral resolution and sensitivity.

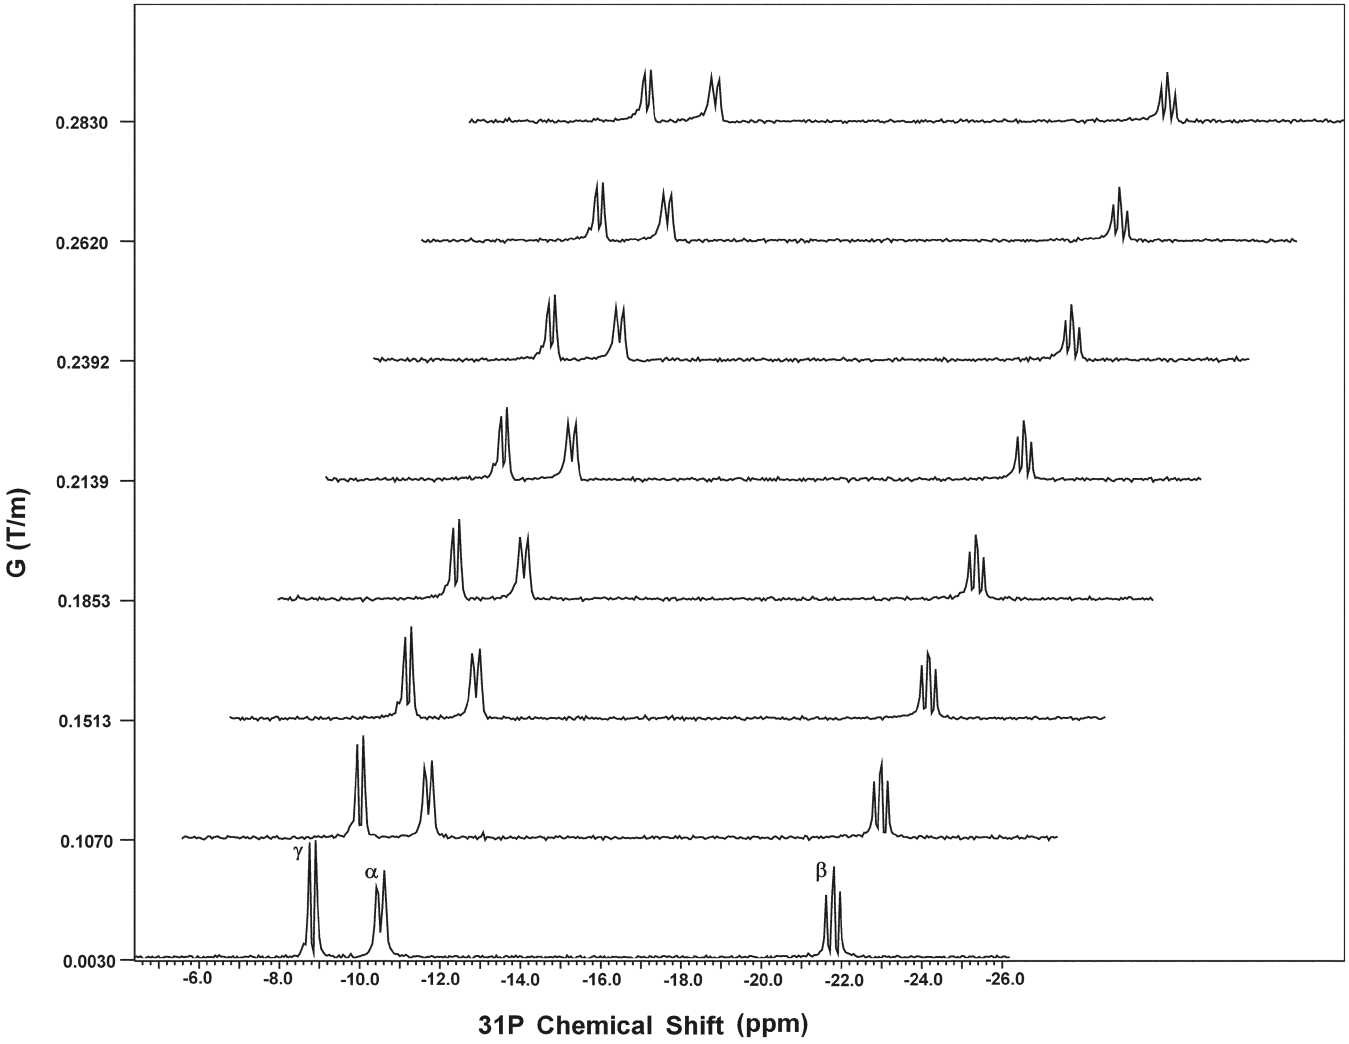
Among other things, serum albumin can serve as a regulator in some adenosine 5′-triphosphate (ATP)-involved bioprocesses, such as G-protein signaling and muscle fiber functioning,[5] whereas the nucleotide ATP in blood plasma may have a role in regulation of coronary blood flow.[37,38] However, direct interactions of serum albumin with nucleotides have not yet been fully recognized, and a certain ambiguity or disagreement still exists in this regard. For instance, Jakob et al.[39] believed that nucleotides were incapable of binding to serum albumin; thus, in their fluorescence studies of ATP binding to Hsp90 and other proteins, bovine serum albumin (BSA) was used as a control, i.e., non-ATP-binding protein. In contrast, Bauer et al.[24] found from their ESR measurements that ATP was able to specifically bind to BSA. Furthermore, Takeda et al.[9] used ultrafiltration to verify that ATP binding to BSA was in a 1:1 molar ratio, and they also obtained different dissociation constants for ATP–BSA complexes under varied pH. These data may illustrate the binding capacity of ATP on a single high-affinity site of serum albumin. However, the low-affinity interactions between nucleotides and serum albumin have been unclear so far.

In this publication, we report a ^{31}P NMR-PFG diffusion investigation for the binding of ATP to HSA or BSA in aqueous solutions. ^{31}P NMR is able to produce sharp, well-separated spectral peaks. It has a greater resonance shift dispersion as compared with ^{1}H NMR, and a higher sensitivity than ^{13}C NMR because of the 100% natural abundance of the ^{31}P nucleus. The ^{31}P NMR-PFG diffusion technique can serve multiple purposes. For instance, it has been used for probing the strong interaction in some covalently bonded organophosphorus–protein complexes or for analyzing the formula weight of phosphorus-containing compounds.[40,41] Our ^{31}P diffusion study presented was focused on the low-affinity interaction between ATP and HSA or BSA. We measured ^{31}P diffusion spectra under varied sample conditions such as ATP concentrations, pH, or temperature, and from these spectra the observed diffusion constants (D_{obs}) were deduced. Some data were analyzed by the "Scatchard plot" to evaluate the apparent binding constant and number of ATP binding sites on serum albumin. In addition, the effect of pH or temperature on ATP affinity was verified, and competitive or noncompetitive binding was found in some ternary samples. These results are important for elucidating the weak-affinity interaction of ATP with serum albumin and its possible impact. The method can be applicable for investigating other nucleotide–protein interactions as well.

Experimental

The analytical grade chemicals (sodium salt of ATP, HSA, and BSA) were purchased from Sigma-Aldrich and used without further purification. NMR samples (ATP, ATP–HSA, or ATP–BSA) were prepared by fully dissolving solid ATP and HSA or BSA in D_2O solvent for the purpose of magnetic field lock. ATP concentrations were varied in the 5–75 mmol/L range, and HSA or BSA concentration was fixed at 1 or 5 mmol/L. Each sample had volume of 1 mL, suited for a 5 mm NMR tube. Sample pH was adjusted using 1 mol/L NaOH and HCl (accurate to pH 0.1), and no other pH buffers were added to avoid any interference by impurities. The prepared samples were "incubated" for a couple of hours prior to NMR acquisition to ensure that equilibrium was reached.

NMR experiments were carried out using a JEOL ECX-300 spectrometer equipped with a 5 mm broadband autotune probe, a PFG unit, and a temperature controller. To calibrate the PFG strength, the ^{1}H spectrum of a water sample was acquired using a single magnetic-field-gradient pulse, resulting in a nearly rectangular peak, and the peak width was measured in Hz then converted into PFG strength in T/m by the spectrometer. ^{31}P NMR-PFG diffusion spectra were measured using a standard stimulated spin-echo (SSE) pulse sequence with 256 scans and a 3 s repetition delay. Other acquisition parameters were typically set as follows: $\pi/2$ pulse length = 10.75 μs, diffusion time Δ = 200 ms, gradient-pulse duration δ = 4 ms, and gradient-pulse strength G incremented in 10 steps from 0.003 to 0.283 T/m, with the maximum strength of 0.3 T/m allowed for this instrument. Based on the relationship between the signal S and D, i.e., S is proportional to $(\gamma G\delta)^2 D(\Delta - \delta/3)$, in which γ is the magnetogyric ratio of the ^{31}P nucleus, the spectral peaks of α-, β-, and γ-phosphates were integrated, and the natural logarithms of the integrals (ln S) were graphed versus G^2. The observed ATP diffusion constants were deduced from the slopes of the linear graphs, i.e., D = slope/$[-\gamma^2\delta^2(\Delta - \delta/3)]$. We found that it was necessary to use peak integrals instead of peak heights for sufficiently accurate data fitting (with correlation coefficients of $R \approx 0.99$). The binding curve of ATP–HSA or ATP–BSA was also analyzed using a Scatchard plot,[42] from which the apparent K and n were obtained.



Results and discussion

^{31}P spectral features

Figure 1 shows a representative ^{31}P NMR-PFG diffusion spectrum of ATP–HSA, obtained at 25 °C and pH 5.5. The α-, β-, and γ-peaks of ATP are well-resolved. Across the slices, the peaks decay steadily under increased PFG strength (G) along the y axis. In Fig. 2, the natural logarithms of these peak integrals (ln S) are depicted as a function of G^2. It shows that the linear declines of the α-, β-, and γ-integrals are identical. In practice, D_{obs} can be derived from the line representing all three peaks.

Because of the lower sensitivity of the ^{31}P nucleus over that of the ^{1}H nucleus, ^{31}P-diffusion measurements often need more acquisition transients, and thus longer experimental time as compared with the conventional ^{1}H-diffusion measurements. However, there are several advantages in utilizing ^{31}P diffusions for our purpose. (*i*) In a ^{31}P-diffusion

Fig. 1. A representative ^{31}P NMR - pulsed-field-gradient (PFG) diffusion spectrum of adenosine 5′-triphosphate (ATP) – human serum albumin (HSA), acquired at 25 °C. The spectral slices show decays of α-, β-, and γ-peaks under increased PFG strength (*G*, T/m).

spectrum, the ATP peaks are exclusive and well-resolved, so the peak decays can be adequately described as a function of PFG strength. In contrast, in a ^{1}H-diffusion spectrum of ATP–HSA or ATP–BSA, the ^{1}H peaks of ATP would be severely overlapped by the overwhelming protein peaks, thus making the ATP data analysis rather difficult. (*ii*) The effect of phosphate spin-lattice relaxation (T_1) on the ^{31}P-diffusion experiment can be neglected. Unlike the spin-echo (SE) pulse sequence, which involves spin-spin relaxation (T_2), in the SSE experiment, the spin relaxation depends primarily on T_1 rather than T_2 relaxation.[43] However, as we verified during our investigation, the T_1 times of the α-, β-, and γ-phosphates of ATP–HSA and ATP–BSA samples were in the range of 1 to 2 s, and they were not affected greatly by varying ATP concentrations over 10–75 mmol/L. These T_1s are much longer with respect to the diffusion time (Δ = 200 ms) used in the SSE pulse sequence, so the signal attenuation caused by phosphate relaxations is not significant. With these spectral features, we are convinced that the observed diffusion constants can be accurately derived from our ^{31}P-diffusion experiments.

ATP concentration dependence

Various ^{31}P-diffusion spectra were acquired for ATP, ATP–HSA, and ATP–BSA samples under varied ATP concentrations and in the presence or absence of HSA and BSA. The D_{obs} for ATP were deduced from the spectra. These D_{obs} values were found to be strongly dependent on the ATP and protein concentrations. For instance, the obtained D_{obs} = 2.8×10^{-10} m^2/s for a sample containing 25 mmol/L ATP, $D_{obs} = 2.0 \times 10^{-10}$ m^2/s for 25 mmol/L ATP in 1 mmol/L BSA, and $D_{obs} = 0.7 \times 10^{-10}$ m^2/s for 25 mmol/L ATP in 5 mmol/L HSA or BSA. A comparison of these results indicates that the decrease in D_{obs} can be attributed to increased sample viscosity when protein content is increased, as well as the effect of ATP binding to HSA or BSA.

Figure 3 depicts the D_{obs} variations of ATP-only, ATP–HSA, and ATP–BSA samples under different ATP concentrations. As expected, the diffusion constants of ATP in ATP-only samples are larger than that in ATP–HSA and ATP–BSA over the entire concentration range because of the higher viscosity in HSA- and BSA-containing samples as well as ATP binding to the albumin. However, when ATP

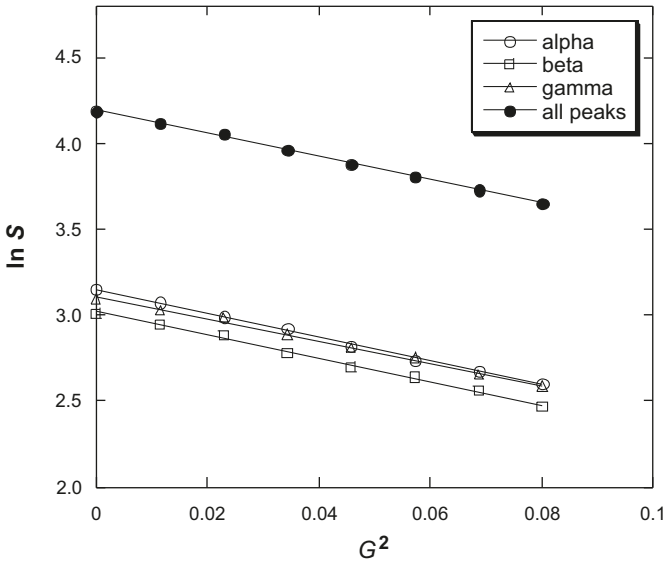
Fig. 2. Linear relationships of the natural logaritm of the signal (ln S) and pulsed-field-gradient strength $(G)^2$, obtained from the integrals of α- (○), β- (□), and γ-peaks (Δ) in an adenosine 5′-triphosphate (ATP) – human serum albumin (HSA) diffusion spectrum (Fig. 1). The observed diffusion constant (D_{obs}) can be derived from the line (●) representing all peaks.



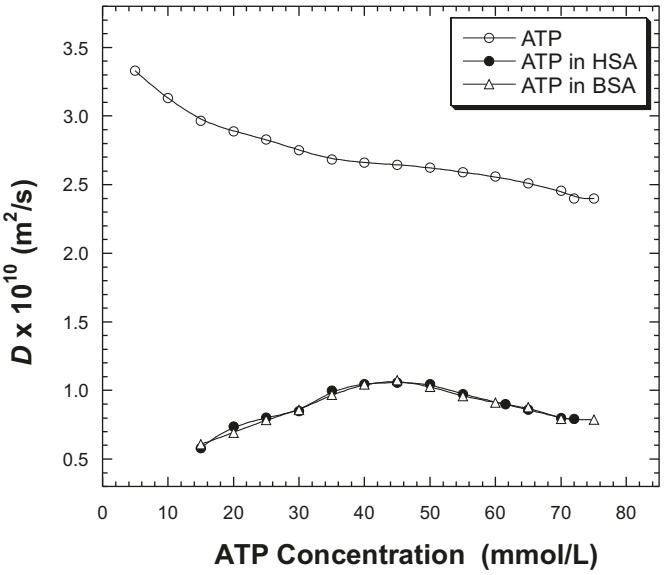


Fig. 3. The observed diffusion constants of adenosine 5′-triphosphate (ATP) (○), ATP – human serum albumin (HSA) (●), and ATP – bovine serum albumin (BSA) (△) obtained from ^{31}P NMR - pulsed-field-gradient (PFG) diffusions under varied ATP concentrations, with 5 mmol/L HSA or BSA, and at pH 5.5 and 25 °C.

concentrations were increased, a steady decrease of ATP self-diffusion was found for ATP-only samples. For instance, the NMR-derived ATP diffusion constants are reduced by ~20% when ATP was increased from 5 mmol/L (at which D_{obs} = 3.3×10^{-10} m²/s) to 75 mmol/L (at which $D_{obs} = 2.6 \times 10^{-10}$ m²/s). We believe that this is mainly due to the steadily increased ATP self-association at increased ATP concentration, resulting in a slower ATP diffusion rate. According to Sigel and Griesser,[44] the ATP self-association is pH-dependent with the self-association constant (K_{SA}) being approximately 2 $(mol/L)^{-1}$ at pH 5.5, and the percentage of ATP self-association also depends on ATP concentration, therefore, when increasing ATP concentration to ~75 mmol/L in a D_2O solution, the ATP monomer decreased from 100% to roughly 80% and the remaining 20% was mainly in the dimer state with a slight amount (~2%–3%) of the trimer. We believe that in this case, the D_{obs} can be assumed as a weighted average of the diffusion constants for the ATP monomer (D_1), dimer (D_2), and trimer (D_3), i.e., $D_{obs} = X_1D_1 + X_2D_2 + X_3D_3$, with $D_1 > D_2 > D_3$ and $X_1 + X_2 + X_3 = 1$. Therefore, as the fraction of monomer (X_1) decreases, but fractions of dimer (X_2) and trimer (X_3) increase under increased ATP concentrations, D_{obs} would decrease. Clearly, our diffusion results for ATP-only samples in Fig. 3 are consistent with the ATP self-association results of Sigel and Griesser.[44]

The D_{obs} curves of ATP–HSA and ATP–BSA in Fig. 3 were obtained from samples with varied ATP (15–75 mmol/L) but fixed 5 mmol/L HSA or BSA (i.e., [ATP]/[protein] = 3–15). We found that if ATP concentration was further lowered to 5–10 mmol/L, at which [ATP]/[protein] = 1–2, the resulting diffusion spectrum would have poor resolution and intensity, apparently because of ATP binding to the high-affinity sites of HSA or BSA under such a low [ATP]/[protein] ratio. In this case, an accurate diffusion constant was not obtainable.

In Fig. 3, the two curves of ATP–HSA and ATP–BSA are almost overlapped. This suggests that the ATP affinities on HSA and BSA are nearly the same. In particular, over the 15–45 mmol/L range (i.e., [ATP]/[protein] = 3–9), the D_{obs} of both ATP–HSA and ATP–BSA are increased under increased ATP concentrations. Such a trend variation is sharply contrary to that of ATP-only samples, characterizing the ATP binding to HSA or BSA. It indicates that, when the ATP concentration increases, the population of free ATP is increased more than that of the bound ATP. The curves of ATP–HSA and ATP–BSA reach a maximum at ~45 mmol/L ATP, suggesting that the binding of ATP to HSA or BSA is saturated around this point. Further increases of ATP result in steadily reduced D_{obs}, similar to that observed for ATP-only samples. This is understandable because increasing ATP concentration beyond the binding saturation of ATP–HSA or ATP–BSA simply means more addition of excess free ATP, which would further increase the ATP self-association and reduce its observed diffusion, as we determined previously.

Finally, it should be noted that the D_{obs} variations of blank ATP, ATP–HSA, and ATP–BSA samples (Fig. 3) are also consistent with what we have observed for blank guanosine 5′-triphosphate (GTP) and GTP–BSA or adesnosine 5′-monophosphate (AMP) and AMP–BSA (data not shown). These results support the conclusion that the nucleotides exhibit similar self-association, self-diffusion, and serum-albumin-binding properties.

The Scatchard plot

We analyzed the binding of ATP to HSA or BSA using a Scatchard equation[42]

$$[1] \qquad \frac{v}{L_f} = nK - Kv$$

where n is the number of binding sites on protein HSA or BSA, K is the apparent binding constant, v is the moles of

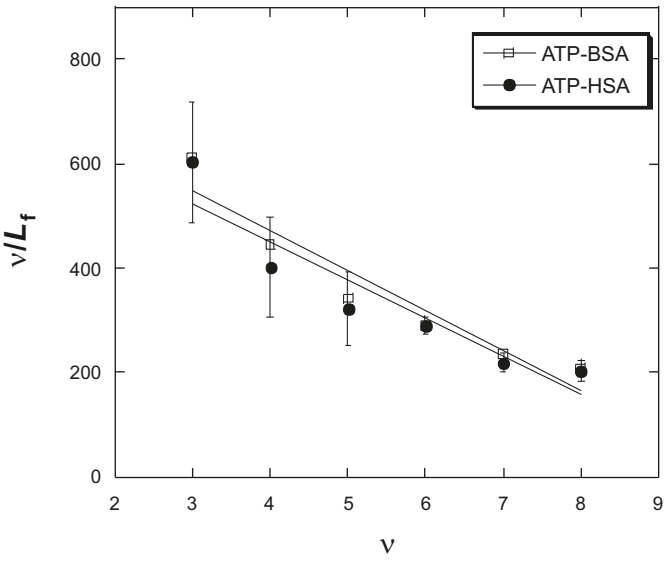
Can. J. Chem. Downloaded from www.nrcresearchpress.com by Renmin University of China on 09/02/12
For personal use only.

bound ligand (ATP) per mole of protein and it ranges from 0 to n, and L_f is the free ligand concentration. A set of L_f for eq. [1] was derived by

$$[2] \qquad L_f = L_0 X_f = L_0(1 - X_b)$$

where L_0 is the initial ligand concentration and X_f and X_b are the molar fractions of free and bound ligand, respectively. The X_b values in eq. [2] were evaluated from the diffusion data of ATP–HSA and ATP–BSA (shown in Fig. 3), i.e.,

$$[3] \qquad X_b = \frac{D_{max} - D_{obs}}{D_{max} - D_{min}}$$



For this X_b calculation, D_{min} ($\approx 0.38 \times 10^{-10}$ m^2/s) was assessed by extrapolating the ATP–HSA or ATP–BSA curve to [ATP] = 0, D_{max} ($\approx 1.06 \times 10^{-10}$ m^2/s) was determined using the curve maximum in Fig. 3, and D_{obs} is the diffusion constant of either ATP–HSA or ATP–BSA observed prior to the binding saturation.

Figure 4 shows a Scatchard plot, i.e., ν/L_f vs ν for ATP–HSA and ATP–BSA, with the error bars assessed from the uncertainty in the D_{obs} measurements of ATP–HSA samples. In general, the data over the ν = 4–8 range show a reasonably good linear relationship, although the ν/L_f value at ν = 3 is overly high. The larger deviation of the latter may be attributed to several factors. First, ligand ATP has a stronger binding tendency at the lower ratio of [ATP]/[HSA] or [ATP]/[BSA], leading to reduced free ATP concentration (L_f) and thus a larger ν/L_f value. Second, the spectral sensitivity or signal-to-noise ratio in the ^{31}P NMR diffusion experiments was significantly reduced when the ATP concentration in the ATP–HSA or ATP–BSA system was relatively lower, inducing some uncertainty in the determination of D_{obs}, which in turn contributed to the larger error in the ν/L_f calculation.

In Fig. 4, we used all the data points for the linear fitting. From the slopes of two straight lines, the apparent binding constants (K = –slope) were derived as 73.60 (mol/L)$^{-1}$ (ATP–HSA) and 76.90 (mol/L)$^{-1}$ (ATP–BSA). The two values are close, consistent with the nearly overlapping curves in Fig. 3, and are averaged to 75.25 (mol/L)$^{-1}$. From the y intercepts, the number of binding sites (n = intercept/K) was derived as $n \approx 10$ for both samples. In fact, the number of ATP binding sites on serum albumin, derived from our ^{31}P NMR diffusion study, is comparable to the number of sites for the binding of alkanones (heptanone, octanone, or nonanone) to BSA ($n \approx$ 6–8) and for the binding of lipoic acid to BSA ($n \approx 10$), which were determined earlier by ^{1}H NMR.[28,45]

The low affinity binding of ATP to serum albumin may have its biological relevance. Albumin accounts for about 60% of the total protein in blood serum with an average of 42 g/L or 6.3×10^{-4} mol/L in concentration,[46] whereas the ATP concentration in human plasma is roughly 10^{-6} mol/L.[47] Assuming these quantities of albumin and ATP are available for their binding interaction, and considering that each albumin molecule is capable of binding 10 ATP molecules with an apparent binding constant of 75.25 (mol/L)$^{-1}$, we estimate that in theory about 3.2×10^{-7} mol/L of ATP, or nearly one-third of its total in blood plasma, could be weakly bound to serum albumin. Such binding might be significant for regulating the delivery, distribution, and activity of ATP in blood plasma, although the actual binding extent can be varied depending on the conditions and complexity in the biological systems.

Fig. 4. The Scatchard plots of adenosine 5′-triphosphate (ATP) – human serum albumin (HSA, ●) and ATP – bovine serum albumin (BSA, □) derived from the diffusion data in Fig. 3. The error bars are assessed from the uncertainty in the observed diffusion constant (D_{obs}) measurements of the ATP–HSA samples.

Effect of pH or temperature

Effect of pH or temperature on ATP affinity was verified by our ^{31}P NMR diffusion measurements of ATP–HSA, conducted under a fixed amount of ATP (30 mmol/L) and HSA (5 mmol/L), but varied pH or temperature.

Figure 5 shows the D_{obs} of ATP–HSA and ATP-only samples as a function of pH. Over the pH 5.0–9.0 range, variation of pH has no significant effect on the diffusion constants of ATP–HSA. The relatively low D_{obs} (~0.8×10^{-10} to 0.85×10^{-10} m^2/s) in this range are indicative of ATP binding on serum albumin. However, the observed diffusion constants are drastically increased in the pH < 5.0 and pH > 9.0 ranges ($D_{obs} \approx 1.4 \times 10^{-10}$ to 1.45×10^{-10} m^2/s at pH 4.0 or pH 11.0). This suggests that the ATP affinity on serum albumin is significantly reduced at low or high pH, apparently because of the pH-induced structural change of serum albumin or protein aggregation.[48] It is believed that serum albumin is capable of multiple pH-dependent transitions between different structural states (expanded ↔ fast ↔ normal ↔ basic ↔ aged), with a mid-point pH of the transition around 2.3, 4.3, 8.0, and 10.0, respectively.[49] Thus, in our experimental range of pH 5.0–9.0, serum albumin is in its normal and (or) basic forms. Our diffusion data demonstrates that only these two structural forms have the regular and identical capacity for low-affinity binding of ATP. It can also be noticed that the pH effect on the D_{obs} of ATP–HSA is quite distinctive as compared with ATP-only samples. The latter have a $D_{obs} \approx 2.7 \times 10^{-10}$ to 2.8×10^{-10} m^2/s over the entire pH range. That is, pH just slightly affects the self-diffusion of ATP-only samples. This outcome is expected and is consistent with the earlier ^{1}H-diffusion studies of ATP.[50,51]

Fig. 5. ^{31}P NMR - pulsed-field-gradient (PFG) diffusion constants of adenosine 5′-triphosphate (ATP, ○) and ATP – human serum albumin (HSA, ●) measured using 30 mmol/L ATP samples in the presence or absence of 5 mmol/L HSA at 25 °C and at varied pH.

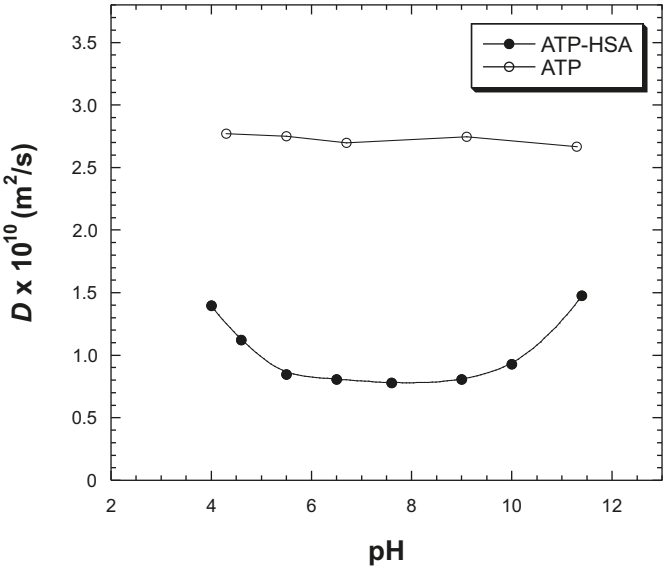

Fig. 6. ^{31}P NMR - pulsed-field-gradient (PFG) diffusion constants of adenosine 5′-triphosphate (ATP) – human serum albumin (HSA) measured using samples of 30 mmol/L ATP + 5 mmol/L HSA at pH 5.5 and at varied temperature.

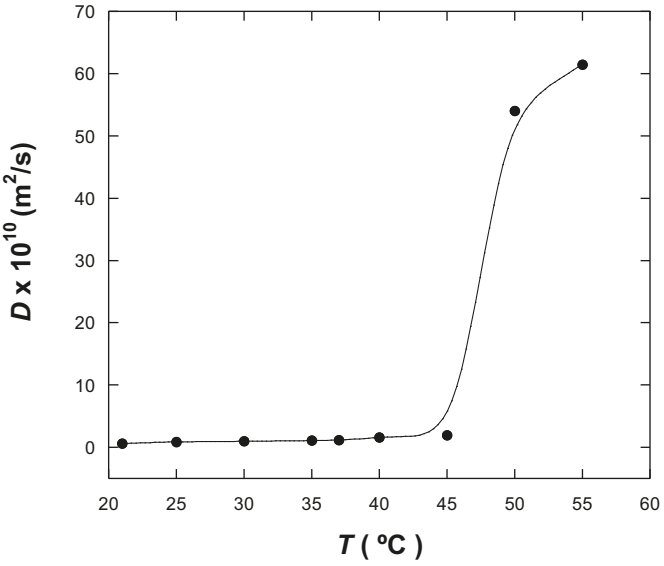

Figure 6 shows the diffusion constants of ATP–HSA as function of temperature. From 21 °C (at which D_{obs} = 0.60 × 10^{-10} m^2/s) to 45 °C (at which D_{obs} = 1.93 × 10^{-10} m^2/s), the diffusion constants steadily increased at elevated temperature. However, further heating above 45 °C lead to a drastic increase of D_{obs}. According to the Stokes–Einstein equation, $D = kT/(6\pi\eta a)$, which strictly applies to spherical particles, the diffusion constant (D) is directly proportional to temperature (T) and inversely related to viscosity (η) and dynamical size (a) of the species.[43] We believe that a steady increase of sample diffusion in the 21–45 °C range is mainly a direct consequence of temperature elevation and (or) viscosity lowering. Furthermore, the D_{obs} of ATP–HSA is a weighted average of bound ATP (D_b) and free ATP (D_f), i.e., $D_{obs} = D_bX_b + D_fX_f$. Therefore, a drastic increase in the diffusion constant over the T > 45 °C range can be attributed to the heat-induced conformation change, degradation, or aggregation of serum albumin,[52] all of which may significantly contribute to the ATP dissociation from HSA. It has been found that increasing temperature to ~50 °C results in an unfolding of the native serum albumin, i.e., a reversible separation of its structure domains I and II, while further increasing temperature to ~70 °C leads irreversibly to its complete denaturation, with an averaged melting temperature (T_m) around 63 °C.[53,54] Our result here indicates that even prior to the complete thermodenaturation, the unfolding of serum albumin in the ~45–60 °C range already causes a dramatic reduction of its ATP affinity.

ATP binding in ternary systems

Some other ligands may compete with ATP for binding to serum albumin. For instance, Bauer et al.[24] reported that the presence of amphiphilic fatty acids, such as palmitate and stearate, could reduce the ATP binding to BSA, and vice versa. Takeda et al.[9] also found that the Cl^- ion strongly inhibited the formation of a 1:1 complex of ATP–BSA; they suggested that ATP might compete with Cl^- for one high-affinity site on BSA. To verify whether the current ^{31}P NMR diffusion method is also effective for identifying binding competition, we did some preliminary measurements for ATP (5 mmol/L) + BSA (1 mmol/L) samples in the absence or presence of heptanone (30 mmol/L), NaCl (100 mmol/L), or adenosine 5′-diphosphate (ADP, 12 mmol/L). The following D_{obs} were obtained: 1.96 × 10^{-10} m^2/s (ATP–BSA), 1.95 × 10^{-10} m^2/s (ATP–BSA–heptanone), 2.02 × 10^{-10} m^2/s (ATP–BSA–NaCl), and 2.88 × 10^{-10} m^2/s (ATP–BSA–ADP). These results suggest that (*i*) the flavor compound heptanone, which has 7–8 low-affinity sites on serum albumin according to Jung et al.,[28] is a noncompetitive binding ligand with respect to ATP, (*ii*) Cl^- ion and ATP are essentially noncompetitive as well regarding their weak-affinity binding to serum albumin, although they can compete for one high-affinity site according to Takeda et al.,[9] and (*iii*) ADP is capable of strongly competing with ATP for binding on serum albumin, leading to a significant decrease of ATP binding and to a related D_{obs} increase in the ternary sample.

In conclusion, our ^{31}P NMR-PFG diffusion study is able to provide valuable information, including the characteristic binding parameters, i.e., apparent binding constant and number of binding sites of ATP on serum albumin, and dependences of ATP binding on various factors such as pH, temperature, and other ligands. These results are important for elucidating the low-affinity interaction of ATP with serum albumin and assessing its possible effect on related bioprocesses. It is also expected that the current NMR approach can be readily applied to the investigation of other nucleotide–protein binding interactions.

Abstract: Tridentate Schiff base complexes of zinc and calcium were prepared and tested in the ring-opening polymerization of ε-caprolactone and *rac*-lactide to generate biodegradable polymeric materials from biocompatible metals. Alteration of the pendant donor arm attached to the imine backbone provides some control over catalyst composition and polymerization activity. Complexes of the formula [ONN]ZnN$(SiMe_3)_2$, where [ONN] = 2-(*N*-donor arm-imine)[4,6-di(*tert*-butyl)phenoxide], were isolated with ethyldimethylamine, ethylpiperidine, and ethylmorpholine substituents, while disproportionation led to the isolation of $[ONN]_2Zn$ complexes with methylpyridine, quinoline, and ethyldiisopropylamine derivatives, two of which were crystallographically characterized. Calcium complexes were more stable and novel [ONN]CaN$(SiMe_3)_2$ complexes with ethylpiperidine and ethyldiisopropylamine substituents were reported. Zinc and calcium catalysts coordinated to a single tridentate ligand were effective at initiating the polymerization of ε-caprolactone, but did not control the polymerizations, whereas the bis(ligand) complexes produced no polymer. These catalysts were effective at controlling the polymerization of *rac*-lactide. Coordinatively saturated complexes inhibit the polymerization, while initiation from either the amido or ligand alkoxide functionalities produces poly(lactic acid) with low polydispersities.

Key words: lactide, caprolactone, zinc, calcium, ring opening polymerization.

Résumé : On a préparé des complexes de zinc et de calcium avec des bases de Schiff tridentates et on a évalué la possibilité de les utiliser dans les polymérisations par ouverture de cycle de la ε-caprolactone et du *rac*-lactide conduisant à des matériaux polymères biodégradables à partir de produits métalliques biodégradables. L'altération du bras donneur pendant attaché au squelette de l'imine permet d'avoir un certain contrôle sur la composition du catalyseur et son activité dans la polymérisation. On a pu isoler des complexes de formule [ONN]ZnN$(SiMe_3)_2$ (dans lesquels [ONN] = 2-(imine avec bras *N*-donneur)[4,6-di(*tert*-butyl)phénolate] portant des substituants éthyldiméthylamine, éthylpipéridine et éthylmorpholine alors qu'une disproportionation permet d'isoler les complexes $[ONN]_2Zn$ avec les dérivés de la méthylpyridine, la quinoléine et l'éthyldiisopropylamine, dont deux ont été caractérisés par cristallographie. Les complexes du calcium sont plus stables et on a isolé pour la première fois les nouveaux complexes [ONN]CaN$(SiMe_3)_2$ avec des substituants éthylpipéridine et éthyldiisopropylamine. Les catalyseurs du zinc et du calcium ne comportant qu'une coordination à un ligand tridentate sont efficaces pour initier la polymérisation de la ε-caprolactone, mais ils ne permettent pas de contrôler les polymérisations alors que les complexes avec un bis(ligand) ne permettent pas de produire des polymères. Ces catalyseurs sont efficaces pour contrôler la polymérisation du *rac*-lactide. Les complexes à coordination saturée inhibent la polymérisation alors qu'une initiation par des groupes fonctionnels amido- ou un ligand alcoolate conduisent à la production d'acide polylactique avec de faibles polydispersités.

Mots-clés : lactide, caprolactone, zinc, calcium, polymérisation par ouverture de cycle.

[Traduit par la Rédaction]

Aliphatic poly(esters) such as poly(lactic acid) (PLA) and poly(ε-caprolactone) (PCL) have gained considerable interest in recent years because of their biodegradability and renewability.[1–4] These aliphatic polymers are also bioassimilable, as hydrolysis produces nontoxic components eliminated via the Krebs cycle as CO_2 and H_2O.[3] These poly(esters) have physical properties that can be tuned and varied during polymer processing by orientation, blending, branching, cross-linking, or plasticization, enabling the application of aliphatic poly(esters) to pharmaceuticals, microelectronics, and other fields.[5,6]

PLA is an important biodegradable polymer of high industrial potential because the lactide monomer can be acquired through the fermentation of renewable resources.[3] The most common application of PCL as a biodegradable polymer involves the development of pharmaceutical drugs such as Capronor, an implanted contraceptive delivery system.[7] PCL is synthesized from the monomer ε-caprolactone, which is

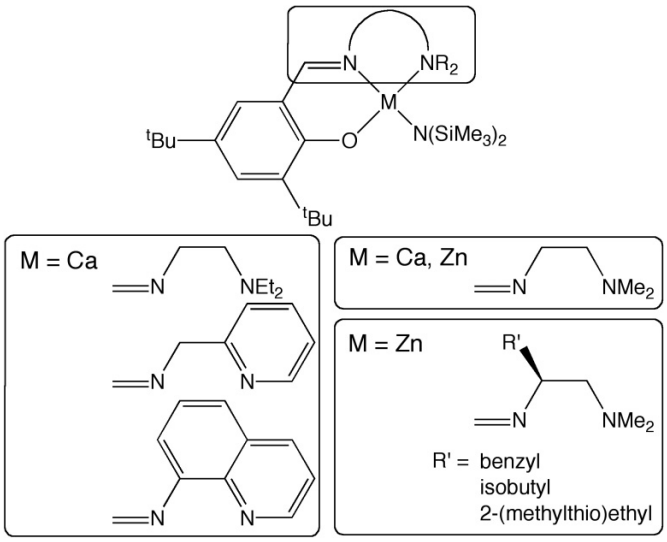
traditionally produced by the Bayer–Villiger oxidation of cyclohexanone with peracids or hydrogen peroxide[8] but can also be produced from the fermentation of starch, suggesting renewability.[9]

Aliphatic poly(esters) are commonly synthesized through ring-opening polymerization (ROP) of the corresponding cyclic ester as it offers greater control over the resulting polymers.[1–4] While ROP of lactide has been accomplished with many metals, calcium and zinc are particularly promising for industrial applications, because of their low cost, high activity, and low toxicity.[10] Ligand sets supporting active zinc and calcium lactide catalysts include β-diketiminates, tris(pyrazol) hydroborates, anilido-oxazolinates, amino-bis(pyrazol)s, N-heterocyclic carbenes, heteroscorpionates, and others.[10] The best systems offer excellent conversions over a broad temperature range and polydispersity indexes (PDIs) as low as 1.1.[10]

ROP of ε-caprolactone with calcium and zinc catalysts is comparatively understudied, although simple organic amido calcium and zinc complexes, $H_2NCaOCHMe_2$ and $Zn(N(SiMe_3)_2)_2$, show high activity and poor control.[10,11] PCL synthesis is also efficiently mediated by heterobimetallic aluminum and zinc complexes with anilido-aldimine ligands[12] and some scorpionate-derived monometallic frameworks.[10]

Inspiration for this study, however, was derived from the work of Darensbourg et al.[13–16] who showed that a series of tridentate Schiff base complexes, shown in Fig. 1, of benign metals were effective in the ROP of cyclic esters. Complexes were variably effective, with pendant dimethylamine donors coordinated to calcium providing the best activity for lactide and trimethylene carbonate, whereas zinc complexes were less effective unless substituted with bulky amino acid derived ligands and used for lactide and ε-caprolactone polymerizations.



Herein we report an extension of this series of complexes, further examining the structure/activity relationships and the role the ligand plays in controlling the ROP of *rac*-lactide and ε-caprolactone. New substitutents include diisopropylamine ($N(i\text{-}Pr)_2$), piperidine (Pip), and morpholine (Mor) functionalities. Complexes substituted with a single tridentate ligand are effective catalysts for the ROP of *rac*-lactide.

Experimental

General experimental procedures

Chemicals and solvents used for the syntheses were purchased from Sigma-Aldrich, Fisher Chemicals, and Acros Chemicals. 3,5-Di-*tert*-butyl-2-hydroxybenzaldehyde (99% pure) and starting amine reagents were all used as received. Dry solvents including tetrahydrofuran (THF), toluene, pentane, and ether were obtained from an Innovative Technology glovebox system, which was fitted with a solvent purification system. The inline purification system was made up of alumina and a copper catalyst. These anhydrous solvents were degassed by three or four freeze–pump–thaw cycles, before taking them into an MBraun LABmaster sp. glovebox. Other solvents, including $CDCl_3$, C_6D_6, and hexamethyldisiloxane, were dried over CaH_2 for at least 24 h, before vacuum transferring or vacuum distilling. The MBraun glovebox was connected to a –35 °C freezer as well as [H_2O] and [O_2] analyzers. Air-sensitive reactions involving zinc and calcium

Fig. 1. Calcium and zinc Schiff base complexes previously developed for the polymerization of cyclic esters.[13–16]

were performed under an N_2 atmosphere in the glovebox or on a Schlenk line. The Schlenk reactions utilized a dual manifold Schlenk line with Kontes valves. All samples were characterized via ^1H and ^{13}C NMR spectroscopy. These spectra were obtained by running samples on a 300 MHz Bruker Avance spectrometer. Elemental analyses were performed at Guelph Analytical Laboratories. A Bruker AXS P4/SMART 1000 diffractometer was used to obtain crystallographic data. Polymerization data were obtained using a PolymerLabs GPC50 equipped with two Jordi Gel DVB mixed bed columns (300 mm × 7.8 mm). The mobile phase used in the system was HPLC grade THF and the polymer samples were dissolved in THF to create a solution for GPC analysis, at 50 °C, at a 1 mg/mL concentration, and at a 1 mL/min flow rate. Molecular weights were measured and corrected relative to styrene standards.[17]

Synthesis and characterization

Ligand frameworks

Ligands ^{NMe_2}[ONN]ME_2 (**1**), ^{Q}[ONN] (**2**), and ^{Py}[ONN] (**3**), where ^{R}[ONN] is 2-(*N*-donor arm-imine)(4,6-di(*tert*-butyl)phenoxide, were synthesized according to a literature procedure.[14]

Synthesis of $^{N(i\text{-}Pr)_2}$[ONN]$(i\text{-}Pr)_2{}^{N(i\text{-}Pr)_2}$[ONN] ***(4)***:

To a stirred solution of 3,5-di-*tert*-butyl-2-hydroxybenzaldehyde (2.51 g, 10.6 mmol) in methanol (25 mL) was added dropwise 2-(diisopropylamino) ethylamine (1.54 g, 10.6 mmol). The bright yellow solution was refluxed at 65 °C for approximately 10 h and then allowed to cool to room temperature. All volatiles were removed in vacuo to yield a bright yellow oil. The oil was dried under vacuum on the Schlenk line for 2 h and then purified by dissolving in cold pentane. The resulting solution was stored at –20 °C overnight, and the same purification process was repeated three times to give a dense yellow solid (1.37 g, 3.8 mmol, 36%). ^1H NMR ($CDCl_3$, ppm) δ:14.0 (1H, s, OH), 8.4 (1H, s, CH=N), 7.4–7.1 (2H, m, Ar–H), 3.6 (2H, t, J = 7 Hz, CH_2),

Can. J. Chem. Downloaded from www.nrcresearchpress.com by Renmin University of China on 09/02/12

3.0 (2H, septet, J = 7 Hz, $CHMe_2$), 2.7 (2H, t, J = 7 Hz, CH_2), 1.5 (9H, s, $C(CH_3)_3$), 1.3 (9H, s, $C(CH_3)_3$), 1.0 (12H, d, J = 7 Hz, *i*-Pr CH_3). ^{13}C NMR ($CDCl_3$, ppm) δ: 166.3 (CH=N), 158.6, 140.0, 136.9, 126.9, 125.9, 118.1 (Ar), 61.6, 49.3, 35.2, 35.0, 34.7, 31.9, 31.8, 29.6. Elemental anal. calcd for $C_{23}H_{40}N_2O$ (%): C 76.61, H 11.18, N 7.77; found: C 76.81, H 11.11, N 7.77.

*Synthesis of ^{Pip}[ONN] (**5**):*

Ligand **5** was prepared analogously to **4**, using 3,5-di-*tert*-butyl-2-hydroxybenzaldehyde (2.56 g, 10.6 mmol), methanol (45 mL), and 4-(2-aminoethyl)piperidine (1.36 g, 10.6 mmol). This yielded a yellow powder (2.42 g, 10.6 mmol, 70%). ^{1}H NMR ($CDCl_3$, ppm) δ: 13.8 (1H, s, OH), 8.4 (1H, s, CH=N), 7.4 (1H, d, J = 2 Hz, Ar–H), 7.1 (1H, d, J = 2 Hz, Ar–H), 3.8 (2H, t, J = 7 Hz, CH_2), 2.7 (2H, t, J = 7 Hz, CH_2), 2.5 (4H, t, J = 5 Hz, CH_2), 1.6 (6H, m, CH_2), 1.5 (9H, s, $C(CH_3)_3$, 1.3 (9H, s, $C(CH_3)_3$). ^{13}C NMR ($CDCl_3$, ppm) δ: 166.75 (C=N), 158.3, 140.1, 136.9, 127.0, 126.0, 118.1 (Ar), 60.0, 57.3, 55.1, 35.4, 35.2, 34.3, 31.7, 26.2, 24.4 (CH_2). Elemental anal. calcd for $C_{22}H_{36}N_2O$ (%): C 76.69, H 10.53, N 8.13; found: C 76.90, H 10.45, N 8.10.

*Synthesis of ^{Mor}[ONN] (**6**):*

Ligand **6** was prepared analogously to **4**, using 3,5-di-*tert*-butyl-2-hydroxybenzaldehyde (2.56 g, 10.6 mmol), methanol (45 mL), and 4-(2-aminoethyl)morpholine (1.39 g, 10.6 mmol) to yield a pale yellow solid (3.82 g, 10.6 mmol, 85%). ^{1}H NMR ($CDCl_3$, ppm) δ: 13.7 (1H, s, OH), 8.4 (1H, s, CH=N), 7.4 (1H, d, J = 2 Hz, Ar–H), 7.1 (1H, d, J = 2 Hz), 3.73 (8H, t, J = 4 Hz, CH_2), 2.7 (2H, t, J = 7 Hz, CH_2), 2.5 (2H, t, J = 7 Hz, CH_2) 1.4 (9H, s, $C(CH_3)_3$), 1.3 (9H, s, $C(CH_3)_3$). ^{13}C NMR ($CDCl_3$, ppm) δ: 167.0 (C=N), 158.3, 140.2, 136.9, 127.1, 126.0, 118.1 (Ar), 67.2 (CH_2), 59.5, 57.0 (CH_2), 54.1 (CH_2), 35.2, 34.3 ($C(CH_3)_3$), 31.7, 29.6 ($C(CH_3)_3$). Elemental anal. calcd for $C_{21}H_{34}N_2O_2$ (%): C 72.79, H 9.89, N 8.08; found: C 72.84, H 9.91, N 8.15.

Zinc complexes

The complex ^{NMe_2}[ONN]ZnN$(SiMe_3)_2Me_2$ (**7**) was synthesized according to a literature procedure.[14]

*Synthesis of ^{Pip}[ONN]ZnN$(SiMe_3)_2$ (**8**):*

To a stirring solution of ^{Pip}[ONN] (2.00 g, 6.16 mmol) in THF (40 mL), a 1:1 stoichiometric ratio of $Zn(N(SiMe_3)_2)_2$ (2.38 g, 6.16 mmol) was added as a THF solution. After 2 h, the THF was removed in vacuo and the compound was isolated. To ensure complete dryness, the resulting solid was left under vacuum for several hours. To purify the solid, a pentane/toluene mixture was used to recrystallize the product. This yielded a yellow solid (1.97 g, 3.42 mmol, 58%). ^{1}H NMR ($CDCl_3$, ppm) δ: 8.2 (1H, s, CH=N), 7.4 (1H, d, J = 3 Hz, Ar–H), 6.9 (1H, d, J = 3 Hz, Ar–H), 3.7 (2H, t, J = 6 Hz, CH_2), 2.9 (2H, t, J = 6 Hz, CH_2), 2.7 (4H, t, J = 5 Hz, N–CH_2), 1.7 (6H, pentet, J = 5 Hz, CH_2), 1.5 (9H, s, $C(CH_3)_3$), 1.3 (9H, s, $C(CH_3)_3$), 0.1 (18H, s, $SiMe_3$). ^{13}C NMR ($CDCl_3$, ppm) δ: 170.1 (C=N), 167.6, 141.6, 134.7, 129.4, 128.0, 117.7 (Ar), 55.7, 55.5 (CH_2), 53.8, 52.6 (N–CH_2), 35.6, 33.8 ($C(CH_3)_3$), 31.3, 29.4 ($C(CH_3)_3$), 25.7, 23.7, 23.0 (CH_2), 5.6 ($Si(CH_3)_3$). Elemental anal. calcd for $C_{25}H_{44}N_3OSiZn$ (%): C 60.52, H 8.94, N 8.49; found: C 60.40, H 9.01, N 8.29.

*Synthesis of ^{Mor}[ONN]ZnN$(SiMe_3)_2$ (**9**):*

Complex **9** was prepared analogously to **8** using ^{Mor}[ONN] (1.01 g, 2.91 mmol), THF (40 mL), and $Zn(N(SiMe_3)_2)_2$ (1.12 g, 2.91 mmol). In contrast to **8**, **9** was mixed with 10 mL of THF and added to a stirring mixture of $Zn(N(SiMe_3)_2)_2$ in 30 mL THF. This synthesis yielded a light yellow solid (1.10 g, 1.92 mmol, 67%). ^{1}H NMR ($CDCl_3$, ppm) δ: 8.2 (1H, s, CH=N), 7.5 (1H, d, J = 3 Hz, Ar–H), 6.9 (1H, d, J = 3 Hz, Ar–H), 3.7 (4H, t, J = 6 Hz, O–CH_2), 2.9 (4H, t, J = 6 Hz, N–CH_2), 2.6 (2H, t, J = 7 Hz, CH_2), 1.9 (2H, t, J = 7 Hz, CH_2), 1.5 (9H, s, $C(CH_3)_3$), 1.3 (9H, s, $C(CH_3)_3$), 0.1 (18H, s, $SiMe_3$). ^{13}C NMR ($CDCl_3$, ppm) δ: 172.9 (C=N), 168.8, 141.7, 135.4, 130.0, 129.5, 117.2 (Ar), 68.2, 67.0 (O–CH_2), 59.0, 57.7 (CH_2), 35.8, 34.0 ($C(CH_3)_3$), 31.6, 29.7 ($C(CH_3)_3$), 5.1 ($SiMe_3$). Elemental anal. calcd for $C_{24}H_{42}N_3O_2SiZn$ (%): C 57.87, H 8.50, N 8.44; found: C 57.81, H 8.30, N 8.39.

*Synthesis of ^{Py}[ONN]$_2$Zn (**10**):*

Complex **10** was prepared analogously to **8**, leading to an impure reaction mixture. Recrystallization led to the isolation of the bis(ligand) complex in 20% yield. Altering reaction conditions to use 2 equiv of ^{Py}[ONN] (1.11 g, 3.42 mmol), THF (40 mL), and 1 equiv of $Zn(N(SiMe_3)_2)_2$ (0.66 g, 1.71 mmol) yielded a brown powder (**10**) in high yield (0.85 g, 1.54 mmol, 90%). ^{1}H NMR ($CDCl_3$, ppm) δ: 8.5 (2H, m, Ar–H), 8.2 (2H, s, CH=N), 7.3–6.8 (10H, m, Ar–H), 4.7 (4H, s, CH_2), 1.4 (18H, s, $C(CH_3)_3$), 1.3 (18H, s, $C(CH_3)_3$). ^{13}C NMR ($CDCl_3$, ppm) δ: 171.6 (C=N), 170.6, 157.1, 149.0, 141.8, 137.5, 133.5, 129.2, 129.1, 122.7, 122.3, 117.9 (Ar), 63.0 (CH_2), 35.8, 34.5 ($C(CH_3)_3$), 31.9, 29.9 ($C(CH_3)_3$). Elemental anal. calcd for $C_{42}H_{34}N_4O_2Zn$ (%): C 70.82, H 7.64, N 7.87; found: C 71.00, H 7.81, N 7.66.

*Synthesis of ^{Q}[ONN]$_2$Zn (**11**):*

Complex **11** was prepared analogously to **10** using ^{Q}[ONN] (3.00 g, 7.76 mmol), THF (40 mL), and $Zn(N(SiMe_3)_2)_2$ (1.40 g, 3.88 mmol). Complex **11** was recrystallized from a mixture of hexamethyldisiloxane and THF prior to use. The synthesis yielded a bright red solid (2.72 g, 34.6 mmol, 88%). ^{1}H NMR ($CDCl_3$, ppm) δ: 9.0 (2H, d, J = 5 Hz, Ar–H), 8.7 (2H, s, CH=N), 8.4 (2H, d, J = 5 Hz, Ar–H), 8.4–7.0 (12H, m, Ar–H), 1.6 (18H, s, $C(CH_3)_3$), 1.3 (18H, s, $C(CH_3)_3$). Elemental anal. calcd for $C_{48}H_{54}N_4O_2Zn$ (%): C 73.50, H 6.94, N 7.14; found: C 73.71, H 7.00, N 7.05.

*Synthesis of $^{N(i\text{-}Pr)_2}$[ONN]$_2$Zn(*i*-Pr)$_2$ (**12**):*

Complex **12** was prepared analogously to **10** using $^{N(i\text{-}Pr)_2}$[ONN](*i*-Pr)$_2$ (1.50 g, 4.15 mmol), THF (50 mL), and $Zn(N(SiMe_3)_2)_2$ (0.80 g, 2.07 mmol). The resulting product was a yellow solid (1.79 g, 3.02 mmol, 86%). ^{1}H NMR ($CDCl_3$, ppm) δ: 8.2 (2H, s, CH=N), 7.4 (2H, d, J = 3 Hz, Ar–H), 7.0 (2H, d, J = 3 Hz, Ar–H) 3.5 (4H, t, J = 9 Hz, CH_2), 2.9 (4H, septet, J = 4 Hz, $CH(CH_3)_2$), 2.7 (4H, t, J = 9 Hz, CH_2), 1.5 (18H, s, ($C(CH_3)_3$), 1.3 (18H, s, $C(CH_3)_3$), 0.9 (12H, d, J = 4 Hz, $CH(CH_3)_2$), 0.8 (12H, d, J = 4 Hz, $CH(CH_3)_2$). Elemental anal. calcd for $C_{46}H_{78}N_4O_2Zn$ (%): C 70.42, H 10.02, N 7.14; found: C 71.55, H 10.50, N 7.50. While repeated elemental analysis tests of isolated crystals were off, suggesting decomposition in shipping, crystals obtained from the same batch on which an X-ray diffraction

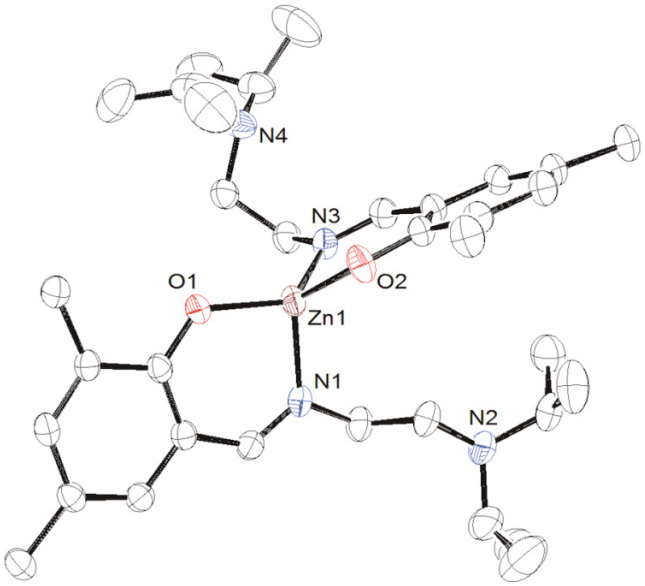
study was performed were used in the reported polymerization reactions.



Calcium complexes

^{NMe_2}[ONN]CaNMe$_2$(SiMe$_3$)$_2$ (**13**) was synthesized according to a literature procedure.[14]

*Synthesis of ^{Pip}[ONN]CaN(SiMe$_3$)$_2$ (**14**):*

^{Pip}[ONN] (0.95 g, 2.76 mmol) and NaN(SiMe$_3$)$_2$ (1.01 g, 5.5 mmol) were dissolved in THF (10 mL) and stirred at room temperature for 5 h. A stirring suspension of CaI$_2$ (0.79 g, 2.68 mmol) in THF was added dropwise to this solution and allowed to stir for 12 h. The solvent was removed in vacuo and the product was dissolved in pentane and filtered through celite. Removal of the volatiles in vacuo afforded **13** as a yellow solid (0.50 g, 9.23 mmol, 33%). ^{1}H NMR (CDCl$_3$, ppm) δ: 8.1 (1H, s, CH=N), 7.7 (1H, d, J = 3 Hz, Ar–H), 7.2 (1H, d, J = 3 Hz, Ar–H), 3.3 (2H, t, J = 6 Hz, CH$_2$), 2.1 (2H, t, J = 6 Hz, CH$_2$), 1.9 (4H, t, J = 5 Hz, CH$_2$), 1.8 (9H, s, C(CH$_3$)$_3$), 1.5 (9H, s, C(CH$_3$)$_3$), 1.2 (6H, pentet, J = 5 Hz, CH$_2$), 0.5 (18H, s, SiMe$_3$). Fig. 4. ORTEP drawing (spheroids at 50% probability) of ^{Q}[ONN]$_2$Zn (**11**). Protons and *tert*-butyl carbons are omitted for clarity.

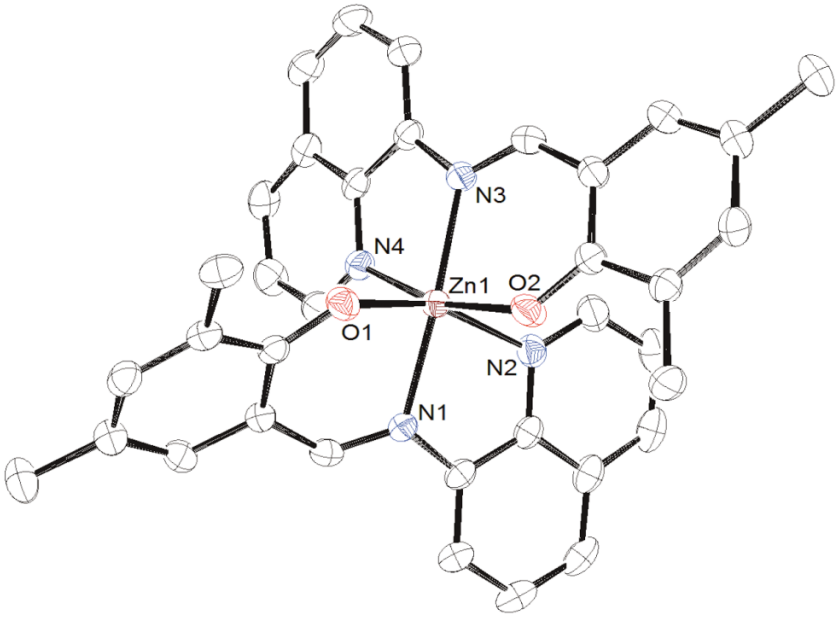
*Synthesis of $^{N(i\text{-}Pr)_2}$[ONN]CaN(SiMe$_3$)$_2$(*i*-Pr)$_2$ (**15**):*

Complex **15** was prepared analogously to **14** using 1 equiv of $^{N(i\text{-}Pr)_2}$[ONN](*i*-Pr)$_2$ (1.01 g, 2.80 mmol), 2 equiv of NaN(SiMe$_3$)$_2$ (1.03 g, 5.60 mmol), THF (30 mL), and CaI$_2$ (0.82 g, 2.80 mmol), isolating **15** as a bright yellow solid (0.80 g, 1.43 mmol, 51%). ^{1}H NMR (CDCl$_3$) δ: 8.3 (1H, s, CH=N), 7.7 (1H, d, J = 3 Hz, Ar–H), 7.2 (1H, d, J = 3 Hz, Ar–H), 3.0 (2H, septet, J = 6 Hz, CH(CH$_3$)$_2$), 2.6 (4H, m, J = 9 Hz, C*H*$_2$), 1.5 (9H, s, C(CH$_3$)$_3$), 1.4 (9H, s, C(CH$_3$)$_3$), 1.0 (12H, d, J = 6 Hz, CH(CH$_3$)$_3$), 0.3 (18H, s, SiMe$_3$). Elemental anal. calcd for C$_{26}$H$_{48}$N$_3$CaOSi (%): C 64.14, H 9.94, N 8.63; found: C 64.07, H 10.01, N 8.47.

Crystal structure analyses

Crystals of **11** and **12** were grown by vapour diffusion using pentane and toluene at –35 °C. Single crystals were coated with Paratone-N oil, mounted using a polyimide MicroMount, and frozen in the cold nitrogen stream of the goniometer. A hemisphere of data was collected on a Bruker AXS P4/SMART 1000 diffractometer using ω and θ scans with a scan width of 0.3° and 10 s (**11**) or 30 s (**12**) exposure times. The detector distance was 5 cm. The data were reduced using SAINT[18] and corrected for absorption with SADABS.[19] The structure was solved by direct methods and refined by full-matrix least-squares on F2(SHELXTL).[20] For **11**, one of the *tert*-butyl groups, attached at C(4), was disordered and the site occupancies determined using an isotropic model at 0.7 (C(9)–C(11)) and 0.3 (C(9′)–C(11′) and fixed in subsequent refinement cycles. All non-hydrogen atoms were refined using anisotropic displacement parameters. Hydrogen atoms were included in calculated positions and refined using a riding model. Graphics were created using the ORTEP program.[21]



Results and discussion

Catalyst synthesis and characterization

Tridentate Schiff base ligands were readily synthesized via

Fig. 5. ORTEP drawing (spheroids at 50% probability) of $^{N(i\text{-}Pr)_2}$[ONN]$_2$Zn(*i*-Pr)$_2$ (**12**). Protons and *tert*-butyl carbons are omitted for clarity.

imine condensation reactions and characterized by ^{1}H and ^{13}C NMR spectroscopy (eq. [1]). Six ligands were used in this study, substituted with dimethylamine, diisopropylamine, pyridine, quinoline, piperidine, and morpholine units.

[1]

Zinc catalysts were prepared by the dropwise addition of the proligand of choice to a stirring solution of bis(bis(trimethylsilyl)amide)zinc in THF. Filtration, drying, and recrystallization from a 1:3 toluene–pentane mixture accessed the desired products. Long recrystallizations promoted a transformation from the desired ^{R}[ONN]ZnN(SiMe$_3$)$_2$ complexes, observed in crude NMR spectra, to the bis(ligand) ^{R}[ONN]$_2$Zn species. This disproportionation reaction significantly lowered isolated yields of the desired products and in some cases prevented the isolation of a pure sample of the desired ^{R}[ONN]ZnN(SiMe$_3$)$_2$ catalyst. Improved yields of the ^{R}[ONN]$_2$Zn species could be obtained from purposefully using a 2:1 ligand–metal ratio. Ligands **1**–**6** and isolated complexes **7**–**12** are shown in Fig. 2. Complex formation was readily identified by a diagnostic shift in the imine resonance to δ 8.2 for alkyl-substituted nitrogen donor arms and δ 8.5 and 8.7 for pyridyl and quinolynyl donor arms, respectively, as well as the disappearance of the hydroxy signals. The integration and presence of N(SiMe$_3$)$_2$ protons at δ 0.1 was diagnostic for the formation of mono- or bis-ligated complexes.

Calcium complexes were prepared via the ^{R}[ONN] sodium salt with 1 equiv of ligand and 2 equiv of NaN(SiMe$_3$)$_2$ reacted for 5 h in THF followed by dropwise addition of CaI$_2$ to the reaction mixture. Removal of solvent after 12 h followed by filtration and recrystallization from pentane afforded three desired complexes of the form ^{R}[ONN]CaN(SiMe$_3$)$_2$ characterized by ^{1}H and ^{13}C NMR spectroscopy (**13**–**15**, Fig. 3). Yields were moderate compared with the corresponding Zn complexes, potentially because of the relative stability of the CaI$_2$. Attempts to improve yields with longer reaction times and higher temperatures were unsuccessful and led to complex decomposition. Of note, pyridine and quinoline functionalities were not employed as the complexes had been previously tested, whereas morpholine substituents promoted the formation of an intractable mixture of solids. Again, the complex formation was noted in spectroscopic

studies by a shift in the imine resonance, the disappearance of hydroxyl resonances, and the presence and integration of $N(SiMe_3)_2$ signals.

Crystals suitable for X-ray diffraction studies were grown for **11** and **12** by vapour diffusion of pentane into toluene. The crystal structure of **11** (Fig. 4) indicates the complex has a distorted octahedral geometry with coordination of the quinoline nitrogens to afford a formally 22-electron complex. This six-coordinate complex, with both tridentate ligands arranged in a meridional geometry, contrasts with similar four-coordinate diphenolato complexes synthesized by Zhang et al.[23] In **11**, Zn–N bonds ranging from 2.10 to 2.27 Å contrast with the stronger Zn–O bonds of 2.00 and 2.03 Å. The structure of **12**, however, shows the Zn centre in a distorted T_d geometry (Fig. 5), similar to a previously published bidentate salicylaldimine structure.[23] A four-coordinate structure is favoured, correlating with the removal of the electron-withdrawing quinoline ring structure and the increased steric hindrance of the isopropyl substituents. As expected, the complex has shorter Zn–O (1.91 Å) and Zn–N (2.00, 2.01 Å) bond lengths compared with **11**. Selected bond distances, bond angles, and crystallographic parameters are provided in Tables 1 and 2.

Ring-opening polymerizations of *rac*-lactide and ε-caprolactone — Screening reactions

Polymerizations of ε-caprolactone mediated by complexes **7**–**15** are summarized in Table 3. Polymerizations with monomer–catalyst ratios of 100:1 were carried out in toluene (3 mL) at room temperature. No additional alcohol initiator was added to the reactions, so initiation from latent trimethylsilylamide or ligand alkoxide functionalities was expected. Temperatures were maintained at room temperature as higher temperatures and bulk polymerization led to significant transesterification and broadened molecular weight distributions, contrasting previous reports,[15,21] but supporting the poor activity of previously reported chiral variants.[22] None of the catalysts were effective at controlling the polymerization, however, certain trends can be highlighted. Complexes with a single ligand and bis(trimethylsilyl)amido initiating group initiate a productive PCL polymerization, however, polydispersities (PDIs) are high and observed molecular weights are higher than expected from monomer conversion. Complexes with two ligands, lacking the amido functionality, are unable to initiate the polymerization. The calcium complexes are significantly faster at polymerizing the ε-caprolactone monomer. Chromatographic analysis of these polymers still suggests a lack of control over this reaction, with multimodal molecular weight distributions. While disproportionation is possible for the monoligated complexes under polymerization conditions, which may explain the lack of control, no disproportionation was observed for **7**–**9** or **13**–**15** in coordinating solvents.

Polymerizations of *rac*-lactide mediated by complexes **7**–**15** are summarized in Table 4. Reactions were carried out at 70 °C in toluene for 30 or 240 min depending upon the observed reactivity of the complexes. Clear trends in catalyst performance are observed. Complexes **7**–**9**, ligated by a single tridentate ligand, produce PLAs of predictable molecular weights and low polydispersities. The fastest catalyst, capable of polymerizing nearly 100 equiv of *rac*-lactide in under 30 min, is the previously reported **7**, substituted with a sterically unencumbered dimethylamine donor arm. Increasing the steric bulk slows the polymerization, as expected. Both the rate of polymerization and the control of the polymerization are inhibited by the morpholine ligand, suggesting the pendant oxygen of the morpholine ring may block lactide coordination and ROP. Bis(ligand) complexes also initate and control the polymerization of lactide, likely inserting into one

[c] Ratio of 400:1 monomer–catalyst used.

of the zinc alkoxide bonds to the ligand.[23,24] Molecular weights were higher than theoretical, suggesting not all ligands may initiate the polymerization. Interestingly, the quinoline-substituted complex, which in the solid state had no open coordination sites, is completely unreactive towards lactide even at higher temperatures and longer reaction times, suggesting this octahedral coordination mode may be maintained in solution. No shift in lactide or catalyst resonances are noted in ^{1}H NMR spectra of 1:1 mixtures of **11** and *rac*-lactide, supporting this statement.

Finally, the calcium complexes prepared were all effective in the polymerization of *rac*-lactide, with similar levels of control regardless of the nature of the pendant donor arm. Reactions were slow, however, requiring longer reaction times to achieve higher conversions. Due to the inferior quality of the catalysts compared with industry standards, full reaction kinetics were not pursued. However, further evidence of polymerization control is offered by variation of [M]:[I] (monomer to initiator) ratios, as shown in Table 4 for catalyst **15**. When polymerizations are quenched at the same conversion, molecular weights increase linearly and correlate well with predicted values. A slight increase in PDI at longer reaction times suggest the catalysts may have limited thermal stability. All catalysts produced atactic PLA and showed no stereospecificity. Interestingly, the calcium complexes show lower activity, potentially because of their larger size and lower Lewis acidity, contributing to a lower overall reactivity.

Conclusions

Nine zinc and calcium complexes supported by phenoxy-imine ligands with various pendant donors were prepared, characterized, and screened as catalysts in the ROP of ε-caprolactone and *rac*-lactide. Seven of these catalysts are novel and include pendant piperidine, morpholine, diisopropylamine, pyridine, and quinoline donors to compare with first-generation catalysts substituted with dimethylamine donors. Zinc complexes have a tendency to disproportionate to form bis(ligand) species, which are ineffective for the polymerization of ε-caprolactone but initiate slowly to produce PLAs of controlled PDIs and molecular weights. Improved control was achieved through the use of zinc and calcium complexes coordinated to a single ligand framework with low PDI.

Abstract: A green and simple procedure for the thiocynation of aromatic and heteroaromatic rings in the presence of a catalytic amount of citric acid in water are described. The reactions proceed in high yields, with short reaction times and under mild conditions.

Key words: thiocyanation, citrc acid, organocatalyst, hydrogen peroxide, water.

Résumé : On a mis au point une méthode simple et écologique d'effectuer la thiocyanuration de noyaux aromatiques et hétéroaromatiques, en présence d'une quantité catalytique d'acide citrique, dans l'eau. Les réactions se font dans des conditions douces, de courts temps de réaction et avec des rendements élevés.

Mots-clés : thiocyanuration, acide citrique, catalyseur organique, peroxyde d'hydrogène, eau.

[Traduit par la Rédaction]

Introduction

Organocatalysis has emerged during the last decade as one of the major issues in the development of catalytic chemical technology.[1] As for conventional catalysis with transition-metal complexes, by using organic catalysts large quantities of products are expected to be prepared using a minimal amount of small organic molecules.[2] The recent organocatalytic protocols are particularly attractive because of the mildness of the reaction conditions, operational simplicity, the potential for the development of large scale production, and the ready availability and low toxicity of the organocatalysts.[3–12] A diverse set of organocatalytic reactions, including C–C, C–N, and C–O bond formation,[13] Diels–Alder,[14,15] Baylis–Hilman,[16,17] Mannich,[14,18–20] Michael,[14,21,22] Friedel–Crafts alkylation,[23] oxidation,[24,25] and carbohydrate synthesis,[26] has benefited from the developments in this area.[27–29] On the other hand, organocatalyzed reactions using water as a solvent have attracted a great deal of attention mainly because of the low cost, the safety, and the environmentally benign nature of water. The synthesis of organic molecules via reactions in water is an extensively investigated topic, which entails the additional challenge of water tolerance for a catalyst. Thus, the development of small organic molecules that catalyze reactions in water is currently an important goal amongst today's synthetic community.[30]

The thiocyanation reaction is one of the most useful carbon–sulfur bond-forming reactions. Thiocyanates have gained considerable importance in various areas of organosulfur chemistry.[31] For example, the thiocyanato group occurs as an important functionality in certain anticancer natural products formed by deglycosylation of glucosinolates derived from cruciferous vegetables.[32–36] On the other hand, thiocyano-substituted compounds are a useful precursor for the synthesis of organosulfur compounds, in which the thiocyanate group will be readily transferred to other functional groups such as sulfide,[35] aryl nitrile,[36] thiocarbamate,[37] and thionitrile.[38] Several methods have been developed for the thiocyanation of arenes by using various reagents[39–41] such as *N*-thiocyanatosuccinimide,[42] ceric ammonium nitrate (CAN),[43] acidic mont K10 clay,[44] iodine/methanol,[45] diethyl azodicarboxylate,[46] IL-$OPPh_2$,[47] pentavalent iodine,[48] IBX,[49] $FeCl_3$,[50] potassium peroxydizulfate – copper(II),[51] and Selectfluor.[52] However, most of the reported methods for the synthesis of aryl thiocyanates are associated with one or more of the following drawbacks such as low yields, long reaction times, the use of large amounts of catalyst, and the use of toxic or expensive catalysts. Thus, the search for finding an efficient, inexpensive, and nonpolluting method for the synthesis of this class of compounds is still of practical importance.

Because of these problems and the recent intense attention on environmentally benign protocols, the search for new and efficient catalysts that are able to promote organic reactions under green conditions is of interest for the production of aryl thiocyanates. In this regard, we report the synthesis of organo thiocyanate derivatives in the presence of a catalytic amount of citric acid in aqueous media.

Results and discussion

For the synthesis of aryl thiocyanate, conversion of indole into its corresponding indole thiocyanate in water and room temperature has been considered as a model reaction (Scheme 1).

In an initial experiment, we examined the reaction of indole and KSCN in aqueous media by using different catalysts such as sodium citrate, benzenesulfonic acid, 1-(phenylthio) acetic acid, 4-chlorobenzoic acid, 4-methoxybenzoic acid, and citric acid. The results are summarized in Table 1. As Table 1 indicates, higher yield and shorter reaction times were obtained when citric acid was utilized as the catalyst. Brønsted acid organocatalysts such as benzenesulfonic acid, 1-(phenylthio)acetic acid, 4-chlorobenzoic acid, and 4-methoxybenzoic acid gave low yields of the corresponding 3-thiocyanato indole. The use of sodium citrate was also examined and a moderate yield of product was obtained. Citric acid very efficiently gave an excellent yield of the corresponding 3-thiocyanato indole in a shorter reaction time. This might be due to the solubility of citric acid in water, which could accelerate the reaction rate.

In the next step, the reaction of indole with H_2O_2 and KSCN was tested by using different amounts of citric acid at room temperature (Table 2). As shown in Table 2, the optimal amount of the catalyst was 10 mol %. In the absence of catalyst when indole was treated with hydrogen peroxide and KSCN, no product was obtained. When the amount of catalyst was less than 10 mol %, the yield of product was greatly reduced. Otherwise, increasing the catalyst loading from 10 to 15 mol % does not significantly change the yield. Also, the solvent effect was investigated using indole as a substrate. We carried out the reaction with the same concentration of the reactants in H_2O, MeOH, CH_3CN, CH_2Cl_2, THF, and AcOEt. Both the yields and the reaction times listed in Table 2 suggested that water was the most favorable solvent for the thiocyanation.

Consequently, 10 mol % citric acid was used in subsequent experiments. We then applied this reaction to a wide range of aromatic and heteroaromatic compounds; the results are summarized in Table 3.

A good range of aromatic and heteroaromatic compounds underwent thiocyanation with high regioselectivities and excellent yields being observed in all cases (Table 3). The reaction was mild and equally good for indoles, anilines, and N- substituted anilines.

As shown in Table 3, indole and electron-rich indoles gave the desired products in excellent yields (Table 3, entries 1–3). Also, electron-deficient indoles such as 5-bromoindole afforded the corresponding 5-bromo-3-thiocyanato indoles in good yields, but required longer reaction times (Table 3, entry 4). This observation can be attributed to the lower electron density of such substrates. The thiocyanation reaction was highly regioselective at the 3-position of the indole ring. Pyrrole was easily transformed into the monothiocyanated product within 15 min. After reviewing the reactions for the heterocycles, we examined the capability of aromatic amines in the thiocyanation reaction. Electron-rich amines such as *o*-toluidine and *m*-toluidine underwent reaction under the same conditions, leading to a high production efficiency (Table 3, entries 9 and 10). Our review showed that electron-deficient amines also carry out this reaction, but they need more time (Table 3, entries 11–14). In N-substituted amines some interesting results were achieved. In all cases, the substrate reacted and produced corresponding aryl thiocyanates (Table 3, entries 6–8 and 16–18). As shown in Table 3, the substitution was highly regioselective, occurring at the para position of the aromatics rings.

In comparison with the previously reported method using other reagents, which requires refluxing conditions for some substrates, the assistance of ultrasonic irradiation, and a toxic solvent or oxidant, this method is suitable and has mild and green reaction conditions.

In conclusion, we have developed an efficient, simple, and green-mediated thiocyanation of aromatic compounds with high regioselectivity. The described method has advantages such as a simple work-up, a short reaction time, is metal free, uses mild reaction conditions, and a clean production of the desired products in high yields.

those reported in the literature. Progress of the reactions was monitored by TLC using silica gel SIL G/UV 254 plates. The ^{1}H NMR (300 MHz) and ^{13}C NMR (75 MHz) were run on a Bruker Avance DPX-250 FT-NMR spectrometer (δ in ppm). Microanalysis was performed on a PerkinElmer 240-B microanalyzer. Melting points were recorded on a Büchi B-545 apparatus using open capillary tubes.

General procedure for the preparation of 3-thiocyanatoindole (1a)

A suspension of indole (0.117 g, 1 mmol), potassium thiocyanate (0.294 g, 3 mmol), and citric acid (0.0164 g, 10 mol %) in H_2O (3–5 mL) was stirred at room temperature for 5 min. Then H_2O_2 (30%, 3 mmol) was added dropwise (2–5 min). The progress of the reaction was monitored by TLC. After completion of the reaction, the reaction mixture was extracted with $CHCl_3$ (2 × 10 mL). Anhydrous Na_2SO_4 (3 g) was then added to the organic layer and filtered off after 20 min. $CHCl_3$ was removed and further purification was achieved by silica gel column chromatography with hexane/AcOEt (5:1).

mp 107–108 °C (no literature value available). FT-IR (KBr): 2156 (SCN), 2222 (CN), 3360 and 3444 (NH_2). ^{1}H NMR ($CDCl_3$) δ: 7.58–7.28 (m, 2H), 6.83 (s, 1H), 4.96 (br s, 2H). ^{13}C NMR ($CDCl_3$) δ: 151.7, 138.4, 137.2, 117.8, 116.3, 111.3, 109.3, 96.7. MS (*m*/*z*) = 175 (M^+). Anal. calcd for $C_8H_5N_3S$: C 54.84, H 2.88, N 23.98; found: C 55.05, H 2.75, N 23.88.

3-Trifluoromethyl-4-thiocyanatoaniline (1m)

mp 148–150 °C (no literature value available). FT-IR (KBr): 2160 (SCN), 3275 and 3369 (NH_2). ^{1}H NMR ($CDCl_3$) δ: 7.80–7.33 (m, 3H), 4.01 (br s, 2H). ^{13}C NMR ($CDCl_3$) δ: 144.6, 135.3, 125.5, 118.8, 117.4, 115.1, 111.7. MS (*m*/*z*) = 218 (M^+). Anal. calcd for $C_8H_5F_3N_2S$: C 44.04, H 2.31, N 12.84; found: C 44.26, H 2.43, N 12.75.

2-Trifluoromethyl-4-thiocyanatoaniline (1n)

mp 119–120 °C (no literature value available). FT-IR (KBr): 2158 (SCN), 3395 and 3435 (NH_2). ^{1}H NMR ($CDCl_3$) δ: 7.68–7.28 (m, 2H), 6.80 (s, 1H), 4.574 (br s, 2H). ^{13}C NMR ($CDCl_3$) δ: 146.7, 137.5, 131.9, 125.6, 114.3, 111.6, 109.2. MS (*m*/*z*) = 218 (M^+). Anal. calcd for $C_8H_5F_3N_2S$: C 44.04, H 2.31, N 12.84; found: C 43.85, H 2.40, N 12.79.

5-Thiocyanatoindoline (1o)

mp 59–60 °C (no literature value available). FT-IR (KBr): 2216 (SCN), 3420 (NH). ^{1}H NMR ($CDCl_3$) δ: 7.19–6.92 (m, 3H), 5.20 (br s, 1H), 4.02 (t, *J* = 9.7 Hz, 2H), 3.23 (t, *J* = 8.5 Hz, 2H). ^{13}C NMR ($CDCl_3$) δ: 142.1, 128.1, 127.8, 127.4, 122.3, 114.89, 110.3, 50.7, 28.51. MS (*m*/*z*) = 176 (M^+). Anal. calcd for $C_9H_8N_2S$: C 61.34, H 4.58, N 15.90; found: C 61.56, H 4.45, N 15.95.

4-Thiocyanato-*N*-phenyl-2,2-iminodiethanol (1p)

mp 66–69 °C (no literature value available). FT-IR (KBr): 2153, 3300. ^{1}H NMR ($CDCl_3$) δ: 7.43 (d, *J* = 6.5 Hz, 1H), 6.70 (d, *J* = 7.1 Hz, 2H), 3.75–3.60 (4H, m), 3.55–3.35 (m, 4H), 2.15 (s, 2H). ^{13}C NMR ($CDCl_3$) δ: 151.8, 132.1, 116.5, 114.3, 111.7, 58.7, 55.9. MS (*m*/*z*) = 238 (M^+). Anal. calcd for $C_{11}H_{14}N_2O_2S$: C 55.44, H 5.92, N 11.76; found: C 55.66, H 5.79, N 11.85.

4-Thiocyanato-*N*-phenylmorpholine (1q)

mp 74–76 °C (no literature value available). FT-IR (KBr): 2156 (SCN). ^{1}H NMR ($CDCl_3$) δ: 7.48 (d, *J* = 8.29 Hz, 2H), 6.92 (d, *J* = 8.42 Hz, 2H), 3.88 (t, *J* = 4.69 Hz, 4H), 3.24–3.21 (t, *J* = 4.83 Hz, 4H). ^{13}C NMR ($CDCl_3$) δ: 152.5, 133.7, 116.1, 111.9, 111.1, 67.1, 48.06. MS (*m*/*z*) = 220 (M^+). Anal. calcd for $C_{11}H_{12}N_2OS$: C 59.97, H 5.49, N 12.72; found: C 59.79, H 5.65, N 12.85.

4-Thiocyanato-*N*-phenyl-15-crown-5 (1r)

mp 77–80 °C (no literature value available). FT-IR (KBr): 2147 (SCN), 1094 (C–O), ^{1}H NMR ($CDCl_3$) δ: 7.35 (d, *J* = 5.5 Hz, 2H), 6.64 (d, *J* = 6 Hz, 2H), 3.57–3.72 (m, 20H). ^{13}C NMR ($CDCl_3$) δ: 149.3, 134.7, 112.8, 105.9, 112.6, 71.2, 70.2, 69.9, 68.01, 52.6. MS (*m*/*z*) = 352 (M^+). Anal. calcd for $C_{17}H_{24}N_2O_4S$: C 57.93, H 6.86, N 7.95; found: C 58.19, H 6.99, N 7.89.

Polarized continuum model study of bond dissociation energies of the O–NO_2 bond — A density functional theory study and natural bond order analysis

Zhang Ruizhou, Fu Zhumu, Li Xiaohong, and Zhang Xianzhou

Can. J. Chem. Downloaded from www.nrcresearchpress.com by Renmin University of China on 09/02/12
For personal use only.

Abstract: Density functional methods (B3LYP, B3PW91, B3P86, and MPWB95) with 6–31G** basis sets and complete basis methods are employed to investigate the bond dissociation energies (BDEs) of the O–NO_2 bond for seven *O*-nitroalcohol compounds in acetonitrile solution. B3LYP/6–31+G**, (RO)B3LYP/6–311++G(2df,2p), and B3LYP/6–311G(d,p) methods are also used. By comparing the calculated results with the experimental values, B3LYP/6–31+G** is the most accurate method to compute the reliable BDEs for the studied compounds. The substituent effects on the O–NO_2 BDEs are analyzed. It is found that electron-withdrawing groups increase the BDE of the parent compound, whereas electron-donating groups decrease the BDE of the parent compound. Further, the natural bond orbital analysis shows that there exist good linear correlations between $E^{(2)}$ and Hammett constants, the BDE, and the difference of the second-order stabilization energies $E^{(2)}$ of $lpO_3 \rightarrow BD^*(O_1–N_1)$ and $lpO_3 \rightarrow BD^*(O_2–N_1)$.

Key words: density functional theory, polarized continuum model, *O*-nitroalcohol compounds, bond dissociation energy, natural bond orbital analysis.
