Selective reduction of NO by CH<sub>4</sub> in the presence of excess oxygen was investigated using H-form zeolite catalysts. H-ZSM-5, H-ferrierite, and H-mordenite showed high catalytic activity and selectivity. On the contrary, H-USY and Al<sub>2</sub>O<sub>3</sub> were not effective for this reaction. Both NO–CH<sub>4</sub> and O<sub>2</sub>–CH<sub>4</sub> reaction hardly proceeded on H-ZSM-5. Higher NO<sub>x</sub> conversion was obtained in the NO<sub>2</sub>–O<sub>2</sub>–CH<sub>4</sub> and NO<sub>2</sub>–CH<sub>4</sub> systems than in the NO–O<sub>2</sub>–CH<sub>4</sub> system under high GHSV condition. It seemed that NO<sub>2</sub> plays an important role for selective reduction of NO by CH<sub>4</sub> on H-form zeolites.

**Keywords:** Nitric oxide; selective reduction; methane; zeolite

### 1. Introduction

Recently, selective catalytic reduction of NO by hydrocarbons in oxygen-rich atmosphere has attracted considerable attention as a new type of reaction alternative for the traditional NH<sub>3</sub>-SCR process. This reaction has been reported to proceed on various cation-exchanged zeolites [1–5], metallosilicates [6, 7], Al<sub>2</sub>O<sub>3</sub> [8, 9] and SiO<sub>2</sub>–Al<sub>2</sub>O<sub>3</sub> [10].

Iwamoto et al. [11] and Hamada et al. [12] have studied the reduction of NO by various hydrocarbons in the presence of oxygen on Cu-ZSM-5 and Al<sub>2</sub>O<sub>3</sub> catalysts, respectively. They have classified reductants into two groups, selective (C<sub>2</sub>H<sub>4</sub>, C<sub>3</sub>H<sub>6</sub>, C<sub>3</sub>H<sub>8</sub>, C<sub>4</sub>H<sub>8</sub>), and non-selective (H<sub>2</sub>, CO, CH<sub>4</sub>, C<sub>2</sub>H<sub>6</sub>) reductants for NO reduction in the presence of O<sub>2</sub> [13]. The CH<sub>4</sub>–O<sub>2</sub> reaction proceeded predominantly and the NO–CH<sub>4</sub> reaction hardly proceeded on Cu-ZSM-5 and Al<sub>2</sub>O<sub>3</sub>. It has been accepted that CH<sub>4</sub> is not effective for selective reduction.

However, hydrocarbon in the exhaust from a gas-cogeneration system is mainly CH<sub>4</sub>. Therefore, it is expected to develop a catalyst which is active for selective reduction of NO by CH<sub>4</sub> in oxygen-rich atmosphere. Recently, Li and Armor [14]

have reported that selective reduction by  $\text{CH}_4$  proceeds on Co-ZSM-5. In our previous study, we have also found that Ga-ZSM-5 shows high catalytic activity and extremely high selectivity for reduction of NO by  $\text{CH}_4$  or  $\text{C}_2\text{H}_6$  [15]. We have recently found that various H-form zeolite catalysts are also active and fairly selective for this reaction. In this paper, we will report the catalytic properties of H-form zeolites and the role of  $\text{O}_2$  for selective reduction of NO by  $\text{CH}_4$ .

## 2. Experimental

Zeolites used in this study were ZSM-5 (molar  $\text{SiO}_2/\text{Al}_2\text{O}_3$  ratio, 23.3), mordenite (19.9), ferrierite (17.8), and USY (14.5), supplied by Tosoh Corporation. Alumina, as a reference catalyst, was obtained from Catalysts & Chemical Ind. Co.

Measurements of catalytic activity were conducted by use of a fixed-bed flow reactor. A mixture of 1000 ppm NO (or  $\text{NO}_2$ ), 10%  $\text{O}_2$ , and 1000 ppm  $\text{CH}_4$  was fed to 0.1–0.5 g catalyst at a rate of  $100 \text{ cm}^3(\text{STP}) \text{ min}^{-1}$ . After reaching steady-state, effluent gases were analyzed by gas chromatography and chemiluminescence detection of  $\text{NO}_x$ . The catalytic activity was evaluated by the level of NO conversion to  $\text{N}_2$ .

## 3. Results and discussion

Fig. 1 shows the temperature dependence of catalytic activities of various H-form zeolites and  $\text{Al}_2\text{O}_3$  for NO reduction by  $\text{CH}_4$ . Among these catalysts, H-ZSM-5 showed the highest activity at  $500^\circ\text{C}$ . H-USY was inactive under these

NO, 1000 ppm;  $\text{CH}_4$ , 1000 ppm;  $\text{O}_2$ , 10%; total flow rate,  $100 \text{ cm}^3 \text{ min}^{-1}$ ; catalyst weight, 0.5 g.

reaction conditions, and its activity was similar to that of  $\text{Al}_2\text{O}_3$ . The  $\text{CH}_4\text{--O}_2$  reaction was predominant and NO reduction hardly proceeded on these catalysts.

The ratio of NO conversion to  $\text{CH}_4$  conversion is a measure of selectivity. As shown in fig. 2, H-ferrierite was most selective and the order of the selectivity for this reaction on these zeolites was as follows:

H-ferrierite > H-mordenite > H-ZSM-5 >> H-2USY.

H-ferrierite exhibited the lowest activity for the  $\text{CH}_4\text{--O}_2$  reaction, resulting in high selectivity for NO reduction. Although a high selectivity of  $\text{Al}_2\text{O}_3$  catalyst for NO reduction by  $\text{C}_3\text{H}_8$  has been reported [2], the selectivity for NO reduction by  $\text{CH}_4$  was extremely low. On the contrary, NO was selectively reduced on H-ZSM-5, H-mordenite, and H-ferrierite.

It has been reported by Hamada and co-workers [2] that the acidity of catalysts is one of the important factors which control the catalytic activity for selective reduction of NO. Fig. 3 shows  $\text{NH}_3\text{--TPD}$  spectra of various zeolites used in this study. H-USY showed very small acidity with weak acid strength, suggesting that the low catalytic activity of H-USY is probably due to its poor acidity.

Fig. 4 shows the catalytic activities of H-ZSM-5 for conversions of NO to  $\text{N}_2$  and  $\text{CH}_4$  to  $\text{CO}_x$  in various reaction temperatures. The NO- $\text{CH}_4$  reaction hardly proceeded at all temperatures in the absence of  $\text{O}_2$ , showing that NO reduction was promoted by  $\text{O}_2$ . Furthermore,  $\text{CH}_4$  oxidation did not proceed below  $500^\circ\text{C}$  in the absence of NO. Since NO reduction occurred under the conditions where the  $\text{CH}_4\text{--O}_2$  reaction did not proceed,  $\text{NO}_2$  should be concerned in selective reduction. All the zeolite catalysts used in this study were inactive for reduction of NO with  $\text{CH}_4$  in the absence of  $\text{O}_2$  and for oxidation of  $\text{CH}_4$  in the absence of NO. It has also

been reported by Hamada and co-workers [16] that selective reduction of NO with  $\text{C}_3\text{H}_8$  on  $\text{Al}_2\text{O}_3$  and H-form zeolites proceeds via  $\text{NO}_2$ – $\text{C}_3\text{H}_8$  reaction and that high selectivity was attributable to  $\text{NO}_2$ – $\text{C}_3\text{H}_8$  reaction and poor activity of these catalysts for  $\text{C}_3\text{H}_8$  oxidation by  $\text{O}_2$ .

In fig. 5, we compare the level of  $\text{NO}_x$  conversion to  $\text{N}_2$  as a function of reciprocal GHSV. Higher  $\text{NO}_x$  conversion was obvious in the  $\text{NO}_2$ – $\text{O}_2$ – $\text{CH}_4$  and  $\text{NO}_2$ – $\text{CH}_4$  systems than in the  $\text{NO}$ – $\text{O}_2$ – $\text{CH}_4$  system in high GHSV condition. In the latter system, NO conversion seems to show an induction period. These results

Fig. 5. Relationships between NO<sub>x</sub> conversion and GHSV on H-ZSM-5. (O) NO, 1000 ppm; CH<sub>4</sub>, 1000 ppm; O<sub>2</sub>, 10%; (Δ) NO<sub>2</sub>, 1000 ppm; CH<sub>4</sub>, 1000 ppm; O<sub>2</sub> 0%; (□) NO<sub>2</sub>, 1000 ppm; CH<sub>4</sub>, 1000 ppm; O<sub>2</sub>, 10%; total flow rate, 100 cm<sup>3</sup> min<sup>-1</sup>; catalyst weight, 0.1–0.5 g; reaction temperature, 500 °C.

lead us to deduce that the first step is NO oxidation to NO<sub>2</sub>, which further reacts with CH<sub>4</sub> to give N<sub>2</sub>, CO<sub>x</sub>, and H<sub>2</sub>O, similarly to the reduction of NO<sub>x</sub> by C<sub>3</sub>H<sub>8</sub> on H-form zeolites [16].

We conclude from these results that reduction of NO proceeds on various H-form zeolites even when CH<sub>4</sub> is used as reductant, and CH<sub>4</sub> can be an effective reductant for selective reduction of NO, and that NO<sub>2</sub> plays an important role in the selective reduction of NO by CH<sub>4</sub>.
