Accepted 29 November 2001

Selective catalytic reduction (SCR) of  $N_2O$  with  $C_2H_6$  took place effectively over Fe ion-exchanged BEA zeolite catalyst (Fe-BEA) even in the presence of excess oxygen. The mechanism in the SCR of  $N_2O$  with  $C_2H_6$  over Fe-BEA catalyst was studied by a transient response experiment and an *in situ* DRIFT spectroscopy. No oxidation of  $C_2H_6$  by  $O_2$  took place below 350 °C (in  $C_2H_6/O_2$ ). In the  $N_2O/C_2H_6/O_2$  system, however, it was found that the reaction of  $C_2H_6$  with  $O_2$  was drastically enhanced by the presence of  $N_2O$  even at low temperatures (200–300 °C). Therefore, it was concluded that  $N_2O$  played an important role in the oxidation of  $C_2H_6$  (*i.e.*, activation of  $C_2H_6$  at an initial step). On the basis of these findings, the mechanism in the SCR of  $N_2O$  with  $C_2H_6$  is discussed.

**KEY WORDS:** SCR,  $N_2O$ ; enhancement of  $C_2H_6$  oxidation; mechanism; Fe-BEA zeolite.

## 1. Introduction

Nitrous oxide ( $N_2O$ ), which also contributes to catalytic stratospheric ozone destruction, is a strong greenhouse-effect gas with a global warming potential (GWP) per molecule of about 300 times that of carbon dioxide ( $CO_2$ ) [1,2]. From the point of view of environment, therefore, it is important to study removal of  $N_2O$  in the emission gases. Selective catalytic reduction (SCR) of  $N_2O$  with reductants such as hydrocarbons [3–11] and ammonia [12,13] have been proposed as the effective method of  $N_2O$  abatement. Recently, we reported that  $CH_4$  reacted selectively with  $N_2O$  to produce  $N_2$ ,  $CO_2$  and  $H_2O$  even in the presence of excess  $O_2$  over Fe-BEA zeolite [7,8]. The oxidation of  $CH_4$  as one of inactive molecules by  $O_2$  required high temperature (above 450 °C) over Fe-BEA zeolite. Nevertheless, the selective oxidation of  $CH_4$  by  $N_2O$  over Fe-BEA zeolite readily occurred at much lower temperatures whether in the presence of  $O_2$  or not [8]. On the other hand, the oxidation behavior of  $C_2H_6$  in the SCR of  $N_2O$  was significantly different from that of  $CH_4$  [10]. The reaction of  $C_2H_6$  with  $O_2$  was significantly enhanced by the presence of  $N_2O$  even at low temperatures (200–300 °C), while the oxidation of  $C_2H_6$  by  $O_2$  did not proceed at these temperatures (below 350 °C in  $C_2H_6/O_2$ ).

The present study is devoted to an investigation of  $C_2H_6$  oxidation in the SCR of  $N_2O$  with  $C_2H_6$  over Fe-BEA catalyst by using a transient response reaction technique and an *in situ* diffuse reflectance infrared

Fourier transform (DRIFT) spectroscopy. The role of  $N_2O$  as oxidant in the oxidation of  $C_2H_6$  and the reaction mechanism in the SCR of  $N_2O$  are investigated.

## 2. Experimental

Fe-BEA catalyst was prepared by ion-exchange with a dilute solution of  $FeSO_4$  at 50 °C for 20 h under nitrogen atmosphere, and calcined in air for 12 h at 500 °C [4,7,14]. The zeolite supports (H-BEA,  $SiO_2/Al_2O_3 = 27.3$ ) were supplied by Tosoh Co. The loading weight of Fe on BEA support was 0.77 wt% (25% exchanged with  $Fe^{2+}$ ,  $1.3 \times 10^{-4}$  mol Fe ion  $\cdot$  g-cat<sup>-1</sup>). The reaction was carried out in a standard fixed-bed flow reactor by passing a gaseous mixture of  $N_2O$  (0–2000 ppm),  $C_2H_6$  (0–300 ppm) and  $O_2$  (10%) in He flow at a total flow rate of 50 cm min<sup>-1</sup> over 50 mg of catalyst (total pressure: 1 atm; space velocity (SV): 60 000 h<sup>-1</sup>). The transient response experiment was carried out in the same apparatus as described previously [11], capable of rapid switching (ON–OFF) of the gases, using a mixture of  $N_2O$  (1300 ppm),  $C_2H_6$  (1000 ppm) and  $O_2$  (10%) in He flow (SV = 60 000 h<sup>-1</sup>). Pretreatment of the samples and analysis of the products were carried out as described previously [11]. The catalytic activity for the reduction of  $N_2O$  with  $C_2H_6$  was evaluated by the percentage conversion of  $N_2O$  and  $C_2H_6$  to  $N_2$  and  $CO_x$  ( $CO_2$  and/or  $CO$ ), respectively. It should be noted that there were no by-products such as  $NO_x$  and other N-containing compounds in the present work, which was confirmed by the mass balance of nitrogen atoms between the reacted  $N_2O$  and the produced  $N_2$ .

\* To whom correspondence should be addressed.

The *in situ* DRIFT measurement was performed using the same set up and experimental procedures as in a previous paper [15]. A clean catalyst-surface spectrum was recorded at the reaction temperature and used as a background to which the measured spectra were corrected; the final spectra were presented in Kubelka–Munk form. The pretreatment and the exposure of the gaseous mixture (N<sub>2</sub>O: 1500 ppm, O<sub>2</sub>: 10%, C<sub>2</sub>H<sub>6</sub>: 1000 ppm) to the sample before the DRIFT measurements were carried out in the same way as in the transient response experiment described above (at 350 °C).

### 3. Results and discussion

#### 3.1. Catalytic activities in various reaction systems

Figure 1 shows N<sub>2</sub>O and C<sub>2</sub>H<sub>6</sub> conversions in various reaction systems over Fe-BEA catalyst. The direct decomposition of N<sub>2</sub>O and the oxidation of C<sub>2</sub>H<sub>6</sub> by O<sub>2</sub> initiated above 370 °C and 350 °C, respectively. However, the catalytic activity of N<sub>2</sub>O removal was drastically assisted by adding C<sub>2</sub>H<sub>6</sub> as reductant even at the low temperatures (200–300 °C). Increasing of N<sub>2</sub>O conversions correlated well with that of C<sub>2</sub>H<sub>6</sub> conversions. This result indicates that SCR of N<sub>2</sub>O with C<sub>2</sub>H<sub>6</sub> takes place effectively even in the presence of excess oxygen. Similar SCR reactions of N<sub>2</sub>O over Fe-zeolite catalysts have also been observed in other hydrocarbons such as CH<sub>4</sub> [3,7,8], C<sub>3</sub>H<sub>8</sub> [4–6] and C<sub>3</sub>H<sub>6</sub> [4–6,11].

The activities in the SCR of N<sub>2</sub>O with CH<sub>4</sub> and the oxidation of CH<sub>4</sub> with O<sub>2</sub> over Fe-BEA are also shown in figure 1 for the comparison, which are taken from

reference [8]. Although the oxidation of CH<sub>4</sub> (CH<sub>4</sub> + 2O<sub>2</sub> → CO<sub>2</sub> + 2H<sub>2</sub>O) over Fe-BEA required high temperatures (above 450 °C), the oxidation of CH<sub>4</sub> in the SCR of N<sub>2</sub>O readily occurred at much lower temperatures (figure 1). In the SCR of N<sub>2</sub>O with CH<sub>4</sub> over Fe-BEA catalyst, we also reported that there was a plateau in CH<sub>4</sub> conversion after N<sub>2</sub>O conversion reached 100% (*ca.* 350–450 °C) [7,8]. This is due to the fact that N<sub>2</sub>O in the mixture gas was completely consumed by the reaction with CH<sub>4</sub> at these temperatures. N<sub>2</sub>, H<sub>2</sub>O and CO<sub>2</sub> were observed as products in this reaction system. These results clearly indicated that CH<sub>4</sub> reacted selectively with N<sub>2</sub>O even in the presence of excess O<sub>2</sub>. Therefore, overall reaction in the N<sub>2</sub>O/O<sub>2</sub>/CH<sub>4</sub> system was represented by [8]

On the other hand, the oxidation behavior of C<sub>2</sub>H<sub>6</sub> in the SCR of N<sub>2</sub>O was significantly different from that of CH<sub>4</sub>. No plateaus in the C<sub>2</sub>H<sub>6</sub> conversion were observed in the N<sub>2</sub>O/O<sub>2</sub>/C<sub>2</sub>H<sub>6</sub> system, while the plateau in the C<sub>2</sub>H<sub>6</sub> conversion curve was observed after the N<sub>2</sub>O conversion reached 100% (in N<sub>2</sub>O/C<sub>2</sub>H<sub>6</sub> system). In the N<sub>2</sub>O/C<sub>2</sub>H<sub>6</sub> system (without O<sub>2</sub>), it should be noted that N<sub>2</sub>O in the mixture gas was completely consumed by the reaction with C<sub>2</sub>H<sub>6</sub> at these temperatures. If C<sub>2</sub>H<sub>6</sub> reacted selectively with N<sub>2</sub>O (in N<sub>2</sub>O/O<sub>2</sub>/C<sub>2</sub>H<sub>6</sub> system, equation (2)) in the same way as the N<sub>2</sub>O/O<sub>2</sub>/CH<sub>4</sub> system (equation (1)), a plateau should be observed at *ca.* 45% in the C<sub>2</sub>H<sub>6</sub> conversion. Therefore, it was found that the oxidation of C<sub>2</sub>H<sub>6</sub> by coexistent O<sub>2</sub> concomitantly occurred. As shown in figure 1, the oxidation of C<sub>2</sub>H<sub>6</sub> by O<sub>2</sub> (in the C<sub>2</sub>H<sub>6</sub>/O<sub>2</sub> system) required much

Figure 1. Conversion of N<sub>2</sub>O and HC in various reaction systems over Fe-BEA catalyst.; N<sub>2</sub>O (950 ppm), O<sub>2</sub> (10%) and HC (CH<sub>4</sub>: 500 ppm, C<sub>2</sub>H<sub>6</sub>: 300 ppm).

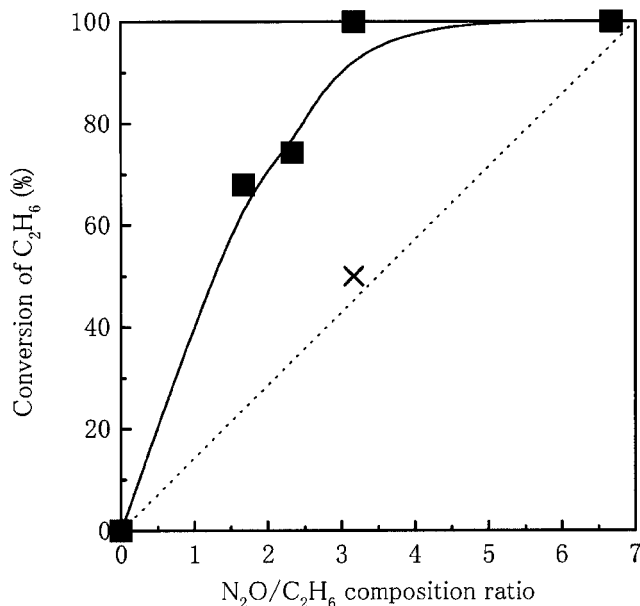

Figure 2. C<sub>2</sub>H<sub>6</sub> conversion as a function of C<sub>2</sub>H<sub>6</sub>/N<sub>2</sub>O composition ratio in the C<sub>2</sub>H<sub>6</sub>/N<sub>2</sub>O/O<sub>2</sub> reaction system at 350 °C. ■: C<sub>2</sub>H<sub>6</sub> 300 ppm (constant), O<sub>2</sub> 10% (constant) and N<sub>2</sub>O (0, 500, 700, 950, 2000 ppm); ×: C<sub>2</sub>H<sub>6</sub> 300 ppm (constant) and N<sub>2</sub>O (950 ppm).

higher temperatures (above 350 °C). This result indicates that the oxidation of C<sub>2</sub>H<sub>6</sub> by O<sub>2</sub> in the SCR of N<sub>2</sub>O is enhanced by the presence of N<sub>2</sub>O, and that N<sub>2</sub>O plays important roles at an initial step in the oxidation of C<sub>2</sub>H<sub>6</sub> by O<sub>2</sub> (*i.e.*, activation of C<sub>2</sub>H<sub>6</sub>).

Additionally, the enhancement of C<sub>2</sub>H<sub>6</sub> oxidation by O<sub>2</sub> in the presence of N<sub>2</sub>O was also confirmed by the catalytic experiments at the different N<sub>2</sub>O/C<sub>2</sub>H<sub>6</sub> composition ratio in the N<sub>2</sub>O (0, 500, 700, 950, 2000 ppm)/O<sub>2</sub> (constant as 10%)/C<sub>2</sub>H<sub>6</sub> (constant as 300 ppm) system. Figure 2 shows the dependence of the N<sub>2</sub>O/C<sub>2</sub>H<sub>6</sub> composition ratio (0, 1.67, 2.33, 3.17, 6.67) in the N<sub>2</sub>O/C<sub>2</sub>H<sub>6</sub>/O<sub>2</sub> system for the C<sub>2</sub>H<sub>6</sub> conversion at 350 °C. The plot of the N<sub>2</sub>O/C<sub>2</sub>H<sub>6</sub> system at 350 °C (in the absence of O<sub>2</sub>, the N<sub>2</sub>O/C<sub>2</sub>H<sub>6</sub> ratio = 3.17) is also shown in figure 2 for comparison. If the ratio of N<sub>2</sub>O conversion to C<sub>2</sub>H<sub>6</sub> conversion was along the stoichiometry of equation (2), the plots should exist on the dotted straight line. The C<sub>2</sub>H<sub>6</sub> conversions in the presence of O<sub>2</sub> exhibit large deviations from the straight line of stoichiometry over the whole range (0 < N<sub>2</sub>O/C<sub>2</sub>H<sub>6</sub> < 7).

### 3.2. Transient reaction experiments and DRIFT measurements

In order to examine in more detail the oxidation behavior of C<sub>2</sub>H<sub>6</sub> in the SCR of N<sub>2</sub>O, we performed the transient reaction experiments in the N<sub>2</sub>O/O<sub>2</sub>/C<sub>2</sub>H<sub>6</sub> system over Fe-BEA catalyst. Figure 3 shows the transient responses for C<sub>2</sub>H<sub>6</sub> oxidation on addition of N<sub>2</sub>O

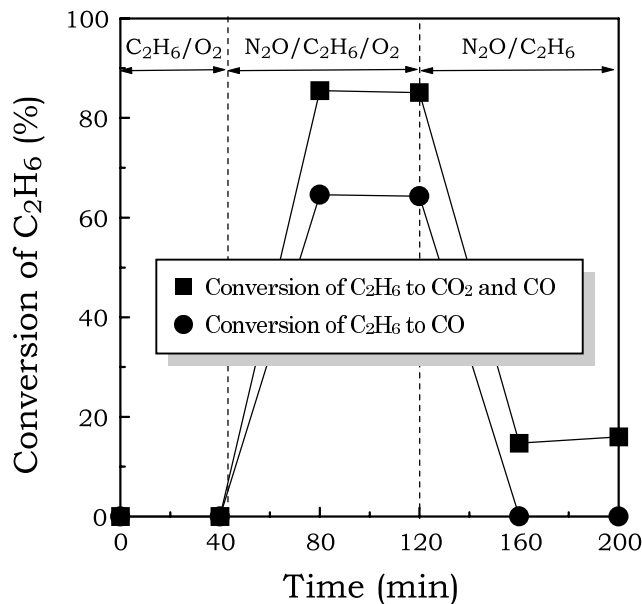

Figure 3. Transient responses for C<sub>2</sub>H<sub>6</sub> oxidation on addition of N<sub>2</sub>O (1300 ppm) to C<sub>2</sub>H<sub>6</sub> (1000 ppm)/O<sub>2</sub> (10%) flow and on removal of O<sub>2</sub> (10%) from N<sub>2</sub>O (1300 ppm)/C<sub>2</sub>H<sub>6</sub> (1000 ppm)/O<sub>2</sub> (10%) flow at 350 °C over Fe-BEA catalyst.

(1300 ppm) to C<sub>2</sub>H<sub>6</sub> (1000 ppm)/O<sub>2</sub> (10%) flow at 350 °C. C<sub>2</sub>H<sub>6</sub> conversion was drastically increased by adding N<sub>2</sub>O to C<sub>2</sub>H<sub>6</sub>/O<sub>2</sub> flow at 350 °C, while oxidation of C<sub>2</sub>H<sub>6</sub> by O<sub>2</sub> hardly occurred. Figure 3 also shows the transient responses for C<sub>2</sub>H<sub>6</sub> oxidation on removal of O<sub>2</sub> from N<sub>2</sub>O/C<sub>2</sub>H<sub>6</sub>/O<sub>2</sub> flow at 350 °C. After changing to the N<sub>2</sub>O/C<sub>2</sub>H<sub>6</sub> flow, the C<sub>2</sub>H<sub>6</sub> conversion decreased. In this case, the C<sub>2</sub>H<sub>6</sub> conversion was small simply due to the depletion of the oxidant (*i.e.*, N<sub>2</sub>O). These results directly demonstrate that the oxidation of C<sub>2</sub>H<sub>6</sub> by O<sub>2</sub> is significantly enhanced by the presence of N<sub>2</sub>O. The behaviors of these catalytic activities are in good agreement with the results in figure 1. In these experiments, CO, CO<sub>2</sub>, H<sub>2</sub>O and N<sub>2</sub> were observed as products. It should be noted that CO formation was observed only at the N<sub>2</sub>O/C<sub>2</sub>H<sub>6</sub>/O<sub>2</sub> flow. As shown in figure 3, the formation of CO<sub>2</sub> occurred in the reaction of C<sub>2</sub>H<sub>6</sub> with N<sub>2</sub>O (in the N<sub>2</sub>O/C<sub>2</sub>H<sub>6</sub> flow). Therefore, this result apparently shows that the formation of CO occurred in the reaction of C<sub>2</sub>H<sub>6</sub> with O<sub>2</sub> (in the N<sub>2</sub>O/C<sub>2</sub>H<sub>6</sub>/O<sub>2</sub> flow).

In order to investigate the correlation between the enhancement of C<sub>2</sub>H<sub>6</sub> oxidation by O<sub>2</sub> in the presence of N<sub>2</sub>O and the formation of the adsorbed surface species, the DRIFT spectra were recorded at 350 °C on Fe-BEA under the similar condition of the transient response experiments shown in figure 3. Figures 4(A) and 4(B) show *in situ* DRIFT spectra during the reaction in the C<sub>2</sub>H<sub>6</sub>/O<sub>2</sub> and N<sub>2</sub>O/C<sub>2</sub>H<sub>6</sub>/O<sub>2</sub> mixture gas at 350 °C over Fe-BEA, respectively. Clear peaks were hardly observed in exposing the C<sub>2</sub>H<sub>6</sub>/O<sub>2</sub> and N<sub>2</sub>O/C<sub>2</sub>H<sub>6</sub>/O<sub>2</sub> mixture (figures 4(A) and 4(B)). This is due to the fact that the activation and/or adsorption of C<sub>2</sub>H<sub>6</sub> hardly occur in the C<sub>2</sub>H<sub>6</sub>/O<sub>2</sub> system at 350 °C, and that

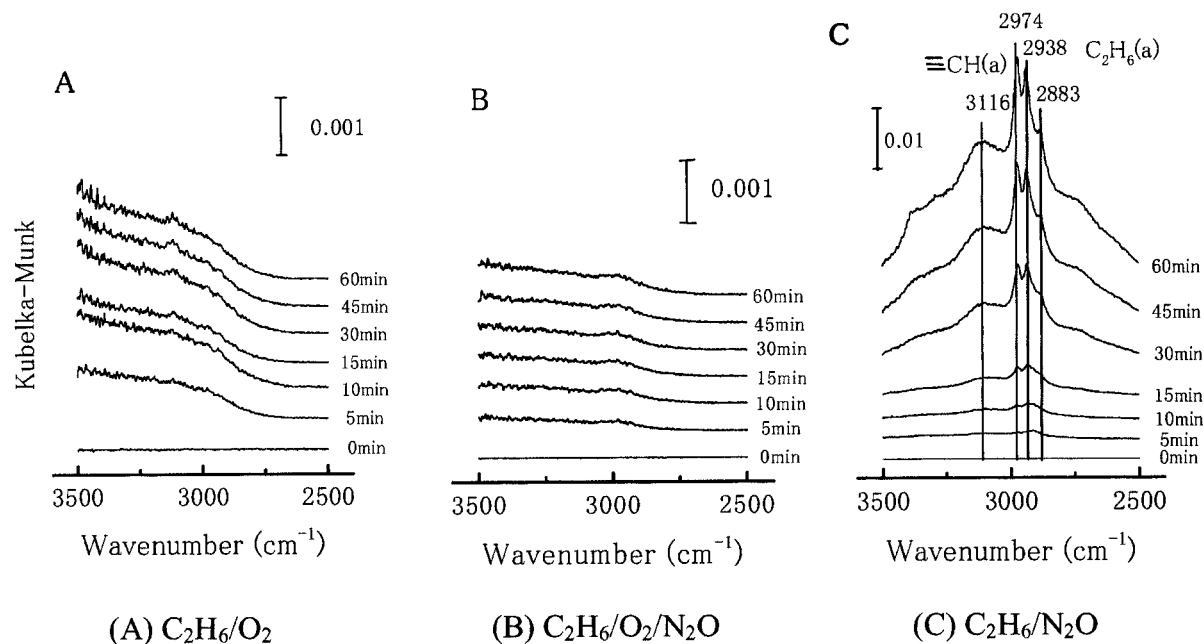

Figure 4. DRIFT spectra in the 3500–2500  $cm^{-1}$  region during the reaction at 350 °C. Gas composition:  $C_2H_6$  (1000 ppm),  $O_2$  (10%),  $N_2O$  (1500 ppm) in He flow.

almost no adsorbed species were present in the  $N_2O/C_2H_6/O_2$  system at 350 °C because of the steady-state reaction at high conversion.

Figure 4(C) shows *in situ* DRIFT spectra during the exposure of the  $N_2O/C_2H_6$  mixture gas at 350 °C over Fe-BEA. Several absorption peaks were observed in exposing the  $N_2O/C_2H_6$  mixture (figure 4(C)). All of these observed peaks increased in intensity with time during the reaction in the  $N_2O/C_2H_6$  mixture. It should be noted that these observed peaks were hardly changed by the He purge at 350 °C for 15 min. In general, it could be admitted that the IR bands observed in the region of 3100–2800  $cm^{-1}$  indicate the CH stretching ( $\nu_{CH}$ ) bands of alkanes or adsorbed C–H bond-containing species [16,17]. The peaks at 2974, 2938 and 2883  $cm^{-1}$  were assigned to  $\nu_{CH}$  of  $C_2H_6(a)$  [17,18]. The increase in the intensities of the other broad band at around 3116  $cm^{-1}$  was also observed (figure 4(C)). Similar broad band observed during the SCR of  $N_2O$  with  $C_3H_6$  over Fe-MFI [11], which was assigned to  $-C\equiv CH(a)$  and/or unsaturated carbonaceous species (*i.e.*,  $C_xH_y(a)$ ) [11,19,20]. In our previous report [11], the partial oxidized species (*i.e.*,  $C_xH_yO_z(a)$ ) as well as  $C_xH_y(a)$  species, which were important active surface species, were observed during the SCR of  $N_2O$  with  $C_3H_6$  over Fe-MFI. In the present work, however, the low-wavenumber region (1700–1400  $cm^{-1}$ ) of the  $C_xH_yO_z$  species ( $\nu_{C=O}$ ,  $\nu_{C=C}$ ,  $\nu_{COO}$ , etc.) bands could not be measured reliably because of the strong absorption band of Fe-BEA (below 1700  $cm^{-1}$ ). Therefore, we do not exclude the presence of  $C_xH_yO_z(a)$  as intermediate surface species over Fe-BEA. These above results suggest that  $C_xH_y(a)$  and/or  $C_xH_yO_z(a)$  species

may be the important active surface species of the  $C_2H_6$  oxidation by coexistent  $O_2$  in the  $N_2O/C_2H_6/O_2$  system. Previously, we reported that  $C_xH_y(a)$  and/or  $C_xH_yO_z(a)$  species react with  $O_2$  (and/or  $N_2O$ ) to produce  $N_2$ ,  $CO_x$  and  $H_2O$  at 350 °C [11].

### 3.3. Proposed reaction mechanism

On the basis of above mentioned findings, we propose the following possible reaction steps for the SCR of  $N_2O$  with  $C_2H_6$  over Fe-BEA catalyst, as shown in figure 5. Firstly, adsorption and activation of  $C_2H_6$  are initiated by the reaction with  $N_2O$  over the Fe ion sites on zeolite (*i.e.*, abstraction of H atom and oxidation to form  $C_xH_y(a)$  and/or  $C_xH_yO_z(a)$  species). At the low temperatures ( $\leq 350$  °C), the formation of  $C_xH_y(a)$  and  $C_xH_yO_z(a)$  species by the reaction of  $C_2H_6$  with  $N_2O$  readily occurred, while the formation of  $C_xH_y(a)$  and  $C_xH_yO_z(a)$  species by the reaction of  $C_2H_6$  with  $O_2$  hardly occurred. Therefore,  $N_2O$  plays important roles in the formation of  $C_xH_y(a)$  and/or  $C_xH_yO_z(a)$  species as active surface species. Finally,  $C_xH_y(a)$  and/or

Figure 5. Proposed reaction steps for the SCR of  $N_2O$  with  $C_2H_6$  over Fe-BEA zeolite catalyst.

C<sub>x</sub>H<sub>y</sub>O<sub>z</sub>(a) species react with O<sub>2</sub> or N<sub>2</sub>O to produce N<sub>2</sub>, CO<sub>x</sub> and H<sub>2</sub>O.

In the oxidation behavior of alkane with O<sub>2</sub>, the difference between the N<sub>2</sub>O/CH<sub>4</sub>/O<sub>2</sub> system and the N<sub>2</sub>O/C<sub>2</sub>H<sub>6</sub>/O<sub>2</sub> system could be attributed to the reactivity of active surface species with O<sub>2</sub> (e.g., CH<sub>x</sub>(a) versus C<sub>x</sub>H<sub>y</sub>(a)). Previously, Panov *et al.* [21] reported that the O atom from the N<sub>2</sub>O molecule (so-called α-oxygen), which cannot be produced by O<sub>2</sub>, readily reacted with CH<sub>4</sub> or benzene to produce CH<sub>3</sub>OH or phenol over Fe/ZSM5 catalyst. The O atom from the N<sub>2</sub>O molecule is much more active than that from the O<sub>2</sub> molecule. In our experiment, therefore, both CH<sub>4</sub> and C<sub>2</sub>H<sub>6</sub> molecules are readily activated by the O atom from the N<sub>2</sub>O molecule to form active surface species. The reaction of CH<sub>4</sub> with N<sub>2</sub>O presumably leads to the formation of CH<sub>x</sub>(a) species etc., although no adsorbed species were detected by the DRIFT technique because of very low concentration of these species. However, the plateau in the CH<sub>4</sub> conversion (*ca.* 350–450 °C, in figure 1) means that the reaction rate of CH<sub>x</sub>(a) etc. with O<sub>2</sub> is much lower than that with N<sub>2</sub>O over Fe-BEA catalyst below 450 °C. Therefore, CH<sub>4</sub> reacts selectively with N<sub>2</sub>O. On the other hand, the formation of C<sub>x</sub>H<sub>y</sub>(a) by the reaction of C<sub>2</sub>H<sub>6</sub> with N<sub>2</sub>O were observed by the DRIFT (figure 4(C)). The reaction of C<sub>x</sub>H<sub>y</sub>(a) species with O<sub>2</sub> as well as N<sub>2</sub>O readily takes place, which leads to the enhancement of C<sub>2</sub>H<sub>6</sub> oxidation.

#### 4. Conclusion

The selective catalytic reduction of N<sub>2</sub>O with C<sub>2</sub>H<sub>6</sub> in the presence of excess O<sub>2</sub> took place efficiently over Fe-BEA catalyst. The present study demonstrates the enhancement of C<sub>2</sub>H<sub>6</sub> oxidation by O<sub>2</sub> in the presence of N<sub>2</sub>O. This result suggests that N<sub>2</sub>O plays an important role in the oxidation of C<sub>2</sub>H<sub>6</sub> (*i.e.*, activation of C<sub>2</sub>H<sub>6</sub> at an initial step).
