(aromatic system). The NMR spectrum of (II) showed the following signals: δ 1.40, s, 6, -C CH_3 ; 1.89, t (J=7 Hz), 2; >C-CH₂-CH₂-C-O; 2.48, t (J=7 Hz), 2, >C-CH₂-C-O; 3.80, s, 3, -COOCH₃; 3.83, s, 3, -OCH₃; 5.63, m, 2, NH₂; 7.27, s, 1, aromatic proton.

Condensation of (II) with $\hat{1}$, 2, 3, 4-tetrahydronorharman-1-one (III) performed with POCl₃ in refluxing toluene¹, gave the dihydroparaensine (IV), $C_{24}H_{23}N_3O_3$ (M+ 401), mp 305° (from isopropyl ether) which was found to be identical (mixed mp, TLC and IR spectrum) with the dihydroderivative of the natural product.

Riassunto. Dalla corteccia della Euxylophora paraënsis Hub. viene isolata la paraensina (I) che si rivela essere il primo alcaloide di tipo indolopiridochinazolinico a contenere una unità isoprenica.

Acknowledgments. The authors thank Prof. L. Canonica for his interest in the work. Thanks are also due to Dr. G. Severini Ricca for the NMR-spectra, and to Dr. T. Salvatori for mass spectra.

CMR Spectral Analysis of Tetrahydrocannabinol and its Isomers¹

The biologically active constituents of *Cannabis sativa* L. (marijuana) have aroused much public and scientific interest in recent years. In view of the advent of a powerful, new tool of structure analysis, 13 C nuclear magnetic resonance (cmr) spectroscopy, its application to investigations of the chemical make-up of the major psychotomimetic marijuana (hashish) principle, $1-\Delta$ 9 -tetrahydrocannabinol (Δ 9 -THC) (1a), and related substances was undertaken.

The δ values of all carbons of six tetrahydrocannabinol substances and model ${\bf 5}$, olivetol dimethyl ether, derived from their noise resonance decoupled and single frequency decoupled spectra¹ are listed in the Table. Assignment of the chemical shifts of the aromatic carbons is based on chemical shift theory² and former electron density calculations³. Shift data of ${\bf 5}$ and consideration of substituent effects among alkanes⁴ leads to the identification of three centers of the n-pentyl chain. The remaining β and γ carbons can be distinguished by inspection of the single

frequency decoupled spectrum of a β , β -dideutero derivative of $\mathbf{5}$, prepared by sodium deuteroxide-induced deuteration of n-butyl 3,5-dimethoxyphenyl ketone and treatment of the product with lithium aluminum hydride and aluminum chloride 5 .

^{*}For sake of comparison the THC numbering system is used for 5. These values within any column may be reversed. Weak signal visible only in the single frequency decoupled spectrum.

Johnson's method of analysis of residual coupling⁶ is utilized on the off-resonance proton-decoupled spectra of A^9 -THC (1a) and A^8 -THC (2) for the differentiation of the bridgeheads C(6a) and C(10a) in 1a, its acetate (1b), 2 and its cis isomer (3). Use of the charge density data³ facilitates distinguishing these bridgeheads from each other in compounds 4. The expected low-field position of an oxygenated, non-protonated carbon identifies the remaining heterocyclic carbon site, -C(6).

The combination of effects of the 9-methyl group deshielding C(8) and C(10), C(1) moderately shielding C(10) and the gem-dimethyl function powerfully shielding C(7) makes the δ values of C(7) and C(10) of substances $\mathbf{2}$, $\mathbf{3}$ and $\mathbf{4}$ predictably different and identifies C(7) and C(8) of Δ^9 -THC ($\mathbf{1a}$) and its acetate ($\mathbf{1b}$). Furthermore, allylic carbons of cyclohexene rings possessing signals normally downfield of their homoallyl neighbors 7 places C(8) of $\mathbf{4a}$ and $\mathbf{4b}$ in proper shift relationship with C(7) and C(10). The assignments of chemical shifts of all other alicyclic carbons evolve from standard theory 2 .

Methylcyclohexane⁸ and 1-methylcyclohexene⁷ serve as models for the 9-methyl group of compounds 4 and the group of substances 1, 2 and 3, respectively. Differentiation of the C(6) methyl groups depends on their conformation, an analysis of which has been recorded⁸, and the expectation of an axial substituent to be upfield of an equatorial one^{8,9}.

Zusammenfassung. Die ¹³C-NMR-Spektren des Tetrahydrocannabinols und seiner Isomeren wurden aufgenommen und vollständig analysiert.
