

98. Akira Yokoyama, Kazuo Ashida, and Hisashi Tanaka : Studies on the Sulfur-containing Chelating Agents. XIV.\*<sup>1</sup> Syntheses of  $\beta$ -Mercaptocinnamamides and their Structures.

(Faculty of Pharmaceutical Sciences, Kyoto University\*<sup>2</sup>)

According to the conclusions described in Part XIII,<sup>1)</sup> concerning the relationship between the chelating abilities and the structures in various types of carbonyl compounds which have a mercapto group at  $\beta$ -position,  $\beta$ -mercaptocinnamamides were expected to be considerably strong chelating agents as well as the esters of  $\beta$ -mercaptothiocinnamic acid.\*<sup>1</sup> This paper deals with the syntheses and the structures of  $\beta$ -mercaptocinnamamides. The investigations on their applicabilities as analytical reagents and also on their antimicrobial activities are to be conducted later, in connection with their chelating abilities.

As an attempt to obtain  $\beta$ -mercaptocinnamamides from  $\beta$ -mercaptocinnamic acid<sup>2)</sup> or its disulfide<sup>2)</sup> through acid chloride was failed, a procedure by the addition of thiourea to phenylpropiolamides was chosen for the purpose. As for the preparations of phenylpropiolamides, Brown<sup>3)</sup> reported that ethylamide (Ia) and anilide (Ie) were obtained from

phenylpropionic acid through phenylpropionyl chloride. The preparations of phenylpropionamides (Ia~Ij) were carried out by the procedure a little modified from Brown's method.<sup>3)</sup> The purifications of Ia~Ij were rather difficult and Id could not be purified completely. The additions of thiourea to Ia~Ij were carried out as described in Part XIII\*<sup>1</sup> and the corresponding isothiuronium salts (IIa~IIj) were obtained with good yield.  $\beta$ -Mercaptocinnamamides (IIIa~IIIj), except IIIc were obtained by hydrolyses of IIa~IIj. A yellowish green solid considered to be IIIc, judging from its properties as described in experimental part, was obtained but its purification was not successful. In the procedure of hydrolysis, ester moieties of IIh and IIi were hydrolyzed at the same time and the corresponding carboxylic acids were obtained. The carboxylic acids (III d, III h, III i) were prepared for the purpose of obtaining hydrophylic chelate compounds.

It was found that alkylamides (IIIa~III d) and arylamides (III e~III j) showed different properties in the following points. These amides (IIIa~III j) showed the reversible color change (yellowish green~purple) on heating, with or without solvent, as observed in esters of  $\beta$ -mercaptothiocinnamic acid reported in Part XIII.\*<sup>1</sup> This color change was observed more remarkably even in lower temperature in the cases of alkylamides than in the cases of arylamides. Alkylamides did not crystallize easily even though they were completely pure, while arylamides crystallized easily. The metals which showed color reactions, probably by the chelate-formations, with these ligands were iron, copper, nickel, cobalt, zinc, lead, bismuth, silver, cadmium, platinum, gold, mercury, and uranium. However, as seen in Table V in experimental part, some of the metals reacted with arylamides but not with alkylamides. In the cases of alkylamides, generally the reactions proceeded more slowly, and the yields of metal-chelates were poorer, compared with the cases of arylamides.

In these amides (IIIa~III j), thioxo-thioenol tautomerism shown in Chart 2 should be considered in connection with their structures and their chelating abilities, as well as in the cases of esters of  $\beta$ -mercaptothiocinnamic acid reported in Part XIII.\*<sup>1</sup> In addition, above-mentioned differences in the chemical properties between alkylamides and arylamides are probably due to the differences of equilibria in the tautomerism. From this point of view, the structures of these amides were investigated by infrared and nuclear magnetic resonance spectroscopy.

The infrared spectra of IIIa and IIIe are shown in Figs. 1 and 2 as the examples of alkylamides and arylamides respectively. Figs. 3 and 4 represent the infrared spectra of the related compounds of IIIa and IIIe, namely N-ethyl- $\beta$ -(ethylthio)cinnamamide (IVa)

Fig. 4. Infrared Spectrum of N-Phenyl- $\beta$ -(ethylthio)cinnamamide (IVe) (in  $\text{CHCl}_3$ )

and N-phenyl- $\beta$ -(ethylthio)cinnamamide (IVe) prepared for the purpose of making comparison, by the procedure shown in Chart 1. As seen in Figs. 1, 2, 3, and 4 and Table I, the stretching bands of SH and C=O were observed in the region of considerably lower frequencies than in the ordinary cases.<sup>4)</sup> This fact shows that the mercapto groups and the carbonyl groups are markedly hydrogen-bonded in these amides (IIIa~IIIj). In other words, the contribution of *cis*-thioenol form (B) is predominant. However, in these amides (IIIa~IIIj), shoulders which are considered to be based on the carbonyl groups in thioxo form (A) or *trans*-thioenol form (C), were also observed at a little higher frequencies than those where hydrogen-bonded C=O stretching bands were observed. In arylamides an empirical rule concerning the stretching bands of C=C and C=O in *cis-trans* configuration of  $\alpha,\beta$ -unsaturated carbonyl compounds<sup>5)</sup> is applicable as the *cis*-thioenol form (B), as in the cases of esters of  $\beta$ -mercaptothiocinnamic acid.\*<sup>1</sup> Namely, the intensities of the stretching bands of C=C were always higher than those of the stretching bands of C=O. While, in alkylamides, this relation between the stretching bands of C=C and C=O was not observed clearly.

The nuclear magnetic resonance spectra of IIIa, IIIe, IVa, and IVe are shown in Figs. 5, 6, 7, and 8. As seen in Figs. 5 and 6, signals from mercapto groups are seen in considerably lower field as observed in ethyl  $\beta$ -mercaptothiocinnamate,\*<sup>1</sup> than in the ordinary cases.<sup>6)</sup> This fact also shows the presence of hydrogen bond between the mercapto and the carbonyl groups, and in other words, *cis*-thioenol form (B) is supported. However, in IIIa, the intensities of the signals from the mercapto proton and olefinic proton were found to be a little lower than in IIIe. Summarizing above-mentioned discussions, *cis*-thioenol form (B) is predominant, and the double bond character of the carbonyl group considerably decreases, but in alkylamides the contribution of thioxo form (A) or *trans*-thioenol form (C) should be taken into consideration to more extent than in arylamides. These differences might be attributed to the mesomeric

effect of the nitrogen atom, which has the tendency to make conjugate system from the benzene ring to the nitrogen atom in arylamides, and hence thioenol form could be taken more easily in arylamides than in alkylamides. In alkylamides and arylamides, the differences in the tautomerism are considered to be corresponding to that seen in the chemical properties, but further investigation would be necessary in this point. Being important in connection with the chelating abilities of these ligands, the above-mentioned tautomerism will be investigated later also with ultraviolet spectroscopy.

#### Experimental\*<sup>4</sup>

**N-Alkyl(or Aryl)propiolamide (Ia~Ij)**—A mixture of 0.1 mole of phenylpropionic acid and 0.12 mole of freshly distilled  $\text{SOCl}_2$  in 50 ml. of dry benzene was warmed at  $60\sim 70^\circ$  with stirring for 3 hr. and evaporated under reduced pressure. To the residue, 50 ml. of dry benzene was added. To this solution of phenylpropionyl chloride, 0.2 mole of alkyl- or arylamine in 50 ml. of dry benzene was added dropwise with stirring under ice-cooling and stirring was continued for 1 hr. The reaction mixture was poured into cold  $\text{H}_2\text{O}$ . The benzene layer was separated, washed with 5%  $\text{HCl}$ ,  $\text{H}_2\text{O}$ , 5%  $\text{Na}_2\text{CO}_3$ , and  $\text{H}_2\text{O}$  successively, and dried over  $\text{Na}_2\text{SO}_4$ . After evaporating the solvent, the residual crude crystal of Ia~Ij was collected and recrystallized from the proper solvent to give pale yellow needles. Yield, 60~70%. IR:  $\nu_{\text{C}\equiv\text{C}}$   $2195\sim 2200\text{ cm}^{-1}$  (Nujol). The compounds synthesized are listed in Table II.

**S-[1-Phenyl-2-(alkyl- or aryl-carbamoyl)vinyl]isothiuronium *p*-Toluenesulfonate (IIa~IIj)**—A mixture of 0.05 mole of Ia~Ij, equimolecular thiourea and *p*-toluenesulfonic acid in 100 ml. of EtOH was refluxed for 3 hr. and evaporated to almost half volume. After cooling,  $\text{Et}_2\text{O}$  was added and crystals of IIa~IIj separated out were collected and recrystallized from EtOH- $\text{Et}_2\text{O}$  to give colorless needles. Yield, 90~95%. The compounds synthesized are listed in Table III.

**N-Alkyl(or Aryl)- $\beta$ -mercaptocinnamamide (IIIa~IIIj)**—i) IIIa~IIIg, IIIj: A mixture of 0.01 mole of IIa~IIg, IIj and 0.02 mole of NaOH in 100 ml. of 50% EtOH was refluxed for 2 hr. After cooling, the reaction mixture was poured into 100 ml. of  $\text{H}_2\text{O}$  and extracted with  $\text{Et}_2\text{O}$ . Aqueous phase was separated and acidified with conc.  $\text{HCl}$  under ice-cooling. In the cases of IIIa, IIId~IIIg, IIIj, the precipitate separated out was collected and recrystallized from proper solvent to give yellow~yellowish green needles. Yield, 50~60%. In the case of IIIb, the precipitate separated out was dissolved in 5%

\*<sup>3</sup> The NMR spectra were measured with a Varian A-60 Spectrometer at 60 Mc.p.s., in  $\text{CDCl}_3$ , using tetramethylsilane as an internal reference.

\*<sup>4</sup> All melting points are uncorrected.

The authors extend their gratitude to Prof. T. Uno of Kyoto University for his helpful advices. They are also indebted to the members of the microanalytical center of Kyoto University for the analytical data. The infrared spectra were determined by Dr. K. Machida, Mr. K. Hanai and Mrs. Y. Miyajima of Kyoto University, and the nuclear magnetic resonance spectra were measured by Mr. T. Shingu of Kyoto University, to whom the authors are also grateful.

### Summary

$\beta$ -Mercaptocinnamamides were prepared as strong chelating agents. Phenylpropionyl chloride was converted into alkyl- or arylamides, and thiourea was reacted in the presence of *p*-toluenesulfonic acid to obtain corresponding isothiuronium salts.  $\beta$ -Mercaptocinnamamides were obtained by the hydrolyses of the isothiuronium salts. Thioxo-thioenol tautomerism in the  $\beta$ -mercaptocinnamamides was investigated by infrared and nuclear magnetic resonance spectroscopy. It was found that *cis*-thioenol form is predominant in these amides but some differences were observed between alkylamides and arylamides. The arylamides were considered to have stronger chelating abilities than the alkylamides judging from their chemical properties, and this difference would be attributed to the difference in thioxo-thioenol tautomerism.
