ANTI-HUMAN IMMUNODEFICIENCY VIRUS PHENOLICS
FROM LICORICE¹⁾

Five phenolics isolated from licorice inhibited the cytopathic activity of a human immunodeficiency virus. One of these a coumarin derivative named licopyranocoumarin, isolated from Xi-bei licorice, had structure 5, based on the chemical and spectroscopic evidence.

KEYWORDS—flavonoid; coumarin; licopyranocoumarin; licorice; Glycyrrhiza; antiviral substance; human immunodeficiency virus; cytopathic activity; OKM-1

A cell line named OKM-1,^{2,3)} sensitive to the cytopathic activity of human immunodeficiency virus (HIV), was recently established from the peripheral blood of a patient with adult T-cell leukemia.³⁾ Giant cells due to the cytopathic activity, were formed within a day on co-culture with HIV-infected Molt-4 cells (OKM-1 : Molt-4 = 3:1).³⁾ As glycyrrhizin, the main component of licorice, reportedly inhibits the HIV-induced giant cell formation for Molt-4 cells,⁴⁾ without reference to the effects of the other components, we have investigated the effects of these components of licorice on the cytopathic activity of HIV using OKM-1 cells.

In this experiment, we found that licochalcone A (1),⁵⁾ isolicoflavonol (2),⁶⁾ glycyrcoumarin (3),⁶⁾ glycyrrhisoflavone (4),⁷⁾ and an additional component (5) of Xi-bei (Si-pei) licorice⁸⁾ named licopyranocoumarin inhibited the giant cell formation at a concentration of 20 µg/ml without any observable cytotoxicity, while glycyrrhizin inhibited analogously at a concentration of 500 µg/ml. However, licochalcone B⁵⁾ was cytotoxic even at this low concentration (20 µg/ml). Isoliquiritin and isoliquiritigenin had no great effect at this concentration.

The isolation of 5, which was not described in our recent publication,⁷⁾ has been carried out as follows. The ethyl acetate extract of Xi-bei licorice was subjected to droplet countercurrent chromatography (DCCC) [chloroform-methanol-water (7:13:8, by volume), descending method], and then to column

chromatography over MCI-GEL CHP-20P. Further purification by preparative thin layer chromatography (silica gel) gave 5.

The compound 5, mp 137 °C, $[\alpha]_D^{25} +14^\circ$ (c=1, acetone), forming yellow crystals, showed the ultraviolet (UV) spectrum [$\lambda_{\max}^{\text{MeOH}}$: 211 (log ϵ 4.62), 262 (sh., 3.94) and 352 nm (4.21)] which is analogous to those of reported 3-arylcoumarins [e.g., glycyrin (6)⁹) and glycyrcoumarin (3)^{5,7}]. The high-resolution electron impact mass spectrum of 5 indicates the molecular formula $\text{C}_{21}\text{H}_{20}\text{O}_7$ (found, 384.1175; calcd., 384.1209) for 5. The ^1H nuclear magnetic resonance (NMR) spectrum (500 MHz, in acetone- d_6) of 5 shows the signals due to a $\text{CH}_2\text{-CH}_2$ system [δ 2.89 (dt, $J=17, 6$ Hz, $\text{H}_a\text{-6}$), 2.82 (ddd, $J=6, 9, 17$ Hz, $\text{H}_b\text{-6}$), 2.0 (in part overlaps with the solvent signals, $\text{H}_a\text{-7}$) and 1.82 (dt, $J=14, 6$ Hz, $\text{H}_b\text{-7}$)], two 3H singlets [δ 3.91 (OCH_3) and 1.31 ($-\text{C-CH}_3$)], and the signals of a hydroxymethyl group [δ 3.63 (d, $J=11$ Hz) and 3.56 (d, $J=11$ Hz)], along with the signals assignable to the protons of the 3-arylcoumarin skeleton: Two 1H singlets [δ 7.97 (H-4) and 6.50 (H-10)] and the signals forming an ABX system [δ 6.42 (dd, $J=2, 8$ Hz, H-5'), 6.47 (d, $J=2$ Hz, H-3') and 7.21 (d, $J=8$ Hz, H-6')]. A nuclear Overhauser effect (11%) was observed for the H-4 signal at δ 7.97, when the methoxyl signal at δ 3.91 was irradiated. This indicates that the methoxyl group should be at C-5 on the 3-arylcoumarin skeleton. Treatment of 5 with diazomethane afforded a methylate (7), $\text{C}_{23}\text{H}_{24}\text{O}_7$, mp 73 °C, $^1\text{H-NMR}$ (in CDCl_3) δ 3.84, 3.83 and 3.79 (3H each, s, 3 x OCH_3). These signals indicate that the methylate (7) has two additional methoxyl groups. Acetylation of 5 in the usual way afforded a triacetate (8), $\text{C}_{27}\text{H}_{26}\text{O}_{10}$, mp 87 °C, $^1\text{H-NMR}$ (in CDCl_3)

δ 2.29, 2.16 and 2.10 (3H each, s, 3 x OCOCH₃). Therefore, the 3-aryl-5-methoxycoumarin structure having two phenolic hydroxyl groups and an alcoholic hydroxyl group was assigned to 5.

Cyclization between the γ , γ -dimethylallyl group and the hydroxyl group at C-7 in glycycomarin (3) afforded a pyranocoumarin (9), C₂₁H₂₀O₆, mp 235 °C (decomp.), whose ¹H-NMR spectrum closely resembles that of 5, except for the presence of the 6H singlet at δ 1.36 (the signal of the gem-dimethyl group) in the spectrum of 9, in place of the 3H singlet at δ 1.31 and the methylene protons of the hydroxymethyl group [at δ 3.56 and 3.63] in the spectrum of 5. Thus, licopyranocoumarin should be formulated as 7,8-dihydro-3-(2,4-dihydroxyphenyl)-8-hydroxymethyl-5-methoxy-8-methyl-2H,6H-benzo[1,2-b:5,4-b']dipyrane-2-one (5).¹⁰⁾ The ¹H-NMR spectra of the esters of 7 with (R)- and (S)-forms of Mosher's acid¹¹⁾ shows that 5 could be in part racemized (ca. 5 %), if it was not racemized during the reactions (methylation and esterification).

ACKNOWLEDGEMENTS We thank Prof. K. Takaishi and Mr. H. Kuwajima, Faculty of Pharmaceutical Sciences, Kinki University, for the high-resolution mass spectra.
