

C-Linked Disaccharide Analogue of the Thomsen–Friedenreich (T)-Epitope α -O-Conjugated to L-Serine

Loay Awad, Jens Riedner, and Pierre Vogel*^[a]

Abstract: Condensation of a silylated β -D-galactopyranosylaldehyde (**3**) with isolevoglucosenone (**4**) in the presence of Et_2AlI provided bicyclic enone **5**. Subsequent addition of BnNHOMe gave adduct **6**, which was converted into 4-*O*-acetyl-1,6-anhydro-3-*C*-[(1*R*)-1,3,4,5,7-penta-*O*-acetyl-2,6-anhydro-D-glycero-L-manno-heptitol-1-*C*-yl]-2-azido-2,3-dideoxy- β -D-galacto-hexopyranose after liberation of the 2-amino group, its transformation into a 2-azido

moiety, desilylation, and peracetylation. Ring-opening of the 1,6-anhydro galactopyranosyl unit and *O*-glycosidation with Fmoc-Ser-*O*-*t*Bu afforded a 5:1 mixture of α - and β -galactosides. Treatment with CH_3COSH gave pure

N-[(9*H*-fluoren-9-ylmethoxy)carbonyl]-{4,6-di-*O*-acetyl-3-*C*-[(1*R*)-2,6-anhydro 1,3,4,5,7-penta-*O*-acetyl-D-glycero-L-manno-heptitol-1-*C*-yl]-2-[(*N*-acetyl)-amino]-2,3-dideoxy- α -D-galactopyranosyl]-L-serine *tert*-butyl ester (**2**), a protected form of a C-disaccharide analogue of the Thomsen–Friedenreich (or T) epitope (β -D-Galp-(1 $\rightarrow$ 3)- α -D-GalNAcp) α -O-conjugated to L-serine.

Introduction

The Thomsen–Friedenreich or Tepitope (β -D-Galp-(1 $\rightarrow$ 3)- α -D-GalNAcp)- α -O has been known for a long time as a tumor-associated antigen.^[1] The presence of T antigen during an early fetal phase, its absence in noncarcinomatous post-fetal tissues, and its association with carcinomas suggest that T antigen is a stage-specific oncofetal carbohydrate antigen. The T antigen is also related to blood group antigens.^[2] In epithelial cells, the Tepitope is carried by mucin (MUC1), which belongs to a family of highly glycosylated proteins present on the apical surfaces of many epithelial cells. On tumor cells MUC1 is post-translationally modified, resulting in incomplete *O*-glycosylation and exposing the Tepitope.^[3] Everyone has “preexisting” anticarcinoma anti-T antibodies, induced predominantly by the intestinal flora, while cellular immune responses to Tepitopes are evoked only by carcinomas and some lymphomas.^[4] The T antigens have been prepared and their immunogenicity in conjugate

vaccines has been confirmed.^[4,5] The clustered antigen motifs such as **1a** prepared by Danishefsky and co-workers^[6] have demonstrated the potential for antitumor vaccines^[7] based on T antigen conjugates.

Disaccharide conjugates are relatively short-lived in the blood stream, because of their hydrolysis catalyzed by ubiquitous glycosidases. Disaccharide mimetics such as C-linked disaccharide analogues offer improved stability towards hydrolysis, as required for a disaccharide-based vaccine. In a preliminary communication we proposed a first approach to

the synthesis of a C-glycoside analogue of epitope T disaccharide **1b**.^[8] As the O-glycosidation of semiprotected forms of L-serine with **1b** (and derivatives of **1b**) failed to generate the desired α -galactopyranosides as required for Tepitope, we were forced to explore other synthetic routes.^[9] We describe one of them here and show that the protected form of a C-linked disaccharide analogue of Tepitope has been obtained. It was necessary to use a 2-azido-2-deoxygalactopyranosyl intermediate for the α -galactosylation of L-serine, and the construction of this has not been straightforward, since the chemistry known for simpler galactosyl derivatives and O-linked disaccharides did not apply to our C-linked disaccharide analogues.^[9] Our studies use enones **5**, which are obtained in good yield by the Oshima–Nozaki condensation^[10] between the D-galactopyranosylcarbaldehyde **3** and the readily available isolevoglucosenone (**4**) (Scheme 1).

Scheme 1. Synthesis of C(1→3)-disaccharide precursors.

Results and Discussion

For the synthesis of this compound, we envisaged the application of the chemistry developed from isolevoglucosenone (**4**) and aldehyde **3**. Under our previous conditions^[8] (0.1 mmol of **3**, -78°C) the yield of the condensation^[10] of aldehyde **3** and isolevoglucosenone (**4**) had been 61 %. With use of large amounts of **3** (10 mmol) and **4** (15 mmol), high concentrations, and slow addition of Et_2AlI at -90°C , the yield of isolated enone **5** climbed to 95 % (Scheme 1).

For the conjugate addition to enone **5**, we chose hydroxylamine derivatives as nitrogen nucleophiles. Because of the α -effect, their nucleophilicities are much higher than those of other amines.^[11] Initially a Lewis acid such as Me_2AlCl was used to activate the enone, but unfortunately no reac-

tion occurred when MeONHBn was added to a mixture of **5** and Me_2AlCl between -78°C and 0°C . In fact, we found that use of a Lewis acid was not necessary for this addition. The best results were obtained with use of no solvent and no catalyst (Table 1).

MeONHBn and enone **5** give a 1:1 mixture of stereomeric adducts **6** and **6'**, which are isomerized during slow chromatography on silica gel at room temperature. Thanks to this, conditions were found under which adduct **6** could be obtained pure in 82 % yield (Scheme 2).

When pure **6** was dissolved in THF with MeONHBn , a mixture of **6** and **6'** was obtained upon standing at 25°C for 2–3 h. Fast column chromatography on silica gave a first fraction containing of mixture of **6** and **6'** (major), and a second fraction of pure **6** (minor). Slow elution led to a smaller fraction of **6** and **6'** and increased amounts of pure **6**

(second fraction), indicating that **6** and **6'** exist in equilibrium in the presence of an amine and that the equilibrium shifts in favor of **6** when the mixture is adsorbed on silica gel. Slower elution thus allows the conversion of adsorbed **6'** into adsorbed **6**, which is finally recovered pure from the column.

It is proposed that the mechanism of the isomerization $\mathbf{6} \rightleftharpoons \mathbf{6}'$ involves reversible $\text{E}_{1\text{cb}}$ -like eliminations ($\mathbf{6} \rightleftharpoons \mathbf{5} + \text{MeONHBn}$ and $\mathbf{6}' \rightleftharpoons \mathbf{5} + \text{MeONHBn}$), both catalyzed by MeONHBn .

Table 1. Conjugate addition of methoxybenzylamine to enone **5**.

Entry	Catalyst	Solvent	T [$^{\circ}\text{C}$]	Yield [%]
1	Me_2AlCl	CH_2Cl_2	$-78 \rightarrow 0$	no reaction
2	Me_2AlCl	CH_2Cl_2	25	20
3	–	CH_2Cl_2	25	18
4	–	no solvent	25	82

In a preliminary work^[8] we showed that treatment of isolevoglucosenone (**4**) with $\text{Me}_2\text{AlNBn}_2$ gave an aluminum enolate that could be treated directly with sugar-derived aldehydes to give the corresponding 2-amino-2-deoxy-3-C-linked disaccharide derivatives in a one-pot fashion. We

Scheme 2. Reversible addition of methoxybenzylamine to enone **5**.

thus attempted to obtain **6** in a similar way by treatment of isolevoglucosenone (**4**) with $\text{Me}_2\text{AlN}(\text{OMe})\text{Bn}$, followed by addition of aldehyde **3**. From related Oshima–Nozaki reactions with **4**, we expected (Zimmerman–Traxler^[12] steric factors) that the double adduct preferred under kinetic control conditions should be **6** (Scheme 3). After several unfruitful

Scheme 3. One-pot double addition.

assays we found that the reaction between **4** and $\text{Me}_2\text{AlN}(\text{OMe})\text{Bn}$ in THF at -78°C gave the expected enolate **4a**. After the addition of **3** to this solution, a slow reaction occurred at -78°C . Subsequent aqueous workup and purification by chromatography on silica gel gave **6** in only 19% yield (Scheme 3). Attempts to run the reaction at higher temperatures and/or for longer times led to decomposition only.

Reduction of ketone **6** with LiBH_4 furnished diol **7** in 90% yield; hydride addition to the *exo* face of the bicyclo-[3.2.1]octanone system is preferred for steric reasons. Treatment of **7** with Bu_4NF (TBAF) in THF (20°C , 3 h) and then with Ac_2O /pyridine and a catalytic amount of 4-dimethylaminopyridine (DMAP) provided peracetate **8** quantitatively (Scheme 4).

Scheme 4. β -O-Galactosidation: participation by the 2-methoxy (benzyl)-amino group.

Ring-opening of the 1,6-anhydrogalactose moiety of **8** with ZnI_2 in CH_2Cl_2 required suitable conditions that would avoid the easy formation of furanoside rather than pyranoside derivatives.^[13] The crude product obtained was therefore not isolated but was immediately desilylated (TBAF, THF) and peracetylated under standard conditions to produce thiogalactoside **9** in 93% yield (Scheme 4). Glycosidation of Fmoc-Ser-OBn with **9** under the conditions of Imamura et al.^[14] led exclusively to the β -D-galactoside **10** (92% yield). The structure of **10** β was deduced from its ^1H NMR spectrum, which showed $^3J(\text{H-1}, \text{H-2}) = 7.4 \text{ Hz}$, and $^3J(\text{H-2}, \text{H-3}) = 12.3 \text{ Hz}$. Thus, participation of the 2-(*N*-benzyl-*N*-methoxy)amino group cannot be avoided (Scheme 4; formation of intermediate **10b**).

It was thought that it may be the bulk of the 2-BnNOMe substituent that does not allow α -glycosidations, so a non-bulky and nonparticipating group that was readily convertible into a 2-acetamido moiety was desired at C-2. Inspired by the work of Wong and co-workers,^[15] we converted the *N*-benzyl-*N*-methoxyamino group of **7** into the corresponding primary amine **11** under Birch's conditions^[16] with subsequent catalytic (Pd/C , H_2) hydrogenation (Scheme 5).^[17] The obtained amine **11** was not isolated but was directly treated with trifluoromethanesulfonyl azide, cupric sulfate, and triethylamine in a $\text{H}_2\text{O}/\text{MeOH}/\text{CH}_2\text{Cl}_2$ mixture. Azide **12** was thus obtained in 81% yield (based on **7**). Smooth ring-opening of the 1,6-anhydrogalactose moiety of **12** involved initial peracetylation (Ac_2O /pyridine/DMAP) and then treatment with $\text{Me}_3\text{SiOSO}_2\text{CF}_3$ in Ac_2O to give **14** in 98% yield. Conversion of galactosyl acetate **14** into the corresponding bromide **15** (92%) was done with TiBr_4 in CH_2Cl_2 (20°C , 12 h).

Königs–Knorr glycosidation ($\text{AgClO}_4/\text{CH}_2\text{Cl}_2$, 2,4,6-collidine, 4 Å molecular sieves)^[18] of *N*-Fmoc-serine *tert*-butyl ester gave a 5:1 mixture of α - (**16a**) and β -galactoside (**16b**) in 93% yield. Flash chromatography provided pure **16a**. The preferred formation of the α -galactoside is ascribed to a kinetic anomeric effect (no participating group at C-2; Scheme 5).^[19]

Treatment of **16a** with ethanethioic acid, collidine, and Ac_2O ^[20] furnished **2**—a protected form of a C-linked analogue of epitope T α -O-conjugated to L-serine—in 89% yield. This form should be suitable for the construction of clusters through peptide synthesis and further conjugation to immunogenic proteins, as demonstrated by Danishefsky and co-workers^[6] for an O-linked analogue of **2**

Scheme 5. Synthesis of C-linked disaccharide α -O-conjugated to L-serine.

that was converted into cluster **1**. We have verified that the disaccharide **2** protected as a peracetate can be deprotected. When **2** was treated with morpholine in DMF, followed by MeONa/MeOH, disaccharide **17** was obtained in 52 % yield after HPLC purification.

Conclusion

The C-linked disaccharide α -O-conjugated with L-serine (**16α**) mimicking epitope T has been obtained for the first time. The method relies on the Oshima–Nozaki condensation of silylated β -D-galactopyranosylcarbaldehyde derivative **3** with isovogluconenone (**4**) to give enone **5**. Stereoselective 1,4-addition of MeONHBn to enone **5** generated a 1,6-anhydro-2-(*N*-benzyl-*N*-methyl)-2-deoxygalactose intermediate **6**, which was converted into the corresponding peracetylated β -galactosyl- β (1-CH(OH)-3)-2-azido-2-deoxygalactopyranosyl bromide **15**. Königs–Knorr glycosidation of Fmoc-Ser-O-*t*Bu with **15** afforded a 5:1 mixture of α - and β -galactosides. The α -galactoside **16α** can be obtained pure and can be converted into **2**. The mimic of epitope T thus obtained is protected in a form suitable for clustering and further conjugation.

Experimental Section

General remarks: Reagents were purchased from Acros, Fluka, Senn, Aldrich, or Merck and were used without further purification. All solvents for extraction and chromatography were distilled prior to use. Anhydrous

THF, Et₂O, and toluene were distilled from sodium benzophenone, CH₂Cl₂ from CaH₂, and methanol from magnesium. Reactions were monitored by TLC (Merck Kieselgel 60F 254 silica gel plates; detection with UV (254 nm) light or molybdate reagent (21 g of (NH₄)₆Mo₇O₂₄·4H₂O, 1 g Ce(SO₄)₂, 31 mL H₂SO₄, and 470 mL H₂O). Flash chromatography (FC) was performed over 230–400 mesh silica gel (Merck No. 9385). Melting points were measured with a Mettler FP52 instrument and were uncorrected. Optical rotations were measured with a JASCO DIP-370 digital polarimeter. UV spectra were recorded on a Kontron Uvikon 810 CW spectrophotometer. IR spectra were recorded on Perkin–Elmer Paragon 1000 FT-IR spectrometer. Mass spectra were recorded on a Nermag R10–10C instrument in chemical ionization mode. Electron spray mass analyses were recorded on a Finnigan MAT S50 710C spectrometer in positive ionization mode. ¹H NMR spectra were recorded on Bruker DPX 400 FT, Bruker ARX 400 FT, or AMX 600 spectrometers; all ¹H signal assignments were confirmed by COSY spectra. ¹³C NMR spectra were recorded on

Bruker DPX 400 FT (100.61 MHz) or Bruker ARX 400 FT (100.61 MHz) machines; all ¹³C signal assignments were confirmed by HMQC spectra. Chemical shifts are in ppm, relative to internal standards, such as residual signals of solvents, and coupling constants are in Hertz. High-resolution FAB mass spectra were recorded on a FAB-LSIMS device (Uniservidad de Sevilla, Spain). Microanalyses were performed by the Ilse Beetz Laboratory, Kronach (Germany).

1,6-Anhydro-3-[(1*R*)-2,6-anhydro-3,4,5,7-tetrakis-*O*-[(*tert*-butyl)dimethylsilyl]-D-glycero-L-manno-heptitol-1-*C*-yl]-2,3-dideoxy- β -D-glycero-hex-2-enopyran-4-ulose (5**):** A solution of Et₂AlI (1 M in toluene, 12 mL, 12.0 mmol) was added dropwise at –78 °C to a mixture of aldehyde **3** (6.0 g, 9.4 mmol) and **4** (2.0 g, 15.9 mmol) in CH₂Cl₂ (100 mL). The solution was stirred at this temperature for 2 h and was diluted with Et₂O (500 mL). Aqueous HCl (2 M, 50 mL) was added, and the aqueous phase was extracted with Et₂O (2 × 200 mL). The combined organic phases were washed sequentially with aqueous HCl (2 M, 50 mL), H₂O (50 mL), and brine (50 mL), dried (MgSO₄), and concentrated. FC (light petroleum ether/EtOAc 9:1) afforded **5** (6.89 g, 96%) as a colorless oil; *R*_f = 0.37 (petroleum ether (PE)/diethyl ether 4:1); [α]_D²⁵ = +79 (*c* = 0.243 in CHCl₃); ¹H NMR (400 MHz, CDCl₃): δ = 7.39 (dd, ³*J*(H-C(1),H-C(2)) = 3.5, ⁴*J*(H-C(2),H-C(1')) = 1.0 Hz; H-C(2)), 5.83 (d, ³*J*(H-1,H-C(2)) = 3.5 Hz; H-C(1)), 4.75 (dd, ³*J*(H-C(5),H-C(6)) = 6.4, ³*J*(H-C(5),H-C(6)) = 1.3 Hz; H-C(5)), 4.45 (dd, ³*J*(H-C(3'),H-C(4')) = 8.6, ³*J*(H-C(2'),H-C(3')) = 7.0 Hz; H-C(3')), 4.26 (d, ²*J* = 12.4 Hz; H_a-C(7')), 4.23 (ddd, ³*J*(H-C(1'),H-C(2')) = 7.0, ³*J*(H-C(1'),OH-C(1')) = 6.7, ⁴*J*(H-C(2),H-C(1')) = 1.0 Hz; H-C(1')), 4.06 (dd, ²*J* = 8.3, ³*J*(H-C(5),H_{exo}-C(6)) = 6.4 Hz; H_{exo}-6), 3.99 (d, ³*J*(H-C(3'),H-C(4')) = 8.6 Hz; H-C(4')), 3.96 (d, ³*J*(H-C(5'),H-C(6')) = 4.1 Hz; H-C(5')), 3.91 (t, ³*J*(H-C(1'),H-C(2')) = ³*J*(H-2', H-3') = 7.0 Hz; H-C(2')), 3.80 (dd, ³*J*(H-C(5'),H-C(6')) = 4.1, ³*J*(H-C(6'),H_b-C(7')) = 1.9 Hz; H-C(6')), 3.75 (dd, ²*J* = 12.7, ³*J*(H-C(6'),H_b-C(7')) = 1.9 Hz; H_b-C(7')), 3.65 (dd, ²*J* = 8.3, ³*J*(H-C(5),H_{endo}-C(6)) = 1.3 Hz; H_{endo}-C(6)), 2.94 (d, ³*J*(H-C(1'),OH-C(1')) = 6.7 Hz; OH-C(1')), 0.94, 0.93, 0.90, 0.90 (4 × s, 4 × 9 H; 4 × *t*Bu), 0.14, 0.12, 0.10, 0.09, 0.08, 0.07, 0.06, 0.05 ppm (8 × s, 8 × 3 H; 8 × SiCH₃); ¹³C NMR (100.6 MHz, CDCl₃): δ = 194.5 (s; C(4)), 143.6 (d, ¹*J*(C,H) = 165 Hz; C(2)), 137.0 (s; C(3)), 96.9 (d, ¹*J*(C,H) = 177 Hz; C(1)), 79.7 (d, ¹*J*(C,H) = 141 Hz; C(2')), 79.1 (d, ¹*J*(C,H) = 160 Hz; C(5)), 73.1 (d, ¹*J*(C,H) =

A solution of **7** (300 mg, 0.329 mmol) in dry THF (5 mL) was added at –78 °C to a stirred mixture of metallic sodium (184 mg, 8.0 mmol, 24 equiv) in liquid NH₃ (10 mL). After the system had been stirred for 30 min at –78 °C, NH₄Cl (540 mg, 10 mmol, 30 equiv) was added and the ammonia was allowed to evaporate at 20 °C. After the addition of H₂O (20 mL), the aqueous phase was extracted with CH₂Cl₂ (20 mL, three times). The combined organic phases were dried and concentrated in vacuo. The residue was dissolved in MeOH (10 mL), and 10 % Pd on charcoal (35 mg) was added. The degassed mixture was stirred under H₂ at 20 °C for 12 h. The catalyst was filtered off, the solvent was evaporated, and the residue was dissolved in CH₂Cl₂ (1 mL). CuSO₄ in H₂O (1 mg in 2 mL) was added, then triethylamine (131 μ L, 0.987 mmol), followed by MeOH (7 mL). The freshly prepared solution of trifluoromethanesulfonyl azide in dichloromethane (1 mL, 0.6 M, 0.6 mmol) was added at once. The reaction was stirred until TLC showed reaction to be complete, and the mixture was extracted with CH₂Cl₂ (15 mL, three times). These combined organic phases were dried and concentrated in vacuo. FC (light petroleum ether/diethyl ether 7:3) afforded **12** (220 mg, 81 %, three steps) as a colorless oil; *R*_f = 0.62 (PE/diethyl ether 7:3); [α]_D²⁵ = +28 (*c* = 0.296 in CHCl₃); ¹H NMR (400 MHz, C₆D₆): δ = 5.43 (s; H–C(1)), 4.81 (t, ³*J*(H–C(4),H–C(3)) = 7.4 Hz; H–C(4)), 4.72 (dd, ²*J* = 12.3, ³*J*(H_a–C(7'),H–C(6')) = 10.5 Hz; H_a–C(7')), 4.47 (dd, ³*J*(H–C(5'),H–C(6')) = 6.2, ³*J*(H–C(5'),H–C(4')) = 2.5 Hz; H–C(5')), 4.38–4.28 (m, 3H; H–C(5),H–C(1'), H–C(2')), 3.25 (d, ²*J* = 7.4 Hz; H_{endo}–C(6)), 4.20 (d, ³*J*(H–C(3'),H–C(4')) = 4.3 Hz; H–C(3')), 4.13 (dt, ³*J*(H_a–C(7'),H–C(6')) = 10.5, ³*J*(H–C(6'),H–C(5')) = 6.2, ³*J*(H–C(6'),H_b–C(7')) = 2.5 Hz; H–C(6')), 3.99 (dd, ³*J*(H–C(4'),H–C(3')) = 4.3, ³*J*(H–C(4'),H–C(5')) = 2.5 Hz; H–C(4')), 3.96 (dd, ²*J* = 12.3, ³*J*(H_b–C(7'),H–C(6')) = 2.5 Hz; H_b–C(7')), 3.63 (d, ³*J*(H–C(2),H–C(3)) = 6.2 Hz; H–C(2)), 3.63–3.50 (brs, 2H; 2 × H–C(OH)), 3.27 (dd, ²*J* = 6.8, ³*J*(H-5,H_{exo}–C(6)) = 4.9 Hz; H_{exo}–C(6)), 2.64 (ddd, ³*J*(H-3,H-2) = 9.9, ³*J*(H-3,H-4) = 7.4, ³*J*(H–C(3), H–C(1')) = 3.1 Hz; H–C(3)), 1.05, 1.01, 0.99, 0.96 (4 × s, 36H; 36 × H–C(Si(CH₃)₃)), 0.28, 0.21, 0.19, 0.17, 0.16, 0.15, 0.11, 0.06 ppm (8 × s, 24H; 24 × H–C(Si(CH₃)₃)); ¹³C NMR (100.6 MHz, C₆D₆): δ = 102.5 (d, ¹*J*(C,H) = 179 Hz; C(1)), 78.9 (d, ¹*J*(C,H) = 147 Hz; C(6')), 74.2 (d, ¹*J*(C,H) = 159 Hz; C(5)), 74.1 (d, ¹*J*(C,H) = 154 Hz; C(4')), 71.5 (d, ¹*J*(C,H) = 141 Hz; C(3')), 70.6 (d, ¹*J*(C,H) = 144 Hz; C(1')), 68.8 (d, ¹*J*(C,H) = 146 Hz; C(2')), 67.9 (d, ¹*J*(C,H) = 146 Hz; C(5')), 66.8 (t, ¹*J*(C,H) = 144 Hz; C(4)), 63.5 (d, ¹*J*(C,H) = 143 Hz; C(2)), 62.7 (t, ¹*J*(C,H) = 154 Hz; C(6)), 59.1 (t, ¹*J*(C,H) = 143 Hz; C(7')), 40.4 (d, ¹*J*(C,H) = 126 Hz; C(3)), 26.3, 26.1, 26.0, 25.9 (4 × q, ¹*J*(C,H) = 125 Hz; (CH₃)₃CSi), 18.5, 18.2, 18.1, 18.0 (4 × s; (CH₃)₃CSi), –4.3, –4.4, –4.4, –4.6, –4.8, –4.9, –5.0, –5.1 ppm (8 × q, ¹*J*(C,H) = 118 Hz; CH₂Si); IR (film): $\tilde{\nu}$ = 3477, 2953, 2856, 1714, 1633, 1471, 1256, 1099, 836, 778, 739 cm^{–1}; HRMS (MALDI-TOF): *m/z*: calcd for C₃₇H₇₇N₃O₉Si₄Na⁺: 842.4634; found: 842.4631; elemental analysis calcd (%) for C₃₇H₇₇N₃O₉Si₄ (920.36): C 54.17, H 9.46, N 5.12; found: C 54.19, H 9.38, N 5.12.
