Organocatalytic Asymmetric Synthesis of Organophosphorus Compounds

From the philosopher's stone to phosphorus: Organophosphorus compounds have found applications in asymmetric organocatalysis for the synthesis of optically active compounds of synthetic or biological

importance. The aim of this review article is to present recent contributions to this developing field of chemistry and to point out synthetic advantages of methodologies developed so far.

COMMUNICATIONS

Friedel–Crafts protocols for the intermolecular, *trans*-selective benzylic arylation of tetralin systems are described (see scheme). The protocols have

broad substrate scope and the use of enantiopure substrates allows the preparation of *trans*-aryl-substituted tetralins in high *ee*.

Benzylic Arylation

L. Schwartz, R. Lomoth,
L. Hammarström,* S. Ott* 60–63

 **High-Turnover Photochemical Hydrogen Production Catalyzed by a Model Complex of the [FeFe]-Hydrogenase Active Site**

Lifting the diiron curtain: 200 equivalents of H₂ per catalyst at a maximum turnover rate of 3.7 H₂ per minute can be obtained in a light-driven proton

reduction process in near-neutral H₂O/DMF (pH 5.5) by using an [FeFe]-hydrogenase active-site model complex as the catalyst (see scheme).

Homogeneous Catalysis

A. Perrier, V. Comte, C. Moïse,
P. Le Gendre* 64–67

 **First Titanium-Catalyzed 1,4-Hydrophosphination of 1,3-Dienes**

Titanium complexes outshine other catalysts: Titanium complexes have been found to catalyze 1,4-hydrophosphination of dienes, which is thought to proceed through an allyl intermedi-

ate (see scheme). Unprecedented regioselectivities (1,4- vs. 1,2-) are reached by using [TiCp₂(PMe₃)₂] or a titanocene complex bearing a pendant phosphine tether as catalysts.

Homogeneous Catalysis

K. Junge, B. Wendt, D. Addis, S. Zhou,
S. Das, M. Beller* 68–73

Copper-Catalyzed Enantioselective Hydrosilylation of Ketones by Using Monodentate Binaphthophosphine Ligands

No base required: The first copper-catalyzed asymmetric hydrosilylation of carbonyl compounds by using monodentate binaphthophosphine ligands is presented. After optimization of the

reaction parameters, high yields and enantioselectivities (up to 96% ee) for a broad range of aryl alkyl, cyclic, heterocyclic, and aliphatic ketones are achieved without a base.

Cross-Coupling

J. Zhao, Y. Yu, S. Ma* 74–80

 **Ligand Effects on the Pd-Catalyzed Cross-Coupling Reaction of 3-Iodoalk-2-enoates with Propargyl/1,2-Allenyllic Metallic Species: An Efficient Regio-divergent Synthesis of 2,4,5-Trienoates**

A ligand makes a big difference: The 1,3-lithium shift of propargyl/1,2-allenyl lithium has been tuned and applied in a subsequent transmetalation and Pd-catalyzed Negishi coupling reaction with 3-iodoalk-2-enoates to

give a highly regioselective and regio-divergent synthesis of 2,4,5-trienoates. It was discovered that ligands play a very important role in the cross-coupling reactions with respect to both regioselectivity and reactivity.

Unlikely bedfellows: Naphthalenedi-imide-based supramolecular nanotubes act as size-selective receptors for ion pairs, as demonstrated by competition experiments with C_{60} (see picture). Fullerene forms mixed complexes inside the cavity of the nanotubes in the presence of the anion and ammonium ions of the appropriate size.

Ion Pairs and C_{60} : Simultaneous Guests in Supramolecular Nanotubes

$SiCl_2$ as a simultaneous σ -donor and -acceptor: The reaction of the Lewis base stabilized dichlorosilylene $L \rightarrow SiCl_2$ with $B(C_6F_5)_3$ (L = imidazol-2-ylidene derivative) afforded the first silylene donor acceptor $L \rightarrow SiCl_2 \rightarrow B-(C_6F_5)_3$ complex (shown here). Charge density analysis revealed that the two $C \rightarrow Si$ and $Si \rightarrow B$ donor bonds are of considerably different quality. However, plain bond length consideration might suggest simple $C-Si$ and $Si-B$ single bonds.

Mechanistic Investigation of the Dipolar [2 + 2] Cycloaddition–Cycloreversion Reaction between 4-(*N,N*-Dimethylamino)phenylacetylene and Arylated 1,1-Dicyanovinyl Derivatives To Form Intramolecular Charge-Transfer Chromophores

Intermediate trapped! A detailed investigation of the cycloaddition–cycloreversion reaction between *N,N*-dimethylanilinoacetylene and arylated 1,1-dicyanovinyl derivatives elucidated its bimolecular, dipolar reaction mechanism, in which the relative height of

reaction barriers is highly sensitive to the substituents. In one case, the cyclobutene formed in the cycloaddition step could be isolated as a crystalline solid and its structure analyzed (see scheme).

Interior design: Metal–organic frameworks (MOFs) that are subjected to postsynthetic modification are shown to have different hydrogen adsorption properties (see picture). These differences are related to both the degree of

modification and the topology of the MOF. These studies provided the basis for the development of a structure–activity relationship for designing the interiors of MOFs for maximum hydrogen storage.

 **Contrasting Effects of Axial Ligands on Electron-Transfer Versus Proton-Coupled Electron-Transfer Reactions of Nonheme Oxoiron(IV) Complexes**

Counterintuitive reactivities: The rates of electron transfer (ET) and proton-coupled electron-transfer (PCET) in the reactions of with ferrocene derivatives are markedly affected by the electron-donating ability of the axial ligands (X) in opposite directions (see figure); the electron-donating axial ligand decelerates the ET rate in the reactions, but enhances the PCET reactivity of **1-X** in the presence of acid.

Self-assembly mechanisms of a self-assembled system were studied by concentration- and temperature-dependent measurements. Both methods were evaluated to determine their effectiveness in identifying and quantifying the self-assembly mechanism for isodesmic and cooperative systems (see figure). For a fast and unambiguous determination of the assembly mechanism and its thermodynamic parameters, temperature-dependent measurements are more appropriate.
