## LEUCOTHOL A, AN ANTHRADITERPENOID FROM LEUCOTHOE GRAYANA MAX.

Akio FURUSAKI, Nobuyuki HAMANAKA, Hidehiro MIYAKOSHI,

Toshikatsu OKUNO and Takeshi MATSUMOTO\*

Chemistry Department, Faculty of Science,

Hokkaido University, Sapporo

The structure of leucothol A,  $C_{20}H_{30}O_3$ , a minor constituent of Leucothoe grayana Max., has been determined as 2 by means of X-ray crystallographic analysis. Leucothol A is the first example of anthraditerpenoid.

A number of A-nor-B-homo-kauranoids (grayanoids) have been isolated from Leucothoe grayana Max.  $^{1)}$  We wish to describe here isolation and characterization of a new diterpenoid leucothol  $A^{2)}$ , which has an unprecedent diterpenoid skeleton, from the same plant.

Leucothol A,  $C_{20}H_{30}O_3^{-3}$ , mp 243°, ORD a = -178, was obtained by careful chromatography in 7.5 x  $10^{-4}\%$  yield from dried leaves and was shown by spectroscopic data to have following groups; three methyls ( $\delta$  (pyridine- $d_5$ , 100 MHz) 1.16, 1.40, and 1.47), a carbonyl (V (nujol) 1703 cm<sup>-1</sup>), a secondary hydroxyl ( $\delta$  4.10, 1H, t, J = 3 Hz) and a vinylidene group (V 1640 cm<sup>-1</sup>,  $\delta$  4.88 and 5.05, each 1H, s). The presence of a tertiary hydroxyl group was indicated by the

formation of monoacetate<sup>3)</sup>, mp 177-177.5°, which still exhibits hydroxyl absorption band at 3300 cm<sup>-1</sup>. The NMR signals in the allyl and  $\alpha$ -keto methine region further demonstrate the presence of the partial structure 1 in leucothol A. Protons  $H_A$  and  $H_B$  in 1 resonate at  $\delta$  2.86 and 2.67 respectively (J = 12 Hz) and the former couples further with  $H_{Ka}$  (J = 12 Hz),  $H_{Ke}$  (J = 4 Hz),  $H_{X}$  (J = 1 Hz) as well as  $H_{Y}$  (J = 1 Hz) and the latter with  $H_{La}$  (J = 12 Hz) as well as  $H_{Le}$  (J = 4 Hz).

Since the partial formula  $\frac{1}{2}$  is not in conformity with grayanane skeleton, leucothol A was subjected to X-ray crystallographic analysis  $^4)$ .

Crystal data are summarized in Table 1. A Rigaku four-circle diffractometer was used to collect 1866 unique intensity data (0° < 9 < 70°), which afforded 363 |E| values above 1.30. Fifty-seven phases were at first expressed by four symbols with the aid of the sum of angles formula and probable numerical values of phases were obtained by means of tangent

Table 1. The crystal data.

formula using the above |E| values.<sup>5)</sup> From the E-map thus calculated the atomic coordinates of 23 carbon and oxygen atoms were readily obtained. After refinement of the atomic parameters by the block-diagonal-matrix least-squares method and subsequent D-synthesis, the locations of 30 hydrogen atoms were also found. Further refinement including hydrogen atoms yielded R = 5.05%. The final atomic coordinates are given in Table 2. The assignment of absolute configuration was done by taking account of the anomalous dispersion effect of oxygen atoms for Cu Ka radiation ( $\triangle$  f" = 0.1). For the 20 quartets of hkl,  $\overline{h}\overline{k}l$ ,  $\overline{h}kl$ , and  $h\overline{k}l$ reflections with  $|F_c(hkl)| - |F_c(\bar{h}\bar{k}\bar{l})|$  values above 3.0  $\sigma(|F_c|)$ , the intensity measurement was made. The results are summarized in Table 3. The observed and calculated inequalities are in good agreement with each other, thus establishing the full structure of leucothol A including the absolute configuration as shown in Fig. 1 and the formula 2. This absolute configuration was supported also by the comparison of R factors for the 100 reflections having the largest  $\Delta F_c/\sigma(|F_c|)$ values; the R factors were 3.87 and 3.93% for the structure shown in Fig. 1 and its antipode respectively. Thus, the new diterpene possesses a hitherto unknown

anthraditerpenoid skeleton (leucothane skeleton), and it should be noted that the absolute configuration at C-l is antipodal to that of known grayanoids.
