$\text{TiO}_2/\text{SiO}_2$  (70-90 wt%  $\text{TiO}_2$ ) prepared by deposition of  $\text{TiO}_2$  on to  $\text{SiO}_2$  gel are significantly effective catalyst supports for Pt in NO-CO reaction. The presence of  $\text{SiO}_2$  distinctly changes the structures and properties of  $\text{TiO}_2$  and definitely increases the thermal stability of the dispersed anatase  $\text{TiO}_2$ , on which Pt is selectively deposited and gives the high catalytic activity.

Recently, studies on the catalytic properties of  $\text{TiO}_2$  are getting more important, since  $\text{TiO}_2$  often behaves as an excellent catalyst or catalyst support in certain reactions.<sup>1-5)</sup> It has been found, for example, that  $\text{Pt/TiO}_2$  is much more effective for the NO-CO reaction in the presence or absence of  $\text{H}_2\text{O}$ ,  $\text{H}_2$ , and  $\text{O}_2$  than  $\text{Pt/Al}_2\text{O}_3$  which is known to be one of typical NO removal catalysts.<sup>1)</sup> However, if  $\text{TiO}_2$  is used as a catalyst or catalyst support, especially as a support for NO removal catalysts in auto exhaust, one should find that it has several definite disadvantages as follows; (1)  $\text{TiO}_2$  supports tend to sinter when they are used at high temperatures. (2) The mechanical strength of high surface area- $\text{TiO}_2$  supports should not be enough to be used in the practical NO removal processes. (3) They are more costly in practice than the typical conventional support materials such as  $\text{SiO}_2$ ,  $\text{Al}_2\text{O}_3$ , etc.. The idea employed in the present work is as follows: if  $\text{TiO}_2$  is deposited or coated over other stable, strong, and cheap high area materials, the disadvantages may be removed without the sacrifice of the advantages of  $\text{TiO}_2$  itself and  $\text{TiO}_2$  will be much more extensively employed in practical catalytic processes, especially in auto exhaust in which the use of  $\text{TiO}_2$ -coated monolithic supports may be expected.<sup>6)</sup> In general, it may become important to study the catalytic properties of the supports prepared by depositing a certain catalytically effective "real" support material over other catalytically inert but essential materials. In the present work, two different  $\text{TiO}_2/\text{SiO}_2$  systems prepared in unusual fashions by the deposition of  $\text{TiO}_2$  on to  $\text{SiO}_2$  gel were employed as support materials for Pt. The structures and some physicochemical properties of  $\text{TiO}_2$  in the  $\text{TiO}_2/\text{SiO}_2$  or  $\text{Pt/TiO}_2/\text{SiO}_2$  systems were investigated by X-ray, EPR, and other experimental techniques and compared with the catalytic activity of  $\text{Pt/TiO}_2/\text{SiO}_2$  in the NO-CO reaction.

$\text{TiO}_2(\text{I})$  was prepared from an HCl-acidic  $\text{TiCl}_4$ -solution ( $\text{pH}=0.0-0.2, 4.0 \text{ mol dm}^{-3}$   $\text{TiCl}_4$ , from Oosaka Titanium Co., Ltd.) by evaporating as such, drying at  $120^\circ\text{C}$  for

18 h followed by air calcination at 550°C for 3 h.  $\text{TiO}_2(\text{II})$  was prepared by neutralization of the  $\text{TiCl}_4$ -solution with ammonia water ( $1 \text{ mol dm}^{-3}$ ) up to a pH of  $6.0 \pm 0.1$ . The resulting precipitate was washed by water several times, dried at 120°C for 18 h and calcined in air at 550°C for 3 h.  $\text{SiO}_2$  (32-60 mesh) was prepared by evaporating a solution of silica (Snowtex 0, from Nissan Chemicals & Industry), drying at 120°C for 18 h, followed by air calcination at 600°C for 4 h.  $\text{TiO}_2/\text{SiO}_2(\text{I})$  were prepared by impregnating the  $\text{SiO}_2$  with the  $\text{TiCl}_4$ -solution, evaporating and drying at 120°C for 18 h, followed by air calcination at 550°C for 3 h.  $\text{TiO}_2/\text{SiO}_2(\text{II})$  were prepared by the following method. The  $\text{TiCl}_4$ -solution was neutralized by the ammonia water up to a pH of  $6.0 \pm 0.1$  in the presence of the  $\text{SiO}_2$ , in which  $\text{TiO}_2$  was deposited over the  $\text{SiO}_2$ . The resulting solid was washed with water several times and dried at 120°C for 18 h, followed by air calcination at 550°C for 3 h.  $\text{Pt}/\text{TiO}_2(\text{I})$ ,  $\text{Pt}/\text{TiO}_2(\text{II})$ ,  $\text{Pt}/\text{TiO}_2/\text{SiO}_2(\text{I})$ , and  $\text{Pt}/\text{TiO}_2/\text{SiO}_2(\text{II})$  were prepared by impregnating the respective support with a solution of  $\text{H}_2\text{PtCl}_6 \cdot 6\text{H}_2\text{O}$ , evaporating and drying at 120°C for 18 h. Before the reaction, the catalysts were activated *in situ* by heating in  $\text{H}_2$  at 500°C for 1 h, followed by dry helium at 500°C for 3 h. The reaction was conducted in a conventional flow reactor. The detail reaction conditions are shown in the legend of Fig.1. The reactants ( $\text{NO}$ ,  $\text{CO}$ ) and products ( $\text{N}_2$ ,  $\text{N}_2\text{O}$ ,  $\text{CO}_2$ ) were analyzed by gas chromatograph. The structures of support materials were determined by a conventional X-ray powder diffraction method. The relative amounts of  $\text{Ti}^{3+}$  in the catalysts or supports were measured at 77 K by an EPR spectrometer. The IR spectra of the catalysts were measured at room temperature by a conventional vacuum cell method<sup>7)</sup>.

The catalytic activity of  $\text{Pt}/\text{TiO}_2/\text{SiO}_2(\text{I})$  in the NO-CO reaction markedly depends on the composition of the support as shown in Fig.1a. The profile of the activity is unique and characterized by several points as follows: (1)  $\text{TiO}_2/\text{SiO}_2(\text{I})$  ( $\geq 60 \text{ wt}\% \text{ TiO}_2$ ) are distinctly more effective than  $\text{TiO}_2/\text{SiO}_2$  ( $< 60 \text{ wt}\% \text{ TiO}_2$ ). The deposition of fairly large amounts of  $\text{TiO}_2$  over  $\text{SiO}_2$  is necessary to obtain a high catalytic activity. (2)  $\text{Pt}/\text{TiO}_2/\text{SiO}_2(\text{I})$  (70-90 %) are significantly more active than  $\text{Pt}/\text{TiO}_2(\text{I})$  and the maximum activity appears around 80 % of  $\text{TiO}_2$ . (3) The deactivation of the catalysts, which is known to be caused by the formation of surface NCO species during the reaction<sup>7)</sup>, is much slower for  $\text{Pt}/\text{TiO}_2/\text{SiO}_2(\text{I})$  than for  $\text{Pt}/\text{TiO}_2(\text{I})$ . The BET surface area ( $S_B$ ) and the number of surface Pt atoms ( $N_s$ ) of the catalysts are shown in Fig.1c.  $S_B$  of the catalyst, which is actually the same as that of the support, monotonously decreases with increase in the concentrations of  $\text{TiO}_2$ .  $N_s$  varies gradually and smoothly with the contents of  $\text{TiO}_2$ . Therefore, the unique activity patterns in Fig.1a may not be attributable to the variation of  $N_s$  as well as  $S_B$ <sup>8)</sup>.

The interactions of Pt with  $\text{TiO}_2/\text{SiO}_2(\text{I})$  were studied by measuring the IR spectra of the NCO species formed on  $\text{Pt}/\text{TiO}_2(\text{I})$ ,  $\text{Pt}/\text{SiO}_2$ , and  $\text{Pt}/\text{TiO}_2/\text{SiO}_2(\text{I})$  during the NO-CO reaction. Comparisons among the spectra shown in Fig.2 indicate that Pt selectively interacts with "TiO<sub>2</sub>" in  $\text{TiO}_2/\text{SiO}_2$  even in the case that the mol ratio of  $\text{TiO}_2$  to  $\text{SiO}_2$  is almost unity. Since the catalytic activity of  $\text{Pt}/\text{TiO}_2/\text{SiO}_2(\text{I})$  (50 wt%  $\text{TiO}_2$ ) is distinctly low, the abrupt change in the activity around 60 wt%  $\text{TiO}_2$  is not ascribed to the change in catalyst components from Pt/"SiO<sub>2</sub>" to Pt/"TiO<sub>2</sub>" in  $\text{Pt}/\text{TiO}_2/\text{SiO}_2(\text{I})$ .

X-ray studies revealed that  $\text{TiO}_2(\text{I})$  is almost pure rutile  $\text{TiO}_2$ , which can be

Fig. 1 Effects of the composition of  $\text{TiO}_2/\text{SiO}_2$  (I) supports on the catalytic activities of  $\text{Pt}/\text{TiO}_2/\text{SiO}_2$  (I) (Pt 1wt%) for the NO-CO reaction, a, and the catalytic properties, b and c; a: Catalyst 0.01g, NO 3%, CO 3%, He balance, Flow rate  $100\text{cm}^3\text{min}^{-1}$ , Reaction temperature  $350^\circ\text{C}$ , (The supports themselves were actually inactive for the reaction under the same conditions.), The catalytic activities decrease with the time on stream because of the formation of the surface NCO species on the catalysts. However, the presence of  $\text{H}_2$ ,  $\text{O}_2$ , and/or  $\text{H}_2\text{O}$  in the reactants decomposes the NCO and keeps the catalytic activities constant and high., b:  $I_A$ ,  $I_R$  see Table 1, I Relative intensities of  $\text{Ti}^{3+}$  in the catalysts., c:  $S_B$ ,  $N_s$  see text,  $N_s$  were estimated by a conventional  $\text{H}_2\text{-O}_2$  titration method.

Table 1 Thermal Stabilities of  $\text{TiO}_2$  and  $\text{TiO}_2/\text{SiO}_2$  Systems

Calcination Conditions	550°C 3h	700°C 1h	800°C 1h
$\text{TiO}_2$ (I)	$I_A$ 15-20	0	0
	$I_R$ 380-400	$\sim 400$	$\sim 400$
	$S_B$ 15-20	3-6	1-3
$\text{TiO}_2$ (II)	$I_A$ 440-460	-----	$\sim 10$
	$I_R$ 0-10	-----	$\sim 400$
	$S_B$ 55-70	-----	3-6
$\text{TiO}_2/\text{SiO}_2$ (I) (80wt%)	$I_A$ 450-470	250-300	$\sim 0$
	$I_R$ 60-90	150-250	350-360
	$S_B$ 65-85	55-65	30-40
$\text{TiO}_2/\text{SiO}_2$ (II) (80wt%)	$I_A$ 470-490	-----	470-490
	$I_R$ 20-30	-----	20-30
	$S_B$ 130-160	-----	110-130
$\text{SiO}_2$	$S_B$ 190-210	-----	160-180

$I_A$ ,  $I_R$ : Integrated Intensities of X-ray Diffraction Peaks/a.u.,  $I_A$  Anatase ( $2\theta=25.3^\circ$ ),  $I_R$  Rutile ( $2\theta=27.4^\circ$ ),  $S_B$ : BET Surface Areas of the Supports/ $\text{m}^2\text{g}^{-1}$

Fig. 2 IR spectra of the NCO formed on  $\text{Pt}/\text{TiO}_2$  (I), A,  $\text{Pt}/\text{TiO}_2/\text{SiO}_2$  (I) (50wt% $\text{TiO}_2$ ), B, and  $\text{Pt}/\text{SiO}_2$ , C, in the NO-CO reaction at  $350^\circ\text{C}$ .

expected by the results reported by Funaki<sup>9)</sup>, while  $\text{TiO}_2/\text{SiO}_2(\text{I})$  has both anatase and rutile. The ratio of anatase to rutile distinctly varies with the composition of the support as shown in Fig.1b. The anatase is predominant in the composition range from 60 to 90 wt%  $\text{TiO}_2$ . A comparison between Fig.1a. and Fig.1b suggests that the crystalline  $\text{TiO}_2$  may take an important role in the high catalytic activity. The difference in the activity between  $\text{Pt}/\text{TiO}_2(\text{I})$  and  $\text{Pt}/\text{TiO}_2/\text{SiO}_2(\text{I})$  (70-90 %) may be *partially* attributable to the difference in the structures of  $\text{TiO}_2$  since one experiment showed that  $\text{Pt}/\text{TiO}_2(\text{II})$ -anatase (see Table 1) is about 1.3 times more active than  $\text{Pt}/\text{TiO}_2(\text{I})$ -rutile in the initial stage of the NO-CO reaction at 350°C.

The EPR studies showed that the concentrations of  $\text{Ti}^{3+}$  in the fresh catalysts markedly vary with the composition of the support as shown in Fig.1b, and  $\text{Pt}/\text{TiO}_2/\text{SiO}_2(\text{I})$  (80 %  $\text{TiO}_2$ ) has larger amounts of the  $\text{Ti}^{3+}$  which can be oxidized by NO or  $\text{O}_2$  and reproduced by CO or  $\text{H}_2$  around 350°C than either  $\text{Pt}/\text{TiO}_2(\text{I})$  or  $\text{Pt}/\text{TiO}_2/\text{SiO}_2(\text{I})$  (50 %  $\text{TiO}_2$ ). The reasons why the catalytic activity varies with the amounts of  $\text{Ti}^{3+}$  is still obscure. However, the following explanation may be conceivable; the variations in the oxidation-reduction properties of the  $\text{Ti}^{3+}/\text{Ti}^{4+}$  system in the catalysts change the electronic properties of Pt on " $\text{TiO}_2$ " and the rate of the oxidation of Pt by the dissociative adsorption of NO and /or that of the reduction of the oxidized Pt by CO are increased.

The X-ray studies also showed that the thermal stabilities of  $\text{TiO}_2$  are markedly increased by the incorporation of  $\text{SiO}_2$  and vary with the preparation methods as shown in Table 1. The table shows that the air calcination of either pure  $\text{TiO}_2$  above 700°C definitely decreases its surface area and changes the structure of  $\text{TiO}_2(\text{II})$  from anatase to rutile, while the anatase over  $\text{SiO}_2$  hardly changes to rutile, especially for  $\text{TiO}_2/\text{SiO}_2(\text{II})$ . The presence of  $\text{SiO}_2$  gel particles stabilizes the dispersed anatase  $\text{TiO}_2$  and keeps  $S_B$  significantly high. Either  $\text{Pt}/\text{TiO}_2/\text{SiO}_2$  (80 wt%  $\text{TiO}_2$ ) which had been calcined at 800°C still had the high catalytic activity, while the catalytic activity of either  $\text{Pt}/\text{TiO}_2$  calcined at 800°C was negligible.
