

Electron-Transfer Oxidation of 9-Alkylanthracenes and the Decay Kinetics of  
Radical Cations in Acetonitrile

Morifumi FUJITA and Shunichi FUKUZUMI\*

Department of Applied Chemistry, Faculty of Engineering, Osaka University, Suita, Osaka 565

Transient absorption spectra of radical cations of 9-alkylanthracenes ( $\text{RAn}^{\bullet+}$ ) formed by the electron-transfer oxidation of 9-alkylanthracenes with  $\text{Fe}(\text{ClO}_4)_3 \cdot 9\text{H}_2\text{O}$  have been detected by using a stopped flow spectrophotometer. The decay rates of  $\text{RAn}^{\bullet+}$  obey the second-order kinetics due to the electron-transfer disproportionation reactions, followed by the nucleophilic attack of  $\text{H}_2\text{O}$  on the resulting dication leading to the final ring-oxygenated products.

Electron-transfer oxidation of hydrocarbons has recently attracted considerable interest in view of a drastic change in the reactivity of the radical cations which become much stronger acids, electrophiles, and oxidants than the parent molecules.<sup>1-4)</sup> For example, the radical cation of toluene has a tremendous acidity ( $\text{pK}_a < -12$ )<sup>2)</sup> and thereby the deprotonation from the alkylbenzene radical cations is the predominant decay process of the radical cations.<sup>3)</sup> In the case of alkylanthracene radical cations, however, the deprotonation leading to the side chain oxidation has recently been shown to be sluggish relative to nucleophilic attack by nucleophiles leading to the ring oxidation.<sup>4)</sup> In order to elucidate the reaction mechanism for the ring oxidation it is certainly preferred to analyze the decay kinetics of the radical cations detected directly. To the best of our knowledge, however, there has so far been no report on the direct kinetic analysis of the radical cations, combined with the product analysis.<sup>5)</sup> This study reports the direct detection of radical cations of 9-alkylanthracenes by  $\text{Fe}(\text{ClO}_4)_3 \cdot 9\text{H}_2\text{O}$  in acetonitrile (MeCN) and the kinetic analysis of the decay process as well as the characterization of the oxygenated products, providing valuable insight into the mechanistic aspects in radical cation chemistry.

When 9-benzylanthracene ( $\text{RAn}$ ,  $\text{R} = \text{PhCH}_2$ ) is oxidized by  $\text{Fe}(\text{ClO}_4)_3 \cdot 9\text{H}_2\text{O}$  in deaerated MeCN, the ring oxidation occurs to yield the four-electron oxidized species, 10-benzyl-10-hydroxy-9(10H)-anthracenone (**1**) as shown in Eq. 1. The product (**1**) was identified by the  $^1\text{H}$  NMR spectrum, elemental analysis, and mass

spectroscopy.<sup>6)</sup> The oxidation of other 9-alkylanthracenes ( $\text{RA}$ ;  $\text{R} = \text{Et}$ ,  $\text{Pr}^i$ ) by  $\text{Fe}^{3+}$  also yields the corresponding 10-alkyl-10-hydroxy-9(10H)-anthracenones. Mixing an MeCN solution of  $\text{Fe}(\text{ClO}_4)_3 \cdot 9\text{H}_2\text{O}$  with  $\text{RAn}$  ( $\text{R} = \text{Pr}^i$ ) in a stopped-flow spectrometer results in an instant appearance of a new absorption band at  $\lambda_{\text{max}} = 700 \text{ nm}$  due to the radical cation ( $\text{RAn}^{\bullet+}$ )<sup>7)</sup> as shown in Fig. 1. The decay of the absorbance due to  $\text{RAn}^{\bullet+}$  ( $\text{R} =$

Fig. 1. Transient absorption spectrum of RAn\*<sup>+</sup> (R = Pr<sup>i</sup>) formed in the electron-transfer oxidation of RAn by Fe(ClO<sub>4</sub>)<sub>3</sub> in deaerated MeCN at 298 K.

PhCH<sub>2</sub>) at λ<sub>max</sub> = 720 nm shown in Fig. 2a obeys the second-order kinetics (Eq. 2) as demonstrated by

$$-d[\text{RAn}^{\bullet+}]/dt = k_{\text{obsd}}[\text{RAn}^{\bullet+}]^2 \quad (2)$$

Fig. 2. (a) Decay of the absorbance due to RAn\*<sup>+</sup> (R = PhCH<sub>2</sub>) formed in the electron-transfer oxidation of RAn (6.25 × 10<sup>-4</sup> mol dm<sup>-3</sup>) by Fe(ClO<sub>4</sub>)<sub>3</sub> (3.04 × 10<sup>-2</sup> mol dm<sup>-3</sup>) in deaerated MeCN at 298 K, and (b) the second-order decay plot of 1/absorbance vs. time.

the linear plot of 1/absorbance vs. time in Fig. 2b. From the intercept at time = 0 of the linear plot of 1/absorbance vs. time is obtained the initial absorbance at 720 nm, which is proportional to the initial concentration of RAn. Thus, the extinction coefficient (ε<sub>max</sub>) is obtained from the initial absorbance, the initial concentration of RAn, and the optical path length (2 mm). The radical cations of other alkylanthracenes (RAn\*<sup>+</sup>; R = Me, Et, PhCH<sub>2</sub>) are also detected in the reactions of RAn with Fe<sup>3+</sup>. The absorption maxima (λ<sub>max</sub>) and the extinction coefficients (ε<sub>max</sub>) of RAn\*<sup>+</sup> are listed in Table 1, together with the one-electron oxidation potentials (E<sup>0</sup><sub>ox</sub>) of RAn, which were determined by the fast cyclic voltammetry measurements.<sup>8)</sup>

a) The experimental error is ±10 nm. b) The experimental error is ±10%.

The second-order decay may be ascribed to the disproportionation of two  $\text{RAn}^{\bullet+}$  molecules to give the corresponding dication ( $\text{RAn}^{2+}$ ) and  $\text{RAn}$  as shown in Scheme 1. Although the electron transfer between the

Scheme 1.

radical cations may be endergonic,<sup>9)</sup> the subsequent facile electron transfer from  $\text{RAn}$  to  $\text{Fe}^{3+}$  as well as addition of  $\text{H}_2\text{O}$  to  $\text{RAn}^{2+}$  results in the overall four electron oxidation of  $\text{RAn}$  to yield 10-alkyl-10-hydroxy-9(10H)-anthracenone (Scheme 1).<sup>10)</sup> By applying the steady state approximation to the  $\text{RAn}^{2+}$ - $\text{RAn}$  pair in Scheme 1, the observed second-order decay rate constant  $k_{\text{obsd}}$  is given by Eq. 3. Judging from the initial fast electron

$$k_{\text{obsd}} = \frac{k_1(k_2[\text{Fe}^{3+}] + k_3[\text{H}_2\text{O}])}{k_{-1} + k_2[\text{Fe}^{3+}] + k_3[\text{H}_2\text{O}]} \quad (3)$$

transfer from  $\text{RAn}$  to  $\text{Fe}^{3+}$ , it is well assumed that  $k_2[\text{Fe}^{3+}] \gg k_3[\text{H}_2\text{O}]$ . In such a case Eq. 3 is rewritten by Eq. 4, which predicts a linear correlation between  $k_{\text{obsd}}^{-1}$  and  $[\text{Fe}^{3+}]^{-1}$ . In

$$k_{\text{obsd}}^{-1} = k_1^{-1}[1 + (k_{-1}k_2[\text{Fe}^{3+}])^{-1}] \quad (4)$$

fact, the plot of  $k_{\text{obsd}}^{-1}$  vs.  $[\text{Fe}^{3+}]$  gives a straight line being in agreement with Eq. 4, as shown in Fig. 3. The deprotonation of  $\text{RAn}^{\bullet+}$  may be negligible under the present experimental conditions, since no side-oxidation takes place and there is no appreciable contribution of the first-order decay of  $\text{RAn}^{\bullet+}$ . Moreover, the addition of  $\text{HClO}_4$  ( $3.9 \times 10^{-2} \text{ mol dm}^{-3}$ ) to the  $\text{RAn-Fe}^{3+}$  system resulted in little

Fig. 3. Plot of  $k_{\text{obsd}}^{-1}$  vs.  $[\text{Fe}^{3+}]^{-1}$  for the decay of  $\text{RAn}^{\bullet+}$  ( $\text{R} = \text{PhCH}_2$ ) formed in the electron-transfer oxidation of  $\text{RAn}$  ( $6.25 \times 10^{-4} \text{ mol dm}^{-3}$ ) by  $\text{Fe}(\text{ClO}_4)_3$  in  $\text{MeCN}$  at 298 K.

change in the  $k_{\text{obsd}}$  value. In contrast, the addition of  $\text{H}_2\text{O}$  ( $0.37 \text{ mol dm}^{-3}$ ) to the above system resulted in a 35% increase in the  $k_{\text{obsd}}$  value, being consistent with Eq. 3. Thus, the 9-alkylanthracene radical cation acts as a strong one-electron oxidant, which can accept an electron from the radical cation itself, rather than a strong acid to be deprotonated, in contrast with the case of alkylbenzene radical cation. The electron-transfer disproportionation of  $\text{RAn}^{\bullet+}$  produces an extremely strong electrophile, *i.e.*,  $\text{RAn}^{2+}$ , which is subjected to the nucleophilic attack of  $\text{H}_2\text{O}$ , leading to the final ring-oxygenated product (Scheme 1).

We are grateful to Professor S. Yanagida for providing us the fast cyclic voltammetry apparatus.
