## Addition of Grignard and Organolithium Reagents to the Negatively Charged Sulfur Atom of 2,2-Bis(diethylamino)ethan-2-ylium-1-dithioate

Juzo Nakayama,\* Takashi Otani, Yoshiaki Sugihara, and Akihiko Ishii Department of Chemistry, Faculty of Science, Saitama University, Urawa, Saitama 338

(Received December 17, 1997; CL-970949)

A range of Grignard and organolithium reagents added to the negatively charged sulfur atom of the inner salt 1, despite the presence of the positively charged carbenium carbon, to give enethiolates 4, which were methylated by MeI to give dithioacetals 3 as the final product in excellent yields. A mechanism involving a single-electron-transfer process from nucleophiles to 1 is presented for this thiophilic addition.

We have been investigating the synthesis, structure, and reactivities of the inner salt, 2,2-bis(diethylamino)ethan-2-ylium-1-dithioate (1), and its related salts. 1-3 Recently, we have reported that the carbenium salt (2), which is easily obtainable from 1, shows ambident reactivities toward a variety of nucleophiles. 3 For example, 2 reacted with soft nucleophiles such as Grignard and organolithium reagents on the sulfur atom of the thiocarbonyl group to give dithioacetals 3 nearly quantitatively, whereas it reacted with a hard nucleophile, hydroxide, on the carbenium carbon atom. In this connection, we have now become interested in the reactivities of 1 toward Grignard and organolithium reagents.

Although the inner salt 1 smoothly reacted with MeMgI in ether at 0 °C with disappearance of the red color due to 1, quenching of the reaction by water gave an intractable mixture. However, treatment of the reaction mixture with excess MeI gave the dithioacetal 3 (R = Me) in 94% isolated yield. These results reveal that MeMgI added to the dithiocarboxylate sulfur atom, but not the carbenium carbon atom, to give the enethiolate 4 (R = Me, M = MgI), which gave 3 on methylation with MeI. Results summarized in Table 1 demonstrate that the reaction is quite general, and a range of Grignard and organolithium reagents added to the sulfur atom to give 4, thus affording 3 as the final product in excellent yields by treatment with MeI. 4 The present reaction is of particular interest in that the negatively charged nucleophiles added to the negatively charged sulfur atom despite the presence of the positively charged carbenium ion center.

  $\xrightarrow{\text{Et}_2N}$   $\xrightarrow{\text{SR}}$   $\xrightarrow{\text{Mel}}$  3  $\xrightarrow{\text{Mel}}$  3  $\xrightarrow{\text{M}}$   $\xrightarrow{\text{M}}$ 

A literature survey revealed that some analogy is found in the reaction of the phosphonium salt 5 with BuLi, which gives 6.5

**Table 1.** Formation of 3 by reactions of 1 with RM followed by treatment with  $Mel^{a,b}$ 

Entry	Solvent	R	М	Yields (%) of 3
1	THF	Methyl	MgI	92
2	Ether	Ethyl	MgI	94
3	THF	Ethyl	MgI	89
4	Ether	n-Butyl	Li	85
5	Ether	Benzyl	MgCl	88
6	Ether	iso-Propyl	MgCl	84
7	THF	Allyl	MgCl	88
8	THF	Phenyl	MgBr	88
9	THF	2-Thienyl	Li	88

<sup>&</sup>lt;sup>a</sup> 1.2 Molar amounts of RM was used while MeI was used in excess. <sup>b</sup> All reactions were carried out at 0 °C under argon.

Reactions of 1 with t-BuLi and t-BuMgCl provide some valuable information on the mechanism of the present reaction (Table 2). The reaction of 1 with 1.2 molar amounts of t-BuLi in ether gave a mixture of dithioacetals 7 and 8 in a moderate yield after treatment with MeI. A considerable amount of 1 remained unchanged. Meanwhile, the reaction of 1 with 2 molar amounts of t-BuLi also gave a 56:44 mixture of 7 and 8 in a better yield (89%) with complete consumption of 1. These results can best be explained as follows. The reaction is initiated by a single-electrontransfer process from t-BuLi to 1 to produce a pair of radicals 9 (M = Li) and 10. Combination of 9 and 10 in a solvent cage would give rise to the enethiolate 11, which is methylated by MeI to afford 7 as one of the final products. Meanwhile, disproportionation of 9 and 10 would produce 12 and isobutene. 6 Then, 12 is lithiated by t-BuLi to give 13, which is dimethylated with MeI to give the other final product 8. This explains the reasons why 1 was recovered in a considerable amount on reaction with 1.2 molar amounts of t-BuLi and why 2 molar amounts of t-BuLi was required for the complete comsumption of 1. The ratio of 7 to 8 is much influenced by the solvent used; in THF, the ratio is reversed (Entries 1 and 2). The ratio is also dependent on the metal ions. Thus, treatment of 1 with t-BuMgCl (2 molar amounts) in ether gave no disproportionation product 8, whereas, in THF, 7 and 8 were formed in the ratio of 82:18 (Entries 3 and 4).<sup>7</sup>

The mechanism presented above should be operative also in the examples given in Table 1. However, for these cases, since steric hindrance is not severe, a pair of radicals combine in a cage to give 4 exclusively.

Although the carbenium salt 2 reacted with a variety of soft nucleophiles such as sulfur, nitrogen, and phosphorus nucleophiles, on the sulfur atom, 1 did not react with these

Entry	Solvent	М	Yields (%) of <b>7</b> + <b>8</b>	Relative Ratio 7:8
1	Ether	Li	89	56:44
2	THF	Li	94	38:62
3	Ether	MgCl	89	100:0
4	THF	MgCl	91	82:18

<sup>&</sup>lt;sup>a</sup> 2 Molar amounts of *t*-BuM was used while MeI was used in excess. <sup>b</sup> All reactions were carried out at 0 °C under argon.

reagents.<sup>3</sup> This can be explained by large difference of the cyclic voltammetric peak potentials between  $1 (E_{\rm p,a}; -1.99, E_{\rm p,c}; -1.80, E_{1/2}; -1.89 \text{ V})$  and  $2 (E_{\rm p,a}; -0.88, E_{\rm p,c}; -0.72, E_{1/2}; -0.80 \text{V})$ . From these values, evidently 1 is much weaker than 2 as a single-electron acceptor and should be less reactive than 2 toward nucleophiles.

In conclusion, the inner salt 1 shows a unique property which enabled it to react with both electrophiles (RI) and nucleophiles (RM) to give 14 and 4, respectively.<sup>9</sup>
