(Received December 28, 1998; CL-980958)

Nonenzymatic kinetic resolution of racemic secondary alcohols is an efficient synthetic method to obtain optically active compounds in organic chemistry. Catalytic asymmetric acylation of racemic secondary alcohols has been successfully performed with achiral benzoyl chloride in the presence of only 0.3 mol% of chiral diamine (**3**) derived from (*S*)-proline, combined with 0.5 equivalent of triethylamine. This asymmetric acylation of various racemic cyclic secondary alcohols, 5, 6, or 8 membered cycloalkanols (**1a–1c**), hydroxyesters (**1d** and **1e**), and bromohydrins (**1f** and **1g**) gave the corresponding optically active benzoates (84–97% ee) and unreacted alcohols (79–95% ee). Racemic acyclic secondary alcohols (**1h–1j**) were also acylated in moderate enantioselectivity.

Kinetic resolution of racemic secondary alcohols is a general efficient synthetic method to obtain optically active alcohols and their variants, and has been widely used for the synthesis of complex natural products and their derivatives.<sup>1</sup> Most methods involved the enzymatic acylation of alcohols;<sup>2</sup> therefore, a nonenzymatic procedure for the synthesis of optically active alcohol variants has been a challenging issue in synthetic organic chemistry. Although some nonenzymatic methods have been reported in recent years, most of them included the use of chiral acylating agents.<sup>3</sup> Very recently, some papers which are based on the catalytic asymmetric acylation of alcohols with achiral acylating agents have emerged in succession.<sup>4</sup> We have also reported that asymmetric acylation of racemic secondary alcohols<sup>5</sup> and of *meso*-1,2-diols<sup>6</sup> could be achieved when they were treated with achiral benzoyl halide in the presence of a chiral diamine derived from (*S*)-proline. Furthermore, we have demonstrated a catalytic asymmetric acylation of *meso*-1,2-diols with benzoyl chloride in the presence of a catalytic amount (0.5 mol%) of the chiral diamine combined with triethylamine.<sup>7</sup> Given that chiral diamines derived from (*S*)-proline are remarkably effective catalysts for the enantioselective asymmetric acylation of *meso*-1,2-diols, we considered whether similar systems could be extended to asymmetric acylation of racemic secondary alcohols.

Here, we describe a conceptually distinct approach which employs a catalytic amount of a chiral diamine derived from (*S*)-proline in combination with a stoichiometric amount of achiral triethylamine.

First, we undertook to examine the reaction of racemic *trans*-2-phenylcyclohexanol (**1a**) as a model substrate, with benzoyl chloride (0.75 equiv.) in the presence of a catalytic amount (5 mol%) of a chiral 1,2-diamine **2**<sup>8</sup> having benzylmethylamino skeleton, which is the most effective for asymmetric acylation of *meso*-1,2-diols, combined with triethylamine (0.5 equiv.) at  $-78^{\circ}\text{C}$  in dichloromethane. After 3 h the usual work-up of the reaction mixture gave the corresponding benzoate, *trans*-1-benzoyloxy-2-phenylcyclohexane (**4a**) in 48% yield with 97% ee and unreacted alcohol, *trans*-2-phenylcyclohexanol (**5a**) in 49%

**Table 1.** Catalytic asymmetric acylation of racemic *trans*-2-phenylcyclohexanol<sup>a</sup>

| 5 <sup>e</sup> | <b>3</b> (0.3)        | 12                     | 97                  | 78                     | 14                  | 75                    |

<sup>a</sup>Molar ratio of **1a** : BzCl : Et<sub>3</sub>N = 1 : 0.75 : 0.5. <sup>b</sup>Isolated yield of purified products. <sup>c</sup>Determined by chiral HPLC analysis (CHIRALPAK AD or CHIRACEL OD). <sup>d</sup>Calculated from the conversion (isolated yield) and ee of the acylated product: C. -S. Chen, Y. Fujimoto, G. Girdaukas, and C. J. Sih, *J. Am. Chem. Soc.*, **104**, 7294 (1982). <sup>e</sup>BzBr was used in place of BzCl.

yield with 97% ee (Table 1, Entry 1). We were encouraged by this excellent result. However, when the amount of the chiral diamine **2** was decreased to 1 mol%, the acylation proceeded slowly to give the benzoate **4a** in low yield (Entry 2). On the other hand, treatment of **1a** with 5 mol% of a chiral diamine **3**<sup>8,9</sup> having dihydroisindoline skeleton also showed satisfactory result (Entry 3). Surprisingly, the use of only 0.3 mol% of **3** smoothly gave **4a** with excellent enantioselectivity (Entry 4). When benzoyl bromide was used as an acylating agent in place of benzoyl chloride, **4a** was obtained in only 12% yield (Entry 5). We have tentatively chosen the reaction conditions of Entry 4 as optimal reaction conditions.

The reaction was conducted with various racemic secondary alcohols under the optimal reaction conditions; the results are summarized in Table 2<sup>10</sup> and can be seen to be uniformly good to excellent in terms of both isolated yield and enantiomeric excess. The acylation of cyclic alcohols (Entries 1, 2, and 3), hydroxyesters (Entries 4 and 5), and bromohydrins<sup>11</sup> (Entries 6 and 7), successfully proceeded and the corresponding benzoates (**4a–g**)

Lijewski, *Tetrahedron Lett.*, **31**, 7415 (1990).

and the unreacted alcohols (**5a–g**) were obtained in good to excellent optical yields, respectively. And the acyclic alcohols (**1h–j**) were acylated in moderate enantioselectivities (Entries 8, 9, and 10).

In summary, the present nonenzymatic asymmetric acylation of

racemic secondary alcohols has the following synthetic advantages: 1) good to excellent enantioselectivities, 2) high efficiency (0.3 mol% of chiral diamine), and 3) experimental convenience. Further investigations to broaden the scope and synthetic applications of this asymmetric acylation are under way in our laboratory.

T. S. thanks the Sasakawa Scientific Research Grant from The Japan Science Society for generous financial support. The authors thank Dr. Ken-ichi Fujita of National Institute of Materials and Chemical Research for generously sharing his chiral HPLC equipment.

- 10 A typical experiment proceeded as follows: To molecular sieves **4A** (400 mg) was added a solution of (*S*)-1-methyl-2-[(dihydroisoindol-2-yl)methyl]pyrrolidine (**3**) (2.2 mg, 0.0102 mmol) in dichloromethane (5 ml), a solution of triethylamine (179.5 mg, 1.774 mmol) in dichloromethane (5 ml), and a solution of racemic *trans*-2-phenylcyclohexanol (**1a**) (598.2 mg, 3.394 mmol) in dichloromethane (5 ml) sequentially at room temperature and a solution of benzoyl chloride (350.2 mg, 2.491 mmol) in dichloromethane (5 ml) at  $-78^\circ\text{C}$  under argon atmosphere. After stirring for 3 h at  $-78^\circ\text{C}$  the reaction mixture was quenched with a phosphate buffer (pH 7) and the organic material was extracted with dichloromethane. The combined extracts were washed with brine, dried over anhydrous sodium sulfate, and concentrated *in vacuo*. The crude product was purified by column chromatography on silica gel to yield 470.7 mg of *trans*-1-benzoyloxy-2-phenylcyclohexane (**4a**) (49%, 96% ee,  $[\alpha]_D^{25} +122.5^\circ$  (c 1.0, CHCl<sub>3</sub>)) and 288.4 mg of *trans*-2-phenylcyclohexanol (**5a**) (48%, 95% ee,  $[\alpha]_D^{25} -53.8^\circ$  (c 1.0, MeOH)).
- 11 *i*-Pr<sub>2</sub>NEt was used instead of Et<sub>3</sub>N. In the case of the reactions performed in the presence of Et<sub>3</sub>N, unreacted halohydrins were obtained in the lower optical yields. **1f** gave **4f** in 46% with 97% ee and **5f** in 45% with 85% ee, and **1g** gave **4g** in 45% with 97% ee and **5g** in 39% with 84% ee.
