(Received June 23, 2003; CL-030562)

Vanadium oxide supported on SBA-15 exhibits superior catalytic performances for the partial oxidation of methane to formaldehyde. A space-time yield of formaldehyde as high as  $93 \text{ mol kg}_{\text{cat}}^{-1} \text{ h}^{-1}$  has been obtained with a formaldehyde selectivity of 94% over 3 wt %  $\text{VO}_x/\text{SBA-15}$  catalyst, significantly higher than those reported so far.

Partial oxidation of methane directly into useful oxygenates such as methanol and formaldehyde remains as one of the biggest challenges in chemistry. A large variety of solid catalysts have been reported for the partial oxidation of  $\text{CH}_4$  to  $\text{HCHO}$  with  $\text{O}_2$  under atmospheric pressure, but the reproducible  $\text{HCHO}$  yield is lower than 4%.<sup>1-5</sup> High  $\text{HCHO}$  space-time yield (STY) combined with high  $\text{HCHO}$  selectivity should be a key criterion for assessing a catalyst. So far, relatively high  $\text{HCHO}$  STY values have been reported over a few catalysts, e.g., ca. 40 and  $27 \text{ mol kg}_{\text{cat}}^{-1} \text{ h}^{-1}$  over Fe-Nb-B oxides and silica-supported vanadium oxide, respectively.<sup>6,7</sup> Recently, it has been shown that  $\text{HCHO}$  STY up to  $75 \text{ mol kg}_{\text{cat}}^{-1} \text{ h}^{-1}$  can be obtained over the vanadium oxide supported on MCM-41, a mesoporous silica with high surface area.<sup>8</sup> However,  $\text{HCHO}$  selectivity was lower than 30% over this catalyst under the conditions used for obtaining high STY values. As compared with MCM-41, SBA-15 possesses larger pores, thicker walls and higher thermal stability and may be a more appropriate support for the selective oxidation reactions occurring at high temperatures since the larger porous channels would be beneficial to the rapid desorption of a partial oxidation product. In this communication, for the first time, we report the excellent catalytic performances especially the high  $\text{HCHO}$  STY and selectivity of the SBA-15-supported vanadium oxide for the partial oxidation of  $\text{CH}_4$  with  $\text{O}_2$ .

SBA-15 was synthesized in a similar manner as reported previously.<sup>9</sup> Typically, a homogeneous mixture containing Pluronic P123 triblock copolymers ( $\text{EO}_{20}\text{PO}_{70}\text{EO}_{20}$ ) as a template and tetraethyl orthosilicate (TEOS) in hydrochloric acid was stirred at  $35^\circ\text{C}$  for 24 h and further treated at  $97^\circ\text{C}$  for 24 h to obtain as-synthesized SBA-15. The as-synthesized SBA-15 was collected by filtration followed by repeated washing with deionized water, drying in vacuum at  $40^\circ\text{C}$  and calcination at  $650^\circ\text{C}$  for 6 h. Vanadium oxide ( $\text{VO}_x$ ) was introduced into SBA-15 by an impregnation method. SBA-15 was immersed into an aqueous solution of  $\text{NH}_4\text{VO}_3$ , followed by drying and calcination at  $650^\circ\text{C}$ . Thus prepared  $\text{VO}_x/\text{SBA-15}$  was characterized by X-ray diffraction and  $\text{N}_2$ -adsorption at 77 K to identify the mesoporous regularity. For comparison,  $\text{VO}_x/\text{MCM-41}$  and  $\text{VO}_x/\text{Cab-O-Sil}$  were also prepared by the same impregnation method. The partial oxidation of  $\text{CH}_4$  was performed on a fixed-bed flow reactor operated at atmospheric pressure. The

products were analyzed by on-line gas chromatography.

Table 1 shows the BET surface area, pore volume and pore diameter obtained from  $\text{N}_2$ -adsorption measurements. BET surface area and pore volume both showed a decrease after introducing 1 wt %  $\text{VO}_x$  (calculated based on the amount of  $\text{V}_2\text{O}_5$ ) into SBA-15, and then kept almost unchanged with increasing  $\text{VO}_x$  content up to 3 wt %. Further increase in vanadium content significantly decreased the surface area and pore volume. The pore diameter was kept at 5.4 nm for the samples with  $\text{VO}_x$  content lower than 3 wt % and decreased slightly to 5.3 nm for the samples with  $\text{VO}_x$  content of 5 and 10 wt %.

SBA-15 showed three X-ray diffraction peaks at  $2\theta$  of ca.  $1.0^\circ$ ,  $1.6^\circ$  and  $1.9^\circ$  assigned to its hexagonal mesoporous regularity. As shown in Figure 1, the three XRD peaks were also observed after the introduction of  $\text{VO}_x$  into SBA-15 and the intensities of the peaks were not significantly decreased, indicating

**Table 1.** Physical properties of the supported vanadium oxide catalysts

Catalyst	Surface area $/\text{m}^2\text{g}^{-1}$	Pore vol. $/\text{cm}^3\text{g}^{-1}$	Pore dia. $/\text{nm}$
SBA-15	645	0.80	5.4
1% $\text{VO}_x/\text{SBA-15}$	545	0.68	5.4
2% $\text{VO}_x/\text{SBA-15}$	549	0.69	5.4
3% $\text{VO}_x/\text{SBA-15}$	560	0.72	5.4
5% $\text{VO}_x/\text{SBA-15}$	418	0.63	5.3
10% $\text{VO}_x/\text{SBA-15}$	321	0.57	5.3
3% $\text{VO}_x/\text{MCM-41}$	871	0.89	2.3
3% $\text{VO}_x/\text{Cab-O-Sil}$	166	—	—

**Figure 1.** XRD patterns of (a) SBA-15, (b) 2 wt %  $\text{VO}_x/\text{SBA-15}$ , (c) 3 wt %  $\text{VO}_x/\text{SBA-15}$ .

the sustaining of the hexagonal regularity at long range. These XRD peaks were still observable even when  $\text{VO}_x$  content increased to 10 wt % (not shown). It should be noted that no diffraction peaks of crystalline  $\text{V}_2\text{O}_5$  were observed at high diffraction angles for the SBA-15-supported  $\text{VO}_x$  samples with  $\text{VO}_x$  content up to 10 wt %, suggesting that  $\text{VO}_x$  species are highly dispersed on the wall surface of SBA-15 or form small vanadium oxide clusters in the mesoporous channels which are hard to be detected by XRD.

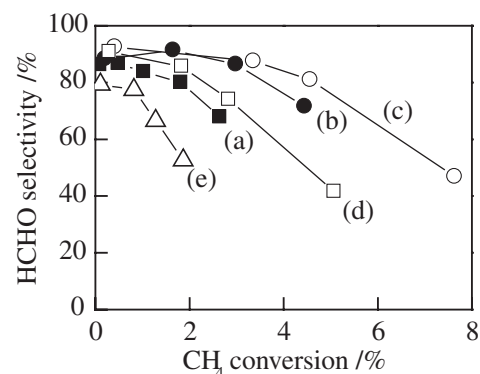

Table 2 shows the catalytic performances of the supported  $\text{VO}_x$  samples for partial oxidation of  $\text{CH}_4$  with  $\text{O}_2$  at  $625^\circ\text{C}$ . SBA-15 alone showed very low  $\text{CH}_4$  conversion although HCHO selectivity was 100%.  $\text{CH}_4$  conversion increased remarkably with introducing  $\text{VO}_x$  into SBA-15 and reached a maximum at  $\text{VO}_x$  content of 3 wt %. The introduction of  $\text{VO}_x$  to SBA-15 formed CO in addition to HCHO. However, the selectivity to HCHO kept at  $>80\%$  and only changed slightly with an increase in  $\text{VO}_x$  content from 1 to 3 wt % while  $\text{CH}_4$  conversion rose from 1.0 to 4.6% at the same time. Further increase in  $\text{VO}_x$  content decreased both  $\text{CH}_4$  conversion and HCHO selectivity significantly.

It is known that HCHO selectivity generally decreases with an increase in  $\text{CH}_4$  conversion because of the consecutive oxidation of HCHO. HCHO selectivity versus  $\text{CH}_4$  conversion obtained over the  $\text{VO}_x/\text{SBA-15}$  with different  $\text{VO}_x$  content was thus compared in Figure 2. This figure clearly shows that the 3 wt %  $\text{VO}_x/\text{SBA-15}$  is the best one for the partial oxidation of  $\text{CH}_4$  to HCHO. Probably, the concentration of the monomeric vanadyl species responsible for the selective oxidation of  $\text{CH}_4$  is the highest over this catalyst. The highest HCHO STY value obtained at  $625^\circ\text{C}$  over this catalyst was  $93 \text{ mol kg}_{\text{cat}}^{-1} \text{ h}^{-1}$  with HCHO selectivity of 94% (Table 2). This STY value is significantly higher than those reported in literatures, and more importantly, much higher HCHO selectivity was obtained simultaneously.<sup>1-8</sup> HCHO selectivity of 94%

**Figure 2.** HCHO selectivity versus  $\text{CH}_4$  conversion over the  $\text{VO}_x/\text{SBA-15}$  with different  $\text{VO}_x$  content. (a) 1 wt %, (b) 2 wt %, (c) 3 wt %, (d) 5 wt %, (e) 10 wt %.

could also be sustained at a single-pass HCHO yield of 3.4%. To our knowledge, this is the highest HCHO selectivity combined with a reasonably high single-pass HCHO yield.

It has recently been reported that the  $\text{VO}_x/\text{SBA-15}$  catalyzes the oxidative dehydrogenation of  $\text{C}_3\text{H}_8$  and photo-assisted oxidation of  $\text{CH}_4$  at low temperatures more efficiently than  $\text{VO}_x/\text{MCM-41}$  and  $\text{VO}_x/\text{SiO}_2$ , respectively.<sup>10,11</sup> Our results suggest that SBA-15 is also a better catalyst support for the partial oxidation of  $\text{CH}_4$ .  $\text{CH}_4$  conversion and HCHO selectivity obtained over  $\text{VO}_x/\text{SBA-15}$  were both higher than those over  $\text{VO}_x/\text{Cab-O-Sil}$  and  $\text{VO}_x/\text{MCM-41}$ . Further investigations on the advantages of SBA-15 as catalyst support for selective oxidations are underway.
