Mn–porphyrin supported on active carbon, which was activated by heat-treatment in Ar, electrochemically catalyzed reduction of O_2 to H_2O_2 by the H_2/O_2 fuel cell method. The electrocatalytic activities were strongly dependent on the heat-treatment temperatures. The maximum H_2O_2 concentration of 3.5 wt % with 47% current efficiency was obtained for the catalyst treated at 450 °C, and a TON (Mn) for the H_2O_2 formation was over $1000\,h^{-1}$.

Hydrogen peroxide is expected a major oxidant for Green Sustainable Chemistry. Price of H₂O₂ is expensive to use for chemical process. Most of all H₂O₂ is manufactured by the anthraquinone process through multisteps operation with a large amount of energy consumption.1 Therefore, it has been desired for development of new direct catalytic synthesis method of H₂O₂. It is well known that Pd² and Au-Pd^{3,4} catalyze H₂O₂ formation from H2 and O2 in acid solutions. We have recently reported the effective H₂/O₂ fuel cell method for H₂O₂ synthesis.5-7 Reduction of O2 to H2O2 at the three-phase boundary (gaseous O2, aqueous electrolyte, and solid cathode) is the character of the fuel cell method. O2 gas is directly supplied to the active site at the three-phase boundary. Therefore, the reduction of O₂ to H₂O₂ is accelerated to compare with the successive reduction of H₂O₂. We have performed the efficient production of H₂O₂ of 7 wt % with a 94% current efficiency by using the [VGCF + XC72 + PTFE]⁸ cathode and NaOH electrolyte $(2 \text{ mol } L^{-1})$. When we chose acid electrolyte $(0.5 \text{ mol } L^{-1})$ H_2SO_4) and the [AC + VGCF + PTFE]⁸ cathode, the maximum concentration of H₂O₂ was 1.1 wt %.6 The successive reduction of H₂O₂ to H₂O was competitive to the reduction of O2 to H2O2, and the two rates were balanced at 1.1 wt % over the cathode. We have to find and develop a new electrocatalyst and cathode for accumulation of $H_2O_2 > 1.1$ wt % in acid electrolyte.

Electrocatalysts prepared from Fe– and Co–porphyrin or phthalocyanine on carbon by heat treatment in inert gas have been expected as nonprecious metal electrocatalyst for four-electron reduction of O_2 to H_2O for PEMFC. Our idea was that uneffective metal–porphyrin derivatives would be candidate for the H_2O_2 formation by our fuel cell method.

Electrocatalysts were prepared from metal–porphyrin¹⁰ CH_2Cl_2 solutions and AC by a conventional impregnation method, stirring the mixture for 6h and dried at 50 °C. This metal–porphyrin/AC powder was activated by heat treatment at T=200-800 °C in Ar stream for 2h, omitted as M–Por/AC (T °C). The cathode and anode (electrode areas = 1.34 cm²) prepared by the hot press-method¹¹ were attached the two compartment cell reactor. A yield of H_2O_2 was determined by the KMnO₄ titration or the Ce^{4+} titration method. A current

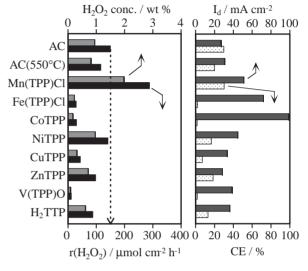

Figure 1. Electrocatalytic activities of metal–porphyrins supported on AC for the H_2O_2 formation by the H_2/O_2 fuel cell method at 25 °C.

efficiency (CE) for H_2O_2 formation was calculated as $2e^-$ reduction, which was corresponding to a H_2O_2 selectivity based on H_2 .

Figure 1 shows electrocatalytic activities of various M–Por/AC (550 °C) for the $\rm H_2O_2$ formation at 25 °C. All metal–porphyrins loadings were 0.5 wt % based on metal. As mentioned above, AC functioned as electrocatalyst for the $\rm H_2O_2$ synthesis in acid electrolyte. As you can see clearly, the formation rate of $\rm H_2O_2$ over the Mn(TPP)Cl/AC (550 °C) was twice higher than that over the AC. A concentration of $\rm H_2O_2$ was 2.0 wt % at 2 h with 30% CE. Fe(TPP)Cl/AC (550 °C) and Co(TPP)Cl/AC (550 °C) were active for the reduction of $\rm O_2$ but not for the $\rm H_2O_2$ formation which was corresponding to the previous reports. Other metal–porphyrin did not show significant electrocatalysis for the reduction of $\rm O_2$. The activated Mn(TPP)Cl/AC (550 °C) shows particular electrocatalysis for the $\rm H_2O_2$ formation.

Various Mn compound $^{10}/AC$ (550 °C, 0.5 wt % Mn loading) electrocatalysts were examined for the $\rm H_2O_2$ synthesis. The Mn loadings on the cathodes were 2.0 μ mol cm $^{-2}$. Order of electrocatalytic activities was Mn(OEP)Cl (356 μ mol cm $^{-2}$ h $^{-1}$) > Mn(TPP)Cl (290) > Mn(TPPS)Cl (265) > Mn(TMPyP)Cl (180) > AC (116) > Mn(salen) (110), Mn(Pc)Cl (99), Mn(acac)_3 (87). N_4-ligand, porphyrin ring was effective for the H_2O_2 synthesis, but phthalocyanine ring was not. Mn(OEP)Cl/AC was the most active electrocatalyst (178 TON h $^{-1}$) for the H_2O_2 synthesis in H_2SO_4 electrolyte (0.5 mol L $^{-1}$) among the Mn compounds though the CE of 35% was not enough.

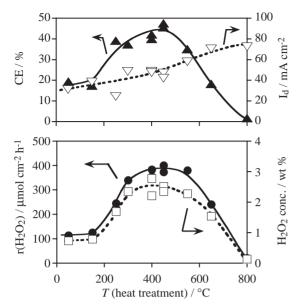

Figure 2. Effects of heat-treatment temperature of Mn(OEP)Cl/AC on the H_2O_2 formation by the H_2/O_2 fuel cell method at 25 °C.

Figure 2 shows effect of the heat-treatment temperatures for Mn(OEP)Cl/AC on the H₂O₂ formation at 25 °C. The formation rates of H₂O₂ over the Mn(OEP)Cl/AC electrocatalyst treated below 150 °C were as low as that over the AC. We could not observe the heat-treatment effect blow 150 °C. The formation rate of H₂O₂ remarkably increased with increasing heat-treatment temperature above 200 °C. The maximum formation rate of H_2O_2 (400 µmol cm⁻² h⁻¹) was obtained by the heat-treatment at 450 °C, and a H₂O₂ concentration was 2.3% in 2 h. The CE of H₂O₂ showed a similar dependence of the formation rate. The maximum CE was 47% at the heat-treatment temperature of 450 °C. When the heat-treatment temperatures increase over 550 °C, the formation rate of H₂O₂ remarkably decreased, $20 \,\mu\text{mol cm}^{-2}\,\text{h}^{-1}$ at $800\,^{\circ}\text{C}$, but the current densities increased. In other words, the O₂ reduction paths to H₂O₂ (2e⁻ reduction) and H₂O (4e⁻ reduction) were drastically changed with the heat-treatment temperatures. This significant influence of the heat treatment is very interesting.

Effects of the Mn(OEP)Cl loading over AC were studied on the H₂O₂ formation. The formation rate of H₂O₂ increased with the Mn(OEP)Cl loading and the maximum formation rate of $450\,\mu mol\,cm^{-2}\,h^{-1}$ was obtained at 0.3 wt % loading based on Mn which turnover number was over 850 in 1 h. The CE of H₂O₂ jumped from 23% (AC) to 45-50% at 0.1-0.6 wt % Mn(OEP)Cl loadings. Excess loadings above 0.6 wt % decrease the formation rate and the CE. When the reaction time was expanded for the H_2O_2 formation over 0.3 wt % Mn–OEP–Cl/AC (450 °C), the H₂O₂ concentration gradually increased from 2.5 wt % at 2 h to an upper limit of 3.5 wt % after 4 h. The total H₂O₂ yield linearly increased with a constant current density of 45 mA cm⁻² after 4h. An apparent upper limit of the H₂O₂ concentration was due to an increase of catholyte volume during the reduction of O₂.⁷ Therefore, we can perform steady production of 3.5 wt % H₂O₂ solutions.

The most important point is active site structure of heattreated Mn(OEP)Cl/AC and what reactions occur during the heat-treatment. We attempted characterizations of the heat-treated Mn(OEP)Cl/AC by XAFS, FT-IR, and CV, but these data are not clear. We have to do more detailed and careful characterization studies to clarify active site structure. However, we observed very interesting spectra of temperature-programmed desorption (TPD) over the Mn(OEP)Cl/AC with 10 °C min⁻¹ from 150 to 800 °C. Desorpiton products directly monitored by an on-line mass spectrometer (Anelva MS-GA200-DM) were CO(m/e = 28), $CO_2(44)$, $CH_4(16)$, $H_2(2)$, HCl(36), and Cl(35). Differences in TPD spectra of CO, CO₂, CH₄, and H₂ were not observed for Mn(OEP)Cl/AC and AC. This result suggests that CO, CO₂, CH₄, and H₂ were produced by decomposition of functional groups on the AC surface. On the other hand, HCl and Cl were observed for the Mn(OEP)Cl/AC from 250 °C, to the maximum at 350 °C, and stopped at 550 °C. They were not observed for AC. This dependence of HCl and Cl desorption on temperature (TPD) is very similar to that of the formation rate of H₂O₂ in Figure 2. This result suggests that desorption of Cl from Mn(OEP)Cl/AC is essential process for generation of the active site forming H₂O₂. It is able to speculate that Mn(OEP) species with no Cl axial ligand would strongly interact with the AC surface and that an open site generates on Mn(OEP)/AC. At higher heat-treatment temperatures over 600 °C, porphyrin ring structure of Mn(OEP)/AC would decompose, 9 and electrocatalysis of Mn site changed from the 2e⁻ reduction to 4e⁻ reduction. As mentioned above, detailed structure of Mn site has not been clarified yet.

The Mn(OEP)/AC(450) cathode can reuse for the H_2O_2 synthesis several times. The formation rate and the CE of H_2O_2 gradually increased with reuse numbers. The maximum TON(Mn) for the H_2O_2 formation was over 1000 in 1 h at 25 °C.
