

INDUCED SUBDIVISIONS IN $K_{s,s}$ -FREE GRAPHS OF LARGE
AVERAGE DEGREE

DANIELA KÜHN, DERYK OSTHUS

Received December 20, 2000

We prove that for every graph H and for every s there exists $d=d(H,s)$ such that every graph of average degree at least d contains either a $K_{s,s}$ as a subgraph or an induced subdivision of H .

1. Introduction

A classical theorem of Mader states that for every graph H there exists $d=d(H)$ such that every graph G of average degree at least d contains a subdivision of H . Obviously, the result becomes false if we ask for an *induced* subdivision of H . Here we prove that this stronger assertion holds if G is ‘locally sparse’ in the sense that it fails to contain some complete bipartite graph $K_{s,s}$:

Theorem 1. *For every graph H and every $s \in \mathbb{N}$ there exists $d=d(H,s)$ such that every graph G of average degree at least d contains either a $K_{s,s}$ as a subgraph or an induced subdivision of H .*

Of course, one cannot replace ‘subdivision’ by ‘subgraph’, as for example there exist graphs which have both arbitrarily large average degree and arbitrarily large girth. On the other hand, Kierstead and Penrice [10] proved that if H is a tree then one can indeed find it as an induced subgraph in any $K_{s,s}$ -free graph of sufficiently large average degree. They used this result to prove a special case of the conjecture of Gyárfás [7] and Sumner [17] that

Mathematics Subject Classification (2000): 05C35, 05D40

given a tree T and $s \in \mathbb{N}$, every K_s -free graph of sufficiently large chromatic number contains an induced copy of T . Scott [16] proved that this conjecture becomes true if we only require an induced subdivision of T . In [16] he also proposed a conjecture which is analogous to [Theorem 1](#) – replacing ‘average degree’ by ‘chromatic number’ and $K_{s,s}$ by K_s . In fact, [Theorem 1](#) was motivated by this conjecture. A simple proof of [Theorem 1](#) for the case when H is a cycle can be found in [12]. Elsewhere we also obtained related results about $K_{s,s}$ -free graphs of large average degree: we proved that such graphs contain rather large cliques as (not necessarily induced) subdivisions [13] and minors [14].

We now briefly outline the organization of this paper and the strategy of our proof of [Theorem 1](#). Consider a $K_{s,s}$ -free graph G of large average degree. In [Section 2](#) we prepare the ground for the proof by collecting some tools which we will need later on. In particular, it turns out that in order to find an induced subdivision of H in G , it suffices to prove the following

Theorem 2. *For all $k, s \in \mathbb{N}$ there exists $d = d(s, k)$ such that every $K_{s,s}$ -free graph G of average degree at least d contains an induced subdivision of some graph H^* where the average degree of H^* is at least k and every edge of H^* is subdivided exactly once.*

We will call such a subdivision an induced *1-subdivision* of H^* . Note that both the set B of branch vertices and the set S of subdividing vertices have to be independent in G . The first step towards finding such a 1-subdivision of H^* is to find a large independent set I in G ([Section 3](#)). Ideally, we would like to find another independent set B^* such that the bipartite subgraph between I and B^* has large average degree. In this case, one can find B in the smaller of B^* and I and S in the larger of the two. Unfortunately, we cannot guarantee that such a set B^* always exists. However, in [Section 4](#) we will show that one can come fairly close: we will find sets $I^* \subseteq I$ and B^* such that the bipartite subgraph between I^* and B^* has large average degree and $G[B^*]$ has small chromatic number. In [Section 5](#), which constitutes the core of our proof, we then show how to find our induced 1-subdivision of H^* within $G[I^* \cup B^*]$. In [Section 6](#) we then put everything together to complete the proof of [Theorem 2](#) (and thus of [Theorem 1](#)). In the final section we mention some open problems.

[Theorem 2](#) also implies induced analogues of a result of Thomassen on subdivisions and of a result of Häggkvist and Scott on cycles in graphs: Thomassen [18] proved that for every $k, \ell \in \mathbb{N}$ there exists $f = f(k, \ell)$ such that every graph of minimum degree at least f contains a subdivision of some graph H with minimum degree at least k in which every edge is subdivided

exactly ℓ times. Combined with [Theorem 2](#) this gives the following analogue for odd integers ℓ :

Corollary 3. *For all $k, s \in \mathbb{N}$ and every odd integer ℓ there exists $g = g(k, \ell, s)$ such that every $K_{s,s}$ -free graph of minimum degree at least g contains an induced subdivision of some graph H with minimum degree at least k in which every edge is subdivided exactly ℓ times.*

Häggkvist and Scott [8] proved that every graph of minimum degree at least $300k^2$ contains k cycles of consecutive even lengths. (Verstraëte [19] improved the bound on the minimum degree to a linear one.) Applying this result to the graph H^* provided by [Theorem 2](#) we obtain k induced cycles in G which are twice as long. In particular, we have

Corollary 4. *For all $k, s \in \mathbb{N}$ there exists $g = g(k, s)$ such that every $K_{s,s}$ -free graph of minimum degree at least g contains k induced cycles whose lengths form an arithmetic progression.*

2. Notation and tools

In this paper, all logarithms are base two. We write $e(G)$ for the number of edges of a graph G , $d(G) := 2e(G)/|V(G)|$ for its *average degree*, $\delta(G)$ for its minimum degree and $\chi(G)$ for its chromatic number. Given a vertex x of G , we denote by $d(x)$ or $d_G(x)$ the degree of x and by $N(x)$ or $N_G(x)$ the set of neighbours of x . Given graphs G and H we say that G is *H -free* if G does not contain H as a subgraph. A *subdivision* of a graph H is a graph G obtained from H by replacing the edges of H with internally disjoint paths between their endvertices. We view $V(H)$ as a subset of $V(G)$ and call these vertices the *branch vertices* of G . A *1-subdivision* of a graph H is the graph obtained from H by replacing the edges of H with internally disjoint paths of length two.

For disjoint sets $A, B \subseteq V(G)$ we write $e(A, B)$ for the number of A – B edges in G and $(A, B)_G$ for the bipartite subgraph of G whose vertex classes are A, B and whose edges are the A – B edges in G . If we say that a bipartite graph (A', B') is a subgraph of (A, B) then we tacitly assume that $A' \subseteq A$ and $B' \subseteq B$. We shall frequently consider the following class of graphs.

Definition. Given non-negative numbers d, i and $k \leq d/4$, we say that a bipartite graph (A, B) is a (d, i, k) -graph if $|A| \geq d^{12i}|B|$ and $d/4 - k \leq d(a) \leq 4d$ for all vertices $a \in A$. (Note that the order of A and B matters here.)

We now list some results which we need later on in the proof of [Theorem 1](#). The following theorem of Mader (for a proof see e.g. [6, Thm. 3.6.1]) implies that [Theorem 1](#) is a consequence of [Theorem 2](#). Indeed, from [Theorem 5](#) it follows that the graph H^* provided by [Theorem 2](#) contains a subdivision of H ; and it is easily checked that the corresponding subdivision of H in G is induced.

Theorem 5. *For every $r \in \mathbb{N}$ there exists $d = d(r)$ such that every graph of average degree at least d contains a subdivision of K_r .*

Bollobás and Thomason [5] as well as Komlós and Szemerédi [11] independently showed that the order of magnitude of $d(r)$ is r^2 .

We shall frequently use the following simple observations. Proofs are for example included in [6, Prop. 1.2.2 resp. Cor. 5.2.3].

Proposition 6. *Every graph G contains an induced subgraph of average degree at least $d(G)$ and minimum degree at least $d(G)/2$.*

Proposition 7. *Every graph G contains an induced subgraph of minimum degree at least $\chi(G) - 1$.*

Clearly, it suffices to prove [Theorem 2](#) for graphs G which do not have subgraphs of average degree $> d(G)$. So the propositions enable us to assume that $\delta(G) \geq d(G)/2$ and $\chi(G) \leq d(G) + 1$.

We shall also use the following well known upper bound for the average degree of $K_{s,s}$ -free graphs (see e.g. [4, p. 74]).

Theorem 8. *The average degree of every $K_{s,s}$ -free graph G is at most $c_s |G|^{1-1/s}$ where c_s is some constant depending on s .*

The next lemma is a special case of Chernoff's inequality (see e.g. [3, Thm. A.1.12 and A.1.13]).

Lemma 9. *Let X_1, \dots, X_n be independent 0-1 random variables with $\mathbb{P}(X_i = 1) = p$ for all $i \leq n$, and let $X := \sum_{i=1}^n X_i$. Then $\mathbb{P}(X \geq 2\mathbb{E}X) \leq (4/e)^{-\mathbb{E}X}$ and $\mathbb{P}(X \leq \mathbb{E}X/2) \leq e^{-\mathbb{E}X/8}$.*

One case which arises in our proof of [Theorem 2](#) is that we first find an induced bipartite subgraph (A, B) of large average degree in G and then find an induced subdivision of H in (A, B) . To carry out this second step, it will turn out to be useful if the vertices in A have almost the same degree and $|B|$ is much smaller than $|A|$. The following lemma shows that by replacing (A, B) with an induced subgraph we can always satisfy these two additional conditions. The lemma is a slight extension of [15, Lemma 2.4]. Although the proof is almost the same, we include it here for completeness.

Lemma 10. *Let $r \geq 2^6$, $s \geq 1$ and $d \geq 8r^{12s+1}$. Then every bipartite graph of average degree d contains an induced copy of an $(r, s, 0)$ -graph.*

Proof. Clearly, we may assume that our given bipartite graph has no subgraph of average degree $> d$. So by [Proposition 6](#) this graph contains an induced subgraph $G = (A, B)$ such that $\delta(G) \geq d/2$, $d(G) = d$ and $|A| \geq |B|$. Thus at least half of the vertices of A have degree at most $2d$ in G . So, writing A' for the set of all vertices in A of degree at most $2d$, we have $|A'| \geq |A|/2 \geq |B|/2$.

Let us now consider a random subset B_p of B which is obtained by including each vertex of B independently with probability $p := r/d$. For every $a \in A'$ let $X_a := |N_G(a) \cap B_p|$. Then $r/2 \leq \mathbb{E}X_a \leq 2r$. Given B_p , let us call $a \in A'$ *useful* if $r/4 \leq X_a \leq 4r$. [Lemma 9](#) implies that

$$\mathbb{P}(a \text{ is not useful}) \leq \mathbb{P}(X_a \geq 2\mathbb{E}X_a) + \mathbb{P}(X_a \leq \mathbb{E}X_a/2) \leq (4/e)^{-r/2} + e^{-r/16} \leq \frac{1}{4}.$$

Hence the expected number of vertices in A' which are not useful is at most $|A'|/4$. So Markov's inequality (which states that $\mathbb{P}(X \geq c\mathbb{E}X) \leq 1/c$ for every $c \geq 1$) implies that

$$\mathbb{P}(\text{at least half of the vertices in } A' \text{ are not useful}) \leq \frac{1}{2}.$$

Moreover, using [Lemma 9](#) again,

$$\mathbb{P}(|B_p| \geq 2p|B|) = \mathbb{P}(|B_p| \geq 2\mathbb{E}|B_p|) \leq (4/e)^{-p|B|} \leq \frac{1}{4}.$$

So the probability that both $|B_p| \leq 2p|B|$ and that at least half of the vertices in A' are useful is at least $1/2 - 1/4 > 0$. Hence there exists a choice B^* for B_p which has these two properties. Let A^* be the set of useful vertices in A' . Then $r/4 \leq d_{(A^*, B^*)_G}(a) \leq 4r$ for every vertex $a \in A^*$ and

$$|A^*| \geq \frac{|A'|}{2} \geq \frac{|B|}{4} \geq \frac{|B^*|}{8p} = \frac{d|B^*|}{8r} \geq r^{12s}|B^*|.$$

Thus $(A^*, B^*)_G$ is an induced $(r, s, 0)$ -subgraph of G . ■

3. Independent sets

Clearly, every graph G of maximum degree Δ has an independent set of size at least $|G|/\chi(G) \geq |G|/(\Delta + 1)$. [Lemma 11](#) shows that we obtain a small but significant improvement if G is $K_{s,s}$ -free. The proof is based on Alon's

elegant proof of the result that any triangle-free graph H of maximum degree Δ contains an independent set of size $c|H|\log \Delta/\Delta$ (see e.g. [3], the result itself is due to Ajtai, Komlós and Szemerédi [1]).

Alternatively, we could have applied another result from [1]: for all ε there exists a constant c_0 so that every graph with maximum degree at most Δ which contains at most $|G|\Delta^{2-\varepsilon}$ triangles has an independent set of size at least $c_0|G|\log \Delta/\Delta$. But [Theorem 8](#) implies that in a $K_{s,s}$ -free graph G the neighbourhood of any vertex x can span at most $c_s d(x)^{2-1/s} \leq c_s \Delta^{2-1/s}$ edges and thus G contains at most $c_s|G|\Delta^{2-1/s}$ triangles. Although the proof of [Lemma 11](#) given below yields a weaker bound, it is simpler and has the advantage of being self-contained.

Lemma 11. *For every $s \in \mathbb{N}$ there exists $c' = c'(s)$ such that for each $\Delta \geq 9$ every $K_{s,s}$ -free graph G of maximum degree at most Δ has an independent set of size at least*

$$f := c'|G| \frac{(\log \Delta)^{1/s}}{\Delta \log \log \Delta}.$$

Proof. Let $n := |G|$. Let I be an independent set chosen uniformly at random from all independent sets of G . For every vertex $x \in G$ define

$$Z_x := \begin{cases} \Delta & \text{if } x \in I; \\ |N(x) \cap I| & \text{otherwise.} \end{cases}$$

Then

$$\sum_{x \in G} Z_x = \sum_{x \in I} Z_x + \sum_{x \notin I} Z_x \leq \Delta|I| + e(I, V(G) \setminus I) \leq 2\Delta|I|.$$

So it suffices to show that $\mathbb{E}(\sum_{x \in G} Z_x) \geq 2\Delta f$. Given any vertex $x \in G$, let $I_x := I \setminus (N(x) \cup \{x\})$. Rather than directly showing that $\mathbb{E}(\sum_{x \in G} Z_x)$ is large, we will show that $\mathbb{E}(Z_x | I_x)$ is large for every vertex x and every I_x .

Let N_x be the set of all neighbours of x which are not adjacent to a vertex in I_x . We will now show that if N_x is large then the average size of an independent subset of N_x is large as well. So suppose first that $|N_x| \geq 2$. Since $G[N_x]$ is $K_{s,s}$ -free, it follows from [Theorem 8](#) that every subgraph H of $G[N_x]$ has average degree at most $c_s|H|^{1-1/s} \leq c_s|N_x|^{1-1/s}$. Thus by [Proposition 7](#) we have that $\chi(G[N_x]) \leq c_s|N_x|^{1-1/s} + 1 \leq 2c_s|N_x|^{1-1/s}$. So $G[N_x]$ has an independent set of size at least $|N_x|^{1/s}/(2c_s) =: \alpha$. Hence $G[N_x]$ contains at least $2^\alpha/2$ independent sets of size at least $\alpha/2$. Put $\beta := \alpha/(4 \log |N_x|)$. Then the number of independent subsets of N_x of size at most β is at most

$$\binom{|N_x|}{0} + \cdots + \binom{|N_x|}{\lfloor \beta \rfloor} \leq |N_x|^{2\beta} = 2^{2\beta \log |N_x|} = 2^{\alpha/2}.$$

If $|N_x| \geq (4c_s)^s$ then $2^\alpha/2 \geq 2^{\alpha/2}$ and $\alpha/2 \geq 2\beta$; and so in this case the average size ℓ_x of an independent subset of N_x is at least β .

Now note that, writing k_x for the number of independent sets in N_x , for every $|N_x| \geq 0$ we have

$$\mathbb{E}(Z_x|I_x) \geq \frac{\Delta + k_x \ell_x}{1 + k_x} \geq \frac{\Delta}{2k_x} + \frac{\ell_x}{2}.$$

Thus, if $|N_x| \geq (\log \Delta)/2$ and if c' is sufficiently small compared with s , then

$$\mathbb{E}(Z_x|I_x) \geq \frac{\ell_x}{2} \geq \frac{\beta}{2} \geq \frac{|N_x|^{1/s}}{16c_s \log |N_x|} \geq \frac{2c'(\log \Delta)^{1/s}}{\log \log \Delta},$$

while if $0 \leq |N_x| \leq (\log \Delta)/2$ then

$$\mathbb{E}(Z_x|I_x) \geq \frac{\Delta}{2 \cdot 2^{|N_x|}} \geq \frac{\Delta}{2 \cdot 2^{(\log \Delta)/2}} = \frac{\sqrt{\Delta}}{2} \geq \frac{2c'(\log \Delta)^{1/s}}{\log \log \Delta}.$$

Hence we have $\mathbb{E}(Z_x) \geq 2\Delta f/n$ and so $\mathbb{E}(\sum_{x \in G} Z_x) = \sum_{x \in G} \mathbb{E}(Z_x) \geq 2\Delta f$, which completes the proof. \blacksquare

Corollary 12. *For every $s \in \mathbb{N}$ there exists $d_0 = d_0(s)$ such that every $K_{s,s}$ -free graph G of average degree $d \geq d_0$ contains an independent set of size at least $|G|(\log d)^{1/(s+1)}/d$.*

Proof. Let G' be the subgraph of G induced by the vertices of degree at most $2d$. Clearly, $|G'| \geq |G|/2$. If d is sufficiently large, then by [Lemma 11](#), G' (and thus G) has an independent set of size at least $|G|(\log d)^{1/(s+1)}/d$. \blacksquare

4. Finding a ‘nearly’ induced bipartite subgraph of large average degree

As remarked in the introduction, we would like to find an induced bipartite subgraph of large average degree in our original graph G . The aim of this section is to prove that if G does not contain such a subgraph, we can still come close to it: by [Corollary 12](#) we may assume that G contains a large independent set I . We will use this to find a subgraph (A, B) of large average degree so that $A \subseteq I$ (so A is independent) and B has small chromatic number and is much smaller than A . The following lemma shows how to construct one colour class of B .

Lemma 13. *Let I be an independent set in a graph G such that $d(x) \geq d/2$ for every $x \in I$ and $|I| = 2c|G|/d$ for some $c \geq 2$. Suppose that $\chi(G) \leq 3d$. Then G has one of the following properties.*

- (i) G contains an induced bipartite subgraph of average degree at least $(\log c)/24$.
- (ii) There are a set $I' \subseteq I$ and an independent set J in $G - I$ such that in G every vertex of I' has exactly one neighbour in J , $|J| \leq |I| \log c/c$ and $|I'| \geq |I|/4(\log c)^2$.

Proof. Put $n := |G|$, $\bar{I} := V(G) \setminus I$ and let Y be the set of all vertices in \bar{I} which have at least $c/2$ neighbours in I . Then $e(I, \bar{I} \setminus Y) \leq c|\bar{I} \setminus Y|/2 \leq cn/2$. On the other hand the degree of every vertex in I is at least $d/2$, and so we have that $e(I, \bar{I}) \geq cn$. Thus $e(I, Y) \geq cn/2$. As $\chi(G) \leq 3d$, there exists an independent set $A \subseteq Y$ such that

$$(1) \quad e(I, A) \geq \frac{e(I, Y)}{3d} \geq \frac{cn}{6d} = \frac{|I|}{12}.$$

Note also that

$$(2) \quad \frac{c}{2} \cdot |A| \leq e(I, A).$$

We may assume that the average degree of $(I, A)_G$ is at most $(\log c)/2$ (otherwise $(I, A)_G$ would be as desired in (i)). Since every vertex in A has at least $c/2 \geq (\log c)/2$ neighbours in I , this implies that $|I| \geq |A|$. Therefore

$$\frac{c}{2} \cdot |A| \leq e(I, A) = \frac{1}{2} \cdot d((I, A)_G)(|I| + |A|) \leq \frac{\log c}{2} \cdot |I|,$$

and hence

$$(3) \quad |A| \leq \frac{|I| \log c}{c}.$$

Using a probabilistic argument, we will show that there exist sets $J \subseteq A$ and $I' \subseteq I$ as desired in (ii). To make this work, we first need to replace I with the set $I_1 \subseteq I$ of all vertices which have at least one and at most $\log c$ neighbours in A . So let us first estimate the size of I_1 . Denote by I_2 the set of all vertices in I which have no neighbours in A and put $I_3 := I \setminus (I_1 \cup I_2)$. We will show that we may assume that both $e(I_1, A) \geq e(I, A)/2$ and $|I_1| \geq |I|/\log c$. Suppose to the contrary that $e(I_1, A) \leq e(I, A)/2$. Then $e(I_3, A) \geq e(I, A)/2$ and so (2) implies that $e(I_3, A) \geq c|A|/4$. Thus on average, a vertex in A has at least $c/4$ neighbours in I_3 . As every vertex in I_3 has at least $\log c$ neighbours in A , it follows that $(I_3, A)_G$ is as desired in (i). Hence we may assume that $e(I_1, A) \geq e(I, A)/2$. Next suppose that $|I_1| \leq |I|/\log c$. Then

$$e(I_1, A) \geq e(I, A)/2 \stackrel{(1)}{\geq} |I|/24 \geq |I_1|(\log c)/24$$

and

$$e(I_1, A) \geq e(I, A)/2 \stackrel{(2)}{\geq} c|A|/4.$$

Thus $(I_1, A)_G$ is as desired in (i). Therefore we may also assume that $|I_1| \geq |I|/\log c$.

Let us now consider a random subset A_p of A which is obtained by including each $a \in A$ independently with probability $p := 1/(2\log c)$. Call a vertex $x \in I_1$ *useful* if it has exactly one neighbour in A_p . Using the definition of I_1 it follows that for every $x \in I_1$

$$\begin{aligned} \mathbb{P}(x \text{ is useful}) &= |N(x) \cap A| \cdot p \cdot (1-p)^{|N(x) \cap A|-1} \geq 1 \cdot p \cdot (1-p)^{\lfloor \log c \rfloor} \\ &\geq p(1-p \lfloor \log c \rfloor) \geq p/2. \end{aligned}$$

(The second inequality can be easily proved by induction.) Hence the expected number of useful vertices in I_1 is at least $p|I_1|/2$. So there exists a choice J for A_p such that at least $p|I_1|/2$ vertices in I_1 are useful. Let I' be the set of these useful vertices. Then

$$|I'| \geq \frac{p|I_1|}{2} = \frac{|I_1|}{4 \log c} \geq \frac{|I|}{4(\log c)^2}$$

and

$$|J| \leq |A| \stackrel{(3)}{\leq} \frac{|I| \log c}{c}.$$

So I' and J are as desired in (ii). ■

By repeated applications of [Lemma 13](#) we obtain the following result.

Lemma 14. *Let $c \geq 2^{512}$, $d > 2c$ and let G be a graph of minimum degree at least $d/2$. Suppose that $\chi(G) \leq d+1$ and that G has an independent set I of size $2c|G|/d$. Put $r := \lfloor \log \log c \rfloor$. Then G has one of the following properties.*

- (i) *G contains an induced bipartite subgraph of average degree at least $(\log c)/48$.*
- (ii) *There are a set $I^* \subseteq I$ and disjoint independent subsets J_1, \dots, J_r of $G - I^*$ such that every vertex of I^* has exactly one neighbour in each J_k , $|I^*| \geq |I|/4^r (\log c)^{2r}$ and $|J_k| \leq 4|I| \log c/c$ for every $k \leq r$.*

Proof. The proof follows from r applications of [Lemma 13](#). Indeed, let $I_0 := I$ and suppose inductively that for some $0 \leq \ell < r$ we already have obtained a set $I_\ell \subseteq I$ and disjoint independent sets J_1, \dots, J_ℓ in $G - I_\ell$ such that every vertex of I_ℓ has exactly one neighbour in each J_k , $|I_\ell| = \lceil |I|/4^\ell (\log c)^{2\ell} \rceil$ and $|J_k| \leq 4|I| \log c/c$ for every $1 \leq k \leq \ell$. Put $n := |G|$, $G' := G - (J_1 \cup \dots \cup J_\ell)$, $n' := |G'|$ and $d' := d/2$. Thus $d_{G'}(x) \geq d/2 - \ell \geq d/4 = d'/2$ for every $x \in I_\ell$.

Moreover, since $|J_k| \leq 4n \log c / c$, we have that $n' \geq n/2$. Let c' be defined by $|I_\ell| = 2c'n'/d'$. Using $|I_\ell| \leq |I|$ it follows that $c' \leq c$. On the other hand

$$\frac{|I|}{4^\ell (\log c)^{2\ell}} \leq |I_\ell| = \frac{2c'n'}{d'} \leq \frac{4c'n}{d},$$

and so

$$c' \geq \frac{c}{2 \cdot 4^\ell (\log c)^{2\ell}} = \frac{c}{2(2 \log c)^{2\ell}}.$$

In particular, $c' \geq 2$. Since also $\chi(G_\ell) \leq d+1 \leq 3d'$, we may apply [Lemma 13](#) to the graph G' and the independent set I_ℓ . As

$$\frac{\log c'}{24} \geq \frac{\log c - 1 - \log((2 \log c)^{2\ell})}{24} \geq \frac{\log c - 1 - 2r \log(2 \log c)}{24} \geq \frac{\log c}{48}$$

we may assume that we have $I_{\ell+1} \subseteq I_\ell$ and $J_{\ell+1}$ satisfying condition (ii) of [Lemma 13](#). Hence

$$|I_{\ell+1}| \geq \frac{|I_\ell|}{4(\log c')^2} \geq \frac{|I_\ell|}{4(\log c)^2} \geq \frac{|I|}{4^{\ell+1}(\log c)^{2(\ell+1)}},$$

and

$$|J_{\ell+1}| \leq \frac{|I_\ell| \log c'}{c'} \leq \frac{2 \cdot 4^\ell \cdot |I_\ell| (\log c)^{2\ell+1}}{c} \leq \frac{4|I| \log c}{c}.$$

Making $I_{\ell+1}$ smaller if necessary, we may assume that $|I_{\ell+1}| = \lceil |I|/4^{\ell+1} (\log c)^{2(\ell+1)} \rceil$, which completes the induction step. \blacksquare

Corollary 15. *For every $s \in \mathbb{N}$ there exists $c(s)$ such that the following holds. Let $c \geq c(s)$, $d > 2c$ and let G be a graph of minimum degree at least $d/2$. Suppose that G has an independent set I of size $2c|G|/d$ and that $\chi(G) \leq d+1$. Put $r := \lfloor \log \log c \rfloor$. Then G has one of the following properties.*

- (i) G contains an induced bipartite subgraph of average degree at least $(\log c)/48$.
- (ii) There are disjoint vertex sets $A, B \subseteq V(G)$ such that A is independent, $\chi(G[B]) \leq r$ and $(A, B)_G$ is an $(r, s, 0)$ -graph.

Proof. Applying [Lemma 14](#) we may assume that G contains independent sets I^* and J_1, \dots, J_r satisfying condition (ii) of [Lemma 14](#). Let $A := I^*$ and $B := J_1 \cup \dots \cup J_r$. Clearly, every vertex of A has degree r in the bipartite graph $(A, B)_G$ and $\chi(G[B]) \leq r$. Thus it remains to show that $|A| \geq r^{12s} |B|$. But

$$\frac{|A|}{|B|} \geq \frac{c}{4^{r+1} r (\log c)^{2r+1}} \geq r^{12s},$$

if c is sufficiently large. \blacksquare

5. Finding an induced 1-subdivision of a graph of large average degree

In the previous section we showed that we may assume that our original graph G contains a bipartite subgraph (A, B) of large average degree such that A is independent in G and $G[B]$ has small chromatic number (or is possibly independent as well). In this section we will show that this (A, B) contains a 1-subdivision of some graph H^* where H^* has large average degree and this 1-subdivision is induced in G .

To accomplish this, we first find a 1-subdivision of some graph H' of large average degree in (A, B) (Corollary 17). The branch vertices of this 1-subdivision are vertices in B , its subdivided edges are paths of length two in (A, B) and so the midpoints of the subdivided edges are vertices in A . In Lemma 18 we then show how to find a subgraph H'' of H' for which every midpoint of a subdivided edge is joined in G only to the two endpoints of this edge and to no other branch vertex. As A is independent, it follows that every edge of G which prevents the 1-subdivision of H'' from being induced must join two branch vertices, i.e. two vertices in B . So if B is also independent then this 1-subdivision is induced in G , as desired. The case when B is not independent is more difficult and dealt with in Lemma 20.

Let us now introduce some notation. A path P of length two in a bipartite graph (A, B) is called a *hat* of G if it begins and ends in B . A set \mathcal{H} of hats of (A, B) is *uncrowded* if any two hats in \mathcal{H} join distinct pairs of vertices and have distinct midpoints. (So the sets of subdivided edges of the 1-subdivisions of the graphs H' and H'' described above are both uncrowded; and conversely, an uncrowded set of hats can serve as the set of subdivided edges of a 1-subdivision whose set of branch vertices is B .)

Lemma 16. *Let $r, i \geq 1$ and $0 \leq k \leq r/8$. Let $G = (A, B)$ be an (r, i, k) -graph. Then either G has an uncrowded set of at least $r^{11}|B|/2^8$ hats or there are a vertex $b' \in B$ and an induced copy (A', B') of an $(r, i-1, k+1)$ -graph in $G - b'$ such that $\emptyset \neq A' \subseteq N_G(b')$.*

Proof. Let us first suppose that every vertex $b \in B$ satisfies

$$|N^2(b)| \geq d(b)/r^{12(i-1)},$$

where $N^2(b)$ is the set of all vertices with distance two from b . In other words, for each $b \in B$ there is a set \mathcal{H}_b of at least $d(b)/r^{12(i-1)}$ hats in G which have b as one endvertex, but whose other endvertices are distinct. Note that every pair of vertices in B belongs to at most two hats in $\bigcup_{b \in B} \mathcal{H}_b$. Hence there are at least $e(G)/2r^{12(i-1)}$ hats with distinct pairs of endpoints. Since the

degree of every vertex $a \in A$ is at most $4r$, at most $(4r)^2$ of these hats have a as their midpoint. Thus G has a uncrowded set of at least

$$\frac{e(G)}{2 \cdot 16r^{12(i-1)+2}} \geq \frac{(r/4 - k)|A|}{2^5 r^{12(i-1)+2}} \geq \frac{(r/4 - k)r^{12i}|B|}{2^5 r^{12(i-1)+2}} \geq \frac{r^{11}|B|}{2^8}$$

hats, as required.

So we may assume that there is a vertex $b' \in B$ with

$$|N^2(b')| < d(b')/r^{12(i-1)}.$$

Let $A' := N(b')$ and $B' := N^2(b')$. Then $(A', B')_G$ has the required properties. ■

The proof of the preceding lemma shows that in the case where we failed to find a large set of uncrowded hats (i.e. a 1-subdivision of some graph of large average degree), there must be a vertex b' so that the set of vertices with distance two from b' is much smaller than the neighbourhood of b' . However, if this happens we can reapply the lemma to the bipartite graph induced by these sets. In case of renewed failure, we can iterate the process – but if we encounter i successive failures, then this means that G contains contains a $K_{i,i}$:

Corollary 17. *Let $s \in \mathbb{N}$ and let $r \geq 8s$. Let $G = (A, B)$ be a $K_{s,s}$ -free $(r, s, 0)$ -graph. Then there exists $0 \leq i \leq s$ such that G contains an induced copy (A', B') of an $(r, s - i, i)$ graph which has an uncrowded set of at least $r^{11}|B'|/2^8$ hats.*

Proof. Applying [Lemma 16](#) repeatedly, assume that there are sequences $(A, B) = (A_0, B_0) \supseteq (A_1, B_1) \supseteq \dots \supseteq (A_s, B_s)$ of induced subgraphs of G and b_1, b_2, \dots, b_s of distinct vertices in B such that, for each $0 < i \leq s$, (A_i, B_i) is an $(r, s - i, i)$ -graph and $\emptyset \neq A_i \subseteq N_G(b_i)$. Note that every vertex in A_s has degree at least $r/4 - s \geq r/8$ and so

$$s \leq \frac{r}{8} \leq |B_s| = r^{12(s-s)}|B_s| \leq |A_s|.$$

Thus together with any s vertices from A_s the vertices b_1, \dots, b_s induce a $K_{s,s}$ in G , a contradiction. ■

We say that an uncrowded set \mathcal{H} of hats of a bipartite graph (A, B) is *induced* if $\bigcup \mathcal{H}$ is an induced subgraph of (A, B) , i.e. if every midpoint of a hat in \mathcal{H} has degree two in (A, B) .

Lemma 18. *Let $r \geq 1$ and let $G = (A, B)$ be a bipartite graph with $d(a) \leq 4r$ for every vertex $a \in A$. Suppose that G has an uncrowded set \mathcal{H} of at least $r^{11}|B|/2^8$ hats. Then there is an induced subgraph $G' = (A', B')$ of G which has an induced uncrowded set \mathcal{H}' of at least $r^9|B'|/2^{15}$ hats.*

Proof. We may assume that A consists only of midpoints of hats in \mathcal{H} . Since \mathcal{H} is uncrowded, every vertex $a \in A$ is the midpoint of exactly one hat in \mathcal{H} , and we say that a *owns* the endvertices of these hat. So every vertex in A owns exactly two vertices in B and

$$|A| = |\mathcal{H}| \geq \frac{r^{11}|B|}{2^8}.$$

Let us consider a random subset B_p of B which is obtained by including each vertex of B independently with probability $p := 1/(8r)$. Given B_p , let us call a vertex $a \in A$ *useful* if $N(a) \cap B_p$ consists precisely of the two vertices owned by a . Thus

$$\mathbb{P}(a \text{ is useful}) = p^2(1-p)^{d(a)-2} \geq p^2(1-p)^{\lfloor 4r \rfloor} \geq p^2(1 - \lfloor 4r \rfloor p) \geq p^2/2,$$

and so the expected number of useful vertices is at least $p^2|A|/2$. Hence there exists a choice B' for B_p such that at least $p^2|A|/2$ vertices in A are useful. Let A' denote the set of these vertices, and let \mathcal{H}' be the set consisting of all hats in \mathcal{H} whose midpoints lie in A' . Then

$$|\mathcal{H}| = |A'| \geq \frac{|A|}{27r^2} \geq \frac{r^9|B|}{2^{15}} \geq \frac{r^9|B'|}{2^{15}},$$

and so $(A', B')_G$ and \mathcal{H}' have the required properties. ■

Corollary 19. *Let $s \in \mathbb{N}$ and $r \geq 8s$. Let $G = (A, B)$ be an $(r, s, 0)$ graph. Then either G contains a $K_{s,s}$ or an induced 1-subdivision of some graph H with $d(H) \geq r^9/2^{14}$.*

Proof. We may apply [Corollary 17](#) and [Lemma 18](#) to obtain an induced bipartite graph $G' = (A', B') \subseteq G$ and a set \mathcal{H}' of hats as in [Lemma 18](#). Let H be the graph whose vertex set is B' and in which $b, b' \in B'$ are joined by an edge if there is a hat in \mathcal{H}' whose endvertices are b and b' . So every edge of H corresponds to a hat in \mathcal{H}' . As \mathcal{H}' is induced, the 1-subdivision of H is induced in G' (and thus in G). Moreover $e(H) = |\mathcal{H}'| \geq r^9|B'|/2^{15}$, as desired. ■

Lemma 20. *Let $r \geq 2^{25}$. Let A, B be a vertex partition of a graph G such that A is independent, $\chi(G[B]) \leq r$ and $d(G') \leq r^3$ for every $G' \subseteq G[B]$. Suppose that $(A, B)_G$ has an induced uncrowded set \mathcal{H} of at least $r^9|B|/2^{15}$ hats. Then G contains an induced 1-subdivision of some graph H with $d(H) \geq r$.*

Proof. Let H_0 be the graph whose vertex set is B and in which $b, b' \in B$ are joined by an edge if they are the endpoints of a hat in \mathcal{H} . Hence G contains a 1-subdivision of H_0 . Note that $e(H_0) = |\mathcal{H}|$ and so $d(H_0) \geq r^9/2^{14}$. Let H_1 be a subgraph of H_0 with

$$(4) \quad \delta(H_1) \geq \frac{r^9}{2^{15}},$$

and put $B_1 := V(H_1)$ (where B_1 is thought of as a subset of B). Let G^* be the 1-subdivision of H_1 contained in G . Note that every edge which prevents G^* from being induced must join two branch vertices of G^* , i.e. vertices in B_1 . Using a probabilistic argument, we will show that H_1 contains a subgraph H_2 of average degree at least r whose 1-subdivision in G is induced. In other words, we are given two graphs H_1 and $F := G[B_1]$ on the same vertex set such that H_1 has large average degree while every subgraph of F has small average degree. The desired subgraph H_2 of H_1 must avoid all edges of F .

Let B'_1 denote the set of all vertices $b \in B_1$ with $d_F(b) \leq 2r^3$. Then

$$2r^3|B_1 \setminus B'_1| \leq 2e(F) = d(F)|F| \leq r^3|B_1|$$

and thus

$$(5) \quad |B'_1| \geq \frac{|B_1|}{2}.$$

Consider a random subset B_p of B_1 which is obtained by including each vertex of B_1 independently with probability $p = 1/(4r^3)$. Given B_p , call a vertex $b \in B'_1$ *useful* if

- (a) $b \in B_p$,
- (b) $N_F(b) \cap B_p = \emptyset$,
- (c) $|(N_{H_1}(b) \setminus N_F(b)) \cap B_p| \geq pr^9/2^{17}$.

Thus every useful vertex is isolated in $G[B_p]$ and in the graph H_1 it has many neighbours which are contained in B_p . The aim now is to show that with non-zero probability the set I_0 of useful vertices is large. As the chromatic number of $G[B_p]$ is small compared to $|N_{H_1}(b) \cap B_p|$ for any useful vertex b , there will be an independent set in $B_p \setminus I_0$ which together with I_0 induces a subgraph H_2 of H_1 with large average degree. Observe that the 1-subdivision of H_2 in G will be induced.

To prove that with non-zero probability B'_1 contains many useful vertices, first note that for every $b \in B'_1$ the random variable $X := |(N_{H_1}(b) \setminus N_F(b)) \cap B_p|$ is binomially distributed with

$$\mathbb{E}X = p|N_{H_1}(b) \setminus N_F(b)| \geq p|\delta(H_1) - d_F(b)| \stackrel{(4)}{\geq} \frac{pr^9}{2^{16}} \geq 8.$$

So Lemma 9 implies that

$$\mathbb{P}(X \leq \frac{pr^9}{2^{17}}) \leq \mathbb{P}(X \leq \frac{\mathbb{E}X}{2}) \leq e^{-\mathbb{E}X/8} \leq \frac{1}{2}.$$

Moreover, note that the events (a), (b) and (c) are mutually independent. Thus for every vertex $b \in B'_1$ we have that

$$\mathbb{P}(b \text{ is useful}) \geq p \cdot (1-p)^{d_F(b)} \cdot \frac{1}{2} \geq p \cdot (1-p)^{\lfloor 2r^3 \rfloor} \cdot \frac{1}{2} \geq \frac{p(1 - \lfloor 2r^3 \rfloor p)}{2} \geq \frac{p}{4}.$$

Fig. 1 Finding an independent set of vertices in F which induces many hats

Hence by (5) the expected number of useful vertices is at least $p|B'_1|/4 \geq p|B_1|/8$. So there exists a choice B_2 for B_p such that at least $p|B_1|/8$ vertices in B'_1 are useful. Let I_0 denote the set of these vertices. Every useful vertex is contained in B_2 and has at least $pr^9/2^{17}$ neighbours in H_1 which are contained in B_2 . Thus there are at least

$$\frac{1}{2} \cdot \frac{pr^9}{2^{17}} \cdot \frac{p|B_1|}{8} = \frac{r^3|B_1|}{2^{25}}$$

edges of H_1 which emanate from vertices contained in I_0 . Since $\chi(G[B]) \leq r$, we may partition $G[B_2 \setminus I_0]$ into r independent sets, I_1, \dots, I_r say. Then there exists $0 \leq i \leq r$ such that at least a $1/(r+1)$ th of the edges of H_1 emanating from I_0 ends in I_i (see Fig. 1). But then the subgraph H_2 of H_1 induced by $I_0 \cup I_i$ has at least

$$\frac{1}{r+1} \cdot \frac{r^3|B_1|}{2^{25}} \geq \frac{r|B_1|}{2}$$

edges and so it has average degree at least r . Moreover, since in F both I_0 and I_i are independent and no vertex in $B_2 \supseteq I_i$ is joined to a vertex in I_0 ,

it follows that $I_0 \cup I_i$ is independent in G . As mentioned above, this implies that the 1-subdivision of H_2 is induced in G . ■

By successively applying [Corollary 17](#) and [Lemmas 18 and 20](#) we obtain the following result.

Corollary 21. *Let $s \in \mathbb{N}$ and $r \geq \max\{8s, 2^{25}\}$. Let G be a $K_{s,s}$ -free graph and let $A, B \subseteq V(G)$ be disjoint sets of vertices such that A is independent, $\chi(G[B]) \leq r$, $d(G') \leq r^3$ for every $G' \subseteq G[B]$ and so that $(A, B)_G$ is an $(r, s, 0)$ graph. Then G contains an induced 1-subdivision of some graph H with $d(H) \geq r$.* ■

6. Proof of Theorem 2

We can now put everything together.

Proof of Theorem 2. Suppose that G is a $K_{s,s}$ -free graph with $d(G) = d \geq d_0$ where d_0 is sufficiently large compared to k and s . Put $n := |G|$. Clearly, we may assume that G has no subgraph of average degree $> d$. So [Propositions 6 and 7](#) enable us to assume that $\delta(G) \geq d/2$ and $\chi(G) \leq d+1$. Also [Lemma 10](#) and [Corollary 19](#) imply that [Theorem 2](#) holds if G contains an induced bipartite subgraph of large average degree – we will make use of this fact twice in what follows.

Turning to the proof itself, we first apply [Corollary 12](#) to G , which gives us an independent set I of size $2cn/d$ where $c \geq (\log d)^{1/(s+1)}/2$. We then apply [Corollary 15](#) to obtain (without loss of generality) disjoint sets $A, B \subseteq V(G)$ as in condition (ii) of the corollary. In other words, A is independent, $\chi(G[B]) \leq r$ and $(A, B)_G$ is an $(r, s, 0)$ -graph, where $r = \lfloor \log \log c \rfloor$. Now if $G[B]$ has an (induced) subgraph G' whose average degree is at least r^3 then, as $\chi(G') \leq r$, there must be two disjoint independent sets B_1, B_2 of G' such that

$$e((B_1, B_2)_{G'}) \geq \frac{e(G')}{\binom{r}{2}} \geq \frac{d(G')|G'|}{r^2} \geq r|G'| \geq r(|B_1| + |B_2|).$$

Hence $(B_1, B_2)_G$ is an induced bipartite subgraph of average degree at least $2r$. So we may assume that $d(G') \leq r^3$ for every $G' \subseteq G[B]$. But then [Corollary 21](#) implies that G contains an induced 1-subdivision of some graph H^* which has average degree at least k , as desired. ■

7. Open problems

An obvious question is that of the growth of $d(s, k)$ in [Theorem 2](#). The bounds which follow from our proof are quite large: k is about the 3-fold logarithm of d even for the case $s = 2$. Also, we are not aware of any nontrivial lower bound on d .

Our proof of [Theorem 2](#) becomes easier if G contains an induced bipartite subgraph of large average degree. This raises the question whether there exists $d(s, k)$ such that every $K_{s,s}$ -free graph of average degree at least $d(s, k)$ contains an induced bipartite subgraph with average degree at least k . The following result implies that much more is true for regular graphs: using a theorem of Johansson [9], Alon, Krivelevich and Sudakov [2, Corollary 2.4] proved that every $K_{s,s}$ -free graph G with maximum degree Δ has chromatic number at most $c\Delta/\log \Delta$ for some constant c depending on s (and thus if G is regular, the largest colour class together with another one induce a bipartite graph of average degree at least $(\log \Delta)/c$). Of course the result of Alon, Krivelevich and Sudakov does not hold if we replace maximum degree by average degree: just consider a $K_{s,s}$ -free graph G whose chromatic number is large and add sufficiently many isolated vertices to G .
