10.13	Rhenium(0) . . . . .	215
10.14	Rhenium carbonyl clusters . . . . .	215
10.15	Thionitrosyl and nitrosyl complexes . . . . .	216
10.16	Cyanides . . . . .	216
References	. . . . .	217

The period of this review essentially coincides with the coverage of Vols. 90 and 91 of Chemical Abstracts. Thus, although a majority of the papers covered were published in 1979, many from 1978 are also included. Although the chemistry of technetium is small compared with that of rhenium, it has been treated separately in order to reflect the different interests stimulating its investigation.

This review concentrates upon the coordination chemistry of technetium and rhenium. No attempt has been made to cover work of an essentially organometallic nature (although carbonyl is treated as an inorganic ligand). Areas of especial interest this year include an extension of the chemistry of nitridorhenium(VII) systems, the preparation of Schiff base complexes of rhenium, studies upon Re—Re bonded systems, and elegant studies upon rhenium cyanide and thionitrosyl derivatives.

## TECHNETIUM

### 10.1 TECHNETIUM(VII)

The electrochemistry of  $[\text{TcO}_4]^-$  has attracted much attention. The reduction of  $[\text{TcO}_4]^-$  in chloride and sulphate media has been studied by polarography, CV and coulometry, and new potential-pH diagrams at  $10^{-4}$  M and  $10^{-7}$  M have been reported [1]. In the presence of pyrophosphate and various other diphosphonate ligands (e.g. 1-hydroxyethane-1,1-diphosphonic acid; see also Section 10.4), the reduction of  $[\text{TcO}_4]^-$  has been studied by normal-pulse polarography as a function of pH. Below pH 6,  $[\text{TcO}_4]^-$  was reduced to Tc(III), which could be reoxidised to Tc(IV). At pH > 10,  $[\text{TcO}_4]^-$  was reduced in two steps (n.b. but see Section 10.2) to Tc(V) and Tc(IV), each of which could be reoxidised to Tc(VII). For  $6 < \text{pH} < 10$ , the results obtained depended upon the ligand present [2]. In the presence of  $\text{SnCl}_2$ , the reduction of  $[\text{TcO}_4]^-$  has been studied by polarography and electronic absorption spectroscopy (at pH 7 in 1 M sodium phosphate solution). A mixed metal complex of Tc(III), Tc(IV) and Sn(II) was observed polarographically, but fixed potential coulometry produced a Tc(III) complex, which was rapidly oxidised by air to Tc(IV) [3].

### 10.2 TECHNETIUM(VI)

The transient species,  $[\text{TcO}_4]^{2-}$ , has been detected and characterised for the first time in aqueous solution. It was produced by pulse radiolysis of

$[\text{TcO}_4]^-$  in an aqueous alkaline medium, and characterised by fast-scan cyclic voltammetry.  $[\text{TcO}_4]^{2-}$  has a lifetime of the order of milliseconds and its electronic spectrum was reported [4].

### 10.3 TECHNETIUM(V)

Reduction of an ethanolic solution of  $[\text{NH}_4][\text{TcO}_4]$  and a dithiol  $\text{HS}-\text{Y}-\text{SH}$  ( $\text{Y} = \text{CH}_2\text{CH}_2$ ,  $\text{CH}_2\text{CHCH}_3$  or  $\text{CH}_2\text{CH}_2\text{CH}_2$ ) with  $\text{Na}[\text{BH}_4]$ , followed by addition of  $[\text{AsPh}_4]\text{Cl}$ , leads to the isolation of the orange salts  $[\text{AsPh}_4][\text{TcO}(\text{S}-\text{Y}-\text{S})_2]$ , which were chemically and spectroscopically characterised [5]. The molecular structure of  $[\text{AsPh}_4][\text{TcO}(\text{SCH}_2\text{CH}_2\text{S})_2]$  reveals the anion to be square-pyramidal [6].

Reaction of  $[\text{TcO}_4]^-/\text{SnCl}_2$  or  $[\text{TcOCl}_5]^{2-}$  with calcium gluconate to give the same complex species in solution has been taken as evidence to indicate that the oxidation state of the Tc in the complex is (V) [7]. The gluconate complex will undergo ligand exchange reactions with *meso* or *racemic* 2,3-dimercaptosuccinic acid, to give isomeric succinatotechnetate(V) complexes [8] and, when treated with sodium 1,2-dicyanoethylenedithiolate ( $\text{Na}_2[\text{S}(\text{CN})\text{C}=\text{C}(\text{CN})\text{S}]$ ) followed by addition of  $[\text{Et}_4\text{N}]\text{Br}$ , gives the brown complex,  $[\text{Et}_4\text{N}][\text{TcO}\{\text{S}(\text{CN})\text{C}=\text{C}(\text{CN})\text{S}\}_2]$  [9].

### 10.4 TECHNETIUM(IV)

The molecular structure of  $[\text{NH}_4]_2[\text{TcCl}_6]$  shows the expected octahedral environment for the metal ( $\bar{r}(\text{TcCl}) = 0.2353 \text{ nm}$ ) [10]. Thermolysis of  $[\text{pyH}]_2[\text{TcCl}_6]$  gives initially  $[\text{pyH}][\text{TcCl}_5(\text{py})]$ , followed by  $[\text{TcCl}_4(\text{py})_2]$  [11]. EPR studies of Tc(IV) in solution in general, and  $[\text{TcCl}_6]^{2-}$  in particular, indicate that EPR will be a valuable tool for studying technetium chemistry [12]. The electrochemical behaviour of  $[\text{TcX}_6]^{2-}$  ( $\text{X} = \text{Cl}$ ,  $\text{Br}$  or  $\text{NCS}$ ) has been investigated by cyclic voltammetry [13].

$[\text{PPh}_4]_2[\text{TcX}_6]$  ( $\text{X} = \text{Cl}$  or  $\text{Br}$ ) reacts with  $\text{acacH}$  to give  $[\text{PPh}_4][\text{TcX}_4(\text{acac})]$ , whereas reaction of  $[\text{TcX}_4(\text{PPh}_3)_2]$  with  $\text{acacH}$  gives  $[\text{TcX}_2(\text{acac})_2]$ ,  $[\text{TcBr}_3(\text{acac})(\text{PPh}_3)_2]$ , or Tc(III) complexes (q.v.), depending upon reaction conditions [14].

1-Hydroxyethane-1,1-diphosphonic acid ( $\text{hedpH}_4$ ; see also Section 10.1) reacts with  $\text{K}_2[\text{TeBr}_6]$  (or with  $[\text{TcO}_4]^-/\text{SnCl}_2$ ) according to pH, to give complexes believed to be  $[\text{Tc}(\text{OH})_3(\text{hedpH}_3)]$ ,  $[\text{Tc}(\text{OH})_3(\text{hedpH}_2)]^-$ ,  $[\text{TcO}(\text{OH})(\text{hedpH})]^{2-}$ ,  $[\text{Tc}_2(\text{OH})_4(\text{hedpH}_3)]^{3+}$ ,  $[\text{Tc}_2(\text{OH})_6(\text{hedpH}_2)]$ ,  $[\text{Tc}(\text{OH})_4(\text{hedp})]^{4-}$  and  $[\text{Tc}(\text{OH})_x(\text{hedpH}_y)_2]^{(4-x-8+2y)+}$  [15].

### 10.5 TECHNETIUM(III)

Reaction of  $[\text{TcX}_4(\text{PPh}_3)_2]$  ( $\text{X} = \text{Cl}$  or  $\text{Br}$ ) with  $\text{acacH}$  gives  $[\text{TcX}_2(\text{acac})(\text{PPh}_3)_2]$ ,  $[\text{TcX}(\text{acac})_2(\text{PPh}_3)]$  or  $[\text{Tc}(\text{acac})_3]$ , depending upon the reaction conditions [14].

## 10.6 TECHNETIUM(I)

The thermodynamic properties of  $[\text{TcX}(\text{CO})_5]$  ( $\text{X} = \text{Cl}, \text{Br}$  or  $\text{I}$ ) have been calculated [16].

## RHENIUM

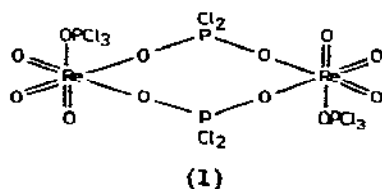

## 10.7 RHENIUM(VII)

## 10.7.1 Halides, oxohalides and nitridohalides

$\text{ReF}_7$  has been prepared, by the direct fluorination of  $\text{ReF}_6$  at  $400^\circ\text{C}$  [17], and its force constants have been calculated [18]. It has also been characterised by photoelectron spectroscopy [17].

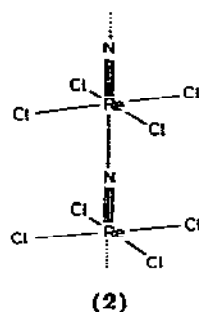

Reaction of  $\text{K}[\text{ReO}_4]$  and  $\text{IF}_5$  gives  $\text{ReO}_3\text{F}$ , whereas direct fluorination of  $\text{ReO}_2$  yields a mixture of  $\text{ReO}_2\text{F}_3$  and  $\text{ReOF}_5$  [17]. The direct fluorination of  $\text{ReO}_2$  or  $\text{ReO}_2\text{F}_3$ , in the presence of  $\text{AgF}_2$ , produces principally  $\text{ReOF}_5$  [17]. The mean amplitudes of vibration and thermodynamic functions have been calculated for  $\text{ReO}_3\text{F}$  [19] and  $\text{ReOF}_5$  [20]; their photoelectron spectra have also been reported [17]. The reactions of  $\text{ReO}_2$ ,  $\text{ReO}_3$ ,  $\text{Re}_2\text{O}_7$ ,  $\text{K}[\text{ReO}_4]$  and  $[\text{NH}_4][\text{ReO}_4]$  with  $[\text{NH}_4][\text{HF}_2]$ ,  $\text{K}[\text{HF}_2]$  or  $\text{HF}$ , to yield various rhenium oxofluorides, have been studied [21].

$\text{ReO}_3\text{Cl}$  reacts with  $\text{AlCl}_3$  [22],  $\text{NbCl}_5$  [22], or  $\text{SbCl}_5$  [23] to give the adducts  $\text{ReO}_3\text{Cl} \cdot \text{AlCl}_3$ ,  $\text{ReO}_3\text{Cl} \cdot \text{NbCl}_5$  or  $\text{ReO}_3\text{Cl} \cdot \text{SbCl}_5$ , respectively, which are all believed (from IR evidence) to contain  $\text{Re}=\text{O} \rightarrow \text{E}$  ( $\text{E} = \text{Al}, \text{Nb}$  or  $\text{Sb}$ ) linkages.  $\text{ReO}_3\text{Cl}$  will react with  $\text{CCl}_4$  at  $20^\circ\text{C}$ , in the presence of  $\text{GaCl}_3$ , to give  $\text{COCl}_2$ , and possibly  $\text{ReO}_2\text{Cl}_3$  [22].  $\text{ReCl}_5$  reacts with  $\text{Cl}_2\text{O}$ , in the presence of  $\text{POCl}_3$ , to give  $\text{ReO}_3(\text{O}_2\text{PCl}_2) \cdot \text{POCl}_3$ , which is postulated to have a dimeric structure (1) [24].

Unstable red-yellow crystals of  $[\text{phenH}_2][\text{ReO}_3\text{Cl}_2(\text{H}_2\text{O})]\text{Cl}$  were prepared by prolonged reaction between  $[\text{ReO}_3\text{Cl}(\text{phen})]$  and concentrated hydrochloric acid in a dessicator over  $\text{P}_2\text{O}_5$ . The molecular structure of the complex reveals the oxo-groups in the anion to be *facial*, but the parameters  $\{\bar{r}(\text{Re}=\text{O}) = 0.173 \text{ nm}, r(\text{Re}-\text{OH}_2) = 0.233 \text{ nm}, \bar{r}(\text{ReCl}) = 0.248 \text{ nm}\}$  are of low precision, due to disorder in the crystal [25].

$\text{ReNCl}_4$  has been prepared by the reaction of  $\text{ReCl}_5$  with  $\text{NCl}_3$ . Its structure, (2), is similar to that of  $\text{WOCl}_4$ , having chains of  $\text{ReNCl}_4$  units, linked by strongly alternated  $\text{Re}\equiv\text{N}-\text{Re}$  bonds  $\{r(\text{Re}\equiv\text{N}) = 0.158 \text{ nm}, r(\text{Re}-\text{N}) = 0.248$

nm,  $r(\text{ReCl}) = 0.227 \text{ nm}$  [26]. Upon heating at  $170^\circ\text{C}$ ,  $\text{ReNCl}_4$  gives  $\text{ReNCl}_3$  and chlorine, whereas its reaction with  $\text{POCl}_3$  yields  $[\text{ReNCl}_3 \cdot \text{POCl}_3]_4 \cdot 2 \text{ POCl}_3$  (and again  $\text{Cl}_2$ ). Reaction of  $\text{ReNCl}_4$  with  $[\text{N}_3]^-$  or  $\text{Cl}^-$  gives  $[\text{ReNCl}_4]^-$  and  $\text{N}_2$  or  $\text{Cl}_2$ , respectively [26].

#### 10.7.2 Oxides, rhenates(VII) and aqueous chemistry

Crystallographic data have been presented for a wide range of actinide, molybdenum and tungsten rhenates(VII), and many double salts thereof [27]. The thermal decomposition of  $\text{Pb}[\text{ReO}_4]_2$  has been studied by mass spectrometry and ions corresponding to  $\text{PbO}$ ,  $\text{Re}_2\text{O}_7$ ,  $\text{Pb}[\text{ReO}_4]_2$  and  $\text{Pb}_2\text{Re}_2\text{O}_9$  were detected in the vapour above the solid [28]. The ternary oxides  $\text{A}_3\text{Re}_2\text{O}_{10}$  ( $\text{A} = \text{Ba}$  or  $\text{Sr}$ ) were prepared by heating  $\text{ACl}_2 \cdot x \text{H}_2\text{O}$  with rhenium metal, whereas  $\text{A}_5\text{Re}_2\text{O}_{12}$  ( $\text{A} = \text{Ca}$  or  $\text{Sr}$ ; see also Section 10.9.2) were prepared by heating  $\text{ACl}_2 \cdot x \text{H}_2\text{O}$  with  $\text{A}[\text{ReO}_4]$ ; the quaternary oxides  $\text{Ca}_3\text{B}_2\text{Re}_2\text{O}_{13}$  ( $\text{B} = \text{La}$ ,  $\text{Pr}$ ,  $\text{Nd}$  or  $\text{Sm}$ ) were also characterised [29]. The structure of  $\text{La}_3\text{ReO}_8$  has been determined [30].

The reactions between  $[\text{ReO}_4]^-$  and  $\text{H}_2\text{E}$  ( $\text{E} = \text{S}$  or  $\text{Se}$ ) have been reported [31]. Evidence for  $[\text{SO}_4]^{2-}$  forming 1 : 1 and 2 : 1 complexes with  $\text{Re(VII)}$  in 1–10 M sulphuric acid solutions has been presented [32,33], and in neutral and acidic ( $\text{H}_2\text{SO}_4$ ) solutions of  $[\text{ReO}_4]^-$ , interaction with thiocyanate occurs; for acid concentrations  $>1 \text{ M}$ , reduction to  $\text{Re(IV)}$  is observed [34].

### 10.8 RHENIUM(VI)

#### 10.8.1 Halides and oxohalides

$\text{ReOF}_4$  has been prepared by the reaction between  $\text{ReF}_6$  and  $\text{ReO}_3$  at  $300^\circ\text{C}$  [17] and by the reaction between  $\text{ReF}_6$  and  $\text{B}_2\text{O}_3$  [35]. The photo-electron spectra of both  $\text{ReF}_6$  and  $\text{ReOF}_4$  have been reported [17] and the mean amplitudes of vibration and thermodynamic functions of the latter have been calculated [20].

$\text{ReOF}_4$  will react with either  $\text{CCl}_4$  or  $\text{BCl}_3$  to give  $\text{ReOCl}_4$  [35].

### 10.8.2 Oxides and rhenates(VI)

Fermi-surface pressure-derivative measurements upon  $\text{ReO}_3$  at 2 K indicate that a novel second-order phase transition occurs, probably involving a tetragonal distortion of the cubic lattice; the high pressure phase is much more compressible than the low pressure phase [36]. The "open orbits" in  $\text{ReO}_3$  have been observed by the induced torque method at 1.4 K [37] and the coefficient of linear expansion of a single crystal of  $\text{ReO}_3$  has been measured [38].

The magnetic and structural properties of the perovskite-related oxides  $\text{A}_2(\text{BRe})\text{O}_6$  {A = Ca, Sr or Ba; B = Ca or Sr} have been re-examined; they show Curie-Weiss behaviour, having magnetic moments  $\sim 1.10 \mu_B$  and Weiss constants  $\sim -150$  K [39]. The ternary oxides  $\text{Ba}_3\text{Re}_2\text{O}_9$  and  $\text{Sr}_2\text{Re}_2\text{O}_9$  have also been prepared and characterised [40].

## 10.9 RHENIUM(V)

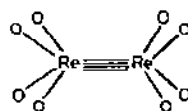

### 10.9.1 Fluorides

A detailed preparation of  $\text{ReF}_5$  has been published [41], and the molecular structure of  $[\text{Re}(\text{CO})_6][\text{F}_5\text{Re}(\mu\text{-F})\text{ReF}_5]$  (prepared by the reaction of  $[\text{ReF}_6]$  with  $[\text{Re}_2(\text{CO})_{10}]$  in HF) has been determined [42].

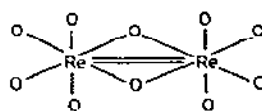

### 10.9.2 Oxides

The thermal decomposition of  $\text{Ca}_5\text{Re}_2\text{O}_{12}$  (see Section 10.7.2) in vacuo yields single crystals of a perovskite-related phase,  $\text{Ca}_3\text{ReO}_{5.5}$  ( $\mu = 4.46 \mu_B$ ;  $\theta = -819$  K), which shows strong magnetic interactions between the  $\text{Re}^{5+}$  sites. This oxide might well be magnetically ordered at a temperature below that of the range studied (80–300 K) [39].

The structure of the mixed oxidation state {Re(V/IV)} ternary oxide  $\text{La}_6\text{Re}_4\text{O}_{18}$  is of especial interest; it comprises isolated  $\text{Re}_2\text{O}_8$  (3) and  $\text{Re}_2\text{O}_{10}$  (4) dimeric units, linked by La ions. The Re-Re separations are 0.2235 and 0.2456 nm, respectively [43].

(3)

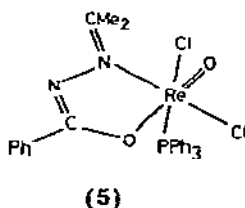

(4)

### 10.9.3 Complexes

The first Schiff base complexes of rhenium have been prepared by reaction of  $[\text{ReOCl}_3(\text{PPh}_3)_2]$  with  $\text{LH}_2$  (L = sal<sub>2</sub>en, sal<sub>2</sub>prop, sal<sub>2</sub>phen or acac<sub>2</sub>en),

in the presence of  $\text{Et}_3\text{N}$  and moist air, to give  $[\text{Re}_2\text{O}_3(\text{L})_2]$ . Under anhydrous conditions  $[\text{ReOCl}(\text{L})]$  forms. In the absence of  $\text{Et}_3\text{N}$ , the products  $[\text{ReOCl}_3(\text{LH}_2)]$  ( $\text{L} = \text{acac}_2\text{en}$ ),  $[\text{Re}_2\text{O}_2\text{Cl}_6(\text{PPh}_3)_2(\text{LH}_2)]$  ( $\text{L} = \text{acac}_2\text{en}$ ) and  $[\text{Re}_2\text{O}_2\text{Cl}_4(\text{PPh}_3)_2(\text{L})]$  ( $\text{L} = \text{sal}_2\text{en}$ ) were isolated [44].

The molecular structure of the propanone benzoylhydrazonido-complex,  $[\text{ReOCl}_2\{\text{PhC}(\text{O})\text{C}=\text{N}-\text{N}=\text{CMe}_2\}(\text{PPh}_3)]$  (5), has shown the hydrazine

moiety to be bonded in the enol form ( $r(\text{Re}=\text{O}) = 0.1685 \text{ nm}$ ,  $r(\text{Re}-\text{O}) = 0.2013 \text{ nm}$ ,  $r(\text{ReN}) = 0.2127 \text{ nm}$  and  $r(\text{ReCl}) = 0.2366 \text{ nm}$ ) [45].

#### 10.9.4 Mixed-oxidation state complexes, $\text{Re}(\text{V}/\text{IV})$

A detailed study of the resonance Raman spectrum of  $\text{Cs}_3[\text{Re}_2\text{OCl}_{10}]$  has been reported. The longest progression reaches  $14\nu_1(a_{1g})$  ( $\nu_s(\text{ReORe}) = 228.2 \text{ cm}^{-1}$ ) and the band excitation profile maximises at ca.  $19900 \text{ cm}^{-1}$ . In total, six progressions were observed at room temperature, and eight at 80 K, thus yielding a wealth of spectroscopic data [46].

### 10.10 RHENIUM(IV)

#### 10.10.1 Hexahalorhenates(IV) and related complexes

$[(\text{C}_{12}\text{H}_{25})_3\text{NH}]\text{F}$  has been used as a phase transfer reagent with  $[\text{ReX}_6]^{2-}$  ( $\text{X} = \text{Cl}, \text{Br}$  or  $\text{I}$ ) to form mixed halide complexes of the type  $[\text{ReF}_n\text{X}_{6-n}]^{2-}$  under mild conditions [47]. Reaction of methyl isocyanide with  $[\text{NBu}_4]_2[\text{Re}_2\text{Cl}_8]$  in ethanol causes oxidation to green  $[\text{NBu}_4][\text{ReCl}_5(\text{CNMe})]$ , which has been characterised by X-ray crystallography [48].

Salts of the hexachlororhenate(IV) anion have been the subject of a number of varied studies. Ammonium ion tunnelling has been observed in powdered  $[\text{NH}_4]_2[\text{ReCl}_6]$  [49] and the structure of this salt has been determined by neutron diffraction [50]. Variable temperature (1.5–300 K) magnetic susceptibility measurements have been made upon the series of compounds  $[\text{Me}_{4-x}\text{NH}_x]_2[\text{ReCl}_6]$  ( $x = 0, 1, 2$  or  $3$ ). The methylammonium and dimethylammonium salts show Néel temperatures at 3.8 and 9.8 K, respectively. The salts of the larger cations show no  $T_N$ , the  $[\text{Me}_4\text{N}]^+$  salt being an ideal paramagnet ( $\theta = 0 \text{ K}$ ) [51]. The reduction of  $[\text{ReCl}_6]^{2-}$  has been studied polarographically [52], and the X-ray  $L_{III}$  absorption-edge structure of Re in  $\text{Cs}_2[\text{ReCl}_6]$  gives an estimate of the Re–Cl bond length as 0.240 nm (cf. 0.232

nm by X-ray crystallography) [53]. Mass spectral studies of  $K_2[ReCl_6]$  vapour have been reported [54] and homogeneous mixed crystals of  $K_2[ReCl_6]$  and  $K_2[ReBr_6]$  can be grown at any composition [55].

Some insight has been gained into the electronic structure of the  $[ReX_6]^{2-}$  species. Near IR luminescence studies upon  $[ReBr_6]^{2-}$  have detected the previously unobserved emission bands  $\Gamma_7(^2T_{2g}) \rightarrow \Gamma_6(^2T_{1g})$ ,  $\Gamma_8(^2E_g)$ ,  $\Gamma_8(^2T_{1g})$  and  $\Gamma_8(^2T_{1g}) \rightarrow \Gamma_8(^4A_{2g})$  [56], and the intensity distributions in the vibronic side bands of the  $\Gamma_7(^2T_{2g}) \rightarrow \Gamma_8(^4A_{2g})$  transition in the emission spectra of  $[ReCl_6]^{2-}$  and  $[ReBr_6]^{2-}$  have been observed [57] and calculated [58]. The electronic Raman spectrum of  $[Et_4N]_2[ReI_6]$  has been observed at 80 K: the totally symmetric  $a_{1g}$  vibrational mode is coupled to the  $\Gamma_8(^4A_{2g}) \rightarrow \Gamma_8(^2T_{1g})$  electronic absorption [59].

CV data for  $[NBu_4]_2[Re(NCS)_6]$  have been reported [60].

### 10.10.2 Oxides

A series of distorted perovskites,  $CaRe_xRe_{1-x}O_3$  ( $x = 0.25, 0.33, 0.66$  or  $0.75$ ) has been prepared and characterised [61].

### 10.10.3 Complexes

$[ReCl_4(PPh_3)_2]$  reacts with  $LH_2$  ( $L = sal_2en, sal_2prop, sal_2phen$  or  $acac_2en$ ), in the presence of  $Et_3N$ , to give the novel Schiff base complexes  $[ReCl_2(L)]$ . In the absence of  $Et_3N$ , the products  $[ReCl_4(LH_2)]$  ( $L = sal_2en$  or  $sal_2prop$ ) were isolated [44].  $ReCl_5$  reacts with acetoxime,  $Me_2C=NOH$ , to give  $[ReCl_4[MeC(O)NHMe]]$  [62].

## 10.11 RHENIUM(III)

### 10.11.1 Halides and halide complexes

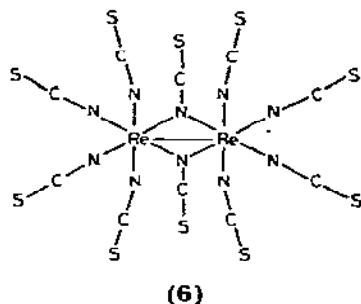

SCF-X $\alpha$ -SW calculations (without relativistic corrections) upon  $Re_3Cl_9$  and  $[Re_3Cl_{12}]^{3-}$  have been reported, and have been used to rationalise the low energy regions of their electronic spectra [63]. Ethanolic solutions of  $Re_3Cl_9$  react with  $L$  ( $L = 3\text{-methyl-1-phenylphosphole}$  or  $3,4\text{-dimethyl-1-phenylphosphole}$ ) to give the expected products,  $[Re_3Cl_9L_3]$  [64].

The crystal structure of  $[NH_4]_2[Re_2Cl_8] \cdot 2 H_2O$  has been determined ( $r(Re-Re) = 0.2234$  nm) [65], and the room temperature emission spectra of  $[Re_2Cl_8]^{2-}$  in  $CH_3CN$  and  $CH_2Cl_2$  have been reported [66].

$[Bu_4N]_2[Re_2I_8]$  (see also [67]) has been prepared by the reaction between  $[Bu_4N]_2[Re_2X_8]$  ( $X = Cl$  or  $Br$ ) and  $HI$  in  $CH_2Cl_2$ ; it is hydrolytically unstable, but stable in organic solvents and in the solid state. It has been characterised by UV, IR and Raman spectroscopy [68]. CV data have been reported for  $[NBu_4]_2[Re_2(NCS)_8]$  [60]. The complex  $[Bu_4N]_3[Re_2(NCS)_{10}]$  {originally believed to be  $[Bu_4N]_3[Re_2(NCS)_8(CO)_2]}$  has been characterised crystallo-

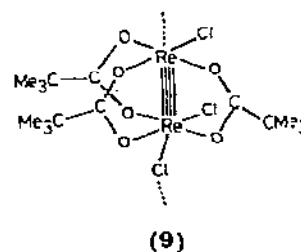

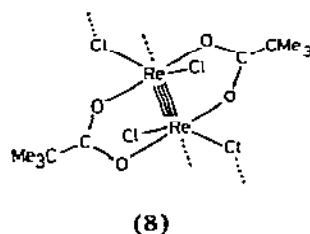

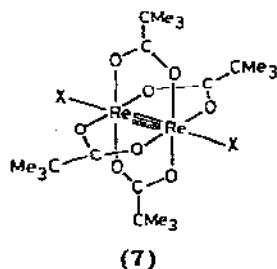

graphically, and shown to contain the anion (6), which contains a novel

bridging mode for  $\text{NCS}^-$ . This Re—Re bonded species ( $r(\text{Re—Re}) = 0.2613 \text{ nm}$ ) is a paramagnetic, mixed-valence complex [69].

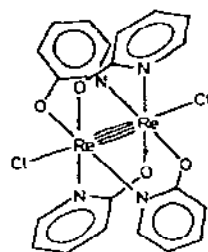

#### 10.11.2 Carboxylates and related systems

In the wake of the current interest in  $\text{M}_2(\text{O}_2\text{CR})_4$  ( $\text{M} = \text{Cr}$  or  $\text{Mo}$ ), the quadruply-bonded  $\text{Re}_2(\text{O}_2\text{CR})_4\text{X}_2$  systems, and many of their derivatives, have been the subject of extensive study. The molecular structures (7) of  $[\text{Re}_2(\text{O}_2\text{CCMe}_3)_4\text{X}_2]$  ( $\text{X} = \text{Cl}$  or  $\text{Br}$ ) reveal the anticipated geometry, with a linear  $\text{X—Re—Re—X}$  skeleton, and the electronic spectra of these systems have been briefly discussed [70]. Thermal decomposition of  $[\text{Re}_2(\text{O}_2\text{CCMe}_3)_4\text{Cl}_2]$  at  $220^\circ\text{C}$  yields the complexes  $[\text{Re}_2(\text{O}_2\text{CCMe}_3)_2\text{Cl}_4]$  (8) and  $[\text{Re}_2(\text{O}_2\text{CCMe}_3)_3\text{Cl}_3]$  (9), which were purified by fractional sublimation. Both (8) and (9) contain chains of dimeric units, linked by halogen bridges [71]; (8)

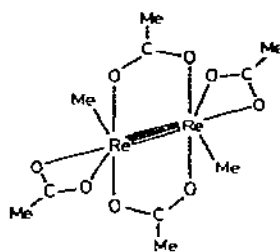

has a transoid structure (i.e. the  $\text{O}_2\text{CR}$  groups are above and below the plane of the  $\text{Re}_2\text{Cl}_4$  unit) [71], whereas  $[\text{Re}_2(\text{O}_2\text{CR})_2\text{Cl}_4]$  ( $\text{R} = \text{H}$  or  $\text{Me}$ ) are known to have cisoid structures [72,73]. *Cis—trans* isomerisation of mixed chloro-carboxylate dimers of dirhenium has now been reported [74] and the molecular structure of  $[\text{Re}_2(\text{O}_2\text{CMe})_2\text{Cl}_4(\text{dmsO})_2]$  (10) has been determined [75].

The reaction of  $[\text{NBu}_4]_2[\text{Re}_2\text{Cl}_8]$  with 2-hydroxypyridine ( $\text{py-2-OH}$ ) gives  $[\text{Re}_2(\text{py-2-O})_4\text{Cl}_2]$  (11), which has a shorter Re—Re bond than the analogous carboxylate complexes (see Table 1) [76]. On each Re atom, the N-atoms are mutually *cis*, as opposed to the more commonly occurring *trans* arrangement.

(11)

(12)

$[\text{Re}_2\text{Me}_2(\text{O}_2\text{CMe})_4]$  (12) has been prepared by the reaction between  $\text{Li}_2[\text{Re}_2\text{Me}_8] \cdot 2 \text{Et}_2\text{O}$  and ethanoic acid [77]; its structure (12) shows an unusual mode of coordination for two of the ethanoates, in that they are chelating rather than bridging [78] and the Re—Re bond is significantly shorter than in, say, (7) (see Table 1). The complexes  $[\text{Re}_2\text{R}_4(\text{O}_2\text{CMe})_2]$  ( $\text{R} = \text{CH}_2\text{SiMe}_3$ ,  $\text{CH}_3\text{CMe}_3$ ,  $\text{CH}_2\text{CMe}_2\text{Ph}$  or  $\text{CH}_2\text{Ph}$ ) were then prepared by reaction of (12) with  $\text{R}_2\text{Mg}$ . Reaction of (12) with  $\text{Cl}_2$  gives a polymeric product  $[\{\text{ReMe}(\text{O}_2\text{CMe})\text{Cl}\}_n]$  and with  $\text{MeOH}$  gives another polymeric species  $[\{\text{ReMe}(\text{O}_2\text{CMe})(\text{OMe})\}_n]$  [77]; the former product may be recrystallised from dmso to give  $[\text{Re}_2\text{Me}_2(\text{O}_2\text{CMe})_2\text{Cl}_2(\text{dmso})]$  (13) [77], whose structure has been determined [78]. It seems likely that both polymeric species thus consist of  $[\text{Re}_2\text{Me}_2(\text{O}_2\text{CMe})_2]$  units linked by Cl or OMe bridges, respectively.

$\text{Re}_3\text{Me}_9$  and  $[\text{Re}_3\text{Cl}_3(\text{CH}_2\text{SiMe}_3)_6]$  react with weak protonic acids (e.g. carboxylic acids,  $\beta$ -diketonates and diphenyltriazene) to give complete or partial loss of terminal alkyl groups as  $\text{CH}_4$  or  $\text{SiMe}_4$ , respectively. The rhenium complexes thus formed retain the *triangulo*- $\text{Re}_3$  skeleton and may be

TABLE 1  
Structural parameters

<sup>f</sup>  $r(\text{ReMe}) = 0.2127$  nm.

either monomeric with respect to this unit {e.g.  $[\text{Re}_3\text{Cl}_3(\text{O}_2\text{CPh})_6]$ ,  $[\text{Re}_3\text{Cl}_3(\text{CH}_2\text{SiMe}_3)_3(\text{O}_2\text{CPh})_3]$ ,  $[\text{Re}_3\text{Me}_6(\text{dik})_3]$  or  $[\text{Re}_3\text{Cl}_3(\text{CH}_2\text{SiMe}_3)_3(\text{PhN}_3\text{Ph})_3]$ } or dimeric, with two  $\text{Re}_3$  units linked by carboxylate bridges to give an  $\text{Re}_6$  species {e.g.  $[\text{Re}_6(\mu\text{-Cl})_6(\text{CH}_2\text{SiMe}_3)_6(\mu\text{-O}_2\text{CMe})_6]$  (14) or  $[\text{Re}_6(\mu\text{-Me})_6\text{Me}_6(\mu\text{-O}_2\text{CMe})_6]$ } [79]. In the structure of (14) as illustrated, the coordination

sphere of the atoms marked \* has been left incomplete for the sake of clarity; the two parallel  $\text{Re}_3$  planes may be eclipsed or staggered.

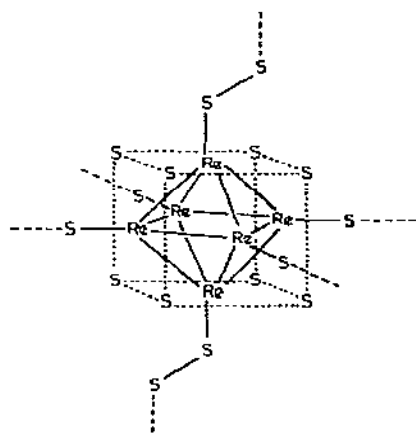

#### 10.11.3 Pentane-2,4-dionato- complexes

Reduction of *cis*- or *trans*- $[\text{Re}(\text{acac})_2\text{Cl}_2]$  with metallic sodium or potassium, or  $\text{Ti}(\text{acac})_3$ , gives green, air-sensitive  $\text{M}[\text{Re}(\text{acac})_2\text{Cl}_2]$  ( $\text{M} = \text{Na}$ ,  $\text{K}$  or  $\text{Ti}$ ).  $\text{K}[\text{Re}(\text{acac})_2\text{Br}_2]$  was prepared in an analogous manner. The anion has the same configuration, irrespective of the geometry of the starting material [80]. The molecular structure of  $[\text{AsPh}_4][\text{Re}(\text{acac})_2\text{Cl}_2]$  (prepared by metathesis from the  $\text{K}^+$  salt) shows the configuration of the anion to be *trans* ( $\bar{r}(\text{ReCl}) = 0.240 \text{ nm}$ ,  $\bar{r}(\text{ReO}) = 0.201 \text{ nm}$ ) [81]. Reduction of  $[\text{Re}(\text{acac})_2\text{Cl}_2]$  with powdered zinc in  $\text{acacH}$  is a convenient preparation for  $[\text{Re}(\text{acac})_3]$  [80].

#### 10.11.4 Sulphides

The reaction of  $\text{Re}$ ,  $\text{K}[\text{ReO}_4]$  or  $\text{ReS}_2$  with an excess of  $\text{A}_2\text{CO}_3$  ( $\text{A} = \text{Na}$  or  $\text{K}$ ) and sulphur at  $750^\circ\text{C}$  gives red crystals of a compound,  $\text{A}_4\text{Re}_6\text{S}_{12}$  (15).

The structure (15) consists of  $\text{Re}_6$  octahedra located in cubes of sulphide

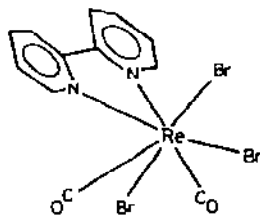

(15)

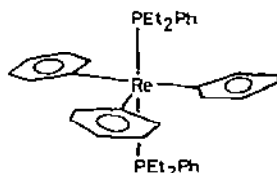

ions, which thus cap the faces of the octahedra. The four equatorial Re atoms are linked by a terminal sulphur atom to adjacent  $\text{Re}_6$  octahedra, whilst the two axial Re atoms are similarly linked via an  $(\text{S}_2)^{2-}$  bridge. The red insulating crystals turn to black semiconducting crystals upon standing in air. The identity of the black form remains to be established [82].

#### 10.11.5 Amine and phosphine complexes

Seven-coordinate  $\text{Re(III)}$  complexes,  $[\text{ReX}_3(\text{CO})_2(\text{LL})]$  ( $\text{X} = \text{Cl}$  or  $\text{Br}$ ,  $\text{LL} = \text{bipy}$ ;  $\text{X} = \text{Br}$ ,  $\text{LL} = 2,9\text{-Me}_2\text{phen}$ ), have been prepared by oxidation of *fac*- $[\text{ReX}(\text{CO})_3(\text{LL})]$  with  $\text{X}_2$  and the molecular structure of  $[\text{ReBr}_3(\text{CO})_2(\text{bipy})]$  (16) shows the Re to be in a capped-octahedral environment [83]. The structure of  $[\text{Re}(\eta^5\text{-Ph})_3(\text{PEt}_2\text{Ph})_2]$  (17) reveals a trigonal bipyramidal structure,

(16)

(17)

with a near-planar array of equatorial phenyl groups, and a relatively short  $\{\bar{r}(\text{ReC}) = 0.2027 \text{ nm}\}$   $\text{Re}-\text{C}$  bond indicates the presence of significant  $d_{\pi}-p_{\pi}$  back-bonding [84].

The molecular structure of  $[\text{Re}(\text{NCS})_3(\text{dppe})(\text{PEt}_2\text{Ph})]$  reveals it to have a *meridional* configuration, with  $\text{Re}-\text{NCS}$  being an *isothiocyanato*-linkage [60].

The complexes  $[\text{Re}(\text{NCS})_3(\text{PEt}_2\text{Ph})(\text{LL})]$  ( $\text{LL} = \text{dppe}$ ,  $\text{bipy}$  or  $\text{phen}$ ) show one reversible oxidation wave (to  $[\text{Re}(\text{NCS})_3(\text{PEt}_2\text{Ph})(\text{LL})]^+$ ) and two reversible reduction waves (to  $[\text{Re}(\text{NCS})_3(\text{PEt}_2\text{Ph})(\text{LL})]^{-/2-}$ ) in their cyclic voltammograms [60].

#### 10.11.6 Isocyanide complexes

Oxidative addition of  $\text{Br}_2$  to  $[\text{Re}(\text{CO})\text{L}_4\text{Br}]$  ( $\text{L} = \text{CNMe}$  or  $4\text{-CN-C}_6\text{H}_4\text{Me}$ ) gives  $[\text{ReL}_4\text{Br}_3]$ . The molecular structure of the 4-tolyl isocyanide complex shows it to be seven-coordinate, with a capped octahedral geometry; it contains three *fac* bromides, three *fac* CNR ligands, and a capping fourth CNR ligand [85].

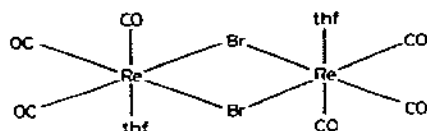

#### 10.12 RHENIUM(I)

As all the chemistry of rhenium(I) published this year has concerned carbonyls, the compounds are classified below according to the anionic ligands present.

##### 10.12.1 Halides

The thermodynamic properties of  $[\text{ReX}(\text{CO})_5]$  ( $\text{X} = \text{Cl}$ ,  $\text{Br}$  or  $\text{I}$ ) have been calculated [16], and a convenient preparation of  $[\text{ReI}(\text{CO})_5]$  from  $[\text{Re}_2(\text{CO})_{10}]$  and  $\text{I}_2$  has been reported [86]. IR and Raman data for  $[\text{ReX}(\text{CO})_5]$  ( $\text{X} = \text{Cl}$  or  $\text{Br}$ ) have also been reported [87].

Prolonged reaction between  $[\text{ReX}(\text{CO})_5]$  ( $\text{X} = \text{Cl}$ ,  $\text{Br}$  or  $\text{I}$ ) and  $[\text{NEt}_4]\text{X}$  yields  $[\text{NEt}_4][(\text{CO})_3\text{Re}(\mu\text{-X})_3\text{Re}(\text{CO})_3]$ , the presence of the triple halide bridge being deduced by vibrational analysis [88]. The presence of the double halide bridge in  $[\text{Re}_2\text{Br}_2(\text{CO})_6(\text{thf})_2]$  (18) has been confirmed by X-ray crystallography  $\{r(\text{ReRe}) = 0.3967 \text{ nm}\}$  [89]. (18) is a convenient starting mate-

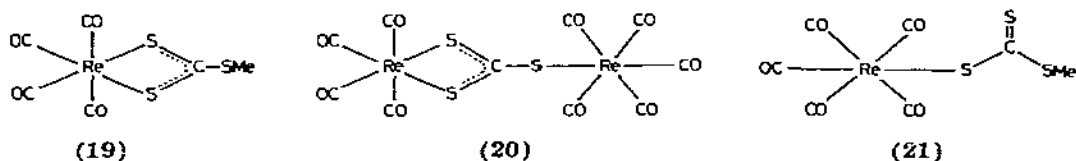

(18)

rial for the preparation of mixed ligand complexes of type  $[\text{ReBr}(\text{CO})_3(\text{L})_2]$  {e.g.  $\text{L} = \text{PPh}_2\text{Cl}$ ,  $\text{PPh}_2\text{H}$  or  $\text{Me}_2\text{NH}$ }, when  $\text{L}$  is in excess. When (18) is in excess, in the reaction with  $\text{PPh}_2\text{H}$ ,  $[\text{Re}_2\text{Br}_2(\text{CO})_6(\text{PPh}_2\text{H})_2]$  forms, which will react with further ligand to give  $[\text{ReBr}(\text{CO})_3(\text{PPh}_2\text{H})_2]$  [89].  $[\text{ReBr}(\text{CO})_5]$  reacts with  $\text{LH}$  ( $\text{LH} = \text{cysteine}$  or  $\text{threonine}$ ) to give *fac*- $[\text{ReBr}(\text{CO})_3(\text{HL})_2]$ , which further reacts with methanolic  $\text{KOH}$  to yield  $[\text{Re}(\text{CO})_3\text{L}]_n$ . This, with pyridine, yields  $[\text{Re}(\text{CO})_3\text{L}(\text{py})]$ , whereas *fac*- $[\text{ReBr}(\text{CO})_3(\text{LH})_2]$  gives only  $[\text{ReBr}(\text{CO})_3(\text{py})_2]$  [90].

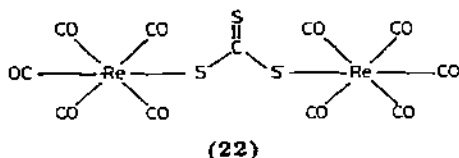

The molecular structure of  $[\text{ReBr}(\text{CO})_3(\text{Me}_2\text{NCH}_2\text{CH}_2\text{NMe}_2)]$  reveals it to be in a *facial* configuration  $\{r(\text{ReBr}) = 0.2636 \text{ nm}\}$  [91]. The structurally related compounds *fac*- $[\text{ReX}(\text{CO})_3(\text{L})_2]$  ( $\text{X} = \text{Cl}, \text{Br}$  or  $\text{I}$ ;  $\text{L} = 4\text{-phenylpyridine}$  or  $4,4'\text{-bipyridine}$ ) luminesce, both in solution at 298 K and at 77 K [92]; these complexes were prepared by the reaction between  $[\text{ReX}(\text{CO})_5]$  and excess  $\text{L}$  at  $60^\circ\text{C}$ . In a similar manner,  $[\text{ReX}(\text{CO})_5]$  ( $\text{X} = \text{Cl}$  or  $\text{Br}$ ) reacts with various 1,4-diazabutadienes to give *fac*- $[\text{ReCl}(\text{CO})_3(\text{RN}=\text{CHCH}=\text{NR})]$  ( $\text{R} = \text{Me}_3\text{C}, \text{Me}_2\text{CH}$  or  $4\text{-MeC}_6\text{H}_4$ ) and *fac*- $[\text{ReBr}(\text{CO})_3(\text{Me}_3\text{CN}=\text{CHCH}=\text{NCMe}_3)]$  [93]. These complexes react with  $[\text{Mn}(\text{CO})_5]^-$  to yield  $[(\text{CO})_5\text{Mn-Re}(\text{CO})_3(\text{RN}=\text{CHCH}=\text{NR})]$  ( $\text{R} = \text{Me}_2\text{CH}$  or  $4\text{-MeC}_6\text{H}_4$ ) [94].

#### 10.12.2 Dithiocarbamate, trithiocarbonate, selenides and related complexes

The reaction of  $\text{Na}[\text{Re}(\text{CO})_5]$  with  $\text{CS}_2$ , followed by addition of  $\text{MeI}$ , gave the trithiocarbonate complexes,  $[\text{Re}(\text{CO})_4(\text{S}_2\text{CSMe})]$  (19) and  $[\{\text{Re}(\text{CO})_4\}(\mu\text{-CS}_3)\{\text{Re}(\text{CO})_5\}]$  (20).  $[\text{Re}(\text{CO})_5\{\text{SC}(\text{S})\text{SMe}\}]$  (21), prepared by the reac-

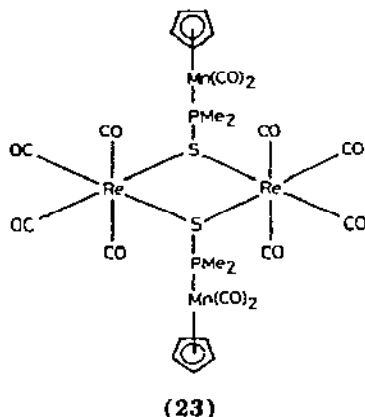

tion of  $[\text{ReBr}(\text{CO})_5]$  with  $\text{Na}[\text{CS}_2(\text{SMe})]$ , readily thermally decarbonylates to give (19). (20) can be formed in high yield by reacting  $\text{Na}[\text{Re}(\text{CO})_5]$  with  $\text{CS}_2$ , followed by  $[\text{ReBr}(\text{CO})_5]$ . Mixed  $\text{Mn}/\text{Re}$  analogues of (20) were also prepared by this route (i.e. using either  $\text{Na}[\text{Mn}(\text{CO})_5]$  or  $[\text{MnBr}(\text{CO})_5]$ ) [95]. When  $\text{S}_8$ , and then  $\text{CS}_2$ , are added to  $\text{Na}[\text{Re}(\text{CO})_5]$ , followed by  $[\text{ReBr}(\text{CO})_5]$ , the complex  $[\{\text{Re}(\text{CO})_5\}(\mu\text{-CS}_3)\{\text{Re}(\text{CO})_5\}]$  (22) is formed [95].

$[\text{ReBr}(\text{CO})_3(\text{Me}_2\text{NH})_2]$  will react with  $\text{CS}_2/\text{Me}_2\text{NH}$  to give  $[\text{Re}(\text{CO})_3(\text{Me}_2\text{NH})(\text{S}_2\text{CNMe}_2)]$ ; reaction of  $[\text{Re}_2\text{Br}_2(\text{CO})_6(\text{thf})_2]$  with  $\text{Et}_2\text{NH}/[\text{Et}_2\text{NCS}_2]^-$  gives  $[\text{Re}(\text{CO})_3(\text{Et}_2\text{NH})(\text{S}_2\text{CNEt}_2)]$ ; treatment of  $[\text{Re}_2\text{Br}_2(\text{CO})_8]$  with  $[\text{R}_2\text{NCS}_2]^-$  ( $\text{R} = \text{Me}$  or  $\text{Et}$ ) in the presence of  $\text{CO}$  gives  $[\text{Re}(\text{CO})_4(\text{S}_2\text{CNR}_2)]$  [89].  $[\text{Re}(\text{CO})_4(\text{S}_2\text{CNMe}_2)]$  has also been prepared by the reaction of  $[\text{ReBr}(\text{CO})_5]$  with  $[\text{NMe}_2\text{H}_2][\text{S}_2\text{CNMe}_2]$  in benzene;  $[\text{Re}(\text{CO})_4\{\text{S}(\text{O})\text{CNMe}_2\}]$  and  $[\text{Re}(\text{CO})_4\{\text{Se}(\text{O})\text{CNMe}_2\}]$  were formed in analogous reactions.  $[\text{Re}(\text{CO})_4(\text{LL}')]$   $\{\text{LL}' = \text{S}(\text{Se})\text{CNMe}_2 \text{ or } \text{Se}_2\text{CNMe}_2\}$  were prepared by treatment of  $[\text{ReBr}(\text{CO})_5]$  with  $[\text{SnMe}_2\text{Cl}\{\text{S}(\text{Se})\text{CNMe}_2\}]$  or  $[\text{SnMe}_2(\text{Se}_2\text{CNMe}_2)_2]$ , respectively [96]. These complexes undergo solid state thermolysis to give the dimers  $[\{\text{Re}(\text{CO})_3\{\text{X}(\text{Y})\text{CNMe}_2\}\}_2]$  ( $\text{XY} = \text{S}_2, \text{SSe}, \text{Se}_2, \text{SO}$  or  $\text{SeO}$ ) or

$[\{\text{Re}(\text{CO})_4[\text{X}(\text{O})\text{CNMe}_2]\}_2]$  ( $\text{X} = \text{S}$  or  $\text{Se}$ ) [96]. Treatment of  $\text{Na}[\text{Re}(\text{CO})_5]$  with  $\text{MeNCS}$ , followed by  $\text{MeI}$ , gives a mixture of *cis*- $[\text{Re}(\text{CO})_4\text{I}(\text{CNMe})]$ ,  $[\text{Re}(\text{CO})_4(\text{S}_2\text{CNHMe})]$  and *fac*- $[\text{Re}(\text{CO})_3(\text{S}_2\text{CNHMe})(\text{CNMe})]$  [97].

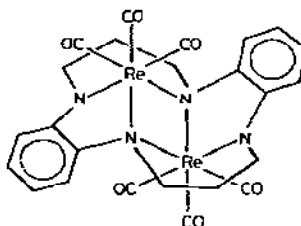

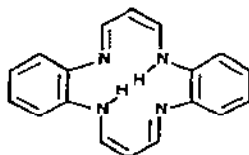

Reaction of  $[\text{ReCl}(\text{CO})_5]$  with  $\text{Na}[(\text{cp})\text{Mn}(\text{CO})_2(\text{PMe}_2\text{S})]$  yields the dimeric complex  $[(\text{CO})_4\text{Re}\{(\text{cp})\text{Mn}(\text{CO})_2(\text{PMe}_2\text{S})\}_2\text{Re}(\text{CO})_4]$  (23) [98].

$[\{(\text{CO})_4\text{Re}(\text{SeX})\}_2]$  ( $\text{X} = \text{H}$  or  $\text{SnMe}_3$ ) reacts with  $\text{PMe}_3$  to give  $[(\text{Me}_3\text{P})(\text{CO})_3\text{Re}(\text{SeX})]_2$  and  $[(\text{Me}_3\text{P})_2(\text{CO})_3\text{Re}(\text{SeX})]$ ; treatment of the  $\text{SnMe}_3$  derivative with  $\text{HCl}$  converts it to the H derivative. The structure of  $[(\text{Me}_3\text{P})_2(\text{CO})_3\text{Re}](\mu\text{-Se})\{\text{Re}(\text{CO})_3(\text{PMe}_3)_2\}$ , a by-product of the above preparation, has been determined by X-ray crystallography [99].

### 10.12.3 Complexes with Group VB ligands

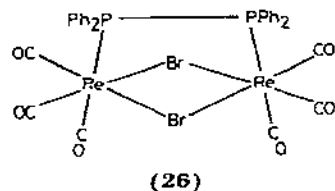

The reaction between  $[\text{Re}_2(\text{CO})_{10}]$  and 1,8-dihydrodibenzo[*b, i*][1,4,8,11]-tetraazaannulene ( $\text{taaH}_2$ ; 24) gives the unusual binuclear complex  $[(\text{CO})_3\text{Re}(\mu\text{-taa})\text{Re}(\text{CO})_3]$  (25), in which each Re atom is bonded to three N atoms,

two of which bridge the metal atoms  $\{r(\text{ReRe}) = 0.3345 \text{ nm}\}$  [100].

$\text{C}_4\text{Ph}_4\text{ECl}$  ( $\text{E} = \text{P}$ ,  $\text{As}$  or  $\text{Sb}$ ) reacts with  $[\text{Re}(\text{CO})_5]^-$  to give the Re-E  $\sigma$ -bonded complexes,  $[\text{Re}(\text{CO})_5(\text{EC}_4\text{Ph}_4)]$ . Upon heating, the phosphole and arsole derivatives lose CO to form dimeric species,  $[(\text{CO})_4\text{Re}(\mu\text{-EC}_4\text{Ph}_4)_2\text{Re}(\text{CO})_4]$  ( $\text{E} = \text{P}$  or  $\text{As}$ ).  $[\text{Re}(\text{CO})_5(\text{EC}_4\text{Ph}_4)]$  ( $\text{E} = \text{P}$ ,  $\text{As}$  or  $\text{Sb}$ ) react with  $\text{Cl}_2$  or

$\text{Br}_2$  to reform  $[\text{ReX}(\text{CO})_5]$  and  $\text{C}_6\text{Ph}_4\text{EX}$  ( $\text{X} = \text{Cl}$  or  $\text{Br}$ ) [101].  $\text{HNSOF}_2$  reacts with  $[\text{Re}(\text{CO})_5(\text{SO}_2)][\text{AsF}_6]$  to give the  $N$ -bonded complex  $[\text{Re}(\text{CO})_5(\text{HNSOF}_2)][\text{AsF}_6]$  [102]. The reaction of  $[\text{ReBr}(\text{CO})_5]$  or  $[\text{Re}_2\text{Br}_2(\text{CO})_6(\text{thf})_2]$  with  $\text{P}_2\text{Ph}_4$  gives  $[(\text{CO})_3\text{Re}(\mu\text{-Br})_2(\mu\text{-P}_2\text{Ph}_4)\text{Re}(\text{CO})_3]$  (26), which has

been characterised by X-ray crystallography [103], whereas the reaction of  $[\text{MnRe}(\text{CO})_{10}]$  with  $\text{As}_2(\text{CF}_3)_4$  gives  $[(\text{CO})_4\text{Re}\{\mu\text{-As}(\text{CF}_3)_2\}_2\text{Mn}(\text{CO})_4]$  [104].

#### 10.12.4 Organometallic derivatives

Methylolithium reacts with  $[\text{ReX}(\text{CO})_5]$  ( $\text{X} = \text{Cl}$ ,  $\text{Br}$ ,  $\text{I}$  or  $\text{H}$ ) at  $-78^\circ\text{C}$ , not to give the expected  $[\text{ReMe}(\text{CO})_5]$ , but to form the acetyl derivatives  $\text{Li}[\text{cis-Re}(\text{CO})_4\text{X}\{\text{C}(\text{O})\text{CH}_3\}]$ . Similar reactions of  $[\text{ReX}(\text{CO})_5]$  ( $\text{X} = \text{Cl}$ ,  $\text{Br}$  or  $\text{I}$ ) with  $\text{Li}[\text{BEt}_3\text{H}]$  yield the corresponding formyl complexes  $\text{Li}[\text{cis-Re}(\text{CO})_4\text{X}\{\text{C}(\text{O})\text{H}\}]$  [86]. Reaction of  $[\text{Re}(\text{CO})_5\{\text{C}(\text{O})\text{R}\}]$  ( $\text{R} = \text{Me}$ ,  $\text{Me}_2\text{CH}$  or  $\text{PhCH}_2$ ) with two equivalents of  $\text{LiMe}$  affords the triacyl anion, *fac*- $[\text{Re}(\text{CO})_3\{\text{C}(\text{O})\text{R}\}\{\text{C}(\text{O})\text{Me}\}_2]^{2-}$ ; analogous reactions occur with  $[\{\text{Re}(\text{CO})_5\{\text{C}(\text{O})(\text{CH}_2)\}_2(\text{CH}_2)_n\}]$  ( $n = 4$  or  $5$ ) [105]. These species are tridentate ligands (cf. triacetyl-methanide anion), and form complexes with various metal ions e.g.  $[\{\text{Re}(\text{CO})_3[\text{C}(\text{O})\text{R}][\text{C}(\text{O})\text{Me}\}_2\text{M}]^-$  ( $\text{M} = \text{Al}$  or  $\text{Ga}$ ) and  $[\{\text{Re}(\text{CO})_3[\text{C}(\text{O})\text{R}][\text{C}(\text{O})\text{Me}\}_2\text{M}]$  ( $\text{M} = \text{Hf}(\text{IV})$  or  $\text{Zr}(\text{IV})$ ) [105].

The reaction of  $[\text{Re}_2\text{Cl}_2(\text{CO})_8]$  with  $\text{K}[\text{HB}(3,5\text{-Me}_2\text{C}_3\text{HN}_2)_3]$  gives the expected  $[\text{Re}\{\text{HB}(3,5\text{-Me}_2\text{C}_3\text{HN}_2)_3\}(\text{CO})_3]$  (cf.  $[\text{Re}(\text{cp})(\text{CO})_3]$ ), as well as the pyrazole derivative,  $[\text{ReCl}(\text{CO})_3(3,5\text{-Me}_2\text{C}_3\text{HN}_2)_2]$ . Reaction of  $[\text{Re}\{\text{HB}(3,5\text{-Me}_2\text{C}_3\text{HN}_2)_3\}(\text{CO})_3]$  with  $\text{Br}_2$  resulted, not in the oxidation of the metal, but in the bromination of the pyrazolyl rings to give  $[\text{Re}\{\text{HB}(3,5\text{-Me}_2\text{-4-BrC}_3\text{N}_2)_3\}(\text{CO})_3]$  [106].

The reaction of  $[\text{ReBr}(\text{CO})_5]$  with  $\text{Ph}_2\text{P}(\text{CH}_2)_3\text{MgCl}$  in *thf* gives the unusual metallacycle  $[(\text{CO})_4\text{Re}(\text{PPh}_2\text{CH}_2\text{CH}_2\text{CH}_2)]$  [107].

#### 10.12.5 Complexes with Group IVB ligands

$[\text{Re}_2(\text{CO})_{10}]$  reacts with  $\text{SnX}_2$  ( $\text{X} = \text{Cl}$ ,  $\text{Br}$  or  $\text{I}$ ) to give  $[(\text{CO})_4\text{Re}\{\mu\text{-SnX-Re}(\text{CO})_5\}_2\text{Re}(\text{CO})_4]$  and  $[\text{X}_2\text{Sn}\{\text{Re}(\text{CO})_5\}_2]$ ;  $[(\text{CO})_4\text{Re}\{\mu\text{-GeI}[\text{Re}(\text{CO})_5\}]_2\text{Re}(\text{CO})_4]$  was formed in an analogous manner [108].  $[\text{Re}(\text{CO})_5(\text{SnPh}_3)]$  has been studied by DTA [109].

The complexes  $[\text{Re}(\text{EPh}_3)(\text{CO})_3(\text{LL})]$  ( $\text{E} = \text{Ge}$  or  $\text{Sn}$ ;  $\text{LL} = \text{bipy}$  or  $\text{phen}$ ) were prepared by treating  $[\text{Re}(\text{CO})_3(\text{LL})]^-$  (formed by  $\text{Na}/\text{Hg}$  reduction of  $[\text{ReCl}(\text{CO})_3(\text{LL})]$ ) with  $\text{Ph}_3\text{GeBr}$  or  $\text{Ph}_3\text{SnCl}$  in tetrahydrofuran. These com-

plexes allow evaluation of the rate constant,  $k^*$ , associated with the excited state homolytic fission of the Re—Ge or Re—Sn bond:

This process competes with radiative decay of the undissociated complex [110].

#### 10.12.6 Complexes with Group IIIB ligands

The reaction between  $\text{InX}$  ( $\text{X} = \text{Cl}, \text{Br}$  or  $\text{I}$ ) and  $[\text{Re}_2(\text{CO})_{10}]$  at  $150\text{--}160^\circ\text{C}$  gives  $[\{(\text{CO})_5\text{Re}\}_2\text{In}(\mu\text{-X})_2\text{In}\{\text{Re}(\text{CO})_5\}_2]$ ; the molecular structure of all three products has been determined [111].

#### 10.13 RHENIUM(0)

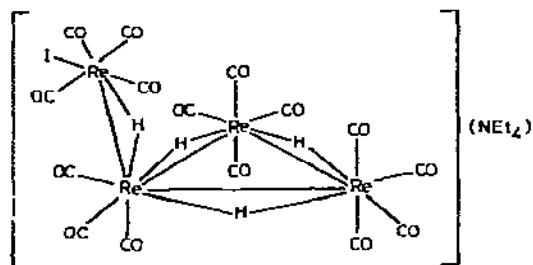

Reduction of the rhenium(I)—phosphinic acid complexes,  $[\text{ReBr}(\text{CO})_4(\text{PR}_2\text{OH})]$  ( $\text{R} = \text{Me}$  or  $\text{Ph}$ ), with  $\text{Na/Hg}$  in ether gives the dimeric rhenium(0) complexes,  $\text{Na}_2[\{(\text{R}_2(\text{O})\text{P}(\text{CO})_4\text{Re}-\text{Re}(\text{CO})_4\{\text{P}(\text{O})\text{R}_2\})\}]$ . Further reaction of these dimers with  $\text{Na/Hg}$  in the presence of dimethylsulphate and thf gives  $[\text{MeRe}(\text{CO})_4\{\text{P}(\text{OMe})\text{R}_2\}]$  [112].

#### 10.14 RHENIUM CARBONYL CLUSTERS

Chemisorption of CO on the  $\text{Re}(0001)$  surface results in a non-uniform attenuation of the strongly angular dependent photoemission from the Re 5d bands of the pure metal [113].

The Raman spectrum of  $[\text{Re}_2(\text{CO})_{10}]$  has been the subject of a detailed investigation [114].

UV irradiation of  $[(\mu\text{-H})_3\text{Re}_3(\text{CO})_{12}]$  in solution leads to the quantitative formation of  $[(\mu\text{-H})_2\text{Re}_2(\text{CO})_8]$ ; photolysis in the presence of CO gives  $[\text{HRe}(\text{CO})_5]$  and  $[(\mu\text{-H})_2\text{Re}_2(\text{CO})_8]$ , the latter thermally reacting with CO to give  $[\text{HRe}(\text{CO})_5]$  and  $[\text{Re}_2(\text{CO})_{10}]$  [115]. Reaction of  $[\text{NEt}_4]_2[\text{H}_4\text{Re}_4(\text{CO})_{15}]$  with ethanolic iodine gave  $[\text{NEt}_4][\text{H}_4\text{Re}_4(\text{CO})_{15}\text{I}]$  (27), implying electrophilic attack of  $\text{I}^+$  on the cluster. The structure of this complex (27) has

(27)

been determined by X-ray crystallography, but the hydrides were not located [116].

The molecular structure of  $[\text{Re}_4(\text{CO})_{12}(\mu_3\text{-InRe}(\text{CO})_5)_4]$  confirms that each  $\{\text{InRe}(\text{CO})_5\}$  group caps a face of the central  $\text{Re}_4$  tetrahedron  $\{\bar{r}(\text{ReRe}) = 0.3016 \text{ nm}\}$ , each Re of which is bonded to three terminal carbonyls [117].

The reaction of either  $[\text{Re}_2(\text{CO})_{10}]$  or  $[\text{ReCl}(\text{CO})_5]$  with water at  $200^\circ\text{C}$  gives a compound  $[\text{Re}(\text{CO})_3(\text{OH})]_4$ . A pseudocubane structure without Re—Re bonds has been proposed, containing triply-bridging hydroxyl groups. The OH groups are acidic, reacting with  $\text{RCHN}_2$  ( $\text{R} = \text{H}$  or  $\text{CH}_3$ ) to give  $[\text{Re}(\text{CO})_3(\text{OCH}_2\text{R})]_4$ , with  $\text{D}_2\text{O}$  in ether to give  $[\text{Re}(\text{CO})_3(\text{OD})(\text{OEt}_2)]_4$ , and with lithium to give  $[\text{Re}(\text{CO})_3\text{O}^-\text{Li}^+]_4$ .  $[\text{Re}(\text{CO})_3(\text{OH})]_4$  also forms adducts with Lewis bases, L, to give  $[\text{Re}(\text{CO})_3(\text{OH})\text{L}]_4$  (where  $\text{L} = \text{thf}$ ,  $\text{OPPh}_3$  or  $\text{Br}^-$ ) [118].

The unusual complexes  $[(\text{CO})_3\text{Re}-\{\text{M}(\text{L}_4)\}-\text{Re}(\text{CO})_3]$   $\{\text{M} = \text{Sn}, \text{Zn}, \text{Mg}$  or  $\text{Co}; \text{L}_4 = \text{phthalocyanine}$  or  $\text{tetraphenylporphyrin}\}$  [119] and  $[(\text{CO})_3\text{ReC}-\{\text{Sn}(\text{TPP})\}\text{CRe}(\text{CO})_3]$   $\{\text{TPP} = \text{tetraphenylporphyrin}\}$  [120] have been prepared, the latter having been structurally characterised by X-ray crystallography.

#### 10.15 THIONITROSYL AND NITROSYL COMPLEXES

The first detailed account of thionitrosyl complexes has finally appeared.  $[\text{ReX}_2\text{N}(\text{PR}_3)_3]$  ( $\text{X} = \text{Cl}$  or  $\text{Br}$ ;  $\text{R}_3 = \text{Me}_2\text{Ph}$ ,  $\text{Et}_2\text{Ph}$  or  $\text{MePh}_2$ ) and  $[\text{ReCl}_2\text{N}(\text{PR}'_3)_2]$  ( $\text{R}'_3 = \text{Ph}_3$  or  $\text{PrPh}_2$ ) react with half an equivalent of  $\text{S}_2\text{Cl}_2$  to give  $[\text{ReCl}(\text{X})(\text{NS})(\text{PR}_3)_3]$  and  $[\text{ReCl}_3(\text{NS})(\text{PR}'_3)_2]$ , respectively; with excess  $\text{S}_2\text{Cl}_2$  ( $\text{X} = \text{Cl}$ ),  $[\text{ReCl}_3(\text{NS})(\text{PR}_3)_2]$  is formed. Similarly, the reaction of  $[\text{ReClN}(\text{dppe})_2]\text{Cl}$  with  $\text{S}_2\text{Cl}_2$  yields  $[\text{ReCl}(\text{NS})(\text{dppe})_2]^+$ . The reaction of  $[\text{ReCl}_2(\text{NS})(\text{PMe}_2\text{Ph})_3]$  with  $[\text{S}_2\text{CNMe}_2]^-$  or  $[\text{SCN}^-]$  gave  $[\text{ReCl}(\text{S}_2\text{CNMe}_2)(\text{NS})(\text{PMe}_2\text{Ph})_2]$  or  $[\text{ReCl}(\text{SCN})(\text{NS})(\text{PMe}_2\text{Ph})_3]$ , respectively, whereas a similar reaction of  $[\text{ReCl}(\text{NS})(\text{dppe})_2]\text{Cl}$  with  $[\text{S}_2\text{CNEt}_2]^-$  gave only  $[\text{ReCl}(\text{NS})(\text{dppe})_2][\text{S}_2\text{CNEt}_2]$  [121].

XPES data for  $\text{A}_2[\text{Re}(\text{NO})\text{X}_5]$ ,  $\text{A}[\text{Re}(\text{NO})\text{X}_4(\text{L})]$ ,  $[\text{Re}(\text{NO})(\text{PPh}_3)_2\text{X}_3]$  and  $[\text{Re}(\text{NO})(\text{dppe})_2\text{I}]\text{I}$   $\{\text{A} = \text{Et}_4\text{N}; \text{X} = \text{Cl}, \text{Br}$  or  $\text{I}; \text{L} = \text{py}$  or  $4\text{-Me-py}\}$  have been presented [122]. The base hydrolysis of  $[\text{Re}(\text{NO})\text{Cl}_3]$  has been studied [123].

#### 10.16 CYANIDES

The complete coordination chemistry of unsubstituted cyanorhenates has been re-investigated, in an excellent study by Griffith et al. [124]. Only the existence of salts of  $[\text{Re}(\text{CN})_6]^{5-}$  and  $[\text{Re}(\text{CN})_7]^{4-}$  has been confirmed, despite a fantastically large range of species which had previously been described in the literature. Space limitations forbid the full description which this work deserves, but the reader is urged to read this elegant example of fundamental research. Other complexes isolated in this study include salts of  $[\text{Re}_4(\text{CN})_{12}(\mu_3\text{-S})_4]^{4-}$ ,  $[\text{Re}_4(\text{CN})_{12}(\mu_3\text{-Se})_4]^{4-}$ ,  $[\text{Re}_2(\text{CN})_8(\mu_2\text{-S})_2]^{4-}$  and  $[\text{Re}(\text{CN})_5(\text{NO})]^{3-}$  [124].
