## A. INTRODUCTION

Since its discovery by Furst in 1963 [1], metal chelation continues to play an important role in the cure and cause of malignancy. The finding of Rosenberg et al. [2] that platinum compounds can be safely used to treat certain types of cancer (Neoplatin is still the largest selling drug for the treatment of cancer in the U.S.A.) placed the coordination chemists on the front line in the fight against cancer. Organotin compounds show a spectrum of biological effects and have been extensively studied as fungicides, bactericides, acaricides and wood preservatives [3,4]. However, only scanty and scattered information is available on their activity against cancer.

This article collects the scattered information in the literature and gives an insight into the present state of the field.

## B. VARIOUS ORGANOTIN COMPOUNDS AND THEIR ACTIVITIES

In 1973 Atsushi et al. [5], in a very important piece of work, reported the very high affinity of tin for tumors (highest among the group 14 elements). This finding was further confirmed by various workers who prepared tin-labelled technetium complexes and used them as imaging agents for tumor localization [6]. Although the first organotin(IV) compound was tested for its antitumor activity in 1929, no systematic study was undertaken afterwards and as a result only 1509 organotin compounds had been tested in various tumor systems by the end of 1981 [7]. As shown in Table 1, 25% of all the compounds tested against the P388 Lymphocyte Leukaemia were active while only 1% showed activity against L1210 Lymphocyte Leukaemia. In both the systems, the most profound activity was shown by diorganotin compounds.

<sup>a</sup> Adducts tested against L1210 Lymphocyte Leukaemia. <sup>b</sup> Data supplied by National Cancer Institute, U.S.A.

Much of the current interest dates back to the work of Brown in the early eighties. In her fundamental work, Brown noted that triphenyltin acetate exhibited antitumor activity in mice, whereas triphenyltin chloride was inactive [8]. She hypothesized that the degree of water solubility was an important factor in organotin anticarcinogenicity. In 1975 Ozaki et al. [9] patented some 2',3'-*O*-dialkylstannyl derivatives of 5-fluorouridine (Fig. 1) as anticarcinogenic agents. The compound caused the shrinkage of the solid tumor when injected directly.

Fig. 1. 2',3'-*O*-Dialkylstannyl derivatives of 5-fluorouridine.

Bulten and Budding [10] also reported on the antitumor activity of  $(\text{ClMe}_2\text{Sn})_2\text{O}$ ,  $(\text{Et}_2\text{SnO})_n$ ,  $\text{Ph}_2\text{Sn}(\text{OH})\text{Cl}$  and 14 other structural analogues.

In 1980, Crowe et al. [11] published the first detailed report on the antitumor activity of a series of diorganotin dihalide and pseudohalide complexes  $\text{R}_2\text{SnX}_2 \cdot 2\text{L}$  ( $\text{R} = \text{Me}$ ,  $\text{Et}$ ,  $\text{Pr}$ ,  $n\text{-Bu}$  or  $\text{Ph}$ ;  $\text{X} = \text{F}$ ,  $\text{Cl}$ ,  $\text{Br}$ ,  $\text{I}$ ;  $2\text{L} = \text{bipyridyl}$ ,  $\text{phenanthroline}$ ,  $2\text{-aminomethylpyridine}$ ;  $\text{L} = \text{dimethyl sulphoxide}$ ,  $\text{pyridine}$  etc.) (Table 2).

A special feature of these complexes was that they were modelled on the active square-planar  $\text{Pt}(\text{II})$  complexes which have *cis* halogen groups. On the basis of the high activity of  $\text{Et}_2\text{SnCl}_2 \cdot 2\text{L}$  complexes, they suggested that since  $\text{Et}_2\text{SnCl}_2$  is active ( $\text{T/C} = 125$  [11]) and the ligands are inactive, the mode of action may involve the initial transportation of the complexed  $\text{Et}_2\text{SnCl}_2$  compound into the tumor cells, followed by reaction of  $\text{Et}_2\text{SnCl}_2$  (or one of its hydrolysis products) at the active sites. This suggestion is further supported by the fact that  $(\text{Et}_2\text{SnO})_n$ , the hydrolysis product of  $\text{Et}_2\text{SnCl}_2$ , is also active in the same system ( $\text{T/C} = 137$  [10]). A comparison of the Lewis acidity of  $\text{R}_2\text{SnX}_2$  compounds and the electronegativity of the halide with the activity of these complexes stimulated them to hypothesize that moderately stable complexes are required for activity.

Barbieri et al. [12] prepared some diorganotin(IV) ( $\text{R} = \text{Me}$ ,  $n\text{-Bu}$ ,  $n\text{-Oct}$  and  $\text{Ph}$ ) complexes of adenine and glycylglycine and screened them against P388 Lymphocyte Leukaemia in mice. These complexes showed high  $\text{T/C}$  values (Table 7) and they were interpreted in relation to the corresponding values for  $\text{R}_2\text{SnX}_2 \cdot 2\text{L}$  complexes.

It was suggested that the action of water on the complex  $\text{R}_2\text{Sn}(\text{ad})_2$  (Fig. 2) and adduct  $\text{R}_2\text{SnX}_2 \cdot 2\text{L}$  could yield the analogous species, owing to possible coordination of  $\text{H}_2\text{O}$  to the metal center followed by hydrolysis and to gradual dissociation of  $\text{Sn-N}$  bonds. As a consequence, the complexed species is transported into the tumor cells which are then attacked by hydrolyzed  $\text{R}_2\text{Sn}^{\text{IV}}$  moieties.

Fig. 2.  $\text{R}_2\text{Sn}(\text{ad})_2$ .

Saxena and Tandon [13] screened a series of di-*n*-butyltin complexes of Schiff bases derived from *S*-substituted dithiocarbazates and *p*-fluoroaniline for their activity against P388 Lymphocyte Leukaemia and suggested that the presence of highly electronegative groups can greatly enhance the activity. At about the same time, Takahashi et al. [14] studied the effects of timing a single intragastric application of dibutyltin dichloride on pancreatic carcinoma induced with *N*-nitroso bis(2-oxopropyl)amine (BOP) in female Syrian golden hamsters.

Haiduc et al. [15] have studied the activity of a series of organotin compounds of the type  $[R_2P(S)S]_2SnR'_2$  ( $R' = \text{Me or Ph}$ ) in vitro against P388 Lymphocyte Leukaemia in mice. They also studied the complexed and uncomplexed diorganotin dihalides, e.g.  $\text{PhMeSnBr}_2$  and  $(\text{PhCH}_2)\text{PhSnCl}_2$ , and found that uncomplexed halides are not only more toxic but also more active. Clercq et al. [16] screened six organotin compounds of the type  $[\text{CF}_3(\text{CF}_2)_5\text{CH}_2\text{CH}_2]_2\text{SnX}_2$  and  $[\text{CF}_3(\text{CF}_2)_5\text{CH}_2\text{CH}_2]_2\text{SnX}_2 \cdot o\text{-phen}$  against murine P388 Lymphocyte Leukaemia. It is speculated that the poor activity of these compounds may be due to low water solubility.

Recently, Crowe et al. [17,18] screened a number of diorganotin halide and pseudohalide adducts against P388 Lymphocyte Leukaemia. These complexes were modelled on active platinum complexes and the results were explained by comparing them with platinum and metallocene derivatives. The T/C values are given in Tables 2–6. It is suggested that diethyltin and/or diphenyltin complexes usually possess the highest activity, and most of the ligands in active complexes contain strong nitrogen donor atoms. Köpf and Köpf-Maier [19] have recently shown that the antitumor activity of metallocene dichlorides ( $\text{Cp}_2\text{MCl}_2$ , where  $\text{M} = \text{Ti, Zr, V, Nb or Mo}$ ) and *cis*-platin may be dependent on the  $\text{Cl-M-Cl}$  bond angle and hence on the corresponding non-bonding  $\text{Cl} \cdots \text{Cl}$  distance. Only those compounds in which the  $\text{Cl-M-Cl}$  angle is less than  $95^\circ$  are active. By analyzing the X-ray crystallographic data of these organotin adducts it was found that the  $\text{Cl-M-Cl}$  angles of both active and inactive adducts are of similar magnitude (ca.  $103\text{--}105^\circ$ ) and well above the limiting value proposed by Köpf. It was an important observation that, although these adducts were modelled on platinum complexes, the mode of action for the formation of metal–base cross-links for organotin adducts takes place via a different route. They observed that the active complexes have an average  $\text{Sn-N}$  bond length equal to or greater than  $2.39 \text{ \AA}$  whereas the inactive ones have a bond length of less than  $2.39 \text{ \AA}$  and suggested that more stable complexes have lower activities.

In 1984 Cardarelli gave a new impetus to the field of organotin compounds in anticarcinogenesis. A number of organotin compounds, i.e. tributyltin fluoride, dibutyltin dichloride  $\cdot$  2,2'-bipyridyl, 1,10-phenanthroline

<sup>a</sup> Data from ref. 11.

dibutyltin complex and dibutyltin histidine were given to cancerous mice in drinking water and tumor growth rates were significantly reduced. Tributyltin fluoride applied dermally to the same mice was found to be inactive [20]. However, the difference in the tumor growth retardation may be due to the feeding effect. Studies on the tin content in various body organs led Cardarelli et al. [21] to hypothesize that soluble organotin compounds of varying types introduced into the body are concentrated in the thymus gland. The tin in the thymus is then processed into one or more biochemicals that act as anticarcinogens and/or antioncogens. The isolation and evaluation of thymic extracts reasonably pointed to the unknown tin-bearing antioncogenic biochemicals of a steroid nature. These tin steroids (Fig. 3),

<sup>a</sup> Ref. 18. <sup>b</sup> Data supplied by National Cancer Institute, U.S.A. <sup>c</sup> Ref. 16.

and probably peptides produced by thymus, are multifunctional and act as hormones in the suppression of oncogenesis.

On the basis of their hypothesis, Cardarelli et al. [22] patented several organotin compounds of steroids which show marked antitumor activity. However, no structure–activity correlations could be made as most of the samples tested contained one or more tin-bearing unit. Yamamoto et al. [23] studied the comparative antitumor activity of a number of organometallic complexes of alkylidene triphenylphosphorine in L1210 Leukaemia in mice. The organotin compounds were found to be second to organolead compounds in activity. Huber et al. [24] recently reported the antitumor activity of 20 diorganotin and triorganotin compounds of the type R<sub>2</sub>SnL (H<sub>2</sub>L = L-cysteinate or DL-penicillamine; R = Me, Bu or Ph), Me<sub>2</sub>Sn complexes of *N*-benzoylglycinate and other substituted glycinate, [RSn(SCH<sub>2</sub>CH<sub>2</sub>SO<sub>3</sub>)<sub>2</sub>]<sup>2-</sup> and Bu<sub>2</sub>Sn(put)<sub>2</sub> or (Ph<sub>3</sub>Sn)<sub>3</sub>(put)<sub>2</sub> (Hput = purine-6-thiol) and correlated the structures with the activity. The T/C values are given in Table 7. A comparison of the structures of active and inactive compounds suggests that in all active compounds there is (i) the availability of coordination positions at Sn, (ii) the occurrence of relatively stable ligand–Sn bonds, Sn–N and Sn–S, (iii) slow hydrolytic decomposition of these bonds. One important feature of the work is that none of the purine-6-thiol complexes showed any activity, though the ligand itself is an antileukaemia drug in clinical use.

Meinema et al. [25] have screened a number of complexes of the type RR'Sn(CH<sub>2</sub>COOMe)<sub>2</sub> (where R = Me, Et, Ph or Bu) and RR'SnO against P388 Lymphocyte Leukaemia in mice. The high T/C values, tabulated in

Fig. 3. Tin-bearing antioncogenic steroid postulated to be present in thymic extracts.

active organotin compounds induce filamentous growth in bacteria, indicative of DNA interaction.

So far most of the studies on antitumor activities of organotin compounds have been confined to the P388 Lymphocyte Leukaemia system in mice. Atassi [26] has very recently reported the activity of two organotin adducts (Fig. 4) in various tumor systems including a newly characterized tumor, i.e. the renal adenocarcinoma. The T/C values in Table 9 indicate the very high activity of these compounds in renal adenocarcinoma.

Fig. 4. Two organotin adducts studied by Atassi [26].

Ruishi et al. [27] have tried to interpret the action of R<sub>2</sub>Sn(IV)glycylglycinates (R = Me, *n*-Bu, *n*-Oct or Ph) on a molecular basis. The reaction of Me<sub>2</sub>Sn(glygly) in aqueous solution seems to consist of a hydrolytic process occurring via the mechanism given in Scheme 1. The species I would

Scheme 1.

structurally correspond to the solid state structure or the structure in organic solvents (in some way mimicking the cell membrane phase). The species II

<sup>a</sup> The results are expressed in micrograms per millimeter of material necessary to inhibit 50% of control growth. Maximum concentration to show activity is 1  $\mu\text{g ml}^{-1}$ . <sup>b</sup> Data taken from ref. 29.

slowly releases R<sub>2</sub>Sn(IV) moieties in aqueous media, which are responsible for the antitumor activity.

Very recently Saxena et al. [28] have studied the antitumor activity of a number of organotin steroids of the type shown in Fig. 5 and compared the activity with that of a number of antitumor drugs (Table 10).

The organotin steroids which have covalent bonding between Sn and O atoms are very active compared with organotin steroids which have coordinate bonds between them.

### C. CONCLUDING REMARKS

These studies clearly show that organotin compounds have vast potential for use as antitumor agents, especially because of their low toxicity. However, much work is needed to explain the mechanism of their activity, and concerted efforts should be made to study the structures of tested compounds in solution (especially in aqueous media), since most of the drugs are administered in solution phase. The low solubility of most organotin compounds in water is also an obstacle to their high activity.

### ACKNOWLEDGEMENTS

The authors thank the Alexander von Humboldt Foundation for the award of a research fellowship to A. S. (1985–1986). They also thank Dr. M. Meyer for carefully reading the manuscript.
