ABSTRACT

Condensation of 4-arylamino-5-nitro-1,8-dihydroxyanthraquinone with arylamines in presence of boric acid affords 1,4-bis(arylamino)-5-nitro-8-hydroxyanthraquinones. These compounds colour polyester fibres in deep blue—green hues of good fastness to light and sublimation. On reduction they yield the corresponding 5-amino derivatives, which can be alkylated to the 5-alkylamino derivatives, the amino compounds dyeing polyesters in much greener hues than the nitro analogues. The 5-nitro derivatives also result from condensation of 4,5-dinitro-1,8-dihydroxyanthraquinone with arylamines, although with more reactive arylamines the formation of 1,4,5-tris(arylamino)-8-hydroxyanthraquinones also occurs as major by-product. The tris(arylamino) derivatives are more readily obtained by condensation of 4,5-bis(arylamino)-1,8-dihydroxyanthraquinones with arylamines. Structure-colour relationships in the dyes are discussed.

1 INTRODUCTION

Condensation of 4,5-dinitro-1,8-dihydroxyanthraquinone (DNCZ) with arylamines in organic solvents results initially in the formation of 4-arylamino-5-nitro-1,8-dihydroxyanthraquinones. Under more stringent

Dyes and Pigments 0143-7208/90/\$03.50 © 1990 Elsevier Science Publishers Ltd, England. Printed in Great Britain

conditions, replacement of both nitro groups by arylamino occurs.² In the presence of boric acid, 4-arylamino-5-nitro-1,8-dihydroxyanthraquinones react with alkylamines by preferential replacement of the 1-hydroxy group,³ and we have previously reported colour–structure relationships in such dyes.⁴ Similar condensation of DNCZ or of 4-arylamino-5-nitro-1,8-dihydroxyanthraquinone with arylamines in presence of boric acid yields 1,4-bis(arylamino)-5-nitro-8-hydroxyanthraquinones (I).⁵

We report here the synthesis of a series of dyes I, together with some analogous 5-amino (II) and 5-arylamino derivatives (III), and an evaluation of colour-structure relationships in these dyes.

2 EXPERIMENTAL

2.1 1,4-Bis(arylamino)-5-nitro-8-hydroxyanthraquinones (I)

Method A

Phenol (30 g) and boric acid (2·32 g) were stirred for 30 min at 125–130°C. 4-Anilino-5-nitro-1,8-dihydroxyanthraquinone (3·76 g, 0·01 mol) was added and stirring continued for 1 h at 125–130°C. Aniline (2·8 g, 0·03 mol) was then added and the mixture stirred at 140°C for 3·5 h. The liquor was cooled, diluted with ethanol (50 ml) and steam-distilled. The residual liquor was treated with potassium hydroxide (15 g) and after stirring and standing overnight was filtered to give a dark blue material (4·4 g). This (0·5 g) was purified by column chromatography on silica gel (see Section 2·5), affording,

from a major blue–green zone, $0.38 \,\mathrm{g}$ of 1,4-bisanilino-5-nitro-8-hydroxy-anthraquinone (I.1), m.p. $310-312^{\circ}\mathrm{C}$ (with sublimation) ($\mathrm{C_{26}H_{17}N_3O_5}$ requires C, 69·2; H, 3·8; N, 9·3. Found: C, 69·0; H, 3·7; N, 9·0%) (P⁺ at m/e 451). From a higher $R_{\rm t}$ green zone was isolated 0·07 g of 1,4,5-trisanilino-8-hydroxyanthraquinone (III.1), identical to the product prepared as below (see Section 2.3).

Starting from the appropriate 4-arylamino-5-nitro-1,8-dihydroxy-anthraquinone, other dyes I were similarly prepared. Reaction times were $2\cdot5-3$ h and products were isolated, as appropriate, as above or by addition of the ethanol-diluted reaction liquor to 20% aq. potassium hydroxide (250 ml), filtering and warming the residue at 60–65°C for 30 min in 10% aq. hydrochloric acid (100 ml). The resultant products were purified by recrystallisation (R) from 2-methoxyethanol or by column chromatography (C). Thus obtained were I.2, 74%, C; I.3, 81%, R; I.4, 70%, R; I.5, 62%, C; I.6, 70%, R; I.7, 74%, R; I.8, 81%, R; I.9, 57%, C; I.10, 58%, C; I.11, 88%, R; I.12, 51%, C. Relevant m.p. and λ_{max} data are shown in Table 1.

Method B

A mixture of DNCZ (2g), boric acid (0·25 g) and o-toluidine (10 ml) were stirred at 150–155°C for 12 h. The mixture was diluted with methanol (20 ml), stirred for 2 h and filtered, to give 2·6 g of a dark greenish-black residue. Two recrystallisations from 2-methoxyethanol (Norit) gave 1·8 g (62%) of 1,4-bis(o-toluidino)-5-nitro-8-hydroxyanthraquinone (I.2), m.p. 232–233°C (P⁺ at m/e 479) (C₂₈H₂₁N₃O₅ requires: C, 70·15; H, 4·4; N, 8·8. Found: C, 69·9; H, 4·2; N, 8·5%).

Similar reaction with 4-aminobenzophenone (15 h) gave, as first crop material after dilution with methanol, $2.5 \,\mathrm{g}$ of a dark blue solid, TLC of which indicated several dark blue components in addition to the expected green product. Column chromatography (of $0.5 \,\mathrm{g}$) afforded $0.24 \,\mathrm{g}$ of 1,4-bis(4-benzoylanilino)-5-nitro-8-hydroxyanthraquinone (I.12), m.p. 271–273°C (P⁺ at m/e 659) (C₄₀H₂₅N₃O₇ requires: C, 72·8; H, 3·8; N, 6·4. Found: C, 71·9; H, 3·6; N, 6·1%).

Similar reaction with aniline, p-toluidine, p-anisidine and p-phenetidine gave products containing dyes I and triarylamino derivatives III (see Section 3.1). DNCZ (2 g), boric acid (0·2 g) and aniline (10 g) heated at 145°C for 3 h gave a crude product which, separated by column chromatography, yielded 80% of 1,4-bisanilino-5-nitro-8-hydroxyanthraquinone (I.1).

2.2 5-Amino-1,4-bis(arylamino)-8-hydroxyanthraquinones (II)

The 5-nitro derivatives I were reduced with sodium sulphide in ethanol using established procedures.⁴ The products, obtained in generally quantitative

yield, were homogeneous by TLC and were recrystallised from 2-methoxyethanol. Relevant characterisation data are shown in Table 2.

2.3 1,4,5-Tris(arylamino)-8-hydroxyanthraquinones (III)

4,5-Bisanilino-1,8-dihydroxyanthraquinone (4·22 g, 0·01 mol) was reacted with aniline (3·72 g, 0·04 mol) following a similar procedure to Method A in Section 2.1. After 4 h of reaction the liquor was diluted with ethanol (20 ml) and worked up as above to give 4·72 g of a dark greenish-black residue. Column chromatography (of 0·5 g) gave, from a high- R_f green zone, 0·38 g (76%) of 1,4,5-trisanilino-8- hydroxyanthraquinone (III.1), m.p. 223–224°C (P⁺ at m/e 497) (C₃₂H₂₃N₂O₃ requires: C, 77·3; H, 4·6; N, 8·45. Found: C, 77·1; H, 4·4; N, 8·2%).

Similarly prepared were III.2, 63%; III.3, 72%; and III.4, 76%. Characterisation data are shown in Table 3.

2.4 5-Propylamino-1,4-bisanilino-8-hydroxyanthraquinone (IV)

The 5-amino derivative II.1 was reacted with 1-iodopropane in o-dichlorobenzene following the procedure used for alkylation of 1-alkylamino-4-anilino-5-amino-8-hydroxyanthraquinone.⁴ Chromatographic purification of the crude product gave 68% of IV, m.p. 180–181°C. (P⁺ at m/e 463) (C₂₇H₂₅N₃O₃ requires: C, 75·1; H, 5·4; N, 9·1. Found: C, 75·0; H, 5·3; N, 8·95%); λ_{max} (log e) in chlorobenzene, 418 nm (3·79), 668 nm (4·28) and 722 nm (4·41).

2.5 General

4-Arylamino-5-nitro-1,8-dihydroxyanthraquinones¹ and 4,5-bis(arylamino)-1,8-dihydroxyanthraquinones² were prepared as previously described. Electronic spectra were recorded on a Pye-Unicam PU 8720 from dye solutions in chlorobenzene. Dyeings on polyester and fastness assessments were carried out as in previous studies.^{1,2}

3 RESULTS AND DISCUSSION

3.1 Syntheses

The selective replacement of the 1-hydroxy group during reaction of 4-arylamino-5-nitro-1,8-dihydroxyanthraquinones with alkylamines in presence of boric acid gives the 1-alkylamino derivatives which colour polyester

fibre in deep greenish-blue hues of good fastness properties.² 1,4-Bis(arylamino) analogues have also been described⁵ as green dyes of excellent fastness properties on synthetic polymer fibres and the related 5-acylamino-1,4-bis(arylamino)-8-hydroxyanthraquinones also give green hues of good fastness on cotton and cotton-polyester blends.⁶

Whilst condensation of DNCZ with arylamines in presence of boric acid gave satisfactory formation of I with less reactive amines such as o-toluidine (cf. Ref. 6, Example 1) and 4-aminobenzophenone, the reaction was difficult to control with more basic amines such as aniline, p-phenetidine and p-anisidine, due to the additionally relatively facile formation of 1,4,5-tris(arylamino) derivatives (III). Thus, condensation of DNCZ with aniline (cf. Ref. 5, Example 1) for 6 h gave a product containing approx. 60% I.1 and 40% III.1. The formation of III.1 was apparent to a slight extent after 90 min of reaction (the major product then being a monoanilino derivative) and optimum yield of I.1 (80%) was obtained after 3 h of reaction.

Dyes I were readily obtained from the partially arylaminated derivatives, viz. 4-arylamino-5-nitro-1,8-dihydroxyanthraquinones, using a modification of the method previously used for the synthesis of 1-alkylamino-4-arylamino-5-nitro-8-hydroxyanthraquinones. Condensation with arylamines in phenol and boric acid gave good yields of I, principal by-products being the reduced analogues II. Little formation of III was apparent and compounds III were obtained in excellent yield from the corresponding 4,5-bis(arylamino)-1,8-dihydroxyanthraquinones using a similar procedure. Reduction of I to the 5-amino derivatives II and further alkylation to the 5-alkylamino derivatives were effected as previously described for analogous 1-alkylamino derivatives.

3.2 Electronic spectra

Replacement of the alkylamino group in 1-methylamino-4-anilino-5-nitro-8-hydroxyanthraquinone ($\lambda_{\rm max}$ 626 nm and 676 nm)⁴ by the anilino group results (for dye **I.1**) in a shift of absorption maxima to 634 nm and 680 nm. The larger shift in the lower-wavelength band is similar to that observed in other tetra-substituted dyes, e.g. 4-methylamino-5-anilino-1,8-dihydroxyanthraquinone, $\lambda_{\rm max}$ 635 nm and 683 nm; 4,5-bisanilino-1,8-dihydroxyanthraquinone, $\lambda_{\rm max}$ 642 nm and 684 nm.

Substitution into the phenyl ring by the electron donor alkyl (I.2–I.4), alkoxy (I.5–I.8) and acylamino substituents (I.9) give only small colour shifts in the longer-wavelength absorption band (up to 5 nm), and similar bathochromic shifts tend to result also with substitution by electron-acceptor groups (I.11, I.12). The shifts in λ_{max} are thus not substantially relatable to the polar nature of the substituent and further exemplify the

more limited influence of substituent effects in polysubstituted anthraquinone dyes^{1,2} compared with less substituted derivatives. The most significant colour shifts are resultant from steric factors, as in the 2'-methyl (I.2) and 1-naphthylamino derivatives (I.10).

The bright greenish hue of I is due in part to the contribution of a very broad blue absorption centred around 400 nm, and the colour shift to green is further apparent in the 5-amino derivatives II. These show bathochromic shifts of 15 nm to 20 nm in both of the long-wavelength absorption bands compared with I. This shift is somewhat lower than observed on reduction of the 1-alkylamino analogues,⁴ but is sufficient to shift the overall absorption towards the 700 nm region, the green hue of the dyes being due to a well defined blue absorption around 420 nm. The influence of this blue absorption is apparent in comparing II.1 with the isomeric 1,5-bisanilino-4-amino-8-hydroxyanthraquinone, which shows λ_{max} at 645 nm and 692 nm (in chlorobenzene) but has no green hue since little absorption in the 420 nm region occurs (Giesse, R. & Peters, A. T., unpublished).

Alkylation of II.1 with 1-iodopropane yielded the 5-propylamino derivative IV, which showed principal absorption maxima at 668 nm and 722 nm, viz. a shift of 22 nm and 27 nm respectively compared with II.1. The absorption at 420 nm also imparts an intense greenish hue.

Phenylation of the 5-amino substituent gives further slight bathochromic shifts, the 1,4,5-trisanilino-8-hydroxy derivative (III.1) showing shifts of 2–5 nm compared with the 5-propylamino derivative IV. Introduction of electron-donor substituents in the phenyl rings gives further shifts, typified by the tris(4-ethoxyanilino) derivative III.5, which has λ_{max} at 686 nm and 732 nm. The influence of the progressive phenylation of the amino groups is exemplified by comparison of III.5 with 1-propylamino-4-anilino-5-amino-8-hydroxyanthraquinone, the longer-wavelength absorption of which (687 nm)⁴ is in the same region as the lower wavelength absorption of III.5 (686 nm).

TABLE 4
Absorption Maxima and Fastness of Some Anthraquinone Dyes

***************************************		λ_{\max} (nm)	Lig	htfast	ness	Sublimation
		in chlorobenzene	0.1%	0.5%	2.5%	(°C)

3.3 Dyeing and fastness properties

Coloration properties of I on polyester were generally good, the dyes building up to greyish-green hue, the alkoxy derivatives I.6—I.8 and the ester derivative I.11 having the best build-up of the dyes investigated. Fastness to light was excellent, being in the order of one point better than the 1-alkylamino-4-arylamino analogues. Increased mass effects resulted also in a slightly improved sublimation fastness. The amino derivatives II showed better build-up than I, yielding deep bluish-green dyeings. Whilst light and sublimation fastness of these dyes were lower than those of I, the fastness properties of II were of a similar order to those of 1-alkylamino-4-arylamino-5-nitro-8-hydroxyanthraquinones, e.g. V, and lightfastness was better than that of the 1-alkylamino-4-arylamino-5-amino-8-hydroxy derivatives, e.g. VI (see Table 4).

Alkylation of the amino group of II resulted in similar bathochromic shifts and improvement in both light and sublimation fastness to similar alkylations in the 1-alkylamino analogues, cf. VI and VII, IV and II.1 (Fig. 1) and dye IV gave deep green colorations on polyester, build-up being similar to that of II. The good overall fastness of the triaminated derivatives is further shown in dyes III, these giving clear green hues with build-up lower than those of II and IV, but of a similar order to I.
