# Fastest 16-Bit SAR ADC

## Superior Speed, Superior Precision

The ADS8422 ADC from Texas Instruments delivers 33% faster speed than the nearest competitive device without compromising performance. Featuring 4MSPS, 16-bit no missing codes, 2LSB INL and 92dB SNR, the ADS8422 provides state-of-the-art speed and precision for demanding applications in medical imaging, test and measurement, industrial automation and scientific instrumentation.

# High-Power, Green-Mode Controller

## Enables Systems to Meet EPA Energy Star Requirements

The new 8-pin, quasi-resonant, **UCC28600** green-mode controller from TI provides high power efficiency in full and light-load operating conditions and decreases power consumption in no-load standby mode. The device enables standby power supplies in HDTVs, LCD and plasma digital TVs to achieve active-power mode efficiencies in excess of 88% and no-load power consumption levels below 150 mW. Additionally, the UCC28600 improves power efficiency in notebook PC and gaming system AC adapters that support 40 W to 200 W.

### ► Applications

- AC adapters
- Standby power supplies for DLP® HDTVs and LCD-TVs
- PDP-TVs and set top boxes
- Energy efficient power supplies: <250 W

### ► Features

- Quasi-resonant mode operation for reduced EMI and low switching losses
- Low standby current for system no-load power consumption: <150 mW
- Green-mode status pin to disable PFC controller at light load
- Low startup current: 25  $\mu$ A (max)
- Multi-functional pins offer high-performance features in small, 8-pin SOIC

Device	Start-up Current	Start-up Threshold Voltage	UVLO Hysteresis	Standby Current	Gate Drive Sink/Source	1k Price Starts
UCC28600	25 $\mu$ A (max)	13 V (typ)	5 V (typ)	550 $\mu$ A (max)	1 A/0.75 A	\$0.49

Technology for Innovators™

TEXAS INSTRUMENTS

THINK Semiconductors.  
THINK Customer Commitment.  
THINK Infineon.

YOUR FOCUS is on designing innovative products with a partner you can trust. Our focus is dedicated to providing you smart chip solutions to help you succeed.

TODAY WE DELIVER innovative semiconductors in the areas of energy savings, mobility, networking and security. In energy savings, our power ICs improve efficiency up to 30% in consumer goods and electronic products and we lead in semiconductors for hybrids. Our mobility solutions keep people connected to data and entertainment anywhere, anytime. Our strength in networking ICs translates into innovative designs for the digital home. And in security, we provide trusted chips for computers, credit cards, phone SIM cards and personal identification. This customer-centric way of doing business has made us one of the world's top semiconductor companies with leading positions in automotive electronics and communications ICs.

WHEN YOU think of innovative designs, think about partnering with the company committed to your success. Think Infineon.

## Magnetic-field measurements hold the key to reducing dc/dc EMI

**57** Power converters free system designers from unwieldy constraints, but the devices radiate unspecified fields that can destroy the signal/noise performance of sensitive circuits nearby. Magnetic-field measurements hold the key to finding and correcting these problems. *by William J Bowthers, Merrimack College*

## PCI Express: ever-faster graphics pipe serves many masters

**71** The new PCI Express spec significantly improves desktop-PC graphics. Developers are now working on generation 2, which will further expand the graphics pipe. *by David L Fair, Intel Corp*

## Hack-proof design

**46** Security requirements now top the embedded-system designer's checklist as networked devices multiply and hackers optimize their attack techniques. *by Warren Webb, Technical Editor*

## Beyond ROHS: the greening of global markets

**38** US and Asian governments are about to impose their own versions of the EU's ROHS directive. Rather than targeting each region's regulations, manufacturers may standardize on the most stringent "green" directive. This move will affect even products that are exempt from regulation, as component manufacturers move away from noncompliant parts.

*by Margery Conner, Technical Editor*

## DESIGN IDEAS

**83** Microprocessor generates programmable clock sequences

**86** Ceramic output capacitors enhance internally compensated integrated switchers

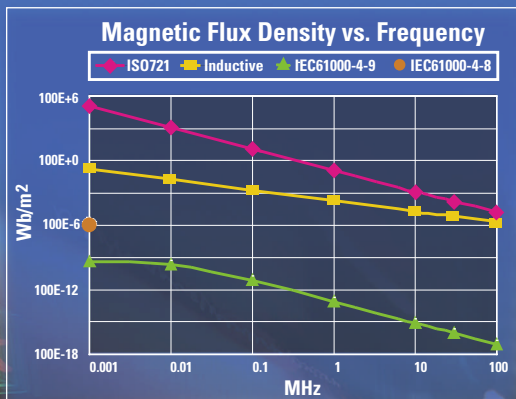

**90** Tapped inductor, boost regulator deliver high voltage

# Total Noise Immunity

## High Speed, Reliable Capacitive Isolation

TI's capacitive digital isolation technology conveys data across an oxide barrier at significantly higher rates than optocouplers, has substantially improved common mode transient immunity and greatly reduced power requirements. The ISO721 – a highly reliable, single component, EMI resistant solution ideal for your data transmission needs.

High Performance. Analog. Texas Instruments.

BY MAURY WRIGHT, EDITOR IN CHIEF

## Contextually correct search: a timesaver for engineers

If you've recently visited our Web site, [www.edn.com](http://www.edn.com), you may have noticed a new search feature, Zibb, in a rectangular, blue box near the top of the page. Our parent company, Reed Business Information, developed Zibb, a search engine that aims to provide contextually correct searches and promises to save users time by returning only relevant search results.

We know from our ongoing research efforts that you constantly use search engines in your daily work. And, like the world at large, engineers primarily use Google, although some also use other options, such as Yahoo and Ask. In fact, you have told us that you will use Google to find information on a vendor's Web site, because Google can often get you to the correct place faster than the vendor's own site search. And we know that many of you use Google to find articles on our site and come to visit following a Google link.

EDN and Reed Business appreciate Google and the traffic that it brings us. In fact, our company has partnered with Google on several initiatives. But we also know that Google isn't perfect. There are still many words that we use in the tech industry that have far different meanings when you use them in broader society. As good as Google is, it often delivers more meaningless links than relevant ones on tech-centric searches. We believed that we could develop an industry-centric search engine to serve vertical communities, such as electronics. The result is Zibb, and a couple of months ago, EDN became the first site in the

Reed universe to roll out the engine.

We rely on the Zibb technology both to greatly improve our site search and to provide contextually correct, broader industry searches. The Zibb box that appears on every EDN Web page is simply a site search. We present it that way because we have many regular visitors who have long used our site-search facility on each page. Having Zibb on each page provides the exact same user interface that the old site search offered. But try it, and I think you will agree that it performs far better than the old site search.

If you click on the Zibb logo to the left of the search box (or go to [www.edn.com/zibb](http://www.edn.com/zibb)), you will reach a

search-landing page that offers additional capabilities. You will reach a similar page whenever you do a site search, as well. The dedicated Zibb search page offers tabs above the search box that allow you to expand your search.

The default tab is the EDN site search. To the right of that tab is one labeled "news." The news tab produces results strictly from electronics-industry trade publications, including our competitors. The next two tabs, products and companies, are works in progress. Note that Zibb is officially still in beta status. But the products and companies tabs will ultimately tie to another Reed Business property, Kelly Search, which focuses on product and company directories. The tab on the far right is labeled "Web" and is essentially the Zibb equivalent of the Google default search. A Web search on Zibb, however, searches only industry vendors, standards bodies, trade associations, trade publications, and other relevant sites.

I encourage you to give Zibb a try. And please let me know what you think. If Zibb fails to turn up a site that should be in our database, I want to know. We want to hear both the bad news and the good. I believe that Zibb will save you time in your electronics-industry searches. But if it doesn't, tell us about it, so that we can try to make it better. **EDN**

# Inverter motor designs: half the energy, cost and time.

50W-3kW

Smart Power Module

IGBT driving and circuit protection

Motion SPM™

energy savings

## Meet energy usage regulations with SPM

Satisfy government energy requirements for home appliances with Fairchild's Smart Power Modules (SPM) for variable speed motor drives. One highly integrated package, with up to 16 discrete components, provides space savings, ease-of-use and greater reliability.

Our SPM portfolio covers inverter motor designs from 50W to 3kW, all with adjustable switching speeds, superior thermal resistance and low EMI. We're also the only company to offer a module for partial PFC switching converters.

Smart Power Modules: where energy is critical, SPM is there.

*Fairchild Smart Power Modules are the optimal solution for variable speed motor drives in home appliance designs.*

For more information on our SPM products, evaluation boards, and all of our design tools, visit [www.fairchildsemi.com/spm](http://www.fairchildsemi.com/spm).

### AD727x Family

**Resolution:** 8-bit to 12-bit  
**Speed:** 3MSPS • **Accuracy:**  $\pm 1\text{LSB INL}$   
**Package:** 6-TSOT • **Price:** Starting at \$1.85

## Small serial

## True bipolar

### AD732x Family

**Resolution:** 12-bit plus sign  
**Sample rate:** 500kSPS to 1MSPS  
**Software selectable input range** • **Price:** Starting at \$3.00

## AD9246/AD9233 Family

**Resolution:** 12-bit to 14-bit • **Sample rate:** 80MSPS to 125MSPS  
**Dynamic range:** Up to 85dBc SFDR with 70MHz input • **Price:** Starting at \$22.75

## Wideband sampling

## Multichannel integration

### AD9228/AD9287/AD9222 Family

**Independent channels:** 4 to 8 • **Sample rate:** 40MSPS to 100MSPS  
**Resolution:** 8-bit to 14-bit • **Price:** Starting at \$15.98

More ADCs, meeting more design requirements, than any other company

## Our selection means satisfying the performance and value you need

With more than 500 ADCs, Analog Devices provides a solution for the most demanding performance and budget requirements, in a range of applications—including automotive, industrial, consumer, communications, and medical equipment. We have the industry's broadest combinations of converter architecture, sample rate, dc accuracy, ac linearity, resolution, and power consumption to meet your specifications. You can also select the number of inputs, types of supplies, package preference, and, of course, price. Our extensive portfolio of data converters, amplifiers, and other analog ICs allows you to optimize your design and only pay for the features you require. So no matter what your design objectives, you can rely on Analog Devices for the performance and value you need.

*Pricing shown is in USD in quantities greater than 1k.*

# EXPRESSFABRIC

## Ultimate Performance...

**Achieve highest system speed  
and better design margin with  
the world's first 65nm FPGAs.**

Virtex™-5 FPGAs feature ExpressFabric™ technology on 65nm triple-oxide process. This new fabric offers the industry's first LUT with six independent inputs for fewer logic levels, *and* advanced diagonal interconnect to enable the shortest, fastest routing. Now you can achieve 30% higher performance, while reducing dynamic power by 35% and area by 45% compared to previous generations.

### Design systems faster than ever before

Shipping now, Virtex-5 LX is the first of four platforms optimized for logic, DSP, processing, and serial. The LX platform offers 330,000 logic cells and 1,200 user I/Os, plus hardened 550 MHz IP blocks. Build deeper FIFOs with 36 Kbit block RAMs. Achieve 1.25 Gbps on all I/Os without restrictions, and make reliable memory interfacing easier with enhanced ChipSync™ technology. Solve SI challenges and simplify PCB layout with our sparse chevron packaging. And enable greater DSP precision and dynamic range with 550 MHz, 25x18 MACs.

Visit [www.xilinx.com/virtex5](http://www.xilinx.com/virtex5), view the TechOnline webcast, and give your next design the ultimate in performance.

**The Ultimate System Integration Platform**

## Improving Video Clock Generation in Modern Broadcast Video Systems

By Alan Ocampo, Applications Engineer

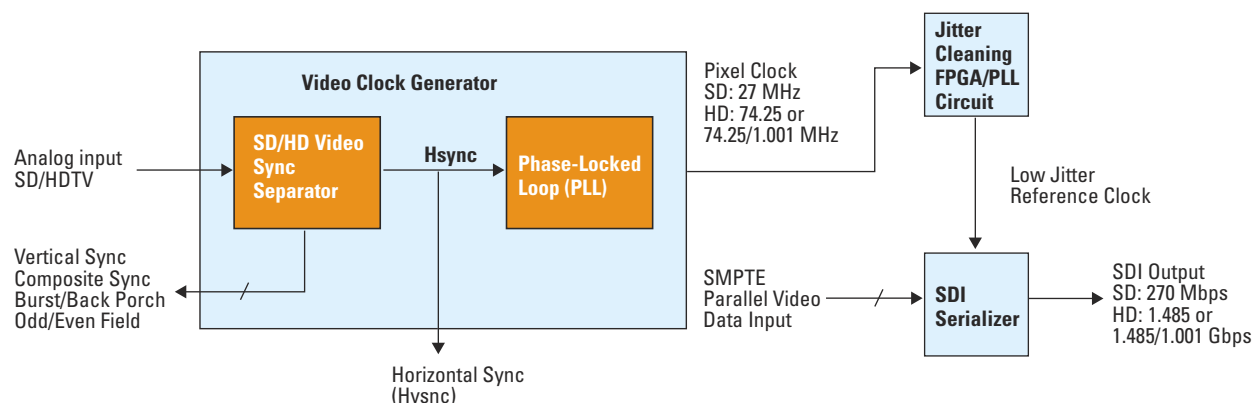

Figure 1. SDI Reference Clock Generator Block Diagram

The old adage “timing is everything” is well embodied in the modern broadcast studio, where precise timing of video clock and synchronization signals are essential to create, acquire, edit, and distribute analog and digital video. Today’s broadcast systems must support industry-standard SD/HD formats, such as NTSC, PAL, 720p, 1080i, and 1080p, over analog and digital interfaces such as composite, component, and Serial Digital Interface (SDI). With high-speed SDI video equipment being increasingly used throughout the studio, improved video sync separation can more effectively produce video clocks with low jitter, which is crucial to meeting the stringent specifications of new SDI standards.

A video clock generator which generates various timing and clock signals from an analog video input consists of a video sync separator and Phase-Locked Loop (PLL). These two circuits are illustrated in the SDI application block diagram in Figure 1.

The video sync separator accepts a 1V<sub>p-p</sub> analog video input with bi-level or tri-level sync and extracts the standard timing signals, such as Horizontal (Hsync), vertical, and composite sync, burst/back porch, and odd/even field outputs. To meet strict timing requirements of the latest HDTV standards, specifications such as HD tri-level sync separation, low output propagation delay, and 50% sync slicing are imperative. The latter ensures precise sync extraction by slicing at the proper 50% point of the bi-level or tri-level sync reference edges. This provides for improved Hsync jitter performance compared to non-adaptive, fixed-level sync slicing, even under irregular input conditions such as double or no 75Ω load termination or transmission loss. Hsync jitter is defined here as the peak-to-peak time variance in Hsync’s falling-edge with respect to the input’s sync reference-edge and is critical to the performance of the pixel clocks generated by the subsequent PLL block.

# Featured Products

## Multi-Format Video Sync Separator

The LMH1981 is a multi-format sync separator for high-definition broadcast and professional video systems. The device automatically detects the input video format and performs all the necessary sync separation to generate low-jitter horizontal and vertical sync signals for standard and high-definition video formats, including NTSC, PAL, SECAM, 480i, 480p, 576i, 576p, 720p, 1080i, and 1080p.

The LMH1981 features the timing outputs needed for any video system, including horizontal, vertical and composite sync, odd/even field, burst/back porch clamp, and a patented automatic video-format detection feature. The device accepts both bi- and tri-level sync video inputs and features 50% slicing to ensure accurate separation of signals that vary in amplitude, offset, and noise. The device has a wide input range, allowing the inputs to accept video signals from 500 mV<sub>P-P</sub> to 2 V<sub>P-P</sub>.

### Features

- 50% sync slicing
- Low jitter horizontal sync output
- Supports NTSC, PAL, SECAM, 480i, 480p, 576i, 576p, 720p, 1080i, and 1080p
- Accepts video signals from 500 mV<sub>P-P</sub> to 2 V<sub>P-P</sub>
- No external programming with  $\mu$ C required
- Horizontal sync output propagation delay <50 ns

The LMH1981 is ideal for use in a wide range of video applications such as, broadcast video equipment, video distribution, DTV and HDTV systems, and is available in TSSOP-14 packaging.

For FREE samples, datasheets, and more, visit [www.national.com/pf/LM/LMH1981.html](http://www.national.com/pf/LM/LMH1981.html)

## Adaptive Cable Equalizer

The LMH0044 adaptive cable equalizer is a monolithic integrated circuit for equalizing data transmitted over cable (or any media with similar dispersive loss characteristics). The equalizer operates over a wide range of data rates from 143 Mbps to 1.485 Gbps and supports SMPTE 292M, SMPTE 344M, and SMPTE 259M. This device implements DC restoration to correctly handle pathological data conditions (DC restoration may be bypassed for low data rate applications). The equalizer may be driven in either a single-ended or differential configuration.

Additional features include separate carrier detect and output mute pins which may be tied together to mute the output when no signal is present. A programmable mute reference is provided to mute the output at a selectable level of signal degradation.

### Features

- SMPTE 292M, SMPTE 344M, and SMPTE 259M compliant
- High data rates: 143 Mbps to 1.485 Gbps
- Equalizes up to 200m of Belden 1694A at 1.485 Gbps or up to 400m of Belden 1694A at 270 Mbps
- 208 mW typical power consumption with 3.3V supply
- Manual bypass and output mute with a programmable threshold
- Single-ended or differential input
- Supports DVB-ASI at 270 Mbps
- 50 $\Omega$  differential outputs
- Single 3.3V supply operation

The LMH0044 is ideal for SMPTE 292M/344M/259M serial interfaces, serial digital data equalization and reception, and data recovery equalization. The LMH0044 is available in LLP-16 packaging.

For FREE samples, datasheets, and more, visit [www.national.com/pf/LM/LMH0044.html](http://www.national.com/pf/LM/LMH0044.html)

## Improving Video Clock Generation in Modern Broadcast Video Systems

The PLL block can generate one or more pixel clocks, which should be phase-locked to the leading-edge of Hsync, the PLL's reference input. To produce both SD and HD pixel clocks will require two PLLs, both designed to give the appropriate output frequency for any given Hsync frequency. Since the PLL derives a higher frequency pixel clock from a lower frequency Hsync, pixel clock jitter will be determined by different sources at different frequencies. Below the loop bandwidth, the clock jitter output by the PLL will be dominated by Hsync jitter, which can be a significant amount depending on the performance and quality of the sync separator. Above the loop bandwidth, it will be dominated by its PLL oscillator, typically a Voltage-Controlled Crystal Oscillator (VCXO) chosen properly for low phase noise and frequency tuning, among other characteristics.

In the block diagram, a pixel clock generator is used to derive a reference clock for an SDI serializer which receives SMPTE-compliant parallel digital video data and then encodes, serializes, and transmits uncompressed serial digital video over coax cable. A serializer requires a clean reference clock for its internal PLL to generate a bit rate clock that maintains the serializer and clocks its output bit-stream. If used to directly clock the serializer, any jitter on the reference clock could potentially transfer to the bit rate clock and consequently appear as SDI output jitter. As shown in *Table 1*, SDI formats use increasingly high data rates and thus require clock sources with sufficient jitter performance.

For example, SMPTE 292M specifies the “timing” and “alignment” jitter requirements for an HD-SDI serializer's output bit-stream. Referring to the table, timing jitter should not be more than 1.0 UI<sup>1</sup> for jitter frequency components from B1 to B3, or 10 Hz to 1485 MHz, per SMPTE 292M. Alignment jitter—which is the high-frequency subset of timing jitter—should be no more than 0.2 UI from B2 (100 kHz) to B3. Outside of their respective frequency limits, both the timing and alignment jitter specifications roll

off at 20 dB per decade. Output jitter above the jitter specifications can result in degradation of error performance at the SDI deserializer. Please see the SDI standards for more information.

The stringent jitter specifications of SDI standards demonstrate the profound need for a low-jitter pixel clock. In most cases, however, a generated pixel clock will have an intolerable amount of jitter, up to 6 ns<sub>p-p</sub> for a typical SD pixel clock, which precludes direct application as a reference clock. Jitter reduction is therefore required to improve such unacceptable clock performance. The most common way to reduce pixel clock jitter is to use jitter-cleaning circuitry, usually implemented with additional Field-Programmable Gate Array (FPGA) or PLL stages. While jitter-cleaning circuitry is routinely applied by system designers, this can add significantly to component count, PCB area, power, and design cost and time.

A more effective way to reduce pixel clock jitter and thus improve SDI output jitter is to use a broadcast-quality video sync separator that has very low Hsync jitter, such as the LMH1981. This improved performance gives designers the flexibility to use smaller FPGAs or otherwise reduce jitter-cleaning circuitry and still produce an SDI output that complies to the jitter specifications.

Although broadcast systems are rapidly transitioning to high-speed SDI formats, the need to generate accurate video clocks from analog sources to process digital video data will be around for years to come. Current solutions require extensive jitter-cleaning circuits for generating an accurate reference clock to produce a SMPTE-compliant SDI output. However, the most fundamental and effective solution is to minimize jitter on the most critical timing reference, Hsync. This can only be accomplished using a high-performance analog video sync separator such as the LMH1981 in the clock generation signal path because, as we now know, timing is everything. ■

Table 1

Format	Standard	Bit Rate	Output Timing Jitter (B1 to B3)*	Output Alignment Jitter (B2 to B3)*
SD-SDI Standard- definition	SMPTE 259M, 334M	270 Mbps, others not widely used	1.0 UI <sup>1</sup> or 3.7 ns <sub>p-p</sub>	0.2 UI or 740 ps <sub>p-p</sub>
HD-SDI High-Definition; HD/SD-SDI Multit-rate	SMPTE 292M	1.485 Gbps 1.485/1.001 Gbps	1.0 UI or 673 ps <sub>p-p</sub>	0.2 UI or 135 ps <sub>p-p</sub>
3-Gbps SDI up to 1080p/60 over a single link	SMPTE 424M	2.970 Gbps 2.970/1.001 Gbps	2.0 UI or 673 ps <sub>p-p</sub>	0.3 UI maximum, 0.2 UI recommended

\*B1, B2, and B3 are the jitter frequency band limits specified in the SMPTE standards.

<sup>1</sup>One UI, or Unit Interval, is equal to one bit period (1/bit rate) of the serial bit-stream.

## Featured Products

### Digital Video Serializer with Ancilliary Data FIFO and Integrated Cable Driver

The LMH0030 is a monolithic integrated circuit that encodes, serializes, and transmits bit-parallel digital video data. The serial data clock frequency is internally generated and requires no external frequency setting, trimming, or filtering components. The LMH0030 performs functions which include: parallel-to-serial data conversion, SMPTE standard data encoding, NRZ to NRZI data format conversion, serial data clock generation and encoding with the serial data, automatic video rate and format detection, ancillary data packet management and insertion, and serial data output driving.

#### Features

- SDTV/HDTV serial digital video standard compliant
- Supports 270 Mbps, 360 Mbps, 540 Mbps, 1.4835 Gbps, and 1.485 Gbps SDV data rates with auto-detection
- Low output jitter: 85 ps (typ), 125 ps (max)
- Low power consumption: 430 mW (typ) from 3.3V
- No external VCO required
- Fast PLL lock time: < 150  $\mu$ s (typ) at 1.485 Gbps
- LVCMOS compatible data and control inputs and outputs
- 75 $\Omega$  ECL-compatible, differential, serial cable-driver outputs
- 3.3V I/O power supply and 2.5V logic power supply operation

The LMH0030 SDTV/HDTV serial-to-parallel digital video interfaces for video cameras, VTRs, telecines, digital video routers and switchers, digital video processing and editing equipment, video test pattern generators and digital video test equipment, and video signal generators. The LMH0030 is available in TQFP-64 packaging.

For FREE samples, datasheets, and more, visit [www.national.com/pf/LM/LMH0030.html](http://www.national.com/pf/LM/LMH0030.html)

### Digital Video Deserializer / Descrambler with Video and Ancillary Data FIFOs

The LMH0031 is a monolithic integrated circuit that deserializes and decodes SMPTE 292M, 1.485 Gbps (or 1.483 Gbps) serial component video data, to 20-bit parallel data with a synchronized parallel word-rate clock. It also deserializes and decodes SMPTE 259M, 270 Mbps, 360 Mbps, and SMPTE 344M (proposed) 540 Mbps serial component video data, to 10-bit parallel data. Functions performed by the LMH0031 include clock/data recovery from the serial data, serial-to-parallel data conversion, SMPTE standard data decoding, NRZI-to-NRZ conversion, parallel data clock generation, word framing, CRC and EDH data checking and handling, Ancillary Data extraction, and automatic video format determination.

#### Features

- SDTV/HDTV serial digital video standard compliant
- Supports 270 Mbps, 360 Mbps, 540 Mbps, 1.483 Gbps, and 1.485 Gbps serial video data rates with auto-detection
- Low power: 850 mW (typ)
- Uses 27 MHz crystal or clock oscillator reference
- Fast VCO lock time: < 500  $\mu$ s at 1.485 Gbps
- Built-in self-test and video test pattern generator
- LVDS and ECL-compatible, differential, serial inputs
- 3.3V I/O power supply and 2.5V logic power supply operation

The LMH0031 SDTV/HDTV serial-to-parallel digital video interfaces for video editing equipment, VTRs, standard converters, digital video routers and switchers, digital video processing and editing equipment, video test pattern generators and digital video test equipment, and video signal generators. Operating over the commercial temperature range (0°C to +70°C), the LMH0031 is available in TQFP-64 packaging.

## Organic semiconductors shine in LED/photodiode combinations

Silicon circuits provide high-speed switching of many tiny circuits and are good for use in small LEDs and photodiodes. Silicon has limitations, however, for systems that need to be cheap, environmentally friendly, disposable, and maybe even bendable. Organic circuits, on the other hand, excel in these areas. Incorporating technology whose developers ultimately won the Nobel Prize in chemistry in 2000, these circuits comprise a conductive-polymer compound that manufacturers can apply in a thick-film process with the same technology that ink-jet printers use.

Organic semiconductors will not replace silicon because they're not particularly fast and they don't support the fine-line geometries of silicon. However, they bear watching if you want inexpensive, perhaps disposable, or large-area LEDs or photodiodes.

Klaus Schroeter, chief executive officer of Austrian start-up Nanoident, says that a common OLED (organic-LED)—at 5×5 mm—is too big to be practical in silicon, but, he claims, is cheap and easy with organics. OLEDs are already finding use in displays for embedded systems. Organic de-

The organic-semiconductor-based Photonics Solution Platform offers spectral-sensitivity ranges from infrared through the visible-light spectrum, depending on the formulation of the organic material, which also determines the photodiodes' dark current and dynamic range.

vices are also intriguing for use in image sensors because, just by changing the voltage polarity on an OLED, you can change it from a light source to a light sensor. For example, you could integrate a fingerprint sensor into a display: If you touch the display, you can verify not only the fingerprint, but also the finger's hemoglobin count, verifying the fact that the finger is alive and thereby foiling the authors of numerous movies and books whose bad guys trick identification units with severed body parts.

Nanoident claims to be the first to develop organic-semi-

conductor-based optoelectronics. The company's new Photonics Solution Platform allows you to design image sensors combining LEDs, photodiodes, and simple IC functions, such as amplifiers. You can start with either a discrete or an array-based photodiode, add an LED array for an illumination source, and top it off with any necessary amplifiers or simple decision-making logic. If you need serious number-crunching ability, you can add a conventional microprocessor chip onto the sensor. Work up the sensor design in collaboration with Nanoident, and the

Photonics Solution Platform delivers the circuit design and component parameters. Nanoident then prints the circuit, including components, on surfaces such as foil, glass, paper, and pc boards.

The display resolutions range from 250 to 1000 dpi. The spectral sensitivity ranges from infrared through the visible-light spectrum, depending on the formulation of the organic material, which also determines the photodiodes' dark current and dynamic range. A representative price for a fingerprint-swipe sensor for a high-volume consumer product, such as a cell phone, is less than \$2.

Organic semiconductors even offer a "green-power" hook: Photovoltaics are close relatives of photodiodes, and several companies, including Nanosolar ([www.nanosolar.com](http://www.nanosolar.com)) and Konarka Technologies ([www.konarka.com](http://www.konarka.com)), are working to exploit the cheap-production aspects of organics. Although organic devices are currently about an order of magnitude or so less efficient than silicon-based photovoltaics, organic photovoltaics are so cheap to manufacture that the low cost of ownership and the rapid payback period more than offset their relative inefficiency.

—by Margery Conner

## Chip offers authentication, protection to single-cell battery packs

Cell-phone battery gauges are neither accurate nor consistent: The battery-charge symbol seems to relate only coincidentally to battery charge, causing users to charge their phones when they don't need to, consequently reducing battery life. However, as the newest generation of cell phones moves into a more intensive data-usage model, service providers are demanding that battery packs have more intelligence. They fear that counterfeit battery packs will explode in phones carrying the providers' brand names, making them liable to expensive lawsuits. Meanwhile, some users suggest that vendors are requiring battery authentication to protect themselves from after-market battery-pack sales (see the online Feedback Loop for "Friend or foe: Battery-authentication ICs separate the good guys from the bad," *EDN*, Feb 2, 2006, pg 59, [www.edn.com/article/CA6301616](http://www.edn.com/article/CA6301616)).

However, Brian Rush, business manager for Maxim's fuel-gauge line, disagrees with these users' viewpoint. Service vendors, such as Verizon ([www.verizon.com](http://www.verizon.com)), are liable in a battery-related accident, he says, so they are pressuring equipment vendors to

provide battery authentication. In addition, both equipment and service vendors want to preserve their brand integrity. So, Maxim and other vendors are setting the stage for a new generation of fuel gauges targeting one-cell battery packs in cell phones. Maxim claims that its new DS2790 fuel gauge is the first single-chip approach offering accurate battery-fuel-gauge and protection circuitry for single-cell packs.

The circuitry precisely measures current, accumulated current, voltage, and temperature, and it runs your cell-phone manufacturers' proprietary fuel-gauge algorithms on its internal 16-bit MAXQ microcontroller. The DS2790 contains 16 kbytes of program memo-

ry, which includes 8 kbytes of password-protected EEPROM and 8 kbytes of ROM; 128 bytes of data EEPROM for storing data such as charge parameters, cell characteristics, and manufacturing data; and 512 bytes of data RAM. The ROM contains routines that allow reprogramming over the I<sup>2</sup>C interface, SHA (Secure Hash Algorithm)-1 authentication, and support for in-circuit debugging. Rush claims that hackers can too easily break simpler authentication codes, so equipment vendors need the complexity of SHA-1. The product is available in 28-pin TSSOP and TDFN packages with prices starting at \$2.50 (1000).—by Margery Conner

### FROM THE VAULT

**"The development of sophisticated design techniques and relatively standard manufacturing processes will permit fabrication of relatively small quantities of truly custom designs (ICs) at attractive costs. During the 1970s, a major shift to custom designs will occur, necessitating a substantial change in vendor-supplier relationships."**

Jack Kilby, assistant vice president and manager of the customer-requirements center at Texas Instruments' Components Group, *EDN*, Jan 1, 1970

### DILBERT By Scott Adams

## Kit eases mobile-TV design

Frontier Silicon's latest evaluation kit allows designers to test and measure the performance of the company's Apollo RF receiver and Kino 2 chip set for mobile-TV applications. The Troy kit receives a T-DMB (terrestrial digital-multimedia-broadcasting) RF signal on Band III and the L Band and delivers an MPEG-2 transport stream to a host processor for audio and video decoding. Troy can simultaneously process as many as four T-DMB streams and display each one in a separate player window on the PC.

Although the kit allows a standard PC to act as the host processor, the interface connector supports multiple supply voltages and signals for connection to all popular media-processor-development kits. Available now, the Troy evaluation kit sells for \$1400.

—by Warren Webb

► **Frontier Silicon**, [www.frontier-silicon.com](http://www.frontier-silicon.com).

A new evaluation kit allows designers to measure the performance of Frontier Silicon's multistandard mobile-TV chip set using a desktop PC.

# SRIO switch for base stations adds preprocessing function, algorithms

The architecture of cellular base stations typically involves a bank of RF front-end cards that sends packetized sample data, generally through SRIO (Serial RapidIO) to an ASIC or FPGA. The ASIC or FPGA acts as a fairly simple switch, routing the packets to a waiting bank of DSPs and control-plane processors at the direction of the control plane. This arrangement begs for an off-the-shelf SRIO switch to form the hub of the processing backplane. Filling this need, IDT has announced a product that adds functions to the switch chip.

The company examined the processing tasks that the DSP chips and fabric's chip-rate hardware were performing and found commonly occurring tasks during the transmitting and receiving operation. Both in-sample data manipulation, such as sign extension and endian conversion, and multipacket operations, such as multicasting, re-

ordering of samples, and summation across samples, occur. Some of these operations occur in the high-speed chip-rate processing hardware, and some occur in the symbol-rate operations on the DSP chips. Because these operations are relatively standard, remain constant with time or context, and occur with some frequency, IDT moved them from the chip- and symbol-rate hardware into dedicated hardware inside the switch chip.

According to IDT Senior Product Manager Bill Beane, when you present this scenario to the base-station design team, the hardware engineers typically want to know the resulting aggregate data rate. The software-team leaders, however, want to know about the offload capability. Anything routine that they can move from DSP code means more code space and more execution time for the more complex operations.

As a result, IDT announced an SRIO switch chip. The chip supports 40 SRIO lanes at speeds as high as 3.125 Gbps each. You can group the lanes in clusters of four, and you can configure the drivers to support either chip-to-chip or backplane-SRIO interconnections. The chip also supports SRIO-standard priority and queuing algorithms to manage data flow in what can become complex multichip conversations. The chip also supports the standard's error-management and -maintenance functions.

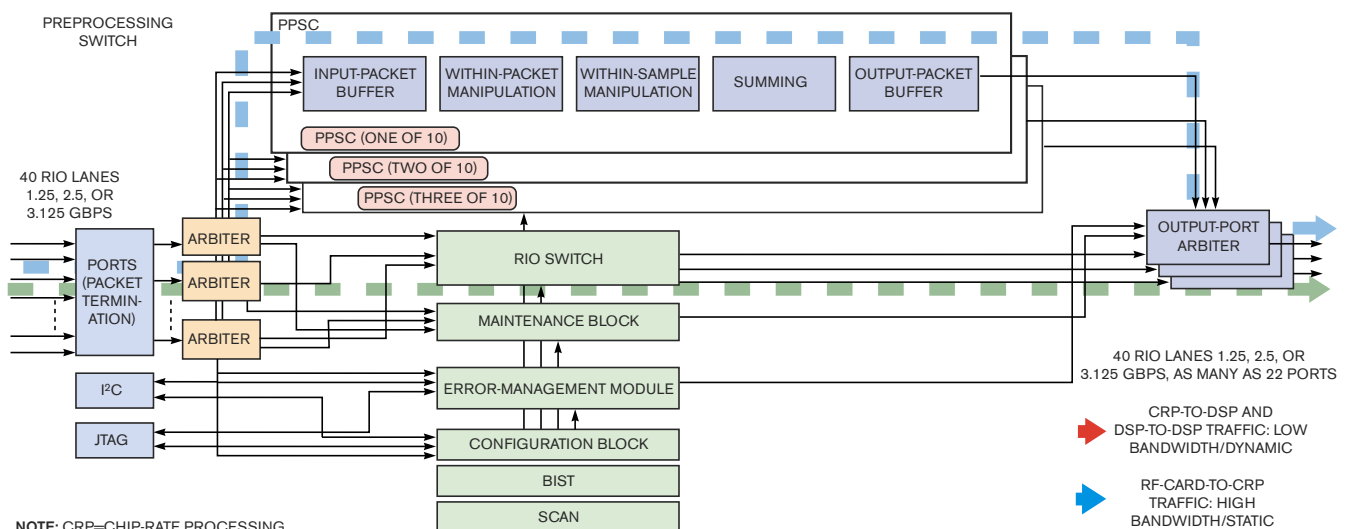

The competing needs for performance, small die, and manageable power dictated a mesh configuration for the switch fabric. Power depends on the usage scenario. Beane says that much of the design effort went into modeling processing topologies and algorithms and examining the data flow and power consumption for each. The offloaded processing tasks oc-

cur in a block that is parallel to the switch fabric, between banks of input and output arbiters. The block comprises 10 identical register-programmed state machines; input and output buffers surround these machines. Each state machine can perform in-sample, multisample, and summing operations, and all 10 machines can operate in parallel.

The result is a repartitioning of the tasks in a typical base-station-processing system. This task is neither trivial in itself, nor trivial in its implications for the packet-processing software team. Consequently, IDT this month will provide an Advanced Mezzanine Card-profile reference design that will include a full, production-capable evaluation board with four Texas Instruments (www.ti.com) Himalaya DSPs and a latency-accurate simulator. The IDT 70K2000Z is available for sampling now, and production will begin in November. Price is approximately \$125 (10,000).

—by Ron Wilson

►IDT, www.idt.com.

IDT's intelligent 70K2000Z combines a 40-port SRIO mesh switch with significant offload-processing capability for both chip- and symbol-rate tasks.

# The FPGA Eye Opener!

6.375-Gbps Transceivers  
Now Shipping!

Transmit eye diagram at 6.375 Gbps. For characterization details, see [www.altera.com/stratix2gx/characterization](http://www.altera.com/stratix2gx/characterization).

## The complete transceiver solution with best-in-class signal integrity.

Stratix® II GX FPGAs offer the industry's most comprehensive solution for high-speed serial applications. With significantly lower power consumption than competing devices, Stratix II GX FPGAs have up to 20 transceivers performing with exceptional noise immunity from 622 Mbps to 6.375 Gbps. Designers have immediate access to Quartus® II software support and an array of intellectual property (IP) cores, system models, development boards, and collateral—everything needed to complete a design in the shortest amount of time.

Discover Stratix II GX FPGAs today at [www.altera.com](http://www.altera.com).

- Up to 20 transceivers with dynamic pre-emphasis, equalization, and output voltage control
- Best-in-class signal integrity from 622 Mbps to 6.375 Gbps with exceptional channel-to-channel noise immunity
- Low power consumption (140 mW/channel at 3.125 Gbps and 240 mW/channel at 6.375 Gbps) while retaining best-in-class jitter performance
- Dedicated circuitry supporting wide range of protocol standards across multiple data rates

## Partners drive WiMax momentum across Asia

Since early in the development of the WiMax wireless-broadband standard, pundits have predicted a lot of deployment in regions such as Asia where large geographic areas lack a wired infrastructure. That scenario is coming true, and chip vendors in North America, Europe, and other regions continue to partner with system and telecommunications OEMs in the target regions. Just recently, OEM Tata Elxsi in Bangalore, India, signed on with Texas Instruments in an IEEE 802.116e mobile-WiMax initiative. Meanwhile, UK-based picoChip has found another Chinese partner for its WiMax silicon.

The TI/Tata Elxsi partnership intends to provide telecom-equipment vendors with an accelerated path to mobile-WiMax-base-station development. Tata Elxsi has developed

802.16e MAC (media-access-control)-software IP (intellectual property) that it will meld with TI's TMS320TC16482 DSPs. The companies based the reference design on Mercury Computer's MTI-203 AMC (Advanced Mezzanine Card), and end systems will likely rely on the ATCA (Advanced Telecom Computing Architecture) standard for building modular communication systems. The partnership is key because Tata Elxsi offers both the wireless-domain experience in technologies such as the MAC and the system-design experience, along with relationships with target equipment vendors.

Meanwhile, picoChip continues to push its programmable-silicon architecture into all WiMax flavors. The latest partnership is with Chinese telecom OEM China GrenTech. The company brings significant

## Ceramic substrate enables distributed processing in vehicles

The automobile has evolved to depend on a complex distribution of computational resources in subsystems ranging from brakes to safety to engine control. But distributing processor-based subsystems into environmentally challenging locations within a vehicle remains a problem. Japan-based Kyocera has just demonstrated an ECU (engine-control unit), which it deployed directly in an automatic transmission from Aisin AW Co. Locating the ECU on the high-torque, six-speed transmission exposes the subsystem to harsh temperatures and vibration. Kyocera developed a multilayer-ceramic substrate that could both handle the harsh environment and deliver on the reliability and small footprint that automakers need. Kyocera recently demonstrated the ECU at the Automotive Engineering Exposition 2006 in Yokohama, Japan.

—by Maury Wright

► Maxtrack MTC-600 Vehicle Tracking System

## Next stop: GPS tracking, networked control

To create its compact, low cost tracking system capable of managing an entire bus fleet or coast-to-coast trucking operation, Maxtrack put Blackfin® in the driver's seat. With 32-bit, 500 MHz performance at 85°C and integrated CAN® controller, Blackfin enables simultaneous processing of complex GPS, GSM/GPRS, audio, and spread spectrum transceiver algorithms, plus networked camera functionality. Blackfin also serves as the central processing unit for all data-driven needs. Now Blackfin is everywhere, on schedule.

## RESEARCH UPDATE

BY MATTHEW MILLER

Researchers prepare to test the condition of a wiring bundle in the cockpit of a retired Boeing 737.

## Sparks could prevent airline crashes

Airline-maintenance crews, not to mention passengers, face a frightening prospect: Somewhere within the miles of wiring inside a commercial airplane, a minuscule physical fault, such as a bit of worn insulation, can cause a catastrophic short circuit. For example, investigators fingered faulty wiring as the cause of a fire that led to the crash in 1998 of Swissair Flight 111, which killed 229 people when it went down off Nova Scotia.

Now, researchers at Sandia National Laboratories have announced a technology that could make it easier for airlines to locate and repair such faults. The suitcase-sized PASD (pulsed-arrest-

ed-spark-discharge) system uses high voltage to propel a nanosecond-long pulse of electricity through as many as 40 wires at a time. Due to the high voltage, the pulse readily jumps from any gap in faulty insulation to the aircraft bulkhead or another faulty wire nearby, causing a spark. The pulse is so short that it cannot do any damage, and the system measures current-return time to pinpoint faults to within inches.

Astronics Advanced Electronic Systems ([www.astronics.com](http://www.astronics.com)) has licensed the technology and plans to offer it commercially starting in September.

► **Sandia National Laboratories**, [www.sandia.gov](http://www.sandia.gov).

## Researchers listen to the sounds of CMOS

Scientists at NIST (National Institute of Standards and Technology), working with IBM and RF Micro Devices, have developed methods to reliably measure the faint thermal noise generated by the random motion of electrons in CMOS transistors. Characterizing this noise allows engineers to better tune systems, such as cellular phones, for optimal signal range, data rate, and battery life, according to NIST. The methods involve measuring the noise on the wafer before cutting and packaging.

The group also detailed its ability to perform "reverse" noise measurements, which focus on the noise that transistor inputs emit when they reflect and scatter incoming signals. This information can help engineers discover the impedance properties that will best minimize noise, according to NIST.

## Molecular electronics gel in a jar

Researchers from Philips Research and the University of Groningen (Groningen, Netherlands) have developed a molecular self-assembly process that reliably produces arrays of 1.5-nm-thick molecular diodes on standard substrates. Previous attempts to build such structures, which feature a single layer of molecules sandwiched between gold electrodes, have suffered from shorting. In this process, an additional plastic electrode layer prevents shorts.

Not a week goes by these days without some research outfit touting an advance in self-assembly, nanoscale circuitry. The Philips/Groningen team, however, claims that its work stands out because it will allow reliable, reproducible measurements of molecular junctions—an essential step in studying the potential applications of such circuits.

## Scratch vinyl goes digital

Professional DJs gave Denon a special request: "We want to play MP3s with all the features of our vinyl rigs, including scratch, reverse, brake, filter, and flanger." But enabling these user control needs, coupled with near-zero latency of audio encoding and decoding, required a unique 32-bit processor. So Denon cued up Blackfin®. With 800 MMACS performance at \$5 cost, Blackfin scratched the competition. Now Blackfin is everywhere, bringing the beats.

## Painting microprocessors in broad strokes

**N**o one likely would argue the microprocessor's place on our roster of Milestones That Mattered. Surely, there'd be heated discussion over who invented the processor. But the benefits of the invention are clear. Productivity has benefited hugely from the processor-based PC. And thousands of processors surround us in our everyday lives, with vendors adding more daily.

One of the themes of our 50th anniversary issue, due this September, will be "softwarization." We know it's not a word. But the movement of functions to software has been an unmistakable and enduring trend, which the microprocessor, at least in the broadest set of applications, has enabled. Designers can implement anything from simple hardware circuits, such as

UARTs, to complex data-coding functions, such as MPEG, in software.

But let's get back to history. Intel claims to have developed the first commercial microprocessor with the launch of the 4004 in 1971. The company built the first design for customer Busicom of Japan and targeted calculators, although Intel later reacquired the rights to the 4004. Ted Hoff and

Federico Faggin of Intel get the credit, although Intel tried at one point to erase Faggin's contribution from history after he defected to Zilog.

Some historians, however, believe that Four Phase Systems was shipping the AL1 processor a year before Intel delivered the 4004. Lee Boysel designed the AL1, but history largely buried the achievement because Motorola acquired the company, which most people forgot about. Texas Instruments also lays claim to early processor development.

What's undeniable is that Intel was most successful in commercializing the technology that would underwrite decades of innovation. You can read the complete original *EDN* account of the 4004 with the online version of this article at [www.edn.com/060720mtm](http://www.edn.com/060720mtm). That early processor sold for \$100 in low volumes. **EDN**

### "Announcing a new era of integrated electronics."

This introduction for a new IC may seem immodest, but Intel Corp. might just be correct. The IC is a single-chip CPU designed for low-speed microprogrammable applications, such as terminals, peripherals, test systems, and process control. The one-chip CPU was described at the *EDN/EEE* seminars in August.

The CPU, Type 4004, is designed to work with other members of Intel's MCS-4 microcomputer set. The other ICs in this kit of standard building blocks are the 4001 ROM, 4002 RAM, and the 4003 shift register (SR).

The minimum system configuration consists of one CPU and one 256×8-bit ROM. For one-of-a-kind applications, an electrically programmable ROM can be used in place of the mask-programmable 4001. The MCS-4 microcomputer is fabricated with silicon-gate, low-threshold MOS technology.

Packaged in a 16-pin ceramic DIP, the CPU chip consists of a 4-bit adder, a 64-bit (16×4) index register, a 48-bit (4×12) program counter and stack, an address incrementer, an 8-bit instruction register and decoder, and control logic. Forty-five instructions are included in the 4004's repertoire. All timing, control, and arithmetic operations are implemented internally.

Information flows between the 4004 and the other chips through a four-line data bus. A system built with the MCS-4 set can have up to 4k×8-bit ROM words, 1280×4-bit RAM characters, and 128 I/O lines without requiring any interface logic. With the use of external

gates, the computer size can be increased even further. The MCS-4 uses a 10.8-μsec instruction cycle. The basic instruction execution requires eight or 16 cycles of a 750-kHz clock. Addition of two 8-digit numbers requires 850 μsec.

Custom systems using this 4004 chip are implemented by microprograms stored in a ROM. The idea of microprogramming a process to implement a special controller is not new. IBM's system 360 computer and HP's 2100A desk calculator are two examples of both large and small systems that have exploited the inherent design and production advantages of microprogramming. In desktop calculators, about 35% of the logic is associated with doing arithmetic. The other tasks are keyboard encoding, printing results, displaying status and general control. These functions can be done by microprogramming rather than by additional random logic. Microprogramming can even be used for keyboard switch debouncing and for converting 4-bit BCD code to seven-segment lamp code. Many features may be added to systems using this chip by providing additional ROMs.

This approach provides a flexible and modular technique for system design in which memory devices are used instead of logic devices. The major limitation to its application is speed. While an IC logic can make a decision in about 5 nsec, and combinatorial networks allow many decisions to take place in parallel, this computer chip performs decisions sequentially at 10.8 μsec per instruction.

# Support Across The Board.™

Ryan Martin  
Avnet,  
Account Manager

Dan Holt  
Atmel,  
Applications Engineer

Brent Duncan  
Paragon Innovations, Inc.,  
Senior Engineer

## Bringing Products to Life.

At Avnet Electronics Marketing (EM), support across the board is much more than a tagline for us. From initial design through end of life — we are deeply committed to driving maximum efficiency throughout the product lifecycle. Take a current design success story involving Paragon Innovations, Inc., for example.

### Paragon / B. Braun – The Challenge

The processor used in Paragon OEM customer and medical device maker B. Braun Medical's product was about to be obsolete; with demand still strong, Paragon needed to replace the main processor while minimizing changes to the circuit board. This revision would need to be made quickly: B. Braun's supply of processors was rapidly dwindling and, at the same time, the FDA would need to review and approve any new design to the product. These were heart stopping challenges confronting Paragon. Enter Avnet.

### Avnet EM and Atmel – The Solution

Avnet and Atmel Corporation engineers studied the B. Braun board, in search of the right ARM solution to replace the obsolete microcontroller, while seeking opportunities to help Paragon improve overall performance, efficiency and cost-effectiveness on the project. On the technical side, Atmel came through with their feature rich ARM9 Smart Microcontroller. Avnet then supported the program on the supply chain side, keeping Paragon informed on the latest pipeline issues as it readied for production. During the entire process, neither Avnet nor Atmel missed a beat, and it really paid off for Paragon.

## Scaling: a balanced view, part three

In the last installment of Analog Domain, the application's matching, noise, and  $1/f$  noise requirements determined the model minimum circuit's load capacitance,  $C_{\text{MIN}}$ —a representation of the following stage's input impedance. Matching varies in inverse proportion to  $1/L_{\text{MIN}}$ ; noise and  $1/f$  noise follow an inverse-square-law relationship with the minimum length (references 1 and 2).

For example, for applications in which matching constrains the dynamic range, such as track-and-hold amplifiers and several ADC architectures, you can express the offset voltage,  $V_{\text{OS}}$ , as

$$V_{\text{OS}} = \frac{n_{\sigma} \gamma T_{\text{OX}}}{\sqrt{WL}}$$

Here,  $n_{\sigma}$  is the number of sigmas that your company's yield model requires,  $\gamma$  is a process-dependent parameter,  $T_{\text{OX}}$  is the gate-oxide thickness, and  $W$  and  $L$  are the device width and length.

The gate capacitance,  $C_{\text{GATE}}$ , of the transistors that must meet the matching requirements is

$$C_{\text{GATE}} = \frac{\epsilon_0 \epsilon_R WL}{T_{\text{OX}}}$$

where  $\epsilon_0$  is the permittivity of free space and  $\epsilon_R$  is the relative permittivity of the gate oxide. Combining these two equations gives the  $C_{\text{MIN}}$  of the transistors that satisfies the matching requirements:

$$C_{\text{GATE}} = \epsilon_0 \epsilon_R n_{\sigma}^2 \gamma^2 T_{\text{OX}} \frac{\text{DR}^2}{V_{\text{SIG(RMS)}}^2},$$

where DR is the application's matching-limited dynamic-range requirement. Due to the strong influence that matching requirements have on  $C_{\text{MIN}}$  and, as a result, dissipation, circuits that demand tight matching between large numbers of transistors often make use of circuit techniques, such as offset can-

cellation, that reduce the requirements for individual devices.

In applications for which white noise limits the dynamic range, including a broad class of small-signal amplifiers, converters, and filters,

$$V_{\text{NOISE}}^2 = \frac{kT}{C_{\text{NOISE}}},$$

though recent efforts suggest methods that beat this traditional floor. Expressing this limit as a minimum capacitance, with dynamic range as a parameter, yields

$$C_{\text{NOISE}} = kT \frac{\text{DR}^2}{V_{\text{SIG(RMS)}}^2}.$$

After determining the load capacitance necessary to meet dynamic-range requirements, the next step is to calculate the current necessary to sufficiently drive this capacitance to meet the application's ac specifications—bandwidth, settling time, slew rate, and total harmonic distortion.

Fundamental to these measures is the MOSFET's transconductance,  $g_m$ :

$$g_m = \frac{2I_D}{V_{\text{GT}}},$$

where  $V_{\text{GT}} = V_{\text{GS}} - V_T$  in strong inversion and

$$V_{\text{GT}} = \frac{2nkT}{q}$$

in weak inversion. Bandwidth, the ratio

of the unity-gain frequency,  $F_0$ , to the dc gain,  $A_0$ , follows from the transconductance and gate capacitance:

$$\text{BANDWIDTH} = \frac{F_0}{A_0} = \frac{g_m}{2\pi A_0 C_{\text{GATE}}}.$$

In certain applications, meeting the application's bandwidth requirements is not insufficient; designs must prevent slew-rate limiting, which can impose another requirement on the minimum current:

$$I_{\text{SR}} = 2\pi F_{\text{SIG}} V_{\text{SIG}} C_L.$$

Similar equations describe the minimum current necessary to attain specific second- and third-harmonic-distortion levels with and without feedback. For these, refer to **Reference 2**.

As was the case with the voltage efficiency, the model requires an assumption of current efficiency,  $\eta_c$ . Given a differential-signal path—a practical departure from the single-transistor string under discussion thus far—and modest current scaling in the bias-current mirror, an  $\eta_c$  of one-third is a good, if somewhat conservative, starting assumption for current efficiency of a single stage. In practice, common circuit-design practices more efficiently distribute bias currents, but the precise number depends upon both bias-generator and signal-path-circuit topologies.

The sum of string currents—or, in the case of differential circuits, the half-circuit currents—multiplied by the current efficiency yields the supply current,  $I_{\text{DD}}$ . The product of supply current and supply voltage, which you calculated from the application's signal-swing requirements, results in the minimum power dissipation necessary to attain the originally stated parametric goals. **EDN**

# It's the 8-bit entry point into a whole new world of opportunity.

## Welcome to the Controller Continuum

---

8-bit solutions from Freescale lead you into the Controller Continuum: our roadmap for 8-bit and 32-bit compatibility. This major expansion of our 8-bit portfolio—from 1K Flash to 128K Flash and from 6 pins to 122 pins—delivers not only unprecedented choice and value, but the ability to scale in all directions from the low to high end. But we're not stopping there. With the Controller Continuum, we'll be rolling out pin-for-pin compatible devices. You can upgrade 8-bit designs to 32-bit performance and share the same set of peripherals and tools, such as the now easier-to-use Fast Track services for the CodeWarrior® tool suite. Now the applications you develop will not only be smarter, how you develop them will be too.

For more go to [freescale.com/8bit](http://freescale.com/8bit)

BY HOWARD JOHNSON, PhD

## Reference-free pair

A correspondent from Capstone Visual needs to carry some high-speed network traces across his two-layer pc board. The board consists of 62-mil-thick FR-4 material. No solid plane layer exists anywhere on this board. To manage skew between the two traces, my correspondent routed them exactly on top of one another—one on the top layer and one on the bottom. He needs a way to calculate the trace width necessary to make a good 100Ω differential configuration using this geometry.

Before I address this issue, I should congratulate my correspondent for recognizing that *any* trace configuration with a uniform cross section makes a perfectly good transmission line. You can use one trace with a solid reference plane, two traces side by side, two traces above and below one another, or four traces in a quad configuration; the possibilities are endless. Just keep the geometry consistent, and then all that matters are the impedance, delay, attenuation, and crosstalk.

My correspondent's traces are short compared with the extent of his network connection, so the trace delay and trace loss are immaterial.

Regarding the differential imped-

**Figure 1** A zero-voltage plane bisects every symmetric differential configuration.

### To calculate the impedance of an above-and-below differential-pc-board-trace setup with no reference plane, just lie to your 2-D field solver.

ance, you can use an “image-plane” method to calculate the impedance of that configuration.

**Figure 1** shows a cross-sectional view of two round conductors, assuming an air dielectric. (The conductors need not be round; any shape gives the same type of picture.) The electric-field patterns in the region surrounding the traces emanate from each trace perpendicular to its surface. A lot of lines flow directly from the positive trace to the negative trace. The lines bulge on either side. Voltages at the top of the drawing are positive, and voltages at

the bottom are negative. Everywhere along a line drawn through the middle they are *exactly* 0V.

The dotted, green horizontal line bisecting the diagram represents an imaginary plane, or image plane, separating the two conductors. “Symmetry” in this case means that, if the differential pair is properly balanced, the voltage everywhere on the image plane remains zero at all times. Therefore, concerning the differential mode of propagation, no circuit can distinguish between, first, the original unreference configuration and, second, the same configuration with a real, physical, 0V reference plane added in the middle.

To calculate the impedance of an above-and-below differential-pc-board-trace setup with no reference plane, just lie to your 2-D field solver. Tell it that there is a solid reference plane dead center in the middle of the stackup. Separately compute the impedance from the top trace to the plane (a normal microstrip arrangement) and double that number to get the complete differential impedance.

The image-plane method makes quick work of the impedance calculation, but what about crosstalk? Lacking a solid reference plane, my correspondent's traces will be particularly sensitive to crosstalk from nearby sources. His circuit may not function for crosstalk reasons, but at least it won't suffer reflections!**EDN**

## Sweating blood over hardware-interface routines

In the 1980s, I obtained a number of consulting contracts to put the Vinten aerial photo camera and various other sensing devices into fixed-wing and helicopter aircraft. Along the way, I developed a computer-control system for the cameras that would adjust the trigger interval to obtain the desired overlap from frame to frame. It used a Commodore 64 with modified video-overlay circuitry.

One of these jobs was for a government agency in Edmonton, AB, Canada. There was a lot to do. The cameras and sensors went into a pod on the bottom of a Jet-Ranger helicopter.

A rack of control equipment mounted on seat rails in the cockpit. The entire system was dual-powered from 117V-ac or large gel-cell batteries.

The system came together in the workshop just days before we were due to ship it. All the subsystems worked correctly, so we moved on to operating the complete system. It ran flawlessly for an hour or so, the cameras triggering correctly every few seconds. Then, in one of those heart-stopping moments that every engineer has experienced, an anomaly: The cameras fired off a burst of frames at high speed and then returned to the original interval.

The Vinten camera draws 20A for a few milliseconds every time it starts, so it's a major source of electrical noise. I had carefully designed the electronic

interface between the computer and the cameras to minimize the effect but, I thought, maybe not carefully enough. The computer interface was an input/output shift-register pair attached to the parallel port. The shift-register parallel connections drove the camera relays, read back the radar altimeter, recorded video ground speed, and controlled other devices. I spent days peering into my scope, looking for noise spikes. Nothing showed. I installed various noise-control circuits, but the problem recurred at random.

Delivery was now late. The client insisted that the hardware appear in Edmonton. Reluctantly, I advised him of the problem—promising that I'd find it eventually—and shipped everything off. A week passed, and I

still had no idea where to look.

The time came to fly to Edmonton. I packed every diagnostic tool I owned and headed out to the airport for a morning flight. Then, as we were watching the in-flight movie—*Back to the Future*—it came to me.

In Edmonton, the client was not happy. I sat down with the equipment, typed in two lines of assembly code, and held my breath. The system operated perfectly.

The problem: Two software routines were accessing the interface hardware. One routine, to read the ground speed, was part of the main loop. Another routine accessed the interface as part of the 60-Hz timing interrupt. Normally, these routines didn't get in each other's way. However, if the main-loop routine was reading the ground speed when a 60-Hz interrupt occurred, it would resume with corrupted ground-speed data, which then misadjusted the camera interval. The solution: Two instructions to disable the 60-Hz interrupt while reading ground speed.

This experience taught me that it's asking for trouble to access hardware from more than one point in the program. There should be a single interface routine that controls access to the hardware. Furthermore, it's important to realize that any section of the code can be interrupted and may corrupt the system state. To prevent this situation, you need to disable and enable interrupts or save additional state as part of the interrupt-service routine. This type of problem is nasty to debug, because it occurs at random intervals. So, you must properly engineer the system.

Testing and test equipment don't always help. As the saying goes, sometimes you have to think about it until little drops of blood appear on your forehead; then, it will come to you. **EDN**

# SYNCHRONOUS RECTIFICATION: NO HEATSINK, ONLY 6 COMPONENTS

*New SmartRectifier™ IC Reduces Part Count by 75% and Boosts System Efficiency by 1%*

## Adaptor Redesign Example:

International Rectifier's new IR1167 SmartRectifier IC for 100W to 300W AC-DC power converters dramatically simplifies design and improves efficiency in secondary synchronous rectification (SR) flyback and resonant half-bridge circuits, enabling a "no heatsink required" design.

## Features

- Increases system efficiency by 1% vs. current transformer
- Reduces component count from 22 to 6 in typical system
- Reduces MOSFET temperature by 10°C
- Works independently from primary-side control
- No current transformer required
- Industry-leading high voltage IC technology

THE POWER MANAGEMENT LEADER

# BEYOND ROHS: THE GREENING OF GLOBAL MARKETS

BY MARGERY CONNER • TECHNICAL EDITOR

US AND ASIAN GOVERNMENTS ARE ABOUT TO IMPOSE THEIR OWN VERSIONS OF THE EU'S ROHS DIRECTIVE. RATHER THAN TARGETING EACH REGION'S REGULATIONS, MANUFACTURERS MAY STANDARDIZE ON THE MOST STRINGENT "GREEN" DIRECTIVE. THIS MOVE WILL AFFECT EVEN PRODUCTS THAT ARE EXEMPT FROM REGULATION, AS COMPONENT MANUFACTURERS MOVE AWAY FROM NONCOMPLIANT PARTS.

For the past three years, the electronics industry has been eyeing this month as the time that the European Union's ROHS (reduction-of-hazardous-substances) directive was supposed to take effect for some electronic products. Barring any last-minute legal maneuvers or postponements, electronic products bound for the multibillion-dollar European consumer market will need to satisfy the directive's limitations on six hazardous materials: lead, mercury, cadmium, hexavalent chromium, polybrominated biphenyls, and polybrominated biphenyl ethers (**Reference 1**). The directive mandates that electronic products that do not comply with the directive's restrictions, calling for the elimination of these six substances, will face removal from the market and their manufacturers will have to pay fines.

Predictions of what will happen this month in Europe as the deadline passes run the gamut from business as usual with a smooth transition to a brave, new, lead-free world to major lawsuits halting the imposition of the directive. Some scenarios even predict a nightmare for European officials as they attempt to establish documentation requirements and enforce them on the fly. Regardless of the short-term outcome, the world of electronics will never go back to its "pregreen" state; rather, EU ROHS is just the first of many government-imposed regulations of environmental substances.

China passed its own version of ROHS in February, with an effective date of March 1, 2007 (**Reference 2**). The law specifies the same six substances as the European ROHS and then throws in a wild card: "other toxic or hazard substances or elements set by the State." China may not only regulate more substances but also allow a different amount of those substances. "'Lead-free' in the EU ROHS means it has less than 1000 ppm of lead in it," says Greg Roberts, marketing vice president of EMA, a value-added reseller of Cadence software. "Other countries selling products into China will

# Embedded Networking? Micrel Has Your Processor Covered

Micrel's KSZ88xx Series Gives Designers One-Stop Shopping For All Networking Interface Needs

The road to network connectivity is never smooth but Micrel has you covered. Whether you need networking via an 8, 16 or 32-bit generic-bus, PCI-bus, MII, RMII, or SNI host interfaces, Micrel has the answer in easy to install single and dual-port Ethernet solutions. The devices address the growing need for streamlined networking connectivity in IP-Set Top Boxes, VoIP phones, Network Printers, Industrial Controls and networked Game Console applications, to name but a few. The dual port devices have the lowest latency (sub 310ns) in the industry and are ideal for daisy-chaining applications, or simply as two port switches to connect to voice, video and data.

All of the ICs incorporate HP Auto-MDIX to take the guesswork out of whether your device is connected using straight or crossover cables. In addition, Micrel's LinkMD™ cable diagnostics function not only determines the length of the cable and the distance to fault, but also diagnoses common cabling faults such as open and short circuits. These features reduce the need for costly customer calls and IT service requests. Along with Micrel's trademark high reliability, outstanding performance, and low power consumption, the KSZ88xx family offers ideal solutions for applications that require compact, cost effective, RoHS compliant networking connections.

For more information, contact your local Micrel sales representative or visit us at: [www.micrel.com/ad/ksz88xx](http://www.micrel.com/ad/ksz88xx).

## AT A GLANCE

- Expect China, Korea, Australia, and California to be among the first to implement "green" regulations.
- It's shortsighted to implement a documentation system that tracks only yes/no compliance for the European Union's ROHS (reduction-of-hazardous-substances) regulation.
- Ensure that your system can adapt to an increasingly regulated industry.
- Long leadtimes, higher prices, and accelerated end-of-life cycles will affect even manufacturers eligible for exemptions for lead parts as component manufacturers seek to standardize on green parts.

be subject to China's ROHS directive, which may have a lower allowable lead content. A product that could be lead-free or ROHS-compliant for Europe may not be compliant in China." (For some suggestions on how to make your designs globally compliant, see **sidebar** "Seven tips for the brave new world of 'green' regulations.")

The EU has not yet spelled out what kind of a documentation system it expects or what is sufficient for a manufacturer to prove it and its suppliers are in full compliance. It will determine what constitutes adequate documentation during these early months of the ROHS implementation, with companies involved in early test cases serving as guinea pigs. However, China's ROHS apparently will be more hands-on, with companies possibly having to prove their compliance upfront by undergoing testing at labs in China.

Some manufacturers currently track their EU ROHS parts' compliance with a simple spreadsheet listing each part and a yes/no check box under ROHS compliance. Is this enough documentation to satisfy the EU's directive? "It is until somebody challenges you," says EMA's Roberts. "The directive says you have 30 days to compile all the documentation on every component in your product line, including the traceability of the information. It requires materials declaration

for everything in your product all the way down to the resistors, including the box it's in and the labels on it."

The OEM that the product packing lists is liable for compliance for the entire system. For example, if you purchase a power supply for your design and the manufacturer claims that it complies with the directive, you as the system manufacturer are still responsible for the liability of that entire assembly. "Many component vendors just give you a certificate and say 'yes, we're compliant,'" says Keith Hopwood, vice president of marketing for Phihong USA. "I say, 'show me.'"

A simple yes/no spreadsheet probably will not survive an EU ROHS challenge, and it has the additional drawback of being unable to adapt as regions impose different regulations. A robust system will go beyond yes/no EU ROHS compliance and track the actual parts-per-million count for all environmentally sensitive substances. However, it may be difficult to achieve that goal in the allotted time frame, cautions Eric Larkin, chief technology officer for Arena Solutions, a provider of Web-based PLM (product-life-cycle management). "If you believe that you're going to be able to get a full substance-level breakdown for every single component on your pc board within the 2006 to 2007 time frame, I don't see that happening," he says. "We know of only four component manufacturers that are looking at publishing the detailed substance-level breakdown."

A survey of customers by Toshiba's Discrete Products Division corroborates Larkin's view. "Lack of material content information is one of the biggest hurdles that many companies are facing right now," says Cynthia Pham, senior quality-assurance engineer for Toshiba.

Despite the well-publicized ROHS deadline of July 1, 2006, regional preparedness varies widely. According to Jim Smith, senior vice president of warehouse and distribution worldwide at Avnet Logistics, EU countries' ROHS readiness is well ahead of the Americas', which in turn is ahead of the Asian countries. The reason that the EU is so far ahead is that the directive is the region's own regulation. Also, although European market share might account for only 15% of US vendors' market share, it accounts for at least half for most European OEMs. A more subtle reason is that Europeans have seen a well-publicized example of the EU's will to enforce environmental regulations. In 2001, the Dutch government blocked the sales of 1.3 million Sony PlayStations in the EU because the systems' cables violated an EU environmental directive limiting the amount of cadmium (**Reference 3**). The incident demonstrates that even large, well-known brands are subject to the regulations. Although Sony's supplier provided the noncompliant cables, Sony incurred the penalties and loss of revenue.

What can trigger an EU ROHS challenge? Companies that have incurred the expense and time of complying with EU ROHS use their compliance as a competitive advantage against less green competitors. They can file a claim, triggering an EU audit of another company's system. Compliant vendors see this whistle-blowing as a fair tactic against noncompliant competitors.

Another reason that Asian manufacturers may lag behind in ROHS compliance is that they are waiting to see what China's ROHS initiative comprises. China's directive may not be significantly stricter than the EU ROHS because one of China's strengths is its competitive market pricing, and the Chinese government may be loath to put that advantage at risk. Regardless of China's eventual stance, you can expect the industry standard to evolve from the regulations of those regions with significant markets and that impose the strictest regulations.

Component manufacturers cannot justify multiple production lines for parts with the same functions. This reluctance or inability to make both green and non-green versions has important implications

Semiconductor  
The Sight & Sound of Information

devices are exempt from EU ROHS compliance and can continue to use leaded solder. "Defense vendors might have a problem before too long, because, once a supplier consigns a part to end-of-life status, raises the price, or extends the lead-time, that has huge ramifications in the supply chain," says Avnet's Smith. "If I'm the manufacturer of a part, I have to

decide: If I can't make money doing both, which do I eliminate?" As EMA's Roberts points out, "The supply chain is the real driver in industry, not legislation."

ROHS has a companion directive, WEEE (waste electrical and electronics equipment), which specifies the marking of electrical and electronic products to facilitate their recycling. Again, deter-

● You can't rely on contract manufacturers to manufacture your products to ROHS (reduction-of-hazardous-substances) specifications. "Your contract manufacturer won't go to court for you," says Greg Roberts, marketing vice president of EMA, a value-added reseller of Cadence software.

- Even if you're exempt, you may still have a supply-chain problem.

**Suppliers will move inexorably to lead-free manufacturing, and other customers will bid up the price of any lead parts vital to their designs.**

- You cannot mix and match lead and lead-free parts. According to electronic-component distributor Newark InOne, you

**can't assume backward compatibility with green, lead-free parts (Reference A).**

- **Manufacturers will gradually remove lead parts from the supply chain, making those parts obsolete. Roberts estimates that it will take four to five years for the supply chain to stabilize; until then, parts availability will remain in flux.**

- The ROHS directives cover more than electronics. You should also pay attention to the mechanical assembly and parts, such as cadmium-plated screws.

- Know what market you are selling your design into, suggests Eric Larkin, chief technology officer for Arena Solu-

tions, a provider of Web-based PLM (product-life-cycle management). This constraint is a new one for design engineers, who have traditionally had little interest in the geographical regions in which their products would sell. If your design is targeting the Chinese market, understand how or whether China's regulations differ from the European Union's ROHS directive.

- Ensure that your vendors assign part numbers to green parts different from those that they assigned to the older, “non-green” parts. Lack of part-number distinction is one of the top concerns in a recent ROHS-customer survey by Toshiba’s Dis-

crete Products Division.

**“All of Toshiba’s lead-free products have a different part number to distinguish the lead-free and non-lead-free versions,” says Cynthia Pham, senior quality-assurance engineer for Toshiba. “Not every company is doing this. It’s a logistics nightmare if you use parts without unique numbers,” she says (Figure A).**

**Figure A** Toshiba's original green product markings say "lead-free" (left), but customers want them to say "ROHS-compatible" or "ROHS-compliant." Toshiba maintains that only completed systems can be ROHS-compliant and marks its products that do not contain restricted substances "ROHS-compatible" (right).

mining how to make disposal and recycling more efficient goes beyond EU countries: Japan has had such a regulation, the HARL (Home Appliances Recycling Law), in place since 2001, and California is moving toward a similar law, with other states likely to follow. HARL and WEEE both require manufacturers to be responsible for accepting and recycling their products. However, the Japanese law allows for the consumer to pay a separate fee for recycling, whereas WEEE requires that the regional price of the equipment include the fee. This new additional cost to the manufacturer will drive designers to allow for the most effective means of recycling their products. Phihong USA's Hopgood gives an example the company encountered: "Under WEEE, if capacitors are over a certain size, they have to be removed from the board before recycling," he says. "Designers will want to avoid using parts that trigger recycling exceptions, if possible."

ROHS is not an anomaly. Arena Solution's Larkin gives this perspective: "Go back to Upton Sinclair's *The Jungle* 100 years ago. When he wrote his novel about the Chicago slaughterhouses, the public became aware that there was a compelling public interest in regulating the quality and preparation of food and medicine. That realization led to the creation of the Food and Drug Administration and the regulatory environment under which

both the food and medical industry work today." Just as today, we take for granted that modern producers provide food and medicine with regulations and laws, so too, will electronic-equipment manufacturing evolve into a regulated process. And the best, most efficient product designs will be ready and able to adapt to these regulations. **EDN**

# HiPerFRED<sup>2</sup>... the New Generation of Ultra Fast Rectifiers

## Fast Recovery Rectifiers with improved thermal behavior

### Features

- Optimized designs for:
  - very low and soft recovery current (DPG-types)
  - ultra low forward voltage (DPF-types)
- Maximum repetitive reverse voltage between 200 and 400 V
- Average forward current from 10 A to 60 A
- Extremely low leakage current < 1µA
- Available in several standard packages and configurations

### Applications

- Switch mode power supplies
- Free Wheeling Diode
- Antisaturation Diode
- Snubber circuits

The light's gone on for even easier system integration—and Agilent has flipped the switch. Agilent Open now includes devices based on LAN eXtensions for Instrumentation (LXI), and you can use this new standard to accelerate your system development and deployment.

The versatility of LXI utilizes Ethernet to enable local and remote measurements, monitoring, and control—and eliminates costly cardcages and proprietary interfaces. With more than 40 member companies supporting the LXI Consortium, the growing number of LXI devices will have you well-equipped to take the next step beyond GPIB.

LXI is one more way Agilent Open continues to simplify system creation. Our products are system ready, can be integrated into your test-software environment, and provide USB, GPIB, and LAN I/O options. Enlighten your whole testing process—get details about LXI and Agilent Open at [www.agilent.com/find/openlxi](http://www.agilent.com/find/openlxi).

# A

BY WARREN WEBB • TECHNICAL EDITOR

s embedded devices permeate society and assume ever more important roles, the consequences of security failures are potentially catastrophic. Embedded devices provide unattended operation for thousands of mission-critical or safety-related systems in sectors such as manufacturing, health care, transportation, finance, and the military. Although we rely on these embedded systems without giving them a second thought, any one could be the potential target of casual hackers, organized crime, terrorists, or even adversary governments. The responsibility to protect against these attacks falls squarely on the shoulders of the system designer, who must secure not only the data that passes through or is stored on his embedded device, but also the intellectual property of the product itself.

Historically, designers physically protected and isolated embedded devices to achieve reasonable data security. Today, widespread interconnectivity may expose a critical embedded system to data extraction or process manipulation from anywhere in the world.

Unlike desktop systems, an embedded product must incorporate all security measures before its deployment. Embedded-system designers cannot wait for a breach and then devise a patch to cover security flaws. Users expect embedded products to perform a function for years without modification, and you can't stop or

reboot many devices without risking loss of life, property, or critical information.

Security must be a prime design consideration from conception through production, deployment, and end-of-life disposal, because it is almost impossible to add to products currently in the field. The NIST (National Institute of Standards and Technology) provides designers with a number of security-related publications at its CSRC (Computer Security Resource Center). These documents outline life-cycle design principles to consider, such as security-policy definition, product design, threat identification, technological options, and programmer education. For example, the first challenge is to identify what data or proprietary information requires protection before selecting safeguards. It may be possible to reduce or even eliminate sensitive data to minimize the security effort. Next, you should

SECURITY  
REQUIREMENTS  
NOW TOP  
THE EMBEDDED-  
SYSTEM DESIGNER'S  
CHECKLIST AS  
NETWORKED  
DEVICES MULTIPLY  
AND HACKERS  
OPTIMIZE  
THEIR ATTACK  
TECHNIQUES.

## AT A GLANCE

Threats to portable devices force designers to include physical packaging protection in addition to traditional software safeguards.

Unlike the desktop-software practice of patch after failure, embedded products must continue operation in spite of security threats.

Widely available cryptography algorithms and secure protocols offer embedded-system designers the best security protection for Internet-connected devices.

New pay-as-you-go business models rely on secure hardware and software architectures to allow customers to pay for pricey systems as they use them.

determine your possible attackers and their level of sophistication. A simple password may stop a curious amateur, but determined intruders require multiple levels of security.

## SEPARATE AND SECURE

An obvious security measure is to physically isolate networked systems from outside influence. If you can collocate the embedded system and server on the same network segment without Internet access, most security problems disappear. Isolation is especially effective in highly critical applications, such as controlling a factory, where disruption would be costly. Minimizing the connection time to the Internet can also thwart many hacking attempts. A short-term connection to exchange data at random times prevents search robots from identifying your system. However, if your embedded system is a target of a hacker, short connections will only delay unauthorized access.

Attackers can steal embedded devices, especially portable products, disassemble them, and probe them with sensitive test equipment to extract data. They can remove memory elements from the products to possibly extract their contents. Likewise, they can use

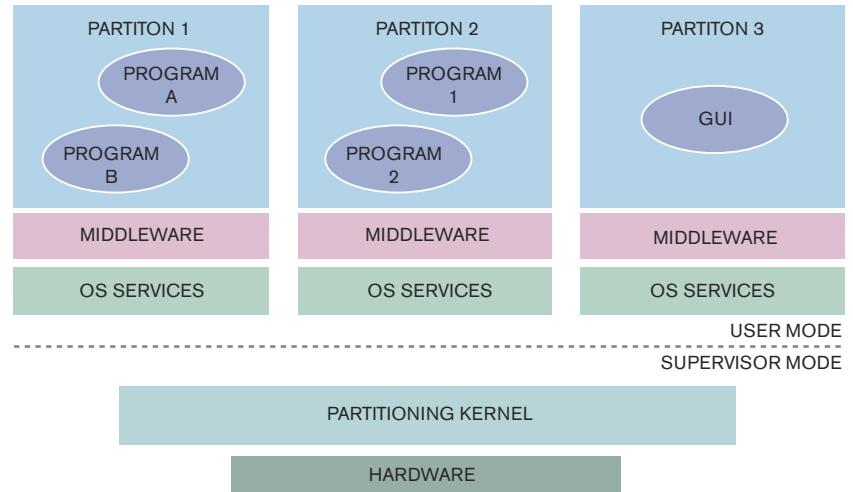

Figure 1 The MILS (Multiple Independent Levels of Security) architecture isolates kernel, middleware, and application components (courtesy LinuxWorks).

active debugging ports and software to read sensitive data or force unintended operation. Attackers may even monitor electromagnetic radiation or force the system to operate outside its design parameters, with extreme temperatures, voltage excursions, and clock variations, to gain information.

Equipment designers should also incorporate physical deterrents to safeguard sensitive or proprietary informa-

tion. A hardened enclosure requiring specialized equipment to open may deter some attacks. Internally, designers should engineer pc boards with security in mind. For example, BGA packages with critical signals hidden on internal board layers complicate probing and reverse-engineering. Although you can remove some formulations with acid, epoxies and conformal coatings also provide protection to all or part of a

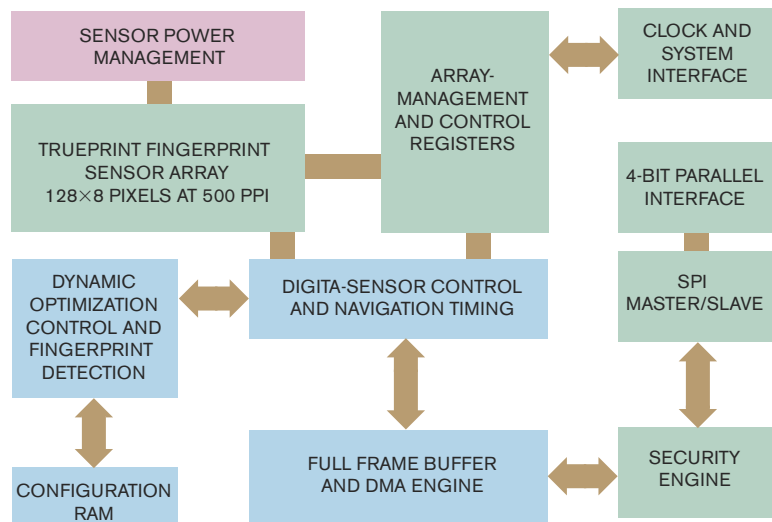

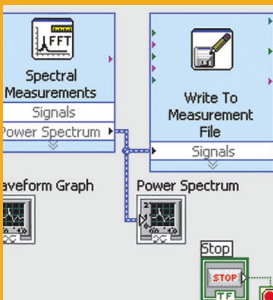

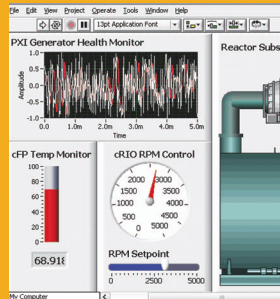

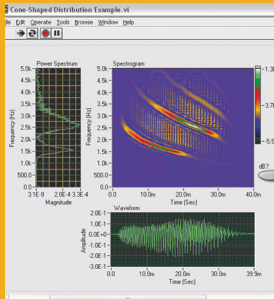

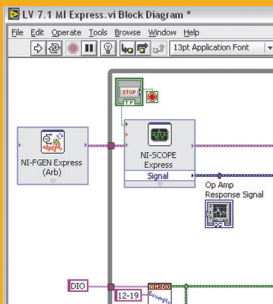

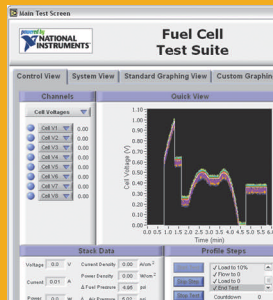

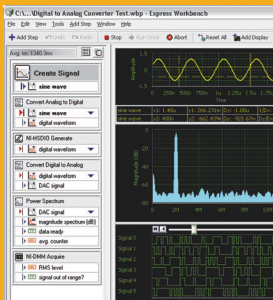

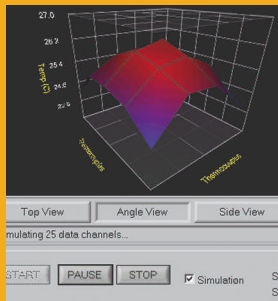

Figure 2 With a 12x5-mm footprint, the EntréPad 1510 slide sensor from AuthenTec enables secure fingerprint authentication on portable devices.

## One Platform, Infinite Solutions

With the flexibility and efficiency of National Instruments LabVIEW graphical development software, engineers and scientists around the world are solving measurement and control application challenges throughout the product lifecycle. From design to validation to production, LabVIEW helps you to meet your application challenges more quickly and efficiently.

product's sensitive internal circuitry.

To establish standards for system security, the United States, Canada, and several European nations created the "Common Criteria for Information Technolo-

gy Security Evaluation" usually referred to as "the Common Criteria." The Common Criteria Web site includes a developer section with guidelines and complete documentation. The Common Criteria

structure allows consumers, developers, and evaluators to specify the security functions of a product in standard-protection profiles and EALs (evaluation-assurance levels). Another embedded-

## SAFEGUARDING KEYS

*By Kris Ardis, Dallas Semiconductor/Maxim*

When most people think about security, they first think of encryption. An embedded system that sends and receives only triple-DES (Data Encrypted Standard)-encrypted commands might seem difficult to crack. However, imagine a house that has the most advanced door locks and an electronic security system; it would also be difficult to crack. An enterprising thief would not try to circumvent the house's protection but instead would attempt to steal the keys or coerce the security code from the homeowner. Embedded systems are prone to the same weakness: All the encryption in the world is futile if someone steals the encryption key.

Proper key protection starts with where you store the keys. The safest place is in the same place you will use them. Embedded systems, therefore, need to store encryption keys inside a microcontroller and never allow the keys to leave. If you store the key in an external memory, such as a serial EEPROM or an external RAM, the microcontroller would need to fetch the key before using it. When the external memory transmits the key to the microcontroller, it transmits it in the clear,

allowing anyone with an oscilloscope or a logic analyzer to discover the key data.

On-chip EEPROM or flash may also be inadequate protection. A determined attacker could remove the microcontroller's plastic packaging and use a microprobe to inspect the memory cells. In high-security applications, losing the key would be catastrophic. An attacker would have unpimpeded access to financial networks or could create undetectable fake-ID cards.

High-security applications present unique challenges for IC designers. Secure microcontrollers, such as Dallas Semiconductor's DS5250, address this design challenge by providing battery-backed, nonvolatile SRAM for on-chip key storage. This custom-designed memory can link to several tamper-detection circuits, both on- and off-chip, and instantly erase when the situation meets one of several tampering criteria. Some on-chip sensors, such as temperature and voltage detectors, respond to fault-injection attacks. Such attacks occur when the secure microcontroller is operating outside its maximum

operating range, attempting to make cryptographic operations fail so that the device leaks key data. Another kind of on-chip sensor detects microprobing attacks. A silicon mesh in the top layer of the chip initiates a "tamper destruct" if someone shorts or breaks its sub-micron traces. Secure microcontrollers also include self-destruct input pins that external mechanisms, such as microswitches, light sensors, and pressure sensors, can trigger.

Although physical protection of the key is critical, so is logical protection. Secure microcontrollers offer encryption accelerators that can quickly and securely execute standard algorithms. Public-key operations such as RSA (Rivest, Shamir, and Adleman) execute in milliseconds, and symmetric algorithms such as triple DES run in microseconds. Hardware accelerators are more resistant to timing attacks than software algorithms, because they complete in the same number of machine cycles regardless of the actual values of the keys or the data. Secure microcontrollers also incorporate hardware random-number generators that vary in behavior over

voltage, temperature, and process variations, making it impossible for an attacker to guess the value of generated keys or blinding values.

Encrypted program memories provide further logical protection for the applications running on secure microcontrollers. When you first initialize the system, the secure microcontroller uses the on-chip random-number generator to create a unique key, which the system uses to encrypt the program space. When the device executes, the system decrypts the encrypted instructions and places them in an on-chip cache in real time. This method not only protects intellectual property and thwarts reverse-engineering, but also prevents an attacker from executing malicious code.

Applications concerned with security have unique challenges to meet. By designing secure microcontrollers with physical and logical security in mind, you can create the safest foundation for applications that must protect secret keys.

# What Are You Made Of?

**eZ430-F2013  
Complete  
Development Tool  
Only \$15**  
*Regular Price \$20*

**WIN**  
one of three  
DLP® HDTVs

Show us what you're made of by entering the MSP430 eZ Design Contest. Pit yourself against other top designers from around the world by submitting your design featuring TI's MSP430 – the world's lowest power microcontroller.

#### Easy to Participate

- No purchase necessary to enter
- Test drive the eZ430-F2013 Development Tool on TechOnLine's VirtuaLab for free
- Receive a 25% discount on the eZ430-F2013
- Submit your entry today

#### Easy to Win

- Submit your entry by October 2, 2006
- Grand prize, first place and second place winners will each receive a DLP® HDTV, airfare, lodging and entry to the MSP430 Advanced Technical Conference in Dallas, Texas November 7-9

software security standard, MILS (Multiple Independent Levels of Security), requires a partitioned real-time operating system that you can certify with rigorous tests (**Figure 1**). Memory protection and guaranteed resource availability allow you to manage secure and nonsecure data on a single processor. The MILS architecture allows designers to create application code with tamperproof security features that you cannot bypass, that you can verify mathematically, and that the system always invokes.

Before a user can interact with a secure embedded system, he must undergo an authentication process to verify his identity. Authentication scenarios may include combinations of a secret password; a physiological trait, such as a fingerprint; or a security device, such as a smart card or key. For example, the EntréPad 1510 slide sensor from AuthenTec enables fingerprint authentication for portable devices such as cell phones. Contained in a 12×5-mm, 40-pin BGA package, the sensor includes a dense 128×8-pixel-detection matrix along with pattern-matching firmware (**Figure 2**). Hackers have been successful in obtaining passwords by visually or electronically capturing keystrokes or simply asking for them through a variety of subterfuges. Often, passwords pass over local wired or wireless networks in the clear or unencrypted, and attackers can capture them with simple packet-capture programs widely available on the Internet.

## CODE AND DECODE

When an embedded system must connect to a network or the Internet, designers turn to encryption to safeguard their data. Effective encryption schemes work equally well over wired, wireless, or power-line communications systems. Two basic types of encryption algorithms are in use today, both relying on a secret key plus an encoding sequence to transform plain text into cipher text and vice versa. With symmetric encryption, the sender and receiver use the same key to encrypt and decipher a message. Asymmetric encryption uses two keys—one for encryption and another for decryption. Public-key cryptography is a popular form of asymmetric encryption that makes one of the keys available publicly and keeps

**Figure 3** The Spartan P630 targets military-manpack applications with a hardened, sealed enclosure and software for preboot access control and data encryption.

the other secret. Key distribution and secrecy are fundamental problems in cryptographic security systems (see **sidebar** “Safeguarding keys”).

The most widely used security protocol for TCP/IP network traffic is the SSL (Secure Sockets Layer), which provides data encryption, server authentication, message integrity, and optional client authentication. SSL comes in 128- and 256-bit versions whose names refer to the length of the session key that encrypted transactions generate. The longer the key, the more secure the encrypted data. IPSec (Internet Protocol Security), another

encryption standard, implements security at the network layer and allows the system to transparently encrypt network traffic. You can install IPSec in a gateway computer to secure all traffic passing onto the Internet without adding overhead to individual network nodes. Like most other security protocols, IPSec includes provisions for both key and message exchange. Virtual private networks use IPSec to create secure networks over the Internet.

Targeting military-manpack applications in which security is paramount, General Micro Systems recently introduced a secure portable PC with a 6.5×3×0.5-in. main-board footprint (**Figure 3**). The Spartan P630 is a hardened PC featuring a 1.4-GHz Pentium-M processor, as much as 2 Mbytes of L2 cache, an embedded GPS (global-positioning-system) receiver, and 802.11b/g wireless communications in a pocket-sized form factor. The company can configure the device with as much as 2 Gbytes of ECC memory, 16 Gbytes of bootable flash, as much as 60 Gbytes of hard-disk drive, and an LCD/touchscreen in a hardened, sealed enclosure. To ensure secure operation, Spartan includes software for preboot access control and data encryption along with automatic file deletion if someone compromises the system. Spartan also features a six-hour bat-

**Figure 4** Security features allow Pure Digital to profitably offer customers a one-time-use video camcorder for less than \$40.

#### APPLICATIONS

- Food Processing Temperature Controllers
- Industrial Gas Analyzers
- Petrochemical Flow Controllers
- Foundry Process Automation
- Numerical Control Machine Systems
- Transducer Calibrators
- Plastic Injection Molding Machines
- Pressure Monitoring
- Level Sensors
- Flow Metering
- Biomedical Patient Monitors

#### FEATURES

- Low offset: 5 $\mu$ V (CS3003/3004)
- Low drift: 0.05 $\mu$ V/°C
- Low noise: 17nV/ $\sqrt{\text{Hz}}$  (CS3003/3004); 25nV/ $\sqrt{\text{Hz}}$  (CS3013/3014)
- High open-loop gain: 150 dB (CS3003/3004); 135 dB (CS3013/3014)
- Rail-to-rail input swing
- Available in 8-lead SOIC and 4x4 mm QFN

## Expanding Family of High-Precision Industrial Op Amps for High-Resolution Analog Measurement

### NEW CS300X PRODUCTS DELIVER SUPERIOR ACCURACY, LOW POWER

Cirrus Logic has broadened its family of high-precision operational amplifiers with the new CS3003/CS3004 and CS3013/CS3014 family of ICs. These op amps deliver the industry's most highly accurate ICs for applications such as temperature control, safety monitoring and factory process controllers, where high-resolution measurement is critical.

The CS3003/3004 family of ICs offer open-loop gain of up to 150 dB (typical) and input offset voltage of only five microvolts, with drift of 0.05 microvolts per degree. Critical noise errors are limited to 17 nanovolts per root-hertz, which

is held flat above 2 kHz bandwidth. This exceptional performance ensures minimal errors due to noise, leakage and drift while offering extremely high gain to preserve measurement accuracy.

The CS3013 and CS3014 also feature low power consumption—approximately 50 percent lower compared to competing ICs—which is important for new generations of battery-powered portable instruments and personal monitoring applications.

With these new products, Cirrus Logic has strengthened its portfolio of high-precision analog ICs for applications demanding superior high-resolution measurement.

# PICO

ULTRA MINIATURE

## Surface Mount Audio Transformers

Low Profile  
.24" ht.

See full Catalog immediately  
[www.picoelectronics.com](http://www.picoelectronics.com)

- Manufactured and tested to MIL-PRF-27
- Frequency range 20 Hz to 250 KHz
- Available from 100 milliwatts to 3 watts
- Impedance from 20 ohms to 100 K ohms
- Operating temperature -55°C to +130°C
- Low Profile .24" ht.

Delivery-  
stock to one week

tery life and is available in a conduction-cooled version operating at -40 to +85°C or a standard convection-cooled version with a 0 to 55°C temperature range. Packaging options include a titanium-aluminum enclosure for rugged applications. Software support for the P630 is available under Windows XP, Linux, QNX, and VxWorks. Prices for the conduction-cooled version start at \$3400 (100).

### SECURE BUSINESS

With improving security, device manufacturers are experimenting with business models to attract more customers. In the pay-as-you-go scenario, customers receive a fully functional device and promise to pay for it as they use it or over the life of a subscription plan. If the customer fails to make a payment, the vendor can disable the device by withholding network-activation codes. A strong security model then prevents the customer from bypassing activation or removing parts.

For example, Microsoft recently announced FlexGo, a pay-as-you-go platform to extend PC ownership into emerging markets. FlexGo requires that system components individually track usage based on active minutes or a specific end date. When a consumer has used all of the available computer time, Microsoft limits access to the PC until the consumer adds more time. The company also imposes usage limitations when there are signs of system tampering. Microsoft has also added secure operating-system components to enable metered use of the software. A FlexGo software-development kit allows businesses to use their own billing systems to manage Microsoft's provisioning system to offer pay-as-you-go computer-use time to customers.

With stand-alone embedded-security challenges, Pure Digital manufactures a pocket-sized, one-time-use camcorder that records as much as 20 minutes of video and audio (Figure 4). The device is available through several camera- and convenience-store outlets for as little as \$20 plus a \$12 processing charge to copy your movies onto a DVD. The device includes a fixed-focus lens, a 1.4-in. color LCD, and speaker plus operator controls

to record, play back, and delete unwanted scenes. Although the device is a hacker's delight, and several Web sites are devoted to extracting the video without returning the camcorder for processing, there are sufficient security measures to deter most users.

Security precautions and potential information-disclosure consequences have changed the fundamental design goals for embedded products. Designers are no longer driven to produce the simplest, lowest cost device for each project. Security requirements have forced designers to beef up resources with faster, more capable processors, secure data storage, and tamperproof hardware to protect the system and data while executing the application. **EDN**

# Support Across The Board.™

Starting with in-depth design support all the way through to total supply chain management – Avnet Electronics Marketing is there for you. From concept to reality, we deliver:

Consultative engineering support and services

Focused product specialization

The broadest supplier partnerships in the industry

Over \$1 billion in top moving inventory “on the shelf”

World-class supply chain services

But, partnering with Avnet Electronics Marketing means much more than just having access to the industry’s broadest array of design and supply chain services. It means working with a company that is truly focused on exceeding your needs and expectations – a company that is dedicated to giving you **Support Across The Board.™**

Ready.

Set.

Go to market.™

Enabling success from the center of technology™

# Typical Field Programmable Gate Array Power Requirements

The flexibility of FPGAs leads to the requirement for multiple supply voltages and currents.

### Core Voltage / Power

In large FPGAs, the logic core generally has the most demanding current requirements, up to tens of amps depending on the number of gates being used and the clock frequency. Designated  $V_{CCINT}$  by Altera, by platform the voltage required is:

- Stratix® and Cyclone® series = 1.5V
- Stratix II series = 1.2V

### I/O Voltage / Power

Designated  $V_{CCO}$  and equal to 1.5V, 1.8V, 2.5V or 3.3V depending on the I/O standard selected. I/O standards can be set independently by block in the FPGA, so more than one I/O voltage for a single FPGA is possible.

## Intersil's Power Management Portfolio of DC/DC Regulators, PWM and LDO Controllers

3.3V Input	$V_{IN}$ (V)		$I_{OUT}$ (max)(A)	# of Outputs	Int. FET	$V_{OUT}$ (V)		Device Description	Package

## The “One-Chip” Power Solution

Intersil’s multi-output family of PWM controllers and Integrated FET regulators support up to four rails, providing a “one-chip” solution for most applications.

### Multiple Output/Multi-Phase IFETs and Controllers

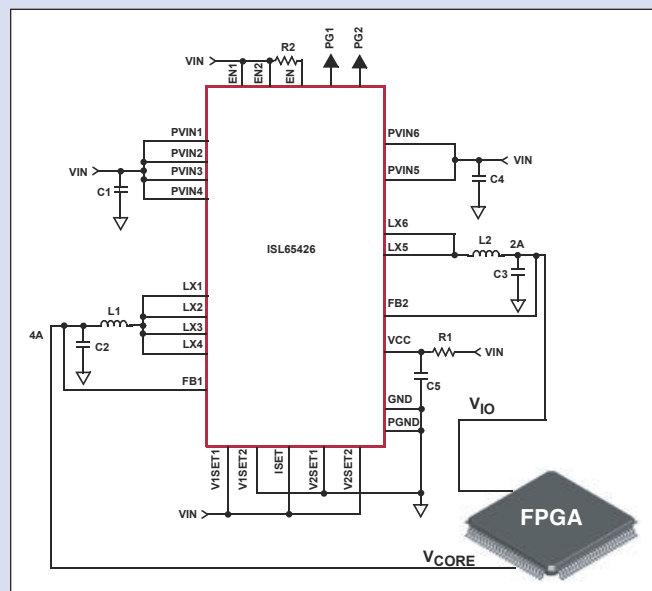

Part Number	Architecture	Input Voltage Range (V)	Output Voltage Range (V)	I <sub>OUT</sub> max (A)
ISL6455	1 PWM Regulator + 2 LDOs	3.0-3.6	0.8-2.5	0.6
ISL6455A	1 PWM Regulator + 2 LDOs	4.5-5.5	0.8-3.3	0.6
ISL8501	1 PWM Regulator + 2 LDOs	6.0-22	0.6-22	1
ISL6440	2 PWMs	4.5-24	0.8-24	10
ISL6445	2 PWMs	4.5-24	0.8-5.5	10
ISL6441	2 PWMs (f <sub>sw</sub> = 1.4MHz) + Linear Controller	4.5-24	0.8-24	20
ISL6442	2 PWMs (f <sub>sw</sub> = 2.5MHz) + Linear Controller	4.5-24	0.8-24	20
ISL6443	2 PWMs (f <sub>sw</sub> = 300kHz) + Linear Controller	4.5-24	0.8-24	20
ISL65424	2 PWM Regulators	2.375-5.5	0.6-5.5	4
ISL65426	2 PWM Regulators	2.375-5.5	0.6-5.5	6
ISL8101	3 Phase PWM	5.0-12	0.6-2.3	100

ISL8103	2 Phase PWM	5.0-12	0.8375-1.6	60-80

### ISL65426: 6A Dual Synchronous Regulators for V<sub>CCINT</sub> and V<sub>CCO</sub>

The ISL65426 is a high efficiency dual output synchronous buck regulator with integrated power MOSFETs, tailor-made for FPGA power solutions. Operating from an input bias ranging from 2.375V to 5.5V, the single chip solution provides two output voltages which are selectable or externally adjustable from 0.8V to 4.0V while delivering up to 6A of total output current. The two regulator outputs can be used to supply V<sub>CCINT</sub> and V<sub>CCIO</sub> with a reduced number of external components and high efficiency.

The power block contains six 1A capable blocks to support one of the four output configuration options (3A:3A, 4A:2A, 5A:1A, 2A:4A).

High integration contained in a thin Quad Flat No-Lead (QFN) package makes the ISL65426 the ideal choice to power small form factor power management applications.

ISET	ISET	IOUT1	CHANNEL1 CONNECTIONS	IOUT2	CHANNEL2 CONNECTIONS
1	1	3A	LX1, LX2, LX3	3A	LX4, LX5, LX6

0	1	5A	LX1, LX2, LX3, LX4, LX6	1A	LX5
0	0	2A	LX1, LX2	4A	LX3, LX4, LX5, LX6

## ISL6521: PWM Controllers for $V_{CCINT}$ and Linear Regulators for $V_{CCO1}$ , $V_{CCAUX}$ , and $V_{CCO2}$

Combination products that incorporate multiple switchers and/or linears in a single package are an excellent choice for many FPGA-based designs. These combination devices can provide all the voltages required from a single IC or board, and they can be adjusted to provide the optimum responses for the end application. Good layout and bypassing techniques plus excellent on-chip isolation prevents the supplies from interacting.

The ISL6521 can provide the required currents and voltages for the latest generation of Altera FPGAs (for example Stratix II, Stratix and Cyclone series) in a 16-pin SOIC package with minimal external components. The ISL6521 implements a highly efficient synchronous buck design and in addition includes three linear regulators, which can provide additional voltages to the board.  $I_{CCO}$  and  $I_{CCAUX}$  currents less than 120mA can be supplied directly from the linear regulator drive pins (as shown here for  $V_{CCO2}$ ) or they can be used to control an external transistor (as shown here for  $V_{CCO1}$  and  $V_{CCAUX}$ ).

The complete datasheet for the ISL6521 is available at [www.intersil.com/data/fn/fn9148.pdf](http://www.intersil.com/data/fn/fn9148.pdf). Simulation tools are also available at [www.intersil.com/isim/](http://www.intersil.com/isim/).

## ISL644X: High Efficiency Dual, Step Down PWM Controllers with Single Linear Controller

### 300kHz to 2.5MHz Family of Dual, 180° Out-of-Phase, PWM Controllers + Linear Controller

The ISL644X family of controllers can create a highly efficient triple-output solution by using 180° out-of-phase synchronous buck switchers to supply  $V_{CCINT}$  and  $V_{CCIO}$ . It also has an internal 5V Linear regulator that can sink and source current. The Linear regulator can source up to 6A using an external transistor. The ISL644X family offers a wide input range of  $V_{IN}$  from 5.6V to 24V and 4.5V to 5.6V.

The two PWMs synchronized 180° out-of-phase reduce the RMS input current and ripple voltage, hence can supply both Core and I/O voltages independently. The ISL644X family incorporates several Protection and supervisory features. Power-up sequencing is available through the integrated programmable Soft-Start. The outputs can be adjustable down to 0.8V and up to 24V. The efficiency of the ISL644X family is enhanced by using the lower MOSFET  $R_{DS(ON)}$ .

The complete datasheet for the ISL6441 is available at [www.intersil.com/data/fn/fn9197.pdf](http://www.intersil.com/data/fn/fn9197.pdf). Simulation tools are also available at [www.intersil.com/isim/](http://www.intersil.com/isim/).

## ISL6420A: Advanced Single Synchronous Buck PWM Controller

The ISL6420A is an excellent solution for all the FPGA family's power requirements. It has a wide input voltage range from 4.5V to 28V and a programmable output current capability up to 20A.

The core or the I/O voltages are supplied by a synchronous buck switcher with fast transient response which makes the solution very efficient. The output voltages of the ISL6420A are fully adjustable from 0.6V to 28V, with a maximum tolerance of  $\pm 1.0\%$  over temperature and line voltage variations.

The switching frequency is resistor selectable from 100kHz to 1.4MHz which offers cost and space savings. The ISL6420A integrates control, output adjustment, monitoring and protection functions into a single package. The ISL6420A is available in QFN and QSOP packages.

The complete datasheet for the ISL6420A is available at [www.intersil.com/data/fn/fn9169.pdf](http://www.intersil.com/data/fn/fn9169.pdf). Simulation tools are also available at [www.intersil.com/isim/](http://www.intersil.com/isim/).

## >20A Solutions: ISL8102 Multi-phase Buck PWM Controller

As the current requirements of the board rise to greater than 20A, more sophisticated power supply solutions are required to maintain well-regulated supply voltages. By distributing the power and load current, implementation of multi-phase converters utilize smaller and lower cost transistors with fewer passives. These reductions are possible due to the phase interleaving process of this topology.

The ISL8102 is a two-phase PWM control IC with Integrated MOSFET drivers. It has the system voltage regulation accuracy up to  $\pm 0.5\%$  over temperature. It integrates an optional Load Line (Droop) programming, using the loss-less inductor DCR current sampling. Precision channel current sharing is implemented using loss-less  $R_{DS(ON)}$  current sampling, which makes it a highly efficient solution.

The complete datasheet for the ISL8102 is available at [www.intersil.com/data/fn/fn9247.pdf](http://www.intersil.com/data/fn/fn9247.pdf). Simulation tools are also available at [www.intersil.com/isim/](http://www.intersil.com/isim/).

# Magnetic-field measurements hold the key to reducing dc/dc EMI

POWER CONVERTERS FREE SYSTEM DESIGNERS FROM UNWILDEY CONSTRAINTS, BUT THE DEVICES RADIATE UNSPECIFIED FIELDS THAT CAN DESTROY THE SIGNAL/NOISE PERFORMANCE OF SENSITIVE CIRCUITS NEARBY. MAGNETIC-FIELD MEASUREMENTS HOLD THE KEY TO FINDING AND CORRECTING THESE PROBLEMS.

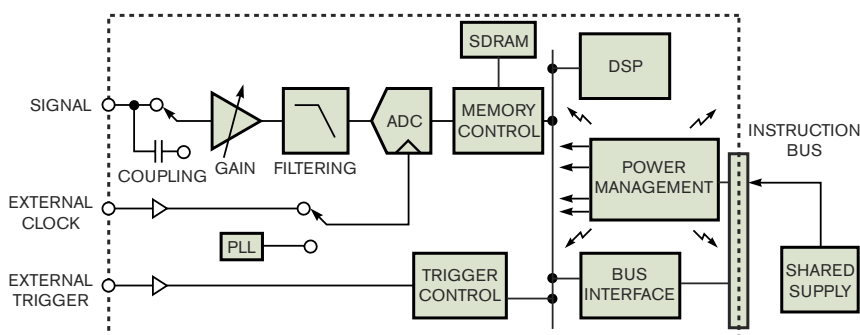

Performance-driven measurement instrumentation requires low-noise, high-bandwidth linear front-end circuits that combine with equally well-performing A/D converters and clocking (**Figure 1**). Designers work to quantize the measurement of interest into a digital signal early in the processing chain to keep out unwanted noise. Look at your favorite instrumentation Web sites. A brief scan of dc-measurement and ac-source-and-measurement instrumentation turns up instruments with dynamic ranges of 120 dB or more. Engineering for dynamic range is a search for the source of every spurious signal. High-performance-instrument designers must be aware of all of the potential noise sources—not just the usual culprits, such as power supplies and digital activity. As dynamic range exceeds 100 dB, engineering for high SNR leads to investigating the charge pump running in the FPGA, the thermal gradient that occurs when the processor starts and stops, and the magnetic coupling from the other instrument that someone set on top of your instrument. A significant part of the design is isolating precision analog circuits from internal and external electromagnetic activity.

Today's instrumentation-and-measurement industry is undergoing a transformation. After years of performance-based engineering, market forces are leading to new open architectures (**Figure 2**). With customers wanting the advantages of open architecture without performance compromise, the new environment brings new engineering challenges.

For example, consider the semiconductor-test industry, in which the test requirements of SOC (system-

**Figure 1** Performance-driven measurement instrumentation requires low-noise, high-bandwidth linear front-end circuits coupled to equivalent-performing A/D converters and clocking. It also requires a power supply, sometimes line-powered, as shown, but often a dc/dc converter.

**Figure 2** After years of performance-based engineering, market forces are leading to new open architectures. At the block-diagram level, open and proprietary architectures are similar, but, at the implementation level, the differences can be significant.

on-chip) ICs drive up the breadth of instrumentation that test systems must contain. Time to market and the cost of ownership of large ATE (automatic-test-equipment) systems have combined to define a critical need for an open-test-system architecture (**Reference 1**). The trend exceeds the bounds of just ATE, however. A growing need exists for high-performance, modular VXI and PXI instrumentation for production testing and characterization. Test-equipment architectures are opening up as a strategy to reduce cost through greater flexibility, which leads to higher efficiency, greater reuse, and lower barriers to competition among suppliers.

So where does this trend leave instrument-development teams? During the era of performance-driven design, development teams had control over a large part of the system architecture. That's not the case in open, card-modular architectures, such as VXI. In such architectures, the backplane interface and physical-packaging limits highly constrain design engineers. Engineers need to place more emphasis on environmental issues, such as cooling, power conversion, and EMI (electromagnetic interference). One of the more significant of these challenges

is EMI from power-conversion components within the instrumentation system. A dc/dc converter within the system relieves a combination of space and power-supply constraints, but it also generates noise, which could be the factor that limits your spurious-free dynamic range. This scenario can occur whether this

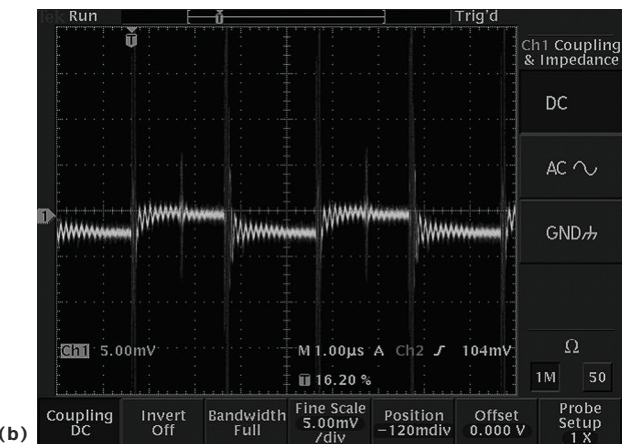

**Figure 4** A wideband amplifier amplifies the pickup-loop output and drives an oscilloscope and a spectrum analyzer. Wiring the signal to the amplifier and from the amplifier to the instruments requires care to avoid introducing spurious signals that can reduce the measurement accuracy.

**Figure 3** A varying magnetic field induces in a pickup loop a voltage proportional to the loop area and rate of change of the field component normal to the plane of the loop.

**Figure 5** The intent is to place the pick-up loop 1 in. above the plane that would represent the surface of the motherboard if the converter were mounted in an appropriate through-hole design.

**Figure 6** Although the two tested dc/dc converters, Brand X (a) and Brand Y (b), are equal in size, have the same basic architecture, and have nearly identical published specifications, the magnetic fields above them differ considerably.

# Intersil Ambient Light Sensors

High Performance Analog

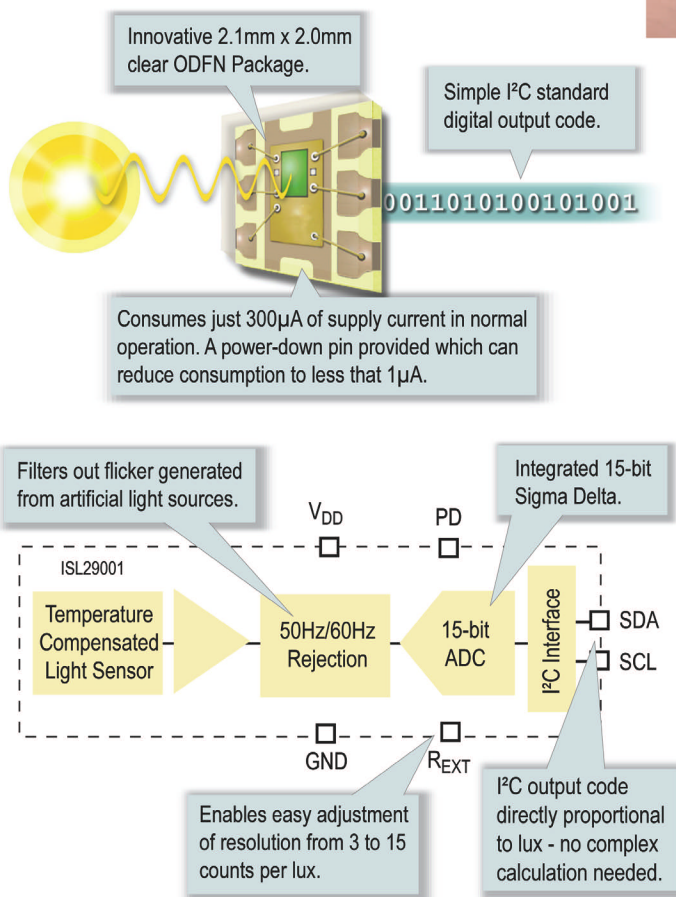

## The Best Ambient Light Sensors and Their Closest Competitor

With light sensitivity only matched by the human eye, Intersil's ISL29001 Light-to-Digital Converter provides simple, pure 15-bit I<sup>2</sup>C digital data.

Drawing less than 300 $\mu$ A of supply current, the ISL29001 provides 15-bit effective resolution. This state-of-the-art device integrates two photodiodes and an ADC into a super small 2.1mm x 2.0mm ODFN package. The digital data in standard I<sup>2</sup>C format couldn't be simpler to use. It's no wonder **EDN Magazine** has selected one of this family's light sensors as a finalist for this year's **Innovation of the Year Award**.

innovation  
EDN MAGAZINE  
2005 FINALIST

### ISL29001 Key Features:

- I<sup>2</sup>C Interface produces simple I<sup>2</sup>C output code, directly proportional to lux
- 0.3 lux to 10,000 lux range
- 50Hz/60Hz rejection to eliminate artificial light flicker
- Human eye response
- 15-bit effective resolution
- Adjustable resolution: 3 to 15 counts per lux
- 2.5V to 3.3V supply
- Temperature compensated
- 6-pin ODFN (2.1mm x 2mm)
- Pb-Free plus anneal available (RoHS compliant)

HIGH PERFORMANCE ANALOG

**Figure 7** Whereas both converters, Brand X (a) and Brand Y (b), have similar switching characteristics, a faster sweep reveals that, although Brand Y's magnetizing inductance keeps emissions lower overall, the unit's leakage inductance resonates at a higher frequency and couples greater peak voltage at the switching transient.

TABLE 1 DATA FROM SAMPLES			
Characteristic		Brand X	Brand Y
Switching frequency (kHz)		420	250
Time domain	Switching field (mV p-p)	9.5	2
	Switching field ( $\mu$ tesla p-p)	14.1	4.94
	Transient field (mV p-p)	20	160
	Transient field (tesla/sec)	24.7	197
Frequency domain	Fundamental field (dBm)	-36	-48
	Fundamental field ( $\mu$ tesla)	3.5	1.4
	Resonance (MHz)	20	9.1
	Resonant field (dBm)	-56	-55
	Resonant field (ntesla)	7	17.1

noise originates in the affected instrument or from a noisy neighbor whose design did not require the same attention to dynamic-range requirements.

Instrumentation for an open architecture must comply with system specifications regardless of whether the instrument in the next slot is a highly dynamic power supply or a bank of 200-MHz digital-pin drivers. In this environment, every instrument must be tested to demonstrate compliance with a field-emission profile that imposes the same emission and susceptibility requirements on all instruments.

## MAGNETIC COUPLING

Near-field, radiated EMI can create noise problems for sensitive instrumentation. Near fields contain both electric and magnetic fields in proportion to the impedance of the source (Reference 2). Low-impedance circuits—that is, low relative to the  $377\Omega$  impedance of free space, or air—emit predominantly magnetic fields, whereas high-impedance circuits emit predominantly electric fields. Coupling includes capacitive and mutually inductive coupling depending upon fields present and the configuration of the victim circuitry. Because circuit impedances in switch-mode power-supply circuits tend to be low and electric fields are relative-

**Figure 8** A broad look at the spectrum of Brand Y's field shows a resonance near 10 MHz with components peaking at 20 to 25 MHz.

ly easy to shield, this article focuses on magnetic coupling (Figure 3).

Faraday's Law leads to an understanding that the electromotive force—essentially voltage plus any resistive losses—in a circuit is proportional to the rate of change of the magnetic flux within the circuit. No voltage is induced if the rate of change is zero. Magnetic interference is an ac issue with a higher degree of coupling as frequency increases.

Magnetic flux,  $\Phi_M$ , can be self-induced, as with the product of inductance and current, or mutually induced, as with the product of flux density and loop area (see sidebar "Magnetic circuits"). The relationship in the following equation is interesting:  $E = -d\Phi_M/dt = d(LI)/dt = -d(BA\cos\theta)/dt$ , where  $I$  is current,  $B$  is

# Intersil Real-Time Clocks

High Performance Analog

## And the Winner is...

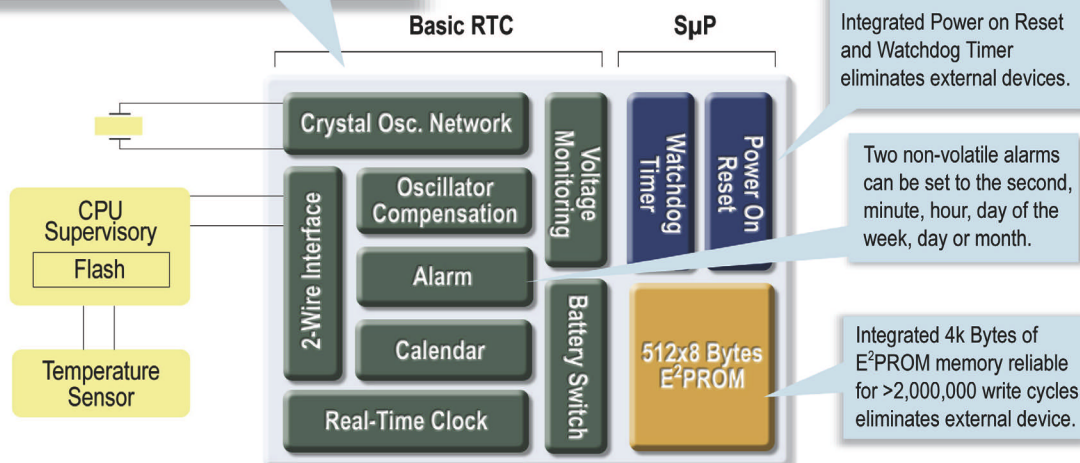

Intersil's low power I<sup>2</sup>C Real-Time Clocks saves costs and board space by integrating 4k Bytes of E<sup>2</sup>PROM memory **AND** CPU Supervisory Functions.

Switching to Intersil's ISL12027, ISL12028 and ISL12029 can save you money and board space two ways. First, we've integrated 4k of E<sup>2</sup>PROM memory, Power On Reset and a Watchdog Timer eliminating two external devices. Secondly, we've added crystal frequency trimming capability to deliver high accuracy timekeeping with a low-cost 32.768kHz crystal. The end result is a highly efficient real-time clock you can rely on for >2,000,000 Write Cycles.

Crystal frequency compensation provides initial crystal trimming and subsequent timing correction due to temperature variation, saving you money by delivering accurate timekeeping with less expensive crystal.

HIGH PERFORMANCE ANALOG

## MAKING YOUR OWN MAGNETIC-FIELD-MEASUREMENT PROBE

A high-bandwidth amplifier provides approximately 20 dB of gain to a signal that a small magnetic loop produces (Figure A). You can observe the probe output on a spectrum analyzer or an oscilloscope depending upon the application requirements. Many ac-source or -measurement instru-

ments need to describe performance in terms of SFDR (spurious-free dynamic range) and would tend toward spectral data. However, dc instrumentation may be more concerned with total rms noise energy and would examine field measurements in the time domain. These com-

ponent measurements look at both.

Figures B and C show the layout of the amplifier and probe tip. The probe tip provides a circular area with 0.4 in. diameter perpendicular to the circuitry on the pc board. An additional design consideration is to provide a balanced input to cancel

any electric fields coupling to the probe tip.

This circuit uses high-bandwidth current-feedback op amps because the dc/dc converters that are most interesting for instrumentation development have resonant components of 25 to 60 MHz.

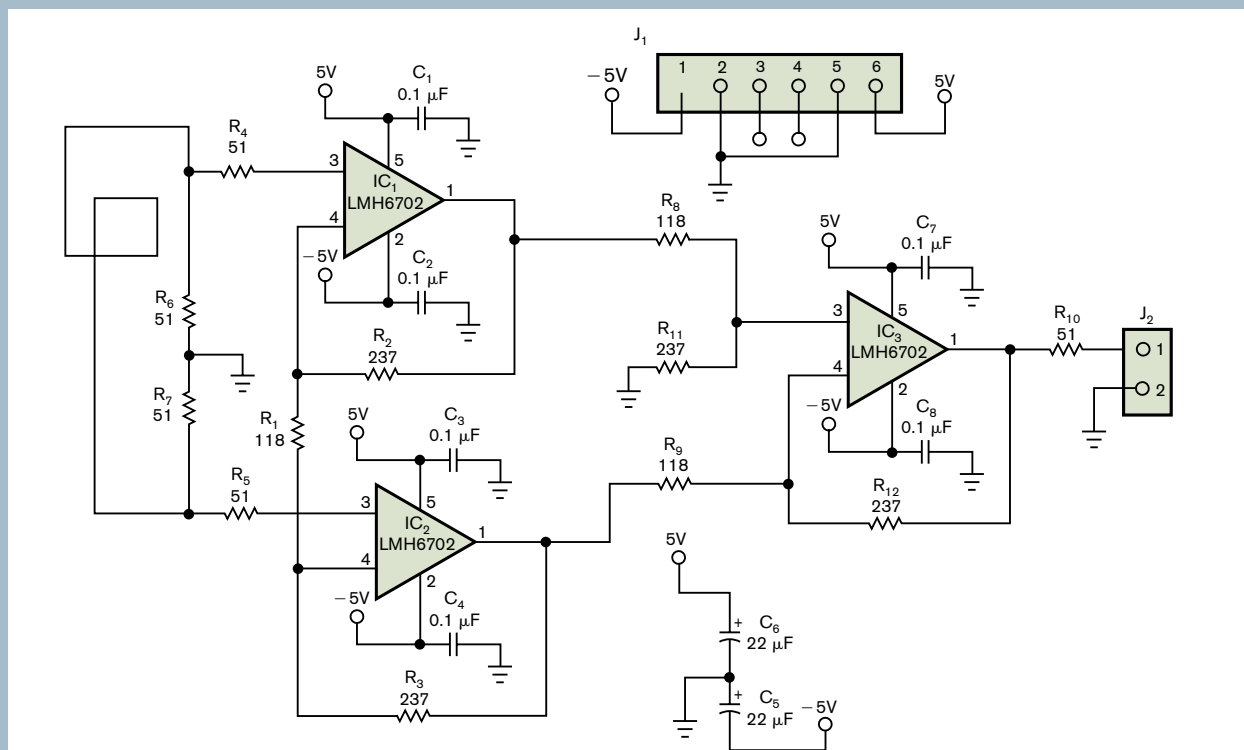

Figure A This high-bandwidth, 20-dB preamplifier amplifies the small signals that the magnetic loop picks up.

Figure B The amplifier layout is orthogonal to the probe tip and as balanced as possible.

Figure C The probe tip provides a circular area 0.4 in. in diameter perpendicular to the circuitry on the pc board. A balanced input cancels any electric fields that couple to the probe tip.

# Intersil Battery Charger ICs

Intersil High Performance Analog

## Unshackle Your Handheld Device

Intersil's ISL6299A is a fully integrated low-cost Li-ion or Li-polymer battery charger that accepts both USB port and desktop cradle charger.

The ISL6299A is a low component count solution that features programmable cradle charge current, charge indication, adapter present indication, and programmable end-of-charge (EOC) current with latch. All these advanced features, along with Intersil's Thermaguard™ technology for an added measure of thermal protection, are delivered in a single 3x3 mm DFN package.

### ISL6299A System

**Cradle input.** The max input voltage tolerance is 28V. Programmable charge current up to 1A and programmable end of charge current. The included end of charge latch is the default input source.

**USB input.** Takes input from USB port or other low voltage supply. Fixed charge current at typically 380mA. Only charges when cradle source is not connected.

Programmable end-of-charge optimizes end-customer applications. High input voltage tolerance protects the device when used with low cost unregulated supplies or in under input transient conditions.

Fast-charging rates of an AC adaptor for when you have access to cradle.

28V tolerant cradle with overvoltage protection.

Sync-up and fuel-up directly from your laptop with convenient USB charger.

### ISL6299A Key Features:

- Dual-input charger for single-cell li-ion/polymer batteries for cradle and USB
- Low component count
- Integrated pass element
- Fixed 380mA USB charge current
- Programmable cradle charge current
- Charge current Thermaguard™ for thermal protection
- 28V maximum voltage for the cradle input
- Charge and adapter presence indicators
- Less than 0.5µA leakage current off the battery when no input power attached
- Programmable end-of-charge current with latch for cradle input
- No external blocking diode required
- Pb-Free plus anneal available (RoHS compliant)

Datasheet, eval kit with USB interface, free samples, and more information available at [www.intersil.com](http://www.intersil.com)

HIGH PERFORMANCE ANALOG

magnetic-flux density, and  $L$  is inductance. The equation says that you can induce an error voltage into a circuit by changing any one or more of the parameters. A given percentage change in current, magnetic field, or inductance (loop area) produces the same effect on induced voltage. Therefore, the design practice of reducing loop areas in high-performance circuits to elim-

inate errors from conducted emissions also reduces errors from magnetic coupling.

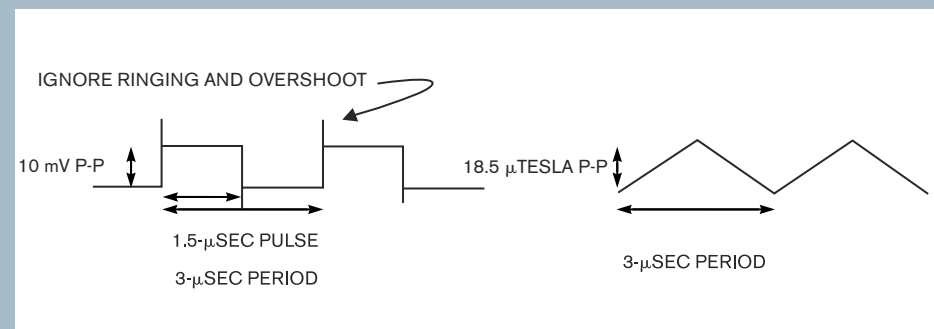

Although high-performance design practice dictates that you minimize loop area and shield necessarily susceptible components, such as filter inductors, it's always better to stop noise emissions at their source. Toward that end, instrument design-

## CONVERTING VOLTAGE MEASUREMENTS TO MAGNETIC-FIELD DATA

An instrument designer characterizing various sources of magnetic interference might find satisfaction with the relative-voltage measurements that a standard loop produces—assuming that the loop represents the loop area and orientation that an instrument might experience. But, because the loops and amplification can differ, it is helpful to convert these voltage measurements into field data.

Current in the emitting circuit creates magnetic flux that cuts through the test loop. The test loop is held stationary, including its angle to the field,  $\theta$ , but the flux density,  $B$ , is changing to induce a voltage:  $|V_{\text{MEASURED}}| = K_A A_L \cos\theta dB/dt$ , where  $K_A$  is the gain of the amplifier,  $A_L$  is the area of the loop in square meters,  $dB/dt$  is the rate of change of the flux density in webers per square meter, or teslas. Plugging in the values and noting that the termination into the spectrum analyzer reduces the gain by a factor of two yields:  $|dB/dt| \cos\theta = 2467 \times V_{\text{MEASURED}}$  (teslas).

Consider a reading of 10 mV p-p for the switching component in Figure A. Ignore the peak deviations at the switch transients because they do not add appreciably to the rms

**Figure A** This typical time-domain measurement converted to the B-field is a 3-μsec, 50%-duty-cycle switching waveform. The 5-mV peak measurement equates to a 12.3-tesla/sec rate of change in flux density.

energy. This example has a 3-μsec, 50%-duty-cycle switching waveform. The 5-mV peak measurement equates to a 12.3-tesla/sec rate of change in flux density. Given that this rate remains 1.5 μsec, the flux density (B-field) in the direction of the pickup loop is 18.5 μtesla p-p.

You measure the magnetizing force, or H-field, in amps per meter, and you can determine it from the B-field by dividing by the permeability of free space, or  $4\pi \times 10^{-7}$ . The 37-μtesla-p-p flux density is equivalent to 29.4A/m in an air-core circuit.

A spectrum analyzer can provide an alternative view of noise coupling. You can examine the issues of ringing and resonance. Reference A provides a derivation that takes advantage of a sinusoidal B-field:  $V_N(\omega) = \omega K_A A_L B_R$

$(\omega) \cos\theta$ , where  $V_N$  and  $B_R$  are rms quantities at the frequency of interest,  $K_A$  is the amplifier gain,  $A_L$  is the loop area, and  $\theta$  is the angle between the field vector and the area perpendicular to the loop area. Plugging in the previously determined values yields:  $B_R \cos\theta = 393 [V_N(f)/f]$  2. For general

application, you can convert this formula into a chart (Figure B).

# Intersil Switching Regulators

High Performance Analog

## Need a Multiple Output PWM that can Tackle a Wide Range of Voltages?

Now you can get true 180° Out-of-Phase PWM performance along with your choice of two or three regulated outputs.

Intersil's new line of wide  $V_{IN}$  PWM Controllers offer industry leading performance and protection, along with unmatched design flexibility. So, no matter what your input voltage, switching frequency, or number of system supply voltage requirements are, we've got the right PWM Controller IC for your design.

### Triple Output PWM Controller

4.5V to 5.5V or  
5.6V to 24V  
Input Voltage

$V_{OUT1}$ : Adjustable, 0.8V to  $V_{IN}$   
 $V_{OUT2}$ : Adjustable, 0.8V to  $V_{IN}$   
 $V_{OUT3}$ : Adjustable, 0.8V to  $V_{IN}$

Synchronized 180° out of phase reducing the RMS input current and ripple voltage.

### Triple Output PWM Controller

4.5V to 5.5V or  
5.6V to 24V  
Input Voltage

$V_{OUT1}$ : Adjustable, 0.8V to  $V_{IN}$   
 $V_{OUT2}$ : Adjustable, 0.8V to  $V_{IN}$   
 $V_{OUT3}$ : Adjustable, 0.8V to  $V_{IN}$

An adjustable overcurrent protection circuit monitors the output current by sensing the voltage drop across the lower MOSFET.

### Dual Output PWM Controller

4.5V to 5.5V or  
5.6V to 24V  
Input Voltage

$V_{OUT2}$ : Adjustable, 0.8V to  $V_{IN}$   
 $V_{OUT3}$ : Adjustable, 0.8V to  $V_{IN}$

### Key Features:

- Operates from wide range of input supplies (4.5V to 24V)
- 1.4MHz switching frequency (ISL6441, ISL6445) for smaller passive components or 300kHz switching frequency (ISL6440, ISL6443) for highest efficiency. ISL64442 switching frequency is adjustable from 300kHz to 2.5MHz.
- Dual (ISL6440, ISL6445) and Triple (ISL6441, ISL64442, ISL6443) regulated outputs
- Internal compensation replaces external components freeing-up valuable board space
- Over current, over voltage, PGOOD and thermal shutdown
- Out of phase operation to reduce input filter requirements and EMI
- Small footprint and excellent thermal resistance in 5x5 QFN package (ISL6441, ISL6443) and 20-ld QSOP (ISL6440, ISL64442, ISL6445)

HIGH PERFORMANCE ANALOG

ers would like to compare near-field performance in the time and the frequency domains before they select power converters for use in instruments. Magnetic-field specifications are not yet at this level of maturity, however, so device characterization is necessary.

## MEASUREMENT EXAMPLE

For example, two similarly specified dc/dc converters have been characterized for magnetic-field emissions with a small loop antenna. Both converters are one-eighth-brick, wide-input-

range devices using the same input voltage, 48V; output voltage, 5V; and load resistance, 4Ω. Both share the same conversion architecture—a fixed-ratio isolation stage following a regulation stage to support a 35 to 75V input range. These converters have two power magnetic sections within the design, but both run at the same frequency. Neither converter provides magnetic-emission data within the specification sheet.

In this characterization setup (Figure 4), a small pickup loop senses magnetic fields in the area above the dc/dc converters (see sidebar “Making your own magnetic-field-measurement

## MAGNETIC CIRCUITS

Electrical engineers appear to be most comfortable working with circuits in which ideal conductors make signal connections. Inductors are OK for helping with frequency-domain issues, such as filtering, but there is a tendency to ignore the magnetic component.

Do not fear a magnetic circuit. Observing the similarities between inductors and capacitors is helpful in developing an understanding of the circuit operation (figures a and b and Reference A). The intensity of the electric field between the plates of a capacitor depends only on the voltage and the physical distance,  $d$ , between the plates:  $E=V/d$  in volts per meter.

The intensity of the magnetic field surrounding a conductor depends only on the current and the physical

width of the conductor,  $w$ :  $H=I/w$  in amps per meter. The magnetic-field strength is sometimes called the magnetizing force.

Capacitance is a function of the plate area, the distance between the plates, and the dielectric material between the plates. The capacitance is  $C=(\epsilon w l)/d$ . The dielectric constant has units of farads per meter. A high dielectric constant produces more capacitance in a given plate area, holding plate separation constant, than a low dielectric constant.

A conductor forms a loop, creating an inductor. The inductance is a function of the area of the loop, the width of the conductor, and the permeability of the material surrounding the conductor:  $L=(\mu d l)/w$ . The core's permeability has

units of henries per meter. Similar to the capacitor, high permeability produces more inductance in a given loop area, holding conductor width constant, than a material with low permeability.

In a capacitor, flux is a measure of the stored charge in coulombs. As the capacitor discharges, this charge becomes the source of current. Electric flux in a capacitor is a function of capacitance and voltage:  $\Phi=CV$ .

Magnetic flux in an inductor is analogous to the electric charge stored in a capacitor. Magnetic flux has units of webers and becomes the source of electromotive force (open-circuit voltage) as the inductor discharges. Magnetic flux is a function of the inductance and voltage:  $\Phi M=LI$ .

The dielectric that influences capacitance per unit also impacts flux density—or charge per unit area. Imagine flux lines between the positive and negative charges on the plate of the capacitor. The number of lines passing through a unit of area represents the flux density:  $D=\Phi/(wl)=\epsilon E$ . The flux density is directly proportional to the dielectric constant of the material between the capacitor plates.

The permeability of the core influences inductance and therefore magnetic flux density. You measure flux density in flux per unit area:  $B=\Phi M/(dl)=\mu H$ .

# A power supply that can pay for itself?

Higher power density and better efficiency equals lower energy consumption...  
...and less cost

## Better technology = more efficiency

The new D1U-W-1600-12-HC has been designed using the latest technologies to be the most efficient 1600W power supply available. Created to service new generation blade servers, it achieves its slim (1U) proportions with a multi-phase interleaved boost PFC, planar transformer and choke, and multi-layer PCBs to replace cabling.

## More efficiency = less cost

While our competitors' typical efficiency is around 85%, the D1U achieves an astonishing 90.6% at full load, bringing huge savings for large installations. For example, in a server farm using 1,000 x 1600W power supplies, an increase in efficiency from 85% to 90.6% could equate to an annual power saving of around 1 million kWh.

MEDICAL AUTOMATION

ROBOTICS

SEMICONDUCTOR

probe"). The amplified-loop output connects to an oscilloscope and a spectrum analyzer. The magnetic emission of the dc/dc converters contains a broad band of energy from the fundamental switching frequency that reaches to 50 MHz or more. It is important to treat the measured signal's distribution network as a high-frequency transmission line. The signal runs past the high-impedance oscilloscope input with a BNC tee at the scope input. The line terminates at the spectrum-analyzer input.

To best represent a victim circuit in a neighboring slot, orient the probe tip in a plane parallel to the converter's pc-board substrate. Scan the surface of the board for maximum output; the strongest field is above the isolation transformer (second stage). The intent of the measurements, which take place about 0.65 in. above the top surface of the transformer, is to place the pickup loop 1 in. above the plane that would represent the surface of the motherboard if you mounted the converter in an appropriate through-hole design (Figure 5).

Viewing measurement results in the time domain, you can see the converter's fundamental frequency and ringing frequency, and you can get a sense of the magnetic-field intensity (Figure 6). These converters demonstrate a trade-off in the converter's magnetic design. The isolation transformer's leakage and magnetizing inductance mutually couples to the measurement probe. Brand X has a significantly lower magnetizing inductance in its isolation transformer, as the higher fundamental field in the measurement shows. Brand Y has lower leakage inductance and therefore higher ringing frequency. The ringing that occurs around the switching transient is the result of leakage inductance and the switch's parasitic capacitance.

You can make two observations based on the derivative relationship of the earlier equation: A square-wave response means that the magnetic flux is changing linearly. The magnetic component is operating in a linear region, and current is increasing linearly. In broad terms, the magnetic field for Brand X is an 18- $\mu$ tesla p-p triangular wave (see sidebar "Converting voltage measurements to magnetic-field data").

Although lower leakage inductance is better for reduced emission, the higher frequency resonance couples greater peak voltage at the higher frequency (Figure 7). A closer observation of the switching transient provides some insight into the resonance within the dc/dc converter.

If your main concern is for spectral interference in an ac-source or -capture instrument, you may be more interested in the information the spectrum analyzer provides. Taking a broad look at Brand Y's magnetic-field spectrum, you can see the resonance near 10 MHz and the components peaking at 20 to 25 MHz (Figure 8). Table 1 summarizes the data from these samples.

Open-instrumentation architectures offer an important role for dc/dc converters. If the converters are not the sources of performance-limiting noise, they open a platform to a large set of applications. This article examines two similar converters using a high-bandwidth magnetic probe and finds different results. Because a system is only as quiet as its noisiest neighbor, anyone wishing to participate in open-instrument development should carefully evaluate to ensure a performance-compatible environment. **EDN**

### AUTHOR'S BIOGRAPHY

William Bowthers teaches undergraduate electrical engineering at Merrimack College (North Andover, MA). His research follows a general interest in measurement technology that he acquired during 25 years of instrumentation development at Teradyne Inc (Boston). Bowthers received a master's degree in electrical engineering from Boston University (Boston) and a bachelor's degree in electrical engineering from Villanova University (Villanova, PA). He is a member of the IEEE and the American Society for Engineering Education.

## R A Q 's

# Rarely Asked Questions

Strange but true stories from the call logs of Analog Devices

## It may be Greek to you, but sigma delta converters are not really hard to understand.

**Q.** Can you please explain, simply, as to a Bear of Little Brain<sup>1</sup>, how sigma-delta converters work?

**A.** By over-sampling, noise shaping and digital filtering.

Athens is a beautiful city, with the ambiance of many millennia of history. I was walking round the Acropolis with Spiros, one of our Greek distributors, when he asked me how sigma-delta ( $\Sigma$ - $\Delta$ ) converters work. "Sigma and delta are letters of our Greek alphabet," he exclaimed, "but every article I have seen about their operation is double dutch<sup>2</sup> to me. They all start with several pages of partial differential equations and then go downhill from there."

If a voltage is measured many times, the average of the measurements will be more accurate than most individual measurements. This is "over-sampling." (Dither<sup>3</sup> may be necessary to randomize the errors in the individual measurements.)

There is a definite theoretical minimum limit to the possible noise of an analog-to-digital converter (ADC). When an ADC samples a signal at a frequency of  $f_s$  the digital output contains the signal and this "quantization noise" is usually spread evenly from dc to  $f_s/2$ . By sampling at a higher rate of  $Kf_s$ , the noise is spread over the wider band from dc to  $Kf_s/2$ . If we then remove all the noise above  $f_s/2$  with a digital filter the signal-to-noise ratio (SNR) of the digital output is improved — effectively improving the ADC resolution.

Normally the SNR increases with the square root of  $K$ , so very high sampling rates are necessary for useful increases in SNR. But a  $\Sigma$ - $\Delta$  modulator does not produce uniformly distributed quantization noise. Although the total noise is unaltered in a  $\Sigma$ - $\Delta$  system, most of it is at high fre-

quencies (HF). This is known as noise shaping and permits much lower values of  $K$ .

If the digital output from the  $\Sigma$ - $\Delta$  modulator is filtered to remove HF, leaving the frequencies from dc to  $f_s/2$  (where the wanted signals are) then the SNR and resolution of the digital output are improved. A  $\Sigma$ - $\Delta$  ADC simply consists of a  $\Sigma$ - $\Delta$  modulator and a digital low-pass filter, both of which are easily made with modern high-density digital technology. The principle of  $\Sigma$ - $\Delta$  ADCs has been known for more than 40 years, but the ability to build one on a chip is relatively recent.

<sup>1</sup> "When you are a Bear of Very Little Brain and you think of Things, you find sometimes that a Thing which seemed very Thingish inside you is quite different when it gets out into the open and has other people looking at it." — AA Milne, "The House at Pooh Corner"

<sup>2</sup> Double dutch means gobbledygook

<sup>3</sup> Dither — the addition of noise or some other AC signal in order to randomize errors.

# PCI Express: Ever-faster graphics pipe serves many masters

THE NEW PCI EXPRESS SPEC SIGNIFICANTLY IMPROVES DESKTOP-PC GRAPHICS. DEVELOPERS ARE NOW WORKING ON GENERATION 2, WHICH WILL FURTHER EXPAND THE GRAPHICS PIPE.

The new PCI (Peripheral Component Interconnect) Express spec provides the biggest improvement in more than a decade in I/O performance for computation systems, significantly improving graphics in desktop PCs and workstations. Intel initially launched the spec in its chip sets in mid-2004, and the technology has become mainstream in high-end systems. But PCI Express is far more than an avenue to better games or video. As have many other PC innovations, PCI Express will enable significant applications, such as medical imaging, and serve in industrial control and many other embedded-system roles.

Serial PCI Express is usurping the parallel AGP (accelerated graphics port) in graphics as just one part of a broad industry trend toward serialization. For example, USB replaced the parallel and serial ports, and SATA and SAS (serial attached SCSI) are replacing parallel ATA and SCSI in storage interfaces. And, like parallel PCI, PCI Express will handle far more than graphics, providing a flexible and scalable data highway for all types of performance-centric add-on functions.

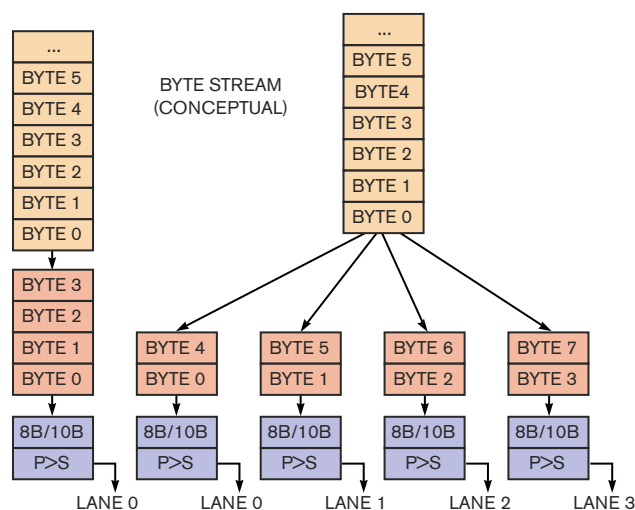

You might ask whether a replacement for PCI-derived AGP is necessary. AGP8× pushed the evolutionary limits of what was possible with a parallel bus—at least at a price point sustainable for volume PC production. Clock skew was the problem plaguing AGP, like other parallel buses touting higher performance. A single clock defines the data-valid period across AGP's 32 data lanes. But the faster the clock runs, the narrower the data-valid window becomes, and the tougher the design challenge becomes (see **sidebar** "History of the graphics pipe").

So, the graphics pipeline became serialized with PCI Express. This serialization means that data carries with it an embedded clock, which a PLL recovers in the receiver circuits. Multiple lanes can carry data in parallel, providing scalable performance, but each lane has its own embedded clock (**Figure 1**). At the receiver end, the data resynchronizes. PCI Express can tolerate as much as four symbols of skew between lanes, dramatically easing the constraints for motherboard and graphics-controller design.

PCI Express is more than just the follow-on to AGP. PCI

Express is also the migration point for applications currently on conventional PCI and PCI-X as they move to higher speeds and performance. These legacy buses will not go away overnight, but, like ISA (Industry Standard Bus), they eventually will. PCI Express reunites the forks that broke away from the original PCI with a common protocol and electrical interface. Moreover, PCI Express technology will make its way to the embedded-system world in CompactPCI implementations.

For graphics implementations, the PCI Express bus comprises 16 lane pairs. Each lane pair has four data wires—a transmitting differential pair and a receiving differential pair. Because PCI Express is dual-simplex, data can flow in both directions unimpeded by data going the other direction, unlike AGP (**Figure 2**). AGP was point-to-point like PCI Express, but AGP

**Figure 1** The PCI Express offers scalability through the concept of lanes. Designers can linearly extend bandwidth by adding lanes. In a one-lane system, such as Lane 0, the data bytes flow sequentially as expected. In a multilane scenario, the bytes are interleaved across the lanes for transmission.

is full-duplex: Data can flow in only one direction at a time. Furthermore, AGP never offered symmetric bandwidth in its implementations, even though nothing about the AGP protocols precludes symmetry. AGP8× achieves 2.1-Gbyte/sec peaks in data flows from the host CPU to graphics controllers, which is the primary direction for graphics traffic. However, in typical system implementations, the real available “back-channel” bandwidth is about one-tenth of that figure. In contrast, PCI Express graphics offers 4-Gbyte/sec peak bandwidth simultaneously in both directions and, in typical implementations, delivers the bulk of that bandwidth in both directions. This highly symmetric bandwidth leads to some interesting new capabilities for graphics based on PCI Express and in many other I/O applications.

AGP implementations yielded weak back-channel bandwidth for several reasons. To achieve the best CPU-to-graphics controller performance, AGP worked from uncached address spaces (the AGP “aperture”). For reads, this assumption makes perfect sense, because caching requires snooping, degrading performance. However, chip-set designers simply did not optimize their chip sets for large data-set writes to this space from the graphics controller because the cost of providing a large number of write-posting buffers was prohibitive. This trade-off made sense

**IN THE DEFINITION OF PCI EXPRESS, THE GRAPHICS INDUSTRY WAS UNANIMOUS IN THE OPINION THAT IT DIDN'T WANT SIMILAR “HELP” IN THE NEW I/O INTERFACE.**

to the chip-set architects, because graphics traffic is primarily in the forward direction.

A second reason for the relative weakness of AGP’s back-channel bandwidth was a limitation in the GART (graphics-address-remapping-table) memory-management system that AGP provided to assist in the graphics controller’s task of managing physical- and virtual-address translations for access to uncachable system-memory space. Again, the theory sounded great, but practical design considerations led to suboptimal graphics performance, because real chip sets never implemented enough TLBs (translation-look-aside buffers). Each 4 kbytes of memory requires a new TLB because 4 kbytes is the default page size in Windows. But even two dozen TLBs support only about 100 kbytes of memory before the onset of TLB “thrash.”

## HISTORY OF THE GRAPHICS PIPE

The demands of graphics were the primary driving force behind the PCI (Peripheral Component Interconnect) bus. The developers of the original ISA (Industry Standard Bus) based it on the PC AT’s Intel 286 processor bus, which debuted in 1984. ISA delivered only 16 Mbytes/sec at 8 MHz, and was woefully inadequate for the fire hose of data that 3-D graphics requires. The VESA (Video Electronics Standards Association) developed the VL (Video Local) Bus as a proposed alternative to ISA. EISA (Extended ISA) was another. The VL Bus designers were clever in getting more than 100-Mbyte/sec bandwidth from the CPU to the graphics controller. However, the bus worked only on graphics because it did not support multiple devices.

Furthermore, it tied only to a specific processor’s bus and, thus, could not adapt to future technologies. These facts explain why PCI, with its 133-Mbyte/sec bandwidth, triumphed over a 32-bit, shared, “multidrop” bus. Intel in 1991 proposed PCI as a scalable replacement for ISA and helped form the PCI-SIG (special-interest group), which in 1993 released the first specification.

You’d think the graphics industry would happily chew on this order-of-magnitude increase in bandwidth for a while, but that scenario didn’t occur. During that era, Microsoft (www.microsoft.com) moved from DOS to Windows, causing a discontinuity in demand for 3-D-graphics capabilities in PCs. Intel in 1997—only three years after PCI

entered production—introduced its Pentium II processor with the AGP (accelerated-graphics port). AGP borrows heavily from PCI technology. AGP is also 32 bits wide, and its protocols build on top of PCI protocols. But AGP is a nonshared, point-to-point bus. It uses a different connector from the one that PCI uses. And, although PCs would commonly have four to six PCI slots, they would have only one AGP slot.

AGP went through many speed bumps to achieve 2.1 Gbytes/sec in its AGP8× version, which its developers released in 2002, a remarkable evolution from its roots in PCI. You’d think the graphics community would be happy now, having fattened the pipe nearly three orders of magnitude in only two decades.

However, graphics vendors believed they’d be taxing this bandwidth within a few short years.

PCI Express began life as 3GIO (third-generation I/O) in the Arapahoe Work Group but moved quickly to become a specification that the PCI-SIG owned. That group in July 2002 released the 1.0 Version. First desktop, workstation, and server products from Intel went into production mid-2004, and the first chip sets for notebooks debuted early in 2005. Now, a range of PCI Express products are available in many categories of devices (Reference A).

**Mentor  
Graphics®**

THE EDA TECHNOLOGY LEADER

A cache thrashes when its miss rate is too high, and it spends most of its time servicing misses. Thrashing, particularly virtual-memory thrashing, is bad for performance, because the relative cost of a miss is so high: It may slow a machine down by a factor 100 or more.

In the definition of PCI Express, the graphics industry was unanimous in the opinion that it didn't want similar "help" in the new I/O interface. With PCI Express graphics, all memory management occurs within the graphics controller. Memory-management performance is under the control of the graphics vendors, who are more economically motivated in general than are chip-set vendors to spend gates on graphics performance.

At this point, it is reasonable to ask why continually increasing the bandwidth of the pipe from the host CPU to the graphics controller is so important. More prosaically, an end user may reasonably want to know what he can do with a notebook, desktop PC, or workstation with PCI Express graphics that is not possible with AGP8× or, for that matter, what PCI Express offers in embedded-system roles. Only a few of today's applications are starting to top the limits of what AGP8× can deliver. It is not difficult to create a demo application that uses the full bandwidth of PCI Express, and the suppliers of graphics controllers use this approach to show off their latest products. But broadly available commercial applications rarely show any advantage just from the fatter pipe when the pipe enters.

The PC world still needs PCI Express graphics, and end users have good reasons for desiring them. To understand this concept, consider the perspective of a developer of graphics-intensive software, such as that for video games or CAD. These developers write their programs to the capabilities of the least-common-denominator hardware in their target customer base. For leading-edge video games and high-end-workstation applications, these hardware units are highly capable, recently introduced systems, but more generally the target is likely to be systems the vendors released over the last two to four years.

The only way to get the software community to continuously raise the bar in graphics capabilities is by continuously increasing the capabilities, including bandwidth, of the client platforms. The impact of AGP8× on software development is happening now. The work to bring PCI Express to market will have its major impact on software applications in the future.

But the end user still has plenty of incentive to purchase PCI Express graphics today. A buyer of PCI Express graphics is well-prepared for the getting the most from the new applications that emerge over the life of that PC. And, second, the suppliers of

---

**THE ONLY WAY TO GET THE SOFTWARE COMMUNITY TO CONTINUOUSLY RAISE THE BAR IN GRAPHICS CAPABILITIES IS BY CONTINUOUSLY INCREASING THE CAPABILITIES, INCLUDING BANDWIDTH, OF THE CLIENT PLATFORMS.**

---

graphics controllers are focusing their latest developments on PCI Express products. So, the client with PCI Express graphics will likely significantly outperform previous generations of products, even if PCI Express cannot, in general, now take credit for that performance advantage.

The performance advantages of PCI Express graphics may emerge more quickly than with previous transitions because of the tremendous increase of CPU performance and memory bandwidth just coming to market. For example, the latest Intel workstation platform exploits as much as 64 Gbytes of fully buffered DIMM with a peak bandwidth of 21 Gbytes/sec. Conjoin those features with additional capabilities in the most recent graphics controllers, and you can more fully exploit the bus.

PCI Express affords system designers an extremely broad range of capabilities. In the graphics world, PCI Express dual-graphics controllers are popular with gamers. Some designers are even contemplating externally cabled PCI Express subsystems (see sidebar "Express outside the box" and the online sidebar "Dual controllers accelerate rendering" at [www.edn.com/ms4201](http://www.edn.com/ms4201)).

## REAL-WORLD ADVANTAGES

PCI Express is a key enabler in some lifesaving applications. For example, consider Vital Images ([www.vitalimages.com](http://www.vitalimages.com)), a leading provider of enterprisewide advanced visualization and analysis software for use in disease-screening applications, clinical diagnosis, and therapy planning. The company's technology gives radiologists, cardiologists, oncologists, and other medical specialists timesaving productivity and communications tools for easy use in the day-to-day practice of medicine. Vital Images' software products include a medical-diagnostic tool that allows physicians to use PCs or notebook computers to gain remote access to 2-, 3-, and 4-D advanced visualization. The software enables users to measure, rotate, analyze, and segment images.

One technical challenge for this medical application stems from the size of data sets that volumetric visualization requires. According to Karel Zuiderveld, PhD, director of technology research at Vital Images, "PCI Express is especially beneficial when dealing with large data sets that do not fit into graphics memory. The size of modern medical data sets, [which the company obtained using computer-tomography], range from hundreds of megabytes to several gigabytes. In addition to a vast amount of CPU and GPU [graphics-processing-unit] resources, fast rendering of such data sets also

**Figure 2** PCI Express implements a full-duplex link in which traffic flows symmetrically and simultaneously in each direction over serial links with the clock embedded in the data.

*Always Affordable!*

**vicorpower**  **com**

requires high transfer speeds to the GPU.” With PCI Express graphics, medical professionals can view 3-D images from alternative perspectives with reasonable response times.

In the past, the graphics bus has not been the bottleneck. When uploading textures to OpenGL, the driver usually “swizzles” the texture—that is, swaps the pixels around so that they are stored in the same way as the original format. It then creates a copy in system memory, according to the OpenGL spec, and writes a copy to the graphics memory. Until recently, the CPU usually performed texture swizzling, resulting in low texture-upload speeds. Each texture requires a read-swizzle-write memory DMA to the graphics card; this approach involves at least two reads and one write to system memory. With the latest workstations, Vital Images’ target applications may fully exploit the bandwidth of PCI Express, says Zuiderveld. Though medical imaging may be a leading application for taxing the PCI Express bus, he believes that the trend toward using resources such as the virtual texture maps that Microsoft’s (www.microsoft.com) DX10 supports, will drive steeply increasing usage of PCI Express’s graphics bandwidth into mainstream applications.

## EXPRESS VIDEO EDITING

One application that can now take advantage of PCI Express’ unique capabilities is video editing. In video applications, PCI Express affords dramatically better back-channel bandwidth than AGP. Back-channel rates are important, because main memory must store intermediate and temporary video-processing results. The files are just too large for the graphics controller’s local store. However, the memory must preserve this data without lossy compression, because the cumulative effects of repeated compressions would visibly degrade the end result. With AGP, these writes of uncompressed data back to main system memory are major performance bottlenecks that PCI Express relieves. Watch for video editors that take advantage of PCI Express to enter the market.

PCI Express is backward-compatible with PCI protocols but

**Figure 3** Nvidia and ATI with their TurboCache and HyperMemory technologies, respectively, use the PCI Express bus back channel to effectively cache their local memory (courtesy ATI).

offers numerous features that go beyond the PCI protocols. One feature—*isochrony*, or equality in length of time—promises to further aid video editing and other heavily multithreaded applications. PCI and AGP provide no guarantee for worst-case latency. Particularly in commercial-scale video editing for broadcast and film, this lack of guarantee for data delivery creates difficult challenges when trying to maintain output at a given frame rate. Isochrony could also ensure that systems running many multithreaded concurrent applications don’t drop display frames. As chip-set and device-hardware vendors and operating-system upgrades add isochrony support, PCI Express will provide this guarantee that AGP could not.

Some graphics vendors have already figured out how to exploit PCI Express’ back-channel bandwidth to create a new class of products. Before PCI Express, graphics memory was either in system memory—for chip sets with integrated graphics—or on an external card with an external graphics controller. Though AGP’s developers intended it to support heavy use of system

## EXPRESS OUTSIDE THE BOX

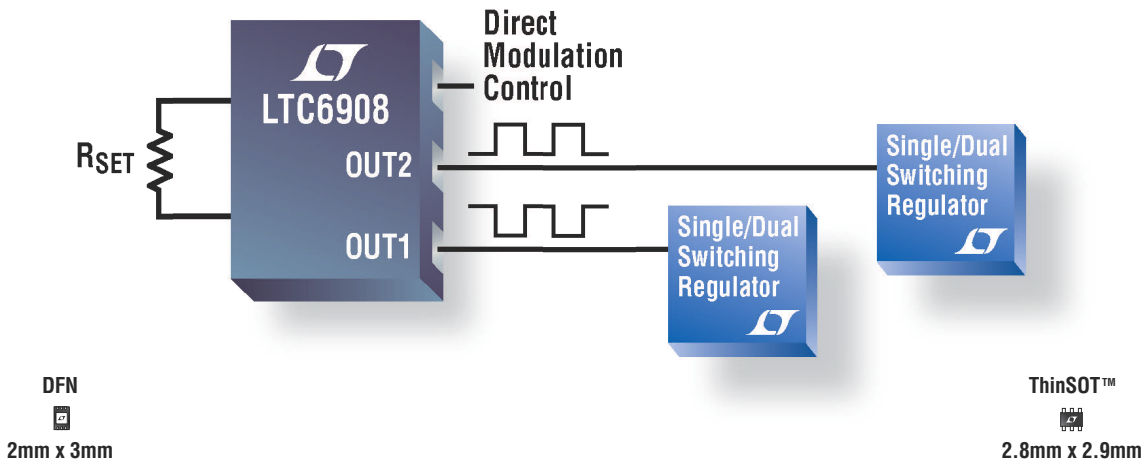

An ongoing development in the PCI-SIG (Peripheral Component Interconnect Special Interest Group) that potentially relates to PCI Express graphics is the definition of a PCI Express cable. PCI Express intends to provide an I/O-attachment point for a host, not to be that I/O itself. The developers of PCI Express had no intention of competing with cabled-I/O interfaces, such as USB, FireWire, Ethernet, InfiniBand, and others.

However, a cable allows the extension of the I/O-attachment point to be remote from a host system. A cable adapter card could plug into a 16-card slot and cable externally to a remote 16-card slot. Depending on distances and adherence to all the PCI Express design rules, this card might get away with containing no active circuitry, or it might contain a PCI Express switch or bridge that acts as a signal repeater.

One intriguing possibility would be a cable adapter card connecting, through a PCI Express cable, to a remote box containing a switch that supports two 16-card slots. Using a 48-lane switch, you could fully provision both of these slots and deliver a spec-compliant option. Such a remote dual-graphics box might afford some additional advantages. For example, by removing the graphics controllers from the base system, it also

removes their power and thermal requirements from burdening the base system. Also, any client with just one 16-card slot becomes “dual-graphics capable.” Such a remote dual-graphics box might prove attractive to OEMs that do not perceive dual graphics to be a mainstream requirement but want to provide their customers the capability and an upgrade path. It also might make an attractive after-market product.

# Tiny Clock Optimized for Switchers

## Next Generation Oscillator Provides Direct Control Over Spread Spectrum Modulation

The LTC®6908 is a tiny silicon oscillator for synchronizing multiple switching regulators. As power densities increase, so do the challenges for electromagnetic compatibility (EMC). Using a single three-state input, you have direct control over the rate of spread spectrum frequency modulation (SSFM) and the ability to optimize EMC performance. This clock requires only a single resistor to set the frequency of the two phase-shifted outputs—perfect for synchronizing single or dual switching regulators.

### ▼ Features

- LTC6908-1: 0°/180° Outputs
- LTC6908-2: 0°/90° Outputs
- 50kHz to 10MHz Frequency Range
- Optional ±10% Frequency Spreading
- -40°C to 125°C Temperature Range
- Fast Start-Up Time: 260µs @ 1MHz
- Outputs Muted Until Stable
- 2.7V to 5.5V Operation

### 2MHz Switcher with and without SSFM

memory, especially for textures, actual AGP implementations failed to deliver sufficient performance. The performance gap was too great between implementations with local frame memory on the graphics card and implementations using the AGP bus to access system memory. So, either you integrated graphics in a chip set, or you put a lot of graphics RAM on the external controller. A significant price and performance difference exists between these two approaches. Nvidia ([www.nvidia.com](http://www.nvidia.com)) and ATI ([www.ati.com](http://www.ati.com)) with their TurboCache and HyperMemory technologies, respectively, use the PCI Express bus back channel to effectively cache their local memory (Figure 3).

This method provides lower performance than that of a large local memory store on the graphics card, although the performance decrease does not approach the degradation that would occur on AGP. Still, these caching technologies allow the removal of significant amounts of RAM from the graphics-controller card. Instead of, say, eight 8-Mbit $\times$ 16-word DDR DRAMs for a traditional, state-of-the-art graphics controller, the controller card using caching over PCI Express could use just a single 4-Mbit $\times$ 32-word DDR DRAM. Memory costs would drop from approximately \$16 in today's prices to \$3.50, and performance would still be better than that of integrated graphics.

The future of PCI Express graphics does not end here. The PCI-SIG (special-interest group) has announced work on a

**MORE AT EDN.COM** ▶

Generation 2 version of PCI Express. Though the specification was under development at press time, the PCI-SIG has announced key aspects of the new version. It will double the clock rate to 5 GHz. The group doesn't plan significant protocol enhancements over PCI Express 1.1, and Generation 2 will be backward-compatible with PCI Express 1.1. The PCI-SIG suggests that Generation 2 could be in production in 2007. When it does arrive, Generation

2 PCI Express will continue the grand tradition of regularly expanding the graphics pipe between host and graphics controller that you have witnessed from ISA to PCI to AGP and now to PCI Express. **EDN**

## AUTHOR'S BIOGRAPHY

David L Fair is enterprise-I/O-technology-initiatives manager at Intel Corp's Server Platforms Group Marketing Division (Santa Clara, CA). He is responsible for driving initiatives such as PCI Express for Intel's server and workstation businesses and managing the independent-hardware-vendor-enabling team. He has a bachelor's degree in physics from Pomona College (Claremont, CA) and a doctorate in the philosophy of science from Princeton University (Princeton, NJ). His personal interests include making broad technology adoption successful, road biking, "lunatic" high-end audio, quantum discontinuities in the ether, and trees that fall in the forest that no one hears.

# We're Proud of Our Low $I_Q$

## 2-Phase, Dual Output, 36V<sub>IN</sub> Controller Draws Only 80µA

The LTC®3827 is a 2-phase, dual, synchronous step-down DC/DC controller with only 80µA of quiescent current ( $I_Q$ ). Low  $I_Q$  and wide input and output voltage range make the LTC3827 ideal for use in battery powered “always-on” applications such as automotive systems where maximum battery energy must be preserved while the system is in standby mode. Optimizing circuit performance is easy with OPTI-LOOP® compensation for faster transient response and phase-lockable switching frequency for lower system noise.

### ▼ Features

- Wide Input Voltage Range:  
 $4V \leq V_{IN} \leq 36V$
- Wide Output Voltage Range:  
 $0.8V \leq V_{OUT} \leq 10V$
- Low Operating  $I_Q$ : 80µA  
(One Channel On)
- Out-of-Phase Operation Reduces  
Input Capacitance and  
Power Supply Induced Noise
- $\pm 1\%$  Output Voltage Accuracy
- Small, Low Profile 5mm x 5mm QFN  
and 28-Lead SSOP Packages
- Available Pb-free and RoHS  
Compliant or in Standard SnPb Finish

### Low Output Voltage Ripple

# 3A, 40V Boost Regulators

## High Frequency, Monolithic, Efficient & Tiny

Linear's growing family of boost regulators provides quick, simple and tiny solutions for step-up converter applications. Common features, such as on-chip high voltage, high current power devices and integrated soft start reduce the external component count. Switching frequencies up to 3.5MHz reduce the size and values of the capacitors and inductors. Our proprietary design techniques enable high efficiency conversion to minimize power dissipation.

# DESIGN NOTES

## Handheld High Power Battery Charger

Design Note 393

Mark Gurries

### Introduction

As the performance of many handheld devices approaches that of laptop computers, design complexity also increases. Chief among them is thermal management—how do you meet increasing performance demands while keeping a compact and small product cool in the user's hand?

For instance, as battery capacities inevitably increase, charge currents will also increase to maintain or improve their charge times. Traditional linear regulator-based battery chargers will not be able to meet the charge current and efficiency demands necessary to allow a product to run cool. What is needed is a switching-based charger that takes just about the same amount of space as a linear solution—but without the heat.

### Small PCB Footprint

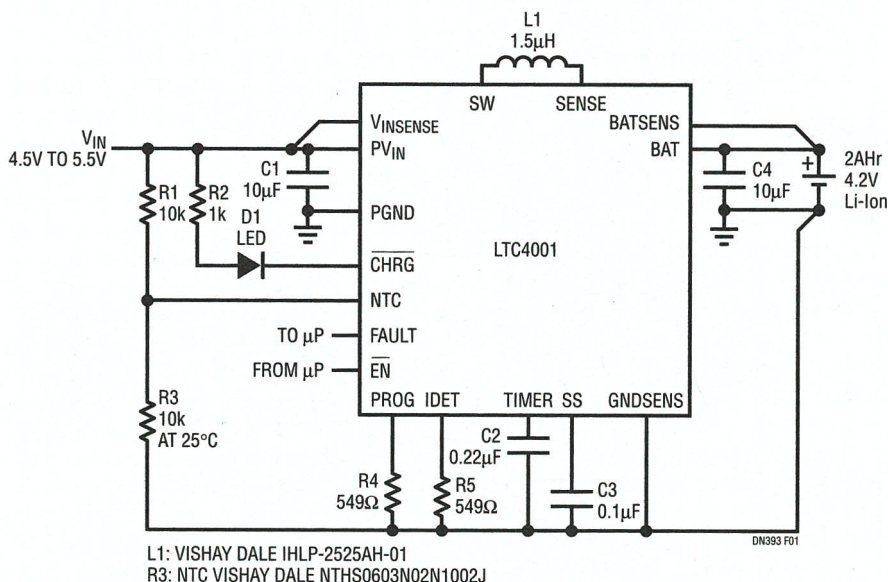

Figure 1 shows how simple a feature-laden LTC®4001-based charger solution can be. This switching-based charger only requires the IC, a small 1.5μH inductor, two

small 1206-size 10μF ceramic capacitors, and a few other tiny components. Furthermore, even simpler configurations are possible (see Figure 2). This monolithic 2A, 1.5MHz synchronous PWM standalone battery charger is packaged in a 4mm × 4mm 16-pin QFN package, which contains the built-in switching MOSFETs and charge termination controller. Figure 3 shows an actual PCB solution.

### Advanced Features and Functions

One of the more unique features of the LTC4001 is its full remote voltage sense capability which permits faster charge rates by bypassing voltage drops in narrow PCB traces, EMI filters or current sense resistors for gas gauge related support; this is placed on the system side of the battery connector. Eliminating these losses in the sense circuit can significantly shorten the constant voltage phase of the overall charge time.

LT, LT, LTC and LTM are registered trademarks of Linear Technology Corporation. All other trademarks are the property of their respective owners.

**Figure 1. Li-Ion Battery Charger with 3-Hour Timer, Temperature Qualification, Soft-Start, Remote Sensing and C/10 Indication**

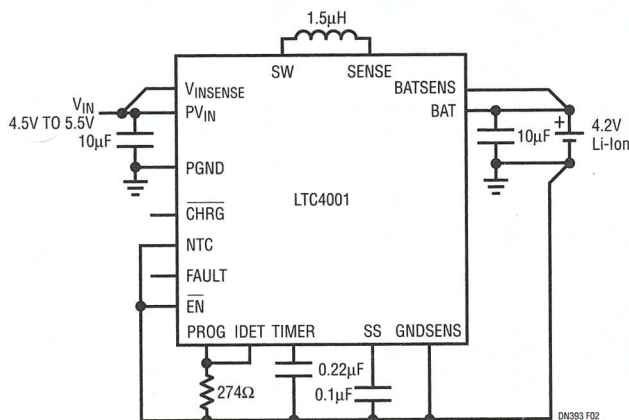

Figure 2. Simple 2A Battery Charger

Another important feature is programmable soft-start, which requires only a small ceramic capacitor on the SS pin. Soft-start saves design time and cost by simplifying the power source requirements, precluding the need to handle fast start-up load transients commonly found with switching power supplies.

Other advanced features include: 50mA trickle charge recovery of over-discharged batteries below 3V/cell; adjustable charge timer via a single capacitor on the TIMER pin; and automatic restart of a charge cycle when the battery voltage falls below 100mV of the full charge voltage.

Two signals provide status. First is the FAULT pin, which in conjunction with the LTC4001 thermistor circuit, reports an out-of-range temperature situation. When a temperature fault occurs, the charge process is stopped immediately. Charging a battery when it is out of its normal temp range can damage it. Second, the CHRG pin shows three states relating to the charge state of the battery or charger. In addition to the normal OFF indication, it also indicates when the battery is below its user programmable  $I_{DET}$  threshold or when in bulk charge mode.

The  $\overline{EN}$  (Enable) pin allows for shutdown of the charger, thus reducing its  $V_{IN}$  quiescent current below 50µA and the battery drain current to less than 3µA. Shutdown also occurs automatically if  $V_{IN}$  falls to less than 250mV above the current battery voltage.

Figure 3. Actual LTC4001 Demo Board Showing a Compact Footprint (Height  $\leq 1.8\text{mm}$ )

### Flexible Options

The LTC4001 provides a number of flexible options in its small package. Bulk charge current is programmable via the PROG pin and a simple resistor, from 2A and below. A separate resistor on the  $I_{DET}$  pin is all that is required to set the full charge current termination or indication threshold independently of the bulk charge current setting. Typically the  $I_{DET}$  threshold is set to 1/10 (C/10) of the bulk charge current, which equates to a battery being about 95% to 98% full. Raising the  $I_{DET}$  current trip threshold significantly reduces charge time by having a full charge indication occur sooner in exchange for a slightly lower full state of charge. Likewise, increasing the trip threshold extends the timer to approach a 100% state of charge if there are no serious time constraints. The type of charge termination is also flexible. In addition to timer-based termination, the charge can be terminated when the  $I_{DET}$  threshold is reached or charge termination can be defeated all together to allow an external power manager to decide.

### Conclusion

The LTC4001 is the charger of choice for the next generation of handheld devices with its tiny solution size, unmatched power capability, high efficiency, protection features and flexible options.

## Microprocessor generates programmable clock sequences

William Grill, Honeywell BRGA, Lenexa, KS

▶ To produce trains of pulses suitable for keying transmitters, testing circuits, and debugging data links, designers requiring continuous or event-driven pulse sequences have traditionally relied on pulse generators or collections of simple circuits. Today's inexpensive microprocessors make it possible to design and build low-cost, dedicated pulse-sequence generators with a minimum of resources. In a small, SOT-23-packaged, 10F200 controller from Microchip ([www.microchip.com](http://www.microchip.com)), the design in **Figure 1** uses a code-based embedded table algorithm to generate an application-settable period and table-based PWM (pulse-width-modulation) sequence. The application produces a continuously pulsed sequence and requires only three constants and a pulse-width profile table that it copies into the microprocessor's assembler-based code before compiling (**Figure 2**).

All code branches undergo equal-

ization to produce a group of 29 constant instruction times. During software development, you can use coded constants and a table-based approach as a flexible method of modifying the pulse sequence. The three parameters that **Figure 2** highlights include the number of PWM cycles that execute between table steps, which the algorithm passes as "temp\_cntK." This parameter defines how many PWM periods of a range from one to 255 repeat within each table step. For three cycles per table step, you use `#define temp_cntK .3`. The next parameter is the number of 29-instruction loops that execute during each PWM period. All branches of the coded instructions equalize to constant 29-instruction periods. When you copy this parameter as "loopsK," it can range from one to 255. Using the 10F200's internal 4-MHz clock and an 8-bit counter to generate 1- $\mu$ sec instruction periods, you can gener-

### DIs Inside

**86** Ceramic output capacitors enhance internally compensated integrated switchers

**90** Tapped inductor, boost regulator deliver high voltage

▶ What are your design problems and solutions? Publish them here and receive \$150! Send your Design Ideas to [edndesignideas@reedbusiness.com](mailto:edndesignideas@reedbusiness.com).

ate a PWM period range of 58 to 7395  $\mu$ sec, which corresponds to a frequency range of 17,241 to 135 Hz. For a 1-msec PWM-cycle period and the sequence in **Figure 2**, you require 31 base loops per cycle, which you obtain by dividing 1 msec by the 29- $\mu$ sec instruction period: `#define loopsK .31`.

You then equate the total number of table profile steps to "table\_maxK." The total number of profile steps that a look-up table includes and that you copy into the code may vary from one to 252. In this application, five table steps correspond to pulse duty cycles of 25, 50, 87.5, 12.5, and 75%. These val-

**Figure 1** A microcontroller and a resistor can deliver a complex PWM output.

**Figure 2** This waveform profile comprises five steps, each using one of three PWM cycles. In continuous mode, the circuit's output repeats indefinitely.

ues undergo scaling according to the following **equation**:  $\text{Duty cycle} = \text{INT}(\%T_{\text{DTY}}/100 \times \text{loopsK} + 0.5)$ , in which INT is the integer value and  $\%T_{\text{DTY}}$  is the percentage of the total duty cycle. In this example,  $\text{loopsK} = 31$ . The number of steps in the table passes to the program as `#define loop_maxK .5`.

The pulse-duty cycle can vary only in increments of a single 29-instruction base loop, and, as a consequence, the pulse duty cycle's resolution varies as the number of basic loops for the waveform's desired period, which you define as  $\text{loopsK} = 31$  loops. Thus, the duty-cycle resolution equals  $1/(\text{loopsK})$ , or  $1/31 = 3.22\%$  for this application.

You can use a spreadsheet or manually calculate the translated and scaled duty-cycle values and store them in the data-profile table. For example, you calculate the value for a 25% duty cycle as  $\text{INT}(25/\text{resolution} + 0.5) = \text{INT}(25/3.22 + 0.5)$ , where INT represents extraction of the integer value of the computed quantity. For required duty cycles of 25, 50, 87.5, 12.5, and 75%, the values that pass to the data-profile table are `retlw_8`, 16, 27, 4, and 23, respectively. The assembly-language program available for

**Figure 3** After undergoing lowpass-filtering, the controller's pulse-width-modulated output (lower trace) reveals its sine-wave origin.

downloading from the online version of this Design Idea at [www.edn.com/060720di1](http://www.edn.com/060720di1) includes these duty-cycle values and the three other parameters.

The program includes two additional features: Connecting Pin 1 to ground enables a continuous-output mode. Connecting Pin 1 to  $+V_{\text{DD}}$  evokes a single output waveform. Pin 3 serves as a high true-output enable when you connect it to  $+V_{\text{DD}}$  or as a positive-edge trigger input when you pull the pin to ground and release it. Note that the program currently includes no contact-debounce routines for either input.

In the example in **Figure 3**, the controller delivers a pulse-width-modulated output (lower trace), which, after processing by a single-pole lowpass filter, corresponds to a sine wave (upper trace). Using another version of the circuit, you can evaluate how a critical midword error affects a serial link's characteristics, system timing, and response latency.

The waveform in **Figure 4** comprises 100 pulses, 99 of which exhibit a nominal duty cycle that varies from 48 to 51%, and a single error pulse with a 75% duty cycle. The waveform-table entries use values of  $\text{loopsK} = 100$ ,  $\text{temp\_cntK} = 1$ , and  $\text{table\_maxK} = 100$  to produce a pulse sequence comprising 74 pulses with nominal duty cycles, a single pulse cycle with a 75% duty cycle, and a final sequence of 25 clocks with nominal duty cycles. The entire sequence repeats at a 345-Hz rate.

Using a 4-MHz-clock-rate version of Microchip's 10F220 controller constrains the basic software-timing loop to a 29- $\mu\text{sec}$  period. You can compile the program into an 8-MHz 10F220 to reduce the timing loop to 14.5  $\mu\text{sec}$  and extend the output's usable bandwidth. You can modify the code in the **listing** to suit other compatible microprocessors to obtain greater bandwidth and integrate additional functions. As is, the circuit requires only 155 bytes of internal EEPROM and occupies an SOT-23 pc-board footprint—not bad for a processor that costs less than \$1. **EDN**

**Figure 4** Devised for testing a serial link's error response, this waveform plot displays pulses' locations within the waveform (horizontal axis) versus the duty cycle for each pulse (vertical axis). The waveform cycle repeats after pulse 100 ends.

# INDUSTRY'S HIGHEST PERFORMING SiGe MIXER PORTFOLIO

## Downconverters with Gain—Best All-Around OIP3, NF, and 2RF-2LO Spurious Performance

- ◆ Up to 10dB of Gain and 35dBm of OIP3 Linearity
- ◆ Noise-Figure Values as Low as 9.5dB
- ◆ Excellent 2 x 2 Performance Eases Receiver Filtering Requirements, Allows Use of Lower IF Frequencies

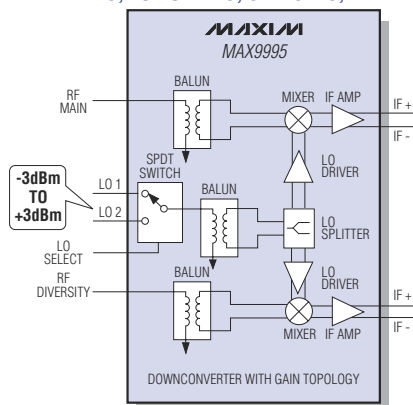

## Passive Up-/Downconverters—Unmatched LO Leakage and IP<sub>1dB</sub> Performance

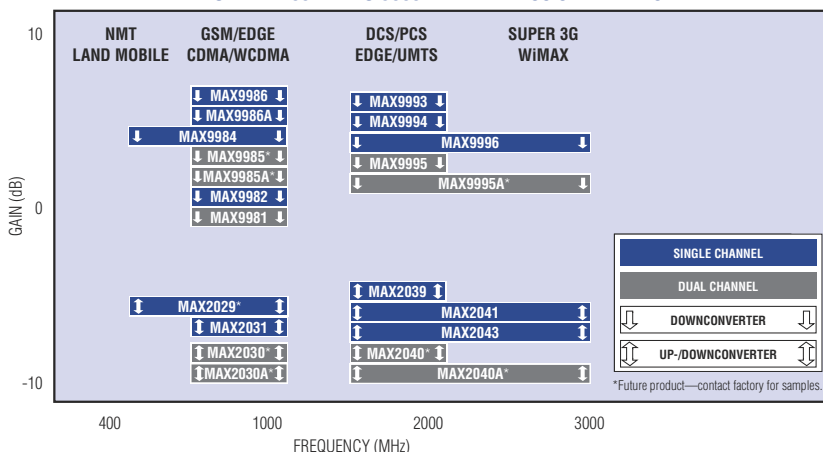

- ◆ Up to 36dBm of IIP3 and 27dBm of IP<sub>1dB</sub> Linearity
- ◆ Only 7dB to 7.5dB of Loss
- ◆ Unparalleled 2 x 2 Performance
- ◆ Up to 67dBc LO  $\pm$ 2IF Spurious Suppression
- ◆ Lowest LO Leakage of -52dBm (MAX2043)

## FULLY INTEGRATED MONOLITHIC MIXER DESIGNS WITH IF AMPS, LO BUFFERS, SWITCHES, AND BALUNS

# Ceramic output capacitors enhance internally compensated switchers

Robert Kollman, Texas Instruments, Dallas, TX

Integrating compensation components with a power-supply controller and buck regulator's power switches can minimize pc-board area, improve reliability, and eliminate assembly errors by reducing the number of components and solder joints. However, integration also limits a designer's range of choices in the selection of output-filter components. **Figure 1a** presents a typical switching regulator based on Texas Instruments' (www.ti.com) TPS5430. The boxed area in **Figure 1b** shows a simplified version of the IC's internal small-signal-equivalent circuit, which includes an error amplifier,  $E_1$ ; passive-compensation components; and a voltage-controlled volt-

age-source,  $E_2$ , which represents the modulator and the power switches. Support components external to the IC include output-filter components and their parasitic resistances, a resistor representing an external load, and a divider comprising  $R_1$  and  $R_2$  that sets the output voltage. The compensation-circuit design accommodates a certain range of output-filter inductance and capacitance and their associated parasitics.

**Figure 2** shows Bode diagrams for the error-amplifier and modulator-gain blocks (**2a**) and the entire regulator system (**2b**). Envisioning that end users would specify aluminum electrolytic capacitors for the output-

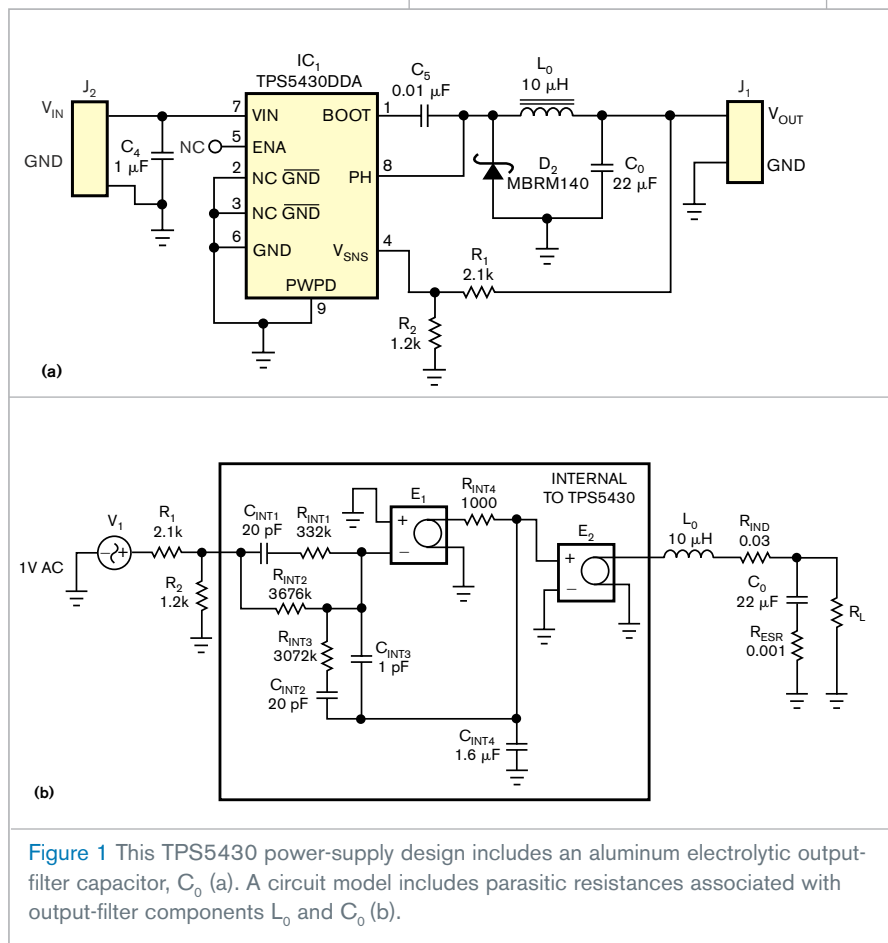

filter circuit, the IC's designer includes a Type 3 compensation circuit to optimize the IC's performance for aluminum capacitors' characteristics. Note that a Type 3 compensation circuit includes a pole at the origin of the circuit's pole-zero plot to provide high gain at dc and an integratorlike high-frequency roll-off augmented with pairs of poles and zeros to provide phase and gain margins at certain frequencies (**Reference 1**).

The regulator's LC-output modulator/filter's amplitude-response curve peaks at the resonant frequency set by the filter's inductor and output capacitor, and then it decreases at a  $-40$ -dB/decade rate until it reaches a zero at a frequency set by the output capacitor and its ESR (equivalent series resistance). Beyond that frequency, the output inductor's and the capacitor's ESRs determine the attenuation curve's slope, resulting in a  $-20$ -dB/decade rate.

For good regulation, the error amplifier provides a high dc gain at low frequencies. However, to ensure stability, the loop gain must decrease as frequency increases. The goal is to approximate a  $-20$ -dB/decade roll-off at all frequencies. Placing two zeros at the output filter's resonant frequency helps cancel the two poles representing the resonance. Adding a pole to the error-amplifier response cancels the zero that the output capacitor and its ESR introduce. Adding a final pole above the power supply's crossover frequency helps further increase the regulator loop's stability. **Figure 2b** shows the sum of the gains of the error amplifier and modulator/filter gain. The power supply's characteristics show a 30-kHz bandwidth and a  $60^\circ$  phase margin that ensures stable operation.

**Figure 1** This TPS5430 power-supply design includes an aluminum electrolytic output-filter capacitor,  $C_0$  (a). A circuit model includes parasitic resistances associated with output-filter components  $L_0$  and  $C_0$  (b).

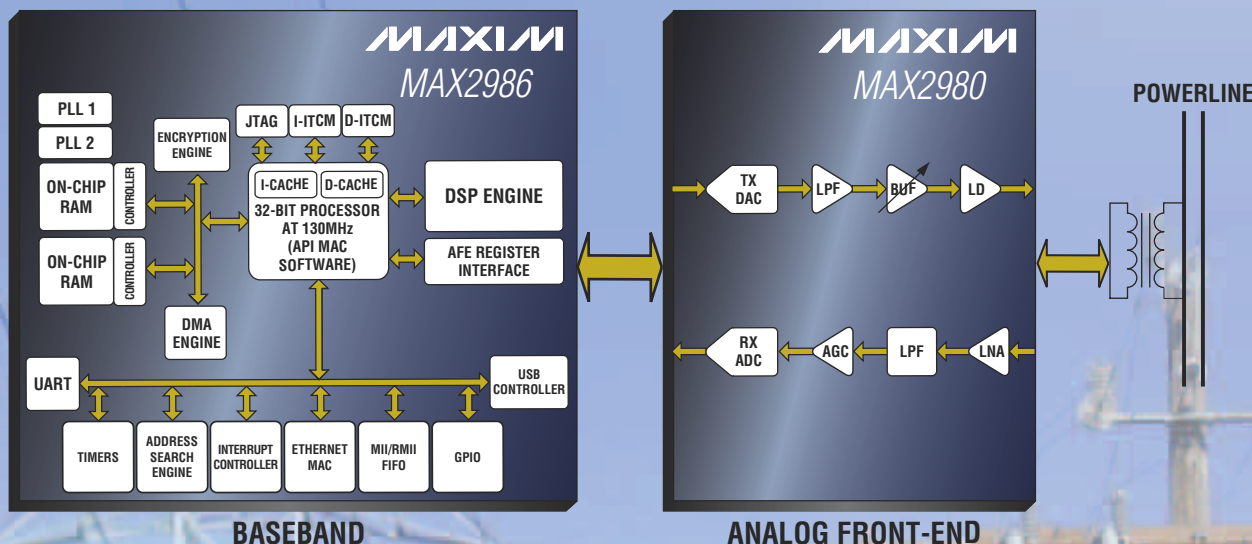

# FIRST PROGRAMMABLE, POWERLINE COMMUNICATION CHIPSET

**Powerful Enough to Run both the Powerline MAC and Your Application Software\***

Maxim's powerline chipset is composed of the **MAX2986** digital baseband transceiver and the **MAX2980** analog front-end. Featuring an open architecture and extensive programmability, this chipset uses existing powerlines to create the most cost-effective data, audio, video, and voice networking solution. Flexibility in spectral shaping and tone notching helps you conform to the disparate and uncertain worldwide regulatory concerns. High integration and a system-level orientation reduce overall costs and shorten time to market.

**Ideal for:**

- ◆ **Broadband**
- ◆ **Industrial and Building Automation**
- ◆ **Monitoring and Control**
- ◆ **Voice and VoIP**
- ◆ **Security and Safety**
- ◆ **LAN**

**Performance:** Adaptive Data Rates Up to 14Mbps

**Privacy:** 56-DES Encryption and Key Management Provide the Highest Level of Data Security

**Interoperability:** Compatible with Third-Party HomePlug® 1.0 Devices

\*Customer-specific application programs are limited by CPU run-time and memory size.  
HomePlug is a registered trademark of HomePlug Power Alliance, Inc.

loop response (Figure 3) illustrates the circuit's behavior when the design includes ceramic-dielectric output-filter capacitors and the same integrated-compensation components in Figure 1. Ceramic capacitors present a much lower ESR than do aluminum electrolytic capacitors, and their capacitance determines the filter's attenuation rather than their ESR. Consequently, at high frequencies, the LC filter's characteristics include a double pole and a steeper,  $-40\text{-dB/decade}$  slope. In addition, filter attenuation increases at the desired crossover frequency, degrading phase and gain margins. Figure 3b indicates that the power supply is unstable and, with no phase margin, will likely oscillate.

Replacing the divider network,  $R_1$  and  $R_2$  in Figure 1 with the passive network in Figure 4 stabilizes the regulation loop and allows an internally compensated controller to use ceramic output capacitors. The network's compo-

nents add two sets of poles and zeros to the compensation network to cancel the consequences of using ceramic output capacitors. For example,  $C_2$  and  $R_3$  provide attenuation that reduces the crossover frequency. You select  $C_2$  to provide attenuation at frequencies much lower than the crossover frequency. Unfortunately,  $C_2$  adds a negative-phase shift that  $R_3$  returns to nearly zero at the design's crossover frequency. Adding  $C_1$  introduces a phase lead that compensates for the ceramic capacitors' negative effects. Without  $C_1$ , the filter's  $180^\circ$  phase shift would reduce the regulator's phase margin to nearly zero.

The phase angle starts increasing at a frequency that  $C_1$  and  $R_1$  determine, and they introduce a zero in the phase-plane plot at that frequency (Figure 5). At a frequency that  $C_1$  and  $R_3$  determine, a pole in the phase-plane plot terminates the phase angle's increase. The geometric mean of the pole and

zero frequencies determines the maximum phase-angle boost.

As a starting point, you can place the first pole, which  $C_2$  and the parallel combination of  $R_1$  and  $R_2$  determine, at a low frequency, such as 100 Hz. Next, adjust the values of  $C_2$  and  $R_3$  to set the first zero's frequency at 1 kHz, which is much less than the gain curve's 0-dB crossover frequency. Finally, set the zero that  $C_1$  and  $R_1$  introduce to a frequency that's at least a factor of two below the zero-gain crossover frequency to ensure a  $45^\circ$  phase margin at the crossover frequency. The Bode plot in Figure 5 features a 30-kHz regulation-loop bandwidth that provides good transient response and more than  $45^\circ$  of phase margin to ensure good stability. **EDN**

## Tapped inductor, boost regulator deliver high voltage

David Ng and Adam Huff, Linear Technology Corp, Milpitas, CA

When you face the task of generating a regulated voltage that's higher than the available power-supply voltage, you may consider a boost regulator. Although a boost converter can in theory gener-

ate almost any voltage that's higher than its input, practical considerations limit the output to approximately eight times its applied voltage. To generate an even higher voltage, consider using a tapped-inductor boost top-

ology. Figure 1 shows an implementation of a converter that boosts a 3V input to 100V dc. The connections to the regulator chip are similar to those of a traditional boost converter, but, to achieve the high boost ratio, this design uses  $L_1$ , a 1-to-6-turns-ratio, tapped inductor.

The waveforms in Figure 2 show the input voltage, the voltage at power-switch  $IC_1$ 's output, Pin 5, and rectifier diode  $D_1$ 's anode voltage. As in any boost circuit, inductor  $L_1$ 's core stores energy when  $IC_1$ 's internal output switch conducts. When the switch turns off, the voltage across its terminals and  $L_{1A}$  goes higher than the input voltage. Due to inductive coupling and the larger number of turns that make up  $L_{1B}$ , the voltage at rectifier diode  $D_1$ 's anode and hence the output voltage goes much higher. Resistors  $R_2$  and  $R_3$  form a feedback-voltage divider that closes the regulation loop. The  $R_4$ - $C_4$  network forms a snubber circuit that suppresses the impact of diode  $D_1$ 's small parasitic capacitance. Without the network,

Figure 1 Using a tapped inductor extends a boost-topology switching regulator's practical output-voltage range.

**Figure 2** For a 3V-dc input (lower trace, horizontal line), the voltage at regulator IC<sub>1</sub>'s SW pin reaches a peak of approximately 18V (lower trace, pulsed waveform). The 1-to-6 step-up turns ratio of inductor L<sub>1</sub> further increases the peak output voltage to 160V (upper trace) to produce 100V dc. The upper trace's lower limit goes to  $-6 \times V_{IN} (-18V)$  due to the tapped inductor.

power switch IC<sub>1</sub> "sees" a capacitance that's 36 times larger due to the multiplicative effect of the tapped inductor's turns ratio.

Measuring only 5.6×6×3.4 mm, Coiltronics' ([www.coiltronics.com](http://www.coiltronics.com)) CTX02-17409 tapped inductor, L<sub>1</sub>, and Linear Technology's ([www.linear.com](http://www.linear.com))

**Figure 3** The entire boost-converter circuit occupies a footprint of less than 1.5×1.25 cm on a single-sided pc board.

com) LT1949 monolithic regulator, IC<sub>1</sub>, available in an eight-lead MSOP package, present small pc-board footprints. When you implement the circuit on a single-layer pc board, the entire circuit occupies less than 1.9 cm<sup>2</sup> of board space (**Figure 3**). For best results, review the board-layout suggestions in the device's data sheet (**Reference 1**) and use multilayer-ceramic capacitors for C<sub>1</sub> and C<sub>3</sub>. **EDN**

## DISCRETE SEMICONDUCTORS

MOSFETs provide high thermal efficiency in compact package

➔ Requiring the same 5×6-mm board area as an SO-8 package, the 20A STK800 and 30A STK850 power MOSFETs come in a PolarPAK package, providing top and bottom heat-dissipation paths, resulting in a 0.8-mm profile. The lead-frame and plastic encapsulation are similar to those for standard power-MOSFET packages, ensuring good die protection and easy handling in manufacturing. Due to its increased heat dissipation, this device can handle twice as much current within the same footprint as standard SO-8 packages. The STK800 and STK850 cost \$1.20 and \$1.60 (1000), respectively.

## No two circuit breaker applications are alike

### Only E-T-A offers more technologies

Many circuit protection applications appear the same but every application is different requiring a specific circuit protection solution. Only E-T-A provides the most complete range of available circuit protection technologies.

More technologies allow for superior, more precise circuit protection. It is critical that your design is protected with the correct circuit protection. Your reputation depends on it.

One call to E-T-A will ensure your design has the right circuit protection technology to enhance your products safety, reliability and brand reputation.

## Power-MOSFET family has a small footprint

➔ Aiming at portable-system applications, the new  $\mu$ Cool family of power MOSFETs comes in a thermally enhanced, 2×2-mm WDFN6 package. These six products feature exposed-drain DFN technology, providing a 38°C/W thermal resistance and a 1.9W power rat-

ing. The devices have the same footprint dimensions as the SC-88 and SC-70-6 packages. The  $\mu$ Cool family costs 29 to 31 cents (10,000).

**On Semiconductor**, [www.onsemi.com](http://www.onsemi.com)

## Ultrafast rectifiers maintain low power-supply losses

➔ The 600V, 8A UH8JT and UHF-8JT rectifiers provide a 25-nsec reverse-recovery time, decreasing switch-mode-power-supply losses. The devices combine improved switching performance with a 150-nsec forward-recovery time under test conditions and a 1.85V forward-voltage-drop rating at 125°C, improving thermal performance and system efficiency. The UH8JT and UHF8JT cost 35 cents each (10,000).

**Vishay Intertechnology**, [www.vishay.com](http://www.vishay.com)

## GaN-transistor family targets cellular, WiMax-base-station markets

➔ This family of GaN (gallium-nitride) HEMTs (high-electron-mobility transistors) targets cellular infrastructures and WiMax base stations. The devices feature a 67% peak drain efficiency at the UMTS (universal-mobile-telecommunications-system) frequency band and a 60% efficiency at the WiMax frequency band. The family's 8, 60, 90, and 120W devices aim at the UMTS or 3G-base-station segment. The 2.5-GHz transistors suit the WiMax-base-station segment and are available in 50, 75, and 100W options; 3.5-GHz, 8 and 50W options are also available.

## Midvoltage MOSFETs target secondary-side synchronous rectification

➔ The 60V IRF7855PbF, 80V IRF7854PbF, and 100V IRF7853PbF

# Which NVRAM would you choose?

Battery-based NVRAMs

## Leaded

Are you being pressured to get rid of the batteries on your board? Trying to get rid of unwanted hazardous materials? If you need a NVRAM and want to "get the lead out" or remove other hazardous materials from your system, Simtek's nvSRAM is the leading solution that requires no batteries. With Simtek's unlimited reads and writes and data automatically stored during a brown-out or power loss, Simtek's nvSRAMs are THE ideal NVRAM solution. With no batteries to worry about, you get higher system reliability and improved manufacturing since you no longer

## Unleaded

need to worry about battery failure, battery shelf-life, or special assembly requirements. For small mobile applications, Simtek's nvSRAMs low profile and low power are a perfect fit where space and power are at a premium. Our densities range from 16 kilobits to 1 megabit with access times as fast as 25 ns. In addition, we have nvSRAMs with integrated real-time-clock (RTC) functions that can operate without a battery for up to six months. And because we're a single-chip solution, our prices are equally attractive against battery-based SRAM solutions.

Check us out and we'll make sure you get rewarded. If we can't provide an attractive price against your battery-based SRAM solution, we'll give you an iPod\* for your efforts.\*

## DISCRETE SEMICONDUCTORS

N-channel HEXFET MOSFETs come in a lead-free SO-8 package. These mid-voltage MOSFETs target ac/dc secondary-side synchronous rectification in 5 to 19V-output-voltage flyback-converter and resonant-half-bridge applications. These devices also suit isolated, medium-power dc/dc applications as primary-side switches in forward or push-pull topologies for 18 to 36V-input-voltage, isolated dc/dc converters. The IRF7855PbF, IRF7854PbF, and IRF7853PbF cost \$1.04, \$1.06, \$1.20, respectively. **International Rectifier, [www.irf.com](http://www.irf.com)**

### Diodes feature a high temperature rating

↘ The HVTD series diodes for down-hole, seismographic, automotive, and traction applications feature a 7000V rating and a 200°C temperature. These devices feature a 1-mA maximum forward current in oil, a 30- $\mu$ A maximum reverse current, and an 18- $\mu$ A typical reverse current. Devices in the HVDT series cost \$4 (100).

**HV Component Associates, [www.hvca.com](http://www.hvca.com)**

## TEST & MEASUREMENT

### Measurement software builds and runs SCS applications

↘ The latest version of DAPstudio measurement software allows users to design filters that roll off at 96 dB per quarter-octave and to build and run applications based on the vendor's SCS (signal-conditioning-system) series, requiring no additional data-acquisition software. Connecting directly to the sensors, the SCS also connects to specialized DAP boards, including iDSC 1816 boards, in PCs, providing additional channels of filtered 16-bit resolution data at  $\pm 10$  mV to  $\pm 10$ V. The SCS/iDSC hardware costs \$1000 per channel. The DAPstudio costs \$199, and a free trial is available for downloading from the vendor's Web site.

**Microstar Laboratories, [www.mstarlabs.com](http://www.mstarlabs.com)**

### PCI Express analyzer aims at AMC form factor

↘ Targeting the AMC (Advanced Mezzanine Card) form factor, the Vanguard Express PCI Express protocol and link analyzer can debug, test, and validate the PCI Express protocol and can test AMC.1 types 1, 2, 4, and 8 modules. Functioning as a self-contained unit, the

analyzer installs between the device under test and the host system, allowing testing with minimal intrusion to the system under test. Features include independent and concurrent operation of both the analyzer and a statistics and protocol checker, a 256-Mbyte trace buffer, and eight trigger events. The Vanguard Express AMC costs \$23,950.

**VMetro, [www.vmetro.com](http://www.vmetro.com)**

### Midrange DAP board uses an onboard Pentium processor

↘ Operating from a 233-MHz Intel Pentium CPU, the midrange DAP (data-acquisition-processor) 5000a/526 board includes 16 analog inputs, two analog outputs, 16 digital inputs, and 16 digital outputs. External rack-mounted hardware allows for extending the channel counts to 512, 66, 128, and 1024, respectively. The device can acquire 14-bit data at 800k samples/sec and can convert 833,000 values/sec on the onboard analog outputs. An onboard processor allows fast real-time processing and a 0.1-msec task-time quantum latency. The DAP 500a/526 costs \$3295.

# PICO

## HIGH VOLTAGE

Over 2500 Std. Models  
Surface Mount and Thru-Hole

## DC-DC Converters

### 3.3 to 10,000 VDC Outputs

Low Profile / Isolated  
Up to 10,000 Volts Standard  
Regulated Models Available

See PICO's full catalog immediately  
[www.picoelectronics.com](http://www.picoelectronics.com)

## High Power

Up to 350 VDC Outputs  
(Units up to 150 Watts)  
Regulated / Wide Input Range  
Isolated Outputs

INDUSTRIAL • COTS • MILITARY  
Delivery Stock to ONE WEEK

YESTERDAY'S HYPE MEETS TODAY'S REALITY

**STATS** 30 hours between recharges / \$1000 price tag / Offered handwriting recognition

## Newton's life lesson

➡ Apple Computer's Newton MessagePad PDA wasn't a big commercial success, but the complex product served a life lesson—to keep it simple—that Apple took to heart in its blockbuster iPod.

The Newton was to be Apple's next step in personal computing and portability beyond its Macintosh lineup. The system had a lot of leading-edge hardware and software to perform a large number of tasks. It combined word processing, a calendar, a calculator, an address book, and an infrared transceiver for wireless communications, among other features, as well as its main feature: handwriting recognition.

The system was one of the first major commercial devices to incorporate low-power ARM processors. The early units used an ARM6-based ARM 610, and later devices used a StrongARMSA-110. The Newton also used 4 Mbytes of flash and 4 Mbytes of DRAM. It offered 30 hours of runtime before needing a recharge—impressive for the mid-'90s. The device also incorporated a versatile OS that synchronized internally running applications with handwriting recognition.

Ultimately, the device failed to take off because it had trouble synchronizing with the outside world, it was too large to fit into a pocket, and it had a \$1000 price tag. Ridicule of the handwriting-recognition feature in the *Doonesbury* comic strip didn't help, either.—by Michael Santarini

### ZiLOG eZ80F915050MOD Development Module

The eZ80F91 operates at 50MHz with 256Kb on-chip Flash memory and 16Kb of internal SRAM, 512Kb of off-chip SRAM, 1Mb of Flash, and a 10/100BaseT Ethernet PHY with an RJ-45 connector. Oper. temp. 0°C to 70°C, 3.3V at 125mA, 2 x 60-pin system; MPU bus/control signals, IrDA transceiver.

### DLP Design DLP-2232M Dual Channel USB Module

Uses FTDI's FT2232C 3rd generation dual channel USB-FIFO/UART; simple solution for interfacing ASIC/MCU/FPGA/DSP-based designs to host computer via USB; up to 8Mb per second, USB 1.1 compliant; no in-depth knowledge of USB required.

## Embedded Products for the Latest Technologies

Reduced time to market is critical for new product designs -- lost time means lost revenue. That's why engineers depend on Mouser to deliver a broad selection of embedded products fast!

And because these components have a solution designed in, engineers can utilize these plug-and-play modules from test through production - saving time and money.

Experience Mouser's time-to-market advantage! Our vast selection of the NEWEST products, NEWEST technologies, no minimums, and same-day shipping on most orders, gets you to market faster. We make it easy to do business with Mouser!

### Lantronix XPort® Embedded Device Server

Reduce design time and build Ethernet/IP connectivity into your products, quickly and simply, with the XPort embedded module. XPort is the most compact, integrated solution available to web-enable any device with a serial interface. XPort is powered by Lantronix's own DSTni™ networking chip, which includes a 10/100 MAC/PHY and 256kb of SRAM.

**LANTRONIX®** [mouser.com/lantronix/a](http://mouser.com/lantronix/a)

### NetBurner MOD5272 32-bit Processor Module

This module features a web-based control interface, full 32-bit architecture, full suite of TCP/IP protocols, and 10/100baseT RJ45 network interface. Adds network capabilities without taking up valuable design time.

[mouser.com/netburner/a](http://mouser.com/netburner/a)

### Rabbit Semiconductor RCM3700 RabbitCore Module

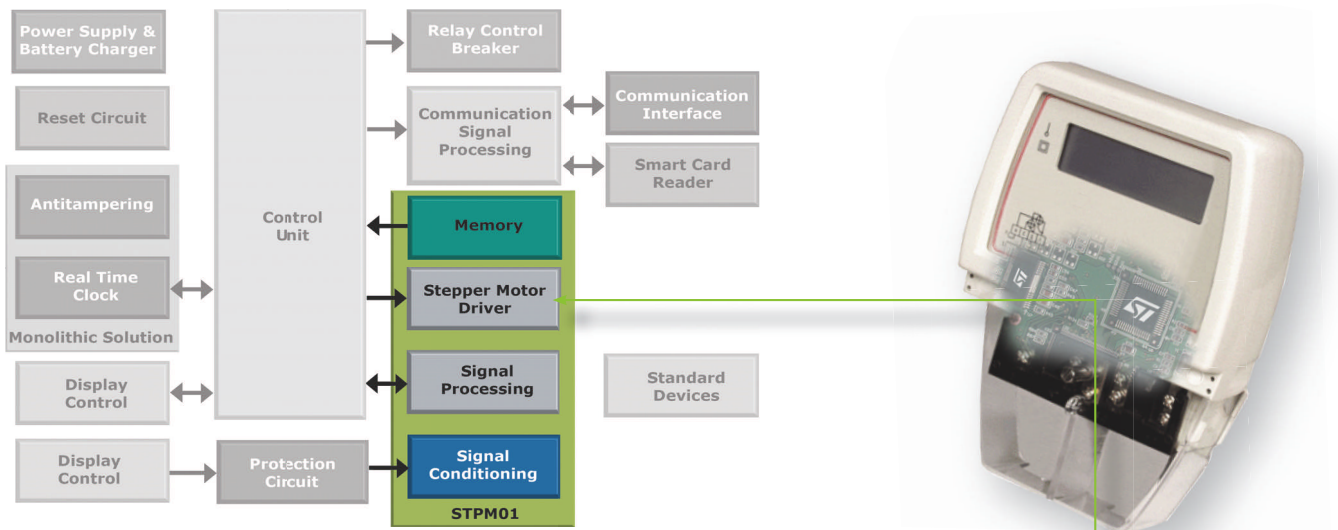

Features up to 512 Flash/ 512K SRAM, 4 serial ports, +5 VDC tolerant I/O, quadrature encoder inputs, PWM outputs, and a low-profile footprint (2.95" x 1.20" x .88").

## The new standard for effective energy measurement in power line systems using Rogowski coil, current transformer, or shunt sensor.

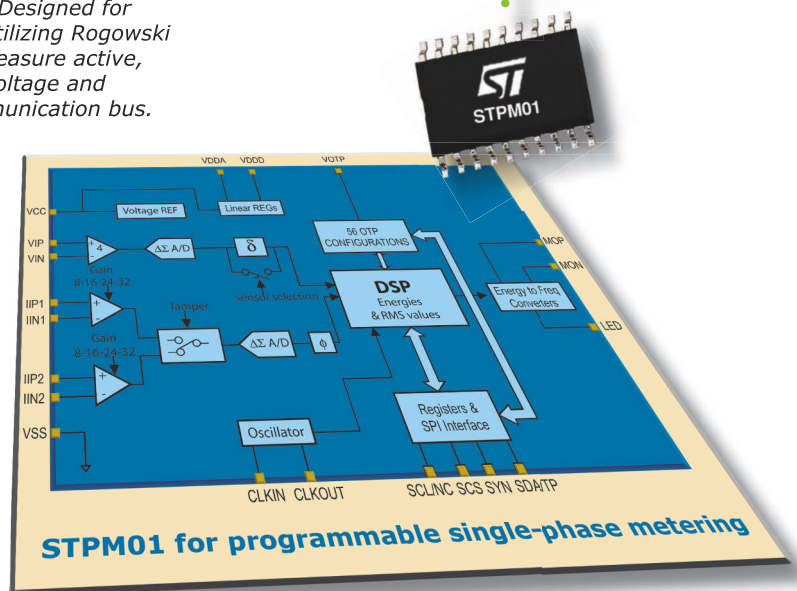

## *Innovative products for multi-segment application systems*

*ST complements its vast range of standard devices with world-beating innovative segment specific products like the STPM01. Designed for effective energy measurement in power line systems utilizing Rogowski coil, current transformer and/or shunt sensor, it can measure active, reactive or apparent energy; RMS and instantaneous voltage and current consumption or line frequency via an SPI communication bus.*

## STPM01 Main Features

- Active, reactive, apparent energies and RMS values
- Shunt, current transformer, Rogowski coil sensors
- Ripple free active energy pulsed output
- Live and neutral monitoring for tamper detection
- Easy and fast digital calibration in only one point over the whole current range
- OTP for calibration and configuration
- Integrated linear VREGS for digital and analog supply
- Selectable RC or crystal oscillator
- Support 50÷60Hz, IEC 62052-11 and IEC 62053-2x specifications
- Less than 0.1% error
- Precision voltage reference: 1.23V and 30 ppm/°C max

For further information, datasheets and application notes visit [www.st.com/stpm01](http://www.st.com/stpm01)
