6. Preparation of [(η^5-C_5Me_5)Rh(CH_2OAc){$P(OMe)_3$}I] (**13**): A solution of 165.5 mg (0.31 mmol) of **7** in 6 ml of benzene was treated with a solution of 194.9 mg (1.60 mmol) of CH_3CO_2Na in 4 ml of acetic acid (100%) and stirred for 6 h at room temp. The solvent was removed, the residue was extracted with 20 ml of ether, and after the extract was filtered, the filtrate was concentrated to ca. 5 ml in vacuo. Pentane (ca. 5 ml) was added and the solution was stored for 12 h at −78°C. Orange-red crystals precipitated which were separated from the mother liquor, washed twice with 2 ml portions of pentane (−20°C) and dried; yield 134 mg (77%); m. p. 70°C (dec.). – IR (KBr): $\tilde{\nu}$ = 1712 cm^{-1} [ν(C=O)]. – ^{1}H NMR (200 MHz, C_6D_6): δ = 5.92 [ddd, *J*(RhH) = 8.2, *J*(PH) = 2.2, *J*(HH) = 6.0 Hz, 1 H, one H of CH_2OAc], 5.10 [ddd, *J*(RhH) = 0.7, *J*(PH) = 4.4, *J*(HH) = 6.0 Hz, 1 H, one H of CH_2OAc], 3.53 [d, *J*(PH) = 10.5 Hz, 9 H, $P(OMe)_3$], 1.78 (s, 3 H, OCH_3), 1.70 [dd, *J*(RhH) = 0.4, *J*(PH) = 4.2 Hz, 15 H, C_5Me_5]. – ^{13}C NMR (22.5 MHz, C_6D_6): δ = 170.4 [s, *C*(O)CH_3], 101.4 [dd, *J*(RhC) = *J*(PC) = 4.4 Hz, *C*$_5$Me$_5$], 57.2 [dd, *J*(RhC) = 27.2, *J*(PC) = 17.7 Hz, $RhCH_2$], 54.0 [d, *J*(PC) = 5.9 Hz, $P(OMe)_3$], 21.2 [s, C(O)*C*H$_3$], 9.7 [d, *J*(RhC) = 1.5 Hz, C$_5$(*C*H$_3$)$_5$]. – ^{31}P NMR (36.2 MHz, C_6D_6): δ = 136.4 [d, *J*(RhP) = 256.1 Hz]. – MS (70 eV); *m/z* (%) = 562 (1) [M^+], 489 (58) [$M^+ - CH_2OAc$], 365 (100) [$C_5Me_5RhI^+$], 362 (1) [$C_5Me_5RhP(OMe)_3^+$], 238 (9) [$C_5Me_5Rh^+$]. – $C_{16}H_{29}IO_5PRh$ (562.2): calcd. C 34.18, H 5.20, Rh 18.31; found C 34.48, H 5.39, Rh 18.13.

7. Preparation of [(η^5-C_5H_5)Rh(CH_2OAc){$P(OMe)_3$}I] (**14**): Compound **14** was prepared analogously to **13** by using 210.2 mg (0.45 mmol) of **8** (in 6 ml of benzene) and 250 mg (3.05 mmol) of CH_3CO_2Na (in 2 ml of 100% acetic acid) as starting materials; time of reaction 90 min at 25°C. Red-brown microcrystalline solid; yield 173 mg (78%); m. p. 76°C (dec.). – IR (KBr): $\tilde{\nu}$ = 1700 cm^{-1} [ν(C=O)]. – ^{1}H NMR (200 MHz, C_6D_6): δ = 6.70 [ddd, *J*(RhH) = *J*(HH) = 4.8, *J*(PH) = 1.4 Hz, 1 H, one H of CH_2OAc], 5.83 [ddd, *J*(RhH) = 2.4, *J*(PH) = 8.5, *J*(HH) = 4.8 Hz, 1 H, one H of CH_2OAc], 5.23 [dd, *J*(RhH) = 0.5, *J*(PH) = 3.1 Hz, 5 H, C_5H_5], 3.47 [d, *J*(PH) = 10.5 Hz, 9 H, $P(OMe)_3$], 1.72 (s, 3 H, OCH_3). – ^{13}C NMR (22.5 MHz, C_6D_6): δ = 169.9 [s, *C*(O)CH_3], 91.0 [dd, *J*(RhC) = *J*(PC) = 4.2 Hz, C_5H_5], 53.9 [d, *J*(PC) = 5.9 Hz, $P(OMe)_3$], 49.3 [dd, *J*(RhC) = 25.0, *J*(PC) = 15.4 Hz, $RhCH_2$], 21.6 [s, C(O)*C*H$_3$]. – ^{31}P NMR (36.2 MHz, C_6D_6): δ = 135.8 [d, *J*(RhP) = 248.6 Hz]. – MS (70 eV); *m/z* (%) = 492 (1) [M^+], 419 (100) [$M^+ - CH_2OAc$], 365 (50) [$M^+ - I$], 295 (70) [$C_5H_5RhI^+$], 292 (18) [$C_5H_5RhP(OMe)_3^+$], 168 (58) [$C_5H_5Rh^+$]. – $C_{11}H_{19}IO_5PRh$ (492.1): calcd. C 26.85, H 3.89, Rh 20.92; found C 27.06, H 3.98, Rh 21.35.

8. Preparation of [(η^5-C_5Me_5)Rh(CH_2OAc)(PMe_3)I] (**15**): Compound **15** was prepared analogously to **4** by using 321.3 mg (0.47 mmol) of **11** (in 5 ml of benzene) and 308.3 mg (3.76 mmol) of CH_3CO_2Na (in 5 ml of 100% acetic acid) as starting materials; time of reaction 5 h at 25°C. An orange-yellow oil was obtained which upon addition of 0.5 ml of pentane gave an orange-yellow microcrystalline solid; yield 190 mg (78%); m. p. 83°C (dec.). – IR (KBr): $\tilde{\nu}$ = 1708 cm^{-1} [ν(C=O)]. – ^{1}H NMR (200 MHz, C_6D_6): δ = 5.57 [ddd, *J*(RhH) = 2.1, *J*(PH) = 8.8, *J*(HH) = 6.5 Hz, 1 H, one H of CH_2OAc], 5.23 [dd, *J*(RhH) = 5.1, *J*(HH) = 6.5 Hz, 1 H, one H of CH_2OAc], 1.70 (s, 3 H, OCH_3), 1.59 [dd, *J*(RhH) = 0.3, *J*(PH) = 2.7 Hz, 15 H, C_5Me_5], 1.35 [dd, *J*(RhH) = 0.7, *J*(PH) = 10.3 Hz, 9 H, PMe_3]. – ^{13}C NMR (22.5 MHz, C_6D_6): δ = 170.3 [s, *C*(O)CH_3], 99.3 [dd, *J*(RhC) = 4.4, *J*(PC) = 2.9 Hz, *C*$_5$Me$_5$], 60.1 [dd, *J*(RhC) = 30.2, Hz, *J*(PC) = 15.4, $RhCH_2$], 21.1 [s, C(O)*C*H$_3$], 17.4 [d, *J*(PC) = 32.4 Hz, PMe_3], 10.0 [br. s, C$_5$(*C*H$_3$)$_5$]. – ^{31}P NMR (36.2 MHz, C_6D_6): δ = 4.8 [d, *J*(RhP) = 157.8 Hz]. – MS (70 eV); *m/z* (%) = 514 (6) [M^+], 441 (100) [$M^+ - CH_2OAc$], 365 (83) [$C_5Me_5RhI^+$], 314 (2) [$C_5Me_5Rh(PMe_3)^+$], 238 (5) [$C_5Me_5Rh^+$]. – $C_{16}H_{29}IO_2PRh$ (514.2): calcd. C 37.37, H 5.70; found C 37.28, H 6.07.

9. Preparation of [(η^5-C_5H_5)Rh(CH_2OAc)(PMe_3)I] (**16**): Compound **16** was prepared analogously to **4** by using 140.1 mg (0.33 mmol) of **12** (in 2 ml of benzene) and 270 mg (3.30 mmol) of CH_3CO_2Na (in 1 ml of 100% acetic acid) as starting materials; time of reaction 6 h at 25°C. After recrystallization from ether (25°C to −78°C) orange-red crystals were obtained; yield 125 mg (85%); m. p. 106°C (dec.). – IR (KBr): $\tilde{\nu}$ = 1720 cm^{-1} [ν(C=O)]. – ^{1}H NMR (200 MHz, $CDCl_3$): δ = 6.60 [dd, *J*(RhH) = 4.9, *J*(HH) = 5.7 Hz, 1 H, one H of CH_2OAc], 5.42 [dd, *J*(RhH) = 0.4, *J*(PH) = 1.4 Hz, 5 H, C_5H_5], 4.97 [ddd, *J*(RhH) = 2.6, *J*(PH) = 8.3, *J*(HH) = 5.7 Hz, 1 H, one H of CH_2OAc], 1.78 [dd, *J*(RhH) = 0.8, *J*(PH) = 11.1 Hz, 9 H, PMe_3], 1.70 (s, 3 H, OCH_3). – ^{13}C NMR (22.5 MHz, C_6D_6): δ = 169.5 [s, *C*(O)CH_3], 89.9 [dd, *J*(RhC) = *J*(PC) = 3.7 Hz, C_5H_5], 51.5 [dd, *J*(RhC) = 27.2, *J*(PC) = 13.4, $RhCH_2$], 19.6 [d, *J*(PC) = 33.8 Hz, PMe_3], 18.9 [s, C(O)*C*H$_3$]. – ^{31}P NMR (36.2 MHz, C_6D_6): δ = 10.3 [d, *J*(RhP) = 160.0 Hz]. – MS (70 eV); *m/z* (%) = 444 (3) [M^+], 371 (100) [$M^+ - CH_2OAc$], 295 (23) [$C_5H_5RhI^+$], 244 (73) [$C_5H_5Rh(PMe_3)^+$], 168 (35) [$C_5H_5Rh^+$]. – $C_{11}H_{19}IO_2PRh$ (444.0): calcd. C 29.75, H 4.31, Rh 23.18; found C 30.01, H 4.40, Rh 23.53.

10. Reaction of Compound **14** *nBuLi:* A solution of 276.5 mg (0.56 mmol) of **14** in 20 ml of benzene was treated under continuous stirring with 0.8 ml of a 1.41 M solution (1.12 mmol) of *n*BuLi in hexane at room temp. After the reaction mixture was stirred for 1 h, the solvent was removed and the residue was extracted with 20 ml of ether. The extract was brought to dryness in vacuo, the oily residue was dissolved in 2 ml of benzene and the solution was chromatographed on Al_2O_3 (neutral, activity grade IV, height of column 5 cm). With hexane, a yellow fraction was eluted from which upon evaporation of the solvent a light yellow oil **18** was obtained; yield 8 mg (3%). Further elution with benzene gave a red fraction which was brought to dryness in vacuo. The residue was dissolved in 10 ml of ether, the extract was concentrated to ca. 1 ml and then stored for 12 h at −20°C. A red-brown microcrystalline solid **17** precipitated which was washed with small portions of pentane and dried; yield 21 mg (8%).

17: ^{1}H NMR (60 MHz, $CDCl_3$): δ = 8.20, 7.07 (both m, 5 H, C_6H_5), 5.03 [dd, *J*(RhH) = 0.5, *J*(PH) = 3.2, 5 H, C_5H_5], 3.32 [d, *J*(PH) = 11.7 Hz, 9 H, $P(OMe)_3$]. − MS (70 eV); *m/z* (%) = 496 (7) [M^+], 419 (11) [$M^+ - C_6H_5$], 292 (100) [$C_5H_5RhP(OMe)_3^+$], 168 (69) [$C_5H_5Rh^+$]. − $C_{14}H_{19}IO_3PRh$ (496.1): calcd. C 33.90, H 3.86; found C 33.56, H 3.98.

18: ^{1}H NMR (60 MHz, C_6D_6): δ = 7.64, 7.37 (both m, 5 H, C_6H_5), 5.17 [dd, *J*(RhH) = 0.4, *J*(PH) = 2.2 Hz, 5 H, C_5H_5], 3.28 [d, *J*(PH) = 11.4 Hz, 9 H, $P(OMe)_3$] 1.1 (br. m, 9 H, C_4H_9). − MS (70 eV); *m/z* (%) = 462 (2) [M^+], 292 (100) [$C_5H_5RhP(OMe)_3^+$], 168 (56) [$C_5H_5Rh^+$].

11. Preparation of [(η^5-C$_5$Me$_5$)Rh{κ^2-C,O-CH$_2$OC(Me)O}(CO)]PF$_6$ (**19**): A solution of 81.2 mg (0.17 mmol) of **4** in 5 ml of acetone was treated under continuous stirring with a solution of 42.9 mg (0.17 mmol) of $AgPF_6$ in 2 ml of acetone at room temp. A pale yellow precipitate of AgI was rapidly formed. After the reaction mixture was stirred for 20 min, it was filtered and the filtrate was concentrated to ca. 2 ml in vacuo. Upon addition of 20 ml of ether, the solution was rigorously stirred until a yellow microcrystalline solid precipitated. This was filtered, washed twice with 5 ml portions of ether and dried; yield 69 mg (83%); dec. temp. 109°C. − Λ = 66 $cm^2\Omega^{-1}mol^{-1}$. − IR (nujol): $\tilde{\nu}$ = 2030 cm^{-1} [ν(CO)], 1605 [ν(C=O)]. − ^{1}H NMR (200 MHz, CD_3NO_2): δ = 6.23 [dd, *J*(RhH) = 0.5, *J*(HH) = 6.0 Hz, 1 H, one H of $RhCH_2$], 5.63 [dd, *J*(RhH) = 4.0, *J*(HH) = 6.0 Hz, 1 H, one H of $RhCH_2$], 2.23 (s, 3 H, CH_3), 1.92 [d, *J*(RhH) = 0.4 Hz, 15 H, C_5Me_5]. − ^{13}C NMR (22.5 MHz, CD_3NO_2): δ = 190.7 [d, *J*(RhC) = 70.5 Hz, Rh(CO)], 187.9 (s, C=O), 107.6 [d, *J*(RhC) = 5.2 Hz, C_5Me_5], 81.0 [d, *J*(RhC) = 23.5 Hz, $RhCH_2$], 18.6 [s, C(O)CH_3], 9.3 [br. s, $C_5(CH_3)_5$]. − $C_{14}H_{20}F_6O_3PRh$ (484.2): calcd. C 37.74, H 4.17; found C 37.44, H 4.31.

12. Preparation of [(η^5-C$_5$Me$_5$)Rh{κ^2-C,O-CH$_2$OC(Me)O}{P(OMe)$_3$}]PF$_6$ (**20**): Compound **20** was prepared analogously to **19** by using 131.7 mg (0.24 mmol) of **13** and 59.9 mg (0.24 mmol) of $AgPF_6$ as starting materials. Yellow microcrystalline solid; yield 131 mg (94%); dec. temp. 66°C. − Λ = 80 $cm^2\Omega^{-1}mol^{-1}$. − IR (nujol): $\tilde{\nu}$ = 1600 cm^{-1} [ν(C=O)]. − ^{1}H NMR (200 MHz, CD_3NO_2): δ = 5.91, 5.77 [both part of an ABPX spin system; from $^1H\{^{31}P\}$: *J*(RhH) = 0.3 and 4.2, *J*(HH) = 6.4 Hz, 1H each, $RhCH_2$], 3.77 [d, *J*(PH) = 11.8 Hz, 9 H, $P(OMe)_3$], 2.14 (s, 3 H, CH_3), 1.76 [dd, *J*(RhH) = 0.4, *J*(PH) = 4.4 Hz, 15 H, C_5Me_5]. − ^{13}C NMR (50.3 MHz, CD_3NO_2): δ = 186.3 (s, C=O), 103.2 [dd, *J*(RhC) = 5.3, *J*(PC) = 3.4 Hz, C_5Me_5], 82.1 [dd, *J*(RhC) = 25.9, *J*(PC) = 23.1 Hz, $RhCH_2$], 53.8 [d, *J*(PC) = 4.7 Hz, $P(OMe)_3$], 18.5 [s, C(O)CH_3], 9.2 [br. s, $C_5(CH_3)_5$]. − ^{31}P NMR (36.2 MHz, CD_3NO_2): δ = 129.4 [d, *J*(RhP) = 256.1 Hz]. − $C_{16}H_{29}F_6O_5P_2Rh$ (580.3): calcd. 16. Preparation of [(η^5-C$_5$Me$_5$)Rh(η^2-CH$_2$O){P(OMe)$_3$}] (**24**): A suspension of 89.7 mg (0.15 mmol) of **20** in 5 ml of methanol was treated at 0°C under continuous stirring with 98.1 mg (1.40 mmol) of KOH. A yellow-brown solution was formed of which after it was stirred for 10 min at 0°C, the solvent was removed in vacuo. The residue was extracted twice with 5 ml of cold ether (0°C) and the combined extracts were brought by cooling with an ice bath to dryness in vacuo. The remaining yellow-brown oil was dissolved in 2 ml of pentane (0°C) and the solution was stored for 10 h at −78°C. A yellow-brown microcrystalline solid precipitated which was filtered, washed twice with small quantities of pentane (−20°C) and dried; yield of oily product 38 mg (62%), yield of solid material 15 mg (26%); m. p. 36°C (dec.). − IR (C_6H_6): $\tilde{\nu}$ = 2805 cm^{-1} [ν(CH_2)], 1220 [ν(C−O)]. − ^{1}H NMR (200 MHz, C_6D_6): δ = 4.62 (m, 2 H, CH_2O), 3.52 [d, *J*(PH) = 12.2 Hz, 9 H, $P(OMe)_3$], 1.89 [dd, *J*(RhH) = 0.5, *J*(PH) = 3.4 Hz, 15 H, C_5Me_5]. − ^{13}C NMR (50.3 MHz, C_6D_6): δ = 97.6 [dd, *J*(RhC) = *J*(PC) = 4.4 Hz, C_5Me_5], 78.1 [dd, *J*(RhC) = 12.0, *J*(PC) = 5.9 Hz, CH_2O], 51.1 [br. s, $P(OMe)_3$], 10.0 [s, $C_5(CH_3)_5$]. − ^{31}P NMR (36.2 MHz, C_6D_6): δ = 149.2 [d, *J*(RhP) = 311.1 Hz]. − MS (70 eV); *m/z* (%) = 392 (2) [M^+], 390 (32) [$M^+ - 2$ H], 362 (100) [$M^+ - CH_2O$], 238 (49) [$C_5Me_5Rh^+$], 30 (2) [CH_2O^+]. − $C_{14}H_{26}O_4PRh$ (392.2): calcd. C 42.87, H 6.68; found C 42.59, H 6.70.

17. Preparation of [(η^5-C$_5$H$_5$)Rh(η^2-CH$_2$O){P(OMe)$_3$}] (**25**): Compound **25** was prepared analogously to **24** by using 95.3 mg (0.19 mmol) of **21** and 88.7 mg (1.26 mmol) of KOH as starting

materials. Yellow-brown solid; yield of oily product 43 mg (71%), yield of solid material 13 mg (22%); m. p. 43°C (dec.). – IR (C_6H_6): $\tilde{\nu}$ = 2825 cm^{-1} [$\nu(CH_2)$], 1232 [$\nu(C-O)$]. – ^1H NMR (200 MHz, C_6D_6): δ = 5.56 [ddd, J(RhH) = 2.5, J(PH) = 0.5, J(HH) = 21.5 Hz, 1 H, one H of CH_2O], 5.29 [dd, J(RhH) = 0.8, J(PH) = 2.6 Hz, 5 H, C_5H_5], 4.60 [ddd, J(RhH) = 2.0, J(PH) = 5.1, J(HH) = 21.5 Hz, 1 H, one H of CH_2O], 3.80 [d, J(PH) = 12.4 Hz, 9 H, $P(OMe)_3$]. – ^{13}C NMR (100.6 MHz, C_6D_6): δ = 86.1 [dd, J(RhC) = J(PC) = 3.1 Hz, C_5H_5], 72.6 [dd, J(RhC) = 13.6, J(PC) = 4.9 Hz, CH_2O], 51.6 [br. s, $P(OMe)_3$]. – ^{31}P NMR (36.2 MHz, C_6D_6): δ = 150.1 [d, J(RhP) = 299.2 Hz]. – $C_9H_{16}O_4PRh$ (322.1): calcd. C 33.56, H 5.01; found C 33.54, H 4.81.

18. Preparation of [(η^5-C_5Me_5)Rh(η^2-CH_2O)(PMe_3)] (**26**): Compound **26** was prepared analogously to **24** by using 105.6 mg (0.20 mmol) of **22** and 85.9 mg (1.22 mmol) of KOH as starting materials. Brownish microcrystalline solid; yield of oily product 39 mg (56%), yield of solid material 20 mg (29%); m. p. 25°C (dec.). – IR (C_6H_6): $\tilde{\nu}$ = 2800 cm^{-1} [$\nu(CH_2)$], 1210 [$\nu(C-O)$]. – ^1H NMR (200 MHz, C_6D_6): δ = 4.48 [ddd, J(RhH) = 3.0, J(PH) = 0.6, J(HH) = 18.2 Hz, 1 H, one H of CH_2O], 4.15 [ddd, J(RhH) = 2.4, J(PH) = 6.1, J(HH) = 18.2 Hz, 1 H, one H of CH_2O], 1.87 [dd, J(RhH) = 0.4, J(PH) = 2.2 Hz, 15 H, C_5Me_5], 0.99 [dd, J(RhH) = 0.9, J(PH) = 8.9 Hz, 9 H, PMe_3]. – ^{13}C NMR (50.3 MHz, C_6D_6): δ = 96.5 [dd, J(RhC) = J(PC) = 3.3 Hz, C_5Me_5], 74.4 [dd, J(RhC) = 14.0, J(PC) = 6.6 Hz, CH_2O], 15.8 [d, J(PC) = 25.7 Hz, PMe_3], 10.7 [s, $C_5(CH_3)_5$]. – ^{31}P NMR (36.2 MHz, C_6D_6): δ = 2.8 [d, J(RhP) = 190.3 Hz]. – MS (70 eV); *m/z* (%) = 344 (2) [M^+], 342 (23) [M^+ – 2 H], 314 (100) [M^+ – CH_2O], 238 (25) [$C_5Me_5Rh^+$], 30 (2) [CH_2O^+]. – $C_{14}H_{26}OPRh$ (344.3): calcd. C 48.85, H 7.61 Rh 29.83; found C 48.34, H 7.55, Rh 29.50.

19. Preparation of [(η^5-C_5H_5)Rh(η^2-CH_2O)(PMe_3)] (**27**): Compound **27** was prepared analogously to **24** by using 98.7 mg (0.21 mmol) of **23** and 103.6 mg (1.48 mmol) of KOH as starting materials. Brownish microcrystalline solid; yield of oily product 39 mg (56%), yield of solid material 20 mg (29%); m. p. 39°C (dec.). – IR (C_6H_6): $\tilde{\nu}$ = 2790 cm^{-1} [$\nu(CH_2)$], 1215 [$\nu(C-O)$]. – ^1H NMR (60 MHz, C_6D_6): δ = 5.70 [ddd, J(RhH) = 2.8, J(PH) = 0.5, J(HH) = 19.8 Hz, 1 H, one H of CH_2O], 5.07 [dd, J(RhH) = 0.3, J(PH) = 1.2 Hz, 5 H, C_5H_5], 4.03 [ddd, J(RhH) = 2.1, J(PH) = 5.0, J(HH) = 19.8 Hz, 1 H, one H of CH_2O], 0.90 [dd, J(RhH) = 0.8, J(PH) = 10.4 Hz, 9 H, PMe_3]. – ^{13}C NMR (100.6 MHz, C_6D_6): δ = 85.0 [br. s, C_5H_5], 67.9 [m, CH_2O], 17.7 [d, J(PC) = 28.4 Hz, PMe_3]. – ^{31}P NMR (36.2 MHz, C_6D_6): δ = 8.0 [d, J(RhP) = 193.5 Hz]. – MS (70 eV); *m/z* (%) = 274 (4) [M^+], 272 (30) [M^+ – 2 H], 244 (100) [M^+ – CH_2O], 168 (50) [$C_5H_5Rh^+$], 30 (4) [CH_2O^+]. – $C_9H_{16}OPRh$ (274.1): calcd. C 39.44, H 5.88, Rh 37.54; found C 39.73, H 6.16, Rh 38.09.

20. Preparation of [(η^5-C_5H_5)Rh{$CH_2OC(O)Ph$}(PMe_3)I] (**28**): A solution of 87.1 mg (0.21 mmol) of **12** in 4 ml acetone/benzene (1:1) was treated with 79.3 mg (0.49 mmol) of $PhCO_2K$ and stirred for 20 h at 50–60°C. After the reaction mixture was cooled to room temp., the solvent was removed and the residue was extracted with 15 ml of ether. The extract was concentrated to ca. 3 ml in vacuo and upon storing for 6 h at –78°C gave orange-red crystals. The crystals were separated from the mother liquor, washed twice with pentane (0°C) and dried; yield 59 mg (56%); m. p. 142°C (dec.). – IR (KBr): $\tilde{\nu}$ = 1712 cm^{-1} [$\nu(C=O)$]. – ^1H NMR (200 MHz, C_6D_6): δ = 8.1, 7.2 (both m, 5 H, C_6H_5), 7.00 [ddd, J(RhH) = 4.8, J(PH) = 0.3, J(HH) = 5.6 Hz, 1 H, one H of $RhCH_2$], 5.33 [ddd, J(RhH) = 1.4, J(PH) = 8.4, J(HH) = 5.6 Hz, 1 H, one H $RhCH_2$], 5.05 [dd, J(RhH) = 0.6, J(PH) = 1.4 Hz, 5 H, C_5H_5], 1.37 [dd, J(RhH) = 0.8, J(PH) = 11.2 Hz, 9 H, PMe_3]. – ^{31}P NMR (36.2 MHz, C_6D_6): δ = 10.0 [d, J(RhP) = 153.3 Hz]. – $C_{16}H_{21}IO_2PRh$ (506.1): calcd. C 37.97, H 4.18; found C 37.67, H 4.61.

21. Preparation of [(η^5-C_5H_5)Rh{κ^2-C,O-$CH_2OC(Ph)O$}(PMe_3)]PF_6 (**29**): A solution of 60.7 mg (0.12 mmol) of **28** in 3 ml of acetone was treated dropwise with a solution of 30.4 mg (0.12 mmol) of $AgPF_6$ in 2 ml of acetone. The reaction mixture was stirred for 10 min at room temp. and then filtered. The filtrate was concentrated to ca. 2 ml in vacuo and under vigorous stirring 15 ml of ether was added. An orange-yellow precipitate was formed which was separated from the mother liquor, washed twice with ether and dried; yield 52 mg (83%); dec. temp. 75°C. – IR (nujol): $\tilde{\nu}$ = 1602 cm^{-1} [$\nu(C=O)$]. – ^1H NMR (60 MHz, $(CD_3)_2CO$): δ = 8.1, 7.7 (both m, 5 H, C_6H_5), 6.17 (m, 1 H, one H of $RhCH_2$), 5.80 [dd, J(RhH) = 0.6, J(PH) = 1.2 Hz, 5 H, C_5H_5], 1.73 [dd, J(RhH) = 0.8, J(PH) = 11.8 Hz, 9 H, PMe_3], signal of one H of $RhCH_2$ partly covered by signal of C_5H_5. – ^{31}P NMR (36.2 MHz, CD_3NO_2): δ = 12.8 [d, J(RhP) = 150.4 Hz]. – $C_{16}H_{21}F_6O_2P_2Rh$ (524.2): calcd. C 36.66, H 4.04; found C 36.73, H 4.29.

22. Thermal Decomposition of **24**: A solution of 36.4 mg (0.09 mmol) of **24** in 0.5 ml of benzene was stored for 5 h at room temp. The reaction was controlled by measuring the ^1H-NMR spectrum in time intervals of ca. 20 min. After 5 h, the signals of **24** disappeared and new signals corresponding to **30**[22] were observed; yield ca 85%.

23. Thermal Decomposition of **25**: A solution of 50.6 mg (0.16 mmol) of **25** in 0.5 ml of benzene was stored for 6 d at room temp. The reaction was controlled by measuring the ^1H-NMR spectrum in time intervals of ca. 2–3 h. After 6 d, the signals of **25** disappeared and new signals corresponding to **31** and **32**[33] were observed; yield almost quantitative; ratio **31**/**32** = 70:30.

24. Preparation of [{(η^5-C_5H_5)RhP($OMe)_3$}$_2$] (**31**): A solution of 88.2 mg (0.27 mmol) of **25** in 0.6 ml of benzene was stored for 7 d at room temp. A characteristic change of color from yellow-brown to deep green occurred. The solvent was removed, the residue was washed twice with 2 ml portions of pentane and then extracted with 10 ml of ether . The extract was concentrated to ca. 1 ml in vacuo and stored for 12 h at –78°C. A green microcrystalline solid precipitated which was repeatedly washed with small quantities of pentane and dried; yield 30.5 mg (39%). – ^1H NMR (60 MHz, C_6D_6): δ = 5.57 [dd, J(RhH) = 0.6, J(PH) = 2.2 Hz, 5 H, C_5H_5], 3.57 [d, J(PH) = 13.1 Hz, 9 H, $P(OMe)_3$]. – ^{31}P NMR (36.2 MHz, C_6D_6): δ = 161.8 [pseudo-quartet, spectrum of AA′XX′ type, N = J(AX) + J(AX′) = 277.6 Hz]. – MS (70 eV); *m/z* (%) = 584 (8) [M^+], 460 (6) [M^+ – $P(OMe)_3$], 292 (88) [$M/2^+$], 233 (100) [$(C_5H_5)_2Rh^+$], 168 (67) [$C_5H_5Rh^+$]. – $C_{16}H_{28}O_6P_2Rh_2$ (584.2): calcd. C 32.90, H 4.83; found C 32.96, H 4.82.

25. Preparation of [(η^5-C_5Me_5)Rh(CH_3)(CO){$P(OMe)_3$}]CF_3SO_3 (**33**): A solution of 47.1 mg (0.12 mmol) of **24** in 3 ml of ether was treated dropwise with 14 µl (0.12 mmol) of $CF_3SO_3CH_3$ at 0°C. Evolution of gas was observed and a pale yellow solid precipitated. After the cooling vessel was removed, the solid was separated from the mother liquor, repeatedly washed with ether and dried; yield 37 mg (55%). – IR (CH_2Cl_2): $\tilde{\nu}$ = 2060 cm^{-1} [$\nu(CO)$]. – ^1H NMR (60 MHz, CD_2Cl_2): δ = 3.78 [d, J(PH) = 11.8 Hz, 9 H, $P(OMe)_3$], 1.86 [dd, J(RhH) = 0.4, J(PH) = 5.0 Hz, 15 H, C_5Me_5], 0.75 [dd, J(RhH) = 2.2, J(PH) = 6.1 Hz, 3 H, $RhCH_3$]. – ^{31}P NMR (36.2 MHz, $CDCl_3$): δ = 120.2 [d, J(RhP) = 218.8 Hz]. – $C_{16}H_{27}F_3O_7PRhS$ (554.3): calcd. C 34.67, H 4.91; found C 34.31, H 5.00.

26. Preparation of [(η^5-C_5Me_5)Rh(CH_3)(CO)(PMe_3)]CF_3SO_3 (**34**): Compound **34** was prepared analogously to **33** by using 44.6

mg (0.13 mmol) of **26** and 15 µl (0.13 mmol) of $CF_3SO_3CH_3$ as starting materials. Pale yellow solid; yield 45 mg (69%). − IR (CH_2Cl_2): $\tilde{\nu}$ = 2045 cm^{-1} [ν(CO)]. − ^1H NMR (200 MHz, CD_2Cl_2): δ = 1.85 [dd, *J*(RhH) = 0.3, *J*(PH) = 3.1 Hz, 15 H, C_5Me_5], 1.55 [dd, *J*(RhH) = 0.8, *J*(PH) = 11.0 Hz, 9 H, PMe_3], 0.51 [dd, *J*(RhH) = 2.2, *J*(PH) = 5.7 Hz, 3 H, $RhCH_3$]. − ^{31}P NMR (36.2 MHz, $CDCl_3$): δ = 4.8 [d, *J*(RhP) = 126.5 Hz]. − $C_{16}H_{27}F_3O_4PRhS$ (506.3): calcd. C 37.95 H 5.38; found C 37.56, H 5.23.

27. Preparation of [(η⁵-C_5H_5)Rh(CH_3)(CO)(PMe_3)]CF_3SO_3 (**35**): Compound **35** was prepared analogously to **33** by using 60.3 mg (0.22 mmol) of **27** and 25 µl (0.22 mmol) of $CF_3SO_3CH_3$ as starting materials. The crude product (dark oil) was dissolved in 8 ml of CH_2Cl_2, the solution was filtered and the filtrate was brought to dryness in vacuo. The residue was dissolved in 1 ml of methanol and the solution was layered with 10 ml of ether. Light brown crystals precipitated which were separated from the mother liquor, washed with ether and dried; yield 16 mg (16%). − IR (CH_2Cl_2): $\tilde{\nu}$ = 2055 cm^{-1} [ν(CO)]. − ^1H NMR (200 MHz, CD_3NO_2): δ = 5.73 [dd, *J*(RhH) = 0.3, *J*(PH) = 1.4 Hz, 5 H, C_5H_5], 1.85 [dd, *J*(RhH) = 0.9, *J*(PH) = 10.8 Hz, 9 H, PMe_3], 1.03 [dd, *J*(RhH) = 2.3, *J*(PH) = 5.2 Hz, 3 H, $RhCH_3$]. − ^{31}P NMR (36.2 MHz, $(CD_3)_2CO$): δ = 12.8 [d, *J*(RhP) = 125.1 Hz]. − $C_{11}H_{17}F_3O_4PRhS$ (436.2): calcd. C 30.29 H 3.91; found C 29.80, H 4.08.

28. Preparation of [(η⁵-C_5H_5)Rh(PMe_3)($SAc)_2$] (**37**): A solution of 146 mg (0.35 mmol) of **36** in 1 ml of benzene and 2 ml of thioacetic acid was treated with 302.9 mg (2.65 mmol) of KSAc at room temp. After the reaction mixture was stirred for 1 h, the solvent was removed and the residue was extracted with 10 ml of benzene. The extract was brought to drynesss in vacuo and upon addition of 1 ml of ether and 1 ml of pentane the oily residue was crystallized to give an orange solid; yield 105 mg (76%); m. p. 150°C (dec.). − IR (C_6H_6): $\tilde{\nu}$ = 1625 cm^{-1} [ν(C=O)]. − ^1H NMR (60 MHz, C_6D_6): δ = 5.40 [dd, *J*(RhH) = 0.4, *J*(PH) = 2.0 Hz, 5 H, C_5H_5], 2.57 (s, 6 H, $SCCH_3$), 1.32 [dd, *J*(RhH) = 0.9, *J*(PH) = 11.7 Hz, 9 H, PMe_3]. − ^{31}P NMR (36.2 MHz, C_6D_6): δ = 12.2 [d, *J*(RhP) = 120.0 Hz]. − MS (70 eV); *m/z* (%) = 394 (7) [M^+], 319 (100) [M^+ − SAc], 244 (65) [$C_5H_5Rh(PMe_3)^+$], 168 (16) [$C_5H_5Rh^+$]. − $C_{12}H_{20}O_2PRhS_2$ (394.3): calcd. C 36.58, H 5.11; found C 36.18, H 5.09.

29. Preparation of [(η⁵-C_5H_5)Rh(CH_2SAc)(PMe_3)I] (**38**): A solution of 104.2 mg (0.25 mmol) of **36** in 4 ml C_6H_6/EtOH (1:1) was treated with 28.3 mg (0.25 mmol) of KSAc and stirred for 1 h at room temp. The solvent was removed, the residue was extracted with 10 ml of benzene and the extract was brought to dryness in vacuo. The residue was now extracted with 5 ml of pentane and the dark red extract was worked up as described below. The remaining solid was dissolved in 2 ml of ether and then 2 ml of pentane was added. After the solution was stored for 12 h at −78°C orange-red crystals of **38** were formed which were separated from the mother liquor, washed twice with pentane and dried; yield 67 mg. The pentane extract was also brought to dryness in vacuo, the residue was dissolved in 1 ml of benzene and the solution was chromatographed on Al_2O_3 (neutral, activity grade IV, height of column 4 cm). With benzene, a red fraction was eluted which upon work up gave red-brown needles of **39**[3]; yield 23 mg (21%). − **38**: m. p. 142°C (dec.). − IR (C_6H_6): $\tilde{\nu}$ = 1670 cm^{-1} [ν(C=O)]. − ^1H NMR (200 MHz, C_6D_6): δ = 4.87 [dd, *J*(RhH) = 0.5, *J*(PH) = 1.6 Hz, 5 H, C_5H_5], 4.10 [ddd, *J*(RhH) = 4.8, *J*(PH) = 3.8, *J*(HH) = 9.2 Hz, 1 H, one H of $RhCH_2$], 3.44 [ddd, *J*(RhH) = 2.2, *J*(PH) = 6.9, *J*(HH) = 9.2 Hz, 1 H, one H of $RhCH_2$], 2.14 (s, 3 H, $SCCH_3$), 1.34 [dd, *J*(RhH) = 0.7, *J*(PH) = 11.1 Hz, 9 H, PMe_3]. − ^{31}P NMR (36.2 MHz, C_6D_6): δ = 7.3 [d, *J*(RhP) = 150.0 Hz]. − MS (70 eV); *m/z* (%) = 371 (95) [M^+ − CH_2SAc], 333 (88) [M^+ − I], 295 (27) [$C_5H_5RhI^+$], 244 (100) [$C_5H_5Rh(PMe_3)^+$], 168 (57) [$C_5H_5Rh^+$]. − $C_{11}H_{19}IOPRhS$ (460.1): calcd. C 28.71, H 4.16; found C 28.48, H 3.84.

30. Preparation of [(η⁵-C_5H_5)Rh(PMe_3)(SAc)I] (**40**): a) A solution of 50.3 mg (0.11 mmol) of **38** in 1.5 ml of benzene was chromatographed on Al_2O_3 (neutral, activity grade IV, height of column 4 cm). With benzene, an orange-yellow fraction was eluted from which the solvent was removed in vacuo. To the oily residue 1 ml of pentane was added and after the mixture was stirred for 1 h an orange solid was obtained; yield 45 mg (91%). − b) A solution of 131.8 mg (0.25 mmol) of **36** in 1.5 ml of benzene and 3 ml of thioacetic acid was treated with 30.1 mg (0.26 mmol) of KSAc and stirred for 2 h at room temp. The solvent was removed, the residue was extracted with 10 ml of benzene and the extract was concentrated to ca. 2 ml in vacuo. The ^1H-NMR spectrum of the solution revealed that the major component of the crude product was **38**. The solution was chromatographed on Al_2O_3 (neutral, activity grade IV, height of column 4 cm) and with benzene two fractions were eluted. The first fraction contained a mixture of products among which **37** could be detected. The second fraction was worked up analogously as described for a) to give an orange microcrystalline solid; yield 80 mg (72%); m. p. 118°C (dec.). − IR (C_6H_6): $\tilde{\nu}$ = 1620 cm^{-1} [ν(C=O)]. − ^1H NMR (200 MHz, C_6D_6): δ = 5.20 [dd, *J*(RhH) = 0.3, *J*(PH) = 1.9 Hz, 5 H, C_5H_5], 2.57 (s, 3 H, $SCCH_3$), 1.50 [dd, *J*(RhH) = 0.7, *J*(PH) = 11.9, 9 H, PMe_3]. − MS (70 eV); *m/z* (%) = 446 (1) [M^+], 371 (50) [M^+ − SAc], 319 (17) [M^+ − I], 295 (16) [$C_5H_5RhI^+$], 244 (60) [$C_5H_5Rh(PMe_3)^+$], 168 (36) [$C_5H_5Rh^+$]. − $C_{10}H_{17}IOPRhS$ (446.1): calcd. C 26.93, H 3.84; found C 27.24, H 3.81.

31. Preparation of [(η⁵-C_5Me_5)Rh(CH_2SAc){$P(OMe)_3$}I] (**43**): A solution of 87.9 mg (0.14 mmol) of **41** in 3 ml of benzene was treated under stirring with a solution of 16.0 mg (0.14 mmol) of KSAc in 1.5 ml of ethanol. After the reaction mixture was continuously stirred for 1 h at room temp., the solvent was removed and the residue was extracted with 10 ml of ether. The extract was brought to dryness in vacuo, the oily residue was washed with 0.5 ml of ethanol and 3 ml of pentane was added. Upon storing for 12 h at −78°C an orange-red solid precipitated which was washed twice with pentane and dried; yield 61 mg (75%). − IR (C_6H_6): $\tilde{\nu}$ = 1670 cm^{-1} [ν(C=O)]. − ^1H NMR (200 MHz, $CDCl_3$): δ = 3.77 [d, *J*(PH) = 11.2 Hz, 9 H, $P(OMe)_3$], 3.20 [ddd, *J*(RhH) = 5.2, *J*(PH) = 2.6, *J*(HH) = 8.4 Hz, 1 H, one H of $RhCH_2$], 2.99 [ddd, *J*(RhH) = 3.2, *J*(PH) = 5.0, *J*(HH) = 8.4 Hz, 1 H, one H of $RhCH_2$], 2.23 (s, 3 H, $SCCH_3$), 1.87 [dd, *J*(RhH) = 0.3, *J*(PH) = 4.5 Hz, 15 H, C_5Me_5]. − ^{13}C NMR (22.5 MHz, C_6D_6): δ = 198.9 (s, C=O), 101.0 [dd, *J*(RhC) = *J*(PC) = 4.4 Hz, C_5Me_5], 54.2 [d, *J*(PC) = 6.6 Hz, $P(OMe)_3$], 29.7 (s, $SCCH_3$), 9.6 [d, *J*(RhC) = 1.5 Hz, $C_5(CH_3)_5$], 5.3 [dd, *J*(RhC) = 27.2, *J*(PC) = 19.1 Hz, $RhCH_2$]. − ^{31}P NMR (36.2 MHz, C_6D_6): δ = 133.6 [d, *J*(RhP) = 248.6 Hz]. − MS (70 eV); *m/z* (%) = 489 (24) [M^+ − CH_2SAc], 365 (41) [$C_5Me_5RhI^+$], 362 (100) [M^+ − CH_2SAc − I], 238 (46) [$C_5Me_5Rh^+$]. − $C_{16}H_{29}IO_4PRhS$ (578.3): calcd. C 33.23, H 5.06; found C 33.47, H 5.18.

32. Preparation of [(η⁵-C_5Me_5)Rh(CH_2SAc)($PMe)_3$I] (**44**): Compound **44** was prepared analogously to **43** by using 87.1 mg (0.15 mmol) of **42** and 17.1 mg (0.15 mmol) of KSAc as starting materials. The ether extract was concentrated to ca. 1 ml in vacuo and then stored for 12 h at −78°C. Orange microcrystalline solid; yield 58 mg (73%); m. p. 137°C (dec.) − IR (C_6H_6): $\tilde{\nu}$ = 1665 cm^{-1} [ν(C=O)]. − ^1H NMR (200 MHz, C_6D_6): δ = 3.60 [ddd, *J*(RhH) =

2.4, J(PH) = 5.0, J(HH) = 8.2 Hz, 1 H, one H of $RhCH_2$], 3.17 [ddd, J(RhH) = J(PH) = 4.1 Hz, J(HH) = 8.2 Hz, 1 H, one H of $RhCH_2$], 2.19 (s, 3 H, $SCCH_3$), 1.72 [dd, J(RhH) = 0.3, J(PH) = 2.8 Hz, 15 H, C_5Me_5], 1.30 [dd, J(RhH) = 0.9, J(PH) = 10.1 Hz, 9 H, PMe_3]. – ^{13}C NMR (22.5 MHz, C_6D_6): δ = 198.7 (s, C=O), 98.8 [dd, J(RhC) = 5.2, J(PC) = 3.7 Hz, C_5Me_5], 29.6 (s, $SCCH_3$), 17.4 [d, J(PC) = 32.4 Hz, PMe_3], 10.0 [br. s, $C_5(CH_3)_5$], 5.9 [dd, J(RhC) = 28.7, J(PC) = 15.4, $RhCH_2$]. – ^{31}P NMR (36.2 MHz, C_6D_6): δ = 2.1 [d, J(RhP) = 140.1 Hz]. – MS (70 eV); m/z (%) = 441 (93) [$M^+ - CH_2SAc$], 365 (100) [$C_5Me_5RhI^+$], 314 (7) [$M^+ - CH_2SAc - I$], 238 (8) [$C_5Me_5Rh^+$]. – $C_{16}H_{29}IOPRhS$ (530.3): calcd. C 36.24, H 5.51; found C 35.83, H 5.53.

33. Preparation of [(η^5-C_5Me_5)Rh(CH_2SAc)(PMe_3)SAc] (**45**): a) A solution of 131.2 mg (0.25 mmol) of **42** in 2 ml of benzene was treated with a solution of 98.5 mg (0.86 mmol) of KSAc in 1 ml of ethanol and stirred for 30 min at room temp. The solvent was removed, the residue was extracted with 10 ml of ether and the extract was concentrated to ca. 1 ml in vacuo. Upon addition of 2 ml of pentane, the solution was stored for 12 h at −78°C. Yellow crystals precipitated which were separated from the mother liquor and dried; yield 80 mg (67%). – b) A solution of 56.6 mg (0.10 mmol) of **44** in 1 ml of benzene was treated with a solution of 12.2 mg (0.11 mmol) of KSAc in 0.5 ml of ethanol. After the reaction mixture was worked up as described for a), a yellow solid was obtained; yield 28 mg (58%); m. p. 163°C (dec.). – IR (C_6H_6): $\tilde{\nu}$ = 1660, 1609 cm^{-1} [ν(C=O)]. – ^{1}H NMR (200 MHz, C_6D_6): δ = 2.70 [ddd, J(RhH) = 2.5, J(PH) = 7.2, J(HH) = 8.5 Hz, 1 H, one H of $RhCH_2$], 2.55, 2.15 (both s, 3 H each, $SCCH_3$), 1.63 [dd, J(RhH) = 0.3, J(PH) = 2.9 Hz, 15 H, C_5Me_5], 1.24 [dd, J(RhH) = 0.9, J(PH) = 10.2 Hz, 9 H, PMe_3], signal of one H of $RhCH_2$ not exactly located. – ^{31}P NMR (36.2 MHz, C_6D_6): δ = 2.2 [d, J(RhP) = 140.0 Hz]. – MS (70 eV); m/z (%) = 478 (0.1) [M^+], 389 (44) [$M^+ - CH_2SAc$], 313 (88) [$C_5Me_5Rh(SAc)^+$], 314 (22) [$C_5Me_5Rh(PMe_3)^+$], 238 (13) [$C_5Me_5Rh^+$]. – $C_{18}H_{32}O_2PRhS_2$ (478.5): calcd. C 45.19, H 6.74; found C 45.35, H 6.46.

34. Preparation of [(η^5-C_5Me_5)Rh(η^2-CH_2S){$P(OMe)_3$}] (**46**): a) A solution of 81.7 mg (0.14 mmol) of **43** in 8 ml of benzene was treated with 85 μl of a 1.6 M solution (0.14 mmol) of nBuLi in hexane and stirred for 10 min at room temp. The solvent was removed and the residue was extracted with 10 ml of pentane. The extract was brought to dryness in vacuo, the oily residue was dissolved in 2 ml of benzene and the solution was chromatographed on Al_2O_3 (neutral, activity grade IV, height of column 5 cm). With benzene, an orange fraction was eluted from which the solvent was removed. The oily residue was dissolved in 8 ml of pentane, the solution was filtered, the filtrate was concentrated to ca. 2 ml and then stored for 12 h at −78°C. Orange-yellow crystals precipitated which were separated from the mother liquor and dried; yield 42 mg (75%). – b) A solution of 85.7 mg (0.14 mmol) of **48** in 5 ml of methanol was treated at room temp. with an excess (ca. 50 mg) of $NaOCH_3$. After the reaction mixture was stirred for 10 min, the solvent was removed and the residue was extracted with 15 ml of pentane. The extract was concentrated to ca. 2 ml in vacuo and then stored for 12 h at −78°C. Orange-yellow crystals; yield 42 mg (73%); m. p. 76°C (dec.). – ^{1}H NMR (90 MHz, C_6D_6): δ = 3.91 [ddd, J(RhH) = 2.7, J(PH) = 0.9, J(HH) = 8.6 Hz, 1 H, one H of CH_2S], 3.34 [d, J(PH) = 12.0 Hz, 9 H, $P(OMe)_3$], 1.77 [dd, J(RhH) = 0.7, J(PH) = 3.9 Hz, 15 H, C_5Me_5], signal of one H of CH_2S partly covered by signal of $P(OMe)_3$. – ^{13}C NMR (50.3 MHz, C_6D_6): δ = 98.5 [dd, J(RhC) = J(PC) = 4.5 Hz, C_5Me_5], 51.5 [d, J(PC) = 6.3 Hz, $P(OMe)_3$], 49.5 [dd, J(RhC) = 18.9, J(PC) = 7.4 Hz, CH_2S], 9.7 [s, $C_5(CH_3)_5$]. – ^{31}P NMR (36.2 MHz, C_6D_6): δ = 143.4 [d, J(RhP) = 290.3 Hz]. – MS (70 eV); m/z (%) = 408 (52) [M^+], 362 (100) [$M^+ - CH_2S$], 238 (40) [$C_5Me_5Rh^+$]. – $C_{14}H_{26}O_3PRhS$ (408.3): calcd. C 41.18, H 6.42; found C 41.50, H 6.55.

35. Preparation of [(η^5-C_5Me_5)Rh(η^2-CH_2S)(PMe_3)] (**47**): Compound **47** was prepared analogously to **46** either by using 68.1 mg (0.15 mmol) of **44** and 90 μl of a 1.6 M solution (0.15 mmol) of nBuLi in hexane or 78.4 mg (0.14 mmol) of **49** and ca. 50 mg of $NaOCH_3$ as starting materials. Orange-brown microcrystalline solid; yield 41 mg (76%) from **44** and 34 mg (68%) from **49** as starting material; m. p. 81°C (dec.). – ^{1}H NMR (200 MHz, C_6D_6): δ = 3.87 (m, 2 H, CH_2S), 1.87 [dd, J(RhH) = 0.5, J(PH) = 2.4 Hz, 15 H, C_5Me_5], 1.07 [dd, J(RhH) = 0.9, J(PH) = 9.0 Hz, 9 H, PMe_3]. – ^{13}C NMR (50.3 MHz, C_6D_6): δ = 96.6 [dd, J(RhC) = J(PC) = 4.4 Hz, C_5Me_5], 46.6 [dd, J(RhC) = 19.9, J(PC) = 5.5 Hz, CH_2S], 15.9 [d, J(PC) = 28.5 Hz, PMe_3], 10.1 [s, $C_5(CH_3)_5$]. – ^{31}P NMR (36.2 MHz, C_6D_6): δ = 4.9 [d, J(RhP) = 184.6 Hz]. – MS (70 eV); m/z (%) = 360 (55) [M^+], 314 (100) [$M^+ - CH_2S$], 238 (21) [$C_5Me_5Rh^+$]. – $C_{14}H_{26}PRhS$ (360.3): calcd. C 46.67, H 7.27; found C 46.48, H 7.52.

36. Preparation of [(η^5-C_5Me_5)Rh{κ^2-C,O-$CH_2SC(Me)O$}-{$P(OMe)_3$}]PF_6 (**48**): Compound **48** was prepared analogously to **19** by using 130.0 mg (0.22 mmol) of **43** and 56.5 mg (0.22 mmol) of $AgPF_6$ as starting materials. Orange-yellow solid; yield 117 mg (89%); dec. temp. 69°C. – Λ = 82 $cm^2\Omega^{-1}mol^{-1}$. – IR (nujol): $\tilde{\nu}$ = 1565 cm^{-1} [ν(C=O)]. – ^{1}H NMR (60 MHz, $(CD_3)_2CO$): δ = 3.83 [d, J(PH) = 11.6 Hz, 9 H, $P(OMe)_3$], 3.37 (m, 2 H, $RhCH_2$), 2.40 (s, 3 H, $SCCH_3$), 1.77 [dd, J(RhH) = 0.3, J(PH) = 4.5 Hz, 15 H, C_5Me_5]. – ^{13}C NMR (22.5 MHz, CD_3NO_2): δ = 226.4 (s, C=O), 103.0 [dd, J(RhC) = 5.9, J(PC) = 4.2 Hz, C_5Me_5], 54.0 [d, J(PC) = 5.9 Hz, $P(OMe)_3$], 27.1 [s, $C(O)CH_3$], 21.5 [dd, J(RhC) = 27.9, J(PC) = 22.8 Hz, $RhCH_2$], 9.2 [d, J(RhC) = 2.2 Hz, $C_5(CH_3)_5$]. – ^{31}P NMR (36.2 MHz, CD_3NO_2): δ = 126.7 [d, J(RhP) = 251.6 Hz]. – $C_{16}H_{29}F_6O_4P_2RhS$ (596.3): calcd. C 32.23, H 4.90; found C 32.10, H 5.11.

37. Preparation of [(η^5-C_5Me_5)Rh{κ^2-C,O-$CH_2SC(Me)O$}-(PMe_3)]PF_6 (**49**): Compound **49** was prepared analogously to **19** by using 159.4 mg (0.30 mmol) of **44** and 78.2 mg (0.31 mmol) of $AgPF_6$ as starting materials. Orange-yellow solid; yield 54 mg (96%); dec. temp. 96°C. – Λ = 73 $cm^2\Omega^{-1}mol^{-1}$. – IR (nujol): $\tilde{\nu}$ = 1552 cm^{-1} [ν(C=O)]. – ^{1}H NMR (200 MHz, $(CD_3)_2CO$): δ = 3.29 [ddd, J(RhH) = 2.9, J(PH) = 0.3, J(HH) = 9.5 Hz, 1 H, one H of $RhCH_2$], 3.07 [ddd, J(RhH) = 9.5, J(PH) = 18.9 J(HH) = 9.5 Hz, 1 H, on H of $RhCH_2$], 2.36 (s, 3 H, $SCCH_3$), 1.71 [dd, J(RhH) = 0.3, J(PH) = 2.7 Hz, 15 H, C_5Me_5], 1.52 [dd, J(RhH) = 0.7, J(PH) = 10.5 Hz, 9 H, PMe_3]. – ^{13}C NMR (22.5 MHz, CD_3NO_2): δ = 226.1 (s, C=O), 100.8 [dd, J(RhC) = 5.9, J(PC) = 2.9 Hz, C_5Me_5], 27.3 [s, $C(O)CH_3$], 21.7 [dd, J(RhC) = 30.2, J(PC) = 15.4 Hz, $RhCH_2$], 13.6 [d, J(RhC) = 30.9 Hz, PMe_3], 9.3 [br. s, $C_5(CH_3)_5$]. – ^{31}P NMR (36.2 MHz, CD_3NO_2): δ = 4.0 [d, J(RhP) = 156.3 Hz]. – $C_{16}H_{29}F_6OP_2RhS$ (548.3): calcd. C 35.05, H 5.33; found C 34.66, H 5.45.

38. Preparation of [(η^5-C_5H_5)Rh(η^2-CH_2S)(PMe_3)] (**50**): Compound **50** was prepared analogously to **46** by using 68.1 mg (0.15 mmol) of **38** and 90 μl of a 1.6 M solution (0.15 mmol) of nBuLi in hexane as starting materials. The yellow microcrystalline solid **50** was identified by comparison of the NMR spectroscopic data with those of an authentic sample;[1d] yield 34 mg (79%).

39. X-ray Structure Determination of Compound **27**[34]: Single crystals of **27** were grown by slow diffusion of ether to a solution of **27** in nitromethane at room temp. Crystal data: orthorhombic, space group $Pbca$, a = 16.857(5), b = 23.538(6), c = 11.048(3) Å, Z = 8, $d_{calcd.}$ = 1.613 g cm^{-3}, μ(Mo-K_α) = 0.98 mm^{-1}; crystal size

0.9 × 1.35 × 0.2 mm; Nicolet P3 diffractometer, Mo-K_α radiation, graphite monochromator; ω scan, $2\Theta_{max} = 55°$; 4276 reflections scanned, 4053 unique reflections, 3919 reflections with $F > 3\sigma(F)$. Intensity data were corrected for Lorentz and polarization effects and a geometrical absorption correction was applied. The structure was solved by the Patterson method. Atomic coordinates and the anisotropic thermal parameters of the non-hydrogen atoms were refined by full-matrix least- squares. The positions of all hydrogen atoms were calculated according to ideal geometry (distance C−H = 0.95 Å). $R = 0.065$, $R_w = 0.070$ [weighting scheme $1/\sigma^2(F)$]; reflections-to-parameter ratio 16.00; residual electron density 2.31 eÅ^{-3}.

☆ Dedicated to Professor *Warren R. Roper* on the occasion of his 60th birthday.

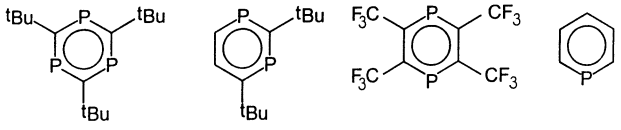
Keywords: 1,3,5-Triphosphabenzene / 1,3-Diphosphabenzene / Photoelectron spectroscopy / Molecular orbital calculations

The structure of 2,4,6-tri-*tert*-butyl-1,3,5-triphosphabenzene (**1**) as well as the He(I) photoelectron spectra of **1** and 2,4-di-*tert*-butyl-1,3-diphosphabenzene (**2**) have been investigated. It was found that **1** is planar with average C–P–C angles of 109.3° (±0.3°) and P–C–P angles of 130.7° (± 0.4°). All P–C bond lengths amount to 1.727 (± 0.008) Å. The PE spectra were interpreted by comparison with the results of ab initio calculations (RHF/ 6-31G*). They reveal a splitting of the lone pairs on P in **2** of 0.7 eV.

With the synthesis of 2,4,6-tri-*tert*-butyl-1,3,5-triphosphabenzene (2,4,6-tri-*tert*-butyl-1λ^3,3λ^3,5λ^3-triphosphinine) (**1**)[1] and of 2,4-di-*tert*-butyl-1,3-diphosphabenzene (2,4-di-*tert*-butyl-1λ^3,3λ^3-diphosphinine) (**2**)[2] the family of phosphorus-containing heterobenzenes is now nearly complete. Earlier investigations led to the synthesis of λ^3-phosphinine **4**[3], numerous substituted λ^3-phosphinines[4] and also of one example of a 1λ^3,4λ^3-diphosphinine **3**.[5] The latter compound, 2,3,5,6-tetrakis(trifluormethyl)-1λ^3,4λ^3-diphosphinine, is stable only in solution. According to their NMR-spectroscopic data (^{31}P, ^{1}H, ^{13}C) mono-, di- and triphosphinines can be conceived as 6π heteroarenes and therefore their trivial names as phosphabenzenes are justified.



1 2 3 4

In order to gain more information about the electronic structure of the two recently prepared diphospha- and triphosphabenzenes **2** and **1**[1][2], we investigated their PE spectra and interpreted the results on the basis of Hartree-Fock ab initio calculations adopting a 6-31G* basis. Furthermore, we present the results of a single-crystal structure analysis of the triphosphabenzene **1** in this paper.

Suitable crystals of compound **1** for an X-ray analysis were obtained as little yellow plates from a pentane solution of **1** at −30°C. As shown in Figure 1 the triphosphabenzene derivative **1** is completely planar. However, in contrast to benzene or pyridine, but in accordance with phosphinines[4] 1,3,5-triphosphinine **1** is far from being regular hexagonal. The average C−P−C angles are 109.3° (±0.3°) (C−C−C angle in benzene 120°, C−N−C angle in pyridine 117°, C−P−C angle in phosphine 101−103°C). In order to accommodate this angular change the P−C−P angles have to exceed 120°. In triphosphabenzene **1** the average P−C−P angles are 130.7° (±0.4°) (P−C−C and C−C−C angles in phosphinines 122−120°[4]). All P−C bond lengths of the P_3C_3 ring are equal with average bond lengths of 1.727 (±0.008) Å, and are in the range of those found for phosphinines (1.73−1.75 Å),[4] considerably longer than P=C bond lengths in phosphaalkenes (1.66−1.68 Å).[6] All these results point towards a delocalization of the six π-electrons of the triphosphabenzene **1**. Our calculations (C_3 symmetry, RHF/6-31G*) reveal geometrical parameters for **1** which are close to the experiment (C=P: calcd. 1.730 Å, found 1.727 Å; C−P−C: calcd. 110.6°, found 109.6°; P−C−P: calcd. 129.4°, found 130.3°).[7]

The He(I) photoelectron (PE) spectra of **1** and **2** are shown in Figure 2. The vertical ionization energies, $I_{v,j}$, are collected in Table 1. The PE spectrum of **1** shows one broad band centered at 8.2 eV separated by 1.8 eV from the next one at 10.0 eV. The PE spectrum of **2** shows also a broad peak at 8.6 eV and a smaller one at 9.5 eV. The ratio between the areas below both peaks in **2** is approximately 3:1.

To assign the PE spectra of **1** and **2** to various ionization processes we assume the validity of Koopmans' theorem[8] which allows us to correlate the recorded vertical ionization

[a] Selected bond lengths [Å] and angles [°]: P1−C1 1.725(5), P1−C3 1.729(5), P2−C1 1.724(5), P2−C2 1.719(4), P3−C2 1.727(4), P3−C3 1.718(4), C3−C12 1.558(6), C1−C4 1.551(7); P1−C1−P2 130.3(3), P2−C2−P3 130.8(3), P1−C3−P3 130.9(3), C1−P1−C3 109.3(2), C1−P2−C2 109.6(2), C2−P3−C3 109.0(2).

energies, $I_{v,j}$, with the calculated orbital energies, $-\varepsilon_j$. To derive the orbital energies we use the Hartree-Fock ab initio method adopting a 6-31G* basis.[9] The results of our calculations are based on the optimized geometries of **1** and **2** and are listed in Table 1.

The calculations predict for **2** three relatively close-lying occupied molecular orbitals (MOs) at 8.38, 8.93 and 9.29 eV, well separated from a fourth one at 10.76 eV.

We assume that the ionizations from these four MOs give rise to two peaks; the first one is due to the overlap of three close-lying bands. The calculations predict that the two highest occupied MOs are of π type followed by linear combinations of the phosphorus lone pairs. All four are shown schematically in Figure 3.

The plausibility of this assignment can be checked by comparing the PE spectrum of **2** with that of phosphabenzene (**4**)[10] and 1,3,5-tri-*tert*-butylphosphabenzene (**5**).[11] The ionization energy of the phosphorous lone pair of **4** was found at 10.0 eV and of **5** at 8.6 eV. These values allow us to estimate the inductive effect of one *tert*-butyl group to 0.47 eV. This leads to the center of gravity of the two lone pairs in **2** at 9.1 eV. This value agrees very well with that found for bands 3 and 4 in the PE spectrum of **2**. A comparison between the energy difference of band 3 and 4 in the PE spectrum of **2** and the values for the corresponding orbital energies show that the calculated energy splitting of the lone pairs is twice as large as the measured one. The splitting of the bands assigned to the lone pairs in **2** (0.7 eV) is half the value found in the PE spectrum of pyrimidine.[12] We ascribe this to the higher p character of the lone pairs in pyrimidine (73%) as compared to 2,4-di-*tert*-butyl-1,3-diphosphabenzene **2** (41%).

Our assignment of the first bands of the PE spectrum of **1** is also based on the comparison between the results of a HF-SCF calculation and the PE experiment. This comparison suggests to assign the first peak in the PE spectrum of **1** to four strongly overlapping bands corresponding to the transition from 27e(π) and 26e(n). The shoulder at 10 eV is assigned to 27a(π). All four MOs are shown in Figure 3.

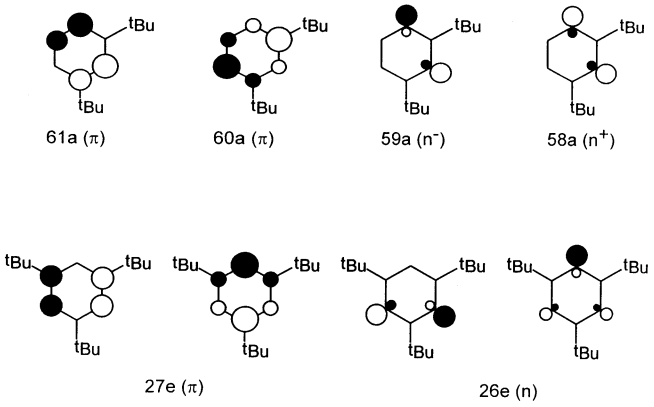
Table 1. Vertical ionization energies, $I_{v,j}$, and calculated orbital energies, $-\varepsilon_j$, of **1** and **2**

	band	$I_{v,j}$ [eV]	assignment	$-\varepsilon_j$ [eV]
1	1	8.2	27 e (π)	8.51
	2			
	3	8.3	26e (n)	9.16
	4			
	5	10.0	27a (π)	11.46
2	1	8.5	61a (π)	8.38
	2	8.6	60a (π)	8.93
	3	8.8	59a (n-)	9.29
	4	9.5	58a (n+)	10.76

Figure 3. Schematic representation of the highest occupied molecular orbitals of **1**and **2**



The assignment of the π bands of **1** yields a center of gravity of 8.8 eV. This value is close to that found for **5** (8.9 eV).

We are grateful to *A. Flatow* for recording the PE spectra of **1** and **2**. We thank the *Deutsche Forschungsgemeinschaft (Graduiertenkolleg "Phosphor als Bindeglied verschiedener chemischer Disziplinen")*, the *Fonds der Chemischen Industrie* and the *BASF Aktiengesellschaft*, Ludwigshafen, for financial support.

Experimental Section

The He(I) PE spectra of **1** and **2** were recorded with a PS18 spectrometer (Perkin Elmer). The recording temperatures were 80°C for **1** and 25°C for **2**. The calibration was performed with Ar and Xe. A resolution of 20 meV on the $P_{3/2}$ Ar line was obtained. The MO calculations on **1** and **2** were carried out with the Gaussian 94 program.[9] The orbital energies are based on the optimized geometries of **1** and **2**.

Crystal Structure Analysis of **1**[13]: Enraf-Nonius CAD4 diffractometer (Cu-K_α radiation), T = 293 K; structure solution by heavy atom method (SHELXS-86[14]) and structure refinement by SHELXL-93[15]; monoclinic, space group $C2/c$, lattice constants a = 31.281(3), b = 6.047(1), c = 19.458(1) Å, β = 93.96(3)°, V = 3672.0(6) Å^3, Z = 8, μ(Mo-K_α) = 2.876 mm^{-1}, crystal size 0.25 × 0.24 × 0.11 mm, Θ_{max} = 33.16°, 4206 measured reflections (R_{int} = 0.04), 3756 independent of which 2262 were considered observed with $I > 2\sigma(I)$, ψscan absorption correction; min./max, transmission 0.860/0.999, max. residual electronic density 0.54 e/Å^3. 157 parameters C and P anisotropic (except the disordered atoms at C4 and C8), the positions of the H atoms were calculated for idealized positions (d_{C-H} = 0.980 Å), R_1 = 0.0909, wR^2 = 0.2438.

Keywords: (1-Alkynyl)carbene complexes / Pyrroles / Imines / Mesoionic compounds / Tungsten complexes

Reaction of the [(1-alkynyl)carbene]tungsten complex $(CO)_5W{=}C(OEt)C{\equiv}CPh$ (**1a**) with non-enolizable imines, e.g. 9-fluorenone imines **2** [NR = N(*i*Pr), N(*c*-C_6H_{11})], affords novel mesoionic pyrrolium carbonyltungstates **3** (by [3+2] cycloaddition) together with dihydropyrroles **4** (by dichotomy of the C=N bond and subsequent insertion of the carbene carbon atom into an NC–H bond). Cross-conjugated azametallatrienes **6** and pentacarbonyltungsten complexes **7** of the dihydropyrroles **4** have been identified to be precursors to compound **4**. Compounds **3b**, **4a**, and **6a** have been characterized by X-ray crystal structure analyses.

Reactions of imines with group-VI heteroatom-stabilized carbene complexes of the Fischer-type are varied and have provided some useful synthetic applications. Depending on the type of carbene complex and the imine, nucleophilic substitution at the carbene carbon atom,[2] condensation at the α-carbon atom (under thermal conditions) or formation of β-lactams[3] (under the influence of sun light) is achieved. The latter type of reaction has been extensively studied by Hegedus et al., and many *N*-substituted imines have been converted into β-lactams. Reactions of imines with α,β-unsaturated carbene complexes are channeled by competing 4-addition of the nitrogen atom to a C=C (or C≡C) bond, and by 2-addition to the M=C, respectively. For example, reactions of *NH*-ketimines $R_2C{=}NH$ (R = alkyl, aryl) with the [(1-alkynyl)carbene]chromium complex $(CO)_5Cr{=}C(OEt)C{\equiv}CPh$ (**1b**) were shown to afford mainly 5-aza-1-chroma-1,3,5-hexatrienes $(CO)_5Cr{=}C(OEt)CH{=}C(Ph)N{=}CR_2$ by 4-addition.[4] Alkenyl *NH*-imidates $R^2CH{=}CR^1{-}C(OEt){=}NH$ (R^1, R^2 = Ph, Me, H) and (1-alkynyl)-carbene complexes **1a**, **b** (M = W, Cr) were found to produce 5-aza-1-metalla-1,3,5,7-octatetraenes $(CO)_5M{=}C(OEt){-}CR{=}CR{-}N{=}C(OEt){-}CR^1{=}CHR^2$ (R = alkyl, aryl) by 4-addition, but also 2,5-diethoxy-2*H*-pyrrole and 2,4-diethoxy-2*H*-dihydroazete complexes, both of which by 2-addition (in an overall [3+2] and [2+2] cycloaddition, respectively).[5] Furthermore, reactions of both alkenyl *N(alkyl)*-imines, and -imidates, respectively, involve participation of the alkenyl unit, but lead to different types of products with (1-alkynyl)carbene complexes **1a**, **b**. Whilst the alkenyl *N(alkyl)*-imines, e.g. PhCH=CH−CH=N(*i*Pr) yield (dihydropyridinyl)carbene complexes (in an overall [4+2] cycloaddition initiated by 4-addition) and mesoionic 1-azonia-5*H*-cycloheptatrien-3-yl carbonylmetalates (in an overall [4+3] cycloaddition initiated by 2-addition),[6][7] alkenyl *N(alkyl)*-imidates, e.g. $RCH{=}CH{-}C(OEt)NR^1$ (R, R^1 = aryl, alkyl) were found to afford binuclear compounds as the only products, resulting from a domino [4+2] and [2+2] cycloaddition of two equivalents of compound **1**.[8] Thus, with respect to the addition of α,β-unsaturated imines to (1-alkynyl)carbene complexes **1**, it should be noted that open-chain adducts as well as four- and five-membered *N*-heterocyclic rings are obtained from *N*-unsubstituted alkenyl imidates, whilst bicyclic systems are generated from *N*-substituted alkenyl imidates, and six- and seven-membered rings are generated from *N*-substituted alkenylimines (but supposedly not from *N*-unsubstituted alkenylimines).

Reaction of (1-Alkynyl)carbene Complex 1a with Non-enolizable Imines 2

The investigation of fundamental reaction paths of imines and imidates with (1-alkynyl)carbene complexes **1** was extended to aliphatic compounds. It was found that enolizable imidates, e.g., *O*-alkyl lactims $\sim(CH_2)_n{-}N{=}C(OR){\sim}$ (n = 3−6) and (1-alkynyl)carbene complexes **1a**, **b** gave 1-azacycloalkene derivatives as the main products, involving the transfer of an α-hydrogen atom.[1] Focusing more strongly on the reactivity of the C=N bonds in aliphatic systems, it was envisaged that non-enolizable imines might yield pyrrolium (= azoniacyclopentadiene) complexes by [3+2] cycloaddition of a C_3 unit of compounds **1** to the C=N bond (Scheme 1). This reaction mode was anticipated as an extension of the recently described access to cyclopen-

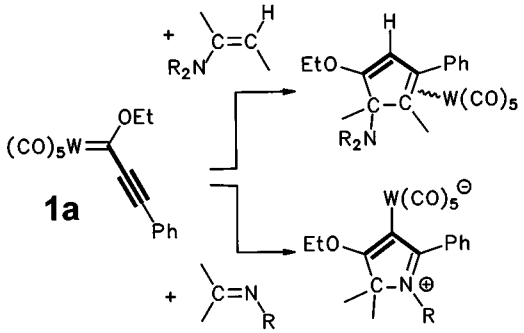
tadienes by [3+2] cycloaddition of (1-alkynyl)carbene complexes to HC=C(N) bonds.[9]

Scheme 1. [3+2] Cycloaddition of [(1-alkynyl)carbene]tungsten complex **1a** to olefines and imines, respectively



Reaction of the (1-alkynyl)carbene complex **1a** with non-enolizable imines, like fluorenone imines **2a**, **b** at 90°C, 2 h, molar ratio 1:1, affords two types of compounds in a clean reaction: (a) novel pyrrolium complexes **3a**, **b** as minor and (b) dihydropyrroles **4a**, **b** as major products (Scheme 2). Compounds **3** and **4** were isolated by chromatography on silica gel and characterized spectroscopically as well as by X-ray crystal structure analyses. Whilst it is quite obvious that compounds **3** are generated in an overall [3+2] cycloaddition as outlined above (Scheme 1), formation of compounds **4** seems to involve a more complicated reaction sequence (v.s.).

Scheme 2. Two different routes to pyrrole derivatives from non-enolizable imines 2 and (1-alkynyl)carbene complex **1a**

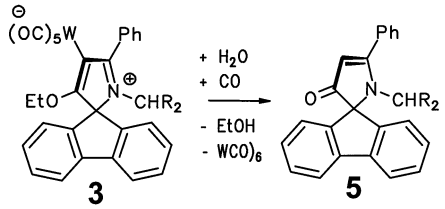
Spectroscopy and Structure Determinations

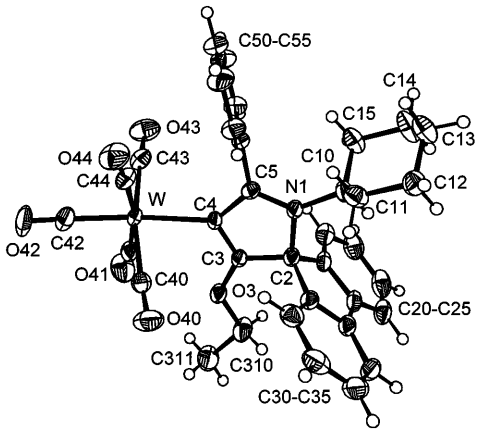
The mesoionic character of the novel pyrrolium compounds **3** is indicated in its ^{13}C-NMR spectrum by a characteristic upfield shift of the signal W–*C*(ring) (**3a**: δ = 187.9; **3b**: δ = 187.3), which now is observed in a range similar to that found for iminium carbonylmetalates[10] derived from vinylogous seven-membered *N*-heterocyclic ligands[7] (W–*C*: δ = 181.9).[6c] Furthermore, the signal of *C*=N$^+$ is appreciably shifted downfield (**3a**: δ = 198.2; **3b**: δ = 197.3) if compared to a normal C=N bond. Compounds **3** are first representatives of a (supposedly) large group of mesoionic pyrrolium complexes, which, like sydnones and related species,[11] can not be satisfactorily described by Lewis formulas excluding charge separation. In line with expectation, compounds **3** were found to undergo hydrolysis of the enol ether unit with formation of a spiro compound **5** as the only detectable product, in addition to $W(CO)_6$ (Scheme 3).

Scheme 3. Hydrolysis of zwitterionic pyrrolium complexes **3**



Structural details of spiro compounds **3** are based on a crystal structure analysis of compound **3b** (Figure 1, Table 1). The distance W–C4 [2.276(4)] Å is longer than in non-heteroatom (carbene)tungsten complexes, such as $(CO)_5W{=}CPh_2$ [2.15(1)][12] and even longer than in pyrylium pentacarbonyltungstates, e.g. 2.193(5).[13] In line with the mesoionic character of compound **3b** is the pattern of alternating bond lengths found in the *N*-heterocyclic ring [N–C2 1.474(5), C2–C3 1.517(5), C3–C4 1.357(5), C4–C5 1.434(6), C5–N 1.324(5) Å] and an essentially planar arrangement of the bonds to the nitrogen atom (sum of valence angles is 360.0°). The plane defined by the five-membered heterocycle bisects the angle between two neighboring carbonyltungsten groups, C3–C4–W–C41 –37.5 (4)°, and is arranged almost perpendicular to the phenyl group, C4–C5–C50–C51 97.6 (5)°.

Figure 1. Molecular structure of the mesoionic pyrrolium complex **3b**



The structure of the dihydropyrroles **4a**, **b** is based on the ^1J-, ^2J-, and $^3J(^{13}C,^1H)$ coupling constants in the NMR

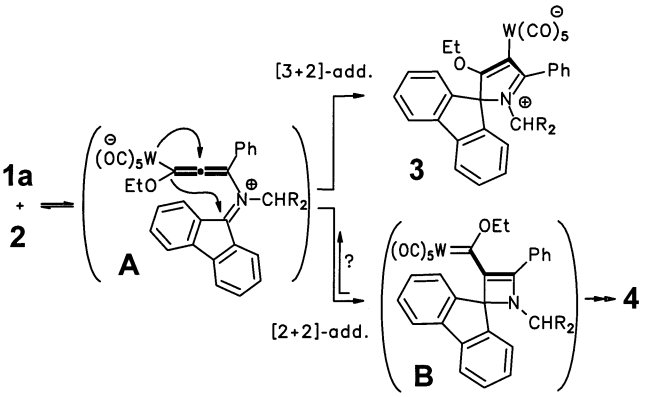
Reaction Course

Since there is ample precedence for reactions of (1-alkynyl)carbene complex $(CO)_5W{=}C(OEt)C{\equiv}CPh$ (**1a**) with nitrogen bases N (and also phosphanes) to form zwitterionic adducts $^{-}(OC)_5W{-}C(OEt){=}C{=}C(Ph)N^{+}$ as initial products,[14] it is suggested for the present case that an intermediate **A** might be generated from addition of an imine **2** to the (1-alkynyl)carbene complex **1a**. A zwitterionic species **A** might act as precursor to both a five-membered cycloadduct **3** and a four-membered dihydroazete derivative **B** (Scheme 4).

Scheme 4. Competing [3+2] and [2+2] cycloadditions of (1-alkynyl)carbene complex **1a** to the C=N bond of non-enolizable imines **2**



It is suggested that dihydroazetes **B** would be key intermediates en route to dihydropyrroles **4**. This assumption is supported by the fact that organometallic intermediates **6** and **7** could be isolated and characterized.

Organometallic Reaction Intermediates

Reaction of (1-alkynyl)carbene complex **1a** with fluorenone imines **2** at 20°C (instead of 90°C, as it has been applied for the reaction given in Scheme 2), affords two colored compounds **6** and **7**, which were isolated by column chromatography on silica gel (Scheme 5). It could be easily demonstrated that the azametallatriene unit of compounds **6** in solution undergoes a thermally induced ring closure to give dihydropyrroles **7**, from which finally pyrroles **4** and $W(CO)_6$ are obtained as the only products.

Scheme 5. Organometallic intermediates en route to dihydropyrroles **4**

	yield [%]		yield [%]

Cross-Conjugated Azametallatrienes 6

Since the signal of the W=C group in the ^{13}C-NMR spectra of compounds **6** (**6a**: δ = 321.8; **6b**: δ = 321.2) is observed in a range typical of non-conjugated (carbene)-tungsten complexes, e.g. $(CO)_5W{=}C(OEt)Me$ (δ = 319.6), little or no π-conjugation is expected within the W=C−C=C moiety. Furthermore, π-conjugation is not expected to be effective within the C=C−C=N group, since the *C*=N signal (**6a**: δ = 157.9; **6b**: δ = 157.8) appears in the normal range. Strong distortion from planarity of the W=C−C=C as well as of the C=C−C=N unit [W−C1−C2−C3 −109.0(3), N28−C21−C2−C3 −94.0(4)°] is confirmed by an X-ray structure analysis of compound **6a** (Figure 3, Table 3). It should be noted that the structural features of the M=C−C(=C)−C=N backbone in compound **6a** are unique and different from that of other cross-conjugated azametallatrienes, e.g. $(CO)_5W{=}C(OEt){-}C(=CHNC_4H_8){-}C(Ph){=}NPh$,[15] in which partial planarisation of the $(CO)_5W{=}C{-}C{=}C(N)$ portion of the ligand is achieved by π-electron delocalization. Rapid equilibration of diastereomers by rotation about the C1−C2 bond of **6a** is indicated by dynamic line-broadening of the ^{1}H-NMR signals of the diastereotopic OCH_2 group at 20°C.

Structural characterization of compound **7b** is based on NMR spectra. The sets of ^{13}C- and ^{1}H-NMR signals of dihydropyrrole **4b** and its pentacarbonyltungsten derivative **7b** are quite similar. Characteristic downfield shifts are observed for the signals *C*=N (**4b**: δ = 170.2; **7b**: δ = 179.2) and *C*−N (**4b**: δ = 77.1; **7b**: δ = 83.3).

Experimental Section

All operations were performed under argon. Dried solvents were used in all experiments. − Melting points are not corrected. − Instrumentation: ^{1}H- and ^{13}C-NMR spectra were obtained with Bruker WM 300, WP 360 and Varian U 600 spectrometers (multiplicities were determined by DEPT. Chemical shifts refer to δ_{TMS} = 0.00. ^{13}C shifts were assigned on the basis of ^1J(CH) and $^{2,3}J$(CH) correlation experiments). Low-temperature NMR measurements were carried out with Bruker AM 360 instrument. − Other analyses: IR Diglab FTS 45; MS Finnigan MAT 312; elemental analysis, Perkin-Elmer 240 elemental analyzer; TLC, Merck DC-Alufolien Kieselgel 60 F_{254}. R_f values refer to TLC tests. − Column-chromatographic purifications were made on Merck Kieselgel 100.

(Fluoren-9-ylidene)alkylamine (**2**) was obtained in high yields by condensation of 9-fluorenone (1.80 g, 10 mmol) with the corresponding amine (10 mmol) in 30 ml of pentane and 15 g of molecular sieves (Acros, 4 Å) at 20°C, 24 h, and were purified by distillation prior to use.

Pentacarbonyl[5-(2,2'-biphenylene)-4-ethoxy-1-isopropyl-2-phenyl-1-azoniacyclopenta-1,3-dien-3-yl]tungstate (**3a**), *3-Ethoxy-4-(fluoren-9-ylidene)-2,2-dimethyl-5-phenyl-3,4-dihydro-2H-pyrrole* (**4a**), *Pentacarbonyl[1-ethoxy-2-(fluoren-9-ylidene)-3-(isopropylimino)-3-phenylprop-1-ylidene]tungsten* (**6a**): To pentacarbonyl(1-ethoxy-3-phenyl-2-propyn-1-ylidene)tungsten (**1a**) (482 mg 1.00 mmol) in a 3-ml screw-top vessel is added (fluoren-9-ylidene)isopropylamine (**2a**) (221 mg, 1.00 mmol) in 3 ml of toluene. The mixture is shaken until homogeneity (ca. 3 min). After ca. 5 min at 20°C, a dark oil begins to precipitate which consists of compound **3a** and $W(CO)_6$. After compound **1a** is consumed completely (ca. 2 d at 20°C according to TLC), the supernatant is decanted and the solid washed with *n*-pentane (3 × 1 ml). The solution is separated by chromatography on silica gel. Elution with pentane/dichloromethane (2:1) affords a brown fraction with compound **6a** (R_f = 0.4 in pentane/dichloromethane, 2:1, 215 mg, 30%, brown crystals from pentane at −40°C, mp 102°C). Elution with diethyl ether affords a yellow fraction of compound **4a** (180 mg, 48%, R_f = 0.8 in diethyl ether, yellow crystals from cyclohexane/dichloromethane (4:1) at −78°C, mp 106°C). The solid residue of the reaction mixture (ca. 240 mg) is dissolved in dichloromethane (ca. 3 ml). $W(CO)_6$ is removed by crystalization at −15°C and compound **3a** is obtained from the mother liquor at 20°C after addition of pentane (2 ml) (ca. 78 mg, 11%, amber-colored crystals). If **1a** (52 mg, 0.11 mmol) and **2a** (22 mg, 0.10 mmol) in 1 ml of C_6D_6 are heated to 90°C for 2 h the ^{1}H-NMR spectrum of the solution shows signals of compounds **4a** and **3a** in a molar ratio of 8:1 as the only products. Removal of the solvent gives a residue of 39 mg, which corresponds to 82% of compound **4a** and 11% of compound **3a**.

3a: ^{1}H NMR (C_6D_6, 600 MHz): δ = 7.33, 7.26 and 7.18 (2:2:1 H; "d", "t", "t"; Ph), 7.30 (2 H, d, 4′-H and 5′-H), 7.10 (2 H, t, 3′-H and 6′-H), 7.05 (2 H, d, 1′-H and 8′-H), 6.95 (2 H, t, 2′-H

X-ray Crystal Structure Analysis of **6a**:[16] Formula $C_{32}H_{25}NO_6W$, M = 703.38, 0.30 × 0.30 × 0.10 mm, a = 9.962(2), b = 12.281(2), c = 12.929(2) Å, α = 88.20(1), β = 85.64(2), γ = 66.31(1)°, V = 1444.3(4) Å^3, $\rho_{calcd.}$ = 1.617 g cm^{-3}, μ = 40.43 cm^{-1}, empirical absorption correction with φ-scan data (0.788 ≤ C ≤ 0.999), Z = 2, triclinic, space group $P\bar{1}$ (No. 2), λ = 0.71073 Å, T = 293 K, ω/2θ scans, 6134 reflections collected (±h, ±k, +l), [(sinθ)/λ] = 0.62 Å^{-1}, 5861 independent and 5338 observed reflections [$I \geq 2\,\sigma(I)$], 375 refined parameters, R = 0.020, wR^2 = 0.052, max. residual electron density 1.02 (−0.90) e Å^{-3}, C18 refined as splitted atom, hydrogen atoms calculated and refined as riding atoms.[17]

Pentacarbonyl[5-(2,2′-biphenylene)-1-cyclohexyl-4-ethoxy-2-phenyl-1-azoniacyclopenta-1,3-dien-3-yl]tungstate (**3b**), *3-Ethoxy-4-(fluoren-9-ylidene)-2-pentamethylene-5-phenyl-3,4-dihydro-2H-pyrrole* (**4b**), *Pentacarbonyl[1-ethoxy-3-cyclohexylimino-2-(fluoren-9-ylidene)-3-phenylprop-1-ylidene]tungsten* (**6b**), *Pentacarbonyl[3-ethoxy-4-(fluoren-9-ylidene)-2-pentamethylene-5-phenyl-3,4-dihydro-2H-pyrrole]tungsten* (**7b**): To pentacarbonyl(1-ethoxy-3-phenyl-2-propyn-1-ylidene)tungsten (**1a**) (482 mg, 1.00 mmol) in a 3-ml screw-top vessel is added fluoren-9-ylidenecyclohexylamine (**2b**) (260 mg, 1.00 mmol) in 2.5 ml of pentane. The mixture is shaken until it becomes homogeneous. After ca. 1−2 h at 20°C, a dark precipitate begins to form consisting of compound **3b** and $W(CO)_6$. After ca. 2−3 d at 20°C (TLC), the reaction is almost complete. The supernatant is decanted and the solid residue washed with toluene (3 × 1 ml). Pentane and toluene extracts are combined, brought to dryness (20°C, 10 Torr) and separated by chromatography on silica gel with pentane/dichloromethane (2:1) to give successively a small amount of red compound **7b** (R_f = 0.6 in pentane/dichloromethane, 2:1, 30 mg, 4%), the brown compound **6b** (R_f = 0.4 in pentane/dichloromethane 2:1, 100 mg, 13%, brown crystals from pentane at −40°C). Elution with diethyl ether affords yellow product **4b** (131 mg, 35%, R_f = 0.3 in pentane/diethyl ether (10:1),

yellow crystals from toluene/pentane 1:1 at −15°C, mp 172°C). The solid residue of the reaction mixture (ca. 260 mg) is dissolved in dichloromethane (ca. 3 ml). $W(CO)_6$ is removed by crystalization at −15°C and compound **3b** is obtained from the mother liquor at 20°C after addition of pentane (2 ml) (ca. 150 mg, 20%, amber-colored crystals). If **1a** (52 mg, 0.11 mmol) and **2b** (26 mg, 0.10 mmol) in 1 ml of C_6D_6 are heated to 90°C for 2 h the ^{1}H-NMR spectrum of the solution shows signals of compounds **4b** and **3b** in a molar ratio of ca. 3.5:1 as the only detectable products. Removal of the solvent and of $W(CO)_6$ leaves a residue of 44 mg, which corresponds to 69% of the pyrrol derivative **4b** and 20% of compound **3b**.

3b: ^{1}H NMR (C_6D_6, 600 MHz): δ = 7.38, 7.30, and 7.22 (2:2:1 H; d, t, t; Ph), 7.36 (2 H, d, 4′-H and 5′-H), 6.99 (2 H, t, 3′-H and 6′-H), 7.15 (2 H, t, 2′-H and 7′-H), 7.10 (2 H, d, 1′-H and 8′-H), 3.30 and 0.70 (2:3 H; q and t, OCH_2CH_3), 2.50 (1 H, m, NCH); 0.98, 0.90, 0.80, 0.75, and 0.11 (2 H each, CH_2 cyclohexyl). − ^{13}C NMR (C_6D_6): δ = 204.8 and 201.0 [1:4, C_q each, *cis*- and *trans*-CO $W(CO)_5$], 197.3 (C_q, C2), 187.1 (C_q, C3), 142.1 (2 C_q, C8a′ and C9a′), 136.5 (2 C_q, C4a′ and C4aa′), 135.6 (C_q, *i*-C Ph), 134.3 (C_q, C4), 130.5 (2 CH, C2′ and C7′), 129.7 (*p*-CH Ph), 129.0 (2 CH, C3′ and C6′), 127.9 (2 *m*-CH Ph), 127.2 (2 *o*-CH Ph), 124.0 (2 CH, C1′ and C8′), 121.1 (2 CH, C4′ and C5′), 83.6 (C_q, C5 ≡ C9′), 65.2 (OCH_2), 59.6 (NCH); 32.9, 25.7, 24.2 (2:2:1, CH_2 each, cyclohexyl), 14.3 (OCH_2CH_3). − IR (diffuse reflection): $\tilde{\nu}$ [cm^{-1} (%)] = 2048.3 (30), 1975.1 (10), 1950.7 (20), 1895.3 (100), 1858.9 (80) [ν(C≡O)]. − MS (70 eV); *m/z* ^{184}W (%): 743 (1) [M^+], 687 (1) [M^+ − 2 CO], 659 (3) [M^+ − 3 CO], 603 (2) [M^+ − 5 CO], 391 (60), 308 (100). − $C_{35}H_{29}NO_6W$ (743.5): calcd. Keywords: Metal complexes / Organic conductors / Selenium / Magnetic properties

Novel metal complexes $(R_4N)[Ni(ddds)_2]$ (R = Me, Et and *n*Bu, ddds = 5,6-dihydro-1,4-dithiin-2,3-diselenolate) have been prepared and their crystal structures determined. The intraligand Se–Se distance is longer than that between the inner sulfur atoms of the five-member ring of the $M(dddt)_2^-$ sulfur analogue and is almost equal to the S–S distance in the six-member ring. Consequently, two-dimensional intermolecular close contacts are expected, and observed in $Ni(ddds)_2$ complexes. The neutral $Ni(ddds)_2$ species was obtained by electrochemical oxidation from the monoanionic $(nBu_4N)[Ni(ddds)_2]$ complex. X-Ray crystal structure analyses of this neutral species show that two $Ni(ddds)_2$ are connected by the two Ni–Se bonds. Thus, the $Ni(ddds)_2$ entities form $[Ni(ddds)_2]_2$ dimers which are arranged face-to-face and rotated by about 90° with respect to each other. The electrochemical behavior of $(nBu_4N)[Ni(ddds)_2]$ indicates the possible formation of cation-radical species. The room temperature magnetic susceptibility measurements showed that the $(R_4N)[Ni(ddds)_2]$ complexes are paramagnetic with μ_{eff} = 1.77–1.83 μ_B, corresponding to one unpaired electron per molecular formula. The temperature dependence of the magnetic susceptibility of $(Et_4N)[Ni(ddds)_2]$ is indicative of weak long-range antiferromagnetic ordering below 9 K. The dimerization in $[Ni(ddds)_2]_2$ results in a strong antiferromagnetic spin coupling within the dimer, and explain the non magnetic state observed for this compound.

Introduction

The development of new organic conductors has made great strides over the last two decades since the discovery in 1973 of the first synthetic metal, i.e., tetrathiafulvalene−tetracyano-*p*-quinodimethane(TTF·TCNQ).[1][2][3][4] Along this line, bis(ethylenedithio)tetrathiafulvalene (BEDT-TTF) has taken a leading role, and a large number of new organic superconductors have been derived from this molecule.[5] On the other hand, the study of transition-metal bis(dithiolene) complexes has an even longer history[6][7] than that of the TTF-based systems and has been an area of great interest because the salts of these complexes show various crystal structures and conducting properties depending on the nature of the central metal atom and counter ion, and the oxidation state.[8] These salts show a tendency to form one-dimensional structure and, consequently, most of those that exhibit high metal-like conductivity at ambient pressure become insulator at low temperature. However, no less than eight superconductors have been discovered within the series of $M(dmit)_2$-based complexes (dmit = 2-thioxo-1,3-dithiole-4,5-dithiolate), namely, $(TTF)[Ni(dmit)_2]_2$, α- and α′-$(TTF)[Pd(dmit)_2]_2$, $(Me_4N)[Ni(dmit)_2]_2$, β-$(Me_4N)[Pd(dmit)_2]_2$, $(Et_2Me_2N)[Pd(dmit)_2]_2$, α-(EDT-TTF)$[Ni(dmit)_2]_2$,[9] and, most recently, β′-$(Et_2Me_2P)[Pd(dmit)_2]_2$.[10]

Among the many chemical modifications of $M(dmit)_2$ systems subsequently studied, metal complexes of 5,6-dihydro-1,4-dithiin-2,3-dithiolate $[M(dddt)_2]$ were synthesized for the first time about ten years ago.[11][12] They have a planar structure remarkably similar to that of BEDT-TTF in which the central C=C bond of BEDT-TTF is substituted by a metal ion. The neutral $M(dddt)_2$ complexes (M = Ni, Pd, Pt, and Au) may be used as donor components in the preparation of partially-oxidized conducting cation-radical salts (as for BEDT-TTF), some of them exhibiting metallic temperature dependence down to low temperature.[13] In this context, the development of selenium analogue compounds of $M(dddt)_2$ has attracted our interest because the expected increase of the dimensionality resulting from enhanced transverse chalcogen−chalcogen interaction obtained through selenium substitution. This increase of the dimensionality is known to stabilize the metallic state by suppressing low-dimensional instabilities (such as the Peierls transition[14]) at low temperature. For example, such a strong stabilization of metallic state has been observed in salts derived from BETS (BETS = bis(ethylenedithio)tetraselenafulvalene),[15] the selenium ana-

logue of BEDT-TTF, and new BETS-based organic superconductors have been recently discovered.[16] Thus, selenium substitution has been applied to $Ni(dddt)_2$ compounds and we report herein on the synthesis, structure and physical properties of new selenium containing metal complexes $(R_4N)[Ni(ddds)_2]$ (ddds = 5,6-dihydro-1,4-dithiin-2,3-diselenolate; R = Me, Et, *n*Bu[17]) and of the neutral $[Ni(ddds)_2]_2$ complex.

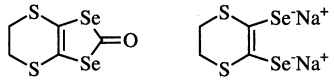
BEDT-TTF

Results and Discussion

The synthesis of tetraalkylammonium salts of $[Ni(ddds)_2]^-$ **1** was performed as follows: the disodium diselenolate ligand, $Na_2(ddds)$ **3**, was generated as a reddish orange solution by the hydrolytic cleavage of 4,5-ethylenedithio-1,3-diselenol-2-one **2** with 20% sodium ethoxide in dry THF at 0°C.[15b] Nickel complexes were obtained as the tetramethylammomium, tetraethylammonium and tetra-*n*-butylammonium salts, respectively, by successive treatment with an ethanol solution of nickel dichloride hexahydrate and the corresponding tetraalkylammonium bromide. The resulting precipitates were collected and washed with methanol and recrystallized in acetone or acetone/isopropanol (1:1) to afford dark green and air stable crystals. All the complexes were found by X-ray crystal analysis and elemental analysis to have a 1:1 cation/anion stoichiometry, indicating that the expected dianionic nickel complexes are easily air-oxidized to their monoanionic species in the course of preparation.



2 **3**

The neutral $Ni(ddds)_2$ species can be prepared by electrochemical oxidation of the monoanionic $(nBu_4N)[Ni(ddds)_2]$ complex in the presence of tetra-*n*-butylammonium perchlorate in acetonitrile. Needle-shaped black single crystals grew on the anode within about 2−3 weeks. In the course of research aiming at coupling $[Ni(ddds)_2]^-$ with nonlinear optical or magnetic cations,[18] the neutral $Ni(ddds)_2$ compound has been also unexpectedly obtained by electrochemical oxidation of $(nBu_4N)[Ni(ddds)_2]$ in the presence of (DAMP)I (4-dimethylamino-1-methylpyridinium iodide), $(HPMS)(PF_6)$ {4′-[2(hydroxymethyl)pyrrolidinyl]-1-methylstilbazolium hexafluorophosphate} and $[Cu(bpy)_2](PF_6)_2$ (bpy = 2,2′-bipyridine). In the last case, two apparently different phases (needles and blocks) of the neutral complex were obtained. Finally, the $Ni(ddds)_2$ neutral complex can be also obtained as black powder by chemical oxidation by iodine of $(nBu_4N)[Ni(ddds)_2]$. However, these powder material being extremely insoluble, the compound could not be recrystallized to obtain pure single crystal samples.

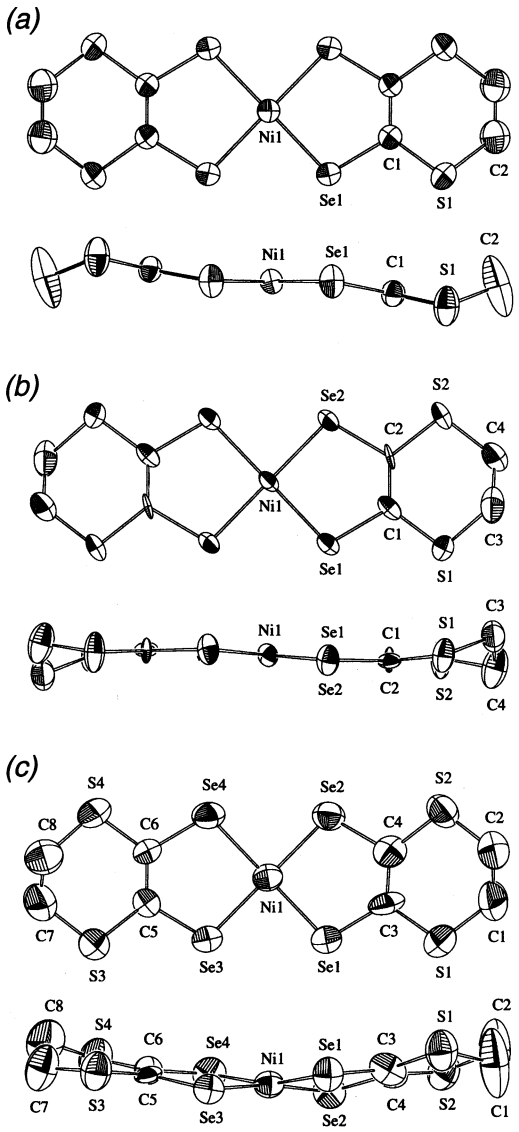
As previously reported,[17] the cyclic voltammogram of $(nBu_4N)[Ni(ddds)_2]$ shows two pairs of reversible redox waves corresponding to the $[Ni(ddds)_2]^{2-}/[Ni(ddds)_2]^-$ and $[Ni(ddds)_2]^-/[Ni(ddds)_2]$ couples. The potentials of the first and second waves (−0.60 V and +0.16 V vs Ag/AgCl, respectively) are about 0.1 V higher than those of the $(nBu_4N)[Ni(dddt)_2]$ sulfur analogue (−0.71 and +0.03 V[11][12]), suggesting that selenium substitution results in a decrease of the electron-donating ability. The redox potential of the $[Ni(ddds)_2]^{2-}/[Ni(ddds)_2]^-$ couple (−0.60 V) is very low, especially when compared to that of the corresponding $[Ni(dmit)_2]^{2-}/[Ni(dmit)_2]^-$ couple (−0.18 V[9a]) and this accounts for the spontaneous air-oxidation of the expected dianionic $(R_4N)_2[Ni(ddds)_2]$ salts observed during the synthesis. Moreover, the cyclic voltammogram of $(nBu_4N)[Ni(ddds)_2]$ also shows an irreversible oxidation wave at +0.71 V, reminiscent to that observed for (nBu_4N)-$[Ni(dddt)_2]$ (+0.99 V[11][12]), indicating the possible formation of cation-radical salts. Up to date, however, because of the low solubility of neutral $Ni(ddds)_2$, or the low stability of derived positively charged species, all attempts to grow crystals of such cation-radical salts failed.

Crystal structure analyses were performed for the monoanionic $(R_4N)[Ni(ddds)_2]$ and neutral $[Ni(ddds)_2]$ complexes. The crystal and experimental data are summarized in Table 4.

The molecular structure of the $[Ni(ddds)_2]^-$ anions and the atomic numbering schemes of the three studied $(R_4N)[Ni(ddds)_2]$ complexes are shown in Figure 1. Selected bond lengths and angles are gathered in Tables 1 and 2. Very similar bond lengths are observed in the three cases. The average C=C double bond length in the $[Ni(ddds)_2]^-$ anions, 1.357 Å, is almost the same as in $[Ni(dddt)_2]^-$ anions, 1.363 Å,[11a][11d][11c] indicating a similar electronic state. The mean Ni−Se distance in the $[Ni(ddds)_2]^-$ anion, 2.27 Å, is longer than that of the corresponding Ni−S distance in the $[Ni(dddt)_2]^-$ anion, 2.132(9) Å,[11c] but the difference of both values (0.14 Å) is in fact almost equal to that between the atomic covalent radius of sulfur and selenium. The intramolecular Se−Se distances, Se(1)−Se(2) = 3.268(3) and Se(3)−Se(4) = 3.267(3) Å, are longer than that between the corresponding sulfur atoms of the inner five-member ring of $[Ni(dddt)_2]^-$, 3.068(3) Å,[11a] and are closer to the S−S distances in the outer six-member ring, S(1)−S(2) = 3.451(8) and S(3)−S(4) = 3.461(7) Å. This suggests that the expansion of the electron clouds of the chalcogen atoms is nearly uniform towards the transverse direction over the whole $[Ni(ddds)_2]^-$ anion, which is in contrast with the case of $[Ni(dddt)_2]^-$ (see below).

The overall structural arrangements of the three monoanionic $(R_4N)[Ni(ddds)_2]$ complexes are also different

Figure 1. ORTEP drawings and atomic numbering schemes of the anion moieties (a) $(Me_4N)[Ni(ddds)_2]$, (b) $(Et_4N)[Ni(ddds)_2]$, and (c) $(nBu_4N)[Ni(ddds)_2]$



from those of the corresponding $R_4N[Ni(dddt)_2]$ (R = Me, Et, *n*Bu) sulfur analogues:[11a][11d][11c]

– $(Me_4N)[Ni(ddds)_2]$: One tetramethylammonium cation and one $[Ni(ddds)_2]^-$ anion are crystallographically independent. The Ni atom of $[Ni(ddds)_2]^-$ and the N(1) atom of the tetramethylammonium cation are located in the mirror plane (*ab* plane) and on the center of inversion. The C(4) atom of the tetramethylammonium cation is in the mirror *ab* plane. Therefore, the tetramethylammonium cation is octahedrally disordered. As shown in Figure 2a, the cations and anions are stacked alternately along the *b* axis and form a layered structure in the *ab* plane. Only the terminal ethylenedithio bridges are slightly overlapping each other. On the other hand, the $[Ni(ddds)_2]^-$ anions are arranged in a zigzag manner along the *c* axis and there is one short intermolecular Se(1)···S(1) contact [3.781(2) Å] between adjacent layers (Figure 2b). The $[Ni(ddds)_2]^-$ anion has a slightly chair-like structural arrangement with a dihedral angle of 11.01° and exhibits a completely planar coordination around the central nickel atom. The terminal C(2)–C(2)* bond length has a very short value, 1.34(2) Å, compared to the C–C single bond lengths (about 1.51 Å) usually observed in analog compounds.[11][12] The C(2) carbon atom has a large temperature factor [B_{eq} = 10.7(4)], indicating a conformational flexibility of the ethylene bridge.

– $(Et_4N)[Ni(ddds)_2]$: The Ni atom of $[Ni(ddds)_2]^-$ is located on the center of inversion and the $[Ni(ddds)_2]^-$ anion moiety is almost planar except for the slightly staggered ethylene bridge. The N(1) atom of the tetraethylammonium cation is also located on the center of inversion and two carbon atoms connected to the nitrogen atom are disordered on two positions [C(5) and C(9), C(8) and C(10)] with occupancy factor of 0.5. The anions form a one-dimensional array along the *a*-axis and there are several intermolecular Se···Se or Se···S contacts between the adjacent anions, indicating strong side-by-side interaction along the *a* axis (Figure 3a). On the other hand, each donor array is completely separated by a layer containing the tetraethylammonium cations and there is no interaction between the anion layers (Figure 3b).

– $(nBu_4N)[Ni(ddds)_2]$: The unit cell contains one crystallographically independent tetrabutylammonium cation and one $[Ni(ddds)_2]^-$ anion. Figure 4 shows the projection onto the *bc* plane. Neither a stacking, nor a columnar structural arrangement of the anions is observed. Only one S···S contact [3.542(10) Å] between anions is found (dotted lines in Figure 4). Each anion is surrounded by a counter tetrabu-

tylammonium cations. The nickel atom is coordinated to the four selenium atoms in a slightly distorted square planar geometry with a dihedral angle of 15.7° between the two five-member rings. This situation is different from that observed in the case of the other complexes with R = Me, Et, in which the coordination geometry around the nickel atom is strictly planar for symmetry reason. This is probably due to the steric hindrance of the bulky tetrabutylammonium cation. Each of the two chelating ligands is almost planar except for the ethylene bridge.

A stated above (see also Experimental Section), two, apparently different phases of the neutral $Ni(ddds)_2$ complex have been obtained, a needle-shaped one and a block-shaped one. The structures of these two phases have been independently determined and are in fact identical.[19] Two $Ni(ddds)_2$ units related by a center of inversion (symmetry

operation $1 - x$, $1 - y$, $2 - z$) are strongly dimerized and connected by the two Ni−Se(2) [2.496(1) Å] bonds to each other [the Ni(1)−Ni(1) distance is 3.178(2) Å]. Consequently, the neutral $Ni(ddds)_2$ complex should be more appropriately described as a dimer, $[Ni(ddds)_2]_2$ (Figure 5). The square coordination around nickel is distorted with a dihedral angle of 21.3°. Within each $Ni(ddds)_2$ entity of the dimer, the nickel atom is displaced by about 0.27 Å from the optimal plane of the four selenium atoms towards the axial selenium atom of the other $Ni(ddds)_2$ entity of the dimer. The large thermal ellipsoids of C(1), C(7) and C(8) and the small C(1)−C(2) and C(7)−C(8) distance indicate a conformational disorder of ethylene bridges. This disorder has been treated in the case of the block phase,[19] but no essential change in the description of the structure results from this treatment. The two ligand parts are heavily crooked and adopt a butterfly-wing shape conformation, probably caused by the steric hindrance introduced by the very short interplanar distance (2.84 Å for the $NiSe_4$ core of $Ni(ddds)_2$ entity). This structure is quite different from that reported for the neutral $Ni(dddt)_2$ analogue complex in which the $Ni(dddt)_2$ entities form uniform stacks and do not connect to each other[12], and rather resembles the dianion structure of $(Bu_4N)_2[Co(dddt)_2]_2$.[20] In $[Ni(ddds)_2]_2$, the $Ni(ddds)_2$ entities form real face-to-face dimers rotated by about 90° with respect to each other (Figure 6). This crystal structure is reminiscent of those reported for neutral BEDT-TTF,[21] or BETS,[15c], though in these compounds there are no actual chemical bonds between the two entities forming the so called "dimer". The $[Ni(ddds)_2]_2$ complexes are arranged side-by-side along the *a*-axis and produce a one-dimensional array. There are several Se(S)···Se(S) contacts between adjacent dimers as indicated by the dotted lines in Figure 7a. This is consistent with the value of the shape ratio *C* {0.98 for the $Ni(ddds)_2$ entity in $[Ni(ddds)_2]_2$} which had been proposed to evaluate the possible extent of the transversal intermolecular interaction in such chalcogen-based compounds.[15c] This $C = 0.98$ value is very close to that calculated for a rectangular shape ($C = 1$), which is predicted as the most favorable one for high intermolecular interaction.

The bond lengths of the ddds ligands in $[Ni(ddds)_2]_2$ are nearly identical, within standard deviations, to those observed for the monoanionic $(R_4N)[Ni(ddds)_2]$ complexes. Especially the C=C double bond length does not change upon oxidation to the neutral species. These results indicate that the decrease of electron density does not occur within the ddds ligands, but it is the central nickel atom which is oxidized. This oxidation of nickel may explain the formation of a pentahedral intradimer coordination bond and the $[Ni(ddds)_2]_2$ dimer structure. Such a situation is quite different from that observed for the $Ni(dddt)_2$ sulfur analogue system. It was inferred from Raman spectra of $Ni(dddt)_2$ that nickel could be unambiguously described as a d^8 ion and that the dddt ligands were involved in oxidation and reduction.[22] Thus, substitution of selenium for sulfur atoms in the dddt ligand seems to affect coordination of the ligand to nickel and change the electron configuration of the resulting neutral complex.

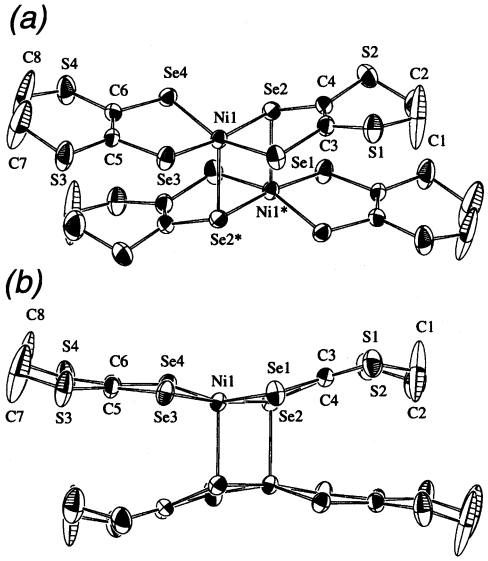

Figure 6. Crystal structure of neutral $[Ni(ddds)_2]_2$ projected onto the *bc*-plane

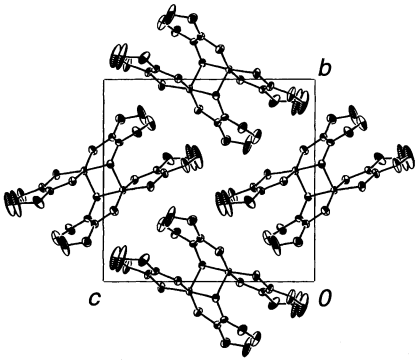

The room temperature magnetic susceptibilities of monoanionic $(R_4N)[Ni(ddds)_2]$ and neutral $[Ni(ddds)_2]_2$ complexes were measured by SQUID magnetometer at 1 Tesla. As shown in Table 3, all the monoanionic complexes show paramagnetism with $\mu_{eff} = 1.77 - 1.83\ \mu_B$ corresponding to one unpaired electron per molecular formula {1.73 μ_B for $s = 1/2$, $g = 2$ spins from the equation of $\mu_{eff}/\mu_B = g[s(s + 1)]^{1/2}$}. On the other hand, no magnetic moment was detected for the neutral $[Ni(ddds)_2]_2$ complex. This non-magnetic state can be explained by the stabilization of a singlet ground state in the $Ni(ddds)_2$ moiety, but more probably, as the X-ray results show that the $Ni(ddds)_2$ entities are structurally strongly dimerized in the neutral species, by a strong antiferromagnetic spin coupling within the dimer.

The temperature dependence of static magnetic susceptibility was measured for the monoanionic complexes. The tetramethylammonium salt showed a Curie-Weiss temperature dependence with a small positive Weiss temperature

Figure 7. Dimer array of neutral $[Ni(ddds)_2]_2$ (a) viewed along the molecular long axis and (b) projected onto the molecular plane. – The interdimer contacts are Se(1)–Se(4) (1 + *x*, *y*, *z*) = 3.993(1), Se(3)–S(4) (1 + *x*, *y*, *z*) = 3.663(3), Se(3)–Se(4) (1 + *x*, *y*, *z*) = 3.807(2), S(3)–S(4) (1 + *x*, *y*, *z*) = 3.639(4), and Se(2)–Se(4) (–*x*, 1 – *y*, 2 – *z*) = 3.897(2) A

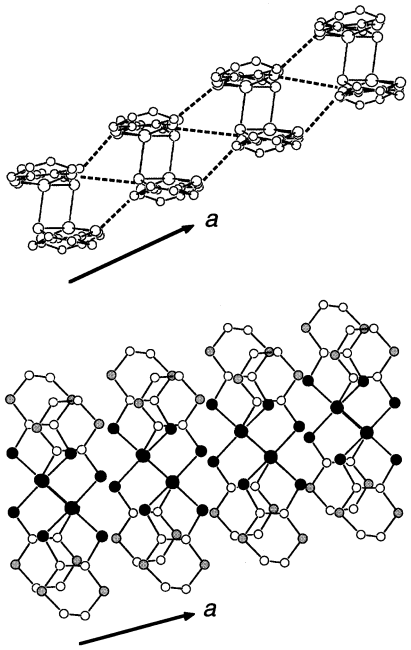

Table 3. Magnetic Properties of $(R_4N)[Ni(ddds)_2]$ at 1 Tesla.

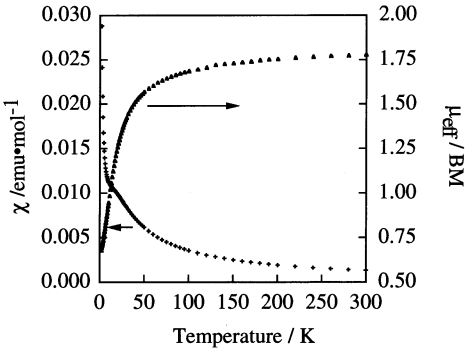
	Magnetic susceptibility/ μ_B at room temperature	Weiss temperature/ K[a]
$(Me_4N)[Ni(ddds)_2]$	1.81	+1.0
$(Et_4N)[Ni(ddds)_2]$	1.77	–18.0
$(nBu_4N)[Ni(ddds)_2]$	1.83	–4.0

[a] Weiss temperature was obtained from the Curie-Weiss law.

(θ = +1.0 K), indicating a slight short-range ferromagnetic interaction between anions. The tetrabutylammonium salt also obeyed a Curie-Weiss law, but the Weiss temperature is –4.0 K indicative of a weak antiferromagnetic interaction. However, both these salts did not show any phase transitions down to 2 K.

By contrast, the magnetic moment of the tetraethylammonium complex decreases as temperature decreases and a strong antiferromagnetic interaction is observed, as indicated by a large Weiss temperature of θ = –18 K in the high temperature region (Figure 8). Furthermore, the temperature dependence suddenly changes around 10 K, and below 9 K the magnetic susceptibility indicates a slight field dependence under magnetic fields below 100 Gauss, suggesting the occurrence of a weak long-range antiferromagnetic ordering. This phenomenon seems to be derived from the side-by-side strong interaction along the one-dimensional array of anions of $(Et_4N)[Ni(ddds)_2]$ (vide supra). A similar situation has been reported for the tetraethylammonium salt of $Ni(dddt)_2$.[11a]

Figure 8. Temperature dependence of magnetic susceptibility and magnetic moment of $(Et_4N)[Ni(ddds)_2]$ measured at 1 Tesla



Conclusions

The selenium substitution of inner sulfur atoms in $Ni(dddt)_2$ complexes was expected to increase the transverse intermolecular interaction and therefore to stabilize metallic state. Indeed, in the resulting $Ni(ddds)_2$ complexes studied in this work, the intraligand Se–Se distance is longer than that of the corresponding inner sulfur atoms in the $M(dddt)_2$ complexes and is almost equal to the S–S distance in the outer six-member ring. Thus, two-dimensional intermolecular close contacts were expected and observed in the $Ni(ddds)_2$ complexes. This intermolecular interaction accounts for the strong antiferromagnetic interaction and weak long-range antiferromagnetic ordering observed for $(Et_4N)[Ni(ddds)_2]$. The neutral $Ni(ddds)_2$ species was obtained by electrochemical oxidation from the monoanionic $(nBu_4N)[Ni(ddds)_2]$ complex. X-Ray crystal structure analyses revealed that in this neutral species intermolecular Ni–Se bonds are formed, resulting in a $[Ni(ddds)_2]_2$ dimer compound. Given the promising CV data indicating the possible formation of cation–radical salts, several attempts, using various electrochemical procedures, were made to prepare such cation–radical salts starting from the neutral $[Ni(ddds)_2]_2$ molecule, but they all failed. This is probably due to the low solubility of $[Ni(ddds)_2]_2$ in common solvents. However, changing the nature of the metal may alleviate this difficulty and we are now engaged in the preparation of other $M(ddds)_2$ complexes such as those with M = Au.

Experimental Section

General: Microanalyses were performed by the Organic Elemental Analysis Center, Department of Chemistry, School of Science, the University of Tokyo, and by the Microanalyses Service at the LCC-CNRS, Toulouse. – ^1H NMR: JEOL FT-NMR EX-270N (270 MHz for ^1H), [D_6]acetone as solvent, TMS as internal standard. – IR: PERKIN-ELMER FTIR-1600.

4,5-Ethylenedithio-1,3-diselenol-2-one was synthesized by literature methods.[15b] THF was distilled over sodium and benzophenone and acetonitrile was distilled over calcium hydride under

nitrogen and stored in the refrigerator until use. Tetra-*n*-butylammonium perchlorate was recrystallized from ethyl acetate, and dried in vacuo. All other reagents were used without purification.

Synthesis of (Me$_4$N)[Ni(ddds)$_2$]: 4,5-Ethylenedithio-1,3-diselenol-2-one (0.302 g; 1.00 mmol) was hydrolyzed with a 20% ethanol solution of sodium ethoxide (1.50 g; 4.40 mmol) in dry THF (10.0 ml), at 0°C and under nitrogen. The color of the solution changed from yellow to reddish-orange as the reaction proceeded. The solution was stirred for 2 hours and a reddish-pink precipitate formed. A solution of nickel(II) chloride hexahydrate (0.128 g; 0.538 mmol) in ethanol (30.0 ml) was added dropwise to the reaction mixture and the resulting solution was stirred for 2 hours at 0°C. The obtained dark brown solution was treated with a solution of tetramethylammonium bromide (0.172 g; 1.12 mmol) in ethanol (10.0 ml), for 1 hour at 0°C, and warmed to room temperature. The resulting dark green precipitate was collected by filtering, washed with methanol and recrystallized from acetone to afford 0.240 g (0.352 mmol) of air-stable needle-shaped dark green crystals in 71% yield. – $C_{12}H_{20}NNiS_4Se_4$ (681.08): calcd. C 21.16, H 2.96, N 2.06, S 18.83, Se 46.37; found C 21.30, H 2.85, N 2.17, S 18.56, Se 46.79. – $\tilde{\nu}$ (KBr) = 2904 cm^{-1}, 1472, 1397, 1278, 1164, 943, 678.

The other $(R_4N)[Ni(ddds)_2]$ complexes with R = Et and *n*Bu were obtained by a procedure similar to that described above for $(Me_4N)[Ni(ddds)_2]$:

Synthesis of (Et$_4$N)[Ni(ddds)$_2$]: Obtained from 4,5-ethylenedithio-1,3-diselenol-2-one (0.303 g; 1.00 mmol), a 20% ethanol solution of sodium ethoxide (1.47 g; 4.31 mmol), a solution of nickel (II) chloride hexahydrate (0.126 g; 0.531 mmol) in ethanol (20.0 ml) and a solution of tetraethylammonium bromide (0.219 g; 1.04 mmol) in ethanol (20.0 ml), as air-stable plate-shaped dark green crystals in 82% yield (0.301 g, 0.408 mmol) – $C_{16}H_{28}NNiS_4Se_4$ (737.18): calcd. C 26.07, H 3.83, N 1.90, S 17.40; found C 26.12, H 3.74, N 2.18, S 17.35. – $\tilde{\nu}$ (KBr) = 2968 cm^{-1}, 2912, 1474, 1398, 1280, 1172, 999, 870, 780.

*Synthesis of (n*Bu$_4$N)[Ni(ddds)$_2$]:* Obtained from 4,5-ethylenedithio-1,3-diselenol-2-one (0.308 g; 1.02 mmol), a 20% ethanol solution of sodium ethoxide (1.41 g; 4.13 mmol), a solution of nickel (II) chloride hexahydrate (0.120 g; 0.505 mmol) in ethanol (30.0 ml) and a solution of tetrabutylammonium bromide (0.172 g; 0.534 mmol) in ethanol (10.0 ml), as air-stable plate-shaped dark green crystals in 84% yield (0.362 g, 0.426 mmol). – $C_{24}H_{44}NNiS_4Se_4$ (849.40): calcd. C 33.94, H 5.22, N 1.65, S 15.10; found C 33.67, H 5.20, N 1.61, S 15.08. – $\tilde{\nu}$ (KBr) = 2954 cm^{-1}, 2923, 2866, 1408, 1377, 1282, 687, 682. – ^{1}H NMR δ = 3.39 (m, 8 H, SCH_2CH_2S), 1.87 (m, 8 H, NCH_2), 1.82 (m, 8 H, NCH$_2$CH_2), 1.50 (m, 8 H, NCH$_2$CH$_2$CH_2), 1.03 (m, 12 H, CH_3).

Electrochemical Synthesis of [Ni(ddds)$_2$]$_2$

Method A: (*n*Bu$_4$N)[Ni(ddds)$_2$] (10 mg) and tetra-*n*-butylammonium perchlorate (51 mg) were dissolved in 15 ml of acetonitrile under nitrogen. Electrochemical oxidation of this solution was carried out with a constant current of 1.0 μA at room temperature. Needle-shaped black single crystals grew on the anode within about 2–3 weeks.

Method B: A solution of (*n*Bu$_4$N)[Ni(ddds)$_2$] (15 mg) in acetonitrile (11 ml) was prepared under nitrogen and placed in the anodic compartment of a U-shaped electrochemical cell. A solution of $Cu(bpy)_2(PF_6)_2$ (14 mg) in acetonitrile was prepared under nitrogen and placed in the cathodic compartment of the cell. Electrochemical oxidation was carried out with a constant current of 0.25 μA at room temperature. Needle-shaped black and block-shaped black single crystals grew on the anode and on the low porosity glass frit between the anodic and cathodic compartments within about ten days.

In both cases, the obtained crystals were filtered, washed with ethanol, and air-dried at room temperature. – $C_{16}H_{16}Ni_2S_8Se_8$ (1213.86): calcd. C 15.83, H 1.35; found C 16.30, H 1.35. – $\tilde{\nu}$ (KBr) = 2945 cm^{-1}, 2906, 2866, 1365, 1324, 1272, 679, 668.

Electrochemical Measurements: Cyclic voltammetry data were obtained using a BAS 100B/W electrochemical workstation. The

measurements were performed at 20°C in benzonitrile containing 0.1 M tetra-*n*-butylammonium hexafluorophosphate as supporting electrolyte with platinum working- and counter-electrode, and a BAS RE-1B Ag/AgCl reference electrode (scan rate: 200 mV s^{-1}).

Magnetic Susceptibility Measurements: Magnetic susceptibility measurements of $(R_4N)[Ni(ddds)_2]$ (R = Me, Et, *n*Bu) and $[Ni(ddds)_2]_2$ were performed on Quantum Design MPMS2 and MPMS7 magnetometers in the temperature range from 2 K to 300 K. The samples were wrapped with a clean aluminum foil whose magnetic susceptibility was separately measured and subtracted. The diamagnetic contribution was calculated from the Pascal's constants.

X-Ray Crystallographic Studies: Data collection for the $(R_4N)[Ni(ddds)_2]$ and needle-shaped crystals of $[Ni(ddds)_2]_2$ was performed on a Rigaku AFC-5R diffractometer with graphite monochromated Mo-*Kα* radiation (λ = 0.71069 Å) and a rotating anode generator. Intensities were collected by the ω-2θ scan technique. Lorentz-polarization (Lp) correction and empirical absorption correction based on azimuthal scans of several reflections were applied. The experimental details and crystal data are listed in Table 4. The structure was solved by direct method (MULTAN88[23] for neutral $[Ni(ddds)_2]_2$ and SHELXS86[24] for other complexes). The atomic scattering factors were taken from the International Tables for X-ray Crystallography.[25] The non-hydrogen atoms were anisotropically refined by full-matrix least-squares method. Hydrogen atoms were included but not refined. All calculations were performed using the teXsan crystallographic software package of Molecular Structure Cooperation[26]. Data collection for the block-shaped crystals of $[Ni(ddds)_2]_2$ was performed on a STOE IPDS (imaging plate diffraction system) using monochromatic Mo-*Kα* radiation (λ = 0.71013 Å), The structure was solved by direct methods (SHELXS-86[24]). Crystal data are given in ref.[19]. Experimental details, atomic coordinates, bond lengths and angles can be found in the Supporting Information section. Crystallographic data (excluding structure factors) for the structures reported in this manuscript have been deposited with the Cambridge Crystallographic Data Centre. The deposition numbers are CCDC-101694, -101695, and -101696 for the $(R_4N)[Ni(ddds)_2]$ (R = Me, Et, *n*Bu) compounds, respectively, 101697 for the needle-shaped $[Ni(ddds)_2]_2$, and 101556 for the block-shaped $[Ni(ddds)_2]_2$. Copies of the data can be obtained free of charge on application to The Director, CCDC, 12 Union Road, GB-Cambridge CB12 1EZ [Fax: (internat.) + 44(0)1223/336−033, E-mail: deposit@ccdc.cam.ac.uk].

Keywords: *tripod* Molybdenum(CO)$_3$ compounds / Conformational ensembles in solution / Modelling NOE contacts / MM2* Force field calculations / Packing forces

NMR-NOE analysis of the three compounds (*RRS*/*SSR*)-$CH_3C(CH_2PPhBz)_3Mo(CO)_3$ (**1**), (*RRR*/*SSS*)-$CH_3C(CH_2PPhBz)_3Mo(CO)_3$ (**2**), and (*RRR*/*SSS*)-$CH_3C[CH_2P(m\text{-Xyl})Bz]_3Mo(CO)_3$ (**3**), leads to experimental values for a number of intramolecular H···H contacts in each case. By the very nature of the NOE method, and with the type of molecules studied here, these values have to be understood as a Boltzmann weighted average over all the conformations accessible to the molecules in solution. – A Boltzmann weighted force field approach is used to predict these values on the basis of sets of force field parameters derived earlier for this class of compounds. The agreement between observed and calculated NOE distances is highly satisfactory in each case (rms = 0.2 Å to 0.3 Å). By a statistical analysis it is shown that the predictions made by applying this Boltzmann weighted force field approach are highly significant. There is only a chance of 3 in 100 000 that this quality of prediction might be obtained by chance. This is taken as a validation, albeit indirect, of the energy scale reproduced by the force field parameters as developed. The methods described give a detailed insight into the conformational flexibility of molecules of the type studied. Solid state structures of the molecules are also correctly modelled by the force field used.

Introduction

When force field methods are used to predict possible structural arrangements of coordination compounds, the parameters describing the interactions involving the metal atom are generally deduced from solid-state structures of a series of similar compounds. An optimisation method based on Genetic Algorithms has been proposed as an unbiased method to derive such parameters from a set of solid-state molecular structures.[1] The success of this novel methodology has been demonstrated by correctly predicting general trends as well as specific conformations in the chemistry of *tripod*Mo(CO)$_3$ compounds [*tripod* = $CH_3C(CH_2X)(CH_2Y)(CH_2Z)$, X, Y, Z = PRR′]. It remains an open question as to whether force field approaches developed on the basis of solid-state molecular structures might have some bearing on the behaviour of molecules in solution. Since most reactions in coordination chemistry, including those mediating homogeneous catalysis, in fact take place in solution, this is a serious question. Only if it can be shown that the conformational properties of coordination compounds in solution are appropriately modelled by these methods, can these methods be of help to the preparative chemist in the design and optimisation of ligand-metal-templates with predefined properties. In order to address this problem, information about the conformational behaviour of coordination compounds in solution is clearly necessary.

It has long been known that the Nuclear Overhauser Effect (NOE) allows the determination of H···H distances of molecules in solution.[2] The application of this type of distance measurement in solution has for decades been the preserve of the specialist. Only in recent years have NMR techniques, both methods and equipment, been developed to a state where this kind of measurement might even become a routine tool. Indeed, NMR analysis of protein structures[3] has made enormous progress in the last few years.[4]

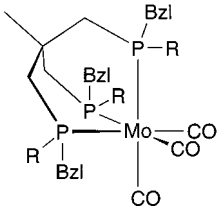
In the chemistry of small molecules including the subclass of coordination compounds considered here, NOE measurements are routine only in their qualitative form, i.e. to find out whether two protons in a given molecule are close together or far away from each other. In a quantitative way the method is not used too often in this context. One reason for this is evident: it is rather easy to obtain a crystal structure determination once a compound has been crystallised. A second reason is more intricate: the number of H···H distances accessible to NOE measurements in small molecules is generally too low to uniquely define a structure. There is kind of a paradox: if a molecule increases in size, the number of NOE distances increases and, even

 © WILEY-VCH Verlag GmbH, D-69451 Weinheim, 1998 1434–1948/98/1111–1641 $ 17.50+.50/0

though a larger molecule will have more degrees of freedom in conformational space, the increased number of measurable distances may well counterbalance this increase so that proteins with (depending on the kind and degree of labelling) 200 or more amino acids may be fully structurally characterised by this method, while simple structures such as the ones considered in this paper still pose severe problems. Nevertheless NOE data represent the most valuable and easy way to access information about an ensemble of conformations of molecules in solution.

It is the purpose of this paper to analyse the appropriateness of the force field description[1] of *tripod*$Mo(CO)_3$ compounds[5][6] by comparing the NOE distances measured for a specific molecule with those predicted by the straightforward application of the force field model. This type of analysis is performed for the three coordination compounds **1**−**3** (Figure 1).

Figure 1. Schematic representation of compounds **1** to **3**. The configuration at the phosphorus centers of the racemates to which the paper refers is indicated by the (*R*/*S*) nomenclature



1 R=C_6H_5 (RRS/SSR)
2 R=C_6H_5 (RRR/SSS)
3 R=3,5-xylyl (RRR/SSS)

Results

Compound 1

Three compounds of the type *tripod*$Mo(CO)_3$[5][6] (**1**−**3**, Figure 1) have been selected for this analysis in the hope that the number of short and hence detectable H···H contacts might be sufficient to warrant a detailed comparison of measured and calculated H···H distances. All three compounds are chiral and the NMR analysis has been performed on the racemate in each case. In addition, compounds **1** and **2** are diastereomers. It was expected that the reduced symmetry of **1** relative to **2**, together with the bulkiness of the substituents, would strongly differentiate the conformational behaviour of these two isomers so that a maximum of information would result from their analysis.

Compound **1** was a member of the data base used to derive the force field approach and its solid state structure[5] is neatly reproduced[1] by the force field as developed.[1] A projection of the structure of **1** as determined by X-ray analysis is given in Figure 2 (the plane of projection is defined by the three P atoms). The designators of the hydrogen atoms that are involved in NOE contacts, as shown in Figure 2, refer to the contacts given in Table 1.

The NOE distances elaborated for **1** in solution in CD_2Cl_2 at 275 K (see Experimental Section) do not fully agree with the distances observed in the crystal structure. This is not an unexpected result since **1**, especially given its benzylic constituents, is expected to have a high degree of flexibility (Figure 2).

Figure 2. Projection of the structure of **1** onto the plane defined by the phosphorus atoms of $CH_3C(CH_2PPhBzl)_3Mo(CO)_3$. The numbering scheme used throughout is indicated as is the configuration at the phosphorus centers for the (*RRS*) enantiomer of the racemic pair of **1** studied

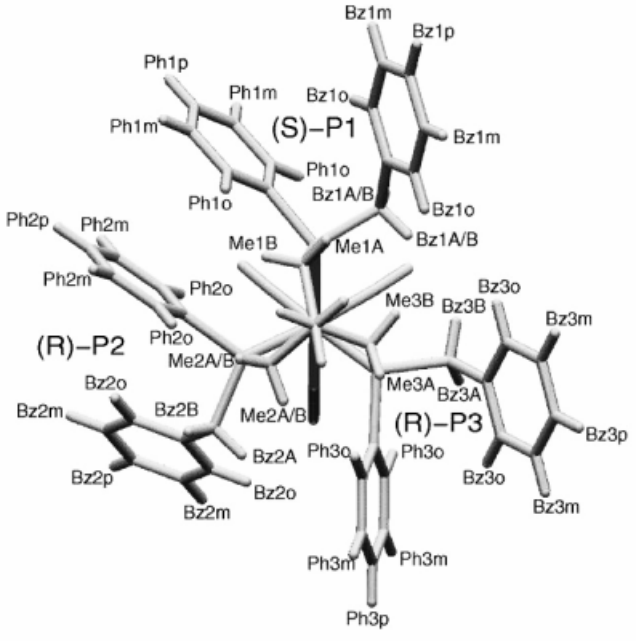


Table 1. Proton-proton distances in **1** as determined by NOE analysis (solution) and X-ray analysis (single crystal) in comparison with these distances as calculated from the force field approach

rms	[Å]	−	1.16	0.34	0.38

[a] *mm2f* and *mm2t* refer to different sets of force field parameters.[1] Column header $d_{Boltzmann}$ refers to the Boltzmann weighted average of the relevant distances in each case. − [b] rms deviation between the experimental NOE distances and the distances derived by the methods given in the respective column headers.

A flexible molecule like **1** might adopt a number of different conformations in solution and a distance extracted from NOE measurements is some kind of weighted average of all these individual distances between a specific pair of H atoms. Due to the fact that the NOE decreases with the inverse sixth power of the distance, there is an experimental limit to H···H contacts leading to NOE signals, which in the present analysis is around 3 Å. Even if only a narrow range of H···H contacts somewhere between 2 and 3 Å has been accessible by NMR for **1**, these distances are quite restrictive as far as the range of possible conformations is concerned. A number of different approaches have been used in the literature to transform the limited information available from a few NOE distances into structural models that are not excluded by the measurements.[7][8] All of these approaches use the constraints set by the measured NOE distances in one way or another to find acceptable conformations.[9]

A different approach is taken in the work described here. Be it assumed for the moment that a force field approach exists that correctly describes the energy hypersurface pertaining to a molecule, and that all the energy minima at this hypersurface are hence correctly placed in both position and in energy (relative to the energy of the global minimum). In this case the Boltzmann weighted average of the NOE-relevant geometric functions should reproduce the average of this function as observed. The function itself is, according to the physics of NOE, proportional to the inverse of the sixth power of the distance between a pair of hydrogen atoms. The NOE distances, as determined by measurement, thus present a criterion to evaluate and possibly validate a specific force field description.[10] Since molecules like **1**−**3** are still small enough for a complete and systematic search to be performed on the energy hypersurface defined by the force field they allow these lines of investigation to be followed.

To effectively scan all of the relevant conformational space[11] defined by the three rotations of phenyl groups (φ, Figure 3), the six rotational parameters describing the orientations of the benzyl groups (ψ, ω, Figure 3), and the three parameters describing the skew of the chelate cage (τ, Figure 3), the following simplifications were introduced to generate an appropriate set of starting conformations. The skew of the scaffolding was represented by just one torsion τ, thus effectively imposing C_3 symmetry on the torsional arrangement of this cage to start with. This simplification is well warranted given the observations made on 82 *tripod* metal compounds whose conformation had been statistically analysed[11] as well as by the observations made on a sample of *tripod*$Mo(CO)_3$ compounds.[1] Of course this constraint imposed on the starting conformations does not exclude the fact that during the conformational search any type of deviation from this C_3 symmetry will occur. The conformational space that has to be analysed is 10-dimensional, i.e. 3 × PPh- (φ) plus 6 × PBzl-rotations (ψ, ω) plus 1 cage twist (τ). A complete grid search was performed. The resolution for producing the starting conformations was defined by any combination of the values of the torsion angles τ, φ, ψ and ω (Figure 3) as given in Table 2. This leads to 11 664 (= $2{\cdot}3^3{\cdot}3^3{\cdot}2^3$) starting geometries.

Figure 3. Schematic drawing corresponding to Figure 2 with the definition of the conformational variables φ, ψ, ω, and τ shown. The definition illustrated here is also adopted for **2** and **3**

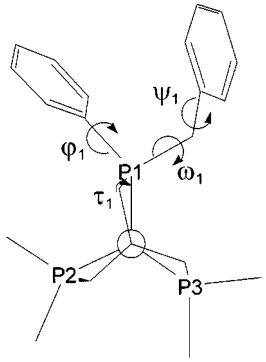

Table 2. Grid values for generating the starting geometries of **1**−**3**[a]

	τ [°]	φ [°]	ψ [°]	ω [°]	combinations	C_3 symmetric starting geometries
1	20 −20	60 0 −60	120 0 −120	90 0	11664	− 11664
2,**3**	20 −20	60 0 −60	120 0 −120	90 0	11664	2·3·3·2 = 36 3912

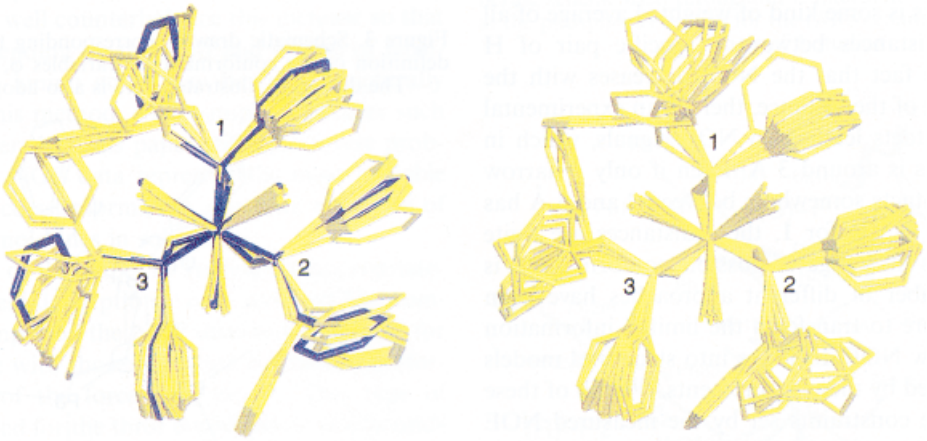
[a] There are 11 664 combinations in each case. Due to the constitutional C_3 symmetry of **2** and **3** the number of geometrically independent starting geometries is reduced to 3912 in these cases.

In a sterically crowded molecule like **1** this a priori setting of conformations may lead to unforeseeable entangling of the individual constituents of the molecule and so the *rubberband* protocol[12] was applied during refinement: the bonds radiating from the phosphorus atoms to the phenyl and benzyl groups were elongated to a distance of 4 Å initially, moving these groups away from the core of the molecule to begin with. During refinement these distances were then allowed to relax in a stepwise manner back to the normal. Entangling of the groups is elegantly[12] avoided by this procedure.

The starting conformations as defined were then allowed to adapt to the force field by an energy minimisation procedure. Depending on the force field implementation used, 191 (*mm2f*[1]) or 165 (*mm2t*[1]) conformations corresponding to local energy minima on the hypersurface were finally found. To illustrate the part of conformational space occupied by these conformations they were clustered according to the distance separating them in the 10-dimensional conformational space as defined by φ, ψ, ω, and τ. The lowest energy conformation in each cluster was used to represent its conformational characteristics. An overlay of these conformations is shown in Figure 4 arranged according to the sense of the torsion of the chelate cage.

It is evident that there is a smaller spread in the orientation of the phenyl groups as compared to that of the

Figure 4. Graphical representation of the section of conformational space occupied by the local minima on the *mm2f* hypersurface of **1**



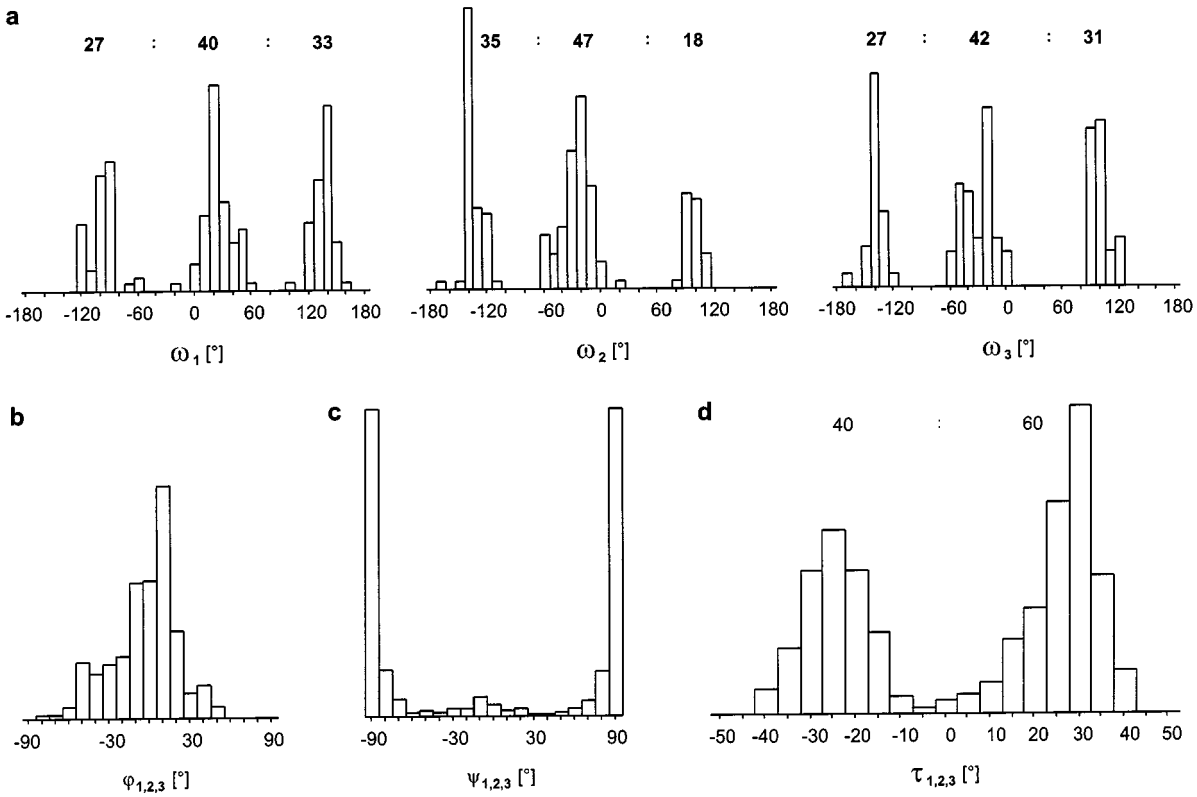
[a] The conformation adopted by **1** in the solid state is shown in blue. On the left hand side conformations with $\tau >= 0°$ are shown; the right hand side represents conformations with $\tau < 0°$. In order to make the diagram clearer the conformations were clustered with respect to their distance in conformational space so that each conformation shown represents the properties within each cluster. Note that the sense of numbering is opposite to the one given in Figure 2 due to the opposing directions of view taken in Figures 2 and 4.

benzyl residues. The conformation as determined by X-ray analysis is also indicated in Figure 4.

An alternative view of the diversity of possible orientations of the individual groups is presented by the histographic analyses of the φ-, ω-, ψ-, and τ-values adopted by the minimum energy conformations (Figure 5).

It is seen that the torsion around the P−C-bonds of the benzylic substituents ω basically conforms to the threefold rotational potential as expected. The different type of neighbourhood of benzyl group 2 in comparison to benzyl groups 1 and 3, i.e. benzyl group 2 having two phenyl neighbours (Figure 2) and benzyl groups 1 and 3 having one phenyl and one benzyl neighbour (Figure 2), is mirrored by a difference in the appearance of the corresponding histograms (compare the percentage values given in Figure 5). The histogram referring to the phenyl rotations φ (Figure

Figure 5. Histographic representation of the variance of the conformational parameters characterising the geometry of **1**

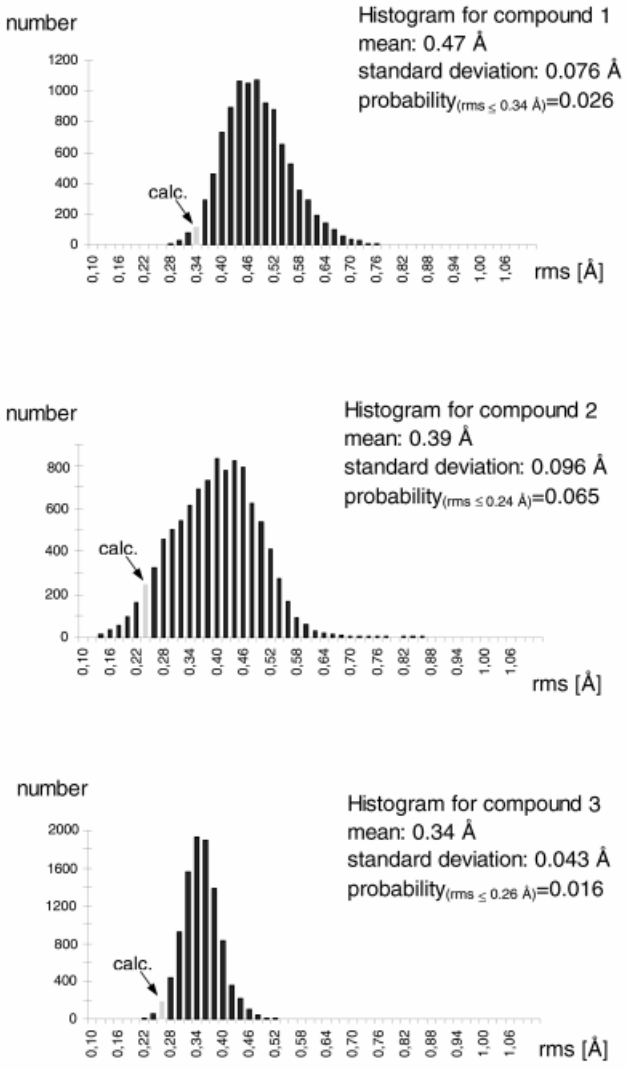


5) shows considerable spread while the histogram referring to the rotation ψ of the phenyl groups at the benzylic positions shows a marked preference at ±90°. The reason for this is that these phenyl groups are by and large outside the sterically crowded part of the molecule and can thus adopt the optimal orientation with respect to the neighbouring CH_2 groups, while the phosphorus-bound phenyl groups have to respond to the steric strain within the core of the molecule. As shown by the histogram, the space accessible to the torsion of the chelate cage (τ) is densely populated not only at the values of ±20° as set for the starting conformations but also at larger and smaller values. Since the analysis was done for the *RRS* enantiomer of the racemic pair **1**, the asymmetry in the distribution of τ values (Figure 5) is not at all unexpected (two (*R*)-configured PRR′ groups opposing only one (*S*)-configured group of this type).

The spread of the conformations, which correspond to local minima on the hypersurface as depicted in Figure 4 and Figure 5, makes no reference to their relative energy. The conformation as found in the crystal structure is at a computed energy of 5 kJ·mol^{-1} (*mm2f*) or 9 kJ·mol^{-1} (*mm2t*) above the global minimum, which differs from it by a 120° rotation around ω_2. As this amount of energy may easily be compensated for by the energy of the crystal lattice this result is not disturbing. With respect to the observation that the NOE distances are not consistent with the crystal structure, it is even a favourable observation. Indeed, none of the conformations, independent of their energy, is able to reproduce the observed NOE distances with an rms of less then 0.57 Å. If it is assumed that just two conformations would be sufficient to reproduce these distances, then all possible pairwise combinations of conformations should be analysed with their relative percentage of contribution being evaluated by a least squares procedure. By testing this hypothesis it was found that the best solution still has an rms deviation of 0.47 Å from the NOE distances. Analysing all possible combinations of three and even four conformations (combinatorial explosion does practically impede the analysis for higher multiples!) does not improve the agreement dramatically (3 conformations: rms = 0.43 Å; 4 conformations: rms = 0.43 Å). A favourable agreement between observed and calculated distances is, however, obtained when a Boltzmann weighted average (referring to d^{-6}) is taken over the complete set of minimum energy conformations. The rms deviation between observed and calculated average distances over all observable H···H pairs amounts to 0.34 Å for the *mm2f* force field and 0.38 Å for the *mm2t* approach (Table 1).

In order to develop a feeling for the relevance of this type of agreement and hence for the relevance of the Boltzmann weighting scheme employed, the following computer experiment was performed: for each conformation the relative energy was set at random in the range between 0.0 and 100 kJ/mol. This randomly generated energy was used to weight each conformation according to the Boltzmann scheme. The weighted average of the relevant distances was calculated and the calculated distances were compared with the measured ones so as to characterise each of these experiments by the corresponding rms value. This experiment was repeated with 10 000 sets of random weights generated in this way. The result of this computer experiment is shown in Figure 6 (**1**) in histographic form.

Figure 6. Computer experiments relevant to the significance of the approach used to predict NOE distances



[a] 10 000 computer experiments were performed in each case. All conformations corresponding to local minima on the *mm2f* hypersurfaces were taken into account. NOE distances were calculated as a Boltzmann type average over all these conformations with the Boltzmann weights set at random in each experiment. For each experiment the rms deviation between the observed and the calculated NOE distances was derived. The spread of these rms values is shown in the diagrams and it is seen that the agreement obtained when the weights are derived by the force field (calc) is rather good. It is highly improbable that this quality of agreement could be fortuitous. The probability of the hypothesis that the results represented by the bars designated with "calc" might be fortuitous is below 7% for each individual compound. The probability that the quality of fit obtained by the approach taken might be fortuitous for all three compounds is in fact less than 3 in 100 000.

It is clear that the 10 000 rms numbers thus generated are not at all exhaustive with respect to the number of possible combinations of conformations and the weights attributed to them. In principle, an exhaustive solution would only be obtained after an infinite number of experiments of this

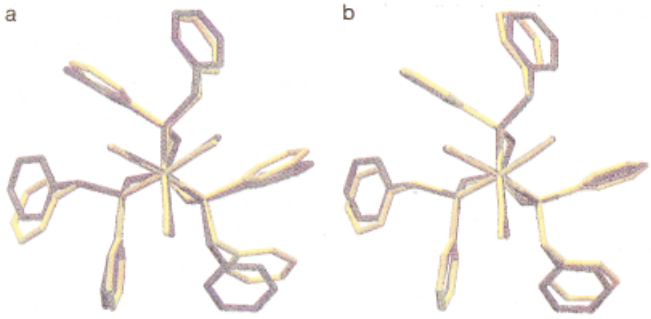
type; even if a discrete approximation were taken in order to allow as many different weights as there are conformations, the total number of combinations between conformations and weights would be $n!$ for a given number n of conformations! The histograms obtained will nevertheless approximate the distribution of possible solutions. It is observed that an rms value as good as that obtained by the Boltzmann weighting scheme as applied is highly unlikely to occur by chance. The probability of obtaining a solution with an rms value of 0.34 Å or lower by chance is only around 3% (Figure 6). The hypothesis that the quality of fit as obtained by using the energies derived from the force field in the Boltzmann weighting approach might be fortuitous may therefore be denied ata high level of significance.

The approach taken here to reproduce the observed NOE contacts by a force field approach was equally applied to compounds **2** and **3** (see below). The histograms reproducing the distribution of rms values as obtained from 10 000 computer experiments are also given in Figure 6. It is seen that the probability of obtaining the quality of fit (Figure 6, calc) derived from using the energies calculated by the force field approach fortitiously is less than 10 (**2**) and 5 (**3**) percent for these compounds. The probability of achieving the degree of approximation as obtained by applying the Boltzmann weighting scheme on the basis of the force field energies for all three compounds fortitiously is less than 3 in 100 000 as judged from the product of the probabilities given for each compound in Figure 6.

Compound 2

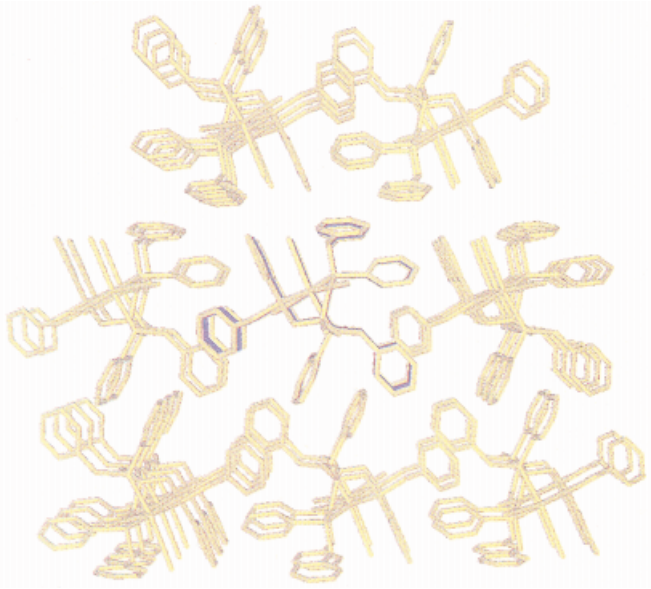
As indicated above the type of analysis as described for **1** was repeated with two additional compounds.The conformational space of **2** was defined by the same set of torsional parameters as already described for **1** (Figure 3). The grid spacing used to populate this space with starting conformations was numerically equal to the one used in the analysis of **1**. From the 11 664 starting conformations thus generated only a subset is symmetrically independent: those conformations that correspond to a C_3 symmetric arrangement occur only once each. The number of such conformations amounts to $2\cdot3\cdot3\cdot2 = 36$ in accordance with the number of values allowed for τ, φ, ω, and ψ. All the others will be represented at three symmetry related points in conformational space as three isoenergetic conformations. Each of these triplets corresponds to just one symmetrically independent conformation. The total number of independent conformations is thus $36 + (11664 - 36)/3 = 3912$ (Table 2). Force field refinement starting from these 3912 points in conformational space leads to 68 (*mm2f*) or 50 (*mm2t*) minimum energy conformations of which nine (*mm2f*) or eight (*mm2t*) have C_3-symmetry. Independent of the parameter set used (*mm2t, mm2f*), the conformation observed for **2** in the crystal closely corresponds to the global minimum in each case. This is a satisfactory result in that compound **2** had not been incorporated in the data base used to derive the force field approach.[1] There is some slight discrepancy between the calculated and the observed conformations as far as the precise orientation of two of the benzyl groups is concerned (Figure 7a).

Figure 7. Comparison of calculated (blue) and observed conformations of **2**; (a) free molecule; (b) molecule embedded in the crystal



Assuming that this discrepancy might be caused by the environment of **2** in the crystal, a force field refinement of the structure in its solid state environment was performed. Contributions from all the atoms that are at a maximum distance of 8 Å from any atom of the molecule to be refined were taken into account. The atoms in this crystal environment were held at fixed positions during refinement. A view of the crystal environment as generated by the nineteen neighbouring molecules that meet the above criterion is given in Figure 8.

Figure 8. Crystal environment of **2** (blue: specified molecule, yellow: crystal surrounding)

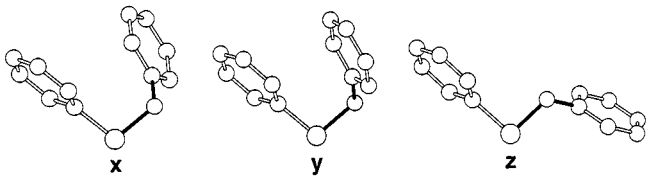


The result of this refinement is shown in Figure 7b (*mm2f*). The agreement between the calculated and the observed structures is significantly increased and the rms difference between the observed and the calculated structures decreases from 0.53 Å to 0.26 Å when the crystal environment is taken into account.

If the ensemble of conformations obtained by the minimisation process is systematically analysed, it is observed that the main difference between the individual confor-

mations may be traced back to the relative orientations that the benzyl groups occupy as characterised by ω. Three individually favourable conformations are possible for each such group, corresponding to the threefold potential governing this rotation (Figure 5). With reference to the coordination polyhedron, these three positions may be described in the following way: the benzyl group may point backward away from the carbonyl groups with its phenyl residue oriented such that it is close to the phenyl group that is directly bound to the phosphorus atom that supports both groups. Referring to Figure 9 this type of orientation is designated as **x**.

Figure 9. Relative orientation of the benzyl groups in **2** and letter codes used to specify them



[a] The plots refer to a plane of projection and direction of view as used in Figure 7.

On the other hand, the benzyl group still pointing backward may be oriented such that its phenyl residue is close to the phenyl residue sustended by the neighbouring phosphorus atom (**z**, Figure 9). A third type of orientation (designated as **y**, Figure 9) results when the benzyl group is oriented towards the side of the carbonyl ligands with its phenyl part close to the phenyl residue supported by the same phosphorus atom. It is observed that there is an energetic preference for the orientations termed **x**. The sequence of orientations **xxx** < **xxy**, **xxz** < **xyy** < **xyz**, **xzy** < **yyy**, **xzz** < **yyz** < **zzy** < **zzz** (e.g. **xxy**: ω_1 = **x**, ω_2 = **x**, ω_3 = **y**; **x**, **y**, **z**: Figure 9) is found by ranking the orientations according to the energy at which they are observed for the first time amongst the manifold obtained from the conformational search procedure. This energetic ordering is also apparent by the selection of conformations shown in Figure 10 where the relative energies of some prototypic conformations are indicated.

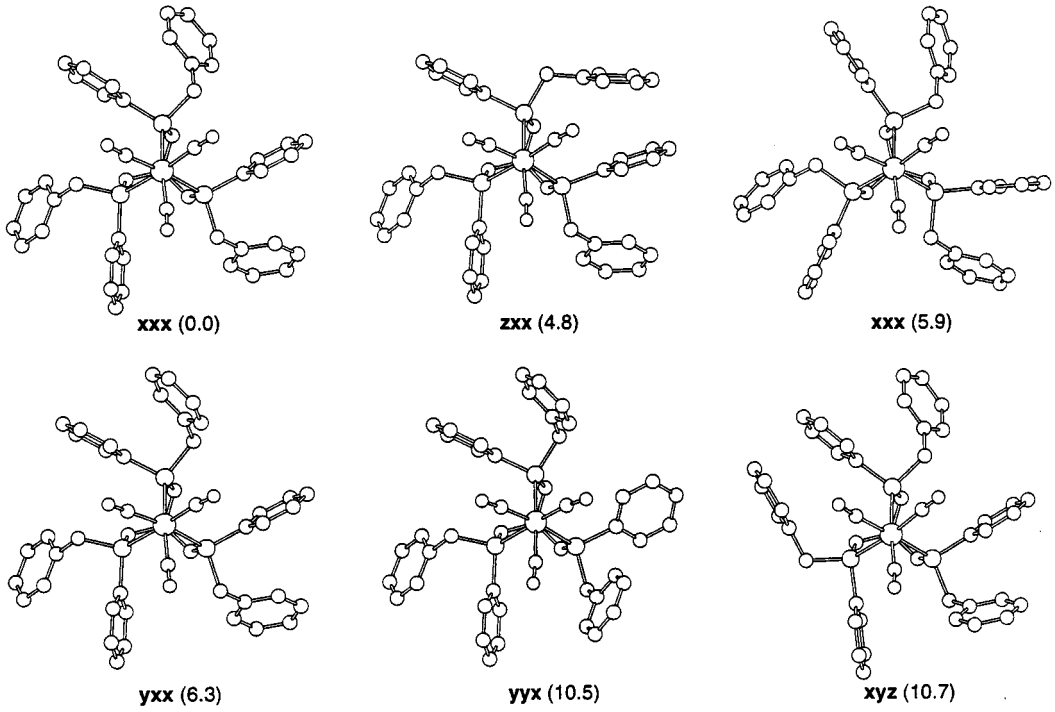
An NOE analysis of **2** resulted in a number of NOE distances (Table 3). The protons involved in these NOE contacts and the designators used for them are shown in Figure 11.

It is seen from Table 3 that the conformation as found in the crystal already reproduces the NOE distances with an rms of only 0.28 Å. It might therefore appear that the conformation adopted by **2** in solution is close to that observed in the crystal, which itself is very close to the conformation calculated as the global minimum (see above).

On the other hand, based on the assumption that the force field approach correctly reproduces the energy hypersurfaces, a Boltzmann weighted average of the relevant geometric parameters should give an unbiased estimate of the NOE distances. Application of this procedure to the 68 conformations corresponding to the 68 energy minima obtained (*mm2f*, see above) leads to an rms discrepancy between the observed and the calculated NOE distances of 0.24 Å. In summing up the individual terms, appropriate care was taken to correctly handle symmetry: while C_1 symmetric conformations will appear at three different points in conformational space, reflecting the constitutional symmetry of the problem, C_3 symmetric conformations will occur just once. For instance, if φ2, φ3, and φ5 [or ω1, ω2, and ω3 etc. (Figure 3)] each have different values, their cyclic permutation will project itself into conformational space onto three different points; if on the other hand the values for φ1, φ3, φ5 etc. are equal, any cyclic permutation will project itself onto one and the same point in this space. The weight accounting for C_3 symmetric conformations is therefore only one third of those showing C_1 symmetry. Application of the same procedure to the conformations obtained by the *mm2t* parameter set likewise gave an rms of 0.33 Å. The result obtained by considering just the minimal energy conformation (rms = 0.25 Å) and that obtained by a Boltzmann weighted average over all conformations are not significantly different (Figure 6, **2**). It is observed that other single conformations, as well as pairwise combinations of conformations, numerically give an even better agreement of 0.19 Å (*mm2f*, single conformation: E_{rel} above global minimum: 5.9 kJ·mol) and 0.13 Å [*mm2f*, 2 conformations: E_{rel} = 5.9 (64%) and 21.1 kJ·mol^{-1} (36%)] respectively. With respect to the computer experimental distribution of rms values (Figure 6) these results are not totally unexpected. There are obviously weighted combinations of conformations in each case analysed (Figure 6) that lead to an rms value lower than that obtained by using the relative energies as the weighting criterion (bars designated with "calc" in Figure 6). This Boltzmann weighted average, however, is an a priori prediction of what the NOE distances should be. These predictions are not left to chance but a definitive formula is used to make these predictions and it is seen from Figure 6 that, by using this predictor, reliable predictions are made for completely independent sets of experiments (**1**−**3**). With the predictor being based on sound physical grounds this result is especially satisfying and, by its very methodology, is far superior to any method involving a posteriori fitting of the weights of individual conformations to achieve optimal agreement.

A caveat is in place here: as shown in the histograms (Figure 6) and in the paragraph above, there are always weighted linear combinations of conformations that neatly reproduce the NOE values with rms values that are even below the ones obtained with the Boltzmann predictor (Figure 6), and there are even single conformations (see above) that meet this criterion. These conformations would, of course, be found as the appropriate solutions by applying a distance geometry approach[8] and would naturally be considered to be very important because of the excellent agreement. In the light of the Boltzmann predictor it appears that these solutions, even though numerically excellent, might well be far from reality. Only if the energy of the relevant conformations is appropriately taken into account, as in the case of the Boltzmann predicting scheme, will a somewhat more realistic view be gained. We feel that

Figure 10. Conformations of **2** ranked according to increasing energy



[a] From the complete set of minimum energy conformations as obtained by an exhaustive conformational search applying the parameter set *mm2f* those members are selected for which a specific arrangement (**x**, **y**, **z**, see Figure 8) of a benzyl group is first observed when scanning through these conformations in the direction of increasing energy.

the approach taken here, while taking away the simple and aesthetically appealing picture of just one dominating conformation, is perhaps more relevant in a physical sense.

Force field based approaches to evaluate NOE distances of conformationally flexible coordination compounds had of course already been used. In this context C. R. Landis has described a very thorough attempt to derive the conformational flexibility of a series of catalytically relevant rhodium complexes containing chiral biphosphines[12] as well as of other coordination compounds.[13] His use of the force field approach is, however, restricted to an a posteriori fit of observed NOE distances to weighted averages of force field derived conformations. These conformations are in turn obtained by clustering individual conformations to a tractable number of average conformations. It was observed, as it is in this paper, that linear combinations of the conformations may be found that neatly reproduce the observed NOE′s. In such an approach any information about the relative energies of the conformations is com-

pletely neglected. No attempt to incorporate these force field derived energies is made. In contrast, in the present paper an a priori prediction of the expected NOE distances is made using all the conformations as well as their energies as given by the force field. With the above caveat in mind the physical relevance of these two approaches might be quite different.

Compound 3

Having been made curious by the results obtained so far, a third molecule (**3**) was analysed by the same type of procedure. Compound **3** is an analogue of **2**: it is a chiral compound, the racemate of which has been analysed. The configuration at each of the three chiral phosphorus centers in **3** is the same (the situation is analogous to the one in **2**). The phenyl substituents at the phosphorus centers in **2** are replaced by 3,5-$Me_2C_6H_3$ residues in **3**. A complete conformational search applying the procedures as already described (see Table 2) reduced the set of 3912 starting conformations to 158 (*mm2f*) or 104 (*mm2t*) conformations corresponding to minimum energy positions on the hypersurface. The conformation of **3** as observed in the solid state is reproduced by these calculations as the global minimum with an rms difference of only 0.46 Å (*mm2f*). The parameter set mm2t gives an equally good agreement (rms = 0.46 Å). The difference between the two estimates (*mm2f* / *mm2t*) is only 0.09 Å.

If the NOE data are compared with the appropriate H···H distances characterising the global minimum conformation, an rms agreement of 0.27 Å is observed (Figure 12, Table 4).

rms	[Å]	–	0.27	0.24	0.34

A Boltzmann-weighted average taken over the whole conformational ensemble leads to rms values of 0.24 Å (*mm2f*) and 0.34 Å (*mm2t*). The hypothesis that it is the ensemble of conformations and not just the one global minimum conformation that gives rise to the observed NOE distances is therefore acceptable. The distribution of rms values given in Figure 6 (**3**) shows that the solution obtained by applying the Boltzmann weighting scheme (calc) has a high level of significance. It is interesting to note that in the case of **3**, in a similar way to the findings made for **2**, there are pairs of conformations that, irrespective of their relative energy, are able to reproduce the experimental findings when used in appropriately weighted combinations. The best pair of such combinations leads to an rms value of only 0.14 Å (*mm2f*) even though the relative energies of the two contributing conformations are computed well above the global minimum (conformation 1: 42%, E_{rel} = 0.0 kJ/mol; conformation 2: 58%, E_{rel} = 24.8 kJ/mol). The best single conformation still gives an rms of 0.24 Å (E_{rel} = 7.5 kJ/mol). This may again be taken as a warning against the application of a merely distance based search procedure that does not appropriately account for the energetic distribution. This warning of course applies to the analysis of highly flexible molecules that are neither thermodynamically nor kinetically trapped in just one single conformation. When this happens, as is usually observed for proteins, the dimensionality of the problem is reduced and a distance based approach will generally lead to one statically correct solution as soon as there are enough NOE data points available to uniquely define the topology.[4]

For flexible small molecules the approach taken here appears to be a more reliable one as compared to mere distance geometry calculations. However, a prerequisite for this approach to work is a force field approximation that reproduces the molecular conformations on an energy hypersurface that is not distorted too far from reality.

Assessment of the Force Fields

Two sets of parameters describing the interactions involving the molybdenum heavy atom were applied in the work described in this paper. Both of these sets had been derived by an optimisation procedure involving Genetic Algorithms[1] on the basis of a large number of solid state conformations. It had already been argued[1] that the parameter set *mm2t* which, as an extension of the *mm2f* set, includes a number of torsional parameters might not be too reliable in view of the insufficient variance of the data basis with respect to these variables.[1] It is now found that in the analysis of **1**−**3** there is a tendency (Tables 1, 3, 4) for the *mm2f* set to better reproduce the experiments. While the static structures, i.e. individual conformations, are closely equivalent when calculated with the two sets of parameters, the dynamic situation analysed in this paper is better reproduced by the *mm2f* parameter set. This means that the energy scales produced by the two sets are different and the one implied by *mm2f* is the more realistic one.

The quality of fit obtained in modelling NOE distances suggests that the relative energies according to which the conformations are sorted by the force field are somehow on scale to reality. Otherwise an agreement such as that observed would not be expected. A more rigorous validation of the statement that the force field correctly assigns relative energies would of course consist in directly comparing energy differences accessible to measurement with their force field derived counterparts. The result of such a test will be described in a forthcoming paper.

Conclusion

With the force field approach used minimum energy conformations are correctly reproduced. It is found that the solid state structures of **2** and **3** correspond to conformations at globally minimal energy. The rms deviation of observed (X-ray) and calculated structures is less than 0.5 Å in each case.

It is observed that the average distances as determined for molecules **1**−**3** by NOE techniques are well reproduced by the force field model. While it is always possible to find weighted linear combinations of conformations that will reproduce the NOE distances, and while even one single conformation irrespective of its energy might give a good fit to the NOE data by an a posteriori analysis, the method reported here makes use of an a priori predictor: a Boltzmann weighted average taken over all conformations that correspond to minima on the relevant hypersurfaces will predict NOE distances with a highly satisfactory agreement. By a statistical analysis of the results obtained it is shown that the agreement achieved is far better than might be expected if it were a chance result. In fact the quality of the results obtained by applying the Boltzmann weighting scheme is estimated to have a statistical probability of below 3 in 100 000, lending considerable significance to the predictor as applied. The fact that this is so is in favour of the statement that the force field approach as applied does correctly place the conformations in space as well as in energy on the molecular hypersurface. It is also evident, however, that more stringent analyses with a more direct experimental access to energy differences have to be performed in order to independently justify the use of the approach reported.

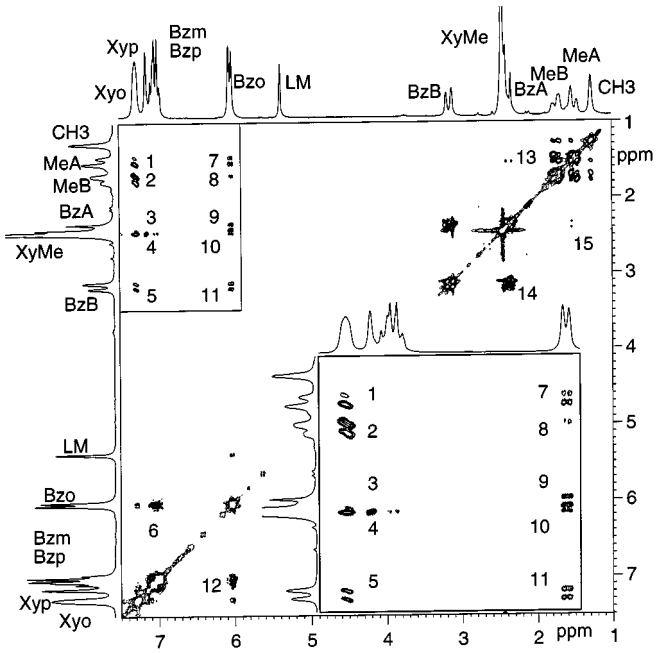
Experimental Section

NMR Analysis: Compounds **1**−**3** were obtained as previously described.[5][6] All measurements were carried out with a Bruker DPX200 (200.130 MHz, 50.323 MHz, and 81.014 MHz for ^{1}H, ^{13}C, and ^{31}P, respectively). For ^{1}H- and ^{13}C-NMR spectra CD_2Cl_2 was used as solvent ($\delta_H = 5.31$, $\delta_C = 53.8$), TMS as external standard, for ^{31}P NMR 85% H_3PO_4 ($\delta = 0$) as external standard. For NMR analysis almost completely saturated solutions of the compounds in CD_2Cl_2 sealed in nmr tubes under argon were used. Unequivocal assignment of all the ^{1}H, ^{13}C, and ^{31}P resonances was performed by a combination of 1D and 2D experiments[14] ({^{1}H-^{13}C}-HMQC,[15] {^{1}H-^{13}C}-HMBC,[16] DQF-COSY,[17] TOCSY[18]). Experimental conditions are listed in Table 5. Assignment and shifts of the ^{1}H-NMR signals of compounds **1**−**3** are given in Table 6.

Two dimensional NOE measurements[19] were performed for each compound at a number of different mixing times. As an example the spectrum obtained for **3** with a mixing time of 200 ms is shown in Figure 13.

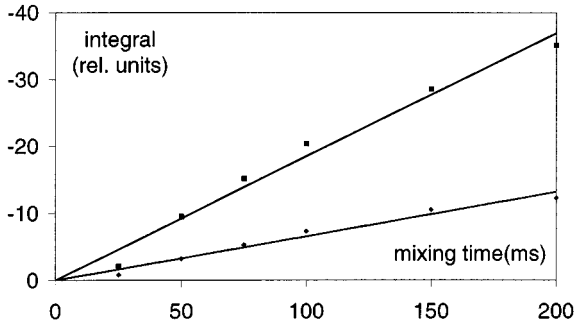
Figure 13. NOESY spectrum of **3** with 200 ms mixing time. The section referring to the arene protons is shown in the inlay in a magnified form. The numbers given in the diagram also refer to Table 7. Black: negative signals; grey: positive signals



In general, the two integral values[20] thus obtained for each correlation were found to be in good agreement. In some cases the value of the integral taken from below the main diagonal was found to be definitely smaller than the one taken from above it. This discrepancy is a systematic one and indicates that, in those cases

where it appeared, the relaxation time was insufficient to allow for a complete relaxation. This will always lead to integrals that are smaller than the maximum obtainable by one NOE effect and it is therefore good practice to take the above diagonal value as the more appropriate data. The initial slope of integral value versus mixing time was evaluated in each case. Correlation coefficients were generally better than 95% (Figure 14) but occasionally coefficients as low as 70% were obtained.

Figure 14. Evolution of NOE cross polarisation with mixing time. The Figure refers to **3** with the pairs Xyo-MeB (upper trace) and Xyo-MeA (lower trace) as two examples



were analysed by three different approaches and the results of these are given in Table 7.

In one approach all the slopes were transformed into distances using the Bzm-Bzo reference (Table 7, aromatic reference). Transformation of the same data using the BzA-BzB distance for all data led to a slightly different set of distances (Table 7, aliphatic reference). In yet another approach the reference distance taken from the arene protons was applied to contacts between aromatic protons. The CH_2 reference distance was applied to contacts between aliphatic protons. Distances between aliphatic and aromatic protons were evaluated by applying the mean between the constants derived from the arene and from the methylene references (Table 7, individual reference). The spread of distances thus calculated (Table 7) from three different systematic approaches is a kind of a measure of the systematic error introduced by the systematically different procedures of evaluation. It is seen that for individual distances the maximum deviation between the three estimates amounts to around 0.3 Å. The average deviation between the three estimates is only $\sigma = 0.1$ Å in the mean. This is in agreement with the estimate of the reliability of the NOE distances determined for **1**−**3** as inferred from the calculus of error propagation. By whatever means an estimate for the reliability of the NOE derived dis-

As far as the distances pertinent to the slopes in each case are concerned, this uncertainty is not dramatic because the physics of the NOE process are such that the distances are proportional to the sixth root of the slopes. Application of the laws of error propagation to the data sets obtained shows that the maximum error inferred from the uncertainty in the slopes is less than 0.1 Å in every case. Reference distances are needed in order to transform the values obtained for the slopes into estimates of proton-proton distances. There are up to three possible choices for such distances for the compounds **1**−**3**: as a standard tool of the absolute assessment of distances, the distance between two vicinal methylene protons at a CH_2 group is often used. This type of reference distance is available for all three compounds (CH_2 in the chelate cage, CH_2 of the benzyl groups, standard value: 1.75 Å). Another standard tool which is often used as an absolute reference is the distance between the protons at *o*- and *m*-positions of a six membered arene ring (accepted standard value: 2.45 Å). The data for compound **1** were evaluated using: Bz2A-Bz2B, Bz3A-Bz3B, Bz1o-Bz1m, Bz2o-Bz2m, Bz3o-Bz3m. The NOE distances of compound **2** were evaluated on the basis of the methylene distance BzA-BzB (Figure 11) as well as on the basis of the Bzo-Bzm distance.

For compound **3** the same type of two different reference distances was used. In order to develop a feel for the reliability of the distances obtained by the different ways of evaluation, the data tances is made, this estimate is around 0.1 Å on average. Since there is no a priori argument as to which of the three approaches applied to evaluate the data should be preferred, the mean of the three estimates[21] was considered throughout (Table 7, average) when experimental and modelled distances had to be compared. The data are thus good enough to allow for the assessment of the force field approach as described.

Force Field Calculations: The commercial program set MacroModel[22] was used for the calculations throughout. Starting conformations were generated using a program, written in C, for this purpose.[1] The torsion angles used to define these conformations have the following meanings (see Figure 3):

φ: torsion angle Du−P−C_{ipso}−C_{ortho} with the position of the Dummy atom Du generated and defined as given[1]

τ: torsion angle Mo−P−$C_{methylene(cage)}$−C

ω: torsion angle Du−P−$C_{methylene(benzyl)}$−C_{ipso}

ψ: torsion angle P−$C_{methylene(benzyl)}$−C_{ipso}−C_{ortho}.

To avoid entangling of individual groups in the starting conformations as well as during refinement, a rubberband protocol was used.[12] The P−C bonds radiating to the phenyl and benzyl substituents respectively were stretched to an initial value of 4 Å with the direction of these bonds unchanged. For the purpose of refine-

[a] The three $CH_2P(Ph)(Bzl)$ groups of **1** are chemically different. Refering to the designators given in Figure 2, data given in row "nucleus xyz" and column "group i" refer to proton xyiz, e.g. the data in the line MeA and the column "group 1" refer to the Me1A. For **2** and **3** these groups are chemically equivalent. – [b] Higher order multiplets, $^2J_{HH}$ coupling constants were determined by DQF-COSY experiments. – [c] The $^2J_{PH}$ coupling-value is given in square brackets. – [d] Higher order multiplets, see for example Bzm, Bzp, Figure 13. The NOE′s observed in this spectral range are by virtue of the geometry of the compounds (Figures 1, 11, 12) due to the dipolar interactions with the *meta*-protons in each case. – [e] Signals of individual groups overlap. – [f] The $^4J_{PH}$ coupling-value is given in square brackets. – [g] The value is given for the phenyl-protons Pho, Phm, or Php respectively; the xylyl-protons are marked by "xyz" in square brackets

[a] Crosspeak refers to the numbering scheme shown in Figure 12; the numbers refer to the numbers assigned to individual crosspeaks (Figure 13). Slope derived from measurements at different mixing times; the numbers in brackets refer to the standard deviation in terms of the least significant digit given in each case. Aromatic reference: The Bzm-Bzo distance (Figure 12) is used throughout. Aliphatic reference: The BzA-BzB distance (Figure 12) is used throughout. Individual reference: The reference distances BzA-BzB (aliphatic) and Bzm-Bzo (aromatic) are used where appropriate. For contacts between aromatic and aliphatic protons the mean between the two estimates is taken. The integrals of the crosspeaks were interpreted with reference to the mean of the two estimates. The numbers given in brackets for these three columns refer to the standard deviations inferred from the standard deviations of the slopes. Average designates the mean derived from the three values in the three columns at left; the numbers in brackets are the root mean square deviations from the mean.

ment these artificial restraints were reduced in a stepwise manner: reducing the distance after every hundred iterations to values of 3 Å, 2.5 Å, and 2.1 Å. The force constants referring to the artificially elongated bonds were set at 100.0, 175.18, 583.4, 1166.7 kJ/Å^2 mol in the sequence given. In the last step, now applying the original P–C equilibrium bond length and the original force constants using the *mm2f* / *mm2** force field (1166.7 kJ/mol = 2.91 mdyn/Å), refinement was performed without constraints (convergence criteria: maximum number of iterations = 99 999, convergence gradient: 0.01 Å/iteration).

The Polak Ribiere Conjugate Gradient algorithm was used for energy minimisation.[23]

In each case the refinement resulted in a largely reduced number of different conformations, each of which corresponding to at least a local minimum (for exact numbers: see text). Once all the conformations were known, the following procedure was applied: for each of the conformations the NOE relevant distances were extracted in the following way: whenever a pair of protons to which the NOE measurement refers could be uniquely assigned, the distances rel-

evant to such pairs were calculated. In those cases where the nmr experiments could not differentiate between constitutionally equivalent sets of protons, as for instance in the case of the conformationally diastereotopic pair of *ortho*-protons at a phenyl residue or, in some cases, for the configurationally diastereotopic protons at a methylene position, the shortest contact amongst the set of experimentally indiscernible contacts of this type was used. Whenever configurationally equivalent, but conformationally different groups were analysed, e.g. PBzPh in **2**, all the contacts relevant to these groups were calculated and again the shortest one was taken as the representative. This means that contacts involving the methyl groups of the 3,5-xylyl groups in **3** were extracted by calculating up to 72 individual distances. This number results from the fact that three methyl protons have to be considered for each individual methyl group; there are six such groups representing a total of 18 different methyl proton positions. If these protons are involved in contacts to *ortho*-hydrogens of the benzyl groups, two positions of these protons at the left hand side as well as on the right hand side are potential candidates thus multiplying the number of possible origins of the protons which may be at three different fixed positions, to a total of $18 \times 4 = 72$.

The diastereotopic protons at the CH_2 constituents of the chelate cages, as well as of the CH_2 phenyl substituents, had been uniquely assigned in the nmr experiments with the exception of the protons Bz1A/B (Figure 2) and Me2A/B (Figure 2) for compound **1**. Independent of this assignment, which had been possible in most cases, the analysis of contacts involving these groups was done without incorporating this specification. All possible combinations corresponding to a specific assignment referring to these groups were evaluated in each case. The quality of the assignment was judged by calculating a Boltzmann weighted average over all conformations with this specific assignment and comparing the predicted distances with the observed ones. For compounds **2** and **3** the assignment as originally deduced from nmr analysis was reproduced by this procedure. With compound **1** the situation is more difficult due to its low symmetry. The best fit was obtained with the assignment shown in Figure 2. To evaluate the sums of states a temperature of $T = 300$ K was used throughout in accordance with the measuring temperature of the NOE experiments.

In order to answer the question of how well the NOE distances might be reproduced on the basis of a combination of just a few conformations, a program was written to find the best linear combination of the weights with which these conformations will contribute. The constraint that the sum of the weights has to add up to one has been incorporated in terms of a Lagrangean multiplier.[24][25]

In order to optimise the structure of compound **2** in its crystal environment, the complete set of those 19 molecules in its neighbourhood was selected for which at least one contact to the given molecule is shorter than 8 Å (Figure 8). This environment was fixed to the coordinate values found in the crystal structure and the selected molecule that is embedded by this crystal surrounding was refined. The crystal environment was generated by using the appropriate feature in the MSI program package, refinement was performed by using MacroModel. The calculations were carried out on two Silicon Graphics Indigo^2 MIPS R4400 workstations, 200 MHz, 128 MB RAM, operating under IRIX 5.3.

[10] The underlying assumption is of course that the system is in its thermodynamic equilibrium. For the compounds studied this means that none of the rotations of either phenyl or benzyl groups is slowed down to such an extent that this assumption would not be valid. For the present case complete dynamic equilibration of the conformers is observed on the NMR time scale.

Keywords: Metalla-β-diketones / Platinum / Bis(acyl)-bridged complexes / Platinum blues / Metal–metal interactions

The platina-β-diketone $[Pt_2\{(COMe)_2H\}_2(\mu\text{-}Cl)_2]$ (**1**) reacts with aliphatic amines [nBuNH$_2$, (iPr)$_2$NH, NEt$_3$], N-methylaniline, and N,N-dimethylaniline, as well as with strong bases, such as a proton sponge or [NMe$_4$]OH, in an equimolar ratio to give the anionic platina-β-diketonato complexes of platina-β-diketones $[BH]_2[\{Cl_2Pt(\mu\text{-}COMe)_2Pt[(COMe)_2H]\}_2]$ (**3**) {B = nBuNH$_2$ (**3a**), (iPr)$_2$NH (**3b**), NEt$_3$ (**3c**), PhNHMe (**3d**), PhNMe$_2$ (**3e**), $C_{10}H_6(NMe_2)_2$ [1,8-bis(dimethylamino)naphthalene] (**3f**) and $[NMe_4]_2[\{Cl_2Pt(\mu\text{-}COMe)_2Pt[(COMe)_2H]\}_2]$ (**3g**)}. All complexes were characterized by microanalysis, and by ^{1}H-NMR and IR spectroscopy. X-ray structure analyses reveal that in the solid state the complexes **3a** · 0.5 CH_2Cl_2 and **3g** · 2 CH_2Cl_2 consist of tetranuclear dianions with zigzag Pt_4 chains [Pt–Pt–Pt angle: 122.92(3)° (**3a**), 119.30(6)° (**3g**)]. The central Pt···Pt distances [**3a**: 3.171(1) Å, **3g**: 3.176(1) Å] give evidence for closed shell d^8-d^8 interactions. Thus, these bis(acyl)-bridged complexes can be regarded as organometallic analogues of platinum blue complexes.

The dinuclear platina-β-diketone $[Pt_2\{(COMe)_2H\}_2(\mu\text{-}Cl)_2]$ (**1**), prepared by the reaction of hexachloroplatinic(IV) acid with silyl-substituted acetylenes in n-butanol, proved to be an electronically unsaturated complex with a kinetically labile ligand sphere[1]. When compared to Lukehart's mononuclear metalla-β-diketones $[L_xM\{(COR)_2H\}]$ (**A**)[2] (L = CO, Cp; M = Mo, W, Mn, Re, Fe, Os), which are electronically saturated and kinetically stable complexes, the complex **1** exhibits a fundamentally different reactivity. These complexes **A** were shown to react with primary amines to give the corresponding metalla-β-ketoimines **B**[3] [Scheme 1(i)] and, after deprotonation (**A′**), with metal salts to give the metalla-β-diketonato metal complexes **C** [Scheme 1(ii) and (iii)][4]. Recently, we reported that the platina-β-diketone **1** reacts with aniline or p-toluidine to yield platina-β-diketonato complexes of platina-β-diketones $[\{(RNH_2)ClPt(\mu\text{-}COMe)_2Pt[(COMe)_2H]\}_2]$ (R = Ph **2a**, pMeC$_6$H$_4$ **2b**) [Scheme 1(iv)][5]. These complexes are neutral complexes containing tetranuclear zigzag Pt_4 chains in the solid state.

Here we report on the reaction of the platina-β-diketone **1** with primary, secondary, and tertiary aliphatic amines, and with N-methyl- and N,N-dimethylaniline as well as with strong bases such as a proton sponge and [NMe$_4$]OH, to give anionic platina-β-diketonato complexes of platina-β-diketones.

Results and Discussion

Treatment of $[Pt_2\{(COMe)_2H\}_2(\mu\text{-}Cl)_2]$ (**1**) with one equiv. of n-butylamine (nBuNH$_2$), diisopropylamine [(iPr)$_2$NH], triethylamine (NEt$_3$), N-methylaniline (PhNHMe), N,N-dimethylaniline (PhNMe$_2$), or the proton sponge 1,8-bis(dimethylamino)naphthalene [$C_{10}H_6$-(NMe$_2$)$_2$] in dichloromethane at ambient temperature af-

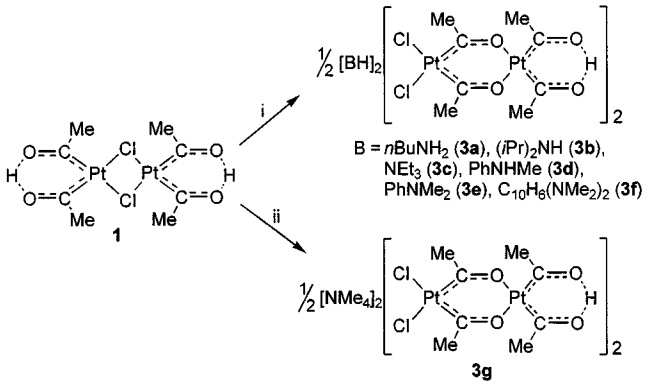
fords, in moderate to good yield (56−82%), the anionic platina-β-diketonato complexes of platina-β-diketones $[BH]_2[\{Cl_2Pt(\mu\text{-}COMe)_2Pt[(COMe)_2H]\}_2]$ [B = nBuNH$_2$ (**3a**), (iPr)$_2$NH (**3b**), NEt$_3$ (**3c**), PhNHMe (**3d**), PhNMe$_2$ (**3e**), $C_{10}H_6(NMe_2)_2$ (**3f**)] [Scheme 2(i)]. An analogous reaction carried out with tetramethylammonium hydroxide forms the complex $[NMe_4]_2[\{Cl_2Pt(\mu\text{-}COMe)_2Pt\text{-}[(COMe)_2H]\}_2]$ (**3g**) in a yield of 60% [Scheme 2(ii)]. No well defined products could be obtained with an excess of amines or [NMe$_4$]OH.

Scheme 2. (i) nBuNH$_2$, (iPr)$_2$NH, NEt$_3$, PhNHMe, PhNMe$_2$ or $C_{10}H_6(NMe_2)_2$ (1:1); (ii) [NMe$_4$]OH (1:1; − H$_2$O)

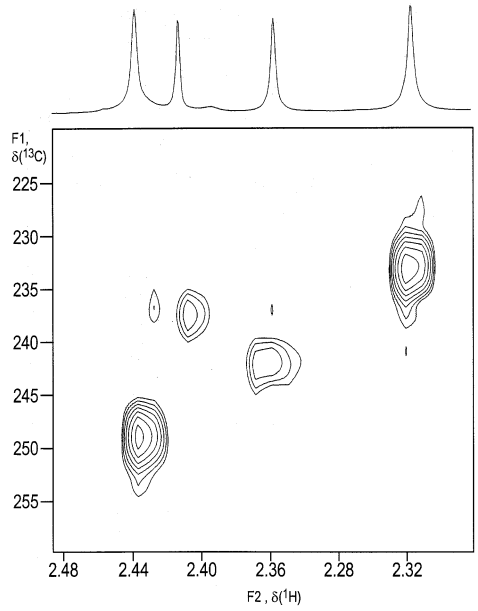


Complex **3a** was obtained as orange crystals and the complexes **3b**, **3c**, and **3f** were obtained as yellow, microcrystalline solids. The complexes **3d** and **3e** were isolated as orange rubberlike solids. After drying briefly, the complex **3g**·CH_2Cl_2 was obtained as orange crystals. All anionic platina-β-diketonato complexes of platina-β-diketones **3** are air-sensitive and decompose between 79 and 110°C. Thus, their thermal stability is similar to that of the neutral platina-β-diketonates of platina-β-diketones **2** [m.p. (dec) = 90−93°C][5], but smaller than that of the starting complex **1** [m.p. (dec) = 183 C][1]. In solution (CH_2Cl_2) complexes of **3** decompose at room temp. within less than 1 h, whereas at low temperatures (< −50°C) the solutions are stable over a period of one week.

Spectroscopic Investigations

At room temp. the ^{1}H-NMR spectra of the anionic complexes **3** show only one broad signal for the methyl protons ($\delta \approx 2.4$). With the exception of the complex **3d**, four methyl resonances are found at low temperatures (< −20°C). These methyl resonances form two pairs, the signals within each pair having the same intensity; and the ratio of intensities between the two pairs of signals being ca. 70:30 in all cases. Because all of the complexes are only slightly soluble in CD_2Cl_2 at −25°C, and due to the restricted thermal stability of these solutions, the carbonyl carbon atoms could not be detected by conventional ^{13}C-NMR spectroscopy. However, from the ^{1}H,^{13}C shift-correlation 2D-NMR spectra of **3g** via one (HMQC) and three bonds (HMBC), recorded at −25°C, the ^{13}C-chemical shifts of the four methyl groups and the corresponding four chemically inequivalent carbonyl carbon atoms (Figure 1) can be extracted and are found to be in in the range δ = 233.2−248.8.

Figure 1. HMBC spectrum of **3g** showing the range of the carbonyl carbon resonances



The temperature dependence of the ^{1}H-NMR spectra points to a dynamic process at room temp. and to the existence of two isomers at temperatures below −20°C. Taking into account the fact that the neutral complex **2b** is dinuclear in chloroform solution at room temp.[5], one isomer should be the dinuclear species **3′** (Scheme 3). **3′** could be in equilibrium with either the tetranuclear complex **3′′** (as was found in the solid state) or with the deprotonated starting complex **1′** (Scheme 3).

The proton resonances of the hydrogen-bonded hydrogen atoms in all anionic platina-β-diketonato complexes of platina-β-diketones **3** appear as a broad signal at $\delta \approx 20$, indicating a downfield shift of about 4 ppm with respect to the platina-β-diketone **1** ($\delta \approx 16$).

Two strong bands in the carbonyl region are found in the IR spectra of the complexes **3**: $\tilde{\nu}$ = 1524−1534 cm^{-1} for the bridging μ-acyl groups in the platina-β-diketonato unit and $\tilde{\nu}$ = 1552−1556 cm^{-1} for the platina-β-diketone unit. In the neutral complexes **2**, there were two bands observed at 1514 cm^{-1} and 1535 cm^{-1} for the bridging μ-acyl unit (the splitting is due to the unsymmetric coordination of the platinum centre) and one band at 1545 cm^{-1} (**2a**) and 1553 cm^{-1} (**2b**), for the platina-β-diketone unit. The C−O stretching vibration in the platina-β-diketone **1** also appears in this region ($\tilde{\nu}$ = 1548 cm^{-1}).

Crystal Structures

The crystal structures of **3a**·0.5 CH_2Cl_2 and **3g**·2 CH_2Cl_2 were obtained by X-ray diffraction analyses. The ORTEP diagram of the anion in **3g**·2 CH_2Cl_2 is shown in

Scheme 3. Possible isomers of the anion $[Cl_2Pt(\mu\text{-}COMe)_2Pt\{(COMe)_2H\}]^-$ (**3**) in solution

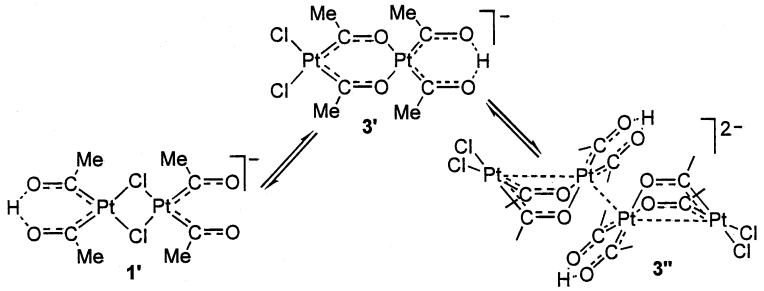


Figure 2. ORTEP-III plot[14] of the anion in **3g**·2 CH_2Cl_2[a], showing atom numbering (displacement ellipsoids at 30% probability); only the H atom in the hydrogen bridge is shown

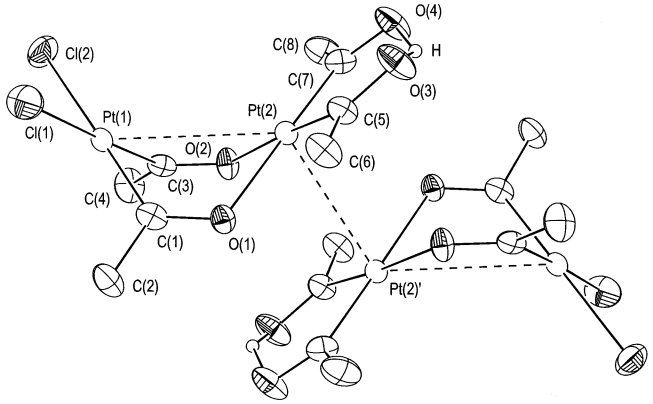

[a] Selected interatomic distances [Å] and angles [°]; values concerning **3a**·0.5 CH_2Cl_2 are given in square brackets: Pt(1)−Cl(1) 2.412(2) [2.417(4)], Pt(1)−Cl(2) 2.408(2) [2.424(4)], Pt(1)−C(1) 1.940(8) [1.91(1)], Pt(1)−C(3) 1.941(8) [1.96(1)], Pt(2)−C(5) 1.94(1) [1.90(2)], Pt(2)−C(7) 1.939(8) [1.93(1)], Pt(2)−O(1) 2.148(5) [2.139(7)], Pt(2)−O(2) 2.138(5) [2.129(8)], C(1)−O(1) 1.25(1) [1.26(1)], C(3)−O(2) 1.27(1) [1.26(2)], C(5)−O(3) 1.25(1) [1.27(2)], C(7)−O(4) 1.26(1) [1.25(2)], O(3)···O(4) 2.397(8) [2.40(2)], Pt(1)···Pt(2) 3.358(1) [3.336(1)], Pt(2)···Pt(2′) 3.176(1) [3.171(1)]; Pt(1)−Pt(2)−Pt(2′) 119.30(6) [122.92(3)], [Pt(1)Cl(1)Cl(2) C(1)C(3)]/[Pt(2)O(1)O(2)C(5)C(7)] 89.1(2) [89.6(3)].

Figure 2. The representation of the anion in **3a**·0.5 CH_2Cl_2 is not shown due to the close similarities to **3g**·2 CH_2Cl_2. Both complexes exhibit crystallographically imposed inversion symmetry. Bond lengths and bond angles of complexes **3a**·0.5 CH_2Cl_2 and **3g**·2 CH_2Cl_2 do not differ significantly. Minor differences were found in the Pt(1)···Pt(2) distance [**3a**: 3.336(1) Å, **3b**: 3.358(1) Å] and in the Pt(1)−Pt(2)−Pt(2′) angle [**3a**: 122.92(3)°, **3b**: 119.30(6)°].

Platinum is square-planar coordinated by two Cl and two C atoms, and by two O and two C atoms, respectively. The Pt−C bond lengths [1.90(1)−1.96(1) Å] and the C−O bond lengths [1.25(1)−1.27(2) Å] are in each case equivalent to within 3σ, and do not differ significantly from those in the platina-β-diketone **1** and in the neutral platina-β-diketonato complexes of platina-β-diketones **2** [d(Pt−C) = 1.95(1)−2.00(2) Å; d(C−O) = 1.21(3)−1.26(1) Å][1][5]. The Pt−O distances [2.129(8)−2.148(5) Å] and the Pt−Cl distances [2.408(2)−2.424(4) Å] are in the range of those observed in **2** [d(Pt−O) = 2.15(1)−2.18(1) Å; d(Pt−Cl) = 2.409(6)/2.390(4) Å]. The O···O distances in the intramolecular O···H···O bonds [**3a**: 2.40(2) Å, **3g**: 2.397(8) Å] are essentially the same as those in the complexes **1** and **2** [2.28(4)−2.37(2) Å].

As for the complexes **2**[5], complexes **3a**·0.5 CH_2Cl_2 and **3g**·2 CH_2Cl_2 are "head-to-head" dimers forming Pt_4 "zigzag" chains. Analogous Pt_4 units are found in platinum blue complexes that were first prepared (1908) by treating an aqueous solution of $[PtCl_2(MeCN)_2]$ with silver nitrate[6] and were structurally characterized (1977) as amidato bridged complexes especially by Lippard[7].

The conformations of the zigzag Pt_4 chains are very similar in all four complexes **2** and **3**. The Pt···Pt distances between the two central platinum atoms [**3a**: 3.171(1)/**3g**: 3.176(1) Å] indicate relatively strong closed shell d^8-d^8 interactions[8]. Similar values are observed in the "classical" platinum blue complexes with platinum in the average oxidation state of 2.0 [d(Pt···Pt) = 2.87−3.24 Å][9], and in platinum(II) complexes with columnar structures [d(Pt···Pt) = 3.09−3.60 Å][10].

In complexes **2** and **3** the coordination planes of Pt(1) and Pt(2) are inclined at angles of 76.4(4)°−89.6(4)°[11]. In the classical platinum blue complexes these angles are markedly smaller (18−40°)[7][9][12]. This may be due to the different numbers of bridging atoms (two in complexes **2** and **3** vs. three in the platinum blue complexes). In accordance with this, the Pt(1)−Pt(2)−Pt(2′) angles in complexes **2** and **3** are distinctly smaller than in the platinum blues [119.30(6)−127.52(3)° vs. 158−170°][7][9][12]. Furthermore, in all complexes **2** and **3,** the central Pt···Pt distances {mean value d[Pt(2)···Pt(2′)] = 3.171 Å} are shorter than the distances between the ligand-bridged platinum atoms {mean value d[Pt(1)···Pt(2)] = 3.284 Å}. The reverse order is observed in the classical platinum blue complexes[7][9][12].

The comparison made between the platina-β-diketonato complexes of platina-β-diketones **2** and **3** and the classical platinum blue complexes reveals many structural similarities. Thus, the bis(acyl)-bridged complexes **2** and **3** can be regarded as organometallic analogues of platinum blue complexes. The investigations show that stable organometallics with Pt_4 chains can appear as neutral complexes **2**[5] or as anionic complexes **3**. Investigations are in progress to synthesize analogous cationic complexes.

Financial support by the *Deutsche Forschungsgemeinschaft* and by the *Fonds der Chemischen Industrie*, as well as gifts of chemicals by the companies *Degussa* (Hanau) and *Merck* (Darmstadt), are gratefully acknowledged.

Experimental Section

All reactions were performed under an Ar atmosphere using standard Schlenk techniques. The solvents were dried and distilled prior to use. − IR: Galaxy Mattson 5000 FT-IR spectrometer using CsBr pellets. − NMR: Varian Gemini 200, VXR 400, and Unity 500 spectrometers. Chemical shifts are relative to C*H*DCl$_2$ (δ_H = 5.32), C*D*$_2$Cl$_2$ (δ_C = 53.8), C*H*Cl$_3$ (δ_H = 7.24), and C*D*Cl$_3$ (δ_C = 77.0) as internal references. − Microanalyses (C, H, N, Cl): University of Halle microanalytical laboratory using CHNS-932 (LECO) and Vario EL (elementar Analysensysteme) elemental analyzers. − The complex [Pt$_2${(COMe)$_2$H}$_2$(μ-Cl)$_2$] (**1**) was prepared according to the literature method[1]. Other chemicals were commercial materials used after distillation or without further purification.

General Procedure for the Synthesis of [BH]$_2$[{Cl$_2$Pt(μ-COMe)$_2$Pt[(COMe)$_2$H]}$_2$] (**3**): The amine [*n*BuNH$_2$; (*i*Pr)$_2$NH; NEt$_3$; PhNHMe; PhNMe$_2$; C$_{10}$H$_6$(NMe$_2$)$_2$] (0.32 mmol) was added to a stirred suspension of [Pt$_2${(COMe)$_2$H}$_2$(μ-Cl)$_2$] (**1**) (200 mg, 0.32 mmol) in dichloro methane (3 ml) at ambient temp., producing a yellow/orange solution within 1 min. Diethyl ether (5 ml) was added and a precipitate was formed within 2 d at −40°C which was filtered off, washed with diethyl ether, and dried briefly in vacuo.

(*B* = *nBuNH$_2$*) (**3a**): Orange crystals. − M.p. (dec) 84−86°C. − Yield: 169 mg (76%). − IR: $\tilde{\nu}$ = 1556 cm^{-1} (sh, CO), 1531 (s, CO), 274 (w, PtCl), 249 (w, PtCl). − ^{1}H NMR (293 K, CDCl$_3$): δ = 0.92 [t, 3 H, N(CH$_2$)$_3$C*H*$_3$], 1.42 [sext, 2 H, N(CH$_2$)$_2$C*H*$_2$], 1.77 (quin, 2 H, NCH$_2$C*H*$_2$), 2.36 [s(br), 6 H, COC*H*$_3$], 2.38 [s(br), 6 H, COC*H*$_3$], 3.10 (t, 2 H, NC*H*$_2$), 7.53 [s(br), 3 H, N*H*$_3$], ca 19.5 [s(br), 1 H, O*H*O]. − ^{1}H NMR (248 K, CDCl$_3$): δ = 0.92 [t, 3 H, N(CH$_2$)$_3$C*H*$_3$], 1.39 [sext, 2 H, N(CH$_2$)$_2$C*H*$_2$], 1.77 (quin, 2 H, NCH$_2$C*H*$_2$), 2.31 (s, 1.8 H, COC*H*$_3$), 2.33 (s, 4.2 H, COC*H*$_3$), 2.36 (s, 1.8 H, COC*H*$_3$), 2.46 (s, 4.2 H, COC*H*$_3$), 3.09 (sext, 2 H, NC*H*$_2$), 7.54 (s, 3 H, N*H*$_3$), 20.10 (s, 1 H, O*H*O). − C$_{12}$H$_{25}$Cl$_2$NO$_4$Pt$_2$ (708.40): calcd. Crystal Structure Determination of Complexes **3a**·0.5 CH$_2$Cl$_2$ *and* **3g**·2 CH$_2$Cl$_2$: Crystals were taken directly from the solution and selected under perfluoro ether. A suitable crystal was quickly mounted on a glass fiber. Intensity data were collected on a Stoe IPDS diffractometer with Mo-K_α radiation (0.71073 Å, graphite monochromator). A summary of the crystallographic data, the data collection parameters and the refinement parameters is given in Table 1. Absorption corrections were carried out numerically. The structures were solved by direct methods using *SHELXS*-86[13] and refined with full matrix least squares routines against F^2 using

SHELXL-93[13]. All non-H atoms were refined with anisotropic displacement parameters. As a result of disorder in **3a**·0.5 CH_2Cl_2 the two outer C atoms of the butyl group in the cation $[n\text{BuNH}_3]^+$ were refined isotropically. The H atoms were added to the model in their calculated positions and refined isotropically, except for the bridging H-atom in **3g**·2 CH_2Cl_2, which was found in the difference Fourier map.

Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited at the Cambridge Crystallographic Data Center as supplementary publication no. CCDC-101858 (**3a**·0.5 CH_2Cl_2) and no. CCDC-101859 (**3g**·2 CH_2Cl_2), respectively. Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge, CB2, 1EZ, UK [Fax: (internat.) + 44(0)1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

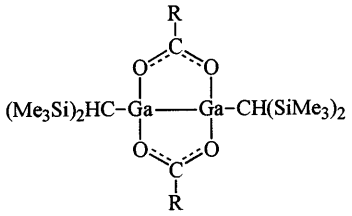
Keywords: Gallium / Low-valent compounds / Macrocycles

Tetrakis[bis(trimethylsilyl)methyl]digallane(4) **1** reacts with dicarboxylic acids like 1,4-benzenedi(methylcarboxylic) acid, 1,4-cyclohexanedicarboxylic acid, 1,6-hexanedicarboxylic acid, and 1,4-butanedicarboxylic acid (adipinic acid) by the release of two equivalents of bis(trimethylsilyl)methane and the retention of the Ga–Ga bond. Products are formed, in which the very short Ga–Ga bonds (237.7 pm on average) are bridged by two carboxylato groups. Two of these moieties are connected in each compound by two spacers (dimethylbenzene, cyclohexane, hexane, or butane) to form macrocyclic compounds with up to 22 atoms in the resultant heteroatomic rings. The dimeric form is also observed in solution. For comparison, the synthesis and structure of the product of the reaction of **1** with 1-adamantanecarboxylic acid is included, which also has the Ga–Ga bond (239.1 pm) bridged by two carboxylato groups.

Recently we published the reactions of tetrakis[bis(trimethylsilyl)methyl]digallane(4) **1**[1] with aromatic carboxylic acids. Remarkably, these reactions did not lead to the expected cleavage of the Ga−Ga bond of **1** as observed for the corresponding dialuminium or diindium derivatives[2], but two alkyl substituents were replaced by two carboxylato groups, and two equivalents of bis(trimethylsilyl)methane were released in an almost quantitative yield[3]. As shown in Scheme 1, the bidentate carboxylato ligands of the products occupy bridging positions across the Ga−Ga bond, which is significantly shortened to 238.5(2) pm compared with that of the starting compound **1** [254.1(1) pm][1]. In contrast, a terminal coordination of chelating diphenyltriazenido ligands was observed in a digallium compound obtained by the reaction of **1** with diphenyltriazene[4]. Also, the product of the reaction with dibenzoylmethane showed a terminal arrangement of the chelating groups[5], which have, however, two atoms more in the resulting heterocycle. The reason for the different coordination is not well understood; it may depend on the distance between the coordinating atoms (bite), and we hope to clarify this problem by the synthesis of some derivatives by systematically changing the size of the chelating groups. In this context, we report here on the structural characterization of the first example of a digallium compound with aliphatic carboxylato ligands in order to exclude an electronic influence of the aromatic groups on the coordination mode.

The reactions of **1** with carboxylic acids yielded the products almost quantitatively without any NMR spectroscopically detectable by-products[3]. Therefore, we were interested in the behavior of bifunctional dicarboxylic acids, which could give two different products: (i) The dicarboxylato ligand might be bound to only one digallium fragment in a chelating manner. But from molecular models it can be deduced that such an intramolecular coordination is not easy to achieve and requires long carbon chains to avoid considerable steric stress in the molecule. (ii) The dicarboxylato ligands could bridge two digallium units by an intermolecular coordination to form dimeric or oligomeric species. The oligomerization of the products would open an easy route to the synthesis of interesting new macrocyclic compounds. The reactions of some dicarboxylic acids with **1** and the complete characterization of the products is described in this article.

Scheme 1



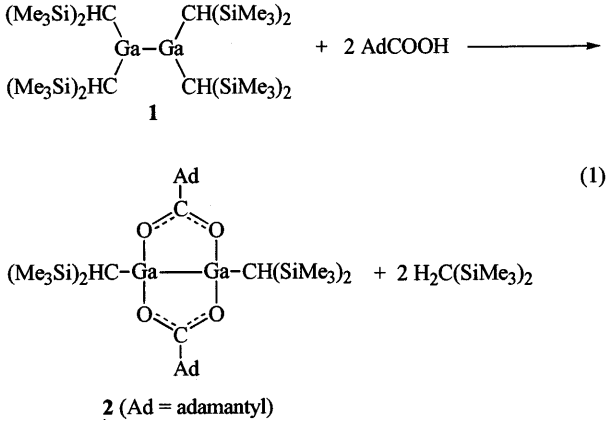
R = -4-Br-C_6H_4

Reaction of Digallane(4) 1 with 1-Adamantanecarboxylic Acid

Two equivalents of 1-adamantanecarboxylic acid reacted rapidly with **1** in *n*-pentane at low temperature, and the yellow color of the digallium(4) compound disappeared already at −15°C. As shown by a NMR spectrum of the reac-

 © WILEY-VCH Verlag GmbH, D-69451 Weinheim, 1998 1434−1948/98/1111−1661 $ 17.50+.50/0

tion mixture, exactly two equivalents of bis(trimethylsilyl)-methane were released per formula unit of **1** (Eq. 1). The colorless, crystalline product (**2**) was isolated after evaporation and recrystallization from pentane in a yield of 79%. Product **2** is readily soluble in hydrocarbons. It is a monomer in benzene solution, as shown by the cryoscopical molar mass determination. The NMR resonances of the methine hydrogen and carbon atoms of the $CH(SiMe_3)_2$ substituents bound to gallium (^1H: $\delta = -0.30$; ^{13}C: $\delta = 4.0$) show a significant high-field shift relative to those of the starting compound **1** (^1H: $\delta = 1.11$; ^{13}C: $\delta = 25.9$[1]), which is very characteristic of an enhancement of the coordination number of the Ga atoms from 3 to 4[3][4][5][6]. The stretching vibration of the CO_2 group with a delocalized electronic π bond is observed in the IR spectrum at 1530 cm^{-1}.

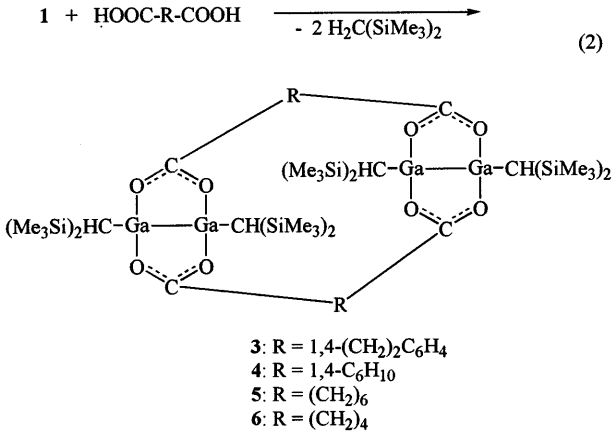


(1)

Reactions of 1 with Dicarboxylic Acids

The reactions of dicarboxylic acids with **1** were much slower than those with the monocarboxylic acids and required reaction times of several days in *n*-pentane at room temperature or some hours in boiling solvents. While, as expected, two equivalents of bis(trimethylsilyl)methane with respect to **1** were released in all reactions, only four acids reacted successfully to gave isolable products in high purity (Eq. 2): 1,4-benzenedi(methylcarboxylic) acid (product **3**), 1,4-cyclohexanedicarboxylic acid (product **4**), 1,6-hexanedicarboxylic acid (product **5**), and 1,4-butanedicarboxylic acid (adipinic acid) (product **6**). In contrast, other acids like maleic acid, 1,2- and 1,4-benzenedicarboxylic acid, 4,4′-oxydibenzoic acid and 2,2-dimethylpropane-1,3-dicarboxylic acid (glutaric acid) yielded only oily residues with mixtures of many unknown products, from which no compound could be isolated in a pure form. The products **3** to **6** were isolated after recrystallization in excellent yields of more than 80%.

The spectroscopic properties of the compounds **3** to **6** are very similar to those described above for **2** with the monocarboxylato ligand. The NMR resonances of the methine groups bound to gallium are shifted to high field (^1H: $\delta = -0.31$ to -0.47; ^{13}C: $\delta = 4.2$ to 4.5) relative to those of digallane(4) **1**, as expected for the enhancement of the coordination number at the Ga atoms to 4. The integration of



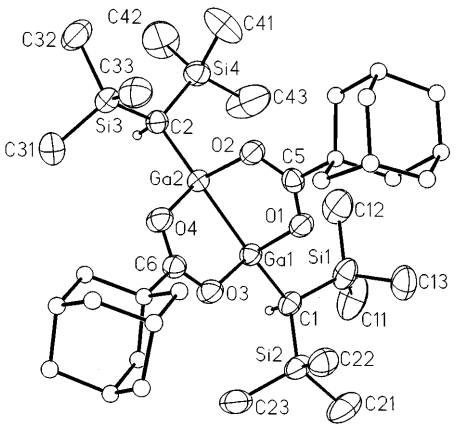
the ^1H-NMR spectra clearly reveals one dicarboxylato ligand each Ga_2R_2 formula unit. In the IR spectra of **3** to **6**, the most characteristic absorptions are those of the CO_2 stretching vibrations in a quite narrow range between 1539 and 1549 cm^{-1}. All products are dimeric in benzene solution as shown by the cryoscopical molar mass determination, so that compounds were formed, which contain two Ga_2R_2 moieties bridged by two dicarboxylato bridges.

Crystal Structures of 2, 3, and 4

The molecular structure of compound **2** is depicted in Figure 1. It is quite similar to the structure of the recently published *p*-bromobenzoate derivative[3] and has the Ga−Ga bond bridged by two adamantyl carboxylato groups. The Ga−Ga bond [239.1(1) pm] is shorter than that of the tetraalkyl compound **1** [254.1(1) pm][1], which may be caused by the carboxylato bridges with a short distance between the coordinating atoms of 223.2 pm on average. Both Ga−Ga distances lie within the broad range of known bond lengths between Ga atoms[7]. Two five-membered heterocycles are formed by the chelating coordination of the Ga−Ga bond, which are almost ideally planar and show a maximum deviation of an atom from the plane of 1.8 and 2.5 pm. Remarkably, these heterocycles arrange perpendicular to one another, and the angle between both chelating groups is 89.3°. The C−Ga−Ga−C center of the molecule is almost linear with large mean C−Ga−Ga angles of 158.7°. Thus, the coordination of the carboxylato groups seems to be based mainly on an interaction with two p orbitals of each Ga atom.

Compounds **3** and **4** contain macrocycles (Figures 2 and 3), and two digallium dicarboxylato units are bridged by hydrocarbon groups. The structure around the Ga−Ga bond of both molecules **3** and **4** is quite similar to that observed in compound **2**. Each Ga−Ga bond is bridged by two carboxylato groups, which results in short Ga−Ga bond lengths of 237.85 pm on average (**3**) and 237.46(4) pm (**4**). The C−Ga−Ga−C moieties are almost linear with C−Ga−Ga angles of 156.6° (**3**) and 155.8° (**4**). As in **2**, the Ga_2O_2C heterocycles are perpendicular to each other, and

Figure 1. Molecular structure and numbering scheme of compound **2**; the thermal ellipsoids are drawn at the 40% probability level; the carbon atoms of one of the disordered adamantyl groups are drawn with an arbitrary radius[a]



[a] Selected bond lengths [pm] and angles [°]: Ga1−Ga2 239.1(1), Ga1−O1 200.2(2), Ga1−O3 200.4(2), Ga1−C1 195.4(3), Ga2−O2 200.6(2), Ga2−O4 201.6(2), Ga2−C2 195.8(3), O1−Ga1−O3 91.1(1), O2−Ga2−O4 91.5(1), Ga2−Ga1−O1 87.67(8), Ga2−Ga1−O3 88.16(8), Ga1−Ga2−O2 87.80(8), Ga1−Ga2−O4 87.25(8), Ga2−Ga1−C1 158.4(1), Ga1−Ga2−C2 159.0(1).

the angles between the chelating ligands show values of 88.5° and 87.3° in **3** and 88.2° in **4**.

These digallium dicarboxylato groups are bridged by a dimethylbenzene group in compound **3** to form a macrocycle containing 22 atoms. The aromatic rings do not, however, adopt the parallel arrangement, which is often observed in phenyl compounds and is caused by weak interactions between the delocalized π electrons, but the rings are perpendicular to one another with an angle between the normals of the planes of 93.1°. The reason is the very long distance between the aromatic rings (C701−C711 583 pm) forced by the geometry of the coordination of the Ga atoms. This distance is much longer than detected or calculated for compounds with a bonding interaction between phenyl groups, in which the separation between the carbon atoms of the phenyl rings is below 400 pm[8]. As can be seen from Figure 2 a quite unsymmetric molecular structure results in the solid state with the Ga−Ga bonds not arranged parallel, but their vectors subtend an angle of 94.4°.

In contrast, **4**, which has bridging cyclohexane groups, is a highly symmetric compound (Figure 3). **4** is located on a crystallographic center of symmetry, and the Ga−Ga bonds adopt a parallel arrangement. The cyclohexane rings have a chair conformation, and one bond to a carbonyl group occupies an axial position (C5−C51), while the other one (C54−C6′) is in an equatorial position. From this conformation, an almost rectangular cage results in the center of the molecule.

The results described here clearly confirm that the reaction of digallane(4) **1** with dicarboxylic acids is a powerful method for the synthesis of large macrocycles. It is of particular interest now to synthesize corresponding macrocyclic compounds that contain heteroatoms like N or S and could possibly act as ligands for the complexation of cations.

Figure 2. Molecular structure and numbering scheme of compound **3**; the thermal ellipsoids are drawn at the 40% probability level; methyl groups are omitted for clarity[a]

We are grateful to the *Deutsche Forschungsgemeinschaft* and the *Fonds der Chemischen Industrie* for generous financial support.

Experimental Section

General: All procedures were carried out under purified argon in dried solvents (diisopropyl ether and toluene with Na/benzophenone, *n*-pentane with $LiAlH_4$). Compound **1** was synthesized as described in ref.[1], commercially available 1-adamantanecarboxylic acid, 1,4-benzenedi(methylcarboxylic) acid, and 1,4-butanedicarboxylic acid were sublimed in vacuo before use, and 1,6-hexanedicarboxylic acid and 1,4-cyclohexanedicarboxylic acid were used without further purification.

Reaction of **1** *with 1-Adamantanecarboxylic Acid, Synthesis of* **2**: Solid 1-adamantanecarboxylic acid (0.207 g, 1.15 mmol) was added

Reaction of **1** *with Ddicarboxylic Acids, General Procedure for the Syntheses of the Compounds* **3** *to* **6**: The solid dicarboxylic acids were added to a cooled (−50°C) solution of an equimolar quantity of yellow digallane(4) **1** (about 0.5 g) in 25 ml of *n*-pentane. The mixtures were warmed to room temperature and stirred for 2 d (**4**) or heated under reflux for 1.5 h (**5** and **6**) or 14 h (**3**). The color changed in each reaction from yellow to colorless. A small quantity of an unknown solid precipitated during the synthesis of **3**, which was filtered off. The filtrate was concentrated and cooled to −50°C to obtain colorless crystals of **3**. The other reaction mixtures were evaporated to dryness and thoroughly dried in vacuo to completely remove $CH_2(SiMe_3)_2$. The residues were recrystallized from different solvents (20/−30°C): **4** from toluene, **5** from diisopropyl ether and **6** from *n*-pentane.

Crystal Structure Determinations: Single crystals of the compounds **2**, **3**, and **4** were obtained by recrystallization from cyclopentane, diisopropyl ether, and toluene, respectively. Crystal data and structure refinement parameters are given in Table 1[11]. The adamantyl groups in **2** are rotationally disordered, and the carbon atoms with the exception of those attached to the carbonyl groups (C51 and C61) were refined in two positions with occupancy factors of 0.5. **4** is located on a crystallographic inversion center.

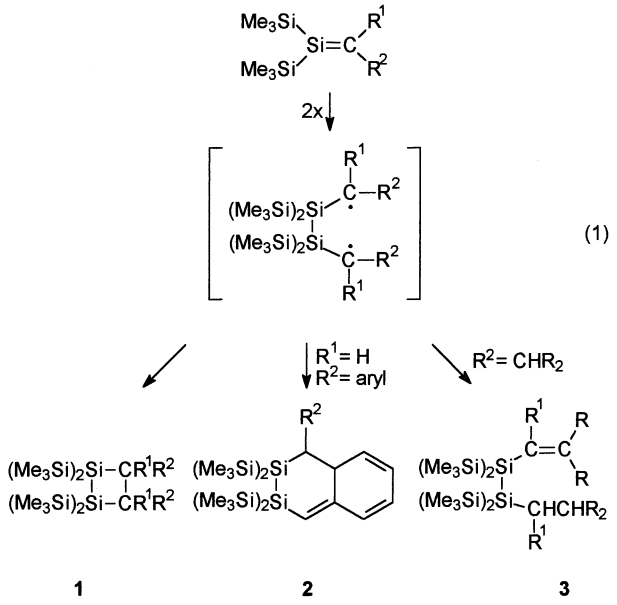
Received July 22, 1998

Keywords: Silicon / Silenes / 1,2-Disilacyclobutanes / 1,3-Disilacyclobutanes / Eliminations

The regiospecifity of the dimerization of the transient 2-(2-methoxyphenyl)-1,1-bis(trimethylsilyl)silene (**6**), synthesized by base-initiated trimethylsilanolate elimination from (2-methoxyphenyl)[tris(trimethylsilyl)silyl]methanol (**5**) according to a modified Peterson mechanism, decisively depends on the donating ability of the solvent in which the silene is generated. In ether, **6** undergoes a formal [2 + 2] dimerization to afford 3,4-bis(2-methoxyphenyl)-1,1,2,2-tetrakis(trimethylsilyl)-1,2-disilacyclobutane (**12**), whereas in toluene the head-to-tail [2 + 2] cyclodimer, 2,4-bis-(2-methoxyphenyl)-1,1,3,3-tetrakis(trimethylsilyl)-1,3-disilacyclobutane (**13**) was obtained. 1,1-Bis(trimethylsilyl)-2-(2,4,6-trimethoxyphenyl)silene (**18**), similarly made by a modified Peterson reaction, under the same conditions reacted with the eliminated trimethylsilanolate with readdition at the polar Si=C bond to give, after hydrolysis,2-(2,4,6-trimethoxybenzyl)-1,1,1,3,3,3-hexamethyl-2-(trimethylsiloxy)trisilane (**19**). A possible mechanism explaining the solvent-dependent regiospecificity of the dimerization of **6** is discussed. The structures of **12** and **13** were determined on the basis of NMR and MS data as well as X-ray structural analyses.

In the absence of trapping agents, sterically congested transient silenes undergo rapid dimerizations, in which head-to-head as well as head-to-tail reactions are observed[1]. The factors influencing the mode of dimerization are not clear, but, obviously, increasing polarity of the Si=C bond favors a head-to-tail coupling. Transient 1,1-bis(trimethylsilyl)silenes, made by the photolysis of acyl-tris(trimethylsilyl)silanes[2] or by a modified Peterson reaction[2][3][4], generally dimerize in a head-to-head mode. The reaction is supposed to proceed through radical intermediates[5]. After Si−Si bond formation the resulting diradicals stabilize with the formation of products, the structures of which depend on the nature of the substituents at the silene carbon atom (Eq. 1). 1,2-disilacyclobutanes **1** are usually obtained as the formal head-to-head [2 + 2] cyclodimers of the transient 1,1-bis(trimethylsilyl)silenes. When at least one of the silene C substituents is an aryl group, moderately stable tetrahydro-2,3-disilanaphthalenes **2**[6] are in some cases isolated as the kinetically preferred formal [2 + 4] silene dimers, which on thermal treatment gradually isomerize to give **1**. Silenes containing α hydrogen in the substituent at the silene C atom ("allylic" hydrogen) stabilize preferentially under hydrogen transfer to give linear dimers **3**[2][3a][5][7].



(1)

Recently we found that 2-(2-dimethylaminophenyl)-1,1-bis(trimethylsilyl)silene (**4**) dimerizes exclusively in a head-to-tail reaction affording the respective 1,3-disilacyclobutane[4]. This unusual regiospecificity was discussed as being effected by the 2-dimethylamino group of the aromatic substituent, causing an intermolecular interaction with the electrophilic silene silicon atom of a neighboring silaethene molecule. This donor−acceptor interaction finally leads to a head-to-tail dimerization following a mechanism, which is discussed later in this text. In this paper we describe the synthesis and dimerization behavior of 2-(2-methoxyphenyl)-1,1-bis(trimethylsilyl)silene, i.e. the dimethylamino do-

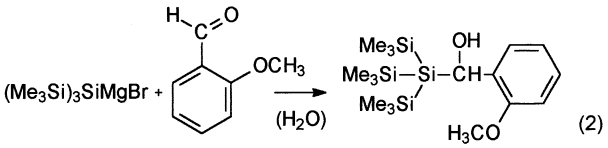
nor group in the above-mentioned silaethene is replaced by a methoxy group, to examine the proposed cyclodimerization mechanism.

The Generation and Cyclodimerization Behavior of the Transient 2-(2-Methoxyphenyl)-1,1-bis(trimethylsilyl)silene (6)

2-(2-Methoxyphenyl)-1,1-bis(trimethylsilyl)silene (**6**) was generated by the base-induced elimination of trimethylsilanol from (2-methoxyphenyl)-[tris(trimethylsilyl)silyl]-methanol (**5**) according to a modified Peterson mechanism. The alcohol **5** was obtained by the standard method[7] from tris(trimethylsilyl)silylmagnesium bromide and 2-methoxybenzaldehyde (Eq. 2).

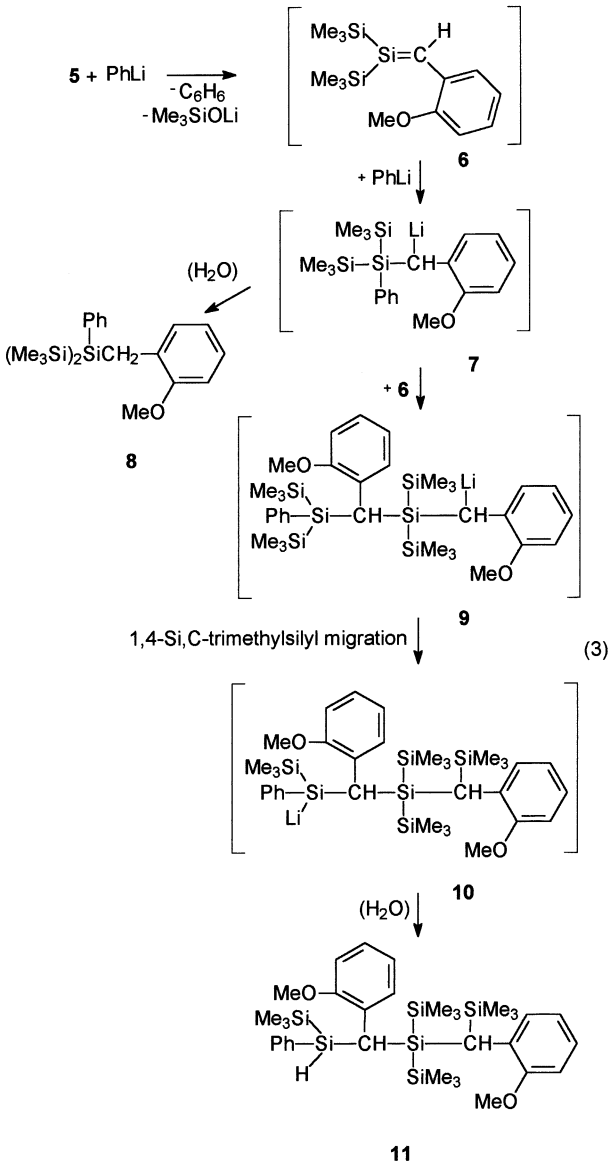


(2)

5

Interestingly, the outcome of the deprotonation reaction of **5** with organolithium reagents markedly depended on the solvent in which the reaction was carried out, and on the reaction conditions applied. Thus, the reaction of **5** with excess phenyllithium in ether led to the trisilane **8** (Eq. 3). This experiment is generally our standard method to check the clean trimethylsilanolate elimination from the starting 1-hydroxyalkyl-tris(trimethylsilyl)silane and the formation of the respective silene[7]. **8** was formed by immediate addition of excess phenyllithium to the Si=C bond of generated **6**, affording after hydrolysis the trisilane **8** . The high yield, in which **8** was obtained (84%), indicates a straightforward silene formation according to the modified Peterson mechanism.

The deprotonation of **5** with stoichiometric quantities of phenyllithium in ether at low temperature (starting at −78 °C and allowing the solution to warm up to room temperature) led to a complex mixture of components, from which only small quantities of a resultant silene product **11** could be separated in a pure form. On the basis of IR, NMR, and MS data, and particularly by means of an X-ray structural analysis it was identified as the silane **11** (Eq. 3). Its formation is interpreted as the result of the addition of phenyllithium at the polar Si=C bond of **6** giving an organolithium derivative **7** which attacks a further silene molecule. The resulting organolithium intermediate **9** undergoes a rapid rearrangement, a 1,4-Si,C-trimethylsilyl migration, with formation of the lithium silanide **10**, which is hydrolyzed during the aqueous workup affording **11**. Such trimethylsilyl migrations are not unusual; some years ago we observed a similar 1,3-Si,C shift[9], and the isomerization **9**→**10** is easily understood in terms of the particular stabilization of the silaanion by the phenyl and trimethylsilyl substituents. As we noticed, the deprotonation step of **5** proceeds comparatively slowly. Assuming that the elimination of lithium trimethylsilanolate is a fast process, the



generated silene will always meet an effective excess of phenyllithium, which initiates this side reaction. The molecular structure of **11** is illustrated in Figure 1. The significant deviations from standard values of the bond distances and angles given characterize **11** as a considerably congested compound.

The clean generation of **6** by deprotonation of **5** with PhLi, indicated by the formation of **8** in high yield, led to the assumption that the mixture of unidentified compounds obtained by the reaction of **5** with stoichiometric quantities of PhLi in ether may probably consist of the various isomers of the formal [2 + 4] head-to-head cycloadducts **2** of the silene **6** (see Eq. 1). These products are known to undergo an isomerization on thermal treatment to give the thermodynamically stable 1,2-disilacyclobutane. This was the reason for changing the procedure of the reaction of **5** with equimolar quantities of PhLi in ether in such a way that after warming-up of the mixture to room temperature and subsequent removal of the solvent the residue was dis-

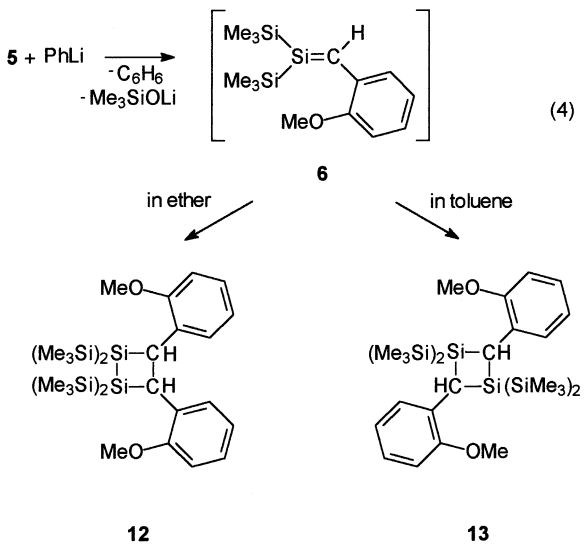
solved in toluene and heated under reflux for 4 h. Aqueous workup actually afforded 42% of (*E*/*Z*)-3,4-di(2-methoxyphenyl)-1,1,2,2-tetrakis(trimethylsilyl)-1,2-disilacyclobutane (**12**). Repeated recrystallization from acetone gave pure (*E*)-**12**.



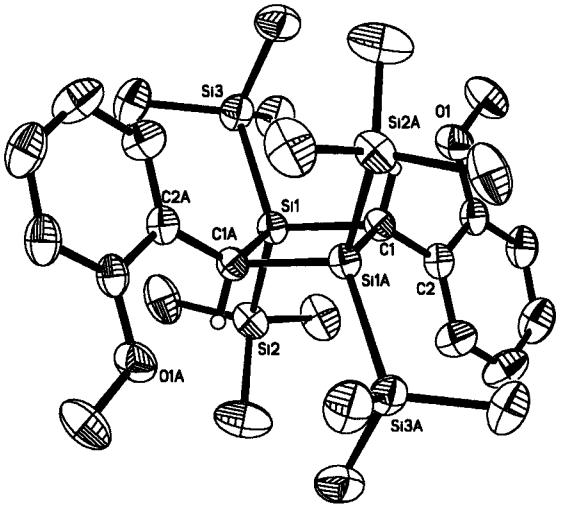
Compound **12** is the expected formal head-to-head [2 + 2] cyclodimer of the silene **6**. Its structure was elucidated by a full spectral analysis and an X-ray structural analysis characterizing the compound investigated as the C_2 symmetrical (*E*)-isomer (Figure 2). The four-membered ring is folded, the torsional angle Si1−Si1−C1−C1 being 24.7°. The C1−Si1 distances are slightly elongated, but most structural parameters are within the expected range.

As mentioned above, the outcome of the reaction of **5** with organolithium reagents decisively depends on the solvent used. A number of products were identified when **5** was deprotonated with equimolar quantities of methyllithium or *n*-butyllithium in toluene at low temperature and the mixture stirred after warming up to room temperature for 4 days. Besides unreacted **5**, traces of **16** and large quantities of a polymeric material a solid compound was isolated, which was unambiguously identified as the 1,3-disilacyclobutane **13**, the formal head-to-tail cyclodimer of the silene **6**. The structure elucidation of **13** was performed by NMR and MS investigations as well as by an X-ray structural analysis. As seen in Figure 3, the compound isolated in a yield of 27% is the (*E*)-isomer of the 1,3-disilacyclobutane **13**. The ring is planar. Apart from slightly elongated ring Si−C distances, which are considered as being due to steric congestion, the bond parameters are in the expected range. The reaction of **5** with organolithium reagents in pentane under the same conditions afforded (*E*)-**13** in 16% yield.

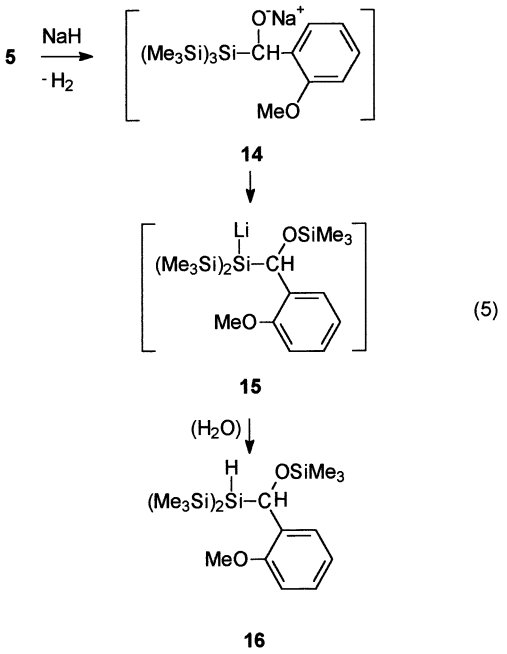
The byproduct **16** is the result of a 1,3-migration of one trimethylsilyl group from the central silicon atom to the alkoxid oxygen atom of deprotonated **5**, followed by hydrolysis of the silanide formed (Eq. 5). The same H-silane **16** is obtained in high yield by treatment of **5** with sodium hydride in ether. Such Si,O migrations were observed for the first time by Brook et al.[8] and appear to be typical of the behavior of 1-hydroxyalkylpolysilanes towards base[7].

Whereas the silene **6**, generated in ether, dimerizes to give the "normal" head-to-head product, a change of the solvent causes a complete reversal of the dimerization regiospecificity. Actually, the yield of **13** was not very high, but it should be emphasized that in the product mixture of the reaction

Figure 3. Molecular structure of *E*-**13** in the crystal [H atoms (except the ring-CH) omitted, ORTEP, 30% probability level][a]



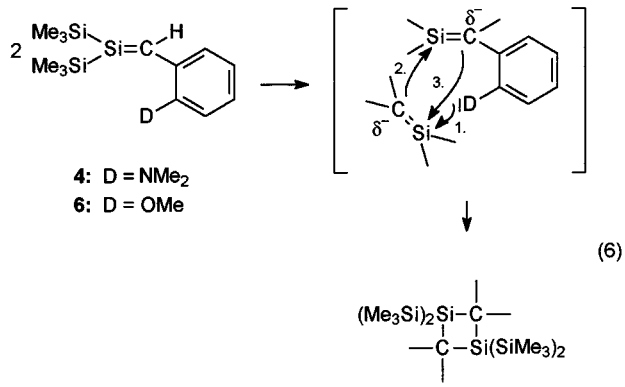
[a] Selected bond lengths [Å] and angles [°]: C1−Si1 1.923(2), Si1−Si2 2.3682(11), Si1−Si3 2.3668(11); C1−Si1−C1A 91.14(10), Si1−C1−Si1A 88.86(10).



(5)

of **5** with methyllithium in toluene no silene head-to-head dimer **12** could be detected. Similarly, no trace of the head-to-tail dimer **13** was observed after the reaction of **5** with MeLi in ether.

This solvent-dependent behavior of the silene **6** is fully consistent with the model proposed for the dimerization of 2-(2-dimethylaminophenyl)-1,1-bis(trimethylsilyl)silene (**4**), affording (in this case also in ether) exclusively the head-to-tail dimer. The deviation of **4** from the usual dimerization pattern of 1,1-bis(trimethylsilyl)silenes was discussed as a consequence of a strong donor−acceptor interaction of the dialkylamino group with the electrophilic silene silicon atom[4]. An effective intramolecular donor−acceptor interaction, which actually is expected to lead to an increase in the polarity of the silene double bond, thus facilitating a head-to-tail dimerization, is rather unlikely for steric reasons. We assume that the head-to-tail dimerization of **4** is achieved by an intermolecular donor−acceptor interaction, the *ortho*-dimethylamino group acting as some kind of anchor. Its interaction with the electrophilic silene silicon atom of a neighboring molecule and the attack of the activated nucleophilic silene carbon atom at the Si=C group of the first silene molecule possibly initiate a head-to-tail dimerization through a cyclic seven-membered transition state. This picture, outlined in eq. 6, can directly be transferred to the dimerization of **6** in toluene.



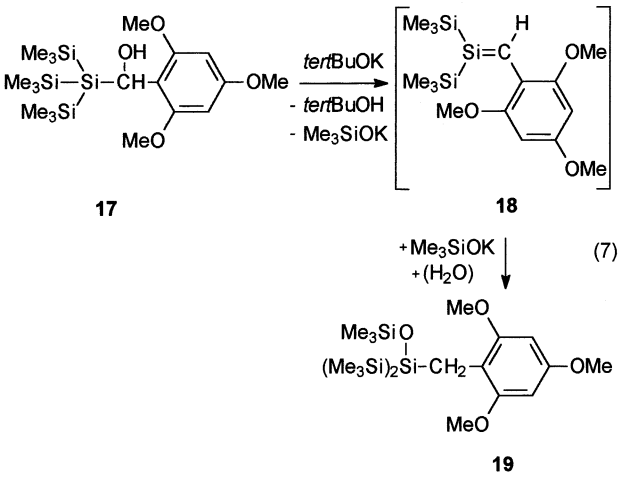
(6)

Of course, the donating ability of the dialkylamino group of **4** is much stronger than that of the methoxy group in **6**. Therefore the dimerization mode of **4** is solvent independent. On the other hand, in case of the generation of the silene **6** in ether, the donor solvent competes successfully with the weakly donating *o*-methoxy group, interrupting the intermolecular interaction. Thus, when ether is used as the solvent, the dimerization of **6** follows the usual reaction pattern providing the head-to-head product **12**.

The Reaction of (2,4,6-Trimethoxyphenyl)[tris(trimethylsilyl)-silyl]methanol (17) with Potassium *tert*-Butoxide

1,1-Bis(trimethylsilyl)-2-(2,4,6-trimethoxyphenyl)silene (**18**), generated through the modified Peterson mechanism from (2,4,6-trimethoxyphenyl)[tris(trimethylsilyl)silyl]methanol (**17**) offers the same structural requirements for following a dimerization pattern comparable to that of **6** and was therefore included in our studies. Unexpectedly, the reaction of **17** with MeLi or PhLi in ether as well as in toluene proceeded very slowly. Better results were obtained when potassium *tert*-butoxide was used as the deprotonating base. However, the reaction of **17** with *t*BuOK in both solvents gave no silene dimer, and we obtained a colorless oil, which was identified as 2-(2,4,6-trimethoxyphenyl)-1,1,1,3,3,3-hexamethyl-2-(trimethylsiloxy)trisilane (**19**) (Eq. 7).

The siloxane **19** is formed by readdition of the silanolate, just eliminated from **17**, at the Si=C bond of the silene **18**. This behavior is typical for highly congested silenes generated by the Peterson process[3b][10]. Obviously, the increase



of the bulkiness of the substituent at the silene carbon atom diminishes the dimerization tendency making the silanolate addition the dominating process.

We gratefully acknowledge the support of our research by the *Deutsche Forschungsgemeinschaft* and the *Fonds der Chemischen Industrie.* We thank Dr. *M. Michalik,* Dr. *W. Baumann* and Prof. *N. Stoll* for recording the NMR and MS spectra.

Experimental Section

General: All reactions involving organometallic reagents were carried out under purified argon. − NMR: Bruker AC 250 or Bruker ARX 300, tetramethylsilane as internal standard. − IR: Nicolet 205 FT-IR. − MS: Intectra AMD 402, chemical ionization with isobutane as the reactant gas. − $(Me_3Si)_3SiLi \cdot 3$ THF[11] and **17**[12] were prepared as reported in the literature.

(2-Methoxyphenyl)[tris(trimethylsilyl)silyl]methanol (**5**): As described previously[7], 14.7 g (0.03 mol) of $(Me_3Si)_3SiLi \cdot 3$ THF were converted in ether with an equimolar quantity of $MgBr_2$ into $(Me_3Si)_3SiMgBr$ and to this suspension 4.1 g (0.03 mol) of 2-methoxybenzaldehyde were added at −78°C. After stirring for 2 h the mixture was allowed to warm up to room temperature, diluted HCl was added, the organic layer was separated, dried with $MgSO_4$, and evaporated. The residue was purified by Kugelrohr distillation (150°C / 0.03 Torr). Yield 8.7 g (75%) pale yellow crystals, m.p. 48°C. **5** is rather unstable and should be kept in the cold. At room temperature the solid gradually decomposes to an oily product of unidentified structure. Attempts to recrystallize **5** were therefore also unsuccessful. − IR (cap.): $\tilde{\nu}$ = 3523 cm^{-1} (OH free), 3439 (OH ass.). − ^{1}H NMR ([D$_6$]benzene): δ = 0.28 (s, $SiCH_3$, 27 H), 1.30 (d, ^3J = 4.0 Hz, OH, 1 H), 3.27 (s, OCH_3, 3 H), 5.38 (d, ^3J = 4.0 Hz, CH, 1 H), 6.42−7.49 (m, ArH, 4 H). − ^{13}C NMR ([D$_6$]benzene): δ = 1.8 ($SiCH_3$), 54.2 (OCH_3), 62.6 (COH), 109.8, 121.0, 126.8, 127.2 (arom. CH), 136.3, 154.5 (arom. quart. C). − ^{29}Si NMR ([D$_6$]benzene): δ = −12.8 ($SiMe_3$)$_3$, − 68.8 (*Si*$SiMe_3$). − MS: *m/z* (%): 383 (6) [M^+ − H], 367 (100) [M^+ − OH]. − $C_{17}H_{36}O_2Si_4$ (384.82): calcd. C 53.06, H 9.43; found C 52.58, H 8.85).

(2-Methoxybenzyl)-1,1,1,3,3,3-hexamethyl-2-phenyltrisilane (**8**)*:* To a solution of 0.5 g (1.3 mmol) of **5** in 20 ml of ether a fivefold molar excess of PhLi was added at room temperature. After stirring for 2 h diluted HCl was added, the ethereal phase separated and dried with $MgSO_4$. The oily product obtained after evaporation was purified by chromatography (silica gel, heptane/ethyl acetate, 20:1) to give 0.4 g (84%) **8**. − ^{1}H NMR ([D$_6$]benzene): δ = 0.16 (s, $SiCH_3$, 18 H), 2.75 (s, CH_2, 2 H), 3.27 (s, OCH_3, 3 H), 6.49−7.61 (m, ArH, 9 H). − ^{13}C NMR ([D$_6$]benzene): δ = −0.2 ($SiCH_3$), 13.9 (CH_2), 54.3 (OCH_3), 110.2, 120.7, 125.9, 128.0, 128.2, 130.3, 135.6 (aromat. CH), 130.0, 137.9, 156.7 (aromat. quart. C). − MS: *m/z* (%) = 357 (8.5) [M^+ − CH_3], 299 (100) [M^+ − $CSiMe_3$]. − $C_{20}H_{32}OSi_3$ (372.73): calcd. C 64.45, H 8.65; found C 64.56, H 8.74.

2,4-Bis(2-methoxyphenyl)-1-phenyl-1,3,3,4-tetrakis(trimethylsilyl)-1,3-disilabutane (**11**): An equimolar quantity of phenyllithium was added to a solution of 0.5 g (1.3 mmol) of **5** in ether at −78°C and stirred for 2 h. After warming of the mixture to room temperature, diluted HCl was added, the organic layer separated, dried with $MgSO_4$, and evaporated. Chromatographic separation of the residue (silica gel, heptane) and recrystallization of the product from acetone gave 0.04 g (9.2%) of **11**. Colorless crystals, m.p. 255°C. − IR (KBr): $\tilde{\nu}$ = 2094 cm^{-1} (SiH). − ^{1}H NMR ([D$_6$]benzene): δ = − 0.18, 0.13, 0.20, 0.28 (4s, $SiCH_3$, 4 × 9 H), 2.87 (s, CH, 1H), 3.28 and 3.58 (2s, OCH_3, 2 × 3 H), 3.44 and 5.06 (2d, ^3J = 5.4 Hz for both, SiH and PhSiCH, 3 × 1 H), 6.48−7.92 (m, ArH, 13 H). − ^{13}C NMR ([D$_6$]benzene): δ = −1.5, 0.5, 2.8, 3.4 ($SiCH_3$), 9.4, 15.6 (CH), 54.2, 54.4 (OCH_3), 110.0, 110.3, 119.8, 120.9, 121.9, 125.4, 125.6, 125.7, 128.8, 132.3, 132.4, 133.3, 135.9, 138.3, 138.4, 155.7 (aromat.C). − ^{29}Si NMR ([D$_6$]benzene): δ = − 22.3 *Si*($SiMe_3$)$_2$, −16.7, −16.3, −15.2 (Si*Si*Me_3, SiH), 1.6 ($CSiMe_3$). − MS: *m/z* (%) 622 (2) [M^+], 651 (7) [M^+ − CCH_3], 593 (100) [M^+ − $CSiMe_3$]. − $C_{34}H_{58}O_2Si_6$ (667.34): calcd. C 61.19, H 8.76; found C 61.33, H 8.72.

(E)-3,4-Bis(2-methoxyphenyl)-1,1,2,2-tetrakis(trimethylsilyl)-1,2-disilacyclobutane (**12**): An equimolar quantity of PhLi was given to a stirred solution of 0.5 g (1.3 mmol) of **5** in 25 ml of ether. After warming up to room temperature, the solvent was removed in vacuo, 20 ml of toluene were added and the solution was refluxed for 4 h. After addition of diluted HCl the organic phase was separated, dried with $MgSO_4$, and evaporated. The oily residue crystallized after addition of a few ml of *n*-heptane to give 0.16 g (42%) of (*E*/*Z*)-**12**, repeated recrystallization from acetone afforded pure (*E*)-**12**, m.p. 175°C. − ^{1}H NMR ([D$_6$]benzene): δ = 0.17, 0.44 (2s, $SiCH_3$, 2 × 18 H), 3.45 (s, OCH_3, 6 H), 4.18 (s, ring CH, 2 H), 6.51−7.12 (m, ArH, 8 H). − ^{13}C NMR ([D$_6$]benzene): δ = 1.9, 2.0 ($SiCH_3$), 29.8 (ring C), 54.7 (OCH_3), 109.4, 120.8, 125.0, 126.5 (arom. CH), 133.4, 156.2 (arom. quart. C). − ^{29}Si NMR ([D$_6$]benzene): δ = −49.9 (ring Si), −14.0, −11.3 ($SiMe_3$). − MS: *m/z* (%): 589 (22) [M^+ + H], 573 (12) [M^+ − CCH_3], 515 (19) [M^+ − $CSiMe_3$], 348 (100) [M^+ − $C(Me_3Si)_2SiSi(SiMe_3)_2$]. − $C_{28}H_{52}O_2Si_6$ (589.24): calcd. C 57.08, H 8.90; found C 57.30, H 8.79.

(E)-2,4-Bis(2-methoxyphenyl)-1,1,3,3-tetrakis(trimethylsilyl)-1,3-disilacyclobutane (**13**): To 0.6 g (1.6 mmol) of **5**, dissolved in 25 ml of toluene, an equimolar quantity of *n*BuLi was added under stirring at −78°C. The solution was allowed to warm up to room temperature within 2 h and afterwards it was refluxed for 4 h. After hydrolysis the organic layer was separated, dried with $MgSO_4$ and evaporated to give an oily residue which crystallized on addition of some heptane. Repeated recrystallization from heptane afforded 0.06 g (13%) of colorless crystals of (*E*)-**13**, m.p. 235°C. − ^{1}H NMR ([D$_6$]benzene): δ = 0.28 (s, $SiCH_3$, 36 H), 3.37 (s, OCH_3, 6 H), 3.87 (s, ring CH, 2 H), 6.47−7.67 (m, ArH, 8 H). − ^{13}C NMR ([D$_6$]benzene): δ = 0.6 ($SiCH_3$), 7.6 (ring C), 54.9 (OCH_3), 110.2, 120.3, 124.4, 130.5 (arom. CH), 133.5, 156.6 (arom. quart. C). − ^{29}Si NMR ([D$_6$]benzene): δ = −13.4 (ring Si), −13.9 ($SiMe_3$). − MS: *m/z* (%): 589 (3) [M^+ + H], 573 (6) [M^+ − CCH_3], 515 (100)

C). − ^{29}Si NMR ([D$_6$]benzene): δ = −19.6 (SiSi-*t*Me$_3$), 0.9 (*Si*SiMe$_3$), 6.3 (OSiMe$_3$). − MS: *m/z* (%): 445 (1) [M^++H], 429 (10) [M^+ − CCH_3], 371 (100) [M^+ − $CSiMe_3$], 355 (12) [M^+ − $COSiMe_3$]. − $C_{19}H_{40}O_4Si_4$ (444.87): calcd. C 51.30, H 9.06; found C 51.23, H 9.03.

Crystal-Structure Determination of **11**, **12**, *and* **13**: The crystal-structure determinations were performed on a SIEMENS P4 four-circle diffractometer with graphite monochromator in the case of compounds **11** and **12** and on a STOE IPDS system with graphite monochromator for **13**. The structures were solved by direct methods (Siemens SHELXTL, 1990, Siemens Analytical X-ray Inst. Inc. for **11** and **12** and SHELXS-86[13] for **13**) and refined by the full-matrix least-squares method of Siemens SHELXTL, Ver. 5.03 (**11**, **12**) and SHELXL-93[14] (**13**). All non-hydrogen atoms were refined anisotropically. The hydrogen atoms were put into theoretical positions and refined using the riding model.

Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication no. CCDC-102330 (**11**), CCDC-102331 (**12**), and CCDC-102332 (**13**). Copies of the data can be obtained free of charge on application to The Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) +44(1223) 336-033; e-mail: deposit@ccdc.cam.ac.uk].

Keywords: Ruthenium / Copper / Oxidations / Catalysis / Alcohols

The oxidation of allylic and benzylic alcohols to aldehydes can be carried out at room temperature with molecular oxygen, in the presence of the bifunctional ruthenium-copper system (nPr$_4$N)(RuO$_4$)–CuCl acting as the catalyst.

The oxidation of alcohols to aldehydes and ketones is a fundamental reaction in organic synthesis, and numerous oxidizing reagents are available to effect this key transformation.[1] In most instances, these reagents are used in stoichiometric amounts and are very often toxic such as the chromium oxidants used in vast amounts in both the laboratory and industry.[1] However, with the ever-growing environmental and economic concerns the development of catalytic processes for alcohol oxidation is becoming increasingly important.

A particularly noteworthy process has been described by Griffith et al.[2] who reported the use of the high oxidation state oxoruthenium compound tetra-*n*-propylammonium perruthenate (nPr$_4$N)(RuO$_4$), TPAP, as a mild catalyst for the oxidation of alcohols with *N*-methylmorpholine *N*-oxide, NMO, as the secondary oxidizing source. More recently, we reported the catalytic oxidation of primary alcohols to aldehydes with *cis*-dioxymolybdenum(VI) complexes and sulfoxides as the co-oxidant.[3] Although both of the above function well as catalytic systems, unpleasant and harmful by-products, amine and sulfide respectively, are produced. This limits the use of these catalysts on an industrial scale. The quest for catalytic systems that use inexpensive, nontoxic, molecular oxygen in the air as the secondary oxidant remains a particularly important goal for the development of a "green method" for converting alcohols to carbonyl products on an industrial scale.[4]

Relatively few ruthenium-based catalytic systems using air or molecular oxygen have been reported for the dehydrogenation of alcohols. These include the trinuclear ruthenium carboxylates [Ru$_3$O(O$_2$CR)$_6$L$_3$]^n (R = CH$_3$ or C$_2$H$_5$; L = H$_2$O or PPh$_3$; n = 0, +1)[5], the ruthenium(II) species [RuCl$_2$(PPh$_3$)$_3$][6], RuO$_2\cdot x$H$_2$O[7], the binuclear [Ru$_2$O$_6$(C$_5$H$_5$N)$_4$]$\cdot$3.5H$_2$O[8], the bimetallic system RuCl$_3$–Co(OAc)$_2$[9] and the triple catalytic system [RuCl(OAc)(PPh$_3$)$_3$]–hydroquinone–[Co(salophen)(PPh$_3$)][10] where H$_2$salophen = *N*,*N*′-bis(salicylidene)-*O*-phenylenediamine. However, these catalysts are rarely selective and are often limited as rather high reaction temperatures and high pressures of molecular oxygen are required and low turnover numbers are observed.

Recently, during the preparation of our manuscript Ley[11] and Markó[12] have communicated the use of tetra-*n*-propylammonium perruthenate, (nPr$_4$N)(RuO$_4$), in the presence of molecular oxygen, as a catalytic oxidant of both primary and secondary alcohols. Markó[12] has also observed that the presence of CuCl$\cdot$phenanthroline (5 mol-%) and K$_2$CO$_3$ (200 mol-%) produced a retarding effect in the oxidation of 4-chlorobenzyl alcohol. We wish to communicate some of our recent results on a similar (nPr$_4$N)(RuO$_4$)–CuCl bimetallic system which is a selective and efficient catalytic system for the oxidation of alcohols with molecular oxygen under mild conditions (25°C), producing water as the only stoichiometric by-product, Scheme 1.

The catalytic oxidation of various alcohols takes place smoothly at 25°C with (nPr$_4$N)(RuO$_4$) (1 mol-%), CuCl (1 mol-%), and 2-aminopyridine (5 mol-%) in the presence of 1 atm of molecular oxygen in toluene, dichloromethane, or acetonitrile. The results are presented in Table 1. The addition of powdered 4-Å molecular sieves results in slightly increased rates, as previously observed in oxidations with (nPr$_4$N)(RuO$_4$) and NMO.[2] This may be because the water formed as a by-product in the reaction degrades the catalyst. Allylic and benzylic alcohols are oxidized with nearly

[a] General reaction conditions: ($n$$Pr_4N$)($RuO_4$) (1 mol-%), CuCl (1 mol-%), 2-aminopyridine (5 mol-%), 0.5 g of powdered 4-Å molecular sieves, 6 ml of dichloromethane, 1 atm of molecular oxygen, and temperature 25°C. − [b] GC determination. − [c] Toluene (6 ml), 100°C. − [d] In the absence of ($n$$Pr_4N$)($RuO_4$). − [e] 4% conversion to the corresponding acid. − [f] In the absence of a nitrogen donor ligand. − [g] Acetonitrile (6 ml), 50°C. − [h] Acetonitrile (6 ml), 25°C. − [i] 20 equivalents of substrate. − [j] Determined by ^{1}H-NMR spectroscopy.

total selectivity to aldehydes with no further oxidation to the corresponding acids observed. Slightly improved rates can be observed in toluene at 100°C (***WARNING:*** Attempted oxidation of 1-butanol in toluene at 100°C resulted in an explosion) and acetonitrile at 50°C. The bifunctional ($n$$Pr_4N$)($RuO_4$)−CuCl catalyst was found to be very selective, with only benzylic and allylic alcohols undergoing any significant oxidation. Aliphatic primary alcohols such as 1-butanol (entry 18) and 1-decanol (entry 20) remain effectively unchanged under the same conditions at 25°C in dichloromethane or acetonitrile, and increasing the temperature to 100°C with toluene as the solvent has little effect (entry 21). Similarly, secondary alcohols were found to undergo very little oxidation (cyclohexanol, entry 25 and 26) or not at all (2-butanol, entry 22 and L-menthol, entry 23), a notable exception being cyclobutanol (entry 24) which was slowly oxidised in dichloromethane. We believe that the dehydrogenation of cyclobutanol results from it being less sterically encumbered than other more common secondary alcohols. The oxidation reactions, therefore, appear to be sensitive to steric factors near the alcohol functional group. This is further supported by the increase in rate of oxidation of 2,4-dichlorobenzyl alcohol (entry 9) compared with 2,6-dichlorobenzyl alcohol (entry 10). This has been observed in the ($n$$Pr_4N$)($RuO_4$)/NMO system[2] but it would seem to a lesser degree, as a range of secondary alcohols readily undergo oxidation with this system. This suggests that as with the ($n$$Pr_4N$)($RuO_4$)/NMO system, the bifunctional ($n$$Pr_4N$)($RuO_4$)−CuCl reagent is sterically demanding, with oxidation presumably occurring through the intermediacy of ruthenate esters. The selectivity of the ruthenium-copper catalyst is significantly different to that of the Griffith ($n$$Pr_4N$)($RuO_4$)/NMO system[2] and the ($n$$Pr_4N$)($RuO_4$)/$O_2$ system of Ley[11] and Markó[12], where benzylic, allylic and aliphatic primary alcohols and secondary alcohols are all readily oxidized. As with the Griffith, Ley, and Markó systems, functional groups such as double bonds remain intact during the oxidations.

The role of the copper compound is unclear. Varying the copper complex used in the system from CuCl to Cu($OCOCH_3$)$_2$, CuO, or [Cu($MeCN$)$_4$][PF_6] has little effect on the rate of oxidation; CuCl shows marginally improved initial rates. The concentration of the copper complex seems to be significant as the addition of 10 equivalents results only in stoichiometric oxidation. The addition of the nitrogen donor ligand (2-aminopyridine) causes a marked improvement on the rate of oxidation (compare entry 2 and 3). This may be as a result of complexation to the copper complex resulting in a more soluble species which is more efficient in activating or binding the molecular oxygen.[13] UV/Vis spectroscopy and electrospray mass spectrometry preclude any involvement of the nitrogen donor ligand with ($n$$Pr_4N$)($RuO_4$). Similar conlusions have been reached for RuO_4 which, unlike OsO_4, is unable to form simple adducts with nitrogen donor ligands.[8][14]Varying the nitrogen donor ligand from 2-aminopyridine to pyridine, 4-dimethylaminopyridine, or 2,6-lutidine has little effect on the rate of oxidation. However, addition of a bidentate nitrogen donor ligand, e.g. 2,2′-bipyridyl results in a decrease in catalytic activity as also noted by Markó.[12]

The observation that cyclobutanol is oxidized to cyclobutanone with total selectivity (entry 24) by this bifunctional catalyst would suggest one-electron processes are not involved in the oxidation process.[15] Similarly, studies on the oxidation of a series of *para*-substituted benzyl alcohols $RC_6H_4CH_2OH$ [R = OMe (entry 6), Cl (entry 7), CF_3 (entry 8), and H (entry 13)] show no correlation with Hammett σ parameters. Hence, benzyl radicals would appear not to be involved in the catalytic process, a conclusion which is further supported by the observation that radical traps, such as 2,4,6-tri-*tert*-butylphenol, have no effect on the rate of oxidation. In kinetic isotope effect experiments, the overall rate of the catalytic oxidation of $C_6H_5CH_2OH$ (entry 14) and $C_6H_5CD_2OH$ (entry 15) in parallel experiments yields the value of $k_H/k_D = 2.2$, indicating that C−H cleavage is involved in the rate-determining step. The nature of the action of the bifunctional ruthenium−copper catalyst is unclear and is currently under further investigation.

Finally, we have found that both the simple $(n\mathrm{Pr}_4\mathrm{N})(\mathrm{RuO}_4)/\mathrm{O}_2$ and $(n\mathrm{Pr}_4\mathrm{N})(\mathrm{RuO}_4)/\mathrm{Cu}/\mathrm{O}_2$ systems give very dark heterogeneous solutions during catalysis. Preliminary experiments seem to indicate the formation of colloidal material in these reactions. We have used different separation methods (e.g. centrifuging and membrane filtration) to remove the major part of the solid material formed. However, the residual solution contains particulate matter (ca. 200 nm, determined by photo correlation spectroscopy) and, interestingly, is still catalytically active. Therefore, whether the catalysis occurs heterogeneously or homogeneously remains unknown. Studies on more stable bifunctional systems are underway to clarify this point.

We gratefully acknowledge the support of this work by the *Centre National de la Recherche Scientifique*. K. S. C. also wishes to thank the *European Commission* for a *Marie Curie Research Fellowship* (ERBFMBICT971873).

Experimental Section

General: Most of the reagents were used without further purification except for the solvents, dichloromethane, acetonitrile, and toluene, which were dried and distilled prior to use. The catalyst $(n\mathrm{Pr}_4\mathrm{N})(\mathrm{RuO}_4)$ and all the substrates described in Table 1 were purchased from Aldrich Chemicals or Lancaster Synthesis. The analyses of the catalytic reactions were carried out with a Hewlett Packard 5890 Series II Gas Chromatograph equipped with a flame ionisation detector (FID) and a methyl silicone gum column of length 10 m, diameter 0.53 mm and 2.65 μm film thickness. ^{1}H-NMR spectra were recorded with a Bruker AC300 spectrometer and referenced internally to TMS.

General Procedure for the Oxidation of Alcohols: In a typical oxidation experiment the alcohol (100 mol-%) and 2-aminopyridine (5 mol-%) were dissolved in dichloromethane (6 ml), and powdered 4-Å molecular sieves added. After stirring the mixture for 10 min at 25°C under an atmosphere of molecular oxygen the copper complex (1 mol-%) was added followed by $(n\mathrm{Pr}_4\mathrm{N})(\mathrm{RuO}_4)$ (1 mol-%). The reaction was monitored by GC, with each sample taken from the reaction first filtered through a small plug of silica gel and washed with diethyl ether to remove any metal compounds.

Keywords: Chirality / Ruthenium / Chiral resolution / Nitrogen heterocycles / Carbonyl complexes

A range of chiral building blocks of the type Δ- or Λ-$[Ru(pp)_2(CO)_2]^{2+}$ {pp = bidentate ligands bpy (2,2′-bipyridine), phen (1,10-phenanthroline) and Me_2bpy (4,4′-dimethyl-2,2′-bipyridine)} have been synthesized, and their enantiomeric purity and absolute configurations determined by CD and NMR studies. Decarbonylation using trimethylamine oxide in the presence of the respective pp ligand at room temperature produced the corresponding tris(bidentate) species $[Ru(pp)_3]^{2+}$ with retention of configuration at the ruthenium(II) centre. A general chromatographic technique for resolution of tris-homoleptic complexes of the type $[Ru(pp)_3]^{2+}$ was investigated, with the absolute configurations of the resolved complexes confirmed by CD studies, and the X-ray structural analyses of Δ-(–)-$[Ru(Me_2bpy)_3]$[(–)-*O*,*O*′-dibenzoyl-L-tartrate] and Λ-(+)-$[Ru(phen)_3]$[(+)-*O*,*O*′-di-4-toluoyl-D-tartrate]. Resolution is also reported for the analogous species containing three potential bridging ligands, $[Ru(bpm)_3]^{2+}$ and $[Ru(HAT)_3]^{2+}$ (bpm = 2,2′-bipyrimidine; HAT = 1,4,5,8,9,12-hexaazatriphenylene). The versatility of the chromatographic procedure was demonstrated by the resolution of a series of bis-heteroleptic complexes $[Ru(pp)_2(pp')]^{2+}$ {pp′ = dpq (dipyrido[3,2-*d*:2,3′-*f*]quinoxaline), dpqc (dipyrido[3,2-*a*:2,3-*d*]-6,7,8,9-tetrahydrophenazine), and dppz {dipyrido[3,2-*a*:2,3′-*d*]phenazine)}.

Introduction

Ruthenium(II) complexes of polypyridyl ligands have received considerable attention as potential chromophoric components in photochemical molecular devices,[1] largely as a consequence of their synthetic versatility, and favourable photophysical and redox properties.[2][3][4]

For polynuclear assemblies based on such octahedral metal centres, stereoisomerism may occur by virtue of chirality or geometrical isomerism in the individual components, particularly when bidentate ligands are involved.[5][6][7] Since the initial chiral resolution of $[Ru(bpy)_3]^{2+}$ (bpy = 2,2′-bipyridine),[8][9][10] increasing attention has been drawn to the stereochemistry of this species and its analogues as a result of the differential interactions of the enantiomeric forms {e.g. of Δ- and Λ-$[Ru(phen)_3]^{2+}$ (phen = 1,10-phenanthroline)} with certain biological molecules such as DNA or oligonucleotides.[11][12][13][14] Additionally, the chiral resolution of $[Ru(pp)_2(BL)]^{2+}$,[15] $[Ru(pp)(pp')(BL)]^{2+}$,[16] {pp = bidentate polypyridyl ligand and BL = bridging ligand}, $[Ru(pp)_2(X)_2]^{n+}$ {X = py, CO, Cl^-, and CN^-},[15][17][18][19][20] and $[Ru(pp)(pp')(py)_2]^{n+}$[16] species have also been investigated in terms of their potential use as chiral building blocks for oligonuclear assemblies with predetermined stereochemistry.[6][7]

In the utilization of these species as chiral building blocks in stereoselective syntheses, or in the investigation of chiral interactions, it is required that they be available in optically pure form and have known absolute configurations. Generally, the chiral resolutions of bis(bidentate)- and tris(bidentate)ruthenium(II) complexes of polypyridyl ligands have been achieved by diastereoisomeric salt formation,[8][10][15][19][20][21][22][23][24] or chromatographic techniques.[15][16][25][26][27][28][29][30][31] The absolute configuration of a number of these enantiomeric forms have been assigned by exciton analysis of their circular dichroism (CD) spectra,[19][32][31][32][33][34][35][36] although more recently X-ray analyses have unambiguously confirmed the absolute configurations of Λ-$[Ru(bpy)_2(py)_2]^{2+}$[37] and Λ-$[Ru(phen)_3]^{2+}$.[38]

We recently communicated details of the chiral resolution of a series of dicarbonyl complexes of the type $[Ru(pp)_2(CO)_2]^{2+}$ {where pp = bpy, phen, and Me_2bpy (= 4,4′-dimethyl-2,2′-bipyridine)} and demonstrated their potential as chiral building blocks in the stereoselective synthesis of oligonuclear assemblies with predetermined stereochemistry.[15] We now report in detail the chiral resolution procedures and assignment of their absolute configurations, an NMR method of determining their optical purity, and the stereochemical consequences of their decarbonylation reactions. Also discussed is the development of a general chromatographic resolution technique for a variety of tris(bidentate)ruthenium(II) species and the factors which in-

fluence this resolution procedure. X-ray structural analyses of Δ-(−)-[Ru(Me_2bpy)$_3$]{(−)-*O,O′*-dibenzoyl-L-tartrate} and Λ-(+)-[Ru(phen)$_3$]{(+)-*O,O′*-di-4-toluoyl-D-tartrate} were used in combination with CD studies to confirm the absolute configurations of the tris(bidentate) species.

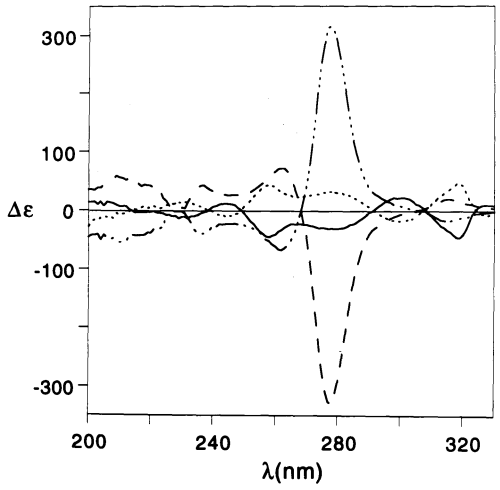
Results and Discussion

Dicarbonyl Species

Stereochemistry

Chiral resolutions of the cations $[Ru(bpy)_2(CO)_2]^{2+}$, $[Ru(phen)_2(CO)_2]^{2+}$, and $[Ru(Me_2bpy)_2(CO)_2]^{2+}$ were achieved by conventional diastereoisomeric salt formation as the antimonyl-(+)- or -(−)-tartrate salts. The CD spectra of the Λ-(+)- and Δ-(−)-$[Ru(phen)_2(CO)_2](PF_6)_2$ and Λ-(+)- and Δ-(−)-$[Ru(bpy)_2(CO)_2](PF_6)_2$ are shown in Figure 1; assignments of the absolute configurations of the three cations are discussed below.

Figure 1. CD spectra of the enantiomeric forms of $[Ru(bpy)_2(CO)_2]^{2+}$; Δ (——) and Λ (·····), and $[Ru(phen)_2(CO)_2]^{2+}$; Δ (------) and Λ (-·-·-·-)

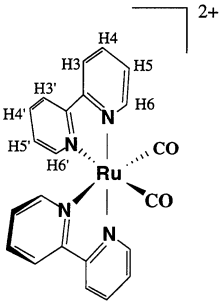


Cation-exchange chromatography utilizing a chiral eluent {e.g. sodium (−)-*O,O′*-dibenzoyl-L-tartrate}[15] was attempted as a resolution procedure but was found to be experimentally difficult due to the colourless character of these dicarbonyl complexes.

Chiral Lanthanide-Shift Reagent Studies

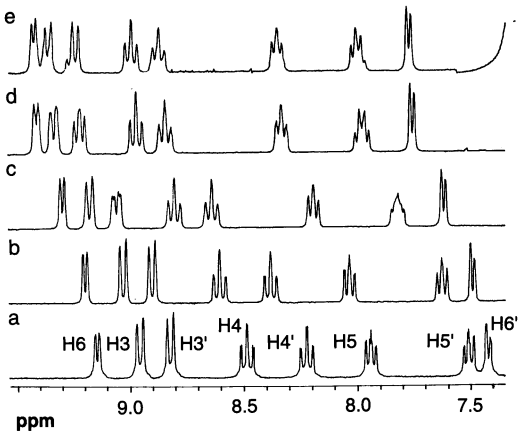
^{1}H-NMR techniques have provided an accurate and definitive method for the determination of enantiomeric purity of a variety of ruthenium(II) complexes of polypyridyl ligands. Such studies involve the addition to the complex of a chiral lanthanide-induced shift reagent[15][20][39][40][41][42] or tartrate derivative,[28] which causes a discrimination in the chemical shifts between the two enantiomeric forms. In the present work, the lanthanide-shift reagent studies of $[Ru(pp)_2(CO)_2]Cl_2$ (pp = bpy, phen, and Me_2bpy) were performed in [D_3]acetonitrile or [D_2]dichloromethane solutions: a non-polar solvent such as [D_2]dichloromethane is preferable in such studies,[40] but for solubility reasons [D_3]acetonitrile was required for the former two complexes. For all three dicarbonyl complexes, chemical shift discriminations between the enantiomeric forms were observed upon the addition of tris[3-(trifluoromethylhydroxymethylene)-*d*-camphorato]europium(III), Eu(tfc)$_3$, with the largest and most pronounced effects occurring for $[Ru(Me_2bpy)_2(CO)_2]Cl_2$ measured in [D_2]dichloromethane solution.

The effect of the sequential addition of Eu(tfc)$_3$ on the ^{1}H-NMR spectrum of $[Ru(bpy)_2(CO)_2]Cl_2$ is shown in Figure 2, where all the protons exhibited an induced downfield chemical shift of a magnitude influenced by their environment. The distinction between the enantiomers can be seen most clearly by comparison of the H3′ and H5′ proton resonances in Figures 2d and 2e (the racemate and a sample enriched in the Λ-(+) form, respectively, under similar conditions).



The complexes $[Ru(phen)_2(CO)_2]Cl_2$ and $[Ru(Me_2bpy)_2(CO)_2]Cl_2$ also showed an induced downfield chemical shift and chiral descrimination. Intersection of initial and final slopes in plots of the induced perturbation in chemical shift as a function of added Eu(tfc)$_3$ for $[Ru(phen)_2(CO)_2]Cl_2$ and $[Ru(bpy)_2(CO)_2]Cl_2$ indicated a ca. 1:1 adduct with the shift reagent. For the complex $[Ru(Me_2bpy)_2(CO)_2]Cl_2$, the ratio of shift reagent to complex exceeded unity.

Figure 2. The effect of [Eu(tfc)$_3$] on the ^{1}H-NMR (300 MHz; CD_3CN) spectrum of $[Ru(bpy)_2(CO)_2]Cl_2$; {a = no Eu(tfc)$_3$; b = 0.25 equiv.; c = 0.6 equiv.; d = 1 equiv.; e ≈ 1 equiv.; sample enriched in Λ isomer}; ^{1}H labelling scheme shown in text}



Stereochemical Consequences of the Decarbonylation Reaction

The stereochemical consequences of the decarbonylation reaction with trimethylamine *N*-oxide (TMNO) were investigated by treating the enantiomerically pure Λ-(+)-$[Ru(phen)_2(CO)_2]^{2+}$, Δ-(−)-$[Ru(bpy)_2(CO)_2]^{2+}$ and Λ-(+)-$[Ru(Me_2bpy)_2(CO)_2]^{2+}$ species (see below for absolute configuration assignments) with the ligands phen, bpy, and Me_2bpy under a variety of conditions, as given in Table 1. The $[Ru(pp)_3]^{2+}$ products from the reactions were isolated and the corresponding $[\alpha]_D$ values compared with those of the independently fully resolved products, allowing an assessment of the enantiomeric excess (*ee*) of the products formed under the various decarbonylation conditions. ^{1}H-NMR techniques utilizing the chiral shift reagent $[Eu(tfc)_3]$ were also used to confirm these *ee* determinations.

Previous studies[15][43] of the decarbonylation reactions of enantiomerically-enriched $[Ru(bpy)_2(CO)_2]^{2+}$ indicated that the three parameters which most significantly influenced the degree of stereoretention were temperature, solvent and ligand concentration. In order to maintain chiral integrity during the decarbonylation process, reaction conditions involved use of the solvent 2-methoxyethanol, ligand concentrations of ca. 10-fold or higher excess and low reaction temperatures. Photoracemization was not observed, but light was excluded in this study as a precaution.[15][43]

All reactions were observed to proceed with complete or near-complete retention of configuration at room temperature, whereas racemization occurred to varying degrees for all complexes at elevated temperatures. The most likely stage at which racemization might occur is subsequent to the removal of one carbonyl group, when competition for the "free" (or solvated) coordination site may occur between the uncoordinated nitrogen of an incoming monodentate pp ligand and a rearrangement involving one of the coordinated bidentate pp ligands. The extent of *racemization* during the decarbonylation reaction agrees with work previously completed by the authors, which demonstrated that retention of *geometric* integrity of an analogous dicarbonyl complex incorporating two non-symmetrical polypyridyl ligands occurred at 25°C, but isomerization took place at elevated temperatures.[44]

Absolute Configuration Determinations

Assignment of the absolute configurations of (+)- and (−)-$[Ru(phen)_2(CO)_2]^{2+}$ and (+)- and (−)-$[Ru(bpy)_2(CO)_2]^{2+}$ was achieved by their reaction with a third bidentate ligand to yield a tris(bidentate) product of known chirality. To ensure the decarbonylation reactions occurred with complete retention of configuration, the reactions were performed at room temperature and in subdued light (see above). The decarbonylation of (−)-$[Ru(bpy)_2(CO)_2]^{2+}$ with TMNO in 2-methoxyethanol in the presence of a 10-fold excess of bpy yielded the product Δ-(−)-$[Ru(bpy)_3]^{2+}$[36] with $[\alpha]_D = -816$ (compared with the literature value of −819[9]). This observation established a Δ configuration for (−)-$[Ru(bpy)_2(CO)_2]^{2+}$ and confirmed complete retention of configuration under those decarbonylation reaction conditions.

The absolute configuration of Λ-(+)-$[Ru(phen)_3]^{2+}$ has been assigned by CD[36] and X-ray crystallographic studies[38] and confirmed in the present work. It was formed by decarbonylation of (+)-$[Ru(phen)_2(CO)_2]^{2+}$ in the presence of phen, but otherwise under identical conditions to those described above for the formation of Δ-(−)-$[Ru(bpy)_3]^{2+}$, thus indicating the Λ configuration for (+)-$[Ru(phen)_2(CO)_2]^{2+}$ (see above). The product showed $[\alpha]_D = +1395$ compared with the literature value of +1340.[10]

The decarbonylation of (+)-$[Ru(Me_2bpy)_2(CO)_2]^{2+}$ under the same conditions described above but in the presence of Me_2bpy yielded the Λ-(+)-$[Ru(Me_2bpy)_3]^{2+}$ product (configuration determined by X-ray structural determination, Figure 4). The synthesized Λ-(+)-$[Ru(Me_2bpy)_3]^{2+}$ showed $[\alpha]_{546} = +1000$ compared to the independently resolved (+)-$[Ru(Me_2bpy)_3]^{2+}$ complex (see below) where $[\alpha]_{546} = +1045$, which may suggest that minor racemization (< 4%) occurs under the above reaction conditions.

The electronic spectrum of $[Ru(phen)_2(CO)_2]^{2+}$ exhibited a strong absorption band at ca. 275 nm which is assigned to an intraligand $\pi \rightarrow \pi^*$ transition, while the weak bands at

	120°C[d]	−300			0.53
Λ-(+)-[pp = Me_2bpy]	25°C	+1000[e]	+1045[e]		0.96
	120°C	+920[e]			0.88

[a] All reactions were performed in subdued light using 2-methoxyethanol as solvent, with 10-fold excess of pp and 3-fold excess of TMNO unless otherwise specified. – [b] Optical rotations measured in water as Cl^- or I^- salt for phen and bpy, respectively. – [c] Reaction conditions of ethylene glycol as solvent and heating under microwave conditions. – [d] Reaction conditions of 30-fold excess of bpy, 20-fold excess of TMNO and 2-methoxyethanol as solvent. – [e] Optical rotations measured as PF_6^- salts in CH_3CN as solvent at λ = 546 nm.

340 and 350 nm are most likely to be $d\pi \rightarrow \pi^*$ transitions.[45][46] The intense circular dichroism band at ca. 280 nm (phen long-axis polarization transition) for (+)-$[Ru(phen)_2(CO)_2]^{2+}$ is strongly positive and the circular dichroism band at higher energy (ca. 260 nm) negative (Figure 1), confirming the (+) isomer as having the Λ absolute configuration.[33]

The electronic spectrum of $[Ru(bpy)_2(CO)_2]^{2+}$ was dominated by $\pi \rightarrow \pi^*$ transitions in the region of ca. 200−300 nm.[45][46] The long-axis polarized transitions of bpy occur at ca. 300 nm:[33] the CD band at 315 nm for the (+)-enantiomer is strongly positive and the high energy band at 300 nm is negative (Figure 1), confirming the assignment as Λ-(+)-$[Ru(bpy)_2(CO)_2]^{2+}$. For the complexes $[Ru(bpy)_2(CO)_2]^{2+}$ and $[Ru(phen)_2(CO)_2]^{2+}$, the lower energy long-axis polarized transitions were red-shifted relative to those reported for the $[Ru(pp)_2(py)_2]^{2+}$ analogues,[19][33] presumably due to the electron-withdrawing carbonyl ligands. Accordingly, the two methods used to determine the absolute configurations of the chirally resolved dicarbonyl complexes (i.e. stereoselective syntheses and CD studies) were in agreement.

Tris(bidentate) Complexes

Stereochemistry

During the course of this study, a chromatographic technique was developed for the resolution of tris(bidentate)ruthenium(II) complexes. The technique is based on a cation-exchange mechanism (SP Sephadex C-25 support) with the mode of resolution significantly influenced by the differential association of the chiral anions of the eluent with the enantiomeric forms of the complex.[30][31] As Sephadex has a dextran base and is itself chiral, it believed to significantly influence the resolution procedure, as demonstrated by the chiral resolution of $[\{Ru(Me_2bpy)_2\}_2(\mu\text{-bpm})]^{4+}$[30] and $[Ru(bpq)_3]^{2+}$ {bpq = 2,3-bis(2-pyridyl)quinoxaline} with the achiral eluent sodium toluene-4-sulfonate.[47]

The resolutions of a number of ruthenium(II) complexes involving α,α′-diimine ligands have recently been reported using CM and SP Sephadex C-25 and (+ or −)-SbOtart salts as eluents.[25][27][28] Generally, these resolution procedures have required the collection of a series of fractions to obtain the resolved complex. The procedure reported below resulted in the clear separation into two bands (i.e. the two enantiomeric forms) of every mononuclear complex examined.

The study was based primarily on the resolution of the four tris-homoleptic tris(bidentate) complexes $[Ru(pp)_3]^{2+}$ (pp = bpy, phen, Me_2bpy, and Me_4bpy), although a number bis-heteroleptic complexes $[Ru(pp)_2(pp')]^{2+}$ were examined to demonstrate the generality of the resolution procedure. The CD spectra of Δ- and Λ-$[Ru(bpy)_3]^{2+}$ and Δ- and Λ-$[Ru(phen)_3]^{2+}$ resolved by the technique were in excellent agreement with the spectra reported previously.[35] The CD spectra of Δ-(−)- and Λ-(+)-$[Ru(Me_2bpy)_3]^{2+}$ and Δ- and Λ-$[Ru(Me_4bpy)_3]^{2+}$ are shown in Figure 3 (the determination of the absolute configuration of Δ-(−)-$[Ru(Me_2bpy)_3]^{2+}$ is discussed below). The Cotton effects of the three complexes $[Ru(pp)_3]^{2+}$ (pp = bpy, Me_2bpy, and Me_4bpy) were near identical, as expected because of their electronic and structural similarity.

Chromatographic Resolutions of Tris-homoleptic Tris(bidentate) Species

In the chromatographic resolutions, large variations in efficiencies were observed between the different eluents for the same complex and between different complexes for the same eluent {where a decreased distance for column resolution ("effective column length", ECL) indicates a more efficient resolution}, as shown in Table 2. ^{1}H-NMR studies have suggested that there is a differential association between the above complexes and the anions in the eluent solutions which involves π-stacking and hydrophobic interactions.[30][31] This is further supported by the X-ray structure of Λ-$[Ru(bpy)_2(py)_2]$\{(+)-*O,O′*-dibenzoyl-L-tartrate\}[37] Δ-$[Ru(Me_2bpy)_3]$\{(−)-*O,O′*-dibenzoyl-L-tartrate\} and Λ-(+)-$[Ru(phen)_3]$\{(+)-*O,O′*-di-4-toluoyl-D-tartrate\}; the latter two are reported herein. The associations leading to the chromatographic resolution are believed to involve three-way interaction between the complex, the chiral eluent and the Sephadex support.[31]

Chromatographic resolution using aqueous sodium (−)-*O,O′*-dibenzoyl-L-tartrate as the eluent is significantly more efficient in complexes containing methyl-substituted ligands {$[Ru(bpy)_3]^{2+}$ (ECL = 55 cm) > $[Ru(Me_2bpy)_3]^{2+}$ (ECL = 30 cm) > $[Ru(Me_4bpy)_3]^{2+}$ (ECL = 20 cm) or $[Ru(Me_4bpy)_2(bpm)]^{2+}$ (ECL = 25 cm) > $[Ru(Me_4bpy)_3]^{2+}$ (ECL = 20 cm)}. For these complexes in which there is an increase in resolution efficiency, it is also noted that there is an enhanced rate-of-travel down the column.

While sodium (−)-*O,O′*-di-4-toluoyl-L-tartrate is more efficient than sodium (+)-*O,O′*-di-4-toluoyl-D-tartrate solution as an eluent in the resolution of $[Ru(bpy)_3]^{2+}$ (ECL = 30 cm and 55 cm, respectively), the opposite is true for $[Ru(Me_2bpy)_3]^{2+}$ (ECL = 80 cm and 30 cm, respectively)

Table 2. Chromatographic resolution efficiency for a range of polypyridyl complexes of ruthenium(II)

Complex	Effective column length (ECL)[a]			
	sodium (−)-*O,O′*-dibenzoyl-L-tartrate[b]	sodium (+)-*O,O′*-dibenzoyl-D-tartrate[b]	sodium (−)-*O,O′*-di-*p*-toluoyl-L-tartrate[b]	sodium (+)-*O,O′*-di-*p*-toluoyl-D-tartrate[b]

and $[Ru(Me_4bpy)_3]^{2+}$ (ECL = 40 cm and 20 cm, respectively). The apparent anomaly may arise from increased steric interactions between the toluoyl substituent in the anion and the methyl substituents on the ligands, which diminish the association between the eluent anion and the substrate cation and thus reduce the degree of chiral discrimination.

Chromatographic resolution using sodium (+)-*O,O′*-di-4-toluoyl-D-tartrate solution as the eluent is also more efficient for resolution of complexes with increased numbers of methyl-substituted ligands, although not with the same predicability as in the case above {e.g. $[Ru(bpy)_3]^{2+}$ (ECL = 120 cm) > $[Ru(bpy)_2(Me_2bpy)]^{2+}$ (ECL = 65 cm) ≈ $[Ru(bpy)(Me_2bpy)_2]^{2+}$ (ECL = 70 cm) compared with $[Ru(Me_4bpy)_3]^{2+}$ (ECL > 120 cm)}. The apparent anomaly in the resolution efficiency of $[Ru(Me_4bpy)_3]^{2+}$ may also have its origins in competing steric interactions, as described above.

The degree of aromaticity of the polypyridyl ligand also has a significant influence in the resolution efficiency. For example, the resolution of $[Ru(phen)_3]^{2+}$ was significantly more efficient than $[Ru(bpy)_3]^{2+}$ using both the (+)-tartrate salts as eluents.

The order of elution of the two enantiomeric forms was also observed to be significantly influenced by the chirality of the eluent. For example, elution of the complex $[Ru(bpy)_3]^{2+}$ with sodium (−)-*O,O′*-di-4-toluoyl-L-tartrate solution or sodium (−)-*O,O′*-dibenzoyl-L-tartrate solutions resulted in resolution with the first eluted band (Band 1) as the Δ-(−) enantiomer and the second eluted band (Band 2) as Λ-(+) enantiomer. This elution order is reversed when eluting with aqueous sodium (+)-*O,O′*-di-4-toluoyl-D-tartrate and sodium (+)-*O,O′*-dibenzoyl-D-tartrate (Table 3). This observation suggests the Δ enantiomer of the complex has a higher degree of association with the (−) forms of the two anions, reducing its effective charge (relative to the Λ enantiomer), and thus leading to the resolution.

However, this "band switching" was not observed in the complexes containing ligands with one or more methyl-substituents (e.g. $[Ru(bpy)_2(Me_2bpy)]^{2+}$ and $[Ru(Me_2bpy)_3]^{2+}$); in those cases the (−)-enantiomer was eluted first independent of the eluent or its chirality. This is presumably a result of the increased hydrophobic interactions between the Sephadex support and the methyl-substituted ligands, leading to the chirality of the Sephadex dominating the elution order of the enantiomeric forms. For the elution order of the enantiomers of $[Ru(bpy)_3]^{2+}$ and $[Ru(phen)_3]^{2+}$ to be dependent on the chirality of the eluent, the interaction between the complex and the eluent must be significantly greater than the interaction of the enantiomeric forms with the Sephadex support. The involvement of the support in the chromatographic resolution of dinuclear complexes has also been reported previously.[30] These simultaneous interactions of the target cation with the support itself and the chiral anion of the eluent may be cooperative or in opposition, with the consequence that the two enantiomeric forms of the eluent have unequal efficiencies in achieving the resolution of a particular substrate.

The study demonstrates the effectiveness of the technique for the chiral resolution of tris(bidentate) polypyridyl complexes of ruthenium, and provides an appreciation of the factors involved for efficient chiral resolution in terms of the nature of the interactions between the complex, Sephadex support and the chiral eluent.

X-ray Structural Studies

The X-ray crystal structures of (−)-$[Ru(Me_2bpy)_3]$\{(−)-*O,O′*-dibenzoyl-L-tartrate\}·6 H_2O (**1**; Figure 4) and (+)-$[Ru(phen)_3]$\{(+)-*O,O′*-di-4-toluoyl-D-tartrate\}·8 H_2O (**2**; Figure 5) are reported. The incorporation of an anion of known chirality allowed ready and unambiguous assignment of the absolute configuration of the respective cations as Δ and Λ. Such assignments are significant: while there have been a number of structural determinations of tris(bidentate)ruthenium(II) complexes containing polypyridyl ligands, a vast majority have involved racemic samples. There are in fact very few structural confirmations of chirality within complexes of this genre, and in view of recent interest in the control of the stereochemistry of polymetallic assemblies incorporating such centres as components,[6][7][49] such confirmations are timely. In this case, the determination of the chirality of the (+)-$[Ru(phen)_3]^{2+}$ cation as Λ

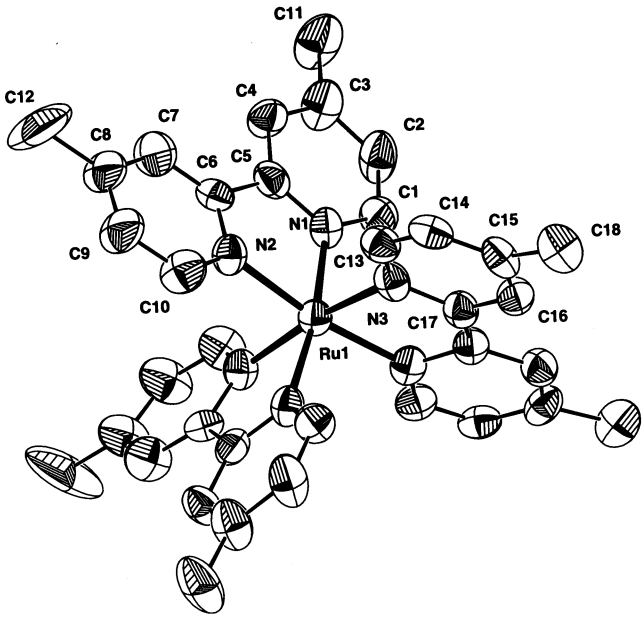
confirms earlier CD analyses based on exciton theory,[32][33][34][35][36] and the recent structural determination by Maloney and MacDonnell,[38] which utilised the technique of fractal analysis in the assignment. Bond lengths and angles are typical for such complexes.[38][50][51][52][53]

Figure 4. X-ray structure of one of the unique Δ-(−)-$[Ru(Me_2bpy)_3]^{2+}$ cations in compound (−)-$[Ru(Me_2bpy)_3]${(−)-*O,O′*-dibenzoyl-L-tartrate} (**1**) which resides on a two-fold rotation axis; hydrogen atoms have been omitted for clarity



The packing diagram for the structure of **2** is shown in Figure 6, and attention is draw to a particular feature. The $[Ru(phen)_3]^{2+}$ cations form layers which alternate with layers containing water molecules. The (+)-*O,O′*-di-4-toluoyl-D-tartrate anions are positioned such that the tartrate backbone (containing the two carboxylate functionalities) reside in the water layer (hydrophilic), while the toluoyl rings penetrate into a virtually hydrophobic region in the complex cations where they essentially π-stack with the phenanthroline rings. The distance between the toluoyl and phenanthroline rings varies in the range 3.4−3.9 Å, which is consistent with π-stacking, for which a spacing of ca. 3.5 Å is considered normal.[54] While this present observation is made in the solid state, the interaction supports our proposal for the mode of association of anions with such complexes in solution (based on ^{1}H-NMR evidence),[30][31] which we assert is a major contributing factor to the mechanism of separation of complexes (and their stereoisomers) in cation-exchange chromatographic techniques involving the organic counter-anions in the eluents.

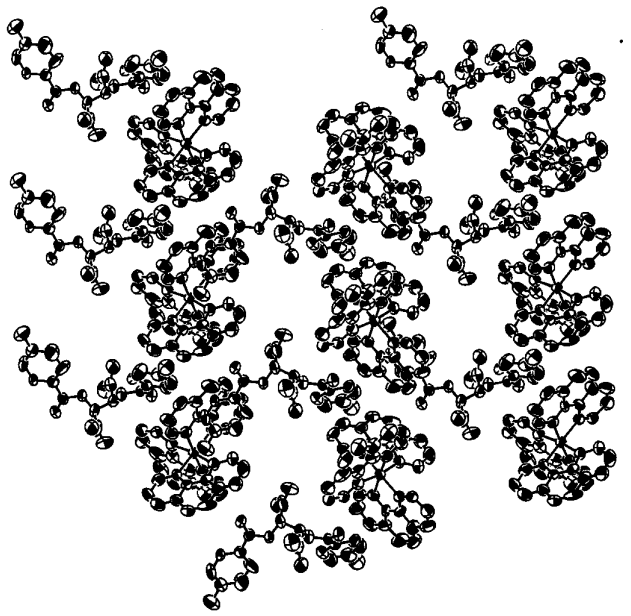
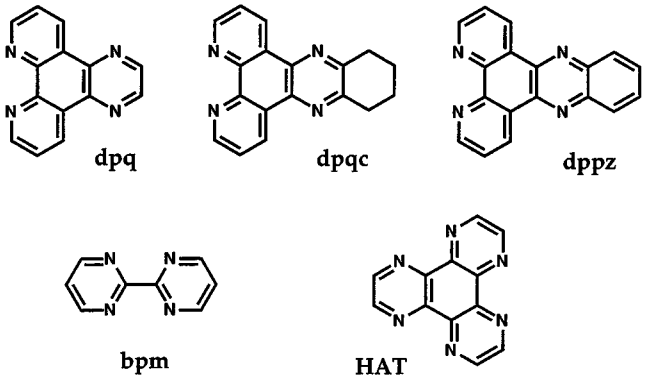
Figure 6. Packing diagram for Λ-(+)-[Ru(phen)$_3$]{(+)-*O,O′*-di-4-toluoyl-D-tartrate}·8 H_2O (**2**) showing penetration of the toluoyl residues of the anion into the hydrophobic cationic layer; the carboxylate groups reside in the hydrophilic layer; water molecules have been omitted for clarity



solved. Each of the complexes [Ru(bpy)$_2$(pp′)]$^{2+}$ and [Ru(Me$_2$bpy)$_2$(pp′)]$^{2+}$ {pp′ = phen (1,10-phenanthroline), dpq (dipyrido[3,2-*d*:2,3′-*f*]quinoxaline), dpqc (dipyrido[3,2-*a*:2,3-*d*]-6,7,8,9-tetrahydrophenazine), and dppz {dipyrido[3,2-*a*:2,3′-*d*]phenazine)}, and [Ru(phen)$_2$(pp′′)]$^{2+}$ (pp′′ = dpq, dpqc, and dppz) were resolved by the cation-exchange chromatographic procedure on SP Sephadex C-25 support using sodium (−)-*O,O′*-dibenzoyl-L-tartrate solution as eluent. Aqueous K (+)-SbOtart solution was also used as eluent for the resolution of [Ru(phen)$_2$(dpqc)]$^{2+}$ and [Ru(phen)$_2$(dppz)]$^{2+}$. Additionally, [Ru(bpy)$_2$(dpqc)]$^{2+}$ and [Ru(bpy)$_2$(dppz)]$^{2+}$ were also obtained in specific enantiomeric forms by the reaction of the respective ligands with resolved [Ru(bpy)$_2$(py)$_2$]$^{2+}$.[19]



This general method for chiral resolution is significant as there have been a number of studies of the nature of the interaction of such complexes with polynucleotides, aimed at the assessment of their potential as photoprobes in sequencing and in cleavage reactions of DNA.[12][13][14]

Analogous bis-heteroleptic complexes [Ru(Me$_2$bpy)$_2$(bpy)]$^{2+}$, [Ru(Me$_2$bpy)(bpy)$_2$]$^{2+}$, [Ru(Me$_2$bpy)$_2$(phen)]$^{2+}$, and [Ru(bpy)(phen)$_2$]$^{2+}$ were also resolved chromatographically {aqueous sodium (+)-*O,O′*-dibenzoyl-D-tartrate solution eluent}. It is also noted that we have previously reported the chromatographic resolution of a tris-heteroleptic species, [Ru(phen)(Me$_4$bpy)(bpm)]$^{2+}$, using aqueous sodium (−)-*O,O′*-dibenzoyl-L-tartrate solution as eluent.[16]

The incorporation of potential bridging ligands such as 2,2′-bipyrimidine (bpm) or 1,4,5,8,9,12-hexaazatriphenylene (HAT) in such chiral tris(bidentate) metal centres provides the potential basis of stereochemical control in the construction of polymetallic ligand-bridged assemblies.[6][7] In such a context, we also chromatographically resolved the tris-homoleptic complexes [Ru(bpm)$_3$]$^{2+}$ and [Ru(HAT)$_3$]$^{2+}$ by these techniques using 0.1 M sodium (−)-*O,O′*-dibenzoyl-L-tartrate solution as eluent.

Summary

The chiral building blocks Δ- and Λ-[Ru(pp)$_2$(CO)$_2$]$^{2+}$ (where pp = bpy, phen, and Me$_2$bpy) were obtained by diastereoisomeric salt formation, and their enantiomeric purity established by ^{1}H-NMR spectroscopy using the chiral lanthanide-shift reagent [Eu(tfc)$_3$]. These species were demonstrated to undergo decarbonylation to form tris(bidentate) complexes with retention of stereochemical integrity under certain reaction conditions. Their absolute configurations were established by comparison of the configuration of the products with the the X-ray crystal structure determinations of the diastereoisomeric salts Δ-(−)-[Ru(Me$_2$bpy)$_3$]{(−)-*O,O′*-dibenzoyl-L-tartrate} and Λ-(+)-[Ru(phen)$_3$]{(+)-*O,O′*-di-4-toluoyl-D-tartrate}, and comparison of CD spectra with compounds whose configuration has previously assigned by exciton analysis.

The development of a cation-exchange chromatographic resolution procedure provided an efficient means of obtaining a wide range of enantiomerically-pure tris(bidentate)ruthenium(II) complexes containing polypyridyl ligands, which have application as chiral building blocks for oligomeric assemblies, or as chiral probes for biological molecules (e.g. polynucleotides, DNA).

This work was supported by the *Australian Research Council,* and Research Grants Schemes with both *James Cook University* and the *University of Western Sydney.* We thank Professor *R. S. Vagg* for access to the CD facilities at Macquarie University, and Ms. *Sue Butler* for measurement of the CD spectra at the University of Wollongong. We are grateful to Dr. *Nick Fletcher* and Dr. *Brett Yeomans* for useful comments on the manuscript.

Experimental Section

Materials, Instrumentation, and Techniques: The following chemicals were used without further purification: 2,2′-bipyridine (bpy, 99+%; Aldrich), 1,10-phenanthroline (phen, 99+% anhydrous; Aldrich), 4,4′-dimethyl-2,2′-bipyridine (Me$_2$bpy, 99%; Aldrich),

tris[3-(trifluoromethylhydroxymethylene)-*d*-camphorato]europium-(III) {Eu(tfc)$_3$, 97%; Fluka}, ruthenium(III) chloride hydrate ($RuCl_3$, 99.9%; Strem), potassium hexafluorophoshate (KPF_6, 98%; Aldrich), 2,3-bis(2-pyridyl)pyrazine (dpp, 98%; Aldrich), 2,2′-bipyrimidine (bpm, 98+%; Lancaster), sodium hydroxide (BDH), sodium chloride (BDH), sodium toluene-4-sulfonate (95%; Aldrich), potassium antimonyl (+)-tartrate hydrate {K(+)-SbOtart, 99+%, $[\alpha]_D$ = +141; Aldrich}, (−)-*O,O′*-di-4-toluoyl-L-tartaric acid (98+%, $[\alpha]_D$ = −139; Fluka), (+)-*O,O′*-di-4-toluoyl-D-tartaric acid (97%, $[\alpha]_D$ = +139; Aldrich), (+)-*O,O′*-dibenzoyl-D-tartaric acid (99%, $[\alpha]_D$ = +117; Fluka), (−)-*O,O′*-dibenzoyl-L-tartaric acid (99+%, $[\alpha]_D$ = −117; Fluka), tetra-*n*-butylammonium bromide (TBABr, 99%; Aldrich), tetra-*n*-butylammonium iodide (TBAI, 98+%; BDH) and tetraethylammonium chloride (TEACl, > 98%; Fluka).

The ligands dpq,[55] dpqc,[56] and dppz[57] were prepared as reported previously.

$[Ru(pp)_2Cl_2]$,[58] $[Ru(CO)_2Cl_2]_n$, $[Ru(pp)(CO)_2Cl_2]$, and $[Ru(pp)_2(CO)_2](PF_6)_2$ pp = Me_2bpy, phen, and bpy),[59] $[Ru(OH_2)_6]$(toluene-4-sulfonate)$_2$,[60] and $[Ru(DMSO)_4Cl_2]$ (DMSO = dimethyl sulfoxide)[61] were prepared as reported previously. $[Ru(bpy)_3](PF_6)_2$, $[Ru(Me_2bpy)_3](PF_6)_2$, $[Ru(bpy)_2(Me_2bpy)](PF_6)_2$ $[Ru(Me_2bpy)_2(bpy)](PF_6)_2$, $[Ru(Me_4bpy)_3](PF_6)_2$ and $[Ru(phen)_3](PF_6)_2$ were synthesized in a manner similar to the literature methods,[62] except that they were isolated as the PF_6^- salts by addition of KPF_6. Their ^{1}H-NMR and electronic spectra were in agreement with those reported previously.[4][63][64] Δ- and Λ-$[Ru(bpy)_2(py)_2]^{2+}$ were obtained by diastereoisomeric salt fomation with the chiral anion *O,O′*-dibenzoyltartrate, as described previously.[18][19]

Trifluoromethanesulfonic acid (3 M) was distilled under vacuum prior to use. Trimethylamine *N*-oxide hydrate (TMNO, Aldrich) was sublimed under vacuum at 120°C and stored under argon. 4,4′,5,5′-Tetramethyl-2,2′-bipyridine (Me_4bpy) was kindly supplied by Michael Quagliotto and was prepared according to a literature method.[16][65] Silver antimonyl (−)-tartrate {Ag (−)-SbOtart} and silver antimonyl (+)-tartrate {Ag (+)-SbOtart} were prepared according to a literature method.[66]

Electronic spectra, elemental analyses, and optical rotations were recorded as described previously.[48] CD (circular dichroism) spectra were measured using either a Jobin Yvon Dichrograph 6 or a JASCO-500C spectropolarimeter. Mass spectra were recorded with a Fisons/VG Biotech Quattra (Altrinchem, U.K.) instrument which is a tandem mass spectrometer with quadrupoles for MS1 and MS2, each with a mass range of 4000 amu for single-charged ions, a hexapole collision cell and photomultiplier detectors. The samples were dissolved in acetonitrile (50−100 pmol/μl).

Chromatographic procedures were carried out using SP Sephadex C-25 cation exchanger as the support and aqueous sodium chloride, sodium toluene-4-sulfonate, sodium (−)-*O,O′*-dibenzoyl-L-tartrate, sodium (+)-*O,O′*-dibenzoyl-D-tartrate, sodium (−)-*O,O′*-di-4-toluoyl-L-tartrate or sodium (+)-*O,O′*-di-4-toluoyl-D-tartrate solutions as eluents. The tartrate salts were prepared by the neutralization of the respective acids with sodium hydroxide. The support was contained in a column approximately 100 cm long × 2 cm diameter and the flow rate was controlled at ca. 1.5 ml/min. When necessary, the column was sealed enabling the complex to be recycled several times down its length with the aid of a peristaltic pump: in these cases, an "effective column length" (ECL) for the separation represents the length of support travelled by the sample for visual band separation. All chromatography was carried out in subdued light.

X-Ray Crystal Structure Determinations: Crystals of (−)-$[Ru(Me_2bpy)_3]$\{(−)-*O,O′*-dibenzoyl-L-tartrate\} (**1**) and (+)-$[Ru(phen)_3]$\{(+)-*O,O′*-di-4-toluoyl-D-tartrate\} (**2**) were grown by slow concentration of aqueous solutions of the respective salts. Unique room-temperature diffractometer data sets ($T \approx 295$ K; monochromatic Mo-K_α radiation, $\lambda = 0.7107_3$ Å; 2θ/θ scan mode; 2−50°) were measured on an Enraf-Nonius CAD4 diffractometer, yielding N_o independent reflections, N_o with $I > 3\sigma(I)$ being considered "observed" and used in the large-block least-squares refinements.

For both compounds, anisotropic thermal parameters were refined for all non-hydrogen atoms, except the oxygen atoms of the hydration water molecules (due to high thermal motion and disorder, see below). Hydrogen atoms were placed in calculated positions and were not refined. Two oxygen atoms in compound **1** were disordered and were successfully modelled with half occupancies {O(5w), O(6w), O(7w) and O(8w)}. Likewise in compound **2** two water molecules were also disordered and were modelled with half occupancies {O(1w), O(4w), O(5w) and O(7w)}. Conventional residuals R, R_w on F are quoted, statistical weights derivatives of $\sigma^2(I) = \sigma^2(I_{diff}) + 0.0004\sigma^4(I_{diff})$ being used. Neutral atom complex scattering factors were employed, and computation was by the XTAL 3.4 program system, implemented by S. R. Hall.[67] A summary of crystal data and data collection is compiled in Table 4 and structures are shown in Figures 4 and 5; material deposited comprises all atomic coordinates and thermal parameters, complete bond lengths and angles and full non-hydrogen atom geometries.

Synthetic and Stereochemical Studies

Homoleptic Dicarbonyl Ruthenium(II) Complexes: The $[Ru(phen)_2(CO)_2](PF_6)_2$ species was converted to the bromide salt by metathesis with TBABr in acetone. For ^{1}H-NMR, UV/Vis, and ORD measurements, the bromide salt was converted to the chloride by anion-exchange chromatography. $[Ru(Me_2bpy)_2(CO)_2](PF_6)_2$ and $[Ru(bpy)_2(CO)_2](PF_6)_2$ were converted to the respective bromide salts by metathesis with TBABr in 2-butanone. The chloride salts were obtained as described above.

^{1}H NMR ([D$_3$]acetonitrile): *[Ru(phen)$_2$(CO)$_2$]Cl$_2$:* δ = 7.63 [m, 4 H], 8.25 [d, 2 H, J = 9 Hz], 8.29 [dd, 2 H, J = 5.5, 8 Hz], 8.36 [d, 2 H, J = 9 Hz], 8.71 [dd, 2 H, J = 5.5, 1.5 Hz], 9.10 [d, 2 H, J = 8 Hz], 9.60 [d, 2 H, J = 5 Hz]. *[Ru(bpy)$_2$(CO)$_2$]Cl$_2$:* δ = 7.42 [d, 2 H, J = 5 Hz], 7.51 [ddd, 2 H, J = 8, 6, 1 Hz], 7.94 [ddd, 2 H, J = 8, 6, 1 Hz], 8.22 [td, 2 H, J = 8, 1 Hz], 8.48 [td, 2 H, J = 8, 1 Hz], 8.82 [d, 2 H, J = 8 Hz], 8.96 [d, 2 H, J = 8 Hz], 9.14 [d, 2 H, J = 5 Hz]. − ^{1}H NMR ([D$_2$]dichloromethane): *[Ru(Me$_2$-bpy)$_2$(CO)$_2$]Cl$_2$:* δ = 2.57 [s, 6 H], 2.61 [s, 6 H], 7.37 [m, 4 H], 7.78 [d, 2 H, J = 5.5 Hz], 9.04 [d, 2 H, J = 5.5 Hz], 9.11 [s, 2 H], 9.28 [s, 2 H]. UV/Vis [λ (ε), H_2O]: *[Ru(phen)$_2$(CO)$_2$]Cl$_2$:* 226 nm (57900), 274 (52100), 305 (15000). *[Ru(bpy)$_2$(CO)$_2$]Cl$_2$:* 210 nm (35600), 250 (26200), 306 (24800). *[Ru(Me$_2$bpy)$_2$(CO)$_2$]Cl$_2$:* 214 nm (43800), 252 (26900), 302 (23300), 312 (22900).

Λ-[Ru(phen)$_2$(CO)$_2$]\{(+)-SbOtart\}$_2$·3 H$_2$O: $[Ru(phen)_2(CO)_2]Br_2$ (1.369 g, 2.019 mmol) was stirred in the minimum of distilled water for dissolution, and Ag(+)-SbOtart (1.589 g, 4.038 mmol) added. The mixture was stirred over glass balls for ca. 30 min in subdued light, then filtered through Celite to remove AgBr, and the filtrate concentrated to dryness. Yield 2.00 g, 90%. − $C_{33}H_{26}N_4O_{17}RuSb_2$: calcd. C 36.2, H 2.39, N 5.1%; found: C 36.2, H 2.25, N 5.0%.

(+)-$[Ru(phen)_2(CO)_2]$\{(+)-SbOtart\}$_2$ was dissolved in a minimum volume of hot water and methanol added dropwise until the appearance of a faint cloudiness. The mixture was stored at 4°C

overnight, the product collected and the precipitation procedure repeated a further two times. The precipitate was collected and either converted to the Cl^- salt by anion exchange or precipitated by the addition of KPF_6 to yield [Ru(phen)$_2$(CO)$_2$]Cl_2 or [Ru(phen)$_2$(CO)$_2$](PF_6)$_2$, respectively. Λ-(+)-[Ru(phen)$_2$(CO)$_2$]Cl_2: $[\alpha]_{365}$ (water) = +2320, $[M]_{365}$ (water) = +13640. Λ-(+)-[Ru(phen)$_2$(CO)$_2$](PF_6)$_2$: CD [λ (Δε), CH_3CN] = 211 nm (−55), 236 (−40), 262(−67), 278 (+315), 316 (−17).

The enantiomeric form was obtained in an analogous manner, using Ag(−)-SbOtart.

Δ-(−)-[Ru(phen)$_2$(CO)$_2$]Cl_2: $[\alpha]_{365}$ (water) = −2330 and $[M]_{365}$ (water) = −13710. Δ-(−)-[Ru(phen)$_2$(CO)$_2$](PF_6)$_2$: CD [λ (Δε), CH_3CN] = 211 nm (+54), 236(+41), 262 (+70), 278 (−322), 316 (+19).

Δ-[Ru(bpy)$_2$(CO)$_2$]{(+)-SbOtart}$_2$·2 H_2O: [Ru(bpy)$_2$(CO)$_2$]{(+)-SbOtart}$_2$·2 H_2O was prepared in an identical manner to that described above, using [Ru(bpy)$_2$(CO)$_2$]Br_2 in place of [Ru(phen)$_2$(CO)$_2$]Br_2. − $C_{29}H_{24}N_4O_{16}RuSb_2$: calcd. C 33.8, H 2.35, N 5.3; found C 33.8, H 2.31, N 5.3. − The diastereoisomer was recrystallized four times from methanol, the collected product being washed with cold methanol, ether, and air-dried. The product was then converted to the chloride and hexafluorophosphate salts as described above. Δ-(−)-[Ru(bpy)$_2$(CO)$_2$]Cl_2: $[\alpha]_{365}$ (water) = −1020 and $[M]_{365}$ (water) = −5570. Δ-(−)-[Ru(bpy)$_2$(CO)$_2$](PF_6)$_2$: CD [λ (Δε), CH_3CN] = 231 nm (−13), 244 (+11), 258 (−46), 278 (−31), 301 (+22), 319 (−47), 327 (+9).

The enantiomeric form was obtained in an analogous manner, using Ag(−)-SbOtart. Λ-(+)-[Ru(bpy)$_2$(CO)$_2$]Cl_2: $[\alpha]_{365}$ (water) = +1025 and $[M]_{365}$ (water) = +5545. Λ-(+)-[Ru(bpy)$_2$(CO)$_2$](PF_6)$_2$: CD [λ (Δε), CH_3CN] = 231 nm (+13), 244 (−10), 258 (+43), 278 (+31), 301 (−18), 319 (+45), 327 (−8).

(+)-[Ru(Me$_2$bpy)$_2$(CO)$_2$]{(+)-SbOtart}$_2$·H_2O: [Ru(Me$_2$bpy)$_2$(CO)$_2$]{(+)-SbOtart}$_2$·H_2O was prepared in an identical manner to that described above using [Ru(Me$_2$bpy)$_2$(CO)$_2$]Br_2 in place of [Ru(phen)$_2$(CO)$_2$]Br_2. − $C_{33}H_{30}N_4O_{15}RuSb_2$: calcd. C 37.1, H 2.83, N 5.3; found C 37.4, H 2.72, N 5.3. − The diastereoisomer was recrystallized twice from methanol. The product was stirred with boiling methanol (ca. 20 ml) and collected by filtration while hot. The precipitate was washed with methanol, ether, and air-dried. The product was then converted to the chloride and hexafluorophosphate salts as described above. (+)-[Ru(Me$_2$bpy)$_2$(CO)$_2$]Cl_2: $[\alpha]_{365}$ (water) = +840 and $[M]_{365}$ (water) = +5006.

Decarbonylation Reactions of Δ- or Λ-[Ru(pp)$_2$(CO)$_2$]$^{2+}$

Λ-(+)-[Ru(phen)$_3$]Cl_2: (+)-[Ru(phen)$_2$(CO)$_2$](PF_6)$_2$ (20 mg, 0.0247 mmol) was dissolved in 2-methoxyethanol (10 ml) and the solution purged with N_2 for 20 min prior to the addition of phen (44 mg, 0.247 mmol). TMNO (12 mg, 0.116 mmol) was then added and the reaction mixture stirred at room temperature in subdued light for 72 h. The reaction mixture was diluted with water and the product purified by cation exchange chromatography (SP Sephadex C25, eluent 0.2 M NaCl). The orange band was collected and precipitated as the PF_6^- salt by the addition of a saturated solution of KPF_6, which was collected by filtration and washed with water, ether, and air dried. Yield: 8 mg, 40%. NMR spectra were in agreement with those published previously for $[Ru(phen)_3]^{2+}$.[63][68] Λ-(+)-[Ru(phen)$_3$](PF_6)$_2$: $[\alpha]_{546}$ (CH_3CN) = +2000. The complex was converted to the chloride salt by metathesis from acetone solution using TEACl. $[\alpha]_D$ (water) = +1385; ref.[10][35] +1340.

The above reaction was repeated at a series of temperatures and reaction times, with all other conditions remaining identical, and $[\alpha]_D$ values measured as the chloride salts in water: 45°C for 24 h; yield 48%, $[\alpha]_D$ = +1330; 60°C for 6 h; yield 62%, $[\alpha]_D$ = +1134; 120°C for 3 h; yield 75%, $[\alpha]_D$ = +980. Microwave (low power) using ethylene glycol/10% water for 40 s; yield 78%, $[\alpha]_D$ = +938.

Δ-(-)-[Ru(bpy)$_3$]I_2: Bpy (30 mg, 0.197 mmol) was dissolved in 2-methoxyethanol (5 ml) and the solution purged with N_2 for 20 min. (−)-[Ru(bpy)$_2$(CO)$_2$](PF_6)$_2$ (15 mg, 0.0197 mmol) and TMNO (10 mg, 0.133 mmol) were added and the mixture stirred at room temperature for 72 h in subdued light, and after addition of water purification was achieved as described for Λ-(+)-[Ru(phen)$_3$]Cl_2.

Yield: 9 mg, 58%. The NMR spectrum was in agreement with the literature.[63][68] The complex was converted to the iodide salt by metathesis with TBAI in 2-butanone solution. $[\alpha]_D$ and $[M]_D$ (water) = −816 and −6740 respectively; ref.[9][35] $[\alpha]_D$ and $[M]_D$ = −819and −6750, respectively.

The above reaction was repeated at 120°C for 3 h with all other conditions identical; yield 81%, $[\alpha]_D$ = −254.

The above reaction was repeated at 120°C for 3 h with a 30-fold excess of bpy and 20-fold excess of TMNO with all other conditions identical; yield 85%, $[\alpha]_D$ = −300.

Λ-(+)-[Ru(Me$_2$bpy)$_3$]Cl$_2$: (+)-[Ru(Me$_2$bpy)$_3$]Cl$_2$ was formed by the decarbonylation of (+)-[Ru(Me$_2$bpy)$_2$(CO)$_2$](PF$_6$)$_2$ in the presence of an excess of Me$_2$bpy, but otherwise under identical conditions to those described for Λ-(+)-[Ru(phen)$_3$]Cl$_2$; yield 40%. The NMR spectrum was in agreement with that described previously.[63] Λ-(+)-[Ru(Me$_2$bpy)$_3$](PF$_6$)$_2$ $[\alpha]_{546}$ (CH_3CN) = +972 and $[M]_{546}$ = +9164. Chromatographically resolved Λ-(+)-[Ru(Me$_2$bpy)$_3$](PF$_6$)$_2$ (see below): $[\alpha]_{546}$ = +1045 and $[M]_{546}$ = +9845. (See above for X-ray structural determination of absolute configuration.)

The above reaction was repeated at 120°C for 3 h with all other conditions identical; yield 84%, $[\alpha]_D$ = +920.

Chromatographic Resolutions: The chromatographic resolutions of the mononuclear complexes were all achieved by cation-exchange chromatography (SP Sephadex C-25) using 0.075 M solutions of the eluent specified in the text. The impact of the enantiomeric identity of the eluent anion on the efficiency of the chromatographic resolution procedure {quoted as ECL for the chiral resolution (cm)}, and on the order of elution of the chiral forms of the cation (sign of optical rotation quoted at 589 nm, or the sign of Δε from the CD spectra at the MLCT absorption maximum at ca. 450 nm), was investigated by separately examining the resolution of complex {30 mg} with the eluents sodium (+)- and (−)-*O,O′*-dibenzoyltartrate and sodium (+)- and (−)-*O,O′*-di-4-toluoyltartrate.

Δ.Λ-[Ru(phen)$_3$]$^{2+}$: Chromatographic resolution was achieved using aqueous sodium (−)-*O-O′*-dibenzoyl-L-tartrate solution as the eluent (ECL ≈ 60 cm). The two bands were collected and the products isolated as the PF_6^- salts by addition of a saturated aqueous solution of KPF_6. The two products were converted to the chloride salts by anion exchange. By comparisons with the literature,[35][38] Band 1 (eluted first) was assigned as Δ-(−)-[Ru(phen)$_3$]$^{2+}$ and Band 2 (eluted second) as Λ-(+)-[Ru(phen)$_3$]$^{2+}$ with $[\alpha]_D$ (water) = −1310 and +1400 respectively (literature values of −1330 and +1340).[10] − CD [λ (Δε), CH_3CN]: Δ-(−): 227 nm (−19), 234 (33), 259 (437), 268 (−602), 296 (−72), 385 (+7), 419 (15), 464 (−22); Λ-(+): 227 (10), 234 (−33), 259 (−430), 268 (582), 296 (87), 385 (−7), 419 (−15), 464 (23).

Elution with sodium (−)-*O,O′*-dibenzoyl-L-tartrate, sodium (+)-*O,O′*-dibenzoyl-D-tartrate, sodium (−)-*O,O′*-di-4-toluoyl-L-tartrate and sodium (+)-*O,O′*-di-4-toluoyl-D-tartrate solutions demonstrated resolution at ECL ≈ 70 cm (Band 1 having a negative and Band 2 a positive rotation), ECL ≈ 30 cm (Band 1 positive), ECL ≈ 80 cm (Band 1 negative) and ECL ≈ 25 cm (Band 1 positive) respectively.

Δ.Λ-[Ru(bpy)$_3$]$^{2+}$: Chromatographic resolution was achieved for [Ru(bpy)$_3$]$^{2+}$ using aqueous sodium (−)-*O,O′*-dibenzoyl-L-tartrate solution at ECL ≈ 55 cm {$[\alpha]_{546}$ (water; I^- salt) − Band 1 = −824 and Band 2 = +817} (literature values of −819[9][35]), sodium (−)-*O,O′*-di-4-toluoyl-L-tartrate at ECL ≈ 30 cm (Band 1 negative rotation) and sodium (+)-*O,O′*-di-4-toluoyl-D-tartrate at ECL ≈ 120 (Band 1 positive rotation). − CD [λ (Δε), CH_3CN]: Δ-(−): 240 nm (24), 257 (−12), 278 (149), 292 (−331), 323 (21), 358 (12), 418 (23), 469 (−18); Λ-(+): 240 (−23), 257 (12), 278 (−147), 292 (347), 323 (−20), 358 (−12), 418 (−22), 469 (18).

Λ-(+)/Δ-(−)-[Ru(Me$_2$bpy)$_3$]$^{2+}$: Chromatographic resolution was achieved for [Ru(Me$_2$bpy)$_3$]$^{2+}$ using aqueous sodium (−)-*O,O′*-dibenzoyl-L-tartrate solution at ECL ≈ 30 cm, $[\alpha]_{546}$ and $[M]_{546}$ (CH_3CN; PF_6^-): Band 1 = −1060 and −10027 respectively and Band 2 = +1045 and +9845, respectively; sodium (−)-*O,O′*-di-4-toluoyl-L-tartrate at ECL ≈ 80 cm (Band 1 negative rotation); and sodium (+)-*O,O′*-di-4-toluoyl-D-tartrate at ECL ≈ 22 cm (Band 1 negative). − CD [λ (Δε), CH_3CN]: Δ-(−): 231 (54), 260 (−7), 277 (142), 292 (−351), 328 (18), 367 (11), 424 (21), 477 (−17); Λ-(+): 231 (−55), 260 (4), 277 (−141), 292 (357), 328 (−18), 367 (−11), 424 (−21), 477 (19).

Λ-(+)/Δ-(−)-[Ru(Me$_4$bpy)$_3$]$^{2+}$: Chromatographic resolution was achieved for [Ru(Me$_4$bpy)$_3$]$^{2+}$ using aqueous sodium (−)-*O,O′*-dibenzoyl-L-tartrate solution at ECL ≈ 20 cm, $[\alpha]_{546}$ and $[M]_{546}$ (CH_3CN; PF_6^-): Band 1 = −831 and −8530 respectively and Band 2 = 839 and +8631 respectively, and for sodium (−)-*O,O′*-di-4-toluoyl-L-tartrate eluent at ECL ≈ 40 cm (Band 1 negative rotation), sodium(+)-*O,O′*-di-4-toluoyl-D-tartrate eluent at ECL > 120 cm (Band 1 negative). − CD [λ (Δε), CH_3CN]: Δ-(−): 234 nm (49), 283 (180), 299 (−361), 329 (19), 366 (12), 418 (22), 468 (−17); Λ-(+): 234 (−48), 283 (−178), 299 (357), 329 (−19), 366 (−12), 418 (−22), 468 (17).

(+)/(−)-[Ru(Me$_2$bpy)$_2$(bpy)]$^{2+}$ and [Ru(Me$_2$bpy)(bpy)$_2$]$^{2+}$: Chromatographic resolution was observed for [Ru(Me$_2$bpy)$_2$(bpy)]$^{2+}$ and [Ru(Me$_2$bpy)(bpy)$_2$]$^{2+}$ using aqueous sodium (+)-*O,O′*-di-4-toluoyl-D-tartrate solution as eluent, where ECL ≈ 65 and 70 cm, respectively (Band 1 negative rotation).

[Ru(pp)$_2$(pp′)](PF$_6$)$_2$ {pp = bpy or Me$_2$bpy; pp′ = phen, dpq, dpqc, or dppz} and [Ru(phen)$_2$(pp′′)](PF$_6$)$_2$ {pp′′ = dpq, dpqc, or dppz} were synthesized by a literature procedure.[69] The respective [Ru(pp)$_2$Cl$_2$] precursor in 50% aqueous ethanol was refluxed in the presence of a slight excess of the third bidentate ligand for 2 h. Ethanol was evaporated from the solution, which was filtered before the dropwise addition of a saturated solution of KPF_6 to give an orange precipitate which was collected by filtration, washed with ice/water, and dried at 100°C. The complexes were purified by chromatography on alumina (acetonitrile eluent). the major band collected and concentrated to dryness. Yields were typically in the range 60−80%. Mass spectra *m/z* observed for all species were within 0.5 amu of the values calculated for [Ru(pp)$_2$(pp′)](PF$_6$)$^+$. ^{1}H-NMR spectra were consistent with the complex formulations. Visible spectra [λ_{max} (MLCT) (ε), CH_3CN]: [Ru(bpy)$_2$(phen)]$^{2+}$ 452 (14900); [Ru(bpy)$_2$(dpq)]$^{2+}$ 449 (14500); [Ru(bpy)$_2$(dpqc)]$^{2+}$ 451 (16200); [Ru(bpy)$_2$(dppz)]$^{2+}$ 448 (16400); [Ru(Me$_2$bpy)$_2$(phen)]$^{2+}$ 456 (14100); [Ru(Me$_2$bpy)$_2$(dpq)]$^{2+}$ 439 (13900); [Ru(Me$_2$bpy)$_2$(dpqc)]$^{2+}$ 452 (15200); [Ru(Me$_2$bpy)$_2$(dppz)]$^{2+}$ 443 (16100); [Ru(phen)$_2$(dpq)]$^{2+}$ 446 (17300); [Ru(phen)$_2$(dpqc)]$^{2+}$ 448 (14300); [Ru(phen)$_2$(dppz)]$^{2+}$ 439 (16100).

Chiral Resolution of [Ru(pp)$_2$(pp′)]$^{2+}$ Cations: All cations were chromatographically resolved on SP Sephadex C-25 support using as eluent aqueous 0.1 M sodium (−)-*O,O′*-dibenzoyl-L-tartrate solution containing 5% acetone to maintain complex solubility. In all cases, two distinct enantiomer bands were observable within ECL ≈ 1.5−2 m, and the separated bands were collected after 3 m of passage down the column. The enantiomer with a negative Δε in the CD spectrum at the absorption maximum (ca. 450 nm) was invariably eluted first; by comparison with the CD characteristics of similar complexes (see above), these were assigned the Δ

absolute configuration. CD [λ (Δε), CH_3CN]: $[Ru(bpy)_2(phen)]^{2+}$ Δ 380 nm (58), 457 (−56) and Λ 380 (−59), 457 (55); $[Ru(bpy)_2(dpq)]^{2+}$ Δ 400 (79), 461 (−67) and Λ 400 (−81), 461 (66); $[Ru(bpy)_2(dpqc)]^{2+}$ Δ 412 (62), 468 (−54) and Λ 412 (−64), 468 (54); $[Ru(bpy)_2(dppz)]^{2+}$ Δ 395 (64), 461 (−58) and Λ 395 (−70), 461 (58); $[Ru(Me_2bpy)_2(phen)]^{2+}$ Δ 400 (53), 465 (−54) and Λ 400 (−59), 457 (56.5); $[Ru(Me_2bpy)_2(dpq)]^{2+}$ Δ 415 (53.6), 476 (−38.8) and Λ 415 (−54), 476 (40); $[Ru(Me_2bpy)_2(dpqc)]^{2+}$ Δ 386 (51), 464 (−46) and Λ 386 (−60), 464 (46); $[Ru(Me_2bpy)_2(dppz)]^{2+}$ Δ 390 (63), 467 (−51) and Λ 390 (−70), 467 (51);$[Ru(phen)_2(dpq)]^{2+}$ Δ 396 (30), 456 (−52) and Λ 396 (−33), 456 (51); $[Ru(phen)_2(dpqc)]^{2+}$ Δ 407 (40), 467 (−54) and Λ 407 (−43), 467 (58); $[Ru(phen)_2(dppz)]^{2+}$ Δ 405 (41), 458 (−49) and Λ 405 (−55), 458 (61) {incomplete separation}.

The complexes $[Ru(phen)_2(dpqc)]^{2+}$ and $[Ru(phen)_2(dppz)]^{2+}$ could also be separated using aqueous 0.1 M potassium antimonyl (+)-tartrate solution (containing 10% acetone) as eluent (ECL ≈ 3 m).

The enantiomers of the complexes $[Ru(bpy)_2(dpqc)]^{2+}$ and $[Ru(bpy)_2(dppz)]^{2+}$ were also obtained by the stereoretentive reactions of Δ- or Λ-$[Ru(bpy)_2(py)_2]^{2+}$ with dpqc or dppz, in an analogous manner to that described previously.[18][19]

Synthesis of $[Ru(bpm)_3](PF_6)_2$: $[Ru(H_2O)_6]$(toluene-4-sulfonate)$_2$[60] (100 mg, 0.079 mmol) and bpm (62 mg, 0.394 mmol) were added to ethylene glycol (30 ml) and heated in a microwave oven (medium high) for 45 s. The reaction mixture was diluted with distilled water and purified by cation-exchange chromatography (SP Sephadex C-25, 0.2 M NaCl). The product was precipitated from the orange band by addition of KPF_6, collected and washed with water and diethylether. Yield = 140 mg, 62%. − $C_{24}H_{18}F_{12}N_{12}P_2Ru$: calcd. C 33.3, H 2.09, N 19.4; found: C 33.2, H 2.08, N 19.4. − UV/Vis data was in agreement with the literature.[70] − ^{1}H NMR ([D$_3$]acetonitrile): δ = 9.12 (dd, 6 H, *J* = 5, 2 Hz], 8.15 (dd, 6 H, *J* = 5, 2 Hz], 7.59 (t, 6 H, *J* = 5.5 Hz].

Resolution of $[Ru(bpm)_3]^{2+}$: Resolution was achieved by cation-exchange chromatography using 0.1 M sodium (−)-*O,O′*-dibenzoyl-L-tartrate as the eluent (ECL ≈ 150 cm). The two bands were collected and the enantiomers precipitated by the addition of a saturated solution of KPF_6, reprecipitated twice from acetone/water solution by the addition of KPF_6, collected, washed with cold water and diethyl ether. Comparisons with similar compounds,[15][19][35] enabled the assignment of Δ-(−)-$[Ru(bpm)_3]^{2+}$ (Band 1) $[\alpha]_{546}$ = −909 and $[\alpha]_D$ = −454, CD [λ (Δε), CH_3CN]: 235 nm (+51), 254 (+45), 268 (−210), 320 (−19), 411 (+22), 468 (−14) and Λ-(+)-$[Ru(bpm)_3]^{2+}$ (Band 2) $[\alpha]_{546}$ = +890 and $[\alpha]_D$ = +451, CD [λ (Δε), CH_3CN]: 235 nm (−48), 254 (−40), 268 (+200), 320 (+19), 411 (−21), 468 (+14).

Synthesis of $[Ru(HAT)_3](PF_6)_2$: $[Ru(HAT)_3]^{2+}$ was synthesiszd in a similar manner to that described by Kirsch-De Mesmaeker et al.[71] $[Ru(DMSO)_4Cl_2]$ (65 mg, 0.2 mmol) was dissolved in distilled water (60 ml) and degassed with N_2 for 20 min. HAT (233 mg, 0.99 mmol) was added and the mixture refluxed for 48 h. The reaction mixture was allowed to cool, then filtered to remove unreacted HAT. The orange product was purified by cation-exchange chromatography (SP Sephadex C-25, 0.2 M NaCl) and collected as described above. Yield 140 mg, 64%. − UV/Vis [λ (ε), CH_3CN]: 212 (63800), 274 (64300), 414 (sh), 436 (14180).[71][72] − ^{1}H NMR ([D$_3$]acetonitrile): δ = 9.40 (s, 6 H), 9.14 (d, 6 H, *J* = 2.5 Hz), 8.43 (d, 6 H, *J* = 2.5 Hz).

Resolution of $[Ru(HAT)_3]^{2+}$: Resolution was achieved by cation-exchange chromatography using 0.1 M sodium (−)-*O,O′*-dibenzoyl-L-tartrate solution as the eluent (ECL ≈ 80 cm). The two bands were collected and precipitated by the addition of a saturated solution of KPF_6, reprecipitated twice from acetone/water solution by the addition of KPF_6, collected, washed with cold water, and diethyl ether. Comparisons with similar compounds,[15][19][35] Λ-(+)-$[Ru(HAT)_3]^{2+}$ (Band 1) $[\alpha]_{546}$ = +974 and $[\alpha]_{589}$ = +623, CD [λ (Δε), CH_3CN]: 232 (+8), 250 (−15), 262 (+4), 282 (−6), 314 (+48), 406 (−13), 462 (+12) and Δ-(−)-$[Ru(HAT)_3]^{2+}$ (Band 2) $[\alpha]_{546}$ = −940 and $[\alpha]_{589}$ = −618, CD (λ nm (Δε), CH_3CN): 232 (−8), 250 (+15), 262 (−2), 282 (+7), 314 (−45), 406 (+14), 462 (−11).

Chiral Lanthanide Shift Reagent Studies: All complexes were converted to the Cl^- salts for the chiral-lanthanide shift reagent (CLSR) studies, which were performed on *rac*- and Δ- or Λ-$[Ru(bpy)_2(CO)_2]Cl_2$, $[Ru(phen)_2(CO)_2]Cl_2$, $[Ru(Me_2bpy)_2(CO)_2]Cl_2$ and $[Ru(Me_4bpy)_2(CO)_2]Cl_2$ in [D$_3$]acetonitrile for the former two and [D$_2$]dichloromethane for the latter two complexes. Mol ratios of [Complex]/[CLSR] varied from 0 to 2, depending on solvent and complex. Shift reagent studies were also performed on $[Ru(Me_2bpy)_3]Cl_2$ in [D$_2$]dichloromethane and $[Ru(Me_4bpy)_3]Cl_2$ in [D$_2$]dichloromethane and [D$_3$]acetonitrile. Complexes were dissolved in the solvent at concentrations between $3\cdot10^{-2}$ M and $3\cdot10^{-3}$ M.

Keywords: Phosphanyl-amine / Nickel / Coordination chemistry / Pentacoordinate Ni complexes / Tetracoordinate Ni complexes

New neutral pentacoordinate nickel(II) complexes of the type $[NiCl_2(PR_3)(P^{\frown}N)]$ [PR_3 = PMe_3, PMe_2Ph, $PMePh_2$; $P^{\frown}N$ = 2-(diphenylphosphanyl)aniline ($P^{\frown}NH_2$), *N*-methyl-2-(diphenylphosphanyl)aniline ($P^{\frown}NHMe$), *N,N*-dimethyl-2-(diphenylphosphanyl)aniline ($P^{\frown}NMe_2$)], as well as cationic tetracoordinate nickel(II) complexes of the type $[NiCl(PR_3)(P^{\frown}N)]^+$ have been synthesized and characterized both in the solid state and in solution. Interesting X-ray structural data have been collected for each class of compounds, which show, inter alia, that the pentacoordinate neutral complexes can be isolated in two different molecular forms, namely square-pyramidal or bipyramidal-trigonal.

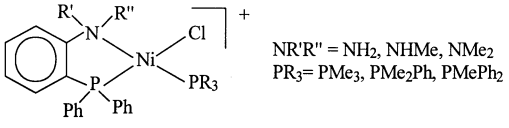
Introduction

The synthesis of metal complexes stabilized by $P^{\frown}N$ ligands and particularly phosphanyl-amines has attracted considerable attention in recent years[1]. The ligands 2-(diphenylphosphanyl)pyridine and 2-(diphenylphosphanyl)aniline give rise to interesting examples. The first is known to exhibit a very versatile coordination behavior towards numerous transition metal centers[2], both in mono- and polynuclear complexes. Remarkably, in these complexes it acts as either a monodentate, a bidentate chelating, or a bidentate bridging ligand. In its monodentate mode, the phosphane ligating site normally exhibits the strongest bonding ability towards metal centers such as nickel(II)[3], cobalt(I)[3], ruthenium(II)[4][5], rhodium(I)[4][6], and palladium(II)[4][7][8]. Conversely, the coordination chemistry of 2-(diphenylphosphanyl)aniline[9] has been widely investigated because of its ability to behave as a bidentate chelating amino[10], amido[11], or imido[12] ligand. This behavior has been further developed in the synthesis of new macrocyclic chelate compounds such as P_2N_2 ligands, which have previously been tested in these laboratories[13]. In particular, the reactivity of the tetradentate ligand *N,N′*-bis[2-(diphenylphosphanyl)phenyl]propane-1,3-diamine, H_2dppd, toward technetium and rhenium has been investigated. This tetradentate phosphanyl-amine behaves both as a ligand and as a reducing agent towards $[MO_4]^-$ (M = Tc, Re) to give hexacoordinate neutral oxo-M^V phosphanyl-amido complexes of the general formula [MO(dppd)X], X = Cl, OH, OMe, OEt, O_2CCF_3.

Similarly, P_2N_2 ligands such as *N,N′*-bis[2-(diphenylphosphanyl)phenyl]ethane-1,2-diamine and *N,N′*-bis[2-(diphenylphosphanyl)phenyl]propane-1,3-diamine have been employed as efficient ligands for preparing unprecedented and previously elusive copper(II) phosphane complexes[14]. These were subjected to X-ray structural analyses and were found to be characterized by authentic thermodynamic stability that was not attributable to kinetic inertness[15]. The finely balanced *soft-hard* character of the $\{P_2N_2\}$ ligating set has been proposed to play a major role in underlying this important result.

The various properties of phosphanyl-amino ligands prompted us to undertake a systematic study aimed at preparing both neutral and cationic nickel(II) complexes of the type shown in Scheme 1 and to evaluate the potential of the cationic species as "SHOP"-type catalysts[16].

Scheme 1



In this paper, we report on the detailed development of this project. Some of the results reported herein were anticipated in a preliminary report[17].

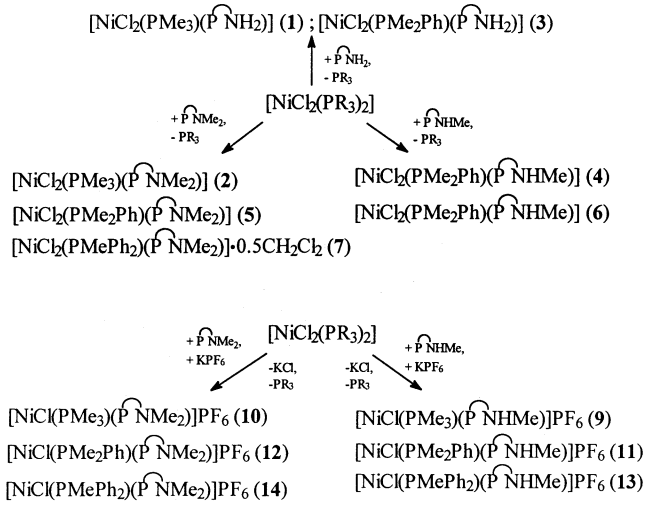
Results and Discussion

A general overview of the scope of the synthetic results is given in Scheme 2. The compounds are obtained upon substitution of one monodentate phosphane by the bidentate one, which chelates the metal through both the P and N atoms.

Scheme 2



$[NiCl_2(PR_3)_2]$ complexes react readily with 2-(diphenylphosphanyl)aniline, $P^{\frown}NH_2$, *N*-methyl-2-(diphenylphosphanyl)aniline, $P^{\frown}NHMe$, and *N*,*N*-dimethyl-2-(diphenylphosphanyl)aniline, $P^{\frown}NMe_2$ (hereafter referred to as $P^{\frown}N$), usually in MeCN solution, to give pentacoordinate species of the type $[NiCl_2(PR_3)(P^{\frown}N)]$ (Table 1).

The same reaction, carried out in CH_2Cl_2 in the presence of KPF_6 as a scavenger of one Cl^- ligand per Ni atom, successfully leads to tetracoordinated species of the type $[NiCl(PR_3)(P^{\frown}N)]^+$ (Table 1), except in the case of $P^{\frown}NH_2$. The action of this tertiary phosphanyl-primary amine on $[NiCl_2(PR_3)_2]$ (PR_3 = PMe_2Ph and $PMePh_2$) leads to the bis-bidentate species $[Ni(P^{\frown}NH_2)_2]^{2+}$[18], and/or to the mononuclear phosphorane-imino complex $[NiCl(PMe_3)(P^{\frown}NP)]^+$[19], [$P^{\frown}NP$ = *N*-(trimethylphosphoranyl)-2-(diphenylphosphanyl)aniline], when PMe_3 is incorporated into the starting material as a mono-tertiary phosphane.

The formation of the pentacoordinate $[NiCl_2(PR_3)(P^{\frown}N)]$ complexes is achieved under stoichiometric conditions in a homogeneous phase after a few hours of reaction time at room temperature. The products can be isolated as analytically pure species either upon spontaneous precipitation or after the addition of Et_2O. All these compounds are rather unstable in solution when exposed to air. Nevertheless, they can be recrystallized from e.g. CH_2Cl_2 (see Experimental Section) and their MeCN solutions provide conductivity measurements consistent with non-conducting species (Table 1).

The formation of the tetracoordinate $[NiCl(PR_3)(P^{\frown}N)]^+$ complexes can also be readily achieved under essentially stoichiometric conditions, by removal of KCl, concentration of the reaction solution, and addition of Et_2O. Cationic complexes $[NiCl(PR_3)(P^{\frown}N)]^+$ can be readily recrystallized from suitable solvent mixtures, such as CH_2Cl_2/EtOH/Et_2O or CH_2Cl_2/EtOH/C_6H_6.

The ability of nickel(II) to give charged and neutral pentacoordinate complexes is well-documented in the literature[20]. Thus, numerous high-spin distorted trigonal-bipyramidal and square-pyramidal complexes are known, which usually contain *hard* donor sites. Quite a few low-spin distorted trigonal-bipyramidal complexes have also been described and, conversely, they typically exhibit an overall *soft* coordination sphere. To the best of our knowledge, only four examples of pentacoordinate complexes with an $\{NP_2Cl_2\}$ donor set have been reported in the literature[17][21][22]; the data presented herein allow the possibility of analyzing this coordination sphere, which is otherwise only poorly documented. The geometry of complex **3** (vide infra) is intermediate between square-pyramidal and trigonal-bipyramidal and this complex is diamagnetic. On the other hand, complexes **5**, **6**·CH_2Cl_2, and **7** are trigonal-bipyramidal and paramagnetic. Ligand sets high in the spectrochemical series are predicted[20] to give diamagnetic trigonal-bipyramidal complexes, but in our case the situation is reversed. Apparently, the ligand field exerted by our ligand set is not large enough to produce a singlet fundamental electronic state. Moreover, complexes **2** and **4** are characterized by magnetic moment values formally corresponding to less than two unpaired electrons (Table 1), which have previously been observed and discussed[23] in terms of a thermally controlled equilibrium between singlet and triplet states. However, the data collected prevent us from invoking such an equilibrium as the sole factor responsible for the magnetic behavior of complexes **2** and **3**.

The $\{NP_2Cl\}$ chromophore invariably produces square-planar nickel(II) complexes for all the PR_3 and $P^{\frown}N$ ligands employed, the structures of which have been validated by single-crystal X-ray analyses. The spectra in the visible range and the diamagnetism of all the complexes **9**, **10**, **11**, and **13**·C_6H_6 are in accordance with this structure[20]. The position of the *d-d* band at 430−450 nm (Table 1) indicates that the $\{NP_2Cl\}$ chromophore is appreciably lower in the spectrochemical series than e.g. $\{P_2(CN)_2\}$[24], for which this band appears at ca. 350 nm. These bands are also observed in solution (lg ε values are also reasonable) and the conductivity figures are consistent with classical behavior of these square-planar nickel complexes.

Proton NMR spectra of the paramagnetic pentacoordinate complexes in $CDCl_3$ show signals spread over the range from δ = +20 to −14. Conversely, complexes **1** and **3**, which retain the unsubstituted phosphanyl-amine $P^{\frown}NH_2$, are diamagnetic; their spectra allow the assignment of the coordinated phosphanyl-amine protons at δ = 2.60 and of the methyl groups of the mono-tertiary phosphanes at δ = 1.26 and 1.78 for **1** and **3**, respectively. These diamagnetic species are subject to fluxional behavior at room temperature in $CDCl_3$ solution, since the $^{31}P\{^1H\}$ spectra exhibit broad signals that lack the multiplicity that would be expected given the presence of two magnetically non-equivalent phosphorus donors in the coordination sphere.

On the other hand, the $^{31}P\{^1H\}$ spectra of square-planar cationic complexes indicate the existence of two types of phosphorus donors; in fact, a double doublet pattern is usually observed, the position of which is primarily determined by the nature of the mono-tertiary phosphane. In addition, a septuplet centred at δ = −144 establishes the presence of the hexafluorophosphate counterion. The methyl groups incorporated at the phosphorus and/or nitrogen donors are distinguishable on the basis of their chemical shifts and relative integrals in the proton spectra, which, where appropriate, also show the coordinated amine protons at δ = 4.90.

X-ray Structure Analysis

In the neutral complexes **3** (Figure 1) and **6**·CH_2Cl_2 (Figure 2), the coordination around the Ni^{II} center is distorted trigonal-bipyramidal with the two axial positions occupied by the phosphorus atom of the monodentate phosphane and by the nitrogen atom of the bidentate ligand ($P^{\frown}NH_2$ in **3** and $P^{\frown}NHMe$ in **6**·CH_2Cl_2). The equatorial sites accommodate the remaining phosphorus of the phosphanylamine and the two Cl donors. The Ni atom is displaced from the equatorial plane in the direction of P(2), by 0.13 Å in **3** and by 0.18 Å in **6**·CH_2Cl_2. The $P^{\frown}N$ ligand mean plane of **3** makes a dihedral angle of 94.6° with the equatorial plane, while the corresponding angle in **6**·CH_2Cl_2 is 67.5°. The five-membered chelate ring, roughly planar in **3** (maximum deviation of 0.05 Å by the nitrogen atom; torsion angles between −6.8° and +9.3°), assumes an envelope (C_s) conformation in **6**·CH_2Cl_2, as shown by the deviation (0.29 Å) of the nitrogen atom and the torsion angle values (from −30.5° to +35.0°). Moreover, superposition of the two structures (Figure 3) gives a high r.m.s. value (0.56 Å) when the fitting is performed on the 12 atoms labelled in the pertinent figure. Based on these differences, the geometry of **3** could alternatively be described as distorted square-pyramidal (Figure 4). In this description, the base could be regarded as comprising the P,N donors of the ligand, the P(2) atom of the monodentate phosphane, and Cl(1). The Ni atom is displaced from the base by +0.27 Å in the direction of Cl(2), but the deviations of the other donors are also dramatic [P(1) −0.31 Å, N(1) +0.35 Å, Cl(1) −0.32 Å and P(2) +0.28 Å]. Moreover, the *trans* angle P(1)−Ni−Cl(1) is only 148.29(6)°, while the *cis* angle P(1)−Ni−Cl(2) is widened to 110.82(6)°. In conclusion, the coordination geometry of **3** is intermediate between trigonal-bipyramidal and square-pyramidal and, accordingly, application of the τ index[25] gives a value of 0.46 (1.0 for trigonal-bipyramidal; 0.0 for square-pyramidal).

In the cationic complexes **9** (Figure 5) and **13**·MeOH (Figure 6), the coordination geometry around Ni^{II} can be

Figure 1. ORTEP view of complex **3**; hydrogen atoms are omitted for clarity; the thermal ellipsoids are drawn at 40% probability

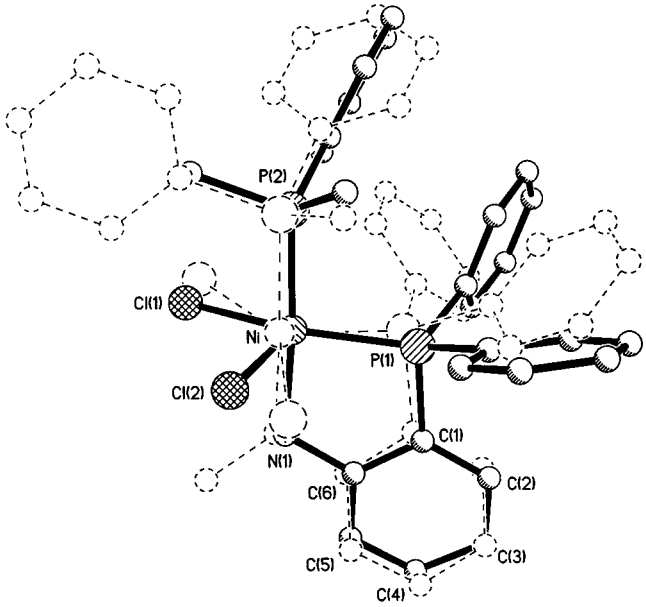

Figure 4. ORTEP view of complex **3** showing the square-pyramidal geometry; hydrogen atoms are omitted for clarity; the thermal ellipsoids are drawn at 40% probability

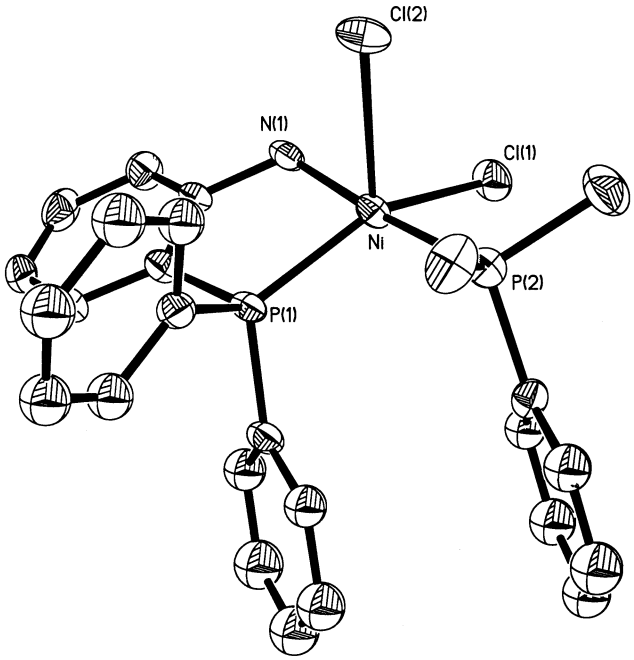

described as square-planar, with the two phosphorus donors located in a mutual *cis* arrangement and the remaining two positions occupied by the secondary amine nitrogen of the bidentate P⌒NHMe ligand and by the Cl donor. The nickel coordination spheres are distorted (Table 2) and the four donor atoms deviate from the mean coordination plane by ±0.17 Å in **9** and by ±0.10 Å in **13**·MeOH. The P⌒N ligand mean plane makes a dihedral angle with the mean coordination plane of 18.8° in **9** and of 23.9° in **13**·MeOH. The conformation of the five-membered NiPCCN chelate ring results in a twist-envelope (C_2) form (torsion angles between −14.2° and 13.2° in **9** and between −24.2° and 19.4° in **13**·MeOH) and superposition of the two structures (Figure 7) reveals only minor differences in the relative orientations of the phenyl rings, the r.m.s. value being 0.13 Å when the fitting is performed on the 11 atoms labelled in the pertinent figure.

For each of the four complexes, the packing does not give rise to intermolecular contacts shorter than the sum of the

van der Waals radii and there are no possibilities for hydrogen bonding. The Ni(II)−donor atom bond lengths in the $[NiCl_2(PR_3)(P^{\frown}N)]$ and $[NiCl(PR_3)(P^{\frown}N)]^+$ complexes merit some comment. Thus, the spread of their values (Table 3) might seem unexpectedly large (Ni−Cl in the range 2.177−2.567 Å; Ni−P 2.139−2.400 Å and Ni−N 1.963−2.353 Å), but this can be rationalized on the basis of coordination number, c.n., and/or geometry arguments. In fact, comparison of the distances with the pertinent "reference" values retrieved from the Cambridge Structural Database (CSD)[26] reveals the following features. (i) The Ni^{II}−Cl distances (mean value of 2.196 Å when c.n. = 4, and of 2.288 Å with c.n. = 5) are slightly shorter than the corresponding CSD values [2.22 (219 obs.) and 2.34 Å (88 obs.), respectively], but they confirm the finding that on going from c.n. 4 to 5 the distance increases. This trend also holds for the Ni−P and Ni−N distances. The Ni−Cl(2) distance in **3** [2.567(2) Å] represents an exception, being the

[a] tb = trigonal-bipyramidal; spy = square-pyramidal; sp = square-planar. − [b] **3**, **6**·CH_2Cl_2, **9**, **13**·MeOH in present work; **5** in ref.[21]; **7** and **14** in ref.[17]; **8** in ref.[19]. − [c] $P^{\frown}NP$ = *N*-(trimethylphosphoranyl)-2-(diphenylphosphanyl)aniline.

second longest distance ever reported in the literature[27]. In the square-pyramidal description (Figure 4), this axial elongation can be correlated with the electron density in the d_{z^2} orbital for the d^8 ion, leading to a pronounced metal−halide electron-electron repulsion. (ii) The geometry seems to govern the Ni−P bond lengths. The corresponding mean values in the trigonal-bipyramidal complexes average 2.310 Å and 2.384 Å for the chelating phosphane ligand and the unidentate ligand axially bonded to Ni^{II}, respectively. The magnitude of this "axial effect" (ca. 0.07 Å) is consistent with similar values encountered in the CSD file. In square-planar complexes, the corresponding mean values are 2.148 Å and 2.193 Å and a parallel situation is presented by **3**, since values of 2.189 Å and 2.170 Å are observed. (iii) The Ni^{II}−N distances in cationic complexes with c.n. = 4 (mean value 2.01 Å) are dramatically shorter than those in the neutral complexes with c.n. = 5 (mean value 2.30 Å), but the paucity of literature data prevents us from making a reliable comparison. In any case, the Ni−N(C_{sp^2})H_2 value of **3** (1.963 Å) conforms to those of the square-planar complexes. Similarly, the P−Ni−N bite angle (86.3°) of **3** closely approaches the mean value (85.6°) found in the four analogous complexes with c.n. 4, while it is compressed to 78.8° in those with c.n. = 5. Finally, the Ni−N−C angle of the five-membered chelate ring averages 115.2° in complexes with c.n. = 4, while it is compressed to 110.0° when the c.n. becomes 5.

Conclusions

Phosphanyl-amines $P^{\frown}NH_2$, $P^{\frown}NHMe$, $P^{\frown}NMe_2$ exhibit good coordination properties towards the nickel(II) center, affording stable neutral pentacoordinate $[NiCl_2(PR_3)(P^{\frown}N)]$ and cationic tetracoordinate $[NiCl(PR_3)(P^{\frown}N)]^+$ complexes starting from the corresponding $[NiCl_2(PR_3)_2]$ precursor.

The neutral pentacoordinate species $[NiCl_2(PR_3)(P^{\frown}N)]$ feature a rather unusual $\{NP_2Cl_2\}$ donor set. Their behavior can be satisfactorily accounted for considering the data collected in the course of this study. The range of magnetic moments they exhibit is unexpected in view of the donor set $\{NP_2Cl_2\}$ and of their crystal structures. While it is possible to assign a trigonal-bipyramidal structure to complex **6**, in analogy to related compounds such as $[NiCl_2(PMe_2Ph)(P^{\frown}NMe_2)]$[21] and $[NiCl_2(PMePh_2)(P^{\frown}NMe_2)]\cdot 0.5\ CH_2Cl_2$[17], complex **3** has a structure intermediate between trigonal-bipyramidal and square-pyramidal, which accounts for the very long Ni−Cl distance.

The cationic tetracoordinate species $[NiCl(PR_3)(P^{\frown}N)]^+$ can be derived from the corresponding $[NiCl_2(PR_3)_2]$ precursor only by the addition of KPF_6 in order to remove one Cl^- ligand per Ni atom. NMR spectra and crystal structures indicate that these complexes consist of the *cis*-P,P isomer. Comparison of some structural features such as the Ni−N, Ni−Cl, and Ni−P bond lengths confirms the finding that on going from c.n. = 4 to 5 the distances increase. In particular, Ni−N is dramatically shorter than the CSD reference value, but the paucity of literature data prevents us from making firm conclusions from this observation.

Benedetto Corain is grateful to the *Alexander von Humboldt Foundation* for supporting his activities at TU München.

Experimental Section

General: All chemicals and solvents were of analytical grade and were used as received unless otherwise stated. The starting $[NiCl_2(PR_3)_2]$ (PR_3 = PMe_3, PMe_2Ph, $PMePh_2$) complexes were prepared according to the literature[28][29], as were the ligands $P^{\frown}NH_2$[9], $P^{\frown}NHMe$[9], and $P^{\frown}NMe_2$[30]. − IR: Mattson 3030 Fourier-transform spectrometer. − UV/Vis in the solid state: Cary 5-E spectrophotometer (1200−220 nm), diffuse reflectance method. − UV/Vis in solution: Cary 17D spectrophotometer (1200−220 nm), ca. 10^{-2} M solutions in CH_2Cl_2 for the pentacoordinate complexes in 0.1-cm cells and 10^{-3}−10^{-5} M solutions in CH_2Cl_2 for square-planar and cationic complexes in 1-cm cells. − NMR: Bruker AC-200 (200 MHz for ^1H and ^{31}P). For ^1H NMR, $CDCl_3$ or CD_2Cl_2 as solvent, TMS as internal standard; for $^{31}P\{^1H\}$ NMR, $CDCl_3$ or CD_2Cl_2 as solvent, 85% aqueous H_3PO_4 as external standard. − Conductivity measurements: Amel conductimeter Mod. 131, ca. 10^{-3} M solutions in MeCN at 25°C. − Magnetic susceptibility measurements: Cahn 2000 microbalance. − Elemental analyses (C, H, N): Fisons EA 1108 elemental analyzer.

[NiCl$_2$(PMe$_3$)(P⌒NMe$_2$)] (**2**): To a solution of 0.196 g of [NiCl$_2$(PMe$_3$)$_2$] (0.68 mmol) in 10 ml of MeCN was added 0.209 g of P⌒NH$_2$ (0.68 mmol). The blood-red solution immediately darkened and was stirred under dinitrogen at room temperature for 3 h. The solution was then concentrated to a volume of 3 ml under a flow of dinitrogen. A dark-blue powder precipitated, which was collected by filtration, washed with 5 ml of Et$_2$O, 5 ml of *n*-hexane and 0.5 ml of EtOH, and dried in vacuo. Yield: 0.140 g (40%). − IR (KBr): $\tilde{\nu}$ = 3047 cm^{-1} s, 1580 m, 1481 m, 1437 s, 1094 s, 959 vs, 753 m, 514 m. − ^{1}H NMR (CDCl$_3$): Several signals in the region δ = +18.0 to −2.0. − $C_{23}H_{29}Cl_2NNiP_2$ (483.01): calcd. C 54.05, H 5.73, N 2.74; found C 54.64, H 5.67, N 2.43.

[NiCl$_2$(PMe$_2$Ph)(P⌒NH$_2$)] (**3**): To a solution of 0.108 g of [NiCl$_2$(PMe$_2$Ph)$_2$] (0.27 mmol) in 10 ml of MeCN was added 0.075 g of P⌒NH$_2$ (0.27 mmol) and the mixture was stirred under dinitrogen at room temperature. The blood-red solution immediately turned dark. After 5 min, a blue compound precipitated and after 15 min the solid was collected by filtration, washed several times with MeCN, and dried in vacuo. Yield: 0.111 g (85%). Crystals were grown by slow evaporation of the solvent from CH$_2$Cl$_2$ solutions. − IR (KBr): $\tilde{\nu}$ = 3236 cm^{-1} m, 3179 m, 3093 s, 1555 m, 1478 m, 1433 s, 1095 m, 914 vs, 698 m, 512 m. − ^{1}H NMR (CDCl$_3$): δ = 1.78 [s, 6 H, P(C*H*$_3$)$_2$], 2.67 (m, 2 H, N*H*$_2$), 6.33−8.38 (m, 19 H, aromatic). − ^{31}P{^{1}H} NMR (CDCl$_3$): δ = −5.2 (br. s, 1 P, *P*Me$_2$), 38.6 (br., 1 P, *P*⌒NH$_2$). − $C_{26}H_{27}Cl_2NNiP_2$ (545.08): calcd. C 57.29, H 5.00, N 2.57; found C 57.17, H 5.37, N 2.57.

[NiCl$_2$(PMe$_2$Ph)(P⌒NHMe)] (**4**): To a solution of 0.100 g of [NiCl$_2$(PMe$_2$Ph)$_2$] (0.25 mmol) in 5 ml of MeCN was added 0.073 g of P⌒NHMe (0.25 mmol) and the mixture was stirred under dinitrogen at room temperature. After 30 min, a blue compound precipitated and after 3 h the solid was collected by filtration, washed twice with 6 ml of *n*-hexane, and dried in vacuo. Yield: 0.065 g (44%). − IR (KBr): $\tilde{\nu}$ = 3246 cm^{-1} w, 3051 s, 2247 w, 1580 m, 1481 m, 1435 s, 1098 s, 913 s, 742 m, 487 s. − ^{1}H NMR (CDCl$_3$): Several signals in the region δ = +18.0 to −2.0. − $C_{27}H_{29}Cl_2NNiP_2 \cdot 0.5\ CH_3CN$ (579.64): calcd. C 58.02, H 5.31, N 3.62; found C 57.75, H 5.06, N 3.64.

[NiCl$_2$(PMePh$_2$)(P⌒NHMe)] (**6**): To a blood-red solution of 0.101 g of [NiCl$_2$(PMePh$_2$)$_2$] (0.19 mmol) in 10 ml of MeCN and 0.5 ml of CH$_2$Cl$_2$ was added 0.055 g of P⌒NHMe (0.19 mmol). The red solution immediately turned brown. After stirring under dinitrogen at room temperature for 3 h, the solution was concentrated to dryness under reduced pressure. The residue was washed with 0.4 ml of MeCN and 0.4 ml of CH$_2$Cl$_2$, and then redissolved in 10 ml of CH$_2$Cl$_2$ and 1.5 ml of C$_6$H$_6$. Addition of 23 ml of Et$_2$O caused the precipitation of a green solid, which was collected by filtration, washed with 5 ml of Et$_2$O, and dried in vacuo. Yield: 0.080 g (60%). Crystals were grown by slow evaporation of the solvent from CH$_2$Cl$_2$ solutions. − IR (KBr): $\tilde{\nu}$ = 3262 cm^{-1} w, 1580 m, 1471 s, 1434 s, 1099 m, 885 s, 685 vs, 502 s. − ^{1}H NMR (CDCl$_3$): Several signals in the region δ = +18.0 to −1.0. − $C_{32}H_{31}Cl_2NNiP_2 \cdot C_6H_6$ (699.3): calcd. C 65.26, H 5.34, N 2.00; found C 65.38, H 5.44, N 1.74.

[NiCl(PMe$_3$)(P⌒NHMe)]PF$_6$ (**9**): To a mixture of 0.131 g of [NiCl$_2$(PMe$_3$)$_2$] (0.46 mmol) and 0.117 g of KPF$_6$ (0.64 mmol) in 10 ml of CH$_2$Cl$_2$ was added 0.134 g of P⌒NHMe (0.46 mmol) under stirring. The blood-red mixture immediately turned dark-red. After 3 h, a yellow solid had been deposited, which was filtered off, washed with 2 ml of H$_2$O, recrystallized from a 1:2 MeCN/Et$_2$O solution (30 ml), and dried in vacuo. The filtrate was concentrated to dryness under reduced pressure and the residue was recrystallized as above, giving a second crop of the yellow solid. Yield: 0.195 g (70%). Crystals suitable for X-ray analysis were grown by slow evaporation of the solvent from CH$_2$Cl$_2$ solutions. − IR (KBr): $\tilde{\nu}$ = 3191 cm^{-1} m, 1583 m, 1462 m, 1104 w, 838 vs (P−F), 557 s. − ^{1}H NMR (CD$_2$Cl$_2$): δ = 1.23 [s, 9 H, P(C*H*$_3$)$_3$], 2.87 (d, $^3J_{HH}$ = 6 Hz, 3 H, NC*H*$_3$), 4.85 (m, 1 H, N*H*), 7.20−7.95 (m, 14 arom. H). − ^{31}P{^{1}H} NMR (CD$_2$Cl$_2$): δ = −144 (sept., J_{PF} = 711 Hz, 1 P, *P*F$_6^-$), −7.80 (m, 1 P, *P*Me$_3$), 42.5 (m, 1 P, *P*⌒NHMe). − $C_{22}H_{27}ClF_6NNiP_3$ (606.56): C 43.56, H 4.50, N 2.31; found C 43.42, H 4.16, N 2.16.

[NiCl(PMe$_3$)(P⌒NMe$_2$)]PF$_6$ (**10**): To a mixture of 0.082 g of [NiCl$_2$(PMe$_3$)$_2$] (0.29 mmol) and 0.074 g of KPF$_6$ (0.40 mmol) in 10 ml of CH$_2$Cl$_2$ was added 0.089 g of P⌒NH$_2$ (0.25 mmol) and the mixture was stirred at room temperature. The blood-red solution immediately turned orange-red. After 3 h, the mixture was filtered and concentrated to a volume of 4 ml under a flow of dinitrogen. Addition of 12 ml of Et$_2$O caused the precipitation of a yellow-orange solid, which was collected by filtration, washed with H$_2$O, and dried in vacuo. The solid was recrystallized from CH$_2$Cl$_2$/EtOH/C$_6$H$_6$ (10:1:19) (20 ml). Yield: 0.121 g (67%). − IR (KBr): $\tilde{\nu}$ = 3070 cm^{-1} w, 1580 m, 1483 m, 1436 s, 1097 m, 836 vs (P−F), 558 s. − ^{1}H NMR (CD$_2$Cl$_2$): δ = 1.26 [d, 9 H, $^2J_{HP}$ = 12.5 Hz, P(C*H*$_3$)$_3$], 3.19 [s, 6 H, N(C*H*$_3$)$_2$], 7.12−8.15 (m, 14 H, aromatic). − ^{31}P{^{1}H} NMR (CD$_2$Cl$_2$): δ = −144 (sept, 1 P, J_{PF} = 713 Hz, *P*F$_6^-$), −9.51 (d, 1 P, $^2J_{PP}$ = 107 Hz, *P*Me$_3$), 38.1 (d, 1 P, $^2J_{PP}$ = 107 Hz, *P*⌒NMe$_2$). − $C_{23}H_{29}ClF_6NNiP_3$ (620.59): calcd. C 44.51, H 4.71, N 2.26; found C 44.41, H 4.56, N 2.26.

[NiCl(PMe$_2$Ph)(P⌒NHMe)]PF$_6$ (**11**): To a mixture of 0.155 g of [NiCl$_2$(PMe$_2$Ph)$_2$] (0.38 mmol) and 0.138 g of KPF$_6$ (0.75 mmol) in 1 ml of CH$_2$Cl$_2$ was added 0.111 g of P⌒NHMe (0.38 mmol) and the mixture was stirred at room temperature. The blood-red mixture slowly turned red-orange. After 3 h, the solution was filtered and concentrated to a volume of 5 ml under a flow of dinitrogen. Addition of 15 ml of Et$_2$O caused the precipitation of an orange solid, which was collected by filtration, washed with H$_2$O, and dried in vacuo. The solid was recrystallized from CH$_2$Cl$_2$/EtOH/C$_6$H$_6$ (7:1.5:19) (27.5 ml). Yield: 0.153 g (60%). − IR (KBr): $\tilde{\nu}$ = 3229 cm^{-1} m, 1584 m, 1506 m, 1437 s, 1102 m, 837 vs (P−F), 557. − ^{1}H NMR (CD$_2$Cl$_2$): δ = 1.64 [s, 6 H, P(C*H*$_3$)$_2$], 2.96 (d, 3 H, $^3J_{HH}$ = 6 Hz, NC*H*$_3$), 4.94 (m, 1 H, N*H*), 6.90−8.04 (m, 19 H, aromatic). − ^{31}P{^{1}H} NMR (CD$_2$Cl$_2$): δ = −144 (sept, 1 P, J_{PF} = 713 Hz, *P*F$_6^-$), 1.30 (m, 1 P, *P*Me$_2$Ph), 48.0 (m, 1 P, *P*⌒NHMe). − $C_{27}H_{29}ClF_6NNiP_3$ (668.63): calcd. C 48.55, H 4.38, N 2.10; found C 48.71, H 4.38, N 2.03.

[NiCl(PMePh$_2$)(P⌒NHMe)]PF$_6$ (**13**): To a mixture of 0.132 g of [NiCl$_2$(PMePh$_2$)$_2$] (0.25 mmol) and 0.092 g of KPF$_6$ (0.50 mmol) in 10 ml of CH$_2$Cl$_2$ was added 0.073 g of P⌒NHMe (0.25 mmol) and the mixture was stirred at room temperature. The blood-red mixture immediately turned red-orange. After 3 h, the solution was filtered and concentrated to a volume of 4 ml under a flow of dinitrogen. Addition of 16 ml of Et$_2$O caused the formation of a red-orange oil, which was separated by decantation. After dissolution of the oil in 7 ml of CH$_2$Cl$_2$, 18 ml of C$_6$H$_6$ was added and upon stirring an orange-yellow solid precipitated. This solid was collected by filtration, washed with H$_2$O, dried in vacuo, and recrystallized from CH$_2$Cl$_2$/EtOH/C$_6$H$_6$ (6:1.5:17) (24.5 ml). Yield: 0.112 g (60%). Crystals were grown from CH$_2$Cl$_2$/MeOH/C$_6$H$_6$/Et$_2$O solutions. − IR (KBr): $\tilde{\nu}$ = 3251 cm^{-1} m, 1581 m, 1436 s, 1099 w, 840 vs (P−F), 557 s. − ^{1}H NMR (CDCl$_3$): δ = 2.01 (d, 3 H, $^3J_{HP}$ = 13 Hz, PC*H*$_3$), 2.33 (s, 3 H, NC*H*$_3$), 7.10−7.84 (m, 26 H, aromatic). − ^{31}P{^{1}H} NMR (CDCl$_3$): δ = −146 (sept., 1 P, J_{PF} = 713 Hz, *P*F$_6^-$), 6.91 (d, 1 P, $^2J_{PP}$ = 83 Hz, *P*Me$_2$Ph), 37.6 (d, 1 P, $^2J_{PP}$ = 83 Hz, *P*⌒NHMe). − $C_{32}H_{31}ClF_6NNiP_3 \cdot C_6H_6$ (808.82): calcd. C 56.08, H 4.59, N 1.72; found C 56.99, H 4.55, N 1.65.

X-ray Crystal Structure Determinations: Many of the details of the structure analyses carried out on complexes **3**, **6**·CH_2Cl_2, **9**, and **13**·MeOH are listed in Table 4.

Crystallographic measurements were made at 293 K with a Siemens Nicolet R3m/V four-circle diffractometer using graphite-monochromated Mo-K_α radiation (λ = 0.71073 Å) (ω−2Θ scan technique). The unit cell was determined by the automatic indexing of 50 centered reflections at 2Θ > 21°. The rather poor quality of crystals of **13**·MeOH was manifested in broad scan-widths during initial search routines with the diffractometer and the diffracting ability of the sample dropped with increasing Bragg angle; much of the higher angle data collected were deemed to be weak. As a consequence, the data collection for **13**·MeOH was restricted to 2Θ = 43°. Corrections for Lorentz polarization effects and extinction were applied in all cases, while an empirical absorption correction, based on ψ scans for six reflections at χ ≈ 90°, was applied only for compounds **3** and **13**·MeOH (minimum and maximum transmission factors 0.63−0.87 and 0.49−0.68 for **3** and **13**·MeOH, respectively). In fact, for **6**·CH_2Cl_2 and **9**, azimuthal scan data proved such correction to be unnecessary. The structures were solved by Patterson methods and refined by full-matrix least-squares methods on F^2 using the SHELXTL/PC[31] and SHELXL-93[32] suites of programs. Atomic scattering factors and anomalous dispersion parameters were taken from ref.[33]. Non-hydrogen atoms were assigned anisotropic thermal parameters, with the exception of the disordered atoms of **6**·CH_2Cl_2, **9**, and **13**·MeOH. The hydrogen atoms were constrained to ride on the atom to which they were attached. The isotropic thermal parameters for the methyl H atoms were refined with 1.5 times, and for all phenyl H atoms with 1.2 times the U_{eq} value of the corresponding atom. On the contrary, the hydrogen atoms attached to nitrogen atoms were located in the final difference maps, but were not included in the refinement. During the refinement procedure it became apparent that the CH_2Cl_2 molecule in **6**·CH_2Cl_2, the PF_6^- anion in **9**, and the MeOH molecule in **13**·MeOH were disordered. The CH_2Cl_2 molecule of **6**·CH_2Cl_2 was found to be severely disordered into a number of partially occupied sites with occupancies of ca. 0.7, 0.2, and 0.1, but efforts to refine these values were not successful and hence this matter was not pursued further. The PF_6^- anion of **9** was modelled using partial F atom occupancies, such that the central P atom had two 100%, four 66% and four 33% occupied F atoms around it. This model still gave rather high thermal parameters (ca. 0.10 Å^2 for all atoms), but resulted in an overall improvement in the structure. Finally, the MeOH molecule of **13**·MeOH was located in a disordered position and was included at half occupancy.

Selected bond lengths and angles are listed in Table 2.

Further details of the crystal structure determination can be ordered from the Fachinformationszentrum Karlsruhe, D-76344 Eggenstein-Leopoldshafen, Germany, on quoting the depository numbers CSD-408520 (**3**), -408521 (**6**·CH_2Cl_2), -408522 (**9**), -408523 (**13**·MeOH).

Keywords: Magnesium anthracene / Active magnesium / Zintl phases / Magnesium intermetallics / EXAFS spectroscopy

Ga, Tl, Sn, Pb, As, Sb, Bi, Cd, and Hg chlorides react with magnesium anthracene · 3 THF (MgA), anthracene-activated magnesium, or "active magnesium" (Mg*) in THF, generating the respective Mg intermetallics in a nanocrystalline or amorphous state (Eqs. 1–3). Mg intermetallics accessible through the wet-chemical route can be exploited by metathetical exchange reactions for the preparation of other, highly active intermetallics and alloys; EXAFS investigation of X-ray amorphous Cu–Sn and Pd–Pb solids thus prepared (Eqs. 13 and 14) shows that they are true bimetallic alloys (solid solutions).

Introduction

In recent publications[1] we have reported the preparation of a series of so-called inorganic Grignard reagents from transition-metal chlorides and organomagnesium compounds or "active magnesium" (Mg*). These soluble systems can be used as reagents for the synthesis of intermetallics and alloys in a finely divided, usually nanoparticulate, state[1]. In contrast to transition-metal chlorides, it was found[1b] that chlorides of heavier group 12−15 metals (MCl_n) in THF react with magnesium anthracene · 3 THF[2] (MgA), Mg*, or ordinary magnesium powder in the presence of catalytic amounts of MgA[3], with formation of magnesium intermetallics (Mg_qM), also in a finely divided, highly active state[4]; the reactions can be described by eqs. 1−3. When MgA is used as the reducing agent (Eq. 1), the reaction progress can be monitored by measuring the increase in anthracene (A) concentration in the reaction solution with time. In some cases, it is advantageous to run the reaction shown in Eq. 1 in two steps. In the first step, MCl_n is reduced to the metallic state in a highly active form (M*, Eq. 1a); subsequently, M* with additional MgA is transformed into Mg_qM (Eq. 1b). In the following, we give an account of the preparation, characterization, and possible application of magnesium intermetallics obtained via these routes[1b][4][5].

$$MCl_n + \left(\frac{n}{2}+q\right)MgA \longrightarrow Mg_qM\downarrow + \frac{n}{2}MgCl_2 + \left(\frac{n}{2}+q\right)A \quad (1)$$

$$MCl_n + \frac{n}{2}MgA \longrightarrow M^*\downarrow + \frac{n}{2}MgCl_n + \frac{n}{2}A \quad (1a)$$

$$M^* + qMgA \longrightarrow Mg_qM\downarrow + qA \quad (1b)$$

$$MCl_n + \left(\frac{n}{2}+q\right)Mg^* \longrightarrow Mg_qM\downarrow + \frac{n}{2}MgCl_2 \quad (2)$$

$$MCl_n + \left(\frac{n}{2}+q\right)Mg \xrightarrow{MgA(A)} Mg_qM\downarrow + \frac{n}{2}MgCl_2 \quad (3)$$

Results

Mg−Ga and Mg−Tl Intermetallics

The Ga-rich Zintl phase Mg_2Ga_5[6] has previously been prepared in bulk form by melting stoichiometric mixtures of high-purity Mg and Ga metal sealed in Ta[6a] or pyrex crucibles[6c]. The preparation of Mg_2Ga_5 in a finely divided, highly reactive crystalline form can now be achieved via a two-step reaction. In the first step (Eq. 4) $GaCl_3$ is reduced with MgA at low temperature to give a highly active gallium (Ga*) suspension in THF. After separating the active metal from $MgCl_2$ and anthracene, Ga* can be converted, with additional MgA, into Mg_2Ga_5 (Eq. 5). Mg_2Ga_5 is obtained as a black pyrophoric powder contaminated with $MgCl_2$, A, and THF (Table 3; Expt. 1).

$$2\,GaCl_3 + 3\,MgA \xrightarrow{-78°C \rightarrow RT} 2\,Ga^*\downarrow + 3\,MgCl_2 + 3\,A \quad (4)$$

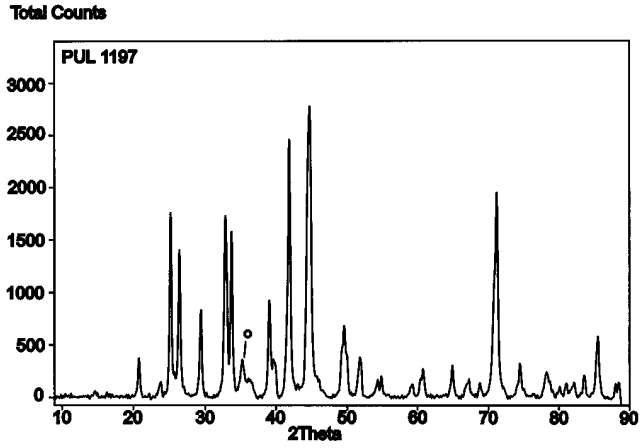
$$5\,Ga^* + 2\,MgA \xrightarrow{RT} Mg_2Ga_5\downarrow + 2\,A \quad (5)$$

[◇] Part 9: R. Benn, B. Bogdanović, M. Brüning, H. Grondey, W. Herrmann, H.-G. Kinzelmann, K. Seevogel, *Chem. Ber.* **1993**, *126*, 225

 © WILEY-VCH Verlag GmbH, D-69451 Weinheim, 1998 1434−1948/98/1111−1699 $ 17.50+.50/0

The XRD pattern of the Mg_2Ga_5 thus prepared (Figure 1) is in accordance with that reported in the literature[7].

Figure 1. X-ray powder diffraction patterns of Mg_2Ga_5, prepared from $GaCl_3$ and MgA; o, diffraction line of Ga

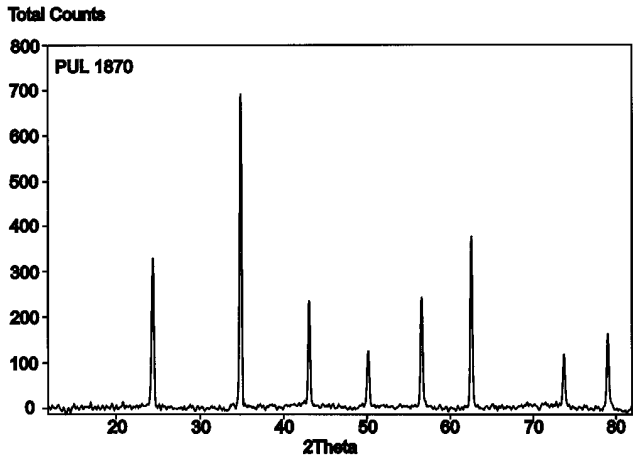


The Mg−Tl Zintl phase MgTl[8][9] can now be prepared in a microcrystalline (nanocrystalline?) form by treating TlCl with an excess of MgA in THF (Eq. 6; Expt. 3.2). MgTl was obtained as a silvery shining powder with the composition $Mg_{0.88}TlCl_{0.01}(CH_2)_{0.2}$. A DSC analysis of the powder showed a weak endothermic peak at 202.7°C (onset temperature; MgTl + Tl eutectic; ref.[10], 202°C) and an intense endothermic peak at 351.3°C (onset temperature) corresponding to the melting point of MgTl (ref.[10], 358°C).

$$TlCl + 1.5\,MgA \longrightarrow MgTl\downarrow + 0.5\,MgCl_2 + 1.5\,A \qquad (6)$$

This result, together with the Mg/Tl ratio of 0.88:1 found through elemental analysis, reveals the presence of Tl in the MgTl thus prepared. However, the XRD powder pattern of this material (Figure 2) exhibited only the diffraction lines of MgTl[11]. The Tl particles if present are, therefore, most likely X-ray amorphous.

Figure 2. X-ray powder diffraction pattern of MgTl, prepared from TlCl and MgA



Mg−Sn and Mg−Pb Intermetallics

Mg forms Zintl phases of the type Mg_2E, E = Ge, Sn, Pb[8] with group 14 metals which crystallize in CaF_2 antiisomorphous structures. Their high melting points reflect the heteropolar character of the bonds between the respective elements. The preparation of Mg_2E in bulk form has been carried out by melting the components in an inert atmosphere in sealed iron or corundum crucibles[8][12].

The reaction of $SnCl_2$ with MgA in THF, as a method for the preparation of Sn or Mg_2Sn, both in a finely divided state, has been investigated in some detail (Table 4). If the reaction is conducted in the 1:1 molar ratio at room or low temperature (Expts. 4.1 and 4.2), a highly reactive, pyrophoric, black form of metallic Sn of 97−98% purity (Sn*, Eq. 7) is obtained. Sn* prepared at low temperature (Expt. 4.2) shows only diffuse Sn and no Mg_2Sn diffraction lines in the XRD spectrum. The high reactivity of Sn* prepared according to Eq. 7 is demonstrated by, amongst other things, its reaction with MgA in THF leading to Mg_2Sn (see below Eq. 10; Expt. 4.6); commercial Sn powder does not react with MgA under such conditions.

$$SnCl_2 + MgA \longrightarrow Sn^*\downarrow + MgCl_2 + A \qquad (7)$$

Reaction of $SnCl_2$ with MgA in the molar ratio of 1:2 gives a mixture of Sn* and Mg_2Sn (Expt. 4.3), which, with additional $SnCl_2$ can again be converted into Sn* (Eq. 8).

$$SnCl_2 + 2\,MgA \longrightarrow \underbrace{(0.5\,Sn^* + 0.5\,Mg_2Sn)}\downarrow + MgCl_2 + 2\,A \qquad (8)$$

$$SnCl_2 \longrightarrow 2\,Sn^* + MgCl_2$$

In order to produce Mg_2Sn free of Sn*, it is necessary to react $SnCl_2$ with MgA in an excess amount with respect to Eq. 9 (e.g. in the molar ratio 1:4, Expt. 4.4). The Mg_2Sn obtained is free of Sn or of the Sn−Mg_2Sn eutectic, according to DSC analysis. The TEM photograph of the Mg_2Sn thus prepared (Figure 3) reveals aggregates of nonuniform nanocrystals of 10−50-nm size.

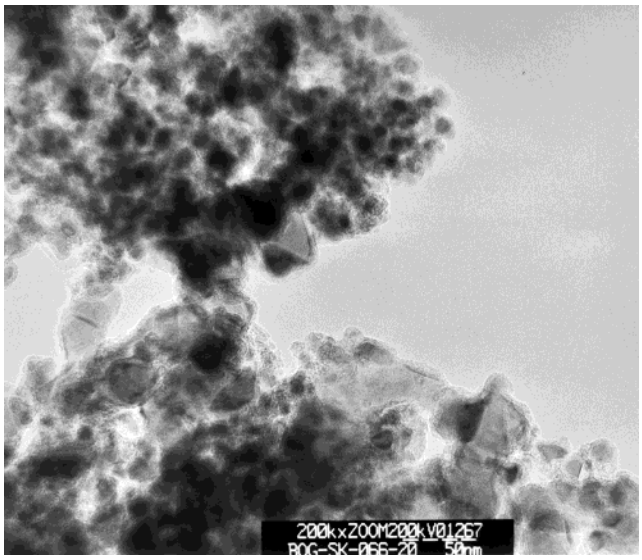
$$SnX_2 + 3\,MgA \longrightarrow Mg_2Sn\downarrow + MgX_2 + 3\,A \qquad (9)$$

X = Cl, Br

On the basis of the widening of the strongest diffraction line in the XRD of this material, an average particle size of 40 ± 4 nm has been estimated, in agreement with the TEM result.

The progress of the reaction of Sn halides with MgA in the molar ration of 1:4.1 at 0°C is represented in Figure 4. Under these conditions (Expt. 4.5) $SnCl_2$ and $SnBr_2$ yielded Mg_2Sn with specific surface areas of 70 and 130 m^2g^{-1}, respectively. X-ray powder diffraction showed sharp Mg_2Sn diffraction lines only. SnI_2 (Figure 4) under the same conditions did not react completely, while hardly any reaction

Figure 3. High-resolution TEM photograph of Mg_2Sn prepared from $SnCl_2$ and MgA



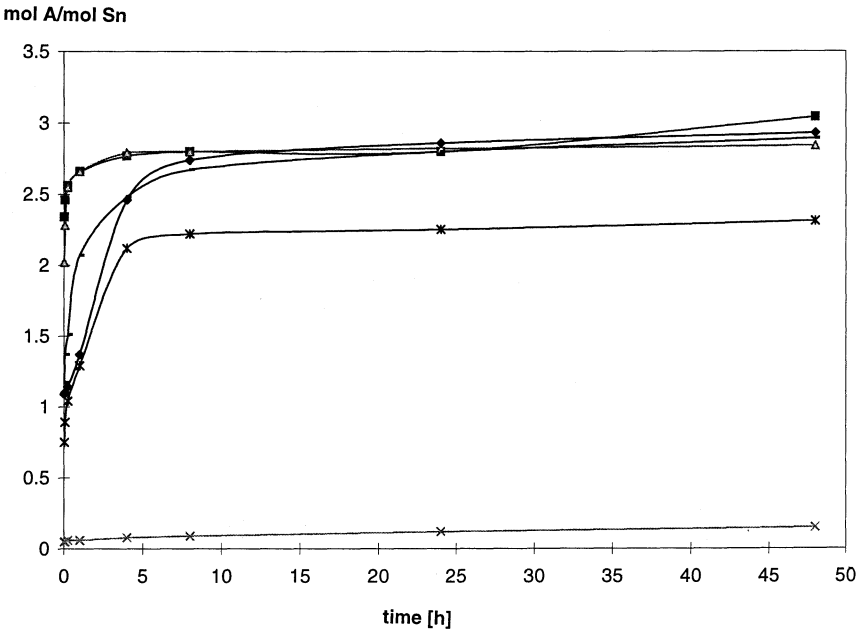
at all was observed with SnF_2, probably due to the insolubility of SnF_2 and MgF_2 in THF.

3A/Mg_2Sn is, in both cases, only reached after ca. 50 h. The reaction is further slowed down when Sn* is separated from $MgCl_2$ and A prior to the reaction with additional MgA (−◆−). Since the reduction of $SnCl_2$ by MgA to Sn* (Eq. 7) is apparently much more rapid than the conversion of Sn* with MgA in Mg_2Sn, it is reasonable to assume that Sn* also acts as an intermediate in the direct formation of Mg_2Sn from $SnCl_2$ and MgA (Eq. 10). The X-ray diffraction pattern of Mg_2Sn prepared according to the two-step reaction (Expt. 4.6) is shown in Figure 5.

$$SnCl_2 + MgA \xrightarrow{\text{rapid}} Sn^{*}\downarrow + MgCl_2 + A \xrightarrow[\text{slow}]{2\ MgA} Mg_2Sn + MgCl_2 + 3\ A \qquad (10)$$

The preparation of Mg_2Pb by the wet-chemical method can be carried out by using either stoichiometric amounts of MgA (Eq. 11) or commercial Mg powder with MgA acting as a "phase transfer catalyst"[1f][13] (Eq. 12). Reaction of $PbCl_2$ with MgA in the molar ratio of 1:3.7 in THF (Expt. 5.1) yielded microcrystalline pyrophoric intermetallic Mg_2Pb which, according to its elemental composition ($Mg_{1.84}Pb$) and X-ray diffractogram, contained minute amounts of Pb. On the other hand, Mg_2Pb which was shown using XRD to contain only traces of Pb (Figure 6)

Figure 4. Progress of the formation reaction of Mg_2Sn from Sn halides (SnX_2) and MgA (1:4.1; [SnX_2] = 0.06 mol/l) in THF at 0°C; −■−, $SnCl_2$, one-step reaction; −▬−, $SnCl_2$, two-step-reaction; −◆−, $SnCl_2$, two-step reaction, Sn* separated from $MgCl_2$ and A; −▲−, $SnBr_2$; −✳−, SnI_2; −×−, SnF_2



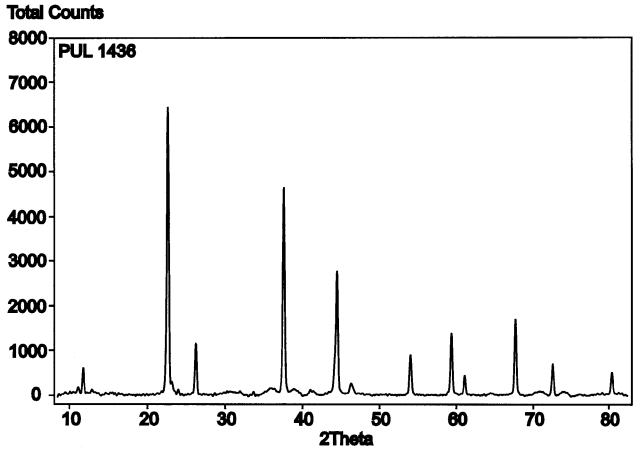
The preparation of Mg_2Sn with a high specific surface area (85 m^2g^{-1}) and free of Sn* is also possible via the two-step reaction. Accordingly, $SnCl_2$ is first reacted with MgA in the molar ratio of 1:1 at room temperature, thus generating Sn*, and then at 0°C with 3 additional equivalents of MgA, giving Mg_2Sn (Expt. 4.6).

As can further be seen in Figure 4, the rate of the two-step reaction (Expt. 4.6; −▬−) is somewhat slower than that of the direct reaction (−■−); but the final ratio of ca. was obtained by reacting $PbCl_2$ with Mg powder and 10 mol-% of MgA at 0°C (Expt. 5.2).

Cu(Mg)−Sn and Pd−Pb Alloys from Mg_2Sn and Mg_2Pb and the Respective Metal Halides

According to preliminary investigations, the highly reactive Mg intermetallics accessible by the wet-chemical route

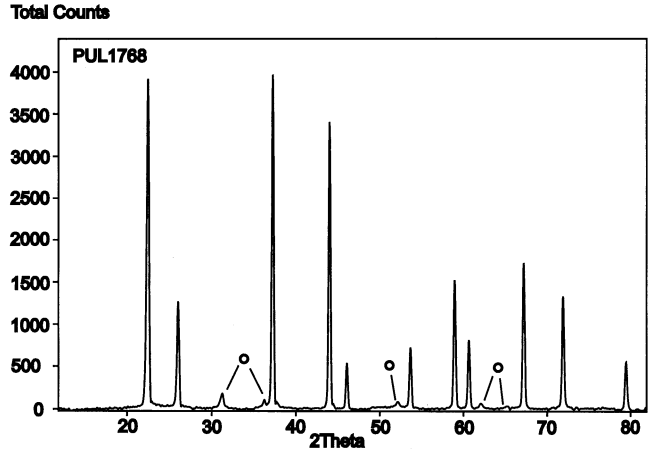
Figure 5. X-ray powder diffraction pattern of Mg_2Sn prepared from $SnCl_2$ and MgA in the two-step reaction



$$PbCl_2 + 3\,MgA \xrightarrow[-78°C \rightarrow RT]{THF} Mg_2Pb(+Pb)\downarrow + MgCl_2 + 3\,A \quad (11)$$

$$PbCl_2 + 3\,Mg \xrightarrow[0\,°C]{THF/MgA} Mg_2Pb(+Pb)\downarrow + MgCl_2 \quad (12)$$

Figure 6. X-ray powder diffraction pattern of Pb_2Sn prepared from $PbCl_2$ and Mg powder in the presence of 10 mol-% of MgA; o, diffraction lines of Pb



(Eqs. 1−3) can be exploited for the preparation of other intermetallics and alloys in a highly active state. As demonstrated in the following, wet-chemically prepared Mg_2Sn and Mg_2Pb react with Cu and Pd chlorides, respectively in THF with exchange of Mg by the metal in question. The reactions can thus be envisaged as a route for the preparation of intermetallics and alloys complementary to that of applying "inorganic Grignard reagents"[1] (see Introduction).

Cu−Sn[14] and Pd−Pb alloys[15] are accessible via metallurgical methods. A colloidal Pd−Pb alloy has recently been prepared by Bönnemann et al.[16] by means of co-reduction of the corresponding metal salts. Pd−Pb metal combinations can be used as catalysts for the *cis*-selective hydrogenation of alkynes to alkenes (Lindlar catalyst)[16][17] and for the hydrodechlorination of chlorofluorocarbons (CFCs)[18].

In order to provide starting materials with a high dispersion and reactivity, Mg_2Sn and Mg_2Pb utilized for the reactions with metal halides were prepared at low temperatures (Expts. 4.8 and 5.1). Mg_2Sn prepared at low temperatures (Expt. 4.7) is, indeed, highly dispersed, as demonstrated by its broad but weak diffraction lines in XRD.

Reactions of Mg_2Sn with $CuCl_2$ and of Mg_2Pb with $PdCl_2$ in the molar ratio of 1:2 (THF, room temperature) gave in quantitative yields solids of the compositions ca. $Cu_{1.6}Mg_{0.2}Sn(MgCl_2)_{0.1}(CH_2)_{0.4}$ (Expt. 6.1) and ca. $Pd_{1.9}Pb(MgCl_2)_{0.1}Cl_{0.1}(CH_2)_{0.9}$ (Expt. 6.2), respectively. From the compositions of the solids and the amount of Mg^{2+} analyzed in THF solutions, it can be concluded that exchange reactions have taken place in the sense of Eqs. 13 and 14. In the first case (Eq. 13), however, these reactions amount only to roughly 80%.

$$Mg_2Sn + 2CuCl_2 \longrightarrow "Cu_2Sn"\downarrow + 2\,MgCl_2 \quad (13)$$

$$Mg_2Pb + 2\,PdCl_2 \longrightarrow "Pd_2Pb"\downarrow + 2\,MgCl_2 \quad (14)$$

According to the Cu−Sn[14] and Pd−Pb[15] phase diagrams, intermetallic compounds of the compositions Cu_2Sn and Pd_2Pb are not known. The X-ray diffractogram for wet-chemically prepared Cu(Mg)−Sn alloy showed weak diffuse reflections (Cu?, Sn) only. After heating a sample to 145 or 400°C, weak diffraction lines for Cu_6Sn_5[19] appeared in the X-ray powder pattern. XRD of the wet-chemically prepared Pd−Pb alloy showed the presence of Pb, but upon programmed heating to 300 or 400°C (in steps of 50°C), the spectrum showed weak diffraction lines for Pd_3Pb[20].

In order to gain more information about their structure, both nonannealed X-ray amorphous alloys were investigated using extended X-ray absorption fine structure (EXAFS) spectroscopy.

Structural Characterization of the Wet-Chemically Prepared Cu(Mg)−Sn and Pd−Pb Alloys Using EXAFS

The Fourier transforms of the $k^3\chi(k)$ functions at the Cu- and Sn-*K* absorption edges of the Cu(Mg)−Sn alloy are dominated by a single peak which at the Cu-*K* edge (Figure 7) is markedly split. An adaption of the Fourier-filtered $k^3\chi(k)$ functions requires, for the Sn central atom, a single coordination shell of Cu atoms. For the Cu central atom, a fit with only a single coordination shell is not possible. Two coordination shells consisting of Cu and Sn backscatterers are needed to reproduce the Cu-*K* EXAFS spectrum. Although only a limited *k* range (3−10 $Å^{-1}$) is available, a clear distinction between Cu and Sn backscatterers is possible. Using only Cu backscatterers, no fit is possible. The structural parameters of the Cu(Mg)−Sn alloy as determined by EXAFS spectroscopy are summarized in Table 1.

The agreement between the values for the Cu−Sn distance (2.68 Å) and for the EXAFS Debye-Waller factor σ

Figure 7. Unfiltered experimental (solid line) and fitted (broken line) $k^3\chi(k)$ functions and their Fourier transforms of the Cu(Mg)−Sn alloy at the Cu- (A) and Sn-K (B) absorption edges

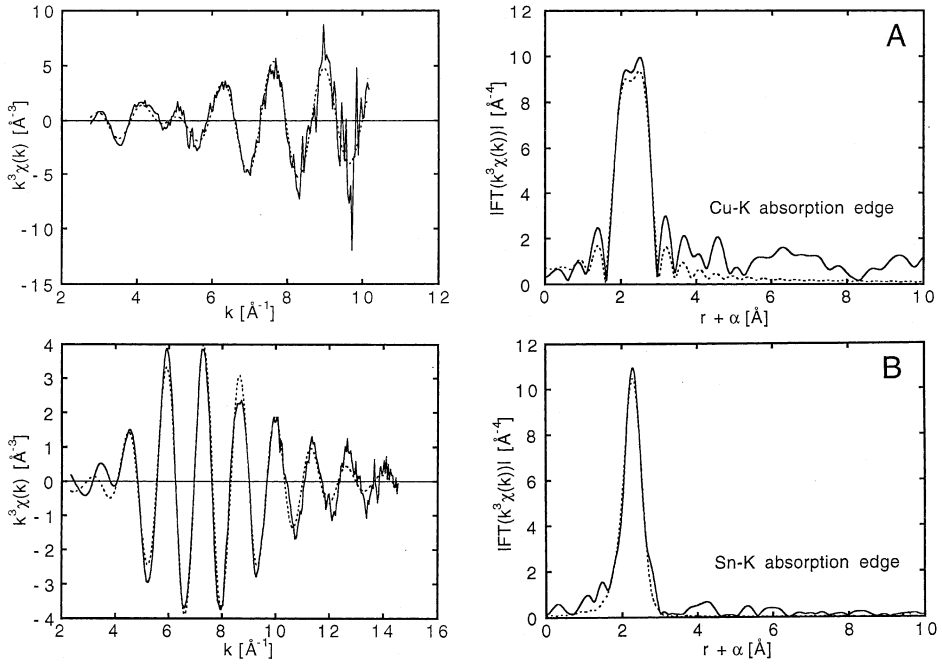


Table 1. Structural parameters of the Cu(Mg)−Sn alloy before annealing determined by EXAFS spectroscopy

absorber	backscatterer	r [Å]	N	σ [Å]
Sn	Cu	2.68	6.5	0.113
Cu	Sn	2.68	2.6	0.114
	Cu	2.56[a]	2.9	0.098

[a] The Cu−Cu distance corresponds to that of the bulk metal.

(0.113 and 0.114) obtained by analysis of the Cu and Sn data shows the structural parameters to be reliable. Although no further-reaching model can be proposed, the structural data (Table 1) allow the following conclusions to be made: (1) for the Sn central atom only Cu backscatterer atoms are observed; the neat Sn phase can therefore only be present to a very low extent, the greatest part of Sn being alloyed with Cu; (2) structural models which postulate the majority of Sn atoms to be on the surface of Cu particles can be excluded because for the Sn central atom ca. 6.5 Cu backscatter atoms are found; (3) the low number of atoms in the coordination shells is characteristic of extremely small metal particles having a large proportion of surface atoms and consisting of no more than a few dozen metal atoms. Coordination numbers determined by EXAFS spectroscopy are influenced by the quality of samples, thus for more accurate determination of coordination numbers further experiments are necessary. This is also especially true for EXAFS investigations of the annealed sample, which exhibit diffractometrically detectable phases and which point to higher coordination numbers; (4) Cu backscatterers at a distance of 2.56 Å are shown to be present using Cu-K EXAFS spectroscopy, demonstrating that a pure Cu phase is present.

The Fourier transforms of the experimental $k^3\chi(k)$ functions at the Pd-K and Pb-L_{III} absorption edges of the Pb(Mg)Pd alloy also show one single peak with a small shoulder at low r values. The nonfiltered, experimental and fitted $k^3\chi(k)$ functions and their Fourier transforms are shown in Figure 8. The curve-fitting procedure shows that the experimental $k^3\chi(k)$ functions at both the Pd-K and at the Pb-L_{III} absorption edge are dominated by the contribution of Pd backscatterers. Therefore, from the analysis of the Pb-L_{III} absorption spectrum, it can be concluded that the Pb atoms are mostly alloyed to Pd. Variations of the structural parameters of the Pd backscatterers influence the agreement between nonfiltered, experimental and fitted $k^3\chi(k)$ functions much more than variations of the structural parameters of the Pb backscatterers.

Both $k^3\chi(k)$ functions can be reproduced by inclusion of only two coordination shells of Pb and Pd atoms. For the final fits, the EXAFS Debye-Waller factors σ_{Pb-Pd} and

Table 2. Structural parameters of the Pd−Pb alloy before annealing determined by EXAFS spectroscopy

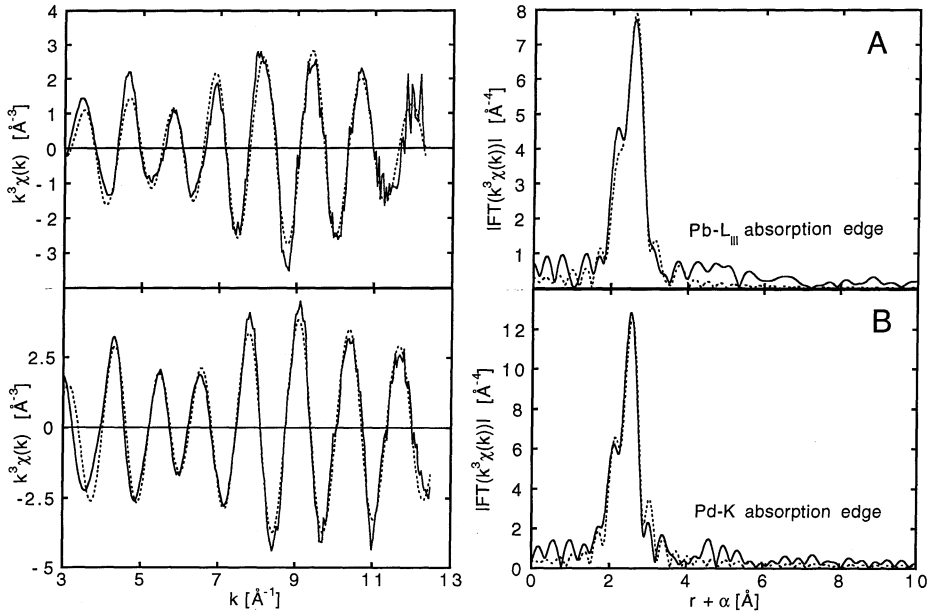
absorber	backscatterer	r [Å]	N	σ [Å]
Pb	Pd	2.8	4.2	0.103[a]
	Pb	3.6	1.9	0.144
Pd	Pb	2.8	2.6	0.103[a]
	Pd	2.8	4.6	0.091

[a] For the final fits, the EXAFS Debye−Waller factors σ_{Pb-Pd} and σ_{Pd-Pb} were constrained to the same value.

σ_{Pd-Pb} were constrained to the same value. The results of the curve fitting procedures are listed in Table 2.

The agreement between the values for the Pb−Pd distance (2.80 Å) derived from both $k^3\chi(k)$ functions confirms the reliability of these structural parameters too.

Figure 8. Unfiltered experimental (solid line) and fitted (broken line) $k^3\chi(k)$ functions and their Fourier transforms for the Pb−Pd alloy at the Pt-L_{III} (A) and the Pd-K (B) absorption edges



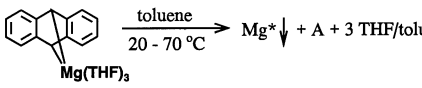
The data allow the following conclusions to be made: (1) only Pd backscatterers can be seen in the first coordination shell of the Pb atoms, suggesting that Pb is predominantly alloyed with Pd and at most a small fraction of Pb atoms exist as a pure Pb phase; (2) Pb atoms contribute significantly to the Pd-K EXAFS spectrum; a considerable part of the Pd atoms are therefore alloyed to Pb atoms; (3) because Pd atoms can also be seen in the first coordination shell of Pd atoms, and the determined Pd−Pd distance of 2.8 Pd Å is close to the Pd−Pd distance in bulk Pd (2.75 Å), a considerable fraction of Pd atoms seem additionally to be present in the form of bulk Pd.

Mg−As, Mg−Sb and Mg−Bi Intermetallics

As, Sb and Bi (M) together with Mg form Zintl phases of the formula Mg_3M_2[8]. Mg_3As_2 has been prepared by Zintl and Huseman[21] from As vapour and Mg at elevated temperatures under hydrogen. Mg_3Sb_2 and Mg_3Bi_2 have been obtained in bulk form by melting stoichiometric mixtures of pure metals in sealed steel crucibles.[8][21][22]

A highly reactive, pyrophoric form of magnesium (Mg*) with specific surface areas of 13−36 m^2g^{-1} can be generated by decomposing MgA in an organic solvent, such as toluene (Eq. 15).[23] By reacting $AsCl_3$, or $BiCl_3$ in THF with the Mg* thus obtained, it is possible to prepare the corresponding Zintl phases Mg_3M_2* in a finely divided, highly active, pyrophoric state (Eq. 16).

Mg_3As_2 (Expt. 7.1) is obtained by this method as a deep-brown, X-ray amorphous powder, with a specific surface area of 167.7 m^2g^{-1}. After annealing (400°C), the presence



(15)

$$2\,MCl_3 + 6\,Mg^* \xrightarrow[RT]{THF} Mg_3M_2 \downarrow + 3\,MgCl_2 \qquad (16)$$

M = As, Bi

of Mg_3As_2 was proved by X-ray diffraction[24] (Figure 9). $BiCl_3$ reacted with Mg* in THF (Expt. 7.2) to give a black pyrophoric powder with the composition $Mg_{1.45}Bi(MgCl_2)_{0.06}(CH_2)_{0.8}$, whose X-ray diffractogram (without annealing; Figure 10) exhibited strong diffraction lines for Mg_3Bi_2[25] and weak ones for Bi.

Reaction of $SbCl_3$ with MgA in THF (Eq. 17; Expt. 7.3) yielded a highly pyrophoric powder with the composition $Mg_{1.49}Sb(MgCl_2)_{0.03}(CH_2)_{1.4}$. The carbon in the solid was shown to be present in the form of THF and anthracene. An X-ray powder pattern of the sample (Figure 11) after annealing (400°C) demonstrated, however, the presence of a mixture of Mg_3Sb_2[26] and Sb.

$$2\,SbCl_3 + 6\,MgA \longrightarrow Mg_3Sb_2(+Sb)\downarrow + 3\,MgCl_2 + 6\,A \qquad (17)$$

Mg−Cd and Mg−Hg Intermetallics

$CdCl_2$ reacted with commercial Mg powder (molar ratio 1:2.2) in THF in the presence of catalytic amounts MgA

Figure 9. X-ray powder diffraction pattern of Mg_3As_2, prepared from $AsCl_3$ and Mg* (after annealing, 400°C)

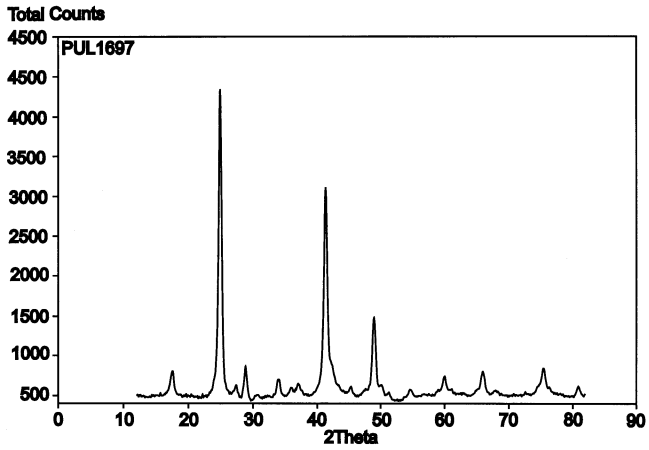


Figure 10. X-ray powder diffraction pattern of Mg_3Bi_2, prepared from $BiCl_3$ and Mg*; o, diffraction lines of Bi

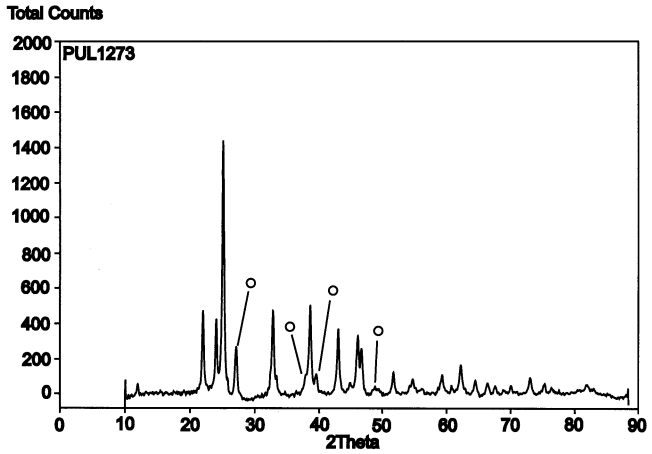

Figure 11. X-ray powder diffraction pattern of Mg_3Sb_2 (+ Sb), prepared from $SbCl_3$ and MgA; o, diffraction lines of Sb (after annealing, 400°C)

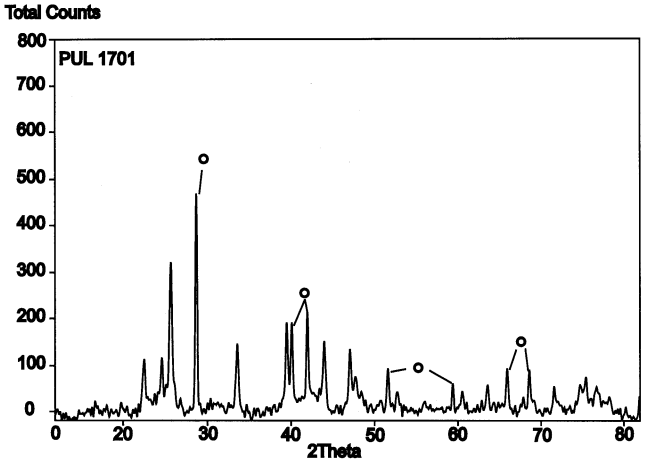

to give a solid of composition $Mg_{1.28}Cd(MgCl_2)_{0.02}(CH_2)_{1.9}$ (Expt. 8.1) which exhibited strong X-ray powder diffraction lines for MgCd and a weak reflection for $MgCd_3$[27] (Figure 12). The formation of a mixture of Mg−Cd intermetallics and the presence of ca. 30% of Cd in the reaction solution, probably indicate a more complex reaction course than that given by Eq. 18.

$$CdCl_2 + 2\,Mg \xrightarrow{MgA/THF} MgCd\downarrow + MgCl_2 \qquad (18)$$

The reaction of $HgCl_2$ with MgA (molar ratio 1:3.8) in THF takes place with a rapid liberation of 2.0 mol anthracene/mol $HgCl_2$ and formation of a finely divided solid having the composition $Mg_{1.32}Hg$ (Expt. 8.2); the X-ray powder pattern of the solid exhibited only sharp diffraction lines for MgHg[28] (Figure 13; Eq. 19).

$$HgCl_2 + 2\,MgA \xrightarrow{THF} MgHg\downarrow + MgCl_2 + 2\,A \qquad (19)$$

Conclusion

Magnesium intermetallics with heavier group 12−15 metals, which were previously known only in bulk form[8], can now be prepared in a highly active, nanocrystalline or amorphous state using a wet-chemical method (Eqs. 1−3).

They have, through metathetical exchange reactions (Eqs. 13 and 14), a synthetic potential as reagents for inorganic and organometallic chemistry, especially for the preparation of bimetallic noble metal−main-group metal heterogeneous catalysts[16][17][18][29][30]. In this sense, they represent main-group metal counterparts of inorganic Grignard reagents[1] (see Introduction). In addition, the low-temperature, kinetically controlled processes, such as for example in Eqs. 13 and 14, may be suitable for the preparation of as yet unknown metastable systems.

The authors thank Prof. Dr. *C. Krüger*, Dr. *C. Lehmann*, Dr. *B. Tesche*, and their coworkers (Max-Planck-Institut für Kohlenforschung) for conducting and discussing the XRD, DSC, TEM, and EDX analyses, and Dr. *J. S. Bradley* for useful comments. Financial support by the *Fonds der Chemischen Industrie* is gratefully acknowledged.

Experimental Section

Instruments: X-ray diffraction patterns: STOE, STAD/2/PL powder diffractometer, Cu-$K_{\alpha 1}$ radiation; the samples were filled into glass capillaries. HREM images: field emission TEM, Hitachi HF 2000, 200 keV. DSC: DuPont 9900; four points temperature and heat calibration method; heating rate, 10°C/min; Al crucible. EXAFS[31] spectra were recorded at station 9.2 at the SRS, Daresbury using a Si(220) double-crystal monochromator (storage-ring conditions: ca. 2.0 GeV, 150−200 mA). In all cases, data were collected in transmission mode. For the measurements, the material was mixed with PE and pressed to form self-supporting wafers. During the experiments the samples were kept under argon. To eliminate higher harmonics the second monochromator crystal was detuned, reducing the intensity of the X-ray beam to 65% (Pd-*K* and Sn-*K* absorption edges) or 50% (Pb-L_{III}, Cu-*K* absorption edges) of its maximum value. During the experiments, the energy calibration of the monochromator was checked with metal foils. Photoelectron threshold energies of 24350 eV, 29202 eV, 13055eV, and 8981 eV were chosen for the Pd-*K*, Sn-*K*, Pb-L_{III} and Cu-*K* absorption edges, respectively. Data evaluation was performed in *k* space using the program package[32] and amplitude and phase data calculated with the program FEFF6[33]. The usable *k* ranges were 2.9−10.2 $Å^{-1}$ at the Cu-*K* edge, 2.4−14.3 $Å^{-1}$ at the Sn-*K* edge, 2.8−12.2 $Å^{-1}$ at the Pb-L_{III} edge and 2.4−12.3 $Å^{-1}$ at the Pd-*K* edge.

Analyses: Elemental analyses and AAS measurements: Dornis and Kolbe, Mülheim an der Ruhr, Germany.

Materials: Magnesium anthracene·3 THF (MgA).[2] Mg powder (270 mesh, PK-31), purchased from the Eckart-Werke, Fürth, Germany, was used in all experiments unless otherwise stated. THF was boiled for several hours over MgA[2] and subsequently distilled under argon. All experiments and manipulations with air-sensitive materials were performed under dry argon. Vacuum = 0.1−0.2 mbar; high vacuum = 10^{-3} mbar.

Two-Step Preparation of Mg_2Ga_5. − Active Gallium (Ga) from $GaCl_3$ and MgA (Expt. 3.1):* 13.0 g (31 mmol) of MgA was suspended in 50 ml of THF. 50 ml of a 0.45 M solution of $GaCl_3$ in THF (22.5 mmol; $GaCl_3$ solutions in THF must be stored at ≤ −20°C, because at room temperature the solution eventually solidifies due to cationic polymerisation of THF) was added over a period of 0.5 h into the stirred MgA suspension previously cooled to −78°C. The colour of the suspension changed from orange to a dark brownish black. The stirred suspension was allowed to warm up to room temperature over a period of 18 h to give a black suspension. The Ga* was allowed to settle on the bottom of the flask and the green- or yellow-coloured supernatant liquid was removed. The solid was washed with several portions of fresh THF until the supernatant liquid was colourless. The metal could also be isolated by separating the reaction slurry using a centrifuge and, after washing, transferring the solid suspended in fresh THF, into a Schlenk flask.

Mg_2Ga_5 from Ga and MgA:* 3.67 g (8.7 mmol) of MgA was transferred at room temperature to the Ga* suspension (see above) in 100 ml of THF. The reaction mixture immediately turned green (reaction of MgA with residual $MgCl_2$ to form the radical anion complex $Mg_2Cl_3(THF)_6^+ A^{-\bullet}$[34]). After stirring at room temperature for 24 h, the product was allowed to settle from the suspension (now dark grey- or black-coloured), washed with several portions of THF, and dried under high vacuum. 1.53 g (83%) of Mg_2Ga_5 was obtained as a crystalline, black pyrophoric powder. Only diffraction lines corresponding to Mg_2Ga_5[7] were noted in the X-ray powder diffraction pattern (Figure 1).

MgTl from TlCl and MgA (Expt. 3.2): Solid TlCl (1.18 g, 4.92 mmol) was added in small portions to a stirred suspension of MgA (15.0 mmol) in THF (100 ml) at room temperature. From time to time 1.0-ml samples were taken from the stirred suspension, quenched with 3.0 ml of a toluene/CH_3OH mixture (25:1 vol./vol.) containing a known amount of *n*-$C_{16}H_{34}$ as an internal standard and the content of A in quenched samples determined by GC. Dependence of the concentration of A in solution (mol A/mol Tl) from the reaction time (h): 0.21(0.17), 0.43(1.0), 1.29(8), 1.37(24), 1.52(120).

After 170 h, the black suspension was filtered, the precipitate washed several times with THF (until the washing liquids become colourless) and dried in vacuum. MgTl (0.95 g, 81%) was obtained as a silvery shining powder. For the discussion of the DSC analysis of MgTl, see the general section. The X-ray diffractogram of MgTl is shown in Figure 2.

Sn from $SnCl_2$ and MgA at Room Temperature (Expt. 4.1):* To a cooled and stirred suspension of 6.45 g (15.4 mmol) of MgA in 50 ml of THF was added, in one portion, a solution of 3.21 g (16.9 mmol) of anh. $SnCl_2$ in 50 ml of THF; the temperature of the reaction mixture rose from 13 to 25°C and a black solid precipitated. During the subsequent stirring of the reaction mixture at room temperature, samples (2 ml) of the solution were taken, and by complexometric titration it was determined that the deposition of tin had already been completed after about 3 min. After this time, upon the hydrolysis of an aliquot of the solution, a molar ratio of A/9,10-dihydroanthracene (DHA) of 30:1 was determined by GC. The suspension was filtered, the precipitate was washed with THF and dried under vacuum. 1.34 g of a black powder was obtained which had the composition and the specific surface area as given in Table 4.

Sn from $SnCl_2$ and MgA at Low Temperatures (Expt. 4.2):* A cooled (ca. −30°C) solution of $SnCl_2$ in THF was added to a stirred suspension of MgA in THF which had been cooled to −70°C. The suspension was allowed to warm up to room temperature (24 h) and thereafter stirred at room temperature for another 24 h. A small part of Sn* was isolated by filtration, washing with THF and drying under vacuum. The Sn* thus obtained exhibited in XRD only broad, diffuse diffraction lines for Sn.

Preparation of the Sn/Mg_2Sn = 1:1 Mixture from $SnCl_2$ and MgA and the Subsequent Reaction of the Mixture with $SnCl_2$ to give Sn* (Expt. 4.3):* To a stirred solution/suspension of 6.94 g (16.6

[a] Based on M.

mmol) of MgA in 50 ml of THF was added dropwise a solution of 1.56 g (8.2 mmol) of anhydrous $SnCl_2$ dissolved in 50 ml of THF at room temperature over a period of 1 h, whereupon a black suspension formed. After stirring at room temperature for 1 h, a 2-ml sample of the suspension was protolyzed with 2 ml of a mixture of toluene/CH_3OH, 25:1, (using *n*-$C_{16}H_{34}$ as an internal standard) and analyzed by GC, whereafter the batch contained 15.4 mmol of anthracene and 0.3 mmol of 9,10-dihydroanthracene. Analysis of the deep-blue THF solution by complexometry showed 9.4 mmol of Mg^{2+} and 0.01 mmol of Sn. The suspension was filtered, and the solid was washed with THF until the washing liquid was colourless. After drying under vacuum, 1.17 g of black pyrophoric solid was obtained which had the composition Mg 12.4, Sn 60.5, C 1.9, H 0.3% (Mg/Sn = 1:1). After hydrolysis (H_2O + 5 N H_2SO_4, 1:1) of a sample of the solid and GC analysis of the organic portion, the solid contained 0.03% of anthracene. According to the X-ray powder analysis the solid was a mixture of Mg_2Sn with elemental Sn.

The preparation of the 1:1 mixture of Mg_2Sn + Sn* was repeated in the same manner as described above and was confirmed by X-ray powder analysis of an isolated small sample of the solid. The moist solid left after filtration was suspended in 50 ml of THF, the stirred suspension was mixed with a solution of 8.2 mmol of $SnCl_2$ in 47 ml of THF, and the mixture was stirred at room temperature for 7 h. The suspension was filtered and the solid was washed with THF and dried under vacuum. According to the X-ray diffractogram, only Sn, with no Mg_2Sn, was present in the solid.

Mg_2Sn from $SnCl_2$ and MgA (Expt. 4.4): 35 ml of a 0.217 M solution of $SnCl_2$ in THF (7.6 mmol) was added dropwise within 15 min to a stirred suspension of 12.82 g (30.6 mmol) of MgA in 100 ml of THF. (Solutions of $SnCl_2$ in THF are stable at room temperature for only ca. 15 min, but can be stored for long periods of time at −20°C.) The colour of the suspension changed from orange to olive green-black during the slightly exothermic reaction. After stirring for 3 h, the suspension was filtered (D4 sinter) and the solid washed with ca. 100-ml aliquots of THF. The filtrate was yellow-green (unreacted MgA) and at the final washing colourless. GC analysis of the combined filtrate showed 25.5 mmol of A and 3.4 mmol of DHA to be present. The black solid was dried under vacuum. Mg_2Sn (1.39 g, 87%) was obtained as a crystalline, black pyrophoric powder with the composition and the specific surface area as given in Table 4. A DSC analysis of a sample of Mg_2Sn thus prepared showed no endothermic peak up to 300°C (confirming the absence of Sn, m.p. 231.97°C, or of a Sn−Mg_2Sn eutectic, m.p. 203.5°C), but a weakly exothermic peak at 219°C. An X-ray diffractogram of a sample of Mg_2Sn was in accordance with the line diagram of Mg_2Sn from ref.[35].

The TEM photograph of Mg_2Sn taken from the experiment is reproduced in Figure 3; point-by-point EDX analyses of the nanocrystals gave Mg/Sn ratios ranging between 1.7 and 2.7, the majority of analyses giving a value of 2.0. Traces of Cl but no free Mg or Sn could be identified by EDX. The results confirm the formation of the intermetallic Mg_2Sn.

Monitoring of the Reaction $SnCl_2$ and MgA to form Mg_2Sn at 0°C (Expt. 4.5): 32.1 mmol of MgA was suspended in 125 ml of THF, the suspension was cooled to 0°C and kept at that temperature throughout the experiment by means of a cryostat. To the stirred suspension were added 1.48 g (7.8 mmol) of solid $SnCl_2$. 2.0 ml samples were taken periodically (see Figure 4) from the stirred suspension, quenched with a standard solution (see Expt. 3.2) and the content of A and DHA in the hydrolyzed samples with respect to the standard were determined by GC analysis. Analogous experiments were also carried out with equimolar amounts of SnF_2, $SnBr_2$, and SnI_2, and the same amounts of MgA and solvent. The results are graphically represented in Figure 4.

The Two-step Preparation of Mg_2Sn from $SnCl_2$ and MgA (Expt. 4.6): A solution of 7.7 mmol of $SnCl_2$ in 30 ml of THF was added dropwise to a stirred suspension of 7.7 mmol of MgA in 100 ml of THF. The black suspension of Sn* was stirred at room temperature for 1 h. The suspension was then cooled down to 0°C and an additional 24.5 mmol of MgA added. The progress of the stirred-batch reaction at 0°C was monitored as described in Expt. 4.5 and is represented graphically in Figure 4. The Mg_2Sn thus prepared was isolated and analyzed as described for Expt. 4.4; X-ray diffractogram, see Figure 5.

Mg_2Sn from $SnCl_2$ and MgA at Low Temperature (Expts. 4.7 and 4.8): The experiments were conducted in an analogous manner to Expt. 4.4, except that $SnCl_2$ was added to MgA each time at −70°C and, thereafter, the temperature of the reaction mixtures slowly raised from −70°C to room temperature (see Table 4). The Mg_2Sn thus prepared (Expt. 4.7) exhibited in the X-ray diffractogram only broad diffuse reflections characteristic of the intermetallic and Sn. The Mg_2Sn prepared in Expt. 4.8 was used for the reaction with $CuCl_2$ to form a Cu−Sn alloy (see Expt. 6.1).

Mg_2Pb from $PbCl_2$ and MgA at Low Temperatures (Expt. 5.1): The experiment was conducted in the same manner as Expts. 4.7 and 4.8. The XRD powder pattern of the reaction product was consistent with Mg_2Pb, except for very weak reflections for Pb; Mg_2Pb thus prepared was used for the reaction with $PdCl_2$ to form a Pd−Pb alloy (Expt. 6.2).

Mg_2Pb from $PbCl_2$, Mg Powder and 10 mol-% of MgA (Expt. 5.2): A suspension of 1.69 g (6.1 mmol) of $PbCl_2$, 19.1 mmol of

[a] Based on Sn. − [b] Only a small fraction of the solid was isolated. − [c] Reaction with $SnCl_2$ to give Sn, see text. − [d] TEM photograph, see Figure 3. − [e] Progression of the reaction with time, see Figure 4. − [f] XRD in Figure 5. − [g] Not isolated; used for the reaction with $CuCl_2$ (Expt. 6.1).

Mg powder and 1.9 mmol of MgA in 200 ml of THF was stirred for 10 days at 0°C. During the first 24 h of reaction the total amount of Mg^{2+} analyzed in the THF solution increased to 7.3 mmol and, thereafter, remained constant. Hydrolysis of an aliquot of the THF solution gave 1.5 mmol of *n*-butanol, expressed in terms of the whole solution (GC analysis) − the product of THF cleavage by Mg[23a]. Mg_2Pb was isolated from the THF solution in the same way as described in Expt. 4.4. XRD powder pattern in Figure 6.

A Cu(Mg)Sn Alloy from Mg_2Sn and $CuCl_2$ (Expt. 6.1): The Mg_2Sn suspension in THF (Expt. 4.8) was allowed to settle, the green supernatant solution was syphoned off, 50 ml of THF was added to the Mg_2Sn, the resulting suspension was stirred for 30 min, and the solution was again syphoned off. This operation was repeated two more times. Then, Mg_2Sn was suspended in 100 ml of fresh THF, the suspension was mixed with 3.48 g (25.9 mmol) of anhydrous $CuCl_2$ and was stirred at room temperature for 65 h. The black suspension was filtered, the solid was washed 4 or 5

times with THF and was dried under high vacuum, yielding 3.23 g of an Mg-containing Cu−Sn alloy which had the composition shown in Table 6. The EXAFS spectra of the Cu(Mg)Sn alloy are shown in Figure 7 and discussed in the text. In the filtrate of the batch were found 20.6 mmol of Mg^{2+} by way of an analysis (79%).

A Pd(Mg)Pb Alloy from Mg_2Pb and $PdCl_2$ (Expt. 6.2): 0.85 g (4.8 mmol) of anhydrous $PdCl_2$ was added to a stirred suspension of 0.63 g of Mg_2Pb from Expt. 5.1 (2.14 mmoles Pb) in 30 ml of THF. The suspension was stirred for 7 d at room temperature, filtered and the resulting solid washed with THF and dried under high vacuum. Yield: 0.99 g of a black powder of the composition as given in Table 6. The EXAFS spectra of the Pd(Mg)Pb alloy are shown in Figure 8 and discussed in the text. Mg^{2+} content of the filtrate: 4.1 mmol.

Mg_3As_2 from $AsCl_3$ and Mg (Expt. 7.1):* 9.21 g (22.2 mmoles) of MgA was suspended in 400 ml of toluene and stirred at room temperature for 24 h yielding a fine grey suspension of Mg*. Most of the solvent toluene was removed by decanting leaving ca. 40 ml of toluene with Mg*. After adding 100 ml of THF and 1.30 g (7.15 mmol) of $AsCl_3$ to Mg*/THF suspension, the reaction mixture was stirred for 5 d at room temperature. After filtration, washing with THF and pentane, and drying under vacuum, 0.95 g of Mg_3As_2 was obtained as a deep brown pyrophoric powder. XRD powder pattern in Figure 9.

Mg_3Bi_2 from $BiCl_3$ and Mg (Expt. 7.2):* The experiment was conducted in the same manner as in Expt. 7.1. XRD powder pattern in Figure 10.

(Mg_3Sb_2 + Sb) from $SbCl_3$ and MgA (Expt. 7.3): $SbCl_3$ was added to the stirred suspension of MgA in THF. The reaction mixture was stirred for several days at room temperature. The solid was isolated in the same manner as described in Expt. 7.1. After a hydrolytic work-up of the solid, THF and anthracene were identified in the organic phase by mass spectrometry.

MgCd(+ $MgCd_3$) from $CdCl_2$, Mg Powder and a Catalytic Amount of MgA (Expt. 8.1): A mixture of 1.33 g (7.24 mmol) of anhydrous $CdCl_2$ and 0.38 g (15.8 mmol) of Mg powder in 100 ml of THF was stirred at room temperature for 72 h; during this time, no reaction took place between $CdCl_2$ and Mg, as shown by the absence of any $MgCl_2$ in the THF solution. After addition of 1.0 mmol of MgA, the mixture was stirred for an additional 48 h, after which 11.0 mmol of Mg in the form of $MgCl_2$ (65.4% of the total amount of Mg used) was determined by complexometry in the solution (Cd^{+2} ions were masked by addition of KCN). After further stirring for several days, the concentration of $MgCl_2$ in the THF solution remained almost unchanged. Filtration, washing with THF and drying under high vacuum yielded 0.91 g of a grey powder with the composition given in Table 8. The X-ray pattern of the powder (Figure 12) exhibited, in addition to one weak signal

The possibility of grafting a series of alkyl polyacrylates and polymethacrylates onto a nickel cathode by electropolymerization of the parent monomers has been investigated and has emphasized the critical importance of the solvent used. Indeed, the intensity of the inhibition peak, which is the electrochemical mark of the cathode passivation as result of the polymer grafting, clearly depends on both the polarity and the donor-acceptor properties of the solvent. The Gutmann concept is used to account for these experimental results. An increase in the donicity of the solvent used for the electrochemical medium has allowed, for the very first time, several polyacrylates and polymethacrylates [such as poly(ethyl acrylate), poly(methyl methacrylate), and poly(2-trimethylsilyloxyethyl methacrylate)] to be electrografted onto Ni. This observation is consistent with a competition process between the monomer and the solvent for being adsorbed on the cathode and amassing in its very close vicinity. The outcome of this competition is controlled by the relative polarity (in case of low donicity) and the relative donor-acceptor properties (when the difference is high enough) of the monomer/solvent pair, and by the monomer concentration (in case of weak competition). A semi-quantitative relationship has also been observed between the monomer ability to be electrografted and the electron-accepting character of the vinyl β-carbon atom as measured by ^{13}C NMR.

Introduction

Although electrochemistry is a well-known technique for coating various conducting substrates by an organic polymer, the achievement of a stable polymer-metal association is usually a challenge, since a poor and short-lived interfacial adhesion is the rule[1][2].

According to the pioneering work by Lécayon et al.[3][4], we have confirmed in a previous paper[5] that polyacrylonitrile (PAN) could be cathodically electrografted onto several transition metals (Ni, Cu, Fe), and made clear that peak I, observed by voltammetry (Figure 1) is the mark of the grafting reaction. The term grafting, which implies a chemical bonding of the polymer to the metal, has been used by these authors on the basis of X-ray emission spectroscopy (EXES) analysis[6]. This quite unusual and promising reaction, originally reported in acetonitrile (ACN), which is a nonsolvent for the polymer (PAN), has been confirmed in a good solvent such as dimethylformamide (DMF)[5]. This observation is a convincing evidence for a highly stable interaction between PAN and the metal in the potential range of peak I. When this potential is increased further (Figure 1, peak II), the originally "grafted" PAN is debonded and dissolved in DMF and the polymerization occurs in solution[7][8].

Until now, only very few monomers are known for their capability of being grafted onto a metallic cathode. In addition to polyacrylonitrile that has been most extensively studied, grafting of poly(*p*-chlorostyrene) has been reported some years ago by Deniau et al.[9]. This conclusion might, however, be distorted by the parasitic loss of the chlorine atom simultaneously observed. A cross-linking reaction[10] gives a better account for the intrinsic insolubility of that polymer in the solvent used (ACN) and thus for the presence of the deposited film. The case of polymethacrylonitrile, recently reported by Tanguy et al.[11][12], is less ambiguous, since this polymer is known to be soluble in the reaction medium (ACN). Furthermore, according to these authors, infrared spectra did not show any structural modification indicating cross-linking[11]. Nevertheless, they noted that the electrografting of polymethacrylonitrile in acetonitrile strongly depended on the monomer concentration, without giving a satisfactory explanation for this experimental observation.

It is clear from the "state of the art" that the actual weakness of the electrografting reaction is the severe restriction on the choice of the polymer to be grafted. Discovery of new monomers prone to electrografting and able to make a stable organic coating reactive is highly desirable for specific technological applications (adhesion in composite materials, ...). The purpose of this paper is to search for experimental conditions under which the electrografting reaction known for acrylonitrile and methacrylonitrile could be extended to a large set of vinyl monomers. There is indeed a complete lack of information that could serve as a guideline for increasing the range of electrografted organic coating. It is interesting to note that the problem of polymer adhesion on various surfaces in different solvents has been discussed in terms of acid-base interactions between polymer and solid, polymer and solvent, and solvent and solid, in order to explain polymer deposition in a particular medium[13][14]. The problem is, however, more complex when the polymer is formed in situ by electropolymerization, since an additional partner has to be considered, i.e. the monomer. Furthermore, at the very first step of the process, only monomer and solvent may compete for adsorption on the metal, which is actually the electrode where electropolymerization is initiated. Once a polymer is formed, sites originally available to polymerization initiation would be progressively occupied until the complete passivation of the electrode. Nevertheless, during the whole process, a competitive monomer/solvent adsorption on sites left unoccupied has to be operative and to control the electrochemical reaction. It is therefore of prime importance to focus on the monomer adsorption on the cathode, a prerequisite step for the polymer grafting according to the early works by Lécayon et al.[15]. In line with these considerations, the adsorption of acrylonitrile ($CH_2=CH_3-CN$, the most widely studied monomer) from gas phase and liquid phase has been experimentally studied in case of metal substrates, i.e. copper[16], gold[17], platinum[18], silver[19], and nickel[20]. According to theoretical models, acrylonitrile interacts with the surface of copper, nickel, and iron[8][21] through both nitrile group and vinyl end, whereas it does not interact strongly with zinc[22]. These authors have also shown that formation of a σ complex between the β-carbon atom of the acrylonitrile C−C double bond and the metal atom is favorable in a moderate electric field, the nitrile substituent of the monomer being aligned along the field[8]. All these results emphasize the importance of the monomer adsorption. The voltammetric curves also suggest that an adsorbed species is involved in the charge-transfer step[23]. The important role played by the solvent in interfacial adsorption processes has been known for a long time in electrochemical experiments[24]. Displacement of solvent molecules by an electroactive molecule is the rule[25] and competitive adsorption of different species is a phenomenon commonly observed in these experiments[26]. Consistently, we have recently reported on the influence of the solvent polarity on the acrylonitrile electrografting, in particular on the monomer concentration in the electrical double layer of the electrode[7]. In this paper, we will discuss the problem of the competitive monomer/solvent adsorption for a series of solvent/monomer pairs, in reference to the well-known Gutmann donor−acceptor concept[27][28], which is a widely accepted criterion in electrochemical processes[29][30]. It will be shown, that the adequate choice of the solvent donor−acceptor properties with respect to the monomer, is a very powerful tool for qualitatively predicting the electrografting of a series of polymers widely used for technological applications [such as poly(ethyl acrylate), poly(methyl methacrylate) and poly(2-trimethylsilyloxyethyl methacrylate)] (Scheme 1), and known as "ungraftable" until now. A semiquantitative criterion will be proposed to evaluate the grafting capacity of new monomers and which solvent would be most appropriate to this purpose.

Results and Discussion

It has been observed for the first time that an acrylate other than acrylonitrile, i.e. ethyl acrylate, could be grafted onto nickel, just by substituting DMF for the commonly used ACN solvent. This observation has led to the detailed analysis reported in this paper.

For the sake of completeness, it must be noted that the widely described behavior of acrylonitrile will serve as a reference to establish whether the grafting of the monomers considered in this work, occurs or not. Numerous criteria have thus to be considered and have been systematically checked for each monomer considered in this study. Since the aim of this paper is to report on the critical effect of the solvent on the electrografting course, this systematic part of the work is not detailed here, but summarized as follows[5].(i) Both passivation (peak I) and diffusion (peak II) peaks can be observed in the recorded voltammograms (see Figure 1 as an example). (ii) When electrolysis is carried out in the potential range of peak I (Ep1), a thin polymer film is formed on the cathode, even in a good solvent for the polymer. No cross-linking reaction may account for this insolubility. When a second forward scan is carried out in this

potential range, the current intensity cannot be recovered as a consequence of the cathode passivation. Except when mentioned in the discussion, no unbound polymer is formed in the potential range of peak I, as attested by a lack of polymer precipitation when the electrochemical bath is poured into a nonsolvent for this polymer. The intensity of peak I (ip1) decreases when the monomer concentration is increased as result of a more rapid formation of an insulating film. No linear relationship between ip1 and $v^{1/2}$ can be found (v is the potential scanning rate). (iii) ip2 increases with the monomer concentration and a linear relationship between ip2 and $v^{1/2}$ confirms the diffusion-controlled origin of peak II. Chain propagation then occurs independently of the cathode (as confirmed by precipitation of the polymer from the electrochemical bath).

Ethyl Acrylate (EA) Reduction in Acetonitrile (ACN) and in Dimethylformamide (DMF)

Cathodic scans have been carried out in an extended range of EA concentration ($5{\cdot}10^{-2}$ to 2 M) in ACN, and only one reduction peak of high intensity is observed (Figure 2a). This unique peak has been previously identified as a diffusion peak, since the peak intensity (ip2) linearly increases with the square root of the potential scanning rate[5]. ip2 is also observed to increase upon increasing EA concentration, while its potential (Ep2) becomes more cathodic. Polymerization then occurs in the electrochemical solution.

The experiments have been repeated in DMF. Starting from the lowest concentration (10^{-2} M), as in ACN, the diffusion peak alone was noticed. Above 0.5 M EA concentration, this unique peak splits in two resolved components of highly different intensity, as shown by voltammetry on nickel in Figure 2b. Actually, the resolution of the two peaks (thus the distance they are apart from each other) increases and the intensity of peak I (ip1) decreases, when the monomer concentration is increased (Table 1). As previously concluded from the AN electrografting[5], the voltammogram strongly depends on the monomer concentration and on the polymerization kinetics. When the EA concentration is increased, the time required for the formation of an insulating film onto the cathode decreases, and so does ip1 since the inhibition occurs faster. When electrolysis is carried out in the potential range of peak I, the current drops down to zero and only a residual current is observed when the potential scan is repeated. Even though the experiment was conducted in DMF, a good solvent for poly(ethyl acrylate) (PEA), a film is clearly bound on the nickel electrode and is responsible for the cathodic passivation. Infrared spectroscopy carried out ex situ confirms the deposition of a PEA film (Figure 3a), since the IR spectrum is identical to the one recorded for a reference PEA film prepared by free-radical polymerization (Figure 3b). The four main bands at 2983, 1740, 1456 and 1183 cm^{-1} have been assigned to $\nu_{as}(CH_2)$, $\nu(C{=}O)$, $\delta(CH_2)$, and $\nu(C{-}O)$.

As discussed in a previous paper[7], the solvent polarity has a critical effect on the electrografting and this has been

Figure 2. Voltammetry of EA on nickel in a 0.05 M TEAP solution in: a) ACN, [EA] = $5{\cdot}10^{-2}$ M; b) DMF, [EA] = 2 M; v = 20 mVs^{-1}

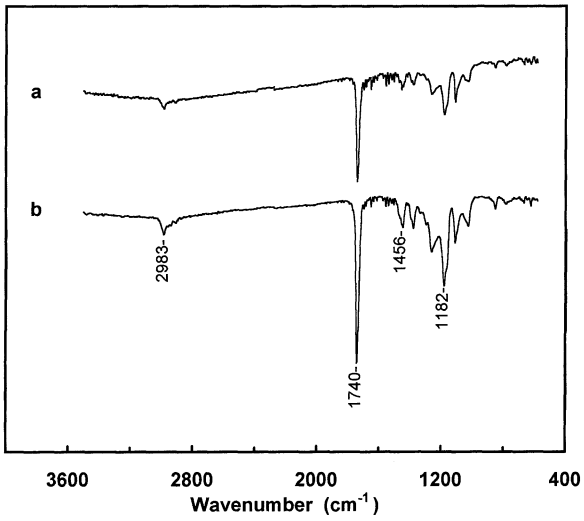
[a] Peak I superimposed to peak II.

explained by a competition between the solvent and the monomer. Depending on this competition, the actual monomer concentration at the cathode will be or will not be high enough for observing the cathode passivation. Since ACN and DMF have a very comparable polarity [ε(ACN) = 38.0; ε(DMF) = 36.1], this parameter cannot explain why EA is not electrografted to the cathode in ACN, although it is in DMF above a defined concentration, all the other conditions being the same. The Gutmann donor-acceptor approach[27][28] could however be a better basis for the qualitative comparison of the solvent and the

Figure 3. Infrared spectrum of a) a PEA film deposited on Ni from a solution of [EA] = 2 M in DMF at potential of peak I; b) a free-radically prepared PEA casted onto a Ni plate



monomer and their possible competition for the occupancy of the cathode surface. The donor number is characteristic of the solvation, coordination, and adsorption properties of the solvent. It is defined for each solvent as the numerical value of the enthalpic variation that occurs when the donor is added to the reference acceptor. Quantitative measurements have been carried out by Gutmann et al.[33], in case of a number of O- and certain N-containing solvent molecules added to antimony(V) chloride as the reference acceptor in 1,2-dichloroethane (the donor number of which has been assigned to 0). The acceptor number[28] is defined as a dimensionless number related to the relative chemical shift of ^{31}P in Et_3PO dissolved in the particular solvent. Hexane and $Et_3PO-SbCl_5$ in 1,2-dichloroethane are the references, to which the acceptor numbers 0 and 100, respectively, have been assigned. Antimony(V) chloride has been used as a standard for both acceptor number and donor number, in order to emphasize the relationship between acceptor properties and their conjugate donicity. Table 2 lists the donor number, the acceptor number and dielectric constant for the solvents which are used in this study. It is interesting to note that the acceptor number decreases from ACN to HMPA, thus in the reverse order to that of the donor number, although this observation is not the rule within the Gutmann scale. Under these specific conditions, the tendency of the solvents (used in this study) to be adsorbed may be discussed in terms of either donor numbers or acceptor numbers. Since the donor number of these solvents (Table 2) extend over ca. half the donor number scale (0−38.8) whereas the acceptor number (Table 2) cover a very short range of the acceptor number scale (0−129), the main discussion will refer to the donor number of the solvent without losing sense. DMF is clearly a stronger donor and a poorer acceptor than ACN. When AN and EA are compared (Scheme 1), the ester substituent of the polymerizable C−C double bond in EA is less efficient than the nitrile substituent in AN in triggering an electron delocalization. In the chemisorption model proposed by Lécayon et al.[15], AN would be properly oriented in the electric field at the cathode, as a result of the strong electron-withdrawing nitrile substituent. The acidic extremity (i.e. the β-carbon atom) of AN would accordingly be in an ideal position with respect to the reactive sites on the cathode (considered as a Lewis base). The β-carbon atom of EA has a lower acceptor capability than AN, which may be a key issue, since adsorption in electrochemistry (here on the cathode) is always a competitive process[24] between the adsorbate (the monomer in this case) and the solvent. Indeed, for an adsorbate molecule to occupy a surface site, a number of solvent molecules have to be displaced. It is therefore quite reasonable to assume that the electrografting of a monomer can only occur in a solvent which has a lower tendency to be adsorbed onto the cathode site, i.e. a solvent which is a poorer acceptor and/or a better donor.

Scheme 1

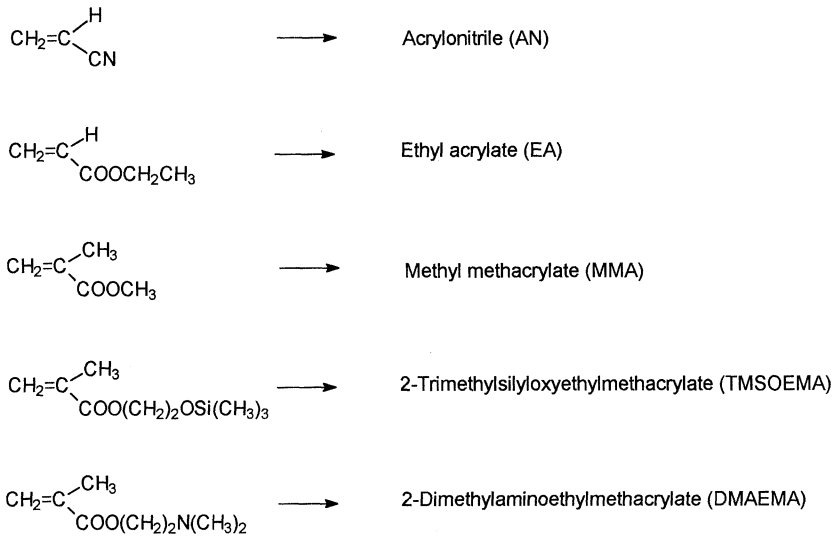


Table 2. Donor number, acceptor number, and dielectric constant of different solvents

Solvents	Donor number[28]	Acceptor number[28]	Dielectric constant[28]
ACN	14.1	19.3	38.0
PC	15.1	18.3	65.0
DMF	26.6	16.0	36.1
PY	33.1	14.2	12.3
HMPA	38.8	10.6	30.0

Several series of experiments are proposed in this paper to support this hypothesis. In a first step, the EA/DMF solution has been added with ACN in order to check the extent to which the electrochemical mark of the electrografting is perturbed.

In a second step, the electropolymerization of AN will be compared in four solvents: ACN, PC, PY, and HMPA, that are all nonsolvents for PAN. ACN and PC have a low and similar donicity, but highly different polarity. The donicity of PY and HMPA is high and quite comparable, whereas the polarity is very different (Table 2). The same cathode (Ni) and the same conducting salt (Et_4NClO_4, $5\cdot10^{-2}$ M) will be used in all the experiments.

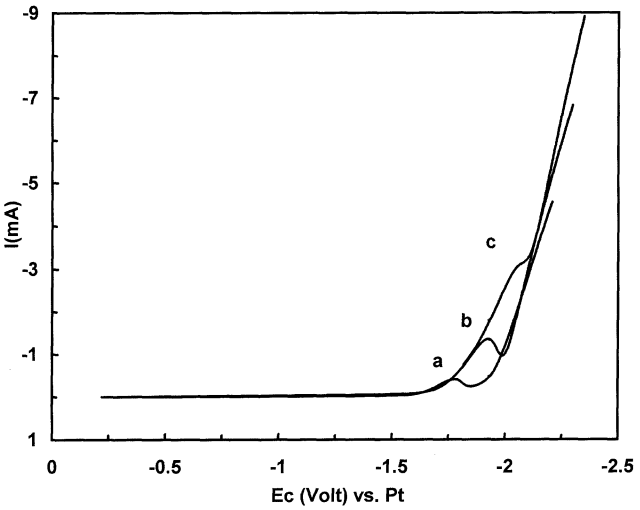
Finally, three methacrylic monomers: methyl methacrylate (MMA), 2-dimethylaminoethyl methacrylate (DMAEMA), and 2-trimethylsilyloxyethyl methacrylate (TMSOEMA) will be studied for investigating the possible effect of the monomer structure on their ability to be grafted onto the cathode.

Ethyl Acrylate (EA) Reduction in a Mixture of DMF and ACN

Figure 4 compares the voltammetric cathodic scans of a 1M EA solution in DMF modified by an increasing percentage of ACN. The monomer concentration is kept unchanged in all the experiments. When EA is electrografted in DMF, the intensity of the inhibition peak is ca. −400μA (Figure 4a). When the relative amount of ACN in the EA/DMF solution is increased, the intensity of peak I increases, whereas the resolution between peak I and peak II decreases (Figure 4 b, c). The dependence of ip1 on the ACN percentage in the EA/DMF solution is such that the cathode is more slowly inhibited, in agreement with a lower EA concentration at the cathode. This observation suggests that the co-solvent (ACN in this case) competes with the monomer for adsorption on the cathode. Since ACN and DMF have the same polarity and are both good solvents for PEA, only a significant difference in the donor-acceptor properties can explain the experimental observations in Figure 4.

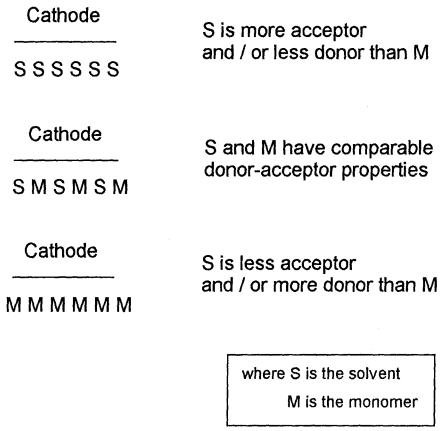
Scheme 2 illustrates this extreme situation where the monomer (e.g. EA) is a poorer acceptor than the solvent (e.g. ACN) and is so far unable to displace the solvent molecules in order to be adsorbed on the cathode sites. No inhibition peak is observed on the voltammogram but only a diffusion peak: this indicates that the monomer reduction

Figure 4. Voltammetry of EA on nickel (v = 20 mVs^{-1}) in a DMF solution, [EA] = 1 M, Ip1 dependence on the addition of ACN: a) without ACN; b) + 3% of the volume; c) + 12% of the volume



can occur at a more cathodic potential, as confirmed by the polymer formation in solution.

Scheme 2



Comparative Reduction of Acrylonitrile (AN) in ACN and PC, in PY and HMPA

Table 3 shows that the intensity of peak I (ip1) increases when PC is substituted for ACN at constant monomer (AN) concentration, thus when polarity is increased in case of solvents of low donicity. Figure 5 shows voltammograms of AN in PY. The intensity of peak I is much lower than in ACN and PC for the same monomer concentration (Table 3). As a rule, the cathode inhibition is controlled by the monomer concentration and ip1 systematically decreases as the AN concentration is increased[5]. So, the small ip1 value in PY might be explained by a high local AN concentration in the electrical double layer and a more rapid formation of an insulating film. As previously discussed the low polarity may account for the experimental observations[6], but the

effect of the solvent donicity may not be ignored. In order to appreciate the relative importance of solvent polarity and solvent donicity, hexamethylphosphoramide (HMPA) which has a high and comparable donicity as PY, but which is 2.5 times more polar has been used. Table 3 shows that there is no significant difference in the voltammograms in PY and HMPA since ip1 remains almost unchanged when HMPA is substituted for PY, all the other conditions being the same. From Table 3, we can draw the conclusion that the solvent polarity has a decisive effect on the AN electrografting only when the solvent is a good enough acceptor and a poor donor (see ACN/PC pair). When the solvent is a poor acceptor and a good enough donor (PY/HMPA pair), the polarity has no longer a significant influence, since that solvent has a small tendency to be adsorbed onto the cathode. Although neglected until now, the relative donor-acceptor properties of the monomer/solvent pair must be considered when the monomer electrografting is concerned.

Table 3. Intensity of peak I (ip1) for various AN concentrations in ACN, PC, PY, HMPA; $v = 20$ mVs^{-1}

Solvents	[AN] = $5\cdot10^{-2}$ M	[AN] = 0.1 M	[AN] = 0.5 M	[AN] = 2 M
ACN	[a]	370 μA	30 μA	25 μA
PC	[a]	650 μA	90 μA	60 μA

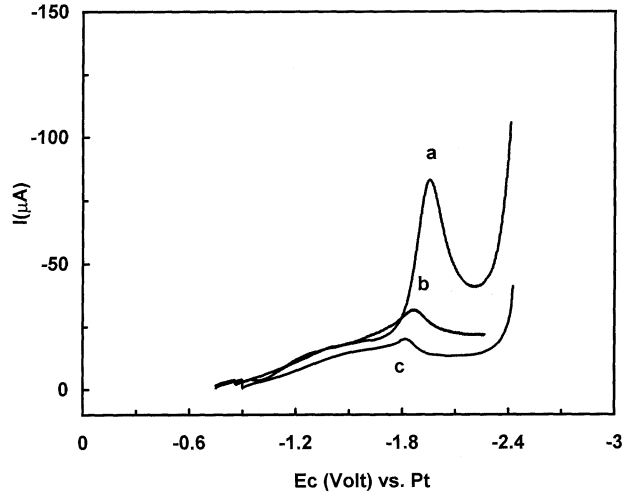
HMPA	30−35 μA	15−17 μA	[b]	[b]

[a] Peak I superimposed to peak II. − [b] Peak I intensity to weak to be detected.

Figure 5. Voltammetry of AN on nickel in a 0.05 M TEAP solution in PY: a) [AN] = $2\cdot10^{-2}$ M; b) [AN] = $5\cdot10^{-2}$ M; c) [AN] = 0.1 M; $v = 20$ mVs^{-1}



Scheme 2 summarizes the main experimental observations, that lead to the following conclusions: (i) As previously pointed out, no electrografting occurs when the solvent is a better acceptor than the monomer, to the point where the solvent is preferably adsorbed on the cathode to the exclusion of the monomer. (ii) When the monomer and the solvent have quite comparable donor-acceptor properties, the adsorption on the cathode is controlled by their relative polarity, the more polar compound being preferably adsorbed. (iii) If the solvent is a better donor and a poor acceptor (compared to the monomer), its tendency to adsorption is low, and any difference in polarity has no remarkable effect on the inhibition peak. The propensity of the monomer to be electrografted will be enhanced by increasing its electron acceptor capability compared to the solvent. Then the inhibition could be so fast that peak I is no longer observed because of an extremely low intensity. The only way to observe it, would be to decrease the monomer concentration.

Methyl Methacrylate (MMA) Reduction in ACN and in DMF

Although donor and acceptor numbers are available for a series of traditional solvents, no pertinent information has been reported in case of monomers, at least to our best knowledge. This situation has prompted us to compare three methacrylate monomers, different by the substituent in the ester group and accordingly by the acceptor properties of the β-carbon of the polymerizable double bond (Scheme 1). The monomers have also been selected on the basis of the "reactivity" of the ester group in order to provide the final organic coating with adhesive properties towards a polymeric matrix, e.g. for producing composite materials. Methyl methacrylate (MMA), the most widely used methacrylate, 2-hydroxyethyl methacrylate (HEMA), and 2-dimethylaminoethyl acrylate (DMAEMA) have been considered in this study (Scheme 1).

Electroreduction of MMA has been first studied in ACN, and only one diffusion peak has been observed, indicating that the solvent is preferably adsorbed onto the cathode within a monomer concentration range of 0.1 M to 3 M.

In reference to Scheme 2, DMF, i.e. a solvent of a higher donicity than ACN (Table 2) was substituted for ACN, in order to increase the probability for the monomer to be preferably adsorbed on the cathode. At MMA concentrations smaller than 2 M, only one reduction peak (diffusion peak) is observed. Beyond 2 M, this unique peak splits into two steadily resolved components. Figure 6 shows the voltammogram when the MMA concentration is 3 M. Undoubtedly when MMA concentration is increased, the intensity of the less cathodic peak rapidly decreases (Table 4) and the resolution between the two peaks increases. This behavior is typical of the inhibition peak observed in experiments conducted with AN and EA. The main difference with respect to these monomers, has to be found in the high concentration required to evidence the MMA electrografting. This observation indicates that MMA can only successfully compete for adsorption onto the cathode when its relative abundance with respect to DMF is high enough. The same experimental observations have been reported for methacrylonitrile[11], which is a poorer acceptor than acrylonitrile due to the electron donating effect of the α-methyl substituent.

Figure 7 shows the cathodic response of a 2 M MMA solution in DMF when the cathodic scan of the potential

[a] Peak I superimposed to peak II.

range of peak I followed by a 20-s voltage hold is repeated. In contrast to what happens when this experiment is conducted with acrylic monomers such as AN or EA, the cathode is not fully passivated after one scan. Indeed, ip1 decreases slowly upon repeated cathodic scans. A film is clearly seen by the naked eye on the cathode when it is withdrawn from the electrochemical cell after one scan. When the number of scans is increased, the PMMA coating is seen as a thick gel-like layer poorly adhering to the metal. This result is quite surprising and in contrast with previously published data for PAN. Indeed the PAN film thickness measured ex situ by ellipsometry does not change when the cathodic scans are repeated in the potential range of peak I[34]. The IR spectrum of the polymer coating (dried in vacuo but not rinsed with solvent) (Figure 8a) confirms the PMMA deposition, the main absorption bands at 3006, 1739, and 1151 cm^{-1} being assigned to $\nu_{as}(CH_2)$, $\nu C{=}O$), and $\nu C{-}O$), respectively. However, the intensity of the absorption bands decreases if the electrode is previously washed with THF, i.e. a good solvent for PMMA, (comparison of Figures 8a and 8b). Since only the polymer chains strongly bound to the electrode remain on it after the washing step, one may suppose that unbound polymer chains are produced simultaneously to grafted ones, which may lead to unreliable film thickness. Consistently, PMMA is formed in solution as demonstrated by PMMA precipitation from the electrochemical bath in methanol (nonsolvent for PMMA, solvent for Et_4NClO_4). This observation is very similar to that one reported by Tanguy et al. for the electrografting of methacrylonitrile (MAN)[11]. Measurements performed with a quartz crystal microbalance[12] have shown that unbound polymethacrylonitrile chains are embedded in a thin layer of grafted ones. On the basis of that observation valid for one monomer (MAN), the authors have proposed a mechanism of "oligomer grafting" instead of the "monomer grafting" they claimed until now[15]. This revision of the grafting mechanism, which is not essential for the purpose of this paper, might, however, be hasty, since unbound polymers in the potential range of peak I (at which the grafting occurs) have never been observed in case of acrylic monomers (such as AN or EA). This observation is actually confined to the electrografting of methacrylates, i.e. methacrylonitrile and MMA, and is certainly not a general behavior. Although the high concentration of methacrylonitrile and MMA which is required for electrografting is in a qualitative agreement with the competitive solvent/monomer adsorption concept, it is not clear yet why unbound methacrylate chains are observed in

Figure 7. Voltammetry of MMA on nickel in a 0.05 M TEAP solution in DMF carried out in the potential range of peak I, [MMA] = 2 M; v = 20 mVs^{-1}: a) first scan; b) second scan

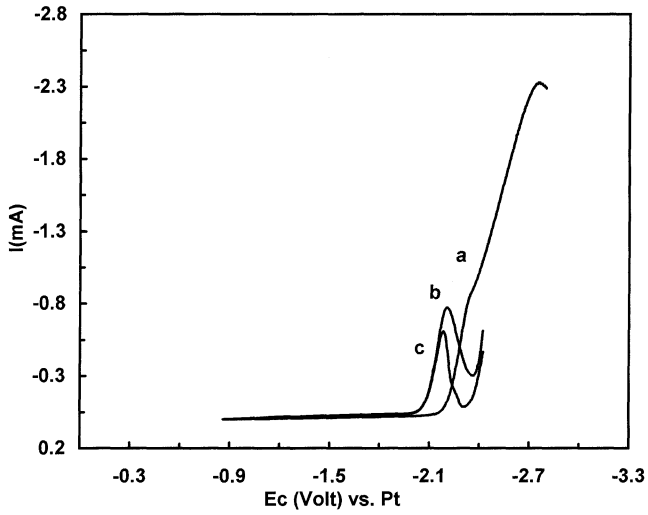
the potential range of peak I. This problem will be discussed in a forthcoming paper.

TMSOEMA and DMAEMA Reduction in ACN and DMF

Nowadays an increasing interest is paid to 2-hydroxyethyl methacrylate (HEMA)[35] and the parent poly(HEMA), which are suitable biomaterials for implants because of their lack of toxicity and their high resistance to degradation[36]. Furthermore, hydroxy groups are reactive towards various topcoats (paint, varnish) that could be used for imparting specific properties to the metal substrate. HEMA may, however, not be used as such, because of the interference of the hydroxy proton reduction. It is the reason why HEMA has to be protected by a trimethylsilyl group, which is easily removed after polymerization. Electrochemical experiments have been conducted with the protected monomer (TMSOEMA) in ACN. Within the 0.1 M to 2 M concentration range, only a diffusion peak is observed. Nevertheless, the classical grafting "signature" has been observed in DMF (poorer acceptor and better donor than ACN) beyond a 0.1 M concentration (Figure 9). It must be noted that in agreement with what happens for MMA and MAN, unbound PTMSOEMA is also embedded in the thin layer of grafted chains when the electropolymerization is conducted in the potential range of peak I.

Finally, the grafting of the third methacrylate, DMAEMA, remained impossible in ACN and in DMF, suggesting so that this monomer cannot compete with these solvents for adsorption onto the cathode.

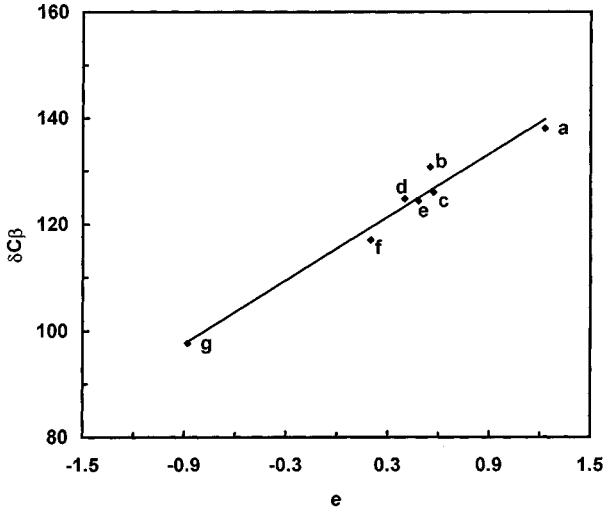
Figure 9. Voltammetry of TMSOEMA on nickel in a 0.05 M TEAP solution in DMF: a) [TMSOEMA] = 0.1 M; b) [TMSOEMA] = 0.2 M; c) [TMSOEMA] = 0.5 M; v = 20 mVs^{-1}



Tentative Prediction of the Cathodic Monomer Grafting

From the experimental results reported in this paper, it appears that the ability of vinyl monomers to be electrografted onto a metal, strongly depends on the electron deficiency of the β-carbon atom double bond. In case of radical copolymerization, the monomer reactivity can be predicted by the Alfrey-Price Q−e scheme[37]. According to these authors, the electrostatic factor e is representative of the monomer polarity and thus of the electron-donor (or -acceptor) character of the vinyl substituent. A linear relationship[38] has been found between the ^{13}C-NMR chemical shifts of the β-carbon atom of the double bond [δ(C-β)] and the corresponding e values[39][40]. By analogy the ^{13}C-NMR spectra of the monomers considered in this paper have been recorded in mixed DMF/$CDCl_3$ solutions. The experimental δ(C-β) values agree with the previously reported data when plotted against e (Figure 10) and they are consistent with an electrografting propensity that decreases when the vinyl β-carbon atom is more shielded, thus less inclined to accept electrons. AN has clearly the less shielded β-carbon atom and is thus the best competitor towards the solvents, since vinyl chloride and vinyl acetate have the more shielded β-carbon atom and have no chance to be adsorbed onto the cathode and to be electrografted as confirmed experimentally. According to the electrochemical experiments reported in this paper, EA is more competitive than MMA towards DMF in agreement with the inductive effect of the α-methyl group in MMA that counterbalances the electron-withdrawing effect of the ester group so that the electron delocalization of the MMA double bond is less pronounced than in EA. This conclusion agrees with the relation of δ(C-β) shown in Figure 10 for EA and MMA. This qualitative consistency is, however, no longer observed when TMSOEMA and DMAEMA are concerned. In a similar way, Figure 10 cannot explain why DMAEMA is not electrografted in DMF. This behavior also remains unexplained when inductive or mesomeric effects are considered. It could, however, be explained by the presence of the silicon group in TMSOEMA and of amino group in DMAEMA. The silicon atom (electron acceptor) can contribute to the monomer adsorption and thus to the electro-

Figure 10. ^{13}C-NMR chemical shifts [δ(C-β)] of monomers vs the corresponding e values: a) AN; b) EA; c) TMSOEMA; d) MMA; e) DMAEMA; f) vinyl chloride; g) vinyl acetate



grafting, whereas the amino group (electron donor) can prevent this adsorption from occurring. These assumptions will be supported by theoretical calculations in a forthcoming paper.

Concluding Remarks

The important potentiality of grafting monomers other than AN has been demonstrated in this paper. We have indeed observed that under suitable conditions, ethyl acrylate (EA), and some methacrylates can be electrografted on e.g. nickel, thus with creation of a stable polymer−metal interface, although the reaction is carried out in a good solvent for the polymer. It is now clear that the choice of the solvent for the cathodic grafting of vinyl monomers has a decisive effect on the issue of the electrochemical reaction by deciding whether a strong chemisorption of the electropolymerized material occurs or not.

The explanation for this solvent effect has to be found in a competition between the solvent and the monomer for the localization at the electrode. The issue of this competition strongly depends on the relative donor-acceptor properties and polarity of the solvent with respect to the monomer as confirmed by a great effect on the potential and intensity of the inhibition peak. The polarity of the solvent is more important as this solvent is a better electron-acceptor (and a poorer donor) than the monomer and has thus higher probability to be adsorbed onto the cathode. Conversely, the effect of the solvent polarity decreases when the solvent is a poor acceptor (and a good donor), thus when this solvent has less chance to be in the electrical double layer. If solvent and monomer have a comparable liability to be adsorbed at the cathode, then the monomer concentration has a decisive effect on the grafting issue.

One important criterion for the cathodic electrografting of a monomer is the choice of a solvent with a weaker acceptor character and higher donicity than the monomer, provided that this solvent is not electroactive in the potential range of interest. As a consequence of this rule, the more the substituent of the polymerizable double bond decreases the acceptor capacity of the monomer, the smaller the ability of this monomer to be electrografted. The measurement of the ^{13}C-NMR chemical shifts for the β-carbon atom of the vinyl double bond could accordingly serve as a preliminary semiquantitative tool for predicting the grafting ability of new monomers. However, some problems can arise when the monomer substituent contains atoms or groups of atoms that do not influence too much the β-carbon atom although they can contribute to the cathode adsorption by their electron acceptor or donor capacity.

A theoretical model accounting for the competitive adsorption of monomer/solvent pairs is currently studied and will be the topic of a forthcoming paper.

Experimental Section

Acrylonitrile (AN: Aldrich, > 99%), ethyl acrylate (EA: Acros, 99.5%), methyl methacrylate (MMA: Acros, 99%), 2-(dimethylamino)ethyl methacrylate (DMAEMA: Acros, 98%), and acetonitrile (ACN: Acros, p.a.) were dried over calcium hydride (Acros: 93%) and distilled under reduced pressure. Dimethylformamide (DMF: Acros, p.a.) was dried over phosphorus pentoxide (Acros 98%) and distilled at 70°C under reduced pressure. Propylene carbonate (PC: Acros, 99%) and 2-hydroxyethyl methacrylate (HEMA: Acros, 96%) were dried over molecular sieves 4 Å for 24 h and distilled at 85°C and 50°C, respectively, under reduced pressure. Pyridine (PY: Acros, 99.5%) was dried over potassium hydroxide (Acros: 98%) for 2 h at 120°C and distilled at 40°C under reduced pressure. Hexamethylphosphoramide (HMPA: Aldrich 99%) was dried over calcium hydride for 24 h and distilled at 80°C under reduced pressure. Tetraethylammonium perchlorate (TEAP: Fluka, > 99%) was heated in vacuum at 80°C for 12 h prior to use.

2-Trimethylsilyloxyethyl methacrylate (TMSOEMA) was synthesized by adding dropwise chlorotrimethylsilane (ClTMS: Acros, 98%) to a mixture of previously dried HEMA and triethylamine (Acros, 99%) in tetrahydrofuran (THF: Acros, p.a.)[31]. The reaction was carried out in THF at 0°C, under an inert and dry atmosphere and stirring for 12 h. Triethylamine hydrochloride was filtered off, and THF distilled off under reduced pressure. The residue was purified just before use by distillation under reduced pressure at 50°C. The product was then identified as TMSOEMA by ^{1}H-NMR spectroscopy [i. e. presence of the trimethylsilyl $-Si(CH_3)_3$ resonance at $\delta = 0.1$ and absence of the hydroxy −OH resonance at $\delta = 3.3$]. The purity was ascertained to be higher than 99.5% by gas chromatography.

Voltammetry (CV) experiments were carried out with each monomer (10^{-2} to 2 M), dissolved in an appropriate solvent containing tetraethylammonium perchlorate (TEAP) as a conducting salt ($5 \cdot 10^{-2}$ M).

The water content was measured by the Karl-Fischer method (Tacussel aqua processor) and ascertained to be lower than 5 ppm. All the experiments were carried out in a glove-box at room temperature under an inert (lower than 10 ppm in oxygen) and dry atmosphere.

The potentiostat used for the voltammetry experiments was a PAR-E. G&G model 273A. The electrochemical cells are described elsewhere[5]. Potentials were measured against a Pt pseudo-reference electrode. The nickel working electrodes of 2 cm^2 area, were mechanically polished with an alumina suspension in water, washed with heptane and acetone, and finally treated overnight in vacuum at 150°C. The residual nickel oxide on the electrode surface was then electrochemically reduced in an ACN/TEAP solution in the glove-box just prior to electropolymerization. The oxide layer was completely removed as assessed by a reduction current dropping down to zero after several potential scans. The rapid transfer of the cathode from one solution to the other within the glove box ensures the absence of oxide at the metal substrate, which is a prerequisite for polymer grafting[32].

A reference poly(ethyl acrylate) sample (PEA) was prepared by free radical polymerization of EA in DMF (0.5 M solution) initiated by 2,2′-azobis(2-methylpropionitrile) (AIBN: Acros, 98%) at 60°C for 6 h. The polymer was precipitated in methanol, washed several times with methanol in order to remove the unreacted monomer and AIBN, and dried in vacuo at 40°C for 24 h. A PEA film was solvent-casted (DMF) onto nickel plates, such that infrared spectra could be recorded by the same technique as for the electrografted films.

Except for specific treatment mentioned in the discussion all the electrografted films were carefully rinsed with a good solvent for the polymer in order to remove any ungrafted chains and conducting salt, and dried in vacuo for 2 h before characterization.

IR spectra were recorded ex situ with a BRUKER (Equinox IFS 66) FTIR spectrometer equipped with a grazing angle accessory (83°) and a polarizer (Specac KRS-5). – ^{13}C-NMR data were recorded in a mixed DMF/$CDCl_3$ medium with a BRUKER AM 400 apparatus operating at 100 MHz.

New alkyl and allyl complexes **1**–**3** {**1**: $[Cp'_2Sm(C_3H_5)]_n$, Cp′ = $Me_3CC_5H_4$; **2**: $[Me_4C_2(C_5H_4)_2]Sm(C_3H_5)_2Li(dme)$, dme = $(CH_3OCH_2CH_2OCH_3)$; **3**: $Cp'_2SmMe_2Li(dioxane)$} were synthesized from $(Cp'_2SmCl)_2$ and from the magnesium derivative $[Me_4C_2(C_5H_4)_2]SmCl \cdot MgCl_2(THF)_4$ (**4**). The ansa anionic complex **2** exhibited good activity for the stereospecific 1,4-*trans* polymerization of isoprene, whereas the neutral derivative **1** was inactive. In the same way, the anionic complex $[Cp'_2SmMe_2]Li(dioxane)$ (**3**) was found to be an ethylene polymerization catalyst of very short lifetime. The lack of reactivity of **1** is related to the associated structure of this coordinatively unsaturated complex: this fact was established by the formation of the carbene adduct $Cp'_2Sm(C_3H_5)[C(NiPr)_2(CMe)_2]$ (**1′**). Crystals of **1′** were isolated but this new compound undergoes a partial rearrangement into a tris-Cp′ species in solution. Similar behaviour is observed for the analogous complex $Cp'_2SmCl[C(NiPr)_2(CMe)_2]$ (**1′′**). The X-ray crystal structure revealed the formation of the adduct, as a toluene solvate, which exists in benzene solution in equilibrium with Cp'_3Sm and $Cp'SmCl_2[C(NiPr)_2(CMe)_2]_2$. The catalytic behaviour of **2** is compared with that of other early lanthanide derivatives.

Introduction

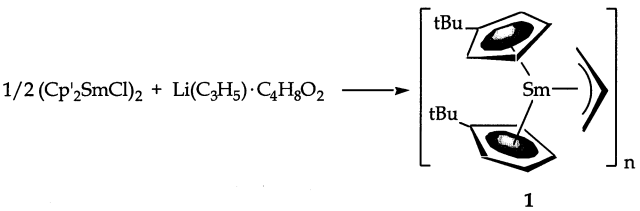
Isoprene polymerization, in relation to the chemistry of elastomers and adhesives, is of current interest[1]. Hydrido- or alkylmetallocenes of lanthanides are efficient catalysts for ethylene polymerization in the absence of the methyl aluminoxane reagent MAO[2][3]. However, the compounds Cp_2*LnH or Cp^*_2LnR, Cp* = C_5Me_5 or related bridged systems, are almost completely unreactive for the polymerization of α-olefins or dienes[4]. We were interested in the determination of the limits of stability of less hindered metallocene hydrides[5] of the early lanthanides and established that the hydride $[Cp'_2SmH]_2$, Cp′ = $Me_3CC_5H_4$, can be observed in solution, whereas the analogous neodymium hydride is only a transient species[6][7]. In this Cp′ series, or preferably in an analogous ansa cyclopentadienyl series [to avoid the easy redistribution leading to tris(cyclopentadienyl) derivatives], it was therefore necessary to synthesize alkyl or allyl derivatives that would be stable compounds capable of catalyzing the diene (and especially isoprene) polymerization without addition of a co-catalyst. The microstructure of a polymer is, to a large extent, controlled by the mode of coordination of the monomer to the catalyst: in a Cp'_2SmR moiety, even when R is a non-bulky alkyl or allyl ligand, only one vacant site will be readily accessible and, consequently, a stereospecific 1,4-*trans* polymerization is expected[8].

Results and Discussion

Synthesis of *tert*-Butylcyclopentadienyl Complexes

The methyl derivative $(Cp'_2SmMe)_2$[5] had been synthesized from $(Cp'_2SmCl)_2$[9] by addition of MeLi. The neutral allylic derivative $[Cp'_2Sm(C_3H_5)]_n$ (**1**) was obtained in a similar way using the dioxane adduct of allyl lithium[10] (Scheme 1).

Scheme 1



1

Compound **1** was isolated in an analytically pure state as a red oil. Due to the fact that no ether ligand remained coordinated, it was inferred that this compound was dimeric or polymeric. Attempts to obtain a monomeric solvated form by crystallization in the presence of oxygenated solvents were unsuccessful. However, crystals could be obtained in the presence of another Lewis base, i.e. the stable carbene 1,3-diisopropylimidazoline-2-ylidene $C(NiPr)_2$-

 © WILEY-VCH Verlag GmbH, D-69451 Weinheim, 1998 1434–1948/98/1111–1721 $ 17.50+.50/0

$(CMe)_2$[11], which has recently been used as a ligand in lanthanide compounds[12]. The nitrogen analysis of these thin red plates was consistent with the formula of a mono adduct $Cp'_2Sm(C_3H_5)[C(NiPr)_2(CMe)_2]$ (**1′**). The crystals were not suitable for X-ray structural analysis because the melting point was just above ambient temperature and, consequently, crystals melted in the sealed capillary. Surprisingly, the ^{1}H-NMR spectrum (C_6D_6 solution) of these monocrystals showed the known signals of Cp'_3Sm (ca. 10%) in addition to the set of signals due to the adduct (90%). A partial redistribution of the ligands could be involved, although no signals corresponding to the concomitant formation of a mono Cp′ derivative were detected.

Although we could not establish unambiguously the behaviour of $Cp'_2Sm(C_3H_5)[C(NiPr)_2(CMe)_2]$ (**1′**) in solution, this was possible in the case of another carbene adduct. Addition of one equivalent of the carbene $C(NiPr)_2(CMe)_2$ to a toluene solution of $(Cp'_2SmCl)_2$ allowed the isolation of yellow crystals [see ORTEP view (Figure 1) and Experimental Section] of an analytically pure toluene solvate of the adduct $Cp'_2SmCl[C(NiPr)_2(CMe)_2]$ (**1″**).

1:3 ratio. The percentage of the carbene adduct **1″** was a function of the concentration and it was found to be higher (nearly 80%) in dilute solution. This equilibrium (Scheme 2) is slow in the NMR timescale and Spin Saturation Transfer (SST) experiments could not be performed.

Synthesis of Ansacyclopentadienyl Complexes

An ansa compound was synthesized from $SmCl_3(THF)_3$ and the Grignard reagent $[Me_4C_2(C_5H_4MgCl)_2](THF)_4$[13]. The X-ray crystal structure of two related samarium complexes $[\{Me_4C_2(C_5H_4)_2\}SmCl(THF)MgCl_2(THF)_3]$ and $[\{Me_4C_2(C_5H_4)_2\}SmCl(THF)]_2$ have been described elsewhere[14][15]. The reasons for the formation of one or other of these complexes were not clear given that the starting

[a] Selected bond lengths [Å] and angles [°]: Sm−C(1) 2.62(2), Sm−Cl 2.648(4), Sm−Ct(1) 2.45(1), Sm−Ct(2) 2.44(1); Ct(1)−Sm−Ct(2) 128.6(14), Ct(1)−Sm−C(1) 106.3(9), Ct(1)−Sm−Cl 107.9(7), Ct(2)−Sm−C(1) 101.8(9), Ct(2)−Sm−Cl 105.6(6), C(1)−Sm−Cl 104.2(3).

After dissolution of these crystals in C_6D_6, the NMR spectrum showed the presence of three compounds: **1″**, a second adduct identified as $Cp'SmCl_2[C(NiPr)_2(CMe)_2]_2$ on the basis of the NMR data, and the unavoidable Cp'_3Sm. The integral values for the Cp signals of $Cp'SmCl_2[C(NiPr)_2(CMe)_2]_2$ and Cp'_3Sm were, as expected, in a

materials and the experimental procedures were quite similar. NMR data were not mentioned and, consequently, it was not established wether the two complexes could be distinguished in solution. The formation of a related monomeric complex, $[Me_4C_2(C_5H_4)_2]SmCl(THF)$, had also been reported, and this involved the oxidative addition of *tert*-

butyl chloride to the Sm^{II} compound $[Me_4C_2(C_5H_4)_2]Sm$. In this case NMR data were obtained[16].

Initially we tried to investigate the reaction on an NMR-scale preparation. By mixing stoichiometric amounts of $SmCl_3(THF)_3$ and $[Me_4C_2(C_5H_4MgCl)_2](THF)_4$ in C_6D_6, a yellow solution and a white precipitate of salts were obtained. The solution was transferred into another tube and the solvent removed under reduced pressure to remove the excess THF originating from the Grignard reagent. After redissolution in C_6D_6, the NMR spectrum showed the presence of four remaining THF molecules per $[Me_4C_2(C_5H_4)_2]Sm$ moiety and no further loss of THF was observed when the same process was repeated. This was interpreted in terms of the formation of the mixed samarium-magnesium compound, $[\{Me_4C_2(C_5H_4)_2\}SmCl(THF)\text{-}MgCl_2(THF)_3]$ (**4**).

The synthesis was then performed on a larger scale, in THF, as described in the literature[15]. After the usual work-up, the NMR spectrum of the crude orange-yellow solid was very different from the one recorded in the previous synthesis (directly in the NMR tube) and could not be interpreted in terms of the formation of a well-defined pure compound. Further attempts were made using toluene as the solvent, but similar results were obtained. It was concluded that if evidence for the quantitative formation of a unique complex was provided by NMR experiments, then the handling of the mixture, leading to undefined materials, was not recommended.

The one-pot synthesis of an allylic derivative was therefore undertaken, initially on an NMR scale, by adding a stoichiometric amount of C_3H_5Li(dioxane) to the crude deuterated benzene solution obtained, as described previously, by mixing $SmCl_3(THF)_3$ and the Grignard reagent $[Me_4C_2(C_5H_4MgCl)_2](THF)_4$. A reaction occurred immediately and a pink-red precipitate deposited, which was partially soluble in the presence of the oxygenated solvents (7 THF + 2 dioxane). At 70°C the NMR spectrum showed a two-allyl signal pattern {2 H and 8 H per $[Me_4C_2(C_5H_4)_2]Sm$ moiety}, revealing a dynamic exchange process. The poor solubility, along with these integral values, indicated that the new complex was an anionic bis(allylic) complex. At ambient temperature the allylic signals coalesced and only the signals due to the ansa ligand could be detected. This could be interpreted as evidence for the partial dissociation of allyl ligands.

The synthesis was then performed on a bulk scale, in toluene, with two equivalents of $C_3H_5Li\cdot$dioxane. The crude compound contained THF and dioxane, which were exchanged by dissolution in DME. The red expanded oil obtained after removal of the solvents was washed with ether and finally gave a red powder of analytically pure **2**, $[Me_4C_2(C_5H_4)_2]Sm(C_3H_5)_2Li(DME)$. This new compound was not soluble in either toluene or benzene: its NMR spectrum was recorded in $[D_8]$THF and the allyl ligands exhibited a typical η^3 three-signal (1 H, 2 H, and 2 H) pattern.

The dianionic ansa cyclopentadienyl ligand $[Me_4C_2(C_5H_4)_2]^{2-}$ was chosen in order to avoid the disproportionation of the bis(cyclopentadienyl) derivatives of the lighter lanthanides[17][18]. Moreover, the stereoelectronic properties of a $[Me_4C_2(C_5H_4)_2]Sm$ moiety should be similar to those of a $(Me_3CC_5H_4)_2Sm$ unit, except that the angle between the metal center and the centroids of the rings would be slightly smaller in the case of an ethylene bridge[19] (the ring-centroid−Yb−ring-centroid angle is 121° and 121.3° in $[Me_4C_2(C_5H_4)_2]YbCl_2,Mg_2Cl_3\cdot 7$ THF[17] and $(Me_3CC_5H_4)_2YbCl\cdot THF$[20], respectively). In addition, in the ansa ligand the rotation of the Cp rings[21][22] is not possible and the effective size of the ligand is therefore smaller. The saturation of the coordination sphere of the metal atom therefore occurs in a different manner: in the Cp′ series, $Cp'_2YbCl\cdot THF$[20] is neutral

whereas the homologous ansa complex $[Me_4C_2(C_5H_4)_2]YbCl_2 \cdot Mg_2Cl_3 \cdot 7\ THF$[17] is anionic.

In a similar manner, the reaction of an equimolar amount of C_3H_5Li with $(Cp'_2SmCl)_2$ leads to a dimer (or a polymer, although the high solubility of **1** in pentane suggests an oligomeric structure), showing that a neutral species is preferred. In the case of the ansa compound, a monomeric anionic complex **2** is formed.

In the presence of an excess of allyl ligand, no anionic compound was formed in the Cp′ series: a redistribution leading to a mixture of Cp'_3Sm[9] and $Sm(C_3H_5)_4Li(dioxane)$[23] was observed (Scheme 3).

Scheme 3

$$3\ Cp'_2Sm(C_3H_5) + Li(C_3H_5)\cdot C_4H_8O_2 \longrightarrow 2\ Cp'_3Sm + Sm(C_3H_5)_4Li\cdot C_4H_8O_2$$

Nevertheless, on using the small monohapto methyl ligand, a bis(alkyl)-anionic complex was obtained in the Cp′ series: treatment of $(Cp'_2SmMe)_2$ or $(Cp'_2SmCl)_2$ with one or two equivalents of MeLi, respectively, led to the same compound Cp'_2SmMe_2Li. After addition of one molar equivalent of $(Cp'_2SmCl)_2$ the neutral dimer could be recovered.

Scheme 4

$$Cp'_2SmMe_2Li + 1/2\ (Cp'_2SmCl)_2 \longrightarrow (Cp'_2SmMe)_2$$

The anionic bis(methyl) compound was isolated in an analytically pure form (pale yellow microcrystals) as a dioxane adduct: $Cp'_2SmMe_2Li \cdot dioxane$.

Catalysis

Allylic lanthanide derivatives are known to catalyse the polymerization of dienes[24] and the new complexes **1** and **2** were tested in the polymerization of isoprene.

The anionic complex **2** was found to be efficient (the turn-over number amounts to ca. 260 mol of isoprene per mol of lanthanide catalyst per hour) and very stereospecific (95%) for 1,4-*trans* polymerization (see Table 2). Molecular weights are in the expected range for this type of polymerization test[1].

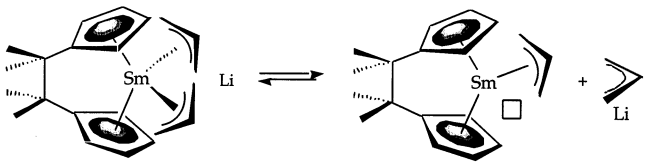
The neutral complex **1** was found to be inactive and its carbene adduct **1′** was found to be almost inactive. This implies that the $[Cp'_2Sm(C_3H_5)]_n$ compound remains strongly associated and isoprene does not possess a sufficiently strong ligand ability [unlike, for example, the nucleophilic carbene $C(NiPr)_2(CMe)_2$] to dissociate the starting material. Attempts to create a more accessible metallic center by addition of 1 equivalent of yttrium chloride as a Lewis acid led to a system of very low activity (yield of polyisoprene 2%).

In contrast, the dissociation of an allylic ligand in the anionic compound **2** is easy and allows the coordination of the diene. The precedent for this ligand dissociation was postulated for other anionic allyllanthanide compounds[8] tested in the polymerization of butadiene.

The tetraallylneodymium complex $Nd(C_3H_5)_4Li(dioxane)_{1.5}$ had been previously found to be a specific (86% of *trans*-1,4-polybutadiene) catalyst for butadiene polymerization[10]. We found that for the polymerization of isoprene, tetraallyllanthanide complexes are less specific (31% and 28% of *trans*-1,4-polyisoprene for neodymium and samarium, respectively). This reaction was thus very dependent on the steric hindrance of the monomer.

In the same way, $C_3H_5Li(dioxane)$ leads to a high (ca. 53%) percentage of *cis* 1-4 polyisoprene; the participation of this species could be invoked for the polymerization obtained from the tetraallylic compounds and this has been discussed previously[8]. However, for the anionic bisallylic complexes (or systems) its role appears negligible because those systems led to an almost pure 1,4-*trans* polymer.

Scheme 5



The performances of other allylic systems towards isoprene polymerization are presented in Table 2 (**A**, the neodymium analogue of **2**, and **B**, an alkoxide derivative, tris-*tert*-butyloxy − "tritox" −). The catalysts are prepared in situ and may contain salts and an excess of oxygenated sol-

Table 2. Polymerization of isoprene (50°C, ratio isoprene/catalyst = 1500)

system B	30	46000	91	0	9	21	50

[a] T.O. = mol of monomer transformed/mol of catalyst/h. − [b] Was found to be inactive in the presence of 4 THF per Nd atom.

vents as ligands, which could modify the process of dissociation of the allylic ligand. Indeed, we found this to be the case for the tetraallylneodymium complex Nd-$(C_3H_5)_4Li(dioxane)_{1.5}$, in which the activity decreases in the presence of 1 THF per molecule, and it becomes inactive with 4 THF per molecule. The turn-over values (Table 2) are lower than for **2**, nevertheless, the catalytic activity is well in evidence: in each case the same stereocontrol is observed, with predominant formation of 1,4-*trans*-polyisoprene.

The ansa and the tritox complexes possess more bulky ligands than the tetraallyl complexes. The isolated complexes are tetracoordinated, and in solution it also seems that no more than four coordination sites are accessible. After the decoordination of the allyl ligand, only one site will be vacant for the coordination of the monomer. As a consequence, a very high stereoselectivity (89 to 95% of 1,4-*trans* polymer) is observed.

The anionic complex **3**, $Cp'_2SmMe_2Li(dioxane)$, was found to be very active (T.O. = 25000 mol of ethylene transformed/mol of catalyst/h) towards the polymerization of ethylene in the absence of MAO, but only within five minutes[25]. The rapid loss of activity was attributed to the ease of rearrangement leading to the inactive tris derivative.

The neutral dimer $(Cp'_2SmMe)_2$ had already been found to be very poorly active towards hydrogenolysis. This lack of reactivity was related to its dimeric structure[5].

Conclusion

New organometallic complexes of samarium have been synthesized, $[Cp'_2Sm(C_3H_5)]_n$ and its carbene adduct $Cp'_2Sm(C_3H_5)[C(NiPr)_2(CMe)_2]$, $[Me_4C_2(C_5H_4)_2]Sm(C_3H_5)_2Li(dme)$, and $Cp'_2SmMe_2Li(dioxane)$. The structures of these complexes are strongly dependent on steric factors: neutral monoallylic and anionic bis(allylic) complexes were characterized. Related complexes were prepared in situ. An X-ray structure analysis could be obtained for $Cp'_2SmCl[C(NiPr)_2(CMe)_2]$, which undergoes rearrangement in solution. The catalytic behaviour of all these new complexes towards polymerization was investigated. Anionic complexes are active: $Cp'_2SmMe_2Li(dioxane)$ is an ethylene polymerization catalyst with a short lifetime and the ansa bis(allylic) complex is a stereospecific 1,4-*trans*-polymerization catalyst.

The authors wish to thank *G. De Demo*, *BTS Chimie Chalon/Saône* (France), for S.E.C. analysis of the polymers.

Experimental Section

All manipulations were carried out under purified nitrogen in a Jacomex glove box or under argon using standard vacuum techniques. Solvents were distilled from the appropriate drying agent, stored over Na/benzophenone and vacuum-transferred to reaction vessels. ^1H- and ^{13}C-NMR spectra were recorded with AC 200 and DRX 500 Bruker spectrometers (297 K). − Polymer Analysis: Molecular weights and polydispersities were obtained by Steric Exclusion Chromatography (S.E.C.) on a Spectra-Physics chromatograph equipped with two detectors (a UV and a refractive index detector) connected in series. The calibration was carried out with PL-Lab polystyrene standards (EasiCal® PS-1, range $\bar{M}_w$ = 580−8.5 × 10^6). Each measurement was performed at 25°C in toluene as eluent, with a 1 ml/min flow rate. Two connected PL-Lab 5μ mixed-C 300 × 7.5 mm columns were used. The calculations for I_p and $\bar{M}_n$ were performed using GPC-Plus® software. Structural analysis of polyisoprene was conducted by ^{13}C- and ^1H-NMR spectroscopy and compared to commercially available samples. The isomeric purity was first evaluated by $^{13}C\{^1H\}$ sequences and then confirmed on the basis of ^1H-NMR data. − $SmCl_3(THF)_3$ and $NdCl_3(THF)_3$[26], $(Cp'_2SmCl)_2$ and $(Cp'_2SmMe)_2$[5] $C_3H_5Li(dioxane)$[10], 1,3-diisopropylimidazoline-2-ylidene $C(NiPr)_2(CMe)_2$[11], tritoxLi[27], $(C_3H_5)_4NdLi(dioxane)_{1.5}$[10], and $[Me_4C_2(C_5H_4MgCl)_2](THF)_4$[13] were prepared as described. $(C_3H_5)_4SmLi(dioxane)$ was synthesized following the procedure described for its neodymium homologue and its NMR data were in accordance with the original synthesis[23]. Ethereal solutions of MeLi were purchased from Aldrich. The diene (isoprene 99%) was dried over molecular sieves and distilled twice to remove the stabiliser. Elemental analyses were performed with a Fisons EA 1108 CHONS apparatus.

$[Cp'_2Sm(C_3H_5)]_n$ (**1**): A solution of $(Cp'_2SmCl)_2$ (0.39 g, 0.91 mmol) was added at −78°C to a slurry of $C_3H_5Li(dioxane)$ (0.13 g, 0.91 mmol) in toluene (20 ml). The mixture was stirred at −78°C for 30 min, and then warmed to room temperature for another 30 min. The solution turned red and LiCl was deposited. After filtration, the solvent was removed under reduced pressure and the residue extracted with pentane (3 × 30 ml). After evaporation of the pentane, a deep red oil was obtained (0.27 g, yield 68%). − $C_{21}H_{31}Sm$ (433.88): calcd. C 58.14, H 7.20; found C 58.27, H 7.33. − ^1H NMR (C_6D_6): δ = 16.79 (s, 1 H), 13.21 (s, 4 H), 9.56 (s, 2 H), 9.21 (s, 4 H), 6.43 (s, 2 H), −2.81 (s, 18 H).

A mixture of 10 mg (23 μmol) of **1** and 3 mg (22 μmol) of $C_3H_5Li(dioxane)$ in C_6D_6 was stirred by sonification, and Cp'_3Sm and $(C_3H_5)_4SmLi$ slowly precipitated from the mixtute and these compounds were detected by NMR.

$Cp'_2Sm(C_3H_5)$, $C(NiPr)_2(CMe)_2$ (**1′**): A mixture of **1** (0.247 g, 0.57 mmol) and 1 equiv. (0.103 g) of $C(NiPr)_2(CMe)_2$ in 20 ml of toluene was stirred at room temperature for 12 h. The solvent was evaporated and the residue extracted with pentane (3 × 20 ml). After filtration and concentration, a dark red solid was obtained (0.273 g, yield 78%). The NMR analysis revealed the presence of the adduct **1′**: ^1H NMR (C_6D_6): δ = 15.97 (s, 1 H), 12.72 (s, 4 H), 9.21 (s, 4 H), 8.10 (s, 4 H), 3.91 (m, 2 H), 1.72 (s, 6 H), 1.47 (d, 12 H), −2.51 (s, 18 H). This compound was accompanied by 10% of Cp'_3Sm. To remove the yellow contaminant Cp'_3Sm, the solid was washed with cold pentane. Red/black crystals were obtained by a further dissolution in pentane (15 ml), followed by filtration and slow concentration to a volume of ca. 3 ml. These crystals seemed suitable for X-ray analysis and one was mounted in a capillary tube. However, the crystal had melted after only a few minutes of exposure. After dissolution in deuterated benzene, NMR showed the invariable presence of 10% of Cp'_3Sm. − $C_{32}H_{51}N_2Sm$ (614.18): calcd. N 4.56; found N 4.58.

Cp'_2SmCl, $C(NiPr)_2(CMe)_2$ (**1″**): To a mixture of $(Cp'_2SmCl)_2$ (0.36 g, 0.84 mmol) and $C(NiPr)_2(CMe)_2$ (0.255 g, 1.41 mmol) was added 30 ml of toluene. The mixture was stirred at room temperature overnight and then filtered. The yellow solution was concentrated slowly to ca. 5 ml. Yellow crystals were collected 12 h later. The crystals were washed with pentane (10 ml) and dried under vacuum. Total yield: 0.235 g, 40%. A crystal was found that was

suitable for X-ray structure analysis (see below for further details), which revealed the presence of one toluene molecule per samarium atom. – Toluene adduct $C_{36}H_{54}ClN_2Sm$ (700.70): calcd. C 61.71, H 7.71, N 4.00; found C 61.24, H 7.93, N 4.37.

^{1}H-NMR analysis of the dissolved crystals revealed the presence of three compounds in solution (C_6D_6): **1″**: δ = 11.38 (s, 2 H), 10.45 (s, 2 H), 8.15 (s, 2 H), 7.94 (s, 2 H), 3.95 (m, 2 H), 1.18 (s, 18 H), 0.91 (s, 6 H), 0.57 (d, 12 H); Cp_3Sm and $Cp'SmCl_2[C(NiPr)_2(CMe)_2]_2$; **1‴**: δ = 10.72 (s, 2 H), 11.57 (s, 2 H), 1.51 (d, 24 H), 0.01 (s, 12 H), −0.5 (br., 9 H).

[Me$_4$C$_2$(C$_5$H$_4$)$_2$]Sm(C$_3$H$_5$)$_2$Li(dme) (**2**): (a) In an NMR tube a mixture of 9.17 mg (19.3 μmol) of $SmCl_3(THF)_3$ and 12 mg (19.3 μmol) of $[Me_4C_2(C_5H_4MgCl)_2](THF)_4$ was stirred by sonification in 0.4 ml of C_6D_6 and then the mixture was warmed at 60°C. First a pale yellow, and then an orange yellow colour developed, and after 20 min the reaction was complete; the ^{1}H-NMR spectrum recorded was consistent with $[Me_4C_2(C_5H_4)_2]SmClMgCl_2(THF)_n$. – NMR ($C_6D_6$) δ = 15.51 (s, 4 H), 8.16 (s, 4 H), 1.51 (s, 18 H). – After evaporation of the solvents, C_6D_6 (0.4 ml) was added. NMR analysis revealed the presence of $[Me_4C_2(C_5H_4)_2]SmCl(THF)MgCl_2(THF)_3$ (**4**) as the unique product. – NMR (C_6D_6): δ = 15.31 (s, 4 H), 8.05 (s, 4 H), 3.73 (s, 16 H), 1.34 (s, 16 H), 1.25 (s, 12 H). – 2 equivalents (5.28 mg) of $C_5H_3Li(C_4H_8O_2)$ were added, the solution became pink/red and a reddish precipitate was deposited that was partially soluble in the presence of the oxygenated solvents (7 THF + 2 dioxane molecules per Sm atom). – **2**: ^{1}H NMR (C_6D_6; 298 K): δ = 8.09 (s, 4 H), 5.97 (s, 4 H), 3.34 (dioxane + THF), 1.89 (s, 12 H), 1.25 (THF), the allylic signals could not be detected; (343 K): δ = 8.54 (s, 4 H), 7.99 (br., 2 H), 6.62 (s, 4 H), 5.76 (br., 8 H), 3.36 (dioxane + THF), 1.81 (s, 12 H), 1.32 (THF).

(b) A toluene solution of $[Me_4C_2(C_5H_4)_2]SmCl(THF)\cdot MgCl_2(THF)_2$ (**4**) was prepared following the published procedure[14] from 0.5 g (1.06 mol) of $SmCl_3(THF)_3$ and 0.66 g (1.06 mol) of $[Me_4C_2(C_5H_4MgCl)_2](THF)_4$ in 20 ml of toluene (instead of THF). Salts were removed by filtration and, at −30°C and with vigourous stirring, 0.29 g (2.12 mmol) of $C_3H_5Li(C_4H_8O_2)$ was added to the bright orange solution. The mixture turned pink within a few minutes and the temperature was allowed to rise to 20°C. Salts were removed by filtration and the solvent was evaporated under reduced pressure to give a red paste. This paste was dissolved in dimethoxyethane (20 ml) and the solvent was evaporated. The crude product was an expanded oil which was washed with ether (3 × 15 ml) to finally give a brick-red powder (yield 60%). – ^{1}H NMR (C_4D_8O): δ = 9.53 (m, 2 H), 8.61 (br., 4 H), 7.94 (s, 4 H), 7.07 (br., 4 H), 5.77 (s, 4 H), 3.35 (dme, 4 H), 3.19 (dme, 6 H), 1.70 (s, 12 H). – Crystals could be obtained as thin plates in a 75−25% mixture of dimethoxyethane and diethyl ether. – $C_{26}H_{40}LiO_2Sm$ (541.95): calcd. C 57.62, H 7.44; found C 57.20, H 7.29.

Cp′$_2$SmMe$_2$Li(dioxane) (**3**): To a stirred solution of $(Cp'_2SmCl)_2$ (0.39 g, 0.91 mmol) in toluene (30 ml) was slowly added, at −78°C, a 1 M ethereal solution of MeLi (2.0 μl, 2.0 mmol). The mixture was stirred for 2 h and then warmed to room temperature and stirred for a further 30 min. The mixture turned pale yellow and LiCl was deposited. The solution was filtered and the solvent evaporated. The residue was extracted with toluene (2 × 10 ml). The clear solution was concentrated and microcrystals were formed. After evaporation of the toluene, the powder was washed with pentane (2 × 10 ml) and dried in vacuo; a pale yellow solid was obtained (0.25 g, yield 64%) that was sparingly soluble in aromatic solvents. – ^{1}H NMR (C_6D_6): δ = 9.16 (s, 4 H), 8.86 (s, 4 H), −0.01 (s, 18 H), −4.08 (s, 6 H). – The solid was dissolved in 30 ml of toluene, a slight excess of dioxane (50 μl) was added and the solution was stirred for 1 h at ambient temperature. Slow evaporation of the solvent under reduced pressure gave pale yellow crystals. – ^{1}H NMR (C_6D_6): δ = 9.77 (s, 4 H), 9.07 (s, 4 H), 4.15 (s, 8 H), −0.05 (s, 18 H), −5.12 (s, 6 H). – $C_{24}H_{40}SmLiO_2$ (517.92): calcd. C 55.66, H 7.79; found C 55.29, H 7.85.

Crystal Data for Cp′$_2$ClSm·C(NiPr)$_2$(CMe)$_2$: $C_{29}H_{46}ClN_2Sm\cdot C_7H_8$, M = 700.6, monoclinic, space group $P2_1/c$, a = 13.351(2), b = 17.005(3), c = 16.443(2) Å, β = 101.011(12)°, V = 3664(1) Å^3, Z = 4, D_c = 1.27 gcm^{-3}, μ(Mo-K_α) = 1.7 mm^{-1}. A yellow crystal was mounted on a capillary on an Enraf-Nonius CAD4 diffractometer at 20°C. Unfortunately, the crystal underwent rapid decomposition under X-ray exposure and only the first shell of data with 17.90° < θ < 20.58° was used to solve and refine the structure (decay = 82%). The solution was obtained by interpretation of the Patterson map[28] and refined on F^2 using all the 1228 independent reflections collected[29]. Due to the lack of data, only the samarium and chlorine atoms were anisotropically refined. Hydrogen atoms were included, when possible, at their calculated positions. The Cp rings were constrained to a regular pentagon and the toluene ring to a regular hexagon. The methyl group of the toluene solvate was not located. The final agreement indices are $R_w(F^2)$ = 0.124 and $R(F)$ = 0.102 for all data (1228 independent reflections) and 135 parameters; $R(F)$ = 0.047 for 822 data with $I > 2\sigma(I)$; goodness of fit = 0.94 and Δρ = 0.344 and −0.260 e Å^{-3}. Crystallographic data (excluding structure factors) for the structure reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication No. CCDC-101393. Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB21EZ, UK [Fax: internat. +44-1223/336-033; E-mail: deposit@ccdc.cam.ac.uk].

In situ Preparation of Catalytic Systems. – System A: In an NMR tube was placed 12 mg of $[Me_4C_2(C_5H_4MgCl)_2](THF)_4$, 9 mg of $NdCl_3(THF)_3$, and 5.3 mg of C_3H_5Li(dioxane). 0.5 ml of C_6D_6 was added and the mixture was stirred by sonification until the signals of the starting materials totally disappeared: a bright green colour developed and white salts precipitated. The benzene (and the excess THF and dioxane) was evaporated and the residue dissolved in toluene. The toluene solution was transferred into a flask and the solvents were evaporated. The green solid was used for polymerization.

System B: To a C_6D_6 solution of 8 mg of tris-*tert*-butylmethanol – "tritoxH" – (dried over molecular sieves), was added 10.3 mg of $(C_3H_5)_4NdLi(dioxane)_{1.5}$. The tube was heated (60°C) and the mixture stirred by sonification, which led to a green, sparingly soluble material; very large allylic signals with paramagnetic shifts in the range δ = −10 to −50 and a paramagnetic *tert*-butyl signal at δ = 10 were observed in the ^{1}H-NMR spectrum. The solvent was partially evaporated, THF was added and the solvents partially evaporated once again. The green solid was then soluble in benzene and the solution was transferred into the polymerization flask. The solvents were evaporated before isoprene was added.

Polymerization Experiments: (1) Diene polymerization: The catalyst (10 mg) was introduced into a flask connected to a vacuum line. The diene (3 ml) was then condensed on to it and the stirred solution was heated at 50°C during 5 h. Depending on the activity of the catalyst, the mixture can become highly viscous; the flask was opened to the air and the contents dissolved in the required volume (5−15 ml) of toluene. The toluene solution was poured into 200 ml of ethanol and the polymer precipitated. The liquors were

decanted and the solid dried (12 Torr, 1−2 d) and weighed before sampling for analysis (^{1}H and ^{13}C NMR, molecular weight, polydispersity).

(2) Ethene polymerization: the reaction was conducted at 60°C and *p*(ethene) = 4 bar[25].

Advances in the Reactivity of Amido-Bridged Binuclear Carbonylruthenium Complexes – Derivative Chemistry of the Cationic Complex $[Ru_2(\mu\text{-dan})(\mu\text{-H})(CO)_6][BF_4]$ (H_2dan = 1,8-Diaminonaphthalene)

Keywords: Ruthenium / Cationic complexes / Hydrido complexes / N ligands / P ligands

The reactivity of the cationic amido-bridged binuclear ruthenium carbonyl complex $[Ru_2(\mu\text{-dan})(\mu\text{-H})(CO)_6]^+$ (H_2dan = 1,8-diaminonaphthalene) (**2**) with some anionic and neutral nucleophilic reagents has been investigated. The reaction of **2** with halide anions gives neutral products, $[Ru_2X(\mu\text{-dan})(\mu\text{-H})(CO)_5]$ [X = Cl (**3**), Br (**4**), I (**5**)], which result from the regiospecific substitution of the halide anion for one of the CO ligands *trans* to the bridging hydride. Compound **3** is more conveniently prepared by treatment of the neutral complex $[Ru_2(\mu\text{-dan})(CO)_6]$ with gaseous hydrogen chloride. The reaction of **2** with triphenylphosphane affords the disubstituted product of C_{2v} symmetry $[Ru_2(\mu\text{-dan})(\mu\text{-H})(PPh_3)_2(CO)_4]^+$ (**7a**), which can be transformed into the asymmetric isomer **7b** under thermal conditions (70 °C, 10 h) or under acid catalysis ($[HOEt_2][BF_4]$, 18 °C, 1 min). Such isomerization reactions can be prevented by adding an excess of triphenylphoshane to the solutions. The complexes **7a** and **7b** can also be prepared by treating the neutral complex $[Ru_2(\mu\text{-dan})(PPh_3)_2(CO)_4]$ with $[HOEt_2][BF_4]$ in the presence (for **7a**) or in the absence (for **7b**) of triphenylphoshane. In addition, compound **3** reacts with triphenylphoshane at room temperature to give the symmetric cationic complex **7a** , whereas the reaction of complex **5** with triphenylphoshane requires higher temperature and gives the asymmetric isomer **7b**.

Introduction

The interest in the synthesis and reactivity of late-transition-metal amido complexes has grown considerably[1]. This research activity has been carried out in parallel to investigations on binuclear carbonylruthenium(I) complexes[2]. In connection with these two research fields, we have previously reported the synthesis of the binuclear amido-bridged carbonylruthenium(I) complex $[Ru_2(\mu\text{-dan})(CO)_6]$ (H_2dan = 1,8-diaminonaphthalene) (**1**)[3][4]. Reactivity studies on compound **1** have shown that it can be protonated at the metal atoms to give the cationic derivative $[Ru_2(\mu\text{-dan})(\mu\text{-H})(CO)_6]^+$ (**2**) and that it readily undergoes carbonyl substitution reactions with phosphane ligands to give disubstituted derivatives such as $[Ru_2(\mu\text{-dan})(PPh_3)_2(CO)_4]$[4]. The basicity and the *cis*-labilizing character of the bridging amido ligand have been suggested as the factors responsible for the observed reactivity. However, compound **1** does not react with hard ligands, such as the halide anions[5].

As cationic complexes should be more prone than their neutral precursors to undergo reactions with basic reagents[6][7], and as the protonation of neutral complexes should increase the hard character of the metal atoms, we thought it would be interesting to study the substitution chemistry of the cationic compound **2** and to compare it with that of its neutral precursor **1**. No such a comparative study is known for binuclear complexes, although related studies with trinuclear carbonylruthenium clusters have been reported[7].

Results and Discussion

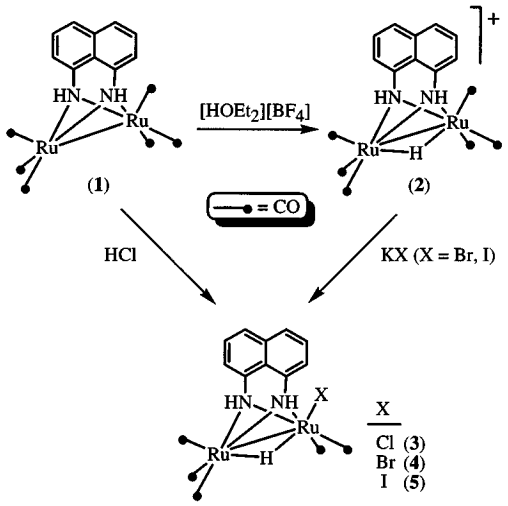
Reactions with Halide Anions

Treatment of the ionic compound $[Ru_2(\mu\text{-dan})(\mu\text{-H})(CO)_6][BF_4]$ (**2**$[BF_4]$) with dichloromethane solutions of [PPN]X (X = Cl, Br, I) or $[Et_4N]$Br led to the instantaneous formation of the neutral derivatives $[Ru_2X(\mu\text{-dan})(\mu\text{-H})(CO)_5]$ [X = Cl (**3**), Br (**4**), I (**5**)] in quantitative spectroscopic (IR) yields. However, this synthetic method did not lead to analytically pure products because the complexes could not be efficiently separated from the ionic tetrafluoroborate byproducts Q$[BF_4]$ (Q = PPN, Et_4N) by either fractional crystallization (similar solubility in organic solvents) or chromatographic methods (the complexes did not elute on silica and alumina). In addition, treatment of **2**$[BF_4]$ with an excess of solid KX (X = Cl, Br, I) in dichloromethane also gave compounds **3**–**5**, but the reactions were slow. The bromo and iodo complexes **4** and **5** were efficiently prepared in pure form by this method, requiring reaction times of 40 and 20 h, respectively. The reaction of **2**$[BF_4]$ with KCl was very slow, being incomplete (ca. 70% conversion) after one week. It should be noted that KCl is nearly insoluble in chlorinated solvents, and that **2**$[BF_4]$ undergoes

 © WILEY-VCH Verlag GmbH, D-69451 Weinheim, 1998 1434–1948/98/1111–1729 $ 17.50+.50/0

deprotonation in basic solvents such as acetone, THF, or water, thus preventing the use of such solvents in the reactions. The most convenient method to prepare the chloro complex **2** in pure form turned out to be the treatment of the neutral hexacarbonyl complex **1** with a dichloromethane solution of HCl.

Scheme 1



The structure proposed for compounds **3**−**5** in Scheme 1 is based on their analytical and spectroscopic data. Their IR spectra are nearly identical, suggesting a common structure for the three compounds, showing the ν(CO) absorptions at lower wavenumbers (2115−1985 cm^{-1}) than those of the cationic starting complex **2** (2136−1991 cm^{-1})[4]. Their ^{1}H-NMR spectra (Table 1) show one hydride resonance and four resonances for the dan ligand (three aromatic and one N*H*), indicating the presence of a mirror plane that divides the dan ligand into two identical halves. The $^{13}C\{^1H\}$-NMR sprectrum of compound **5** (taken as a representative example) shows three carbonyl resonances in a 2:2:1 ratio (relaxation delay 2 s), confirming the presence of five CO ligands. Interestingly, only the smallest carbonyl signal is split into a doublet in the proton-coupled ^{13}C-NMR spectrum, indicating that only one CO ligand is in a *trans* position to the hydride. Thus, these data confirm the structure shown in Scheme 1 and rule out an alternative structure which would have the hydride and halide ligands in terminal and bridging positions, respectively.

It seems that the *acidic* (and not merely the *cationic*) character of complex **2** might be responsible for the observed reactivity. In fact, complex **2** could reversibly protonate the halide anions to give the corresponding hydrogen halides which would then react in a *concerted* way with the conjugated base **1** to give the substituted products **1**−**3**.

As halide anions are worse π-acceptor ligands than carbon monoxide, the substitution of halide anions for carbonyl ligands in ruthenium complexes has been previously observed only on a few occasions on neutral[8][9] and cationic[6b][6c][10] carbonyl cluster compounds. As mentioned in the Introduction, the neutral compound **1** does not react with halide anions[5]. Curiously, it has been reported that the anionic binuclear osmium(I) complexes $[PPN][Os_2X(\mu\text{-}O_2CMe)_2(CO)_5]$ (X = Cl, I) can be prepared by treatment of the solvated complex $[Os_2(\mu\text{-}O_2CMe)_2(CO)_5(thf)]$ with [PPN]X[11]. Unfortunately, all attempts to prepare any solvated derivative of complex **1** were unsuccessful.

Table 1. Comparative ^{1}H- and $^{31}P\{^1H\}$-NMR data for compounds **2**−**7**[a]

Comp.	δ_H(μ-H)	δ_H(dan)	δ_P(PPh_3)
2[b][c]	−10.95 (s)	7.82 (d) [7.7], 7.60 (d) [7.7], 7.43 (t) [7.7], 7.56 (s, br.)	
3	−15.30 (s)	7.62 (dd) [7.6, 1.1], 7.25 (t) [7.6], 7.16 (dd) [7.6, 1.1], 5.14 (s, br.)	
4	−14.37 (s)	7.65 (dd) [7.6, 1.1], 7.29 (t) [7.6], 7.35 (dd) [7.6, 1.1], 5.05 (s, br.)

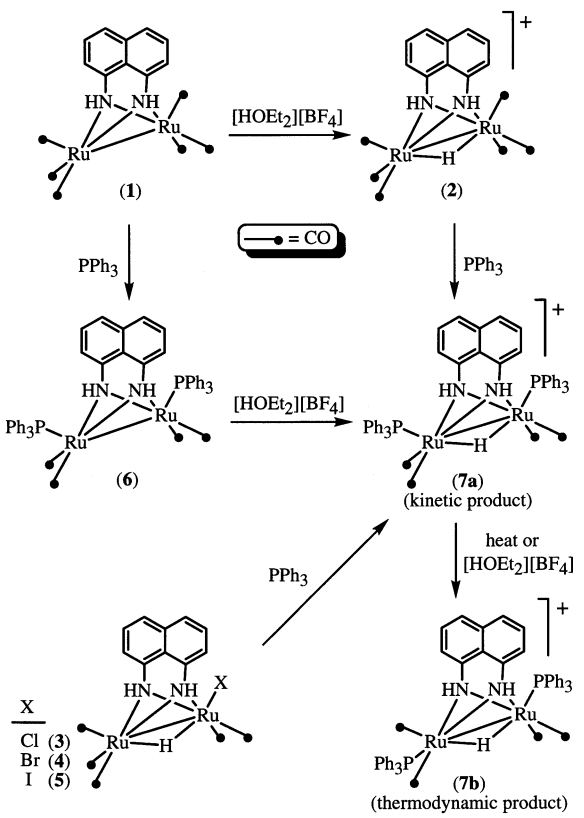
[a] Spectra recorded in $CDCl_3$; multiplicities are given in parentheses; coupling constants (Hz) are given in square brackets [$J_{H\text{-}H}$] or braces {$J_{H\text{-}P}$}. − [b] Data taken from ref.[4]. − [c] Spectrum recorded in $(CD_3)_2CO$ containing 10% $[HOEt_2][BF_4]$. − [d] Other resonances of the dan ligand are obscured by those of the PPh_3 ligand.

Reactions with Triphenylphosphane

Complex **2** reacted instantaneously with triphenylphosphane at room temperature to give the disubstituted derivative $[Ru_2(\mu\text{-dan})(\mu\text{-H})(PPh_3)_2(CO)_4]^+$ (**7a**), regardless of the ratio of the reactants. The use of a phosphane/complex ratio smaller than two resulted in a mixture of **7a** and unreacted **2**. The symmetric (C_{2v}) structure shown for the cation **7a** in Scheme 2 is based on spectroscopic data. The $^{31}P\{^1H\}$- and ^{1}H-NMR spectra (Table 1) are consistent with the existence of two mirror planes, since they only show one singlet in the $^{31}P\{^1H\}$ spectrum and five resonances in the ^{1}H spectrum (four for the dan ligand and one for the hydride). In particular, the hydride resonance is a triplet with a large J(H-P) coupling constant (41.4 Hz). It is generally accepted that large (> 20 Hz) ^2J(H-P) coupling constants are indicantive of a trans arrangement of hydride and phosphane ligands on a metal carbonyl complex[7], although some exceptions to this rule have been reported for pentacoordinated iron complexes[12].

In an attempt to make **7a**$[BF_4]$ by an alternative route, we treated a dichloromethane solution of the symmetric (C_{2v}) neutral disubstituted compound $[Ru_2(\mu\text{-dan})(PPh_3)_2(CO)_4]$ (**6**) with an excess of $[HOEt_2][BF_4]$ in diethyl ether. The reaction was instantaneous but, to our surpise, the product was not **7a** but the asymmetric isomer **7b** (Scheme 2), as inferred from its $^{31}P\{^1H\}$ spectrum, which consists of two singlet resonances, and from its ^{1}H spectrum, which shows

Scheme 2



the hydride resonance as a doublet of doublets with J(H-P) coupling constants (43.5 and 7.4 Hz) in agreement with a structural assignment in which the hydride is *trans* to a phosphorus atom and *cis* to the other[7].

The reactions of the halide derivatives **3** and **5** with triphenylphosphane were also studied. The chloro complex **3** reacted slowly (6 h) with two equivalents triphenylphosphane in 1,2-dichloroethane at room temperature to give the symmetric cationic derivative **7a**. No monosubstituted derivatives were detected when the reaction was monitored by IR or $^{31}P\{^1H\}$ NMR. Curiously, no reaction was observed with the iodo derivative **5** under the same conditions, but it gave the asymmetric cationic derivative **7b** within 30 min when the reaction was carried out at reflux.

The above results prompted us to try to establish whether the transformations of **7a** into **7b** or of **7b** into **7a** were possible. We found that (a) complex **7a** can be quantitatively transformed into **7b** under thermal conditions (1,2-dichloroethane, reflux temperature) and that the rate of the cation isomerization depends on the accompanying anion, being faster for chloride (30 min) than for tetrafluoroborate (10 h), (b) the isomerization reaction is catalysed by acids, since the addition of $[HOEt_2][BF_4]$ to a dichloromethane solution of **7a** at room temperature resulted in its instantaneous transformation into **7b**, (c) this isomerization process is inhibited by the presence of free triphenylphosphane, regardless of the presence of acid in the solution, and (d) by no means could the transformation of **7b** into **7a** be achieved. Therefore, it is clear that **7a** is the kinetic isomer and that **7b** is the thermodynamic isomer, and that the isomerization takes place through a dissociative mechanism which requires the decoordination of triphenylphosphane in the activation step.

To our knowledge, no previous isomerization reactions of phosphane-substituted ligand-bridged binuclear ruthenium complexes have been described, but a few examples of such reactions have been reported for trinuclear clusters[7].

Further work on the reactivity of binuclear cationic carbonylruthenium complexes, extending the reactions to other P-donor ligands, such as phosphites, diphosphanes, etc., is in progress.

Financial support from the *Dirección General de Enseñanza Superior* (Project PB95−1042) is gratefully acknowledged.

Experimental Section

General: IR: Perkin-Elmer FT 1720-X. − NMR: Bruker AC-200 and AC−300, 20°C, internal TMS (for ^1H and ^{13}C) or external 85% H_3PO_4 (for ^{31}P) as standards. − Microanalyses: Perkin Elmer 2400. − Solvents were dried with sodium diphenyl ketyl (diethyl ether, hydrocarbons) or CaH_2 (dichloromethane, 1,2-dichloroethane) and distilled under nitrogen prior to use. The reactions were carried out under nitrogen with Schlenk vacuum-line techniques, and were routinely monitored by solution IR spectroscopy (carbonyl stretching region). Compounds **1**, **2**, and **6** were prepared as described previously[4]. A saturated solution of HCl in dichloromethane was prepared by bubbling gaseous HCl (formed by addition of 98% sulfuric acid to solid NaCl) through the solvent. All the other reagents were purchased from Aldrich and were used as received.

[$Ru_2Cl(\mu$-dan$)(\mu$-H$)(CO)_5$] (**3**): A saturated solution of HCl in dichloromethane (2 ml) was added to a solution of compound **1** (100 mg, 0.190 mmol) in the same solvent (10 ml). The original pale yellow colour slightly darkened and the IR spectrum of the resulting solution revealed the complete transformation of **1** into a new compound. The solvent was removed under reduced pressure and the residue was washed with hexane (2 × 10 ml) and dried to give complex **3** as a yellow solid (83 mg, 82%). − $C_{15}H_9ClN_2O_5Ru_2$ (534.86): calcd. C 33.68, H 1.70, N 5.24; found C 33.21, H 1.46, N, 4.91. − IR (CH_2Cl_2): $\tilde{\nu}$ = 2115 cm^{-1} (m), 2053 (s), 1985 (m).

[$Ru_2Br(\mu$-dan$)(\mu$-H$)(CO)_5$] (**4**): Solid KBr (96 mg, 0.807 mmol) was added to a solution of **2**[BF_4] (50 mg, 0.081 mmol) in dichloromethane (10 ml). The resulting suspension was stirred for 40 h, when the IR spectrum of the solution revealed the absence of the starting material. The suspension was filtered through a Celite filter and the resulting yellow solution was concentrated to dryness. The solid residue was washed with hexane (2 × 5 ml) and dried to give complex **4** as a yellow solid (35 mg, 75%). − $C_{15}H_9BrN_2O_5Ru_2$ (579.31): calcd. C 31.10, H 1.57, N 4.84; found C 30.91, H 1.66, N 4.65. − IR (CH_2Cl_2): $\tilde{\nu}$ = 2115 cm^{-1} (m), 2052 (s), 1987 (m).

[$Ru_2I(\mu$-dan$)(\mu$-H$)(CO)_5$] (**5**): Solid KI (132 mg, 0.795 mmol) was added to a solution of **2**[BF_4] (50 mg, 0.081 mmol) in dichloromethane (10 ml). The resulting suspension was stirred for 20 h, when the IR spectrum of the solution revealed the absence of the starting material. The suspension was filtered through a Celite filter and the resulting solution was concentrated to dryness. The solid residue was washed with hexane (2 × 5 ml) and dried to give complex **5** as a yellow-orange solid (34 mg, 67%). − $C_{15}H_9IN_2O_5Ru_2$

(626.31): calcd. C 28.77, H 1.45, N 4.47; found C 28.51, H 1.58, N 4.09. – IR (CH_2Cl_2): $\tilde{\nu}$ = 2114 cm^{-1} (m), 2051 (s), 1986 (m). – $^{13}C\{^1H\}$ NMR (CD_2Cl_2): δ = 196.9 (2 CO), 190.2 (2 CO), 181.9 (1 CO), 148.7 (2 C), 135.4 (1 C), 126.1 (2 C), 125.3 (1 C), 124.5 (2 C), 114.7 (2 C) (all singlets); the resonances at δ = 181.9, 126.1, 124.5, and 114.7 are split into doublets in the proton-coupled spectrum.

[$Ru_2(\mu$-dan)(μ-H)(PPh_3)$_2$(CO)$_4$][BF_4] (**7a**[BF_4], symmetric isomer): Solid **2**[BF_4] (25 mg, 0.041 mmol) was added to a stirred solution of PPh_3 (22 mg, 0.084 mmol) in dichloromethane (10 ml). The reaction was instantaneous (IR). No changes were observed in the IR spectrum of this solution after 20 h. The solvent was removed under reduced pressure and the residue was washed with hexane (2 × 5 ml) and dried to give **7a**[BF_4] as a yellow solid (36 mg, 80%). – $C_{50}H_{39}BF_4N_2O_4P_2Ru_2$ (1082.79): calcd. C 55.46, H 3.63, N 2.59; found C 54.92, H 3.94, N 2.30. – IR (CH_2Cl_2): $\tilde{\nu}$ = 2063 cm^{-1} (s), 2047 (m), 1998 (s).

[$Ru_2(\mu$-dan)(μ-H)(PPh_3)$_2$(CO)$_4$][BF_4] (**7b**[BF_4], asymmetric isomer): An excess of [$HOEt_2$][BF_4] (0.2 ml, 60% solution in diethyl ether) was added to a solution of complex **6** (100 mg, 0.100 mmol) in dichloromethane (10 ml). The reaction was instantaneous (IR).- The solvent was removed under reduced pressure and the oily residue was washed with diethyl ether (3 × 5 ml) and dried to give **7b**[BF_4] as a yellow solid (87 mg, 80%). – $C_{50}H_{39}BF_4N_2O_4P_2Ru_2$ (1082.79): calcd. C 55.46, H 3.63, N 2.59; found C 55.42, H 3.83, N 2.39. – IR (CH_2Cl_2): $\tilde{\nu}$ = 2063 cm^{-1} (m), 2051 (s), 2000 (s). – $^{13}C\{^1H\}$ NMR ($CDCl_3$): δ = 196.5 (d, *J* = 11.1 Hz, 1 CO), 196.4 (d, *J* = 12.6 Hz, 1 CO), 194.7 (d, *J* = 12.9 Hz, 1 CO), 190.4 (t, *J* = 10.9 Hz, 1 CO), 150.3 (1 C), 147.4 (1 C), 135–112 (complex mixture of signals).

Protonation of Complex **6** *in the Presence of Triphenylphosphane:* An excess of [$HOEt_2$][BF_4] (0.2 ml, 60% solution in diethyl ether) was added to a solution of PPh_3 (105 mg, 0.400 mmol) and complex **6** (100 mg, 0.100 mmol) in dichloromethane (10 ml). After 3 min, the IR spectrum of the resulting solution showed only the presence of the symmetric complex **7a**, remaining unchanged after 12 h. The solvent was removed under reduced pressure and the residue was washed with diethyl ether (3 × 5 ml) and dried to give pure **7a**[BF_4] (IR, ^{31}P NMR) (75 mg, 69%).

Reaction of Complex **3** *with Triphenylphosphane:* A solution of complex **3** (100 mg, 0.187 mmol) and triphenylphosphane (98 mg, 0.375 mmol) in 1,2-dichloroethane (10 ml) was stirred at room temperature for 6 h, when the IR spectrum of the solution showed the complete transformation of **3** into the symmetric cationic derivative **7a**.

Reaction of Complex **5** *with Triphenylphosphane:* A solution of complex **5** (35 mg, 0.056 mmol) and triphenylphosphane (30 mg, 0.113 mmol) in 1,2-dichloroethane (10 ml) was stirred at room temperature for 1 h, but no reaction was observed (IR). The solution was then heated to reflux temperature. After 30 min, the IR spectrum showed the complete transformation of **5** into the asymmetric cationic derivative **7b**.

Thermal Isomerization of **7a** *to* **7b**: A solution of **7a**[BF_4] (50 mg, 0.046 mmol) in 1,2-dichloroethane (20 ml) was stirred at reflux temperarure. The reaction was monitored by IR spectroscopy, which showed the complete transformation of **7a** into **7b** after 10 h. When the chloride salt **7a**[Cl] was used as starting material, under analogous conditions, the transformation of **7a** into **7b** took only 30 min.

Acid-Catalysed Isomerization of **7a** *to* **7b**: [$HOEt_2$][BF_4] (0.2 ml, 60% solution in diethyl ether) was added to a solution of **7a**[BF_4] (50 mg, 0.046 mmol) in dichloromethane (20 ml). The IR spectrum of the resulting solution showed the complete transformation of **7a** into **7b**.

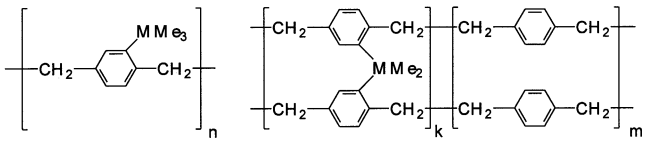
Keywords: Cyclophanes / σ-Bonded silyl-, germyl-, stannyl derivatives / Grignard reactions

Symmetrically 4,16-disubstituted (**3a–c**) and bridged (**6a**, **b**) organometallic paracyclophane derivatives have been synthesized for use as monomeric precursors of organometallic poly-*p*-xylylenes. Both types of compounds were obtained by lithiation of the appropriately substituted paracyclophane bromides (**1** or **4**) and subsequent quenching of the resulting lithioparacyclophane derivatives with organometallic electrophiles. For the synthesis of 4,16-bis(trimethylsilyl)[2.2]paracyclophane (**3a**) we also examined the Grignard reaction, and as a result the first successful use of a 4,16-bis Grignard reagent is described. According to the spectral data, the bridged compounds **6a, c** are formed as diastereomeric mixtures of a *meso*- and a *d,l* form. The diastereomers were separated by fractional recrystallization and characterized.

Although numerous functional groups have been introduced into the [2.2]paracyclophane nucleus[1], relatively little is known about these bridged aromatic compounds when they bear metal-containing substituents. To date, only mono(trimethylstannyl)-[2], 4,16-bis(triphenylphosphanegold)-[3], and several trimethylsilyl-substituted paracyclophane derivatives[4] have been synthesized, among them the *meso* and *d,l* diastereomers of dimethylbis([2.2]paracyclophan-4-yl)silane[5].

In principle, these derivatives could find wide application. They are not only of interest because of their stereochemical properties − any monosubstituted [2.2]paracyclophane is chiral, regardless of the position of the substituent in the system − but they could serve as ligands for new metal complexes and be used as monomeric precursors of novel, metal-containing polymers. The parent hydrocarbon is an important monomer in polymer chemistry − the poly-*p*-xylylene (PPX) polymer derived from it is called parylene®. Recently, we succeeded in preparing PPX films containing nanosize metal particles[6][7], which could be used as sensor devices for the detection of gaseous compounds in air[8]. In our methodology, developed for the preparation of polymer−metal nanocomposites, an organometallic PPX film (A or B in Scheme 1) is first produced by pyrolytic polymerization of the corresponding disubstituted or bridged paracyclophane monomers.

Scheme 1. PPX films containing silyl, germyl and stannyl functions



Further annealing of the polymers A and B leads to cleavage of the M−C bonds and the formation of metal nanocrystals in a polymer matrix. In contrast to the previously reported methods[9], we were able to obtain polymer coatings of uniform thickness that contained evenly distributed metal particles. Preliminary investigations on Ge-containing nanocomposites have shown these systems to be very promising sensor materials for air humidity[8].

In this paper we report on the synthesis of new disubstituted (**3a−c**, M = Si, Ge, Sn) and bridged (**6a**, **b**, M = Ge,

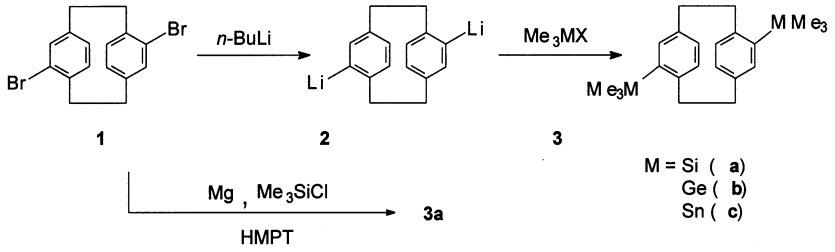
 © WILEY-VCH Verlag GmbH, D-69451 Weinheim, 1998 1434−1948/98/1111−1733 $ 17.50+.50/0

Sn; for Si compound see ref.[5]) paracyclophane monomers, which we plan to employ as monomers for the aforementioned polymer synthesis.

Results and Discussion

Dibromide **1** was obtained according to ref.[10] and lithiated with excess *n*-butyllithium in diethyl ether[11]. The resulting intermediate dilithio derivative **2** was then treated with trimethylsilyl chloride, trimethylgermanium bromide or trimethyltin chloride to yield the derivatives **3a–c** (Scheme 2).

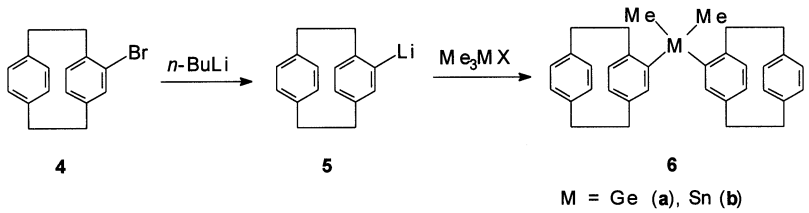
Scheme 2. The preparation of dimetallated [2.2]paracyclophanes



It is known that aromatic silylation can also be performed via organomagnesium reagents[12]. In the paracyclophane series, the mono Grignard reagent has been prepared and used for the synthesis of [2.2]paracyclophane-4-carboxylic acid[13]. Also, the coupling reaction of 4-bromo-[2.2]paracyclophane has been carried out via an organomagnesium intermediate[14]. To study the applicability of the organomagnesium route for the preparation of **3a**, we used the Barbier procedure[15], which has been applied previously for the synthesis of polysilylated benzenes[16]. In this approach, the aryl halide, magnesium and trimethylsilyl chloride are refluxed together in hexamethyl phosphoric triamide (HMPT) in a one-pot reaction. Compared with the lithation of **1**, this required more severe conditions (HMPT, heating, longer reaction time) and produced **3a** in substantially lower yield. Nevertheless, this metallation/quenching is the first example of the successful application of a disubstituted organomagnesium paracyclophane derivative in synthesis.

The bridged paracyclophane derivatives **6a**, **b** were synthesized from the monobromide **4**[17] via the monolithiated cyclophane **5**[18] (Scheme 3).

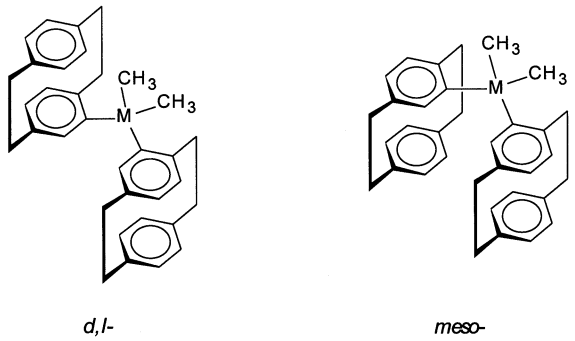
Scheme 3. The preparation of metal-bridged [2.2]paracyclophanes



One of the most striking properties of [2.2]paracyclophanes is their planar chirality, which appears as soon as one hydrogen atom of the parent molecule is replaced by another substituent, with the substituents being introduced into the aromatic nuclei in most cases. Since compounds **6a**, **b** are constructed from two chiral elements, they could in principle be obtained as a mixture of diastereomers, a chiral *d,l* enantiomeric pair and an achiral *meso* form (Scheme 4).

In both cases, the reaction mixtures were analyzed by HPLC (RP-18, methanol or methanol/water) and ^{1}H-NMR spectroscopy. The title compounds were indeed shown to have been formed as a diastereomeric mixture. According

Scheme 4. The *d,l* and *meso* form of a metal-bridged [2.2]paracyclophane



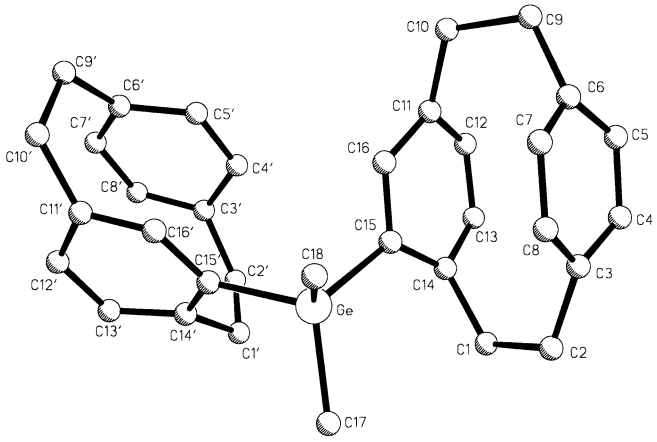
to their ^{1}H-NMR data, the diastereomers **6a**, **b** are formed in a *d,l*/*meso* ratio of about 2:1. The diastereomers could be separated by fractional recrystallization, with the *meso* form usually precipitating from the mixture. The separation of **6b** from the reaction mixture is difficult, since this compound is not stable on silica gel. Fractional recrystallization of the reaction mixture in this case only leads to the *meso* dia-

stereomer in pure form. Full spectral characterization of the diastereomers obtained was performed (see Experimental Section).

The chiral enantiomeric and the *meso* stereoisomers of both compounds **6a**, **b** could also be distinguished directly. Thus, the protons of CH_3 groups in the chiral isomer are related by a C_2 axis, so that they are homotopic and give rise to a single singlet. The corresponding protons in the *meso* form are surrounded by different chiral paracyclophane moieties and are therefore diastereotopic. The signals of these groups are detected as two singlets with a shift difference of 0.2 ppm. It is noteworthy that although the *meso* forms of **6a**, **b** can be unambiguously characterized by ^{1}H-NMR spectroscopy, in the ^{13}C-NMR spectra of these compounds the signals of the methyl C atoms are not resolved.

Furthermore, crystals suitable for an X-ray structural determination could be obtained in the case of *d,l*-**6a**′′. According to X-ray data, the [2.2]paracyclophanyl units of this derivative are very similar to one another and display the typical [2.2]paracyclophane geometry (Figure 1).

Figure 1. The structure of *d,l*-**6a**′′ in the crystal; radii are arbitrary



The aromatic rings are puckered into a boat form, with the bridgehead carbon atoms displaced out of the plane formed by the remaining four carbon atoms of the rings by 0.153−0.163 Å for the unsubstituted, and by 0.168−0.175 Å for the substituted rings. The C(sp^3)−C(sp^3) bond lengths of the ethano bridges range from 1.554 to 1.568 Å, i.e. they are slightly shorter than that in the parent [2.2]-paracyclophane molecule[5]. The lengths of the germanium−carbon bonds (such as Ge−C15) to the paracyclophanyl groups range from 1.955 to 1.962 Å, consistent with what is normally observed for Ge−Ar bonds[19].

The use of these new [2.2]paracyclophanes as monomers for novel metal-containing polymers is under active investigation, and we hope to report on these studies shortly.

Experimental Section

General: ^{1}H and ^{13}C NMR: Bruker AM-400 (400.13 and 100.6 MHz, for ^{1}H and ^{13}C, respectively), $CDCl_3$ as solvent, TMS as internal standard. − MS: Varian CH5, EI (70 eV). − IR: Nicolet 320 FT-IR spectrometer. − UV/Vis: Hewlett-Packard 8452A. − Column chromatography: Kieselgel 60, 70−230 mesh (Merck, Darmstadt). − Diastereomer compositions were determined by analytical HPLC (Milton-Roy HPLC system, methanol/water, 19:1, reversed-phase (S_5 octadecylsilane, SiC_{18} Spherisorb). − Et_2O was distilled from benzophenone ketyl under argon immediately prior to use. Dichloromethane was distilled from P_2O_5. Hexamethylphosphortriamide (HMPT) was distilled from CaH_2 in vacuo and stored under nitrogen. $(CH_3)_3SiCl$, $(CH_3)_3GeBr$, $(CH_3)_2GeCl_2$ were distilled from CaH_2. Other reagents were purchased from Aldrich and were used without purification.

4,16-Bis(trimethylsilyl)[2.2]paracyclophane (**3a**) *via Organolithium Compound* **2**: To a stirred suspension of 1.0 g (2.73 mmol) of **1** in 60 ml of dry diethyl ether under nitrogen, was added 9.76 ml of a 1.64 M *n*BuLi solution in hexane (16 mmol). The reaction mixture was stirred for 3 h, and then 2.03 ml (16 mmol) of $(CH_3)_3SiCl$ was added by means of a syringe over a period of 15 min. The reaction mixture was stirred overnight, heated for an additional 1 h, and then quenched with saturated NH_4Cl solution. The organic layer was washed several times with water, and dried with Na_2SO_4. The solvent was evaporated under reduced pressure. Column chromatography of the residue (pentane/dichloromethane, 8:1) gave 0.64 g (67%) of **3a**, m.p. 156°C. − IR (KBr): $\tilde{\nu}$ = 2930 cm^{-1} (m), 2880 (w), 1240 (s), 1105 (m), 905 (m), 860 (s), 842 (s), 832 (s), 755 (m), 720 (m). − UV/Vis (CH_3CN): λ_{max} (lg ε) = 230 nm (3.95), 255 (3.27), 266 (3.06). − ^{1}H NMR ($CDCl_3$): δ = 0.4 (s, 18 H, CH_3), 2.96−3.35 (m, 8 H, CH_2CH_2), 6.29 (d, *J* = 7.8 Hz, 2 H, 8-, 12-H), 6.37 (dd, *J* = 7.8, *J* = 1.9 Hz, 2 H, 7-, 13-H), 6.82 (d, *J* = 1.9 Hz, 2 H, 5-, 15-H). − ^{13}C NMR ($CDCl_3$): δ = 1.00 (s, CH_3), 35.67, 35.82 (s, C-1, -2, -9, -10), 133.47, 134.37, 137.15, 137.9, 138.76, 146.2 (s, all C-Ar). − MS (70 eV); *m/z* (%): 352 (10) [M$^+$], 337 (13), 176 (100), 160 (85), 145 (15). − $C_{22}H_{32}Si_2$ (352.67): calcd. C 74.93, H 9.15; found C 74.80, H 8.74.

4,16-Bis(trimethylsilyl)[2.2]paracyclophane (**3a**) *via an Organomagnesium Derivative:* Under nitrogen, 0.36 g (14.9 mmol) of magnesium and 2.0 g (5.46 mmol) of **1** in dry HMPT (8 ml) were placed in a two-necked round-bottomed flask equipped with a dropping funnel and a condenser, and the mixture was stirred for 10 min. Then, 2.52 ml (19.86 mmol) of $(CH_3)_3SiCl$ was added, the mixture was heated to 50°C, and reaction was initiated by adding a few drops of 1,2-dibromomethane (frothing and temperature increase). The reaction mixture was refluxed at 60°C for 40 h and, after cooling to room temp., was hydrolyzed by pouring it into a 0.5% sodium hydrogen carbonate solution, while the neutrality of the solution was tested at regular intervals. The resulting mixture was extracted with hexane, and the organic phase was washed several times with water and dried with Na_2SO_4. The solvent was evaporated under reduced pressure, and column chromatography of the residue on silica gel (pentane/dichloromethane, 8:1) gave 0.8 g (42%) of **3a**.

4,16-Bis(trimethylgermanyl)[2.2]paracyclophane (**3b**): 4,16-Dilithio[2.2]paracyclophane (**2**) was obtained as described above from 1.0 g (2.73 mmol) of **1** and 9.76 ml (16 mmol) of *n*BuLi (1.64 M solution in hexane). Subsequent reaction of **2** with 2.05 ml (16 mmol) of $(CH_3)_3GeBr$ and work-up of the reaction mixture were performed as in the case of **3a**. Column chromatography on silica gel of the resulting solid (heptane/benzene, 6:1) afforded 0.39 g (32%) of **3b**, m.p. 158−159°C. − IR (KBr): $\tilde{\nu}$ = 2925 cm^{-1} (m),

2900 (w), 1225 (m), 1105 (w), 905 (m), 855 (s), 840 (s), 822 (s), 750 (w), 720 (m). − UV/Vis (CH_3CN): λ_{max} (lg ε) = 230 nm (4.03), 255 (3.30), 266 (3.10). − ^1H NMR ($CDCl_3$): δ = 0.48 (s, 18 H, CH_3), 2.94−3.33 (m, 8 H, CH_2CH_2), 6.30 (br. s, 4 H, 7-, 8-, 12-, 13-H), 6.72 (br. s, 2 H, 5-, 15-H). − ^{13}C NMR ($CDCl_3$): δ = 1.14 (s, CH_3), 34.22, 34.38 (s, C-1, -2, -9, -10), 131.92, 132.38, 134.85, 136.70, 140.32, 143.70 (s, all C-Ar). − MS (70 eV); *m/z* (%): 444 (29) [M^+], 429 (25), 310 (24), 222 (100), 207 (78), 177 (30), 118 (46). − $C_{22}H_{32}Ge_2$ (441.72): calcd. C 59.83, H 7.30, Ge 32.87; found C 59.73, H 7.24.

4,16-Bis(trimethylstannyl)[2.2]paracyclophane (**3c**): 10 ml of a 3.0 N *n*BuLi solution in hexane (30 mmol) was added to a stirred suspension of 0.50 g (1.37 mmol) of **1** in 50 ml of dry diethyl ether under argon. The reaction mixture was stirred for 5 h, and then a solution of 5.98 g (30 mmol) of $(CH_3)_3SnCl$ in dry diethyl ether was added dropwise over a period of 30 min. The reaction mixture was left overnight, and was then quenched with saturated NH_4Cl solution. The organic layer was washed several times with water and dried with Na_2SO_4. The solvent was evaporated under reduced pressure to give 0.45 g (62%) of **3c**, m.p. 162−164°C. − IR (KBr): $\tilde{\nu}$ = 2922 cm^{-1} (m), 2886 (w), 1170 (s), 1100 (s), 1050 (s), 920 (w), 868 (s), 860 (s), 845 (s), 762 (s), 722 (w). − UV/Vis (CH_3CN): λ_{max} (lg ε) = 230 nm (4.20), 2.55 (3.39), 266 (3.18). − ^1H NMR ($CDCl_3$): δ = 0.35 [dt, 18 H, $J(^{117}Sn\text{-}H)$ = 51.6 Hz, $J(^{119}Sn\text{-}H)$ = 53.6 Hz, CH_3], 2.94−3.16 (m, 4 H, CH_2CH_2), 3.24−3.34 (m, 4 H, CH_2CH_2), 6.26 (dd, J_1 = 7.8, J_2 = 1.9 Hz, 2 H, 7-, 13-H), 6.37 (d, J = 7.8 Hz, 2 H, 8-, 12-H), 6.71 (d, J = 1.9 Hz, 2 H, 5-, 15-H). − ^{13}C NMR ($CDCl_3$): δ = −9.36 (s, CH_3), 34.36, 36.48 (s, C-1, -2, -9, -10), 131.13, 132.67, 136.61, 137.31, 142.85, 145.34 (s, all C-Ar). − MS (70 eV); *m/z* (%): 534 (2.5) [M^+], 519 (10) [$M^+ - CH_3$], 253 (100), 223 (34), 185 (64), 165 (62), 104 (84). − $C_{22}H_{32}Sn_2$ (533.88): calcd. C 49.50, H 6.04, Sn 44.46; found C 49.87, H 5.91, Sn 44.20.

Dimethylbis([2.2]paracyclophane-4-yl)germane (**6a**): To a stirred solution of 1.0 g (3.49 mmol) of **4** in dry diethyl ether (80 ml) under dry nitrogen, was added 2.5 ml of a 1.64 M *n*BuLi solution in hexane (4.1 mmol). After 3 h, 0.2 ml (1.75 mmol) of $Ge(CH_3)_2Cl_2$ was slowly added by means of a syringe, the reaction mixture was stirred for 2 h, and left to stand overnight. Saturated aqueous NH_4Cl solution was then added, the organic layer was washed twice with water, and dried with Na_2SO_4. The solvent was removed in vacuo, and the residue was separated by column chromatography on silica gel using CCl_4 as eluent, to afford a diastereomeric mixture of **6a** (1.28 g, 71%). − MS (70 eV); *m/z* (%): 518 (68) [M^+], 503 (95), 414 (36), 399 (56), 309 (42), 205 (100), 191 (78), 104 (36). − $C_{34}H_{36}Ge$ (517.25): calcd. C 78.95, H 7.02, Ge 14.03; found C 78.98, H 7.08. − The diastereomeric mixture was recrystallized from 2-propanol/dichloromethane (5:1, v/v). The precipitated solid was removed by filtration: 0.71 g (40%) of dimethyl-*meso*-bis([2.2]paracyclophane-4-yl)germane (**6a′**): M.p. 244°C. − IR (KBr): $\tilde{\nu}$ = 2923 cm^{-1} (s), 2891 (m), 2850 (m), 1410 (w), 1237 (w), 902 (m), 833 (m), 798 (s), 720 (s), 576 (m). − UV/Vis (CH_3CN): λ_{max} (lg ε) = 228 nm (4.54), 256 (3.86), 266 (3.64). − ^1H NMR ($CDCl_3$): δ = 0.72 (s, 3 H, CH_3), 0.92 (s, 3 H, CH_3), 2.67−3.27 (m, 16 H, CH_2CH_2), 6.20 (dd, J_1 = 7.8, J_2 = 1.3 Hz, 2 H), 6.30 (dd, J_1 = 7.8, J_2 = 1.3 Hz, 2 H), 6.38 (d, J = 7.8 Hz, 2 H, 8-, 8′-H), 6.44 (dd, J_1 = 7.8, J_2 = 1.6 Hz, 2 H, 7-, 7′-H), 6.55 (m, 4 H), 6.73 (d, J = 1.6 Hz, 2 H, 5-, 5′-H). − ^{13}C NMR ($CDCl_3$): δ = 35.65 (s, 6 C), 36.35 (s, 2 C) (C-1, -1′, -2, -2′, -9, -9′, -10, -10′), 132.51, 132.56, 132.94, 133.40, 134.16, 134.29, 137.00, 138.77, 139.41, 139.78, 140.40, 145.65 (s, all C-Ar). − The filtrate, after concentration and recrystallization of the residue from hexane, yielded 0.18 g (10%) of dimethyl-*d,l*-bis([2.2]paracyclophane-4-yl)germane (**6a′′**): M.p. 163°C. − IR (KBr): $\tilde{\nu}$ = 2923 cm^{-1} (s), 2891 (m), 2850 (m), 1410 (m), 1237 (m), 902 (m), 833 (m), 805 (s), 718 (s), 580 (w). − UV/Vis (CH_3CN): λ_{max} (lg ε) = 228 nm (4.28), 256 (3.76), 266 (3.60). − ^1H NMR ($CDCl_3$): δ = 0.89 (s, 3 H, CH_3), 2.80−3.27 (m, 16 H, CH_2CH_2), 6.07 (dd, J_1 = 7.9, J_2 = 1.7 Hz, 2 H), 6.33 (dd, J_1 = 7.9, J_2 = 1.7 Hz, 2 H), 6.37−6.49 (m, 4 H), 6.51−6.62 (m, 4 H), 6.76 (d, J = 1.9 Hz, 2 H). − ^{13}C NMR ($CDCl_3$): δ = −0.67 (s, CH_3), 34.15, 34.21, 34.36, 34.68 (C-1, -1′,-2, -2′, -9, -9′, -10, -10′), 131.10 (2 C), 131.41, 131.78, 131.71 (2 C), 135.49, 136.96, 137.98, 138.24, 139.34, 143.85 (s, all C-Ar).

Dimethylbis([2.2]paracyclophane-4-yl)stannane (**6b**): Monolithio[2.2]paracyclophane **5** was obtained as described above from 1.0 g (3.49 mmol) of **4** and 2.5 ml (4.1 mmol) of *n*BuLi (1.64 M solution in hexane). Subsequent reaction of **4** with 0.387 g (1.75 mmol) of $(CH_3)_2SnCl_2$ and work-up of the reaction mixture were performed as in the case of **6a**. Since this compound is not stable on silica gel, the mixture of diastereomers could not be separated by column chromatography. Recrystallization (three times) from 2-propanol/dichloromethane (4:1, v/v) yielded 0.85 g (43%) of dimethyl-*meso*-bis([2.2]paracyclophane-4-yl)stannane (**6b′**): M.p. 208°C. − IR (KBr): $\tilde{\nu}$ = 2926 cm^{-1} (s), 2890 (m), 2851 (s), 1410 (w), 1181 (w), 1092 (m), 898 (w), 742 (m), 720 (s), 520 (m), 510 (m). − UV/Vis (CH_3CN): λ_{max} (lg ε) = 228 nm (4.51), 256 (3.85), 266 (3.62). − ^1H NMR ($CDCl_3$): δ = 0.61 [dt, 3 H, $J(^{117}Sn\text{-}H)$ = 51.6 Hz, $J(^{119}Sn\text{-}H)$ = 53.6 Hz, CH_3], 0.77 [dt, 3 H, $J(^{117}Sn\text{-}H)$ = 51.6 Hz, $J(^{119}Sn\text{-}H)$ = 53.6 Hz, CH_3], 2.71−3.29 (m, 16 H, CH_2CH_2), 6.21 (br d, 2 H), 6.36 (br d, 2 H), 6.40−6.59 (m, 8 H), 6.76 (br s, 2 H). − ^{13}C NMR ($CDCl_3$): δ = 35.73, 35.75, 35.80, 38.16 (s, C-1, -2, -9, -10), 132.72, 132.87, 133.05, 133.20, 133.61, 134.21, 138.84, 139.25, 139.34, 139.90, 143.81, 146.90 (s, all C-Ar). − MS (70 eV); *m/z* (%): 564 (100) [M^+], 549 (98), 445 (74), 413 (16), 309 (32), 205 (84), 191 (58), 135 (18), 104 (36). − $C_{34}H_{36}Sn$ (563.35): calcd. C 72.49, H 6.44; found C 71.95, H 6.07.

X-ray Crystallographic Study of Dimethyl-d,l-bis([2.2]paracyclophan-4-yl)germane (*d,l*-**6a′′**): Crystal data: $C_{34}H_{36}Ge$, 517.25 g mol^{-1}, a = 14.001(3), b = 17.814(4), c = 10.554(2) Å, β = 93.09 (3)°, V = 2628.5 (10) $Å^3$, Z = 4, d = 1.307 mg/m^3, monoclinic crystals, space group $P2(1)/c$. Data collection: A colorless prism of dimensions 0.45 × 0.30 × 0.28 mm was mounted in inert oil. Data were collected to $2\theta_{max}$ = 50° [$I > 2\sigma(I)$] with an Enraf-Nonius CAD-4 diffractometer, Mo-K_α radiation (λ = 0.71073 Å), β-filter monochromator. Of 1965 measured data, 1844 were unique (R_{int} = 0.0155). μ = 1.186 mm^{-1}, T = 20°C. The structure was solved by direct methods and refined anisotropically on F^2 (program SHELXL-93, G. M. Sheldrick, Univ. Göttingen). Hydrogen atoms were refined in isotropic approximation. The final $wR^2(F^2)$ was 0.0553 for 461 parameters. Conventional $R(F)$ = 0.022, S = 1.086; max Δ/σ < 0.001; max Δρ 0.332 e$Å^{-3}$. Crystallographic data (excluding structure factors) for the structure *d,l*-**6a′′** reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication no. CCDC-101369. Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [Fax: (int. code) + 44(1223)336-033; E-mail: deposit@ccdc.cam.ac.uk; World Wide Web: http://www.ccdc.cam.ac.uk].

Keywords: Isomerization / Allylic alcohol / Nickel / Homogeneous catalysis / Two-phase catalysis

The nickel-catalyzed isomerization of geraniol and prenol in homogeneous and two-phase systems has been investigated. The best results in terms of activity and selectivity have been obtained in homogeneous systems with a bis(cycloocta-1,5-diene)nickel(0)/1,4-bis(diphenylphosphanyl)butane/trifluoroacetic acid combination. Catalyst deactivation occurs in the course of the reaction owing to coordination of the formed aldehyde group to the nickel species or as a result of protonolysis of hydrido- or (π-allyl)nickel complexes.

Introduction

The ability of homogeneous nickel complexes to promote double-bond positional isomerization of simple alkenes and polyenes as well as skeletal isomerization of some dienes is well documented[1]. While the reactions of unfunctionalized alkenes have been quite extensively studied, the case of alkenes bearing polar functional groups has received less attention. Thus, there have been only two reports on the nickel-catalyzed isomerization of allylic alcohols[2][3][4]. The first describes the selective transformation of allyl alcohol into propanal in the presence of a catalytic amount of the Ni^{I} complex $Ni_2(CN)_2(dppb)_3$ [dppb = 1,4-bis(diphenylphosphanyl)butane], which is either preformed or generated in situ from $Ni(dppb)_2$ and HCN[2]. The second describes a sluggish catalytic system consisting of ethylene(tri-*o*-tolyl phosphite)nickel(0) and hydrogen chloride for the isomerization of various allylic alcohols[3]. Surprisingly, although the catalytic isomerization of terpenic alcohols and related compounds could be of great industrial interest[4h], no attention has been directed towards these substrates in the previous studies.

Our continuing interest in the reactivity of zerovalent nickel−phosphane catalysts towards allylic substrates[5] has led us to explore the catalytic activity of various homogeneous Ni^0/diphosphane/acid systems in the isomerization of geraniol and prenol. We report herein that nickel efficiently catalyzes this process and point out how the catalyst is deactivated in the course of the reaction. An alternative water-soluble catalytic system has also been developed and evaluated.

Results and Discussion

In the light of literature reports and of our own work[5], we decided to use as catalyst precursor the complex $Ni(dppb)_2$, which is easily generated in situ from $Ni(COD)_2$ and two equiv. of dppb[6]. Preliminary experiments aimed at evaluating the efficiencies of the added Brønsted acids were first conducted using geraniol (**1**) as the substrate. Besides the expected isomerization product, citronellal (**2**), several compounds were formed in variable amounts depending on the reaction conditions (Scheme 1). Thus, some of the **2** present was converted into the diastereomeric alcohols isopulegol (**3**) and neoisopulegol (**4**) as a result of a proton-catalyzed cyclization process[7]. Two further side-products **5** and **6** were generated due to esterification of the starting substrate by the carboxylic acid added as a co-catalyst, and acetalization of **2** by **1**, respectively. The results are summarized in Table 1.

The isomerization of **1** did not proceed when 1.5 mol-% of $Ni(dppb)_2$ was used at 80°C in the absence of a co-catalyst (entry 1) or in the presence of methanol (entry 2). In these cases, only small amounts of the dehydration products of **1**, i.e. myrcene (**8**) and ocimene (**9**) were formed, most probably by oxidative addition of **1** followed by a β-H elimination process as these products were not observed in the absence of the nickel catalyst (Schemes 2 and 6).

The addition of 4 equiv. of acetic acid (with respect to Ni) allowed the selective, but sluggish formation of **2** (entry 3). An increase in the amount of acetic acid up to 50 equiv. improved the catalytic activity, but the selectivity significantly decreased with time because of the formation of the ester **5** as a side-product (entry 4). Use of TFA as the co-catalyst proved much more advantageous. With 1 equiv., an almost total selectivity for **2** could be observed, although the reaction stopped after 2 h, reaching a maximum of 30% conversion of **1**. Increasing the amount of TFA up to 2 or 4 equiv. led to a slight improvement of the catalytic activity in the initial stages of the reaction, but the limitation of termination of the reaction after ca. 50% conversion was

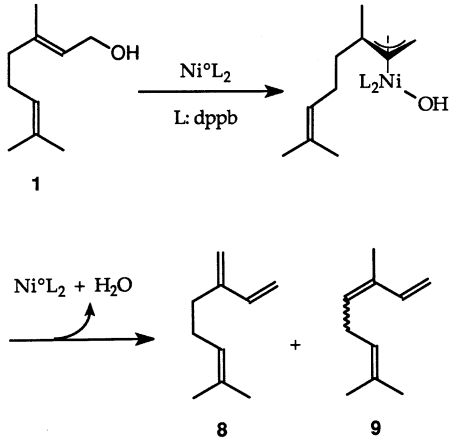
[a] Reaction conditions: $Ni(COD)_2$ 0.13 mmol, dppb 0.26 mmol, geraniol (**1**) 9.1 mmol, toluene 5 ml, $T = 80°C$. – [b] mol equivalent of protic co-reagent with respect to Ni. – [c] Selectivity = (mmol of product)/(mmol of converted geraniol) × 100; conversion of **1** and selectivities of the formed products were determined by quantitative GLC analysis. – [d] The **3**/**4** ratio was always 60:40. – [e] Myrcene and ocimene account for the conversion. – [f] Two-phase system: $Ni(COD)_2$ 0.13 mmol, dppbts 0.26 mmol, geraniol (**1**) 9.1 mmol, toluene 5 ml, water 10 g, $T = 110°C$. – [g] Same conditions as in footnote [f] except water 5 g and dimethylformamide 5 g. – [h] Reaction conducted in the presence of butane-1,2-diol (13.7 mmol, 1.5 equiv. with respect to **1**). – [i] The first value indicates the yield of free citronellal (**2**) and the value in brackets the total yield including free and acetalized citronellal (**2** + **15**). – [j] The first value indicates the selectivity for free citronellal (**2**) and the value in brackets the total selectivity including free and acetalized citronellal (**2** + **15**).

still observed (entries 6, 7). Moreover, the presence of an excess of acid with respect to nickel catalyst promoted the cyclization and acetalization, and to a lesser extent the esterification (entry 7).

Similar results were also obtained for the isomerization of prenol (**10**) into isovaleraldehyde (**11**) using the $Ni(dppb)_2$/TFA (1:2) catalyst system (Scheme 3). Besides **11**, the isomeric 3-methyl-3-buten-1-ol (**12**), resulting from isomerization of the double bond in the carbon backbone, was also formed in small amounts. The results are summarized in Table 2.

With 1 equiv. of TFA with respect to $Ni(dppb)_2$, isomerization rapidly ceased, thus allowing the attainment of modest yields only (Table 2, entry 13). On the other hand, excess TFA proved to be detrimental to the selectivity due to acetalization of **11** to give **13** (Table 2, entry 15). A TFA/

Scheme 2. Suggested formation of myrcene (**8**) and ocimene (**9**) from geraniol (**1**)



In order to gain further insight into the aforementioned limitation to the extent of conversion, an experiment was conducted with the $Ni(dppb)_2$/TFA (1:2) catalytic system, in which the temperature was varied during the course of the reaction. The experiment was started at room temperature and the temperature was increased when the progress of the reaction was seen to falter (Figure 1).

It was found that the limit to the degree of conversion of **1** into **2** increased with temperature, i.e. 5% at 20°C, 13% at 50°C, and ca. 50% at 80°C. As the isomerization of allylic alcohols is a non-reversible process[8], the above data cannot stem from a thermodynamic control of the reaction and are much more likely to be attributable to catalyst deactivation. In fact, we assume that the aldehydes **2** or **11** reversibly coordinate to Ni[9] to form an inactive species, the stability of which would decrease with temperature (Scheme 4).

Scheme 3. Isomerization of prenol (**10**) into isovaleraldehyde (**11**) and reaction side-products

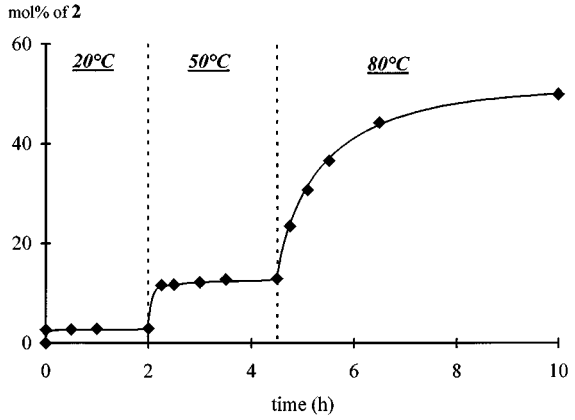
[a][b] See Table 1. – [c] Selectivity = (mmol of product)/(mmol of converted prenol) × 100; conversion of **10** and selectivities of the formed products were determined by quantitative GLC analysis. – [d] Calculated selectivity for attainable isovaleraldehyde after hydrolysis. – [e] Isoprene accounts for the conversion. – [f] Two-phase system: $Ni(COD)_2$ 0.13 mmol, dppbts 0.26 mmol, prenol (**10**) 9.1 mmol, toluene 5 ml, water 5 g, dimethylformamide 5 g, $T = 110$°C. – [g] Reaction conducted in the presence of butane-1,2-diol (13.7 mmol, 1.5 equiv. with respect to **11**). – [h] The first value indicates the yield of free isovaleraldehyde (**11**) and the value in brackets the total yield including free and acetalized isovaleraldehyde (**11** + **16**). – [i] The first value indicates the selectivity for free isovaleraldehyde (**11**) and the value in brackets the total selectivity including free and acetalized isovaleraldehyde (**11** + **16**).

Ni ratio of 2 appeared to be a good compromise (Table 2, entry 14) but, as in the case of geraniol, a rapid decrease in the catalytic activity after 2 h of reaction and a limit to the degree of conversion was observed.

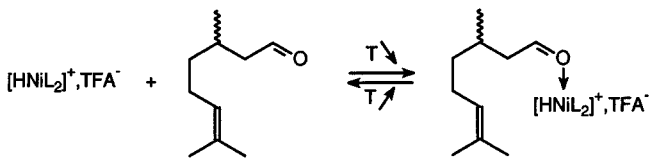
To check this hypothesis, two approaches were considered:

(i) The first of these involved the use of an aqueous/organic two-phase system where the organic compounds, i.e.

Figure 1. Influence of the temperature on the isomerization of geraniol (**1**) into citronellal (**2**); experimental conditions: $Ni(COD)_2$: 0.13 mmol, dppb: 0.26 mmol, **1**: 9.1 mmol, toluene: 5 ml, TFA: 0.52 mmol



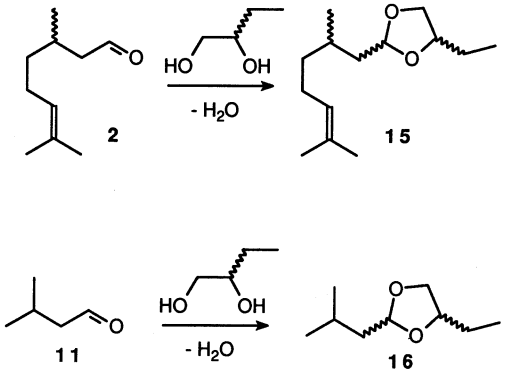
Scheme 4. Reversible coordination of the aldehyde to the nickel center



the allylic alcohol and the aldehyde, were in a different phase from that containing the catalytic system. In such a system, the coordination of the aldehyde group should be less favorable. Unfortunately, the performance of the corresponding water-soluble catalytic system, i.e. a nickel complex of tetrasulfonated 1,4-bis(diphenylphosphanyl)butane in an acidic aqueous solution[10], turned out to be rather disappointing (entries 8–10). Indeed, in a genuine two-phase system, i.e. without a co-solvent, the isomerization of **1** into linalool (**7**) was the major reaction (Scheme 1) and **2** was obtained only in very poor yield (3%, entry 8). Experiments conducted in the absence of a nickel catalyst proved unequivocally that **7** is formed by a proton-assisted process[11]. Such a process did not occur in homogeneous media, probably because of the lower stability of the intermediate allylic carbocation in non-polar organic media. Interestingly, the use of a co-solvent such as dimethylformamide (DMF) reduces the polarity of the aqueous layer and consequently suppresses this undesirable reaction. Indeed, although this catalytic system gave **2** in poor yields irrespective of the acid used, the selectivity for the desired aldehyde reached 86%, compared to 3% without DMF (entries 9, 10). Owing to the high solubility of prenol in water, it is noteworthy that DMF does not suppress the proton-catalyzed side reaction (Table 2, entry 16). Furthermore, in all biphasic reactions, a rapid colour change of the aqueous layer from orange to pale-green was observed, thus indicating an irreversible catalyst decay.

(ii) The second approach involved trapping of the aldehyde by acetalization, by including an excess of butane-1,2-diol in the reaction mixture (Scheme 5). Butane-1,2-diol was preferred to ethane-1,2-diol for trapping of the aldehydes because of its total solubility in the reaction mixture.

Scheme 5. Acetalization of citronellal (**2**) and isovaleraldehyde (**11**) by butane-1,2-diol



Under these conditions, higher final yields of aldehyde derivatives and higher conversions of **1** and **10** compared to the runs conducted without butane-1,2-diol were obtained. For instance, for the isomerization of **1**, the amounts of by-products **3**–**6** were significantly decreased in favour of **2** and the corresponding dioxolane **15** (entry 11). In the case of **10**, aldehyde **11** was produced in essentially 90% yield in 16 h (compared with 47% yield in the absence of butane-1,2-diol; Table 2, entry 17). These results are clearly fully supportive of the aforementioned hypothesis of a competitive coordination between the double bond of the alcohol and the aldehyde function to the Ni.

However, even in the presence of butane-1,2-diol, substrates **1** and **10** could not be completely converted and a limit to the degree of conversion was still observed. As the coordination of the aldehyde group leads to unreactive but stable species (Figure 1, vide supra), the progressive loss of activity in the course of the reaction cannot be attributed

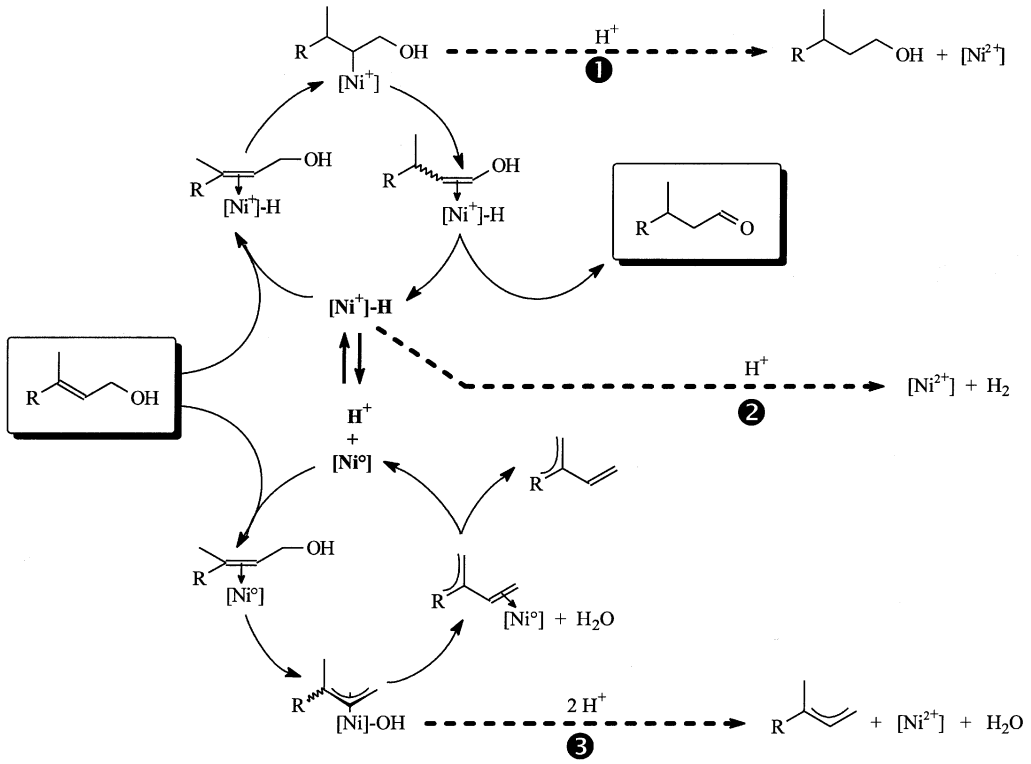
Figure 2. Scheme 6. Suggested catalytic cycle for isomerization of allylic alcohols and irreversible deactivation pathways of the catalyst



to this phenomenon, but rather to a slow and irreversible catalyst decay. The latter was confirmed by carrying out two further separate experiments under the same reaction conditions, i.e. the isomerization of pure **1** and of a 50:50 mixture of **1** and **2** (Figure 2).

In the first case, the conversion reached 50%, i.e. the same composition as the starting mixture of the second experiment, while in the second case 40% of the **1** initially present was isomerized. This clearly indicates that the **2**/Ni ratio is not the sole parameter affecting the catalytic activity. A further experimental indication of the catalyst decay came from the aforementioned progressive colour change of the homogeneous and biphasic solutions in the course of the reactions. Possible mechanistic pathways for this catalyst deactivation are the well-known protonolysis of the active hydride−nickel species[12] or of a π-allyl− or alkyl−nickel species resulting from allylic alcohol insertion into the hydride−nickel bond during the isomerization catalytic cycle (pathways 1, 2, and 3 in Scheme 6).

Conclusion

Although catalyst deactivation appears to be a non-negligible reaction, this study proves that the Ni^0/1,4-bis(diphenylphosphanyl)butane/trifluoroacetic acid combination is efficient for the isomerization of the trisubstituted carbon−carbon double bond in terpenic alcohols and related compounds. Thus, provided that the reaction is conducted in the presence of butane-1,2-diol, a turnover number of 60 and a selectivity of 98% for the free and acetalized isovaleraldehydes can be attained using a homogeneous system. Further experiments aimed at increasing the stability of the catalytic system and with a view to performing asymmetric isomerization are currently under way in our laboratories.

Experimental Section

General: Bis(cycloocta-1,5-diene)nickel, 1,4-bis(diphenylphosphanyl)butane (dppb), trifluoroacetic acid (TFA), geraniol (**1**), and prenol (**8**) were purchased from Strem Chemicals or Aldrich Chemical Co. in the highest available purity and used without further purification. The sodium salt of tetrasulfonated 1,4-bis(diphenylphosphanyl)butane (dppbts) was synthesized according to a literature procedure[13]. All catalytic reactions were performed under nitrogen using standard Schlenk techniques. All solvents and liquid reagents were degassed by two freeze-thaw cycles prior to use.

General Procedure for Isomerization Reactions of Allylic Alcohols: In a typical experiment (Table 1, entry 6), to $Ni(COD)_2$ (36 mg, 0.13 mmol) in a 50-ml glass reactor fitted with a Teflon cap was added a degassed solution of dppb (111 mg, 0.26 mmol) in toluene (5 ml). The solution rapidly turned orange. After 15 min of magnetic stirring, geraniol (**1**) (1.4 g, 9.1 mmol), decane (0.5 g, GLC internal standard) and finally a toluene solution of TFA (0.6 M, 0.85 ml, 0.51 mmol) were added. The solution immediately became deep-red-orange. Quantitative GLC analysis of this solution (Chrompack, CP Sil 5-CB column, 25 m × 0.32 mm) indicated that 5 mol-% of **1** had been converted into citronellal (**2**). The solution was stirred at 80°C and the reaction was monitored by removing aliquots and subjecting them to GLC analysis. A progressive colour change deep-red-orange to yellow was observed. Reactions in the presence of butane-1,2-diol were conducted in a similar manner.

All products were identified by comparison of retention times and spectral properties with those of authentic samples.

General Procedure for Isomerization Reactions of Allylic Alcohols in Biphasic Media: In a typical experiment, $Ni(COD)_2$ (35 mg, 0.13 mmol), dppbts (217 mg, 0.26 mmol), and either water (10 g) or a mixture of water (5 g) and dimethylformamide (5 g) were introduced under nitrogen into a glass tube reactor. After stirring with a magnetic bar for 2 h at 80°C, the solution took on an orange color and the insoluble $Ni(COD)_2$ had disappeared. This solution was then added to a mixture of **1** (1.4 g, 9.1 mmol), toluene (5 ml), and the chosen acid (0.52 mmol). The resulting mixture was stirred at 1000 rpm at 110°C and the reaction was monitored by GLC analysis of aliquots withdrawn from the organic phase.

Keywords: Palladium / Platinum / Aryl rotation / Through-space coupling interactions / Turnstile mechanism

The square-planar complexes $[MR_2L_2]$ (M = Pd, Pt; R = 3,5-$C_6Cl_2F_3$) [L_2 = $OPPyPh_2$ (Py = 2-pyridyl); $SPPyPh_2$; $OPPy_2Ph$; DMBI (3,3′-dimethyl-2,2′-biindazole); OPPyPh(NHTol-*p*); *p*-TolNPPy_2Ph] have been prepared by treating *cis*-$[MR_2(THF)_2]$ (THF = tetrahydrofuran) with the appropriate chelate ligands. The ^{19}F-NMR spectra of these complexes show the presence of intramolecular through-space F-F couplings between *ortho*-fluorine atoms of nonequivalent R groups, which provide information for the assignment of the different *ortho*-fluorine signals and can be used to study the dynamic behavior of the mentioned complexes such as: a) Rotation of the R group in either Pd or Pt complexes, at the same or at different rates for each R groups depending on the neutral ligand; and b) exchange of the coordination sites of the chelating ligand, either by Berry or by turnstile mechanisms. The activation parameters for some of the processes are given.

Introduction

Fluoroaryl ligands have been profusely used in organometallic chemistry because of the stability of their complexes, which enables the isolation of compounds not easily obtained with nonfluorinated analogs[1]. The thermal stability of the complexes obtained is such that it allows not only their use as models in mechanistic studies, but also the synthesis of some thermotropic metal-containing liquid crystals[2]. Another advantage of fluoroaryl ligands is the simplicity of their ^{19}F-NMR spectra relative to the usually blurred ^{1}H-NMR aromatic region. Although higher field NMR instruments have decreased the importance of this second advantage, for detailed mechanistic and dynamic studies fluoroaryl ligands, particularly the pentafluorophenyl group, are still preferred[3].

However, the simplicity of the ^{19}F-NMR spectra of C_6F_5 derivatives is often deceptive. In the course of our work on asymmetric *cis*-bis(pentafluorophenyl) derivatives of palladium and platinum we have used systematically ^{19}F-^{19}F COSY-NMR experiments to help with the assignment of the two sets of ^{19}F signals of the two nonequivalent C_6F_5 rings. This methodology permits to observe the presence of scalar coupling cross-peaks between the *ortho*-fluorine signals of different C_6F_5 groups, although clear observation of the splitting pattern due to these couplings is possible only for few complexes, by selective-decoupling experiments on the F_{meta} nuclei when these have almost coincident chemical shifts. The observation of through-space coupling is not uncommon in ^{19}F-NMR spectroscopy, and it has been reported that the magnitude of the coupling depends on the distance between the interacting nuclei[4]. A detailed study of these *J*(F-F) has been carried out for the different atropisomers of $[Pd(2\text{-}C_6BrF_4)_2L_2]$ and $[Pd(3\text{-}C_6BrF_4)_2L_2]$ (L_2 = $OPPy_2Ph$, 2 tht, etc.), establishing that through-space interactions contribute importantly to them[5]. This study revealed that the magnitude of the coupling between *ortho*-fluorine atoms at the same side of the coordination plane (*syn*) in *cis*-bis(polyfluorophenyl) complexes is larger than that for *ortho*-fluorine atoms at different sides (*anti*) (Figure 1). Hence, even if the ^{19}F-NMR spectra show well-separated chemical shifts and well-resolved signals for each inequivalent nucleus (which is a quite common case), in complexes with two or more fluoroaryl rings coordinated to the same metallic center the presence of through-space F-F couplings prevents easy simulation of the spin system, measurement of *J*(F-F) values, and the use of line-shape analysis (LSA) for quantitative measurement of dynamic processes when pentafluorophenyl or tetrafluorophenyl groups are used.

Figure 1. F-F coupling constants measured in $[Pd(2\text{-}C_6BrF_4)_2L_2]$ complexes

In order to minimize this undesired complication we have started to use 3,5-dichlorotrifluorophenyl instead of the pentafluorophenyl[6]. In this group the spin system is very simple: The coupling between the fluorine atoms in position

 © WILEY-VCH Verlag GmbH, D-69451 Weinheim, 1998 1434−1948/98/1111−1745 $ 17.50+.50/0

2 and 4, and between those in 4 and 6, is usually less than the half-height band width; then any multiplicity observed in the signals in the ^{19}F-NMR spectra is due only to intra-ring or inter-ring coupling of nuclei in the *ortho* position to the metal center (F_{ortho}). We will show here that this allows more stereochemical and dynamic information to be obtained than with the pentafluorophenyl rings, since the changes in the spin system due to the maintenance or not of the through-space coupling is an additional source of information. Another important advantage is that the longitudinal relaxation times T_1 for the F nuclei of 3,5-$C_6Cl_2F_3$ (1.5 to more than 3 s) are much longer than for C_6F_5, thus increasing the range of validity of the magnetization-transfer (MT) experiments for low exchange rates[7].

Results

The complexes [MR_2L_2] (M = Pd, **a** or Pt, **b**; R = 3,5-$C_6Cl_2F_3$) [L_2 = $OPPyPh_2$ (Py = 2-pyridyl), **1**; $SPPyPh_2$, **2**; $OPPy_2Ph$, **3**; DMBI (3,3′-dimethyl-2,2′-biindazole), **4**; OPPyPh(NHTol-*p*), **5**; *p*-TolNPPy_2Ph, **6**] were obtained by substitution of tetrahydrofuran in *cis*-[$MR_2(THF)_2$] under gentle conditions (Figure 2).

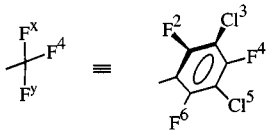
4

The solid-state IR spectra for all the isolated complexes show the characteristic infrared absorptions of the R group, and the presence of a split band in the region 710−670 cm^{-1} is in accordance with the presence of a *cis*-MR_2 arrangement[6a]. The shift to lower wavenumbers observed for ν(P=E) [E = O, S, N(C_6H_4Me-*p*)] for complexes **1**, **2**, **5**, and **6** relative to those of the free ligands[8][9] (see Experimental Section) suggests that, at least in the solid state, they are acting as E,N(Py) chelates. This is confirmed for their solutions by molecular-mass determinations with a vapor-pressure osmometer, which indicate monomeric species, and by the $^{31}P\{^1H\}$-NMR spectra which show the presence of only one isomer. However, the $OPPy_2Ph$ ligand behaves as N,N chelate in complexes **3**, as found for the C_6F_5 analogues[9b].

In the 300-MHz ^{1}H-NMR spectra of complexes **1**, **2**, **3**, **5**, and **6** the resonances due to the Py groups can be detected, although in some cases they overlap with Ph peaks. The analysis of the Py first-order subspectra is trivial[10]. The H^6 (the atom on C^6 in the Py groups) signal corresponds to a multiplet slightly broadened by the quadrupolar effect of the ^{14}N nucleus. Its chemical shift is very sensitive to coordination of the group and, when coordinated, to the *cis* ligand[9][11]. For a coordinated Py group in these complexes H^6 has a negative coordination-induced shift value, indicating its close proximity to the shielding zone of the adjacent R ring. The same effect is observed in the ^{1}H-NMR spectrum of **4**, where the H^7 (and $H^{7'}$) signal of the coordinated DMBI shows a clear upfield shift relative to the free ligand[12].

The complexes studied here have different symmetry elements giving rise to different chemical or magnetic equivalence situations in the ^{19}F-NMR spectra in a static situation. Moreover, they undergo some dynamic processes. Altogether they constitute good models of the possible static and dynamic circumstances that can occur in square-planar coordination, and illustrate how the 3,5-$C_6Cl_2F_3$ groups behave, or how they reflect these circumstances. Each situation is discussed in turn in the following. A schematic representation of the group, as shown in Figure 3, is used in the figures.

Figure 3. Schematic representation of the 3,5-$C_6Cl_2F_3$ group

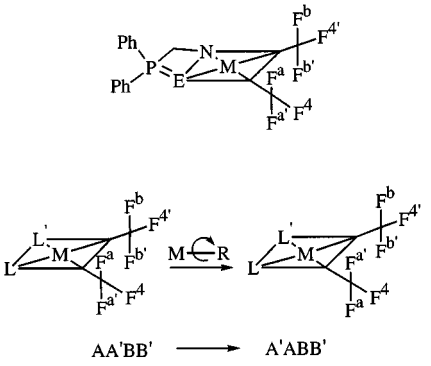


Complexes of Type I: [$MR_2(OPPyPh_2)$] (1) and [$MR_2(SPPyPh_2)$] (2)

These complexes have been studied both in $CDCl_3$ and [D_6]acetone solutions. The ligands $OPPyPh_2$ and $SPPyPh_2$ are coordinated through the pyridine nitrogen and the oxygen (in **1**) or the sulfur atom (in **2**) in an almost planar chelate ring. We have shown previously that there is a fast envelope-shift movement of the chelating ring, with a very low activation energy, which allows us to consider the five-membered metallacycle as planar for the rest of the discussion[9]. Thus, in a static situation the complexes have a C_s symmetry and the four F_{ortho} should give rise to an AA′BB′ spin system (Figure 4). The rotation of the R groups around the Pd−C bond in these complexes would produce exchange of chemically equivalent but magnetically inequivalent F_{ortho} nuclei.

Variable-temperature studies of **1a** and **1b** in $CDCl_3$ reveal that at room temperature the rotation of at least one of the R groups (most probably that *cis* to the oxygen atom, R^a, according to the results obtained for the related complexes **5**; see later) is fast, but on cooling the rotation is arrested. Thus, the appearance of the F_{ortho} signals changes from multiplets at low temperature, corresponding to an AA′BB′ spin system with J(AA′) and J(BB′) ≈ 0, to triplets (A_2B_2 system) as a result of the rotation of R^a which

Figure 4. Static structure of complexes of type I, and interconversion of the F_{ortho} as a result of the rotation of R[a]



interconverts the *ortho*-fluorine atoms as shown in Figure 4.

It is possible to obtain kinetic data for the rotation of R by LSA provided that the different J values can be estimated by simulation of the static spectrum (Table 1). However, the variation of the coupling constants with temperature observed, and the short range of temperatures in which the line-shape changes are detectable [which is related to $J(AB) - J(AB')$] prevent accurate calculation of activation parameters other than $\Delta G^{\neq}$. With these limitations, only the spectra of **1a** in $CDCl_3$ and [D_6]acetone at 235.2 K have been simulated, yielding similar values of $\Delta G^{\neq}$ (Table 2). For **1b** we could not obtain numerical values of $\Delta G^{\neq}$, but the change in the appearance of the F_{ortho} signals shows that it is probably in the same order of magnitude.

The room temperature ^{19}F-NMR spectra of **2a** and **2b** in $CDCl_3$ and [D_6]acetone show that their F_{ortho} signals give rise to an AA′BB′ spin system indicating a rigid structure for these complex in which the R groups are not rotating around the Pd−C bond. However, on raising the temperature from 293 K to 332 K the appearance of the *ortho*-fluorine signals undergoes changes characteristic of the rotation of at least one of the R groups (Figure 5). These changes are more evident for **2b** in a shorter temperature interval, showing the smaller difference between $J(AB)$ and $J(AB')$ (Table 1) which average their values in the fast exchange limit. The values of $\Delta G^{\neq}$ calculated for **2a** ([D_6]acetone) and **2b** ($CDCl_3$) at 324.7 K are in accordance with the higher steric hindrance imposed by the bulkier S atom (or the Py group) compared to the O atom[9b].

Another possible process in compounds of type I is that N and O (in **1**) or S (in **2**) exchange their sites. In the fast-exchange limit all the F_{ortho} signals of both R groups should average, and also their F_{para} signals. In practice, this limit is not reached for any of the complexes, but above 282 K this exchange is easily detected for **1a** in [D_6]acetone by the broadening of all the signals. The temperature dependence of the exchange rate, measured by MT experiments and

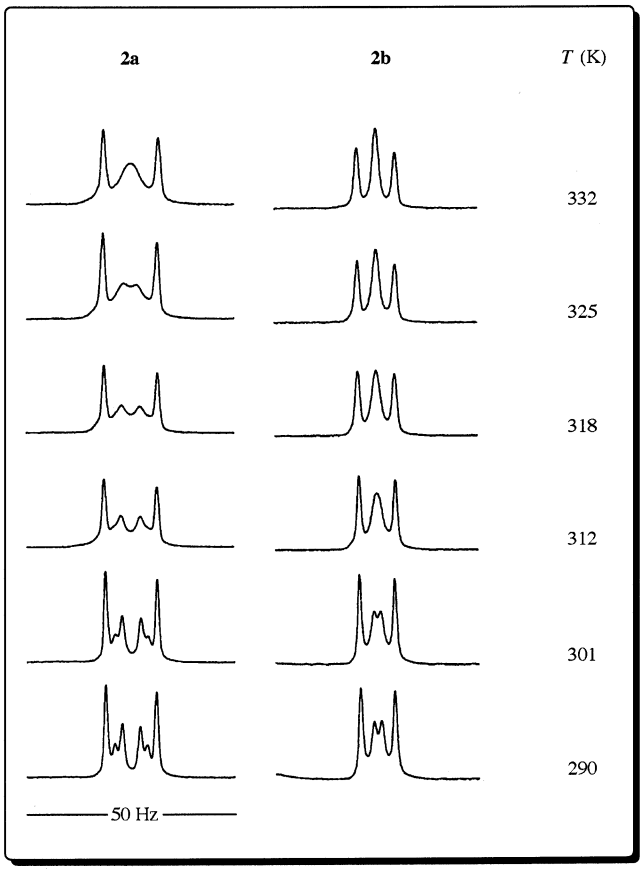
Figure 5. Temperature dependence of the AA′ part in the range 290−332 K for **2a** ([D_6]acetone) and **2b** ($CDCl_3$)



LSA on the F_{para} signals, allows us to calculate the activation parameters collected in Table 2. The exchange is solvent-dependent, and in $CDCl_3$ it is clearly much slower. The behavior of **2a** in [D_6]acetone is similar but with a lower rate; although the signals do not become broad it has been possible to measure k_{exch} at 298 K by MT experiments. In the platinum complexes, **1b** and **2b**, the exchange is not observed by MT.

The most plausible interpretation of this dependence on both the solvent and the metal center is a double substitution mechanism in which the solvent substitutes the weaker end of the chelating ligand (the oxygen atom in **1** or the sulfur or the Py nitrogen atom in **2**) at a rate measurable only in the kinetically labile Pd^{II} complexes, followed by the intramolecular substitution of the Py by the O or S atom, or by a reorganization in a pentacoordinate intermediate and the extrusion of the solvent molecule. However, the data available do not unequivocally support this hypothesis.

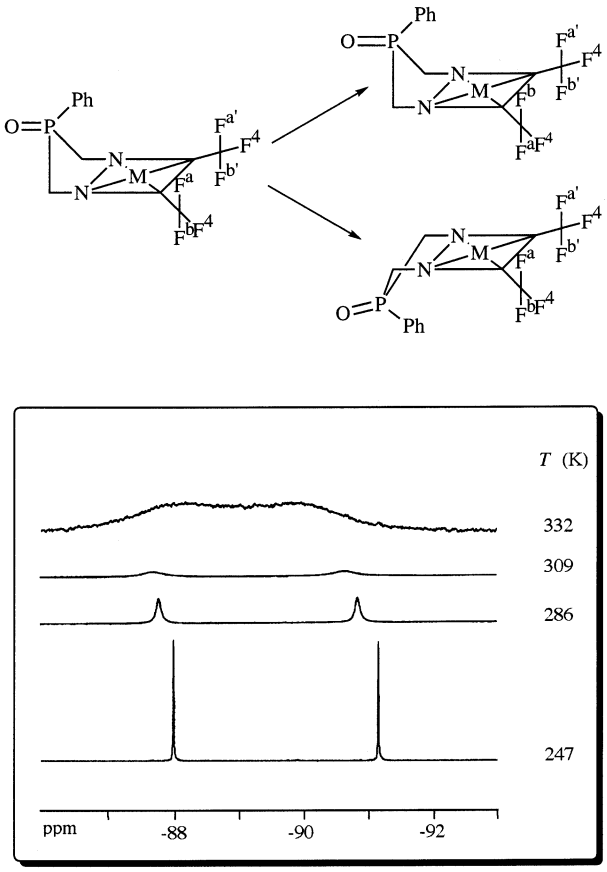
Complexes of Type II: [$MR_2(OPPy_2Ph)$] (3)

A detailed study of the related complexes [$M(C_6F_5)_2(OPPy_2Ph)$] has been recently published[9b]. The complexes [$MR_2(OPPy_2Ph)$] (**3**) have a C_s symmetry. In the slow-exchange limit the spin system of the F_{ortho} nuclei is AA′BB′ although the signals appear as broad singlets (approximately 4 Hz band width at half-height). The exchange, produced indistinctly by R rotation or by N,N exchange, renders equivalent the two sides above and below the coordination plane. Thus, in the fast-exchange limit the spin system becomes A_4 (Figure 6). In the case of **3**, the exchange is due to R rotation in the square-planar species without dissociation, which was measured and quantified by MT experiments or by LSA (Table 2).

Complexes of Type III: [$PdR_2(DMBI)$] (4a)

These complexes have a C_2 symmetry, common in enantiomerically pure ligands. With the ligand DMBI only the palladium compound has been studied, since with platinum an insoluble product was formed. The spin system of the F_{ortho} nuclei is again AA′BB′, but now the stereochemically

Figure 6. Interconversion of the F_{ortho} as a result of the rotation of R or by N,N exchange, and variable temperature ^{19}F-NMR spectra of [$PdR_2(OPPy_2Ph)$] (**3a**) in the F_{ortho} region



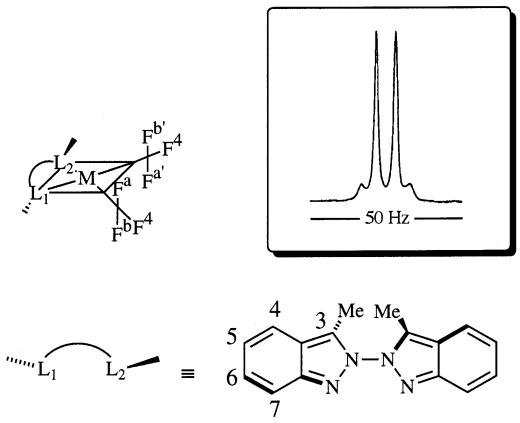
inequivalent nuclei are at the same side of the coordination plane (Figure 7). The origin of the nonplanarity of the coordinated DMBI is the methyl-methyl interaction. The twist of both indazole moieties about the N−N bond brings the protons H^7 and $H^{7'}$ close to the upfield F_{ortho} nuclei, which show some unresolved coupling (it can be removed by ^{1}H irradiation).

In this type of complexes the rotation of the aryl group should produce the equivalence of the *ortho*-fluorine nuclei (A_4). On the other hand, the two R groups (or their F_{para}) are equivalent by symmetry, so any exchange between the N coordination sites will not produce any observable effect, unless it occurs with concurrent R rotation. The latter should be the case if the exchange of coordination sites involved ligand dissociation, since R rotation becomes faster in a three-coordinate intermediate. The very slow exchange of the *ortho*-fluorine nuclei detected by MT at 329.1 K (Table 2) indicates a quite hindered rotation of the R groups in the tetracoordinate species.

Complexes of Type IV: [MR_2{OPPyPh(NHTol-*p*)}] (5) and [MR_2(*p*-TolNPPy_2Ph)] (6)

Complexes of type IV have the lowest symmetry, and in all the fluorine atoms are chemically inequivalent, giving

Figure 7. Static structure of complexes type III, and the AA′ part of the AA′BB′ spin system of the F_{ortho} for **4a** ($CDCl_3$, 293 K)



rise to an ABCD spin system in the low-exchange limit. The rotation of each group can be studied separately and also the stereochemistry of the exchange of the coordination sites of the chelated ligand.

As we have already mentioned, IR and ^{1}H- and ^{31}P{^{1}H}-NMR data indicate that the ligand OPPyPh(NHTol-*p*) is acting as O,N(Py) chelate in complexes **5**, like $OPPyPh_2$ in complexes **1**. In addition, only one stereoisomer is detected in solution for both complexes **5**, due to a rapid amine inversion process. Accordingly, four signals are expected in their ^{19}F-NMR spectra for the nonequivalent F_{ortho} nuclei. However, their ^{19}F-NMR spectra in [D_6]acetone at 293 K show only three signals in the F_{ortho} region, two of them with some splitting and the other very broad, in an intensity ratio of 1:1:2. This indicates that the two complexes behave similarly with one of the R groups (R^a) rotating fast at room temperature around the M−C bond, and the other apparently static. This is illustrated in Figure 8. The exchange interconverts the *ortho*-fluorine atoms according to the scheme ABCD ⇌ BACD, and F^4 and $F^{4'}$ remain unaffected.

Irradiation at room temperature of the broad signals assigned to R^a in **5a** and **5b** (F^a and F^b in Figure 8) led to the following results: For **5a** a simplification of the signals corresponding to R^b (the nonrotating group) from triplets to singlets is observed, which shows that for R^b $J(F^c\text{-}F^{4'})$ and $J(F^d\text{-}F^{4'})$ are smaller than the half-height band width. If the irradiation is used to presaturate the signal, a remarkable loss of intensity is observed in the others, confirming that a slow exchange is occurring between R^a and R^b. This last process will be further analyzed below considering the *para*-fluorine signals. For **5b** a simplification in R^b signals also occurs. Irradiation gives rise to two doublets from which it is possible to measure $J(F^c\text{-}F^d) = 2.8$ Hz.

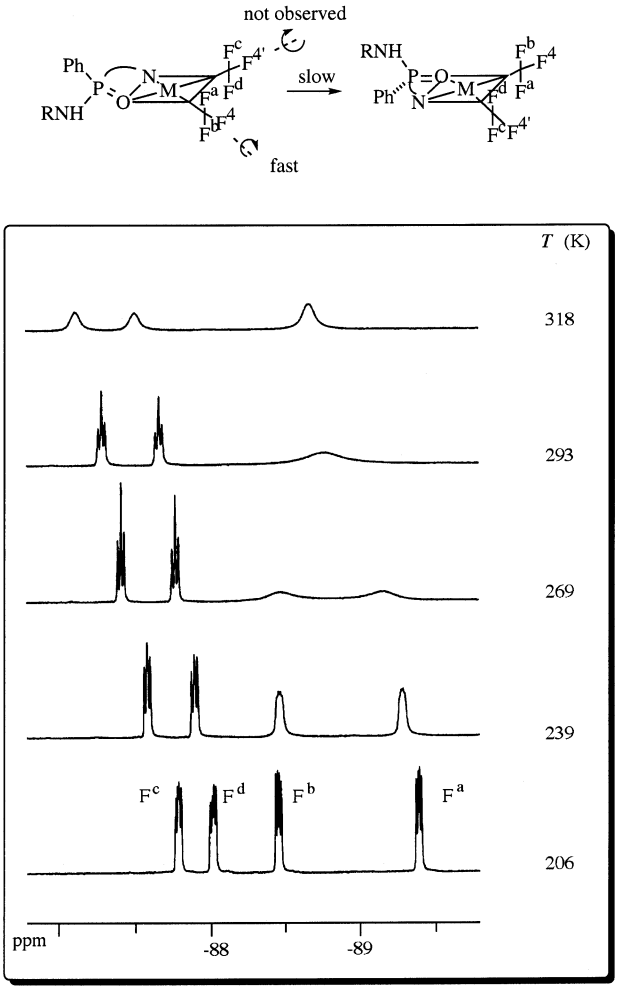
At low temperature the rotation of the R^a group is arrested leading to inequivalence of its two F_{ortho} nuclei. The coalescence temperatures for **5a** and **5b** are 281 and 269 K, respectively.

For **5a** at temperatures below 258 K there is a change in the appearance of the signals; the *ortho*-fluorine atoms of R^b change from triplets in system A_2CD, with $J(CD) = 0$

Hz] to doublets of doublets [ABCD with $J(AB) = J(CD) = 0$ Hz]. Thus, in the slow-exchange limit the spectrum of the palladium complex **5a** consists of four doublets of doublets (Table 1, Figure 8). The signal assignment of the fluorine atoms on the same side of the coordination plane is straightforward considering the relative magnitudes of their coupling constants. Unfortunately, ^{1}H-^{19}F NOE experiments do not give clear results and it is not possible to tell F^a and F^c from F^b and F^d.

The activation parameters for the rotation of R^a in **5a** (Table 2) were determined by MT experiments and LSA in the range 200−282 K. The exchange between the N and O coordination sites in **5a** is also observable (Figure 8), and it has been possible to perform kinetic studies by MT experiments and LSA in the range 275−330 K in the F_{para} region, to determine the corresponding activation parameters.

Figure 8. Illustration of the rotation of R^a and the exchange between the N and O coordination sites for complexes **5**, and variable-temperature ^{19}F-NMR spectra of [PdR_2{OPPyPh(NHTol-*p*)}] (**5a**) in the F_{ortho} region

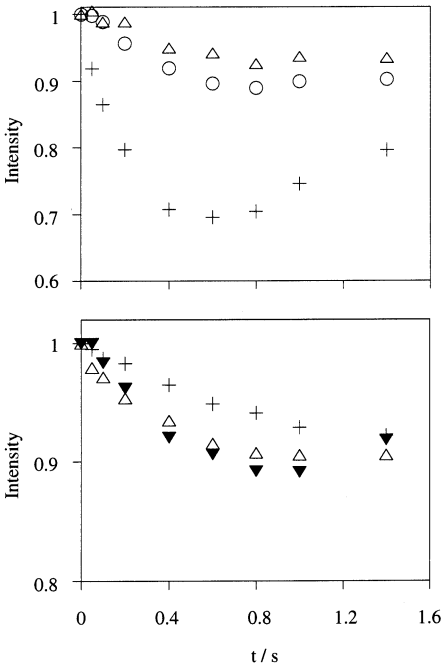


For the platinum complex **5b** LSA was performed in the temperature range in which the F_{ortho} signals are broad. There is no detectable exchange between R^a and R^b in this complex. The values of $^3J(^{195}Pt$-$^{19}F)$ measured in this complex confirm the assignment of R^a and R^b made in **5a**[6a][9b][13].

The room-temperature ^{1}H-NMR spectra of **6a** and **6b** in [D_6]acetone display the signals expected for two nonequivalent Py groups, one of them coordinated, and the ^{19}F-NMR spectra reveal four distinct fluorine environments associated with the F_{ortho} of the two nonequivalent R groups, which corresponds to a static structure for both complexes. Thus, their room-temperature spectra resemble the low-temperature spectra of **5a** and **5b** but with larger through-space coupling constants. When the temperature was increased **6a** and **6b** behaved differently. For **6b** a noticeable broadening of two F_{ortho} signals was observed and although the fast-exchange limit was not reached, this feature corresponds to the rotation of one of the R groups (R^a). Accordingly, the fine structure of the F_{ortho} signals of the nonrotating group (R^b) modified its appearance due to averaging of the couplings with the F_{ortho} of the rotating ring, in agreement with the simulated spectra. A good set of simulated band shapes was obtained for the spectra recorded, and the activation parameters derived are given in Table 2. Neither exchange between R^a and R^b, nor between the nonequivalent Py groups was detected for **6b** up to 325 K.

For **6a** only a slight broadening of the F_{ortho} signals was observed at 325 K, being the aryl rotation slow in the *J* time scale. MT experiments on ^{1}H Py signals and on ^{19}F F^4 signals of **6a** at 298 K confirm the slow exchanges between R^a and R^b [$k_{exch}(R^a \rightarrow R^b) = 0.30 \pm 0.01$] and between the nonequivalent Py groups [$k_{exch}(Py_{free} \rightarrow Py_{coord}) = 0.38 \pm 0.06$]. The similarity of both k_{exch} values (identical within the error limit) suggests that the two exchanges are produced by the same mechanism. The MT experiments on the *ortho*-fluorine nuclei at 298 K show a multi-step transfer (Figure 9). After the selective inversion of F^a, the intensity of the F^b signal decreased 30% after 0.6 s due to the rotation of the R group. There is also MT to F^c, which decreased 10% after 0.8 s, and to a smaller extent to F^d, which decreased 5% after 0.8 s (using the same numbering scheme as for complexes **5** in Figure 8). This experiment shows that the rotation of R^a is faster than the exchange between the N and N′ sites, and that the N,N′ exchange is stereoselective, since the magnetization is transferred from F^a preferentially to F^c. When the same experiment was performed by inversion of F^c there was simultaneous transfer to F^d and F^a, which decreased 10% after 1 s, while the transfer to F^b was slower and the signal decreased 7% after 1.4 s. Then the rotation of R^b has a rate comparable to the N,N′ exchange. The very low transfer of magnetization from F^a to F^d in the first experiment, or from F^c to F^b in the second, seems to be due to the fact that there is no transfer form the selectively inverted signal, but from the others when the MT has affected them. This selectivity supports a faster rotation for one of the aryl groups than for the other, as observed for **6b** and also for complexes **5**. It also suggests that the exchange between aryl groups takes place by a turnstile mechanism, with coordination of the free Py group to produce a square-pyramidal intermediate, supporting our previous observation that

Figure 9. Top: evolution of the signals of F^d (△), F^c (○) and F^b (+) after the selective inversion of F^a (▼) in complex **6a** ([D_6]acetone, 298 K); bottom: the same experiment by selective inversion of F^c



turnstile mechanisms are preferred to Berry mechanism for ligands favoring square-pyramidal geometry[14].

Conclusions

The compounds described in this paper allow the study of the inter-ring F-F coupling constants in *cis*-bis(3,5-dichlorotrifluorophenyl)palladium and -platinum units. In addition, they show that the use of this partially fluorinated ligand greatly facilitates their characterization and the study of their behavior in solution, which reveals the occurrence of the following processes: (a) fluoroaryl rotation, and (b) exchange between the coordination sites of the chelating ligand. The $\Delta G^{\neq}$ values associated with the aryl rotation processes (Table 2) reinforce our previous ideas suggesting that the rate of aryl rotation in square-planar complexes depends mainly on the steric hindrance by the atoms (or groups of atoms) coordinated to the metal center *cis* to the aryl ligand[9b].

Conversely, the patterns observed for the fluorine signals can be used to assign the coordination mode of the neutral ligands, or to detect some dynamic processes they might be undergoing. Thus, exchange between the coordination sites of the chelating ligand has been observed for the palladium complexes **1a**, **2a**, **5a**, and **6a**, and the low values of $\Delta S^{\neq}$ for **1a** and **5a** suggest an associative mechanism by a pentacoordinate mechanism. An incoming solvent does not impose any geometric restriction in the pentacoordinate intermediate, so a Berry mechanism seems most probable[15], but when the pentacoordination is achieved with the aid of one arm of the chelating ligand with a small bite angle (as for **6a**), the turnstile mechanism seems to be preferred[14].

We are very grateful to Dr. *A. L. Casado* for helpful discussions. Financial support was granted by the *Dirección General de Enseñanza Superior* (Project No. PB96-0363) and the *Junta de Castilla y León* (Project No. VA18/97). The *Ministerio de Educación y Cultura* is gratefully acknowledged for a fellowship to M. A. A.

Experimental Section

General Considerations: All reactions were performed under nitrogen in deoxygenated solvents, although subsequent manipulations were carried out in air, except where otherwise stated. Solvents were dried by standard methods and freshly distilled under nitrogen prior to use[16]. − C,H,N analyses were obtained with a Perkin-Elmer 2400B microanalyzer. − Molecular-mass determinations were carried out with a Knauer vapour-pressure osmometer, in $CHCl_2CHCl_2$ at 303 K (the solubility of **3b**, **4a**, and **5b** was too low to carry out this determination). − IR spectra were recorded (in the range 4000−200 cm^{-1}) with a Perkin-Elmer 883 spectrophotometer using samples mulled in Nujol between polyethylene films. − ^1H-, ^{19}F-, and $^{31}P\{^1H\}$-NMR spectra were recorded with a Bruker ARX 300 spectrometer (300.13, 282.35, and 121.44 MHz, respectively) equipped with a VT-100 variable-temperature unit. Temperature calibration was performed before measurements using the temperature-dependent chemical shift differences of the ^1H resonances of methanol (175−313 K) or ethylene glycol (310−410 K)[17]. Chemical shifts are relative to TMS (^1H), $CFCl_3$ at 293 K (^{19}F), or external 85% H_3PO_4 (^{31}P), with downfield values reported as positive. In some of the kinetic studies the magnetization transfer from a selective inverted peak was observed as a function of time. The selective excitation was executed using the known 1-1 sequence or with a Gaussian-shaped soft pulse, and the data analysis was carried out as described in the literature[18]. The computer simulation of the variable-temperature NMR spectra was carried out by line-shape analysis using the standard DNMR 6 program[19]. − The following starting materials were prepared according to published procedures: $OPPyPh_2$[20], $SPPyPh_2$[21], $OPPy_2Ph$[20], DMBI[22], *cis*-$[MR_2(THF)_2]$[6a]. The monophosphazene (*p*-MeC_6H_4)$NPPy_2Ph$ was synthesized by reaction of equimolar amounts of PPy_2Ph (made as reported for PPy_3[23], but starting from $PPhCl_2$) and the organic azide[24] in toluene. Hydrolysis in chloroform of this monophosphazene produced the ligand $OPPyPh\{NH(C_6H_4Me\text{-}p)\}$.

Preparation of the Complexes [MR_2L_2]: To a solution of *cis*-$[MR_2(THF)_2]$ (0.2 mmol) in 20 ml of $CHCl_3$ was added 0.2 mmol of the ligand ($OPPyPh_2$: 56 mg; $SPPyPh_2$: 60 mg; $OPPy_2Ph$: 56 mg; DMBI: 53 mg; OPPyPh(NHTol-*p*): 62 mg; *p*-$TolNPPy_2Ph$: 74 mg). The solution was stirred for 1 h and then concentrated to ca. 5 ml and stored at 243 K. Yellow or white crystals precipitated which were filtered off, washed with diethyl ether, and vacuum-dried.

[$PdR_2(OPPyPh_2)$] (**1a**): Yield: 132 mg (84%). − IR (cm^{-1}): $\tilde{\nu}$ = 1134 (P=O) (free ligand 1203), 706, 692 (R). − ^1H NMR ($CDCl_3$, 293 K): δ = 7.99 (m, 1 H, H^6 Py), 7.95 (m, 1 H, H^4 Py), 7.90−7.45 (12 H). − ^{19}F NMR ($CDCl_3$, 293 K): δ = −88.91 (t, *J* = 7 Hz, 2 F, F_{ortho}), −90.68 (t, *J* = 7 Hz, 2 F, F_{ortho}), −118.68 (s, 1 F, F_{para}), −119.68 (s, 1 F, F_{para}). − $^{31}P\{^1H\}$ NMR ($CDCl_3$, 293 K): δ = 49.8 (free ligand 21.5). − $C_{29}H_{14}Cl_4F_6NOPPd$ (785.61): calcd. Keywords: Silicon / Silylene / Azobenzene / 1-Adamantyl azide / Addition reactions

Reactions of the sterically encumbered silylenes R_2Si**:** (R = 2,4,6-$Me_3C_6H_2$, 2,4,6-$iPr_3C_6H_2$) with azobenzene are thought to proceed via the [2+1] cycloaddition products, followed by insertion of the N–N single bond into the *ortho*-C–H bond of one of the phenyl rings or into the C–*H*Me_2 bond of one of the *ortho*-isopropyl groups to furnish the 1,3-diaza-2-silaindan (**4**) or 1-aza-2-silaindan (**5**) derivatives, respectively. The reactions of these silylenes with 1-adamantyl azide seem to proceed through the silanimines and 4-azahomoadamantene intermediates which, by [2+2] cycloadditions, afford the 1,3-diaza-2-silacyclobutane derivatives **11** and **12**. The structures of **4**, **5**, **11**, and **12** were determined by X-ray crystallography.

Introduction

The addition of silylenes, R_2Si**:**, to homo- and heteronuclear multiple bonds is now an established method for the preparation of three-membered ring systems containing silicon atoms. The reactions are particularly facilitated by the presence of bulky alkyl or aryl groups which hinder subsequent rearrangements of the primarily formed three-membered rings.[2][3] However, the course of silylene addition to nitrogen−nitrogen double bonds is still somewhat ambiguous. Even though the first − and as yet only − diazasilirane of the type **3** was prepared in 1982 by a different route,[4] a structural characterization of this three-membered ring system has not yet been achieved. Recently, Ando et al.[5] reported on the photolysis of hexamesitylcyclotrisilane, which is known to decompose into dimesitylsilylene and tetramesityldisilene on exposure to light,[6] in the presence of azobenzene. Although the [2+2] cycloaddition product of the disilene to the N=N double bond was completely characterized, the putative [2+1] cycloaddition product of the silylene was only obtained in the form of a hydrolysis product of the diazasilirane ring system.

We now describe the reactions of two diarylsilylenes bearing sterically demanding substituents with azobenzene and with 1-adamantyl azide (**6**) and the unusual addition and rearrangement products isolated thereby.

[◇] Part 67: See ref.[1].

Results and Discussion

Irradiation of a solution of the trisilane **1**, which results in the silylene R_2Si**:** (R = 2,4,6-$Me_3C_6H_2$) together with hexamethyldisilane, in the presence of azobenzene furnished, after separation of a brown oil, colorless crystals for which the analytical and mass-spectral data were in agreement with reported values[2][5] suggestive of a 1:1 adduct of type **3**. However, the NMR- and IR-spectral data were not concordant with this proposal because they demonstrated, for example, the presence of an N−H bond in the molecule. The structure of this addition product was elucidated by X-ray crystallography which revealed that the bicyclic system **4** with a 1,3-diaza-2-silaindan skeleton (Figure 1) had been formed instead of the expected three-membered ring compound **3**.

The reaction of dimesitylsilylene with azobenzene presumably proceeds through an addition of the electron-sextet species to the N=N double bond to furnish **3** as an intermediate. The well-known weakness of the N−N single bond[7] which in this case will experience a further lowering of the bond dissociation energy by its incorporation into a strained three-membered ring probably provides the driving force for the cleavage of this bond with the simultaneous formation of one N−H and one N−C bond. The result is the more or less strain-free five-membered ring part of the bicyclic compound **4**. Surprisingly, this simple bicyclic compound apparently represents the first example of a novel ring system. A search of the Cambridge Crystallographic

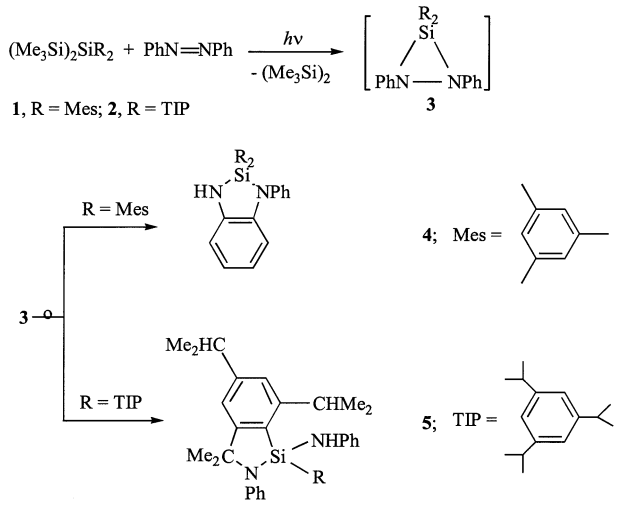

Figure 1. Molecular structure of **4** in the crystal (hydrogen atoms omitted)[a]

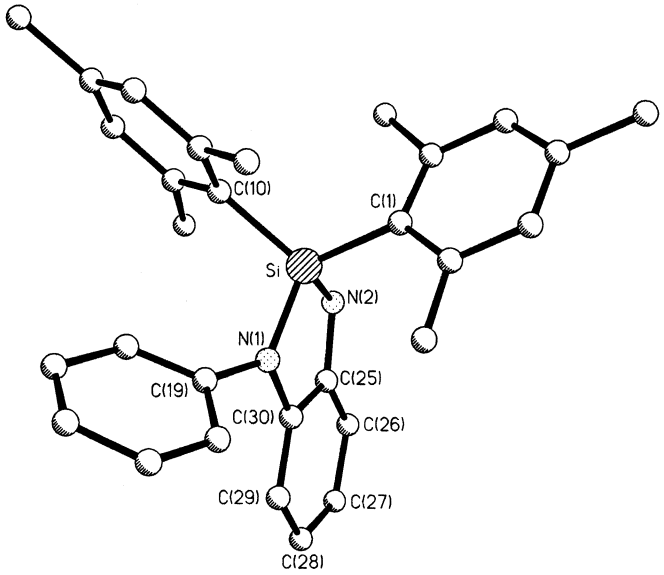


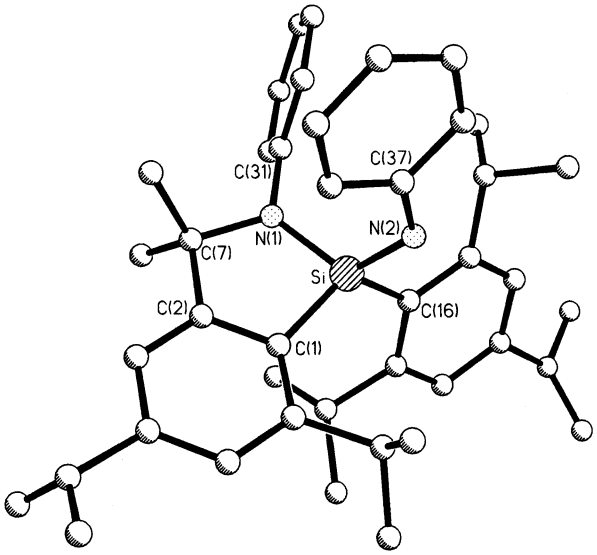
[a] Selected bond lengths [pm] and angles [°]: Si−C(1) 191.7(5), Si−C(10) 192.5(5), Si−N(1) 174.9(8), Si−N(2) 173.1(7); N(1)−Si−N(2) 90.8(4).

Data File revealed only one novel silylene with a similar atomic arrangement.[8]

In order to determine whether this reaction behavior is applicable to other silylenes, we allowed the trisilane **2**, photolysis of which furnishes hexamethyldisilane and the sterically highly overcrowded bis(2,4,6-triisopropylphenyl)silylene, to react with azobenzene under otherwise identical conditions. We isolated a light yellow crystalline product whose elemental analysis and mass-spectral data were again indicative of a 1:1 adduct of the starting materials. However, similarly to compound **4**, the spectroscopic data did not support the formation of an azadisilirane **3** as reaction product. The first assumption of a product analogous to **4** was not confirmed by the X-ray-crystallographic analysis (Figure 2). Although product **5** also contains a five-membered ring as a part of a bicyclic system, the product is not formed by insertion of the nitrogen atom into the *ortho*-C−H bond of the phenyl ring but rather by insertion into a methine C−H bond of one of the *ortho*-isopropyl groups. Assuming the siladiazirane **3** as an intermediate, the subsequent preferred reaction course apparently depends on the bulk of the substituents at the silicon atom and leads to the product with the least ring strain.

With regard to the relatively low yields of **4** (33%) and **5** (17%) it is obvious that several competitive reactions occur which, however, could not be elucidated.

Figure. 2. Molecular structure of **5** in the crystal (hydrogen atoms omitted)[a]

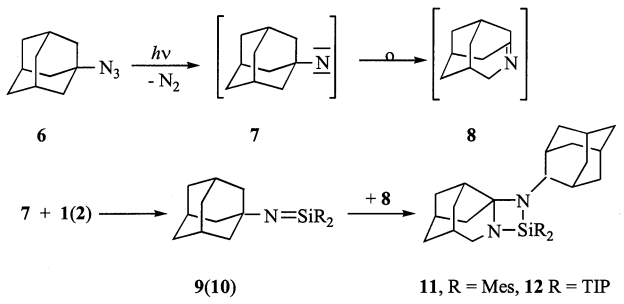


[a] Selected bond lengths [pm] and angles [°]: Si−C(1) 186.1(4), Si−C(16) 194.6(4), Si−N(1) 172.0(6), Si−N(2) 173.4(6); N(1)−Si−N(2) 116.8(3), C(1)−Si−C(16) 124.1(2).

A different form of nitrogen−nitrogen multiple bond is present in the covalent azides and can be described by the two mesomeric forms $R-N=N^+=N^- \leftrightarrow R-N^-=N^+\equiv N$. Which of the two forms dominates depends strongly on the nature of the substituent R.[9] A few years ago we investigated the reactions of the sterically overcrowded tri-*tert*-butylsilyl azide with silylenes bearing voluminous substituents. These reaction were assumed to proceed through cleavage of molecular nitrogen to the nitrene $t\mathrm{Bu_3Si-N}$ and reaction of this species with the silylenes to furnish the silanimines $t\mathrm{Bu_3Si-N=SiR_2}$. Most of these products, however, proved to be unstable and underwent various subsequent reactions. Thus, for example, the product obtained from dimesitylsilylene undergoes [1,5]-hydrogen shift followed by a conrotatory electrocyclic ring closure to afford a silacyclobutene derivative.[10] The reactions of 1-adamantyl azide (**6**) with the trisilanes **1** and **2** described in the present paper follow a completely different and previously unobserved course.

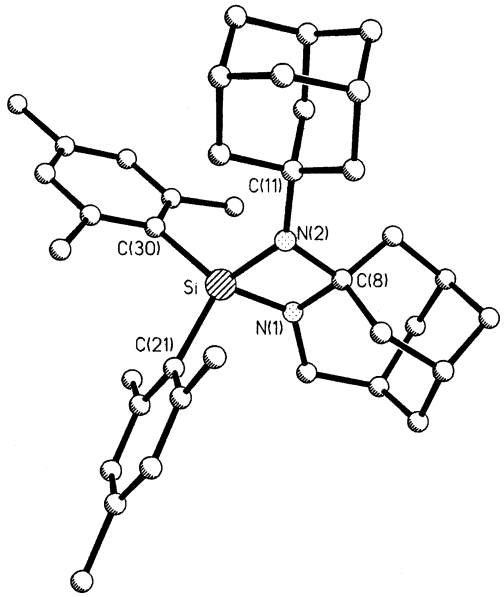
Cophotolysis of **6** and the trisilane **1** affords, through cleavage of nitrogen and hexamethyldisilane, colorless crystals of a compound shown by elemental analytical and spectroscopic data to be a 2:1 adduct of the nitrene **7** and dimes-

Scheme 2



itylsilylene. The constitution of the isolated, crystalline product was elucidated by X-ray crystallography (Figure 3) and unexpectedly found to be that of the 1,3-diaza-2-silacyclobutane derivative **11** in which one of the nitrogen atoms is incorporated into a 4-homoazaadamantane unit.

Figure. 3. Molecular structure of **11** in the crystal (hydrogen atoms omitted)[a]



[a] Selected bond lengths [pm] and angles [°] for **11** and **12**: For **11**: Si−N(1) 173.6(5), Si−N(2) 173.3(4), N(1)−C(8) 147.7(7), N(2)−C(8) 150.0(7); N(1)−Si−N(2) 77.6(2), Si−N(1)−C(8) 94.4(3), N(1)−C(8)−N(2) 93.8(4), Si−N(2)−C(8) 93.7(3). For **12**: Si−N(1) 172.7(4), Si−N(2) 172.5(4), N(1)−C(8) 148.7(5), N(2)−C(8) 151.1(5); N(1)−Si−N(2) 78.8(2), Si−N(1)−C(8) 93.5(2), N(1)−C(8)−N(2) 93.9(3), Si−N(2)−C(8) 92.7(2).

In order to explain the formation of **11** it must be assumed that two parallel reactions with similar reaction rates occur. Firstly, the azide **6** is transformed via the nitrene **7** to the 4-azahomoadamantan-3-ene (**8**). The occurence of the latter intermediate upon photolysis of **6** has been confirmed by numerous trapping reactions.[11] Concomitantly, the silylene generated from the trisilane reacts with another molecule of nitrene **7** to furnish the silanimine **9**. A [2+2] cycloaddition of the two intermediates **8** and **9** would then provide a plausible rationale for construction of the novel polycyclic ring system **11**.

The differing reaction behaviors of **1** and **2** in cophotolysis with azobenzene prompted us to allow the silylene bearing sterically more demanding substituents generated from **2** to react with the azide **6**. Irradiation of a mixture of the two components furnished colorless crystals consisting, similarly to the case of **11**, of a 2:1 adduct of the nitrene **7** and the silylene. Once again, the complicated NMR spectra did not furnish diagnostic information about the structure of the isolated compound. However, X-ray crystallography did indeed reveal that the structure of the product **12** was analogous to that of **11** so that a separate view of the structure is not necessary.[12] Compound **12** is also presumed to be the result of an analogous reaction sequence while the somewhat higher yield (**12**: 38%; **11**: 25%) is attributed to the higher stability of the silanimine **10**.

Financial support of our work by the *Deutsche Forschungsgemeinschaft* and the *Fonds der Chemischen Industrie* is gratefully acknowledged.

Experimental Section

All manipulations were performed under dry nitrogen or argon by using Schlenk techniques. Solvents were purified, dried, and distilled under argon. − ^{1}H, ^{13}C, and ^{29}Si NMR: Bruker AM 300 or Bruker AMX 300. − MS: Varian MAT 212. − IR: Bio-Rad FTS-7. − Elemental analyses: Analytische Laboratorien, D-51779 Lindlar, Germany. − Photolyses were carried out by using a high-pressure mercury immersion lamp (Heraeus TQ 150).

3-Phenyl-2,2-bis(2,4,6-trimethylphenyl)-1,3-diaza-2-silaindan (**4**): At room temp., a solution of **1** (0.41 g, 1.0 mmol) and azobenzene (0.19 g, 1.0 mmol) in 80 ml of *n*-pentane was irradiated for 6 h. After this time, the volatile compounds were distilled off and the residue redissolved in a minimum amount of *n*-pentane. Cooling to −50°C provided a brown oil which was separated by decantation. Cooling of the remaining solution at −30°C furnished 0.150 g (33% yield) of colorless, air-sensitive crystals of **4**, m.p. 171°C. − ^{1}H NMR (C_6D_6): δ = 2.03 (s, 6 H), 2.25 (s, 12 H), 3.6 (s, 1 H, NH), 6.45−7.39 (m, 9 H), 6.63 (s, 4 H). − ^{13}C NMR (C_6D_6): δ = 21.01, 24.11, 111.21, 112.08, 118.17, 119.77, 124.67, 127.34, 129.23, 129.76, 134.07, 138.96, 139.61, 140.19, 143.12, 143.27. − MS (CI, isobutane); *m/z* (%): 449 (100) [MH^+]. − IR (nujol): $\tilde{\nu}$ [cm^{-1}] = 3418 (w, NH). − $C_{30}H_{32}N_2Si$ (448.67): calcd. C 80.30, H 7.18; found C 80.16, H 7.13.

[5,7-Diisopropyl-3,3-dimethyl-2-phenyl-1-(2,4,6-triisopropylphenyl)-2-aza-1-sila-1-indanyl]phenylamine (**5**): A solution of **2** (0.58 g, 1.0 mmol) and azobenzene (0.19 g, 1.0 mmol) in 80 ml of *n*-pentane was irradiated for 7 h at room temp. All volatile compounds were distilled off and the residue was redissolved in a minimum amount of *n*-hexane. Cooling at −30°C afforded 0.110 g (17% yield) of pale yellow crystals of **5**, m.p. 158°C. − ^{1}H NMR (C_6D_6): δ = 1.00 (d, 6 H, $^3J_{H,H}$ = 6.35 Hz), 1.17 (d, 6 H, $^3J_{H,H}$ = 7.0 Hz), 1.22 (d, 6 H, $^3J_{H,H}$ = 7.0 Hz), 1.24 (d, 6 H, $^3J_{H,H}$ = 7.0 Hz), 1.33 (d, 6 H, $^3J_{H,H}$ = 6.35 Hz), 1.55 (s, 3 H), 1.60 (s, 3 H), 2.72 (sept, 1 H), 2.84 (sept, 1 H), 3.21 (sept, 1 H), 3.60 (br., 2 H), 4.45 (s, 1 H, NH), 6.63−7.10 (m, 10 H), 7.15 (s, 2 H), 7.22 (s, 1 H), 7.24 (s, 1 H). − ^{13}C NMR (C_6D_6): δ = 23.30, 23.87, 23.96, 26.02, 29.09, 31.60, 34.18, 34.48, 34.83, 35.89, 65.26 (C_q, ring), 117.69, 118.89, 119.89, 122.14, 125.94, 129.03, 129.41, 129.56, 131.88, 133.86, 143.51, 146.91, 150.60, 151.86, 154.04, 156.99. − ^{29}Si NMR (C_6D_6): δ = −26.82. − MS (CI, isobutane); *m/z* (%): 618

Formation of Compound **12**: At room temp., a solution of **2** (0.52 g, 1.0 mmol) and **6** (0.36 g, 2.0 mmol) in 80 ml of *n*-pentane was irradiated for 8 h, after which the reaction was shown to be complete by the dissappearance of **2** (TLC monitoring). All volatile compounds were distilled off and the residue redissolved in a minimum amount of *n*-pentane. Cooling at 4°C afforded 0.280 g (38% yield) of colorless crystals of **12**, m.p. 242°C. − ^{1}H NMR (C_6D_6): δ = 0.30 (d, br., 6 H), 1.21−1.31 (accumulation of signals, 21 H), 1.31−1.72 (accumulation of signals, 24 H), 1.90−2.90 (accumulation of signals, 15 H), 2.75 (sept, 2 H), 3.09 (sept, 1 H), 3.23 (sept, 1 H), 5.13 (sept, 1 H), 5.68 (sept, 1 H), 6.95 (s, 1 H), 6.96 (s, 1 H), 7.21 (s, 2 H). − ^{13}C NMR (C_6D_6): δ = 23.02, 23.07, 23.10, 24.11, 24.63, 24.92, 25.14, 25.15, 25.52, 26.18, 26.69, 29.18, 29.57, 30.26, 30.50, 30.65, 33.05, 34.47, 34.50, 34.59, 35.10, 35.48, 36.59, 36.83, 40.84, 45.87, 47.38, 50.27, 52.97, 53.29, 87.76, 121.63, 122.47, 122.73, 122.85, 136.34, 136.71, 149.51, 150.50, 152.86, 153.19, 154.10, 155.43. − ^{29}Si NMR (C_6D_6): δ = −10.87. − MS (CI, isobutane); *m/z* (%): 733 (100) [MH$^+$]. − $C_{50}H_{76}N_2Si$ (733.24): calcd. for **12** · 1/2 pentane C 79.96, H 10.11, N 3.72; found C 79.84, H 10.81, N 3.57.

X-ray Structural Analyses of Compounds **4**, **5**, **11**, *and* **12**: Crystal and numerical data of the structure determinations are given in Table 1.[12] In each case, the crystal was mounted in a thin-walled glass capillary. Data collection was performed at room temp. with a Siemens Stoe AED 2 diffractometer using graphite-monochromated Mo-K_α radiation. The structures were solved by direct-phase determination using the Siemens SHELXTL PLUS and SHELX 93[13] program systems and refined by full-matrix least-squares techniques. Hydrogen atoms were placed in the calculated positions, and all other atoms were refined anisotropically.

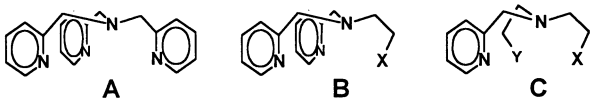
Keywords: Tripodal ligands / Nitrogen–sulfur ligands / Zinc complexes / Structure determination

Attachment of 2-pyridylmethyl units to cysteine amide and 2-mercaptobenzylamine leads to the new tripodal N_3S ligands N^{α}-(4-methylbenzoyl)-L-cysteine-bis(2-pyridylmethyl)amide (**CBPA-H**) and 2-mercaptobenzyl-bis(2-pyridylmethyl)amine (**MBPA-H**). Their treatment with zinc halides yields the neutral complexes **L** · ZnHal (Hal = Cl, Br, I). With zinc perchlorate **MBPA** forms the ionic compound [**L** · Zn] ClO_4, presumed to be a thiolate bridged dimer. Structure determinations of **MBPA** · ZnHal (Hal = Cl, Br) have confirmed the tripodal nature of the ligand in the trigonal-bipyramidal complexes.

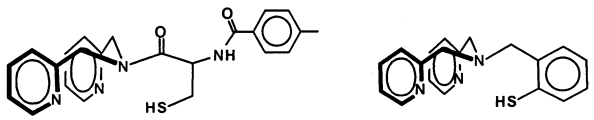
Metal ions in biological systems are coordinated by the aminoacids′ side chain donor functions (O of aspartate and glutamate, N of histidine, S of cysteine). In terms of modelling their structural and functional properties this asks for the design of ligands with an arrangement of the donor atoms similar to that in the protein. As a result modern model ligands are polydentate and chelating.

For complexes modelling zinc enzymes the requirements on the suitability of the polydentate ligands are especially pronounced, because the zinc ion profits neither from preferred coordination numbers or geometries nor from ligand field effects. Typically, all attempts to model the tetrahedral $ZnNS_2O$ coordination in the enzyme alcohol dehydrogenase[1] using amine-bisthiols as tridentate NS_2 ligands have resulted in thiolate-bridgted oligonuclear zinc complexes so far[2][3][4][5]. The high tendency for thiolate bridging has prevented the formation of the desired complexes, and similarly the highly preferred tetrahedral ZnN_2S_2 coordination has rendered futile many efforts invested in the synthesis of N_2S or N_3S ligands[6][7][8].

The ligands of choice for zinc complex model chemistry seem to be the tripodal ones, especially when they serve the further need of encapsulating the zinc ion by suitably attached substituents. The best results so far have been achieved here with the pyrazolylborates[9][10][11]. The pyrazolylborates, however, are confined for synthetic reasons to be N_3 ligands, and only recently have ways been found to modify them in the form of N_2S[12] or NS_2[13] ligands. It is this limitation of the pyrazolylborates that has directed the attention of other researchers and ourselves to the class of tetradentate tripodal ligands derived from ammonia, for which tripicolylamine (**A**) is the prototype. Ligands of this class can be synthesized step by step from ammonia or amines, and in the mono- and difunctionalized variants **B** and **C** all kinds of donor functions can be incorporated[14]. Thereby the disadvantage of these ligands in zinc model chemistry (their tetradentate nature) may be overcome by their versatility.



In the field of zinc model complexes N_4 ligands like **A** have been used mostly so far[15], followed by N_3O ligands like **B**[16]. We have contributed variations of **A**[17][18][19] and complexes of N_3O ligands with caboxylate and phenolate functions including a chiral variant[20][21][22]. In this paper we wish to present two thiolate-containing ligands of type **B**. **CBPA-H** is a derivative of cysteine, **MBPA-H** one of 2-mercaptobenzylamine. To our knowledge no such thiolate ligands with a N_3S donor set have been reported so far[23][24]. Some simple zinc complexes of the two ligands have been prepared to establish an entry to the modelling of zinc enzymes in which the metal is anchored, among others, by one thiolate function to the protein.



Ligand Synthesis

Both new ligands are derived from amine thiols, derivatized to contain two additional pyridyl donor functions. For the syntheses this meant that the thiol functions had to be protected until the last synthetic step. We found the use of the corresponding disulfides to be the only approach to do that. Schemes 1 and 2 show the reaction sequences.

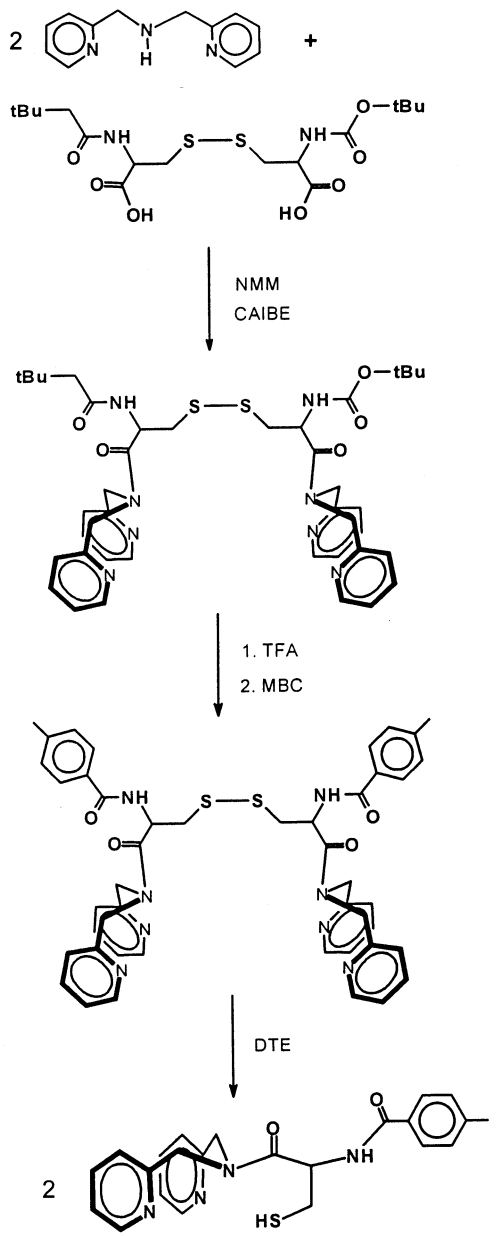
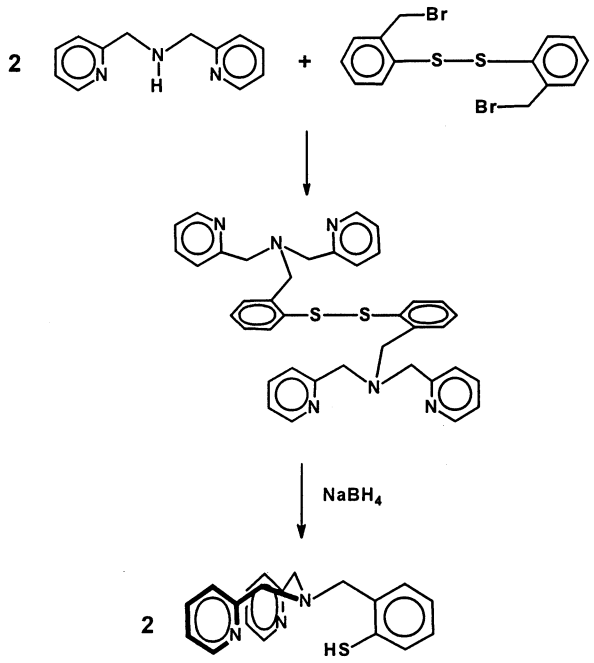
Scheme 1. Synthesis of **CBPA-H**. Abbreviations: CAIBE = isobutylchloroformate, NMM = *N*-methylmorpholine, TFA = trifluoroacetic acid, MBC = 4-methylbenzoylchloride, DTE = dithioerythritol



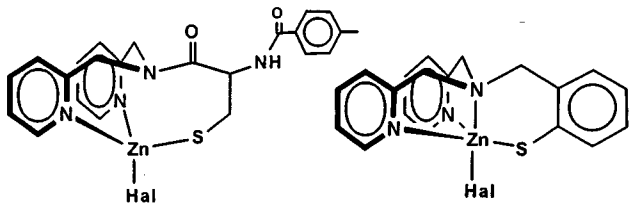
Scheme 2. Synthesis of **MBPA-H**



Ligand **CBPA-H** was obtained from cystine (in the *t*Boc protected form) by the standard procedures of activation, coupling, and deprotection. Ligand **MBPA-H** resulted from bis[(2-bromomethyl)phenyl] disulfide[25] in two reaction steps. The two pyridyl donor functions were introduced in the form of dipicolylamine in both cases. The sluggish reactions of the voluminous molecules allowed only mediocre overall yields. After the reductive cleavage of the disulfide precursors the thiol ligands had to be purified by HPLC. Thereby **CBPA-H** and **MBPA-H** were obtained pure, as evidenced by ^{1}H-NMR spectroscopy, but containing variable amounts of trifluoroacetic acid. Their identification rests on the spectra, their EI mass spectra showing the parent peak, and the full characterization of their zinc complexes.

Zinc Complexes

Reactions of **CBPA-H** with the zinc halides in acetonitrile in the presence of triethylamine produced complexes **1a**−**c** in good yields. **1a**−**c** precipitate from the reaction solutions and are soluble only in very polar solvents like water, DMSO or DMF. In addition to the spectra (see below) a EI mass spectrum of **1c** has verified the identity and monomeric nature of the complexes.



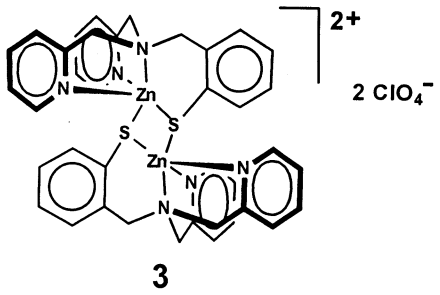
1a: Hal = Cl
1b: Hal = Br
1c: Hal = I

2a: Hal = Cl
2b: Hal = Br
2c: Hal = I

It was possible to prepare the zinc halide complexes of ligand **MBPA-H** the same way. **2a**−**c** could, however, be obtained in a more convenient way when after the last synthetic step in the formation of **MBPA-H**, i.e. the disulfide cleavage with $NaBH_4$, the corresponding hydrohalic acid was used for acidification and the corresponding zinc halide was added in excess. After neutralization **2a**−**c** were precipitated in a crystalline form. **2a**−**c** are of equally low solubility as **1a**−**c** in nonpolar solvents. This time in addition

to the spectra the structure determinations (see below) ascertained the constitution of the complexes.

When $HClO_4$ was used as before for acidifying and zinc perchlorate was added, complex **3** was precipitated. **3** could not be obtained in the form of X-ray quality crystals, nor were informative MS data obtained from it. Its ^{1}H-NMR spectrum is, however quite similar to that of the zinc perchlorate derivative of the analogous phenolate containing ligand which was characterized by a structure determination[22]. We therefore feel safe in assigning the given constitution to **3**. In contrast to the molecular complexes **1** and **2** the ionic complex **3** has a reasonable solubility not only in water, but also in methanol. It is therefore conceivable that a derivative chemistry of $[MBBA \cdot Zn]^+$ species may start with **3**.



3

Product Identification

The free ligands are characterized by their ^{1}H-NMR spectra (see Experimental). In their IR spectra they show the SH band and their typical double bond bands. The pertinent ^{1}H-NMR data of the zinc halide complexes are listed in Tables 1 and 2 in comparison to those of the free ligands. Typical coordination shifts are observed for the pyridyl H_A and for the NCH_2 signals. In the IR spectra of the zinc halide complexes (see Experimental Section) the SH band is missing as expected, and the intense pyridine band around 1600 cm^{-1} is shifted to lower wavenumbers. As a rule, the IR and ^{1}H-NMR spectra of complexes **2** are very similar to those of the zinc complexes of the ligand which is the phenolate analogue of **MBPA**[22]. This holds also for complex **3** whose IR and NMR data (see Table 2) are noticeably different from those of complexes **2**.

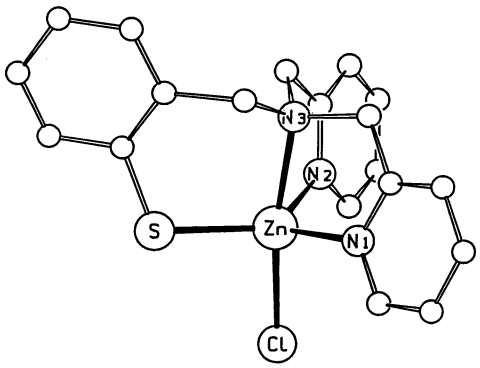
Confirmation of the tetradentate nature of the tripodal ligands and the molecular nature of the halide complexes was obtained by the structure determinations of **2a** and **b**. The two compounds are isostructural and share the property that the asymmetric unit contains two independent molecules. Hence only **2a** is discussed here. Figure 1 shows one of the two molecules. The geometrical differences between the two molecules are significant, becoming most visible for the axial and equatorial intraligand angles.

Figure 1. Molecular structure of complex **2a**. Pertinent bond lengths and angles: molecule 1: Zn−Cl 2.371(1), Zn−S 2.289(1), Zn−N1 2.091(2), Zn−N2 2.096(2), Zn−N3 2.304(2) Å; N3−Zn−Cl 170.52(4), N1−Zn−N2 107.00(7), N1−Zn−S 121.58(6), N2−Zn−S 126.75(6)°. Molecule 2: Zn−Cl 2.335(1), Zn−S 2.302(1), Zn−N1 2.092(2), Zn−N2 2.100(2), Zn−N3 2.325(2); N3−Zn−Cl 163.79(5), N1−Zn−N2 124.23(7), N1−Zn−S 108.49(5), N2−Zn−S 120.27(6)°



The coordination geometry of the complexes is severely distorted trigonal bipyramidal. The distortion cannot be related to the binding preferences of the tripodal ligand, as the two independent molecules are distorted in quite different ways. Furthermore the complex whose molecular shape is most similar to that of **2a**, i.e. the one with oxygen in place of sulfur[22], shows yet another kind of distortion and does not crystallize with two independent molecules. This is a good demonstration of the fact that the transitions between trigonal bipyramidal and square pyramidal geometries are "soft" in the coordination chemistry of zinc. The bond lengths at zinc are in the normal range. For the axial ligands the Zn−Cl bond length is at the upper end of the range observed for axial Zn−Cl bonds[22][26][27][28][29], and correspondingly the Zn−N3 bond length is at the lower end of its range[15][16][17][18][20][21][22][26][27][28][29]. To our knowledge no other zinc complexes with a ZnN_3SHal ligand set have been described yet.

Conclusions

This paper has shown that tripodal ligands offering a N_3S donor set for trigonal bipyramidal metal complexes with equatorial N_2S coordination are accessible, though with some synthetic effort. As a first step in exploiting their zinc complex chemistry the compounds L·ZnHal have been prepared which may serve as a starting point for obtaining functional species L·Zn−X. In the complexes L·Zn−Hal the tendency of the thiolate sulfur to bridge two zinc ions is suppressed. It seems to be operative, however, in the cationic species $[(MBPA)Zn]^+$ resulting in its existence as a sulfur-bridged dimer.

This work was supported by the *Deutsche Forschungsgemeinschaft*. We thank *A. Trösch* and *M. Tesmer* for help with the spectra and the structure determinations.

Experimental Section

General experimental methods and measuring techniques: see ref.[30]. All reactions were carried out in a nitrogen atmosphere. Starting materials were obtained commercially or prepared according to the given references. The complete ^{1}H-NMR data are given here for the two ligands only. Those of the complexes are very similar except for the resonances given in Tables 1 and 2.

Ligand Syntheses

CBPA-H: Step 1: 5.00 g (11.35 mmol) of bis(*tert*-butyloxycarbonyl)-L,L-cystine in 100 ml of THF at −15°C were stirred and treated with 2.49 ml (2.29 g, 22.70 mmol) of NMM and 2.94 ml (3.09 g, 22.70 mmol) of CAIBE. After 15 min 4.51 g (22.70 mmol) of bis(2-pyridylmethyl)amine were added. Within 24 h of stirring the temperature was raised to ambient. After filtration and evaporation to dryness the residue was picked up in 200 ml of ethylacetate. The solution was extracted three times with 70 ml of water, three times with 70 ml of a 4% $NaHCO_3$ solution, and five times with 100 ml of water. After drying with Na_2SO_4, filtration, and evaporation to dryness 8.25 g (91%) of bis(*tert*-butoxycarbonyl)-L,L-cystinebis[bis(2-pyridylmethyl)amide] remained as a colourless solid.

Step 2: The material obtained in the preceding step (8.25 g, 10.28 mmol) was treated with 50 ml of TFA and stirred for 2 h. Then the mixture was evaporated to dryness and the remaining brownish oil washed three times with 20 ml of ether. 13.22 g of a colourless powder remained which corresponds to a quantitative formation of L,L-cystinebis[bis(2-pyridylmethyl)amide] as the TFA adduct.

Step 3: The product obtained (13.22 g, 10.27 mmol) was dissolved in 100 ml of THF and treated at 0°C with 12.43 ml (11.43 g, 112.8 mmol) of NMM and then 3.42 ml (3.96 g, 25.67 mmol) 4-methylbenzoylchloride. After stirring for 24 h at room temp. the mixture was filtered and evaporated to dryness. After dissolving the residue in 300 ml of ethylacetate the yellow solution was washed three times with 60 ml of a 4% $NaHCO_3$ solution and then five times with 100 ml of water. After drying with Na_2SO_4 the solution was evaporated to dryness leaving behind 6.73 g (78%) of bis(4-methylbenzoyl)-L,L-cystinebis[bis(2-pyridylmethyl)amide] as a brownish oil.

Step 4: The brownish oil (6.73 g, 8.02 mmol) was dissolved in 70 ml of methanol and treated with 1.61 g (10.43 mmol) of DTE in 10 ml of methanol and then 12 ml of 0.2 M NaOH. After stirring for 4 h, 5 ml of TFA were added and then the mixture evaporated to dryness. The remaining brownish oil was dissolved in 80 ml of water and the solution washed four times with 30 ml of ether. After freeze-drying 6.83 g of the raw product remained as a yellowish oil. This was purified by HPLC using a reversed phase column (Merck LiChrosorb RP 18, 7 μm) eluting first for 45 min with acetonitrile/water/TFA (20:80:0.1) and then 20 min with acetonitrile/water/TFA (60:40:0.1). After freeze-drying 2.23 g (20%) of N^{α}-4-methylbenzoyl-L-cysteinebis(2-pyridylmethyl)amide (**CBPA-H**) were obtained as a pale yellow, very hygroscopic powder. The product contains approx. 2.5 mole equivalents of TFA as determined by potentiometric titration.

$C_{23}H_{24}N_4O_2S \cdot 2.5\ CF_3COOH$ (420.5 + 285.1), calcd.: C 47.66, H 3.79, N 7.94; found: C 47.47, H 3.91, N 8.07. − IR (KBr): $\tilde{\nu}$ = 3306 s (NH), 2516 w (SH), 1675 s (carboxylate), 1537 m (amide). −^{1}H NMR (D_2O): 2.18 [s, 3 H, CH_3], 2.84 [dd, J = 6.7, 14.1 Hz, 2 H, Cys-C_bH], 4.98 − 5.51 [m, 5 H, NCH_2 and Cys-C_aH], 7.09 [d, J = 8.0 Hz, 2 H, Ph (3,5)], 7.27 [d, J = 8.0 Hz, 2 H, Ph (2,6)], 7.55 [t, J = 6.7 Hz, 1 H, Py-H_B], 7.78 [d, J = 7.3 Hz, 1 H, Py-H_D], 7.87 [t, J = 6.7 Hz, 1 H, Py-$H_{B'}$], 8.19 [d, J = 7.3 Hz, 1 H, Py-$H_{D'}$], 8.28 [dt, J = 7.3, 1.3 Hz, 1 H, Py-H_C], 8.39 [dt, J = 7.3, 1.3 Hz, 1 H, Py-$H_{C'}$], 8.45 [d, J = 6.7 Hz, 1 H, Py-H_A], 8.59 [d, J = 6.7 Hz, 1 H, Py-$H_{A'}$].

MBPA-H: Step 1: 3.20 g (7.92 mmol) of bis[(2-bromomethyl)phenyl]disulfide were dissolved in 50 ml of dioxane. A mixture of 3.15 g (15.84 mmol) of bis(2-pyridylmethyl)amine and 2.21 ml (1.60 g, 15.84 mmol) of triethylamine in 50 ml of dioxane was added dropwise with stirring. The resulting red mixture was stirred overnight, filtered, and the filtrate evaporated to dryness. The remaining red oil was picked up in 200 ml of dichloromethane, washed three times with 20 ml of a 4% $NaHCO_3$ solution and then five times with 50 ml of water. After drying with Na_2SO_4 the solution was evaporated to dryness, the remaining red oil was dissolved in cyclohexane/ethylacetate (1/1) and chromatographed with neutral Al_2O_3, activity V, to yield 2.98 g (63%) of bis[{2-bis(2-pyridylmethyl)aminomethyl}phenyl] disulfide as an orange oil.

Step 2: 212 mg (0.331 mmol) of the product obtained before were dissolved in 30 ml of methanol. 50 mg (1.32 mmol) of $NaBH_4$ were added with stirring, resulting in a colour change of the solution from orange to yellow. After stirring overnight the mixture was evaporated to dryness. The residue was picked up in 10 ml of doubly distilled water and acidified to pH 6 with TFA. The solution was extracted three times with 20 ml of dichloromethane. The combined extracts were evaporated to dryness. Purification by HPLC as above using water/acetonitrile/TFA (80:20:0.1) as eluent yielded 191 mg (47%) of [*N*,*N*-bis(2-pyridylmethyl)-*N*-(2-mercaptobenzyl)]-amine (**MBPA-H**) as a yellow oil. The product contains approx. 2.5 mole equivalents of TFA as determined by potentiometric titration.

$C_{19}H_{19}N_3S \cdot 2.5\ CF_3COOH$ (321.4 + 285.1), calcd.: C 47.53, H 3.57, N 6.93; found: C 47.88, H 3.55, N 7.17. − IR (KBr): = $\tilde{\nu}$ = 2498w (SH), 1684s (carboxylate), 1620s, 1588m (pyridine). ^{1}H NMR ($CDCl_3$): 3.79 [s, 2 H, NCH_2Ph], 4.25 [s, 1 H, SH], 4.32 [s, 4 H, NCH_2Py], 6.95−7.35 [m, 4 H, Ph], 7.62−7.73 [m, 2 H, Py-H_B], 7.90 [d, J = 7.8 Hz, 2 H, Py-H_D], 8.13−8.24 [m, 2 H, Py-H_C], 8.83 [d, J = 5.6 Hz, 2 H, Py-H_A], 13.27 [s, 3 H, Py-NH^+].

Complex **1a**: To 134 mg (0.19 mmol) of **CBPA-H**·2.5 TFA in 30 ml of acetonitrile were added with stirring 0.09 ml (67 mg, 0.67 mmol) of triethylamine and 26 mg (0.19 mmol) of $ZnCl_2$ in 5 ml of acetonitrile. After reducing the volume to 10 ml in vacuo the solution was allowed to stand, slowly precipitating the product. Filtration, washing with a few ml of cold acetonitrile and drying in vacuo yielded 55 mg (56%) of colourless **1a** of m.p. 252°C. − $C_{23}H_{23}ClN_4O_2SZn$ (520.4), calcd.: C 53.09, H 4.45, N 10.77, Zn

Yield 92 mg (39%) of pale-yellow **2c**, m.p. 274°C (dec.). − $C_{19}H_{18}IN_3SZn$ (512.7), calcd.: C 44.51, H 3.54, N 8.20; found: C 43.90, H 3.40, N 7.89. − IR (KBr): $\tilde{\nu}$ = 16.05 s, 1570 m (pyridine bands).

3: Like **2a** from 150 mg (0.23 mmol) of **BAPD**, 35 mg (0.92 mmol) of $NaBH_4$, 343 mg (0.92 mmol) of $Zn(ClO_4)_2 \cdot 6\ H_2O$, and 1 ml of conc. $HClO_4$. Yield 156 mg (35%) of colourless **3**, m.p. 181°C. − $C_{19}H_{18}ClN_3O_4SZn$ (485.3), calcd.: C 47.03, H 3.74, N 8.66, Zn 13.47; found: C 48.11, H 3.75, N 8.59, Zn 13.10. − IR (KBr): $\tilde{\nu}$ = 1606s, 1574 m (pyridine bands), 1092 vs (ClO_4).

Structure Determinations[31]: Crystals were obtained from the reaction solutions. Diffraction data were recorded with the ω/2θ technique on a Nonius CAD4 diffractometer fitted with a molybdenum tube (K_α, λ = 0.7107 Å) and a graphite monochromator. No absorption corrections were applied. The structures were solved with direct methods and refined anisotropically with the SHELX program suite[32]. Hydrogen atoms were included with fixed distances and isotropic temperature factors 1.2 times those of their attached atoms. Parameters were refined against F^2. The *R* values are defined as $R_1 = \Sigma F_o - F_c / \Sigma F_o$ and $wR_2 = [\Sigma[w(F_o^2 - F_c^2)^2 / \Sigma[w(F_o^2)^2]]^{1/2}$. Drawings were produced with SCHAKAL[33]. Table 3 lists the crystallographic data.

Thermodynamic Stability of Zirconium(IV) Complexes with Hydroxy Ions

Anne Veyland, Laurent Dupont, Jean-Claude Pierrard, Jean Rimbault, and Michel Aplincourt*

GRECI, Université de Reims Champagne-Ardenne,
B. P. 1039, F-51687 Reims Cédex 2, France

Received May 27, 1998

Keywords: Zirconium(IV) / Hydroxy ion / Complexes / Protometry / Equilibrium constant / Solubility product

A protometric study on the speciation of zirconium(IV) was performed in an aqueous solution at 25 °C in KNO_3 and four ionic strengths (0.2, 0.5, 1, and 2 mol·dm^{-3}). This study indicates the formation of the soluble species $Zr(OH)_3^+$, $Zr_2(OH)_7^+$, and $Zr(OH)_4$ in the pH range 1.5–3.5. The use of an appropriate titration technique allows the precipitation of the zirconium hydroxide to be limited. The overall stability constants β_{mlh} of these three hydroxo complexes were computed and refined, by the program PROTAF, for each ionic strength. The solubility product *K*s of $Zr(OH)_4$ was calculated by taking these β_{mlh} constants into account. The thermodynamic values were determined by extrapolation at zero ionic strength (Specific ion Interaction Theory method): log $\beta°_{10-3}$ = –0.52 (0.01); log$\beta°_{20-7}$ = −2.22(0.07); log$\beta°_{10-4}$ = −4.52 (0.07); log*K*s° = −55.26(0.08).

For about fifty years zirconium has been a strategic metal. Its importance in the military and industrial nuclear fields is due to its mechanical and thermal properties and its outstanding resistance to corrosion, as well as to a low neutron capture cross-section. It is an essential constituent of the core of the nuclear power station and for confining fissile materials.

The running of nuclear installations relies on the processing of nuclear fuels and fission by-products, but also on the long-term storage, in protected sites, of confined materials which have acquired an appreciable radioactivity.

In the long-term one may expect the possibility of corrosion and fissuring of the confining containers leading to a contamination of soils and waters.

Modelling programs which take into account the whole local physical parameters as well as the physicochemical data allow the quantification of these contamination risks. The values used for these simulations, especially those relating to zirconium, have to be as reliable as possible in order to yield realistic estimations.

The chemistry of zirconium(IV) in aqueous media is dominated by the complexation of Zr^{4+} with OH^-. The data currently available on zirconium hydroxide complexes comes from studies carried out (essentially) before 1975[1][2][3][4][5][6][7][8][9]. The advanced species formulae and, above all, the values of the corresponding complexation constants, seem questionable.

Baes and Mesmer[10] have reviewed bibliographical results concerning zirconium hydrolysis in aqueous solution. When the zirconium concentration is low (< 10^{-4} mol·dm^{-3}), they conclude that there is formation of mononuclear complexes $Zr(OH)_h^{(4-h)+}$ where $h = 1-5$.

According to these two authors, only the stability of the $ZrOH^{3+}$ species has been determined with a reasonable accuracy: log $\beta_{10-1} = 0.3 \pm 0.05$ at zero ionic strength[9]. The hydrolysis constants of the more hydrolysed complexes [$Zr(OH)_2^{2+}$ through to $Zr(OH)_5^-$] are only rough estimates [for instance log $K \leq -1.8$ for the equilibrium $ZrOH^{3+} + H_2O \rightleftharpoons Zr(OH)_2^{2+} + H^+$]. Increasing zirconium concentration induces the formation of polynuclear species $Zr_m(OH)_h^{(4m-h)+}$. In accordance with studies from Zielen and Connick[2], Johnson and Kraus[11], and Angstadt and Tyree[12], Baes and Mesmer conclude that the existence of a trimer, $Zr_3(OH)_4^{8+}$ or $Zr_3(OH)_5^{7+}$, and of the tetramer $Zr_4(OH)_8^{8+}$ is probable.

Aja et al.[13] also published a review concerning the aqueous chemistry of zirconium(IV). They principally take into account the results obtained by Russian scientists[5][6][8][14]. They consider that the values of the formation constants of the mononuclear hydroxide complexes depend little on the ionic strength and the nature of the supporting electrolyte. For these constants, they have retained average values which are very different from those given by Baes and Mesmer.

More recently, Adair et al.[15] published an article entitled "A review of the aqueous chemistry of the zirconium-water system" in which they simply give the same values of constants that Baes and Mesmer indicated for the mono- and polynuclear zirconium hydroxide complexes at 25°C.

In short, numerous studies deal with the formation of zirconium-hydrolysed complexes in aqueous solution but many discrepancies exist from one author to another concerning the major species formed and the values of the corresponding constants of formation. It must be pointed that in these studies the stoichiometry of the soluble species have not been experimentally determined.

The purposes of the present work are:

– The study of the complexation reactions between zirconium(IV) and hydroxy ions in aqueous solution. The stoichiometry of soluble species are determined from the position of the equivalent points on the titration curves and from the initial pH of the zirconium oxychloride solutions.

 © WILEY-VCH Verlag GmbH, D-69451 Weinheim, 1998 1434−1948/98/1111−1765 $ 17.50+.50/0

– The determination of the thermodynamical constants corresponding to the formation of the complex species by using the Specific ion Interaction Theory (SIT method).

Results

Stoichiometry of Complexes Formed

At the beginning of the titrations (pH < 2), the initial concentration of protons in $ZrOCl_2$ solutions corresponds to the liberation of one equivalent of proton per zirconium atom and to the formation of $Zr(OH)_3^+$ according to:

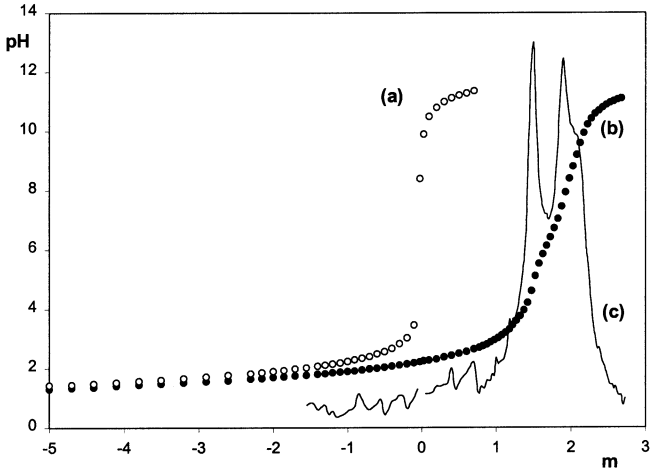
$$Zr(OH)_2^{2+} + 2\ H_2O \rightarrow Zr(OH)_3^+ + H_3O^+$$

Figure 1 shows that the potentiometric titration curve of the system $ZrOCl_2/HNO_3$ (curve b) is displaced to the right relative to the curve of nitric acid alone (curve a). In order to facilitate the interpretation of the results, the pH value is given versus the number (m) of OH^- equivalents per zirconium mol, calculated after the neutralisation of nitric acid. The derivative curve c shows two equivalent points at pH = 4 and pH = 8 which correspond to 1.5 and 2 equiv. of OH^- added, respectively. Both equivalent points correspond to the formation of species which contain 3.5 and 4 OH^- per zirconium atom according to:

$$Zr(OH)_3^+ + H_3O^+ + 1.5\ OH^- \rightarrow Zr(OH)_{3.5}^{0.5+} + 2\ H_2O$$
$$\text{and } Zr(OH)_3^+ + H_3O^+ + 2\ OH^- \rightarrow Zr(OH)_4 + 2\ H_2O$$

For the species "$Zr(OH)_{3.5}^{0.5+}$", computation led us to envisage the formation of the dimer $Zr_2(OH)_7^+$. As for the species "$Zr(OH)_4$", they are very likely to be polymeric species in which the ratio $[OH^-]/[Zr]$ is equal to four. For simplicity, these polymeric species are denoted as $[Zr(OH)_4]_n$.

Figure 1. Titration curves for (a) nitric acid ($4\cdot10^{-2}$ mol·dm^{-3}), (b) zirconium oxychloride ($8\cdot10^{-3}$ mol·dm^{-3}) in the presence of nitric acid ($4\cdot10^{-2}$ mol·dm^{-3}), (c) derivative curve of (b); the pH is given versus the number (m) of OH^- equivalents per zirconium, calculated after neutralisation of nitric acid



Precipitation occured after pH = 3.5 when the complex $Zr_2(OH)_7^+$ was still predominant. This means that the solid phase has a composition close to the composition of a ionic salt in which $Zr_2(OH)_7^+$ is associated with a counter anion, either nitrate or chloride.

To refine the composition of the solid phase several analyses were made. The precipitate was separated from the solution by centrifugation and filtration and washed with KNO_3. The solid was then dispersed in a KNO_3 solution which was titrated with KOH (0.1 mol dm^{-3}). The titration curve obtained shows that hydrolysis still occcurs at pH > 3.5, because we obtain one equivalent point at pH = 8.5 for 0.5 equiv. of OH^- added. This point corresponds to the formation of the polymeric species $[Zr(OH)_4]_n$ which confirms the previous formation of an insoluble salt at pH = 3.5. Chloride ions were titrated in the supernatant by potentiometry. The result indicates that all the chloride ions are present in solution and, consequently, that the solid phase does not contain any chloride. Infrared spectra of the solid phase were recorded and shows a band at 1380 nm which confirms the presence of nitrate anion.

A similar trend is observed in perchlorate medium; precipitation occurs at pH = 3.5, the titration curves show two inflexion points at pH = 4.4 for 1.75 equiv. of OH^- and pH = 8.5 for 2 equiv. of OH^-. These points correspond to the formation of species having the stoichiometry $Zr_3(OH)_{11}^+$ and $[Zr(OH)_4]_n$, respectively.

Determination of Stability Constants

The overall stability constants are related to the general equilibrium:

$$m\ Zr^{4+} + 2h\ H_2O \rightleftharpoons Zr_m(OH)_h^{(4m-h)+} + h\ H_3O^+$$

$$\beta^c_{m0-h} = \frac{[Zr_m(OH)_h^{(4m-h)+}][H_3O^+]^h}{[Zr^{4+}]^m}$$

The neutralisation curves were computed taking into account the species $Zr(OH)_3^+$, and $Zr_2(OH)_7^+$ and also the soluble monomeric species $Zr(OH)_4$. The concentration range of zirconium used in the calculation varies from 10^{-3} to 8×10^{-3} mol·dm^{-3}. The validity of the hypothesis was checked for lower concentrations up to 8×10^{-5} mol·dm^{-3} of Zr^{IV}. For the calculation of stability constants, data obtained in the heterogeneous phase was removed. However, further simulations were made over the whole pH range to confirm the stoichiometry of the insoluble species. Calculated curves were in good agreement with experiment over the whole pH range studied. We have included in our hypothesis the formation of polynuclear species cited in the literature[1][2][7][11][12]. After calculation, polynuclear species were not selected, and improved least square refinements were found considering only the three species previously proposed.

The precision on some log β_{10-4} values is weak because in the homogeneous phase $Zr(OH)_4$ can be considered as a very minor species. The species distribution curve shows

Table 1. Overall stability constants of $Zr(OH)_3^+$, $Zr(OH)_4$, and $Zr_2(OH)_7^+$[a] (KNO_3 medium, 25 ± 0.1°C)

I [mol·dm^{-3}]	log β^c_{10-3}	logβ^c_{20-7}	logβ^c_{10-4}
0.2	−2.02 (0.01)	−5.26 (0.04)	−6.09 (0.03)
0.5	−2.18 (0.01)	−5.39 (0.04)	−6.7 (0.2)
1	−2.27 (0.01)	−5.48 (0.04)	−6.71 (0.04)
1[b]	−2.29 (0.05)	−5.56 (0.11)	−6.51 (0.08)
2	−1.77 (0.03)	−4.35 (0.05)	−6.9 (0.3)

[a] Values in parentheses represent 1 σ standard deviation. – [b] $NaClO_4$ medium, 25 ± 0.1°C.

that its proportion in solution is lower than 10% at pH = 4.0. It is also interesting to note that for I = 1 mol·dm^{-3}, the values of the stability constants were similar in nitrate and perchlorate media, which seems to indicate that there is no complexation between zirconium and nitrate ions.

Determination of Solubility Products

The values of the solubility product of zirconium hydroxide $Zr(OH)_4$ proposed in the literature[3][4] vary between 10^{-52} and 10^{-54}, but it is worth pointing out that most of the authors do not take into account the stability constants of soluble species in their calculations.

In our experiments, the solubility product is determined from the pH value and the free concentration of Zr^{4+} calculated for each solution from the stability constants of the soluble species $Zr(OH)_3^+$ and $Zr_2(OH)_7^+$, using the following expression where [Zr(t)] is the total concentration of zirconium:

$$\frac{2\beta_{20-7}}{[H_3O^+]^7}[Zr^{4+}]^2 + \left(1 + \frac{\beta_{10-3}}{[H_3O^+]^3}\right)[Zr^{4+}] - [Zr(t)] = 0$$

The solubility product is then calculated using the usual expression $Ks = [Zr^{4+}][OH^-]^4$.

The mean values of the logarithms of the solubility products are reported in Table 2 for the four different ionic strengths.

Table 2. Solubility products of $Zr(OH)_4$; (KNO_3 medium, 25 ± 0.1°C)

I [mol·dm$^-$]^3	log Ks [a]
0.2	−52.71 (0.05)
0.5	−52.49 (0.06)
1	−52.72 (0.06)
2	−53.49 (0.03)

[a] Values in parentheses represent 1 σ standard deviation.

Determination of the Thermodynamical Formation Constants

The constants of formation have been determined in solution containing KNO_3 as supporting electrolyte (0.2−2 mol·dm^{-3}). The specific interaction theory[20][21][22][23] is used for the comparison of data at different ionic strengths and also for the calculation of the thermodynamic formation constants corresponding to the standard state.

The activity coefficient of a cation i of charge z is calculated from the following expression:

$$\log \gamma_i = -z_i^2 \, D + \Sigma_j \, \varepsilon(i, j) \times m_j$$

where $D = \dfrac{0.5091\sqrt{I_m}}{1+1.5\sqrt{I_m}}$ is the Debye-Hückel term (for long-range electrostatic interactions); $\varepsilon(i, j)$ is the specific interaction coefficient between the cation i of charge z and the others ions j of opposite charge in the solution and m_j is the molality of the ions j.

In our study, the concentration of the nitrate ions of the supporting electrolyte KNO_3 is much larger than these of the other ionic species. Consequently, it is the main contributor to the value of log γ_i:

$$\log \gamma_i = -z_i^2 \, D + \varepsilon(i, NO_3^-) \times I_m$$

with I_m ionic strength equal to the molal concentration of the supporting electrolyte.

For the general formation reaction,

$$m \, Zr^{4+} + 2 \, h \, H_2O \rightleftharpoons Zr_m(OH)_h^{(4m-h)+} + h \, H_3O^+$$

$$\beta^c_{m0-h} = \frac{[Zr_m(OH)_h^{(4m-h)+}][H_3O^+]^h}{[Zr^{4+}]^m}$$

The apparent stability constant β^c_{m0-h} is calculated from the molar concentrations of the reacting species. This value is then converted to molality units (β^m_{m0-h} value) according to the conversion factors determined by Baes and Mesmer[10]. Finally, the thermodynamical stability constant β°_{m0-h} is determined from the experimental constants β^m_{m0-h}, by using a weighted linear extrapolation to zero ionic strength.

$$\beta^\circ_{m0-h} = \frac{a_{Zr_m(OH)_h^{(4m-h)+}} \, a_{H_3O^+}^h}{a_{Zr^{4+}}^m \, a_{H_2O}^{2h}}$$

The expression of the logarithm of the thermodynamical stability constant may be written as:

$$\log \beta^\circ_{m0-h} = \log \beta^m_{m0-h} + \log \gamma_{Zr_m(OH)_h^{(4m-h)+}} + h \cdot \log \gamma_{H_3O^+} - m \cdot \log \gamma_{Zr^{4+}} - 2h \cdot \log a_{H_2O}$$

with the logarithms activity coefficients:

$$\log \gamma_{Zr_m(OH)_h^{(4m-h)+}} = -(4m-h)^2 \cdot D + \varepsilon(Zr_m(OH)_h^{4m-h)+}, NO_3^-) \cdot I_m$$
$$\log \gamma_{H_3O^+} = -D + \varepsilon(H_3O^+, NO_3^-) \cdot I_m$$
$$\log \gamma_{Zr^{4+}} = -16 \, D + \varepsilon(Zr^{4+}, NO_3^-) \cdot I_m$$

Consequently:

$$\log \beta^m_{m0-h} + D\,[16m - h - (4m - h)^2] - 2h \log a_{H_2O} = \log \beta^o_{m0-h} - \Delta\varepsilon \cdot I_m$$

where $\Delta\varepsilon$ is the summation of the specific interaction terms:

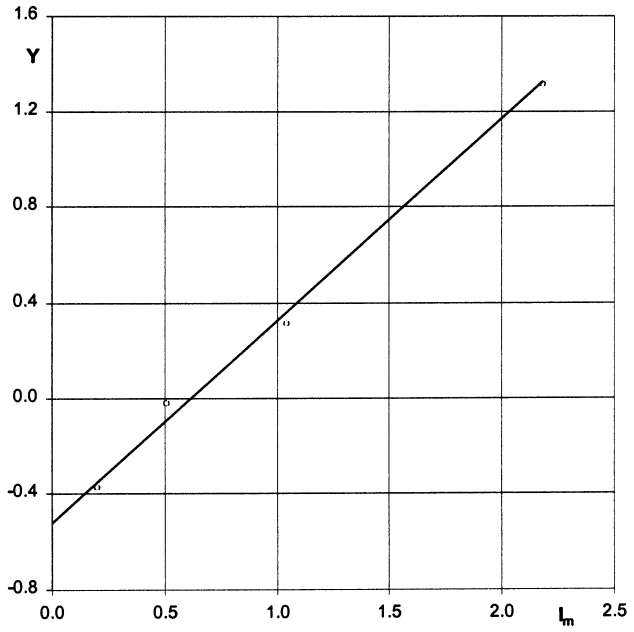
$$\Delta\varepsilon = \varepsilon[Zr_m(OH)_h^{(4m-h)+}, NO_3^-] + h\varepsilon[H_3O^+, NO_3^-] - m\varepsilon[Zr^{4+}, NO_3^-]$$

Since the solvent is a chemically reacting species, its activity must be calculated and incorporated into the expression for the thermodynamic constant.

$$\log a_{H_2O} \approx \frac{-2 \cdot \Phi \cdot I_m}{55.51 \cdot \ln(10)} \quad (I_m = m_{K+} = m_{NO_3^-})$$

Φ is the osmotic coefficient which can be calculated from Stockes[24] equation.

Figure 2. Extrapolation of the logarithm of the thermodynamical formation constant of $Zr(OH)_3^+$ by weighted linear regression



The value of $\log \beta^\circ_{m0-h}$ is obtained using a weighted linear regression of the quantity Y as a function of the ionic strength[25].

$$Y = \log \beta^m_{m0-h} + D[16m - h - (4m - h)^2] - 2h \log a_{H_2O} = \log \beta^\circ_{m0-h} - \Delta\varepsilon \cdot I_m$$

This procedure has been applied for the determination of $\log \beta^\circ_{10-3}$, $\log \beta^\circ_{20-7}$, $\log \beta^\circ_{10-4}$, and $\log K^\circ_s$ solubility product of $Zr(OH)_4$. For the determination of $\log \beta^\circ_{10-3}$ see, for example, Figures 2 and 3. All the results are reported in Table 3.

Discussion

The hydrolysis reactions of zirconium(IV) have been monitored by protometry, using a specific titration procedure which consist of adding the titrant very slowly (0.5 µl per 5 s) with vigorous stirring. This procedure avoids the precipitation of insoluble hydroxide at the tip of the burette and errors on the measurement of pH values.

Figure 3. Variation of the logarithm of the experimental formation constant of complex $Zr(OH)_3^+$ as a function of ionic strength (molality)

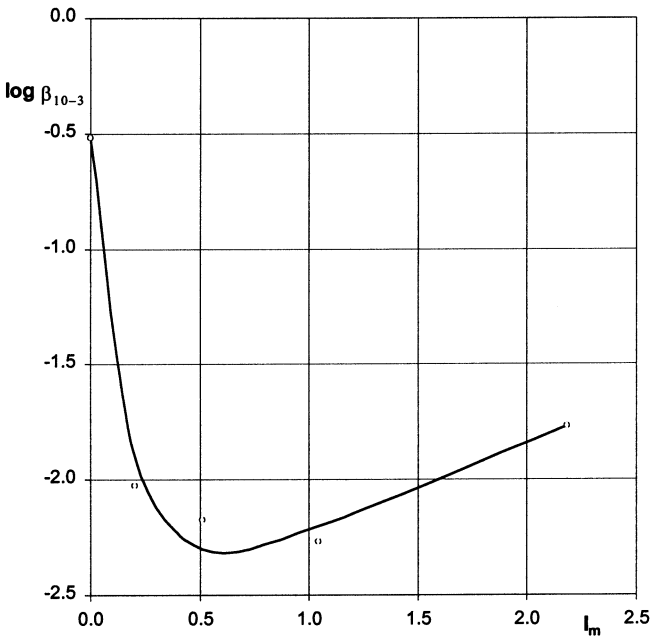


Table 3. Thermodynamic values of the logarithms of the formation constants of soluble complexes and of the solubility product of $Zr(OH)_4$; values in parentheses represent 1 σ standard deviation

$Zr(OH)_3^+$	$\log \beta^\circ_{10-3}$	−0.52 (0.01)
$Zr_2(OH)_7^+$	$\log \beta^\circ_{20-7}$	−2.22 (0.07)
$Zr(OH)_4$	$\log \beta^\circ_{10-4}$	−4.52 (0.07)
$Zr(OH)_4$	$\log Ks^\circ$	−55.26 (0.08)

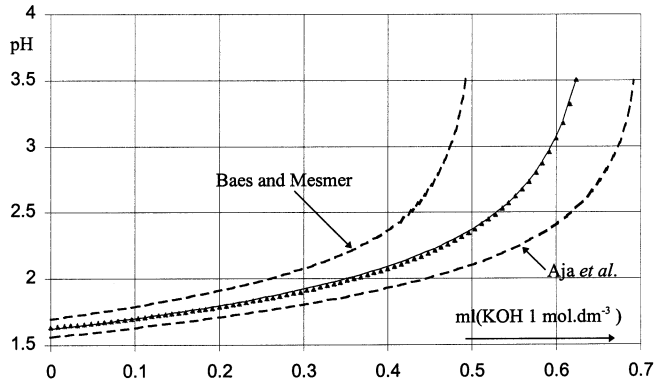
In order to verify that pH measurements realised with KOH of 0.1 mol·dm^{-3} were not influenced by kinetic phenomena, we have also used KOH of $2.5 \cdot 10^{-2}$ mol·dm^{-3}. With the same rate of KOH addition (0.5 µl per 5 s) a protometric titration lasted for about one week. The pH measurements lead to stability constants values identical with those obtained with KOH of 0.1 mol·dm^{-3}.

The stability constants values of Zr hydrolysed complexes, reported by Baes and Mesmer[10] and Aja et al.[13], have been estimated from results contained in several publications. Different methods have been used in these works for studying Zr hydrolysis (e.g.: solvent extraction, spectroscopy, complexometry, solubility measurements). It must be noted that the values of Aja et al. take no account of the ionic strength variation. For calculating the thermodynamic constants values, Baes and Mesmer admit that the ionic strength dependence of β_{mlh} is similar to that found in the case of other cations, e.g. U^{4+}.

In this work, the protometric titrations of zirconium oxychloride solutions by KOH allow verification of the consistency between our obtained values and those reported by Baes and Mesmer and Aja et al. In the pH range where the solutions are homogeneous (pH $\leq$ 3.5), the experimental pH values were compared to those calculated from the sta-

bility constants. For example, in the Figure 4 the experimental titration curve of zirconium oxychloride solution ($4\cdot10^{-3}$ mol·dm^{-3}) in the presence of nitric acid ($2\cdot10^{-2}$ mol·dm^{-3}) is represented. The calculated curves obtained by using Baes and Mesmer or Aja et al. constants are represented by dashed lines. The stability constants given at zero ionic strength by Baes and Mesmer were calculated for $I = 1$ by using the relation between β_{mlh} and I they indicate in their paper[10] ($\log \beta_{10-1} = -0.6$; $\log \beta_{10-2} = -2.3$; $\log \beta_{10-3} = -6.3$; $\log \beta_{10-4} = -11.0$; $\log \beta_{10-5} = -17.1$; $\log \beta_{30-4} = 4.5$ or $\log \beta_{30-5} = 5.2$; $\log \beta_{40-8} = 8.0$).

Figure 4. Titration curves of zirconium oxychloride solution ($4\cdot10^{-3}$ mol·dm^{-3}) in the presence of nitric acid ($2\cdot10^{-2}$ mol·dm^{-3}); ionic strength = 1; KOH = 1 mol·dm^{-3}; ▲ experimental curve, (—) calculated curve with our results, (-----) calculated curves with results of Baes and Mesmer[10] or Aja et al.[13]



There is a large discrepancy between the experimental curve and the two calculated curves. By using the results of Baes and Mesmer, the plot of the distribution curves of the different mono- and polynuclear hydroxo complexes shows that $Zr_4(OH)_8^{8+}$ is practically the only species formed. This tetrameric ion is that encountered in the solid zirconium oxychloride, so the dissolution of this solid compound should not modify the pH solution, which disagrees with our observations and with those of Larsen and Gammill[1]. On the other hand, the constants values reported by Aja et al. lead to the predominance of $Zr(OH)_4$ at pH = 1.5−3.5. Under these conditions, the studied solutions would not be homogeneous because of the precipitation of $[Zr(OH)_4]_n$.

For all these reasons, we have envisaged the existence of other soluble species under our experimental conditions ($1.5 \leq$ pH ≤ 3.5, and $8\cdot10^{-5}$ mol·dm$^{-3} \leq [Zr] \leq 8\cdot10^{-3}$ mol·dm^{-3}). Our hypotheses are based on the following experimental results:

− The pH value at the beginning of the titrations corresponds to the liberation of one equivalent of proton per zirconium and therefore to the formation of the $Zr(OH)_3^+$ species.

− The positions of the equivalent points of the titration curves at 1.5 (in nitrate medium), 1.75 (in perchlorate medium) and 2 equiv. of OH^- per zirconium. These positions are independent of the zirconium concentration which indicates that the stoichiometry of the formed species is well defined: $Zr_2(OH)_7^+$ in nitrate medium and $Zr_3(OH)_{11}^+$ in perchlorate medium.

− The existence of $Zr_2(OH)_7^+$ is confirmed by the precipitation of the ionic salt $[Zr_2(OH)_7]NO_3$ at pH ≈ 3.5.

In short, at the beginning of the titrations, one may expect the formation of the $Zr(OH)_3^+$ species. The hydrolysis of this species leads to the formation of soluble $Zr(OH)_4$ which is always a very minor species in solution because, when its concentration increases, $Zr(OH)_4$ bonds to $Zr(OH)_3^+$ by hydroxo bridges leading to $Zr_2(OH)_7^+$. Then, in KNO_3 medium, at pH > 3.5, there is a precipitation and the probable formation of polymeric species such as $Zr_3(OH)_{11}^+$ $[Zr_2(OH)_7^+ + Zr(OH)_4]$ or $Zr_4(OH)_{15}^+$ $[Zr_3(OH)_{11}^+ + Zr(OH)_4]$. When the acidity of the solution decreases the existence of the $Zr_4(OH)_{15}^+$ species has also been suggested by Gimblett and Massey[26]. Then, according to these authors, the complex ion $Zr_4(OH)_{15}^+$ hydrolyses to a neutral tetrameric hydroxide which polymerises slowly to form colloidal particles and ultimately a solid hydroxide precipitate. Finally, at the second equivalence point of the titration curves (pH ≈ 6), the precipitated species is very likely to be a polymer of the formula $[Zr(OH)_4]_n$ because this precipitate does not dissolve in solution, even in very acidic medium.

Conclusion

The aqueous chemistry of zirconium(IV) can be explained by the formation of the soluble species $Zr(OH)_3^+$, $Zr_2(OH)_7^+$, and $Zr(OH)_4$ in KNO_3 media, in the pH range of 1.5−3.5 and for zirconium concentrations varying from $8\cdot10^{-5}$ to $8\cdot10^{-3}$ mol·dm^{-3}.

The formation constants of the species $Zr(OH)_3^+$, $Zr_2(OH)_7^+$, and $Zr(OH)_4$ as well as the solubility product of zirconium hydroxide have been determined in KNO_3 media at four ionic strengths. The values of these β_{mlh} constants were extrapolated to the standard state in order to determine the thermodynamic constants $\beta°_{mlh}$. The $\beta°_{mlh}$ constants were determined at zero ionic strength by putting the Specific ion Interaction Theory (SIT method) into practice.

We have also obtained some results in heterogeneous medium, at pH > 10, which lead us to consider the formation of the $Zr(OH)_5^-$ species. Unfortunately, these results cannot be used in this case to determine the formation constant of $Zr(OH)_5^-$. A useful evaluation of the solubility of zirconium(IV) in aqueous medium is obtained by plotting the total zirconium concentration (on a logarithmic scale) as a function of pH (Figure 5).

Such a plot shows that the insoluble species $Zr(OH)_4$ is predominant between pH = 5 and pH = 12. This species distribution diagram was established at pH > 8 by using the result of Sheka et al.[3] for the formation constant of $Zr(OH)_5^-$ ($\log \beta°_{10-5} \approx -19.3$).

Experimental Section

Reagents: All chemicals used were of analytical grade. Zirconium oxychloride and potassium nitrate were purchased from Fluka. Nitric acid and potassium hydroxide were purchased from Merck. Solutions of zirconium oxychloride were prepared with an excess of nitric acid ($[H_3O^+]/[Zr] = 5$) to prevent the formation of less reactive polymers[16]. These solutions were standardised by edta titration using an excess of Fe^{III} ions, and salicylic acid as an indicator following the procedure described by Kragten et al.[16] and Milner et al.[17]. Potassium nitrate stock solutions were filtered on Millipore filters (pore size 1.2 μm) before use and storage.

Protometric Measurements: All measurements were performed at 25 ± 0.1°C. Experiments were made at different ionic strengths (I = 0.2, 0.5, 1, and 2 mol·dm^{-3}) and adjusted with potassium nitrate. A few experiments were carried out in sodium perchlorate medium to ensure that there is no complexation reaction with nitrate ions.

The protometric measurements were carried out in a thermoregularized cell with a nitrogen stream over the solution to avoid dissolution of carbon dioxide. The glass electrode Metrohm type "U" has a very low alkaline error. The reference element Hg/Hg_2Cl_2 was in contact with a solution containing KCl of a concentration of 0.1 mol·dm^{-3} and a variable concentration of KNO_3 to adjust ionic strength to the required value. The procedures and apparatus used for protometric measurements have been previously described[18]. For pH values below 2, a polynomial correction was used.

Because of the slow kinetics of the hydrolysis reactions, and also because of the formation of local precipitate as a consequence of the addition of the alkaline reagent, experimental procedures have been refined in order to obtain accurate and reproducible pH measurements. Titrations were made under the conditions of vigorous stirring and very slow addition of the titrant (0.5 μl per 5 s), so for high concentrations of zirconium, a titration can last several days.

Solutions of zirconium oxychloride in the concentration range of $8\cdot10^{-5}$ to $8\cdot10^{-3}$ mol·dm^{-3} were titrated by KOH (0.1 mol·dm^{-3}) up to pH = 12. Further titrations with a less concentrated reagent (KOH of 0.04 mol·dm^{-3}) were performed to ensure that the equilibrium is effectively reached throughout the experiments. The results were similar in both cases and so validate the titration procedure.

Solubility Measurements: The solubility of zirconium hydroxide $Zr(OH)_4$ was measured as a function of pH at four ionic strengths in order to evaluate its solubility product. Zirconium hydroxide was prepared by the precipitation of zirconyl chloride with ammonia. An amount of solid was introduced in zirconyl chloride solutions of variable concentration and ionic strength. After the equilibrium was reached (up to 15 d), the solutions were centrifuged and filtered using a Sartorius filter (pore size 0.45 μm). The pH value and the total concentration of zirconium for the supernatant were determined. The pH ranged from 1 to 3.5 and the zirconium concentration varied from 0.1 to 0.001 mol dm^{-3}. For each ionic strength a series of ten solutions was prepared.

Computations: The protometric data were processed by the computer program Protaf[19] in order to obtain the best-fit chemical model and refined stability constants β_{mlh} (β_{mlh} refers to the species $M_mL_lH_h$; a negative h value refers to the hydroxy ion). The program Protaf, which is based on the weighted least squares of the residues of the experimental variables (volume of titrant, pH), allows a simultaneous processing of ten titrations, each including 150 pairs of data (volume, pH).

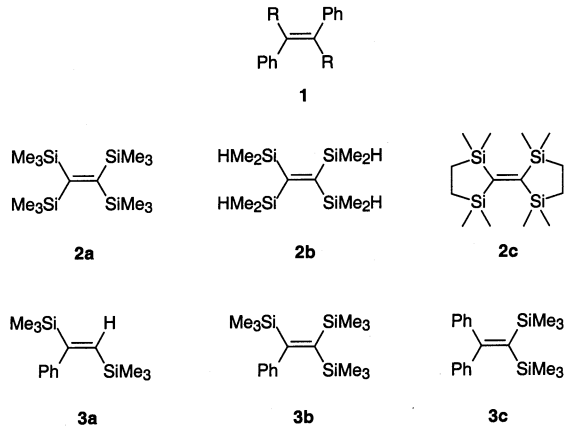
Keywords: Dianions / Organolithium compounds / Reductive metallation / HOESY / Lithium NMR

1,2-Diphenyl-1,2-bis(trimethylsilyl)ethene (**5**) undergoes a smooth reductive metallation with metallic lithium to yield the corresponding dilithioethane derivative (Li_2·**5**). The structure of this new compound in [D_8]THF solution was determined by NMR spectroscopy (^{1}H, ^{13}C, ^{6}Li, ^{7}Li NMR and ^{6}Li,^{1}H-HOESY). It is shown that the phenyl rings have a high quinoid character and that the lithium cations are relatively mobile.

Introduction

It has been known since 1928 that stilbene (**1**, R = H) and related aryl-substituted ethene derivatives (**1**, R = alkyl, aryl) react readily with alkali metals to afford π-delocalized benzylic carbanions[1][2]. Similar reductive metallations can be achieved with ethenylsilanes **2a–c**[3], in which the negative charges are stabilized by the adjacent silyl substituents. In compounds such as **3a–c**, both stabilizing effects are present[4].

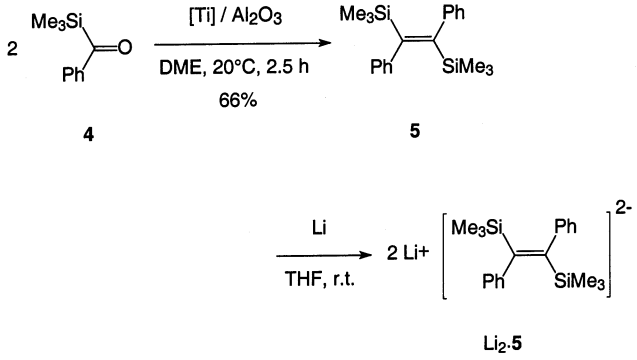


These metallations proceed in a stepwise fashion: a first single electron transfer (s.e.t.) leads to short-lived radical anions which rapidly undergo a second s.e.t. to afford the corresponding dianions[5]. The latter have attracted considerable attention in recent years as stabilized analogues of the still elusive 1,2-dilithioethane[6]. Several in-depth studies employing X-ray crystallography or NMR have provided a detailed – but rather static – picture of the bonding situation in such dimetallic compounds[1][2][3][4]. In the following we describe not only the solution structure of a further missing congener of this series, i. e. the dilithio derivative of 1,2-diphenyl-1,2-bis(trimethylsilyl)ethene (Li_2·**5**), but also show that within this molecule the metal cations are highly mobile.

Results and Discussion

Recently, McMurry-type coupling reactions have been extended to substrates other than aldehydes and ketones[7]. We found that aromatic acylsilanes react reasonably well with low-valent titanium [Ti] to afford the corresponding 1,2-disilylethene derivatives as the major products.

Scheme 1



Specifically, treatment of benzoyltrimethylsilane **4** with [Ti] formed from $TiCl_3$ and "high surface sodium" (Na/Al_2O_3)[8] as the preferred coupling agent provides compound **5** in 66% yield as colorless crystals[9]. This product undergoes a smooth reductive metallation on exposure to an excess of lithium metal in thoroughly dried and degassed THF, leading to a dark-red solution of the corresponding dianion Li_2·**5**. This derivative is thermally stable for prolonged periods of time and can be isolated as a dark-red solid upon removal of the THF. However, Li_2·**5** is extremely sensitive in solution as well as in the solid state towards

 © WILEY-VCH Verlag GmbH, D-69451 Weinheim, 1998 1434–1948/98/1771–1774 $ 17.50+.50/0

traces of air which immediately re-convert it into the starting disilylethene **5**.

Although various conditions have been used to crystallize the compound, no crystals of $Li_2 \cdot$ **5** suitable for an X-ray analysis have been obtained. Therefore the structure of this compound was studied by NMR spectroscopy. A complete and unambiguous assignment of the ^1H and ^{13}C spectra (Table 1) was achieved using 2D-NMR techniques.

[a] $\Delta\delta_n = [\delta_n(Li_2 \cdot \mathbf{5}) - \delta_n(\mathbf{5})]$.

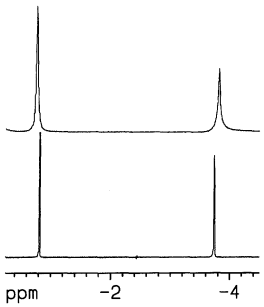
As can be seen from Table 1, five proton and six ^{13}C signals are observed at 303 K for the phenyl groups. Detailed analysis of these spectra and further experiments including COSY revealed that the two arene groups are equivalent but that within each group all the carbon atoms and protons are different. The number of signals in the ^1H- and ^{13}C-NMR spectra is unchanged when the sample is cooled to 193 K and no broadening of any of these signals is observed (cf. Experimental Section). Thus, the phenyl groups remain equivalent on the NMR time scale over the range 300 K to 193 K.

The inequivalence of the *ortho* positions (3 and 7) and of the *meta* positions (4 and 6) within each phenyl group indicates that the barrier to rotation about the C-1,C-2 bond in Li_2·**5** must be high. No exchange cross peaks could be detected in a ^{13}C 2D-EXSY spectrum recorded at 303 K. Taking into account the relatively high signal-to-noise ratio of this 2D spectrum and that the cross peaks due to exchange were not larger than the peak-to-peak noise, the barrier to rotation of the arene ring is estimated to be at least 90 kJ/mol.

The resonance of C-1 is observed at $\delta = 69.4$, i. e. an upfield shift of 89.7 ppm relative to the olefin **5** ($\delta = 159.1$). Moreover, the ^{13}C data indicate that the negative charges are also delocalized to a large extent over the arene rings. Specifically, the *para*-^{13}C signal of C-5 resonates at $\delta = 97.9$, corresponding to a low-frequency shift of ca. 27.7 ppm by comparison with the signal of **5**. Similarly, the *ortho* signals ($\delta = 107.4$ and 117.6) are shifted to lower frequency by 20.6 and by 10.4 ppm. These observations and the high barrier to rotation indicate that the phenyl substituents have a strong quinoid character, a conclusion which is in accordance with previous studies on related ethylene anions[3][4].

Further structural information was gained from the lithium-NMR spectra. Both the ^7Li-NMR spectra of the natural abundance compound and ^6Li spectra of a ^6Li-enriched sample were measured. Surprisingly, the temperature dependence of the ^6Li- and ^7Li-NMR spectra contrasts strongly with that observed for the ^1H- and ^{13}C-NMR spectra. At 293 K a single, broadened signal is observed in the ^6Li spectrum (88.3 MHz) at $\delta_{Li} = -2.4$ (linewidth 500 Hz), which on lowering the temperature splits into two well-resolved lines at $\delta_{Li} = -0.8$ and -3.8 (Figure 1). The separation of these signals (3.0 ppm) is large as compared to the usual range of lithium chemical shifts[10], suggesting that the environments of the lithium cations are rather different. This result is in contrast to previous investigations on dilithioethane derivatives, in which the Li signals either coincide or resonate within a narrow shift range[3][4].

Figure 1. ^7Li-NMR (233.3 MHz) spectrum (top) and ^6Li-NMR (88.3 MHz) spectrum (bottom) of Li_2·**5** recorded at 193 K



The ^6Li-enriched samples were prepared to obtain additional information on the *location* of the cations using ^6Li,^1H heteronuclear Overhauser effects, which were measured using the 2D HOESY (HOESY = heteronuclear Over-

hauser effect spectroscopy) technique[10][11]. The HOESY spectrum reveals strong cross peaks between the lithium signal at $\delta_{Li} = -3.8$ and the TMS group, the *ortho* proton at $\delta_H = 5.89$ (3-H) and the adjacent *meta* proton (4-H). Additional, but weaker, cross peaks are found to the *para* proton (5-H) and the other *ortho* proton (7-H). The HOESY cross peaks of the second lithium signal at $\delta_{Li} = -0.8$ are weaker and correlate with the TMS group and both *ortho* protons (Figure 2). Since ^{6}Li,^{1}H heteronuclear Overhauser effects can only be detected over short distances[10], these results show that *both* lithium cations must be close to the organic anion and that in Li_2·**5** tight ion contacts are present. ^{6}Li- and ^{7}Li-NMR spectra recorded in the presence of excess TMEDA support this conclusion: although TMEDA usually dissects oligomeric organolithium compounds in solution, the lithium chemical shifts of Li_2·**5** are hardly affected even when 2.5 equivalents of TMEDA are added.

Figure 2. ^{6}Li,^{1}H-HOESY-NMR spectrum (contour plot) of Li_2·**5** recorded in [D$_8$]THF at 193 K

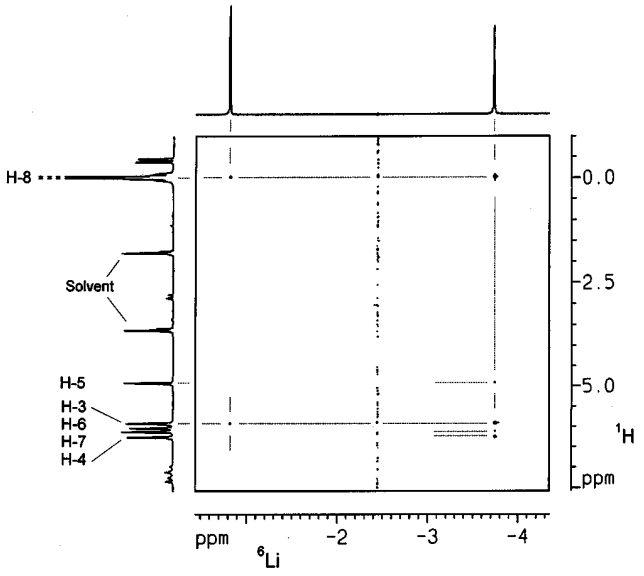


Table 1 also documents the large differences between the chemical shifts of the *ortho* carbon atoms C-3 and C-7 in Li_2·**5** (10.2 ppm). The signal shifted more strongly to high field arises from the *ortho* carbon atom on side of the ring having the stronger interaction with Li. Similarly, significant shift differences are found between the *meta* carbon atoms C-4/C-6 (3.5 ppm), as well as the *ortho* protons H-3/H-7 (0.29 ppm) and the *meta* protons H-4/H-6 (0.22 ppm). We interpret these data and the HOESY spectra described above as showing that the lithium cation giving rise to the resonance at $\delta = -3.8$ interacts with the phenyl groups, particularly with the sides of these groups towards the inside of the molecule (Figure 3). If the lithium atom interacts with both phenyl rings simultaneously, then the dianion cannot be planar: the torsional angle about the C-1, C-1′ bond must be reduced to ca. 90°. This is also consistent with ^{1}H-NOE data, since strong cross peaks are observed between the trimethylsilyl protons and both *ortho* protons of the arenes. Note also that the non-planar scaffold of Li_2·**5** implies an axially chiral environment. A schematic representation of the structure and bonding situation in Li_2·**5** is given in Figure 3.

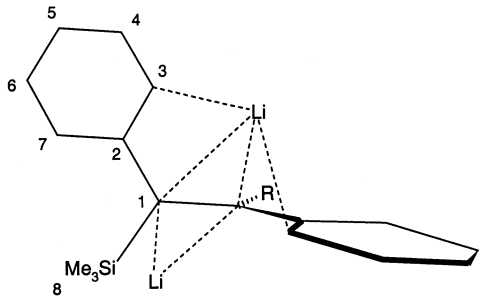
Figure 3. Schematic representation of the structure and bonding situation in Li_2·**5**



There is evidence that additional fast exchange processes are occurring. In both, the ^{6}Li and ^{7}Li spectra, the Li signal at $\delta = -0.8$ becomes narrower when the temperature is reduced to below 250 K but the Li signal at $\delta = -3.8$ remains somewhat broadened. This is apparently caused by additional exchange phenomena involving this lithium atom alone which remain fast on the NMR time scale. It is possible that the lithium cation jumps between different sites on the phenyl groups and the observed broadening may be due to a slowing of this rate of exchange. However, we have no corroborating evidence for this from the ^{1}H- or ^{13}C-NMR spectra and this interpretation remains speculative. When TMEDA is added to the sample, this phenomenon becomes much more marked. Not only does the high-field ^{6}Li signal below 200 K split into two signals of intensities ca. 2:1 but in this case the phenyl *ortho* proton signal also shows similar behaviour.

In summary, the NMR data are consistent with the presence of contact ionic interactions in Li_2·**5** with the anion having a C_2-symmetrical twisted, axially chiral conformation with a torsional angle of about 90°. As a result of their high quinoid character, the phenyl rings cannot rotate. On time average the two lithium cations are found on the plane orthogonal to the central C−C bond and passing through its midpoint. At room temperature the lithium cations exchange locations with one another rapidly but at 193 K this exchange is slow on the NMR time scale. One of the lithium cations lies between the phenyl rings and interacts strongly with the *ortho* positions.

We thank the *Fonds der Chemischen Industrie*, Frankfurt, for generous financial support.

Experimental Section

General: All reactions as well as the sample preparations for NMR were carried out under Ar using Schlenk techniques. All glassware was thoroughly flame-dried in vacuo. Natural abundant Li and ^{6}Li powder (Aldrich, 95% ^{6}Li, dispersion in mineral oil) were repeatedly washed with pentane and dried in vacuo prior to

use. [D_8]THF was dried by distillation from Na/K alloy and transferred under Ar. Substrate **5** was prepared by a McMurry-type coupling reaction as previously described[9a].

NMR Spectroscopy: All the NMR spectra were measured with a Bruker DMX-600 NMR spectrometer: ^{1}H (600.2 MHz), ^{6}Li (88.3 MHz), ^{7}Li (233.3 MHz), and ^{13}C (150.9 MHz). The chemical shifts were determined relative to the β-methylene signals of the solvent and converted to the TMS scale (^{1}H, β-CH_2, δ_H = 1.78; ^{13}C, β-CH_2, δ_C = 25.2). The sequence of proton signals 3-H to 6-H was determined in the COSY spectrum and confirmed by NOESY. These assignments were transferred to ^{13}C using data from the ^{1}H,^{13}C correlation. The strongest ^{6}Li,^{1}H cross-peaks in the HOESY spectrum were to the protons at 5.89 (*ortho*) and 6.27 (adjacent *meta*), allowing the "outer" and "inner" sides of the phenyl ring to be identified. The lithium chemical shifts are given relative to external 0.1 M LiBr in THF solution (0 ppm). The HOESY experiments were recorded using the experiment hoesytp from the standard Bruker pulse library using a mixing time of 1.8 s (256 experiments each of 64 scans, 1 K in f_2, magnitude calculation in f_1, exponential multiplication in both dimensions using lb = 2).

Preparation of Diphenyl-1,2-bis(trimethylsilyl)ethanediyldilithium (Li_2·**5**). To a stirred suspension of lithium powder (35 mg, 5.04 mmol) in 5 ml of [D_8]THF was added a solution of alkene **5** (144 mg, 0.44 mmol)[9a] in 5 ml of [D_8]THF. The reaction mixture turned dark-red within a few minutes and stirring was continued overnight. An aliquot of the supernatant dark-red liquid was transferred via cannula into a thoroughly dried NMR tube, the rest was filtered off and concentrated to afford a dark-red amorphous solid. – ^{7}Li NMR ([D_8]THF, 303 K) δ = −2.2, $\Delta\nu_{1/2}$ = 265 Hz. – ^{7}Li NMR ([D_8]THF, 193 K) δ = −0.78, −3.82. – ^{1}H NMR ([D_8]THF, 193 K): δ = 6.25, 6.10, 6.02, 5.92, 4.91, −0.03. – ^{13}C NMR ([D_8]THF, 193 K) δ = 153.0, 130.6, 127.0, 117.0, 107.4, 97.9, 68.2. – After addition of TMEDA: ^{1}H NMR ([D_8]THF, 303 K): δ = 6.27, 6.19, 6.03, 5.90, 4.95, 0.02. – ^{1}H NMR ([D_8]THF, 193 K): δ = 6.25, 6.17, 5.98, 5.87, 4.90, −0.02. – ^{7}Li NMR ([D_8]THF, 193 K): δ = −2.2, $\Delta\nu_{1/2}$ = 350 Hz. – ^{7}Li NMR ([D_8]THF, 193 K): δ = −0.75, −3.68 (br.). – For the assignment and additional data see Table 1.

Keywords: 3,4-Bis(isopropylidene)-1,2,5-thiadiborolane / *nido*-2,4,5-Thiadicarbahexaboranes(5) / Isomeres / Thiadicarbanonaborane(8) / IGLO

The 3,4-bis(isopropylidene)-2,5-dichloro-1,2,5-thiadiborolane (**5b**), obtained from 3,4-bis(dichloroboryl)-2,5-dimethyl-2,4-hexadiene (**4**) and $(Me_3Si)_2S$, reacts with $Li[RBH_3]$ (R = H, C_6H_5, C_6Me_4H) to yield the corresponding derivatives of the *nido*-4,5-diisopropyl-2,4,5-thiadicarbahexaboranes **2**. Replacements of the chlorine atoms in **5b** with two hydrido, or with one hydrido and one aryl (phenyl or duryl) group, followed by the hydroboration of the isopropylidene substituents with RBH_2 (R = H, C_6H_5, C_6Me_4H) lead to four *nido*-2,4,5-thiadicarbahexaboranes (**2a–d**) in low yields. Their composition follows from MS and NMR data; not refined X-ray structural data of **2d** support the proposed skeletal structure. In addition to **2a**, larger thiacarboranes were detected by GC/MS and ^{11}B NMR. The structure of the nine-vertex cluster **6a** could be identified by applying the ab initio/IGLO/NMR method. Geometry optimizations at the MP2(fc)/6–31G* level rule out the C_s *nido*-$SC_2B_6H_8$ isomer **7**. The C_{2v} structure of **6** consists of a nine-vertex cluster with two elongated B–B distances. As this 22e cluster **6** represents an exception to the Wade rules, the nature of the bonding of nine-vertex clusters with different electron counts is discussed.

The thiacarboranes and thiadicarboranes with nine to eleven skeletal atoms, *arachno*-SCB_7H_{11}[1][2], *arachno*-SCB_8H_{12}[2], *nido*-SCB_9H_{11}[2], *arachno*-$SC_2B_6H_{10}$[3], *nido*-$SC_2B_8H_{10}$,[4][5][6] have been obtained from the reactions of neutral carboranes or their anions with sulfur or sulfur compounds. Among the smaller but still unknown thiacarboranes, the *nido*-$SC_2B_3H_5$ cluster (**2**) is of particular interest to us, since it could be isoelectronic with 2,3,5-tricarbahexaborane(7) (**1**)[7]. Formal replacement of the CH_2 group in **1** by sulfur leads to **2**. The axial hydrogen in **1** bends and is involved to some extent in a 3c,2e CHB bonding.[7][8] The reaction of the $C_2B_{10}H_{13}^-$ anion with $KHSO_3$ in acid degrades the carborane and incorporates a sulfur atom to yield *arachno*-8,6-$SCH_2B_7H_9$[5]. The analogous reaction of **1** or its anion $C_3B_3H_6^-$ with $KHSO_3$ does not seem feasible, because no BH groups should be eliminated. Such BH units are needed to abstract the oxygen atoms of $KHSO_3$ (as is the case with $C_2B_{10}H_{13}^-$). The structurally and electronically related *nido*-$SC_2B_8H_{10}$ (**3**) is obtained in aqueous solution from the reaction of $K_2S_2O_5$ with K[7,8-$C_2B_9H_{12}$]. One BH group and a hydrogen atom are replaced by a sulfur atom to give **3**. The cluster **3** differs from **2** by the $(BH)_5$ belt.

We now present our results on the designed synthesis of derivatives of **2**, obtained from the hydroboration substitution reactions of the unsaturated 1,2,5-thiadiborolane derivative **5b**. Other products are formed as well. Of these, the thiadicarbanonaborane **6a** could be identified by GC-MS, ^{11}B-NMR spectra, and by applying the ab initio/IGLO/NMR method.

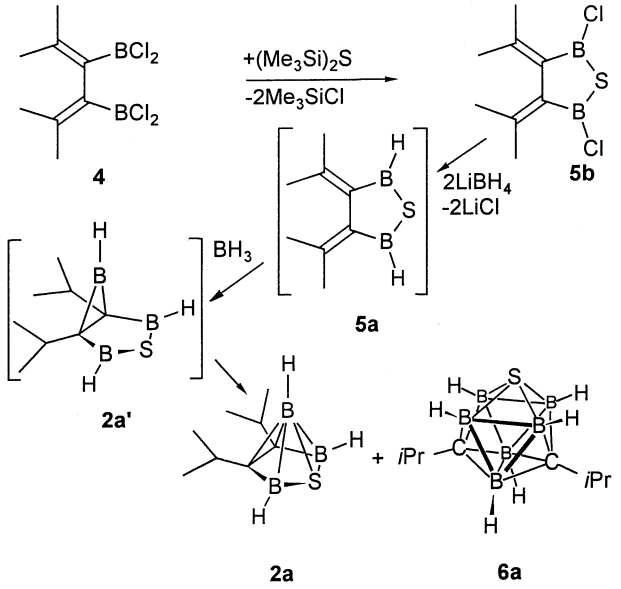
Results and Discussion

The reaction of 3,4-bis(dichloroboryl)-2,5-dimethyl-2,4-hexadiene (**4**)[9] with hexamethyldisilathiane leads to elimination of chlorotrimethylsilane to give 3,4-bis(isopropylidene)-2,5-dichloro-1,2,5-thiadiborolane (**5b**) in 86% yield (Scheme 1). Compound **5b** is isolated as a slightly yellow liquid[10] by distillation in vacuum. It is extremely air- and moisture-sensitive due to the high reactivity conferred by the B−Cl and B−S bonds. The composition of **5b** follows from NMR and MS data, whereas the assignment of the ^{1}H- and ^{13}C-NMR signals for the *exo*- and *endo*-methyl

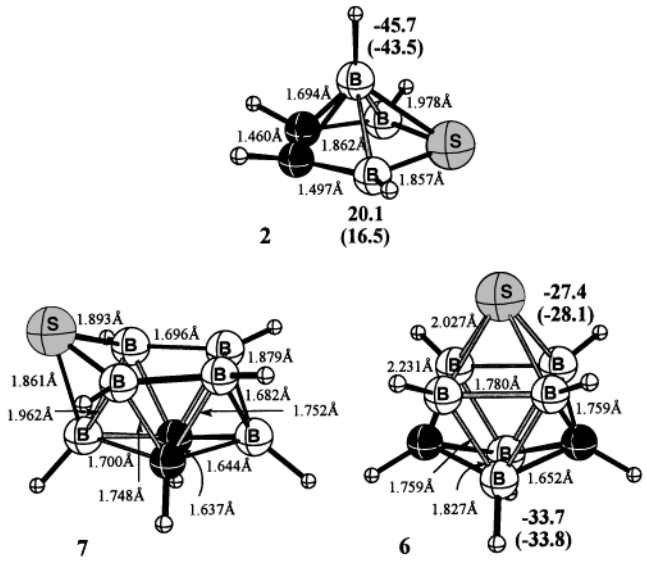


substituents of the isopropylidene groups was not possible.

The reactions of **5b** with lithium borates, Li[RBH$_3$] (R = H, C_6H_5, C_6Me_4H), yield several products. We presume that the first step involves substitution of the chlorine atoms in **5b** by hydrogen from $LiBH_4$ to give **5a**, but it was not isolated. In the next step, BH_3, formed in situ, hydroborates the double bonds of **5b**. The bicyclic organothiaborane **2a′** is an isomer of the product **2** whose existence as an intermediate may be supposed, but was not proven.With the formation of the *nido*-thiacarborane **2a** the coordination numbers increase from three to six for the apex boron atom and from three to four for the basal boron atoms. In addition to **2a**, other products are formed which could not be separated completely by distillation. The ^{11}B-NMR spectrum shows low-field signals for organoboranes and organothiaboranes as well as high-field signals. Unexpectedly, the GC-MS spectrum of the reaction mixture exhibits the molar peak for the thiadicarbanonaborane(8) derivative **6a** at m/z = 213 with the correct isotopic pattern for six boron atoms. In the {^{1}H}^{11}B-NMR spectrum three sets of signals at δ = 1.3/2.2 (intensity ratio ca. 2:1), −20.1/−20.7 (ca. 1:2) and at −28.2/−33.8 (ca. 1:2) are observed, the latter signals are assigned to **6a**.

If S were to contribute four bonding electrons, the product S(CR)$_2$(BH)$_6$ would have a 22 skeletal electron count[11]; this suggests a nine-vertex *nido* cluster. Structure **7** is a *ni*-9<V> cluster with a pentagonal open face. The MP2(fc)/6−31G* optimized structure of **7** is shown in Figure 1 together with the computed IGLO ^{11}B-NMR chemical shifts for **2** and **6**. The experimental 2:1 ^{11}B intensity pattern would be in line with structure **7** only if the S atom fluctuated from one BBB capping position to the other. However, the averaged theoretical shifts (4.3, −6.4) which might result from such fluctuation are in gross disagreement with the experimental values (−28.2, −33.8). Hence, structure **7** can be discarded from consideration. While the sulfur atom is at the vertex of lowest connectivity (k = 3), the carbon atoms in **7** are placed at k = 5 and not at the more favorable $k = 4x$ positions. For alternatives with carbons in the open face (at k = 4 positions), more than the observed two signals in the ^{11}B NMR spectrum are expected.

Figure 1. Computed geometries and ^{11}B chemical shifts of $SC_2B_3H_5$(**2**), C_s isomer $SC_2B_6H_8$ (**7**), and C_{2v} isomer $SC_2B_6H_8$ (**6**)

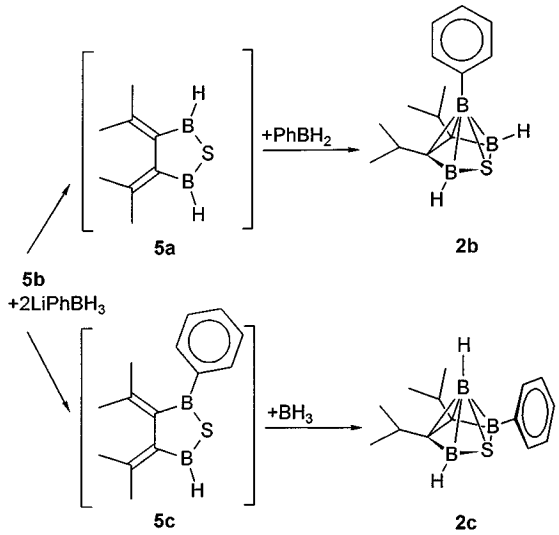


A C_{2v} starting geometry, where the S resides above a BBBB rectangular face, would be optimized to structure **6**; it is 66.3 kcal mol^{-1} lower in energy than **7**. Since the chemical shifts computed for **6** are very close to the values measured for **6a**, both have the same basic structure. The framework of **6** can be regarded as a triply capped trigonal prism and all hetero atoms are at the capping k = 4 positions. There are two large BB separations (2.23 Å) which suggest that the cluster should be considered as a *ni*-9<IV+IV> cluster with two tetragonal faces[12]. Such a cluster would be consistent with the *nido* electron count provided the S atom contributes four to a total of 22 skeletal electrons. For clarification we applied the NBO localization scheme.[13] Only one lone pair orbital on sulfur with an occupancy close to 2 (1.966) was found. This implies that the remaining four valence electrons are involved in cluster bonding which results in a *nido* electron count for $SC_2B_6H_8$, **6** (22 skeletal electrons).

The parent nine-vertex cluster anion *closo*-[B_9H_9]$^{2-}$is unusual in having non-degenerate frontier orbitals: HOMO-1, HOMO, and LUMO (A_1', A_2', and A_2'', respectively). This

implies that addition of two or removal of two or even four skeletal electrons need not cause symmetry reduction and disruption of the basic D_{3h} cluster structure. However, reduction or oxidation of $[B_9H_9]^{2-}$ changes the cluster B−B separations depending on the bonding and antibonding character of the occupied MOs. Both addition and removal of two electrons from $[B_9H_9]^{2-}$ elongate the B1-B1′ and shorten the B1−B1 distance (for numbering the atoms compare Table 2). The same effects are observed if all three capping HB vertices in $[B_9H_9]^{2-}$ are replaced by isolobal HC^+ groups to give the isoelectronic $[C_3B_6H_9]$ species: "hypo-*closo*", "*closo*", or "*nido*" (Table 2). With capping sulfur atoms (S^{2+} is isolobal to HC^+), adding two electrons to *closo*-$[S_3B_6H_6]^{4+}$ also results in shortening of B1−B1 and elongation of B1−B1′. However, the B1−B1′ bonds are larger in $[S_3B_6H_6]^{4+}$ and $[S_3B_6H_6]^{2+}$ than in the other cases. Hence, the large B1−B1′ separation (2.231 Å) involving the S cap in **6** turns out to be normal for a *nido* electron count in the nine-vertex cluster. This is in agreement with structural data of the unusual silicid compound $Rb_{12}Si_{17}$, which contains four crystallographically different Si_9^{4-} clusters besides Si_4^{4-} tetrahedra. Three of them (**B**, **C**, and **D**) are described as tricapped trigonal prisms elongated along the threefold axes. The cluster **B** has two long edges (3.09) and one short edge (2.63 Å).[14] In the Zintl phase K_4Pb_9 two different clusters, a monocapped square antiprism and an elongated tricapped trigonal prism with two long edges (3.90) and one short edge (3.45 Å) are present.[15]

Scheme 2



The analogous reaction of **5b** with lithium phenylborate yields the isomers **2b** and **2c** which could not be separated. According to the NMR data, the isomers are formed in a 5:1 molar ratio, the isomer with the phenyl group in the apex position being favored. This finding indicates that the chlorine atoms in **5b** are predominantly substituted by hydrogen atoms (leading to **2b**) rather than by the phenyl group (**2c**).

In order to study the steric influence of the aryl group on the formation of isomers, **5b** was reacted with lithium durylborate. Surprisingly this reaction leads to derivative **2d** with the duryl group in a basal position (Figure 2). This result may be interpreted in terms of the different reactivities of the lithium borates.

Spectra and Structural Characterization

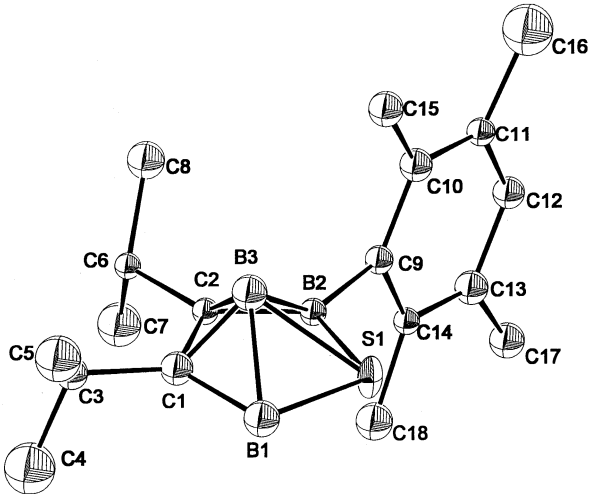
The ^{11}B-NMR data support the assigned structures of the compounds **2a−d**. Their substitution patterns follow from the ^{1}H- coupled ^{11}B-NMR spectra, which clearly show doublets for **2a**, **c**, **d** at high field (δ = −39 to −41). The absence of this signal for **2b** indicates that the phenyl group is in the apex position. Both **2a** and **2b** have C_s symmetry, whereas **2c** and **2d** have C_1 symmetry and show three different ^{11}B-NMR signals in a 1:1:1 ratio. The ^{1}H-NMR spectra of **2c** and **2d** exhibit two sets of signals for the isopropyl group, in agreement with C_1 symmetry. The ^{13}C-NMR data also support the proposed constitutions. Since a mixture of compounds was present, it was not possible to assign the ^{1}H- and ^{13}C-NMR signals to **6a**.

Despite numerous crystallisation attempts, only **2d** yielded single crystals. A structure analysis was carried out on a crystal belonging to the orthorhombic space group $Pn2_1a$ with a = 7.518 (5), b = 20.12 (2), c = 12.86 (1) Å, V = 1946 Å^3, Z = 4. The bad quality of the crystals yielded only a very limited data set, which allowed the solution of the structure but not a reliable refinement. However, the analysis supports the proposed connectivity of the atoms in a *nido* arrangement. Due to the large uncertainty in bond distances and angles these details are not discussed here. The computed geometry parameters of **2** (see Figure 1) should be reliable and closely resemble the geometric features of **2a** as suggested by the close agreement between experimental ^{11}B-NMR chemical shifts for **2a** and values computed for **2**. The open five-membered face is essentially planar (the angle between the BCCB and the BSB plane is 176.1°) and the bond lengths S−B = 1.857, B−C = 1.497, C−C = 1.460 Å are shorter than in the analogous *nido*-thiadicarbaundecaborane(10) **3** (S−B = 1.915, B−C = 1.597, C−C = 1.542 Å).[16]

Computational Details

Geometries of **2**, **6**, and **7** have been optimized at HF/6−31G* and MP2(fc)/6−31G* levels of theory using the Gaussian 94 program.[17] The structures correspond to local minima on the SCF potential energy surface as shown by analytical frequency calculations (absence of imaginary frequencies). Chemical shifts have been computed with the IGLO program[18] applying Huzinaga's basis set[19] of DZ or II′ quality in the recommended contraction scheme[18c]. A gas phase chemical shift of 16.6 ppm[20] for B_2H_6 and shielding constants of 115.6 (DZ) and 103.0 (II′) have been used as reference to the experimental standard, $BF_3 \cdot OEt_2$.

Figure 2. Molecular structure of compound **2d**



Model compounds listed in Table 2 have been optimized by the B3LYP DFT (density functional theory) method using the three parameter exchange parameter by Becke (B3)[21] and the correlation functional by Lee, Yang, and Parr (LYP),[22] including both local and non-local terms, as implemented in Gaussian 94.[17]

Experimental Section

All reactions and manipulations were performed in dry glassware under argon by using standard Schlenk techniques. Solvents were distilled from appropriate drying agents under argon before use. − $Et_2O \cdot BF_3$ was used as the external standard for ^{11}B NMR. As internal standards for ^{1}H-and ^{13}C-NMR spectra the signals of the deutero solvents were used and calculated for TMS. NMR: $CDCl_3$ solutions, Bruker AC 200. − MS: Varian MAT CH7 and GCMS HP 5971. − The following starting materials were prepared by methods described in literature: 3,4-bis(dichloroboryl)-2,5-dimethyl-2,4-hexadiene (**4**)[9], lithium phenylborate[9], lithium durylborate[23]. Hexamethyldisilathiane and lithium borate were commercially obtained.

2,5-Dichloro-3,4-bis(isopropylidene)-1,2,5-thiadiborolane (**5b**): 6.84 g (38.4 mmol) of hexamethyldisilathiane were added dropwise to a solution of 10.44 g (38.4 mmol) of **4** in 150 ml of n-hexane at 0° C. After 4 h heating to reflux, the solvent was removed under vacuum. Distillation yielded 7.68 g (33.0 mmol, 86%) of slightly yellow **5b**, b.p. 61° C/ $8 \cdot 10^{-3}$ Torr. − ^{1}H NMR ($CDCl_3$, 200 MHz): δ = 1.74, 2.21 (2 s, 2×6 H, $CCH_{3\ exo}$ or *endo*). − ^{11}B NMR ($CDCl_3$, 64 MHz): δ = 62. − ^{13}C NMR ($CDCl_3$, 50 MHz): δ = 23.1, 26.6 (2 s, $CCH_{3\ endo}$ or *exo*), 142 [s, br, $BCC(CH_3)_2$], 149.7 [s, $C(CH_3)_2$]. − MS(EI), *m/z* (%) = 232 [M^+] (42.0), 217 [$M^+ - CH_3$] (39.4), 190 [$M^+ - C_3H_6$] (17.8), 41 ($C_3H_5^+$, 78.7).

nido-4,5-Diisopropyl-2,4,5-thiadicarbahexaborane(5) (**2a**): 215 mg (9.87 mmol) of lithium borate were suspended in 20 ml of hexane and 880 mg (3.78 mmol) of **5b** in 5 ml of hexane were added at −78° C. After 1 h at this temp. the mixture was stirred 12 h at room temp.. The suspension was filtered and the solvent was removed under vacuum. Distillation yielded 70 mg (0.39 mmol, 10%) of colorless impure **2a**, b.p. 70° C/1.5 Torr, which could not be separated from **6a** and other by-products. − ^{1}H-NMR data of **2a** ($CDCl_3$, 200 MHz): δ = 1.17, 1.27 [2 d, 2×6 H, $HC(CH_3)_2$, $^3J_{H,H}$ = 6,8 Hz *endo* or *exo*], 2.45 [sept, 2 H, $HC(CH_3)_2$, $^3J_{H,H}$ = 6.8 Hz], (HB not detected). − ^{11}B-NMR data of **2a** ($CDCl_3$, 64 MHz): δ = −43.5 (d, 1 B, $^1J_{B,H}$ = 208 Hz), 16.5 (d, 2 B, $^1J_{B,H}$ = 167 Hz). MS(EI) data of **2a** : *m/z* (%) = 178 [M^+] (40.9), 163 [$M^+ - CH_3$] (17.5), 135 [$M^+ - C_3H_7$] (19.1), 41 [$C_3H_5^+$] (100). − ^{11}B-NMR data of **6a** ($CDCl_3$, 64 MHz): δ = −28.1 (d, 2 B, $^1J_{B,H}$ = 179 Hz), −33.8 (d, 1 B, $^1J_{B,H}$ = 173 Hz). − MS(EI) data of **6a**: *m/z* (%) = 213 [M^+] (100), 198 [$M^+ - CH_3$] (33.0), 170 [$M^+ - C_3H_7$] (29.6), 41 [$C_3H_5^+$] (15.5).

Mixture of nido-4,5-Diisopropyl-1-phenyl-2,4,5-thiadicarbahexaborane(5) (**2b**) *and nido-4,5-Diisopropyl-3-phenyl-2,4,5-thiadicarbahexaborane(5)* (**2c**): 780 mg (8.0 mmol) of lithium phenylborate were suspended in 50 ml of hexane and 930 mg (4.0 mmol) of **5b** solved in 20 ml of hexane were added under reflux conditions. After 2 h at this temp. the mixture was stirred 12 h at room temp.. The suspension was filtered and the solvent was removed under vacuum. Distillation yielded 180 mg (0.7 mmol, 18%) of colorless **2b**, **c**, b.p. 60−75° C/ $5 \cdot 10^{-2}$ Torr. − NMR data of **2b**: ^{1}H NMR ($CDCl_3$, 200 MHz): δ = 1.27, 1.32 [2d, 2x6 H, $HC(CH_3)_{2\ endo}$ or *exo*, $^3J_{H,H=6}$,8 Hz], 2.75 [sept, 2 H, $HC(CH_3)_2$, $^3J_{H,H}$ = 6,8 Hz], 7.12−7.67 (m, 5 H, C_6H_5). − ^{11}B NMR ($CDCl_3$, 64 MHz): δ = −31.8 (s, 1 B), 20.0 (d, 2 B, $^1J_{B,H}$ = 155 Hz). − ^{13}C NMR ($CDCl_3$, 50 MHz): δ = 24.4, 25.6 (2 s, $CCH_{3\ endo}$ or *exo*), 27.8 [s, $HC(CH_3)_2$], 127.4, 127.6 (2 s, *ortho*- or *meta*-C), 138.6 (s, *para*-C),

(CB not detected). NMR data of **2c**: ^{1}H NMR ($CDCl_3$, 200 MHz): δ = 1.00, 1.13, 1.25, 1.34 [4d, 4×3 H, HC(CH_3)$_2$, $^3J_{H,H}$ = 6.8 Hz], 2.53 [sept, 2 H, $HC(CH_3)_2$, $^3J_{H,H}$ = 6,8 Hz], 7.12−7.67 (m, 5 H, C_6H_5). − ^{11}B NMR ($CDCl_3$, 64 MHz): δ = −41.4 (d, 1 B, $^1J_{B,H}$ = 206 Hz), 15.3 (d, 1 B, $^1J_{B,H}$ = 172 Hz), 27.5 (s, 1B). − ^{13}C NMR ($CDCl_3$, 50 MHz): δ = 23.6, 23.9, 24.0, 24.9 [4 s, HC(CH_3)$_2$], 27.1, 28.8 [2 s, H*C* (CH_3)$_2$], 131.2, 133.9 (2 s, *ortho*- or *meta*-C), 138.6 (s, *para*-C), (CB not detected). − MS(EI): *m*/*z* (%) = 254 [M^+] (100), 239 [$M^+ - CH_3$] (13.1), 211 [$M^+ - C_3H_7$] (24.2), 41 [$C_3H_5^+$] (93.8).

nido-4,5-Diisopropyl-3-duryl-2,4,5-thiadicarbahexaborane(5) (**2d**): 1.6 g (10.0 mmol) of lithium durylborate were suspended in 100 ml of hexane and 1.16 mg (5.0 mmol) of **5b** solved in 100 ml of hexane were added under reflux conditions. After 2 h at this temp. the mixture was stirred 12h at room temp., then filtered, and the solvent was removed under vacuum. Sublimation yielded 480 mg (1.5 mmol, 31%) of colorless **2d**, s.p. 105° C/ $5\cdot10^{-2}$ Torr. − ^{1}H NMR ($CDCl_3$, 200 MHz): δ = 1.01, 1.12, 1.26, 1.34 [4d, 4×3 H, HC(CH_3)$_2$, $^3J_{H,H}$ = 6,8 Hz], 2.15, 2.24, 2.26, 2.32 (4 s, 4×3 H, *ortho*- or *meta*-CH_3), 2.50, 2.56 [2 sept, 2×1 H, $HC(CH_3)_2$, $^3J_{H,H}$ = 6,8 Hz], 7.00 (s, 1 H, *para*-CH). − ^{11}B NMR ($CDCl_3$, 64 MHz): δ = −39.5 (d, 1 B, $^1J_{B,H}$ = 203 Hz), 16.0 (d, 1 B, $^1J_{B,H}$ = 145 Hz), 28.4 (s, 1 B). − ^{13}C NMR ($CDCl_3$, 50 MHz): δ = 19.9, 20.4, 20.5, 20.6 (4 s, *ortho*- or *meta*- C*C*H_3), 22.9, 23.0, 24.9, 25.7 [4 s, HC(CH_3)$_2$], 27.7, 27.8 [2 s, H*C*(CH_3)$_2$], 109, 121 (2 s, br, CB), 131.7, 133.2, 133.3, 135.0 (4 s, *ortho*- or *meta*-*C*CH_3), 138.0 (s, *para*-CH). − MS(EI): *m*/*z* (%) = 310 [M^+] (100), 295 [$M^+ - CH_3$] (5.0), 267 [$M^+ - C_3H_7$] (62.2), 41 [$C_3H_5^+$] (49.8).

Reaction of tetracarbonyl[2-{(η^6-phenyl)tricarbonylchromium-$\kappa C^{2'}$}pyridine-κN]manganese(I), **2a**, with phenyllithium quantitatively affords an acylmanganese anion **3a** that can be isolated and spectroscopically characterized. In-situ *O*-alkylation of the latter anion by means of $MeOSO_2CF_3$ at low temperature, yields a new neutral *syn*-facial heterobimetallic analog **4a** of (η^5-cyclohexadienyl)-benzylidene complexes. The treatment of bimetallic carbonyl complexes of 3-methyl, 2-phenyl-pyridine and 2-phenyl-quinoline, **2b** and **2c**, with PhLi and subsequently with $MeOSO_2CF_3$ affords deep purple crystalline products **4b** and **4c** that have been structurally characterized by X-ray diffraction analyses. The molecular structures of **4b** and **4c** display, among other features, an overall helical shape with a pronounced π-stacking of the aromatic groups and a weak interaction between the chromium and the manganese centered units.

Introduction

We recently reported that cyclomanganated 2-phenylpyridine derivatives undergo a nucleophilic attack at a coordinated carbonyl ligand upon treatment with aryllithium reagents[1]. ^{13}C-NMR and IR spectroscopic measurements have revealed the formation of anionic acylmetalate intermediates which were shown to be prone either to decomposition by a reductive elimination process when kept in a solution at ambient temperature or to conversion into new chelated η^3-benzylic manganese complexes upon alkylation with $MeOSO_2CF_3$. These results demonstrated that chelated octahedral (tetracarbonyl)manganese(I) complexes display a reactivity toward organolithium reagents similar to that of the widely studied hexacarbonylmetal complexes of the chromium triade[2]. To our knowledge, this constituted the first report for a non-oxidative chemical transformation producing a new class of organomanganese compounds from cyclomanganated substrates[3]. In our continuing efforts to find new reactivity patterns for cyclomanganated aromatics we were naturally lead to study the behaviour of the peculiar class of chelated complexes derived from (η^6-arene)tricarbonylchromium complexes[4]. We[4a][4b] and other authors[4c] did previously report that such bimetallic complexes can be readily synthesized in preparative scale. Some examples have been used in the stereoselective insertion reactions of alkynes leading to π-coordinated indenol complexes[4c]. Herein, we report that the addition of phenyllithium to cyclomanganated 2-[(η^6-phenyl)-tricarbonylchromium]pyridine yields an air- and temperature-sensitive acylmanganate intermediate. Further alkylations of this and other analogous anionic intermediates afford novel neutral chelated *syn*-facial heterobimetallic (η^5-cyclohexadienyl)benzylidene complexes in which the two metallic centers, e.g. chromium and manganese, are involved in a weak metal−metal interaction that resembles a metal−metal dative bond[5].

Results and Discussion

1. Synthesis of Chelated Bimetallic (η^5-Cyclohexadienyl)benzylidene Complexes 4a−c

The reaction of an orange solution of complex **2a** with 1 equiv. of phenyllithium in DME[6] at −50°C yielded within

 © WILEY-VCH Verlag GmbH, D-69451 Weinheim, 1998 1434−1948/98/1111−1781 $ 17.50+.50/0

seconds a dark brown solution containing the acylmanganate **3a**-Li (Scheme 1). In order to properly characterize this reaction product we isolated the latter and exchanged the lithium cation for the more bulky PPN^+ counter cation. The $^{13}C\{^1H\}$-NMR analysis of the resulting compound, e.g. **3a**-PPN, confirmed the presence of only one product. In the carbonyl ligand resonance region we detected singlets at δ = 219.7, 222.9, and 231.1 that we assigned to the ^{13}C resonances of the $Mn(CO)_3$ group, an intense signal at δ = 237.5 produced by the carbonyl ligands of the $Cr(CO)_3$ moiety and a downfield singlet at δ = 289.5 attributed to the acyl carbon of the benzoyl group located on the manganese center. From this spectrum it was clear that the nucleophilic attack did not take place at a carbonyl ligand of the $Cr(CO)_3$ moiety but rather selectively at a CO ligand located on the manganese center. Similar chemical shifts for the carbonyl ligands of the $Mn(CO)_3$ group were previously obtained for lithium (benzoyl)(tricarbonyl)[2-(phenyl-$\kappa C^{2'}$), pyridine-κN]manganate(I)[1].

The infrared spectrum of **3a**-PPN in CH_2Cl_2 displays three intense absorption bands at 1972, 1930, and 1847 cm^{-1}, a shoulder at 1878 cm^{-1} and a weak band at 1560 cm^{-1} that may be assigned to as the C−O streching vibration of the benzoyl group. The former set of three intense signals can be considered reasonably as the result of the overlap of the two sets of A_1+E vibration modes related to the *fac*-$L_3Cr(CO)_3$ group and to a *fac*-$L_3Mn(CO)_3$ moiety. A *mer*-$L_3Mn(CO)_3$ moiety resulting from a nucleophilic attack at an equatorial CO ligand would have given three distinct absorption bands, e.g. $2A_1+B_2$, with the two A_1 vibration modes showing up at the higher frequencies[7].

Analogous anionic intermediates can be prepared starting from **2b** and **2c** by reaction with PhLi under experimental conditions similar to those used for the formation of **3a**-Li. In situ alkylation of the anionic adducts originating from **2a−c** at −20°C with $MeOSO_2CF_3$ gave rise to a dramatic change in colour of the reaction mixture from dark brown to dark red. Isolation of the corresponding reaction products afforded after chromatographic purification, the complexes **4a**, **4b**, and **4c** in 67, 70 and 45% yield respectively (based on the starting bimetallic substrates).

2. Molecular Structures of Complexes 4b and 4c

Crystallization of compounds **4b** (Figure 1) and **4c** (Figure 2) from mixtures of dichloromethane and hexane at −18°C afforded crystals suitable for X-ray crystal structure analysis. Details of data collection and refinement are summarized in Table 3. Selected interatomic distances, bond angles and torsion angles are given in Table 1 for compound **4b** and in Table 2 for compound **4c**.

The two molecules represented in Figures 1 and 2 reveal a quite compact intramolecular arrangement. Both metal-carbonyl fragments are coordinated to the same face of the organic ligand and the carbonyl ligands occupy positions that minimize steric interactions. The average Cr−Mn distance of 3.03 Å indicates interaction between what may be considered a formally closed shell 18 electron chromium(0) center and an electron-deficient 16 electron manganese(I) center. Obviously, the electron bookkeeping for each metal and the transcription of the relevant formulae rise several questions. At first glance, resonance forms depicted for **4a−c** in Scheme 1 have different chemical meanings[8]. The formula denoted as **A** includes a dative bond between the two metals whereas **B**, includes a single covalent bond. A choice between these two formulations must rely at least on thorough theoretical investigations that are not available so far for the type of bridging ligand described here. To our knowledge, only a few theoretical studies are available on donor-acceptor or dative transition metal-metal interactions involving[9] or not[10] bridging ligands. This ambiguity was already addressed for other bimetallic compounds that fit neither of the two aforementioned metal to metal interaction types[11]. At this stage of our study, we chose an intermediate "dashed bond" formulation for the molecular structures of **4a−c** which emcompasses the main structural informations extracted from the two available molecular structures (vide infra). In this formulation, the dashed lines indicate interactions of uncertain nature.

A close analysis of the metal-centered bond angles for the chelated $Mn(CO)_3$ fragment indicates that in both **4b** and **4c** the manganese atom is located in a slightly distorted octahedral coordination geometry (Tables 1 and 2). In this

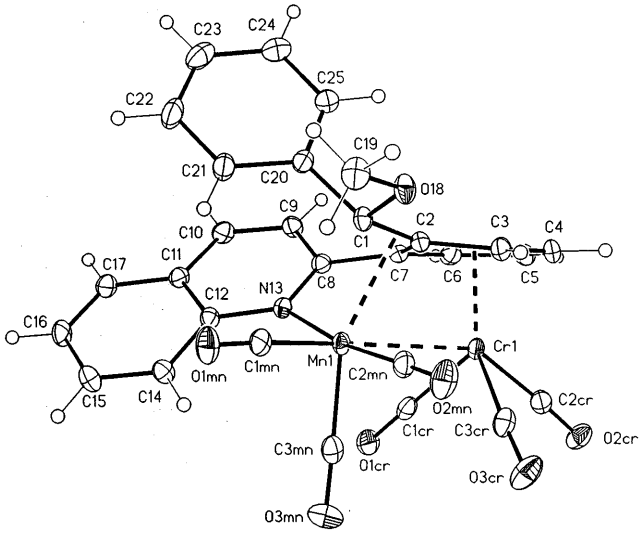
configuration the chromium atom, the pyridyl or quinolinyl group, and two carbonyl ligands occupy four equatorial positions, the two axial positions being held by the pseudo-benzylic carbon C(1) and by the third carbonyl ligand. The pseudo-benzylic and heterocyclic rings connected through C(7)−C(8) are twisted around this axis by about 45° [torsion angle C(2)−C(7)−C(8)−N(13) for **4b**: −42.9(2)°, for **4c**: 137.38(19)°] which is about 5° more than that observed for the mononuclear analog **5**[1].

The geometry of the $Cr(CO)_3$ moiety does not change dramatically from that commonly observed in (η^6-arene)-tricarbonylchromium complexes. The two chromium-bound CO ligands that are oriented towards the manganese center form a OC−Cr−CO bond angle of approximately 96° which may be considered intermediate between the average value of 89° generally observed in common (η^6-arene)tricarbonylchromium complexes[12] and the value of 105° for neutral tricarbonyl(η^5-cyclohexadienyl)(triphenyltin)chromium(*Cr-Sn*) complexes[13]. This relatively wide angle reflects not only a steric hindrance but also some peculiar bonding interactions between the chromium center and its surrounding ligands[14].

We reported previously[1] that in complex **5** the manganese center was more likely bound to the benzylic ligand through a η^1:η^2 bonding mode rather than via an ideal symmetric η^3 allylic-like mode. This conclusion was based on the analysis of the metal-to-carbon atom distances. The shortest distance of 2.104(4) Å was obtained for the pseudo-benzylic carbon-to-Mn bond, C1−Mn (Scheme 2), and the longest distance of 2.438(4) Å for the *ipso*-aromatic carbon-to-Mn bond C7−Mn (Scheme 2).

Figure 2. ORTEP diagram and atom numbering scheme of the molecular structure of **4c**. Ellipsoids are scaled to enclose 30% of the electronic density



In **4b** and **4c** the corresponding average Mn(1)−C(7) bond distance of 2.91 Å is beyond the range of generally accepted C−Mn bond lengths of either σ- or π-coordinated carbon atoms[15]. The Mn(1)−C(2) (2.40 Å and 2.36 Å) and Mn(1)−C(1) (2.15 Å) are consistent with an altered π-type coordination between Mn(1), C(1), and C(2) even though the C(1)−C(2) bond distance of 1.45 Å in **4b** and **4c** is longer than that of a typical metal-coordinated C=C bond. This is supported by the fact that amongst all the aromatic

carbon atoms bound to the chromium, C(2) is the farthest with an average Cr(1)−C(2) bond distance for **4b** and **4c** of 2.38 Å as compared to the remainder average Cr(1)−C_{Ar} bond distance of 2.22 Å. A reasonable compromise to describe the coordination mode of atom C(2) is to present it as a part of a multicenter bonding system (Scheme 1).

The asymmetric bonding mode of the arene can be well characterized by the angle θ defined as the angle formed between the mean planes C(3)−C(2)−C(7) and C(3)−C(4)−C(5)−C(6)−C(7) in complexes **4b−c**. The calculation of the least square planes indicated no major deviation from the plane for C(5). The calculated values of θ were 8.3° for **4b** and 11.0° for **4c**. In other terms the structural features of the coordinated arene rather confirm a quasi η^5-coordination to the $Cr(CO)_3$ group[16].

As previously underlined for complex **5** (Scheme 2), compounds **4b** and **4c** possess a marked helicity characterized by the overlying of the aromatic rings originating from the N-heterocycles and the phenyl group attached to C(1). In the compounds described herein, the spacial arrangement of the aromatic rings implies relevant geometric distortions of the coordinated arene. Indeed, atoms C(1) and C(8) are forced in opposite directions with respect to the mean plane of the chromium-coordinated arene ring [C(1) towards the uncomplexed arene ring and C(8) towards manganese]. This distortion is evident in both complexes as the torsion angle C(1)−C(2)−C(7)−C(8) amounts 16°.

3. Spectroscopic Properties of Complexes 4a−c

The infrared spectra of compounds **4a−c** present four different signals at approximate frequencies of 2010 (sharp and strong), 1960 (strong), 1924 (medium and broad), and 1890 (medium and broad) cm^{-1} in CH_2Cl_2. This pattern is consistent with the overlap of two A_1+E vibration modes patterns of the *fac*-$Cr(CO)_3$ (1960 and 1890 cm^{-1}) and *fac*-$Mn(CO)_3$ (2010 and 1924 cm^{-1}) fragments, respectively.

A rough comparison of the frequency of the E mode absorption band produced by the chromium tripod in **4a−c** with that of the simple monometallic complexes **1a−c** (Scheme 2) informs about the magnitude of the electron density exchange between the manganese and the chromium atoms. For instance, if we consider both complexes **1a** (Scheme 2) and **4a**, the absorption band arising from the E vibration mode of the $Cr(CO)_3$ fragment undergoes a relative bathochromic shift $\Delta\nu_E$ ($\Delta\nu_E = \nu_{E1a} - \nu_{E4a}$) upon

intimate interaction with the $L_2Mn(CO)_3$ moiety of about 10 cm^{-1} suggesting an electron density transfer from the manganese to the chromium center. Similar values can be calculated for the couples **1b/4b** and **1c/4c**. It must be pointed out that the value of Dn_E is only a rough estimation since the coordinated arenes in **1a/4a** are slightly different in nature.

A more reliable comparative study can be based on the carbonyl ligand absorptions of complexes **4a** and **5** that differ by the absence of the $Cr(CO)_3$ moiety in the latter compound[1]. One may consider the A_1 absorption bands of the $Mn(CO)_3$ fragment that are detected at 2000 cm^{-1} in CH_2Cl_2 for **5** and at 2010 cm^{-1} in CH_2Cl_2 for **4a**. A new bathochromic shift value can be defined as

$$\Delta\nu_{Cr} = \nu_{Mn-Cr} - \nu_{Mn},$$

with ν_{Mn} defining the frequency of the A_1 mode band in the η^3-benzyl manganese complex **5** and ν_{Mn-Cr} designing the corresponding A_1 mode band in the *syn*-facial heterobimetallic compound **4a**. The difference of 10 cm^{-1} obtained for **5** and **4a** confirms a loss of electron density on the Mn-centered fragment as a consequence of the concomittant interaction with the $Cr(CO)_3$ moiety and structural rearrangements of the molecule. A similar effect of 8 cm^{-1} for $\Delta\nu_{Cr}$ is obtained for compound **4c** and its monometallic η^3-benzylic analog[1].

The ^{1}H-NMR spectra of compounds **4a**−**c** recorded at room temperature display very similar features. In all three cases the protons of the arene coordinated to the $Cr(CO)_3$ tripod resonate at ca. δ = 4.3−5.3 as two doublets and one triplet each integrating one proton and at ca. δ = 6.3 as a triplet integrating also one proton. A combination of two dimensional NMR experiments − e.g. COSY, NOESY and ^{1}H-^{13}C heteronuclear correlation − and the careful analysis of the multiplicities allowed the exact assignment of the proton resonances of the coordinated arene of compound **4a**. For instance, we assigned the signals at δ = 4.28 (d, 1 H), 4.39 (d, 1 H), 5.23 (t, 1 H), and 6.32 (m, 2 H) to respectively H^6, H^3, H^4, and H^5; the latter overlaps with a signal of the pyridyl group. This wide outspreading of the ^{1}H resonances of the coordinated arene over a range of 2 ppm is reminiscent of that observed in tricarbonyl(η^5-cyclohexadienyl)chromium complexes[17]. It suggests that the arene coordinated to the chromium center in **4a** as well as in **4b** and **4c** has a much more pronounced η^5-cyclohexadienyl character than that suspected in reported cases of anionic (η^5-cyclohexadienyl)benzylidenetricarbonylchromium complexes[18]. Indeed, in known structurally characterized examples of tricarbonyl(η^5-cyclohexadienyl)chromium complexes the protons at the 2-, 3-, and 4-positions with respect to the sp^3 carbon atom resonate at δ = 2.4, 3.7, and 6.0, respectively. The analogy made here lies on the assumption that at least H^3, H^4, and H^5 in complex **4a** are not submitted to some peculiar intramolecular magnetic anisotropy. Proton H^6 that resonates at a much lower frequency than H^4 may have underwent a slight shielding produced by the vicinal twisted pyridyl group. The significant geometrical distortions observed in the molecular structures of **4b** and **4c** support a "partial" η^5-bonding mode for the coordinated arene group.

Similarly to the observations made for complex **5**[1], the proton resonances of the phenyl group attached to the

Figure 3. Temperature dependence of the ^{1}H NMR spectrum of **4a** in $CDCl_3$ in the so-called aromatic region. Asterisks designate the signals originating from the "slowly" rotating phenyl group

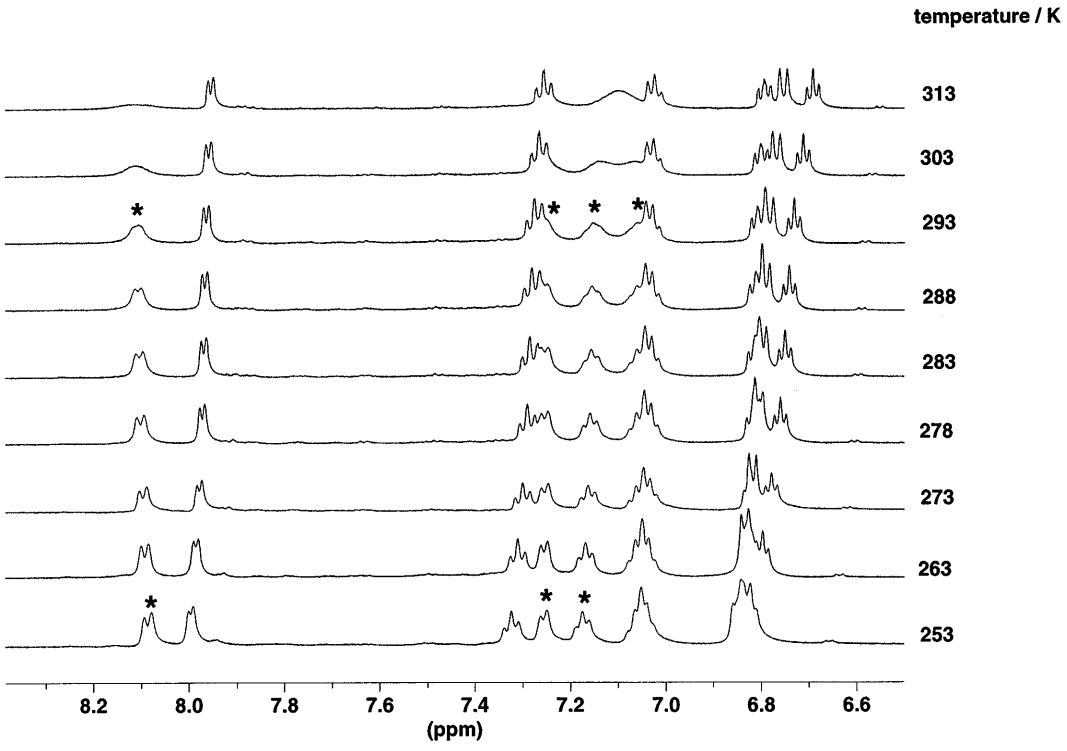

Figure 4. Temperature dependence of the ^{13}C-NMR resonances of the $Cr(CO)_3$ carbonyl ligands of **4a** in [D_8]THF. The asteriks indicate the signals that are involved in a dynamic process

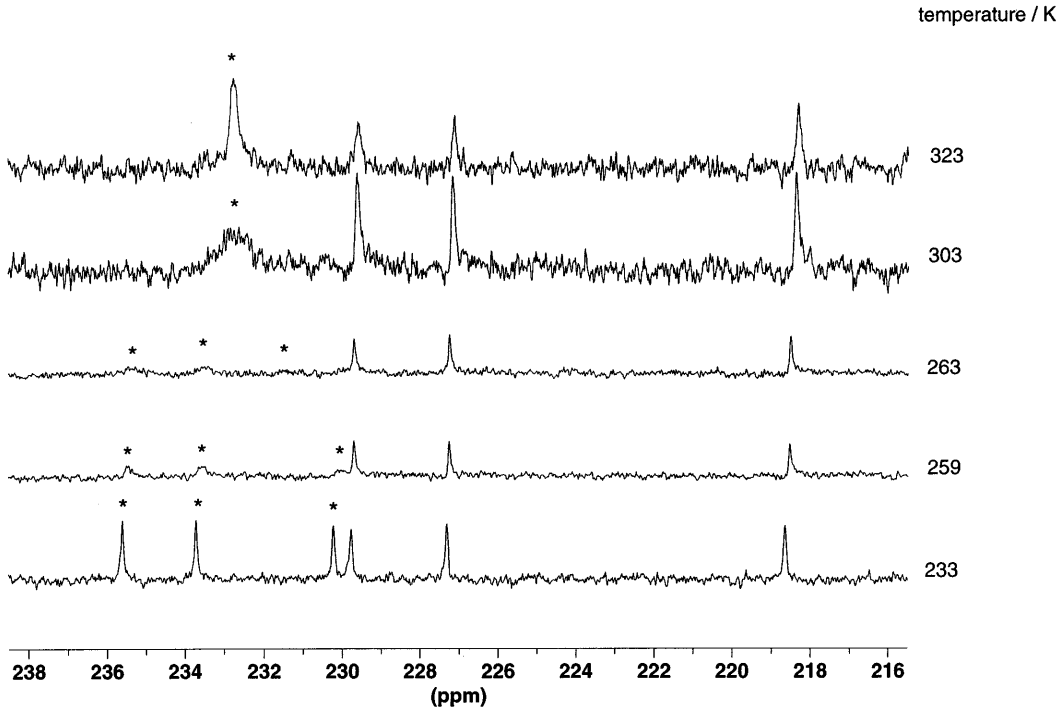


pseudo-benzylic carbon of complexes **4a** and **4c** display a clear temperature dependence. At 293 K in [D_6]acetone, the signals of the phenyl group of **4a** appear as broad signals at δ = 7.10, 7.30, and 8.10 (Figure 3).

Cooling the sample to 253 K induces the decoalescence of these broad peaks, and leads to a consecutive sharpening of the signals and an increased resolution (Figure 3). Hence at that temperature, one may detect three distinct signals, a doublet at δ = 8.08 (*ortho* proton), a doublet at δ = 7.26 (*ortho* proton) and a triplet at δ = 7.18. The other signals produced by the phenyl fragment, two triplets for instance, remain mostly hidden behind several intense multiplets attributed to the protons of the pyridyl group approximately at δ = 7.05 and 6.85. Due to the large separation in frequency between two exchanging protons the coalescence temperature of the two-site-exchange systems composed of two related doublets and two related triplets is not readily detectable. Heating the sample even up to 313 K did not provide a clear localization of the fast exchange signals (Figure 3).

Complex **4b** behaves in a slightly different way since at room temperature the signals of the phenyl group reflect, in the NMR time scale, a pattern consistent with a slow two site exchange[19]. Among the seven signals that can be readily observed at 298 K in deuterated acetone in the range from 6.7 to 8.5 ppm two resolved signals produced by the phenyl group are clearly separated from the rest of the spectrum and are detected at δ = 7.88 (d, 1 H) and 7.21 (t, 1 H). The integration of the overall area of the spectrum in the δ = 6.7−8.5 range confirms the presence of eight aromatic protons.

The steric bulk encountered in both molecular structures of **4b** and **4c** implies an underlying fluxional behavior of the $Cr(CO)_3$ rotor. Consequently, the ^{13}C-NMR spectra of **4a**−**c** performed at 298 K show a broad signal at about δ = 233 accounting for the rotating $Cr(CO)_3$ moiety and three sharp signals at δ = 229, 228, and 218 that can be assigned undoubtedly to the carbonyl resonances of the chelated static $Mn(CO)_3$ fragment. Variable-temperature NMR experiments were carried out with [D_8]THF solutions of compound **4a** (Figure 4).

At 233 K, complete decoalescence already took place and the resulting spectrum reveals, apart from the resonances of the manganese-coordinated carbonyl ligands at δ = 229.7, 227.3, and 218.6, three other low field sharp singlets at δ = 235.6, 233.7, and 230.2 consistent with a $Cr(CO)_3$ moiety which rotates relatively slowly in an asymmetric environment[20] (Figure 4). Further experiments are underway with ^{13}CO enriched samples that should yield the main thermodynamical factors related to the hindered rotation of $Cr(CO)_3$.

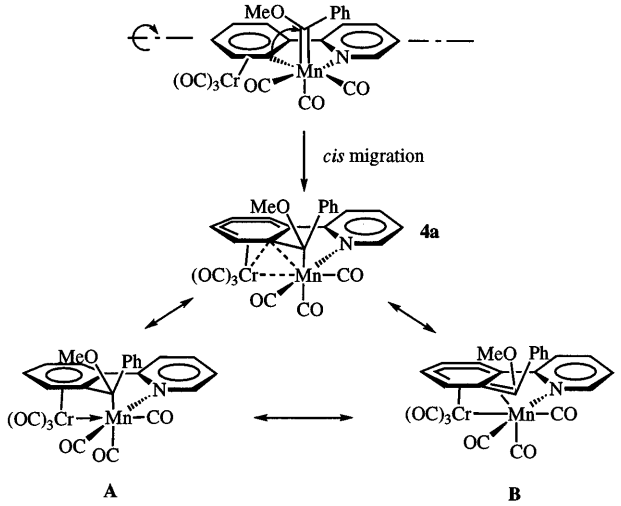
4. Discussion

The facile cyclomanganation of (η^6-arene)tricarbonylchromium complexes bearing nitrogen based chelating ligands has offered us an interesting starting point for the further exploration of possible applications of chelated $Mn(CO)_4$ complexes. In a recent paper we addressed the reactivity of 2-phenylpyridine−$Mn(CO)_4$ complexes toward organolithium reagents. This study indicated that the reac-

tivity of these metallacycles, that may also be formulated as *cis*-$L_2Mn(CO)_4$, toward organolithium reagents, RLi, corresponds to that of the intensively studied $M(CO)_6$ complexes (M = Cr, Mo, W). The main difference between these two systems is the fact that addition of RLi in the reaction involving $Mn(CO)_4$ chelates takes place exclusively at an axial carbonyl ligand. The trapping of the anionic acyl intermediates and subsequent NMR analyses never provided evidence for the formation of more than one anionic isomer. A study carried out with an analogous $Re(CO)_4$ complex allowed us to isolate and characterize an acetylrhenate complex that bears the CH_3CO- fragment at an axial position, *trans* to a CO ligand[21]. The addition of PhLi to the bimetallic starting materials selectively takes place at one carbonyl ligand of the $Mn(CO)_4$ moiety. Given the steric bulk of the $Cr(CO)_3$ tripod the *exo* axial CO ligand of the $Mn(CO)_4$ fragment is preferred to undergo a facile nucleophilic addition leading to a benzoylmanganate intermediate. The resulting anionic intermediate is greatly stabilized by a large delocalisation of the negative charge throughout the molecule. Three limit formulae may account reasonably for the charge redistribution as it is shown in Scheme 1 for **3a–c**.

We proposed in our early studies[1] that the treatment of the anionic acyl manganates by a hard alkylating agent such as MeOTf may yield a transient electrophilic alkoxyalkylidene complex[22]. A similar proposal can be made here (Scheme 3).

Scheme 3



We speculate that such a species may undergo a *cis*-migration of the $Cr(CO)_3$-coordinated phenyl group to the manganese bound alkylidene carbon atom resulting in a *syn*-arrangement of the two tricarbonylmetal fragments (Scheme 3). We already reported that in the process leading to **5** the manganese atom must coordinate in part to the vicinal aromatic ligand to meet the 18 valence electrons requirement. In the new compounds presented here, this electronic requirement seems to be met through a dative or a donor-acceptor interaction with the saturated chromium atom. The results of the low temperature ^{13}C-NMR experiments done with **4a** indicate that $Cr(CO)_3$ still behaves as a rotor and that the Mn–Cr interaction must be quite weak. Indeed, each complete rotation of the $Cr(CO)_3$ tripod must correspond to at least three single metal-metal bond disruptions.

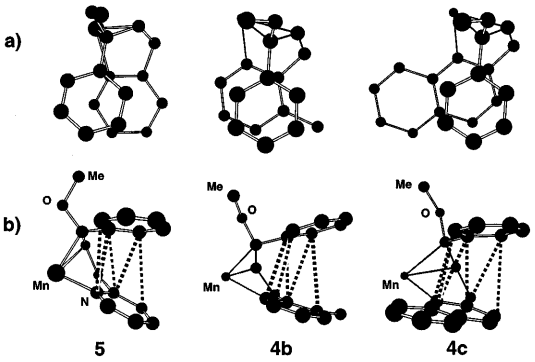
In a very recent study Ceccon and co-workers have reported the preparation and the structural chacterization of *syn*-facial heterobimetallic complexes *syn*-[$Cr(CO)_3$-μ,η:η-indenyl–ML] (M = Rh[23], L = COD, $(CO)_2$, NBD; M = Ir[24], L = COD). In most of these cases a weak non-covalent chromium-metal interaction, Cr–M, is invoked to explain the stability of the complexes. Similar to our two examples the $Cr(CO)_3$ tripod is shifted away from its common η^6 bonding mode to rather pronounced η^5 and η^4 hapticities. In general, a relevant distortion of the indenyl ligand accompanies these peculiar metal–metal interactions. Although a hindered rotation of the $Cr(CO)_3$ tripod is very likely it is not mentioned. The latter Cr–M interactions are even suspected by the authors to thermodynamically stabilize the *syn*-facial isomers whereas the analogous *trans* bimetallic complexes offer a much different reactivity. Depending on the steric bulk and the electronic nature of the ligand coordinating either Rh or Ir in these cases the Cr–M (M = Rh, Ir) distances vary from typically 3.07 Å (M = Ir, L = COD) to 3.3 Å (M = Rh, L = NBD). Similar significant differences for the Cr–Mn interatomic distance are not observed for **4b** and **4c**. However, we definitively may assess that metal-metal electronic interactions play a role. Ceccon′s *syn*-facial heterobimetallic complexes are synthesized by a ligand exchange reaction between $(CH_3CN)_3Cr(CO)_3$ and a η^3 coordinated indenyl iridium or rhodium complex in THF. A similar synthetic pathway applied to complex **5** did not yield compound **4a** even when the ligand-exchange reaction was done at 80°C in DME.

The main common trend that exists between the three crystallographically characterized complexes **5**, **4b**, and **4c** is the overlaying of the phenyl, pyridyl, and quinolinyl groups. This is well illustrated by the overlap diagrams grouped in the upper part of Figure 5 which outlines that in the more sterically hindered complexes **4b-c** the overlay of the phenyl and the N-heterocyclic ring is larger. In the lower part of Figure 5 the dashed lines indicate those interatomic distances between the two stacked rings that are inferior or equal to 3.5 ±0.1 Å, a value generally ascertained for optimal stabilizing π-stacking interactions in polyaromatic molecules or in crystal lattices of aromatic compounds[25]. The values of the interplanar angles between the phenyl group and the vicinal N-heterocycle in **4b–c** are 34.9° and 25.0°.

It is well established that the nature of the inter- or intramolecular π-stacking interactions is determined by five different categories of effects: the Van der Waals and electrostatic interactions, the induction energy, the charge-transfer and the desolvation of each molecule/fragment before interaction. Each of these effects depends directly on the nature of the aromatics that are involved and contributes in various orders of magnitude in a given interaction[25b].

It is noteworthy that the process which leads to the *syn*-facial bimetallic complexes afford solely the eclipsed stereo-

Figure 5. π-Stacking of phenyl and N-heterocyclic groups in compounds **5**, **4b**, **4c**. The adjacent aromatic ring has been omitted for clarity. a) top views and overlap diagrams. b) side views of the stakking interactions: the dashed bonds indicate interatomic distances that are shorter than 3.5 ± 0.1 Å



isomers in which the phenyl group eclipses the N-heterocycle as in **5** and **4b−c**. The other possible staggered product, which was not detected, would place the methoxy group above the heterocycle. At this point one might propose that the apparent selectivity of the reaction leading to **5** and **4a−c** from the alkylation of the corresponding acylmanganate species stems from a thermodynamic control that favors the eclipsed isomer through an intramolecular π-π interaction. Further experiments are underway to verify this hypothesis.

In conclusion, the reaction of cyclomanganated (η^6-arene)tricarbonylchromium complexes with PhLi and subsequent treatment with MeOTf yields new *syn*-facial heterobimetallic cyclohexadienylbenzylidene complexes in which the manganese atom interacts directly with the metal centre of the $Cr(CO)_3$ tripod. Although the exact nature of this interaction is not yet established it ressembles a donor-acceptor metal-metal bond. In this paper we have described a new methodology for the synthesis of *syn*-facial organobimetallic complexes and we have found a novel application of cyclometallated (η^6-arene)tricarbonylchromium complexes. We intend to further investigate the mechanistic aspects of their formation as well as the theoretical underlying issues.

We gratefully acknowledge the financial support provided by the *Centre National de la Recherche Scientifique*, the *Deutsche Forschungsgemeinschaft* and the *Fonds der Chemischen Industrie*. We thank Ms. *Ulrike Weynand* (Kékulé Institute of Organic Chemistry and Biochemistry − University of Bonn) for performing the low temperature NMR experiments and Dr. *Kamel Harrata* for HR-MS measurements.

Experimental Section

General: All reactions were carried out under a dry nitrogen atmosphere. (η^6-Arene)tricarbonylchromium complexes were prepared using the procedure of Pauson and co-workers[26]. Benzylpentacarbonylmanganese[27] and complexes **1a**, **2a**, **1b**, and **2b** were prepared by following literature procedures[4b]. The reaction products were separated by flash chromatography on silica gel (Merck, 60 μm) under a dry nitrogen atmosphere. High-resolution mass spectra were recorded at the Mass Spectrometry Service of the Iowa State University, U.S.A. Elemental analyses were done in presence of a combustion aid (V_2O_5) at the "Service de Microanalyse de l'Institut de Chimie", Strasbourg, France. Subambient temperature NMR experiments were done at the Analytical Center of the Chemical Institutes, University of Bonn, Germany. − IR: Perkin-Elmer FT. − NMR: Bruker AC 300, DRX 500 (300 MHz and 500 MHz for ^{1}H, 75 MHz and 125 MHz for ^{13}C). ^{13}C NMR spectra reported herein were all done with proton decoupling. The atom numbering used in the systematic nomenclature of the undermentioned compounds does not follow necessarily the one used for convenience throughout the results and discussion parts.

2-[(η^6-Phenyl)tricarbonylchromium]quinoline (**1c**): In a mixture of 8 ml of THF and 80 ml of di-*n*-butyl ether were dissolved 2-phenylquinoline (0.94 g, 4.58 mmol) and hexacarbonylchromium (1.51 g, 6.87 mmol). The resulting mixture was brought to refluxed for 51 hours under an atmosphere of nitrogen until signs of decomposition appeared in the reaction medium. The solution was cooled to room temperature and filtred over Celite, and both the solvents and the unreacted $Cr(CO)_6$ were removed under reduced pressure. The crude oily residue was then redissolved in dry diethyl ether and the solution mixed with silica gel. The solvent was removed under reduced pressure, and the resulting coated silica gel was loaded on the top of a silica gel column packed in dry and degassed hexane. The unreacted arene ligand was eluted first with CH_2Cl_2/hexane (4:6). The 2-[(η^6-phenyl)tricarbonylchromium]-quinoline complex, **1c**, was then eluted with CH_2Cl_2/hexane (8:2). The solvents were evaporated under reduced pressure. Recrystallization from dry hexane gave 1.17 g of **1c** (75%) as orange crystals, m.p. 130°C. − IR (CH_2Cl_2): $\tilde{\nu}$ = 1971 (CO), 1897 cm^{-1} (CO). − ^{1}H NMR ($CDCl_3$): δ = 5.52 (m, 3 H, H_{ArCr}), 6.37 (d, *J* = 5.4 Hz, 2 H, H_{ArCr}), 7.56 (t, *J* = 7.1 Hz, 1 H, H_{Ar}), 7.65 (d, *J* = 8.8 Hz, 1 H, H_{Ar}), 7.74 (t, *J* = 7.6 Hz, 1 H, H_{Ar}), 7.83 (d, *J* = 8.3 Hz, 1 H, H_{Ar}), 8.10 (d, *J* = 8.5 Hz, 1 H, H_{Ar}), 8.22 (d, *J* = 8.3 Hz, 1 H, H_{Ar}). − ^{13}C NMR ($CDCl_3$): δ = 91.8 (C_{ArCr}), 92.6 (C_{ArCr}), 92.7 (C_{ArCr}), 105.2 (C_{ArCr}), 117.6, 127.0, 127.5, 127.7, 129.6, 130.1, 137.0, 147.7, 153.4, 232.4 (Cr-*CO*). − $C_{18}H_{11}CrNO_3$ (341.3): calcd. C 63.29, H 3.22, N 4.10; found C 63.51, H 3.16, N 4.10.

*[2-[(η^6-Phenyl-κ$C^{1'}$)tricarbonylchromium](quinoline-κ*N*)]tetracarbonylmanganese* (**2c**): A solid mixture of complex **1c** (275 mg, 0.806 mmol) and $PhCH_2-Mn(CO)_5$ (253 mg, 0.887 mmol) was dissolved in a minimum volume (10 ml) of dry heptane and gently stirred at the boiling temperature of the solvent. After 4 hours, the reaction mixture was cooled to room temperature, and evaporated under reduced pressure. The residue was redissolved in CH_2Cl_2 and mixed with silica gel. The solvent was removed under reduced pressure, and the resulting coated silica gel loaded on the top of a silica gel column packed with dry and degassed hexane. [2-{(η^6-Phenyl-κ$C^{1'}$)tricarbonylchromium}(quinoline-κ*N*)]-tetracarbonylmanganese, **2c**, was eluted with CH_2Cl_2/hexane (4:6). The solvents were then evaporated under reduced pressure and recrystallization of the resulting solid from dry hexane gave 267 mg of **2c** (65%), red crystals, m.p. 190°C (decomposition). − IR (CH_2Cl_2): $\tilde{\nu}$ = 2086, 2007, 1985, 1955, 1944, 1884 cm^{-1}. − ^{1}H NMR ($CDCl_3$): δ = 5.47 (t, *J* = 6.2 Hz, 1 H, H_{ArCr}), 5.58 (t, *J* = 6.4 Hz, 1 H, H_{ArCr}), 5.92 (d, *J* = 6.1 Hz, 1 H, H_{ArCr}), 6.24 (d, *J* = 6.3 Hz, 1 H, H_{ArCr}), 7.63−7.71 (m, 2 H, H_{Ar}), 7.85 (m, 2 H, H_{Ar}), 8.32 (d, J = 8.5 Hz, 1 H, H_{Ar}), 8.62 (d, J = 9.3 Hz, 1 H, H_{Ar}). − ^{13}C NMR ($CDCl_3$): δ = 90.05 (C_{ArCr}), 92.72 (C_{ArCr}), 92.86 (C_{ArCr}), 104.69 (C_{ArCr}), 112.83 (C_{ArCr}), 116.93 (C_{ArCr}), 127.5, 127.9, 128.4, 129.1, 131.7 139.7 140.1, 149.8, 167.3 210.2 (Mn-*CO*), 211.1 (Mn-*CO*), 212.5 (Mn-*CO*), 220.1 (s, Mn-*CO*), 234.5 (s, Cr-*CO*). − $C_{22}H_{10}CrMnNO_7$ (507.3): calcd. C 52.09, H 1.99, N 2.76; found C 52.23, H 1.99, N 2.72.

General Procedure for the Synthesis of Complexes **4a**−**c**: Bimetallic complexes **2a-c** were separately dissolved in DME and the solution was cooled to −50°C. A solution of phenyllithium (1.8 M in cyclohexane/ether, Aldrich Chemicals) was then added and the temperature of the reaction mixture was allowed to reach −20°C. After 10 min at −20°C, the reaction mixture was cooled to −40°C. Methyltrifluoromethanesulfonate was added and the reaction mixture slowly warmed to room temperature. The solvent was removed in vaccuo and the residue dissolved in CH_2Cl_2 and mixed with silica gel, the solvent removed under reduced pressure. The resulting coated silica gel was loaded on the top of a silica gel column that was packed in dry and degassed hexane and eluted with mixtures of CH_2Cl_2 and hexane.

2-{2',3',4',5',6'-η⁵-[1'(α-methoxybenzylidene-κC^α)cyclohexadienyl-κC^1']tricarbonylchromium}(pyridine-κN)tricarbonylmanganese(Cr-Mn) (**4a**): Complex **2a** (413 mg, 0.90 mmol), PhLi (0.55 ml, 0.99 mmol), MeOTf (0.14 ml, 1.26 mmol). Chromatography on SiO_2 with CH_2Cl_2/hexane (7:3). Evaporation of the solvents gave 331 mg of **4a** (67%), as a red amorphous powder, m.p. 200−210°C (decomposition). − IR (CH_2Cl_2): $\tilde{\nu}$ = 2010.0, 1962.1, 1929.1, 1885.8 cm^{-1}. − ^1H NMR (C_3D_6O): δ = 3.29 (s, 3 H, OMe), 4.47 (d, *J* = 7.5 Hz, 1 H, H_{ArCr}), 4.82 (d, *J* = 6.3 Hz, 1 H, H_{ArCr}), 5.56−5.61 (m, 1 H, H_{ArCr}), 6.68−6.80 (m, 3 H), 7.01 (d, *J* = 7.0 Hz, 1 H), 7.09 (broad, 2 H, H_{Ar}), 7.25 (t, *J* = 7.9 Hz, 2 H), 7.93 (d, *J* = 5.5 Hz, 1 H), 8.08 (broad, 1 H). − ^1H NMR (CD_2Cl_2): δ = 3.33 (s, 3 H, OMe), 4.28 (d, 1 H, H_{ArCr}), 4.39 (d, 1 H, H_{ArCr}), 5.23 (t, 1 H, H_{ArCr}), 6.32 (m, 2 H), 6.57 (m, 1 H), 6.97−7.04 (m, 2 H, H_{Ar}), 7.10 (broad), 7.20 (broad), 7.84 (d, 1 H, H_{Ar}), 8.10 (broad). − ^{13}C NMR (CD_2Cl_2): δ = 55.2 (Me), 80.3 (C_{ArCr}), 82.9 (C_{ArCr}), 85.9 (C_{ArCr}), 88.7 (1 C, C_{ArCr}), 91.5 (C_{ArCr}), 91.6 (C_{ArCr}), 96.6, 118.8, 123.4, 127.0, 128.1, 131.3 (broad, 1 C), 134.5 (broad, 1 C), 138.0, 142.5, 152.9 , 159.0 , 220.3 (1 C, Mn-*CO*), 229.3 (1 C, Mn-*CO*), 231.0 (1 C, Mn-*CO*), 234.1 (broad, 3 C, Cr-*CO*). − $C_{25}H_{16}CrMnNO_7$ (549.34): calcd. C 54.66, H 2.94, N 2.55; found C 54.82, H 2.92, N 2.51.

[2-{2',3',4',5',6'-η⁵-[1'(α-methoxy-benzylidene-κC^α)cyclohexadienyl-κC1']tricarbonylchromium},3-methylpyridine-κN]tricarbonylmanganese(Cr−Mn) (**4b**): Complex **2b** (387 mg, 0.82 mmol) in 10 ml of DME at −50°C. Addition of PhLi (0.50 ml, 0.90 mmol), MeOTf (0.12 ml, 1.08 mmol). Chromatography on SiO_2 with CH_2Cl_2/hexane (7:3). Evaporation of the solvents gave 323 mg of **4b** (70%) as red crystals, m.p. 210°C (decomposition). − IR (CH_2Cl_2): $\tilde{\nu}$ = 2009, 1960, 1927, 1884 cm^{-1}. − MS (EI): *m/z* = 562.9 $[M]^+$, 507.0 $[M - 2\ CO]^+$, 479.1 $[M - 3\ CO]^+$, 395.1 $[M - 4\ CO - Mn]^+$, 340.1, 310.1, 257.2. − ^1H NMR (C_3D_6O): δ = 1.86 (s, 3 H, Me), 3.33 (s, 3 H, OMe), 4.43 (dd, ^3J = 7.4 Hz ^4J = 1.1 Hz, 1 H, H_{ArCr}), 4.74 (dd, ^3J = 6.2 Hz ^4J = 1.2 Hz, 1 H, H_{ArCr}), 5.49−5.54 (m, 1 H, H_{ArCr}), 6.60−6.70 (m, 2 H), 6.98−7.05 (m, 3 H), 7.21 (broad, 1 H, H_{Ar}), 7.37 (broad, 1 H), 7.85 (broad, 1 H), 7.88 (d, *J* = 5.5 Hz, 1 H). − ^{13}C NMR (CD_2Cl_2): δ = 21.2 (Me), 56.7 (OMe), 82.0 (C_{ArCr}), 85.5 (C_{ArCr}), 87.0 (C_{ArCr}), 90.9 (C_{ArCr}), 91.2 (C_{ArCr}), 93.0 (C_{ArCr}), 100.4 124.3, 128.8, 129.6, 130.0 132.5, 133.8, 135.0, 141.9, 144.3, 152.2, 157.7, 222.0 (1 C, Mn-*CO*), 231.4 (1 C, Mn-*CO*), 232.6 (1 C, Mn-*CO*), 236.5 (broad, 3 C, Cr-*CO*). − $C_{26}H_{18}CrMnNO_7$ (563.36): calcd. C 55.43, H 3.22, N 2.49; found C 56.71, H 2.83, N 2.45.

[2-{2',3',4',5',6'-η⁵-[1'(α-methoxybenzylidene-κC^α)cyclohexadienyl-κC^1']tricarbonylchromium}quinoline-κN]tricarbonylmanganese(Cr-Mn) (**4c**): Complex **2c** (226 mg, 0.44 mmol), PhLi (0.27 ml, 0.49 mmol), MeOTf (0.10 ml, 0.90 mmol). Chromatography on SiO_2 with CH_2Cl_2/hexane (5:5). Evaporation of the solvents gave 119 mg of **4c** (45%) as red crystals, m.p. 190°C (decomposition). − MS (EI): *m/z* 599.0 $[M]^+$, 542.9 $[M - 2\ CO]^+$, 433.1 $[M - 3\ CO - Cr]^+$, 372.9, 344.9, 293.2. − IR (CH_2Cl_2): $\tilde{\nu}$ = 2009, 1960, 1927, 1885 cm^{-1}. − ^1H NMR (CD_2Cl_2): δ = 3.34 (s, 3 H, OMe), 4.25 (dd, ^3J = 6.1 Hz ^4J = 1.4 Hz, 1 H, H_{ArCr}), 4.37 (dd, ^3J = 7.5 Hz ^4J = 0.9 Hz, 1 H, H_{ArCr}), 5.23−5.26 (m, 1 H, H_{ArCr}), 6.36 (d, *J* = 8.5 Hz, 1 H, H_{Ar}), 6.40 (td, ^3J = 6.1 Hz ^4J = 0.9 Hz, 1 H, H_{ArCr}), 6.57 (broad, 1 H, H_{Ar}), 6.85−6.87 (m, 1 H, H_{Ar}), 7.06 (broad, 1 H, H_{Ar}), 7.32 (broad, 1 H, H_{Ar}), 7.43 (broad, 1 H, H_{Ar}), 7.48−7.51 (m, 3 H), 7.87−7.91 (m, 1 H), 8.46−8.48 (m, 1 H). − ^{13}C NMR (CD_2Cl_2): δ = 55.4 (OMe), 81.2, 81.9, 85.1, 88.3, 90.9, 91.7, 96.9, 116.7, 127.4−129.0 (m, 8 C), 132.6, 134.2, 139.6, 142.1, 147.8, 160.6, 221.0 (1 C, Mn-*CO*), 231.8 (2 C, Mn-*CO*), 234.9 (broad, 3 C, Cr-*CO*). − $C_{29}H_{18}CrMnNO_7$ (599.40): calcd. C 58.11, H 3.03, N 2.34; found C 58.31, H 2.92, N 2.28. − High-resolution MS (EI) for $C_{29}H_{18}CrMnNO_7$: calcd. 598.986921; found (deviation) 598.98786 (1.4 ppm).

Isolation and Spectroscopic Characterization of Complex **3a**-PPN: A THF solution of complex **2a** was combined with a solution of phenyllithium in hexane at −50°C. The resulting dark orange solution was warmed to −20°C after 40 min and evaporated. The resulting oily residue was triturated with hexane. The supernatant was removed and the air and temperature sensitive solid residue dried under vacuum and added with PPN^+Cl^-. The solid mixture was dissolved in a minimum amount of dichloromethane. A few drops of diethyl ether were added to the solution in order to induce the precipitation of LiCl and the mixture filtered through celite. The filtrate was then evaporated under vacuum and the oily redish

Table 3. Details of data collection and refinement for compounds **4b** and **4c**

residue washed twice with diethyl ether to induce crystallization of **3a**-PPN. Elemental analysis of the latter did not provide satisfactory values due to fast decomposition during the sample preparation process. – IR (CH_2Cl_2): $\tilde{\nu}$ = 1972 (m), 1930 (m), 1844 (vs), 1558 (w) cm^{-1}. – ^1H NMR (CD_2Cl_2): 5.23 (t,1 H), 5.36 (t, 1 H), 5.95 (d, 1 H), 6.27 (d, 1 H), 6.95–7.19 (m, 6 H), 7.16–7.71 (m, 32 H), 8.90 (d, 1 H). – ^{13}C NMR (CD_2Cl_2): 90.8 (C_{ArCr}), 91.2 (C_{ArCr}), 93.3 (C_{ArCr}), 105.8, 118.6, 121.2, 123.7 , 126.3 , 126.9, 127.1, 127.7, 129.8 (m, PPN^+), 132.4 (m, PPN^+), 134.0 (s, PPN^+), 135.3, 153.0, 154.8, 164.3, 164.8, 168.8, 219.7 (Mn-*CO*), 222.9 (Mn-*CO*), 231.1 (Mn-*CO*), 237.5 (Cr-*CO*), 289.5 (Ph*CO*-Mn).

Procedure for the Structure Determination of **4b** *and* **4c**: The molecular structures of **4b** and **4c** were solved by direct methods (SHELXTL-Plus)[28]. The non hydrogen atoms were refined anisotropically on F^2 (SHELXL-93)[29]. Hydrogen atoms were refined isotropically using a riding model. An empirical absorption correction was applied (**4b**: $T_{max./min.}$ = 0.4956/0.4442, **4c**: $T_{max./min.}$ = 0.7996/0.6693). In **4b** the solvent is disordered. Further details are given in Table I. Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication no. CCDC-101430. Copies of the data can be obtained free of charge on application to The Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [Fax: int. code +44 (1223) 336–033; e-mail: deposit@ccdc.cam.ac.uk].

Keywords: *p*-Ethynylphenylalanine / Alkyne-bridged α-amino acids / N,O-Chelate complexes / Ferrocenes / Schiff bases / Platinum / Gold

The palladium-mediated coupling of *p*-ethynylphenylalanine (*p*-epa) with different halogenated benzenes yielded alkyne-bridged α-amino acids. A series of cationic mono- to hexanuclear $(Ph_3P)_2Pt$ complexes with the anions of *p*-ethynylphenylalanine and alkynyl- or benzene-bridged di-, tri-, tetra- and hexa-ethynyl phenylalanines as N,O-chelate ligands was prepared. *N*-*t*-Boc-*p*-ethynylphenylalanine methyl ester was metal-substituted to give complexes of the types $Ph_3PAu\text{-}C{\equiv}C\text{–}R$ and $(Et_3P)_2Pt(C{\equiv}CR)_2$. The benzene-bridged di-, tri-, tetra- and hexa-*p*-ethynylphenylalanine methyl esters form Schiff bases with ferrocene aldehyde and a tripodal ligand was obtained from $Ph_2PCH_2CH_2CH_2NH_2$ and the benzene-bridged triethynylphenyl-alanine. The structure of $(Ph_3P)_2Pt[NH_2C(H)(CH_2C_6H_4C{\equiv}CH)CO_2]^+\ BF_4^-$ was determined by X-ray diffraction.

Non-proteinogenic amino acids influence the biological properties of peptides and are useful for the synthesis of peptidomimetics[3]. The synthesis of unnatural amino acids is based either on electrophilic[4] or nucleophilic[5] equivalents. A valuable building block for the derivatization of phenylalanines has been developed by Schwabacher et al.[6]. *p*-Iodophenylalanine was used as starting material to build, under palladium catalysis, amino acids which are bridged by a heteroatom[6] or the iodo substituent was replaced by sulfur-containing fragments or trimethyltin[7]. The palladium-mediated coupling of terminal acetylides with *p*-iodophenylalanine afforded fluorescent marker molecules[8a], which find growing attention in organometallic chemistry[8b-e]. Undheim et al. and Savi et al. reported the Pd-catalyzed synthesis of a series of α,α′-hydrocarbon bis(α-amino acids), including α,α′-alkynyl-bridged bis(glycines) and of alkyne−bridged oxazolidines[9].

By means of the Heck[10], especially the Sonogashira reaction[11], we were able to synthesize various acetylide-bridged phenylalanines[12a]. *p*-Ethynylphenylalanine was proven to be a potent inhibitor of the enzyme tryptophan-hydroxylase[13]; therefore structural details of this compound appear of interest. The bis-, tris-, tetra- and hexapodal[12b] amino acids should be useful starting compounds in peptide chemistry, for the synthesis of organic as well as metallo-dendrimers[14], and for linearly-bridged metal complexes with unusual optical or electrical properties[15]. The scope of organometallic complexes of α-amino acids and peptides has been recently reviewed[16].

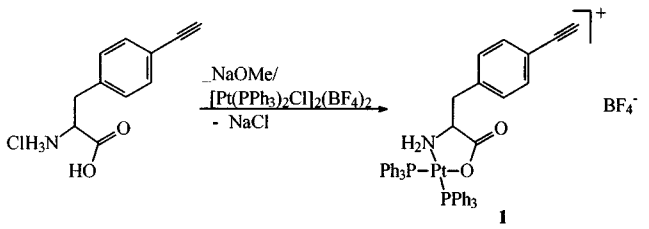
In this paper we wish to present the coordination chemistry of the new amino acid derivatives.

[◇] For part CVII see ref.[1].

Results and Discussion

Chloro-bridged metal complexes have proven to be ideal starting materials for the synthesis of N,O-α-aminocarboxylate metal compounds[16]. We have chosen the chloro-bridged complexes $[(Ph_3P)_2Pt(\mu\text{-}Cl)_2Pt(PPh_3)_2]^{2+}$, $(Et_3P)(Cl)Pd(\mu\text{-}Cl)Pd(Cl)(PEt_3)$ and $Cp^*(Cl)Rh(\mu\text{-}Cl)_2Rh(Cl)Cp^*$ from which N,O-chelates with natural α-amino acids have been obtained in our group.[16][17][18][19]

The reaction of the chloro-bridged cationic complex $\{[(Ph_3P)_2Pt(\mu\text{-}Cl)]_2\}\{BF_4\}_2$ with the anion of *p*-ethynylphenylalanine yielded the cationic N,O-chelate **1**.



1

Suitable crystals for structure determination by X-ray diffraction of **1** were obtained by liquid-liquid diffusion of diethyl ether into an methanolic solution of **1** at room temperature. By this means the structure of the new non-proteinogenic amino acid *p*-ethynylphenylalanine (*p*-epa)[12a] has been established. The Pt−ligand atom distances are close to those of similar complexes, e.g. $(nBu_3P)(Cl)Pt(O_2CCH_2N{=}C(H)NMe_2)$[20a], (dppe)Pt[N(COMe)$CH_2$-$CO_2$][20b] and $(Ph_3P(Cl)Pt(NH_2CMe_2CO_2)$[20c].
The bond angle C11−C10−C7 is not exactly linear.

The analogous reactions of bis-, tris-, tetra- and hexa-ethynylphenylalanine derivatives gave the cationic complexes **2**−**7**.

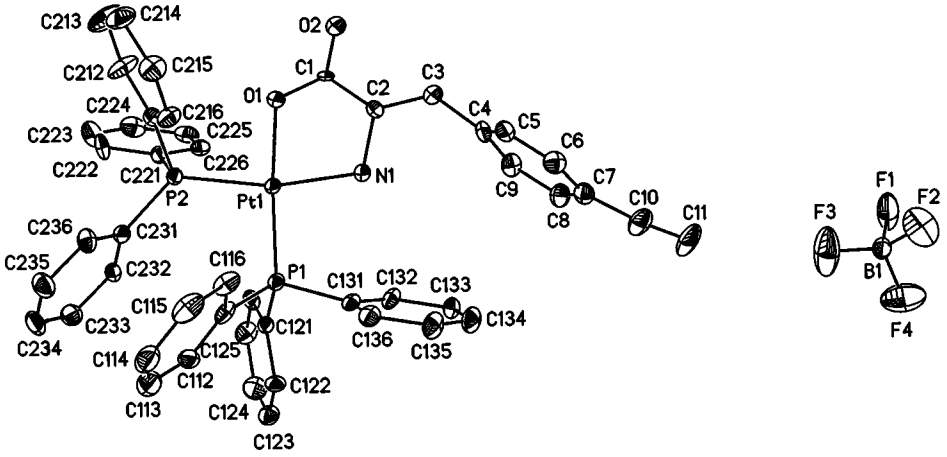
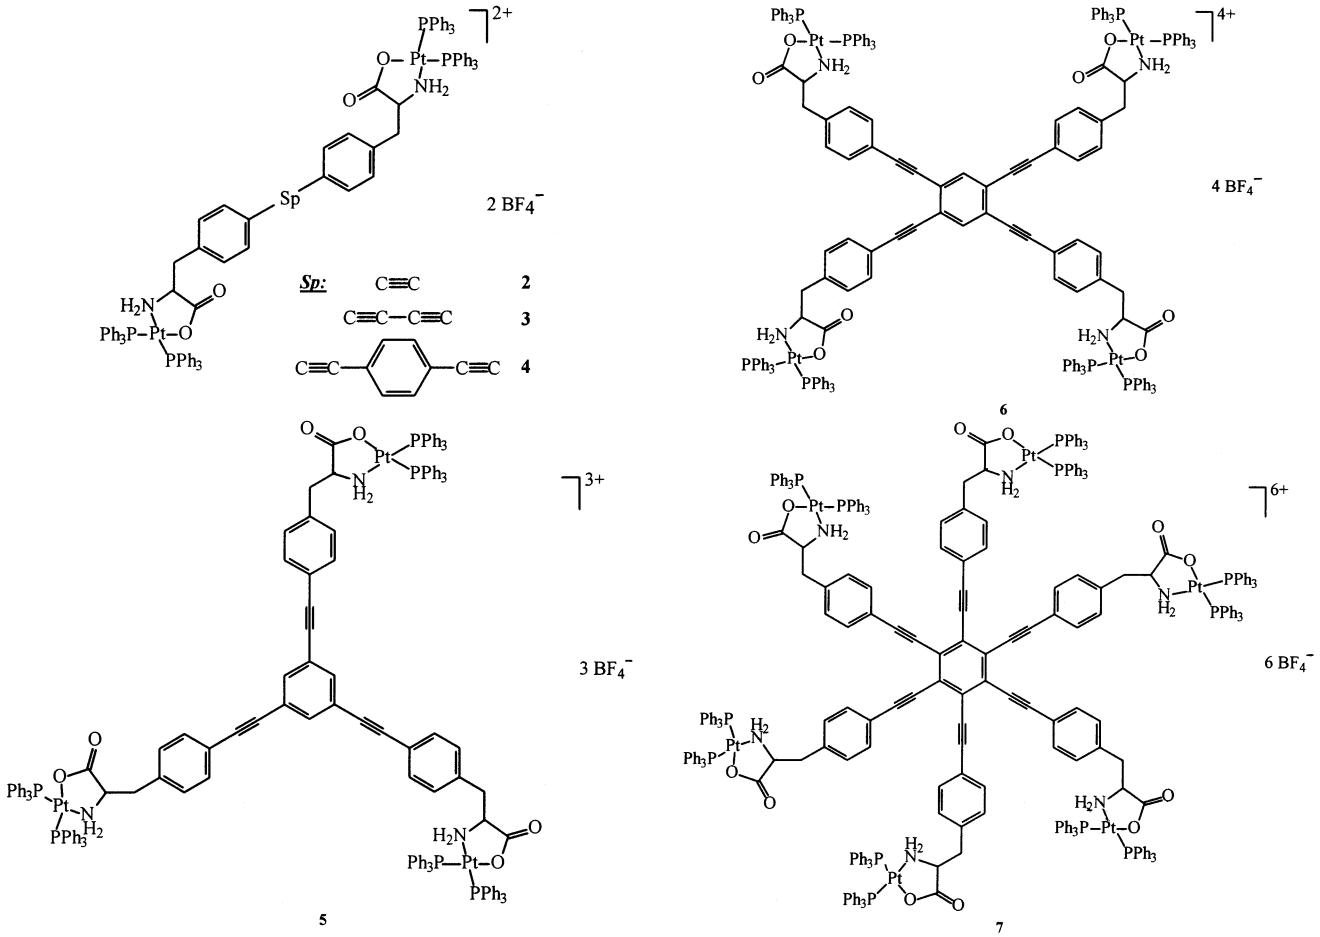
Figure 1. Structure of complex **1**[a]

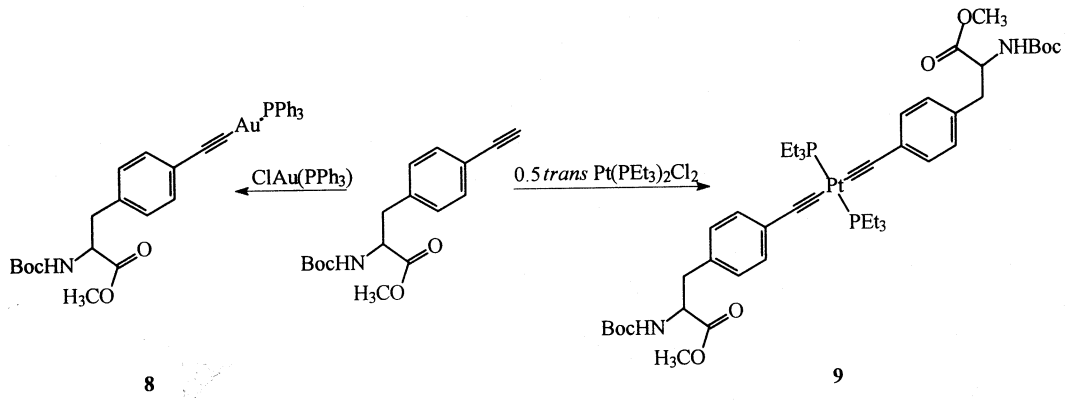


[a] Selected bond lengths [pm] and angles [°]: Pt−P1 225.3 (2), Pt−P2 225.8 (2), Pt−N1 209.5 (8), Pt−O1 207.1 (7), C10−C11 117.2 (17); N1−Pt−P2 165.9 (2), N1−Pt−P1 95.0 (2), O1−Pt−N1 81.0 (3), O1−Pt−P2 85.18 (19), C7−C10−C11 173.1 (16).

The IR spectra of the compounds **2**−**7** exhibit characteristic absorptions for η^2-coordinated α-amino carboxylates at $\nu \approx 1675\ cm^{-1}$ next to the ν(C≡C) vibrations at $\nu \approx 2205\ cm^{-1}$. The high symmetry of **2**−**7** is manifested in the ^{1}H- and ^{13}C-NMR spectra. Only one set of signals is observed. The ^{31}P-NMR spectra show a set of double doublets due to the different ligands *trans* to the P atoms with corresponding platinum satellites (^{195}Pt- ^{31}P coupling).

Terminal acetylide functions in organic molecules have successfully been used to build metal acetylide complexes which are also of interest for nonlinear optics. On the other hand the metal atom of bis(acetylide) complexes can func-



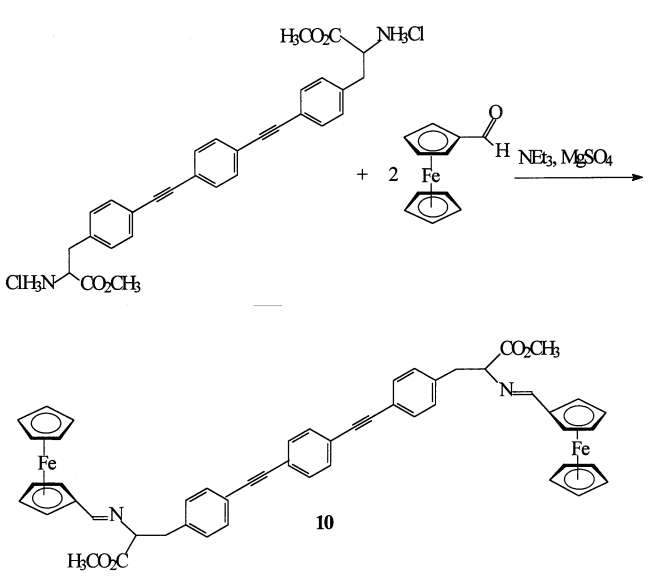


8 **9**

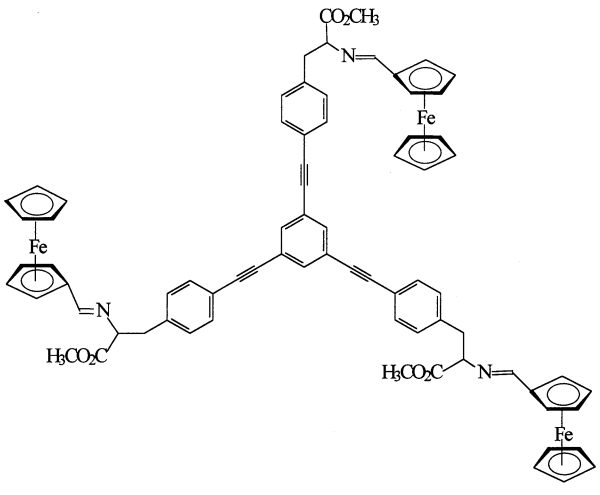
tion as a linker and support the conjugation of biological molecules[21]. Following known procedures[22] *p*-epa was treated with Ph_3PAuCl and *trans*-$(Ph_3P)_2PtCl_2$ to yield the compounds **8** and **9**.

Complexes **8** and **9** were characterized by IR-, ^1H-, ^{13}C- and ^{31}P-NMR spectroscopy. For **9** the characteristic $\nu(C{\equiv}C)$ absorption is found at 2103 cm^{-1}. The other spectroscopic data could be compared to similar known compounds[22].

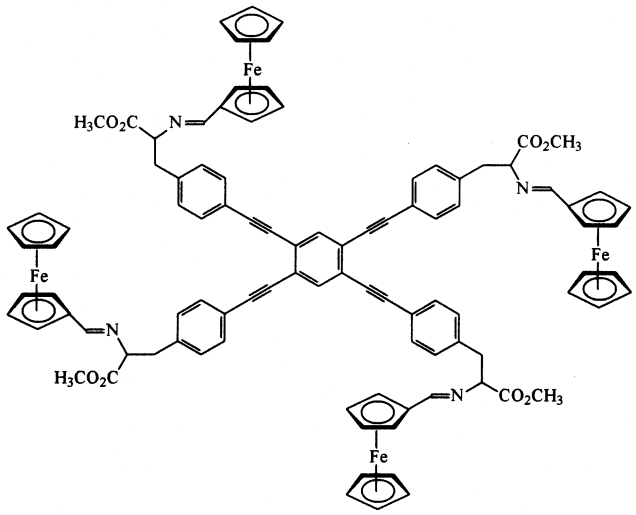
Ferrocenyl Schiff base complexes of amino acids find application as lipophilic and chromophoric groups for masking of peptide bonds[23a]. Also interactions of the redoxac-



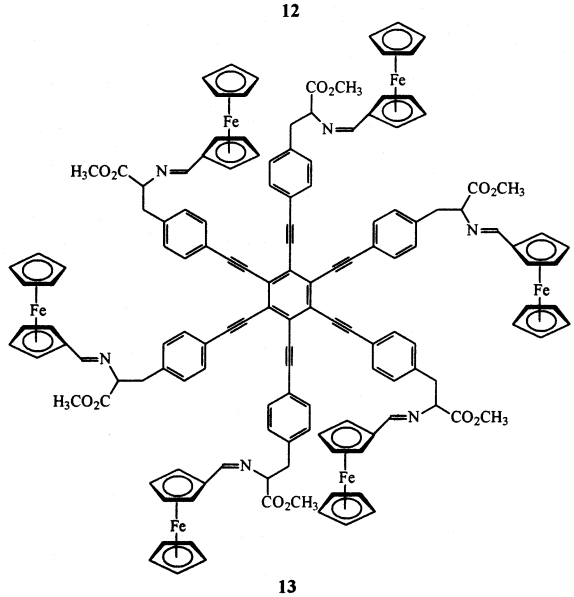
10



11



12

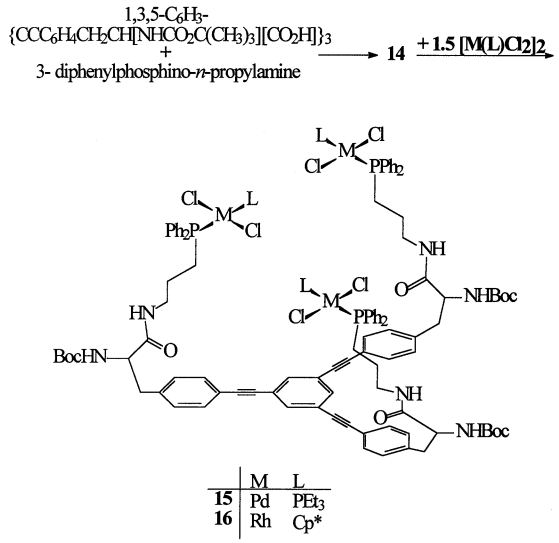


13

tive ferrocenyl unit and redoxactive enzymes are objects of investigations[23b]. The condensation between ferrocenecarbaldehyde and the corresponding phenylalanine esters afforded the orange Schiff base complexes **10**−**13**. For recent examples of star-shaped metal complexes derived from 1,3,5-triethynylbenzene as in **5** and **11** see ref.[24].

The successful formation of the Schiff base is proven by the intense ν(C=N) IR absorption band at 1636 cm^{-1} and by the imine proton signal (δ ≈ 7.90) in the ^{1}H-NMR spectrum. The ^{1}H-NMR signal of the H atom at α-C was not observed. A correlated ^{1}H/^{1}H-NMR experiment showed that the α-proton has the same chemical shift as the OCH_3 group of the methyl ester.

Using common methods of peptide chemistry the tripodal tris amino acid was derivatized and treated with 3-diphenylphosphanyl-*n*-propylamine to give the tripodal phosphane ligand **14** which may function as a tridentate chelate ligand. The reaction of **14** with 0.5 equivalents of $[Rh(COD)Cl]_2$ (COD = 1,5-cyclooctadiene) gave no defined compound, probably because the phosphane groups are not pre-organized. On the other hand the reactions of **14** with 1,5 equivalents of $[(Et_3P)PdCl(\mu\text{-}Cl)]_2$ or [Cp* $RhCl(\mu\text{-}Cl)]_2$ (Cp* = pentamethylcyclopentadienyl) yielded the three core complexes **15** and **16**.



The ^{31}P-NMR spectrum of **15** shows several signal sets due to *cis* and *trans* isomers with the most intensive one having a coupling constant of 538 Hz. This coupling constant is typical for *trans*-situated phosphanes[25]. In contrast, compound **16** is formed as one isomer with a doublet in the ^{31}P-NMR spectrum due to the $^1J_{Rh\text{-}P}$ coupling of 143 Hz.

Experimental Section

General: All reactions were carried out in dry solvents under argon. − NMR: Jeol GSX 270 (^{1}H 270.0; ^{13}C 67.9; ^{31}P 109.3 MHz). Tetramethylsilane as internal standard; H_3PO_4 (85%) as external standard. − IR: 5ZDX FT-IR. − $ClAu(PPh_3)$[26], *trans*-$Pt(PEt_3)_2Cl_2$ [27a], $\{[(Ph_3P)_2Pt(\mu\text{-}Cl)]_2\}\{BF_4\}_2$ [28], $[(Et_3P)PdCl(\mu\text{-}Cl)]_2$ [27b], [Cp* $RhCl(\mu\text{-}Cl)]_2$ [29], 3-diphenylphosphanyl-*n*-propylamine[30] and the acetylide-substituted phenylalanines were prepared according to literature procedures[12]. Formylferrocene was purchased from Fluka and stored in the dark under argon.

$\{(Ph_3P)_2Pt[(NH_2)(O_2C)CHCH_2C_6H_4C{\equiv}CH]\}BF_4$ (**1**): To a solution of 34 mg (0.15 mmol) of *p*-ethynylphenylalanine hydrochloride in 10 ml of methanol was added 0.30 mmol of NaOMe and the mixture was stirred for 5 min. at room temperature. After addition of a solution of 120 mg (0.075mmol) of $\{[(Ph_3P)_2Pt(\mu\text{-}Cl)]_2\}\{BF_4\}_2$ in 10 ml of dichloromethane, the mixture was stirred for additional 3 h. The volatiles were evaporated, the residue was washed two times with 5 ml of water and dried at 50°C in vacuo. The resulting powder was finally recrystallized several times from dichloromethane/diethyl ether. Yield 121 mg (81%), colorless powder, m.p. 250°C (decomp.). − IR (KBr): $\tilde{\nu}$ = 3295 cm^{-1} m (NH_2), 1654 s (CO_2), 1084 s (BF_4). − ^{1}H NMR ($CDCl_3$): δ = 2.85 (dd, ^2J = 14.6 Hz, ^3J = 3.4 Hz, 1 H, CH′H), 3.13 (dd, ^2J = 14.6 Hz, ^3J = 7.5 Hz, 1 H, CHH′), 3.16 (s, 1 H, CH), 3.19−3.30 (m, 1 H, CH), 3.98−4.12 (m, 2 H, NH_2), 6.95 (d, ^3J = 8.1 Hz, 2 H, C_6H_4), 7.15−7.50 (m, 32 H, C_6H_4, PPh_3). − ^{13}C NMR ($CDCl_3$): δ = 38.90 (CH_2), 56.58 (CH), 77.76 (C≡*C*H), 83.41 (*C*≡CH), 120.85, 125.33 (d, ^1J = 84.1 Hz, *i*-PPh_3), 126.38 (d, ^1J = 83.5 Hz, *i*-PPh_3), 128.61 (d, ^3J = 11.4 Hz, *m*-PPh_3), 129.17 (d, ^3J = 11.5 Hz, *m*-PPh_3), 129.60, 131.66 (d, ^4J = 2.3 Hz, *p*-PPh_3), 132.21 (d, ^4J = 2.2 Hz, *p*-PPh_3), 132.66, 133.91 (d, ^2J = 10.8 Hz, *o*-PPh_3), 134.59 (d, ^2J = 10.6 Hz, *o*-PPh_3), 136.91, 182.94 (CO_2). − ^{31}P NMR ($CDCl_3$): δ = 7.70 (d, ^2J = 24.3 Hz, ^1J = 3586 Hz), 8.54 (d, ^2J = 24.3 Hz, ^1J = 3484 Hz). − $C_{47}H_{40}BF_4NO_2P_2Pt$ (994.7): calcd. General Procedure for the Preparation of the Complexes **15** *and* **16**: To a solution of 81 mg (0.05 mmol) of ligand **14** in 10 ml of dichloromethane were added 45 mg of [(Et_3P)PdCl(µ-Cl)]$_2$ or 46 mg of [Cp*RhCl(µ-Cl)]$_2$ (0.075 mmol each). The solutions were stirred at room temp. for 16 h, concentrated in vacuo and the residues were washed with 10 ml of diethyl ether and 30 ml of pentane.

1,3,5-C_6H_3{C≡C$C_6H_4CH_2CH[NHCO_2C(CH_3)_3][CO_2$-$(CH_2)_3PPh_2]Pd(PEt_3)(Cl)_2\}_3$ (**15**): Yield 123 mg (98%), yellow powder, m.p. 183°C (decomp.). − IR (KBr): $\tilde{\nu}$ = 3428 cm^{-1} m (NH), 2213 (C≡C), 1713, 1677 s (CON), 354, 329 w (Pd−Cl). − ^{1}H NMR ($CDCl_3$): δ = 0.93 (dt, $^3J_{PH}$ = 17.8 Hz, $^3J_{HH}$ = 7.7 Hz, 27 H, CH_3, B), 1.16 (dt, $^3J_{PH}$ = 16.5 Hz, $^3J_{HH}$ = 7.5 Hz, 27 H, CH_3, A), 1.37 (s, 18 H, CH_3, A+B), 1.51−1.65 (m, 6 H, CH_2, A+B), 1.81−1.95 (m, 18 H, CH_2, A+B), 2.14−2.32 (m, 6 H, CH_2, A+B), 2.89−3.41 (m, 12 H, CH_2, A+B), 4.25−4.40 (m, 3 H, CH, A+B), 5.09 (d, ^3J = 6.8 Hz, 3 H, NH, A+B), 6.52 (t, ^3J = 5.0 Hz, 3 H, NH, A+B), 7.19 (d, ^3J = 8.2 Hz, 4 H, C_6H_4), 7.29−7.84 (m,

39 H, C_6H_4, C_6H_3, PPh_2). – ^{13}C NMR ($CDCl_3$): δ = 8.23, 8.60 (d, ^2J = 1.5 Hz; 3.2 Hz, CH_3, A+B), 14.33 (dd, ^1J = 25.7 Hz, ^3J = 3.1 Hz, CH_2, A), 16.70 (d, ^1J = 30.4 Hz, CH_2, B), 21.99 (d, ^1J = 27.8 Hz, CH_2, A+B), 24.00 (CH_2, A+B), 28.26 [$C(CH_3)_3$, A+B], 39.20 (CH_2, A+B), 39.74 (d, ^2J = 14.4 Hz, CH_2, A+B), 55.64 (CH, A+B), 79.83 [$C(CH_3)_3$, A+B], 87.77, 90.55 (C≡C, A+B), 121.07, 124.02, 128.39–133.69 (m, 6 C, C_6H_4, C_6H_3, PPh_2, A+B), 133.95, 137.93, 155.12 (CON, A+B), 170.93 (CON, A+B). – ^{31}P NMR ($CDCl_3$): δ = 11.37 (d, $^2J_{trans}$ = 538 Hz), 14.85 (d, $^2J_{cis}$ = 234 Hz), 25.09 (d, $^2J_{trans}$ = 538 Hz), 30.15 (d, $^2J_{cis}$ = 234 Hz). – $C_{117}H_{150}Cl_6N_6O_9P_6Pd_3$ (2502.3): calcd. C 56.16, H 6.04, N 3.36; found C 56.51, H 5.95, N 3.34.

1,3,5-C_6H_3{C≡$CC_6H_4CH_2CH[NHCO_2C(CH_3)_3][CO_2(CH_2)_3PPh_2]Rh(Cp^*)(Cl)_2$}$_3$ (**16**): Yield 123 mg (97%), orange powder, m.p. 209°C (decomp.). – IR (KBr): $\tilde{\nu}$ = 3341 cm^{-1} m (NH), 2213 (C≡C), 1713, 1674 s (CON). – ^1H NMR ($CDCl_3$): δ = 1.29 (s, 18 H, CH_3), 1.31 (s, 15 H, CH_3), 1.42–1.58 (m, 6 H, CH_2), 2.47–3.19 (m, 18 H, CH_2), 4.29 (pq, ^3J = 6.7 Hz, CH), 5.13–5.37 (m, 3 H, NH), 6.24–6.46 (m, 3 H, NH), 7.18 (d, ^3J = 7.6 Hz, 6 H, C_6H_4), 7.32 (d, ^3J = 7.6 Hz, 6 H, C_6H_4), 7.38–7.52 (m, 18 H, PPh_2), 7.58 (s, 3 H, C_6H_3), 7.69–7.86 (m, 12 H, PPh_2). – ^{13}C NMR ($CDCl_3$): δ = 8.62 (Cp^*), 23.48 (CH_2), 26.74 (d, ^1J = 28.7 Hz, CH_2), 28.20 [$C(CH_3)_3$], 38.68 (CH_2), 39.86 (d, ^2J = 13.4 Hz, CH_2), 55.34 (CH), 79.57 [$C(CH_3)_3$], 87.51, 90.69 (C≡C), 98.69 (dd, J_{PC} = 6.7 Hz, J_{RhC} = 2.4 Hz, cp^*), 120.72, 124.11, 128.35 (dd, J_{PC} = 9.8 Hz, J_{RhC} = 3.9 Hz, PPh_2), 129.62, 130.89 (d, J_{PC} = 12.3 Hz, PPh_2), 131.53, 133.28 (d, J_{PC} = 9.6 Hz, PPh_2), 133.67, 133.92 (d, J_{PC} = 9.0 Hz, PPh_2), 138.38, 155.19 (CON,), 170.01 (CON). – ^{31}P NMR ($CDCl_3$): δ = 27.34 (d, J_{RhP} = 143 Hz). – $C_{129}H_{150}Cl_6N_6O_9P_3Rh_3 \times CH_2Cl_2$ (2627.9): calcd. C 59.42, H 5.83, N 3.19; found C 59.59, H 6.08, N 3.10.

X-ray-Structural Determination of **1**: $C_{47}H_{40}BF_4NO_2P_2Pt$, MW = 994.64, crystal size 0.15 × 0.15 × 0.1mm^3. The slightly yellow prism was covered with perfluoropolyether oil, mounted on a glass fiber and centered at 183(2) K. All reflections in the range 2 θ = 13.7–49.4° (index ranges $-33 < h < 33$, $-33 < k < 33$, $-10 < l < 17$) were measured by using a Siemens P4 diffractometer equipped with a CCD area detector. Hexagonal, space group $R3$, a = 28.708(5), b = 28.708(5), c = 14.458(3) Å, V = 10320(4) Å^3, Z = 9, d(calcd.) = 1.440 Mg/m^3, = 3.182 mm^{-1}, F(000) = 4446, independent reflections 6091 [R(int) = 0.0534], 5890 observed with $I > 4\,\sigma(I)$; at semiempirical absorption correction, max./min. transmission 0.972/0.698. The structure was solved by the heavy-atom method, and the non-hydrogen atoms were refined anisotropically. H atoms in calculated positions were included – the final refinement against F^2 using a riding model (SHELX93 programs). 523 variables, $R1$ = 0.0408, $wR2$ = 0.1015, largest residual peak: 2.624 e/Å^3 close to Pt.

Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Center as supplementary publication no. CCDC-102301. Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [fax: (+44)1223-336-033; e-mail: deposit@ccdc.cam.ac.uk].

☆ Dedicated to Professor *Meinhart Zenk* on the occasion of his 65th birthday.

Received July 3, 1998

Keywords: Atom-transfer polymerisation / Methyl methacrylate / Copper(I) / Schiff base

The synthesis and characterisation of a series of novel bis(imine)copper(I) complexes and their use in atom-transfer polymerisation of methyl methacrylate is described. Several *N*-alkyl-(2-pyridyl)methanimines (alkyl = *n*-butyl, isobutyl, *sec*-butyl, *n*-propyl) and *N*-(*n*-propyl)-1-(2-pyridyl)ethanimine as ligands have been fully characterised. Three bis[*N*-alkyl-(2-pyridyl)methanimine]copper(I) complexes, $[Cu\{(C_5H_4N)CH=N(iBu)\}_2][BF_4]$, $[Cu\{(C_5H_4N)C(CH_3)=N(nPr)\}_2][PF_6]$, and $[Cu\{(C_5H_4N)CH=N(sBu)\}_2][BF_4]$ have been structurally characterised; all having a distorted tetrahedral arrangement of co-ordinating nitrogen atoms surrounding the metal centre. All of the catalysts were found to be effective atom-transfer polymerisation catalysts for the polymerisation of MMA in hydrocarbon solution. However, it was discovered that the performance of the catalysts containing *n*-alkyl substituents was superior to those containing branched alkyl substituents. The presence of branching in the alkyl substituent results in a reduction of reaction rate and a corresponding broadening of the polydispersity index.

Introduction

Copper complexes containing chelating bis(imine) ligands are used increasingly as catalysts for a wide range of synthetic organic reactions.[1] Chiral ligands, in particular, are finding use in asymmetric organic catalysis,[2] such ligands being simply prepared from commercially available, and enantiomerically pure, primary amines. Atom-transfer addition, ATA, a technique used to effect organic transformation reactions, utilises transition-metal complexes[3] to promote carbon−carbon bond formation.[4] Transition-metal complexes able to function as halogen carriers with an available $n+1$ oxidation state, e.g. Cu^{I}/Cu^{II} are typical catalysts for ATA.

Recently, this chemistry has been extended and modified for use in polymerisation reactions. The groups of Matyjaszewski[5a][5b][5c][5d] and Sawamoto,[5e][5f][5g][5h] working independently from each other have reported the use of transition-metal-mediated polymerisation derived from the ATA reaction. It is believed that the mechanism of atom-transfer polymerisation depends upon the formation of a favourable equilibrium, shown in Scheme 1, where: R_n-X represents both the initiator and dormant polymer chain, X and X′ halogen atoms, L_m an unspecified, *m*, number of donor ligands and $R^{\bullet}$ represents both the initiating species and the propagating polymeric radical. The position of the equilibrium is pivotal to the control of the polymerisation reaction; easily oxidised complexes, i.e. catalysts having a too stable $n+1$ oxidation state, cause a movement to the right of the equilibria, ultimately resulting in a relatively high concentration of free radicals. At high free-radical concentration termination occurs by radical−radical combination and/or disproportionation, which results in a lack of control over the polymerisation and results in polymer having an increased polydispersity index, PDI, and ultimately loss of the linear relationship between the number-average molecular mass, M_n, and the ratio of monomer to initiator which is observed for *living polymerisation*. Conversely, if the metal complex is unable to increase its oxidation number then the equilibria will lie far to the left and the rate of polymerisation reaction will be too slow to lead to useful products on a sensible time-scale. Propagation of the polymerisation takes place from, an as yet, undetermined active centre. The active centre is either a carbon-centred free radical or a metal-complexed radical, or insertion at the metal centre takes place. At present a free-radical process is preferred by most authors but the exact mechanism is proving very difficult to determine unequivocally.

Scheme 1

$$R_n-X + [L_mCu(I)X'] \rightleftharpoons [R_n\ldots X\ldots CuL_mX'] \rightleftharpoons R_n^{\bullet} + [XCuL_mX']$$

The ligand choice is considered crucial in controlling the position of the equilibrium either by acting as electron donors, or acceptors, to the metal centre. In systems where copper(I) halides are used the ligand also serves to solubilise the particularly insoluble copper salt, and perhaps more importantly, the low-lying LUMO π* orbital, present in the conjugated π system (N=C-C=N) of the ligand, is able to accept electron density from the metal centre, which is

thought to be central to the action of these particular atom-transfer polymerisation catalysts.

Recently, we have reported on the use of a series of *N*-alkyl-(2-pyridyl)methanimine ligands which, when complexed with copper halides, give rise to highly effective atom-transfer polymerisation catalysts.[6] We have been interested in examining the structure of atom-transfer catalysts with a view to further understanding the mechanism of the reaction. Ultimately, we believe this to help in the optimisation of the ligands/catalysts for each monomer system thus giving greater control over this rapidly emerging polymerisation chemistry. The mode of co-ordination of this type of Schiff base ligand to metal centres in both the solution and solid state has been reported to vary depending upon many variables. Indeed in the case of copper(I) complexes, a simple change in the counter-ion can dramatically alter the nature of the predominant species[7]. Thus, structural determinations may play an important role in elucidating the mechanism of atom-transfer polymerisation. The results presented in this paper show how increasing the steric hindrance in the alkyl group of the imine ligand affects the kinetics of the polymerisation and the dramatic effects these apparently small changes in ligand have on the molecular mass control and molar mass distribution of the resulting poly(methyl methacrylate). Three of the catalysts used in this work have been fully characterised by single-crystal X-ray diffraction. Similar "*living*" polymerisation systems mediated by transition-metal complexes have been reported by a range of other research groups[8].

Results and Discussion

The *N*-alkyl-(2-pyridyl)methanimine ligands, **L1**−**L5** (see Scheme 2), were prepared from the condensation of 2-pyridinecarboxaldehyde (or 2-acetylpyridine in the case of **L5**) with the respective primary amine. Figure 1(a) shows the ^{1}H-NMR spectrum of **L1**, and Figure 1(b) shows the spectrum of the complex between **L1** and CuBr, **C1** (see Scheme 3)[9]. The assignments were made using NOE difference experiments by irradiating at H^6 so as to determine H^4 long−range COSY and ^{1}H-^{13}C heteronuclear correlation. The remaining ring protons were assigned by further decoupling experiments. In solution the ligand can exist in the *trans* conformation; however, on complexation to copper(I) we observe changes in the spectrum associated with the ligand adopting a *cis* conformation. The signal of the imine proton H^6 shifts approximately 0.6 ppm downfield on complexation. Figures 2(a) and 2(b) show the ^{13}C{^{1}H}-NMR spectrum of **L1** and **C1**, respectively. The assignments were made using heteronuclear shift-correlated 2D-NMR experiments. The pair C^5/C^1 changes its relative position whilst C^6 remains at highest field. These proton and carbon ring assignments are applicable to all ligands used in this study.

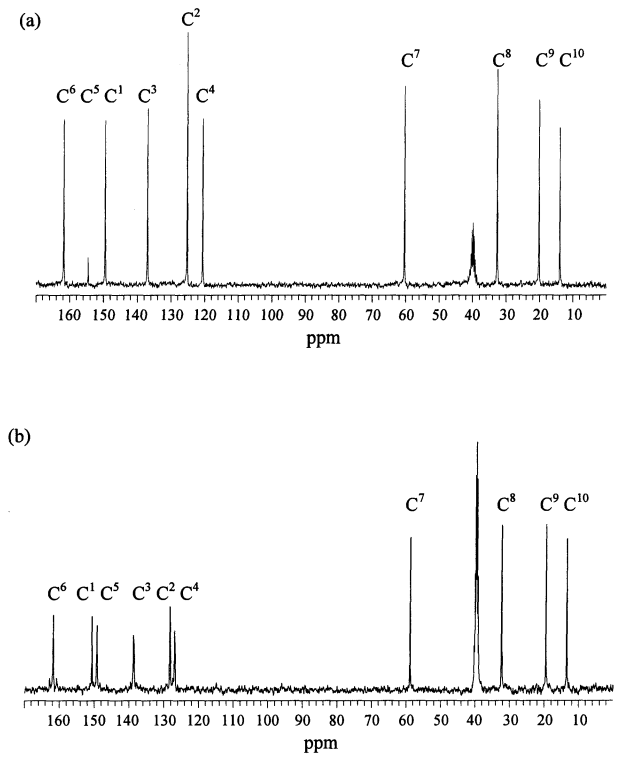
Polymerisation of Methyl Methacrylate Using C1 to C5 as Atom-Transfer Polymerisation Catalysts

Methyl methacrylate was polymerised in xylene solution at 90°C using ethyl 2-bromoisobutyrate as initiator in the

Figure 2. $^{13}C\{^1H\}$-NMR spectrum of (a) the free ligand **L1** and (b) the complex **C1** in [D_6]DMSO; the assignments were made using heteronuclear shift-correlated 2D-NMR experiments; for peak assignments see Figure 1(c)



The effectiveness of the catalysts **C1**−**C5** for promoting controlled atom-transfer polymerisation was determined in three ways: (1) the relationship between the number-average molecular weight (M_n) and conversion to polymer. Living polymerisation processes lead to a linear increase in M_n with conversion.[6b] (2) The polydispersity index, PDI, of the polymer, free-radical polymerisation of methyl methacrylate has a PDI larger than 1.5. (3) The appearance of a first-order rate plot. For a living polymerisation a plot of ln $[M]_0/[M]$ against time gives a linear plot with the gradient equal to the pseudo first-order rate coefficient, k^{app}, which gives an indication of the rate of reaction. k^{app} is defined by Equation 1, where [M] is the monomer concentration, $[M]_0$ is the initial monomer concentration, k_p is the propagation rate coefficient, $[R^\bullet]$ is the concentration of active species, and t is time.

$$\ln [M]_0/[M] = k_p[R^\bullet]t = k^{app}t \quad (1)$$

Figure 3 shows the dependence of the number-average molecular weight (M_n) on polymer conversion for the catalysts **C1**−**C5**. In all cases, M_n increases approximately linearly with conversion, as is expected for a *living* polymerisation. The actual values of M_n are slightly higher than the theoretical line, which suggests that the initiator efficiency is less than unity i.e. the initiator is involved in secondary, as yet undetermined reactions such as coupling of carbon-centred radicals in the initial stages of the reaction. The presence of **C1**−**C5** catalysts (see Scheme 3). The catalysts were prepared in situ by the addition of ligands **L1**−**L5**, respectively, to CuBr in the xylene reaction solution. Polymer conversion and molecular weight data are listed in Table 1.

Table 1. Conversion and molecular-weight data for polymerisations using **C1**−**C5**

Catalyst	Time [min]	Conversion	M_n[a]	M_w[b]	PDI[c]	$M_{n,theo}$[d]	Initiator[e] efficiency	k^{app} [s^{-1}][f]

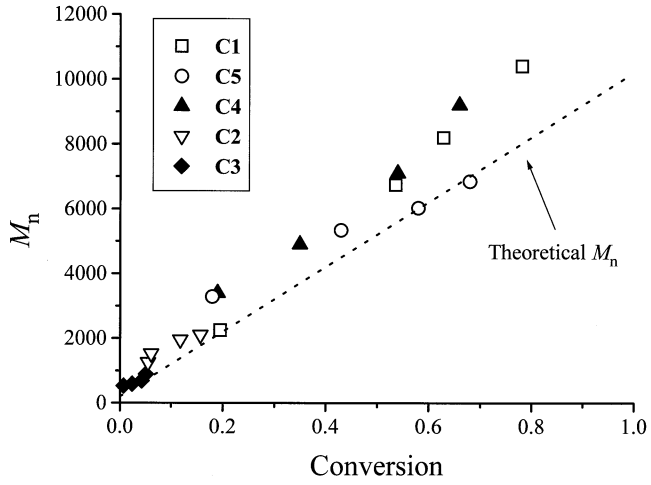
	180	0.58	6030	9280	1.54	5810	0.96	
	240	0.68	6850	10900	1.59	6810	0.99	

[a] Number-average molecular weight. − [b] Weight-average molecular weight. − [c] Polydispersity index = M_w/M_n. − [d] $M_{n,theo}$ = Conversion · [Monomer]/[Initiator]. − [e] Initiator efficiency = $M_{n,theo}/M_n$. − [f] Pseudo first-order rate coefficient determined from the slope of the line of best fit in Figure 4.

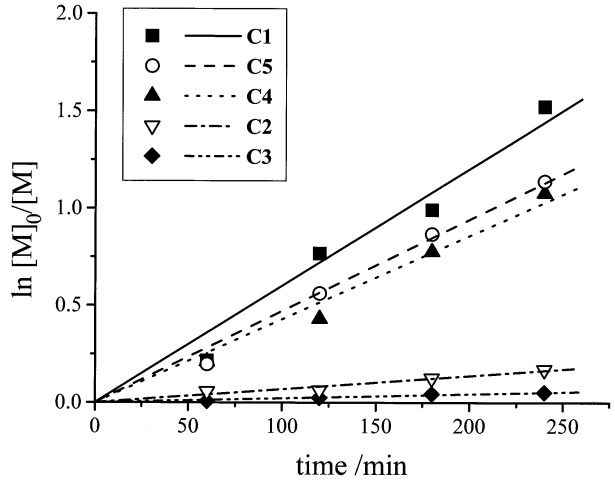
PDIs (Table 1) are narrower for polymer produced using catalysts **C1**, **C3**, and **C4**, than catalysts **C2** and **C5**, which are quite broad for a *living* polymerisation (> 1.5). In general the PDI becomes narrower during the course of the reaction.

Figure 3. Dependence of the number-average molecular weight, M_n, on conversion for polymerisations using catalysts **C1**−**C5**



The first-order rate plots are shown in Figure 4. The lines through the data represent the best fit and correspond to the pseudo first-order rate coefficient, k^{app}. These plots are characteristic of *living* polymerisation;[6b] in all cases the plots are linear, indicating that the number of active species is constant and effects from termination of growing polymer chains by combination/disproportionation or chain transfer are not significant. It is immediately obvious, from Figure 4 and Table 1, that the catalysts **C2** and **C3** give a significantly lower rate of polymerisation (approximately one order of magnitude) than when **C1**, **C4**, and **C5** are used as catalysts . Thus, the catalysts using branched substituents at either the α or β positions in the ligand give significantly lower rates of polymerisation.

Figure 4. First-order log plots for polymerisations using catalysts **C1**−**C5**



Overall, **C1** and **C4** show the best performance as atom-transfer polymerisation catalysts, giving both narrow PDI polymer and acceptable rates of reaction. Catalyst **C3** gives reasonable PDI but has a very low rate of reaction, **C5** gives good rate but broad PDI and **C2** is the least effective catalyst in this series, yielding both a low rate of reaction and broad PDI.

Single-Crystal X-ray Structural Study of Copper Complexes with L2, L3, and L5

X-ray structural studies were carried out for the compounds $Cu[BF_4]\cdot(\mathbf{L2})_2$, $Cu[BF_4]\cdot(\mathbf{L3})_2$, and $Cu[PF_6]\cdot(\mathbf{L5})_2$ which were isolated as crystalline salts from slowly cooled (5°C) solutions in methanol. Compounds formed from the reaction of $Cu(CH_3CN)_4[BF_4]$ with the ligands **L1** and **L4**, however, could not be isolated as crystals of suitable quality for X-ray analysis.

The compounds $Cu[BF_4]\cdot(\mathbf{L2})_2$, $Cu[BF_4]\cdot(\mathbf{L3})_2$, and $Cu[PF_6]\cdot(\mathbf{L5})_2$ all have the same basic distorted tetrahedral arrangement of co-ordinating nitrogen atoms which sur-

Figure 5. The crystal structure of $Cu[BF_4]\cdot(\mathbf{L2})_2$ (BF_4 counter ion not shown for clarity)

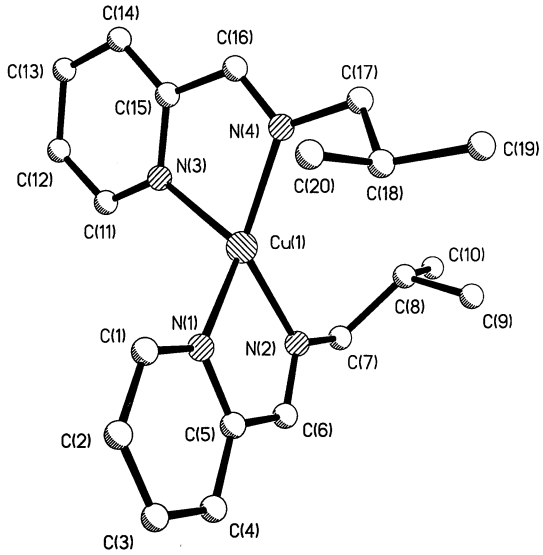


Figure 6. The crystal structure of $Cu[BF_4]\cdot(\mathbf{L3})_2$ (BF_4 counter ion not shown for clarity)

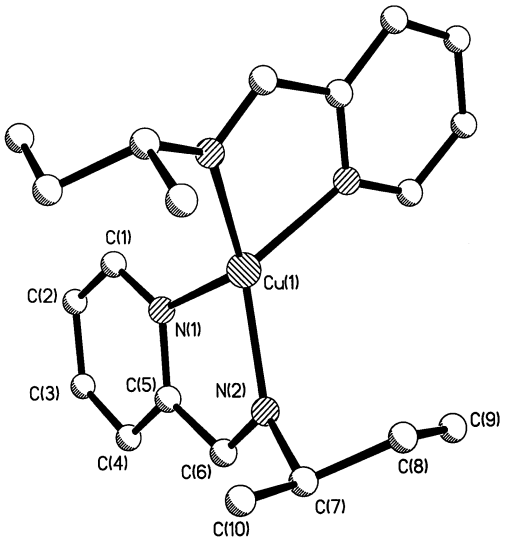

Figure 7. The crystal structure of $Cu[PF_6]\cdot(\mathbf{L5})_2$ (PF_6 counter ion not shown for clarity)

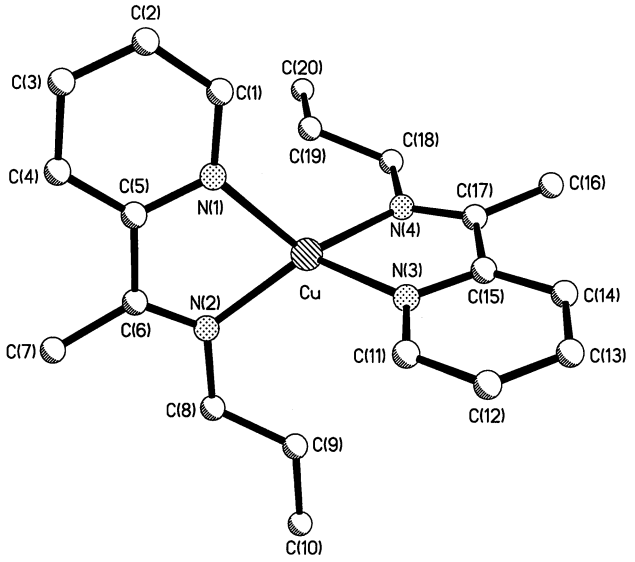

round the metal centre. Table 2 compares angles and average bond lengths to other similar published structures. The interligand dihedral angle between the mean planes defined by the central copper ion and each pair of chelating nitrogen atoms is 86.8° for $Cu[BF_4]\cdot(\mathbf{L2})_2$, 86.5° for $Cu[BF_4]\cdot(\mathbf{L3})_2$, and 85.3° for $Cu[PF_6]\cdot(\mathbf{L5})_2$ these values fall between 68° for the tetramethylbipyridine complex (entry 8) and 89.7° for the *N*-(α-methylbenzyl)-(2-pyridyl)methanimine complex (entry 4). The Cu−N bond lengths for $Cu[BF_4]\cdot(\mathbf{L2})_2$ are in the range of Cu(1)−N(1) = 2.080(3) Å, Cu(1)−N(2) = 2.005(2) Å, Cu(1)−N(3) = 2.047(3) Å, and Cu(1)−N(4) = 2.013(3) Å, for $Cu[BF_4]\cdot(\mathbf{L3})_2$ the Cu−N bond lengths are similar, with Cu(1)−N(1) = 2.092(2) Å and Cu(1)−N(2) = 2.008(2) Å. The Cu−N distances for $Cu[PF_6]\cdot(\mathbf{L5})_2$, tend to be, in most cases, somewhat shorter than those seen for $Cu[BF_4]\cdot(\mathbf{L2})_2$ and $Cu[BF_4]\cdot(\mathbf{L3})_2$, with Cu−N(1) = 2.028(2) Å, Cu−N(2) = 2.011(3) Å, Cu−N(3) = 2.034(3) Å, and Cu−N(4) = 2.001(2) Å. From Table 2 it can be seen that the average Cu−N bond lengths for $Cu[BF_4]\cdot(\mathbf{L2})_2$ and $Cu[BF_4]\cdot(\mathbf{L3})_2$ lie within the values measured for other $[CuL_2]^+$-type complexes, the average Cu−N distance for $Cu[PF_6]\cdot(\mathbf{L5})_2$ falling slightly below the other measured values. The N−Cu−N angles for $Cu[BF_4]\cdot(\mathbf{L2})_2$, $Cu[BF_4]\cdot(\mathbf{L3})_2$, and $Cu[PF_6]\cdot(\mathbf{L5})_2$ are similar and differ by only 0.37° at most, these values being comfortably within the estimated standard deviations.

Conclusion

A series of *N*-alkyl-(2-pyridyl)methanimines have been fully characterised. The bis[*N*-alkyl-(2-pyridyl)methanimine]copper(I) complexes characterised exhibit a distorted tetrahedral arrangement of co-ordinating nitrogen atoms surrounding the metal centre in the solid state. All of the catalysts tested were found to polymerise MMA effectively in hydrocarbon solution by an atom-transfer polymerisation process. Catalysts which contain *n*-alkyl substituents are more efficacious than those containing branched alkyl substituents in the imine group. The presence of branching in the alkyl substituent results in a loss of control over the polymerisation manifested by a slowing of the reaction rate and a broadening of the polydispersity index. The cause of these efffects of branching at the α-carbon atom of the imine on the final polymer properties is currently not known and is under further investigation in our laboratory.

We wish to thank the *EPSRC* (GR/K90364, MCC, DK; GR/L10314, DJD, SAFB; AMH, AJS studentships) for funding and *Courtaulds and Zeneca Specialties* for support of this work. We also thank Dr. *Adam Clarke* for help with the NMR analysis.

Experimental Section

General Remarks: The reagents 2-pyridinecarboxaldehyde (Avocado, 99%), 2-acetylpyridine (Avocado, 98%), *n*-butylamine (Acros, 99.5%), isobutylamine (Avocado, 99%), *sec*-butylamine (Avocado, 99%), *n*-propylamine (Avocado, 99%), ethyl 2-bromoisobutyrate (Aldrich, 98%), xylene (Fisons, 99.8%), diethyl ether (BDH, 98%), and magnesium sulfate (Philip Harris) were used as received. Copper(I) bromide (Aldrich, 98%) was purified according to the method of Keller and Wycoff[10]. Methyl methacrylate (Aldrich, 99%) was purified by passing through a column of activated basic alumina to remove the inhibitor 4-methoxy phenol. All manipulations were performed using standard Schlenk line and syringe techniques under nitrogen.

NMR spectra were recorded using a Bruker WH 400 spectrometer. X-ray crystallographic data was collected with a Siemens R3m diffractometer.

Polymer conversions were determined by gravimetry and molecular-weight distributions were measured using size-exclusion chromatography (SEC), with a system equipped with a guard column, one 30-cm mixed E column (Polymer Laboratories) and a differential refractive-index detector, using tetrahydrofuran at 1 ml min^{-1} as the eluent. Poly(methyl methacrylate) standards in the range ($6 \cdot 10^4$ to 200 g mol^{-1}, Polymer laboratories) were used to calibrate the SEC.

N-Alkyl-(2-pyridyl)methanimine Ligands **L1**−**L4**: A solution of 2-pyridinecarboxaldehyde (15 g, 0.140 mol) in 100 ml of diethyl ether was placed into a 250-ml flask under dry nitrogen together with 2−3 g of anhydrous $MgSO_4$. The appropriate amount of amine was added dropwise to this solution. (**L1** nBuNH$_2$, **L2** iBuNH$_2$, **L3** sBuNH$_2$: 10.22 g, 0.140 mol; **L4** nPrNH$_2$: 8.26 g, 0.140 mol), with gentle cooling of the flask with iced water. After the addition of amine was complete, the reaction was stirred for ca. 3 h, after which time the solvent was removed by rotary evaporation and the residual oil further purified by vacuum distillation (**L1**, **L2**, **L3**, **L4**). The products were isolated as pale yellow liquids, yields were typically 94%.

L1: B.p. 105−106°C at 1.2 Torr. − IR: $\tilde{\nu}$ = 1649 cm^{-1} (C=N). − ^{1}H NMR (250 MHz, 298 K, $CDCl_3$): δ = 8.50 (d, J = 4.92 Hz, 1 H), 8.26 (s, 1 H), 7.86 (d, J = 7.72 Hz, 1H), 7.57 (t, J = 8.08 Hz, 1 H), 7.14 (m, J = 6.32 Hz, 1 H), 3.17 (t, J = 7.00 Hz, 2 H), 1.50 (quint, J = 7.00 Hz, 2 H), 1.13 (sext, J = 7.36 Hz, 2 H), 0.72 (t, J = 7.36 Hz, 3 H). −^{13}C{^{1}H} NMR (250 MHz, 298 K, [D$_6$]DMSO): δ = 161.57, 154.62, 149.29, 136.39, 124.47, 121.07, 61.15, 32.70, 20.34, 13.79. − MS (+EI); m/z: 163 [M$^+$].

L4: B.p. 50° at 0.2 Torr. − IR: $\tilde{\nu}$ = 1650 cm^{-1} (C=N). − ^{1}H NMR (250 MHz, 298 K, $CDCl_3$): δ = 8.44 (d, J = 4.24 Hz, 1 H), 8.20 (s, 1 H), 7.80 (d, J = 7.72 Hz, 1 H), 7.57 (t, J = 7.72 Hz, 1 H), 7.10 (t, J = 4.92 Hz, 1 H), 3.45 (t, J = 7.00 Hz, 2 H), 1.56 (sext, J = 7.00 Hz, 2 H), 0.77 (t, J = 7.36 Hz, 3 H). − ^{13}C{^{1}H} NMR (250 MHz, 298 K, $CDCl_3$): δ = 161.53, 154.50, 149.21, 136.29, 124.37, 120.97, 63.11, 23.58,11.65. − MS (+EI); m/z: 149 [M$^+$ + 1], 133 [M$^+$ − Me].

N-(n-Propyl)-1-(2-pyridyl)ethanimine (**L5**): A solution of 2-acetylpyridine (10 g, 0.0825 mol) in 60 ml of diethyl ether was placed in a 250-ml flask under dry nitrogen, together with 2−3 g of $MgSO_4$. The flask was cooled gently in iced water whilst *n*-propylamine (8 ml, 0.0973 mol) was added dropwise with stirring. After addition of the amine, the reaction was allowed to warm up to room temperature and the solution stirred overnight. After this time, the solvent was removed by rotary evaporation and the residual oil purified further by vacuum distillation. − B.p. 60°C at 0.4 Torr. − IR: $\tilde{\nu}$ = 1639 cm^{-1} (C=N). − ^{1}H NMR (250 MHz, 298 K, [D$_6$]DMSO): δ = 8.64 (d, J = 4.88 Hz, 1 H), 8.00 (d, J = 4.88 Hz, 1 H), 7.59 (m, J = 8.28, 7.33 Hz, 1 H), 7.16 (m, J = 7.33, 8.23 Hz, 1 H), 3.40 (t, J = 7.03 Hz, 2 H), 2.27 (s, 2 H), 1.70 (m, J = 7.33, 7.03 Hz, 2 H), 0.94 (t, J = 7.33 Hz, 2 H). − ^{13}C{^{1}H} NMR (250 MHz, 298°C, $CDCl_3$): δ = 166.51, 158.32, 148.48, 136.68, 124.28, 121.10, 54.58, 24.39,12.52, 14.21. − MS (+EI); m/z: 163 [M$^+$ + 1], 106 [M$^+$ − Et].

Bis[N-(isobutyl)-(2-pyridyl)methanimine]copper(I) Tetrafluoroborate (Cu[BF$_4$]·(**L2**)$_2$; [Cu{(C$_5$H$_4$N)CH=N(iBu)}$_2$][BF$_4$]): To a slurry of [Cu(CH$_3$CN)$_4$][BF$_4$][9b] (1.0 g, 3.22 mmol) in degassed methanol (30 ml) was added **L2** (1.008 g, 6.22 mmol) under nitrogen. The solution was stirred at room temperature overnight, filtered, and concentrated to ca. 10 ml. Slow cooling to 5°C resulted in the formation of red crystalline Cu[BF$_4$]·(**L2**)$_2$ (75%). − IR: $\tilde{\nu}$ = 1622 cm^{-1} [ν(C=N)]. − ^{1}H NMR (250 MHz, 298 K $CDCl_3$): δ = 8.63 (s, 1 H), 8.39 (d, 1 H), 8.05 (t, 1 H), 7.92 (d, 1 H), 7.61 (m, 1 H), 3.63 (d, 2 H), 2.00 (m, 1 H), 0.87 (d, 6 H). − ^{13}C{^{1}H} NMR (250 MHz, 298 K, $CDCl_3$) δ = 161.32, 150.66, 149.28, 138.93, 128.71, 127.42, 67.62, 30.20, 20.28. − MS (+EI) m/z : 387 [M$^+$], 225 [M$^+$ − **L2**].

Bis[N-sec-butyl)-(2-pyridyl)methanimine]copper(I) Tetrafluoroborate (Cu[BF$_4$]·(**L3**)$_2$; [Cu{(C$_5$H$_4$N)CH=N(sBu)}$_2$][BF$_4$]): An identical procedure to that used for Cu[BF$_4$]·(**L2**)$_2$, using **L3**, was followed yielding red crystals of Cu[BF$_4$]·(**L3**)$_2$ (70%). − IR: $\tilde{\nu}$ = 1620 cm^{-1} [ν(C=N)]. − ^{1}H NMR (250 MHz, 298 K, $CDCl_3$): δ = 8.72 (s, 1 H), 8.30 (d, 1 H), 7.96 (m, 2 H), 7.54 (m, 1 H), 3.71 (m, 1 H), 1.44 (br., 2 H), 1.13 (br., 3 H), 0.77 (t, 3 H). −^{13}C{^{1}H} NMR (250 MHz, 298 K, $CDCl_3$): δ = 159.68, 150.67, 148.39, 138.41, 127.79, 126.91, 66.65, 30.81, 22.50, 10.83. − MS (+EI); m/z: 387 [M$^+$], 225 [M$^+$ − **L3**].

Bis[N-(n-propyl)-1-(2-pyridyl)ethanimine}]copper(I) Hexafluorophosphate (Cu[PF$_6$]·(**L5**)$_2$; [Cu{(C$_5$H$_4$N)C(CH$_3$)=N(nPr)}$_2$]-[PF$_6$]): To a slurry of [Cu(CH$_3$CN)$_4$][PF$_6$][9b] (1.5 g, 4.839 mmol) in degassed methanol (40 ml) was added **L5** (1.568 g, 9.678 mmol) under nitrogen. The resulting red solution was stirred at room temperature overnight, filtered and concentrated to ca. 15 ml. Slow cooling to 5°C resulted in the formation of red crystalline Cu[PF$_6$]·(**L5**)$_2$ (65%). − IR: $\tilde{\nu}$ = 1591 cm^{-1} [ν(C=N)]. − ^{1}H NMR (250 MHz, 298 K, $CDCl_3$): δ = 8.37 (s, 1 H), 8.00 (br., 2 H), 7.55 (m, 1 H), 3.55 (br., 2 H), 2.42 (s, 3 H), 1.50 (m, 2 H), 0.74 (m, 3 H). − ^{13}C{^{1}H} NMR (250 MHz, 298 K, $CDCl_3$): δ = 164.5, 151.63, 147.60,137.41, 126.69, 123.59, 54.34, 23.34, 23.66, 14.26, 10.94. − MS (+EI); m/z: 387 [M$^+$], 225 [M$^+$ − **L5**].

[a] X-ray data collected with a Siemens 3-circle diffractometer equipped with a SMART CCD area detector; graphite-monochromated radiation Mo-K_α radiation (λ = 0.71073 Å). Anisotropic thermal parameters were used for all non-H atoms. Hydrogen atoms were inserted at calculated positions and fixed, with isotropic thermal parameters U = 0.08 Å^3. − [b] $R = \Sigma|F_o - F_c|/\Sigma F_o$ [for $F_o \geq 4\sigma(F_o)$]. − [c] $wR2 = \{\Sigma[w(F_o^2 - F_c^2)^2]/\Sigma[w(F_o^2)^2]\}^{1/2}$ for all data. − [d] Peaks of unsassigned residual electron density. − [e] $w^{-1} = \sigma^2(F_o^2) + aP + bP$, where $P = [\max(F_o^2,0) + 2F_c^2]/3$, where $\max(F_o^2,0)$ indicates that the larger of F_o^2 or 0 is taken, a and b are values set by the program.

Polymerisation Reactions: 0.134 g of CuBr ($9.35\cdot10^{-4}$ mol) was placed in a Schlenk tube, containing a magnetic stirring bead, and pumped/filled three times with nitrogen to remove air from the apparatus. Deoxygenated MMA (10 ml, 0.0935 mol) and deoxygenated xylene (20 ml) were added via syringe to the Schlenk tube at room temperature, followed by the appropriate ligand (2 molar equivalents on CuBr, $1.87\cdot10^{-3}$ mol). The Schlenk tube was then placed into an oil bath at 90°C with stirring, followed by the addition of the initiator, ethyl 2-bromoisobutyrate (0.137 ml, $9.35\cdot10^{-4}$ mol). Periodically, 1−2-ml samples were removed for conversion and molecular-weight analysis.

Crystal-Structure Determinations: Crystallographic data for complexes $Cu[BF_4]\cdot(\mathbf{2})_2$, $Cu[BF_4]\cdot(\mathbf{3})_2$, and $Cu[PF_6]\cdot(\mathbf{5})_2$ are summarised in Table 3. The corresponding molecular structures are shown in Figures 5−7. Suitable crystals were quickly glued to quartz fibres, coated with dry nujol, and cooled in the cold nitrogen gas stream of the diffractometer. The structures were solved by direct methods. Anisotropic thermal parameters were used for all non-H atoms, whilst hydrogen atoms were inserted at calculated positions and fixed, with isotropic thermal parameters (U = 0.08 Å^3), riding on the supporting atom. The structure solutions were carried out using SHELXTL[16a] version 5 software with a Silicon Graphics Indy workstation, refinements were carried out using SHELX 96[16b] software, minimising on the weighted R factor $wR2$. − Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication no. CCDC-101884, -101885, -101886. Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [Fax: int. code + 44(1223)336-033; E-mail: deposit@ccdc.cam.ac.uk].

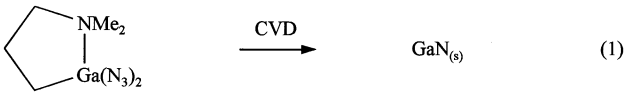
Keywords: Aluminum hydrides / Matrix isolation / IR spectroscopy / Ab initio calculation / Thermolyses

High-vacuum thermolyses of the intramolecularly coordinated alanes $Me_2N(CH_2)_3AlX_2$ with X = Cl, Br (**1**, **2**) were investigated with matrix isolation techniques. Among the products, which were identified with IR spectroscopy, ab initio calculations, and known literature data, are monomeric $HAlCl_2$ and $HAlBr_2$. The experimental vibrational frequencies of these hydrides matches well the calculated harmonic frequencies at the MP2(fc)/6–311G+(2d, p) and B3LYP/6–311G+(2d, p) level of theory. Beside the monomeric $HAlX_2$, the argon matrices of the thermolysis experiments contained CH_4, HCN, $H_2C{=}CH_2$, $H_2C{=}NMe$, $[H_2CCHCH_2]^{\bullet}$, $H_2C{=}CHCH_3$, and AlX_n (n = 1–3; X = Cl or Br).

Introduction

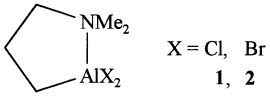
The group-13 nitrides are promising materials for advanced microelectronic and optoelectronic devices.[1][2] Suitable single-source precursors for the chemical vapor deposition of AlN[3], GaN[4], and InN[5] are intramolecularly coordinated group-13 metal azides containing the 3-(dimethylamino)propyl ligand. Recently, we started to investigate these deposition reactions with the matrix isolation technique. We intend to trap reactive intermediates produced by the fragmentation of a single-source precursor on its pathway to the resulting nitride film. By the characterization of these molecules we expect to get insights into the reaction mechanisms of these CVD processes (e.g., Eq. 1), which so far are unknown.



(1)

In order to get first results on the fragmentation pattern of intramolecularly coordinated molecules, we chose model compounds to begin with. In this article we report on gas-phase thermolysis experiments with the chloro- and the bromoalane, **1** and **2**, respectively.

Scheme 1



Results and Discussion

The two alanes **1** and **2** are volatile and moisture-sensitive compounds, which can be purified by sublimation in high vacuum. While the dichloro compound was published in 1991[6], no data on the bromide **2** has appeared in the literature.[7] As expected, compound **2** could readily be synthesized from aluminum bromide and $Li(CH_2)_3NMe_2$[8]. The crystal structures of **1** and **2** are unknown, but the ^{27}Al-NMR shift of δ = 139 for **1** and **2** clearly reveals the expected tetra-coordination of aluminum in solution.[3b][9]

We carried out a series of high-vacuum thermolyses of **1** and **2**, respectively (see Experimental Section). Between ambient temperature and oven temperatures of ca. 750°C the IR spectra of the matrix isolated alanes **1** and **2**, respectively, were unchanged. Around ca. 850°C new IR bands appeared, indicating the beginning of fragmentation; above ca. 950°C the typical IR absorptions of the precursors **1** or **2** could no longer be detected in the argon matrices.

Figure 1 shows a typical IR spectrum recorded after a thermolysis of the alane **2** at ca. 1000°C. The strongest absorption appears at 634.5 cm^{-1} followed by intensive bands at 476.0 and 1952.5 cm^{-1}. The latter lies in the characteristic region of aluminum−hydrogen stretching vibrations, which suggests the formation of a molecule with an AlH bond. Beside the experimental spectrum Figure 1 exhibits a theoretical IR spectrum of $HAlBr_2$ calculated at the B3LYP/6-311G+(2d, p) level of theory. Evidently, there is a good agreement between the major IR absorptions of the experimental spectrum and the theoretical one. In the case of the dichloro compound **1**, the AlH-stretching mode absorbs at 1966.0 cm^{-1}. Even without any calculation, there is no doubt that monomeric $HAlCl_2$ was formed in the pyrolysis of the alane **1**. This species has been synthesized photochemically in argon matrices before (Eq. 2) and was

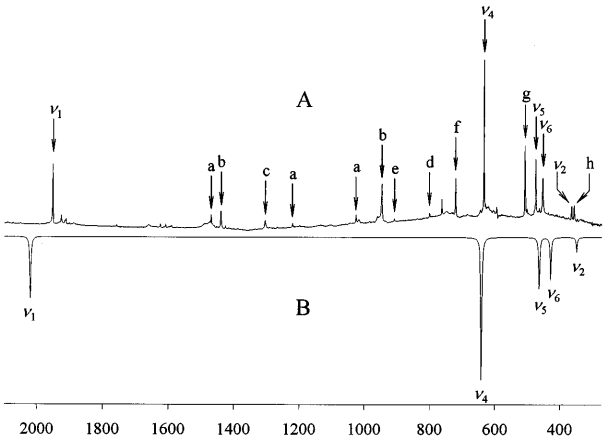
Figure 1. Experimental and calculated IR spectra: X-axis, 250−2100 cm^{-1}; Y-axis, Absorbance (dimensionless). Spectrum A: products of the thermolysis of compound **2** at ca. 1000°C trapped in argon at 15 K (assignment $\nu_1-\nu_6$ see Table 1); a: $H_2C{=}NMe$[17] (2900.5[a], 2854.5[a], 1469.5, 1221.0, 1026.5 cm^{-1}), b: $H_2C{=}CH_2$[14a][16] (1440.0, 947.0 cm^{-1}), c: CH_4[14] (1305.0 cm^{-1}), d: $[H_2CCHCH_2]^{\bullet}$ [18] (801.0 cm^{-1}), e: $H_2C{=}CHCH_3$[19] (909.0 cm^{-1}), f: HCN[15] (3305.0[a], 721.0 cm^{-1}), g: $AlBr_3$[20] (508.5 cm^{-1}), h: AlBr[20] (357.5 cm^{-1}). The signal of $AlBr_2$[20] at 458.0 cm^{-1} is too weak to be seen in this spectrum. The strongest among the unassigned bands was found at 763.5 cm^{-1}[b] (see also text). Spectrum B: $HAlBr_2$ calculated at the B3LYP/6−311+G(2d, p) level (half band width of 2 cm^{-1})



[a] Out of the depicted range; [b] For $HAlCl_2$ an unassigned signal was found at 770.0 cm^{-1}

unequivocally characterized by IR spectroscopy and normal coordinate analysis.[10] Within experimental error, the IR frequencies match with the published IR data of $HAlCl_2$ (Table 1, figures in braces).

In Table 1 the experimental and calculated vibrational data of $HAlCl_2$ and $HAlBr_2$ are compiled. The ab initio calculations predict C_{2v}-symmetrical equilibrium geometries for these aluminum hydrides (Table 2); thus, one expects six normal modes belonging to the irreducible representations A_1 (3), B_1 (2), and B_2 (1). In accordance with the calculations (Table 1) only five of the six modes were measured; the calculated frequencies of the XAlX-deformation vibration ν_3 are out of our detectable range of 240−4000 cm^{-1}.

Table 2. Calculated bond length (Å) and angles (deg) of $HAlCl_2$ and $HAlBr_2$[a]

	X = Cl	X = Br

[a] MP2(fc)/6−311G+(2d, p) and B3LYP/6−311G+(2d, p); results of the B3LYP calculations in parentheses.

For reliable assignments of the IR bands we chose the MP2 and B3LYP methods with the 6-311G+(2d, p) basis set to calculate the harmonic frequencies. As known from the literature[11] MP2 results in higher wavenumbers compared with B3LYP, which is also valid for all of the calculated frequencies in Table 1. Usually, calculated wavenumbers are too large in comparison with the real values, but B3LYP often results in frequencies which are too small for the low energy modes.[12] From that point of view, the two alanes are illustrative examples: the AlH stretch ν_1, the only mode at high energy, is described slightly better by the B3LYP than by the MP2 calculations, while all other detected modes are below 655.0 cm^{-1} (ν_2, ν_4, ν_5, and ν_6) with mean observed/calculated frequency ratios of 0.995 ($HAlCl_2$) and 1.002 ($HAlBr_2$) for the MP2 calculations, whereas the respective ratios are 1.020 and 1.029 for the B3LYP method.

All experimental IR bands of $HAlCl_2$ are found at higher wavenumbers than those of $HAlBr_2$. This is mainly due to the higher molecular mass of bromine compared with chlorine; thus, the effect is strongly pronounced for the two AlX-stretching modes with differences between the chloro and the bromo derivative of 115.5 for ν_2 and 103.5 cm^{-1} for ν_5.

The dihaloalanes are most likely formed by β-hydrogen eliminations (Eq. 3).

There is evidence in the literature that the intramolecularly coordinated 3-(dimethylamino)propyl ligand can be split off by a β-hydrogen elimination pathway;[6a] and, indeed, allyldimethylamine was detected by NMR spec-

Table 1. Experimental and calculated vibrational data for $HAlCl_2$ and $HAlBr_2$. Experimental IR frequencies (cm^{-1}) and observed/calculated frequency ratios (in parentheses for MP2; in square brackets for B3LYP); harmonic frequencies (cm^{-1}) and intensities (in parentheses, km mol^{-1}) calculated at the MP2(fc)/6−311G+(2d, p) and the B3LYP/6−311G+(2d, p) level

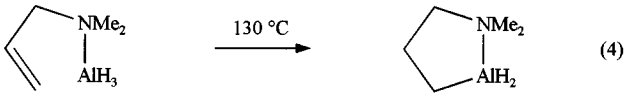
1, **2** X = Cl, Br

troscopy in the exhaust gases of the CVD process as shown by Eq. 1.[4b] The reverse reaction, the hydroalumination, is well known in organic and organometallic syntheses; the synthesis of 3-(dimethylamino)propylalane is given as an example (Eq. 4).[6b]



However, in none of the thermolysis experiments of compound **1** or **2** did we detect allyldimethylamine in argon matrices.[13] Beside the two dihaloalanes, we identified CH_4,[14] HCN,[15] $H_2C{=}CH_2$,[14a][16] $H_2C{=}NMe$,[17] $[H_2CCHCH_2]^{\bullet}$,[18] and $H_2C{=}CHCH_3$[19] (see Figure 1). One might believe that allyldimethylamine is produced by the thermolyses according to Eq. 3, and because the temperatures are so high that it is further pyrolyzed. In order to prove this speculation, we conducted thermolysis experiments with amine/argon mixtures (1:500). The fragmentation of the amine begins around 800°C, and at ca. 1150°C we could not detect any allyldimethylamine in argon matrices. All the mentioned above molecules were found, but they were produced in different ratios than for the thermolysis experiments of compound **1** and **2**, respectively. Furthermore, there were new, unidentified IR bands, which we have not identified so far. As mentioned before, allyldimethylamine was detected in the exhaust gases of the deposition reaction Eq. 1, and with increasing deposition temperatures increasing amounts of $H_2C{=}CH_2$ and NMe_3 were found; however, we did not find NMe_3 amoung the thermolyses products of compound **1** and **2**.

Among the pyrolysis products, the aluminum halide species AlX [X = Cl: 455.0 ($Al^{35}Cl$) and 450.0 ($Al^{37}Cl$) cm^{-1}; X = Br: 357.5 cm^{-1}], AlX_2 [X = Cl: 564.0 ($Al^{35}Cl_2$) and 561.5 ($Al^{35}Cl^{37}Cl$) cm^{-1}; X = Br: 458.0 cm^{-1}], and AlX_3 [X = Cl: 619.0 ($Al^{35}Cl_3$) and 615.0 ($Al^{35}Cl_2{}^{37}Cl$) cm^{-1}; X = Br: 508.5 cm^{-1}] could be unequivocally identified by comparison with known literature data.[20] At this point we will not suggest various reaction pathways which explain the AlX_n species, because they would be purely speculative; obviously, further experiments are necessary.

Conclusion

Up to date, only two monomeric aluminum hydrides of the type H_nAlX_{3-n} (n = 1−3) have been characterized, i.e., AlH_3[21] and $HAlCl_2$[10]; with $HAlBr_2$ we examined a third example. However, it is surprising that the hydrides $HAlX_2$ withstand the rather harsh thermolyses conditions. We hope to expand the method described in this paper to get access to new, reactive group-13 molecules. As mentioned in the introduction, **1** and **2** were chosen as model compounds for intramolecularly coordinated group-13 metal azides in order to get first insights into the fragmentation mechanism of these types of substances. The results reported here demonstrate that the fragmentation of the compounds **1** and **2** are not as simple as it seems at first glance. Further investigations are in progress and we will report on this outcome shortly.

We are grateful to the *Deutsche Forschungsgemeinschaft* for generous financial support and to the *Rechenzentrum der RWTH Aachen* for providing generous computer time. Especially, we would like to thank *T. Eifert* and *J. Risch* for their support, *P. Pilgram* for the synthesis of **2**, and *P. Geisler* for the construction of the thermolysis oven.

Experimental Section

General Remarks: All procedures for syntheses were carried out under a dry nitrogen atmosphere with standard Schlenk techniques. Solvents were dried by standard procedures, distilled, and stored under nitrogen and molecular sieves (4 Å). The reagents Me_2N-$(CH_2)_3AlCl_2$ (**1**)[6b] and $Li(CH_2)_3NMe_2$[8] were prepared according to the literature procedures. − NMR: Varian Unity 500 (ambient temp.; 499.843, 130.195, and 125.639 MHz for ^1H, ^{27}Al, and ^{13}C, respectively); calibrated against residual protons of the deuterated solvents. ^1H- and ^{13}C-chemical shift are reported relative to TMS and ^{27}Al-NMR values relative to the external standard [Al(acac)$_3$] in C_6D_6. As a result of the electric quadrupole moment of the ^{27}Al nucleus the carbon atoms bound to aluminum could not be detected in the ^{13}C-NMR measurement. − Elemental analyses (C, H, N): Carlo-Erba elemental analyzer, Model 1106. − MS: Finnigan MAT 95.

Dibromo[3-(dimethylamino)propyl]aluminum (**2**): 2.60 g (27.95 mmol) of $Li(CH_2)_3NMe_2$ were added to a solution of 7.45 g of $AlBr_3$ (27.95 mmol) in 50 ml of toluene, and the reaction mixture was stirred overnight. The suspension was filtered, and the solid was washed with two 10-ml portions of toluene. After removal of the solvent in high vacuum, sublimation (50−75°C, 10^{-3} mbar) gave 5.51 g of **2** (72%) as a colorless solid, m.p. 98−101°C. − ^1H NMR (C_6D_6): δ = 0.35 (t, ^3J = 7.78 Hz, 2 H, $AlCH_2$), 1.16 (pseudo quintet, ^3J = 6.71 Hz, 2 H, $AlCH_2CH_2$), 1.68 (t, ^3J = 6.41 Hz, 2 H, NCH_2), 1.70 (s, 6 H, CH_3). − $^{13}C\{^1H\}$ NMR (C_6D_6): δ = 20.02 ($AlCH_2CH_2$), 45.51 (CH_3), 62.12 (NCH_2). − ^{27}Al NMR (C_6D_6): δ = 139 ($h_{1/2}$ = 750 Hz). − MS (70 eV), *m/z* (%): 273 (100) [M^+], 245 (45) [$M^+ - C_2H_4$], 230 (76) [$M^+ - C_2H_5N$], 192 [M^+ − Br], 187 (41) [$M^+ - (CH_2)_3N(CH_3)_2$]. − $C_5H_{12}AlBr_2N$ (272.95): calcd. C 22.00, H 4.43, N 5.13; found C 21.66, H 4.50, N 5.11.

Matrix Isolation: The matrix apparatus consists of a vacuum line (Leybold Turbovac 151; Leybold Trivac D4B) and a Displex CSW 202 cryogenic closed-cycle system (APD Cryogenics Inc.) fitted with CsI windows. In a typical experiment the starting compound was kept in a small metal container in high vacuum at constant temperature (10^{-6} to 10^{-7} mbar; compound **1**: 35−50°C; compound **2**: 50−60°C), while a flow of argon was conducted over the sample (Linde 6.0; flow = 1.0 sccm; MKS mass flow controller type 1179). Subsequently, this gaseous mixture was passed through an Al_2O_3 tube (inner diameter of 1 mm; heated by tungsten wire coiled around the last 10 mm). The hot end of the pyrolysis tube was just 25 mm away from the cooled CsI window to assure that a maximum amount of volatile fragments emerging from the oven were trapped in the matrix. For the temperature determination of

the pyrolysis oven a current-to-temperature relation was measured with a thermocouple (Thermocoax: NiCr/NiAl) inside of the Al_2O_3 tube.

The concentrations of the samples in the matrices are unknown. Therefore, several experiments under various conditions were carried out to insure that the molecules were indeed matrix-isolated. The concentration of the samples decreases significantly at lower sublimation temperatures (20°C for **1** and 35°C for **2**), but no differences in the IR spectra were observed. At higher concentrations the half band widths of IR bands increased and new broad IR bands appeared indicating that notable parts of the molecule are no longer matrix-isolated under these conditions.

The IR spectra of the matrices (15 K) were recorded on a Perkin-Elmer FTIR 1720x from 240 to 4000 cm^{-1} with a resolution of 1 cm^{-1}.

Ab initio Calculations: The GAUSSIAN 94 package[22], run on a cluster of workstations (*Rechenzentrum der RWTH Aachen*), was applied for all ab initio calculations. The total energies E_h (in Hartrees) and the ZPVE (in kJ mol^{-1}; in parentheses) are as follows: – $HAlCl_2$: −1162.046298 (26.64) for MP2(fc)/6−311+G(2d, p); −1163.649857 (25.97) for B3LYP/6−311+G(2d, p). – $HAlBr_2$: −5387.697127 (24.64) for MP2(fc)/6−311+G(2d, p); −5391.474382 (24.01) for B3LYP/6−311+G(2d, p).

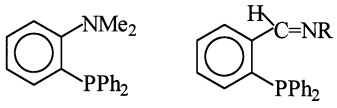
New neutral organometallic palladium(II) complexes, [PdPhI($PNMe_2$)] (**1**), [PdPhI(PC=NMe)] (**2**), [PdPhI(PC=NEt)] (**3**), and [PdMeCl($PNMe_2$)] (**4**), {$PNMe_2$ means *N*,*N*-dimethyl-2-(diphenylphosphanyl)aniline; PC=NMe means *N*-[2-(diphenylphosphanyl)benzylidene]-*N*-methylamine; PC=NEt means *N*-[2-(diphenylphosphanyl)benzylidene]-*N*-ethylamine} have been synthesized by oxidative addition of PhI to [$Pd(dba)_2$] in the presence of the P∩N ligand (**1**–**3**), or by substitution reaction on [PdMeCl(COD)] with $PNMe_2$ (**4**). Cationic σ-organometallic species [PdR(PPh_3)(P∩N)]$^+$ are obtained upon treating complexes of the type [PdRX(P∩N)] with PPh_3 and $AgCF_3SO_3$ and consist predominantly of the *trans*-P,P isomer in $CDCl_3$ solution, as shown by NMR spectroscopic studies. The cationic η^3-allyl complex [Pd(η^3-all)($PNMe_2$)]PF_6 has also been prepared and characterized, both in solution and in the solid state. Compounds [PdPhI($PNMe_2$)] ($P2_1/n$), [PdPhI(PC=NMe)] ($P\bar{1}$), [PdPhI(PC=NEt)] ($P\bar{1}$), and [Pd(η^3-all)($PNMe_2$)]PF_6 ($P\bar{1}$) have been authenticated by X-ray analysis

Introduction

We have recently synthesized a number of nickel(II) complexes featuring mixed *soft-hard* coordination spheres[1][2][3] of the types {P_2NCl_2} and {P_2NCl}. The ultimate aim of this work was the evaluation of these species as potential catalysts in the oligomerization of olefins (Shell Higher Olefin Process, SHOP[4]). Although the catalytic results turned out to be unsatisfactory, P∩N ligands of the type depicted in Scheme 1 are expected to exhibit hemilabile behavior when coordinated to a *soft* metal center such like palladium(II)[5]. This feature, coupled with the known ability of palladium(II) complexes to promote catalytically a series of important C−C bond-forming reactions (such as the oligomerization of olefins[6], copolymerization of CO/ethylene[7], and the telomerization of butadiene[8]), prompted us to extend our investigations to this metal center[*].

Scheme 1



$PNMe_2$ **PC=NR**

The P∩N ligands employed in this work can be expected to exhibit rather different coordinating behavior. While the $PNMe_2$ ligand clearly contains *hard* (N) and *soft* (P) donor atoms and forms five-membered metal chelates[9], the imino nitrogen in PC=NR can be expected to possess appreciable *soft* character (π-acceptor properties) and the ligands clearly afford six-membered rings upon metal coordination. In this context, it is remarkable that the coordinating ability

[*] Preliminary catalytic results indicate that the new complexes reported in this paper, [PdMe(PPh_3)($PNMe_2$)]$CF_3SO_3 \cdot C_6H_6$, and [Pd(η^3-all)($PNMe_2$)]PF_6, are efficient catalysts in the telomerization of butadiene with MeOH.

 © WILEY-VCH Verlag GmbH, D-69451 Weinheim, 1998 1434−1948/98/1111−1811 $ 17.50+.50/0

of these imino ligands remains largely unexplored, with the exception of their behavior towards rhodium(I)[10].

The importance of ligands based on a P,N set of donor atoms is well illustrated by other results obtained, e.g. by Vrieze with 1-(dimethylamino)-8-(diphenylphosphanyl)-naphthalene and 1-(dimethylamino)-3-(diphenylphosphanyl)propane[11], and by Venanzi with 2-(2-pyridyl)-4,5-dimethylphosphinine[12].

Results and Discussion

The investigated P$^{\frown}$N ligands form neutral and cationic η^3-allyl and σ organometallic complexes, characterized as (i) neutral complexes: [PdPhI($PNMe_2$)] (**1**), [PdPhI(PC=NMe)] (**2**), [PdPhI(PC=NEt)] (**3**), [PdMeCl($PNMe_2$)]·0.5 C_6H_6 (**4**), and (ii) cationic complexes: [PdMe(PPh_3)($PNMe_2$)]$CF_3SO_3\cdot C_6H_6$ (**5**), [PdPh(PPh_3)($PNMe_2$)]$CF_3SO_3\cdot 0.5\ C_6H_6$ (**6**), [PdPh(PPh_3)(PC=NMe)]$CF_3SO_3\cdot 0.5\ C_6H_6$ (**7**), [PdPh(PPh_3)(PC=NEt)]$CF_3SO_3\cdot 0.5\ C_6H_6$ (**8**), [Pd(η^3-all)($PNMe_2$)]PF_6 (**9**), where $PNMe_2$ means *N*,*N*-dimethyl-2-(diphenylphosphanyl)aniline, PC=NMe stands for *N*-[2-(diphenylphosphanyl)benzylidene]-*N*-methylamine, and PC=NEt for *N*-[2-(diphenylphosphanyl)benzylidene]-*N*-ethylamine.

While the phosphanylamine $PNMe_2$ is well-known as a ligand from the literature[9] and its reactivity with many metal centers[1][2][3][13], including palladium(II)[9], has been widely investigated, only a few rhodium(I)[10], molybdenum(0)[14], and iridium(I)[15] complexes with PC=NR (R = Me, Et) have been produced, and generally speaking, the coordination chemistry of ligands of this type has yet to be fully explored.

Synthesis and Characterization of the Neutral σ Organometallic Complexes [PdRX(P$^{\frown}$N)]

Two routes have been followed for the synthesis of complexes [PdPhI($PNMe_2$)] (**1**), [PdPhI(PC=NMe)] (**2**), [PdPhI(PC=NEt)] (**3**), and [PdMeCl($PNMe_2$)]·0.5 C_6H_6 (**4**), depending on the type of organic group. The phenyl complexes [PdPhI(P$^{\frown}$N)] were prepared by oxidative addition of iodobenzene to the palladium(0) complex [Pd($dba)_2$][16] (dba = dibenzylideneacetone) in the presence of the P$^{\frown}$N ligand (see Eq. 1)[17].

$$[Pd(dba)_2] + PhI + P^{\frown}N \xrightarrow[N_2,\ THF]{50\,^{\circ}C,\ 45\ min} [PdPhI(P^{\frown}N)] + 2\ dba \quad (1)$$

The complexes [PdPhI(P$^{\frown}$N)] were obtained as colored powders (yellow or pink-yellow) after filtration of the reaction mixture through Celite to eliminate metallic Pd, concentration of the filtrate to dryness, and repeated washing with Et_2O. No further recrystallization was necessary and crystals suitable for X-ray analysis could be grown by slow evaporation of the solvent from Me_2CO/MeOH solutions.

The methyl complex [PdMeCl($PNMe_2$)]·0.5C_6H_6 (**4**) was prepared by a substitution reaction on the complex [PdMeCl(COD)][18] (see Eq. 2) (COD = 1,5 cyclooctadiene), similar to that employed with related P$^{\frown}$N ligands[11].

$$[PdMeCl(COD)] + PNMe_2 \xrightarrow[N_2,\ C_6H_6,\ 24\ h]{r.t.} [PdMeCl(PNMe_2)]\cdot 0.5\ C_6H_4 + COD \quad (2)$$

Some IR and NMR spectroscopic data of the complexes [PdRX(P$^{\frown}$N)] and of the corresponding free ligands are reported in Table 1.

Direct evidence for the coordination modes of the ligands $PNMe_2$, PC=NMe, PC=NEt has been obtained from X-ray analyses of complexes **1**, **2**, and **3** (see below). The coordination of the P$^{\frown}$N ligands through both the P and N atoms has also been deduced in solution on the basis of NMR data, where the resonances of the ^{31}P nucleus and of the protons of the amino or imino alkyl groups are shifted towards lower fields than the corresponding resonances of the free ligand. NMR data also give useful information about the composition of the reaction product mixtures in $CDCl_3$ solutions. In fact, both reactions 1 and 2 produce only one isomer of complexes **2**–**4**, while [PdPhI($PNMe_2$)] (**1**) is obtained as a mixture of *trans* P,I and *cis* P,I isomers in a 3:1 ratio (Table 1). IR data are less helpful in distinguishing the type of coordination; in fact, the typical C=N stretching bands (at 1637 cm^{-1}) of the phosphanyl-imines PC=NMe and PC=NEt in the spectra of **2** and **3** are practically unchanged relative to those of the free ligands. However, at the same time, coordination of the ligand slightly affects the aromatic C=C stretching values.

The available data are not helpful in unambiguously establishing the geometries of [PdPhI(PC=NMe)] and [PdPhI(PC=NEt)], which are present as single isomers in solution. As a matter of fact, upon crystallization, the *trans*-P,I isomer is obtained. In contrast to these cases, the assignment of the molecular structure as *trans*-P,Cl in solution is possible for [PdMeCl($PNMe_2$)]·0.5 C_6H_6 by virtue of the $^3J_{PH}$ coupling constant value[11].

Synthesis and Characterization of the Cationic Palladium(II) Complexes

The cationic complexes of the type [PdR(PPh_3)(P$^{\frown}$N)]$^+$ (with $CF_3SO_3^-$ as the counterion), [PdMe(PPh_3)($PNMe_2$)]$^+\cdot C_6H_6$ (**5**), [PdPh(PPh_3)($PNMe_2$)]$^+\cdot 0.5\ C_6H_6$ (**6**), [PdPh(PPh_3)(PC=NMe)]$^+\cdot 0.5\ C_6H_6$ (**7**), [PdPh(PPh_3)(PC=NEt)]$^+\cdot 0.5\ C_6H_6$ (**8**), were synthesized by adding an $AgCF_3SO_3/PPh_3$ solution in Me_2CO to a CH_2Cl_2 solution of the corresponding neutral precursor [PdRX(P$^{\frown}$N)] at 0°C (see Eq. 3). Removal of the silver salt by filtration and recrystallization of the product from CH_2Cl_2, C_6H_6, and Et_2O afforded the pure products as white or off-white powders. Complexes **5**–**8** are stable in the solid state, but they tend to decompose slowly in solution (over a period of days).

$$[PdRX(P^{\cap}N)] + AgCF_3SO_3 + PPh_3 \xrightarrow[CH_2Cl_2,\ Me_2CO]{0\,^{\circ}C,\ 45\ min} [PdR(PPh_3)(P^{\cap}N)]CF_3SO_3 + AgX \quad (3)$$

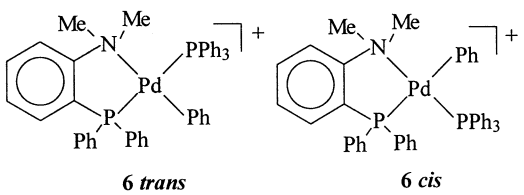
The more stable allyl complex $[Pd(\eta^3\text{-all})(PNMe_2)]PF_6$ (**9**) was obtained as a cream-coloured powder following a different synthetic procedure, employing $[Pd(\eta^3\text{-all})Cl]_2$[19], two equivalents of the ligand $PNMe_2$, and a large excess of KPF_6 (see Eq. 4).

$$[Pd(\eta^3\text{-all})Cl]_2 + PNMe_2 + 2\ KPF_6 \xrightarrow[CH_2Cl_2,\ 3\ h]{r.t.} 2\ [Pd(\eta^3\text{-all})(PNMe_3)]PF_6 + 2\ KCl \quad (4)$$

All the cationic complexes have been characterized by means of the usual physicochemical techniques. Molar conductivity values of 152 $ohm^{-1}cm^2mol^{-1}$ (see Experimental Section) confirm that they are uni-univalent electrolytes[20] and the presence of the anions $CF_3SO_3^-$ and PF_6^- is confirmed by very sharp, intense bands in their solid-state IR spectra at 1265 cm^{-1} [ν(S−O)] and 834 cm^{-1} [ν(P−F)], respectively[21].

In the case of complexes $[PdR(PPh_3)(P^{\cap}N)]^+$, the presence of two nonequivalent ^{31}P nuclei and the value of their coupling constants[22] (Table 2) permits the assignment of their molecular structures in $CDCl_3$ solution. This is fortunate, since no crystal structure could be determined. Thus, the $^{31}P\{^1H\}$ spectrum of $[PdPh(PPh_3)(PNMe_2)]^+$ is very informative and the complex is found to consist of a mixture of isomers (Figure 1), the *trans* isomer being prevalent (82%) (the terms *cis* and *trans* refer here to the mutual P positions).

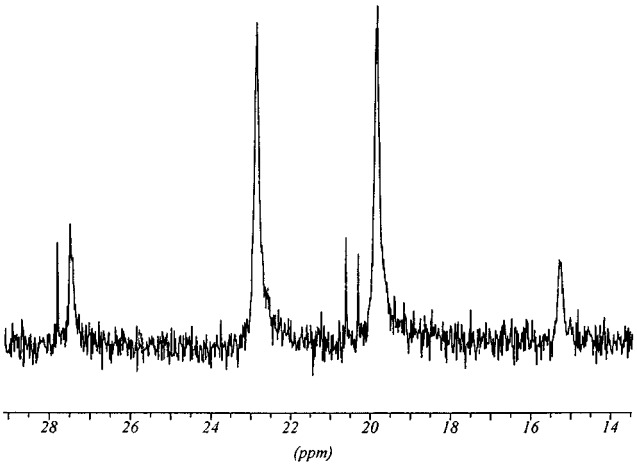
Figure 1. The *trans* and *cis* isomers of complex **6**



6 ***trans*** **6** ***cis***

In the $^{31}P\{^1H\}$ spectrum of complex **6** (Figure 2), the AB system ($^2J_{PP}$ = 372 Hz) is associated with the *trans* species, while the AX system ($^2J_{PP}$ = 24 Hz) is associated with the *cis* species.

Figure 2. $^{31}P\{^1H\}$-NMR spectrum of the mixture of isomers of complex **6**



On the basis of these findings, and the values reported in Table 2, it can be stated that the phosphanyl-imino complexes **7** and **8** exhibit only the *trans* configuration.

The methyl σ organometallic cationic complex $[PdMe(PPh_3)(PNMe_2)]^+$ (**5**) gives rise to an interesting ^1H-NMR spectrum, which indicates the presence of the two expected isomers; while the *cis* species is stereochemically rigid at room temperature [the signal of the methyl group bound to palladium(II) of this isomer appears as a doublet of doublets at δ = 0.67 with $^3J_{HP}$ = 2.2 and 6.6 Hz] (Figure 3a), the *trans* species is stereochemically nonrigid. Broad signals at δ = 0.53 (Figure 3a) and δ = 2.87 can be attributed to the protons of the methyl group bound to palladium(II) and of the methyl groups of the dimethylamino ligand, respectively. This isomer is the prevalent species, as deduced from integration of the signals. In the $^{31}P\{^1H\}$ spectrum,

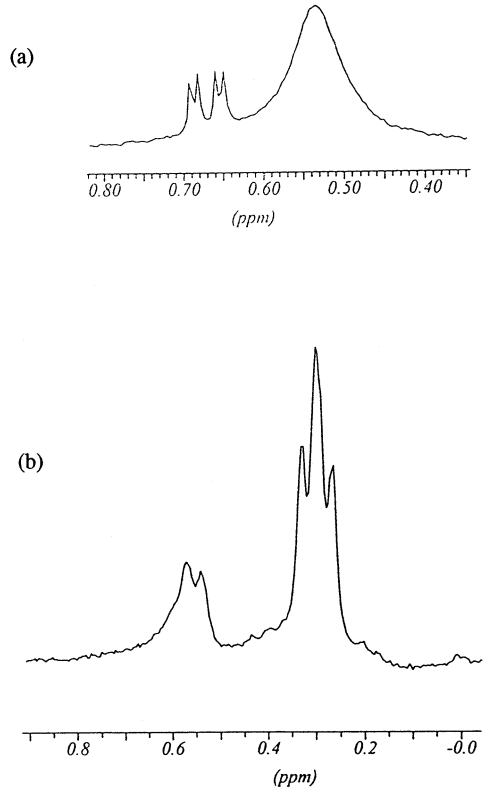
[a] In $CDCl_3$. − [b] $H^{1'}H^1C^1C^2H^2C^3H^{3'}H^3$, where C^1 is *trans* to P. − [c] In CD_3CN.

Figure 3. (a) ^{1}H-NMR signals of the methyl groups bound to palladium(II) of the mixture of isomers of complex **5** at 25°C; (b) ^{1}H-NMR signals of the methyl groups bound to palladium(II) of the mixture of isomers of complex **5** at −20°C

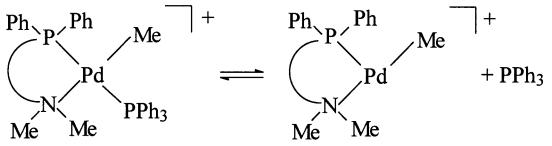


only the *cis* isomer gives rise to well-defined, sharp signals ($^2J_{PP}$ = 26 Hz).

Lowering of the temperature blocks the stereochemical nonrigidity of the *trans* species and at −20°C the AB system of the stereoisomer eventually appears (δ = 27.0 and δ = 31.7 with $^2J_{PP}$ = 375 Hz). The signal of the methyl group bound to palladium(II) (Figure 3b) becomes a triplet at δ = 0.30 with $^3J_{HP}$ = 6.5 Hz, this value being of the same order as the corresponding value of 5 Hz observed in the ^{1}H-NMR spectrum of *trans*-[PdMeI(PPh_3)$_2$][23].

We speculate that at low temperature (−20°C) the *trans* species is undissociated. When the temperature is increased, a fast dissociation process takes place so that the triplet, arising from the coupling of the protons of the methyl bound to palladium(II) with the two ^{31}P nuclei, merges into one very broad singlet. Considering the high *trans* effect of the phosphane group and the stabilization of the P∩N ligand due to the chelate effect, we postulate that this dissociation process involves the PPh_3 ligand, leading to a T-shaped intermediate (Figure 4).

Figure 4. Dissociation of the PPh_3 group and formation of a T-shaped intermediate in the case of *trans*-[PdMe(PPh_3)($PNMe_2$)]$^+$

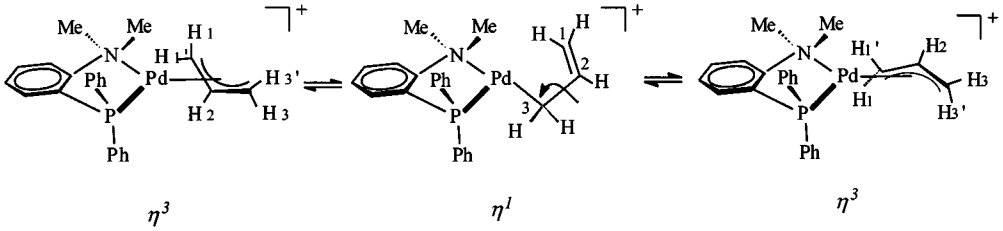


The complex [Pd(η^3-all)($PNMe_2$)]PF_6 is also stereochemically nonrigid in $CDCl_3$ as a consequence of a selective *syn-anti* interchange of the allyl protons *trans* to the NMe_2 group through the usual η^3−η^1−η^3 interconversion process (Scheme 2).

This fluxional phenomenon has been observed previously[24]. The PPh_2 group weakens the *trans* Pd−CH_2 bond, thus promoting the opening of the allyl ring and, by rotation about the σ bonds, the interchange of the *syn-anti* H^3 and $H^{3'}$ protons.

The relevant signal is not discernible in the ^{1}H-NMR spectrum owing to its partial overlap with that of the $N(CH_3)_2$ group (Figure 5) and only a broad absorption can be observed. On the contrary, the signals of the other three

Scheme 2



protons (Figure 6) are well defined: the multiplet between $\delta = 5.80$ and $\delta = 6.15$ is due to the central allyl proton H^2, while the two doublets of doublets at $\delta = 4.95$ ($^3J_{HH} = 7.7$ Hz and $^3J_{HP} = 5.3$ Hz) and at $\delta = 4.17$ ($^3J_{HH} = 13.9$ Hz and $^3J_{HP} = 9.5$ Hz) can be assigned to H^1 (*anti* in relation to H^2) and $H^{1'}$ (*syn* in relation to H^2), respectively, on the basis of the magnitudes of the coupling constants[25].

Figure 5. Overlapping of the signals of the protons of the $N(CH_3)_2$ group and of the protons H^3 and $H^{3'}$ in the ^{1}H-NMR spectrum of complex **9** in $CDCl_3$

X-ray Structure

The unique portion of the unit cells is different in compounds **1**, **2**, **3**·3/2 H_2O, and **9**. In **1**, the asymmetric unit consists of a single molecule of the neutral complex [PdPhI($PNMe_2$)] (Figure 7), while two molecules of [PdPhI(PC=NMe)] are present in **2** (Figure 8). In **3**·3/2 H_2O, the unique portion comprises two molecules of [PdPhI(PC=NEt)], along with three molecules of water (Figure 9), and in **9** two molecules of the salt [Pd(η^3-C_3H_5)($PNMe_2$)]PF_6 are likewise present (Figure 10). In **2**, **3**·3/2 H_2O, and **9**, the geometries shown by the two such independent and chemically well-separated molecules are practically superimposable (Figure 11), the differences being restricted to minor features only. This is also confirmed by the fact that no bond distance differs by more than two standard deviations in any of these molecule pairs. Hence, in the present discussion, all geometrical parameters refer to the mean values.

In **1** and **9**, the bidentate P∩N ligand coordinates to palladium(II) forming a five-membered chelate ring, which adopts a somewhat envelope-like (C_s) conformation (pertinent torsion angles in the range from −16.1° to +16.1°). The

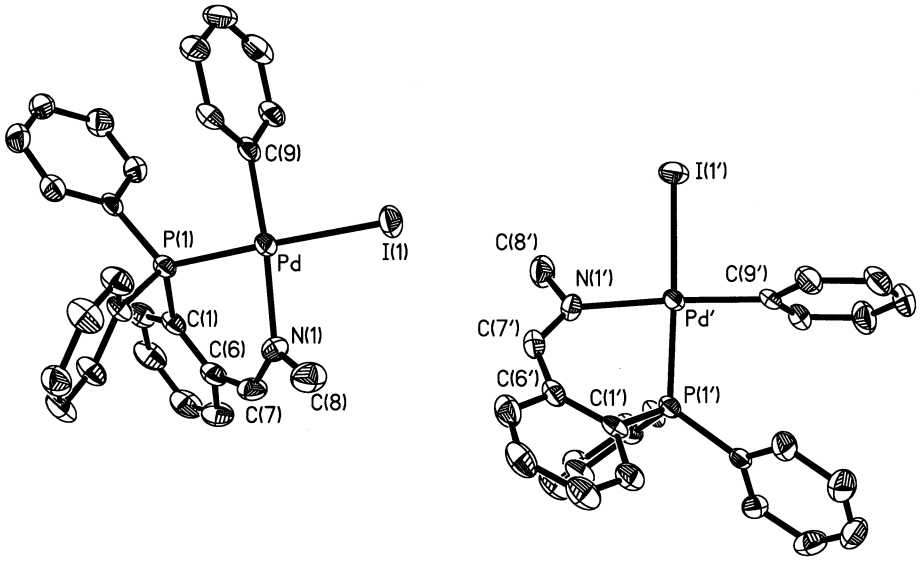

Figure 9. The asymmetric unit of **3**·3/2 H_2O. H atoms have been omitted for clarity. The C(9′) atom obscures N(1′).

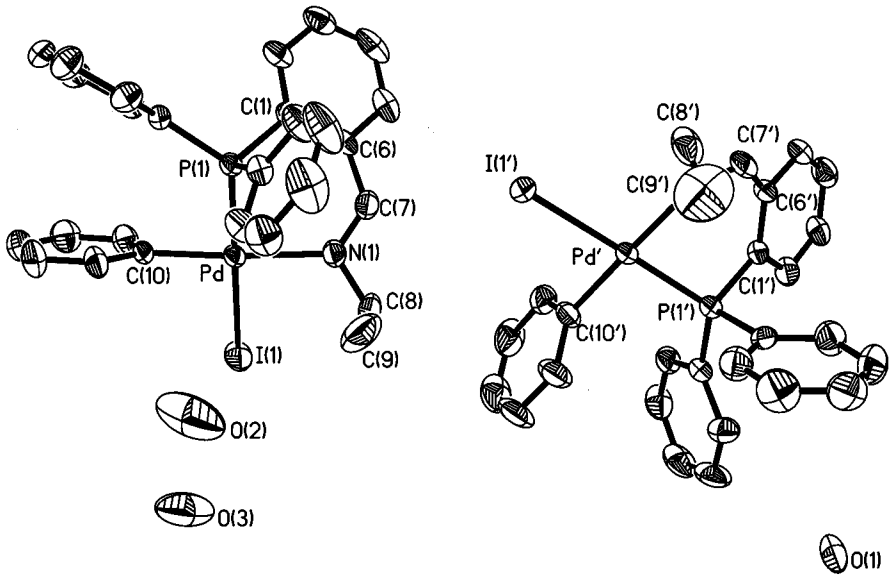

Figure 10. The asymmetric unit of **9**. H atoms have been omitted for clarity

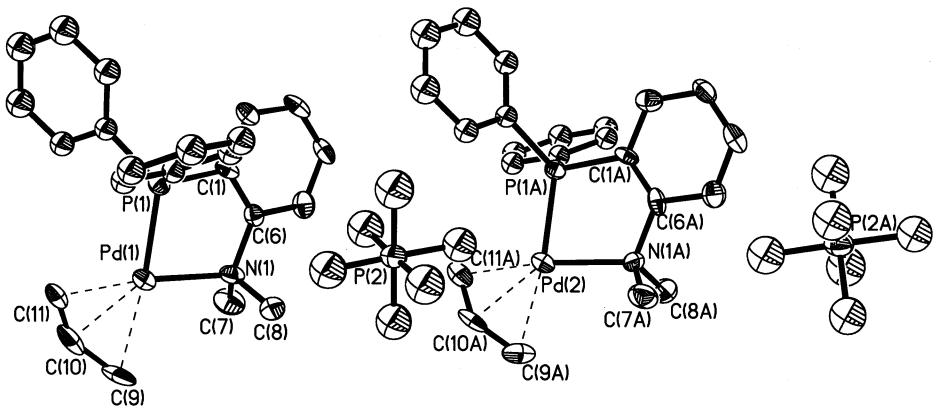

Figure 11. Superimposition of the two independent moieties of **2**, **3**·3/2 H_2O, and **9**. Weighted root mean square deviation of 0.02, 0.05, and 0.03 Å, respectively, when fitting is performed on the labelled atoms

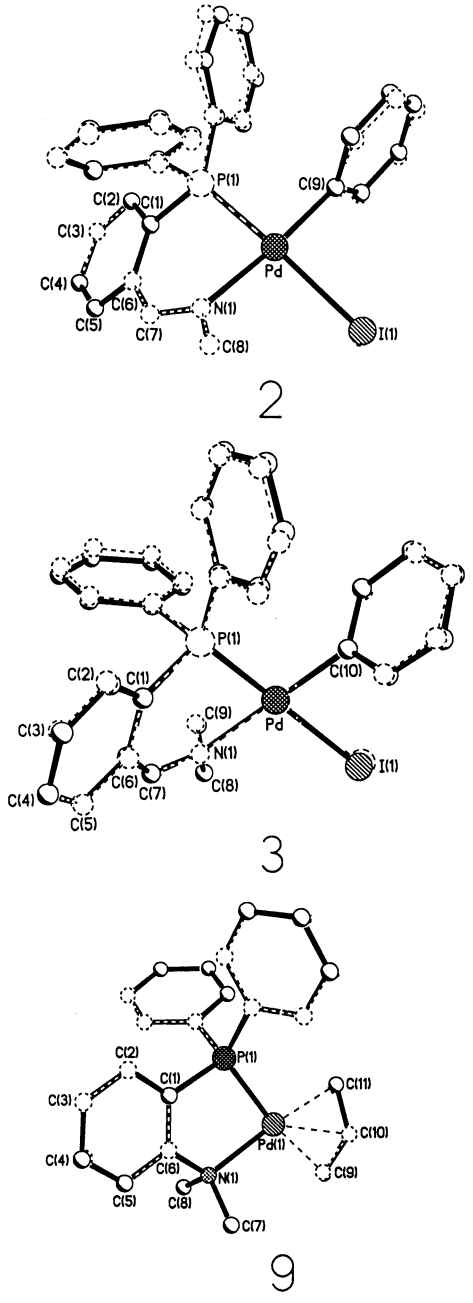

coordination sphere of **1** is completed by an iodide and a phenyl ligand, whereas the remaining coordination positions in **9** are occupied by the η^3-allyl ligand. In the latter compound, the coordination plane can be defined by the P,N donor atoms and by the terminal carbon atoms of the allyl group, the central carbon atom residing 0.50 Å above this plane. The mean plane defined by the eight atoms P(1), C(1)−(6), N(1) forms dihedral angles of 5.4° and 5.1° with the mean coordination plane in **1** and **9**, respectively. The P−N "bite" distance and the P−Pd−N angle are 3.00(1) Å and 85.1(3)° in both complexes. The Ph ligand in **1** is roughly orthogonal to the mean coordination plane (dihedral angle of 82.1°).

In **2** and **3**·3/2 H_2O, the P∩N ligand forms a six-membered chelate ring with the palladium(II) center. In this arrangement, the Pd and N(1) atoms in **2** deviate by +1.56 Å and +0.49 Å from the mean plane defined by the eight atoms P(1), C(1)−(7). The corresponding values in **3**·3/2 H_2O are +1.41 and +0.32 Å. The latter plane forms dihedral angles ("elbow angles") of 55.8° and 53.9° with the coordination plane in **2** and **3**·3/2 H_2O, respectively. In turn, the Ph ligand forms a dihedral angle with the coordination plane of 72.0° (in **2**) and of 75.3° (in **3**·3/2 H_2O). The "bite" distances and angles match those found in **1** and **9** [2.95(1) Å, 84.0(2)° in **2** and 3.00(1) Å, 85.8(2)° in **3**·3/2 H_2O].

The donor atoms deviate from the mean coordination plane by ±0.04 Å in **1**, ±0.07 Å in **2**, ±0.04 Å in **3**·3/2 H_2O, and ±0.06 Å in **9**, with the palladium(II) correspondingly out by 0.02, 0.02, 0.04, and 0.09 Å. In all the complexes, the major departure from the ideal square-planar geometry is manifested in the "bite" angle. From comparison of the distances with reference values obtained from the Cambridge Structural Database[26], the following comments can be made: (i) The Pd^{II}−I distance (mean 2.654 Å) is consistent with both the reference value (2.639 Å) derived from 164 observations and the sum of the covalent radii (1.33 + 1.31 Å)[27]; (ii) the Pd^{II}−P distance in the three neutral complexes (mean 2.228 Å), which is slightly shorter than that in the allyl cationic complex (2.260 Å), is remarkably shorter than the $Pd^{II}-PPh_3$ bond reference value (2.302 Å) encountered in 248 entries, and falls at the short end of a wide range (2.21−2.46 Å); (iii) the $Pd^{II}-C_{Ph}$ distance (mean 2.015 Å) matches the reference value (2.013 Å) derived from 34 observations, and (iv) the Pd^{II}−N distance in **1** (2.252 Å) is considerably longer than the corresponding distances in **2** and **3**·3/2 H_2O (mean 2.17 Å), which may be ascribed to the different environment of the nitrogen. Accordingly, on going from a five- to a six-membered chelate ring, the Pd−N(sp^3)−C angle (113.6°) widens to the mean value of 125.5° observed for Pd−N(sp^2)=C.

The packing observed for the four complexes does not show intermolecular contacts shorter than the sum of the van der Waals' radii, the shortest I−H approach being 3.1 Å. The opportunity for hydrogen bonding seems to be restricted to that between the water molecules of **3**·3/2 H_2O, which show O−O separations of 2.8 Å.

Conclusions

The phosphanyl-amine $PNMe_2$ and the phosphanyl-imines PC=NMe and PC=NEt are able to stabilize organometallic neutral and cationic palladium(II) complexes, acting as chelating bidentate ligands via their P and N donor atoms, forming five- or six-membered rings with the metal center in the expected manner.

The neutral complexes [PdRX(P∩N)] are stable species, both in solution and in the solid state. The phenyl com-

plexes [PdPhI(P⌒N)] and [PdMeCl(PNMe$_2$)] exist as the *trans*-P,I isomer in the solid state, as indicated by X-ray analysis, as well as *trans*-P,Cl isomer in solution, as deduced from the ^{1}H-NMR spectrum in $CDCl_3$.

The σ organometallic cationic complexes [PdR(PPh_3)(P⌒N)]$^+$ can be obtained by the reaction of the neutral precursor with PPh_3 and $AgCF_3SO_3$ and exist in solution mainly as *trans*-P,P species. In particular, a fluxional behavior is observed for *trans*-[PdMe(PPh_3)(PNMe$_2$)]$^+$, probably due to the dissociation of a PPh_3 molecule. The η^3-allyl complex [Pd(η^3-all)(PNMe$_2$)]PF_6, obtained from the dimer [Pd(η^3-all)Cl]$_2$ and a stoichiometric amount of $PNMe_2$ in the presence of excess KPF_6, also exhibits fluxional behavior in $CDCl_3$ solution, owing to the selective interchange of the protons of the CH_2 group *trans* to the phosphorus of the diphenylphosphanyl group.

Comparison of the crystal structure of [Pd(η^3-all)(PNMe$_2$)]PF_6 with those of the neutral complexes containing the phosphanyl-imines PC=NMe and PC=NEt reveals moderate differences relating to the size of the chelate ring in terms of bond lengths and the "bite" angle P−Pd−N.

Experimental Section

General: All chemicals and solvents were of analytical grade and were used as received unless otherwise stated. Anhydrous Et_2O and C_6H_6 were distilled from potassium/benzophenone under N_2; anhydrous THF was freshly distilled from potassium/benzophenone under N_2. The complexes [Pd(dba)$_2$][16], [PdMeCl(COD)][18], [Pd(η^3-all)Cl]$_2$[19] and the ligands PNMe$_2$[9], PC=NR (R = Me, Et)[10] were synthesized according to literature procedures. − IR: Mattson 3030 Fourier transform spectrometer. − ^{1}H and ^{31}P{^{1}H} NMR: Bruker AC-200 (200 MHz for ^{1}H and 80.9 MHz for ^{31}P). Typical NMR samples were prepared by dissolving the complexes (20 mg) in 0.4 ml of the deuterated solvent. For ^{1}H NMR, $CDCl_3$ as solvent, TMS as internal standard; for ^{31}P{^{1}H} NMR, $CDCl_3$ as solvent, 85% aqueous H_3PO_4 as external standard. − Conductivity measurements: Amel conductimeter Model 131, ca. 10^{-3} M solutions in MeCN at 25°C. − Elemental analyses (C, H, N): Fisons EA 1108 elemental analyzer.

Synthesis of **1**−**3** − *General Procedure:* To a blood-red solution of 0.633 g of [Pd(dba)$_2$] (1.1 mmol) in 90 ml of dry THF at 50°C under N_2, a stoichiometric amount of the P⌒N ligand and 520 μl of PhI (4.4 mmol, d = 1.73 g/ml) were added, and the mixture was stirred under N_2 at the same temperature. After 45 min, the yellow-green mixture was concentrated under a flow of N_2 and filtered through Celite. The solvent was removed from the filtrate under reduced pressure and the residue was washed several times with Et_2O until the washings were colorless. The residual solid was then dried in vacuo. Crystals suitable for X-ray analysis were grown by slow evaporation of the solvent from Me_2CO/MeOH solutions (Crystals of complex **3** from Me_2CO/MeOH/H_2O solutions).

Synthesis of **4**: To a solution of 0.508 g of [PdMeCl(COD)] (0.19 mmol) in 60 ml of dry C_6H_6 under N_2, was added 0.058 g of the phosphanyl-amine $PNMe_2$ (0.19 mmol) and the mixture was stirred under N_2. After 15 min, a white solid began to precipitate. After 24 h, the pale-yellow mixture was filtered and the white solid was collected, washed with C_6H_6 and Et_2O, and dried in vacuo. The filtrate was concentrated under a flow of N_2 and upon addition of Et_2O a precipitate was formed. This was filtered off, washed with Et_2O and a small volume of THF, and dried in vacuo.

Synthesis of **5**−**8** − *General Procedure:* To a solution of the neutral complex [PdRX(P⌒N)] (0.41 mmol) in 5 ml of CH_2Cl_2 at 0°C under N_2, a solution containing 0.108 g of PPh_3 (0.41 mmol) and 0.106 g of $AgCF_3SO_3$ (0.41 mmol) in 3 ml of Me_2CO was added dropwise, resulting in immediate silver halide precipitation. After 45 min., the mixture was concentrated under a flow of N_2 and filtered, and the solvent was removed from the filtrate in vacuo. The residue was redissolved in CH_2Cl_2 and upon addition of Et_2O a precipitate was deposited, which was separated from the solution by decantation of the supernatant and redissolved in a small amount of CH_2Cl_2. Addition of C_6H_6 and Et_2O under vigorous stirring caused the formation of a solid, which was filtered off, washed with C_6H_6 and Et_2O, and dried in vacuo.

Synthesis of **9**: To a solution of 0.130 g of [Pd(η^3-all)Cl]$_2$ (0.36 mmol) in 10 ml of CH_2Cl_2 was added 0.265 g of KPF_6 (1.44 mmol) followed by 0.282 g of the ligand $PNMe_2$ (0.40 mmol), and the yellow mixture was stirred at room temperature. After 3 h, the colorless mixture was filtered and the filtrate was concentrated under reduced pressure. Addition of Et_2O caused the formation of a white precipitate, which was filtered off, washed with Et_2O, and dried in vacuo. The solid was recrystallized from MeCN and Et_2O and dried in vacuo. Crystals suitable for X-ray analysis were grown by slow evaporation of the solvent from CH_2Cl_2/EtOH/Et_2O solutions.

X-ray Crystal Structure Determinations: The crystals were mounted on glass fibres, coated with epoxy resin, and were transferred to a Siemens Nicolet R3m/V four-circle automated diffractometer. Using graphite-monochromated Mo-K_α radiation, accurate cell parameters were determined and diffraction intensities (up to Θ 23°) were measured. Two standard reflections were measured after every 150 data points to check for crystal deterioration and/or misalignment. No significant deterioration in intensity was observed. Data were corrected for Lorentz, polarization and absorption (using ψ scans) effects.

The crystals of **3**·3/2 H_2O were found to be slightly sensitive to X-rays (decay of up to 19% during data collection) and decomposed after prolonged irradiation. Consequently, the empirical absorption correction was not applied. No unusually high correlation values were noted between any of the variables in the last cycle of full-matrix least-squares refinements on F^2 and the final difference maps were essentially featureless. Programs used and the sources of scattering factors are contained in the SHELXTL (PC version

4.20 or 5.03) software package provided by Siemens Analytical X-ray Instruments[28][29]. Some details of the data collection and refinements are given in Table 3. Selected bond distances and angles are presented in Table 4.

Further details of the crystal structure determination can be obtained from the Fachinformationszentrum Karlsruhe, D-76344 Eggenstein-Leopoldshafen, Germany, on quoting the depository numbers CSD 408513 (**1**), 408514 (**2**), 408515 (**3**·3/2 H_2O), and 408516 (**9**).

Keywords: Diazonium cations / Diphosphonium cations / Calculations / Ab initio methods

Ab initio quantum-chemical investigations are used to outline the main differences between the phenyldiazonium cation $[PhN_2]^+$ (**1a**,**b**) and its P analogue $[PhP_2]^+$ (**2a**,**b**). Our results show that in contrast to **1**, **2b** exists preferentially as a bridged structure. The phenyl ion affinity toward P_2 has been determined and suggests that the phenyldiphosphonium cation should be stable in the gas phase and that it is probably accessible by reaction between P_2 and Ph^+.

Introduction

The theoretical, structural and synthetic aspects of diazonium ions, $[RN_2]^+$, have been comprehensively studied and discussed in numerous monographs and reviews.[1] In contrast, data on the chemistry of their phosphorus analogues is much more limited. Thus, the sterically crowded salts $[Ar^*NP]^+ X^-$ ($Ar^* = 2,4,6\text{-}tBu_3C_6H_2$) are the only compounds isolated to date containing the phosphoazonium (phosphanetriylammonium) cation.[2] The area of the respective diphosphonium (phosphanetriylphosphonium) cations, $[RP_2]^+$, is even less well explored. Mass-spectrometric evidence has been presented for the formation of the $[iPr_2NP_2]^+$ cation,[3] but the characterization of this species by other physicochemical methods has yet to be accomplished. The closest approach to $[RP_2]^+$ cations has been our work on protonated *P*-aminodiphosphenes, $Ar^*-P=P-NR_2$.[4] We succeeded in the synthesis of the donor-stabilized arenediphosphonium cation, $[Ar^*PP(PPh_3)]^+$, but the free cation was found to be unstable and could not be directly observed in solution. It is evident that further synthetic design of diphosphonium ions requires a detailed theoretical examination of the electronic structure of these species and of the electronic influence of the substituent R on the stability and structure of the molecule. Earlier theoretical investigations on phosphorus analogues of diazonium ions based on ab initio calculations focused on the protonated $[HP_2]^+$[5a] and methyl-substituted $[MeNP]^+$, $[MePN]^+$ and $[MeP_2]^+$ species.[5b][5c][5d][5e] For the latter, the end-on structure appeared to be favoured. This fact could be rationalized in terms of a preference for a carbon coordination number of four. However, this hypothesis does not explain the end-on geometry adopted in the case of $[PhN_2]^+$. The purpose of this article is to compare the structures deduced from theory for $[PhN_2]^+$ and $[PhP_2]^+$ cations, so as to permit more considered interpretation of these geometrical preferences.

Computational Methods

Ab initio calculations were performed using Gaussian 94/DFT.[6][7] The optimization and the vibrational analysis were carried out at the RHF/6-31 G (d,p) level of theory with the inclusion of dynamic electron correlation at the MP2 (full)/6-31 G (d,p) level, as well as with density functional theory[8] using the hybrid Becke 3LYP[9] method in conjunction with the 6-31 G (d,p) basis set. The vibrational zero-point energies determined at the MP2 level and with the DFT method[10] are known to be accurate and were used unscaled. Graphical representations of the nature of the molecular orbitals were obtained using the Molden program.[11]

Results and Discussion

Phosphorus analogues of alkyldiazonium ions have recently been investigated theoretically by Glaser.[5c][5d][5e] In these reports, different geometric structures are advanced for RP_2^+, based on energetic considerations of a protonation process on the one hand, and a clear polarization of the P_2 fragment upon electrophilic attack on the other. However, no information is provided concerning the phenyldiphosphonium ion. In this work, we present the first theoretical investigation concerning the phenyl-substituted ion and its electronic characteristics.

Our theoretical approximation is more than adequate considering the large size of the molecule. Glaser[12] noted that regarding isomer stability of the phenyldiazonium ions, the MP2 results agree qualitatively with the CISD predic-

 © WILEY-VCH Verlag GmbH, D-69451 Weinheim, 1998 1434–1948/98/1111–1821 $ 17.50+.50/0

tions, but tend to underestimate the stability of the bridged structure. Furthermore, many studies have shown the quality of the results obtained using B3LYP to describe geometries, as well as in estimating heats of formation.[13]

Considering the phenyldiazonium ion, we found at both the MP2 and DFT levels, two local minima **1a** and **1b**, which are associated with the linear and the out-of-plane edge-on approaches of N−N to the singlet phenyl cation, respectively. These results are consistent with earlier theoretical research[12], and suggest that the dative bond description with an overall neutral N_2 moiety is clearly preferable. However, the latter less stable structure **1b** is isoenergetic with the dissociated phenyl cation and N_2, and is not accessible by reaction between these components.

For the benzenediphosphonium ion, two local minima are found at the same level of calculation, but linear end-on coordinated **2a** is less favoured than the symmetrically bridged local minimum **2b** by 16.29 kcal/mol [6-31 G (d,p)/MP2], 16.84 kcal/mol [6-31 G (d,p)/B3LYP]. Furthermore, regarding the affinity of P_2 towards the phenyl cation, our results suggest that **2b** should be stable in the gas phase. Affinities are calculated to be 52.83 kcal/mol by HF/MP2 (45.50 kcal/mol by B3LYP) for the end-on coordination, and 69.67 kcal/mol by HF/MP2 (61.79 kcal/mol by B3LYP) for the bridged local minimum. It should be pointed out that, in contrast to **1b**, the generation of the phenyldiphosphonium ion **2b** by reaction between P_2 and the phenyl cation is not excluded in the gas phase.

Energies and geometries of **1a**,**b** and **2a**,**b** are summarized in Figure 1. For **2a**, differences are apparent between the optimal geometries computed with MP2 and DFT. A linear structure is found at the DFT/6-31 G (d,p) and RHF/6-31 G (d,p) levels, but a bent geometry appears as a minimum at the MP2 (full)/6-31 G (d,p) level. The potential energy surface characteristics for the edge-on coordinated structure are greatly affected by electron correlation. Structure **2b** is calculated to be the only minimum (MP2 and DFT levels) corresponding to the out-of-plane edge-on approach. The distance C−P is proportionally shorter than the C−N distance in **1b**. This fact explains the widening of the P−C−P angle (60°) compared to the N−C−N angle (41°). It is noteworthy that theoretical models do not affect the P−C−P and C−P−P angles, which are quasi-similar. In addition, the bond length alternation suggests that the π electrons are not fully delocalized into the phenyl ring. A significant lengthening is observed for the C−C bond in the α position of C_{spiro} compared to that in the phenyldiazonium ion.

Figure 1. Energies and geometrical parameters of **1**(**a**,**b**) and **2**(**a**,**b**) calculated at the MP2/6-31 G** and B3LYP/6-31G** levels of theory. Total energies, E_{tot}, in atomic units; zero-point vibrational energies, ZPVE, in kcal/mol; angles in°, and bond lengths in Å

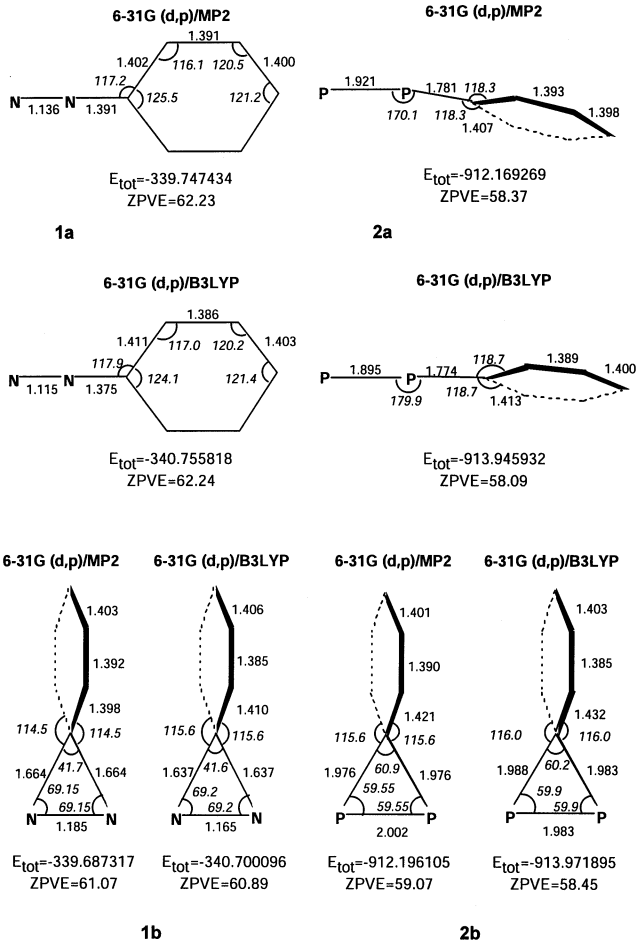

Figure 2. Charges of **1**(**a**,**b**) and **2**(**a**,**b**) calculated at the MP2/6-31 G** and B3LYP/6-31G** levels of theory

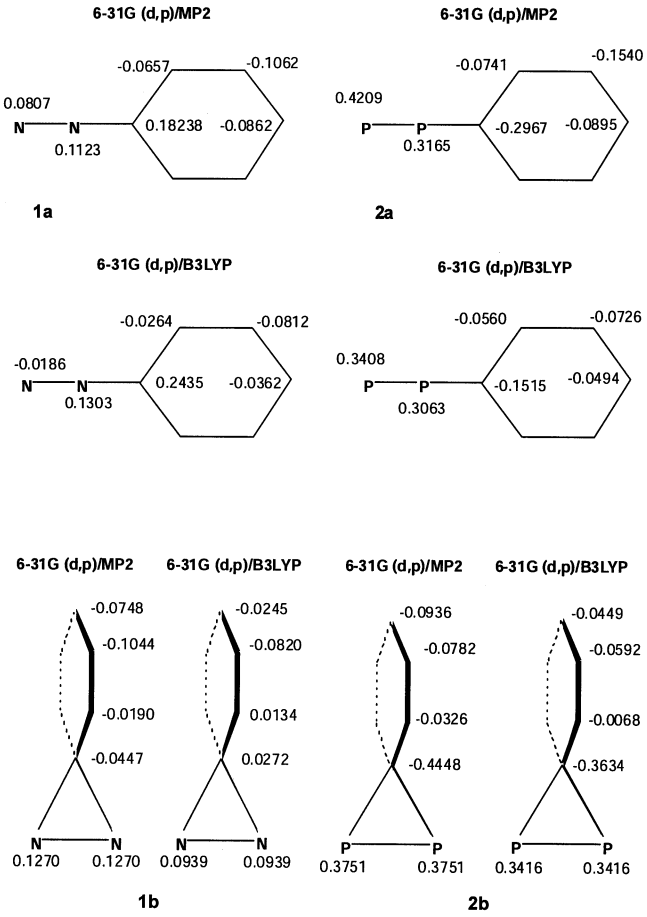

A key difference to the diazonium cation is seen in the polarization of these systems. Considering the charges displayed in Figure 2, it is clear that the positive charge (for **2a** and **2b**) is distinctly localized on the P−P moiety, while the stable structure of diazonium analogous **1a** can be viewed as a phenyl cation with a closely associated nitrogen molecule.

An examination of the molecular orbital interactions that occur in these two systems is clearly relevant, since these directly affect the nature of the preferentially adopted structure and thus will be a source of information with regard to the synthesis and detection of such species.

Localization and energetic positions of MOs allow us to visualize these interactions as in Figures 3 and 4[14]. If we analyse them for the end-on coordination structures **1a** and **2a**, they are very well described as an interaction between the σ_{XX} orbital and the LUMO of the phenyl cation [$\sigma_{XX} \rightarrow \sigma^*_{Ph}$ −17.29 eV (X = N), −13.32 eV (X = P)] and a back-donation from π_2 (phenyl cation) to the π^*_{XX} orbital of the same symmetry [$\pi_{2Ph} \rightarrow \pi^*_{XX}$ −12.78 eV (X = N), −11.75 eV (X = P)]. Furthermore, the formation of σ_{PC} becomes easier than that of σ_{NC} as a consequence of the σ_{PP} energetic position in comparison with that of σ_{NN}. In fact, experimentally determined ionic state energies for N_2 and P_2 [$^2\Sigma^+_g$ and $^2\Pi^+_u$ associated with the ejection of an electron from $^1\pi_u$ (π bond) and $^3\sigma_g$ (σ_{XX}) orbitals] are observed at 15.60, 16.98 and 10.81, 10.62 eV, respectively. The electron transfer should be more important in the case of P_2 than in the case of N_2, and the π back-donation is not expected to compensate this transfer. In agreement with this hypothesis, the charges are found to be negative at C_{ipso} and positive on the two phosphorus atoms. It is noteworthy that a slightly less pronounced polarization is obtained by using B3LYP than at the MP2 level.

Figure 3. Selected molecular orbitals (MO) of the linear compound **1a** calculated at the B3LYP/6-31 G** level

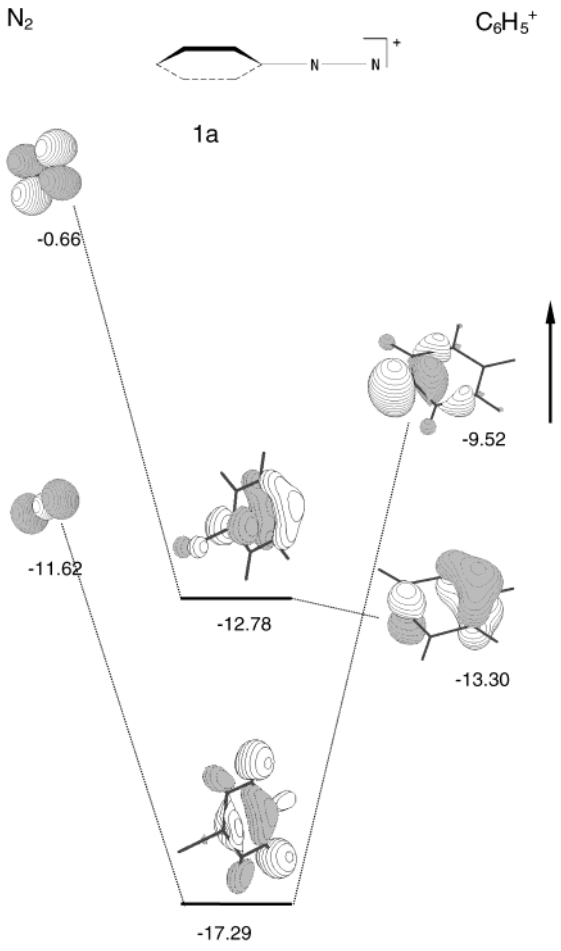

Figure 4. Selected molecular orbitals (MO) of the linear compound **2a** calculated at the B3LYP/6-31 G** level

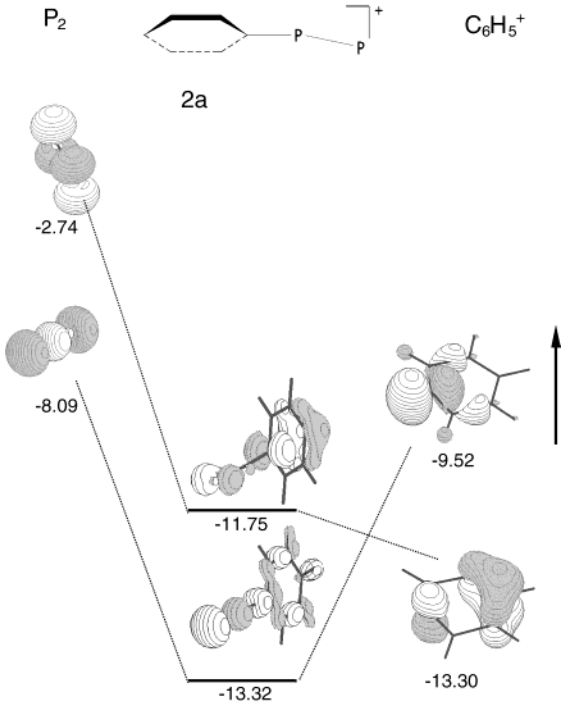

If we consider the bridged structures **1b** and **2b**, the LUMO σ^* of the phenyl cation is seen to interact with the π_{XX} orbital. Regarding the energetic gap between the LUMO Ph^+ and π_{XX}, this interaction will be easier in the case of P_2 (ΔE = 1.70 eV cf. 3.06 eV for N_2/Ph^+). This is well represented for the phosphonium ion by the MO at −14.38 eV.

We note that, in contrast to the aforementioned behaviour, in the case of N_2, a destabilizing interaction occurs between π_{NN} and the lower $\sigma_{Ph}{}^+$ orbitals. If we consider the charges, notable differences are evident in their distribution between the phenyldiphosphonium cation and the phenyldiazonium cation. The large positive charge localized on each phosphorus atom and the negative one on C_{ipso}, could be explained first of all by the high σ transfer, which is not sufficiently compensated by the π back-donation (vide infra).

Finally, π back-donation appears as for the linear molecule, involving the $\pi_{2Ph}{}^+$ and the π^*_{XX} orbitals, which can be visualized by the MO at −12.69 eV for the phosphorus compound, and at −13.29 eV for the nitrogen analogue.

Figure 5. Selected molecular orbitals (MO) of the bridged compound **1b** calculated at the B3LYP/6-31 G** level

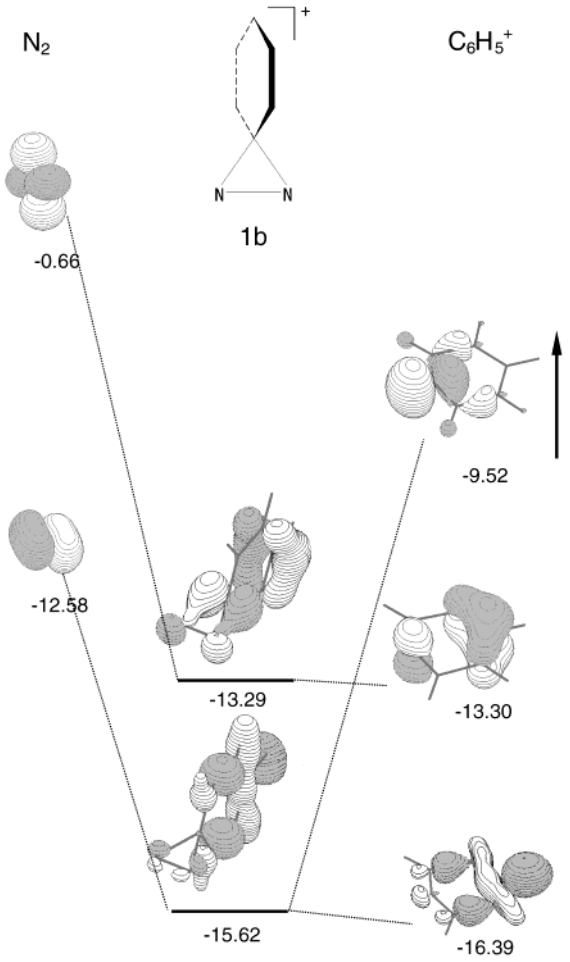

Figure 6. Selected molecular orbitals (MO) of the bridged compound **2b** calculated at the B3LYP/6-31 G** level

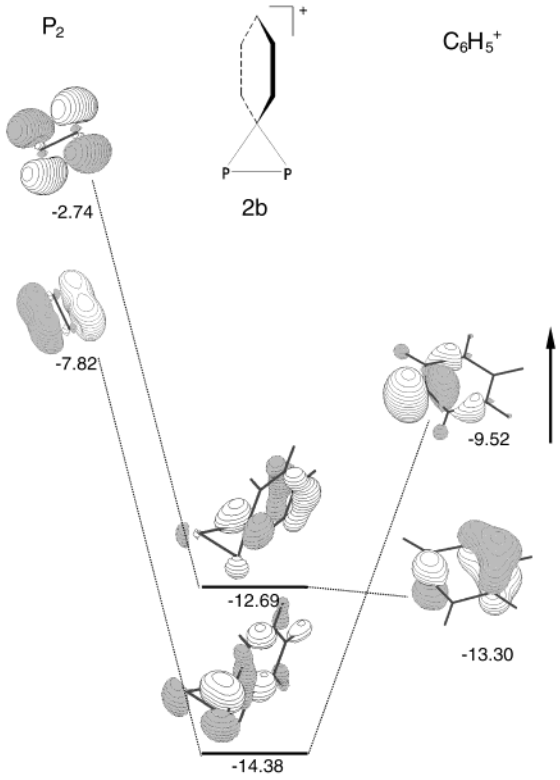

Why is the bridged form **2b** stabilized in comparison with the linear one? An explanation is found mainly in the stabilizing interactions and notably in the interaction $\pi^{+}_{PP} \rightarrow \sigma^{*}_{Ph}{}^{+}$, which is observed only in the bridged form. Naturally, other interactions play an important role in determining the stability of these systems, such as the interaction $\pi 2Ph^{+} \rightarrow \pi^{*}_{PP}$, but these are in fact found in both isomers. Nevertheless, the interaction $\pi^{+}_{PP} \rightarrow \sigma^{*}_{Ph}{}^{+}$ leads to a more effective overlap, compared with the $\sigma_{PP} \rightarrow \sigma^{*}_{Ph}{}^{+}$ interaction that exists in the linear form. In other words, the overlap is more effective with two phosphorus atoms (bridged form) than with only one (linear form). Finally, taking into account the energetic positions, the molecular orbitals π_{PP} and σ_{PP} remain localized on this moiety, while π_{NN} and σ_{NN} are mixed with the σ-MO from the phenyl ring (destabilizing interactions).

Conclusion

The new insight given by the present study shows that aromatic diphosphonium ions might be stable species. To date, all attempts to isolate these molecules have failed, mainly due to difficult kinetic control rather than because of thermodynamic factors. However, considering the σ^{*}_{PP}-MO energetic position (−7.69 eV) for the bridged structure, the availability of the diazonium ion complex, and the position of the corresponding σ* MO (−7.66 eV), we can reasonably expect that it should be possible to stabilize the system by means of nucleophilic assistance.

Financial support of this work by the *CNRS* (France) is gratefully acknowledged. We also thank the *Institut du Développement de Ressources en Informatique Scientifique* (*IDRIS*, Orsay, France), administered by the *CNRS*, for the calculation facilities, and Dr. *Gijs Schaftenaar* for allowing us to use his graphics program Molden. We also thank Mrs. *F. Gracian* for her invaluable help in the realization of the figures.

[14] It is well known that ab initio orbitals do not derive from a purely one-electron Hamiltonian and therefore do not possess the property of associativity necessary to justify a construction from fragment orbitals. Thus, we preferred to present Kohn-Sham orbitals, which are more appropriate from this point of view.

Vinylidene Transition-Metal Complexes, 47[◇]

Synthesis and Molecular Structure of Six-Coordinate Dichlorodihydridoruthenium(IV) and Five-Coordinate Vinylideneruthenium(II) Complexes☆

Keywords: Ruthenium / Terminal alkynes / Carbene complexes / Hydrido complexes / Vinylidene complexes

The dichlorodihydridoruthenium(IV) compound $[RuH_2Cl_2(PiPr_3)_2]$ (**4**) was prepared from $[RuCl_2(C_8H_{12})]_n$ (**3**), $PiPr_3$, and H_2 in 2-butanol via the chlorohydridoruthenium(II) derivative $[RuHCl(H_2)(PiPr_3)_2]$ (**5**) as an intermediate. The synthesis of **5** was achieved under similar conditions from **3**, $PiPr_3$, H_2, and 2-butanol in the presence of NEt_3. Compound **4**, which was characterized by X-ray crystal structure analysis, reacts with excess phenylacetylene to give the phenylvinylidene complex $[RuCl_2(=C=CHPh)(PiPr_3)_2]$ (**7**) and with propargylic alcohols or derivatives thereof to afford the vinylcarbene complexes $[RuCl_2(=CHCH=CR_2)(PiPr_3)_2]$ (**9**, **10**), respectively. From **5** and terminal alkynes RC≡CH the chlorohydridovinylidene compounds $[RuHCl(=C=CHR)(PiPr_3)_2]$ (**11**, **12**) were obtained. The phenylvinylidene complex $[RuCl_2(=C=CHPh)(PCy_3)_2]$ (**15**) was prepared from phenylacetylene and either $[RuH_2Cl_2(PCy_3)_2]$ (**14**) or one of the carbene derivatives $[RuCl_2(=CHR)(PCy_3)_2]$ (**16**, **17**) as starting materials. The X-ray crystal structure analysis of **15** confirms a distorted square-pyramidal geometry with the vinylidene ligand in the apical position. The interconversion of **4** to **5** and of the tricyclohexylphosphane counterparts **14** to **13** was achieved by hydrogen transfer from 2-propanol in the presence of PR_3. The reverse reaction occurs upon treatment of **5** or **13** with the corresponding phosphonium salt $[HPR_3]Cl$ or HCl, respectively.

In the course of our investigations aimed to prepare bis(trialkylphosphane) transition-metal complexes containing *coordinatively unsaturated* metal centers, we recently described the synthesis of the dichlorodihydridoosmium(IV) compounds $[OsH_2Cl_2(PiPr_3)_2]$ (**1**) and $[OsH_2Cl_2(PtBu_2Me)_2]$ (**2**), in which osmium, although six-coordinate, has 16 electrons in its valence shell.[1] These compounds, in particular **1**, have a rich chemistry which has opened the gate not only to carbyne- but also to vinylideneosmium complexes.[2][3]

Since it was known from our work on the reactivity of compounds such as $[MCl_2\{\kappa^2(P,O)\text{-}iPr_2PCH_2CH_2OMe\}_2]$ and $[MCl_2\{\kappa^2(P,O)\text{-}iPr_2PCH_2CO_2R\}_2]$ (M = Ru, Os) that the ruthenium derivatives react more readily with terminal alkynes and propargylic alcohols to give the corresponding vinylidene and allenylidene complexes,[4] we set out to prepare the hitherto unknown ruthenium(IV) compound $[RuH_2Cl_2(PiPr_3)_2]$ (**4**). After initial attempts with $RuCl_3 \cdot aq$ as starting material failed, we found that the reaction of $[RuCl_2(C_8H_{12})]_n$ (**3**) with triisopropylphosphane in 2-butanol under H_2 gave the dichlorodihydrido complex **4**.[5] Most recently, Caulton and coworkers reported the synthesis of the analogous compound $[RuH_2Cl_2(PtBu_2Me)_2]$ using our methodology with the cycloocta-1,5-diene derivative **3** as the starting material.[6]

In this article we describe the preparation and characterization of **4** and its PCy_3 counterpart **13**, and the use of these dichlorodihydridoruthenium(IV) compounds as well as of the related chlorohydrido(dihydrogen)ruthenium(II) derivatives to obtain five-coordinate vinylideneruthenium(II) complexes. Part of these studies has been communicated.[5]

Results and Discussion

As was mentioned above, instead of $RuCl_3 \cdot aq$, which reacts with $PiPr_3$ in boiling methanol to give $[RuHCl(CO)(PiPr_3)_2]$,[7] compound **3** has to be used as starting material for the preparation of **4** (Scheme 1). On treatment of a suspension of **3** in 2-butanol with 3 equiv. of $PiPr_3$ in the presence of H_2 a red solution is formed which, due to the ^1H- and ^{31}P-NMR spectra, contains the dihydrogen complex **5**. This compound was originally prepared by Chaudret et al. from $[Ru(\eta^4\text{-}C_8H_{12})(\eta^6\text{-}C_8H_{10})]$, $PiPr_3$, and $CHCl_3$ under 4 atm of dihydrogen.[8] If the red solution obtained from **3** was brought to dryness in vacuo and the oily residue recrystallized from ether, orange crystals of **4** (but not **5**) were

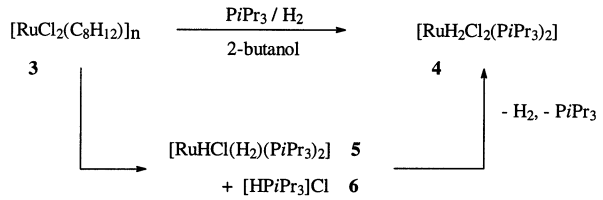
Scheme 1



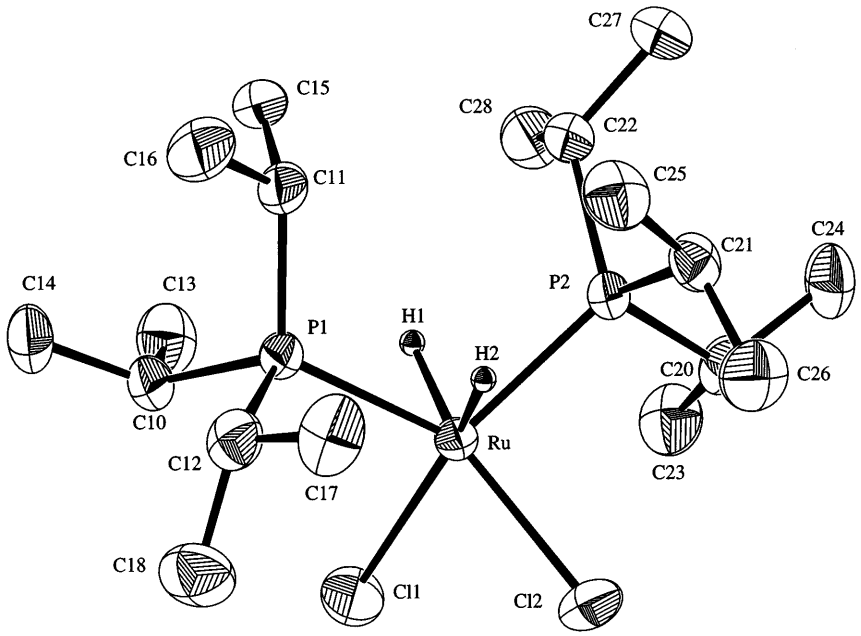
isolated in 92% yield. The conversion of **5** to **4** is promoted by the phosphonium salt **6** which is generated as a byproduct in the reaction of **3**, P*i*Pr$_3$, 2-butanol, and H_2.

In order to confirm the proposal that the initial product in the reaction of **3** with triisopropylphosphane under the conditions used is indeed the dihydrogen complex **5**, a suspension of the oligo- or polymeric cycloocta-1,5-diene compound **3** was treated with P*i*Pr$_3$/H_2 in 2-butanol in the presence of NEt_3 as a base. After removal of the solvent and extraction of the residue with pentane, a red oil was obtained which by comparison of the NMR data with those published by Chaudret is the dihydrogenruthenium(II) derivative **5**.[8] This compound reacts with the phosphonium salt [HP*i*Pr$_3$]Cl (**6**) in CH_2Cl_2 to afford, by evolution of gas (H_2), quantitatively P*i*Pr$_3$ and the dichlorodihydrido complex **4**. The latter is an orange solid which is readily soluble in CH_2Cl_2 and $CHCl_3$, but almost insoluble in hydrocarbons. The characteristic feature in the ^{1}H-NMR spectrum of **4** is the triplet resonance for the two hydrido ligands in the high-field region at $\delta = -12.30$.

The result of the X-ray crystal structure analysis of **4** is shown in Figure 1. The coordination geometry around the six-coordinate metal center is very similar to that of the osmium analogue **1**.[1a] It is best described as a somewhat distorted variant of a D_{4d} square antiprism with the two vacant coordination sites in alternate positions at one square base of this polyhedron. The other square base is made up by the two phosphorus atoms and the two hydrido ligands, the positions of which could be located in a difference Fourier synthesis. The Ru−P and Ru−Cl distances of **4** are almost identical to the corresponding bond lengths in **1**, and this is also true for the P−M−P, P−M−Cl, and Cl−M−Cl bond angles (M = Ru, Os). The distances Ru−H1 and Ru−H2 of 1.46(5) and 1.56(5) Å are in the range found for other hydridoruthenium(II) and -ruthenium(IV) complexes.[9] We note that recently Gusev, Berke, Eisenstein, Caulton et al. observed that the molecules [OsH_2X_2(P*i*Pr$_3$)$_2$] (X = Cl, Br, I) exist *in solution* as two rapidly interconverting isomers, one having C_2 symmetry (as seen in the crystal) and the other having no symmetry.[10] In contrast, the tricyclohexylphosphane derivative **13** which was prepared independently by Chaudret and coworkers[11] and by us (see below), shows a fluxional process attributed to the interconversion of two *symmetrical* isomers.

The dichlorodihydridoruthenium(IV) compound **4** does not only react with phenylacetylene[5] but also with propargylic alcohols and derivatives thereof. The results are summarized in Scheme 2. The reaction of **4** with PhC≡CH in CH_2Cl_2 yields a mixture of two products **7** and **8** of which the first is by far the most dominating species. Compound **7** is exclusively formed if the initially generated mixture, after removal of the solvent, is treated again with phenylacetylene and heated to 80°C for a short period of time. The isolated yield of **7** is then ca. 70%. The minor component

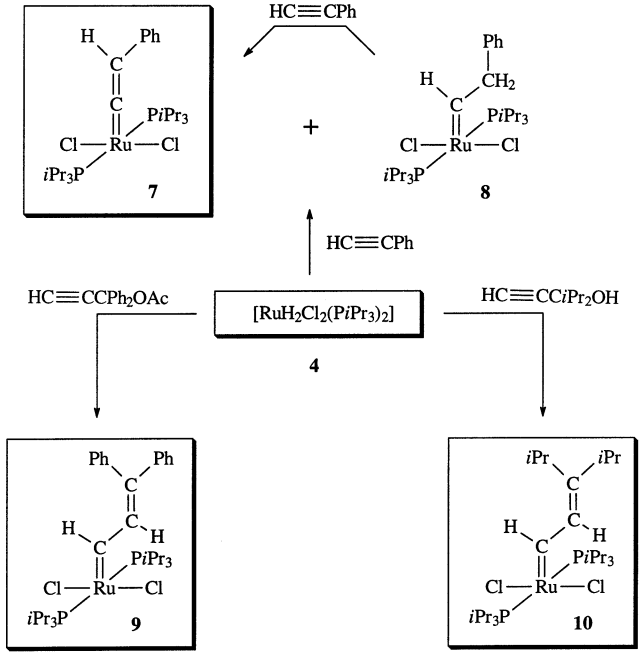
Figure 1. Molecular structure (ORTEP plot) of **4**;[a] the hydrogen atoms besides H1 and H2 are omitted for clarity



[a] Selected bond lengths [Å] and angles [°]: Ru−P1 2.270(1), Ru−P2 2.297(1), Ru−Cl1 2.400(1), Ru−Cl2 2.401(1), Ru−H1 1.46(5), Ru−H2 1.56(5); P1−Ru−P2 111.69(3), Cl1−Ru−Cl2 84.29(3), P1−Ru−Cl1 92.18(3), P1−Ru−Cl2 139.14(3), P2−Ru−Cl1 145.07(3), P2−Ru−Cl2 92.60(3).

of the reaction mixture is the benzylcarbene complex **8** which has already been characterized by X-ray crystal structure analysis.[5] Compound **8** belongs to the class of Grubbs-type carbene complexes $[RuCl_2(=CHR)(PR'_3)_2]$ that were originally prepared from $[RuCl_2(PPh_3)_3]$ and cyclopropene or diazoalkane derivatives[12] and are now widely used as highly active catalysts for olefin metathesis including ROMP and RCM.[13]

Scheme 2



The vinylideneruthenium(II) compound **7** is a brown, only moderately air-sensitive solid that has been characterized by elemental analysis and spectroscopic techniques. The ^{13}C-NMR spectrum displays two triplets at δ = 341.1 and 109.3, which by comparison[4][14] are assigned to the α- and β-carbon atoms of the vinylidene ligand. In the ^{31}P-NMR spectrum a singlet resonance appears at δ = 29.0, the chemical shift of which is similar to that observed at δ = 27.2 for the PPh_3 ligands in $[RuCl_2(=C=CHtBu)(PPh_3)_2]$.[15] With regard to the mechanism of formation of **7**, we assume that the starting material **4**, containing a metal center with a 16-electron configuration, affords in the initial step of the reaction a 1:1 adduct with the alkyne. This seven-coordinate species could react by insertion of the alkyne into one of the Ru−H bonds to generate a hydrido(vinyl) intermediate (also with a 16-electron configuration at the metal center). This compound could then give upon addition of a second molecule of PhC≡CH, followed by reductive elimination of styrene, the alkyne complex $[RuCl_2(PhC{\equiv}CH)(PiPr_3)_2]$. The conversion of this species to the isomer **7** possibly occurs by a slippage of the π-bonded alkyne to an η^2-CH-coordinated complex which undergoes a 1,2-hydrogen migration to yield the final product. Quite recently, Wakatsuki et al. showed by ab initio MO calculations that the reaction of $[RuX_2(PPh_3)_3]$ with tBuC≡CH, which gives the compounds $[RuX_2(=C=CHtBu)(PPh_3)_2]$ (X = Cl, Br), follows a similar route.[16] It should be mentioned that the formation of styrene from **4** and phenylacetylene was confirmed by GC/MS analysis.

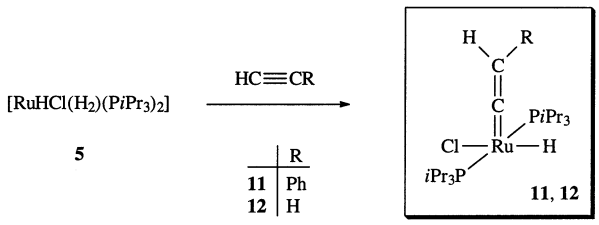
The synthesis of the vinylcarbene complexes **9** and **10** (Scheme 2) from **4** is a somewhat surprising result. Taking earlier work by Selegue,[17] Dixneuf,[18] and by some of us[4b][4c][19] into consideration, we anticipated that on treatment of **4** with propargylic alcohols $HC{\equiv}CCR_2OH$, in particular for R = Ph, allenylidenemetal derivatives $[RuCl_2(=C=C=CR_2)(PiPr_3)_2]$ would be formed. However, instead of these species the related vinylcarbene complexes **9** and **10** were obtained. We found that the reaction of **4** with $HC{\equiv}CCPh_2OH$ in CH_2Cl_2 leads to a mixture of products among which **9** could be detected as a major component by ^{1}H-NMR spectroscopy. In contrast, by using the corresponding acetate $HC{\equiv}CCPh_2OAc$ as a carbene source, compound **9** has been isolated in excellent yield. This (vinylcarbene)ruthenium(II) derivative was originally prepared by Grubbs and coworkers from $[RuCl_2(PPh_3)_3]$ and 1,1-diphenylcyclopropene followed by ligand exchange of PPh_3 for $PiPr_3$.[12c]

The formerly unknown complex **10**, which was isolated as a violet solid in 70% yield, resembles in its properties the diphenyl analogue **9**. The ^{1}H-NMR spectrum of **10** displays in the low-field region two doublets at δ = 19.56 and 8.06 with an H−H coupling of 11.2 Hz which is typical for an $M{=}CH{-}CH{=}CR_2$ unit.[12][14] In the ^{13}C-NMR spectrum of **10** the signal for the carbene-C atom appears at δ = 288.3 and is split into a triplet due to P−C coupling. Mechanistically, the formation of **9** and **10** from **4** is best understood if we assume that in analogy to the course of the reaction of **4** with phenylacetylene a functionalized hydrido(vinyl) species $[RuH(CH{=}CHCR_2OR')Cl_2(PiPr_3)_2]$ (R′ = H, Ac) is generated as an intermediate which yields the product by elimination of HOR′.

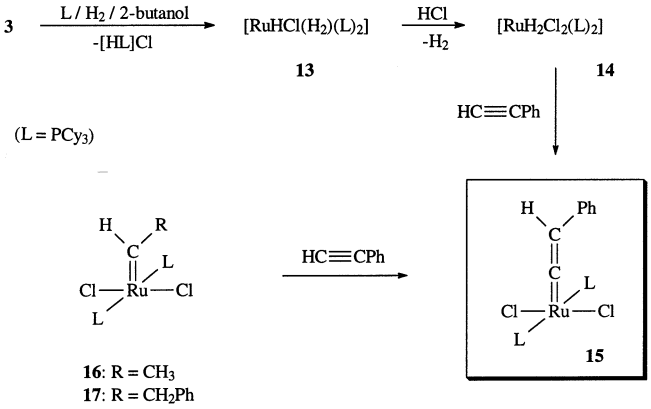
In a similar way to the dihydridoruthenium(IV) compound **4,** the hydridoruthenium(II) derivative **5** reacts with phenylacetylene to give the hydrido(phenylvinylidene) complex **11** (Scheme 3). Moreover, the parent hydrido(vinylidene) compound **12** was obtained from **5** and acetylene. Although a clean reaction between **5** and the terminal alkynes occurs, the isolated yields of **11** and **12** is only moderate (ca. 40%) mainly due to the good solubility of the products in pentane. Quite recently, Olivan, Eisenstein, and Caulton reported that on treatment of $[RuHCl(H_2)(PtBu_2Me)_2]$ with terminal alkynes RC≡CH the analogous hydrido(vinylidene) compounds $[RuHCl(=C=CHR)(PtBu_2Me)_2]$ (R = Ph, $SiMe_3$) are formed which, according to ab initio DFT calculations, possess a distorted trigonal-bipyramidal geometry with the phosphanes in the apical positions.[20] The osmium analogue of **11** was recently prepared by Esteruelas et al. by a different route, namely from the six-coordinate carbyne(hydrido) complex $[OsHCl_2(\equiv CCH_2Ph)(PiPr_3)_2]$ by elimination of HCl with NaOMe.[21]

The ^{13}C-NMR spectra of both **11** and **12** display in the low-field region the typical signals for the vinylidene α- and β-carbon atoms at δ = 329.3 and 109.7 (for **11**) and at δ =

Scheme 3



Scheme 4



326.3 and 87.1 (for **12**) which are all split into triplets due to P−C coupling. In the ^{1}H-NMR spectrum the hydride resonance also appears as a triplet at $\delta = -12.48$ (for **11**) and −15.03 (for **12**). In contrast to **7**, the methyl groups of the triisopropylphosphane ligands in **11** and **12** are diastereotopic and thus two sets of signals are observed for the CH_3 protons and carbon nuclei in the NMR spectra. It should be mentioned that in agreement with recent work from our laboratory[22][23] compounds **11** and **12** react with the phosphonium chloride [HP*i*Pr$_3$]Cl to give the carbene complexes [RuCl$_2$(=CHCH$_2$R)(P*i*Pr$_3$)$_2$] (R = Ph, H) in excellent yield.

The analogues of the chlorohydrido and dichlorodihydrido compounds **5** and **4** with two PCy$_3$ instead of two P*i*Pr$_3$ ligands, **13** and **14**, are also accessible from the cycloocta-1,5-diene derivative **3** as the starting material. Like **5**, the corresponding ruthenium(II) complex **13** was first prepared by Chaudret and coworkers from the ruthenium(0) compound [Ru(η^4-C$_8$H$_{12}$)(η^6-C$_8$H$_{10}$)].[8] While this work was in progress,[24] Grubbs et al. published an experimental procedure for **13** that followed our methodology using the (cycloocta-1,5-diene)ruthenium(II) derivative **3** as the precursor.[25] Regarding the dichlorodihydridoruthenium(IV) complex **14**, very recently Chaudret and coworkers reported a synthesis which is different to that one described in this work and based on the reaction of the "polyhydride" [RuH$_2$(H$_2$)$_2$(PCy$_3$)$_2$] with aqueous HCl in ether.[11] The same authors also confirmed by VT NMR measurements that **14** shows a fluxional process in solution which is attributed to the interconversion between two stereoisomers having C_{2v} symmetry.[11] Our observations are in agreement with these results.[23]

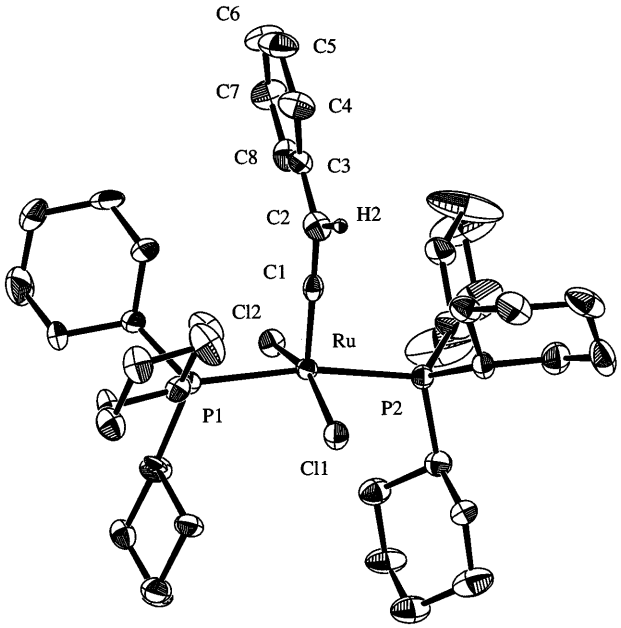
Compound **14** does not only react with CO to give [RuHCl(CO)$_2$(PCy$_3$)$_2$][11] but also with phenylacetylene in the molar ratio of 1:10 to yield the vinylidene complex **15** (Scheme 4). Alternatively, **15** can be prepared upon treatment of the carbene derivatives **16** and **17** with PhC≡CH. In both cases the isolated yield is 60−70%. To the best of our knowledge, there has been only one other compound of the general composition [RuCl$_2$(=C=CHR)(PCy$_3$)$_2$] (with R = H) reported in the literature which was obtained from [RuCl$_2$(=CHPh)(PCy$_3$)$_2$] and a tenfold excess of allene.[12d][12e] The phenylvinylidene complex **15** (which is an almost air-stable solid) is only sparingly soluble in common organic solvents at room temperature and thus the ^{1}H-, ^{13}C-, and ^{31}P-NMR spectra were measured in $CDCl_3$ at 40°C. The NMR data for **15** and the related bis(triisopropylphosphane) complex are quite similar and therefore deserve no further comment.

The molecular structure of **15** is shown in Figure 2. The ORTEP plot reveals that the configuration around the metal center is distorted square-pyramidal with the vinylidene unit in the apical position. In the basal plane the two chloro and the two phosphane ligands are *trans* disposed. Although according to ab initio calculations this geometry represents the energy minimum on the potential surface,[16] it was found that in contrast to **15** the analogous compound [RuBr$_2$(=C=CH*t*Bu)(PPh$_3$)$_2$] possesses a trigonal-bipyramidal structure with the PPh$_3$ groups in the apical positions.[16] Therefore it seems that for the preferred configuration of the five-coordinate complexes steric requirements play a dominant role. The Ru−C1−C2 axis is nearly linear with an Ru−C1 distance that is slightly shorter than in [RuBr$_2$(=C=CH*t*Bu)(PPh$_3$)$_2$] [1.77(2) Å][16] and in the six-coordinate compound [RuCl$_2$(=C=CHPh){κ^1(*P*)-Me$_2$PCH$_2$CH$_2$OMe}{κ^2(*P,O*)-Me$_2$PCH$_2$CH$_2$OMe}] [1.815(2) Å][26] but almost identical to that in [RuCl$_2$(=C=CHPh)-{κ^1(*P*)-*i*Pr$_2$PCH$_2$CH$_2$OMe}{κ^2(*P,O*)-*i*Pr$_2$PCH$_2$CH$_2$OMe}] [1.749(7) Å].[4a] The P1−Ru−P2 axis is somewhat bent [169.82(7)°] and this is even more so for the Cl1−Ru−Cl2 unit [158.31(7)°]. The C1−C2 distance is in the expected range and this is true also for the Ru−Cl and Ru−P bond lengths.

Finally, a special comment is appropriate concerning the interconversion of the ruthenium(II) and ruthenium(IV) complexes **5** and **4** (see Scheme 5). In the context of the preparation of **4** from **3** it has already been mentioned that in this process compound **5** is generated as an intermediate which reacts with the byproduct **6**, after removal of 2-butanol, to give **4**. However, the surprising observation is that the red solution, which is initially formed from **3**, P*i*Pr$_3$, and H$_2$ in 2-butanol, is quite stable and can be stored for days without the conversion of the two components **5** and **6** to the ruthenium(IV) complex **4**.

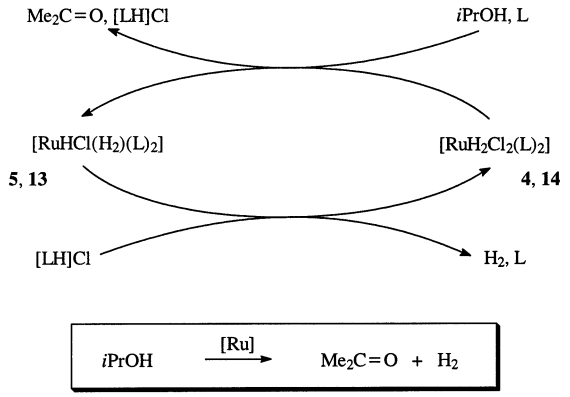
In order to explain this seeming inconsistency it should be emphasized that although **5** and **6** react by elimination of H$_2$ to give **4** and P*i*Pr$_3$, in the presence of a secondary alcohol such as 2-butanol, or even better 2-propanol, the

Figure 2. Molecular structure (ORTEP plot) of **15**;[a] the hydrogen atoms are omitted for clarity



[a] Selected bond lengths [Å] and angles [°]: Ru−C1 1.747(7), Ru−P1 2.429(2), Ru−P2 2.410(2), Ru−Cl1 2.342(2), Ru−Cl2 2.355(2), C1−C2 1.33(1), C2−C3 1.45(1); C1−Ru−Cl1 102.8(2), C1−Ru−Cl2 98.9(2), C1−Ru−P1 94.6(2), C1−Ru−P2 94.9(2), P1−Ru−P2 169.82(7), P1−Ru−Cl1 88.97(7), P1−Ru−Cl2 88.42(6), P2−Ru−Cl1 85.47(7), P2−Ru−Cl2 93.59(7), Cl1−Ru−Cl2 158.31(7), Ru−C1−C2 178.2(6), C1−C2−C3 129.4(7).

Scheme 5



mixture of **4** and triisopropylphosphane is reconverted to **5** and **6**. The formation of acetone as a byproduct has been confirmed by GC/MS analysis which indicates that 2-propanol serves as the hydrogen source. An analogous but significantly slower reaction takes place between compound **14** and PCy_3 in 2-propanol. In this case the chlorohydrido complex **13** precipitates due to its lower solubility (compared with **5**) in the alcohol. The ^{31}P-NMR spectrum of the mother liquor indicates that besides **13** a small quantity of a sideproduct is formed which has not been identified as yet. For the conversion of **13** to **14** it is preferable to use instead of the phosphonium salt $[HPCy_3]Cl$ aqueous HCl as a proton source which yields the ruthenium(IV) compound almost quantitatively.

This work was supported by the *Deutsche Forschungsgemeinschaft* (SFB 347) and the Fonds der *Chemischen Industrie*. We are grateful to the latter in particular for a Kekulé stipend (to W. S.). Moreover, we thank Dr. *W. Buchner* and Mrs. *M.-L. Schäfer* for NMR measurements, Mrs. *R. Schedl* and Mr. *C. P. Kneis* for performing the elemental analyses and DTA measurements, and Mrs. *I. Geiter* for technical assistance. Generous support by the BASF AG and the Degussa AG (gifts of chemicals) is also gratefully acknowledged.

Experimental Section

All operations were carried out under argon using Schlenk techniques. The starting materials **3**,[27] and **16**, **17**[22] were prepared as described in the literature. The alkynes were commercial products from Aldrich, Strem, and ABCR. − NMR: Bruker AC 200 and AMX 400 [dvt = doublet of virtual triplets; $N = {}^3J(PH) + {}^5J(PH)$ or $^2J(PC) + {}^4J(PC)$, respectively]. − Melting points determined by DTA.

1. *Preparation of [$RuH_2Cl_2(PiPr_3)_2$]* (**4**): A suspension of 220 mg (0.79 mmol for $n = 1$) of **3** in 20 ml of 2-butanol was treated with 463 µl (2.37 mmol) of $PiPr_3$ and heated under hydrogen (1.5 bar) for 6 h at 80°C. Upon cooling the resulting red solution to room temperature, the solvent was removed in vacuo and 5 ml of diethyl ether was added to the oily residue. After 2 h, an orange solid crystallized, which was washed with 5 ml of diethyl ether and dried in vacuo; yield 359 mg (92%); m. p. 60°C (dec.). − ^1H NMR (200 MHz, CD_2Cl_2): δ = 2.30 (m, 6 H, PC*H*CH_3), 1.22 [dd, $J(PH) = 14.9$, $J(HH) = 7.1$ Hz, 36 H, PCHC*H*$_3$], −12.30 [t, $J(PH) = 19.0$ Hz, 2 H, RuH_2]. − ^{13}C NMR (100.6 MHz, CD_2Cl_2): δ = 29.7 (m, P*C*HCH$_3$), 19.6 (s, PCH*C*H$_3$). − ^{31}P NMR (162.0 MHz, CD_2Cl_2): δ = 103.2 (s). − $C_{18}H_{44}Cl_2P_2Ru$ (494.5): calcd. C 43.72, H 8.97, Ru 20.44; found C 43.41, H 8.83, Ru 19.85.

2. *Preparation of [$RuHCl(H_2)(PiPr_3)_2$]* (**5**) *from* **3**: A suspension of 119 mg (0.42 mmol für $n = 1$) of **3** in 15 ml of 2-butanol was treated with 200 µl (1.02 mmol) of $PiPr_3$ and 117 µl (0.84 mmol) of NEt_3 and then heated for 6 h under hydrogen (1.5 bar) at 80°C. Upon cooling to room temperature, the solvent was removed in vacuo and the orange residue was extracted with 15 ml of pentane. After the extract was brought to dryness in vacuo, a red oil was obtained which by comparison of the NMR data was identified as **5**.[8] Yield almost quantitative.

3. *Reaction of Compound* **5** *with [HPiPr$_3$]Cl* (**6**): A solution of compound **5**, prepared from 25 mg (0.09 mmol) of **3**, 45 µl (0.23 mmol) of $PiPr_3$ and 25 µl (0.18 mmol) of NEt_3 in 5 ml of 2-butanol, was brought to dryness in vacuo. The oily residue was extracted with 10 ml of pentane and, after removal of the solvent, was dissolved in 3 ml of CH_2Cl_2. The red solution was treated with 37 mg (0.19 mmol) of **6**, which led to a rapid evolution of gas (H_2). After the solution was stirred for 5 min, the solvent was removed and the remaining orange solid identified as **4** by comparison of the NMR data with those of an authentic sample. Yield almost quantitative.

4. *Preparation of [$RuCl_2(=C=CHPh)(PiPr_3)_2$]* (**7**): A solution of 142 mg (0.29 mmol) of **4** in 10 ml of CH_2Cl_2 was treated with 63 µl (0.57 mmol) of phenylacetylene and stirred for 5 min at room temperature. The solvent was removed in vacuo to give a red oil which according to the ^1H- and ^{31}P-NMR spectra consisted of a mixture of **7** (90%) and **8** (10%). The oily material was dissolved in 5 ml of benzene, the solution was treated with 30 µl (0.27 mmol)

of phenylacetylene and heated for 10 min at 80°C. After cooling to room temperature, the solvent was removed in vacuo and 3 ml of methanol were added to the brownish residue. Upon storing the mixture for 2 h, a brown microcrystalline solid was obtained which was separated from the mother liquor and dried in vacuo; yield 113 mg (66%); m. p. 97°C (dec.). – ^{1}H NMR (400 MHz, C_6D_6): δ = 7.23–7.02 (m, 5 H, C_6H_5), 4.71 [t, *J*(PH) = 3.6 Hz, 1 H, =C=C*H*Ph], 2.79 (m, 6 H, PC*H*CH_3), 1.29 [dvt, *N* = 13.2, *J*(HH) = 6.6 Hz, 36 H, PCHC*H*$_3$]. – ^{13}C NMR (100.6 MHz, C_6D_6): δ = 341.1 [t, *J*(PC) = 15.1 Hz, =*C*=CHPh], 133.8 [t, *J*(PC) = 2.5 Hz, *ipso*-C of C_6H_5], 128.5, 125.6, 124.4 (each s, C_6H_5), 109.3 [t, *J*(PC) = 4.3 Hz, =C=*C*HPh], 23.7 [vt, *N* = 19.0 Hz, P*C*HCH_3], 20.1 (s, PCH*C*H$_3$). – ^{31}P NMR (162.0 MHz, C_6D_6): δ = 29.0 (s). – $C_{26}H_{48}Cl_2P_2Ru$ (594.6): calcd. C 52.52, H 8.14; found C 52.85, H 7.86.

5. *Preparation of [RuCl$_2$(=CHCH=CPh$_2$)(PiPr$_3$)$_2$]* (**9**) *from* **4**: A solution of 116 mg (0.23 mmol) of **4** in 10 ml of CH_2Cl_2 was treated with 121 mg (0.48 mmol) of HC≡CCPh$_2$OAc and stirred for 1 h at room temperature. The solvent was removed in vacuo and 5 ml of pentane was added to the oily residue. After the mixture was stored for 2 h, a red solid precipitated which was filtered and dried in vacuo. It was identified by comparison of the ^{1}H- and ^{13}C-NMR data with those reported by Grubbs et al. for compound **9**.[12b]

6. *Preparation of [RuCl$_2$(=CHCH=CiPr$_2$)(PiPr$_3$)$_2$]* (**10**): A solution of 120 mg (0.24 mmol) of **4** in 10 ml of CH_2Cl_2 was treated with 85 µl (0.55 mmol) of HC≡CC*i*Pr$_2$OH and stirred for 10 min at 60°C. After cooling to room temperature, the solvent was removed in vacuo. Upon addition of 5 ml of pentane, a purple solid precipitated which was filtered and dried in vacuo; yield 103 mg (70%); m. p. 124°C (dec.). – ^{1}H NMR (400 MHz, C_6D_6): δ = 19.56 [d, *J*(HH) = 11.2 Hz, 1 H, =C*H*CH=C*i*Pr$_2$], 8.06 [d, *J*(HH) = 11.2 Hz, 1 H, =CHC*H*=C*i*Pr$_2$], 3.87 [sept, *J*(HH) = 6.8 Hz, 1 H, C*H*CH_3], 2.82 (m, 6 H, PC*H*CH_3), 2.38 [sept, *J*(HH) = 6.8 Hz, 1 H, C*H*CH_3], 1.24 [dvt, *N* = 13.2, *J*(HH) = 6.6 Hz, 36 H, PCHC*H*$_3$], 1.04, 0.98 both d, *J*(HH) = 6.8 Hz, 12 H, CHC*H*$_3$]. – ^{13}C NMR (100.6 MHz, C_6D_6): δ = 288.3 [t, *J*(PC) = 7.0 Hz, =*C*HCH=C*i*Pr$_2$], 152.4 [s, =CH*C*H=C*i*Pr$_2$], 143.3 [s, =*Ci*Pr$_2$], 30.8, 29.0 (both s, *C*HCH$_3$), 22.3 [vt, *N* = 19.8 Hz, P*C*HCH_3], 21.8, 19.4 (both s, PCH*C*H$_3$), 18.3 (s, CH*C*H$_3$). – ^{31}P NMR (162.0 MHz, C_6D_6): δ = 45.5 (s). – $C_{27}H_{58}Cl_2P_2Ru$ (616.7): calcd. C 52.59, H 9.48; found C 52.13, H 9.13.

7. *Preparation of [RuHCl(=C=CHPh)(PiPr$_3$)$_2$]* (**11**): A solution of compound **5**, prepared from 113 mg (0.40 mmol for *n* = 1) of **3**, 193 µl (0.99 mmol) of P*i*Pr$_3$, and 115 µl (0.83 mmol) of NEt_3 in 20 ml of 2-propanol under hydrogen, was brought to dryness in vacuo and the oily residue was extracted with 20 ml of hexane. The extract was treated with 96 µl (0.88 mmol) of phenylacetylene and the solution was stirred for 10 min at room temperature. The solvent was then removed at 0°C in vacuo, the residue was dissolved in 10 ml of pentane, and the solution was filtered through Celite. The filtrate was concentrated to ca. 4 ml and then stored at –78°C. Olive-green crystals precipitated which were separated from the mother liquor, washed with 2 ml of pentane (–20°C) and dried; yield 83 mg (37%); m. p. 78°C (dec.). – ^{1}H NMR (400 MHz, C_6D_6): δ = 7.16–6.87 (m, 5 H, C_6H_5), 4.36 [t, *J*(PH) = 3.4 Hz, 1 H, =C=C*H*Ph], 2.51 (m, 6 H, PC*H*CH_3), 1.24, 1.22 both m, in ^{1}H{^{31}P} d, *J*(HH) = 7.7 Hz, 36 H, PCHC*H*$_3$], –12.48 [t, *J*(PH) = 17.2 Hz, 1 H, RuH]. – ^{13}C NMR (100.6 MHz, C_6D_6): δ = 329.3 [t, *J*(PC) = 15.1 Hz, =*C*=CHPh], 133.8 [t, *J*(PC) = 2.5 Hz, *ipso*-C of C_6H_5], 128.5, 123.6, 123.5 (each s, C_6H_5), 109.7 [t, *J*(PC) = 3.5 Hz, =C=*C*HPh], 24.7 [vt, *N* = 19.4 Hz, P*C*HCH_3], 20.4, 20.2 (both s, PCH*C*H$_3$). – ^{31}P NMR (162.0 MHz, C_6D_6): δ = 50.4 (s). – $C_{26}H_{49}ClP_2Ru$ (560.2): calcd. C 55.75, H 8.82; found C 55.47, H 8.49.

8. *Preparation of [RuHCl(=C=CH$_2$)(PiPr$_3$)$_2$]* (**12**): A solution of compound **5**, prepared from 122 mg (0.43 mmol for *n* = 1) of **3**, 215 µl (1.10 mmol) of P*i*Pr$_3$, and 120 µl (0.87 mmol) of NEt_3 in 20 ml of 2-propanol under hydrogen, was brought to dryness in vacuo and the oily residue was extracted with 20 ml of hexane. A slow stream of acetylene was passed at –78°C through the hexane solution, which led to a rapid change of color from red to brown. The solvent was removed at 0°C in vacuo and the residue was worked up as described for **11**. A brown solid was obtained; yield 85 mg (41%); m. p. 83°C (dec.). – ^{1}H NMR (400 MHz, C_6D_6): δ = 2.64 (m, 8 H, PC*H*CH_3 and =C=CH_2), 1.28, 1.24 both m, in ^{1}H{^{31}P} d, *J*(HH) = 7.2 Hz, 36 H, PCHC*H*$_3$], –15.03 [t, *J*(PH) = 18.3 Hz, 1 H, RuH], signal of =C=C*H*$_2$ obscured by signal of PC*H*CH_3. – ^{13}C NMR (100.6 MHz, C_6D_6): δ = 326.3 [t, *J*(PC) = 14.6 Hz, =*C*=CH_2], 87.1 [t, *J*(PC) = 3.7 Hz, =C=*C*H$_2$], 24.4 [vt, *N* = 19.5 Hz, P*C*HCH_3], 20.4, 20.3 (each s, PCH*C*H$_3$). – ^{31}P NMR (162.0 MHz, C_6D_6): δ = 51.0 (s). – $C_{20}H_{45}ClP_2Ru$ (484.1): calcd. C 49.63, H 9.37; found C 49.36, H 9.11.

9. *Preparation of [RuHCl(H$_2$)(PCy$_3$)$_2$]* (**13**) *from* **3**: A suspension of 220 mg (0.79 mmol for *n* = 1) of **3** in 20 ml of 2-butanol was treated with 886 mg (3.16 mmol) of PCy_3 and heated for 6 h under hydrogen (1.5 bar) at 80°C. After the reaction mixture was cooled to room temperature, the solution was decanted from the precipitate. The orange solid was washed twice with 10 ml of 2-butanol and dried in vacuo. It was characterized by comparison of the ^{1}H- and ^{31}P-NMR data with those found in the literature.[8] Yield 470 mg (85%).

10. *Preparation of [RuH$_2$Cl$_2$(PCy$_3$)$_2$]* (**14**) *from* **13**: A solution of 130 mg (0.19 mmol) of **13** in 10 ml of CH_2Cl_2 was treated with 0.5 ml of a 2 M aequous solution of HCl and stirred for 3 h at room temperature. The resulting dark red mixture was cooled to –40°C to remove excess HCl and then filtered. The filtrate was brought to dryness in vacuo and the dark red microcrystalline solid was dried; yield 119 mg (87%); m. p. 74°C (dec.). –The ^{1}H- and ^{31}P-NMR data were identical to those reported by Chaudret et al.[11] – ^{13}C NMR (100.6 MHz, CD_2Cl_2): δ = 38.9 [d, *J*(PC) = 28.6 Hz, *ipso*-C of C_6H_{11}], 29.4 (s, C_6H_{11}), 27.4 [d, *J*(PC) = 11.0 Hz, C_6H_{11}], 26.1 (s, C_6H_{11}).

11. *Preparation of [RuCl$_2$(=C=CHPh)(PCy$_3$)$_2$]* (**15**): a) A solution of 119 mg (0.162 mmol) of **14** in 5 ml of CH_2Cl_2 was treated with 178 µl (1.62 mmol) of PhC≡CH at –78°C. After the solution was warmed to room temperature, it was stirred for 30 min and then concentrated to ca. 2 ml in vacuo. Addition of 10 ml of acetone led to the precipitation of a purple solid, which was filtered, washed twice with 10 ml of acetone, and dried; yield 91 mg (67%). – b) A solution of 172 mg (0.21 mmol) of **16** in 10 ml of benzene was treated with 226 µl (2.10 mmol) of PhC≡CH and the resulting brown solution heated for 15 h at 45°C. After the solution was cooled to room temperature, it was worked up as described for a); yield 103 mg (60%); m. p. 88°C (dec.). If instead of **16** the analogous compound **17** was used as starting material, the yield of the product was about the same. – ^{1}H NMR (200 MHz, $CDCl_3$, 40°C): δ = 7.14–7.07, 6.90–6.80 both m, 5 H, C_6H_5), 4.34 [t, *J*(PH) = 3.1 Hz, 1 H, =C=C*H*Ph], 2.70–2.54, 2.14–2.02, 1.68–1.50 (each m, C_6H_{11}). – ^{13}C NMR (50.3 MHz, $CDCl_3$, 40°C): δ = 342.8 [t, *J*(PC) = 15 Hz, =*C*=CHPh], 133.2, 127.9, 125.1, 123.3, (each s, C_6H_5) 108.6 (br s, =C=*C*HPh), 33.3 (vt, *N* = 22.0 Hz, *ipso*-C of C_6H_{11}), 30.1 (s, C_6H_{11}), 27.9 (vt, *N* = 8.0 Hz, C_6H_{11}). – ^{31}P NMR (81.0 MHz, $CDCl_3$, 40°C): δ = 22.0 (s). –

$C_{44}H_{72}Cl_2P_2Ru$ (834.98): calcd. C 63.29, H 8.69; found C 63.48, H 8.73.

12. *Conversion of Compound* **4** *to* **5** *with PiPr$_3$ and 2-Propanol:* In an NMR tube a suspension of 25 mg (0.05 mmol) of **4** in 0.5 ml of 2-propanol was treated with 20 µl (0.10 mmol) of P*i*Pr$_3$. After 2−3 min, a clear red solution was formed which due to the ^{1}H- and ^{31}P-NMR spectra contained the two compounds **5** and **6** in equimolar amounts. Moreover, the presence of acetone was confirmed by GC/MS analysis.

13. *Conversion of Compound* **14** *to* **13** *with PCy$_3$ and 2-Propanol:* A solution of 50 mg (0.068 mmol) of **14** in 5 ml of 2-propanol was treated with 76 mg (0.272 mmol) of PCy_3 at room temperature. Upon stirring for 12 h an orange precipitate was formed, which was filtered, washed with 2 ml of 2-propanol and dried in vacuo; yield 29 mg (61%).

14. *Determination of the X-ray Crystal Structure of* **15**[28] (for data of compound **4** see ref.[5]): Single crystals of **15** were grown upon cooling of a saturated solution of **15** in $CHCl_3$ from 50°C to room temperature. Crystal data (from 25 reflections, $4° < \Theta < 11°$): monoclinic; space group $P2_1/n$ (No. 14); a = 14.505(2), b = 16.816(1), c = 20.057(3) Å, β = 108.438(6)°; V = 4641(1) Å^3, Z = 4; $d_{calcd.}$ = 1.366 gcm^{-3}; µ(Mo-K_α) = 0.720 mm^{-1}; crystal size 0.15 × 0.10 × 0.10 mm; Enraf-Nonius CAD4 diffractometer, Mo-K_α radiation (0.71073 Å), graphite monochromator, zirconium filter (factor 16.4); T = 173(2) K; ω/θ scan, max. 2θ = 48°; 9081 reflections measured, 6500 independent ($R_{int.}$ = 0.0533), 4196 with $I > 2\sigma(I)$. Intensity data were corrected for Lorentz and polarization effects and an empirical absorption correction (Ψ scan method) was applied (min. transmission 98.29%). The structure was solved by the Patterson method (SHELXS-86)[29]. Atomic coordinates and the anisotropic thermal parameters of non-hydrogen atoms were refined by full-matrix least squares on F^2 (SHELXL-93)[30]. The positions of all hydrogen atoms except of H2 were calculated according to ideal geometry and refined by using the riding method. The position of H2 could be located in a final difference Fourier synthesis and refined with fixed U_{eq}. The asymmetric unit includes one molecule of $CHCl_3$ which was refined anisotropically without any restrictions. Conventional R = 0.0588 [for 4196 reflections with $I > 2\sigma(I)$], and weighted wR_2 = 0.1337 for all 6500 located reflections; reflection/parameter ratio 13.51; residual electron density +0.819/−0.685 eÅ^{-3}.

☆ Dedicated to Professor *Bernt Krebs* on the occasion of his 60th birthday.

Received July 30, 1998

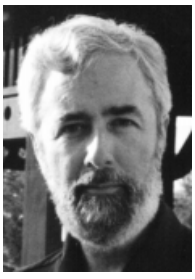
Keywords: Clusters / Catalysis / Carboxylato complexes / Hydrogenations

A strategy of using functionalized clusters as ligands for cationic metal centers facilitates the construction of designed transition metal cluster assemblies. Examples of cluster metal carboxylates with conventional as well as novel structures are given and an application of these large molecular species to the generation of heterogeneous hydrogenation catalysts with unusual activities and selectivities is described.

The synthesis of complex species for defined chemical roles is one common goal of both organic and inorganic chemistry. In the latter area, the synthesis of complex extended solid-state structures from the elements under thermodynamic control, e.g., zeolites, provides an impressive example of the power of synthesis. Many of these subdisciplines are covered in the interdisciplinary area known supramolecular chemistry.[1]

Interest in the construction of large, complex inorganic species is driven by an eclectic set of applications which include molecular electronics[2], photochemically driven electron transfer[3], liquid crystalline materials[4], host-guest chemistry[5], cryptate chemistry[6], nanocluster borderline solids[7], chemical sensors[8], ferrimagnetic solids[9], and others. The structures involved range from one dimensional chains of clusters[10], to cluster aggregates[11], to rigid-rod polymers[12], to metal spheres[13], to supramolecular chiral networks[14], to supported clusters[15], to dendritic systems[16][17], and more. The synthetic approaches are equally varied and include step-wise formation of oligomers[18],

Xinjian Lei: After graduating with his M.S. from the Fujian Institute of Research on the Structure of Matter, Chinese Academy of Sciences, P. R. China in 1988, Xinjian Lei was a research associate in the following four years. He obtained his Ph.D. in inorganic chemistry in 1997 at the University of Notre Dame and continues as a research associate. His research has been focused on the synthesis, characterization, and reactivity of new cluster compounds, as well as their catalytic evaluation.



Eduardo E. Wolf: After receiving a B.S. degree from the University of Chile, Santiago, a M.S. degree from the University of California, Davis, and a Ph.D. degree from the University of California, Berkeley, Eduardo E. Wolf joined the faculty of the Chemical Engineering Department of the University of Notre Dame where he is presently hold the rank of Professor. He works in the area of catalysis and reaction engineering where he specializes in the design of novel catalytic materials and novel catalytic reactors.

Thomas P. Fehlner: After receiving a B.S. degree from Siena College and M.A and Ph.D. degrees from The Johns Hopkins University, Thomas P. Fehlner joined the faculty of the Chemistry Department of the University of Notre Dame where he is presently Grace-Rupley Professor of Chemistry. He has previously studied small inorganic species in the gas phase (reactivity of free BH_3, photoelectron spectra of unstable species) but more recently has worked on the syntheses of metallaboranes and organometallic cluster chemistry.

MICROREVIEWS: This feature introduces the readers to the authors' research through a concise overview of the selected topic. Reference to important work from others in the field is included.

modular assembly of rings[19][20], polymerization[21], development of molecular tinkertoys[22] and carborods.[23] Another synthetic approach, the use of functionalized main group[24][25][26], transition metal complexes[27][28] or clusters,[29][30][31][32] is of particular relevance to this contribution.

Our interest in large assemblies of clusters was piqued when we found that $(CO)_9Co_3(\mu_3\text{-}C(CH_2)_nOH$, a major product of the decomposition of $(CO)_4CoBH_2\cdot THF$ above 0 °C, crystallized in hexagonal columns with the hydrophilic hydrogen-bonded OH groups at the columnar axes and the hydrophobic metal carbonyl clusters on the surfaces (Scheme 1).[33] Even in solution this cluster derivative forms small aggregates reflecting its ambiphilic behavior. At the time, and still, the organization of metal clusters on various supports, principally for the generation of new catalysts, commanded considerable attention[34] and we wondered if suitably functionalized clusters would self-organize. This would eliminate the need for a complex substrate and, in doing so, introduce more uniformity into the cluster arrays.

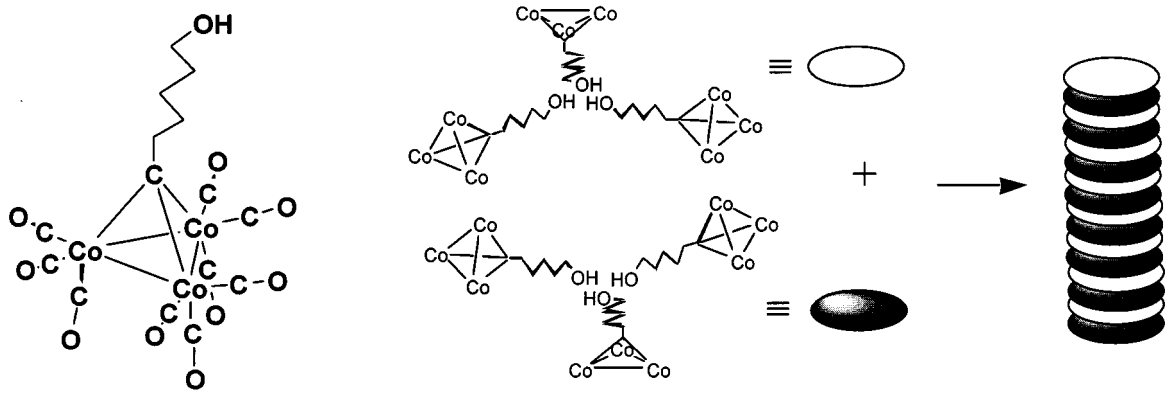
As the weak forces holding $(CO)_9Co_3[\mu_3\text{-}C(CH_2)_nOH]$ molecules together seemed inadequate for our purposes, we sought functionalization that would permit a cluster to serve as a ligand in a classical Werner coordination compound, i.e., the metal cluster would simply replace the usual organic foliage of the typical ligand. These coordination compounds would constitute cluster assemblies in which the central metal cationic moiety would determine both the number of clusters (coordination number) and the spatial array of clusters (coordination geometry). In a sense, the relatively small, well-defined cationic metal center would replace the large substrate of the typical supported cluster.

The idea of cluster coordination compounds presented a number of attractive aspects. First, by using the established principles of coordination chemistry, we could construct a predetermined cluster array from monofunctional clusters. In principle, these cluster building blocks could be made di- and trifunctional in order to construct chains and nets as well. Indeed the Schauer group has made considerable progress in this direction by using bidentate cluster ligands in which main group atoms in the cluster itself act as ligating sites.[18][35][36][37] Curiously, monodentate clusters of the same type form trimeric rings by an intermolecular ligand displacement reaction on the cluster itself.[38] Second, metal clusters are very different from a typical organic substituent, e.g., CH_3R vs $(CO)_9Co_3(\mu_3\text{-}CR)$.[39][40][41][42][43][44][45][46][47] In terms of electronic effects, the metals within the clusters plus their ancillary ligands constitute electron reservoirs capable of donating or accepting electron density. The fact that even the smallest clusters have a substantial steric bulk must affect the products formed in cluster coordination reactions. Consequently, we expected to find significant differences between the coordination chemistry of a cluster ligand and that of a typical main group ligand.

Perhaps the most attractive aspect of an externally functionalized metal cluster is that cluster size, composition as well as ligand type and extension are quantities that can, in principle, be varied.[48] Unfortunately, cluster synthetic chemistry, although continuously developing, is in a rudimentary state relative to, e.g., organic ligand synthesis. Many cluster types are derived from reactions that are unselective thereby requiring tedious separations resulting in modest yields.[48] Much of the interesting structural chemistry[49] is based on metals such as Os and Rh which put an economic damper on thoughts of gram scale syntheses from low yield reactions. Thus, little of the cluster derivative chemistry in the literature was suitable for our purposes.

For these reasons we decided to focus on the well studied tricobalt akylidyne cluster system and began our exploration of cluster coordination chemistry using $(CO)_9Co_3(\mu_3\text{-}CCOOH)$ as a precursor to the corresponding cluster carboxylate ligand, $[(CO)_9Co_3(\mu_3\text{-}CCOO)]^-$.[40][41] This is a fortunate choice as metal carboxylate chemistry is a mature area of coordination chemistry of considerable interest.[50] Importantly, this cluster ligand precursor can be prepared in good yield from commercially available $Co_2(CO)_8$ and $Cl_3CC(O)OR$ on a multigram scale by undergraduates. Its main drawback, and one that figures in its chemistry, is cluster degradation which is facile under basic conditions. For this reason, simple salts of the free ligand $[(CO)_9Co_3(\mu_3\text{-}CCOO)]^-$ are unavailable and only efficient coordination reactions lead to simple chemistry. However, this cluster ligand is selective and metal carboxylate formation reactions are usually clean giving good to excellent yields even for obviously complex reaction pathways. In the following we highlight the varied coordination chemistry of

Scheme 1



the $[(CO)_9Co_3(\mu_3\text{-}CCOO)]^-$ ligand established in our laboratory over the last few years.

Cluster Metal Carboxylate Chemistry

Organic carboxylate anions (RCO_2^-) have been known for over a hundred years as versatile ligands capable of forming metal carboxylates with almost all the metal elements in the periodic table. The resulting metal carboxylates exhibit a variety of core structures, coordination modes, and coordination numbers depending on the properties of the elements used.[50] Recently the chemistry of transition metal carboxylates has drawn renewed attention as such compounds can serve as precursors for the synthesis nanometer-sized polynuclear aggregates with unusual structural and magnetic properties. These compounds may also help to further improve our understanding of the transition from the molecular to the solid state in the biomineralization process or in the development of molecular magnets.[51][52][53]

Likewise, the chemistry of alkylidynetricobalt nonacarbonyl cluster compounds, $(CO)_9Co(\mu_3\text{-}CR)$, has been extensively investigated since the appearance of the first member of this class of compounds, $(CO)_9Co_3(\mu_3\text{-}CCH_3)$ in 1958.[41][54] These complexes are all deeply colored and most are air-stable in solution and in the solid state. In general the alkylidynetricobalt nonacarbonyls undergo degradation by oxidizing agents, bases, and nucleophiles. For example, reactions of potassium permanganate or water with $(CO)_9Co(\mu_3\text{-}CR)$ complexes lead to evolution of carbon monoxide, the formation of inorganic cobalt salts and carboxylic acids derived from the apical organic substituents. Fortunately from the point of view of the work described here, most alkylidynetricobalt nonacarbonyl complexes are soluble in organic solvents, stable toward protonic and Lewis acids, and possess an extensive chemistry.[34][41][42][48][55][56] Our interest in cluster assemblies joins these two fields, i.e. the carboxylic acid derivative of the alkylidynetricobalt nonacarbonyl complex, $(CO)_9Co(\mu_3\text{-}COOH)$, is used as a cluster carboxylate ligand precursor to synthesize cluster metal carboxylates.

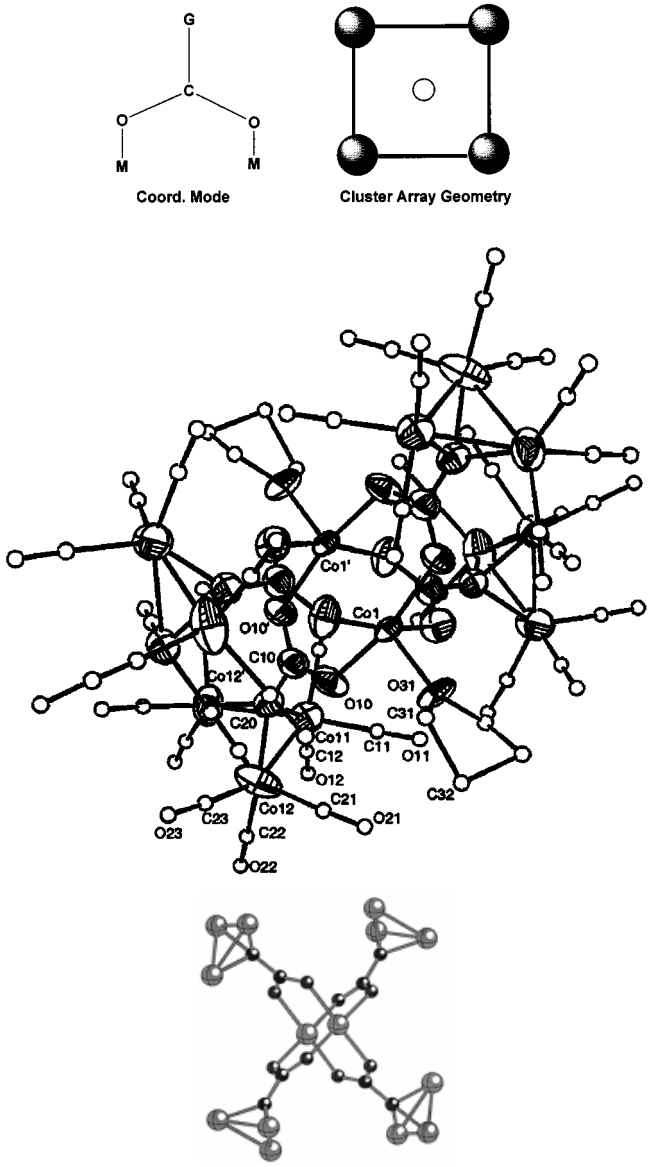
Structures of the Cluster Metal Carboxylates

The principal means of characterization of the cluster metal carboxylates was single crystal X-ray diffraction. In all cases, the bond distances and angles of the tricobalt cluster substituents are unchanged within experimental error from those of free tricobalt clusters. In some cases, the cluster acid functions just like an organic carboxylic acid and analogs of known metal carboxylates are obtained. In other cases the combination of steric and electronic properties associated with the cluster substituent on the acid made novel structural types accessible. The compounds featured below illustrate analogs of organic carboxylates, unusual metal carboxylate structural types, and varied spatial arrangements of the tricobalt cluster assemblies. As will be seen, the cluster carboxylate ligand exhibits the same variety of coordination modes as organic metal carboxylates but also generates some novel structures.

Cluster Carboxylate Mimics of Known Metal Carboxylates

$[M_2\{(CO)_9Co_3(\mu_3\text{-}CCO_2)\}_4L_2]$ ($M = Co$, $L = THF$; $M = Mo$, $L = (CO)_9Co_3(\mu_3\text{-}CCO_2H)$:[57][58] As an example, the structure of $[Co_2\{(CO)_9Co_3(\mu_3\text{-}CCO_2)\}_4(THF)_2]$ is shown in Scheme 2. In this first scheme the complete structure from the crystallographic results is shown, and below, for clarity, a simplified structure. As some of the succeeding structures are considerably more cluttered, the representations have been simplified principally by removing the carbonyl ligands of the cobalt clusters. As with similar organic carboxylate analogs,[59] the cluster carboxylate ligands symmetrically bridge two cobalt centers. Consequently, the four tricobalt clusters are arranged in a square

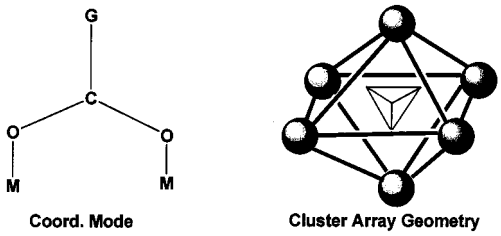
Scheme 2

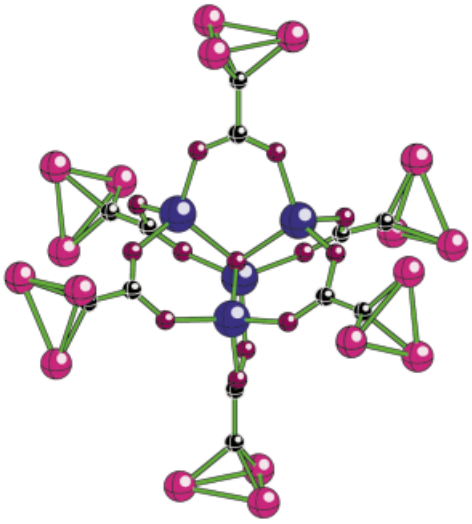


planar array perpendicular to Co−Co bond axis. Each metal atom is coordinated in the equatorial positions by four oxygen atoms from the four carboxylate ligands and in an axial position by one from the THF solvent.

[$M_4O\{(CO)_9Co_3(\mu_3\text{-}CCO_2)\}_6$] (M = Zn, Co): [60][61][62] As shown in Scheme 3, the core structure of the cluster zinc carboxylate consists of an M_4 tetrahedron with a centered oxygen atom. The six carboxylate moieties bridge the six metal-metal edges, resulting an octahedral spatial distribution of the tricobalt clusters. These cluster metal carboxylates are direct analogs of classical $M_4O(RCO_2)_6$ "basic" metal carboxylates which are known for M = Be, Zn, Co.[50]

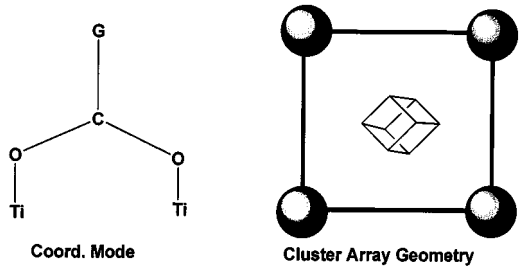
Scheme 3

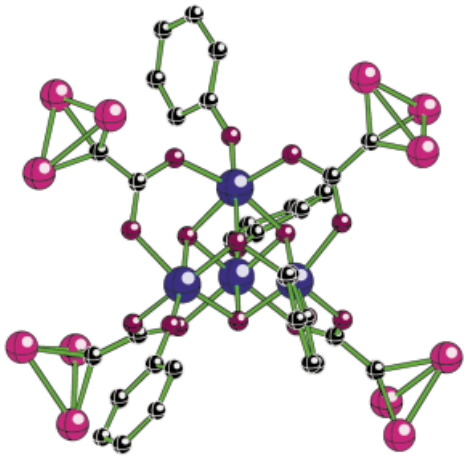




[$Ti_4O_4(OR)_4\{(CO)_9Co_3(\mu_3\text{-}CCO_2)\}_4$] (R = CH(Me)$_2$, $(CH_2)_3CH_3$, C_6H_5, 2,6-$(CH_3)_2$-C_6H_3):[63] The structure of the phenoxide derivative is shown in Scheme 4. The core is a distorted Ti_4O_4 cube with titanium and oxo oxygen atoms occupying alternate vertices. As expected, the coordination sphere of each Ti atom contains six oxygen atoms in a distorted octahedral arrangement. The cluster carboxylates bridge four of the six edges of the Ti_4 tetrahedron and the four tricobalt clusters lie roughly in a plane with one transoid pair being above and the other below the plane which results in a slightly distorted square-shape as indicated in Scheme 4. There is considerable open space in the structures, but this decreases with increasing size of the R group. One organic analog has been reported.[64]

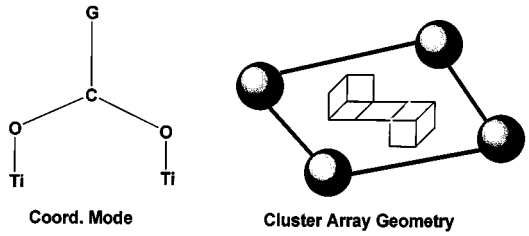
Scheme 4

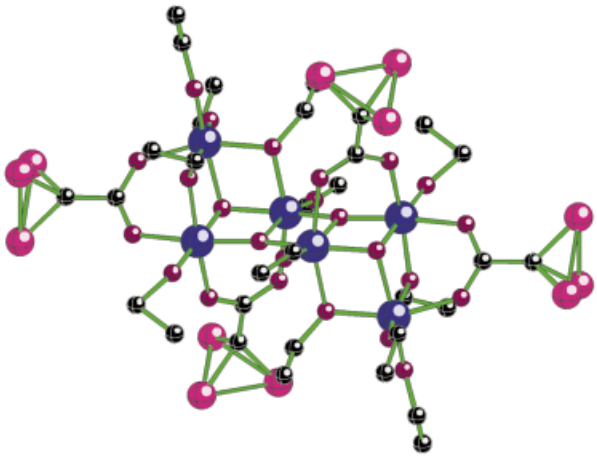




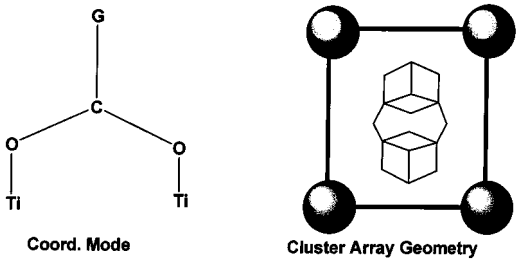
[$Ti_6O_4(OCH_2CH_3)_{12}\{(CO)_9Co_3(\mu_3\text{-}CCO_2)\}_4$] and [$Ti_6O_4(OCH(CH_3)_2)_4(1,2\text{-}O_2C_6H_4)_4\{(CO)_9Co_3(\mu_3\text{-}CCO_2)\}_4$]:[63] The structure of the first cluster metal carboxylate (Scheme 5) shows that it is a dimer of two Ti_3O_4 units linked together by TiO edges oriented so that the

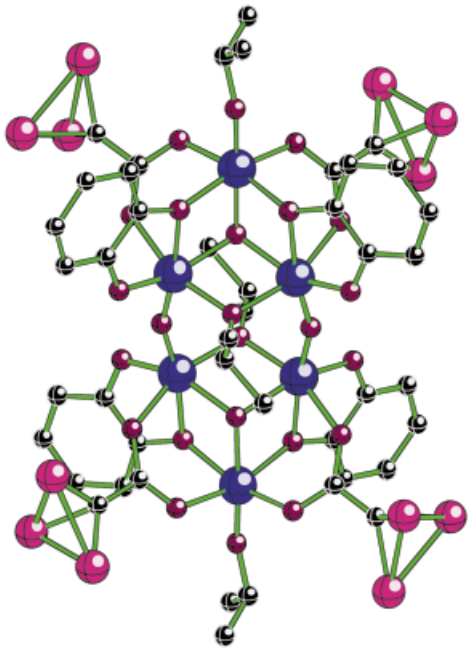
Scheme 5





Scheme 6





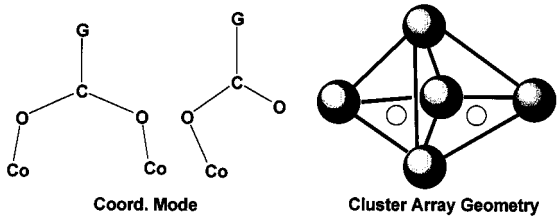
Ti_3O_4 units are related to each other by a crystallographic inversion center. Each Ti_3O_4 unit is bridged by two cluster ligands and the remaining coordination positions are occupied by six ethoxy ligands, two of which are bridging. The cluster carboxylates symmetrically bridge Ti centers, resulting a rhombic arrangement of the four tricobalt clusters elongated in the direction of the ladder-like Ti_6 core.

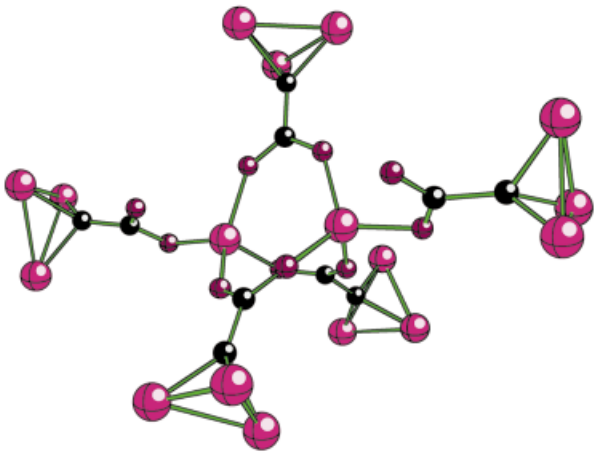
The structure of the second compound (Scheme 6) reveals that it is an isomeric form of the first resulting from different interconnects between the two Ti_3O_4 units. The catechol ligand uses one oxygen to bridge two Ti atoms and the other to coordinate to one of the two Ti centers in a terminal fashion. Each cluster carboxylate symmetrically bridges two Ti centers resulting a rectangular arrangement of the tricobalt clusters in the direction of the ladder-like Ti_6 core. Both cluster metal carboxylates have structurally characterized organic analogs[65][66][67][68]

Unique Cluster Metal Carboxylates

$[C_{10}H_6(NMe_2)_2][Co_2\{(CO)_9Co_3(\mu_3\text{-}CCO_2)\}_5]$:[69] As shown in Scheme 7, this anionic cluster metal carboxylate consists of two tetrahedral Co centers with very long Co−Co separation [3.47(4)Å]. The two Co atoms are held together by three bridging cluster ligands while the two remaining cluster ligands are terminally coordinated to each Co center in a unidentate fashion thereby generating a tetrahedral ligand environment for each Co atom and a triangular bipyramidal geometry for the spatial distribution of the five tricobalt clusters.

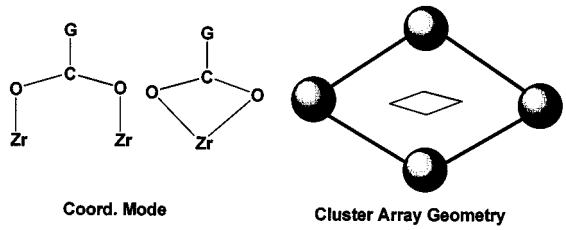
Scheme 7

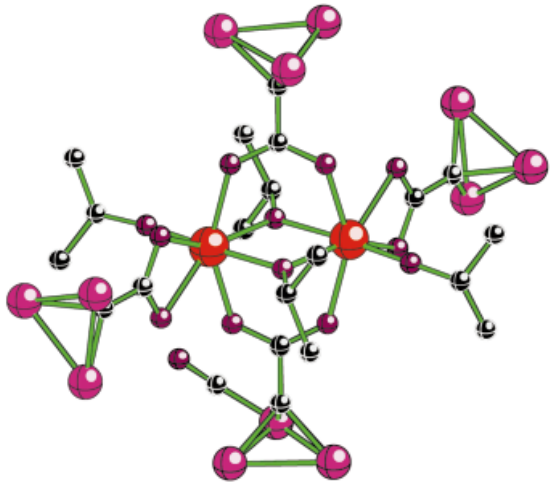




$[Zr_2(OCHMe_2)_4\{(CO)_9Co_3(\mu_3\text{-}CCO_2)\}_4]$:[63] This compound represents the first example of a structurally

Scheme 8

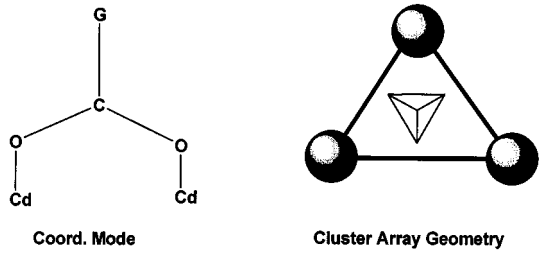


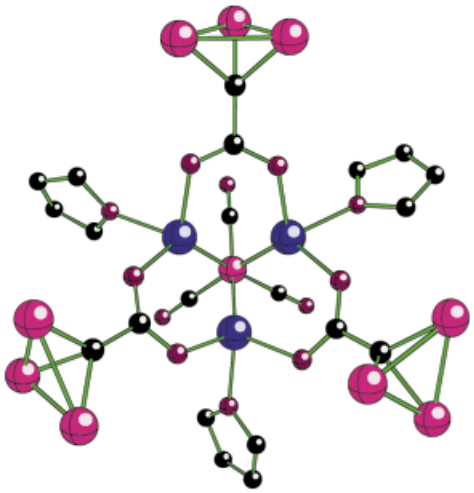


characterized zirconium alkoxy carboxylate. The structure (Scheme 8) reveals that there are two kinds of coordination modes for the cluster ligands, bridging and chelating. The coordination sphere of each zirconium atom is a slightly distorted pentagonal bipyramid in which the five equatorial positions are occupied with two oxygen atoms from a chelating cluster ligand, two from bridging cluster ligands, and one from a bridging isopropoxy group. The apical positions are occupied with oxygen atoms from one terminal and one bridging isopropoxy group. The spatial distribution of the four tricobalt clusters is a rhombic shape within which the rhombic Zr_2O_2 core is located.

[{Co(CO)$_3$}Cd$_3${(CO)$_9$Co$_3$(μ_3-CCO$_2$)}$_3$(THF)$_3$]:[70] This unusual hybrid compound consists of an equilateral triangle of Cd atoms capped with a $Co(CO)_3$ fragment with each Cd−Cd edge bridged by a cluster ligand (Scheme 9). In addition, each Cd atom is coordinated to a THF molecule. Although the bonding of the Cd_3Co core is very interesting, in terms of the spatial distribution of the clusters, the compound can be described as an equilateral triangle of tricobalt clusters in which an equilateral triangle of Cd atoms capped by a $Co(CO)_3$ fragment is inscribed.

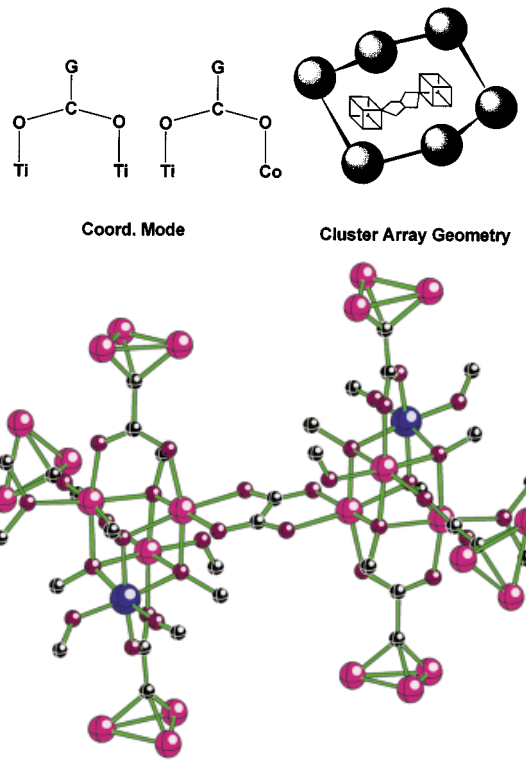
Scheme 9





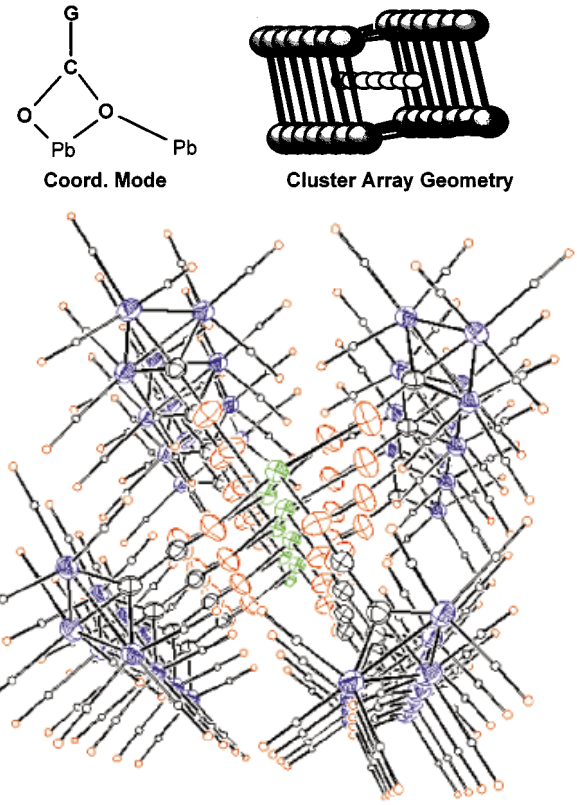
[{Co$_3$Ti(OMe)$_6$(HOMe)(THF){(CO)$_9$Co$_3$(μ_3-CCO$_2$)}$_3$}$_2$-(O$_2$CCO$_2$)]:[63] The structure (Scheme 10) consists of two complete $Co_3Ti(OMe)_4$ cubes, related by a inversion center, and joined by a bridging tetradentate oxalate ligand. The coordination environments of both the Ti and core Co atoms are both nearly octahedral. For a single cube, the three tricobalt clusters lie in an approximate plane, but the cluster planes of each cube are displaced with respect to each other, resulting a chair-like arrangement of

Scheme 10



the six tricobalt clusters. The coordination modes of the cluster ligands fall into two groups: homonuclear bridging and heteronuclear bridging.

Scheme 11



$[Pb\{(CO)_9Co_3(\mu_3\text{-}CCO_2)\}_2]_n$:[71] Each Pb atom is primarily coordinated by two cluster carboxylates but secondary Pb−O interactions occur between an oxygen atom of each chelating carboxylate and its adjacent Pb^{II} thereby generating a chainlike structure (Scheme 11) and unusual, solvent free six-coordinate Pb centers.[72] The three distinct Pb−O distances differ considerably. Viewed along the Pb−Pb direction, the tricobalt clusters generate an infinite square columnar array.

Synthetic Routes

The differences between the cluster acid and an organic acid originate in the instability of the metal framework, the capability of the cluster acting as either an electron donor or acceptor, and the steric bulk of the cluster. Consequently, some methods used to prepare organic metal carboxylates are not applicable to these cluster metal carboxylates, e.g., reactions involving carboxylate salts. Some of the successful approaches used for the metal cluster substituted acids are set out below.

Spontaneous Reaction: The cluster acid, $(CO)_9Co_3(\mu_3\text{-}CCO_2H)$, is soluble in polar solvents such as ether, THF, CH_2Cl_2, acetone, and methanol. However, when exposed to air, the solutions spontaneously precipitate the cluster oxo tetrametal carboxylate, $Co_4O\{(CO)_9Co_3(\mu_3\text{-}CCO_2)\}_6$ (Scheme 3) in high yield (Eq. 1).[61]

$$22\ (CO)_9Co_3(\mu_3\text{-}CCO_2H) + 7\ O_2 \rightarrow Co_4O\{(CO)_9Co_3(\mu_3\text{-}CCO_2)\}_6 + 44\ CO + 11\ H_2O \quad (1)$$

The origin of the Co^{II} ions is the tricobalt cluster which illustrates how the intrinsic lability of the metal cluster can control the coordination chemistry observed. Unless suitable precautions are taken, this reaction competes with all the other reactions described and generates unusable mixtures of products.

Reactions with Metal Alkyls: The preparation of anhydrous metal carboxylates using the elimination of an alkane from a metal alkyl as the driving force has been effectively used for the formation or organic metal carboxylates. Unlike the organic acids, $(CO)_9Co_3(\mu_3\text{-}CCO_2H)$ reacts with $ZnEt_2$ in ether giving a cluster oxo tetrametal carboxylate, $Zn_4O\{(CO)_9Co_3(\mu_3\text{-}CCO_2)\}_6$ (Scheme 3). A pathway involving formation of a cluster ester is postulated as shown in Eq. 2.[61]

$$8\ (CO)_9Co_3(\mu_3\text{-}CCO_2H) + 4\ ZnEt_2 \rightarrow Zn_4O\{(CO)_9Co_3(\mu_3\text{-}CCO_2)\}_6 + \{(CO)_9Co_3(\mu_3\text{-}CCO)\}_2O \quad (2)$$

Although the reaction of $(CO)_9Co_3(\mu_3\text{-}CCO_2H)$ and $CdMe_2$ under similar conditions may yield a simple cluster metal carboxylate, heating the reaction mixture in toluene at 70°C resulted in the formation of an unexpected product, $[\{(\mu_3\text{-}Co(CO)_3)\}Cd_3\{(CO)_9Co_3(\mu_3\text{-}CCO_2)\}_3(THF)_3]$ (Scheme 9) in good yield. Note that $(CO)_9Co_3(\mu_3\text{-}CCO_2H)$ also serves as a source of the $Co(CO)_3$ fragment that caps the Cd_3 triangle thereby demonstrating another way in which the metal cluster can participate in the reaction.

Exchange Reactions with Metal Carboxylates The exchange reactions between lower metal carboxylates and carboxylic acids have been used in the preparation of higher carboxylates. The lower carboxylic acid generated can be removed azeotropically from the reaction mixture when suitable solvents are employed. The reaction of binuclear carboxylates, $M(CH_3CO_2)_2$, (M = Cr, Mo,W, Cu) with $(CO)_9Co_3(\mu_3\text{-}CCO_2H)$ afforded a series of cluster carboxylates with the formula $[M_2(CH_3CO_2)_{4-n}\{(CO)_9Co_3(\mu_3\text{-}CCO_2)\}_nL_2]$ (L = the axial coordination ligand) via Eq. 3 with structures based on that illustrated in Scheme 2.[57][73][74]

$$n\ (CO)_9Co_3(\mu_3\text{-}CCO_2H) + [M(CH_3CO_2)_2]_2 \rightarrow [M\{(CO)_9Co_3(\mu_3\text{-}CCO_2)\}_n(CH_3CO_2)_{2-n}]_2 + n\ CH_3COOH \quad (3)$$

Although solvents often play an important role and are found coordinated in the product cluster metal carboxylates, this is not always the case. Organic lead carboxylates have a notable tendency to pick up water, but no coordinated or uncoordinated water is found in the crystal lattice of chain-like $[Pb\{(CO)_9Co_3(\mu_3\text{-}CCO_2)\}]_n$ (Scheme 11) even though present in the reaction system.[71]

Reactions with Metal Alkoxides and Aryloxides: The advantage of the reactions of metal alkoxides with carboxylic acids is that a variety of mixed alkoxide-carboxylate complexes can be produced by simply changing the stoichiometric ratios of the reactants.[67][68][75][76][77] The reaction of the cluster acids and group 4 alkoxides afforded cluster alkoxycarboxylates (Eqs. 4 and 5):

$$4\ (CO)_9Co_3(\mu_3\text{-}CCO_2H) + [Zr(OCHMe_2)4{\cdot}HOCHMe2]_2 \rightarrow [Zr_2\{(CO)_9Co_3(\mu_3\text{-}CCO_2)\}_4(OCHMe_2)_4] + 6\ HOCHMe_2 \quad (4)$$

$$4\ (CO)_9Co_3(\mu_3\text{-}CCO_2H) + Ti(OR)_4 \rightarrow [Ti_4O_4\{(CO)_9Co_3(\mu_3\text{-}CCO_2)\}_4(OR)_4] + 4\ ROH + 4\ ROR \quad (5)$$

Complex, Competitive Degradation: Some of the cluster carboxylates are unstable in the solution and undergo complicated redox reactions assisted by either the center metal or solvents to yield new cluster metal carboxylates. The exchange reaction of $Hg(CH_3CO_2)_2$ and $(CO)_9Co_3(\mu_3\text{-}CCO_2H)$ in CH_2Cl_2 led to $Hg\{(CO)_9Co_3(\mu_3\text{-}CCO_2)\}_2$ which is soluble in THF. Crystallization attempts in acetone led to the oxotetracobalt cluster, $[Co_4O\{(CO)_9Co_3(\mu_3\text{-}CCO_2\}_6]$ and mercury metal whereas crystallization in THF afforded $[Co_2\{(CO)_9Co_3(\mu_3\text{-}CCO_2\}_4(THF)_2]$ (Scheme 2) as well as mercury metal. It is believed that in solution a slow redox reaction takes place resulting in precipitation of either $[Co_4O\{(CO)_9Co_3(\mu_3\text{-}CCO_2\}_6]$ or $[Co_2\{(CO)_9Co_3(\mu_3\text{-}CCO_2\}_4(THF)_2]$. It is important to note that the direct reaction of cobalt acetate with $(CO)_9Co_3(\mu_3\text{-}CCO_2H)$ only generates the cluster oxo tetracobalt carboxylate.

With similar complexity, the reactions of $[M^{II}\{(CO)_9Co_3(\mu_3\text{-}CCO_2)\}_2]$ (M = Mn, Fe) with MeOH gave rise to $[M^{III}_2Co_2(MeO)_6(MeOH)_2\{(CO)_9Co_3(\mu_3\text{-}CCO_2)\}_4]$ with cubane-like cores.[78] Further, when $(CO)_9Co_3(\mu_3\text{-}CCO_2H)$ was treated with $Ti(OMe)_4$ in THF, a heteronuclear octameric species, $[\{Co_3Ti(OMe)_6(HOMe)(THF)\{(CO)_9Co_3(\mu_3\text{-}$

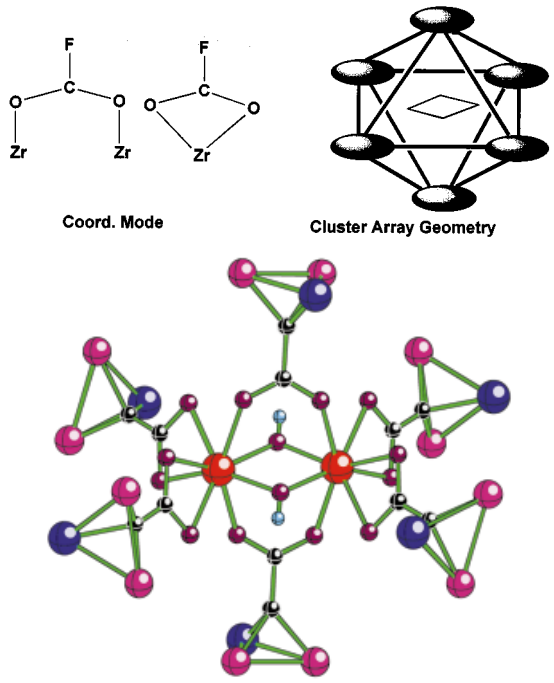
$CCO_2)\}_3\}_2(O_2CCO_2)]$ was isolated in good yield (Scheme 10). Both the Co^{II} ions and oxalate ligand arise from the degradation of the tricobalt cluster in situ.

Modified Cluster Acids and Their Reactivities

The $CpM(CO)_2$ (M=Mo, W) fragment can be substituted for one of the $Co(CO)_3$ fragments in $(CO)_9Co_3(\mu_3$-CR) to yield $CpM(CO)_2Co_2(CO)_6(\mu_3$-CR).[79] This method works well on a gram scale provided the acid group is protected as an ester from which the acid can be regenerated after metal fragment exchange.[80] The reaction of the heterometal cluster acids with Ti and Zr alkoxides was examined in order to directly compare their chemistry with that of $(CO)_9Co_3(\mu_3$-$CCO_2H)$. The compounds structurally characterized are $Zr_2(OH)_2\{CpMo(CO)_2Co(CO)_6(\mu_3$-$CCO_2)\}_6$ and $Ti_4O_4(OR)_4\{CpMo(CO)_2Co(CO)_6(\mu_3$-$CCO_2)\}_4$.[80] The former exhibits two bridging cluster ligands, four chelating cluster ligands, and two hydroxyl groups, generating a Zr_2O_{14} core and a coordination number of eight for each Zr center with an octahedral spatial distribution of the six modified clusters (Scheme 12). The Ti clusters show the same structural motif as those of tricobalt cluster ligands, i.e., that shown in Scheme 4.

Interestingly, the Cp rings of the $CpM(CO)_2$ moieties in all the compounds are proximal (Cp ring adjacent to the capping carbon) rather distal (Cp ring positioned away from the capping carbon) and the $CpM(CO)_2$ carbonyls are semibridging to the Co atoms. The exclusive presence of the proximal isomer of the coordinated cluster ligand relative to the more stable distal isomer for the uncoordinated cluster[81][82][83] reflects the existence of a cluster electronic effect in the coordination properties of the carboxylic group.

Scheme 12



Reactivity and Physical Properties Imparted by the Cluster Substituent

Cluster substituted carboxylic acids are weaker acids than acetic acid and are expected to form more basic carboxylates.[61][80] It is not surprising, then, that the cluster substituent can alter the chemical selectivity of the carboxylate moiety. Thus, the reactions of the cluster acids with group 4 metal alkoxides exhibit significantly different chemistry than that of organic acids. For example, in contrast to acetic acid[68], the cluster carboxylate observed does not depend on the reaction stoichiometry. That this is a cluster effect is established by the reactivity of the modified cluster ligands, $CpM(CO)_2Co_2(CO)_6(\mu_3$-$CCO_2H)$. These are of similar size to the tricobalt cluster but under same reaction conditions the products from the reaction of the cluster acids with zirconium isopropoxide are different.

The physical properties of the cluster metal carboxylates show some interesting differences from those of their organic analogs. The presence of the carbonyl clusters has a large effect on the intermolecular interactions. For example, $[Ti_4O_4(OR)_4\{(CO)_9Co_3(\mu_3$-$CCO_2)\}_4]$ with molecular weights of ca. 2500 are soluble in hexane. All compounds are deeply colored, and their absorption spectra are similar to that of $(CO)_9Co_3(\mu_3$-$CCO_2H)$ with extinction coefficients roughly proportional to the number of the tricobalt units in the cluster arrays. Exceptions are $[M_2\{(CO)_9Co_3(\mu_3$-$CCO_2)\}_4]$ (M = Cr, Mo, W) which show intense absorption in the visible range, presumably due to the charge transfer from M center to the tricobalt units.[73]

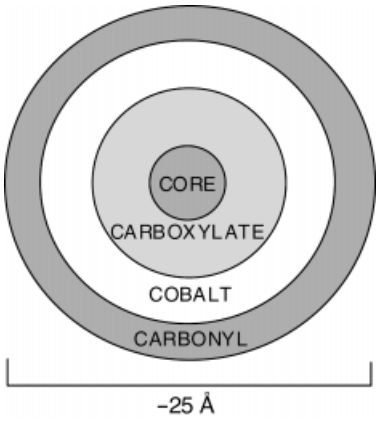
As with organic metal carboxylates the IR bands associated with the $-CCO_2$ moiety provide useful fingerprints to distinguish and identify new compounds.[50] In the cluster metal carboxylates the carbonyl ligand stretching bands 1900 to 2200 cm^{-1} are also useful, albeit less sensitive, probes of coordination. These two regions provide useful fingerprints to distinguish and identify new compounds. In general, the deprotonation and coordination of a cluster acid results in a reduction of the number of carbonyl bands and the frequencies of the antisymmetrical and symmetrical stretching modes of the COO^- group are significantly decreased.

Cluster Arrays as Catalyst Precursors

Metal clusters are attractive catalysts or catalyst precursors[34][84] and the use of supported metal clusters potentially provides a catalyst with homogeneous set of multimetal active sites. Such a heterogeneous catalyst would preempt one of the most attractive aspects of homogenous catalysts while retaining those of heterogeneous catalysts. Indeed, recent work has been very promising.[15][85]

As already indicated in the introductory paragraphs, our approach is to limit the "support" to a minimal metal core thereby producing identical nanosized cluster assemblies with different shapes but related compositions. Indeed these cluster metal carboxylates may be considered as layered particles as shown in Scheme 13 with shapes ranging from

Scheme 13



spheres to less symmetric solids. For the spherical particle, a cationic core is covered with a set of carboxylate moieties attached to a set of carbyne carbons, then a set of cobalt atoms, and, on the outside, a layer of carbonyl groups. In several of the compounds, one finds the 20 to 30 Å diameter molecular assemblies in a close-packed array in the solid state.

Ideally it was our intention to activate these species for catalysis by removing some or all of the external carbonyl ligands thereby forming reactive cobalt-covered nanoparticle spheres. Several issues had to be resolved experimentally. These included the relative lability of the outer Co−CO links vs the inner CCO_2−M links, the ease of metal diffusion resulting in Co crystallite formation (sintering), the surface areas of the active materials, and, most importantly, the catalytic activities and selectivities for selected reactions. In the following we describe the nature of the solid produced from the cluster assemblies by thermolysis, the catalytic properties of the solids in a standard hydrogenation reaction, and the unique properties of these catalysts for the selective hydrogenation of an α,β-unsaturated aldehyde to an unsaturated alcohol.

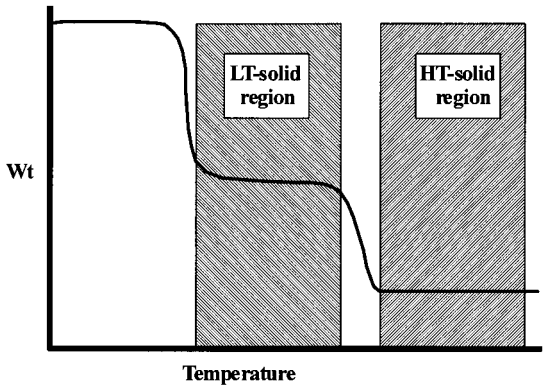
Properties of Solids Formed from Cluster Metal Carboxylates

The behavior of single crystals of cluster metal carboxylates on heating gave us the first indication of the special properties of these molecular cluster carboxylate solids.[86] For example, a single, well formed, shiny, dark colored crystal that diffracted X-rays was converted into a single smaller, but similarly shaped, apparent crystal with a metallic luster. The product did not, however, diffract X-rays and a close examination of the faces of the product showed extensive pitting. Indeed, density measurements revealed a substantial void volume in the product solid. Additional preliminary experiments also showed considerable hydrogenation activity and, thus, we set out to characterize the nature of these solids as well as their catalytic properties.

As long-range order in the molecular solids was lost on pyrolyzing the cluster carboxylates, unambiguous structure determination was out of the question. Further it appeared clear that there was some dependence of material properties on the activation procedure. Hence, the first efforts were directed towards establishing the nature of the chemical conversion of precisely characterized, but inactive, molecular precursors to amorphous, but active, solids.[87]

Thermal gravimetric analyses usually showed two stable regimes, i.e., a constant mass over a certain temperature range, depending on carboxylate structure type. Scheme 14 (labeled low temperature, LT, ca. 100−200°C: high temperature, HT, > ca. 200°C). Mass spectrometry showed that in the LT regime mainly CO loss occurred and CO_2 loss was predominant in the HT regime. Actual mass loss and gas composition suggested loss of the outer CO layer to reach to first regime and loss of the carboxylate links to reach the second regime. In situ IR measurements (DRIFTS) corroborated this interpretation in that the terminal carbonyl bands of the tricobalt disappeared followed by loss of the carboxylate bands as the temperature was raised.

Scheme 14



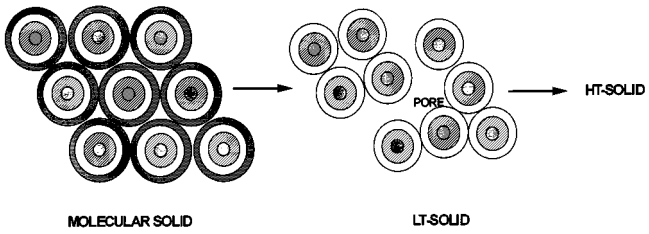
To say that only and all CO links are broken to reach the LT solids would be an oversimplification but it does appear that in the HT solids only the carbyne carbon remains in the amorphous product. This remaining carbon content is viewed as important in the same sense that main group elements are important in stabilizing amorphous metal alloys relative to crystallization.[88] This stability sustains the Co metal dispersion as well as the porous nature of the solid. However, there are limits and heating to 300°C and higher led to diffusion of the Co metal and the formation of α-Co crystallites detectable by X-ray diffraction.

The surface areas of the LT- and HT-solids ranged from 50 to 250 m^2/g which is well within usable range for catalytic purposes.[89] Heating to 300°C and higher led to loss of surface area which is consistent with the formation of the metal crystallites observed by X-ray diffraction. Transmission electron microscopy of cast thin films of the precursor, annealed to various temperatures, confirmed the porous nature of the solid implied by the density and surface area measurements. Electron diffraction of films heated to 300°C and higher showed cobalt crystallites of average size 100 Å. In the X-ray photoelectron spectroscopic experiments, the shift to lower binding energy on formation of the LT-, HT-solids is consistent with conversion of cobalt

carbonyl fragments to cobalt metal and reveals that both the LT- and HT-solids have cobalt metal on exposed surfaces.

A model for the chemical conversion of the molecular cluster metal carboxylates into the two solids based on these data is shown in Scheme 15. Loss of the external CO ligands reduces the size of the cluster assemblies which are still supported by internal core−cluster carboxylate bonds. Formation of inter-assembly metal−metal bonds follows thereby opening channels and generating an amorphous, high surface area, porous solid. Further heating leads to the destruction of the internal metal carboxylate bonding and the formation of larger metal aggregates of indeterminate structure, albeit with retention of significant surface area for the solid as a whole. These are the two meta-stable, amorphous, high surface area solids that were tested as catalysts.

Scheme 15



In order to establish the level of catalytic activity as well as to compare catalysts prepared from the different types of cluster metal carboxylates under a variety of conditions, the hydrogenation of 1,3-butadiene was used as a benchmark reaction.[90][74][89] This reaction was selected because the molecule is easily hydrogenated and high conversions can be achieved with small amounts of catalysts and relatively low temperatures. In addition, the reaction has been thoroughly studied with other transition and noble metal catalysts and a substantial literature exists for comparative purposes. In the event, the LT- and HT-solids tested were sufficiently active catalysts so that a gas phase, steady state flow system could be used for evaluation. This permitted a wide range of conditions to be expeditiously explored.

The activities and selectivities of the LT-solids produced from a variety cluster metal carboxylates showed similar, if not identical, behaviors. 1-Butene is the main product at low conversions whereas butane becomes the main product at high conversions.. On the other hand, the activities and selectivities of the HT-solids are markedly different from those of the LT-solids as well different among themselves. Core dependence appears to be important only for the HT-solids consistent with the model of solid formation summarized above. Importantly, these catalysts were stable (4−7 days on stream) and reproducible.

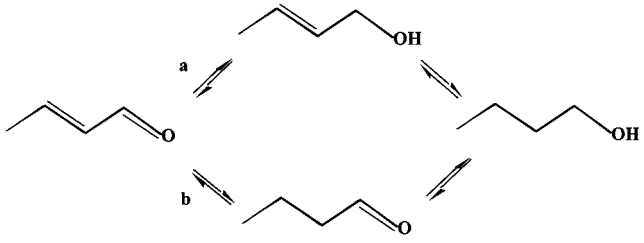
The catalytic behavior of solids produced from the tricobalt cluster alone and of conventional supported cobalt metal under identical conditions is very different from that of catalysts derived from the cluster arrays. This confirms that the catalytic behavior observed for the activated cluster assemblies is due in large part to properties derived from the cluster metal carboxylate precursors. Some carry over of structure from precursor to catalyst must take place in that octahedral and square planar cluster assemblies, both possessing cobalt cores, yield significantly different catalytic behaviors. The latter demonstrates structural as opposed to compositional control of activity and selectivity.

These studies suggest that carbonyl loss (outer cluster decomposition) before carboxylate ligand disruption is important and that core properties can modulate catalytic behavior but only for the HT-solids in which the cores are exposed. Chemical tests of these deductions were carried out. First, cluster metal carboxylates were synthesized using the very thermally stable 1,2-$C_2B_{10}H_{12}$ carborane as the external cluster. Thermolysis of these carboxylates resulted initially in the loss of CO_2 plus some free, intact carborane. This was followed by complex chemistry. The solids produced were of little use and clearly in this case the loss of the core-cluster bonding resulted in total collapse of the cluster assembly.[91] Second, a cluster lead carboxylate with an infinite chain-like structure was used as a catalyst precursor.[71] The LT-solid was an active catalyst with properties similar to any of the catalysts derived from tricobalt cluster metal carboxylates. However, the HT-solid was totally inactive and X-ray photoelectron spectroscopy showed the surface to be severely poisoned by lead metal. These observations are consistent with the model in which the LT-solid possesses an intact assembly core and the HT-solid a disrupted core.

Selective Hydrogenation of Crotonaldehyde

The selective hydrogenation of α,β-unsaturated aldehydes to unsaturated alcohols (path a, Scheme 16) is a challenging reaction for heterogeneous catalysis as C=C double bond reduction is thermodynamically favored at high temperatures and typical metal hydrogenation catalysts also favor C=C double bond reduction over the C=O double bond, i.e., path b in Scheme 16. For this reason a useful catalyst must have high activity at low temperatures as well as high selectivity for path a. As the catalytic solids derived from the cluster metal carboxylates expressed unusual activities and selectivity for the hydrogenation of butadiene, we were drawn to an investigation of the catalytic reduction of crotonaldehyde (2-butenal).[92][93][94]

Scheme 16



The catalyst activities and 2-butenol selectivities observed were good and depended on the type of metals in the core as well as the precursor structure. For cobalt core metals

the highest yield (28%) of 2-butenol resulted from the HT-solid produced from an octahedral cobalt cluster assembly with a cobalt core whereas the highest selectivity (100%) resulted from the HT-solid produced from a square planar cluster assembly also with a cobalt core. The activity and regioselectivity of the former material give the highest yield for a heterogeneously catalyzed reaction reported in the open literature. Results of kinetic studies show that this high regioselectivity resides in increased barrier heights for the various reaction steps. The simultaneous high activity requires the active participation of a large fraction of sites on the catalyst. That is, these solids show the behavior expected for catalysts that possess sites having a narrow activity distribution. This, in turn, is in accord with the model of these solids drawn from the spectroscopic as well as chemical studies.

The activities and selectivities of these catalysts are constant for periods of times that are several fold higher than those reported with supported catalysts and the materials do not show deactivation up to 50 hours of time on stream. Catalysts derived from tricobalt cluster assemblies with heterometal cores give uniformly poorer results relative to the homometallic systems of the same structure type. Solids produced from the tricobalt cluster alone were less active with poor selectivity.

Summary

We have demonstrated the coordination of cluster-substituted carboxylates to cationic metals as a successful strategy for the assembly of large transition metal cluster arrays. In terms of the coordination modes of the cluster carboxylate ligand, most exhibited by organic metal carboxylates have been observed. In terms of core structure, rhombic, tetrahedral, cubane-like, ladder-like, double cubane-like, as well as chain-like geometries have been generated. In terms of the spatial arrangement of the clusters, triangular, square, triangular bipyramidal, octahedral, chair-like, and column-like types have been observed. The observed compounds reveal the unique properties of the functionlized clusters as ligands over convertional organic carboxylates. These studies also show that the catalytic properties of solids produced from molecular cluster metal carboxylates depend on the molecular composition and structure of the cluster assembly. Further, the detailed catalytic behavior suggests that the high activities and unusual selectivities observed are derived from a high number of uniform active sites. Both conclusions are consistent with catalytic solids that "remember" their molecular origins. Although no practical catalyst has been uncovered for the selective crotonaldehyde reduction, only small changes in relative reaction barrier heights are needed to do so. In turn this suggests that relatively minor changes in precursor structure and composition are required. It remains to experimentally define these changes. This requires the continued development synthetic cluster chemistry in order to produce additional useful cluster ligands.

We thank our talented co-workers listed in the references for their contributions to the synthetic and catalytic chemistry and we appreciate the support of the *National Science Foundation*.

Received July 20, 1998

Keywords: Intramolecular coordination / Donor groups / Phosphorus compounds / X-ray structures / Ligands exchange

This review describes phosphanes and phosphane derivatives as well as phosphenium salts in which increase in coordination number was achieved by intramolecular coordination of donor groups. This effect was established by X-ray crystal structure analysis and was also inferred from ^{1}H-NMR studies in solution. Where possible, comparison with the corresponding silicon compounds was made.

4. Conclusion

1. Introduction

It is well established that the silicon atom can extend its coordination number beyond four and that, in many cases, such an increase in coordination number can be achieved by intramolecular coordination of donor groups[1]. The phosphorus atom can also increase its coordination number through intramolecular coordination by donor groups[2]. However, this aspect has been mainly studied with regard to phosphoranes and this matter has recently been reviewed[3]. For our part, we have studied intramolecular coordination of NMe_2 donor groups in P^{III} and P^{IV} phosphorus compounds. The purpose of this review is to survey these compounds, with emphasis on the physical techniques used to establish their structures in the solid state and in

Claude Chuit was born in Paris in 1935. He obtained his Doctorat d'Etat from the University of Orsay under the supervision of Dr. H. Felkin. After one year of postdoctoral studies at the University of Stirling (Scotland) with the late Professor W. Parker, he spent 10 years in Professor J. F. Normant's laboratory at the University P. and M. Curie in Paris. Since 1980 he has worked on hypercoordinate silicon and phosphorus compounds in Professor R. Corriu's laboratory at the University of Montpellier. He was appointed Directeur de Recherche at the CNRS in 1990. His current interests concern the elaboration of materials by the sol-gel process.

Catherine Reyé was born in France (Deux Sèvres). She received her Ph.D. from the University of Montpellier II under the supervision of Professor R. J. P. Corriu. Her principal research interests were then focussed on the chemistry of hypercoordinate silicon and phosphorus compounds. Initially, she worked in the area of reactions catalyzed by nucleophiles involving hypercoordinate silicon intermediates. Subsequently, she studied the structure and the reactivity of hypercoordinate silicon and phosphorus compounds. Her current interests concern the study of hybrid organic-inorganic materials obtained by hydrolytic polycondensation.

MICROREVIEWS: This feature introduces the readers to the authors' research through a concise overview of the selected topic. Reference to important work from others in the field is included.

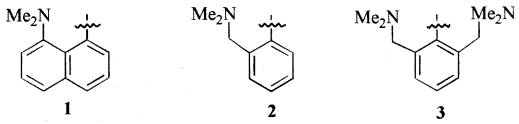
solution. Phosphanes with intramolecular N→P interactions are referred to as pseudo-hypercoordinate phosphanes, taking into account the phosphorus lone electron pair. Comparisons with the corresponding silicon compounds are made where analogies exist between hypercoordinate silicon and phosphorus chemistry[4][5]. Phosphenium salts stabilized by intramolecular coordination of two NMe_2 donor groups at the phosphorus atom are also surveyed. Analogies with the corresponding stabilized silylenium salts are noted.

Intramolecular chelation at the phosphorus atom can principally be achieved by using ligands **1**, **2**, and **3**, introduced by van Koten and co-workers[6] in tin chemistry, and used extensively in silicon chemistry[1]. Each of these has its own particularly interesting features. The rigid geometry of ligand **1**, in which the donor group is fixed in close proximity to the phosphorus centre, facilitate intramolecular coordination. In contrast, the geometry of ligand **2** does not enforce coordination to the phosphorus centre. However, a favourable conformation allowing interaction between the donor atom and the phosphorus atom exists, which is adopted when suitable substituents are also attached at the phosphorus. Finally, ligand **3** permits the study of mono- or bis-coordination at the phosphorus atom, also as a function of the other ligands. Furthermore, it allows the study of fluxional coordination-decoordination processes.

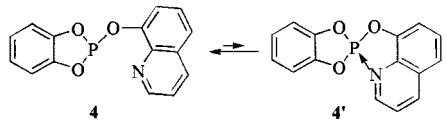


1 **2** **3**

2. Hypercoordinate P^{III} and P^{IV} Phosphorus Derivatives

2.1 Pentacoordinate Phosphonite, Phosphonate, and Thiophosphonate Compounds

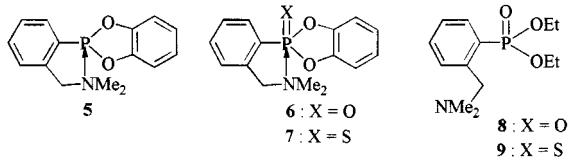
An intramolecular N→P interaction was suggested for compound **4**[7] in view of its temperature-dependent ^{31}P-NMR spectrum, the chemical shift decreasing from δ = +125 at 25°C to δ = +121.4 at −80°C. This observation was attributed to an equilibrium between **4** and **4′** (Eq. 1).



4 **4'** (1)

Following this result, we prepared compounds **5**, **6**, **7**, **8**, and **9**[8], which all include the potentially chelating ligand **2**. In Table 1, we report the ^{31}P-NMR resonances of **5**−**9**, alongside those of the corresponding phosphorus derivatives lacking the NMe_2 group.

Significant upfield shifts are observed for **5**, **6**, and **7**, suggesting N→P interactions in these derivatives. Such shifts were not evident for **8** and **9** and the lack of N→P interactions in **8** and **9** was confirmed by their ^{1}H-NMR spectra, in which the signal of the NMe_2 group appears as



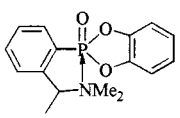
5 **6** : X = O, **7** : X = S **8** : X = O, **9** : X = S

Table 1. ^{31}P-NMR chemical shifts (at 293 K) of **5**−**9** compared to those of the corresponding phosphorus derivatives lacking NMe_2 groups

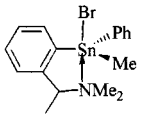
Compound	δ (ppm)	Compound	δ (ppm)	Δδ
 **5**	+130.7		+177.0[9]	-46.0
 **6**	+13.3		+35.7[10]	-22.4
 **7**	+72.9		+107.1[11]	-34.2
 **8**	+19.6		+16.9[12]	-2.7
 **9**	+83.3		+86.7[8]	+0.4

a singlet over the temperature range studied (183−293 K) in both cases. In contrast, it was found that **7** is pentacoordinated at room temperature: Its ^{1}H-NMR spectrum displays two doublets attributable to the NMe_2 protons. These signals appear as doublets because of P,H coupling [^3J(PH) = 4.8 Hz]. The situation for **5** and **6** is intermediate. At 183 K, the ^{1}H-NMR spectra of **5** and **6** display two singlets for the NMe_2 protons. On raising the temperature, coalescence of these signals is observed ($\Delta G^{\neq}_{233K}$ = 48 kJ mol^{-1} for **5** and $\Delta G^{\neq}_{218K}$ = 46 kJ mol^{-1} for **6**). Two processes could explain the equivalence of the methyl groups, namely pseudorotation around the phosphorus atom or cleavage of the N→P bond with subsequent rotation about the CH_2−N bond and inversion at nitrogen prior to recoordination. In order to clarify this point, we prepared compound **10** bearing a ligand with an asymmetric benzylic carbon atom. From the ^{1}H-NMR spectrum at room temperature, it was inferred that **10** exists as two isomers in solution in an 80:20 ratio, the NMe_2 protons of each isomer appearing as sharp singlets. The major isomer was isolated and was found to slowly epimerize (CH_2Cl_2, 3 h, 20°C) to give the 80:20 equilibrium mixture. On lowering the temperature, the singlet attributable to the NMe_2 protons of the minor diastereoisomer splits into two signals ($\Delta G^{\neq}_{223K}$ = 47 kJ mol^{-1}), while the singlet of the major diastereoisomer gives only a broad signal ($\Delta G^{\neq}_{158K}$ = 32 kJ mol^{-1}). The equilibration of the diastereoisomers of **10** can be explained

by slow rotation about the P−C_{ipso} bond during the coordination-decoordination process. It is noteworthy that similar results have been observed for the tin derivative **11**[13], and the same explanation has been proposed.

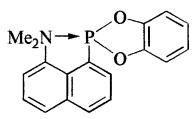


10

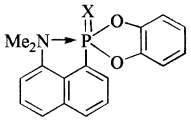


11

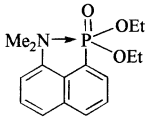
We have also prepared compounds **12**−**14**[8] incorporating ligand **1**, which imposes intramolecular coordination at the phosphorus atom. As a result, it is possible to study the permutational isomerization processes in these derivatives by dynamic ^{1}H-NMR spectroscopy. The ^{1}H-NMR spectra of **12**−**14** exhibit only one singlet for the NMe_2 protons at room temperature. However, on lowering the temperature, the singlet splits into two signals in each case. From the coalescence temperature of the methyl group signals (273 K for **12** and **13**; 255 K for **14**), $\Delta G^{\neq}$ values of 57−58 kJ mol^{-1} can be estimated for the pseudorotation processes in these three compounds. For **15**, only one singlet is observed for the *N*-methyl protons, even at low temperature, indicating either a facile permutational isomerization process about the phosphorus atom or a symmetrical arrangement of the molecule. Therefore, the X-ray crystal structure of this compound was determined (Figure 1). It reveals a dissymmetric geometry, the lone pair of the nitrogen atom being directed towards the phosphorus atom *trans* to a P−OEt bond, with an N−P distance of 2.87 Å. Furthermore, the basic pyramidal configuration around the phosphorus atom is only slightly deformed, so that the molecule can be described as a mono-capped tetrahedron in which the phosphorus atom is [4+1] coordinated[8]. Thus, the non-diastereotopy of the NMe_2 protons is probably due to a fast permutational isomerization process occurring at the phosphorus centre.



12

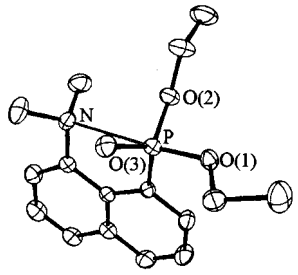


13 : X = O
14 : X = S

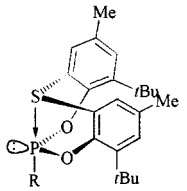


15

Figure 1. X-ray crystal structure of **15**



Similarly, Holmes et al.[14] have recently prepared the chloro and amino phosphites **16a** and **16b**, as well as the phosphate **17**. In these compounds, intramolecular S→P interactions are observed. Indeed, X-ray crystal structure determinations for these compounds have revealed S−P distances notably shorter than the sum of the van der Waals radii for phosphorus and sulfur (2.816, 2.952, and 3.114 Å for **16a**, **16b**, **17**, respectively), the geometry around the phosphorus atom being a pseudo-trigonal bipyramid for **16a** and **16b** and a trigonal bipyramid for **17**, with the eight-membered ring in the boat-boat conformation.



16 a : R = Cl

17

2.2 Pseudo-Pentacoordinate Phosphanes and Pentacoordinate Phosphane Derivatives

Phosphanes **18**[15−18], **19**[19,20], **20**[21], and **21**[22−24] have previously been prepared in order to study their abilities to act as mono- or bis-chelating ligands. However, to the best of our knowledge, the potential occurrence of N→P interactions has not been considered for these phosphanes, apart from in the case of **21**[22]. We have prepared phosphanes **21**[25], **22**[26], **23**[26], and **24**[27], as well as phosphane oxide **25**, phosphane sulphide **26**, and phosphonium salts **27**−**29**, all of which incorporate the rigid ligand **1**. X-ray crystal structure analyses of phosphanes **21**[25] and **23**[26] (Figure 2) and of the phosphonium salt **29**[26] reveal that the phosphorus atom resides in a nonsymmetric environment in each case, the lone pair of the nitrogen atom being directed towards the phosphorus atom *trans* to one P−C bond in **21** and **23**, and *trans* to the benzyl group in **29**[26]. The N−P distances in **21**, **23**, and **29** are 2.71, 2.62, and 2.83 Å, respectively, and these distances increase as a result of steric hindrance around the phosphorus atom. Furthermore, in these three compounds, the pyramidal configuration around the phosphorus atom is retained with only a slight deformation. Thus, the geometry of these compounds can be described as mono-capped tetrahedral, where the phosphorus atom is pseudo-[4+1]-coordinated in **21** and **23**, and [4+1]-coordinated in **29**. It is noteworthy that the silicon compound **30** also has a dissymmetrical structure, with the lone pair of the nitrogen atom directed towards the silicon atom, *trans* to an Si−C_{sp} bond[26], with an N−Si bond length of 2.72 Å.

Dynamic ^{1}H-NMR studies of compounds **21**−**28** have been carried out in solution. At 273 K, the spectrum of phosphane **21** (CD_2Cl_2/$CFCl_3$) exhibits a singlet due to the NMe_2 protons, which splits into two signals[25] on lowering the temperature. The same behaviour is observed for phosphane **23**[26] and the phosphane derivatives **25**−**28**[25,27].

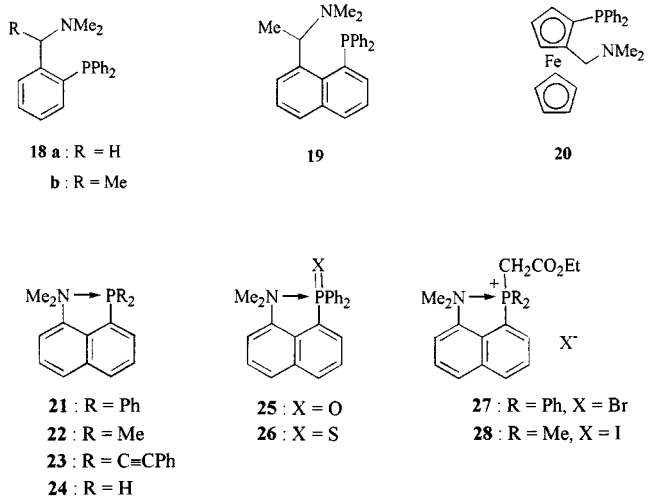

Figure 2. X-ray crystal structures of **21** (left) and **23** (right)

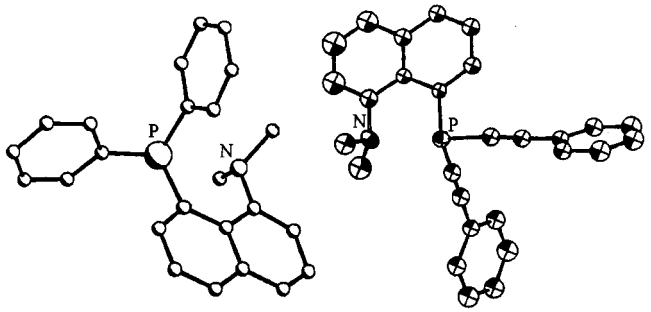

For phosphanes **22**[26] and **24**[27], only broadening of the singlet attributable to the NMe_2 protons is observed at 173 K. This shows that all these compounds (**21**−**29**) are pseudo-pentacoordinated or pentacoordinated in solution, with dissymmetrical geometries, in agreement with the solid-state structures of **21**, **23**, and **29**. In solution at room temperature they undergo a fast permutational isomerization process, the calculated $\Delta G^{\neq}$ values of which are reported in Table 2. These values indicate that isomerization is easier for phosphanes than for phosphane derivatives. This process should also be easier for compounds with Me substituents at the phosphorus atom than for compounds with Ph substituents, since the decoalescence of the NMe_2 signals could not be observed for phosphanes **22** or **24**. It is noteworthy that the behaviour in solution of the silicon compound **30**[26] has also been studied by ^{1}H-NMR spectroscopy. It is similar to that of **23**, with a $\Delta G^{\neq}$ value of 55.2 kJ mol^{-1} for the equivalence of the NMe_2 groups.

The diphosphane **31** has also been prepared[26]. It was found by ^{1}H-NMR studies that **31** and **21** show similar behaviour in solution. Thus, at room temperature, all the NMe_2 protons are equivalent and appear as a singlet, which splits into two signals at 178 K. This indicates that **31** is pentacoordinated in solution and undergoes a permutational isomerization process at room temperature. The calculated $\Delta G^{\neq}$ for this process is 36.8 kJ mol^{-1}, this value being very similar to that found for phosphane **21**.

2.3 Pseudo-Hexacoordinate Phosphanes and Hexacoordinate Phosphane Derivatives

We have prepared phosphanes **32** and **33**, as well as their derivatives **34**−**37**. X-ray structure analyses of the phosphane **32**[28] and of phosphorus derivatives **35**[29] and **37**[28] have been performed (Figure 3). In each case, they reveal that the nitrogen lone pairs are directed towards the phosphorus atom, one NMe_2 group being *trans* to the P−Ph bond, while the other is opposite to a P−naphthyl bond with N−P−N angles of 102.4°, 94.9°, and 106.9°. The N−P distances are 2.70−2.73 Å in **35**, 2.78−2.79 Å in **32**, and 3.01 Å in **37**. The longer distance in **37** is probably due to the steric hindrance at the phosphorus atom, while the short distance in **35** is most probably attributable to the positive charge on the phosphorus atom. In each case, the pyramidal configuration around the phosphorus atom is retained and the geometries of these compounds correspond

to a bi-capped distorted tetrahedron (taking into account the nitrogen lone pair in **32**) rather than to a distorted octahedron. It is noteworthy that X-ray structure analysis of the analogous silicon compound **38**[30] showed the same geometry.

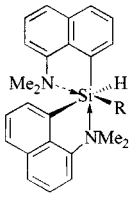
37



38 (R = H, F)

The solution ^{1}H-NMR spectra of phosphanes **32** and **33**, that of phosphane oxide **34**, and those of phosphonium salts **35** and **36**, at limiting temperatures for slow exchange, display four sharp signals attributable to the NMe_2 protons[31]. Selective irradiation of each methyl signal shows a transfer of saturation occurring between pairs of equivalent sites, one methyl of an NMe_2 group being equivalent to one methyl of the other NMe_2 group. At the same temperature, the ^{1}H-NMR spectra of these derivatives also show two discrete sets of naphthyl group signals. These data indicate that compounds **32**–**36** are hexacoordinated in solution, with dissymmetrical geometries, in agreement with the X-ray structures of **32**, **35**, and **37**. Furthermore, the ^{1}H-NMR spectra of these compounds are temperature-dependent. On raising the temperature there is coalescence of the four methyl signals into two essentially well-resolved signals (Table 3). Dynamic ^{1}H-NMR study of phosphonium salt **36**, which is the first known phosphonium salt with two P–H bonds, was not possible since it decomposes in solution at room temperature[27]. The ^{1}H-NMR spectrum of

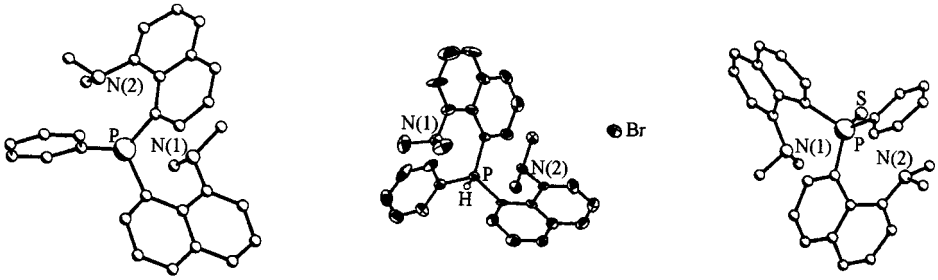
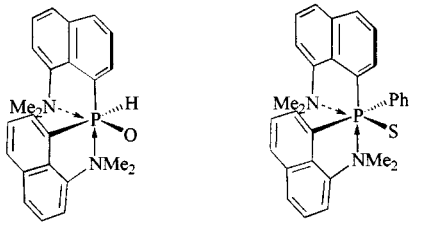
phosphane oxide **34** at 233 K shows a strongly deshielded signal at δ = 9.78. This downfield signal was assigned to the proton of the naphthyl group located in the deshielding zone of the P=O bond. This suggests that **34** adopts a conformation in which the N→P bond interaction is *trans* to the P=O bond (Figure 4). The coalescence of the four methyl group signals to give two signals can be explained

Figure 3. X-ray crystal structures of **32** (left), **35** (centre), and **37** (right)



by a permutational isomerization process around the phosphorus atom, which occurs without cleavage of the N→P bond. The $\Delta G^{\neq}$ value for this process lies in the range 58−62 kJ mol^{-1} (Table 3). We note that similar solution behaviour was observed for the silicon compound **38** (R = F) by ^{1}H-NMR spectroscopy, the permutational isomerization process[32] taking place with a $\Delta G^{\neq}$ value of 62.4 kJ mol^{-1}.

Figure 4. Schematic representation of **34** and of the minor isomer of **37**

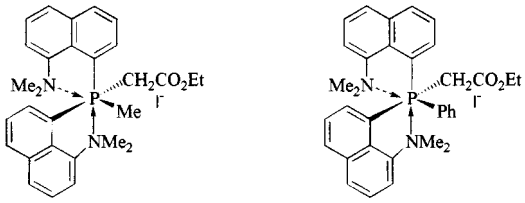


34 **37** (minor isomer)

Further raising of the temperature leads to the decomposition of **34** and **35** above 400 K. Coalescence of the two slightly separated signals into one was observed only for phosphane **32** (at 418 K in [D_4]-*o*-dichlorobenzene), thus indicating the cleavage of the N→P bond with an estimated $\Delta G^{\neq}$ value of 90 kJ mol^{-1}.

The solid-state ^{31}P-NMR spectrum of **37** shows one signal at δ = 50.9. In contrast, the ^{31}P-NMR spectrum of **37** in C_6D_6 displays two resonances at room temperature (at δ = 63.9 and δ = 53.5), which indicates that **37** exists as two isomers in solution. This was confirmed by a dynamic ^{1}H-NMR study. At the limiting temperature for slow exchange, the ^{1}H-NMR spectrum of **37** exhibits eight signals for the *N*-methyl protons, indicating the existence of two isomers in solution, the ratio of which depends on the solvent (50:50 in bromoform and 80:20 in toluene). Furthermore, comparison of the ^{31}P-NMR chemical shifts of **37** in solution and in the solid state shows that one of the isomers observed in solution (δ = 53.5) is presumably that present in the solid state (δ = 50.9). The structure of the other isomer (δ = 63.9 in C_6D_6) was inferred from a low-temperature ^{1}H-NMR study of the naphthyl protons. At 233 K (in [D_8]toluene), the ^{1}H-NMR spectrum of this isomer displays one signal at δ = 9.8, suggesting a structure similar to that of **34**, with the N→P bond lying *trans* to the P=S bond (Figure 4). COSY experiments on the mixture of isomers of **37** show that each methyl group of the NMe_2 groups exchanges with the other three, indicating an interconversion of the two isomers in solution. On raising the temperature, each methyl signal broadens, and they finally coalesce into a very broad signal at 373 K. Further raising of the temperature leads to the decomposition of the isomers at 405 K. Thus, two phenomena take place: (a) a permutational isomerization process occurring independently on each isomer, and (b) the interconversion of these isomers. This latter phenomenon was detected by means of COSY and NOESY experiments.

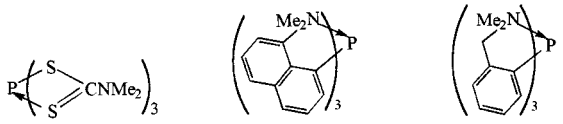
The ^{1}H-NMR spectra of **39** and **40** at room temperature show that these compounds are also hexacoordinated in solution, with dissymmetrical geometries[29]. Indeed, the ^{1}H-NMR spectrum of **39** exhibits four sharp singlets for the methyl groups and two sets of naphthyl proton signals. The PCH_2 protons are diastereotopic and appear as doublets of doublets. The ^{1}H-NMR spectrum of **40** displays eight singlets for the methyl groups and a multiplet for the diastereotopic PCH_2 protons, thus indicating that this compound exists as two isomers in solution, as in the case of **37**. Further evidence for the existence of two isomers is provided by the ^{31}P-NMR spectrum of **40**, which also exhibits two resonances.



39 **40**

2.4 Pseudo-Heptacoordinate Phosphanes

The first pseudo-heptacoordinate P^{III} phosphorus derivative **41** was described by Paine and co-workers[33]. This complex was obtained by insertion of CS_2 into the P−N bond of the aminophosphane $P(NMe_2)_3$. Single-crystal X-ray structure analysis of **41** showed that the phosphorus centre is formally seven-coordinated, with six sulfur atoms (three short P−S bonds of mean length 2.178 Å and three long P−S bonds of mean length 2.966 Å) and the phosphorus lone pair forming a distorted capped trigonal antiprism.

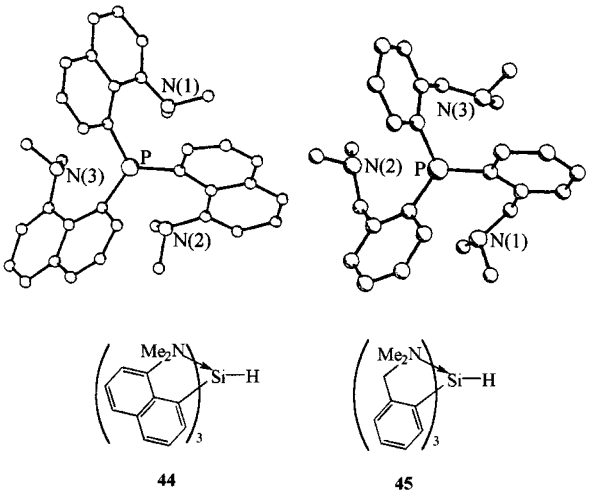


41 **42** **43**

We have prepared the phosphanes **42** and **43**[34], the X-ray crystal structures (Figure 5) of which reveal in both cases three weak N→P interactions with N−P distances of 2.80, 2.84, and 2.85 Å in **42** and 3.00, 3.01, and 3.07 Å in **43**. The pyramidal configuration around the phosphorus atom is retained and nitrogen coordination is observed *trans* to a P−C bond. Thus, the geometry of these phosphanes corresponds to a tri-capped tetrahedron[34] (taking into account the nitrogen lone pair). It is important to emphasize that phosphanes **42** and **43** adopt the same geometry, even though there is no steric constraint in phosphane **43** to force the NMe_2 groups to interact with the phosphorus centre. However, their ^{1}H-NMR spectra are notably different. Thus, while the ^{1}H-NMR spectrum of **43** exhibits only one sharp singlet for the methyl protons, even at low temperature, that of **42** displays two singlets for the

methyl protons, even up to 90°C (250 MHz). This notable difference indicates that N→P interactions are maintained in solution in the case of **42**, while an equilibrium between the opened and closed forms should be operative in solution for **43**. The same tri-capped tetrahedral geometry was also found in the silanes **44**[35] and **45**[36].

Figure 5. X-ray crystal structures of **42** (left) and **43** (right)



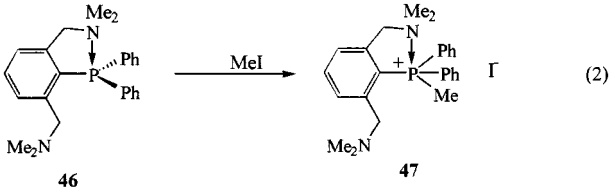
44 **45**

2.5 Reactivity of Pseudo-Hypercoordinate Phosphanes

The reactivity of phosphanes **21**, **32**, and **42**, incorporating one, two, or three 8-(dimethylamino)naphthyl ligands **1** decreases with the increasing number of ligands **1**, undoubtedly because of the increasing steric hindrance at the phosphorus atom and of the increasing number of N lone pairs in the P coordination sphere.

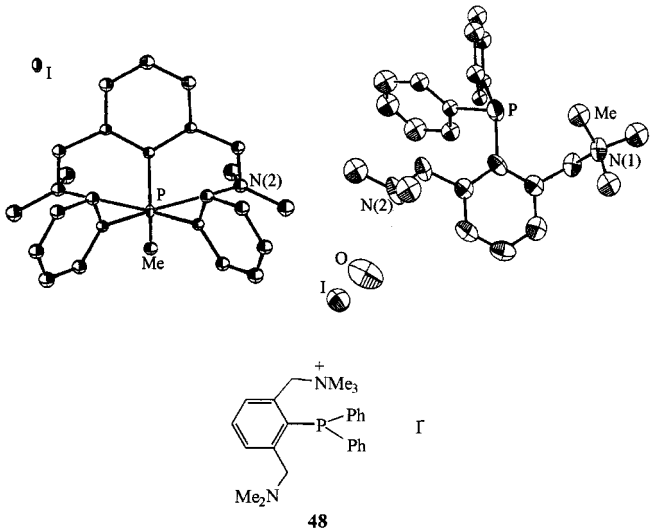
The reactivity of the pseudo-pentacoordinate phosphane **21** is very similar to that of triphenylphosphane. Thus, treatment of **21** with H_2O_2, S_8, CH_3I, or $BrCH_2CO_2Et$ affords the expected products in satisfactory yields[37] (58−65%). The pseudo-hexacoordinate phosphane **32** is less reactive than **21**. While its oxide and sulfide can be prepared under the classical reaction conditions in 60 and 67% yield, respectively, the formation of the phosphonium salt **40** required reaction with ICH_2CO_2Et for 24 h in refluxing toluene[27]. Finally, the reactivity of the pseudo-heptacoordinate phosphane **42**[34] is very different from that of **21** and **32**, as well as that of triphenylphosphane. It was not possible to obtain the corresponding oxide, nor the phosphane sulfide. However, reaction of **42** with CH_3I furnished the corresponding phosphonium salt in low yield (32%) after 10 days heating in a sealed tube at 100°C. In contrast, the pseudo-heptacoordinate phosphane **43**, incorporating three flexible ligands **2**, shows a reactivity similar to that of triphenylphosphane towards H_2O_2 or sulfur, but reacts with MeI to afford only the product of methylation at one amino group in 62% yield after 3 h at 100°C. This difference of reactivity between **42** and **43** towards MeI is consistent with their ^{1}H-NMR data in solution, which indicate a stronger N→P interaction in **42** than in **43**.

Phosphane **46**, incorporating the potentially bis-chelating ligand **3**, reacts with MeI to give the phosphonium salt **47** (Eq. 2), which undergoes a coordination-decoordination process in solution[38]. An X-ray structure determination of **47** (Figure 6) shows that the lone pairs of the two nitrogen atoms are directed symmetrically towards the phosphorus atom, with N−P distances of 3.14 and 3.16 Å. Furthermore, the tetrahedral geometry of the phosphorus atom is maintained so that the geometry around the phosphorus centre is that of a slightly distorted bi-capped tetrahedron. This conformation of the NCN ligand is similar to those found in transition-metal compounds incorporating this ligand[39]. During crystallization of **47**, a very small number of atypical crystals were found, the structure of which (Figure 6) revealed that they were composed of the ammonium salt **48**. The striking feature of this structure is that one methyl of the NMe_3^+ group is positioned close to the phosphorus atom, at a distance of 3.44 Å. This suggests that MeI could react with **46** to afford first the ammonium salt **48**, which should then undergo a fast rearrangement to **47** due to the favorable geometry of the NMe_3^+ group in relation to the P atom.



46 **47**

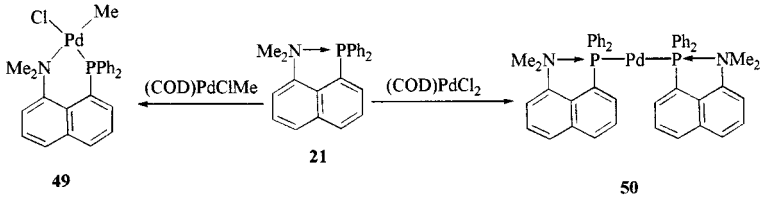
Figure 6. X-ray crystal structures of **47** (left) and **48** (right)



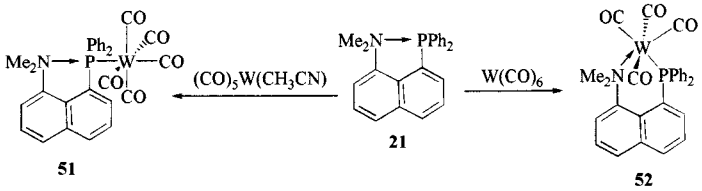
48

The reactivity of phosphanes **21**, **32**, and **42** towards transition-metal compounds was also investigated. The pseudo-pentacoordinate phosphane **21** may act as a monodentate ligand via the phosphorus atom or as a bidentate ligand via both the phosphorus and nitrogen atoms, depending on the experimental conditions. Thus, when $[(COD)PdCl_2]$ was allowed to react with 2 equiv. of **21**, complex **50** was formed, in which **21** coordinates to the Pd centre only via the phosphorus atom. On the other hand, **21** reacts with

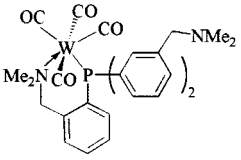
Scheme 1



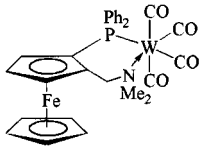
Scheme 2



[(COD)PdClMe] as a bidentate ligand[24] to afford **49** (Scheme 1). Similarly, **21** reacts with $[(CO)_5W(CH_3CN)]$ as a monodentate ligand to afford complex **51** (Scheme 2), but with $W(CO)_6$ as a bidentate ligand to form complex **52**, the X-ray structure analysis[24] of which was performed. Phosphane **32** does not react appreciably with $W(CO)_6$ and no complex was isolated under these conditions. As regards phosphane **42**, it is completely unreactive towards $W(CO)_6$, as well as towards $[THF{\cdot}W(CO)_5]$. Phosphane **43**, incorporating three flexible ligands **2**, reacts with $W(CO)_6$ to give complex **53**, an X-ray structure determination[37] of which showed that the tungsten atom is complexed by one nitrogen atom and by the phosphorus centre, leaving two free NMe_2 groups. A similar bidentate carbonyltungsten complex **54** had previously been proposed[21] on the basis of IR and ^{1}H-NMR spectra. The pattern of CO stretching bands in the IR spectrum of complex **52** (2012, 1885, 1856 cm^{-1}) is similar to that seen for **54** (2018, 1889, 1832 cm^{-1}), but different from that in the case of complex **51** (2070, 1978, 1834 cm^{-1}). This latter spectrum closely resembles that of $Ph_3PW(CO)_5$ (2075, 1980, 1938 cm^{-1})[40].



53



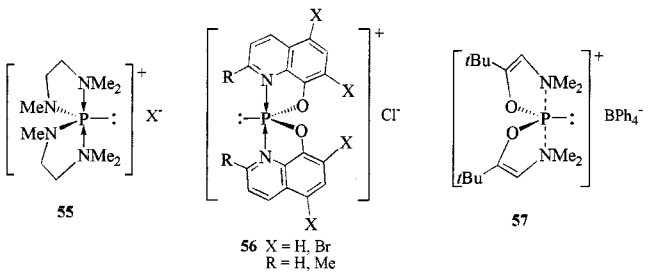
54

2.6 Reactivity of Hypercoordinate Phosphonium Salts

We have investigated the reactivity of some hypercoordinate phosphonium salts under Wittig conditions in order to study the effect of the N→P interaction on the rate and stereoselectivity of this reaction[29]. Some selected results are reported in Table 4. The pentacoordinate phosphonium salts **27** and **28** were found to react readily with benzaldehyde under Wittig conditions to give ethyl cinnamate, with **28** being more reactive than **27**. Furthermore, both substrates proved to be much more reactive than $Ph_3P^+CH_2CO_2Et$ under the same conditions, furnishing ethyl (*E*)-cinnamate with very good stereoselectivity. However, they were unreactive towards ketones under Wittig

Table 4. Results of Wittig reactions of phosphonium salts **27**, **28**, **39** and **40** with benzaldehyde under different experimental conditions; yields (*E*/*Z* ratio) of ethyl cinnamate

Phosphonium Salt	Reaction conditions: $NaNH_2$ / Et_2O [reaction times]	Reaction conditions: NaOH / C_6H_6 / H_2O [reaction times]
 **28**	75% (95/5) [1 h]	40% (86/14) [5 min]
 **27**	51% (99/1) [22 h]	77% (86/14) [2 h]
$Ph_3P^+CH_2CO_2Et$ Br^-	8% (97/3)	-
 **39**	0% [44 h]	60% (92/8) [44 h]
 **40**	0% [96 h]	20% (97/3) [96 h]



55 **56** X = H, Br; R = H, Me **57**

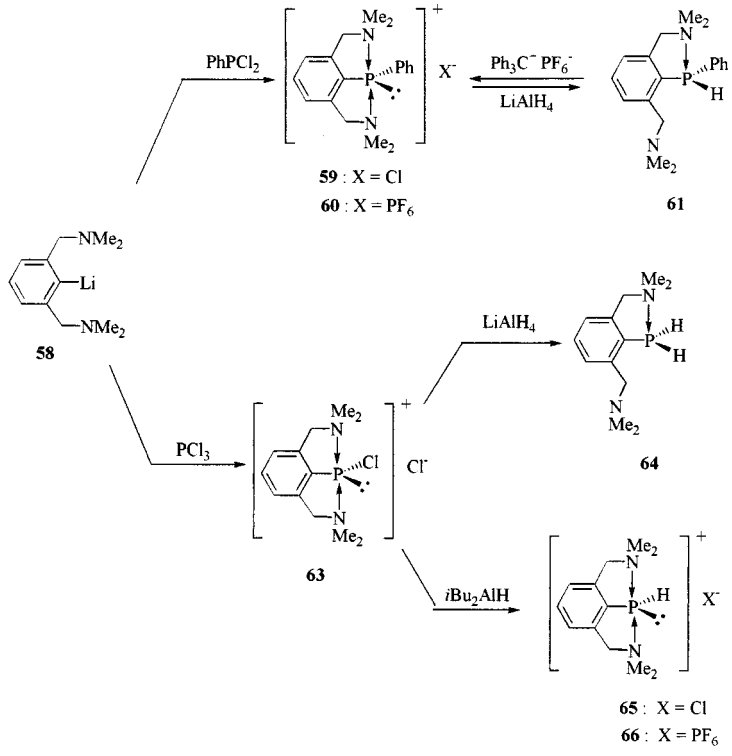
conditions. Due to the steric hindrance at the phosphorus atom, hexacoordinate phosphonium salts **39** and **40** are much less reactive than **27** and **28**. They react with PhCHO only under particular experimental conditions (Table 4), nevertheless showing good stereoselectivity. Thus, it can be concluded that electronic factors dominate over steric ones for compounds **27** and **28**, whereas for hexacoordinate phosphonium salts **39** and **40** incorporating two rigid ligands **1**, steric factors dominate the outcome of the Wittig reaction, resulting in poor reactivity.

3. Pseudo-Pentacoordinate Stabilized Phosphenium Salts

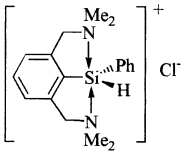
Phosphenium ions are reactive species[41] which can be stabilized by inter-[42–44] or intramolecular[45,46] coordination of donor groups on the phosphorus atom. The stabilization of phosphenium ions by twofold intramolecular coordination by nitrogen atoms was proposed by Schmutzler and Becker[47], who prepared the salt **55**. Subsequently, Lamandé and Munoz obtained salts **56**[48], the structures of which were inferred from ^{13}C- and ^{31}P-NMR studies. Finally, an X-ray crystal structure analysis of the salt **57**[49] revealed the pseudo-pentacoordination of the phosphorus atom in the cation, in a geometry close to a trigonal bipyramid, with N→P bond distances of 2.05 and 2.06 Å.

Ligand **3**, which has been found to stabilize silylenium ions[50–52], also permits the stabilization of phosphenium ions. Thus, reaction of the lithium derivative **58** with $PhPCl_2$ did not afford the phosphane $(Ar)_2PPh$, but rather an extremely air- and moisture-sensitive white powder **59** (Scheme 3), the ^1H-NMR spectrum of which featured two singlets for the NMe_2 protons and one AB pattern for the benzylic protons. The same ^1H-NMR pattern was found for the silylenium ion **62**[50–52]. Treatment of **59** with $NaPF_6$ furnished the corresponding hexafluorophosphate salt **60**, the ^{31}P-NMR spectrum of which exhibits two signals of equal intensity, one at $\delta = +95.5$, very close to that observed for **59**, and the other at $\delta = -143.6$ (PF_6^-). All these data are clearly consistent with an ionic structure for **59**. Reaction of this salt with $LiAlH_4$ afforded the phosphane **61** (Scheme 3), the ^{31}P-NMR chemical shift of which is upfield [$\delta = -77.5$, $^1J(PH) = 225$ Hz] with respect to that of Ph_2PH[53] ($\delta = -41.0$), thus suggesting an intramolecular N→P interaction. From the ^1H-NMR spectrum, it was inferred that phosphane **61** is pseudo-pentacoordinated at the phosphorus atom due to a rapid coordination-decoordination process of the NMe_2 groups. The increase in coordination number of the phosphorus atom in **61** gives rise to an unusual reactivity of the P−H bond. Indeed, **61** undergoes hydride abstraction upon reaction with Ph_3C^+-

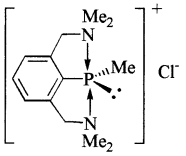
Scheme 3



PF_6^- (Scheme 3), reforming the stabilized phosphenium salt **60**. It is noteworthy that hydride abstraction does not occur in the case of "classical" secondary phosphanes, but rather quaternization of the phosphane takes place[54]. The modification of the reactivity of a bond because of extra coordination is a well-known phenomenon in silicon chemistry[1], but has not previously been observed in phosphorus chemistry. Reaction of the lithium derivative **58** with PCl_3 gives rise to the phosphorus salt **63**, which was found to be extremely air- and moisture-sensitive. $LiAlH_4$ reduction of **63** gave phosphane **64**, while iBu$_2$AlH reduction unexpectedly afforded **65**, which represents the first stabilized phosphenium ion with a P−H σ bond (Scheme 3). The ^{1}H-NMR spectrum of this compound exhibits the same pattern for the NMe_2 and benzylic protons as **59**, indicating the coordination of both NMe_2 groups to the phosphorus atom[55]. The ^{1}H-NMR signals of the CH_2NMe_2 "arms" in the analogous P−Me salt **67**[27] are different from those in the case of salts **59** and **65**. At room temperature, the NMe_2 groups in **67** give rise to a single broad signal, while the benzylic protons appear as an AB pattern. On lowering the temperature, the NMe_2 signal splits into two signals and at 253 K the pattern due to the CH_2NMe_2 arms is the same as that seen for **59** and **65**. These observations can be explained in terms of a fast fluxional coordination-decoordination process of the NMe_2 groups at the phosphorus centre, which renders these groups equivalent at room temperature. However, the chirality at the phosphorus atom[27] is maintained, probably because of a slow rotation about the P−C_{ipso} bond, thus explaining the diastereotopy of the benzylic protons. An X-ray crystal structure determination of the hexafluorophosphate **66**[55] has confirmed the pseudo-pentacoordination at the phosphorus atom, the geometry of the cation being that of a distorted trigonal bipyramid with N−P distances of 2.08 and 2.07 Å, distances very close to those observed in the salt **57**.



62



67

4. Conclusion

In this review, we have described hypercoordinate phosphorus compounds in which extra coordination at the phosphorus centre is provided by intramolecular interaction of strategically positioned NMe_2 groups. Pseudo-hypercoordinate phosphanes have structures very similar to those of the corresponding silicon derivatives with an Si−H bond, and both series of compounds show similar fluxional behaviour in solution. The N−P distances are generally rather long (2.7−3.0 Å), but amount to less than the sum of the van der Waals radii of phosphorus and nitrogen atoms (3.4 Å[56]). The geometry at the phosphorus atom invariably corresponds to a capped tetrahedron, which is generally somewhat distorted. It is noteworthy that the structural characteristics of the pseudo-hexacoordinate phosphanes and the hexacoordinate phosphane derivatives are quite different from those of the hexacoordinate phosphoranes in that the P−N distances are less than 2 Å[3] in the latter, which have octahedral geometries. This can be explained in terms of the generally high electronegativities of the ligands surrounding the phosphorus atoms in phosphoranes. Intramolecular N→P donor-acceptor interactions induce an increase in the reactivity of the phosphorus derivatives. Thus, the pentacoordinate phosphonium salts are much more reactive than the corresponding phosphorus derivatives lacking the NMe_2 groups. Indeed, an unusual reactivity of a P−H bond due to extra coordination at the phosphorus atom has been observed for the first time in the case of a hypercoordinate phosphane.

Keywords: Calixarenes / Uranyl / Caesium / Supramolecular chemistry

The reaction of $[UO_2Cl_4]^{2-}$ with *t*Bu-calix[6]arene (H_6L) is made possible by the presence of Cs^+ leading to the formation of a trimetallic inclusion complex. An alkali metal can definitely influence the coordination chemistry of *t*Bu-calix[6]arene.

Calixarenes as ligands is a fast developing field of supramolecular chemistry. However, it almost exclusively concerns calix[4]arene derivatives.[1] Amongst all metal complexes currently studied, those of the lanthanides[2] and actinides[3] are receiving particular attention due to environmental needs.[4] Although calix[6]arene derivatives were soon recognised as matching the coordination geometry required by the uranyl ion,[5] it has not been possible to isolate the simple inclusion complex with UO_2^{2+}. Structural information on how this family of ligands binds to metals are still scarce[6][3d]. Recently, Gibson suggested that "alkali-metal ions could influence the coordination and reactivity of calix[4]arene at transition metal centres".[7] In order to test this idea for larger calixarenes, we decided to study the possible effect of an alkali metal on the reactivity of *t*Bu-calix[6]arene (H_6L) towards uranyl. We report here the dramatic influence of Cs^+ on the reaction of H_6L with $[UO_2Cl_4]^{2-}$ and the synthesis, X-ray determination, and NMR study of the new caesium inclusion complex $[Cs][HNC_5H_5]_3[UO_2Cl_2]_2[H_2L]\cdot 7\ NC_5H_5$ (**1**).

When $[HNC_5H_5]_2[UO_2Cl_4]$[8] was treated with H_6L in pyridine, no reaction was observed. Even after refluxing the two components for 12 hours, the ^1H NMR of the calixarene and the visible spectrum of the uranyl cation were identical to the ones of the starting materials.

Scheme 1

$$2\ [HNC_5H_5]_2[UO_2Cl_4] + H_6L \xrightarrow[\text{pyridine}]{} \text{no reaction}$$

However, when one equivalent of caesium triflate was added to the mixture, the pale yellow colour immediately turned to a deep red.

Scheme 2

$$2\ [HNC_5H_5]_2[UO_2Cl_4] + H_6L \xrightarrow[\text{pyridine}]{Cs^+} [Cs][HNC_5H_5]_3[UO_2Cl_2]_2[H_2L] + 4\ [HNC_5H_5]Cl$$

The solution was allowed to stand and after two days red crystals of **1** suitable for X-ray crystallography (59% yield) were isolated as the sole reaction product. The structure was solved and revealed an heterotrimetallic complex of *t*Bu-calix[6]arene where two uranyl cations and a caesium atom were coordinated to the macrocycle (Figure 1).

Of the ten pyridine molecules found in the lattice, six were found to form three pyridinium dimers (N−H···N bond distance of 2.66 Å), implying that the macrocycle was deprotonated four times to result in the observed stoichiometry for **1**: $[Cs][HNC_5H_5]_3[UO_2Cl_2]_2[H_2L]\cdot 7\ NC_5H_5$.

The two uranyl cations are bound in an external fashion to the macrocycle through the deprotonated oxygen of the phenolate groups. Mean U=O, U−O, and U−Cl bond distances are 1.789(7), 2.214(8), and 2.711(4) Å, respectively, and are comparable with those of the literature.[3b][3c][3d][3e][3f][5c][9] The geometry around uranyl is four-coordinate equatorial with the two phenolate oxygen atoms and the two chloride atoms in *cis* arrangements. This arrangement is unprecedented for an anionic moiety of uranyl ($[UO_2X_2Y_2]^{2-}$) and the only related example found in the literature is the *cis* arrangement of two phosphane oxides and two chlorides in $[UO_2Cl_2(OPPh_3)_2]$.[9]

The caesium cation is bound to the two protonated oxygens of the calixarene that do not form bonds with uranium [O(6) and O(3)]. The mean Cs−O distance is 3.045(8) Å, in agreement with the one found for coordinate bonds in crown ether (3.0−3.3 Å)[10] or in complexes where coordination of an alcohol group to caesium was observed [3.006(6)−3.323(7) Å][11]. More unusual are the short contacts of 3.390(9) and 3.454(8) Å found between the caesium and the two uranyl oxygen atoms [O(1B) and O(2B)]. Although they can not formally be considered as bonds, those interactions probably help to stabilise the caesium inside its host. The alkali cation is also bound in nearly a η^6-fashion to the faces of the two phenolic rings. Cs−C distances range between 3.41(1) and 3.87(1) Å, and the three shortest distances correspond to the phenol- and methylene-substituted

[a] Selected bond lengths [Å] and angles [°] with estimated standard deviations in parentheses: U(1)−O(1A) 1.788(7), U(1)−O(1B) 1.788(7), U(1)−O(4) 2.235(8), U(1)−O(5) 2.196(8), U(1)−Cl(1) 2.723(4), U(1)−Cl(2) 2.708(4), U(2)−O(2A) 1.791(7), U(2)−O(2B) 1.792(7), U(2)−O(1) 2.228(7), U(2)−O(2) 2.197(7), U(2)−Cl(3) 2.694(3), U(2)−Cl(4) 2.718(4), Cs−O(1B) 3.389(8), Cs−O(2B) 3.454(8), Cs−O(3) 3.021(7), Cs−O(6) 3.067(8), O(4)−U(1)−O(5) 87.7(3), O(4)−U(1)−Cl(2) 90.0(2), O(5)−U(1)−Cl(1) 92.5(2), Cl(1)−U(1)−Cl(2) 89.9(1), O(1)−U(2)−O(2) 86.2(3), O(1)−U(2)−Cl(4) 87.9(2), O(2)−U(2)−Cl(3) 95.2(2), Cl(3)−U(2)−Cl(4) 90.9(1), O(3)−Cs−O(6) 133.5(2).

positions. The mean Cs−centroid distance is 3.35(1) Å. The shortest Cs−C separations are shorter than those found for caesium−methyl (3.53 Å),[12] and for caesium complexes of *t*Bu-calix[4]arene and bis(homooxa)-*t*Bu-calix[4]arene [3.53(1) to 4.17(1) Å, with a Cs−centroid distance of 3.57(1) Å].[13] They are more in the range of those found for selective caesium extractants like 1,3-calix[4]arene crowns [3.273(5)−3.770(5) Å] although in the latter, the alkali cation is only bound in η^2 or η^3 fashion to the phenolic faces.[14] The short Cs−O and Cs−C distances in **1** imply that caesium is strongly bound within the macrocycle, which, in the case of a ligand as flexible as *t*Bu-calix[6]arene,[15] seems to indicate that the alkali cation guest is not held within the cavity by the suitable size of the host as noticed for the calix[4]arene analogues,[13a][16] but participates in holding together the ligand conformation. The crystal structure of **1** is not only a rare example of a metal complex of an underivatized calix[6]arene,[6a][6c][6e][3d] but is also the first crystallographic example of cationic π-bonding to the inner faces of the phenolic rings of anything other

than a calix[4]arene derivative.

The organic macrocycle adopts a pinched-cone conformation reminiscent of that found in the other complex of H_6L and uranyl present in the literature,[3d] but is more distorted. In compound **1**, the angle formed by the two planes of the phenolic rings bound to caesium by their oxygen atoms [O(3) and O(6)] is 18(1)°, and the one formed by the two phenolic rings bound in a polyhapto fashion to caesium, and therefore brought towards each other, is 32(2)°, inverted with respect to the cone conformation (relative to 62° and 11° for equivalent positions in reference 3d).

Synthesis of the analytically pure compound on a preparative scale was achieved by treating $[Cs]_2[UO_2Cl_4]$[8] with H_6L in pyridine.

^{1}H- and ^{133}Cs-NMR spectroscopy was employed to obtain information about the role of caesium in the formation of the complex. One equivalent of caesium triflate was added to a solution of H_6L in pyridine and a significant shift (−23 ppm) for the caesium signal was observed, as well as the enlargement and shift of the signals of the acidic protons [+0.57 ppm, Full Width at Half Maximum (FWHM) +53 Hz] and methylenic protons (−0.02 ppm, FWHM +7 Hz), demonstrating the modification of the geometry of the calixarene and the formation of a complex with the alkali metal. Although from these NMR data, it is not possible to draw conclusions about the resulting shape of the macrocycle, or the kind of bonding involved, it is possible to imagine that the formation of such Cs−*t*Bu-calix[6]arene species could then enable the reaction with uranyl.

Scheme 3

$$2\,[UO_2Cl_4]^{2-} + [H_6L] + Cs^+ \rightarrow '[Cs{-}H_6L]' \rightarrow [Cs][UO_2Cl_2]_2[H_2L]^{3-}$$

Unlike the reaction with calix[4]arene complexes of Nb and Ta where metallation of the ligand has been used to bind alkali metal cations in the cavity,[17] the reaction with the alkali metal occurs prior to reaction with uranium in the formation of **1**.

Contrary to observations for the free ligand, the ^{1}H-NMR spectrum of **1** is characteristic of the restricted motion of the macrocycle, with methylene, *tert*-butyl, and phenyl protons split into several resonances. ^{133}Cs-NMR spectrum of **1** exhibits three peaks, none of them corresponding to the signal of free Cs^+ as obtained for caesium triflate, thus demonstrating that encapsulation of the alkali metal is retained in solution. The three peaks proved to be in slow exchange, but no coalescence could be obtained by temperature change (276 to 346 K) or by addition of excess caesium triflate (up to one equivalent). We assume that this set of peaks could be due to different positions of the caesium atom inside its host, as observed for the calix[4]arene derivatives.[13b]

In conclusion, we have found that the reaction of *t*Bu-calix[6]arene with $UO_2Cl_4^{2-}$ could be activated by the presence of caesium. We have characterised a heterotrimetallic complex displaying external coordination of uranyl and inclusion of caesium. The evidence of an initial interaction between the calixarene and Cs^+ demonstrates the influence of the alkali metal on the coordination chemistry reaction. Studies are currently in progress to determine the exact nature of the interaction of caesium and *t*Bu-calix[6]arene in pyridine, and to extend this research to other calixarenes and to other alkali metals.

Experimental Section

General: All experiments were carried out with exclusion of air and moisture in a glove box. ^{1}H- and ^{133}Cs-NMR spectra were recorded in [D$_5$]pyridine on a Bruker DRX-500 spectrometer at T = 297 K. All NMR tubes were charged to obtain a Cs^+ concentration of approximately 2 mmol/l. The 65.6 MHz ^{133}Cs-NMR spectra were calibrated externally relatively to a 0.5 mol/l D_2O solution of CsBr. − Elemental analyses were performed at Service de Microanalyse, CNRS, 91191 Gif-sur-Yvette.

[Cs][HNC$_5$H$_5$]$_3$[UO$_2$Cl$_2$]$_2$[H$_2$L] (**1**): $[Cs]_2[UO_2Cl_4]$ (CAS no. 17631-98-0) (0.28 g, $4{\cdot}10^{-4}$ mol) was treated with H_6L (0.20 g, $2{\cdot}10^{-4}$ mol) in pyridine (30 ml) at 323 K for 12 hours. After filtration of a white powder of CsCl, the solution was concentrated and compound **1** was obtained as a red powder. After recrystallisation in pyridine, the powder was dried under vacuum and gave satisfactory elemental analysis for $[Cs][HNC_5H_5]_3[UO_2Cl_2]_2[H_2L]$ (0.27 g, $1.3{\cdot}10^{-4}$ mol, 65%). − ^{1}H NMR δ = 1.34 (m, 18 H, *t*Bu), 1.21 (m, 36 H, *t*Bu), 3.39, 3.82, 4.00, 4.11, 5.31, 6.16, 6.54 (br s, 12 H, ArCH$_2$Ar), 6.86, 7.24, 7.30, 7.41, 7.78 (12 H, ArH), 9.86, 12.75 (5 H, H$^+$): − ^{133}Cs NMR δ = 23 (br s, 20 Cs), −78(br s, 10 Cs), −128 (br s, 24 Cs). − $C_{81}H_{98}Cl_4CsN_3O_{10}U_2$ (2023): calcd. C 48.05, H 4.84, N 2.08; found C 47.98, H 5.09, 2.41.

Reaction of H_6L with Caesium Triflate: An NMR tube was charged with H_6L (10 mg, $1{\cdot}10^{-2}$ mmol) in [D$_5$]pyridine (0.4 ml) and caesium triflate (3 mg, $1{\cdot}10^{-2}$ mmol) was added. − ^{1}H NMR δ = 1.21 (s, 54 H, *t*Bu), 4.10 (s, 12 H, ArCH$_2$Ar, FWHM = 15 Hz), 7.31 (s, 12 H, ArH), 11.37 (br s, 6 H, H$^+$, FWHM = 97 Hz), − ^{133}Cs NMR δ = −5(br).

Reference ^{1}H NMR Spectrum of H_6L: δ = 1.21 (s, 54 H, *t*Bu), 4.12 (s, 12 H, ArCH$_2$Ar, FWHM = 8 Hz), 7.29 (s, 12 H, ArH), 10.80 (br s, 6 H, H$^+$, FWHM = 44 Hz).

Reference ^{133}Cs NMR spectrum of Caesium Triflate: δ = 18(s).

X-ray Crystallographic Study: Crystal data of **1**; $C_{116}H_{133}Cl_4CsN_{10}O_{10}U_2$ (2578.09), 0.75 × 0.55 × 0.40 mm^3, triclinic, $P\bar{1}$, Z = 2, a = 15.391(4), b = 17.059(7), c = 24.356(4) Å, α = 83.86(3), β = 88.60(2), γ = 67.60(4)°, V = 5877(3) Å^3, ρ_{calcd} = 1.457g.cm^{-3}, F(000) = 2572, $2\theta_{max}$ = 24°, μ_{Mo} = 3.206 cm^{-1}, Enraf-Nonius Mach 3 diffractometer (ω/2θ scans, T = 293 K, Mo-*Kα* radiation λ = 0.71069 Å). The structure was solved by the heavy-atom method and refined on F^2 using SHELXTL with all atoms considered as anisotropic except solvated pyridine molecules which were constrained to regular hexagons. One of them was found to be disordered over two positions which could be refined to final occupations 0.89(2) and 0.13(2). Absorption was corrected using ψ-scans (min. transmission = 57.7%, max. transmission = 99.9%). 15765 measured reflections, 11403 of which were considered as observed ($I > 2\sigma I$), 823 refined parameters, $R1$ = 0.0608 , $wR2$ = 0.1558 (all data), residual electron density 0.82 eÅ^{-3}. Crystallographic data (excluding structure factors) have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication no. CCDC-101252. Copies of the data can be obtained free of charge on application to CCDC, 12 Union

Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336-033; E-mail: deposit@ccdc.cam.as.uk].

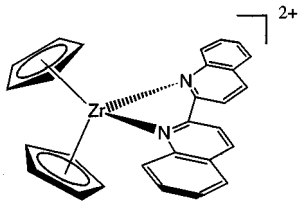
The lowest energy electronic transition of [(cyclopentadienyl)$_2$Zr^{IV}(2,2′-biquinoline)]$^{2+}$, which appears in absorption at λ_{max} = 360 nm and in emission at λ_{max} = 518 nm, is of the Cp$^-$ → biq ligand-to-ligand charge-transfer-type.

Coordination compounds which contain reducing and oxidizing ligands are frequently characterized by long-wavelength ligand-to-ligand charge-transfer (LLCT) absorptions in their electronic spectra[1][2]. Such optical electron transfer between two ligands is a special type of light-induced charge separation which plays an important role in areas such as artificial photosynthesis[3] and nonlinear optics[4]. In the case of LLCT a metal mediates the electronic interaction between donor and acceptor. Appropriate acceptor ligands include 1,2-diimines (e.g. 2,2′-bipyridyl), while anions such as thiolates can be donor ligands. As yet little attention has been paid to organometallic compounds, although recently photoreactive LLCT states have been identified in complexes with alkyl anions as donor ligands[5][6][7][8]. However, in general, the large potential of organometallic compounds for optical LLCT has not yet been utilized. The present report includes an investigation of novel features such as $C_5H_5^-$ ligands as donors and an early transition metal as a template and mediator. Moreover, we report on emission from a LLCT state of an organometallic compound, which we believe to be a new observation. Finally, some intriguing analogies between our target compound and the photosynthetic reaction center will be mentioned.

The desired complex [Cp$_2$Zr(biq)]$^{2+}$ (Cp$^-$ = $C_5H_5^-$ and biq = 2,2′-biquinoline) was designed taking into account the following considerations. Cp$^-$ is a suitable donor ligand as indicated by the appearance of long-wavelength LMCT absorptions in the spectra of complexes such as Cp_2Fe^+[2][9][10][11] or $CpReO_3$[2][12]. The metallocene moiety Cp_2M^{IV} (M = Ti, Zr, Hf) provides an obliquely oriented pair of Cp$^-$ ligands and a d^0 metal center, which can provide no interference from low-energy LF and MLCT states. Moreover Zr^{IV}, in contrast to Ti^{IV}, is barely oxidizing[2][13]. Accordingly, low-energy Cp$^-$ → Zr^{IV} LMCT transitions do not occur. 1,2-Diimines such as 2,2′-bipyridyl (bipy) or 9,10-phenanthroline (*o*-phen) are well-known electron acceptors in CT transitions[9][10][14][15]. Complexes of the type [Cp$_2$Ti^{IV}(diimine)]$^{2+}$, with bipy and *o*-phen, have been prepared previously[16]. Unfortunately, the corresponding Zr^{IV} complexes are not stable, and undergo a dissociation owing to the tendency of Cp_2ZrL_2 complexes to expand their coordination sphere to Cp_2ZrL_3[17][18][19]. However, if bulkier ligands are introduced Cp_2ZrL_2 complexes become stable because access to a further ligand is blocked[18]. As a bidentate diimine the ligand biq meets this requirement, and the complex [Cp$_2$Zr(biq)]$^{2+}$ is prepared by the reaction of $Cp_2Zr(THF)(CF_3SO_3)_2$[19] with biq. Mixing of the colourless solutions leads to the precipitation of a bright yellow crystalline material.



The electronic spectrum of [Cp$_2$Zr(biq)]$^{2+}$ (Figure 1) shows absorptions at λ_{max} = 360 (ε/dm^3 mol^{-1} cm^{-1} = 7700), 341 (8800), 329 (7400), 315 (5300), 304 (sh, 4300), 262 nm (20400). The bands at 341, 329, 315, 304, and 262 nm appear at almost the same wavelength as those of free biq and are thus attributed to intraligand (IL) transitions. However, while Cp_2Zr^{IV} compounds such as Cp_2ZrCl_2 and related complexes are colourless, [Cp$_2$Zr(biq)]$^{2+}$ is bright yellow owing to a new absorption at λ_{max} = 360 nm which extends into the visible spectral region. The complex is solvatochromic, and the longest wavelength absorption undergoes a blue shift with increasing solvent polarity (Figure 2[20]). This band is assigned to an LLCT transition[1][2] from the $(Cp^-)_2$ donor ligands to the biq acceptor, and the intensity of the band is consistent with this assignment. Complexes of the type $Cp_2M^{IV}L_2$ with M = Ti, Zr, and Hf including [Cp$_2$Ti(diimine)]$^{2+}$ are pseudotetrahedral[16] (C_{2v}). The highest occupied orbitals of such Cp_2ML_2 compounds

Figure 1. Electronic absorption (a, – – – – –) and emission (e, ·····) spectra of $2.18 \cdot 10^{-5}$ M $[Cp_2Zr(biq)]^{2+}$ at room temp. under argon in THF in a 1-cm cell; emission: $\lambda_{exc} = 380$ nm, intensity in arbitrary units

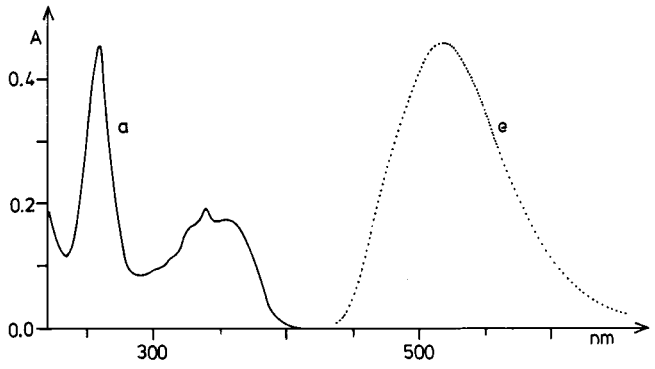

Figure 2. Energies of the LLCT absorption ($\tilde{\nu}_{max}$) of $[Cp_2Zr(biq)]^{2+}$ plotted against solvent parameters E^*_{MLCT}[20]

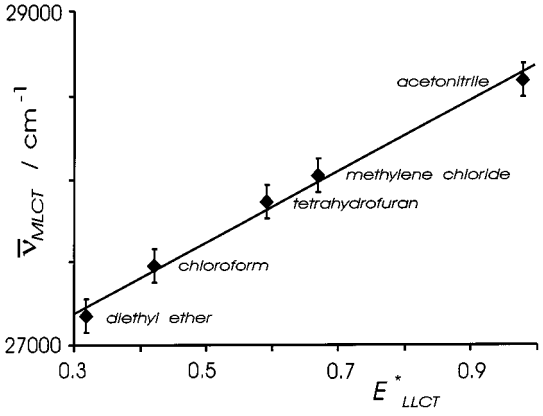

are derived from the Cp^- ligands and are of the b_2, b_1, a_2, and a_1 symmetry in close energetic proximity[21]. The LUMO is a π^* orbital (b_1) at the diimine ligand. While the $b_2 \rightarrow b_1$ transition is forbidden the other $Cp^- \rightarrow$ biq LLCT transitions ($b_1 \rightarrow b_1$, $a_2 \rightarrow b_1$ and $a_1 \rightarrow b_1$) are allowed[22].

The cation $[Cp_2Zr(biq)]^{2+}$ shows a bright yellow/green luminescence at $\lambda_{max} = 518$ nm in solution (Figure 1) and 524 nm in the solid state at room temp. The quantum yield of the emission is $\phi = 0.01$ (calibrated by comparison with rhodamine B)[23]. This luminescence is not of the intraligand (biq) type, and this is indicated by the absence of any vibrational structure at 77 K, since at low temperatures structured bands are typical for intraligand emissions[24][25]. The excitation spectrum matches the absorption spectrum and it is concluded that the luminescence originates from the lowest energy LLCT excited state, which is most likely to be a triplet state, in agreement with the general behavior of diamagnetic complexes with metals of the second transition row.

In summary, the lowest energy transition of $[Cp_2Zr(biq)]^{2+}$ is of the LLCT type and involves an electron transfer from the $(Cp^-)_2$ moiety to biq (absorption) and back (emission). The complex shares some remarkable features with the photosynthetic reaction center, which is characterized by a pair of two bacteriochlorophyll molecules in close proximity but in an oblique orientation. In the primary photochemical step this "special pair" undergoes a light-induced electron transfer to an electron acceptor. A variety of models have been developed to mimic the initial charge separation in the reaction center. In $[Cp_2Zr(biq)]^{2+}$ the special pair corresponds to both $C_5H_5^-$ ligands, which are also planar π-electron systems in an oblique orientation. However, in both the natural system and artificial models[3] charge separation takes place by excited-state electron transfer, whilst in our organometallic model it occurs as an optical transition since the metal facilitates an electronic coupling of donor and acceptor.

Other aspects of our observations may be also of interest as metallocene dihalides are well known to exhibit antitumor activity[26][27]. Since extended planar ligands can intercalate in DNA[28] the luminescence of $[Cp_2Zr(biq)]^{2+}$ and related compounds may be utilized to monitor such interactions. In this context it should be also mentioned that a few reports on the luminescence of some other d^0 complexes[29][30][31][32][33] including metallocene derivatives[34][35][36] have appeared recently. In these cases the emission apparently originates from LMCT excited states.

Experimental Section

General: Absorption spectra: Hewlett Packard 8452A diode array spectrophotometer, spectrograde solvents. – Emission and excitation spectra: Hitachi 850 spectrofluorometer equipped with a Hamamatsu 928 photomultiplier for measurements up to 900 nm. – Luminescence spectra: Corrected for monochromator and photo-multiplier efficiency variations. Absolute emission quantum yields were determined by comparison of the integrated emission intensity with that of Rhodamine B under identical conditions such as exciting wavelength, optical density, and apparatus parameters.

Preparation of [$Cp_2Zr(biq)(CF_3SO_3)_2$]: All solvents were dried and saturated with argon. The starting chemicals were used as purchased without further purification. A solution of 1.28 g ($5 \cdot 10^{-3}$ mol) of $AgCF_3SO_3$ in 10 ml of THF was added to a solution of 0.73 g ($2.5 \cdot 10^{-3}$ mol) of Cp_2ZrCl_2 in 10 ml of THF. The combined solutions were stirred for 30 min. AgCl precipitated and was removed by filtration. A solution of 1.02 g ($4 \cdot 10^{-3}$ mol) of biq in 40 ml of THF was added to the filtrate under strirring. The solution immediately turned intensely yellow and yellow crystals started to deposit. After 1 h, the crude product was collected by filtration and washed with a little THF/ether, and dried under vacuum. The product was purified by repeated recrystallization from THF/ether, yield: 0.6 g (31%). – $C_{30}F_6H_{22}N_2O_6S_2Zr$ (775.86): calcd. C 46.44, H 2.86, N 3.61; found C 46.52, H 2.98, N 3.69.

Received September 3, 1998

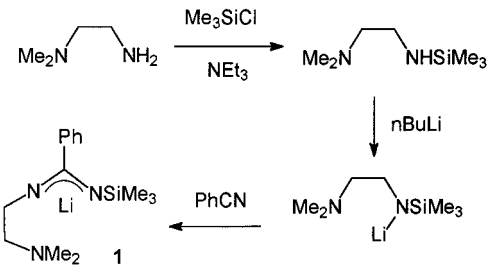
Keywords: Vanadium / Amidinate / Ethene Polymerization / Catalysis

A new type of amidinate ancillary ligand has been prepared, which incorporates a pendant tertiary amine functionality. The crystal structure of a vanadium(III) derivative, $[SiMe_3NC(Ph)NCH_2CH_2NMe_2]VCl_2(THF)$ (**1**), shows that the ligand can adopt a facial geometry, with an unusual distortion of the amidinate nitrogen bearing the pendant functionality. With $AlEt_2Cl$ cocatalyst the compound **1** produces a single-site catalytic system for the polymerization of ethene.

Amidinates $[RC(NR')_2]^-$ are extensively being used as ligands for transition metals, lanthanides as well as main group elements, in which they act most frequently as bidentate 4-electron monoanionic ligands.[1] Various routes are available to prepare amidinates with a range of substitution patterns, and steric and electronic features of these ligands are readily varied.[2] For Group 4 transition metals, amidinates have been used as ancillary ligands in olefin polymerization catalysts.[3] The applicability of these ligands could be enhanced considerably with the ability to introduce additional functionalities as pendant groups on the amidinate ligand framework. In this contribution we describe the synthesis of such a functionalized amidinate, $[SiMe_3NC(Ph)NCH_2CH_2NMe_2]^-$, which has a pendant (dimethylamino)ethyl group attached to one of the amidinate nitrogens. A *facial* coordination mode of this ligand is illustrated by the structure of a vanadium(III) derivative, $[SiMe_3NC(Ph)NCH_2CH_2NMe_2]VCl_2(THF)$ (**1**), indicating that the new ligand may be compared with other, well-known face-capping monoanionic ligands like tris(pyrazoyl)borate and cyclopentadienyl. Compound **1** is active in the polymerization of ethene when activated by $AlEt_2Cl$ cocatalyst.

The synthesis of the (dimethylamino)ethyl-functionalized benzamidinate $[SiMe_3NC(Ph)NCH_2CH_2NMe_2]^-$ is based on the well-known reaction of lithium trimethylsilylamides with benzonitrile to give lithium *N*-(trimethylsilyl)benzamidinates.[2a] A suitable silylamide, $Me_2NCH_2CH_2NHSiMe_3$ was prepared by reaction of $Me_2NCH_2CH_2NH_2$ with Me_3SiCl and NEt_3 as base (in a preparation similar to that of $Me_2NCH_2CH_2N(Me)SiMe_3$[4a]), and isolated by vacuum distillation. Lithiation with *n*BuLi yields the lithium amide $Me_2NCH_2CH_2N(Li)SiMe_3$ which was obtained as a crystalline solid.[4b] This lithium amide readily reacts with benzonitrile in THF solvent to give the functionalized lithium benzamidinate $[SiMe_3NC(Ph)NCH_2CH_2NMe_2]Li$ (Scheme 1). The route appears to be quite versatile, and this methodology should be applicable to a range of *N*-monofunctionalized, *N'*-trimethylsilyl benzamidinates.

Scheme 1



Reaction of one equivalent of $[SiMe_3NC(Ph)NCH_2CH_2NMe_2]Li$ with $VCl_3(THF)_3$ in THF produces the highly air sensitive, paramagnetic (by ^1H NMR), green V(III) mono(amidinate) dichloride complex[5] $[SiMe_3NC(Ph)NCH_2CH_2NMe_2]VCl_2(THF)$ (**1**), which was obtained as crystals suitable for X-ray diffraction by diffusion of pentane vapor into a THF solution of the compound. The structure of **1** (Figure 1) shows a distorted octahedral coordination of the metal, with the functionalized amidinate ligand adopting a facial geometry. The amidinate nitrogen bearing the (dimethylamino)ethyl functionality, N(2), is distinctly non-planar, the sum of the angles around N(2) being 336.4° as compared to 359.9° for N(1). This is unusual for metal amidinates, and may suggest that the ligand has partial amido-imine character. Indeed, the V−N(2) distance is 0.1 Å shorter than V−N(1), but the C(1)−N distances in the amidinate backbone differ only slightly (if significantly), with C(1)−N(1) being 0.017 Å

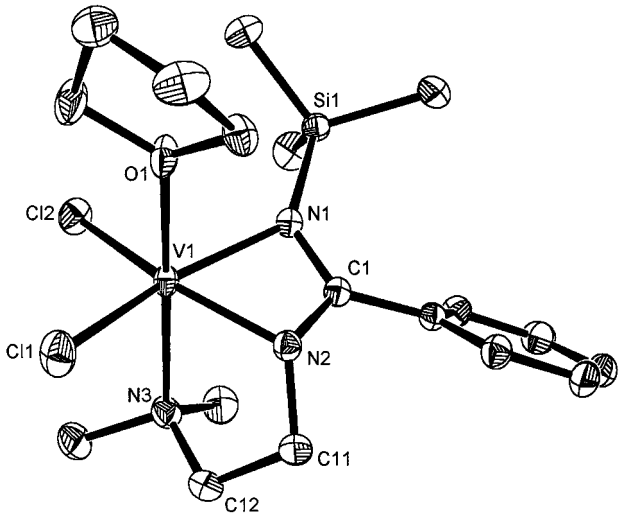
Figure 1. ORTEP diagram of the molecular structure of **1**. Hydrogen atoms are omitted for clarity. The unlabeled atoms are carbon[a]



[a] Selected interatomic distances [Å] and angles [°]: V−Cl(1) = 2.3477(5), V−Cl(2) = 2.3153(4), V−O = 2.103(1), V−N(1) = 2.124(1), V−N(2) = 2.016(1), V−N(3) = 2.230(1), C(1)−N(1) = 1.322(2), C(1)−N(2) = 1.339(2), Cl(1)−V−Cl(2) = 106.47(2), O−V−N(3) = 172.50(5), N(1)−V−N(2) = 64.10(4), N(1)−V−N(3) = 100.62(5), N(2)−V−N(3) = 74.91(5), N(1)−V−Cl(1) = 156.44(3), N(2)−V−Cl(2) = 151.99(4), V−N(2)−C(1) = 93.77(8), V−N(2)−C(11) = 121.41(9), C(11)−N(2)−C(1) = 121.21(9), N(1)−C(1)−N(2) = 111.4(1).

(8σ) shorter than C(1)−N(2). A highly asymmetrically bound amidinate was also observed in $[MeC(N\mathit{i}Pr)_2]_2Ge$ (with a relatively small nonplanarity of one of the amidinate nitrogen atoms), but this only showed similarly small differences in the C−N distances of the amidinate backbone.[6]

The geometry around the metal center in **1** is significantly more distorted than in other octahedral vanadium(III) complexes with monoanionic tridentate ligands such as Tp* VCl_2L (Tp* = (3,5-dimethyl-1-pyrazoyl)borate; L = DMF,[7] 4-methylpyridine[8]). In the latter complexes, the N−V−N angles and V−N distances involving the tridentate ligand are all rather similar (around 86° and 2.12 Å respectively), whereas in **1** both features vary over a considerable range [from 64.10(4)° to 100.62(5)° and from 2.016(1) Å to 2.230(1) Å respectively].

When activated with $AlEt_2Cl$ (20 mol per mol V), **1** catalyzes the polymerization of ethene in toluene. Table 1 shows activity and GPC data for 30 minutes ethene polymerization runs at three different temperatures (30, 50, and 80°C). The catalyst is most active at 30°C, with a productivity of 447 kg mol^{-1} h^{-1} bar^{-1}, and the product molecular weight distribution is characteristic for the presence of a single active site. At 50°C the overall productivity drops substantially, indicating a limited thermal stability of the catalyst. At 80°C catalyst decomposition is rapid, and the molecular weight distribution of the polyethene formed is bimodal. For comparison, polymerization runs with a vanadium catalyst with an unfunctionalized amidinate ligand, $\{[PhC(NSiMe_3)_2]VCl_2(THF)\}_2$ (**2**), are given in Table 1 as well. At 30°C this system has a substantially lower activity than **1**/$AlEt_2Cl$, and forms polyethene with a significantly higher molecular weight. The catalyst activity is higher at 50°C but this is accompanied by a broadening of the polymer molecular weight distribution. Again, this system suffers from catalyst degradation at 80°C accompanied by formation of a bimodal distribution of the PE product. Thus the introduction of a pendant Lewis-base functionality on the benzamidinate ligand significantly increases the polymerization activity of the homogeneous V^{III} amidinate catalyst system at temperatures close to ambient, but does not improve the thermal stability of the catalytic species.

In conclusion, we have developed a convenient route to a new amidinate ligand with a tethered dialkylamine functionality. A vanadium(III) complex with this ligand was prepared and structurally characterized, revealing the possibility of this ligand to adopt a facial coordination mode. As such, this ligand is complementary to the familiar, more symmetrical facial monoanionic 6-electron tridentate ligands such as tris(pyrazoyl)borate and cyclopentadienyl. We are presently pursuing the scope of this synthesis method for the attachment of other functionalities to the benzamidinate framework and the use of these ligands with a variety of transition metals.

This investigation was carried out in connection with *NIOK*, the *Netherlands Institute for Catalysis Research*, and supported by the *Department of Economic Affairs of the Netherlands.*

Experimental Section

General: All experiments were performed under nitrogen atmosphere using standard Schlenk and glove-box techniques unless mentioned otherwise. Deuterated solvents (Aldrich) were dried over Na/K alloy and vacuum transferred before use. Other solvents were distilled from Na/K alloy or Na (toluene) before use. For the polymerization experiments toluene (Aldrich, 99.8%) was percolated over molecular sieves (3 Å) before use, ethene (AGA polymer

[a] Toluene solvent, 6 bar ethene, 10 μmol V, V:Al = 1:20, 30 min run time. − [b] Bimodal distribution.

grade) was passed over a supported copper scavenger (BASF R 3-11) and molecular sieves (3 Å) before being passed to the reactor. − NMR spectra were run on Varian Gemini 200 and VXR 300 spectrometers. − IR spectra were recorded from Nujol mulls between KBr disks on a Mattson-4020 Galaxy FT-IR spectrophotometer. − GPC analyses were performed on solutions of the polymers in distilled 1,2,4-trichlorobenzene on a PL-GPC210 instrument of Polymer Laboratories. − Elemental analyses were carried out at the Micro-Analytical Department of the University of Groningen.

Preparation of (N,N-dimethyl-N′-trimethylsilyl)ethylene Diamine: To a solution of (*N,N*-dimethyl)ethylenediamine (35.4 g, 0.4 mol) and an excess of triethylamine (1.28 mol) in 200 mL of 1,4-dioxane, trimethylsilylchloride (66.6 ml, 0.44 mol) was added dropwise in 20 minutes. A white precipitate (triethylamine hydrochloride) formed, and the mixture was stirred for 16 h. The mixture was filtered and the residual salts extracted with 3 × 50 ml of diethyl ether. The combined filtrates were concentrated under reduced pressure, and pentane was added to precipitate any remaining salts. The mixture was filtered, the filtrate concentrated again and distilled under reduced pressure. The fraction boiling at 73.5−74.0°C (45 mmHg) consisted of the title compound (36.06 g, 0.22 mol, 50%). − ^{1}H NMR ([D$_6$]benzene): δ = 0.00 [s, 9 H, Si(C*H*$_3$)$_3$], 0.98 (s, 1 H, N*H*), 2.17 (s, 6 H, N(C*H*$_3$)$_2$), 2.24 (t, $^3J_{HH}$ = 6.5, 2 H, C*H*$_2$), 2.74 (t, $^3J_{HH}$ = 5.3, 2 H, C*H*$_2$).

Preparation of N′-lithio(N,N-dimethyl-N′-trimethylsilyl)ethylene Diamine: In 30 minutes, 30 mL of a 2.5 M *n*BuLi/hexane solution was added to a solution of 12.07 g (75 mmol) of (*N,N*-dimethyl-*N′*-trimethylsilyl)ethylene diamine in 200 ml of ether at −50°C. The mixture was allowed to warm to room temperature after which the volatiles were removed in vacuo. This yielded 11.0 g (66 mmol, 88%) of the title compound as a white solid. − ^{1}H NMR ([D$_8$]toluene/[D$_8$]THF): δ = 0.19 [s, 9 H, Si(C*H*$_3$)$_3$], 2.06 [s, 6 H, N(C*H*$_3$)$_2$], 2.38 (br, 2 H, C*H*$_2$), 3.23 (t, $^3J_{HH}$ = 5.3, 2 H, C*H*$_2$). − ^{13}C NMR ([D$_8$]toluene/[D$_8$]THF): δ = 62.51 (*C*NLi), 45.70, 45.21 (Me$_2$N*C*H$_2$, N*C*H$_3$), −2.15 (Si(*C*H$_3$)$_3$). − C$_7$H$_{19}$LiN$_2$Si (166.27): calcd. C 50.57, H 11.52, N 16.85; found C 50.22, H 11.37, N 15.94.

Preparation of [Me$_3$SiNC(Ph)NCH$_2$CH$_2$NMe$_2$]Li: To a solution of 0.98 g (5.88 mmol) of *N′*-lithio(*N,N*-dimethyl-*N′*-trimethylsilyl)ethylene diamine in 20 ml of THF, 0.60 ml of benzonitrile was added at −40°C. After 30 minutes the solvent was removed in vacuo and the residue stripped of remaining THF by repeatedly stirring with portions of pentane which were then pumped off. This yields the title compound as a pale yellow powder. Yield: 1.29 g (4.76 mmol, 81%). − ^{1}H NMR ([D$_6$]benzene): δ = 0.01 [s, 9 H, Si(C*H*$_3$)$_3$], 1.96 [s, 6 H, N(C*H*$_3$)$_2$], 2.10 (t, $^3J_{HH}$ = 5.3, 2 H, C*H*$_2$), 2.82 (t, $^3J_{HH}$ = 5.3, 2 H, C*H*$_2$), 7.2−7.1 (5 H, Ph). − ^{13}C NMR (C$_6$D$_6$): δ = 178.13 (N*C*N), 143.59 (Ph *ipso*-C), 128.31, 126.75, 126.43 (Ph *C*H), 58.38 (N*C*H$_2$), 41.70, 41.21 (Me$_2$N*C*H$_2$, N*C*H$_3$), −1.86 [Si(*C*H$_3$)$_3$].

Preparation of [SiMe$_3$NC(Ph)NCH$_2$CH$_2$NMe$_2$]VCl$_2$(THF) (**1**): For this synthesis the lithium salt of the ligand was conveniently generated in situ. To a solution of 1.43 g (8.58 mmol) of *N′*-lithio(*N,N*-dimethyl-*N′*-trimethylsilyl)ethylene diamine in 90 ml of THF 0.88 ml (8.62 mmol) of benzonitrile was added at −40°C. The mixture was allowed to warm to room temperature and stirred for 30 min. Subsequently, the mixture was cooled to −50°C and 3.32 g (8.88 mmol) of VCl$_3$(THF)$_3$ was added. The mixture was allowed to warm to room temperature and was stirred overnight, giving a dark brown solution. The solvent was removed in vacuo and the residue was extracted with 50 ml of diethyl ether. The solvent was removed from the extract in vacuo, and the residue dissolved in 5 mL of THF. Slow diffusion of pentane vapor into the solution resulted in formation of green crystals of **1** (2.78 g, 6.1 mmol, 58%). − ^{1}H NMR ([D$_6$]benzene): δ = 12.68 (Δν$_{1/2}$ = 150 Hz), 2.02 (Δν$_{1/2}$ = 150 Hz), −0.94 (Δν$_{1/2}$ = 250 Hz). − IR (Nujol, KBr): $\tilde{\nu}$ = 1503 (m), 1400 (m), 1240 (m), 1190 (w), 1086 (w), 1044 (m), 1022 (s), 943 (m), 912 (m), 866 (s), 839 (s), 797 (m), 756 (w), 721 (m), 691 (w), 517 (m), 496 (w), 478 (w) cm^{-1}. − C$_{18}$H$_{32}$Cl$_2$N$_3$OSiV (456.40): calcd. C 47.37, H 7.07, N 9.21; found C 47.49, H 7.10, N 9.24.

Crystal Structure Analysis of **1**: Enraf-Nonius CAD4-F diffractometer, Mo-K_α radiation (λ = 0.71073 Å) , T = 130 K; triclinic, $P\bar{1}$, a = 10.286(1), b = 10.461(1), c = 10.710(1) Å, α = 93.648(5), β = 100.075(5), γ = 98.924(5)°, V = 1114.1(2) Å^3, Z = 2, D_x = 1.361 g cm^{-3}, μ = 7.5 cm^{-1}. The structure was solved by Patterson methods and extended by direct methods applied to difference structure factors. A final refinement on F^2 converged at $wR(F^2)$ = 0.0766 for 4849 reflections with $F_o^2 \geq 0$ and $R(F)$ = 0.0274 for 4524 reflections with $F_o \geq 4.0\,\sigma(F_o)$ and 363 parameters. Crystallographic data (excluding structure factors) for the structure reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication no. CCDC-102816. Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [Fax: int. code + 44(1223)336-033; E-mail: deposit@ccdc.cam.at.uk].

Preparation of {[PhC(NSiMe$_3$)$_2$]VCl$_2$(THF)}$_2$ (**2**): To a suspension of VCl$_3$(THF)$_3$ (5.28 g, 14.1 mmol) in 80 mL of THF, cooled to −78°C, was added 4.80 g (14.0 mmol) of [PhC(NSiMe$_3$)$_2$]-Li(THF). The mixture was allowed to warm to room temperature while stirring, and the resulting brown-green solution was stirred for 4 h. Subsequently, the volatiles were removed in vacuo and the residue was stirred with 20 mL of pentane which was subsequently pumped off. Extraction with diethyl ether and cooling the extract to −30°C yielded a mixture of brown **2** and green [PhC(NSiMe$_3$)$_2$]VCl$_2$(THF)$_2$[5c] which was dissolved in 50 mL of toluene and warmed to 50°C for 10 min after which the solvent was pumped off. Recrystallization from diethyl ether at −30°C yielded 3.50 g (3.83 mmol, 55% yield on amidinate) of brown crystalline **2**. − ^{1}H NMR ([D$_6$]benzene): δ 11.24−7.36 (Δν$_{1/2}$ = 70−380 Hz, 5 H, Ph), 3.64 (Δν$_{1/2}$ = 90 Hz, 4 H, α-THF), 1.47 (Δν$_{1/2}$ = 120 Hz, 4 H, β-THF), −0.51(Δν$_{1/2}$ = 120 Hz, 18 H, SiMe$_3$). − IR (Nujol mull, KBr, cm^{-1}): $\tilde{\nu}$ = 1503(w), 1445(s), 1361(s), 1261(m), 1248(s), 1175(w), 1074(w), 1047(w), 1030(w), 1001(m), 988(s), 922(w), 841(s), 785(m), 764(m), 743(w), 704(m), 690(m), 530(m), 446(w). − C$_{17}$H$_{31}$Cl$_2$N$_2$OSi$_2$V (457.46): calcd. C 44.63, H 6.83, Cl 15.50, N 6.12, V 11.14; found C 44.34, H 6.61, Cl 15.78, N 6.58, V 10.91.

Ethene Polymerization Experiments: Polymerizations were carried out in a fully temperature and pressure controlled Medimex 1 L stainless steel autoclave. The autoclave was charged with 250 mL of toluene containing 0.10 mmol of AlEt$_2$Cl, brought to the desired temperature and saturated with ethene (6 bar). Subsequently, a solution of the catalyst precursor (10 μmol of vanadium) with 0.10 mmol of AlEt$_2$Cl in 5 mL of toluene (mixed 15 min prior to injection) was injected into the reactor. During the reaction the monomer was fed continuously to the reactor. After 30 min the reaction was quenched by injection of 10 mL of methanol. The contents of the reactor were stirred in 100 mL of acidified methanol for 1 h. The precipitated polymer was rinsed repeatedly with ethanol and dried at 60°C for 2 d.

Keywords: Cobalt complexes / Carbonyl complexes / Nitrosyl complexes

The bond lengths Co–C(CO), Co–N(NO) and angles L–Co–C(CO), L–Co–N(NO) in six tetrahedral complexes, determined by X-ray crystallography, were analysed and compared with the calculated compound $Co(CO)_2(NO)PH_3$. Distinct differences were found which allow a differentiation of the two similar ligands CO and NO. These differences are used to assign CO and NO ligands in cases where this has not been possible before including a structure in which the two independent molecules in the unit cell are diastereomers. The relationship seems to hold not only for tetrahedral compounds but also for other polyhedral coordination types.

Introduction

In an extensive review Tolman determined the steric demand, i.e. the cone angles, of a huge number of ligands exept the linear two-atom ligands CO and NO.[2] In many reports on X-ray structure analyses it was stated that the CO and NO groups could not be distinguished due to their similar size, for example, in complexes of the type $Co(CO)(NO)L_2$.[3][4] The structure of $Co(CO)_3(NO)$ was determined by gas-phase electron diffraction.[5] During our investigations on optically active carbonyl(nitrosyl)cobalt complexes[6][7] we realised that there might be a distinct difference between the ligands CO and NO, which could be used for future assignments.

Ab initio Molecular Structures

Covalent and nonbonding intramolecular interactions determine the shape of the molecular potential energy hypersurface. However, geometries as observed in the solid state result from the interplay of intra- and intermolecular interactions. For flexible organometallic species molecular structure and crystal packing influence each other in a complex manner.[8]

To improve the reliability of the experimentally observed molecular structure parameters and to exclude the possibility of molecular structures being determined by intermolecular interactions we optimised the gas phase structure of $Co(CO)_2(NO)PH_3$ employing the density functional code DMOL[9] We used "DNP" basis sets[10] with inner cores frozen, a "FINE" integration grid, and the Vosko, Wilk, Nusair parametrization[11] of the exchange correlation energy in the homogeneous electron gas. The local approximation was applied in SCF iterations and the final LDA density was used for nonlocal corrections of both energy and gradients using the functions proposed by Perdew and Wang[12] and Becke[13] for correlation and exchange, respectively. The geometries were fully optimised without any symmetry constraints employing a mode following Newton-Raphson technique and the BFGS updating scheme for the Hessian.[14]

To check the agreement the molecular structures were minimised starting with coordinates taken from two different crystal structure determinations, SAPFIY = $[Co(CO)_2(NO)]_2(C_{31}H_{35}N_2O_2P_3)$[15] and GEHCIF = $Co(CO)_2(NO)(C_{16}H_{13}N_2O_2P)$][16] and with P-ligands adjusted to PH_3. Finally, C and N atoms of the GEHCIF structure were exchanged (GEHCIF*) and the structure minimised starting from this "wrong" assignment. There is a good agreement between the results of these calculations with both the experimental gas phase structure[5] and the DFT minimised structure[17] of $Co(CO)_3(NO)$ (Table 1). However, as already noticed in ref.[17] the computed metal−C and metal−N distances are too short and the errors in the bond lengths are larger as for pure carbonyl compounds.[18]

All three minimisations converge to nearly identical geometries. The Co−C(CO) distance is 1.77 Å and the Co−N(NO) distance is 0.12 Å shorter, a difference that is larger than bond length errors of XRD structure determinations. This difference has been used before to assign carbonyl and nitrosyl groups in M(CO)(NO) fragments.[19][20] The most remarkable result, however, is the difference be-

Table 1. Experimental and ab initio gas-phase geometries (in Å and degrees) of carbonyl(nitrosyl)cobalt complexes

Parameter	SAPFIY[15]	GEHCIF[16]	GEHCIF*	$Co(CO)_3(NO)$, DFT[17]	$Co(CO)_3(NO)$, Exp.[5]
R_{Co-N}	1.651	1.649	1.650	1.665	1.671
R_{Co-C}	1.768	1.767	1.767	1.810	1.843
	1.767	1.768	1.770		
R_{N-O}	1.178	1.177	1.177	1.178	1.180
R_{C-O}	1.162	1.162	1.162	1.163	1.136
	1.162	1.162	1.162		
R_{Co-P}	2.172	2.175	2.170	–	–
$\alpha_{(N)-Co-(C)}$	118.3	117.2	114.8	114.7	107.7
	117.5	115.9	118.9		
$\alpha_{(C)-Co-(C)}$	103.5	103.7	103.5	103.9	111.2
$\alpha_{(C)-Co-(PH3)}$	101.7	102.9	102.1	–	–
	99.5	101.0	101.3		
$\alpha_{(N)-Co-(PH3)}$	113.6	114.1	114.0	–	–

tween the P−Co−C(CO) and the P−Co−N(NO) angles which has not been documented before. The latter is more than ten degrees larger than the former. The values found are 113.6−114.1° for the P−Co−N(NO) angles and 99.5−102.9° for the P−Co−C(CO) angles. Given these pronounced differences in structural parameters, it should be possible to unequivocally assign NO and CO groups in XRD structure determinations.

Crystal Structure Analyses

Crystal structure refinements were carried out for the six carbonyl(nitrosyl)cobalt complexes shown in Figure 1.

Details of the structure determinations and the crystal structure parameters were previously published.[6][7] However, for the present study all the structures were refined again in a consistent manner applying the SHELX-97 program package.[21] SHELXL refines against F^2 and all data were used in the full-matrix least-squares method. We also avoided any restraints, except for complex **5** for which DELU restraints were applied to remedy for the small reflex/parameter ratio. For compound **4** a new and larger data set was collected. Methyl H atoms were placed in idealised positions based on difference electron synthesis and torsion angles were refined with fixed isotropic displacement parameters of $1.5U_{eq}$ (parent C). All other H atoms were placed in idealised positions and refined with fixed isotropic displacement parameters of $1.2U_{eq}$ (parent C). All other atoms were refined anisotropically. The weighting scheme recommended by the program was used and refinement was continued until complete convergence (maximum shift/esd < 0.001) was achieved. It should be noted that the smaller isotropic temperature factor of nitrogen than that of carbon has been used previously for nitrosyl/carbonyl differentiation.[19][20]

For each complex two refinements were carried out. These differ only in the SFAC number used at the sites of the carbon atom of the CO group and the nitrogen atom of

the NO group. In Table 2 the resulting refinement parameters are listed.

Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication no. CCDC-101715. Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [Fax: int. code +44(1223)336−033; E-mail: deposit@ccdc.cam.ac.uk].

Carbonyl and nitrosyl groups were initially assigned according to the observed bond length differences. For all six complexes the correct configuration gives slightly smaller values for the *R* indices. However, the differences for the two possible configurations at the cobalt atom are by no means significant and would not allow a conclusive assignment of NO and CO groups. The configuration space is large enough to allow good agreement between observed and calculated structure factors even for the wrong configurations. As expected, neither are meaningful differences displayed in the Flack parameters. Whereas *R* indices are rather insensitive, wrong assignment is clearly documented in the displacement parameters (Table 3).

Both ligands CO and NO bind to the same metal centre and are expected to have very similar displacement parameters. For the correct cobalt configuration the parameters of the nitrogen atom of the NO group and of the carbon atom of the CO group are indeed of the same magnitude. After exchange of the SFAC numbers of these two atoms, the parameters at the C site become larger and those at the N site become smaller. U_{eq} parameters at the C site (calculated as a nitrogen atom) are up to three times larger than those at the position N (calculated as a carbon atom). This is illustrated for two representative examples in Figure 2 (only the central cobalt coordination sphere is shown).

In a preceding paper we were not able to determine the absolute configuration of the complexes **2** and **4**.[7] With the results presented here we are able to do so. The investigated crystal of complex **2** is assigned the configuration (S_{Co},S_C), while for complex **4** the configuration can unambiguously be determined as (R_{Co},S_C).

An even more spectacular result was obtained for complex **6**. In complex **6** two independent molecules are arranged in a pseudo-centrosymmetric way in the unit cell; only the methyl group at the asymmetric C atom disturbs the inversion symmetry. We first assumed the same configuration for both cobalt atoms. During the present study we realised that this was not correct. In fact the two molecules seem to have different configurations. In other words the unit cell contains the two diastereomeric complexes that differ only in the configuration at the cobalt centre. Molecule A has a (R_{Co},S_C) and molecule B (S_{Co},S_C) configuration. This explains the fact that we were not able to separate the diastereomers of **6**, whereas in all other cases at least enriched samples could be obtained by fractional crystallization.[7]

The bond distances Co−C(CO) and Co−N(NO) of complexes **1**−**6** are listed in Table 4. For the correct configuration the values are in line with expected values. They range from 1.703 to 1.749 Å for the Co−C(CO) distance and

Table 3. Anisotropic, equivalent, and main axis displacement parameters for C and N of the CO and NO groups

[a] See explanation in Table 2. – [b] See refs.[6][7] for labeling scheme.

from 1.643 to 1.702 Å for the Co−N(NO) distance. Only complex **5** does not fit into this picture. This might be because the number of measured reflections is too small relative to the number of parameters for a reliable refinement. After exchanging the carbon and nitrogen atom in **5** the distances remain rather constant for each site.

A conclusive assignment could also be based on the P−Co−N(NO) and P−Co−C(CO) angles as listed in Table

Figure 2. Platon plots of the core of the complexes **1** (left) and **4** (right). After exchanging the SFAC cards for the carbon and nitrogen atoms the anisotropic displacements parameters differ strongly (bottom)

[a] See explanation in Table 2.

5. As expected from the gas-phase structures for complex **1** P−Co−N(NO) angles are 22° and 14° larger than the corresponding P−Co−C(CO) angles. For the other complexes this difference is about 5 to 10°. These results indicate that the nitrosyl group has a larger steric demand than the carbonyl group.

To further back these conclusions a statistical analysis has been carried out on other carbonyl-nitrosyl complexes registered in the Cambridge Structural Database. We found 41 octahedral complexes and 18 trigonal-bipyramidal or tetrahedral complexes (in addition to the six cobalt complexes discussed above). The octahedral complexes contain 95 M(CO)(NO)P groups and the other complexes another 31 such groups. We did not try to assess the quality of the deposited structural data nor did we check on what basis the authors assigned the nitrosyl and carbonyl groups. This would be difficult and unreliable without the original data sets at hand. However, at a first glance the data confirm the results of the present study. We compared the values of P−M−C(CO) and P−M−N(NO) angles. In 41 cases the latter angle is more than 5° larger than the former. In another 42 cases the difference is between 1° and 5°, still with the P−M−N(NO) angle being the larger one. A small difference of less than ±1° is found for 19 pairs. Only in 24 cases the P−M−C(CO) angle is found to be more than 1° larger than the P−M−N(NO) angle.

Keywords: Crystal structures / Diastereomers / Half-sandwich complexes / Ruthenium

Condensation of (*R*)-2-aminobutanol with salicylaldehyde and 2-pyrrolecarbaldehyde gave the chiral chelate ligands HLL_1* and HLL_2*, respectively. The diastereomeric complexes (R_{Ru},R_C)- and (S_{Ru},R_C)-[(η⁶-arene)Ru(LL_1*)Cl], η⁶-arene = *p*-cymene (**1a/1b**), η⁶-arene = benzene (**2a/2b**), and (R_{Ru},R_C)- and (S_{Ru},R_C)-[(η⁶-arene)Ru(LL_2*)Cl], η⁶-arene = *p*-cymene (**3a/3b**), η⁶-arene = benzene (**4a/4b**), which only differ in the ruthenium configuration, were prepared by the reaction of $[(\eta^6\text{-arene})RuCl_2]_2$ with the anion of the corresponding ligand HLL*. X-ray analyses of **1a/1b** and **3a/3b** showed a structural peculiarity. The unit cell of these complexes contained diastereomers with the same configuration at the carbon atoms but opposite configuration at the metal centers in a 1:1 ratio. Weak intramolecular O−H···Cl hydrogen bridges were formed in all the complexes. ^{1}H-NMR studies demonstrated the configurational lability at the Ru center. The iodo complexes (R_{Ru},R_C)- and (S_{Ru},R_C)-[(η⁶-*p*-cymene)Ru(LL*)I], LL* = LL_1* (**5a/5b**) and LL* = LL_2* (**6a/6b**), were synthesized by halogen exchange.

Introduction

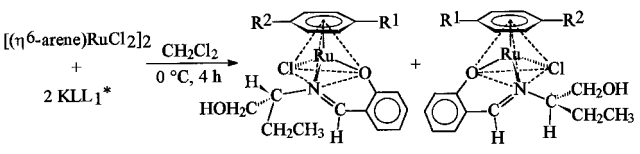
Optically active (η⁶-arene)ruthenium half-sandwich complexes have attracted interest in enantioselective catalysis[2][3][4][5], including Diels−Alder and olefin isomerization reactions.[6][7][8] There is a series of structural studies on optically active chiral-at-Ru complexes of the type [(η⁶-arene)Ru(LL*)L] and [(η⁶-arene)Ru(LL*)L]X, arene = *p*-cymene, mesitylene, benzene, LL* = anionic or neutral unsymmetrical ligand, L = halide or unidentate ligand, X = anion.[9][10][11][12][13][14][15] Resolution of (η⁶-arene)ruthenium half-sandwich complexes usually is carried out using optically active chelate ligands HLL* containing optically active amine components. Diastereomers are formed, which only differ in the configuration at the stereogenic Ru atom.

Diastereomers are different molecules. Therefore, ubiquitously, single crystals obtained from a mixture of diastereomers contain only one diastereomer. This, in effect, is the basis of diastereomer separation by crystallization. There are, however, examples, in which the presence of both diastereomers with opposite configuration at the metal center in one crystal is reported.[14][15][16] In the present paper we describe the syntheses and the X-ray structures of ruthenium half-sandwich complexes, two of which show this structural peculiarity.[17]

Results and Discussion

2-*N*-[(*R*)-1-Hydroxybut-2-yl)]salicylaldimine[18] (HLL_1*) was obtained by condensation of (*R*)-2-aminobutanol with salicylaldehyde. HLL_1* was deprotonated in dichloromethane with KO*t*Bu and $[(\eta^6\text{-arene})RuCl_2]_2$ (arene = *p*-cymene, benzene) was added. The formation of the diastereomeric complexes (R_{Ru},R_C)- and (S_{Ru},R_C)-[(η⁶-*p*-cymene)Ru(LL_1*)Cl] (**1a**, **b**) and [(η⁶-benzene)Ru(LL_1*)Cl] (**2a**, **b**) is depicted in Scheme 1.

Scheme 1



R^1 = *i*Pr, R^2 = Me (*R*Ru,*R*C) - **1a** (*S*Ru,*R*C) - **1b**

R^1 = H, R^2 = H (*R*Ru,*R*C) - **2a** (*S*Ru,*R*C) - **2b**

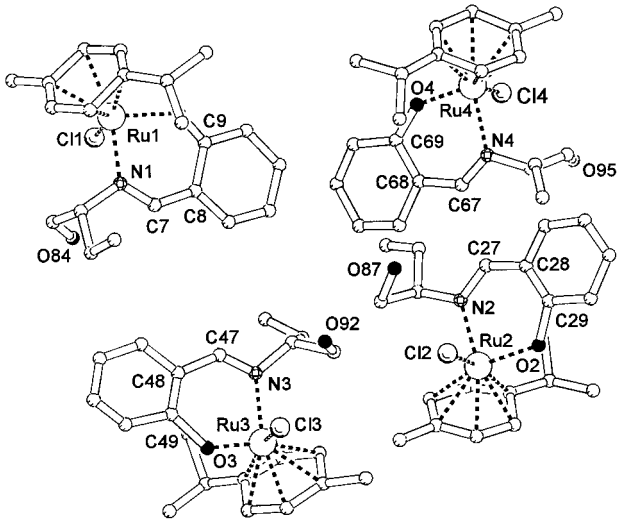
The ^{1}H-NMR spectrum of the *p*-cymene complex in $CDCl_3$ showed the presence of two diastereomers **1a** and **1b** in a ratio of 91:9. As there is no "β−phenyl effect"[13][19], no assignment of major/minor isomer to **1a/1b** can be made. The isomer ratio was obtained from the intensities of the singlets of the imine protons at δ = 7.75 and δ = 7.85. There are two doublets at δ = 1.15 and δ = 1.26 for the CH*Me*$_2$ groups of the *p*-cymene ligand in the major diastereomer and two doublets at δ = 1.08 and δ = 1.24 for the minor diastereomer indicating their diastereotopicity. Similarly, the benzene complex forms two diastereomers **2a** and **2b**. Integration of the singlets of the imine protons at δ = 7.77 and δ = 8.39 in $CDCl_3$ gave a ratio of 76:24.

Crystallization of the diastereomeric mixture **1a/1b** from dichloromethane/thf/pentane at 3°C gave triangular plates of X-ray analytical quality. To our surprise the structural study showed the presence of both isomers **1a** and **1b** in the asymmetric unit in a 1:1 ratio. The molecules **1a** and **1b** have the same configuration at the carbon atom but differ in the configuration at the metal center. There are four independent molecules in the unit cell, two with (R_{Ru}) and two with (S_{Ru}) configuration. Figure 1 displays the molecular structure of **1a/1b**.

Figure 1. Crystal structure of (R_{Ru},R_C/S_{Ru},R_C)-[(η^6-*p*-cymene)-Ru(LL$_1$*)Cl] **1a/1b**



In all four independent molecules the chiral Schiff base is bonded through the phenolic oxygen and the imine nitrogen. The stereogenic carbon atom of the chelate ligand has the expected (R_C) configuration introduced in the synthesis. The *i*Pr group of the π-bonded *p*-cymene ligand lies above the phenolic oxygen. Thus, the *p*-methyl group is located near the chloride ligand. The oxygen atom of the hydroxymethyl group is oriented towards the chloride ligand. The configuration of the stereogenic ruthenium centers is determined according to the priority sequence η^6-*p*-cymene > Cl > O > N.[20][21][22] (*R*) configuration is assigned to Ru1 and Ru2, (*S*) configuration to Ru3 and Ru4. In the unit cell the pairs of diastereomers Ru1/Ru3 and Ru2/Ru4 are almost centrosymmetric, except the arrangement of the 2-amino-but-1-yl substituents which have the same (R_C) configuration at the stereogenic carbon atom. Selected bond distances and angles are listed in Table 1.

Table 1. Selected bond lengths and angles of **1a/1b**; estimated standard deviations are shown in parentheses

	$R_{Ru(1)}$	$R_{Ru(2)}$	$S_{Ru(3)}$	$S_{Ru(4)}$
Ru−Cl	2.459(4)	2.467(4)	2.434(4)	2.431(4)
Ru−O	2.153(9)	2.108(10)	1.728(11)	2.028(9)
Ru−N	2.106(11)	2.096(11)	2.134(11)	2.185(12)
Ru−(arene)	1.634(5)	1.680(4)	1.687(4)	1.669(8)
Cl−Ru−O	83.6(3)	86.3(3)	91.5(4)	81.4(3)
Cl−Ru−N	85.4(3)	83.3(3)	83.5(3)	84.1(4)
O−Ru−N	88.8(4)	89.9(4)	90.0(5)	85.9(4)

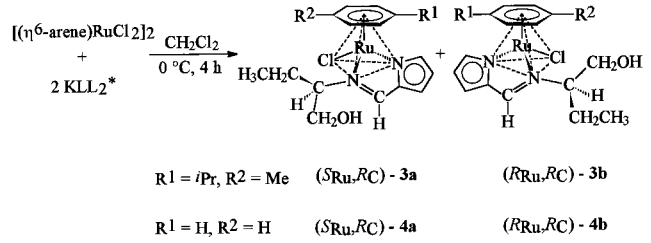
The bond distances and angles are similar to those observed in related complexes.[13][14] However there is a very short Ru3−O3 distance. The complexes with (S_{Ru}) configuration show longer Ru−N distances, whilst the Ru−Cl and Ru−O distances are smaller than in complexes with (R_{Ru}) configuration. The distances of the oxygen atoms to the chloride ligands are: O84···Cl1 3.24 Å, O87···Cl2 3.20 Å, O92···Cl3 3.01 Å, and O95···Cl4 3.13 Å. Weak O−H···Cl hydrogen bridges are described for O···Cl distances between 2.92 and 3.18 Å.[23] The formation of these O−H···Cl hydrogen bridges may be the driving force which orients the OH groups of the (*R*)-2-aminobut-1-yl substituents towards the chloride ligands.

The X-ray structure analysis demonstrated the presence of both diastereomers **1a** and **1b** in the crystal in a 1:1 ratio. However, the ^{1}H-NMR spectrum of crystals dissolved in $CDCl_3$ at room temperature showed a 91:9 ratio which did not change after stirring for 1 d at r.t. Furthermore, crystals of the complex **1a/1b** were dissolved at −80°C in CD_2Cl_2. Integration of the low temperature ^{1}H-NMR spectrum gave a diastereomer ratio of 95:5, proving the configurational lability at the metal center even at −80°C. Thus, the equilibrium **1a** ⇌ **1b** must have been established during the solution procedure at −80°C which took 1 h. Obviously, the energy barrier of the epimerization at the Ru atom in **1a/1b** is very low as observed for similar compounds with related chiral salicylaldiminato ligands.[12][13] Surprisingly, however, crystallization of a solution in which one of the two diastereomers is dominant, gives a 1:1 ratio of **1a/1b** in the crystal lattice.

Condensation of (*R*)-2-aminobutanol with 2-pyrrolecarbaldehyde afforded the ligand 2-*N*-[(*R*)-1-hydroxybut-2-yl)]-pyrrolecarbaldimine[17][24] (HLL$_2$*). The formation of the diastereomeric complexes (R_{Ru},R_C)- and (S_{Ru},R_C)-[(η^6-*p*-cymene)Ru(LL$_2$*)Cl] (**3a**, **b**) and [(η^6-benzene)Ru(LL$_2$*)Cl] (**4a**, **b**) is depicted in Scheme 2.

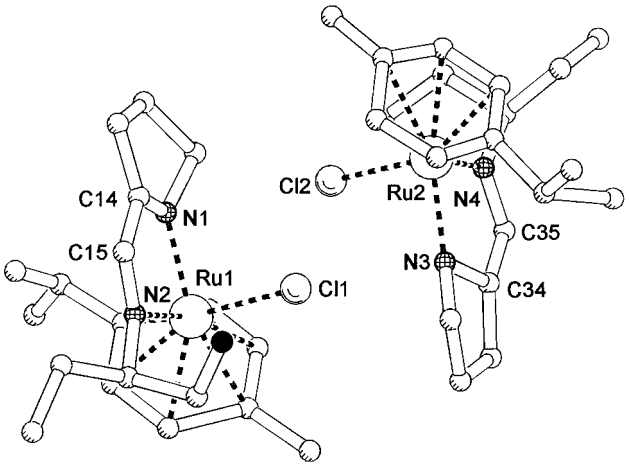
The ^{1}H-NMR spectrum of **3a/3b** in $CDCl_3$ showed a diastereomer ratio of 1:1, which did not change after refluxing for 3 h. A measurement in [D$_6$]acetone demonstrated that solvent polarity had no influence on the equilibrium ratio. The diastereomer ratio of 79:21 in $CDCl_3$ for the complexes **4a**, **b** was similar to the ratio found for the complexes **2a**, **b** (76:24).

Scheme 2



From a mixture of CH_2Cl_2, thf, and pentane crystals of the complex **3a/3b** suitable for X-ray structure analysis were obtained. There are two independent molecules in the unit cell with opposite configurations at the Ru centers. The molecular structure of **3a/3b** is shown in Figure 2.

Figure 2. Crystal structure of (R_{Ru},R_C/S_{Ru},R_C)-[(η6-*p*-cymene)-Ru(LL2*)Cl] **3a/3b**



The chiral Schiff base is coordinated through the pyrrole nitrogen and the imine nitrogen. The stereogenic carbon atom of the chelate ligand has the expected (R_C) configuration.The *i*Pr group of the cymene ring is located in the vicinity of the imine nitrogen. Both methyl groups of the *i*Pr substituent tend away from the chelate ring and the *p*-methyl group fills the space between the imine nitrogen and the chloride ligand. The oxygen atom of the hydroxymethyl group is oriented towards the chloride ligand. Both molecules are arranged in a quasi centrosymmetric manner. However, there is no real centrosymmetry due to the given (R_C) configuration at the stereogenic carbon atoms. According to the priority sequence η6-*p*-cymene > Cl > N(imine) > N(pyrrolate) the configuration of the stereogenic ruthenium centers is (*S*) for Ru1 and (*R*) for Ru2. Selected bond distances and angles are listed in Table 2.

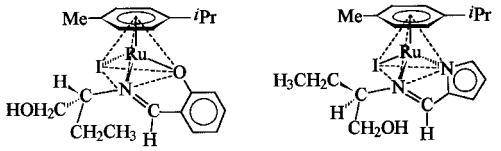
The bond lengths and angles are similar to those observed in related complexes.[12]. The distances of the oxygen atoms to the chloride ligands are O1···Cl1 3.28 Å and O2···Cl2 3.00 Å, indicating the formation of weak O−H···Cl hydrogen bridges as observed for **1a/1b**.

The dissociation of the chloride ligand in ruthenium half-sandwich complexes[12][13][25][26][27] can be used for halogen exchange reactions.[27] Stirring the complexes **1a/1b** in MeOH in the presence of a 10 M excess of NaI for 1 h at rt gave the complexes [(η6-*p*-cymene)Ru(LL1*)I] (**5a**, **b**) (Scheme 3) in nearly quantitative yield.

Table 2. Selected bond lengths and angles of **3a/3b**; estimated standard deviations are shown in parentheses

	$R_{Ru(1)}$	$S_{Ru(2)}$
Ru−Cl	2.481(11)	2.361(10)
Ru−N(pyrr)	2.082(26)	2.041(26)
Ru−N(imine)	2.137(27)	2.119(27)
Ru−(arene)	1.626(14)	1.711(17)
Cl−Ru−N(pyrr)	84.7(7)	84.8(7)
Cl−Ru−N(imine)	85.8(7)	84.4(8)
N (pyrr)−Ru−N	75.3(10)	80.1(10)

Scheme 3. Structural formulae of the iodo complexes **5a/5b**, **6a/6b**. Only one diastereomer is shown



5a,b **6a,b**

There were hardly differences in the chemical shifts of the iodo complex **5a/5b** and the chloro complex **1a/1b**. In the iodo complex the *p*-methyl group of the cymene ligand was shifted 0.17 ppm to low field, whereas the imine proton was shifted 0.16 ppm to high field relative to the chloro complex. The diastereomer ratio of **5a**, **b** (88:12) was similar to that found for **1a**, **b** (91:9). Thus, the exchange of the *p*-cymene ligand in **1** for benzene in **2** had a much stronger impact on the diastereomer ratio than the exchange of chloride in **1** for iodide in **5**.

The preparation of [(η6-*p*-cymene)Ru(LL2*)I] (**6a/6b**) (Scheme 3) from **3a/3b** was carried out as described for the system **1** → **5**. In the FD mass spectrum of **6a/6b** only the peak of the iodo complex was detected confirming quantitative halogen exchange. The integration of the imine protons at δ = 7.44 and 7.48 in $CDCl_3$ gave a diastereomer ratio of 65:35.

Experimental Section

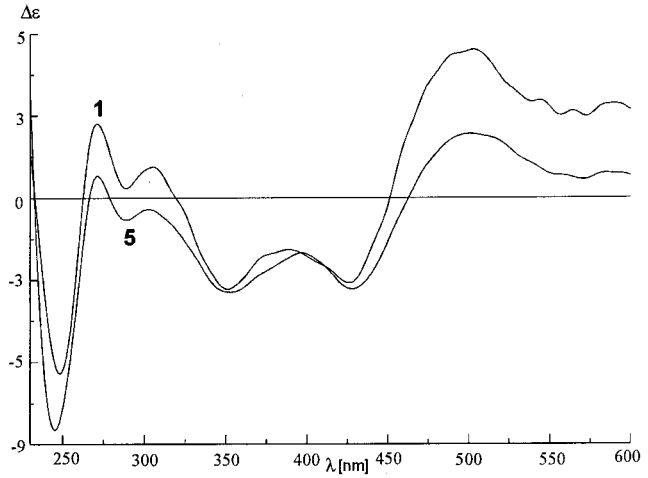
General Remarks: Preparation of the ruthenium complexes was carried out under an atmosphere of dry nitrogen with standard Schlenk techniques. − IR spectra: Beckman IR 4240 spectrometer. − Mass spectra: field desorption method (Finnigan MAT 95). − ^{1}H-NMR spectra: Bruker ARX 400 spectrometer (400 MHz). − UV/Vis spectroscopy: Kontron Uvikon 922 spectrophotometer. − CD spectra Jasco J-710 spectrophotometer. − Polarimetric measurements: Perkin-Elmer 241 instrument. − Melting points: Büchi SMP 20. Elemental analyses: microanalytical laboratory of the University of Regensburg. − [(η6-*p*-cymene)$RuCl_2]_2$[28−30] and [(η6-benzene)$RuCl_2]_2$[28][29][30] were prepared as published from $RuCl_3 \cdot xH_2O$. 2-*N*-[(*R*)-1-hydroxybut-2-yl)]salicylaldimine[18] (HLL*-**1**) and 2-*N*-[(*R*)-1-hydroxybut-2-yl)]pyrrolecarbaldimine[17][24] (HLL*-**4**) were synthesized by the literature methods. −

X-ray structure analyses: Syntex R3 diffractometer, Mo-K_α radiation, T = 296 K. Solution by direct methods using the program SHELXTL Plus (release 4.2/800), PC version. Further details of the crystal structure investigation may be obtained from the Fachinformationszentrum Karlsruhe, D-76344 Eggenstein-Leopoldshafen (Germany) (e-mail: crysdata@fiz-karlsruhe.de) on quoting the respective depository CSD number (vide infra).

Preparation of the Complexes [(η⁶-arene)Ru(LL)Cl]:* 2.07 mmol of the appropriate ligand HLL* was dissolved in abs. CH_2Cl_2 and KO*t*Bu (2.07 mmol) was added. The mixture was stirred for 1 h at room temp. After adding CH_2Cl_2 the mixture was cooled to 0°C. $[(\eta^6\text{-arene})RuCl_2]_2$ (1.00 mmol) was added and the solution was stirred for 4 h at 0°C. The solution was filtered through Celite and concentrated. The product was precipitated quantitatively by slow addition of petroleum ether with stirring. The red microcrystalline residue was washed with petroleum ether and dried.

[(η⁶-p-Cymene)Ru(LL₁)Cl]* (**1a**, **b**): Yield: 705 mg (83%), m.p. 136°C (decomp.). − IR (KBr): $\tilde{\nu}$ = 1615 cm^{-1} (C=N), 1600, 1540, 1470 (C=C). − $[\alpha]^{24}$ (c = 0.14, $CHCl_3$) (589 nm) +770, (578 nm) +1025, (546 nm) +1277. − UV/Vis (c = 1.32·10^{-4} mol l^{-1}, CH_2Cl_2) λ_{max} (lg ε) = 277 nm (3.67). − CD data (c = 1.80·10^{-4} mol l^{-1}, CH_2Cl_2) λ_{max} (Δε) = 248 nm (−6.40), 261 (0.0), 271 (2.71), 305 (1.14), 320 (0.0), 351 (−3.31), 426 (−3.11), 450 (0.0), 503 (5.41). − ^{1}H NMR ($CDCl_3$): δ = 1.15 (m, 6 H, C*H*$_3$, C*H*$_3$-*i*Pr), 1.26 (d, J = 6.9 Hz, 3 H, C*H*$_3$-*i*Pr), 1.97 (m, 2 H, C*H*$_2$CH$_3$), 2.25 (s, 3 H, C*H*$_3$-cymene), 2.75 (sept, J = 6.9 Hz, 1 H, C*H*-*i*Pr), 3.71 (m, 1 H, C*H*), 3.98 (m, 1 H, *H*CHOH), 4.44 (m, 1 H, HC*H*OH), 4.99/5.40 (AB, d, J = 5.7 Hz, 2 H, *H*-cymene), 5.46/5.47 (AB, d, J = 6.5 Hz, 2 H, *H*-cymene), 6.44 (m, 1 H, *H*^{4}-sal), 6.95 (m, 2 H, *H*^{3},*H*^{6}-sal), 7.19 (m, 1 H, *H*^{5}-sal), 7.75 (7.85, 9%) (s, 1 H, N=C*H*). − MS-FD (EtOH); *m*/*z* (%): 463 (100) [M^+] rel. to ^{102}Ru. − $C_{21}H_{28}ClNO_2Ru$ (462.98): calcd. C 54.48, H 6.10, N 3.03; found C 54.24, H 6.31, N 3.04.

Figure 3. CD spectra of the chloride and iodide complexes **1a**, **b** (91:9) and **5a**, **b** (88:12) in dichloromethane. [c(**1**) = 1.80·10^{-4} mol l^{-1}, c(**5**) = 1.59·10^{-4} mol l^{-1}]



Crystals for X-ray analysis were obtained from a mixture of CH_2Cl_2, thf, and pentane at 3°C. X-ray structure analysis of (R_{Ru},R_C/S_{Ru},R_C)-[(η⁶-*p*-cymene)Ru(LL$_1$*)Cl]: dark red triangular plates, crystal size 0.25 × 0.45 × 0.55 mm^3, monoclinic, space group C_2^2, $P2_1$ (no 4), a = 7.715(2), b = 17.859(4), c = 29.359(8) Å, β = 94.90(2)°, V = 4031(2) Å^3, Z = 4·2, d_{calc} = 1.52 g cm^{-3}, empirical absorption correction (7 reflections 4.6° < 2θ < 41.2°), ω scans, 2θ range 3.0° < 2θ < 59.0°, Friedel pairs 3.0° < 2θ < 35.0°, transmission factors 0.86−1.00, μ = 0.93 mm^{-1}, F(000) = 1896; 13919 unique, 8505 observed reflections [I > 2.5σ(I)]. Parameters blocked 4·115, total 457; R = 0.074, Rw = 0.067, residual electron density 4.60/−2.00 e Å^{-3}. CSD 408883.

[(η⁶-benzene)Ru(LL₁)Cl]* (**2a**, **b**): Yield: 363 mg (72%), m.p. 167°C (decomp.). − IR (KBr): $\tilde{\nu}$ = 1620 cm^{-1} (C=N), 1600, 1540, 1470 (C=C). − $[\alpha]^{20}$ (c = 0.12, CH_2Cl_2) (589 nm) +920, (578 nm) +1111, (546 nm) +1547. − CD data (c = 1.48·10^{-4} mol l^{-1}, CH_2Cl_2) λ_{max} (Δε) = 247 nm (−2.30), 269 (0.0), 282 (0.18). − NMR data for the minor diastereomer are added in parentheses when different to the major diastereomer. ^{1}H NMR ($CDCl_3$): δ = 1.16 (0.92) (t, J = 7.2 (7.4) Hz, 3 H, C*H*$_3$), 2.00 (m, 2 H, C*H*$_2$CH$_3$), 3.76 (m, 1 H, C*H*), 3.99 (m, 1 H, *H*CHOH), 4.51 (m, 1 H, HC*H*OH), 5.60 (s, 6 H, *H*-benzene), 6.48 (m, 1 H, *H*^{4}-sal), 6.98 (m, 2 H, *H*^{3},*H*^{6}-sal), 7.22 (m, 1 H, *H*^{5}-sal), 7.77 (8.39) (s, 1 H, N=C*H*). − MS-FD (CH_2Cl_2); *m*/*z* (%): 407 (100) [M^+] rel. to ^{102}Ru. − $C_{17}H_{20}ClNO_2Ru$ (406.87): calcd. Crystals of **3a/3b** for X-ray analysis were obtained from a mixture of CH_2Cl_2, thf, and pentane at 3°C. X-ray structure analysis of (R_{Ru},R_C/S_{Ru},R_C)-[(η⁶-*p*-cymene)Ru(LL$_2$*)Cl]: orange-red needles, crystal size 0.08 × 0.10 × 0.08 mm^3, monoclinic, space group C_2^2, $P2_1$ (no 4), a = 10.036(3), b = 9.415(3), c = 21.132(7) Å, β = 101.44(2)°, V = 1957(1) Å^3, Z = 2·2, d_{calc} = 1.48 g cm^{-3}, empirical absorption correction (8 reflections 4.2° < 2θ < 35.2°), ω scans, 2θ range 3.0° < 2θ < 50.0°, Friedel pairs 3.0° < 2θ < 42.0°, transmission factors 0.86−1.00, μ = 0.95 mm^{-1}, F(000) = 896; 5465 unique, 3069 observed reflections [I > 2.5σ(I)]. Parameters 213; R = 0.119, Rw = 0.096, residual electron density 1.93/−2.47 e Å^{-3}. CSD 408884.

[(η⁶-benzene)Ru(LL₂)Cl]* (**4a**, **b**): Yield: 340 mg (66%), m.p. 110°C (decomp.). − IR (KBr): $\tilde{\nu}$ = 1620 cm^{-1} (C=N), 1580, 1435 (C=C). − $[\alpha]^{20}$ (c = 0.17, CH_2Cl_2) (589 nm) −321, (578 nm) −381, (546 nm) −669. − NMR data for the second diastereomer are added in parentheses when different to the first diastereomer. ^{1}H NMR ($CDCl_3$): δ = 1.06 (1.12) (t, J = 7.4 Hz, 3 H, C*H*$_3$), 1.79 (1.92) (m, 2 H, C*H*$_2$CH$_3$), 3.55 (m, 1 H, C*H*), 3.72 (m, 1 H, *H*CHOH), 3.92 (m, 1 H, HC*H*OH), 5.70 (5.62) (s, 6 H, η^6-C$_6$*H*$_6$), 6.34 (dd, J = 3.8 Hz, J = 1.1 Hz, 1 H, *H*^{4}-pyrr), 6.71 (dd, J = 3.8 Hz, J = 1.1 Hz 1 H, *H*^{3}-pyrr), 7.53 (broad, 1 H, *H*^{5}-pyrr), 7.59 (7.62) (s, 1 H, N=C*H*). − MS-FD (acetone); *m*/*z* (%): 380 (100) [M^+] rel. to ^{102}Ru. − $C_{19}H_{19}ClN_2ORu$ (379.85): calcd. C 45.28, H 5.32, N 7.04; found C 45.00, H 5.12, N 6.33.

Preparation of the complexes [(η^6-*p*-cymene)Ru(LL*)I]: 0.15 mmol of the appropriate ruthenium complex (**1a**, **b**) or (**3a**, **b**) was dissolved in abs. MeOH (15 ml). NaI (1.5 mmol) was added. The solution was stirred for 1 h at r.t. The solvent was evaporated and the red residue was dissolved in CH_2Cl_2 and filtered. After removing the solvent an analytically pure red powder was obtained in nearly quantitative yield.

[(η^6-p-cymene)Ru(LL_1)I]* (**5a**, **b**): m.p. 80°C (decomp.).– $[\alpha]^{21}$ (c = 0.08, $CHCl_3$) (589 nm) +29, (578 nm) −29, (546 nm) −29. – UV/Vis (c = $1.27\cdot10^{-4}$ mol l^{-1}, CH_2Cl_2) λ_{max} (lg ε) = 270 nm (3.92), 293 (3.92). – CD data (c = $1.59\cdot10^{-4}$ mol l^{-1}, CH_2Cl_2) λ_{max} (Δε) = 245 nm (−8.47), 264 (0.0), 271 (0.81), 279 (0.0), 302 (−0.41), 353 (−3.44), 428 (−3.32), 461 (0.0), 501 (2.33). – NMR data for the minor diastereomer are added in parentheses when different to the major diastereomer. ^{1}H NMR ($CDCl_3$): δ = 1.12 (0.91) (t, J = 7.4 (7.5) Hz, 3 H, CH_3), 1.16 (d, J = 6.8 Hz, 3 H, CH_3-*i*Pr), 1.29 (d, J = 6.8 Hz, 3 H, CH_3-*i*Pr), 2.00 (m, 2 H, CH_2CH$_3$), 2.42 (2.35) (s, 3 H, CH_3-cymene), 2.88 (sept, J = 6.8 Hz, 1 H, C*H*-*i*Pr), 3.74 (m, 1 H, C*H*), 4.26 (m, 2 H, CH_2OH), 4.89/5.49 (AB, d, J = 5.3 Hz, 2 H, *H*-cymene), 5.30/5.62 (AB, d, J = 5.7 Hz, 2 H, *H*-cymene), 6.42 (m, 1 H, H^4-sal), 6.92 (m, 2 H, H^3,H^6-sal), 7.15 (m, 1 H, H^5-sal), 7.59 (7.66) (s, 1 H, N=C*H*). – MS-FD (CH_2Cl_2); *m*/*z* (%): 555 (100) [M^+] rel. to ^{102}Ru, 428 (20) [M^+ − I]. – $C_{21}H_{28}INO_2Ru$ (554.43): calcd. The regioselectivity of benzylic deprotonation of a number of conformationally restricted (arene)$Cr(CO)_3$ complexes has been examined in order to ascertain whether stereoelectronic effects play a role in such reactions. The complexes *rac*-**5**, *rac*-**6**, *rac*-**7**, *rac*-**8** and *rac*-**9** were diastereoselectively synthesized from the corresponding C_2-symmetric ligands (2,3-disubstituted *trans*-1,2,3,4-tetrahydronaphthalene and *trans*-1,2,3,4,4a,9,9a,10-octahydroanthracene derivatives). Due to the desymmetrization caused by the $Cr(CO)_3$ complexation, all four benzylic protons could be distinguished by ^1H NMR and were assigned in all cases by a combination of H,H-COSY spectra and the observation of H/D exchange at both *exo* positions (*tert*-BuOK/[D_6]DMSO). Deprotonation (*n*-butyllithium)/deuteration (D_2O or CF_3CO_2D) experiments revealed a very high, unforeseen regioselectivity in the cases of *rac*-**5** and *rac*-**7**, while the other substrates showed a low selectivity (*rac*-**6**) or could not be deuterated at all under these conditions (*rac*-**8**, *rac*-**9**). In the case of *rac*-**5**, the regioselectivity of the deprotonation was further confirmed by acylation (AcCl) or alkylation (MeI) of the lithiated intermediate. These results clearly rule out the notion that the regioselectivity is due to the preferred abstraction of pseudoaxially oriented benzylic hydrogen atoms. The crystal structures of *rac*-**1**, *rac*-**5** and *rac*-**7** suggest a possible link between the preferred conformation of the $Cr(CO)_3$ tripod and the regioselectivity of the benzylic deprotonation. In analogy to a commonly accepted picture often used to explain the regioselectivity of nucleophile additions to (arene)$Cr(CO)_3$ complexes, it was anticipated that those benzylic positions which are activated by an eclipsed CO ligand should be preferentially deprotonated (kinetically controlled). This (new) stereoelectronic model was corroborated by experiments using complexes *rac*-**60** and *rac*-**62**, which were regioselectively deprotonated at the predicted position. In summary, it has been shown for the first time that the preferred conformation of the $Cr(CO)_3$ tripod may have a directing influence on the regioselectivity of benzylic deprotonation in (arene)$Cr(CO)_3$ complexes, at least in conformationally unambiguous situations where no obvious electronic effects are operative.

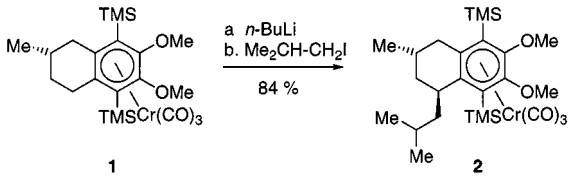
Introduction

(Arene)$Cr(CO)_3$ complexes represent a unique class of transition metal complexes, which are of considerable value for the synthesis of complex organic molecules[1]. One of the most useful effects of the $Cr(CO)_3$ fragment is the stabilization of negative charge in benzylic positions, which can be exploited for efficient benzylic deprotonation/alkylation reactions[2][3].

In the course of our program on the use of chiral (arene)$Cr(CO)_3$ complexes as building blocks for the total synthesis of bioactive compounds[4][5], we recently discovered that complex **1** is deprotonated by *n*-butyllithium in a highly regioselective fashion, permitting the regio- and diastereoselective preparation of benzylic alkylated products such as **2** (Scheme 1)[5].

While the regioselectivity of the benzylic deprotonation of (arene)$Cr(CO)_3$ complexes has hitherto been explained more or less exclusively in terms of electronic[1c][2][6] or complex-induced proximity effects[7], any rationalization of the high degree of regiocontrol during the deprotonation of **1** must be based on different concepts.

Scheme 1



1 **2**

The crystal structure of *rac*-**1** (see below) shows that the molecule preferentially adopts a half-chair conformation (**1′**; Figure 1). As a result, the two relevant benzylic *exo* hydrogen atoms, which have comparable steric environments, differ in that one (the one that is attacked by the base) adopts a pseudoaxial position, while the other is pseudoequatorially oriented. Therefore, it could not a priori be ruled out that the deprotonation step (leading to the anionic intermediate **3**) is stereoelectronically controlled[8].

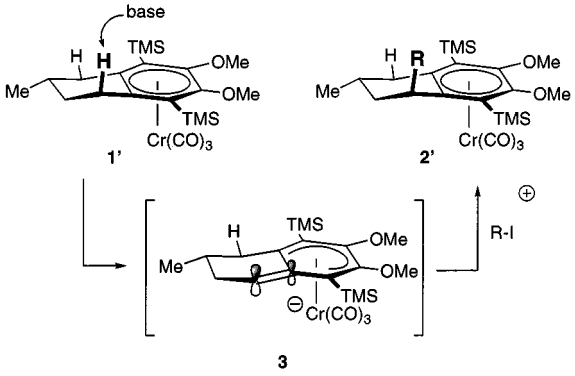
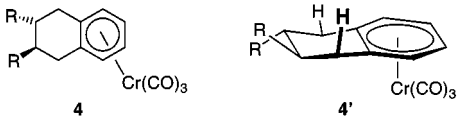
Figure 1. On the regio- and stereochemistry of the deprotonation/alkylation of complex **1**



In order to investigate whether such conformational or stereoelectronic effects do indeed play a role in the benzylic deprotonation of (arene)$Cr(CO)_3$ complexes, we decided to explore conformationally more rigid substrates of type **4** (Figure 2). Compared to **1**, these compounds should exhibit an even stronger preference for a half-chair conformation (**4′**)[9] and, as a result of the symmetry of such structures, the two benzylic positions are essentially electronically equivalent.

Figure 2. Preferred half-chair conformation of 2,3-disubstituted tetralin complexes of type **4**; the two benzylic *exo*-hydrogen atoms can be classified as pseudoaxial and pseudoequatorial, respectively

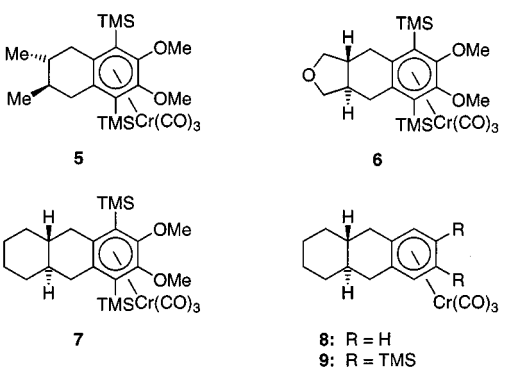


We report here on the synthesis and structural characterization of several (tetralin)- and (*trans*-octahydroanthracene)$Cr(CO)_3$ complexes (*rac*-**5**, *rac*-**6**, *rac*-**7**, *rac*-**8**, *rac*-**9**) as well as on investigations of their benzylic deprotonation. Furthermore, we present a modified mechanistic interpretation to explain the effects governing the regioselectivity of the benzylic deprotonation of such complexes.

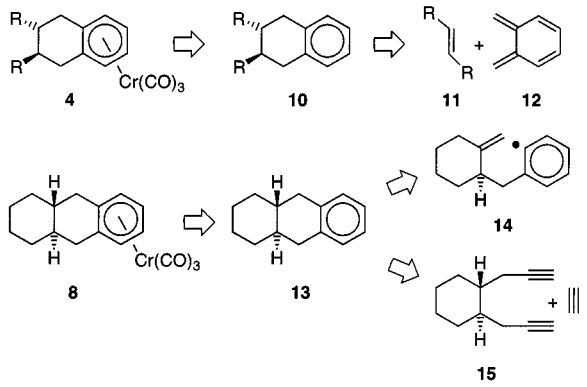
Synthesis of the Complexes

Strategic Considerations

The syntheses of the various complexes were envisaged as being possible by the general routes outlined in Scheme 2. Retrosynthetically, the target compounds stem from C_2-symmetric ligands in each case. For the synthesis of 2,3-*trans*-disubstituted tetralin derivatives of type **10**, a Diels-Alder reaction of an (*E*)-configured dienophile **11** with an *o*-quinodimethane of type **12** was envisaged[10]. For the diastereoselective preparation of *trans*-octahydroanthracenes such as **13**[11], either a 6-*endo* cyclization of a radical intermediate of type **14**[12], or a metal-mediated [2+2+2]-cycloaddition (Vollhardt reaction)[13] employing the *trans*-bis(alkyne) **15** were considered. For the purposes of the anticipated deprotonation studies, it was sufficient to focus merely on synthetic methods that would furnish the target complexes in racemic form.



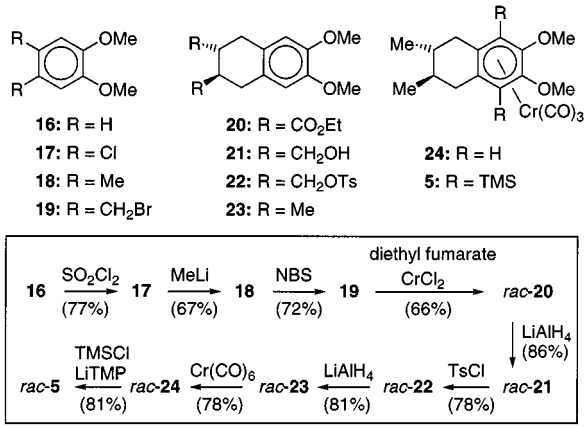
Scheme 2



Synthesis of *rac*-5

Compound **19**, the precursor of the dimethoxy-substituted *o*-quinodimethane, was prepared from veratrole (**16**) in three steps employing modified literature procedures[14]. The dichlorinated derivative **17** was converted to 4,5-dimethylveratrole (**18**) by reaction with methyllithium in diethyl ether[14a][14b]. Subsequent benzylic bromination of **18**[14c] with 2 equiv. of dry NBS in the presence of molecular sieves (4 Å) afforded **19** in 72% yield.

Scheme 3



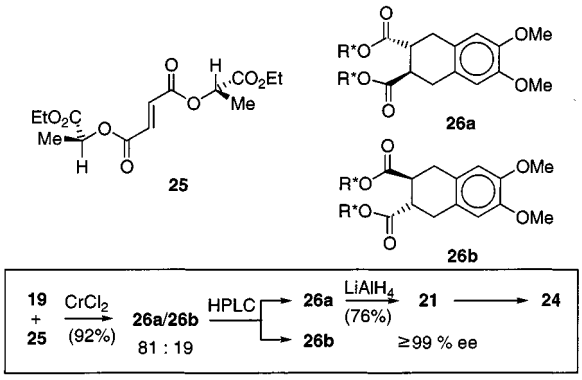
In situ generation of the *o*-quinodimethane from **19** by reductive debromination with $CrCl_2$ in THF[15] in the presence of diethyl fumarate at 0°C yielded the desired Diels-Alder product *rac*-**20** in 66% yield as the pure *trans* dia-

stereomer[16]. Reduction of *rac*-**20** with $LiAlH_4$ in diethyl ether (30°C, 0.5 h) afforded the diol *rac*-**21**. Deoxygenation of the diol *rac*-**21** was then achieved in 63% overall yield by $LiAlH_4$ reduction of the corresponding bis(tosylate) (*rac*-**22**)[17]. It proved to be important to carry out the ditosylation (*rac*-**21** → *rac*-**22**) at low temperature (0−4°C), otherwise the cyclic ether *rac*-**27** (see below) became the major product. Heating of *rac*-**22** with $Cr(CO)_6$ (1.1 equiv.) under standard conditions[18] (*n*-Bu_2O/THF; reflux) gave complex *rac*-**23** in 78% recrystallized yield. The introduction of the two trimethylsilyl substituents was finally accomplished in a one-pot procedure[5] using the reagent combination chlorotrimethylsilane/lithium tetramethylpiperidide[19] to afford the bis(silylated) complex *rac*-**5** in high yield. The crystal structure of *rac*-**5** is depicted in Figure 5.

Synthesis of Complex 24 (Nonracemic Series)

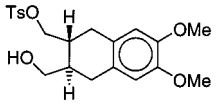
We also briefly investigated the Diels-Alder reaction of the **19**-derived *o*-quinodimethane employing chiral fumarates as dienophiles. While the use of dimenthyl fumarate[20] led only to a low selectivity (33% *de*; 92% yield), the lactic acid derivative **25** was found to be a much better chiral dienophile (Scheme 4)[21]. Thus, when **19** was treated with $CrCl_2$ in the presence of an excess of **25**, an 81:19 mixture of the two diastereomeric cycloaddition products **26a** and **26b** was obtained in high yield. After HPLC separation, the major diastereomer (**26a**) was converted by $LiAlH_4$ reduction to the optically active diol **21**, which was shown to be of ≥ 99% *ee* by means of HPLC on a chiral stationary phase[22]. It is remarkable that, compared to diethyl fumarate (see Scheme 3), the (more bulky) chiral fumarates generally gave much higher yields (>90%) in the Diels-Alder reactions. Following the procedures established for the racemic series, **21** was transformed to **24** (Scheme 4). The absolute and relative configuration of **24** was unequivocally established by means of a crystal structure analysis (see Figure 4), which (retrospectively) allowed assignment of the configurations of **26a** and **26b**.

Scheme 4



Synthesis of *rac*-6

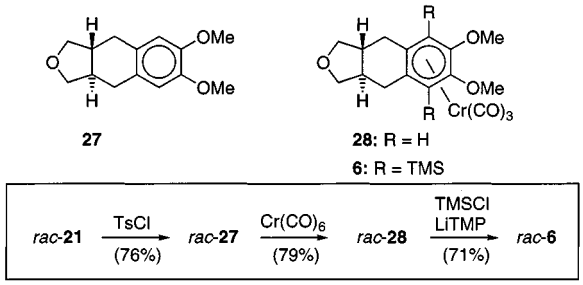
The tetrahydrofuran derivative *rac*-**27**, which was initially obtained as an undesired side-product during the preparation of *rac*-**22** (see above), was isolated in 76% yield when *rac*-**21** was treated with *p*-TsCl in pyridine at 60°C, even when 3 equiv. of *p*-TsCl was used. Clearly, the S_N2-type cyclization of the monotosylated intermediate *rac*-**29** was faster than the second tosylation under these conditions[23].



29

Since *rac*-**27** also represents a conformationally restricted tetralin derivative, it was converted to the corresponding $Cr(CO)_3$ complex *rac*-**28** (Scheme 5), which in turn was disilylated under the one-pot conditions described above to give *rac*-**6**.

Scheme 5

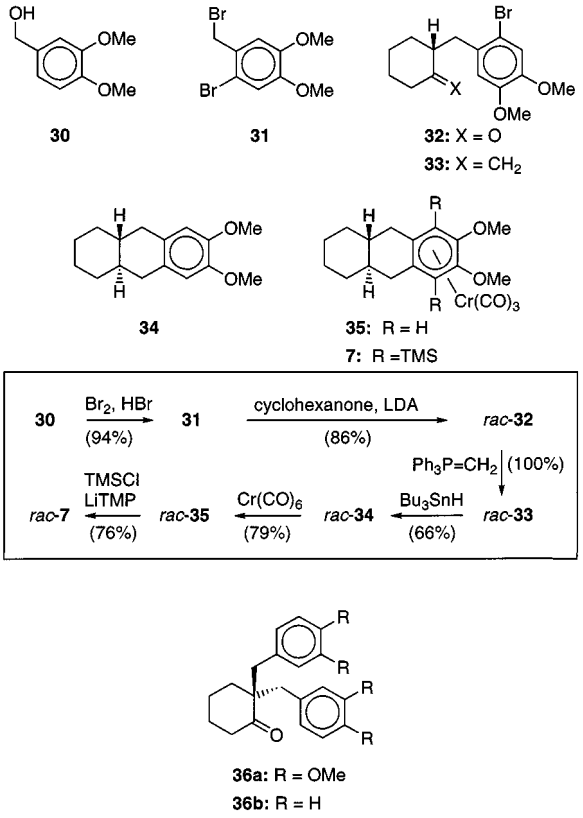


Synthesis of *rac*-7

The synthesis of *rac*-**7** (Scheme 6) was performed following the radical cyclization route outlined in Scheme 2. Starting from veratrum alcohol **30**, the dibromide **31** was prepared in high yield by treatment with bromine (1 equiv.) in benzene. Some hydrogen bromide was added to ensure completion of the reaction.

Alkylation of the enolate anion, prepared from **31** and cyclohexanone with LDA in THF, proceeded smoothly to give the ketone *rac*-**32** in high yield, together with small amounts of the doubly alkylated by-product **36a**, which could be easily separated by chromatography.

Scheme 6



Wittig methylenation of *rac*-**32** furnished the cyclization precursor *rac*-**33** in essentially quantitative yield. The crucial radical cyclization[24] of *rac*-**33** was performed in benzene, with slow addition of tributyltin hydride in the presence of AIBN. The *6-endo* cyclization product *rac*-**34** was obtained as the major product in 66% yield. Complexation of *rac*-**34** with $Cr(CO)_6$ (→ *rac*-**35**) followed by double silylation afforded *rac*-**7** in good overall yield (Scheme 6). X-ray crystal structure analysis (see Figure 6) of *rac*-**7** proved its relative configuration.

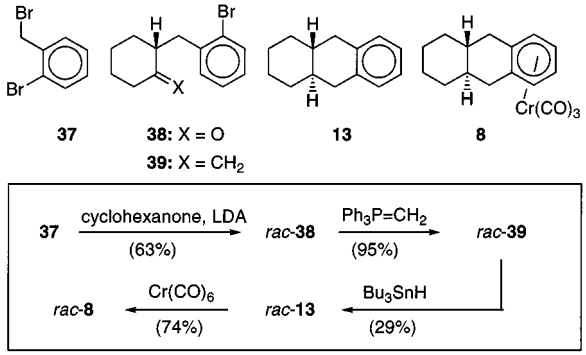
Synthesis of *rac*-8

The synthesis of the *trans*-octahydroanthracene ligand *rac*-**13** was accomplished following the same strategy. Alkylation of cyclohexanone (LDA, subsequent addition of the dibromide **37**, 3 h reflux in THF) afforded an 80:20 mixture of *rac*-**38** and the double-alkylation product **36b**, from which pure *rac*-**38** was isolated by kugelrohr distillation. Methylenation of *rac*-**38** to *rac*-**39** followed by radical cyclization afforded *rac*-**13** (Scheme 7)[12][25]. Subsequent complexation of *rac*-**13** with $Cr(CO)_6$ furnished *rac*-**8** in good yield (Scheme 7).

Synthesis of *rac*-9

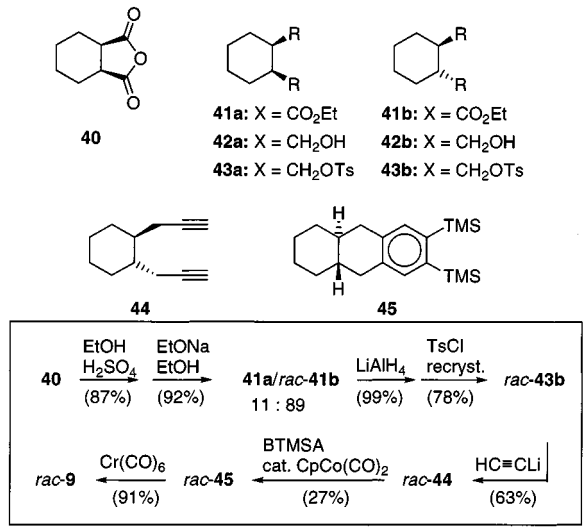
The *cis*-diester **41a**[26], obtained from hexahydrophthaloyl anhydride (**40**) in 87% yield, was converted to the *trans* isomer *rac*-**41b** by refluxing with ethanolic sodium ethoxide[27]. In contrast to a literature report[27], an inseparable mixture (*rac*-**41b**/**41a** = 89:11) was obtained rather

Scheme 7



than the pure *trans* product. Reduction with $LiAlH_4$ in diethyl ether quantitatively afforded the corresponding mixture of diols (*rac*-**42b**/**42a** = 89:11). Fortunately, tosylation with *p*-TsCl in pyridine and recrystallization of the crude product mixture led to the isolation of the essentially pure *trans*-ditosylate *rac*-**43b** in 78% yield. Conversion of *rac*-**43b** to the cyclization precursor, the dialkyne *rac*-**44**, was achieved by treatment with a 2 M solution of the lithium acetylide·ethylenediamine complex in DMSO at 8°C[28]. Vollhardt cyclization[13] employing *rac*-**44** and bis(trimethylsilyl)acetylene (BTMSA) in the presence of catalytic amounts of $CpCo(CO)_2$ afforded only a moderate yield of the C_2-symmetric ligand *rac*-**45**, which was finally converted to the desired complex *rac*-**9** in 91% yield (Scheme 8).

Scheme 8



Characterization of the Complexes

General Aspects

All complexes synthesized as described above were fully characterized by ^1H NMR, ^{13}C NMR, IR, MS and elemental analysis (see Experimental Section). All data were in accordance with the constitutional and (relative) configurational assignments implied in the structural formulae. In

particular, the fact that all benzylic hydrogen atoms were found to be non-equivalent in the ^{1}H-NMR spectra (see below) and that a full set of ^{13}C signals was observed in each case (see Experimental Section) immediately proves the *trans* configuration on grounds of symmetry.

X-ray Crystal Structure Investigations

The crystal structures of the complexes *rac*-**1** (Figure 3), **24** (Figure 4), *rac*-**5** (Figure 5) and *rac*-**7** (Figure 6) were determined[29] so as to reveal detailed information about configurational and conformational aspects.

The X-ray structure of complex *rac*-**1** (Figure 3) shows that the cyclohexene ring adopts a (slightly distorted) half-chair conformation with one homobenzylic ring carbon atom lying 0.32 Å below, and the other lying 0.50 Å above, the molecular plane defined by the arene ring. The methyl group on the cyclohexene ring is in a pseudoequatorial position. The benzene ring shows a slight deviation from planarity. The largest torsion angle in the benzene ring is 8.4°. The puckering of the benzene ring may be due to the presence of the bulky substituents. The Cr−C(ring) distances range from 2.228 to 2.273 Å. The benzene $Cr(CO)_3$ group has an eclipsed conformation.

The X-ray structure of complex **24** (Figure 4) shows two independent molecules with very similar conformations of the hydrocarbon ligand. The cyclohexene ring adopts a conformation between a twist-boat and an envelope form. The two methyl groups on the cyclohexene ring have pseudoequatorial orientations. One of the homobenzylic ring carbon atoms in molecule I lies 0.48 Å below and the other 0.26 Å above the molecular plane defined by the arene ring (0.54 Å and 0.26 Å for molecule II, respectively). The benzene ring shows only a very small deviation from planarity. The largest torsion angle in the benzene ring is 3.1° (molecule I) and −4.2° (molecule II). The Cr atom lies 1.75 Å below the plane of the benzene ring and the Cr−C(ring) distances range from 2.205 to 2.308 Å. The (benzene)$Cr(CO)_3$ group adopts an almost eclipsed conformation in both independent molecules which, however, differ in that the $Cr(CO)_3$ tripod is rotated through ca. 60°. The absolute configuration of **24** was established with the aid of anomalous scattering.

The X-ray structure of *rac*-**5** (Figure 5) shows a disorder, with two independent molecules in a ratio of ca. 60:40. In both molecules,which differ in the orientation of the $Cr(CO)_3$ tripod, the cyclohexene ring is in a half-chair conformation, with the methyl substituents in equatorial positions and with one homobenzylic ring carbon atom lying 0.42 (0.44) Å below and the other lying 0.36 (0.37) Å above the molecular plane defined by the arene ring. The benzene ring shows a slight deviation from planarity. The Cr−C(ring) distances range from 2.233 to 2.265 Å. As in the case of **24**, the benzene $Cr(CO)_3$ group has an eclipsed conformation in both independent molecules, but with different orientations (60° rotation).

The X-ray structure of *rac*-**7** (Figure 6) also shows two independent molecules with very similar conformations. As expected, the central cyclohexene ring has a twist-boat (half-chair) conformation and the saturated cyclohexane ring has a purely chair conformation. Interestingly, the benzene ring shows a significant deviation from planarity. The ring carbon atoms attached to the TMS groups deviate by about 0.07 Å from the plane of the other four ring atoms and are closer to the Cr Atom. The Cr−C(ring) distances range from 2.217(3) to 2.261(3) Å. The (benzene)$Cr(CO)_3$ group has an almost eclipsed conformation.

Figure 3. X-ray crystal structure of *rac*-**1**; only one enantiomer is depicted

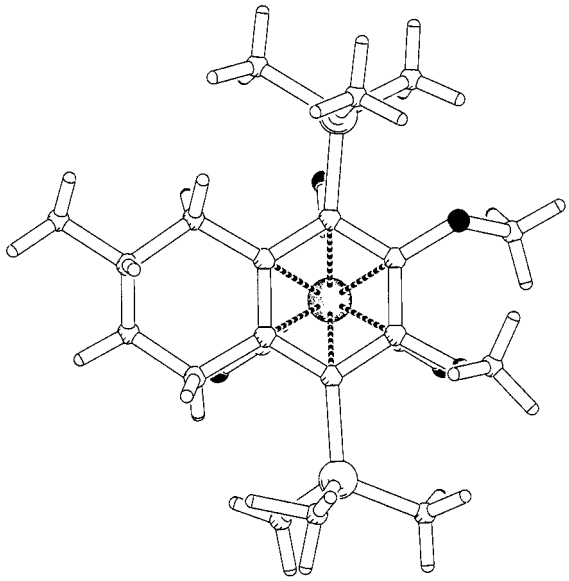


Figure 4. X-ray crystal structure of **24**; only one of two independent conformers is depicted

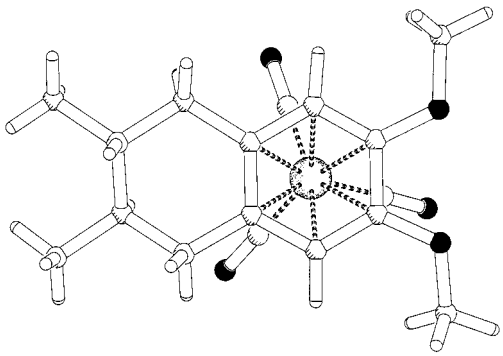

NMR-Spectroscopic Investigations

The ^{1}H-NMR and ^{13}C-NMR spectra of the various complexes (in $CDCl_3$) exhibit a number of interesting features. The signals for the benzylic hydrogen atoms are of particular interest. They all appear as double doublets (compare Figure 8) and are well separated in most cases − an important prerequisite for the unambiguous assignments necessary for the anticipated deprotonation/deuteration studies (see below).

As originally expected and confirmed by the crystal structures, the cyclohexene rings of the complexed ligands adopt half-chair conformations. Thus, the four dia-

Figure 5. X-ray crystal structure of *rac*-**5**; only one of two independent conformers and only one enantiomer is depicted

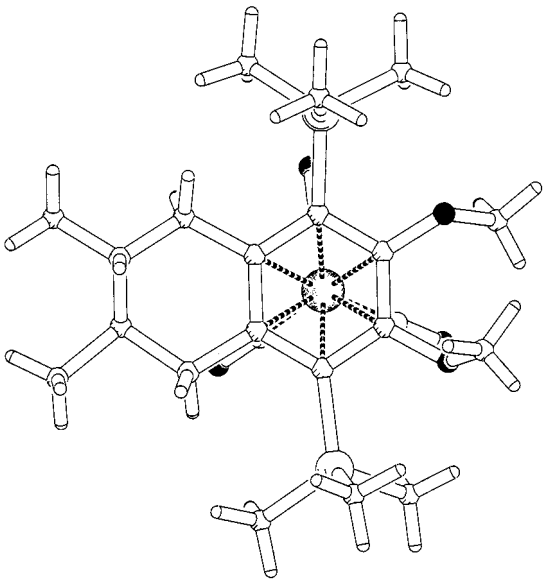

Figure 6. X-ray crystal structure of *rac*-**7**; only one enantiomer is depicted

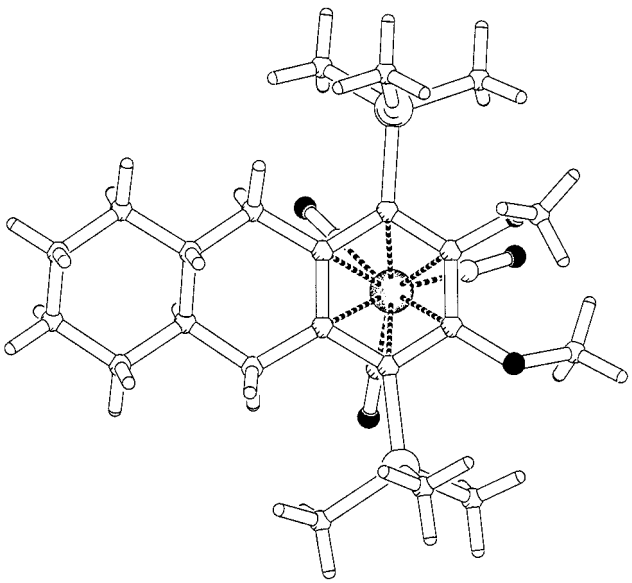
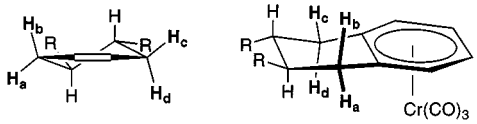
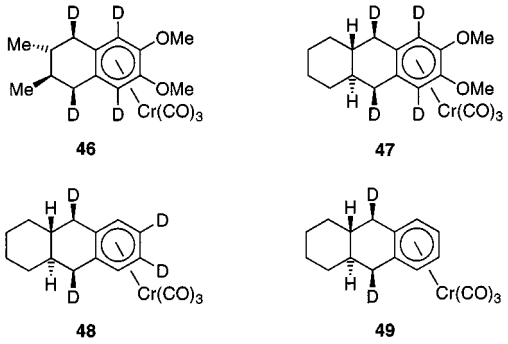


stereotopic benzylic protons may be classified as follows (Figure 7): *endo*-pseudoequatorial (H_a), *exo*-pseudoaxial (H_b), *exo*-pseudoequatorial (H_c) and *endo*-pseudoaxial (H_d).

By means of H,H-COSY spectra[30], it was possible to unambiguously designate the pairs of geminal hydrogen atoms (H_a,H_b; H_c,H_d) for all the complexes. Alternatively, the benzylic *exo*-hydrogen atoms could be identified in several cases by H/D exchange experiments with potassium *tert*-butoxide in [D_6]DMSO (1 h, 25°C). It has been established previously that only the *exo*-hydrogen atoms are substituted under these conditions[3c]. The results of these deuteration experiments are summarized in Table 1. It should be noted that the trimethylsilyl groups in *rac*-**5**, *rac*-**7** and *rac*-**9** were also displaced by deuterium under the reaction conditions (formation of *rac*-**46**, *rac*-**47** and *rac*-**48**). The degree of deuteration was determined in each case by means of ^{1}H-NMR spectroscopy. In addition, the formation of the multiply deuterated compounds was proven by mass spectrometry.

Figure 7. Labelling of the four diastereotopic benzylic hydrogen atoms of the (tetralin)$Cr(CO)_3$ complexes as used for the assignments of the NMR data (Table 2)





46 **47**

48 **49**

By combining the information obtained from both types of experiments (H,H-COSY and H/D exchange), a full assignment of all the benzylic hydrogen atoms in the complexes *rac*-**24**, *rac*-**35** and *rac*-**8** could readily be made. The assignments for the other complexes (*rac*-**5**, *rac*-**28**, *rac*-**6**, *rac*-**7** and *rac*-**9**) could then be deduced by means of analogy. The assignments and the relevant coupling constants of the benzylic resonances are summarized in Table 2.

The data presented in Table 2 highlights the close relationship between the following pairs of complexes: *rac*-**24**/*rac*-**35**, *rac*-**5**/*rac*-**7** and *rac*-**8**/*rac*-**9**. In all cases, the geminal coupling constants were measured as 16 ± 1 Hz. The vicinal coupling constants for the pseudoaxial hydrogen atoms (H_b and H_d) were found to be 11 ± 1 Hz, those for the pseudoequatorial hydrogen atoms (H_a and H_c) 5 ± 1 Hz. Apart from in the case of the hexahydronaphthofuran complexes *rac*-**28** and *rac*-**6**, the chemical shifts of the pseudoaxial hydrogen atoms (H_b and H_d) lie in the range δ = 2.1−2.4 and those for the pseudoequatorial hydrogen atoms (H_a and H_c) in the range δ = 2.5−2.8. The uncomplexed ligands show the corresponding signals at δ = 2.42 ± 0.03 (^3J = 9−12 Hz, pseudoaxial H) and at δ = 2.73 ± 0.05 (^3J = 4−5 Hz, pseudoequatorial H). These apparent similarities of the ^{1}H-NMR data reflect the very close structural relationship of the complexes and indicate that the complexation does not cause major conformational changes of the arene ligands. The ^{13}C-NMR data (see Experimental Section) also support this picture.

Deprotonation Studies

Having assigned the signals of the relevant benzylic protons, the regioselectivity of the deprotonation was deter-

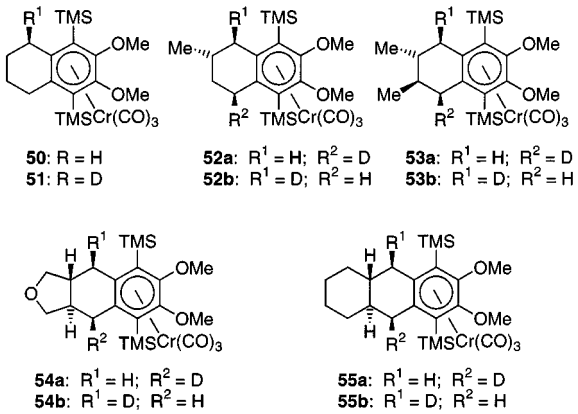
[a] ^{1}H-NMR ($CDCl_3$) data for the benzylic hydrogens of the various complexes: chemical shifts (δ) are given in ppm and coupling constants (*J*) in Hz. The uncertainty in the *J* values is estimated to be ± 0.5–1.0 Hz.

mined by lithiation of the various complexes (*rac*-**5**, *rac*-**6, rac**-**7**, *rac*-**8** and *rac*-**9**) followed by deuteration. Lithiation was carried out under conditions similar to those employed previously for the selective alkylation of **1** (see above). Preliminary experiments employing complexes *rac*-**1** and **50**[31] had shown that *n*-butyllithium in THF in the presence of hexamethyl phosphoric triamide (HMPA) as cosolvent represents a very suitable system[32]. In the absence of HMPA, significantly lower degrees of deuteration were observed.

In a typical experiment, the complex was dissolved in the solvent mixture (THF/HMPA, 10:1) and 1.5–3 equivalents of *n*-butyllithium was added. The development of a red color indicated the formation of a benzylic lithiated intermediate[3c]. Deuteration was then achieved by injecting D_2O or the more acidic D^+ source CF_3CO_2D. The latter had to be used in order to obtain a reasonably fast protonation of the anions derived from *rac*-**5** and *rac*-**7**, whereas the protonation of the anions derived from *rac*-**1** and **50** proceeded very rapidly, even with D_2O. After extractive work-up, the reisolated (deuterated) starting material was purified by chromatography and recrystallization. The degree and regioselectivity of the deuteration were then analyzed by means of ^{1}H-NMR spectroscopy[33] based on the assignments for the benzylic hydrogen atoms given above (Table 2). The purified deuterated samples were usually obtained in yields of 40–70%. In some experiments, losses were caused due to partial desilylation or decomplexation.



In particular, it should be noted that no suitable conditions were found for the deprotonation of complexes *rac*-**8** and *rac*-**9** with *n*-butyllithium. These compounds preferentially underwent desilylation (*rac*-**9**) or gave rise to a mixture of decomplexed substances after the usual work-up procedure (*rac*-**8**). In a preliminary experiment, it was shown that deprotonation of *rac*-**8** with *s*-butyllithium in THF at –100 °C occurs unselectively at the (less hindered) aryl positions, thus giving rise to a 1:1 mixture of the 6- and 7-methylated products upon treatment of the lithiated intermediates with methyl iodide.

The results of the various deuteration experiments are summarized in Table 3. The most important results are as

Table 3. Selective benzylic deprotonation/deuteration experiments[a]

Entry	Starting complex	Product(s)[b]	Conditions[b]	Degree of deuteration [%]	Regioselectivity [c]
1	**50**	*rac*-**51**	B	95 ± 2	–

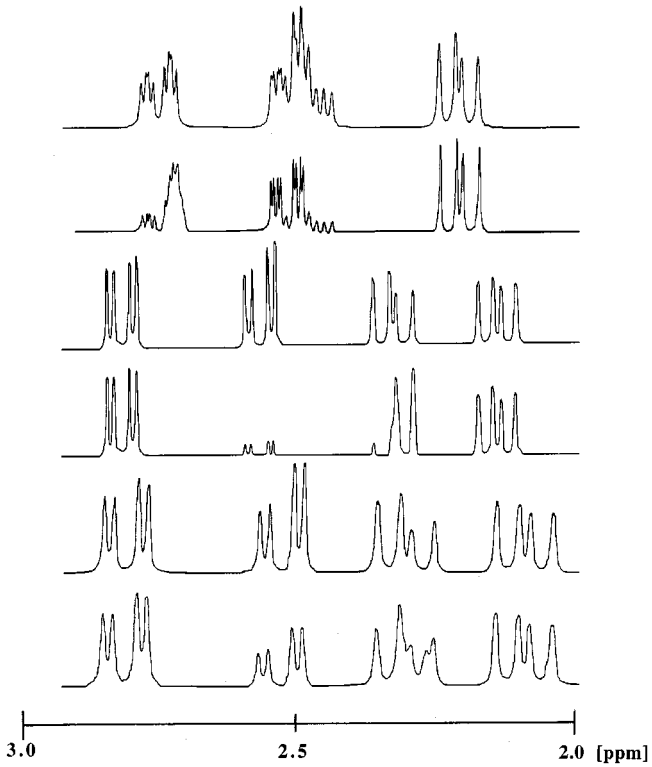
[a] Results of the deprotonation/deuteration experiments with *n*BuLi. – [b] A: 2 equiv. *n*BuLi; THF/HMPA, 10:1, −78°C → 25°C, 30 min, then CF_3COOD, −78°C → 25°C, 30 min; B: 1.5 equiv. *n*BuLi; THF/HMPA, 10:1, −70°C → 25°C, 15 min, then D_2O, 25°C, 15 min; C: 3 equiv. *n*BuLi; THF/HMPA, 10:1, 25°C, 30 min, then D_2O, 25°C, 30 min. – [c] Determined by means of ^{1}H-NMR spectroscopy on the assumption that a deviation ≥ 5% of the integrals of the benzylic hydrogen atoms must result from deuteration. – [d] In this case, the product mixture was completely desilylated with TBAF/SiO_2 before the degree of deuteration was determined. – [e] In this case, the lithiated intermediate was protonated by addition of CF_3COOH. – [f] According to the ^{1}H-NMR spectrum, ca. 15% of the high overall deuteration occurred at the C-4 position (*exo*-pseudoaxial).

Figure 8. ^{1}H-NMR signals ($CDCl_3$) of the benzylic protons for the following complexes (from top to bottom): *rac*-**1**, *rac*-**52a** (90% D), *rac*-**5**, *rac*-**53b** (80% D), *rac*-**7** and *rac*-**55b** (50% D)



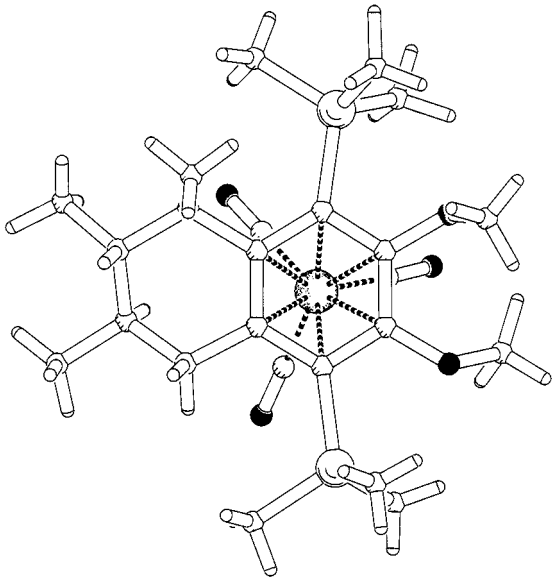
follows: (a) High regioselectivities were observed in the case of *rac*-**1**, *rac*-**5** and *rac*-**7** (see Table 3, entries 2–5, 7; see also Figure 8); (b) in contrast, *rac*-**6** showed only a very low regioselectivity (Table 3, entry 6); (c) the regioselectivity of the deprotonation of *rac*-**5** and *rac*-**7** indicates that the pseudoequatorial benzylic *exo*-hydrogen atoms were abstracted (formation of *rac*-**53b** and *rac*-**55b**), while the deprotonation of *rac*-**1** afforded selectively the *exo*-pseudoaxially deuterated product *rac*-**52a** as expected (see Scheme 1); (d) when the already deuterated complexes *rac*-**53b** and *rac*-**55b** were subjected to a second deprotonation/deuteration cycle, the degree of deuteration was further enhanced (Table 3, entries 8 and 10)[34]; (e) in accordance with the latter experiments, the corresponding deprotonation (dedeuteration)/protonation cycle (Table 3, entries 9 and 11) resulted mainly in the loss of the deuterium substitution (reversion to *rac*-**5** and *rac*-**7**). This also demonstrates that proton (or D^+) abstraction and reprotonation (redeuteration) occur at the same position[35].

In order to evaluate the synthetic potential of the aforementioned highly regioselective deprotonations, we also tried to trap the lithiated intermediates by alkylation and acylation. In the case of *rac*-**5**, treatment of the anion with methyl iodide or acetyl chloride afforded the products *rac*-**56** and *rac*-**57**, respectively, in good yields (Scheme 9). The relative configurations of these compounds were determined by means of ^{1}H-NMR spectroscopy and, in the case of *rac*-**56**, by X-ray crystallography as well (Figure 9)[36]. The results gave an independent proof that the benzylic deprotonation of *rac*-**5** occurs regioselectively at the pseudoequatorial position (H_c, see Figure 6), thereby corroborating the results of the deuteration studies described above. In contrast, the corresponding methylation and acetylation products derived from *rac*-**7** were found to be highly unstable and therefore of little synthetic value[37].

Discussion and Additional Experiments

The experimental results described in the previous section clearly show (for the cases of *rac*-**1**, *rac*-**5** and *rac*-**7**) that benzylic deprotonation of (arene)$Cr(CO)_3$ complexes can proceed with remarkably high regioselectivity, even if the position of the proton abstraction cannot a priori be predicted using the usual electronic arguments. Additionally, *our initial assumption that pseudoaxial benzylic hydrogen atoms are preferentially abstracted as a result of commonly invoked stereoelectronic factors*[8] *(see Introduction) has clearly been disproved* as, in contrast to the deprotonation

Figure 9. X-ray crystal structure of *rac*-**56**



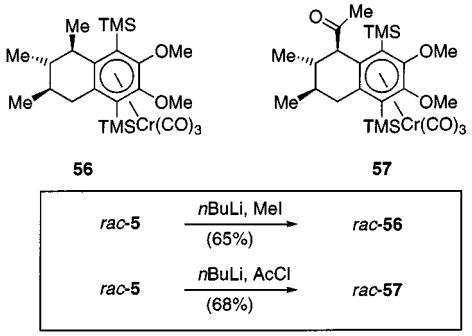
of *rac*-**1**, complexes *rac*-**5** and *rac*-**7** were selectively deprotonated at their pseudoequatorial positions.

The inspection of molecular models suggests an almost comparable steric environment at the competing benzylic positions in all cases. It is therefore unlikely that the complete reversal of the regioselectivity (changing from *rac*-**1** to *rac*-**5** or *rac*-**7**, respectively) is due to a simple steric effect.

At this point, we asked ourselves whether the conformation of the $Cr(CO)_3$ tripod could possibly have an influence on the regioselectivity of the benzylic deprotonation. Could such a previously unnoted or even cursorily excluded[38] effect be responsible for the observed selectivities?

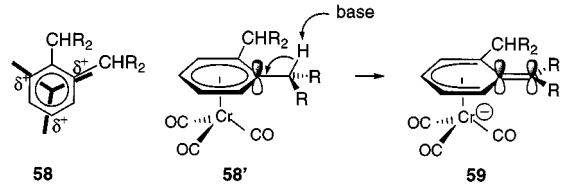
It is a broadly accepted hypothesis that the regioselectivity of kinetically controlled nucleophilic additions to (arene)chromium complexes is influenced by the preferred conformation of the $Cr(CO)_3$ tripod[1a]. This picture is based on the assumption that in the case of charge-controlled reactions, those arene carbon atoms that are eclipsed by a Cr−CO bond are preferentially attacked by a nucleophile due to the positive charge induced by the eclipsing CO ligand[39][40][41][42][43]. Analogous arguments have also been advanced in connection with regioselective ring lithiations of (arene)$Cr(CO)_3$ complexes[44].

Scheme 9



In a similar fashion, one could imagine that the (kinetic) acidity of a benzylic proton increases with an increasing positive partial charge at the adjacent arene center. Thus, if one of two competing benzylic positions is eclipsed by a CO ligand (substructure **58**), the proton abstraction at this center should be (stereoelectronically) favored (Figure 10).

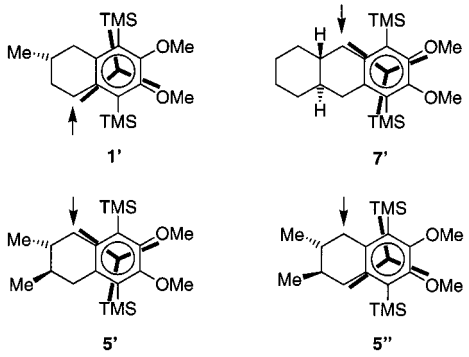
Figure 10. Explanation of the stereoelectronic effect resulting in the preferred deprotonation of those benzylic hydrogen atoms which are activated by an eclipsed CO ligand



The resulting anionic species (which is best represented by a formula of type **59**[45]) should also preferentially adopt an eclipsed conformation, since the deprotonated side-chain represents a strong donor substituent at the (arene)$Cr(CO)_3$ nucleus[46].

Further inspection of the crystal structures of the substrates *rac*-**1**, *rac*-**5** and *rac*-**7** (see above) revealed that in the case of *rac*-**1** and *rac*-**7**, the benzylic center at which the deprotonation preferentially takes place is indeed eclipsed by a CO ligand in the crystalline state (as indicated by the arrow in Figure 11). However, as mentioned above, the crystals of *rac*-**5** were found to contain two independent molecules with different conformations (**5′** and **5′′**), of which only one conformer (**5′**) reflected the observed regioselectivity of deprotonation (Figure 11).

Figure 11. Preferred conformation of the $Cr(CO)_3$ tripod (depicted by the bold lines) for complexes **1**, **7** and **5** as found in their crystal structures; the arrows mark those benzylic positions which were found to be preferentially attacked by *n*-BuLi

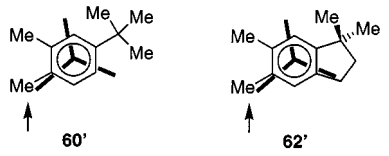


Of course, one can never unequivocally conclude a preferred conformation in solution from a crystal structure. More importantly, if the equilibration of the $Cr(CO)_3$ conformers[47] takes place rapidly compared to the deprotonation, the Curtin-Hammett principle[48] should apply and the regioselectivity would only be governed by the difference in energy between the competing transition states. Nevertheless, as mentioned above for nucleophile additions to (arene)$Cr(CO)_3$ complexes, the preferred conformation of the $Cr(CO)_3$ tripod may have an influence on the regioselectivity of attacking reagents. In such cases, the same fac-

tors determining the preferred ground state conformation also seem to be effective in the transition state and the most stable transition state is derived from the most stable ground state conformation (principle of least motion)[49]. In other words, the deprotonation is accompanied by a change of the overall electronic structure and the position of all atoms involved (delocalization). Therefore, the rate of proton transfer should be enhanced if the degree of structural and electronic reorganization is minimal[50].

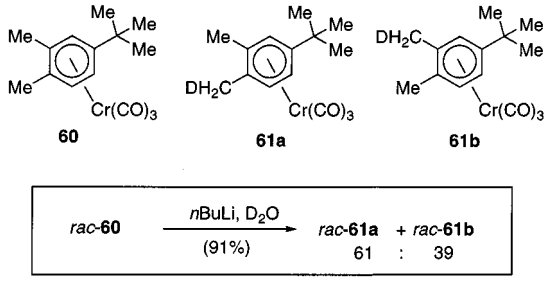
To probe the general applicability of this theory, we investigated the regioselectivity of the deprotonation/deuteration of complex *rac*-**60**[51] employing our tried and tested conditions (*n*-BuLi, D_2O). This substrate had previously been examined by Brocard[6d][38] under different conditions (*t*BuOK, DMSO, CH_2O), but no selectivity was observed. Due to the bulkiness of the *tert*-butyl group, *rac*-**60** should adopt the conformation depicted in formula **60′**. Accordingly, we would predict that the deprotonation should occur preferentially at the methyl group *para* to the *tert*-butyl substituent (as indicated by the arrow in Figure 12).

Figure 12. Lowest energy conformation of complexes **60** and **62**; the arrows mark those benzylic positions which are expected to be preferentially attacked by a base



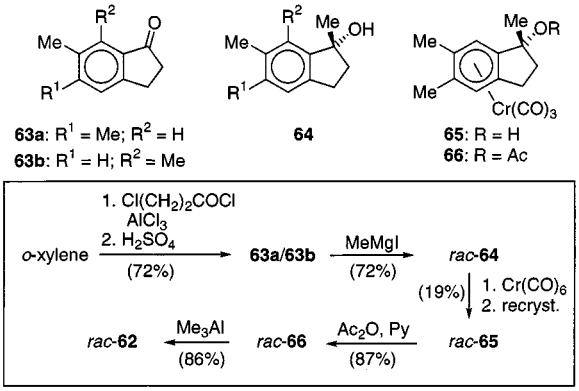
Indeed, when *rac*-**60** was first treated with *n*-butyllithium in THF at −78°C and then the resulting red solution was quenched with D_2O, a 61:39 mixture of the monodeuterated products *rac*-**61a** and *rac*-**61b** was isolated in high yield (Scheme 10)[52].

Scheme 10



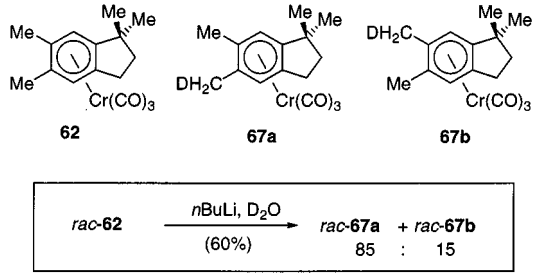
As a second probe of our hypothesis, we also studied complex *rac*-**62**, which was synthesized as indicated in Scheme 11. Thus, Friedel-Crafts acylation of *o*-xylene with 3-chloropropionic chloride and subsequent acid-catalyzed cyclization[53] afforded a 3:1 mixture of the indanones **63a**[54] and **63b**. After treatment with methylmagnesium iodide (→ *rac*-**64**) and (*endo*-selective)[55] complexation, the resulting mixture of regioisomeric indanol complexes was separated by fractional crystallization to furnish the pure regioisomer *rac*-**65**. *O*-Acetylation followed by treatment of the resulting acetate *rac*-**66** with trimethylaluminum[56] finally gave the desired complex *rac*-**62**.

Scheme 11



When *rac*-**62** was subjected to the proven deprotonation/deuteration conditions, the monodeuterated isomers *rac*-**67a** and *rac*-**67b** were formed in a ratio of 85:15 (Scheme 12). The assignments were unambiguously confirmed by NOE measurements. As in the case of *rac*-**60**, the regioselectivity of the benzylic deprotonation of *rac*-**62** can be understood in terms of a conformational picture (see Figure 12) and the assumption that the proton abstraction occurs predominantly at the methyl group that is activated by the eclipsing CO ligand.

Scheme 12



Conclusion

A series of conformationally restricted (arene)$Cr(CO)_3$ complexes has been synthesized and the regioselectivity of their benzylic deprotonation has been investigated. Our findings show that high regioselectivities can be obtained even in cases where no major electronic or steric effects are operative. The original assumption that pseudoaxially oriented hydrogen atoms are preferentially attacked by the base due to stereoelectronic reasons was clearly refuted by experiments employing (η^6-tetralin)- and (η^6-*trans*-octahydroanthracene)$Cr(CO)_3$ derivatives (*rac*-**5** and *rac*-**7**, respectively). On the other hand, experiments with the complexes *rac*-**60** and *rac*-**62** indicated that the conformation of the $Cr(CO)_3$ tripod exerts an influence on the regioselectivity.

Based on our current level of understanding, we wish to draw the following general picture: In the case of (arene)$Cr(CO)_3$ complexes with two competing benzylic positions, deprotonation occurs preferentially at that position

where the adjacent aryl center bears the greater positive partial charge. In the case of unambiguous electronic circumstances, the conformation of the $Cr(CO)_3$ tripod plays only a minor role[2][6], merely reflecting (and possibly amplifying) the polarization induced by the substituents. Should, however, the electronic effects not lead to a favorization of one position (e.g. due to a symmetric substitution pattern or the absence of polar substituents), the preferred conformation of the $Cr(CO)_3$ tripod may become important. In such cases, those benzylic positions which are eclipsed by a CO ligand in the lowest energy conformation are preferentially deprotonated (kinetic stereoelectronic effect).

It must be emphasized that this picture is as yet rather an empirical one and it would be interesting if it could be supported by quantum-chemical calculations and by more detailed structural information on the intermediates resulting from benzylic deprotonation of (arene)$Cr(CO)_3$ complexes. Investigations in this area are currently being performed in this laboratory.

Höhne* for recording the MS spectra, and to Ms. *C. Klose* for recording the IR spectra. A 600-MHz NMR spectrum of *rac*-**67** was kindly provided by Dr. *P. Schmieder*, Institute of Molecular Pharmacology, Berlin.

Experimental Section

General: Manipulations involving air-sensitive compounds were carried out under argon using Schlenk and syringe techniques. Anhydrous solvents were obtained by distillation from sodium benzophenone ketyl (THF and diethyl ether), from P_2O_5 (CCl_4), from CaH_2 (HMPA), or by filtration through ICN Alumina B Grade Super 1 (toluene and nBu_2O). Reagents (generally ≥ 98%) were used as received from Aldrich, Fluka, Merck, Acros and Chemetall without further purification, unless otherwise stated. The concentration of organolithium solutions was determined by titration with menthol in THF in the presence of 1,10-phenanthroline[57]. The organic solutions resulting from aqueous work-up were concentrated under reduced pressure using a rotary evaporator. All reactions were monitored by analytical thin-layer chromatography (TLC) using Merck silica gel 60 F 254 glass plates. The chromatograms were visualized with UV light or by staining with a cerium reagent (prepared by dissolving 2 g of phosphomolybdic acid and 1 g of cerium(IV) sulfate in a mixture of 10 ml conc. H_2SO_4 and 90 ml EtOH] followed by heating. Flash chromatography[58] was performed on silica gel 60 (230−400 mesh) from Merck. Preparative thin-layer chromatography (PTLC) was carried out using a chromatotron (Harrison Research Model 7924 T) on glass plates coated with 1−4 mm layers of silica gel containing gypsum (Merck PF 60 F 254). NMR spectra were recorded in $CDCl_3$ with Bruker instruments (AM 250, AM 270 or AM 400) using residual undeuterated solvent as an internal reference. The spectra are reported in ppm relative to tetramethylsilane using the following abbreviations to express the multiplicities: s = singlet; d = doublet; t = triplet; q = quadruplet; br = broad. ^{13}C chemical shifts were determined from ^1H-decoupled spectra, the number of protons bound directly to each carbon atom was determined employing the DEPT sequence[59] (q = CH_3; t = CH_2; d = CH; s = quaternary carbon atoms). Mass spectrometry was carried out at 70 eV using a Varian MAT 711 instrument. Infrared spectra were obtained using a Nicolet Magna FT-IR 750 instrument. Optical rotations were measured with a Perkin-Elmer 241 polarimeter, concentrations (*c*) are given in g/100 ml. Melting points were measured in open capillary tubes and are uncorrected.

1,2-Dichloro-4,5-dimethoxybenzene (**17**)[14a]: To 46 ml (0.36 mol) of veratrole (**16**), 66 ml (0.82 mol) of sulfuryl chloride was added dropwise over a period of 30 min. The mixture was stirred for 1 h at room temp. and, after fitting the flask with a reflux condenser, was heated to 80°C for 2 h. The reflux condenser was then replaced by a distillation set-up and the excess sulfuryl chloride was distilled off under reduced pressure (ca. 100 Torr). On cooling the mixture to room temp., a solid formed, which was washed with cold hexane (2 × 20 ml) and recrystallized from EtOH (30 ml) at 4°C yielding 57.70 g (77%) of **17** as colorless crystals, m.p. 82.5°C (ref.[14a]: m.p. 84°C). − R_f = 0.23 (hexane/EtOAc, 10:1). − IR (KBr): $\tilde{\nu}$ = 3003 (w), 2965 (w), 2937 (w), 2906 (w), 2836 (w), 1508 (m), 1432 (m), 1363 (m), 1260 (m), 1211 (m), 1179 (m), 1132 (m), 1027 (m), 920 (m), 840 (m), 794 (m), 678 (m), 1594 (w), 1337 (w), 1190 (w) cm^{-1}. − ^1H NMR (270 MHz): δ = 3.85 (s, 6 H), 6.91 (s, 2 H). − MS *m/z* (%): 208 (64), 206 [M^+] (98), 193 (32), 191 (50), 165 (8), 163 (13), 130 (8), 128 (25), 113 (12), 99 (16). − $C_8H_8Cl_2O_2$ (207.06): calcd. C 46.23, H 3.88; found C 46.46, H 3.99.

1,2-Dimethoxy-4,5-dimethylbenzene (**18**)[14b]: To a stirred solution of **17** (15 g, 72.2 mmol) in anhydrous diethyl ether (150 ml) was added methyllithium (100 ml, 160 mmol, 1.6 M in ether) at −20°C. The reaction flask was fitted with a reflux condenser and the temperature was allowed to rise to −7°C. At this point, an exothermic reaction took place, which was moderated by means of a suitably sized cooling bath. The cooling bath was then replaced by an oil bath and the brown solution was refluxed for 2 h. After cooling to 0°C, the reaction mixture was carefully quenched with 150 ml of water. The resulting mixture was extracted twice with diethyl ether, and the combined extracts were washed with 2 N HCl, saturated $NaHCO_3$ and brine, and dried with $MgSO_4$. The solvent was removed in vacuo and the dark-brown residue was kugelrohr-distilled (61°C, 0.6 Torr) yielding 8.08 g (67%) of **18** as a colorless oil, which solidified on standing; m.p. 42.5°C (ref.[14b]: m.p. 43°C). − R_f = 0.28 (hexane/EtOAc, 10:1). − IR (KBr): $\tilde{\nu}$ = 2999 (m), 2939 (m), 2846 (m), 1607 (m), 1519 (br), 1469 (s), 1394 (m), 1336 (s), 1266 (s), 1120 (br), 1105 (br), 997 (s), 854 (s), 828 (m), 732 (w) cm^{-1}. − ^1H NMR (270 MHz): δ = 2.20 (s, 6 H), 3.84 (s, 6 H), 6.67 (s, 2 H). − $C_{10}H_{14}O_2$ (166.22): calcd. C 72.26, H 8.49; found C 72.19, H 8.53.

1,2-Bis(bromomethyl)-4,5-dimethoxybenzene (**19**)[14c]: To a suspension of 3 g of powdered molecular sieves (4 Å) in 125 ml anhydrous CCl_4 was added **18** (5.0 g, 30.1 mmol), anhydrous NBS (10.76 g, 60.2 mmol) and AIBN (10 mg) and the mixture was refluxed for ca. 1 h whilst being irradiated with a 200-W lamp (Note: On completion of the reaction, the slightly reddish solution turns completely colorless). The mixture was then allowed to cool to room temp. and filtered successively through short pads of Celite and silica 60. After removing the solvent in vacuo, a slightly yellow oil was obtained, which crystallized spontaneously. Recrystallization from hexane/EtOAc (3:1) yielded 7.03 g (72%) of **19** as yellowish needles, m.p. 105°C (ref.[14c]: m.p. 109°C). − R_f = 0.27 (hexane/EtOAc, 4:1). − IR (KBr): $\tilde{\nu}$ = 3002 (w), 2954 (w), 2904 (w), 2828 (w), 1522 (s), 1460 (m), 1402 (w), 1357 (m), 1277 (s), 1239 (m), 1203 (s), 1127 (s), 1090 (m), 1032 (w), 1000 (m), 896 (w), 872 (m), 748 (m), 670 (w) cm^{-1}. − ^1H NMR (270 MHz): δ = 3.90 (s, 6 H),

4.63 (s, 4 H), 6.84 (s, 2 H). − MS; *m/z* (%): 324 [MH_2^+] (10), 323 [MH^+] (6), 245 (60), 243 (60), 231 (10), 229 (10), 165 (24), 163 [$MH^+ - 2Br$] (100), 149 (16), 121 (25). − $C_{10}H_{12}Br_2O_2$ (324.01): calcd. C 37.07, H 3.73; found C 36.58, H 3.66.

Diethyl (2RS,3RS)-6,7-Dimethoxy-1,2,3,4-tetrahydronaphthalene-2,3-dicarboxyate (*rac*-**20**): A solution of **19** (6.48 g, 20 mmol) and 10 ml (62.8 mmol) of diethyl fumarate in 200 ml of anhydrous THF was cooled to 0°C. To this was added 6.8 g (55.4 mmol) of chromium(II) chloride (Merck, assay ca. 90%) to give a greenish suspension that rapidly turned purple. The mixture was kept at 0°C for 5 h, then the ice-bath was removed and the deep-purple solution was stirred at room temp. for 1 h; 50 ml H_2O was added and after 5 min the mixture was extracted with hexane/EtOAc (2:1, 3 × 100 ml). The combined organic layers were washed with brine and dried with $MgSO_4$. The solvent was removed under reduced pressure and the remaining oil was crystallized from hexane/EtOAc (3:1) yielding 4.44 g (66%) of the Diels-Alder product *rac*-**20** as colorless crystals. An analytical sample was additionally purified by PTLC (hexane/EtOAc, 3:1), m.p. 80°C. − R_f = 0.29. − IR (KBr): $\tilde{\nu}$ = 2991 (m), 2963 (m), 2940 (m), 2920 (m), 2837 (m), 1728 (br, C=O), 1611 (s), 1518 (s), 1467 (s), 1378 (s), 1302 (s), 1247 (s), 1182 (s), 1116 (s), 1020 (s), 997 (s), 919 (m), 849 (s) cm^{-1}. − ^1H NMR (250 MHz): δ = 1.28 (t, *J* = 7.1 Hz, 6 H), 2.97 (m, 6 H), 3.84 (s, 6 H), 4.17 (q, *J* = 7.1 Hz, 4 H). − MS; *m/z* (%): 336 [M^+] (19), 291 (4), 262 (6), 189 (14), 115 (18), 100 (18), 57 (100). − $C_{18}H_{24}O_6$ (336.39): calcd. C 64.28, H 7.19; found C 64.17, H 7.12.

(2RS,3RS)-2,3-Bis(hydroxymethyl)-6,7-dimethoxy-1,2,3,4-tetrahydronaphthalene (*rac*-**21**): 0.5 g (13.2 mmol) of $LiAlH_4$ was added in small amounts to a solution of 2.02 g (6 mmol) of *rac*-**20** in anhydrous diethyl ether over a period of 10 min. The suspension was heated to 30°C on a water bath for 40 min, cooled to 0°C, and then quenched by the dropwise addition of 10 ml EtOAc followed by 80 ml of 2 N HCl. The mixture was stirred until all the precipitated aluminates had dissolved and was then extracted with hexane/EtOAc (1:10, 6 × 50 ml) (Note: The resulting diol *rac*-**21** shows a surprisingly high solubility in water; longer reaction times lead to an increased formation of by-products). The combined organic extracts were washed with saturated aqueous $NaHCO_3$ and brine, and dried with $MgSO_4$. The solvent was removed in vacuo and the colorless oil was crystallized from EtOAc yielding 1.28 g (86%) of the diol *rac*-**21** as colorless crystals, m.p. 135°C. − R_f = 0.23 (EtOAc). − IR (KBr): $\tilde{\nu}$ = 3481 (br, OH), 3386 (br, OH), 2906 (m), 2833 (C−H), 1517 (s), 1462 (m), 1353 (m), 1242 (s), 1219 (m), 1123 (s), 1098 (m), 1065 (m), 1027 (m), 988 (m), 895 (w), 849 (w), 745 (w) cm^{-1}. − ^1H NMR (270 MHz): δ = 1.83 (m, 2 H), 2.56 (dd, J_1 = 10.1 Hz, J_2 = 15.7 Hz, 2 H), 2.69 (dd, J_1 = 4.0 Hz, J_2 = 16.6 Hz, 2 H), 2.95 (br, 2 H, exchanges with D_2O), 3.65 (dd, J_1 = 6.3 Hz, J_2 = 10.9 Hz, 2 H), 3.78 (dd, J_1 = 3.3 Hz, J_2 = 10.9 Hz, 2 H), 3.83 (s, 6 H, OMe), 6.59 (s, 2 H). − MS; *m/z* (%): 252 [M^+] (100), 220 (20), 203 (75), 189 (14), 188 (15), 165 (25), 164 (32), 71 (30), 69 (41), 57 (88), 55 (70). − $C_{14}H_{20}O_4$ (252.31): calcd. C 66.65, H 7.79; found C 66.37, H 7.91.

(2RS,3RS)-6,7-Dimethoxy-2,3-bis(tosyloxymethyl)-1,2,3,4-tetrahydronaphthalene (*rac*-**22**): A stirred solution of 2.15 g (8.5 mmol) of diol *rac*-**21** in 25 ml of anhydrous pyridine was cooled to 0°C and 7.65 g (40 mmol) of *p*-toluenesulfonyl chloride was added within 5 min. The orange-red solution was stirred at this temperature for 1 h and then kept at 4°C for 24 h. The solution was then poured slowly into a vigorously stirred mixture of 100 ml conc. HCl, 100 g of ice and 200 ml of CH_2Cl_2, and stirring was continued while the mixture was allowed to warm to room temp. The layers were then separated and the aqueous layer was extracted with CH_2Cl_2 (2 × 100 ml). The combined organic layers were washed with saturated aqueous $NaHCO_3$ and brine, and dried with $CaCl_2$. The solvent was removed under reduced pressure and 50 ml of EtOAc was added, whereupon 3.729 g (78%) of bis(tosylate) *rac*-**22** precipitated as a colorless crystalline powder, m.p. 150°C. − R_f = 0.27 (hexane/EtOAc, 1:1). − IR (KBr): $\tilde{\nu}$ = 3000 (w), 2939 (w), 2834 (w), 1597 (m), 1519 (s), 1468 (m), 1350 (s), 1248 (s), 1175 (s), 1100 (s), 950 (s), 868 (m), 835 (s), 779 (m), 665 (s) cm^{-1}. − ^1H NMR (270 MHz): δ = 2.04 (m, 2 H), 2.46 (s, 6 H), 2.52 (dd, J_1 = 7.2 Hz, J_2 = 16.4 Hz, 2 H), 2.68 (dd, J_1 = 4.5 Hz, J_2 = 16.6 Hz, 2 H), 3.81 (s, 6 H), 3.97 (d, *J* = 4.8 Hz, 4 H), 6.48 (s, 2 H), 7.35 (d, *J* = 8.1 Hz, 4 H), 7.76 (d, *J* = 8.3 Hz, 4 H). − MS; *m/z* (%): 560 [M^+] (22), 388 (4), 258 (4), 234 (4), 220 (4), 69 (60), 57 (100), 55 (88). − $C_{28}H_{32}O_8S_2$ (560.68): calcd. (2RS,3RS)-6,7-Dimethoxy-2,3-dimethyl-1,2,3,4-tetrahydronaphthalene (*rac*-**23**): 2.00 g (3.6 mmol) of the ditosylate *rac*-**22** was dissolved in 80 ml of anhydrous diethyl ether and 0.5 g of $LiAlH_4$ was added portionwise. The suspension was refluxed for 30 min, then allowed to cool to room temp., whereupon 10 ml of EtOAc was added dropwise, followed by 50 ml of 2 N HCl. The solution was stirred until all the precipitated aluminates had dissolved and was then extracted with hexane/EtOAc (2:1, 3 × 30 ml). The combined organic extracts were washed with saturated aqueous $NaHCO_3$ and brine, and dried with $MgSO_4$. The solvent was removed under reduced pressure and the colorless residue was purified by PTLC (4 mm layer SiO_2; hexane/EtOAc, 10:1) yielding 642 mg (81%) of *rac*-**23** as colorless, clear crystals, m.p. 82°C. − R_f = 0.25 (hexane/EtOAc, 10:1). − IR (KBr): $\tilde{\nu}$ = 2988 (m), 2955 (m), 2927 (m), 2880 (m), 2854 (m), 2832 (m), 1520 (s), 1465 (m), 1450 (m), 1247 (s), 1224 (s), 1112 (s), 1003 (m), 850 (m) cm^{-1}. − ^1H NMR (270 MHz): δ = 1.03 (d, *J* = 6.1 Hz, 6 H), 1.48 (m, 2 H), 2.39 (dd, J_1 = 10.4 Hz, J_2 = 15.7 Hz, 2 H), 2.73 (dd, J_1 = 3.4 Hz, J_2 = 16.8 Hz, 2 H), 3.83 (s, 6 H), 6.56 (s, 2 H). − ^{13}C NMR (62.7 MHz): δ = 19.5 (q), 35.4 (d), 38.0 (t), 55.6 (q), 111.4 (d), 128.7 (s), 146.9 (s). − MS; *m/z* (%): 221 (16), 220 [M^+] (100), 205 (12), 189 (8), 164 (65), 151 (8), 149 (7), 121 (7). − $C_{14}H_{20}O_4$ (252.31): calcd. C 76.33, H 9.15; found C 75.94, H 9.12.

(2RS,3RS,8aSR)-Tricarbonyl(η⁶-6,7-dimethoxy-2,3-dimethyl-1,2,3,4-tetrahydronaphthalene)chromium(0) (*rac*-**24**): A 50-ml Schlenk flask equipped with a reflux condenser and an Hg bubbler was flame-dried in vacuo and flushed with argon. All connections were made air-tight by using Teflon sleeves. After charging with 1.19 g (5.4 mmol) of the ligand *rac*-**23** and 1.24 g (5.6 mmol) of $Cr(CO)_6$, 25 ml of nBu_2O was added and the whole apparatus was evacuated and flushed with argon several times. After adding 2.5 ml of anhydrous THF, the solution was refluxed at 150°C (oil-bath temperature) for 20 h, protected from light for most of the time. The clear, yellow solution thus obtained was allowed to cool to room temp., the solvents were removed in vacuo, and the residue was dissolved in ca. 25 ml of EtOAc. The resulting solution was filtered through a 2-cm pad of silica, the solvent was removed under reduced pressure, and the residue (yellow oil) was crystallized from hexane/EtOAc (3:1) yielding 1.48 g (78%) of the chromium complex *rac*-**24** as yellow cubes, m.p. 167°C. − R_f = 0.3 (hexane/EtOAc, 3:1). − IR (KBr): $\tilde{\nu}$ = 2969 (w), 2912 (w), 2842 (w), 1942 (br, C=O), 1874 (br, C=O), 1848 (br, C=O), 1949 (m), 1428 (m), 1266 (m), 1235 (m), 1113 (m), 991 (m), 675 (m), 633 (all m) cm^{-1}. − ^1H NMR (250 MHz)[60]: δ = 1.00 (d, *J* = 3.1 Hz, 3 H), 1.02 (d, *J* = 3.1 Hz, 3 H), 1.36 (m, 1 H), 1.53 (m, 1 H), 2.29 (dd, J_1 = 22.1 Hz, J_2 = 10.7 Hz, 1 H), 2.36 (dd, J_1 = 22.8 Hz, J_2 = 10.9 Hz, 1 H), 2.53 (dd, J_1 = 21.7 Hz, J_2 = 4.4 Hz, 1 H), 2.59 (dd, J_1 = 20.9 Hz, J_2 = 3.9 Hz, 1 H), 3.74 (s, 3 H), 3.78 (s, 3 H), 5.15 (s, 1 H)

5.18 (s, 1 H). − ^{13}C NMR (63 MHz): δ = 18.8 (q), 34.1 (d), 35.0 (d), 36.0 (t), 37.5 (t), 56.9 (q), 57.1 (q), 78.3 (d), 78.8 (d), 101.9 (s), 103.6 (s), 132.2 (s), 132.3 (s), 234.0 (s). − MS; *m/z* (%): 357 (8), 356 [M$^+$] (24), 300 (15), 273 (54), 272 (100), 243 (25), 242 (90), 220 (10), 186 (23), 164 (8). − $C_{17}H_{20}CrO_5$ (356.34): calcd. (2R,3R)-2,3-Bis(hydroxymethyl)-6,7-dimethoxy-1,2,3,4-tetrahydronaphthalene (**21**): To a solution of 0.48 g (1.1 mmol) of **26a** in 30 ml of dry diethyl ether was added 0.2 g (13.2 mmol) of $LiAlH_4$. The suspension was heated to reflux for 1 h, then cooled to 0°C, whereupon 10 ml of EtOAc was added dropwise, followed by 20 ml of 2 N HCl. The mixture was stirred until all the precipitated aluminates had dissolved and then extracted with hexane/EtOAc, (1:10, 5 × 25 ml) (Note: The resulting diol is rather soluble in water). The combined extracts were washed with saturated aqueous $NaHCO_3$ and brine, and dried with $MgSO_4$. The solvent was removed in vacuo and the resulting colorless oil was purified by PTLC (2-mm layer SiO_2; EtOAc) to yield 190 mg (76%) of diol **21** (> 99.4% *ee* according to HPLC), m.p. 135°C. − R_f = 0.23 (EtOAc). − Anal. HPLC (Daicel Chiralcel OJ, 0.7 ml/min, 254 nm): R_T (**21**) = 15.54 min; R_T (*ent*-**21**) = 14.10 min. − IR (KBr): ṽ = 3507 (br, OH), 3395 (br, OH), 2935 (m), 2908 (m), 2834 (m), 1611 (m), 1519 (s), 1460 (s), 1359 (m), 1254 (s), 1126 (s), 1063 (s), 998 (s) cm^{-1}. − ^{1}H NMR (270 MHz): δ = 1.82 (m, 2 H), 2.54 (dd, J_1 = 10.1 Hz, J_2 = 15.7 Hz, 2 H), 2.89 (dd, J_1 = 4.0 Hz, J_2 = 16.6 Hz, 2 H), 3.10 (br, 2 H, exchanges with D_2O), 3.64 (dd, J_1 = 6.3 Hz, J_2 = 10.9 Hz, 2 H), 3.78 (dd, J_1 = 3.3 Hz, J_2 = 10.9 Hz, 2 H), 3.83 (s, 6 H), 6.58 (s, 2 H). − $[\alpha]_D^{20}$ = −56, $[\alpha]_{578}$ = −58, $[\alpha]_{546}$ = −66, $[\alpha]_{436}$ = −122, $[\alpha]_{365}$ = −223 (*c* = 0.120 in $CHCl_3$). − MS; *m/z* (%): 252 [M$^+$] (100), 203 (98), 189 (17), 188 (18), 165 (46), 164 (26), 151 (13), 115 (13). − $C_{14}H_{20}O_4$ (252.31): calcd. C 66.65, H 7.79; found C 66.38, H 7.77.

(2R,3R)-6,7-Dimethoxy-2,3-bis(tosyloxymethyl)-1,2,3,4-tetrahydronaphthalene (**22**): 390 mg of the diol **21** was treated with 1.635 g (8.5 mmol) of *p*-TsCl in 10 ml of pyridine according to the procedure described above for the preparation of *rac*-**22**. Yield: 560 mg (67%) of the optically active ditosylate **22**. − M.p. 149°C. − R_f = 0.30 (hexane/EtOAc, 1:1). − IR (KBr): ṽ = 2998 (w), 2960 (w), 2901 (w), 2836 (w), 1515 (m), 1365 (s), 1176 (s), 968 (s), 853 (m), 553 (s) cm^{-1}. − ^{1}H NMR (270 MHz): δ = 2.05 (m, 2 H), 2.44 (s, 6 H), 2.53 (dd, J_1 = 7.2 Hz, J_2 = 16 Hz, 2 H), 2.67 (dd, J_1 = 5 Hz, J_2 = 17 Hz, 2 H), 3.81 (s, 6 H), 3.97 (d, *J* = 5 Hz, 4 H), 6.47 (s, 2 H), 7.35 (d, *J* = 8 Hz, 4 H), 7.76 (d, 4 H). − $[\alpha]_D^{20}$ = −14, $[\alpha]_{578}$ = −16, $[\alpha]_{546}$ = −19, $[\alpha]_{436}$ = −41, $[\alpha]_{365}$ = −73 (*c* = 0.494 in $CHCl_3$). − MS; *m/z* (%): 560 [M$^+$] (13), 430 (8), 388 (3), 272 (4), 234 (4), 233 (5), 217 (40), 216 (63), 204 (16), 203 (100), 201 (21), 189 (17), 188 (16), 58 (41). − HRMS: 560.1539 as calcd. for $C_{28}H_{32}O_8S_2$.

(2R,3R)-6,7-Dimethoxy-2,3-dimethyl-1,2,3,4-tetrahydronaphthalene (**23**): 841 mg (1.5 mmol) of the ditosylate **22** was treated with 240 mg (6.3 mmol) of $LiAlH_4$ in 50 ml of dry diethyl ether according to the procedure described above for the preparation of *rac*-**23**. 1-Bromo-2-(bromomethyl)-4,5-dimethoxybenzene (**31**): A solution of 5.05 g (30 mmol) of 3,4-dimethoxybenzyl alcohol (**30**) in 50 ml of dry benzene was cooled to 0°C and a solution of 1.60 ml (31 mmol) of Br_2 in 50 ml of dry benzene was added over a period of 20 min. Then, 5 ml of HBr (33% in AcOH) was added, the cooling bath was removed, and the red solution was stirred at ambient temperature for 30 min. The mixture was then sequentially washed with saturated aqueous $Na_2S_2O_3$ (50 ml), water (50 ml) and brine, and the organic solution was dried with $MgSO_4$. The solvent was removed under reduced pressure and the yellow, oily residue was crystallized from hexane/EtOAc (3:1) to yield 8.71 g (94%) of the dibromide **31** as thin, colorless needles, m.p. 81°C. − R_f = 0.35 (hexane/EtOAc, 3:1). − IR (CCl_4): $\tilde{\nu}$ = 3006 (w), 2959 (w), 2909 (w), 2841 (w), 1507 (s), 1464 (m), 1383 (m), 1262 (s), 1226 (s), 1210 (s), 1168 (s), 1036 (m) cm^{-1}. − ^1H NMR (270 MHz): δ = 3.87 (s, 3 H), 3.89 (s, 3 H), 4.59 (s, 2 H), 6.93 (s, 1 H), 7.02 (s, 1 H). − MS; *m/z* (%): 312 (7), 310 [M^+ + 2] (14), 308 [M^+] (6), 232 (20), 231 (99), 230 (20), 229 [MH^+ − Br] (100), 215 (5), 187 (7), 185 (9), 108 (13), 107 (17). − $C_9H_{10}Br_2O_2$ (309.99): calcd. C 34.77, H 3.25; found C 34.90, H 3.14.

(2RS)-2-(2′-Bromo-4′,5′-dimethoxybenzyl)cyclohexanone (*rac*-**32**): A stirred solution of diisopropylamine (4.65 ml, 33 mmol) in

100 ml anhydrous THF was cooled to −78°C and *n*-butyllithium (21 ml, 31.1 mmol, 1.48 M in hexane) was added by means of a syringe. After 20 min, a solution of cyclohexanone (4.7 ml, 36 mmol) in anhydrous THF (20 ml) was added slowly (over a period of ca. 30 min) and the resulting mixture was stirred for 10 min at −78°C. A solution of 9.3 g (30 mmol) of the dibromide **31** in anhydrous THF (50 ml) was then added over a period of 5 min, the temperature was allowed to rise, and stirring was continued for 3 h at 0°C and for 10 h at room temp. After quenching with 2 N HCl (100 ml), the mixture was extracted with EtOAc (3 × 100 ml). The combined organic extracts were washed with saturated aqueous $NaHCO_3$ and brine, and dried with $MgSO_4$. After removing the solvent in vacuo, the resulting yellow oil was purified by flash chromatography (hexane/EtOAc, 5:1) yielding 8.48 g (86%) of the alkylation product *rac*-**32** as a colorless oil, which solidified upon standing within 48 h. In addition, 1.01 g of the dialkylated by-product **36a** was obtained. An analytical sample of *rac*-**32** was recrystallized from hexane/EtOAc (5:1); m.p. 72°C. − R_f = 0.16 (hexane/EtOAc, 5:1). − IR (CCl_4): $\tilde{\nu}$ = 3003 (w), 2936 (m), 2858 (w), 2839 (w), 1713 (s, C=O), 1580 (s), 1497 (s), 1260 (s), 1233 (s), 1165 (s) cm^{-1}. − ^1H NMR (270 MHz): δ = 1.40 (m, 1 H), 1.60 (m, 2 H), 1.82 (m, 1 H), 2.04 (m, 2 H), 2.32 (m, 1 H), 2.38 (m, 1 H), 2.48 (dd, J_1 = 7.5 Hz, J_2 = 19 Hz, 1 H), 2.63 (m, 1 H), 3.20 (dd, J_1 = 6 Hz, J_2 = 19 Hz, 1 H), 3.90 and 3.93 (both s, 3 H), 6.77 and 6.95 (both s, 1 H). − ^{13}C NMR (63 MHz): δ = 25.2 (t), 28.0 (t), 33.7 (t), 35.2 (t), 42.2 (t), 51.0 (d), 55.9 (q), 56.0 (q), 114.2 (d), 115.2 (d), 131.6 (s), 147.8 (s), 147.9 (s), 212.3 (s). − MS; *m/z* (%): 328 (12), 326 [M^+] (12), 248 (17), 247 (100), 231 (55), 229 (57), 151 (11). − $C_{15}H_{19}BrO_3$ (327.22): calcd. C 55.02, H 5.89; found C 55.06, H 5.85.

2,2-Bis(2′-bromo-4′,5′-dimethoxybenzyl)cyclohexanone (**36a**): ^1H NMR (270 MHz): δ = 1.74−2.06 (m, 6 H), 2.52 (m, 2 H), 3.23 (AB signal, 4 H), 3.80 (s, 6 H), 3.85 (s, 6 H), 6.70 (s, 2 H), 6.98 (s, 2 H).

(1′RS)-1-Bromo-4,5-dimethoxy-2-(2′-methylenecyclohexylmethyl)benzene (*rac*-**33**): A suspension of 18.7 g of methyltriphenylphosphonium bromide in 250 ml of anhydrous THF was cooled to −78°C and *n*-butyllithium (29 ml, 47 mmol, 1.6 M in hexane) was added by means of a syringe. The temperature was allowed to rise to −30°C over a period of 30 min. At this point, 11.45 g of *rac*-**32** was added, the cooling bath was replaced by an oil bath, and the orange solution was refluxed for 1 h. The cooled mixture was then washed with water (2 × 30 ml) and brine, and dried with $MgSO_4$. The solvent was removed under reduced pressure and 100 ml of hexane was added to the residue, resulting in the precipitation of Ph_3PO. The solution was filtered through a pad of Celite and silica. The solvent was removed under reduced pressure yielding 11.35 g (> 99%) of the methylenated product *rac*-**33** as an essentially pure, slightly yellow oil, which crystallized within two weeks, m.p. 61°C. − R_f = 0.57 (hexane/EtOAc, 5:1). − IR (CCl_4): $\tilde{\nu}$ = 2934 (m, C−H), 3082 (w), 3002 (w), 2856 (w), 2839 (w), 1509 (s), 1496 (m), 1439 (m), 1219 (s), 1496, 1165 (m) cm^{-1}. − ^1H NMR (270 MHz): δ = 1.20 − 1.74 (m, 6 H), 2.08 (m, 1 H), 2.37 (m, 1 H), 2.66 (dd, J_1 = 5.5 Hz, J_2 = 14 Hz, 1 H), 3.00 (dd, J_1 = 9.5 Hz, J_2 = 14 Hz, 1 H), 5.60 (pseudo s, 1 H), 5.69 (pseudo s, 1 H), 6.66 (s, 1 H), 7.00 (s, 1 H). − ^{13}C NMR (63 MHz): δ = 24.6 (t), 28.6 (t), 32.7 (t), 35.3 (t), 38.4 (t), 43.3 (d), 56.0 (q), 56.1 (q), 105.8 (t), 113.8 (d), 114.6 (s), 115.4 (d), 132.5 (s), 147.7 (s), 148.0 (s), 152.3 (s). − MS; *m/z* (%): 326 (6), 324 [M^+] (7), 245 (32), 244 (24), 231 (98), 230 (100), 151 (6), 107 (6). − $C_{16}H_{21}BrO_2$ (325.25): calcd. C 59.09, H 6.51; found C 59.34, H 6.57.

(4aRS,9aRS)-6,7-Dimethoxy-1,2,3,4,4a,9,9a,10-octahydroanthracene (*rac*-**34**): To a refluxing solution of 1.63 g (5 mmol) of the olefin *rac*-**33** in 50 ml of dry benzene, a solution of 1.59 ml (5.2 mmol) of tributyltin hydride and 20 mg of azobis(isobutyronitrile) in 8 ml of dry benzene was added over a period of 5 h by means of a syringe pump. Refluxing was continued for 1 h, and then a solution of 5 g of KF in 20 ml of water was added to the cooled (room temp.) mixture. The resulting two-phase system was stirred vigorously overnight. The organic layer was separated and the aqueous layer was extracted with EtOAc (3 × 30 ml). The combined organic layers were washed with water (2 ×) and brine, and dried with $MgSO_4$. The solvent was removed under reduced pressure and the resulting colorless oil was purified by PTLC (4-mm layer SiO_2; hexane/CH_2Cl_2/EtOAc, 2:1:0.02). The product was finally crystallized from hexane to yield 810 mg (66%) of the cyclization product *rac*-**34** as clear, colorless prisms, m.p. 110°C. − R_f = 0.15 (hexane/CH_2Cl_2/EtOAc = 2:1:0.02). − IR (CCl_4): $\tilde{\nu}$ = 2998 (w), 2919 (m), 2854 (w), 2832 (w), 1518 (s), 1249 (m), 1224 (m), 1129 (w), 1112 (w) cm^{-1}. − ^1H NMR (270 MHz): δ = 1.06 (m, 2 H), 1.35 (m, 4 H), 1.84 (m, 4 H), 2.39 (dd, J_1 = 9 Hz, J_2 = 14.5 Hz, 2 H), 2.69 (dd, J_1 = 4.5 Hz, J_2 = 14.5 Hz, 2 H), 3.86 (s, 6 H), 6.56 (s, 2 H). − ^{13}C NMR (63 MHz): δ = 26.3 (t), 33.8 (t), 37.1 (t), 38.8 (d), 55.9 (q), 111.5 (d), 128.6 (s), 146.9 (s). − MS; *m/z* (%): 247 (18), 246 [M^+] (100), 231 (20), 229 (14), 206 (9), 164 (23), 151 (55), 149 (15), 57 (39), 55 (38). − HRMS: 246.1620 as calcd. for $C_{16}H_{22}O_2$.

(4aRS,8aSR,9aRS)-Tricarbonyl(η⁶-6,7-dimethoxy-1,2,3,4,4a,9,9a,10-octahydroanthracene)chromium(0) (*rac*-**35**): As described above for the preparation of *rac*-**24**, 1.06 g (4.3 mmol) of the ligand *rac*-**34** was heated with 0.99 g (4.5 mmol) of $Cr(CO)_6$ in 45 ml nBu_2O and 4.5 ml THF in a 100-ml Schlenk flask for 22 h at 150°C (oil-bath temperature). The resulting clear yellow solution was allowed to cool to room temp., whereupon a yellow precipitate formed. Cooling was continued in an ice bath for 1 h, and then the supernatant solution was carefully decanted off and the residue washed twice with cold diethyl ether. The yellow powder thus obtained was dried in vacuo to yield a first fraction of *rac*-**35**. The solvent of the decanted organic solution was removed in vacuo and the residue was purified by PTLC (1 mm SiO_2; hexane/EtOAc, 3:1). Recrystallization from EtOAc afforded 1.300 g (79%) of the complex *rac*-**35** as small yellow crystals, m.p. 201°C. − R_f = 0.38 (hexane/EtOAc, 10:1). − IR (KBr): $\tilde{\nu}$ = 2925 (w), 2854 (w), 1950 (s, C=O), 1874 (s, C=O), 1851 (s, C=O), 1495 (m) cm^{-1}. − ^1H NMR (270 MHz)[60]: δ = 0.96−1.54 (m, 6 H), 1.77 (pseudo dd, 4 H), 2.30 (dd, J_1 = 16 Hz, J_2 = 11.5 Hz, 1 H), 2.35 (dd, J_1 = 16 Hz, J_2 = 11 Hz, 1 H), 2.47 (dd, J_1 = 16.5 Hz, J_2 = 4 Hz, 1 H), 2.57 (dd, J_1 = 16.5 Hz, J_2 = 6 Hz, 1 H), 3.75 (s, 3 H), 3.79 (s, 3 H), 5.16 (s, 1 H), 5.20 (s, 1 H). − ^{13}C NMR (63 MHz, $CDCl_3$): δ = 25.8 (t), 26.0 (t), 33.1 (t), 34.7 (t), 36.4 (t), 37.2 (d), 38.2 (d), 57.0 (q), 57.1 (q), 78.3 (d), 79.0 (d), 101.7 (s), 103.4 (s), 132.2 (s), 132.3 (s), 234.1 (s). − MS; *m/z* (%): 382 [M^+] (16), 326 [M^+ − 2CO] (6), 299 (36), 298 [M^+ − 3CO] (100), 260 (15), 268 (56), 186 (6). − $C_{19}H_{22}CrO_5$ (382.38): calcd. (2RS)-2-(2′-Bromobenzyl)cyclohexanone (*rac*-**38**): A stirred solution of 3.23 ml (33 mmol) of diisopropylamine in 100 ml of dry THF was cooled to −78°C and 13.8 ml (22 mmol) of a solution of *n*-butyllithium (1.6 M in hexane) was added by means of a syringe. After 10 min, a solution of 2.5 ml (25 mmol) of cyclohexanone in 10 ml of dry THF was added dropwise over a period of 20 min. The mixture was stirred for 1 h at −78°C and then transferred dropwise over a period of 1 h to a cold (0°C) stirred solution of α-bromobenzyl bromide (**37**) (5.0 g, 20 mmol) in 80 ml THF. The cooling bath was removed and the mixture was heated to reflux for 3 h. The cooled mixture was subsequently treated with 100 ml of 2 N HCl and extracted with EtOAc (3 × 100 ml). The combined organic extracts were washed with satd. aqueous $NaHCO_3$ and with brine, dried with $MgSO_4$, and the solvent was removed in vacuo. The crude product (yellow oil) consisted of *rac*-**38** contaminated with ca. 30% of the dialkylated product **36b** (NMR). Kugelrohr distillation (85°C, 0.5 Torr) afforded 4.23 g (63% yield) of the pure monoalkylated ketone *rac*-**38** as a colorless oil and 1.83 g (33%) of **36b** as a slightly yellow oil (130°C, 0.5 Torr); R_f = 0.33 (hexane/EtOAc, 10:1). − IR (ATR): $\tilde{\nu}$ = 3058 (w), 2932 (m), 2859 (w), 1708 (s, C=O), 1469 (m), 1444 (m), 1128 (w), 1021 (m), 745 (m) cm^{-1}. − ^1H NMR (400 MHz): δ = 1.42 (pseudo qd, 1 H), 1.54−1.73 (m, 2 H), 1.84 (m, 1 H), 2.00−2.12 (m, 2 H), 2.24 (pseudo dd, J_1 = 5.2 Hz, J_2 = 12.8 Hz, 1 H), 2.43 (m, 1 H), 2.55 (dd, J_1 = 8 Hz, J_2 = 16 Hz, 1 H), 2.65−2.75 (m, 1 H), 3.34 (dd, J_1 = 5.4 Hz, J_2 = 16.2 Hz, 1 H), 7.05 (pseudo td, J_1 = 2.5 Hz, J_2 = 8.5 Hz, 1 H), 7.18−7.27 (m, 2 H), 7.51 (pseudo d, J = 8 Hz, 1 H). − ^{13}C NMR (63 MHz): δ = 25.2 (t), 28.1 (t), 33.7 (t), 35.2 (t), 42.2 (t), 50.5 (d), 124.6 (s), 127.1 (d), 127.7 (d), 131.8 (d), 132.7 (d), 139.7 (s). − MS; *m/z* (%): 187 [M^+ − Br] (100), 171 (16), 169 (17), 119 (43), 107 (22), 69 (10). − HRMS: calcd. for $C_{13}H_{15}O$ (M − Br): 187.1123; found: 187.1118. − $C_{13}H_{15}BrO$ (267.17): calcd. C 58.44, H 5.66; found C 58.17, H 5.67.

2,2-Bis(2′-bromobenzyl)cyclohexanone (**36b**): ^1H NMR (270 MHz): δ = 1.63−1.88 (m, 6 H), 2.03−2.18 (m, 2 H), 3.18 (pseudo d, J = 13.9 Hz, 2 H), 3.33 (pseudo d, J = 14.0 Hz, 2 H), 7.06 (m, 2 H), 7.21 (m, 4 H), 7.55 (m, 2 H).

(1′RS)-1-Bromo-2-(2′-methylenecyclohexylmethyl)benzene (*rac*-**39**): To a stirred suspension of 9.0 g (25.3 mmol) of methyltriphenylphosphonium bromide in 100 ml of dry THF at −78°C, 13.9 ml (22.3 mmol) of a solution of *n*-butyllithium (1.6 M in hexane) was added by means of a syringe and the temperature was allowed to rise to −30°C over a period of 30 min. To the resulting orange solution was added 4.5 g (16.8 mmol) of *rac*-**38**, the cooling bath was replaced by an oil bath, and the mixture was heated to reflux for 2 h. The cooled mixture was then partitioned between water (50 ml) and EtOAc (50 ml) and the aqueous phase was extracted with further EtOAc (50 ml). The combined organic extracts were washed with brine, dried with $MgSO_4$, and the solvent was removed under reduced pressure. The residue was treated with 50 ml of hexane and filtered through a short pad of Celite (1 cm) and silica (1 cm). The solvent was removed under reduced pressure yielding 4.22 g (95%) of the methylenated product *rac*-**39** as a slightly yellow oil; R_f = 0.75 (hexane/EtOAc, 10:1). − IR (CCl_4): $\tilde{\nu}$ = 3067 (w), 2927 (s), 2853 (m), 1643 (m), 1469 (m), 1437 (m), 1023 (s), 882 (m), 745 (s) cm^{-1}. − ^1H NMR (270 MHz): δ = 1.18−1.76 (m, 6 H), 2.12 (m, 1 H), 2.32−2.59 (m, 2 H), 2.66 (dd, J_1 = 9.5 Hz, J_2 = 13 Hz, 1 H), 3.10 (dd, J_1 = 5.5 Hz, J_2 = 13 Hz, 1 H), 4.62 (pseudo s, 1 H), 4.74 (pseudo s, 1 H), 7.03 (pseudo dt, J_1 = 2 Hz, J_2 = 8 Hz, 1 H), 7.10−7.24 (m, 2 H), 7.54 (pseudo dd, J_1 = 1.5 Hz, J_2 = 9.5 Hz, 1 H). − ^{13}C NMR (63 MHz): δ = 24.6 (t), 28.7 (t), 32.8 (t), 35.3 (t), 38.8 (t), 42.8 (d), 105.9 (t), 124.9 (s), 127. 0 (d), 127.4 (d), 131.3 (d), 132.8 (d), 140.5 (s), 152.2 (s). − MS; *m/z* (%): 262 (20), 185 [M^+ − Br] (100), 171 (13), 169 (14), 129 (11), 117 (32), 95 (96), 94 (22), 79 (15), 67 (19). − $C_{14}H_{17}Br$ (265.19): calcd. Diethyl (1RS,2SR)-Cyclohexane-1,2-dicarboxylate (**41a**)[26]: To a solution of 51.4 g (0.33 mol) of *cis*-hexahydrophthaloyl anhydride (**40**) in 300 ml of dry EtOH was added 2.5 ml of conc. sulfuric acid and the mixture was refluxed for 5 h. After cooling to room temp., EtOAc (300 ml) was added and the mixture was sequentially washed with water (2 × 100 ml), saturated aqueous $NaHCO_3$ (100 ml), and brine. The aqueous extracts were back-extracted three times with 100 ml of EtOAc and the combined organic layers were dried with $MgSO_4$. The solvent was removed under reduced pressure and the resulting oil was distilled in vacuo (89°C, 0.5 Torr) through a 10-cm Vigreux column to yield 74.40 g (87%) of the *cis*-diester **41a** (containing ca. 1.5% of the *trans* isomer *rac*-**41b**), R_f = 0.15 (hexane/EtOAc, 10:1). − IR (CCl_4): $\tilde{\nu}$ = 2982 (w), 2938 (w), 2859 (w), 1793 (w, C=O), 1733 (s, C=O), 1245 (m), 1215 (m), 1180 (m) cm^{-1}. − ^1H NMR (270 MHz): δ = 1.24 (t, 6 H), 1.44 (m, 4 H), 1.77 (m, 2 H), 2.01 (m, 2 H), 2.79 (pseudo t, 2 H), 4.13 (q, *J* = 8 Hz, 4 H). − ^{13}C NMR (63 MHz): δ = 13.3 (q), 22.9 (t), 25.4 (t), 41.8 (d), 59.5 (t), 172.93 (s). − MS; *m/z* (%): 228 [M^+] (3), 183 (30), 154 (23), 109 (33), 95 (21), 81 (100).

Diethyl (1RS,2RS)-Cyclohexane-1,2-dicarboxylate (*rac*-**41b**)[26]: To a solution of 2.2 g (96 mmol) of sodium in 200 ml of dry EtOH was added 45.85 g (201 mmol) of the *cis*-diester **41a** and the mixture was refluxed for 5 h. After cooling to room temp., 200 ml of EtOAc was added and the mixture was washed with water (2 × 100 ml), 2 N HCl (100 ml), saturated aqueous $NaHCO_3$ (100 ml) and brine. The aqueous phases were re-extracted with EtOAc (3 × 100 ml) and the combined organic layers were dried with $MgSO_4$. The solvent was removed under reduced pressure and the residue was dried in vacuo yielding 42.30 g (92%) of *trans*-diester *rac*-**41b** (containing about 11% of the *cis*-diester according to NMR). − R_f = 0.15 (hexane/EtOAc, 10:1). − IR (CCl_4): $\tilde{\nu}$ = 2985 (w), 2938 (w), 2861 (w), 1733 (s, C=O), 1216 (s), 1178 (m) cm^{-1}. − ^1H NMR (270 MHz; only the signals of *rac*-**41b** are given): δ = 1.24 (t, *J* = 7 Hz, 6 H), 1.32 (m, 4 H), 1.79 (m, 2 H), 2.07 (pseudo d, 2 H), 2.59 (m, 2 H), 2.79 (pseudo t, 2 H), 4.12 (dq, J_1 = 8 Hz, J_2 = 4 Hz, 4 H). − ^{13}C NMR (63 MHz): δ = 14.0 (q), 25.1 (t), 28.8 (t), 44.8 (d), 60.3 (t), 175.0 (s). − MS; *m/z* (%): 228 [M^+] (2), 183 (47), 182 (27), 155 (25), 154 (50), 109 (37), 108 (33), 81 (100).

(1RS,2RS)-1,2-Bis(hydroxymethyl)cyclohexane (*rac*-**42b**)[27]: To a stirred suspension of 9.48 g (242 mmol) of $LiAlH_4$ in 150 ml of dry diethyl ether was added a solution of 23.05 g (101 mmol) of the mixture containing principally diester *rac*-**41b** (*rac*-**41b**/**41a** = 89:11) in 100 ml of dry diethyl ether, so that the mixture refluxed gently. After completion of the addition, refluxing was continued for 1 h. The cooled mixture was then quenched by the dropwise addition of 50 ml of EtOAc followed by 300 ml of 5 N HCl. Stirring was continued until most of the precipitate had dissolved. The layers were separated and the organic layer was washed with saturated aqueous $NaHCO_3$ and brine. The aqueous layers were re-extracted with EtOAc (5 × 50) and the combined organic layers were dried with $MgSO_4$. After removing the solvent under reduced pressure, 14.42 g (99%) of the diol mixture (*rac*-**42b**/**42a** = 89:11) was obtained, which crystallized spontaneously. An analytical sample was recrystallized from hexane/benzene (3:1) yielding colorless prisms of pure *rac*-**42b**, m.p. 55°C (ref.[27]: m.p. 57°C). − R_f = 0.35 (EtOAc). − IR (CCl_4): $\tilde{\nu}$ = 3272 (br, OH), 2925 (s), 2856 (m), 1061 (s), 1448 (m), 1030 (w), 966 (w) cm^{-1}. − ^1H NMR (270 MHz): δ = 1.07 (m, 2 H), 1.26 (m, 4 H), 1.63 (pseudo dd, 2 H), 1.86 (m, 2 H), 3.20 (br, 2 H, OH, exchanges with D_2O), 3.54 (pseudo dq, 4 H). − ^{13}C NMR (63 MHz): δ = 26.1 (t), 29.8 (t), 44.7 (d), 67.86 (t). − MS; *m/z* (%): 127 [$MH^+ - H_2O$] (68), 109 (42), 93 (70), 81 (100), 79 (47), 67 (88), 55 (36). − $C_8H_{15}O$ (127.21): calcd. C 66.63, H 11.18; found C 66.36 H 11.16.

(1RS,2RS)-1,2-Bis(tosyloxymethyl)cyclohexane (*rac*-**43b**)[27]: To a cold (0°C), stirred solution of 11.3 g (0.078 mol) of the diol *rac*-**42b** in 100 ml of dry pyridine, 60 g (0.315 mol) of *p*-TsCl was slowly added and stirring was continued for 1 h. The orange solution was kept at 4°C for 20 h, and then was poured slowly into a mixture consisting of conc. HCl (300 ml), ice (300 g) and CH_2Cl_2 (200 ml) under vigorous stirring. After 10 min, the layers were separated and the aqueous layer was extracted with CH_2Cl_2 (2 × 100 ml). The combined organic layers were washed with saturated aqueous $NaHCO_3$ and brine, and dried with $CaCl_2$. The solvent was removed under reduced pressure to give an oily residue, which was crystallized from MeOH to yield 27.69 g (78%) of the ditosylate *rac*-**43b** as a pure diastereomer (the *cis* isomer **43a** could be not detected by either HPLC or NMR), m.p. 100°C (ref.[27]: m.p. 108°C). − R_f = 0.1 (hexane/EtOAc, 10:1); IR (CCl_4): $\tilde{\nu}$ = 2929 (w), 2859 (w), 1189 (s), 1178 (s), 1372 (m), 946 (m) cm^{-1}. − ^1H NMR (270 MHz): δ = 1.17 (m, 4 H), 1.63 (m, 6 H), 2.45 (s, 6 H), 3.87 (pseudo dq, 4 H), 7.37 (d, 4 H), 7.73 (d, *J* = 5 Hz, 4 H). − ^{13}C NMR (63 MHz): δ = 21.7 (q), 25.2 (t), 28.9 (t), 37.7 (d), 72.1 (t), 127.9 (d), 129.9 (d), 132.6 (s), 144.9 (s). − MS; *m/z* (%): 452 [M^+] (4), 281 (11), 280 (10), 155 (40), 125 (53), 109 (100), 91 (90), 67 (32), 65 (15). − $C_{22}H_{28}O_6S_2$ (452.58): calcd. C 58.39, H 6.24; found C 58.74, H 6.26.

(1RS,2RS)-1,2-Diprop-2′-ynylcyclohexane (*rac*-**44**): A solution of 9.83 g (107 mmol) of lithium acetylide ethylenediamine complex in 55 ml of dry DMSO was cooled to 8°C and 15.80 g (34.9 mmol) of the ditosylate *rac*-**43b** was added in small portions. Stirring was continued for 4.5 h and the temperature was allowed to rise to ambient. The dark-brown solution was then cooled to 8°C once more and 55 ml of water was added slowly, causing the mixture to foam. The mixture was subsequently extracted with hexane (4 × 50 ml) and the combined organic extracts were dried with $MgSO_4$. After removal of the solvent under reduced pressure, the crude product (4.8 g, ca. 90% pure) was kugelrohr-distilled (100°C, 0.1 Torr) to yield 3.65 g (63%) of the dialkyne *rac*-**44** as a colorless oil (Note: The product turns yellow quickly upon standing at room temp. but can be stored as a solid at −20°C), m.p. ca. 5−10°C. − R_f = 0.28 (hexane). − IR (CCl_4): $\tilde{\nu}$ = 3313 (m, C≡C−H), 2926 (m), 2857 (s), 1189 (s), 1178 (s), 1373 (m), 949 (m) cm^{-1}. − ^1H NMR (400 MHz): δ = 1.25 (m, 4 H), 1.45 (m, 2 H), 1.72 (m, 4 H), 1.95 (t, *J* = 3 Hz, 2 H), 2.27 (m, 4 H). − ^{13}C NMR (63 MHz): δ = 22.5 (t), 25.8 (t), 31.3 (t), 38.8 (d), 69.4 (s), 82.1 (d). − MS; *m/z* (%): 159 [$M^+ - 1$] (8), 145 (21), 131 (30), 117 (50), 105 (22), 104 (12), 95 (25), 93 (45), 91 (65), 81 (100), 79 (97), 77 (54), 67 (44), 55 (28). − HRMS as calcd. for $C_{12}H_{16}$: 159.1174.

(4aRS,9aRS)-6,7-Bis(trimethylsilyl)-1,2,3,4,4a,9,9a,10-octahydroanthracene (*rac*-**45**): A flame-dried Schlenk flask was fitted with a reflux condenser topped with an Hg bubbler. All joints were made air-tight using Teflon sleeves. The apparatus was flushed with argon and then charged with 1.143 g (8.7 mmol) of bis(trimethylsilyl)acetylene, 39 mg (0.2 mmol 10 mol-%) of dicarbonyl(cyclopentadienyl)cobalt[61] and 30 ml of dry octane. The apparatus was briefly evacuated and flushed with argon several times and then the mixture was heated to reflux (180°C oil-bath temperature). A separately prepared and degassed solution of 332 mg (2 mmol) of the dialkyne *rac*-**44**, 381 mg of bis(trimethylsilyl)acetylene and 39 mg

(0.2 mmol, 10 mol-%) of dicarbonyl(cyclopentadienyl)cobalt in 4.5 ml of octane was then added to the refluxing mixture by means of a syringe pump over a period of 11 h, under irradiation from a 200-W bulb. The resulting black solution was allowed to cool to room temp. and filtered through a short pad of Celite and silica. The solvent was removed under reduced pressure and the residue (black tar) was purified by PTLC (4-mm layer SiO_2; hexane). The product was crystallized from EtOAc/MeOH to yield 180 mg (27%) of *rac*-**45** as colorless plates (Note: Our attempts to run the reaction on a larger scale resulted in significantly lower yields); m.p. 74°C. − R_f = 0.65 (hexane). − IR (CCl_4): $\tilde{\nu}$ = 2920 (m), 2905 (m), 2951, 2877 (w), 2854 (w), 1249 (s), 854 (s), 839 (s) cm^{-1}. − ^1H NMR (270 MHz): δ = 0.36 (s, 18 H), 1.08 (m, 2 H), 1.37 (m, 4 H), 1.82 (pseudo dd, 4 H), 2.45 (dd, J_1 = 15.5 Hz, J_2 = 12 Hz, 2 H), 2.77 (dd, J_1 = 17 Hz, J_2 = 3.5 Hz, 2 H), 7.39 (s, 2 H). − ^{13}C NMR (63 MHz): δ = 2.0 (q), 26.3 (t), 29.7 (t), 37.3 (t), 38.8 (d), 136.1 (d), 136.6 (s), 142.3 (s). − MS; *m/z* (%): 330 [M^+] (29), 315 (100), 299 (84), 131 (6), 73 (14). − $C_{20}H_{34}Si_2$ (330.66): calcd. C 72.65, H 10.36; found C 72.57, H 1.37.

(4aRS,8aSR,9aRS)-Tricarbonyl[η⁶-6,7-bis(trimethylsilyl)-1,2,3,4,4a,9,9a,10-octahydroanthracene]chromium(0) (*rac*-**9**): As described above for the preparation of *rac*-**24**, 590 mg (1.8 mmol) of the ligand *rac*-**45** was heated with 440 mg (2.0 mmol) of $Cr(CO)_6$ in 20 ml nBu_2O and 2 ml of dry THF for 22 h at 150°C (oil-bath temperature). The clear, yellow solution thus obtained was allowed to cool to room temp. and filtered through a short pad of silica. The solvent was removed in vacuo and the residue was purified by PTLC (4-mm layer SiO_2; hexane/EtOAc, 10:1) to give 825 mg (91%) of *rac*-**9** as pale-yellow crystals, m.p. 162°C. − R_f = 0.31 (hexane). − IR (CCl_4): $\tilde{\nu}$ = 2924 (w), 2905 (w), 2856 (w), 1961 (s), 1891 (s), 1254 (m), 853 (m), 844 (m), 836 (m) cm^{-1}. − ^1H NMR (270 MHz)[60]: δ = 0.36 and 0.38 (both s, 9 H), 1.07 (m, 2 H), 1.36 (m, 4 H), 1.82 (pseudo dd, 4 H), 2.34 (dd, J_1 = 16.5 Hz, J_2 = 12 Hz, 2 H), 2.40 (dd, J_1 = 17 Hz, J_2 = 11 Hz, 2 H), 2.52 (dd, J_1 = 17.5 Hz, J_2 = 5.5 Hz, 2 H), 2.60 (dd, J_1 = 17 Hz, J_2 = 6 Hz, 2 H), 5.27 and 5.28 (both s, 1 H). − ^{13}C NMR (63 MHz): δ = 1.8 (q), 1.9 (q), 25.8 (t), 26.0 (t), 33.2 (t), 34.8 (t), 36.4 (t), 37.3 (d), 38.4 (d), 100.4 (d), 104.9 (s), 105.0 (s), 109.2 (s), 110.0 (s), 234.1 (s). − MS (*m/z*): 466 [M^+] (4), 382 [M^+ − 3CO] (100), 315 (13), 299 (12), 73 (6), 52 (6). − $C_{23}H_{34}CrO_3Si_2$ (466.69): calcd. C 59.16, H 7.34; found C 59.05, H 7.45.

General Procedure A: Deuteration of Cr(CO)₃ Complexes with tBuOK in [D₆]DMSO: In a small, flame-dried Schlenk flask, *t*BuOK (ca. 11 mg, 0.1 mmol) was dissolved under argon in 0.5 ml of dry [D_6]DMSO and 0.02−0.06 mmol of the respective chromium complex was added (for the exact amounts, see the individual experiments described below). The solution was stirred at room temp. for 1 h and then quenched with EtOAc (10 ml). The resulting mixture was transferred to a separatory funnel, washed with water (2 × 10 ml), and dried with $MgSO_4$. The solvent was removed in vacuo and the yellow residue was chromatographed on a 1-mm SiO_2 layer. The pure fractions of the major component were combined, the solvent was removed in vacuo, and the residue was characterized by ^1H NMR and MS.

*Preparation of rac-***46** *{(1RS,4SR)-1,4,5,8-[D₄]-rac-***24***}*: Complex *rac*-**5** (10 mg, 0.02 mmol) was treated with *t*BuOK/[D_6]DMSO as described above (General Procedure A) to afford 0.8 mg (11%) of the tetradeuterated complex *rac*-**46** as a yellow film. − ^1H NMR (270 MHz)[60]: δ = 1.00 (d, J = 3 Hz, 3 H), 1.02 (d, J = 3 Hz, 3 H), 1.38 (m, 1 H), 1.53 (m, 1 H), 2.29 (dd, J_1 = 22 Hz, J_2 = 11 Hz, 0.25 H), 2.37 (dd, J_1 = 23 Hz, J_2 = 11 Hz, 1 H), 2.52 (dd, J_1 = 21 Hz, J_2 = 4.5 Hz, 1 H), 2.60 (dd, J_1 = 20 Hz, J_2 = 5 Hz, 0.2 H), 3.75 (s, 3 H), 3.78 (s, 3 H), 5.15 (s, 0.16 H), 5.18 (s, 0.1 H). − MS; *m/z* (%): 360 [M^+] (22), 359 (12), 304 (8), 276 (100), 275 (55), 246 (55), 221 (52), 220 (51), 205 (45), 190 (18), 167 (29), 149 (74), 129 (18), 91 (36), 69 (32), 55 (34). − HRMS: calcd. for $C_{17}H_{16}D_4CrO_5$ 360.099; found 360.0993.

*Preparation of rac-***47** *{(9RS,10SR)-5,8,9,10-[D₄]-rac-***35***}*: Complex *rac*-**7** (20 mg, 0.036 mmol) was treated with *t*BuOK/[D_6]DMSO as described above (General Procedure A) to afford 8 mg (58%) of the tetradeuterated complex *rac*-**47** as a yellow film. − ^1H NMR (270 MHz)[60]: δ = 1.02 (m, 2 H), 1.30 (m, 4 H), 1.84 (pseudo dd, 4 H), 2.35 (d, J_1 = 12.2 Hz, 1 H), 2.45 (d, J_1 = 16.5 Hz, J_2 = 4 Hz, 1 H), 3.73 (s, 3 H), 3.77 (s, 3 H), 5.15 (s, 0.08 H), 5.19 (s, 0.08 H). − MS; *m/z* (%): 386 [M^+] (10), 330 (5), 302 (100), 272 (31), 250 (13), 43 (17). − HRMS: calcd. for $C_{19}H_{18}D_4CrO_5$ 386.1123; found 386.1118.

*Preparation of rac-***48** *{(9RS,10SR)-6,7,9,10-[D₄]-rac-***8***}*: Complex *rac*-**9** (20 mg, 0.043 mmol) was treated with *t*BuOK/[D_6]DMSO as described above (General Procedure A) to afford 14 mg (98%) of the tetradeuterated complex *rac*-**48** as a yellow film. − ^1H NMR (400 MHz)[60]: δ = 1.05 (m, 2 H), 1.31 (m, 4 H), 1.77 (pseudo dd, 4 H), 2.32 (d, J = 15.6 Hz, 0.3 H), 2.39 (d, J = 9.2 Hz, 1 H), 2.51 (pseudo d, J_1 = 17 Hz, $J \approx$ 3 Hz, 1 H), 2.61 (dd, J_1 = 16.3 Hz, J_2 = 5.8 Hz, 0.3 H, H-10), 5.24 (s, 2 H). − MS; *m/z* (%): 326 [M^+] (11), 243 (61), 241 (100), 240 (46), 151 (29), 150 (14), 52 (67). − HRMS: calcd. for $C_{17}H_{14}D_4CrO_3$ 326.0912; found 326.0920.

*Preparation of rac-***49** *{(9RS,10SR)-9,10-[D₂]-rac-***8***}*: Complex *rac*-**8** (20 mg, 0.062 mmol) was treated with *t*BuOK/[D_6]DMSO as described above (General Procedure A) to afford 14 mg (70%) of the dideuterated complex *rac*-**49** as a yellow film. − ^1H NMR (400 MHz)[60]: δ = 1.05 (m, 2 H), 1.31 (m, 4 H), 1.77 (pseudo dd, 4 H), 2.39 (d, J = 9.8 Hz, 1 H), 2.52 (pseudo s, 1 H), 5.24 (m, 4 H). − MS; *m/z* (%): 325 (11), 324 [M^+] (12), 269 (6), 268 (6), 241 (95), 240 (100), 189 (10), 188 (12), 120 (12), 107 (12), 52 (54). − HRMS: calcd. for $C_{17}H_{16}D_2CrO_3$ 324.0786; found 324.0780.

General Procedure B: Deprotonation of Cr(CO)₃ Complexes with n-Butyllithium and Deuteration with D₂O: A flame-dried 25-ml Schlenk flask was charged under argon with the respective chromium complex (0.08−0.1 mmol; for the exact amounts, see the individual experiments described below) and 5 ml of dry THF and 0.5 ml of dry HMPA were added. Then, *n*-butyllithium (190 µl, 0.3 mmol, 1.6 M in *n*-hexane) was injected into the stirred yellow solution at room temp. The solution usually turned red within 5 min, indicating the formation of a benzylic anion. After 30 min, D_2O (200 µl, 10 mmol) was injected and stirring was continued for at least another 30 min. The mixture was then diluted with EtOAc (30 ml), transferred to a separatory funnel, washed with 2 N HCl (2 × 20 ml), saturated aqueous $NaHCO_3$ (20 ml) and brine (20 ml), and dried with $MgSO_4$. The solvent was removed in vacuo and the yellow residue was purified by PTLC (for the exact conditions, see the preparations of the nondeuterated compounds) to furnish the deuterated samples in yields of 45−70%. Prior to the determination of the degree of deuteration by ^1H-NMR spectroscopy, the samples were further purified by recrystallization.

General Procedure C: Deprotonation of Cr(CO)₃ Complexes with n-Butyllithium and Deuteration with CF₃CO₂D: A flame-dried 25-ml Schlenk flask was charged under argon with the respective chromium complex (0.08−0.1 mmol; for the exact amounts, see the individual experiments described below) and 10 ml of dry THF and 1 ml of dry HMPA were added. The yellow solution was cooled to −78°C and *n*-butyllithium (120 µl, 0.2 mmol, 1.6 M in *n*-hexane) was injected with stirring. The mixture was allowed to warm to

room temp., whereupon its color changed to red within 10−20 min. After stirring for 30 min, the mixture was cooled to −78°C once more and CF_3CO_2D (77 µl, 1 mmol) was injected. The solution reverted to its original color within a few seconds and stirring was continued for a further 20 min. The mixture was then diluted with EtOAc (30 ml) and worked up as described in General Procedure B. The deuterated samples, obtained in yields of 50−75%, were further purified by recrystallization prior to determination of the degrees of deuteration by ^{1}H NMR.

Deprotonation/Deuteration of **50**: A solution of complex **50** (236.3 mg, 0.5 mmol) in 10 ml of dry THF and 1 ml of HMPA was cooled to −50°C and *n*-butyllithium (0.4 ml, 0.64 mmol, 1.6 M in hexane) was added by means of a syringe. Stirring was continued for 2 h at 0°C, and then the mixture was quenched with D_2O (0.5 ml, 45 mmol), diluted with hexane, washed with water and brine, and dried with $MgSO_4$. Upon removal of the solvent in vacuo, the deuterated (95% D) complex *rac*-**51** was obtained (230 mg, 97%). − ^{1}H NMR (270 MHz): δ = 0.54 (s, 18 H), 1.50−1.75 (m, 4 H), 2.49 (m, 1.05 H), 2.68 (m, 2 H), 3.71 (s, 6 H).

Deprotonation/Deuteration of rac-**1**: A stirred solution of complex *rac*-**1** (41 mg, 0.08 mmol) in 1 ml of dry THF and 0.1 ml of HMPA was cooled to −70°C and *n*-butyllithium (0.08 ml, 0.13 mmol, 1.6 M in hexane) was added by means of a syringe. Stirring was continued for 5 min at −70°C and then for 15 min at room temp. The mixture was subsequently quenched with D_2O (0.5 ml, 45 mmol), diluted with hexane, washed with water and brine, and dried with $MgSO_4$. Upon removal of the solvent in vacuo, the deuterated (90% D) complex *rac*-**52a** was obtained (38 mg, 93%). − ^{1}H NMR (250 MHz)[60]: δ = 0.45 (s, 9 H), 0.47 (s, 9 H), 1.01 (d, J = 6.5 Hz, 3 H), 1.18−1.33 (m, 1 H), 1.50−1.58 (m, 1 H), 1.69−1.76 (m, 1 H), 2.24 (dd, J_1 = 16.0 Hz, J_2 = 11.7 Hz, 1 H), 2.52 (ddd, J_1 = 16.0 Hz, J_2 = 11.0 Hz, J_3 = 5.0 Hz, 0.1 H), 2.57 (dd, J_1 = 16.0 Hz, J_2 = 5 Hz, 1 H), 2.78 (ddd, J_1 = 16.3 Hz, J_2 = 5.2 Hz, J_3 = 3.6 Hz), 3.71 (pseudo s, 6 H). − In a separate experiment, complex *rac*-**1** (49 mg, 0.1 mmol) was deuterated following General Procedure B. In this case, the ^{1}H-NMR spectrum of the product showed it to be a mixture of *rac*-**52a** and *rac*-**52b** in a ratio of approx. 4:1 (85 ± 3% D).

Deprotonation/Deuteration of rac-**5**: Complex *rac*-**5** (50 mg, 0.1 mmol) was deuterated following General Procedure C, yielding *rac*-**53b** (35.5 mg, 71%, 65% D). − ^{1}H NMR (270 MHz)[60]: δ = 0.50 (pseudo s, 18 H), 0.96 (pseudo t, J = 6.2 Hz, 6 H), 1.25 (m, 1 H), 1.39 (m, 1 H), 2.13 (dd, J_1 = 16.1 Hz, J_2 = 10.1 Hz, 1 H), 2.35 (dd, J_1 = 16.0 Hz, J_2 = 11.9 Hz, 1 H), 2.58 (dd, J_1 = 16.3 Hz, J_2 = 5.0 Hz, 0.35 H), 2.82 (dd, J_1 = 16.1 Hz, J_2 = 4.9 Hz, 1 H), 3.74 (pseudo s, 6 H). In a separate experiment, complex *rac*-**5** (50 mg, 0.1 mmol) was deuterated following General Procedure B. In this case, the ^{1}H-NMR spectrum indicated the formation of *rac*-**53b** with only ca. 50% D incorporation. When a sample of *rac*-**53b** (50 mg, 0.1 mmol, 65% D) was subjected to a second deprotonation/deuteration cycle following General Procedure C, the degree of deuteration was enhanced to 80% D (yield: 36 mg, 72%). In contrast, when a sample of *rac*-**53b** (50 mg, 0.1 mmol, 65% D) was treated with *n*-butyllithium as described in General Procedure C, with subsequent quenching with CF_3CO_2H (instead of CF_3CO_2D), the isolated material *rac*-**5** (18 mg, 35%) was found to contain less than 10% D.

Deprotonation/Deuteration of rac-**6**: Complex *rac*-**6** (41 mg, 0.08 mmol) was deuterated following General Procedure B, yielding a mixture of *rac*-**54a** and *rac*-**54b** with an overall degree of deuteration of 90 ± 10% D according to the ^{1}H-NMR spectrum. Since the crude material contained significant amounts of desilylated byproducts it was completely desilylated by treatment with tetrabutylammonium fluoride/silica (2 equiv., THF, 1 h, 25°C). ^{1}H NMR (270 MHz)[60]: δ = 1.94 (m, 1 H), 2.14 (m, 1 H), 2.48 (dd, J_1 = 15.2 Hz, J_2 = 11.6 Hz, 0.6 H), 2.59 (dd, J_1 = 15.7 Hz, J_2 = 11.7 Hz, 1 H), 2.74 (dd, J_1 = 10.6 Hz, J_2 = 4.6 Hz, 1 H), 2.80 (dd, J_1 = 11.2 Hz, J_2 = 4.9 Hz, 0.5 H), 3.44 (pseudo d, J = 10.3 Hz, 1 H), 3.46 (pseudo d, J = 10.3 Hz), 3.76 (s, 3 H), 3.80 (s, 3 H), 4.10 (pseudo t, J = 7.5 Hz, 1 H), 4.20 (pseudo t, J = 7.5 Hz, 1 H), 5.18 (s, 1 H), 5.21 (s, 1 H).

Deprotonation/Deuteration of rac-**7**: Complex *rac*-**7** (53 mg, 0.1 mmol) was deuterated following General Procedure C, yielding *rac*-**55b** (26 mg, 50%, 50% D). − ^{1}H NMR (270 MHz)[60]: δ = 0.46 (pseudo s, 18 H), 0.94 (m, 2 H), 1.28 (m, 4 H), 1.78 (m, 4 H), 2.09 (dd, J_1 = 16.5 Hz, J_2 = 11 Hz, 1 H), 2.31 (dd, J_1 = 15.5 Hz, J_2 = 10.8 Hz, 1 H), 2.53 (dd, J_1 = 16 Hz, J_2 = 5.5 Hz, 0.5 H), 2.80 (dd, J_1 = 16.2 Hz, J_2 = 5.5 Hz, 1 H), 3.72 (pseudo s, 6 H). − When a sample of *rac*-**55b** (53 mg, 0.1 mmol, 50% D) was subjected to a second deprotonation/deuteration cycle following General Procedure C, the ^{1}H-NMR spectrum of the isolated material (25 mg, 48%) indicated that deuteration had occurred at both benzylic *exo* positions: 75% D at C-1 (pseudo-equatorial) and 15% at C-4 (pseudo-axial). When a sample of *rac*-**55b** (53 mg, 0.1 mmol, 50% D) was treated with *n*-butyllithium as described in General Procedure C, with subsequent quenching with CF_3CO_2H (instead of CF_3CO_2D), the isolated material *rac*-**7** (11 mg, 20%) contained less than 18% D. Additionally, 18 mg (40%) of a mixture of monosilylated compounds was isolated.

(1RS,2RS,3RS,4aRS)-Tricarbonyl[η⁶-6,7-dimethoxy-1,2,3-trimethyl-5,8-bis(trimethylsilyl)-1,2,3,4-tetrahydronaphthalene]chromium(0) (*rac*-**56**): A solution of *rac*-**5** (200 mg, 0.4 mmol) in dry THF (40 ml) and dry HMPA (4 ml) was cooled to −78°C and *n*-butyllithium (0.5 ml, 0.8 mmol, 1.6 M in *n*-hexane) was added. The cooling bath was removed and the mixture was stirred for 30 min while being slowly warmed to room temp. After cooling to −50°C, methyl iodide (0.25 ml, 4 mmol) was injected. Stirring was continued for 1 h, then the mixture was diluted with EtOAc (100 ml) and washed sequentially with 2 N HCl (2 × 20 ml), saturated aqueous $NaHCO_3$ and water. After drying with $MgSO_4$, the solvent was removed in vacuo and the product was purified by PTLC (hexane) followed by crystallization from hexane/EtOAc (10:1) at −30°C to yield *rac*-**56** (143 mg, 65%) as dark-yellow cubes; m.p. 114°C. − R_f = 0.55 (hexane/EtOAc, 10:1). − IR (KBr): $\tilde{\nu}$ = 2955 (w), 2901 (w), 2873 (w), 1955 (s, C=O), 1885 (s, C=O), 1452 (w), 1360 (m), 1320 (m), 1251 (m), 1229 (s), 1017 (m), 856 (m) cm^{-1}. − ^{1}H NMR (270 MHz): δ = 0.45 (s, 9 H), 0.47 (s, 9 H), 0.91 (m, 1 H), 0.95 (d, J = 6.5 Hz, 3 H), 1.05 (d, J = 6.5 Hz, 3 H), 1.21 (d, J = 7.1 Hz, 3 H), 1.33 (m, 1 H), 1.88 (dd, J_1 = 15.2 Hz, J_2 = 11.4 Hz, 1 H), 2.49 (dd, J_1 = 15.2 Hz, J_2 = 3.1 Hz, 1 H), 2.65 (pseudo q, J = 6.9 Hz, 1 H), 3.77 (s, 3 H), 3.78 (s, 3 H). − MS; *m/z* (%): 514 [M$^+$] (6), 458 (9), 432 (17), 431 (43), 430 (100), 428 (7), 73 (10). − HRMS: 514.1663 as calcd. for $C_{24}H_{38}CrO_5Si_2$. − $C_{24}H_{38}CrO_5Si_2$ (514.73): calcd. C 56.00, H 7.44; found C 55.87, H 7.52.

(1RS,2RS,3RS,4aRS)-Tricarbonyl[η⁶-1-acetyl-6,7-dimethoxy-2,3-dimethyl-5,8-bis(trimethylsilyl)-1,2,3,4-tetrahydronaphthalene]chromium(0) (*rac*-**57**): A solution of *rac*-**5** (200 mg, 0.4 mmol) in dry THF (40 ml) and dry HMPA (4 ml) was cooled to −78°C and *n*-butyllithium (0.5 ml, 0.8 mmol, 1.6 M in *n*-hexane) was added. The cooling bath was removed and the mixture was allowed to stir for 30 min while slowly warming to room temp. After cooling to −50°C, acetyl chloride (0.2 ml, 2.8 mmol) was injected. Stirring was continued for 30 min, then the mixture was

diluted with EtOAc (100 ml) and washed sequentially with 2 N HCl (2 × 20 ml), saturated aqueous $NaHCO_3$ and water. After drying with $MgSO_4$, the solvent was removed in vacuo and the product was purified by PTLC (hexane/EtOAc, 3:1) followed by crystallization from the same solvent mixture at −4°C to yield *rac*-**57** (143 mg, 68%) as dark-yellow cubes; m.p. 68°C. − R_f = 0.32 (hexane/EtOAc, 10:1). − IR (KBr): $\tilde{\nu}$ = 2950 (w), 1957 (s, C=O), 1888 (s, C=O), 1360 (w), 1334 (w), 1252 (w), 1025 (w), 857 (w) cm^{-1}. − ^1H NMR (270 MHz): δ = 0.42 (s, 9 H), 0.46 (s, 9 H), 0.99 (d, *J* = 6.5 Hz, 3 H), 1.25 (d, *J* = 6 Hz, 3 H), 1.34 (m, 1 H), 1.44 (m, 1 H), 1.89 (dd, J_1 = 11 Hz, J_2 = 15.5 Hz, 1 H), 2.06 (s, 3 H), 2.57 (dd, J_1 = 3.5 Hz, J_2 = 15.5 Hz, 1 H), 3.69 (d, *J* = 5.5 Hz, 1 H), 3.78 (s, 3 H), 3.79 (s, 3 H). − MS; *m*/*z* (%): 542 [M^+] (7), 461 (19), 460 (45), 459 (100), 363 (9), 221 (6), 73 (10). − HRMS: 542.1612 as calcd. for $C_{25}H_{38}CrO_6Si_2$. − $C_{24}H_{38}CrO_5Si_2$ (514.73): calcd. C 55.83, H 7.06; found C 56.06, H 6.70.

Deprotonation/Deuteration of rac-**60**: In a small, flame-dried Schlenk flask, a stirred solution of *rac*-**60** (20 mg, 0.07 mmol) in 0.5 ml of dry THF was cooled to −78°C and *n*-butyllithium (48 µl, 0.08 mmol, 1.6 M in hexane) was added. The solution was kept at −78°C for 10 min, whereupon it rapidly turned red. It was stirred at −50°C for 30 min, then 0.1 ml (5 mmol) of D_2O was added, and after 5 min the cooling bath was removed. The mixture was subsequently diluted with 20 ml of EtOAc, transferred to a separatory funnel, and washed sequentially with 2 N HCl (20 ml), saturated aqueous $NaHCO_3$ (20 ml) and brine (20 ml). After drying with Na_2SO_4, the solvent was removed in vacuo and the yellow residue was purified by PTLC (hexane/EtOAc, 10:1) yielding 18.4 mg (91%) of a mixture of the monodeuterated complexes *rac*-**61a**/*rac*-**61b** with an overall degree of deuteration of 80%. − ^1H NMR (400 MHz): δ = 1.27 (s, 9 H, *t*Bu), 2.16 (pseudo s, 5.2 H, Me), 5.19 (d, 1 H), 5.39 (d, 1 H), 5.47 (s, 1 H). − MS; *m*/*z* (%): 299 [M^+] (23), 243 (7), 216 (36), 215 (100), 148 (7), 120 (3), 52 (40). − HRMS: calcd. for $C_{15}H_{17}DO_3Cr$ 299.0724; found 299.0727. Since the determination of the *rac*-**61a**/*rac*-**61b** ratio was not possible at this stage, the mixture was completely decomplexed by exposure to sunlight and air (Et_2O, 4 h) to provide a 5:3 mixture of 4-*tert*-butyl-1-[D_3]methyl-2-methylbenzene and 4-*tert*-butyl-1-methyl-2-[D_3]-methylbenzene. − ^1H NMR (400 MHz): δ = 1.29 (s, 9 H, *t*Bu), 2.21−2.24 (m, 2.5 H, Me at C-1), 2.25−2.28 (m, 2.7 H, Me at C-2), 5.19 (d, 1 H), 5.39 (d, 1 H), 5.47 (s, 1 H); the assignment of the methyl groups was accomplished by NOE experiments.

5,6-Dimethylindan-1-one (*rac*-**63**): A 250-ml flask was charged with $AlCl_3$ (32 g, 0.24 mol) and 80 ml of 1,2-dichloroethane (DCE). After cooling to 0°C, a solution of 3-chloropropionyl chloride (20.2 ml, 0.21 mol) in 20 ml of DCE was added over a period of 10 min. The mixture was stirred for 10 min at this temperature, and then a solution of *o*-xylol (24.1 ml, 0.2 mol) in 25 ml of DCE was added dropwise over a period of 1 h. The reaction mixture was stirred for 90 min (0°C → 22°C), quenched under external cooling by the addition of water (50 ml), and extracted with *tert*-butyl methyl ether (3 × 100 ml). The organic extracts were washed with water, saturated aqueous $NaHCO_3$, and further water, and then dried with $MgSO_4$. The solvent was removed in vacuo and the residue was filtered through a pad of silica gel/Celite with hexane/EtOAc (3:1). Crystallization from the same solvent system afforded 36.7 g (93%) of 3-chloro-1-(3,4-dimethylphenyl)propan-1-one (brown needles). 25 g (127 mmol) of this material was dissolved in conc. H_2SO_4 (150 ml) and the stirred solution was heated to 90°C over a period of 30 min and maintained at this temperature for a further 45 min. The dark-red mixture was then cooled to room temp. and carefully poured onto ca. 800 g of crushed ice. After extraction with *tert*-butyl methyl ether, the organic solution was washed with water, saturated aqueous $NaHCO_3$ and brine, and dried with $MgSO_4$. The solvent was removed in vacuo and the residue was filtered through a pad of silica gel and Celite with hexane/EtOAc (5:1). Crystallization from hexane/EtOAc (5:1) finally afforded 16.3 g (80%) of a 3:1 mixture of *rac*-**63a**/*rac*-**63a** as pale-brown plates. − IR (ATR): $\tilde{\nu}$ = 3012 (w), 2978 (w), 2943 (w), 2925 (w), 1696 (s), 1614 (m), 1462 (w), 1446 (w), 875 (m) cm^{-1}. − ^1H NMR (400 MHz): δ = 2.30 (s, 3 H), 2.35 (s, 3 H), 2.63−2.72 (m, 2 H), 3.00−3.08 (m, 2 H), 7.25 (s, 1 H), 7.52 (s, 1 H). − ^{13}C NMR (67 MHz): δ = 19.7 (q), 20.7 (q), 25.3 (t), 36.4 (t), 124.0 (d), 127.3 (d), 135.2 (s), 136.1 (s), 144.8 (s), 153.3 (s), 206.9 (s). − MS; *m*/*z* (%): 160 [M^+] (100), 145 (6), 132 (38), 117 (54), 115 (18), 103 (8), 91 (10). − HRMS: calcd. for $C_{11}H_{12}O$ 160.08882; found 160.0889.

(1RS)-1,5,6-Trimethylindan-1-ol (*rac*-**64**): To Mg turnings (170 mg, 7 mmol) in 5 ml of dry diethyl ether, MeI (980 mg, 6.9 mmol) was slowly added at room temp. After 30 min, the stirred mixture was heated to reflux for 30 min, then cooled to 0°C, whereupon a solution of *rac*-**63a**/*rac*-**63b** (1.0 g, 6.2 mmol) in 5 ml of diethyl ether was added dropwise. Stirring was continued for 30 min at room temp. and then the mixture was heated to reflux for 1 h. After quenching with water, the mixture was diluted with EtOAc and washed with water and brine. After drying with Na_2SO_4, the solvent was removed in vacuo and the residue was purified by PTLC (hexane/EtOAc, 10:1) to give 784 mg (72%) of *rac*-**64** as an inseparable mixture of regioisomers (3:1 ratio). In addition, 185 mg (19%) of the corresponding H_2O elimination products were obtained. − IR (ATR): $\tilde{\nu}$ = 3395 (m), 2964 (m), 2925 (m), 1687 (m), 1451 (m), 1384 (m), 1313 (m), 1180 (m) cm^{-1}. − ^1H NMR (400 MHz): δ = 1.58 (s, 3 H), 1.90 (br s, 1 H), 2.16−2.22 (m, 2 H), 2.74−2.83 (m, 1 H), 2.93−3.03 (m, 1 H), 2.28 (m, 3 H), 2.29 (s, 3 H), 7.04 (s, 1 H), 7.16 (s, 1 H). − ^{13}C NMR (100 MHz): δ = 19.8 (q), 27.2 (q), 28.9 (t), 42.5 (t), 81.1 (s), 124.9 (d), 125.9 (d), 135.0 (s), 136.6 (s), 140.2 (s), 145.9 (s). − MS; *m*/*z* (%): 176 [M^+] (8), 161 [$M^+ - CH_3$] (100), 158 [$M^+ - H_2O$] (25), 143 (28), 128 (15), 119 (10), 115 (10). − HRMS: calcd. for $C_{12}H_{16}O$ 176.12012; found 176.1212.

(1RS,3aRS)-Tricarbonyl(η⁶-1,5,6-trimethylindan-1-ol)chromium(0) (*rac*-**65**): A mixture of *rac*-**64** (518 mg, 2.94 mmol), $Cr(CO)_6$ (970 mg, 4.41 mmol), anhydrous nBu_2O (16 ml) and dry THF (1.6 ml) was heated to reflux for 18 h according to the procedure described above for the preparation of *rac*-**24**. The crude product was purified by PTLC (hexane/EtOAc, 3:1) to give 560 mg (61%) of a mixture regioisomers (m.p. 107°C), from which a sample of pure *rac*-**65** (176 mg, 19%) was obtained by fractional recrystallization from hexane/EtOAc. − M.p. 129°C. − IR (ATR): $\tilde{\nu}$ = 3581 (w), 2970 (w), 2927 (w), 1948 (s, C=O), 1861 (s, C=O), 1452 (w), 1389 (w), 670 (w) cm^{-1}. − ^1H NMR (270 MHz): δ = 1.44 (s, 3 H), 1.83 (br s, 1 H), 1.95−2.15 (m, 2 H), 2.16 (s, 3 H), 2.20 (s, 3 H), 2.60−2.75 (m, 2 H), 5.23 (s, 1 H), 5.64 (s, 1 H). − ^{13}C NMR (67 MHz): δ = 19.0 (q), 19.1 (q), 27.0 (q), 27.7 (t), 41.6 (t), 79.3 (s), 90.2 (d), 91.6 (d), 104.9 (s), 110.0 (s), 113.1 (s), 119.7 (s), 233.9 (s). − MS; *m*/z (%): 312 [M^+] (32), 256 (10), 228 (26), 229 (26), 226 (100), 210 (66), 195 (6), 159 (92), 144 (20), 129 (30). − HRMS: calcd. for $C_{15}H_{16}CrO_4$ 312.04537; found 312.0455. − $C_{15}H_{16}CrO_4$ (312.29): calcd. (3aRS)-Tricarbonyl(η⁶-1,1,5,6-tetramethylindane)chromium(0) (*rac*-**62**): In a flame-dried Schlenk flask, a solution of *rac*-**66** (95 mg, 0.27 mmol) in 7 ml of CH_2Cl_2 was cooled to −78°C and Me_3Al (0.14 ml, 1 mmol) was added dropwise. The mixture was stirred for 30 min at −78°C and for 30 min at 0°C, and then hexane (25 ml) and saturated aqueous NH_4Cl were carefully added. After the addition of some EtOAc, the mixture was washed with 2 N HCl and with brine, and dried with Na_2SO_4. The solvent was removed in vacuo and the residue was purified by PTLC (hexane/EtOAc, 10:1) to give 72 mg (86%) of pure *rac*-**62**, m.p. 103°C. – IR (ATR): $\tilde{\nu}$ = 2958 (w), 2928 (w), 1933 (s, C=O), 1870 (m, C=O), 1852 (s, C=O), 1826 (w), 1459 (w), 1389 (w), 671 (w) cm^{-1}. – ^1H NMR (400 MHz): δ = 1.14 (s, 3 H), 1.36 (s, 3 H), 1.79 (dd, J_1 = 7.5 Hz, J_2 = 12.5 Hz, 1 H), 1.95 (ddd, J_1 = 8.5 Hz, J_2 = 11.0 Hz, J_3 = 12.5 Hz, 1 H), 2.13 (s, 3 H), 2.19 (s, 3 H), 2.57 (dd, J_1 = 8.5 Hz, J_2 = 15.5 Hz, 1 H), 2.81 (ddd, J_1 = 7.5 Hz, J_2 = 11.0 Hz, J_3 = 15.5 Hz, 1 H), 5.18 (s, 1 H), 5.43 (s, 1 H). – ^{13}C NMR (67 MHz): δ = 19.0 (q), 19.1 (q), 27.5 (q), 28.8 (t), 29.2 (q), 39.3 (t), 42.9 (s), 90.0 (d), 92.6 (d), 103.8 (s), 109.2 (s), 115.0 (s), 122.6 (s), 234.6 (s). – MS; *m/z* (%): 310 [M^+] (12), 254 (6), 226 (100), 210 (2), 159 (6), 144 (2), 129 (2). – HRMS calcd. for $C_{16}H_{18}CrO_3$ 310.06610; found 310.0666.

Deprotonation/Deuteration of rac-**62**: In a small, flame-dried Schlenk flask, a stirred solution of *rac*-**62** (20 mg, 0.065 mmol) in 1 ml of dry THF was cooled to −78°C and *n*-butyllithium (123 µl, 0.2 mmol, 1.6 M in hexane) was added. The solution was stirred at −78°C for 30 min, then at −50°C for 30 min, before 0.1 ml (5 mmol) of D_2O was added. After 5 min, the cooling bath was removed, the mixture was diluted with 20 ml of EtOAc, washed with brine, and dried with Na_2SO_4. The solvent was removed in vacuo and the residue was crystallized from hexane/EtOAc to give 12 mg (60%) of a mixture of the monodeuterated complexes *rac*-**67a**/*rac*-**67b** with an overall degree of deuteration of 76%. ^1H NMR (400 MHz): δ = 1.14 (s, 3 H), 1.37 (s, 3 H), 1.79 (dd, J_1 = 7.5 Hz, J_2 = 12.5 Hz, 1 H), 1.95 (ddd, J_1 = 8.5 Hz, J_2 = 11.0 Hz, J_3 = 12.5 Hz, 1 H), 2.13 (s, 3 H), 2.17 (pseudo t, 2 H, 1 D), 2.57 (dd, J_1 = 8.5 Hz, J_2 = 15.5 Hz, 1 H), 2.81 (ddd, J_1 = 7.5 Hz, J_2 = 11.0 Hz, J_3 = 15.5 Hz, 1 H), 5.18 (s, 1 H), 5.43 (s, 1 H). – MS; *m/z* (%): 311 [M^+] (10), 255 (6), 227 (100), 211 (2), 160 (10), 145 (2), 129 (4). – HRMS: calcd. for $C_{16}H_{17}DCrO_3$ 311.07239; found 311.0716. – The exact ratio of the isomers was determined to be 85:15 (*rac*-**67a**/*rac*-**67b**) by means of a 600-MHz ^1H-NMR spectrum.

☆ Dedicated to Professor *E. O. Fischer* on the occasion of his 80th birthday.

[8] The lithiated species can be assumed to possess a structure **3**, in which the deprotonated center is part of a newly formed double bond (see refs.[1c][2]). In analogy to the deprotonation of ketones, the C–H bond to be broken during the deprotonation step should, for stereoelectronic reasons, be as close to parallel as possible in relation to the aryl π orbitals, so that the developing p orbital can be stablized early. For related discussions, see, for instance: [8a] P. Deslongchamps, *Stereoelectronic Effects in Organic Chemistry*, Pergamon, Oxford, **1983**, pp. 243–267, and references cited therein. – [8b] K. [16] It should be noted that mild conditions (0°C) are required to achieve a reasonably high yield. At higher temperatures, an increased formation of by-products was observed and the isolated yield of *rac*-**20** dropped, for instance, to 32% when the reaction was performed at 40°C. Addition of HMPA, which is reported to give improved yields in some comparable cases[15], resulted only in a decreased yield of *rac*-**20** (ca. 30% at 0°C).

[29] [29a] X-ray crystal structure analysis of *rac*-**1**: Enraf-Nonius CAD4 diffractometer, Cu-K_α radiation, $2\Theta_{max}$ = 120°, empirical absorption correction (ψ scans). Structure determination by direct methods (SHELXS-90). The H atoms of the cyclohexene ring were refined with isotropic thermal parameters. The others were placed at calculated positions and were not refined. $C_{22}H_{34}O_5CrSi_2$, monoclinic, space group $P2_1/n$, a = 12.457 (2) Å, b = 13.710 (4) Å, c = 15.124 (3) Å, β = 99.04 (2)°, V = 2551 (2) Å^3, Z = 4, $\rho_{calcd.}$ = 1.267 gcm^{-3}, μ = 48.9 cm^{-1}; 3644 independent reflections with $I > 0$ were used; R = 0.054, Rw = 0.056, S = 2.14. The residual electron density was less than 0.68 eÅ^{-3}. – [29b] X-ray crystal structure analysis of **24**: Enraf-Nonius CAD4 diffractometer, Cu-K_α radiation, $2\Theta_{max}$ = 130°, empirical absorption correction (ψ scans). Structure determination by direct methods (SHELXS). A refinement with split positions for C8 and C9 revealed superposition of two molecular conformations. The H atoms were placed at calculated positions and were not refined. A refinement of the wrong absolute configuration gave R = 0.068. $C_{17}H_{20}O_5Cr$, monoclinic, space group $P2_1$, a = 9.8632 (8) Å, b = 12.414 (1) Å, c = 14.144 (2) Å, β = 101.489 (9)°, V = 1697.1 (5) Å^3, Z = 4, $\rho_{calcd.}$ = 1.395 gcm^{-3}, μ = 58.2 cm^{-1}; 5584 independent reflections with $I > 0$ were used; R = 0.048, Rw = 0.048, S = 1.79. The residual electron density was less than 0.43 eÅ^{-3}. – [29c] X-ray crystal structure analysis of *rac*-**5**: Siemens Smart diffractometer, measurement at −140°C, Mo-K_α radiation, $2\Theta_{max}$ = 65°, empirical absorption correction (SADABS). Structure determination by direct methods (SHELXS). A refinement with split positions for C8 and C9 (cyclohexene ring) revealed superposition of two molecular conformations. The H atoms of the methoxy groups were taken from a difference synthesis. The remaining H atoms were placed at calculated positions and were not refined. $C_{23}H_{36}O_5CrSi_2$, monoclinic, space group $C2/c$, a = 39.493 (4) Å, b = 7.6645 (9) Å, c = 18.310 (2) Å, β = 107.139 (8)°, V = 5296 (1) Å^3, Z = 8, $\rho_{calcd.}$ = 1.256 gcm^{-3}, μ = 5.37 cm^{-1}; 8133 independent reflections with $I > 0$ were used; R = 0.099, Rw = 0.063, S = 1.19. The residual electron density was less than 0.35 eÅ^{-3}. – [29d] X-ray crystal structure analysis of *rac*-**7**: Enraf-Nonius CAD4 diffractometer, Cu-K_α radiation, $2\Theta_{max}$ = 120°, empirical absorption correction (ψ scans). Structure determination by direct methods (SIR92). A refinement with split positions for C8 to C13 (saturated six-membered ring of molecule I) revealed superposition of two molecular conformations. The H atoms of the methoxy groups were taken from a difference synthesis. The remaining H atoms were placed at calculated positions and were not refined. $C_{25}H_{38}O_5CrSi_2$, triclinic, space group $P\bar{1}$, a = 12.206 (3) Å, b = 12.289 (3) Å, c = 18.973 (6) Å, α = 81.36 (2)°, β = 87.69 (2)°, γ = 85.02 (2)°, V = 2802 (5) Å^3, Z = 4, $\rho_{calcd.}$ = 1.249 gcm^{-3}, μ = 44.9 cm^{-1}; 8022 independent reflections with $I > 0$ were used; R = 0.058, Rw = 0.060, S = 2.23. The residual electron density was less than 0.59 eÅ^{-3}. – Crystallographic data (excluding structure factors) for the structure reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication no. CCDC-101004. Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [Fax: int. code + 44(1223)336-033; E-mail: deposit@ccdc.cam.ac.uk].
[30] W. P. Aue, E. Bartholdi, R. R. Ernst, *J. Magn. Reson.* **1977**, *28*, 542.
[31] Complex *rac*-**1** was prepared as described in ref.[5]; complex **50** was obtained from 6,7-dimethoxytetralin by complexation and disilylation: H.-G. Schmalz, A. Schwarz, unpublished results.
[32] It should be noted that all our attempts to achieve a more or less selective monodeuteration under the *t*BuOK/[D_6]DMSO conditions (lower temperatures and/or shorter reaction times) failed.
[33] The degree of deuteration (and the level of inaccuracy) was determined (estimated) by comparison with the integrals observed for the methoxy or the TMS groups.
[34] The fact that no significant loss of regioselectivity was found in these experiments indicates that the inherent directing effect must be stronger than the primary kinetic isotope effect.
[35] A protonation at the chromium atom of the anionic intermediate, which would eventually have resulted in the formation of an *endo*-protonated complex could thereby be excluded.
[36] X-ray crystal structure analysis of *rac*-**56**: Enraf-Nonius CAD4 diffractometer, Cu-K_α radiation, $2\Theta_{max}$ = 120°, empirical absorption correction ψ scans). Structure determination with direct methods (SIR92). The H atoms were taken from difference Fourier synthesis and refined using isotropic thermal parameters. All other atoms were refined using anisotropic thermal parameters. $C_{24}H_{38}O_5CrSi_2$, monoclinic, space group $P2_1/a$, a = 13.557 (9) Å, b = 11.076 (2) Å, c = 19.411 (6) Å, β = 107.08 (4)°, V = 2786 (4) Å^3, Z = 4, $\rho_{calcd.}$ = 1.227 gcm^{-3}, μ = 45.1 cm^{-1}; 3974 independent reflections with $I > 0$ were used; R = 0.044, Rw = 0.043. The residual electron density was less than 0.24 eÅ^{-3}. Further details of the crystal structure investigations are available on request from the CCDC; for details see ref.[29d].
[37] The formation of benzylic alkylation products derived from *rac*-**7** was established by NMR of the crude product mixture but purification was not successful due to rapid decomposition.
[38] Brocard and Lebibi (ref.[6d]) summarize their experiments: "The regiospecificity of the benzylic functional group of arenetricarbonylchromium cannot be explained by preferential attack at the carbon which is eclipsed by the chromium–carbonyl bond. Electronic effects in directing the regiospecificity of benzylic attack were found to predominate."

[45] This representation is favorable due to the experimental fact that the anions possess a high configurative stability; see, for instance: S. E. Gibson, M. J. Schneider, M. H. Smith, *J. Chem. Soc., Chem. Commun.* **1996**, 839. Our own NMR data of some lithiated species (see: T. Volk, Dissertation, TU Berlin, **1996**) support this picture.
[46] It is a commonly accepted fact that the $Cr(CO)_3$ unit tends to be eclipsed with an electron donor (e.g. methoxy) substituent and *anti* to electron acceptors (e.g. CN, R_3Si) and that the arene ligand carbon atoms which are eclipsed with a CO ligand are predicted to be more electrophilic (see: refs.[1a][40][41], as well as: T. A. Albright, P. Hofmann, R. Hoffmann, *J. Am. Chem. Soc.* **1977**, *99*, 7546).
[47] The barrier to rotation of the $Cr(CO)_3$ tripod about the Cr−ring-centroid axis is usually small, but it can increase up to 9−10 kcal·mol^{-1} in the case of highly substituted systems. Keywords: Phosphorus ylides / Allylic reactivity / Disproportionation / Phosphorus heterocycles / NMR Spectroscopy

The equation 7 **1** + 11 PCl_3 → 2 **7** + **11** + 21 HCl describes in part the reaction of allylidenetriphenylphosphorane (triphenylphosphonium allylide) **1** with PCl_3. It involves the substitution of all α- and γ-hydrogen atoms of **1** and a concomitant disproportionation of the phosphorus. The reduction product **11** and its less highly substituted precursor **9** are new examples of the favoured family of 3-phosphonio 1,2-diphospholides and 1,2,4-triphospholides. The cation of the ionic oxidation product **7** has a phenalene structure with three peripheric PCl ring members and a chlorophosphonium center. In the crystal two of these bowl-shaped cations encapsulate a chloride anion. This is shown by an X-ray structure investigation. The structure of other products is elucidated by ^{31}P-NMR spectroscopy.

Allylidenetriphenylphosphorane [(prop-2-enediyl)triphenylphosphorane] (**1**) may be understood as phosphonio-substituted allyl anion and is expected to exhibit the reactivity of an asymmetric allyl anion[1][2][3][4].

1

With phosphorus trichloride it consequently may interact at its α- or γ-carbon atom leading to compounds **2** or **3** as the primary substitution products and it also may interact at both sites with the same PCl_3 molecule or with two different of them to give compounds **4** or **5** as secondary products. All in all there are three hydrogen atoms of **1** that can be substituted. The different alternatives of this reaction were considered earlier[5]. The actual experiment (in benzene with an excess of **1**) gave a product which was assumed to be the hydrochloride of the "tris-ylene" **6**. It would be the result of the substitution of three molecules of **1** exclusively at the γ-position by the same PCl_3 molecule. Compound **6** was obtained from its hydrochloride by reaction with sodium amide. It is described as a deep red, very reactive, air-sensitive substance.

We repeated the reaction of **1** with PCl_3 in pyridine, which in similar cases had proved as a convenient solvent, able to take up the hydrogen chloride lost from the reaction partners in the substitution reaction[6].

Reaction and Products

The reaction of phosphorus trichloride with **1** in pyridine at 0 °C was visually observable. ^{31}P-NMR spectroscopy was used to monitor several experiments with different molar ratios. The spectra always indicated complex mixtures of products. These mixtures at room temperature continued to change their composition for a long time (up to several months). At long reaction times the spectra tended to become simpler. Naturally the reaction of the three-functional PCl_3 with the three-functional partner **1** can be expected to take various pathways with numerous intermediates. In the course of the reaction more and more of the functions are used, and the number of alternatives should decrease.

With a 3:1 initial molar ratio of **1** and PCl_3, compound **7** becomes the main product after 2 d. Its identity follows from its $^{31}P\{^1H\}$-NMR spectrum of $[AB]_3D$ type. As only the two-bond coupling constants J_{AB} and J_{BD}, and the four-bond coupling constant J_{AD} are large enough to influence the signal splitting significantly ($J_{AA'}$, $J_{AB'}$ and $J_{BB'}$ are too small), the spectrum is rather simple in appearance (Figure 1). The chemical shifts δ_A, δ_B and δ_D are in the expected range, δ_D in particular is characteristic for a chlorophosphonium center (Table 1).

No intermediate on the way to **7** could be identified from the spectra. In particular compound **6** (or its hydrochloride) was not found; however, it cannot be excluded as an intermediate either. It would be expected to possess a highly reactive phosphane center which easily becomes oxidized.

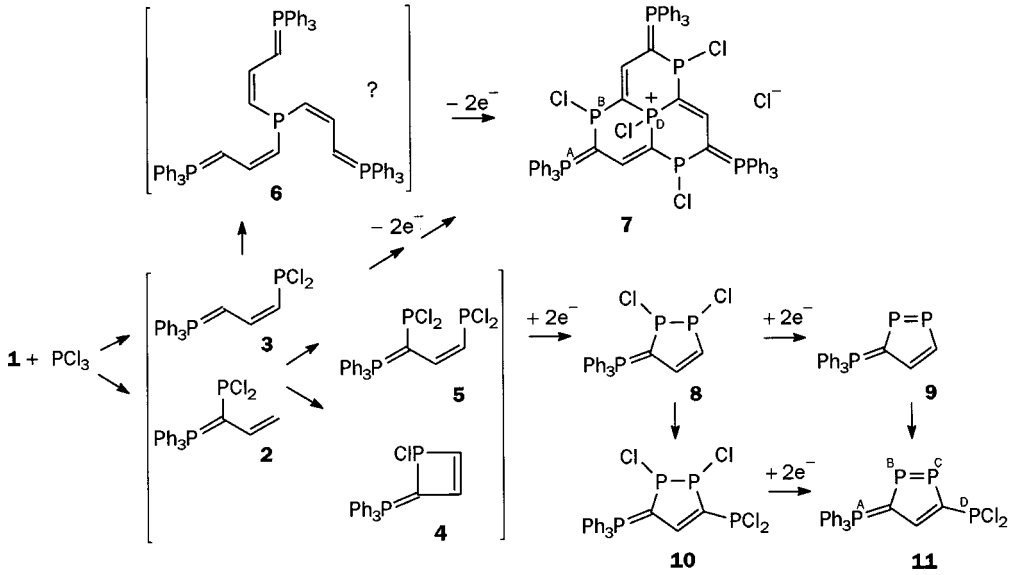

Figure 1. Experimental and calculated $^{31}P\{^{1}H\}$-NMR spectrum of **7**; ν_o = 109.380 MHz

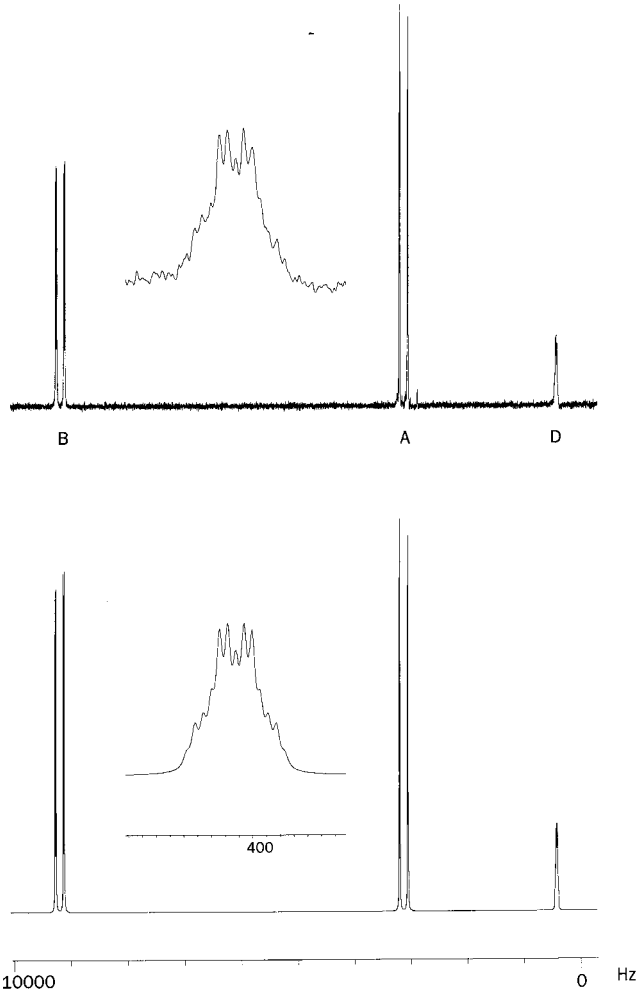


In fact, the overall formation of **7** as represented by equation (1) in Scheme 1 involves an oxidation.

Table 1. ^{31}P-NMR data of the tetraphosphaphenalenes **7** and **18** (in pyridine); coupling constants J in Hz

	7	**18**
δ_A	28.5	27.6
δ_B	83.9	−20.6
δ_C		−23.1
δ_D	3.8	11.2
$^2J_{AB}$	145.0	139.0
$^3J_{AC}$		7.6
$^4J_{AD}$	6.0	3.7
$^1J_{BC}$		−141.0
$^2J_{BD}$	17.8	17.6

Scheme 1. Equations leading to the products **7**−**11** (R = Ph_3PC_3H, RH_3 = **1**, Py = pyridine)

$$3\,RH_3 + 4\,PCl_3 + 9\,Py \xrightarrow{-2e^-} \underset{\mathbf{7}}{R_3P_4Cl_4^+} + 9\,PyH^+ + 8\,Cl^- \quad (1)$$

$$RH_3 + 2\,PCl_3 + 2\,Py \xrightarrow{+2e^-} \underset{\mathbf{8}}{RHP_2Cl_2} + 2\,PyH^+ + 4\,Cl^- \quad (2)$$

$$RH_3 + 2\,PCl_3 + 2\,Py \xrightarrow{+4e^-} \underset{\mathbf{9}}{RHP_2} + 2\,PyH^+ + 6\,Cl^- \quad (3)$$

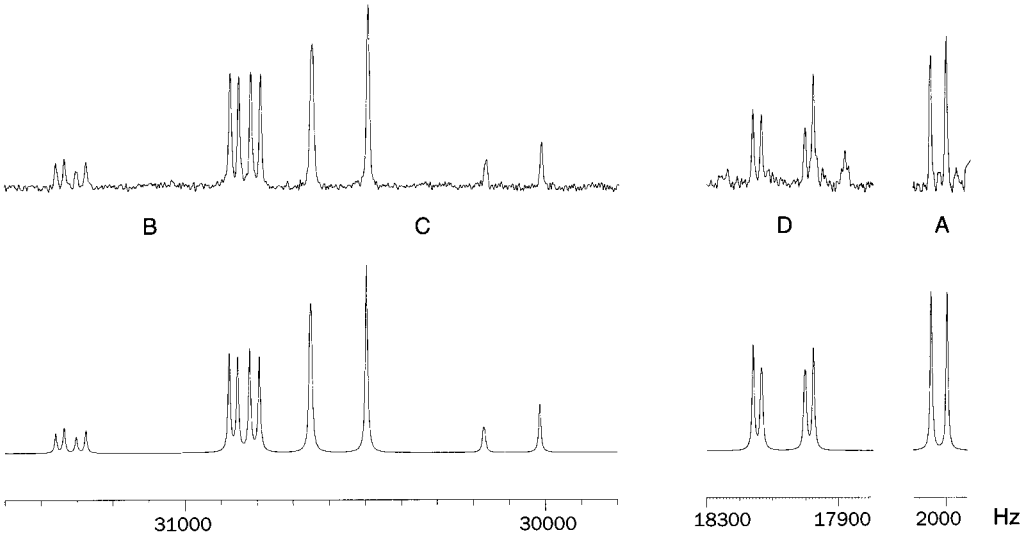
$$RH_3 + 3\,PCl_3 + 3\,Py \xrightarrow{+2e^-} \underset{\mathbf{10}}{RP_3Cl_4} + 3\,PyH^+ + 5\,Cl^- \quad (4)$$

$$RH_3 + 3\,PCl_3 + 3\,Py \xrightarrow{+4e^-} \underset{\mathbf{11}}{RP_3Cl_2} + 3\,PyH^+ + 7\,Cl^- \quad (5)$$

With equimolar amounts of **1** and PCl_3 the reaction is similar to the one described above in that **7** finally becomes the main product. In this case it takes several months, however. As before several intermediates are observed, which already contain the central chlorophosphonium unit as in **7** (with $\delta^{31}P = 0-5$) but which are less symmetric. After 10

months their signals have disappeared in favour of **7**. This suggests that in the synthesis of **7** at first triallylphosphanes such as **6** form and become oxidized before the rings are closed by the peripheral PCl units. As a second final product, compound **11** is observed in this reaction. It is readily recognized by its $^{31}P\{^{1}H\}$-NMR spectrum (Figure 2) representing an ABCD spin system, and in particular by the low-field chemical shifts δ_B and δ_C and by the large coupling constant J_{BC} (see below, Table 2).

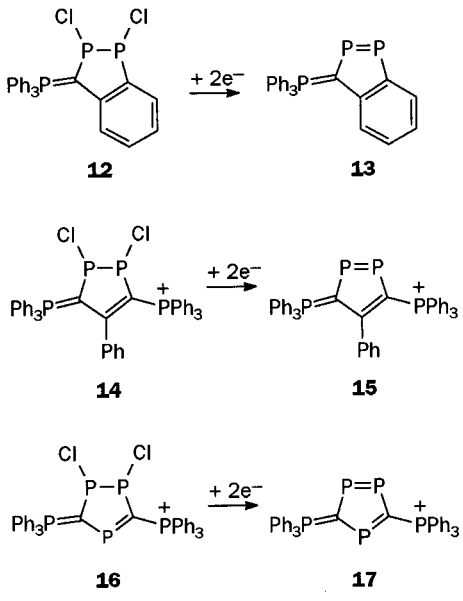
Figure 2. Experimental and calculated $^{31}P\{^{1}H\}$-NMR spectrum of **11**; ν_o = 109.380 MHz



If a still smaller molar ratio (3:4) of the reaction partners is used, compound **10** is observed in an early stage of the reaction (after 12 h) followed again by **11**. The formation of **10** and **11** involves a reduction and is described by equations (4) and (5) in Scheme 1. A combination of (1) and (4) or of (1) and (5) allows the formulation of a consistent overall reaction.

The identified products **7**, **10**, and **11** have in common an exhaustive substitution of **1** in which all three α- and γ-hydrogen atoms are replaced by phosphorus. In the formation of **10** and **11** it cannot be decided at what stage of substitution the PP bond is formed and the five-membered ring is closed.

A little further insight is provided by the reactions with a low molar ratio (1:3) of the partners and with an additional reducing agent (PBu_3). Although an excess of PCl_3 was used and unreacted PCl_3 is still present, compounds **8** and **9** are observed in this case (equations 2 and 3). In these compounds one γ-hydrogen atom of **1** is left unsubstituted. The added tributylphosphane apparently makes the reduction faster than the last step of substitution. Compounds **10** and **11** seem to form from **8** and **9** by a consecutive substitution.



1,2-Diphosphole Derivatives

The formation of **8** from **1** is closely related to that of its benzo derivative **12** in the reaction of benzyl triphenylphosphonium bromide with PCl_3 in presence of a base[7]. The *ortho* position of the ylide here displays a reactivity similar to that of the γ position in **1**. Furthermore, **12** is readily reduced to **13**, which is the benzo derivative of **9**.

The reaction of a γ-phosphonio-substituted allylidene phosphorane with PCl_3 also parallels the formation of **8** and leads to its symmetrically substituted derivative **14**[8]. In this reaction a four-membered dihydrophosphete ring was observed as an intermediate and consequently the analogous compound **4** has to be considered as an intermediate on the way to **8**.

The preferred formation of five-membered rings of type **8** is documented by still another example: The reaction of [bis(trimethylsilyl)methylene]phosphorane with PCl_3 yields as a secondary product the dihydrotriphosphole **16**[9], which is the 4-phospha derivative of **14**. Both **14** and **16** can be

reduced to give the corresponding diphosphole **15** and triphosphole **17**.

Table 2. ^{31}P-NMR data of the dihydrodiphosphole/diphosphole pairs **8/9** (in pyridine), **10/11** (in pyridine), **12/13** (in CH_2Cl_2)[7], **14/15** (in CH_2Cl_2)[8], and of the dihydrotriphosphole/triphosphole pair **16/17** (in CH_2Cl_2/C_6D_6)[9]. δ_A refers to 3-PPh_3, $\delta_{B,C}$ refer to P-1,2 as indicated in formula **11**. Coupling constants J in Hz.

	δ_A	δ_B	δ_C	δ_D	$^2J_{AB}$	$^3J_{AC}$	$^1J_{BC}$	$^3J_{BD}$	$^2J_{CD}$

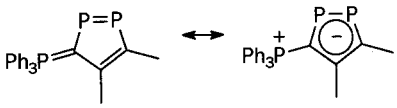
[a] Superimposed.

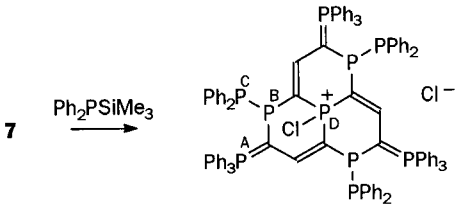
In Table 2 the ^{31}P-NMR data of the new compounds **8**−**11** are compared to the related known compounds **12**−**17**. In case of the unsymmetrically substituted compounds **8**, **10**, **12** and **9**, **11**, **13**, the phosphorus atom P^B which is adjacent to the ylidic ring member and which consequently is more strongly influenced[10], always appears less shielded than P^C. The difference for **8**−**11** is smaller, however, than for **12** and **13**. The reduction is always accompanied by a downfield chemical shift of the now two-coordinate phosphorus atoms ($\delta_{B,C}$ = 229−366) and by a sharp increase in the one-bond coupling constant ($|^1J_{BC}|$ = 465−487 Hz).

The charge of the phosphonio substituents according to δ_A seems to decrease somewhat on reduction. It nevertheless corresponds to the polar resonance formula for the reduced compounds **9**, **11**, **13**, **15**, **17**.



Tetraphosphaphenalene Derivatives

For a further chemical identification of **7** it was treated with diphenyl(trimethylsilyl)phosphane. In a clean reaction only the chlorine atoms at P^{III} are replaced by PPh_2 groups while the central P^VCl unit remains unchanged. This leads to compound **18**. Its $^{31}P\{^1H\}$-NMR spectrum (Figure 3) represents a $(ABC)_3D$ spin system (Table 1).



18

ture analysis. They contain 2.7 pyridine molecules per formula unit of **7**. Whereas the cation lattice is of good quality, the location of the chloride anions and the solvent molecules is rather uncertain due to strong disorder. Figure 4 shows the structure of a cation. Its skeleton is built from three allylic units C1,2,3 joined by three phosphorus atoms P2 to give a twelve-membered ring and by the central P1 to give a tetraphosphaphenalene system. The allylic carbon atoms C1, C2, and C3 lie in a plane together with the four phosphorus atoms P1, P2, P2B, and P3 bonded to them. The three planes meet at the central atom P1 forming a flat bowl. Under the influence of the three ylide units attached to the chlorophosphonium center the P1−Cl1 bond becomes rather long (Table 3)[11][12]. The bonds P2−Cl2 point to the same direction, i.e. to the convex side of the bowl.

In the crystal two of the described bowl-shaped cations approach each other with their concave sides face to face to encapsulate a chloride ion Cl3 like a shell encapsulates a pearl (Figure 5). The bonds P1−Cl1 of the two cations and Cl3 lie on a three-fold symmetry axis around which the two cations are mutually twisted by 60° against each other. The chloride ion Cl3 thus becomes walled in by six phenyl groups belonging alternately to PPh_3 units of one or the other cations. The *o*- and *m*-hydrogen atoms of these phenyl groups approach Cl3 at 284 and 296 pm, which is less than the sum of the van der Waals radii (320 pm). At the origin

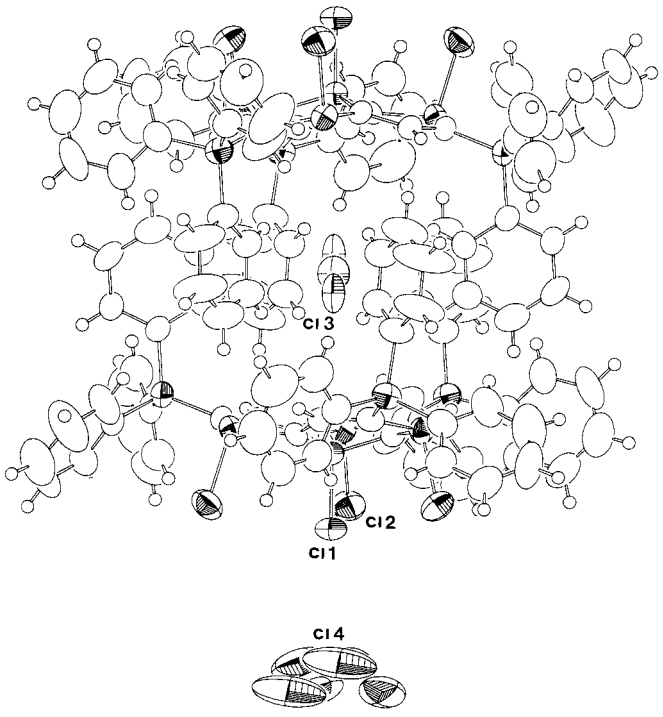
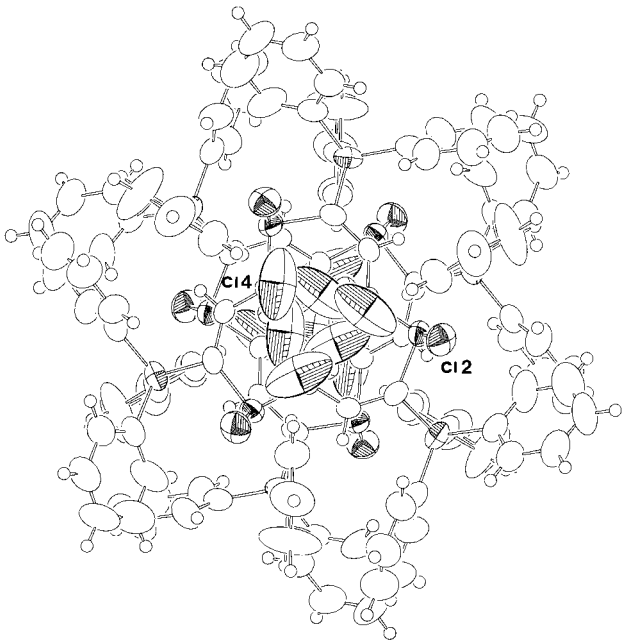
Figure 5. A $(cation)_2Cl^+$ unit and a Cl^- anion of **7** viewed perpendicular to the threefold axis; Cl3 (within the $(cation)_2Cl^+$ unit) is split and disordered along the threefold axis; Cl4 (the isolated Cl^- anion) is split and disordered on two levels around the threefold axis. The pyridine molecules are not shown



within the cage formed thus, the position of Cl3 is split. The other chloride ion Cl4 distributes on 2 × 3 symmetry-equivalent positions close to the threefold axis (Figures 5

and 6). The crystal lattice is eventually composed of an equal number of the $(cation)_2Cl^+$ units and isolated Cl^- anions alternating along the threefold axis and of 5.4 molecules of pyridine on 2×3 positions of 0.5 occupancy and 2×3 positions of 0.4 occupancy around one sequence of these ions.

Figure 6. View along the *c*-axis of **7**; Cl4 is split and disordered on two positions near the threefold axis. The pyridine molecules are not shown



Experimental Section

All manipulations were carried out in flame-dried glassware under argon with Schlenk tube techniques. Dry pyridine was used as obtained (Fluka). Pentane was dried over molecular sieves (4 Å).

NMR: Jeol EX 400 (^{1}H), Jeol GSX 270 (^{31}P) with Me_4Si (int.) and 85% H_3PO_4 (ext.) as standards.

Allylidenetriphenylphosphorane (**1**)[5] was prepared from 3-bromopropene and Ph_3P and subsequent deprotonation of the resulting phosphonium bromide with $NaN(SiMe_3)_2$[13].

Reaction of **1** *with* PCl_3. − *a) In a 3:1 Molar Ratio:* To **1** (0.56 g, 1.9 mmol) in 25 ml of pyridine at 0°C was added PCl_3 (0.054 ml, 0.6 mmol). The dark red solution brightened for a few minutes before becoming dark red again. After 2 d at room temperature the $^{31}P\{^1H\}$-NMR spectrum showed a wide variety of signals among which those of **7** were found with 12% of the total intensity. After 10 months the relative intensity had increased to 27%.

b) In a 3:4 Molar Ratio: **1** (0.97 g, 3.2 mmol) and PCl_3 (0.37 ml, 4.2 mmol) were added as before. In the $^{31}P\{^1H\}$-NMR spectrum after 12 h at room temperature among a large variety of signals only those of **10** were identified with 2% relative intensity. During 10 more months pyridinium chloride separated from the dark red solution and was removed. The spectrum of the filtrate showed **7** (41%), **10** (10%), and **11** (13% relative intensity). In this solution dark yellow crystals of **7** formed which were used for X-ray analysis; they decomposed at 93°C. − ^{1}H NMR (CD_2Cl_2): δ = 7.27−7.59 (m, 3 H, \$-H), 7.58−7.68 (m, 36 H, *o*-, *m*-H), 8.67−8.69 (m, 9 H, *p*-H).

c) In a 1:3 Molar Ratio and Additional PBu_3*:* To **1** (1.69 g, 5.6 mmol) PCl_3 (1.46 ml, 16.7 mmol) was added as before. After 10 min, PBu_3 (0.90 ml, 5.6 mmol) was added to the red solution. In the $^{31}P\{^1H\}$-NMR spectrum after 12 h at room temperature among a variety of signals those of **8** (1%), **9** (5%), **10** (2%), and **11** (0.5%) were identified. After heating under reflux for 2 d the spectrum showed **7** (3%), **8** (8%), **9** (9%), **10** (11%), and **11** (0.5%).

Reaction of **7** *with* Ph_2PSiMe_3*:* To a solution of **7** (42 mg, 0.04 mmol) in 0.5 ml of pyridine was added Ph_2PSiMe_3 (40 mg, 0.15 mmol). After 10 min a $^{31}P\{^1H\}$-NMR spectrum of the orange solution showed the signals of **18**.

Crystal Structure Analysis of **7**: Table 4; the chloride anion Cl3 is disordered on the threefold axis and the chloride anion Cl4 is disordered on the split position Cl4/Cl4A near the threefold axis, thus leading to 2 times 3 positions. Cl4/Cl4A were refined with the same U_{ij} temperature factor components. One of the pyridine solvent molecules is disordered around a center and the other is on a common position. Both pyridine molecules were fitted by restraints during the least squares procedure. Further details are available from the Cambridge Crystallographic Data Center on quoting the depository number CCDC-101626, the names of the authors and the journal citation (E-mail: deposit@ccdc.cam.ac.uk).

Keywords: Hydrogenations / Parahydrogen / Platinum / Alkynes / Alkenes

The mechanism of hydrogenation of alkynes catalyzed by the $[(PR_3)_2PtHX]/SnX_2$ system (PR_3 = PPh_3, $PMePh_2$; X = Cl, Br) has been studied by means of parahydrogen-induced polarization of ^1H spectra (PHIP). Dihydride intermediates confirming the stepwise hydrogenation at room temperature were observed when the reaction was run in acetone. The obtained ^1H-PHIP spectra, together with NMR data for related species, are consistent with the formulation of these intermediates as *cis*-$[H_2Pt(PR_3)(SnX_3)(\sigma\text{-alkenyl})(acetone)]$, where the σ-alkenyl ligand originates from an insertion reaction of the alkyne (1-phenyl-1-propyne, 1-phenyl-1-butyne, diphenylacetylene, 3,3-dimethylbutyne). At elevated temperatures, the hydrogenation in acetone proceeds as a *cis*-synchronous transfer of the two hydrogen atoms of parahydrogen to the substrate molecule. A mechanism for this synchronous hydrogenation is suggested.

Introduction

The parahydrogen-induced polarization (PHIP) phenomenon was first observed accidentally by Bryndza and coworkers as early as 1983[1]. This NMR technique is now recognized as a valuable mechanistic probe for investigating homogeneously catalyzed hydrogenation reactions[2]. The phenomenon was proposed theoretically in 1986 by Bowers and Weitekamp[3], and soon thereafter was confirmed experimentally[4]. Furthermore, it was recognized that PHIP allows examination of the reaction mechanisms of the single-step transfer of the two parahydrogen atoms to the substrate molecule, and sometimes allows identification of the unstable dihydride intermediates participating in the catalytic cycle[5][6]. Moreover, study of the hydrogenation mechanism by traditional methods is troublesome because in many cases the reaction is accompanied by significant degrees of isomerization of the starting materials and/or products[7]. The PHIP technique offers further information, even on the stereochemistry of the fundamental step of the addition of dihydrogen to the organometallic catalyst. Quite possibly, in situ PHIP-NMR spectroscopy may provide the data relating to the structures of active intermediates that are otherwise difficult or impossible to obtain.

The physical aspects of the processes leading to PHIP-NMR spectra are discussed in a number of papers (e.g., refs.[8][9]). Using this technique, hydrogenation reactions catalyzed by rhodium[10−13], iridium[14][15], palladium[16][17], and ruthenium[18] complexes have been studied.

Although platinum complexes are well-known catalysts for hydrogenation[19−21], hydroformylation[22−25], and hydrosilylation[26] reactions, there have been only a few mechanistic studies using the PHIP technique. In a previous paper, we showed that spin-polarized products arise from the hydrogenation of alkynes in the presence of Pt^0 complexes with either coordinated alkynes or alkenes, as well as with the usual Pt^{II} phosphane hydrido chloro complexes, activated by tin(II) chloride[27].

In principal, the latter fact is contradictory to the generally accepted mechanism for $Pt^{II}/SnCl_2$ mediated hydrogenations (Scheme 1).

Since 1965, it has been accepted that the first step of the hydrogenation is the reduction of the pre-catalyst, accompanied by the formation of platinum monohydrides **2**[28][29]. These monohydrides have been shown to undergo rapid, equilibrium addition reactions to carbon−carbon multiple bonds of the substrate, with the formation of σ-C intermediates **3**[30][31]. Furthermore, the third step of the asynchronous hydrogenation, namely hydrogenolysis of the Pt^{II}−C(alkyl) bond in **3**, has been shown to proceed under relatively mild conditions[32]. The appearance of polarized products during $Pt^{II}/SnCl_2$ mediated hydrogenation using para-H_2 prompted us to engage in a more detailed study of the reaction mechanism using the PHIP technique.

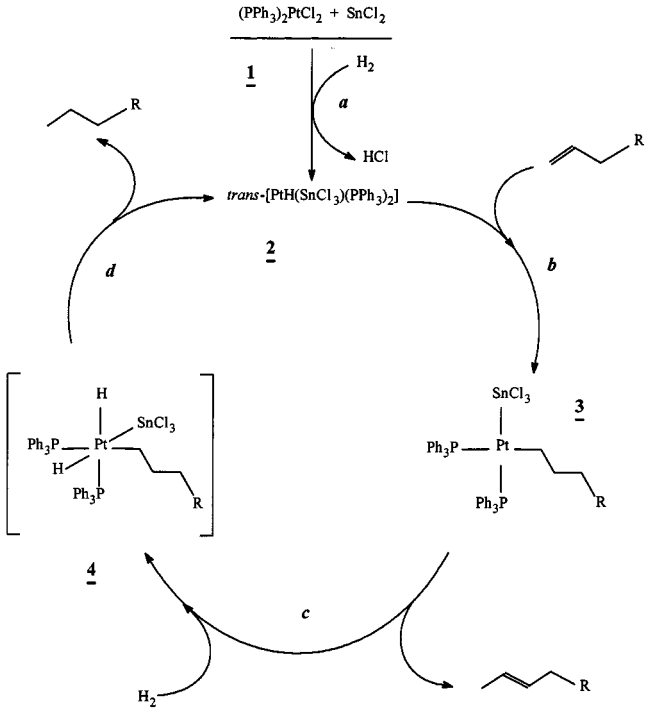
Scheme 1. Generally assumed mechanism for the Pt^{II}–tin dichloride catalyzed hydrogenation, asynchronous mechanism



It is well known that activation of Pt^{II} complexes by tin(II) halides is strongly solvent-dependent. Solvents of medium solvating ability and polarity, such as acetone, play quite a significant role in platinum-phosphane chemistry, promoting extensive phosphane redistribution reactions[33–35]. This dependence can also result in changes in catalytic activity and selectivity[22], as well as of the reaction mechanism, therefore necessitating studies in a variety of solvents.

In this paper we describe the results of PHIP studies of the Pt^{II}/Sn^{II} mediated hydrogenation of alkynes and alkenes in acetone and some other solvating media.

Results and Discussion

PHIP in the System [$(PPh_3)_2PtHCl$]/$SnCl_2$/1-Phenyl-1-propyne

Since the generally accepted catalytic cycle involves platinum hydride as an active intermediate, we avoided the activation stage (***a***, Scheme 1), as well as extensive HCl formation, by the use of pre-synthesized platinum hydride instead of the usually employed dichloro complex. The interaction of platinum monohydride with $SnCl_2$ in acetone proceeds rapidly, and the resulting clear, orange-yellow solution shows new signals in its ^{1}H-NMR spectrum attributable to *trans*-[$(PPh_3)_2PtH(SnCl_3)$], **2**, {δ(PtH) = −9.75 [br, ^1J(PtH) = 1105 Hz]}, as well as to the products resulting from a phosphane redistribution reaction {$[(PPh_3)_3PtH]^+$, δ(PtH) = −5.75 [br, d, ^1J(PtH) = 154 Hz]; *trans*-$[(PPh_3)PtH(SnCl_3)_2]^-$, δ(PtH) = 13.355 [d, ^2J(PH) = 131 Hz, ^1J(PtH) = 412 Hz]} in accord with previously published data[34]. The spectra in ref.[34] were recorded at −90°C and thus the minor discrepancies with these data are obviously due to the different temperatures used.

Though the dihydrido-dichloro Pt^{IV} complexes were previously shown to arise as a result of an oxidative addition of HX to Pt^{II} monohydrides[36–38], our attempts to observe them using the PHIP technique during the reduction of dichloride **1** by parahydrogen were unsuccessful. Moreover, no polarization patterns were found as a consequence of the parahydrogen action on platinum–tin monohydrides. On the other hand, we observed strong, sharp polarization signals after the addition of an alkyne followed by parahydrogen to the tin-activated monohydride acetone solution (Figure 1). The relatively high field values of the chemical shift of the observed polarization patterns are consistent with Pt^{IV} species, since published data show a substantial high-field shift for Pt^{IV} dihydrides as compared to analogous Pt^{II} complexes[36][39][40][41].

The obtained PHIP patterns exhibit features that allow us to establish the structures of the transient platinum dihydrides. First of all, two isomers with similar couplings are

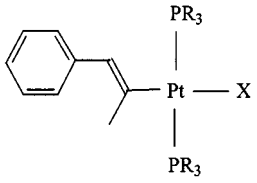
clearly discernible. This conclusion was confirmed experimentally upon cooling of the solution under parahydrogen (Figure 1, b) which resulted in a non-concerted change in the intensities and widths of the relevant resonances. Each isomer exhibits a typical ABX pattern, with large *trans*- and small *cis*-^{1}H−^{31}P couplings (Figure 1a, Table 1). The patterns for both isomers are accompanied by ^{195}Pt and $^{117/119}$Sn satellites, permitting an unambiguous assignment of the ligands in the equatorial plane of the coordination octahedron of **6a**. Only one phosphane ligand is incorporated into the coordination sphere of the transient dihydride, since the spectrum exhibits only one ^{1}H-^{31}P coupling for each proton. This was confirmed by PHIP simulations of the spectra of the mono- and diphosphane dihydrides (Figure 1, d, e, f). The assignment of the axial positions is not so clear-cut, but is supported by the observation that the presence of both an alkyne and acetone is essential for the development of polarization patterns. We suggest that the possible role of acetone lies in promoting the dissociation of one phosphane ligand, which, apparently, is followed by coordination to the platinum center. It has previously been well-documented[34][35] that the reaction of excess tin dihalides with platinum hydrides in acetone at room temperature rapidly leads to the formation of mixture of phosphane redistribution products, which contain monophosphane complexes.

Addition of 1-phenyl-1-propyne to an acetone solution of **2** leads to the disappearance of the Pt-H signals in the hydride region in the thermal spectrum and gives rise to a broadened singlet at approximately δ = 0.7. This singlet is symmetrically surrounded by broadened signals, the positions and intensities of which are consistent with the notion that they are in part ^{195}Pt and unresolved $^{119/117}$Sn satellites. The singlet was thus assigned to the methyl resonance of the σ-alkenyl ligand, resulting from an insertion of the triple bond of the substrate into the Pt−H bond (vide infra). This signal was invariably present in all cases where polarization in the Pt−H region was observed, which prompted us to ascribe the key role of a σ-bonded carbon ligand in the formation of PHIP-active Pt^{IV} dihydrides. The suggestion of the presence of this ligand was also derived from the following considerations: (a) the role of the substrate could be either to coordinate to platinum as a π-ligand or to insert into a Pt−H bond, thereby producing a σ-bonded carbon ligand; (b) the obtained PHIP corresponds to the spectrum of a dihydride, and not to a trihydride, establishing the insertion suggestion in (a); and (c) the isolated insertion product, i.e. the σ-phenylpropenyl platinum complex, shows analogous though more simple polarization patterns upon reaction with parahydrogen (Figure 1, c). The precise structure of the alkenyl radical in the transient dihydride is not clear, but it seems plausible that the existence of the two dihydrides is due to an isomerism of the alkenyl radical and, therefore, the dihydrides are in fact 2-phenyl-1-methylethenyl and 1-phenylprop-1-enyl complexes.

We were fortunately also able to isolate the product of insertion of 1-phenyl-1-propyne into the Pt−H bond of the starting monohydride. Light-yellow crystals of the product were formed on leaving to stand an acetone solution of the $[(PPh_3)_2PtH(SnCl_3)]$ complex together with the alkyne in the absence of hydrogen, as well as during hydrogenation experiments. The ^{1}H-NMR spectrum of this product in CD_2Cl_2 clearly shows the signal of the CH_3 protons of the σ-alkenyl ligand with a full set of ^{195}Pt and $^{117/119}$Sn satellites, and the signal of the proton adjacent to the double bond with partially obscured satellite signals. The ^{1}H spectrum is essentially similar to published data for the analogous triethylphosphane complex[42], in spite of the large deviation of the chemical shift value for methyl protons [δ = 2.23, ^3J(PtH) = 56.5 Hz[42]], which is apparently due to the difference between an acido ligand and the phosphane. Together with the obtained ^{13}C and ^{31}P data, this spectrum allows the unambiguous assignment of the structure of this product as **5a**. The doublet splitting of the main methyl resonance (ca. 2 Hz) can be attributed to a ^4J *cis*-coupling with the olefinic proton. Large values of $^4J(^{119/117}$Sn-^{1}H) are in accord with a *trans*-position of the trichlorostannato ligand relative to the alkenyl group, and they match published values for tin−proton couplings in



5a X = $SnCl_3$

6 d R = H, R′ = CMe_3, X = Cl;
6 e R = R′ = Ph, X = Br

other platinum trichlorostannato complexes[43]. It is also noteworthy that addition of several equivalents of DMF results in the cleavage of the trichlorostannato ligand with formation of the corresponding chloro complex, **5b**, in accord with the reported behavior of σ-alkylplatinum complexes[31].

The polarization spectrum originating from reaction of parahydrogen with the solution of **5a** in dichloromethane indicates the presence of only one isomer. These patterns are much less intense than those obtained for catalytic mixtures in acetone, which is apparently due to the fact that acetone is present in the system only in minor amounts as an impurity or as a solvent of crystallization, as is evident from the ^{1}H and ^{13}C spectra. The low intensity of the polarization signals can be also attributed to the enhanced stability of the isolated isomer, which is hydrogenated only to a small extent. The differences between the PHIP ^{1}H-NMR spectra obtained for the isolated insertion product and those obtained from the catalytic system are due to the change of medium, since addition of 0.15 ml of $[D_6]$acetone to a $CDCl_3$ solution of **5a**, followed by parahydrogen, shifts the dihydride signals towards coincidence with the position observed in situ (Table 1).

Catalytic Systems with Other Substrates

Besides 1-phenyl-1-propyne, other substrates can give transient dihydrides detectable by the PHIP technique. Thus, we have attempted to hydrogenate alkynes (phenylacetylene, diphenylacetylene, 1-phenyl-1-butyne, 1,4-diphenylbutadiyne), and alkenes (norbornadiene, 3,3-dimethylbutene) under the same conditions as used for 1-phenyl-1-propyne. Our observations are summarized qualitatively in Table 2.

The interaction of the system $[(PPh_3)_2PtHCl]/SnCl_2$/1-phenyl-1-butyne/acetone with parahydrogen proceeds similarly to the reaction of 1-phenyl-1-propyne (Figure 2). Polarization patterns show clearly resolved ^{117}Sn and ^{119}Sn sat-

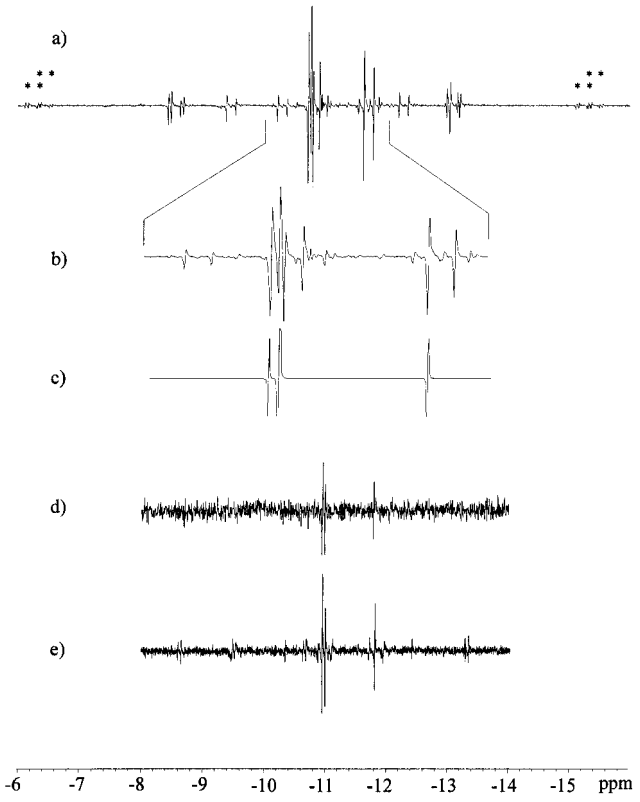
ellites for both isomers, confirming the general assignment of the transient dihydrides to the structures **6b**. Upon heating, extensive isomerization of the alkenyl part of the σ-ligand occurs, complicating the spectrum and leading to the appearance of a third isomer. This isomer could be due to an isomerization of the side-chain of the alkyne into an allenic structure. With 1-phenyl-1-butyne as the substrate, the insertion product was not discernible in the ^{1}H spectrum owing to the low intensity and complicated patterns due to its ethyl group, but it was readily observable in the ^{31}P spectrum of the reaction mixture [δ_P = 17.75, ^1J(Pt−P) = 2995 Hz].

Figure 2. PHIP ^{1}H-NMR spectra of the systems *trans*-[$(PPh_3)_2$PtHCl]/$SnCl_2$/alkyne/para-H_2 ([D_6]acetone, room temp.); **a)** alkyne = 1-phenyl-1-butyne; **b)** central lines of the spectrum (a) in the range δ = −10 to −12; **c)** PHIP++ simulation of the central part of the spectrum (a); **d)** alkyne = diphenylacetylene; **e)** alkyne = 3,3-dimethylbutyne

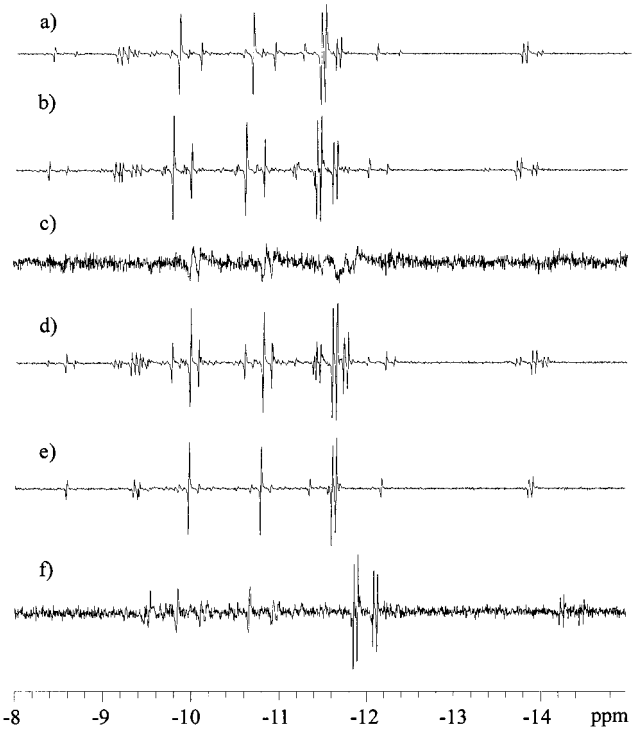


As expected, the system [$(PPh_3)_2$PtHCl]/$SnCl_2$/diphenylacetylene produced simple polarization patterns upon reaction with parahydrogen in acetone (Figure 2, d) due to the symmetry of the substrate and, therefore, resulted in the presence of only one dihydride, **6c**. The intensity of the signals was much lower than in the case of the 1-phenyl-1-propyne system. The reaction with 3,3-dimethylbutyne (Figure 2, e) also gave a simple polarization spectrum, despite the lack of symmetry of the substrate. This simplicity is apparently due to the fact that one alkenyl isomer strongly predominates in this case. The major isomer is suggested to be the 3,3-dimethylbutenyl-1 complex (**6d**), in view of the considerable steric requirements of the *tert*-butyl group. When the PHIP spectrum is recorded at elevated temperatures, a reversible formation of the second isomer is observable. Since in this case no changes in the alkenyl ligand can readily occur without undergoing skeletal rearrangements, we suggest these two reversible isomers to be the 3,3-dimethylbutenyl-1-platinum complex as the major component, and the corresponding -2-platinum complex as the minor component. Phenylacetylene and 1,4-diphenylbutadiyne gave no detectable dihydrides, but polarized signals of styrene and 1,4-diphenyl-3-en-1-butyne, respectively, were seen on heating (vide infra).

PHIP in Related Catalytic Systems

Bromide Systems: The interactions of the systems [$(PPh_3)_2$PtHBr]/$SnBr_2$/alkyne (alkyne = 1-phenyl-1-propyne, 1-phenyl-1-butyne, diphenylacetylene) in acetone with parahydrogen also give rise to polarization in the Pt−H spectral region (Figure 3). The difference in chemical shifts of the two hydride resonances provides clear evidence for first-order patterns of an AMX spin system in these cases. In general, bromide systems give more intense and sharp signals compared to the corresponding hydrido chloro complexes. The resulting Pt^{IV} dihydrides possess an enhanced thermal stability compared with the chloro analogues, and are readily observable even upon heating. Furthermore, the initial patterns are fully restored on cooling once more (al-

Figure 3. PHIP ^{1}H-NMR spectra of the systems [L_2PtHBr]/$SnBr_2$/alkyne/para-H_2 in [D_6]acetone; **a)** L = PPh_3, alkyne = 1-phenyl-1-propyne, room temp.; **b)** L = PPh_3, alkyne = 1-phenyl-1-butyne, room temp., before heating; **c)** L = PPh_3, alkyne = 1-phenyl-1-butyne, on heating; **d)** L = PPh_3, alkyne = 1-phenyl-1-butyne, at room temp. after heating; **e)** L = PPh_3, alkyne = diphenylacetylene, room temp.; **f)** L = $PMePh_2$, alkyne = 1-phenyl-1-propyne, room temp.



kyne = 1-phenyl-1-propyne, Figure 3, a). With 1-phenyl-1-butyne, the additional third isomer of the dihydride is formed only after heating (Figure 3, b−d). With diphenylacetylene, the bromide system gives strong and well-resolved polarization patterns with a full set of satellite signals (Figure 3, e).

Variation of the Phosphane Ligands: Generally speaking, electron-donating phosphanes show less intense and poorly resolved polarization patterns in the Pt−H region under the conditions employed. The results obtained for the $[(PR_3)_2PtHX]/SnX_2$/alkyne/acetone systems are summarized in Tables 2 and 3. The triethylphosphane monohydride system did not give rise to PHIP. The system $[(PMePh_2)_2PtHCl]/SnCl_2$/1-phenyl-1-propyne/acetone produces only weak polarization in the Pt−H region (Figure 3, f). diphenylacetylene in the presence of $[(PPh_3)_2PtHCl]/SnCl_2$. Nevertheless, in addition to these signals, in some cases relatively strong polarization patterns are observed on heating (Figure 4). In general, hydrogenation of 1-phenyl-1-butyne and 1-phenyl-1-propyne gives moderately intense polarization signals of the corresponding *cis*-alkenes (Figure 4, a, b). Phenylacetylene is hydrogenated readily, giving rise to strongly polarized styrene signals as a result of *cis*-addition of parahydrogen (Figure 4 c). The *cis*-addition of para-H_2 was confirmed by means of the PHIP++ program simulation. Due to the ALTADENA conditions of the hydrogenation (i.e. the addition of parahydrogen proceeds in the Earth′s magnetic field, and the subsequent transfer to the strong B_0 field for the NMR measurement is adiabatic), extensive polarization transfer to the methyl and phenyl

Table 3. Spectral NMR parameters of intermediate dihydrides observed in systems with other phosphanes, $[(PR_3)_2PtH(SnX_3)]$/1-phenyl-1-propyne/$[D_6]$acetone (δ, relative to $[D_5]$acetone; *J*, Hz). The letter **a** corresponds to the major isomer, the letter **b** to the minor isomer.

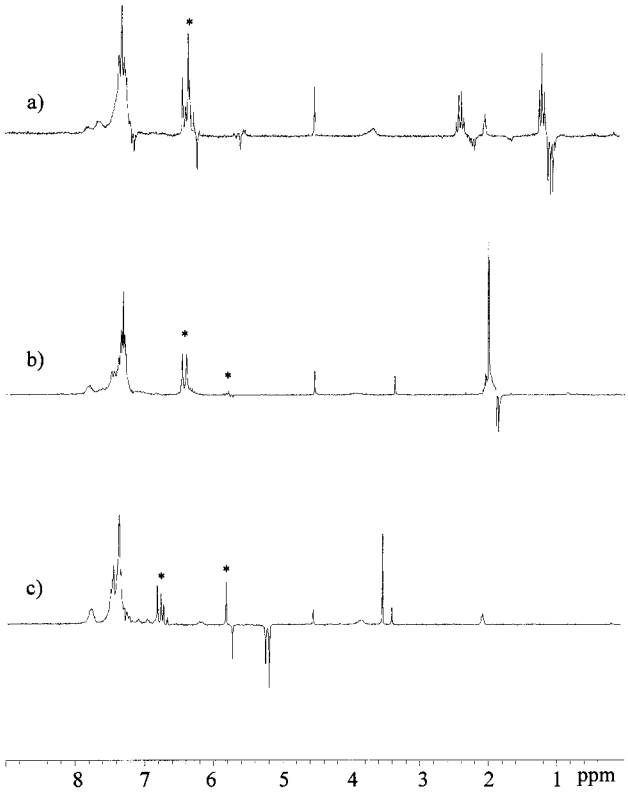
[a] One isomer.

The methyl resonance attributable to the insertion product, analogous to **5**, is also observable in this system [$\delta(CH_3)$ = 1.24, $^3J(^{195}Pt-H)$ = 53.4 Hz]. Due to the low intensity and broadness of the signals, the exact composition of the insertion product remains unclear.

Using the $[(PMePh_2)_2PtHBr]/SnBr_2$ system, the hydrogenation of 1-phenyl-1-propyne proceeds rapidly at room temperature, mainly via an asynchronous mechanism, i.e. not pairwise. This is reflected in the low polarization signals of the hydrogenation product, as opposed to rapidly arising thermal ones, and furthermore, the polarization in the Pt−H region is low. These Pt-H PHIP signals become stronger upon heating. It should be noted, however, that the signals attributable to the insertion product are clearly visible even at elevated temperature.

Only weak and poorly-resolved polarization patterns in the Pt^{IV} dihydride region are observed in the course of hydrogenation of PhC≡CMe in the presence of $[(PMe_2Ph)_2PtHCl] + SnCl_2$ in acetone. This hydrogenation proceeds without polarization of the product signals.

Figure 4. Polarization of product signals during hydrogenation with para-H_2 of alkynes in the presence of $[(PPh_3)_2PtHX]/SnX_2$ catalytic systems in $[D_6]$acetone on heating; **a)** X = Br, alkyne = 1-phenyl-1-butyne; **b)** X = Br, alkyne = 1-phenyl-1-propyne; **c)** X = Cl, alkyne = phenylacetylene. The absorption signals of the products, i.e. of the *cis*-alkenes, are marked *.



The Relationship between Synchronous (Pairwise) and Asynchronous Hydrogenation Mechanisms

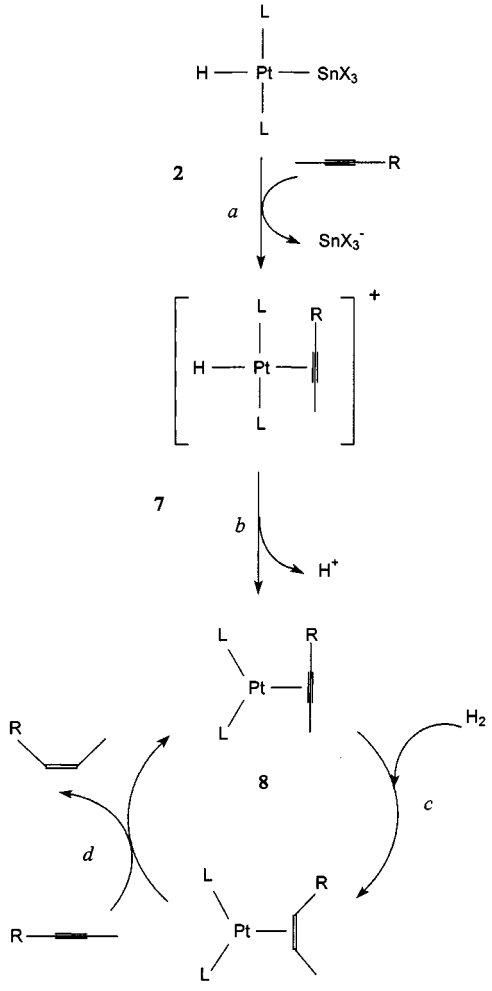
The observed Pt^{IV} dihydrides are assumed to be the intermediates in the stepwise hydrogenation of an alkyne. Decomposition of these dihydrides leads via reductive elimination to an alkene and a platinum monohydride. Consequently, only thermal signals are observed from the product, as is the case during the hydrogenation of

groups of the substrate is also observed. The efficient polarization transfer under these conditions is due to strong isotropic mixing of the proton spin functions in the whole molecule at low magnetic field[44], as was previously shown for the hydrogenation of the diphenylacetylene-Pt^0 complex, $[(PPh_3)_2Pt(PhC{\equiv}CPh)]$[27]. Alternatively, for the hydrogenation of 1-phenyl-1-propyne, the polarized signals of the methyl group of the product can be accounted for by assuming a 1,3-dihydrogen addition to the intermediate platinacyclobutene, formed by methyl C−H activation, although the geometry of such an addition should favor the *trans*-alkene as a primary product, rather than the *cis*-isomer, which is in fact obtained. Furthermore, the same effect is also operative for the methyl group of 1-phenyl-1-butyne, and seems to have the same origin.

The mechanism of the synchronous dihydrogen addition observed in the SnX_2-activated systems described here is suggested to be related to the Pt^0-mediated hydrogenation.

This mechanism could involve the η^2-coordination of an alkyne, and the reductive elimination of HX together with SnX_2, followed by oxidative addition of dihydrogen to the resulting Pt^0 complex with subsequent formation of an alkene (Scheme 2). The formation of the Pt^0 intermediate

Scheme 2. The proposed mechanism for the synchronous hydrogenation of alkynes catalyzed with the $[(PR_3)_2PtHX]-SnX_2$ system in acetone



should be favored at higher temperatures, as well as by an increased electronegativity of the π ligand. This process is of little significance for alkenes, where asynchronous hydrogenation is observed, giving rise to thermal signals of the products. It is also noteworthy that the Pt^{IV} dihydrides (**6a**) are not usually observable in the spectrum at elevated temperatures in cases where the polarized signals of the products appear instead.

The Role of Structural Factors and Reaction Conditions for the Appearance of PHIP in the Pt^{II}/Sn^{II} Catalytic Systems

Solvent Effects: The described polarization patterns of the Pt^{IV} dihydrides were observed only with acetone as the solvent. The sole exception was the interaction of isolated **5a** with parahydrogen in dichloromethane solution, as discussed above. The synchronous hydrogenation of alkynes proceeded well in acetone, but was hardly reproducible in benzene or in other non-solvating media. Experiments in acetonitrile, which is a much poorer solvent for $SnCl_2$, did not lead to any PHIP effects either. Strongly solvating additives, such as DMF and THF, can easily destroy the catalytic system, facilitating the cleavage of solvated SnX_2 molecules from the active platinum hydride and/or from a σ-carbon intermediate (**3** in Scheme 1[31][45]). Since Pt^{IV} dihydride contains only one phosphane ligand, the promotion of phosphane dissociation by the attached trihalotin ligand and acetone as the solvent seems to be necessary for the generation of PHIP-detectable dihydrides. It is noteworthy that phosphane redistribution proceeds only for platinum monohydrides with PPh_3 and $PMePh_2$[46], and correspondingly, polarized Pt^{IV} dihydrides are observable mainly with these ligands. Furthermore, the processes suggested to be essential for synchronous hydrogenation, the formation of cationic intermediates **7** (Scheme 2), as well as their deprotonation with formation of Pt^0 intermediates **8**, are strongly favored with polar, solvating acetone as the solvent.

Substrate and Halide Ligands: The appearance of polarized Pt^{IV} dihydrides depends principally on the hydrogenation substrate. The intensity of the polarization pattern reflects the suggested stability of the insertion product, while the number of isomers corresponds to the possible number of isomeric alkenyl radicals. For symmetrical alkynes, only one isomer is observed; for 1-phenyl-1-propyne two main insertion products are possible, giving rise initially to two dihydrides. Accordingly, 1-phenyl-1-butyne, being able to form more isomers, gives a complicated mixture of polarized dihydrides after heating. Alkenes, especially internal ones, generally adopt a quite unfavorable equilibrium position for insertion into Pt−H bond[31]. This factor is believed to be the reason for the failure to observe intermediates of type **6** in the course of the hydrogenation of alkenes such as NBD and 3,3-dimethylbutene. Furthermore, steric bulkiness of an alkyne (e.g. diphenylacetylene) can prevent extensive formation of the alkenyl complex, thereby decreasing the intensity of the signals of the Pt^{IV} dihydrides.

Tribromostannato hydrides give insertion products with higher equilibrium constants, and the resulting σ-insertion products are less fluxional compared to the chloro analogues. This feature is reflected in the higher intensity and sharpness of the corresponding polarization patterns.

We thank the *Russian Foundation for Basic Research (RFBR)*, and the *Deutsche Forschungsgemeinschaft (DFG)* for financial support, and Dr. *S. Klages* for many helpful discussions.

Experimental Section

General Remarks: The ^{1}H-, ^{1}H-PHIP-, and ^{31}P-NMR spectra were recorded with a Bruker AMD 200 MHz spectrometer with an Aspect 2000 operating system. In order to obtain the PHIP spectra, one 8K FID signal was acquired using 45° excitation pulses covering the spectral range between δ = −30 and δ = +10. To record the conventional or "thermal" ^{1}H-NMR spectra, the same parameters were used, except for the pulse width, which was set at 90°. The ^{13}C spectra were recorded with a Varian VXR-400 spectrometer operating at 100.6 MHz. The ^{1}H- and ^{13}C-NMR spectra were referenced to residual protons of known chemical shift and the ^{13}C signals of the solvent, respectively, while ^{31}P spectra were referenced to external 85% H_3PO_4.

The simulation of the PHIP ^{1}H-NMR spectra was performed with the OS/2-based PHIP++ program, developed by Greve[47].

Deuterated solvents for NMR spectroscopy were purchased from Aldrich, dried ($CDCl_3$) and degassed prior to use, and stored under vacuum.

Tin dichloride and tin dibromide (anhydrous) were both obtained from Aldrich, and used without additional purification.

The platinum complexes, *trans*-[$(PR_3)_2$PtHCl] (PR_3 = PPh_3,[37]; $PMePh_2$, PMe_2Ph[48]) were synthesized as described previously. The corresponding hydrido bromo complexes were obtained according to ref.[49], by reaction of the hydrido chloro complex with excess NaBr in acetone.

Typical Preparation of Solutions for Hydrogenation Studies: Weighed amounts of *trans*-[$(PPh_3)_2$PtHCl] (10 mg, 13 μmol) and $SnCl_2$ (7.5 mg, 40 μmol) were placed in a screw-capped NMR tube attached to a vacuum line, and 0.7 ml of dry degassed [D_6]acetone was condensed into the tube. After thawing and filling the tube with dry argon, it was disconnected from the vacuum line and fitted with a septum stopper. About 15 μl of the substrate was then added to the sample by means of an Eppendorf micropipette. Parahydrogen was subsequently introduced into the NMR tube through a stainless steel needle through the septum at a pressure of 3 bar. After shaking of the solution in the parahydrogen atmosphere, the tube was inserted into the probehead, and the ^{1}H-PHIP spectrum was recorded immediately thereafter.

(σ-1-Phenylpropen-2-yl)(trichlorostannato)bis(triphenylphosphane)platinum (**5a**): [$(PPh_3)_2$PtHCl] (100 mg, 0.132 mmol) and $SnCl_2$ (100 mg, 0.53 mmol) were taken up in 2 ml of dry degassed acetone. Upon formation of a clear, orange solution, an excess of 1-phenyl-1-propyne (0.2 ml) was added under argon. The solution was degassed and sealed in a tube. After 5 min at +100°C, the tube was stored at 0°C for 48 h. Light-yellow crystals were deposited, which were collected, washed with acetone, and dried in vacuo (72 mg, 52%); m.p. 165−166°C. − ^{1}H NMR: δ = 0.69 [d, CH_3, ^3J(PtH) = 51.2, ^4J(HH) = 1.3, $^4J(^{117/119}$SnH) = 76.4 Hz], 6.45 [br, =C*H*Ph, ^3J(PtH) = 82.2, $^4J(^{117/119}$SnH) = 119.5 Hz]. − ^{13}C NMR: δ = 150.67 [t, Pt*C*, ^1J(PtC) = 772, ^2J(PC) = 9.2 Hz], 139.35 [s, *C*Ph, ^2J(PtC) = 94.8 Hz], 23.50 [s, *C*H_3, ^2J(PtC) = 28.9 Hz]. − ^{31}P NMR: δ = 18.85 [s, ^1J(PtP) = 3007, $^2J(^{119}$SnP) = 240.4, $^2J(^{117}$SnP) = 230.7 Hz].

Reaction of **5a** *with Dimethylformamide:* To a solution of isolated **5a** (46 mg, 43 μmol) in 0.7 ml of CD_2Cl_2, 10 μl of dimethylformamide was added. ^{1}H NMR of **5b**: δ = 1.131 [s, ^3J(PtH) = 48.8 Hz]. − ^{31}P NMR: δ = 24.607 [s, ^1J(PtP) = 3306 Hz].

Received November 27, 1997 (Revised September 2, 1998)

Keywords: Tetramethylpiperidine–aluminum trihalide adducts / Tetramethylpiperidine–monochloroalane / Conductivity measurements / ^{27}Al-NMR spectroscopy

2,2,6,6-Tetramethylpiperidine (tmpH) reacts smoothly with aluminum trihalides AlX_3 (X = Cl, Br, I) and monochloroalane AlH_2Cl · 2 thf to give the addition compounds tmpH · AlX_3 (X = Cl, Br, I) and tmpH · AlH_2Cl, respectively. These adducts of the secondary amine tmpH are stable and do not undergo intramolecular elimination of HX or H_2 with formation of the aminoalanes $tmpAlX_2$ or tmpAl(H)Cl. In the solid state, tmpH · AlX_3 (X = Cl, Br, I) and tmpH · AlH_2Cl are tetracoordinated molecular adducts. While this is also true for solutions of tmpH · AlX_3 (X = Br, I) and tmpH · AlH_2Cl, the compound tmpH · $AlCl_3$ dissolves in CH_2Cl_2 as the salt $[tmpAlCl_3]$-$tmpH_2$ and the adduct tmpH · Al_2Cl_6, as is evident from its NMR spectra and from conductivity measurements. This behavior is supported by a semiempirical AM1 calculation.

Due to their importance in industrial processes, addition compounds of aluminum halides AlX_3 (in particular X = Cl) and ether donors have been the subject of extensive studies with regard to their solution and solid-state behavior[3]. Depending on the method of preparation, the tetra-, penta-, or hexacoordinated species $AlX_3 \cdot Do_n$ (Do = ether donor; $n = 1-3$) exist either as molecular adducts[4][5] or as salts {e.g. $AlCl_3 \cdot (thf)_2$ and $[AlCl_2(thf)_4]AlCl_4$}. The latter is also true for the addition compounds with pyridine[6], DMSO[7], and acetonitrile[8] (L), leading to the general compound type $[AlCl_2L_4^+]$-AlX_4^-. In solution, salt formation can readily be detected by ^{27}Al-NMR and conductivity measurements, including Fuoss-Kraus plots for analysis of the dissociation patterns[9]. Owing to facile H_2 or HX elimination, the chemistry of the addition compounds of the aluminum halides AlX_3 or AlH_2X (X = Cl, Br, I) with primary or secondary amines has scarcely been examined. However, two recent publications demonstrate the existence and importance of these species: Raston et al.[10] described a stable AlH_3 adduct with the sterically encumbered secondary amine tmpH (2,2,6,6-tetramethylpiperidine), while Atwood[11] later observed salt formation upon the addition of excess *t*$BuNH_2$ to R_2AlX (X = Cl, Br, I; R = Me, Et) when chloride was replaced by bromide or iodide. Recently, we reported on the synthesis of monomeric bis(tetramethylpiperidino)aluminum halides tmp_2AlX (X = Cl, Br, I) and on their derivatives[12]. In the course of these studies, addition compounds of tmpH and AlX_3 (X = Cl, Br, I) and AlH_2Cl were identified as by-products. For their full characterization, these adducts tmpH · AlX_3 [X = Cl (**1a**), Br (**1b**), I (**1c**)] and tmpH · AlH_2Cl (**2**) have now been independently synthesized from their respective components. Herein, we report on their solution and solid-state behavior.

Synthesis and Characterization

Addition of one equivalent of tmpH to $AlCl_3$ (in CH_2Cl_2) or $AlBr_3$, AlI_3, and AlH_2Cl · 2(thf) solutions (in toluene) leads to immediate formation of the adducts tmpH · AlX_3 [X = Cl (**1a**), Br (**1b**), I (**1c**)] and tmpH · AlH_2Cl (**2**).

$$tmpH + AlX_3 \longrightarrow tmpH^+AlX_3^- \quad (1a)$$

X = Cl **1a**, Br **1b**, I **1c**

$$tmpH + AlH_2Cl{\cdot}thf_2 \longrightarrow tmpH^+AlH_2Cl^- + 2\ thf \quad (1b)$$

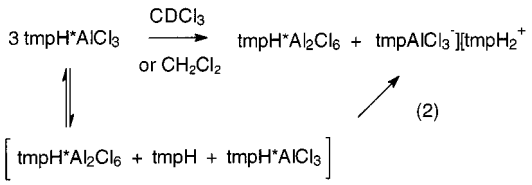
2

Evolution of hydrogen or HX was not observed. **1b**, **c** and **2** proved to be molecular monomers in benzene solution. They give rise to single sharp signals in the ^{27}Al-NMR spectra. The chemical shifts of these addition compounds follow the substitution pattern, the iodide being observed at highest field ($\delta^{27}Al = 12$, $\Delta_{1/2} = 140$ Hz), followed by the bromide ($\delta^{27}Al = 88$, $\Delta_{1/2} = 130$) and AlH_2Cl ($\delta^{27}Al = 123$). Distinct lines for axial and equatorial methyl groups (^{1}H- and ^{13}C-NMR) as well as for the ring-hydrogen atoms (^{1}H-NMR) are observed. Thus, axial and equatorial positions of the hydrogen and carbon atoms in the piperidine ring in **1b**, **c** are magnetically inequivalent.

Whereas **1b**, **c** and **2** retain their molecular character upon dissolution in aromatic and chlorinated solvents, the chloro compound **1a** behaves differently. In the solid state, **1a** exists as a tetracoordinated molecular adduct of the type tmpH · $AlCl_3$ (vide infra), but in solution it disproportionates according to Eq. 2.

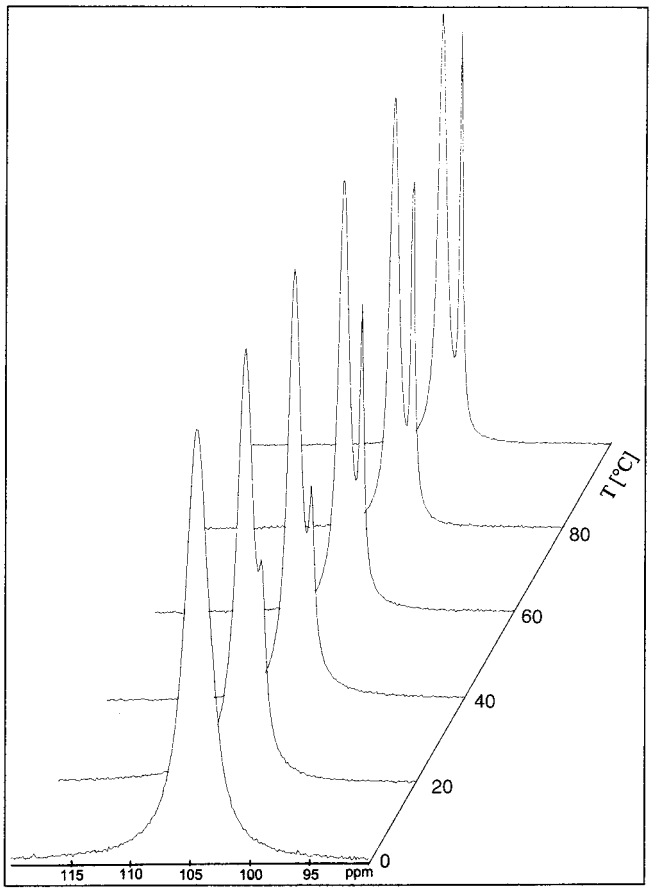
Two signals at $\delta^{27}Al = 108$ and 106, $\Delta_{1/2} = 120$ and 47 Hz, with an integral ratio of 2:1 are found (100°C), corresponding to a conversion of **1a** to tmpH · Al_2Cl_6 and

 © WILEY-VCH Verlag GmbH, D-69451 Weinheim, 1998 1434–1948/98/1212–1925 $ 17.50+.50/0



$[tmpAlCl_3]tmpH_2$. The line widths of the ^{27}Al-NMR signals are found to be temperature-dependent. At 0°C, only one broad line at $\delta^{27}Al = 106$ is observed. Heating the sample to 100°C ($[D_8]$toluene) leads to the resolution of two well-separated lines (see Figure 1), indicating the absence of rapid exchange processes and the presence of two distinct species.

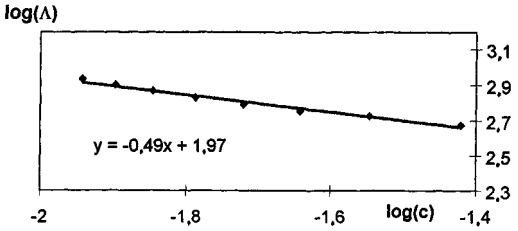
Figure 1. ^{27}Al-NMR spectra of $tmpH \cdot AlCl_3$ (**1a**) at various temperatures ($[D_8]$toluene)



The "dissociation" of **1a** is indicated by the appearance of three sets of signals for the different tmp ligands, represented by the formulae ($tmpH \cdot Al_2Cl_6$; $[tmpAlCl_3]tmpH_2$). Two signals are observed in the range $\delta = 57-60$ for the carbon atoms bonded to nitrogen atoms, indicating the presence of two distinct tmp groups with tetracoordinated nitrogen atoms. The third ligand has a tricoordinated nitrogen atom, since the respective $^{13}C(C-N)$ resonance is found at $\delta = 53.2$ {cf. for example $tmpAlI_2 \cdot$ py: $d^{13}C(C-N) = 53.3$ (tricoordinated nitrogen atom); $[(Me_3Si)_3SiAlCl_3]$ $tmpH_2$: $d^{13}C(C-N) = 58.0$ (tetracoordinated nitrogen atom)}[12][13]. Furthermore, two broad lines for the N−H protons in a ratio of 2:1 (1:6 and 1:12 to each of the tmp methyl signals) as well as three distinct tmp methyl groups are observed in the ^1H-NMR spectrum.

To further prove the "dissociation" pattern of the salt $[tmpAlCl_3]tmpH_2$ (as represented by Eq. 2), **1a** has been subjected to conductivity measurements in CH_2Cl_2.

Figure 2. Fuoss-Kraus plot for $tmpH \cdot AlCl_3$ (**1a**) calculated from conductivity measurements in CH_2Cl_2



According to the gradient of the Fuoss-Kraus[14] plot ($a = -0.5$, depicted in Figure. 2), the solution contains a simple A^+B^- system. Since the molecular adduct $tmpH \cdot Al_2Cl_6$ is not involved in ion formation, only the conductivity induced by the $[tmpAlCl_3]tmpH_2$ species, an A^+B^- compound, is detected.

Crystal Structures

In contrast to the solution behavior of **1a**, the structures of **1a** (Figure 3), **1b** (Figure 4), **1c** (Figure 5), and **2** (Figure 6) in the solid state all represent simple adducts with tetracoordinated aluminum centers. Crystals of **1a−c** are found to be monoclinic, space group $P2_1/n$ (**1a**) and $P2_1/c$ (**1b**, **c**), respectively, while **2** crystallizes in the orthorhombic space group $P2_12_12_1$. All unit cells contain four molecules. Selected structural parameters are summarized in Table 1.

In each of the adducts, the aluminum atom is coordinated by a nitrogen atom, with the halogen and/or hydrogen atoms arranged in a distorted tetrahedral manner. Whereas the angles X−Al−X in **1a−c** are close to 109.5°, the N−Al−X bond angles deviate by +9.7/−10.5° from this value. This behavior seems to depend on the size of the halogen atoms, as these deviations are reduced to +2.5 and −8.3°, respectively, in **2**. One halogen atom resides between the two equatorial methyl groups, on the same side as the N−H atoms. The respective H−N−Al−X torsion angles vary from 7.38° (**1a**), through 5.0° (**1b**) and 0.3° (**1c**), to 23.5° (**2**). The geometry at the nitrogen atom (C_2NAl plane) is close to planar, as is indicated by the sums of the respective bond angles (**1a**: 350.1°; **1b**: 350.2°; **1c**: 350.3°; **2**: 346.5° vs. $3 \times 109.5 = 328.5°$). The Al−N distances span a range from 2.009(5) (**1b**) to 2.038(9) Å (**1c**). This corresponds with the upper range of known Al−N distances in amine adducts of aluminum halides or hydrides, such as $AlCl_3 \cdot NMe_3$ [d(Al−N) = 1.96(1) Å][15] or $tmpH \cdot AlH_3$ [d(Al−N) = 2.04(1) Å][10]. Since chlorine and bromine have a stronger negative inductive effect than hydrogen, and thus increase the acceptor strength of the aluminum center, the Al−N distances in **1a**, **b** and **2** are shorter than that found

Table 1. Bonding parameters of compounds tmpH·AlX_3 (X = Cl, Br, I) and tmpH·AlH_2Cl

Figure 3. Molecular structure of tmpH · $AlCl_3$ (**1a**) in the solid state; thermal ellipsoids are shown at a 25% probability level; structural parameters are compiled in Table 1

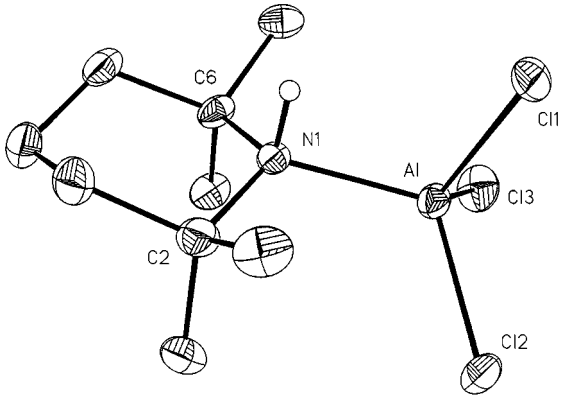

Figure 5. Molecular structure of tmpH · AlI_3 (**1c**) in the solid state; thermal ellipsoids are shown at a 25% probability level; structural parameters are compiled in Table 1

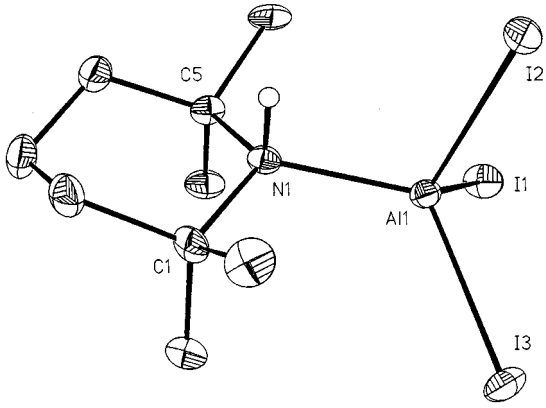

Figure 4. Stereoplot of the unit cell contents of tmpH · $AlBr_3$ (**1b**); view down the *c* axis (*a* axis to the right)

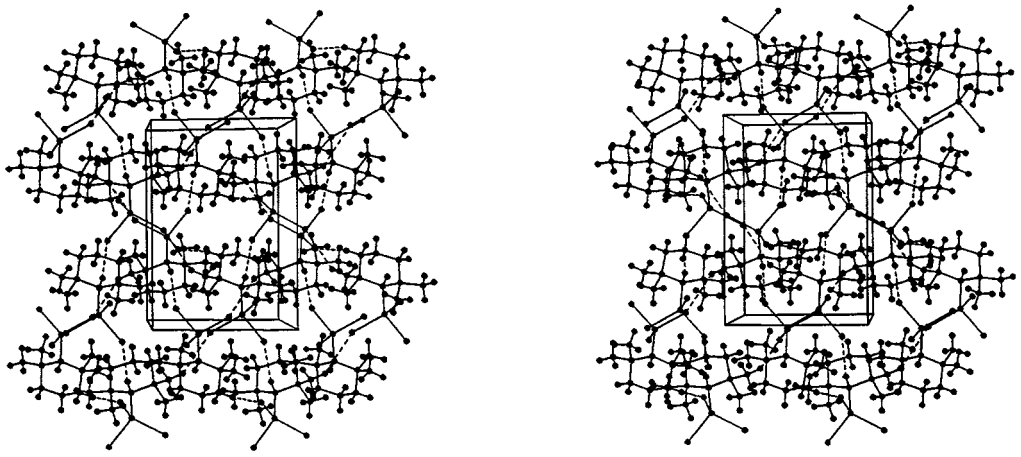
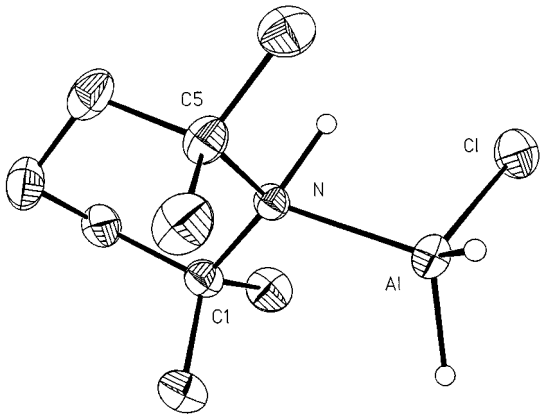


in tmpH · AlH_3. In **1c**, two opposing effects are responsible for the relatively long Al−N bond length: AlI_3 is the strongest Lewis acid amongst the aluminum halides[3], and, therefore, one would expect a short Al−N distance. However, the iodine atoms are considerably larger than the chlorine or bromine atoms and thus increase the steric strain. For this reason, *d*(Al−N) reaches its minimum values in **1a**, **b**, and not in **1c**. The aluminum−halogen bond lengths in these systems vary only slightly: the average Al−Cl distances are 2.131 Å (**1a**) and 2.154 Å (**2**), respectively, Al−Br is 2.288 Å (**1b**, av.), and Al−I is 2.536 Å (**1c**, av.). These values are close to those observed in $AlCl_3$ · NMe_3

Figure 6. Molecular structure of tmpH·AlH_2Cl (**2**) in the solid state; thermal ellipsoids are shown at a 25% probability level; structural parameters are compiled in Table 1



[d(Al−Cl) = 2.11(1)−2.14(1) Å][15], $AlMe_2I \cdot NMe_3$ [d(Al−I) = 2.58 Å][16] and $AlI_3 \cdot$ iq [iq = isoquinoline; d(Al−I) = 2.504(4) Å][13].

In spite of the fact that the adducts **1a−c** are present in space group No. 14, the arrangement of the molecules in the lattice is different in each case. Thus, in the chloride **1a**, the shortest intermolecular contacts are between a Cl atom of the $AlCl_3$ group and a hydrogen atom of a CH_3 group [(d(H···Cl) = 2.844 Å, angle Cl···H···C 169.7°]. In contrast, in **1b** there is an intermolecular N−H−Br contact with an H···Br distance of 2.978 Å (angle Br···H−N 169.0°) as well as an H···Br contact to a CH_3 group (3.019 Å). In the iodide **1c**, there are H···I contacts between two different I atoms and H atoms of two different CH_3 groups (4.021 and 3.191 Å, with Al−I···H angles of 148.2 and 125.7°, respectively). In contrast, there are no close intermolecular contacts between the Cl atom and H atoms bonded to either N or C in compound **2**.

Discussion

At first sight it is not easy to understand why only the aluminum trichloride adduct **1a** undergoes a structural change in solution. In fact, this could even be seen as a contradiction, because Atwood[11] found that only the bromo- and iodoalanes R_2AlX (X = Cl, Br, I; R = Me, Et) could be forced to ionize by the addition of excess tBuNH$_2$. This was attributed to the lower Al−Br and Al−I bond enthalpies and this argument should also be valid for the compounds described here. Since **1a** is found to "dissociate" according to Eq. 2, a decisive factor is clearly the formation of an ion pair (additional coulombic energy) and the chloro-bridged species tmpH · Al_2Cl_6. Thus, in this process nine terminal Al−Cl bonds are transformed into seven terminal and four bridging Al−Cl bonds. The relevant mean bond enthalpies are 425 kJ/mol for a terminal Al−Cl bond[3] and 289 kJ/mol for a bridging Al−Cl bond[17].

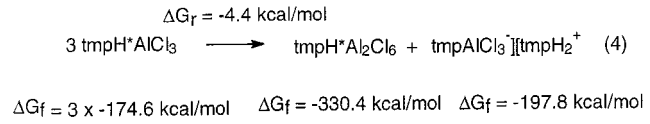
Hence, nine terminal Al−Cl bonds amount to an enthalpy of 3825 kJ/mol, while seven terminal and four bridging bonds represent 4131 kJ/mol, and consequently the "dissociated" species is favored by about 200 kJ/mol. As the bond enthalpies for Al−X−Al bridges decrease dramatically on going from X = Cl (ΔE_{bond} = 289 kJ/mol) to X = I (ΔE_{bond} = 192 kJ/mol)[17], the formation of halide bridges is not favored for X = Br, I. Due to the large steric requirement of the tetramethylpiperidine ligand, another usual pathway to dissociation, as described by Eq. 3, is not applicable here.

Figure 7. Calculated heats of formation of all compounds involved in Eq. 4 and estimated enthalpy of formation of tmpH · Al_2Cl_6 and [tmpAlCl$_3$]tmpH$_2$



This assumption is corroborated by a semiempirical AM1 calculation[18] of all the heats of formation of compounds that appear in Eq. 4 (see Figure 7). This allows an estimate of the overall reaction enthalpy. In the gas phase, the dissociated species are found to be favored by about 4.4 kcal/mol over the molecular starting material. Moreover, polar solvents such as dichloromethane should exert an additional stabilizing effect, thereby assisting in the formation of ion pairs. As this additional stabilization is not provided by the crystal lattice, the undissociated monomeric species **1a** turns out to be more stable in the solid state.

Conclusion

The tetramethylpiperidine alane adducts **1a−c** and **2** are stable towards HX and H_2 elimination, and thus formation of compounds tmpAlX_2 or tmpAl(H)X does not occur. In the solid state, they are present as monomeric tetracoordinated species. This is also true for solutions of **1b**, **c** and **2**. In contrast, upon dissolution of tmpH · $AlCl_3$, a transformation takes place according to Eq. 2. Whether this behavior is general or is specific to this compound will be addressed in future investigations; it is surprising to us that such simple systems raise such interesting and unforeseen questions.

We thank the *Fonds der Chemischen Industrie* and the *Chemetall mbH* for support of our research. We are also grateful to Mrs. *Käser* and Mrs. *R. Ullmann* for performing C/H/N analyses, Mr. *P. Mayr*, Dr. *R. Waldhör* and Dr. *C. Miller* for recording many NMR spectra, Mrs. *D. Ewald* for mass spectra and Mrs. *E. Kiesewetter* for IR spectra.

Experimental Section

All manipulations were performed using Schlenk techniques under dinitrogen. All solvents were rigorously dried prior to use and stored under dinitrogen or argon. − NMR: Bruker ACP 200, Jeol GSX400, and Jeol GSX270. − IR: Nicolet FT-IR spectrometer model 6000, CsI plates, Nujol. − MS: Varian Atlas CH7 spectrometer.

tmpH · $AlCl_3$ (**1a**): To a suspension of $AlCl_3$ (0.65 g, 4.87 mmol) in 10 ml of CH_2Cl_2, tmpH (0.83 ml, 4.87 mmol) was added at ambient temperature and the mixture was exposed to ultrasound for 3 h. The resulting yellow solution was stored at −20°C overnight, whereupon 0.90 g (67%) of colorless crystals of tmpH · $AlCl_3$ separated, m.p. 130°C. − ^{1}H NMR ($CDCl_3$, 400 MHz): δ = 1.40 (s, 12 H, tmp-CH_3), 1.61 (s, 12 H, tmp-CH_3), 1.73 (s, 12 H, tmp-CH_3), 2.88 (br. s, 2 H, N-*H*), 4.83 (br. s, 1 H, N-*H*), some additional multiplets at δ = 1.45 and 1.60−1.80 were also observed, but were not readily assigned. − ^{13}C NMR ($CDCl_3$, 100 MHz): δ = 15.7 (tmp-γ-*C*H$_2$), 16.5 (tmp-γ-*C*H$_2$), 23.5 (tmp-*C*H$_3$), 29.1 (tmp-*C*H$_3$), 33.5 (tmp-*C*H$_3$), 36.1 (tmp-*C*), 41.1 (tmp-*C*), 53.3 (tmp-*C*), 57.2 (tmp-*C*), 59.6 (tmp-*C*). − ^{27}Al NMR ($CDCl_3$, 70 MHz): δ = 106 ($\Delta_{1/2}$ = 47 Hz), 108 ($\Delta_{1/2}$ = 120 Hz). − IR (Nujol): $\tilde{\nu}$ = 3172 cm^{-1} s (N−H), 496 ss (Al−Cl), 421 ss (Al−Cl). − $C_9H_{19}NAlCl_3$ (274.60): calcd. C 39.37, H 6.97, N 5.10; found C 38.33, H 7.02, N 4.97.

tmpH · $AlBr_3$ (**1b**): tmpH (0.85 ml, 5.0 mmol) in 5 ml of benzene was added to a solution of $AlBr_3$ (1.3 g, 5.0 mmol) in 20 ml of benzene with stirring. The addition was accompanied by an immediate color change from brown to light-yellow. Successive partial evaporation of the solvent and cooling to 8°C led to the precipitation of colorless crystals of tmpH · $AlBr_3$. These were recrystallized from 15 ml of benzene, m.p. 137−139°C (darkening). Yield of **1b**: 1.46 g (76%). − ^{1}H NMR (C_6D_6, 270 MHz): δ = 0.35 (m, 1 H, tmp-CH_2), 0.52 (m, 1 H, tmp-CH_2), 0.72 (dt, 2 H, tmp-CH_2), 0.91 (dt, 2 H, tmp-CH_2), 1.20 (s, 6 H, tmp-CH_3), 1.53 (s 6 H, tmp-CH_3). − ^{13}C NMR (C_6D_6, 100 MHz): δ = 15.3 (tmp-*C*4), 23.6, 33.8 (tmp-*C*7-10), 40.8 (tmp-*C*3,5), 60.1 (tmp-*C*-N). − ^{27}Al NMR (C_6D_6, 70 MHz): δ = 88 ($\Delta_{1/2}$ = 130 Hz). − IR (Nujol) [ν(Al−Br) range]: $\tilde{\nu}$ = 411 cm^{-1} vs, 384 s. − $C_9H_{19}NAlBr_3$ (407.95): calcd. C 26.50, H 4.69, N 3.43, Al 6.6, Br 58.8; found C 27.18, H 5.13, N 3.17, Al 6.7, Br 60.4.

tmpH · AlI_3 (**1c**): To a solution of AlI_3 (0.81 g, 2.0 mmol) in 20 ml of toluene, a solution of tmpH (0.34 ml, 2.0 mmol) in 5 ml of toluene was added at ambient temperature. The addition was accompanied by an immediate color change from brown to yellow. The resulting solution was reduced to one-third of its original volume. Upon cooling to −20°C, colorless crystals of tmpH · AlI_3 separated, which were recrystallized from 10 ml of toluene; m.p. 141−143°C (decomp.), yield of **1c**: 0.81 g (74%). − ^{1}H NMR (C_6D_6, 270 MHz): δ = 0.33 (m, 1 H, tmp-CH_2), 0.56 (m, 1 H, tmp-CH_2), 0.81 (dt, 2 H, tmp-CH_2), 1.00 (dt, 2 H, tmp-CH_2), 1.25 (s, 6 H, tmp-CH_3), 1.70 (s, 6 H, tmp-CH_3). − ^{13}C NMR (C_6D_6, 100 MHz): δ = 14.4 (tmp-*C*4), 23.5, 33.9 (tmp-*C*7-10), 41.1 (tmp-*C*3,5), 60.4 (tmp-*C*-N). − ^{27}Al NMR (C_6D_6, 70 MHz): δ = 12 ($\Delta_{1/2}$ = 140 Hz). − IR (Nujol) [ν(Al−I) range]: $\tilde{\nu}$ = 347 cm^{-1} vs, 295 s. − $C_9H_{19}NAlI_3$ (548.95): calcd. C 19.69, H 3.49, N 2.55, Al 4.9, I 69.4; found C 19.66, H 3.72, N 2.50, Al 5.3, I 70.1.

tmpH · AlH_2Cl (**2**): To a solution of $AlH_2Cl(thf)_2$ (14.1 g, 67.4 mmol) in 50 ml of thf, 11.5 ml of tmpH (67.4 mmol) in 50 ml of toluene was added at −40°C. The mixture was allowed to warm to ambient temperature and was then heated to reflux for 3 h. Thereafter, all volatiles were removed in vacuo and the residue was extracted with 100 ml of pentane. The organic extract was filtered to afford a colorless solution. Cooling to −20°C provided 10.1 g (72%) of colorless crystals of **2**, m.p. 85°C. − ^{1}H NMR (C_6D_6, 270 MHz): δ = 0.84 (m, 4 H, tmp-β-CH_2), 1.16 (s, 12 H, tmp-CH_3), 1.68 (s, 2 H, tmp-γ-CH_2). − ^{13}C NMR (C_6D_6, 100 MHz): δ = 18.8

(tmp-*C*4), 32.4 (tmp-*C*7-10), 38.6 (tmp-*C*3,5), 49.6 (tmp-*C*-N). – ^{27}Al NMR (C_6D_6, 70 MHz): δ = 123. – IR (Nujol): $\tilde{\nu}$ = 1891 cm^{-1} vs, 1831 vs [ν(AlH)], [ν(N–H) range] 3137 m [ν(NH)]. – $C_9H_{21}NAlH_2Cl$ (205.7): calcd. Al 13.1, Cl 17.3; found Al 12.3, Cl 18.6.

X-ray Crystal-Structure Determinations: Data collection for X-ray structure determinations was performed with a Siemens P4 or a Syntex R3 four-circle diffractometer using graphite-monochromated Mo-K_α (λ = 0.71073 Å) radiation. Single crystals were mounted in Lindemann capillaries and sealed under argon. Data collection was performed at −80 to −100°C. All calculations were performed with PCs and workstations using the Siemens SHELXTL-Plus[19] or SHELX-93[20] software packages. The structures were solved by direct or heavy-atom methods with successive interpretation of the difference Fourier maps, followed by least-squares refinement. All non-hydrogen atoms were refined anisotropically. The hydrogen atoms were included in the refinement in calculated positions by a riding model using fixed isotropic parameters. Data relevant to the crystallography, data collection and refinement are compiled in Table 2. Further details on the crystal structure determinations have been deposited at the Cambridge Crystallographic Data Centre and may be requested by quoting the depository number CSD-103180 (**1a**), -103181 (**1b**), -103182 (**1c**) and -103183 (**2**), the names of the authors, and the full journal citation.

Keywords: Aluminium / Lithium hydridoaluminates / Alanes / Hydrazides / Structure elucidation

Several monomeric dimethylaluminium hydrazide ether adducts $Et_2O/THF \times Me_2AlNR–NR'R''$ (**5–7**) were obtained by deprotonating the respective hydrazines with *n*BuLi, followed by reaction with Me_2AlCl. The hydrazines Ph(H)N–$N(SiMe_3)_2$ and *t*Bu(H)N–N(H)$SiMe_3$ react with $LiAlH_4$ in the presence of either ether or THF with the formation of dimeric lithium hydrazino(hydrido)aluminates, e.g. **8** and **9**. Their structures depend on the number of acidic hydrogen atoms bonded to the nitrogen atoms of the starting hydrazine. The hydrazine Ph(H)N–$N(SiMe_3)_2$ (**1**) reacts with $LiAlH_4$ to form monometallated $LiAlH_3[(Ph)N–N(SiMe_3)_2] \times 2\ Et_2O$ (**8**) with elimination of one equivalent of H_2. The molecule is dimeric and features an $(AlHLiH)_2$ eight-membered ring. In contrast, the reaction of *t*Bu(H)N–N(H)$SiMe_3$ with $LiAlH_4$ in the presence of THF leads to the formation of dimeric 2 THF × $LiAlH_2[(tBu)N–N(SiMe_3)]$ (**9**) with a central $(AlNN)_2$ six-membered ring. A dimeric aluminium hydrazide **10** was obtained by allowing *t*Bu(Li)N–N(H)$SiMe_3$ to react with Me_2AlCl in a hexane/toluene solution. The structure of **10** features a six-membered Al_2N_4 ring in chair conformation.

Introduction

In recent years great progress has been achieved in the structural chemistry of alkali metal hydrazides[1]. Among the structural principles such as "laddering" and "stacking"[2], well known for alkali metal amides, additional arrangements such as "butterfly" or "side-on" coordination play an important role in the structure of the hydrazides. However, the structural chemistry of the amino alanes is mainly determined by the steric requirements of the organyl groups as well as by additional ligands. There are subtle differences; for example, $(Me_2AlNMe_2)_2$ possesses a planar four-membered Al_2N_2 ring while a six-membered Al_3N_3 ring was observed for $(Me_2AlNHMe)_3$, which exists in either a chair or a "skew-boat" conformation[3]. Furthermore, the structural motifs found for imidoalanes vary from heterocubanes, e.g. $(PhAlNPh)_4$, to different kinds of bridged or fused cage structures[4]. To date, much of the structural chemistry of group-13 elements has focused on amides and imides[8][15]. In contrast, information on the hydrazido derivatives is still scarce, even though a renewed interest in the investigation of these compounds in the last few years can be noted[5]. Since the synthesis and structural knowledge of borylated hydrazines are well developed[5a][5b][5c][5d], we present here work related to new hydrazinoalanes and hydrazino(hydrido)aluminates.

Results and Discussion

Preparation and NMR-Spectroscopic Characterization

Among the various possible routes to hydrazinoalanes only two have been pursued in this study, the metathesis of R_2AlCl with a lithium hydrazide and secondly the reaction of $LiAlH_4$ with a hydrazine. Four alkyl-, phenyl- and silyl-substituted hydrazines, **1**−**4**, were deprotonated by *n*BuLi and the Li compounds were allowed to react with Me_2AlCl. The deprotonation of **1**−**3** (Eq. 1) was carried out in the presence of donor molecules. A conceivable Si−N bond cleavage with formation of Me_3SiCl for reactions (1) and (2), well-known for the reaction of aminosilanes with aluminium trihalides[6], was not observed. However, the alkyl-substituted hydrazide **10** was obtained from a hexane/toluene solution (Eq. 2). Furthermore the deprotonation of **1** and **4** with $LiAlH_4$ proceeded smoothly with H_2 evolution producing the hydrazino(hydrido)aluminates **8** and **9** (Eqs. 3 and 4).

The use of ether as a solvent or cosolvent for reactions (1) and (3) was due to the fact that lithiated phenyl hydrazides and $LiAlH_4$, respectively, are only sparingly, if at all, soluble in both aliphatic and aromatic hydrocarbons. This proved to be essential for good yields.

Although several aluminium hydrazides have already been investigated[5e][5f][5g], no ^{27}Al-NMR data have so far been reported. However, ^{27}Al-NMR spectroscopy is a useful tool not only for monitoring the course of the reaction but also for obtaining structural information. Thus, the formation of **5**, **6** and **7** (Eq. 1) can be readily deduced from ^{27}Al-NMR spectroscopy. Resonances at $\delta = 151$ (**5**), $\delta = 165$ (**6**) and $\delta = 170$ (**7**), with half widths of 5600−6100 Hz, are indicative of asymmetrically tetracoordinated aluminium centers[7], and the chemical shifts are comparable with those of dimeric dialkylaluminium amides, e.g. $[iBu_2AlNC_6H_{12}]_2$[8]. The ^{1}H- and ^{13}C-NMR spectra of **5**, **6** and

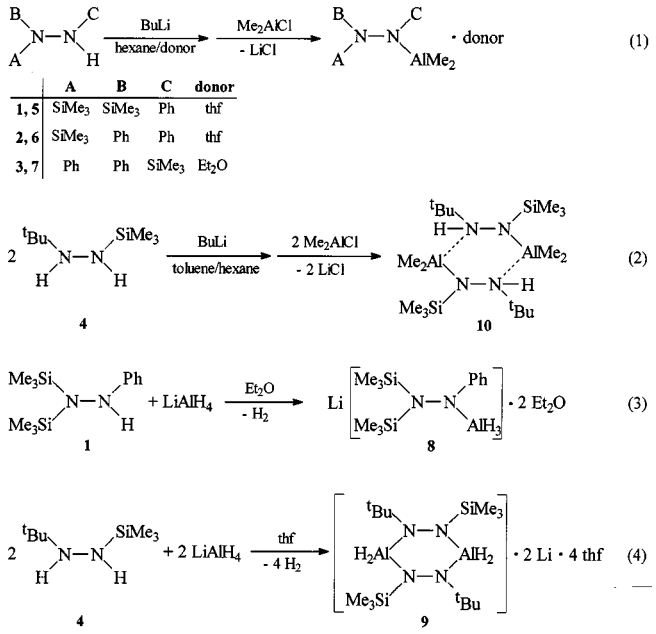
Scheme 1



7 show one resonance for the methyl groups residing at the aluminium atom, indicating free rotation about the Al−N bond at room temperature.

For the dimeric compound **10** a ^{27}Al-NMR chemical shift of δ = 141 is observed with a half width of 2200 Hz. The ^{1}H-NMR data at room temperature reveal two resonances for the methyl groups attached to the aluminium center in accordance with its structure in the solid state. In contrast, the ^{13}C-NMR spectrum shows only a single resonance for the $Al(CH_3)_2$ group at room temperature, but at −60°C two resonances for the methyl groups can be detected in the ^{13}C NMR. Because there is no temperature-dependent line broadening, this behavior is thus best interpreted as being due to a coincidentally equal chemical shift at room temperature.

The ^{27}Al-NMR data of **8** and **9** suggest the formation of a tetracoordinated H_3Al- and a H_2Al- species, respectively, by analogy to $[tripAlH_3LiOEt_2]_n$[9] (trip = 2,4,6-*i*$Pr_3C_6H_2-$), $[2,6\text{-}tBu_2C_6H_3OAlH_3Li(OEt_2)_2]_2$ and $(mentO)_2AlH_2Li(THF)_2$[10] (ment = 2-*i*Pr-5-MeC_6H_9-). The ^{27}Al-NMR spectrum of **8** in deuteriobenzene solution consists of a quadruplet at δ = 110 [^{1}J(Al, H) = 178 Hz]. However, the ^{7}Li-NMR resonance shows a half width of 12 Hz and it was not possible to resolve an Li−H coupling in the temperature range of −80°C to room temperature. Until recently, little information had been reported on ^{1}J(Li, H) coupling constants, and we are aware of only two examples, 10.5 Hz for $[(Me_3Si)_2N]_2AlH_2Li(OEt_2)_2$[11a] and 8.4 Hz for [Cp*IrH3Li(pmdta)] (pmdta = pentamethylethylenetriamine)[11b], both smaller than the observed half width for **8**.

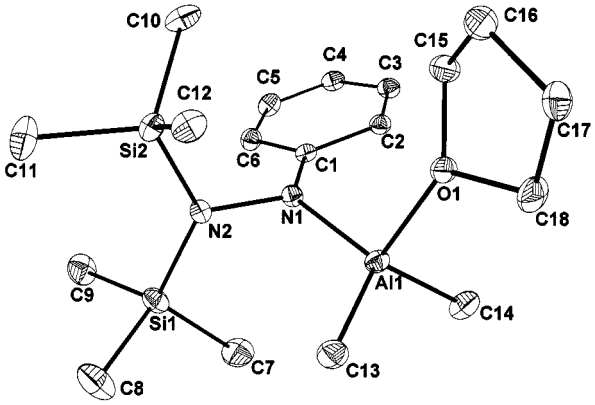
The spectrum of **9** shows a ^{27}Al-NMR resonance at δ = 119 with a half width of 1520 Hz. Even at −80°C it was not possible to observe a ^{1}J(Al, H) coupling as for compound **8**. In addition, the ^{7}Li-NMR spectrum shows a broad resonance with a half width of 30 Hz.

Molecular Structures

The Aluminium Hydrazide $Me_2Al(Ph)N-N(SiMe_3)_2 \times THF$ (**5**)

Compound **5** crystallizes in the orthorhombic system, space group $Pna2_1$ with four molecules in the unit cell. Figure 1 depicts the molecular structure.

Figure 1. ORTEP plot of the aluminium hydrazide **5**; hydrogen atoms are omitted for clarity; thermal ellipsoids are drawn at the 25% probability level



The aluminium atom is tetracoordinated by one oxygen, one nitrogen and two carbon atoms. However, the bond angles reveal a significant distortion from an ideal tetrahedral array as indicated by bond angles N1−Al1−C13 of 115.9(1)°, O1−Al1−C13 of 102.2(1)° and C13−Al1−C14 of 114.7(1)°, respectively. The Al−O distance is larger than the Al−N distance with a difference of 0.063 Å. The sum of bond angles, Σ, at the oxygen atom and the two nitrogen atoms is close to 360° (O1: 357.8°, N1: 358.3°, N2: 360.0°). Therefore, the nitrogen atoms N1 and N2 can be considered as being essentially sp^2-hybridized and this seems also to hold for the oxygen atom. Nevertheless, the latter geometry can also be readily explained in terms of ion-dipole interactions between the metal ion and the THF molecule[12].

While the N−N bond length is 1.469(3) Å, we note that the planes around the nitrogen atoms stand almost orthogonal to one another, as shown by the interplanar angle C1N1Al1/Si1N2Si2 of 85.2°. The phenyl group is twisted against the plane N2N1Al1 by 20.8°. Although the N−N−Si bond angles differ from one another by up to 8.4°, the Si−N bond lengths of 1.742(2) Å and 1.746(2) Å are equal to within the 3σ standard deviation.

The Aluminium Hydrazide $Me_2Al(Ph)N-N(Ph)SiMe_3 \times THF$ (**6**)

Compound **6** crystallizes in the monoclinic system, space group *Cc* with four molecules in the unit cell. The molecular structure is shown in Figure 2.

Its aluminium atom is tetracoordinated by the oxygen atom of one molecule of THF, one nitrogen atom and two

Table 1. Selected bond lengths [Å] and angles [°] of **5**, **6**, **7** and **10**

	5	**6**	**7**	**10**
Al−N	1.869(2)	1.863(3)	1.847(2)	N1: 2.016(2) N2: 1.874(2)

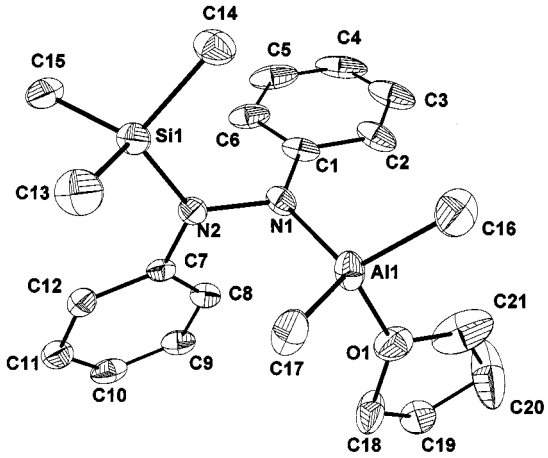
C−Al−C	114.7(1)	102.1(7)	116.0(1)	106.7(1)
N−N−Al	118.1(1)	114.2(2)	116.1(1)	122.7(1)

Figure 2. The molecular structure of the aluminium hydrazide **6** in ORTEP representation; hydrogen atoms are omitted for clarity; thermal ellipsoids are drawn at the 25% probability level



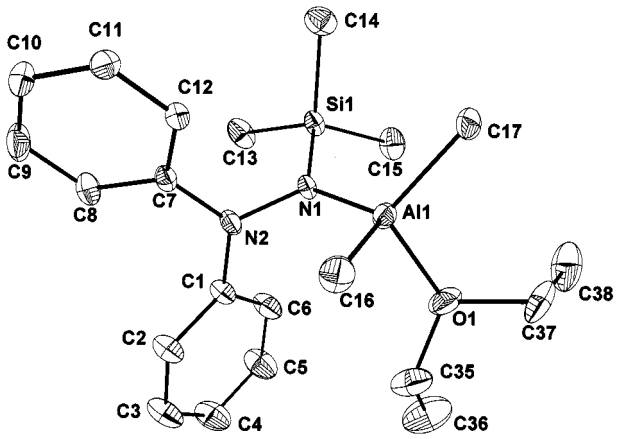
carbon atoms of the methyl groups. The Al−N and Al−O bond lengths of 1.863(3) Å and 1.879(3) Å, respectively, are very similar to each other, in contrast to those in compounds **5** and **7**. Both nitrogen atoms are tricoordinated in a planar environment, the sum of bond angles, Σ, amounting to 360.0° both for N1 and N2. Even the oxygen atom shows a tricoordinate-planar environment.

It is found that the planes around the nitrogen atoms are even closer to perpendicular in comparison with **5**, as demonstrated by the torsion angle C1−N1−N2−C7 of 89.7°. Moreover, the N−N distance of 1.449(3) Å is noticeably shorter than that determined for compound **5**, differing by 0.019 Å. In contrast to **5**, the Si−N bond of 1.766 Å is slightly lengthened (0.020 Å). The phenyl groups are twisted by 3.2° at N1 and 17.4° at N2 with respect to the N2N1Al and N1N2Si plane, respectively, in accordance with the N−C distances of 1.396(4) Å and 1.405(4) Å, indicating N−C π bonding.

The Aluminium Hydrazide $Me_2AlN(SiMe_3)-NPh_2 \times Et_2O$ (**7**)

Compound **7** crystallizes in the triclinic system, space group $P\bar{1}$. There are two independent molecules in the unit cell whose structural parameters differ only insignificantly. Therefore we depict only one of these in Figure 3.

Figure 3. ORTEP plot of the aluminium hydrazide **7**; hydrogen atoms are omitted for clarity; thermal ellipsoids are drawn at the 25% probability level



The tetracoordinated aluminium atom shows again a distorted tetrahedral array as described for compound **5**. The geometry at both nitrogen atoms is almost planar with a sum of bond angles, Σ, of 359.6° for N1 and 359.9° for N2. The Al−N distance of 1.847(2) Å in **7** is slightly shorter than in compounds **5** or **6**. The Al−O bond length of 1.928(2) Å is comparable with that in compound **5**, despite the weaker base strength of diethyl ether.

The N−N bond length of 1.446(2) Å corresponds to that found in compound **6**. The planes at the nitrogen atoms Si1N1Al1/C1N2C7 are again close to perpendicular (the interplanar angle is 81.2°) and both phenyl groups are twisted against the plane around N2 by 27.5° and 28.3°, respectively. The Si−N bond length of 1.746 (2) Å is comparable to that in compound **5**.

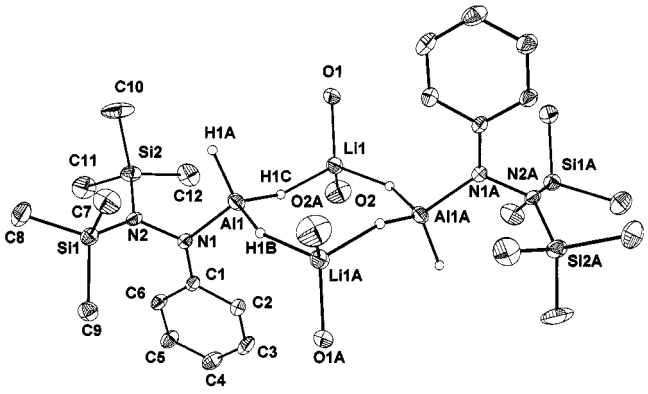
The Lithium Hydrazino(hydrido)aluminate $LiAlH_3[(Ph)N-N(SiMe_3)_2] \times 2\ Et_2O$ (**8**)

The colorless prisms of **8** belong to the triclinic system, space group $P\bar{1}$. There are two molecules $LiAlH_3[(Ph)N-N(SiMe_3)_2] \times 2\ Et_2O$ in the unit cell which are symmetry-related by a crystallographical inversion center in the midpoint of an $(LiH_2Al)_2$ eight-membered ring as shown in Figure 4. For molecular parameters of compounds **8** and **9** see Table 2.

Thus, two hydrazidoaluminate units are linked by two H−Li−H bridges. The resulting eight-membered ring shows a striking feature: six atoms build up exactly a plane, without significant deviation. Two hydrogen atoms, H1c and H1ca, lie 0.36 Å above and below this plane, respectively.

The aluminium atom is almost tetrahedrally coordinated by three (one terminal and two bridging) hydrogen atoms and one nitrogen atom. The lithium atom is also tetracoordinated by two oxygen atoms and two hydrogen atoms in a slightly distorted tetrahedral array as indicated by the O1−Li1−O2 bond angle of 116.9(3)°. The Al−H bond lengths are 1.50(4) Å for the terminal hydrogen atom and

Figure 4. ORTEP representation of the lithium hydrazino(hydrido)aluminate **8** including selected hydrogen atoms; the ethyl groups of the ether molecules are omitted for clarity; thermal ellipsoids are drawn at the 25% probability level



1.58(4) Å and 1.61(4) Å for the bridging hydrogen atoms. The Li−H atom distances of 1.86(4) Å and 1.85(4) Å are longer than those to the aluminium atoms but clearly shorter than in ionic LiH (2.08 Å)[13]. The Al−N bond length of 1.869(3) Å corresponds to that found in the aluminium hydrazide $Me_2Al(Ph)N-N(SiMe_3)_2$ × THF (**5**). The hydrazide unit in **8** shows the same tendencies in bond lengths and angles as described for compound **5**. Both nitrogen atoms are almost sp^2-hybridized with sum of bond angles, Σ, of 359.1° for N1 and 358.3° for N2. Furthermore the planes around the nitrogen atoms are almost perpendicular to one another, as indicated by the torsion angle C1−N1−N2−Si1 of 81.3°. The phenyl group is twisted slightly against the plane around N1 (N2Al1C1) by 11.1°.

Table 2. Selected bond lengths [Å] and angles [°] of **8** and **9**

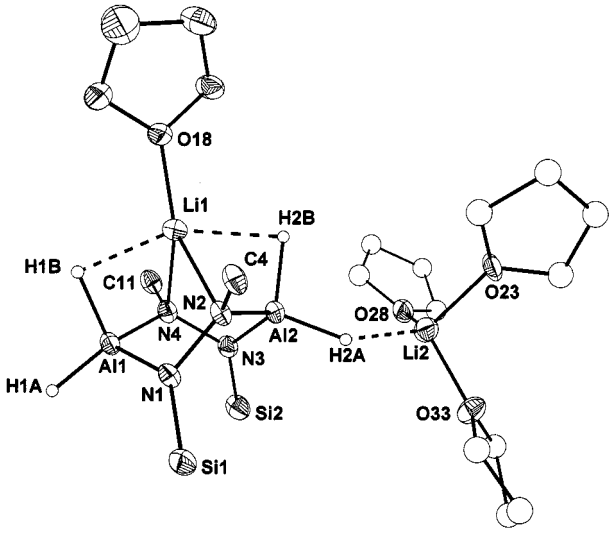
	8	**9**
Al−N	1.869(3)	N1: 1.843(3)/N3: 1.841(3) N2: 1.871(3)/N4: 1.895(3)
Al−H	1.50(4)−1.61(4)	1.54(3)−1.61(3)
N−N	1.460(4)	N1: 1.508(3)/N3: 1.504(4)
Li−H	1.85(4)−1.86(4)	Li1: 2.09(3)/2.26(4) Li2: 1.89(4)
N−Si	Si1: 1.730(3) Si2: 1.735(3)	Si1: 1.707(3) Si2: 1.705(3)
Σ N1 (N3)	359.1	358.6 (357.6)
Σ N2 (N4)	358.3	356.1 (354.8)

The Lithium Hydrazino(hydrido)aluminate *$LiAlH_2[(tBu)N-N(SiMe_3)]$ × 2 THF* (**9**)

Compound **9** crystallizes in the monoclinic system, space group $P2_1/n$, with four molecules in the unit cell. It should be noted that due to some disorder of the THF molecules the carbon atoms of the THF molecules around Li2 were refined only isotropically.

The most remarkable feature of compound **9**, depicted in Figure 5, are two differently coordinated lithium atoms. Li1 is tricoordinated by the nitrogen atoms of the *t*BuN groups of the $(Al-N-N)_2$ six-membered ring and one oxygen

Figure 5. ORTEP plot of **9** including selected hydrogen atoms; the methyl groups on C4, C11 (*t*Bu); Si1 and Si2 ($SiMe_3$) are omitted for clarity; thermal ellipsoids are drawn at the 25% probability level



atom of a THF molecule, whereas Li2 is tetracoordinated by three oxygen atoms and one hydrogen atom of an AlH_2 unit.

In addition, Li1 exhibits two close contacts with two hydrogen atoms of the AlH_2 units with distances of 2.09(3) Å (for H1b) and 2.26(4) Å (for H2b). Taking these contacts into account, we arrive at pentacoordination with a distorted trigonal-bipyramidal array with the hydrogen atoms in apical positions. This is an unexpected situation, because usually the most electronegative partners occupy the apices of the trigonal bipyramid. The deviation from the ideal trigonal-bipyramidal array is indicated by the bond angle H1b−Li1−H2b of 153(2)°. It should be noted that the Li1−N distances [2.278(7) Å and 2.213(7) Å] are longer than the Li1−O18 distance [1.920(6) Å] in accordance with the larger effective radius of the nitrogen atoms compared to the oxygen atom.

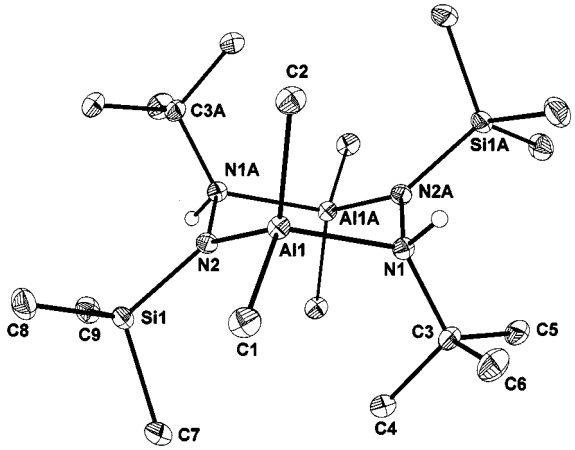
The aluminium atoms are not bonded symmetrically to the neighboring nitrogen atoms. Due to the electron-releasing properties of the $SiMe_3$ group, the corresponding Al−N bond lengths, Al1−N1 and Al2−N3 are shortened. For example, Al1−N1 and Al1−N4 differ by 0.052 Å. Comparing the sum of bond angles, Σ, at the nitrogen atoms, we found in accordance with the aluminium−nitrogen bond lengths, that the Σ of N1 (358.6°) and N3 (357.6°) are closer to 360° than those of N2 (356.1°) and N4 (354.8°) (neglecting the Li···N interaction), which are slightly pyramidalized. It is particularly noteworthy that the N−N bond lengths of 1.508(3) Å (N1−N2) and 1.504(4) Å (N3−N4) are quite long. One reason for this is certainly the twisted planes around the nitrogen atoms, as indicated by the interplanar angles Al1N1Si1/Al2N2C4 (75.0°) and Al2N3Si2/Al1N4C11 (78.3°), causing a repulsion of the π electrons at the nitrogen atoms. But surely the most significant factor in the elongation of the N−N bond is the four-coordination observed for N2 and N4. Finally, we note comparatively

short N−Si bond lengths of 1.707(3) Å (Si1−N1) and 1.705(3) Å (Si2−N3), respectively.

The Aluminium Hydrazide [$Me_2AlN(SiMe_3)-N(tBu)H]_2$ (**10**)

The solvent-free compound **10** crystallizes in the orthorhombic system, space group *Pbca*, with 8 molecules in the unit cell. The molecular structure is depicted in Figure 6.

Figure 6. ORTEP representation of **10**; hydrogen atoms, except on the nitrogen atoms, are omitted for clarity; thermal ellipsoids are drawn at the 25% probability level



10 forms a centrosymmetric dimer with an $(AlN_2)_2$ six-membered ring in chair conformation with the methyl groups in axial (C2) and equatorial (C1) positions. The aluminium atom is tetracoordinated to carbon atoms of the methyl groups and two nitrogen atoms in a distorted tetrahedral array. The fairly long Al−N1 distance of 2.016(2) Å indicates a coordination of the nitrogen atom N1 across its lone pair of electrons to the aluminium atom. This is supported by the sum of bond angles of N1, neglecting the Al···N1 interaction, of 323.3°, indicating clearly a pyramidal geometry with (*S*) configuration at N1 and (*R*) configuration at its symmetry equivalent, N1A. In contrast to that, the Al−N2 bond length of 1.872(2) Å is comparable to those found in **5**, **6** and **7**. However, N2 shows a trigonal-planar geometry with a sum of bond angles of 359.9°.Due to sp^3 hybridization of N1, the N−N bond length of 1.486(2) Å is slightly lengthened compared to the monomeric ether adducts **5**−**7**.

Discussion

The ether adducts **5**, **6** and **7** are the first structurally characterized monomeric aluminium hydrazides. It should be noted that in all three reported compounds the β-nitrogen atom of the hydrazide unit is not involved in coordination to the aluminium center due to the fact that this nitrogen atom is sterically and electronically less suited for coordination than atom N1. As previously shown for alkali metal hydrazides[1g], oligomerization can be inhibited by suitable donor molecules coordinating to the metal center, thus preventing the formation of additional metal−nitrogen interactions. One reason for this is certainly the planarity at the nitrogen atoms that decreases the basicity of the R_2N group. The Al−N bond lengths of **5**, **6** and **7** are comparable to those in aluminium amides with tetracoordinated aluminium atoms and tricoordinated nitrogen atoms[14]. These bond lengths vary from 1.869(2) Å in **5** to 1.847(2) Å in **7**. Although the weaker donor ability of diethyl ether in contrast to THF is expected to lead to longer Al−O distances, the Al−O bond length of 1.928(2) Å in compound **7** is comparable to that found in **5** [1.932(2) Å]. The reason for the short Al−N bond of **7** may be the higher acidity of the nitrogen atom, due to the neighboring $SiMe_3$ group. This effect is also observed in compound **10**. Therefore, the metallation took place at the silyl-substituted nitrogen atom. The Al−N bond length of 1.874(2) Å is somewhat longer than in the ether adducts **5**, **6** and **7**, but reasonably shorter than the Al−N bond length of 2.016(2) Å of the coordinating nitrogen atom in compound **10**, which compares well to those found in alane amines such as $Me_2ClAl(NHBz_2)$ (Bz = benzyl)[15a] or $Me_3Al(NHBz_2)$[15b]. In contrast to the solvates **5**, **6** and **7**, the β-nitrogen atom of the aluminium hydrazide **10** is also involved in coordination to the aluminium atom. Dimeric **10** forms a six-membered Al_2N_4 ring in chair conformation with the *tert*-butyl groups in axial positions. These results differ from the structural observations recently reported for the dimeric aluminium hydrazide, $[Me_2Al-\mu\text{-}N(H)NMe_2]_2$[5e], which forms an $(AlN)_2$ four-membered ring in a *trans* configuration in the solid state with tetracoordinated aluminium and nitrogen atoms and therefore with fairly long Al−N bond lengths of 1.958(3) Å and 1.953(3) Å. This structural feature is already known for amino alanes, e.g. $[Np_2Al-N(H)Ph]_2$ (Np = Me_3CCH_2-)[16] or $[iBu_2AlNC_6H_{12}]_2$[8].

The structure of the hydrazino(hydrido)aluminate **9** can be readily derived from the aluminium hydrazide **10**. The six-membered ring in chair conformation may be slightly twisted due to the coordination of two facing nitrogen atoms to one lithium center. The two nitrogen atoms are slightly pyramidalized, but the sum of their bond angles (356.1°, 354.8°) is still close to 360°, suggesting an Li···N-p_z interaction which is in accordance with the fairly long Li−N bond lengths of 2.278(7) Å and 2.213(7) Å, respectively. The most striking feature of compound **9** is the fact that this lithium atom faces the ring directly above its center, completing its coordination sphere by one molecule of THF and two additional Li···H contacts, while the lateral lithium atom Li2 is solvated by three THF molecules, contacting the ring via a hydrogen bond. In contrast to **9**, the hydrazino(hydrido)aluminate **8** forms an $(LiHAlH)_2$ eight-membered ring. This characteristic feature was also observed for $[(Me_3Si)_2NAlH_3Li(OEt_2)_2]_2$[11a] and [(2,6-di-*t*Bu)$C_6H_3OAlH_3Li(OEt_2)_2]_2$[10]. The β-nitrogen atom is neither involved in coordination with the aluminium atom nor the lithium atom. The Al−N bond lengths of both compounds, **8** and **9**, ranging from 1.841(3) Å to 1.895(3) Å, are typical for tetracoordinated aluminium and tricoordinated nitrogen atoms and comparable to those found in $[(Me_3Si)_2$-

$NAlH_3Li(OEt_2)_2]_2$ and $[(Me_3Si)_2N]_2AlH_2Li(OEt_2)_2$[11a]. The average Li−H bond length for **8** is 1.86 Å and is distinctly shorter than in lithium hydride (2.08 Å)[13]. This is also true for Li2 [1.89(4) Å] in compound **9**, but additionally we note two fairly long Li−H contacts of 2.09(3) Å and 2.26(4) Å of the trigonal-bipyramidal-coordinated lithium atom Li1.

Conclusion

The most significant general result derived from the structure determinations of aluminium hydrazides is that the hydrazine units adopt planar geometries in which the lone pairs are orientated orthogonally. Moreover, the aluminium centers prefer OEt_2 or THF as a coordination partner over the NRR′ unit of the hydrazino group. This occurs only when Et_2O or THF is excluded in the preparation.

One can envisage that aluminium hydrazides $Me_2Al-NR-NR'SiMe_3$ and $Me_2Al-NR-N(SiMe_3)_2$ will decompose at higher temperatures with loss of $SiMe_4$, with the formation of oligomeric clusters of the type $[MeAl-NR-NR']_n$ or $[MeAl-NR-N(SiMe_3)]_m$. These may then decompose into AlN at sufficiently high temperatures, as has recently been shown for some gallium organylhydrazides[5i][5h]. This aspect has not yet been investigated nor have we made attempts to prepare tris(hydrazino)alanes $Al(NR-NR'R'')_3$ which may be associated (small R groups) or monomeric (bulky R groups). Provided that the two amino groups of the hydrazino units remain in a perpendicular orientation new structural coordination patterns can be realized.

We thank the *Fonds der Chemischen Industrie* and *Chemetall GmbH* for support of our research. In addition, thanks are due to Dipl.-Chem. *C. Strauhal* and *M. Vosteen* for recording NMR spectra and Mrs. *G. Hanatschek* and Mrs. *E. Kiesewetter* for recording the IR spectra. Last but not least, we thank Mr. *T. Stuehler* for well-conducted experiments.

Experimental Section

General Remarks: All reactions were performed under argon using Schlenk techniques. Solvents were dried by conventional methods ($LiAlH_4$, potassium/benzophenone, P_4O_{10}) and stored under argon. The compounds $PhNH-NH_2$, $Ph_2N-NH_2 \times HCl$, $Ph(H)N-N(H)Ph \times HCl$, *n*-butyllithium, Me_3SiCl, 2 M solution of Me_2AlCl in hexane, Me_3SiCl, C_6D_6 and [D_8]toluene were used as purchased. $Ph(H)N-N(SiMe_3)_2$ (**1**), $Ph(H)N-N(Ph)SiMe_3$ (**2**), $Ph_2N-N(H)SiMe_3$ (**3**) and $H(tBu)N-N(H)SiMe_3$ (**4**)[17] were prepared according to literature methods.

Elemental analyses of the compounds were often unreliable, most likely as a result of the formation of silicon carbide or to their hydrolytic sensibility. In addition, they lose coordinated solvent quite readily. Therefore, the purities were checked by the interpretation of the ^{1}H-NMR signals and the single signal found in the ^{27}Al-NMR spectra.

X-ray Structure Analysis (see Table 3): All crystals had to be handled carefully under argon, preferably in a glove box or in a

closed Schlenk system. Once the selected crystals were covered with oxygen-free perfluoroether oil, they were mounted in a glass capillary or on a glass fibre and transferred to the goniometer head of Siemens P4 diffractometer (Mo-K_α radiation, λ = 0.71063 Å, graphite monochromator) equipped with a CCD detector, and cooled in the cold stream of the Siemens LT2 device. Determination of the unit-cell parameters was performed with the data of reflections collected with a total of 75 frames, taking 15 frames each with ω rotation of 0.3° for five different settings. The axes calculated for the unit cell were checked by recording the reflections in the 100, 010 and 001 planes. The final unit-cell parameters were calculated from the whole set of observed reflections. Data collection was performed in a standard manner with an exposure time of 10 s per frame and a 0.3° difference in φ orientation. Data reduction was performed with the program SAINT[18], and the structure was solved by direct methods or by the sharpened Patterson method as implemented in the SHELXTL system[19]. The SHELX97 program[20] was used for the final refinement. All non-hydrogen atoms were refined anisotropically and hydrogen atoms isotropically in calculated positions as a riding model. Further details of the crystal structure determinations are deposited at the Cambridge Crystallographic Data Centre and may be obtained by quoting the depository numbers CCDC-101834 (**5**), -101835 (**6**), -101836 (**7**), -101837 (**8**), -101838 (**9**), -101839 (**10**), the names of the authors and the journal citation.

Dimethylaluminium N-Phenyl-N′,N′-bis(trimethylsilyl)hydrazide −Tetrahydrofuran (**5**): A solution of *n*BuLi in hexane (7.4 ml, 11.5 mmol) was slowly added dropwise to a stirred solution of $Ph(H)N-N(SiMe_3)_2$ (2.91 g, 11.5 mmol) in tetrahydrofuran (20 ml). The mixture was kept at reflux until butane evolution had ceased. Then one equivalent of a 1 M solution of dimethylaluminium chloride in heptane (11.5 mmol) was slowly added at −69°C. After warming to room temperature, the mixture was stirred for 48 h. The solvent was removed and the residue was dissolved in 20 ml of hexane. After removal of insoluble material (LiCl) by filtration, the filtrate was stored at −20°C. Colorless single crystals which were suitable for an X-ray structure investigation could be isolated after a few days. Yield 3.45 g (79%); m.p. 86°C (dec.). − ^{1}H NMR (C_6D_6, 270 MHz): δ = −0.32 (s, 6 H, $AlMe_2$); 0.34 (s, 18 H, $SiMe_3$); 0.91 (t, 4 H, THF); 3.45 (t, 4 H, THF); 6.73 [t, ^3J(H,H) = 7.1 Hz, 1 H, *p*-Ph]; 7.05 [d, ^3J(H,H) = 8.1 Hz, 2 H, *o*-Ph]; 7.28 [t, ^3J(H,H) = 7.5 Hz, 2 H, *m*-Ph]. − ^{13}C NMR (C_6D_6, 100 MHz) δ = −7.8 ($AlMe_2$); 2.8 ($SiMe_3$); 24.65 (THF); 71.3 (THF); 113.1 (*o*-Ph); 115.1 (*p*-Ph); 128. 8 (*m*-Ph); 157.9 (*i*-Ph). − ^{29}Si NMR (C_6D_6 54 MHz): δ = 7.1. − ^{27}Al NMR (hexane, 70 MHz): δ = 151 ($h_{1/2}$ = 5570 Hz). − $C_{18}H_{37}AlN_2OSi_2$ (380.66): calcd. C 56.79, H 9.82, N 7.36, Al 7.09; found C 53.85, H 9.22, N 6.79, Al 7.12.

Dimethylaluminium N,N′-Diphenyl-N′-trimethylsilylhydrazide−Tetrahydrofuran (**6**): A solution of *n*BuLi in hexane (4.5 ml, 7.1 mmol) was slowly added to a stirred solution of $Ph(H)N-N(Ph)SiMe_3$ (1.83 g, 7.1 mmol) in 40 ml of tetrahydrofuran. The mixture was heated to reflux for 1 h until butane evolution had ceased. After cooling to −69°C, one equivalent of a 1 M solution of dimethylaluminium chloride in heptane (7.1 mmol) was added slowly and the mixture was allowed to attain room temperature and was stirred further for 12 h. The solvent was then removed and the residue dissolved in 50 ml of hexane. After removal of insoluble material (LiCl), the filtrate was stored at −20°C. After 2 weeks, colorless single crystals had separated. Yield 2.16 g (80%); m.p. 97°C. − ^{1}H NMR (C_6D_6, 400 MHz): δ = −0.46 (s, 6 H, $AlMe_2$); 0.42 (s, 9 H, $SiMe_3$); 0.87 (m, 4 H, THF); 3.41 (m, 4 H, THF); 6.74 [t, ^3J(H,H) = 7.2 Hz, 1 H, *p*-Ph]; 6.77 [t, ^3J(H,H) = 7.5 Hz, 1 H, *p*-Ph]; 6.95 [d, ^3J(H,H) = 7.2 Hz, 2 H, *o*-Ph]; 7.02 [d, ^3J(H,H) = 7.5, 2 H, *o*-Ph]; 7.13 [t, ^3J(H,H) = 7.2 Hz, 2 H, *m*-Ph]; 7.22 [t, ^3J(H, H) = 7.5 Hz, 2 H, *m*-Ph]. − ^{13}C NMR (C_6D_6, 100 MHz): δ = 0.5 ($AlMe_2$); 1.5 ($SiMe_3$); 24.7 (THF); 71.6 (THF); 113.1 (*o*-Ph); 115.4 (*o*-Ph); 116.3 (*p*-Ph); 117.9 (*p*-Ph); 128.8 (*m*-Ph); 129.3 (*m*-Ph); 152.1 (*i*-Ph); 156.1 (*i*-Ph). − ^{27}Al NMR (C_6D_6, 104 MHz): δ = 165 ($h_{1/2}$ = 6100 Hz). − ^{29}Si NMR (C_6D_6, 79 MHz): δ = 10.3. − $C_{21}H_{33}AlN_2OSi$ (384.56): calcd. C 65.24, H 9.12, N 7.25, Al 7.02; found C 62.38, H 8.70, N 7.45, Al 7.14.

Dimethylaluminium N′,N′-Diphenyl-N-trimethylsilylhydrazide −Diethyl Ether (**7**): A solution of *n*BuLi in hexane (4.2 ml, 6.6 mmol) was slowly added dropwise to a stirred solution of $(Ph)_2N-N(H)SiMe_3$ (1.67 g, 6.5 mmol) in 40 ml of diethyl ether. The mixture was heated to reflux until butane evolution had ceased. After cooling to −69°C, one equivalent of a 1 M solution of dimethylaluminium chloride in heptane (6.5 mmol) was added slowly. This mixture was allowed to reach room temperature and was stirred for another 12 h. The solvent was removed in vacuo and the residue was treated with 40 ml of hexane. After insoluble material (LiCl) had been removed, the filtrate was kept at −20°C. Four weeks later colorless single crystals were isolated. Yield 1.46 g (56%); m.p. 61°C. − ^{1}H NMR (C_6D_6 400 MHz): δ = −0.45 (s, 6 H, $AlMe_2$); 0.27 (s, 9 H, $SiMe_3$); 0.59 (t, 6 H, Et_2O); 3.25 (q, 4 H, Et_2O); 6.73 [t, ^3J(H,H) = 7.4 Hz, 2 H, *p*-Ph]; 7.11 [t, ^3J(H,H) = 7.4 Hz, 4 H, *m*-Ph]; 7.48 [d, ^3J(H,H) = 7.4 Hz, 4 H, *o*-Ph]. − ^{13}C NMR (C_6D_6, 100 MHz): δ = −0.5 ($AlMe_2$); 2.6 ($SiMe_3$); 1.4 (Et_2O); 66.1 (Et_2O); 119.6 (*o*-Ph); 119.71 (*p*-Ph); 128.6 (*m*-Ph); 150.0 (*i*-Ph). − ^{27}Al NMR (C_6D_6, 104 MHz): δ = 170 ($h_{1/2}$ = 5770 Hz). − ^{29}Si NMR (C_6D_6, 79 MHz): δ = 0.0. − $C_{21}H_{35}AlN_2OSi$ (386.58): calcd. C 65.24, H 9.12, N 7.25, Al 6.98; found C 63.38, H 8.70, N 7.45, Al 6.84.

Lithium Trihydrido[N-phenyl-N′,N′-bis(trimethylsilyl)hydrazino]aluminate−Diethyl Ether(1/2) (**8**): A 1.75 M solution of $LiAlH_4$ in diethyl ether (3.7 ml, 6.5 mmol) was slowly added at −69°C to a stirred solution of $Ph(H)N-N(SiMe_3)_2$ (1.63 g, 6.5 mmol) in 30 ml of diethyl ether. After the mixture had attained room temperature, it was heated to reflux for 1 h. A small amount of insoluble material, which proved to be compound **3**, was filtered off and the filtrate was stored at −20°C. Colorless single crystals of **8** formed within a week. Yield 2.33 g (82%); m.p. 93°C. − ^{1}H NMR (C_6D_6, 270 MHz): δ = 1.99−4.71 (s, br., 3 H, AlH_3); 0.34 (s, 18 H, $SiMe_3$); 0.95 [t, ^3J(H,H) = 7.0 Hz, 12 H, Et_2O]; 3.32 [q, ^3J(H,H) = 7.0 Hz, 8 H, Et_2O]; 6.69 [t, ^3J(H,H) = 7.1 Hz, 1 H, *p*-Ph]; 7.08−7.34 (m, 4 H, *o,m*-Ph). − ^{13}C NMR (C_6D_6, 100 MHz): δ = 2.4 ($SiMe_3$); 14.8 (Et_2O); 65.6 (Et_2O); 112.6 (*o*-Ph); 118.6 (*p*-Ph); 129.1 (*m*-Ph); 158.6 (*i*-Ph). − ^{27}Al NMR (C_6D_6, ^{1}H-decoupled, 70 MHz): δ = 110 ($h_{1/2}$ = 87 Hz). − ^{27}Al NMR (C_6D_6, ^{1}H-coupled, 70 MHz): δ = 110 [q, ^1J(Al,H) = 178 Hz]. − ^{29}Si NMR (C_6D_6, 54 MHz): δ = 6.2. − ^{7}Li NMR (C_6D_6, 105 MHz): δ = 0.40 ($\Delta h_{1/2}$ = 12 Hz). − IR (hostaflon): $\tilde{\nu}$ = 1781 cm^{-1} (vs, br., Al−H). − $C_{20}H_{46}AlLiN_2O_2Si_2$ (436.69): calcd. C 55.00, H 10.63, N 6.42, Al 6.18; found C 52.16, H 9.82, N 6.73, Al 6.28.

Lithium [N′-tert-Butyl-N-trimethylsilylhydrazino](μ-N,N′-dihydrido)aluminate−Tetrahydrofuran (2/4) (**9**): A solution of *t*Bu(H)N−N(H)$SiMe_3$ (1.79 g, 11.2 mmol) in 20 ml of THF was slowly added to a stirred 1.58 M solution of $LiAlH_4$ in THF (7.08 ml, 11.2 mmol). Stirring was continued at 50°C for 4 h. A small amount of insoluble material was removed by filtration, and the filtrate was then kept at −20°C. After 5 d, colorless crystals had formed, which were not suitable for an X-ray structure investigation. Recrystallization from diethyl ether provided single crystals of **9**. Yield 1.97 g (52%); m.p. 83°C (dec.). − ^{1}H NMR ([D$_8$]tol-

uene, 400 MHz): δ = 0.54 (s, 18 H, $SiMe_3$); 1.43 (m, 16 H, THF); 1.61 (s, 18 H, *t*Bu); 3.58 (m, 16 H, THF). – ^{13}C NMR ([D_8]toluene, 100 MHz): δ = 5.1 ($SiMe_3$); 25.7 (THF); 32.2 (*t*Bu); 56.9 (*t*Bu); 68.4 (THF). – ^{27}Al NMR ([D_8]toluene, 104 MHz): δ = 119 ($h_{1/2}$ = 1520 Hz). – ^{29}Si NMR (THF, 54 MHz): δ = −2.0. – ^{7}Li NMR ([D_8]toluene, 155 MHz): δ = 0.35 ($h_{1/2}$ = 30 Hz). – IR (hostaflon): $\tilde{\nu}$ = 1723 cm^{-1} (s, br., Al−H), 1652 (m, br., Al−H). – $C_{15}H_{36}AlLiN_2O_2Si$ (338.47): calcd. C 53.22, H 10.74, N 8.28, Al 7.97; found C 47.55, H 9.33, N 7.20, Al 7.91.

Dimethylaluminium N-tert-Butyl-N′-(trimethylsilyl)hydrazide (**10**): A solution of *n*BuLi in hexane (6.4 ml, 10.0 mmol) was slowly added to a stirred solution of *t*Bu(H)N−N(H)$SiMe_3$ in 50 ml of toluene. The mixture was heated to reflux for 1 h until the butane evolution had ceased. After cooling to −50°C, one equivalent of a 1 M solution of dimethylaluminium chloride in heptane (10.0 mmol) was slowly added. Work up by analogy to **9**. Colorless single crystals of **10** were isolated after a week. Yield 1.58 g (73%), m.p. 126°C. – ^{1}H NMR (C_6D_6, 25°C, 400 MHz): δ = −0.33 (s, 3 H, AlMe); −0.24 (s, 3 H, AlMe); 0.26 (s, 9 H, $SiMe_3$); 1.13 (s, 9 H, *t*Bu); 4.04 (s, br., 1 H, NH). – ^{1}H NMR (C_6D_6, 80°C): δ = −0.35 (s, br., 6 H, $AlMe_3$). – ^{13}C NMR (C_6D_6, 25°C, 100 MHz): δ = 1.4 ($AlMe_2$); 3.8 ($SiMe_3$); 28.4 (*t*Bu); 59.7 (*t*Bu). – ^{13}C NMR ([D_8]toluene, −60°C, 100 MHz): δ = 1.2 ($AlMe_2$); 1.6 ($AlMe_2$). – ^{29}Si NMR (C_6D_6, 54 MHz): δ = 15.2. – ^{27}Al NMR (C_6D_6, 104 MHz): δ = 141 ($h_{1/2}$ = 2200 Hz). – IR (Nujol, Hostaflon): $\tilde{\nu}$ = 3246 cm^{-1} (s, N−H), 1380, 1365 (s, *t*Bu). – $C_9H_{25}AlN_2Si_2$ (216.38): calcd. C 49.95, H 11.65, N 12.95, Al 12.47; found C 46.33, H 10.38, N 11.67, Al 12.35.

Keywords: Superoxide dismutase mimic / Pulse radiolysis / Imidazolato-bridged dicopper(II) complex / Copper / Radicals

The ability of a dicopper(II) complex with a pentadentate, imidazolato-bridged ligand having two different coordination environments to mimic the reactivity of superoxide dismutase has been investigated by pulse radiolysis. Pseudo first-order kinetics were observed for superoxide scavenging, with a very high rate constant of $1.9 \pm 0.4 \times 10^9$ M^{-1} s^{-1}, consistent with catalytic dismutation of superoxide by the complex. This value is essentially constant over the pH range of 5 to 7, and agrees with earlier results obtained with the nitroblue tetrazolium assay.

The superoxide anion radical ($O_2^{\bullet -}$) may be involved in deleterious biological processes, such as lipid peroxidation,[1] aging,[2] and cancer.[3] This anion radical is very efficiently scavenged by the enzyme superoxide dismutase which catalyses the dismutation of superoxide to dioxygen and hydrogen peroxide.[4] The rate constants for reduction and reoxidation of the copper ion of Cu,Zn superoxide dismutase are known:[5] $k_1 = k_2 = 2.4 \cdot 10^9$ $M^{-1}s^{-1}$. These rate constants indicate that the reactions are nearly diffusion-controlled.[6]

An alternative pathway for reoxidation of copper(I) involves the reaction with the hydrogen peroxide product of the dismutation reaction, with formation of a copper−peroxo complex (Eq. 1)[7][8] which could react directly,[8] or decompose to form the hydroxyl radical[8][9] which in turn would react with the surrounding ligand or biomolecule.[10] The formation of an oxidizing copper(III) species is also possible since four-nitrogen ligands in a square-planar coordination would stabilize copper(III). Theoretical considerations[11] and experimental results[10][12] indicate that the occurrence of a copper(III) oxide(1+) species can be excluded.

$$Cu^{I} + H_2O_2 \rightarrow CuH_2O_2^{+} \quad (1)$$

A relative measure of superoxide dismutase activity can easily be obtained from indirect assays in which a very small and stationary amount of superoxide is generated usually by the action of xanthine oxidase on xanthine, and a detector molecule such as nitroblue tetrazolium[13] or cytochrome *c*[14] is used to follow the reaction kinetics spectrophotometrically. In these assays, the rate of reduction of the detector molecule by superoxide is measured, and the reactivity of superoxide dismutase or of superoxide dismutase mimics is inferred from the rate decrease in the presence of these species. This approach cannot provide absolute rate data, since the superoxide dismutation reaction itself is too rapid to be followed directly, and hence no mechanistic information about the reaction can be obtained. Pulse radiolysis is a superior method to investigate superoxide dismutation as one can selectively and at will generate superoxide and hydrogen dioxide in the absence of extraneous and interfering enzyme systems and reporter molecules, and one can make measurements in the microsecond time scale.

Amino acid sequences[15][16] and structures[17][18][19][20] of various Cu,Zn superoxide dismutases are known. The active site is composed of an imidazolato-bridged dinuclear center containing copper(II) and zinc(II). The coordination geometry is distorted square-pyramidal for copper(II) and distorted tetrahedral for zinc(II). For many years efforts have been made to obtain model compounds that show structural, spectroscopic, and catalytic properties similar to that of the active site in Cu,Zn superoxide dismutase.[21][22][23][24][25][26][27][28][29] However, many of the superoxide dismutase mimics prepared to date are unstable in aqueous solution. Further, results obtained with complexes that have been studied in aqueous solution are weakened by the possibility that the observed catalysis is actually carried out by free copper.

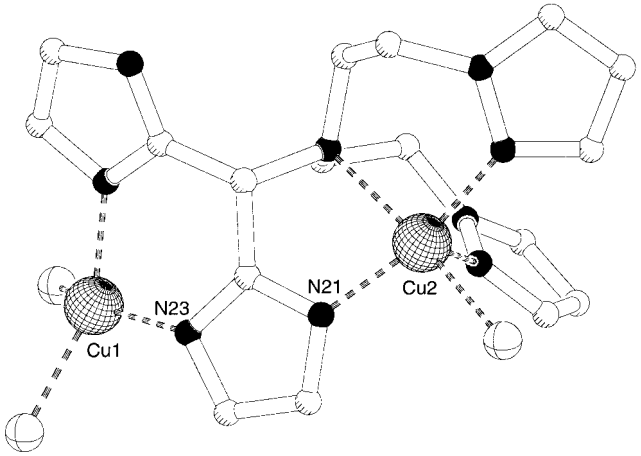
In the present work, the pulse radiolysis technique was used to measure the superoxide dismutase activity of an imidazolato-bridged dicopper(II) complex, 1,5-bis(1-pyrazolyl)-3-[bis(2-imidazolyl)methyl]-3-azapentane ($[Cu_2L]^{3+}$, Figure 1) which has a coordination geometry strikingly similar to that of the active site of native Cu,Zn superoxide dismutase.[30]

Figure 1. Structure of $[Cu_2(L)Cl_3]$ showing the imidazolate bridge



Dismutation of superoxide leads to formation of dioxygen and hydrogen peroxide; interaction of the latter with the $Cu^{I}Cu^{II}$ or $Cu^{I}Cu^{I}$ complex would produce the hydroxyl radical. For this reason the interaction of this radical with the complex was also briefly investigated.

Results

Superoxide Dismutation Experiments

In Figure 2 a typical decay of the superoxide absorbance as a function of time is shown. Depending on the concentration of copper complex and the presence or absence of phosphate buffer, different rate constants were obtained, see Table 1. The dose-dependent amount of acid produced during the irradiation leads to a proton concentration of approximately 10^{-5} M. The change in pH results in partial protonation of superoxide ($pK_a = 4.7$), therefore reactions of the hydrogen dioxide radical were taken into consideration. The pH under the different experimental conditions was evaluated by calculating the ratio $[HO_2^{\bullet}]/[O_2^{\bullet-}]$ from the maximum absorbance after the pulse. A correction of smaller than 10% in the rate of dicopper(II) complex dependent dismutation was required on the basis of the rate of dismutation of superoxide in the absence of complex.

The rate constant for dismutation of superoxide by aqueous copper species increases with pH. Values for the rate constant obtained by statistical treatment of the steady-state rate constant, $k_{ss,O_2^{\bullet-}}$, are shown in Table 1. At pH = 7, $k_{ss,O_2^{\bullet-}}$ is $(1.9 \pm 0.4) \times 10^9$ $M^{-1}s^{-1}$. Values for $k_{ss,HO_2^{\bullet}}$ for the unbuffered solutions were calculated on the basis of equation 15 (see Experimental Section − Methods), with the help of $k_{ss,O_2^{\bullet-}}$ determined in buffered solutions.

Figure 2. Experiment and fit (heavy line) for unbuffered solution at 22°C with a dose of 88 Gy, $[Cu_2L]^{3+} = 4$ mM, optical pass length of 2 cm, observed at 280 nm; the residual absorption from the fit is also given(lower noisy trace); from the least-square fits it is evident that a second-order fit is systematically wrong

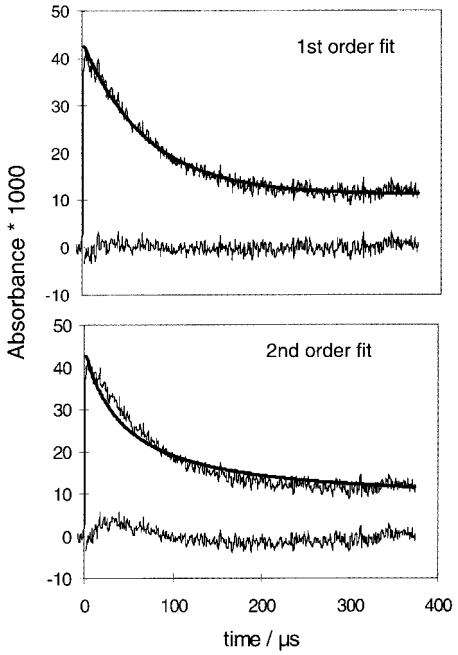


Figure 3. Comparison of the extinction coefficients of $[Cu_2L]^{3+}$ at concentrations of 5 µM and 0.5 mM

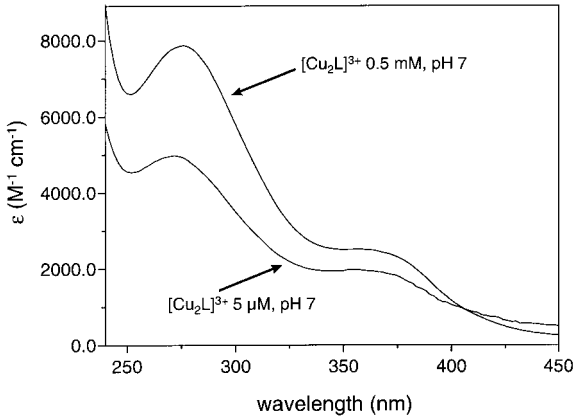

The speciation of copper in solutions of the copper−imidazolato complex is not straightforward. The integrity of the dicopper(II) complex was evaluated from the UV/Vis spectrum of a 5 µM solution. On the basis of the absorbance at 375 nm, corresponding to the absorbance maximum of the Cu−Im−Cu chromophore,[30] it was calculated that ca. 80% of the dicopper(II) complex retained the original structure (Figure 3).

We performed a control experiment in which we dermined the catalytic activity of copper ion in a solution that did not contain the imidazole ligand, but was otherwise identical, and found a $k_{ss,O_2^{\bullet-}}$ of $(1.6 \pm 0.2) \times 10^9$ M^{-1} s^{-1}.

No transient spectrum attributable to formation of a copper(II)−superoxide complex was observed. A residual ab-

sorbance that decayed over 0.8 ms was always observed in the experiments with 4 μM complex, possibly due to the presence of partially reduced copper complex in the steady state.

Hydroxyl Radical Experiments

The absorbance decay under conditions of $[Cu_2L]^{3+} >> [HO^{\bullet}]$ follows a pseudo first-order kinetics: a rate constant of 1.7 ± 0.3 × 10^{10} $M^{-1}s^{-1}$ was found. The absorbance decay of the radical species formed was fitted to an apparent second-order reaction with a rate constant of $k/\Delta\varepsilon$ of (1.3 ± 0.4) × 10^7 $cm^{-1}s^{-1}$. It should, however, be noted that the structure of any putative radical product(s) has not been determined, that many reaction mechanisms are possible, and that it is impossible to report the exact kinetic order at this stage.

Discussion

As discussed by Costanzo et al.,[31] studies which report catalytic rate constants of copper complexes regrettably hardly ever address the issue of speciation. Sometimes not even the ratio of ligand to metal is stated. This raises the suspicion that the reported catalytic activity was due to free copper, rather than the complex. In our experiments spectrophotometric measurements show that ca. 20% of the complex is hydrolysed. Since the copper(I + II) aquo complex reacts with superoxide with a catalytic rate constant of $k_{ss,O_2^{\bullet -}} = 9 \times 10^9$ $M^{-1}s^{-1}$,[32][33][34][35] it was appropriate to consider whether the observed activity is due to undefined complexes of copper in various oxidation states with water and solutes.

The catalytic activity of the hydrolysed copper was determined in control experiments lacking the imidazolato-containing ligand. The activity measured here equals that of solutions in which the complex had hydrolysed completely and in which the copper was bound to formate, phosphate, hydroxide, etc. Had the measured catalytic activity of 1.9 × 10^9 $M^{-1}s^{-1}$ been due to such copper complexes, and not to the imidazolato-bridged complex, then the catalytic rate constant would have been 5 times higher, namely 9 × 10^9 $M^{-1}s^{-1}$. If the activity of the copper complex had been found to be clearly lower than that for the control solution, it would not have been possible to ascribe the activity to the complex with certainty.

The decay of superoxide is first order, indicating steady-state kinetics. In phosphate-buffered solution the influence of the hydrogen dioxide radical is negligible, and the steady-state rate constant found for $k_{ss,O_2^{\bullet -}} = 1.9 \pm 0.4 \times 10^9$ $M^{-1}s^{-1}$. The rate, determined here by pulse radiolysis, is in good agreement with that determined by the indirect assay[30] and comparable to that of Cu,Zn superoxide dismutase. This may represent the first unequivocal demonstration of superoxide dismutase mimicry by a low molecular weight copper complex.

At lower pH, where $HO_2^{\bullet}$ is present at 16–90% and the contribution of $k_{ss,HO_2^{\bullet}}$ to the overall observed rate constant is strong, the observed rate constants are higher than those obtained in buffered solution. The lowest single determination of $k_{ss,HO_2^{\bullet}}$ was 3.9 × 10^9 $M^{-1}s^{-1}$, indicating that the dicopper(II) complex is also extremely active in the conversion of hydrogen dioxide.

The absence of a transient spectrum due to a copper(II)–superoxide adduct is understood when one takes into account that the superoxide radical can undergo fast outer-sphere electron-transfer reactions. This interpretation is supported by the exceptionally high rate constants; inner-sphere reactions of copper(II) are expected to be at least one order of magnitude lower.[36] An alternative explanation is that the transient spectrum of the hypothetical adduct has an absorbance too low to be observed.

We cannot exclude an interaction of either the dicopper(II) [= copper(I)–copper(I)] or the copper(II)–copper(I) complex with hydrogen peroxide released after the catalyzed dismutation of superoxide anion. Such an interaction would lead to a degradation of the ligand, probably through the generation of the hydroxyl radical. Thus, the rate of reaction of the hydroxyl radical with the dicopper(II) complex was evaluated. The reaction is apparently pseudo first-order with a rate constant of 1.7 ± 0.3 × 10^{10} $M^{-1}s^{-1}$, which is about one order of magnitude higher than corresponding rate constants of free imidazole and bis(2-imidazolyl)methane.[33][37]

Experimental Section

Methods

General: The pulse radiolysis setup with a Febetron 705 2-MeV accelerator (Hewlett-Packard) has been described before.[12][32] All experiments were carried out at room temperature (20−22°C) with an effective 50-ns irradiation pulse and a 2-cm optical path length in a quartz cell. Solutions were prepared from triply distilled water. Uncertainties for rate constants are expressed at the 99% confidence limit.

The conditions for the experiments were carefully chosen: a) the concentration of phosphate was set at 75 μM to buffer the solution at pH = 7 to maximize the concentration of the imidazolato-bridged dicopper(II) complex, since at pH < 6.8 the bridging may be compromised to some extent and at pH > 8.0 hydrolytic species are formed,[30] and to minimize formation of hydrogen dioxide radicals; and b) the concentration of formate was set at 100 μM to maximize the yield of superoxide and to minimize the formation of the copper-formate complexes. Phosphate concentrations were kept at the minimum necessary to maintain the desired pH as phosphate can dramatically influence the rate of reaction of superoxide with copper-containing catalysts.[32] An excess of phosphate can shift the equilibria towards the formation of copper(II) phosphate. The influence of phosphate in experiments with buffered solutions was evaluated by comparison with experiments performed with unbuffered solutions.

Superoxide Experiments: The dicopper(II) complex was dissolved in 100 mM sodium formate (Merck puriss p.a.) and adjusted to pH = 7.3 with sodium hydroxide. Three groups of solutions were prepared: unbuffered solutions having total copper concentrations of 2 and 4 μM, and a buffered solution (75 μM phosphate, pH = 7.3) with 1 μM copper. Solutions were saturated with oxygen (> 99.5%, Pan Gas) for approximately 20 min. A dose of 75−100 Gy was applied to generate superoxide (44−60 μM) in excess over the dicopper(II) complex. Under these conditions a steady state is achieved and the decay of superoxide follows a pseudo first-order kinetics, because the concentrations of reduced and oxidized forms of copper in the complex are constant.

Irradiation of oxygen-saturated solutions containing formate generates primary radicals which are converted to superoxide within 2 μs of the end of the pulse;[38] the corresponding change in absorbance was followed at different wavelengths ranging from 245 to 295 nm. The total concentration of superoxide and hydrogen dioxide was calculated from the dose. The pH after the pulse was calculated from the published pK_a and extinction coefficients.[39]

Hydroxyl Radical Experiments: Solutions of the dicopper(II) complex at concentrations of 20.7 or 81 μM prepared in water adjusted to pH = 7.3 with sodium hydroxide were saturated with N_2O (> 99.5%, Pan Gas) for approximately 20 min. The more dilute solution was used to follow the absorbance decay at different wavelengths, following radiation doses of about 100 Gy ([HO•] = 60 μM). The kinetics of the reaction was followed at 300 and 350 nm with the 81 μM solution of complex and an irradiation dose of about 20 Gy ([HO•] = 12 μM).

Kinetics: Superoxide dismutation catalyzed by copper aquo complexes is pH-dependent and faster for superoxide than for hydrogen dioxide.

$$Cu^{2+}(aq) + O_2^{\bullet -} \rightarrow Cu^{+}(aq) + O_2 \quad (2)$$

$$Cu^{+}(aq) + O_2^{\bullet -} + 2\,H^{+} \rightarrow Cu^{2+}(aq) + H_2O_2 \quad (3)$$

$$Cu^{2+}(aq) + HO_2^{\bullet} \rightarrow Cu^{+}(aq) + O_2 + H^{+} \quad (4)$$

$$Cu^{+}(aq) + HO_2^{\bullet} + H^{+} \rightarrow Cu^{2+}(aq) + H_2O_2 \quad (5)$$

If superoxide radicals are in large excess, the steady-state condition for $Cu^{2+}(aq)$ is obtained where

$$k_{ss} = (2\,k_2k_3)/(k_2 + k_3) = 8.7\cdot 10^9\ \text{M}^{-1}\text{s}^{-1}\ [32] \quad (6)$$

which is ca. four times higher than k_{ss} of Cu/Zn superoxide dismutase. Hydrogen dioxide radicals react with aqueous copper much more slowly:

$$k_{ss} = (2\,k_4k_5)/(k_4 + k_5) = 1.6\cdot 10^8\ \text{M}^{-1}\text{s}^{-1}\ [32] \quad (7)$$

In the case of the dicopper(II) imidazolato complex investigated here we investigated only the overall (i.e. steady-state) reaction rate as is commonly reported for superoxide dismutases. Microscopically, several reactions may be involved (formulated for deprotonated species only):

$$[Cu^{II}Cu^{II}L]^{3+} + O_2^{\bullet -} \rightarrow [Cu^{I}Cu^{II}L]^{2+} + O_2 \quad (8)$$

$$[Cu^{I}Cu^{II}L]^{2+} + O_2^{\bullet -} \rightarrow [Cu^{I}Cu^{I}L]^{+} + O_2 \quad (9)$$

$$[Cu^{I}Cu^{I}L]^{+} + O_2^{\bullet -} + 2H^{+} \rightarrow [Cu^{I}Cu^{II}L]^{2+} + H_2O_2 \quad (10)$$

$$[Cu^{I}Cu^{II}L]^{2+} + O_2^{\bullet -} + 2H^{+} \rightarrow [Cu^{II}Cu^{II}L]^{3+} + H_2O_2 \quad (11)$$

the sum of which is:

$$4\,O_2^{\bullet -} + 4\,H^{+} \rightarrow 2O_2 + 2\,H_2O_2 \quad (12)$$

with a steady-state rate law of:

$$d[O_2^{\bullet -}]/dt = k_{ss,O_2^{\bullet -}}\,[Cu_2L][O_2^{\bullet -}],\ k_{ss,O_2^{\bullet -}} = (1.9 \pm 0.4)\times 10^9\ \text{M}^{-1}\text{s}^{-1} \quad (13)$$

$$d[HO_2^{\bullet}]/dt = k_{ss,HO_2^{\bullet}}\,[Cu_2L][HO_2^{\bullet}],\ k_{ss,HO_2^{\bullet}} > 3\times 10^9\ \text{M}^{-1}\text{s}^{-1} \quad (14)$$

Under conditions where superoxide/hydroperoxyl radical is present in great excess (15- to 60-fold) over the dicopper complex, the steady-state condition is reached where the kinetics obey a pseudo first-order rate law.

Near pH = 4.7, the pK_a of hydrogen dioxide, both Eq. 13 and 14 must be considered. The apparent rate constant k'_{ss} is

$$k'_{ss} = 1/(1+\beta)\times k_{ss,HO2} + 1/(1+\beta)\times k_{ss,O2^-} \quad (15)$$

where

$$\beta = [O_2^{\bullet -}]/[HO_2^{\bullet}] = 10^{(\text{pH} - \text{p}K\text{HO2})}$$

and at pH = 4.7 reduces to

$$k'_{ss} = 0.5\times k_{ss,HO_2} + 0.5\times k_{ss,O_2^-} \quad (16)$$

Keywords: Phosphenium complexes / Cycloadditions / Heteroallenes / Phosphametallacycles / Diastereoselectivity / Spiro compounds

Reaction of the phosphenium complexes $Cp(OC)_2W{=}P$-(*t*Bu)(R) [R = *t*Bu (**2a**), Ph (**2b**)] with ethyl isothiocyanate (**3**) leads to the formation of the phosphametallacycles $Cp(OC)_2W{-}P(tBu)(R){-}C(=NEt){-}S(W{-}S)$ (**4a**, **b**) by [2 + 2] cycloaddition. In contrast, the "in situ" reaction of **2a**, **b**, generated from $Cp(OC)_2[H(tBu)(R)P]W{-}Cl$ (**1a**, **b**) with DBU in the presence of **3** leads to the spirocyclic phosphorus metal compounds $\{Cp(OC)_2W{-}P(tBu)(R){-}N(Et){-}C^a[N(Et){-}(CH){-}N$-$(Et)C^bH_2]{-}S(W{-}S)(C^a{-}C^b)\}Cl$ (**6a**, **b**). The structure of **6a** has been proved by X-ray analysis.

Introduction

Transition metal mediated synthesis of organic compounds is one of the outstanding areas of organometallic chemistry. Extension of this approach to organophosphorus chemistry has drawn increasing attention in recent times, involving phosphenium ($M{=}PR_2$)[1] or phosphinidene ($M{=}PR$)[2] complexes. In this context it has been demonstrated that the M=P unit of the phosphenium complexes $Cp(OC)_2M{=}PR_2$ (M = Mo, W) exhibits a pronounced propensity for the addition of Brønstedt acids, carbenoids, and their analogues as well as diverse organic multiply bonded systems, offering efficient routes to new types of organophosphorus units. Within the scope of this topic we recently described the chemo- and regioselective cycloaddition of the phosphenium complexes $Cp(OC)_2M{=}P(R)$(*o*-Tol) (M = Mo, W; R = Ph, *o*-Tol) to organic isocyanates yielding the [2 + 2] cycloaddition products $Cp(OC)_2M{-}P(R)$(*o*-Tol)$-C(=O)-NEt(M{-}N)$[3].

We now report about the cycloaddition reaction between the diorganophosphenium complexes $Cp(OC)_2W{=}P(tBu)(R)$ [R = *t*Bu (**2a**), Ph (**2b**)] bearing one or two *tert*-butyl ligands at the phosphorus atom and EtNCS affording, in addition to the expected cycloadduct, an unusual coupling product as a consequence of "in situ" generation.

Results

Reaction of the phosphenium complexes **2a**, **b**, obtained from the bifunctional complexes **1a**, **b** by DBU-assisted dehydrohalogenation, with EtNCS in toluene at room temperature after 12 (**2b**) and 24 h (**2a**), leads to the formation of the four-membered phosphametallacycles **4a**, **b**, representing the product of a [2 + 2] cycloaddition. The coupling reaction exclusively involves the C=S bond of the isothiocyanate, whereby, in contrast to the isocyanate reaction, not the nitrogen but the sulfur atom is coordinated to the metal atom while the electrophilic carbon atom is in both cases bonded to the phosphorus atom. This finding characterizes the isothiocyanate reaction as chemo- and regiospecific (Scheme 1).

Pure **4a**, **b** is isolated by column chromatography in good yield as a deep red and orange crystalline powder, respectively. The structure is proved by the ^{31}P-NMR spectra, with signals at δ = 39.7 (**4a**) and 11.9 (**4b**) and ^1J(WP) couplings of 213.8 (**4a**) and 230.2 Hz (**4b**) appearing in the characteristic range of four-membered phosphametallacycles[3]. The signal of the *P*-bonded sp^2-carbon atom of **4b** is observed in the ^{13}C-NMR spectrum as a doublet in the typical low-field region at δ = 183.0 with a ^1J(PC) coupling of 49.6 Hz. **4b**, which contains two stereogenic centers as i.e. the metal and the phosphorus atoms, is generated highly diastereoselectively, according to the NMR spectra.

In order to promote metal-assisted organophosphorus synthesis it is reasonable to avoid isolation of the thermally

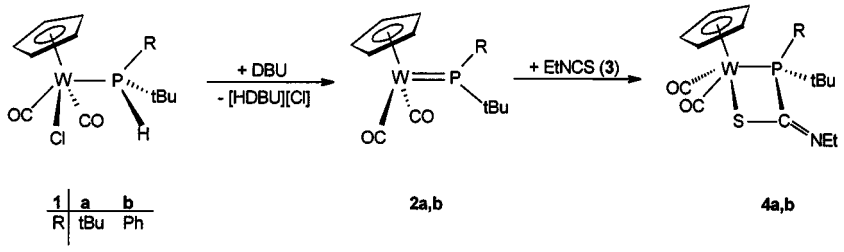
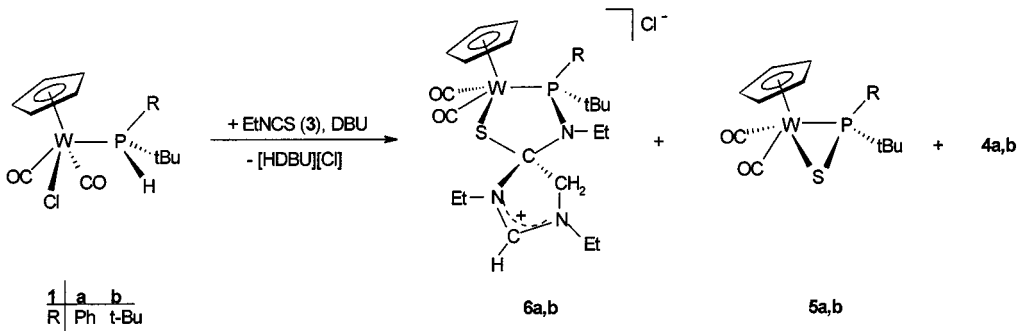
Scheme 1



unstable phosphenium complexes. According to this approach **2a**, **b** were generated "in situ" by combining the precursor complex **1** with **3** followed by addition of DBU. After removal of insoluble material, mainly [HDBU]Cl, the solution was reduced to a volume of 2 ml and the residue separated by column chromatography. This procedure yields, besides **4a**, **b**, the spirocyclic compounds **6a**, **b** as well as the three-membered heterocycles **5a**, **b**.

Scheme 2



The spirocycles **6a**, **b** are isolated in yields of 25% as orange powders, which show good solubilities in all organic solvents except for alkanes. Heterocycles **5a**, **b** could not be separated from **4a**, **b** but were alternatively prepared by the well-established addition of elemental sulfur to the W=P double bond of **2a**, **b**.

The spirocyclic compounds **6a**, **b** contain a five-membered phosphametalla heterocycle showing the ^{31}P-NMR low-field signals at δ = 143.4 (**6a**), 127.5 (**6a′**) and 120.0 (**6b**), 139.8 (**6b′**) with ^{1}J(WP) coupling constants of 277.0 (**6a**), 265.7 (**6a′**) Hz and 280.8 (**6b**), 280.5 (**6b′**) Hz. Presumably it is formed by a 1,3-dipolar cycloaddition of ethyl isothiocyanate to the W=P double bond. The carbon atom of the added isothiocyanate is responsible for the spirocyclic structure, formed by the coupling with two ethyl isocyanate molecules followed by protonation of the carbon atoms. The generation of the ethyl isocyanate incorporated in the spirocycle is verified under the reaction conditions by ring contraction of the [2 + 2] cycloadducts **4a**, **b** to give W−P−S cycles, as proved in a separate experiment. This is a further example of easy cleavage of the carbon−sulfur bond in isothiocyanates in the presence of a transition metal resulting in the generation of complexes having both the sulfur atom and the isocyanide incorporated[4].

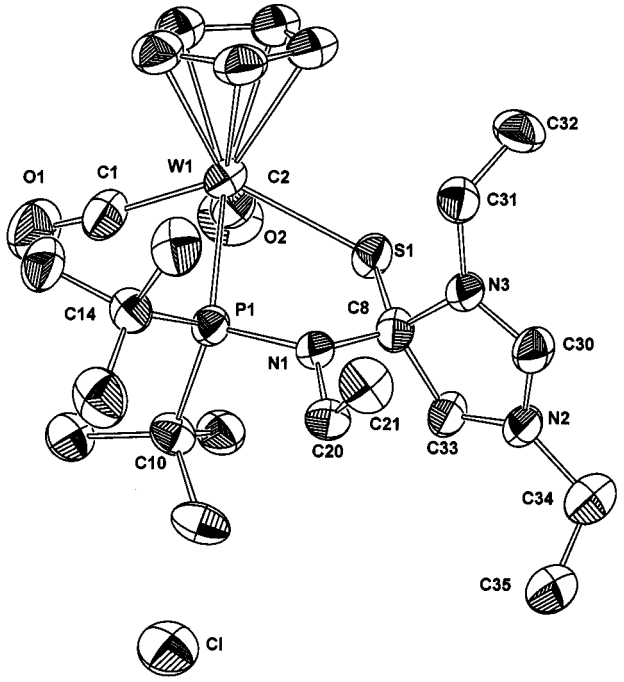
Despite the large number of postulated reaction steps, **6a**, **b**, which have two or three stereogenic centers, are formed highly diastereoselectively [*d. r.* = 96:4 (**6a**), 85:15 (**6b**)], indicating efficient stereocontrol by the metal fragment.

Final proof for the structure of **6a**, composed of two five-membered cycles connected by a spiro-carbon atom, is obtained by X-ray analysis. The spiro junction adopts a *syn* arrangement of the nitrogen atom N3 and the Cp ligand at the metal. The metal-phosphorus-containing ring shows an envelope conformation with a nearly planar P1−N1−C8−S1 unit [torsion angle: 12.9(10)°] with the folding along the W1−N1 axis resulting in an inclination of the phosphorus towards the Cp ligand. This arrangement is obvious from the different torsion angles W1−S1−C8−N1 [17.0(8)°] and W1−P1−N1−C8 [−35.4(8)°] and has its origin in the sterical interaction of the *tert*-butyl moiety (C14−C17) with the Cp unit. In the diaza ring the atoms N3, C30, N2, C33 are found in a plane [torsion angle: 6.9(13)°] from which the spiro atom C8 is only slightly deflected [C8−C33−N2−C30 15.4(12)°]. As shown by the angle Cp(Z)−W1−C8−N3 (1.16°), the plane of the ring is oriented nearly perpendicularly to the Cp(Z)−W axis.

Delocalization within the bonding system N2−C30−N3, involving an sp^2-hybridized carbon atom, is proved by the nearly identical values of the bond lengths N2−C30 [1.341(13) Å] and N3−C30 [1.345(13) Å], while the sp^3-hybridized carbon atom C33 is saturated by two hydrogen atoms.

The W1−P1 distance of 2.540(3) Å lies within the range of a single bond and is comparable with the values of other phosphane-substituted tungsten complexes[3][5]. The W1−S1 distance is slightly shorter than expected for a single bond [2.459(3) Å], while for the P1−N1 bond [1.720(8) Å] a single bond character is found[6].

Figure 1: ORTEP plot of {$Cp(OC)_2W-P(tBu)_2-N(Et)-C^a[N(Et)-C(H)-N(Et)-C^bH_2]-S(W-S)(C^a-C^b)$}Cl (**6a**)[a]



[a] Selected bond lengths [Å], bond and torsion angles [°]: W1−C2 1.927(12), W1−C1 1.948(12), W1−P1 2.540(3), W1−S1 2.459(3), S1−C8 1.823(11), P1−N1 1.720(8), N1−C8 1.437(12), N2−C30 1.341(13), N2−C33 1.449(12), N3−C30 1.345(13), N3−C8 1.472(12), C8−C33 1.558(13); W1−S1−C8 112.8(2), P1−W1−S1 74.2(8), W1−P1−N1 107.4(5); C8−S1−W1−P1 28.7(6), S1−W1−P1−N1 31.4(5), W1−P1−N1−C8 35.4(1), P1−W1−S1−C8 12.9(5); N1−C8−S1−W1 16.9(9), C30−N3−C8−C33 13.9(4), N3−C8−C33−N2 16.7(2), C8−C33−N2−C30 15.5(1), C33−N2−C30−N3 6.9(4), Cp(Z)−W1−C8−N3 1.16.

In conclusion, these studies demonstrate a metal-mediated multistep synthesis, starting from easily accessible secondary phosphane complexes with the corresponding phosphenium complexes as the crucial intermediates. Furthermore, this process proceeds with a high degree of diastereoselectivity, a feature which promises future application of these phosphametallaspirocycles in enantioselective synthesis.

Support of this research by the *Deutsche Forschungsgemeinschaft* (Sonderforschungsbereich 347, *"Selektive Reaktionen Metall-aktivierter Moleküle"*) is gratefully acknowledged.

Experimental Section

General: All manipulations were performed under dried and purified nitrogen. Solvents were rigorously dried with an appropriate drying agent, distilled before use and saturated with nitrogen. $Cp(OC)_2[H(tBu)(R)P]W-Cl$ and $Cp(OC)_2W=P(tBu)(R)$ (R = *t*Bu[7], Ph[1j]) were prepared according to the literature. All other reagents were obtained commercially and used without further purification. − ^{1}H-, ^{13}C-, and ^{31}P-NMR spectra were obtained on a Bruker AMX 400 spectrometer. δ(^{1}H)/(^{13}C) chemical shifts are reported downfield from Me_4Si referenced to the residual proton signal (^{1}H) or natural abundance carbon signal (^{13}C) of the deuterated solvent. δ(^{31}P) chemical shifts are measured relative to external H_3PO_4 (85%). Shifts downfield from the standard were assigned positive δ values. − Infrared spectra were measured in solution on a Perkin-Elmer 283 grating spectrometer in NaCl cells with 0.1-mm path length. − Melting points: Differential thermoanalysis (Du Pont 9000). − Elemental analyses were performed in the laboratory of the Institut für Anorganische Chemie der Universität Würzburg.

1. *$Cp(OC)_2W-P(tBu)_2-C(=NEt)-S(W-S)$* (**4a**): A solution of 170 mg (0.38 mmol) of $Cp(OC)_2W=P(tBu)_2$ (**2a**) in 10 ml of toluene was combined with 33 mg (0.38 mmol) of ethyl isothiocyanate (**3**) and the mixture stirred for 24 h at room temperature. The reaction mixture was reduced in vacuo to a volume of 1 ml and worked up by column chromatography (column 10 × 1.5 cm, alumina III, neutral, toluene). The eluate of the dark red zone was concentrated in vacuo and remaining **4a** was recrystallized from 7 ml of pentane. − Yield: 153 mg (75%). − Dark red microcrystalline powder. − M.p. 183°C. − ^{1}H NMR (400.1 MHz, [D$_6$]benzene): δ = 4.91 (s, 5 H, H_5C_5), 3.73 [qd, ^3J(HCCH) = 7.4 Hz, ^4J(PCNCH) = 2.5 Hz, 2 H, H_2CN], 1.32 [d, ^3J(PCCH) = 16.5 Hz, 9 H, $(H_3C)_3C$], 1.26 [t, ^3J(HCCH) = 7.4 Hz, 3 H, H_3CCH_2N], 1.04 [d, ^3J(PCCH) = 16.5 Hz, 9 H, $(H_3C)_3C$]. − ^{31}P NMR (162.0 MHz, [D$_6$]benzene): δ = 39.7 [s, ^1J(WP) = 213.8 Hz]. − IR (toluene): $\tilde{\nu}$ = 1936, 1853 (CO) cm^{-1}. − $C_{18}H_{28}NO_2PSW$ (537.31): calcd. Keywords: Rhodium catalysis / C–C coupling / C–H activation / Alkynes / Trisubstituted naphthalenes

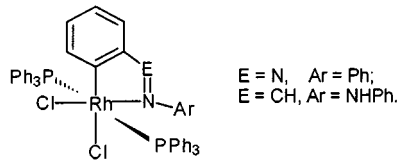
$RhCl(PPh_3)_3$ in the presence of excess hydrochloric acid and azobenzene in refluxing 1-pentanol catalyzes the cyclodimerization of arylalkynes to 1,2,3-substituted naphthalene derivatives. This enables an easy access to 1,2,3-triphenylnaphthalene (**1**), 7-methoxy-1,2,3-tris(*p*-methoxyphenyl)naphthalene (**2**), 7-methyl-1,2,3-tris(*p*-methylphenyl)naphthalene (**3**), and 7-nitro-3-(*p*-nitrophenyl)-1,2-diphenylnaphthalene (**4**). A co-cyclodimerization of tolan with 4-octyne affords 3-phenyl-1,2-dipropylnaphthalene (**5**). The structure of **4** was resolved by single-crystal X-ray structural analysis. The rate of formation of **1** is first-order with respect to tolan and $RhCl(PPh_3)_3$ and exhibits activation parameters of $\Delta H^{\ddagger}$ = 94.7 ± 10 kJ mol^{-1} and $\Delta S^{\ddagger}$ = 36 ± 6 J K^{-1} mol^{-1}. Replacing HCl by HBr and HI decreases the rate by 28 and 55%, respectively. Although naphthalene formation occurs also in the absence of azobenzene, its presence stabilizes the catalyst, accelerates the reaction, and inhibits formation of 1-chlorostilbene, which is the major by-product. When $RhCl(PCy_3)_2$ is used as the catalyst, naphthalene formation even in the absence of azobenzene is highly selective, but proceeds much slower. No reaction is observed in non-protic solvents.

Introduction

Transition-metal-assisted or -catalyzed oligomerizations of alkynes afford a variety of linear-chain or annulated compounds by direct C−C coupling. In general, annulation does not involve a C−H activation step.[2−5] Except photochemical reactions, direct syntheses of naphthalene derivatives through cyclodimerization of aryl alkynes were scarcely reported. For example metallic lithium suspensions assist formation of 1,2,3-triphenylnaphthalene from tolan.[6] Phenylacetylene was stoichiometrically dimerized to 1-phenylnaphthalene by "active" palladium ($PdCl_2$ and $NaBH_4$) while tolan and other diarylalkynes were inert.[7] Cyclodimerization of the latter alkynes occurred as a side-reaction in the $RhCl_3 \cdot 3\ H_2O$ and Aliquat-336® catalyzed cyclotrimerization; an oxidative C−H addition involving an intermediate Rh^V complex was proposed to rationalize the naphthalene formation.[8] Wilkinson et al. reported a similar synthesis of 1,2-diphenylbenzylideneindene.[9] During our investigations on the rhodium-catalyzed indole synthesis from tolan and azobenzene[10] we observed that in refluxing 1-pentanol solution 1,2,3-triphenylnaphthalene is produced through cyclodimerization of tolan when $RhCl_2(C,N\text{-}C_6H_4N{=}NC_6H_5)(PPh_3)_2$ and 2-chloroazobenzene or $RhCl_2(C,N\text{-}C_6H_4CH{=}NNHC_6H_5)(PPh_3)_2$ were present, but the reaction was slow and of poor chemoselectivity (Figure 1).[11][12]

Figure 1. $RhCl_2(C,N\text{-}C_6H_4E{=}NC_6H_5)(PPh_3)_2$



Different to the indole synthesis, where catalytic amounts of acetic acid improved both rate and selectivity, no beneficial effect was observed for naphthalene formation. However, this was the case when mineral acids were employed. In the following we describe a novel catalytic system which allows the easy synthesis of 1,2,3-triphenylnaphthalene (**1**), 7-methoxy-1,2,3-tris(*p*-methoxyphenyl)naphthalene (**2**), 7-methyl-1,2,3-tris(*p*-methylphenyl)naphthalene (**3**), 7-nitro-3-(*p*-nitrophenyl)-1,2-diphenylnaphthalene (**4**), and 3-phenyl-1,2-dipropylnaphthalene (**5**).

Results and Discussion

Cyclodimerization of Tolan by Various Catalysts

During investigations of the synthesis of **1** in the presence of *ortho*-metalated azobenzene and hydrazone com-

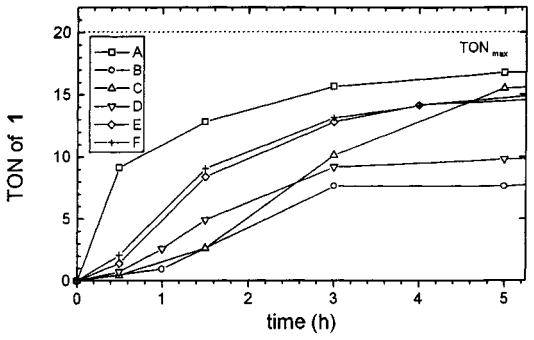
Figure 2. Time dependence of the turnover number of **1** in the presence of various catalytic systems; 0.05 mmol of rhodium complex and 2.0 mmol of tolan in the presence of 0.15 mL of HCl (aq. 37%)in 25 mL of refluxing 1-pentanol solution: $RhCl(PPh_3)_3$ and PhN=NPh (0.25 mmol) (A); $RhCl(PPh_3)_3$ (B); $RhCl_2(C,N\text{-}C_6H_4N{=}NC_6H_5)(PPh_3)_2$ (C); $RhCl_2(C,N\text{-}C_6H_4CH{=}NNHC_6H_5)(PPh_3)_2$ (D); $RhHCl(C,N\text{-}CH_3C_6H_3N{=}NC_6H_4CH_3)(PCy_3)_2$ (E); $RhCl(PCy_3)_2$ (F)



plexes,[13] we found that $RhCl(PPh_3)_3$ and $RhCl(PCy_3)_2$ are also catalytically active but require the presence of HCl. In Figure 2 the catalytic activity of various systems is summarized.

Highest TON (turn over number) values were obtained with $RhCl(PPh_3)_3$ and azobenzene (catalyst **I**, Figure 2, curve A), followed by $RhCl_2(C,N\text{-}C_6H_4N{=}NC_6H_5)(PPh_3)_2$ (curve C), $RhHCl(C,N\text{-}CH_3C_6H_3N{=}NC_6H_5)(PCy_3)_2$ (curve E) and $RhCl(PCy_3)_2$ (curve F). The hydrazone complex $RhCl_2(C,N\text{-}C_6H_4CH{=}NNHC_6H_5)(PPh_3)_2$ (curve D), and Wilkinson′s complex (curve B) were less active.

When azobenzene in the catalytic system **I** was replaced by hydrazobenzene, benzylidenephenylimine, aniline, triethylamine, and various other monodentate nitrogen ligands, formation of **1** still occurred, however at a much lower rate. This clearly indicates that an anticipated *ortho*-metalation of azobenzene is not involved in its positive action. Addition of bidentate nitrogen ligands like phenanthroline and 2,2′-bipyridyl instead of azobenzene inhibited the reaction completely. When $RhCl(PPh_3)_3$ was employed without azobenzene the initial rate did not change significantly but the catalyst was easily deactivated and the reaction stopped after 3 h (Figure 2, curve B); furthermore, the addition product of HCl to tolan, 1-chlorostilbene, was produced in an amount of 20% relative to **1**. This value increased to 30% when HCl and $RhH(PPh_3)_4$ were preheated for 20 min. From these results it can be concluded that azobenzene efficiently prevents addition of HCl to the alkyne mediated by rhodium complexes. In the absence of HCl, the reaction of tolan with $RhCl(PPh_3)_3$, $RhH(PPh_3)_4$, or $RhH(CO)(PPh_3)_3$ alone in refluxing pentanol did not afford **1**.

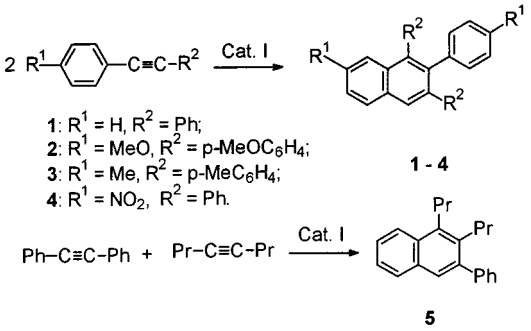
When Wilkinson's catalyst was replaced by $RhCl(PCy_3)_2$, even in the absence of azobenzene a highly selective production of **1** occurred without the concomitant formation of any by-products. However, the reaction proceeded with only moderate rate, comparable to that of the two orthometalated complexes (Figure 2, curve F).

Cyclodimerization of Arylalkynes

It was found that only diarylalkynes can be cyclodimerized to naphthalene derivatives (Scheme 1). Introduction of electron-donating substituents accelerated the reaction while electron-withdrawing ones had the opposite effect. According to HPLC analysis, unsymmetrically substituted diarylalkynes like *p*-nitrophenylacetylene afforded four regioisomers with a slight preference of the product formed by *ortho*-metalation of the *p*-nitrophenyl group. Isolated yields of **1**−**3** and **4**−**5** were in the range of 60−85% and 37%, respectively. Mixed alkyl/aryl-substituted alkynes were difficult to cyclodimerize, especially when electron-withdrawing substituents were present. Accordingly, PhC_2CO_2Et and PhC_2COMe could not be converted to the corresponding naphthalene. Contrary to that, the latter alkyne can be cyclodimerized by $RhCl_3$ and Aliquat-336® in a mixed tetrachloroethane/water solvent.[8]

In an attempt to accomplish a co-cyclodimerization, tolan and 4-octyne were employed as the substrates. Although **5** was produced in moderate yield, it could not be obtained analytically pure (Scheme 1).

Scheme 1



The structures of the naphthalene derivatives were confirmed by multidimensional H-H COSY, NOEs, NOESY, C-H HETCOR, COLOC NMR techniques.[14] A single-crystal X-ray analysis of **4** confirmed the proposed structure (Figure 3, Table 1). The C−C bonds of the naphthalene ring agree with the values reported for perchloro-1,2,3-triphenylnaphthalene.[15] The three phenyl rings at C1, C2, and C3 are twisted out of the naphthalene plane by 76.3°, 69.0°, and 126.4°, respectively, and both nitro groups are aligned with the corresponding ring planes.

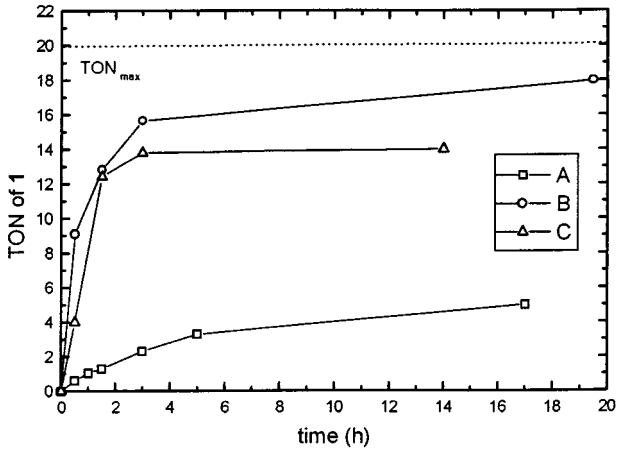
Mechanistic Investigations

The reaction is strongly solvent-dependent and does not occur in non-protic solvents like THF, acetonitrile, triethylamine, toluene, chlorobenzene, DMF, tetrachloroethane, nitrobenzene, aniline, and DMSO. In methanol, even upon refluxing for 3 days, no naphthalene could be detected, whereas this was possible when the boiling point of the alcohol was above 100°C. All of the following experiments were performed with catalyst **I** in refluxing 1-pentanol solution.

Influence of the Acid

Changing the molar ratio [HCl]/[Rh] from 34:1 to 1:1 decreased the initial turnover rate (TOR) of **1** from 18 to 0.7 h^{-1} indicating that stoichiometric amounts of HCl cannot sustain a high catalytic activity (Figure 4). Varying the same ratio to 68:1, reduced the TOR down to 8 h^{-1}. When HCl_{conc} was substituted by HBr_{conc} and HI_{conc}, the TOR decreased from 18 to 13 and 6, respectively.

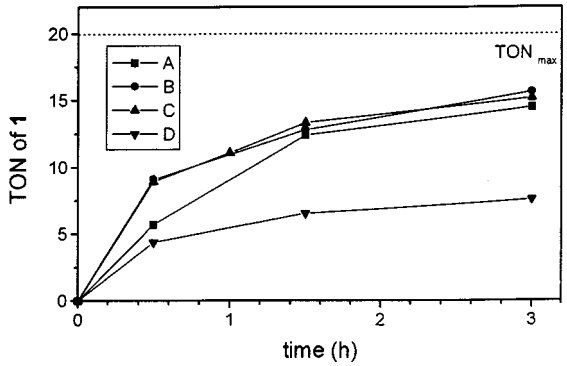
Figure 4. Influence of HX on catalytic activity of catalyst **I**: [HCl]/[Rh] = 1:1 (A), 34:1(B), 68:1 (C)



Influence of Azobenzene

Upon variation of the ratio [Rh]/[PhN_2Ph] at a fixed [Rh]/[PhC_2Ph] value from 1:1 to 1:5, 1:10, and 1:40, it turned out that the highest TORs were observed at the values of 1:5 and 1:10 (Figure 5).

Figure 5. Influence of azobenzene concentrations on catalytic activity catalyst **I**: [Rh]/[azobenzene] = 1:1 (A), 1:5 (B), 1:10 (C), 1:40 (D)



Kinetic Measurements

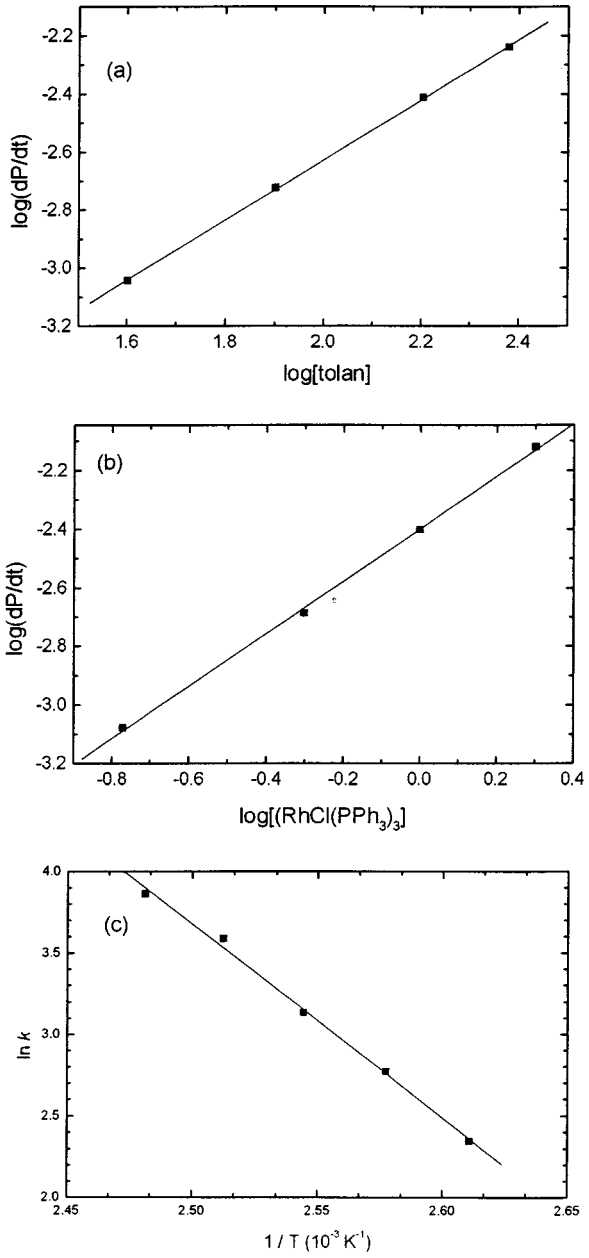
The initial reaction rate as function of different substrate concentrations was measured by monitoring the formation of **1** by HPLC (d*P*/d*t*, Figures 6a, 6b). From the slopes of 1.03 and 0.9 as obtained from a plot of logarithm of initial rate vs. logarithm for tolan and $RhCl(PPh_3)_3$, respectively, a reaction order of unity is assumed for both components. When the catalyst concentration was increased above 0.5 mol/L, the reaction became slower while a higher concentration of tolan favored cyclotrimerization to hexaphenylbenzene. These results suggest that the transition state of the rate-determining step contains one molecule of tolan coordinated to a mononuclear rhodium complex. Activation parameters of $\Delta H^{+} = 94.7 \pm 10$ kJ mol^{-1} and $\Delta S^{+} = 36 \pm 6$ J K^{-1} mol^{-1} were calculated from the temperature dependence of the rate constant in the range of 105−130°C (Figure 6c).

Postulated Catalytic Cycle

From the results presented above a plausible mechanism for the cyclodimerization in the presence of catalyst **I** is schematically depicted in Scheme 2.

It is recalled that in the absence of HX tolan and azobenzene undergo a $RhCl(PPh_3)_3$-catalyzed co-cyclodimerization affording *N*-anilino-2,3-diphenylindole.[10] This reaction is inhibited by the presence of the mineral acid in favor of the alkyne cyclodimerization to 1,2,3-triphenylnaphthalene. According to the reaction conditions it is assumed that the first step is loss of a PPh_3 ligand followed by oxidative addition of HX to **A** affording the rhodium(III) intermediate **B** (Scheme 2). Since it is known from the literature that HX reacts with $RhCl(PR_3)_3$ (R = Ph, Cy) already at room temperature,[16][17] it seems unlikely that the slower naphthalene formation in the presence of HBr and HI is due to slowing down of this reaction step. Subsequent insertion of the alkyne into the Rh−H bond should be a fast process

Figure 6. Plot of log(d*P*/d*t*) vs. logarithm of the concentration of tolan (a) and $RhCl(PPh_3)_3$ (b); Arrhenius plot (c)



as known for the corresponding reaction of acetylene with $RhHCl_2(PPh_3)_2$.[17][18] Successive *cis*/*trans* isomerization of the vinyl ligand leads to **C**. Although this is a rhodium(III) complex, it is postulated to undergo *ortho*-metalation as reported for comparable cases.[18][19] In view of the presence of weak intramolecular $CH\cdots XRh^{III}$ interactions in related hexacoordinated rhodium(III) complexes,[1] a multicenter transition state as depicted in Figure 7 is proposed. This would rationalize the slower rate found in the presence of HBr and HI since the interaction is weaker when the electronegativity of X decreases.[20] In agreement with the observed rate law, this step should be rate-determining. As a competitive reaction, reductive $C(sp^2)-Cl$ elimination from **C** leads to 1-chlorostilbene, the major by-product in the absence of azobenzene, but only formed in traces in its presence. As a weak base, azobenzene may facilitate elimination of HX and therefore favor *ortho*-metalation of tolan over reductive elimination of 1-chlorostilbene. As indicated in Scheme 2, azobenzene or a derivative thereof may be coordinated to the rhodium center throughout the whole catalytic cycle. Insertion of the second alkyne into an Rh−C bond of **D** and reductive $C(sp^2)-C(sp^2)$ elimination leads to **1** and the starting complex **A**.

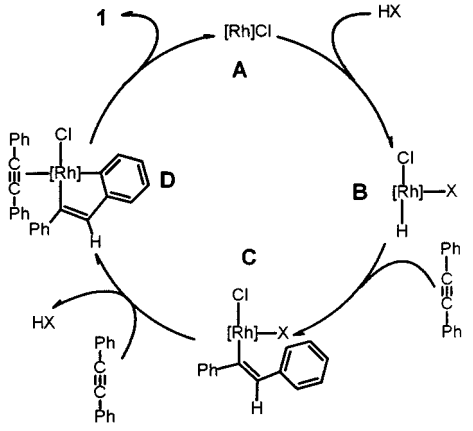

Figure 7. Transition state postulated for the *ortho*-metalation step; see also Scheme 2

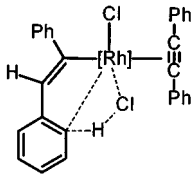
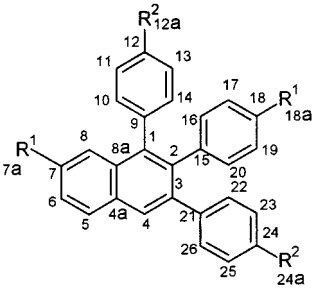


This work was supported by the *Deutsche Forschungsgemeinschaft*, the *Fonds der Chemischen Industrie* and the *Degussa AG*. We thank Dr. *M. Moll* for the NMR measurements. L. H. is indebted to the *Hanns-Seidel-Stiftung* and the *Chinese Government* for a fellowship.

Experimental Section

General: Unless otherwise mentioned, all operations were performed under dry and oxygen-free nitrogen using standard Schlenk techniques. All solvents were degassed and saturated with nitrogen before use. Rhodium trichloride hydrate was obtained from Degussa AG. Commercial triphenylphosphane, and *trans*-azobenzene (Aldrich, Merck) were used after recrystallization from ethanol. Commercial tolan, 4-octyne, 1-phenyl-1-propyne, ethyl 3-phenylpropiolate, 4-phenyl-3-butyn-2-one, dimethyl acetylenedicarboxylate, 3-pentyn-1-ol were directly used without any purification. $RhCl(PPh_3)_3$,[21] $RhCl(PCy_3)_2$,[22] $RhCl_2(C,N\text{-}C_6H_4N{=}NC_6H_5)(PPh_3)_2$[23], $RhCl_2(C,N\text{-}C_6H_4CH{=}NNHPh)(PPh_3)_2$,[11] $RhHCl(C,N\text{-}CH_3C_6H_3N{=}NC_6H_4CH_3)(PCy_3)_2$,[24] $Rh(CO)Cl(PPh_3)_2$,[25] $RhH(PPh_3)_4$[26] and $RhH(CO)(PPh_3)_3$[27] were prepared according to literature procedures.

Scheme 3. Atom numbering of compounds **1**−**4** used for NMR signal assignment



^{1}H- and ^{13}C-NMR spectra were measured in $CDCl_3$ as solvent and TMS as internal standard at 400 (or 270) and 100 (or 67) MHz, respectively, and IR spectra in KBr unless otherwise noted. − NMR: Jeol FT-JNM-LA 400 and Jeol FT-JNM-EX 270. − IR: Perkin-Elmer 983 and FT IR 1600. − UV/Vis: Shimadzu UV-3101 PC. − MS: Jeol MStation 700 and Varian MAT 212 (70eV). − Elemental analysis: Carlo Erba 1106 (CHN). − HPLC: Knauer HPLC pump 64 with analytical and preparative pump head, Knauer UV/Vis filter photometer at λ = 220 nm as detector. − Analytical measurements: Precolumn (30 mm × 8 mm) attached to main column (250 mm × 8 mm) and both filled with Spherisorb ODS2, 5 μm (RP C18), eluting with CH_3CN/H_2O = 5:1 (v/v) at a flow rate of 5.0 mL/min. − Preparative isolations: 1 mL of the acetonitrile solution was injected; identical elution agent and filling material was used while the size of precolumn and main column was 30 mm × 32 mm and 250 mm × 32 mm, respectively; the flow rate was 35 mL/min.

General Procedure for the Synthesis of Trisubstituted Naphthalenes: A solution of 46.2 mg (0.05 mmol) of $RhCl(PPh_3)_3$ in 5 ml of 1-pentanol and 0.15 ml (1.71 mmol) of HCl (conc., 37%) were stirred upon refluxing in an oil bath at 160°C for 1 min. Thereafter, 48 mg (0.25 mmol) of azobenzene, dissolved in 5 ml of 1-pentanol, was added to the reaction mixture and stirred under reflux for 20 min. Subsequently, 356 mg (2.0 mmol) of tolan or 2.0 mmol of a derivative thereof, dissolved in 20 ml of 1-pentanol were added dropwise within 15 to 20 min. Stirring the reaction mixture under reflux was continued for another 3 h. After removal of the solvent, the resulting orange residue was chromatographed on silica gel (SiO_2-60, d = 1.5 cm, l = 10 cm) with toluene as eluting agent. A colorless fraction was collected, the solvent removed and the gray residue recrystallized from CH_2Cl_2/MeOH = 1:5 (v/v). 216 mg (1.2 mmol, 60%) of **1** (mp. 151°C) was obtained. − $C_{28}H_{20}$ (356.5): calcd. C 93.94, H 5.60; found C 94.13, H 5.60. − MS (FD, CH_2Cl_2); *m/z*: 356 [M^+]. − ^{1}H NMR ($CDCl_3$, 270 MHz): d = 7.93 (s, 1 H, 4-H), 7.90 (d, 1 H, 5-H), 7.57 (d, 1 H, 8-H), 7.47 (t, 1 H, 6-H), 7.35 (t, 1 H, 7-H), 7.10−7.25 (m, 10 H) and 6.82−6.95 (m, 5 H) for the 15 protons of the three substituent phenyl rings. − ^{13}C NMR ($CDCl_3$, 100 MHz): d = 124.4 (C-12), 125.6 (C-18), 125.6 (C-24), 126.0 (C-6), 126.1 (C-7), 126.8 (C-17), 126.8 (C-19), 126.8 (C-8), 127.5 (C-11), 127.5 (C-13), 127.5 (C-23), 127.5 (C-25), 127.9 (C-5), 128.7 (C-4), 130.0 (C-10), 130.0 (C-14), 131.2 (C-22), 131.2 (C-26), 131.5 (C-16), 131.5 (C-20), 132.0 (C-8a), 132.6 (C-4a), 138.1 (C-3), 139.1 (C-2), 139.4 (C-9), 139.9 (C-1), 140.0 (C-21), 142.0 (C-15).

Various Catalytic Systems: General procedure described above; catalysts and TON of **1** were given as follows: (1) $RhCl(PPh_3)_3$ and azobenzene: 9 (0.5 h), 13 (1.5 h), 16 (3 h), 17 (5 h), 18 (19.5 h); (2) $RhCl(PPh_3)_3$: 1 (1 h), 8 (3 h), 9 (5 h), 12 (17 h); (3) $RhCl_2$(*C,N*-$C_6H_4N{=}NC_6H_5$)$(PPh_3)_2$: 0.4 (0.5 h), 3 (1.5 h), 10 (3 h), 16 (5 h), 16 (7 h); (4). $RhCl_2$(*C,N*-$C_6H_4CH{=}NNHC_6H_5$)$(PPh_3)_2$: 0.7 (0.5 h), 3 (1 h), 5 (1.5 h), 9 (3 h), 9 (5 h), 12 (20 h); (5) RhHCl(*C,N*-$CH_3C_6H_3N{=}NC_6H_4CH_3$)$(PCy_3)_2$: 1.4 (0.5 h), 8 (1.5 h), 13 (3 h), 14 (4 h), [thereafter solid tolan was added, the TON of **1** reached 325 (TON_{max} = 500) upon refluxing for 4 d]; (6) $RhCl(PCy_3)_2$: 2 (0.5 h), 9 (1.5 h), 14 (3 h), 14 (4 h). [thereafter, addition of solid tolan afforded a TON of 174 (TON_{max} = 250) upon refluxing for 4 d]. Unless otherwise noted, the general procedure as described for **1** was applied for the following syntheses. The resulting residue obtained from column chromatography was further purified by preparative HPLC.

Synthesis of 2−5

7-Methoxy-1,2,3-tris(4-methoxyphenyl)naphthalene (**2**): 476 mg (2.0 mmol) of 4,4′-dimethoxytolan and 46.2 mg (0.05 mmol) of $RhCl(PPh_3)_3$ were refluxed for 5 h. The raw product was recrystallized from hexane, yielding 367 mg (1.54 mmol, 84%) of **2** (mp 177°C). − $C_{32}H_{28}O_4$ (476.6): calcd. C 80.65, H 5.92; found C 80.39, H 6.09. − MS (FD, CH_2Cl_2); *m/z*: 476 [M^+]. − ^{1}H NMR: ($CDCl_3$, 400 MHz): d = 7.79 (s, 1 H, 4-H), 7.75 (d, 1 H, 5-H), 7.14 (dd, 1 H, 6-H), 7.05 (dt, 2 H, 22/26-H), 7.03 (dt, 2 H, 10/14-H), 6.88 (s, 1 H, 8-H), 6.77 (dt, 2 H, 11/13-H), 6.74 (dt, 2 H, 16/20-H), 6.70 (dt, 2 H, 23/25-H), 6.49 (dt, 2 H, 17/19-H), 3.77 (s, 3 H, 24a-OMe), 3.73 (s, 3 H, 12a-OMe), 3.67 (s, 3 H, 7a-OMe), 3.65 (s, 3 H, 18a-OMe). − ^{13}C NMR ($CDCl_3$, 100 MHz): d = 54.9 (C-18a), 55.0 (C-7a), 55.1 (C-24a), 55.9 (C-12a), 105.5 (C-8), 112.5 (C-17), 112.5 (C-19), 113.0 (C-23), 113.0 (C-25), 113.2 (C-11), 113.2 (C-13), 118.4 (C-6), 128.3 (C-4), 128.7 (C-4a), 129.4 (C-5), 131.1 (C-22), 131.1 (C-26), 132.2 (C-9), 132.2 (C-10), 132.2 (C-14), 132.5 (C-16), 132.5 (C-20), 133.0 (C-15), 133.5 (C-8a), 134.9 (C-21), 137.6 (C-1), 137.9 (C-3), 138.6 (C-2), 157.3 (C-18), 157.7 (C-7), 157.9 (C-12), 157.9 (C-24). − HPLC (CH_3CN/H_2O = 5:1 (v/v), 5 mL/min): retention time [min] = 6.4.

7-Methyl-1,2,3-tris(4-methylphenyl)naphthalene (**3**): 412 mg (2.0 mmol) of 4,4′-dimethyltolan and 46.2 mg (0.05 mmol) of $RhCl(PPh_3)_3$ were refluxed for 2 h; 264 mg (1.28 mmol, 64%) of **3** (mp. 148°C). − $C_{32}H_{28}$ (412.6): calcd. C 93.16, H 6.84; found C 92.84 H 6.92. − MS (FD, CH_2Cl_2); *m/z*: 412 [M^+]. − ^{1}H NMR: ($CDCl_3$, 400 MHz): d = 7.83 (s, 1 H, 4-H), 7.78 (d, 1 H, 5-H), 7.31 (ds, 1 H, 8-H), 7.29 (t, 1 H, 6-H), 7.04 (dt, 2 H, 10/14-H), 7.02 (dt, 2 H, 22/26-H), 7.01(dt, 2 H, 23/25-H), 6.95 (dt, 2 H, 11/13-H), 6.73 (dt, 2 H, 16/20-H), 6.73 (dt, 2 H, 17/19-H), 2.37 (s, 3 H, 7a-Me), 2.31 (s, 3 H, 24a-Me), 2.23 (s, 3 H, 12a-Me), 2.14 (s, 3 H, 18a-Mea). − ^{13}C NMR: ($CDCl_3$, 100 MHz): d = 21.1 (C-18a), (C-24a), 21.3 (C-12a), 22.7 (C-7a), 125.8 (C-8), 127.6 (C-16), 127.6 (C-20), 127.7 (C-4), 128.1 (C-6), 128.2 (C-11), 128.2 (C-13), 128.2 (C-22), 128.2 (C-26), 128.4 (C-5), 129.9 (C-10), 129.9 (C-14), 131.0 (C-8a), 131.1 (C-23), 131.3 (C-17), 131.3 (C-19), 132.3 (C-4a), 131.1 (C-25), 134.7 (C-7), 135.5 (C-12), 135.5 (C-18), 135.5 (C-24), 136.6 (C-21), 137.3 (C-15), 138.2 (C-9), 138.5 (C-3), 139.1 (C-1), 139.5 (C-2). − HPLC [CH_3CN/H_2O = 5/1 (v/v), 5 mL/min]: retention time [min] = 17.65.

7-Nitro-2-(4-nitrophenyl)-1,3-diphenylnaphthalene (**4**) *and Regioisomers:* 447 mg (2.0 mmol) of 4-nitrotolan and 46.2 mg (0.05 mmol) of $RhCl(PPh_3)_3$ were refluxed for 15 h. Three different regioisomers were detected by analytical HPLC with retention times of 5.07, 5.47, 5.71 min, the ratio of the integration areas was 5:1:1. After removal of the solvent, the gray residue was washed with 5 mL of methanol. Since one regioisomer was rather insoluble in acetonitrile, 161 mg (0.72 mmol, 36%) of **4** could be isolated as an analytically pure yellow powder. − $C_{28}H_{18}N_2O_4$ (447.1): calcd. C 75.33, H 4.06, N 6.27; found C 75.33 H 4.02, N 6.17. − MS (FD, CH_2Cl_2); *m/z* 446 [M^+]. − ^{1}H NMR: ($CDCl_3$, 270 MHz): d = 8.56

[ds, 1 H, ^4J(8-H, 6-H) = 2.2 Hz, 8-H], 8.31 [dd, 1 H, ^3J(5-H, 6-H) = 10 Hz, ^4J(8-H, 6-H) = 2.2 Hz, 6-H], 8.07 [d, 1 H, ^3J(5-H, 6-H) = 10 Hz 5-H], 8.06 (s, 1 H, 4-H), 7.84 [dt, 2 H, ^3J(17-H, 16-H) = 9 Hz, 17/19-H], 7.32 (m, 3 H, 11/12/13-H), 7.23 (m, 3 H, 23/24/25-H), 7.14 (m, 4 H, 10/14/22/26-H), 7.04 (dt, 2 H, 16/20-H). − ^{13}C NMR ($CDCl_3$, 100 MHz): d = 120.2 (C-8), 112.9 (C-11), 122.4 (C-17), 122.4 (C-19), 123.9 (C-6), 127.5 (C-24), 128.2 (C-25), 128.0 (C-12), 128.2 (C-23), 128.8 (C-17), 128.4 (C-13), 128.4 (C-11), 128.9 (C-4), 137.3 (C-2), 129.7 (C-5), 129.7 (C-14), 129.7 (C-10), 130.1 (C-8a), 130.8 (C-22), 130.8 (C-26), 132.1 (C-16), 132.1 (C-20), 135.5 (C-7), 136.9 (C-4a), 138.0 (C-18), 140.1 (C-9), 141.7 (C-21), 143.1 (C-2), 146.1 (C-3), 146.1 (C-15), 146.5 (C-1). − HPLC [CH_3CN/H_2O = 5:1 (v/v), 5 mL/min]: retention time (integrated area) [min] of raw material = 5.07 (5.48 × 10^5) (**4**); 5.47 (9.27 × 10^4) (**4′**); 5.71 (1.37 × 10^5) (**4′′**) (ratio of **4/4′/4′′** = 5:1:1). − **4′** and **4′′** exhibited identical molecular peaks at *m/z* 446 (FD-MS). Due to the similar HPLC retention times of all three regioisomers, further purification by preparative HPLC was not attempted. − Single crystals for X-ray analysis of **4** were obtained from a CH_3CN solution exposed to air. Intensity data were collected with a Siemens P4 diffractometer at 200 K, using graphite-monochromated Mo-K_α radiation (λ = 0.71073 Å). Cell constants were obtained from the setting angles of 18 reflections in the range of 32.2° < 2θ < 35.0°. The ω-scan technique was applied using variable scan speeds (3.0−30°/min). The structure was solved by direct methods (SHELXS-86).[28] Structure refinement was carried out using full-matrix least-squares methods on F^2 (SHELXL-93).[29] All non-hydrogen atoms with anisotropic displacement parameters. All hydrogen atoms could be localized in a difference fourier map and were isotropically refined. The relevant crystal data are listed in Table 2. Further details of crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Center as supplementary publication no. CCDC-101516. Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (Fax: int. code + 44(1223)336-033; E-mail: deposit@ccdc.cam.ac.uk)

Table 2. Crystal data and details of structure refinement parameters for **4**

formula	$C_{28}H_{18}N_2O_4$

Attempted Reactions with Various Alkynes: Upon applying the general synthesis procedure for **1** to 1-phenylpropyne, 4-phenyl-3-butyn-2-one, and ethyl 3-phenylpropiolate no dimerization products were detected by analytical HPLC after 3 d of refluxing in 1-pentanol.

3-Phenyl-1,2-dipropylnaphthalene (**5**): A mixture of 356 mg (2 mmol) of tolan and 220 mg (2 mmol) of 4-octyne in 20 mL of 1-BuOH was added dropwise to a solution of 46.2 mg (0.05 mmol) of $RhCl(PPh_3)_3$ in 5 mL of 1-BuOH. After refluxing for 5 h, **5** and **1** were formed in a molar ratio of **5/1** = 5:1. After 14 h of refluxing, both alkynes were completely consumed and the ratio of **5/1** changed to 5:3. After removal of the solvent, the residue was chromatographed on SiO_2-60 with toluene as eluting agent. The resulting gray residue was further purified by prep. HPLC affording 226 mg (0.78 mmol, 39%) of a white oil of **5**. − $C_{22}H_{24}$ (288.4): calcd. C 91.61, H 8.39; found C 89.54, H 9.04.[30] − MS (FD, CH_2Cl_2); *m/z*: 288 [M$^+$]. − ^{1}H NMR ($CDCl_3$, 270 MHz): d = 8.03 (d, 1 H, 8-H), 7.75 (d, 1 H, 5-H), 7.52 (s, 1 H, 4-H), 7.40−7.42 (m, 2 H, 6/7-H), 7.33−7.42 {m, 5 H, [7.34 (t, 1 H, 25/27-H), 7.38 (t, 17/19-H), 7.37 (d, 2 H, 16/20-H)]}, 3.09 (td, 2 H, 9/9′-H of C-1-CH_2CH$_2$CH$_3$), 2.69(td, 2 H, 12/12′-H of C-2-CH_2CH$_2$CH$_3$), 1.75 (td, 2 H, 10/10′-H of C-1-CH$_2$CH_2CH$_3$), 1.41(td, 2 H, 13/13′-H of C-2-CH$_2$CH_2CH$_3$), 1.14 (td, 3 H, 11/11′-H of C-1-CH$_2$CH$_2$CH_3), 0.78 (td, 3 H, 14/14′-H of C2-CH$_2$CH$_2$CH_3). − ^{13}C NMR ($CDCl_3$, 100 MHz): d = 14.9 (C-11), 24.6 (C-10), 31.1 (C-9), 32.5 (C-12), 24.6 (C-13), 124.0 (C-8), 124.9 (C-6), 125.7 (C-7), 127.4 (C-4), 14.6 (C-14), 127.8 (C-16), 128.5 (C-5), 129.4 (C-17), 126.7 (C-18), 129.4 (C-19), 127.8 (C-20), 131.9 (C-8a), 132.5 (C-4a), 136.2 (C-1), 136.4 (C-2), 141.3 (C-3), 143.0 (C-15). − HPLC [CH_3CN/H_2O = 5:1 (v/v), 5 mL/min]: retention time (integrated area) [min] of raw material (4 h refluxing) = 8.5 (1.3 × 10^5) (**1**); 13.4 (6.9 × 10^5) (**5**); (ratio of **5/1** = 5:1); (14 h refluxing) = 8.5 (4.4 × 10^5) (**1**); 13.4 (9 × 10^5) (**5**); (ratio of **5/1** = 2:1).

Kinetic Measurements

General: For the measurement of the initial rate as a function of substrate concentration the general procedure as described for the synthesis of **1** was applied except that the oil bath was thermostated to 130.0 ± 0.1 °C. Samples of 200 μL were withdrawn after 30, 60, 90, and 120 min, concentrated to dryness without further separation of the catalyst and redissolved in 4 mL of acetonitrile. The concentrations of **1** (given in the following as dimensionless numbers in the unit of 10^{-3} mol L^{-1}) were determined via a calibration curve. Reproducibility was within ±10%. Detailed data are available as Supporting Information.

Keywords: Luminescence / Lanthanides / Calixarenes / 2,2′-Bipyridine *N,N′*-dioxide / Podands / Cryptands

Members of a new family of lanthanide complexes of the cone-shaped podand **1** and the barrel-shaped cryptand **2**, based on calix[4]arenes incorporating bipyridine *N,N′*-dioxide chromophores, have been synthesized and characterized. The complexes were found to be stable in water and coordinating solvents. High molar absorption coefficients {ε = 28000 and 36000 $M^{-1}cm^{-1}$ for $[Eu(\mathbf{1})]^{3+}$ and $[Eu(\mathbf{2})]^{3+}$, respectively} and high metal luminescence quantum yields {Φ = 0.19 and 0.11 for $[Eu(\mathbf{1})]^{3+}$ and $[Eu(\mathbf{2})]^{3+}$, respectively} were obtained. The effect of OH oscillators, attached at the lower rim of the calixarenes, on the non-radiative deactivation to the ground state has been demonstrated.

Luminescence spectroscopy is attracting immense interest in the scientific community owing to its potential application in growing fields of great economical and social impact, such as environmental sciences, medical diagnostics, and cell biology.[1][2][3][4] In particular, the synthesis, characterization, and application of many luminescent labels and sensors has opened up a lot of opportunities for solving complex analytical problems, among which the fluorescence immunoassay certainly has a central role.[1][5]

The major drawback in photoluminescence analysis, particularly when dealing with biological material, is the interference caused by autofluorescence and light scattering. Time resolved spectroscopy, which requires the use of labels with very long luminescence lifetimes, can efficiently exclude this kind of background light. For this reason, over the past decade great interest has been centered on the design of luminescent complexes containing the Eu^{3+} and Tb^{3+} ions, which possess luminescence lifetimes in the micro- to millisecond range.[1][6][7][8][9] To obtain an efficient luminescent label, the ligand needs to be able to form stable complexes with the lanthanide ions in coordinating solvents, to shield the ion from deactivating solvent molecules, and, particularly importantly, to absorb light and to transfer it to the metal ion with high efficiency, thereby overcoming the intrinsic low absorption coefficients of the metal ions.[6][7][8][9] With these goals in mind, and thanks to the great progress made in the field of supramolecular chemistry, many encapsulating ligands possessing the required characteristics have been synthesized,[6] and, among these, particular attention has been focused on functionalized calixarenes.[10][11][12][13][14][15][16][17][18][19] In this context, we report here on the synthesis of new functionalized calix[4]arene ligands incorporating bipyridine *N,N′*-dioxide chromophores and on the luminescence of their Eu^{3+}, Tb^{3+}, and Gd^{3+} complexes.

Results

Ligands **1** and **2** and their lanthanide complexes were prepared as outlined in Schemes 1 and 2 using well-established synthetic procedures for 1,3-disubstituted calix[4]arene ethers in the cone conformation.[20][21] The initially designed ligand **1** was prepared by reaction of *p-tert*-butylcalix[4]arene with 5-bromomethyl-5′-methyl-2,2′-bipyridine *N,N′*-dioxide in anhydrous acetonitrile using K_2CO_3 as base (Scheme 1). Ligand **2** (Scheme 2) was prepared under similar conditions starting from *p-tert*-butylcalix[4]arene and 5,5′-bromomethyl-2,2′-bipyridine *N,N′*-dioxide. Both ligands were isolated in a pure state after chromatography on neutral alumina. In solution at room temperature, they adopt a fixed cone conformation with the ligating groups on the same side of the plane formed by the macrocycle, as was deduced from their ^{1}H-NMR spectra. In both ligands, the methylene protons give rise to an AB quadruplet, at δ = 3.75 (J_{AB} = 13.1 Hz and Δν = 168.5 Hz) in **1** and at δ = 3.81 (J_{AB} = 13.3 Hz and Δν = 172.2 Hz) in **2**. The aromatic

protons of the calix[4]arene skeleton give rise to two singlets at δ = 7.05 and 6.81 for **1** and at δ = 7.09 and 6.82 for **2**, while the phenol groups resonate at δ = 6.98 in **1** and δ = 7.03 in **2**. Ligand **3** was prepared by deprotonation of **1** by treatment with NaH in anhydrous dimethylformamide, followed by quenching with D_2O (Scheme 1). The proton-deuterium exchange was monitored by ^1H NMR, which showed the absence of phenolic proton signals, and was verified by FAB^+ MS.

The lanthanide complexes were prepared by treating equimolar quantities of the ligands with the appropriate nitrate salts in methanol. Double recrystallization from ethyl acetate/hexane gave the pure complexes, which were characterized by UV/Vis and IR spectroscopy, FAB^+ MS, and elemental analysis.

The Eu^{3+}, Tb^{3+}, and Gd^{3+} complexes of the ligands **1** and **2** were found to be chemically and photochemically stable in methanolic solution, in line with expectation con-

Table 1. Absorption and luminescence properties of the Eu^{3+} and Tb^{3+} complexes in methanol solutions

	Absorption		Luminescence					
	λ_{max} [nm]	ε_{max} [M^{-1} cm^{-1}]	τ(300 K, OH) [ms]	Φ(300 K, OH)	τ(300 K, OH) [ms]	Φ(300 K, OH)	τ(77 K, OH) [ms]	τ(77 K, OH) [ms]

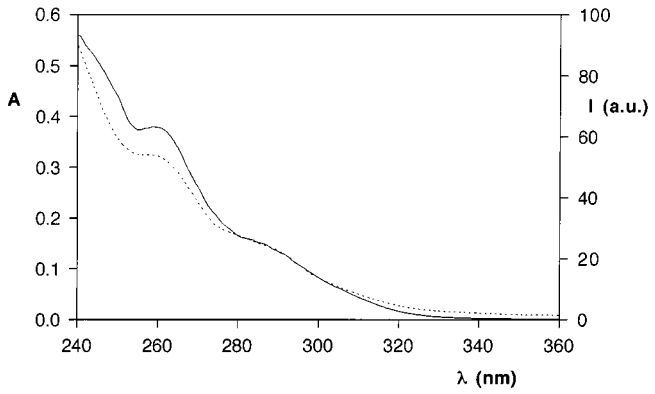
sidering the better complexation properties of the $bpyO_2$ groups compared with those of the bpy ligand.[22] Good stabilities were also observed in aqueous solution, although the solubilities in water were somewhat lower. For this reason, all the photophysical data collected in Table 1 were obtained using methanolic solutions. The absorption spectra of all the complexes are dominated by the bands of the $bpyO_2$ groups {see, for example, Figure 1 for $[Eu(\mathbf{1})]^{3+}$}, which are characterized by high molar absorption coefficients and cover the absorption bands due to the calixarene moieties, which lie in the same spectral region and have typically much lower absorption coefficients (of the order of 10^3 M^{-1} cm^{-1}).[10][11][12][13][14][15][16][17][18]

Room temperature excitation of the Gd complexes did not lead to any appreciable luminescence. At 77 K, a weak, structured phosphorescence band was observed {τ = 2.1 and 2.2 ms for $[Gd(\mathbf{1})]^{3+}$ and $[Gd(\mathbf{2})]^{3+}$, respectively}, the highest energy feature of which peaked at 475 nm.

Upon excitation in the absorption bands of the ligand, the Eu^{3+} complexes showed a very intense metal-centered luminescence {Φ = 0.19 and 0.11 for $[Eu(\mathbf{1})]^{3+}$ and $[Eu(\mathbf{2})]^{3+}$, respectively, see Table 1}, with a rather short lifetime. Neither the lifetimes nor the quantum yields showed any noticeable change upon deuteration of the solvent or lowering of the temperature (Table 1). The metal luminescence excitation spectra were very similar to the absorption spectra {see, for $[Eu(\mathbf{1})]^{3+}$, Figure 1}.

Figure 1. Absorption (full line) and metal luminescence excitation (λ_{em} = 615 nm, dotted line) spectra of a $1.4 \cdot 10^{-5}$ M methanolic solution of $[Eu(\mathbf{1})]^{3+}$



In contrast to the aforementioned observations for the Eu^{3+} complexes, the corresponding Tb^{3+} complexes did not exhibit any appreciable metal-centered luminescence at room temperature when excited in the absorption bands of the ligand. However, at 77 K, a quite intense luminescence from the Tb^{3+} ion was again observed (Table 1). Excitation spectra recorded under these conditions were very similar to the absorption spectra of the Tb^{3+} complexes.

Discussion

Gd^{3+} Complexes

The absence of low-energy, metal-centered (MC) excited states in the Gd complexes is often exploited for investigating the behaviour of the ligand-centered (LC) excited states in a structure identical to other lanthanide complexes.[23] For the complexes of ligands **1** and **2**, the absence of a fluorescence band, both at room temperature and at 77 K, prevents us from estimating the energy of the $^1\pi\pi^*$ LC level, while from the highest energy feature of the phosphorescence band observed at 77 K the zero-zero energy of the $^3\pi\pi^*$ LC level is found to be 21000 cm^{-1}.

Eu^{3+} Complexes

The similarity between the absorption and metal luminescence excitation spectra for all the complexes suggests that energy transfer from the $bpyO_2$ groups to the metal ion takes place. On the other hand, it is very difficult to evaluate the efficiency of the energy transfer process from the calixarene moiety because of its low absorption coefficient. The efficiency of the energy transfer from the $bpyO_2$ groups, together with the radiative and non-radiative rate constants of the luminescent $^5D_0$ Eu^{3+} level, can be estimated from the luminescence data collected in Table 1.[21][22][23][24]

The overall rate constant Σk for the decay of the luminescent $^5D_0$ Eu^{3+} level can be expressed by Eq. 1,

$$\Sigma k = 1/\tau = k_r + k_{nr} \quad (1)$$

where k_r is the (temperature-independent) radiative rate constant and k_{nr} is the non-radiative rate constant. The non-radiative rate constant can be further divided into two terms; the first one, $k_{nr}(T)$, being temperature-dependent, which plays a role when short-lived, high-lying excited states are thermally accessible, and the second one, k'_{nr}, accounting for the phonon-assisted deactivation to the

ground state. Usually, the most significant contribution to the temperature-independent term comes from the decay through coupling with high-energy vibrations of the solvent (O−H vibration in water and methanol solutions), k_{nr}(OH), while the contribution from the coupling with other vibrations, k_{nr} (other vibr.), is usually small.

$$\Sigma k = 1/\tau = k_r + k_{nr}(T) + k_{nr}(\mathrm{OH}) + k_{nr}(\text{other vibr.}) \quad (2)$$

In rigid matrices of deuterated methanol or water at 77 K, $k_{nr}(T)$ and k_{nr}(OH) can be neglected, and Eq. 2 becomes

$$\Sigma k\ (77\ \mathrm{K, OD}) = 1/\tau(77\ \mathrm{K, OD}) = k_r + k_{nr}(\text{other vibr.}) \quad (3)$$

where τ(77 K, OD) is the lifetime measured at 77 K in deuterated solvents.

With the usual assumption that k_{nr}(other vibr.) can be neglected, k_r becomes equal to 1/τ(77 K, OD). In the present case, the values of k_r calculated in this way are 1470 and 1450 s^{-1} for [Eu(**1**)]$^{3+}$ and [Eu(**2**)]$^{3+}$, respectively. It is important to note at this point that these values are very high compared with those observed for other Eu^{3+} complexes,[6] for which the radiative rate constants lie in the range 350−900 s^{-1}. In fact, we thought it very unlikely that [Eu(**1**)]$^{3+}$ and [Eu(**2**)]$^{3+}$ could have such markedly different radiative rate constants compared to the previously observed values for complexes with many different ligands. As a first hypothesis, we thought that the OH groups present on the lower rim of the calixarene macrocycles, which point towards the metal ions, might, at least in part, be responsible for a non-negligible value of the term k_{nr} (other vibr.) in our systems. Considering the k_{nr}(OH) values reported in the literature for Eu complexes, it is apparent that these contain a contribution of ca. 1000 s^{-1} per coordinated water molecule or ca. 500 s^{-1} per coordinated methanol molecule, i.e. ca. 500 s^{-1} per OH oscillator.[6][24][25] For the [Eu(**1**)]$^{3+}$ complex, where two OH oscillators are present in the ligand, a value of ca. 1000 s^{-1} for k_{nr}(other vibr.) could, in principle, be expected. In order to assess this hypothesis, we synthesized the Eu^{3+} complex with ligand **3**, possessing OD groups, since NMR measurements in deuterated methanol have shown that there is no exchange between the hydrogen of the OH groups of the complex and the deuterium atoms of the solvent. The observed lifetime of this complex in deuterated methanol was 0.76 ms at room temperature and 0.77 ms at 77 K. From Eq. 3, for the complex with the deuterated ligand, the term $k_r + k_{nr}$(other vibr.) becomes equal to 1300 s^{-1}. This value, although lower than that observed for the non-deuterated ligand, is still high, indicating that other oscillators present in the ligand might be responsible for the non-radiative deactivation to the ground state besides the OH groups. By comparison with the value obtained with the non-deuterated ligand, we can estimate that the contribution to the non-radiative rate constant attributable to the OH group is 170 s^{-1}. This contribution, although not negligible, shows that the OH groups are rather distant in relation to the metal ion. A similar contribution in the analogous complex possessing bpy groups instead of the $bpyO_2$ groups is consistent with the lifetime observed in acetonitrile solutions.[19]

The values of k_{nr}(300 K) and k_{nr}(OH) can be estimated from the measured luminescence lifetimes (Table 1) according to Eqs. 4 and 5.

$$k_{nr}(300\ \mathrm{K}) = 1/\tau(300\ \mathrm{K, OD}) - 1/\tau(77\ \mathrm{K, OD}) \quad (4)$$

$$k_{nr}(\mathrm{OH}) = 1/\tau(300\ \mathrm{K, OH}) - 1/\tau(300\ \mathrm{K, OD}) \quad (5)$$

The calculated values are very low (< 50 s^{-1}) for both the complexes, showing that no solvent molecules are coordinated to the central metal ion and that thermally activated processes (typically, for Eu^{3+} complexes, ligand-to-metal charge-transfer processes) do not play a significant role in these systems, as previously reported for other complexes containing $bpyO_2$ groups.[26]

The efficiency of the ligand-to-metal energy-transfer process (η_{et}) is usually estimated from Eq. 6, with the assumption that k_{nr}(other vibr.) is negligible. In the present case, as discussed above, it is reasonable to consider this assumption as being less than fully adequate; the efficiency calculated from this equation is thus just a limiting value, and is found to be 0.19 and 0.11 for [Eu(**1**)]$^{3+}$ and [Eu(**2**)]$^{3+}$, respectively.

$$\eta_{et} = \Phi_l \cdot \tau(300\ \mathrm{K, OH})/\tau(77\ \mathrm{K, OD}) \quad (6)$$

A quite large difference is observed between the ligand-to-metal energy-transfer efficiencies estimated for [Eu(**1**)]$^{3+}$ and [Eu(**2**)]$^{3+}$. We believe that this difference is due to the greater conformational rigidity of ligand **2**, in which the additional calixarene moiety prevents the $bpyO_2$ groups from maximizing their interaction with the central metal ion.

A comment has to be made regarding the coordination number at the central metal ion. Ligands **1** and **2** provide a smaller number of donor atoms than that usually required by Eu^{3+} ions. While the photophysical data allow us to exclude coordination of the metal ion by solvent molecules, coordination by some counterions cannot be ruled out, although no changes were observed in the luminescence spectra and lifetime on replacing the nitrate by chloride anions. It is likely that anions are coordinated in the solid state, as often observed in lanthanide X-ray structures.[27]

Tb^{3+} Complexes

The lack of a metal-centered luminescence on exciting the ligand-centered band of [Tb(**1**)]$^{3+}$ and [Tb(**2**)]$^{3+}$ at room temperature is not surprising, since the low-lying (21000 cm^{-1}) triplet excited state of the $bpyO_2$ groups allows, as previously observed for other complexes,[6][22] an efficient non-radiative deactivation of the metal emitting state, via back energy transfer to the ligand. This process is no longer kinetically feasible at 77 K, where a strong metal luminescence is again observed (see Table 1). In this case, a detailed examination of the rate constants of all the processes occurring after excitation in the ligand-centered band is pre-

vented by the aforementioned lack of room temperature metal-centered luminescence, although again a very large value of k_r can be estimated from Eq. 3, as observed for the Eu^{3+} complexes of this series. A contribution to the overall rate constant by the OH and other oscillators present in the ligands can also be invoked in this case.

Conclusion

Ligands **1** and **2**, containing $bpyO_2$ subunits, form Tb^{3+} and Eu^{3+} complexes that are stable in coordinating solvents such as methanol and water, and which show intense absorption bands in the UV region. The Tb^{3+} complexes, however, do not show any appreciable metal-centered luminescence at room temperature, presumably because of an efficient back energy transfer to the ligand. For the Eu^{3+} complexes, this process is not thermodynamically feasible, and a strong metal-centered luminescence appears on exciting the ligand-centered absorption bands. Interestingly, this luminescence is not affected by the temperature or by deuteration of the solvent, showing that the ligands efficiently shield the metal ion from solvent interaction, and that thermally activated processes do not play a significant role in these complexes. A small but non-negligible contribution to the non-radiative deactivation to the ground state due to the OH oscillators present in the ligand has been demonstrated.

This work was supported by the *Ministero dell'Università e della Ricerca Scientifica e Tecnologica* (MURST), by the *University of Bologna* (Funds for Selected Research Topics) in Italy, and by the *Centre National de la Recherche Scientifique* and the *Engineer School of Chemistry, ECPM*, in France.

Experimental Section

General Methods: Nuclear magnetic resonance spectra were recorded at room temperature with Bruker SY-200 or AC-200 instruments operating at 200.1 MHz for ^1H. ^1H-NMR chemical shifts are reported in parts per million (ppm) relative to the proton residues in the solvents ($\delta = 7.26$ for $CDCl_3$). − Fast-atom bombardment (FAB, positive mode) spectra were recorded with a ZAB-HF-VB analytical apparatus with *m*-nitrobenzyl alcohol (*m*-NBA) as the matrix; Ar atoms were used for the bombardment (8 keV). All relevant patterns exhibited the expected isotopic profiles, as compared with simulated profiles. Electrospray mass spectra (ES-MS) were recorded with a Bio-Q analytical apparatus, in acetone solution, using grammicidim as internal standard. − Routine absorption spectra were measured in CH_3CN solutions at room temperature using a Kontron Uvikon 941 spectrophotometer. − FT-IR spectra were measured in KBr pellets or in solution with KBr cells with a Bruker IFS 25 spectrometer. − The molecular formulae given, as well as the purities of the samples, were assessed on the basis of ^1H-NMR, FAB^+-MS or ES-MS, and elemental analysis data.

Materials: *p-tert*-Butylcalix[4]arene[28], 5-bromomethyl-5′-methyl-2,2′-bipyridine *N,N′*-dioxide[28], and 5,5′-bromomethyl-2,2′-bipyridine *N,N′*-dioxide[29] were prepared according to literature procedures. Alumina (Merck), potassium carbonate (Prolabo), NaH (Fluka), europium(III) nitrate hexahydrate (Janssen), terbium(III) nitrate hexahydrate (Ventron), and gadolium(III) nitrate pentahydrate (Janssen) were obtained commercially as indicated.

Ligand **1**: A solution of *tert*-butylcalix[4]arene (0.500 g, 0.77 mmol) and potassium carbonate (0.817 g, 7.71 mmol) in dry acetonitrile (30 ml) was heated at 80°C for 30 min, after which solid 5-bromomethyl-5′-methyl-2,2′-bipyridine *N,N′*-dioxide (0.477 g, 1.62 mmol) was added. The mixture was heated at 80°C for 1 d and then quenched with water. Extraction with dichloromethane (5 × 50 ml), drying of the combined organic layers over magnesium sulfate, twofold chromatography (on alumina, using dichloromethane/methanol, 9:1, as eluent), and finally recrystallization from dichloromethane/hexane gave the analytically pure title compound (0.390 g, 47%) ($R_f = 0.55$, dichloromethane/methanol, 96:4, v/v). − ^1H NMR (200 MHz, $CDCl_3$, 25°C): $\delta = 8.62$ (s, 2 H), 8.10 (s, 2 H), 7.79 (s, 4 H), 7.55 (d, 2 H, $^3J = 8.1$ Hz), 7.14 (d, 2 H, $^3J = 8.1$ Hz), 7.05 (s, 4 H, Ar-*H* calix.), 6.98 (s, 2 H, O*H*), 6.81 (s, 4 H, Ar-*H* calix.), 5.04 (s, 4 H, bipy-CH_2-O), 3.75 (AB q, 8 H, $J_{AB} = 13.1$ Hz, $\Delta\nu = 168.5$ Hz, Ar-CH_2-Ar calix.), 2.30 (s, 6 H, bipy-CH_3), 1.28 (s, 18 H, *t*Bu), 0.95 (s, 18 H, *t*Bu). − IR (KBr): $\tilde{\nu} = 3408, 3049, 2958, 2868, 1688, 1602, 1484, 1393, 1364, 1278, 1201, 1171, 1123, 1025, 953, 872, 816$ cm^{-1}. − UV/Vis (CH_3CN): λ (ε) = 264 (43100), 216 nm (103300 M^{-1}cm^{-1}). − FAB^+ MS (*m*-NBA): *m/z* = 1077.5 [M + H]$^+$, 1061.5 [M − O], 1045.5 [M − 2 O], 1029.5 [M − 3 O]. − $C_{68}H_{76}O_8N_4 \cdot H_2O$ ($M_r = 1077.38 + 18.01$): calcd. C 74.56, H 7.18, N 5.11; found C 74.52, H 7.13, N 5.08.

Ligand **2**: A mixture of *tert*-butylcalix[4]arene (0.473 g, 0.73 mmol) and potassium carbonate (0.387 g, 2.80 mmol) in dry acetonitrile (50 ml) was heated at 80°C for 30 min. After cooling to room temperature, 5,5′-bromomethyl-2,2′-bipyridine *N,N′*-dioxide (0.300 g, 0.80 mmol) was added and the suspension was heated overnight at 80°C. The solvent was then removed in vacuo and the organic products were extracted with dichloromethane (5 × 50 ml). Analytically pure compound **2** was obtained after twofold chromatography (alumina, dichloromethane/methanol, 9:1) and recrystallization from dichloromethane/hexane (0.469 g, 37%) ($R_f = 0.66$, dichloromethane/methanol, 96:4, v/v). − ^1H NMR (200 MHz, $CDCl_3$, 25°C): $\delta = 8.70$ (s, 4 H), 7.97 (d, 4 H, $^3J = 8.1$ Hz), 7.77 (d, 4 H, $^3J = 8.1$ Hz), 7.09 (s, 8 H, Ar-*H* calix.), 7.03 (s, 4 H, O*H*), 6.82 (s, 8 H, Ar-*H* calix.), 5.11 (s, 8 H, bipy-CH_2-O), 3.81 (AB q, 16 H, $J_{AB} = 13.3$ Hz, $\Delta\nu = 172.2$ Hz, Ar-CH_2-Ar calix.), 1.31 (s, 36 H, *t*Bu), 0.94 (s, 36 H, *t*Bu). − IR (KBr): $\tilde{\nu} = 3435, 3052, 2959, 2867, 1726, 1602, 1484, 1398, 1362, 1268, 1199, 1114, 1024, 953, 872, 811$ cm^{-1}. − UV/Vis (CH_3CN): λ (ε) = 284 (45000), 220 nm (76900 M^{-1}cm^{-1}). − FAB^+ MS (*m*-NBA): *m/z* = 1723.0 [M + H]$^+$, 1706.0 [M − O], 1690.0 [M − 2 O], 1674.0 [M − 3 O]. − $C_{112}H_{128}O_{12}N_4 \cdot 2\,H_2O$ ($M_r = 1722.28 + 32.02$): calcd. C 76.51, H 7.57, N 3.19; found C 76.40, H 7.51, N 3.12.

Ligand **3**: To a solution of the calix[4]arene-25,27-diol **1** (0.065 g, 0.06 equiv.) in freshly distilled dimethylformamide (20 ml) was added sodium hydride in its commercial form (60%, 0.0036 g). The mixture was heated at 60°C overnight, after which D_2O was added. The solvent was removed and the analytically pure product was obtained after recrystallization from dichloromethane/hexane (0.040 g, 61%). − ^1H NMR (200 MHz, $CDCl_3$, 25°C): $\delta = 8.62$ (s, 2 H), 8.10 (s, 2 H), 7.79 (s, 4 H), 7.56 (d, 2 H, $^3J = 8.1$ Hz), 7.11 (d, 2 H, $^3J = 8.1$ Hz), 7.06 (s, 4 H, Ar-*H* calix.), 6.81 (s, 4 H, Ar-*H* calix.), 5.06 (s, 4 H, bipy-CH_2-O), 3.75 (AB q, 8 H, $J_{AB} = 13.1$ Hz, $\Delta\nu = 168.5$ Hz, Ar-CH_2-Ar calix.), 2.33 (s, 6 H, bipy-CH_3), 1.29 (s, 18 H, *t*Bu), 0.95 (s, 18 H, *t*Bu). − IR (KBr): $\tilde{\nu} = 3404, 3051, 2958, 2864, 1602, 1484, 1393, 1364, 1278, 1201, 1171, 1120, 1026, 955, 872, 814$ cm^{-1}. − UV/Vis (CH_3CN): λ (ε) = 262 (42600), 215 nm (104600 M^{-1}cm^{-1}). − FAB^+ (*m*-NBA): *m/z* =

1079.2 [M + H]$^+$, 1063.2 [M − O], 1047.3 [M − 2 O], 1031.2 [M − 3 O]. − $C_{68}H_{74}D_2O_8N_4$ (M_r = 1079.39): calcd. C 75.67, H 6.91, N 5.19; found C 75.39, H 6.68, N 5.02.

General Procedure for the Synthesis of Lanthanide Complexes: To a solution of the appropriate ligand (0.020 g, 1 equiv.) in methanol (10 ml) was added the lanthanide salt (1.1 equiv.). The mixture was stirred at 60°C overnight and then allowed to cool to room temperature. In the case of the nitrate salts, the lanthanide complexes precipitated during the course of the reaction. The solvent was removed in vacuo and the solid was recrystallized twice from ethyl acetate/hexane. The analytically pure complexes were obtained in 75−92% yield.

*[Eu(**1**)](NO$_3$)$_3$: Yield: 88%. − IR (KBr): ṽ = 3445, 3059, 2959, 2867, 1632, 1487, 1383, 1271, 1200, 1165, 1113, 1030, 955, 875, 828 cm^{-1}.* − FAB$^+$ (*m*-NBA): *m/z* = 1353.3 [M − NO_3]$^+$, 1337.3 [M − NO_3 − O], 1321.3 [M − NO_3 − 2O], 1290.3 [M − 2 NO_3 + H], 1227.3 [M − 2 NO_3 − 4 O]. − $C_{68}H_{76}O_{17}N_7Eu \cdot 5\ H_2O$ (M_r = 1415.36 + 90.07): calcd. Spectroscopic Measurements: The solvents employed for photophysical measurements were methanol (Merck UVASOL) and CH_3OD (99.8 atom-% from Fluka), which were used without further purification. Absorption spectra were recorded with a Perkin-Elmer lambda 16 spectrophotometer. Uncorrected emission, corrected excitation spectra, and phosphorescence lifetimes were obtained with a Perkin-Elmer LS 50 spectrofluorimeter.

Luminescence quantum yields (uncertainty ±15%) were determined using quinine sulfate (Φ = 0.546[30] in 1 N H_2SO_4 aqueous solution) for Tb^{3+} and $[Ru(bpy)_3]^{2+}$ (Φ = 0.028 in aerated water[31]) for Eu^{3+} as standards. In order to permit comparisons of emission intensities, corrections for instrument response, inner filter effects, and phototube sensitivity were made.[32] A correction for differences in the refraction indices was introduced where necessary. Emission spectra at 77 K were obtained in a rigid, opaque methanol matrix using quartz tubes immersed in a quartz Dewar vessel filled with liquid nitrogen.

Keywords: Sulfonamidosilanes / [4 + 4] Octacoordinated silicon / Capped tetrahedron / X-ray structures

Spirocyclic compounds containing an $Si(N)_4$ core have been prepared from 1,2-ethane- and 1,3 propanediamines bearing the electron-withdrawing *p*-toluenesulfonyl groups at the four N atoms. According to the X-ray structure analysis of the compounds **8a** and **13**, the spirocyclic rings are almost perpendicular to each other. In both cases a distorted dodecahedral arrangement of a [4 + 4] octacoordinate Si atom is found in which one O atom of each of the four sulfonyl groups caps one of the planes defined by the $Si(N)_4$ tetrahedron. The O···Si distances are 2.85–3.02 Å and the two O···Si···O angles are 145–159°. According to the X-ray structure analysis of the monocyclic compound **16**, one O atom of the *p*-toluenesulfonyl group caps the plane defined by O1–N2–C13 of the distorted $S(N_2)(O)C$ tetrahedron.

The intriguing properties of main-group elements of the second row like silicon (and phosphorus) to form five- and six-coordinated complexes have found increasing attention.[1][2][3][4][5][6] This is inter alia due to the observation that ligands become more labile and can be displaced readily. Thus, nucleophilic substitution reactions at tetracoordinate silicon are discussed in terms of associated processes with pentacoordinate Si species as intermediates. Whereas five- and six-coordinate Si compounds are by now well known, only a few complexes have been described where silicon is surrounded by seven or even eight atoms. Based on X-ray structure analyses of the silicon complexes **1**−**3**, Auner and co-workers and Corriu and co-workers have suggested heptacoordination for the structures of these compounds. Corriu has discussed the structure of **4** in terms of a [4 + 4] octacoordination.[7][8][9] In view of the rather long Si−N bonds, ranging from 2.88 to 3.49 Å, the authors have described these complexes in terms of a SiR_3X core with the "outer sphere" NR_2 groups capping three or four of the planes of the distorted tetrahedron in SiR_3X and SiR_2H_2. According to the X ray structure analysis the spirosilane **5** contains hexacoordinated silicon with the N−Si bond approaching that of a covalent bond.[10] ^{1}H- and ^{29}Si-NMR measurements show a dynamic behaviour, suggesting that the NMe_2 groups displace each other by way of a heptacoordinate transition state.

Recently, we have prepared the rather stable spiro compound **6**, the X-ray structure of which also revealed [4 + 4] octacoordinated silicon.[11] Here the four planes of the tetrahedron defined by the SiN_4 core are capped by one O atom of each of the four sulfonyl groups. In a search for further examples of this unique [4 + 4] octacoordination of Si we prepared a variety of silatetraazaspiro compounds with different ring sizes bearing *p*-toluenesulfonyl (tosyl) groups at the four N atoms and determined the molecular structure of two of the spirosilanes by X-ray analysis.

Results and Discussion

The spirocyclic tetraazasilanes were prepared according to Scheme 1. Treatment of the *N*,*N*′-disulfonyldiamines **7a**,**b**, **9** and **12** with BuLi and $SiCl_4$ gave the silatetraazaspiro compounds **8a**,**b**, **10** and **13**, respectively, in moderate to good yields. The propensity to form spirocycles was reduced with increasing length of the chain connecting the bidentate tosylamines. The reaction of *N*,*N*′-ditosylpropane-1,3-diamine (**9**) gave in addition to **10** the monocyclic silane **11**. In an attempt to prepare a silatetraazaspiro[6.6]-dodecane from *N*,*N*′-ditosylbutane-1,4-diamine (**14**), a polymeric material was formed and the attempted reaction of the *N*,*N*′-ditosylbiphenyl-2,2′-diamine (**15**) with $SiCl_4$ gave the heterocyclic compound **16** rather than a spirocyclic compound.

Structure Determination

The structure of the 1,3-diaza-2-silaspiroalkanes **8a**,**b**, **10** and **13** is supported by mass spectra and ^{1}H- and ^{13}C-NMR spectra. Since the number of signals in the ^{13}C-NMR spectra is half the number of the C atoms these spiro compounds apparently have two-fold symmetry. In **8a**,**b** and **10**

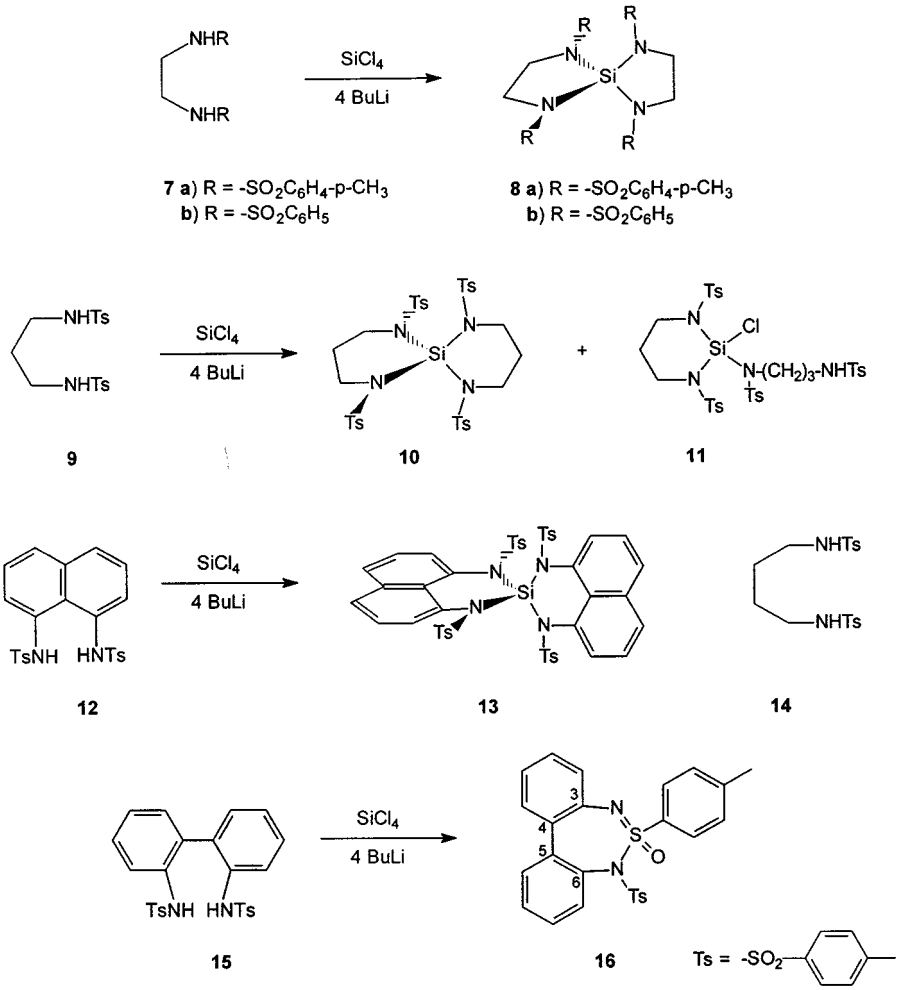
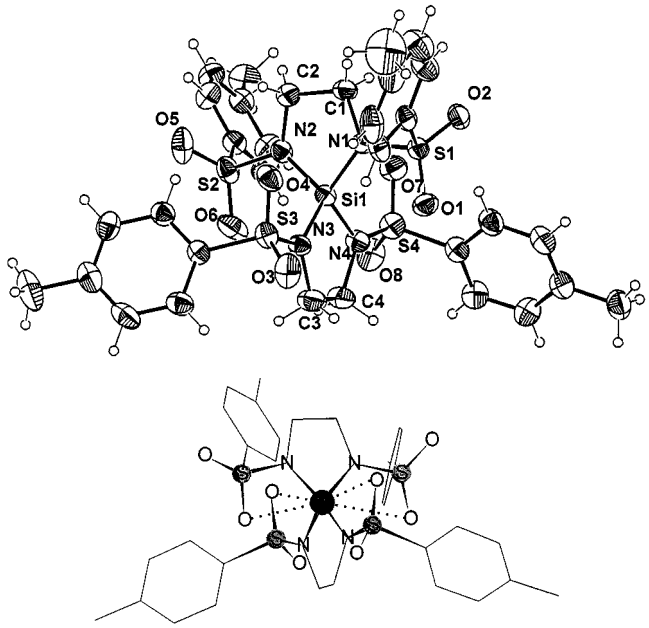
Scheme 1



the ^{1}H signals of the $-NCH_2$ groups appear as sharp lines. This suggests that in **8a** and **8b** the two five-membered silaimidazolidine moieties are either planar, rapidly equilibrating through a planar form or undergo rapid inversion at N.[12][13] In **10** the two siladiazacyclohexane ring systems may adopt a quasi-chair conformation with planar or rapidly inverting N centers. The ^{1}H-NMR signals of the $-NCH_2$ groups are consistently shifted downfield by approximately 0.30 ppm from those found in the precursor *N,N′*-ditosyldiamines. In the ^{29}Si-NMR spectra of **8a**,**b** and **11** (and **13**), the signals are shifted upfield by more than 20 ppm relative to $Si[N(CH_3)_2]_4$ ($\delta = -28.1$).[14] In the spirocyclic tetraazasilane **10** the ^{29}Si-NMR signal appears at $\delta = -69.9$ and is thus close to that of $Si(OCH_3)_4$ ($\delta = -79.0$).[15] These chemical shifts indicate that the Si nucleus in these spirocyclic compounds has a different substitution pattern. In the IR spectra of **10** and **13** the absorption band occurring at 930 cm^{-1} can be assigned to an asymmetric Si−N vibration.[16] In order to obtain more detailed information about structural details, X-ray structure analyses were performed on the silatetraazaspiro compounds **8a** and **13**. Since the ^{1}H- and ^{13}C-NMR spectra as well as the elemental analysis of **16** indicated that the *N,N′*-ditosylbiphenyl-2,2′-diamine (**15**) had reacted in the presence of $SiCl_4$ in a different way, an X-ray analysis was also performed on this product.

Figure. 1. Top: A perspective view of molecule **8a**, showing the numbering scheme used (thermal ellipsoids at 50% probability level)[a]; bottom: drawing of **8a**, illustrating the octahedral coordination



[a] Selected bond lengths [Å], bond and torsional angles [°]: N1−Si1 1.727(4), N1−S1 1.626(4), S1−O1 1.427(3), S1−O2 1.438(3), N2−Si1 1.709(4), N3−Si1 1.714(4), N4−Si1 1.715(4); N1−Si1−N2 91.7(2), N3−Si1−N4 92.1(2), N2−Si1−N3 117.9(2), N2−Si1−N4 118.6(2);N2−C2−C1−N1 −27.63; N3−C3−C4−N4 11.53; O1···Si1 3.043(2), O3···Si1 2.920(4), O6···Si1 2.974(4), O7···Si1 2.968(3).

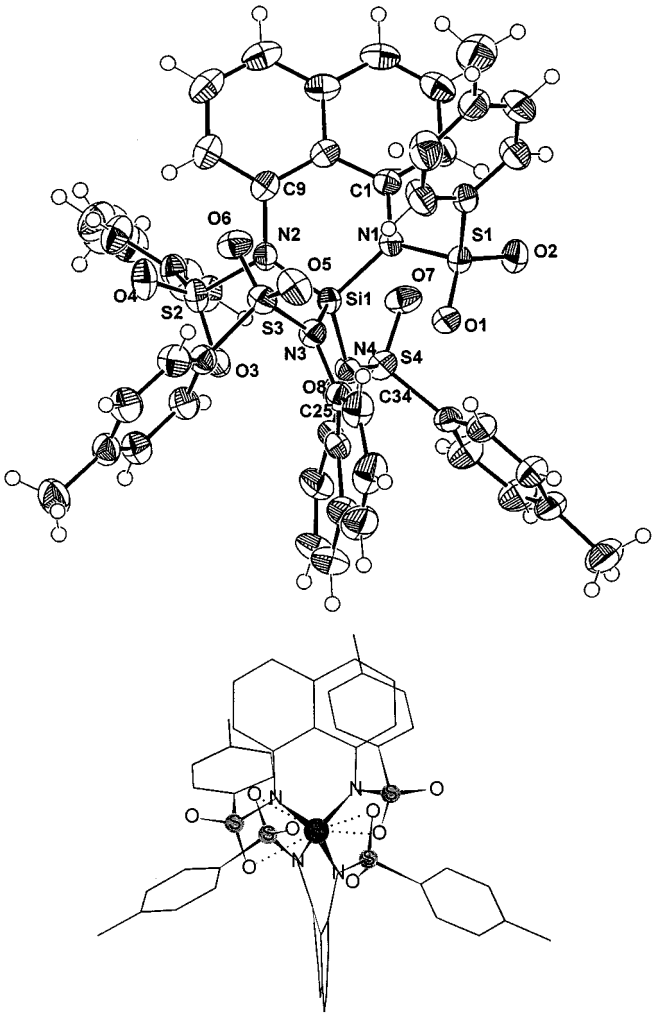
X-ray Structure Analysis

The structure analysis of **8a** reveals that the two silaimidazolidine rings adopt a twist conformation (Figure 1) with an angle of 89.84° between the two planes defined by N1−Si1−N2 and N3−Si1−N4, meaning that the rings are almost perpendicular to each other (Figure 1 bottom). The endocyclic bond angle N1−Si1−N2 and its counterpart N3−Si1−N4 are significantly smaller [91.7(2)° and 92.1(2)°] than the average of the exocylic bond angles (118.3° and 119.6°). The torsion angles S1−N1−Si1−N2 [−175.4(3)°] and S3−N3−Si1−N4 [+173.1(3)°] as well as S2−N2−Si1−N1 [−175.5(3)°] and S4−N4−Si1−N3 [+177.5(3)°] indicate a small pyramidalization at the N atoms. In comparison with the average N−Si bond length found in **6** (1.734 Å) and those reported for N−Si−N substructures in five-membered ring systems, the average N−Si bond length of 1.714(4) Å is rather short in **8a**.[11][17] As observed for **6** one oxygen atom of each of the four sulfonamide groups caps the $Si(N)_4$ tetrahedron, with each bisecting one of the tetradron faces (Figure 1, bottom).[11] The O···Si distances are [2.922 (4)−3.043 (3) Å] and the angles O1···Si1···O3 and O6···Si1···O7 are 159.9(1)° and 157.4(1)°, respectively. These values are very similar to those found in **6**.[11]

In the molecular structure of **13** (Figure 2, top) the angle between the two planes defined by N1−Si1−N2 and N3−Si1−N4 is 89.60°. Thus, the two six-membered rings forming the spirocycle are almost perpendicular to each other. In each of these rings, the C atoms of the naphthalene ring bonded to the nitrogen atoms are located out of the planes defined by N1−Si1−N2 and N3−Si1−N4. According to the torsional angles the pyramidalisation at the four N atoms is slightly larger in this compound than in **8a**. In **13** the average N−Si bond length is 1.744 Å and thus longer than in **8a**. In line with the arrangement found for the tosyl groups in **6** and **8a**, the four sulfonyl groups in **13** are arranged in such a way that one oxygen atom of each of the sulfonyl groups is located above one of the planes defined by the $Si(N)_4$ tetrahedron with O···Si distances ranging from 2.845 to 3.023 Å (Figure 2 bottom). The angles between these non-bonded O atoms and the central Si atom are in the same range as found for **8a** [O1···Si1···O3 145.1(06)° and O6···Si1···O7 154.03(06)°] and are considerably larger than 109.48°, the angle between the two lines passing through the centres of two planes in a tetrahedron.

As mentioned above, no silatetraazaspiroundecane had been formed in the reaction of the biphenyldiamine **15** with $SiCl_4$. As revealed by the X-ray structure analysis, **15** had been transformed in an intramolecular condensation reaction into the diazathiaheptatriene **16** (Figure 3). In this structure the angle C3−C4−C5−C6 46.2(5) (cf. **16** in Scheme 1), which lies within the expected range for the torsional deformation between the two phenyl groups in biphenyl-2,2′-diamines. A salient feature of this monocyclic compound is the location of the oxygen atom O2 of the sulfonyl group, which caps the plane defined by O1, N2, C13 of the distorted $S(N)_2(O)(C)$ tetrahedron.

Figure 2. Top: A perspective view of molecule **13**, showing the numbering scheme used (thermal ellipsoids at 50% probability level)[a]; bottom: drawing of **13**, illustrating the octahedral coordination

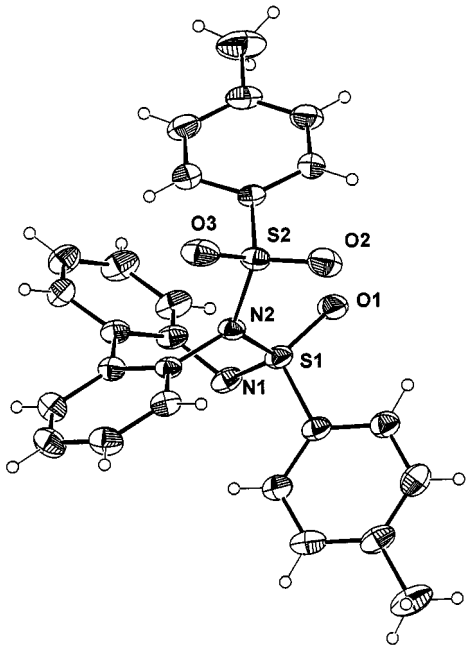


[a] Selected bond lengths [Å], bond and torsional angles [°]: N1−Si1 1.746(2), N2−Si1 1.740(2), N3−Si1 1.745(2), N4−Si1 1.744(2); N2−Si1-N1 101.04(11), N2−Si-N3 113.75, N2−Si1−N4 113.77(12); N1−C1−C10−C9 −15.57, N2−C9−C10−C1 −17.81; O1···Si1 2.845(2), O3···Si1 2.866(2), O6···Si1 3.023(2), O7···Si1 2.951(2).

Concluding Remarks

It has been shown that spirocyclic compounds containing an $Si(N)_4$ core can be prepared from 1,2-diamines bearing the electron-withdrawing *p*-toluenesulfonyl substituents at the N atoms. The first example of a 2-sila-1,3,7,11-tetraazaspiro[5.5]undecane **13**, containing six-membered rings has been obtained. Attempts to prepare tetraazaspirosilanes containing larger rings by base-induced reaction of an appropriate ditosyl diamine were not successful. According to the X-ray structure of the spirocyclic tetraazasilanonane **8a** and the benzannulated tetraazasilaundecane **13**, the *p*-toluenesulfonyl groups are oriented in such a way that one oxygen atom each caps a plane of the distorted $Si(N)_4$ tetrahedron. While the $Si(N)_4$ core retains a geometry with bond lengths close to a covalent N−Si bond, the O···Si distances

Figure 3. A perspective view of molecule **16** showing the numbering scheme used (thermal ellipsoids at 50% probability level)[a]



[a] Selected bond lengths [Å], bond and torsional angles [°]: N1−S1 1.578(4), N2−S1 1.704(3), N2−S2 1.738(3); N1−S1−N2 103.4(2), O1−S1−N1 126.5(2), O1−S1−N2 106.7(2); C1−C6−C7−C12 46.21(0.50).

are much longer than those found in alkoxysilanes.[17] These geometries can best be described as a distorted dodecahedral arrangement of a [4 + 4] coordinated Si.[8][11] At present it is unclear whether this type of coordination in these silicon compounds is due to an additional stabilisation of the spiro silacycle or is caused by the crystal packing.

Experimental Section

General: Chemicals were purchased from commercial suppliers and used without further purification. Ts: *p*-toluenesulfonyl (tosyl). BuLi (Fluka): 1.6 M solution in hexane. − Reactions were performed under argon. − M.p.: Büchi 510 melting point apparatus, uncorrected values. − Thin layer chromatography: Silica gel plates SIL G/UV_{254} (Macherey & Nagel), eluent: EtOAc/cyclohexane, ratio given. − Column chromatography (CC): J. T. Baker flash gel (40mm), eluent: EtOAc/cyclohexane in the ratio specified. − IR spectra: Perkin-Elmer 782 IR spectrophotometer. − NMR spectra: Bruker AC 300 spectrometer [^{1}H, 300 MHz, ^{13}C, 75 MHz] and Bruker DRX 500 spectrometer [^{29}Si, 99.325 MHz]), δ in ppm rel. to internal $Si(CH_3)_4$, st = stack, heavily overlapping signals. − Mass spectra (MS): Varian MAT CH7A (70eV, EI); FAB-MS: Fisons VG Autospec Q spectrometer (Cs^+, 32 kV).

N,N′-Ditosylethane-1,2-diamine (**7a**): A solution of TsCl (0.23 mol) in 150 ml diethyl ether was slowly added to a cooled solution of ethane-1,2-diamine (0.113 mol) and 18 g NaOH in 450 ml H_2O. After stirring overnight at room temp., the ditosylate was filtered

off and recrystallized from CH_3OH, white needles, yield 33g (81%), m.p. 162−163°C (162−164°C[18][19]). − R_f (1:1) = 0.37. − ^1H NMR (CD_3COCD_3): δ = 7.76 (dt, *J* = 8.1, 1 Hz, 4 H), 7.44 (dt, *J* = 8.1, 1 Hz, 4 H), 6.57 (br., 2 H), 3.00−3.03 (m, 4 H), 2.44 (s, 6 H). − ^{13}C NMR (CD_3COCD_3): δ = 143.7 (s), 138.6 (s), 130.3 (d), 127.6 (d), 43.5 (t), 21.2(q). − IR (KBr): $\tilde{\nu}$ = 3295 cm^{-1}, 1590, 1410, 1330, 1150. − MS (EI): *m/z* (%): 369 (5) $[M + 1]^+$, 339 (40), 213 (94), 184 (96), 155 (100), 139 (18), 91 (88), 65 (20).

The following derivatives of the diamines were prepared as described for **7a**.

N,N′-Dibenzenesulphonylethane-1,2-diamine (**7b**): Recrystallization from ethanol gave white needles (28.8 g, 75%), m.p. 166−167°C.[20]. − R_f (1:1) = 0.20. − ^1H NMR (CD_3COCD_3): δ = 7.85−7.88 (m, 4 H), 7.59−7.72 (m, 6 H), 6.67 (br., 2H), 3.04−3.06 (m, 4 H). − ^{13}C NMR (CD_3COCD_3): δ = 141.5 (s), 133.1 (s), 129.8 (d), 127.5 (d), 43.5 (t). − IR (KBr): $\tilde{\nu}$ = 3270 cm^{-1}, 3320, 1320, 1150. − MS (EI); *m/z* (%): 341 (2) $[M + 1]^+$, 199 (17), 170 (88), 141 (65), 125 (6), 97 (6), 77 (100), 31 (30).

N,N′-Ditosylpropane-1,3-diamine (**9**): Yield 80%, m.p. 138−139°C (134−136°C[19][21]). − R_f (1:1) = 0.35. − ^1H NMR (CD_3COCD_3): δ = 7.72−7.76 (d, *J* = 8.1 Hz, 4 H), 7.40−7.44 (d, *J* = 8.1 Hz, 4 H), 6.48 (br., 2 H), 2.95 (m, 4 H), 2.45 (s, 6 H), 1.71 (5, *J* = 6.7 Hz, 2 H). − ^{13}C NMR (CD_3COCD_3): δ = 143.7 (s), 138.9 (s), 130.4 (s), 127.7 (s), 41.3 (t), 30.0 (t), 21.3 (q). − IR (KBr): $\tilde{\nu}$ = 3270 cm^{-1}, 1590, 1460, 1320,1155. − MS (EI): *m/z* (%): 393 (2) $[M + 1]^+$, 227 (80), 164 (40), 171(12), 155 (100), 91 (80), 65 (18), 56 (80).

N,N′-Ditosylnaphthalene-1,8-diamine (**12**): Yield 80%, m.p. 203−204 °C (207°C[22]). − R_f (2:3) = 0.35. − ^1H NMR ($CDCl_3$): δ = 7.63−7.68 (m, 6 H), 7.20−7.26 (m, 6 H), 7.01−7.04 (dd, 2 H), 2.37 (s, 6 H). − ^{13}C NMR ($CDCl_3$): δ = 144.5 (s), 135.9 (s), 134.9 (s), 130.2 (s), 129.4 (s), 130.0 (d), 129.8 (d), 127.1 (d), 125.1 (d), 121.3 (d), 21.6 (q). − IR (KBr): $\tilde{\nu}$ = 3200 cm^{-1}, 1575, 1415, 1340, 1300, 1150. − MS (EI); *m/z* (%): 467 (33) $[M + 1]^+$, 466 (100) $[M^+]$, 311 (48), 247 (26), 232 (10), 155 (58), 129 (8), 127 (6). − $C_{24}H_{22}N_2O_4S_2$ (466.56): calcd. C 61.78, H 4.75, N 6.01; found C 61.71, H 4.75, N 5.96.

N,N′-Ditosylbutane-1,4-diamine (**14**): Yield 80%, m.p. 137−138°C (m.p. 125−125°C[23], 139°C[24]). − ^1H NMR (CD_3COCD_3): δ = 7.73−7.76 (dt, *J* = 8.5, 1 Hz, 4 H), 7.40−7.43 (dt, *J* = 8.8, 1 Hz, 4 H), 6.37 (br., 2 H), 2.85−2.89 (m, 4 H), 2.43 (s, 6 H), 1.50−1.55 (m, 4 H). − ^{13}C NMR (CD_3COCD_3): δ = 142.9 (s), 138.3 (s), 129.6 (d), 127.0 (d), 42.6 (t), 26.6 (t), 20.6 (q). − IR (KBr): $\tilde{\nu}$ = 3295 cm^{-1}, 1590, 1410, 1330, 1150. − MS (EI); *m/z* (%): 397 (2) $[M + 1]^+$, 241 (82) $[M - Ts]^+$, 224 (100), 184 (70), 155 (95), 139 (18), 91 (85), 70 (50).

N,N′-Ditosylbiphenyl-2,2′-diamine (**15**): (2,2′-Biphenyldiamine was prepared according to ref.[25][26]), m.p. of compound **15** 168−171°C. − R_f (1:3) = 0.26. − ^1H NMR ($CDCl_3$): δ = 7.67−7.69 (dt, *J* = 7.3, 1 Hz, 2 H), 7.49−7.52 (dt, *J* = 8.1, 1 Hz, 2 H), 7.33−7.39 (td, *J* = 8.0, 1.9 Hz, 2 H), 7.23−7.26 (d, *J* = 8.0 Hz, 2 H), 7.02−7.07 (td, *J* = 7.4, 1 Hz, 2 H), 6.48−6.50 (dd, *J* = 7.4, 1.5 Hz, 2 H), 5.88 (s, 2 H,), 2.43 (s, 6 H). − ^{13}C NMR ($CDCl_3$): δ = 144.6 (s), 135.9 (s), 134.9 (s), 127.5 (d), 130.3 (s), 130.0 (d), 129.9 (d), 127.5 (d), 127.1 (d), 125.1 (d), 121.3 (d), 21.6 (q). − IR (KBr): $\tilde{\nu}$ = 3330 cm^{-1}, 3280, 1395, 1270, 1090, 750 1340,1170. − MS (EI): *m/z* (%): 492 (98) $[M^+]$, 337 (45), 321 (40), 273 (20), 182 (90), 181 (100),167 (46), 154 (45).

General Procedure for the Preparation of the Tetraazasilaspiro Compounds: After addition of BuLi (6 ml, 1.6 M in hexane, 9.6 mmol) to a solution of the bis(sulfonamide) (4.8 mmol) in 50 ml of dry THF and stirring for 30 min, $SiCl_4$ (2.4 mmol), dissolved in 3 ml of THF, was added. The reaction mixture was refluxed for the time given, cooled to room temp., filtered and concentrated to dryness. The residue was purified by CC or recrystallization.

1,4,6,9-Tetratosyl-1,4,6,9-tetraaza-5-silaspiro[4.4]nonane (**8a**): Purification by CC (1:1) gave 0.95 g (60%) of product as colourless crystals which were recrystallized from CH_3CN. Crystals suitable for X-ray analysis were grown from CH_3CN as colourless blocks. M.p. 254−255°C. R_f (1:1) = 0.61. − ^1H NMR ($CDCl_3$): δ = 8.06 (d, *J* = 8.4 Hz, 8 H), 7.35 (d, *J* = 8.4 Hz, 8 H), 3.36 (s, 8 H), 2.41 (s, 12 H). − ^{13}C NMR ($CDCl_3$): δ = 144.5 (s), 134.5 (s), 129.7 (d), 128.8 (d), 43.3 (t), 21.7 (q). − ^{29}Si NMR: −50.86. − IR (KBr): $\tilde{\nu}$ = 1600 cm^{-1}, 1235, 1160, 1115, 1090, 1025,1010. − MS (EI): *m/z* (%): 605 (58) $[M - Ts]^+$, 564 (14), 549 (100), 485 (20), 450 (55), 411 (52), 139 (23). − $C_{32}H_{36}N_4O_8S_4Si$ (760.12): calcd. C 50.50, H 4.77,N 7.37, found C 50.52, H 4.77, N 7.36.

1,4,6,9-Tetrakis(benzenesulfonyl)-1,4,6,9-tetraaza-5-silaspiro-[4.4]nonane (**8b**): Yield 0.510g, 30%, recrystallization from CH_3CN, m.p. 265−267°C. − R_f (1:1) = 0.35. − ^1H NMR ($CDCl_3$): δ = 8.15−8.20 (m, 8 H), 7.52−7.66 (m, 12 H), 3.41 (s, 8 H). − ^{13}C NMR ($CDCl_3$): δ = 137.3 (s), 133.5 (d), 129.0 (d), 128.7 (d), 42.4 (t). − ^{29}Si NMR($CDCl_3$): −50.46. − IR (KBr): $\tilde{\nu}$ = 1020 cm^{-1}. − MS (FAB): *m/z* (%): 705 (10) $[M + 1]^+$, 639 (3), 565 (3), 439 (50), 383 (18), 307 (6), 155 (100), 121 (25). − $C_{28}H_{28}N_4O_8S_4Si$ (704.06): calcd. C 47.71, H 4.00, N 7.95, found C 47.65, H 3.87, N 8.13.

1,5,7,11-Tetratosyl-1,5,7,11-tetraaza-6-silaspiro[5.5]undecane (**10**) *and 2-Chloro-N,N′-ditosyl-2-[tosyl(3-tosylaminopropyl)-amino]-1,3-diaza-2-silacyclohexane* (**11**): CC of the reaction mixture gave 0.470 g (25%) of **10** and 0.40 g (20%) of **11**.

10: White needles after recrystallization from CH_3CN, m.p. ca. 295 °C. − R_f (1:1) = 0.61. − ^1H NMR ($CDCl_3$): δ = 8.07−8.09 (d, *J* = 8.4 Hz, 8 H), 7.26−7.31 (d, *J* = 8.4 Hz, 8 H), 3.48 (br., 8 H), 2.40 (s, 12 H), 2.02 (m, 4 H). − ^{13}C NMR ($CDCl_3$): δ = 143.9 (s), 135.2 (s), 129.3 (d), 129.1 (d), 47.2 (t), 24.1 (t), 21.6 (q). − ^{29}Si NMR ($CDCl_3$): δ = −69.96. − IR (KBr): $\tilde{\nu}$ = 1330 cm^{-1}, 1155, 965, 930. − MS (FAB): *m/z* (%): 789 (1.4) $[M^{2+}]$, 635 (2), 613 (3), 581 (2), 461 (3), 309 (30), 275 (8), 155 (42). − $C_{34}H_{40}N_4O_8S_4Si$ (789.03): calcd. C 51.75, H 5.11, N 7.10, found C 51.63, H 5.11, N 7.05.

11: White solid after recrystallization from EtOAc/cyclohexane, m.p. 145−147°C. − R_f (1:1) = 0.46. − ^1H NMR ($CDCl_3$): δ = 8.06−8.09 (d, *J* = 8.1 Hz, 2 H), 7.90−7.93 (d, *J* = 8.1 Hz, 4 H), 7.68−7.71 (d, *J* = 8.1 Hz, 2 H), 7.37−7.40 (d, *J* = 8.1 Hz, 2 H,), 7.31−7.40 (d, *J* = 8.1 Hz, 4 H), 7.25−7.28 (d, *J* = 8.1 Hz, 2 H), 4.39 (t, *J* = 6.3 Hz, 1 H), 3.40−3.50 (m, 4 H), 3.19−3.26 (m, 2 H), 2.84−2.90 (m, 2 H), 2.45 (s, 3 H), 2.43 (s, 6 H), 2.39 (s, 3 H), 1.78−1.90 (m, 4 H). −^{13}C NMR ($CDCl_3$): δ = 144.9 (s), 144.4 (s), 143.3 (s), 136.8 (s), 135.3 (d), 134.9 (s), 129.8 (d), 129.7 (d), 129.6 (d), 129.1(d), 128.3(d), 127.1(d), 46.7 (t), 45.1 (t), 40.7 (t), 28.6 (t), 26.0 (t), 21.7 (q), 21.6 (q), 21.5 (q). − ^{29}Si NMR ($CDCl_3$): δ = −53.64. − IR (KBr): $\tilde{\nu}$ = 1340 cm^{-1}, 1160, 1090, 1025, 930, 865. − MS (FAB): *m/z* (%): 825 (5) $[M + 1]^+$, 671 (6), 517 (2), 443 (100), 425 (5), 289 (10), 229 (3), 139 (12). − $C_{34}H_{41}ClN_4O_8S_4Si$ (824.13): calcd. C 49.46, H 5.01, N 6.79, found C 49.92, H 5.15, N 6.54.

1,1′,3,3′-Tetratosyl-1,1′,3,3′-tetraaza-2-silaspiro[2.2′]-2,3-dihydro-1H-phenalene (**13**): The reaction mixture was refluxed for 48 h. Recrystallization from CH_2Cl_2/CH_3CN gave 0.80 g (35%) **13** as white needles. Crystals of **13** suitable for X-ray analysis were grown from CH_2Cl_2/CH_3CN as colourless blocks, m.p.

Crystal Structure Analyses: Crystal data are presented in Table 1. Data collection: For all three compounds, **8a**, **13** and **16**, intensity data were collected at room temp. with a Stoe AED2 4-circle diffractometer using Mo-K_α graphite-monochromated radiation, using ω/2Θ scans in the range 4–51° in 2Θ. Lattice parameters were optimized from a least-squares refinement of the ± ω values of 29 (**8a**), 24 (**13**) and 23 (**16**) reflections (and their equivalents) in the 2Θ ranges 25.4–33.7° (**8a**), 25.6–35.6° (**13**) and 28.1–35.8° (**16**). Crystallographic data are summarized in Table 1. The structures were solved by direct methods using the program SHELXS-97.[27] The refinement and all further calculations were carried out using SHELXL-97.[28] Complex neutral-atom scattering factors used were those contained in the program SHELXL-97. All of the H atoms were included in calculated positions and treated as riding atoms using SHELXL-97 default parameters. The non-H atoms were refined anisotropically using weighted full-matrix least squares on F^2. Corrections for extinction were applied but not for absorption. Final atomic coordinates are given in Table 2 and selected bond lengths and angles in Table 3. The structural diagrams were drawn using the program Xtal GX.[29]

Full tables of atomic parameters and bond lengths and angles for the structures reported in this paper may be obtained from the Cambridge Crystallographic Data Centre. Copies of the crystallographic data [CCDC-101700 (**8a**), -101701 (**13**), -101702 (**16**)] may be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44(1223)336-033, E-mail: deposit@ccdc.cam.ac.uk).

Keywords: Supramolecular chemistry / Metallamacrocycle / Hydrogen bonding / Phosphane

Two novel phosphane ligands **3** and **4** based on the rigid diphenylglycoluril molecule have been synthesized and characterised. Binding studies with **3** and **4**, using 1,3-dihydroxybenzene derivatives reveal that ligands **3** and **4** behave similarly to clip molecule **5**, which has the same binding site as ligands **3** and **4**. The size of the flexible spacers in the ligands has been varied and the effect of this variation on the association constant of resorcinol derivatives has been determined. These cavity-containing ligands are able to coordinate two transition metal centres, leading to bimetallic macrocycles. The metallamacrocycles formed from **4** containing platinum or rhodium bind the guest, olivetol (5-pentylbenzene-1,3-diol), almost four times as strongly as the free tetrapodant **4**. Complexes of **4** having palladium centres display similar or reduced binding affinities for resorcinol derivatives, when compared to free **4**. Metal complexes of ligand **3** do not form host-guest complexes, probably because of a too small a ring-size of the metallamacrocycle.

Introduction

The use of enzymes as catalysts for organic reactions is a major topic in modern chemistry. Enzyme-catalysed reactions can reach incredibly high rates and selectivities. Man-made catalysts do not reach that level of supremacy yet, but recently some elegant examples of synthetic enzymes (synzymes) have been published. These synzymes consist of the building block diphenylglycoluril (= DPGU),[1−5] a cyclodextrin[6−8] or a cyclophane[9] and a catalytically active centre. Synzymes do not match the natural enzymes in reactivity, but they are interesting molecules to study the fundamental processes taking place in enzyme catalysis. In this way processes like substrate coordination and substrate-metal interactions can be studied in a less complicated environment. The knowledge obtained can then be used in the development of shape-selective catalysts.[3−5,10,11] Non-covalent binding interactions like hydrogen bonding, π-π stacking, electrostatic, and van der Waals interactions induce substrate discrimination in the processes mentioned above.

In this paper two tetrapodant host molecules **3** and **4** based on the rigid building block DPGU are described. The binding affinities of these host molecules towards 5-substituted resorcinol (1,3-dihydroxybenzene) derivatives will be presented. Several transition metal complexes of **3** and **4** were prepared and the effect of metal complexation on the bond strength between host and guest was investigated. These results are of interest for future applications of metal complexes of **3** and **4** as catalysts for e.g. the hydroformylation reaction or cross-coupling reactions.

Results and Discussion

Ligand Synthesis

The tetrapodant starting compounds **1** and **2** were prepared according to literature procedures[12] and subsequently converted into **3** and **4** after reaction with four equivalents of $LiPPh_2$ (see Scheme 1). The two tetradentate ligands **3** and **4** were obtained in 80% and 67% yield, respectively. Also, we tried to synthesize compound **4** from **2** and four equivalents of $HPPh_2$ in the presence of 10 equivalents of *t*BuOK. This reaction afforded only small amounts of the desired product. Under these conditions, the main reaction that occurred was cleavage of the ether moieties.

The two ligands (**3** and **4**) are moderately air-sensitive, but they are stable under an inert atmosphere. When the products were not carefully worked up or stored, ^{31}P-NMR spectra showed signals in the phosphane oxide region (δ = + 30). These oxide contaminations could be removed by

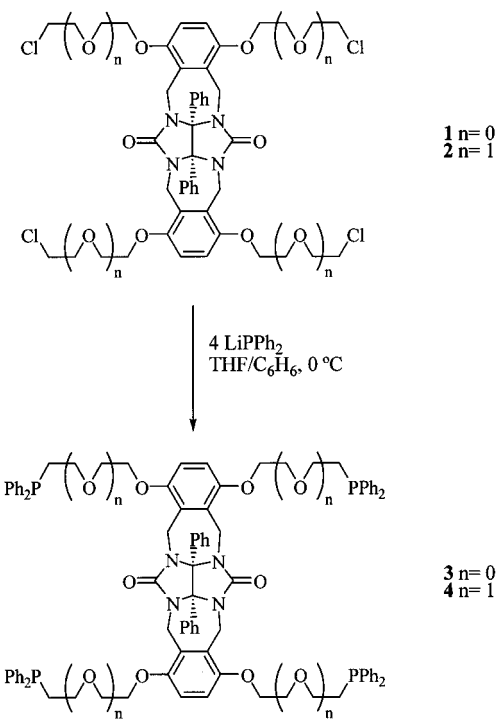
reduction with an excess of $HSiCl_3$ in the presence of 3 equivalents of NEt_3 per $HSiCl_3$ in refluxing benzene.[13]

Scheme 1. Synthesis of ligands **3** and **4**



Metal Complex Synthesis

The starting compounds in the metal complexation reactions and the yields are summarised in Table 1. Most of the complexes of **3** and **4** were synthesized from starting metal complexes containing triphenylphosphane. After addition of the tetradentate ligands **3** or **4** to these PPh_3-containing compounds, the bimetallic complexes of **3** or **4** were formed. The driving force of this reaction is the replacement of a triarylphosphane ligand by an alkyldiphenylphosphane, which is a stronger donor ligand. The reaction is also entropy-driven; a monodentate ligand is always replaced by a bidentate ligand having similar electronic and steric properties.

A phosphane-free precursor compound [e.g. $(COD)PdCl_2$] could also be used, provided that a small amount of PPh_3 was added to the reaction mixture. When the syntheses were performed without PPh_3, large amounts of insoluble compounds were formed in addition to the desired product. The replacement of COD or CH_3CN by a phosphane ligand is fast compared to a phosphane-by-phosphane replacement. Before intramolecular ring closure can occur, intermolecular complexation takes place. The polymeric complexes precipitate and cannot equilibrate to form the desired bimetallic complexes. These reactions were also performed at lower concentrations (3×10^{-4} M), but always some insoluble product was formed. A suspension of precipitated (polymeric) complex could be treated with a small amount of PPh_3 to redissolve the polymeric products. The PPh_3 that remained after the reaction could be removed with the same ease as weakly bound ligands such as COD and CH_3CN. A simple precipitation of the metal complex after the addition of pentane, hexane or diethyl ether, followed by filtration or decantation of the suspension was sufficient to remove PPh_3.

There are two exceptions to the general procedure described above: the formation of $\mathbf{L}[Pd(BF_4)_2]_2$ and $\mathbf{L}[Pd(TCNE)]_2$ (**L** = **3** or **4**, TCNE= tetracyanoethylene). For the preparation of the aforementioned ionic palladium compounds, CH_3CN was used as a cosolvent. The products formed still contained two molecules of CH_3CN, which increased the solubility of the products. Hence, polymeric structures did not precipitate and the desired products were obtained. For the formation of the $\mathbf{L}[Pd(TCNE)]_2$ complexes the reaction of $Pd(DBA)_2$ (DBA= dibenzylideneacetone) with either **3** or **4** was chosen. This resulted in the initial formation of $\mathbf{L}[Pd(DBA)]_2$ complexes. The replacement of the second DBA molecule is known to be less favourable,[14] but this could be achieved by the addition of TCNE, an extremely electron-poor alkene. Complexes possessing other electron-poor alkenes like maleic anhydride, dimethyl fumarate or fumaronitrile could not be isolated. These alkenes are not as tightly bound to the Pd centre as TCNE and therefore afford less stable compounds.

Table 1. Starting compounds, products, yields and spectroscopic data of the bimetallic macrocycles of **3** and **4**

Entry	Starting compound	Product	Yield [%]	$\delta(^{31}P)$ [ppm] ($^1J_{M\text{-}P}$ [Hz])	$\nu(CX)$[f] [$^{-1}$]

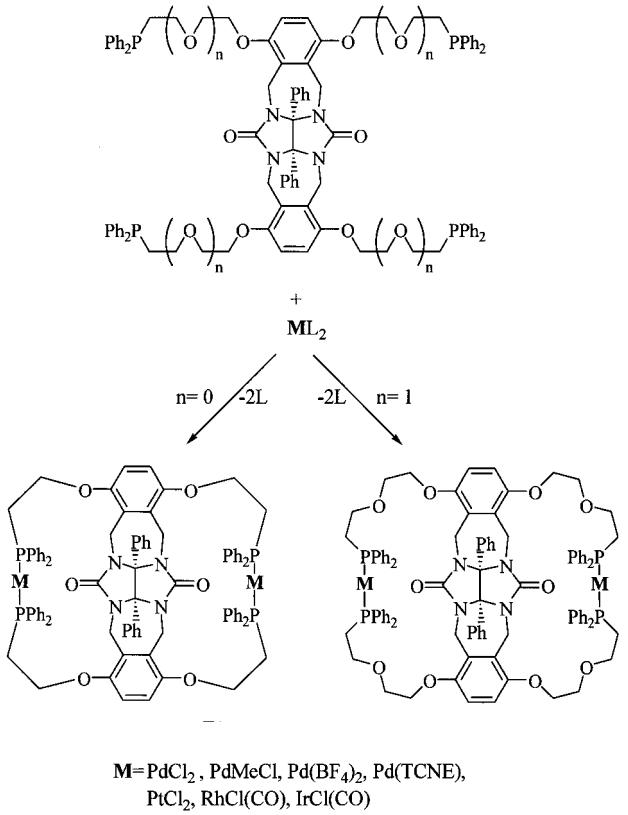
Identification

The ^{1}H-NMR spectra of the metal complexes of **3** and **4** have characteristic signals, viz. a doublet, at $\delta = 5.5-5.7$. This signal is due to one of the inequivalent (CO)NCHH′ protons. The coupling constant of these two protons is in the range of $J = 15-16$ Hz.[4,15−20] The other doublet is generally found at $\delta \approx 3.8$ depending on the solvent. When a large deviation from this ppm value is found, the three-dimensional structure of the building block is distorted. Another characteristic signal in the ^{1}H-NMR spectrum is the singlet arising from the hydroquinone walls at $\delta = 6.5 \pm 0.1$. This signal was used in the determination of the host-guest association constants (see below). The IR spectra of DPGU derivatives always show a strong absorption of the urea carbonyl groups [ν(CO) at 1705 ± 5 cm^{-1} (KBr disk)]. This carbonyl stretching frequency can be used to observe interactions involving the carbonyl group. For example, hydrogen bonding between the carbonyl group and resorcinol derivatives induces a shift of -25 ± 5 cm^{-1}, as has been described in the literature [16,21,22].

The ^{1}H- and ^{13}C-NMR spectra of **3** and **4** indicated that the concave part of the host, i.e. where the binding of substrates occurs, is similar to that of the rigid clip molecule **5** (see Figure 2). The coupling constant of the doublet at $\delta \approx 5.5$ and the chemical shift of the hydroquinone parts were in good agreement with literature values for these type of compounds[4,15,16,18−20]. In the ^{31}P{^{1}H}-NMR spectrum singlets at $\delta = -21.1$ and -21.7 were found for **3** and **4**, respectively, which are values similar to those of other alkyldiphenylphosphanes. The IR spectra of **3** and **4** showed a carbonyl resonance at the expected frequency around 1710 cm^{-1}. The elementary analyses of ligands **3** and **4** showed that two molecules of water are present in the host in the solid state. This could be confirmed by IR and NMR spectroscopy, which both revealed small amounts of water. These water molecules did not seem to disturb any of our further studies and therefore no attempts were made to remove them.

The various transition metal complexes of ligands **3** and **4** have ^{31}P-NMR resonances (see Table 1) at higher ppm values compared to the free tetrapodants. The difference between the chemical shift of the free ligand and that of its transition metal complex ($\Delta\delta_{compl}$) is a suitable tool to determine what type of complex has been formed. The ^{31}P-NMR values of these complexes are similar to phosphanemetal complexes known from literature,[23][24] showing that ligands **3** and **4** are suitable ligands for coordination chemistry studies. A comparison of the change in chemical shift on coordination ($\Delta\delta_{compl}$) with values found in literature leads to the following conclusions about the immediate surroundings of the transition metal centres. All complexes except **L**[Pd(TCNE)]$_2$ have a square planar conformation. Complexes containing the PdMeCl fragment have two equal, *trans*-coordinated phosphane moieties, which can be derived from the singlet in the ^{31}P{^{1}H}-NMR spectrum. Complexes **L**(PdCl$_2$)$_2$ displayed a singlet in the ^{31}P{^{1}H}-NMR spectrum around $\delta = 13$. From literature it

Scheme 2. Schematic representation of the synthesis of the metal complexes (used starting compounds: $(PPh_3)_2PdCl_2$; $(COD)PdCl_2$; $(PPh_3)_2PdMeCl$; (COD)PdMeCl; i) $Pd(DBA)_2$, ii) TCNE; $(CH_3CN)_4Pd(BF_4)_2$; $(PPh_3)_2PtCl_2$; $(PPh_3)_2RhCl(CO)$; $[PPh_3)_2IrCl(CO)]$



is known that the value of $\Delta\delta_{compl}$ after the formation of a *cis*-$PdCl_2$ complex is 43−47 ppm, whereas 32−36 ppm is found when *trans* complexes are formed.[24] In our case the values are $\Delta\delta_{compl} = 34.2$ for **3**(PdCl$_2$)$_2$ and 36 ppm for **4**(PdCl$_2$)$_2$, which indicates that bimetallic *trans*-coordinated complexes have been formed.

In this series of complexes, **3**(PtCl$_2$)$_2$ and **4**(PtCl$_2$)$_2$ are the only *cis*-coordinated compounds we were able to isolate. The ^{31}P-NMR spectra of these complexes showed coupling constants around $^1J_{Pt\text{-}P} = 3500$ Hz (Table 1, entries 9 and 10), which indicates the formation of *cis* complexes.[23] These coupling constants were also observed in the ^{195}Pt-NMR spectrum of **4**(PtCl$_2$)$_2$, which afforded a triplet at $\delta = -4390$. In addition to the magnitude of the coupling constant ($^1J_{Pt\text{-}P}$), the ^{195}Pt chemical shift itself is indicative of a *cis*-coordinated complex. The typical chemical shift value of a *trans* complex is found at $\delta = -3950$.[25] For electronic reasons, i.e. the larger *trans* influence of phosphanes compared to chloride, $PtCl_2$ complexes of phosphane ligands with small cone angles prefer *cis* coordination.

The zero-valent palladium complexes (Table 1, entries 7 and 8) are stabilised by the electron-poor alkene TCNE, which reduces the electron density on the Pd^0 centre. The coordination mode around the metal centre is probably pseudo-tetrahedral, as has been found for several crystal structures of related Pd^0 complexes.[26] The IR spectra of

3[Pd(TCNE)]$_2$ and **4**[Pd(TCNE)]$_2$ showed sharp bands of the CN vibration of the TCNE molecule. The values were found at 2213 cm^{-1} and 2220 cm^{-1}, respectively, which are in good agreement with values reported in the literature for TCNE metal complexes.[26] The urea carbonyl groups in the ligands gave rise to strong and sharp bands at 1707 cm^{-1} and 1710 cm^{-1} in **3**[Pd(TCNE)]$_2$ and **4**[Pd(TCNE)]$_2$, respectively.

The two ionic palladium(II) complexes of **3** and **4** are square-planar complexes. The phosphane moieties in these complexes are coordinated in a *trans* fashion as can be seen from the phosphorus chemical shift values[27] (δ = 38.4 and 42.8 for **3**[Pd(BF$_4$)$_2$]$_2$ and **4**[Pd(BF$_4$)$_2$]$_2$, respectively). In the solid state the two Pd^{II} tetrafluoroborate complexes still contain one molecule of CH_3CN per Pd atom, as could be concluded from the elementary analyses of **3**[Pd(BF$_4$)$_2$]$_2$ and **4**[Pd(BF$_4$)$_2$]$_2$. However, their IR spectra did not show a band at 2100−2000 cm^{-1}, the typical region of a coordinated CH_3CN molecule. The IR spectra did show strong carbonyl bands at 1648 cm^{-1} for **3**[Pd(BF$_4$)$_2$]$_2$ and at 1670 cm^{-1} for **4**[Pd(BF$_4$)$_2$]$_2$. The shifts of 60 cm^{-1} and 40 cm^{-1} compared to the **L**(PdCl$_2$)$_2$ complexes, indicate that there is an interaction between the carbonyl group of the ligand and the cationic palladium centre. Electron donation of the urea carbonyl group to the Pd^{II} centre will result in a reduced bond strength, leading to an absorption at a lower frequency. This frequency shift is larger in **3**[Pd(BF$_4$)$_2$]$_2$ than that in **4**[Pd(BF$_4$)$_2$]$_2$, probably because the shorter spacer groups in the latter complex enforce a shorter metal-to-carbonyl distance. The interaction between the carbonyl group and the metal centre could not be detected in solution. The cationic complexes dissolve in polar, coordinating solvents only (e.g. CH_3CN or DMSO), which replace the coordinated carbonyl groups.

The iridium and rhodium complexes in Table 1 are similar in structure to the original Vaska complex[28] that contains two triphenylphosphane ligands coordinated in a *trans* fashion to an iridium centre. The rhodium complex showed a doublet in the $^{31}P\{^1H\}$-NMR spectrum with $^1J_{Rh\text{-}P}$ = 124 Hz, indicative of *trans* coordination.[29] We also determined the ^{103}Rh chemical shift of **4**[RhCl(CO)]$_2$, which was found at δ = −419, close to that of reference compound (PPh$_3$)$_2$RhCl(CO).[25] The IR spectra of **3**[RhCl(CO)]$_2$ and **4**[RhCl(CO)]$_2$ showed bands for the urea carbonyl groups ($\tilde{\nu}$ = 1710 and 1708 cm^{-1}) and for the carbon monoxide ligand [ν(CO)$_{Rh}$]. The latter absorptions were found at 1970 and 1972 cm^{-1}, respectively, which are slightly lower values than those found in (PPh$_3$)$_2$RhCl(CO). Finally, we determined the molecular weight of complex **4**[RhCl(CO)]$_2$ in a dichloromethane solution (by vapour pressure osmometry) and found a value of 1850 ± 100 (calcd. 1919). The molecular weight determination of **3**[RhCl(CO)]$_2$ proved to be difficult due to its poor solubility.

The $^{31}P\{^1H\}$-NMR spectra of the iridium complexes of **3** and **4** showed a singlet for both compounds (see Table 1, entries 13 and 14), proving the formation of a *trans* complex. The peaks of the CO ligand [ν(CO)$_{Ir}$] in the infra red spectra of **3**[IrCl(CO)]$_2$ and **4**[IrCl(CO)]$_2$ were found at a frequency 3 cm^{-1} below that of the original Vaska complex (1962 cm^{-1}). In these iridium complexes the band of the urea carbonyl group was found at 1710 ± 2 cm^{-1} (in KBr).

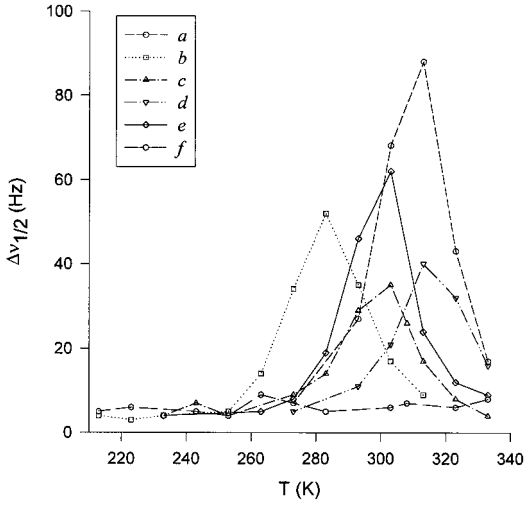
We attempted to isolate the cationic complexes **3**[Rh(CO)$^+$]$_2$ and **4**[Rh(CO)$^+$]$_2$, by the reaction of $AgBF_4$ with the two **L**[RhCl(CO)]$_2$ complexes. Turbid solutions containing a fine precipitate were formed after the addition of $AgBF_4$, but the precipitate could not be removed; centrifugation and subsequent filtration with Celite did not result in the removal of AgCl. IR measurements on the crude complexes showed that the $\nu(CO)_{Rh}$ had shifted to a higher frequency (1990 cm^{-1}). The peaks of the urea carbonyl group shifted approximately 30 cm^{-1} to a lower frequency in both **3**[Rh(CO)$^+$]$_2$ and **4**[Rh(CO)$^+$]$_2$. These frequency shifts for both the urea carbonyl and the coordinated CO molecule strongly indicate the formation of a cationic Rh^I complex in which an interaction exists between the cationic Rh centre and the urea carbonyl group. The positive shift of $\nu(CO)_{Rh}$ indicates a reduced π back donation of the electron-poor cationic rhodium(I) centre to the coordinated CO molecule. The negative shift of the urea carbonyl band indicates that the carbonyl group coordinates to the cationic rhodium(I) centre. This electron donation was also found in the aforementioned cationic palladium(II) complexes, which showed a larger shift of $\Delta\nu$ = −60 cm^{-1} and $\Delta\nu$ = −40 cm^{-1} for **3**[Pd(BF$_4$)$_2$]$_2$ and **4**[Pd(BF$_4$)$_2$]$_2$, respectively.

Variable-Temperature NMR Experiments

To investigate a possible interaction between the phosphane end groups of **4** and guests we recorded the ^{31}P-NMR spectra of **4** and five host-guest complexes of **4** with resorcinol derivatives. Figure 1 shows the temperature dependence of the $^{31}P\{^1H\}$ line width of these complexes. At 333 K all the $^{31}P\{^1H\}$-NMR signals were visible as sharp singlets having a line width of $\Delta\nu_{1/2}$ = 5−7 Hz. These are the normal values in $^{31}P\{^1H\}$-NMR spectra. When **4** was measured without additives, this sharp singlet remained in the temperature range of T = 223−333 K. The metal complex **4**[RhCl(CO)]$_2$ also gave rise to a sharp signal in this temperature range. Experiments using a mixture of **4** and a resorcinol derivative , however, showed a gradual increase in the $\Delta\nu_{1/2}$ of the ^{31}P signal on lowering of the temperature. The $\Delta\nu_{1/2}$ passed through a maximum value at T_{max}, followed by a decrease in $\Delta\nu_{1/2}$ on further lowering of the temperature. The chemical shift of the ^{31}P signal also shifted on variation of the temperature. At high temperatures the signal was found at δ = −20.5, whereas at low temperatures, the signal shifted to δ = −24. The substrate apparently has an influence on both the value of $\Delta\nu_{1/2}$ and the T_{max} at which the maximum broadening is found. T_{max} and $\Delta\nu_{1/2}$ were also affected by the amount of substrate present. When a mixture of one equivalent of **4** and 6.5 equivalents of octyl 3,5-dihydroxybenzoate was measured, the value of T_{max} was found at 313 K having a $\Delta\nu_{1/2}$ of 88 Hz. When the host-guest ratio was lowered to 1:2, the value of T_{max} was found at a lower temperature (283 K) and the maxi-

mum broadening was now 52 Hz. The size of the substituent on resorcinol also had an effect on the value of $\Delta\nu_{1/2}$. 5-Chlororesorcinol, for example, had a smaller effect on $\Delta\nu_{1/2}$ than the aforementioned octyl ester of 3,5-dihydroxybenzoic acid. These measurements indicate that the flexible spacer groups, attached to the concave part of tetrapodant **4**, have an interaction with an incoming substrate. In a reference experiment without addition of a substrate no change in line width was observed. This indicates that the presence of a substrate is required to induce this line broadening. The nature of the interaction between **4** and the substrates, however, cannot be determined from these experiments.

Figure 1. Plot of the line width ($\Delta\nu_{1/2}$) of the ^{31}P-NMR signal of **4** versus temperature (T) in the presence of various resorcinol derivatives (*a:* [**4**]/[octyl 3,5-dihydroxybenzoate] = 1:6.5; *b:* [**4**]/[octyl 3,5-dihydroxybenzoate] = 1:2; *c:* [**4**]/[olivetol] = 1:7.4; *d:* [**4**]/[5-chlororesorcinol] = 1:6.5; *e:* [**4**]/[5-(*p*-tol)resorcinol] = 1:4; *f:* **4** without additives) (conditions: solvent $CDCl_3$, [**4**] = 8×10^{-3} M)



Association Constant Determinations

In order to determine the association constants of host-guest complexes between **1**−**4** and guests the ^{1}H-NMR shifts of the aromatic-wall protons of the tetrapodants were monitored. These signals shift to lower ppm values on association with an aromatic guest molecule and a chemically induced shift (CIS) is observed. Dihydroxybenzenes bind in the cavity of the host molecule via hydrogen bonds between the hydroxy groups of the guest and the urea carbonyl groups of the host molecule[15,16,22]. A second interaction is π-π stacking between the aromatic walls of the host and the aromatic ring of the guest molecule. Thirdly, electrostatic repulsion might occur, which diminishes the total bond strength between the host and its guest.

Resorcinol derivatives containing electron-withdrawing groups at the 5-position bind relatively strongly to **4** (see Table 2). Titration experiments using 5-chlororesorcinol and **4** resulted in an association constant of $K = 4704$ M^{-1}. Electron-donating groups on the resorcinol ring, like alkyl substituents have a slightly negative influence on the association constant of **4** and a guest, e.g. K is 1676 M^{-1} for olivetol (5-pentylbenzene-1,3-diol). Resorcinol derivatives with an aromatic substituent at the 5-position also give rise to increased association constants ($K > 6200$ M^{-1}). An additional π-π stacking interaction between the phenyl groups of the diphenylphosphane moieties and the additional aromatic ring of the substrates may be responsible for this increase in binding affinity. These numbers (except those found with aryl-substituted resorcinol derivatives) are in reasonably good agreement with the values recently published by Reek and co-workers.[16] They used compound **5** in their studies of the binding properties of molecular clips based on DPGU and showed that electron-donating groups on the resorcinol guests lead to reduced association constants. Electron-withdrawing groups on the guest increase the acidity of the hydroxy groups and the π-π stacking interactions, which both result in an increase in association constant. Reek and co-workers tested a number of resorcinol derivatives in their study and found a linear Hammet relationship between the free energy of association (ΔG_{ass}) and the σ_m' values of the substituents on the 5-position of resorcinol.

Table 2. Association constants of tetrapodant **4** with several resorcinol derivatives

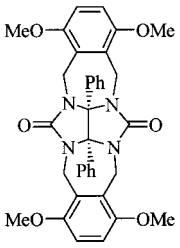
Guest	K [M^{-1}][a]	CIS [ppm]
olivetol	1676 (61)	−0.45
5-chlororesorcinol	4704 (407)	−0.43
5-bromoresorcinol	5360[b] (164)	−0.34
5-iodoresorcinol	3952 (272)	−0.37
5-phenylresorcinol	6537[b] (257)	−0.44
5-(4-chlorophenyl)resorcinol	6228 (132)	−0.44
5-(4-methylphenyl)resorcinol	6437 (556)	−0.48
octyl 3,5-dihydroxybenzoate	7406 (431)	−0.45

[a] Duplo experiments, obtained from NMR titrations using $0.25-0.75 \times 10^{-3}$ M solutions of host and $2.5-7.5 \times 10^{-3}$ M solutions of guest compound in $CDCl_3$, errors are given in parentheses, $T = 293$ K. − [b] Single experiment; association constants were calculated using the Granot[42] procedure.

A plot of the ΔG_{ass} values calculated from the data collected in Table 2 versus σ_m, did not show a linear relationship. The only difference between our tetrapodants and **5** is that the latter does not contain flexible spacer groups (including the PPh_2 moieties). These spacer groups are probably responsible for the non-linear relationship between σ_m and ΔG_{ass}. They can interact with an incoming substrate, as shown by the lineshape analyses of the $^{31}P\{^1H\}$-NMR spectra (vide supra), and therefore influence the association constant. In the case of **3** and **4** the steric bulk of the end group will also be of great importance and contribute to the magnitude of the association constant. The two resorcinol derivatives substituted with alkyl chains (olivetol and octyl 3,5-dihydroxybenzoate), for example, give rise to relatively low association constants compared to the values that would be expected on the basis of their σ_m values.

The results obtained for tetrapodants **1**−**4** and olivetol (see Table 3), lead to two conclusions: Larger end groups

Figure 2. Molecular clip **5** used in association constant studies by Reek[16] and co-workers



5

on the ethylene glycol chains have a negative effect on the association constant using olivetol as the guest. Replacement of the chlorine groups in **1** by diphenylphosphane moieties giving **3** causes a decrease of the association constant of 20%. A similar decrease of 20% is found when **2** (chloro compound) and **4** (PPh_2 compound) are compared. This is probably the result of a steric interaction between the large PPh_2 groups and the substrate. Another explanation for this drop in binding affinity might be that one of the phenyl groups of the PPh_2 moieties is clammed between the aromatic walls of the cavity, which will compete with binding of the guests. The latter explanation could not be confirmed by low-temperature NMR because of the low solubility of **4** at lower temperatures.

Table 3. Association constants of tetrapodants **1**–**4** with olivetol in $CDCl_3$

Host	K [M^{-1}][a]	CIS [ppm]
1	2769 (148)	−0.56
2	2025 (98)	−0.54
3	2201 (165)	−0.46
4	1676 (61)	−0.45

[a] Duplo experiments, obtained from NMR titrations using 0.5×10^{-3} M solutions of host and 5×10^{-3} M solutions of guest compound, errors are given in parentheses, $T = 293$ K; association constants were calculated using the Granot[42] procedure.

The increase of the number of ethylene glycol units in the spacer arms also has a negative effect on the association constant between host and guest, as can be seen when **1** is compared with **2** and when **3** is compared with **4**. A decrease of the association constant of approximately 20% is found when the flexible arms are extended with one ethylene glycol unit. This decrease of the association constant is probably caused by a difference in entropy loss after the formation of a host-guest complex. Binding of a guest molecule will restrict the rotational and translational movements of the side arms of the host. In particular rotation around the $ArO-CH_2$ bond will be hampered. This can be derived from the ^{1}H-NMR spectra of the host in the presence of guest molecules. The CH_2 groups of the side arms give rise to two signals, which indicates a restricted rotation. It should be noted that the effect becomes less for the distant CH_2 groups in host **4**.

In the absence of a substrate, the "small" tetrapodants **1** and **3** possess less degrees of freedom compared to their "larger" analogues **2** and **4**, because less rotational movements are available. Therefore, after binding of a guest, the ΔS_{ass} value will be less for hosts **1** and **3** than that of **2** and **4**. A less negative ΔS_{ass} value will result in a more negative ΔG_{ass} value and thus higher association constants for **1** and **3**.

Table 4. Association constants of bimetallic complexes of **3** and **4** with olivetol

Metallohost	K [M^{-1}][a]	CIS [ppm]
3$(PdCl_2)_2$	n.d.[b]	n.d.[b]
3$(PdMeCl)_2$	562 (367)	−0.02
3$[Pd(TCNE)]_2$	n.d.[b]	n.d.[b]
3$(PtCl_2)_2$	n.d.[b]	n.d.[b]
3$[RhCl(CO)]_2$	164 (73)	−0.02
4$(PdCl_2)_2$	2346 (499)	−0.44
4$(PdMeCl)_2$	2502 (77.83)	−0.47
4$[Pd(TCNE)]_2$	960 (362)	−0.48
4$(PtCl_2)_2$	4314[c] (338)	−0.47
4$[RhCl(CO)]_2$	4514[c] (835)	−0.51

[a] Single-fold experiments, obtained from NMR titrations using 5×10^{-3} M solutions of host and 50×10^{-3} M solutions of guest compound in $CDCl_3$, errors are given in parentheses, $T = 293$ K. – [b] n.d. = not determined, NMR signals did not change and $K < 100$ M^{-1}. – [c] Duplo experiment; association constants were calculated using the Granot[42] procedure.

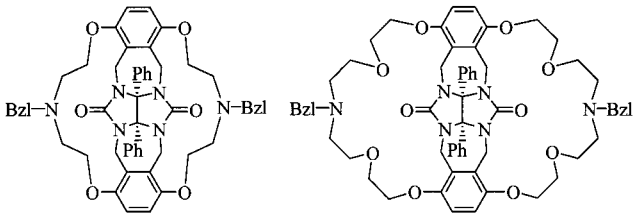
Host-Guest Binding Properties of Metal Complexes

As discussed above the tetrapodant ligands **3** and **4** and appropriate transition metals form basket-shaped bimetallic complexes, which have different cavity sizes. The binding properties of transition metal complexes of **3** were found to be rather poor compared to the free ligand. The complexes **3**$[RhCl(CO)]_2$ and **3**$(PdMeCl)_2$ have binding constants of $K = 164$ M^{-1} and $K = 562$ M^{-1}, respectively, for olivetol (see Table 4). From the small chemically induced shifts (CIS) values of these host-guest complexes it can be concluded that there is hardly any interaction between host and guest. The ^{1}H-NMR signals of complexes **3**$(PtCl_2)_2$, **3**$(PdCl_2)_2$, and **3**$[Pd(TCNE)]_2$ did not change after addition of 10 equivalents of olivetol. These NMR experiments show that, after coordination of **3** to two transition metal centres, a basket is formed that is too small for substrate binding. Coordination of the phosphane moieties to a metal centre should facilitate the binding of a substrate in the cavity because a preshaped cavity is formed and less entropy will be lost during the association process. However, the cavity of complexes of ligand **3** is not large enough to give access to resorcinol derivatives.

A similar effect has been observed for host **6**, which is formed by a ring-closure reaction between **1** and benzylamine.[12,30,31] A crystal structure of **6** showed that, due to the small ring size in **6**, the $ArOCH_2$ groups (see Figure 3) are directed towards the cavity and block the entrance of this cavity[20] for entering guests. Although the transition metal complexes of ligand **3** possess a larger cavity than **6**, i.e. instead of one amine two phosphanes and a transition metal are now incorporated in the macrocycle, the cavity is probably still too small to allow a strong interaction of the host with resorcinol guest molecules.

Host **7** and its derivatives do bind dihydroxybenzene derivatives as was shown in previous studies.[3,15,20,30,32] The cavity of this host is large enough to give access to resorcinol derivatives and 2,7-dihydroxynaphthalene. The metal complexes of ligand **4** have an even larger macrocyclic cavity than **7** and will therefore be accessible for organic substrates. This is confirmed by the experimental data (see Table 4).

Figure 3. Basket-shaped host molecules **6** and **7**



Compared to free **4**, complex **4**Pd(TCNE) has a lower binding affinity to olivetol. All the other complexes of **4** show an increased affinity to this guest. The increase in association constant is partly caused by fixation of the flexible arms of the tetrapodant. The degrees of freedom are reduced compared to the free ligand, resulting in an increase in the ground-state free energy. After complexation of a substrate, a relatively small loss in entropy (ΔS_{ass}) will result in a more negative ΔG_{ass} value, and a higher association constant.

Compounds **4**$(PtCl_2)_2$ and **4**$[RhCl(CO)]_2$ form host-guest complexes with olivetol which display association constants of 4314 M^{-1} (Pt) and 4514 M^{-1} (Rh), respectively. These association constants are nearly three times as high as the value of the free phosphane tetrapodant **4**. Complexes **4**$(PdCl_2)_2$ and **4**$(PdMeCl)_2$ also show an increase in association constant when compared to free **4** and values of K = 2346 M^{-1} and 2505 M^{-1} were found, respectively.

There are several possible explanations for the observed increase in binding affinity of the metal complexes and olivetol: (i) An additional interaction between the substrate and the metal centre, e.g. a dipole-dipole interaction, (ii) a weak interaction between the oxygen atom or the aromatic ring of the substrate with the metal centre, e.g. coordination at the axial position of the metal centre, (iii) extra hydrogen-bonding interactions between the hydroxy groups of olivetol and auxiliary ligands in the complexes, e.g. Cl or CO at the metal centre, (iv) difference in flexibility of the spacer groups, (v) conformational differences between the metal complexes.

To investigate an interaction between olivetol and a transition metal centre, we measured the ^{195}Pt and ^{103}Rh chemical shifts of mixtures of **4**$(PtCl_2)_2$ with olivetol and **4**$[RhCl(CO)]_2$ with olivetol. Changes in the second and outer coordination sphere of the metal centre, as well as steric or electronic variations are known to have a pronounced effect on the chemical shift of the transition metal.[25] Addition of eight equivalents of olivetol to an NMR sample containing **4**$(PtCl_2)_2$ or **4**$[RhCl(CO)]_2$, did not affect the transition metal chemical shift of either the rhodium or the platinum complex. This indicates that, although the metal centre is probably able to come into close proximity of the binding site, it does not have an interaction with the guest.

Infrared spectroscopy was used to investigate the nature of hydrogen-bond formation between host and guest. The experiments indicated that additional hydrogen bonds between the carbon monoxide ligand of the rhodium complex and the hydroxy groups of the guest could be excluded; after the addition eight equivalents of olivetol a shift of +4 cm^{-1} was found in the IR spectrum of **4**$[RhCl(CO)]_2$. This is a too small a difference to be the result of hydrogen bonding and additionally, the shift is in the wrong direction. Hydrogen bonds to the carbon monoxide ligand would shift the carbonyl frequency to a lower value, as described by Kazarian and co-workers for other carbon monoxide containing compounds.[33] Hydrogen bonds to the metal centre itself would induce a positive shift,[33] but the reported shifts are usually larger than 20 cm^{-1}.

One example of a hydrogen bond between a platinum coordinated chloride and a phenolic hydroxy group has been reported in the literature.[34] Evidence for hydrogen bonding between a chloride ligand of our metal complex and a hydroxy group of the substrate, however, could not be found.

Monitoring the carbonyl frequency of the urea carbonyl group, showed that ligand **4** as well as its metal complexes bind olivetol via hydrogen bonds. After addition of eighth equivalents of olivetol to several **4**M_2 complexes the IR spectrum showed a shift of ν(CO) of -30 cm^{-1}. Apparently, unlike Na^+ ions the metal centres do not prevent the formation of hydrogen bonds between host and guest. Hosts of type **7** bind two Na^+ ions to their crown ether parts. In these host-guest complexes the sodium ions are responsible for the binding of olivetol, as hydrogen bonds between the carbonyl groups of the host and hydroxy groups of the guest could not be detected.[21]

Summarising, we can state that a different type of binding is not responsible for the change in binding affinity with the guest. Conformational changes in the metal complexes or restricted flexibility of the spacer groups might therefore be a likely explanation. The difference in flexibility of the spacer groups might be caused by partial ligand dissociation in solution. Perhaps the palladium–phosphorus bond in complex **4**$[Pd(TCNE)]_2$ is more labile compared to the metal–phosphorus bond in the other complexes. This may have an effect on the flexibility of the crown ether fragments, which are not as rigidly oriented as in the other metal complexes. The crown ether fragments may still have an interaction with the incoming substrate, and a compound more similar to the parent ligand **4** is formed. The lower association constant can then be explained by the larger end group on the spacer groups (i.e. PPh_2–Pd instead of PPh_2 only) which will result in a relatively low association constant (K = 960 M^{-1}).

The crown ether fragments of complexes **4**$(PtCl_2)_2$ and **4**$[RhCl(CO)]_2$ may be more hampered in their movements

and form a preshaped cavity for an incoming guest. Since the loss in entropy after complexation of a guest (ΔS_{ass}) will be smaller for these complexes compared to the parent ligand **4**, an increase in binding affinity of a factor of 2.5 is found. The same positive effect on the association constant was found for complexes **4**$(PdCl_2)_2$ and **4**$(PdMeCl)_2$, although the increase in binding affinity is only a factor of 1.5 for these complexes. Finally, a change in conformation, induced by the transition metals, cannot be excluded but the required structural information about these complexes is still lacking.

Conclusions

In this paper we report novel host molecules that possess a cavity in which substrates can be bound in addition to two transition metal centres that are potential catalysts for many reactions. A surprising increase in binding affinity for olivetol was found upon coordination of ligand **4** to various transition metals, whereas the transition metal complexes of ligand **3** are unable to bind substrates.

For host molecules **3** and **4** the association equilibria are influenced by the following factors: (i) the presence of flexible spacers, (ii) the bulk of the spacer, (iii) the size and σ_m value of substituents on the resorcinol derivative, (iv) the ring size of the (metalla)macrocycle after coordination of the phosphane moieties to a metal centre and finally, (v) the metal centre itself. As yet, not all contributing factors can be understood in full detail. These results are promising in view of future catalytic applications with this type of host compounds.

Experimental Section

General: NMR: ^1H NMR (300.1 MHz), $^{31}P\{^1H\}$ NMR (121.5 MHz), $^{13}C\{^1H\}$ NMR (75.5 MHz), ^{195}Pt NMR (64.3 MHz) and ^{103}Rh NMR (9.48 MHz) were measured with Bruker AMX 300 and DRX 300 machines. The external references were: TMS (^1H NMR and ^{13}C NMR), H_3PO_4 (^{31}P NMR) and K_2PtCl_6 (^{195}Pt NMR), $\Xi(^{103}Rh$ NMR) = 3.16 MHz at 100 MHz. ^{195}Pt NMR was measured directly, ^{103}Rh NMR was measured via the ^{31}P-inverse HMQC technique.[35][36] − IR spectra were measured with a Nicolet 510m FT-IR spectrophotometer. − Melting points were determined with a Gallenkamp MFB-595 melting-point apparatus, the values are uncorrected. − Column chromatography was performed with silica gel 60, 70−230 mesh ASTM (Merck). − Analytical TLC was performed on TLC aluminium foil, silica gel 60 F_{254} (Merck). − Microanalyses were carried out in our own laboratory with an Elementar Vario EL apparatus (Foss Electric). − M_w determinations were performed with a Hewlett-Packard vapour-pressure osmometer model 301A, with benzil as the reference compound.

Chemicals: CH_3CN and CH_2Cl_2 were distilled from CaH_2, C_6H_6 was distilled from Na/benzophenone. $CDCl_3$ used in association constant determinations was distilled from P_2O_5 before use. 1,4,8,11-Tetrakis(2-chloroethoxy)-5,7,12,13b,13c,14-hexahydro-13b,13c-diphenyl-6 H,13*H*-5a,6a,12a,13a-tetrabenz[5,6]azuleno-[2,1,8-*ija*]benz[*f*]azulene-6,13-dione[12] (**1**), 1,4,8,11-tetrakis[2-(2-chloroethoxy)ethoxy]-5,7,12,13b,13c,14-hexahydro-13b,13c-diphenyl-6 H,13*H*-5a,6a,12a,13a-tetraazabenz[5,6]azuleno[2,1,8-*ija*]benz[*f*]azulene-6,13-dione[12] (**2**), $(PPh_3)_2RhCl(CO)$,[37] $(PPh_3)_2IrCl(CO)$,[28] $Pd(DBA)_2$,[38] $(CH_3CN)_4Pd(BF_4)_2$,[39] $(COD)PdCl_2$[40] and all the 5-substituted resorcinol derivatives[41] were prepared according to literature procedures. $(PPh_3)_2PdCl_2$ and $(PPh_3)_2PtCl_2$ were obtained after refluxing PPh_3 and $PdCl_2$ or $PtCl_2$ in CH_3CN, followed by evaporation of the solvent.

Ligands

1,4,8,11-Tetrakis[(2-diphenylphosphanyl)ethoxy]-5,7,12,13b,13c,14hexahydro-13b,13c-diphenyl-6H,13H-5a,6a,12a,13a-tetrabenz[5,6]azuleno[2,1,8-ija]benz[f]azulene-6,13-dione (**3**): A solution of 2.5 g of compound **1** (3.1 mmol) in 40 ml of THF and 40 ml of benzene was titrated under N_2 at 0°C with 20 ml of a THF solution of $LiPPh_2$. The $LiPPh_2$ solution was prepared from 2.52 g of $HPPh_2$ (13.6 mmol) and 5.4 ml of 2.5 M *n*BuLi in hexane (13.5 mmol). When the solution remained orange, 40 ml of degassed H_2O was added. The H_2O layer was separated and washed with 20 ml of benzene. The collected organic layers were dried with $MgSO_4$ and concentrated. The product was dissolved in 15 ml of CH_2Cl_2 and precipitated with 100 ml of diethyl ether. After filtration, the remaining solvent was removed in vacuo. The product was purified by column chromatography with silica gel, eluent $MeOH/CH_2Cl_2$ (1:99, v/v). Yield 3.47 g (80%) of a white solid, m.p. > 195°C (dec.). − NMR ($CDCl_3$): δ_H = 7.45−7.29 (m, 40 H, P−*Ar*), 7.08−7.01 (m, 10 H, Ar*H*), 6.47 (s, 4 H, H−Ar side wall), 5.45 [d, 4 H, (CO)NCH*H*, ^2J = 15.8 Hz], 4.15 (m, 4 H, OC*H*H), 3.94 (m, 4 H, OCH*H*), 3.76 [d, 4 H, (CO)NC*H*H, ^2J = 15.8 Hz], 2.65−2.59 (m, 8 H, CH_2P); δ_P = −21.7 (s); δ_C = 158.2 (*C*=O), 150.5 (Ar*C*−O), 138.5−138.2, 134.7, 133.12−132.8, 128.8−128.5, 128.3, 113.52, 85.3 [N*C*(Ar)N], 67.59 (d, O−*C*H$_2$, $^2J_{P\text{-}C}$ = 24.8 Hz), 37.31 (N*C*H$_2$Ar), 28.61 (d, *C*H$_2$−P, $^1J_{P\text{-}C}$ = 12.8 Hz). − IR (KBr): $\tilde{\nu}$ = 3051 cm^{-1} (w), 2911 (w, OC−H), 1730 (s), 1710 (s, CO), 1482 (m), 1461 (s), 1433 (m), 1255 (m). − M_w (CH_2Cl_2): calcd. 1411; found 1445 ± 100. − $C_{88}H_{78}N_4O_6P_4 \cdot H_2O$ (1414): calcd. Metal Complexes

3*(PdCl$_2$)$_2$:* Compound **3** (20.3 mg, 14.3 μmol) was dissolved in 10 ml of benzene and 20.1 mg (28.6 μmol) of $(PPh_3)_2PdCl_2$ was added. The yellow solution was stirred for 2 h and the volume was

reduced to approximately 2 ml. The product was precipitated with 10 ml of pentane, the yellow suspension was decanted and the product was washed twice with 10 ml of pentane. The product was dried in vacuo. Yield 14.5 mg (58%) of a light yellow powder, m.p. > 245°C (dec.). – NMR ([D$_6$]benzene): δ_H = 8.2–6.7 (m, 50 H, Ar*H*), 6.26 (s, 4 H, *H*–Ar side wall), 5.66 (m, 4 H, ArOCH*H*), 5.58 [d, 4 H, (CO)NCH*H*, ^2J = 15.9 Hz], 4.33 (m, 4 H, ArOC*H*H), 3.49 (m, 4 H, C*H*HP), 3.23 [d, 4 H, (CO)NC*H*H, ^2J = 15.9 Hz], 3.20 (m, 4 H, CH*H*P); δ_P = 12.5. – IR (KBr): $\tilde{\nu}$ = 1710 cm^{-1} (s, CO), 1480 (s), 1461 (s), 1435 (s), 1351 (w), 1248 (m). – $C_{88}H_{78}Cl_4N_4O_6P_4Pd_2 \cdot 6\ H_2O$ (1764.8): calcd. C 56.39, H 4.84, N 2.98; found C 56.54, H 5.43, N 2.33.

4*(PdCl$_2$)$_2$:* Compound **4** (22.5 mg, 14.2 μmol) was dissolved in 5 ml of dichloromethane and 8.3 mg of (COD)PdCl$_2$ (28.4 μmol) was added. A small amount of PPh$_3$ was added to the solution and a clear yellow solution was obtained. After 2 h of stirring, the volume was reduced to 2 ml and 10 ml of pentane was added. The yellow suspension was decanted and the product was washed twice with 10 ml of pentane. The product was dried in vacuo. Yield 20.7 mg (75%) of a yellow powder, m.p. > 180°C (dec.). – NMR ([D$_6$]benzene): δ_H = 8.0–6.6 (m, 50 H, Ar*H*), 6.37 (s, 4 H, *H*–Ar side wall), 5.93 [d, 4 H, (CO)NCH*H*, ^2J = 15.8 Hz], 4.6–3.7 (m, 24 H, OCH_2), 3.53 [d, 4 H, (CO)NC*H*H, ^2J = 15.8 Hz], 3.08 (m, 4 H, CH$_2$C*H*HP), 2.92 (m, 4 H, CH$_2$CH*H*P); δ_P = 14.9. – IR (KBr): $\tilde{\nu}$ = 1710 cm^{-1} (s, CO), 1480 (m), 1461 (s), 1435 (s), 1248 (m). – $C_{96}H_{94}Cl_4N_4O_{10}P_4Pd_2$ (1940.8): calcd C 59.36, H 4.88, N 2.88; found C 59.08, H 5.35, N 2.70.

3*(PdMeCl)$_2$:* Compound **3** (100 mg, 71 μmol) was dissolved in 5 ml of CH_2Cl_2 and 97 mg (142 μmol) of (PPh$_3$)$_2$PdMeCl, dissolved in 10 ml of benzene, was added. The colourless solution was stirred for 2 h and the volume was reduced to approximately 2 ml. The product was precipitated with 10 ml of pentane, the suspension was decanted and the product was washed twice with 10 ml of pentane. The product was dried in vacuo. Yield 103 mg (84%) of a white powder, m.p. > 176°C (dec.). – NMR ($CDCl_3$): δ_H = 7.8–6.9 (m, 50 H, Ar*H*), 6.59 (s, 4 H, *H*–Ar side wall), 5.63 [d, 4 H, (CO)NCH*H*, ^2J = 15.9 Hz], 4.96 (m, 4 H, ArOC*H*H), 4.15(m, 4 H, ArOCH*H*), 3.64 [d, 4 H, (CO)NC*H*H, ^2J = 15.9 Hz], 3.22(m, 4 H, C*H*HP), 2.95(m, 4 H, CH*H*P), –0.36(t, 6 H, Pd–CH_3, $^3J_{P\text{-}H}$ = 6.0 Hz); δ_P = 15.4. – IR (KBr): $\tilde{\nu}$ = 1710 cm^{-1} (s), 1482 (m), 1461 (s), 1435 (s), 1253 (m). – Satisfactory analysis could not be obtained due to hygroscopicity of the compound.

4*(PdMeCl)$_2$:* Compound **4** (30 mg, 18.9 μmol) was dissolved in 5 ml of CH_2Cl_2, followed by addition of 2 ml CH_2Cl_2, containing 10 mg of (COD)PdMeCl (37.8 μmol) and a small amount of PPh$_3$. The colourless solution was stirred for 2 h, the volume was reduced to 2 ml and 10 ml of pentane was added. The suspension was decanted and the product was washed twice with 10 ml of pentane. The product was dried in vacuo. Yield 30 mg (85%) of a white powder, m.p. > 154°C (dec.). – NMR ($CDCl_3$): δ_H = 7.8–6.9 (m, 50 H, Ar*H*), 6.63 (s, 4 H, *H*–Ar side wall), 5.59 [d, 4 H, (CO)NCH*H*, ^2J = 15.8 Hz], 4.5–3.7 (m, 24 H, CH_2O), 3.66 [d, 4 H, (CO)NC*H*H, ^2J = 15.8 Hz], 3.07 (m, 4 H, C*H*HP), 2.92 (m, 4 H, CH*H*P), –0.05 (t, 6 H, Pd-CH_3, $^3J_{P\text{-}H}$ = 6.0 Hz); δ_P = 21.9. – IR (KBr): $\tilde{\nu}$ 1710 cm^{-1} (s, CO), 1483 (m), 1460 (s), 1433 (s), 1248 (m). – $C_{98}H_{100}Cl_2N_4O_{10}P_4Pd_2 \cdot 4\ H_2O$ (1899.8): calcd. C 59.64, H 5.52, N 2.84; found C 59.73, H 5.34, N 2.52.

3*[Pd(BF$_4$)$_2$]$_2$:* A solution of 24.8 mg of compound **3** (17.5 μmol) in 2 ml of CH_2Cl_2 was added to a solution of 15.5 mg of (CH$_3$CN)$_4$Pd(BF$_4$)$_2$ (35 μmol) in 5 ml of CH_3CN. After stirring for 3 h, the solution was concentrated to dryness, yielding 35.5 mg (95%) of a yellow powder, m.p. > 175°C (dec.). – NMR (CD_3CN): δ_H = 7.8–7.3 (m, 50 H, Ar*H*), 7.18 (s, 4 H, *H*–Ar side wall), 5.5 [d, 4 H, (CO)NCH*H*, ^2J = 16.1 Hz], 4.62 (m, 4 H, OCH*H*), 4.41 (m, 4 H, OC*H*H), 4.02 [d, 4 H, (CO)NC*H*H, ^2J = 16.1 Hz], 3.53 (m, 4 H, C*H*HP), 3.37 (m, 4 H, CH*H*P); δ_P = 38.4. – IR (KBr): $\tilde{\nu}$ = 3444 cm^{-1} (m, O–H), 3365 (m, O–H), 3062 (w), 2924 (w), 1648 (s, CO), 1586 (m), 1470 (s), 1437 (s), 1400 (s). – $C_{88}H_{78}B_4F_{16}N_4O_6P_4Pd_2 \cdot 2\ H_2O \cdot 2CH_3CN$ (1796.8): calcd. C 52.87, H 4.25, N 4.02; found C 52.46, H 4.45, N 4.36.

4*[Pd(BF$_4$)$_2$]$_2$:* This compound was prepared in a similar way as **3**[Pd(BF$_4$)$_2$]$_2$ with the following amounts: 13 mg of (CH$_3$CN)$_4$Pd(BF$_4$)$_2$ (29.3 μmol) and 23.3 mg of compound **4** (14.7 μmol). Yield 32.1 mg (93%) of a white powder, m.p. > 172°C (dec.). – NMR (CD_3CN): δ_H = 8.1–7.0 (m, 50 H, Ar*H*), 6.82 (s, 4 H, *H*–Ar side wall), 5.70 [d, 4 H, (CO)NCH*H*, ^2J = 16.0 Hz], 4.7–3.7 [m, 28 H, (CO)NC*H*H, CH_2O], 3.08 (m, 8 H, CH_2P); δ_P = 42.8. – IR (KBr): $\tilde{\nu}$ = 3381 cm^{-1} (m, O–H), 3060 (m, O–H), 2928 (m), 2883 (w, OC–H), 1670 (s, CO), 1587 (m), 1478 (s), 1437 (s), 1259 (m). – $C_{96}H_{94}B_4F_{16}N_4O_{10}P_4Pd_2 \cdot 2\ CH_3CN$ (1972.8): calcd. Keywords: Diene complexes / Metallacycles / Palladium

The complexes *rac*-**5** and *rac*-**6** of the *trans*-5-palladatricyclo-[4.1.0.0^{2,4}]heptane *rac*-**2a** with norbornadiene and 1,5-cyclooctadiene were prepared and investigated by X-ray structure determination. With open-chained, unsaturated substrates, e.g. **7** and **8**, no complexes could be isolated. In all cases no insertion of the olefin into the metal–carbon bond of the palladacycloalkane was observed.

trans-5-Palladatricyclo[4.1.0.0^{2,4}]heptanes (PTHs) are an interesting class of organometallic compounds in which two chiral carbon atoms are directly bound to a palladium center. The first derivatives described in the literature were Binger's racemic phosphane complexes *rac*-**1**.[1] We recently published the preparation and resolution of *rac*-PTH-tetracarboxylates **2**.[2] **2** itself is a coordination polymer,[3] monomeric complexes are for example obtained with diphosphanes[2] or acetone[3][4] as ligands. The PTHs are chiral bis-homo derivatives of the corresponding palladoles[5] − the latter being important catalysts for the enyne cyclization[6], the enyne metathesis[6][7] and related reactions.[8] That the PTHs show catalytical properties has been proven by their ability to catalyze the cycloisomerization/dimerization of allenyl ketones to furans.[9]

In reactions catalyzed by PTHs, a coordination of unsaturated substrates is the first step. Here we describe the first diolefin complexes of PTHs which may serve as model compounds for the coordination of such unsaturated substrates during catalysis reactions.

rac-**1** L = PR_3 **2** E = CO_2R a R = Me

Synthesis of the Diene Complexes

For our investigation we used the PTH *rac*-**2a**.[2] We focused on chelating dienes, norbornadiene (NBD, **3**) and 1,5-cyclooctadiene (COD, **4**) were used. An excess of **3** or **4** was added to solutions of *rac*-**2a** in acetone. Then most of the acetone was evaporated in vacuo and pentane was added to the remaining solution. On cooling to 0°C the complexes *rac*-**5** and *rac*-**6** crystallized. Efforts with other unsaturated substrates like the diyne **7** or the enyne **8** without a rigid structure did not lead to defined products.

X-ray Structure Determination and Discussion

By the method described above, suitable crystals of *rac*-**5** and *rac*-**6** for X-ray structure determination could be obtained. The ORTEP plot of *rac*-**5** is shown in Figure 1, the one of *rac*-**6** in Figure 2. Selected crystallographic data of both compounds are listed in Table 1.[10]

rac-**5** approximately has a two-fold symmetry with the exception of the relative orientation of the methoxycarbonyl

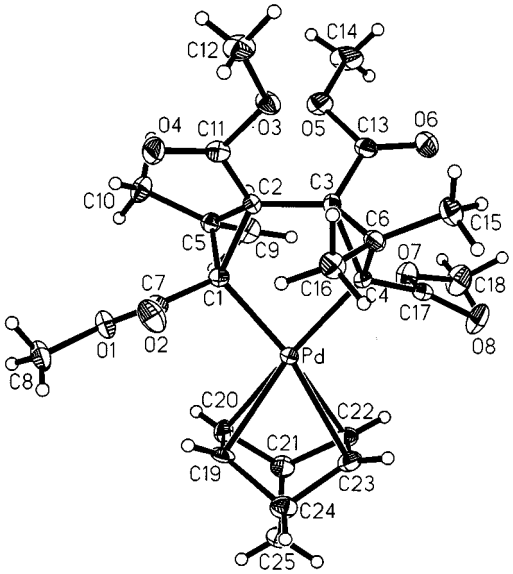

Figure 2. ORTEP plot of *rac*-**6**

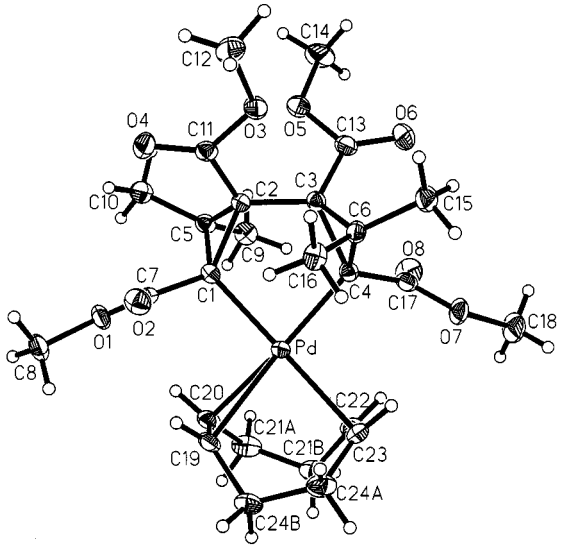

groups attachted to C1 and C4. Two molecules of *rac*-**6** crystallize in the asymmetric unit, their structures show only small differences in their conformations. The Pd−C1 and Pd−C4 bond lengths are 2.05 Å in *rac*-**5** and 2.06−2.08 Å in *rac*-**6**. This is slightly longer than in the acetone complexes of PTHs (2.02 Å)[3][4] and slightly shorter than in the phosphane complexes of PTHs (2.11 and 2.13 Å, respectively)[2] and reflects the *trans* influence[11] of the different donors.

In *rac*-**5** the distances from Pd to the C atoms of the NBD group range from 2.26 to 2.31 Å. Similar distances have been found in the crystal structure of the corresponding NBD-tetrakis(methoxycarbonyl)palladole complex[12]. The hydrogen atoms at C19, C20, C22, and C23 deviate about 0.14 Å from the planes of the C−C double bonds in a direction away from the Pd atom. The molecular conformation is stabilised by a number of weak, electrostatic, intramolecular O···H contacts with distances equal to the van der Waals contact distance of 2.4 Å [O2···H16a: 2.40(3) Å; O4···H10a: 2.32(5) Å; O6···H15a: 2.34(5) Å; and O7···H9a: 2.48(4) Å]. Similar intramolecular interactions have been observed in the PTH part of *rac*-**6**. The crystal packing shows no short intermolecular contacts.

Table 1. Selected bond lengths [Å], bond angles [°], and dihedral angles [°] for *rac*-**5** and *rac*-**6**

	rac-**5**	*rac*-**6** (molecule 1)	*rac*-**6** (molecule 2)

C1−Pd−C23	162.4(1)	162.6(1)	167.3(1)
C4−Pd−C19	162.2(1)	163.5(1)	163.0(1)
C4−Pd−C1−C2	1.9(3)	−3.2(1)	2.5(1)
C1−Pd−C4−C3	−5.0(3)	0.1(1)	−4.9(1)
C1−C2−C3−C4	−5.7(5)	−5.8(2)	−4.2(2)

The COD ligand in *rac*-**6** occupies a twist-boat conformation as known from most of the other (COD)Pd^{II} complexes.[13] The bond lengths of Pd to the olefinic carbon atoms of the COD range from 2.28 to 2.34 Å, such values were also reported for the known (COD)Pd^{II} complexes.[8] Different from the NBD ligand in *rac*-**5**, one hydrogen atom of each double bond of the COD ligand in *rac*-**6** shows weak intramolecular O···H contacts with distances equal to the van der Waals contact distance (2.46 and 2.41 Å, respectively) to the ether oxygen atom of the ester group at C1 and C4 of the PTH framework.

The angle between the plane through C1−Pd−C4 and the plane through Pd and the midpoints of the C19−C20 and C22−C23 double bonds is 2.6° in *rac*-**5** and 0.4° for molecule 1 and 4.5° for molecule 2 in *rac*-**6**! Essentially this is, like in the bis(acetone) complexes (6.9 and 9.3°, respectively),[3][4] the square planar coordination as one would expect for Pd^{II}. On the other hand in complexes with sterically demanding bidentate phosphanes a tilt of up to 30° was observed.[2]

Ittel's and Ibers's[14] structural parameters α and β characterize the hybridization changes at the coordinated olefinic carbon atoms. α is defined as the angle between the normals of the two planes defined by the three atoms of each $R_2C=$ unit of the olefin, so α would be 0° for a planar alkene. β and β′ are the angles between the olefinic C=C bond and the normals mentioned before, so the β angles decrease from 90° with increasing distortion. For *rac*-**5** and *rac*-**6** these parameters are listed in Table 2. Clearly, the ole-

fins are non-planar, but the values correspond to those of other related complexes,[13] so the coordinated olefin does not experience any unusual distortion.

Table 2. Structural parameters for *rac*-**5** and *rac*-**6**

	rac-**5**	*rac*-**6** (molecule 1)	*rac*-**6** (molecule 2)
	C19−C20, C22−C23	C19−C20, C22−C23	C19−C20, C22−C23
α	19°, 23°	18°, 15°	18°,16°
β	85°, 75°	82°, 80°	81°, 81°
β′	77°, 82°	81°, 85°	82°, 84°

PTHs are the first palladacycloalkanes without stabilizing ligands at the palladium center, the coordination sphere is saturated by easily substitutable solvent molecules.[4][9] Since it is part of a cyclopropyl ring, the carbon atom attached to the palladium center has a hybridization close to sp^2.[15] The fact that only coordination but no insertion of the olefins was observed, proves the stability of the Pd−C bonds in these exceptional palladacycloalkanes. This is in agreement with the formation of the PTHs: even when the Pd^0 precursor was subjected to an excess of cyclopropene, only the PTH was formed and the remaining cyclopropene remained untouched. This is in contrast to Binger's results. He also observed the formation of seven-membered metallacycles[16] and nine-membered[17] palladacycles or products of a reductive elimination from such insertion products, i.e. cyclic trimers[18] or tetramers[17][18] of the cyclopropene. For catalysis reactions this suggests that the PTH framework is also not destroyed readily by insertion (maybe followed by reductive elimination) reactions.

^{1}H- and ^{13}C-NMR Spectra

The chemical shifts of the coordinated and uncoordinated diene ligand are listed in Tables 3 and 4.

Table 3. NMR data of free NBD and *rac*-**5** in $CDCl_3$ at 298 K[a]

	free NBD	*rac*-**5**	Δδ
^{1}H NMR	1.95	1.98	0.03
	3.53	3.96	0.43
	6.66	5.71	−0.95
		6.23	−0.43
^{13}C NMR	50.4	50.4	0.0
	75.2	73.4	−1.8
	143.2	107.6	−35.6
		113.8	−29.4

[a] Chemical shifts in ppm (δ).

In the coordinated dienes the symmetry is reduced, thus some NMR signals of the free diene split into several new signals of the corresponding nuclei in the coordinated diene. As one can see, only the chemical shift of the olefinic hydrogen and carbon atoms experience a relevant change.

While in the coordinated COD the signals of the olefinic hydrogen atoms are both shifted to lower and higher field by the same amount, in the NBD they are both shifted to lower field. The signals of the olefinic carbon atoms are all shifted downfield by coordination to *rac*-**2a**, but again the effect is stronger in the NBD ligand. The C_2 symmetry of the PTHe leads to a chemical shift difference between the signals of the two non-equivalent carbon atoms of the coordinated olefin of about 5 ppm in both *rac*-**5** and *rac*-**6**, but the signals of the two non-equivalent hydrogen atoms differ by 0.52 ppm in *rac*-**5** and 1.13 in *rac*-**6**.

Table 4. NMR data of free COD and *rac*-**6** in $CDCl_3$ at 298 K[a]

	free COD	*rac*-**6**	Δδ

Conclusion

PTHs readily form complexes with chelating, rigid dienes. In these complexes, where Pd is surrounded by six carbon atoms, only a small deviation from a perfect square planar coordination (considering the midpoints of the double bonds) was observed. Like the related bis(acetone) complexes of PTHs, this demonstrates that the strong deviation from a square-planar coordination geometry observed with diphosphanes originates from intramolecular sterical repulsion of the latter ligands and substituents on the PTH framework. No insertion of the olefins into the Pd−C bond of the PTH was observed. This suggests that the PTHs remain intact during catalysis reactions or at least show a low tendency for insertion of unsaturated substrates.

This work was supported by the *Deutsche Forschungsgemeinschaft* and the *Fonds der Chemischen Industrie*. Furthermore we are grateful to the *Degussa AG* for the donation of palladium salts.

Experimental Section

General: All operations were carried out under N_2 and in dry solvents. *rac*-**2a**[2][4] was prepared according to literature procedures. − IR: Perkin-Elmer 1600. − NMR: Bruker AM 250 (250 and 62.9 MHz for ^{1}H and ^{13}C, respectively). $CDCl_3$ as solvent δ_H = 7.25; δ_C = 77.0. The degree of substitution of the C atoms was determined by a combination of DEPT-135 and DEPT-90. − MS: VG-Instruments-Micro-Mass Tris 2000, EI 70 eV, quadrupol analysator and Finnigan CH7A (80 eV). − Melting points (uncorrected): Kofler hot-stage.

rac-**5**: To 50 mg (10.5 μmol) of *rac*-**2a** in 5 ml of acetone 2 equiv. of norbornadiene (**3**, 19.3 mg, 21.0 μmol) were added. After 30 min at room temparatue, the solution was concentrated to about 0.5 ml in a rotary evaporator and 0.5 ml of pentane was added. Then the soution was placed in a refrigerator (0°C), over night 38.8 mg (65%) of *rac*-**5** precipitated as yellow crystals. − M.p. 197°C. − IR (neat, NaCl): $\tilde{\nu}$ = 2947 cm^{-1}, 1715, 1691, 1432, 1369, 1310, 1221,

Keywords: Iridium / Rhodium / Amino acids / Sandwich complexes / Bioorganometallic chemistry / Relativistic effects

η^5-Pentamethylcyclopentadienyliridium(III) and -rhodium-(III) sandwich complexes of the type [(η^5-Cp*)M(η^6-aa)]-(CF_3SO_3)$_2$ (M = Ir, Rh; **3–14**) containing L-tyrosine, L-tryptophan and L-phenylalanine derivatives (aa) can be prepared by treatment of [(η^5-Cp*)ML_3] (CF_3SO_3)$_2$ [L = thf, $(CH_3)_2CO$, CH_3CN] with the appropriate bioligand in thf for *N*-protected compounds and in CF_3COOH for α-amino acids with unprotected amino groups. Coordination to the Cp*M^{III} fragments stabilizes the ketonic form of the tyrosine aromatic side chains, leading to a marked enhancement in the acidity of the *p*-hydroxy function. The crystal structure of [Cp*Ir(ActyrOMe)] (CF_3SO_3)$_2$ (**3b**, ActyrOMe = *N*-acetyltyrosine methyl ester) confirms a marked distortion towards an η^5-oxohexadienyl coordination mode as may be gauged from the tilting of the *p*-OH plane C13/C14/C15 by no less than θ = 12.9° from that of the remaining ring atoms. Facial isomers are present in an effective 1:1 ratio for all tryptophan derivatives. Whereas the Cp*Ir^{III} sandwich complexes of aromatic α-amino acids are stable in polar solvents, rapid decay is observed for analogous Cp*Rh^{III} complexes of *N*-unprotected derivatives in polar solvents. Comparative nonrelativistic and relativistic all-electron density functional calculations on the cationic sandwich complexes [Cp*M(η^6-C_6H_5Me)]$^{n+}$ (n = 2, M = Ir, Rh; n = 1, M = Ru) confirm that all three metals bind more tightly to Cp* than to toluene as gauged by the respective force constants ($k_1 > k_2$). A much larger relativistic enhancement of k_2 for M = Ir (279 vs 207 Nm^{-1}) could be responsible for the greater stability of Cp*Ir^{III} complexes in solution.

The analytical and synthetic perspectives of bioorganometallic chemistry have been highlighted in recent articles by Jaouen et al.[1] and Krämer[2]. Labeling of aromatic amino acid side-chains by η^6-coordinated transition metal half-sandwich fragments offers considerable potential in this respect. For instance, the group of Pearson[3] and Rich[4] has demonstrated that the diaryl coupling, required for the total synthesis of cyclic diphenyl ether peptides such as the protease inhibitor K-13, may be achieved under mild conditions by activation of protected *p*-Cl-phenylalanine through η^6-coordination of the CpRu^{II} fragment. We ourselves have recently employed both [(Cp*RuCl)$_2$(μ-Cl)$_2$] and [Cp*Ru(MeCN)$_3$]$^+$ for the first direct preparation of organometallic sandwich complexes of the free amino acids phenylalanine (L-HpheOH), tyrosine (L-HtyrOH) and tryptophan (L-HtrpOH)[5][6]. The feasibility of employing individual CpRu^{II}-coordinated amino acids for the construction of labeled peptides was demonstrated in the course of these activities by the synthesis of [Cp*Ru{η^6-cyclo-(phephe)}]$^+$ using the carbodiimide method[6].

Unfortunately, the applicability of the Cp*Ru^{II} fragment in the bioorganometallic field is restricted by the relative instability of its sandwich complexes in aqueous solution[5], a state of affairs that prompted us to investigate the suitability of alternative transition metal half-sandwich compounds. After recently reporting on η^6-CyRu^{II} complexes (Cy = *p*-cymene) of aromatic amino acids and peptides[7][8], we have now turned our attention to the compounds [Cp*IrL$_3$](CF_3SO_3)$_2$ [L = thf (**1a**), $(CH_3)_2CO$ (**1b**)] and [Cp*RhL$_3$](CF_3SO_3)$_2$ [L = thf (**2a**), $(CH_3)_2CO$ (**2b**), CH_3CN (**2c**)][9][10].

Results

In contrast to the tris(acetonitrile) half-sandwich complex [Cp*Ru(MeCN)$_3$](CF_3SO_3), which affords the entropically favoured sandwich compounds on treatment with free aromatic amino acids in thf[6], the analogous reaction of [CyRu(acetone)$_3$](CF_3SO_3)$_2$ leads[7][8] to formation of κ^2N,O-chelated products in CH_2Cl_2. Under such conditions, bis(η^6-arene)Ru^{II} sandwich compounds can only be prepared for fully protected amino acids such as *N*-acetyltyrosine ethyl ester (ActyrOEt). η^6-Coordination of the CyRu^{II} fragment by half-protected or free aromatic amino acids can, however, be achieved by carrying out the reaction in CF_3COOH. Protonation of the amino and/or carboxylato groups under such strongly acid conditions prevents their participation in the metal coordination sphere.

Similar considerations also apply to the Cp*Ir^{III} and Cp*Rh^{III} half-sandwich fragments. However, in these cases, the aromatic ring systems of *N*-protected amino acids such as *N*-acetyltyrosine (ActyrOH) can be successfully labeled in

 © WILEY-VCH Verlag GmbH, D-69451 Weinheim, 1998 1434–1948/98/1212–1991 $ 17.50+.50/0

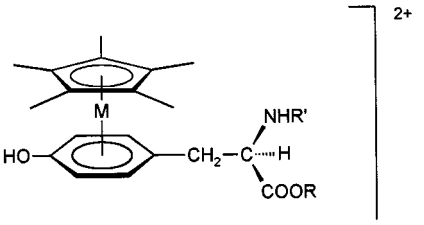
thf, as, for instance, in $[Cp^*Rh(ActyrOH)](CF_3SO_3)_2$ without competition from κ^1O-coordinated species. Sandwich complexes of *O*-protected or free amino acids are obtained in good yield (68−85%) by heating the reactants to 50°C for 24 h in CF_3COOH. ^{13}C-NMR spectra reveal a consistent pattern of upfield shifts of ca. 20−40 ppm for the signals of carbon atoms directly coordinated to the metal atom in comparison to those registered for the aromatic amino acids themselves. The formation of sandwich compounds is also confirmed by characteristic lowfield shifts for the ^{1}H-NMR signals of the Cp^*M^{III} (M = Ir, Rh) methyl protons. Furthermore, the typical chemical shift ranges of δ = 1.94−2.08, 2.25−2.28 and 2.40−2.44, in CD_3OD, associated with respectively η^6-coordinated tryptophan, tyrosine and phenyalanine derivatives, allow a straightforward assignment of the Cp^*Ir^{III} site in mixed oligopeptides. The marked kinetic instability of the analogous Cp^*Rh^{III} sandwich complexes in polar solvents prevents a general employment of this fragment in chemoselective organometallic labeling. However, our limited results indicate that a discrimination between η^6-coordinated tryptophan (δ = 1.96 in **11**) and tyrosine (δ = 2.09−2.20 in **6**−**8**) derivatives should once again be feasible.

η^5-Oxohexadienyl Coordination of Tyrosine Derivatives

Coordination to the Cp^*Ru^{II} and Cp^*M^{III} (M = Rh, Ir) fragments[10][11][12][13] stabilizes the ketonic form of phenol and its derivatives, leading to a marked enhancement in the acidity of the *p*-hydroxy substituent. Distortion towards an η^5-oxohexadienyl coordination mode in such sandwich complexes may be gauged from the shortness of the C−O bond distance and the degree of tilting between the plane of the *m*- and *p*-carbon atoms and the rest of the aromatic ring as expressed in the apposite dihedral angle θ. Relatively large θ values of 19° in $[Cp^*Ir(C_6H_3Me_2O)](BF_4)$[14], 14° in $[Cp^*Rh(C_6H_5O)](BF_4)\cdot H_2O$[13] and 13.2° in $[CyRu(HtyrOH)](CF_3SO_3)_2$[8] are accompanied by short C−O distances of 1.23, 1.25 and 1.274 Å, that are indicative of a pronounced degree of double-bond character. These structures differ markedly from that of $[Cp^*Ru(C_6H_5O)]\cdot 2$ PhOH[12] in which the phenol ring system is almost flat [θ = 4°, *d* (C−O) = 1.28 Å].

In $CyRu^{II}$ sandwich complexes, the *p*-hydroxy function of tyrosine derivatives is effectively fully deprotonated in aqueous solution. The concomitant increase in shielding for the aromatic ring protons causes their resonances to move upfield to values between δ = 5.6 and 6.6 in D_2O solution[8]. An analogous state of affairs is apparent for the Cp^*Ir^{III} complexes $[Cp^*Ir(ActyrOEt)](CF_3SO_3)_2$ (**3a**), $[Cp^*Ir(HtyrOMe)](CF_3SO_3)_2$ (**4**) and $[Cp^*Ir(HtyrOH)](CF_3SO_3)_2$ (**5**, HtyrOMe = tyrosine methyl ester) prepared in this work. The upfield shift is most pronounced for the *m*-protons adjacent to the tyrosine hydroxy function which are registered as separate doublets. Formation of the *N*-protonated zwitterions of HtyrOMe and HtyrOH further facilitates deprotonation of this aromatic substituent in **4** and **5** and leads of an additional upfield shift for the H atoms to δ = 5.83 and 5.86 in comparison to δ = 6.20 for **3a** in CD_3OD solution. This interpretation is confirmed by the remarkable ^{13}C-NMR chemical shifts of δ = 164.9 and 163.7 for the *p*-hydroxy-substituted tyrosine carbon atoms in **4** and **5**, values that are indicative of pronounced double-bond character for the associated C−O bonds. The analogous ^{13}C-NMR signal for **3a** at δ = 157.7 is registered only ca. 4 ppm downfield to that observed in free tyrosine derivatives. In contrast to the analogous Cp*Rh complexes **6**−**8**, the Cp*Ir sandwich complexes **3**−**5** of tyrosine derivatives are indefinitely stable in polar solvents such as water and methanol over a period of 14 days.

Scheme 1. Sandwich cations of $[Cp^*M(R'tyrOR)](CF_3SO_3)_2$ (**3**−**8**); **3a**: M = Ir, R = Et, R′ = Ac; **4**: M = Ir, R = Me, R′ = H; **5**: M = Ir, R = R′ = H; **6**: M = Rh; R = Et, R′ = Ac; **7**: R = H, R′ = Ac; **8**: M = Rh, R = Me, R′ = H



Attempts to obtain suitable crystals for X-ray-structural analysis unfortunately remained unsuccessful for **4** and **5** with their unprotected amino functions. However, colourless prisms of $[Cp^*Ir(ActyrOMe)](CF_3SO_3)_2$ (**3b**, ActyrOMe = *N*-acetyltyrosine methyl ester) could be grown by gas diffusion of diethyl ether into a methanol solution of $[Cp^*Ir(ActyrOH)](CF_3SO_3)_2$ prepared under similar conditions to **3a**. Solvent participation is apparent for the formation of η^6-coordinated ActyrOMe. The structure of the sandwich dication is depicted in Figure 1. Although the *p*-hydroxy oxygen atom O41 must be protonated for the fully protected tyrosine derivative ActyrOMe in the sandwich cation of **3b** [*d*(C34−O41) = 1.33(4) Å], the plane C33/C34/C35 is tilted by no less than θ = 12.9° from that of the remaining ring atoms C31−C33, C35 and C36. This pronounced departure from planarity may also be gauged from the Ir1−C34 distance of 2.36(4) Å, which is markedly longer than those to the remaining tyrosine ring atoms [2.22−2.30 Å]. The ^{1}H-NMR spectra of **3**−**5** in D_2O indicate that the tyrosine *p*-hydroxy function in Cp*Ir sandwich complexes is a moderately strong acid, a finding that is also reflected in the participation of O41 in relatively strong O41−H41···O21 hydrogen bonds of length 2.51 Å to the *N*-acetyl function of a symmetry-related complex cation. In view of the pronounced downfield shifts for the ^{13}C-NMR signal of C34 in **4** and **5**, for which the formation of *N*-protonated *O41*-deprotonated zwitterions is possible, it is reasonable to predict that the dihedral angle θ in these compounds will be even larger than in **3b** and perhaps close to that of 19° in $[Cp^*Ir(C_6H_3Me_2O)](BF_4)$[14].

Both Maitlis[10] and Jaouen[13] have commented on the instability of the sandwich complex $[Cp^*Rh(\eta^6\text{-phenol})]^{2+}$

Scheme 2. Stabilization of the ketonic form of the aromatic side chain of ActyrOEt in the Cp^*Rh^{III} complex **6**

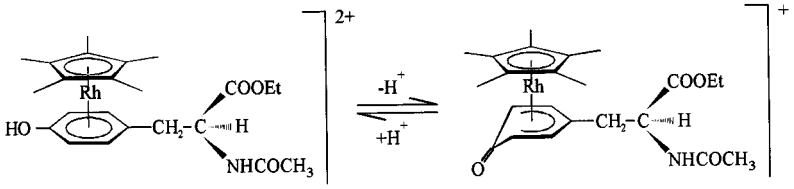


Figure 1. X-ray structure of the cation of $[Cp^*Ir(ActyrOMe)](CF_3SO_3)_2$ (**3b**)

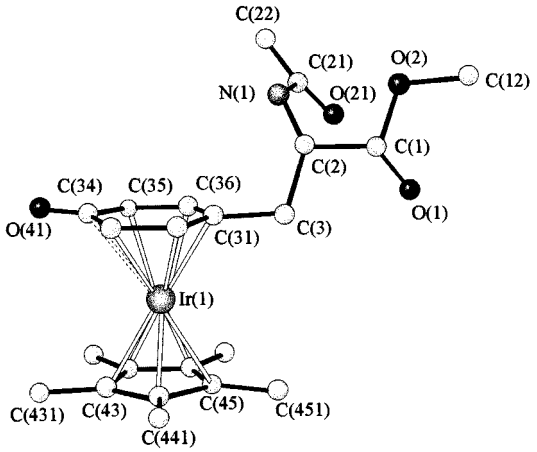
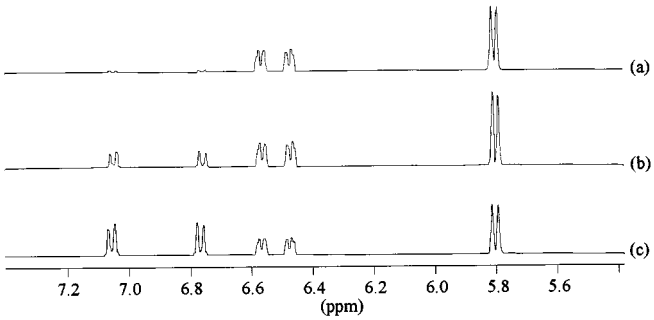


in polar solvents. Maitlis observed that $[Cp^*Rh)_2(phO)(phOH)](PF_6)_3$ is converted to 40% to $[(Cp^*Rh)_2(\mu\text{-}F_2PO_2)_3](PF_6)$ on standing for 48 h in acetone. Stabilization may be achieved by addition of base leading to formation of the η^5-oxocyclohexadienyl monocation $[Cp^*Rh(\eta^5\text{-}C_6H_5O)]^+$. Our time-dependent ^{1}H-NMR studies on $[Cp^*Rh(ActyrOEt)](CF_3SO_3)_2$ (**6a**) in D_2O solution, that are depicted in Figure 2, confirm a similar ca. 50% decay for the sandwich compound to $[Cp^*Rh(D_2O)_3]^{2+}$ and ActyrOEt within 24 hours at room temperature. A further ^{1}H-NMR spectrum taken after 5 days is similar to that of Figure 2c. It is interesting to note that Jaouen has postulated that the triflate counter anion $CF_3SO_3^-$ may stabilize the phenolic form of π-bonded arenes by participating in hydrogen bonds to the OH substituent of the aromatic ring system. For instance, whereas $[Cp^*Ir(\eta^6\text{-phenol})](BF_4)(CF_3SO_3)$ was very stable in aqueous solution, $[Cp^*Ir(\eta^6\text{-phenol})](BF_4)_2$ rapidly decays to a half-sandwich complex and could not be isolated. We have, therefore, performed comparative ^{1}H-NMR kinetic studies on $[Cp^*Rh(ActyrOEt)](PF_6)_2$ (**6b**) and $[Cp^*Rh(ActyrOEt)](BF_4)_2$ (**6c**) in D_2O solution. Suprisingly, whereas **6b** exhibits a decay rate similar to that of **6a**, as displayed in Figure 3 for **6c**, the sandwich cation $[Cp^*Rh(ActyrOEt)]^{2+}$ exhibits long-term stability in the presence of BF_4^- counter anions. Only ca. 20% formation of $[Cp^*RhL_3]^{2+}$ and ActyrOEt is apparent after 7 days. This finding suggests that a more subtle interplay of opposing factors may be responsible for the stabilizing effect of a particular anion.

Distortion towards the η^5-oxohexadienyl coordination mode in the Cp^*Rh^{III} sandwich complexes **6** and **7** leads the ^{1}H-NMR signals of the aromatic tyrosine protons to shift upfield to δ values between 5.8 and 6.6 in polar solvents (see Figures 2a and 3a). Figure 4 depicts the aromatic regions of the ^{1}H-NMR spectrum of $[Cp^*Rh(ActyrOEt)](CF_3SO_3)_2$ (**6a**) in (a) D_2O and (b) CD_3NO_2. In view of the instability of **6**–**8** in polar solvents, NMR data for these compounds are only reported for the latter solvent in the Experimental Section of this paper. It is interesting to note that the increase in shielding for the tyrosine *meta* protons of **6a** (δ = 5.82) in CD_3OD is similar to those of **4** and **5** (δ = 5.83 and 5.86) with their unprotected tyrosine amino functions. We were successful in growing suitable crystals of **6a** by gas diffusion of diethyl ether into a methanol solution and Figure 5 shows the X-ray structure of the sandwich cation in this compound. The dihedral angle θ of 5.09° is associated with a C34–O41 distance of 1.34(1) Å and is smaller than in the analogous Cp^*Ir^{III} complex **3b**. Distortion towards the η^5-oxohexadienyl coordination mode may also be gauged from the Rh1–C34 bond length of 2.339(8) Å, which is markedly longer than those to the remaining aromatic carbon atoms in the range 2.243(9)–2.259(7) Å. As in **3b**, relatively strong O–H···O hydrogen bonds [d(O41–H41···O21) = 2.51 Å] are present between the hydroxy and *N*-acetyl oxygen atoms of neighbouring dications. The triflate counter ions participate in weaker O···N1–H1 interactions of length 2.91 Å to the amide proton of N1.

Figure 2. Time-dependent ^{1}H-NMR spectra of $[Cp^*Rh(ActyrOEt)](CF_3SO_3)_2$ (**6a**) in D_2O at room temperature: (a) after 5 min, (b) after 1.5 h and (c) after 24 h



Compound **7** with ActyrOH as sandwich ligand was recrystallized from an acetone/hexane solution for X-ray analysis and displays a structure similar to that of **6a**. Tilting of the C33/C34/C35 plane leads to a Rh1–C34 distance of 2.337(11) Å and a dihedral angle θ of 2.97°. O41 exhibits a C34–O41 bond length of 1.31(1) Å and once again participates in intermolecular O–H···O hydrogen bonding to the *N*-acetyl O21 oxygen atom. It is interesting to note that whereas the metal–ring distances to the Cp* planes in **3b**,

Figure 3. Time-dependent ^{1}H-NMR spectra of [Cp*Rh(ActyrOEt)]$(BF_4)_2$ (**6c**) in D_2O at room temperature: (a) after 5 min, (b) after 48 h and (c) after 7 d

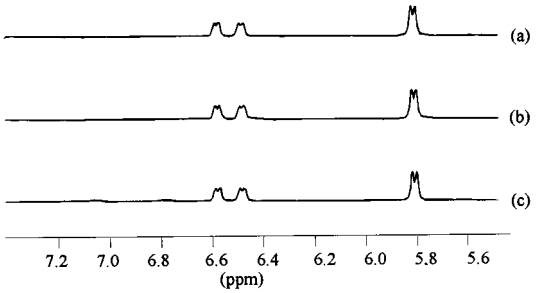


Figure 4. Aromatic regions of the ^{1}H-NMR spectra of [Cp*Rh(ActyrOEt)]$(CF_3SO_3)_2$ (**6a**) in (a) D_2O and (b) CD_3NO_2

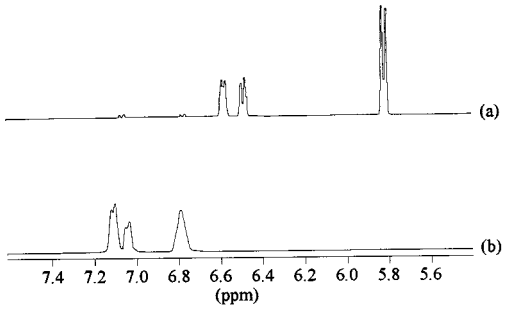

Figure 5. X-ray structure of the cation of [Cp*Rh(ActyrOEt)]$(CF_3SO_3)_2$ (**6a**)

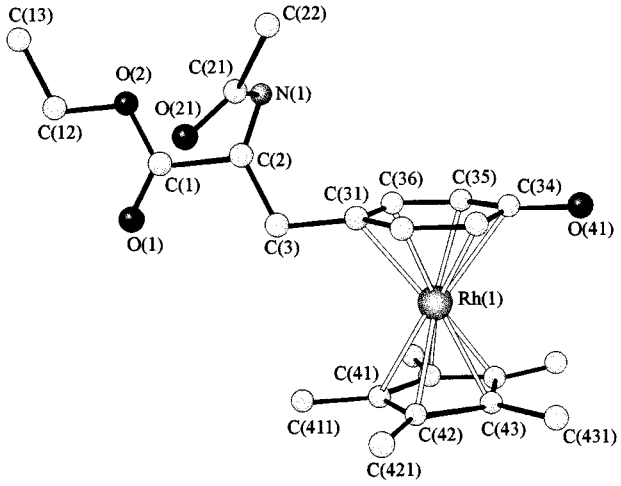


6a and **7** are all very similar [1.817, 1.807 and 1.796 Å], the opposite Ir-η^5-ActyrOMe distance in **3b** [1.738 Å] is markedly shorter than the analogous values for Rh^{III} in **6a** and **7** [1.763 and 1.771 Å].

[Cp*Rh(HtyrOMe)]$(CF_3SO_3)_2$ (**8**) decays immediately in polar solvents to the starting materials and ^{1}H-NMR spectra could, therefore, only be recorded in CD_3NO_2. This typical instability of Cp^*Rh^{III} sandwich compounds of *N*-unprotected aromatic amino acids also prevents the isolation of the analogous π-bonded dication of tyrosine itself. Formation of an *N*-protected zwitterion allows effectively complete deprotonation of the tyrosine *p*-hydroxy function in **8** even in CD_3OD, as evidenced by the upfield shift of the *meta* proton doublets to δ = 5.54 and 5.58 in this solvent. The pronounced downfield shift of the ^{13}C-NMR signal for *C*OH from δ = 147.2 in **7** to 156.3 in **8** (CD_3NO_2 solutions) underscores this interpretation for the *N*-unprotected tyrosine derivative.

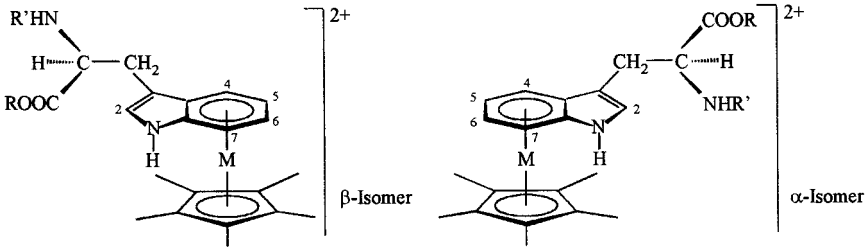
Facial Chirality in Tryptophan Complexes

η^6-Coordination of the aromatic indole system in tryptophan derivatives allows the formation of diastereomers owing to the possibility of facial chirality (Scheme 3). As we have already demonstrated for $CyRu^{II}$ sandwich compounds[8], opposite shifts are characteristic for ^{1}H-NMR signals of the protons of the π-bonded arene ring system. For instance, the signals of the inner protons H^5 and H^6 appear at higher field in [Cp*Rh(ActrpOMe)]$(CF_3SO_3)_2$ [**11a**; δ = 6.67 (m)], whereas a pronounced lowfield shift to δ = 7.75 (m) is observed for the signals of the outer protons H^4 and H^7. Assignment was achieved by use of HMQC-TOCSY spectra. Metal coordination of the neighbouring indole six-membered ring also leads to a marked change in the electron-density distribution in the condensed pyrrole ring as evidenced by pronounced shifts to lower field for both the H^2 [^{1}H NMR: δ = 8.28, 8.33 (2 s, 1 H)] and C^2 [^{13}C NMR: δ = 141.4] resonances of **11a** in CD_3NO_2 solution. Similar shifts were recorded for the analogous signals of the Cp^*Ir^{III} sandwich compounds **9** and **10**, whose ^{1}H- and ^{13}C-NMR spectra were recorded in CD_3OD and D_2O solutions, respectively. The H^2 singulets for the α and β isomers are well resolved in **9**, **10** and **11a** and their integral values indicate that both diastereomers must be present in a ca. 1:1 ratio in all three compounds. After successful fractional crystallization, the H^2 resonance at higher field could be assigned to the diastereomer of [CyRu(ActrpOMe)]-$(CF_3SO_3)_2$ with β-facial chirality. It seems reasonable to assume that the same face of ActrpOMe is also preferred in [Cp*Rh(ActrpOMe)]$(PF_6)_2$ (**11a**) for which the H^2 signals [^{1}H NMR: δ = 8.27, 8.32 (2 s, 1 H)] are observed at the integral ratio of ca. 6:1 in CD_3NO_2. Whereas the Cp^*Ir^{III} sandwich complexes **9** and **10** are stable over a period of 14 days in aqueous solution, both **11b** and the analogous compound [Cp*Rh(ActrpOMe)]$(CF_3SO_3)_2$ (**11a**) rapidly decay to ActrpOMe and appropriate tris(solvent) half-sandwich complex in water and methanol.

Stability of Cp^*Ir^{III} and Cp^*Rh^{III} Complexes in Solution

This relative instability of Cp^*Rh^{III} sandwich complexes is also apparent for phenylalanine and its derivatives. As for the aromatic indole system of tryptophan, η^6-coordination can only be achieved with Cp^*Rh^{III} when both the amino and carboxyl functions are protected. In accordance with similar observations for the analogous tyrosine and tryptophan complexes [Cp*Rh(AcpheOMe)]$(CF_3SO_3)_2$ (**14**) decays rapidly in polar solvents. ^{1}H-NMR signals for the aromatic protons of both this and the Cp^*Ir^{III} sandwich compounds [Cp*Ir(AcpheOMe)]$(CF_3SO_3)_2$ (**12**) and [Cp*

Scheme 3. α and β isomers of [Cp*M(R′trpOR)]$(CF_3SO_3)_2$ (**9**−**11**); **9**: M = Ir, R = Me, R′ = Ac; **10**: M = Ir, R = R′ = H; **11**: M = Rh, R = Me, R′ = Ac



$Ir(H_2pheOMe)](CF_3SO_3)_3$ (**13**) lie in a close range (δ = 7.26−7.65) and are shifted marginally to lower field in comparison those of the free amino acid. The X-ray structure of the complex cation of **12** is depicted in Figure 6. Similar Ir−C distances [2.209−2.277 Å] are observed for all carbon atoms of the phenyl ring which itself is effectively planar.

Scheme 4. Sandwich cations of [Cp*M(R′pheOMe)]$(CF_3SO_3)_n$ (**12**−**14**); **12**: M = Ir, R′ = Ac, n = 2; **13**: M = Ir, R′ = H_2, n = 3; **14**: M = Rh, R′ = Ac, n = 2

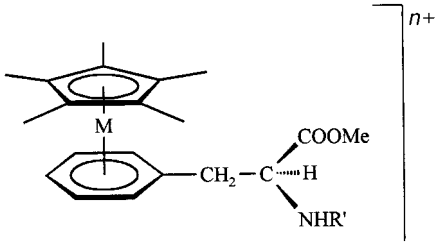


Figure 6. X-ray structure of the cation of [Cp*Ir(AcpheOMe)]$(CF_3SO_3)_2$ (**12**)

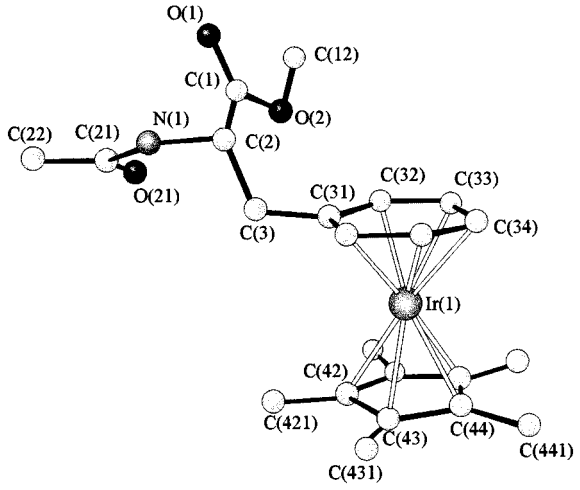


Although the greater stability of Cp^*Ir^{III} sandwich compounds in comparison to their rhodium analogues has been commented upon[15][16], attempts to fully understand this phenomenon still remain somewhat unsatisfactory. The introduction of π-arenes such as benzene or the cyclopentadienyl ion into hexaaqua cations $[M(H_2O)_6]^{2+}$ leads to a drastic increase in the lability of the three remaining water molecules, an effect that is more pronounced for anionic ligands[17]. This behaviour may be understood as a manifestation of the general principle that metal atoms usually tend to prefer either *hard* or *soft* ligands in their coordination spheres but not both at the same time[15]. Koelle et al. have demonstrated[17] that water exchange in half-sandwich triaqua complexes $[Cp^*M(H_2O)_3]^{2+}$ is faster by a factor of 6.3 for Rh^{III} in comparison to Ir^{III}.

Studies by Merbach[18] on the ligand-exchange reactions of $[Cp^*ML_3]^{2+}$ (L = CH_3CN, dmso) indicate that a dissociative mechanism must be involved. As previously reported by Maitlis[18], dmso was found to coordinate Rh^{III} through its oxygen, to Ir^{III} through its sulfur atom. Both this behaviour and the enhanced stability of Cp^*Ir^{III} sandwich compounds in polar solvents are in accordance with an increased preference of the heavier group-9 metal for *softer* ligands (e.g. π-arenes, κ*S*-dmso) in its coordination sphere. Of the members of the Co triad, Rh^{III} should be electronically best equipped to accommodate both *soft* and *hard* ligands in its coordination sphere, as is indeed suggested by the rapid decay of Cp^*Rh^{III} sandwich compounds to species $[Cp^*RhL_3]^{2+}$ in polar solvents (L = H_2O, CH_3OH).

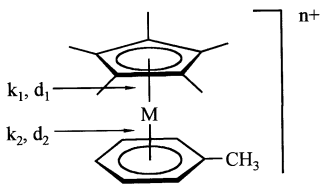
Relativistic Effects

In structural organometallic chemistry, the consideration of relativistic effects[19] is essential to understand trends within a transition-metal triad, especially when going from the second to the third row. Classically speaking, electrons in heavy atoms move so fast that their velocity becomes comparable to the velocity of light. This leads to a contraction and stabilization of s- and p-orbitals but to an expansion and destabilization of d- and f-orbitals. The relativistic destabilization of the 5-d shell results in an increased softness of third-row transition metals.

The importance of relativistic effects can only indirectly be estimated from experiment (e.g. from unexpected trends in the periodic table) since nature is inherently relativistic. Quantum-mechanical calculations on the other hand can be performed either with or without taking care of relativity, and the difference between such computational results indicates the magnitude of relativistic effects. For transition-metal compounds, one generally finds a contraction and stabilization of metal−ligand bonds. These effects lead to similar molecular structures, but higher binding energies if isostructural complexes of homologous 4d and 5d metals are compared.

We have carried out nonrelativistic and relativistic all-electron density functional calculations on the $[Cp^*Rh(\eta^6\text{-}C_6H_5Me)]^{2+}$, $[Cp^*Ir(\eta^6\text{-}C_6H_5Me)]^{2+}$ and $[Cp^*Ru(\eta^6\text{-}C_6H_5Me)]^{+}$ cationic sandwich complexes. For details of the computational method, the reader is referred to ref.[20]. A full geometry optimization has been performed, and the force constants of the two coordinates describing the metal−ring distances have been evaluated. It is suggested that these force constants, which indicate how tightly the aromatic rings are bound to the metal atom, may serve as a measure for the *kinetic* stability of the complexes. Some results of these calculations have been collected in Table 1. The relativistic results are given, together with the results from the nonrelativistic calculations in parentheses. Both aromatic rings are essentially planar, and the coordinates d_1 and d_2 (Figure 7) are the distance between the metal atom and the planes of the Cp* and toluene aromatic ring, respectively. The force constants k_1 and k_2 are the second derivatives of the total energy with respect to the coordinates d_1 and d_2. For $[Cp^*Ir(\eta^6\text{-}C_6H_5Me)]^{2+}$, we can compare the calculated metal−ring distances (1.841 and 1.792 Å) to the X-ray result for $[Cp^*Ir(\eta^6\text{-AcpheOMe})](CF_3SO_3)_2$ (**12**; 1.811 and 1.744 Å) and find reasonable agreement. The nonrelativistic calculations give much larger values especially for the distance between iridium and the toluene ring (nonrelativistic: 1.925 Å, relativistic: 1.792 Å). As relativistic-effects scale with the square of the nuclear charge, the bond contractions are much smaller for the Rh (Z = 45) compounds than for Ir (Z = 77) complexes. Looking at the force constants, we find that both metals bind more tightly to Cp* than to toluene ($k_1 > k_2$). This is consistent with the experimental finding that in the first stages of the decay, the Cp^*Rh^{III} or Cp^*Ir^{III} units remain intact. For the kinetic stability of the complex, the value of k_2 appears to be most important. The calculations find 207 and 279 Nm^{-1}, respectively, for the Rh^{III} and Ir^{III} sandwich complexes, consistent with the much higher stability of the latter. This does not follow from the nonrelativistic data: it is the much larger relativistic enhancement of k_2 that makes the iridium complex so stable.

Figure 7. Definition of the distances d_1, d_2 and the force constants k_1, k_2 in sandwich cations of the type $[Cp^*M(\eta^6\text{-}C_6H_5Me)]^{n+}$ (n = 2, M = Ir, Rh; n = 1, M = Ru)



Similar calculations for $[Cp^*Ru(\eta^6\text{-}C_6H_5Me)]^{+}$ are also included in Table 1 and indicate as for the analogous Cp^*Rh^{III} sandwich cation that relativistic effects are less marked for second-row transition metals. The distances presented for d_1 and d_2 [1.840 and 1.751 Å] may be compared with the average experimental values[6] of 1.816 and 1.704 Å in $[(Cp^*Ru)_2\{cyclo\text{-(phephe)}\}]^{2+}$. Despite the much shorter distance to the η^6-coordinated toluene ligand the force constants k_1 and k_2 are in accordance with tighter binding to Cp*, although the difference is less pronounced than in the Cp^*Ir^{III} and Cp^*Rh^{III} sandwich complexes.

Table 1. Metal−ring distances and force constants for $[Cp^*Rh(\eta^6\text{-}C_6H_5Me)]^{2+}$, $[Cp^*Ir(\eta^6\text{-}C_6H_5Me)]^{2+}$ and $[Cp^*Ru(\eta^6\text{-}C_6H_5Me)]^{+}$ from relativistic density functional calculations; nonrelativistic results are given in parentheses

Compound	d_1 [Å]	d_2 [Å]	k_1 [Nm^{-1}]	k_2 [Nm^{-1}]
$[Cp^*Rh(\eta^6\text{-}C_6H_5Me)]^{2+}$	1.840	1.830	358	207
	(1.862)	(1.876)	(334)	(182)
$[Cp^*Ir(\eta^6\text{-}C_6H_5Me)]^{2+}$	1.841	1.792	413	279
	(1.908)	(1.925)	(351)	(193)
$[Cp^*Ru(\eta^6\text{-}C_6H_5Me)]^{+}$	1.840	1.751	367	299
	(1.861)	(1.781)	(346)	(269)

Experimental Section

All manipulations and reactions were performed under argon in carefully dried solvents using standard Schlenk techniques. − FTIR[20]: Perkin-Elmer 1760; in KBr. − FAB MS: Fisons VG Autospec with 3-nitrobenzyl alcohol as the matrix. − ^1H and ^{13}C NMR: Bruker DRX 400; chemical shifts are reported as δ values relative to the signal of the deuterated solvent. − Elemental analyses were performed by Beller, Mikroanalytisches Labor, Göttingen. − The starting compounds $[(\eta^5\text{-}Cp^*)IrL_3](CF_3SO_3)_2$ [L = thf (**1a**), $(CH_3)_2CO$ (**1b**)] and $[(\eta^5\text{-}Cp^*)RhL_3](CF_3SO_3)_2$ [L = thf (**2a**), $(CH_3)_2CO$ (**2b**), CH_3CN (**2c**)] were prepared from respectively $[(\eta^5\text{-}Cp^*)IrCl_2]_2$ or $[(\eta^5\text{-}Cp^*)RhCl_2]_2$ by addition of an appropriate quantity of $Ag(CF_3SO_3)$ and filtration of the precipitated AgCl in the chosen solvent L[10]. Amino acids were purchased from Bachem (Heidelberg) and Calbiochem-Novabiochem (Bad Soden) and were used as received.

$[(\eta^5\text{-}Cp^*)Ir(ActyrOEt)](CF_3SO_3)_2$ (**3a**): N-acetyltyrosine ethyl ester (ActyrOEt, 37.2 mg, 0.15 mmol) was added to a solution of **1a** (122.6 mg, 0.15 mmol) in 12 mL of thf and the reaction mixture heated at reflux for 18 h. The resulting solid was stirred for 24 h with diethyl ether and dried in vacuo after centrifugation to afford **3**. Yield 112 mg (86%). − $C_{25}H_{32}F_6IrNO_{10}S_2$ (876.5): calcd. C 34.3, H 3.7, N 1.6; found C 34.6, H 3.8, N 2.0. − FAB MS; *m/z* (%): 727 (1) $[M - CF_3SO_3]^+$, 578 (100) $[M - 2\ CF_3SO_3]^+$, 445 (3) $[M - 2\ CF_3SO_3 - NHAc - CO_2Et]^+$. − ^1H NMR (CD_3OD): δ = 1.32 (t, 3 H, CH_3 OEt), 2.04 (s, 3 H, CH_3 Ac), 2.28 (s, 15 H, CH_3 Cp*), 2.83/3.03 (2 dd, 2 H, β-CH_2), 4.27 (q, 2 H, CH_2 OEt), 4.79 (dd, 1 H, α-C*H*), 6.20 (2 d, 2 H, H_{meta} tyr), 6.70/6.78 (2 d, 2 H, H_{ortho} tyr). − ^{13}C NMR (CD_3OD): δ = 9.9 (CH_3 Cp*), 14.7 (CH_3 OEt), 22.7 (CH_3 Ac), 35.0 (β-*C*), 54.1 (α-*C*), 63.5 (CH_2 OEt), 84.1 (C_{meta} tyr), 97.9 (C_{ortho} tyr), 102.0 (CCH_3 Cp*), 103.2 (*C* tyr), 157.7 (*C*OH tyr), 171.4 (*C*OO), 173.8 (NH*C*O). − IR: $\tilde{\nu}$ = 3273 s (NH), 1743 s (CO), 1582, 1531 m (NH) cm^{-1}.

$[(\eta^5\text{-}Cp^*)Ir(HtyrOMe)](CF_3SO_3)_2$ (**4**): Tyrosine methyl ester (HtyrOMe, 38 mg, 0.2 mmol) was stirred with **1b** (160 mg, 0.2 mmol) for 24 h in 12 mL of CF_3COOH at 50°C and the solution reduced in volume to 3 mL. After precipitation with diethyl ether, the resulting solid was dried in vacuo to afford **4**. Yield 139.5 mg (85%). − $C_{22}H_{28}F_6IrNO_9S_2$ (820.8): calcd. C 32.2, H 3.4, N 1.7; found C 32.1, H 3.6, N 1.5. − FAB MS; *m/z* (%): 522 (100) $[M - 2\ CF_3SO_3]^+$. − ^1H NMR (CD_3OD): δ = 2.25 (s, 15 H, CH_3 Cp*), 3.04 (2 dd, 2 H, β-CH_2), 3.91 (s, 3 H, COCH_3), 4.55 (dd, 1 H, α-C*H*), 5.83 (2 d, 2 H, H_{meta} tyr), 6.51, 6.57 (2 d, 2 H, H_{ortho} tyr). −

^{13}C NMR (CD_3OD): δ = 10.8 (*C*H$_3$ Cp*), 34.6 (β-*C*), 55.0 (α-*C*), 55.5 (*C*H$_3$OMe), 84.0, 84.2 (C_{meta} tyr), 97.2, 98.7 (C_{ortho} tyr), 99.3 (*C*CH$_3$ Cp*), 103.1 (*C* tyr), 164.9 (*C*OH tyr), 170.3 (*C*OO). − IR: $\tilde{\nu}$ = 3284 s (NH), 1746 s (CO), 1573 m (NH) cm^{-1}.

[(η5-Cp)Ir(HtyrOH)](CF3SO3)2* (**5**): The preparation was performed with tyrosine (27.9 mg, 0.15 mmol) and **1a** (128 mg, 0.15 mmol) in CF_3COOH in an analogous manner to **4**. Yield 82.2 mg (68%). − $C_{21}H_{26}F_6IrNO_{10}S_2$ (806.2): calcd. C 31.3, H 3.2, N 1.7; found C 31.1, H 3.5 N 1.7. − FAB MS; *m/z* (%): 658 (1) [M − CF_3SO_3]$^+$, 508 (100) [M − 2 CF_3SO_3]$^+$, 462 (6) [M − 2 CF_3SO_3 − CO_2H]$^+$. − ^{1}H NMR (CD_3OD): δ = 2.26 (s, 15 H, C*H*$_3$ Cp*), 3.03 (m, 2 H, β-C*H*$_2$), 4.49 (dd, 1 H, α-C*H*), 5.86 (2 d, 2 H, H_{meta} tyr), 6.59, 6.63 (2 d, 2 H, H_{ortho} tyr). − ^{13}C NMR (CD_3OD): δ = 9.9 (*C*H$_3$ Cp*), 33.7 (β-*C*), 54.1 (α-*C*), 83.1 (C_{meta} tyr), 97.4 (C_{ortho} tyr), 98.5 (*C* tyr), 102.2 (*C*CH$_3$ Cp*), 163.7 (*C*OH tyr), 170.1 (*C*OO). − IR: $\tilde{\nu}$ = 3178 s (NH), 1742 s (CO), 1559 m (NH) cm^{-1}.

[(η5-Cp)Rh(ActyrOEt)](CF3SO3)2* (**6a**): ActyrOEt (75.4 mg, 0.3 mmol) and **2b** (213.2 mg, 0.3 mmol) were stirred for 2 d in 15 mL of thf and the resulting solid removed by centrifugation. After washing with diethyl ether, the product was dried to afford **6.** Yield 198.5 mg (84%). Recrystallization by gas diffusion of diethyl ether into a methanol solution provided suitable crystals for X-ray analysis. − $C_{25}H_{32}F_6NO_{10}RhS_2$ (787.6): calcd. C 38.1, H 4.1, N 1.8; found C 37.6, H 4.0, N 1.8. − FAB MS; *m/z* (%): 637 (1) [M − CF_3SO_3]$^+$, 488 (100) [M − 2 CF_3SO_3]$^+$, 237 (11) [M − 2 CF_3SO_3 − ActyrOEt]$^+$. − ^{1}H NMR (CD_3NO_2): δ = 1.21 (t, 3 H, C*H*$_3$ OEt), 1.93 (s, 3 H, C*H*$_3$ Ac), 2.19 (s, 15 H, C*H*$_3$ Cp*), 2.97, 3.16 (2 dd, 2 H, β-C*H*$_2$), 4.17 (q, 2 H, C*H*$_2$ OEt), 4.79 (dd, 1 H, α-C*H*), 6.79 (2 d, 2 H, H_{meta} tyr), 7.05, 7.18 (2 d, 2 H, H_{ortho} tyr). − ^{13}C NMR (CD_3NO_2): δ = 8.9 (*C*H$_3$ Cp*), 12.8 (*C*H$_3$ OEt), 21.1 (*C*H$_3$ Ac), 33.6 (β-*C*), 52.3 (α-*C*), 62.1 (*C*H$_2$ OEt), 93.8 (C_{meta} tyr), 106.3, 106.5 (C_{ortho} tyr), 110.9 (*C*CH$_3$ Cp*), 112 (*C* tyr), 147.2 (*C*OH tyr), 169.4 (*C*OO), 171.5 (NH*C*O). − IR: $\tilde{\nu}$ = 3274 s (NH), 1742 s (CO), 1539 m (NH) cm^{-1}.

[(η5-Cp)Rh(ActyrOH)](CF3SO3)2* (**7**): The preparation was performed with *N*-acetyltyrosine (ActyrOH, 66.7 mg, 0.3 mmol) and **2c** (198.1 mg 0.3 mmol) in a manner similar to **6** with the exception that the thf was refluxed for 16 h. Yield 177.7 mg (78%). Recrystallization by covering an acetone solution with hexane provided suitable crystals for X-ray analysis. − $C_{23}H_{28}F_6NO_{10}RhS_2$ (759.5): calcd. C 36.4, H 3.7, N 1.8; found C 36.0, H 3.7, N 1.6. − FAB MS; *m/z* (%): 609 (1) [M − CF_3SO_3]$^+$, 460 (100) [M − 2 CF_3SO_3]$^+$, 205 (11) [M − 2 CF_3SO_3 − ActyrOH]$^+$. − ^{1}H NMR (CD_3NO_2): δ = 1.97 (s, 3 H, C*H*$_3$ Ac), 2.20 (s, 15 H, C*H*$_3$ Cp*), 2.95, 3.20 (2 dd, 2 H, β-C*H*$_2$), 4.77 (dd, 1 H, α-C*H*), 6.76, 6.80 (2 d, 2 H, H_{meta} tyr), 6.90, 7.04 (2 d, 2 H, H_{ortho} tyr), 7.09 (s, 1 H, N*H*CO). − ^{13}C NMR (CD_3NO_2): δ = 8.9 (*C*H$_3$ Cp*), 21.1 (*C*H$_3$ Ac), 33.6 (β-*C*), 52.2 (α-*C*), 93.8 (C_{meta} tyr), 106.2, 106.6 (C_{ortho} tyr), 110.9 (*C*CH$_3$ Cp*), 111.6 (*C* tyr), 147.2 (*C*OH tyr), 170.1 (*C*OO), 171.6 (NH*C*O). − IR: $\tilde{\nu}$ = 3284 s (NH), 1749 s (CO), 1573 m (NH) cm^{-1}.

[(η5-Cp)Rh(HtyrOMe)](CF3SO3)2* (**8**): The preparation was performed with HtyrOMe (57 mg, 0.3 mmol) and **2b** (213.2 mg, 0.3 mmol) in a manner similar to **4** and **5**. Yield 177.7 mg (81%). − $C_{22}H_{28}F_6NO_9RhS_2$ (731.4): calcd. [(η⁵-Cp)Rh(AcpheOMe)](CF₃SO₃)₂* (**14**): AcpheOMe (51.1 mg, 0.2 mmol) was refluxed with **2b** (150.5 mg, 0.2 mmol) in 15 mL of thf for 20 h and the solution reduced in volume to 3 mL. After precipitation with *n*-hexane, the resulting solid was washed with diethyl ether and dried in vacuo to afford **14**. Yield 109.1 mg (72%). − $C_{24}H_{30}F_6NO_9RhS_2$ (757.5): calcd. C 38.1, H 4.0, N 1.9; found C 37.4, H 3.8, N 1.4. − FAB MS; *m/z* (%): 608 (3) $[M - CF_3SO_3]^+$, 459 (60) $[M - 2\ CF_3SO_3]^+$, 237 (15) $[M - 2\ CF_3SO_3 - AcpheOMe]^+$. − ^{1}H NMR ($CD_3NO_2$): δ = 1.42 (2 s, 3 H, CH_3 Ac), 2.11 (s, 15 H, CH_3 Cp*), 3.23 (2 dd, 2 H, β-CH_2), 3.61 (2 s, 3 H, CH_3 OMe), 4.12 (m, 1 H, α-C*H*), 7.26 (m, 5 H, phe). − ^{13}C NMR (CD_3NO_2): δ = 9.7 (CH_3 Cp*), 14.11 (CH_3 Ac), 37.5 (β-*C*), 52.9 (α-*C*), 65.1 (CH_3 OMe), 106.3, 107.1, 107.3, 107.6, 107.9 (*C* phe), 113.1, 113.2 (CCH_3 Cp*, *C* phe), 176.5 (NH*C*O), 177.5 (*C*OO). − IR: $\tilde{\nu}$ = 1668, 1744 (CO), 1541 (NH) cm^{-1}.

X-ray-Structural Analyses: Siemens P4 diffractometer, graphite-monochromated Mo-K_α radiation (λ = 0.71073 Å). Empirical absorption correction (DIFABS)[22] were applied to the reflection intensities for **6** and **12**. Semi-empirical absorption corrections were applied to the intensity data for **3b** and **7** by use of ψ scans. The structures were solved by direct methods or Patterson syntheses and refined by full-matrix least squares against F^2 using SHELXL-93[23]. Hydrogen atoms were included at calculated positions with isotropic temperature factors[24].

[(η⁵-Cp)Ir(ActyrOMe)](CF₃SO₃)₂* (**3b**): $C_{24}H_{30}F_6IrNO_{10}S_2$, M = 862.8, T = 295 K, orthorhombic, space group $P2_12_12_1$ (no. 19), a = 9.174(2), b = 13.133(3), c = 27.022(5) Å, V = 3255.7(12) Å^3, Z = 4, $D_{calcd.}$ = 1.760 g·cm^{-3}, μ = 4.31 mm^{-1}. Metal-Mediated Conversion of Methylcycloarsoxane $(CH_3AsO)_n$ to Macrocyclic Octa- and Decanuclear Ligands –Trigonal Bipyramidal Coordination of Trivalent Arsenic

Iris M. Müller and William S. Sheldrick*

Lehrstuhl für Analytische Chemie, Ruhr-Universität Bochum,
D-44780 Bochum, Germany

Received July 20, 1998

Keywords: Arsenic / Methylcycloarsoxane / Ruthenium / Platinum / Macrocyclic ligands

Reaction of *cyclo*-$(CH_3AsO)_n$ with $MCl_3 \cdot x\ H_2O$ in acetonitrile at 100 °C affords $[MCl_2\{cyclo\text{-}(CH_3AsO)_8\}]$ [M = Ru (**1**), M = Os (**2**)] in which cyclooctamers $(CH_3AsO)_8$ are stabilised in a $\kappa^4As^{1,3,5,7}$ binding mode in the equatorial coordination sphere of the Group 8 metals. In contrast treatment of K_2PtCl_4 with alternatively $AgNO_3$ or Ag_2CO_3 and *cyclo*-$(CH_3AsO)_n$ at 100 °C in the same solvent leads to the formation of respectively octa- or decanuclear cagelike ligands in $[Pt_2\{[cyclo\text{-}(As[CH_3]OAs[NC(O)CH_3]O)_2]_2\}]$ (**3**) and $[Pt_2\{[\{CH_3C(O)N\}_2As_5(CH_3)_5O_4]_2\}]$ (**4**) by metal-assisted reactions between *cyclo*-$(CH_3AsO)_n$ and acetonitrile. λ^5-As^{III} atoms in these complexes participate in square-planar Pt^{II} coordination and themselves exhibit distorted trigonal bipyramidal coordination geometries.

Introduction

Although $(CH_3AsO)_n$ was synthesised some 140 years ago by A. von Baeyer[1] as the first example of an alkylcycloarsoxane, it is only in the past decade that the potential of this class of compounds as ambidentate macrocyclic ligands has been recognised and exploited[2]. Both mesityl- and methylcycloarsoxane have been crystallised as cyclic tetramers $(RAsO)_4$ and characterised by X-ray structural analysis[3][4]. In contrast to this apparent preference for the tetrameric form in the solid state, ^{1}H-NMR investigations have demonstrated that $(CH_3AsO)_n$ and $(C_2H_5AsO)_n$ are present as a mixture of cyclic oligomers ($n = 2-5$) in solution[5][6][7] for which the nuclearities $n = 3$ and 4 predominate. The dynamic equilibria between such cyclic ionophores can be influenced by the addition of alkali metal cations. Whereas Na^+ cations stabilise the crown shaped cyclic tetramer in $[Na\{cyclo\text{-}(C_2H_5AsO)_4\text{-}\kappa^4O\}_2]SCN$, employment of larger cations allows the isolation of pentagonal antiprismatic sandwich units in compounds of the type $[M\{cyclo\text{-}(C_2H_5AsO)_5\text{-}\kappa^5O\}_2]X$ ($M = K^+$, NH_4^+, Cs^+)[8][9].

The presence of an alternative set of *soft* As donor atoms coupled with their apparent low energy barriers to ring contraction or expansion in organic solvents suggests that the alkylcycloarsoxanes should also be capable of exhibiting a rich variety of binding modes in the coordination spheres of transition metals. Indeed, the metal-mediated ring expansion from the predominate cyclic trimers and tetramers to hexameric $(RAsO)_6$ has been confirmed for the carbonyl transition metal complexes $[\{M(CO)_3\}_2\{\mu\text{-}[cyclo\text{-}(RAsO)_6]\}]$ (M = Mo; R = CH_3[10], C_2H_5[12]; M = Cr, W; R = C_2H_5[7]) and $[\{ReBr(CO)_2\}_2\{\mu\text{-}[cyclo\text{-}(C_2H_5AsO)_6]\}]$[11], in which the metal atoms are facially coordinated by the upper or lower three As atoms of a flattened As_6O_6 cuboctahedron. An analogous $\kappa^3As^{1,3,5}$ mode has also recently been established in the mononuclear complexes $[RuCl_2\{cyclo\text{-}(C_2H_5AsO)_6\}]$ and $[RhCl_3\{cyclo\text{-}(C_2H_5AsO)_6\}]$[11]. Analysis of the molecular geometry of the alkylcycloarsoxanes indicates that, whereas $(RAsO)_6$ cuboctahedra should be capable of facial coordination of a transition metal fragment such as $M(CO)_3$ with a minimum of conformational change, severe ring strain would clearly be introduced in the case of $(RAsO)_3$. Extension of these geometrical arguments leads to the prediction that fourfold equatorial coordination of a transition metal should best be achieved by the $\kappa^4As^{1,3,5,7}$ mode of a cyclooctamer $(RAsO)_8$. Such oligomers are previously unknown as either isolated or coordinated species and have also not been detected in solutions of alkylcycloarsoxanes[5][6][7].

We now report our studies on the reactions of $MCl_3 \cdot H_2O$ (M = Ru, Os) and K_2PtCl_4 with $(CH_3AsO)_n$ in acetonitrile at 100 °C, which we believed might enable the stabilisation of $(CH_3AsO)_8$ in the octahedral coordination spheres of M^{II} (obtained by reduction of $MCl_3 \cdot H_2O$) or the square-planar coordination sphere of Pt^{II}.

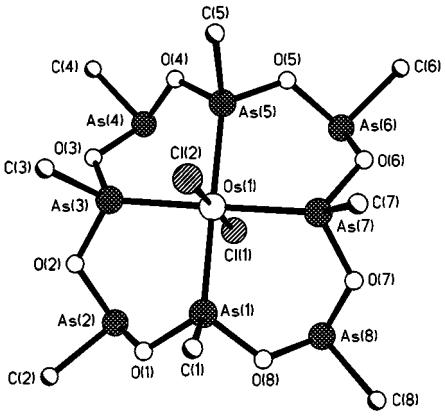
Results

$[RuCl_2\{cyclo\text{-}(CH_3AsO)_8\}]$ (**1**) and $[OsCl_2\{cyclo\text{-}(CH_3AsO)_8\}]$ (**2**) are isostructural and contain unprecedented cyclooctamers $(CH_3AsO)_8$ that are stabilised in the equatorial coordination plane of the Group 8 transition metals. The required reduction of M^{III} in the starting compounds $MCl_3 \cdot x\ H_2O$ (M = Ru, Os) to M^{II} in **1** and **2** is accompanied by ligand cleavage and oxidation to $CH_3AsO(OH)_2$, which can be isolated from the filtrate of

 © WILEY-VCH Verlag GmbH, D-69451 Weinheim, 1998 1434–1948/98/1212–1999 $ 17.50+.50/0

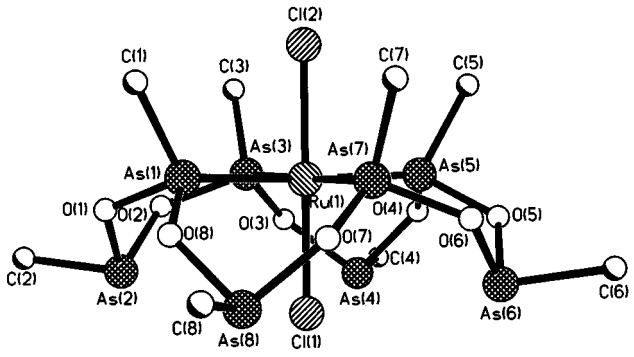
the final reaction mixture. Inspection of the As−Os−As angles [average values 90(1) and 177.4(2)°] and Os−As distances [2.400(3) Å] for the Os^{II} octahedral complex **2** depicted in Figure 1 confirm the suitability of the very flexible 16-membered As_8O_8 macrocycle for its adopted $\kappa^4As^{1,3,5,7}$ coordination mode. Similar average As−M−As angles [90(1) and 177.5(2)°] and M−As distances [2.400(4) Å] are found in the isostructural Ru^{II} complex **1**. As−O distances to the coordinated arsenic atoms As1, As3, As5, and As7 are on average [**1**, 1.758(7); **2**, 1.75(1) Å] shorter than those to the remaining non-coordinated Group 15 atoms [**1**, 1.799(7); **2**, 1.79(1) Å]. A concomitant widening of the O−As−O angles for the former atoms is apparent [**1**, 99.7(4)° vs. 97.0(2)°; **2**, 99.9(7)° vs. 97.4(8)°].

Figure 1. Molecular structure of $[OsCl_2\{cyclo\text{-}(CH_3AsO)_8\}]$ (**2**) viewed from above the equatorial $OsAs_4$ coordination plane



1 and **2** exhibit approximately C_{4V} molecular symmetry in which both the coordinating arsenic atoms and their non-coordinating O and As neighbours all effectively belong to common planes. For instance, whereas the former atoms are sited at ± 0.006 Å from the equatorial Ru^{II} coordination plane in **1**, the remaining arsenic atoms As2, As4, As6, and As8 display alternating deviations of ± 0.107 Å from the second As_4 plane of an As_8O_8 "double crown" (Figure 2). This conformation of the 16-membered macrocycle is characterised by a torsion angle pattern of the type $(a, b, -b, -a)_4$, in which the absolute value of *a* varies between 104.5(4) and 124.3(5)° in **1** [105.0(9) and 124.6(9)° in **2**] that of *b* between 59.5(5) and 75.0(4)° [58.7(9) and 74.7(9)° in **2**].

Figure 2. Molecular structure of $[RuCl_2\{cyclo\text{-}(CH_3AsO)_8\}]$ (**1**) viewed from the side



As mentioned in the Introduction previous examples of metal-mediated ring expansion for alkylcycloarsoxanes have been restricted to cyclopentamers and -hexamers. However we have recently investigated the analogous reaction of $MCl_3 \cdot H_2O$ (M = Ru, Os) with *cyclo*-$(C_2H_5AsS)_n$ in toluene[12], which leads to the assembly of the novel macrocyclic hexadentate ligand $[(C_2H_5)_6As_8S_{10}]^{2-}$ in the octahedral coordination spheres of Ru^{II} and Os^{II} at temperatures of 105 and 140°C, respectively. In contrast to the cyclooctamers $(CH_3AsO)_8$ reported in the present work, two alkyl substituents of the potential macrocyclic ligand $(C_2H_5AsS)_8$ are replaced by terminal thiolate sulphurs in $[(C_2H_5)_6As_8S_{10}]^{2-}$. These *soft* donor atoms then occupy *cis*-sited positions in the resulting transition metal coordination spheres. Contrasting small As−Os−S angles of 80.5(2) and 82.3(3)° in the five-membered chelate rings of $[Os\{(C_2H_5)_6As_8S_{10}\}]$ and large As−Os−As angles of 101.2(1) and 100.5(1)° in the six-membered chelate rings of this complex reflect a pronounced deviation from an idealised octahedral geometry.

Macrocyclic Cleavage Products

The apparent suitability of $(CH_3AsO)_8$ for $\kappa^4As^{1,3,5,7}$ equatorial coordination of transition metals prompted us to investigate whether this cyclooctamer can also be stabilised in the square-planar coordination sphere of Pt^{II}. However, we were unable to isolate methylcycloarsoxane complexes by treatment of Pt^{II} with $(CH_3AsO)_n$, following initial precipitation of chloride ions in K_2PtCl_4 as AgCl. In contrast, the direct reaction of K_2PtCl_4 with $AgNO_3$ or alternatively Ag_2CO_3 and $(CH_3AsO)_n$ in acetonitrile at 100°C in a Carius tube did lead to the stabilisation of macrocyclic octa- and decanuclear As-O ligands, albeit as metal-mediated cleavage products of the original methylcycloarsoxane. Two dimeric Pt^{II} complexes, $[Pt_2\{[cyclo\text{-}(As[CH_3]OAs[NC(O)CH_3]O)_2]_2\}]$ (**3**) and $[Pt_2\{[\{CH_3C(O)N\}_2As_5(CH_3)_5O_4]_2\}]$ (**4**) were isolated in relatively low yields (ca. 25%) under such conditions, depending on the molar ratio of the starting materials. For instance, whereas a 2:3:4 stoichiometric ratio of $K_2PtCl_4/Ag_2CO_3/(CH_3AsO)_n$ (for n = 1) affords **3**, the arsenic-richer complex **4** can be generated by increasing the $(CH_3AsO)_n$ content of the starting mixture (molar ratio 2:3:6). An increased Pt/As relationship is required in the presence of $AgNO_3$ [e.g. a $K_2PtCl_4/AgNO_3/(CH_3AsO)_n$ molar ratio of 1:3:6 for **3**] to compensate for the partial oxidation of $(CH_3AsO)_n$ to $CH_3As(O)(OH)_2$ by NO_3^- anions under such conditions. The red crystal sheafs could be separated without difficulty in each case in a manual fashion from precipitated AgCl. To our surprise both compounds contained novel octadentate anionic ligands, that result from metal-assisted reactions between $(CH_3AsO)_n$ and acetonitrile. The role of Ag^+ cations in directing ligand construction still remains unclear.

As depicted in Figures 3 and 4, the solvent molecules are converted into acetamido $[CH_3C(O)N]$ building units, whose trigonal planar amide nitrogens (N1−N4 in **3**; N1,

Figure 3. Molecular structure of $[Pt_2\{[cyclo\text{-}(As[CH_3]OAs[NC(O)CH_3]O)_2]_2\}]$

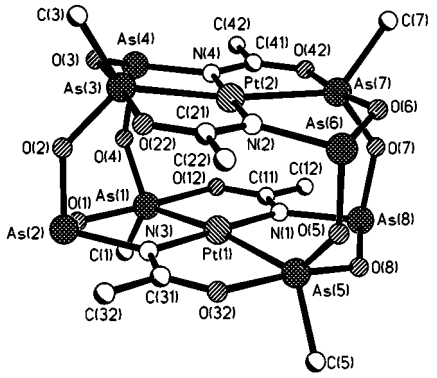


Figure 4. Molecular structure of $[Pt_2\{[\{CH_3C(O)N\}_2As_5(CH_3)_5O_4]_2\}]$

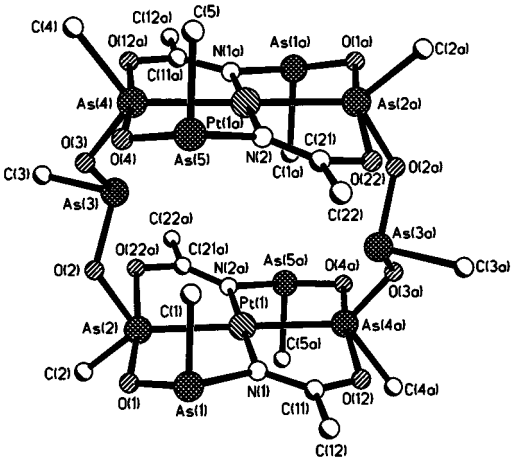

N2 and C_i symmetry-related atoms in **4**) are bonded to both Pt^{II} and As^{III} atoms. Refinements of alternative structural models, in which the positions of the N and O atoms in all four such moieties are exchanged (model 2 in Figure 5), led in both cases to significant deterioration in the R and wR_2 values. The latter reliability index increases on going from model 1 to model 2 from 0.144 to 0.147 for **3** and from 0.118 to 0.121 for **4** under these circumstances. Structural corroboration of the chosen atom assignments in the macrocyclic As-O ligands of **3** and **4** is provided by the short *trans* sited N−Pt distances [average values: **3**, 2.04(2); **4**, 2.03(1) Å] and the very long coordinative axial O→As distances [average values: **3**, 2.20(2); **4**, 2.27(2) Å], whose values would be most unreasonable for a possible alternative formulation as O→Pt and N−As bonds (model 2). The respectively octa- and decanuclear ligands in these complexes may be regarded as being composed of the monomeric units shown in Figure 6. These are linked into dimers through the weak dative O→As interactions already discussed. Eight-membered As_4O_4 rings can be identified for **3**, As_5O_4 chains for **4**. The average C−O, C−N and C−C distances of 1.26(2), 1.32(3) and 1.48(3) Å in the $[CH_3C(O)N]$ units of **3** are similar to the values found for the analogous moieties in **4** [1.30(4), 1.30(4), 1.50(4) Å].

Figure 5. Alternative structural models 1 and 2 for the $[CH_3C(O)N]$ building units in **3**

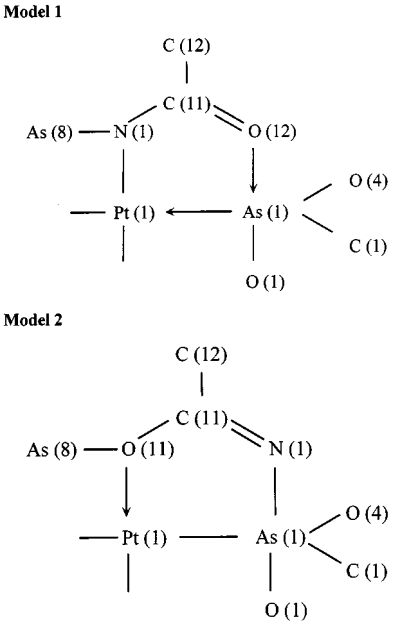

Figure 6. Monomeric units in the macrocyclic ligands of $[Pt_2\{[cyclo\text{-}(As[CH_3]OAs[NC(O)CH_3]O)_2]_2\}]$ (**3**) and $[Pt_2\{[\{CH_3C(O)N\}_2As_5(CH_3)_5O_4]_2\}]$ (**4**)

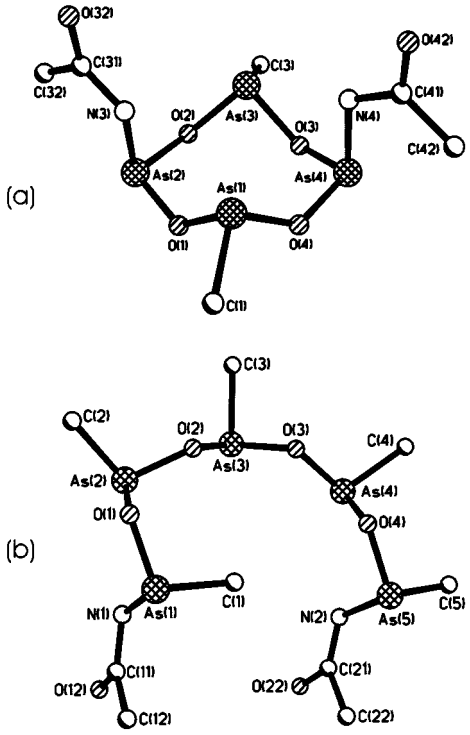

The Pt^{II} atoms in both complexes exhibit square-planar As_2N_2 coordination spheres with donor atoms of the same type sited *trans* to one other. Their separation increases from 3.01(1) to 5.49(1) Å on going from **3** to **4**, a state of affairs that is reflected in a concomitant marked decrease in density $D_{calcd.}$ from 3.226 to 2.679 g cm^{-3}. Four of the arsenic atoms in **3** [As2, As4, As6, As8] and six such atoms

in **4** [As1, As3, As5, and C_i symmetry related atoms] display typical ψ-tetrahedral coordination geometries.

Trigonal Bipyramidal Coordination of As^{III}

The remaining arsenic atoms in **3** and **4** participate in Pt^{II} coordination and themselves exhibit unique distorted trigonal bipyramidal coordination geometries. Average bond lengths and angles to these λ^5-As atoms are summarised in Table 1. As^{III} can be regarded as a weak Lewis acid in its trihalides AsX_3 and its ability to extend its coordination number to 4 (ψ-trigonal bipyramidal), 5 (ψ-octahedral), and even 6 (octahedral) is now structurally well documented for such compounds[13][14][15]. A similar tendency to participate in secondary bonds has also been reported for $As^{III}O_3$ units, e.g. O···As interactions of length 2.68 Å in $Ba_2As_6O_{11}$[16]. A characteristic property of organoarsenic(III) compounds is, of course, their pronounced Lewis basicity and examples of their dative As→M bonds (M = metal), in which the As^{III} atoms display a tetrahedral coordination geometry, are myriad. In contrast, to our knowledge, **3** and **4** provide to first examples of As^{III} atoms in a trigonal bipyramidal coordination environment, i.e. of trivalent arsenic behaving simultaneously as a Lewis base and Lewis acid. An analysis of the bond distances in **3** and **4** indicates that the possible alternative assignment of the oxidation state IV to the λ^5-As atoms would be inappropriate. For instance the axial donor O→As interactions involving the acetamino units are much weaker than the opposite As(O)−As bonds (Table 1). This state of affairs manifests itself in the pronounced distortion of the trigonal bipyramidal coordination spheres of the λ^5-As atoms towards the tetrahedra, that are characteristic for organoarsenic(III) complexes. The degree of distortion in **3** may be gauged from the displacements Δ of 0.179−0.203 Å for the λ^5-As atoms from the planes of their equatorial substituents towards the axial acetamido O atoms. Δ increases on going from **3** to **4** (As2 0.2320 Å, As4 0.2620 Å).

Our present work demonstrates that the previously unknown cyclooctamers $(CH_3AsO)_8$ can be stabilised in the equatorial coordination plane of transition metals. At elevated temperatures, cleavage and metal-mediated reaction with solvent acetonitrile can afford novel cagelike multidentate ligands. The presence of silver cations (as provided by $AgNO_3$ or Ag_2CO_3) to remove chloride ions as AgCl is a necessary prerequisite for the construction of the respectively octa- and decanuclear ligands in **3** and **4**.

Experimental Section

All manipulations were performed in an Ar atmosphere in carefully dried solvents. − FAB MS: Fisons VG Autospec with 3-nitrobenzyl alcohol as matrix. − FTIR: Perkin-Elmer 1760X. − Elementary analyses: Carbo Erba 1106 (for **3** and **4**) and Mikroanalytisches Labor Beller, Göttingen (for **1** and **2**). − *cyclo*-$(CH_3AsO)_n$ was prepared by alkaline hydrolysis[7] of CH_3AsCl_2.

[RuCl₂{cyclo-(CH₃AsO)₈}] (**1**): $RuCl_3 \cdot x\ H_2O$ (21 mg, 0.1 mmol) was combined in a Carius tube (Duran glass, medium-walled 4 mm, diameter 16 mm, length 12 cm, volume approximately 10 cm^3) with *cyclo*-$(CH_3AsO)_n$ (106 mg, 1.0 mmol for $n = 1$) dissolved in 1.5 ml of acetonitrile. The tube was flame sealed, heated to 100°C over 40 h and allow to cool slowly to room temperature over a further 80 h. After opening, the solid state product was filtered off and washed with acetonitrile to afford yellow **1**. Yield 72.4 mg (71%). − $C_8H_{24}As_8Cl_2O_8Ru$ (1019.6): calcd. C 9.4, H 2.4, As 58.8; found C 9.4, H 2.3, As 58.8. − FAB-MS [*m*/*z* (%)]: 482(1) $[As_5Me_4O_3]^+$, 395(4) $[As_4Me_2O_4]^+$, 329(10) $[As_4Me_2]^+$, 289(13) $[As_3MeO_3]^+$, 259(16) $[As_2Me_3O_4]^+$. − IR (KBr): $\tilde{\nu}$ = 2999 cm^{-1} (w), 2907 (w), 830 (s), 803 (s), 773 (s), 684 (s), 623 (m), 584 (s), 526 (s, br).

[OsCl₂{cyclo-(CH₃AsO)₈}] (**2**): $OsCl_3 \cdot x\ H_2O$ (31 mg, 0.1 mmol) and *cyclo*-$(CH_3AsO)_n$ (106 mg, 1.0 mmol for $n = 1$) were heated in 1.5 ml of acetonitrile in a Carius tube with the similar temperature programme as for **1**. Yield 74.3 mg of yellow **2** (67%). − $C_8H_{24}As_8Cl_2O_8Os$ (1108.7): calcd. C 8.7, H 2.2, As 54.0; found C 8.6, H 2.1, As 53.9. − FAB-MS [*m*/*z* (%)]: 482(2) $[As_5Me_4O_3]^+$, 395(5) $[As_4Me_2O_4]^+$, 329(12) $[As_4Me_2]^+$, 289(13) $[As_3MeO_3]^+$, 259(22) $[As_2Me_3O_4]^+$. − IR (KBr): $\tilde{\nu}$ = 3001 cm^{-1} (m), 2907 (m), 829 (s), 773 (s), 683 (s), 628 (s), 584 (s), 528 (s, br).

[Pt₂{[cyclo-(As[CH₃]OAs[NC(O)CH₃]O)₂]₂}] (**3**): K_2PtCl_4 (105 mg, 0.25 mmol), $AgNO_3$ (127 mg, 0.75 mmol), and *cyclo*-$(CH_3AsO)_n$ (159 mg, 1.50 mmol for $n = 1$) were heated to 100°C in 1.5 ml of acetonitrile over a period of 16 h in a sealed Carius tube. After cooling to room temperature over 80 h the tube was opened and the sheafs of red crystals of **3** separated manually from precipitated AgCl. Yield after washing 34.2 mg (26%). − $C_{12}H_{24}As_8N_4O_{12}Pt_2$ (1405.9): calcd. C 10.2, H 1.7, N 4.0; found C 9.3, H 1.4, N 3.6. − FAB-MS [*m*/*z* (%)]: 329(13) $[As_4Me_2]^+$, 289(14) $[As_3MeO_3]^+$. − IR (KBr): $\tilde{\nu}$ = 3011 (w), 2920 (w), 1516 (s), 1385 (s), 1029 (m), 820 (s), 781 (s), 679 (m), 628 (m), 597 (m), 477 (s).

[Pt₂{[{CH₃C(O)N}₂As₅(CH₃)₅O₄]₂}] (**4**): K_2PtCl_4 (206 mg, 0.50 mmol), Ag_2CO_3 (208 mg, 0.75 mmol), and *cyclo*-$(CH_3AsO)_n$ (159 mg, 1.50 mmol for $n = 1$) were heated to 100°C in 1.5 ml of acetonitrile with the similar temperature programme as for **3**. After cooling to room temperature the tube was opened and the sheafs of red crystals of **4** separated manually from precipitated AgCl. Yield after washing 33.0 mg (25%). − $C_{18}H_{42}As_{10}N_4O_{12}Pt_2$ (1645.9): calcd. C 13.1, H 2.6, N 3.4; found C 12.8, H 2.4, N 3.1. − FAB-MS [*m*/*z* (%)]: 603(1) $[As_4Me_4O_3Pt]^+$, 498(2) $[As_5Me_4O_4]^+$, 482(2) $[As_5Me_4O_3]^+$, 345(10) $[As_2Pt]^+$, 329(11) $[As_4Me_2]^+$, 289(13) $[As_3MeO_3]^+$. − IR (KBr): $\tilde{\nu}$ = 3001 (w), 2965 (w), 1499 (s), 1402 (s), 1231 (w), 1022 (w), 792 (m), 763 (m), 731 (s), 698 (s), 567 (m), 511 (m).

X-ray Structural Analyses: Siemens P4 diffractometer, graphite monochromator, Mo-K_α radiation (λ = 0.71073 Å), SHELXS-86[17] for structure solution by direct methods and SHELXL-93[18] for refinement by full-matrix least squares. Semi-empirical absorption corrections were applied to the intensity data by use of ψ scans. Hydrogen atoms were included at calculated positions[19].

Keywords: Carbene complexes / Tungsten / Phosphorus / 2*H*-Azaphosphirene complexes / Cyclization

The first syntheses of pentacarbonyl[2-(pentamethyl-2,4-cyclopentadien-1-yl)-2*H*-azaphosphirene]tungsten complexes are reported, using a one-pot reaction of dichloro(pentamethyl-2,4-cyclopentadien-1-yl)phosphane (Cp^*PCl_2) with triethylamine and {[amino(aryl)carbene]pentcarbonyltungsten(0)}. [Pentamethyl-2,4-cyclopentadien-1-yl]phosphanediyl-bridged dinuclear carbene complexes are formed as long-lived intermediates, which, by elimination and rearrangement reactions, led to the final products. If traces of water were present, then by-products were formed; in one case, a dinuclear carbene complex with a P(Cp*)–O–P(Cp*) bridging unit was isolated. Under ordinary reaction conditions 2*H*-azaphosphirene complexes are slowly transformed into {pentacarbonyl[chloro(pentamethyl-2,4-cyclopentadien-1-yl)phosphane]tungsten(0)}. NMR-spectroscopic and single-crystal X-ray structural data of some dinuclear carbene complexes and 2-(pentamethyl-2,4-cyclopentadien-1-yl)-2*H*-azaphosphirene complexes are presented.

The chemistry of (2*H*-azaphosphirene)tungsten complexes has recently been the subject of increased interest, because of their widespread applicability in the synthesis of three-,[2] four-[3] and five-membered[4] heterocycles. Therefore, our interest in further synthetic investigations was enhanced, and one of our most important aims was to develop a new access to 2*H*-azaphosphirene complexes using amino(aryl)carbene complexes, a base and dichloro(organo)phosphanes. Compared to [bis(trimethylsilyl)methylene]chlorophosphane, which was used in our initial synthetic approach,[5] the advantages should be: the ease of accessibility, the option of introducing *P*-functional groups into 2*H*-azaphosphirene complexes and the potential extension of this method to condensation reactions of other dichloro(organo)element compounds of group-15 elements. Furthermore, in order to mimic the bulkyness of the bis(trimethylsilyl)methyl substituent, which is useful for kinetic stabilization, we chose pentamethyl-2,4-cyclopentadien-1-yl (denoted hereafter as Cp*) and the corresponding dichlorophosphane,[6] Cp^*PCl_2.

Our first attempts to treat amino(aryl)carbene complexes **1a**, **b**,[7] **c**,[8] **d**, **e**[7] with Cp^*Cl_2 (**2**) at ambient temperature in ether with an excess of triethylamine failed. Therefore, we switched to the more polar solvent dichloromethane for the reactions reported hereafter. According to ^{31}P-NMR-spectroscopic investigations, the first condensation step and subsequent transformations (paths **a** and **b**) must have occurred very fast, because the mono-condensation products **3** could not be detected. Instead, the first products formed in these reactions were the (Cp*-phosphanediyl)-bridged dinuclear (carbene)metal complexes **4a**–**e**, aside with small amounts of the 2*H*-azaphosphirene complexes **6a**–**e** and complex **7**. **4a**–**e** were most probably formed, according to the two pathways **a**, **b** depicted in Scheme 1. Path **a** describes a further condensation, yielding **4a**–**e**, whereas a base-induced hydrogen chloride elimination, followed by addition of one equivalent of **1** to the short-lived intermediates **5** (cf. ref.[9]), would also explain the generation of the complexes **4a**–**e** (path **b**). Interestingly, upon prolonged reaction, complexes **4a**–**e** eliminated **1** yielding the 2*H*-azaphosphirene complexes **6a**–**e**, probably by unspecified rearrangements of **5**; this elimination reaction has been proven for the case of **4c** by treating a pure sample of **4c** with triethylamine yielding **6c**. We observed that one of the factors that limited the yields of **6a**–**e** was the rate of the reaction of complexes **6a**–**e** with triethylammonium chloride, which led to [{Cp*P(H)Cl}$W(CO)_5$] (**7**) in all cases (Scheme 1). This latter reaction was found to depend strongly on the nature of the *para*-phenyl substituent, the concentration and, most importantly, on the reaction temperature. Therefore, the temperature had to be kept between 0 and 18°C throughout the reactions and subsequent manipulations. Apart from complexes **4a**–**e**, **6a**–**e** and **7**, two other unidentified products (amounts < 5%) were formed transi-

ently; e.g. after generating complex **4c** by treating two equivalents of complex **1c** with one equivalent of **2**, ^{31}P-NMR signals appeared at δ = 42.1 [d, ^{1}J(P,H) = 503.0 Hz] and δ = 28.2 [d, ^{1}J(P,H) = 511.0 Hz]. Based on these ^{31}P-NMR-spectroscopic observations, we tentatively assign these resonances to products with $\sigma^4\lambda^5$-PH-functional structural units, which could arise from hydrogen-shift reactions from the nitrogen to the phosphorus atom in **4c**.

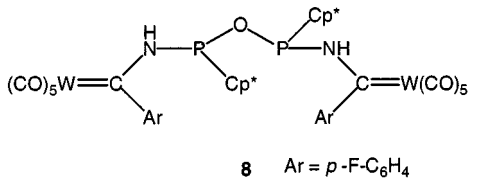
Scheme 1. Proposed reaction course for the formation of metal complexes **4a−g**, **6a−g** and **7**

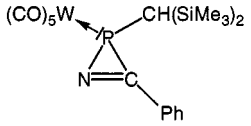
	1a-6a	1b-6b	1c-6c	1d-6d	1e-6e	1f-6f	1g-6g
X	CF_3	Cl	H	F	CH_3	OCH_3	$N(CH_3)_2$

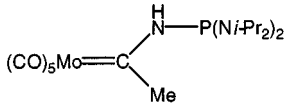
If reactions of **1** with **2** were carried out in the presence of traces of water, other products were formed; in the reaction of **1c** with **2**, we were able to isolate the dinuclear (carbene)metal complex **8** (Scheme 2) having the P(Cp*)−O−P(Cp*) instead of the P(Cp*) bridging unit. This P−O−P bridge most probably resulted from a condensation reaction of two transiently formed (carbene)metal complexes, one having a PCl- and the other a POH-functional group.

Although all complexes described herein have been separated and purified by low-temperature column chromatography and crystallization, we were unable to obtain exact elemental analyses, for reasons that are unclear. Nevertheless, the products were unambigously characterized by several spectroscopic methods. NMR-spectroscopic data of

Scheme 2







complexes **4a−e**, **6a−e**, **7** and **8** are presented in Tables 1 and 2; information on crystallographic data collection and structure determination of complexes **4a**, **b**, **6b**, **c** and **8** are summarized in Table 3, characteristic structural data of complexes **4a**, **b** and **8** are given in Table 4 and those of **6b**, **c** together with **9**, {2-[bis(trimethylsily)methyl]-3-phenyl-2*H*-azaphosphirene-κP}pentacarbonyltungsten(0)[7], in Table 5.

Significant structural units of complexes **4a−g** and **8** such as W=CR_2, Ar−C1 and Cp*P(NR_2)X (X = O, NR_2) are characterized by their typical NMR resonances (Table 1), the latter units displaying chemical shift values in their ^{31}P-NMR spectra at δ = 63±2 and the former at low field at δ = 285±3 (W=CR_2) and 152±4 (Ar-*C*1). It should be noted that the ^{31}P-^{13}C coupling-constant magnitudes are very small for the W=CR_2 carbon atoms (in all cases the signals could not be resolved) and ca. 10 Hz for the Ar-*C*1 carbon atoms. Although no temperature-dependent NMR measurements were undertaken to investigate circumambulatory 1,5-sigmatropic rearrangements of the phosphorus moiety along the Cp* ring in **4a−g**, these compounds should show degenerate rearrangements of this type, in contrast to coordinated phosphorus compounds (such as the 2*H*-azaphosphirene complexes **6a−g**).[6][10]

2*H*-azaphosphirene complexes **6a−g** display trends in chemical shift values and coupling constants (Table 2) that are quite similar, but less pronounced than those of recently

described 2-(*p*-phenyl)-substituted 2*H*-azaphosphirene complexes with the bis(trimethylsilyl)methyl group at phosphorus atom.[7] Compared to the latter complexes, **6a**−**g** have 2*H*-azaphosphirene ring carbon atom resonances that are generally more upfield shifted and have smaller ^{31}P-^{13}C coupling-constant magnitudes. There are remarkable upfield shifts in the ^{1}H- and ^{13}C-NMR resonances of the Cp*−C1 methyl groups, which are even more shielded than in compounds such as Cp*PH_2 (δ = 1.10).[6] Although the origin of this significant effect is not yet understood, two further aspects seem relevant. First, in order to enable better comparison with complex **9**, the ^{15}N-NMR resonance of **6c** was determined [**6c**: δ = −65.2, ^{1}J(P,N) = 39.0 Hz; versus **9**: δ = −53.2, ^{1}J(P,N) = 36.9 Hz]; this presumably points to a higher electron density at the nitrogen atom in **6c**. The second point is discussed below.

Table 2. Selected ^{13}C-[a], ^{31}P-NMR- spectroscopic[a] data of (4-X-phenyl)-substituted complexes **6a**−**g** (exclusively ring atoms of the 2*H*-azaphosphirene ring system)

[a] $CDCl_3$, room temp.; δ/[ppm], J/[Hz]. − [b] Reaction solution. − [c] Not determined.

The molecular structures of the complexes **4a**, **b**, as determined by X-ray crystallography (Figures 1, 2 and Table 3), consist of two Cp*P-bridged amino(aryl)carbene complex moieties, which have an (*E*,*E*) configuration of the pentacarbonyltungsten and the Cp*P fragment with respect to the C−N bond and which differ mainly in their metal−carbon and nitrogen−phosphorus bond lengths of their W−C−P−N skeletons (Table 4). Compared to the structure of [{*N*-[bis(diisopropylamino)phosphanyl]amino}-(methyl)methylene]pentacarbonylmolybdenum(0)[11] (**10**), all P−N bonds of **4a**, **b** are shorter than the related P−N bond of **10** [1.803(2) Å] (Table 4). It is noteworthy that **4a**, **b** always show combinations of short P−N bonds and small N−P−C angles (or the opposite); these differences in bonding *may* serve as picture for an early stage of the elimination process, which was shown to proceed in solution. In contrast to these findings, complex **8** (Figure 3) displays less dissimilar bonds and angles of its structural subunits (Table 4).

2*H*-azaphosphirene complexes **6b**,**c** have molecular structures (Figures 4, 5 and 6) which are somewhat different from the previously reported structure[7] of complex **9** (Table 5). Interesting features are the PCN/arene interplanar angles of 15.4° (**6b**) and 21.3° (**6c**) versus 2° in **9** and the increased bond angles of the C−P−W moieties of **6b**,**c** [C refers in these cases to the directly phosphorus-bonded carbon atoms of the Cp* and $CH(SiMe_3)_2$ groups; Figure 5 shows a better view of the arrangement of the

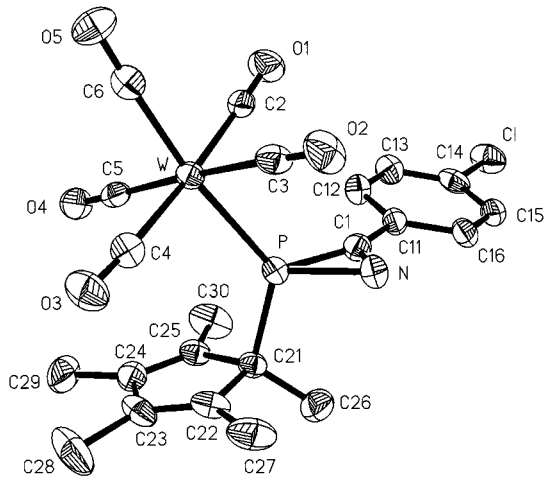

Figure 4. Molecular structure of **6c** in the crystal (ellipsoids represent 50% probability levels, hydrogen atoms are omitted for clarity)

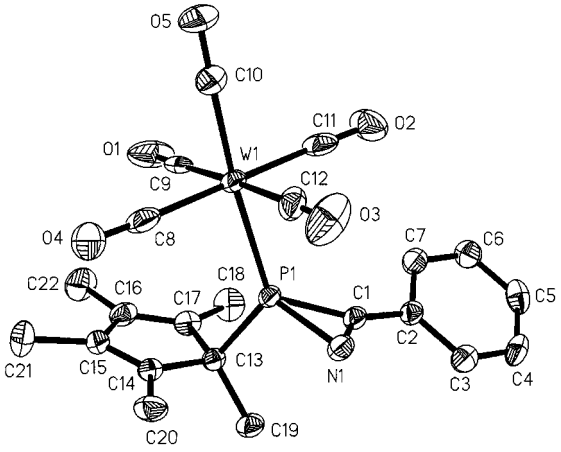

Figure 5. Molecular structure of **6c** in the crystal (view showing the spatial arrangement of the three planar groups of **6c**)

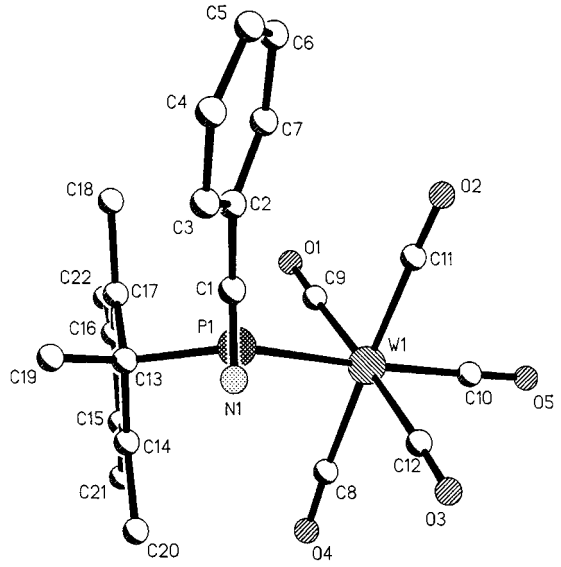

Figure 6. Molecular structure of **8** in the crystal (hydrogen atoms are omitted for clarity)

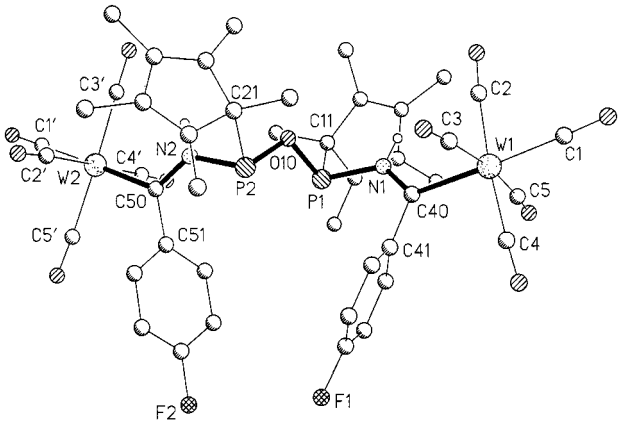

planar groups of **6c**]. Remarkable are also the arrangements of the Cp* [and $CH(SiMe_3)_2$; cf. ref.[7][9]] group(s); the sterically bulky substituents point away from the pentacarbonyltungsten fragment. Because of this, the Cp*−C1 methyl group points towards the midpoint of the C=N double bond and, therefore, to the π-electron system. If this orientation is retained in solution, a through-space shielding of the atoms of such methyl groups could contribute to the unusual upfield shift of the NMR resonances of the Cp*−C1 methyl group signals.

The chemistry of the compounds reported here is under current investigation with special respect to thermal and photochemical reactions.

Support of the *Deutsche Forschungsgemeinschaft* and the *Fonds der Chemischen Industrie* and ^{15}N-NMR measurements by Priv.-Doz. Dr. *Dietrich Gudat* (Universität Bonn) are gratefully acknowledged.

Experimental Section

General: All reactions and manipulations were carried out under deoxygenated dry nitrogen, using standard Schlenk techniques with conventional glassware; solvents were dried according to standard procedures. − NMR spectra were recorded with a Bruker AC-200 or a Bruker AMX-300 spectrometer (AC-200: 200 MHz for ^1H; 50.3 MHz for ^{13}C; 81.0 MHz for ^{31}P; AMX-300: 30.4 MHz for ^{15}N, 12.5 MHz for ^{183}W) using [D]chloroform and [D_6]benzene as solvents, the latter as internal standard; shifts are given relative to ext. tetramethylsilane (^1H, ^{13}C), H_3CNO_2 (^{15}N), 85% H_3PO_4 (^{31}P) and WO_4^{2-} (^{183}W). ^{15}N-NMR spectra were recorded using ^{31}P- and ^1H-based polarisation-transfer techniques (INEPT); ^{183}W spectra were obtained from two-dimensional ^{31}P, $^{183}W\{^1H\}$ (HMQC) spectra. − Mass spectra were recorded with a Finigan Mat 8430 (70 eV); apart from *m/z* values of the molecule ions, only *m/z* values with intensities of more than 20% are given. − Infrared spectra were recorded with a Biorad FT-IR 165 (selected data given). − Melting points were obtained with a Büchi 535 capillary apparatus. − Elemental analyses were performed using a Carlo Erba analytical gas chromatograph. − The κ*P* notation serves to differentiate between *P* and *N* coordination of the appropriate heterocycle to the metal center.

General Procedure for the Synthesis of Dinuclear (Carbene)-tungsten Complexes **4a−g** *and 2H-Azaphosphirene Complexes* **6a−g**: To a solution of 2.1 g (5 mmol) of [amino(aryl)carbene]-tungsten complexes **1a−g** in 50 ml of CH_2Cl_2 was added 25 ml of NEt_3 and 1.2 g (5 mmol) of $Me_5C_5PCl_2$ (**2**) at 0°C. The reaction mixtures were stirred at ambient temp. until **2** was consumed (^{31}P NMR). The dark orange reaction mixtures were concentrated to dryness under reduced pressure (0.1 mbar). The crude product mixtures containing approximately 50% of **4**, 40% of **6** and 5% of **7** (according to ^{31}P-NMR signal integration), were separated and purified by low-temperature chromatography [Al_2O_3 (neutral), hexane/diethyl ether 97.5:2.5] and most of them crystallized from pentane at −20°C.

N,N′-[(Pentamethyl-2,4-cyclopentadien-1-yl)phosphanediyl]bis-{[amino(4-trifluoromethylphenyl)methylene]pentacarbonyltungsten(0)} (**4a**): 0.43 g of **4a** (28%) was obtained as a yellow powder, m.p. 148°C (decomp.). − IR (KBr): $\tilde{\nu}$ = 3292 (sw), 3244 (sw) (NH), 2064 (s), 1993 (br), 1980 (br), 1952 (br), 1933 (br), 1916 (br), 1904 (br), 1872 (s) (CO). − ^1H NMR ($CDCl_3$): δ = 1.19 [d, ^3J(P,H) = 17.4 Hz, 3 H, Cp*−C1−CH_3], 1.91 (s, 6 H, Cp*−CH_3),

Crystal Structure Analyses:[12] Crystal data and refinement details are presented in Table 3. Data were collected with Mo-K_α radiation (λ = 0.71073Å) at low temperature; diffractometer type Stoe Stadi-4 (**4a**, **6b**, **c**) or a Siemens P4 (**4b**, **8**). Absorption corrections were based on ψ scans. Structures were solved by the heavy-atom method and refined anisotropically on F^2 (program SHELXL-93, G. M. Sheldrick, Univ. Göttingen). Hydrogen atoms were included as rigid methyl groups or with a riding model. Weighting schemes were of the form $w^{-1} = \sigma^2(F^2) + (aP)^2 + bP$, where $3P = (2F_c^2 + F_o^2)$ and *a* and *b* are constants optimized by the program.

☆ Dedicated to Professor *Peter Jutzi* on the occasion of his 60th birthday.

Keywords: Cyanuric azide / Tetrazole / Triazine / Nitrogen compounds

2,4-Bis(triphenylphosphanimino)tetrazolo[5,1-*a*][1,3,5]triazine (**1**) was synthesized by reaction of cyanuric azide with triphenylphosphane. **1** is characterized by X-ray structural analysis, IR, Raman, and NMR spectroscopy. The obtained spectra showed that the remaining azide group in **1** reacts with the N4 atom of the triazine ring and forms a tetrazole. An improved crystal structure for 2,4,6-triazido-1,3,5-triazine (**2**) was determined and for the first time a ^{14}N-NMR spectrum was obtained. CAUTION: **2** (Cyanuric azide) is explosive! The explosive nature increases with greater purity and crystal size.

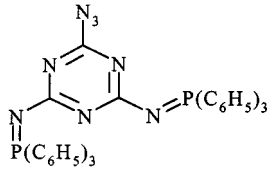
Introduction

Since the discovery of cyanuric azide by H. Finger[1] in 1907 and the development of an improved method in 1921 by E. Ott and E. Ohse[2], there has been considerable interest in the reactivity and the explosive character of cyanuric azide[1]-[11]. In this present study we determined an improved structure[4] of cyanuric azide and investigated the reaction of cyanuric azide with triphenylphosphane, first attempted by W. Kesting in 1923[10].

According to Staudinger and Meyer[12], phenylazide reacts with triphenylphosphane in anhydrous ether to form a phosphazide. The intermediate cannot be isolated at room temperature and spontaneously emits nitrogen to form triphenylphosphanophenylimine. This can be isolated in almost quantitative yield.

In Kesting's application of the Staudinger-Meyer reaction, substituting **2** for phenyl azide[10], the proposed reaction path is given in Equation 1.

$$(N_3CN)_3 + 2\ P(C_6H_5)_3 \xrightarrow[-\,2\,N_2]{Et_2O} \quad (1)$$



The product was, however, only characterized by elemental analyses and melting point. The compound 2,4-bis(triphenylphosphanimino)-6-azido-1,3,5-triazine that W. Kesting described showed no shock or heat sensitivity, in spite of the remaining azide group. In this paper, we report our studies on the synthesis, characterisation, and crystal structure of $C_{39}H_{30}N_8P_2$ (**1**).

Results and Discussion

In the reaction of **2** at room temperature with two equivalents of triphenylphosphane the color changed from colorless to yellow-green. This is thought to be due to the formation of $R-NNN-P(C_6H_5)_3$ (R = residue)[12]. This adduct has only fleeting existence and decomposes by giving off N_2, while the solution again becomes colorless. The end product is shown below (**1**). Raman- and ^{31}P-NMR spectroscopy indicates that **1** is not an azide, due to the absence of the asymmetric and symmetric vibrations of the azide group in the Raman spectrum and two ^{31}P-NMR signals found at δ = 21.7 (s) and δ = 17.2 (s). The single crystal X-ray structure analysis for **1** further confirms that there is no azide group in the molecule.

The azide group reacts with the N4 atom of the triazine ring and forms a tetrazole (Equation 2).

$$(N_3CN)_3 + 2\ P(C_6H_5)_3 \xrightarrow[-\,2\,N_2]{Et_2O} \quad (2)$$

Looking at the calculated (Mulliken) partial charges[13] (N4: −0.38 e; N5: −0.36 e; PM3 level) of the azide, it can be seen, that the ring closure could not take place from the electrostatic point of view. Even the tetrazole has an "unusual" charge distribution with N4: −0.03 e and N5: −0.19 e (assignment see Figure 2).

The driving force for the ring-closure in reaction (2) can only be explained in terms of a π-stabilization of the tetrazole-triazine ring-system. This reaction is therefore orbital controlled. This is confirmed by the symmetry of the molecular orbital shown in Figure 1. Here, only the N5−N4 or N5−N8 interaction is symmetry allowed.

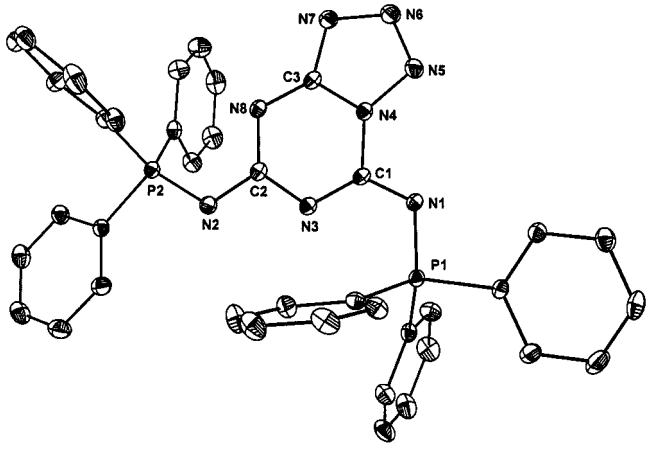
[a] Calcd. for hydrogen derivative.

Crystal Structure of 1

The crystallographic data and refinement details for compound **1** are summarized in the experimental section. **1** crystallizes from chloroform in the monoclinic space group $P2_1/n$ with four molecules and two solvent molecules per tetrazole molecule in the unit cell. Figure 2 shows the crystal structure of compound **1**.

Figure 2. Molecular Structure of **1**



The P−N distance in **1** is 1.614 Å and 1.608 Å. This corresponds to a bond order between one and two. In comparison, the sum of the covalent radius (PN) is 1.8 Å and a typical P−N bond length is found in R_3−P=N−R compounds to be 1.602 Å[15]. The bond lengths and angles of the tetrazole ring (N5−N6: 1.292 Å, N6−N7: 1.364 Å, N5−N6−N7: 112.7°) also correspond to the literature[16]. The C1−N1 and C2−N2 bond lengths in **1** are 1.323 Å and 1.349 Å, respectively their bond order is also between one and two. The sum of the covalent radii (CN) is 1.47 Å for a single bond and 1.27 Å for a double bond[14]. Selected bond lengths [Å] and angles [°] for **1** are given in Table 1.

Table 1. Selected bond lengths [Å] and angles [°] for **1**

P(1)−N(1)	1.614(2)	P(2)−N(2)	1.608(2)
N(1)−C(1)	1.323(3)	N(2)−C(2)	1.349(3)
N(3)−C(1)	1.323(3)	N(3)−C(2)	1.374(3)
N(4)−C(3)	1.359(3)	N(4)−N(5)	1.371(3)
N(4)−C(1)	1.397(3)	N(5)−N(6)	1.292(3)
N(6)−N(7)	1.364(3)	N(7)−C(3)	1.337(3)
N(8)−C(3)	1.334(3)	N(8)−C(2)	1.354(3)
C(1)−N(1)−P(1)	121.50(18)	C(2)−N(2)−P(2)	118.45(18)
C(1)−N(3)−C(2)	119.5(2)	C(3)−N(4)−N(5)	109.3(2)
C(3)−N(4)−C(1)	121.2(2)	N(5)−N(4)−C(1)	129.3(2)
N(6)−N(5)−N(4)	104.9(2)	N(5)−N(6)−N(7)	112.7(2)
C(3)−N(7)−N(6)	105.7(2)	C(3)−N(8)−C(2)	114.0(2)
N(1)−C(1)−N(3)	127.5(2)	N(1)−C(1)−N(4)	115.9(2)
N(3)−C(1)−N(4)	116.5(2)	N(2)−C(2)−N(8)	119.6(2)
N(2)−C(2)−N(3)	115.0(2)	N(8)−C(2)−N(3)	125.4(2)
N(8)−C(3)−N(7)	129.7(2)	N(8)−C(3)−N(4)	122.9(2)
N(7)−C(3)−N(4)	107.4(2)		

The difference in the bond lengths of the triazine (C1−N4 = 1.397 Å, C1−N3 = 1.323 Å) can be explained by different donor-acceptor interactions of the free p-orbital (p-LP) of N1 or N2 with the unoccupied antibonding σ* orbital of the C1−N4 and C2−N3 bond respectively in the ring. From a steric point of view there is more electron density in the antibonding σ* orbital of the C1−N4 bond. This bond therefore is weaker than the C1−N3 bond. This hyperconjugation destabilizes the C−N bond and also explains the π-character of the N1−C1 bond.

Crystal Structure of 2

Cyanuric azide crystallizes from acetone in the hexagonal space group $P\bar{3}$ with two molecules in the unit cell (Figure 3). The C−N−C angle in the triazine ring is 113.09(14)° and the N−C−N angle is 126.91(14)°. The molecule is planar and the distance between the layers is 2.947 Å.

Figure 3. Molecular Structure of **2**

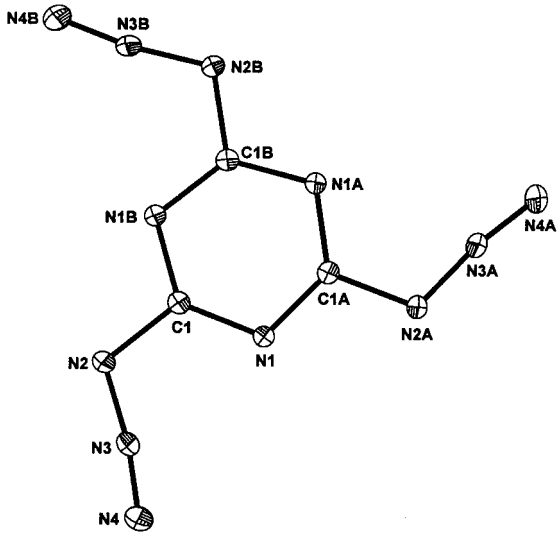


Table 2. ^{14}N- and ^{15}N-NMR shifts for **2**

compound	chemical shift δ [ppm] rel. nitromethane (= 0 ppm)				coupling constant ^1J [Hz]		solvent
	N2	N3	N4	N_{ring}	N2−N3	N3−N4	
$(CNN_3)_3$	−271	−146	−137	−162			acetone
$(CN^{15}N)_3$[9]	−258	−142	−131		16.1	6.1	CD_2Cl_2

The N2−N3 bond length is 1.2658(17) Å, respectively the bond order is between one and two. The covalent radius[14] for single bonded nitrogen atom is r_{cov} = 0.7 Å, 0.6 Å for a double bonded nitrogen atom and 0.55 Å for a triple bonded nitrogen atom. The bond order for N3−N4 [1.1156(19) Å] is between two and three. The angle of the azide group (N2−N3−N4) is 172.00(15)°. With the results of the X-ray structure analysis and the calculated (Mulliken) partial charges[13] (C1: 0.22 e; N1: −0.29 e; N2: −0.42 e; N3: 0.75 e; N4: −0.27 e; PM3 level) the ^{14}N-NMR signals are assigned as shown in Table 2.

The assignment further confirms to the results J. Müller[9] obtained for the ^{15}N-NMR shifts of the azide group.

The crystallographic data and refinement details for **2** are shown in the Experimental Section.

The financial support of this research by the *University of Munich* and the *Fonds der Chemischen Industrie* is gratefully acknowledged.

Experimental Section

General Remarks: CAUTION: **2** is explosive! The explosive nature increases with greater purity and crystal size. Only PE equipment should be used during the preparation and handling of cyanuric azide and safety equipment like leather gloves and face-shield is recommended.

Used solvents were freshly distilled, dried and stored under nitrogen. − NMR: Jeol EX400 Delta (^1H, ^{13}C, chemical shifts refer to δ_{TMS} = 0.00 according to the chemical shifts of residual solvent signals; ^{14}N, external standard: $\delta(CH_3NO_2)$ = 0.00; ^{31}P, external standard $\delta(H_3PO_4, 85\%)$ = 0.00. − IR: Nicolet 520 FT-IR (as KBr pellets or in Nujol on KBr). − Raman: Perkin Elmer Spectrum 2000R NIR FT. − CHN analyses: Analysator Elementar Vario EL. − MS: Finnigan MAT 90. − Melting points are uncorrected (Büchi B540).

2 was prepared according to the procedure given in the literature[2], but the solution was cooled to 5°C for recrystallization from acetone and the crystals were dried in vacuo.

2,4-Bis(triphenylphosphanimino)tetrazolo[5,1-a][1,3,5]triazine (**1**): To a solution of 0.5 g ($2.45 \cdot 10^{-3}$ mol) of **2** in anhydrous ether, a solution of 1.4 g ($5.3 \cdot 10^{-3}$ mol) of PPh_3 was added in two hours at room temperature. The solution was refluxed for 12 h. **1** can be purified by recrystallization from chloroform. $C_{39}H_{30}N_8P_2$ (672.3) Yield: quantitative, colorless crystals; m.p. 239°C (dec.), ref.[10]: 243°C. − IR (KBr): $\tilde{\nu}$ = 3078 cm^{-1} (CH) (w), 1597 (C=C) (s). − Raman (460 scans, 400 mW, 180°, 20°C): $\tilde{\nu}$ = 3064 cm^{-1} (4.5) (CH), 1592 (6.0) (CC), 1576 (1.5) (CC), 1522 (0.5), 1484−1455 (0.5), 1440 (0.7), 1340 (0.5), 1296 (4.0), 1223 (0.6), 1186 (1.0), 1164 (2.0), 1112 (2.0), 1088 (0.5), 1032 (3.5), 1004 (10) (CH), 966 (1.0), 900−854 (0.5), 691 (1.0), 648 (0.7), 620 (1.5), 583 (2.0), 261 (2.5). − ^1H NMR ($CDCl_3$, 400 MHz, 25°C): δ = 7.35−7.98 (m, 30 H, aromatic H). − ^{13}C NMR ($CDCl_3$, 101 MHz, 25°C): δ = 127−134 (m, 36 C, aromatic C), 152 (dd, J_{CP} = 6.9 Hz / 3.1 Hz, $C_{triazine}$), 159 (d, J_{CP} = 1.5 Hz, $C_{triazine}$), 167 (s, $C_{triazine}$). − ^{31}P NMR ($CDCl_3$, 162 MHz, 25°C) δ = 17.3 (s, P), 21.7 (s; P). − MS (EI, 70 eV); *m/z* (%): 672.1 (11) [M^+], 645 (3) [M^+-N_2], 386 (100), 262.0 (44) [PPh_3^+], 185 (37) [PPh_2^+], 77 (9) [Ph^+]. − $C_{39}H_{30}N_8P_2 \cdot 2\ CHCl_3$ (911.39): calcd. Keywords: MRI / Gd^{III} complexes / NMR spectroscopy / NMRD / Lanthanides

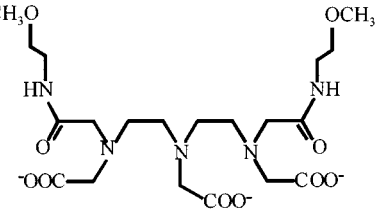
A study including variable-temperature and -pressure, multiple-field ^{17}O NMR, EPR and NMRD has been performed on the MRI contrast agent, [Gd(DTPA-BMEA)(H_2O)]. The water exchange rate [$k_{ex}^{298} = (0.39 \pm 0.02) \times 10^6$ s^{-1}] and the activation volume ($\Delta V^{\neq} = +7.4 \pm 0.4$ cm^3 mol^{-1}), hence the mechanism, are identical to those for [Gd(DTPA-BMA)(H_2O)]. The longer rotational correlation time of [Gd(DTPA-BMEA)(H_2O)], as obtained from a global analysis of ^{17}O-NMR, EPR and NMRD data, and compared to that of [Gd(DTPA-BMA)(H_2O)], can be explained by water molecules hydrogen-bonded to the ether oxygen atoms of the ligand side chain.

Application of paramagnetic complexes of Gd^{3+} for contrast enhancement in clinical Magnetic Resonance Imaging (MRI) is now routine.[1] The first-generation contrast agents approved were ionic chelates, $[Gd(DTPA)(H_2O)]^{2-}$ (in Magnevist™)[2][3] and $[Gd(DOTA)(H_2O)]^-$ (in Dotarem™).[3][4] The search for low osmolar, highly hydrophilic agents that can be administered at higher doses with fewer adverse side effects has led to the development of several neutral agents, such as [Gd(DTPA-BMA)(H_2O)] (in Omniscan™),[3][5] [Gd(HP-DO3A)(H_2O)] (in ProHance™)[3] or [Gd(DTPA-BMEA)(H_2O)] (in OptiMARK®) (Scheme 1).[6–11]

Scheme 1. Structure of the ligand 1,7-bis[(*N*-methoxyethylcarbamoyl)methyl]-1,4,7-tris(carboxymethyl)-1,4,7-triazaheptane (DTPA-BMEA)



The proton relaxation enhancement due to presence of the contrast agent is expressed as proton relaxivity and depends on several factors, for example the rates of water exchange, molecular rotation, and electronic relaxation. In principle, measurement of the variation of proton relaxivity as a function of the magnetic field strength, the nuclear magnetic relaxation dispersion (or NMRD) profile, provides information on all of these parameters. In reality, the separation of the contributions of water exchange, rotation and electronic relaxation to the measured relaxivity is difficult, thus it is necessary to determine these parameters by independent methods. Water exchange rates can be directly obtained by ^{17}O-NMR measurements, whereas EPR experiments yield electronic relaxation rates. Here we report a variable temperature and pressure, multiple field ^{17}O-NMR experiment together with an EPR and NMRD study on [Gd(DTPA-BMEA)(H_2O)]. Analysis of these experiments provided the parameters describing water exchange, rotation and electronic relaxation. Certainly, the real effectiveness of the complex as a contrast agent needs to be tested in tissues or tissue-like models, as the complex-protein interactions may affect the paramagnetic enhancement in vivo.[12–14]

Results and Discussion

UV/Vis spectra were obtained of the analogous europium complex, [Eu(DTPA-BMEA)(H_2O)], in the range of $579 < \lambda < 581$ nm, and yielded a single absorption band that was invariant between 0 and 90°C. The $^7F_o \rightarrow {}^5D_0$ transition band of the Eu^{3+} ion that occurs in this region is very sensitive to changes in the coordination environment of the metal ion.[15] Therefore, the invariance of the spectrum excludes any equilibrium between differently hydrated species, i. e. the only species present is the europium complex with one inner sphere water molecule. Since Gd is very similar to Eu, this finding could be extended to the Gd^{III} complex as well. This is also supported by the value of the ^{17}O scalar coupling constant, $A/\hbar$, which is in the usual range for Gd^{III} complexes with one water molecule in the first coordination sphere (Table 1).[16]

^{17}O NMR, EPR and NMRD

The variable-temperature ^{17}O-NMR, EPR and NMRD data were analysed in a simultaneous fitting procedure, which is based on the several parameters that are common to these techniques (all relevant equations are given in the Appendix). Details of this approach have been previously described.[16] A variable-pressure ^{17}O-NMR study permitted determination of the activation volume for the water exchange process. The resulting curves are shown in Figures 1 and 2 and the fitted parameters are given and compared to those of other Gd^{III}-based contrast agents in Table 1.

Water Exchange

The rate (k_{ex}^{298}) and the activation volume ($\Delta V^{\neq}$), thus the mechanism of the water exchange, are identical for the two bisamide complexes, [Gd(DTPA-BMEA)(H_2O)] and [Gd(DTPA-BMA)(H_2O)]. This is a general finding based on several monomer, dimer or polymer Gd^{III} complexes, i.e. the water exchange rate is not affected by structural changes outside the inner coordination sphere.[17−20] As compared to [Gd(DTPA)(H_2O)]$^{2-}$, the exchange rate is about one order of magnitude lower for the bisamide complexes, whereas the exchange mechanism remains dissociative interchange. The decrease in the exchange rate was explained in terms of a decreased steric crowding around the metal ion when carboxylates are replaced by amide groups.[19] In dissociative interchange processes, high steric crowding helps bond breaking. This effect is less important for amide complexes, which results in a slower water exchange compared to the corresponding carboxylates.

Electronic Relaxation

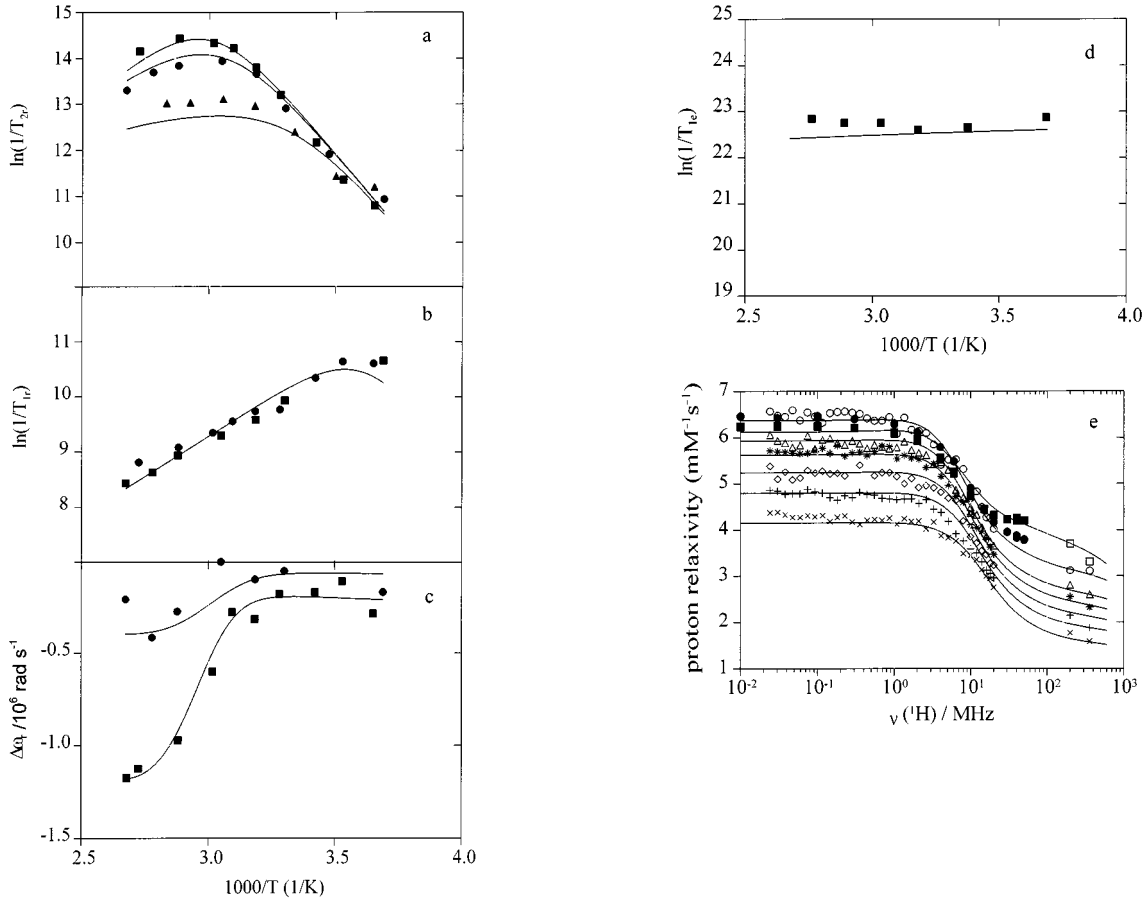
The parameters describing electronic relaxation (the mean square zero-field splitting energy, Δ^2, and the correlation time for the modulation of the zero-field splitting, τ_v^{298}) are identical for the [Gd(DTPA-BMA)(H_2O)] and [Gd(DTPA-BMEA)(H_2O)] complexes.

Rotation

The rotational correlation time is determined by the longitudinal ^{17}O relaxation rates and by the ^{1}H-NMRD data. Both methods have the same drawback as far as the absolute value of τ_R is concerned, i. e. reliance on distance estimates (Gd−H distance for NMRD, or the Gd−O distance for ^{17}O NMR), which have a strong influence on the absolute value of τ_R. In NMRD, the outer sphere contribution to relaxivity is also important, whereas in ^{17}O NMR it is negligible.[21] Due to the practical importance of NMRD data for MRI, contrast agents are generally characterized by the rotational correlation times as obtained from NMRD. In the simultaneous treatment of NMRD and ^{17}O-NMR data a single τ_R is fitted, which we attribute to the rotation of the Gd−water vector. There is very often a discrepancy between the τ_R values obtained in separate fits of ^{17}O- and ^{1}H-NMR data (τ_R from ^{17}O NMR is much longer), due to the use of the incompatible Gd−H and Gd−O distances. In the simultaneous treatment we allow for this by fitting either the Gd−oxygen(water) distance (r_{GdO}) or the quadrupolar coupling constant [$\chi(1 + \eta^2/3)^{1/2}$], which practically means that the rotational correlation time obtained in this way is determined only by the proton relaxation rates.[16]

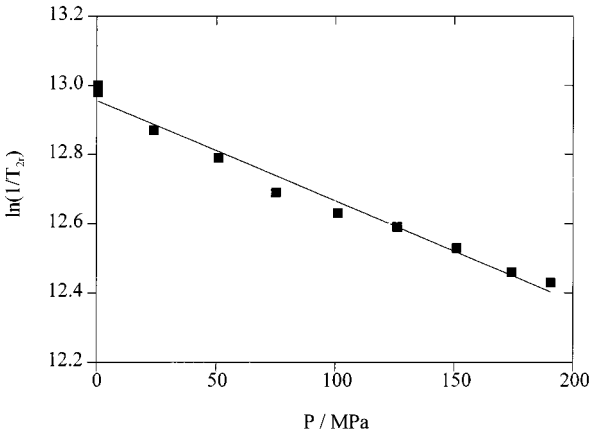
The rotational correlation time for [Gd(DTPA-BMEA)(H_2O)], as obtained from the simultaneous fit, τ_R^{298} = 93 ps, is longer than the one for [Gd(DTPA-BMA)(H_2O)] (66 ps). This increase is larger than what would correspond to the increase in the molecular weight. A reasonable explanation can be that there are water molecules hydrogen-bonded to the ether oxygen atoms of the DTPA-BMEA side chains, a situation that may slow down the rotation of the complex. This seems to be also supported by the higher value of the diffusion constant obtained for [Gd(DTPA-BMEA)(H_2O)], as compared to [Gd(DTPA-BMA)(H_2O)] or [Gd(DTPA)(H_2O)]$^{2-}$. It should be noted, however, that the rotational correlation times obtained from ^{17}O longitudinal relaxation rates (by fixing the Gd−O distance to 2.5 Å and the quadrupolar coupling constant to 7.58 MHz) are very similar for the two bisamide complexes {167 and 172

Figure 1. Temperature dependence of reduced transverse (a), longitudinal (b) ^{17}O-relaxation rates and chemical shifts (c) at B = 14.1 T (■), 4.7 T (●) and 1.41 T (▲); transverse electronic relaxation rates (d) and NMRD profiles (e) at T = 5°C (□, ■), 35°C (○, ●), 43°C (▲), 48°C (*), 53°C (◇), 60°C (+) and 70°C (×) (■ and ● obtained from Seymour Koenig, 360- and 600-MHz data with Bruker spectrometers, otherwise with Stelar FFC relaxometer); the lines represent the simultaneous least-squares fit to all data points as described in the text



ps for [Gd(DTPA-BMA)(H_2O)] and [Gd(DTPA-BMEA)-(H_2O)], respectively}.

Figure 2. Pressure dependence of reduced transverse ^{17}O relaxation rates of [Gd(DTPA-BMEA)(H_2O)] at 298.2 K and B = 9.4 T; the line represents the least-squares fit that yields an activation volume of $\Delta V^{\neq}$ = +(7.4 ± 0.4) cm^3 mol^{-1}



Conclusion

The complexes [Gd(DTPA-BMA)(H_2O)] and [Gd-(DTPA-BMEA)(H_2O)] are identical in respect to water exchange and electronic relaxation. The rotational correlation time for [Gd(DTPA-BMEA)(H_2O)] appears to be longer according to the global analysis of ^{17}O-NMR, EPR and NMRD data, probably due to hydrogen-bonded water molecules around the ether oxygen atoms of the ligand.

We thank the *Swiss National Science Foundation* and the *Office for Education and Science* (OFES) for financial support. This research was carried out in the frame of the EC COST D8 action and the EU-BIOMED program (MACE project). We are grateful to *Mallinckrodt Inc.*, St. Louis MO for their financial support. We wish to thank *Marga Spiller* (Department of Neurosurgery, The New York Medical College, Valhalla, NY) and *Seymour Koenig* (Relaxometry Inc., Mahopac, NY) for use of unpublished NMRD profiles and for discussion.

Experimental Section

General: [Gd(DTPA-BMEA)(H_2O)] was obtained from Mallinckrodt Inc.[22] For the ^{17}O-NMR measurements, solutions of 44

mmol/kg (pH = 5.1) and 118 mmol/kg (pH = 4.7) were used. To improve the sensitivity, ^{17}O-enriched water (10% $H_2{}^{17}O$, Yeda R& D Co., Israel) was added to the Gd complex solutions to yield in 2% ^{17}O enrichment. A 44 mmol/kg solution was used for the EPR study. The absence of free Gd^{3+} ions in all solutions was verified by using xylenol orange indicator.[23] The [Eu(DTPA-BMEA)] solution (0.169 M) was prepared by adding an equimolar quantity of the ligand to a $Eu(ClO_4)_3$ solution and adjusting the pH to 4.7. − The UV/Vis measurements were performed in thermostated cells with a 10-cm optical path length in a Perkin-Elmer Lambda 19 spectrophotometer. − Transverse and longitudinal ^{17}O relaxation rates and chemical shifts were measured at three different magnetic fields using Bruker spectrometers: AMX2-600, 14.1 T, 81.4 MHz; AC-200, 4.7 T, 27.1 MHz; and a 1.41-T 8.14-MHz electromagnet connected to an AC-200 console. The technique used for the ^{17}O-NMR measurements has been described previously.[24] − The EPR spectra were recorded at X-band (0.34 T) using a Bruker ESP 300E spectrometer. − The $1/T_1$ NMRD profiles were obtained with a field-cycling relaxometer in the Department of Neurosurgery, The New York Medical College, Valhalla, NY,[25][26] or with a Stelar Spinmaster FFC relaxometer, in Lausanne ([Gd] = 1−2 mM). − High-field NMRD values (360 MHz and 600 MHz) were measured with Bruker spectrometers.

Data Analysis: The least-squares fitting was performed with Scientist® for Windows™ by Micromath®, version 2.0. The reported errors correspond to one standard deviation obtained by the statistical analysis.

Appendix

Oxygen-17 NMR: From the measured ^{17}O-NMR relaxation rates and angular frequencies of the paramagnetic solutions, $1/T_1$, $1/T_2$ and ω, and of the acidified water reference, $1/T_{1A}$, $1/T_{2A}$ and ω_A, one can calculate the reduced relaxation rates and chemical shift, $1/T_{1r}$, $1/T_{2r}$ and $\Delta\omega_r$, which may be written as in Eqs. 1−3[27], where $1/T_{1m}$, $1/T_{2m}$ are the relaxation rates of the bound water, $\Delta\omega_m$ is the chemical shift difference between bound and bulk water.1

$$\frac{1}{T_{1r}} = \frac{1}{P_m}\left[\frac{1}{T_1} - \frac{1}{T_{1A}}\right] = \frac{1}{T_{1m} + \tau_m} \tag{1}$$

$$\frac{1}{T_{2r}} = \frac{1}{P_m}\left[\frac{1}{T_2} - \frac{1}{T_{2A}}\right] = \frac{1}{\tau_m}\frac{T_{2m}^{-2} + \tau_m^{-1}T_{2m}^{-1} + \Delta\omega_m^2}{(\tau_m^{-1} + T_{2m}^{-1})^2 + \Delta\omega_m^2} \tag{2}$$

$$\Delta\omega_r = \frac{1}{P_m}(\omega - \omega_A) = \frac{\Delta\omega_m}{(1+\tau_m T_{2m}^{-1})^2 + \tau_m^2\Delta\omega_m^2} + \Delta\omega_{os} \tag{3}$$

$\Delta\omega_m$ is determined by the scalar coupling constant, $A/\hbar$, according to Eq. 4, where B represents the magnetic field.

$$\Delta\omega_m = \frac{g_L\mu_B S(S+1)B}{3k_B T}\frac{A}{\hbar} \tag{4}$$

The outer-sphere contribution to the ^{17}O chemical shift is proportional to $\Delta\omega_m$, where C_{os} is an empirical constant (Eq. 5).

$$\Delta\omega_{0S} = C_{0S}\Delta\omega_m \tag{5}$$

The ^{17}O longitudinal relaxation rates are given by Eq. 6[28], where γ_S is the electron and γ_I is the nuclear gyromagnetic ratio (γ_S = 1.76×10^{11} rad s^{-1} T^{-1}, $\gamma_I = -3.626 \times 10^7$ rad s^{-1} T^{-1}), r is the effective distance between the electron charge and the ^{17}O nucleus, I is the nuclear spin (5/2 for ^{17}O), χ is the quadrupolar coupling constant and η is an asymmetry parameter:

$$\frac{1}{T_{1m}} = \left[\frac{1}{15}\left(\frac{\mu_0}{4\pi}\right)^2\frac{\hbar^2\gamma_I^2\gamma_S^2}{r_{GdO}^6}S(S+1)\right]\times\left[6\tau_{d1} + 14\frac{\tau_{d2}}{1+\omega_S^2\tau_{d2}^2}\right] + \frac{3\pi^2}{10}\frac{2I+3}{I^2(2I-1)}\chi^2(1+\eta^2/3)\tau_R \tag{6}$$

$$\tau_R = \tau_R^{298}\exp\left[\frac{E_R}{R}\left(\frac{1}{T} - \frac{1}{298.15}\right)\right] \tag{7}$$

In the transverse relaxation the scalar contribution, $1/T_{2sc}$, is the most important one (Eq. 8)[21]. In Eq. 8, $1/\tau_{sj}$ is the sum of the exchange rate constant and the electron spin relaxation rate.

$$\frac{1}{T_{2m}} \cong \frac{1}{T_{2sc}} = \frac{S(S+1)}{3}\left(\frac{A}{\hbar}\right)^2\left(\tau_{s1} + \frac{\tau_{s2}}{1+\omega_s^2\tau_{s2}^2}\right) \tag{8}$$

$$\frac{1}{\tau_{sj}} = \frac{1}{\tau_m} + \frac{1}{T_{je}} \qquad j = 1,2$$

The binding time (or exchange rate, k_{ex}) of water molecules in the inner sphere is assumed to obey the Eyring equation (Eq. 9), where $\Delta S^{\neq}$ and $\Delta H^{\neq}$ are the entropy and enthalpy of activation for the exchange process, and $k_{ex}{}^{298}$ is the exchange rate at 298.15 K.

$$\frac{1}{\tau_m} = k_{ex} = \frac{k_B T}{h}\exp\left\{\frac{\Delta S^{\neq}}{R} - \frac{\Delta H^{\neq}}{RT}\right\} = \frac{k_{ex}^{298}T}{298.15}\exp\left\{\frac{\Delta H^{\neq}}{R}\left(\frac{1}{298.15} - \frac{1}{T}\right)\right\} \tag{9}$$

EPR: The ZFS terms can be expressed by Eqs. 10 and 11[29][30], where Δ^2 is the trace of the square of the transient zero-field-splitting tensor, τ_v is the correlation time for the modulation of the ZFS with the activation energy E_v, and ω_s is the Larmor frequency of the Gd^{3+} electron spin.

$$\left(\frac{1}{T_{1e}}\right)^{ZFS} = \frac{1}{25}\Delta^2\tau_v\{4S(S+1) - 3\}\left(\frac{1}{1+\omega_S^2\tau_v^2} + \frac{4}{1+4\omega_S^2\tau_v^2}\right) \tag{10}$$

$$\left(\frac{1}{T_{2e}}\right)^{ZFS} = \Delta^2\tau_v\left[\frac{5.26}{1+0.372\omega_S^2\tau_v^2} + \frac{7.18}{1+1.24\omega_S\tau_v}\right] \tag{11}$$

$$\tau_V = \tau_V^{298}\exp\left\{\frac{E_V}{R}\left(\frac{1}{T} - \frac{1}{298.15}\right)\right\} \tag{12}$$

The contribution arising from spin rotation is given by Eq. 13, where $\delta g_L{}^2$ is the deviation from the free electron g_L value and τ_R is the rotational correlation time.

$$\left(\frac{1}{T_{ie}}\right)^{SR} = \frac{\delta g_L^2}{9\tau_R} \qquad i = 1,2 \tag{13}$$

NMRD: The measured proton relaxivities [normalized to 1 mM Gd^{III} concentration] contain both inner-sphere and outer-sphere contributions (Eq.13).

$$r_1 = r_{lis} + r_{los} \tag{14}$$

The inner-sphere term is given by Eq. 15, where q is the number of inner-sphere water molecules.

$$r_{lis} = \frac{1}{1000}\times\frac{q}{55.55}\times\frac{1}{T_{1m}^H + \tau_m} \tag{15}$$

$$\frac{1}{T_{1m}{}^{H}} = \frac{2}{15}\left(\frac{\mu_o}{4\pi}\right)^2 \frac{\hbar^2\gamma_S^2\gamma_I^2}{r_{GdH}^6} S(S+1)\left[\frac{3\tau_{d1}}{1+\omega_I^2\tau_{d1}^2} + \frac{7\tau_{d2}}{1+\omega_S^2\tau_{d2}^2}\right] \qquad (16)$$

The longitudinal relaxation rate of inner-sphere protons, $1/T_{1m}{}^{H}$ can be expressed as in Eq. 16[31][32].

In Eq. 16, r_{GdH} is the effective distance between the Gd^{III} electron spin and the water protons, ω_I is the proton resonance frequency, and τ_{di} is given by Eq. 17.

$$\frac{1}{\tau_{di}} = \frac{1}{\tau_m} + \frac{1}{\tau_R} + \frac{1}{T_{ie}} \qquad i = 1, 2 \qquad (17)$$

The outer-sphere contribution can be described by Eq. 18[25][33], where N_A is the Avogadro constant, and J_{os} is a spectral density function.

$$^{24}r_{os} = \frac{32N_A\pi}{405}\left(\frac{\mu_0}{4\pi}\right)^2 \frac{\hbar^2\gamma_S^2\gamma_I^2}{a_{GdH}D_{GdH}} S(S+1)\left[3J_{os}(\omega_I, T_{1e}) + 7J_{os}(\omega_S, T_{2e})\right] \qquad (18)$$

$$J_{os}(\omega, T_{je}) = \mathrm{Re}\left[\frac{1 + 1/4\left(i\omega\tau_{GdH} + \frac{\tau_{GdH}}{T_{je}}\right)^{1/2}}{1 + \left(i\omega\tau_{GdH} + \frac{\tau_{GdH}}{T_{je}}\right)^{1/2} + 4/9\left(i\omega\tau_{GdH} + \frac{\tau_{GdH}}{T_{je}}\right) + 1/9\left(i\omega\tau_{GdH} + \frac{\tau_{GdH}}{T_{je}}\right)^{3/2}}\right]$$

$$j = 1, 2 \qquad (19)$$

For the temperature dependence of the diffusion coefficient for the diffusion of a water proton away from a Gd^{III} complex, D_{GdH}, we assume an exponential temperature dependence, with an activation energy E_{DGdH} (Eq. 20).

$$D_{GdH} = D_{GdH}^{298}\exp\left\{\frac{E_{DGdH}}{R}\left(\frac{1}{T} - \frac{1}{298.15}\right)\right\} \qquad (20)$$

Keywords: β-Donor bonds / Silicon / Electrostatic interactions / Negative hyperconjugation

The compounds $Cl_2Si(ONMe_2)_2$ and $Cl_2Ge(ONMe_2)_2$ were prepared by the reaction of the appropriate tetrachlorides with *N,N*-dimethylhydroxylamine in the presence of 2,6-lutidine as an auxiliary base. The compounds were obtained as crystalline solids and characterised by elemental analysis, IR and NMR spectroscopy (nuclei ^1H, ^{13}C, ^{15}N, ^{17}O, and ^{29}Si). Their molecular structures were determined by single-crystal X-ray diffraction. The compounds are isostructural and both show the presence of weak secondary bonds between the nitrogen and silicon centres (β-donor bonds), as is indicated by the small angles SiON [102.8(1) and 103.7(1)°] and GeON [102.0(1)°], and the distances Si···N (2.438 and 2.450 Å) and Ge···N (2.519 and 2.520 Å). The conformation is anti-gauche in both compounds (one O–Si–O–N torsion angle being about 180°, the other 60°), but the strength of the β-donor interaction is not significantly affected by the different *anti*-substituents at the nitrogen centres, although such behaviour was expected from earlier studies carried out on $ClH_2SiONMe_2$. The β-donor interactions are also weaker than those found in $ClH_2SiONMe_2$.

β-Donor interactions, i.e. donor-acceptor interactions between atoms in a geminal position to one another, are now well established in p-block chemistry. In a number of reports we have shown them to contribute significantly to the molecular structures of compounds containing Si−O−N[1] and Si−N−N units[2]. Examples are the (4 + 4)-coordinate $Si(ONMe_2)_4$,[3] and the (4 + 2)-coordinate $H_2Si(ONMe_2)_2$, which has an Si−O−N angle of only 95.2°,[4] and some silyl oximes.[5] The strongest β-donor bond found so far in Si−O−N systems occurs in $ClH_2SiONMe_2$, which has a Si−O−N angle of only 79.7° in the crystal, corresponding to a Si···N distance of 2.028 Å, which comes close to the sum of covalent radii of silicon and nitrogen atoms (1.87 Å).[6] According to a gas-phase structural analysis of $ClH_2SiONMe_2$ the vapour consists of two conformers. The *anti*-conformer (torsion angle Cl−Si−O−N 180°) has a substantially stronger β-donor interaction (smaller Si−O−N angle 87.1°) than the *gauche*-conformer (104.7°). It is obvious that the *anti*-positioned silicon substituent predominantly determines the strength of the β-donor interaction. In the *gauche* conformation, a H atom is in an *anti* position relative to the nitrogen donor centre, as is the case in $H_3SiONMe_2$, and the *gauche*-conformers of $ClH_2SiONMe_2$ and $H_3SiONMe_2$ have very similar Si−O−N angles. The β-donor interaction cannot be described as a simple electrostatic attraction between unevenly charged geminal centres, but negative hyperconjugation between the lone pair of electrons at the donor centre and empty σ^*-orbitals at the acceptor centre can be used as a rationale.[6] Another possible explanation involves intramolecular dipole interactions, but these models have not been explored in detail.

Other examples for β-donor interactions are found in the crystal structure of $Me_2AlONMe_2$[7] and the aminomethyl lithium compound Me_2NCH_2Li, as was shown very recently by Steinborn et al.[8] The interest in aminoxysilanes also arises from their use as cold curing catalysts in silicone polymer synthesis,[9] and the catalytic activity of hydroxylamines in the alcoholysis of Si−H functions.[10]

Our current aim was the synthesis of the compound $Cl_2Si(ONMe_2)_2$ and its germanium analogue, in order to answer the following questions: Does the strength of a β-donor interaction increase with an increasing number of electronegative substituents at the acceptor atom, or will effects like "back-bonding" reduce the acceptor ability? Which of the *anti*-substituents is preferred, O or Cl? Is the structure of $Cl_2Si(ONMe_2)_2$ more comparable to that of $H_2Si(ONMe_2)_2$ (∠SiON 95.2°) or to that of $ClH_2SiONMe_2$ (∠SiON 79.7°), or comparable to neither? The following study will show that finding the answers to these questions is actually more difficult than expected and that the nature of β-donor interactions is not yet sufficiently understood.

Results and Discussion

Synthesis: The compounds $Cl_2Si(ONMe_2)_2$ and $Cl_2Ge(ONMe_2)_2$ have been prepared by the reaction of *N,N*-dimethylhydroxylamine with the corresponding tetrachloride of silicon and germanium in the presence of the auxiliary base 2,6-lutidine with pentane as a solvent. The formation of these compounds seems to be favoured under these conditions, as attempts to prepare the triply substituted compounds $ClSi(ONMe_2)_3$ and $ClGe(ONMe_2)_3$ also

 © WILEY-VCH Verlag GmbH, D-69451 Weinheim, 1998 1434−1948/98/1212−2023 $ 17.50+.50/0

resulted in the formation of $Cl_2Si(ONMe_2)_2$ and $Cl_2Ge(ONMe_2)_2$, despite the application of an excess of *N,N*-dimethylhydroxylamine. A suitable temp. to perform the reactions is −60°C. The overall yields achieved in this way are typically >60%.

$$2\ Me_2NOH + SiCl_4 + 2\ C_7H_9N \rightarrow Cl_2Si(ONMe_2)_2 + 2\ C_7H_9N \cdot HCl$$

$$2\ Me_2NOH + GeCl_4 + 2\ C_7H_9N \rightarrow Cl_2Ge(ONMe_2)_2 + 2\ C_7H_9N \cdot HCl$$

Both compounds are crystalline solids soluble in organic solvents. They are air-sensitive, and the solutions fume in moist air. The compounds can be stored at ambient temp. under an inert atmosphere.

Spectroscopy: The identity of the compounds $Cl_2Si(ONMe_2)_2$ and $Cl_2Ge(ONMe_2)_2$ was proved by gas-phase IR spectroscopy, by NMR spectroscopy of the nuclei ^1H, ^{13}C, ^{15}N, ^{17}O, and ^{29}Si and by mass spectrometry.

The solution-NMR spectra recorded at 21°C do not show any preference for certain conformations. Both Me_2NO groups are magnetically equivalent. The proton and proton-decoupled carbon spectra show one singlet each. The occurrence of a quartet of quartets in the proton-coupled carbon spectra verify the presence of a Me_2N group.

The ^{15}N-NMR chemical shifts of $Cl_2Si(ONMe_2)_2$ and $Cl_2Ge(ONMe_2)_2$ are δ = −228.5 and δ = −231.8, which is a shift of about 20 ppm to higher frequencies as compared to the shifts of $ClH_2SiONMe_2$ (δ = −249.5) and the compounds $H_{4-n}Si(ONMe_2)_n$ (n = 1−4, δ = −248.1 to −249.2. The ^{17}O-chemical shift of $Cl_2Si(ONMe_2)_2$ and $Cl_2Ge(ONMe_2)_2$ are δ = 188 and δ = 193. This corresponds to a shift to higher frequencies relative to the shifts of the compounds $H_{4-n}Si(ONMe_2)_n$ (n = 1−4, δ = 135−141) and ClH_2SiOMe_2 (δ = 137). The NMR data do not indicate the existence of inter- or intramolecular donor-acceptor interactions, but rather show such interactions to be efficiently broken by the solvent (C_6D_6), which has also been observed in comparable compounds.

Crystal Structure Determination of $Cl_2Si(ONMe_2)_2$ and $Cl_2Ge(ONMe_2)_2$: Single crystals of $Cl_2Si(ONMe_2)_2$ and $Cl_2Ge(ONMe_2)_2$ were grown by crystallisation from pentane and ether, respectively. Both compounds crystallise in the monoclinic space group $P2_1/c$ with Z = 4 formula units in the unit cell. They are isostructural, with only slightly different cell parameters.

In the crystals of both compounds the molecules are present as monomers. Intermolecular contacts, which would normally be regarded as significant, are absent.

Both compounds adopt the same conformation, which is *anti-gauche*, i.e. one torsion angle OSiON is close to 180° [$Cl_2Si(ONMe_2)_2$: −177.5(1), $Cl_2Ge(ONMe_2)_2$: −178.1(1)°], whereas the other is close to 60° [$Cl_2Si(ONMe_2)_2$: −64.8(1), $Cl_2Ge(ONMe_2)_2$: −64.5(1)°]. The nitrogen atoms of *gauche*-substituents have chlorine atoms in an *anti*-position in almost perfect orientation [torsion Cl(Si/Ge)ON $Cl_2Si(ONMe_2)_2$: 176.1(1), $Cl_2Ge(ONMe_2)_2$: 176.4(1)°].

Despite the different *anti*-substituents, the Si−O−N and Ge−O−N angles on either side of the molecule are almost the same. The angles GeON in $Cl_2Ge(ONMe_2)_2$ are only slightly smaller than the angles SiON in $Cl_2Si(ONMe_2)_2$. This is surprising with reference to the results of crystal structures of $ClH_2SiONMe_2$ (∠SiON 79.7°) and $H_2Si(ONMe_2)_2$ (∠SiON 95.2°): First of all the angles in $Cl_2Si(ONMe_2)_2$ and $Cl_2Ge(ONMe_2)_2$ are much larger than in the compounds referred to above. Secondly, the influence of the *anti*-substituent on the magnitude of the SiON angle seems to be negligible in this case. At this stage it might be concluded that either the increased steric requirements at the acceptor atom, or its reduced acceptor character by

backbonding from the lone pairs at the chlorine and oxygen substituents, is the reason for the weaker β-donor interactions in $Cl_2Si(ONMe_2)_2$ and $Cl_2Ge(ONMe_2)_2$. In fact the SiON angles in these compounds are similar to that of the parent compound $H_3SiONMe_2$, with no further electronegative substituents at the silicon atom apart from that of the single aminoxy substituent.

The bond lengths of both parts of the molecules are very similar. According to the negative hyperconjugation model for the description of β-donor interactions, one would have to expect the E−O and E−Cl bonds in an *anti*-position relative to a nitrogen donor centre to be slightly lengthened with respect to those in a *gauche* position. The conformations of $Cl_2Si(ONMe_2)_2$ and $Cl_2Ge(ONMe_2)_2$ provide us with one of each of these possibilities. In fact the *anti*-positioned chlorine atoms Cl(2) have slightly longer bonds to the central atom than the atoms Cl(1), and the same is the case for the Ge−O(2) bond in $Cl_2Ge(ONMe_2)_2$, which is slightly longer than the Ge−O(1) bond. However, the two Si−O bonds in $Cl_2Si(ONMe_2)_2$ are of the same length within experimental errors.

Conclusion

The present study shows that the occurrence of strong β-donor interactions in SiON systems, which is represented by small SiON angles, is not simple to predict. Although the silicon (and germanium) atom in $Cl_2Si(ONMe_2)_2$ bears more electronegative substituents than in $ClH_2SiONMe_2$ the SiON angle in the first case is much larger. This cannot be understood in terms of simple electrostatic interactions. However, it has already been shown for $ClH_2SiONMe_2$ that a simple electrostatic model cannot explain the very different Si−O−N angles in the *gauche* and *anti* conformers of this compound,[6] and that compounds with even higher positive charges at silicon, such as $Si(ONMe_2)_4$, have wider SiON angles.[4] Therefore the influence of electrostatics should not be overestimated. Clearly the steric requirements at the silicon centre in $Cl_2Si(ONMe_2)_2$ are very different from that in $ClH_2SiONMe_2$, which might account for the differences. A similar argument for the rationalisation of the angle at the oxygen atom can be based upon the low directionality of the Si−O bonds, which is predominantly ionic.[11] However, $Cl_2Si(ONMe_2)_2$ and $H_3SiONMe_2$ have similar SiON angles but the silyl groups are very different in size. Steric requirements and electrostatic interactions could be competing effects, but even a consideration of both could not fully account for the structures observed in SiON compounds.

We are presently investigating the intramolecular electronic effects concerning β-donor-acceptor systems, including dipole interactions and the distribution of electron density, in more detail. Studies on other compounds with geminal acceptor and donor centres in geminal positions should also improve our knowledge on those systems.

This work was supported by the *Bayerischer Staatsminister für Unterricht, Kultus, Wissenschaft und Kunst* (*Bayerischer Habilitationsförderpreis* 1996 for N. W. M.), by the *Deutsche Forschungsgemeinschaft*, the *Fonds der Chemischen Industrie*, the *Leonhard-Lorenz-Stiftung*, and to *Bayer AG, Leverkusen*, for a donation of *N,N*-dimethylhydroxylamine hydrochloride. We thank Mr. *J. Riede* for assistance with the crystallographic data collection and we are grateful to Professor *H. Schmidbaur* for his generous support.

Experimental Section

The experiments were carried out using a standard Schlenk line or a vacuum line with greaseless stopcocks (Young taps), directly attached to the gas cell in an FTIR spectrometer (Midac Prospect FTIR). *N,N*-Dimethylhydroxylamine was liberated from its hydrochloride in liquid ammonia.[12] − NMR: Jeol JNM-LA400 spectrometer; samples in sealed tubes with C_6D_6 as a solvent (21°C) directly condensed onto the sample from K/Na alloy.

Bis(dimethylaminoxy)dichlorosilane: A solution of *N,N*-dimethylhydroxylamine (3.0 ml, 42 mmol) and 2,6-lutidine (4.9 ml, 42 mmol) in pentane (25 ml) was added dropwise to a cooled solution (−60°C) of tetrachlorosilane (2.4 ml, 21 mmol) in pentane (50 ml). The mixture was slowly warmed to ambient temp. After filtration from the salt the solvent was removed in vacuo. The residue was dissolved in 5 ml of diethyl ether and kept at −18°C for 1 d. Bis(dimethylaminoxy)dichlorosilane was isolated as large colourless crystals extremely sensitive to moist air (3.1 g, 67%). − ^{1}H NMR: δ = 2.43 (s, 12 H, H_3C). − ^{13}C NMR: δ = 49.8 (q q, $^1J_{CH}$ = 136.0 Hz, $^3J_{CNCH}$ = 5.4 Hz, CH_3). − ^{15}N{^{1}H} NMR: δ = −228.5 (s). − ^{17}O NMR: δ = 188 (s). − ^{29}Si NMR: δ = −51.9 (s). − MS(CI): *m/z* (%) = 174 (100) [$M^+ - NMe_2$]. − $C_4H_{12}N_2O_2Cl_2Si$ (171.1): calcd. C 22.0, H 5.5, N 12.8; found C 22.0, H 5.5, N 12.9.

Bis(dimethylaminoxy)dichlorogermane: A solution of *N,N*-dimethylhydroxylamine (2.0 ml, 28 mmol) and 2,6-lutidine (3.3 ml, 28 mmol) in pentane (25 ml) was added dropwise to a cooled solution (−60°C) of tetrachlorogermane (1.6 ml, 14 mmol) in pentane (50 ml). The mixture was slowly warmed to ambient temp.. After filtration from the salt the solution was slowly fractionated through a series of cooled traps and bis(dimethylaminoxy)dichlorogermane remained as a small amount of colourless crystals, extremely sensitive to moist air. − ^{1}H NMR: δ = 2.41 (s, 12 H, H_3C). − ^{13}C NMR: δ = 50.3 (q q, $^1J_{CH}$ = 136.0 Hz, $^3J_{CCCH}$ = 5.4 Hz, CH_3). − ^{15}N{^{1}H} NMR: δ = −231.8 (s). − ^{17}O NMR: δ = 193 (s). −MS(CI): *m/z* (%) = 264 (85) [$M^+ - H$]. − $C_4H_{12}Cl_2GeN_2O_2$ (263.63): calcd. C 18.2, H 4.6, N 10.6; found C 18.7, H 4.6, N 10.4.

Crystal Structure Determinations: Single crystals of $Cl_2Si(ONMe_2)_2$ and $Cl_2Ge(ONMe_2)_2$ were selected under a polarisation microscope and mounted into a glass capillary under Ar [$Cl_2Si(ONMe_2)_2$] and under inert perfluoropolyether [Fomblin, $Cl_2Ge(ONMe_2)_2$], respectively. Diffractometer: Enraf-Nonius CAD4, Mo-K_α radiation, graphite monochromator (λ = 0.71073 Å). Solution: direct methods;[13] refinement: SHELXL93.[14] No absorption correction applied. Non-H atoms were refined with anisotropic thermal displacement parameters, hydrogen atoms were located in difference Fourier maps and refined isotropically.

Admission of molecular oxygen to a solution containing $Ni(PMe_3)_4$ and substituted phenols (ArOH) affords bisphenolatonickel compounds *trans*-$Ni(OAr)_2(PMe_3)_2$ [ArOH = 2-chlorophenol (**1**), 2-bromophenol (**2**), 2,4,6-trichlorophenol (**3**)]. In the absence of dioxygen the phenols reversibly protonate the nickel complex to form ionic compounds $[NiH(PMe_3)_4]^+ Y^-$ containing hydrogen-bonded anions Y = $[H_2(2\text{-}Cl\text{–}C_6H_4O)_3]$ (**4**), $[H(2\text{-}OH\text{–}C_6H_4COO)_2]$ (**5**). As a side-reaction, formal insertion of nickel to give 2-hydroxyphenylnickel compounds Ni(Ar′) $X(PMe_3)_3$ [Ar′ = 2-OH–C_6H_4; X = Br (**6**), I (**7**)], *trans*-Ni(Ar′)$Cl(PMe_3)_2$ [Ar′ = 2-OH–3,5-Cl_2–C_6H_2 (**8**)] and *trans*-Ni(OAr)$Cl(PMe_3)_2$ [Ar = 2,4,6-Cl_3–C_6H_2 (**9**)] is observed. An X-ray crystal structure determination of **1** shows a *trans* square planar arrangement of donor atoms, that of **6** shows a distorted square pyramid, while **4** contains tetrahedral nickel cations with a delocalized hydrogen atom and triphenolate anions $H_2(ArO)_3^-$.

Introduction

Steric protection is the key feature in the synthesis of molecular diphenolato-bis(trimethylphosphane) nickel compounds starting from substituted phenols, $Ni(PMe_3)_4$, and dioxygen.[1] Prior to the admission of dioxygen the colour of the pale yellow solution is observed to deepen depending on the phenol and on solvent polarity. In our first attempts to isolate a reaction intermediate we recovered mixtures of the starting materials. However, the introduction of halide substituents into the phenols led to the crystallization, in high yields, of ionic compounds containing the hydridotetrakis(trimethylphosphane)nickel cation and hydrogen-bonded oligophenolate anions. Under these conditions we also observed formation of arylnickel complexes in a side-reaction and investigated the factors supporting formation of Ni−C bonds.

Results and Discussion

From pale yellow solutions containing $Ni(PMe_3)_4$ and 2-halogenophenol (except 2-iodophenol, see below) in ether at −78 °C a yellow solid precipitated. Upon admission of dioxygen the precipitate dissolved to fom a red solution according to an overall Eq. 1.

The diphenolatonickel complexes **1**−**3** are red or brown solids that are stable in air for several hours. Recrystallization from pentane or ether afforded dark red crystals that can be dried in vacuo without loss of phosphane ligands. Infrared spectra contain fingerprint absorptions of diphenolatonickel complexes and do not show νOH bands. The proton resonance of the trimethylphosphane groups is a singlet, indicating fast exchange of ligands, and no paramagnetic shift or line broadening is observed. Physical and spectroscopic data are thus in accordance with molecular compounds in a low-spin state and square planar coordination of nickel.[1] When compared with 2-*tert*-butyl-substituted diphenolatonickel complexes no significant downfield shift of the 6-H proton resonance signal is detected and hence no steric congestion in the coordination plane is indicated. Indeed, freely oriented 2-chlorophenolato groups are apparent in the molecular structure of complex **1** (Figure 1).

The nickel atom resides at a crystallographic centre of symmetry, and the P−Ni−O angles attain almost ideal values because there is no steric strain, unlike in the case of 2-*tert*-butyl-substituted analogs in which the angle P−Ni−O is opened up by CH_3−CH_3 repulsion of trimethylphosphanes with bulky substituents R^1 and R^2 (Table 1). In two

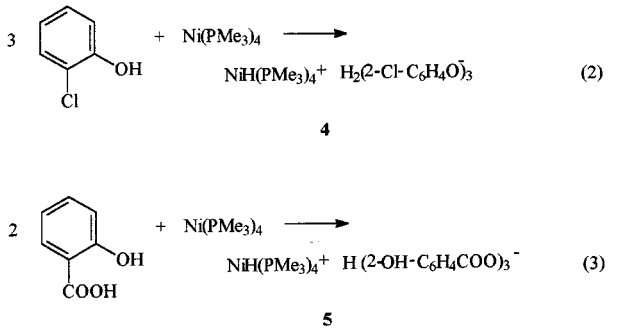
Ion Pair Intermediates

The exclusion of dioxygen from the reaction mixture induces precipitation of a yellow solid by 2-chlorophenol in 85% yield according to Eq. 2.

Recrystallization from toluene gives pale yellow needles in low yield, and solid **4** under argon at 20°C decomposes within two weeks. The crystalline solid may be stored for several months at −20°C and, on rapid heating, decomposes above 162°C.

The use of salicylic acid leads to the formation of a crystalline precipitate according to Eq. 3. Solid **5** may be stored under argon at 20°C for several weeks and in solution is thermally more stable than **4**. The infrared spectra of nujol mulls of **4** and **5** in the region 3000−1600 cm^{-1} contain several broad bands, and a broad absorption at 1950 cm^{-1} is assigned to an Ni−H vibration. A deuterated sample, **4D**, obtained by reaction according to Eq. 1 using 2-



$Cl-C_6H_4-OD$ displayed the expected bathochromic shift of bands, which coincided within a multitude of bands in the fingerprint region. In the NMR experiment freshly prepared samples of **4** in CD_3CN or of **5** in [D_6]THF gave a resonance at δ = −17.2, which is typical for cationic NiH species. After 30 min the signal of **4**, which was not detected in [D_6]THF, gave way to broad resonances of unknown paramagnetic species while that of **5** persisted for some hours.

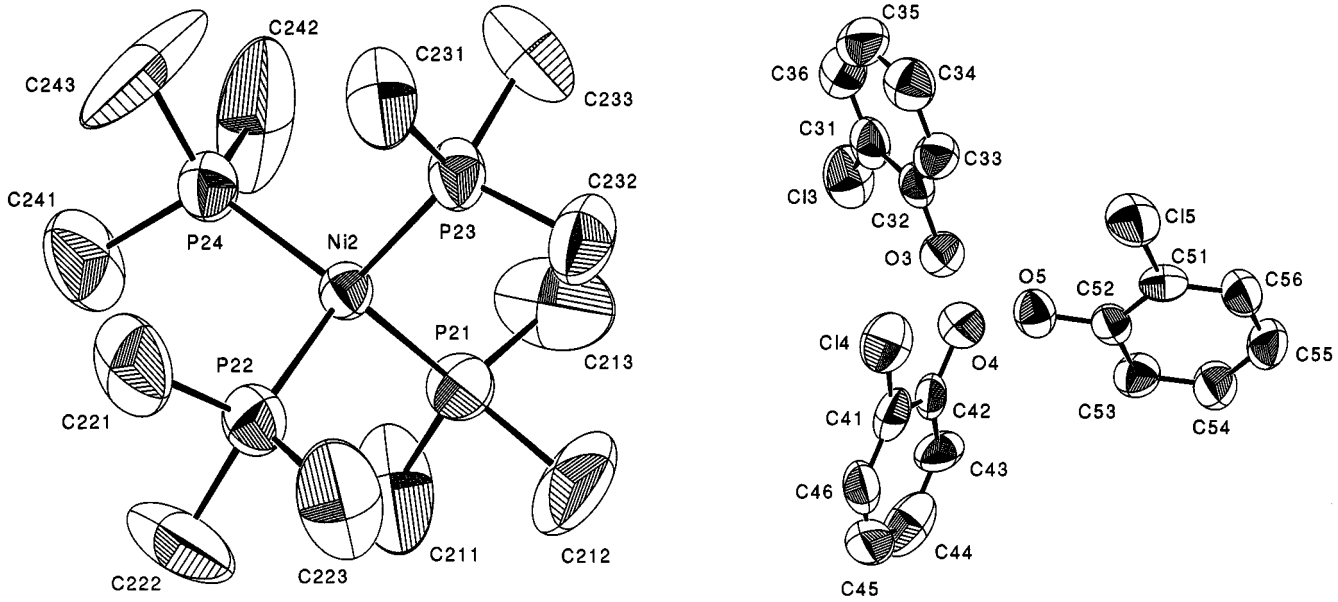
A pale yellow prismatic single crystal of **4** was subjected to an X-ray diffraction experiment. The lattice of **4** consists of separate nickel cations and triphenolate anions with no bonding contacts between the units. The molecular structure of one of the two metal complex cations in the cell is shown on the left hand side of Figure 2. The frame of heavy atoms, NiP_4, appears as an almost ideal tetrahedron with Ni−P distances in the range 2.213(3)−2.236(3) Å (average 2.224 Å) and angles P−Ni−P in the range 105.93(13)−112.60(14)°.

The two anions in the cell consist of three 2-chlorophenolate entities, each arranged with their anionic O atoms in an approximate equilateral triangle with distances O1−O6 = 2.56(1), O2−O6 = 2.53(1), and O1−O2 = 4.26(1) Å (not depicted) or O3−O5 = 2.53(1), O4−O5 = 2.56(1), and O3−O4 = 4.06(1) Å (Figure 2), respectively, which imply two in-plane hydrogen bridges at angles O1−O6−O2 = 112.9(5)° or O3−O5−O4 = 105.9(5)°, respectively. The phenyl rings are oriented roughly perpendicular to that plane with an up-up-down orientation of the 2-chloro substituents. These structural features are in accordance with the presence of a triphenolate anion, which has been previously observed with *para*-cresolates and a ruthenium complex counterion.[2]

Although the structure of the tetrahedral cation $Ni(PMe_3)_4^+$ in $\{Ni(PMe_3)_4][BPh_4]$[3] displays significantly shorter Ni−P bond distances [2.213(3)−2.221(3) Å, average 2.216 Å], the presence of an additional hydrogen atom in **4** appears questionable based solely on structural parameters. Therefore experiments were designed in order to test the presence of the NiH^+ moiety.

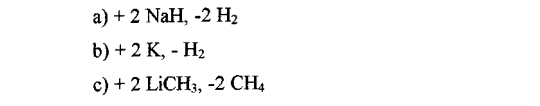
No reaction of **4** or **5** was observed with cyclopentene or carbon dioxide as substrates for an insertion into a metal hydride function. While **4** and **5** failed to protonate trimethylphosphane, action of strong base (NaH, K, or MeLi) on a suspension of **4** or **5** in pentane at −78°C liberated the

Figure 2. Molecular structure of **4** (ORTEP plot without hydrogen atoms)[a]

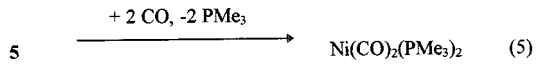


[a] Principal bond lengths [Å] and angles [°]: Ni2−P21 2.223(3), Ni2−P22 2.228(3), Ni2−P23 2.220(4), Ni2−P24 2.236(3), O3−O5 2.53 (1), O4−O5 2.56(1), O3−O4 4.06(1), O3−C32 1.357(9), Cl3−C31 1.733(9), O4−C42 1.354(9), Cl4−C41 1.745(8), O5−C52 1.367(8), Cl5−C51 1.717(7); P21−Ni2−P22 108.52(13), P21−Ni2−P23 108.33(13), P21−Ni2−P24 112.60(14), P22−Ni2−P23 110.5(2), P22−Ni2−P24 106.82(13), P23−Ni2−P24 110.08(14), O3−O5−O4 105.9(5).

expected volume of gas, and quantitative amounts of $Ni(PMe_3)_4$ were recovered (Eq. 4).



(4)

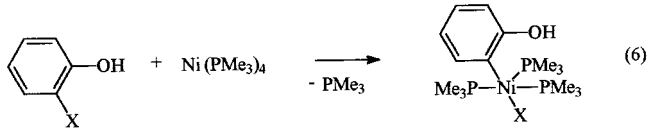


(5)

Protonation of $Ni(PMe_3)_4$ by the phenolic acids was reversed in **4** and **5** under 1 bar CO according to Eq. 5. Thus all successful reactions of **4** and **5** point to the presence of an NiH function exhibiting protic reactivity.

Insertion Reactions

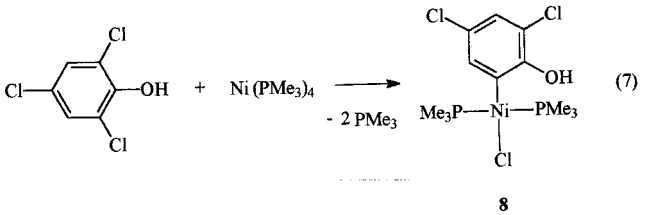
The exclusion of oxygen from the mixtures of $Ni(PMe_3)_4$ and 2-bromo- and 2-iodophenol led to oxidative addition reactions of C−X bonds according to Eq. 6.



(6)

6: X = Br
7: X = I

The pentacoordinate 2-hydroxyphenylnickel complexes **6** and **7** were obtained from ether as red crystals that are air-sensitive and under argon decompose above 100°C. 2-Chlorophenol does not react under these conditions. Additional activation in 2,4,6-trichlorophenol affords a square planar complex according to Eq. 7. The yellow crystals of **8** are stable in air for several hours and under argon decompose above 102°C. Sharp infrared absorptions at 3204 cm^{-1} (**6**), 3264 cm^{-1} (**7**), and at 3264 cm^{-1} (**8**) indicate the presence of an OH group, which is supported by broad proton resonances at δ = 6.7 (**6**), δ = 7.6 (**7**), and δ = 6.1 (**8**).



(7)

8

The molecular structure of **6** (Figure 3) shows a pentacoordinate nickel atom in an approximately square pyramidal surrounding of atoms ($CBrP_3$). The axial distance [Ni−Br = 2.805(2) Å] is considerably longer than the equatorial distances in $NiBr_2(PMe_3)_3$ (Ni−Br = 2.426−2.580 Å).[4] There are two short Ni−P distances in the *trans*-PNiP unit and a longer one roughly opposite to the Ni−C bond reflecting a considerable *trans*-influence. A sizeable *trans*-effect is believed to operate and cause exchange of chloride and phenolato ligands involving **8** and **3** under conditions where both oxidation and insertion reactions occur concurrently according to Eq. 8.

A mixed phenolato-chloro compound (**9**) was found to crystallize from the mixture as violet crystals that are air-stable and melt at 162−164°C. The spectroscopic data support a *trans* square-planar coordination geometry of nickel,

and 2,4,6-trichlorophenol is recovered from the reaction with concentrated hydrochloric acid.

Conclusion

Molecular diphenolatobis(trimethylphosphane)nickel complexes can be prepared in high yields starting from substituted phenols, $Ni(PMe_3)_4$, and dioxygen, if halide substituents in the 2-position of the phenolato ligand prevent condensation reactions. Hydrido(trimethylphosphane)-nickel cations and oligomeric hydrogen phenolate counterions are observed as ion-pair intermediates. Single bromide and iodide or multiple chloride substituents in the absence of dioxygen give rise to insertion reactions that, with the exception of iodophenols, are usually dominated by the faster oxidation processes.

Experimental Section

General Procedures and Materials: All air-sensitive and volatile materials were handled by standard vacuum techniques and kept under argon. Details have been given elsewhere.[5] $Ni(PMe_3)_4$ was prepared by literature methods,[6] phenols and salicylic acid (Merck-Schuchardt) were used as purchased. Measured volumes of oxygen were admitted to the reaction mixture at −70°C in vacuo.

trans-Di(2-chlorophenolato)bis(trimethylphosphane)nickel (**1**): 830 mg of $Ni(PMe_3)_4$ (2.29 mmol) and 2000 mg of 2-chlorophenol (15.6 mmol) in 70 ml of THF at −78°C were combined with 50 ml of dioxygen. Upon warming, the pale yellow solution turned red/brown. After 72 h at 20°C the volatiles were removed in vacuo and the residue was extracted with pentane over a glass-sinter disc (G3). Crystallization at −20°C afforded dark red rhombs. Yield 575 mg (54% based on nickel), m.p. 179−181°C. − IR (Nujol): $\tilde{\nu}$ = 1577 cm^{-1} (C=C), 1033 (C−O), 949 ρ(PCH_3). − ^1H NMR ([D_8]toluene): δ = 0.98 [s(br), 18 H, $P(CH_3)_3$], 6.31 (t, *J* = 7.2 Hz, 2 H, 4-H), 6.95 (d, *J* = 7.4 Hz, 2 H, 6-H), 7.03 (t, *J* = 7.4 Hz, 2 H, 5-H), 8.15 (m, 2 H, 3-H). − ^{13}C NMR ([D_8]THF): δ = 9.39 [s(br), $P(CH_3)_3$], 112.98 (s, C-6), 120.47(s, C-4), 123.26 (s, C-2), 126.11, 127.63 (C-3, C-5), 160.21 (s, C-1). − $C_{18}H_{26}Cl_2NiO_2P_2$ (466.0): calcd. C 45.40, H 5.62, P 13.33; found C 45.99, H 5.54, P 14.78.

trans-Di(2-bromophenolato)bis(trimethylphosphane)nickel (**2**): 720 mg of $Ni(PMe_3)_4$ (1.98 mmol) and 1000 mg of 2-bromophenol (5.78 mmol) in 60 ml of THF at −78°C were combined with 50 ml of dioxygen. Upon warming, the pale yellow solution turned dark red. After 16 h at 20°C the volatiles were removed in vacuo and the residue was washed with 50 ml of ether and extracted with THF over a glass-sinter disc (G3). Crystallization at −20°C afforded dark red rhombs. Yield 640 mg (58% based on nickel), m.p. 175−177°C. − IR (Nujol): $\tilde{\nu}$ = 1571 cm^{-1} (C=C), 1021(C−O), 948 ρ(PCH_3). − ^1H NMR ([D_8]toluene): δ = 1.08 [s(br), 18 H, $P(CH_3)_3$], 6.26−8.26 (m, 8 H). − $C_{18}H_{26}Br_2NiO_2P_2$ (554.9): calcd. C 38.96, H 4.72, P 11.16; found C 39.06, H 4.46, P 11.30.

trans-Bis(2,4,6-trichlorophenolato)bis(trimethylphosphane)nickel (**3**): 700 mg of $Ni(PMe_3)_4$ (1.93 mmol) and 761 mg of 2,4,6-trichlorophenol (3.86 mmol) in 80 ml of THF at −78°C were combined with 50 ml of dioxygen. After stirring the mixture at 20°C for 16 h the volatile components were removed in vacuo and the dark brown residue was washed with pentane and extracted with ether to afford dark brown crystals. Yield 650 mg (56% based on nickel), m.p. 176−178°C. − IR (Nujol): $\tilde{\nu}$ = 1564 cm^{-1} (C=C), 1071 (C−O), 948 ρ(PCH_3). − ^1H NMR ([D_8]THF): δ = 1.64 [s(br), 18 H, $P(CH_3)_3$], 6.90 (m, 4 H). − ^{13}C NMR ([D_8]THF): δ = 13.82 [s(br), $P(CH_3)_3$], 126.44 (s). − $C_{18}H_{22}Cl_6NiO_2P_2$ (603.7): calcd. C 35.81, H 3.67, P 10.26: found C 35.72, H 3.68, P 10.30.

Hydridotetrakis(trimethylphosphane)nickel−Dihydrogentris(2-chlorophenolate) (**4**): 1000 mg of $Ni(PMe_3)_4$ (2.76 mmol) and 1060 mg of 2-chlorophenol (8.28 mmol) were combined in 80 ml of ether at −70°C to give a yellow precipitate. After warming to 20°C the solid was isolated by decantation and drying in vacuo. Yield (1340 mg, 65%). Recrystallization from ether at −27°C afforded 370 mg of yellow crystals (18%), m.p. 162−164°C. − IR (Nujol): $\tilde{\nu}$ = 1950 cm^{-1} (NiH), 1568 (C=C), 1028 (C−O), 940 ρ(PCH_3). − ^1H NMR ([D_8]THF): δ = −17.24 (m, 1 H, NiH), 1.35 [s(br), 36 H, $P(CH_3)_3$], 6.62 (t, *J* = 6.7 Hz, 1 H), 7.00 (m, 2 H, 3-H, 5-H). − ^{13}C NMR ([D_8]toluene): δ = 11.88 [s(br), $P(CH_3)_3$], 20.92 (s, CH_3), 29.94 [$C(CH_3)_3$], 35.21 [s, $C(CH_3)_3$], 114.89 (s, C-3), 124.80 (s, C-5), 128.90 (s, C-4), 141.45 (s, C-2), 143.96 (C-6), 163.07 (s, C-1). − $C_{30}H_{47}Cl_3NiO_3P_4$ (748.7): calcd. C 48.13, H 6.87, Cl 14.21, Ni 7.84, P 16.62; found C 47.68, H 6.91, Cl 14.26, Ni 7.87, P 16.44.

Hydridotetrakis(trimethylphosphane)nickel−Hydrogendisalicylate (**5**): 1210 mg of $Ni(PMe_3)_4$ (3.33 mmol) and 920 mg of salicylic acid (6.66 mmol) were combined in 70 ml of pentane at −78°C to give a pale yellow precipitate. After warming to 20°C the solid was

Chloro(2-hydroxy-3,5-dichlorophenyl)bis(trimethylphosphane)nickel (**8**): 880 mg of Ni(PMe_3)$_4$ (2.42 mmol) and 945 mg of 2,4,6-trichlorophenol (4.85 mmol) were combined in 50 ml of THF at −78°C and after warming to 20°C the solution attained an intense yellow color. After 18 h the volatiles were removed in vacuo and the resulting solid was recrystallized from pentane to afford 240 mg of red crystals (24%), m.p. 102−103°C. − IR (Nujol): $\tilde{\nu}$ = 3486 cm^{-1} (OH), 1552 (C=C), 1063 (C−O), 948 ρ(PCH_3). − ^{1}H NMR ([D$_6$]benzene): δ = 0.92 [s(br), 18 H, P(CH_3)$_3$], 6.11 (m, 1 H, OH), 7.36 (s, 1 H), 7.42 (s, 1 H). − ^{13}C NMR ([D$_8$]THF): δ = 17.68 [s(br), P(CH_3)$_3$], 120.78 (s, CCl), 130.95, 131.84 (s, CH), 132.54 (s, CNi), 162.75 (s, CO). − $C_{12}H_{21}Cl_3NiOP_3$ (408.3): calcd. C 35.30, H 5.18, P 15.17; found C 35.49, H 5.52, P 14.99.

trans-Chloro(2,4,6-trichlorophenolato)bis(trimethylphosphane)nickel (**9**): 880 mg of Ni(PMe_3)$_4$ (2.42 mmol) and 944 mg of 2,4,6-trichlorophenol (4.85 mmol) in 50 ml of THF were combined at −78°C and after warming to 20°C the solution attained an intense yellow color. After stirring for 16 h 50 ml of dioxygen was admitted and a violet coloration was observed. The mixture was stirred for another 3 h, the volatiles were removed in vacuo and the residue extracted with 50 ml of pentane to afford 70 mg of violet crystals (24% based on Ni), m.p. 162−164°C. − IR (Nujol): $\tilde{\nu}$ = 1564 cm^{-1} (C=C), 1077 (C−O), 948 ρ(PCH_3). − ^{1}H NMR ([D$_6$]acetone): δ = 1.57 [m, 18 H, P(CH_3)$_3$], 6.88 (s, 2 H). − ^{13}C NMR ([D$_8$] acetone): δ = 10.65 [t′, ^1J(PC) + ^3J(PC) = 23.9 Hz, P(CH_3)$_3$], 120.94 (s, CH). − $C_{12}H_{20}Cl_4NiOP_2$ (442.8): calcd. C 32.55, H 4.55, P 13.99; found C 32.82, H 4.60, P 14.05.

Crystal Structure Analyses: Crystal data are presented in Table 2.

Data Collection. − *Complex* **1**: A dark red specimen was sealed under argon in a glass capillary and mounted on a Siemens R3m/V diffractometer. Using graphite-monochromated Mo-K_α radiation, lattice parameters were obtained from 25 centered reflections. ω scan data were collected and Lp and empirical absorption corrections were applied. Structure solution was performed by direct methods, full-matrix least-squares refinement based on F^2. All non-hydrogen atoms were treated anisotropically and hydrogen atoms

were fixed at idealized positions. − *Complex* **4**: A yellow specimen (from ether) was sealed under argon in a glass capillary and mounted on a Siemens P4 diffractometer. Data collection, corrections (without ψ-scans), and structure solution and refinement were as for **1**. − *Complex* **6**: A dark red specimen was sealed under argon in a glass capillary and mounted on a Siemens R3m/V diffractometer. Data collection, corrections, and structure solution and refinement as before.

Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre. The reaction of the trialkylalane $(Me_3Si)_3CAlMe_2 \times THF$ (**1**) with H_2S in toluene at room temperature results in the formation of the dimeric sulfido compound $[(Me_3Si)_3CAl(\mu\text{-}S)]_2 \times 2$ THF (**3**), while the reaction of the homologous gallane $(Me_3Si)_3CGaMe_2$ (**2**) with H_2S under similar conditions affords the heterocubane $[(Me_3Si)_3CGa(\mu_3\text{-}S)]_4$ (**4**). Heating of compound **3** in vacuo gives a mixture of the symmetrically substituted $[(Me_3Si)_3CAl(\mu_3\text{-}S)]_4$ (**5**) and the unsymmetrically substituted heterocubane $[\{(Me_3Si)_3CAl(\mu_3\text{-}S)\}_3MeAl(\mu_3\text{-}S)]$ (**6**). Reaction of the trialkylmetalanes **1** and **2** with elemental selenium in refluxing toluene results in the formation of the corresponding selenolates $[(Me_3Si)_3CMMe(\mu\text{-}SeMe)]_2$ (**7**, M = Al; **8**, M = Ga). The compounds exhibit a high thermal stability and can not be converted to the corresponding selenides $[(Me_3Si)_3CM(\mu_3\text{-}Se)]_n$ (M = Al, Ga) upon heating. In contrast, the trialkylalane **1** does not react with tellurium metal in refluxing toluene at all, while the trialkylgallane **2** affords the tellurolate $[(Me_3Si)_3CGaMe(\mu\text{-}TeMe)]_2$ (**9**) under similar conditions. Compounds **3–9** have been characterized by ^1H- and ^{29}Si-NMR, mass, and IR spectroscopy. Furthermore, the molecular structures of compounds **3** $\cdot$ C_6H_6, **4** $\cdot$ 1.5 C_6H_6, **6**, **7** $\cdot$ C_6H_6 and **9** have been determined by X-ray crystallography.

Introduction

Organometallic cage compounds of aluminum and gallium with bonds to group 15 elements with composition $[RMER']_x$ (M = Al, Ga; E = N, P; R, R′ = H, alkyl, aryl) have been intensively studied over the last two decades[1] especially due to their potential use as precursors of group 13-15 materials. In contrast, only a few of fully characterized cage compounds $[RME]_x$ (R = alkyl, aryl; M = Al, Ga; E = S, Se, Te) of groups 13 and 16 have been reported.[2] This is surprising, since materials with compositions ME and M_2E_3 (M = Ga, In; E = S, Se) have interesting electronic and optoelectronic properties and could possibly find applications for nonlinear optics,[3] photovoltaics,[4] and electronic devices.[5] Moreover, the cubic phase of gallium sulfide prepared from the single source precursor $[t\text{BuGa}(\mu_3\text{-}S)]_4$ has been shown to passivate GaAs[6] and was used to realize a new class of GaAs transistors.[7] Syntheses of mixed-metal chalcogenides such as $CuInE_2$ (E = S, Se) from single-source precursors[8] have also been successful and their efficiency as photovoltaic cells is documented.[9]

The few examples of structurally characterized 13-16 cage compounds $[RME]_x$[2] have been preferentially prepared by a) protolysis of R_3M with H_2E, b) reaction of $RMCl_2$ with $E(SiMe_3)_2$, c) oxidation of RM with elemental chalcogens, and d) reaction of R_3M with elemental chalcogens. The last mentioned process occurs via the corresponding chalcogenates $[R_2M(\mu\text{-}ER)]_2$ as the first insertion products, which could be trapped in a few cases.[9b][9c] The compounds are of particular interest as selective reagents in organic synthesis, e.g. $[i\text{Bu}_2\text{AlER}]_x$ (R = alkyl; E = S, Se, Te) for the conversion of aldehydes to thiol-, selenol-, and tellurol esters.[10]

We have recently reported on hydrolysis studies of the trialkylmetalanes $(Me_3Si)_3CAlMe_2 \cdot$ THF (**1**) and $(Me_3Si)_3CGaMe_2$ (**2**) leading to the isolation and structural characterization of some unusual alkylaluminum- and -gallium-hydroxo(oxo) compounds.[11] In continuation of our systematic studies on group 13-16 chemistry, we now report on the synthesis and characterization of some new alkylaluminum- and -gallium chalcogen compounds with the bulky tris(trimethylsilyl)methyl ("trisyl") ligand.

Results and Discussion

Reaction of $(Me_3Si)_3CAlMe_2 \cdot$ THF (**1**) with H_2S in toluene at room temperature yielded the dimeric trisylaluminum sulfido compound $[(Me_3Si)_3CAl(\mu\text{-}S)]_2 \cdot 2$ THF (**3**) (Eq. 1), presumably via an unstable hydridosulfido intermediate, i.e. $[(Me_3Si)_3CAlMe(\mu\text{-}SH)]_2 \cdot 2$ THF. The softer Lewis base

 © WILEY-VCH Verlag GmbH, D-69451 Weinheim, 1998 1434–1948/98/1212–2033 $ 17.50+.50/0

H_2S seems to be unable under the given reaction conditions to replace the harder Lewis base THF at the hard Lewis acidic aluminum center. Under similar conditions the trialkylgallane $(Me_3Si)_3CGaMe_2$ (**2**) gave the tetrameric compound $[(Me_3Si)_3CGa(\mu_3\text{-}S)]_4$ (**4**) (Eq. 2).[12] The hydridosulfido intermediate could not be trapped, in contrast to the reaction of tBu$_3$Ga with H_2S, which allows the isolation of the thermal stable hydridosulfido product $[t\text{Bu}_2\text{Ga}(\mu\text{-SH})]_2$.[9a]

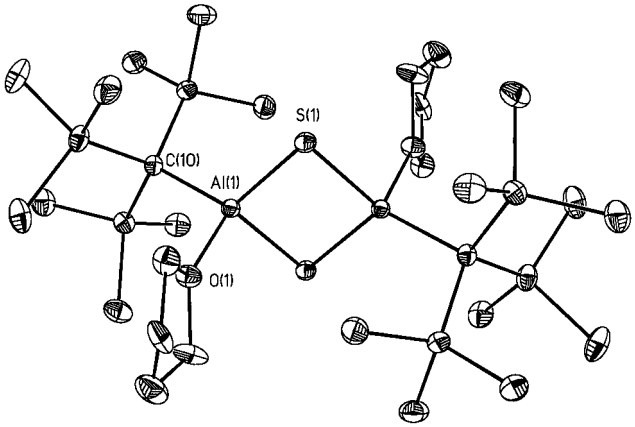
Compounds **3** and **4** have been fully characterized by ^{1}H- and ^{29}Si-NMR, mass, and IR spectroscopy as well as elemental analyses. In addition, recrystallization from benzene gave single crystals of **3** · C_6H_6 and **4** · 1.5 C_6H_6 suitable for X-ray diffraction analyses.

Figure 1 shows the molecular structure of compound **3**, which crystallizes with half of a molecule in the asymmetric unit in the orthorhombic space group Pbca. The planar Al_2S_2 core is elongated in the direction of the S−S axis (Al−S−Al 81.2°, S−Al−S 98.8°) comparable to the recently reported sulfide $[\text{Mes*Al}(\mu\text{-S})]_2 \cdot 2\ Me_2SO$ (Mes* = 2,4,6-tBu$_3$C$_6$H$_2$) (Al−S−Al 83.5°, S−Al−S 95.9°, average) with a nonplanar Al_2S_2 ring.[13] Both aluminum centers show distorted tetrahedral coordination by two bridging sulfur atoms, one THF molecule and one trisyl group. The Al−S (224.8 pm) and Al−C (202.9 pm) distances in **3** · C_6H_6 are in good agreement with those observed for [Mes*Al(μ-S)]$_2$ · 2 Me_2SO (Al−S 225.1 pm, Al−C 202.2 pm).[13] The Al−O distance in **3** · C_6H_6 (195.3 pm) is slightly shorter than that in the starting material **1** (196.8 pm)[11] due to electron-withdrawing properties of the sulfur atoms.

The molecular structure of the tetrameric compound $[(Me_3Si)_3CGa(\mu_3\text{-}S)]_4$ (**4**), which crystallizes in the trigonal space group $P\bar{3}c1$ with four tetramers and six benzene molecules in each unit cell, is depicted in Figure 2. The core of compound **4** consists of a distorted cube with Ga and S atoms at alternating corners. The pseudotetrahedral coordination sphere at each gallium atom is completed by a trisyl group. The average Ga−S distances (237.8 pm) are in the range of those observed for $[t\text{BuGa}(\mu_3\text{-S})]_4$ (235.9 pm),[2a] $[Me_2EtCGa(\mu_3\text{-S})]_4$ (235.6 pm),[2f] $[(Cp(CO)_2Fe)Ga(\mu_3\text{-S})]_4$ (237.5 pm)[2g] and $[\text{tmpGa}(\mu_3\text{-S})]_4$ (tmp = 2,2,6,6-tetramethylpiperidyl) (235.6 pm).[2h] The deviation from a perfect cube in **4** (average: Ga−S−Ga 86.4°, S−Ga−S 93.5°) is somewhat smaller than in $[t\text{BuGa}(\mu_3\text{-S})]_4$ (average: Ga−S−Ga 82.1°, S−Ga−S 97.3°),[2a] $[Me_2EtCGa(\mu_3\text{-S})]_4$ (average: Ga−S−Ga 82.2°, S−Ga−S 97.2°),[2f] $[(Cp(CO)_2\text{-Fe})Ga(\mu_3\text{-S})]_4$ (average: Ga−S−Ga 84.1°, S-Ga-S 95.6°),[2g] and $[\text{tmpGa}(\mu_3\text{-S})]_4$ (average: Ga−S−Ga 84.2°, S−Ga−S 95.5°).[2h] The average Ga−C distance (202.0 pm) is a little shorter than the Ga−C_{trisyl} distance in $(Me_3Si)_3CGaMe_2$ · THF (204.6 pm)[11] due to the higher effective positive charge of the gallium atoms caused by the electronegative sulfur atoms.

Figure 1. Crystal structure of $[(Me_3Si)_3CAl(\mu\text{-S})]_2 \cdot 2$ THF (**3**), with anisotropic displacement parameters depicting 50% probability. Hydrogen atoms have been omitted for clarity[a]

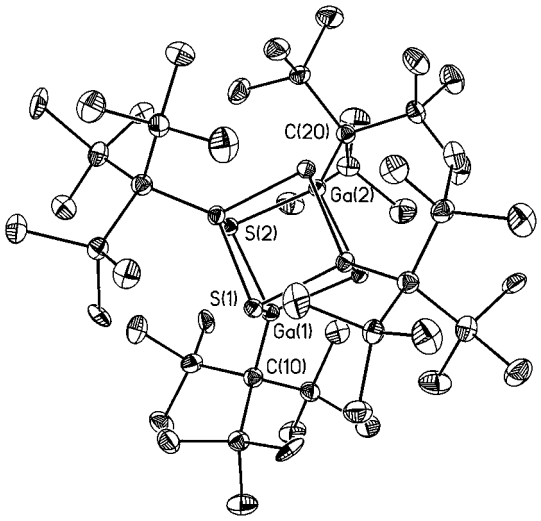


[a] Selected bond lengths [pm] and angles [°]: Al(1)−C(10) 202.9(2), Al(1)−O(1) 195.29(17), Al(1)−S(1) 224.83(9), Al(1)−S(1A) 223.47(9); C(10)−Al(1)−O(1) 107.17(8), C(10)−Al(1)−S(1) 120.97(7), C(10)−Al(1)−S(1A) 121.21(7), O(1)−Al(1)−S(1) 103.27(6), O(1)−Al(1)−S(1A) 102.87(6), S(1)−Al(1)−S(1A) 98.79(3), Al(1)−S(1)−Al(1A) 81.21(3).

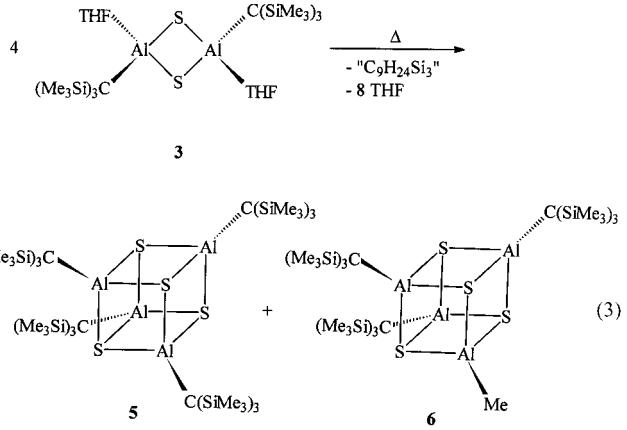
The cubane **4** exhibits high thermal stability and can be easily purified by sublimation in vacuo (180 °C, 10^{-2} mbar). A topological reorganization of the polyhedral core as reported for the formation of $[t\text{BuGaS}]_x$ (x = 6, 7, 8) by thermolysis of $[t\text{BuGa}(\mu_3\text{-S})]_4$[14] has not been observed for **4**.

Interestingly, the mass spectrum of **3** shows, in addition to the signals for characteristic fragment ions of the dimeric sulfide, at elevated temperatures (above 200 °C) signals with higher masses (e.g. m/z 1147, 929), indicating formation of larger aggregates. These observations encouraged us to examine the thermolysis of **3** on a preparative scale. Heating of $[(Me_3Si)_3CAl(\mu\text{-S})]_2 \cdot 2$ THF (**3**) in vacuo (220 °C, 10^{-2} mbar) for 30 minutes gave, after workup, a yellowish solid which was identified by ^{1}H- and ^{29}Si-NMR, and mass spectroscopy as a mixture of the tetrameric organoaluminum sulfides $[(Me_3Si)_3CAl(\mu_3\text{-S})]_4$ (**5**) and $[\{(Me_3Si)_3CAl(\mu_3\text{-S})\}_3MeAl(\mu_3\text{-S})]$ (**6**) (≈ 30:70) (Eq. 3). To our knowledge

Figure 2. Crystal structure of $[(Me_3Si)_3CGa(\mu_3\text{-}S)]_4$ (**4**), with anisotropic displacement parameters depicting 50% probability. Hydrogen atoms have been omitted for clarity[a]



[a] Selected bond lengths [pm] and angles [°]: Ga(1)−C(10) 202.0(4), Ga(1)−S(1) 237.90(10), Ga(1)−S(2) 237.91(11), Ga(1)−S(2A) 237.63(11), Ga(2)−C(20) 201.9(6), Ga(2)−S(2) 237.74(10); C(10)−Ga(1)−S(1) 122.56(10), C(10)−Ga(1)−S(2) 122.31(11), C(10)−Ga(1)−S(2A) 123.45(11), S(1)−Ga(1)−S(2) 93.46(4), S(1)−Ga(1)−S(2A) 93.53(4), S(2)−Ga(1)−S(2A) 93.41(4), C(20)−Ga(2)−S(2) 122.80(3), S(2)−Ga(2)−S(2A) 93.43(3), Ga(1)−S(1)−Ga(1A) 86.37(4), Ga(1)−S(2)−Ga(1A) 86.43(3), Ga(1)−S(2)−Ga(2) 86.44(3), Ga(1A)−S(2)−Ga(2) 86.51(4).



such a fragmentation of the trisyl group under chemical conditions is unprecedented.

However, we were neither able to separate this mixture by fractional crystallization or sublimation nor to obtain pure compounds by variation of the reaction conditions. The recrystallization of the mixture from toluene at room temperature results in the formation of single crystals of both compounds, which differ in their shape (**5** rods, **6** blocks). Unfortunately, only the single crystals of compound **6** were suitable for X-ray diffraction analysis.

Figure 3 shows the molecular structure of the unsymmetric substituted cubane $[\{(Me_3Si)_3CAl(\mu_3\text{-}S)\}_3MeAl(\mu_3\text{-}S)]$ (**6**), which crystallizes in the triclinic space group $P\bar{1}$. The distorted central Al_4S_4 heterocubane core (Al−S−Al 83.5°, S−Al−S 96.1°, average) is comparable with that observed for the symmetrically substituted cubane $[Me_2EtCAl(\mu_3\text{-}S)]_4$ (Al−S−Al 82.2°, S−A−S 97.3°, average),[2f] which is the only other example of a structurally characterized Al-S cubane. Due to the lower symmetry of the molecule caused by the different substituents at the aluminum atoms in **6**, the bond lengths and angles of the core are in a wider range than those of $[Me_2EtCAl(\mu_3\text{-}S)]_4$.[2f] For the Al coordinated by the methyl group the Al−S bonds are relatively similar (230.3−230.7 pm), while for the Al atoms coordinated by the trisyl ligands one long Al−S distance (235.5−235.8 pm), one distance in a middle range (233.7−234.2 pm) and one comparatively short distance (231.0−231.5 pm) are observed. In total, the Al−S distances (average: 232.8 pm) are close to those observed for $[Me_2EtCAl(\mu_3\text{-}S)]_4$ (average: 231.3 pm)[2f] but are distinctly longer than those of the starting material **3** (224.8 pm) and the recently reported dimeric organoaluminum sulfide $[Mes^*Al(\mu\text{-}S)]_2$ (Mes* = 2,4,6-tBu$_3$C$_6$H$_2$) (221.0 pm)[13] due to the higher coordination number of the sulfur atoms. On the other hand the nearly equal $Al-C_{trisyl}$ distances (average: 197.7 pm) are little shorter than those in the starting material **3** (average: 202.9 pm).

As mentioned above, a second method for the preparation of group 13-16 cage compounds is the reaction of trialkylmetalanes with elemental chalcogens. Because of the very high toxicity of H_2Se and H_2Te we tried to prepare the corresponding selenides and tellurides following this route.

Reactions of $(Me_3Si)_3CAlMe_2 \cdot THF$ (**1**) and $(Me_3Si)_3CGaMe_2$ (**2**) with elemental selenium in a 1:1 ratio in refluxing toluene resulted in the formation of the corresponding selenolates $[(Me_3Si)_3CMMe(\mu\text{-}SeMe)]_2$ (**7**: M = Al, **8**: M = Ga) in good yields (Eqs. 4, 5).

In both cases, the selenium reacted within 2 h, and the color of the reaction mixture changes from colorless through green to yellow. Compounds **7** and **8** are colorless, air- and moisture-sensitive, and extremely malodorous solids, which were fully characterized by ^{1}H- and ^{29}Si-NMR, mass, and IR spectroscopy as well as by elemental analyses (see Experimental Section). Additionally, recrystallization from benzene afforded single crystals of $\mathbf{7} \cdot C_6H_6$ suitable for X-ray diffraction analysis.

Figure 4 shows the crystal structure of the aluminum selenolate **7**, which crystallizes in the orthorhombic space group *Ibam* with eight dimers and eight benzene molecules in the unit cell. The central core of **7** is characterized by a distorted four-membered Al_2Se_2 ring (Al−Se−Al 86.2°, Se−Al−Se 84.0°, average) tilted towards the methyl groups at both aluminum and selenium in a *cis* conformation [angle between the planes defined by Al(1)/Se(1)/Se(2) and Al(1A)/Se(1)/Se(2) 133.6°]. In contrast, the ring of the only other structurally characterized dimeric aluminum selenolate $[Mes_2Al(\mu\text{-}SeMe)]_2$ (Mes = 2,4,6-Me$_3$C$_6$H$_2$)[15] is planar and nearly undistorted (Al−Se−Al 89.4°, Se−Al−Se 90.6°, average) with the methyl substituents on the selenium in the *trans* conformation. This different behaviour can be explained by minimization of steric crowding caused by the bulky trisyl ligands. The Al−Se distances in **7** (average:

Figure 3. Crystal structure of [{$(Me_3Si)_3CAl(\mu_3\text{-}S)\}_3MeAl(\mu_3\text{-}S)$] (**6**), with anisotropic displacement parameters depicting 50% probability. Hydrogen atoms have been omitted for clarity[a]

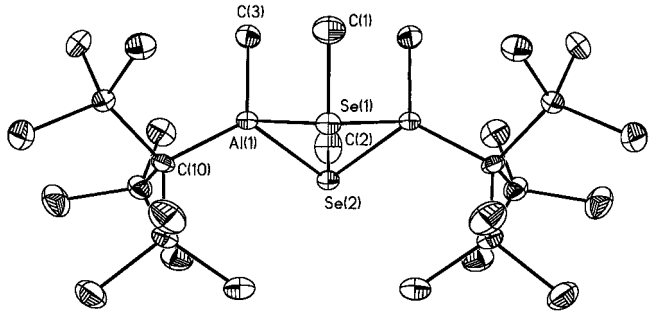
Figure 4. Crystal structure of $[(Me_3Si)_3CAlMe(\mu\text{-}SeMe)]_2$ (**7**), with anisotropic displacement parameters depicting 50% probability. Hydrogen atoms have been omitted for clarity[a]



[a] Selected bond lengths [pm] and angles [°]: Al(1)−C(3) 196.6(6), Al(1)−C(10) 200.0(3), Al(1)−Se(1) 252.71(11), Al(1)−Se(2) 254.35(10), Se(1)−C(1) 196.8(5), Se(2)−C(2) 196.1(5); C(3)−Al(1)−C(10) 118.46(13), C(3)−Al(1)−Se(1) 107.28(11), C(3)−Al(1)−Se(2) 107.89(11), C(10)−Al(1)−Se(1) 117.21(9), C(10)−Al(1)−Se(2) 116.65(9), Se(1)−Al(1)−Se(2) 84.01(3), Al(1)−Se(1)−Al(1A) 86.48(5), Al(1)−Se(1)−C(1) 103.70(12), Al(1A)−Se(1)−C(1) 103.71(12), Al(1)−Se(2)−Al(1A) 85.79(5), Al(1)−Se(2)−C(2) 106.68(13), Al(1A)−Se(2)−C(2) 106.68(13).

The metal selenolates **7** and **8** show high thermal stabilities, and can be sublimed in vacuo (180−200°C, 10^{-2} mbar) without decomposition. Their EI mass spectra show no signs for the formation of the corresponding metal selenides. In contrast, the selenolates $[t\text{Bu}_2M(\mu\text{-Se-}t\text{Bu})]_2$ (M = Al, Ga) give the corresponding tetrameric metal selenides $[t\text{BuM}(\mu_3\text{-Se})]_4$ (M = Al, Ga) upon heating.[2b][2c]

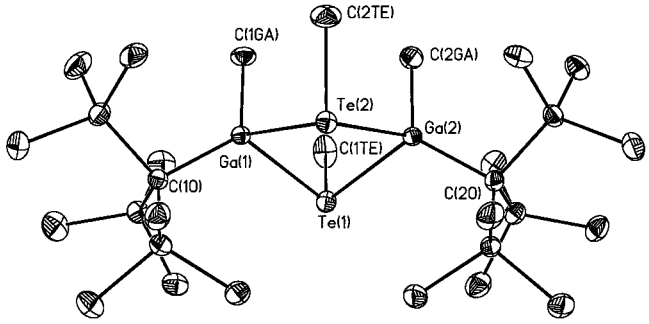
A different behaviour was observed for the reaction of the trialkylmetalanes **1** and **2** with elemental tellurium. While the reaction of the trialkylgallane **2** with tellurium powder in refluxing toluene results in the formation of the corresponding tellurolate $[(Me_3Si)_3CGaMe(\mu\text{-TeMe})]_2$ (**9**) in good yield within 3 h (Eq. 5), the trialkylalane **1** does not react with tellurium metal at all. Even after refluxing in toluene with a fivefold excess of tellurium for two days compound **1** and tellurium have been recovered nearly quantitatively.

The gallium tellurolate **9** is a greenish, very air- and moisture-sensitive, malodorous solid which was fully characterized by ^1H- and ^{29}Si-NMR, mass, and IR spectroscopy as well as by elemental analysis (see Experimental Section). Additionally, recrystallization from toluene at

room temperature gave single crystals suitable for X-ray diffraction analysis.

The molecular structure of the gallium tellurolate **9**, which crystallizes in the monoclinic space group *C*2/c, is depicted in Figure 5. The distorted central four-membered Ga_2Te_2 ring (Ga−Te−Ga 85.5°, Te−Ga−Te 87.5°, average) has a conformation [angle between the planes defined by Ga(1)/Te(1)/Te(2) and Ga(2)/Te(1)/Te(2) 139.9°] similar to the aluminum selenolate **7** and the two other structurally characterized dimeric organogallium tellurolates $[(t\text{-}BuCH_2)_2Ga(\mu\text{-}TePh)]_2$ (Ga−Te−Ga 83.8°, Te−Ga−Te 92.0°, angle between Ga1/Te1/Te2 and Ga2/Te1/Te2 148°)[16] and $[(PhCH_2)_2Ga(\mu\text{-}Te\text{-}t\text{Bu})]_2$ (Ga−Te−Ga 81.8°, Te−Ga−Te 92.0°, angle between Ga1/Te1/Te2 and Ga2/Te1/Te2 141°),[17] but in these molecules the substituents on the Te are in the *trans* position relative to the ring. The Ga−Te distances in **9** (average: 274.6 pm) are in the range of those observed for $[(t\text{BuCH}_2)_2Ga(\mu\text{-TePh})]_2$ (average: 275.5 pm)[16] and $[(PhCH_2)_2Ga(\mu\text{-Te-}t\text{Bu})]_2$ (average: 269.3 pm)[17] but are distinctly longer than the sum of the covalence radii of Ga and Te (262 pm).[18] The $Ga-C_{trisyl}$ (202.5 pm) and $Ga-C_{methyl}$ distances (198.3 pm) are slightly shorter than those observed for $(Me_3Si)_3CGaMe_2 \cdot THF$ (204.6 and 197.9 pm, respectively).[11]

Figure 5. Crystal structure of $[(Me_3Si)_3CGaMe(\mu\text{-TeMe})]_2$ (**9**), with anisotropic displacement parameters depicting 50% probability. Hydrogen atoms have been omitted for clarity[a]



[a] Selected bond lengths [pm] and angles [°]: Ga(1)−C(1GA) 198.5(6), Ga(1)−C(10) 202.6(6), Ga(1)−Te(1) 274.34(8), Ga(1)−Te(2) 274.39(7), Ga(2)−C(2GA) 198.1(6), Ga(2)−C(20) 202.3(6), Ga(2)−Te(1) 274.19(8), Ga(2)−Te(2) 275.37(8), Te(1)−C(1TE) 215.4(7), Te(2)−C(2TE) 215.3(6); C(1GA)−Ga(1)−C(10) 120.8(3), C(1GA)−Ga(1)−Te(1) 104.93(19), C(1GA)−Ga(1)−Te(2) 104.34(19), C(10)−Ga(1)−Te(1) 116.10(17), C(10)−Ga(1)−Te(2) 117.64(16), Te(1)−Ga(1)−Te(2) 87.58(2), C(2GA)−Ga(2)−C(20) 120.4(3), C(2GA)−Ga(2)−Te(1) 104.9(2), C(2GA)−Ga(2)−Te(2) 104.14(19), C(20)−Ga(2)−Te(1) 116.41(16), C(20)−Ga(2)−Te(2) 118.13(17), Te(1)−Ga(2)−Te(2) 87.41(2), C(1TE)−Te(1)−Ga(1) 97.8(2), C(1TE)−Te(1)−Ga(2) 99.23(19), Ga(1)−Te(1)−Ga(2) 85.57(2), C(2TE)−Te(2)−Ga(1) 98.76(18), C(2TE)−Te(2)−Ga(2) 99.7(2), Ga(1)−Te(2)−Ga(2) 85.34(2).

In contrast to $[t\text{Bu}_2Ga(\mu\text{-Te-}t\text{Bu})]_2$, which has been converted to the corresponding tetrameric telluride $[t\text{BuGa}(\mu_3\text{-Te})]_4$ upon heating,[2c] thermolysis of compound **9** results in the formation of an ochre colored powder which was identified by ^{1}H- and ^{29}Si-NMR spectroscopy as a complex mixture of unknown products.

Conclusions and Remarks

In summary we have shown that compounds $(Me_3Si)_3CAlMe_2 \cdot THF$ (**1**) and $(Me_3Si)_3CGaMe_2$ (**2**) are ideal starting materials for the preparation of various chalcogen-containing derivatives. Under the reaction conditions reported the $Al-C(SiMe_3)_3$ and the corresponding Ga−C bond was not cleaved either using H_2S or the heavier elements of group 16,leading to products which could be recrystallized from organic solvents. The MOCVD experiments using the compounds described in this paper are still in progress. However, these results will be reported elsewhere.

We are grateful to the *Deutsche Forschungsgemeinschaft* and the *Göttinger Akademie der Wissenschaften* for financial support.

Experimental Section

General: All experiments were performed with standard Schlenk techniques under dry nitrogen atmosphere due to the extreme sensitivity of reactants and products toward air and moisture. A Braun MB 150-GI glovebox was used to store the compounds and to prepare the samples for spectroscopic characterizations. All solvents were dried over sodium/benzophenone, freshly distilled and degassed prior to use. H_2S, Se metal, and Te metal were purchased from Aldrich Chemical Co., $(Me_3Si)_3CAlMe_2 \cdot THF$ and $(Me_3Si)_3CGaMe_2$ were prepared as described in the literature.[11] Elemental analyses were performed by the Analytisches Labor des Instituts für Anorganische Chemie der Universität Göttingen. It is well-known that the analysis for carbon in group 13 compounds is often low due to the generation of metal carbides.[19] In compounds containing silicon, the content of carbon is decreased further by formation of silicon carbide. − NMR spectra were recorded on Bruker AM 200 and Bruker AM 250 instruments, and were externally referenced to tetramethylsilane in ppm with low-field shift positive. − FT-IR spectra were measured on a Bio-Rad FTS-7 as nujol mulls between KBr plates in the range of 4000−400 cm^{-1} (abbreviations used: vs, very strong; s, strong; m, medium) and EI mass spectra on Finnigan MAT 8230 or Varian MAT CH 5 instruments. The most intensive peak of each isotopic distribution is given. − Melting points were measured in sealed glass tubes and are not corrected.

Synthesis of [(Me$_3$Si)$_3$CAl(μ−S)]$_2$ · 2 THF (**3**): Dry H_2S was bubbled slowly through a solution of 3.70 g of $(Me_3Si)_3CAlMe_2 \cdot THF$ (10.3 mmol) in toluene (100 ml) at room temperature for 45 minutes. The opaque reaction mixture was stirred at room temperature for 1 h and then filtered through celite. Removal of all volatiles in vacuo gave analytically pure compound **3**. Yield: 2.60 g (87%), colorless solid, m.p. 235°C. − ^{1}H NMR (200.13 MHz, C_6D_6): δ = 3.77 (m_c, 8 H, OCH_2CH_2), 1.33 (m_c, 8 H, OCH_2CH_2), 0.49 (s, 54 H, $SiCH_3$). − ^{29}Si NMR (49.69 MHz, C_6D_6): δ = −3.7. − MS (70 eV): *m/z* (%) 1147 (30) [{$(Me_3Si)_3CAlS$}$_4$ − Me], 929 (46) [{$(Me_3Si)_3CAlS$}$_4$ − $C(SiMe_3)_3$], 565 (50) [M^+ − Me − 2 THF], 275 (90) [$(M/2)^+$ − Me − THF], 201 (100) [$C(SiMe_3)_3$ − 2 Me]. − IR: $\tilde{\nu}$ = 1346 (m), 1253 (vs), 1095 (m), 1042 (m), 1012 (m), 989 (m), 917 (m), 848 (vs), 793 (s), 752 (m), 721 (m), 669 (s), 642 (m), 616 (m), 533 (m), 490 (m), 447 (s), 424 (m) cm^{-1}. − $C_{28}H_{70}Al_2O_2S_2Si_6$ (725.49): calcd. C 46.36, H, 9.73; found: C 45.6, H, 9.7.

Synthesis of [(Me$_3$Si)$_3$CGa(μ$_3$-S)]$_4$ (**4**): Dry H_2S was bubbled slowly through a toluene solution (160 ml) of 4.00 g of $(Me_3Si)_3CGaMe_2$ (12.1 mmol) at room temperature for 45 minutes. After 2

h stirring at room temperature, the opaque solution was filtered through celite. Removal of all volatiles in vacuo and washing of the residue with pentane (20 ml) gave compound **4**. Yield: 3.7 g (92%); colorless, air- and moisture-sensitive solid; m.p. 316°C. – ^{1}H NMR (200.13 MHz, C_6D_6): δ = 0.47 [C(SiCH$_3$)]. – ^{29}Si NMR (49.69 MHz, C_6D_6): δ = -1.0. – MS (70 eV): *m/z* (%) 1317 (1) [M^+ – Me], 1101 (3) [M^+ – $C(SiMe_3)_3$], 769 (5) [(3/4 M)$^+$ – $C(SiMe_3)_3$], 666 (15) [(M/2)$^+$], 651 (60) [(M/2)$^+$ – Me], 317 (100) [(M/4)$^+$ – Me], 201 (45) [$C(SiMe_3)_3$ – 2 Me]. – IR: ṽ = 1288 (m), 1262 (s), 1250 (s), 1099 (m), 1019 (m), 980 (m), 854 (vs), 849 (vs), 785 (m), 726 (m), 673 (s), 663 (s), 630 (m), 616 (m), 556 (m) cm^{-1}. – $C_{40}H_{108}Ga_4S_4Si_{12}$ (1333.50): calcd. C 36.03, H 8.16; found C 36.3, H 8.7.

Synthesis of [(Me$_3$Si)$_3$CAl(μ$_3$-S)]$_4$ (**5**) *and [{(Me$_3$Si)$_3$CAl(μ$_3$-S)}$_3${MeAl(μ$_3$-S)}]* (**6**): Compound **3** (2.00 g, 2.76 mmol) was heated in vacuo (10^{-2} mbar) without solvent to 220°C for 30 minutes. The slightly yellow residue was extracted with toluene (50 ml) and filtered through celite. Storage at −26°C gave colorless crystals of a mixture of the compounds $[(Me_3Si)_3CAl(\mu_3\text{-}S)]_4$ (**5**) and $[\{(Me_3Si)_3CAl(\mu_3\text{-}S)\}_3MeAl(\mu_3\text{-}S)]$ (**6**) (1.10 g), which could not be separated by crystallization or sublimation. – ^{1}H NMR (200.13 MHz, C_6D_6): δ = 0.48 (s, SiCH_3 of **6**), 0.44 (s, SiCH_3 of **5**), 0.13 (s, AlCH_3 of **6**). – ^{29}Si NMR (49.69 MHz, C_6D_6): δ = −2.24 (**6**), −2.31 (**5**). – MS (70 eV): *m/z* (%) 1147 (25) [**5** – Me], 929 (90) [**6** – Me], 275 (85) [(**5**/4) – Me], 201 (100) [$C(SiMe_3)_3$ – 2 Me]. – IR (KBr, Nujol): ṽ = 1496 (m), 1413 (m), 1341 (m), 1294 (m), 1260 (s), 1252 (s), 1096 (m), 1081 (m), 1030 (m), 1012 (m), 849 (vs), 837 (vs), 794 (s), 752 (m), 727 (m), 714 (m), 667 (vs), 644 (s), 619 (m), 577 (m) cm^{-1}.

Synthesis of [(Me$_3$Si)$_3$CAlMe(μ-SeMe)]$_2$ (**7**): To a suspension of 0.44 g of gray selenium (5.54 mmol) in toluene (20 ml) was added a solution of 2.00 g of $(Me_3Si)_3CAlMe_2 \cdot THF$ (5.54 mmol) in toluene (30 ml) at room temperature. The reaction mixture was stirred for 15 h at room temperature, and then heated under reflux for 2 h. During this time the color changed from colorless through green to yellow, and the selenium was completely consumed. After filtration of the solution through celite and concentration to 15 ml, compound **7** crystallized as a colorless solid on cooling to −26°C. Yield: 1.55 g (76%); colorless, air- and moisture-sensitive crystals; m.p. 278°C. – ^{1}H NMR (200.13 MHz, C_6D_6): δ = 1.79 (s, 6 H, SeCH_3), 0.37 (s, 54 H, SiCH_3), −0.13 (s, 6 H, AlCH_3). – ^{29}Si NMR (49.69 MHz, C_6D_6): δ = −3.6. – MS (70 eV): *m/z* (%) 368 (1) [(M/2)$^+$], 353 (15) [(M/2)$^+$ – Me], 273 (100) [(M/2)$^+$ – SeMe]. – IR: ν = 1260 (s), 1248 (s), 1195 (m), 855 (vs), 789 (s), 721 (m), 671 (s), 613 (m), 603 (m) cm^{-1}. $C_{24}H_{66}Al_2Se_2Si_6$ (735.20): calcd. C 39.21, H 9.05; found: C 39.7, H 9.0.

Preparation of [(Me$_3$Si)$_3$CGaMe(μ-SeMe)]$_2$ (**8**): A solution of 2.00 g of $(Me_3Si)_3CGaMe_2$ (6.04 mmol) in toluene (30 ml) was slowly added to a suspension of 0.48 g of gray selenium (6.04 mmol) in toluene (20 ml) at room temperature. The reaction mixture was stirred at room temperature for 8 h and then heated under reflux for 2 h. During this time the color changed from colorless through green to yellow, and the selenium was consumed completely. After filtration of the opaque solution through celite and concentration to 25 ml compound **8** crystallized as a slightly yellow solid on cooling to −26°C. Yield: 1.95 g (79%), slightly yellow air- and moisture-sensitive crystals, m.p. 256°C. – ^{1}H NMR (200.13 MHz, C_6D_6): δ = 1.79 (s, 6 H, SeCH_3), 0.36 (s, 54 H, SiCH_3), 0.29 (s, 6 H, GaCH_3). – ^{29}Si NMR (49.69 MHz, C_6D_6): δ = −2.5. – MS (70 eV): *m/z* (%) 775 (7) [M^+ – 3 Me], 760 (7) [M^+ – 4 Me], 745 (10) [M^+ – 5 Me], 395 (12) [(M/2)$^+$ – Me], 365 (20) [(M/2)$^+$ – 3 Me], 315 (50) [(M/2)$^+$ – SeMe – Me], 201 (100) [$C(SiMe_3)_3$

C 31.40, H 7.25; found C 32.2, H 7.4.

Crystal-Structure Determinations: Single crystals of compounds **3** · C_6H_6, **4** · 1.5 C_6H_6 and **7** · C_6H_6, **6** and **9** were obtained by recrystallization from benzene and toluene at room temperature, respectively. Crystal data and structure refinement parameters are given in Table 1. Data for structures **3** · C_6H_6, **4** · 1.5 C_6H_6, and **9** were collected on a Stoe-Siemens-Huber four-circle diffractometer equipped with a Siemens SMART CCD area detector and for structures **6** and **7** · C_6H_6 on a Stoe-Siemens AED four-circle diffractometer. Mo-K_α radiation (λ = 71.073 pm) was used in all cases. All structures were solved by direct methods (SHELXS-97)[20] and refined against F^2 using SHELXL-97.[21] All heavy atoms were refined anisotropically, hydrogen atoms were included using the riding model with U_{iso} tied to the U_{iso} of the parent atom. For structure **9** an extinction correction was employed.

In structures **4** · 1.5 C_6H_6 and **7** some of the trisyl ligands were disordered. They were refined with distance restraints and restraints for the anisotropic displacement parameters. The anisotropic displacement parameters of the Si atoms lying opposite to each other were constrained to be the same. Additionally the THF molecules in **3** · C_6H_6 and one benzene molecule in **7** · C_6H_6 were disordered. Again distance restraints and restraints for the anisotropic displacement parameters were used.

Crystallographic data (excluding structure factors) have been deposited with the Cambridge Crystallographic Data Center (CCDC) as supplementary publication numbers CCDC-102100, 102101, 102102, 102103, and 102104. The syntheses of *N*,*N*′-bis-[(2-pyridylmethyl)]-1,3-diamidopropane ($papH_2$) and *N*,*N*′-bis-[(2-pyridylmethyl)]-1,3-diamido-2-hexadecylpropane ($C_{16}papH_2$) are reported together with the results of potentiometric titrations of $papH_2$ with Co(II), Ni(II), Cu(II) and Zn(II), spectroscopic and electrochemical data of [Ni(pap)] and [Cu(pap)], structural studies involving the X-ray analyses of the metal-free $papH_2$ ligand and the corresponding Ni(II) and Cu(II) complexes [Ni(pap)] × 2 H_2O and [Cu(pap)] × 3 H_2O, and force-field calculations (MM) of [Co(pap)], [Ni(pap)], [Cu(pap)] and [Zn(pap)] and the corresponding complexes of the ligand with *ortho*-methyl-substituted pyridyl groups (Me_2papH_2); the results of metal ion transport [Co(II), Ni(II), Cu(II) and Fe(II)] from aqueous solutions through $C_{16}papH_2$ containing dichloromethane phases are also given. The extractability with $C_{16}papH_2$ increases along the series Fe(II) < Co(II) < Ni(II) < Cu(II), and this is confirmed by the potentiometric data ($papH_2$, aqueous solutions; $\log\beta_{ML}$[Co(II)] = 1.75; $\log\beta_{MLH-2}$[Ni(II)]=–11.49; $\log\beta_{ML}$[Cu(II)]=3.41; $\log\beta_{MLH-2}$-[Cu(II)] = –4.491; $\log\beta_{ML}$[Zn(II)] = 1.87). The structural data (X-ray and MM) indicate that, due to the *ortho* protons of the pyridyl groups and in dependence of the electronic configuration of the metal center, there is a considerable tetrahedral twist of the central MN_4 chromophores {square planar: θ = 0°; tetrahedral: θ = 90°; [Co(pap)]: θ = 15° (MM); [Ni(pap)]: θ = 16° (X-ray), 16° (MM); [Cu(pap)]: θ = 18° (X-ray), 18° (MM); [Zn(pap)]: θ = 23° (MM)}, and this may be enhanced by *ortho*-methyl substitution of the pyridyl donors {[Co(Me_2pap)]: θ = 20° (MM); [Ni(Me_2pap)]: θ = 20° (MM); [Cu(Me_2pap)]: θ = 24° (MM); [Zn(Me_2pap)]: θ = 31° (MM)}, and thus possibly a decrease in the complex stability of Cu(II) and Ni(II) in favor of Zn(II).

Introduction

Metal-ion selectivity, i.e. the enhanced stability of a coordination compound with a given ligand and a specific metal ion, relative to that with other metal ions, may be traced back to electronic effects and the coordination geometry, partly enforced by the ligand system. Donor-atom−metal-ion orbital overlap, the HSAB concept, and ligand field effects describe contributions to the electronic terms, and for hexacoordinate compounds these contribute to the well-known pattern of the *Irving-Williams* series[1]. The steric contributions based on the ligand structure include the reorganization of the most stable conformation of the metal-free ligand to that observed in the coordination compound (unfavorable enthalpy and entropy effects) and steric strain imposed by the metal ion on the ligand and vice versa. Thus, highly preorganized systems, which in the original definition[2] are by necessity relatively rigid ligands which, in the conformation observed in the metal complex, are relatively strain free, lead to comparably high complex stabilities. These properties include the metal ion′s preference for a particular metal-ligand distance and for a particular angular distribution of the donor atoms, and they are therefore metal-ion dependent. Hence, molecular mechanics was supposed to be a powerful tool for predicting the steric contribution to metal ion selectivities[3]. There are many reasons why, in reality, this is not necessarily correct[4] but for specific applications encouraging results may be obtained[3][4][5].

Our aim was to develop a type of ligand with the following properties: (i) it should generally lead to relatively high complex stabilities with Co(II), Ni(II), Cu(II) and Zn(II); (ii) substitution of the ligand backbone should lead to a predictable variation of the coordination geometry, with the aim of tuning the metal-ion selectivity by modification of the coordination geometry; (iii) derivatives with a similar complexation behavior should be available for quantitative investigations in aqueous solution and for metal ion extractions into organic phases. *N*,*N*′-bis[(2-pyridylmethyl)]-1,3-diamidopropane ($papH_2$, see formula scheme) fulfills these requirements: Tetradentate ligands with amide and pyridyl donors are appropriate complexing agents for divalent metal ions[6]; the substituted diamidopropane fragment is rather rigid, the hexadecane-substituted ligand *N*,*N*′-bis[(2-pyridylmethyl)]-1,3-diamido-2-hexadecylpropane, $C_{16}papH_2$, is easily accessible and leads to a hydrophobic ligand and complexes that are soluble in organic phases; the *ortho*-protons of the pyridyl groups of tetradentate ligands with *cis*-disposed pyridyl groups enforce a tetrahedral twist from square-planar geometry[7] and lead therefore to a steric destabilization of complexes with electronic preferences of the

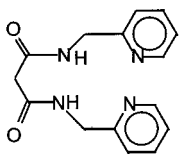
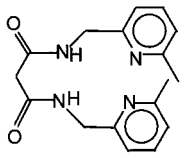
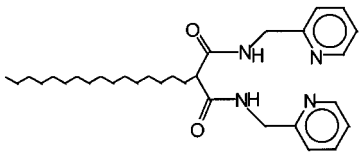
metal center for square-planar coordination geometry; derivatives with *ortho*-substituted pyridyl groups (e.g. Me_2-$papH_2$, see formula scheme) should enhance this effect and thus lead to an increased preference for Zn(II) with respect to Ni(II) and Cu(II).



papH$_2$



Me$_2$papH$_2$



C$_{16}$papH$_2$

Results and Discussion

Syntheses, Spectroscopy and Electrochemistry

$C_{16}papH_2$ was prepared by alkylation of diethyl malonate with hexadecyl bromide in presence of CH_3CH_2ONa, and subsequent nucleophilic substitution of the alkylated malonic ester with α-picolylamine (Scheme 1); $papH_2$ was obtained in a similar reaction. Cu(II) and Ni(II) compounds of $papH_2$ were isolated from aqueous solutions of the metal-free ligands and the metal sulfate salts, or from methanolic solutions and the corresponding tetrafluoroborates; X-ray quality crystals were obtained by slow evaporation of the complex solutions. Spectroscopic and electrochemical parameters of the compounds are listed in Table 1.

Structures

$papH_2 \cdot HBF_4 \cdot H_2O$: The metal-free ligand crystallizes with a molecule of H_3O^+ BF_4^- in the lattice, and hydrogen bonds are formed between the H_3O^+ ion and the nitrogen atoms of the amide group (2.64 Å). An ORTEP[8] plot of the ligand molecule appears in Figure 1a, and structural

parameters are listed in Table 2. Bond distances and valence and torsional angles are as expected and similar to those of the coordinated ligand. The geometry around the amide nitrogen and carbon atoms is planar, with little deviation of the corresponding valence angles from 120°. The main differences with respect to the coordinated ligand are: (i) a significantly longer $N_{amide}-C_{amide}$ bond (1.345 Å vs. 1.315 Å); (ii) a smaller $C_{amide}-C_{methylene}-C_{amide}$ valence angle (112° vs. 122° [Ni(II)], 125° [Cu(II)]); (iii) a slightly larger torsion around the $C_{pyridine}-C_{methylene}$ bond (17° vs. 2−10°); (iv) significant changes in the torsion around the $N_{amide}-C_{methylene}$ bond (80° vs. 180°), and (v) significant changes of the torsion around the $C_{amide}-C_{methylene}$ bond (125° vs. 7−18°).

[Cu(pap)] × 3 H_2O: The geometry of the Cu(II) compound is shown in Figure 1b, and the relevant structural parameters are presented, together with those of the Ni(II) compound, in Table 3. An oxygen atom of a neighboring Cu(II) complex molecule is coordinated in an axial position (Cu−O = 2.79 Å). There is also a network of hydrogen bonds between the copper complexes. The central four-coordinate chromophore is unlikely to be perturbed by the axial interactions in the present case. The tetrahedral twist of the CuN_4 chromophore is, as expected, slightly larger than that of the nickel(II) compound (θ° = 18.1°), the torsion around the $Cu-N_{pyridine}$ bond is 10−14° and the resulting α-H ··· α-H distance is 2.17 Å. As in the Ni(II) structure, the six-membered chelate ring is approximately flat and coplanar to the plane defined by the amide donors and the metal center. The five-membered chelate rings are essentially planar. There is a considerable asymmetry with respect to the metal-donor distances but on average the $Cu-N_{pyridine}$ and the $Cu-N_{amide}$ distances are as expected from comparable chromophores[9].

[Ni(pap)]·2H$_2$O: An ORTEP[8] plot of the Ni(II) compound appears in Figure 1c, and the relevant geometric parameters are listed in Table 3. The nickel cation is four-coordinate with a considerable tetrahedral distortion from square-planar geometry [θ = 16.3° (square planar: θ = 0°; tetrahedral: θ° = 90°)]. The Ni−N$_{pyridine}$ and the Ni−N$_{amide}$ distances (1.91 Å and 1.85 Å, respectively) are as expected from comparable chromophores[10]. The tetrahedral distortion is due to the α-hydrogen atoms of the pyridine donor groups (H···H = 2.195 Å), and part of this stress is relaxed by a torsion of the pyridine donor around the Ni−N$_{pyridine}$ axis (14−18°). The five-membered chelate rings are essentially planar.

Molecular Mechanics: The structures of [M(pap)] [M = Co(II), Ni(II), Cu(II), Zn(II)] were computed by strain-energy minimization, using the MOMEC program[11] and force field[12]. All complexes have been modeled as four-coordinate with no axial ligands. So far, MOMEC has mainly been used for five- and six-coordinate transition metal compounds. Metal-ion-related force field parameters are dependent from the coordination geometry[13], i.e. new parameter sets were required for the present study. Also, the approach used in MOMEC for modeling the angular geometry around metal centers is based on 1,3-nonbonded interactions (ligand−ligand repulsion) and, for hexacoordinate compounds, a small perturbation based on the electronic preferences for donor−metal−donor angles of 90°[12b]. For the four-coordinate species considered here, the metal-center-dependent twist from tetrahedral geometry (minimum repulsion) toward square planar coordination was modeled with an out-of-plane term that involves the metal center and the four donor atoms[14]. The force constants and ideal distances for the metal-donor stretching mode and the out-of-plane force constants were fitted to relevant structures available from the Cambridge Structural Data Base (CSD), and five, seven, eight and three sets of X-ray data were used for Co(II), Ni(II), Cu(II) and Zn(II), respectively. The parameters not available before[12] are listed in Table 4. There is good overall agreement between the widely varied experimental data sets and the corresponding computed structures, and the quality of the parameterization with respect to the type of compounds discussed here is demonstrated in Tables 3 and 5, where the computed structural parameters for [Ni(pap)] and [Cu(pap)]

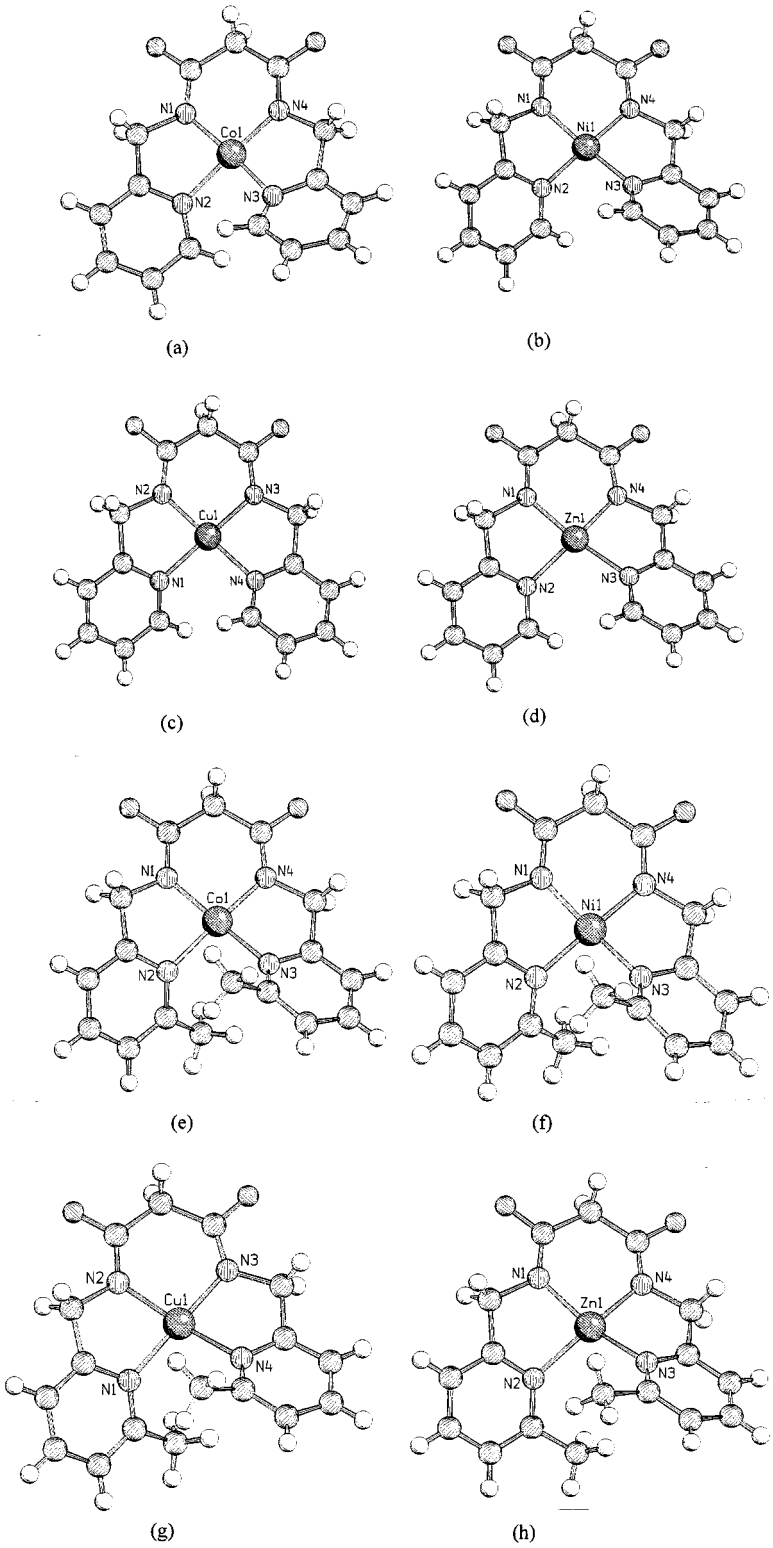
[Zn(pap)]		1.97		2.08		22.5
[Zn(Me$_2$pap)]		1.96		2.07		31.2

are compared to the experimental data. The geometric parameters of the chromophores of Co(II), Ni(II), Cu(II) and Zn(II), coordinated to pap and Me_2pap are assembled in Table 5, and the calculated structures are presented as SCHAKAL[15] plots in Figure 2.

The computed tetrahedral distortion of [Cu(pap)] and [Ni(pap)] are in good agreement with the experimentally observed twist angles (see Table 5). As expected for a metal ion with d^{10} configuration, the tetrahedral twist of the zinc(II) compound is larger than that of the other com-

Figure 2. SCHAKAL[15] plots of the computed structures of (a) [Co(pap)], (b) [Ni(pap)], (c) [Cu(pap)], (d) [Zn(pap)], (e) [Co(papMe)], (f) [Ni(papMe)], (g) [Cu(papMe)], (h) [Zn(papMe)]

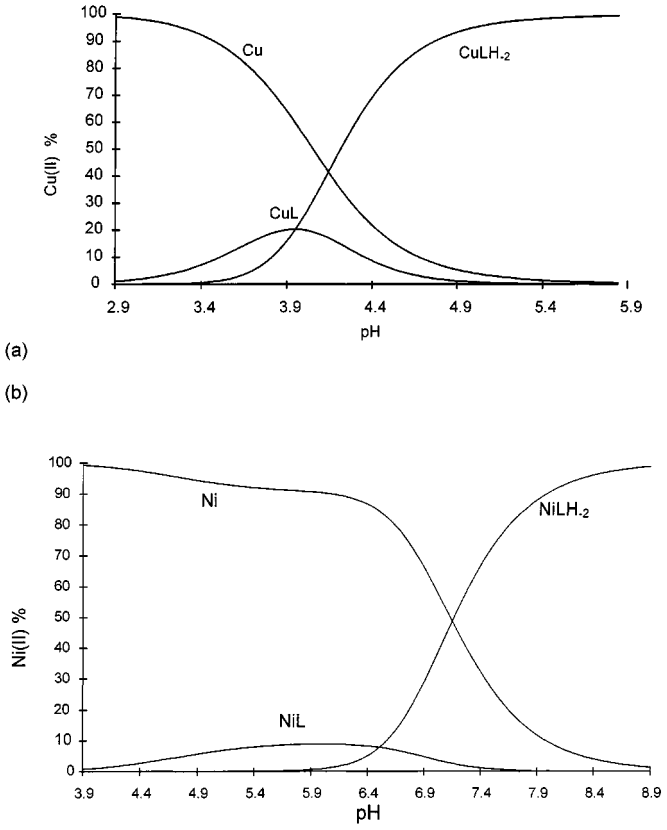


plexes, indicating that Zn(II) may relax the ligand imposed strain most efficiently. Substitution of the ortho hydrogen atoms of the pyridine rings with methyl groups (Me_2papH_2) increases this tetrahedral twist and may thus enhance the zinc(II) selectivity of this type of ligand.

Stabilities

The brutto stability constants of the complexes with $papH_2$ were determined by potentiometric titration [T = 298 K, μ = 0.2 mol dm^{-3} (KCl)]. Table 6 lists the protonation constants of the metal-free ligand and the logβ values of the complex species. The species distribution curves of the Cu(II)/$papH_2$ and the Ni(II)/$papH_2$ systems are shown in Figure 3. The main coordination mode of $papH_2$ with Cu(II) and Ni(II) is through the four nitrogen donors (MLH_{-2} in Figure 3). The supposedly N_2O_2 coordinated compounds [Cu($papH_2$)] and [Ni($papH_2$)] (ML in Figure 3) are minor species in acidic medium, where the amide nitrogen atoms are not deprotonated. The higher stability of [Cu(pap)] than that of [Ni(pap)] is in agreement with the larger flexibility towards tetrahedral distortion (d^9 vs low spin d^8), and this also emerges from the experimentally determined copper(II) selectivity of $C_{16}papH_2$ in the two-phase experiment. From the titration of $papH_2$ in presence of Co(II) and Zn(II) it emerges that [Co($papH_2$)] and [Zn($papH_2$)] are the only complex species present in solution. Thus, this is a good example to demonstrate the limits of computer-assisted design of metal ion selective ligands, i.e. MM does not allow to predict the stoichiometry of the compounds formed in solution[4] (see also Introduction).

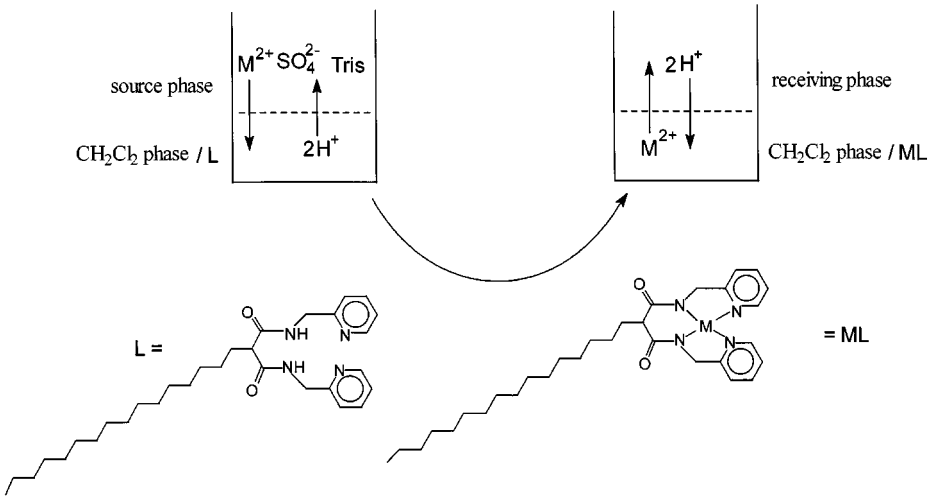
Figure 3. Species distribution of the M(II)/$papH_2$ system [M(II) = (a) Cu(II), (b) Ni(II); $c_M = 2 \times 10^{-3}$ mol dm^{-3}; $c_L = 2 \times 10^{-3}$ mol dm^{-3}; μ = 0.2 (KCl)].



Metal-Ion Extraction

$C_{16}papH_2$ is soluble in the most common organic solvents and insoluble in water. The extraction through the liquid membrane (CH_2Cl_2/$C_{16}papH_2$) was studied in two separate experiments, i.e. extraction form the aqueous source phase to the organic phase and extraction form the organic phase to the aqueous receiving phase, and a pH gradient was used to drive the two extraction steps (see Scheme 2). The thermodynamics and kinetics of this type of experiment are dependent on the medium (solvent, pH, ion concentrations), temperature, type of stirring and time for the extraction[16][17]. Also, the stoichiometry of the complex species in the organic phase is not necessarily identical

Scheme 2



to that in aqueous solution (see comment above). Thus, the extraction data (Table 7) and the results of the potentiometric studies (Table 6) are not comparable on a quantitative basis. Studies in dependence of $[M^{2+}]$ and extraction time indicated that extraction of copper(II) at a relativly low concentration ($[Cu^{2+}] = 5 \times 10^{-3}$ mol dm^{-3}) at ambient temperature and at pH 7.5 (aqueous to organic) and pH 3 (organic to aqueous), respectivly, was complete, i.e. reaching a steady state distribution, after $\leq$ 10 min. At higher $[Cu^{2+}]$ (experiments were performed up to $[Cu^{2+}] =$ 0.02 mol dm^{-3}) the extraction time had to be increased (by a factor of 20 with the above parameters). Also, the extraction kinetics of the four metal ions studied indicate that under the conditions of our experiments, the selectivity for Cu^{2+} was enhanced to some degree. On a qualitative basis the extraction studies and the potentiometric titrations are in good agreement, and the Cu^{2+} selectivity is in agreement with the prediction from the molecular mechanics calculations.

Experimental Section

General: Commercially available chemicals of the highest possible grade were used without further purification.^{13}C-NMR spectra at 50.32 MHz were obtained with a Bruker AS 200 instrument with sodium 3-(trimethylsilyl)propianate-d_4 as an internal reference. EPR spectra (10^{-3} m in DMF/water (1:2), 298 or 100 K) were recorded with a Bruker ESP 300E instrument (ER 041 XK X-band microwave bridge). The spin-Hamiltonian parameters were determined by simulation of the spectra with the computer program EPR50F[18]. UV/VIS spectra were obtained with Varian Cary IE or Cary 2300 spectrophotometers. Electrochemical measurements (cyclovoltametry) were made with a BAS 100B system using 10^{-3} mol dm^{-3} solutions of [Ni(pap)] in 0.1 mol dm^{-3} tetrabutylammoniumperchlorat CH_3CN solution at a glassy carbon electrode with a Ag/AgCl reference and a Pt auxiliary electrode with a scan rate of 100 mVs^{-1}, or using 10^{-3} mol dm^{-1} solutions of [Cu(pap)] in 0.1 mol dm^{-3} LiCl aqueous solution at a mercury drop electrode with a Ag/AgCl reference and a Pt auxiliary electrode with a scan rate of 100 mVs^{-1}. The pH-metric titrations were performed on 5 or 10 ml samples in the concentration range of 2×10^{-3} to 8×10^{-3} mol dm^{-3} at metal ion to ligand ratios of 2:1, 1:1 and 1:2. Argon was bubbled through the samples to ensure the absence of oxygen and for stirring the solutions. All pH-metric measurements were carried out at 298 K and at a constant ionic strength of 0.2 mol dm^{-3} (KCl). Measurements were made with a Radiometer pHM64 pH-meter, equipped with a CMAWL/S7 combined pH electrode and a Dosimat 715 (Metrohm) autoburette, containing carbonate-free potassium hydroxide at a known concentration. The pH output was converted into $[H^+]$ as described previously[19]. Protonation constants of the ligands and the brutto stability constants of the binary systems were calculated with PSEQUAD[20]. AAS measurements were made on a Perkin-Elmer 1100B instrument using an air-acetylene flame. The spectrometer was calibrated with standard Merck solutions. The wave lengths: 324.7 nm (Cu), 232 nm (Ni), 240.7 nm (Co), 248.3 nm (Fe). Elemental analyses were obtained from the microanalytical laboratory of the chemical institutes of the University of Heidelberg.

For molecular mechanics calculations MOMEC[11] was used, which also produced the Schakal[15] files for plotting. The force field has been described previously[11], except for parameters that are described in the text and in Table 4.

$papH_2$: α-picolylamine (2.7 g, 25 mmol) was added slowly to a hot and stirred aqueous solution (100 ml, 100°C) of diethyl-malonate (16 g, 6.25 mmol), and left at this temperature for 8h. After cooling to ambient temperature, ethanol (10 ml) and ether (100 ml) were added to precipitate the yellowish white product, which was collected after 24h (refrigerator) and recrystallized from ethyl acetate. Yield of the white crystalline ligand: 25.56 g (89.9 mmol, 90%). Calcd. for $C_{15}H_{16}N_4O_2$: C 63.35, H 5.68, N 19.71; found: C 63.29, H 5.73, N 19.78. ^{13}C-NMR (50.32 MHz, CD_3OD, 25°C, TMS): 169.7 (CO), 158.9, 149.7, 138.8, 123.7, 122.9 ($C_{pyridine}$), 53.8 ($CH_2(CO)_2$), 45.5 (pyridine, CH_2-NHR).

$C_{16}papH_2$: Diethyl malonate (8 g, 50 mmol) was slowly added by syringe to a solution of sodium (1.15 g, 50 mmol) in warm ethanol (abs., 25 ml, 50°C). Upon slow addition (syringe) of hexadecyl bromide (15.5 g, 50.25 mmol), a white product precipitate. The reaction mixture was then refluxed for 6 h and left in a refrigerator for 12 h. The precipitated diethyl hexadecylmalonate was collected by filtration, washed with water and dried over P_2O_5. Yield: 16.7 g (43.4 mmol, 87%). Calcd. for $C_{23}H_{44}O_4$: C 71.81, H 11.54; found: C 72.01, H 11.63. ^{13}C NMR (50.32 MHz, $CDCl_3$, 25°C, TMS): δ = 169.6 (CO), 61.2 (CH_2, ester), 52.1 ($C_{16}-CH-R_2$), 14.1 (CH_3, ester), mult (alkyl chain).

α-Picolylamine (18 g, 166.4 mmol) and the alkylated diethyl malonate (16 g, 41.6 mmol) were allowed to react for 8 h at 100°C

without a solvent. The product mixture was poured into 50 ml of cold water, and the precipitate was collected on a filter, after standing for 4 h in the refrigerator. After washing with water and drying under reduced pressure, the diamide was recrystallized from dichloromethane. Yield: 14.82 g (29.13 mmol, 70%). Calcd. for $C_{31}H_{48}N_4O_2$: C 73.17, H 9.52, N 11.02; found: C 72.99, H 9.47, N 10.95. ^{13}C NMR (50.32 MHz, $CDCl_3$, 25°C, TMS): δ = 170.8 (CO), 156.4, 149.1, 136.6, 122.2, 121.6 ($C_{pyridine}$), 55.2 ($C_{16}-CH-(CO)_2$), 44.6 (pyridine, CH_2-NHR), mult (alkyl chain).

[Cu(pap)]: An aqueous solution (30 ml) of $CuSO_4 \times 5\ H_2O$ (0.44 g, 1.76 mmol) was added to an aqueous solution (30 ml) of papH$_2$ (0.5 g, 1.76 mmol), set at pH 7.5 (0.1 M aqueous NaOH). A crystalline product was obtained after slow evaporation of the solvent at ambient temperature. Yield: 0.57 g (1.43 mmol, 81.4%). Calcd. for $C_{15}H_{20}CuN_4O_5$: C 45.05, H 5.04, N 14.01; found: C 44.99, H 5.07, N 14.04.

[Ni(pap)]: An aqueous solution (30 ml) of $Ni(BF_4)_2$ (0.41 g, 1.76 mmol) was added to an aqueous solution (30 ml) of papH$_2$ (0.5 g, 1.76 mmol), set at pH 7.5 (0.1 M aqueous NaOH). A crystalline product was obtained after slow evaporation of the solvent at ambient temperature. Yield: 0.42 g (1.11 mmol, 63.6%). Calcd. for $C_{15}H_{18}N_4NiO_4$: C 47.79, H 4.81, N 14.86; found: C 47.52, H 4.80, N 14.83. ^{13}C NMR (50 MHz, CD_3OD, 25°C, TMS): 176.2 (CO), 165.7, 150.6, 140.7, 125.7, 123.0 ($C_{pyridine}$), 57.6 ($CH_2(CO)_2$), 44.9 (pyridine, CH_2-NR).

Crystal Structure Analyses: The X-ray data of papH$_2$ × HBF$_4$ × H$_2$O ($C_{15}H_{19}N_4O_3 \times BF_4$), [Ni(pap)] × 2 H$_2$O ($C_{15}H_{14}N_4O_2Ni \times 2\ H_2O$) and [Cu(pap)] × 3 H$_2$O ($C_{15}H_{14}CuN_4O_2 \times 3\ H_2O$) were measured at room temperature on a Nicolet R3-diffractometer employing graphite monochromated Mo-K_α radiation (λ = 0.7107 Å); ω scan mode, data reduction and application of Lorenz, polarization absorption corrections were carried out. Details of the measurements and analyses are given in Table 8. The atom numbering is defined in Figure 1. The crystallographic data have been deposited at the Cambridge Crystallographic Data Centre (CCDC) as supplementary publication no. CCDC-103064 (for $C_{15}H_{14}N_4O_2Ni \cdot 2H_2O$), -103065 (for $C_{15}H_{19}N_4O_3BF_4$), -103066 (for $C_{15}H_{14}N_4O_2Cu \cdot 3H_2O$). Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road Cambridge CB2 1EZ, UK [Fax: (internat.) + 44-1223/336033; E-mail: deposit@ccdc.cam.ac.uk].

The structure of papH$_2$ × HBF$_4$ × H$_2$O was solved with direct methods; full-matrix least-squares methods were used to refine 2790 variables out of 1643 reflections with $I > 2.5\sigma$ (I); the structure converged at R = 8.4% and R_W = 6.9%; residual electron density −0.42, 0.71 e/Å^{-3}. Weight = $1/\sigma^2(F_0)$; goodness of fit = 4.19. The structures [Ni(pap)] × 2 H$_2$O and [Cu(pap)] × 3 H$_2$O were solved by Patterson-Fourier Methods with the SHELXTL PLUS program[21]; hydrogen atoms were included at calculated sites with fixed isotropic thermal parameters. The refinement (full-matrix, least-squares methods, $|F|$) of 5553 ([Ni(pap)]), 5174 ([Cu(pap)]) variables out of 3269 ([Ni(pap)]), 4938 ([Cu(pap)]) reflections with $I > 2.5\sigma$ (I) converged at R = 6.1% ([Ni(pap)]), 4.7% ([Cu(pap)]) and R_W = 5.0% ([Ni(pap)]), 10.17% ([Cu(pap)]); residual electron density −0.45, 0.54 ([Ni(pap)]), −0.327, 0.522 e/Å^{-3} ([Cu(pap)]). Weight = $1/\sigma^2(F_0)$; goodness of fit = 1.91 ([Ni(pap)]), 1.092 ([Cu(pap)]).

Extraction Experiments: The volume of each phase (aqueous source phase, organic phase, aqueous receiving phase) was 50 ml. The M^{2+} concentration (M = Fe, Co, Ni, Cu) of the aqueous source phase was ca. 5 × 10^{-3} mol dm^{-3} (pH 7.5, 0.1 mol dm^{-3} Tris, filtration to remove hydroxides) and measured by AAS (1 ml samples). The organic phase (CH_2Cl_2) contained 10^{-3} mol dm^{-3} C_{16}papH$_2$ and the pH of the aqueous receiving phase was 3 (0.1 mol dm^{-3} phthalate). The extractabilities were determined by AAS as decreasing [M^{2+}] in the aqueous source and increasing [M^{2+}] in the aqueous receiving phase. The conditions for all extractions were identical (298 K, stirring at 750 r.p.m. (magnetic stirrer) for 10.0 min). The data reported in Table 7 are averages of 3 determinations (deviation ≤ 5%).

Keywords: Schiff bases / Chiral recognition / Equilibrium constants / Nickel / Cobalt

The syntheses of new chiral 1,2-diphenylethylene-bridged nickel(II) and methylcobalt(III) Schiff base complexes are described. The equilibrium constants for the axial addition of the chiral bases (*R*)- and (*S*)-1-phenylethylamine to the enantiomerically pure metal complexes have been determined by means of spectrophotometric titrations. Comparison of the constants for the cyclohexanediyl-bridged complexes (type **1**) with those for the more bulky 1,2-diphenylethylene-bridged complexes (type **2**) reveals that chiral recognition is only observed in the case of type-2 complexes.

Introduction

In recent years, catalytic asymmetric synthesis has become increasingly important[1]. In this context, the enantioselective epoxidation of unfunctionalized alkenes reported by Jacobsen and Katsuki et al. has been one of the highlights of the current decade[2]. Recently, Mukaiyama et al. reported on the enantioselective hydrogenation of ketones with sodium tetrahydroborate in the presence of optically active cobalt(II) complexes[3]. These reactions are mediated by chiral metal complex catalysts and are based on the capacity of such species for chiral recognition of the substrates. Thus, some metal Schiff base complexes have emerged as particularly effective catalysts by virtue of their chiral carbon centers being situated in the vicinity of the central atom.

Our work is concerned with studies of the structure-reactivity relationships of Schiff base complexes with regard to the basic features of reactivity that are of importance for the catalytic performance, i.e. investigations of the redox behavior and Lewis acidity of coordinatively unsaturated planar complexes.

In previous publications we reported on new chiral nickel and copper $[N_2O_2]$-coordinated Schiff base complexes derived from 1,2-diaminocyclohexane and β-oxo aldehydes. These were characterized with regard to their ability to bind Lewis bases at their free axial coordination sites (Lewis acidity) and to accept electrons (redox potentials). However, upon applying the chiral bases (*R*)- and (*S*)-1-phenylethylamine, no chiral recognition could be observed[4]. The same result was found by Elias et al. for the addition of (*S*)-(−)-nicotine to chiral salene complexes[5].

Differences in the adduct stabilities were observed for the diastereomeric complexes *meso*-Ni**1a** and (*R,R*)-Ni**1a**, which can be attributed to the orientation of the cyclohexanediyl group in relation to the $[N_2O_2]$ plane[6].

In the present work, new chiral nickel and cobalt Schiff base complexes derived from 1,2-diphenylethylenediamine are described (type 2). Spectrophotometric titrations with chiral bases have been carried out so as to allow the determination of the stability constants of the adducts. Planar nickel complexes are known to give consecutive equilibria associated with 1:1 and 1:2 base adduct formation. Because of the change of spin state from S = 0 to S = 1, the octahedral 1:2 adduct is normally strongly favored ($K_2 >> K_1$). For investigations of pure 1:1 adduct formation we used a pentacoordinated methylcobalt(III) derivative. Such complexes usually have a sufficiently high Lewis acidity at the sole vacant coordination site and allow the determination of the equilibrium constants for the 1:1 base addition with high precision[7]. This is seemingly the first time that chiral recognition has been observed in measurements of this kind.

Results and Discussion

The ability of complexes to show chiral recognition depends mainly on the steric environment of the active site, i.e. the central metal atom. In view of the aforementioned negative results concerning the addition of chiral bases to complexes with the 1,2-cyclohexanediyl group as the chiral bridge, this group was replaced by the sterically more demanding 1,2-diphenylethylene bridge (Figure 1).

The substituents R^1 and R^2 also have a considerable influence on the electronic properties of the metal, as well as being responsible for steric effects. Substitution pattern **b** is sterically more demanding than arrangement **a**. However, the Lewis acidity of Ni**2b** is too low to permit quantitative studies of axial ligation. Spectral changes upon base addition could only be observed for nickel complexes with the electron-withdrawing substituents CN and OEt (type **a**). In

b: R^1 = Ph; R^2 = COOEt

contrast to the nickel complexes, where both types (Ni**2a** and Ni**2b**) could be prepared, we were not successful in isolating the corresponding cobalt complex Co**2a**. Thus, only the complex (*R*,*R*)-Co**2b** could be synthesized, which was subsequently methylated at the axial position so as to obtain the diamagnetic methylcobalt(III) complex (*R*,*R*)-MeCo**2b**. Such organocobalt complexes are very suitable as base acceptors in spectrophotometric titrations, since the spectral changes that accompany the transition from the pentacoordinated to the octahedral state are highly sensitive, and usually the calculated constants are of such an order of magnitude and of such a high precision that gradations of the constants for titrations with relatively weak bases can be determined unambiguously[7].

The compounds were characterized by means of NMR spectroscopy. As expected, in the ^{1}H-NMR spectrum of (*R*,*R*)-MeCo**2b** the protons attached to the chiral carbon atoms, as well as the olefinic protons (N−CH=), exhibit a double set of signals, i.e. they are no longer equivalent. This non-equivalence is due to the C_2 symmetry and the axial methyl group. This effect could not be observed in the spectrum of the corresponding square-planar nickel complex (*R*,*R*)-Ni**2a** or in that of (*R*,*R*)-Ni**2b**. Upon addition of [D_5]pyridine to the solution of (*R*,*R*)-MeCo**2b** used to record the NMR spectrum, the signal of the axial methyl group is shifted to lower field ($\delta = 2.70 \rightarrow 2.98$).

Spectrophotometric titrations were carried out using the (*S*,*S*) enantiomers of the optically active complexes Ni**1a** and Ni**2a** with both enantiomers of the chiral base 1-phenylethylamine in chloroform and in benzene (Ni**2a** only). Nickel complexes preferentially form octahedral base diadducts, i.e. $K_1 < K_2$ for equations 1 and 2.

$$\mathrm{NiL} + \mathrm{B} \overset{K_1}{\rightleftharpoons} \mathrm{NiLB} \qquad (1)$$

$$\mathrm{NiLB} + \mathrm{B} \overset{K_2}{\rightleftharpoons} \mathrm{NiLB_2} \qquad (2)$$

The constants K_1 (= β_1) and β_2 (K_1K_2) thus determined are listed in Table 1. It was confirmed that the cyclohexanediyl-bridged complex (*S*,*S*)-Ni**1a** cannot distinguish between (*R*)- and (*S*)-1-phenylethylamine. For these substrates, the measured constants are the same within the margin of error. However, following introduction of the sterically more demanding chiral 1,2-diphenylethylene bridge into the complex [(*S*,*S*)-Ni**2a**], the β_2 values differ significantly. In both the solvents used, i.e. $CHCl_3$ and benzene, the constants determined by titration with the (*R*)-amine are significantly higher than those determined by titration with the (*S*)-amine. This means that the base adduct of (*S*,*S*)-Ni**2a** with (*S*)-1-phenylethylamine is thermodynamically less stable than the adduct with the (*R*)-amine. The reason for this should be that the addition of the (*S*) enantiomer of the base is sterically more hindered by the chiral diamine bridge than that of the (*R*) enantiomer. Unfortunately, the margin of error in K_1 (and K_2) is much higher than that in β_2 and thus it is not possible to establish whether the chiral recognition occurs to a greater extent in the first or the second step of the axial base addition.

Furthermore, we carried out titrations of the organocobalt(III) complex (*R*,*R*)-MeCo**2b** with (*R*)- and (*S*)-1-phenylethylamine in benzene. (This complex is very light-sensitive in solution, and hence preparations and the measurement itself had to be carried out in the dark.) In the course of the base addition, a transition from the pentacoordinated to the octahedral state occurs, as depicted in Scheme 1.

An example of a titration of (*R*,*R*)-MeCo**2b** with a chiral base is illustrated in Figure 2. The intense charge transfer band at 645 nm is seen to decrease with increasing concentration of (*S*)-1-phenylethylamine.

The calculated values of *K* are listed in Table 2. It can be seen that the difference between the constants derived from the two titrations is even larger than in the case of the nickel complex (*S*,*S*)-Ni**2a**. The constant for the adduct of (*R*,*R*)-MeCo**2b** with (*S*)-1-phenylethylamine is approximately three times larger than that of the adduct with the (*R*)-amine. It seems that the bulky substituents R^1 = phenyl and R^2 = COOEt enhance the differentiation of the stabilities of the corresponding base adducts, i.e. with (*R*)- or (*S*)-1-phenylethylamine, respectively.

From the equation K = [CoLB]/([CoL][B]) for the equilibrium according to Scheme 1, it follows that for the titration of complex (*R*,*R*)-MeCo**2b** with the racemic base 1-phenylethylamine, one would obtain an adduct mixture of a composition such that $[CoLB_{(R)}]/[CoLB_{(S)}] = K_{(R)}/K_{(S)}$, where (*R*) and (*S*) refer to (*R*)- and (*S*)-1-phenylethylamine, respectively. Thus, in the present case, a mixture of 36.4% of the (*R*)-amine adduct and 63.6% of the (*S*)-amine adduct would result.

Conclusions

The results show the significant influence of the complex periphery on chiral recognition properties. Such an effect has been observed simply by replacing the cyclohexadienyl group in previously studied compounds by the sterically

more demanding 1,2-diphenylethylene bridge. To the best of our knowledge, this is the first time that chiral recognition has been observed in the addition of a base to coordinatively unsaturated complexes. The results are of importance with regard to enantioselective catalytic investigations. Appropriate experiments are in progress, the results of which will be reported in due course.

We would like to thank the *Deutsche Forschungsgemeinschaft* and the *Fonds der Chemischen Industrie* for financial support.

Experimental Section

The following chemicals were used without further purification: Ethyl 2-cyano-3-ethoxyacrylate (Merck), (1*S*,2*S*)-(+)- and (1*R*,2*R*)-(−)-1,2-diphenylethylenediamine (97%, Fluka), (*R*)-(+)- and (*S*)-(−)-1-phenylethylamine (98%, Fluka). Ethyl (ethoxymethylene)-benzoylacetate was prepared according to a literature method[8]. – NMR spectra were recorded with a Bruker AC-200 spectrometer (^{1}H, ^{13}C, ^{1}H-^{13}C-COSY, ^{13}C APT NMR) and are reported as δ in ppm from HMDS. – FT IR spectroscopy was performed with a Perkin-Elmer 2000 FT-IR instrument. – Mass spectra were obtained with a Finnigan MAT SSQ 710 spectrometer. – Elemental analyses were carried out with a Leco CHNS-932 analyzer (CHN) and by complexometric titration (Ni, Co), respectively. – Specific rotation values were determined with a Polartronic E polarimeter (Schmidt-Haensch). – Spectrophotometric titrations were carried out at constant temperature with a Varian Cary 5E spectrophotometer equipped with a temperature controller. The calculation of the equilibrium constants was carried out at six wavelengths λ(*i*) and with at least twenty base (axial ligand) concentrations $c_B(j)$, under optimized conditions as described in the literature[9a]. The constants β_1 (= K_1) and β_2 (K_1K_2) as well as the extinction coefficients $\varepsilon_1(\lambda)$ and $\varepsilon_2(\lambda)$ for the 1:1 and the 1:2 adduct, respectively, were calculated iteratively by a non-linear fit of the absorbance data $A = E/(c_K d)$ (*E:* extinction; c_K: total complex concentration) according to

$$A_{i,j} = \Sigma\varepsilon_{\nu,i}\beta_\nu[B]_j^\nu/(\Sigma\beta_\nu[B]_j) \quad (3)$$

$(\nu = 0, 1, 2; \beta_0 \equiv 1)$

A home-made computer programme SPEGA was used for the iteration, based on the algorithm of Marquardt[9b]. A special procedure was included to calculate the equilibrium base concentrations $[B]_j$ from the known total concentrations c_{Bj} by iteration according to

$$c_{Bj} = [B]_j + c_{Kj}\Sigma\nu\beta_\nu[B]_j^\nu/(\Sigma\beta_\nu[B]_j^\nu) \quad (4)$$

$(\nu = 0, 1, 2; \beta_0 \equiv 1)$

Ligands: Diethyl (Z,Z)-(trans)-3,3′-(1,2-Diphenyl-1,2-ethanediyldiimino)bis(2-cyano-2-propenoate) [(*R*,*R*)- and (*S*,*S*)-2H**2a**]: 105 mg (0.5 mmol) of (*R*,*R*)- or (*S*,*S*)-diphenylethylenediamine was dissolved in 10 ml of methanol. To this solution, 170 mg (1 mmol) of ethyl 2-cyano-3-ethoxyacrylate, dissolved in 5 ml of methanol, was added dropwise. The mixture was refluxed for 30 min. The solvent was then partially evaporated in vacuo until a white powder precipitated. To the obtained amalgam, 1.44 g (2.14 mmol) of (*R*,*R*)-Co**2b**, dissolved in 25 ml of dry THF, was added. The mixture was stirred for 12 h, whereupon a violet colour appeared. The solution was then decanted from the mercury and cooled at −78°C. At this temperature, a solution of 0.456 g (3.2 mmol) of iodomethane in 10 ml of dry THF was added dropwise, resulting in the precipitation of a red solid. The suspension was poured into water, and the red solid was filtered off and dried in air. The obtained product still contained traces of water and THF, which could not be removed in vacuo. However, in non-coordinating solvents these molecules dissociate. These green solutions are very light-sensitive, yield 1.53 g (94%). − EI MS; *m*/*z* (%): 688 $[M^+]$ (2), 673 $[M - CH_3]^+$ (16), 366 $[M - L/2 - CH_3]^+$ (17). − IR (Nujol): $\tilde{\nu}_{max} = 1667\ cm^{-1}$ ($C{=}O_{str}$), 704 ($C{-}H_{def}$). − ^1H NMR (200 MHz; $CDCl_3$): δ = 0.74 (t, 6 H, CH_2CH_3), 2.70 (s, 3 H, CH_3), 3.78 (q, 4 H, CH_2CH_3), 4.69 (ds, 1 H, N−CHPh), 4.96 (ds, 1 H, N−CHPh), 7.05−7.35 (m, 20 H, Ph), 7.65 (s, 1 H, N−CH=), 7.79 (s, 1 H, N−CH=). − ^{13}C NMR (200 MHz, $CDCl_3$): δ = 13.5 (CH_2CH_3), 29.7 (CH_3), 59.6 (CH_2), 78.8, 81.1 (N−*C*HPh), 102.8, 103.6 (CH=*C*), 125.9−130.6 (Ph), 136.1, 136.9, 141.2 (C_q, Ph), 162.7, 163.9 (*C*H=C), 184.6 (C=O). − $C_{39}H_{37}CoN_2O_6$: calcd. Keywords: *N*-Acetylcysteine / Amino acids / Captopril / Rhenium / S ligands

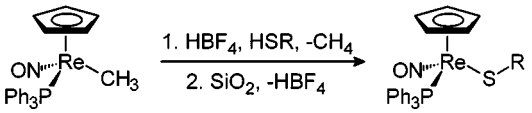
Chiral racemic rhenium thiolate complexes [CpRe(NO)(PPh_3)(SR)] were obtained under either acidic or basic conditions. Thus, when [CpRe(NO)(PPh_3)(CH_3)] (**1**) was treated with etheral HBF_4 and HSR the thiolate complexes [CpRe(NO)(PPh_3)(SR)] [SR = SCH_2(2-furyl) (**2**), SCH_2C(O)OEt (**3**)] were obtained after chromatographic workup. Ligand exchange reactions between [CpRe(NO)(PPh_3)(OC_4H_8)]BF_4 (**4**) and sodium thiolates yielded analogous complexes with SR = SH (**5**), SCH_2CH_2Ph (**6**), $SCH_2CH{=}CH_2$ (**7**). SR groups which tolerate strongly alkaline conditions may be introduced by treatment of **4** with HSR in the presence of sodium ethoxide as demonstrated by the high-yield synthesis of **2** as well as of complexes with SR = SCH_2CH_2NHAc (**8**), $SCH_2CH_2C(O)OH$ (**9**). A milder synthesis using hydrated sodium carbonate as a base provided **8** and compounds with SR = $SCH_2CH_2C(O)OMe$ (**10**), $SCH_2CH_2C(O)NHCH_2Ph$ (**11**) in high yields. Using similar methods, thiolate complexes of (*R*)-*N*-acetylcysteine (**13**), its methyl ester (**14**), (*R*)-*N*-phthaloylcysteine (**16**), and *N*-[(*S*)-3-mercapto-2-methylpropionyl]-*S*-proline (Captopril) (**17**) were obtained as diastereomeric pairs. The formation of **13** was preceded by the O-bonded isomer **12** which slowly rearranges in solution. **13** can be converted under acidic conditions into its methyl (**14**) or ethyl (**15**) esters. The diastereomers of **16** were separated by crystallization, and the structure of the (*R*,*R*)-isomer **16a** determined.

Thiolate ligands have some remarkable properties which are exploited by nature in a number of important metalloenzymes.[2] SR groups being soft donors bind strongly to most of the transition metal ions. Due to their high polarizability and π-donor capacity,[3] they are able to stabilize various oxidation states of the metal and to promote the formation of clusters[2][4] which can function as electron reservoirs for redox processes. Enzymatic reactions which lead to the transformation of coordinated thiolate ligands seem to be comparatively rare. One of the few prominent examples is the penicillin biosynthesis[5] whose first step involves the oxidative dehydrogenation of an iron-coordinated, cysteine-containing tripeptide to a thioaldehyde intermediate.[6] We have recently described a similar oxidative route for the synthesis of stable thioaldehyde complexes of ruthenium[7][8] and rhenium.[9] In order to further exploit the characteristic reactivity of coordinated thioaldehydes in nucleophilic additions and cycloadditions[8][10][11][12] we decided to investigate thiolate complexes bearing various functional groups on the SR ligand.

Results

Achiral Thiolates

Two synthetic strategies were chosen in which the rhenium–sulfur bond is formed under either acidic[8] or basic conditions. Treatment of the racemic methylrhenium complex **1**[13] with a twofold excess of etheral HBF_4 and 2-(mercaptomethyl)furan or ethyl mercaptoacetate followed by chromatography over silica gave the corresponding rhenium thiolate complexes **2** and **3** in fair to good yields (Eq. 1).



(1)

1 **2** (52%) **3** (94%)

SR: SCH_2(2-furyl) (**2**), SCH_2C(O)OEt (**3**)

Since the strongly acidic conditions of this route may not be compatible with a number of functional groups, a synthesis based on a nucleophilic substitution at rhenium was sought. The tetrahydrofuran complex [CpRe(NO)(PPh_3)(OC_4H_8)]BF_4 (**4**) which is easily obtained through acid cleavage of **1**[14] seemed to be an appropriate starting material. Although **4** was noted to be labile[14] it has found only sporadic use in ligand exchange reactions.[15] When **4** was treated with isolated sodium thiolates in THF/ethanol, the corresponding thiolate complexes **5–7** were formed in good

[◇] Part 6: Ref.[1].

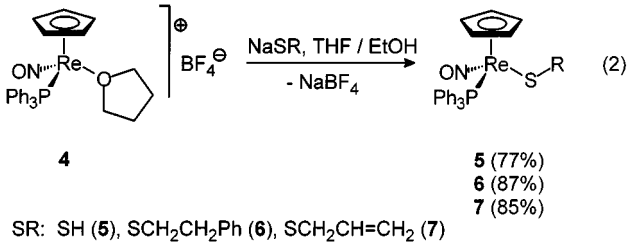
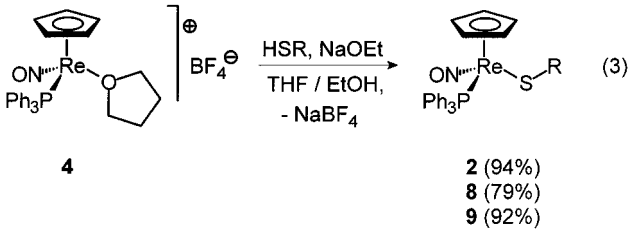
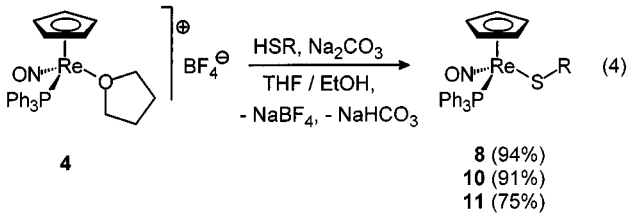
yields (Eq. 2). The thiolate anions may also be generated in situ from thiol and sodium ethoxide. This was demonstrated by the high-yield synthesis of **2**, **8**, and **9** (Eq. 3).





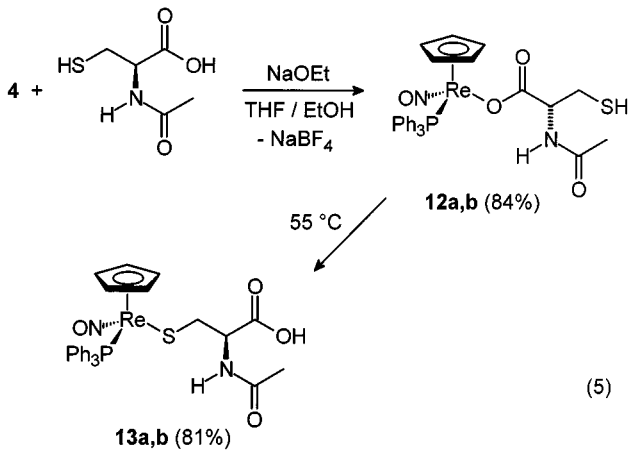
The use of ethoxide as a base may, however, cause problems when chiral thiolates are to be employed which would racemize under strongly alkaline conditions. Hydrated sodium carbonate, which finds some use in peptide syntheses,[16] was expected to be mild enough to circumvent this obstacle. Indeed, simple stirring of a mixture of **4**, $Na_2CO_3 \cdot 10\ H_2O$, and a thiol produced the expected thiolate complexes **8**, **10**, and **11** in high purity and yield (Eq. 4).

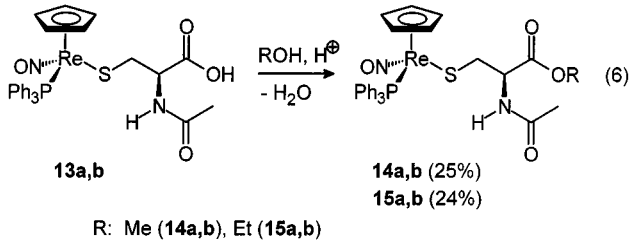


The new thiolate complexes are yellow, slightly air-sensitive crystalline solids which are more or less readily soluble in all common organic solvents. Typical spectroscopic features include low NO stretching frequencies in the infrared spectra which hint at the high donor ability of the SR ligand. In the ^1H NMR spectra, all methylene protons of the SR group are diastereotopic; those in α position give widely separated signals which are easily analyzed. The SH complex **5** exhibits a high-field signal at $\delta = 0.09$ which is split into a doublet due to coupling with phosphorus. In the ^{13}C-NMR spectra the α carbon signal is shifted by approximately 15 ppm to lower field compared to the uncoordinated thiol, and split into a doublet due to coupling with phosphorus. In cases of doubt such as **7**–**11** this serves as unambiguous proof that the SR ligand is indeed coordinated through the sulfur atom.

Chiral, Enantiomerically Pure Thiolates

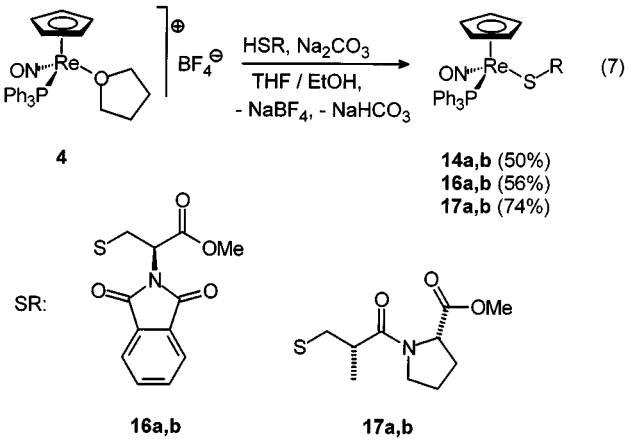
Reaction of the THF complex **4** with (*R*)-*N*-acetylcysteine and sodium ethoxide initially gave the orange-brown carboxylate complex **12a**, **b** as a 1:1 mixture of diastereoisomers. Upon prolonged storage in solution or refluxing in acetone, **12a**, **b** converts almost quantitatively into the yellow S-bonded isomer **13a**, **b** (Eq. 5) which, after one crystallization, was obtained in 17% de. Conversely, solutions of **13a**, **b** revert back to an equilibrium mixture containing approximately 5% **12a**, **b**.





For a further elaboration of the thiolate side chain it may be desirable to have the carboxylate group protected as ester. To this end, the diastereomeric complexes **13a**, **b** were treated with alcohol and acid (Eq. 6). This reaction was also intended to be an additional test of the stability of the rhenium complex. The expected esters **14a**, **b** and **15a**, **b** were indeed obtained, albeit in less than satisfactory yields. Spectroscopic analysis of the crude reaction mixtures indicated that the losses were primarily due to the chromatographic workup which was necessary to remove the acid, rather than destruction of the rhenium complex. Obviously it is advisable to convert amino acids to their esters before coordinating them to the transition metal. Thus, **4** was reacted with the methyl esters of (*R*)-*N*-acetylcysteine, (*R*)-*N*-phthaloylcysteine, and *N*-[(*S*)-3-mercapto-2-methylpropionyl]-*S*-proline in the presence of sodium carbonate (Eq. 7). The three products were isolated as 1:1 mixtures of diastereoisomers. **17a**, **b** was partially enriched by crystalliza-

tion to 15% de while diastereomerically pure **16a** crystallized from an acetone solution.



The physical properties of the diastereomeric thiolate complexes **13a**,**b**–**17a**,**b** closely resemble those of the other members of this series. As expected, they give double sets of signals in their ^{1}H-, ^{13}C-, and ^{31}P-NMR spectra. Coordination to rhenium via the sulfur atom is unequivocally inferred from the large coupling of the α carbon with the phosphorus atom. This clearly distinguishes **13a**, **b** from their carboxylate-bound isomers **12a**, **b** whose ^{13}C-NMR spectra exhibit doublet resonances for the carboxylate carbon atom.

Crystal and Molecular Structure of 16a

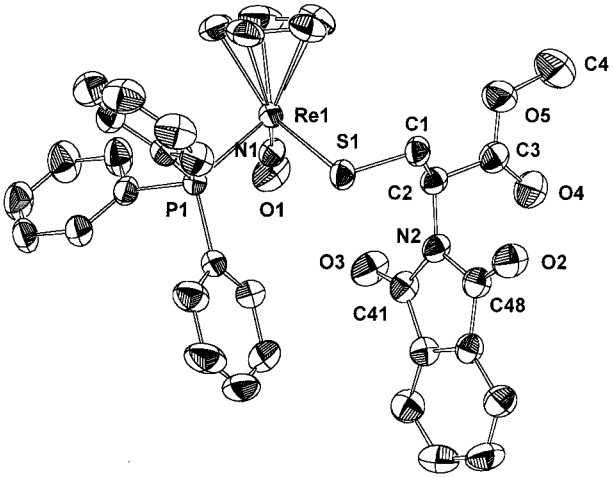
From an acetone solution of **16a**, **b** diastereomerically pure **16a** was obtained by slow crystallization. A suitable single crystal was analyzed by X-ray diffraction. It belonged to the enantiomorphic space group $P2_1$ which immediately showed that it is an enantiomerically pure compound. The stereocenters at both rhenium and carbon have the (*R*) configuration (Figure 1) which is in line with the Flack parameter. Bond distances and angles are well within the normal range for complexes of the type [CpRe(NO)(PPh_3)(SR)].[17][18]

The angle S–Re–N(1) [102.35(11)°] is surprisingly large for both **16a** and the (diarylmethyl)thiolate complex investigated by Gladysz.[18] As there are not any obvious steric interactions between the NO and SR ligands, the driving force of this distortion must be electronic in origin.[1] Also of note is the transoid arrangement of the groups at rhenium and sulfur [dihedral angle P–Re–S–C(1) = 167.4°] which simultaneously minimizes steric interactions as well as the repulsion between the lone pairs at sulfur and the HOMO of the [CpRe(NO)(PPh_3)] complex fragment.[1]

Discussion

This work was aimed at the synthesis of chiral racemic rhenium thiolate complexes [CpRe(NO)(PPh_3)(SR)]. Three routes proceeding under acidic, basic, or close to neutral

Figure 1. Molecular structure (*R*,*R*)-[CpRe(NO)(PPh_3)($SCH_2CH(NC_8H_4O_2)COOMe$)] (**16a**) (without H atoms)[a]



[a] Selected distances [pm] and angles[°] (standard deviations in parentheses): Re(1)–S(1) 239.45(10), Re(1)–P(1) 235.44(12), Re(1)–N(1) 176.3(4), N(1)–O(1) 119.7(5), S(1)–C(1) 182.2(5), S(1)–Re(1)–P(1) 87.31(6), S(1)–Re(1)–N(1) 102.35(11), P(1)–Re(1)–N(1) 92.80(13), Re(1)–S(1)–C(1) 106.2(2), P(1)–Re(1)–S(1)–C(1) 167.4(2).

conditions were developed in order to ensure tolerance for a range of functional groups. Acid cleavage of the methyl complex **1** produces the solvent-stabilized 16-electron species $[CpRe(NO)(PPh_3)]^+$ which immediately picks up any stronger Lewis base present in the solution.[19] The thiol complexes [CpRe(NO)(PPh_3)(HSR)]BF_4 thus formed eliminate HBF_4 simply upon chromatography over silica.[9] This route produces thiolate complexes in good yields but is limited of course to SR groups which tolerate strongly acidic conditions.

Gladysz et al., in their seminal work on chiral rhenium complexes,[20] made extensive use of the dichloromethane complex [CpRe(NO)(PPh_3)($ClCH_2Cl$)]BF_4[21] in ligand exchange reactions. With the strongly nucleophilic thiolate ions this compound, in addition to ligand exchange, undergoes nucleophilic substitution at carbon which leads to the formation of (chloromethyl)thioether complexes in sizeable quantities.[9] The tetrahydrofuran complex **4** whose synthesis[14] can easily be scaled up to multigram quantities, finally proved to be the starting material of choice.

For potentially ambidentate ligands such as allyl thiolate or the anions of cysteine and its derivatives, coordination through sulfur is favored thermodynamically. Nevertheless, for cysteine itself, which under the conditions of equation 5 exists in solution in its doubly deprotonated form, the carboxylate isomer is formed as the kinetic product. A similar observation was not made in the case of the 3-mercaptopropionic acid complex **9** (Eq. 3), due probably to the absence of bulky groups around the sulfur atom. Bond formation between the chiral rhenium complex and the various SR ligands was not expected to be accompanied by kinetic resolution. Nevertheless it is gratifying that partial or even full diastereomer separation could easily be effected by simple crystallization.

Conclusions

It has been shown here that the chiral Lewis acid $[CpRe(NO)(PPh_3)]^+$ can be efficiently connected to simple thiolates as well as those derived from biologically relevant molecules such as the amino acid (*R*)-cysteine or *N*-[(*S*)-3-mercapto-2-methylpropionyl]-*S*-proline, an ACE (*angiotensin converting enzyme*) inhibitor which under the brand name "Captopril" is used as an antihypertension drug. Apart from the more classical use of the rhenium complex fragment as a protective group for the thiolate function and a chiral auxiliary[20] for stereoselective addition reactions, one can also envisage that compounds such as **13–17** might find uses as specific "organometallic markers" in biochemistry[22] or as carriers of heavy atoms for protein crystallography.[23]

This work has been supported by the *Deutsche Forschungsgemeinschaft* (SFB 344 "Selektive Reaktionen Metall-aktivierter Moleküle").

Experimental Section

All experiments were carried out in Schlenk tubes under an atmosphere of nitrogen using suitably purified solvents. – IR: Perkin-Elmer 283, Bruker IFS 25. – ^{1}H NMR: Bruker AMX 400, δ values relative to TMS. – ^{13}C NMR: Bruker AMX 400, δ values relative to TMS; assignments were routinely checked by DEPT; in some cases the ^{13}C-NMR signals of quarternary carbon atoms were too weak to be detected. – ^{31}P NMR: Bruker AMX 400, δ values relative to 85% H_3PO_4. The ^{1}H- and ^{13}C-NMR signals of the PPh_3 ligand are very similar for all compounds and have therefore been omitted from the lists of spectral data. – Elemental analyses: Analytical Laboratory of the Institut für Anorganische Chemie. The following starting materials were obtained as described in the literature: $[CpRe(NO)(PPh_3)(CH_3)]$ (**1**),[13] $[CpRe(NO)(PPh_3)(OC_4H_8)]BF_4$ (**4**),[14] NaSH,[24] other sodium thiolates,[25] $HSCH_2CH_2C(O)NHCH_2Ph$,[26] (*R*)-*N*-phthaloylcysteine.[16] All other reagents were used as purchased.

[CpRe(NO)(PPh$_3$)(SCH$_2$C$_4$H$_3$O)] (**2**): To a solution of **1** (225 mg, 0.40 mmol) and 2-(mercaptomethyl)furan (115 mg, 1.00 mmol) in toluene (15 ml) was added at –70 °C a solution of HBF_4 in diethyl ether (1.00 mmol). The mixture was allowed to warm up to 20 °C, and all volatiles were removed under vacuum. The semi-solid residue was chromatographed with THF/ether over a short silica column and further purified by crystallization from dichloromethane/pentane. Yield 137 mg (52%), m.p. 153 °C. – ^{1}H NMR (400 MHz, [D$_6$]acetone, 20 °C): δ = 3.73, 3.77 [AB system, ^2J(H,H) = 14.2 Hz, 2 H; SCH_2], 5.28 (s, 5 H; C_5H_5), 6.13 [dd, ^3J(H,H) = 3.2 Hz, ^4J(H,H) = 0.8 Hz, 1 H; CH], 6.28 [dd, ^3J(H,H) = 3.1 Hz, ^3J(H,H) = 1.9 Hz, 1 H; CH], 7.36 [dd, ^3J(H,H) = 1.8 Hz, ^4J(H,H) = 0.9 Hz, 1 H; CH]. – ^{13}C NMR (100 MHz, [D$_6$]acetone, 20 °C): δ = 39.4 [d, ^3J(P,C) = 9 Hz; SCH_2], 92.3 (s; C_5H_5), 106.2 (s; CH), 111.1 (s; CH), 141.2 (s; CH), 158.9 (s; CH). – ^{31}P NMR (162 MHz, [D$_6$]acetone, 20 °C): δ = 19.6 (s). – IR (CH_2Cl_2): $\tilde{\nu}$ = 1654 (NO), 1606 cm^{-1} (C=C). – $C_{28}H_{25}NO_2PReS$ (656.8) calcd C 51.21, H 3.84, N 2.13, S 4.88; found C 50.90, H 3.88, N 1.98, S 5.16.

[CpRe(NO)(PPh$_3$)(SCH$_2$C(O)OEt)] (**3**): This compound was prepared analogously from **1** and ethyl mercaptoacetate. Yield 149 mg (94%), m.p. 106 °C. – ^{1}H NMR (400 MHz, [D$_6$]acetone, 20 °C): δ = 1.24 [t, ^3J(H,H) = 7.1 Hz, 3 H; CH_3], 3.07, 3.45 [AB system, ^2J(H,H) = 12.1 Hz, 2 H; SCH_2], 4.07, 4.12 [AB system of quartets, ^2J(H,H) = 10.8 Hz, ^3J(H,H) = 7.1 Hz, 2 H; OCH_2], 5.35 (s, 5 H; C_5H_5). – ^{13}C NMR (100 MHz, [D$_6$]acetone, 20 °C): δ = 14.5 (s; CH_3), 43.6 [d, ^3J(P,C) = 9 Hz; SCH_2], 60.6 (s; OCH_2), 92.6 (s; C_5H_5), 174.0 (s; CO). – ^{31}P NMR (162 MHz, [D$_6$]acetone, 20 °C): δ = 19.5 (s). – IR (CH_2Cl_2) $\tilde{\nu}$ = 1721 (CO), 1653 cm^{-1} (NO). – $C_{27}H_{27}NO_3PReS$ (662.8) calcd C 48.93, H 4.11, N 2.11, S 4.84; found C 48.91, H 4.01, N 1.97, S 5.08.

[CpRe(NO)(PPh$_3$)(SH)] (**5**): A solution of **4** (281 mg, 0.40 mmol) and NaSH (28 mg, 0.50 mmol) in THF (20 ml) and ethanol (20 ml) was stirred 1 h at 20 °C. The mixture was taken to dryness, and the residue dissolved in benzene and filtered over Celite. The filtrate was partially evaporated and the product precipitated by adding pentane. Yield 178 mg (77%), m.p. 60 °C (dec). – ^{1}H NMR (400 MHz, C_6D_6, 20 °C): δ = 0.09 [d, ^3J(P,H) = 12.6 Hz, 1 H; SH], 4.77 (s, 5 H; C_5H_5). – ^{13}C NMR (100 MHz, C_6D_6, 20 °C): δ = 91.4 (s; C_5H_5). – ^{31}P NMR (162 MHz, C_6D_6, 20 °C): δ = 23.0 (s). – IR (CH_2Cl_2): $\tilde{\nu}$ = 1655 cm^{-1} (NO). – $C_{23}H_{21}NOPReS$ (567.7) calcd C 47.91, H 3.67, N 2.43, S 5.56; found C 47.91, H 3.75, N 2.25, S 5.41.

[CpRe(NO)(PPh$_3$)(SCH$_2$CH$_2$Ph)] (**6**): This compound was prepared analogously from **4** and sodium 2-phenylethanethiolate. Yield 237 mg (87%), m.p. 168 °C. – ^{1}H NMR (400 MHz, C_6D_6, 20 °C): δ = 2.88–3.34 (m, 4 H; CH_2CH_2), 4.80 (s, 5 H; C_5H_5). – ^{13}C NMR (100 MHz, C_6D_6, 20 °C): δ = 42.1 (s; CH_2), 45.1 [d, ^3J(P,C) = 8 Hz; SCH_2], 91.1 (s; C_5H_5). – ^{31}P NMR (162 MHz, C_6D_6, 20 °C): δ = 20.2 (s). – IR (CH_2Cl_2): $\tilde{\nu}$ = 1644 cm^{-1} (NO). – $C_{31}H_{29}NOPReS$ (680.8) calcd C 54.69, H 4.29, N 2.06, S 4.71; found C 54.39, H 4.30, N 2.05, S 4.66.

[CpRe(NO)(PPh$_3$)(SCH$_2$CH=CH$_2$)] (**7**): This compound was prepared analogously from **4** and sodium allylthiolate. Yield 210 mg (85%), m.p. 202 °C. – ^{1}H NMR (400 MHz, $CDCl_3$, 20 °C): δ = 3.02, 3.39 [AB system of doublets, ^2J(H,H) = 13.0 Hz, ^3J(H,H) = 7.2 Hz, 2 H; SCH_2], 4.87 [ddd, ^2J(H,H) = 2.0 Hz, ^3J(H,H) = 9.9 Hz, ^4J(H,H) = 1.0 Hz, 1 H; =CH_2], 4.95 [dd, ^2J(H,H) = 1.9 Hz, ^3J(H,H) = 16.9 Hz, 1 H; =CH_2], (s, 5 H; C_5H_5), 5.87 [ddt, ^3J(H,H) = 16.9 Hz, ^3J(H,H) = 9.8 Hz, ^3J(H,H) = 7.2 Hz, 1 H; =CH] . – ^{13}C NMR (100 MHz, $CDCl_3$, 20 °C): δ = 45.3 [d, ^3J(P,C) = 7 Hz; SCH_2], 91.3 (s; C_5H_5), 113.2 (s; =CH_2), 141.2 (s; =CH). – ^{31}P NMR (162 MHz, $CDCl_3$, 20 °C): δ = 19.0 (s). – IR (CH_2Cl_2): $\tilde{\nu}$ = 1645 (NO), 1608 cm^{-1} (C=C). – $C_{26}H_{25}NOPReS$ (616.7) calcd C 50.64, H 4.09, N 2.27, S 5.20; found C 50.99, H 4.31, N 2.20, S 4.50.

[CpRe(NO)(PPh$_3$)(SCH$_2$C$_4$H$_3$O)] (**2**): To a solution of **4** (281 mg, 0.40 mmol) and 2-(mercaptomethyl)furan (57 mg, 0.50 mmol) in THF (20 ml) and ethanol (20 ml) was added at 20 °C a solution of sodium ethoxide in ethanol (0.50 mmol). After 1 h the mixture was taken to dryness, and the residue dissolved in benzene and filtered over Celite. The filtrate was partially evaporated and the product precipitated by adding pentane. Yield 257 mg (94%).

[CpRe(NO)(PPh$_3$)(SCH$_2$CH$_2$NHAc)] (**8**): This compound was prepared analogously from **4** and *N*-acetylcysteamine. Yield 209 mg (79%), m.p. 154 °C. – ^{1}H NMR (400 MHz, C_6D_6, 20 °C): δ = 1.71 (s, 3 H; CH_3), 2.48 (m, 1 H; CH_2), 2.96 (m, 1 H; CH_2), 3.37 (m, 1 H; SCH_2), 3.95 (m, 1 H; SCH_2), 4.87 (s, 5 H; C_5H_5), 5.77 (s, br, 1 H; NH). – ^{13}C NMR (100 MHz, C_6D_6, 20 °C): δ = 23.2 (s; CH_3), 40.3 [d, ^3J(P,C) = 8 Hz; SCH_2], 43.3 (s; CH_2), 91.5 (s; C_5H_5), 168.9 (s; CO). – ^{31}P NMR (162 MHz, C_6D_6, 20 °C): δ = 20.2 (s). – IR (CH_2Cl_2): $\tilde{\nu}$ = 1650 (NO), 1513 cm^{-1} (CONH). – $C_{27}H_{28}N_2O_2PReS$ (661.8) calcd C 49.00, H 4.26, N 2.23, S 4.85; found C 49.14, H 4.51, N 3.98, S 4.65.

[CpRe(NO)(PPh$_3$)(SCH$_2$CH$_2$COOH)] (**9**): This compound was prepared analogously from **4** and 3-mercaptopropionic acid. Yield 239 mg (92%), m.p. 205 °C (dec). – ^{1}H NMR (400 MHz, C_6D_6, 20 °C): δ = 2.56 (m, 1 H; CH_2), 2.27–2.89 (m, 2 H; CH_2), 3.09 (m, 1 H; CH_2), 4.77 (s, 5 H; C_5H_5). – ^{13}C NMR (100 MHz, C_6D_6, 20 °C): δ = 37.5 [d, ^3J(P,C) = 8 Hz; SCH_2], 39.6 (s; CH_2), 91.2 (s; C_5H_5), 177.8 (s; CO). – ^{31}P NMR (162 MHz, C_6D_6, 20 °C): δ = 19.5 (s). – IR (CH_2Cl_2): $\tilde{\nu}$ = 1742 (COOH), 1661 cm^{-1} (NO). – $C_{26}H_{25}NO_3PReS$ (648.7) calcd C 48.14, H 3.88, N 2.16, S 4.94; found C 48.23, H 3.95, N 2.01, S 4.77.

[CpRe(NO)(PPh$_3$)(OCOCH(NHAc)CH$_2$SH)] (**12a**, **b**): This compound was prepared analogously from **4** and (*R*)-*N*-acetylcysteine. Yield 237 mg (84%), orange-brown crystalline solid, dec. 57 °C. – Both diastereoisomers: ^{1}H NMR (400 MHz, [D$_6$]acetone, 20 °C): δ = 1.33 [t, ^3J(H,H) = 8.5 Hz, 1 H; SH], 1.40 [dd, ^3J(H,H) = 9.0 Hz, ^3J(H,H) = 7.8 Hz, 1 H; SH], 1.78 (s, 3 H; CH_3), 1.84 (s, 3 H; CH_3), 2.39, 2.56 [AB system of dd, ^2J(H,H) = 13.3 Hz, ^3J(H,H) = 8.9 Hz, ^3J(H,H) = 8.3 Hz, ^3J(H,H) = 4.8 Hz, ^3J(H,H) = 4.0 Hz, 2 H; SCH_2], 2.39, 2.66 [AB system of dd, ^2J(H,H) = 13.3 Hz, ^3J(H,H) = 8.9 Hz, ^3J(H,H) = 7.2 Hz, ^3J(H,H) = 4.8 Hz, ^3J(H,H) = 4.2 Hz, 2 H; SCH_2], 4.10 [dt, ^3J(H,H) = 6.4 Hz, ^3J(H,H) = 4.3 Hz, 1 H; CH], 4.18 [dt, ^3J(H,H) = 6.6 Hz, ^3J(H,H) = 4.5 Hz, 1 H; CH], 5.40 (s, 2 × 5 H; C_5H_5), 6.62 [d, ^3J(H,H) = 6.1 Hz, 1 H; NH], 6.69 [d, ^3J(H,H) = 5.7 Hz, 1 H; NH]. – ^{13}C NMR (100 MHz, [D$_6$]acetone, 20 °C): δ = 22.9 (s; CH_3), 23.0 (s; CH_3), 27.8 (s; SCH_2), 27.9 (s; SCH_2), 55.1 (s; CH), 55.3 (s; CH), 91.9 (s; C_5H_5), 169.1 (s; HNCO), 177.2 [d, ^3J(P,C) = 3 Hz, COORe], 177.3 [d, ^3J(P,C) = 2 Hz, COORe]. – ^{31}P NMR (162 MHz, [D$_6$]acetone, 20 °C): δ = 21.2 (s), 21.4 (s). – IR (CH_2Cl_2): $\tilde{\nu}$ = 1674 cm^{-1} (NO). – $C_{28}H_{28}N_2O_4PReS$ (705.8) calcd C 47.65, H 4.00, N 3.97, S 4.54; found C 47.52, H 4.00, N 3.65, S 4.46.

[CpRe(NO)(PPh$_3$)(SCH$_2$CH(NHAc)COOH)] (**13a**, **b**): The material from the above reaction was dissolved in acetone and stirred for 3 d at 20 °C. The product was isolated by evaporation and crystallization from benzene/pentane. NMR analysis revealed **13a**, **b** in 17% de and some residual **12a,b** which does not disappear even after refluxing. Yield 229 mg (81%, based on **4**), dec. 216 °C. – Major diastereoisomer: ^{1}H NMR (400 MHz, [D$_6$]acetone, 20 °C): δ = 1.96 (s, 3 H; CH_3), 2.76, 3.07 [AB system of d, ^2J(H,H) = 13.1 Hz, ^3J(H,H) = 8.1 Hz, ^3J(H,H) = 4.2 Hz, 2 H; SCH_2], 4.44 [dd, ^3J(H,H) = 8.1 Hz, ^3J(H,H) = 4.2 Hz, 1 H; CH], 5.35 (s, 5 H; C_5H_5), NH and OH signals not detected. – ^{13}C NMR (100 MHz, [D$_6$]acetone, 20 °C): δ = 22.8 (s; CH_3), 43.0 [d, ^3J(P,C) = 8 Hz; SCH_2], 56.4 (s; CH), 92.5 [d, ^2J(P,C) = 1 Hz; C_5H_5], 170.4 (s; HNCO), 173.1 (s; COOH). – ^{31}P NMR (162 MHz, C_6D_6, 20 °C): δ = 19.4 (s). – Minor diastereoisomer: ^{1}H NMR (400 MHz, [D$_6$]acetone, 20 °C): δ = 1.97 (s, 3 H; CH_3), 2.71, 2.86 [AB system of d, ^2J(H,H) = 12.8 Hz, ^3J(H,H) = 9.3 Hz, ^3J(H,H) = 5.5 Hz, 2 H; SCH_2), 4.60 (dd, ^3J(H,H) = 9.3 Hz, ^3J(H,H) = 5.6 Hz, 1 H; CH], 5.45 (s, 5 H; C_5H_5), NH and OH signals not detected. – ^{13}C NMR (100 MHz, [D$_6$]acetone, 20 °C): δ = 22.8 (s; CH_3), 41.7 (d, ^3J(P,C) = 8 Hz; SCH_2), 55.6 (s; CH), 92.8 (s; C_5H_5), 169.9 (s; HNCO), 172.9 (s; COOH). – ^{31}P NMR (162 MHz, C_6D_6, 20 °C): δ = 19.3 (s). – IR (CH_2Cl_2): $\tilde{\nu}$ = 1749 (COOH), 1657 (NO), 1607 cm^{-1} (CONH).

[CpRe(NO)(PPh$_3$)(SCH$_2$CH(NHAc)COOMe)] (**14a**, **b**): To a solution of **13a**, **b** (200 mg, 0.28 mmol) in methanol (10 ml) a few droplets of HBF_4 (54% in ether) were added. The mixture was stirred 3 d at 20 °C. After evaporation to dryness the residue was chromatographed over silica using THF/ether as an eluent. The product zone was evaporated and the residue recrystallized from dichloromethane/pentane. Yield 50 mg (25%), dec. 163 °C. – Both diastereoisomers ^{1}H NMR (400 MHz, $CDCl_3$, 20 °C): δ = 1.98 (s, 3 H; CH_3), 2.02 (s, 3 H; CH_3), 2.67 [dd, ^2J(H,H) = 13.6 Hz, ^3J(H,H) = 3.6 Hz, 1 H; SCH_2], 2.86 [dd, ^2J(H,H) = 13.2 Hz, ^3J(H,H) = 6.0 Hz, 1 H; SCH_2], 3.21–3.27 (m, 2 H; SCH_2), 3.67 (s, 3 H; OCH_3), 3.76 (s, 3 H; OCH_3), 4.58–4.64 (m; 2 × 1 H; CH), 5.19 (s, 5 H; C_5H_5), 5.22 (s, 5 H; C_5H_5), 6.44 [d, ^3J(H,H) = 7.2 Hz, 1 H; NH], 6.74 [d, ^3J(H,H) = 5.6 Hz, 1 H; NH]. – ^{13}C NMR (100 MHz, $CDCl_3$, 20 °C): δ = 23.0 (s; CH_3), 23.2 (s; CH_3), 42.0 [d, ^3J(P,C) = 8 Hz ; SCH_2], 45.0 [d, ^3J(P,C) = 8 Hz; SCH_2], 52.1 (s; OCH_3), 52.3 (s; OCH_3), 54.7 (s; CH), 55.3 (s; CH), 91.5 [d, ^2J(P,C) = 1 Hz; C_5H_5], 91.6 (s; C_5H_5), 169.8, 170.1, 172.1, 172.2 (s; HNCO and COOMe). – ^{31}P NMR (162 MHz, $CDCl_3$, 20 °C): δ = 18.6 (s), 18.7 (s). – IR (CH_2Cl_2): $\tilde{\nu}$ = 1748 (COOMe), 1651 cm^{-1} (NO). – $C_{29}H_{30}N_2O_4PReS$ (719.8) calcd C 48.39, H 4.20, N 3.89, S 4.45; found C 48.32, H 4.12, N 3.75, S 4.32.

Keywords: Alkynes / Polymers / 1,2,3-Substituted ferrocene / Directed *ortho* metallation

A $-CH_2NMe_2$ group attached to ferrocene can be used as an *ortho*/*ortho*-directing group to selectively synthesize 1,2,3-substituted ferrocenes, which are used as starting materials for novel 1,3-linked ferrocene polymers and oligomers. The Sonogashira coupling reaction of 1-(I),2-(CH_2NMe_2)-ferrocene with $HC{\equiv}CSiEt_3$ results in 1-($C{\equiv}CSiEt_3$),2-(CH_2NMe_2)-ferrocene (**1b**), which – following an *ortho*-lithiation/iodination sequence – is converted into 1-(I),2-(CH_2NMe_2),3-($C{\equiv}CSiEt_3$)-ferrocene (**1d**). Removal of the $-SiEt_3$ protective group yields 1-(I),2-(CH_2NMe_2),3-($C{\equiv}CH$)-ferrocene, which can be polymerized under Sonogashira conditions to yield a soluble, bimodal ferrocene-acetylene polymer of M_W = 3700/7100 and M_n = 4272. To understand the properties of the polymer better and to evaluate the effect of 1,3-substitution on the electronic communication between the metal centers, a divergent-convergent approach was used to synthesize defined di-, tri- and tetranuclear ferrocenes. Accordingly, **1d** was cross-coupled with 1-(CH_2NMe_2),2-($C{\equiv}CH$)-ferrocene to give [2-(CH_2NMe_2)-ferrocene-1-yl]-$C{\equiv}C$-[2-(CH_2NMe_2),3-($C{\equiv}CSiEt_3$)-ferrocene-1-yl] (**2a**). Removal of the protective group in **2a** led to [2-(CH_2NMe_2)-ferrocene-1-yl]-$C{\equiv}C$-[2-(CH_2NMe_2),3-($C{\equiv}CH$)-ferrocene-1-yl] (**2b**), which was treated with [1-(I),2-(CH_2NMe_2)-ferrocene-3-yl]-$C{\equiv}C$-[2-(CH_2NMe_2),3-($C{\equiv}CSiEt_3$)-ferrocene-1-yl] (**2c**) to result in the corresponding tetrameric ferrocene (**4a**).

Introduction

Organic polymers such as polypyrrole, poly(*p*-phenylene),[1] polythiophene,[2] poly(*p*-phenylenevinylene)[3][4] or -ethynylene[5] display interesting properties like photo- and electroluminescence and conductivity, which are useful in antistatic coatings, battery materials or blue-light photo diodes.[6][7] Organometallic polymers could offer all of this and even more as the metal may impart unusual magnetic, electronic and optical properties on such materials.[8][9] Prominent in this field are ferrocene polymers,[10] which either consist of an organic backbone to which ferrocenyl groups are attached (e.g. polyvinylferrocene) or of 1,1′-ferrocenediyl groups in the polymer backbone; other metallocenes have been used less frequently.[11] One breakthrough in the synthesis of soluble, high molecular weight ferrocene polymers has been the discovery of an ROP-type coupling of strained ferrocenophanes by Manners and coworkers.[12] Despite the progress made recently, virtually all known ferrocene polymers, with a few (mostly poorly soluble) exceptions,[13] still suffer from two basic disadvantages: typically the different ferrocene units are linked by electronically insulating bridges that only allow electrostatic interactions between the different metal centers and, in addition, most often 1,1′-ferrocenediyl units are used as repeat units.

It is quite obvious that ferrocene polymers are more likely to display exceptional properties when the different metal centers are coupled intimately through suitable unsaturated bridging units.[14][15] We therefore decided to initiate a program aimed at synthesizing novel types of soluble 1,3-linked ferrocenediyl polymers.

Results and Discussion

Synthesis

A few 1,3-substituted ferrocenes have been described in the literature,[16] but starting from ferrocene itself, it is difficult to selectively introduce two substituents in the 1,2- or 1,3-positions of ferrocene. We therefore reasoned that it should be easier to synthesize 1,3-substituted ferrocenes by using an *ortho*/*ortho*-directing group to obtain 1,2,3-substituted ferrocenes instead.[17] In this respect the $-CH_2NMe_2$ unit in $FcCH_2NMe_2$ appears to be a suitable group for directed *ortho*/*ortho* metallation[18] and appears very convenient as $FcCH_2NMe_2$ is commercially available or can be synthesized at low cost.[19] Another advantage of $FcCH_2NMe_2$ is that the amine can be quaternized easily to give $-NMe_3^+$, which happens to be a good leaving group in nucleophilic substitution reactions.[20]

The reaction of $FcCH_2NMe_2$ first with *n*BuLi and then with iodine leads to the known 1-(I),2-(CH_2NMe_2)-ferrocene (**1a**),[21] which was coupled with $HC{\equiv}CSiEt_3$ in a Sonogashira-type reaction[22][23] to produce 1-($C{\equiv}CSiEt_3$),2-(CH_2NMe_2)-ferrocene (**1b**) (yield > 90%) (Scheme 1).[24]

Compound **1b** can be deprotonated regioselectively with *n*BuLi at the other *ortho* position (with respect to the $-CH_2NMe_2$ unit) to yield, after reaction with iodine,

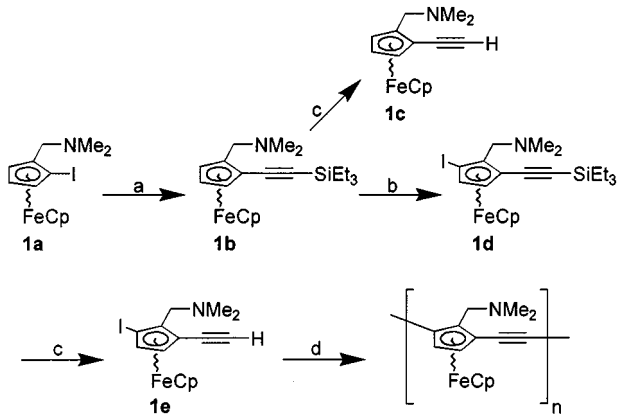
Scheme 1. a: $PdCl_2(PPh_3)_2$, CuI, $HCCSiEt_3$, solvent iPr_2NH, reflux; b: 1. BuLi, 0°C, Et_2O, 2 h, 2. $+I_2$, −78°C; c: $nBu_4N^+F^- \cdot 3\ H_2O$; d: $PdCl_2(PPh_3)_2$, CuI, solvent iPr_2NH, reflux



the 1,2,3-substituted ferrocene 1-(I),2-(CH_2NMe_2),3-(C≡$CSiEt_3$)-ferrocene (**1d**) (yield 66%). This reaction works very well for the −$SiEt_3$-protected acetylene, but only gives low yields (ca. 20%) of the respective 1,2,3-substituted ferrocene with an −$SiMe_3$-protected acetylene. Obviously, the latter protecting group is not entirely stable towards *n*BuLi. Cleavage of the −$SiEt_3$ protective group in **1b** or **1d** is easily effected with aq. 50% KOH or $nBu_4N^+F^- \cdot 3\ H_2O$ to produce the respective 1-(C≡CH),2-(CH_2NMe_2)-ferrocene (**1c**) and 1-(I),2-(CH_2NMe_2),3-(C≡CH)-ferrocene (**1e**) in 75−80% yield.

The 1,2,3-substituted ferrocene **1e** has two functional groups that can be coupled under Sonogashira conditions to form a dark red, glassy material (> 90% yield). This mixture was purified by flash chromatography and gave low molecular weight oligomers and a polymeric fraction. An attempted determination of the molecular mass of the latter material by standard GPC techniques was not successful, since an affinity-type chromatographic separation was observed. Obviously, this is caused by the polar nature of this material. We therefore had to resort to GPC-LALLS (gel-permeation chromatography/low-angle laser-light scattering) in an extremely polar mobile phase (DMF, 0.1 M guanidinium hydrochloride) to suppress affinity-type interactions with the stationary phase. With this method a characteristic bimodal molecular-weight distribution with M_W = 3700 and 7100 was found (Figure 1). This polymer is highly soluble in polar solvents (CH_2Cl_2, $CHCl_3$), which may appear surprising given its rigid backbone. In this respect it should, however, be noted that the polymer formed is a diastereomeric mixture with random orientations of the CpFe units with respect to the polymer backbone. This may be a disadvantage with respect to the characterization of the low molecular weight oligomers, but should not unfavorably influence the electronic properties of the polymers. On the other hand this disorder could very well be responsible for the good solubility of these materials.

Another advantage of the −CH_2NMe_2 group is that it can be functionalized easily by alkylation, followed by reaction of the quaternary ammonium salt with various nucleophiles (see Scheme 2). We have tested this by treating **1e** with MeI to give [1-(C≡CH),2-(CH_2NMe_3)-ferrocene]$^+I^-$ (**1f**) (yield 91%). This salt was treated with aza-12-crown-4 to produce the crown ether substituted monomer (1-C≡CH),[2-CH_2(aza-12-crown-4)]-ferrocene (**1g**) (yield 29%), which was polymerized under Sonogashira coupling conditions to give a redox-active crown ether polymer. This polymer is potentially attractive as the utility of such materials as electro-active sensors for metal ions has been demonstrated by Bäuerle,[25] Garnier[26] and Swager.[27] The dark-red mixture of oligomers and polymers was separated by flash-chromatography. The GPC-LALLS investigation of this polymer initially suggested much higher molecular weights (M_W = 61000, M_n = 58000), but the strong tailing of the GPC traces casts some doubt on these results, and may very well be the result of an aggregation process involving several polymer molecules. It is interesting in terms of chain-termination reactions that the oligomeric fractions from both polymerizations display vinylic resonances in the ^{1}H-NMR spectrum. The same phenomenon was also observed in related coupling reactions of mononuclear complexes of sterically more demanding acetylene derivatives of chiral FcCH(Me)NMe_2.[28]

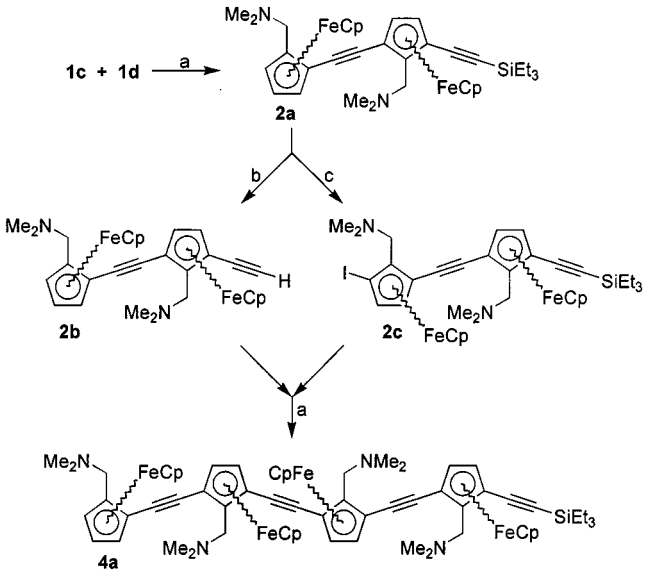
In order to better understand the electronic properties of the polymeric materials we have prepared defined oligomers using a divergent-convergent approach, which has been used successfully by Tour et al.[29] and Moore et al.[30] in the synthesis of related oligothiophenes and oligoethynylarenes. Starting from **1c** and **1d** a Sonogashira coupling generates [2-(CH_2NMe_2)-ferrocene-1-yl]-C≡C-[2-(CH_2NMe_2),-3-(C≡$CSiEt_3$)-ferrocene-1-yl] (**2a**) (yield > 90%) (Scheme 3). This batch was split and the first half used for a lithiation/iodination sequence resulting in [2-(CH_2NMe_2),3-(I)-ferrocene-1-yl]-C≡C-[2-(CH_2NMe_2),3-(C≡$CSiEt_3$)-ferrocene-1-yl] (**2c**) (yield 65%), while the remaining **2a** was de-

protected with nBu$_4$N$^+$F$^-\cdot$3 H$_2$O to give [1-(CH$_2$NMe$_2$)-ferrocene-2-yl]-C≡C-[2-(CH$_2$NMe$_2$),3-(C≡CH)-ferrocene-1-yl] (**2b**) (yield 80%). Both **2b** and **2c** were then coupled according to the Sonogashira protocol to give the tetramer [2-(CH$_2$NMe$_2$)-ferrocene-1-yl]-C≡C-[2-(CH$_2$NMe$_2$)-ferrocene-1,3-diyl]-C≡C-[1-(CH$_2$NMe$_2$)-ferrocene-1,3-diyl]-C≡C-[2-(CH$_2$NMe$_2$),3-(C≡CSiEt$_3$)-ferrocene-1-yl] (**4a**) (yield 73%). The highly polar nature of this tarry, red material caused tailing and repeated chromatography was necessary to obtain analytically pure samples since **4a** could not be recrystallized. These purification problems also were the reason why we did not attempt to extend our synthetic procedure to the octameric ferrocene.

Scheme 3. a: PdCl$_2$(PPh$_3$)$_2$, CuI, HCCSiEt$_3$, solvent iPr$_2$NH, reflux; b: nBu$_4$N$^+$F$^-\cdot$3 H$_2$O; c: 1. + BuLi, 0°C, Et$_2$O, 2 h, 2. + I$_2$, −78°C

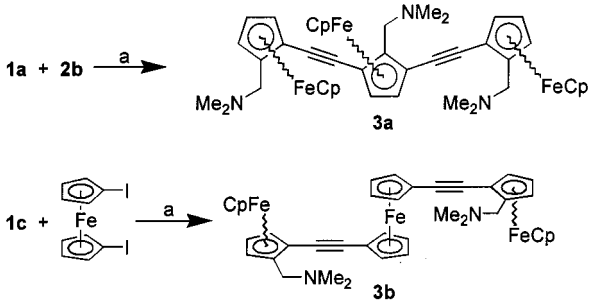


In order to be able to compare the influence of the substitution pattern (1,3- or 1,1′-) on the electronic properties of the ferrocene-acetylenes, we synthesized the two trinuclear ferrocenes **3a** and **3b** (Scheme 4). Both complexes only differ in that **3a** has a 1,3-substituted ferrocene core, while **3b** has a 1,1′-substituted ferrocene unit. The coupling reaction of **1a** and **2b** gave **3a**, while the respective coupling of 1,1′-diiodoferrocene and **1c** produced **3b**, both in yields of around 75%. A closer investigation of these compounds should provide evidence of the better electronic delocalization of the ring with the 1,3-substitution pattern than that with the 1,1′-positions.

NMR Spectroscopy

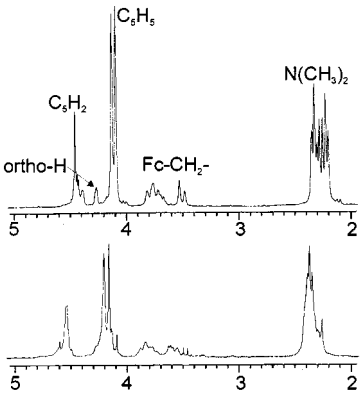
The ^{1}H-NMR spectra of the mononuclear ferrocenes are straightforward, while those of the oligomers are characterized by more complex spin systems. For example the number of −N(CH$_3$)$_2$ resonances found (δ = 2.20−2.35 in **4a**), correspond to the number of diastereomers, e.g. four lines in **2a**. Accordingly, the large number of −N(CH$_3$)$_2$ resonances in **4a** reflects the large number of diastereomers

Scheme 4. a: PdCl$_2$(PPh$_3$)$_2$, CuI, HCCSiEt$_3$, solvent iPr$_2$NH, reflux



(Figure 2, top). The fact that the −CH$_2$− groups have diastereotopic protons in the 1,2,3-substituted species leads to another complex set of resonances that usually appear in two groups (δ = 3.48−3.53 and δ = 3.65−3.81 in **4a**). The C$_5$H$_5$ resonances of the unsubstituted cyclopentadienyl ring are typically split into no more than two resonances, while those of the C$_5$H$_2$ unit in 1,2,3-substituted cyclopentadienyl rings are observed as a group of signals at low field (δ = 4.38−4.45 in **4a**) with respect to C$_5$H$_5$. In between these two signals, the characteristic resonances of the *ortho*-H (hydrogen atom next to −CH$_2$NMe$_2$ in 1,2-substituted ferrocenes) can be found at δ = 4.26 (in **4a**).

Figure 2. ^{1}H-NMR spectra of the tetramer **4a** (top) and polymer I (bottom)



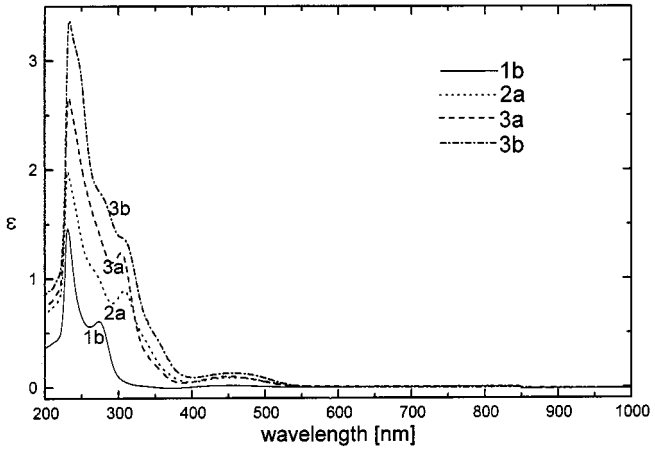
With this knowledge in mind the ^{1}H-NMR spectrum of polymer I can be understood. The typical signals of the tetramer are found (in broadened form) in the polymer, reflecting the large number of different microenvironments for each functional group. Most striking in the spectrum of the polymer is the apparent absence of the *ortho*-H, since an ideal polymer entirely consists of 1,2,3-substituted ferrocenes.

The ^{13}C-NMR spectra of the oligomers are complicated and it is difficult to extract useful information; there are simply too many lines that show up more readily in the ^{13}C-NMR spectra due to their larger signal dispersion. However, again it is possible to distinguish different groups of signals for the different chemical units (CH$_3$, CH$_2$, cyclopentadienyl ring and −C≡C− groups).

UV/Vis Spectroscopy

The UV/Vis spectra of ferrocene and its derivatives are characterized by two weak bands around 325 nm and 440 nm, which are both attributed to d-d transitions.[31] Any perturbation of the electronic structure of the ferrocenes, i.e. conjugation within a conjugated chain, should lead to a bathochromic shift of the respective UV/Vis transitions. Consequently, the UV/Vis spectra of our ferrocenes were measured (Figure 3) and the characteristic d-d transition proved to be quite informative: **1b**: λ_{max} = 441 nm (ε [L/M·cm] = 206); **2a**: 452 (850); **3a**: 456 (1220); **3b**: 448 (926); **4a**: 466 (1560); polymer: 468 nm. The long-wavelength shift and the stronger extinction of **3a** vs. **3b** support the idea of a better electronic delocalization in the 1,3-linked species.

Figure 3. UV/Vis spectra of the mononuclear **1b**, the dinuclear **2a** and the trinuclear ferrocenes **3a** and **3b** (10^{-4} M in CH_2Cl_2)



Cyclic Voltammetry

To complement the UV/Vis studies and in order to better understand the degree of electronic communication between the ferrocene units in the oligomers and polymers described here,[32] we attempted to determine the redox potentials of these compounds. However, the electrochemical experiments performed with the aminoferrocenes **1**−**4** were not very successful and we were only able to observe reversible electron-transfer processes with mononuclear ferrocenes when the cyclic voltammetric experiments were carried out at low temperatures (T = −20°C).

The respective studies of the ferrocene oligomers **2**−**4**, however, were rather disappointing as we could not observe reversible or at least quasi-reversible electron-transfer processes. Despite testing several solvents (acetonitrile, acetone, dichloromethane, dimethylformamide) under varying conditions, the voltammograms of the dimers and higher oligomers were complicated by numerous extremely broad redox waves (deposition on the electrode surface?) and/or a number of additional unexplained waves. In the case of the polymers the cyclic voltammogram consists of several uncharacteristic broad humps, from which we could not extract any meaningful information. These observations may be rationalized in the light of recent results by Robinson, Simpson et al.[33] who investigated the electrochemistry of related 2,2′′-bis(1-dialkylamino)-1,1′′-ferrocenes. In their study it was found that oxidation processes involving binuclear dialkylamino-ferrocenes are complicated by amine oxidation as well as oxidatively induced protonation and deprotonation processes. The fact that the former compounds are closely related to our binuclear ferrocenes might serve as an explanation for the problems experienced by us. Nonetheless, the disappointing electrochemistry of these compounds must be viewed as a major drawback.

Summary and Conclusions

We have shown that the $-CH_2NMe_2$ group can be used as an *ortho*/*ortho*-directing substituent in ferrocene chemistry to allow easy access of 1,2,3-substituted ferrocenes. This synthetic route was used to prepare 1-(I),2-(CH_2NMe_2),3-(C≡CH)-ferrocene, which can be polymerized in a Sonogashira-type coupling reaction to yield a soluble, bimodal 1,3-linked ferrocene-acetylene polymer of M_w = 3700/7100. Starting from 1-(I),2-(CH_2NMe_2),3-(C≡CSiEt$_3$)-ferrocene, defined ferrocene oligomers were also available through a divergent-convergent synthesis to give a tetrameric ferrocene-acetylene.

By studying model compounds with ferrocene-acetylene substituents in either the 1,3- or the 1,1′-position it was shown, by the more pronounced bathochromic shift of the ferrocene d-d transitions in the former compound, that the electronic communication in 1,3-linked ferrocenes is better than in 1,1′-linked species and it is therefore proposed that the 1,3-linked ferrocene polymers will display superior intermetallic electronic communication as compared to their 1,1′-linked relatives. Unfortunately, it was not possible to further support this by electrochemical experiments since all oligonuclear 1,2,3-substituted compounds derived from $FcCH_2NMe_2$ described here do not display reversible electron-transfer processes.

In conclusion the $-CH_2NMe_2$ unit attached to ferrocene is very useful for synthetic transformations and should allow the synthesis of a variety of 1,2,3-substituted ferrocenes. It is, however, a major drawback of this functional group in terms of redox reactions that the electrochemistry of ferrocenes with several $-CH_2NMe_2$ groups is not straightforward.

This work was supported by the *Deutsche Forschungsgemeinschaft*, the *Fonds der Chemischen Industrie*, the *Freiburger Wissenschaftliche Gesellschaft* and the *Institut für Anorganische und Analytische Chemie*, Universität Freiburg. We wish to thank cand.-chem. *J. Seebacher* for experimental assistance and a referee for interesting suggestions.

Experimental Section

General: Commercially available solvents and reagents were purified according to literature procedures. − Chromatography was performed on silica gel MN60. − NMR spectra were recorded at 300 K with a Bruker Avance (^{1}H NMR 200 MHz, ^{13}C NMR 50.3

MHz,). ^{1}H-NMR signals were referenced to residual ^{1}H impurities in the solvent and ^{13}C-NMR signals to the solvent signals: $CDCl_3$ (δ = 7.26, δ = 77.0), C_6D_6 (δ = 7.16, δ = 128.0), CD_3CN (δ = 1.93, δ = 1.30). For the purpose of ^{1}H-NMR signal assignment CpH denotes a proton attached to the sp^2-carbon atom of cyclopentadiene or to the carbon atom of a ferrocene η^5-cyclopentadienyl ring. − Mass spectra: Finnigan MAT 3800. − IR spectra were recorded with a Bruker IFS-25 in $CHCl_3$ solution. − UV/Vis spectra were recorded with a JASCO-UV-570 spectrometer in CH_2Cl_2 solution. − Elemental analyses: Mikroanalytisches Laboratorium der Chemischen Laboratorien, Universität Freiburg. For several compounds, especially for the oligomeric and polymeric materials, we could not obtain analytically pure samples due to phosphorus-based impurities from the catalyst,[34] which proved difficult to remove by chromatography. Recrystallisation of the oily, highly viscous materials was not possible. All chromatographic purifications were performed on alumina-N deactivated with 10% water. − Gel-permeation chromatography with a low-angle laser-light scattering detector was performed in dimethylformamide/0.1 M guanidinium chloride solvent using a Milton-Roy type KMX 6 detector, a Knauer HPLC-PUMP 64, a Pharmacia LKB VWM 2141 UV meter and Waters 10^3-10^5 Å columns. The calibration of the hydrodynamic volumina/molecular mass was routinely performed with polystyrene standards (PSS, PL) in THF.

1-(I),2-(CH_2NMe_2)-ferrocene (**1a**): Modified from the literature procedure.[21] To a solution of [(dimethylamino)methyl]ferrocene (21.5 g, 0.100 mol) in diethyl ether (300 ml) was added *n*BuLi (50 ml, 0.125 mol). After stirring for 4 h at room temp., the reaction mixture was cooled to −78°C and a solution of I_2 (30.5 g, 0.120 mol) in THF (75 ml) added dropwise. The solution was slowly allowed to warm to room temp. during approx. 1 h. After stirring for further 15 min, the reaction mixture was added to water (500 ml) to extract LiI. The organic layer was separated and the water extracted once more with diethyl ether. The combined organic extracts were dried with $MgSO_4$, filtered and concentrated to dryness. The residue was purified by flash chromatography (alumina-B, $CHCl_3$). The solvents were evaporated to yield the product as dark-red oil, which slowly solidified upon standing, yield 24.0 g (65%), red oily crystals. − ^{1}H NMR ($CDCl_3$): δ = 2.25 [s, 6 H, $N(CH_3)_2$], 3.38 (s, 2 H, CH_2), 4.11 (s, 5 H, CpH), 4.22 ("t", J = 1.8 Hz, 1 H, CpH), 4.31 (br., 1 H, CpH), 4.43 (br., 1 H, CpH). − ^{13}C NMR ($CDCl_3$): δ = 43.56, 57.55, 69.94, 70.27, 71.89, 73.05, 75.57, 80.62.

1-(C≡CSiEt$_3$),2-(CH_2NMe_2)-ferrocene (**1b**): To a deoxygenated solution of 1-(I),2-(CH_2NMe_2)-ferrocene (4.80 g, 13 mmol) and (triethylsilyl)acetylene (1.82 g, 13 mmol) in diisopropylamine (75 ml) were added $(Ph_3P)_2PdCl_2$ (92 mg, 0.13 mmol) and CuI (49 mg, 0.72 mmol). The reaction mixture was heated under reflux for 18 h, filtered, the precipitate washed with diethyl ether and the volatiles evaporated to dryness. The remaining red oily product was almost pure and used as such for the subsequent reactions, yield 4.60 g (92%), red liquid. − ^{1}H NMR ($CDCl_3$): δ = 0.62 (q, J = 5.7 Hz, 6 H, $SiCH_2$), 1.06 (t, J = 5.5 Hz, $SiCH_2CH_3$), 2.21 [s, 6 H, $N(CH_3)_2$], 3.50 (s, 2 H, CH_2), 4.11 (s, 5 H, C_5H_5), 4.15 ("t", J = 1.9 Hz, 1 H, CpH), 4.29 (cm, 1 H, CpH), 4.43 (cm, 1 H, CpH). − ^{13}C NMR ($CDCl_3$): δ = 4.60, 6.61, 44.75, 56.95, 66.89, 68.09, 70.42, 70.63, 71.25, 85.65, 90.13, 104.63. − IR: $\tilde{\nu}$ = 2147 cm^{-1}. − $C_{21}H_{31}FeNSi$ (381.42): calcd. C 66.13, H 8.19, N 3.67; found C 66.02, H 7.95, N 3.70.

1-(C≡CH),2-(CH_2NMe_2)-ferrocene (**1c**): A solution of 1-(C≡CSiEt$_3$),2-(CH_2NMe_2)-ferrocene (8.30 g, 0.88 mmol) in CH_3OH (10 ml) was treated with aqueous KOH (1 ml, 50%) and stirred under nitrogen for 1 h. The volatiles were evaporated, water was added and the residue extracted with diethyl ether. The ethereal layer was separated, dried with $MgSO_4$, filtered and concentrated. The remaining oil was purified by chromatography (cyclohexane/ethyl acetate, 10:1), yield 4.80 g (73%), red oil. − ^{1}H NMR ($CDCl_3$): δ = 2.21 [s, 6 H, $N(CH_3)_2$], 2.82 (s, 1 H, ≡CH), 3.48 (s, 2 H, CH_2), 4.14 (s, 5 H, C_5H_5), 4.16 ("t", J = 2 Hz, 1 H, CpH), 4.29 (m, 1 H, CpH), 4.45 (m, 1 H, CpH). − ^{13}C NMR: δ = 44.80, 57.03, 65.62, 68.09, 70.55, 71.53, 75.70, 81.84, 85.81. − $C_{15}H_{16}FeIN$ (393.0): calcd. C 45.84, H 4.10, N 3.56; found C 45.26, H 4.42, N 3.29.

1-(C≡CSiEt$_3$),2-(CH_2NMe_2),3(I)-ferrocene (**1d**): A solution of 1-(C≡CSiEt$_3$),2-(CH_2NMe_2)-ferrocene (4.60 g, 12.1 mmol) in diethyl ether (75 ml) was treated with BuLi (6.0 ml, 15 mmol) at −78°C and slowly warmed to room temp. After stirring for 1 h, the reaction mixture was cooled to −78°C and a solution of I_2 (3.05 g, 12.0 mmol) in THF (10 ml) added dropwise and then the reaction mixture was slowly warmed to room temp. After stirring for further 15 min, the reaction mixture was added to water (100 ml) and the LiI extracted. The organic layer was separated and the water extracted once more with diethyl ether. The combined organic extracts were dried with $MgSO_4$, filtered and concentrated to dryness. The remaining oil was purified by flash chromatography (cyclohexane/ethyl acetate, 10:1), yield 4.0 g (66%), red oil. − ^{1}H NMR ($CDCl_3$): δ = 0.65 (q, J = 7.9 Hz, 6 H, $SiCH_2$), 1.05 (t, J = 8 Hz, 9 H, CH_3), 2.28 [s, 6 H, $N(CH_3)_2$], 3.40−3.62 (m, 2 H, NCH_2), 4.10 (s, 5 H, C_5H_5), 4.46−4.52 (m, 2 H, CpH). − ^{13}C NMR ($CDCl_3$): δ = 4.50, 7.58, 45.85, 57.20, 66.11, 72.30, 73.55, 75.08, 87.85, 91.47, 103.48. − $C_{21}H_{30}FeINSi$ (507.31): calcd. C 49.72, H 5.96, N 2.76; found C 50.13, H 6.02, N 2.54.

1-(C≡CH),2-(CH_2NMe_2),3-(I)-ferrocene (**1e**): To a solution of 1-(C≡CSiEt$_3$),2-(CH_2NMe_2),3-(I)-ferrocene (4.00 g, 7.9 mmol) in CH_3OH (75 ml) was added KOH (4 g) and the mixture was stirred under nitrogen for 3 h. The volatiles were evaporated, water was added and the residue extracted with diethyl ether. The ethereal layer was separated, dried with $MgSO_4$, filtered and concentrated. The remaining oil was purified by flash chromatography (cyclohexane/ethyl acetate, 10:1), yield 2.30 g (75%), red oil. − ^{1}H NMR ($CDCl_3$): δ = 2.27 [s, 6 H, $N(CH_3)_2$], 2.86 (s, 1 H, ≡CH), 3.49 (s, 2 H, CH_2), 4.12 (s, 5 H, C_5H_5), 4.46−4.53 (m, 2 H, CpH). − ^{13}C NMR ($CDCl_3$): δ = 45.53, 57.09, 64.85, 72.44, 75.00, 76.77, 80.80, 87.74. − $C_{15}H_{16}FeIN$ (393.0): calcd. C 45.84, H 4.10, N 3.56; found C 45.55, H 4.00, N 3.67.

[1-(C≡CH),2-(CH_2NMe_3),3-(I)-ferrocene]$^+$I$^-$ (**1f**): A solution of 1-(C≡CH),2-(CH_2NMe_2),3-(I)-ferrocene (2.30 g, 5.80 mmol) in diethyl ether (25 ml) was treated with CH_3I (1.65 g, 11.6 mmol) and the mixture stirred for 12 h at room temp. The yellow precipitate was filtered off, washed with diethyl ether and dried in vacuo, to yield a yellow powder, yield 2.85 g (91%), yellow powder. − ^{1}H NMR (CD_3CN): δ = 3.10 [s, 9 H, $N(CH_3)_3$], 3.42 (s, 1 H, ≡CH), 4.27 (s, 5 H, C_5H_5), 4.53−4.76 (m, 4 H, CH_2), 4.84−4.88 (m, 2 H, C_5H_2). − $C_{16}H_{19}FeI_2N$ (535.0): calcd. C 35.92, H 3.58, N 2.62; found C 36.26, H 3.89, N 2.11.

1-(C≡CH),2-[CH_2(N-12-c-4)],3-(I)-ferrocene (**1g**): A mixture of [1-(C≡CH),2-(CH_2NMe_3),3-(I)-ferrocene]$^+$I$^-$ (535 mg, 1.00 mmol), aza-12-crown-4 (210 mg, 1.20 mmol) and K_2CO_3 (0.5 g) in acetonitrile was heated under reflux for 12 h. The cold solution was filtered and the filtrate concentrated to dryness. The residue was dissolved in $CHCl_3$, filtered through an alumina-N plug, concentrated to dryness and chromatographed on alumina-N with cyclohexane/ethylacetate/diethylamine (10:1:1), yield 150 mg (29%), red oil. − ^{1}H NMR ($CDCl_3$): δ = 2.79−2.86 (m, 4 H, NCH_2), 2.89 (s, 1 H, ≡CH), 3.60−3.88 (m, 12 H, CH_2O + $CpCH_2$), 4.14 (s, 5

H, C_5H_5), 4.49−4.54 (m, 2 H, C_5H_2). − ^{13}C NMR ($CDCl_3$): δ = 44.90, 54.13, 54.60, 64.97, 69.88, 70.45, 71.38, 71.86, 72.68, 73.58, 75.37, 81.18, 88.37. − $C_{21}H_{26}FeINO_3$ (523.2): calcd. C 48.21, H 5.01, N 2.68; found C 48.56, H 5.21, N 2.59.

[1-(CH_2NMe_2)-ferrocene-2-yl]-C≡C-[2-(CH_2NMe_2),3(C≡CSiEt_3)-ferrocene-1-yl] (**2a**): Typical coupling procedure: 1 mol-% Pd catalyst, 2 mol-% CuI. Scale: 1-(I),2(-CH_2NMe_2),3-(C≡C$SiEt_3$)-ferrocene (**1d**) (2.54 g, 5.00 mmol), 1-(C≡CH),2-(CH_2NMe_2)-ferrocene (**1c**) (1.97 g, 5.00 mmol). Yield 2.68 g (83%), red oil. Chromatography: cyclohexane/ethyl acetate (10:1), R_F = 0.4. − ^{1}H NMR ($CDCl_3$): δ = 0.66 (q, 6 H, $SiCH_2$), 1.07 (t, 9 H, CH_3), 2.17, 2.25, 2.32, 2.34 (s, 12 H, 4 × CH_3), 3.53−3.78 (m, 4 H, CH_2), 4.14 (s, 10 H, C_5H_5), 4.19 ("t", *J* = 2.5 Hz, 1 H, CpH), 4.32 (br., 1 H, CpH), 4.44 (m, 1 H, CpH), 4.48 (s, 2 H, CpH). − ^{13}C NMR ($CDCl_3$): δ = 4.54, 7.60, 44.87, 45.92, 45.29, 45.38, 55.51, 55.66, 57.20, 57.35, 67.13, 67.18, 67.65, 67.72, 68.07, 68.83, 70.38, 70.43, 71. 04, 71.13, 71.36, 72.47, 72.51, 84.78, 84.89, 85.60, 85.07, 85.07, 85.72, 87.14, 87.40, 93.27, 103.00.

[2-(CH_2NMe_2)-ferrocene-1-yl]-C≡C-[2-(CH_2NMe_2),3(C≡CH)-ferrocene-1-yl] (**2b**): Typical cleavage procedure: 24 h CH_3OH/aq. KOH, [2-(CH_2NMe_2)-ferrocene-1-yl]-C≡C-[2-(CH_2NMe_2),3-(C≡C-$SiEt_3$)-ferrocene-1-yl] (**2a**) (1.29 g, 2.0 mmol). Yield 0.79 g (74%), red oil. Chromatography: cyclohexane/Et_2NH (10:1), R_F = 0.2. − ^{1}H NMR ($CDCl_3$): δ = 2.25 [s, 3 H, $N(CH_3)_2$], 2.28 [s, 3 H, $N(CH_3)_2$], 2.32 [s, 3 H, $N(CH_3)_2$], 2.34 [s, 3 H, $N(CH_3)_2$], 2.85 (s, 1 H, ≡CH), 3.53−3.77 (m, 4 H, CH_2), 4.15−4.32 (m, 11 H, 2 × C_5H_5 + CpH), 4.33 (br., 1 H, CpH), 4.44 (br., 1 H, CpH), 4.48−4.52 (m_c, 2 H, CpH). − ^{13}C NMR ($CDCl_3$): δ = 44.85, 44.89, 45.30, 55.58, 55.78, 57.17, 57.31, 66.10, 67.61, 68.06, 68.08, 68.97, 70.36, 70.42, 71.04, 71.07, 71.48, 72.36, 72.41, 75.98, 81.27, 84.76, 85.06, 87.13, 87.40.

[1-(I),2-(CH_2NMe_2)-ferrocene-3-yl]-C≡C-[2-(CH_2NMe_2)-3-(C≡C$SiEt_3$)-ferrocene-1-yl] (**2c**): Typical sequence of lithiation and iodination: [2-(CH_2NMe_2)-ferrocene-1-yl]-C≡C-[2-(CH_2-NMe_2),3-(C≡C$SiEt_3$)-ferrocene-1-yl] (**2a**) (1.29 g, 2.0 mmol) *n*BuLi (2.4 mmol), I_2 (0.508 g, 1.95 mmol). Yield 0.97 g (63%), red oil. Chromatography: cyclohexane/ethyl acetate (5:1), $R_{F\ =\ 0}$.6. − ^{1}H NMR ($CDCl_3$): δ = 0.66 (q, *J* = 7.8 Hz, 6 H, $SiCH_2$), 1.06 (t, *J* = 7.7 Hz, 9 H, CH_3), 2.26−2.38 [m, 12 H, $N(CH_3)_2$], 3.54−3.61 (m, 2 H, CH_2), 3.72−3.80 (m, 2 H, CH_2), 4.08−4.19 (m, 10 H, C_5H_5), 4.46−4.53 (m, 4 H, C_5H_2). − ^{13}C NMR ($CDCl_3$): δ = 4.50, 7.62, 45.16, 45.21, 45.67, 45.76, 55.46, 5.64, 57.38, 57.59, 66.94, 67.06, 67.52, 67.59, 68.20, 68.25, 71.22, 71.52, 71.81, 72.03, 72.49, 72.52, 73.37, 73.40, 73.61, 84.64, 84.74, 85.99, 86.11, 86.70, 87.00, 87.22, 90.70, 103.79.

[1-(CH_2NMe_2)-ferrocene-2-yl]-C≡C-[2-(CH_2NMe_2)-ferrocene-1,3-diyl]-C≡C-[2-(CH_2NMe_2)-ferrocene-1-yl] (**3a**): Typical coupling procedure: [2-(CH_2NMe_2)-ferrocene-1-yl]-C≡C-[2-(CH_2-NMe_2),3-(C≡CH)-ferrocene-1-yl] (**2b**) (532 mg, 1.0 mmol), (1-I),(2-CH_2NMe_2)-ferrocene (**1a**) (369 mg, 1.0 mmol). Yield 670 mg (87%), red oil. Chromatography: cyclohexane/ethyl acetate/Et_2NH (10:1:1). − ^{1}H NMR ($CDCl_3$): δ = 2.27 [s, 6 H, $N(CH_3)_2$ in Fc-1 and Fc-3], 2.29 [s, 6 H, $N(CH_3)_2$ in Fc-1 and Fc-3], 2.36−2.42 [m, 6 H, $N(CH_3)_2$ in Fc-2], 3.55 (s, 2 H, CH_2, Fc-1 and Fc-3), 3.59 (s, 2 H, CH_2, Fc-1 and Fc-3), 3.79−3.88 (m, 2 H, CH_2, Fc-2), 4.16 (s, C_5H_5, Fc-1 and Fc-3), 4.19 (s, 2 H, C_5H_5, Fc-2 + CpH at Fc-1 and Fc-3), 4.33 (cm, 2 H, CpH, Fc-1 and Fc-3), 4.45 (cm, 2 H, CpH, Fc1 and Fc-3), 4.52 (s, 2 H, CpH, Fc-2). − ^{13}C NMR ($CDCl_3$): δ = 44.86, 44.91, 45.32, 55.90, 56.03, 57.19, 57.34, 67.68, 67.75, 68.09, 68.50, 68.64, 68.69, 70.40, 70.44, 71.06, 72.20, 72.25, 72.30, 84.74, 85.00, 85.69, 85.78, 85.98, 86.22, 86.47, 86.88.

1,1′-Bis(1″-ethynyl-2″-(CH_2NMe_2)-ferrocene-1-yl)-ferrocene (**3b**): Typical coupling procedure. Scale: **1c** (2.44 g, 9.2 mmol), 1,1′-diiodoferrocene (2.00 g, 4.6 mmol), $(Ph_3P)_2PdCl_2$ (1 mol-%), CuI (2 mol-%), $^iPr_2NH$ (75 ml). Yield 2.70 g (83%), brown-red oil. Chromatography: R_f = 0.5 (cyclohexane/ethyl acetate/Et_2NH, 10:1:1). − ^{1}H NMR ($CDCl_3$): δ = 2.27 (s, 12 H, NCH_3), 3.56 (s, 4 H, NCH_2), 4.17 (s, 10 H, CpH), 4.23 (s, 8 H, CpH), 4.33 (m, 6 H, CpH_3).

[1-(CH_2NMe_2)-ferrocene-2-yl]-C≡C-[2-(CH_2NMe_2)-ferrocene-1,3-diyl]-C≡C-[1-(CH_2NMe_2)-ferrocene-1,3-diyl]-C≡C-[2-(CH_2NMe_2),3-(C≡CSiEt_3)-ferrocene-1-yl] (**4a**): To a deoxygenated solution of [1-(I),2-(CH_2NMe_2)-ferrocene-3-yl]-C≡C-[2-(CH_2NMe_2),3-(C≡CSiEt_3)-ferrocene-1-yl] (**2c**) (0.772 g, 1 mol) and [2-(CH_2NMe_2)-ferrocene-1-yl]-C≡C-[2-(CH_2NMe_2),3-(C≡CH)-ferrocene-1-yl] (**2b**) (0.532 g, 1.0 mmol) in diisopropylamine (75 ml) were added $(Ph_3P)_2PdCl_2$ (7.0 mg, 1 mol-%) and CuI (7.7 mg, 2 mol-%). The reaction mixture was heated under reflux for 24 h, filtered, the precipitate washed with diethyl ether and the volatiles evaporated to dryness. The remaining solid was purified by chromatography (cyclohexane/ethyl acetate/Et_2NH, 10:1:1), yield 0.86 g (73%), red glassy solid. − ^{1}H NMR ($CDCl_3$): δ = 0.70 (q, *J* = 7.8 Hz, 6 H, CH_2), 1.08 (t, *J* = 7.8 Hz, 9 H, CH_3), 2.28−2.43 (m, 24 H, NMe_2), 3.58 (d, *J* = 9.4 Hz, 2 H, NCH_2), 3.70−3.90 (m, NCH_2, 6 H), 4.17 (s, 10 H, CpH), 4.19 (s, 10 H, CpH), 4.26 (br. s, 1 H), 4.45−4.52 (m, 8 H, CpH). − $C_{66}H_{79}Fe_4N_4Si$ (1179.9): calcd. C, 67.9, H 6.75, N, 4.75; found C 67.78, H 6.89, N 4.76. − ESI-MS; *m/z*: 1178.5.

Polymerisation of **1e**, *Polymer I:* Typical coupling procedure. Scale: **1c** (1.18 g, 3.0 mmol), $(Ph_3P)_2PdCl_2$ (5 mol-%), CuI (10 mol-%), *i*Pr_2NH (75 ml), 36 h reflux. The mixture of oligomers and polymers obtained was fractionated by flash chromatography. A low molecular fraction was eluted with cyclohexane/Et_2NH (1:1) while the polymers were eluted by using $CHCl_3$/MeOH (10:1) or cyclohexane/Et_2NH (3:1). The yields of the polymeric (dark-red glassy) material varied between 40 and 60%. − ^{1}H ($CDCl_3$): δ = 2.26−2.38 (br., 6 H, NMe_2), 3.50−3.65 (br. m, 1.8 H, NCH_2), 3.70−3.95 (br. m, 2.2 H, NCH_2), 4.09−4.21 (br. + 2 s at δ = 4.16 and 4.20, 4.3 H, C_5H_5), 4.53−4.60 (br., 2 H, CpH). − In the ^{13}C-NMR spectrum at least 50 different peaks (diastereomers) were observed.

Polymerisation of **1g**, Polymer II: Typical coupling procedure. Scale: **1c** (0.262 g, 0.50 mmol), $(Ph_3P)_2PdCl_2$ (5 mol-%), CuI (10 mol-%), *i*Pr_2NH (25 ml), 24 h reflux. The mixture of oligomers and polymers was fractionated by flash chromatography. A low-molecular fraction was eluted with cyclohexane/Et_2NH (10:1) while the polymers were eluted with $CHCl_3$/MeOH (10:1). − ^{1}H NMR ($CDCl_3$): 2.65−2.80 (br.), 3.50−3.8 (br. m), 3.48 (s, C_5H_5), 4.08 (s), 4.35−4.50 (m). − In the ^{13}C-NMR spectrum at least 50 different peaks (diastereomers) were observed.

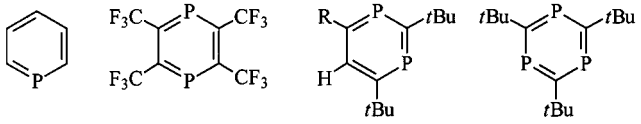
Received July 30, 1998

Keywords: Phosphorus heterocycles / Phosphaalkynes / Triphosphabenzene / Tetraphosphabarrelenes / Tetraphosphasemibullvalene

2,4,6-Tri-*tert*-butyl-1,3,5-triphosphabenzene **4** reacts with phosphaalkynes P≡C−R [R = *t*Bu (**5a**), *t*Pen (**5b**)] at room temperature in a formal [4 + 2] cycloaddition to yield the corresponding 1,3,5,7-tetraphosphabarrelene derivatives **8a** and **8b**, respectively. The analogous reaction of **4** with the aminophosphaethyne P≡C−N(*i*Pr)$_2$ (**9**) unexpectedly leads to the 1,3,4,7-tetraphosphasemibullvalene derivative **10** as the only product. The single-crystal X-ray analysis of **10** exhibits a diphosphirane unit with a very long PP distance of 2.274(1) Å together with a large extension of the PCP angle in the three-membered ring to 75.3(1)°.

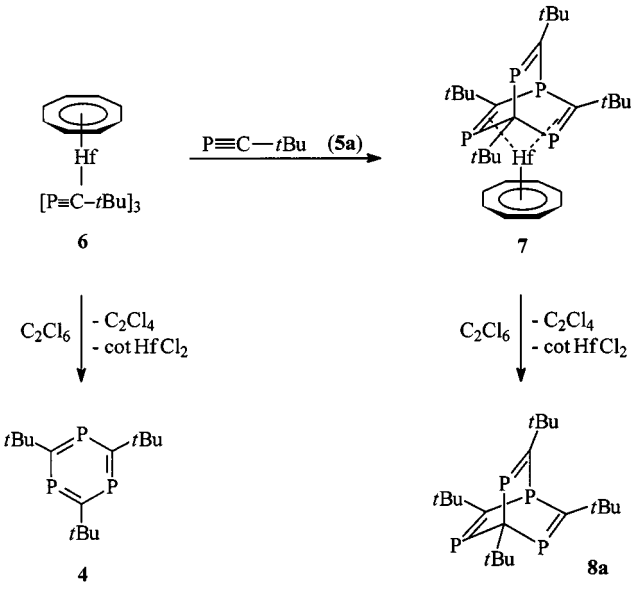
Whereas the λ^3-phosphinine (phosphabenzene) **1**[1] as well as a great number of its functional derivatives[2] have been thoroughly investigated, only little information is published on "all-λ^3" di- or triphosphinines. So far the 1,4-diphosphabenzene derivative **2** was only detected in solution, but its NMR data are not complete.[3] As first representatives of the 1λ^3,3λ^3-diphosphinines[4] and 1λ^3, 3λ^3,5λ^3-triphosphinines[5] compounds **3** and **4**, respectively, have been isolated in pure form by using transition metal complex templates for the cyclotrimerization of *tert*-butylphosphaethyne **5a**, followed by oxidative replacement, and characterized.



1 **2** **3** **4**

The preparation of **4** was accomplished by oxidative cleavage of the hafnium complex [(COT)Hf(*t*BuCP)$_3$] (**6**) with the useful reagent hexachloroethane. Template **6** was also used for the preparation of the η^4-1,3,5,7-tetraphosphabarrelene complex **7** by reaction with *t*BuC≡P (**5a**) (Scheme 1). Cleavage of **7** with C_2Cl_6 yields the 1,3,5,7-tetraphosphabarrelene derivative **8a**, which had been isolated before from the reaction of bis(cyclooctatetraene)zirconium with **5a**.[6] It is of particular interest that the valence isomers of **4**, 1,3,5- and 1,2,4-triphospha-Dewar-benzene[5][7] can be prepared selectively by the same synthetic procedure on use of modified cyclooctatetraene ligands for production of precursor analogues of **6**, and by variation of the reaction temperatures. In addition, Binger et al.[8] reported recently on homo-Diels−Alder reactions of 2,4,6-tri-*tert*-butyl-1,3,5-triphospha-Dewar-benzene.

Scheme 1



In 1998 Regitz et al.[9] presented a new effective method for the synthesis of **4** and other alkyl-substituted analogues, based on the use of the strong Lewis acid *t*BuN=VCl$_3$ as

[+] Present address: Fachbereich Chemie der Universität Kaiserslautern, Erwin-Schrödinger-Straße, D-67663 Kaiserslautern, Germany; Fax: (internat.) +49 (0)631/ 205-3921.

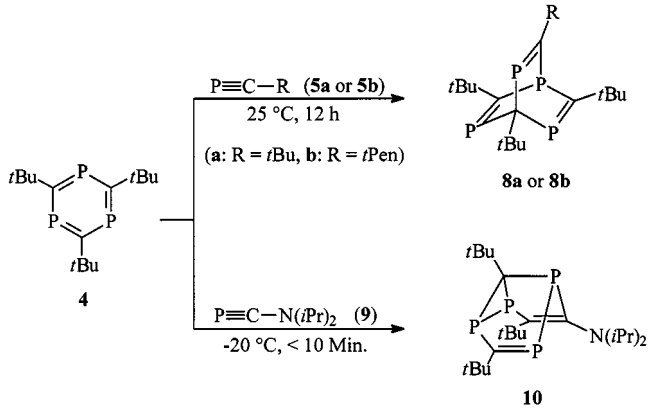
cyclotrimerization agent. The availability of **4** by the procedures mentioned above allowed reactivity studies of the 6π-heteroarene, in particular with respect to cycloaddition reactions.

For instance, the tetraphosphabarrelenes **8a** or **8b** (Scheme 2) are formed nearly quantitatively within 12 h by treating a pentane solution of **4** with the phosphaethynes **5a** and **5b**, respectively. This result demonstrates that the addition of a further phosphaalkyne molecule is possible even without coordination of a cyclotrimer of **5** to a complex fragment. Of particular interest is the possibility to prepare unsymmetrically substituted tetraphosphabarrelenes like **8b**. The reactions proceed under mild conditions indicating an astonishing reactivity of **4** against dienophiles. So far, similar reactions of phosphinines or their *P*-coordinated tungsten complexes with *t*BuC≡P (**5a**) have not been observed.[10] However, phosphinines undergo [4 + 2] cycloadditions with electron-deficient olefins under forced conditions. These reactions can be enhanced by σ-complex formation with $[(CO)_5W(THF)]$.[2b] The reactivity of phosphaarenes is also considerably increased if they contain an additional N or P atom in the 6π-system as in case of the 1,3-azaphosphinines published by Märkl et al.[11][12] or of the 1,4-diphosphinine **2**[3b], though fairly extreme conditions (100−120°C, high pressure vessel) are necessary for reactions with alkynes[3b][12] or **5a**.[11]

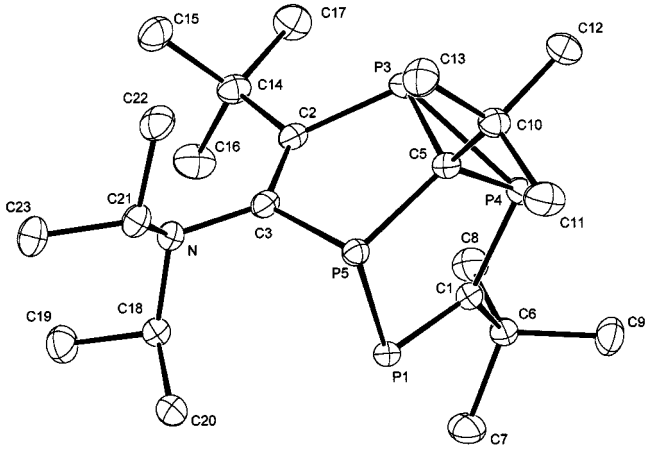
Scheme 2



The analogous reaction of **4** with di(isopropylamino)-phosphaethyne **9** leads to a really unexpected result: According to a ^{31}P-NMR control experiment the starting compounds already react at −20°C quantitatively within a few minutes to give the tetraphosphasemibullvalene derivative **10**. The unsymmetrical molecular structure of **10** is proven by three different ^{1}H-NMR signals for the *t*Bu groups as well as by four separate ^{31}P resonances of equal intensities. Only one of them is found at chemical shifts typical for phosphaalkene fragments (δ_P = 347.5). Chemical shifts and coupling constants of all ^{31}P signals are in good accordance with those of the tetra-*tert*-butyltetraphosphasemibullvalene reported by Regitz et al.[13]. The same is true for the ^{13}C-NMR data of both compounds. Fluxional behaviour as observed for the corresponding hydrocarbon derivatives (Cope rearrangement) was not detected for **10** at room temperature. Measurements at higher temperatures failed because **10** already decomposes at 20°C even in inert solvents.

The molecular structure of **10** was deduced from a single-crystal X-ray analysis and supports the conclusions drawn from the NMR spectroscopic investigations. Figure 1 shows one of the enantiomers observed in the crystal lattice.

Figure 1. Molecular structure of **10** in the crystal; the hydrogen atoms are omitted for clarity[a]



[a] Selected bond lengths [Å] and angles [°]: P1−P5 2.207(1), P3−P4 2.274(1), P3−C5 1.858(2), P4−C5 1.865(2), P5−C5 1.856(2), P1−C1 1.693(2), P3−C2 1.809(2), P4−C1 1.796(2), P5−C3 1.874(2), C2−C3 1.366(2), N−C3 1.450(2), N−C18 1.506(2), N−C21 1.494(2); C1−P1−C5 100.4(1), C5−P3−P4 52.5(1), C2−P3−P4 111.8(1), C5−P3−C2 99.4(1), C5−P4−C1 101.5(1), C1−P4−P3 107.1(1), C5−P4−P3 52.2(1), C5−P5−P1 99.7(1), C5−P5−C3 97.3(1), C3−P5−P1 87.7(1), C3−C2−P3 116.6(1), C2−C3−P5 116.2(1), P4−C5−P3 75.3(1), P5−C5−P3 109.2(1), P5−C5−P4 115.1(1).

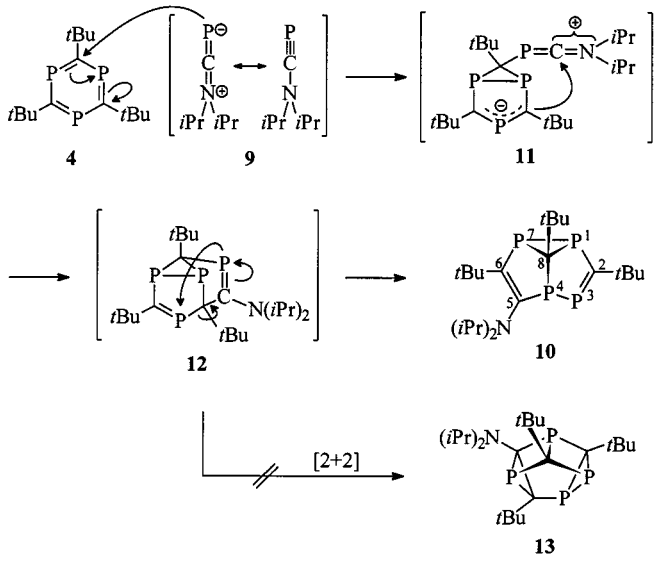
As to be expected, the P−(sp^2)C single bonds in the tricyclic phosphorus/carbon skeleton of **10** are significantly shorter (P3−C2: 1.809, P4−C1: 1.796 Å) than P−(sp^3)C distances (1.856 to 1.874 Å). The P1−C1 bond length of 1.693 Å is very close to the average value (1.67 Å) of localized P=C double bonds.[14] The distance P3−P4 amounts to 2.274 Å and, so far, represents the longest PP bond in diphosphirane derivatives.[9][13][15][16] Consequently the angle P3−C5−P4 within the three-membered ring is opened to 75.3°.

The formation of **10** from **4** and **9** is not directly evident, although **9**, due to its electronic structure[17], often shows a different behaviour to alkyl-substituted phosphaalkynes, especially in cycloaddition reactions.[18] Assuming that the π-donor interaction of the R_2N substituent enhances the nucleophilicity of the *P*-atom, an attack of **9** at one of the ring carbon atoms seems reasonable as the first reaction step followed by a ring closure to the tricyclic intermediate **12**. The stable end product is reached by a further nucleophilic attack of the aminophosphaalkene *P*-atom and by valence isomerization. The competitive intramolecular [2 + 2] cycloaddition with formation of the pentacyclic compound **13** is less probable for two reasons:

(i) Aminophosphaalkenes are not suited for cycloaddition reactions due to the loss of olefinic character,

(ii) high-level ab initio calculations[19] on different $(HCP)_4$ isomers favour the semibullvalene system over the cuneane structure.

Scheme 3



In conclusion, the work presented in this paper has led to a selective synthesis of the tetraphosphabarrelene derivatives **8a** and **8b** from the 1,3,5-triphosphabenzene **4** and to a surprising reaction of **4** with **9** affording the novel tetraphosphasemibullvalene derivative **10**, thus enlarging our knowledge about cyclotetramers of phosphaalkynes[20] and clearly demonstrating the important influence of *C*-amino groups on the reactivity of P≡C systems.

This work was supported by the *Deutsche Forschungsgemeinschaft* (Graduiertenkolleg "Phosphor als Bindeglied verschiedener chemischer Disziplinen", Universität Kaiserslautern; and Graduiertenkolleg "Hochreaktive Mehrfachbindungssysteme", Universität Münster) and by the *Fonds der Chemischen Industrie*.

Experimental Section

All experiments were carried out under argon (or by using a standard vacuum line) in anhydrous solvents. Reaction vessels were either Schlenk flasks or ampoules with several break seals and an NMR tube. $-^1$H and ^{13}C NMR: Bruker AC 200, AC 300, and AMX 400; chemical shifts relative to the solvent signals, calibrated to TMS. $-^{31}$P NMR: Bruker AC 200, AC 300, external standard H_3PO_4. 2,4,6-Tri-*tert*-butyl-1,3,5-triphosphabenzene **4**[5][9] and the Phosphaalkynes *t*BuC≡P (**5a**)[21a], *t*PenC≡P (**5b**)[21b], $(i\text{Pr})_2$NC≡P (**9**)[22] were prepared according to the literature.

Standard Procedure for the Preparation of the Tetraphosphabarrelenes **8a**, **8b**: A pentane solution (2 ml) of the phosphaalkyne **5a** (80 mg, 0.8 mmol) or **5b** (100 mg, 0.9 mmol) was added at room temperature to a pentane solution (3 ml) of the triphosphabenzene derivative **4** (200 mg, 0.67 mmol). The mixture was stirred for 12 h, and volatile components were removed in vacuo. The residue was taken up in pentane and filtered through a layer of silica gel. After evaporation of the solvent in vacuo the tetraphosphabarrelene **8a** and **8b**, respectively, was obtained as a yellow powder (**8a**: 260 mg, 0.65 mmol, 98% yield; **8b**: 265 mg, 0.64 mmol, 96% yield).

2,4,6,7-Tetra-tert-butyl-1,3,5,8-tetraphosphabicyclo[2.2.2]octa-2,5,7-triene (**8a**) was characterized by comparison of the NMR data with those of an authentic sample.[6]

[4,6,7-Tri-tert-butyl-2-tert-pentyl]-1,3,5,8-tetraphosphabicyclo-[2.2.2]octa-2,5,7-triene (**8b**): $-^1$H NMR (C_6D_6, 200.1 MHz, 25°C): δ = 0.70 (q, *J* = 7.4 Hz, 2 H, CH_2CH_3), 1.39 (3 H, CH_2CH_3), 1.43 [s, br., 15 H, $C(CH_3)_3$ and $C(CH_3)_2CH_2$], 1.77 [s, br., 18 H, $C(CH_3)_3$]. $-^{13}$C {^{1}H} NMR (C_6D_6, 50.3 MHz, 25°C): δ = 28.3 [m, CH_3CH_2 and $(CH_3)_2C$], 30.5 [m, $(CH_3)_3C$], 30.7 [m, ^3J(P,C) = 0.3 and 14.9 Hz, $(CH_3)_3C$], 33.4 [t, ^3J(P,C) = 9.5 Hz, CH_3CH_2], 35.8 [q, ^2J(P,C) = 16.1 Hz, $C(CH_3)_3$], 41.6 [m, $C(CH_3)_3$], 44.8 [dd, ^2J(P,C) = 19.1 and 25.4 Hz, $C-CH_2CH_3$], 101.1 [m, C-4], 225.4 [m, C-2], 227.3 [m, C-6, C-7]. $-^{31}$P{^{1}H} NMR (C_6D_6, 81.0. MHz, 25°C): δ = -92.0 [q, ^2J(P,P) = 12.6 Hz, *P*−C=P], 320.7 [t, ^2J(P,P) = 12.6 Hz, P=C−$C(CH_3)_3$], 324.8 [q, ^2J(P,P) = 12.6 Hz, P=C−$C(CH_3)_2C_2H_5$]. −MS (EI, 70 eV); *m/z* (%): 414 (68) [M^+], 314 (9) [$M^+ - PC_5H_9$], 300 (3) [$M^+ - PC_6H_{11}$], 276 (74) [$M^+ - 2\,C_5H_9$], 262 (100) [$M^+ - C_5H_9 - C_6H_{11}$], 200 (22) [$M^+ - PC_5H_9 - PC_6H_{11}$].

*2,6,8-Tri-tert-butyl-5-diisopropylamino-1,3,4,7-tetraphosphatricyclo[5.1.0.0 4,8]*octa-2,5-diene (**10**): 80 mg (0.27 mmol) of the triphosphabenzene derivative **4** were placed in an ampoule with break seals and an NMR tube together with 0.5 ml [D_8]toluene. 45 mg (0.31 mmol) of di(isopropyl)aminophosphaethyne **9** were then introduced by vacuum condensation at −196°C. During warm−up to −20°C the mixture was continuously stirred and afterwards tranfused in the NMR tube. Measurements at −30°C indicated a complete reaction of the triphosphabenzene **4** and the quantitative formation of the tetraphosphasemibullvalene derivative **10**. Orange crystals of **10** were obtained on cooling the [D_8]toluene solution at −78°C. Their quality was sufficient for a single-crystal X-ray structure analysis. $-^1$H NMR (C_7D_8, 400.1 MHz, −30°C): δ = 0.90 [s, 9 H, $C(CH_3)_3$)], 1.21 [d, *J* = 6.5 Hz, 6 H, $CH(CH_3)_2$], 1.28 [d, *J* = 6.5 Hz, 6 H, $CH(CH_3)_2$], 1.38 [s, 9 H, $C(CH_3)_3$], 1.48 [s, 9 H, $C(CH_3)_3$], 3.38 [sept, *J* = 6.5 Hz, 2 H, $CH(CH_3)_2$]. $-^{13}$C {^{1}H} NMR (C_7D_8, 75.5 MHz, −35°C): δ = 24.8 [s, $CH(CH_3)_2$], 29.6 [s, br., $C(CH_3)_3$ at C-8], 32.3 [d, ^3J(P-6,C) = 11.3 Hz, $C(CH_3)_3$ at C-6], 34.3 [dd, ^3J(P-3,C) = ^3J(P-1,C) = 7.6 Hz, $C(CH_3)_3$ at C-2], 34.9 [q, ^2J(P-1,C) = ^2J(P-4,C) = ^2J(P-7,C) = 11.7 Hz, $C(CH_3)_3$ at C-8], 37.3 [d, ^2J(P-7,C) = 25.2 Hz, $C(CH_3)_3$ at C-6], 42.2 [dd, ^2J(P-3,C) = 22.6, ^2J(P-1,C) = 13.6 Hz, $C(CH_3)_3$ at C-2], 55.6 [s, br., $CH(CH_3)_2$], 63.0 (m, C-8), 156.1 [dm, ^1J(P-7,C) = 65.5 Hz, C-6], 177.7 [d, ^1J(P-4,C) = 39.9 Hz, C-5], 211.8 [t, ^1J(P-3,C) = ^1J(P-1,C) = 83.0 Hz, C-2] (for numbering see Scheme 3). $-^{31}$P{^{1}H} NMR (C_7D_8, 121.5. MHz, −35°C): δ = −92.1 [dd, ^1J(P-1,P-7) = 174.6, ^2J(P-4,P-7) = 16.4 Hz, P-7], −19.6 [ddd, ^1J(P-1,P-7) = 174.6, ^2J(P-1,P-3) = ^3J(P-1,P-4) = 23.5 Hz, P-1], 88.7 [ddd, ^1J(P-3,P-4) = 270.0, ^2J(P-1,P-4) = 23.5, ^2J(P-4,P-7) = 16.4 Hz, P-4], 347.5 [dd, ^1J(P-3,P-4) = 270.0, ^2J(P-1,P-3) = 23.5 Hz, P-3] (for numbering see Scheme 3).

Crystal Structure Analysis of **10**[23]: Enraf-Nonius-CAD4 Diffractometer (Mo-K_α radiation), *T* = 100 K; structure solution by heavy-atom method (SHELXS-86[24]) and structure refinement by SHELXL-93[25]; monoclinic, space group $P2_1/c$; lattice constants *a* = 10.0494(10), *b* = 20.4954(10), *c* = 12.3895(10) Å, β = 99.983(10)°; *V* = 2513.2(3) Å^3; *Z* = 4; μ(Mo-K_α) = 0.308 mm^{-1}, crystal size 0.42 × 0.39 × 0.35 mm; 9113 independent reflections (R_{int} = 0.0648) 28745 measured of which 6630 were considered observed with $I > 2\sigma(I)$; residual electronic density 0.481 and −0.357 e/Å^3. 408 parameters (C, N, and P anisotropic, the positions of the H-Atoms were found and refined isotropically); R_1 = 0.0441; wR^2 = 0.1180.

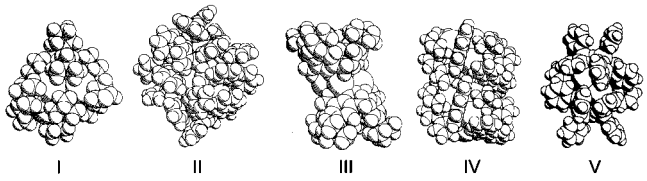
Keywords: Polyion aggregates / Crystal structure / Density functional theory calculations

The structure determination of the lipophilically wrapped cluster $\{[Al_2Li_4O_{18}](C_{36}H_{44})\}_\infty$, a novel material crystallized from a mixture of $[(C_2H_5)_3Al]_2$, *n*BuLi, and catechol in DME solution, reveals five-coordinate Al^{++} and Li^+ centers. According to density functional theory calculations, the eight negative charges are well-delocalized over the oxygen-rich framework.

Recent Results on Main-Group Ion Clusters

Lipophilically wrapped polyion aggregates, in which a cluster ion nucleus guarantees thermodynamic stability, and where a surrounding hydrocarbon skin offers both kinetic shielding as well as solubility in non-polar solvents, are representative of a rather favourable self-organization principle,[2][3][4][5][6][7][8] for main-group element compounds (Table 1).

Table 1. Examples of novel lipophilically wrapped main-group element clusters with space-filling structure representation and specification of their components



I II III IV V

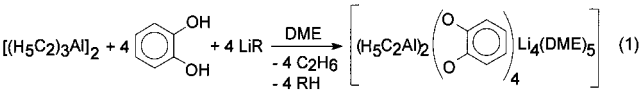
Component	[Lit.]	Cluster	Structure	Lipophilic Skin
I. $[Ba]_x + (H_3C)_3COH$	[4]	$[Ba_6Li_2O_2]^{\oplus 11}$	Octahedron + Prismane	$(^{\ominus}OC(CH_3)_{11})$
II. $Na^{\oplus}(RO)_2P\text{-}N\text{-}P(OR)_2$	[5]	$[Na(OPNPO)]_6$	Ellipsoid	$(C_{144}H_{120}O_{24})$
III. $LiNH_2$ + Calix[4]aren	[6]	$[Li_6(NH_3)_2O_6]$	Double tetrahedron	$(C_{88}H_{110}O_2)$
IV. $K^{\oplus}$(aci-nitrofluorene)	[7]	$[K_6O_{12}]$	Octahedron	$(C_{102}H_{80}N_6)$
V. Silanoles + {LiR, $[Na]_x$, KH}	[8]	$[Li_4O_4]$, $[Na_4O_4]$, $[K_4O_4]$	Cubes	$(C_{96}H_{84}O_{10}Si_8)$, $(C_{96}H_{84}O_6Si_8)$, $(C_{72}H_{60}Si_4)$

Density functional calculations[4] based on structural data confirm the ionic compositions of the aggregates (e.g.[4] Ba^{++}, Li^+, and O^{--}) and their considerable cluster stability (e.g.[5] $\Delta H_f > 5000$ kJ mol^{-1}). In contrast, the energy contributions of the hydrocarbon shells, as estimated from a statistical evaluation of phenyl ring centroid interactions, are only small (e.g.[5] $\Delta H_f \approx 50$ kJ mol^{-1}).

Based on the general principles outlined above, numerous and multifaceted supramolecular compounds can be anticipated.[9] In view of the considerable bond enthalpy difference, $\Delta H_b(Al-C) - \Delta H_b(Al-O) = (274 - 500) = -226$ kJ mol^{-1},[9] alumoxane clusters are expected to be especially favorable candidates.

Preparation and Structure Determination

A mixture of flammable triethylaluminum dimer and a stoichiometric amount of *n*-butyllithium[4] reacts vigorously with catechol in aprotic dimethoxyethane (DME) solution under argon (1) (see Experimental Section).



(1)

A crystalline reaction product can be isolated, provided that exposure to air and/or moisture is carefully avoided. Its structure determination (Figure 1), performed on a sample cooled to 150 K in a flow of nitrogen (see Experimental Section), reveals the formation of $\{[(DME_{1.5}Li^+)\text{-}(H_5C_2Al^{++--}O_2C_6H_4)_2^{--}(Li^+DME)]_2\}_\infty$ (DME = $H_3COCH_2CH_2OCH_3$). The product contains a total of 18 oxygen centers in its polymer chain and is thus the most oxygen-rich polyion aggregate isolated to date (Table 1).

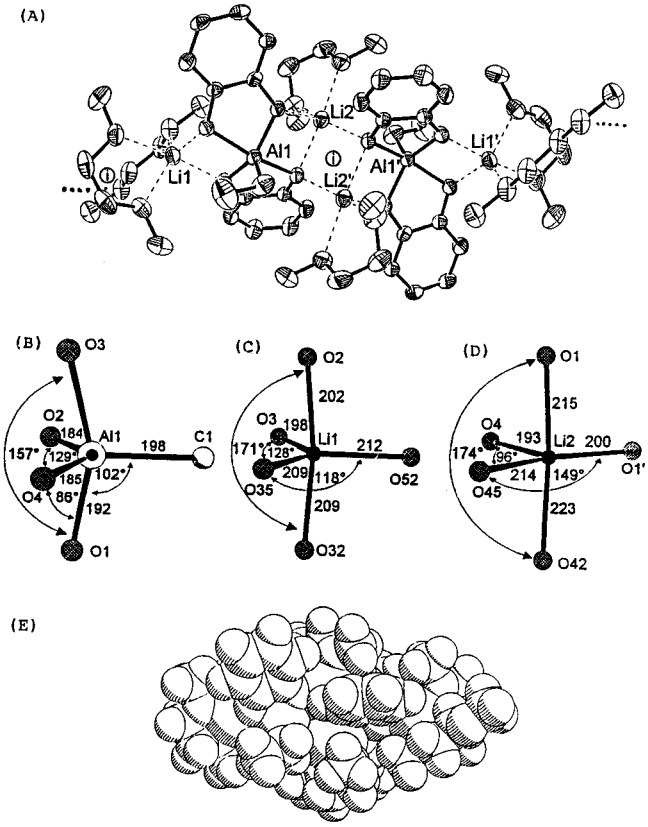
Figure 1. (A) Dimeric subunit of the lithium/aluminum organic polymer with thermal ellipsoids drawn at the 50% probability level and metal center notation; (B) to (D) Al^{++} and Li^{+} coordination spheres, and (E) space-filling side view

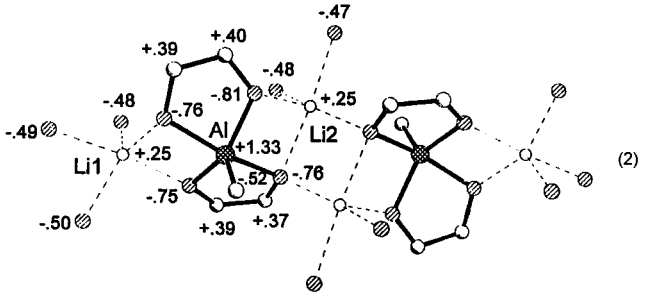


The crystal is seen to contain polymeric strands of dimethoxyethane-bridged subunits, the four-membered central (Li_2O_2) rings of which contain centers of inversion (Figure 1/A: ⓘ). The formally dipositive $(C_2H_5)Al^{++}$ center is fourfold coordinated to the four catecholate O^{-} centers and forms a distorted trigonal bipyramid with longer axial Al−O distances of 191 pm and the C center of lower effective nuclear charge in the expected equatorial position (Figure 1: B). The Li^{+} countercations are also fivefold coordinated: Li1 to two catecholate and three DME oxygen centers, and Li2 to three catecholate and two DME oxygen centers (Figure 1: C and D). Due to the four-membered (Li_2O_2) ring formation, the trigonal bipyramids around the symmetry-equivalent countercations Li2 and Li2′ are more strongly distorted with O−Li2−O angles of up to 149° (Figure 1: D). The space-filling representation (Figure 1: E) illustrates how the hydrocarbon ($C_{36}H_{44}$) shell shields the oxygen-rich $[(Al^{++})_2(Li^{+})_4(O_{18})^{-8}]$ cluster and renders it completely soluble in apolar solvents (see Experimental Section).

A search of the Cambridge Structural Database for cluster structures predominantly composed of Al, Li, and O atoms revealed only one monomer[10] bearing no relation to our polyion aggregate. In the meantime, we have been able to isolate crystals from an analogous mixture (1) with the parent molecule phenol.[11] According to their structure determination, these crystals contain a quadruple ion $\{[(H_5C_6O)_3(H_5C_2)Al]^{-}\cdots Li^{+}\cdots{}^{-}[Al(C_4H_9)(OC_6H_5)_3]\}^{-}[Li^{+}(DME)_3]^{+}$, consisting of a complex triple-ion anion and a DME solvent-separated countercation.[12] Despite the fact that this system is also wrapped by a hydrocarbon skin ($C_{40}H_{40}$), there is no real analogy with the catechol-substituted $[Al_mLi_nO_x]$ polyion aggregate presented (Figure 1), since Al−O−Li connections are in this case completely absent.

Density Functional Calculations

For the polyion aggregate, with its molecular size exceeding 100 atoms, density functional calculations at the B3LYP level using 6-31G* basis sets (see Experimental Section) have been performed, based on the determined structural coordinates (Figure 1). Despite some uncertainty concerning the polarity within the ($Li_4Al_2O_{18}$) cluster, the following calculated Mulliken-type charge distribution (2) will be discussed.



(2)

For the ethyl-substituted and four-fold catecholate oxygen-coordinated Al centers, Mulliken charge densities of +1.33 are calculated, indicating covalent contributions to the ionic interactions $Al^{++}\cdots{}^{-}O$ as well. Furthermore, the catecholate anion charges are partially delocalized towards the Li^{+} countercations, which are strongly solvated (Figure 1: C and D) by a total of six oxygen centers of three sterically unhindered dimethoxyethane chelate ligands. The total charges of the essential cluster components amount to approximately −1.0 for the catecholate ligands, −0.3 for the ethyl substituents, and about +0.2 for the DME solvent molecules. Considering the 18 differently charged oxygen centers, each transfers an average of about 0.7 of a negative charge to the six metal cations, decreasing the polyion aggregate character by metal−oxygen bonding contributions.

Conclusion and Perspectives

A vigorous reaction between triethylaluminum dimer, *n*-butyllithium, and catechol (1) yielded the title compound, which according to its structure determination is an unprecedented oxygen-rich polyion aggregate $[Li_4Al_2O_{18}]$ wrapped by a lipophilic hydrocarbon skin ($C_{36}H_{44}$). The predominantly ionic interactions assumed are supported by density functional calculations.

This result encourages us to attempt further crystallizations of main-group element clusters, of which only the sim-

plest examples are as yet known. It also suggests further exploration of (alkylaluminum + phenol) reaction mixtures, especially by those interested in novel ceramic materials, which are presumably accessible by firing hydrocarbon-wrapped clusters $[Li_nAl_mO_x]$.

The project "Interactions in Molecular Crystals" is supported by the *Hoechst Corporation*, the *Deutsche Forschungsgemeinschaft*, the *State of Hessen*, and the *Fonds der Chemischen Industrie.*

Experimental Section

Preparation and Crystallization: In a rigorously dried Schlenk trap, 352 mg (3.2 mmol) of catechol was dissolved in 40 ml of anhydrous dimethoxyethane (DME). At −70°C, 1.6 ml (1.6 mmol) of a 1 M solution of triethylaluminum dimer in *n*-hexane followed by 1.5 ml (2.4 mmol) of a 1.6 M solution of *n*-butyllithium in *n*-hexane were quickly injected under argon. The mixture was shaken repeatedly during warming to room temperature. The surface of the solution was then covered with a layer of *n*-hexane and crystallization began after about 2 h. After 1 d, large transparent prisms had grown.

Crystal Structure Determination: $C_{24}H_{38}AlLi_2O_9$ (511.4), colourless prisms, crystal dimensions: 0.82 × 0.48 × 0.46 mm, temperature 150 ± 2 K, a = 1863.6(1), b = 1486.6(1), c = 2080.6(2) pm, β = 1104.93(1)°, V = 5569.6(7) Å^3, Z = 8, $\rho_{calcd.}$ = 1.220 gcm^{-3}, μ(Mo-K_α) = 0.711 Å, monoclinic, space group $C2/c$ (No. 15), Siemens P4 four-circle diffractometer, 5598 measured reflections in the range $3° \leq 2\theta \leq 52°$, of which 5410 were independent and 4188 had $I > 2\sigma(I)$. Structure solution by direct methods (SHELXS), 331 parameters refined against F^2 (SHELXL-93), R = 0.041, wR_2 = 0.096, residual electron density +0.28/−0.26 eÅ^{-3}, S = 1.035. The positions of Li, C, O, and Al were refined anisotropically; H centers were ideally geometrically positioned and refined using fixed displacement parameters within a riding model. Atomic coordinates, bond lengths and angles, and thermal parameters have been deposited at the Cambridge Crystallographic Data Centre (CCDC). Any request to the CCDC for this material should quote the full literature citation and the reference number CCDC-103178.

Density functional calculations were performed using the Gaussian-94 program. For the 104 cluster atoms, a total of 2576 Gaussian functions within 6-31G* basis sets were applied. The NEC SX4 computer system at the high performance computing center, Stuttgart, Germany, required 14.8 h of CPU time to calculate the total energy as −4053, 414614 a.u.

A series of linear primary polyamines $H_2N–CH_2–(CH–NH_2)_n–CH_2–NH_2$ ($1 \leq n \leq 3$) was prepared from the corresponding polyalcohols. The polyamines were isolated as HCl adducts and the acidity constants in aqueous solution were determined. The crystal structure of the fully protonated tetraamine ($n = 2$) was elucidated by an X-ray diffraction study. Complex formation of the triamine ($n = 1$) with Ni^{2+}, Cu^{2+}, Zn^{2+}, Cd^{2+} was re-investigated in aqueous solution. The pH-dependent formation of a variety of species $M_xL_yH_z$ was established by potentiometric titrations and was compared with previous reports. The crystal structure of the Cu complex $[CuL_2]Cl_2$ exhibited a chain structure with a five-coordinate Cu^{II} centre in which two amino groups of the triamine ligands are coordinated to one Cu centre, while the third amino group of one of the ligands is bonded to a neighbouring Cu atom. The compound shows weak antiferromagnetic coupling interactions between the Cu^{II} centres within the chain.

Introduction

Aggregation of metal complexes has turned out to be a powerful concept for the design and preparation of extended polymeric structures[1]. Such molecular arrays have been discussed in the context of crystal engineering and supramolecular chemistry[2]. Different types of interactions have been used to connect the monomeric precursors to the polymeric forms. Zaworotko and coworkers exploited hydrogen bonding for the synthesis of a variety of indefinite coordination polymers[3]. Interconnection of metal centres by bridging counterions is another well-known strategy for the generation of such polynuclear structures. Hydrolytic polymerisation (where the metal centres are connected by bridging OH^- or O^{2-} ligands) is a prominent representative in this type of interaction[4]. In addition, a variety of tailored chelating ligands has been developed, where the binding of more than one metal cation is promoted by the specific steric characteristics of the ligand[5]. A series of multidentate chelators, based on the bipyridyl entity, has been developed by Lehn and coworkers[6]. These ligands allowed the systematic design of one-dimensional chains and helices, two-dimensional grids, and three-dimensional networks. The coordination chemistry of poly(ethyleneimines) with transition metal cations in aqueous solution has been investigated by Schläpfer et al., who suggests that these ligands have a considerable potential for technical applications[7]. The ability of polyalcohols such as the sugar alcohols or the tripodal tris(hydroxymethyl)aminoethane to act as sequestering agents, preventing formation of solid metal oxides or hydroxides in alkaline aqueous solution, has been well known for many years[8]. The linear polyalcohols $HO-CH_2-[CH-OH]_n-CH_2-OH$, $n > 1$ (sugar alcohols), are of particular interest with respect to the formation of polynuclear complexes. For steric reasons, it is not possible to bind all donor groups of one ligand molecule to a single metal centre and consequently these compounds could potentially serve as interesting building blocks for polymeric structures[9].

Although the sugar alcohols represent a well-known group of compounds that is widespread in nature, the corresponding linear polyamines $H_2N-CH_2-[CH-NH_2]_n-CH_2-NH_2$ have not been investigated to a great extent or are even completely unknown. This is of course, not true for 1,2-diaminoethane (en), the first member of

 © WILEY-VCH Verlag GmbH, D-69451 Weinheim, 1998 1434–1948/98/1212–2079 $ 17.50+.50/0

this series ($n = 0$), for which innumerable reports of the coordinating properties have appeared in the literature[10]. In most of these reports, 1,2-diaminoethane acts as a simple, bidentate ligand. However, a bridging coordination mode of the diamine, where the two nitrogen donors are coordinated to two different metal centres, has also been established[11]. For 1,2,3-triaminopropane (trap), there have only been a limited number of reports describing the coordinating properties[12–17]. A tridentate coordination mode of trap has been established in the bis-complex of Co^{III}[14]. For the tetraamines, two different stereoisomers must be considered. Both isomers (the *threo* and the *erythro* form) have been prepared as intermediates in the synthesis of tetraazadecalins, but the free amines have not been isolated[18][19]. To the best of our knowledge, the pentaamine has not been described at all.

By analogy with the corresponding polyalcohols, linear primary polyamines could serve as novel building blocks for coordination polymers, since for $n > 1$ it is not possible to coordinate the complete donor set to one single metal centre. We have therefore initiated a comprehensive investigation of the coordination chemistry of this class of compounds and intend to publish a series of papers, where the interactions of these ligands with a variety of metal cations will be described. In the first contribution, we present the synthesis and characterisation of the ligands and we describe the coordination chemistry of the triamine with divalent metal centres in aqueous solution and in the solid state.

Results and Discussion

Preparation and Characterisation of the Ligands

1,2,3-Triaminopropane (trap, $n = 1$), *meso*-1,2,3,4-tetraaminobutane (tab) and 1,2*R*,3,4*S*,5-pentaaminopentane (pap) were prepared by a classical procedure from the corresponding polyalcohols, with the poly(benzenesulphonates) and polyazides as intermediates[20]. Conversion of the polyazides to the corresponding polyamines could be achieved either by reduction with $LiAlH_4$ or by hydrogenation in an autoclave[14][18]. The latter method proved to be more convenient and gave slightly higher yields. Due to the potential hazards of polyazides, a procedure was developed that did not require the isolation of these intermediates as pure substances. The solutions of the azides were rather transferred directly into the autoclave and hydrogenated to give the polyamines, which were finally isolated as the corresponding hydrochlorides trap . 3HCl, tab · 4HCl and pap · 5HCl. Chromatography on a strongly acidic cation exchange resin proved to be a very efficient procedure to remove any by-products, and the pure, linear polyamines could readily be isolated in their fully protonated form ($H_2N-CH_2-[CH-NH_2]_n-CH_2-NH_2)\cdot(n+2)HCl$[21]. This procedure was particularly helpful for the recovery of the amines after the titration experiments, where a large excess of salts such as KCl or KNO_3 had been added to the sample solutions. The synthetic method reported here thus represents a convenient, two-step procedure, allowing the preparation of these compounds in multi-gram quantities.

The free bases trap, tab and pap could be obtained in CO_2-free water by the simple action of a strongly basic anion resin in the OH^- form. Concentration of the resulting solution yielded the corresponding polyamines as hygroscopic and CO_2-sensitive oils. Since the crystalline polyhydrochlorides can be handled and stored without problems, the free amines were only prepared in situ in solution and were usually not isolated. Prolonged storage of tab · 4HCl and pap · 5HCl resulted in some loss of HCl (1–2%) and recrystallisation from conc. HCl was required to obtain a pure sample.

According to NMR-spectroscopic measurements and an X-ray diffraction analysis, the configuration of the ligands is retained during this synthetic procedure: conversion of erythritol yielded the corresponding *meso* isomer of the tetraamine. The ^{13}C-NMR spectrum of tab. 4 HCl exhibited a total of two signals, and the crystal structure depicted in Figure 1, showing two crystallographically independent ligand molecules, established the expected *erythro* configuration. It is noteworthy that the conformations of the two H_4tab^{4+} cations are distinctly different from a structure that would be assumed, for an isolated molecule, to be of lowest energy[13]. Only one N–C–C–N substructure exhibited a torsional angle of 161° and thus corresponds to a staggered orientation. All the other N–C–C–N torsional angles fall in the range of 66–93°, corresponding to conformations intermediate between a synclinal and an anticlinal orientation. This may be attributed to strong anion-cation interactions within the crystal lattice, with the H_4tab^{4+} cations binding several Cl^- counter ions in a bidentate mode by N–H···Cl hydrogen bonding.

The acidity constants (pK_a values) of the three ligands have been determined by potentiometric measurements (Table 1). Inspection of corresponding ΔpK_a values clearly indicates that the two positive charges of the doubly protonated species are located at the terminal amino groups. For H_3pap^{3+}, the data are consistent with a protonation in the 1-, 3- and 5-positions. These findings are in agreement with simple electrostatic considerations, where a maximal distance between the positive charges is achieved. For the fully protonated species trap · 3HCl, tab · 4HCl and pap · 5HCl an increasing acidity is observed in this order in aqueous solution (Table 1). The pK_a values (25°C, 0.1 M KCl) are 3.63 for H_3trap^{3+} and 1.4 ± 0.3 for H_4tab^{4+}. H_5pap^{5+} behaves as a strong acid in water and the pK_a for the first deprotonation step could not be determined by the potentiometric method.

Complex Formation with trap in Aqueous Solution

A variety of potentiometric measurements using total M/total L ratios of 1 and 0.5 was performed to elucidate the compositions of the different species and to determine their formation constants. Some of these systems have previously been investigated by Prue and Schwarzenbach[12],

Figure 1. Molecular structure of the two crystallographically independent cations of tab·4HCl·H_2O; the thermal ellipsoids are drawn at the 50% probability level; hydrogen atoms are shown as spheres of arbitrary size; range of bond lengths [pm]: C−N: 147.6(2)−149.7(2), C−C: 151.7(2)−153.7(2)

[a] The estimated standard deviations are less than 0.01 unless otherwise noted. − [b] $\sigma_{pH} = [\Sigma w(pH_{obsd.} - pH_{calcd.})^2/\Sigma w]^{1/2}$, $w = [pH_{i+1} - pH_{i-1}]^{-2}$.

and more recently by Cini et al.[17]. The authors of the latter paper investigated complex formation at 25°C and in 0.15 M NaCl. We performed the measurements at 25°C in 0.1 M KNO_3 or 0.1 M KCl (Table 2), which have become standard conditions for the determination of stability constants[22]. This allows a direct comparison with corresponding formation constants of other ligands that were measured under the same conditions[23]. Considering the difference in the media, the agreement between our values and the results of Cini et al. is good. However, we also noted some characteristic differences that led us to draw different conclusions. The most significant disagreement is the fact that we could not find an unambiguous indication for the formation of a complex of composition $[CuL]^{2+}$. In the titration experiments with a total Cu/total trap ratio of 1:2, a protonated complex of composition $[Cu(HL)]^{3+}$ is formed in the acidic range. At higher pH, coordination of an additional ligand occurred rather than the deprotonation of the coordinated HL^+ entity (Figure 2). The titration experiments, where a total L/total Cu ratio of 1:1 was used, could not be evaluated in the alkaline range because precipitation of solid $Cu(OH)_2$ was observed. This was in contrast to the Ni^{2+} system, where the formation of both $[NiL]^{2+}$ and $[NiL_2]^{2+}$ could be established unambiguously. Cini et al. performed calorimetric measurements and they deduced a tridentate coordination mode for trap in $[CuL]^{2+}$. However, a comparison of the formation constants of trap with the bidentate en does not support this interpretation: the overall protonation constants κ_2 (= $[H_2L]\cdot[L]^{-1}\cdot[H]^{-2}$) for the generation of the diprotonated H_2en^{2+} and H_2trap^{2+} are in close agreement (en: log κ_2 = 17.00; trap: log κ_2 = 17.50)[23], indicating that the formation of H_2trap^{2+} is slightly favoured. The Ni^{2+} complexes of trap are, however, of significantly higher stability (en: log β_1 = 7.3, log β_2 = 13.4; trap: log β_1 = 9.5, log β_2 = 17.3). This is not the case for Cu^{2+} where log β_2 is 19.6 for the en complex and 19.5 for the trap complex. The value for log β_1 of $[Cu(trap)]^{2+}$ in 0.15 M NaCl has been reported to be 10.4, once again showing no further increase in stability on going from the diamine to the triamine ligand (en: log β_1 = 10.50 at 25°C in 0.1 M KNO_3)[23]. Furthermore, these considerations are supported by the favoured formation of the protonated species $[Cu(HL)]^{3+}$, $[CuL(HL)]^{3+}$ and $[Cu(HL)_2]^{4+}$ and by the results of our X-ray diffraction study (see next section), where a tridentate coordination mode of trap was also not observed for Cu^{2+}.

Figure 2. Species distribution plot for an equilibrated aqueous solution with total Cu 0.5×10^{-3} mol dm^{-3} and total trap (= L) 1×10^{-3} mol dm^{-3}; only metal-containing species are shown; the charges of the different species are omitted for clarity; the equilibrium constants listed in Tables 1 and 2 were used for the calculations

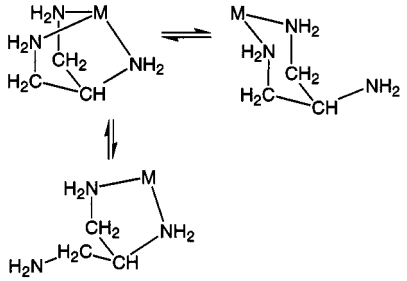
Assuming a bidentate coordination mode for trap in the bis-complexes of Cu, a free amino group would be present in an alkaline medium (Scheme 1), and thus the formation of polynuclear, trap-bridged species must also be considered. As shown in the next section, such bridging interactions can indeed be observed in the solid state. However, careful evaluation of the potentiometric data provided no evidence for the formation of polynuclear species in dilute solutions such as those used in the present investigation. This may, however, be different for more concentrated solutions of complexes, where such aggregation processes are more likely to occur.

Scheme 1



Crystal Structure and Magnetic Properties of $[Cu(trap)_2]Cl_2$

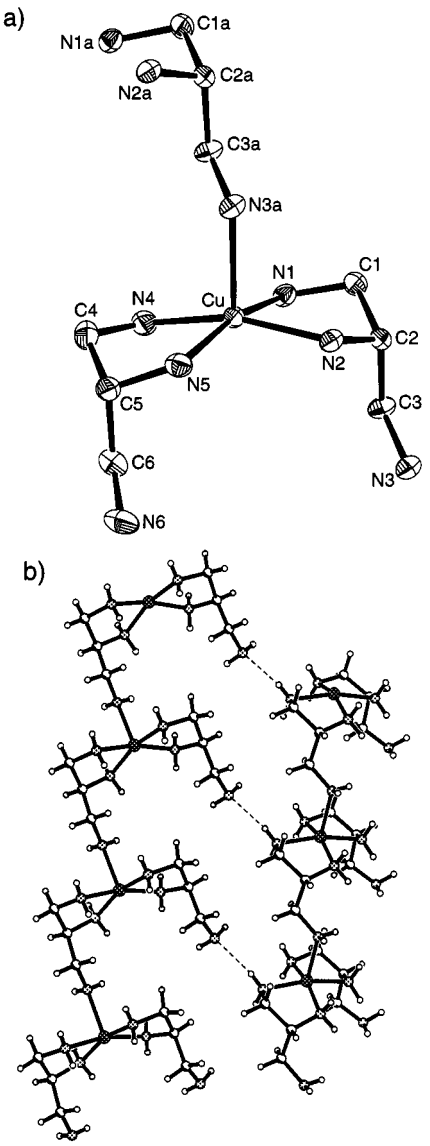
The dichloride salt of the bis-complex crystallises in the polar space group *Cc*. A view of the molecular structure is presented in Figure 3.

Both trap ligands coordinate the Cu^{II} centre in a bidentate mode, forming five-membered chelate rings. The four nitrogen donors of the two ligands form a slightly distorted square. The two ligands differ, however, with respect to the orientation of the third amino group. In the first ligand, the third amino group is coordinated to a neighbouring Cu atom. This bridging interaction of one of the trap ligands generates an infinite chain structure with five coordinate Cu^{II} cations. The coordination sphere of the Cu^{II} centre can be described as a slightly distorted tetragonal pyramid with the amino group of the bridging ligand in the apex. The Cu−N distances of the four amino groups of the square basis (2.02−2.05 Å) and of the apical amino group (2.27 Å) all fall within the expected ranges[24]. The third amino group of the second trap ligand is engaged in a weak hydrogen bond of the type N−H···Cl. This is a remarkable result since this amino group is not protonated and only minor internal rearrangements would be required to bring it into a position where coordination to the Cu centre would be possible (the Cu···N distance to this non-coordinating amino group is 4.60 Å).

A tridentate coordination mode of trap has been observed for $[Co^{III}(trap)_2]^{3+}$ and this has been confirmed by crystal structure analysis[14]. This is not surprising since Co^{III}, with its low-spin d^6-electron configuration, has a strong preference for a regular octahedral CoN_6 coordination. However, molecular mechanics calculations showed that this tridentate coordination mode causes some degree of strain in the ligand backbone, due to the formation of a six-membered chelate ring having an unfavourable boat conformation (Scheme 1)[15].

Due to the Jahn−Teller effect, Cu^{II}-hexaamine complexes usually exhibit strong tetragonal distortion[25], and the facial coordination of a triamine such as trap to Cu^{II} is particularly disfavoured. The X-ray structural analysis together with the potentiometric measurements supports indeed a bidentate coordination mode for the Cu^{II} complexes of trap. Similar conditions could be expected for Pd^{II}, Pt^{II}, or Ag^{I}, where a tridentate binding mode is also unfavourable. In such complexes, additional free amino groups must be present and trap could thus serve as an interesting build-

Figure 3. Molecular structure of $[Cu(trap)_2]Cl_2$; (a) the $[Cu(trap)_3]^{2+}$ cation, (b) section of the infinite chain structure; the thermal ellipsoids are drawn at the 50% probability level; hydrogen atoms are omitted (a) or shown as spheres of arbitrary size (b), the Cl^- counter ions are omitted for clarity; selected bond lengths [pm] and angles [°]: Cu−N(1) 201.6(3), Cu−N(2) 204.5(3), Cu−N(4) 202.7(3), Cu−N(5) 204.6(3), Cu−N(3a) 226.8(3); N(1)−Cu−N(2) 84.1(1), N(1)−Cu−N(3a) 97.6(1), N(1)−Cu−N(4) 92.9(1), N(1)−Cu−N(5) 166.4(1), N(2)−Cu−N(3a) 93.9(1) N(2)−Cu−N(4) 162.7(1), N(2)−Cu−N(5) 94.9(1), N(4)−Cu−N(3a) 103.3(1), N(4)−Cu−N(5) 84.0(1), N(5)−Cu−N(3a) 96.0(1); symmetry-related atoms were generated by the symmetry operation (a): $x + 1, y, z$



ing block for the synthesis of polymeric complexes of these metal cations.

Coordination polymers of paramagnetic cations are of particular interest with regard to their magnetic properties[26]. It is to be expected that interactions between the cations within the polymeric structure would result in antiferromagnetic coupling. Magnetic susceptibility measurements of $[Cu(trap)_2]Cl_2$ established Curie−Weiss behaviour with $\Theta = 1.1$ K and $C = 0.40$ emu K mol^{-1}. Since significantly different Cu···Cu distances are observed for the neighbouring Cu atoms within the chain (6.14 Å) and between two different chains (7.81 Å), the Bonner and Fisher equation for antiferromagnetic coupling interactions of paramagnetic centres within a linear infinite chain was used to fit the data (Figure 4)[27]. The experimental findings could be well reproduced with $g = 2.07$ and $J = 0.82$ cm^{-1}. The g value determined by this method was in good agreement with $g_{\parallel} = 2.19$, $g_{\perp} = 2.07$ observed in the EPR spectrum of a powder sample at room temperature.

Figure 4. Temperature dependence of $\chi \times T$ for $[Cu(trap)_2]Cl_2$; observed data are shown as squares, a theoretical behaviour, calculated for $g = 2.07$ and $J = 0.82$ cm^{-1} is shown as a solid line

Experimental Section

General: ^{1}H- and ^{13}C-NMR spectra were measured in $CDCl_3$ or D_2O at 28°C with a Bruker DRX 500-MHz NMR spectrometer. Chemical shifts (on the δ scale) are given relative to sodium (trimethylsilyl)propionate (D_2O) or tetramethylsilane ($CDCl_3$) as internal standard (δ = 0). C, H and N analyses were performed by H. Feuerhake, Institut für Anorganische Chemie, Universität des Saarlandes. 1,2,3-Propanetriol, benzenesulphonyl chloride, NaN_3, $LiAlH_4$, 5% Pd/C, *meso*-erythritol, xylitol, $CuCl_2 \cdot 2H_2O$ and the organic solvents were commercially available products of reagent-grade quality. They were used without further purification. Dowex 50 W-X2 (100−200 mesh, H^+ form) and Dowex 2-X8 (50−100 mesh, Cl^- form) were from Fluka. The OH^- form of the anion resin was obtained from the Cl^- form by elution with 0.3 M NaOH, followed by extended rinsing with CO_2-free water until a neutral eluent was observed. The temperature dependence of the static magnetic susceptibility was measured with a Metronique Ing. MS02 SQUID magnetometer at 1.0 T operating in the range of 2−250 K. The data were corrected for the contribution of the sample holder and for the diamagnetism using Pascal′s constants. The EPR spectrum of a polycrystalline powder sample of $[Cu(trap)_2]Cl_2$ was recorded at room temperature at the X-band frequency with a Varian ESR9 spectrometer.

1,2,3-Propanetriyl Tribenzenesulphonate: A solution of propane-1,2,3-triol (2.30 g, 25 mmol) in 50 ml of dry pyridine was cooled to 0°C using an NaCl/ice bath. Benzenesulphonyl chloride (26.49 g, 150 mmol) was added dropwise over a 1-h period. During that

time, the colour turned to red and a white precipitate appeared. The resulting mixture was stirred overnight at room temperature and then filtered. The red solution was poured with stirring into a mixture of ice (75 g) and concentrated HCl (25 ml). An oily product was obtained from which the aqueous layer was decanted. The oil was dissolved in a mixture of methanol (75 ml) and acetone (12.5 ml) and heated until a yellow solution was obtained. The volume of the solution was reduced to 50% and the product was allowed to crystallise. It was then separated by filtration and washed with 0.5 M HCl and then hot EtOH. After drying in vacuo (12 h, 25°C), the product was obtained as a white solid (7.84 g, 61%). − $C_{21}H_{20}O_9S_3$ (512.6): calcd. C 49.21, H 3.93; found C 49.48, H 3.91. − ^{1}H NMR ($CDCl_3$): δ = 4.13 (d, 4 H, CH_2, J = 5 Hz), 4.75 (quint, 1 H, CH), 7.53−7.58 (m, 6 H, aryl-H), 7.67−7.71 (m, 3 H, aryl-H), 7.81−7.83 (m, 6 H, aryl-H). − ^{13}C NMR: δ = 66.4, 74.6, 128.0, 129.5, 134.3, 134.9.

1,2,3-Triazidopropane: Caution: Organic polyazides are highly explosive. They should only be handled in dilute solutions and should not be isolated as pure substances. 1,2,3-Propanetriyl tribenzenesulphonate (15.36 g, 30 mmol), NaN_3 (9.75 g, 150 mmol) and dry DMF (350 ml) were heated at 100°C for 4 h and stirred at room temperature for additional 14 h. The mixture was cooled to 10°C and diluted with 130 ml H_2O. The orange solution was extracted with Et_2O (6 × 100 ml) and the combined ether extracts were washed with water (2 × 100 ml). The ether solution was dried with $MgSO_4$. For characterisation, only a small sample (5 ml) was separated and set aside until the solvent had evaporated, and a solution of the residual brown oil in $CDCl_3$ was used to measure the NMR spectra. − ^{1}H NMR: δ = 3.40−3.48 (m, 4 H, CH_2), 3.65 (quint, 1 H, CH). − ^{13}C NMR: δ = 51.8, 60.4. − For the preparation of the triamine by method A, the solution of the azide in Et_2O was immediately used without further manipulations, while for method B, the volume of the Et_2O solution was reduced to one half by evaporation at reduced pressure and the resulting solution was then diluted by adding 150 ml of EtOH.

1,2,3-Triaminopropane·3HCl. − Method A: To a suspension of $LiAlH_4$ (8.33 g, 220 mmol) in 500 ml of dry Et_2O, the azide solution obtained from 29.3 mmol of 1,2,3-propanetriyl tribenzenesulphonate was added slowly under gentle reflux, and the mixture was then heated under reflux for another 18 h. After cooling and addition of water (10 ml), 15% NaOH (10 ml) and water (30 ml), the resulting precipitate was extracted for 18 h from a Soxhlet thimble using refluxing isopropyl alcohol (500 ml). After removing the solvent under reduced pressure, EtOH was added to the resulting oil. An excess of 6 M HCl was added to the cooled solution with stirring. The white solid which precipitated was collected by filtration and redissolved in 500 ml of H_2O. The resulting solution, having a pH ≈ 2, was sorbed onto Dowex 50 W-X2. The column was washed with water and eluted with 1 M HCl. The second fraction was concentrated to dryness under reduced pressure yielding 2.59 g (45%) of a white solid. − $C_3H_{14}Cl_3N_3$ (198.5): calcd. C 18.15, H 7.11, N 21.17; found C 18.34, H 6.90, N 20.99. − ^{1}H NMR (D_2O, pD < 2): δ = 3.34−3.40 (m, 1 H, CH), 3.21−3.25 (dd, 2 H, CH_2), 2.95−2.30 (dd, 2 H, CH_2); (pD > 12): δ = 2.68−2.73 (m, 2 H), 2.65−2.66 (m, 1 H), 2.48−2.51 (m, 2 H). − ^{13}C NMR (pD < 2): δ = 45.3, 50.0; (pD > 12): δ = 47.1, 57.1. − *Method B:* The solution of the triazide (obtained from 40.2 mmol of 1,2,3-propanetriyl tribenzenesulphonate) in EtOH/Et_2O and 885 mg of 5% Pd/C were placed in an autoclave. The mixture was hydrogenated at 4.0 bar under vigorous stirring until TLC did not show any remaining starting material. The solution was filtered twice and then cooled. An excess of 6 M HCl was added with stirring. The protocol reported for method A was then used for the isolation of the trihydrochloride. Elution from a Dowex 50 W-X2 column with 1 M HCl yielded 4.42 g (55%) of a white solid. The product was further characterised as $[Co(trap)_2]Cl_3$: trap·3HCl (602.5 mg; 3.04 mmol) was dissolved in water (60 ml) and NaOH (15%) was added until pH = 8 was reached. $CoCl_2·6H_2O$ (0.361 g; 1.52 mmol), dissolved in 60 ml of water, was added and oxygen was passed through the solution at 80°C for 24 h. The mixture was filtered, acidified to pH = 1 (HCl) and diluted with 100 ml of water. The solution was sorbed onto a column of Dowex 50W-X2. Elution with 3.0 M HCl yielded a yellow fraction which was concentrated to dryness. The brown residue (440 mg) was dissolved in water again and sorbed onto a column of SP-Sephadex. Elution with 0.2 M trisodium citrate gave two well-separated bands. A minor red band was discarded. The major orange fraction was desalted on Dowex 50W-X2 and concentrated to dryness. Yield: 272.4 mg (52%). − $C_6H_{22}Cl_3CoN_6$ (343.6): calcd. C 20.98, H 6.45, N 24.46; found: C 20.67, H 6.33, N 22.98. − Single crystals were grown from H_2O/EtOH. A single-crystal analysis revealed the same structure as reported by Henrick et al.[14].

[Cu(trap)$_2$]Cl$_2$: trap·3HCl (400 mg, 2.01 mmol) was dissolved in 25 ml of water and deprotonated using Dowex 2-X8 (OH^- form). The solution was concentrated to dryness under reduced pressure. The oily residue was dissolved in 5 ml of water and a solution of $CuCl_2·2H_2O$ (153.4 mg, 0.9 mmol) in 5 ml of water was then added. Deep blue crystals were grown by layering the solution with EtOH. − $C_6H_{22}Cl_2CuN_6$ (312.7): calcd. C 23.04, H 7.09, N 26.87; found C 23.04, H 6.93, N 26.48.

1,2,3,4-Butanetetrayl Tetrabenzenesulphonate: meso-Erythritol (6.12 g, 50 mmol) and benzenesulphonyl chloride (52.99 g, 300 mmol) were treated in dry pyridine (150 ml) as described above for the preparation of 1,2,3-propanetriyl tribenzenesulphonate. The precipitate was filtered and washed with 0.5 M HCl and then hot EtOH. After drying in vacuo (60°C, 14 h), a white solid was obtained (24.28 g, 71%). − $C_{28}H_{26}O_{12}S_4$ (682.8): calcd. C 49.26, H 3.84; found C 49.26, H 4.06. − ^{1}H NMR ($CDCl_3$): δ = 4.02−4.19 (m, 4 H, CH_2), 4.80 (m, 2 H, CH), 7.53−7.82 (m, 20 H, aryl-H). − ^{13}C NMR: δ = 66.2, 75.7, 128.1, 129.5, 134.3, 134.6.

1,2,3,4-Tetraazidobutane: Caution: Organic polyazides are highly explosive. They should only be handled in dilute solutions and should not be isolated as pure substances. 1,2,3,4-Butanetetrayl tetrabenzenesulphonate (12.16 g, 17.8 mmol) was treated with NaN_3 (6.95 g, 106.9 mmol) in dry DMF (200 ml) as described for 1,2,3-propanetriyl tribenzenesulphonate. The solution turned deep brown and was diluted with H_2O (150 ml), and extracted with ether (4 × 150 ml). The ether extract was washed with H_2O (2 × 200 ml). − ^{1}H NMR ($CDCl_3$): δ = 3.68−3.70 (m, 2 H, CH), 3.55−3.58 (m, 4 H, CH_2). − ^{13}C NMR: δ = 51.9, 61.4.

1,2,3,4-Tetraaminobutane·4HCl: Method B was used. A solution of the tetraazide (obtained from 17.8 mmol 1,2,3,4-butanetetrayl tetrabenzenesulphonate) in EtOH (150 ml) was hydrogenated at 4.0 bar using 300 mg of 5% Pd/C as catalyst. The mixture was worked up as described above and sorbed onto Dowex 50W-X2. Elution with 3 M HCl yielded 2.16 g (46%) of a white solid. − $C_4H_{18}Cl_4N_4$ (264.0): calcd. C 18.20, H 6.87, N 21.22; found C 18.15, H 6.73, N 21.02. − ^{1}H NMR (D_2O, pD < 2): δ = 3.17−3.22 (dd, 2 H, CH_2), 3.37−3.41 (dd, 2 H, CH_2), 3.50−3.54 (m, 2 H, CH); (pD > 12): δ = 2.53 (br., 2 H), 2.68 (br., 2 H), 2.76−2.78 (br., 2 H). − ^{13}C NMR (pD < 2): δ = 43.4, 54.0; (pD > 12): δ = 46.0, 58.3.

1,2,3,4,5-Pentanepentayl Pentabenzenesulphonate: Xylitol (7.61 g, 50 mmol) was treated with benzenesulphonyl chloride (88.31 g, 500 mmol) in dry pyridine (200 ml) as described above for the preparation of 1,2,3-propanetriyl tribenzenesulphonate. Traces of pyri-

dine were extracted with a mixture of ice (300 g) and concentrated HCl (100 ml) and the product was washed with MeOH (150 ml) and acetone (25 ml). Drying in vacuo at 60°C yielded 27.25 g (64%) of a white solid. – $C_{35}H_{32}O_{15}S_5$ (852.9): calcd. C 49.29, H 3.78; found C 49.20, H 3.83. – ^{1}H NMR: δ = 4.00–4.14 (4 H, CH_2), 4.81–4.92 (3 H, CH), 7.27–7.97 (25 H, aryl-H). – ^{13}C NMR: δ = 65.9, 74.0, 74.3 (3 C, aliphatic), 126.0–141.5 (12 C, aryl).

1,2,3,4,5-Pentaazidopentane: ***Caution:*** Organic polyazides are highly explosive. They should only be handled in dilute solutions and should not be isolated as pure substances. 1,2,3,4,5-Pentanepentayl pentabenzenesulphonate (27.25 g, 31.95 mmol) was treated with NaN_3 (16.6 g, 255.6 mmol) in dry DMF (400 ml) as described for 1,2,3-propanetriyl tribenzenesulphonate. The reaction mixture turned deep brown. The solution was diluted with H_2O (430 ml), and extracted with ether (8 × 200 ml). The ether extracts were combined and washed with H_2O (6 × 150 ml). – ^{1}H NMR ($CDCl_3$): δ = 3.60–3.68 (m, 7 H). – ^{13}C NMR: δ = 51.5, 61.1, 63.1.

1,2,3,4,5-Pentaaminopentane·5HCl: 1,2,3,4,5-Pentaaminopentane·5HCl was prepared using Method B. A solution of the pentaazide (obtained from 31.95 mmol of 1,2,3,4,5-pentanepentayl pentabenzenesulphonate) in EtOH (150 ml) was hydrogenated at 4.0 bar using 404 mg of 5% Pd/C as catalyst. The mixture was worked up as described above and sorbed onto Dowex 50W-X2. Elution with 3 M HCl yielded 2.27 g (22%) of a white solid. – $C_5H_{22}Cl_5N_5$ (329.5): calcd. C 18.22, H 6.73, N 21.25; found C 18.33, H 6.62, N 21.01. – ^{1}H NMR (D_2O, pD < 2): δ = 3.34–3.39 (2 H), 3.46–3.49 (2 H), 3.51–3.52 (1 H), 3.79–3.83 (2 H); (pD > 12): δ = 2.56 (br., 3 H), 2.76 (br., 4 H). – ^{13}C NMR (pD < 2): δ = 43.4, 53.2, 54.1; (pD > 12): δ = 47.2, 56.9, 57.1.

Potentiometric Measurements: Potentiometric titrations were carried out with a Metrohm 713 pH/mV meter and a Metrohm combined glass electrode with an internal Ag/AgCl reference. The sample solutions were titrated with 0.1 M KOH, using a Metrohm 665 piston burette. The ionic strength of the 50-ml sample solutions was 0.1 M KCl or 0.1 M KNO_3 and the stability of the electrode was checked by two calibration titrations prior to, and after, each measurement. All titrations were performed at 25.0°C under nitrogen (scrubbed with an aqueous solution of 0.1 M KCl or 0.1 M KNO_3). The measuring time per point was 2 min for the pK_a determinations, 5 min for the Cu complex solutions and 10 min for all other metal complexes. For the pK determination of trap, tab and pap, several alkalimetric titrations were carried out with analytically pure samples of the corresponding hydrochlorides (total concentration: 2×10^{-3} M or 1×10^{-3} M). Solutions for the titration experiments of $[M(trap)]^{2+}$ and $[M(trap)_2]^{2+}$ were prepared by dissolving trap·3HCl and $M(NO_3)_2$ (M = Cu, Zn, Cd) or $NiCl_2$ in a 1:1 and 1:2 molar ratio with total M = 1.0×10^{-3} or 0.5×10^{-3} M. The solutions were made up by using standardised aqueous stock solutions of $NiCl_2$, $Cu(NO_3)_2$, $Zn(NO_3)_2$ and trap·3HCl and solid $Cd(NO_3)_2·4H_2O$.

Calculations of Equilibrium Constants: All equilibrium constants were calculated as concentration constants. The pK_a values of the ligands and the formation constants of the metal complexes were calculated using the computer program SUPERQUAD[28] and double-checked with the computer program BEST[29]. The formation constants were evaluated with fixed values for the total concentrations of the reactants and for pK_w (13.79)[23]. For the evaluation of the titration experiments of the metal complexes, only the formation constants of the metal-containing species were varied and fixed values were used for the total concentrations of M, trap, and H, and the protonation constants of trap as obtained from the pK_a determination.

Crystal-Structure Determination of tab · 4HCl · H_2O[30]: Data were collected at 253 K with a Stoe IPDS diffractometer using monochromated Mo-K_α radiation. 220 exposures were taken in the 0–220° φ range with a crystal-to-detector distance of 72 mm and an exposure time of 2 min. Monitoring of control reflections during data collection indicated no crystal decay during the measurement. Corrections were made for Lorentz and polarisation effects. An absorption correction was not performed. The structure was solved using Direct Methods[31] and refined by full-matrix least-squares calculations[32] on F^2. All non-hydrogen atoms were refined using anisotropic displacement parameters. The hydrogen atoms were located in a difference Fourier map. Atomic coordinates and isotropic displacement parameters were refined free for all ammonium H atoms. All H atoms belonging to CH and CH_2 groups were refined riding on their C atom with isotropic displacement parameters set to 1.2 and 1.3 times the U_{eq} of the corresponding C atom, respecively. The coordinates and isotropic displacement parameters of the H atoms at the water molecule O1w were refined free, while the O–H distances in O2w had to be restrained to one common value. Further details are summarized in Table 3.

Crystal-Structure Determination of [Cu(trap)$_2$]Cl$_2$[33]: Data were collected with a Siemens P4 diffractometer using monochromated Mo-K_α radiation. Intensities were measured by ω scans. Monitoring of control reflections during data collection indicated no crystal decay during the measurement. Corrections were made for Lorentz and polarisation effects. An absorption correction was not performed. The structure was solved using Direct Methods[31] and refined by full-matrix least-squares calculations[32] on F^2. The value

Franz Fehér (1903−1991): A Personal and Professional Portrait

On February 16, 1991 − shortly after his 88th birthday − Dr.-Ing. Franz Fehér, retired full professor of inorganic chemistry at the University of Cologne, passed away after a brief illness. This came as a great surprise to his friends, colleagues, and the large group of his former students. His death interrupted an active and practical interest in chemistry and terminated a life dedicated to science. He himself was presumably not expecting his life to end so suddenly as he had numerous plans for further publications, papers that will now remain unwritten.

In the mean time more than half a decade has passed and it is now opportune and possible to present an objective laudatio about the life and scientific achievements of this personality in inorganic chemistry − a man who made a significant contribution to the renaissance of the chemistry of non-metals after the Second World War.

Childhood, Adolescence, and University Education

Franz Fehér's life was decisively influenced by his origins as well as the political and economic events of this century. He was born on January 22, 1903 in the small town of Szentamas in southern Hungary as the third of five children. His father, a member of the Hungarian ethnic group, a mechanical engineer and businessman, owned a company dealing in agricultural machinery. His mother, maiden name Sieler, belonged to the German ethnic group that settled there in the 18th century. Together with two brothers and two sisters he enjoyed his childhood in a happy, natural family atmosphere. However, this free and easy life came to an end at the age of ten years when he entered a boarding school (Humanistisches Gymnasium) in the county town of Neu-Verbas and could only return home during the school holidays. He had no problems with his school education and, although good in all subjects, mathematics and natural sciences attracted his attention the most. In later conversations he occasionally mentioned his everlasting gratitude to his mathematics teacher.

The First World War began during his high school time, the further course of which led to enormous changes in this part of eastern Europe. At the end of the war in 1918 south Hungary became part of the newly formed kingdom of Serbia, Croatia, and Slovenia, the recently disintegrated Yugoslavia. This meant that his home town was renamed Srbobran and that the language in his school, previously Hungarian, changed to Serbian. In spite of these difficulties Franz Fehér mastered the last three years of high school and left it in June 1921 at the age of 18 with an excellent certificate of education (Reifezeugnis). With this he had made a decisive step towards fulfillment of his long held dream to read chemistry in Germany. This choice of subject was without doubt based on his proficiency for both abstract scientific thought and practical work with his hands.

During his search for a suitable place to study he was given the rather misleading advice from the German embassy in his country that one could read chemistry in Germany at a technical university (Technische Hochschule) − but not with the additional information that one could also read chemistry at a normal university albeit without the possibility of receiving a Diploma certificate. Thus, in the

winter semester of 1921/1922 Franz Fehér registered at the Technische Hochschule Hannover where Wilhelm Biltz was director and professor of inorganic chemistry. However, it was the year 1921 and veterans of the First World War were still seeking admission to higher education, especially since possibilities in other occupations were scarce because of the economic situation prevailing at that time. Hence, Wilhelm Biltz regretfully had to inform Franz Fehér at the beginning of the first semester that he could not provide a laboratory place and that the waiting time for one was uncertain. The young student, therefore, could only attend the basic lectures in chemistry and physics while applying for admission to other technical universities.

He was finally accepted by the Technische Hochschule Stuttgart for the summer semester 1922 where he continued his education with practical instruction in inorganic chemistry. Here he also attended, among others, lectures on experimental inorganic chemistry by A. Gutbier, organic chemistry by W. Küster, and physical chemistry by G. Grube. In July 1925, after only seven semesters (including a Diploma thesis on an electrochemical topic under the supervision of G. Grube) he successfully completed the first stage of his chemical education and obtained his Diploma certificate. But then his financial resources were at an end; money transferred from home became worthless from one day to the next on account of the galloping inflation in Germany at that time. Thus Franz Fehér was forced to interrupt his further scientific education for two years and to take up a teaching position for mathematics, physics, and chemistry at the Oberrealgymnasium (state high school) in his home town.

In autumn of 1927 he returned to Technische Hochschule Stuttgart to prepare a doctoral thesis under the supervision of A. Simon at the Institute of Inorganic Chemistry. His thesis entitled "Beiträge zur Kenntnis der Mangandioxydhydrate und der Manganoxyde" (Contributions to the Chemistry of Manganese Dioxide Hydrates and Manganese Oxides) was awarded the Gutbier prize of the Technische Hochschule Stuttgart. In spite of the two-year break he received the title Dr.-Ing. (graded excellent) at the age of 26.

Even during this post-graduate work, Franz Fehér's special ability to successfully solve experimental problems by the design and construction of original but simple apparatus became apparent. For example, for tensiometric investigations on various manganese oxides he developed a novel, automatic cryostat for low temperature work. A short while later this system was also used by E. Zintl and W. Klemm and reported to work very reliably. Investigations on the vapor tension curve and isobaric degradation of manganese heptoxide presented particular challenges. First of all, the preparation of the pure, highly explosive compound Mn_2O_7 in preparatively useful amounts was decisively improved. Furthermore, Franz Fehér invented a new method to measure small pressures by remote monitoring since, as he wrote, being present in the room for the accurate measurement of small pressures during the thermal treatment of manganese heptoxide proved to be highly hazardous just on account of the explosive nature of the substance. With the developed system the required pressure measurements could be made safely in a different room, at a safe distance from the decomposition apparatus.

After receiving his doctor's degree Franz Fehér participated in several research projects of his supervisor and during this time decided to follow a career in the university. At the same time he was involved in teaching at the inorganic institute in Stuttgart, first as a Hilfsassistent ("temporary assistant") and then as an Außerordentlicher Assistent ("associate assistant"). In a later conversation he once explained the significance of the latter position: during the worldwide economic crisis of 1931, many ex-students of the institute who had taken up positions in industry were dismissed by their companies and sought to return to the technical university. In order to help this group of people the planmäßigen Assistenten-Stellen ("regular assistant positions") were first divided into two and then even into four part time positions. Thus, Franz Fehér's times of financial restraint were not yet finished. As Praktikums-Assistent ("assistant in a laboratory course") he met the chemistry student Magdalena Fischer from Temesvar in Rumania who, from her father's side, belonged to the German ethnic group there. They were married in September 1931. In April of the same year he had taken on the Germany nationality. From the point of view of his home country, this meant that he had evaded his military service obligations, a serious offence. Accordingly, he was never able to return home again and later even avoided any trips to the former German Democratic Republic for fear that he could be extradited from there to Yugoslavia.

The Years in Dresden and Göttingen

In 1932 Franz Fehér accompanied A. Simon to the Technische Hochschule Dresden as Planmäßiger Assistent ("full assistant"). Here, the couple moved into a modest apartment belonging to the institute where their three daughters Magda (born in 1935), Therese (born in 1937), and Franziska (born in 1942) spent their first years of childhood.

The ten years in Dresden served first of all to survey the field of inorganic chemistry for an independent research area with a clear potential for development. Already during his time in Stuttgart, shortly after the discovery of the Raman effect in 1928, Franz Fehér had carried out first studies on the use of Raman spectroscopy to solve constitutional problems in the chemistry of non-metals. These investigations were continued in Dresden − at first in cooperation with A. Simon. For the oxo-acids of phosphorus and arsenic, the constitutions of which were a subject of controversy in the literature at that time, it was possible with the help of the Raman spectra to provide unambiguous answers to the questions as to whether and which of these anhydrous acids existed in the "aci-" or "pseudo"-form. In addition, direct information on the question of the bonding of hydrogen to the central non-metallic atom was obtained. Further work was concerned with constitutional problems of orga-

nometallic compounds. A major topic of interest from the middle of the 1930's on was the elucidation of the constitution of hydrogen peroxide and its derivatives for which at that time a Y-shaped structure with a double bond between the two oxygen atoms was assumed. Since infrared spectroscopy was then just at the beginning of its instrumental development, Raman spectroscopy was the method of choice for the solution of these constitutional questions. In addition, X-ray crystallography, the evaluation procedures for which were still also in their infancy and very laborious, was included in the investigations. A decisive prerequisite for these investigations was the often difficult synthesis of the required compounds in a pure state such as, for example, 100% hydrogen peroxide or deuterium peroxide and their preparation for crystal structure analyses. Thus, for example, single crystals of pure hydrogen peroxide were grown in the cold room of a slaughter house in Dresden. The investigations on hydrogen peroxide in which the constitutional and conformational analogies to hydrazine were demonstrated unequivocally resulted in the award of the title Dr. Ing. habil. (Habilitation) in 1938 and shortly thereafter to the "venia legendi" (authorization to hold lectures) for the subjects inorganic and analytical chemistry. They were further honored in 1941 by the award of the Carl-Bosch Prize from the former I. G. Farbenindustrie.

Even so, Franz Fehér could not continue his work at the university without interruption. Between 1935 and 1939 he was drafted to attend several training courses for the German army and took part in the operations against Poland at the beginning of the 2nd World War. Subsequently, however, within the framework of the Osenberg plan intended to protect young university lecturers and to ensure the continuation of research after the war period, he was declared an indispensable person and so could return to the Technische Hochschule Dresden. As assistant lecturer he managed the laboratory courses in quantitative analysis and preparative inorganic chemistry and held courses on the theory of chemical bonding as well as the basic principles of Raman spectroscopy and X-ray crystallographic analysis. He was generally admired and respected by his students not only because of his quiet, friendly and helpful nature but also for his extensive knowledge; he was known throughout the institute as Uncle Franz. During this time he took on a new field of interest, the acyclic sulfur compounds and above all the higher homologues of hydrogen sulfide. Continuation of this work in Cologne later led to the complete characterization of the series of sulfanes H_2S_n and chlorosulfanes S_nCl_2 up to the corresponding octasulfanes ($n = 8$) by Raman spectroscopy. These results are still to be found in all textbooks of inorganic chemistry.

In 1942 Franz Fehér was invited by Adolf Windaus to join the department of inorganic chemistry in the chemical institute at the University of Göttingen as senior assistant. He could not resist this opportunity to experience a *university* chemical institute where, according to the prevailing traditions, inorganic chemistry was only represented by a department. In the stimulating atmosphere of the institute directed by Adolf Windaus, Franz Fehér was able to continue his studies of acyclic sulfur compounds on a broader basis. In 1944 he was appointed Außerplanmäßiger Professor. Franz Fehér gained many lasting impressions from the vital scientific atmosphere of the science faculty in Göttingen. Above all, he encountered Adolf Windaus whom he admired not only as a university teacher and scientist but also as an impressive personality who served as an ideal for the rest of his life. In later conversations he often mentioned that he considered Adolf Windaus to be his truely academic teacher. During this time and with an increasing group of coworkers the Raman spectroscopic investigations on sulfanes were consequently expanded by the development of new preparative approaches as well as methods for the analytical and physicochemical characterization of the individual homologues. In spite of the difficult working and living conditions during the World War II and immediate post-war years, the seven years in Göttingen were among the most fulfilling and molding in Franz Fehér's life.

Cologne

On September 1, 1949 Franz Fehér took up the position as extraordinary professor of inorganic and analytical chemistry and head of the department of inorganic chemistry in the Institute of Chemistry of the University of Cologne. Here he faced the task of rebuilding the teaching and research facilities whose apparatus had mostly been lost during the war. Furthermore, at the beginning of the winter semester of 1949/1950 he found a long queue of prospective students waiting in front of his office, all wanting to apply for a laboratory place. Remembering his own problems at the start of his academic life, he did everything possible to help: he also held practical courses in the semester holidays, gave lectures on experimental inorganic chemistry twice a day in addition to his lectures on analytical chemistry and special inorganic chemistry.

In spite of this heavy teaching load during the first years in Cologne his research interests were not neglected. The studies of acyclic sulfur compounds started in Dresden and continued in Göttingen were systematically expanded in several directions with the help of an increasing number of coworkers. One of the questions addressed was whether, in analogy to the sulfanes, H_2S_n, other series of the compounds of the general formula S_nX_2 with skeletons made up of chain-linked sulfur atoms would exist. If so they could be considered as derivatives of the corresponding parent compounds H_2S_n and would provide possibilities for new synthetic approaches to widely differing sulfur compounds having ring and chain skeletons. Of particular interest in this context were the halosulfanes and especially the chlorosulfanes, S_nCl_2. Up till then only the compounds SCl_2 and S_2Cl_2 were known with the constitution of the latter still being uncertain. A second field of interest was the parent compound series H_2S_n with the objectives of finding new methods of synthesis and optimizing those already developed for the individual homologues. The actual purpose

behind these investigations was to achieve a practically complete spectroscopic and physicochemical characterization of these new compounds for which appropriate amounts of highly pure substances were needed. Finally, the investigations of open-chain sulfur compounds were systematically expanded to include elemental sulfur.

In the work on chlorosulfanes evidence for the existence of compounds more rich in sulfur than S_2Cl_2 was obtained in the so-called "hot-cold" tube. In this process S_2Cl_2 was allowed to react with hydrogen at 860−875°C: HCl was eliminated and the formed products were shock cooled to room temperature. In this way orange-yellow oils with the sum compositions $S_{20}Cl_2$ to $S_{24}Cl_2$ were obtained. Raman spectroscopic examinations showed that these oils consisted mainly of mixtures of higher homologous sulfur chlorides with varying chain lengths. A major breakthrough was the discovery of a preparatively more simple and more efficient method of synthesis on the basis of the observation that, under suitable conditions, the sulfanes H_2S_n undergo condensation reactions with S_2Cl_2 or SCl_2 with quantitative elimination of HCl to furnish more sulfur-rich members of the homologous series. Since the primarily formed molecules could also react similarly with elimination of HCl and chain lengthening, chlorosulfane mixtures with an average composition of S_xCl_2 were obtained from which pure S_3Cl_2 and S_4Cl_2 as well as highly enriched S_5Cl_2 were isolated by short-path, high vacuum distillation. The concentrations of all occurring molecules in dependence on the molar ratios of the starting materials were deduced by considering the kinetics of the reactions. By use of a large excess of the chlorosulfane component subsequent reactions of the primary products were suppressed so that, after removal of the excess, formula-pure higher chlorosulfanes were obtained directly. In this way sulfur-rich homologues up to S_8Cl_2 were prepared by reaction of H_2S_n with excess S_mCl_2 and subsequent removal of unconsumed chlorosulfane (Scheme 1).

Scheme 1. Preparation of chlorosulfanes

$$Cl{-}S_m{-}Cl + H{-}S_n{-}H + Cl{-}S_m{-}Cl \xrightarrow[-2\ HCl]{} Cl{-}S_{2m+n}{-}Cl$$

$m = 1, 2;\ n = 1, 2, 3, 4$

The same synthetic concept was then applied to higher members of the sulfane series itself. Of these, the compounds H_2S_2 to H_2S_6 had been prepared during the work in Göttingen from the "crude sulfane" obtained, in turn, by acidic decomposition of an aqueous solution of sodium polysulfide. With this new access at hand, the compounds H_2S_5 and H_2S_6 were prepared in high purity and, furthermore, the higher homologues H_2S_7 and H_2S_8 were also obtained.

This same synthetic route also provided an access to widely differing sulfane *derivatives*. Thus, condensation of sulfanes with chlorosulfonic acid resulted in the formation of sulfanemonosulfonic acids, $H_2S_nO_3$, reaction of which with chlorosulfanes gave the sulfur-rich sulfanedisulfonic acids (polythionic acids) $H_2S_nO_6$. In this way the free octa-, nona-, deca-, undeca-, and dodecathionic acids were prepared for the first time as oily liquids that were stable at lower temperatures (Scheme 2).

Scheme 2. Synthesis of sulfanemonosulfonic acids and sulfanedisulfonic acids (polythionic acids)

$$H{-}S_{n\text{-}1}{-}H + Cl{-}SO_3H \xrightarrow[-HCl]{} H{-}S_{n\text{-}1}{-}SO_3H$$

$$HO_3S{-}S_{n\text{-}1}{-}H + Cl{-}S_m{-}Cl + H{-}S_{n\text{-}1}{-}SO_3H \xrightarrow[-2\ HCl]{} HO_3S{-}S_{2(n\text{-}1)+m}{-}SO_3H$$

In addition, the already known diorganyl polysulfides R_2S_n, although their constitutions at that time had not been clarified with certainty, were prepared by an analogous route as were also some new representatives of this compound class. Investigations of their properties (see below) then unequivocally confirmed their identity as organo-substituted sulfanes with unbranched sulfur chains. The synthesis of "perchlorodimethyl tetrasulfide" ($Cl_3CS_4CCl_3$) from Cl_3CSCl and H_2S_2 and the determination of its structure by Raman spectroscopy can be mentioned as a typical example of these efforts. A large range of unsymmetrically substituted sulfane derivatives of the type RS_nCl and RS_nH was prepared by reaction of excess chlorosulfane or sulfane, respectively, with monofunctional compounds such as RSH, R_2NH, and RS_mCl.

Attempts to transfer the chlorosulfane synthesis to the corresponding pure bromosulfanes S_nBr_2 ($n > 2$) were not successful since the excess of dibromodisulfane S_2Br_2 remaining, on account of its high boiling point, could not be removed at the completion of the condensation without decomposition of the formed higher homologues. However, the preparation of practically pure, sulfur-richer bromosulfanes up to S_8Br_2 were possible by reaction of the corresponding chlorosulfane with hydrogen bromide.

Raman spectroscopic investigations of the already long known compounds $S(CN)_2$, $(SCN)_2$, $S(SCN)_2$, and $S_2(SCN)_2$ led to their recognition as the starting members of a homologous series of cyanosulfanes $S_n(CN)_2$ and the series was extended up to $S_8(CN)_2$ (Scheme 3).

Scheme 3. Synthesis of sulfur-rich cyanosulfanes

$$Cl{-}S_n{-}Cl + Hg(SCN)_2 \xrightarrow[-HgCl_2]{} NC{-}S_{n+2}{-}CN$$

$n = 3-6$

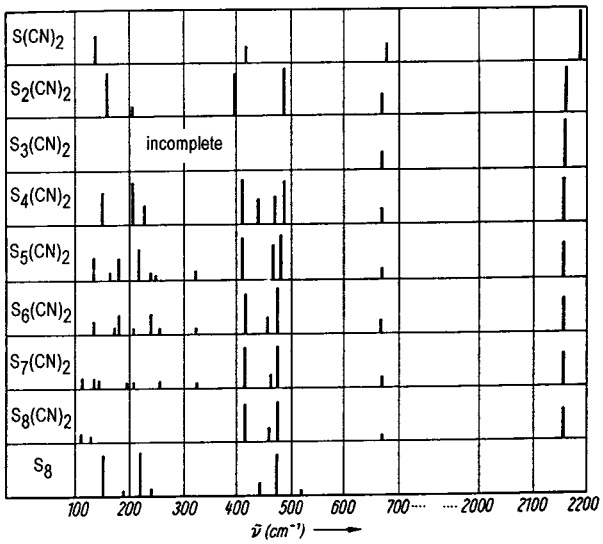
The electrolytic reduction of aqueous SO_2 solutions as a means to obtain larger amounts of sulfane mixtures with average compositions of H_2S_8 to H_2S_{13} was studied intensively. After clarification of the electrode processes a laboratory apparatus was developed that allowed, under continuous operation and good current yield, the simultaneous cathodic preparation of sulfane oils and the anodic production of ammonium peroxodisulfate.

The alkali metal compounds $M^I_2S_n$ were also included in the investigations as *sulfane derivatives* and detailed studies on the various anhydrous polysulfides in the systems sodium−sulfur, potassium−sulfur, rubidium−sulfur, and cesium−sulfur were carried out.

In all of the classes of compounds investigated, Franz Fehér's main target was not merely the preparation of new substances; spectacular momentary successes were not the driving force of his work. Rather, his interest was always directed towards the comprehensive exploration of a new area in inorganic chemistry. This objective required intensive structural and physicochemical characterization of the newly prepared compounds, aspects that played a decisive role in the scientific work of Franz Fehér.

Elucidation of the constitutions of the sulfanes and their various derivatives was based mainly on the results from Raman spectroscopy. As an example, the Raman spectra of the cyanosulfanes $S_n(CN)_2$ (n = 1−8) are depicted in Figure 1. These spectra show that the respective substances are chemically individual species without any traces of physically dissolved elemental sulfur. The appearance of an individual spectrum is always characteristic for the respective number of chain-linked sulfur atoms in the molecular skeleton. Electronic spectra of the various classes of compounds were also investigated systematically and discussed on the basis of Kuhn's electron gas model. These results indicated that, in addition to normal σ-bonding, delocalized π electrons were also present in the sulfur chains.

Figure 1. Raman spectra of cyanosulfanes $S_n(CN)_2$ (n = 1−8) and of S_8



The individual compounds among the metal polysulfides were studied by X-ray methods and characterized on the basis of their powder diagrams while single crystal X-ray structural analyses of the cyanosulfanes were carried out.

The physicochemical properties of the sulfanes and chlorosulfanes were subjected to extensive studies in particular regard to the constitutions of the individual compounds. It was found that the molar volumes, molar fractions, molar enthalpies of evaporation, and the logarithms of the viscosity were linear functions of the length of the sulfur chain and that no branched chain skeletons were present. For the sulfanes H_2S_2 to H_2S_5 the boiling points and critical data were also estimated by means of vapor pressure measurements. Furthermore, the heats of decomposition of the catalytic degradation into hydrogen sulfide and sulfur were measured by calorimetry and the data used to determine the enthalpies of formation for the individual homologues up to H_2S_6. The respective values for the formation of *liquid* sulfanes from the elements in their standard states are all negative; their absolute values decrease linearly with increasing number of sulfur atoms. On the other hand, all sulfanes are metastable towards a decomposition to hydrogen sulfide and sulfur at room temperature. Their existence can be attributed to a relatively high activation barrier of the decomposition reaction which was determined to be about 25 kcal/mol for H_2S_2.

Very early in the course of these comprehensive investigations on various classes of compounds with chains of sulfur atoms, Franz Fehér recognized the many relations to the chemistry of open-chain hydrocarbons. Aside from this he had always considered the molecular chemistry of the nonmetals as a single topic and did not draw any arbitrary boundaries between inorganic and organic chemistry in his research work. His efforts to clearly express the analogies between the compounds H_2S_n and the n-alkanes C_nH_{2n+2} in the nomenclature by replacement of the then usual terms with the name "sulfanes" become understandable in this light. This results in the names "disulfane" (H_2S_2), "trisulfane" (H_2S_3) and so on for the individual homologues. This nomenclature system also clearly shows the genetic relationships between the compound classes H_2S_n, S_nX_2 (X = halogen, monofunctional group), S_nR_2 (R = alkyl, aryl), and $M^I_2S_n$ and has now been widely accepted by the chemical community. As a direct consequence, "cross-products" of sulfanes and alkanes, in particular compounds with the general formula $RS(CH_2S)_nR$ − termed "bunte" sulfanes in Fehér's laboratory − were investigated. A series of thiaalkanes was then prepared and their properties determined for the first time.

The studies on sulfur-chain compounds prompted Franz Fehér in the mid 1950's to take up an intensive investigation of elemental sulfur. It was found that many of the older results on the properties of molten sulfur were not correct since the samples investigated were of insufficient purity. Thus Fehér's group developed methods for the purification of sulfur by electrophoretic means and especially by zone melting; that latter has proved to be very suitable for obtaining highly pure sulfur. In the course of this work, the then usual analytical methods for detecting small amounts of carbon and other contaminants in sulfur had to be improved considerably. Using the thus obtained and characterized pure samples, the temperature dependence of the density and specific heat of molten sulfur in the range 120 to 400 °C was measured. Both parameters also exhibited anomalies in the region of the known viscosity increase and these were discussed in terms of the processes occurring in liquid sulfur (cleavage of S_8 rings and formation of longer S_x chains). Furthermore experiments on the electrical conductivity of molten sulfur were performed and the mecha-

nism of charge transport elucidated on the basis of these data.

In the second half of the 1950's as a supplement to the continuing work on sulfur and its compounds, increasing interest was directed to studies on the higher silicon and germanium hydrides as well as the chemistry of hydrazine and its derivatives as new research topics. In the planning of his scientific work, Franz Fehér was never influenced by current mode topics or predetermined research projects but always followed his own scientific ideas. He viewed the development and work of a scientist to be closely analogous to that of an artist. After completing her doctoral thesis and a few years of postdoctoral work in the field of sulfur chemistry, the present author asked her supervisor if he thought her abilities were sufficient for a Habilitation. After a short pause he answered "I have heard that you want to be an opera singer, then go ahead and sing" and then added the phrase "but please not on the sulfur stage!" This meant: a successful Habilitation cannot in general be predicted; it depends on the further "vocal" development and the continuing desire to "sing" in spite of the monotonous daily practicing. This example illustrates Fehér's love for colorful language that often surprised his listeners with unexpected comparisons and metaphors but always correctly reflected the topic of the conversation. The additional phrase was intended to avoid future competition between different groups in the same institute but, above all, it provided the possibility for his former student to attain an independent image in the scientific community at an early stage in her career.

In the year 1958 chemistry in Cologne experienced a drastic change accompanied by numerous new tasks for Franz Fehér . On June 20 the director of the chemistry institute of the university, the Nobel prize winner Kurt Alder died at the age of only 55 and left behind a research group consisting of over 40 diploma and doctoral students. Franz Fehér was appointed deputy director and head of the entire institute by the faculty of mathematics and sciences. It was of major importance for him that not even one of Alder's students should suffer any personal loss in his or her further education. Although the diploma students were able to move to other groups within a short time, conclusion of the doctoral thesis projects already in progress proved to be a serious problem. The scientific supervision was continued by the extraordinary professor of organic chemistry, Leonhard Birkofer and Alder's assistants. However, Kurt Alder had only been able to finance such a large research group with the help of considerable external research funds which all stopped suddenly with his death. Thus, it was essential to persuade the managers of the various sources that financial support of Alder's work was necessary for about two years more. This meant numerous applications, accountings, and reports as well as taking on the full responsibility for the use of the then personally granted research funds. Franz Fehér was fully rewarded for his efforts when, two years later, the last of Alder's postgraduate students completed his thesis and oral examination without requiring any extra time.

In spring of 1960 Franz Fehér was offered the position of full professor and director of the institute for inorganic chemistry at the university of Hamburg. This was not an easy decision for him. New buildings for the chemical institute were to be built both in Hamburg and Cologne. In Hamburg, completion of the buildings in 1965 was expected although land ownership problems still had to be solved whereas concrete building plans were already in existence in Cologne. As had already happened in other chemical institutes in Germany, the faculty for mathematics and sciences in Cologne decided under the given circumstances to divide the chemical institute into two separate institutes, one for inorganic and one for organic chemistry and started negotiations with Franz Fehér to keep him in Cologne. Decisive criteria for Franz Fehér were the working conditions for the eleven years remaining until his retirement. After careful consideration of the starting situations for the two building projects he decided in August 1960 to remain in Cologne and was appointed full professor and director of the newly founded institute for inorganic chemistry in 1961. It was one of the biggest disappointments in his life that he could only move into the new building in 1975 as retired professor while the buildings in Hamburg were indeed completed by 1965. Even so, being fully aware of his responsibilities to the future working conditions in his discipline, he spent a major part of his last decade as institute director with detail planning and supervision of the new buildings for the inorganic institute and the common lecture rooms.

The scientific work on the various research topics continued in this period with unchanged élan. Work with the higher silicon and germanium hydrides demanded new inert gas techniques to allow handling of these air- and moisture-sensitive compounds − in contrast to the classical Stock methods − also outside of closed systems. Fehér reported on the respective developments for the first time at the IUPAC congress in Munich in 1959. His experience in handling spontaneously inflammable substances was indeed in demand and led to numerous consultations with the chemical industry on similar problems. Apart from these new research interests, the chemistry of the sulfanes and their derivatives was systematically expanded with particular emphasis at this time on the development of synthetic routes to novel heterocyclic sulfur compounds.

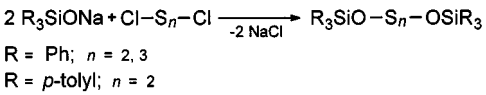
With such widely divergent activities words such as "holidays" or "relaxation" were more or less unknown to Franz Fehér. Only his enjoyment of driving was occasionally satisfied in car journeys to the Alps or Italy with his Munich colleague Walter Hieber. Even during the years in Dresden Franz Fehér was a passionate motorcyclist who would make a short trip to the Baltic coast over the weekend − which for assistants in those days only began on Saturday afternoon − and return punctually to the institute on Monday morning. After the interruption of the war and immediate post-war years, the purchase of his first car, a Volkswagen, at the beginning of the 1950's was a major event. As

well as the joy of driving, the response of the machine to the driver's actions was always a source of pleasure for the son of a mechanical engineer. However, he could also relax in the circle of his coworkers during occasional celebrations.

With the improved working conditions of the inorganic chemistry institute the investigations on open-chain and cyclic sulfur compounds were consequently expanded. In the case of *sulfane derivatives*, the enthalpies of formation of the chlorosulfanes S_nCl_2 ($n = 2-5$) were determined by calorimetric measurements of the chlorination reactions. The corresponding values were then estimated for the higher homologues up to S_8Cl_2 on the basis of the linear dependence of the values on the length of the sulfur chain. Together with the already known enthalpies of formation of the sulfanes H_2S_n the thermal requirements of the various condensation reactions between sulfanes and chlorosulfanes thus became available.

In this period, however, the main interest in sulfane chemistry was directed towards the preparative investigation of new series of compounds containing chains of sulfur atoms; these were mainly synthesized by condensation of a chlorosulfane with an appropriate monofunctional, nonmetal compound. Examples are the preparation of bis(imidazolyl)sulfanes as well as bis(triorganosilyl)- and bis(triorganosiloxy)sulfanes (Scheme 4).

Scheme 4. Synthesis of bis(imidazolyl)sulfanes, bis(triorganosilyl)-sulfanes, and bis(triorganosiloxy)sulfanes

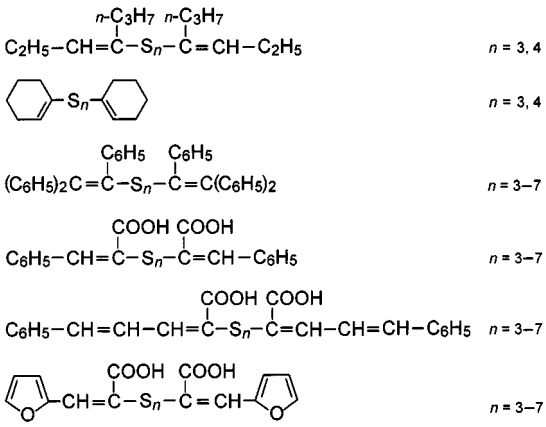


Compounds with a C=C bond directly adjacent to the sulfur chain were obtained by reactions of α,β-unsaturated mercaptans (enethiols) with chlorosulfanes. The UV spectra of these bis(enethiol)sulfanes (Scheme 5) reveal a conjugation effect of the S_n chain that is larger than the substituent effect of a *single* sulfur atom but markedly smaller than that of C=C bonds.

When the chlorosulfanes in these reactions are replaced by the bis(chlorodisulfanyl)alkanes, $ClS_2-(CH_2)_y-S_2Cl$ ($y = 1-5$) obtained from the reaction of dithiols with SCl_2, a new "crossed-type" product from alkanes and sulfanes is obtained. In the compound $Ph_3Si-S_3-(CH_2)_5-S_3-SiPh_3$ obtained from the reaction of the pentane derivative with Ph_3SiSNa the silyl groups are linked by an eleven-membered heteroatom chain.

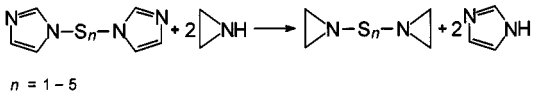
Specific synthetic routes have also been developed for particular substance classes. Thus, Fehér and his group

Scheme 5. Bis(enethiol)sulfanes prepared



found that the bis(aziridinyl)sulfanes $(C_2H_4)-N-S_n-N(C_2H_4)$ ($n = 1-5$), only difficulty accessible via the trimethylsilyl derivative of ethyleneimine according to Scheme 4, can be obtained by smooth transfer of the sulfur chains of the corresponding bis(imidazolyl)sulfanes to ethyleneimine (Scheme 6).

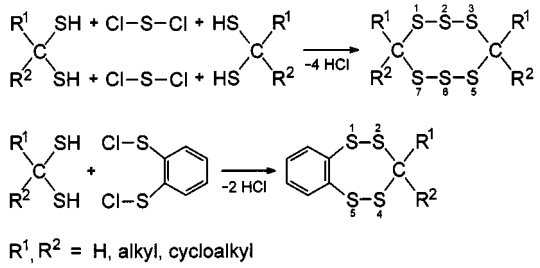
Scheme 6. Synthesis of bis(aziridinyl)sulfanes



In the mid 1960's systematic investigations on a further aspect of sulfur chemistry, heterocyclic compounds containing directly linked sulfur atoms, were started. A major topic of interest for the inorganic chemist in this field were those compounds in which the individual atoms of homocyclic sulfur rings have been replaced by other bifunctional, nonmetallic groups. When these are organic units the products are the cyclocarbasulfanes. Fehér and his coworkers found that this class of compounds could, in general, be accessed by reactions of the appropriate dithiols with chlorosulfanes of varying chain lengths with the cyclocondensation being favored over polymerization by application of the Ruggli−Ziegler dilution principle. The first representative of the series S_nCH_2 to be prepared was a derivative of the S_8 ring, heptathiocane, S_7CH_2 with a crown-like eight-membered ring, from the reaction of dichloropentasulfane with methanedithiol. By analogous reactions, hexathiepane (S_6CH_2), pentathiane (S_5CH_2, with a six-membered ring analogous to that of cyclohexane), tetrathiolane (S_4CH_2), and undecathiacyclododecane (monocarbacyclododeca-sulfane, $S_{11}CH_2$) were then prepared in the pure states. *C*-Alkyl-substituted derivatives of the corresponding ring systems were obtained by use of other *geminal* aliphatic dithiols. Furthermore, sulfur rings containing two or − by reaction of the dithiols with 1,2-bis(chlorosulfanyl)benzene − also three carbon "heteroatoms" such as 1,2,3,5,6,7-hexathiocane or

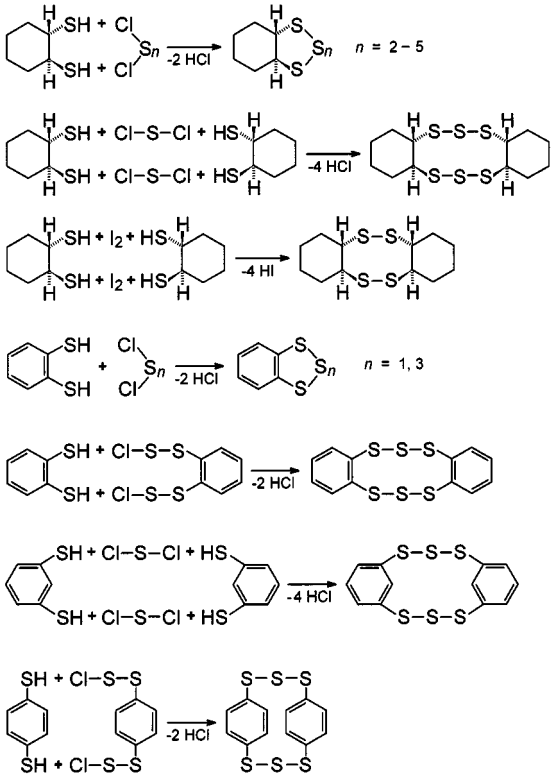
1,2,4,5-benzotetrathiepine and their derivatives were also prepared (Scheme 7).

Scheme 7. Synthesis of 1,2,3,5,6,7-hexathiocane and 1,2,4,5-benzotetrathiepine and their alkyl derivatives



Application of the cyclocondensation reaction to vicinal dithiols such as *trans*-cyclohexane-1,2-dithiol led to bicyclic sulfur compounds with the chlorosulfanes S_nCl_2 ($n = 2-5$) and to tricyclic ring systems with dichloromonosulfane or iodine as reaction partner. Analogous reactions of 1,2-dimercaptoarenes generally led to compounds containing C=C bonds while the corresponding tricyclic systems were prepared directly by reactions of the 1,2-dithiols with 1,2-bis(chlorodisulfanyl)benzenes. Novel hexathia[3.3]cyclophanes became accessible by reactions of 1,3- and 1,4-dimercaptoarenes with dichloromonosulfane or − preparatively more favorable − 1,3- and 1,4-bis(chlorodisulfanyl)benzenes (Scheme 8).

Scheme 8. Synthesis of saturated and unsaturated bi- and tricyclic sulfur compounds bearing C_2, C_3, and C_4 groups



Single crystal X-ray crystallographic analyses of many of the prepared heterocyclic sulfur compounds were carried out in order to be able to compare the molecular parameters, in particular the ring conformation in the solid state, with those of the corresponding homocyclic sulfur compounds. Information on conformation changes in solution was obtained from the ^{1}H-NMR spectra recorded at differing temperatures. All new compounds were also comprehensively characterized by means of UV, IR, and Raman spectroscopy and the results interpreted from structural and bonding theory points of view.

The rich palette of topics in open-chain and cyclic sulfur compounds investigated in the ten years between the founding of the inorganic institute and Franz Fehér's retirement was only possible with the help of a relatively large group of coworkers in whom he had inspired a particular interest for the problems of the preparative chemistry of non-metallic elements. Franz Fehér was personally present in the laboratory from morning to evening and often for hours also on Sundays. He regularly attended the most important congresses for his discipline and held numerous lectures at other universities; however, he only reluctantly left his laboratories and the ongoing investigations to do so. In a critically ironic tone he designated colleagues who were often away on trips as "chemical tourists". As well as his wealth of ideas Franz Fehér provided his postgraduate students with sufficient freedom to define their research tasks and thus inspired them to individual initiative so that a fertile and trustworthy cooperation resulted. Even so, he always took the time to give advice on personal matters and provided indispensable help for the future careers of his students. Many of his students attained their Habilitation either in Cologne (M. Baudler, K.-H. Linke, H. D. Lutz) or at other universities (H. J. Berthold, G. Winkhaus) where he had smoothed the way for them. He furnished all of his 130 postgraduate students not only with a scientific education but also served them as an example for future life through his friendly open-mindedness, his unerring grasp of the essentials, and his personal modesty. However, it was not always easy to completely satisfy his strict requirements for accuracy in experiment and precise written formulations. Once he had made up his mind about a scientific or university matter on the basis of careful and well-founded considerations it was difficult to induce him to view the matter from a different direction. In general, however, he was open to compromise and revealed his personality as an academic teacher and researcher by his particular power of persuasion.

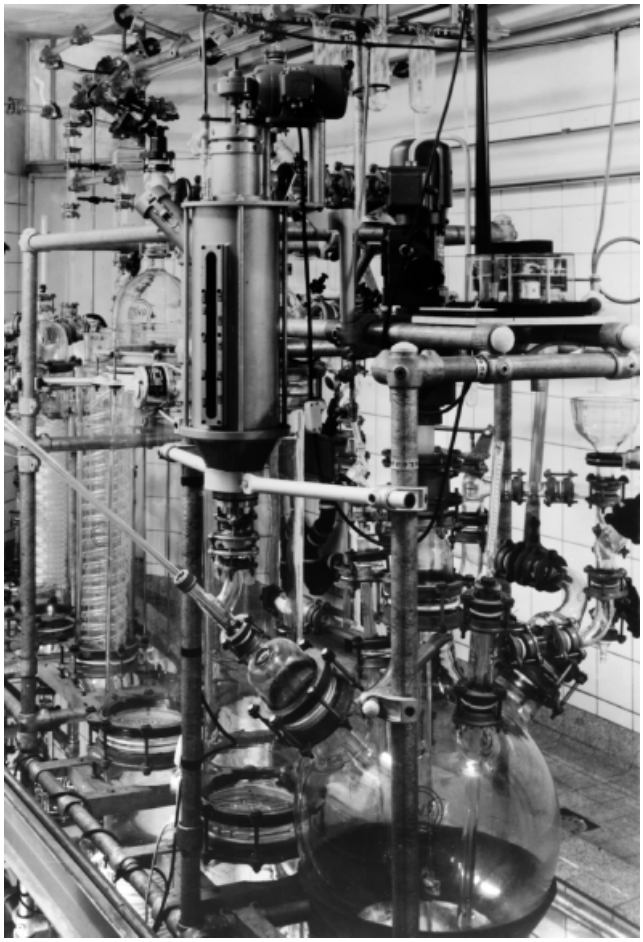
During this period, in addition to the work on the various classes of sulfur compounds, investigations on the higher silicon hydrides were continued with a small group of coworkers. After his retirement in 1971, Franz Fehér concentrated his research activities exclusively to this topic. His objectives were to continue and extend the classical works of Alfred Stock on silicon hydrides (1916−1926) with the help of modern preparative and experimental techniques and to develop a systematic chemistry of the higher silanes. By means of a specially designed high-vacuum apparatus Stock had isolated for the first time from the silicon

hydride mixture arising from the acid decomposition of magnesium silicide, in addition to monosilane (SiH_4) and disilane (Si_2H_6), small amounts of trisilane (Si_3H_8), tetrasilane (Si_4H_{10}), and a residual gas containing higher silanes. The relationships with the saturated hydrocarbons (C_nH_{2n+2}) were recognized and the name silanes adopted for the silicon hydrides Si_nH_{2n+2}. This work was interrupted in the mid 1920's because Stock was expecting an increasing instability of the higher silanes which he felt he could not master with the then available experimental techniques. In the following years, R. Schwarz postulated a mechanism for the silicide decomposition according to which the putative intermediacy of an SiH_2 biradical would be followed by the exclusive formation of silanes with unbranched Si−Si chains. However, no experimental evidence was ever presented for this hypothesis. Other methods of preparation (decomposition of magnesium silicide in non-aqueous media or reaction of silicon chlorides with lithium alanate) gave rise to mono- and disilanes but not to higher silanes. During his renewed investigation of this topic in silicon chemistry Franz Fehér was fully aware of the potential applications of higher silanes in the fields of semiconductor technology and surface coatings.

Since the acidic decomposition of magnesium silicide was then the only available method for the preparation of higher silanes and since the amounts in the formed silicon hydride mixture ("crude silane") decreased with increasing chain length, Stock's method to prepare the crude silane mixture required considerable modification as well as a scaling up to a semi-technical process. Thus, it was found in systematic studies that the yield of liquid silanes does not only depend on the rate of decomposition and the particle size of the silicide but also above all on its method of preparation. Furthermore, phosphoric acid was used in place of hydrochloric acid for the decomposition and highly pure nitrogen in place of hydrogen as carrier gas for the volatile reaction products. In particular, however, improvements in the design and construction of the apparatus with use of new inert gas techniques (see above) enabled the scale of the individual experiments to be increased and the reaction mixtures to be worked-up in rapid sequence with a high safety. Improvements over the years allowed stepwise increases in the reactor volume from at first 1 liter, to 5, 8, and finally 50 liters. With an almost technical scale apparatus (Figure 2) at hand, 2.8 liters of liquid crude silane Si_nH_{2n+2} ($n > 2$) were prepared from 80 kg of magnesium silicide within 10 days; the thus obtained material was stored in special steel vessels at room temperature.

The composition of the silane mixture formed from the silicide decomposition, which Stock could only determine with difficulty, was now easily analysed by gas chromatography. Thus, it was found that liquid crude silane contains compounds of the silane series Si_nH_{2n+2} up to pentadecasilane ($n = 15$). The proportions of the individual compounds decrease with increasing numbers of silicon atoms in the molecule. However, in contrast to earlier expectations the higher silanes are not increasingly less stable but in fact

Figure 2. Apparatus for the semi-technical production of crude silane



are rather easier to handle than mono- and disilane on account of their lower vapor pressures. Furthermore, it was demonstrated that the earlier postulated principle of formation of exclusively unbranched silanes (see above) is not in accord with the experimental results. Starting with tetrasilane (Si_4H_{10}) structural isomers with branched silicon chains were identified; hence, the analogy between silanes and alkanes is even closer than was assumed at that time.

Separation of the silane mixture into major fractions was achieved by column distillation and isolation of the various isomers mainly by preparative gas chromatography. It was found that the higher homologues, beginning with the heptasilanes, are no longer spontaneously inflammable. Even higher silanes are solids at room temperature, resembling the paraffins, but decompose slowly in the air. The pure compounds trisilane, *n*-tetrasilane, 2-silyltrisilane (*iso*-tetrasilane), *n*-pentasilane, 2-silyltetrasilane, *n*-hexasilane, 2-silylpentasilane, 3-silylpentasilane, and *n*-heptasilane were comprehensively characterized by physicochemical (melting points, boiling points, enthalpies of evaporation, densities, refractive indices, viscosities, surface tension measurements) and spectroscopic (Raman, IR, UV, mass, PE, ^{1}H-NMR, ^{29}Si-NMR) methods. Of these methods nuclear magnetic

resonance spectroscopy proved to be especially valuable for structure determinations.

These results revealed that some of the structural isomers of the silanes exist in very small amounts or are even absent in the liquid crude silane while the isomers with unbranched silicon chains generally dominate. Thus specific synthetic routes were developed for those isomers which were present only in traces or were absent in the mixture resulting from silicide decomposition. Starting points for these syntheses were the richly abundant compounds with small chain lengths. Thus, for example, the hexasilane isomers 2-silylpentasilane and 2,3-disilyltetrasilane were prepared by the reaction of trisilane with di-*tert*-butylmercury. Analogously, the heptasilane isomer 2,3-disilylpentasilane was obtained from a trisilane/*n*-tetrasilane mixture and the octasilane isomers 3,4-disilylhexasilane or, respectively, 2,2,3,3-tetrasilyltetrasilane were prepared from *n*-tetrasilane and *iso*-tetrasilane. A spontaneous silane isomerization in favor of the formation of the symmetrical isomer was observed for the first time between the two above-mentioned octasilane isomers. Accordingly, an isomerization of unbranched silanes to the corresponding branched homologues can in general be achieved by heating the substrate with a catalytic amount of aluminum chloride in an aromatic solvent.

The photolytic disproportionation was also investigated thoroughly as a further route to the higher silanes. It was found that the first steps of the reaction are highly selective and that the process is thus suitable as a preparative procedure. Accordingly UV irradiation of *n*-tetrasilane furnished 3-silylpentasilane, while the new branched hepta- and octasilane isomers 2-silylhexasilane, 3-silylhexasilane, 3,3-disilylpentasilane, 3-silylheptasilane, 4-silylheptasilane, and 2,3,3-trisilylpentasilane were generated by irradiation of *n*- and *iso*-pentasilane as well as *n*-hexasilane. All of these products were isolated in the pure state by gas chromatography and unequivocally characterized by spectroscopic methods.

The more highly branched isomers neopentasilane [$Si(SiH_3)_4$] and neohexasilane [$(SiH_3)_3Si-SiH_2-SiH_3$] were each prepared by multi-step reactions starting from silylpotassium ($KSiH_3$) and di- or trisilane. The initially formed mixture of more silicon-rich anions was converted to the corresponding phenyl derivatives by treatment with chloro(phenyl)silane while these derivatives were separable by gas chromatography. Cleavage of the phenyl groups by reaction with hydrogen bromide and hydrogenation of the thus formed bromosilanes then gave the respective pure silane isomers.

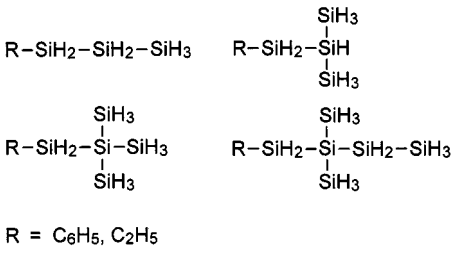
The last-mentioned investigations provided the compounds for numerous studies by Fehér's group on the chemical reactivity of higher silanes about which little was known at that time. The objective of this work was to develop the chemistry of the silanes to a close analogy of that of the alkanes with particular interest being focussed on reactions leading to the formation of new Si−Si bonds. This was intended to make the synthesis of more silicon-rich compounds from silicon-poorer derivatives possible and thus provide a simpler alternative to the laborious preparative route via the crude silane mixture. This topic occupied Franz Fehér up to the end of his active participation in experimental work at the age of 85. The strategy involved the initial synthesis of silane derivatives with suitably active leaving groups which would then react with formation of new Si−Si bonds. In this context, the branched isomers and their derivatives were of special interest in the light of the differing reactivities of the primary, secondary, and tertiary hydrogen atoms of these silanes.

In the class of partially halogenated silanes some already known mono- and disilane derivatives as well as a large number of novel chloro-, bromo-, and iodosilanes with two to five silicon atoms in the molecule were prepared. An important result of this work was the discovery that higher silanes did not react explosively with elemental halogens when the reactions were performed in highly diluted solutions at low temperatures. Cleavage of the Si−Si bonds only occurred to a minor extent under these conditions. Tin(IV) chloride also proved to be a suitable chlorination reagent with which mono-substituted products could be obtained preferentially. The halosilanes formed were then separated from the reaction mixtures by gas chromatography.

Alkali metal silanides of the general composition $M^ISi_nH_{2n+1}$ (M^I = K, Na) as a further group of functionalized silanes were of particular interest. During investigations on the synthesis of neopentasilane and neohexasilane (see above) it was found that di- or trisilane reacted with potassium monosilanide (silylpotassium, $KSiH_3$) via disproportionation and transmetallation to give a mixture of more silicon-rich anions. In order to make this finding of preparative utility, the known metallation of monosilane with potassium was optimized with regard to the laboratory-scale preparation of pure $KSiH_3$ and transferred to sodium. Then the reactions of the monosilanides with various silanes were studied in detail. In the course of this work, solutions of pure disilanylpotassium (KSi_2H_5), 2-trisilanylpotassium [$KSiH(SiH_3)_2$], and 2-*iso*-tetrasilanylpotassium [$KSi(SiH_3)_3$] in 1,2-dimethoxyethane were prepared starting from $KSiH_3$ and Si_2H_6 or Si_3H_8. The stability of these solutions increases from disilanyl to 2-*iso*-tetrasilanyl but complete decomposition occurs on removal of the solvent. Of preparative significance was the observation that both monosilanides also reacted with SiH_4 to afford mixtures of the more silicon-rich silanides $M^ISi_nH_{2n+1}$ (n = 2−6). These species were then converted to preparatively separable derivatives by reaction with suitable halogen-containing reaction partners such as chloro(phenyl)silane (see above) or alkyl and aryl halides. This opened a new and general route for the synthesis of new compounds containing silicon-silicon bonds starting from the easily accessible monosilane. For example, various partially organo-substituted silanes were prepared in this way (Scheme 9).

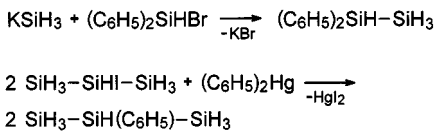
Some partially phenylated disilanes and trisilanes were prepared by specific reactions of silylpotassium with appropriate bromo(phenyl)silanes or by reactions of the corresponding iodosilanes with diphenylmercury (see Scheme 10

Scheme 9. 1-Organotrisilane, 1-organo-*iso*-tetrasilane, organoneopentasilane, and 1-organohexasilane



for examples). Because of the shortage of time still available to him Franz Fehér was only able to illustrate the enormous synthetic potential of the various metal silanides on a few exemplary reactions.

Scheme 10. Synthesis of 1,1-diphenyldisilane and 2-phenyltrisilane



Furthermore it was found that the known reactions of monosilane and disilane with organolithium compounds could be transferred to higher homologues of the silane series. In this way the unbranched butylsilanes $C_4H_9SiH_2-(SiH_2)_n-SiH_3$ and $C_4H_9SiH_2-(SiH_2)_n-SiH_2C_4H_9$ (n = 1−3 in each case) were prepared from trisilane, *n*-tetrasilane, and *n*-pentasilane by reaction with *n*-butyllithium.

Photolytic reactions of trisilane, *n*-tetrasilane, *iso*-tetrasilane, and *n*-pentasilane in the presence of acetone gave rise to constitutional isomers of the corresponding isopropoxysilanes $[(CH_3)_2CHO]_xSi_nH_{2n+2-x}$ (x = 1−3) which were separated by gas chromatography. Hydrolyses of the preferentially formed mono-substituted products with dilute, non-oxidizing acids then furnished the bis(silanyl) ethers of tri-, *n*-tetra-, and *iso*-tetrasilane with retention of the Si−Si bonds.

The special inert gas technique developed by Franz Fehér was used in all experiments with the air-sensitive silanes and was continuously refined depending on the actual requirements. Since Franz Fehér continued to participate in the supervision of advanced inorganic chemistry laboratory courses even as retired professor in order to assist his colleagues in the years with large numbers of students, it often happened that students would specifically apply for a place in his silane laboratory for these courses. They knew that they would then have an opportunity to learn special working techniques that would be useful in their future professional careers. At the same time it was a great pleasure for Franz Fehér to personally instruct these 50-year-younger chemistry students in their experimental work and to provide them with a survey of the state of development and perspectives in a fascinating field of inorganic chemistry. Figure 3 shows Franz Fehér at the age of 84 with two students in an advanced laboratory course in his silane laboratory.

Figure 3. Franz Fehér in his silane laboratory with two students of an advanced inorganic chemistry practical course (March 1987)

In addition to his interest in the "element-near" chemistry of sulfur and silicon, Franz Fehér was involved with numerous other topics during his sixty years of active research work. Most of these individual works can be classified into three subject groups:

i. synthesis and detailed characterization of new compounds in widely differing classes of substances;

ii. resolving analytical problems that Franz Fehér considered to be an essential part of his teaching responsibilities (see above);

iii. development of new apparatus or improvement of evaluation methods for widely varying procedures that he employed in his reaseach.

The first subject group includes, among others, numerous investigations of silicophosphorus acid esters, silicothiophosphorus acid esters as well as the preparation of anhydrous hydrazine and the synthesis of germanium hydrides from magnesium germanide in the former compound as solvent. The syntheses of partially substituted, symmetrical phenyldigermanes and phenyl-substituted cyclic silicon-sulfur compounds must also be mentioned in this context. In addition, Franz Fehér carefully carried out comprehensive investigations on the crystal structure of lithium peroxide, Li_2O_2, and the spatial structures of sulfides of sodium and potassium. Furthermore, other studies were directed at the synthesis of $H_2N-NH-C(Se)-SeH\cdot N_2H_4$ and its transformation to selenocarbohydrazide, $H_2N-NH-C(Se)-NH-NH_2$.

The analytical work was mainly in connection with the investigations on open-chain sulfur compounds and on the properties of sulfur melts. Thus, for example, a gravimetric and a volumetric method were developed for the characterization of sulfanes which, however, only yielded information on the gross compositions of the respective samples. Routine determination of the contained homologues only became possible with the further development of various spectroscopic techniques. In addition, procedures for the titrimetric determination of alkali polysulfides and for the de-

termination of sulfur in zinc blendes and organic substances by digestion with hydrogen peroxide were described. Numerous experiments were concerned with the analytical characterization of elemental sulfur and, in particular, the quantitative analysis of traces of carbon down to 0.001% (see above). A polarographic method for assaying DDT was devised that was suitable both for trace analysis and for the detection of larger amounts of DDT in technical products. Taken together, the analytical works of Franz Fehér reveal a marked tendency for the application of instrumental methods and especially spectroscopic procedures.

The third group of topics includes among many others the description of a simple projector to measure weak spectral lines which at the time was of relevance for the evaluation of photographically recorded Raman spectra. In connection with the investigations of sulfur melts an adiabatic, automatically controlled calorimeter was designed for measurement of the specific heats of substances with low thermal conductivities. The studies on sulfur radicals at low temperatures required a specially designed apparatus to enable the spectroscopic characterization of short-lived photolysis products. Also, his detailed evaluation of the characteristics of the first direct-recording Raman spectrometer that replaced the old photographic spectrometer in Cologne in 1955 is an illustration of his continuous efforts to optimize the measuring techniques that he employed. The same is true for the interpretation of the respective results with regard to accuracy and concomitant simplicity. Examples of this are the description of a graphic evaluation of Debye-Scherrer exposures and an evaluation procedure for measurements in a differential heat-flow calorimeter for determining reaction enthalpies and rate constants.

The complete scientific works of Franz Fehér to which he was able to devote more than six decades of his life are documented in review articles and more than two hundred original papers, of which the last was published posthumously in 1991. In 1962, nearly thirty years earlier, the Deutsche Akademie für Naturforscher Leopoldina had elected him as a member in recognition of his outstanding scientific achievements. Franz Fehér always felt a close affection for this academic society whose election motto "Nunquam otiosus" he could have called his own since it effectively described the guiding principle of his life and he attended the general meetings even at an advanced age.

Franz Fehér was a prominent German chemist with a particular interest in experimental inorganic chemistry: whenever the properties of a substance permitted, it had to be prepared on a laboratory scale in the pure state and investigated as thoroughly as possible with all available analytical, physicochemical, and spectroscopic methods (including X-ray crystallography). In his research work he repeatedly disregarded the boundaries to physical and organic chemistry, being aware that the division of chemistry into the various fields was reasonable under organizational aspects but of no relevance from a scientific point of view. Many of the results from his work and ideas from his original discussions have long been held to be common scientific property and are − often in ignorance of their source − still widely used. On the whole it can be stated that Franz Fehér and his students made major advances in widely differing fields which have provided decisive impulses for the development of the chemistry of the non-metallic elements.

In the middle of his 85th year Franz Fehér's physical strength began to decline so that his attendances in the institute became less frequent. Even so he still participated intensively in the general scientific life and academic events at the University of Cologne. During a short hospitalization for cardiovascular support he suddenly but painlessly passed away and thus a varied life dedicated with extraordinary consequence to chemistry came to an end.

Acknowledgement

I warmly thank his daughter, Dr. *Magda Fehér*, for providing the photographs and much useful information as well as for the preparation of the list of publications. I am also grateful to Dr. *R. E. Dunmur* (Ditzingen) for the English translation of this manuscript.
