
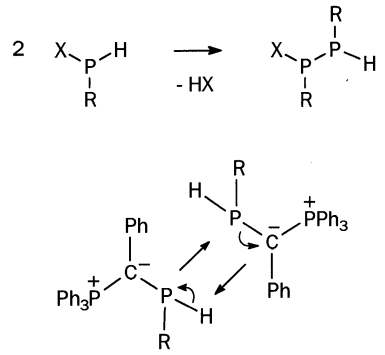
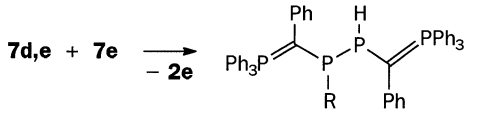
A condensation of the general type shown below, as it is observed here for the case of X = Ph_3PCPh (e.g. in the reaction 2 × **7** → **2e** + **11**) is unknown in the case of other organo substituents X, but is well known in case of amino substituents X[6] and phosphino substituents X. The latter reaction has been described as a disproportionation of a diphosphane[7]. All these reactions may be understood by a four-centred mechanism involving a proton transfer and a nucleophilic/electrophilic interaction of the two tervalent phosphorus atoms.

The bis(ylidyl)phosphane **7e** (R = Ph_3PCPh) also decomposes rapidly at 60 °C. As a primary product, the respective diphosphane **18e** can be detected in the ^{31}P-NMR spectrum. In addition, however, the primary ylidylphosphane **9a** and the bis(ylidyl)diphosphane **10a** are observed. As ylidyl-



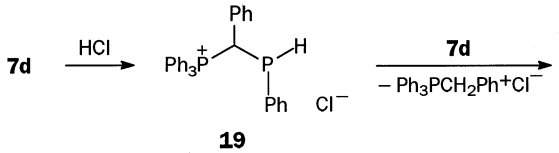
substituted cyclophosphanes seem not to be stable, the thermolysis finally yields a complex mixture which cannot be analyzed. If an equimolar mixture of **7e** and **7d** is heated, only the 1,2-bis(ylidyl)diphosphane **18d** is observed as product and not its 1,1-isomer. This suggests that the course of the reaction is determined by the proton transfer step; in the case under discussion the course is thus decided by the higher basicity of the ylidic carbon atoms of **7e** as compared to that of **7d**. In contrast to **7a**,**b**, and **d**, the *tert*-butyl derivative **7c** is thermally stable and remains unchanged in refluxing benzene for at least one week.



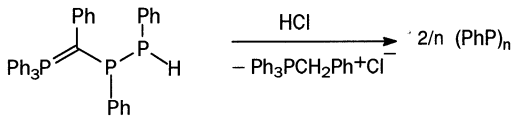
18d R = Ph
18e R = CPhPPh$_3$

Protonation and Alkylation of Ylidylphosphanes

Instead of warming, the formation of ylidyldiphosphanes from **7** can also be initiated by adding half an equivalent of HCl. From a 2:1 reaction of **7d** with HCl in ether, the benzylphosphonium chloride precipitates and the ylidyldiphosphane **11d** remains in solution. With more HCl added, the ylidyldiphosphane is converted to more phosphonium chloride and a mixture of cyclophosphanes. In addition, a minor amount of $PhPH_2$ is observed as a product of further reduction.

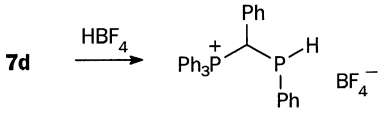


19

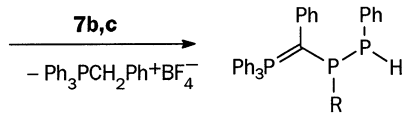


11d

The ylidyldiphosphane obviously results from the condensation of the primary product of protonation **17** with more ylidylphosphane **7d**. Consequently, the protonation of an ylidylphosphane **7** without a concomitant condensation can be achieved, if any temporary excess of **7** is avoided, i.e. if **7d** is added to HBF_4. In this way the phosphanyl benzylphosphonium tetrafluoroborate **20** precipitates from THF and is isolated as a mixture of two diastereomers. Followed with a second molecule of **7**, the cation of **20** enters the expected condensation and this way an access to mixed substituted ylidyldiphosphanes is provided. With **7b**, **c** the ylidyldiphosphanes **11f**, **g** are obtained. Their formation can be understood to result from a nucleophilic attack of the ylidylphosphane **7** on the cation of **20**.



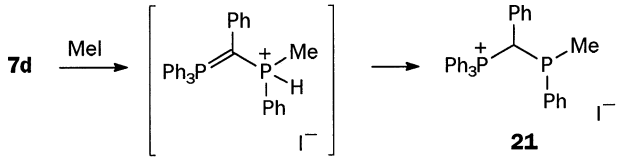
20



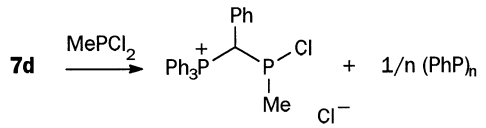
11f R = Et
11g R = ^{t}Bu

The *tert*-butylsubstituted ylidylphosphane **7c**, which resists the thermal condensation (see above), does not undergo an HCl-initiated condensation either. Its hydrochloride **19c** and hydrotetrafluoroborate **20c** therefore are stable even in presence of excess **7c**.

Methyl iodide alkylates **7d** at the phosphorus atom with a concomitant shift of the proton to the carbon atom to give the phosphonium iodide **21** which corresponds to the product **17** from the initial protonation step. With a chlorophosphane such as $MePCl_2$ **7d** reacts in a way analogous to HCl yielding the phosphonium chloride **22** and a mixture of phenyl cyclophosphanes.



21



22

NMR Spectra of Ylidyl Di- and Triphosphanes

For most of the diphosphanes **10**, **11**, and **18**, two diastereomers are observed in the ^{31}P-NMR spectrum with slightly different coupling constants $^1J_{PP}$ (Table 3). For the phenyl derivative **11d**, this difference is quite large and allows a tentative assignment of the signals to the individual diastereomers. Due primarily to the steric interaction of the ylidyl substituent at the one phosphorus atom with the

phenyl substituent at the other phosphorus atom, the share of the *trans* conformation should be smaller for the (*R*,*R*)- than for the (*R*,*S*)-isomer and consequently $^1J_{PP}$ should be larger for the (*R*,*R*)- than for the (*R*,*S*)-isomer. In all cases a $^3J_{PP}$ coupling is observed for only one of the two diastereomers. In agreement with the phenyl derivative **11d**, this is assigned to the (*R*,*S*)-isomer for all the other derivatives too. For the ylidyltriphosphane **12b** all four diastereomers can be identified in the ^{31}P-NMR spectrum (Table 3).

The ylidylphosphane **7c** adds in a 2:1 ratio to platinum dichloride. The complex **25** contains the unchanged ligand in a *trans*-coordination and is formed as a roughly equimolar mixture of two diastereomers. Their ^{31}P-NMR data are almost identical and result, therefore, in overlapping spectra which could, however, be analyzed by calculation[8]. The coordination to platinum is demonstrated by the coordination shift from $\delta^{31}P^{III} = -33.2$ to 6.0, by the increase in P−H-coupling from $^1J_{PH} = 207.1$ to 379.0 Hz, and the decrease of P−P-coupling from $^2J_{PP} = 154.9$ to 14.5 and

Table 3. ^{31}P-NMR data of ylidyldiphosphanes **10**, **11,** and **18** and ylidyltriphosphanes **12** (in C_6H_6 or THF, coupling constants *J* in Hz)

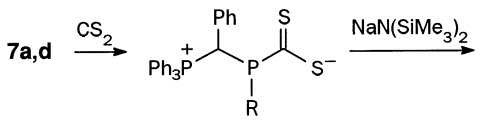
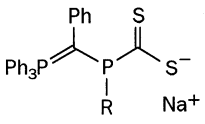
Adduct and Complex Formation of Ylidylphosphanes

As it is well known of other phosphanes, the ylidylphosphanes **7** also add to carbon disulfide. The adduct undergoes a proton shift to the ylidic carbon atom to give the betaine **23** which can be deprotonated, yielding the ylidylphosphanyl dithioformate **24**.

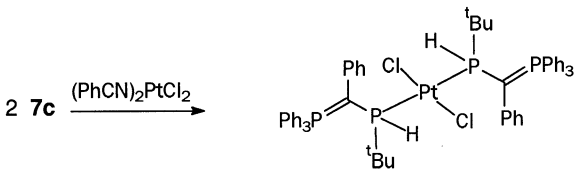


23a R = Me
23b R = Ph



24

16.6 Hz as well as by the satellite signals originating from the ^{195}Pt-containing isotopomer with $^1J_{PtP} = 2331.4$ Hz. The coupling constant $^2J_{PP} = 513.6$ Hz between the coordinated phosphorus atoms of the two ligand molecules is characteristic of a *trans* coordination[9].



25

Complex formation in which an ylidylphosphane makes use not only of its phosphane site is exemplified by the complex of **7c** with the 16-electron fragment $CpMn(NO)CO^+$. Through an additional nucleophilic interaction of the ylidic carbon atom with the carbonyl group, a four-membered ring is formed in this case[10].

Experimental Section

All manipulations were carried out in flame-dried glassware under argon using Schlenk tube techniques. Dry dichloromethane and benzene were used as obtained (Fluka). Pentane was dried over molecular sieves (4 Å). Tetrahydrofuran was dried by refluxing with sodium/benzophenone and subsequent distillation. Melting points were determined in sealed capillaries. – NMR: JEOL GSX 270 (^{7}Li, ^{31}P), JEOL EX 400 (^{1}H, ^{13}C) with Me_4Si (int.), 85% H_3PO_4 (ext.), and aqueous LiCl (ext.) as standards. The aromatic hydrogen atoms in *ortho*, *meta*, and *para* positions of C-Ph are identified as 2-, 3-, 4-H, those of P^{III}-Ph as 6-, 7-, 8-H and those of Ph_3P as *o*-, *m*-, *p*-H. – The ylidyl chlorophosphanes **6**[2] and **8**[1] were prepared as described.

[α-(Methylphosphanyl)benzylidene]triphenylphosphorane (**7a**): To a stirred suspension of $LiAlH_4$ (0.76 g, 20.0 mmol) in 20 ml of THF, a solution of **6a** (8.65 g, 20.0 mmol) in 175 ml of THF was added dropwise at −40°C over 2 h. After cooling the grey suspension for an additional 6 h, it was warmed up to ambient temperature over 2 h. The precipitate was filtered off, and the orange filtrate was concentrated to 50% of its original volume. After standing at room temperature for 12 h, orange crystals were filtered off, washed with THF, and dried in vacuo. By concentration of the filtrate to about 20% of its original volume a second crop could be obtained. Yield 6.78 g (78%) of **7a**·0.5 THF, dec. > 60−63°C. – ^{1}H NMR (C_6D_6): δ = 1.35 (t, $^2J_{PH}$ = 6.0 Hz, $^3J_{HH}$ = 6.0 Hz, CH_3), 5.04 (ddq, $^1J_{PH}$ = 205.8 Hz, $^3J_{PH}$ = 24.3 Hz, $^3J_{HH}$ = 6.6 Hz, 1 H, P-H), 6.75 (tm, *J* = 7.3 Hz, *J* = 0.7 Hz, 1 H, 4-H), 6.93−7.09 (m, 11 H, arom. H), 7.42 (d, $^4J_{PH}$ = 7.9 Hz, 2 H, 2-H), 7.62−7.69 (m, 6 H, *o*-H). – ^{13}C{^{1}H} NMR (C_6D_6): δ = 8.6 (dd, $^1J_{PC}$ = 15.3 Hz, $^3J_{PC}$ = 3.8 Hz, CH_3), 26.6 (dd, $^1J_{PC}$ = 115.2, 22.9 Hz, C=PPh_3), 118.5 (s, 4-C), 126.7 (d, $^4J_{PC}$ = 10.7 Hz, 3-C), 128.5 (d, $^3J_{PC}$ = 11.4 Hz, *m*-C), 130.1 (dd, $^1J_{PC}$ = 86.2 Hz, $^3J_{PC}$ = 5.0 Hz, *i*-C), 131.4 (d, $^4J_{PC}$ = 3.1 Hz, *p*-C), 133.2 (d, $^3J_{PC}$ = 9.2 Hz, 2-C), 134.5 (dd, $^2J_{PC}$ = 9.2 Hz, $^4J_{PC}$ = 2.3 Hz, *o*-C), 145.5 (d, $^2J_{PC}$ = 11.5 Hz, 1-C). – $C_{26}H_{24}P_2 \cdot 1/2\ C_4H_8O$ (434.48): calcd. C 77.41, H 6.50; found C 77.12, H 6.35.

[α-(Ethylphosphanyl)benzylidene]triphenylphosphorane (**7b**): Prepared as described above from (0.53 g, 14.0 mmol) of $LiAlH_4$ and **6b** (6.19 g, 13.9 mmol). Yield 4.97 g (80%) of **7b**·0.5 THF, dec. > 66°C. – ^{1}H NMR (C_6D_6): δ = 1.06 (dt, $^3J_{PH}$ = 17.1 Hz, $^3J_{HH}$ = 7.8 Hz, 3 H, CH_3), 1.42 (m, 2 H, THF), 1.78−1.96 (m, 2 H, CH_2), 3.56 (m, 2 H, THF), 4.91 (dddd, $^1J_{PH}$ = 204.6 Hz, $^3J_{PH}$ = 20.0 Hz, $^3J_{HH}$ = 7.8, $^3J_{HH}$ = 3.4 Hz, 1 H, P-H), 6.72 (tt, *J* = 7.3 Hz, *J* = 1.0 Hz, 1 H, 4-H), 6.95−7.07 (m, 11 H, arom. H), 7.42 (d, $^4J_{PH}$ = 8.3 Hz, 2 H, 2-H), 7.63−7.69 (m, 6 H, *o*-H). – ^{13}C{^{1}H} NMR (C_6D_6): δ = 11.8 (d, $^2J_{PC}$ = 16.8 Hz, CH_3), 16.7 (dd, $^1J_{PC}$ = 10.6 Hz, $^3J_{PC}$ = 3.0 Hz, CH_2), 25.8 (s, THF), 25.9 (dd, $^1J_{PC}$ = 114.4 HZ, $^1J_{PC}$ = 24.4 Hz, C=PPh_3), 67.8 (s, THF), 118.5 (s, 4-C), 126.6 (d, $^4J_{PC}$ = 10.2 Hz, 3-C), 128.5 (d, $^3J_{PC}$ = 10.7 Hz, *m*-C), 130.1 (dd, $^1J_{PC}$ = 87.0 Hz, $^3J_{PC}$ = 6.1 Hz, *i*-C), 131.4 (s, *p*-C), 133.2 (d, $^3J_{PC}$ = 10.7 Hz, 2-C), 134.6 (d, $^2J_{PC}$ = 9.2 Hz, *o*-C), 146.0 (d, $^2J_{PC}$ = 10.7 Hz, 1-C). – $C_{27}H_{26}P_2.1/2\ C_4H_8O$ (448.50): calcd. C 77.66, H 6.74; found C 76.84, H 7.07.

[α-(tert-Butylphosphanyl)benzylidene]triphenylphosphorane (**7c**): Prepared as described above from (0.84 g, 22.1 mmol) of $LiAlH_4$ and **6c** (10.56 g, 22.2 mmol). Yield 6.53 g (67%) of **7c**, m.p. 124−126°C. – ^{1}H NMR (C_6D_6): δ = 1.53 (d, $^3J_{PH}$ = 12.5 Hz, CH_3), 5.27 (dd, $^1J_{PH}$ = 210.7 Hz, $^3J_{PH}$ = 25.6 Hz, P-H), 7.01 (t, *J* = 7.1 Hz, 1 H, 4-H), 7.26−7.37 (m, 11 H, arom. H), 7.85 (d, $^4J_{PH}$ = 8.6 Hz, 2 H, 2-H), 7.95−8.01 (m, 6 H, *o*-H). – ^{13}C{^{1}H} NMR (C_6D_6): δ = 27.7 (dd, $^1J_{PC}$ = 111.0 Hz, $^1J_{PC}$ = 31.3 Hz, C=PPh_3), 30.9 (d, $^2J_{PC}$ = 15.6 Hz, CH_3), 32.6 [dd, $^1J_{PC}$ = 15.6 Hz, $^3J_{PC}$ = 4.2 Hz, C-$(CH_3)_3$], 119.3 (s, 4-C), 127.6 (s, 3-C), 128.4 (d, $^3J_{PC}$ = 11.8 Hz, *m*-C), 130.4 (dd, $^1J_{PC}$ = 85.8 Hz, $^3J_{PC}$ = 4.6 Hz, *i*-C), 131.4 (d, $^4J_{PC}$ = 3.1 Hz, *p*-C), 134.1 (d, $^3J_{PC}$ = 19.8 Hz, 2-C), 134.8 (dd, $^2J_{PC}$ = 8.8 Hz, $^4J_{PC}$ = 1.9 Hz, *o*-C), 146.4 (dd, $^2J_{PC}$ = 11.1, 1.1 Hz, 1-C). – $C_{29}H_{30}P_2$ (440.50): calcd. C 79.07, H 6.86; found C 78.40, H 6.99.

[α-(Phenylphosphanyl)benzylidene]triphenylphosphorane (**7d**): Prepared as described above from (0.82 g, 21.6 mmol) of $LiAlH_4$ and **6d** (10.75 g, 21.7 mmol). Yield 9.53 g (89%) of **7d**·0.5 THF, dec. > 84°C. – ^{1}H NMR (C_6D_6): δ = 1.42 (m, 2 H, THF), 3.56 (m, 2 H, THF), 5.86 (dd, $^1J_{PH}$ = 220.6 Hz, $^3J_{PH}$ = 21.4 Hz, P-H), 6.69 (tt, *J* = 7.3 Hz, *J* = 1.0 Hz, 1 H, 4-H), 6.91−7.21 (m, 14 H, arom. H), 7.45 (d, $^3J_{PH}$ = 8.1 Hz, 2 H, 2-H), 7.68−7.74 (m, 8 H, *o*-H/6-H). – ^{13}C{^{1}H} NMR (C_6D_6): δ = 25.6 (s, THF), 26.2 (dd, $^1J_{PC}$ = 114.5 Hz, $^1J_{PC}$ = 19.2 Hz, C=PPh_3), 67.6 (s, THF), 118.4 (s, 4-C), 125.8 (d, $^4J_{PC}$ = 11.5 Hz, 3-C), 126.0 (s, 8-C), 127.8 (C_6D_6), 128.1 (superimposed, *i*-C), 128.2 (d, superimposed, 7-C), 128.4 (d, $^3J_{PC}$ = 11.5 Hz, *m*-C), 129.8 (d, $^2J_{PC}$ = 15.4 Hz, 6-C), 131.4 (d, $^4J_{PC}$ = 3.1 Hz, *p*-C), 132.2 (d, $^3J_{PC}$ = 10.0 Hz, 2-C), 134.3 (dd, $^2J_{PC}$ = 9.2 Hz, $^4J_{PC}$ = 1.5 Hz, *o*-C), 143.9 (dd, $^1J_{PC}$ = 20.0 Hz, $^3J_{PC}$ = 6.9 Hz, 5-C), 146.2 (d, $^2J_{PC}$ = 12.3 Hz, 1-C). – $C_{31}H_{26}P_2 \cdot 1/2\ C_4H_8O$ (496.55): calcd, C 79.82, H 6.09; found C 79.57, H 5.57.

[α-(Phosphanyl)benzylidene]triphenylphosphorane (**9a**): To a stirred suspension of $LiAlH_4$ (0.73 g, 19.2 mmol) in 20 ml of THF, a solution of **8a** (3.47 g, 7.7 mmol) in 20 ml of THF was added dropwise at −40°C over 30 min. The brown suspension was stirred for an additional 30 min. The precipitate was filtered off, and the orange filtrate was concentrated to 50% of its original volume. Compound **9a** is stable in solution below −40°C.

[(3-Methylphenyl)phosphanylmethylidene]triphenylphosphorane (**9b**): Prepared as described above from (112 mg, 2.9 mmol) of $LiAlH_4$ and **8b** (0.55 g, 1.2 mmol). **9b** is stable in solution below −40°C.

[(3-Methylphenyl)phosphanylmethylidene]triphenylphosphorane (**9c**): Prepared as described above from $LiAlH_4$ (0.12 mg, 3.2 mmol) and **8c** (0.71 g, 3.2 mmol). Compound **10c** is observed as a by-product. After standing at ambient temperature for 10 h, **9c** and **10c** can no longer be detected by ^{31}P NMR.

Deprotonation of **7d**: In an NMR tube, **7d** (105 mg, 0.2 mmol) was dissolved in 0.5 ml of THF. A 1.56 mol/l solution of *n*BuLi (0.13 ml, 0.2 mmol) in hexane was added. After 10 min, a ^{31}P-NMR spectrum of the deep red solution was recorded at room temp. ^{31}P{^{1}H} NMR (THF, hexane): AB (40%), δ_A = 21.6 δ_B = −54.9 (broad, superimposed), J_{AB} = 57.1 Hz, AB (21%), δ_A = 20.8, δ_B = −54.9 (broad, superimposed), J_{AB} = 57.6 Hz, δ = 8.6 (s, 7%), 4.5 (s, 11%), −6.5 (d, *J* = 187.9.5 Hz, 5%), −32.7 (d, *J* = 188.4 Hz, 4%). In the ^{1}H-coupled ^{31}P-NMR spectrum no $^1J_{PH}$ could be detected. – ^{7}Li{^{1}H} NMR (THF, hexane): δ = 2.3 (s).

Thermolysis of Ylidylphosphanes **7a**, **b**, **d**, **e**: In an NMR tube a solution of **7a**, **b**, **d**, **e** (0.3 mmol) in 0.05 ml of THF was warmed to 60°C for 120 seconds. After 5 min a ^{31}P-NMR spectrum of the red (**7d** orange) solution was recorded at room temp. (For results see text and Table 3). Further heating of **7a**, **b**, **d** to 60°C for an additional 5 h yielded a mixture of the cyclophosphanes **15**, **16**, and **17** and the ylide **2e**. A solution of **7c** in C_6H_6 remains unchanged after refluxing for 7 d.

Cothermolysis of **7d** *and* **7e**: In an NMR tube, a solution of **7d** (91 mg, 0.2 mmol) and **7e** (146 mg, 0.2 mmol) in 0.7 ml of THF was warmed at 60°C for 240 seconds. After 5 min, a ^{31}P-NMR

spectrum of the red solution showed a mixture of **2e**, **18d**, and starting materials.

Ylidyl Diphosphane **11d**: To a stirred solution of **7d** (3.75 g, 7.6 mmol) in 60 ml of THF, a solution of 1.0 mol/l HCl (3.78 ml, 3.8 mmol) in diethyl ether and 20 ml of THF was added dropwise at 0°C over 30 min. The white precipitate of $Ph_3P-CH_2Ph^+Cl^-$ was filtered off, and 80 ml of pentane was added to the yellow solution. After cooling to −20°C for 12 h, the yellow precipitate was filtered off, washed twice with THF/pentane (1:1) and dried in vacuo. The ^{31}P NMR of the precipitate showed the signals for **11d** and for small residues of **7d**.

Reaction of **7d** *with HCl:* To a fresh solution of **7d** (210 mg, 04 mmol) in 5 ml of dichloromethane 1.0 mol/l HCl (0.47 ml, 0.5 mmol) in diethyl ether was added. After 5 min, a ^{31}P-NMR spectrum was recorded. It showed the signals of **19d**, $Ph_3P-CH_2Ph^+Cl^-$, **16d**, **17d**, and $PhPH_2$.

Preparation of **20d**: A solution of **7d** (2.10 g, 4.2 mmol) in 20 ml of THF was added dropwise to a solution of 54% HBF_4 (0.82 ml, 4.2 mmol) in diethyl ether and 8 ml of THF at −60°C over 10 min. After additional stirring for 10 min, the white precipitate was filtered off, washed twice with pentane and dried in vacuo. Yield: 2.09 g (91%) of **20d** (2 diastereomers), m.p. 162−165°C. − ^1H NMR ($CDCl_3$): δ = 4.41 (ddd, $^1J_{PH}$ = 222.9 Hz, $^3J_{PH}$ = 8.8 Hz, $^3J_{HH}$ = 7.8 Hz, PH), 4.89 (ddd, $^1J_{PH}$ = 216.9 Hz, $^3J_{HH}$ = 5.0 Hz, J = 1.2 Hz, PH), 4.98 (dd, $^2J_{PH}$ = 17.3 Hz, $^3J_{HH}$ = 7.7 Hz, CH), 5.42 (dd, $^2J_{PH}$ = 14.5 Hz, $^3J_{HH}$ = 4.9 Hz, CH), 6.69−7.74 (m, 50 H, arom. H). − $C_{31}H_{27}BP_2F_4$ (548.31): calcd. C 67.91, H 4.96; found C 67.38, H 4.82.

Reaction of **7c** *with HCl:* In an NMR tube, 1.0 mol/l HCl (0.25 ml, 0.3 mmol) in diethyl ether was added to a solution of **7c** (213 mg, 0.5 mmol) in 0.5 ml of THF. After 30 min, a ^{31}P-NMR spectrum was recorded and showed signals of equal amounts for **7c** and **20c**.

Ylidyldiphosphane **11f**: In an NMR tube, **20d** (158 mg, 0.3 mmol) and **7b** (126 mg, 0.3 mmol) were suspended in 0.5 ml of THF. After 10 min, a ^{31}P-NMR spectrum was recorded and showed the signals for **11f**, **3d**, $Ph_3P-CH_2Ph^+Cl^-$, and **2e**.

Ylidyldiphosphane **11g**: As described above from **20d** (103 mg, 0.2 mmol) and **7c** (81 mg, 0.2 mmol). A ^{31}P NMR showed the signals for **7c**, **11g**, and **20c**.

Reaction of **7d** *with MeI:* To a stirred solution of **7d** (0.16 g, 0.3 mmol) in 7 ml of THF, a solution of MeI (0.02 ml, 0.4 mmol) in 5 ml of THF was added dropwise. After 1 h, a white precipitate had formed. $^{31}P\{^1H\}$ NMR (THF, CH_2Cl_2): **7d**, AB (**21**), δ_A = 21.2, δ_B = 13.7, J_{AB} = 59.9 Hz, $(PhP)_3$.

Reaction of **7d** *with* $MePCl_2$*:* As described earlier from **7d** (0.20 g, 0.4 mmol) and methyldichlorophosphane (0.039 ml, 0.4 mmol). 5 ml of dichloromethane were added to the suspension to yield a colourless solution. $^{31}P\{^1H\}$ NMR (THF, CH_2Cl_2): AB (**22**), δ_A = 97.6, δ_B = 24.9, J_{AB} = 62.2 Hz, **16d**, **17d**.

Reaction of **7a** *with* CS_2*:* To a stirred suspension of **7a** (1.48 g, 3.4 mmol) in 25 ml of THF, a solution of carbon disulfide (0.21 ml, 3.5 mmol) in 10 ml of THF was added at 0°C over 15 min. After 10 min the pale red precipitate was filtered off, washed twice with THF/pentane (1:1) and dried in vacuo. − $^{31}P\{^1H\}$ NMR (CH_2Cl_2): AB (**23a**), δ_A = 25.1, δ_B = 13.4, J_{AB} = 89.3 Hz, δ = 23.6 (s). In an NMR tube, 110 mg of the precipitate and $NaN(SiMe_3)_2$ (45 mg) were dissolved in 0.5 ml of THF, to yield a red solution. − $^{31}P\{^1H\}$ NMR (THF): AB (**24**), δ_A = 28.9, δ_B = 19.1, J_{AB} = 191.0 Hz, δ = 8.4 (s).

Reaction of **7d** *with* CS_2*:* As described above from **7d** (0.90 g, 1.8 mmol) and carbon disulfide (0.11 ml, 1.8 mmol). − $^{31}P\{^1H\}$ NMR (CH_2Cl_2): AB (**23b**), δ_A = 25.7, δ_B = 18.2, J_{AB} = 98.1 Hz, δ = 23.1 (s). The product was recrystallized from dichloromethane/pentane (2:1). − ^1H NMR ($CDCl_3$): δ = 5.32 (m, broad, 1 H, CH), 6.69−6.91 (m, 4 H, arom. H), 6.96 (t, J = 7.81 Hz, arom. H), 7.21−7.50 (m, 9 H, arom. H, *m*-H), 7.57−7.74 (m, 10 H, arom. H, *o*-H). − $^{13}C\{^1H\}$-NMR ($CDCl_3$): δ = 47.8 (dd, $^1J_{PC}$ = 54.2 Hz, 50.4 Hz, CH).

PtCl₂ Complex of **7c**: In an NMR tube, $PtCl_2(PhCN)_2$ (53 mg, 0.1 mmol) was added to a solution of **7c** (104 mg, 0.2 mmol) in 0.5 ml of THF. After 30 min, a ^{31}P-NMR spectrum of the yellow solution was recorded. − $^{31}P\{^1H\}$ NMR (THF): AB (**7c**, 57%), $[AB]_2$ (**25**, diastereomer I, 16%), $[AB]_2X$ (**25**, X = Pt, 7%), δ_A = 18.8, δ_B = 6.0 (superimposed), $^2J_{AB}$ = 16.6 Hz, $^1J_{BX}$ = 2331.4 Hz, $[AB]_2$ (**25**, diastereomer II, 10%), $[AB]_2X$ (**25**, X = Pt, 5%), δ_A = 18.6, δ_B = 6.0 (superimposed), $^2J_{AB}$ = 14.5 Hz, $^1J_{BX}$ = 2331.4 Hz.

Crystal Structure Determinations: Specimens of suitable quality and size were mounted in glass capillaries and used for measurements of precise cell constants and intensity data collection on an Enraf Nonius CAD4 diffractometer [Mo-K_α radiation, λ(Mo-K_α) = 0.71073 Å]. During data collection, three standard reflections were measured periodically as a general check of crystal and instrument stability. No significant changes were observed for either compound. Lp correction was applied, but intensity data were not corrected for absorption effects. The structures were solved by direct methods (SHELXS-86) and completed by full-ma-

trix-least squares techniques against F^2 (SHELXL-93). The thermal motion of all non-hydrogen atoms was treated anisotropically, except for those of the solvent THF molecules, which were disordered in both compounds. C−*H* atoms were placed in idealized calculated positions and allowed to ride on their corresponding carbon atoms with fixed isotropic contributions ($U_{iso(fix)} = 1.5 \times U_{eq}$ of the attached C atom). The P−*H* atoms were found and included with isotropic (**7a**·THF) and fixed isotropic contributions (**7d**·0.5 THF, $U_{iso(fix)} = 0.08$ Å^2). Further information on crystal data, data collection and structure refinement are summarized in Table 4. Important interatomic distances and angles are shown in Table 2. Anisotropic thermal parameters, tables of distances and angles, and atomic coordinates have been deposited with Fachinformationszentrum Karlsruhe, Gesellschaft für wissenschaftlich-technische Information mbH, D-76344 Eggenstein-Leopoldshafen. The data are available on request on quoting CSD-407613 (**7a**·THF), -407614 (**7d**·0.5 THF).

Keywords: Substitution mechanism / Platinum / Pressure dependence / Kinetics / Dinuclear complex

Both reaction steps observed for the substitution of water by thiourea in the complexes $[Pt(en)(OH_2)_2]^{2+}$ and $[Pt(phen)(OH_2)_2]^{2+}$ (en = ethylenediamine, phen = 1,10-phenanthroline) were investigated under pseudo-first-order conditions using the stopped-flow technique. The substitution of the second water molecule in each complex was also studied under high pressure. The observed pseudo-first-order rate constants k_{obs} (s^{-1}) obeyed the equation $k^{1,2}{}_{obs} = k^{1,2}[tu]$ (tu = thiourea), where "1" and "2" refer to the first and the second substitution reactions, respectively. Kinetic parameters associated with the substitution process are: $k^1{}_{en}$ (25.0°C, pH = 3.0, I = 0.1 M) = 25.6 M^{-1} s^{-1}, $\Delta H^{\#}$ = 51 kJ mol^{-1}, $\Delta S^{\#}$ = −48 J K^{-1} mol^{-1}; $k^2{}_{en}$ (same conditions) = 12.1 M^{-1} s^{-1}, $\Delta H^{\#}$ = 30 kJ mol^{-1}, $\Delta S^{\#}$ = −124 J K^{-1} mol^{-1}, $\Delta V^{\#}$ = −7 cm^3 mol^{-1}; $k^1{}_{phen}$ (25.0°C, pH = 1.0, I = 0.1 M) = 2900 M^{-1} s^{-1}, $\Delta H^{\#}$ = 41 kJ mol^{-1}, $\Delta S^{\#}$ = −41 J K^{-1} mol^{-1}; $k^2{}_{phen}$ (same conditions) = 1170 M^{-1} s^{-1}, $\Delta H^{\#}$ = 37 kJ mol^{-1}, $\Delta S^{\#}$ = −61 J K^{-1} mol^{-1}, $\Delta V^{\#}$ = −5 cm^3 mol^{-1}. The temperature and pressure dependence of all the processes studied suggest an associative substitution mechanism. The hydroxo-bridged dinuclear complex $[\{Pt(phen)(\mu\text{-}OH)\}_2]^{2+}$ is formed from $[Pt(phen)(OH_2)_2]^{2+}$ in aqueous solution unless the solution is very dilute and highly acidic. The X-ray structure of $[\{Pt(phen)(\mu\text{-}OH)\}_2](F_3CSO_3)_2 \cdot 2\ H_2O$ was determined. It belongs to the triclinic space group $P\bar{1}$ and has one formula unit in the unit cell. The unit cell dimensions are a = 7.126(5), b = 9.665(5), c = 12.774(7) Å; α = 71.85(5) , β = 85.52(5), γ = 73.12(5) deg; V = 799.9(8) $Å^3$. The structure was solved with the Patterson method and refined to R = 0.061. A square planar coordination of the platinum centers is observed, with no deviations from planarity but distortions due to the small bite angle of phen and the four-membered ring. No significant lengthening of the Pt−O bond [mean value: 2.03(1) Å] is observed in comparison with $[\{Pt(NH_3)_2(\mu\text{-}OH)\}_2]^{2+}$.

Introduction

The substitution kinetics of d^8 transition metal complexes are both of fundamental[1][2][3][4][5] and practical importance, the latter stemming from applications in catalysis[6][7] and cancer chemotherapy[8][9][10][11][12]. In particular the influence of spectator ligands has found considerable attention. For example, a recent study showed that the rate of DMSO-exchange on *cis*-$[Pt('N_2')(CH_3)(DMSO)]^+$ ($'N_2'$ = *N,N*-chelating ligand) can vary by ten orders of magnitude depending on the nature of the non-leaving $'N_2'$ spectator group[13]. The more labile complexes of platinum and palladium often contain electron-withdrawing groups such as phenanthroline, bipyridine or terpyridine[13][14][15][16][17].

We are mainly interested in complexes which offer two labile substitution sites and two non-leaving N-donors in the *cis*-position, since similar systems are used in tumor therapy. Complexes of the structure *cis*-$[Pt^{II}am_2x_2]$ (am = am(m)ine, x = leaving group) have been investigated systematically since the discovery by Rosenberg, that *cis*-$[Pt(NH_3)_2Cl_2]$ (Cisplatin) exhibits anti-tumor activity[18]. Since then, Cisplatin has been very succesfully used against testicular cancer and with good results against ovarian tumors, cancer of the head, neck, and bladder. Unfortunately, the anti-tumor activity of Cisplatin and structurally related compounds does not extend to the most common tumors like lung tumors or adenotumors of the gastrointestinal tract[10]. Promising results were recently obtained with platinum complexes containing α-diimine ligands instead of amine ligands[19][20][21][22]. This prompted us to investigate the substitution behaviour of complexes with two *cis*-bound labile ligands and an electron-withdrawing non-leaving α-diimine group in aqueous solution.

In the present study we have chosen to investigate the substitution of water by thiourea, a strong nucleophile, in $[Pt(phen)(OH_2)_2]^{2+}$. For comparison, we have investigated the corresponding reactions with $[Pt(en)(OH_2)_2]^{2+}$. The complex $[Pt(phen)(OH_2)_2]^{2+}$ was generated by cleaving the hydroxo-bridged dimer $[\{Pt(phen)(\mu\text{-}OH)\}_2]^{2+}$ with perchloric acid. X-ray structural data for the dimer were obtained.

Results and Discussion

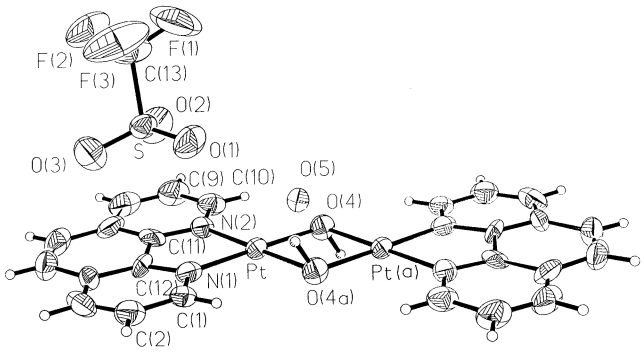
Structure of $[\{Pt(phen)(\mu\text{-}OH)\}_2](F_3CSO_3)_2 \cdot 2\ H_2O$

An ORTEP view of the molecular structure of $[\{Pt(phen)(\mu\text{-}OH)\}_2](F_3CSO_3)_2 \cdot 2\ H_2O$ together with the atom numbering scheme of the most important unique atoms is shown in Figure 1, whereas the crystallographic

 © WILEY-VCH Verlag GmbH, D-69451 Weinheim, 1998 1434−1948/98/0303−0389 $ 17.50+.50/0

data are summarized in Table 1 and the relevant intramolecular distances and angles in Table 2. Some intermolecular distances and angles are also shown in Table 2, which suggest that the structure is stabilized by the water molecule of crystallization. The latter apparently forms hydrogen bonds to both the oxygen atoms of the $F_3CSO_3^-$ ion and the hydrogen atom of the μ-hydroxo groups. There is a crystallographic center of inversion between the two platinum atoms. The $N_2PtO_2PtN_2$ moiety is planar, and deviations from the best plane calculated through the eight atoms are within the error limits. The mean deviation from the best plane is smaller than 0.01 Å. The phen ligand is nearly planar, but slightly twisted. A torsion of 7.2° N(1)−C(12)−C(11)−N(2) is found. The chelate ligand forces a bite angle N(1)−Pt−N(2) of 81.3(4)°. The geometric features of the phen ligand are in good agreement with values reported in the literature for other phen containing complexes of platinum or palladium[23][24][25]. Pt−O distances of 2.02(1) and 2.03(1) Å are found together with Pt−N distances of 1.99(1) and 2.01(1) Å. It is noteworthy, that the Pt−O distances are within the experimental error limits the same as found in the cations[26][27][28] $[\{Pt(NH_3)_2(\mu\text{-}OH)\}_2]^{2+}$ and $[\{Pt(N,N\text{-dimethylethylenediamine})(\mu\text{-}OH)\}_2]^{2+}$. Since the phen ligand causes an increase (with respect to the amine derivative) in the rate of substitution of the *trans* ligands by a factor of 10^2 (see below), it is quite remarkable, that this enhanced reactivity is not mirrored in the Pt−O bond distance of the dimer. A strong kinetic *trans*-effect without a corresponding static *trans*-influence is an effect caused by π-acceptor ligands[29]. This clearly shows that the increase in lability in this case does not result from bond weakening to the leaving group. Therefore, the structural data support the interpretation of the kinetic data in terms of an associatively activated substitution mechanism (see below).

Figure 1. View of $[\{Pt(phen)(\mu\text{-}OH)\}_2](F_3CSO_3)_2 \cdot 2\ H_2O$ showing the atomic numbering scheme. For clarity's sake only one counterion and water molecule are shown. The thermal ellipsoids are 50% equiprobability envelopes, with hydrogens as spheres of arbitrary diameter.



Reaction of $[Pt(en)(OH_2)_2]^{2+}$ with Thiourea

The reaction of $[Pt(en)(OH_2)_2]^{2+}$ with thiourea (tu) was studied at a pH of 3.0 in order to prevent formation of hydroxo-bridged oligomers (see above). Preliminary studies were performed by ^{1}H-NMR. A 0.1 M solution of $[Pt(en)(OD_2)_2]^{2+}$ (300 μl) was prepared and reacted in an NMR tube with 200 μl of 0.4 M tu. DNO_3 was used to preadjust the pH* to 3.00. Before mixing, the signal of $[Pt(en)(OD_2)_2]^{2+}$ (singlett at δ = 2.51 with satellites, $^3J_{H\text{-}Pt}$ = 24 Hz) was observed, while after mixing a signal due to $[Pt(en)tu_2]^{2+}$ δ = 2.83 ($^3J_{H\text{-}Pt}$ = 24 Hz) was seen. After 48 h a product indicative of a very slow reaction was observed: the appearence of a signal due to uncoordinated en (δ = 3.06, no satellites) was accompanied by an increase in pH* to 8.1. These observations point to a substitution of en by tu, which is thought to be due to the strong *trans*-effect of the already coordinated tu. The initial substitution of water by tu, however, was too fast to be measured by NMR and was therefore followed by UV-Vis spectroscopy. Two reactions were observed in accord with reactions (1) and (2).

A clear separation of two reaction rates which differ only by a small factor (approximately 2 in the present case, as

$$[Pt(en)(OH_2)_2]^{2+} + tu \xrightarrow{k_1} [Pt(en)tu(OH_2)]^{2+} + H_2O \quad (1)$$

$$[Pt(en)tu(OH_2)]^{2+} + tu \xrightarrow{k_2} [Pt(en)(tu)_2]^{2+} + H_2O \quad (2)$$

will be shown below) by UV-Vis spectroscopy depends on the changes in absorbance associated with the two reactions. A favourable situation is the case where the absorbance change for the first reaction is much smaller than the absorbance change for the second reaction. This enables the observation of a typical induction curve, from which both rates can be obtained with a rather low error. A series of measurements at different wavelengths demonstrated that the reaction can be followed at 276 nm, where this condition is best fulfilled. It can be seen from the spectra shown in Figure 2, that the absorbance change for the second substitution step at 276 nm is more than five times larger than the absorbance change for the first substitution step. Under these conditions an induction behaviour is observed (Figure 3). The observed time trace was fitted to a two exponential model. The fitted curve is shown in the lower part of Figure 3, whereas the deviation from the fit (residuals) is indicated in the upper part of Figure 3. The two exponential model is confirmed by the fact that the residuals are statistically scattered. A linear dependence of the observed rate constants on the tu concentration was found (Figure 4). The absence of an intercept suggests that both steps are irreversible in nature.

The two observed reactions were assigned to the substitution steps (1) and (2) by pre-mixing the complex solution with sub-stoichiometric amounts of thiourea. The absorbance change associated with the fast reaction decreases to a much larger extent than the absorbance change associated with the slower reaction with increasing amount of pre-added thiourea, which provides evidence that the first reaction is the faster one. The temperature dependence results in the activation parameters quoted in Table 3.

The effect of high pressure on the reaction could not be followed at 276 nm due to the absorption properties of the pressure medium employed (*n*-heptane). Therefore the absorbance change at 330 nm was used, which, however, did not allow the evaluation of the first substitution step, since the absorbance changes for the two steps are too similar (see Figure 2) to allow separation. Following the arguments outlined for the very similar spectral situation of the Pt(phen) system below, the second (slower) reaction can be followed at 330 nm. For this step (Figure 5) the dependence of ln(k) on the applied pressure was linear within the experimental error limits. From this dependence an activation volume of -7.1 ± 0.9 cm^{3}mol^{-1} was obtained. These activation parameters are in accord with those generally observed for associative substitution reactions of d^8 complexes[4][30]. The more negative entropy of activation for the second step might be due to the steric hindrance caused by the thiourea ligand already coordinated during the first step. The $\Delta H^{\#}$ values are discussed below.

Figure 2. UV-Vis spectra of the reactants, intermediate and product for the two-step substitution reaction obtained using a 0.88 cm tandem cuvette. Conditions: [Complex] = 0.1 mM, pH = 3.0, I = 0.1 M, T = 25°C. The spectrum of $[Pt(en)(OH_2)tu]^{2+}$ was obtained from an equilibrated solution containing a fourfold platinum excess over thiourea and was corrected for the excess platinum background. The spectrum of an equimolar amount of uncoordinated tu was then added arithmetically in order to show the overall absorbance change observed for the formation of the 1:1 complex.

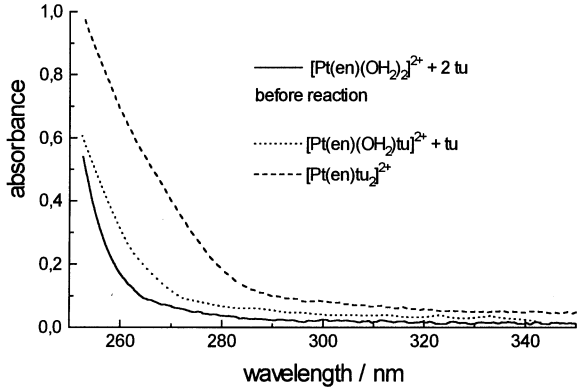

Figure 3. Fit of two exponentials and residuals (upper part) for the reaction of $[Pt(en)(OH_2)_2]^{2+}$ (0.1 mM) with thiourea (5 mM) followed at 276 nm. pH = 3.0, I = 0.1 M ($NaClO_4$), T = 25.0°C.

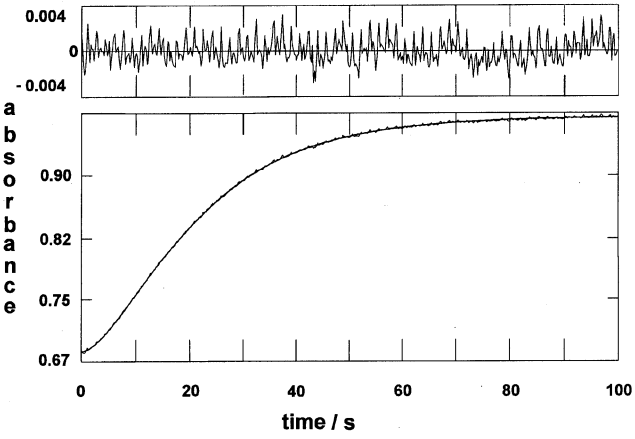

The Equilibrium Between $[Pt(phen)(OH_2)_2]^{2+}$ and $[\{Pt(phen)(\mu\text{-}OH)\}_2]^{2+}$

During the investigation of the hydrolysis behaviour of Cisplatin the property of complexes of the type $[Pt('N_2')(OH_2)_2]^{2+}$ ('N_2' = am(m)ine$_2$ or bidentate amine) to form dimeric[26][27][28][31], trimeric[32][33][34] and (rarely) tetrameric[35] species of the general formula $[\{Pt('N_2')(\mu\text{-}OH)\}_n]^{n+}$ was discovered. In dilute solutions the higher oligomers are not formed, but dimeric species must be taken into account in the appropriate pH range. Preparation of the monomeric diaqua complexes is possible at a pH of 2 or 3. Attempts to synthesize the diaqua complex in the case where 'N_2' is an aromatic α-diimine, the central atom being platinum or palladium, has led to studies[36][37][38][39] that were criticized later by Wimmer and Castan[31][40], who showed that under the selected conditions reported for synthesis and reaction, the dimeric species is the main species present in solution. In the present study attempts were made to apply the synthetic route for the preparation of

Figure 4. Reaction of $[Pt(en)(OH_2)_2]^{2+}$ (0.1 mM) with thiourea; k_{obs} as a function of thiourea concentration, followed at 276 nm. pH = 3.0, I = 0.1 M ($NaClO_4$), T = 25.0°C.

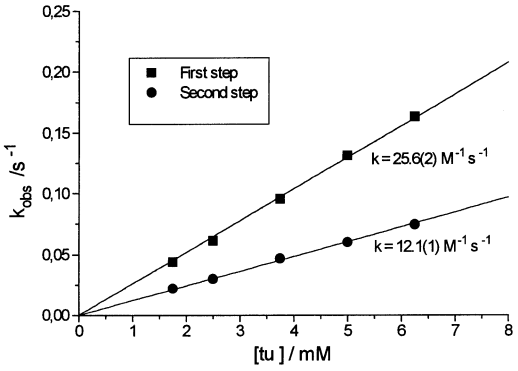

Table 3. Temperature dependence and activation parameters for the first (k_1) and second (k_2) step in the irreversible substitution of water by thiourea (6.25 mM) in $[Pt(en)(OH_2)_2]^{2+}$ (0.1 mM) at pH = 3.0, I = 0.1 M, reaction followed at λ = 276 nm

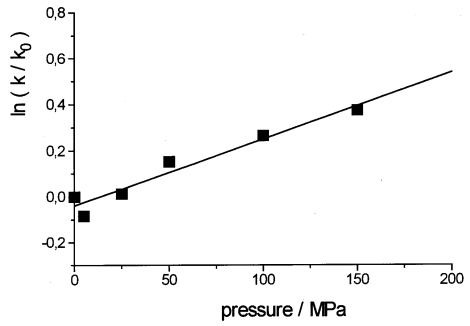
Figure 5. Determination of the volume of activation for the substitution of the remaining water molecule in $[Pt(en)(OH_2)tu]^{2+}$ by thiourea. This is done by plotting the logarithm of the ratio k/k_0 (where k and k_0 denote the rate constant for elevated and ambient pressure, respectively) according to: $\delta(\ln k)/\delta p = -\Delta V^{\#}/RT$. The measured values are shown together with the linear regression results; $\Delta V^{\#} = -7.1 \pm 0.9$ cm^3 mol^{-1}. Experimental conditions: [Pt] = 0.8 mM, [tu] = 25 mM, pH = 3.0, I = 0.1 M, T = 25.0°C, reaction followed at 330 nm.



$[Pt('N_2')(OH_2)_2]^{2+}$ to the phen complex. Even at pH 2, the formation of a precipitate was observed, which was yellow or orange red, depending on whether silver trifluormethanesulfonate or silver perchlorate was used. UV-Vis spectroscopy, IR spectroscopy and elemental analysis showed this to be identical with the dimer reported in the literature[31][40]. During our investigations we found that the dimer does react with strong nucleophiles, which is in accord with the well known reactivity of analogous halo-bridged dimers[41][42][43]. Its reaction with thiourea is currently being investigated in more detail. In contrast to the behaviour observed for terminal hydroxo ligands bound to platinum or palladium[44][45][46], which cannot easily be substituted, bridging hydroxo-groups are relatively labile, which could be responsible for the high and unspecific toxicity[47][48][49] of these compounds. Preliminary studies on the reactivity of $[\{Pt(phen)(\mu\text{-}OH)\}_2]^{2+}$ with thiourea, however, have shown that the dimeric complex reacts ca. 100 times slower than the monomeric one. This allowed us to distinguish between the reactions of the dimer and the monomer species and conditions suitable for complete cleavage of the dimer were found (see next section).

Reaction of $[Pt(phen)(OH_2)_2]^{2+}$ with Thiourea

The cleavage of the hydroxo-bridged dimer to give the monomeric diaquacomplex is complete following hydrolyses of a 0.05 mM (with respect to platinum) solution of the dimer in 0.1 M perchloric acid for 40 min at 100°C. The reaction of $[Pt(phen)(OH_2)_2]^{2+}$ with thiourea had to be studied at very low thiourea concentrations, since the separation of both substitution steps was only possible at a wavelength of 260 nm, where the reactant and the intermediate (1:1 complex) have almost identical absorptivities which lead to the favourable observation of an induction curve. The observation at 260 nm is made impossible by the absorption of thiourea itself (broad and intense band with a maximum at 238 nm), if a concentration higher than 0.5 mM is used. First the reaction of 2.5×10^{-5} M $[Pt(phen)(OH_2)_2]^{2+}$ with 0.5 mM thiourea was followed over a spectral range from 250 to 370 nm for 10 s and a Global Analysis evaluation was performed. This revealed that two first-order reactions occurred and gave preliminary k_{obs} values of 1.3 s^{-1} and 0.6 s^{-1}. The residuals of the fit were smaller than 2% of the absorbance change and statistically scattered. The spectra of $[Pt(phen)(OH_2)_2]^{2+}$, $[Pt(phen)(OH_2)tu]^{2+}$ (calculated using the Global Analysis software) and $[Pt(phen)(tu)_2]^{2+}$ are shown in Figure 6. The spectral changes do not show very characteristic features, since the bands observed are due to intraligand π-π^* transitions of the phen ligand. These are known to show a relatively weak dependence on the nature of the coordination sphere of the metal centre[31][40][50]. The aim of the Global Analysis treatment was to confirm the two-step mechanism and to provide a spectrum of the intermediate 1:1-complex. For the determination of the exact rate constants the kinetics were followed at a single wavelength, 260 nm, using complex concentrations of 2.5×10^{-5} and 1.0×10^{-5} M for the temperature and concentration dependence, respectively. Each k_{obs} value reported is the mean value of at least five measurements. From the concentration dependence (Figure 7) bimolecular rate constants of 2900±40 M^{-1} s^{-1} and 1170±10 M^{-1} s^{-1} were obtained. The assignment of the two reactions was done by pre-mixing (see above), showing that also in this case the first reaction step is the faster one. Activation parameters are derived from the temperature de-

pendence and summarized in Table 4. In the case of the $[Pt(phen)(OH_2)_2]^{2+}$ complex the $\Delta H^{\#}$ values for the first and the second substitution step do not differ significantly. The fact that the second reaction is slower seems to be completely due to the more negative entropy of activation, resulting from steric hindrance due to the thiourea molecule already coordinated. This contrasts with the observations for the $[Pt(en)(OH_2)_2]^{2+}$ complex, where an even more negative $\Delta S^{\#}$ for the second step in comparison to the first one is accompanied by a decrease in $\Delta H^{\#}$ by 20 kJ mol^{-1} (Table 3). We believe that this anomaly of the en complex is caused by hydrogen bonding of the amine protons to thiourea in the transition state. It could be argued, that the fact that we observe the second step to be slower by a factor of roughly two (at room temperature) for the en- as well as for the phen-system is due to a statistical factor in the sense that the first entering tu can substitute two water positions, whereas the second one only one. This probability consideration would be valid for a dissociative mechanism, where the probability of dissociation is proportional to the number of coordinated water molecules. It would not be valid for the case of a limiting associative mechanism, where the bond to the leaving group is not weakened during formation of a five-coordinate intermediate. The nucleophilic attack governs the rate and will not be influenced by the number of possible leaving groups. For an interchange mechanism, where bond-making and bond-breaking take place simultaneously, certainly a statistical factor will contribute, which however will be difficult to estimate. In the present system all observations point to a mechanism which is associative in nature: thus either a limiting associative (A) or an associative interchange (I_a) mechanism.

It is generally accepted that the determination of the volume of activation can elucidate the nature of the intimate mechanism. If no charge is neutralized or created during the reaction, a significantly negative volume of activation points to an associative (A) or associatve interchange (I_a) mechanism. For the system under investigation, the pressure dependence of the reaction could not be followed at 260 nm because of the absorption of the pressure medium (*n*-heptane). This made the simultaneous observation of both steps under high pressure impossible. However, the observation of the second step was possible due to the spectral properties of the species involved and the ratio of the reaction rates. This effect is described in the literature[51]. For a biphasic first-order process, the absorption changes in the following way as function of time (R, I, and P denoting reactant, intermediate and product, respectively):

$$Abs = d[R]_0\{e^{-k_1 t}\left(\varepsilon_R + \frac{e^{-k_1 t}}{e^{-k_2 t}-e^{-k_1 t}}\varepsilon_I - \frac{e^{-k_2 t}}{e^{-k_2 t}-e^{-k_1 t}}\varepsilon_P\right) + \varepsilon_P + e^{-k_2 t}\left(-\frac{e^{-k_1 t}}{e^{-k_2 t}-e^{-k_1 t}}\varepsilon_I + \frac{e^{-k_1 t}}{e^{-k_2 t}-e^{-k_1 t}}\varepsilon_P\right)\} \quad (3)$$

For the system under investigation, it was found experimentally that $k_1 \approx 5/2\ k_2$. Insertion of $k_1 \approx 5/2\ k_2$ into equation (3) leads to a monophasic time-dependence of the absorbance $Abs_{(t)}$, if $\varepsilon_I - \varepsilon_R \approx 2/3\ (\varepsilon_P - \varepsilon_I)$.

This condition is fulfilled at 350 nm (compare Figure 6), such that the second reaction step can be followed at this wavelength under the assumption that the ratio k_1/k_2 remains approximately constant. This assumption was confirmed by the fact that even under high pressure, single exponential kinetics were always observed at this wavelength. From the pressure dependence of the rate constants (Figure 8) a volume of activation of -5.0 ± 0.8 cm^3/mol was calculated. This confirms the assignment of an associative or associative interchange mechanism. The activation volumes found in the present study compare well with available data on the substitution of water by uncharged sulfur donor nucleophiles in related complexes (Table 5).

Figure 6. UV-Vis spectra of reactant, intermediate (calculated using Global Analysis) and product. pH = 1.0, I = 0.1M, T = 25.0°C, [Pt] = 0.025 mM. Background absorption of thiourea (0.5 mM) was subtracted.

Conclusion

We conclude that the results of this study have shown that the use of phenanthroline instead of ethylenediamine increases the substitution rates of diaqua complexes by a factor of 10^2, during which the associative way of substitution is retained. This effect was investigated in aqueous media for a platinum complex exhibiting two labile positions. As far as we know, we are the first to have generated the complex $[Pt(phen)(OH_2)_2]^{2+}$ (and not the dimer) in solution and have investigated its reactivity. The observations are in good agreement with earlier studies on monophasic substitution reactions by sulfur-containing nucleophiles performed in non-aqueous media on complexes of Pt or Pd bearing aliphatic amines and aromatic imines by way of comparison. A factor of approximately 10^2 (the factors range between 41 and 64) was found in the latter studies[14][16]. The factor of 2×10^4 reported by Romeo et al.[13] for DMSO exchange on the complexes $[Pt(phen)Me(DMSO)]^+$ and $[Pt(en)Me(DMSO)]^+$, obviously calls for a further explanation beyond the electron-withdrawing effect of phen alone. The electronic effects of the *cis* Pt−C bond and of the *trans* phen ligand seem to act cooperatively.

As far as possible anti-tumor activity is concerned, it seems a reasonable assumption, that platinum complexes of α-diimines exhibiting two labile positions can bind to DNA in a fashion similar to the well-established binding mode of Cisplatin[52][53], using both substitution sites for the covalent binding of purine bases. The enhanced reactivity for both substitution steps is a feature which adds to the unique properties of such ligands as DNA intercalators[54][55][56].

Experimental Section

Materials: All chemicals were used as received. $[Pt(phen)Cl_2]$ and AgF_3CSO_3 were purchased from Aldrich in the highest quality available. Thiourea and $HClO_4$ were p.a. quality from Merck. $NaClO_4$ was p.a. quality from Fluka. Non-aqueous solvents were purchased from Roth in p.a. quality (ROTIPURAN®). Ultra pure water was used for the kinetic measurements.

Syntheses

$[Pt(en)Cl_2]$ and $[Pt(en)(OH_2)_2]^{2+}$: The $[Pt(en)Cl_2]$ complex was prepared in 76% yield using a procedure from the literature[59]. Calc. for $[Pt(en)Cl_2]$: C 7.37, H 2.47, N 8.59%; found: C 7.19, H 2.41, N 8.37%. The IR spectrum was in excellent agreement with that reported in the literature[60]. A stock solution of the diaqua complex was prepared according to literature methods[61] by treating the dichloro complex with $AgNO_3$ in acidic solution, followed by filtration of the AgCl precipitate. A MILLIPORE filter (0.2 μm) was used for this purpose.

$[\{Pt(phen)(\mu\text{-}OH)\}_2](F_3CSO_3)_2 \cdot 2\ H_2O$: The title complex was prepared in the following way: 335 mg of $[Pt(phen)Cl_2]$ (0.75 mmol) was stirred together with 580 mg of AgF_3CSO_3 (2.25 mmol) in 50 ml of EtOH/H_2O (9:1) at 75°C in the dark for 4 h. The fine bright yellow precipitate, which formed was filtered off with a MILLIPORE-filter (0.2 μm). The product was extracted from the wet precipitate by stirring in 100 ml of an acetone/H_2O mixture (1:1) at 50°C. AgCl was removed from this suspension by filtering the yellow solution with a MILLIPORE-filter (0.2 μm). On cooling to room temperature, yellow crystals (ca. 0.5 mm in diameter) formed within 24 h. These were washed with H_2O, EtOH, and Et_2O and dried under vacuum for 2 h. Yield: 200 mg (48%). The experimental analysis was in excellent agreement with the theoretically expected values for the dihydrate. Calc. for $[\{Pt(phen)(\mu\text{-}OH)\}_2](F_3CSO_3)_2 \cdot 2\ H_2O$: C 27.91, H 1.98, N 5.01%; found: C 28.05, H 1.88, N 4.94%. − ^{1}H-NMR ([D$_7$]DMF, 300.13 MHz, assignment based on coupling pattern and constants): δ = 9.05 [d, 4 H, $^3J_{H\text{-}H}$ = 8.1 Hz, aromat. CH *para* to N]; 9.00 [d, 4 H, $^3J_{H\text{-}H}$ = 5.3 Hz, aromat. CH *ortho* to N]; 8.27 [dd, 4 H, $^3J_{H\text{-}H}$ = 8.1, 5.3, aromat. CH *meta* to N]; 8.16 [s, 4 H, aromat. CH, middle ring of phen]. ^{13}C-NMR ([D$_6$]acetone/D_2O (1:1), 100.62 MHz, tentative assignment according to similar complexes): δ = 151.4 [*ortho* to N]; 147.4 [*ipso, ortho* to N]; 142.0 [*para* to N]; 131.6; 129.9; 127.9.

$[Pt(phen)(OH_2)_2](ClO_4)_2$: The diaqua complex was prepared as a 0.05 mM solution by cleavage of the hydroxo-bridged dimer according to the following procedure: 5 ml of a 0.5 mM stock solution of $[\{Pt(phen)(\mu\text{-}OH)\}_2](F_3CSO_3)_2$ in water was diluted to 80 ml. This solution was then heated to boiling. To this solution 0.01 mol $HClO_4$ in the form of a 60% solution was added. An orange coloured precipitate of $[\{Pt(phen)(\mu\text{-}OH)\}_2](ClO_4)_2$ appeared and

dissolved after some minutes. After boiling for 40 min. the volume was adjusted to 100 ml. This solution was prepared freshly for each measurement.

Instrumentation: UV-Vis spectra were recorded on a Shimadzu UV-2101-PC spectrophotometer. − IR spectra were recorded on a Mattson Polaris FT-IR-spectrophotometer using KBr pellets. − NMR spectra were measured on an Avance DPX 300 (Bruker) with TSP as internal standard. − The pH values measured in D_2O are referred to as "pH*" and reported without any correction for the isotope effect. − Chemical analyses were performed on a Carlo Erba Elemental Analyser 1106. − Kinetic measurements on the en complexes were performed on a Biologic SFM-3/S (Claix, France) stopped-flow instrument coupled to an on-line data aquisition system. The syringe control device MPS-51 and the BIOKINE-Software V3.0 from the same supplier were used. The kinetic traces were converted into olis-format with BIOKOLIS (1990) and evaluated using the OLIS KINFIT (Bogart, GA) program. Measurements on the phen complexes were performed using SX-18MV hardware and software from APPLIED PHOTOPHYSICS. The Global Analysis evaluation of the data was done with the Pro-Kineticist software, which is part of the SX-18MV software. Rapid scan spectra were recorded with a J&M-Tidas 16-416 diode-array detector connected to the SX-18MV stopped-flow apparatus. Measurements under high pressure were performed on a home-made high-pressure stopped-flow instrument[62]. Kinetic measurements, unless otherwise stated, were performed at a temperature of 25.0±0.1 °C and an ionic stength of 0.1 M, which was adjusted with $NaClO_4$ if necessary. The pH of the solution was 1.0 and 3.0 for the phen and the en complexes, respectively. All kinetic measurements were performed under pseudo-first-order conditions and a pseudo-first-order behaviour was found.

X-ray Crystallography: Crystals of $[\{Pt(phen)(\mu\text{-}OH)\}_2](F_3CSO_3)_2 \cdot 2\,H_2O$ suitable for X-ray crystallography were obtained by slow evaporation of the solvent from a saturated solution of the complex in acetone/H_2O (20:1). The scattering data were collected using a CAD-4 (Enraf-Nonius) diffractometer. All reflections with $I > 2\sigma(I)$ were used in the analysis. Details on data collection and the crystal data are given in Table 1[63]. Standard software and literature was used[64][65][66][67]. The structure was solved using the Patterson method and refined anisotropically (non-hydrogens) by the full-matrix least-squares method. The hydrogen atom of the hydroxo-bridge was found in the Fourier map. As a refinement of the O(4)−H(11) distance was not possible, this distance was fixed using the option DFIX of the SHELX software (distance = 0.99 Å, σ = 0.03) and the orientation refined.

Organometallic Selenolates, 8[◇]

The Reaction of Potassium Polyselenides with [CpW(CO)$_3$Cl] in DMF Formation and Crystal Structure of [CpW(CO)$_3$SeC(O)NMe$_2$] and {[CpW(CO)$_3$]$_2$Se$_4$}

Keywords: Polychalcogenides / Selenium / Selenocarbamato complexes / ^{77}Se NMR / Crystal structure

The reactions of the potassium polyselenides "K_2Se_6" and "K_2Se_8" with [CpW(CO)$_3$Cl] and 18-crown-6 in DMF lead to a mixture of the selenido complexes {[CpW(CO)$_3$]$_2$Se$_4$} **1** and [(18-crown-6)K]$^+$[CpW(Se$_4$)$_2$]$^-$ **3** and the Se−bonded selenocarbamato complex [CpW(CO)$_3$SeC(O)NMe$_2$] **2** in yields depending on the selenium content of the used potassium polyselenides ("K_2Se_6" or "K_2Se_8"). A similar reaction in THF produces {[CpW(CO)$_3$]$_2$Se$_4$} as the main product. X-ray structures of **1** and **2** were determined. In **1** the Se$_4$-chain is bonded in a μ^2-η^1 fashion, with corresponding W−Se bond lengths of 264.0(1) and 264.3(1) pm. The Se−Se bond lengths lie in the range 232 to 237 pm. The first example of an η^1 Se-bonded selenocarbamato ligand is observed in the crystal structure of **2**, with a W−Se bond length of 263.1(1) pm. The ^{77}Se-NMR data are compared with the corresponding data of related complexes.

The synthesis of oligoselenido complexes via reactions of alkali-metal polyselenides with appropriate transition metal complexes is widely applicable and the resulting oligoselenido complexes are of particular interest because of their potential use as solid state precursors and the versatile binding modes of Se_n^{2-} [1]. However, the synthesis of organoselenolato complexes using the same route is restricted to accessible organic selenolates or diselenides[2]. For this reason, there is still a need for new synthetic methods that can avoid this difficulty. Recently, we described the formation of organometallic selenolates via selenium insertion into the alkali-metal−transition-metal bonds of appropriate carbonylates such as MM′Cp(CO)$_3$ (M = Li, Na, K; M′ = Mo, W) and MMn(CO)$_5$[3]. The resulting selenolates react with a variety of organic electrophiles to form the corresponding organoselenolato complexes, whereas oxidation with O_2 in the presence of SiO_2 leads to oligoselenido complexes[4]. Here we report on the reaction of the potassium polyselenides "K_2Se_6" and "K_2Se_8" with CpW(CO)$_3$Cl in DMF, producing the organoselenolato complex [CpW(CO)$_3$SeC(O)NMe$_2$] and the tetraselenido complexes {[CpW(CO)$_3$]$_2$Se$_4$} and [(18-crown-6)K]$^+$[CpW(Se$_4$)$_2$]$^-$.

Results and Discussion

Potassium polyselenides can be easily prepared by reducing elemental selenium with KBEt$_3$H in DMF at 150°. The resulting nearly black solutions contain formally "K_2Se_6" or "K_2Se_8", if an appropriate Se/KBEt$_3$H ratio is used[5]. The exact composition of such polyselenides is very difficult to predict, since complicated equilibria can be observed in solution[6]. Thus a reaction of such polyselenides with metal halide complexes can lead to various products depending on the metal center, the solvent and the temperature.

When [CpW(CO)$_3$Cl] is stirred overnight with a DMF solution of "K_2Se_6" in the presence of 18-crown-6, three products can be separated: {[CpW(CO)$_3$]$_2$Se$_4$} **1** (10%), [CpW(CO)$_3$SeC(O)NMe$_2$] **2** (40%), and the salt [(18-crown-6)K]$^+$[CpW(Se$_4$)$_2$]$^-$ **3** (9%).

The reaction mechanism is not clear, since the formyl group of DMF must be deprotonated in the initial step of the formation of **2**. A few reports concerning the synthesis of η^1-bonded selenocarbamato complexes have been published in which [Me$_2$NH$_2$][SeC(O)NMe$_2$] or CSe_2 in the presence of Me$_2$NH are required as the starting materials[7]. However, these alternative routes are not widely applicable and can lead also to the chelated η^2-derivatives.

If "K_2Se_8" is employed instead of "K_2Se_6", **3** is the main product and only traces of **1** and **2** are produced. The reason for this difference seems to be the high stability of $M(Se_4)_n^{2-}$ complexes (M = Zn, Cd, Hg, Ag, Au, Mo, W, Pd, Rh, Ir, Ru, Ni, Pt, Mn) that contain five-membered MSe_4 rings[8]. However, if THF is used as the solvent in the reaction of "K_2Se_6" with [CpW(CO)$_3$Cl], **1** is formed as the main separable product (35%) together with some decomposition products. A more straightforward synthesis of **1** has been developed recently in our laboratory. It comprises the insertion of three seleniums into the Li−W bond of LiWCp(CO)$_3$ and subsequent oxidation with O_2 in the presence of SiO_2[4].

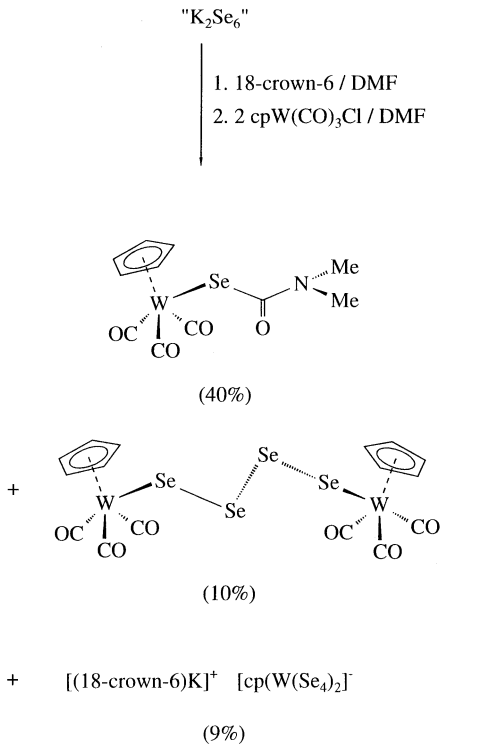
Scheme 1. The reaction of "K_2Se_6" with $[CpW(CO)_3Cl]$ and 18-crown-6 in DMF



The ^{77}Se-NMR data of **1**, **2**, and **3** are consistent with their structures and comparable with related complexes. The ^{77}Se-NMR spectrum of **1** has been already described and seems to be typical of oligoselenido complexes with μ^2-η^1 bonded selenium chains in which the metal-bonded selenium atom is usually shifted highfield[4]. The chemical shifts in the ^{77}Se-NMR spectra are strongly influenced by electronic and steric effects and cannot always be interpreted by simple means. Thus, the spectrum of **3** shows a completely different pattern. The metal-bonded selenium atoms are deshielded; ^{183}W satellites and a corresponding ^{77}Se-^{183}W coupling constant of 80 Hz are observed. There are only few reported $^1J(^{77}Se\text{-}^{183}W)$ coupling constants and the values range from 35 Hz in $[CpW(CO)_3SeC(O)Ph]$[9] to 112 Hz in the $W_3Se_9^{2-}$ anion[8b]. Recently the cp* derivative $[(\sigma\text{-}C_5Me_5)(CO)_5WSeMe]$ has been published with a $^1J(^{77}Se\text{-}^{183}W)$ value of 49 Hz[10]. Unfortunately, for **2**, no ^{183}W satellites could be observed because of the broadness of the signal, but the chemical shift of −136.1 ppm is in good accordance with the data of related complexes[3a][3b][3c][3d][3e][3f].

Crystal Structures of $\{[CpW(CO)_3]_2Se_4\}$ (1) and $[CpW(CO)_3SeC(O)NMe_2]$ (2)

The crystal structure of **1** is presented in Figure 1. It consists of two $cpW(CO)_3$ moieties, which are bridged by an Se_4 chain in a μ^2-η^1 fashion. This structural motif is rare and the only reported examples are $[Cp_2Hf(\mu\text{-}O)(\mu\text{-}Se_4)HfCp_2]$ and $[Au_2(\mu\text{-}Se_2)(\mu\text{-}Se_4)]^-$[11].The conformation of the Se_4 group in **1** can be described by its torsion angles [W1−Se1−Se2−Se3: 75.51(6)°; Se1−Se2−Se3−Se4: 51.81(7)°, Se2−Se3−Se4−W2: 78.70(6)°] as a helical chain with corresponding bond angles at selenium ranging from 104.53(6) to 110.69(5)°. In the triselenido complex $\{[CpW(CO)_3]_2Se_3\}$, comparable absolute values of the torsion angles were observed [W1−Se1−Se3−Se2: 83.12(7)°; Se1−Se3−Se2−W2: 88.31(7)°][4]. The W−Se bond lengths, W1−Se1 263.99(11) pm and W2−Se4 264.29(10) pm, are comparable with the W−Se bond lengths in $\{[CpW(CO)_3]_2Se_3\}$ (263.2(1), 265.1(1) pm). Similar bond lengths were also found in a series of organoselenolato tungsten complexes and they are attributable to W−Se single bonds (vide infra). The W-bonded Se_2 moieties display Se−Se bond lengths of 232.1(2) and 232.2(2) pm, whereas the central Se−Se bond Se2−Se3 [236.7(2) pm] is 4.5 pm longer, indicating that this bond should display a more pronounced reactivity.

The crystal structure of **2** is presented in Figure 2. The atoms W, C4, O4, N, C5, and C6 are approximately coplanar (mean deviation 1.3 pm); the selenium atom lies 20

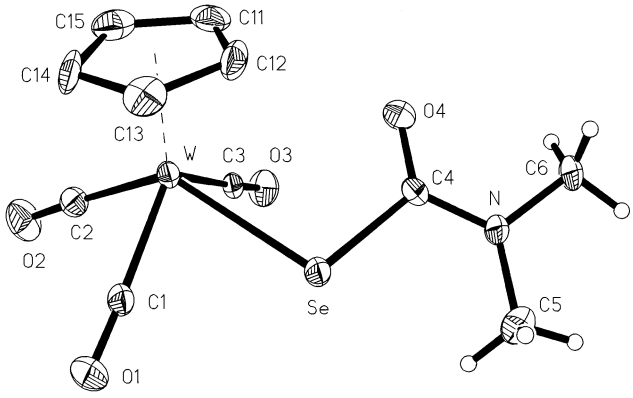
[a] Selected bond lengths [pm] and angles [°]: W1−Cp (ring center) 201.0, W1−Se1 263.99(11), Se1−Se2 232.1(2), Se2−Se3 236.7(2), Se3−Se4 232.2(2), Se4−W2 264.29(10), W2−Cp (ring center) 200.6; C1−W1−Se1 75.1(3), C2−W1−Se1 75.9(3), C3−W1−Se1 130.2(3), W1−Se1−Se2 110.69(5), Se1−Se2−Se3 104.53(6), Se2−Se3−Se4 105.49(6), Se3−Se4−W2 109.65(5), C4−W2−Se4 129.3(3), C5−W2−Se4 75.3(2), C6−W2−Se4 74.7(3).

Figure 2. Molecular structure of $[CpW(CO)_3SeC(O)NMe_2]$ (**2**) (50% probability ellipsoids, cp hydrogens omitted for clarity)[a]



[a] Selected bond lengths [pm] and angles [°]: W−Cp (ring center) 200.6, W−Se 263.08(8), Se−C4 196.1(6), C4−N 133.6(8), N−C5 146.3(8), N−C6 146.7(8); C1−W−Se 74.3(2), C2−W−Se 129.4(2), C3−W−Se 75.6(2), W−Se−C4 103.8(2), Se−C4−N 114.5(4), O4−C4−N 123.8(6), Se−C4−O4 121.7(5), C4−N−C5 124.4(5), C4−N−C6 118.0(5), C5−N−C6 117.3(5).

pm out of this plane. The W−Se bond length of 263.08(8) pm is comparable with other W−Se bond lengths in organoselenolato tungsten complexes with terminal selenolato ligands {e.g. 258.8(2) pm in $[(\eta^7\text{-}C_7H_7)(CO)_2WSePh]$[12]; 263(2) pm in $[CpW(CO)_3SeCH_2CHCH_2]$[3d] and 262.3(1) pm in $[CpW(CO)_3SeCH_2Ph]$[3a]}, whereas complexes with bridging selenolato groups display considerably shorter W−Se bond lengths {e.g. 251.3(5) pm in $[W_2Cl_4(\mu\text{-}SePh)(\mu\text{-}Cl)(dppm)_2]$[13] and 254.9(1) pm in $[PPh_4]_2[Cl_3W(\mu\text{-}SeCl)(\mu\text{-}SePh)_2WCl_3]$[14]}. The selenium atom displays a slightly distorted tetrahedral angle of 103.8(2)°.

Experimental Section

All manipulations were carried out under a dry nitrogen atmosphere using conventional Schlenk techniques. − NMR: Bruker AC 200 (^{1}H 200 MHz, ^{13}C 50.3 MHz, ^{77}Se 38.2 MHz). The spectra were recorded using $CDCl_3$ or C_6D_6 as solvents. Standards: ^{1}H, ^{13}C TMS internal; ^{77}Se Me_2Se external. − IR: Biorad FTS 165. − MS: Finnigan MAT 8430. − *N,N*-Dimethylformamide (DMF) was distilled under nitrogen prior to use. Tetrahydrofuran (THF) was dried over sodium in nitrogen atmosphere. $KBEt_3H$ (1 M in THF), Se, and 18-crown-6 were purchased from Aldrich and used as received. $[CpW(CO)_3Cl]$ was prepared according to the literature method[15].

Reaction of "K_2Se_6"/18-Crown-6 with $[CpW(CO)_3Cl]$ in DMF: 2.7 ml of a solution of $KBEt_3H$ (1 M in THF, 2.7 mmol) were added to 20 ml of DMF. After 10 min of stirring, 0.64 g of Se (8.1 mmol) were added, and the mixture was refluxed for 2 h. After cooling to room temperature, 0.71 g of 18-crown-6 (2.7 mmol) were added to the deep green solution, which was then combined with a solution of 1 g of $[CpW(CO)_3Cl]$ in 20 ml of DMF over a period of 10 min via a syringe. Stirring for 18 h afforded a dark green reaction mixture, which was evaporated to dryness. The residue was extracted three times with 50-ml portions of diethyl ether, leaving a black residue. The work-up procedure of the red organic extract comprised removal of the solvent in vacuo and column chromatography (SiO_2, 20 × 4 cm, CH_2Cl_2/acetone, 95:5, as eluent). The first red band was characterized as $\{[CpW(CO)_3]_2Se_4\}$ **1**[4]. The second orange band corresponds to $[CpW(CO)_3SeC(O)NMe_2]$ **2**. The black precipitate was treated with 10 ml of CH_2Cl_2/acetone, 9:1. The crude mixture was then filtered and column chromatography in the same solvent mixture (SiO_2, 20 × 4 cm) afforded $[(18\text{-crown-}6)K]^+[CpW(Se_4)_2]^-$ **3** in the deep green band accompanied by a small amount of immobile brown impurities.

1: Yield 0.122 g (10%), m.p. 126°C. The spectroscopic data were consistent with those previously described[4].

2: Yield: 0.520 g (40%), m.p. 138°C. − ^{1}H NMR (C_6D_6): δ = 2.65 (s, 3 H, CH_3), 2.87 (s, 3 H, CH_3), 4.9 (s, 5 H, C_5H_5). − ^{13}C NMR (C_6D_6) δ = 36.4 (s, CH_3), 39.8 (s, CH_3), 93.1 (s, C_5H_5), 164.8 (s, μ-CO), 213.9, 226.2 (s, CO). − ^{77}Se NMR (C_6D_6): δ = −136.1 (s). − IR (CH_2Cl_2): $\tilde{\nu}$ = 2029, 1951, 1925 (CO), 1626 (μ−CO). − MS (70 ev); *m/z* (%): 457 (88) [M^+ − CO], 429 (43) [M^+ − 2 CO], 401 (100) [M^+ − 3 CO]. − $C_{11}H_{11}NO_4SeW$ (484.0): calcd. C 27.30, H 2.29, N 2.89; found C 27.31, H 2.38, N 2.84.

3: Yield: 0.140 g (9% on Se), m.p. 153°C. − ^{1}H NMR ($CDCl_3$): δ = 3.47 (s, 24 H, CH_2), 5.02 (s, 5 H, C_5H_5). − ^{13}C NMR ($CDCl_3$): δ = 70.1 (s, CH_2), 94.6 (s, C_5H_5). − ^{77}Se NMR ($CDCl_3$): δ = 486.1 (s, Se-*Se*-*Se*-Se), 866.3 [s, ^{183}W satellites, $J(^{77}Se\text{-}^{183}W)$ 80 Hz, W-*Se*). − MS (70 ev); *m/z* (%): 303 (100) [M^+]. − $C_{17}H_{29}KO_6Se_8W$ (1184.0): calcd. C 17.25, H 2.47; found C 17.41, H 2.46.

Reaction of "K_2Se_6"/18-Crown-6 with $[CpW(CO)_3Cl]$ in THF: A similar reaction in THF employing the same quantities of Se, 18-crown-6, and $[CpW(CO)_3Cl]$ led to the formation of **1** as the main product in 40% yield, together with insoluble inorganic tungsten selenides.

Reaction of "K_2Se_8"/18-Crown-6 with $[CpW(CO)_3Cl]$ in DMF: The reaction was performed as described above using 0.85 g of Se (10.8 mmol). After evaporating to dryness, the black residue was washed three times with 25 ml portions of diethyl ether. In contrast to the reaction with "K_2Se_6", the organic extract contained only traces of **1** and **2**. The remaining black precipitate was treated as described above, yielding 0.48 g **3** (30%), accompanied by immobile brown impurities.

Crystal Structure Determinations[16]: Suitable crystals of **1** and **2** were obtained by layering CH_2Cl_2 solutions with hexanes (ambient temperature), mounted on glass fibers in inert oil and transferred to the cold gas stream of the diffractometer (Siemens P4, −100°C) equipped with an LT-2 low-temperature attachment. Mo-K_α radiation (λ = 0.71073 Å, graphite monochromator) was used to collect the intensity data in the ω-scan mode. Cell constants were refined from setting angles of 62 reflections in the 2 Θ range 8−23°. Absorption corrections based on ψ-scans were applied. The crystallographic program system used was SHELXL-93[17]. Both structures were solved by direct methods and refined by full-matrix least-squares procedures on F^2. All non-H atoms were refined anisotropically; hydrogen atoms were included using a riding model or as rigid methyls. The final difference Fourier maps were featureless; in the case of **1**, the highest peak of 1.95 e Å^{-3} is located near the

Keywords: Rhodium / N ligands / Carbonyl complexes / Methoxycarbonyl / Dinuclear complexes

The reaction of 1,4,7-trimethyl-1,4,7-triazacyclononane (Cn*) with [{(CO)$_2$Rh(μ-Cl)}$_2$] in methanol at 0°C, followed by the addition of NH_4PF_6, results in the formation of the mononuclear carbonyl complex [Cn*Rh(μ-CO)$_2$]PF_6 ([**1**]PF_6), the dinuclear carbonyl complex [Cn*Rh(μ-CO)$_3$RhCn*](PF$_6$)$_2$ {[**2**](PF$_6$)$_2$} and the dinuclear methoxycarbonyl complex [Cn*Rh(C(O)OMe)(μ-CO)$_2$RhCn*]PF_6 ([**3**]PF_6). The reaction of [**2**](PF$_6$)$_2$ with NaOMe results in formation of [**3**]PF_6 by the attack of the methoxide at a bridging carbonyl. Treatment of [**3**]PF_6 with NH_4PF_6 regenerates [**2**](PF$_6$)$_2$, thus showing that the methoxylation of [**2**](PF$_6$)$_2$ is reversible. The structures of [**1**]PF_6, [**2**](PF$_6$)$_2$ and [**3**]PF_6 have been determined by single-crystal X-ray diffraction. For [**3**]PF_6 an unprecendented facile, reversible, migration of the C(O)OMe ligand between the two rhodium centres of the Rh(μ-CO)$_2$Rh core is observed.

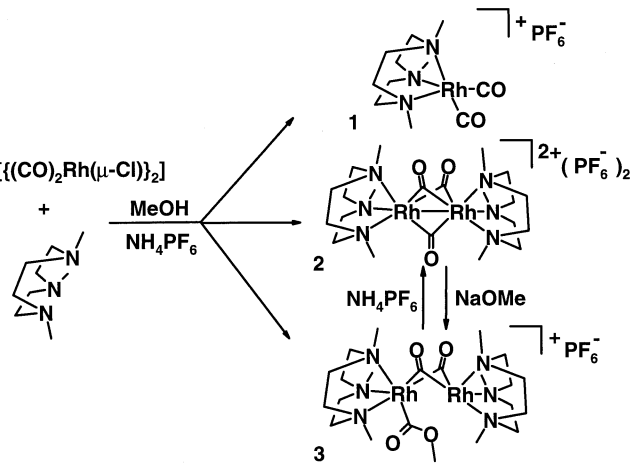
Tridentate N-donor ligands ('N_3' ligands) have so far found a limited application in the area of the organometallic chemistry of rhodium. Interesting reactivities have however been reported for rhodium complexes with *fac*-coordinating 1,4,7-trimethyl-1,4,7-triazacyclononane (Cn*) and [hydrotris(3,5-pyrazolyl)borate] (Tp^{Me2}) [1][2], and *mer*-coordinating pyridine-2,6-diimine (2,6-(C(R)=N-R')$_2$-C_5H_3N).[3] For ['N_3' Rh^I(cod)]$^+$, ['N_3' is Cn* or *N*-butyl-*N,N*-di-(2-pyridylmethyl)amine], we have recently reported on the oxidation of the cod ligand by H_2O_2 to a bicyclooxanonadiyl fragment.[4] In an extension of our explorative studies on the structure and reactivities of 'N_3' Rh sites, we now report on the carbonyl chemistry of Cn*Rh^I sites.

Results and Discussion

The reaction of the rigid *fac*-ligand Cn* with {[(CO)$_2$Rh(μ-Cl)]$_2$} in methanol at 0°C, followed by addition of NH_4PF_6, leads to the precipitation of a mixture of yellow [**2**](PF$_6$)$_2$ and orange [**3**]PF_6. Upon cooling of the filtrate, further precipitation of [**2**](PF$_6$)$_2$ and [**3**]PF_6 occurred, and a few bright-orange crystals of [**1**]PF_6 deposited (Scheme 1).

From the solid mixture that was obtained by filtration, the crystals of [**1**]PF_6 were removed by hand. We were able to interconvert [**2**](PF$_6$)$_2$ and [**3**]PF_6 in the resulting mixture; reaction with approx. 5.5 mol NaOMe per mol of [**2**](PF$_6$)$_2$ in MeOH resulted in the quantitative formation of [**3**]PF_6. Treatment of the same mixture with approx. 7 mol NH_4PF_6 per mol of [**3**]PF_6 in MeOH under reflux resulted in quantitative conversion to [**2**](PF$_6$)$_2$ (Scheme 1). [**2**](PF$_6$)$_2$ and [**3**]PF_6 were isolated as pure compounds via these procedures. Attempts to prepare [**2**](PF$_6$)$_2$ by refluxing an acetone solution of [**1**]PF_6 resulted in the almost quantitative recovery of [**1**]PF_6. Attempts to prepare [**1**]PF_6 by exposure of an acetone solution of [**2**](PF$_6$)$_2$ to 40 bar CO were also unsuccessful.

Scheme 1. Synthesis of [**1**]PF_6, [**2**](PF$_6$)$_2$ and [**3**]PF_6



Structure of [**1**]PF_6

The structure of [**1**]PF_6 was determined by single-crystal X-ray diffraction (Figure 1). Selected bond lengths and angles are given in Tables 1 and 2.

The cation [**1**]$^+$ contains two terminal carbonyl groups. The coordination geometry can best be described as a pseudo trigonal bipyramid. The equatorial positions are occupied by one carbonyl and two nitrogens of the Cn* ligand; the axial-positions by the second carbonyl and the

[a] For atom labelling see Figures 1, 2, and 3. − [b] In accord with the labelling for $[\mathbf{3}]^+$, the symmetry related atoms of N4, N6, C2, and O2 (obtained by applying m) in $[\mathbf{2A}]^{2+}$ and $[\mathbf{2B}]^{2+}$, are presented as N5, N7, C3, and O3, respectively, for reasons of comparison.

third nitrogen of Cn*. Remarkably, the N donors in the trigonal plane (N4 and N5) span the smallest N−Rh−N angle [76.41(11)°]. In order to be closer to the ideal 120° angle for a trigonal bipyramid, these N donors would be expected to span the largest N−Rh−N angle.

The axial Rh−N distance [Rh1−N31: 2.139(3) Å] is shorter than the equatorial Rh−N distances. [Rh1−N4: 2.261(3) Å, Rh1−N6: 2.320(3) Å]. The Rh−C and C−O distances of the equatorial and the axial carbonyl groups of cation $[\mathbf{1}]^+$ are equal within the experimental error (averaged distances: Rh−C: 1.83 Å, C−O: 1.14 Å) and are comparable to those in known five-coordinate $(L)_3Rh^I(CO)_2$ complexes.[5][6] In contrast to $[\mathbf{1}]^+$, these are all neutral complexes containing a monoanionic ligand, mostly a Cp-derivative. (Observed range in Rh−C distances: 1.824−1.867 Å, C−O distances: 1.109−1.154 Å.) Thus far, the hydrotrispyrazolylborate ($Tp^{R,R'}$) complex $[(Tp^{CF3,Me})Rh^I(CO)_2]$ was the only "five-coordinate" $'N_3'Rh^I(CO)_2$ complex with a reported X-ray structure.[6] In this complex, one of the three pyrazolyl groups is only weakly bound to the apical position in a square pyramidal geometry [Rh−N: 2.636(5)]. The basal Rh−N distances are 2.116(4) and 2.114(5) Å. Other reported bond lengths are: Rh−C: 1.824(7), 1.832(9) Å, C−O: 1.145(12), 1.146(9) Å. In solution $[(Tp^{CF3,Me})Rh^I(CO)_2]$ behaves like other $[Tp^{R,R'}Rh^I(CO)_2]$ derivatives in that it gives rise to equilibria between four and five coordination.[7]

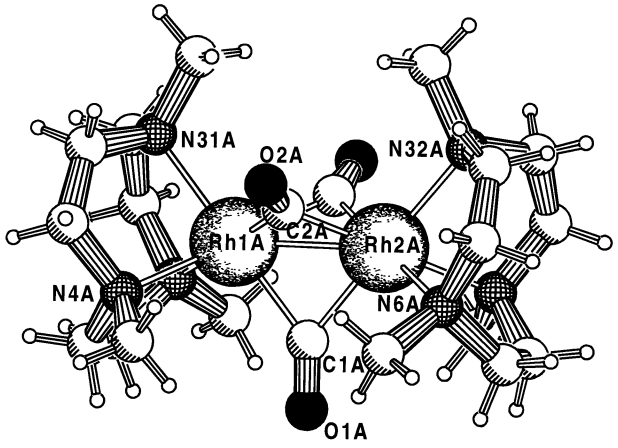
The positions of the terminal ν_{CO} bands in the IR spectra of $[\mathbf{1}]PF_6$ in the solid state (KBr: 2054 and 1962 cm^{-1}) differ significantly from those in solution (CH_3CN: 2063 and 1980 cm^{-1}). A square pyramidal or even a square planar

geometry for [**1**]PF_6 in solution can therefore not be excluded. The latter geometry however seems unlikely, as it would require the rather rigid Cn* ligand to be κ^2-coordinated in solution. The ^{1}H-NMR spectrum of [**1**]PF_6 in [D$_6$]acetone or CD_3CN shows one singlet for the three N−CH_3 groups of the Cn* ligand, and one AA′BB′-multiplet pattern for its diastereotopic N−CH_aH_b− protons. The ^{13}C-spectrum of [**1**]PF_6 shows only one doublet at δ = 189 ($^1J_{C-Rh}$ = 73 Hz) for both carbonyl groups. The equivalence of its N−CH_2− and its N−CH_3 groups in the ^{1}H-NMR spectrum and the two carbonyls in the ^{13}C-spectrum must result from the rapid exchange of positions by Cn* nitrogens and carbonyl carbons at room temp.

Structure of [**2**]$(PF_6)_2$

Bright yellow crystals of compound [**2**]$(PF_6)_2$ were obtained from a saturated MeOH solution. From one of these crystals the structure of the cation [**2**]$^{2+}$ was determined by X-ray diffraction (Figure 2). Selected bond lengths and angles are given in Tables 1 and 2.

Figure 2. Crystal structure of cation [**2A**]$^{2+}$



In the crystal structure two independent cations, [**2A**]$^{2+}$ and [**2B**]$^{2+}$, are found per unit cell. Each cation only slightly deviates from C_{2v} symmetry. A crystallographic mirror-plane passes through Rh1, Rh2, and C1. The two rhodium centers are bridged via three carbonyl groups. The coordination geometry of the two (μ-CO)$_3$ bridged rhodium atoms can best be described as distorted octahedral. In contrast to [**1**]$^+$, all N−Rh−N angles in [**2A**]$^{2+}$ and [**2B**]$^{2+}$ are found at approx. 81°.

The rather short Rh−Rh distances of the two independent cations, Rh1A−Rh2A 2.5888(14) and Rh1B−Rh2B 2.5930(12) Å, are in accordance with a Rh−Rh single bond, resulting from application of the 18 VE rule. Theoretical calculations however indicated that actual M−M binding in M(d8)(μ-CO)$_3$M(d8) systems is much weaker.[8] The various Rh−N, Rh−C, and C−O distances are equal within experimental error (averaged distances: Rh−N: 2.20 Å, Rh−C: 2.01 Å, C−O: 1.16 Å). There are a few literature reports of complexes containing the [Rh(μ-CO)$_3$Rh]$^{2+}$ core.[9] The distances and angles of the [Rh(μ-CO)$_3$Rh]$^{2+}$ core of [**2**]$(PF_6)_2$ compare well with those of [Rh(μ-CO)$_3$Rh]$^{2+}$ cores that have previously been characterized by single crystal X-ray diffraction; They involve ′N_3′ ligands, viz. methyl(trispyrazolyl)gallate[10] and two macrocyclic hexaamine-type ligands,[11] and a tripod ′O_3′ ligand.[12] On the basis of spectral and analytical data, complexes containing the [Rh(μ-CO)$_3$Rh]$^{2+}$ core have been proposed with the ′N_3′ ligands tris(pyrazolyl-1-yl)methane,[13] a macrocyclic hexaamine[14] and hydrotris(pyrazolyl)borate.[15] For the ′S_3′ ligand 2,5,8-trithia[9]-*o*-cyclophane it was reported that two [′S_3′Rh(CO)$_2$]$^+$ species exist in equilibrium with [′S_3′Rh(μ$_2$-CO)$_3$Rh′S_3′]$^{2+}$ [16], in marked contrast with our own observations for [′N_3′Rh(CO)$_2$]$^+$ and [′N_3′Rh(μ$_2$-CO)$_3$Rh′N_3′]$^{2+}$ (vide supra).

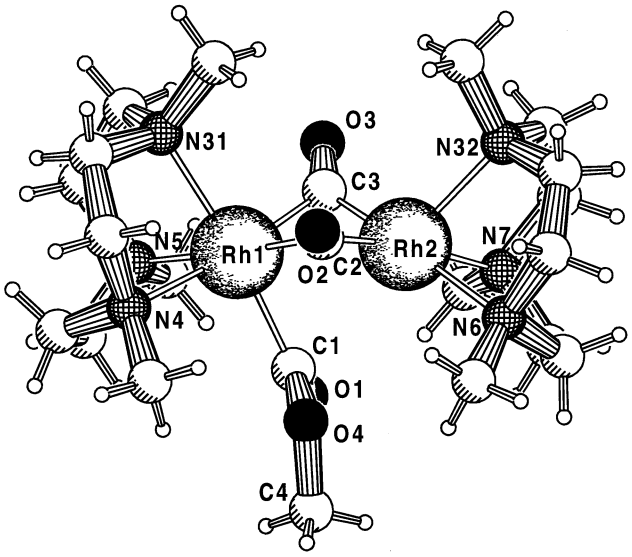
The IR band at 1810 cm^{-1} (CH_3CN) and the triplet ^{13}C-NMR signal at δ = 222 ($^1J_{C-Rh}$ = 28.7 Hz) indicate that the tri(μ-carbonyl) bridge is maintained in solution. The ^{1}H-NMR and ^{13}C-NMR signals for the two Cn* ligands show that [**2**]$^{2+}$ has an effective D_{3h} symmetry in solution. The N−CH_2− groups are observed as one singlet in the ^{1}H-NMR spectrum in [D$_6$]acetone, but the chemically inequivalent *endo*- and *exo*-protons are observed as the expected AA′BB′ multiplet in CD_3CN.

[**2**]$(PF_6)_2$ must be stored in the dark, since exposure to normal (glass-filtered) daylight results in a colour change from yellow, via intermediate green,[17] to dark blue, both in the solid state and in CH_3CN solution. The nature of the resulting blue compound is currently under investigation.[18]

Structure of [**3**]PF_6

Pale orange crystals of [**3**]PF_6 were obtained from a saturated MeOH solution, and the structure of cation [**3**]$^+$ was determined by X-ray diffraction (see Figure 3). Selected bond lengths and angles are given in Tables 1 and 2.

Figure 3. Crystal structure of cation [**3**]$^+$



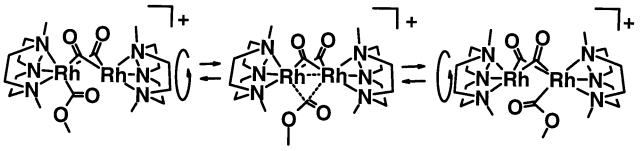
Comparison of Figures 2 and 3 shows that one of the three μ-carbonyl groups in [**2**]$^{2+}$ has been converted to a methoxycarbonyl group in [**3**]$^+$. This group is bound to

only one of the two rhodium centres, at a Rh1−C1 distance of 2.114(8) Å, thus leaving the other rhodium centre apparently coordinatively unsaturated at a Rh2−C1 distance of 2.709(10) Å. The Rh1−C1 distance in $[\mathbf{3}]^+$ is relatively long compared to those in previously reported Rh−C(O)OR complexes, viz. 1.918(9),[19] 2.041(5)[20] and 2.088(11)[21]Å. These complexes are all Rh^{III}-complexes. Ir−C distances in Ir−C(O)OR complexes have been found in the range 2.005 to 2.084 Å,[22] with the exception of a value of 2.20(4) Å reported for Ir−C(O)OMe in $[Ir_4(CO)_{11}\{C(O)OMe\}]^-$.[23] The Rh−Rh distance in $[\mathbf{3}]^+$, 2.6512(6) Å, is somewhat elongated compared to that in $[\mathbf{2}]^{2+}$, perhaps indicating the absence of a Rh−Rh bond in $[\mathbf{3}]^+$. This would make Rh1 a 18 VE, six-coordinate Rh^I site and Rh2 a 16 VE, five-coordinate Rh^I site. Strikingly, the Cn* ligands in $[\mathbf{3}]^+$ are found to be bound equally strongly to Rh1 and Rh2. Also there appear to be no significant differences between the Rh−N distances for N trans to μ-CO and N trans to the methoxycarbonyl-group or the vacant site. The average Rh−N distance in $[\mathbf{3}]^+$, 2.26 Å, is approx. 0.06 Å longer than that in $[\mathbf{2}]^+$. The largest difference between $[\mathbf{2}]^+$ and $[\mathbf{3}]^+$ is seen in the bonding of the bridging carbonyls. The addition of a methoxy anion to one of the three carbonyls in $[\mathbf{2}]^+$ has resulted in an asymmetric coordination of the remaining two bridging carbonyls. They are bound approx. 0.1 Å more tightly, and their O−C−Rh angles are approx. 5° less acute for the "coordinatively unsaturated" Rh2. The Rh1−C2 and Rh1−C3 distances in $[\mathbf{3}]^+$ are comparable to those found for $[\mathbf{2}]^+$. In the IR spectrum of $[\mathbf{3}]PF_6$ (KBr), three C−O stretching modes at 1771(w), 1708(s), and 1607(m) are observed. The first two are considered to be μ-CO vibrations, the latter is assigned to the carbonyl group of the C(O)OMe fragment. The appearance of a peak at *m/z* = 777 ($[M - OMe]^+$), besides peaks at *m/z* = 808 ($[M]^+$) and *m/z* = 663 ($[M-PF_6]^+$), in the FAB-MS spectrum shows loss of MeO^- under FAB conditions.

Fluxional Behaviour of in $[\mathbf{3}]^+$ *in Solution: C(O)OMe Migration*

The IR spectrum of $[\mathbf{3}]PF_6$ in CH_3CN [ν_{CO} 1774 (w), 1715 (s), 1618 (m)] is quite similar to that recorded in KBr, indicating that the structure of $[\mathbf{3}]^+$ is maintained in solution. In the ^{1}H-NMR spectrum of $[\mathbf{3}]^+$ the methoxy protons are observed as a singlet at δ = 3.5. In [D$_6$]acetone at room temperature only two singlets are observed for both Cn* groups, one singlet for all the N−CH_3 groups and one for all the N−CH_2− groups. In the ^{1}H-NOESY spectrum of $[\mathbf{3}]PF_6$ NOE contacts are observed between the methoxy group and the methyl and methylene protons of the Cn* ligands. As observed for $[\mathbf{2}]^{2+}$, in CD_3CN the N−CH_2− signal splits into an AA′BB′ pattern. Apparently $[\mathbf{3}]^+$ has effective D_{3h} symmetry in which the two Cn* ligands, and the N−CH_2− and N−CH_3 groups within the Cn* ligands are equivalent on the NMR timescale. In the room temperature ^{13}C-spectrum in CD_3CN, the 18 different carbons in the two distinct Cn* ligands found in the X-ray structure give only two averaged ^{13}C signals, one at δ = 58.0 for the twelve N−CH_2− groups and one at δ = 51.5 for the six N−CH_3 groups. This must result from a fast equilibrium in solution. Two triplet signals are observed for the carbonyl groups, one at δ = 248.1 ($^1J_{Rh-C}$ = 37.5 Hz) for the μ-CO groups and one at δ = 179.9 ($^1J_{Rh-C}$ = 17.3 Hz) for the carbonyl of the C(O)OMe ligand, with relative intensity of 2:1. The apparently equal coupling of the C(O)OMe carbonyl signal with both rhodium centres must be the result of a rapid migration of the methoxycarbonyl ligand between Rh1 and Rh2. (Figure 4) As a result, each Rh-atom becomes alternately five and six coordinate. The observed apparent $^1J_{Rh-C}$ of 17.3 Hz is quite small compared to that in other Rh−C(O)OR compounds (31−55 Hz)[19][20][21]. It converts to an actual value of 34.6 Hz, comparable to the literature values, under the assumption that $^3J_{Rh-C}$ in the static structure of $[\mathbf{3}]^+$ is close to zero.

Figure 4. Proposed mechanism of methoxycarbonyl migration in $[\mathbf{3}]PF_6$



We propose that the observed averaging of NMR signals for the N−CH_2− and the N−CH_3 groups of the two Cn* ligands in $[\mathbf{3}]^+$ results from a combination of two fast processes: reversible migration of the C(O)OMe ligand between both Rh centres, and exchange of nitrogen donor atom positions at the five-coordinate rhodium centre. The latter is also observed in five-coordinate $[\mathbf{1}]^+$ (vide supra).

We thank *Unilever Research laboratory Vlaardingen* for a generous supply of 1,4,7-trimethyl-1,4,7-triazacyclononane.

Experimental Section

General Procedures: All reactions were performed under a nitrogen atmosphere using standard Schlenk techniques. Solvents (p.a.) were deoxygenated by bubbling through a stream of N_2, or by the freeze-pump-thaw method. $[\{(CO)_2Rh(\mu\text{-}Cl)\}_2]$ was prepared according to a literature procedure.[24] 1,4,7-trimethyl-1,4,7-triazacyclononane (Cn*) was generously supplied by Unilever Research. All other chemicals are commercially available and were used without further purification. − FT-IR: Perkin Elmer 1720X. − NMR: Bruker DPX200 (200 MHz and 50 MHz for ^{1}H and ^{13}C, respectively), Bruker AC300 (300 MHz and 75 MHz for ^{1}H and ^{13}C, respectively). Solvent shift reference for ^{1}H NMR: [D$_6$]acetone δ_H = 2.05, CD_3CN δ_H = 1.98. For ^{13}C NMR: [D$_6$]acetone δ_C = 29.50, CD_3CN δ_C = 1.28. − FAB-MS: VG7070E.

Preparation of a Mixture of $[\mathbf{1}]PF_6$, $[\mathbf{2}](PF_6)_2$ *and* $[\mathbf{3}]PF_6$: In a typical experiment 200 mg of (1.16 mmol) Cn* was dissolved in 15 ml of MeOH and the resulting solution was cooled to 0°C. 234 mg (0.6 mmol) of $[\{(CO)_2Rh(\mu\text{-}Cl)\}_2]$ was subsequently added and the orange solution was stirred for approximately 1 h. Evolution of a slight amount of gas was noticed. The addition of 800 mg (4.91 mmol) of NH_4PF_6, dissolved in 5 ml of MeOH, to the reaction mixture caused the precipitation of a mixture of $[\mathbf{2}](PF_6)_2$ and $[\mathbf{3}]PF_6$, which was collected by filtration. Combined yield 650 mg, ca. 60% based on $[\{(CO)_2Rh(\mu\text{-}Cl)\}_2]$. The filtrate was used to isolate a minor fraction of compound $[\mathbf{1}]PF_6$.

[**1**]PF_6: [**1**]PF_6 was obtained as bright orange crystals, suitable for X-ray diffraction, by cooling the filtrate of the reaction mixture described above to −30°C. Besides further precipitation of [**2**]$(PF_6)_2$ and [**3**]PF_6 a small amount of bright orange crystals of [**1**]PF_6 slowly deposited after some days. A few large crystals of [**1**]PF_6 could be isolated (hand-picking) from the resulting solid mixture.− ^{1}H NMR (200 MHz, CD_3CN): δ = 3.3−2.8 (m, 12 H, N−CH_2−), 3.19 (d, 9 H, $^3J_{Rh-H}$ = 1 Hz, N−CH_3). − ^{13}C NMR (50 MHz, CD_3CN): δ = 189 (d, $^1J_{Rh-C}$ = 73 Hz, Rh−*C*O), 59.6 (N−CH_2−), 55.3 (N−CH_3). − FT-IR (KBr): $\tilde{\nu}$ = 2054 cm^{-1}, 1962 (CO). − FT-IR (CH_3CN): $\tilde{\nu}$ = 2063 cm^{-1}, 1980 (CO). − FAB-MS; *m/z*: 273 [M−$(CO)_2$−PF_6−H]$^+$. − CHN analysis was not performed due to the small amount of pure [**1**]PF_6 obtained.

[**2**]$(PF_6)_2$: 800 mg (4.91 mmol) of NH_4PF_6 was added to 600 mg of the solid mixture of [**2**]$(PF_6)_2$ and [**3**]PF_6, prepared as decribed above. 15 ml of MeOH was subsequently added, and the mixture was refluxed (all solid material redissolved) for approximatly 10 min. After cooling to room temp., the MeOH solvent was partially evaporated. Compound [**2**]$(PF_6)_2$ crystallized as bright yellow cubes from the solution at −30°C, and was collected by filtration. Yield 550 mg (ca. 80%). − ^{1}H NMR (200 MHz, CD_3CN): δ = 3.30−2.90 (m, 24 H , N−CH_2−), 2.84 (s, 18 H, N−CH_3). − ^{1}H NMR (200 MHz, [D_6]-acetone): δ = 3.44 (s, 24 H , N−CH_2−), 3.14 (s, 18 H, N−CH_3). − ^{13}C NMR (50 MHz, [D_6]-acetone): δ = 221.9 (t, $^1J_{Rh-C}$ = 28.7 Hz, μ_2-CO), 58.5 (N−CH_2−), 52.0 (N−CH_3). − FT-IR (KBr): $\tilde{\nu}$ = 1803 cm^{-1} (μ-CO). − FT-IR (CH_3CN): $\tilde{\nu}$ = 1810 cm^{-1} (μ-CO). − FAB-MS; *m/z*: 777 [M−PF_6]$^+$, 748 [M−CO−PF_6]$^+$, 604 [M−CO−2PF_6]$^+$, 316 [M−2PF_6]$^{2+}$. − Calculated for $C_{21}H_{42}F_{12}N_6O_3P_2Rh_2$: C 27.35, H 4.59, N 9.11 Found: C 27.33, H 4.57, N 8.98.

[**3**]PF_6: 100 mg (1.9 mmol) of NaOMe was added to 300 mg of the solid mixture of [**2**]$(PF_6)_2$ and [**3**]PF_6, prepared as decribed above. 15 ml of MeOH was subsequently added, and the mixture was refluxed (all solid material redissolved) for approximatly 10 min. After cooling to room temp., the MeOH solvent was partially evaporated. Compound [**3**]PF_6 crystallized as pale orange needles from the solution at −30°C, and was collected by filtration. Yield 200 mg (ca. 70%). − ^{1}H NMR (200 MHz, [D_6]acetone): δ = 3.54 (s, 3 H, OCH_3), 2.90 (s, 24 H, N−CH_2−), 2.81 (d, $^3J_{C-Rh}$ = 0.8 Hz, 18 H, N−CH_3). − ^{13}C NMR (50 MHz, [D_6]acetone): δ = 57.7 (N−CH_2−), 51.1 (N−CH_3), 50.9 (OCH_3) (^{13}C-carbonyl signals undetected, due to low solubility). − ^{1}H NMR (300 MHz, CD_3CN): δ = 3.52 (s, 3 H, OCH_3), 2.90−2.55 (m, 24 H, N−CH_2−), 2.76 (d, $^3J_{H-Rh}$ = 0.80 Hz, 18 H, N−CH_3). − ^{13}C NMR (75 MHz, CD_3CN): δ = 248.1 (t, $^1J_{C-Rh}$ = 37.5 Hz, μ-CO), 179.9 (t, $^1J_{C-Rh}$ = 17.3 Hz, *C*(O)OMe), 58.0 (N−CH_2−), 51.5 (N−CH_3), 51.4 (OCH_3). − FT-IR (KBr): $\tilde{\nu}$ = 1771 cm^{-1} (w), 1708 (s) (μ-CO), 1607 (m) (C=O), 1048 (C−O). − FT-IR (CH_3CN): $\tilde{\nu}$ = 1774 cm^{-1} (w), 1715 (s) (μ-CO), 1618 (m) (C=O), (C−O) obscured by solvent vibrations. − FAB-MS; *m/z*: 808 [M]$^+$, 777 [M−OMe]$^+$, 663 [M−PF_6]$^+$, 604 [M−PF_6−OMe−CO]$^+$, 576 [M−PF_6−OMe−2CO]$^+$. − Calculated for $C_{22}H_{45}F_6N_6O_4PRh_2$: C 32.69, H 5.61, N 10.40 Found: C 32.33, H 5.37, N 10.06.

X-ray Structure Determination of [**1**]PF_6, [**2**]$(PF_6)_2$ *and* [**3**]PF_6: Crystals of [**1**]PF_6, [**2**]$(PF_6)_2$ and [**3**]PF_6 suitable for X-ray diffraction studies were obtained by cooling a saturated solution of the corresponding compound in MeOH to −30°C. Single crystals were mounted in air on glass fibres. Intensity data were collected at room temp. For all three compounds an Enraf-Nonius CAD4 single-crystal diffractometer was used, graphite monochromatized Cu-*Kα* radiation, θ-2θ-scan mode. Unit cell dimensions were determined from the angular setting of 25 reflections. Intensity data were corrected for Lorentz and polarization effects. Semi-empirical absorption correction (*Ψ*-scan) was applied for all three compounds.[25]

Structures were solved by the program system DIRDIF[26] using the program PATTY[27] to locate the heavy atoms and were refined with standard methods (refinement against F^2 of all reflections with SHELXL97[28]) with anisotropic parameters for the nonhydrogen atoms. For **[1]**PF_6 the hydrogens were initially placed at calculated positions and were subsequently refined freely. For **[2]**$(PF_6)_2$ and **[3]**PF_6 all hydrogens were refined riding on the parent atoms. Details of the crystal parameters, data collections and structure refinements are given in Table 3. Crystallographic data (tables of structure determinations summaries, lists of anisotropic displacement parameters, lists of atom coordinates and full lists of bond lengths and angles, excluding structure factors) have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication no. CCDC-179-100725. Copies of the data can be obtained free of charge on application to The Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) +44(1223) 336-033; E-mail: deposit@ccdc.cam.ac.uk].

Received November 14, 1997

Keywords: Ruthenium / Phosphorus / Triphos complexes / Fluxionality / Arm-off dissociation

Structural fluxionality is apparent in the ^{1}H- and ^{31}P-NMR spectra of compounds of the type [Ru(L)(MeCN)(triphos)](CF_3SO_3), **2**−**5**, at 25°C, where L represents a diorganyldithiocarbamate or a heterocyclic κ^2N,S coordinating thioamide. In contrast, complexes [Ru(Et_2NCS_2)(Y)(triphos)]$^{n+}$ (**6**, n = 1, Y = CO; **7**, n = 0, Y = CN^-; **8**, n = 0, Y = H^-) are stereochemically rigid in solution at this temperature, indicating that MeCN dissociation must occur for the crowded octahedral coordination spheres of **2**−**5**. Reaction of [Ru$(MeCN)_3$(triphos)]$(CF_3SO_3)_2$, **1**, with Na(Et_2NCS_2) at a 1:2 molar ratio yields [Ru$(Et_2NCS_2$-$\kappa^2S)(Et_2NCS_2$-$\kappa S)$(triphos)], **9**, which slowly converts to [Ru$(Et_2NCS_2$-$\kappa^2S)_2$(triphosO-κ^2P)], **10**, on recrystallization from ethanol/acetone under air [triphosO is O=P$(Ph)_2CH_2C(CH_3)(CH_2PPh_2)_2$]. A similar $\kappa^3P\rightarrow\kappa^2P$ arm-off dissociation leads to the formation of [Ru(mpy-$\kappa^2N,S)_2$(triphosO-κ^2P)] (**13**) and [Ru(mmim-$\kappa^2N,S)_2$(triphosO-κ^2P)] (**14**) (Hmpy = 2-mercaptopyridine, Hmmim = 2-mercapto-1-methylimidazole). Crystal structures are reported for [Ru(mbt-κ^2N,S)(MeCN)(triphos-κ^3P)](CF_3SO_3) (**4**) (Hmbt = 2-mercaptobenzothiazole), [Ru(mpym-κ^2N,S)(mpym-κS)(triphos-κ^3P)] (**11**) (Hmpym = 2-mercaptopyrimidine) and **14**, the latter of which is present as the OC-6-13 isomer.

The employment of transition metal complexes of tripodal polyphosphanes such as $CH_3C(CH_2PPh_2)_3$ (triphos) in homogeneous catalysis has attracted considerable interest[1][2][3][4].Although triphos is often regarded as a typical innocent ligand, whose neopentyl skeleton $CH_3C(CH_2)_3$ allows a relatively unstrained occupation of three facial sites in a square-pyramidal, trigonal-bipyramidal or octahedral coordination sphere[5], dissociation of a phosphane arm to provide the more flexible κ^2P binding mode has been implicated for a number of five-coordinate Rh^I and Ir^I complexes[6][7][8][9][10][11][12][13]. The kinetic lability of M^I-P bonds (M = Rh, Ir) can also lead to structural fluxionality at higher temperatures. For instance dissociation of a triphosphane arm in [IrCl(CO)(triphos)] at room temperature enables exchange between the two phosphorus environments and the ^{31}P-NMR spectrum consists solely of a singlet at $\delta = -16.1$[14]. An explanation for this behavior has been sought in the marked reduction in ring strain that may be achieved on going from the facial κ^3P geometry in an $18e^-$ trigonal-bipyramidal complex to the open κ^2P geometry of a square planar $16e^-$ species[11][15].

The idealized P−M−P angles in octahedral Rh^{III} or Ir^{III} complexes provide a relatively unstrained κ^3P geometry for a tripodal polyphosphane, so that the energetic advantage of an open κ^2P coordination mode should be less pronounced than for five-coordinated M^I complexes. However an arm-off dissociation has been implicated for the reaction of the octahedral Rh^{III} complexes [RhL_3(triphos)] (L = Me, H) with CO and H_2[7][15] and ^{1}H- and ^{31}P-NMR evidence have been presented for a $\kappa^3P\rightleftharpoons\kappa^2P$ equilibrium of the triphosphane ligand in solutions of [$RhMe_2$(MeCN)(triphos)]$^+$ at room temperature[11]. We ourselves have recently reported[16][17] the stereochemical non-rigidity of the complex cations [RhL(MeCN)(triphos)]$^{2+}$ in which L represents the bidentate diorganyldithiocarbamates $R_2NCS_2^-$ (R = Et, Bz) or the heterocyclic thioamide $mpym^-$ (Hmpym = 2-mercaptopyrimidine). Both CH_3CN and phosphane arm-off dissociation processes can be proposed to explain the fluxional behavior of such species. κ^2P coordinated complexes of the type [RhL_2(triphos-κ^2P)]$^+$ (L = $Et_2NCS_2^-$, $Me_2NCS_2^-$ $mpym^-$) may be obtained on treating the starting compound [Rh$(MeCN)_3$(triphos)]$^{3+}$ with two equivalents of the potentially chelating ligands L.

These results prompted the present comparative study of fluxionality and phosphane arm-off reactions for analogous isoelectronic octahedral Ru^{II} complexes. Our continuing choice of diorganyldithiocarbamates and heterocyclic thioamides as ligands L was motivated by their ability to coordinate in both a mono- or bidentate fashion[18][19], by the pronounced *trans* effect of their sulfur donor atoms and by their relatively restricted steric demands owing to a small chelating angle of bite. The ambidentate thioamides $mpym^-$, mpy^- (Hmpy = 2-mercaptopyridine), and $mmim^-$(Hmmim = 2-mercapto-1-methylimidazole) were employed for a mechanistic study of isomer formation for complex cations of the type [RuL_2(triphos-κ^2P)]$^+$ and [RuL_2(triphosO-κ^2P)]$^+$ [triphosO is O=P$(Ph)_2CH_2$-$C(CH_3)(CH_2PPh_2)_2$].

Results

Treatment of [Ru$(MeCN)_3$(triphos)]$(CF_3SO_3)_2$ (**1**) with selected anionic ligands L affords the octahedral complexes [Ru(Et_2NCS_2)(MeCN)(triphos)](CF_3SO_3) (**2**), [Ru(pyrdtc)(MeCN)(triphos)](CF_3SO_3) (**3**) (pyrdtc$^-$ = pyrrolidindithi-

 © WILEY-VCH Verlag GmbH, D-69451 Weinheim, 1998 1434−1948/98/0303−0407 $ 17.50+.50/0

ocarbamate), [Ru(mbt)(MeCN)(triphos)](CF_3SO_3) (**4**) (Hmbt = 2-mercaptobenzothiazole), and [Ru(mpym)(MeCN)(triphos)](CF_3SO_3) (**5**) (schemes 1 and 2). Mononuclear structures for the complex cations of **2**−**5** are confirmed by their highest FAB mass peaks, which each correspond to [M − MeCN − CF_3SO_3]$^+$. In contrast, the reduced steric demands of the facially coordinated cyclic thioether 1,4,7-trithiacyclononane ([9]aneS_3) allow the adoption of tridentate μ-1κ*S*:2κ^2*S*,*S*′ and μ-1κ*S*:2κ^2*N*,*S* bridging modes by respectively $Me_2NCS_2^-$ and mbt$^-$ in the dinuclear complexes [{Ru(μ-Me_2NCS_2)([9]aneS_3)}$_2$](CF_3SO_3)$_2$[20] and [{Ru(μ-mbt)([9]aneS_3)}$_2$](CF_3SO_3)$_2$[21]. The latter coordination pattern has also been reported for the organometallic half-sandwich complex [{Ru(μ-mtz)(C_6H_6)}$_2$Cl]Cl[18] (Hmtz = 2-mercapto-2-thiazoline).

4 **5**

Figure 1 depicts the molecular structure of the monocation of **4**. As a result of the very small angle of bite [S(1)−Ru−N(1) = 66.1(2)°] of the coordinating heterocyclic thioamide mbt$^-$, an acetonitrile ligand can occupy the vacant sixth position of a coordination octahedron. However, the narrow S(1)−Ru−N(1) angle causes pronounced distortions in the geometry of the chelating polyphosphane cage. Whereas P(1)−Ru−P(2) [90.6(1)°] remains close to the idealised octahedral angle, both P(1)−Ru−P(3) and P(2)−Ru−P(3) narrow markedly [84.7(1), 86.4(1)°]. A marked *trans* influence of the thioamide sulfur atom is not apparent, indeed Ru−P(2) [2.302(2) Å] is slightly shorter than Ru−P(1) or Ru−P(3) [2.314(2), 2.307(2) Å]. It is instructive to contrast the formation of octahedral monocations in **2**−**5** with the recently reported five-coordinated product [Rh(bdt)(triphos)]$^+$ of the reaction of [$RhCl_3$(triphos)] with Na_2(bdt) [bdt = *o*-benzenedithiolate(2−)][22]. The angle of bite of the κ^2*S* coordinated *o*-benzenedithiolate ligand is no less than 20.3° wider than that of the κ^2*N*,*S* chelating 2-mercaptobenzothiazolate ligand in **4**. This finding suggests that the large Tolman cone angle of at least 220° for the tripodal polyphosphane ligand[23] will prevent the occupation of the potential sixth coordination site in [Rh(bdt)(triphos)]$^+$.

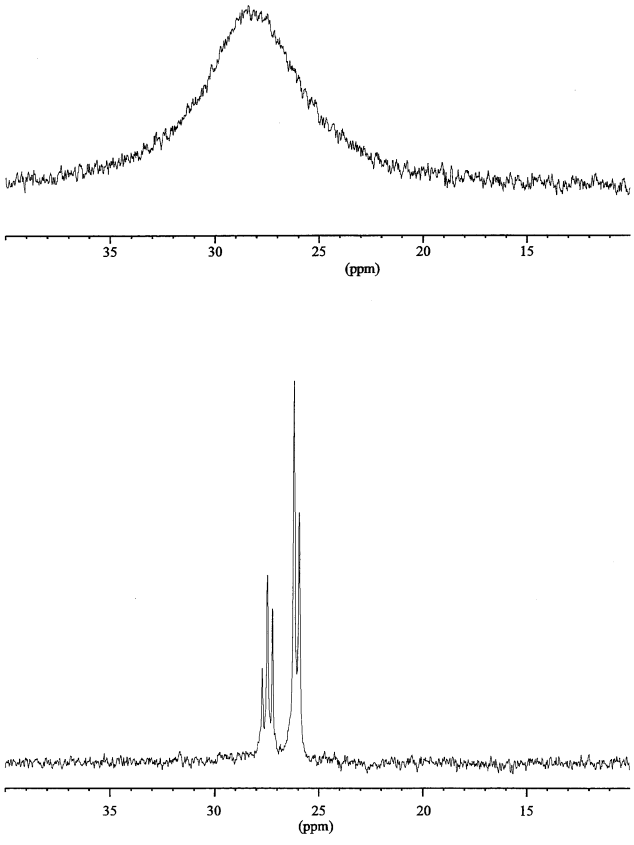
[a] Selected bond lengths [Å] and angles [°]: Ru−P(1) 2.314(2), Ru−P(2) 2.302(2), Ru−P(3) 2.307(2), Ru−S(1) 2.503(2), Ru−N(1) 2.242(6), Ru−N (61) 2.095(5), S(1)−C(1) 2.242(6), Ru−N(61) 2.095(5), S(1)−C(1) 1.714(8), S(2)−C(1) 1.723(8), S(2)−C(3) 1.735(9), S(1)−Ru−P(2) 168.9(1), N(1)−Ru−P(3) 169.9(2), N(61)−Ru−P(1) 178.2(2), P(1)−Ru−P(2) 90.6(1), P(1)−Ru−P(3) 84.7(1), P(2)−Ru−P(3) 86.4(1), S(1)−Ru−N(1) 66.1(2).

Stereochemical non-rigidity is observed for each of the monocations of **2**−**5** at room temperature. Whereas a doublet and triplet at an integral ratio of 2:1 would be expected for the magnetically inequivalent phosphorus atoms of the diorganyldithiocarbamate complexes **2** and **3**, their ^{31}P-NMR spectra in various solvents ($CDCl_3$, MeOD, [D_6]acetone) consist of a single broad uncontoured resonance (in $CDCl_3$ **2** δ = 22−36, **3** δ = 22−32) at ambient temperature [see Figure 2(a)]. As illustrated for **2** in Figure 2(b), cooling to −30°C provides the predicted spin pattern with resolved doublets (**2** δ = 26.10, **3** δ = 25.70) for the P atoms *trans* to the diorganyldithiocarbamate S atoms and a triplet (**2** δ = 27.44, **3** δ = 28.56) for the single P atom *trans* to acetonitrile. Each of the phosphorus atoms in the thioamide-con-

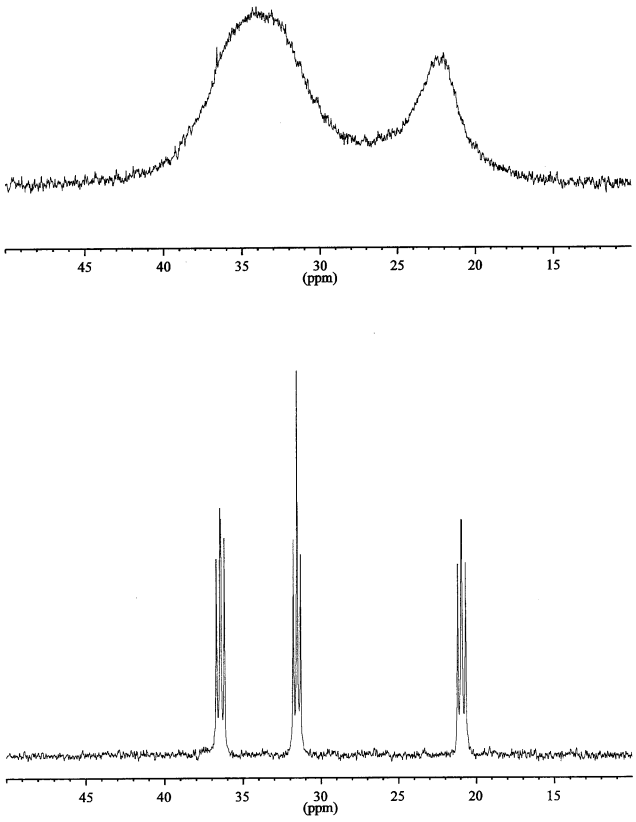
taining cations of **4** and **5** should generate its own separate ^{31}P-NMR resonance. In fact, the fluxional behavior of **4** in $CDCl_3$ solution leads to the observation of only two broad resonances at room temperature [Figure 3(a)]. Although three signals can be identified for **5** at this temperature, they are likewise broad and without fine structure. As may be seen for **4** in Figure 3(b), cooling to −30°C once again provides stereochemical rigidity and three individual triplets (**4** δ = 20.92, 31.52, 36.53; **5** δ = 19.89, 28.05, 37.59) appear in the ^{31}P-NMR spectrum at this temperature. The ^1H-NMR spectra of **2**−**5** are also in accordance with cation fluxionality at room temperature. For instance, whereas only a single broad resonance at δ = 2.43 can be observed for the triphos CH_2 protons of **2** at 25°C, three multiplets can be identified in $CDCl_3$ solution at −30°C: δ = 2.19, 2.30, 2.68). Restricted rotation about the diorganyldithiocarbamate C−N bond also leads to the observation of two signals for the ethyl CH_2 protons of this cation at −30°C (δ = 3.64, 3.84), which then coalesce to a single resonance (δ = 3.82) at ambient temperature.

Figure 2. ^{31}P-NMR spectrum of **2** in $CDCl_3$: (a) at room temperature, (b) at −30°C.



Both CH_3CN and phosphane arm-off dissociation can be discussed as possible mechanisms to explain the stereochemical non-rigidity of the cations $[Ru(L)(MeCN)(triphos)]^+$ of **2**−**5** in solution at 25°C. The position and width of the sharp MeCN singlets in the ^1H-NMR spectra of these complexes in $CDCl_3$ (−30°C: **2** δ = 1.80, **3** δ = 1.87, **4** δ = 1.87, **5** δ = 1.61) remain effectively unchanged on raising the solution temperature from −30°C to 25°C and, therefore, provide no evidence for a rapid acetonitrile exchange process. This finding prompted us to investigate whether fluxionality is also a general phenomenon for other sterically crowded Ru^{II} complexes of the type $[Ru(Et_2NCS_2)(Y)(triphos)]^{n+}$ (**6**, n = 1, Y = CO; **7**, n = 0, Y = CN^- **8**, n = 0, Y = H^-) depicted in Scheme 3. However, ^1H and ^{31}P NMR spectra for **6**−**8** in $[D_6]DMSO$ or $CDCl_3$ at both 25°C or 60°C indicate that these non-acetonitrile complexes are, in fact, all stereochemically rigid in solution. Pronounced highfield shifts are apparent for the P atom in *trans* position to the monodentate ligand Y in both **6** (**6**, L = CO, δ = 3.54) and the hydride complex **8** (δ = 5.29).

Figure 3. ^{31}P-NMR spectrum of **4** in $CDCl_3$: (a) at room temperature, (b) at −30°C.



The implicated lack of triphos arm-off dissociation for Ru^{II} complexes of the type $[Ru(L)(Y)(triphos)]^{n+}$ in solution led us to investigate whether κ^2P coordinated triphos complexes with a dangling phosphone arm can be stabilized by the presence of an excess of a small bite chelating ligand such as $Et_2NCS_2^-$, $mpym^-$, mpy^-, or $mmim^-$. A facial replacement of one binding P atom is observed when $[Rh(MeCN)_3(triphos)]^{3+}$ is treated with two equivalents of bidentate ligands L, thereby yielding[16][17] κ^2P coordinated complexes such as $[Rh(R_2NCS_2\text{-}\kappa^2S)_2(triphos\text{-}\kappa^2P)][CF_3SO_3]$ (R = Et, Me) or $[Rh(mpym\text{-}\kappa^2N,S)_2(triphos\text{-}\kappa^2P)][CF_3SO_3]$. In contrast, retention of a κ^3S facial coordination mode has been reported for the cyclic thioether [9]$aneS_3$ in [Rh(mpym-κ^2N,S)(mpym-

Scheme 3. $[Ru(Et_2dtc)(CO)(triphos)]^+$ cation of **6** and molecules $[Ru(Et_2dtc)(L)(triphos)]^+$ [(L = CN (**7**), H (**8**)]

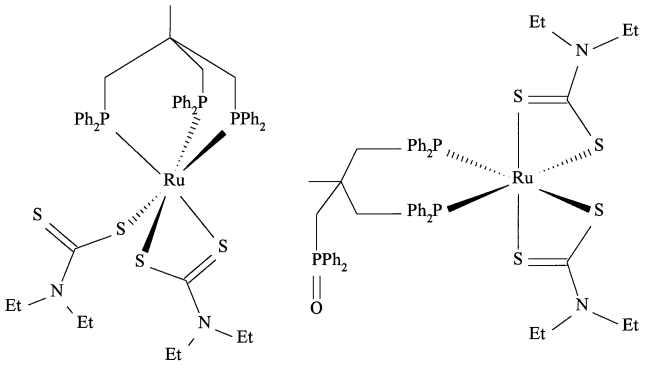
κS)([9]aneS$_3$-$\kappa^3 S$)][CF_3SO_3][19] and [Ru(mbt-$\kappa^2 N,S$)(mbt-κS)([9]aneS$_3$-$\kappa^3 S$)][21]. The presence of both mono- and bidentate dimethyldithiocarbamate ligands has been confirmed for the organometallic half-sandwich complex [Rh(η^5-C_5Me_5)(Me_2NCS_2-$\kappa^2 S$)(Me_2NCS_2-κS)][24].

Treatment of **1** with Na(Et_2NCS_2) at a 1:2 or 1:3 ratio affords the $\kappa^3 P$-triphos coordinated complex [Ru(Et_2NCS_2-$\kappa^2 S$)(Et_2NCS_2-κS)(triphos-$\kappa^3 P$)] (**9**), whose structure (Scheme 4) was established by elemental analysis, FAB mass spectrometry, and NMR spectroscopy. **9** exhibits a doublet at δ = 19.06 for the P atoms *trans* to the $\kappa^2 S$ coordinated chelating ligand and a triplet at δ = 32.37 for the remaining P atom *trans* to the monodentate $Et_2NCS_2^-$ ligand. The presence of a singlet at δ = ca. −25 to −30 would be characteristic for the P atom of a free dangling phosphane arm in a $\kappa^2 P$ coordinated complex[16][17]. Both the ^{1}H- and ^{31}P-NMR spectra are in accordance with stereochemical rigidity of **9** in $CDCl_3$ solution at 25°C. However attempts to recrystallize **9** from an ethanol/acetone solution under air led to formation of the $\kappa^2 P$ coordinated complex [Ru($EtNCS_2$-$\kappa^2 S$)$_2$(triphosO-$\kappa^2 P$)] (**10**) over a period of 14 d in relatively good yield (50%). The oxidation of the uncoordinated P atom is confirmed by the observation of a FAB MS basis peak *m*/*z* for $[M]^+$ at 1038, by a characteristic IR absorption band for $\tilde{\nu}$(PO) at 547 cm^{-1}, and by the presence of a typical ^{31}P-NMR resonance at δ = 26.86, a value very similar to that of 27.18 found for the analogous Rh^{III} complex [Rh(Et_2NCS_2-$\kappa^2 S$)$_2$(triphosO-$\kappa^2 P$)]Cl[16]. It is possible to follow the required $\kappa^3 P \rightarrow \kappa^2 P$ arm-off reaction of the initially $\kappa^3 P$ coordinated triphos in **9** by ^{31}P NMR spectroscopy. After 2d, respective singlets at δ = −26.00 and 26.86 for the dangling phosphorus atom in $\kappa^2 P$ coordinated triphos and its oxidation product triphosO in the final product **10** can be identified. These resonances also appear in the ^{31}P-NMR spectrum of the mixture of [Ru(Et_2NCS_2)$_2$(triphos-$\kappa^2 P$)] and [Ru(Et_2NCS_2)$_2$(triphos-O-$\kappa^2 P$)] present after 7 d in a $CDCl_3$ solution of **9** exposed to air. Whereas overlapping signals for the coordinated P atoms of these complexes may be located in the range δ = 38−40, the phosphorus resonances of **9** (δ = 19.06, 32.37) are now completely absent. It may be assumed that the driving force for the $\kappa^3 P \rightarrow \kappa^2 P$ arm-off reaction will be provided by the thermodynamic advantage of $\kappa^2 S$ chelation of both $Et_2NCS_2^-$ ligands. However, this process proceeds much more slowly than for the analogous Rh^{III} complexes, for which intermediate products of the type [Rh(R_2NCS_2-$\kappa^2 S$)(R_2NCS_2-κS)(triphos-$\kappa^3 P$)]$^+$ cannot be isolated[16].

Scheme 4. [Ru(Et_2dtc)$_2$(triphos)] (**9**) and [Ru(Et_2dtc)$_2$(triphosO)] (**10**)



9 **10**

The reaction of **1** with 2 equivalents of the ambidentate heterocyclic thioamides $mpym^-$, mpy^-, and $mmim^-$ was studied to provide information on possible preferred isomer formation for products of the type [Ru(L)$_2$(triphosO-$\kappa^2 P$)]. As for diethyldithiocarbamate $Et_2NCS_2^-$, $\kappa^3 P$-triphos coordinated complexes [Ru(mpym-$\kappa^2 N,S$)(mpym-κS)-(triphos)] (**11**) and [Ru(mpy-$\kappa^2 N,S$(mpy-κS)(triphos)] (**12**) can be isolated in high yield at room temperature. Both are once again stereochemically rigid in solution at 25°C and may be characterized by their FAB MS basis peaks $[M]^+$ and the presence of three ^{31}P NMR triplets in the range δ = 21.5−29.2. In contrast to **10** or **12**, the 2-mercaptopyrimidinate complex **11** is stable in solution under air and may be recrystallized from $CHCl_3$/MeOH to afford crystals suitable for X-ray analysis (Figure 4). The small angle of bite [S(1)−Ru−N(1) 65.9(2)°] of the coordinating thioamide causes a marked narrowing of the opposite P(2)−Ru−P(3) angle to 85.0(1)°. As a result of the weaker *trans* influence of N, the Ru−P(2) distance of 2.291(2) Å is somewhat shorter than for the remaining triphos P atoms [2.301(2), 2.322(2) Å]. On leaving **12** to stand in $CHCl_3$ solution under air a color change from yellow to orange may be followed over a period of 3 d and the triphosO-$\kappa^2 P$ complex [Ru(mpy-$\kappa^2 N,S$)$_2$(triphosO-$\kappa^2 P$)] (**13**) may be isolated in effectively quantitative yield after 14 d. Rapid oxidation of the dangling phosphane arm is typical for analogous $\kappa^2 P$ coordinated Rh^{III} complexes[16][17] and has also been reported for square-planar Rh^I and Ni^{II} complexes[6][25]. Whereas **12** exhibits three triplets for its magnetically inequivalent P (δ 21.55, 26.60, 29.17 ppm) atoms, a singlet at δ = 25.89 and an AB pattern at δ = 42.45 for two nuclei with closely similar chemical shifts were recorded for **13**. The position of the former resonance is typical for the oxid-

ized phosphorus of triphosO and the latter spin system would be expected for either the OC-6-22 (N *trans* to N) or OC-6-13 (S *trans* to S) isomer but not the third possible OC-6-32 (S *trans* to N) isomer of Scheme 6. Although attempts to obtain crystals suitable for X-ray analysis remained unsuccessful, the molecular structure of the analogous κ^2P-triphosO complex [Ru(mmim-$\kappa^2N,S)_2$(triphosO-κ^2P)] (**14**) was determined. As previously also established for two Rh^{III} complexes [Rh(mpy-$\kappa^2N,S)_2$(triphosO-κ^2P)]Cl[16] and [Rh(mmim-$\kappa^2N,S)_2$(triphosO-κ^2P)]-[CF_3SO_3][17], **14** is present as the OC-6-13 isomer. The observation of individual resonances for the coordinated triphosO P atoms (δ = 47.8, 49.9) and the duplication of the $mmim^-$ methyl singlet (δ = 2.94, 2.98) and aromatic proton doublets (δ = 5.93, 6.09, 6.52, 6.61) indicates that the molecular geometry of **14** must deviate significantly from an idealized C_2 symmetry. This is confirmed by the observed distortions in the Ru^{II} coordination sphere of the X-ray structure (Figure 5). In view of the similarity of the ^{31}P NMR data for **13** and **14** it seems reasonable to assume that the former complex is also present as the OC-6-13 isomer with S atoms in *trans* position to one another.

Figure 4. Molecular structure of **11**. Phenyl rings are omitted for clarity[a]

Our present results indicate that the fluxionality of octahedral Ru^{II} complexes [Ru(L)(MeCN)(triphos-κ^3P)]$^+$ of bidentate ligands L^- results from a facile acetonitrile dissociation to a five-coordinate species [Ru(L)(triphos-κ^3P)]$^+$. In contrast to the analogous acetonitrile complexes, κ^3P-triphos compounds of the type [Ru(L)(Y)(triphos-κ^3P)]$^{n+}$ (n = 1, Y = CO; n = 0, Y = CN^-, H^-) are stereochemically rigid in solution at both 25°C and 60°C. Arm-off $\kappa^3P \rightarrow \kappa^2P$ reactions are apparently less favorable for Ru^{II} than for Rh^{III}, thereby allowing the isolation of com-

Figure 5. Molecular structure of **14**. Phenyl rings are omitted for clarity[a]

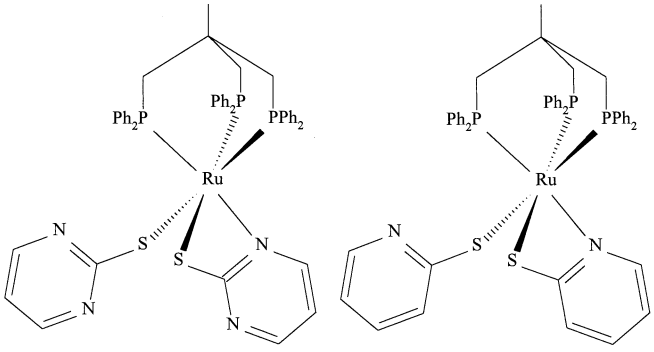
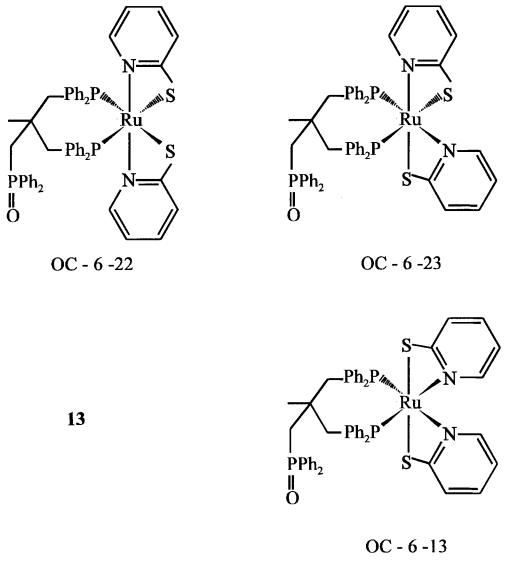
Scheme 5. [Ru(mpym)$_2$(triphos)] (**11**) and [Ru(mpy)$_2$(triphos)] (**12**)



plexes such as [Ru(Et_2NCS_2-κ^2S)(Et_2NCS_2-κS)(triphos-κ^3P)] (**9**) or the analogous $mpym^-$ and mpy^- complexes **11** and **12**. However **9** and **12** do exhibit a slow arm-off phosphane dissociation and subsequent oxidation to afford the thermodynamically favorable bis-chelates [Ru(Et_2NCS_2-$\kappa^2S)_2$(triphosO-κ^2P)] (**10**) and [Ru(mpy-$\kappa^2N,S)_2$(triphosO-κ^2P)] **13**. As **13** and **14** are both formed from κ^3P-triphos

Scheme 6. Possible isomers of [Ru(mpy)$_2$(triphosO)] **13**



complexes it may be assumed that the first reaction stage will involve a slow $\kappa^3P \rightleftharpoons \kappa^2P$ dissociation. This must be followed by rapid isomerisation of the five-coordinated intermediate to allow nucleophilic attack of the N atom of the previously κS coordinated thioamide at a site *trans* to a κ^2P-triphos phosphorus. The resulting octahedral complex will then exhibit the observed OC-6-13 geometry. Relief of steric crowding and the energetic advantage of the associated formation of a second κ^2S or κ^2S,N chelate may be presumed to provide the driving force behind such a triphos arm-off dissociation.

Experimental Section

Where not otherwise stated reactions were performed under Ar in carefully dried solvents. − FAB MS: Fisons VG Autospec with 3-nitrobenzyl alcohol as the matrix. − FT-IR: KBr, Perkin-Elmer 1760. − ^{1}H and ^{31}P{^{1}H} NMR: Bruker AM 400; chemical shifts are reported as δ values relative to the signal of the deuterated solvent (for ^{1}H) or relative to 85% H_3PO_4 as external standard (for ^{31}P). − Elemental analyses: Carlo Erba 1106. − The starting compound [Ru(MeCN)$_3$(triphos)][CF_3SO_3] (**1**) was prepared according to the literature procedure[26] from $RuCl_3 \cdot x\ H_2O$, which was a gift from Degussa AG.

[Ru(Et$_2$NCS$_2$)(MeCN)(triphos)](CF$_3$SO$_3$) (**2**): Na(Et$_2$NCS$_2$)·3 H_2O (33.8 mg, 0,15 mmol) was added to a solution of **1** (172.0 mg, 0.15 mmol) in 10 ml of MeOH and the reaction mixture heated at reflux for 3 h. After filtration the red solution was reduced in volume to 3 ml and left to stand at room temperature to afford a yellow precipitate of **2** within 24 h. Recrystallisation from ethanol provided **2**·0.5 C_2H_5OH. Yield 111.0 mg (68%). − FAB MS, *m/z* (%): 874 (100) [M − MeCN − CF_3SO_3]$^+$. − ^{1}H NMR ($CDCl_3$, −30°C): δ = 1.24 (t, 6 H, CH_3 Et$_2$NCS$_2$), 1.58 (s, 3 H, CH_3 triphos), 1.80 (s, 3 H, MeCN), 2.19 (m, 2 H, CH_2 triphos), 2.30 (m, 2 H, CH_2 triphos), 2.68 (m, 2 H, CH_2 triphos), 3.64 (m, 2 H, CH_2 Et$_2$NCS$_2$), 3.84 (m, 2 H, CH_2 Et$_2$NCS$_2$), 6.87−7.38 (m, 30 H, Ph triphos). − ^{31}P NMR ($CDCl_3$, −30°C): δ = 26.10 (d, 2 P, *trans* to Et$_2$NCS$_2$), 27.44 (t, 1 P, *trans* to MeCN). − $C_{49}H_{52}F_3N_2O_3P_3RuS_3 \cdot 0.5\ C_2H_5OH$ (1088.2): calcd. C 55.2, H 5.1, N 2.6; found C 55.0, H 5.4, N 2.3.

[Ru(pyrdtc)(MeCN)(triphos)](CF$_3$SO$_3$) (**3**): The preparation of **3** was performed using **1** and NH_4(pyrdtc) (pyrdtc$^-$ = pyrrolidinedithiocarbamate) under conditions analogous to those for **2**. Yield 119.5 mg (75%). − FAB MS, *m/z* (%): 872 (100) [M − MeCN − CF_3SO_3]$^+$. − ^{1}H NMR ($CDCl_3$, −30°C): δ = 58 (s, 3 H, CH_3 triphos), 1.87 (s, 3 H, MeCN), 1.97, 2.08, 2.14 (3×2 H, 3 m, CH_2 pyrdtc$^-$ and triphos), 2.32 (m, 2 H, CH_2 triphos), 2.64 (m, 2 H, CH_2 triphos), 3.64 (m, 4 H, CH_2 pyrdtc$^-$), 6.87−7.39 (m, 30 H, Ph triphos). − ^{31}P NMR ($CDCl_3$, −30°C): δ = 5.70 (d, 2 P, *trans* to pyrdtc$^-$), 28.56 (t, 1 P, *trans* to MeCN). − $C_{49}H_{50}F_3N_2O_3P_3RuS_3$ (1062.1): calcd. C 55.4, H 4.7, N 2.6; found C 54.5, H 5.1, N 2.3.

[Ru(mbt)(MeCN)(triphos)](CF$_3$SO$_3$) (**4**): 2-Mercaptobenzothiazole Hmbt (25.2 mg, 0.15 mmol) was dissolved in 10 ml MeOH in the presence of 0.15 mmol 1 M NaOH. After addition of **1** (172.0 mg, 0.15 mmol) the reaction mixture was heated for 2 h at reflux and subsequently filtered; the volume of the red-brown solution was then reduced to 1 ml. Standing at −18°C led to crystallization of yellow-brown prisms of **4**·1/2 MeOH suitable for X-ray analysis. Yield 120.2 mg (73%). − FAB MS, *m/z* (%): 892 (100) [M − MeCN − CF_3SO_3]$^+$. − ^{1}H NMR ($CDCl_3$, −30°C): δ = 1.59 (s, 3 H, CH_3 triphos), 1.87 (s, 3 H, MeCN), 2.27 (m, 2 H, CH_2 triphos), 2.46 (m, 3 H, CH_2 triphos), 2.60 (m, 1 H, CH_2 triphos), 6.30 (d, 1 H, mbt), 6.80−7.39 (m, 32 H, Ph triphos and mbt), 7.68 (d, 1 H, mbt). − ^{31}P NMR ($CDCl_3$, −30°C): δ = 20.92 (t, 1 P), 31.52 (t, 1 P), 36.43 (t, 1 P). − $C_{51}H_{46}F_3N_2O_3P_3RuS_3 \cdot 0.5$ MeOH (1098.1): calcd. C 56.3, H 4.4, N 2.6; found C 55.9, H 4.4, N 2.4.

[Ru(mpym)(MeCN)(triphos)](CF$_3$SO$_3$) (**5**): The preparation of **5** was carried out with **1** and 2-mercaptopyrimidine (Hmpym) in a manner analogous to that employed for **4**. Yield 126.3 mg (82%). − FAB MS, *m/z* (%): 986 (2) [M$^+$], 837 (100) [M − MeCN − CF_3SO_3]$^+$. − ^{1}H NMR ($CDCl_3$, −30°C): δ = 1.61 (s, 3 H, MeCN), 1.63 (s, 3 H, CH_3 triphos), 2.05 (m, 1 H, CH_2 triphos), 2.26 (m, 2 H, CH_2 triphos), 2.78 (m, 3 H, CH_2 triphos), 6.60−7.56 (m, 31 H, Ph triphos and mpym), 7.78 (d, 1 H, mpym), 8.45 (d, 1 H, mpym). − ^{31}P NMR ($CDCl_3$, −30°C): δ = 19.89 (t, 1 P), 28.05 (t, 1 P), 37.59 (t, 1 P). − $C_{48}H_{45}F_3N_3O_3P_3RuS_2$ (1027.0): calcd. C 56.1, H 4.4, N 4.1; found C 55.4, H 5.1, N 3.6.

[Ru(Et$_2$NCS$_2$)(CO)(triphos)](CF$_3$SO$_3$) (**6**): CO was bubbled through a solution of **2** (119.7 mg, 0.11 mmol) in 20 ml CH_2Cl_2 leading to loss of the initial deep red color. After filtration and reduction in volume to 2 ml addition of 10 ml of diethyl ether led to precipitation of **6** which was centrifuged off and dried in vacuum. Yield 87.9 mg (76%). − FAB MS, *m/z* (%): 902 (26) [M − CF_3SO_3]$^+$, 874 (87) [M − CO − CF_3SO_3]$^+$. − ^{1}H NMR ([D$_6$]DMSO): δ = 1.14 (t, 6 H, CH_3 Et$_2$NCS$_2$), 1.70 (s, 3 H, CH_3 triphos), 2.53−2.85 (m, 6 H, CH_2 triphos), 3.54 (m, 2 H, CH_2 Et$_2$NCS$_2$), 3.71 (m, 2 H, CH_2 Et$_2$NCS$_2$), 6.94−7.49 (m, 30 H, Ph triphos). − ^{31}P NMR ([D$_6$]DMSO): δ = 3.54 (t, 1 P, *trans* to CO), 21.20 (d, 2 P, *trans* to Et$_2$NCS$_2$). − IR: $\tilde{\nu}$ = 2002 s cm^{-1} (CO). − $C_{48}H_{49}F_3NO_4P_3RuS_3$ (1051.1): calcd. C 54.9, H 4.7, N 1.3; found C 53.4, H 4.6, N 1.7.

[Ru(CN)(Et$_2$NCS$_2$)(triphos)] (**7**): NaCN (4.4 mg, 0.09 mmol) was added to **1** (95.2 mg, 0.09 mmol) in 10 ml of ethanol and the reaction mixture stirred for 18 h at room temperature. The resulting solid was filtered off and redissolved in 2 ml of CH_2Cl_2. Addition of 10 ml of diethyl ether led to precipitation of **7** which was dried in vacuum. Yield 54.3 mg (67%). − FAB MS, *m/z* (%): 900 (26) [M]$^+$, 874 (14) [M − CN]$^+$, 752 (3) [M − Et$_2$dtc]$^+$. − ^{1}H NMR ([D$_6$]DMSO): δ = 1.08 (t, 6 H, CH_3 Et$_2$NCS$_2$), 1.42 (s, 3 H, CH_3 triphos), 2.20−2.45 (m, 6 H, CH_2 triphos), 3.43 (m, 2 H, CH_2 Et$_2$NCS$_2$), 3.67 (m, 2 H, CH_2 Et$_2$NCS$_2$), 6.77−7.79 (m, 30 H, Ph triphos). − ^{31}P NMR ([D$_6$]DMSO): δ = 19.26 (t, 1 P, *trans* to CN),

27.40 (d, 2 P, *trans* to Et_2NCS_2). − IR: $\tilde{\nu}$ = 2094 s cm^{-1} (CN). − $C_{47}H_{49}N_2P_3RuS$ (900.0): calcd. C 62.7, H 5.5, N 3.1; found C 61.8, H 5.9, N 3.1.

[Ru(Et$_2$NCS$_2$)(H)(triphos)] (**8**): $NaBH_4$ (11.3 mg, 0.3 mmol) was added to **1** (108.8 mg, 0.1 mmol) in 20 ml at room temperature leading to gas formation and lightening of the solution color. After stirring at room temperature for 18 h the resulting solid was filtered off, washed with ethanol and ethyl ether and dried in vacuum. Yield 66.5 mg (76%). − FAB MS, *m/z* (%): 874 (100) $[M - H]^+$. − ^{1}H NMR ($CDCl_3$): δ = −5.47 (d, 1 H, $^2J_{PH}$ (*trans* to H) = 109.4 Hz, $^2J_{PH}$ (*trans* to S) = 16.6 Hz), 1.24 (t, 6 H, CH_3 Et_2NCS_2), 1.38 (s, 3 H, CH_3 triphos), 2.10−2.23 (m, 6 H, CH_2 triphos), 3.61 (m, 2 H, CH_2 Et_2NCS_2), 3.91 (m, 2 H, CH_2 Et_2NCS_2), 6.87−7.39 (m, 26 H, Ph triphos), 7.74 (s, 4 H, Ph triphos). − ^{31}P NMR ($CDCl_3$): δ = 5.29 (m, 1 P, *trans* to H), 47.10 (d, 2 P, *trans* to Et_2NCS_2). − IR: $\tilde{\nu}$ = 1846 s cm^{-1} (RuH). − $C_{46}H_{50}NP_3RuS_2$ (875.0): calcd. C 63.1, H 5.8, N 1.6; found C 61.9, H 5.8, N 1.4.

[Ru(Et$_2$NCS$_2$-κ^{2}S)(Et$_2$NCS$_2$-κS)(triphos)] (**8**): $Na(Et_2NCS_2)\cdot 3\ H_2O$ (67.0 mg, 0.3 mmol) was added to a solution of **1** (172.0 mg, 0.15 mmol) in 10 ml of MeOH and the reaction mixture heated at reflux for 3 h. After filtration and reduction in volume to 3 ml the resulting solution was left to stand at 4°C to afford a yellow precipitate of **9** within 24 h. Yield 127.3 mg (83%). − FAB MS, *m/z* (%): 874 (100) $[M - Et_2NCS_2]^+$. − ^{1}H NMR ($CDCl_3$): δ = 0.86, 1.01 (2 t, 2×6 H, CH_3 Et_2NCS_2), 1.52 (s, 3 H, CH_3 triphos), 2.23, 2.42 (m, 6 H, CH_2 triphos), 3.31, 3.54 (m, 8 H, CH_2 Et_2NCS_2), 6.60−7.70 (m, 30 H, Ph triphos). − ^{31}P NMR ($CDCl_3$): δ = 19.06 (d, 2 P, *trans* to Et_2NCS_2-κ^2*S*), 32.37 (t, 1 P, *trans* to Et_2NCS_2-κ*S*). − $C_{51}H_{59}N_2P_3RuS_4$ (1022.3): calcd. C 59.9, H 5.8, N 2.7; found C 59.8, H 5.0, N 2.6.

[Ru(Et$_2$NCS$_2$-κ^{2}S)$_2$(triphosO-κ^{2}P) (**10**): Slow crystallization of **9** from an ethanol/acetone solution at room temperature under air affords **10** in 50% yield over a period of 14 d. − FAB MS, *m/z* (%): 1038 (100) $[M]^+$, 890 (41) $[M - Et_2NCS_2]^+$. − ^{1}H NMR ($CDCl_3$): δ = 0.80−1.01 (m, 15 H, CH_3 of Et_2NCS_2 and triphosO), 2.13−3.60 (m, 14 H, CH_2 of Et_2NCS_2 and triphosO), 6.80−7.80 (m, 30 H, Ph triphosO). − ^{31}P NMR ($CDCl_3$): δ = 26.86 (s, 1 P, P=O) 38.96, 40.38 (2d, 2 P, *trans* to Et_2NCS_2). − IR: $\tilde{\nu}$ = 574 m cm^{-1} (δPO). − $C_{51}H_{59}N_2OP_3RuS_4$ (1038.3): calcd. C 59.0, H 5.7, N 2.7; found C 58.5, H 5.3, N 2.6.

[Ru(mpym-κ^{2}N,S)(mpym-κS)(triphos) (**11**): Hmpym (33.6 mg, 0.3 mmol) was dissolved in 10 ml of MeOH in the presence of 0.3 ml of 1 M NaOH. After addition of **1** (172.0 mg, 0.15 mmol) and refluxing for 3 h the solvent was removed and the resulting solid dissolved in a $CHCl_3$/MeOH mixture (2:3). Slow evaporation afforded yellow crystals of **11**. Yield 122.0 mg (74%). − FAB MS, *m/z* (%): 948 (1) $[M]^+$, 837 (100) $[M - mpym]^+$. − ^{1}H NMR ($CDCl_3$): δ = 1.53 (s, 3 H, CH_3 triphos), 2.05 (m, 1 H, CH_2 triphos), 2.45 (m, 2 H, CH_2 triphos), 2.68 (m, 3 H, CH_2 triphos), 5.62 (s, 1 H, mpym), 6.25 (s, 1 H, mpym) 6.60−8.00 (m, 34 H, mpym and Ph triphos). − ^{31}P NMR ($CDCl_3$): δ = 25.17 (t, 1 P), 26.39 (t, 1 P), 29.05 (t, 1 P). − $C_{49}H_{45}N_4P_3RuS_2\cdot MeOH\cdot CHCl_3$ (1099.4): calcd. C 55.7, H 4.6, N 5.1; found C 56.8, H 4.8, N 5.1.

[Ru(mpy-κ^{2}N,S)(mpy-κS)(triphos) (**12**): The preparation of **12** was performed with Hmpy and **1** under conditions analogous to those for **11**. It was recrystallized within 1 d from a $CHCl_3$ solution covered with hexane. Yield 100.7 mg (63%). − FAB MS, *m/z* (%): 947 (1) $[M]^+$, 836 (100) $[M - myp]^+$. − ^{1}H NMR ($CDCl_3$): δ = 1.43 (s, 3 H, CH_3 triphos), 2.39 (m, 6 H, CH_2 triphos), 5.94 (6, 1 H, mpy), 6.15 (d, 1 H, mpy), 6.53 (t, 1 H, mpy), 6.70−8.00 (m, 35 H, mpy and Ph triphos). − ^{31}P NMR ($CDCl_3$): δ = 21.55 (t, 1 P), 26.60 (t, 1 P), 29.17 (t, 1 P). − $C_{51}H_{47}N_2P_3RuS_2\cdot CHCl_3$ (1065.4): calcd: C 58.6, H 4.5, N 2.6; found C 58.0, H 4.9, N 2.6.

[Ru(mpy-κ^{2}N,S)$_2$(triphosO-κ^{2}P) (**13**): On leaving a reaction solution of **12** in $CHCl_3$ to stand under air the color changed over 3 d from yellow to orange. After 14 d the solution was reduced in volume to afford **13** as a yellow solid. $C_{51}H_{47}N_2OP_3RuS_2$ (962.1): calcd. C 63.7, H 4.9, N 2.9; found C 62.8, H 5.2, N 2.8. − FAB MS, *m/z* (%): 962 (84) $[M]^+$, 852 (30) $[M - mpy]^+$. − ^{1}H NMR ($CDCl_3$) 0.63 (s, 3 H, CH_3 triphosO), 2.19 (m, 2 H, CH_2 triphosO), 2.58, 2.79, 2.86, 3.19 (m, 4 H, CH_2 triphosO), 6.06 (m, 2 H, mpy), 6.22, 6.37 (d, 2 H, mpy), 6.76, 6.82 (m, 2 H, mpy) 6.90−7.70 (m, 32 H, Ph triphosO and mpy). − ^{31}P NMR ($CDCl_3$) 25.89 (s, 1 P, P=O), 42.45 (AB system, 2 P). − IR: $\tilde{\nu}$ = 1200 m (νPO), 568 m cm^{-1} (δPO).

[Ru(mmim-κ^{2}N,S)$_2$(triphosO-κ^{2}P) (**14**): Hmmim (34.2 mg, 0.3 mmol) was dissolved in 10 ml of MeOH in the presence of 0.3 ml of 1 M NaOH. After addition of **1** (172.0 mg, 0.15 mmol) the solution was refluxed for 4 h and then left to stand under air for 2 d. This was followed by filtration and reduction in volume to 1 ml to afford yellow-brown crystals of **14** at 4°C. Yield 100.2 mg (69%). − FAB MS, *m/z* (%): 968 (25) $[M]^+$, 855 (100) $[M - mmim]^+$. − ^{1}H NMR ($CDCl_3$): δ = 0.92 (s, 3 H, CH_2 triphosO), 2.94, 2.98 (s, 6 H, CH_3 mmim), 5.93, 6.09, 6.52, 6.61 (d, 4 H, CH mmim), 6.52 − 7.79 (m, 30 H, Ph triphosO). − ^{31}P NMR ($CDCl_3$): δ = 26.74 (s, 1 P, P=O), 47.8, 49.9 (AB system, 2 P). − IR: $\tilde{\nu}$ = 571 m cm $^{-1}$ (δPO). − $C_{49}H_{49}N_4OP_3RuS_2$ (968.1): calcd. C 60.8, H 5.1, N 5.8; found C 61.6, H 4.7, N 6.2.

X-Ray Structural Analyses Siemens P4 diffractometer, graphite-monochromated Mo-*Kα* radiation (λ = 0.71073 Å). Semi-empirical absorption corrections were applied to the intensity data by use of ψ scans. The structures were solved by a combination of Patterson and Fourier difference syntheses and refined by full-matrix least squares against *F* for **4**, **11**, and **14** (SHELXTL PLUS programs[27]). Hydrogen atoms were included where possible at calculated positions with isotropic temperature factors[28].

4·1/2 CH_3OH: $C_{51}H_{46}F_3N_2O_3P_3RuS_3\cdot 1/2\ CH_3OH$, M = 1098.1, orthorhombic, space group $Pca2_1$ (No. 29), a = 17.3490(3), b = 11.315(4), c = 25.440(6) Å, V = 4994(2) Å^3, Z = 4, D_{calc} = 1.460 g·cm^{-3}, μ = 0.59 mm^{-1}. Crystal size 0.42 × 0.48 × 0.49 mm; ω scan , scan range: 4 ≤ 2θ ≤ 50°(−20 ≤ h ≤ 0, −13 ≤ k ≤ 0, 0 ≤ l ≤ 30), 4963 reflections collected, 4530 symmetry-independent reflections (R_{int} = 0.049); max./min. transmission: 0.516/0.470; 613 parameters refined; $w^{-1} = \sigma^2(F_o) + 0.003\ F_o^2$, R = 0.040, R_w = 0.044 for 3896 reflections with $F_o^2 > 2\sigma(F_o^2)$; largest difference peak: 0.55 eÅ^{-3}. The $CF_3SO_3^-$ anion exhibits rotational disorder about the C−S axis and site occupation factors (s.o.fs) of 0.50 were employed for the F and O atoms of the two observed orientations. Anisotropic temperature factors were introduced for all nonhydrogen atoms of the cation, the anion S atoms and the C and O atoms of a disordered methanol molecule (s.o.fs = 0.5).

11·$CHCl_3\cdot CH_3OH$: $C_{49}H_{45}N_4P_3RuS_2\cdot CHCl_3\cdot CH_3OH$, M = 1099.4, monoclinic, space group $P2_1/c$ (No. 14), a = 12.611(3), b = 21.605(4), c = 18.757(4) Å, β = 91.01(3)°, V = 5110(2) Å^3, Z = 4, D_{calc} = 1.429 g·cm^{-3}, μ = 0.68 mm^{-1}. Crystal size 0.32 × 0.39 × 0.42 mm; ω scan , scan range: 4 ≤ 2θ ≤ 50° (0 ≤ h ≤14, −25 ≤ k ≤ 0, −22 ≤ l ≤ 22), 9602 reflections collected, 8898 symmetry-independent reflections (R_{int} = 0.032); max./min. transmission: 0.497/0.445; 512 parameters refined; $w^{-1} = \sigma^2(F_o) + 0.001\ F_o^2$, R = 0.061, R_w = 0.058 for 5639 refelctions with $F_o^2 > 2\sigma(F_o^2)$; largest difference peak: 1.13 eÅ^{-3}. Anisotropic temperature factors were introduced for all nonhydrogen atoms.

14·CH_3OH·1/2 H_2O: $C_{49}H_{49}N_4OP_3RuS_2$·CH_3OH·1/2 H_2O, M = 1009.1, triclinic, space group $P\bar{1}$(No. 2), a = 10.9610(4), b = 13.944(6), c = 17.590(3) Å, α = 76.90(3), β = 88.68(3), γ = 88.94(3)°, V = 2618(2) Å^3, Z = 2, D_{calc} = 1.280 g·cm^{-3}, μ = 0.50 mm^{-1}. Crystal size 0.28 × 0.34 × 0.40 mm; ω scan , scan range: 3 ≤ 2θ ≤ 45° (0 ≤ h ≤ 11, −15 ≤ k ≤ 15, −18 ≤ l ≤ 18), 7081 reflections collected, 6659 symmetry-independent reflections (R_{int} = 0.050); max./min. transmission: 0.804/0.627; 305 parameters refined; $w^{-1} = \sigma^2(F_o) + 0.005\ F_o^2$, R = 0.088, R_w = 0.081 for 2803 reflections with $F_o^2 > 2\sigma(F_o^2)$; largest difference peak: 1.13 eÅ^{-3}. The asymmetric unit contains a disordered water molecule and two disordered solvent methanols. S.o.fs of 0.5 were employed for the relevant O and C atoms. Anisotropic temperature factors were introduced for the Ru, S, P, and O atoms of **15**.

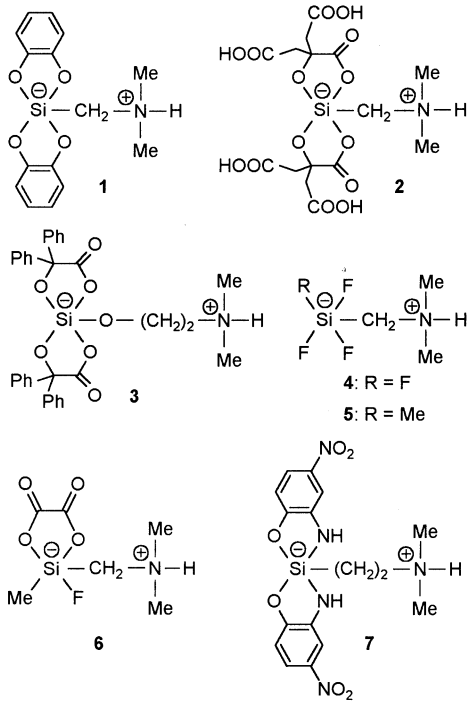
Received September 29, 1997

Keywords: Pentacoordinate silicon / Zwitterionic λ^5*Si*-silicate / SiO_2N_2C framework / Hypervalent compounds / Main-group elements

The reaction of $(Me_2N)_3SiCH_2CH_2NMe_2$ with 2-amino-4-nitrophenol (molar ratio 1:2) in acetonitrile yields the zwitterionic spirocyclic λ^5*Si*-silicate [2-(dimethylammonio)ethyl]-bis[4-nitrobenzene-2-aminato-1-olato(2−)]silicate (**7**). Compound **7** was characterized by ^1H, ^{13}C, and ^{29}Si solution-state and ^{29}Si solid-state NMR spectroscopy, in addition to single-crystal X-ray diffraction. The SiO_2N_2C framework of **7** is characterized by five "normal" covalent bonds.

In the past few years, we have reported on the synthesis and structural characterization of a series of zwitterionic λ^5*Si*-silicates, such as **1**,[1a] **2** · H_2O,[1b] **3** · DMF,[1c] **4**,[1d] **5**,[1d] and **6**.[1e] These molecular pentacoordinate silicon compounds contain an SiO_4C (**1**, **2**), SiO_5 (**3**), SiF_4C (**4**), SiF_3C_2 (**5**), or SiO_2FC_2 (**6**) framework. With the synthesis of [2-(dimethylammonio)ethyl]bis[4-nitrobenzene-2-aminato-1-olato(2−)]-silicate (**7**), we have now succeeded in obtaining a zwitterionic λ^5*Si*-silicate with an SiO_2N_2C unit. To the best of our knowledge, this is the first pentacoordinate silicon compound which is characterized by two "normal" covalent Si−O and Si−N bonds (two of each) and one "normal" covalent Si−C bond, rather than a bonding system involving four "normal" covalent bonds and one significantly longer dative bond (4+1 coordination).[2][3]



Results and Discussion

Compound **7** was synthesized according to Scheme 1, starting from trichloro(vinyl)silane. The reaction of trichloro(vinyl)silane with a mixture of $LiNMe_2$ and $HNMe_2$ in tetrahydrofuran gave tris(dimethylamino)[2-(dimethylamino)ethyl]silane (**8**), in a yield of 86%, which was then treated with two mol equivalents of 2-amino-4-nitrophenol in acetonitrile to give **7**, in a yield of 73%, as an orange-colored crystalline solid. The identity of **7** was established by elemental analysis (C, H, N), and both solution-state ([D_6]DMSO; ^1H, ^{13}C, ^{29}Si) and solid-state (^{29}Si CP/MAS) NMR studies. In addition, **7** was characterized by a single-crystal X-ray diffraction study.

Compound **7** crystallizes in the space group *Pc* with two crystallographically independent zwitterions in the asymmetric unit. The structures of these two molecules (see Figure 1) are very similar. The geometries of the coordination polyhedra surrounding the central silicon atoms Si and Si′ can be described as strongly distorted trigonal bipyramidal structures (transition trigonal bipyramid → square pyramid: 24.6%, Si; 35.7%, Si′; pivotal atoms C1 and C1′),[4] with each of the axial positions occupied by the oxygen atoms. The Si−O distances in the two molecules of **7** [1.806(6)−1.829(6) Å] are marginally longer than those observed for the axial Si−O distances of **1** and related spirocyclic zwitterionic λ^5*Si*-silicates containing ligands of the benzene-1,2-diolato(2−) type (typical values: 1.75−1.79 Å).[5] In contrast, the Si−C distances [1.875(9) Å, 1.867(8) Å] correspond to those observed for **1** and its derivatives (typical values: 1.87−1.89 Å).[5] The Si−N distances [1.741(7)−1.764(6) Å] are similar to those reported for the equatorial Si−N bonds of azasilatranes (typical values:

Scheme 1. Synthesis of the zwitterionic λ^5*Si*-silicate **7**

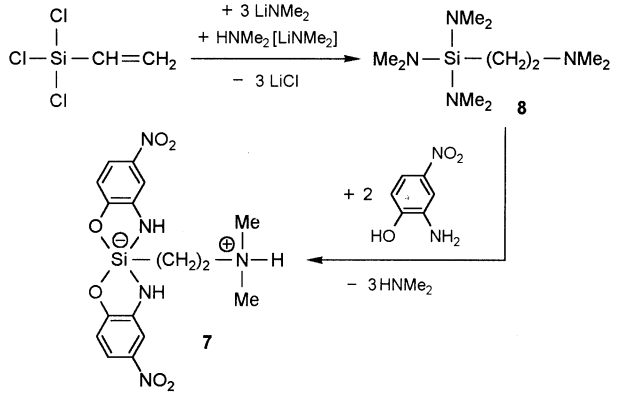

Figure 1. Structures of the two crystallographically independent zwitterions in the crystal of **7**[a]

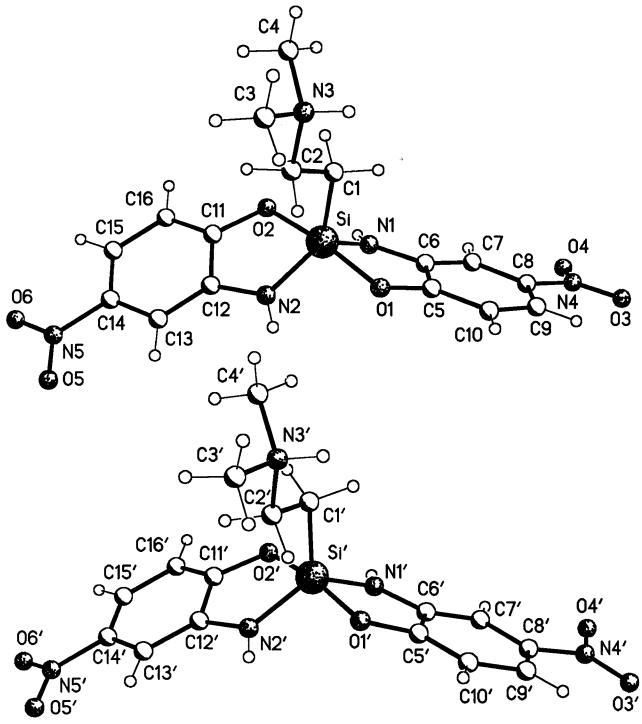

[a] Selected distances [Å] and angles [°] (standard deviations in parentheses): Si−O1 1.829(6), Si−O2 1.806(6), Si−N1 1.741(7), Si−N2 1.751(7), Si−C1 1.875(9); O1−Si−O2 171.8(3), O1−Si−N1 86.6(3), O1−Si−N2 89.3(3), O1−Si−C1 92.9(4), O2−Si−N1 90.0(3), O2−Si−N2 87.0(3), O2−Si−C1 95.3(4), N1−Si−N2 128.3(4), N1−Si−C1 114.4(4), N2−Si−C1 117.3(4). − Si′−O1′ 1.821(6), Si′−O2′ 1.809(6), Si′−N1′ 1.753(7), Si′−N2′ 1.764(6), Si′−C1′ 1.867(8); O1′−Si′−O2′ 167.3(3), O1′−Si′−N1′ 85.3(3), O1′−Si′−N2′ 89.2(3), O1′−Si′−C1′ 94.6(3), O2′−Si′−N1′ 89.0(3), O2′−Si′−N2′ 85.9(3), O2′−Si′−C1′ 98.1(3), N1′−Si′−N2′ 130.9(3), N1′−Si′−C1′ 116.5(3), N2′−Si′−C1′ 112.5(4).

1.73−1.77 Å).[3] All these data clearly demonstrate that the SiO_2N_2C framework of **7** is built up by five "normal" covalent bonds, and does not involve a bonding system in the sense of the 4+1 coordination usually observed for pentacoordinate silicon species with Si−N bonds.

As would be expected from the presence of the potential NH donor functions and acceptor atoms of **7**, several intermolecular N−H···O interactions are observed in the crystal, leading to the formation of a complex hydrogen bonding network.[6]

In the ^{29}Si CP/MAS NMR experiment, only one resonance signal was obtained for the two crystallographically independent silicon atoms (isotropic ^{29}Si chemical shift: δ = −77.2). As this chemical shift is very similar to that observed for **7** in [D_6]DMSO (δ = −78.6), it is concluded that the SiO_2N_2C framework is also present in solution. In addition, the ^{1}H chemical shifts observed for the NCH_3 (s, δ = 2.63), CCH_2N (m, δ = 3.18−3.23), and CNH groups (br. s, δ = 9.0) indicate the presence of an ammonium group. These and all other NMR data (see Experimental Section) are in accordance with the structure of **7** and thus clearly demonstrate that this zwitterionic compound is also present in solution.

This work was supported by the *Deutsche Forschungsgemeinschaft* and the *Fonds der Chemischen Industrie*. We would like to thank Professor *D. Stalke*, University of Würzburg, for helpful discussions in context with the crystal structure analysis.

Experimental Section

General: The syntheses were carried out under dry nitrogen. The solvents used were dried and purified according to standard procedures and stored under nitrogen. − Melting points: DuPont Instruments differential scanning calorimeter, type Thermal-Analyzer 910. − ^{1}H, ^{13}C, and ^{29}Si solution-state NMR spectra: recorded at room temp. on a Bruker DRX-300 NMR spectrometer (^{1}H, 300.1 MHz; ^{13}C, 75.5 MHz; ^{29}Si, 59.6 MHz); $CDCl_3$ and [D_6]DMSO were used as solvents; chemical shifts (ppm) were determined relative to internal $CHCl_3$ (^{1}H, δ = 7.24; $CDCl_3$), $CDCl_3$ (^{13}C, δ = 77.0; $CDCl_3$), [D_5]DMSO (^{1}H, δ = 2.49; [D_6]DMSO), [D_6]DMSO (^{13}C, δ = 39.5; [D_6]DMSO), and TMS (^{29}Si, δ = 0; $CDCl_3$, [D_6]DMSO); assignment of the ^{13}C-NMR data was supported by DEPT 135 experiments. − ^{29}Si CP/MAS NMR: recorded at room temp. on a Bruker DSX-500 NMR spectrometer at 11.74 T with double air bearing rotors of ZrO_2 (diameter 7 mm) containing 200 mg of sample [99.35 MHz; TMS as external standard (δ = 0)]. − Mass spectra: Finnigan MAT-711 mass spectrometer (EI MS, 70 eV); the selected *m/z* values given refer to the isotopes ^{1}H, ^{12}C, ^{14}N, and ^{28}Si.

[2-(Dimethylammonio)ethyl]bis[4-nitrobenzene-2-aminato-1-olato(2−)]silicate (**7**): The triaminosilane $(Me_2N)_3Si(CH_2)_2NMe_2$ (**8**) (3.05 g, 13.1 mmol) was added dropwise at room temp. within 2 min to a stirred solution of 2-amino-4-nitrophenol (4.04 g, 26.2 mmol) in acetonitrile (50 ml). After the mixture was stirred for 2 h at room temp., part of the solvent (ca. 25 ml) was removed at 40°C under reduced pressure (formation of a precipitate). The precipitate was filtered off and recrystallized from acetonitrile (slow cooling of a satd. boiling solution to room temp.) and dried in vacuo (0.01 Torr, 20°C, 6 h) to yield 3.88 g (73%) of orange-colored crystals, mp. 230°C (decomp.). − ^{1}H NMR ([D_6]DMSO): δ = 0.96−1.03 (m, 2 H, $SiCH_2C$), 2.63 (s, 6 H, NCH_3), 3.18−3.23 (m, 2 H, CCH_2N), 5.68 (s, 2 H, SiNH), 6.40 [d, $^3J_{HH}$ = 8.6 Hz, 2 H, 6-*H*, 4-nitrobenzene-2-aminato-1-olato(2−) (NBAO)], 7.21 (d, $^4J_{HH}$ = 2.8 Hz, 2 H, 3-*H*, NBAO), 7.39 (dd, $^3J_{HH}$ = 8.6 Hz, $^4J_{HH}$ = 2.8 Hz, 2 H, 5-*H*, NBAO), 9.0 (br. s, 1 H, CNH). − ^{13}C{^{1}H} NMR ([D_6]DMSO): δ = 15.0 ($SiCH_2C$), 38.9 (NCH_3), 53.7 (CCH_2N),

99.6 (*C*-3, NBAO), 105.3 (*C*-6, NBAO), 112.7 (*C*-5, NBAO), 135.4, 138.9, and 157.3 (odd NBAO C atoms). – $^{29}Si\{^1H\}$ NMR ([D$_6$]DMSO): δ = −78.6. – ^{29}Si CP/MAS NMR (spinning rate 4383 Hz, 308 transients, contact time 7 ms, 90° ^{1}H transmitter pulse length 6.8 μs, repetition time 25 s): δ = −77.2 ($\upsilon_{1/2}$ = 267 Hz). – $C_{16}H_{19}N_5O_6Si$ (405.4): calcd. C 47.40, H 4.72, N 17.27; found C 47.7, H 4.7, N 17.3.

Tris(dimethylamino)[2-(dimethylamino)ethyl]silane (**8**): A 1.6 M solution of *n*-butyllithium in hexane (312 ml, 499 mmol of *n*BuLi) was added dropwise at −25°C within 40 min to a stirred solution of dimethylamine (29.3 g, 650 mmol) in THF (150 ml). After the mixture was warmed to −15°C within 30 min and stirred for 1 h at this temp., a solution of trichloro(vinyl)silane (24.2 g, 150 mmol) in THF (150 ml) was added dropwise at −15°C within 30 min. The resulting mixture was stirred for 14 h at −5°C, and a solution of chlorotrimethylsilane (6.52 g, 60.0 mmol) in THF (20 ml) was added dropwise. The mixture was stirred for 2 h at −15°C and then allowed to warm to room temp. After the precipitate was filtered off and the solvent removed under reduced pressure, *n*-pentane (100 ml) was added to the residue. The resulting precipitate was filtered off, the solvent removed under reduced pressure, and the residue distilled in vacuo to give 30.1 g (86%) of a colorless liquid; bp. 54°C/0.02 Torr. – ^{1}H NMR ($CDCl_3$): δ = 1.05−1.12 (m, 2 H, $SiCH_2C$), 2.19 (s, 6 H, $CNCH_3$), 2.42−2.49 (m, 2 H, CCH_2N), 2.46 (s, 18 H, $SiNCH_3$). – $^{13}C\{^1H\}$ NMR ($CDCl_3$): δ = 12.8 ($SiCH_2C$), 38.6 ($SiNCH_3$), 45.8 ($CNCH_3$), 56.2 (CCH_2N). – $^{29}Si\{^1H\}$ NMR ($CDCl_3$): δ = −17.2. – EI MS: *m*/*z* = 232 (3) [M^+], 188 (80) [$M^+ - N(CH_3)_2$], 160 (100) [$M^+ - CH_2CH_2N(CH_3)_2$]. – $C_{10}H_{28}N_4Si$ (232.4): calcd. C 51.67, H 12.14, N 24.10; found C 51.5, H 12.1, N 24.0.

Crystal Structure Determination: A suitable single crystal of **7** was obtained by crystallization from acetonitrile (slow cooling of a satd. boiling solution to room temp.). The crystal was mounted in inert oil (RS 3000, Riedel-de Haën) on a glass fiber and then transferred to the cold gas stream of the diffractometer (Enraf-Nonius four-circle diffractometer; graphite-monochromated Mo-K_α radiation (λ = 0.71073 Å); for the low-temp. attachment, see ref.[7]). Cell parameters were obtained from least-squares fits to the settings of 25 reflections in the range of 20° ≤ 2θ ≤ 25°. No significant deviations in intensity were registered for two monitor reflections recorded at regular intervals. The structure was solved by direct methods (program SHELXS-96)[8a] and refined on F^2 (program SHELXL-96).[8b] The non-hydrogen atoms were refined anisotropically; for the refinement of the hydrogen atom positions a riding model was employed. Further information about the crystal data, data collection, and structure refinement is summarized in Table 1. Crystallographic data (excluding structure factors) for the structure reported in this paper have been deposited at the Cambridge Crystallographic Data Centre as supplementary publication no. CCDC-100592. Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) +44 (1223) 336-033; E-mail: deposit@ccdc.cam.ac.uk].

[3] Azasilatranes are also pentacoordinate silicon species comprising covalent Si−N bonds. However, these compounds contain four "normal" covalent bonds (including the equatorial Si−N bonds; typical Si−N distances 1.73−1.77 Å) and one significantly longer axial dative Si←N bond (typical Si←N distances 2.03−2.25 Å) (4+1 coordination): [3a] A. [4] The quantification of the distortion in this form relates to the transition from the ideal trigonal bipyramid toward the ideal square pyramid along the reaction coordinate of the Berry pseudorotation. The degree of distortion was calculated according to the dihedral angle method described in the literature,[9] using the values given there for the reference geometry of the ideal square pyramid.

The influence of metals, alkyne substituents, Cp substitution and additional ligands on the stability of bridged and unbridged η^2-alkyne−titanocene and −zirconocene complexes has been investigated. The reduction of the complex [(η^5-C_5H_4)−$SiMe_2$−(η^5-C_5H_4)]$TiCl_2$ with magnesium in the presence of tolan (PhC_2Ph) does not give the expected alkyne−titanocene complex [(η^5-C_5H_4)−$SiMe_2$−(η^5-C_5H_4)]Ti(η^2-PhC_2Ph) but by coupling of two tolan molecules the corresponding titanacyclopentadiene [(η^5-C_5H_4)−$SiMe_2$−(η^5-C_5H_4)]TiC_4Ph_4 (**1**) was obtained. In the analogous reaction with $Me_3SiC_2SiMe_3$ the stable η^2-alkyne complex without additional ligands [(η^5-C_5H_4)−$SiMe_2$−(η^5-C_5H_4)]Ti(η^2-$Me_3SiC_2SiMe_3$) (**2**) was formed, due to the sterical influence of the alkyne substituents. The compounds without additional ligands $(thi)_2Ti(\eta^2\text{-}PhC_2Ph)$ (**3**) and $(thi)_2Ti(\eta^2\text{-}Me_3SiC_2SiMe_3)$ (**5**) were isolated from the unbridged titanocene complex $(thi)_2TiCl_2$ (thi = tetrahydroindenyl). Two equivalents of complex **3** reacted with one equivalent of water to yield the dimeric alkylidene-μ-oxo complex $[(thi)_2Ti(CPh{=}CHPh)]_2(\mu\text{-}O)$ (**6**). The reaction of the unbridged zirconocene compound $(thi)_2ZrCl_2$ gave the alkyne complex $(thi)_2Zr(THF)(\eta^2\text{-}Me_3SiC_2SiMe_3)$ (**7**) which is stabilized by THF. At higher temperature THF was eliminated from the orange complex **7** forming the green complex $(thi)_2Zr(\eta^2\text{-}Me_3SiC_2SiMe_3)$. This behaviour was investigated in detail using NMR spectroscopy and compared to similar complexes such as $Cp_2Zr(\eta^2\text{-}Me_3SiC_2SiMe_3)$ (not stable without THF), $(ebthi)_2Zr(\eta^2\text{-}Me_3SiC_2SiMe_3)$ (ebthi = ethylenebistetrahydroindenyl; stable without THF) and $Cp^*{}_2Zr(\eta^2\text{-}Me_3SiC_2SiMe_3)$ (Cp^* = pentamethyl-Cp, stable without THF). All complexes were characterized by spectroscopic methods. X-ray structural determinations were conducted for the complexes **1**, **3** and **7**. Compound **3** is the first example of a structurally characterized tolan−titanocene complex without additional ligands.

Introduction

Alkyne complexes of group-IV metallocenes can be used synthetically for many purposes.[1] We were the first to produce titanocene complexes of silylalkynes without additional ligands, e.g. $Cp_2Ti(\eta^2\text{-}Me_3SiC_2SiMe_3)$[2a] and also zirconocene complexes with additional ligands such as $Cp_2Zr(L)(\eta^2\text{-}Me_3SiC_2SiMe_3)$[2b][2c] as well as the first example of a zirconocene without additional ligands *rac*-$(ebthi)_2Zr(\eta^2\text{-}Me_3SiC_2SiMe_3)$.[3]

More recently, we reported the synthesis, spectral characteristics and X-ray structural determination of other examples such as Cp-bridged alkyne complexes of the type [(η^5-C_5H_4)-*ansa*-(η^5-C_5H_4)]Ti(η^2-$Me_3SiC_2SiMe_3$) (*ansa* = $Me_2Si{-}O{-}SiMe_2$) and [(η^5-C_5H_4)-*ansa*-(η^5-C_5H_4)]Zr(L)-(η^2-$Me_3SiC_2SiMe_3$) (*ansa* = $Me_2Si{-}O{-}SiMe_2$, L = py; *ansa* = $SiMe_2$, L = py).[4] The special feature of these reagents when used in conjunction with bis(trimethylsilyl)acetylene is their ability to generate the metallocene [Cp_2M] or *ansa* systems such as [(η^5-C_5H_4)$SiMe_2OSiMe_2$(η^5-C_5H_4)M], [(η^5-C_5H_4)$SiMe_2$(η^5-C_5H_4)M] and *rac*-[(ebthi)M], (M = Ti, Zr) under mild conditions. This tendency depends not only on the alkyne substituents but also on the nature of the additional ligands. The factors which determine whether alkyne complexes with or without additional ligands are formed remained unclear, because the stability and reactivity depend strongly on the character of this additional interaction. The use of different additional ligands allows a tuning of the stoichiometric[5a] and catalytic[5b][5c] reactions.

In this paper we report on the influence of metals, alkyne substituents, Cp substitution and additional ligands on the stability of bridged and unbridged η^2-alkyne−titanocene and −zirconocene complexes with and without additional ligands.

Complex Synthesis

The reduction of the complex [(η^5-C_5H_4)−$SiMe_2$−(η^5-C_5H_4)]$TiCl_2$[6] with magnesium in the presence of tolan (PhC_2Ph) in THF at room temperature does not give the expected alkyne−titanocene complex [(η^5-C_5H_4)−$SiMe_2$−(η^5-C_5H_4)]Ti(η^2-PhC_2Ph). Instead, the corresponding titanacyclopentadiene [(η^5-C_5H_4)−$SiMe_2$−(η^5-C_5H_4)]TiC_4Ph_4 (**1**) is obtained in 35% yield by coupling of two tolan molecules (Scheme 1).

This coupling with a second tolan molecule is typical behaviour for coordinatively and electronically unsaturated

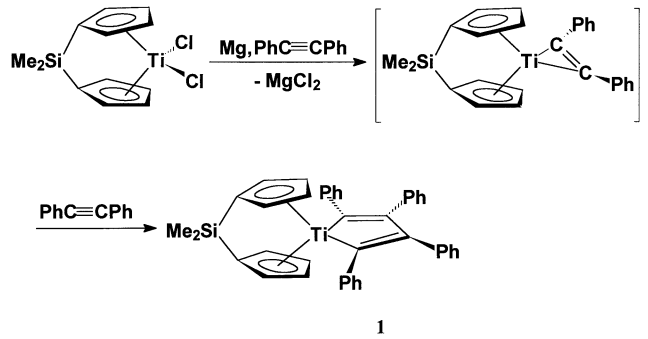
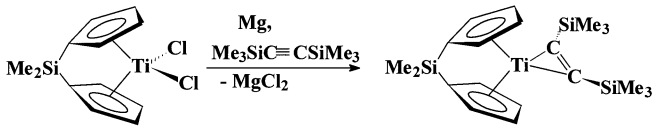
Scheme 1



1

tolan complexes such as $Cp_2Ti(\eta^2\text{-}PhC_2Ph)$[7]; the titanacyclopentadiene with unbridged Cp ligands that is obtained is well-known. By using another alkyne, $Me_3SiC_2SiMe_3$, instead of tolan, the complex $[(\eta^5\text{-}C_5H_4)\text{-}SiMe_2\text{-}(\eta^5\text{-}C_5H_4)]Ti(\eta^2\text{-}Me_3SiC_2SiMe_3)$ (**2**) can be isolated (Scheme 2). This is explained by the special character of the silylalkyne which prevents a coupling reaction by sterical hindrance of the large substituents.

Scheme 2



2

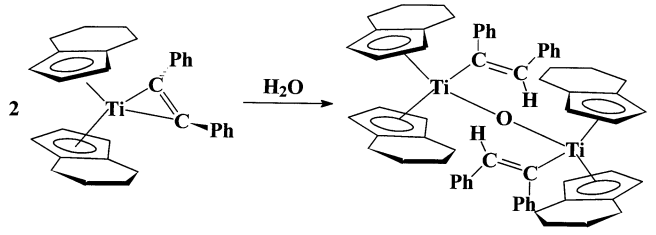
In the reaction of the unbridged complex $(thi)_2TiCl_2$[8] the compound without additional ligands $(thi)_2Ti(\eta^2\text{-}PhC_2Ph)$ (**3**) was isolated. The analogous complexes **4** and **5** were also obtained using other alkynes such as PhC_2SiMe_3 and $Me_3SiC_2SiMe_3$ (Scheme 3).

Scheme 3

3 $R^1=R^2=Ph$;
4 $R^1=Ph$, $R^2=SiMe_3$
5 $R^1=R^2=SiMe_3$

Two equivalents of complex **3** react with one equivalent of water to yield the dimeric alkenyl-μ-oxo complex $[(thi)_2Ti(CPh{=}CHPh)]_2(\mu\text{-}O)$ (**6**) (Scheme 4).

Scheme 4

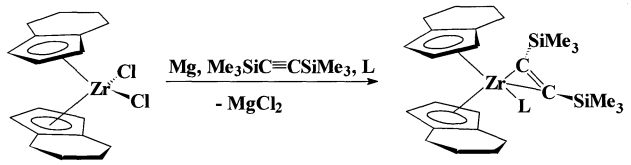


6

This reaction is a typical example of a tolan–titanocene complex, also found in the case of $Cp_2Ti(\eta^2\text{-}PhC_2Ph)$[7], but differs from those of the silylalkyne complex $Cp_2Ti(\eta^2\text{-}Me_3SiC_2SiMe_3)$, which gave only the elimination of the alkyne[9].

In the reaction of the unbridged zirconocene complex $(thi)_2ZrCl_2$[8] in THF at room temperature, the alkyne complex $(thi)_2Zr(THF)(\eta^2\text{-}Me_3SiC_2SiMe_3)$ (**7**), stabilized by THF, was formed (Scheme 5).

Scheme 5



L = thf 7, L = py 8

Complex **7** is an analogue of the compound $Cp_2Zr(THF)(\eta^2\text{-}Me_3SiC_2SiMe_3)$[2b]. Just as for this Cp complex,[2c] coordination by py is also possible for the thi complex **7** which gives $(thi)_2Zr(py)(\eta^2\text{-}Me_3SiC_2SiMe_3)$ (**8**).

Spectral Characteristics

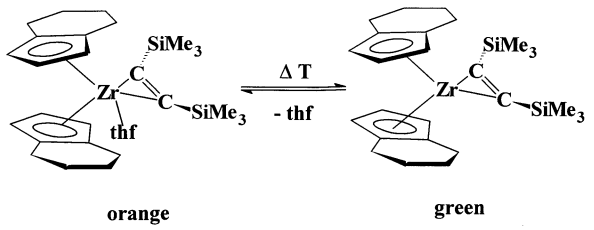
Complex **1** did not show any IR absorption of a complexed triple bond in the expected region of 1600–1800 cm^{-1}. IR absorptions for other complexes (**2**: 1683 cm^{-1}; **3**: 1671; **4**: 1652; **5**: 1629) and the ^{13}C-NMR-spectroscopic signals of the acetylenic C atoms (**2**: δ = 248.9; **3**: 198.8; **4**: 213.6, 220.0; **5**: 242.3) are typical of values for such alkyne complexes[10] and prove that complexes **2**, **3**, **4** and **5** have a titanacyclopropene structure. These data again show larger spectroscopic shifts (IR, NMR) for the potential π-acceptor groups $SiMe_3$ as alkyne substituents.

Complex **3** is the second example of a tolan–titanocene complex without additional ligands. The other complex $Cp_2Ti(\eta^2\text{-}PhC_2Ph)$[7] is characterized by an IR absorption at 1713 cm^{-1} and ^{13}C-NMR signals at δ = 196.5. Previously, only the complex with a stabilizing ligand, e.g. $Cp_2Ti(CO)(\eta^2\text{-}PhC_2Ph)$, had been reported.[11] In the latter, the alkyne formally acts as a two-electron donor, while it is regarded as contributing four electrons in **3**. This also follows from the frequencies of the C–C stretching vibrations (**3**: 1671 cm^{-1}; CO complex: 1780) in the IR spectra.

The IR and ^{13}C-NMR spectra of complex **7** are typical of those also found for the compound $Cp_2Zr(THF)(\eta^2\text{-}Me_3SiC_2SiMe_3)$.[2b] The higher shifts of complex **7**, e.g. the absorption in the IR spectra (Cp compound: 1581 cm^{-1}; **7**: 1559) and the ^{13}C-NMR signals of the acetylenic C atoms (Cp compound: 212.9; **7**: δ = 222.0) are typical of values[12] for substituted Cp ligands (Cp* and thi) which are stronger donors than Cp itself. At higher temperatures the orange complex **7** eliminates THF reversibly to give the green complex $(thi)_2Zr(\eta^2\text{-}Me_3SiC_2SiMe_3)$ (Scheme 6), a reaction

which is unknown for the Cp complex $Cp_2Zr(THF)(\eta^2\text{-}Me_3SiC_2SiMe_3)$.

Scheme 6

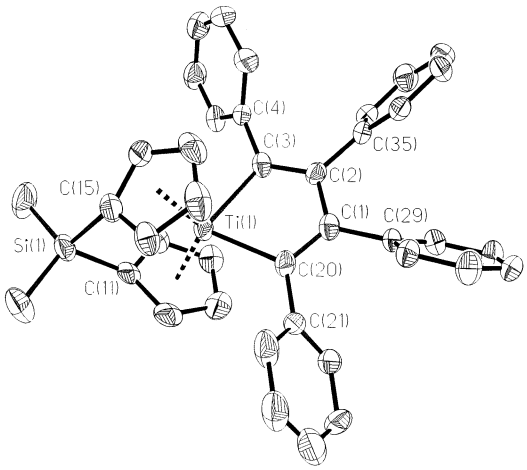


This reaction was identified using NMR spectroscopy after warming up to 343 K by a low-field shift from δ = 222.0 to 244.0. The same effect has been found for complexes similar to $Cp_2Zr(THF)(\eta^2\text{-}Me_3SiC_2SiMe_3)$ which are not stable without THF, *rac*-$(ebthi)_2Zr(\eta^2\text{-}Me_3SiC_2SiMe_3)$ being stable without THF at room temperature and $Cp^*_2Zr(\eta^2\text{-}Me_3SiC_2SiMe_3)$, which did not coordinate with THF at any of the temperatures investigated.[13]

Structural Investigations

The structure of **1** in the crystal is shown in Figure 1. The analogous complex with unsubstituted Cp has already been investigated by X-ray structure analysis.[14] Table 1 lists the relevant data of this complex in comparison with those of complex **1**.

Figure 1. Molecular structure of **1**; shown by an ORTEP plot (50% probability)[a]



[a] Selected distances [Å] and angles [°]: C1−C20 1.364(5), C2−C3 1.362(5), Ti1−C3 2.172(4), Ti−C20 2.160(3); C4−C3−C2 124.5(3), C3−C2−C35 123.1(3), C1−C20−C21 123.0(3), C20−C1−C29 121.0(3), C15−Si−C11 92.7(2).

The bond lenghts and angles of the central five-membered titanacycle are nearly identical and are not influenced by the substitution at the Cp ligands. The structure of **3** in the crystal is shown in Figure 2.

Complex **3** is the first example of a structurally well-characterized tolan−titanocene complex that is stable without additional ligands. Previously, only the structures of complexes with stabilizing ligands, e.g. $Cp_2Ti(CO)(\eta^2\text{-}PhC_2Ph)$, have been described.[11] The comparison is between a complex with one alkyne group acting as a two-electron donor (CO complex) and in the other case as a four-electron donor (**3**). In Table 2 the relevant data of both complexes are listed and compared.

Table 1. Comparision of structural data of $Cp_2TiC_4Ph_4$ and **1**

	$Cp_2TiC_4Ph_4$	**1**
Distances [Å]		
Ti−C3	2.172(5)	2.172(4)

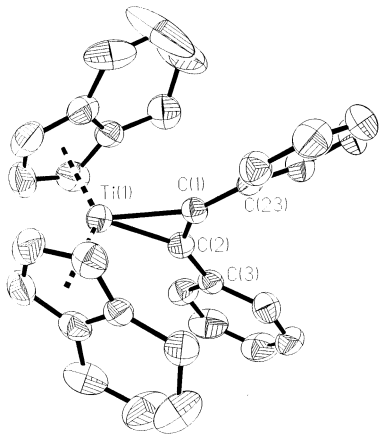
Angles [°]		
C20−Ti−C3	80.3(2)	79.8(1)
Ti−C3−C2	112.5(3)	112.1(3)
Ti−C20−C1	111.0(3)	111.4(2)
C3−C2−C1	117.4(4)	117.2(3)
C20−C1−C2	118.5(4)	119.1(3)
Cp′−Ti−Cp′	134.8(3)	130.7(5)

Figure 2. Molecular structure of **3**, shown by an ORTEP plot (50% probability)[a]



[a] Selected distances [Å] and angles [°]: C1−C2 1.287(6), Ti−C1 2.086(4), Ti−C2 2.044(5); C1−Ti−C2 36.3(2), C23−C1−C2 140.7(4), C3−C2−C1 138.7(5), Cp′−Ti−Cp′ 137.5(4).

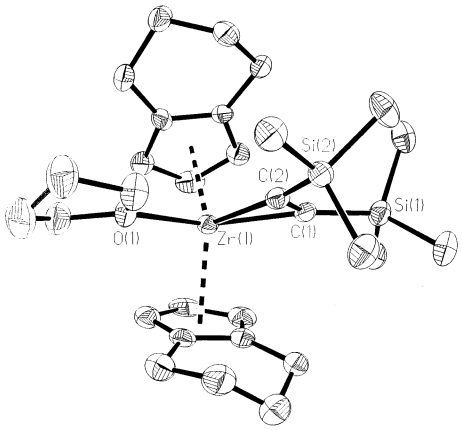
Table 2. Comparison of structural data of $Cp_2Ti(CO)(\eta^2\text{-}PhC_2Ph)$ and **3**

Compound	$Cp_2Ti(CO)(\eta^2\text{-}PhC_2Ph)$	**3**
Distances [Å]		
C1−C2	1.29(1)	1.287(6)
Ti−C1	2.107(7)	2.086(4)
Ti−C2	2.230(7)	2.044(5)
Ti−C(O)	2.050(8)	−
Angles [°]		
C(O)−Ti−C2	71.9(3)	−
C1−Ti−C2	34.3(3)	36.3(2)
C23−C1−C2	138.8(7)	140.7(4)
C3−C2−C1	145.8(7)	138.7(5)
Cp′−Ti−Cp′	133.5(5)	137.5(4)

Both titanocene complexes contain different ligands (Cp and thi) and a detailed comparison and investigation of the influence of the additional CO ligand on the complexation

of tolan is therefore not possible. The Ti−C bond lengths are shorter in complex **3**, indicating a stronger complexation of the alkyne as expected. On the other hand, the additional ligand CO alone makes less space available in the coordination sphere at the central atom, reducing the interaction of the alkyne with the titanium atom. The structure of **7** in the crystal is shown in Figure 3.

Figure 3. Molecular structure of **7**, shown by an ORTEP plot (50% probability)[a]



[a] Selected distances [Å] and angles [°]: C1−C2 1.340(7), Zr1−C1 2.218(5), Zr1−C2 2.271(5), Zr1−O1 2.404(4); C1−Zr1−C2 34.7(2), Si1−C1−C2 141.1(4), Si2−C2−C1 124.5(4), C2−Zr1−O1 86.7(1); the structural data of the Cp and the corresponding thi complex **7** are listed and compared in Table 3.

Table 3. Comparison of structural data of $Cp_2Zr(THF)(\eta^2\text{-}Me_3SiC_2SiMe_3)$ and **7**

Compound	$Cp_2Zr(THF)(\eta^2\text{-}Me_3SiC_2SiMe_3)$	**7**
Distances [Å]		
C1−C2	1.302(9)	1.340(7)
Zr−C1	2.204(7)	2.218(5)
Zr−C2	2.260(7)	2.271(5)
Zr−O1	2.390(5)	2.404(4)
Angles [°]		
C1−Zr−C2	33.9(2)	34.7(2)
C1−C2−Si2	134.4(6)	124.5(4)
C2−C1−Si1	143.5(6)	141.1(4)
C2−Zr−O1	86.8(2)	86.7(1)
Cp′−Zr−Cp′	130.5(3)	131.0(3)

The relatively small differences in the structures of both complexes again demonstrate that the above-mentioned spectroscopical shifts (IR, NMR) are better suited for the characterization of the interaction of the alkyne with the metal atom than the results of an X-ray crystal structural analysis.

Discussion

The influence of metals, alkyne substituents, Cp substitution and additional ligands on the stability of bridged and unbridged η^2-alkyne−titanocene and −zirconocene complexes with and without additional ligands are summarized in Tables 4 and 5 {Cp- and $[(\eta^5\text{-}C_5H_4)-SiMe_2-(\eta^5\text{-}C_5H_4)]$-ligated complexes are shown as Cp complexes because both show a similar behaviour}. For titanocene the existence of the complex **3** demonstrates clearly the stabilizing effects of the thi ligands compared to Cp {and also $[(\eta^5\text{-}C_5H_4)-SiMe_2-(\eta^5\text{-}C_5H_4)]$}. The effect of the thi ligands is not found for the zirconocene complexes because zirconium is larger.

Table 4. Existence of complexes $L_2M(\eta^2\text{-}RC_2R)$; influence of metals, alkyne substituents and Cp substitution

	R=SiMe$_3$		R=Ph	
L/L_2	Ti	Zr	Ti	Zr
Cp	+	−	+	−
thi	+	−	+	−
rac-ebthi	+	+	unknown	−
Cp*	+	+	+	+

Table 5. Existence of complexes $L_2Zr(L')(\eta^2\text{-}Me_3SiC_2SiMe_3)$; influence of Cp substitution in ligands L and additional ligands L′

L/L_2	without L′	L′ = THF	L′ = py
Cp	−	**+**	**+**
thi	> 320 K	< 320 K	+
rac-ebthi	**+**	< 194 K	**+**
Cp*	**+**	− until 77 K[13]	−

The complexes of the type $L_2Zr(\eta^2\text{-}Me_3SiC_2SiMe_3)$ can coordinate with additional ligands L′ to give the complexes $L_2Zr(L')(\eta^2\text{-}Me_3SiC_2SiMe_3)$. The restriction for this comes mostly from the nature of L/L_2. With ligands such as *rac*-ebthi and Cp*, complexes without additional ligands L′ are stable at room temperature. Due to the enhanced flexibility of these ligands at lower temperature in some cases, such as *rac*-ebthi, the coordination of L′ (< 194 K) was observed. With thi as the ligand L the coordination of L′ occurs at room temperature and the complex with an additional THF ligand is stable, but eliminates L′ at higher temperature (< 320 K). With Cp no complex without L′ is stable and with Cp* no complex with L′.

The reason for the stability of the THF complexes toward dissociation of THF seems to come mostly from sterical interactions of alkyne substituents and the ligands L/L_2 and L′ and not from electronic effects. Complexes with the flat pyridine ligand are more stable compared to the corresponding THF complexes.

Conclusion

Complexes of the type $L_2M(\eta^2\text{-}RC_2R)$ without stabilizing ligands are sterically and electronically unsaturated. The size of zirconium is larger than that of titanium and as a result, it has a greater tendency to coordinate additional ligands; complexes without additional ligands are very rare and exist only with large alkyne substituents ($SiMe_3$) *and* sterical demanding Cp substitution (*rac*-ebthi[15], Cp*[13]). For the smaller titanium atom, sterically demanding alkyne *or* Cp substituents alone make alkyne complexes without additional ligands possible.

On the basis of these results it seems that it is now possible to understand the stability as well as the reactivity of bridged and unbridged alkyne−titanocene and −zir-

conocene complexes better. Control of stability is possible only by empirical tailoring of the complexes using different metals, alkyne substituents, Cp substitution and additional ligands.

This research was supported by the *Max-Planck-Gesellschaft* and the *Fonds der Chemischen Industrie*.

Experimental Section

All operations were carried out in argon with standard Schlenk techniques. Solvents were freshly distilled from sodium tetraethylaluminate under argon prior to use. Deuterated solvents were treated with sodium or sodium tetraethylaluminate, distilled and stored under argon. − The following spectrometers were used: NMR, Bruker ARX 400; IR, Nicolet Magna 550 (Nujol mulls using KBr plates); MS, AMD 402. − Melting points were measured in sealed capillaries with a Büchi 535 apparatus. − X-ray crystallographic study: Data were collected with a STOE-IPDS diffractometer using graphite-monochromated Mo-K_α radiation. The structures were solved by direct methods (SHELXS-86)[16] and refined by full-matrix least-squares techniques against F^2 (SHELXL-93).[17] The hydrogen atoms were included at calculated positions. All other nonhydrogen atoms were refined anisotropically. Cell constants and other experimental details are compiled in Table 6. XP (SIEMENS Analytical X-ray Instruments, Inc.) was used for structure representations.

Preparation of [(η⁵-C₅H₄)−SiMe₂−(η⁵-C₅H₄)]TiC₄Ph₄ (**1**): 1.10 g of [(η⁵-C_5H_4)−$SiMe_2$−(η⁵-C_5H_4)]$TiCl_2$ (3.62 mmol) was dissolved in 20 ml of THF and 0.09 g (3.62 mmol) of magnesium turnings and 0.64 g (3.62 mmol) of tolan were added. The solution was heated to 50°C and the colour changed from red to yellow-brown. The reaction mixture was stirred for 3 h at room temp. and the solvent was removed and replaced by *n*-hexane. After filtration at −30°C, red-brown crystals were formed. The crystals were washed in *n*-hexane and dried in vacuo to give 0.75 g (35%) of **1**, m.p. 203−204°C. − $C_{40}H_{34}SiTi$ (590.68): calcd. C 81.34, H 5.80; found C 81.22, H 5.85. − ^{1}H NMR (C_6D_6): δ = −0.04 $SiMe_2$ (s, 6 H); 4.99, 8.17 CH (d, 4 H each); 6.75−7.10 Ph (m, 20 H). − ^{13}C NMR (C_6D_6): δ = −6.2 $SiMe_2$; 105.0 $C_{q.}$; 117.4, 123.6 CH; 124.8, 125.9, 127.0, 128.1, 128.3, 131.4 Ph; 141.3, 148.7 Ph(q.); 135.3, 201.3 C(alkyne). − MS (70 eV); *m/z*: 590 [M^+], 234 [(η⁵-C_5H_4)−$SiMe_2$−(η⁵-C_5H_4)Ti^+], 178 [PhC_2Ph^+].

Preparation of [(η⁵-C₅H₄)−SiMe₂−(η⁵-C₅H₄)]Ti(η²-Me₃SiC₂SiMe₃) (**2**): Using the same procedure as described for **1**, the title compound was prepared using 0.37 g (1.20 mmol) of [(η⁵-C_5H_4)−$SiMe_2$−(η⁵-C_5H_4)]$TiCl_2$ in 15 ml of THF using 0.029 g of magnesium turnings and 0.27 ml (1.20 mmol) of bis(trimethylsilyl)-acetylene. Yield 0.20 g (41.2%) of a yellow-brown oily solid. − ^{1}H NMR (C_6D_6): δ = −0.3 $SiMe_3$ (s, 18 H); 0.27 $SiMe_3$ (s, 6 H); 5.05, 9.33 CH (4 H each). − ^{13}C NMR (C_6D_6): δ = −6.0 $SiMe_2$; 0.6 $SiMe_3$; 114.6 C(C_5H_4); 121.8, 126.9 C_5H_4; 248.9 C(alkyne). − IR (Nujol): $\tilde{\nu}$ = 1683 cm^{-1}, $\nu(C{=}C)_{coord.}$ = 1251 cm^{-1} [δ_s (CH_3−Si)]. − MS (70 eV); *m/z*: 234 [M − alkyne$^+$], 234 [(η⁵-C_5H_4)−$SiMe_2$−(η⁵-C_5H_4)Ti^+], 170 [alkyne$^+$].

Preparation of (thi)₂Ti(η²-PhC₂Ph) (**3**): To 0.30 g (0.84 mmol) of $(thi)_2TiCl_2$, dissolved in 15ml of THF, were added 0.02 g (0.84 mmol) of Mg turnings and 0.15 g (0.84 mmol) of diphenylacetylene. The colour turned from red to green-brown and the solution was stirred for 3 h at room temp. After removing the solvent and replacing it by *n*-hexane, the brown solution was filtered and allowed to stand at −30°C, to induce precipitation of dark brown crystals (yield 0.25 g, 64%), m.p. 111°C. − $C_{32}H_{32}Ti$ (464.49): calcd. C 82.75, H 6.94; found C 82.32, H 6.99. − ^{1}H NMR (C_6D_6): δ = 1.11−1.22, 1.43−1.58, 1.90−2.02, 2.50−2.62 CH_2 (4 H each); 5.45 CH (2 H); 6.14 CH (4 H); 6.80−6.92 Ph (m, 4 H); 7.10−7.28 Ph (m, 6 H). − ^{13}C NMR (C_6D_6): δ = 22.8, 24.7 CH_2; 126.1 $C_{q.}$; 110.7, 111.4 CH; 142.1 (*ipso*), 125.5, 126.6, 128.6 Ph; 198.8 C(alkyne). − IR (Nujol): $\tilde{\nu}$ = 1671 cm^{-1} $\nu(C{\equiv}C)_{coord.}$ = 1585 cm^{-1} Ph.

Preparation of (thi)₂Ti(η²-PhC₂SiMe₃) (**4**): 0.30 g (0.84 mmol) of $(thi)_2TiCl_2$ was dissolved in 20 ml of THF and treated with 0.02 g (0.84 mmol) of magnesium turnings and 0.28 ml (1.23 mmol) of phenyl(trimethylsilyl)acetylene. The solution was heated to 50°C until the colour changed to violet. Preparation was the same as described for **2**; violet crystals, yield 0.290 g (75%). m.p. 158−160°C. − $C_{29}H_{36}SiTi$ (460.57): calcd. C 75.63, H 7.88; found C 75.57, H 7.92. − ^{1}H NMR (C_6D_6): δ = 0.03 $SiMe_3$; 2.23−2.70 (10 H), 1.90−1.99 (2 H), 2.51−2.62 (2 H), 2.75−2.83 (2 H) CH_2; 5.66 (2 H), 5.93 (2 H), 6.16 (2 H) CH; 6.45 *o*-Ph (2 H); 6.80 *p*-Ph (1 H); 7.03 *m*-Ph (2 H). − ^{13}C NMR (C_6D_6): δ = 1.4 $SiMe_3$; 23.3, 23.4, 25.4, 25.5 CH_2; 111.2, 111.8, 112.1 CH; 127.8, 127.9 $C_{q.}$; 126.1, 126.8, 129.6, 141.2(q) Ph; 213.6, 220.0 C(alkyne). − IR (Nujol): $\tilde{\nu}$ = 1652 cm^{-1}, $\nu(C{=}C)_{coord.}$ = 1589 cm^{-1} Ph, 1242 cm^{-1} [δ_s (CH_3−Si)]. − MS (70 eV) *m/z*: 286 [$(thi)_2Ti^+$], 174 [alkyne$^+$].

Preparation of (thi)₂Ti(η²-Me₃SiC₂SiMe₃) (**5**): To a solution of 0.30 g (0.84mmol) of $(thi)_2TiCl_2$ in 15 ml of THF 0.10 ml of bis(trimethylsilyl)acetylene and 0.20 g of magnesium turnings were added. Reaction and workup according to **4** resulted in the formation of a dark yellow solid. − ^{1}H NMR (C_6D_6): δ = −0.14 $SiMe_3$ (18 H); 1.22−1.39 (4 H), 1.58−1.83 (8 H), 2.68−2.73 (4 H) CH_2; 5.68 CH (2 H); 6.05 CH (4 H). − ^{13}C NMR (C_6D_6): δ = 2.1 $SiMe_3$; 23.6, 25.4 CH_2; 112.2, 113.0 CH; 131.0 $C_{q.}$; 242.3 C(alkyne). − IR (Nujol): $\tilde{\nu}$ = 1629 cm^{-1}, $\nu(C{=}C)_{coord.}$ = 1243 cm^{-1} [δ_s (CH_3−Si)]. − MS (70 eV); *m/z*: 286 [$(thi)_2Ti^+$], 170 [alkyne$^+$].

Preparation of [(thi)₂Ti(CPh=CHPh)]₂(μ-O) (**6**): 0.20 g of **3** were dissolved in 15 ml of wet *n*-hexane. After standing for 3 d, 0.15 g (74.3%) of yellow needles appeared, m.p. 127−128°C. − $C_{64}H_{58}OTi_2$ (938.92): calcd. C 81.87 H 6.23; found C 81.25 H 6.30. − ^{1}H NMR (C_6D_6): δ = 1.39−1.49 (8 H) 1.50−1.59, 1.62−1.73, 2.10−2.18, 2.21−2.30, 2.45−2.54, 2.68−2.78 (4 H) CH_2; 4.84, 5.19, 6.15 (4 H) CH; 6.95−7.20 (20 H) Ph; 7.76 (2 H) CH. − ^{13}C NMR (C_6D_6): δ = 21.4, 21.5, 23.2, 23.4, CH_2; 105.3, 106.7, 115.4 CH; 122.5, 124.8 $C_{q.}$; 123.6, 125.2, 125.9, 126.4, 130.5, 131.0, 139.1 (q), 152.6 (q) Ph; 130.5, 193.5 C(alkene).

Preparation of (thi)₂Zr(THF)(η²-Me₃SiC₂SiMe₃) (**7**): 1.30 g (3.24 mmol) of $(thi)_2ZrCl_2$ was dissolved in 20 ml of THF and treated with 0.08 g magnesium turnings and an equimolar amount of bis(trimethylsilyl)acetylene. The solution was stirred at room temp. until all magnesium had disappeared. The honey-yellow solution was concentrated to dryness, the residue was dissolved in hexane/THF (3:1), filtered, and cooled to −30°C to give 0.65 g (35%) **7** after 3 d, m.p. up to 50°C (elimination of THF). − $C_{30}H_{48}OSi_2Zr$ (572.10): calcd. C 62.98 H 8.46; found C 62.57 H 8.54. − ^{1}H NMR ([D_8]THF): δ = 0.21 $SiMe_3$ (18 H); 1.56 CH_2 (8 H); 2.05, 2.30 CH_2 (4 H each); 1.75, 3.70 THF (4 H each); 5.33 CH (4 H); 5.55 CH (2 H). − ^{13}C NMR ([D_8]THF): δ = 5.1 $SiMe_3$; 24.0, 25.1 CH_2; 100.4, 107.5 CH; 124.3 $C_{q.}$; 222.0 C(alkyne). − IR (Nujol): $\tilde{\nu}$ = 1559 cm^{-1}, $\nu(C{=}C)_{coord.}$ = 1241 cm^{-1} [δ_s (CH_3−Si)]. − MS (70 eV); *m/z*: 500 [M − THF^+], 329 [$(thi)_2Zr^+$], 170 [alkyne$^+$].

Preparation of (thi)₂Zr(py)(η²-Me₃SiC₂SiMe₃) (**8**): As described for complex **7**, the title compound was formed by adding 0.32 ml (0.40 mmol) of pyridine after all magnesium had disappeared. The red-brown solution was concentrated to dryness and the residue was dissolved in *n*-hexane and filtered. After standing for 2 d at −30°C, 0.98 g (55%) of complex **8** deposited as orange-

brown crystals, m.p. 141−142°C. − $C_{31}H_{45}NSi_2Zr$ (579.10): calcd. Keywords: Ethylene polymerization / Group 5 metal complexes / Hydridotris(pyrazolyl)borates / Alkyne ligands / Migratory insertion

Substituted hydridotris(pyrazolyl)borato (Tp′) niobium complexes of the type [Tp′$NbMe_2$(PhC≡CMe)] polymerize ethylene (under 1 atm, at room temp. and in toluene) when treated with an equimolar amount of $B(C_6F_5)_3$. A clear relationship is observed between the stereoelectronic nature of the complex and catalytic activity. This is discussed on the basis of electrochemical data for the dichloro complexes [Tp′$NbCl_2$(PhC≡CMe)], and the rates of alkyl migration in [Tp′Nb(Cl)(R)(PhC≡CMe)] (R = CH_2Me, CH_2SiMe_3). For a given electron density at the metal, the bulky $Tp^{Me2,4\text{-}Cl}$ yields a catalyst which is more than 6 times as active as the unsubstituted Tp based catalyst.

Several attempts have recently been made, with related group 5 metal complexes, to mimic the outstanding activity in the polymerization of olefins of group 4 metal molecular complexes[1]. It is also hoped that the group 5 catalysts would be more tolerant to functionalized monomers, a highly desirable property if co-polymers are targeted. Most of the approaches have relied on an isoelectronic comparison with the 14-electron metallocene alkyl cations $[Cp_2MR]^+$, known to be the active species in group 4 catalysis[1]. As far as we are aware, a true Nb- or Ta-based catalyst, akin to $[Cp_2MR]^+$, has not so far been isolated, so we will base this discussion on its precursor. The combination [Cp′M(diene)X_2]/MAO (MAO = methylaluminoxane) gives polyethylene (PE) with a maximum activity of 39 (kg of PE) (mol of catalyst)$^{-1}$ h^{-1}. Interestingly the PE has a very narrow polydispersity (1.05)[2]. Based on the isolobal analogy, developed by Gibson and co-workers, between the bent metallocene Cp_2Zr and the imido CpNb(=NR) moieties[3], several systems have been explored. However, their activity is highly dependant on the substituents bound either to the metal or to the imido nitrogen, as well as on the activation mode[4]. The highest reported activity is 61 kg mol^{-1} h^{-1} for the [Cp*Ta(=N−Si*t*Bu_3)(η^1-allyl)(η^3-allyl)]/MAO system[4a], whereas some other imido complexes are, at best, only marginally active[4c]. The borollide−Cp ligand set leads to a deceptively low activity (2 kg mol^{-1} h^{-1} for [Cp*(η^5-$C_4H_4BNR_2$)$TaCl_2$/MAO)][5]. Imidovanadium complexes [LV(=NR)Cl_2] [L = Cp, Tp′ (Tp′ = a substituted hydridotris(pyrazolyl)borate)] generate active systems[4c][6], particularly with respect to propene polymerization.

Given the similarity between imido and (4e)-alkyne ligands[7] and between Cp and Tp′ ligands[8], we describe here preliminary results: (i) showing that complexes of the type [Tp′$NbMe_2$(alkyne)] do polymerize ethylene when properly activated; (ii) providing a basis for a stereoelectronic/activity relationship in this series of complexes, which has not been previously made for the group 5 metal catalysts. Related studies have been reported for Tp′-supported yttrium catalysts[9].

In Table 1, we summarize the data for ethylene polymerization by the system [Tp′$NbMe_2$(PhC≡CMe)]/$B(C_6F_5)_3$ (Tp′ = Tp, Tp^{Me2}, $Tp^{Me2,4\text{-}Cl}$, see Scheme 1)[10], electrochemical behaviour for the first monoelectronic reduction of the parent dichloro complexes [Tp′$NbCl_2$(PhC≡CMe)], and first-order rate constants k for alkyl migration to the alkyne in [Tp′Nb(Cl)(CH_2SiMe_3)(PhC≡CMe)] and [Tp′Nb(Cl)(CH_2Me)(PhC≡CMe)] (a reaction which ultimately yields [Tp′Nb(Cl)(Me)(PhC≡CCH_2SiMe_3)] and [Tp′Nb(Cl)(Me)(PhC≡CCH_2Me)] respectively, as shown elsewhere[11]). Several of these compounds are new and their syntheses and full characterization may be found in the Experimental Section.

Table 1. Ethylene polymerization activity for [Tp′$NbMe_2$-(PhC≡CMe)]/$B(C_6F_5)_3$, electrochemical data for [Tp′$NbCl_2$-(PhC≡CMe)] and first-order rate constants k for alkyl migration to the alkyne in [Tp′Nb(Cl)(R)(PhC≡CMe)], as a function of Tp′

Tp′	Activity[a]	$E_{1/2}$ (ΔE_p, i_a/i_c)[b]	$k \times 10^5$ [c]	$k \times 10^5$ [d]
Tp^{Me2}	100	−1.18 (0.15, 0.9)[e]	2.3[f]	3.0[f]
$Tp^{Me2,\ 4\text{-}Cl}$	130	−0.97 (0.10, 0.9)	2.2	4.75
Tp	20	−0.93 (0.25, 0.5)[e]	3.5	−

[a] Average of at least 3 runs, kg of PE (mol of catalyst)$^{-1}$ h^{-1}. − [b] V vs SCE. − [c] s^{-1}, R = CH_2SiMe_3. − [d] s^{-1}, R = CH_2Me. − [e] From ref.[10]. − [f] From ref.[11].

The first observation is that the dimethyl complexes [Tp′$NbMe_2$(PhC≡CMe)] do polymerize ethylene when activated by the methyl abstracting agent $B(C_6F_5)_3$ in a tolu-

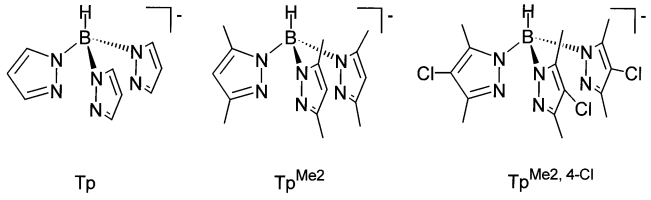
Scheme 1



ene solution[12], with the activities being higher than those observed for previously described systems based on heavier group 5 metal complexes. When red-purple [$Tp^{Me2}NbCl_2$(PhC≡CMe)] is treated with 500 equiv. of MAO in toluene, a light yellow solution is obtained which fails to polymerize ethylene. The choice of the activator is critical in other group 5 systems[4a]. We have also verified (^{1}H NMR) that toluene solutions of yellow [$Tp^{Me2}NbMe_2$(PhC≡CMe)] do not react with ethylene (1 atm).

The second observation is that the activity is notably dependent on the nature of Tp′. Bulky Tp^{Me2} and $Tp^{Me2,4-Cl}$ lead to a much higher catalytic activity than the less sterically demanding, unsubstituted Tp. Increased electrophilicity, as probed by comparison of the reduction potential $E_{1/2}$ for the parent dichloro Tp^{Me2} and $Tp^{Me2,4-Cl}$ complexes, only slightly increases the catalytic activity. By way of contrast, steric protection is mandatory: Tp and $Tp^{Me2,4-Cl}$ offer virtually the same electron density at the metal (cf. $E_{1/2}$), but catalytic production is dramatically favored by the bulky ligand[13]. We propose that these effects result from a steric shielding of the metal center by Tp^{Me2} and $Tp^{Me2,4-Cl}$ which prevents decomposition of the catalytic species via some kind of association. Several decomposition processes of the group 4 catalysts involve the formation of dinuclear species[1].

Parallel experiments lend further support to this view. We have previously studied in detail the mechanism of alkyl exchange in [Tp^{Me2}Nb(Cl)(R)(PhC≡CMe)] that leads to [Tp^{Me2}Nb(Cl)(Me)(PhC≡CR)] via the rate determining step of migratory insertion of R on to the alkyne[11]. The disappearance of [Tp^{Me2}Nb(Cl)(R)(PhC≡CMe)] at 343 K occurs with first-order rate constants of $2.3\cdot10^{-5}$ s^{-1} and $3.0\cdot10^{-5}$ s^{-1} for R = CH_2SiMe_3 and CH_2Me, respectively[11]. The corresponding Tp and $Tp^{Me2,4-Cl}$ complexes have thus been synthesized and their thermolysis studied by ^{1}H NMR in [D_6]benzene at 343 K. The experimental first-order rate constants k provided in Table 1 indicate that, again, the steric bulk of the Tp′ ligand largely governs the stability of the complexes and the alkyl group migration on to the alkyne. On one hand, for similar electron density at the metal, the rate constant for alkyl migration is significantly higher when a less sterically demanding ligand is used (cf. rate and electrochemical data for Tp and $Tp^{Me2,4-Cl}$). On the other hand, ligands of similar size such as Tp^{Me2} and $Tp^{Me2,4-Cl}$ which significantly differ in their electron-donating ability provide a similar barrier to alkyl migration as soon as the migrating R becomes too bulky. When R = CH_2Me, the migration is slightly faster for $Tp^{Me2,4-Cl}$ as expected, whereas there is no difference for the bulkier R = CH_2SiMe_3. In addition, the rearrangement of [TpNb(Cl)(CH_2SiMe_3)(PhC≡CMe)], although faster, is accompanied by important decomposition while putative [TpNb(Cl)(CH_2Me)(PhC≡CMe)] decomposes during its attempted synthesis. In the same vein, the chemical and electrochemical reversibilities of the first one-electron reduction of the parent dichloro complexes are low for Tp only. These observations may be ascribed to steric protection of the metal by the bulkier Tp′.

Assuming that these alkyl to alkyne migrations mimic with sufficient reliability the migration of a growing alkyl chain to a coordinated ethylene at least with respect to steric interactions, we conclude that a more active catalyst is obtained when an efficient protection of the metal is realized at the expense of faster intramolecular migration of alkyl chains. Since ethylene coordination is expected to be easier for the less bulky Tp, the central role played by the size of Tp′ is to be emphasized.

Hydridotris(pyrazolyl)borato group 5 complexes can indeed be used as ethylene polymerization catalysts. Such ligands provide a high degree of steric control which prevents catalyst decomposition, a major feature of the polymerizations reported herein. Up to now, attempts at observing putative naked or base-stabilized alkyl cations such as [Tp′NbMe(PhC≡CMe)]$^+$ or [Tp′NbMe(PhC≡CMe)(L)]$^+$ have failed. Further studies aimed at improving the activity of ethylene polymerization and studying α-olefins are in progress.

We thank Dr. *D. de Montauzon* for the electrochemical experiments.

Experimental Section

General: All experiments were carried out under a dry dinitrogen atmosphere using either Schlenck tube or glove box techniques. THF was obtained after refluxing a purple solution of Na/benzophenone under dinitrogen. Toluene, *n*-hexane, and pentane were dried by refluxing over CaH_2 under dinitrogen. Toluene used for the polymerization reactions was treated with concentrated sulfuric acid, washed three times with water, stored over $CaCl_2$, then further dried by refluxing over CaH_2 under dinitrogen before use. [D_6]Benzene (used unless otherwise stated) and $CDCl_3$ were dried over molecular sieves and stored under dinitrogen. − ^{1}H and ^{13}C NMR (only pertinent $^1J_{CH}$ are quoted): Bruker AC 200 (200, 50 MHz resp) and AM 250 (250, 62.9 MHz resp). − Elemental analyses: Perkin Elmer 2400 Series II. DTA: Sétaram 92−16.18. − Cyclic voltammetry data (home-made potentiostat interfaced with a PC-computer, scan rate 100 mV s^{-1}): Pt disk (1 mm) working electrode, THF solution, 0.1 M Bu_4NBF_4 as supporting electrolyte, Pt wire as auxiliary electrode, SCE as reference electrode.

The new compounds [$Tp^{Me2,4-Cl}NbCl_2$(PhC≡CMe)], [$Tp^{Me2,4-Cl}NbMe_2$(PhC≡CMe)], [$Tp^{Me2,4-Cl}$Nb(Cl)(CH_2Me)(PhC≡CMe)], [$Tp^{Me2,4-Cl}$Nb(Cl)(CH_2SiMe_3)(PhC≡CMe)], [TpNb(Cl)(CH_2SiMe_3)(PhC≡CMe)] have been obtained following published procedures established for related Tp and Tp^{Me2} complexes[10][11]. Yields and full characterization of these new compounds are provided below. Tp^{Me2} and $Tp^{Me2,4-Cl}$ complexes exist as a mixture of discrete alkyne rotamers[10][11]. Some NMR resonances of the minor isomer may be obscured.

[TpNbMe$_2$(PhC≡CMe)] could not be obtained cleanly from [TpNbCl$_2$(PhC≡CMe)] and 2 equiv. of LiMe. Its synthesis from MeMgCl is described below. B(C_6F_5)$_3$ (ref.[14]) was sublimed in vacuo before use. Kinetic data on the rearrangement of [Tp′Nb(Cl)(R)(PhC≡CMe)] were obtained from [D_6]benzene solutions at 343 K as previously reported[11].

[Tp$^{Me2,4\text{-}Cl}$NbCl$_2$(PhC≡CMe)]: Yield 59%. − $C_{24}H_{27}BCl_5N_6Nb$ calcd: C 42.4, H 4.0, N 12.35; found: C 42.3, H 4.0, N 12.20. − ^{1}H NMR: Major isomer δ = 6.90−6.60 (m, 5 H, *Ph*C≡CMe), 3.84 (s, 3 H, PhC≡C*Me*), 2.94, 1.97 (s, 3 H each, Tp$^{Me2,4\text{-}Cl}$*Me*), 1.85, 1.79 (s, 6 H each, Tp$^{Me2,4\text{-}Cl}$*Me*). [Tp$^{Me2,4\text{-}Cl}$Nb(Cl)(CH$_2$SiMe$_3$)(PhC≡CMe)]: Yield 34%. − $C_{28}H_{38}BCl_4N_6NbSi$ calcd: C 45.9, H 5.2, N 11.5; found: C 46.5, H 5.5, N 10.8. − ^{1}H NMR: Major isomer δ = 7.00−6.80 (m, 5 H, *Ph*C≡CMe), 3.65 (s, 3 H, PhC≡C*Me*), 3.06 (d, *J* = 12.4 Hz, 1 H, NbC*H*$_2$SiMe$_3$), 2.82, 2.09, 2.06, 1.91, 1.73, 1.65 (s, 3 H each, Tp$^{Me2,4\text{-}Cl}$*Me*), 0.27 (d, *J* = 12.4 Hz, 1 H, NbC*H*$_2$SiMe$_3$), −0.17 (s, 9 H, Si*Me*$_3$). Minor isomer: δ = 8.14 (d, 2 H, *o-Ph*C≡CMe), 7.40 (t, 2 H, *m-Ph*C≡CMe), 3.45 (d, *J* = 11.8 Hz, 1 H, NbC*H*$_2$SiMe$_3$), 2.87 (s, 3 H, PhC≡C*Me*), 2.30, 2.09, 2.02, 1.98, 1.85 (s, 3 H each, Tp$^{Me2,4\text{-}Cl}$*Me*), 0.37 (d, *J* = 11.8 Hz, 1 H, NbC*H*$_2$SiMe$_3$), −0.44 (s, 9 H, Si*Me*$_3$). − ^{13}C NMR: Major isomer: δ = 251.5, 221.4 (Ph*C*≡*C*Me), 149.7, 149.6, 148.2, 141.2, 138.2 (Tp$^{Me2,4\text{-}Cl}$*C*Me), 138.3 (*ipsoPh*), 129.8, 129.6, 128.9 (*Ph*), 111.4, 110.9, 110.5 (Tp$^{Me2,4\text{-}Cl}$*C*Cl), 81.5 (dd, J_{CH} = 106, 124 Hz, Nb*C*H$_2$SiMe$_3$), 24.0 (PhC≡C*Me*), 14.5, 14.0, 12.9, 11.0, 10.7, 10.6 (Tp$^{Me2,4\text{-}Cl}$*Me*), 2.3 (Si*Me*).

[TpNbMe$_2$(PhC≡CMe)]: 0.7 ml of a 3.0 M THF solution of MeMgCl was added dropwise to a stirred cooled (0°C) toluene solution (50 ml) of [TpNbCl$_2$(PhC≡CMe)] (0.49 g, 1.0 mmol). Stirring was continued at 0°C for 4 h as the colour of the solution turned from red-purple to yellow greenish. The solution was then pumped to dryness. Extraction with pentane (30 ml), and filtration through a Celite pad, followed by several washings, afforded a yellow solution which was then evaporated to dryness. Crystallization from pure pentane afforded yellow crystals of the title compound (0.20 g, 0.44 mmol, 44%). The yield is limited by the high solubility of the compound. −$C_{20}H_{25}BN_6Nb$ calcd: C 53.1, H 5.5, N 18.6; found: C 53.1, H 4.9, N 18.3. − ^{1}H NMR: δ = 7.98, 7.45 (br s, 1 H each, Tp-3-C*H* and Tp-5-C*H*), 7.40−7.10 (m, 5 H, *Ph*C≡CMe), 7.45, 6.92 (br s, 2 H each, Tp-3-C*H* and Tp-5-C*H*), 6.06 (br s, 1 H, Tp-4-C*H*), 5.69 (br s, 2 H, Tp-4-C*H*), 3.28 (s, 3 H, PhC≡C*Me*), 1.14 (s, 6 H, Nb*Me*). − ^{13}C NMR: δ = 242.0, 227.7 (Ph*C*≡*C*Me), 143.3, 142.4, 135.0, 134.4 (br, Tp-3-*C*H and Tp-5-*C*H), 139.3 (*ipsoPh*), 130.7, 128.8, 128.4 (*Ph*), 105.7, 104.9 (br, Tp-4-*C*H), 55.0 (q, J_{CH} = 118 Hz, Nb*Me*), 22.0 (PhC≡C*Me*).

[TpNb(Cl)(CH$_2$SiMe$_3$)(PhC≡CMe)]: Yield 88%. − $C_{22}H_{29}BClN_6NbS$ calcd: C 48.5, H 5.4, N 15.4; found: C 48.9, H 5.0, N 15.1. − ^{1}H NMR: δ = 8.40, 7.42, 7.31, 7.00, 6.93 (d, *J* = 2.2 Hz, 1 H each, Tp-3-C*H* and Tp-5-C*H*), 7.30−7.00 (m, 5 H, *Ph*C≡CMe), 5.99, 5.71, 5.50 (t, *J* = 2.2 Hz, 1 H each, Tp-4-C*H*), 3.34 (s, 3 H, PhC≡C*Me*), 1.93 (s, 2 H, NbC*H*$_2$SiMe$_3$), −0.09 (s, 9 H, Si*Me*$_3$). − ^{13}C NMR: δ = 242.8, 225.9 (Ph*C*≡*C*Me), 144.7, 144.5, 144.0, 135.0, 134.9, 134.4 (Tp-3-*C*H and Tp-5-*C*H), 138.0 (*ipsoPh*), 131.1, 129.2, 128.7 (*Ph*), 105.8, 106.3 (Tp-4-*C*H), 83.1 (t, J_{CH} = 108 Hz, Nb*C*H$_2$SiMe$_3$), 23.3 (PhC≡C*Me*).

Typical Ethylene Polymerization Run: In the glove box [Tp$^{Me2,4\text{-}Cl}$NbMe$_2$(PhC≡CMe)] (12.8 mg, 0.02 mmol), a magnetic stir bar and purified toluene (5 ml) were introduced in a Fischer-Porter bottle equiped with a side arm. To this side arm was attached (Teflon joint, screw connection, Teflon stopcock) a glass vessel containing B(C_6F_5)$_3$ (10.4 mg, 0.02 mmol) dissolved in toluene (5 ml). The apparatus was removed from the glove box, and attached to a double manifold vacuum line connected to an ethylene tank through molecular sieves and CuO purifying devices. The main Fischer-Porter volume, containing the vigorously stirred (500 rpm) yellow solution of the niobium complex, was saturated with ethylene under 1 atm. No reaction occured at that stage. The Teflon stopcock of the side arm was opened to allow instantaneous mixing of the co-catalyst, then closed again. A chronometer was started. Virtually instantaneous precipitation of a whitish powder commenced together with temp. increase. Methanol (10 ml) containing a few drops of an aqueous HCl solution was introduced through the side arm after 5 min to quench the polymerization reaction. The precipitate was collected on a frit in air, washed several times with methanol and then diethyl ether, and dried to a constant weight in an oven (75°C). 0.212 mg of a white solid, corresponding to a catalytic activity of 125 kg mol^{-1} h^{-1}, were obtained. − $(C_2H_4)_n$ calcd: C 85.6, H 14.4, N 0.0; found: C 85.6, H 15.2, N 0.0. − DTA: m.p. 133.5°C.

Keywords: Osmium / Thiolate / Molecular wire / Molecular devices / Structure elucidation

The molecule (*p,p*)-$HSC_6H_4C{\equiv}CC_6H_4C{\equiv}CC_6H_5$ has been attached to a triosmium cluster and characterized crystallographically. The complex $Os_3(CO)_{10}(\mu\text{-}H)(\mu\text{-}SC_6H_4C{\equiv}CC_6H_4C{\equiv}CC_6H_5)$ (**1**) was obtained in 49% yield from the reaction of the thiol $HSC_6H_4C{\equiv}CC_6H_4C{\equiv}CC_6H_5$ with $Os_3(CO)_{10}(NCMe)_2$. The sulfur atom bridges two metal atoms on the edge of a triangular cluster of three osmium atoms. The three aryl rings are nearly coplanar. The ligand is 18.27(2) Å in length from the sulfur atom to the *para*-carbon atom of the third aryl ring. This compound may serve as a model for the coordination of thiol-terminated molecular wires to metallic probe surfaces.

Future computational systems will eventually consist of logic devices that are ultra dense, ultra fast, and ultra small[1][2][3]. The slow step in existing computational architectures is not usually the switching time, but the time it takes for an electron to travel through the circuit. By using molecular-scale electronic interconnects[4], electronic transmission times will be minimized and the resulting computational operations will occur at far greater speeds than those attainable from conventional patterned architectural arrays[1].

Although it is well documented that bulk conjugated organic materials can be semiconducting or even conducting when doped[5], recent studies have shown that oriented thiol-terminated conjugated rigid-rod molecules[6] can conduct electrons through a single undoped conjugated molecule, "molecular-scale wire", to and from a metallic surface[7]. However, initial studies have indicated the presence of a transmission barrier at the metal-organic interface[8]. A detailed knowledge of the bonding of thiols to metallic surfaces will be crucial to developing an understanding of electron-transport mechanisms and the constuction of devices involving the metal-organic interfaces. The metal-thiol linkage is usually regarded to be a single metal−sulfur bond with transfer of the hydrogen atom to the metal surface. Therefore, we have undertaken a study to determine the nature of the structures and modes of attachment of some thiol-terminated molecular wires to metal clusters serving as models for metal surfaces.

The complex $Os_3(CO)_{10}(\mu\text{-}H)(\mu\text{-}SC_6H_4C{\equiv}CC_6H_4C{\equiv}CC_6H_5)$ (**1**) was obtained in 49% yield from the reaction of (*p,p*)-$HSC_6H_4C{\equiv}CC_6H_4C{\equiv}CC_6H_5$ with $Os_3(CO)_{10}(NCMe)_2$. Crystals of **1**, suitable for X-ray crystallographic analysis, were obtained by slow evaporation of solvent from a solution in CH_2Cl_2 solvent at 25°C. An ORTEP diagram of the molecular structure of **1** is shown in Figure 1. The molecule consists of a linear $SC_6H_4C{\equiv}CC_6H_4C{\equiv}CC_6H_5$ ligand linked to the triosmium cluster by the sulfur atom bridging two of the three osmium atoms. The reaction has produced cleavage of the thiol sulfur−hydrogen bond and transfer of the hydrogen atom to the osmium cluster to become a hydride ligand. The position of the hydride ligand was located and refined crystallographically. It bridges the Os(1)−Os(2) bond of a triangular cluster of three osmium atoms, Os(1)−H(1) = 1.9(1) Å and Os(2)−H(1) = 1.81(8) Å, and exhibits the characteristic high-field resonance shift in the ^{1}H-NMR spectrum, $\delta = -17.04$. The sulfur atom bridges the same two metal atoms on the other side of the Os_3 plane, Os(1)−S = 2.423(3) Å and Os(2)−S = 2.421(4) Å. These values are similar to those found for other bridging thiolate−triosmium linkages that have been structurally characterized previously[9]. The alkyne C−C bonds are short, C(46)−C(47) = 1.16(2), C(54)−C(55) = 1.19(2) Å as expected for C−C triple bonds, and the alkyne groups are linear. The sulfur−carbon distance, S−C(40) = 1.82(1) Å, is typical of a carbon−sulfur single bond. The overall length of the ligand is an interesting feature. The distance from S to C(59) is 18.27(2) Å. Although the central aryl ring is twisted approximately 10° away from the planes of the two other rings, the three aryl rings are nearly coplanar. This is a feature that would facilitate electron transmission through the π-orbital network.

Figure 2 shows the packing of the molecules in the crystal. All aryl rings are nearly coplanar. The intermolecular spacings between the rings of the different molecules are determined largely by the size of the cluster.

Studies have shown that bis(phenylethynyl)arenes exhibit strong fluorescence and are effective receptors for chemiluminescence processes[10]. We have found that **1** exhibits a single strong UV absorption at 332 nm ($\varepsilon = 48500\ M^{-1}\ cm^{-1}$)

A. and the *Defense Advanced Research Projects Agency* to J. M. T. We thank Professor *Catherine J. Murphy* for assistance with the UV/Vis-spectral measurements.

Experimental Section

The reaction was performed under nitrogen. 24.0 mg of $HSC_6H_4C{\equiv}CC_6H_4C{\equiv}CC_6H_5$[6b] (0.0773 mmol), dissolved in 4 ml of CH_2Cl_2, was added to a solution of 75.0 mg of $Os_3(CO)_{10}(NCMe)_2$ (0.0804 mmol) in 50 ml of CH_2Cl_2. After stirring for 2 h at 25°C, the solvent was removed and the residue separated by TLC (in air) on silica gel by using a hexane/CH_2Cl_2 (3:1) solvent mixture. This yielded a yellow band containing 44.1 mg of $Os_3(CO)_{10}(\mu\text{-}H)(\mu\text{-}SC_6H_4C{\equiv}CC_6H_4C{\equiv}CC_6H_5)$ (**1**) (49%). − IR (νCO in hexane, cm^{-1}): 2110 (m), 2069 (vs), 2060 (m), 2026 (vs), 2020 (m), 2003 (m), 1992 (w), 1987 (w). − ^1H NMR (δ in $CDCl_3$): 7.52−7.25 (m, 13 H, Ph), −17.04 (s, 1 H, Os-H). − $C_{32}H_{14}O_{10}Os_3S$ (1161.12): calcd. C 33.10, H 1.22; found 32.98, 1.37.

Crystal Data: Space group = $P\bar{1}$, a = 15.019(3), b = 13.831(2), c = 9.299(1) Å, α = 90.21(1), β = 72.67(2), γ = 114.77°, Z = 2; 3221 reflections, R = 0.035. Diffraction measurements at 20°C were made on a Rigaku AFC6S four-circle diffractometer using Mo-K_α radiation. The structure solution and refinement were made by using the TEXSAN MOTIF structure-solving program library (v. 1.8) of the Molecular Structure Corp., The Woodlands, TX on a Silicon Graphics Indigo^2 computer. An absorption correction (DIFABS) was applied. − Crystallographic Data (excluding structure factors) for the structure reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication no. CCDC-101062. Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ [Fax: int code + 44(1223)336-033, E-mail: deposit@ccdc.cam.ac.uk).

[4] "Molecular electronics" is a poorly defined term since some authors refer to it as any molecular-based system such as a film or a liquid-crystalline array. Other authors, including us, have preferred to reserve the term "molecular electronics" for single-molecule tasks, such as single-molecule-based devices or single-molecular wires. Due to this confusion, we have chosen here to follow the Petty et al. [M. C. Petty, M. R. Bryce, D. Bloor (Eds.) in *Introduction to Molecular Electronics*, Oxford Univ. Press, New York, **1995**] terminology by using two subcategories, namely "molecular materials for electronics" for bulk applications and "molecular-scale electronics" for single-molecule applications.

Keywords: Silicon amidinates / Germanium amidinates / Bidentate coordination

The synthesis of novel bis(amidinate) silicon and germanium complexes is described. The reaction of two equiv. of $[MeC(N\textit{i}Pr)_2]Li\cdot THF$ (**1**) with $SiCl_4$, $GeCl_4$ or $GeCl_2$·dioxane affords $[MeC(N\textit{i}Pr)_2]_2SiCl_2$ (**2**), $[MeC(N\textit{i}Pr)_2]_2GeCl_2$ (**3**) and $[MeC(N\textit{i}Pr)_2]_2Ge$ (**4**), respectively. The complexes **2** and **4** have been structurally characterized. The crystallographic results confirm a bidentate coordination of the amidinate ligands at the Si/Ge center, as indicated by spectroscopic studies.

Introduction

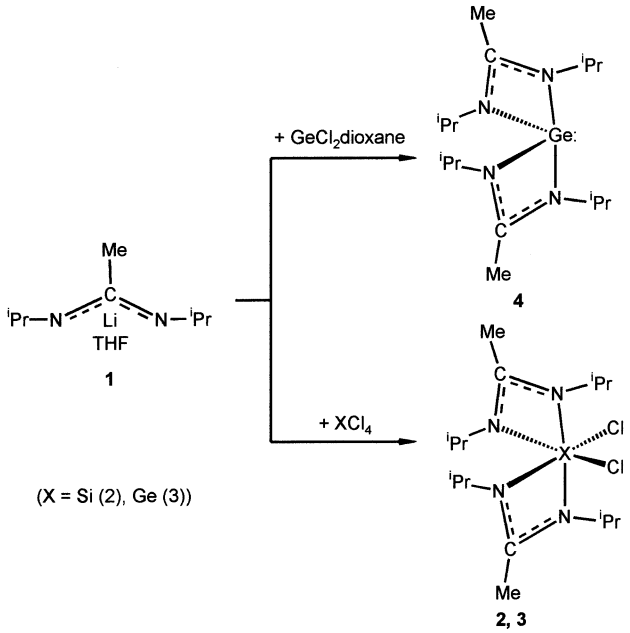
The coordination chemistry of amidinates is well established, not only for the transition metals[1][2] and the lanthanoides[3], but also for main group elements[4][5][6][7][8]. The main importance lies in the generation of element−nitrogen bonds as needed for CVD methods[9], and for the synthesis of new catalysts. However, the amidinate chemistry of Group 14 elements has hitherto only been investigated for tin and lead[10][11]. Amidinates of silicon and germanium are largely unknown, with only a few exceptions.

Thus, $PhC(NSiMe_3)[N(SiMe_3)_2]$[12] and $[PhC(NSiMe_3)_2]M\cdot(THF/Et_2O)_n$ (M = Li, Na, K, Rb)[11] are well known starting materials in amidinate chemistry. $PhC(NSiMe_3)[N(SiMe_3)_2]$ is the only compound of this type for which a crystal structure determination is available, and this confirms a monodentate amidinate coordination[11]. In contrast, a bidentate coordination was deduced from a $\delta^{29}Si$ value of −101.9 for the only other known amidinate silicon derivative, $PhC(NSiMe_3)_2SiCl_3$[14]. A report on structural investigations of two other silicon amidinate derivatives is currently in press[13]. With the aim of obtaining access to a new generation of molecular silicon−nitrogen compounds, which might easily be converted to polymeric materials of different but easily tunable structural units resembling silicate structures but with pseudochalcogenide bridges {i.e. $[N-C(R)-N(R')]^{2-}$ instead of O^{2-}}, and which further might be converted to Si/C/N/X materials, we have initiated a comprehensive study of silicon and germanium amidinate chemistry. We have found that modification of the organic substituents on the nitrogen as well as on the bridging carbon atom exerts a considerable effect on the coordination to the silicon or germanium center[15]. We report herein on preliminary results concerning the synthesis and characterization of novel bis(amidinate) complexes of Si^{IV}, Ge^{IV}, and Ge^{II}.

Results and Discussion

The anionic amidinate compound $[MeC(N\textit{i}Pr)_2]Li\cdot THF$ (**1**) was obtained by reaction of *i*Pr−N=C=N*i*Pr with MeLi (THF, room temp.) and was isolated as a white, crystalline solid in good yield according to the published procedure[16]. Reactions of 2 equiv. of **1** with 1 equiv. of $SiCl_4$, $GeCl_4$ or $GeCl_2\cdot$dioxane resulted in the formation of the new complexes $[MeC(N\textit{i}Pr)_2]_2SiCl_2$ (**2**), $[MeC(N\textit{i}Pr)_2]_2GeCl_2$ (**3**), and $[MeC(N\textit{i}Pr)_2]_2Ge$ (**4**) (Scheme 1), which were obtained as colorless, crystalline solids.

Scheme 1. Reactions of $SiCl_4$, $GeCl_4$, and $GeCl_2\cdot$dioxane with $[CH_3C(N\textit{i}Pr)_2]Li\cdot THF$ (**1**)



The constitutions of the complexes were established on the basis of their ^1H-, ^{13}C-NMR and mass spectra, as well as by elemental analyses.

The room-temperature ^1H-NMR spectrum of **2** shows four doublets of equal intensity in the aliphatic region due to the methyl protons of the isopropyl groups, and two septets due to the CH protons of the isopropyl groups of the amidinate ligands. The CH_3 group of the bridging unit is

 © WILEY-VCH Verlag GmbH, D-69451 Weinheim, 1998 1434−1948/98/0404−0433 $ 17.50+.50/0

observed as a singlet. Temperature-dependent NMR measurements establish a rigid molecular skeleton in the range −80 °C to +80 °C. In marked contrast, the analogous germanium compound **3** shows fluctional behavior. At room temp., four doublets are again observed for the isopropyl groups, but these broaden on heating and coalesce to one broad singlet at 80 °C.

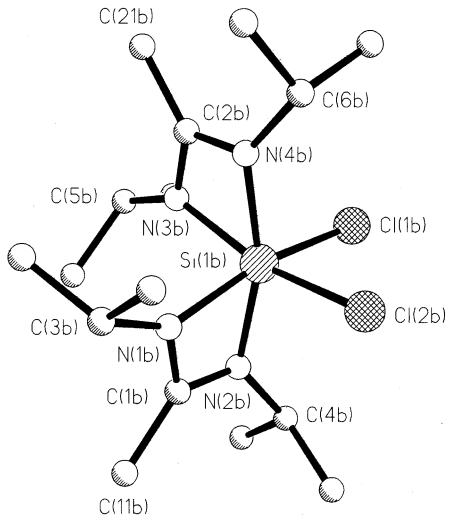
However, the germanium(II) compound **4** exhibits a single set of amidinate resonances over the whole temperature range, indicating equivalence of the two donor nitrogen atoms and symmetrical coordination to the germanium center on the NMR timescale.

The ^{29}Si-NMR resonance of **2** ($\delta = -169.33$) indicates hexacoordination at silicon. All three complexes show remarkable thermal stability. For example, **2** can be heated in toluene at 100 °C for several days without noticeable decomposition. No reaction was observed upon treatment with potassium or sodium metal (THF, room temp.).

Confirmation of the bidentate coordination mode of the amidinate ligands was obtained from X-ray structure determinations of **2** and **4**.

X-ray Analysis of $[CH_3C(NiPr)_2]_2SiCl_2$ (**2**) *and* $[CH_3C(NiPr)_2]_2Ge$ (**4**): The X-ray analysis of the colorless crystals of compound **2** (from toluene) shows two identical molecules in the asymmetric unit (see Table 2). The molecular geometry and atom numbering scheme are shown in Figure 1; selected bond distances [Å] and angles [°] are listed in Table 1.

Figure 1. Molecular structure of **2**



Both amidinate ligands are coordinated in a bidentate fashion, with one nitrogen in an axial and the other in an equatorial position of a distorted octahedron. Two chlorine atoms complete the *cis*-octahedral coordination sphere of the central silicon atom. As expected, the axial Si−N bond lengths [Si(1b)−N(2b): 1.837(2) Å, Si(1b)−N(4b): 1.841(2) Å] are slightly shorter than the equatorial distances [Si(1b)−N(1b): 1.915(2) Å, Si(1b)−N(3b): 1.914(2) Å]. This is accompanied by a slight shortening of the $C-N_{eq}$ bonds [N(1b)−C(1b): 1.312 Å, N(3b)−C(2b): 1.305(4) Å] compared to the $C-N_{ax}$ bonds [N(2b)−C(1b): 1.333(4) Å, N(4b)−C(2b): 1.341(4) Å] within the amidinate ligands, both being approximately intermediate between C−N double-bond and C−N(sp^2) single-bond distances. The four-membered Si−N−C−N rings are essentially planar, as are the arrangements about the nitrogen and carbon atoms. The overall structure of **2** resembles that of the structurally characterized tin compound $[MeC(NCy)_2]_2SnCl_2$[10a].

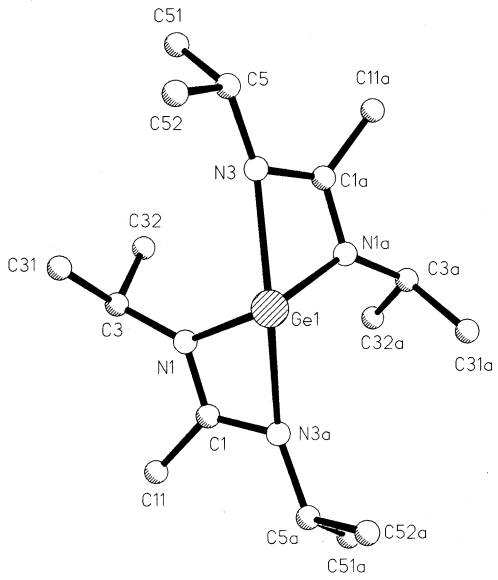
N(3b)−C(2b)−N(4b)	106.7(2)		

Figure 2. Molecular structure of **4**



The X-ray structure determination of the colorless crystals of **4** (from pentane) reveals the presence of one-half of the molecule in the asymmetric unit (see Table 2). The whole molecule can be generated by symmetric transformations. The molecular geometry and atom numbering

scheme are shown in Figure 2; selected bond distances [Å] and angles [°] are listed in Table 1.

In the monomeric molecule, the germanium atom is surrounded by four nitrogen atoms originating from two amidinate ligands, each spanning an axial and an equatorial site of a heavily distorted Ψ-trigonal bipyramid, with the "lone pair" of germanium(II) occupying the third equatorial position. Although, as in the case of **2**, the four-membered rings are almost planar, only the equatorial nitrogen atoms N(1)/(1a) are planar [sum of angles at N(1)/(1a): 359.9°]. The respective Ge(1)−N(1)/(1a) bonds [1.982(3) Å] are significantly shorter than the axial Ge(1)−N(3)/(3a) bonds [2.300(1) Å], which coincides with a considerable deviation from planarity of the N(3)/(3a) atoms [sum of angles at N(3)/(3a): 352.5°]. The axial N(3)−Ge(1)−N(3a) bond angle [145.7(1)°] is very small compared the ideal tbp value of 180° and highlights the considerable ring strain in **4**. The angle N(1)−Ge(1)−N(1a) is also rather small (100.7°). Instead of a Ψ-tbp structure, the geometry might be classified as a distorted tetragonal pyramid − in fact, an intermediate state is the best compromise for an adequate description. In this regard, the structure resembles those of other Ge^{II} compounds bearing four-membered chelate rings[17]. As a consequence of this structural dilemma, fluctional behavior may be anticipated and is indeed observed (see above). Again, small element to nitrogen distances [Ge−N(1)/(1b): 1.982(3) Å] coincide with slightly longer C−N distances in the ligand [C(1)−N(1)/C(1a)−N(1a): 1.325(4) Å] and vice versa: the long Ge(1)−N(3)/(3a) bond [2.300(2) Å] corresponds to a short C(1)−N(3)/(3a) bond [1.302(3) Å]. The amidinate bite angle [N(1a)−Ge(1)−N(3)] is rather acute (61.0°), which is compensated by a concomitant widening of the N−C−N bond angle (125.4°).

Conclusions

Monoanionic, bidentate four-electron donor amidinates are highly suitable ligands for stabilizing low oxidation states and/or high coordination numbers at group 14 element centers (Si, Ge). The newly synthesized *cis*-dichlorosilicon bis(amidinate) complex **2** may be a potentially useful precursor for novel stable Si^{II} compounds. Work in this area is currently in progress.

Experimental Section

General: All reactions were carried out under dry nitrogen. The solvents used were distilled under nitrogen from Na/K alloy. MeLi (1.6 M in Et_2O) and *i*PrNCN*i*Pr were used as purchased. $SiCl_4$ and $GeCl_4$ were freshly distilled from K_2CO_3 prior to use. *$GeCl_2 \cdot dioxane$*[18] and *[MeC(NiPr)$_2$]Li·THF* (**1**)[16] were prepared according to literature procedures. Elemental analyses were obtained on a Vario EL CHN Automat Analyzer at the microanalytical laboratory of the TU München. − NMR: Jeol GX 270 and 400 FT-NMR spectrometers. All chemical shifts are reported in parts per million and coupling constants *J* in Hz. Spectra were recorded at 25 °C unless otherwise stated. − MS: Varian MAT 311A, CI.

Preparation of [MeC(NiPr)$_2$]$_2$SiCl$_2$ (**2**): To a suspension of 13.85 mmol (3.05 g) of **1** in 50 ml of Et_20, 6.58 mmol (0.83 ml) of $SiCl_4$ was added at −78 °C. The reaction mixture was allowed to warm to room temp. with stirring. After 18 h, the solvent was replaced by 40 ml of toluene and the resulting suspension was filtered. Evaporation of the solvent from the filtrate afforded 2.4 g (95%) of colorless crystals. − ^{1}H NMR (C_6D_6): δ = 0.96 (d, $^3J_{HH}$ = 8.0, 6 H, CH_3CH), 1.28 (d, $^3J_{HH}$ = 8.0, 6 H, CH_3CH), 1.37 (d, $^3J_{HH}$ = 8.0, 6 H, CH_3CH), 1.41 (s, 6 H, CH_3C), 1.48 (d, $^3J_{HH}$ = 8.0, 6 H, CH_3CH), 3.33 (sept, 2 H, $^3J_{HH}$ = 8.0, CH$_3$C*H*), 4.30 (sept, 2 H, $^3J_{HH}$ = 8.0, CH$_3$C*H*). − ^{13}C NMR (C_6D_6): δ = 12.37 (*C*H$_3$C), 21.76 (*C*H$_3$CH), 23.24 (*C*H$_3$CH), 23.32 (*C*H$_3$CH), 23.59 (*C*H$_3$CH), 45.19 (CH$_3$*C*H), 46.37 (CH$_3$*C*H), 166.77 (N*C*N). − ^{29}Si NMR (C_6D_6): δ = −169.33. − MS (CI, 150 eV): *m/z* (%) = 380 (2) [M$^+$], 345 (100) [M − Cl], 262 (11) [M − Cl − CN*i*Pr], 239 (50) [M − *i*PrNC(Me)N*i*Pr]. − $C_{16}H_{24}Cl_2N_4Si$ (381.46): calcd. C 50.38, H 8.98, N 14.69; found C 48.15, H 8.75, N 12.90.

Preparation of [MeC(NiPr)$_2$]$_2$GeCl$_2$ (**3**): To a suspension of 8.42 mmol (1.85 g) of **1** in 50 ml of THF, 4.00 mmol (0.46 ml) of $GeCl_4$ was added at −78 °C and the reaction mixture was allowed to warm to room temp. After stirring for 18 h at room temp., the solvent was replaced by 40 ml of pentane. The residue was extracted several times. The combined extracts were slowly concentrated in vacuo to afford 1.41 g (83%) of colorless crystals. − ^{1}H NMR (20 °C, [D$_8$]toluene): δ = 1.11 (d, $^3J_{HH}$ = 6.4, 6 H, CH_3CH), 1.46 (d, $^3J_{HH}$ = 6.4, 6 H, CH_3CH), 1.63 (d, $^3J_{HH}$ = 6.4, 6 H, CH_3CH), 1.65 (d, $^3J_{HH}$ = 6.4, 6 H, CH_3CH), 1.55 (s, 6 H, CH_3C), 3.49 (sept, $^3J_{HH}$ = 6.4, 2 H, CH$_3$C*H*), 4.22 (sept, $^3J_{HH}$ = 6.4, 2 H, CH$_3$C*H*). − ^{1}H NMR (80 °C, [D$_8$]toluene): δ = 1.51 (br, 24 H, CH_3CH), 1.62 (s, 6 H, CH_3C), 3.6−4.2 (br, 4 H, CH$_3$C*H*). − ^{13}C NMR (C_6D_6): δ = 11.06 (*C*H$_3$C), 21.68, 23.23, 23.46, 23.73 (*C*H$_3$CH), 46.34 (CH$_3$*C*H), 47.36 (CH$_3$*C*H), 162.46 (N=*C*N). − MS (CI, 150 eV): *m/z* (%) = 391 (58) [M − Cl], 285 (39) [M − MeC(N*i*Pr)$_2$], 141 (100) [MeC(N*i*Pr)$_2$]. − $C_{16}H_{34}Cl_2GeN_4$ (425.99): calcd. C 45.11, H 8.04, N 13.15; found C 45.28, H 8.00, N 12.61.

Preparation of [MeC(NiPr)$_2$]$_2$Ge (**4**): To a mixture of 8.12 mmol (1.79 g) of **1** and 3.45 mmol (0.8 g) of $GeCl_2 \cdot$dioxane, 40 ml of Et_2O was added at −78 °C. The reaction mixture was slowly allowed to warm to room temp. and stirred for a further 18 h. The solvent was then removed and the product was extracted with 50 ml of pentane. The pentane extract was concentrated and **4** was isolated as colorless crystals (1.02 g, 81%). − m.p. 41 °C. − ^{1}H NMR (C_6D_6): δ = 1.31 (d, $^3J_{HH}$ = 6.5, 24 H, CH_3CH), 1.53 (s, 6 H, CH_3C), 3.63 (sept, $^3J_{HH}$ = 6.5, 4 H, CH$_3$C*H*). − ^{13}C NMR (C_6D_6): δ = 11.91 (*C*H$_3$C), 24.89 (*C*H$_3$CH), 47.16 (CH$_3$*C*H), 162.53 (N*C*=N). − MS (CI, 150 eV): *m/z* (%) = 357 (15) [M], 183 (3) [M − 4 *i*Pr], 143 (100) [MeC(N*i*Pr)$_2$]. − $C_{16}H_{34}GeN_4$ (355.08): calcd. C 54.12, H 9.65, N 15.77; found C 51.93, H 9.50, N 14.77.

Crystal Structure Determination: Suitable crystals of **2** and **4** were sealed into glass capillaries. The structures were solved by direct methods and refined by full-matrix least-squares calculations against F^2 (SHELXL-93)[19]. Crystal data and numerical data of the structure determinations are given in Table 2. The thermal motion of all non-hydrogen atoms was treated anisotropically. All hydrogen atoms were calculated in ideal positions. Further information may be obtained from the Fachinformationszentrum Karlsruhe, D-76344 Eggenstein-Leopoldshafen (Germany), on quoting the depository numbers CSD-408153 (**2**) and CSD-408152 (**4**).

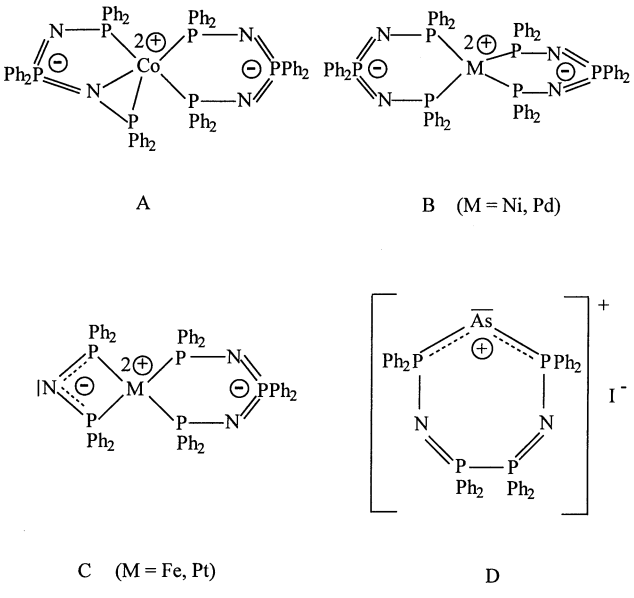
Keywords: Lead(1+) / Indium(3+) / Organylphosphanylamide complexes / Phosphazene / ^{207}Pb-NMR spectra

The reaction of $PbCl_2$ with $LiN(PPh_2)_2$ (**1**) at −78°C affords the P−P coupled phosphazene $Ph_2P-N{=}PPh_2-PPh_2{=}N-PPh_2$ (**2**) as an oxidation product and, as a reduction equivalent, the novel lead(1+) complex $[(Pb^{1+})_2(\mu\text{-}Ph_2P{=}N{=}PPh_2^-)_2](Pb-Pb)$ (**3**). The crystal structure determination of the red compound **3** shows a Pb−Pb bond length of 304.1(1) pm. The ^{31}P- and ^{207}Pb-NMR spectra of **3** are complicated due to the presence of a higher order spin system (AA′A′′A′′′X for the mono-^{207}Pb isotopomer, AA′A′′A′′′XX′ for the bis-^{207}Pb isotopomer). Simulations of the ^{31}P and ^{207}Pb spectra both on material with natural isotope abundance and on the ^{207}Pb-labelled compound (**3***) reveal a large Pb,Pb coupling constant of 7708 Hz, indicative of a covalent Pb−Pb bond. − Though $InCl_3$ is diagonally related to $PbCl_2$, no significant redox process is observed in the reaction between $InCl_3$ and **1**. The yellow crystals of $[In^{3+}(Ph_2P{=}N{=}PPh_2^-)_3]$ (**4**) that are obtained were also investigated by X-ray analysis. These show a propeller-like configuration of the three four-membered chelate rings with indium(3+) as the centre.

Previously[2][3][4] we published data on the unusual *oxidative splitting* and scrambling of lithium bis(diphenylphosphanyl)amide, $LiN(PPh_2)_2$ (**1**)[5][6][7][8], by MCl_2 (M = Co, Fe, Ni, Pd, Pt) that resulted in spirocyclic[2][3] and bicyclic[4] complexes of the types A, B, and C (Scheme 1). In contrast, the *oxidative coupling* of **1** with iodine[9] leads to the P−P coupled diphosphazene $Ph_2P-N{=}PPh_2-PPh_2{=}N-PPh_2$ (**2**), that can also be obtained by the reaction of **1** with anhydrous iron(3+) fluoride, copper(2+) fluoride[10], bismuth tribromide or antimony triiodide[11]. On the other hand, a mixture of arsenic triiodide and **1** in the molar ratio of 1:2 reacts at 20°C to yield **2** and the As(1+) complex D[11].

As a part of our studies on the chemical behaviour of **1** towards metal halides, we now report on the reaction of **1** with $PbCl_2$ and $InCl_3$, the latter having a diagonal relationship with $PbCl_2$.

Scheme 1



The Binuclear Lead(1+) Complex

The reaction of lead dichloride with two equivalents of **1** at −78°C, allowed to warm up to 20°C, in THF affords the diphosphazene **2** and a new complex, **3,** with lead in the rare oxidation state of 1+ (Scheme 2).

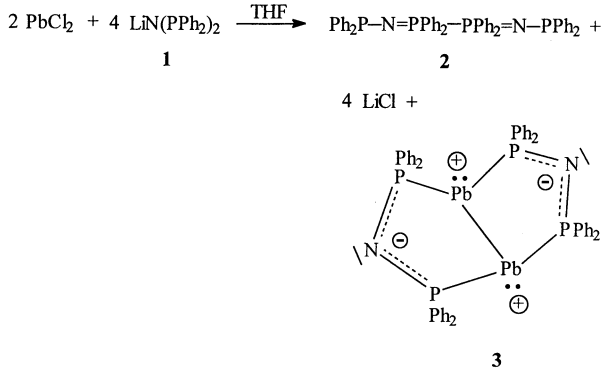
Scheme 2



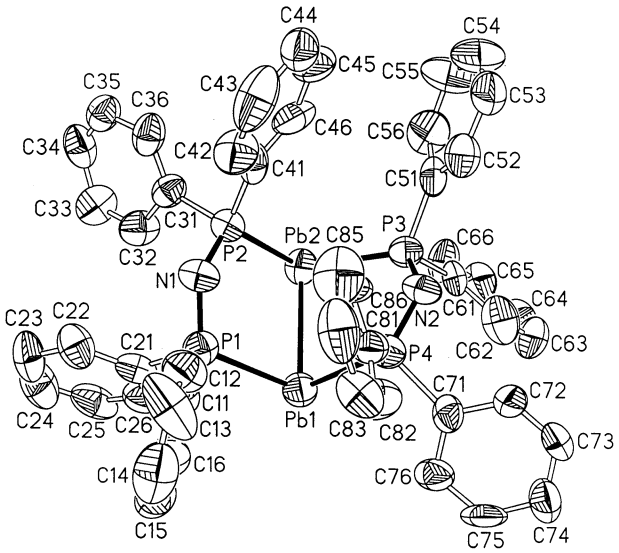
Compounds **2** and **3** can be isolated as pale yellow and deep red crystals, respectively, from THF by precipitation with *n*-pentane. In order to separate **2** and **3,** the crystal conglomerate was treated with cold toluene, in which **3** dissolves. Compound **2** was filtered off and identified by infrared spectroscopy[11].

Crystallization of **3** from toluene by slow solvent diffusion with *n*-pentane yielded large red rhombic crystals which were suitable for X-ray structural analysis.

The result of the structure determination of **3** is shown in Figure 1. The molecule contains a $[Pb^{1+}-Pb^{1+}]$ unit with an interatomic distance of 304.1(1) pm, which is considerably shorter than the interatomic Pb···Pb distance (349 pm)[12] in metallic lead. This indicates the possibility of a covalent $Pb^{1+}-Pb^{1+}$ bond in **3**, and this is confirmed by the ^{207}Pb-NMR spectrum of the ^{207}Pb-labelled **3** (= **3***) which shows a large ^{207}Pb,^{207}Pb coupling constant of 7708 Hz (see later). In the polylead anions Pb_5^{2-}, Pb_7^{4-}, Pb_9^{4-}, and in organometallic diplumbanes of type $R_3Pb-PbR_3$ (R = Ph, *c*-C_6H_{11}) Pb−Pb distances in the range of 284−324 pm are found[13]. The Pb(1)−Pb(2) bond of **3** is bridged by two bis(diphenylphosphanyl)amide anions, $[N(PPh_2)_2]^-$, forming a butterfly-like structure with P(1)−Pb(1)−P(4) and P(2)−Pb(2)−P(3) angles of 93.7(2)° and 95.5(2)°, respectively. All other angles at the Pb(1) and Pb(2) atoms also approach the "p-only" value of 90°. Therefore, the two vicinal lone electron pairs at the lead atoms (Scheme 2) have mainly s-character.

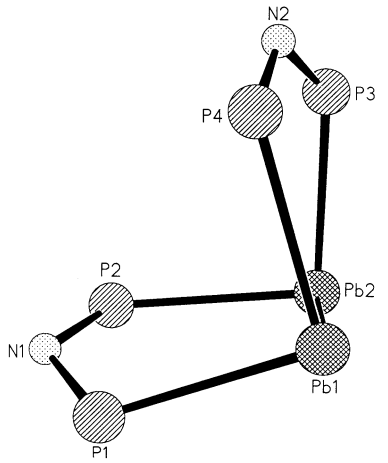
The average P−N bond length of 160(2) pm, which is typical for complexes with the *bridging* $[N(PPh_2)_2]^-$ entity[14][15][16], indicates a considerable amount of double-bond character. The two five-membered rings connected by the Pb(1)−Pb(2) bond show significant deviations from planarity (Figure 2). Whereas in the Pb(1)−P(1)−N(1)−P(2)−Pb(2) ring the P(1) atom is displaced by 30 pm from the least-squares plane, the deviation for the P(3) atom in the homologous Pb(1)−P(4)−N(2)−P(3)−Pb(2) ring is 26 pm. The dihedral angle between the two least-squares planes calculated for the two five-membered rings amounts to 89.4°. The P−N−P angles of 123.4(9)° and 125.2(11)°, respectively, are the same as those found in $(THF)_3LiN(PPh_2)_2$ [124.7(3)°][8].

Figure 1. Molecular structure (ORTEP plot) of **3**[a]



[a] Selected bond lengths [pm] and angles [°]: Pb(1)−P(1) 273.6(6), Pb(1)−P(4) 278.0(6), Pb(1)−Pb(2) 304.10(13), Pb(2)−P(3) 270.9(6), Pb(2)−P(2) 274.0(6), P(1)−N(1) 160(2), P(1)−C(11) 180(2), P(1)−C(21) 181(2), P(2)−N(1) 160(2), P(3)−N(2) 163(2), P(4)−N(2) 158(2); P(1)−Pb(1)−P(4) 93.7(2), P(1)−Pb(1)−Pb(2) 84.94(13), P(4)−Pb(1)−Pb(2) 88.93(12), P(3)−Pb(2)−P(2) 95.5(2), P(3)−Pb(2)−Pb(1) 84.32(12), P(2)−Pb(2)−Pb(1) 88.30(12), C(11)−P(1)−C(21) 99.7(10), N(1)−P(1)−Pb(1) 116.9(7), C(11)−P(1)−Pb(1) 113.6(8), C(21)−P(1)−Pb(1) 105.6(8), N(2)−P(3)−Pb(2) 120.1(7), N(2)−P(4)−Pb(1) 114.6(7), P(1)−N(1)−P(2) 123.4(9), P(4)−N(2)−P(3) 125.2(11).

Figure 2. Arrangement and distortion of the five-membered rings in **3**



^{31}P- and ^{207}Pb-NMR Spectra

Whereas phosphorus is an element consisting of a pure isotope (100% ^{31}P, spin $I = 1/2$), lead consists of only 22.4% of the isotope ^{207}Pb (spin $I = 1/2$). Other stable lead isotopes are magnetically inactive (spin $I = 0$). Hence, according to the binomial coefficients, the natural isotope abundance distribution in **3** is 61%, 34%, and 5% for the presence of zero, one, and two ^{207}Pb isotopes, respectively.

The skeleton of magnetically active P and Pb nuclei in **3** is shown in Figure 3. For the sake of convenience we use the numbering shown in Figure 3 in the following discussion. In

the trivial case of the major isotopomer in which no ^{207}Pb isotope is present, the four ^{31}P nuclei are equivalent and give rise to a singlet at $\delta = 60.7$ in the ^{31}P-NMR spectrum (c.f. Figure 4). In the isotopomer shown in Figure 3a, with one ^{207}Pb isotope, an AA′A′′A′′′X spin system (A = A′ = A′′ = A′′′ = ^{31}P; X = ^{207}Pb) is present which results in rather complex ^{31}P and ^{207}Pb spectra (Figures 4a and 5a). Of crucial interest is the isotopomer with the lowest abundance, in which two ^{207}Pb nuclei are present (Figure 3b): here, an AA′A′′A′′′XX′ spin system exists with complex ^{31}P and ^{207}Pb spectra that are entirely different from those arising from the presence of only one ^{207}Pb isotope (Figures 4b and 5b).

Figure 3. Skeleton of magnetically active P and Pb nuclei in **3**. a) Isotopomer with one ^{207}Pb; b) isotopomer with two ^{207}Pb

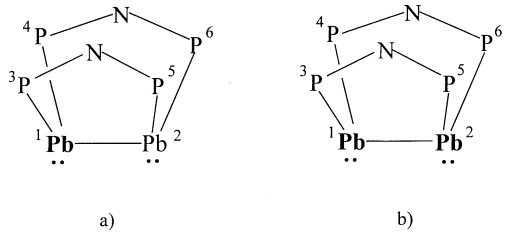


Figure 4. Simulated (a−c) and experimental (d) ^{31}P-NMR spectrum of **3**, natural isotope abundance, C_6D_6, satd. solution, +23°C. Spectrum (c) is a superposition of spectrum (a) (mono-^{207}Pb isotopomer) and spectrum (b) (bis-^{207}Pb isotopomer) with scaling to the appropriate isotopomer abundances. Signals in spectrum (d) which do not match the signals of the simulated spectrum are due to impurities from thermal decomposition

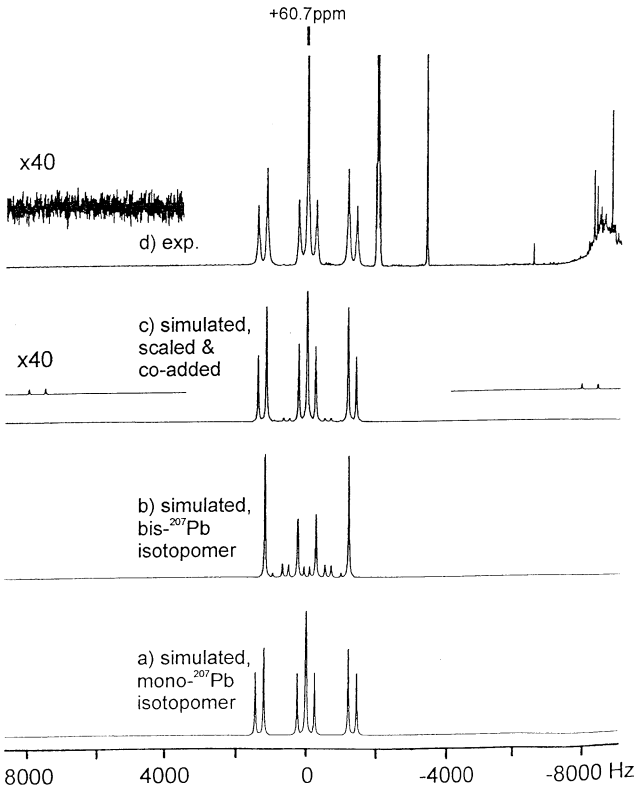
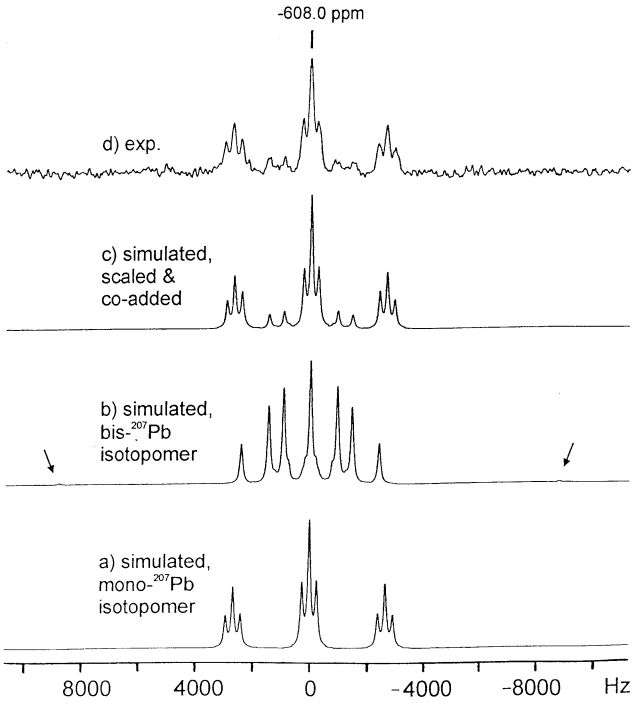


In order to elucidate the coupling constants involved, the ^{31}P- and ^{207}Pb-NMR spectra were simulated for the isotopomers with one and with two ^{207}Pb nuclei (Figures 4 and 5). The simulated spectra were scaled according to the abundances of the isotopomers and superimposed (Figures 4c and 5c). The corresponding experimental spectra are shown in Figures 4d and 5d. The ^{31}P- and ^{207}Pb-chemical shifts are $\delta = 60.7$ and $\delta = -608.0$, respectively. It should be noted that the simulation software employed cuts off signals below a certain intensity. Hence, simulations by using different software may reveal additional weak signals.

Figure 5. Simulated (a−c) and experimental (d) ^{207}Pb-NMR spectrum of **3**, natural isotope abundance, C_6D_6, satd. solution, +23°C. Spectrum (c) is a superposition of spectrum (a) (mono-^{207}Pb isotopomer) and spectrum (b) (bis-^{207}Pb isotopomer) with scaling to the appropriate isotopomer abundances



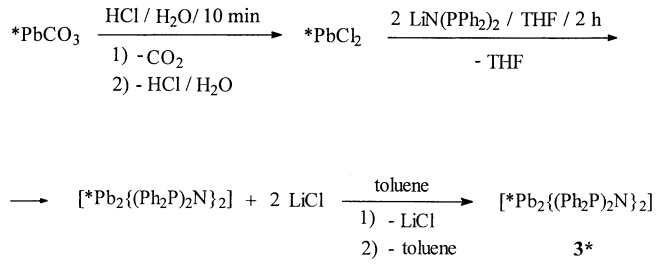
The coupling constants J_{13}, J_{15}, and J_{35} were relatively easily determined after some variation cycles. By contrast, the coupling constant "of interest", J_{12}, manifests only as very weak "satellites", which are visible in the simulation only after a large zoom of the vertical scale (Figures 4c and 5b). Variation of J_{12} over a wide range results in no significant changes in the center "multiplet". In the experimental ^{31}P and ^{207}Pb spectra of the natural abundance material these satellites are completely lost in the spectrum noise.

The simulated spectra are not sensitive to the sign of the homonuclear couplings J_{12} and J_{35} (J_{46}). Permutations of the signs of these coupling constants resulted in absolutely identical spectra. Hence, it is not possible to determine the signs of these coupling constants from the simulations. In contrast, the simulated spectra are sensitive to the relative signs of the heteronuclear coupling constants J_{13} and J_{15}. The simulations clearly indicate that the signs of J_{13} and J_{15} are unlike. Although many one bond (^1J)Pb,Pb couplings have been measured[17], the sign has been determined only recently[18] for a larger variety of compounds. Thus, J_{12} is

negative throughout for, e.g., tBu$_3$Pb-PbR$_3$ (R = Me, Et, iPr, n-C$_6$H$_{11}$, c-C$_6$H$_{11}$) and amounts up to −9200 Hz for R = n-C$_6$H$_{11}$. Only in Pb$_2$Me$_6$ J_{12} has been found to be positive[19]. It is save to assume that J_{12} is negative in **3**, especially when the influence of the 6s electron pairs is taken into account[20][21]. Tentatively, we hold the same to be true for J_{13} in **3**. Accordingly, the geminal coupling constant J_{15} must be positive.

In order to make visible the very weak "satellite" signals which are indicative of the Pb,Pb coupling constant in **3**, we carried out isotopic labelling. The synthesis of the labelled material is shown in Scheme 3. The ^{207}Pb-labelled compound is referred to as **3*** in the following text.

Scheme 3



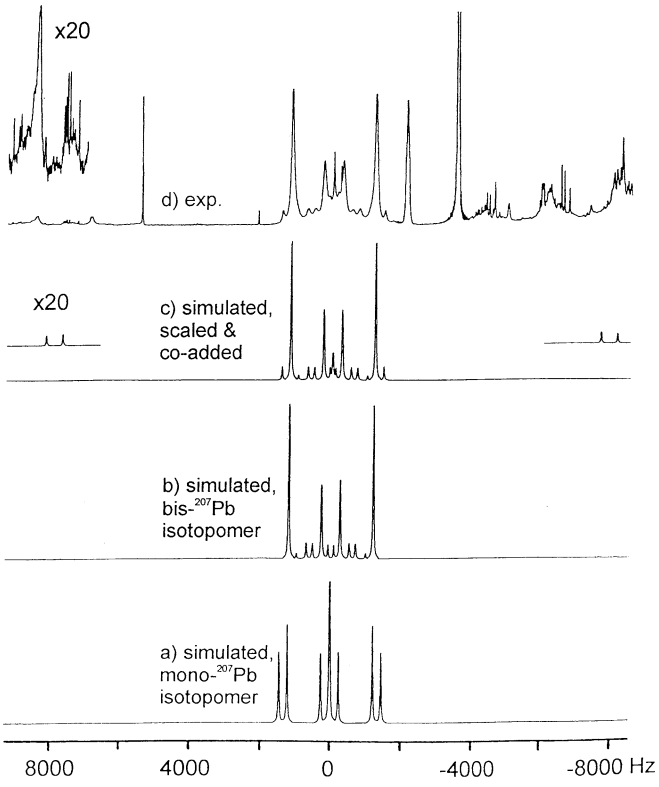
The ^{207}Pb enrichment of the initially employed ^{207}PbCO$_3$ is 92.8%. Hence, the distribution of the isotopomers of **3*** with zero, one, and two ^{207}Pb nuclei is 0.5%, 13.3%, and 86.2%, respectively. As for the ^{31}P- and ^{207}Pb-NMR measurements of the natural abundance material, crystals of **3*** were dissolved in [D$_6$]benzene. Due to the limited thermal stability of **3*** the ^{31}P spectrum (Figure 6d) is blurred due to the presence of signals from decomposition products. Unfortunately, these overlap heavily with the "satellite" signals of interest (Figure 6c) which would be indicative of the magnitude of the Pb,Pb coupling. Hence, even for the ^{207}Pb-labelled compound the relevant constant J_{12} could not be extracted from the ^{31}P spectrum.

Fortunately, however, the ^{207}Pb spectrum of **3*** (Figure 7d) finally yielded the desired information. The overall measuring time of this ^{207}Pb spectrum was 126 h. Spectra of several freshly prepared samples were superimposed. Although ^{207}Pb is generally a nucleus that is easy to detect, the broadness of the signals generally leads to a poor signal-to-noise ratio. This broadness is very likely due to chemical shift anisotropy (CSA) relaxation, a well known phenomenon with high field spectrometers[22]. When the simulation is carried out using the Pb,Pb coupling constant $|J_{12}|$ = 7708 Hz, the outer satellites in Figures 7b and 7c match the experimentally observed ones in Figure 7d.

Table 1 summarizes the results of the spin simulations. Diagonal numbers represent chemical shifts whereas off-diagonal numbers indicate coupling constants.

The large Pb,Pb coupling constant of 7.7 kHz clearly indicates that a covalent Pb−Pb bond must be present in **3**. Therefore, complex **3** bears a remote resemblance to [Ge$_2${C(SiMe$_3$)(PMe$_2$)$_2$}$_2$], which contains a covalent Ge−Ge bond[23].

Figure 6. Simulated (a−c) and experimental (d) ^{31}P-NMR spectrum of **3***, isotopically labelled by 92.8% ^{207}Pb, C$_6$D$_6$, satd. solution, +23°C. Spectrum (c) is a superposition of spectrum (a) (mono-^{207}Pb isotopomer) and spectrum (b) (bis-^{207}Pb isotopomer) with scaling to the appropriate isotopomer abundances. Signals in spectrum (d) which do not match the signals of the simulated spectrum are due to impurities from thermal decomposition



The ^{1}H-NMR spectrum of **3** is simple and does not have any unusual features. As a result of P,C coupling, the resonances for C-i and C-o of the phenyl groups in the ^{13}C{^{1}H}-NMR spectrum are split into multiplets. The IR spectroscopic data of **3** are listed in the Experimental Section. The assignments of the P−C$_6$H$_5$ modes[6] are based on the Whiffen nomenclature[24] in the more currently used description of Maslowsky[25]. The mass spectrum (EI) of **3** does not show the molecular ion peak of **3**$^+$, but instead shows the [M − PPh] fragment along with various peaks due to P−N and P−Ph fragments.

It is also worth pointing out that ligands which are similar to our system, i. e. [N(SiMe$_3$)$_2$]$^-$, [N(SiMe$_3$)(CMe$_3$)]$^-$, [N(SPPh$_2$)$_2$]$^-$, and [CH(PPh$_2$)$_2$]$^-$ generally yield different complexes with the lower main group-15 metal(2+) halides, e. g. [Pb{N(SiMe$_3$)$_2$}$_2$][26], [Pb{N(SiMe$_3$)(CMe$_3$)}$_2$][27], [Sn{N(SiMe$_3$)$_2$}$_2$][28], [Pb{(SPPh$_2$)$_2$N}$_2$][29], [Sn{CH(PPh$_2$)$_2$}$_2$][30], or [Pb{CH(PPh$_2$)$_2$}$_2$][30][31][32].

The Mononuclear Indium(3+) Complex

Reaction of InCl$_3$ with LiN(PPh$_2$)$_2$ (**1**) in the molar ratio of 1:3 in THF at 20°C affords LiCl and the yellow complex [In(Ph$_2$P=N=PPh$_2^-$)$_3$] (**4**), which was isolated after separation from LiCl with benzene/n-pentane as yellow moisture-sensitive crystals. These crystals were suitable for an X-

Figure 7. Simulated (a−c) and experimental (d) ^{207}Pb NMR spectrum of **3***, isotopically labelled by 92.8% ^{207}Pb, C_6D_6, satd. solution, +23°C. Spectrum (c) is a superposition of spectrum (a) (mono-^{207}Pb isotopomer) and spectrum (b) (bis-^{207}Pb isotopomer) with scaling to the appropriate isotopomer abundances

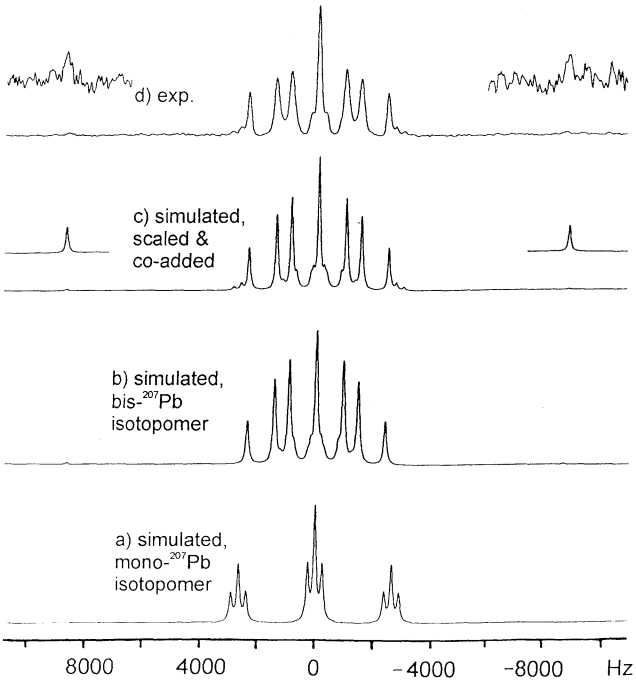


Table 1. ^{31}P- and ^{207}Pb-chemical shifts (δ, diagonal, ppm) and coupling constants (*J*, off-diagonal, Hz) in **3** and **3***, respectively, as derived from spectra simulations. The signs of the coupling constants are tentative (see text), however, it is certain that J_{13} (J_{14}, J_{25}, J_{26}) and J_{15} (J_{16}, J_{23}, J_{24}) have unlike signs

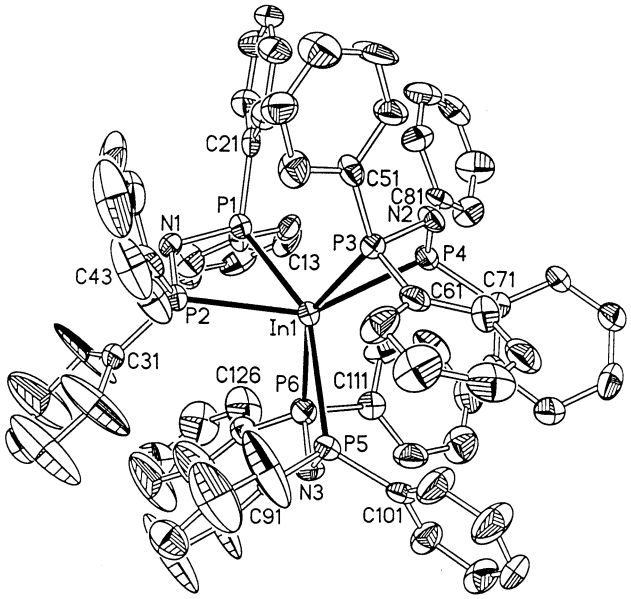
ray crystal analysis. Surprisingly there is no reduction of $InCl_3$ to indium(1^+) derivatives by **1**.

The crystal structure determination shows that compound **4** consists of a tricyclic ring system with indium(3+) as the centre (Figure 8).

At the indium centre the four-membered P−N−P−In chelate rings are oriented in a propeller-like conformation. The main deviation from a regular octahedral arrangement is caused by the fact that the P−In−P angle for each bidentate $[N(PPh_2)_2]^-$ ligand is close to 58°. In the four-membered ring In(1)−P(3)−N(2)−P(4), the differences between the two P−N and In−P bond lengths as well as the two In−P−N angles are small. These differences in the related bond distances and angles increase in the In(1)−P(1)−N(2)−P(2) ring and are remarkable in the In(1)−P(5)−N(3)−P(6) ring [e.g. P(5)−N(3): 167.3(6), P(6)−N(3): 158.7; In(1)−P(5): 284.7(2), In(1)−P(6): 273.9(2) pm; In(1)−P(5)−N(3): 91.8, In(1)−P(6)−N(3): 97.9(2)°]. Accordingly, the tris(chelate) **4** does not contain a threefold symmetry axis and shows only C_1 symmetry. This clearly demonstrates that an octahedral or trigonal prismatic coordination polyhedron is not expected for **4**. The stereochemistry of complexes with coordination number 6 depends mainly on the normalized bite "*b*" of the bidentate ligand[33], which is defined in the case under discussion as *b* = P···P/In−P (distance between the donor atoms of the chelate/metal-donor atom distance). For the three four-membered rings mentioned above the *average* and normalized bites "*b*" are 1.02, 1.01, and 1.03, respectively. They are near the lowest limit known to date for tris(chelate) complexes with four-membered rings (*b* = 1.05 to 1.25)[33], e.g. $[Co(Ph-N=N-N-Ph^-)_3]$[34] *b* = 1.07[33]. The exceptional structure of **4** has no relationship with regular coordination polyhedras and is therefore best described as "propeller-like". The average value of the P−N bond lengths is 164.0(6) pm, and this is typical for complexes with the *chelating* $[N(PPh_2)_2]^-$ entity[4] and indicates π-electron delocalization.

Figure 8. Molecular structure (ORTEP plot) of **4**[a]



[a] Selected bond lengths [pm] and angles [°]: In(1)−P(1) 272.4(2), In(1)−P(6) 273.9(2), In(1)−P(4) 277.0(2), In(1)−P(2) 277.5(2), In(1)−P(3) 279.5(2), In(1)−P(5) 284.7(2), P(1)−N(1) 164.5(6), P(1)−C(21) 180.4(9), P(1)−C(11) 182.1(8), P(2)−N(1) 162.9(6), P(3)−N(2) 165.2(5), P(4)−N(2) 165.7(6), P(5)−N(3) 167.3(6), P(6)−N(3) 158.7(6), P(1)···P(2) 270.5(3), P(3)···P(4) 272.9(3), P(5)···P(6) 270.2(3); P(1)−In(1)−P(6) 101.14(7), P(1)−In(1)−P(4) 96.69(7), P(6)−In(1)−P(4) 106.61(6), P(1)−In(1)−P(2) 58.93(6), P(6)−In(1)−P(2) 99.34(6), P(4)−In(1)−P(2) 147.65(7), P(1)−In(1)−P(3) 105.26(7), P(6)−In(1)−P(3) 150.96(7), P(4)−In(1)−P(3) 58.71(6), P(2)−In(1)−P(3) 104.48(7), P(1)−In(1)−P(5) 149.72(7), P(6)−In(1)−P(5) 57.80(7), P(4)−In(1)−P(5) 109.65(6), P(2)−In(1)−P(5) 100.35(6), P(3)−In(1)−P(5) 101.17(7), N(1)−P(1)−C(21) 108.8(3), N(1)−P(1)−C(11) 109.3(3), C(21)−P(1)−C(11) 102.7(4), N(1)−P(1)−In(1) 95.3(2), C(21)−P(1)−In(1) 124.3(3), N(1)−P(2)−In(1) 93.8(2), N(2)−P(3)−In(1) 93.9(2), N(2)−P(4)−In(1) 94.7(2), N(3)−P(5)−In(1) 91.8(2), N(3)−P(6)−In(1) 97.9(2), P(2)−N(1)−P(1) 111.4(3), P(3)−N(2)−P(4) 111.1(3), P(6)−N(3)−P(5) 111.9(4).

Because it was impossible to record an IR spectrum in KBr under nitrogen, the air moisture caused sample decomposition during scanning, resulting in formation of $HN(PPh_2)_2$ (**5**) and decolorization. Compound **5** was identified by its IR spectrum[6]. It was not possible to anneal NMR tubes and so the NMR spectra of **4** contain signals of the impurity **5**.

Garcia-Montalvo* acknowledges *CONACYT* (Consejo Nacional de Ciencia y Tecnologia, México) for a post doctoral visiting fellowship.

Experimental Section

General: All operations were carried out under an atmosphere of pre-purified dry dinitrogen using standard Schlenk and vacuum line techniques. Solvents were dried and purified prior to use by conventional methods. Chemicals of the best available commercial grade were used: *n*-butyllithium (1.6 M solution in *n*-hexane, Merck-Schuchardt), $PbCl_2$ (Aldrich), $^{207}PbCO_3$ (Campro Scientific), $InCl_3$ (Aldrich). $HN(PPh_2)_2$ (**5**) was prepared according to literature procedures[6][35]. − IR: Perkin Elmer 983. − The NMR spectra of **3** and **3*** were recorded on a JEOL Alpha 500 spectrometer (11.7 Tesla) at 104.7 MHz (^{207}Pb) and 202.4 MHz (^{31}P), respectively. ^{207}Pb-NMR spectra are referenced to $Pb(NO_3)_2$ $\delta = -2961$ as a secondary reference ($PbMe_4$ $\delta = 0$). ^{31}P-NMR spectra are referenced to 85% H_3PO_4. No corrections for bulk susceptibilities have been applied. Samples of natural abundance and isotopically labelled compounds were prepared as saturated solutions of crystalline material in C_6D_6. Measurements were carried out at +23°C. A multinuclear 5 mm probehead was employed. ^1H-broadband decoupling was applied throughout. Samples were non-spinning. Spectral widths were 60 kHz (^{207}Pb) and 38 kHz (^{31}P), respectively. Recycle delays were 5 s (^{207}Pb) and 2.5 s (^{31}P). Pulse widths were 90° (13 μs, ^{207}Pb) and 60° (8 μs, ^{31}P). Measuring times were 43 h (Figure 4), 258 h (Figure 5), 20 h (Figure 6), and 126 h (Figure 7). Due to the thermal instability of **3** and **3***, the spectra of several freshly prepared samples were superimposed. Spectrum simulations were performed using the COMIC software package (JEOL). A Lorentzian line width of 30 Hz was used to match the experimental spectra. NMR of **4**: JEOL JNM-GX-270 (269.60 MHz for ^1H, 69.70 MHz for $^{13}C\{^1H\}$, 109.40 MHz for $^{31}P\{^1H\}$). Chemical shifts are relative to solvent signals, which in turn are referenced to TMS; for $^{31}P\{^1H\}$ NMR, 85% H_3PO_4 was employed as external standard. − MS: Varian MAT 212 (70 eV). − Microanalyses: Carlo Erba 1106 and 1108. − Melting points (uncorrected): Electrothermal IA 6304.

Preparation of Bis-μ-[bis(diphenylphosphanyl)amido-P,P']dilead(1+)(Pb−Pb) (**3**) *and Separation from 1.1.3.3.4.4.6.6-Octaphenyl-2.5-diaza-1.6-($\sigma^3\lambda^3$)diphospha-3.4-($\sigma^4\lambda^5$)diphosphahexane* (**2**): To a solution of 1.72 g (4.47 mmol) of $HN(PPh_2)_2$ (**5**) in 35 ml of THF was added 2.80 ml (4.48 mmol) of *n*-butyllithium (1.6 M solution in *n*-hexane) and the mixture was stirred for 30 min at −78°C. After addition of 0.62 g (2.23 mmol) of solid $PbCl_2$ and removal of the refrigerant, the colour of the suspension slowly changed from light yellow to deep red, while the mixture became a clear solution. Stirring was continued for 3 h at 20°C, then one third of the solvent was removed in vacuo. The residual clear deep red solution was layered with 85 ml of *n*-pentane and kept at 20°C for 5 d; deep red rhombic crystals of **3** and yellow cubes of **2** crystallized simultaneously. The two compounds were separated by decanting the solvent mixture of THF and *n*-pentane and treating the crystal conglomerate with cold toluene. While **3** dissolved, **2** was filtered off, washed with cold toluene and dried in vacuo to yield 0.45 g (52%). Mp. 155°C, mp.[10] 157°C.

Recrystallization of **3** from toluene by slow solvent diffusion (*n*-pentane) techniques afforded large red rhombic crystals after 3 d at 20°C; yield 0.84 g (63%), m.p. 140°C (dec.).

Preparation of [$^{207}Pb_2$(μ-$Ph_2P-N-PPh_2$−P,P')$_2$] (**3***): 0.155 g (0.580 mmol) of $^*PbCO_3$ was mixed with 12 ml of a concentrated aqueous solution of HCl. After the initially brisk foaming up had ceased the clear colourless solution was stirred for 10 min at 20°C. The solvent was removed under reduced pressure and the resulting $^*PbCl_2$ was dried at 100°C in vacuo for 4 h to exclude any traces of water. A conversion of 100% from $^*PbCO_3$ to $^*PbCl_2$ was assumed. 0.447 g of $HN(PPh_2)_2$ (**5**, 1.160 mmol) in 7 ml of THF was lithiated with 0.80 ml (1.280 mmol) of *n*-butyllithium (1.6 M solution in *n*-hexane), and the yellow solution was added to the solid $^*PbCl_2$ prepared as described above. After stirring for 2 h at 20°C the solvent from the red solution was evaporated in vacuo and the red residue was suspended in 7 ml of toluene for the separation of LiCl. Filtration with a D4 filter was followed by removal of the solvent from the filtrate to yield the red product [$^*Pb_2\{(Ph_2P)_2N\}_2$] that had traces of the by-product $Ph_2P-N=$

$PPh_2-PPh_2=N-PPh_2$ (**2**) as an impurity, but was nevertheless used for NMR experiments. Due to the low yield of the product [$*Pb_2\{(Ph_2P)_2N\}_2$] and its sensitivity to moisture, oxygen and various solvents we decided not to perform further purification. Yield 0.419 g (61%). The residue of the filtration consisted of traces of $Ph_2P-N=PPh_2-PPh_2=N-PPh_2$ (**2**) and LiCl that was detectable by $AgNO_3$ and flame spectrum.

Preparation of Tris[bis(diphenylphosphanyl)amido-P,P']-indium(3+) (**4**): To a solution of 1.49 g (3.87 mmol) of $HN(PPh_2)_2$ (**5**) in 50 ml of THF was added 2.60 ml (4.16 mmol) of *n*-butyllithium (1.6 M solution in *n*-hexane) and the mixture was stirred for 15 min at 20°C. Addition of 0.29 g of $InCl_3$ (1.29 mmol) resulted in a yellow suspension that turned into a clear yellow solution within 6 h. The solvent was removed in vacuo and the bright yellow residue was separated from LiCl by suspending it in 30 ml of benzene and filtering the mixture. The clear yellow filtrate was layered with 120 ml of *n*-pentane; after 48 h yellow crystals precipitated which were filtered off, washed with 5 ml of *n*-pentane and dried in vacuo, yielding 1.19 g (73%) of [$In\{(Ph_2P)_2N\}_3$], m.p. 182°C. – The crystals were suitable for an X-ray analysis. – ^1H NMR (C_6D_6, 21.5°C): δ = 7.65–6.60 (m, aromatic H), 3.55 (m, traces of THF), 3.02 (m, NH due to traces of moisture during sample preparation), 1.40 (m, traces of THF). – $^{13}C\{^1H\}$ NMR (C_4D_8O, 24.4°C): δ = 144.15 (m, C-*i*, Ph), 132.10 (pseudo-t, C-*o*, Ph), 129.05 (s, C-*p*, Ph), 128.75 (pseudo-t, C-*m*, Ph). – $^{31}P\{^1H\}$ NMR (C_6D_6, 22.0°C): δ = 80.06 (s); 40.74 [s, ≈ 5% of $(Ph_2P)_2NH$ due to traces of moisture during sample preparation]. – EI-MS (70 eV): *m/z* (%): 1270 (1.8) [$In\{HN(PPh_2)_2\}_3^+$], 385 (95) [$HN(PPh_2)_2^+$], 262 (95) [PPh_3^+]. – $C_{72}H_{60}InN_3P_6$ (1267.9): calcd. C 68.20, H 4.77, N 3.31; found C 67.54, H 5.15, N 2.89.

Crystal Structure Determinations: Suitable single crystals of **3** and **4** were sealed into glass capillaries and used for measurement of precise cell constants and intensity data collection. Three standard reflections measured periodically during data collection showed no significant changes. Diffraction intensities were corrected for Lorentz and polarization effects. In the case of **3**, absorption effects were corrected empirically using Psi-scans of 40 reflections (min transmission = 0.002; max. transmission = 0.013). To minimize remaining absorption effects an additional correction using ΔF^2 methods[36] was applied (min. transmission = 0.089; max. transmission = 0.146). No absorption correction was applied in the case of **4**. The structures were solved by direct methods and refined by full-matrix least-squares calculations against F^2[37]. All non-hydrogen atoms were refined with anisotropic displacement parameters. The hydrogen atom positions of **3** and **4** were calculated and allowed to ride on their corresponding carbon atoms, their isotropic thermal parameters were tied to those of the adjacent carbon atoms by a factor of 1.5. Details of the crystal data, data collection, and structure refinement are summarized in Table 2. Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication no. CCDC-100811. Copies of the data can be obtained free of charge on application to The Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [fax: int. code + 44(1223)336-033, e-mail: deposit@chemcrys.cam.ac.uk].

Metal Complexes with Tetrapyrrole Ligands, LXXIII[◇]

Oxidation and Reduction of Cerium(IV) Sandwich Complexes with Porphyrin Ligands Linked by Aliphatic Diether Bridges of Variable Chain Length

Johann W. Buchler* and Torsten Dippell

Institut für Anorganische Chemie, Technische Universität Darmstadt,
Petersenstraße 18, D-64287 Darmstadt, Germany

Received September 22, 1997

Keywords: Cerium(IV) bisporphyrinates / Sandwich complexes / Diporphyrins / π Radical-cations and dications / Cerium(III) bisporphyrinate anions

Starting from 5-(4-hydroxyphenyl)-10,15,20-tris(4-methylphenyl)porphyrin (**2a**), the new bis(porphyrinyloxy)alkanes **4a** and **4d** were synthesized by ether formation with the α,ω-dibromoalkanes $Br(CH_2)_nBr$ (n = 8, 11; **3a**, **3d**). **4a** was obtained by a two-step reaction with the 5-[4-(8-bromooctyloxy)phenyl]-10,15,20-tris(4-methylphenyl)porphyrin (**2b**) as an intermediate. The diporphyrins **4a** and **4d** were metalated with cerium(III) acetylacetonate to yield the new (porphyrin)-cerium sandwich complexes **1a** and **1d** which were characterized by UV/Vis, IR, ^{1}H-NMR, ^{13}C-NMR spectroscopy and cyclic voltammetry. The mono- and dications and the cerium(III) bisporphyrinate anions of **1a-d** were produced by electrochemical oxidation and reduction, respectively, and were examined by UV/Vis/NIR spectroscopy. The length of the lateral chains does not have a specific effect on the first and second oxidation potentials of the porphyrin rings and the reduction potentials of the cerium ions in the bisporphyrinate systems, and on the energy of the NIR bands of the monocations.

Synthetic aggregates of porphyrins or metalloporphyrins and quinones are presently being studied in order to understand the elementary steps of light-induced charge separation in photosynthesis. Most of these contain covalent links between the individual functional groups or chromophores[1]. The (porphyrin-quinone)zinc systems prepared by Staab et al.[2] were especially stimulating for our work devoted to (porphyrin)cerium(IV) double-deckers in which the two porphyrin systems were linked by a quinone-containing bridge[3]. In the course of that work, cerium(IV) double-deckers of the type $Ce[ttpO(CH_2)_nOttp]$ (**1**)[4], namely **1b** and **1c**, were constructed in which the two porphyrin rings are bridged by aliphatic diether chains containing 9 or 10 methylene groups (n = 9 or 10), respectively. Since **1c** had shown unexpectedly high oxidation potentials at the porphyrin rings, the investigation was extended to the double-deckers **1a** and **1d** which have either a somewhat shorter (8 methylene groups, n = 8) or a longer "ansa" chain (11 methylene groups, n = 11). The electrochemical oxidations and reductions of all four species **1a**−**d** were coherently followed by cyclic voltammetry and digital coulometry[5]. The results are reported below.

Very recently, novel species have been added to those bisporphyrinate double-deckers of tetravalent metal ions mentioned[3] so far: Aida et al.[6] have obtained chiral zirconium(IV) and cerium(IV) bisporphyrinates and succeeded in the separation of their enantiomers.

n	8	9	10	11

Synthesis

The cerium double-deckers **1b** and **1c** had been prepared starting from the monofunctionalized tetraarylporphyrin H_2(HOttp) (**2a**) which is easily accessible from a mixed condensation-oxidation reaction of pyrrole, *p*-tolualdehyde, and *p*-hydroxybenzaldehyde[7] and can be transformed into a diporphyrin by ether formation with α,ω-dibromoalkanes, e. g. 1,9-dibromononane (**3b**) and 1,10-dibromodecane (**3c**),

[◇] Part LXXII: Ref.[3].

 © WILEY-VCH Verlag GmbH, D-69451 Weinheim, 1998 1434−1948/98/0404−0445 $ 17.50+.50/0

respectively[3][7]. Although sandwich formation leading to $Ce(HOttp)_2$ is possible with **2a**[8], the application of lateral bridges was unsuccessful because $Ce(HOttp)_2$ exists as a mixture of vicinal and transversal isomers. Thus, sandwich formation had been performed[3] starting from the respective diporphyrins **4b** or **4c** obtained from **2a** and **3b** or **3c**, respectively, and the new sandwiches **1a** and **1d** had to be prepared starting from **2a** by the diporphyrin route as well.

No.	R
2a	H
2b	$(CH_2)_8Br$
2c	$(CH_2)_9Br$
2d	$(CH_2)_{10}Br$
2e	$(CH_2)_{11}Br$

$Br—(CH_2)_n—Br$ **3** For n see **1**

Indeed, the diporphyrin **4d** could be made by directly coupling two equivalents of **2a** with **3d** in the presence of cesium carbonate in dimethylformamide at 100°C (see Experimental Section, protocol 1; 93%). The monofunctionalized porphyrin **2e** was also formed as a byproduct as already observed for **2c** and **2d**[3] and could be separated by column chromatography. However, because of the formation of many decomposition products, the former procedure failed for **4a** which then was prepared stepwise[5] by first, formation of the [(bromoalkoxy)phenyl]porphyrin **2b** (protocol 2; 89%) from **2a** and **3a**, and then coupling of the resulting **2b** with another equivalent of **2a** (protocol 3; 28%).

The formation of the double-deckers **1a** (11%) and **1d** (15%; protocol 4) was managed as described previously[3] for **1b** (24%) and **1c** (11%), by lithiation of the diporphyrins **4a** and **4d**, respectively, with *n*-butyllithium and subsequent addition of cerium(III) acetylacetonate in trichlorobenzene (TCB). The yields (given above in parentheses) were comparably small for all four double-deckers with a small preference for the chain length $n = 9$. Thus, all these lateral chains appear to fit the gap between the vicinal pair of phenolic oxygen atoms in the cerium double-decker system of **1a–d**.

Analytical Characterization

All the new compounds were identified by their UV/Vis, ^{1}H-NMR, IR, and mass spectra (for individual data, see protocols 1–4). The new diporphyrins **4a** and **4d** were prepared in the same manner as the known[3] species **4b** and **4c**. An additional identification came from the determination of their R_f values which increase in the series **4a** < **4b** < **4c** < **4d** (see Experimental Section, Table 4) indicating a decrease in polarity as the chain length of the diether bridge increases.

The new double-deckers **1a** and **1d**, as well as newly prepared[5] samples of **1b** and **1c**, which otherwise showed spectra identical with those of the original samples[3], were additionally characterized by ^{13}C-NMR data which are compiled in Table 1. The assignments were corroborated by DEPT experiments.

UV/Vis Spectra

The UV/Vis spectra of the new alkane-bridged double-deckers **1a** and **1d** resemble those of their unbridged analogs $Ce(ttp)_2$[9] and $Ce(HOttp)_2$[8] as much as the spectra of the double-deckers **1b** and **1c**, see Table 2a. All complexes show the typical Soret (B) band and four characteristic Q

Cyclic Voltammetry

In dichloromethane, cerium(IV) bisporphyrinates $Ce^{IV}(p)_2$ [e. g. $Ce(tpp)_2$, $Ce(ttp)_2$, or $Ce(oep)_2$] usually show two reversible oxidations (E_1, E_2) occuring at the porphyrin system and producing the π cation $[Ce(p)_2]^+$ and the π dication $[Ce(p)_2]^{2+}$, respectively[11]. The first quasireversible reduction (E_3) occurs at the metal center[11a] and generates a cerium(III) double-decker anion, $[Ce^{III}(p)_2]^-$. These essential processes are characterized in Eq. (1) by their respective reduction steps.

$$[Ce^{IV}(p^\bullet)(p^\bullet)]^{2+} + e^- \rightarrow [Ce^{IV}(p^\bullet)(p)]^+ + e^- \rightarrow Ce^{IV}(p)_2 + e^- \rightarrow [Ce^{III}(p)_2]^- \quad (1)$$

In order to clarify whether the previously found abnormally high oxidation potential of **1b** could be reproduced, and if it existed, were due to some steric abnormity of **1b**, the whole series **1a–d** was studied by cyclic voltammetry. New samples of **1b** and **1c** were prepared[5] as previously described[3] and measured anew. To our disappointment, all the double-deckers **1a–d** showed the three redox steps E_1, E_2, and E_3 at potentials very close to those of the reference compound $Ce(ttp)_2$ (see Table 3). A typical voltammogram is shown in Figure 1.

Figure 1. Cyclic voltammogram of the bridged double-decker **4a** (CH_2Cl_2, room temperature, NBu_4PF_6 as supporting electrolyte, calomel electrode)

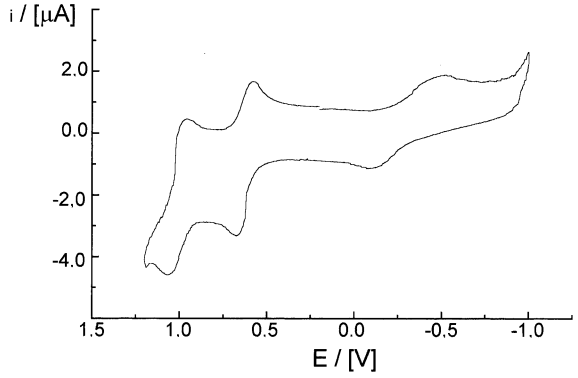

Table 3. Comparison of the redox potentials of the double-deckers $Ce(ttp)_2$ and **1a–d** (CH_2Cl_2, room temperature, NBu_4PF_6 as supporting electrolyte, saturated calomel electrode)

	E_1 [V]	E_2 [V]	E_3 [V]
$Ce(ttp)_2$	1.000	0.620	–0.290
1a	1.000	0.605	–0.300
1b	1.019	0.632	–0.303
1c	1.018	0.627	–0.310
1d	1.020	0.630	–

The similarity of all the redox potentials implies that the variation of the chain length ($8 < n < 11$) in the four double-deckers does not alter the mutual π-π interactions of the two porphyrin rings in these double-deckers. Thus, contrary to our previous speculation, the relative orientation of the two porphyrin ligands may not be altered by this variation of the length of the lateral chain.

Oxidation and Reduction

In order to record the UV/Vis/NIR spectra of the species connected by the redox processes defined by Eq. (1), the laterally bridged sandwich complexes **1a–d** were subjected

to electrolysis at controlled potentials (see protocol 5). The oxidations occurring at the porphyrin system produce the π radical-cation $[Ce(p^{\bullet}-p)]^{+}$ and the π dication $[Ce[p^{\bullet}-p^{\bullet})]^{2+}$, respectively, $(p-p)^{2-}$ symbolizing the diporphyrinate ligands derived from **3a**−**d**. The reduction takes place at the metal center and generates the double-decker anion $[Ce^{III}(p-p)]^{-}$.

On oxidation, the UV/Vis/NIR spectra show a hypsochromic shift of the B band from 398 via 393 (π radical-cation) to 389 nm (π dication; see Tables 2b and 2c). The typical feature of the π radical-cations $[Ce^{IV}(p^{\bullet})(p)]^{+}$ is a broad NIR band, found at 1350 nm for $[Ce^{IV}(tpp^{\bullet})(tpp)]^{+}$.[12] For $[Ce(p^{\bullet}-p)]^{+}$ it appears at 1383 nm. For the π dications $[Ce^{IV}(tpp^{\bullet})(tpp^{\bullet})]^{2+}$ and $[Ce^{IV}(p^{\bullet}-p^{\bullet})]^{2+}$, similar bands are observed at 1017[12] and 1044 nm, respectively. Reduction at the cerium ion yielding the double-decker anions $[Ce^{III}(p-p)]^{-}$ is indicated by a bathochromic shift of the B band to 415 nm (Table 2d), as found earlier for a series of lanthanoid(III) bisporphyrinate anions $[Ln(tpp)_2]^{-}$[13] An NIR band does not appear.

Financial support by the *Deutsche Forschungsgemeinschaft* and the *Fonds der Chemischen Industrie* is gratefully acknowledged. The authors thank Prof. Dr. *J. J. Veith* and Mr. *M. Fischer* for performing mass spectra, Dr. *S. Braun*, *K. Jungk*, and *K.-O. Runzheimer* for performing NMR spectra and the *Bayer AG* for a gift of trichlorobenzene.

Experimental Section

Spectrometers and chemicals used were specified in a previous paper of this series[8]. − Electrochemistry: Princeton Applied Research potentiostat M 173 contolled by an interface M 175 with the software M 270/250. − 1,8-Dibromooctane, 1,11-dibromoundecane, Cs_2CO_3, and DMF were obtained from Fluka Chemie AG, *n*-butyllithium (1.6 M in *n*-hexane) from Acros, and $Ce(acac)_3 \times H_2O$ from Aldrich. − *p*-(Hydroxyphenyl)tris(*p*-tolyl)porphyrin[7] (**2a**) was prepared by a literature method. − Elemental analyses were performed by Analytical Laboratories, P.O.B. 1106, D-51779 Lindlar. − Analytical thin layer chromatography was performed on commercial aluminium sheets coated with silica gel 60 F_{254} (Merck). A comparison of the R_f values found for the diporphyrins **4a**−**4d** is given in Table 4.

Table 4. Comparison of the R_f values of the diporphyrins **4a**−**d** determined by thin-layer chromatography (silica gel, toluene, room temperature)

4a	**4b**	**4c**	**4d**
0.50	0.55	0.59	0.64

Protocol 1: 1,11-Bis[4-{10,15,20-tris(4-methylphenyl)porphyrin-5-yl}phenoxy]undecane (**4d**): To a solution of 310 mg (0.46 mmol) of **2a** and 1.3 g (3.99 mmol) of anhydrous cesium carbonate in 15 ml of DMF a solution of 339 mg (1.08 mmol) of **3d** in 25 ml of DMF was added dropwise under nitrogen at 100°C. After cooling and filtration, the solvent was removed in vacuo. The residue was treated with 10 ml of toluene and chromatographed on an alumina column (II, neutral, 15 × 3.5 cm). Fractions were obtained as follows: with toluene a violet forerun of the monofunctionalized [(ω-bromoundecyloxy)phenyl]porphyrin **2e** and with CH_2Cl_2 the violet fraction of the diporphyrin **4d**. Evaporation of the solvent in vacuo and crystallization from CH_2Cl_2/MeOH (1:1) yielded the diporphyrin **4d** as a violet powder. 319 mg (93%). − MS; *m/z* (%): 748 (100) $[M^{2+}]$, 1496 (69) $[M^{+}]$. − UV/Vis (CH_2Cl_2): λ_{max} (lg ε) = 420 nm (5.78), 517 (4.36), 553 (4.15), 592 (3.93), 648 (3.93). − IR (KBr), 6 most intensive bands and NH band: $\tilde{\nu}$ [cm^{-1}] = 803, 970, 1247, 1470, 1512, 2925, 3314 (NH). − ^1H NMR (CD_2Cl_2): δ = −2.84 (s, 4 H, NH), 1.55−1.70 [m, 14 H, $OCH_2CH_2(CH_2)_7CH_2CH_2O$], 1.97−2.02 [m, 4 H, $OCH_2CH_2(CH_2)_7CH_2CH_2O$], 2.66−2.68 (m, 18 H, CH_3, tolyl), 4.24 [t, *J* = 8 Hz, 4 H, $OCH_2CH_2(CH_2)_7CH_2$-CH_2O], 7.26 (d, *J* = 8 Hz, 4 H, *m*-phenoxy-H), 7.51−7.56 (m, 12 H, *m*-tolyl-H), 8.04−8.09 (m, 16 H, *o*-tolyl- and *o*-phenoxy-H), 8.84−8.88 (m, 16 H, pyrrole-H).

Protocol 2: 5-[4-(8-Bromooctyloxy)phenyl]-10,15,20-tris(4-methylphenyl)porphyrin (**2b**): 1.68 g (6.2 mmol) of **3a** were added under nitrogen to a solution of 424 mg (0.63 mmol) of **2a** and 1.74 g (5.34 mmol) of anhydrous cesium carbonate in 50 ml of DMF. After stirring at 50°C for 5 h, the solution was filtered and the solvent removed in vacuo. 484 mg (89%) of the porphyrin **2b** were obtained as a violet powder after chromatography on an alumina column (II, neutral, 15 × 3.5 cm, isolation of the first violet fraction) with toluene and crystallization from CH_2Cl_2/MeOH (1:1). − MS; *m/z* (%): 863 (100) $[M^{+}]$. − UV/Vis (CH_2Cl_2): λ_{max} (lg ε) = 420 nm (5.64), 517 (4.23), 553 (3.98), 592 (3.70), 648 (3.70). − IR (KBr), 6 most intensive bands and NH band: $\tilde{\nu}$ [cm^{-1}] = 801, 967, 1177, 1246, 1472, 1506, 3319 (NH). − ^1H NMR (CD_2Cl_2): δ = −2.79 (s, 2 H, NH), 1.49−1.63 [m, 8 H, $OCH_2CH_2(CH_2)_4CH_2CH_2Br$], 1.70−2.00 [m, 4 H, $OCH_2CH_2(CH_2)_4CH_2CH_2Br$], 2.69 (s, 9 H, CH_3, tolyl), 3.40 [t, *J* = 8 Hz, 2 H, $OCH_2CH_2(CH_2)_4CH_2CH_2Br$], 4.23 [t, *J* = 8 Hz, 2 H, $OCH_2CH_2(CH_2)_4CH_2CH_2Br$], 7.27 (d, *J* = 8 Hz, *m*-phenoxy-H), 7.55 (m, 6 H, *m*-tolyl-H), 8.08 (m, 8 H, *o*-tolyl- and *o*-phenoxy-H), 8.85 (m, 8 H, pyrrole-H).

Protocol 3: 1,8-Bis{4-[10,15,20-tris(4-methylphenyl)porphyrin-5-yl]phenoxy}octane (**4a**): A suspension of 172 mg (0.20 mmol) of **2b**, 316 mg (0.47 mmol) of **2a** and 1.3 g (3.99 mmol) of Cs_2CO_3 in 25 ml of DMF was stirred for 5 h under nitrogen at 100°C. After cooling, 100 ml of water was added and the mixture was filtered. The violet residue was dried at 100°C and chromatographed on an alumina column (II, neutral, 15 × 3.5 cm). Fractions were obtained as follows: with toluene a violet forerun of the remaining monofunctionalized [(8-bromooctyloxy)phenyl]porphyrin **2b** and with CH_2Cl_2 the violet fraction of the diporphyrin **4a**. Evaporation of the solvent in vacuo and crystallization of the residue from CH_2Cl_2/MeOH (1:1) yielded 82 mg (28%) of **4a** as a violet powder. − MS; *m/z* (%): 1454 (100) $[M^{+}]$. − UV/Vis (CH_2Cl_2): λ_{max} (lg ε) = 420 nm (5.66), 517 (4.25), 553 (4.01), 592 (3.74), 648 (3.74). − IR (KBr), 6 most intensive bands and NH band: $\tilde{\nu}$ [cm^{-1}] = 801, 969, 1179, 1245, 1472, 1508, 3320 (NH). − ^1H NMR (CD_2Cl_2): δ = −2.78 (s, 4 H, NH), 1.59−1.76 [m, 8 H, $OCH_2CH_2(CH_2)_4CH_2$-CH_2O], 2.02−2.09 [m, 4 H, $OCH_2CH_2(CH_2)_4CH_2CH_2O$], 2.67−2.69 (m, 9 H, CH_3, tolyl), 4.29 [t, *J* = 8 Hz, 4 H, $OCH_2CH_2(CH_2)_4CH_2CH_2O$], 7.29 (d, *J* = 8 Hz, *m*-phenoxy-H), 7.51−7.56 (m, 12 H, *m*-tolyl-H), 8.06−8.13 (m, 16 H, *o*-tolyl- and *o*-phenoxy-H), 8.84−8.88 (m, 16 H, pyrrole-H).

Protocol 4: General procedure of the metalation of the diporphyrins **4a** and **4d** with $Ce(acac)_3 \times H_2O$: A solution of 1.6 mmol of BuLi in 0.25 ml of *n*-hexane was added to a solution of 100 mg of **4a** (0.069 mmol) or **4d** (0.067 mmol) in 50 ml of TCB under nitrogen. The resulting solution was stirred for 10 min at room temperature. After the addition of 313 mg (0.69 mmol) or 303 mg (0.67 mmol) of $Ce(acac)_3 \times H_2O$, the solution was heated at reflux for 6 h. After cooling and filtration, the solvent was evaporated in vacuo. The residue was purified on an alumina column (II, neutral,

15 × 3.5 cm) with toluene. The first brown fraction contained the double-decker followed by the second violet fraction of the corresponding diporphyrin. After evaporation of the solvent from the first fraction and recrystallization of the residue from CH_2Cl_2/MeOH (1:1) the following double-deckers were isolated as brown powders:

1,8-Bis{4-[10,15,20-tris(4-methylphenyl)porphyrin-5-yl]-phenoxy}octanatocerium(IV) (**1a**): 9 mg (11%). − MS; *m/z* (%): 1590 (100) [M^+]. − UV/Vis (CH_2Cl_2): λ_{max} (lg ε) = 399 nm (5.38), 478 (4.14), 545 (4.02), 584 (3.52), 646 (3.45). − IR (KBr), 9 most intensive bands: $\tilde{\nu}$ [cm^{-1}] = 802, 983, 1023, 1096, 1178, 1263, 1325, 1511, 2930. − ^{1}H NMR ($CDCl_3$): δ = 1.77−1.82 [m, 8 H, $OCH_2CH_2(CH_2)_4CH_2CH_2O$], 2.11−2.25 [m, 4 H, $OCH_2CH_2(CH_2)_4CH_2CH_2O$], 2.72−2.74 (m, 18 H, CH_3, tolyl), 4.46/4.58 [m, 4 H, $OCH_2CH_2(CH_2)_4CH_2CH_2O$], 6.29 (m, 8 H, *exo* *o*-tolyl- and *o*-phenoxy-H), 6.50 (m, 2 H, *exo* *m*-phenoxy-H), 7.07 (m, 6 H, *exo* *m*-tolyl-H), 7.50 (m, 2 H, *endo* *m*-phenoxy-H), 7.93 (m, 6 H, *endo* *m*-tolyl-H), 8.15−8.54 (m, 16 H, pyrrole-H), 9.48 (m, 8 H, *endo* *o*-tolyl- and *o*-phenoxy-H). − ^{13}C NMR ($CDCl_3$): δ = 21.59 (CH_3, tolyl), 25.44−28.06 [$OCH_2CH_2(CH_2)_4CH_2CH_2O$], 28.86 [$OCH_2CH_2(CH_2)_4CH_2CH_2O$], 68.42 [$OCH_2CH_2(CH_2)_4CH_2CH_2O$], 123.88−153.34 ($C_{arom.}$, $C_{heteroarom.}$), 158.18 ($C_{arom.}$−O). − CV (CH_2Cl_2/NBu_4PF_6): *E* = 1.000 V, 0.605, −0.300. − $C_{102}H_{82}CeN_8O_2 \times 4\ H_2O$ (1664.00): calcd. C 73.62, H 5.45, N 6.73; found C 73.95, H 5.82, N 6.26.

1,11-Bis{4-[10,15,20-tris(4-methylphenyl)porphyrin-5-yl]-phenoxy}undecanatocerium(IV) (**1d**): 16 mg (15%). − MS; *m/z* (%): 1632 (100) [M^+]. − UV/Vis (CH_2Cl_2): λ_{max} (lg ε) = 398 nm (5.29), 478 (4.09), 545 (3.94), 584 (3.42), 638 (3.40). − IR (KBr), 9 most intensive bands: $\tilde{\nu}$ [cm^{-1}] = 801, 981, 1026, 1100, 1178, 1261, 1326, 1512, 2970. − ^{1}H NMR ($CDCl_3$): δ = 1.64−1.80 [m, 14 H, $OCH_2CH_2(CH_2)_7CH_2CH_2O$], 2.03−2.15 [m, 4 H, $OCH_2CH_2(CH_2)_7CH_2CH_2O$], 2.71−2.72 (m, 18 H, CH_3, tolyl), 4.34/4.48 [m, 4 H, $OCH_2CH_2(CH_2)_7CH_2CH_2O$], 6.28 (m, 8 H, *exo* *o*-tolyl- and *o*-phenoxy-H), 6.50 (m, 2 H, *exo* *m*-phenoxy-H), 7.05 (m, 6 H, *exo* *m*-tolyl-H), 7.60 (m, 2 H, *endo* *m*-phenoxy-H) 7.93 (m, 6 H, *endo* *m*-tolyl-H), 8.17−8.41 (m, 16 H, pyrrole-H), 9.48 (m, 8 H, *endo* *o*-tolyl- and *o*-phenoxy-H). − ^{13}C NMR ($CDCl_3$): δ = 21.59 (CH_3, tolyl), 26.00−29.50 [$OCH_2CH_2(CH_2)_4CH_2CH_2O$], 29.81 [$OCH_2CH_2(CH_2)_4CH_2CH_2O$], 68.52 [$OCH_2CH_2(CH_2)_4CH_2CH_2O$], 123.69−153.24 ($C_{arom.}$, $C_{heteroarom.}$), 158.58 ($C_{arom.}$−O). − CV (CH_2Cl_2/NBu_4PF_6): *E* = 1.020 V, 0.630, −0.305. − $C_{105}H_{88}CeN_8O_2 \times 5\ H_2O$ (1724.10): calcd. C 73.15, H 5.73, N 6.50; found C 73.40, H 5.68, N 6.04.

Protocol 5: General procedure for the electrochemical oxidations and reductions of the cerium(IV) bisporphyrinates **1a**−**d**: A solution of 1.40 mg (8.8×10^{-4} mmol) of **1a**, 1.45 mg (9.04×10^{-4} mmol) of **1b**, 1.63 mg (1.01×10^{-3} mmol) of **1c**, or 1.64 mg (1.01×10^{-3} mmol) of **1d** in 60 ml of a 0.1 M solution of NBu_4PF_6 in CH_2Cl_2 was electrolyzed by a three-potential cycle. Along the first two oxidations at +0.9 V and +1.3 V, charges of about 81 to 95 mC and 87 to 95 mC, respectively, were transferred while the solutions changed their colors from orange/brown via yellow to yellow/green. Thereafter, the solutions were reduced by a constant potential at −0.6 V. During this three-step reduction of the dications to the double-decker anions the color changes reversed with the appearance of orange/brown and then yellow/green for the last reduction step with total charges between 200 and 254 mC being transferred. After the first two oxidations and the total reduction, samples were taken, appropriately diluted, and placed into cuvettes for UV/Vis/NIR spectroscopy producing the spectral data given in Tables 2b−d.

Keywords: Calixarene / Phosphinite / Calixphosphane / Transition metals / X-ray diffraction

A cone-shaped calix[4]arene-derived monophosphinite, 25,27-di(ethoxycarbonylmethoxy)-26-hydroxy-28-(diphenylphosphinooxy)calix[4]arene (**L¹**), has been prepared in two steps from calix[4]arene. Treatment of **L¹** with [AuCl(tetrahydrothiophene)] in tetrahydrofuran gave the phosphinite complex [AuCl**L¹**] (**1**). Reaction of $[PdCl_2(PhCN)_2]$ with two equivalents of **L¹** gave selectively *trans*-$[PdCl_2\mathbf{L^1}_2]$ (**2**). Complex **2** · 2 CH_2Cl_2 crystallizes in the triclinic space group $P\bar{1}$. The molecule is centrosymmetric, leading to a divergent array of the two calixarene moieties. The palladium atom resides outside both cones. As a result of steric interactions, the *meta* and *para* carbon atoms of the PPh_2-bearing aryl ring are significantly pushed to the interior of the cavity. The related platinum complex *trans*-$[PtCl_2\mathbf{L^1}_2]$ (**3**), was obtained similarly from $[PtCl_2(PhCN)_2]$ and presents in the solid state a structure which is isomorphous to that of **2**. The diphosphinite 25,27-di(ethoxycarbonylmethoxy)-26,28-bis(diphenylphosphinoxy)calix[4]arene (cone) (**L²**) has also been prepared and reacts with $[PtCl_2(PhCN)_2]$ to yield oligomeric material.

The calix[4]arene structural framework has been extensively used as an important building block for the preparation of cavernous multifunctional podands[1][2][3][4][5][6][7]. Many of these ligands appear suitable for the selective recognition and complexation of metal cations[8][9][10][11][12][13][14][15][16][17] and/or for use as sensorial devices for anionic species[18][19]. An important feature which contributes to the valuable binding properties of functionalized calix[4]arenes in the *cone* conformation concerns the plasticity of the calixarene matrix. The flexibility of the cavity allows adoption of numerous geometries ranging from an almost C_4-symmetrical structure[20][21] to that of a so-called "pinched cone"[22][23]. In most structures where the latter shape has been encountered, two of the opposite aryl rings of the calixarene matrix lie almost coparallel, with the other two being essentially perpendicular.

As an extension of our earlier studies on calixarene-derived ligands suitable for transition metal complexation[24][25][26][27][28][29] we now report new examples of bulky calix[4]arene-derived phosphinites that form stable gold(I), palladium(II), and platinum(II) complexes. By reference to X-ray crystallography and NMR data, we describe the unusual structural attributes resulting from coordination of two such bulky ligands to a single metal center and, in particular, the resultant stereochemically-induced modification of the calixarene matrix. The present study complements previous results obtained with somewhat related compounds in which the calixarene ligands bear *tert*-butyl groups in the *para* positions, and for which inadequate X-ray crystallographic data were obtained[23]. In order to isolate the effects of metal complexation on the structural properties of the calixarenes of the macrocycle from steric effects relating to organic substituents, we have focussed our attention on the synthesis of calixarenes with freely accessible cavities. In fact omission of the *t*Bu groups allows intimate structural details to be elucidated. In addition such open cavities being equipped with a metal center at the bottom of the well may provide access to novel catalytic systems based on molecular recognition properties[30][31]. Here we describe the synthesis of open-ended calixarenes bearing two remote ester functions specifically designed to allow complexation of transition metals. Note, that investigations on the complexation properties of calixphosphinite ligands with three[9] and four[9][32][33] phosphorus atoms have recently been published.

Results and Discussion

Monophosphinite **L¹**, described here for the first time, was prepared in a two-step synthesis in which the first stage involved blocking of two distal hydroxy groups of calix[4]arene (Scheme 1). Intermediate **L⁰**, which is a key reactant for the formation of both **L¹** and **L²**, was obtained in 55% yield using conventional alkylation procedures[5]. It was deduced that of the four conformations possible for **L⁰**, the cone conformer was the only species detectable by ^{1}H- and ^{13}C-NMR spectroscopy. In particular, a unique ^{13}C-chemi-

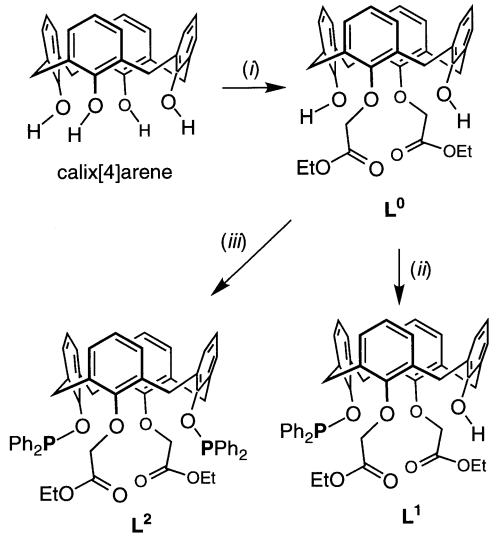
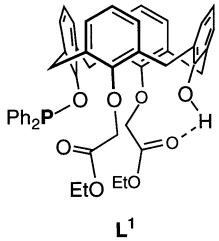
cal shift of $\delta = 31.32$ was observed for the bridging methylene carbon atoms which, according to the diagnostic criteria outlined by Jaime et al. corresponds exactly to that expected for the cone conformation[34]. In fact similar studies made for the other non-metallated calixarene derivatives described here confirmed that these also persisted in the cone conformation.

Scheme 1. (*i*) K_2CO_3 (1 equiv.), RT, 15 h, acetone; then $BrCH_2CO_2Et$ (2 equiv.), 24 h , reflux; (*ii*) NEt_3 (2.5 equiv.), 0°C, in THF, 1 h; then addition of Ph_2PCl (2 equiv.); (*iii*) $LiNiPr_2$ (2 equiv.), 0.5 h, in THF (−78°C); then Ph_2PCl (2 equiv.)



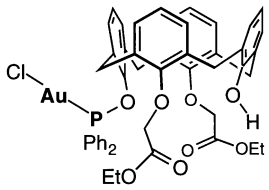
Monophosphination of $\mathbf{L^0}$ was achieved under mild conditions using NEt_3 as base. A signal typical of phosphinite residues is apparent at $\delta = 123.8$ in the ^{31}P-NMR spectrum. The IR (KBr) spectrum of $\mathbf{L^1}$ shows two strong absorption bands in the ester region (1760, 1737 cm^{-1}). The lower-energy band, located at 1737 cm^{-1}, is attributed to an ester having the carbonyl group hydrogen-bonded to a neighbouring hydroxy group. On this basis, the higher-energy band must arise from a non-hydrogen bonded carbonyl group. More surprisingly, precursor $\mathbf{L^0}$ also exhibits two well-resolved carbonyl bands in the IR spectrum (1761, 1742 cm^{-1}). This situation, which we have observed in other functionalized calixarenes bearing appended carbonyl moieties[23], is tentatively interpreted in terms of a mixture of free and hydrogen-bonded esters within the same molecule. X-ray investigations performed on complexes obtained from $\mathbf{L^1}$ corroborate this interpretation (vide infra).



$\mathbf{L^1}$

Despite using forcing conditions, it was not possible to attach two phosphinites to the calixarene using mildly basic reagents (such as NEt_3). Synthesis of the bis-phosphinite $\mathbf{L^2}$ required more basic conditions, but was conveniently accomplished using two equivalents of $LiNiPr_2$ (Scheme 1). The ^{31}P-NMR spectrum of this compound displays a single peak at $\delta = 122.0$, indicating magnetic equivalence of the two phosphinites. The four bridging methylene groups of the macrocycle give a typical AB spectrum, as expected for a cone conformation. Interestingly, the aromatic region of the ^{1}H-NMR spectrum of $\mathbf{L^2}$ displays an AB_2 signal (6 H, $\delta = 6.21$, *p*-ArH_{calix}, 5.92, *m*-ArH_{calix}) significantly shifted upfield with respect to the other aromatic hydrogen atoms. Presumably, the two bulky phosphino groups cause steric crowding around the ester groups and thereby push the *meta* and *para* hydrogen atoms of two opposite aryl rings into the shielding zone of the other two aromatic rings of the calixarene matrix. These studies however do not allow distinction of which of the two aryl rings, namely those bearing the PPh_2 groups or those connected to the esters, are pinched together.

To show that phosphinite $\mathbf{L^1}$ is suitable for transition metal complexation, we investigated its coordinative properties towards a relatively small metal fragment, namely the "AuCl" unit. Thus, treatment of $\mathbf{L^1}$ with [AuCl(THT)] (THT = tetrahydrothiophene) in tetrahydrofuran gave the gold complex **1** as a white solid. The FAB mass spectrum of **1** shows an intense peak at 977.0 (with the expected isotopic profile) corresponding to the $[M^+ - Cl]$ ion. As for $\mathbf{L^1}$, the ^{1}H-NMR spectrum of **1** contains two AB patterns for the $ArCH_2Ar$ hydrogen atoms and an AB pattern for the two opposite $OCH_2C(O)$ groups. The ^{31}P-NMR spectrum displays a single peak at $\delta = 118.4$; this chemical shift is in agreement with those reported recently by Puddephatt et al. for other phosphinito-calixarene gold(I) complexes[9].

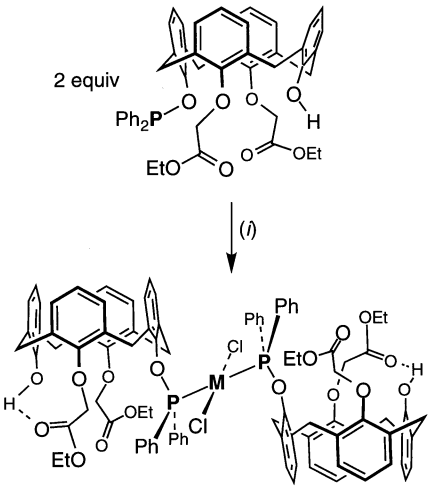


1

Reaction of $\mathbf{L^1}$ with $[PdCl_2(PhCN)_2]$ resulted in formation of complex **2** with high yield (Scheme 2). The *trans* stereochemistry around the metal center was inferred from the FAR IR spectrum which shows a single ν(Pd−Cl) band at 360 cm^{-1} and was confirmed by an X-ray diffraction study (vide infra). Despite the presence of the bridging P−Pd−P unit, the cone conformation of the two terminal calixarenes is retained. In marked contrast to the behaviour described above for $\mathbf{L^2}$, only a single aryl ring appears to be distorted out of its regular (i.e. non-metallated) position. Thus, NMR studies made with **2** indicate that there is an enhanced shielding effect for the *meta* and *para* hydrogens of only one aryl ring from each calixarene whereas with $\mathbf{L^2}$ two opposite rings are mutually distorted. Presumably,

deformation in **2** refers to the aryl rings lying closest to the metal center.

Scheme 2. (*i*) $[MCl_2(PhCN)_2]$ (M = Pd, Pt) in CH_2Cl_2



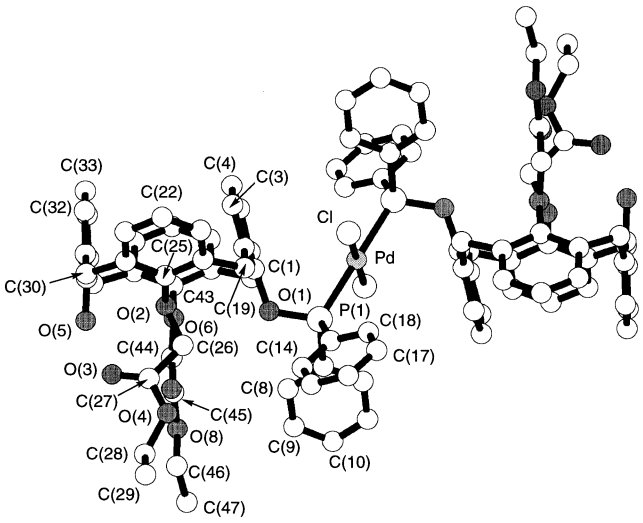
2, M = Pd ; **3**, M = Pt

The corresponding platinum analogue, **3**, also having *trans* sterochemistry [*J*(PPt) = 3006 Hz[35]] was obtained in a similar manner but starting from $[PtCl_2(PhCN)_2]$ (Scheme 2). Comparable upfield shifts on *meta* and *para* H atoms of a single aryl ring of each calixarene were observed. In fact, the ^{1}H-NMR properties of **2** and **3** were very similar, suggesting that a common structural feature persists in both metallated calixarenes. It is noteworthy that for complex **1** bearing the relatively small Au−Cl fragment all *m*-ArH hydrogen atoms lie above δ = 6.61 so that it appears reasonable to assign the upfield shifts observed for certain aromatic CH atoms in **2** and **3** to steric effects.

Both metal complexes, **2** and **3**, were fully characterized by X-ray structural analyses, but since these complexes are isomorphous, only one of them, namely the palladium complex **2**, will be described below. A summary of the crystal data is given in Table 1 (complex **2**) and Table 3 (complex **3**). Important distances and angles may be found in Table 2 (complex **2**) and Table 4 (complex **3**) . A view of **2** is represented in Figure 1. Examination of Figure 1 shows that half of the molecule is symmetry-generated since the palladium atom lies at the centre of symmetry. This leads to a solid-state structure with two divergent cavities, as defined by the calixarene units. The overall length of the molecule is ca. 18 Å. The complex exhibits square-planar coordination around the metal center with Pd−Cl and Pd−P bond lengths of 2.3014(6) and 2.3251(6) Å, respectively. The shape of the calixarene units strongly deviates from an ideal cone. In particular, two opposite aryl rings lie nearly perpendicular (dihedral angle Δ = 86°) with the other two making an angle of 12°. Each phosphorus atom is directed away from the cavity defined by the calixarene, the O−P−Pd plane being essentially orthogonal to the corresponding O-aryl ring (dihedral angle ca. 80°).

Several interesting facets emerge from the solid state structure (Fig. 1). Firstly, it is noticeable that the bulky diphenylphosphino groups adopt the position that causes minimal steric perturbation to the terminal calixarene units. Secondly, it is clearly demonstrated that the upper end of the phosphinated aryl ring is pushed towards the center of the cavity. The dihedral angle between the calixarene reference plane and the P-bearing phenoxy ring is 57.7(1)°. This "perturbation" of a single aryl unit was inferred from the NMR studies but is now shown unequivocally to exist in the solid state. Several complementary factors contribute to this effect. Although interactions between the d_{z^2} orbital on the palladium center and the adjacent aryl ring provide some minor repulsive force [Pd···C(1), 3.313 Å], the primary perturbing influence arises from steric interaction with the distant PPh_2 moiety {contacts: H(13)···C′(5) = 3.21 Å and H(13)···C′(6) = 3.33 Å [H(13) on C(18)]}. Thirdly, the above mentioned structural distorsion results in a rather narrow entrance to the cavity. This effect is illustrated by the comparatively short C(4)−C(33) separation of 4.64 Å and is reminiscent of the so-called *bis-roof* structure recently described by Shinkai et al.[36][37][38]. In the latter case, two distal aryl rings are made to approach each other by their involvment in π-complexes with $Cr(CO)_3$ fragments. This is a very different perturbing mode than that outlined for **2** and **3**, since the major structural feature of pinching of the calixarene unit results from mutual attraction of electron-deficient walls. In our case, a *single* wall is forced inwards by external steric influences. Finally, the short O(7)−O(5) distance (2.87 Å) indicates hydrogen bonding between the hydroxy function and the C(45)−O(7) carbonyl group. This finding corroborates our interpretation of the IR spectra.

Figure 1. MolView drawing of complex **2** with partial labeling scheme. The distance between C(4) and C(33) is 4.64 (1) A



Considerable effort was expended to generate the corresponding cis isomers of **2** and **3**, but to no avail; examination of molecular models suggests that the bulky calixarene fragment provide undue steric barriers to formation of the cis complexes.

Reaction of $\mathbf{L^2}$ with $[PtCl_2(PhCN)_2]$ in CH_2Cl_2 gave a sparingly soluble white material in keeping with the overall formulation of $[PtCl_2(\mathbf{L^2})]_n$ to which we assign a polymeric

structure. The ^{31}P-NMR spectrum shows a broad peak at δ = 102.8, with a J(PPt) coupling constant of 3009 Hz, indicating that the stereochemistry about platinum is exclusively *trans*. The ^{1}H-NMR spectrum shows broad signals, suggesting the formation of a polymer and/or a mixture of oligomeric compounds. Because of its poor solubility, a molecular weight determination could not be performed. It is worth mentioning here that with previously reported diphosphinites having Bu^{t} groups occupying the *p*-positions of the calixarene moiety, cyclic tetrameric compounds were obtained[23]. The driving force for formation of oligomeric arrays arises from the fact that each of the phosphino groups in the bis derivative **L^{2}** is forced to lie outside of the cavity. Formation of bis(phosphinite) complexes with large metallo fragments such as "$PdCl_2$" or "$PtCl_2$" is then most easily accomplished by taking phosphorus from two separate calixarenes. With considerably smaller metallo-fragments such as CuCl, it is feasible that a mononuclear chelate could be generated[32]. Similar behaviour has also recently been observed with smaller phosphorus substituents[33].

In summary, we have described two novel phosphinites having open-ended cavities. Conditions are described which permit the selective attachment of one or two phosphino groups to the lower rim of a 1,3-difunctionalized calix[4]arene. The appended phosphino groups remain accessible for complexation with appropriate metallo-fragments and well-defined complexes have been observed with $PdCl_2$ and $PtCl_2$. In these cases and regardless of the presence of *t*Bu groups on the upper rim, it was only possible to isolate complexes demonstrating *trans* stereochemistry at the metal atom. The bulkyness of the two *trans* arranged phosphinites causes subtle modification to the structure of the calixarene unit, pushing one phenoxy ring into the cavity. In view of the fact that metallocalixarenes **2** or **3** contain two divergent cavities suitable for inclusion of neutral species, such nanostructures may provide further valuable complexation and/or catalytic opportunities.

We are grateful to *C. B. Dieleman* for his kind assistance. We are indebted to *Johnson Matthey* for a generous loan of precious metals.

Experimental Section

Reagents and Physical Measurements: All manipulations were performed in Schlenk-type flasks under argon. Solvents were dried by conventional methods and distilled immediately prior to use. $CDCl_3$ was eluted from a 5 cm thick alumina column and stored under argon over molecular sieves (0.4 nm). − IR spectra were recorded on a Perkin Elmer 1600 spectrometer (4000−400 cm^{-1}) and a Bruker FIR spectrometer (500−90 cm^{-1}). − ^{1}H-, ^{31}P{^{1}H}-, and ^{13}C{^{1}H}-NMR spectra were recorded with a FT Bruker WP-200 SY instrument. The ^{1}H-NMR data were referenced to residual protiated solvents (7.27 for $CDCl_3$), ^{13}C chemicals shifts are reported relative to deuterated solvents (δ = 77.0 for $CDCl_3$, δ = 67.40 for [D$_8$]THF) while the ^{31}P-NMR data are given relative to external H_3PO_4. − Mass spectra of complexes **2** and **3** were recorded on a ZAB HF VG Analytical instrument with *m*-nitrobenzyl alcohol as a matrix. The mass spectrum of **L^{2}** was recorded on a TSQ-70 spectrometer. Calix[4]arene[39], [AuCl(THT)] (THT = tetrahydrothiophene)[40], $[PdCl_2(PhCN)_2]$[41], and $[PtCl_2(PhCN)_2]$[41], were prepared using literature procedures.

Preparations

25,27-Di(ethoxycarbonylmethoxy)-26,28-(dihydroxy)calix[4]arene (**L^{0}**): A suspension of calix[4]arene (6.000 g, 14.13 mmol) was treated with K_2CO_3 (2.150 g, 15.55 mmol) in acetone (150 cm^3) for 15 h at room temperature. $BrCH_2CO_2Et$ (4.957 g, 29.68 mmol) was then added and the resultant mixture was heated under reflux for 24 h. After filtration, the solvent was removed in vacuo. The residue was recrystallized from CH_2Cl_2-MeOH, yielding **L^{0}** as a white analytically pure solid (6.600 g, 78%), R_f = 0.12 (SiO_2, CH_2Cl_2), m.p. 180°C. − IR (KBr): $\tilde{\nu}$ = 3387 br (OH), 1761 (C=O), 1742 (C=O···HO). − ^{1}H NMR ($CDCl_3$): δ = 7.66 (s, 2 H, OH), 7.07 (d, 4 H, *m*-ArH, ^{3}J = 7.5 Hz), 6.92 (d, 4 H, *m*-ArH, ^{3}J = 7.5 Hz), 6.75 (t, 2 H, *p*-ArH, ^{3}J = 7.5 Hz), 6.67 (t, 2 H, *p*-ArH, ^{3}J = 7.5 Hz), 4.75 (s, 4 H, OCH_2), 4.50 and 3.41 (AB spin system, 8 H, $ArCH_2Ar$, ^{2}J = 13 Hz), 4.34 (q, 4 H, OCH_2CH_3, ^{3}J = 7.1 Hz), 1.37 (t, 6 H, CH_3, ^{3}J = 7.1 Hz). − ^{13}C{^{1}H} NMR ($CDCl_3$): δ = 168.70 (CO), 152.82, 152.20, 132.95, 127.98 (4 C aromatic), 128.97, 128.34, 125.44, 118.95 (4 CH aromatic), 72.29 ($ArOCH_2$), 61.24 (OCH_2CH_3), 31.32 ($ArCH_2Ar$), 13.97 (CH_3). − $C_{36}H_{36}O_8 \cdot 0.5$ MeOH (596.68 + 16.02): calcd. C 71.55; H 6.25; found: C 71.03; H 5.70. The formation of a solvate was confirmed by ^{1}H-NMR spectroscopy.

25,27-Di(ethoxycarbonylmethoxy)-26-hydroxy-28-(diphenylphosphinooxy)calix[4] arene (**L^{1}**): To a solution of **L^{0}** (3.320 g, 5.60 mmol) in THF (100 cm^3) at 0°C was added triethylamine (1.420 g, 14.01 mmol). After stirring for 1 h, a solution of Ph_2PCl (1.360 g, 6.16 mmol) in THF (25 cm^3) was added slowly accompanied by formation of Et_3NHCl. The mixture was shaken for a further 24 h and the precipitate was removed by filtration before the solvent was evaporated in vacuo. Recrystallization of the residue from toluene-hexane gave **L^{1}** as a white solid (3.500 g, 80%), R_f = 0.43 (SiO_2, CH_2Cl_2), m.p. 148−150°C. − IR (KBr): $\tilde{\nu}$ = 3409 (OH), 1760 (C=O), 1737 (C=O···HO). − ^{1}H NMR ($CDCl_3$): δ = 7.80−7.78 and 7.49−7.47 (10 H, $OPPh_2$), 7.05−6.60 (12 H, ArH_{calix}), 4.62 and 3.31 (AB spin system, 4 H, $ArCH_2Ar$, ^{2}J = 13.5 Hz), 4.51 and 4.08 (AB spin system, 4 H, OCH_2CO_2, ^{2}J = 15.6 Hz), 4.29 and 3.01 (AB spin system, 4 H, $ArCH_2Ar$, ^{2}J = 13.2 Hz), 4.13 (q, 4 H,OCH_2CH_3, ^{3}J = 7.0 Hz), 3.67 (s, 1 H, OH), 1.24 (t, 6 H, OCH_2CH_3 , ^{3}J = 7.0 Hz). − ^{13}C {^{1}H} NMR ($CDCl_3$): δ = 169.44 (s, CO), 154.26−118.50 (s, C_{arom}), 71.75 (s, OCH_2CO), 60.78 (s, OCH_2CH_3), 31.17 and 30.95 (s, $ArCH_2Ar$), 13.97 (s, OCH_2CH_3). − ^{31}P{^{1}H} NMR ($CDCl_3$): δ = 123.8. − $C_{48}H_{45}O_8P$ (780.86): calcd. C 73.83; H 5.81; found: C 73.57; H 5.55.

25,27-Di(ethoxycarbonylmethoxy)-26,28-bis(diphenylphosphinooxy)calix[4]arene (**L^{2}**): To a cold (−78°C) solution of BuLi (1.5 M, 4.05 cm^3, 6.07 mmol) in THF (50 cm^3) was added slowly a solution of diisopropylamine (0.614 g, 6.07 mmol) in THF (20 cm^3), pre-cooled at −78°C. The mixture was kept at this temperature for 30 min before slow addition of a solution of the precursor **L^{0}** (1.800 g, 3.03 mmol) in THF (20 cm^3, −78°C). After 1 h, Ph_2PCl (1.339 g, 6.07 mmol) was added dropwise. The solution was stirred for 2 h, filtered through Celite, and evaporated to dryness. The residue was dissolved in toluene (50 cm^3) and the resulting suspension filtered through Celite in order to remove LiCl. Concentration of the filtrate and addition of hexane precipitated **L^{2}** as a white solid (2.490 g, 85%), R_f = 0.89 (SiO_2, CH_2Cl_2-MeOH, 95:5, v/v). − IR (KBr): $\tilde{\nu}$ = 1762 (C=O). − ^{1}H NMR ($CDCl_3$): δ = 7.76−6.70 (24H aromatics), 6.20 (t, 2 H, *p*-ArH, ^{3}J = 7.6 Hz), 5.91 (d, 4 H, *m*-ArH, ^{3}J = 7.6 Hz), 4.76 (s, 4 H, OCH_2), 4.41 and 2.84 (syst. AB, 8 H, $ArCH_2Ar$, ^{2}J = 14.5 Hz), 3.99 (q, 4 H, OCH_2CH_3,

^3J = 7.2 Hz), 1.37 (t, 6 H, CH_3, ^3J = 7.2 Hz). − $^{31}P\{^1H\}$ NMR ($CDCl_3$): δ = 122.0 (s, $OPPh_2$). This product is very sensitive to hydrolysis. We detected by NMR the formation of **L¹** and **L⁰** when traces of water were present. − MS (EI); *m/e* (%): 964.2 (10) [M^+]. − $C_{60}H_{54}O_8P_2$ (965.042): calcd. C 74.68; H 5.64; found: C 74.72; H 5.80.

Chlorobis[25,27-di(ethoxycarbonylmethoxy)-26-hydroxy-28-(diphenylphosphinooxy)calix[4]arene]gold(I) (**1**)**:** A solution of [AuCl(THT)] (0.160 g, 0.50 mmol) in THF (15 cm^3) was added to a solution of compound **L¹** (0.390 g, 0.50 mmol) in THF (15 cm^3). After 1 h the resultant solution was concentrated to ca. 5 cm^3; addition of pentane gave **1** as a white powder which was recrystallised from THF-pentane (0.380 g, 75%), m.p. 112−114°C (dec). − IR (KBr): $\tilde{\nu}$ = 3430 br (OH), 1752 (C=O), 1728 (C=O···HO). − ^1H NMR ([D_8]THF): δ = 8.27−8.17 and 7.74−7.73 (10 H, $OPPh_2$), 7.32−6.57 (12 H, ArH_{calix}), 4.68 and 3.13 (AB spin system, 4 H, $ArCH_2Ar$, ^2J = 13.3 Hz), 4.39 and 4.19 (AB spin system, 4 H, OCH_2CO_2, ^2J = 16.0 Hz), 4.31 and 3.32 (AB spin system, 4 H, $ArCH_2Ar$, ^2J = 13.5 Hz), 4.23 (q, 4 H,OCH_2CH_3, ^3J = 7.0 Hz), 3.76 (s, 1 H, OH), 1.30 (t, 6 H, OCH_2CH_3 , ^3J = 7.0 Hz). − $^{13}C\{^1H\}$ NMR ([D_8]THF): δ = 179.90 (s, CO), 154.80−119.18 (s, C_{arom}), 72.70 (s, OCH_2CO), 61.40 (s, OCH_2CH_3), 32.36 and 31.74 (s, $ArCH_2Ar$), 14.41 (s, OCH_2CH_3). − $^{31}P\{^1H\}$NMR ($CDCl_3$): δ = 118.4. − MS (FAB MS); *m/e* (%): 977 (100) [M^+ − Cl]. − $C_{48}H_{45}AuClO_8P$ (1013.28): calcd. C 56.90; H 4.48; found: C 57.22; H 4.77.

trans-Dichlorobis[25,27-di(ethoxycarbonylmethoxy)-26-hydroxy-28-(diphenylphosphinooxy)calix[4]arene]palladium(II) (**2**): A solution of [$PdCl_2$(PhCN)$_2$] (0.384 g, 0.310 mmol) in THF (50 cm^3) was added slowly to a solution of **L¹** (0.484 g, 0.620 mmol) in THF (40 cm^3). After 2 h the solution was reduced to one-third and hexane was added, yielding **2** as a yellow solid (0.456 g, 84%), R_f = 0.84 (SiO_2, MeOH-CH_2Cl_2, 5/95, v/v), m.p. 238−240°C (dec). − IR spectrum (KBr): $\tilde{\nu}$ = 3414 (OH), 1750 (CO) , 1731 (C=O···HO). − Far FT-IR: $\tilde{\nu}$ = 360 (PdCl). − ^1H NMR ($CDCl_3$): δ = 7.84−6.32 (19 H, CH aromatic), 7.74 (1 H, OH, exchanges with D_2O), 6.21 (t, 1 H, *p*-ArH_{calix}, ^3J = 7.5 Hz), 5.92 (d, 2 H, *m*-ArH, 3J = 7.5 Hz), 5.11 and 4.59 (AB spin system, 4 H, OCH_2, ^2J = *1*6 Hz), 4.67 and 3.22 (AB spin system, 4 H, $ArCH_2$, ^2J = *1*3 Hz), 4.35 and 3.22 (AB spin system, 4 H, $ArCH_2Ar$, ^2J = 16.8 Hz), 4.24 (q, 8 H, OCH_2CH_3, ^3J = 7.1 Hz), 1.28 (t, 6 H, OCH_2CH_3, ^3J = 7.1 Hz). − $^{13}C\{^1H\}$ NMR ($CDCl_3$): δ = 171.35 (s, CO), 157.09−119.02 (C aromatic), 71.64 (OCH_2CO), 60.93 (OCH_2CH_3), 32.57 and 31.97 (2s, $ArCH_2Ar$), 13.97 (OCH_2CH_3). − $^{31}P\{^1H\}$ NMR ($CDCl_3$): δ = 111 (s). − MS (FAB MS); *m/e* (%): 1703 (0.5) [M^+ − Cl]. − $C_{96}H_{90}Cl_2O_{16}P_2Pd$ (1739.03): calcd. C, 66.31; H, 5.22; found: C, 66.34; H, 5.33.

trans-Dichlorobis[25,27-di(ethoxycarbonylmethoxy)-26-hydroxy-28-(diphenylphosphinooxy)calix[4]arene]platinum(II) (**3**)**:** To a solution of **L¹** (0.303 g, 0.390 mmol) in THF (40 cm^3) was added slowly a solution of [$PtCl_2$(PhCN)$_2$] (0.091 g, 0.195 mmol) in THF (50 cm^3). After 2h the solution was concentrated and hexane was added, yielding **3** as a white solid (0.293 g, 82%) which was dried in vacuo overnight, R_f = 0.8 (SiO_2, MeOH/CH_2Cl_2, 5/95, v/v), m.p. 271−275°C. − IR (KBr): $\tilde{\nu}$ = 3415br (OH), 1756 (C=O), 1731 (C=O···HO). − Far FT-IR: $\tilde{\nu}$ = 349 (PtCl). − ^1H NMR ($CDCl_3$): δ = 7.86−6.32 (19 H, CH aromatics), 7.72 (s, 1 H, OH, exchanges with D_2O), 6.22 (t, 1 H, *p*-ArH, ^3J = 7.6 Hz), 5.89 (d, 2 H, *m*-ArH, ^3J = 7.6 Hz), 5.14 and 4.65 (AB spin system, 4 H, OCH_2CO_2, ^2J = 16.4 Hz), 4.67 and 3.23 (AB spin system, 4 H, $ArCH_2Ar$, ^3J = 13.7 Hz), 4.42 and 3.20 (AB spin system, 4 H, $ArCH_2Ar$, ^2J = 14.8 Hz), 4.26 (q, 8 H, OCH_2CH_3, ^3J = 7.1 Hz), 1.29 (t, 6 H, OCH_2CH_3, ^3J = 7.1 Hz). − $^{13}C\{^1H\}$ NMR ($CDCl_3$): δ = 171.39 (CO), 157.20−119.07 (C aromatics), 71.63 (OCH_2CO_2), 60.97(OCH_2CH_3), 32.56 ($ArCH_2Ar$), 31.11 ($ArCH_2Ar$), 14.00 (OCH_2CH_3). − $^{31}P\{^1H\}$ NMR ($CDCl_3$): δ = 102.7 [s with Pt satellites, ^2J(PPt) = 3006.3 Hz]. − MS (FAB MS); *m/e* (%): 1827 (1) [M^+], 1790 (7) [M^+ − Cl]. − $C_{96}H_{90}Cl_2O_{16}P_2Pt$ (1827.72): calcd C, 63.09; H, 4.96; found: C, 62.79; H, 4.89.

Reaction of [PtCl₂(PhCN)₂] with **L²**: A solution of [$PtCl_2$(PhCN)$_2$] (0.168 g, 3.56 mmol) in CH_2Cl_2 (30 cm^3) was added to a solution of **L²** (0.344 g, 3.56 mmol) in CH_2Cl_2 (20 cm^3). After 1 h the solution was concentrated and hexane was added, yielding a white precipitate (0.329 g, 75%) which was poorly soluble in $CHCl_3$, CH_2Cl_2, and THF, m.p. 263−266°C. − ^1H NMR ($CDCl_3$): δ = 1.19 (t, OCH_2CH_3, ^3J = 7.0 Hz); all other signals are broad probably owing to a fluxional behaviour in solution or to the presence of several oligomeric compounds. $^{31}P\{^1H\}$ NMR ($CDCl_3$): δ 102.8 [s with Pt satellites, ^2J(P-Pt) = 3009 Hz]. − $C_{60}H_{54}Cl_2O_8P_2Pt$ (1231.04): calcd. C, 58.04; H, 4.42; found: C, 58.11; H, 4.32.

X-ray Crystallographic Studies: Complex **2**: Crystal data are given in Table 1. A suitable crystal of **2** · 2 CH_2Cl_2 was obtained by slow diffusion of hexane into a solution of complex **2** in CH_2Cl_2 at room temperature. Data were collected on an ENRAF-NONIUS MAC3 diffractometer at room temperature with graphite mono-

chromatic Mo-K_α radiation $\lambda = 0.7107$ Å. The cell parameters were obtained by fitting a set of 25 high-theta reflections. The data collection ($\omega/2\theta$ scan type, $2\theta_{max} = 56°$, $+h \pm k \pm l$), intensity controls without appreciable decay (0.2%) gives 10309 reflections from which 7418 were independant with $I>3\sigma(I)$. After Lorenz polarization and absorption (ψ scan) corrections, the structure was solved by direct methods. After refinement of the heavy atoms, a Fourier-difference map revealed maxima of residual electronic density close to the positions expected for hydrogen atoms; they were introduced into structure-factor calculations by their computed coordinates (C−H 0.95 Å) and isotropic thermal parameters such as B(H) = 1.3 B_{eq}(C) Å but not refined. Full least squares refinements against F with weights $\omega = 1/\sigma^2(F)$, $\sigma^2(F^2) = \sigma^2$ (counts) + $(pI)^2$. Anisotropic thermal parameters were assigned to all non-hydrogen atoms except for C(28), C(29), C′(28), and C′(29). Final positive and negative electron density residues: 0.81/−0.24 e·Å^{-3}. Atomic scattering factors were from International Tables for X-ray Crystallography (1983)[42]. All calculations were performed on a DEC AXP 3100 computer with the OpenMolEN[43] package (Enraf-Nonius, 1990). The ethyl group of one ester (C28) was found to be disordered over two positions in the ratio 1:1. The plot of **2** was drawn using MolView[44].

Complex **3**·*2 CH_2Cl_2:* Crystal data are given in Table 3. Crystals of **3** · 2 CH_2Cl_2 were obtained by slow diffusion of hexane into a solution of complex **3** in CH_2Cl_2. Data collection as described above. The data collection ($\omega/2\theta$ scan type, $2\theta_{max} = 52°$, $+h \pm k \pm l$), intensity controls without appreciable decay (0.2%) gives 9588 reflections from which 8843 were independant with $I>3\sigma(I)$. After Lorenz polarization and absorption (ψ scan) corrections, the structure was solved by direct methods. After refinement of the heavy atoms, a Fourier-difference map revealed maxima of residual electronic density close to the positions expected for hydrogen atoms; they were introduced into structure-factor calculations by their computed coordinates (C−H 0.95 Å) and isotropic thermal parameters such as B(H) = 1.3 B_{eq}(C) Å but not refined. Full least squares refinements against F with weights $\omega = 1/\sigma^2(F)$, $\sigma^2(F^2) = \sigma^2$ (counts) + $(pI)^2$. Anisotropic thermal parameters were assigned to all non-hydrogen atoms. Final positive and negative electron density residues: 0.771/−0.112 e·Å^{-3}. Complete atomic coordinates, thermal parameters and bond lengths and angles for both complexes have been deposited at the Crystallographic Data Centre (CCDC number 100858).

Carbon Monoxide and Isonitrile Insertion into the B−B Bond of Five-Membered Cyclic Organo-1,2-diboranes☆

Jens Teichmann, Harald Stock, Hans Pritzkow, and Walter Siebert*

Anorganisch-Chemisches Institut der Universität Heidelberg,
Im Neuenheimer Feld 270, D-69120 Heidelberg, Germany

Received October 22, 1997

Keywords: 1,2-Diboraheterocycles / Carbon monoxide insertion / Isonitrile insertion / Dimerisation / Spiro insertion products

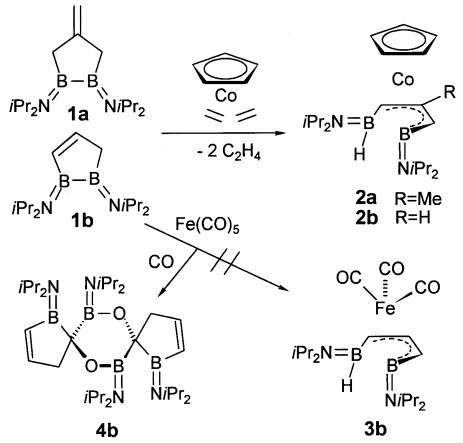
The insertion of CO into the B−B bond of 1,2-bis(diisopropylamino)-2,5-dihydro-1*H*-1,2-diborole (**1b**) and 1,2-bis(diisopropylamino)-3-methylidene-1,2-diborolane (**1c**) leads to the dimeric spiro products 1,7,9,14-tetrakis(diisopropylamino)-6,13-dioxa-1,7,9,14-tetraboradispiro[4.2.4.2]tetradeca-2,10-diene (**4b**) and 1,7,9,14-tetrakis(diisopropylamino)bismethylidene-6,13-dioxa-1,7,9,14-tetraboradispiro[4.2.4.2]tetradecane (**4c**). Insertions of CO into the B−B bonds of the cyclic organo-1,2-diborane compounds **5**, **6**, and **7** are not observed. The reaction of **1b** with *tert*-butyl isocyanide and 2,6-dimethylphenyl isocyanide in THF leads to the formation of the monomeric insertion products 1,3-bis(diisopropylamino)-2-*tert*-butylimino-1,3-diboracyclohex-4-ene (**10b**) and 1,3-bis(diisopropylamino)-2-(2′,6′-dimethylphenylimino)-1,3-diboracyclohex-4-ene (**11b**). The treatment of **1c** with the isonitriles yields 2-*tert*-butylimino-1,3-bis(diisopropylamino)-4-methylidene-1,3-diboracyclohexane (**10c**) and 1,3-bis(diisopropylamino)-2-(2′,6′-dimethylphenylimino)-4-methylidene-1,3-diboracyclohexane (**11c**). The steric requirements of the isonitrile insertion products **10b**, **c** and **11b**, **c** prevent their dimerisation and rearrangement. **11b** rearranges to 1-(diisopropylamino)-2-(diisopropylaminohydroxyboryl)-2-(2′,6′-dimethylphenylamino)-1-boracyclopent-3-ene (**12b**) upon reaction with water from sodium sulfate decahydrate. The compositions of the compounds are derived from the ^{1}H-, ^{11}B-, ^{13}C-NMR data as well as from mass-spectral and C, H, N analyses. In the cases of of **4b** and **12b** they have been proven by X-ray structure analyses.

The synthesis and structural characterization of the η^4-(4-boryl-1-borabutadiene)-η^5-cyclopentadienylcobalt complexes **2a**[1] from the 4-methylene-1,2-diborolane **1a**,[2] as well as **2b**[3] from the 1*H*-1,2-diborole **1b**[3] and bis(ethene)-cyclopentadienylcobalt, led to the expectation that related compounds should be formed with other 14 VE complex fragments. However, **1b** and either $Fe(CO)_5$ or $Fe_2(CO)_9$ did not yield the corresponding η^4-(4-boryl-1-borabutadiene)-tricarbonyliron complex **3b**. A few colorless crystals could be separated from the reaction mixture and mass-spectrometric data indicated the presence of a dimer of a reaction product of carbon monoxide and **1b**. Its constitution was elucidated by an X-ray structure analysis (see below) which showed the presence of the dimeric spiro compound **4b**.[4]

Reactions of CO with organoboranes are long since known and are well documented.[5] The insertion of CO into the B−B bond of three-membered heterocycles was first observed by Paetzold et al.[6] Tri-*tert*-butylazadiboriridine [$NB_2(CMe_3)_3$] and CO yield the tricyclic compound 1,3,4,5,7,8-hexa-*tert*-butyl-4,9-dioxa-1,7-diaza-2,5,8,10-tetraboradispiro[2.2.2.2]decane. The proposed mechanism describes, in the first step, the insertion of CO into the B−B bond to give a four-membered $NB_2C{=}O$ ring, which then undergoes a [3+3] cyclodimerisation of the BC=O chain to yield the corresponding six-membered ring. Sigmatropic migrations of the amino groups from the boron to the carbon atoms result in the final product.

Analogously, isonitriles (RNC) insert into the B−B bond of $NB_2(CMe_3)_3$ to form the corresponding four-membered rings $NB_2C{=}NR$. With R = Me, Et the primary products undergo a [3+3] cyclodimerisation of the BC=N chain to result in the tricyclic compounds.[7]

Scheme 1



In the following we report on our findings concerning CO and C=NR insertion into the B−B bond of five-membered cyclic organodiboranes.

Results and Discussion

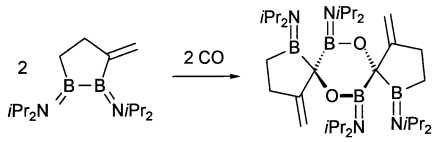
Reactions of Cyclic Organo-1,2-diboranes with Carbon Monoxide

The compound **4b**[4] is formed in a good yield when dried CO is bubbled into a THF solution of **1b**.[3] Due to its weak

 © WILEY-VCH Verlag GmbH, D-69451 Weinheim, 1998 1434−1948/98/0404−0459 $ 17.50+.50/0

solubility **4b** precipitates as a solid which is less sensitive to air and moisture. The reaction between the 3-methylidene-1,2-diborolane **1c**[1] and CO leads to the analogous dimeric spiro product 1,7,9,14-tetrakis(diisopropylamino)bismethylidene-6,13-dioxa-1,7,9,14-tetraboradispiro[4.2.4.2]tetradecane (**4c**).[4] We assume that, besides **4c**, two other isomers have been formed due to various positions of the exocyclic double bonds. Mass-spectral data and C, H, N analyses were obtained, but no NMR data could be obtained due to its very low solubility in organic solvents. The mass spectra of the reaction product of **1c** and $Fe(CO)_5$ indicate that the η^4-(1-boryl-2-methyl-1-borabutadiene)-tricarbonyliron complex (analogous to **3b**) was present[4], however, it could not be isolated. The reaction of **1a** with $Fe(CO)_5$ also led to traces of the analogous complex.

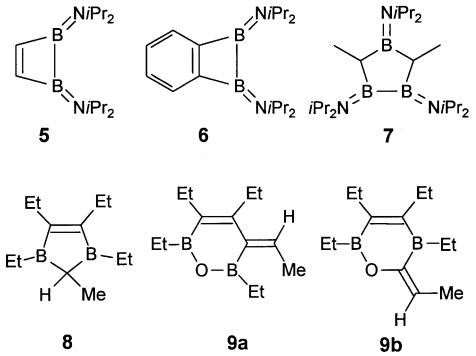
Scheme 2



1c **4c**

In addition to **1a–c**, the cyclic organo-1,2-diborane compounds 1,2-bis(diisopropylamino)-1,2-diboret (**5**)[8], 1,2-bis(diisopropylamino)-1,2-benzodiboret (**6**)[9], and 1,2,4-tris(diisopropylamino)-3,5-dimethyl-1,2,4-triboracyclopentan (**7**)[10] were treated with dried CO. None of the expected insertion products were formed and the starting materials were recovered.

Scheme 3



5 **6** **7**

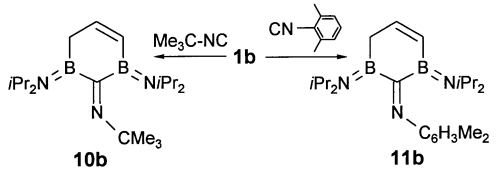
8 **9a** **9b**

It is of interest to note that we did not observe any insertion into the B–C bonds of the compounds **1a–c**. This is in contrast to the reaction of CO with the 1,3,4,5-tetraethyl-2-methyl-2,3-dihydro-1,3-diborole (**8**), which leads to product **9a** and **9b**.[11] The formation of **9b** can be explained by insertion of CO into the B–CHMe bond of **8**, and exchange of the CHMe group for the oxygen of the inserted CO. The product **9a** is formed analogously by insertion of CO into the B–CEt bond and exchange of the CHMe group for the oxygen of the inserted CO, which yields the B–O–B bridge. When **8** is treated with $Ni(CO)_4$,[11] presumably **9a** is the precursor for the formation of a nickel complex with two cyclic allyl ligands.

Reactions of Organo-1,2-diboranes with Isonitriles

The failure of CO to insert into the B–B bond of the compounds **5–7** is also observed with the isonitriles. The reaction of the 1,2-diborole **1b** with *tert*-butyl isocyanide and with 2,6-dimethylphenyl isocyanide at −30°C in THF leads to colorless, slightly soluble monomeric products, 2-*tert*-butylimino-1,3-diboracyclohex-4-ene (**10b**) and 2-(2′,6′-dimethylphenylimino)-1,3-diboracyclohex-4-ene (**11b**). As a sideproduct in the reaction with **1b** its rearrangement to the known 1,3-bis(diisopropylamino)-2,3-dihydro-1,3-diborole[12][13] was observed. MS and ^{1}H-, ^{11}B-, and ^{13}C-NMR data confirmed the composition of the products formed.

Scheme 4



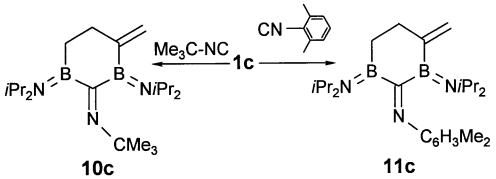
10b **11b**

In the ^{1}H-NMR spectra all four septuplets of the methine protons of the isopropyl groups of **10b** have different chemical shifts, whereas the compound **11b** shows only one multiplet and one septuplet for the four groups. This result indicates a rigid structure at room temperature.[10] There is a high double-bond character between the boron and nitrogen atoms.

Because of the quadrupole effect of the boron atoms the signals of the protons at the vicinal carbon atoms have very low intensities. The methylene protons can be detected near $\delta = 2.2$ as a doublet, and the methine protons of the double bond in the ring are not detected. The signal for the proton in 4-position is observed at $\delta = 6.30$, and that for the 5-position at $\delta = 6.85$. In **11b** the signal of the proton in the 5-position cannot be observed, because the signals of the aromatic substituent appear between $\delta = 6.8$ and 7.1.

The reaction between the 3-methylidene-1,2-diborolane **1c** and the two isonitriles leads to the 2-*tert*-butylimino-4-methylidene-1,3-diboracyclohexane **10c** and the 2-(2′,6′-dimethylphenylimino)-4-methylidene-1,3-diboracyclohexane **11c.**[10]

Scheme 5



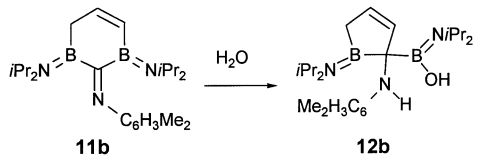
10c **11c**

The ^{11}B-NMR shifts of **10c** and **11c** are $\delta = 38$ and 39, which are within the expected region.[14] The ^{1}H-NMR data of **11c** are comparable to those of **11b**. The products are soluble only in THF.

The steric demand of the five-membered rings **1b** and **1c**, and that of the alkyl substituents of the isonitriles both prevent dimerization and rearrangement of the corresponding insertion products **10b**, **c** and **11b**, **c**. To induce a rearrange-

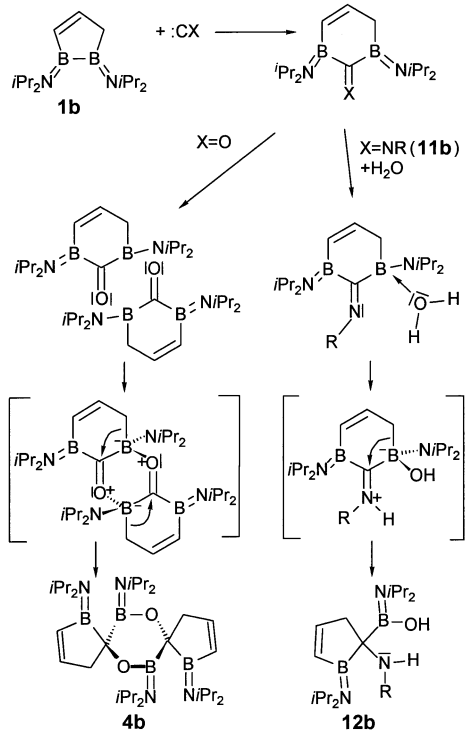
ment a small dipolar reagent such as water is needed. Therefore, **10b** and sodium sulfate decahydrate were heated in THF to yield the hydrolysis product **12**, which was characterized by an X-ray structure analysis. **12** can be described as one half of a spiro dimer, formed by ring contraction. The five-membered ring in **12** contains the terminal carbon atom of the isonitrile and only one boron atom.

Scheme 6



The formation of the dimeric insertion and rearrangement products **4a**, **b**, the insertion compounds **10b**, **c** and **11b**, **c** and the product of hydrolysis **12**, give evidence for the reaction path of insertion and rearrangement to the dimeric molecules. As proposed, the first step is an insertion of carbon monoxide or isonitrile into the B−B bond of the boron heterocycles.[6] The formed products are stable, if the steric requirements of the isonitriles or the heterocycles are suitable as in the isonitrile insertion products **10b**, **c** and **11b**, **c**. Rearrangement under ring contraction is the following step. This is supported by using water as a dipolar reagent to induce rearrangement with formation of **12**. In the case of CO insertion the dimeric spiro compounds **4b**, **c** are formed. The proposed reaction paths are in agreement with the mechanistic conclusions of Paetzold et al.[6][7]

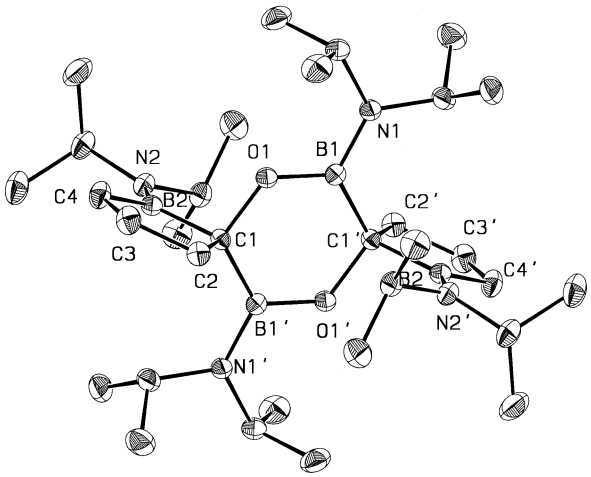
Scheme 7



Crystal Structures of 4b and 12b

The centrosymmetric molecule in **4b** is built up by the central planar 6-membered ring (max. deviation ±0.01 Å) and, almost perpendicular (88.5°) to it, by the outer BC_4 rings, which are slightly puckered (±0.05 Å). The B−N units are planar indicating π interaction. The lengths of the B−C and B−N distances differ, which can be rationalized in terms of the other atoms connected to the boron atoms. The B−N distance at B2, bonded to C1 and C4, is slightly shorter than that at B1, which is bonded to O1 and C1′. The B−C distance involving an sp^2 carbon atom (B2−C4) is significantly shorter than those with sp^3 carbon atoms. In **12b** the same 5-membered ring is present, but instead of the 6-membered ring two independent groups are attached to C1, one of which [B(N*i*Pr$_2$)O] is similar to that part of

Figure 1. Molecular structure of **4b**[a]



[a] Selected bond lengths [Å] and angles [°]: C1−B1′ 1.592(2), C1−O1 1.481(2), C1−C2 1.557(2), C1−B2 1.624(2),O1−B1 1.368(2), B1−N1 1.422(2), B2−N2 1.397(2), B2−C2 1.569(2); C2−C1−B2 103.1(1), B1′−C1−O1 112.5(1), C1−B2−C4 105.1(2), C1−B1′−O1′ 121.2(1), C1−O1−B1 126.3(1).

[a] Selected bond lengths [Å] and angles [°]: C1−B1 1.617(2) C1−N3 1.548(2), C1−C2 1.556(2), C1−B2 1.6 29(2), O1−B1 1.376(2), B1−N1 1.416(2), B2−N2 1.402(2), B2−C2 1.562(2); C2−B1−B2 102.4(1), B1−C1−N3 106.0(1), C1−B2−C4 105.7(1), C1−B1−O1 115.9(1).

the ring in **4b**, while the other [$HN(C_6H_3Me_2)$] substitutes for the oxygen in **4b**. The distances exhibit the same range of values as found in **4b** and the angles are almost identical, apart from those around C1. The 5-membered ring is planar, in contrast to **4b** where the steric repulsion of the diisopropylamino group at B1 pushes the 5-membered ring towards O1 and causes the distortion of the ring which adopts a slight envelope form. In **12b** this is not possible, as the dimethylphenyl group at N3 does not allow a tipping of the ring, which remains planar and lies symmetrically between the two groups. The angles at C1 in **4b** also show the effect of the distortion. A rotation around the bond C1−N3 would suspend the steric repulsion of the dimethylphenyl group, but the hydrogen atom at O1 forms an intramolecular hydrogen bond with N3, hindering the rotation around C1−N3.

Support of this work by the *Deutsche Forschungsgemeinschaft* (SFB 247), the *Fonds der Chemischen Industrie*, and the *BASF AG* is gratefully acknowledged.

Experimental Section

All reactions and manipulations were performed in dry glassware under nitrogen by using standard Schlenk techniques. Solvents were distilled from appropriate drying agents under nitrogen before use. The commercial carbon monoxide was bubbled through KOH for drying. − $Et_2O \cdot BF_3$ was used as the external standard for ^{11}B NMR. Internal standards for ^1H and ^{13}C were the signals of the deuterium-labeled solvents. NMR: $CDCl_3$ and C_6D_6 solutions, Jeol-FX-90 and Bruker AC 200. − MS: Varian MAT CH7 and Finnigan Mat 8230. − The following starting materials were prepared by previously described methods: 1,2-bis(diisopropylamino)-2,5-dihydro-1*H*-1,2-diborole (**1b**)[3], 1,2-bis(diisopropylamino)-3-methylidene-1,2-diborolane (**1c**)[3], 1,2-bis(diisopropylamino)-1,2-benzodiboret (**6**)[9], 1,2,4-tris(diisopropylamino)-3,5-dimethyl-1,2,4-triboracyclopentane (**7**).[10]

1,7,9,14-Tetrakis(diisopropylamino)-6,13-dioxa-1,7,9,14-tetraboradispiro[4.2.4.2]tetradeca-2,10-diene (**4b**): CO was bubbled through a solution of 950 mg (3.6 mmol) of **1b** in 40 ml of THF at room temp. for 1 h. After 15 min, a colorless solid was formed. Filtration of the mixture and washing of the residue with THF and hexane yielded 520 mg (0.9 mmol, 50%) of **4b**, m.p. 282°C. The remaining **1b** in the filtrate can be used for further reactions. − ^1H NMR ($CDCl_3$, 200 MHz): δ = 0.86, 0.88, 0.89, 1.12, 1.15, 1.27 (m, 48 H), 2.75, 2.94, 3.25, 3.75 (sept, 8 H), 7.05 (d, 2 H, $^3J_{H,H}$ = 7.95 Hz), 6.19 (d, 2 H, $^3J_{H,H}$ = 7.95 Hz), 2.33 (d, 2 H, $^3J_{H,H}$ = 19.0 Hz), 2.70 (d, 2 H, $^3J_{H,H}$ = 19.5 Hz). − ^{11}B NMR ($CDCl_3$, 29 MHz): δ = 44 (C_2BN), 32 (CB(N)O). − ^{13}C NMR ($CDCl_3$, 50 MHz): δ = 23.0, 23.3, 23.6, 24.9, 25.5, 26.0, 26.4 ($CHCH_3$), 44.6, 45.3, 47.6, 49.3 (NCH), 32.5 (CCH_2C), 159.3 ($CCHC$), (CB not detected). − MS (EI), *m/z* (%): 580 (100) [M^+], 453 (85) [M^+ − $BON(CH(CH_3)_2)_2$], 289 (45) [$M^+/2$ − H], 43 (74) [$CH(CH_3)_2$]. − $C_{32}H_{64}O_2B_4N_4$ (580.1) calcd. C 66.25, H 11.12, N 9.66; found C 65.70, H 11.12, N 9.65.

1,7,9,14-Tetrakis(diisopropylamino)bismethylidene-6,13-dioxa-1,7,9,14-tetraboradispiro [4.2.4.2]tetradecane (**4c**): 700 mg (2.54 mmol) of **1c** were treated with CO as in the previous experiment. The workup furnished 440 mg (0.72 mmol, 44%) of the colorless solid **4c**, m.p. 289°C (decomp.). The product was almost insoluble in all organic solvents. − MS (EI), *m/z* (%): 608 (45) [M^+], 303 (27) [$M^+/2$ − H], 481 (36) [M+ − $BON(CH(CH_3)_2)_2$], 43 (73) [$CH(CH_3)_2$], 28 (100) [CO; C_2H_4]. − $C_{34}H_{68}O_2B_4N_4$ (608.2) calcd. C 67.15, H 11.27, N 9.21; found C 66.80, H 11.23, N 9.18.

2-tert-Butylimino-1,3-bis(diisopropylamino)-1,3-diboracyclohex-4-ene (**10b**): 415 mg (5 mmol) of *tert*-butyl isocyanide, dissolved in 20 ml of THF, was added to a solution of 1.30 g (5 mmol) of **1b** in 30 ml of THF at −30°C. After 15 h at room temp., the solvent was removed under vacuum. Distillation yielded 600 mg (2.3 mmol, 46%) of colorless **10b**, b.p. 63°C/5·10^{-2} Torr. − ^1H NMR (C_6D_6, 200 MHz): δ = 0.9−1.4 [br., 24 H, $CH(CH_3)_2$], 1.43 [s, 9 H, $C(CH_3)_3$], 2.21 (d, 2 H, BCH_2), 2.95 (m, 1 H, NCH), 3.18 (m, 1 H, NCH), 3.53 (m, 1 H, NCH), 4.81 (m, 1 H, NCH), 6.25 (d, br., 1 H, BCH), 6.85 (m, br., 1 H, CH_2CHCH). − ^{11}B NMR (C_6D_6, 64 MHz): δ = 40 (sh), 45.

1,3-Bis(diisopropylamino)-2-(2',6'-dimethylphenylimino)-1,3-diboracyclohex-4-ene (**11b**): A preparation analogous to **10b,** using 660 mg (5 mmol) of 2,6-dimethylphenyl isocyanide and 1.3 g (5 mmol) of **1b,** resulted in 900 mg (3.5 mmol, 69%) of colorless **11b**, b.p. 80°C/5·10^{-2} Torr. − ^1H NMR (C_6D_6, 200 MHz): δ = 0.8−1.4 [m, 24 H, $CH(CH_3)_2$], 2.11 (s, 6 H, H_3CAr), 2.21 (d, 2 H, $CHCHCH_2$), 3.15 [m, 3 H, $CH(CH_3)_2$], 4.5 [sept, 1 H, $CH(CH_3)_2$], 6.25 (d, 1 H, $BCHCH$), 6.9 (m, 1 H, $CHCHCH_2$), 6.95 (m, 3 H, C_6H_3). − ^{11}B NMR (C_6D_6, 64 MHz): δ = 40. − MS (EI), *m/z* (%): 394 (36) [M^+ + 1], 378 [M^+ − CH_3], 43 (100) [$CH(CH_3)_2$].

2-tert-Butylimino-1,3-bis(diisopropylamino)-4-methylidene-1,3-diboracyclohexane (**10c**): 1.4 g (5 mmol) of **1c** was treated with 415 mg (5 mmol) of *tert*-butyl isocyanide under the same reaction conditions as in the previous experiments to yield 300 mg (0.8 mmol, 16%) of **10c**, b.p. 75°C/5·10^{-2} Torr. − ^{11}B NMR (C_6D_6, 64 MHz)): δ = 39. − MS (EI), *m/z* (%): 360 (87) [M^+ + 1], 57 (100) [C_4H_9], 43 (89) [C_3H_7].

1,3-Bis(diisopropylamino)-2-(2',6'-dimethylphenylimino)-4-methylidene-1,3-diboracyclohexane (**11c**): The preparation analogous to **10b** using 1.4 g (5 mmol) of **1c** and 660 mg (5 mmol) of 2,6-dimethylphenyl isocyanide yielded 800 mg (1.8 mmol, 36%) of **11c**, b.p. 105°C/5·10^{-2} Torr. − ^1H NMR (C_6D_6, 200 MHz): δ = 0.93 [m, 6 H, $CH(CH_3)_2$], 1.2 (m, 2 H, CH_2CH_2C), 1.45 [m, 18 H, $CH(CH_3)_2$], 2.16 (s, 6 H, H_3CAr), 2.75(m, 2 H, BCH_2CH_2), 3.3 [m, 3 H, $CH(CH_3)_2$], 3.95 [m, 1 H, $CH(CH_3)_2$], 5.2 (m, 1 H, $C=CH_2$), 7.00 (m, 1 H, $C=CH_2$), 7.06 (m, 3 H, C_6H_3). − ^{11}B NMR (C_6D_6, 64 MHz): δ = 38.

1-(Diisopropylamino)-2-(diisopropylaminohydroxyboryl)-2-(2',6'-dimethylphenylamino)-1-boracyclopent-3-ene (**12**): 390 mg (1 mmol) of **11c** and 33 mg (0.1 mmol) of $Na_2SO_4 \cdot\cdot 10\ H_2O$, dissolved in 50 ml of THF, were refluxed for 2 h. The hot solution was filtered through a G3 sintered-glass funnel. Crystallisation from a THF solution at 5°C gave 220 mg (0.5 mmol, 50%) of **12**, m.p. 60°C. − ^{11}B NMR (C_6D_6, 64 MHz): δ = 38.

Crystal-Structure Determinations of **4b** *and* **12b**: Crystal data and details of the structure determinations are listed in Table 1. Unique sets of intensity data were collected at −70°C with a four-circle diffractometer (Mo-K_α radiation λ = 0.7107 Å, graphite monochromator, ω scan). An empirical absorption correction (ψ scans) was applied. The structures were solved by direct methods [SHELXS86][15] and refined by least-squares methods based on F^2 with all measured reflections [SHELXL97].[16] All non-hydrogen atoms were refined anisotropically. Hydrogen atoms were included in calculated positions (CH in **4b**), or as part of the rigid group (CH_3 in **4b** and **12b**). All other hydrogen atoms were located in difference Fourier maps and refined.

Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with the Cam-

Boryl- and Bridging Boryleneiron Complexes from Aminodichloroboranes

Holger Braunschweig*, Carsten Kollann, and Ulli Englert

Institut für Anorganische Chemie der Technischen Hochschule,
Templergraben 55, D-52056 Aachen, Germany
E-mail: holger.braunschweig@ac.rwth-aachen.de

Recieved October 30, 1997

Keywords: Boron / Iron / Boryl complexes / Borylene complexes / Iron−boron bond

Depending on the nature of the amino group bound to the boron atom, the reactions of various aminodichloroboranes R_2NBCl_2 with $Na[(\eta^5\text{-}C_5R'_5)Fe(CO)_2]$ yield either boryl or bridging borylene complexes of iron. The compounds $[(C_5R'_5)(CO)_2Fe\{BCl(NR_2)\}]$ (**1a**, $C_5R'_5 = C_5H_5$, R = Me; **1b**, $C_5R'_5 = C_5H_4Me$, R = Me; **1c**, $C_5R'_5 = C_5Me_5$, R = Me) and $[(\eta\text{-}BNR_2)(\mu\text{-}CO)\{(C_5R'_5)Fe(CO)\}_2]$ (**2a**, $C_5R'_5 = C_5H_5$, R = $SiMe_3$; **2b**, $C_5R'_5 = C_5H_4Me$, R = $SiMe_3$) were isolated as orange (**1a−c**) or red (**2a**, **b**) crystalline solids, and characterized by multinuclear NMR methods and IR spectroscopy. The structures of **1c** and **2b** in the crystalline state were determined by single-crystal X-ray studies.

Since 1990, when the first transition-metal complex with a two-center, two-electron bond between the metal and a threefold coordinated boron atom was structurally characterized[1], such boryl complexes have become of increasing interest, as they are known to be important intermediates in transition-metal-catalyzed hydroboration[2][3][4], and, very recently, the selective functionalization of alkanes in terminal position was achieved by photolysis of a boryl-tungsten complex[5]. During the last seven years a large number of structurally authentic boryl complexes have been described and the 1,2-dioxobenzo or "catechol" group, as ligand to boron, has had a pivotal role in obtaining these compounds, since most of them were either obtained by the reaction of an anionic transition-metal complex with CatBCl (Cat = 1,2-$O_2C_6H_4$)[6a][6b][6c][6d], or by oxidative addition of CatBH or CatBBCat to a suitable transition-metal center[7a][7b][7c][7d][7e][7f].

In contrast to the well-developed chemistry of boryl transition metal complexes, knowledge about the corresponding borylene complexes is restricted to only one example (and derivatives of this). Originally, this compound, a bridging dinuclear manganese complex, was obtained by an unprecedented and unexpected reaction of different diboranes(4) with $Na[(C_5H_4Me)Mn(SiMePh_2)(CO)_2]$[8]; more recently, the syntheses of these highly unusual compounds has been significantly improved by employing the corresponding manganese hydride complex $Na[(C_5H_4Me)MnH(CO)_2]$[9]. Interestingly, the borylene complexes of the type $[\eta\text{-}BX\{(C_5H_5)Mn(CO)_2\}_2]$ (X = NMe_2, Cl), undergo substitution reactions at the boron atom with preservation of the central Mn_2B core[10]. Due to their kinetic lability[11], however, boryl complexes generally react with cleavage of the boryl moiety[6a][6d][7e][11], regardless of the strength of the metal−boron bond, which in certain cases was calculated to be stronger than corresponding metal−carbon bonds[12a][12b].

In the course of our investigations on transition-metal complexes of boron with alternative boron-bound ligands[13a][13b], we report on the reactions of different aminodichloroboranes R_2NBCl_2 with $Na[(\eta^5\text{-}C_5R'_5)Fe(CO)_2]$ to yield amino-substituted boryl or bridging borylene complexes of iron.

Results and Discussion

The reaction of $Na[(\eta^5\text{-}C_5R'_5)Fe(CO)_2]$ with Me_2NBCl_2 in benzene at room temperature according to Scheme 1 affords the aminoboryl complexes $[(C_5R'_5)(CO)_2Fe\{BCl(NR_2)\}]$ (**1a**, $C_5R'_5 = C_5H_5$, R = Me; **1b**, $C_5R'_5 = C_5H_4Me$, R = Me; **1c**, $C_5R'_5 = C_5Me_5$, R = Me).

The products were obtained from hexane at −30°C as air- and moisture-sensitive dark-orange materials in yields

 © WILEY-VCH Verlag GmbH, D-69451 Weinheim, 1998 1434−1948/98/0404−0465 $ 17.50+.50/0

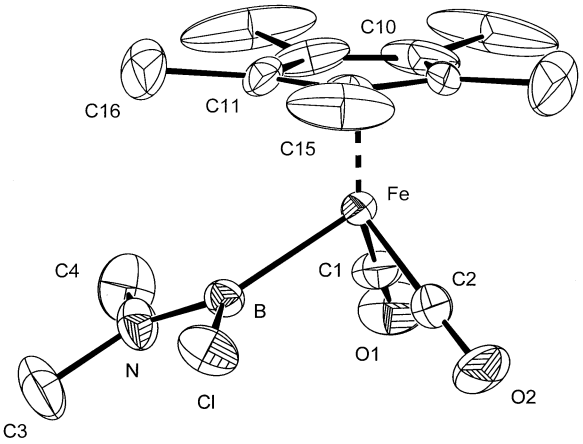
of up to 65%. While **1a**, **c** show melting points of 35°C and 120°C, respectively, **1b** proved to be an oil at room temperature. As might be expected, the spectroscopic data of **1a**−**c** in solution are to some extent related to those of the corresponding diborane(4)yl complex $[(C_5H_5)Fe(CO)_2\{B_2(NMe_2)_2Cl\}]$[13a]. The ^{1}H- and ^{13}C-NMR spectra show double sets of signals for the dimethylamino group, due to the restricted rotation with respect to the B−N double bond. In the case of **1b** the variable-temperature ^{1}H-NMR studies show a coalescence of the two corresponding resonances at 83°C, from which a value for the rotation barrier of $\Delta G^{\neq} = 72.3$ kJ/mol can be calculated. This is in the range expected for aminosubstituted boranes[14a][14b]. The formation of the boron−iron bond results in characteristically deshielded ^{11}B-NMR signals at $\delta = 56.4$ (**1a**), 56.9 (**1b**), and 59.1 (**1c**), which are shifted to low field with respect to the signal of Me_2NBCl_2 at $\delta = 30.5$[15]. For a similar boryliron complex, $[CpFe(CO)_2BCat]$ (Cat = 1,2-$O_2C_6H_4$), a modest Fe−B π bonding in solution was deduced from the high CO stretching frequencies at 2024 cm^{-1} and 1971 cm^{-1}[6c]. In the case of **1a**−**c** the IR spectra gave no evidence for a metal−boron backbonding, since the CO stretching frequencies (**1a**, 2005 cm^{-1}, 1946 cm^{-1}; **1b**, 2002 cm^{-1}, 1944 cm^{-1}; **1c**, 1988 cm^{-1}, 1928 cm^{-1}) are equal to, or even lower than, those for the corresponding alkyliron complexes at 1999−2005 cm^{-1} and 1938−1944 cm^{-1}[16]. So far this finding is true for all fully characterized nitrogen-substituted boryliron complexes, e.g. $\{(C_5H_5)Fe(CO)_2[B_2(NMe_2)_2Cl]\}$[13a] and $\{[(C_5H_4Me)Fe(CO)_2]_2ClB_3N_3H_3\}$[13b].

As a representative of the new complexes, an X-ray structure analysis was carried out for $[(C_5Me_5)(CO)_2Fe\{BCl(NMe_2)\}]$ (**1c**) (Figure 1). Suitable crystals of **1c** were obtained, after some days, from solutions in hexane at −30°C. The complex crystallizes in the noncentrosymmetric space group $P2_12_12_1$, and the molecule adopts C_1 symmetry in the crystal. The almost perpendicular orientation (87.4°) of the N−B−Cl plane with respect to the Cp(centroid)−Fe−B plane provides no evidence for an iron−boron π interaction in the crystalline state[6c][17]. This is supported by an Fe−B distance of 202.7(5) pm, which is significantly longer than that in $[CpFe(CO)_2BCat]$ [195.6(6) pm]. For the latter compound a π interaction in the solid state is facilitated by the different orientation of the boryl ligand[6c]. A boron−nitrogen double bond, already established for the aminoboryl complexes **1a**−**c** in solution, is also found for **1c** in the crystal, as indicated by a B−N distance of 137.7(6) pm.

The corresponding bridging borylene complexes $[(\eta\text{-}BNR_2)(\mu\text{-}CO)\{(C_5R'_5)Fe(CO)\}_2]$ (**2a**, $C_5R'_5 = C_5H_5$, R = $SiMe_3$; **2b**, $C_5R'_5 = C_5H_4Me$, R = $SiMe_3$) were obtained by a similar reaction of $[(Me_3Si)_2N]BCl_2$ at room temperature with two equivalents of $Na[(C_5R'_5)Fe(CO)_2]$ in benzene (Scheme 2).

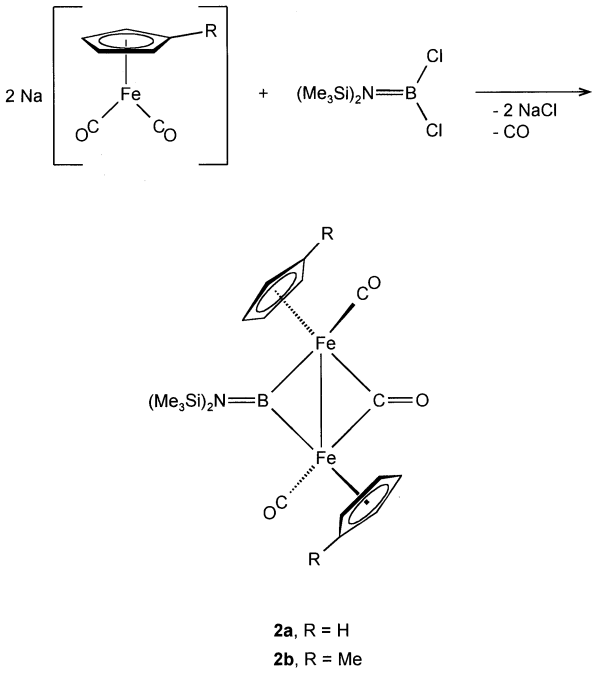
The products, which are formed with loss of one CO group from the initial iron complex, were isolated from hexane at low temperatures as dark-red solids in yields of about 25%, and proved to be extremely sensitive to air and moisture. This is in contrast to the known characteristics of the related borylenemanganese complex $[(\eta\text{-}BNMe_2)\{(C_5H_5)Mn(CO)_2\}_2]$[10]. Interestingly the formation of the borylene complexes **2a**, **b**, as the only boron-containing products, was observed under all conditions, even with an excess of $[(Me_3Si)_2N]BCl_2$, while the reaction of Me_2NBCl_2 with $Na[(C_5R'_5)Fe(CO)_2]$ always led to the formation of the boryl complexes $[(C_5R'_5)(CO)_2Fe\{BCl(NR_2)\}]$ (**1a**, $C_5R'_5 = C_5H_5$, R = Me; **1b**, $C_5R'_5 = C_5H_4Me$, R = Me; **1c**, $C_5R'_5 = C_5Me_5$, R = Me). In the latter cases a further exchange of a boron-bound chloride ligand could not be achieved. We attribute this result to the electronic influence of the silyl groups, which despite their size make the $[(Me_3-$

Figure 1. Structure of **1c** in the crystal (ellipsoids at 30% probability[25])[a]



[a] Selected distances [pm] and angles [°]: Fe−B 202.7(5), B−N 137.7(6), B−Cl 183.4(5), Fe−centroid 173.5(1); Fe−B−Cl 116.0(2), Fe−B−N 131.9(4), Cl−B−N 112.0(3).

Scheme 2



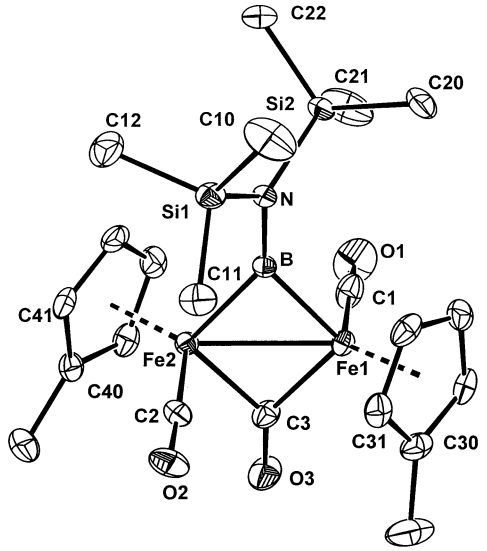
2a, R = H
2b, R = Me

$Si)_2N]BCl_2$ more reactive by weakening the boron−nitrogen double bond.

The structure of **2a**, **b** in solution is derived from the NMR and IR spectra. Due to the formation of two iron−boron linkages the borylene complexes show ^{11}B-NMR signals at $\delta \approx 119$. These are significantly shifted to low field with respect to the signals found for the boryl complexes **1a**−**c**. The IR and ^{13}C-NMR data resemble those of the isoelectronic vinylidenediiron complexes, where the presence of one bridging and two terminal CO groups has already been established[18].

Suitable single crystals of **2b** were obtained in a similar manner to those of **1c**, and the results of the X-ray structure analysis (Figure 2) showed that the compound crystallizes in the monoclinic space group $P2_1/c$.

Figure 2. Structure of **2b** in the crystal (ellipsoids at 30% probability[25])[a]



[a] Selected distances [pm] and angles [°]: Fe1−Fe2 254.8(1), Fe1−B 200.7(3), Fe2−B 200.2(3), B−N 141.2(4), Fe1−centroid1 175.5, Fe2−centroid2 174.6; Fe1−B−Fe2 78.9(1), Fe1−C3−Fe2 83.6(1).

In the crystal the borylene complex **2c** shows a *trans* orientation of the MeC_5H_4 and CO groups with respect to the Fe_2B unit. These three atoms form an isosceles triangle with Fe−B distances of 200.7(3) and 200.2(3) pm, and an Fe−Fe distance of 254.8(1) pm. Obviously, the Si1−B−Si2 plane is twisted by 53.7(1)° with respect to the Fe1−B−Fe2 plane due to the bulky Me_3Si groups. Hence, in connection with the extended B−N distance of 141.2(4) pm, a less effective backbonding from the nitrogen to the boron atom can be assumed. The overall molecular structure of **2c** resembles that of the structurally characterized vinylidenediiron complexes[18].

Conclusion

This study presents the synthesis and characterization in solution and in the crystal of various amino-substituted boryl and bridging borylene complexes of the type $[(C_5R'_5)(CO)_2Fe\{BCl(NR_2)\}]$ (**1a**, $C_5R'_5 = C_5H_5$, R = Me; **1b**, $C_5R'_5 = C_5H_4Me$, R = Me; **1c**, $C_5R'_5 = C_5Me_5$, R = Me) and $[(\eta\text{-}BNR_2)(\mu\text{-}CO)\{(C_5R'_5)Fe(CO)\}_2]$ (**2a**, $C_5R'_5 = C_5H_5$, R = $SiMe_3$; **2b**, $C_5R'_5 = C_5H_4Me$, R = $SiMe_3$). The formation of the products is obviously dominated by electronic rather than steric criteria, since the more bulky, but also more electrophilic, $[(Me_3Si)_2N]BCl_2$ yields the borylene complexes **2a**, **b** by substitution of both boron-bound chloride ligands by $[(\eta^5\text{-}C_5R'_5)Fe(CO)_2)]$ moieties, whereas the boryl complexes **1a**−**c** are formed from Me_2NBCl_2 by substitution of only one chloride ligand. These results show that aminodichloroboranes may serve as the starting materials for different types of transition-metal complexes of boron, and that the access to bridging borylene complexes is no longer restricted to the use of diborane(4) derivatives.

Experimental Section

All manipulations were carried out under dry nitrogen in Schlenk glassware. Solvents and reagents were dried by standard procedures, distilled and stored under nitrogen and molecular sieves. $Na[(\eta^5\text{-}C_5R_5)Fe(CO)_2]$[19], Me_2NBCl_2[20], and $[(Me_3Si)_2N]BCl_2$[21] were synthesized according to the literature. − NMR: Varian Unity 500 at 499.843 (^{1}H, standard TMS internal), 150.364 (^{11}B, standard $BF_3\cdot OEt_2$ in C_6D_6 external), 125.639 MHz ($^{13}C\{^1H\}$, APT, standard TMS internal); all NMR spectra were recorded in C_6D_6 as solvent. − Elemental analyses (C, H, N): Carlo-Erba elemental analyzer, model 1106. − IR: Perkin-Elmer FT-IR 1720x.

[Dicarbonyl{chloro(dimethylamino)boryl}(η^5-cyclopentadienyl)iron] (**1a**): 1.92 g (9.60 mmol) of $Na[(C_5H_5)Fe(CO)_2]$ was suspended in 50 ml of benzene and 1.21 g (9.60 mmol) of Me_2NBCl_2 was added dropwise by a syringe at ambient temp. After stirring for 20 min, all volatiles were removed in vacuo and the solid residue was treated with 40 ml of hexane, filtered, and the remaining solid washed with 20 ml of hexane, 1.65 g (65%) of **1a** was recovered from the filtrate at −30°C as orange crystals, m.p. 35°C. − ^{1}H NMR: δ = 2.70 (s, 3 H, NMe), 2.91 (s, 3 H, NMe), 4.11 (s, 5 H, C_5H_5). − ^{11}B NMR: δ = 56.4. − ^{13}C NMR: δ = 41.14 (NMe), 43.60 (NMe), 83.80 (C_5H_5), 215.76 (CO). − IR (toluene): $\tilde{\nu}$ = 2006 cm^{-1}, 1946 (CO). − $C_9H_{11}BClFeNO_2$ (267.29): calcd. C 40.44, H 4.15, N 5.24; found C 39.88, H 4.32, N 5.30.

[Dicarbonyl{chloro(dimethylamino)boryl}(η^5-methylcyclopentadienyl)iron] (**1b**): As described for **1a**, 0.93 g (4.35 mmol) of $Na[(C_5H_4Me)Fe(CO)_2]$ was treated with 0.55 g (4.35 mmol) of Me_2NBCl_2, and 0.78 g (64%) of **1b** was obtained as a dark orange oil by evaporating the filtrate in vacuo. − ^{1}H NMR: δ = 1.57 (s, 3 H, C_5H_4Me), 2.77 (s, 3 H, NMe), 2.93 (s, 3 H, NMe), 4.09 (m, 4 H, C_5H_4Me). − ^{11}B NMR: δ = 56.9. − ^{13}C NMR: δ = 12.90 (C_5H_4Me), 41.17 (NMe), 43.66 (NMe), 82.55, 84.62, 101.28 (C_5H_4Me), 216.19 (CO). − IR (toluene): $\tilde{\nu}$ = 2002 cm^{-1}, 1944 (CO). − $C_{10}H_{13}BClFeNO_2$ (281.33): calcd. C 42.69, H 4.66, N 4.98; found C 42.06, H 4.85, N 4.72.

[Dicarbonyl{chloro(dimethylamino)boryl}(η^5-pentamethylcyclopentadienyl)iron] (**1c**): As described for **1a**, 0.24 g (0.90 mmol) of $Na[(C_5Me_5)Fe(CO)_2]$ was treated with 0.11 g (0.90 mmol) of Me_2NBCl_2, and 0.17 g (55%) of **1c** was obtained as orange crystals, m.p. 120°C. − ^{1}H NMR: δ = 1.53 (s, 15 H, C_5Me_5), 2.87 (s, 3 H, NMe), 2.96 (s, 3 H, NMe). − ^{11}B NMR: δ = 59.1. − ^{13}C NMR: δ = 9.76 (C_5Me_5), 41.37 (NMe), 43.82 (NMe), 95.23 (C_5Me_5), 217.60 (CO). − IR (toluene): $\tilde{\nu}$ = 1988 cm^{-1}, 1928 (CO). −

$C_{14}H_{21}BClFeNO_2$ (337.42): calcd. C 49.83, H 6.27, N 4.15; found C 49.68, H 6.52, N 4.13.

[μ-{Bis(trimethylsilyl)aminoboranediyl}-bis{(η⁵-cyclopentadienyl)dicarbonyliron}Fe-Fe] (**2a**): As described for **1a**, 2.69 g (13.45 mmol) of $Na[(C_5H_5)Fe(CO)_2]$ were reacted with 1.30 g (5.38 mmol) of $[(Me_3Si)_2N]BCl_2$ and 0.70 g (26%) of **2a** isolated as dark red crystals. – ^{1}H NMR: δ = 0.32 (s, 18 H, $SiMe_3$), 4.41 (s, 10 H, C_5H_5). – ^{11}B NMR: δ = 118.4 . – ^{13}C NMR: δ = 4.75 ($SiMe_3$), 87.75 (C_5H_5), 215.52 (CO), 276.63 (μ-CO). – IR (hexane): $\tilde{\nu}$ = 1924 cm^{-1}, 1770 (CO). – $C_{19}H_{28}BFe_2NO_3Si_2$ (497.11): calcd. C 45.90, H 5.68, N 2.82; found C 45.84, H 5.80, N 2.67.

[μ-{Bis(trimethylsilyl)aminoboranediyl}bis{dicarbonyl(η⁵-methylcyclopentadienyl)iron}Fe–Fe] (**2b**): As described for **1a**, 1.76 g (8.23 mmol) of $Na[(C_5H_4Me)Fe(CO)_2]$ was treated with 0.99 g (4.11 mmol) of $[(Me_3Si)_2N]BCl_2$ and 0.86 g (25%) of **2b** isolated as dark-red crystals. – ^{1}H NMR: δ = 0.36 (s, 18 H, $SiMe_3$), 1.96 (s, 6 H, Me), 4.01–4.61 (br., 8 H, C_5H_4). – ^{11}B NMR: δ = 119.1. – ^{13}C NMR: δ = 4.82 ($SiMe_3$), 12.29 (C_5H_4Me), 84.39, 85.09, 88.30, 90.35, 103.73 (C_5H_4Me), 215.83 (CO), 279.26 (μ-CO). – IR (hexane): $\tilde{\nu}$ = 1925 cm^{-1}, 1770 (CO). – $C_{21}H_{32}BFe_2NO_3Si_2$ (525.14): calcd. C 48.03, H 6.14, N 2.67; found C 48.30, H 6.28, N 2.61.

X-ray Structure Determination for **1c**: $C_{14}H_{21}BClFeNO_2$, M = 337.44 g mol^{-1}, crystal data a = 8.2617(6), b = 9.915(1), c = 20.100(3) Å, V = 1646.5(3) Å^3, orthorhombic, $P2_12_12_1$ (No. 19), Z = 4, $\rho_{calcd.}$ = 1.361 g cm^{-3}, μ(Mo-K_α) = 10.77 cm^{-1}, F(000) = 704. Orange platelet, crystal size [mm] 0.6 × 0.6 × 0.4. ENRAF-Nonius CAD4; Mo-K_α radiation (λ = 0.7107 Å, graphite monochromator); intensity data from ω-2-Θ scans at 203 K. 7812 reflections in the range 3° < Θ < 27°, structure solution[23] with 3592 independent reflections, refinement[24] with 2819 observations with $I > \sigma(I)$ for 181 variables; H atoms were included as riding in idealized geometry [C–H = 98 pm, U_{iso}(H) = 1.3 · U_{eq}(C)]. Pronounced anisotropic displacement parameters were encountered for the carbon atoms in the pentamethylcyclopentadienyl ring and these indicate librational or static disorder of this moiety. Convergence at R = 0.051, R_w = 0.056, $w^{-1} = \sigma^2(F_o)$. Received November 4, 1997

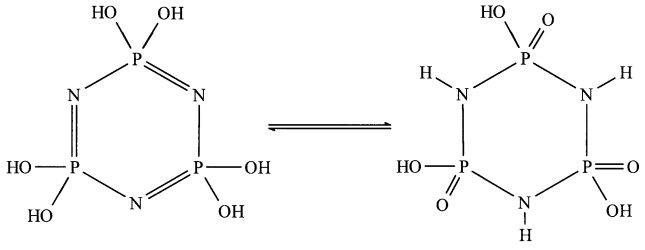
Keywords: Cage compounds / Crystal structure / Hafnium / Trimetaphosphimates / Zirconium

The (trimetaphosphimato)hafnates and -zirconates $Na_4\{Hf_4(\mu_4\text{-}O)(\mu\text{-}OH)_6[(PO_2NH)_3]_4\}\cdot 18\ H_2O$ [**1**, $Pa\bar{3}$, a = 22.687(3) Å, Z = 8], $Na_4\{Hf_4(\mu_4\text{-}O)(\mu\text{-}OH)_6[(PO_2NH)_3]_4\}\cdot 21\ H_2O$ [**2**, $R\bar{3}$, a = 14.350(2), c = 50.348(10) Å, Z = 6], $Na_4\{Zr_4(\mu_4\text{-}O)(\mu\text{-}OH)_6[(PO_2NH)_3]_4\}\cdot 18\ H_2O$ [**3**, $Pa\bar{3}$, a = 22.693(3) Å, Z = 8], and $Na_4\{Zr_4(\mu_4\text{-}O)(\mu\text{-}OH)_6[(PO_2NH)_3]_4\}\cdot 21\ H_2O$ [**4**, $R\bar{3}$, a = 14.303(2), c = 50.284(10) Å, Z = 6] were obtained by the stoichiometric reaction of $HfOCl_2\cdot 8\ H_2O$ and $ZrOCl_2\cdot 8\ H_2O$ with an aqueous solution of $Na_3(PO_2NH)_3\cdot 4\ H_2O$, followed by the diffusion-controlled addition of methanol. During these reactions compounds **1** and **2**, or **3** and **4**, crystallized simultaneously and the hafnium and zirconium complexes **1** and **3**, as well as **2** and **4**, were found to be isostructural and isomorphous. The characteristic structural feature which is central to **1**, **2**, **3**, and **4** is the complex tetranuclear anion $\{M_4(\mu_4\text{-}O)(\mu\text{-}OH)_6[(PO_2NH)_3]_4\}^{4-}$ with M = Zr or Hf. The anion consists of five corner-sharing adamantanoid cages. The central cage, $\{M_4(\mu_4\text{-}O)(\mu\text{-}OH)_6\}^{8+}$, has a tetracoordinated oxygen atom in the middle, and the other cages are formed by the trimetaphosphimate ions acting as tridentate ligands which coordinate to Hf or Zr. The water content of the compounds **1**−**4** could not be determined unequivocally by chemical analyses since the compounds are always obtained as mixtures of the rhombohedral (**2/4**) and cubic (**1/3**) phases. Thermal decomposition of compounds **1**−**4** starts above 120 °C and leads to the formation of HfP_2O_7 and ZrP_2O_7/$NaZr_2(PO_4)_3$, with the evolution of H_2O and NH_3. DSC measurements gave no evidence that the compounds **1** and **2,** or **3** and **4**, might be transformed into each other by heating.

In contrast to the cyclotrimetaphosphates[1], whose structures have been well investigated, little is known concerning the X-ray-crystallographic results of the cyclotrimetaphosphimates (tri-μ-imidocyclotriphosphates), although the first synthesis of cyclotrimetaphosphimates was described in 1896.[2] Since there is the possibility of tautomeric forms, $[P(NH)O_2]_3^{3-}$ and $[PNO(OH)]_3^{3-}$, these compounds have been investigated intensively using IR spectroscopy,[3] but until now only a few crystal structures of the trimetaphosphimates have been known.[4] The two tautomeric forms of trimetaphosphimic acid are shown in Figure 1. IR spectroscopy, as well as single-crystal structure analyses, have confirmed the existence of the μ-imido form in both the solid state and solution. In principle coordination by both nitrogen and oxygen is possible, but up to the present exclusively coordination via oxygen has been found. Nevertheless, interactions between Ag and N are observed in $Ag_3(PO_2NH)_3$, leading to a strong distortion of the P_3N_3 ring.[4c] This interaction is also confirmed by the existence of $Ag_6(PO_2N)_3$, which was first described by Stokes;[2] however, the crystal structure has not yet been determined. The trimetaphosphimate ion can act as a monodentate ligand in combination with monovalent ions such as Na^+, K^+, Ag^+, NH_4^+, or $C(NH_2)_3^+$,[4] as bidentate and bridging ligand with the divalent ions Cu^{2+}, Co^{2+}, Zn^{2+} in $Na_4\{Cu[(PO_2NH)_3]_2\}\cdot 10\ H_2O$ and $Na\{M(PO_2NH)_3\}\cdot 7\ H_2O$ (M = Zn, Co),[5] as a tridentate ligand with Ga^{3+} in $Na_3\{Ga[(PO_2NH)_3]_2\}\cdot 12\ H_2O$,[6] and as tridentate and bridging ligand in $K_{1.3}(NH_4)_{1.7}\{Pr[(PO_2NH)_3]_2\}\cdot 8\ H_2O$.[7]

Figure 1. Tautomeric forms of trimetaphosphimic acid $H_3(PO_2NH)_3$



Because of the interesting properties of zirconium phosphates and zirconium phosphorus oxide nitrides, which means that they can be used as ion exchangers and catalysts,[8][9] we investigated the reaction of $Na_3(PO_2NH)_3\cdot 4H_2O$ with zirconium or hafnium salts, and the use of these trimetaphosphimates as nitrogen-containing precursors for the synthesis of oxonitridophosphates.

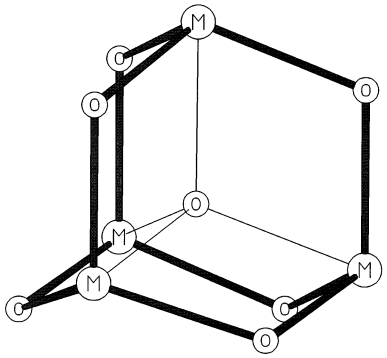
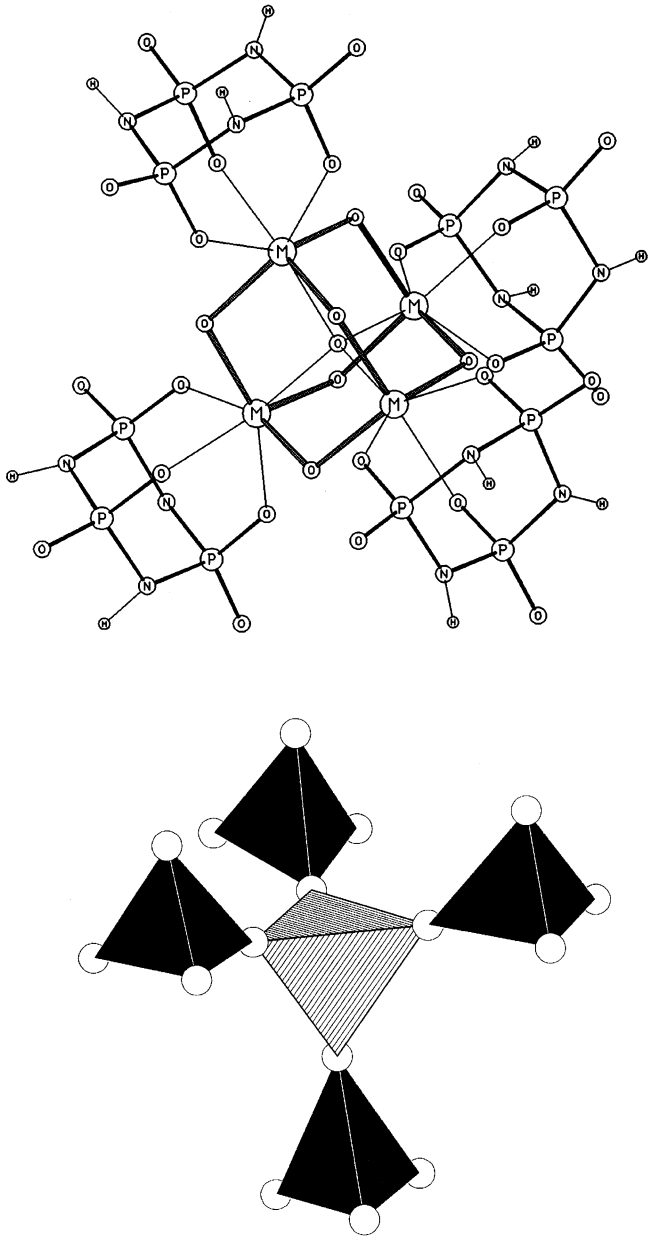
Figure 2. Adamantanoid metal-oxygen cage in the $[M_4(\mu_4\text{-}O)(\mu\text{-}OH)_6]^{8+}$ core (M = Zr, Hf)



Results

The reaction of $Na_3(PO_2NH)_3 \cdot 4\ H_2O$ with $HfOCl_2 \cdot 8\ H_2O$ or $ZrOCl_2 \cdot 8\ H_2O$, leads to the formation of the four new compounds $Na_4\{Hf_4(\mu_4\text{-}O)(\mu\text{-}OH)_6[(PO_2NH)_3]_4\} \cdot 18\ H_2O$ (**1**), $Na_4\{Hf_4(\mu_4\text{-}O)(\mu\text{-}OH)_6[(PO_2NH)_3]_4\} \cdot 21\ H_2O$ (**2**), $Na_4\{Zr_4(\mu_4\text{-}O)(\mu\text{-}OH)_6[(PO_2NH)_3]_4\} \cdot 18\ H_2O$ (**3**) and $Na_4\{Zr_4(\mu_4\text{-}O)(\mu\text{-}OH)_6[(PO_2NH)_3]_4\} \cdot 21\ H_2O$ (**4**) which are always obtained as mixtures (**1/2** and **3/4**) of the rhombohedral (**2/4**) and cubic (**1/3**) phases. The respective Zr and Hf compounds (**1/3** and **2/4**) are isotypic and isomorphous, with distinct crystals of cubic and rhombohedral habit. The characteristic structural feature of all four compounds are the tetranuclear complex anions $\{M_4(\mu_4\text{-}O)(\mu\text{-}OH)_6[(PO_2NH)_3]_4\}^{4-}$ with M = Hf, Zr. Despite the topologically differing crystal structures of **1/3** (cubic phase) and **2/4** (rhombohedral phase) the anions $\{M_4(\mu_4\text{-}O)(\mu\text{-}OH)_6[(PO_2NH)_3]_4\}^{4-}$ have almost exactly the same topology in both cases. The cores of the $\{M_4(\mu_4\text{-}O)(\mu\text{-}OH)_6[(PO_2NH)_3]_4\}^{4-}$ ions consist of a slightly distorted tetrahedral arrangement of the transition metal, Hf or Zr (Table 1), with six edge-bridging OH groups (μ-OH) and one tetracoordinated O atom (μ_4-O) at the center of the M_4 tetrahedron, thus forming an adamantanoid cage $M_4(\mu_4\text{-}O)(\mu\text{-}OH)_6^{8+}$ as shown in Figure 2. The H atoms of the bridging μ-OH groups have not been localized, but on the basis of the analytical results which show the molar ratio to be Na/P/N/M = 1:3:3:1 for all four compounds, the μ-OH groups have to be assumed to be connecting the Zr and Hf atoms. In addition to this centered cage, four more adamantanoid cages are formed by tridentate coordination of the trimetaphosphimate ions, $(PO_2NH)_3^{3-}$, to the metal ions. The trimetaphosphimate ions exhibit the chair conformation and are bound to the metal centers through the three oxo groups. The entire complex ion $\{M_4(\mu_4\text{-}O)(\mu\text{-}OH)_6[(PO_2NH)_3]_4\}^{4-}$, consisting of five corner-linked adamantanoid cages, is shown in Figure 3. Similar to monoclinic ZrO_2 (baddeleyite), and one polymorphic form of HfO_2, the metal atoms exhibit the coordination number seven. The anions have the crystallographic symmetry C_3 with the tetracoordinated oxygen atom and one of the metal atoms (M2, M = Hf, Zr) situated on the threefold axes. The M−O bond lengths of the adamantanoid central cages in **1**−**4** (Table 1) compare well with the average bond lengths

Figure 3. View of the $\{M_4(\mu_4\text{-}O)(\mu\text{-}OH)_6[(PO_2NH)_3]_4\}^{4-}$ ions (M = Hf, Zr) in the cubic phase and rhombohedral phase [top: ball-stick model; bottom: polyhedron formed by metal (grey) and P atoms (white)]



in corresponding compounds which have a coordination number of seven $\{[Zr_4(\mu_4\text{-}O)(\mu\text{-}O\mathit{n}Pr)_6]^{8+}$/Zr−O: 215−223 pm[10], monoclinic HfO_2: 203−225 pm[11], monoclinic ZrO_2: 205−227 pm[12]$\}$. The $M_4(\mu_4\text{-}O)(\mu\text{-}OH)_6^{8+}$ cage is only slightly distorted from the ideal tetrahedral symmetry. Unlike the situation for the trimetaphosphimato zirconates, where the distortion of the $Zr_4(\mu_4\text{-}O)(\mu\text{-}OH)_6^{8+}$ cage in the cubic phase (**3**) is slightly smaller than in the rhombohedral phase (**4**), the opposite is found for the distortion of the $Hf_4(\mu_4\text{-}O)(\mu\text{-}OH)_6^{8+}$ cages in the (trimetaphosphimato)hafnates **1** and **2** (Table 1). Therefore, within the accuracy of the measurements, the metal atoms of the central ada-

mantanoid cage $M_4(\mu_4\text{-}O)(\mu\text{-}OH)_6^{8+}$ in **1** and **4** exhibit the ideal tetrahedral symmetry.

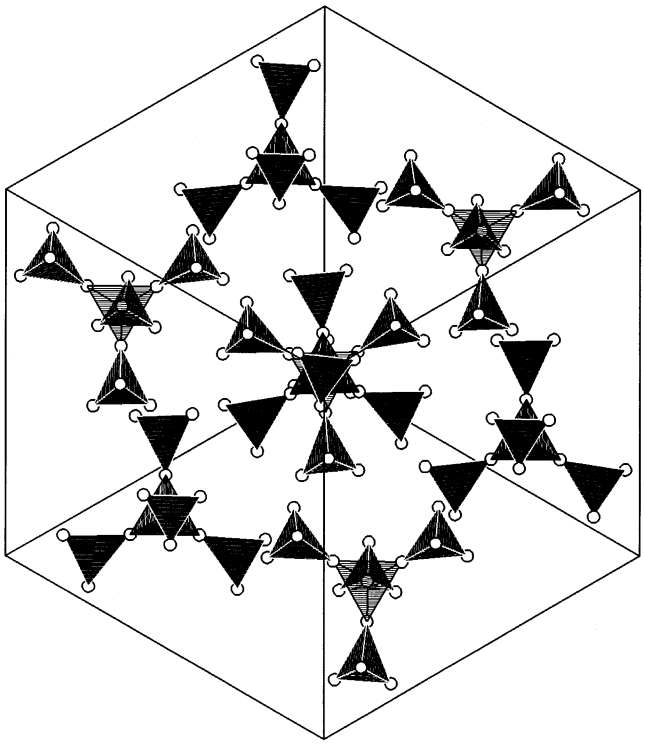
The trimetaphosphimate rings in $\{M_4(\mu_4\text{-}O)(\mu\text{-}OH)_6[(PO_2NH)_3]_4\}^{4-}$ M = Zr, Hf exhibit the chair conformation. The average P−O bond lengths of the oxygen atoms (O1A to O4A) coordinating to the metal (Zr: 152.1, 151.7 pm and Hf: 151.8, 152.1 pm for the cubic and the rhombohedral phase, respectively) are significantly longer than the average P−O bond lengths of oxygen atoms (O1B to O4B) coordinating to Na^+ or water molecules (Zr: 148.0, 147.7 pm and Hf: 147.7, 148.2 for the cubic and the rhombohedral phase, respectively). These values, as well as the corresponding P−N bond lengths and angles, differ only slightly among the compounds **1**, **2**, **3**, and **4**. Thus, the average P−N bond length is 167.6 pm and the average P−N−P angle is 118.4°. These findings are in accordance with the results obtained from trimetaphosphimates of monovalent cations, where there is a larger range of values but they are nevertheless similar to the results obtained in this work. The μ-imido H atoms have been unambiguously located in all four compounds by difference Fourier analyses. In comparison to other trimetaphosphimates these μ-imido groups are structurally directing, by forming hydrogen bonds between the trimetaphosphimate rings as can be

seen by comparing the structures of analogous trimetaphosphates with the corresponding trimetaphosphimates.[4] In the latter compounds the N−H groups of the $(PO_2NH)_3^{3-}$ are usually involved in extensive hydrogen-bonding interactions, forming a three-dimensional network in $(NH_4)_3(PO_2NH)_3 \cdot H_2O$[4a], bilayers in $Ag_3(PO_2NH)_3$,[4c] and pairs in $Na_3(PO_2NH)_3 \cdot H_2O$,[4b] and $K_3(PO_2NH)_3$.[4c]

Arrangement of the Complex Ions $\{M_4(\mu_4\text{-}O)(\mu\text{-}OH)_6[(PO_2NH)_3]_4\}^{4-}$ in the Cubic Phase

The two cubic compounds $Na_4\{M_4(\mu_4\text{-}O)(\mu\text{-}OH)_6[(PO_2NH)_3]_4\} \cdot 18\ H_2O$ (**1/3**) with M = Zr, Hf were found to be isostructural and isomorphous. The arrangement of the $\{M_4(\mu_4\text{-}O)(\mu\text{-}OH)_6[(PO_2NH)_3]_4\}^{4-}$ ions is shown in Figure 4. The anions are interconnected by coordination to the sodium ions and by hydrogen bonding, forming a three-dimensional network. Thus all H atoms of the μ-NH groups are bound to O atoms of the trimetaphosphimato ligands [N1−H1···O1B, N2−H2···O3B, N2−H2···O4B, N3−H3···O1B, N4−H4···O3B, N···O: 289−315 pm, N−H···O: 121−142° for **1** and N···O: 288−313 pm, N−H···O: 121−142° for **3**]. Na1 is octahedrally surrounded by three oxygen atoms of the water molecules [Na1−Ow1, −Ow2, −Ow3: 248.7(8), 234.6(8), 254.6(11) pm for **1** and 247.1(6), 234.1(6), 253.8(8) pm for **3**] and three oxygen atoms of the trimetaphosphimate rings [Na1−O2B, −O3B, −O4B: 237.9(5), 256.6(6), 236.0(5) pm for **1** and 236.7(4), 257.8(4), 235.2(4) pm for **3**]. The other sodium ion Na2 is located in a general position with an occupancy factor 1/3. Na2 is surrounded by five oxygen atoms of the water molecules [Na2−Ow1, −Ow2, −Ow3, −Ow4, −Ow6: 252(2), 276(2), 236(2), 262(2), 243(2) pm for **1** and 252(2), 281(2), 245(2), 252(2), 244(2) pm for **3**], as well as by two oxygen atoms of the trimetaphosphimate rings [Na2−O1B, −O2B: 276(2) and 242(2) for **1** and 274(2), 240(2) pm for **3**]. The residual electron density found for **1** (2.75 $e^-/Å^3$) and **3** (3.10 $e^-/Å^3$) is located on a special position $^1/_2{}^1/_2 0$. No other atoms are located within a radius of 3 Å around this site.

Figure 4. Crystal-packing diagram of the $\{M_4(\mu_4\text{-}O)(\mu\text{-}OH)_6[(PO_2NH)_3]_4\}^{4-}$ ions (M = Hf, Zr) in the cubic phase, view along [111]



Arrangement of the Complex Ions $\{M_4(\mu_4\text{-}O)(\mu\text{-}OH)_6[(PO_2NH)_3]_4\}^{4-}$ in the Rhombohedral Phase

The two rhombohedral compounds $Na_4\{M_4(\mu_4\text{-}O)(\mu\text{-}OH)_6[(PO_2NH)_3]_4\} \cdot 21\ H_2O$ (**2/4**) with M = Zr, Hf, were found to be isostructural and isomorphous. The arrangement of the $\{M_4(\mu_4\text{-}O)(\mu\text{-}OH)_6[(PO_2NH)_3]_4\}^{4-}$ ions is shown in Figure 5. The structure consists of bilayers with a stacking sequence $A_\downarrow B_\uparrow C_\downarrow A_\uparrow B_\downarrow C_\uparrow$ of the anionic layers along [001]. The arrows describe the direction of the tip of the anion, i.e. the position of M2 (M = Hf, Zr), relative to the center of gravity of the cages with respect to [001]. Within the bilayers the anions are connected by hydrogen bonds N−H···O between the trimetaphosphimate rings [N3−H3···O3, N3−H3···O4, N4−H4···O3, N···O: 290−321 pm, N−H···O: 122−136° for **2** and N···O: 286−320 pm, N−H···O: 121−137° for **4**] and by coordination to Na1. The sodium ion Na1 is coordinated by six O atoms, three oxygen atoms of the water molecules Ow1, Ow2, Ow3 [Hf: $d_{av.}$ Ow−Na: 244.1 pm, Zr: $d_{av.}$ Ow−Na: 244.1 pm] and three O atoms of the trimetaphosphimate rings O1B, O3B, O4B [Hf: $d_{av.}$ O−Na: 241.8 pm, Zr: $d_{av.}$ O−Na: 241.8 pm], forming a distorted octahedron. The other sodium ion Na2 is located on a general position with an occupancy factor of 1/3. These Na2 ions are surrounded by six oxygen atoms, two oxygen atoms of the trimetaphosphimate rings [O1B, O2B: 278(6), 266(6) pm for **2**, 258(3), 278(3) pm for **4**] and four oxygen atoms of the water molecules [Ow2, Ow5, Ow7, Ow7′: 277(6), 217(7), 241(7) 246(7) pm for **2**, 260(3), 228(3), 241(6), 265(4) pm for **4**] thus connecting the bilayers. This connection is reinforced by extensive hydrogen bonding with O2B acting as a bridging atom [N1−H1···O2B···H2−N2; N1···O2···N2: 296, 299 for **2** and 295, 293 for **4**]. Thus a void centered at $00^1/_2$ is formed by connecting six $\{M_4[(PO_2NH)_3]_4(\mu_4\text{-}O)(\mu\text{-}OH)_6\}^{4-}$ units by hydrogen bonding between the $(PO_2NH)_3^{3-}$ rings. The hole has a radius of approximately 3 Å. The residual electron density which is found for **2** (2.27 $e^-/Å^3$) is located on the special position $^1/_3{}^2/_3{}^1/_6$ and no other atoms are located within a radius of 3 Å. In **4** no notable residual electron density was observed.

Discussion

In the (trimetaphosphimato)hafnates and -zirconates having the general composition $Na_4\{M_4(\mu_4\text{-}O)(\mu\text{-}OH)_6[(PO_2NH)_3]_4\} \cdot 18\ H_2O$ (**1**, **3**) and $Na_4\{M_4(\mu_4\text{-}O)(\mu\text{-}OH)_6[(PO_2NH)_3]_4\} \cdot 21\ H_2O$ (**2**, **4**) with M = Zr, Hf, for the

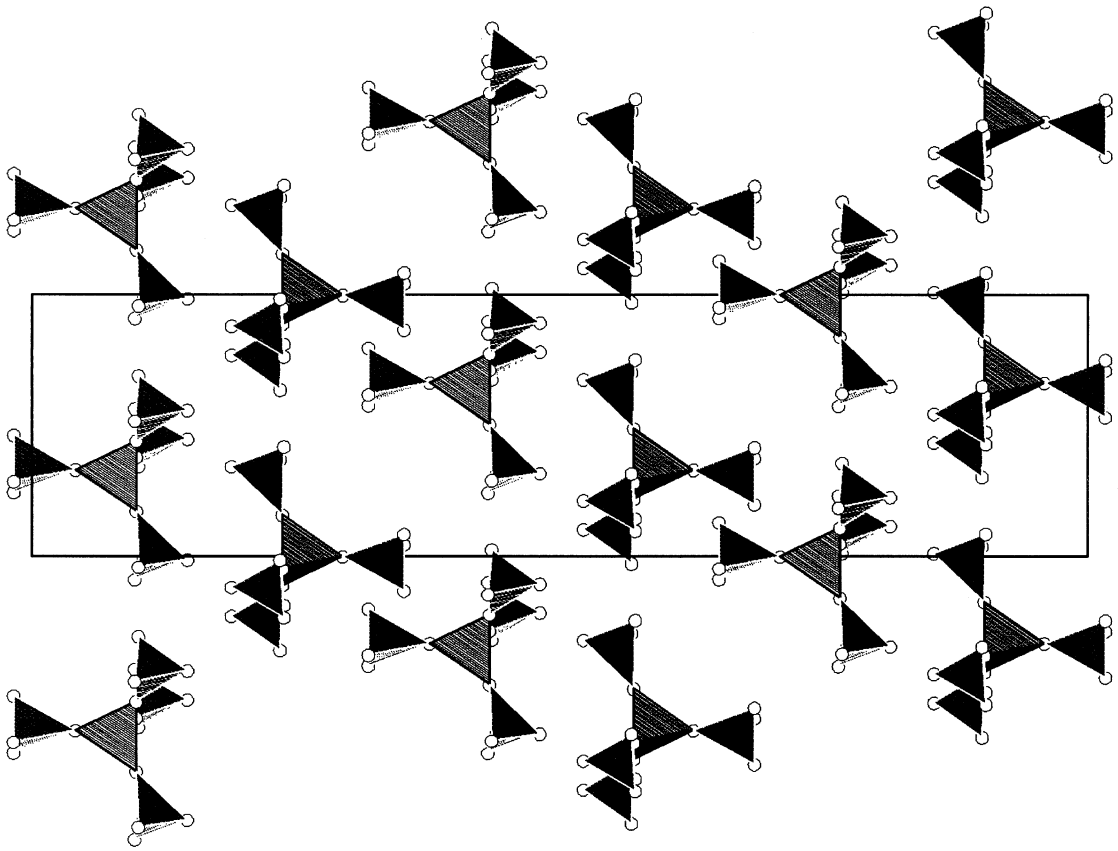
first time a metal oxide fragment incorporating four metal atoms was stabilized by trimetaphosphimate ions acting as tridentate ligands, thus stabilizing the tetranuclear anion. The synthesis of the compounds **1**−**4** succeeded when zirconyl chloride and hafnyl chloride were used, whereas the use of $ZrCl_4$ or $ZrSO_4 \cdot 4\ H_2O$ led to the formation of X-ray-amorphous products. The assumption that the preformed eight-membered rings $\{M(OH)_2\}_4^{8+}$ in the solutions of $HfOCl_2 \cdot 8\ H_2O$ and $ZrOCl_2 \cdot 8\ H_2O$ is preserved during the syntheses could not unambiguously be confirmed since the use of a mixture of $HfOCl_2 \cdot 8\ H_2O$ and $ZrOCl_2 \cdot 8\ H_2O$ in one reaction led to the formation of mixed crystals, containing Hf as well as Zr, in a 1:1 ratio. This was confirmed by EDX analysis.

Neither the cubic nor the rhombohedral phase of the (trimetaphosphimato)zirconates or -hafnates have been obtained as a single-phase product. Although the addition of NaCl during the synthesis of (trimetaphosphimato)zirconates resulted in the formation of some large single crystals of the cubic phase (**4**) analogous experiments using $HfOCl_2 \cdot 8\ H_2O$ did not lead to a pure single-phase cubic product **1**. In the same way neither varying the reaction temperature, nor varying the pH value by the addition of NaOH or HCl, resulted in single-phase products. Since the formulas of the cubic and rhombohedral phases obtained from the single-crystal structure determination differ only in their water content, and because the characteristic structural feature in the compounds **1**−**4** are the discrete tetranuclear complex anions $\{M_4(\mu_4\text{-}O)(\mu\text{-}OH)_6[(PO_2NH)_3]_4\}^{4-}$, a direct structural correlation between the respective cubic and rhombohedral phases was anticipated. However, a direct structural correlation (e.g. stacking variants, group-subgroup relations) can be ruled out since strongly differing arrangements of the anions occur.

Conclusion

Unlike the known trimetaphosphimato complexes where only monometallic complexes are formed in the title compounds, the trimetaphosphimato groups stabilize the metal oxide fragments $\{M_4(\mu_4\text{-}O)(\mu\text{-}OH)_6\}^{8+}$ (M = Zr, Hf) by acting as tridentate ligands. Thus the tetranuclear complex anion $\{M_4(\mu_4\text{-}O)(\mu\text{-}OH)_6[(PO_2NH)_3]_4\}^{4-}$ is obtained. The existence of a tetranuclear ring in $\{M_4[(OH)_2]_4(H_2O)_{16}\}^{8+}$ as the starting material seems to be important for the formation of the adamantanoid cage $\{M_4(\mu_4\text{-}O)(\mu\text{-}OH)_6\}^{8+}$, which is then stabilized by trimetaphosphimate ions. Despite the similarity of the characteristic anion $\{M_4(\mu_4\text{-}O)(\mu\text{-}OH)_6[(PO_2NH)_3]_4\}^{4-}$ in the four title compounds, cubic (**1**/**3**) and rhombohedral (**2**/**4**) products have been obtained exhibiting strongly differing topologies. As with many other Hf and Zr compounds isotypic products (**1**/**3** and **2**/**4**) are formed.

Figure 5. Crystal-packing diagram of the $\{M_4(\mu_4\text{-}O)(\mu\text{-}OH)_6[(PO_2NH)_3]_4\}^{4-}$ ions (M = Hf, Zr) in the rhombohedral phase, view along [010]



This work was supported by the *Fonds der Chemischen Industrie* and, in particular, by the *Deutsche Forschungsgemeinschaft* (Gottfried-Wilhelm-Leibniz-Programm).

Experimental Section

$Na_3(PO_2NH)_3 \cdot 4\ H_2O$ was obtained by a procedure described previously {Eq. (a)[13]}. $(PNCl_2)_3$ (Fluka, purum, 5 g, 14.38 mmol) was dissolved in 20 ml of dioxane (Merck, p.a.) in a round-bottom flask. A solution of $NaOOCCH_3 \cdot 3\ H_2O$ (Merck, p.a., 25 g, 0.184 mol) in 40 ml of H_2O was added while stirring (60°C, 24 h). The product precipitated as a white microcrystalline powder which was filtered and washed with ethanol and acetone. The product was recrystallized from water by the addition of ethanol (yield: 4.5 g, 83%).

$$(PNCl_2)_3 + 9\ Na(OOCCH_3) \cdot 3\ H_2O \rightarrow Na_3(PO_2NH)_3 \cdot 4\ H_2O + 6\ NaCl + 9\ HOOCCH_3 + 17\ H_2O \quad (a)$$

$HfOCl_2 \cdot 8\ H_2O$ (Alfa) was used as obtained, and $ZrOCl_2 \cdot 8\ H_2O$ (Fluka, puriss.) was recrystallized, from hydrochloric acid according to the literature.[14] For the synthesis of the (trimetaphosphimato)hafnates and -zirconates equimolar (3.35×10^{-5} M) aqueous solutions of $Na_3(PO_2NH)_3 \cdot 4\ H_2O$ (25 mg, 6.67×10^{-2} mmol in 2 ml of H_2O) and $HfOCl_2 \cdot 8\ H_2O$ (27.3 mg, 6.67×10^{-2} mmol in 2 ml of H_2O) or $ZrOCl_2 \cdot 8\ H_2O$ (21.5 mg, 6.67×10^{-2} mmol in 2 ml of H_2O) were mixed together at room temperature in a small glass vessel (V = 8 ml). The mixtures became turbid at once but cleared after 5 min without further stirring. They were cautiously covered with methanol and placed in a larger vessel (V = 40 ml) filled with 25 ml of methanol allowing very slow diffusion. The mixture was kept undisturbed at room temperature. After 3 d, crystals were observed growing on the inner glass wall of the smaller vessels. The crystallization was complete after approximately 8 d and led to the formation of two distinct types of crystals, exhibiting rhombohedral and quadratic habit. The reaction of $HfOCl_2 \cdot 8\ H_2O$ resulted in large crystals with rhombohedral as well as quadratic contours. In the case of $ZrOCl_2 \cdot 8\ H_2O$ the same procedure led to the formation of large crystals of only rhombohedral contour (however, small quadratic crystals of 10 μm edge length were observed under the scanning electron microscope). Large crystals of the (trimetaphosphimato)zirconate with a quadratic shape were obtained by adding sodium chloride (12 mg, 0.2 mmol) to the solution of $Na_3(PO_2NH)_3 \cdot 4\ H_2O$.

After the precipitation was complete, the mother liquor was removed and the crystals were washed with acetone (yield: 70%). Energy-dispersive X-ray microanalyses (Fa. Leo, Oberkochen) showed the atomic ratio Na/P/M (M = Hf, Zr) to be 1:3:1 for all four compounds. Chemical analysis of **4** was performed for Na, Zr, O, N, P, H and for **1** and **2** for Na and Hf, to confirm the occupancy factor of $^1/_3$ for Na2 in the general position. Phase separation was accomplished manually according to the shape of the crystals and due to their optical properties under the polarization microscope. $Na_4\{Hf_4(\mu_4\text{-}O)(\mu\text{-}OH)_6[(PO_2NH)_3]_4\} \cdot 18\ H_2O$ (**1**, 2184.11 g/mol): calcd. Hf 32.69, Na 4.21; found Hf 31.6, Na 4.06. $Na_4\{Hf_4(\mu_4\text{-}O)(\mu\text{-}OH)_6[(PO_2NH)_3]_4\} \cdot 21\ H_2O$ (**2**, 2238.16 g/mol): calcd. Hf 31.90, Na 4.11; found Hf 31.5, Na 4.06. $Na_4\{Zr_4(\mu_4\text{-}O)(\mu\text{-}OH)_6[(PO_2NH)_3]_4\} \cdot 21\ H_2O$ (**4**, 1889.08 g/mol): calcd. H 3.20, N 8.89, Na 4.87, O 44.04, P 19.68, Zr 19.32; found H 3.3, N 8.63, Na 4.96, O 42.0, P 19.3, Zr 18.6.

As the products **1/2** and **3/4** are always obtained as mixtures, the water content was not determined by chemical analysis but taken from the structural determination. Powder-diffraction investigations (Siemens D5000) revealed the existence of only two phases, **1/2** and **3/4**. All reflections have been indexed and their observed intensities correspond to a calculated diffraction pattern based on the single-crystal-structural data.

All four compounds are obtained as colorless solids and transparent crystals with well developed faces. They are stable in air and are water-soluble, however recrystallization from these solutions was not possible. Furthermore the existence of a ^{31}P-NMR signal [δ^{31}P (D_2O) = −0.544] in the solution NMR spectra (Bruker ARX 250) of **1/2** indicated decomposition of the complex anion $\{M_4(\mu_4\text{-}O)(\mu\text{-}OH)_6[(PO_2NH)_3]_4\}^{8-}$ (M = Hf, Zr) in water. This NMR shift is in accordance with the ^{31}P-NMR signal of the free $(PO_2NH)_3^{3-}$ ion as found in aqueous solutions of $K_3(PO_2NH)_3$ [δ^{31}P (D_2O) = −0.553].[4c]

Thermal decomposition of the products starts above 120°C with evolution of H_2O and NH_3. Reaction of mixtures of (**1/2**) or (**3/4**), respectively, for 2 d at 200−700°C were carried out in sealed quartz ampoules. The only X-ray crystalline products detectable were HfP_2O_7 and ZrP_2O_7 as well as $NaZr_2(PO_4)_3$. Therefore, nitrogen was not incorporated into the products, but NH_3 was formed as a condensation product.

IR spectra (Bruker IFS 66v; KBr pellets) of the cubic and rhombohedral (trimetaphosphimato)hafnates have been obtained after the separation of the crystals according to their shape and optical properties under the polarization microscope. The IR spectra of **1**−**4** are very similar, exhibiting the following IR absorptions $\tilde{\nu}$ [cm^{-1}] = 3600, 3270, 2704, 1642, 1316, 1256, 1110, 1052, 919, 825, 642, 553, 415.

Crystal Structure Analyses: X-ray diffraction data were collected on an image-plate diffractometer (STOE IPDS). Reflections shaded by the goniometer head were removed. The data sets were employed in the crystal shape optimization and the subsequent numerical absorption correction using HABITUS.[15] Afterwards identical reflections, which were measured multiply due to the measurement method, were averaged, and their mean values were used for the structure determination. Relevant crystallographic data and details of the data collection of the compounds **1**−**4** are listed in Table 2. According to the observed extinctions for the cubic phases the space group $Pa\bar{3}$ (no. 205) was unequivocally determined and the structures were solved by direct methods using SHELXTL-Plus.[16] For the rhombohedral phases the space groups $R3$ (no. 146) and $R\bar{3}$ (no. 148) have been considered. The crystal structures of these compounds were solved by direct methods using SHELXTL-Plus[16] in the centrosymmetric space group $R\bar{3}$. After the anisotropic refinement of the displacement parameters of all non-hydrogen atoms except Na2 for the cubic and the hexagonal phases, the μ-imido hydrogen atoms were located and refined using a riding model with a fixed N−H distance of 86 pm. The sodium ions Na2 in **1**−**4** were located on the basis of bonding lengths and coordination. They were located on general positions occupied to $^1/_3$. Therefore these partially occupied Na positions were only refined using isotropic displacement parameters. Since the compounds were always obtained as mixtures of the cubic and rhombohedral phase, the water content was determined exclusively from the diffraction data. Tables 3 and 4 show the positional parameters and the equivalent isotropic displacement parameters U_{equiv} for **1** and **2**. Corresponding parameters of the isotypic zirconium compounds (**3** and **4**) are omitted. Table 1 gives interatomic distances and angles in **1** and **2**.[17]

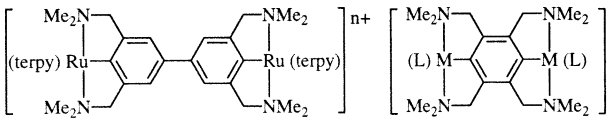
Keywords: Ruthenium / Bridging bis(bidentate) tetraphosphane ligand / Diruthenium(II) coordination complex / Cyclometallation versus *o-P,P′* chelation

The tetrakis(phosphane oxide) $C_6H_2\{CH_2P(O)Ph_2\}_4$-1,2,4,5 (**5**), has been prepared in high yield from the Arbuzov reaction of $C_6H_2(CH_2Br)_4$-1,2,4,5 (**4**), with excess (7 equiv.) of Ph_2POEt. Subsequent reduction of **5** with $HSiCl_3$ (12 equiv.) in $C_6H_4Cl_2$-1,2 afforded the new tetraphosphane $C_6H_2(CH_2PPh_2)_4$-1,2,4,5 (**6**), in high yield. The reaction of **6** with $[RuCl_2(PPh_3)_4]$ in CH_2Cl_2 afforded the green dinuclear ruthenium(II) coordination complex [{$RuCl_2(PPh_3)$}$_2${C_6H_2-$(CH_2PPh_2)_4$-1,2,4,5-*P,P′,P′′,P′′′*}]·0.5 CH_2Cl_2 (**8**), in 39% isolated yield. The solid-state molecular geometry of **8**, determined by X-ray analysis, shows that the tetraphosphane is *ortho-P,P′*-chelated to each of the two $[Ru^{II}Cl_2(PPh_3)]$ units.

Introduction

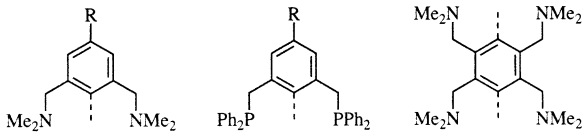
In recent years there has been an increasing interest in dinuclear organometallic complexes and such species have been used to model fundamental properties of multi- and polymeric organometallic materials[1] that have potential optical and/or electronic applications. Recently, we reported on the selective synthesis of 4,4′-biphenylene- and 1,4-phenylene-bridged bimetallic complexes of some platinum-group metals containing anionic *N,C,N′*-terdentate ligands (Figure 1)[2]. In addition to their interesting photochemical behavior[2a], these complexes have potential in the development of multimetallic materials, such as "molecular wires".

Figure 1. Some examples of 4,4′-biphenylene- and 1,4-phenylene-bridged organometallic complexes containing ligands with anionic *N,C,N′*-terdentate coordination moieties



We have also investigated the synthesis of ruthenium(II) complexes of monoanionic (functionalized) *N,C,N′*-terdentate ligands $[C_6H_2(CH_2NMe_2)_2$-2,6-R-4$]^-$ (= NCN-R-4) and *P,C,P′*-terdentate ligands $[C_6H_2(CH_2PPh_2)_2$-2,6-R-4$]^-$ (= PCP-R-4) (Figure 2). The use of these ligands, which can be derived from the aryl compounds $C_6H_3(CH_2ER'_2)_2$-1,3-R-5 (**1**), either by transmetallation (of **1a**-Li) or direct cyclometallation (of **1b**), has resulted in a new series of stable organoruthenium complexes (see Scheme 1)[3].

Figure 2. Schematic representation of the monoanionic aryl ligands NCN-R-4 (R = H, Ph, $Me_3SiC{\equiv}C$, Me_3Si) and PCP-R-4 (R = H, Ph) and the dianionic C_2N_4 ligand



The PCP-R-4 ruthenium(II) complexes **2b** can be obtained directly by cyclometallation[4] of the corresponding diphosphanes **1b** with $[RuCl_2(PPh_3)_4]$. In contrast, the NCN-R-4 ruthenium(II) complexes **2a** were prepared by transmetallation of organolithium reagents $[LiC_6H_2$-$(CH_2NMe_2)_2$-2,6-R-4$]_2$ derived from the aryldiamines **1a**. Some NCN-R-4 and PCP-R-4 ruthenium(II) complexes have also been used as catalysts in various hydrogen-transfer reactions[5].

Recently, we have also developed a synthetic strategy for the preparation of homo- and heterodinuclear organometallic complexes of the bis(*N,C,N′*-terdentate) coordinating dianionic 1,4-phenylene-bridging ligand $[C_6(CH_2NMe_2)_4$-2,3,5,6$]^{2-}$ (= C_2N_4; Figure 2)[6] and extension of this re-

search has been aimed at the generation of the related dianionic 1,4-phenylene ligand with two potentially *P,C,P′*-terdentate coordination motifs, i.e., an analog to the tetraaminophenylene dianion C_2N_4 shown in Figure 2. As part of this research we have explored the synthesis of the tetraphosphane $C_6H_2(CH_2PPh_2)_4$-1,2,4,5 (**6**), which is a potential precursor to the ligand $[C_6(CH_2PPh_2)_4\text{-}1,2,4,5]^{2-}$. We now report the successful synthesis of **6** and its complexation reaction with $[RuCl_2(PPh_3)_4]$.

Results

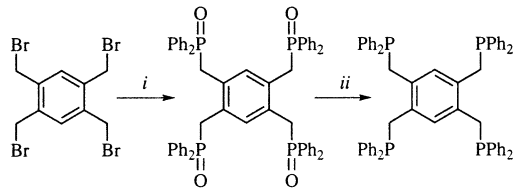
The target compound of this study is tetraphosphane-substituted benzene $C_6H_2(CH_2PPh_2)_4$-1,2,4,5 (**6**). The synthetic protocol used involves an Arbuzov reaction[7] of a phosphanic ester (i.e., Ph_2POEt) with a benzylic bromide [i.e., $C_6H_2(CH_2Br)_4$-1,2,4,5 (**4**)] to afford a P^V oxide compound, **5**[8]. The latter is then reduced to the corresponding desired tetraphosphane **6** (see Scheme 2).

Synthesis of $C_6H_2(CH_2PPh_2)_4$-1,2,4,5 (5)

Compound **5** can be obtained in high yield, as a white solid, by treatment of the known $C_6H_2(CH_2Br)_4$-1,2,4,5 (**4**)[9] with excess of ethyldiphenylphosphanite (Ph_2POEt) in *m*-xylene at 140°C in a slight modification of a previously described procedure that gives an improved yield[8]. The ^{1}H-NMR data of the poorly soluble tetrakis(phosphane oxide) **5** (in warm CD_3OD solution) were identical to those reported previously[8].

Typical procedures described for the reduction of phosphane oxides to phosphanes failed to completely reduce compound **5** to phosphane **6**. For example, $HSiCl_3$ reduction of **5** in benzene, toluene or xylene at reflux temperature[10] did not result in the formation of the desired phosphane. Similarly, $LiAlH_4$ (or $LiAlH_4 \cdot CeCl_3$) reductions[11] in THF also failed to reduce **5** selectively. In the latter case, a new product formed in ca. 10% yield with over 85% of the starting material still present. This new product has not been isolated in a pure form but on the basis of ^{31}P-NMR data of the crude material, its air stability and its water solubility we believe that it is likely to be an ionic phosphonium species (vide infra). It was felt that the poor reactivity of **5** in the attempted reduction reactions was possibly due to its inherent low solubility. Therefore, alternative solvents were examined and it has been found that for the reduction of **5** with $HSiCl_3$, hot 1,2-dichlorobenzene was the solvent of choice. In practice, a suspension of **5** in 1,2-dichlorobenzene was heated to 180°C and kept at this temperature for 10 min to dissolve all solid material. The solution temperature was then reduced to 140°C and $HSiCl_3$ was added by syringe. The reaction mixture was kept for 1 h at this temperature and, after appropriate work-up, the desired tetraphosphane **6** was obtained as a white solid in very good yield (96%). Compound **6** is air-sensitive and reasonably soluble in aromatic and chlorinated solvents. Analytically pure crystals of **6** can be obtained by slow diffusion of MeOH into a solution of **6** in benzene.

Scheme 2. Synthesis of the tetraphosphane $C_6H_2(CH_2PPh_2)_4$-1,2,4,5 (**6**). – *i:* Ph_2POEt, *m*-xylene, 140°C, –EtBr. – *ii:* $HSiCl_3$, $C_6H_4Cl_2$–1,2, 140°C, 1 h.



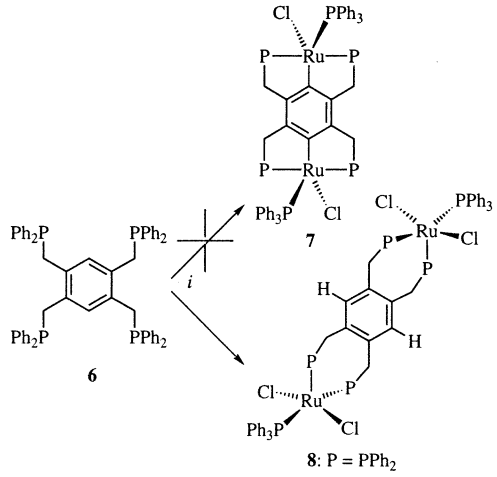
Reaction of Tetraphosphane 6 with $[RuCl_2(PPh_3)_4]$

It was anticipated that phosphane **6** would be susceptible to cyclometallation and that with $[RuCl_2(PPh_3)_4]$[12] the product of this reaction would be a bimetallic species related to the ruthenium(II) complex **3b** (Scheme 1) obtained when $C_6H_3(CH_2PPh_2)_2$-1,3-R-5 (**1b**), is used as the phosphane[3c][3d]. To test the reactivity of the new tetraphosphane **6** towards $[RuCl_2(PPh_3)_4]$, these two species were mixed in a 1:2 molar ratio in CH_2Cl_2 (Scheme 3) at room temperature and after 1 h a green precipitate had been formed. After appropriate work-up, this precipitate was isolated as a green solid, whose poor solubility in common organic solvents (benzene, toluene, THF, CH_2Cl_2, etc.) has prevented us from identifying this material, **8**, by solution-NMR spectroscopy and also prevented successful recrystallization. However, elemental microanalysis data suggested that this crude product has an overall formula $[\{RuCl_2(PPh_3)\}_2(\mathbf{6})] \cdot 0.5\ CH_2Cl_2$.

In a second experiment, aimed at directly obtaining a purer, more crystalline product **8**, we carried out the original reaction under slightly different conditions. To this end, a CH_2Cl_2 solution of two equivalents of $[RuCl_2(PPh_3)_4]$ was

carefully layered with a solution of tetraphosphane **6** in CH_2Cl_2 and the reaction mixture was left undisturbed for 24 h at room temperature. This produced analytically pure green crystals of **8** (isolated yield: 38%) which were suitable for an X-ray crystallographic study. This study afforded a solid-state structure (vide infra) which shows this product to be $[\{RuCl_2(PPh_3)\}_2\{C_6H_2(CH_2PPh_2)_4$-1,2,4,5-*P,P′,P″,P‴*$\}]\cdot 0.5\ CH_2Cl_2$ (**8**); the molecular geometry is depicted in Figure 3 and selected geometrical details are collected in Table 1. Complex **8** has a composition that corresponds to the original microanalytical data and it can be seen to be a dinuclear coordination complex of **6** in which this tetraphosphane functions as a bridging ligand that coordinates in a *P,P′*-bidentate manner to each of the identical metal centers. Thus, under the experimental conditions used or at reflux temperature in CH_2Cl_2, compound **6** does not undergo cyclometallation with the ruthenium(II) center to afford a product such as **7**. This behavior is different to that of aryldiphosphane $C_6H_4(CH_2PPh_2)_2$-1,3 which cyclometallates with $[RuCl_2(PPh_3)_4]$ under identical conditions to afford $[RuCl\{C_6H_3(CH_2PPh_2)_2$-2,6$\}(PPh_3)]$[3].

Scheme 3. Reactivity of **6** with $[RuCl_2(PPh_3)_4]$ in CH_2Cl_2 to afford coordination complex **8** rather than the cyclometallated species **7**. − *i:* 2 equiv. $[RuCl_2(PPh_3)_4]$, CH_2Cl_2, room temp., 1 h, −6 equiv. PPh_3.



In the X-ray crystallographic structure of **8**, the tetraphosphane ligand bridges between the two identical 5-coordinate ruthenium(II) metal centers that have approximate square-pyramidal geometries; the molecule has a center of inversion positioned in the central aromatic ring of this tetraphosphane. The square pyramidal ligand array comprises in the basal plane plane two *trans*-Cl atoms [Cl(1) and Cl(2)] and two *trans*-P atoms [P(2) of the bridging ligand and P(3) of PPh_3] and at the apex there is a phosphorus atom P(1) of the bridging ligand. The bridging phosphane employs two mutually *ortho*-CH_2PPh_2 substituents for *ortho-P,P′* chelation to each metal center, thus forming a 7-membered chelate ring in which the bite angle P(1)−Ru(1)−P(2) is 97.46(9)°. The geometrical parameters found for **8**, including Ru−P bond lengths in the range of 2.208(3) to 2.391(2) Å and a Cl(1)−Ru(1)−Cl(2) bond angle of 160.96(9)°, are similar to those reported for related complexes with the general formula $[RuCl_2(Ph_2PR)_3]$[13a][13b] (see Discussion). The $P-C_{aryl}$ bond lengths fall in the range of 1.815(10) to 1.853(9) Å and the $Ru-P-C_{aryl}$ bond angles vary from 100.0(3) to 124.7(3)°. Interestingly, the proton H(31) situated on triphenylphosphane *ortho*-carbon atom C(31) is fairly close to the ruthenium(II) center with a Ru(1)···H(31) distance of 2.82 Å that is substantially shorter than the sum of the van der Waals radii (3.40 Å).

In further experimental studies aimed at promoting cyclometallation of the neutral phosphane **6** present in complex **8**, this latter complex was suspended in 1,2-dichlorobenzene and heated to 140°C together with PPh_3 and trioctylamine as a base. Although NMR-spectroscopic studies of the resulting solution indicated that a new orthometallated product had been formed, it was in fact the coordinated PPh_3 ligand, and not **6**, that had been cyclometallated. Unfortunately, a pure sample of this new cyclometallated product could not be separated for further identification.

Discussion

Synthesis of the Tetraphosphane

The choice of the Arbuzov-reaction/reduction sequence for the synthesis of tetraphosphane **6** is a consequence of the poor results that we achieved in preliminary experiments using the tetrabromide **4** as starting material in the well-known nucleophilic substitution of a benzylic bromide with $NaPPh_2$ in liquid ammonia[3c][14]. The main product of this latter reaction is not the desired phosphane **6**, but a mixture of phosphonium salts. These phosphonium salts are probably formed as a result of an intramolecular nucleophilic substitution reaction of a CH_2Br group with an *ortho*-positioned CH_2PPh_2 group that has been produced by an initially successful intermolecular nucleophilic substitution (see Scheme 4). The success of the route we employ to form **6** (Scheme 2) comes from the fact that the product of the Arbuzov reaction is a non-nucleophilic phosphane oxide and the initially formed $CH_2P(O)Ph_2$ unit is inert to intramolecular attack by an *ortho*-positioned benzylic bromide.

The solvent used in the $HSiCl_3$-mediated reduction reaction of the tetrakis(phosphane oxide) **5** to the tetraphosphane **6** was found to be crucial and the best experimental conditions that we found was the use of 1,2-dichlorobenzene at high temperature. It appears that for phosphane oxides like **5**, which have poor solubility characteristics, it is important to use a solvent that not only has a high boiling point but also one that has a good degree of polarity, and this combination of physical properties is found in 1,2-dichlorobenzene.

Solid-State Structure of 8

The complex formed by the undisturbed reaction of $[RuCl_2(PPh_3)_4]$ with **6** in CH_2Cl_2 was not one containing the expected cyclometallated tetraphosphane ligand **7**. In-

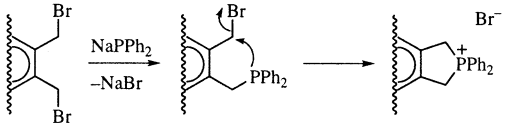
Scheme 4. Schematic formation of phosphonium species from the reaction of $NaPPh_2$ with *ortho*-bis(bromomethyl)arenes



stead, the product is a bimetallic coordination complex of neutral tetraphosphane **6** in which two *ortho*-positioned phosphane donor substituents are coordinated to a ruthenium(II) metal center. The related tetraphosphane ligand 1,2,4,5-tetrakis(diphenylphosphano)benzene has been reported to form similar, non-metallated, bridged bimetallic (and polymeric) coordination complexes with several transition metals[15]. It appears that this type of initial *P,P′*-chelation forms a species that is relatively inert to Ru−P bond cleavage and as a consequence the C_{aryl}−H bond of the central aromatic ring cannot approach the metal center for intramolecular activation and subsequent C−Ru bond formation.

Bisruthenium(II) complex **8** is one of only a few structurally characterized 5-coordinate ruthenium(II) species in which the ligand array comprises two halide atoms and three phosphanes. Moreover, in complex **8** the presence of a close contact between the metal center and an *ortho* H atom of one of the PPh_3 C_{aryl}−H units is a noteworthy feature; interestingly, the structure of [$RuCl_2(PPh_3)_3$] has a similar interaction which was concluded to be substantially repulsive,[13a] and not to be an agostic interaction[13c][13d] of this C_{aryl}−H bond with the metal center. The authors described the overall structure of this complex as a distorted square pyramid with this *ortho*-H atom occupying the open coordination site of an octahedral ligand array. More recently, Cotton and Matusz[13b] have reported the solid-state structure of another square-pyramidal ruthenium complex, [$RuCl_2(Ph_2PCH_2SiMe_3)_3$], in which this type of M···H−C interaction was not found and the bulky benzylic substituent would appear to be shielding the vacant sixth coordination site in this 16-electron species. Comparison of some selected bond lengths and interbond angles collected in Table 2, shows that the overall solid-state structures of bimetallic **8** with *P,P′*-chelation and the mononuclear complexes [$RuCl_2(Ph_2PR)_3$] (R = Ph, CH_2SiMe_3) with monodentate-bonded phosphanes are surprisingly similar.

P,P′-Chelation versus Cyclometallation

Cyclometallation of aryldiphosphanes with ruthenium(II) species is a well-known reaction and has been successfully employed by us[3c] and others[3e] in earlier studies to form a series of complexes containing [$C_6H_2(CH_2PPh_2)_2$-2,6-R-4]$^-$, PCP-R-4 (Scheme 1). However, as reported here, the neutral tetraphosphane **6** has to date not been found to undergo such cyclometallation reactions and it is worthwhile considering the unique aspects of this compound that result in it having a different reactivity

Table 2. Selected bond parameters of **8** and the known ruthenium(II) complexes $[RuCl_2(Ph_2PR)_3]$ (R = Ph, CH_2SiMe_3)

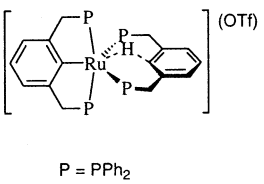
[a] Data obtained from ref.[12a]. – [b] Data obtained from ref.[12b]. – [c] P_A and P_B are the apical and basal phosphorus atoms, respectively.

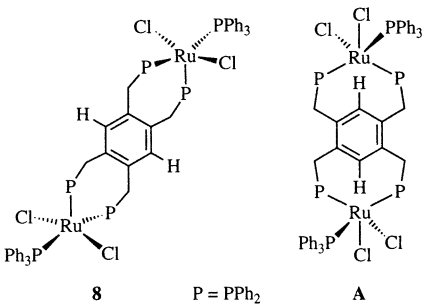
pattern. For reaction of the neutral aryldiphosphanes $C_6H_3(CH_2PPh_2)_2$-1,3-R-5 (**1b**), with $[RuCl_2(PPh_3)_4]$ we proposed that prior to cyclometallation an 8-membered cyclic coordination complex is formed by replacement of PPh_3 ligands of $[RuCl_2(PPh_3)_3]$ (vide supra) by the more basic phosphorus donor substituents of **1b**[3c]. In this resulting intermediate complex the two *meta*-positioned CH_2PPh_2 substituents are coordinated to the ruthenium(II) metal center in a bidentate *P,P′*-chelate mode. As a consequence the metal center is brought into proximity to the C−H bond which can then be activated. Because this intermediate has not been detected by NMR-spectroscopic methods we assume that the formation of this intermediate is rate-determining and that the following step, i.e. C−H bond cleavage and generation of the new Ru−C σ bond, is a much faster process. In one rare and unique case, an example of an agostic interaction of a C_{aryl}−H bond of an aryldiphosphane, **1b** (R = H), at an Ru^{II} center afforded by *P,P′*-chelate bonding has been confirmed by an X-ray crystallographic study[3d]; the molecular geometry of the monocationic complex reported in this study is schematically presented in Figure 4.

Figure 4. Schematic representation of aryl C−H bond activation at a Ru^{II} center in an intermediate whose structure has been determined by an X-ray crystallographic study



Tetraphosphane **6** should, like diphosphanes **1b**, displace PPh_3 from $[RuCl_2(PPh_3)_3]$ since the CH_2PPh_2 groups are more basic P donors than PPh_3. Several different coordination complexes could be formed, and two of these based on *P,P′*-chelation are the observed dinuclear coordination complex **8** as well as the alternative chelation complex **A** (See Figure 5). The difference between these complexes is that in **8** there is chelation of two *ortho*-positioned CH_2PPh_2 groups, whereas in **A** there is chelation two *meta*-positioned CH_2PPh_2 groups.

Figure 5. Schematic representation of two different coordination complexes **8** and **A** which could be formed from **6** and $[RuCl_2(PPh_3)]_4$



In complex **A**, there are two 8-membered chelate rings that allow the metal centers to be brought close to the aryl C−H bonds at positions 3 and 6 on the central aromatic ring; as a result of geometric (steric) restraints each ring has limited flexibility. In contrast, complex **8** contains two 7-membered chelate rings that have a good degree of conformational flexibility, and therefore this situation is energetically more favorable than that in **A**. However, unlike the situation in **A** the ruthenium(II) centers in **8** are unable to approach the central C−H bonds to undergo cyclometallation and form complex **7** (Scheme 3). The favorable situation found in complex **8** is emphasized by the fact that this complex does not undergo cycloruthenation during the synthetic procedure. In principle, the excess of free PPh_3 present in the reaction mixture (see Scheme 2) could induce the formation of an η^1-*P*-coordinated ligand **6** in complex **8**, and this would be sufficient to generate a situation where the an aryl C−H bond (as in **A**) is close enough to the metal center for cyclometallation to occur. However, the poor solubility characteristics of **8** in common organic solvents prevents the possibility of this situation.

Conclusion

In this report we have shown that the new neutral tetraphosphane ligand $C_6H_2(CH_2PPh_2)_4$-1,2,4,5 (**6**) can be easily prepared in high yield. The synthetic strategy, which involves an Arbuzov reaction, has great potential as an alternative (and less hazardous) route to many other aryl- and alkylphosphanes. In this strategy the choice of 1,2-dichlorobenzene as a high-temperature solvent for the reduction of the corresponding phosphane oxide was crucial. With ruthenium(II) centers the new tetraphosphane **6** affords *P,P′*-bidentate chelation from two *ortho*-positioned, rather than *meta*-positioned, CH_2PPh_2 substituents such that C−H bond activation and formation of a *P,C,P′*-terdentate-coordinated ruthenium(II) species does not occur.

This work was supported in part (P. S., N. V., A. L. S.) by the *Netherlands Foundation for Chemical Research (SON)* with financial aid from the *Netherlands Organization for Scientific Research (NWO)*.

Experimental Section

General: All synthetic procedures were performed under dry dinitrogen. Hexane and benzene were freshly distilled from sodium benzophenone ketyl, CH_2Cl_2 from CaH_2, and xylenes and 1,2-dichlorobenzene from molecular sieves (5 Å). − Spectroscopic measurements ($^{1\ H,\ 13}C\{^1H\}$ and $^{31}P\{^1H\}$ NMR) were performed with a Bruker AC200 or AC300 spectrometer, with chemical shifts referenced to either Me_4Si or 85% H_3PO_4. − Elemental analyses were carried out by Dornis und Kolbe, Mikroanalytisches Laboratorium, Mülheim, Germany. − The compounds $C_6H_2(CH_2Br)_4$-1,2,4,5 (**4**)[9], Ph_2POEt[16], and $[RuCl_2(PPh_3)_4]$[17] were prepared according to previously described methods. $RuCl_3 \cdot 3\ H_2O$ was purchased from Degussa.

$C_6H_2(CH_2P(O)Ph_2)_4$-1,2,4,5 (**5**): A modification of a procedure described in the literature[8] was used. In a two-necked 100-ml round bottom flask, a stirred colorless solution of Ph_2POEt (20.52 g, 89 mmol) and $C_6H_2(CH_2Br)_4$-1,2,4,5 (5.35 g, 11.9 mmol) in xylenes (20 ml) was heated at 140°C for 0.5 h, while a gentle stream of nitrogen was bubbled through the reaction mixture. After this time, the reaction mixture was cooled to 50°C (ice bath) and the white solid which had precipitated was filtered off. This solid was washed once with hot benzene (100 ml), filtered off and dried in vacuo to afford the tetraphosphoryl compound **5** as a white solid which was sufficiently pure for further synthesis. Yield: 9.53 g (86%), mp > 220°C (ref.[8]: 315−317°C). − ^1H NMR (CD_3OD, 200 MHz, 335 K): δ = 7.62 (m, 40 H, ArH), 6.42 (s, 2 H, ArH), 3.52 (d, 8 H, $^2J_{P\text{-}H}$ = 12 Hz, CH_2P). − $^{31}P\{^1H\}$ NMR (CD_3OD, 81 MHz, 335 K): δ = 32.4 (s).

$C_6H_2(CH_2PPh_2)_4$-1,2,4,5 (**6**): In a two-necked 100-ml round bottom flask equipped with a reflux condensor and a septum, was heated a stirred suspension of the tetraphosphoryl compound **5** (1.89 g, 2.02 mmol) in 1,2-dichlorobenzene (50 ml) at reflux temperature until all solids had dissolved. The resulting clear solution was then allowed to cool to 140°C and $HSiCl_3$ (2.46 ml, 24.4 mmol) was carefully added through the septum over a period of 5 min by means of a syringe. The reaction mixture was then stirred at 140°C for 1 h, after which a clear solution was obtained. This solution was then cooled to 0°C with an ice bath. Degassed aqueous NaOH (50 ml, 4 M) was carefully added through the septum over a period of 5 min by means of a syringe while the mixture was stirred vigorously. This resulted in the formation of a two-layer system, from which the organic layer was collected. The aqueous layer was extracted with CH_2Cl_2 (2 × 25 ml) and the combined organic fractions were dried with $MgSO_4$ and filtered. The filtrate was concentrated in vacuo to ca. 10 ml. Hexane (50 ml) was slowly added, which induced the crystallization of a white solid. This solid was collected by filtration, washed with hexane (2 × 25 ml) and dried in vacuo to afford analytically pure tetraphosphane **6** as white crystals. Yield: 1.68 g (96%), mp 125°C. − ^1H NMR ($CDCl_3$, 300 MHz, 298 K): δ = 7.28 (m, 40 H, ArH), 6.22 (s, 2 H, ArH), 2.96 (s, 8 H, CH_2P). − $^{13}C\{^1H\}$ NMR ($CDCl_3$, 75 MHz, 298 K): δ = 138.4 (d, $^1J_{P\text{-}C}$ = 16 Hz, Ar), 133.0 (d, $^2J_{P\text{-}C}$ = 19 Hz, Ar), 131.2 (d, $^3J_{P\text{-}C}$ = 12 Hz, Ar), 128.4 (d, $^3J_{P\text{-}C}$ = 23 Hz, Ar), 32.6, 32.4 (d, $^1J_{P\text{-}C}$ = 15 Hz, CH_2P). − $^{31}P\{^1H\}$ NMR ($CDCl_3$, 81 MHz, 298 K): δ = −12.3 (s). − $C_{58}H_{50}P_4$: calcd. C 79.99, H 5.79; found C 79.84, H 5.72.

[{$RuCl_2(PPh_3)$}$_2${$C_6H_2(CH_2PPh_2)_4$-1,2,4,5-P,P′,P″,P‴}]·0.5 CH_2Cl_2 (**8**): A colorless solution of tetraphosphane **6** (0.38 g, 0.44 mmol) in CH_2Cl_2 (20 ml) was added to a brown solution of $[RuCl_2(PPh_3)_4]$ in CH_2Cl_2 (20 ml) at room temperature and the resulting reaction mixture was stirred for 2 h at this temperature. During this time a green precipitate formed. After 2 h, the green precipitate was filtered off, washed with CH_2Cl_2 (2 × 20 ml) and dried in vacuo to afford the pure bisruthenium(II) complex **8** in 38% yield as a green insoluble solid (mp > 200°C). − $C_{94}H_{78}Cl_4P_6Ru_2 \cdot 0.5\ CH_2Cl_2$: calcd. C 63.69, H 4.58; found C 63.83, H 4.65. − When a CH_2Cl_2 solution of $[RuCl_2(PPh_3)_4]$ was

layered with a CH_2Cl_2 solution of tetraphosphane **6** and the resulting reaction mixture was left undisturbed for 24 h, green-brown X-ray quality crystals (mp > 200°C) of bisruthenium complex **8** were obtained. These crystals were collected by filtration, washed with CH_2Cl_2 (2 × 20 ml), dried in vacuo and subsequently subjected to an X-ray structure determination.

X-ray Structure Determination of **8**: X-ray data were collected with an ENRAF-NONIUS CAD4 diffractometer on rotating anode for a needle-shaped green-brown crystal. Numerical data are collected in Table 3. The structure was solved by Direct Methods (SHELXL86)[18] and refined on F^2 using SHELXL96[19]. Data were corrected for absorption effects using the DIFABS algorithm as implemented in PLATON[20]. Hydrogen atoms were introduced at calculated positions and refined riding on their carrier atoms. Geometrical calculations and the ORTEP illustration were done with PLATON.

Keywords: 2-Phenyl-4-R-5(4*H*)-oxazolones / Iridium / Palladium / Platinum / Iron / Chromium / *C-o,N*-Bridging 2-phenyloxazolone / Peptide labelling

Reactions of 2-phenyl-4-R-5(4*H*)-oxazolones (R = Me, CH_2Ph, CHMeEt) with $[(\eta^5\text{-}C_5Me_5)IrCl_2]_2$ afforded the cyclometallated complexes $(\eta^5\text{-}C_5Me_5)(Cl)Ir(L)$ (**1**−**3**) [L = 2-phenyl-4-R-5(4*H*)-oxazolone(*C-o,N*)]. 2-Phenyl-5(4*H*)-oxazolone reacts with $[(\eta^5\text{-}C_5Me_5)IrCl_2]_2$ and palladium(II) acetate to give complexes with a *C-o,N*-bridging oxazolone $[(\eta^5\text{-}C_5Me_5)(Cl)Ir]_2(\mu\text{-}Cl)(\mu\text{-L-H}^+)$ (**4**) and $Pd_3(\mu\text{-ac})_5(\mu\text{-L-H}^+)$ (**5**). 2-Phenyloxazolone anions were added to the π ligands of $[(\eta^5\text{-}C_6H_7)Fe(CO)_3]^+$ and $[(\eta^7\text{-}C_7H_7)Cr(CO)_3]^+$ to give the adducts **6**−**11**. Dipeptide derivatives **12**−**18** were obtained by reaction of **1**, **2** and by reaction of the adduct **6** from $[(\eta^5\text{-}C_6H_7)Fe(CO)_3]^+$ and the anion of 2-phenyloxazolone with α-amino acid esters. These reactions may be used for the labelling of peptides. Saponification of **15**−**18** yields the organometallic substituted peptide acids **19**−**22**. Their dianions (deprotonation of COOH and peptide amide) were used as ligands towards $(Ph_3P)_2PtCl_2$ to yield the bimetallic complexes **23**−**25**. The structures of **4**, **5**, **9** and **10** were determined by X-ray diffraction.

5(4*H*)-Oxazolones which can be considered as activated α-amino acid derivatives are important intermediates and starting materials in organic synthesis.[3] Recently, we reported on some metal complexes with neutral 2-phenyl-5(4*H*)-oxazolones.[4] In the following some cyclometallated complexes from these oxazolones and the use of the delocalized oxazolone anion[5] as nucleophile for the addition to π-coordinated ligands are described. Some of the compounds obtained may be of use for the labelling of peptides[6].

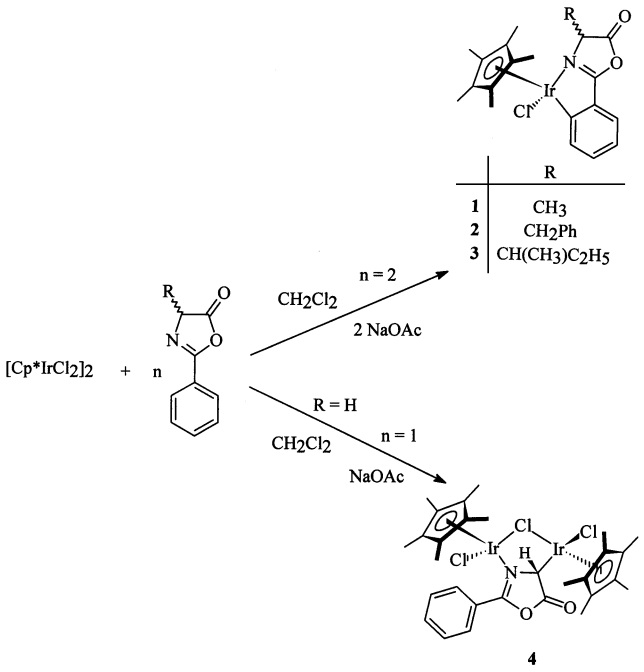
Results and Discussion

1. Cyclometallated Complexes

The reaction of the chloro-bridged iridium(III) complex $[Cp^*IrCl_2]_2$ with the substituted 2-phenyl-4-R-5(4*H*)-oxazolones gave the complexes **1**−**3**. Cyclometallation with phenyl-containing donors has been observed for several iridium complexes[7].

The complexes **1**−**3** contain an "asymmetric" metal center which causes doubling of the ^{1}H-NMR signals of the C_5Me_5 ligands (**1**: 5:1; **2**: 20:1; **3**: 1:1), due to diastereoisomer formation.

An unexpected complex **4** was obtained from the unsubstituted 2-phenyl-5(4*H*)-oxazolone and its structure was established by X-ray diffraction. In the complex **4** the two iridium atoms are bridged by a chlorine atom and a *C-o,N*-bound 2-phenyloxazolone ligand.



In the five-membered ring Cl−Ir−C−N−Ir the C atom is situated outside the almost planar arrangment of the other four atoms. The ^{1}H-NMR spectrum of **4** exhibits only

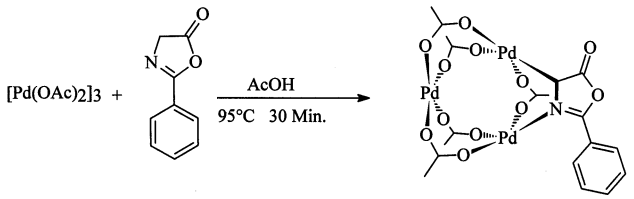
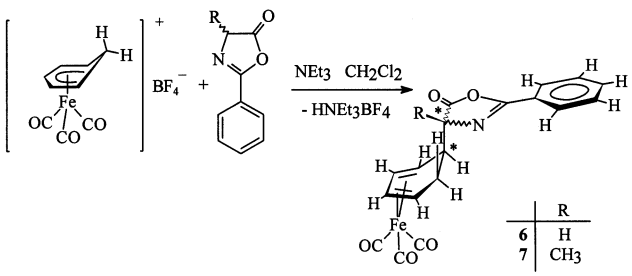
[a] Selected bond lengths [Å] and angles [°]: Pd3−O8 1.995(3), Pd3−O11 2.002(3), Pd2−O12 2.087(3), Pd2−O10 2.019(3), Pd2−C1 2.025(4), Pd1−N1 2.003(3), Pd1−O7 2.015(3), Pd1−O5 2.005(3); O11−Pd3−O6 166.40(13), O12−Pd2−C1 179.57(15), O7−Pd1−N1 175.47(13), O10−Pd2−O4 166.48(12).

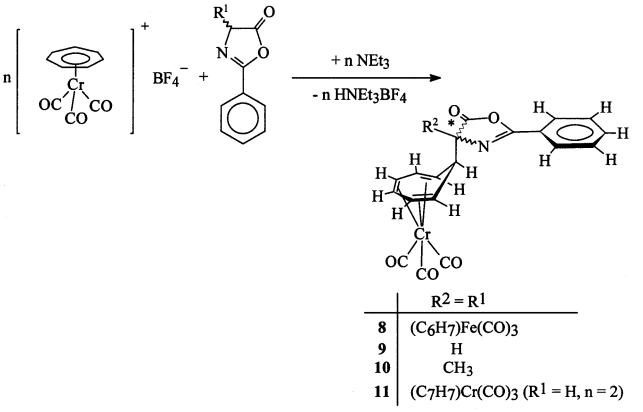
two C_5Me_5 signals which implicates that only one diastereoisomer is formed. The same bridging occurs in the trinuclear palladium complex **5** which was obtained from Pd^{II} acetate and 2-phenyl-5(4*H*)-oxazolone. In **5** one acetate bridge of Pd_3ac_6[8] is substituted by a *C-o,N*-bridging 2-phenyloxazolone.



5

The molecular structure of **5** is very similar to that of Pd_3ac_6[8] with the exception that the Pd2−O12 distance [2.087(3) Å] is longer than the other Pd−O bonds (ca. 2.01 Å). This can be attributed to the *trans* influence of the strong C donor.





2. Addition of the 2-Phenyloxazolone Anion to Unsaturated Hydrocarbons of Cationic Complexes

The addition of organic and organometallic nucleophiles to π-coordinated hydrocarbons is a very well studied and important reaction[9]. The addition of the 2-phenyl-5(4*H*)-oxazolone anion to the cyclopentadienyl and the cycloheptatrienyl ligand afforded the complexes **6**−**11**.

In **6** and **7** two stereogenic centers are formed and the two diastereoisomers (**6**: 1:1.2; **7**: 1:1.8) can be detected in their ^{1}H- and ^{13}C-NMR spectra. For almost all atoms two sets of signals are observed. Interestingly, for **8** one diastereoisomer is formed in high excess. In the ^{1}H-NMR spectrum only some weak signals can be assigned to the second isomer; *exo* addition is proven for **6** and **7** by the signals of

the $CH-CH_2$ group and for **9** and **10** by X-ray structure determination.

3. Formation of Dipeptide Derivatives from 1, 2 and 6

The nucleophilic addition of α-amino acid esters[10] to **1**, **2** and **6** gave the dipeptide derivatives **12**−**18**.

The shift of the carbonyl IR absorption to lower wavenumbers (ca. 1590 cm^{-1}) in **12**−**14** is characteristic for coordination of the CO function[11]. The two stereogenic centers of **15** give rise to two diastereoisomers (1:1.2), whereas four diastereoisomers of **16**−**18** (1:1:1.2:1.2) (from three

20	CH_2Ph
21	$CH_2CH_2SCH_3$
22	CH_2CH_2COOH

Compounds **19**−**22** were used as dianionic chelate ligands (deprotonation of the amide and carboxylic group) towards $(Ph_3P)_2PtCl_2$ to afford the heterobimetallic complexes **23**−**25**. Recently, several examples for complexes with dianionic *N*-acyl-α-amino carboxylates have been reported[12] which can be considered as simple models for *O*,*N* coordination of peptides.

Two diastereoisomers of **23** (as for **15**) and four isomers of **24** and **25** (as for **16** and **17**) were observed in the ^{31}P-NMR spectra.

Conclusions

The reaction of oxazolones with organometallic complexes leads to a versatile chemistry and the reaction of **1**, **2** and **6** with α-amino acid esters (or peptide esters) provides a method for the labelling of peptides at the amino terminus.

Support by the *Deutsche Forschungsgemeinschaft*, the *Fonds der Chemischen Industrie* and the *Wacker Chemie, München,* is gratefully acknowledged.

Experimental Section

All reactions were carried out in dry solvents under nitrogen. − NMR: Jeol GSX 270 or Jeol EX 400, using the solvent as internal standard. − IR: Nicolet 520 FT-IR. − The starting materials were prepared according to literature procedures ($[Cp^*IrCl_2]_2$[13], $[(C_6H_7)Fe(CO)_3]BF_4$[14], $[(C_7H_7)Cr(CO)_3]BF_4$[15], $(COD)PtCl_2$[16], 2-phenyl-5(4*H*)-oxazolones[17]). Pd^{II} acetate was purchased from Aldrich and purified by dissolving it in hot benzene, filtering and evaporating off the solvent. Glacial acetic acid was refluxed over $KMnO_4$ for several hours and distilled prior to use. The α-amino acid ester hydrochlorides were purchased from Merck or Fluka. − PE = polyethylene.

General Procedure for the Preparation of **1**−**3**: To a mixture of the oxazolone and 66 mg (0.81 mmol) of NaOAc in 5 ml of CH_2Cl_2 a deep red solution of 319 mg (0.4 mmol) of $[Cp^*IrCl_2]_2$ in 5 ml of the same solvent was added. After stirring overnight, the light-red mixture was filtered to remove NaCl, and the solvent was removed in vacuo. The yellow product was washed twice with 3 ml of Et_2O and dried in vacuo at 60°C for 5 h.

1: 142 mg (0.81 mmol) of 4-methyl-2-phenyl-5(4*H*)-oxazolone was used. Yellow powder. − IR (KBr): $\tilde{\nu}$ = 1844 cm^{-1} s (C=O), 1627 s (C=N); (PE): $\tilde{\nu}$ = 288 cm^{-1} s (M−Cl). − ^1H NMR (400 MHz, $CDCL_3$): δ = 1.66 (d, ^3J = 7.5 Hz, 3 H, CH_3), 1.76/*1.82* [each s, 15H 5:*1*, $C_5(CH_3)_5$], 4.43 (q, ^3J = 7.5 Hz, 1 H, C*H*CH_3), 7.04 (m, 1 H, C_6H_4), 7.27 (m, 1 H, C_6H_4), 7.53 (m, 1 H, C_6H_4), 7.82 (m, 1 H, C_6H_4). − ^{13}C NMR (100.5 MHz, $CDCl_3$): δ = 9.44/9.94 [$C_5(CH_3)_5$], 15.97 (CH_3), 58.86 (*C*HCH_3), 88.53/89.27 [$C_5(CH_3)_5$], 122.53, 127.63, 128.84, 134.05, 135.85 (C_6H_4), 166.37 (OC=N), 174.91 (Ir−C), 177.94 (C=O). − $C_{20}H_{23}ClIrNO_2$ (536.7): calcd. General Procedure for the Preparation of **6** *and* **7**: A stirred mixture of 150 mg (0.49 mmol) of $[(C_6H_7)Fe(CO)_3]BF_4$ and the appropriate oxazolone in 15 ml of CH_2Cl_2 was cooled (see below). A solution of 64.8 µl (0.47 mmol) of triethylamine in 5 ml of CH_2Cl_2 was slowly added. After 30 min of stirring at low temp., the yellow solution was allowed to warm up to room temp. and stirred for another 2 h. After concentrating to about 4 ml, triethylammonium chloride was precipitated with 40 ml of pentane and filtered off. The filtrate was concentrated and the residue was dissolved in 30 ml of pentane. This yellow solution was filtered through Celite and concentrated in vacuo to about 4 ml. Cooling to −78°C for 3 min gave a colourless precipitate which was filtered off. Removal of the solvent from the filtrate in vacuo gave the yellow, oily product which was dried in vacuo at room temp. for a few days.

6: 75 mg (0.47 mmol) of 2-phenyl-5(4*H*)-oxazolone was used. The addition of NEt_3 was carried out at −15°C. − IR (film NaCl): $\tilde{\nu}$ = 2045 cm^{-1} s (Fe−CO), 1964 s br. (Fe−CO), 1824 s (C=O), 1653 s (C=N). − ^{1}H NMR (400 MHz, $CDCl_3$): δ = *1.77* (dm, *1 H*, $^2J_{6endo}$ = 15.3 Hz, 6*exo*-C_6H_7)/1.61 (ddd, 1 H, $^2J_{6endo}$ = 15.0 Hz, $^3J_1$ = 3.7 Hz, $^3J_5$ = 2.6 Hz, 6*exo*-C_6H_7), *2.14*/2.06 (each ddd, *1 H*/1 H, $^2J_{6exo}$ = 15.1 Hz, $^3J_1$ = 11.1 Hz, $^3J_5$ = 4.0 Hz, 6*endo*-C_6H_7), 2.74 (m, *1 H* + 1 H, 1-C_6H_7), *2.92* (ddd, *1 H*, $^3J_3$ = 6.3 Hz, $^3J_1$ = 3.3 Hz, $^4J_4$ = 1.4 Hz, 2-C_6H_7)/3.06, 3.06 [m, *1 H* + 1 H (+ 1 H, 2-C_6H_7), 5-C_6H_7], *4.20*/4.24 [each d, *1 H*/1 H, $^3J_1$ = 6.0 Hz, NC*H*(C_6H_7)COO], *5.32* (ddd, *1 H*, $^3J_2$ = 6.1 Hz, $^3J_4$ = 4.4 Hz, $^4J_5$ = 1.6 Hz, 3-C_6H_7)/5.39, 5.39 [m, *1 H* + 1 H (+ 1 H, 3-C_6H_7), 4-C_6H_7], 7.43−7.60 (ABB′, *3 H* + 3 H, 3,4,5-C_6H_5), 7.96−8.00 (CC′, *2 H* + 2 H, 2,6-C_6H_5). − ^{13}C NMR (100.5 MHz, $CDCl_3$): δ = *27.77*/26.50 (6-C_6H_7), *40.25*/40.98 (1-C_6H_7), *59.38*/59.39, *59.26*/58.83 (2,5-C_6H_7), *70.03*/69.99 [CN*C*H(C_6H_7)COO], *86.06*/86.51, *85.83*/85.48 (3,4-C_6H_7), *125.95, 128.20, 129.14, 133.16,* 126.11, 128.22, 129.12, 133.14 (C_6H_5), *162.07*/161.95 [*C*NCH(C_6H_7)COO], *176.90*/177.29 [CNCH(C_6H_7)*C*OO], 211.69 (Fe−*C*O). General Procedure for the Preparation of **8**−**11**: A stirred mixture of $[(C_7H_7)Cr(CO)_3]BF_4$ and the appropriate oxazolone in 15 ml of THF was cooled to 0°C. A solution of triethylamine in 5 ml of THF was slowly added. After stirring overnight, the red solution was concentrated to about 4 ml, triethylammonium chloride was precipitated with 40 ml of Et_2O and filtered off. The filtrate was taken to dryness and the residue was dissolved in 30 ml of Et_2O. This solution was filtered through Celite and the solvent was removed in vacuo. The residue was dissolved in 1 ml of CH_2Cl_2 and added to excess pentane to give the product as orange solid which was washed twice with pentane and dried in vacuo at 50°C for several hours.

8: 98 mg (0.31 mmol) of $[(C_7H_7)Cr(CO)_3]BF_4$, 117 mg (0.31 mmol) of **6** and 43.5 µl (0.31 mmol) of NEt_3 were used. The reaction was carried out in CH_2Cl_2 instead of THF. The CH_2Cl_2/pentane mixture had to be slowly concentrated to give the product. − IR (KBr): $\tilde{\nu}$ = 2045 cm^{-1} s (Fe−CO), 1979 s br. (Fe−CO, Cr−CO), 1924 s, 1884 s, 1878s, 1870 s (Cr−CO), 1807 s (C=O), 1653 s (C=N). − ^{1}H NMR (270 MHz, $CDCl_3$): δ = 1.42 (ddd, 1 H, $^2J_{6endo}$ = 14.9 Hz, $^3J_1$ = 3.6 Hz, $^3J_5$ = 2.5 Hz, 6*exo*-C_6H_7), 1.87 (*2.00*) (ddd, 1 H, $^2J_{6exo}$ = 14.9 Hz, $^3J_1$ = 10.8 Hz, $^3J_5$ = 4.2 Hz, 6*endo*-C_6H_7), 2.59 (ddd, 1 H, $^3J_{6endo}$ = 10.6 Hz, $^3J_{6exo}$ = 3.5 Hz, $^3J_2$ = 3.5 Hz, 1-C_6H_7), 2.68 (ddd, 1 H, $^3J_3$ = 5.1 Hz, $^3J_1$ = 3.5 Hz, $^4J_4$ = 2.2 Hz, 2-C_6H_7), 2.94 (*3.06*) (ddd, 1 H, $^3J_4$ = 7.9 Hz, $^3J_{6endo}$ = 3.7 Hz, $^3J_{6exo}$ = 2.2 Hz, 5-C_6H_7), 3.61 (m, 3 H, 1,2,7-C_7H_7), 4.82 (*5.00*) (m, 2 H, 3,6-C_7H_7), 5.23 (*5.36*) (m, 2 H, 3,4-C_6H_7), 5.85 (m, 1 H, 4-C_7H_7), 5.98 (m, 1 H, 5-C_7H_7), 7.50 (BB′, 2 H, 3,5-C_6H_5), 7.60 (A, 1 H, 4-C_6H_5), 7.86 (*7.78*) (CC′, 2 H, 2,6-C_6H_5). Diastereoisomeric ratio about 13:*1*. − ^{13}C NMR (100.4 MHz, $CDCl_3$): δ = 26.70 (6-C_6H_7), 41.12 (1-C_7H_7), 44.44 (1-C_6H_7), 56.51, 58.62 (2,5-C_6H_7), 62.39, 64.27 (2,7-C_7H_7), 83.34 (N*C*RR′COO), 85.56, 86.18 (3,4-C_6H_7), 97.50, 98.03, (4,5-C_7H_7), 102.04, 102.29 (3,6-C_7H_7), 125.60, 128.25, 129.21, 133.23 (C_6H_5), 160.30 [O*C*(Ph)N], 176.91 (CRR′*C*OO), 211.52 (Fe−CO). − $C_{28}H_{19}CrFeNO_8$ (605.3): calcd. 3,4,5-C_6H_5), 7.75−7.84 (m, 2 H, 2,6-C_6H_5). − $C_{25}H_{26}FeN_2O_9$ (554.3): calcd. C 54.17, H 4.73, N 5.05; found C 53.95, H 4.38, N 5.28.

General Procedure for the Preparation of **19**−**22**: To a solution of **15**−**18** in 10 ml of ethanol/water (4:1) a slight excess of NaOH (0.1 N) was slowly added. After stirring for a few hours, an equimolar amount of HCl (0.1 N) was added and after 30 min of further stirring the solvents were removed under reduced pressure. The residue was taken up in Et_2O/THF (1:1) (**19**), Et_2O/acetone (10:1) (**22**), or Et_2O (**20**, **21**) and filtered through Celite to remove NaCl. After concentrating in vacuo, the solution was added to excess pentane to precipitate the colourless product which was collected, washed once with pentane and dried in vacuo at 50°C for a few days.

19: 43 mg (0.092 mmol) of **15**, 0.93 ml of 0.1 N NaOH and 0.93 ml of 0.1 N HCl were used. − IR (KBr): $\tilde{\nu}$ = 3407 cm^{-1} m br., 3305 s br. (O−H, N−H), 2046 s (Fe−CO), 1973 s br. (Fe−CO), 1729 s (COOH), 1637 s (CONH-I), 1535 s (CONH-II). − ^{1}H NMR (400 MHz, [D$_6$]acetone): δ = 1.60 (m, 1 H, 6*exo*-C_6H_7), ca. 2.00 (m, 6*endo*-C_6H_7), 2.80 (m, 1 H, 1-C_6H_7), 3.27 (m, 2 H, 2,5-C_6H_7), 3.96 (m, 2 H, CH_2), 4.48 (m, 1 H, PhCONHC*H*), 5.61 (m, 2 H, 3,4-C_6H_7), 7.42−7.58 (m, 3 H, 3,4,5-C_6H_5), 7.88−8.00 (m, 2 H, 2,6-C_6H_5), 9.96 (s, 1 H, COOH). − $C_{20}H_{18}FeN_2O_7$ (454.2): calcd. C 52.89, H 3.99, N 6.17; found C 52.44, H 3.90, N 6.16.

20: 70 mg (0.125 mmol) of **16**, 1.3 ml of 0.1 N NaOH and 1.3 ml of 0.1 N HCl were used. Four stereoisomers. − IR (KBr): $\tilde{\nu}$ = 3428 cm^{-1} s br. (O−H, N−H), 2045 s (Fe−CO), 1970 s br. (Fe−CO), 1729 s (COOH), 1641 s (CONH-I), 1523 s (CONH-II). − ^{1}H NMR (270 MHz, $CDCl_3$): δ = 1.34 (m, 1 H, 6*exo*-C_6H_7), 1.91 (m, 1 H, 6*endo*-C_6H_7), 2.37−3.33 (m, 5 H, CH_2, 1-C_6H_7, 2,5-C_6H_7), 3.63, 4.38 (2 m, 1 H, PhCONHC*H*), 4.78 [m, 1 H, CONHC*H*(CH_2Ph)], 5.28 (m, 2 H, 3,4-C_6H_7), 6.72 (m, 1 H, NH), 6.96−7.60 (m, 9 H, NH, $CH_2C_6H_5$, 3,4,5-C_6H_5), 7.66−7.86 (m, 2 H, 2,6-C_6H_5). − $C_{27}H_{24}FeN_2O_7$ (544.3): calcd. C 59.58 H 4.44, N 5.15; found C 59.59, H 4.61, N 5.19.

21: 51 mg (0.094 mmol) of **17**, 0.98 ml of 0.1 N NaOH and 0.98 ml of 0.1 N HCl were used. Four stereoisomers. − IR (KBr): $\tilde{\nu}$ = 3403 cm^{-1} m br., 3300 s br. (O−H, N−H), 2047 s (Fe−CO), 1970 s br. (Fe−CO), 1723 s (COOH), 1636 s (CONH-I), 1532 s (CONH-II). − ^{1}H NMR (400 MHz, [D$_6$]acetone): δ = 1.60 (m, 1 H, 6*exo*-C_6H_7), ca. 2.00 (m, 6*endo*-C_6H_7, CH_2, SCH_3), 2.56 (m, 2 H, CH_2), 2.78 (m, 1 H, 1-C_6H_7), 3.24 (m, 2 H, 2,5-C_6H_7), 4.38−4.64 [m, 2 H, PhCONHC*H*, CONHC*H*(CH_2Ph)], 5.57 (m, 2 H, 3,4-C_6H_7), 7.43−7.57 (m, 3 H, 3,4,5-C_6H_5), 7.88−7.95 (m, 2 H, 2,6-C_6H_5). − $C_{23}H_{24}FeN_2O_7S$ (528.4): calcd. C 52.29, H 4.58, N 5.30; found C 52.73, H 4.70, N 5.27.

22: 95 mg (0.171 mmol) of **18**, 3.5 ml of 0.1 N NaOH and 3.5 ml of 0.1 N HCl were used. Four stereoisomers. − IR (KBr): $\tilde{\nu}$ = 3429 cm^{-1} s br. (O−H, N−H), 2047 s (Fe−CO), 1971 s br. (Fe−CO), 1723 s, 1720 s (2 COOH), 1644 s (CONH-I), 1527 s (CONH-II). − ^{1}H NMR (270 MHz, [D$_6$]acetone): δ = 1.59 (m, 1 H, 6*exo*-C_6H_7), ca. 2.00 (m, 6*endo*-C_6H_7, CH_2), 2.42 (m, 2 H, CH_2), 2.84 (m, 1 H, 1-C_6H_7), 3.20 (m, 2 H, 2,5-C_6H_7), 4.50 [m, 2 H, PhCONHC*H*, CONHC*H*(CH_2Ph)], 5.54 (m, 2 H, 3,4-C_6H_7), 7.41−7.62 (m, 3 H, 3,4,5-C_6H_5), 7.87−7.95 (m, 2 H, 2,6-C_6H_5). − $C_{23}H_{22}FeN_2O_9$ (526.3): calcd. C 52.49, H 4.21, N 5.32; found C 52.33, H 3.94, N 5.04.

General Procedure for the Preparation of **23**−**25**: To a solution of (COD)$PtCl_2$ in 10 ml of CH_2Cl_2 two equiv. of PPh_3, one equivalent of **19**−**21** and a slight excess of Ag_2O were added. This mixture was refluxed in the dark for 6 h and then, after cooling to room temp., filtered through Celite. The solvent was evaporated and the residue dried in vacuo for 2 h. After dissolving in 1 ml of CH_2Cl_2, petroleum ether was added to precipitate the colourless product which was washed with petroleum ether and dried in vacuo at room temp. for several days.

23: 9 mg (0.024 mmol) of (COD)$PtCl_2$, 11 mg (0.024 mmol) of **19**, 13 mg (0.05 mmol) of PPh_3 and 12 mg (0.052 mmol) of Ag_2O were used. − IR (KBr): $\tilde{\nu}$ = 3410 cm^{-1} s br. (N−H), 2042 s (Fe−CO), 1965 s br. (Fe−CO), 1653 s br. (coord. COO, CONH-I), 1512 s (CONH-II). − ^{1}H NMR (270 MHz, $CDCl_3$): δ = 1.55 (m, 1 H, 6*exo*-C_6H_7), 1.98 (m, 6*endo*-C_6H_7), 2.60 (m, 1 H, 1-C_6H_7), 3.05 (m, 4 H, 2,5-C_6H_7, NCH_2COO), 4.40 [m, 1 H, NHC*H*(C_6H_7)CON], 5.35 (m, 2 H, 3,4-C_6H_7), 6.99−7.82 (m, 35 H, 7 C_6H_5). − ^{31}P NMR: δ = 2.97 (d, $^2J_{P\text{-}P}$ = 18.6 Hz, $^1J_{P\text{-}Pt}$ = 3665 Hz, P *trans* to O), *4.08* (d, $^2J_{P\text{-}P}$ = 23.1 Hz, $^1J_{P\text{-}Pt}$ could not be determined, P *trans* to O), *10.36* (d, $^2J_{P\text{-}P}$ = 23.1 Hz, $^1J_{P\text{-}Pt}$ could not be determined, P *trans* to N), 18.61 (d, $^2J_{P\text{-}P}$ = 18.6 Hz, $^1J_{P\text{-}Pt}$ = 3921 Hz, P *trans* to N). Diastereomeric ratio 6:*1*. − $C_{56}H_{46}FeN_2O_7P_2Pt \times 0.5\ CH_2Cl_2$ (1214.3): calcd. C 55.89, H 3.90, N 2.31; found C 55.16, H 3.90, N 2.32.

24: 16 mg (0.043 mmol) of (COD)$PtCl_2$, 23 mg (0.042 mmol) of **20**, 22 mg (0.084 mmol) of PPh_3 and 20 mg (0.086 mmol) of Ag_2O were used. − IR (KBr): $\tilde{\nu}$ = 3430 cm^{-1} m br. (N−H), 2042 s (Fe−CO), 1967 s br. (Fe−CO), 1653 s br. (coord. COO, CONH-I), 1509 s (CONH-II). − ^{1}H NMR (270 MHz, $CDCl_3$): δ = 1.48 (m, 1 H, 6*exo*-C_6H_7), 1.85 (m, 6*endo*-C_6H_7), 2.24 (m, 1 H, 1-C_6H_7), 2.90 (m, 4 H, 2,5-C_6H_7, CH_2Ph), 3.72 [m, 1 H, NC*H*(CH_2Ph)COO], 4.30 [m, 1 H, NHC*H*(C_6H_7)CON], 5.25 (m, 2 H, 3,4-C_6H_7), 6.78−7.82 (m, 40 H, 8 C_6H_5). − ^{31}P NMR: δ = 2.85, 2.87, 2.92, 2.98 (each d, $^2J_{P\text{-}P}$ = 18.9 Hz, $^1J_{P\text{-}Pt}$ = 3669 Hz, P *trans* to O), 18.33, 18.36, 18.38, 18.41 (each d, $^2J_{P\text{-}P}$ = 18.3 Hz, $^1J_{P\text{-}Pt}$ = 3893 Hz, P *trans* to N). Diastereomeric ratio about 1:1:1.5:1.5. − $C_{63}H_{52}FeN_2O_7P_2Pt \times 0.5\ CH_2Cl_2$ (1304.5): calcd. C 58.01, H 4.02, N 2.15; found C 57.78, H 4.33, N 2.04.

25: 13.5 mg (0.036 mmol) of (COD)$PtCl_2$, 19 mg (0.036 mmol) of **21**, 18.9 mg (0.072 mmol) of PPh_3 and 18 mg (0.078 mmol) of Ag_2O were used. − IR (KBr): $\tilde{\nu}$ = 3415 cm^{-1} s br. (N−H), 2042 s (Fe−CO), 1967 s br. (Fe−CO), 1652 s br. (coord. COO, CONH-I), 1512 s (CONH-II). − ^{1}H NMR (270 MHz, $CDCl_3$): δ = 1.52 (m, 1 H, 6*exo*-C_6H_7), 1.85 (m, 6*endo*-C_6H_7, CH_2), 1.94, 2.01, 2.03 [each s, together 3 H, SCH_3 (1:1:2)], 2.50 (m, 3 H, 1-C_6H_7, CH_2), 2.98 (m, 2 H, 2,5-C_6H_7), 3.52, 3.74 [each m, together 1 H, NC*H*($CH_2CH_2SCH_3$)COO], 4.40 [m, 1 H, NHC*H*(C_6H_7)CON], 5.31 (m, 2 H, 3,4-C_6H_7), 7.08−7.89 (m, 35 H, 7 C_6H_5). − ^{31}P NMR: δ = 2.79, 2.80, 2.91, 2.97 (each d, $^2J_{P\text{-}P}$ = 19.2 Hz, $^1J_{P\text{-}Pt}$ = 3690 Hz, P *trans* to O), 18.24, 18.25, 18.34, 18.41 (each d, $^2J_{P\text{-}P}$ = 19.2 Hz, $^1J_{P\text{-}Pt}$ = 3881 Hz, P *trans* to N). Diastereomeric ratio about 1:1:1:2. − $C_{59}H_{52}FeN_2O_7P_2PtS \times CH_2Cl_2$ (1330.9): calcd. C 54.15, H 4.09, N 2.11; found C 53.53, H 4.23, N 2.31.

X-ray Diffraction Analyses[18]: Data collection: Enraf Nonius CAD4 Diffractometer (**4**, **5**), Siemens P4 Diffractometer (**9**, **10**), Mo-K_α radiation, λ = 0.71073 Å, graphite monochromator, cell constants from 25 centered reflections, ω-2Θ scan, intensity of three standard reflections checked every 2 h. Structure solution by SHELXS-86 and refinement by SHELXL-93 (G. M. Sheldrick, University of Göttingen, Germany), non-hydrogen atoms refined anisotropically, hydrogen atoms with U_i = 1.2 × U_{eq} of the adjacent carbon atom (**4**, **5**, **10**). For **9** hydrogen atoms found and refined freely. Full-matrix refinement against F^2. See Table 1 for crystal data and structure refinement.

Keywords: Heterobimetallics / μ-Isonitrile complexes / μ-Aminocarbyne complexes / Bis(diphenylphosphanyl)amine / Iron / Platinum

Addition of isonitriles to $[(OC)_3Fe(\mu\text{-}CO)(\mu\text{-}Ph_2PNHPPh_2)Pt(PPh_3)]$ **1** produces the μ-isonitrile complexes $[(OC)_3Fe(\mu\text{-}C{=}NR)(\mu\text{-}Ph_2PNHPPh_2)Pt(PPh_3)]$ **2**, which are transformed to the μ-aminocarbyne complexes $[(OC)_3Fe\{\mu\text{-}CN(El)R\}(\mu\text{-}Ph_2PNHPPh_2)Pt(PPh_3)]^+$ **3** and **4** by electrophilic addition of $[El][BF_4]$ or $[El][OSO_2CF_3]$ (El = H, Me). The dppa backbone of **4** is readily deprotonated by $KOSiMe_3$ to yield the very stable zwitterionic aminocarbyne complex $[(OC)_3Fe\{\mu\text{-}CN(Me)2,6\text{-}xylyl\}(\mu\text{-}Ph_2PNPPh_2)Pt(PPh_3)]$ **5**.

Isonitriles (RNC) are often employed as ligands in coordination chemistry, since steric and electronic variation of the group R permits a fine tuning of the properties of a metal complex.[1][2] In addition to the innumerable examples of mononuclear isonitrile complexes, many heterobimetallic complexes and higher-nuclearity clusters bearing *terminal* isonitrile ligands have now been documented. However, polymetallic systems containing an isonitrile bridge between *two different* metal centers are still extremely scarce.[3a][3b][3c] We recently obtained the bis(diphenylphosphanyl)methane-bridged μ-isonitrile complex $[(OC)_3Fe(\mu\text{-}C{=}N\text{-}xylyl)(\mu\text{-}dppm)Pt(PPh_3)]$ by treatment of $[(OC)_3Fe\{Si(OMe)_3\}(\mu\text{-}dppm)Pt(H)(PPh_3)]$ with 2,6-dimethylphenylisonitrile under formal loss of $HSi(OMe)_3$.[3c] We report here on a different route for the synthesis of the bis(diphenylphosphanyl)amine-bridged μ-isonitrile complexes $[(OC)_3Fe(\mu\text{-}C{=}NR)(\mu\text{-}dppa)Pt(PPh_3)]$ and on their transformation to μ-aminocarbyne complexes, which have been characterized by multinuclear NMR techniques and single-crystal X-ray diffraction studies.

Results

In a manner similar as described by Shaw. et al. for the synthesis of the dppm-bridged complex $[(OC)_3Fe(\mu\text{-}CO)(\mu\text{-}dppm)Pt(PPh_3)]$[4], we obtained the dppa-bridged analogue $[(OC)_3Fe(\mu\text{-}CO)(\mu\text{-}dppa)Pt(PPh_3)]$ **1** containing a μ-carbonyl ligand by reaction of $[(OC)_4Fe(dppa\text{-}P)]$[5] with $[Pt(H_2C{=}CH_2)(PPh_3)_2]$ in 79% yield, as shown in Scheme 1. Addition of *o*-anisylisonitrile or 2,6-xylylisonitrile in a 1:1 ratio to the latter complex yields *selectively* within 10 min. at ambient temperature the heterobimetallic species $[(OC)_3Fe(\mu\text{-}C{=}NR)(\mu\text{-}dppa)Pt(PPh_3)]$ (**2a**: R = 2,6-xylyl; **2b**: R = *o*-anisyl) by substitution of the bridging carbonyl in **1**. There was no indication for a competing formation of an isomer bearing a terminal isonitrile ligand.

The most significant change in the IR spectra that accompanies the conversion of **1** to **2** is the replacement of the ν(CO) stretch of the bridging carbonyl of **1** (1761 cm^{-1}) by a broadened ν(C=N) stretch of medium intensity (**2a**: 1674; **2b**: 1670 cm^{-1}). The latter bands fall in the typical range for bridging isonitrile ligands with a strongly *bent* C=N−R group. The $^{31}P\{^1H\}$-NMR spectra of all the compounds reported herein characteristically show three mutually coupled resonances, as exemplified by that of **2a**. The spectrum of this μ-isonitrile complex features a doublet of doublets at δ = 114.3, attributable to the iron-bound dppa-phosphorus atom, which shows a strong coupling [^{2+3}J(P−P) = 174 Hz] to the platinum-bound dppa phosphorus at δ = 90.3. These signals are split further due to the presence of the PPh_3 ligand. The latter gives rise to a doublet of doublets at δ = 40.4, with couplings of 44 and 6 Hz. All signals are flanked by ^{195}Pt satellites, the Pt−P couplings of which are also evident in the ^{195}Pt-NMR spectrum (see Experimental Section).

Addition of excess of $HBF_4 \cdot Et_2O$ or $HOSO_2CF_3$ to a solution of **2** in dichloromethane led instantaneously to formation of the stable *N*-protonated cationic μ-aminocarbyne complexes $[(OC)_3Fe\{\mu\text{-}CN(H)R\}(\mu\text{-}dppa)Pt(PPh_3)][X]$ (**3a**: R = 2,6-xylyl, X = BF_4^-; **3b**: R = *o*-anisyl, X = $OSO_2CF_3^-$) in almost quantitative yields. It seems that in

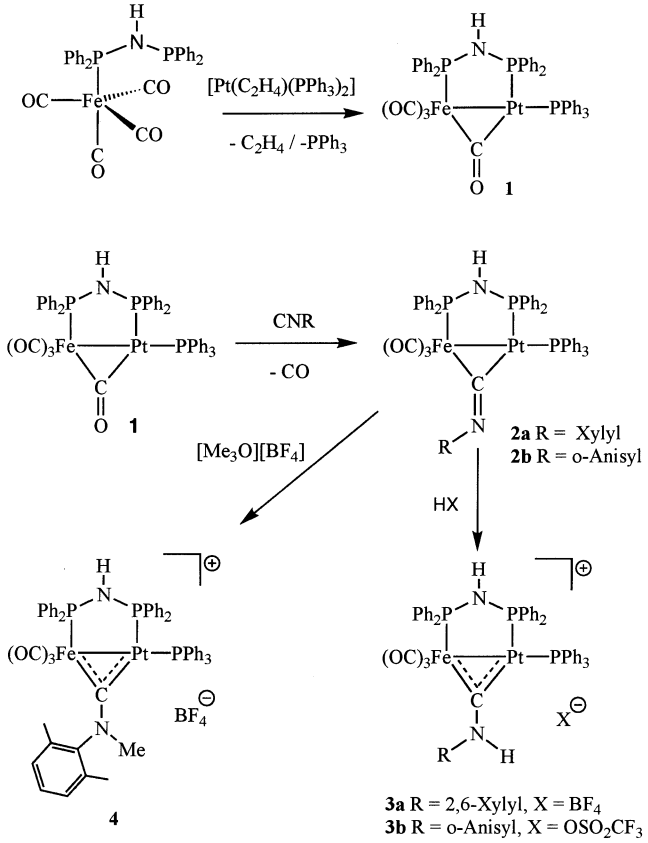
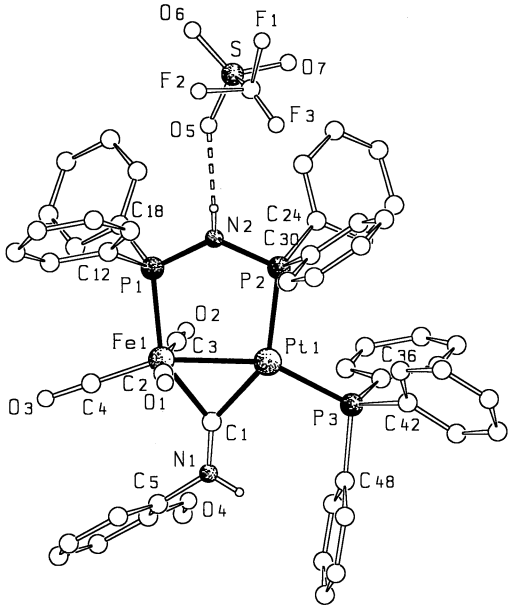
Scheme 1



this case protonation of the nitrogen atom of the μ-CNR ligand is preferred to protonation of the metal-metal bond or a metal center yielding a heterometallic hydride complex, a reaction which would be a priori also conceivable. For example, protonation of $[(OC)_3Fe(\mu\text{-}CO)(\mu\text{-}dppm)Pt(PPh_3)]$ with HBF_4 is reported to give the cationic hydride-complex $[(OC)_4Fe(\mu\text{-}dppm)Pt(H)(PPh_3)][BF_4]$.[4]

The spectroscopic data obtained in solution were in agreement with the results of a single-crystal X-ray diffraction study performed on **3b**. The latter shows that the μ-aminocarbyne ligand symmetrically bridges [Fe−C(1) 1.975(6), Pt−C(1) 1.923(5) Å] the two metal centers, the separation of which, 2.5282(10) Å, is indicative of the presence of a metal-metal bond. Due to steric factors, only the isomer with the anisyl group oriented towards the iron center is formed. The short bond length between C(1) and N(1) of 1.263(7) Å reflects the partial C=N double-bond character of the μ-aminocarbyne unit, which, therefore, may alternatively be considered as a dimetallated iminium salt ligand. To date, to the best of our knowledge, only one other example of a *heterobimetallic* μ-aminocarbyne complex has been structurally described. A C−N distance of 1.29(2) Å was observed for this tungsten-gold complex bridged by a CN(Et)Me ligand.[6] The triflate counterion of **3b** is hydrogen-bonded to the N−H group {*d*[N(2)−H(2)...O(5)] 2.867 Å; H(2)···O(5) 2.10(7) Å} of the dppa ligand. The position of H(2) could be located and was isotropically refined. A comparable distance of 2.91 Å has been reported by Ellermann et al. for the hydrogen-bridged complex $[Cu(CN)(dppa)PPh_3]\cdot MeOH$.[7] Overall, the structure of **3b** shows strong similarities to that of the recently published μ-vinylidene complex $[(OC)_3Fe\{\mu\text{-}C{=}C(H)Ph\}(\mu\text{-}dppm)Pt(PPh_3)]$.[8]

Figure 1. View of the crystal structure of **3b** showing the atom-numbering scheme[a]



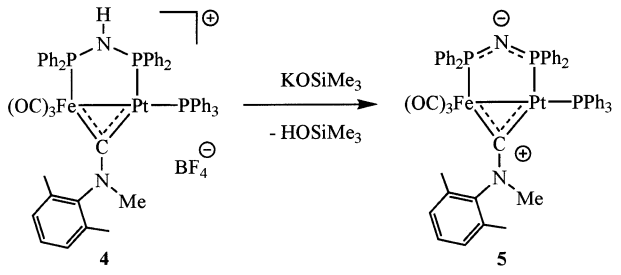
[a] Selected bond lengths [Å] and angles [°]: Fe−Pt 2.528(1), Fe−P(1) 2.226(3), Pt−P(2) 2.327(2), Pt−P(3) 2.291(1), Fe−C(1) 1.975(6), Pt−C(1) 1.923(5), C(1)−N(1) 1.263(7), P(1)−N(2) 1.668(9), P(2)−N(2) 1.697(9); C(1)−N(1)−C(5) 126.1(5), Pt−C(1)−Fe 80.9(2), Fe−Pt−C(1) 48.7(2), Pt−Fe−C(1) 50.5(2), C(1)−Fe−P(1) 146.9(2), C(1)−Pt−P(2) 144.2(2), C(1)−Pt−P(3) 103.5(2), P(1)−Fe−Pt 96.45(5), P(2)−Pt−P(3) 112.18(5), Fe−Pt−P(3) 151.32(4), P(1)−N(2)−P(2) 126.9(3).

In a similar manner, upon treatment of **2a** with a slight excess of $[Me_3O][BF_4]$, electrophilic addition affords the stable *N*-alkylated product $[(OC)_3Fe\{\mu\text{-}CN(Me)xylyl\}(\mu\text{-}dppa)Pt(PPh_3)][BF_4]$ **4**, which has been fully characterized by multinuclear NMR techniques and elemental analysis. Characteristic for this type of aminocarbyne complex is the ^{13}C resonance of the μ-C atom, which is observed in the lowfield region at $\delta = 311.7$ as a doublet of doublets of doublets with $^2J(P-C)$ coupling constants of 3, 11, and 82 Hz. Upon treatment of **3** with weak bases such as NEt_3 or $KOSiMe_3$, deprotonation of the μ-aminocarbyne ligand yields the precursor compounds **2**.

However, addition of $KOSiMe_3$ to a solution of **4** did not yield the anticipated μ-siloxycarbene complex.[9] Instead, deprotonation of the dppa backbone occurred, with formation of the stable zwitterionic μ-aminocarbyne complex $[(OC)_3Fe\{\mu\text{-}CN(Me)xylyl\}(\mu\text{-}Ph_2PNPPh_2)Pt(PPh_3)]$ **5**.

In addition to a detailed spectroscopic investigation in solution (see Experimental Section), the solid-state structure of **5** has been determined by a single-crystal X-ray diffraction study. Comparison with the structure of **3b** reveals that deprotonation of the dppa backbone has no significant influence on the metal-metal [Fe−Pt 2.517(1) Å] and metal-

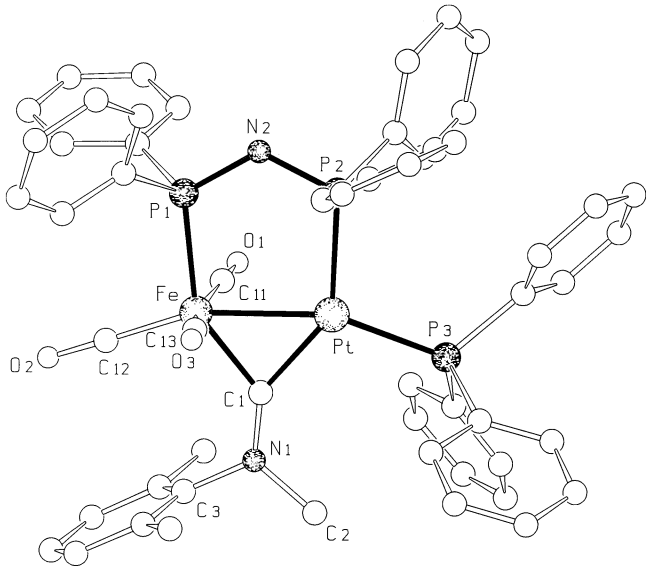
Scheme 2



4 **5**

phosphorus distances. Only the shortened P(1)−N(2) and P(2)−N(2) distances of 1.608(4) and 1.633(4) Å may reflect a charge delocalization in the bis(diphenylphosphanyl)-amide bridge. These values are comparable to the P−N distances [1.626(7) and 1.598(7) Å] found in the bis(diphenylphosphanyl)amide-bridged dinuclear complex $[Co_2(\mu\text{-}CO)(CO)_4(\mu\text{-}Ph_2PNPPh_2)(\mu\text{-}PPh_2)]$ and the mononuclear chelate $[Pd(Cl)(Ph_2PNPPh_2)(PEt_3)]$, as reported recently by Ellermann[10] and Muller.[11] Compared to the P−N−P angle of **3b** [126.9(3)°], that of **5** is somewhat more acute and amounts to 123.4(2)°.

Figure 2. View of the crystal structure of **5** showing the atom-numbering scheme[a]



[a] Selected bond lengths [Å] and angles [°]: Fe−Pt 2.517(1), Fe−P(1) 2.276(2), Pt−P(2) 2.349(2), Pt−P(3) 2.277(1), Fe−C(1) 1.918(4), Pt−C(1) 1.996(5), C(1)−N(1) 1.296(6), P(1)−N(2) 1.608(4), P(2)−N(2) 1.633(4); C(1)−N(1)−C(2) 124.6(4), Pt−C(1)−Fe 80.0(2), Fe−Pt−C(1) 48.6(1), C(1)−Fe−Pt 51.3(2), C(1)−Fe−P(1) 146.9(2), C(1)−Pt−P(2) 141.40(13), C(1)−Pt−P(3) 109.5(1), P(1)−Fe−Pt 95.60(5), P(2)−Pt−P(3) 108.97(5), Fe−Pt−P(3) 157.14(4), P(1)−N(2)−P(2) 123.4(5).

To the best of our knowledge, the solid-state structures of **3b** and **5** represent the first examples of X-ray crystal-structure determinations performed on heterometallic bis(diphenylphosphanyl)amine- and bis(diphenylphosphanyl)amide-bridged systems. We are currently investigating the steric and electronic factors that govern the bonding mode of the coordinated isonitrile ligand (bridging vs. terminal)[12] and the reactivity of the amide bridge of $[(OC)_3Fe\{\mu\text{-}CN(R)(R')\}(\mu\text{-}Ph_2PNPPh_2)Pt(PPh_3)]$ towards electrophiles. Preliminary results using an $[AuPPh_3]^+$ fragment indicate that this route permits the synthesis of heterotrimetallic μ-aminocarbyne complexes of the type $[(OC)_3(L)Fe\{\mu\text{-}CN(R)(R')\}\{\mu\text{-}Ph_2PN(AuPPh_3)PPh_2\}Pt(PPh_3)]^+$ (L = CO, CNR).

The *Deutsche Forschungsgemeinschaft* and the *Fonds der Chemischen Industrie* is gratefully thanked for habilitation grants and financial support to M. K and C. S. and *Degussa AG* for a generous gift of Pt salts. We are also indebted to Prof. *M. Veith* for his support and for providing the institute facilities.

Experimental Section

All reactions were performed in Schlenk-tube flasks under purified nitrogen. Solvents were dried and distilled under nitrogen before use, toluene and hexane over sodium, dichloromethane from P_4O_{10}. Nitrogen was passed through BASF R3-11 catalyst and molecular-sieve columns to remove residual oxygen and water. Elemental C, H and N analyses were performed on a Leco Elemental Analyser CHN 900. − The ^1H-, $^{31}P\{^1H\}$-, and $^{13}C\{^1H\}$-NMR spectra were recorded at 200.13, 81.01 and 50.32 MHz, respectively, on a Bruker ACP 200 instrument. Phosphorus-chemical shifts were referenced to 85% H_3PO_4 in H_2O with downfield shifts reported as positive. ^{195}Pt-chemical shifts were measured on a Bruker ACP 200 instrument (42.95 MHz) and externally referenced to K_2PtCl_4 in water with downfield chemical shifts reported as positive. NMR spectra were recorded in pure $CDCl_3$, unless otherwise stated. The presence and amount of CH_2Cl_2 retained in **3a** and **4** was determined from the ^1H-NMR spectra. − The reactions were generally monitored by IR spectroscopy in the ν(CO) region. − $[Me_3O][BF_4]$ and 2,6-xylylisonitrile were obtained from Aldrich and Fluka and were used as received; dppa was prepared as described by Meinel and Nöth.[13]

Preparation of [(CO)$_3$Fe(μ-CO)(μ-dppa)Pt(PPh$_3$)] (**1**): To a solution of $[Pt(H_2C{=}CH_2)(PPh_3)_2]$ (751 mg, 1.0 mmol) in toluene (10 ml) one equivalent of $[(OC)_4Fe(dppa\text{-}P)]$ (553 mg, 1.0 mmol) was added. After stirring for 20 min. at ambient temperature, the orange-red solution was concentrated and **1** was precipitated by slow addition of hexane. The resulting crude yellow-orange product, which was sufficiently pure for further reactions, was then dried in vacuo. Yield: 798 mg (79%). Analytically pure **1** was obtained in form of red-orange crystals by recrystallization from toluene/Et_2O. − IR (KBr): $\tilde{\nu}$ = 2006 cm^{-1} (s), 1939 (vs), 1925 (sh), 1761 (m, br.) ν(CO). − ^1H NMR: δ = 4.97 [m, br., NH, $^3J(Pt-H)$ = 95.0 Hz], 7.00−7.69 (m, 35 H, phenyl). − $^{31}P\{^1H\}$ NMR: δ = 118.1 [dd, P^1(Fe), $^{2+3}J(P^1-P^2)$ = 213, $^{3+4}J(P^1-P^3)$ = 4, $^{2+3}J(Pt-P)$ = 30 Hz], 93.4 [dd, P^2(Pt), $^1J(Pt-P)$ = 2877 Hz], 42.0 [dd, P^3(Pt), $^2J(P^2-P^3)$ = 63, $^1J(Pt-P)$ = 4628 Hz]. − $^{195}Pt\{^1H\}$NMR: δ = −2543 [ddd, $^{2+3}J(Pt-P^1)$ = 30, $^1J(Pt-P^2)$ = 2877, $^1J(Pt-P^3)$ = 4628 Hz]. − $C_{46}H_{36}FeNO_4P_3Pt\cdot Et_2O$ (1010.65 + 74.12): calcd. C 55.36, H 4.27, N 1.29; found C 55.48, H 4.04, N 1.08.

Preparation of [(CO)$_3$Fe(μ-CN-xylyl)(μ-dppa)Pt(PPh$_3$)] (**2a**): To a solution of **1** (202 mg, 0.2 mmol) in CH_2Cl_2 (5 ml), one equivalent of 2,6-xylylisonitrile, dissolved in CH_2Cl_2 (5 ml), was added dropwise. After stirring for 15 min. at ambient temperature (evolution of CO), the orange-red solution was concentrated and **2a** was precipitated by the slow addition of hexane. The resulting microcrystalline yellow-orange product was dried in vacuo. Yield: 194

mg (87%). – IR (CH_2Cl_2): $\tilde{\nu}$ = 2004 cm^{-1} (s), 1934 (vs) ν(CO); 1671 (m, br.) ν(CN). – IR (KBr): $\tilde{\nu}$ = 3270 cm^{-1} (w) ν(NH); 2000 (m), 1934 (s), 1922 (s) ν(CO); 1674 (m, br.) ν(C=N). – ^1H NMR: δ = 2.07 (s, 3 H, xylyl-CH_3), 4.96 [m, br., NH, ^3J(Pt−H) = 89.0 Hz], 6.84−7.88 (m, 38 H, phenyl). – $^{31}P\{^1H\}$ NMR: δ = 114.3 [dd, P^1(Fe), $^{2+3}J(P^1-P^2)$ = 174, $^{3+4}J(P^1-P^3)$ = 6, ^{2+3}J(Pt−P) = 50 Hz], 90.3 [dd, P^2(Pt), ^1J(Pt−P) = 2866 Hz], 40.4 [dd, P^3(Pt), $^2J(P^2-P^3)$ = 44, ^1J(Pt−P) = 4326 Hz]. – $^{195}Pt\{^1H\}$NMR: δ = −2678 [ddd, $^{2+3}J(Pt-P^1)$ = 50, $^1J(Pt-P^2)$ = 2856, $^1J(Pt-P^3)$ = 4328 Hz]. – $C_{54}H_{45}FeN_2O_3P_3Pt$ (1113.82): calcd. Preparation of [(CO)$_3$Fe{μ-CN(H)-o-anisyl}(μ-dppa)Pt(PPh$_3$)][BF$_4$] (**3b**): This complex was prepared by adding excess $HOSO_2CF_3$ to a solution of **2b** (0.112 g, 0.1 mmol) in CH_2Cl_2 (10 ml) at 253 K. After warming to ambient temperature, all volatiles were removed under reduced pressure. The orange-red residue was rinsed with Et_2O (3 ml) and dried in vacuo. – IR (CH_2Cl_2): $\tilde{\nu}$ = 2042 cm^{-1} (m), 1979 (vs) ν(CO); 1532 (w) ν(CN). – ^1H NMR: δ = 3.67 (s, 3 H, OCH_3), 6.94 [m, br., NH, ^3J(Pt−H) = 84 Hz], 6.87−7.42 (m, 39 H, phenyl), 7.91 (m, br., NH). – $^{31}P\{^1H\}$ NMR: δ = 102.2 [dd, P^1(Fe), $^{2+3}J(P^1-P^2)$ = 99, $^{3+4}J(P^1-P^3)$ = 14, $^{2+3}J(P^1-Pt)$ = 73 Hz], 79.0 [dd, P^2(Pt), $^2J(P^2-P^3)$ = 12, $^1J(P^2-Pt)$ = 2868 Hz], 37.3 [dd, P^3(Pt), $^1J(P^3-Pt)$ = 3791 Hz]. – $^{195}Pt\{^1H\}$ NMR: δ = −2510 [ddd, $^{2+3}J(P^1-Pt)$ = 73, $^1J(P^2-Pt)$ = 2868, $^1J(P^3-Pt)$ = 3791 Hz]. – $C_{54}H_{44}F_3FeN_2O_7P_3PtS$ (1265.83): calcd. C 50.18, H 3.70, N 2.17; found C 51.23, H 3.51, N 2.21.

Preparation of [(CO)$_3$Fe{μ-CN(Me)xylyl}(μ-dppa)Pt(PPh$_3$)][BF$_4$] (**4**): $[Me_3O][BF_4]$ (118 mg, 0.8 mmol) was added to a solution of **2a** (557 mg, 0.5 mmol) in CH_2Cl_2 (15 ml). After stirring for 16 h, the yellow solution was concentrated to a volume of ca. 10 ml and then layered with Et_2O. After 2 d, yellow air-stable crystals were formed, which were suitable for analysis by X-ray crystallography. Yield: 465 mg (74%). – IR (KBr): $\tilde{\nu}$ = 3217 cm^{-1} (w) ν(NH); 2028 (m), 1961 (vs) ν(CO); 1542 (w) ν(CN). – ^1H NMR: δ = 2.24 (s, 6 H, xylyl-CH_3), 2.83 (s, 3 H, NMe), 6.38 [m, br., NH, ^3J(Pt−H) = 91 Hz], 6.96−7.62 (m, 38 H, phenyl). – $^{13}C\{^1H\}$ NMR: δ = 311.7 [ddd, μ-C, ^2J(P−C) = 82, ^2J(P−C) = 11, ^2J(P−C) = 3 Hz], 209.3 [dd, 2 CO, ^2J(P−C) = 27, ^3J(P−C) = 5 Hz], 208.5 [d, 1 CO, ^2J(P−C) = 7 Hz], 117.9−138.4 (m, phenyl), 51.6 [dt, N−CH_3, ^4J(P−C) = 9, ^4J(P−C) = 3 Hz], 17.1 (s, xylyl-CH_3). – $^{31}P\{^1H\}$ NMR: δ = 102.6 [dd, P1(Fe), ^{2+3}J(P1−P2) = 110, ^{3+4}J(P1−P3) = 11, ^{2+3}J(P1−Pt) = 70 Hz], 81.1 [dd, P2(Pt), ^2J(P2−P3) = 8, ^1J(P2−Pt) = 2837 Hz], 37.2 [dd, P3(Pt), ^1J(P3−Pt) = 3810 Hz]. – $^{195}Pt\{^1H\}$ NMR: δ = −2717 [ddd, ^{2+3}J(P1−Pt) = 70, ^1J(P2−Pt) = 2837, ^1J(P3−Pt) = 3808 Hz]. – $C_{55}H_{48}BF_4FeN_2O_3P_3Pt\cdot 0.5\ CH_2Cl_2$ (1215.66 + 42.47): calcd. C 52.98, H 3.93, N 2.23; found C 52.55, H 4.05, N 2.20.

Preparation of [(CO)$_3$Fe{μ-CN(Me)xylyl}(μ-Ph$_2$PNPPh$_2$)Pt(PPh$_3$)] (**5**): $KOSiMe_3$ (3 mmol) was added to a suspension of **4** (0.5 mmol) in Et_2O (25 ml). The deprotonated product gradually dissolved within a period of 1 h. The yellow solution was then filtered and concentrated under reduced pressure. After addition of hexane, analytically pure **5** was precipitated. The product was filtered off and was dried in vacuo for 2 h. Yield: (447 mg, 84%). Suitable crystals for analysis by X-ray crystallography were obtained by layering a concentrated solution of **5** in CH_2Cl_2 with hexane. – IR (KBr): $\tilde{\nu}$ = ν(CO) 2002 cm^{-1} (m), 1934 (vs) ν(CO); ν(CN) 1538 (w) ν(CN). – ^1H NMR: δ = 2.22 (s, 6 H, xylyl-CH_3), 2.67 (s, 3 H, NMe), 7.01−7.85 (m, 38 H, phenyl). – $^{13}C\{^1H\}$ NMR: δ = 312.0 [dd, μ-C, ^2J(P−C) = 80, ^2J(P−C) = 19 Hz], 209.8 [dd, 2 CO, ^2J(P−C) = 27, ^3J(P−C) = 6 Hz], 208.6 [d, 1 CO, ^2J(P−C) = 8 Hz], 117.9−150.2 (m, phenyl), 51.4 [dt, N−CH_3, ^4J(P−C) = 9, ^4J(P−C) = 4 Hz], 17.4 (s, xylyl-CH_3). – $^{31}P\{^1H\}$ NMR: δ = 88.0 [br. d, P1(Fe), ^{2+3}J(P1−P2) = 130 Hz], 72.3 [br. d, P2(Pt), ^1J(P2−Pt) = 2554 Hz], 35.3 [d, P3(Pt), ^2J(P2−P3) = 12, ^1J(P3−Pt) = 3757 Hz]. – $^{195}Pt\{^1H\}$ NMR: δ = −2504 [br. dd, ^1J(P2−Pt) = 2554, ^1J(P3−Pt) = 3757 Hz]. – $C_{55}H_{47}FeN_2O_3P_3Pt$ (1127.85): calcd. C 58.57, H 4.20, N 2.48; found C 58.25, H 4.05, N, 2.10.

Crystal-Structure Determination of **3b**[14][15]: Collection of crystallographic data: Siemens Stoe AED 2 diffractometer; Mo-K_α radiation (λ = 0.71073 Å), graphite monochromator; intensity data were collected using the Ω/2Θ scan mode at 293 K. $C_{54}H_{44}F_3N_2FeO_7P_3PtS$: yellow crystals with approximate dimensions of 0.5 × 0.3 × 0.2 mm, triclinic, space group $P\bar{1}$; a = 13.105(3), b = 14.387(3), c = 14.997(7) Å, α = 81.29(3), β = 71.77(3), γ = 78.09(3)°, V = 2616.3(10) Å^3, Z = 2, ρ_{calcd} = 1.607 g cm^{-3}, F(000) = 1260; 9608 independent reflections in the scan range 2.38 < 2θ < 52.0°, of which 8455 with $I > 2\sigma(I)$ were used in the structure solution and refinement for 654 parameters; $R1 = \Sigma F_{o-Fc}/\Sigma F_o$ = 0.0411[$I > 2\sigma(I)$], $wR2 = [\Sigma w(F_o^2 - F_c^2)^2/\Sigma wF_o^4]^{1/2}$ = 0.1222 (all data), GoF = 1.114; anisotropic refinement for non-hydrogen atoms; hydrogen atoms in idealized geometries, except for H(2), which was refined isotropically. Highest residual electron density 0.793 eÅ^{-3}.

Crystal Structure Determination of **5**: Collection of crystallographic data: Siemens Stoe AED 2 diffractometer; Mo-K_α radiation (λ = 0.71073 Å), graphite monochromator; intensity data were collected using the Ω/2Θ scan mode at 293 K. $C_{55}H_{47}FeN_2O_3P_3Pt$: yellow crystals with approximate dimensions of 0.65 × 0.4 × 0.35 mm, monoclinic, space group $P2_1/c$; a = 11.026(6), b = 18.524(9), c = 23.708(12) Å, β = 90.49(4)°, V = 4842.4(4) Å^3, Z = 4, ρ_{calcd} = 1.547 g cm^{-3}, F(000) = 2256; 7614 independent reflections in the scan range 1.72 < 2θ < 48.0°, of which 6095 with $I > 2\sigma(I)$ were used in the structure solution and refinement for 589 parameters; $R1 = \Sigma|F_o - F_c|/\Sigma|F_o|$ = 0.0295 [$I > 2\sigma(I)$], $wR2 = [\Sigma w(F_o^2 - F_c^2)^2/\Sigma wF_o^4]^{1/2}$ = 0.0765 (all data), GoF = 1.036; anisotropic refine-

ment for non-hydrogen atoms; hydrogen atoms in idealized geometries. Highest residual electron density 0.793 eÅ^{-3}.

Keywords: Metallomesogens / Azo compounds / Palladium / Platinum / Cyclopentadienyl complexes

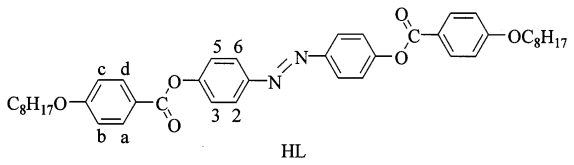
The mesogenic 4,4′-bis[4-(*n*-octyloxy)benzoyloxy]azobenzene (HL) ligand reacts with $[(PhCN)_2PdCl_2]$ to give the dinuclear cyclometalated complex $[(\mu\text{-Cl})(L)Pd]_2$ (**1**), from which the mononuclear half-sandwich $[(\eta^5\text{-}C_5H_5)(L)Pd]$ (**2**) species has been obtained by reaction with $Tl(C_5H_5)$. The Pt^{II} analogue of **2**, $[(\eta^5\text{-}C_5H_5)(L)Pt]$ (**4**), has been prepared in a similar manner starting from $[(\mu\text{-Cl})(L)Pt]_2$ (**3**). Both dinuclear complexes **1** and **3** display a smectic C phase (S_C) stable over 80°C. Whereas **4** is the first example of an 18-electron Pt^{II} mesogen, both mononuclear **2** and **4** are mesomorphic materials that exhibit a nematic phase spanning a wide temperature range.

Introduction

Cyclometalation of group-10 metals[1] still attracts a steady interest since the pioneering work of early sixties.[2] The interest has been considerably revived upon the discovery of thermotropic mesomorphism (i.e. liquid-crystal behaviour under temperature variation) in some halo-bridged dinuclear *ortho*-palladated complexes.[3] Since then, the area of transition-metal-based mesogens (*metallomesogens*)[4] has enlarged considerably, becoming rapidly a hot topic in materials science.[5][6] Although the variety of species has increased in recent years,[7][8] most molecular organometallic mesogens are of the cyclometalated type (and cyclopalladated for the most part) and their chemistry is predominantly that of planar 16-electron complexes.

Recently, we became involved in the design of high-coordination-number mesogenic complexes, a challenging task currently pursued by many different groups.[9] In a previous communication we described the first examples of liquid-crystalline cyclopalladated azobenzene complexes containing the $\eta^5\text{-}C_5H_5$ ligand.[10] Our aim was to see whether the $(\eta^5\text{-}C_5H_5)Pd$ fragment could be incorporated into a thermotropic molecule without suppressing its mesomorphism. Following our communication, very recently, Lydon et al.[11] reported similar compounds derived from mesogenic Schiff bases. In particular, we proved that the use of symmetrically substituted nematogenic azobenzene ligands ($R = R' = C_6H_{13}$; $R = R' = OC_6H_{13}$) leads to the isolation of low-melting solids which do not exhibited liquid-crystal behaviour, whilst a more anisotropic ligand ($R = OC_6H_{13}$, $R' = OCOC_6H_4OC_8H_{17}$) gave a mesomorphic complex. However, although the latter ligand was able to compensate the reduction in structural anisotropy that originates from the lateral substitution of the organic molecule with a bulky $(\eta^5\text{-}C_5H_5)Pd$ group, a second problem arose. Metalation of the unsymmetrical azobenzene is not stereospecific, and a pair of isomers was obtained as a result of reaction at either one of the phenyl rings which form the azobenzene core.[10]

In order to gain more reliable mesogenic materials (in terms of a reproducible thermal behaviour), it is preferable to avoid isomeric mixtures with uncontrolled composition. Therefore, we decided to go back to symmetrically substituted azobenzene ligands. Thus, taking advantage of the observed beneficial role that the $OCOC_6H_4OC_8H_{17}$ group exerts on the mesomorphism, we considered the 4,4′-bis[4-(*n*-octyloxy)benzoyloxy]azobenzene (HL) ligand.



HL

We report here the synthesis of HL and its cyclometalated (cyclopentadienyl)palladium(II) and -platinum(II) derivatives. The mesomorphic properties of both the ligand and complexes are also reported and discussed.

Results and Discussion

Synthesis

The synthesis of HL was carried out by esterification of 4-(*n*-octyloxy)benzoic acid and 4,4′-dihydroxyazobenzene in the presence of 1,3-dicyclohexylcarbodiimide and catalytic amounts of 4-pyrrolidinopyridine. HL is a red solid which was characterized by ^{1}H-NMR spectroscopy (see Experimental Section).

The cyclopalladation of HL with $[(PhCN)_2PdCl_2]$ in benzene/methanol occurred with formation of the dinuclear species $[(\mu\text{-Cl})(L)Pd]_2$ (**1**) in good yield. Both the elemental

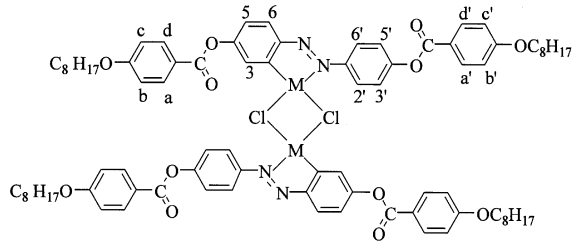
analysis and ^{1}H-NMR spectrum of **1** account for the expected formula (Experimental Section).



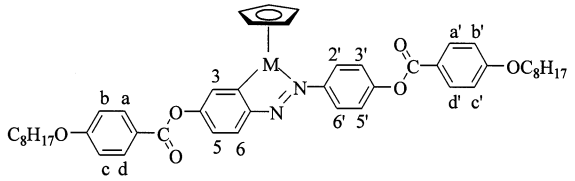
1 M = Pd
3 M = Pt

The subsequent bridge-splitting reaction with $Tl(C_5H_5)$[10][12] gives directly the monocyclopentadienyl complex [(η^5-C_5H_5)(L)Pd] (**2**). Compound **2** is a very soluble, purple-blue (λ_{max} = 574 nm), air-stable solid. Beside the signals of the *o*-deprotonated L ligand, the ^{1}H-NMR spectrum of **2** shows a singlet at δ = 5.88 which corresponds to a cyclopentadienyl ring bound in an η^5 fashion.[12b][13][14] The X-ray structure of the homologous [(η^5-C_5H_5)(pap)Pd] [pap = 2-(phenylazo)phenyl] has been previously reported. The C_5H_5 fragment was observed to assume an η^5 coordination with relevant asymmetry in the Pd−C bonds.[15]

Mesomorphic cycloplatinated complexes are still rare[16][17][18] compared to their palladium counterparts. Synthetic efforts were pushed forward when cycloplatination under mild conditions became affordable through the use of reagents such as [(μ-Cl)(η^3-C_4H_7)Pt]$_2$.[19] Thus, we set out to prepare complex **4**, the platinum analogue of **2**. The best procedure involves the formation of the dinuclear precursor [(μ-Cl)(L)Pt]$_2$ (**3**) through reaction of HL and [(μ-Cl)(η^3-C_4H_7)Pt]$_2$ under reflux conditions. Complex **3** is a dark-red solid wherein *o*-platination is apparent from its ^{1}H-NMR spectrum (see Experimental Section). On further treatment of the dinuclear species with $Tl(C_5H_5)$ no reaction occurred. As earlier noted by Cross et al.[20] this same reaction did not take place for [(μ-Cl)(pap)Pt]$_2$ whatever the excess of $Tl(C_5H_5)$. The reaction instead smoothly proceeds to the desired product if the addition of $Tl(C_5H_5)$ is preceded by bubbling CO through a solution of the chloro-bridged cycloplatinated dimer.[20] Starting from **3**, in situ formation of the orange complex [(CO)(Cl)(L)Pt] [$\tilde{\nu}_{CO}$ = 2102 cm^{-1} (KBr)] was followed by the chloride displacement reaction on addition of an excess of $Tl(C_5H_5)$. Complex [(η^5-C_5H_5)(L)Pt] (**4**) was recovered as a dark-red (λ_{max} = 520 nm), air-stable solid upon purification by cromatography on silica gel. The ^{1}H-NMR spectrum of **4** shows in the region of aromatic protons the pattern typical for an *o*-metalated phenyl ring with no $^nJ(^1H^{195}Pt)$ coupling. A singlet at δ = 5.87, showing satellites due to ^{195}Pt coupling ($^3J_{PtH}$ = 13 Hz), can be safely assigned to an η^5-C_5H_5 ligand.[12b]

Mesomorphic Properties

The mesomorphic properties of the parent ligand HL and complexes **1**−**4** are reported in Table 1. The mesophases were assigned on the basis of their optical textures observed by thermal polarizing microscopy. Thermal and thermodynamic data were obtained through differential scanning calorimetry (DSC).



2 M = Pd
4 M = Pt

Table 1. Phase-transition data and assignments[a] for HL, [(μ-Cl)(L)M]$_2$ [M = Pd (**1**); Pt (**3**)], [(η^5-C_5H_5)(L)M] [M = Pd (**2**); Pt (**4**)]

Compound	Transition	*T* [°C]	ΔH [kJ mol^{-1}]

	N−I	250.0[b]	

[a] C: crystal; S_C: smectic C; N: nematic; I: isotropic liquid. − [b] Decomposition.

HL exhibited enantiotropic smectic C (S_C) and nematic (N) phases, and both showed a marbled texture. Notwithstanding this, the S_C−N transition was clearly indicated by the appearance of characteristic transition bars.[21] The mesomorphism of HL is dominated by the nematic state which occurs over a wide range (some 150°C), whereas the fairly high clearing temperature is related to the high polarizability of the large rigid core of the molecule.

The dinuclear chloro-bridged complexes [(μ-Cl)(L)M]$_2$ (**1**, **3**) are mesogens which display only a smectic C phase (schlieren texture) between 249 and 330°C for **1** and between 262 and 342°C for **3** and decompose at the clearing point. The metal complexation in both cases narrows the mesomorphic range of the ligand with transition temperatures for the platinum complex **3** higher than those of the palladium homologue.

The mononuclear palladium complex **2** melted to a nematic phase which exhibited a marbled texture on heating and a schlieren one on cooling from the melt. Thus, the mesomorphism of the mononuclear palladium derivative becomes dominated by the nematic phase. This is not surprising if one considers the presence of a large substituent (i.e. the organometallic fragment) in the middle of the molecule (which opposes lateral interactions)[9c][22] and of the

two medium-sized alkyl chains (which are unable to stabilize smectic behaviour in this case). With respect to HL, the mononuclear compound **2** preserves a similar melting temperature although the stability of the nematic phase is much reduced. Both the presence of a single, nematic phase and the substantial lowering of the clearing point (some 90°C) are a likely consequence of the reduced anisotropy of molecular shape,[9d][9e][23][24] at least if no further effects (e.g. changes in the polarizability anisotropy and/or dipole moment variations following the lateral substitution) must be taken into account.

Changing palladium complex **2** for platinum complex **4** increases about 20°C both the melting and the clearing temperatures of the complex (Table 1), in line with the expected increase in polarizability by introduction of platinum. This trend has been seen at work in other Pd and Pt homologous series of calamitic mesogens.[15][18][25] However, more examples are needed to establish a general, less controversial behaviour since an opposite trend has occasionally been observed.[26] The increased stability of the nematic phase of **4** with respect to **2** is, however, thwarted by its lower thermal stability (toward decomposition) in the isotropic state.

Conclusions

Palladium(II) and platinum(II) mesogens are commonly available as planar, 16-electron species. In principle, the possibility to prepare metallomesogens with higher coordination numbers is restricted only by the loss of structural anisotropy as a consequence of extra coordination. However, from related studies on high-coordination-number calamitic mesogens we know that this disadvantage can be overcome by using ligands with high structural anisotropy.[22]

We have now demonstrated that the metalation of the highly anisotropic, mesogenic HL ligand through well-tested synthetic procedures allows the formation of 18-electron Pd^{II} and Pt^{II} species which are nematic liquid crystals. Interestingly, reporting the only other example of an 18-electron half-sandwich, isomerically pure palladium mesogen, the authors have pointed out the high tendency of this class of compounds to give preferentially nematic phases.[11][27] In conclusion, sterically demanding organometallic Pd^{II} and Pt^{II} mesogens can be conveniently prepared using the cyclopentadienyl group as a co-ligand. Whilst the only price to pay at this stage is a reduction in thermal stability of the mesogenic azobenzene precursor, this approach opens the way to further novel organometallic materials with interesting physical properties.

We thank the *Ministero dell' Università e della Ricerca Scientifica e Tecnologica* (MURST) and the *Consiglio Nazionale delle Ricerche* (CNR) for financial support.

Experimental Section

4-(*n*-Octyloxy)benzoic acid, 1,3-dicyclohexylcarbodiimide (DCC), 4-pyrrolidinopyridine (PPy), and thallium cyclopentadienide were available from Aldrich, and they were used as received. 4,4′-Dihydroxyazobenzene was prepared according to a published method.[28] − IR spectra were recorded as KBr pellets or nujol mulls with a Perkin Elmer System-2000 FT spectrophotometer. − ^{1}H-NMR spectra were obtained with a Bruker AC300 spectrometer with tetramethylsilane as an internal standard. − Elemental analyses were performed using a Perkin Elmer 2400 microanalyzer. − Absorption spectra were recorded with a Hitachi U-2000 spectrophotometer. − Phase transitions and optical textures were assigned by thermal optical microscopy by means of a Zeiss Axioskop polarizing microscope, equipped with a heating stage and a temperature-control unit. Transition temperatures and enthalpies were determined by differential scanning calorimetry (DSC) using a Perkin Elmer DSC-7 calorimeter operating at a scanning rate of 10°C min^{-1}.

4,4′-Bis[4-(n-octyloxy)benzoyloxy]azobenzene (HL): A mixture of 4,4′-dihydroxyazobenzene (0.40 g, 1.87 mmol), 4-(*n*-octyloxy)-benzoic acid (0.94 g, 3.74 mmol), DCC (0.85 g, 4.11 mmol), and PPy (0.055 g, 0.37 mmol) in dichloromethane (40 ml) was stirred at room temperature for 7 d. A grey solid was filtered off and the orange filtrate was washed with H_2O (2 × 30 ml), 5% CH_3COOH (2 × 25 ml), and H_2O (2 × 30 ml). The organic layer was dried with $NaSO_4$, then taken to dryness under reduced pressure. The yellow solid residue was recrystallized from dichloromethane/diethyl ether. Yield 0.69 g (54%). − ^{1}H NMR (300 MHz, $CDCl_3$): δ = 8.17 (d, *J* = 8.8 Hz, 2 H, $H^{a,d}$), 8.01 (d, *J* = 8.8 Hz, 2 H, $H^{2,6}$), 7.37 (d, *J* = 8.8 Hz, 2 H, $H^{3,5}$), 6.99 (d, *J* = 8.8 Hz, 2 H, $H^{b,c}$), 4.05 [t, *J* = 6.6 Hz, 2 H, $OCH_2(CH_2)_6CH_3$], 1.83 [m, 2 H, $OCH_2CH_2(CH_2)_5CH_3$], 1.50−1.29 [m, 10 H, $OCH_2CH_2(CH_2)_5CH_3$], 0.90 (t, *J* = 6.6 Hz, 3 H, CH_3). − IR (KBr): $\tilde{\nu}$ = 1740, 1730 cm^{-1} (COO). − $C_{42}H_{50}N_2O_6$ (678.9): calcd. C 74.31, H, 7.42, N, 4.13; found C 73.86, H, 7.45, N, 4.36.

Preparation of [(μ-Cl)(L)Pd]$_2$ (**1**): A suspension of the HL ligand (0.3 g, 0.44 mmol) in methanol (15 ml) was added to a stirred solution of an equimolar amount of $[(PhCN)_2PdCl_2]$ in benzene (15 ml) and the mixture was heated for 48 h at 100°C. The resulting orange solid was filtered off and recrystallized from hot methanol. Yield 0.29 g (80%). − ^{1}H NMR (300 MHz, $CDCl_3$): δ = 8.09 (d, 2 H, $H^{a,d}$), 8.07 (d, 2 H, $H^{a',d'}$), 7.92 (d, 2 H, $H^{2',6'}$), 7.89 (d, 1 H, H^6), 7.34 (d, 2 H, $H^{3',5'}$), 7.18 (d, 1 H, H^3), 7.13 (dd, 1 H, H^5), 6.92 (d, 2 H, $H^{b,c}$), 6.89 (d, 2 H, $H^{b',c'}$), 4.03 [t, 2 H, $OCH_2(CH_2)_6CH_3$], 3.97 [t, 2 H, $OCH_2(CH_2)_6CH_3$]. − $C_{84}H_{98}Cl_2N_4O_{12}Pd_2$ (1639.4): calcd. C 61.54, H 6.02, N 3.42; found C 61.35, H 6.11, N 3.07.

Preparation of [(η^5-C$_5$H$_5$)(L)Pd] (**2**): $Tl(C_5H_5)$ (0.03 g, 0.12 mmol) was added to a solution of $[Pd(\mu\text{-}Cl)(L)]_2$ (0.1 g, 0.06 mmol) in benzene (10 ml) and the mixture was stirred under nitrogen. After 4 h, the mixture was filtered and the dark filtrate was concentrated in a rotary evaporator. Recrystallization of the solid residue from chloroform/ethanol afforded the product as a dark blue microcrystalline solid. Yield 0.083 g (80%). − ^{1}H NMR (300 MHz, $CDCl_3$): δ = 8.28 (d, *J* = 8.6 Hz, 1 H, H^6), 8.17 (d, *J* = 8.8 Hz, 2 H, $H^{a,d}$), 8.16 (d, *J* = 8.8 Hz, 2 H, $H^{a',d'}$), 7.93 (d, *J* = 8.8 Hz, 2 H, $H^{2',6'}$), 7.72 (d, *J* = 2.3 Hz, 1 H, H^3), 7.27 (d, *J* = 9.0 Hz, 2 H, $H^{3',5'}$), 7.08 (dd, *J* = 8.6, 2.3 Hz, 1 H, H^5), 6.99 (d, *J* = 8.8 Hz, 4 H, $H^{b,c}$ + $H^{b',c'}$), 5.88 (s, 5 H, Cp), 4.06 [t, *J* = 6.6 Hz, 4 H, $OCH_2(CH_2)_6CH_3$], 1.84 [m, 4 H, $OCH_2CH_2(CH_2)_5CH_3$], 1.51−1.30 [m, 20 H, $OCH_2CH_2(CH_2)_5CH_3$], 0.90 (t, *J* = 6.6 Hz, 6 H, CH_3). − IR (nujol): $\tilde{\nu}$ = 1724 cm^{-1} (COO). − UV/Vis (3 × 10^{-5} M $CHCl_3$ solution): λ_{max} (ε) = 264 (56300), 331 (18100), 418 (11850), 574 nm (5780). − $C_{47}H_{54}N_2O_6Pd$ (849.3): calcd. C 66.46, H 6.41, N 3.30; found C 67.02, H 6.41, N 3.05.

Preparation of [(μ-Cl)(L)Pt]$_2$ (**3**): A solution of $[(\mu\text{-}Cl)(\eta^3\text{-}C_4H_7)Pt]_2$ (0.08 g, 0.15 mmol) and HL ligand (0.2 g, 0.30 mmol) in 15 ml of toluene was refluxed for 12 h and then cooled. The

precipitate was collected by filtration and purified by recrystallization from chloroform/diethyl ether to give a dark-red solid. Yield 0.174 g (65%). – ^{1}H NMR (300 MHz, $CDCl_3$): δ = 8.10 (d, *J* = 9.1 Hz, 2 H, $H^{a,d}$), 8.07 (d, *J* = 9.1 Hz, 2 H, $H^{a',d'}$), 7.96 (d, *J* = 8.4 Hz, 1 H, H^6), 7.86 (d, *J* = 8.8 Hz, 2 H, $H^{2',6'}$), 7.39 (d, *J* = 8.8 Hz, 2 H, $H^{3',5'}$), 7.13 (d, *J* = 2.0 Hz, 1 H, H^3), 7.09 (dd, *J* = 8.4, 2.0 Hz, 1 H, H^5), 6.94 (d, *J* = 9.1 Hz, 2 H, $H^{b,c}$), 6.89 (d, *J* = 9.1 Hz, 2 H, $H^{b',c'}$), 4.04 [t, *J* = 6.6 Hz, 4 H, $OCH_2(CH_2)_6CH_3$], 4.00 [t, *J* = 6.6 Hz, 4 H, $OCH_2(CH_2)_6CH_3$]. – $C_{84}H_{98}Cl_2N_4O_{12}Pt_2$ (1816.8): calcd. C 55.53, H 5.46, N 3.08; found C 56.23, H 5.64, N 3.31.

Preparation of [(η^5-C$_5$H$_5$)(L)Pt] (**4**): A brown suspension of $[(\mu\text{-Cl})(L)Pt]_2$ (0.14 g, 0.08 mmol) in benzene/diethyl ether (50 ml, 3:2, v/v) turned dark-orange after bubbling CO through the mixture and stirring was continued for 3 h. $Tl(C_5H_5)$ (0.21 g, 0.78 mmol) was added to the mixture which turned dark-red, then dark-violet within 1 h. After filtration of the greyish solid, the solution was concentrated in a rotary evaporator to give a sticky, dark solid. The crude product was chromatographed by using silica gel with *n*-hexane/diethyl ether (1:1) as eluent. The product was eluted first as a dark-red fraction. Removal of the solvent afforded **4** as a dark-red powder. Yield 0.083 g (55%). – ^{1}H NMR (300 MHz, $CDCl_3$): δ = 8.33 (d, *J* = 8.7 Hz, 1 H, H^6), 8.18 (d, *J* = 8.9 Hz, 2 H, $H^{a,d}$), 8.17 (d, *J* = 8.9 Hz, 2 H, $H^{a',d'}$), 7.84 (d, *J* = 8.9 Hz, 2 H, $H^{2',6'}$), 7.82 (d, *J* = 2.4 Hz, 1 H, H^3), 7.27 (d, *J* = 8.9 Hz, 2 H, $H^{3',5'}$), 7.01 (dd, *J* = 8.7, 2.4 Hz, 1 H, H^5), 6.98 (d, *J* = 8.8 Hz, 4 H, $H^{b,c}$ + $H^{b',c'}$), 5.87 [s, ^3J(PtH) = 13 Hz, 5 H, Cp], 4.06 [t, *J* = 6.6 Hz, 4 H, $OCH_2(CH_2)_6CH_3$], 1.84 [m, 4 H, $OCH_2CH_2(CH_2)_5CH_3$], 1.49–1.30 [m, 20 H, $OCH_2CH_2(CH_2)_5CH_3$], 0.90 (t, *J* = 6.6 Hz, 6 H, CH_3). – IR (nujol): $\tilde{\nu}$ = 1722 cm^{-1} (COO). – UV/Vis (3 × 10^{-5} M $CHCl_3$ solution): λ_{max} (ε) = 263 (30270), 342 (8400), 366 (8200), 520 nm (6450). – $C_{47}H_{54}N_2O_6Pt$ (938.0): calcd. C 60.18, H 5.80, N 2.99; found C 60.40, H 5.81, N 2.91.

Received October 15, 1997

Keywords: Chlorobis(dimethylamino)(3-indenyl)diborane(4) / Bis(dimethylamino)bis(1-indenyl)diborane(4) / Bis(dimethylamino)(1-indenyl)(3-indenyl)diborane(4) / Bis(dimethylamino)bis(3-indenyl)diborane(4) / Rearrangement / X-ray structures

Indenyllithium reacts with dichlorobis(dimethylamino)diborane(4) with formation of bis(dimethylamino)bis(1-indenyl)-diborane(4) which rearranges on heating to the isomer bis(dimethylamino)bis(3-indenyl)diborane(4). The "mixed" bis(dimethylamino)(1-indenyl)(3-indenyl)diborane(4) is obtained from indenyllithium and chlorobis(dimethylamino)(3-indenyl)diborane(4). The main structural differences between the two isomers **3** and **4** are a slightly shorter B−B bond in **4**, as well as a stronger twist about the B−B bond (89.9° vs. 67.4°) and, as expected, a shorter B−C bond. There is, however, no significant B−C π bonding.

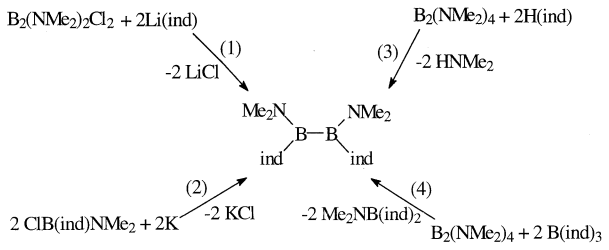
Bis(dimethylamino)diorganyldiboranes(4) $(Me_2N)RB-BR(NMe_2)$ may either be reduced to their dianions $[B_2(NMe_2)_2R_2]^{2-}$ which feature a B=B double bond[2] or may be deprotonated to a diborabutadiene dianion $[R'_2=B(NMe_2)-B(NMe_2)=R']^{2-}$ (R′ = CHR'_2) provided that the organyl group carries a sufficiently acidic hydrogen atom[3]. The first route has been verified for R = phenyl,[2] the second for R′ = fluorenyl[3][4] and benzyl[5]. The alkali-metal salts of $B_2(NMe_2)_2(CR'_2)_2^{2-}$ not only show a noticeable variation of structures[3][5] but have also proved to be useful reagents for the preparation of new heterocycles such as 1-stanna-3,4-diborolanes or 1-plumba-3,4-diborolanes and 1,2-diboretanes[6]. Other diorganyldiboranes(4) that might readily be deprotonated are indenyl and cyclopentadienyl derivatives. These are expected to exhibit a different reactivity compared to the fluorenyldiborane(4) compounds because they are less acidic, are sterically less demanding, and their alkali-metal salts may therefore display different structural motifs. Here we report on the synthesis and structural characterisation of bis(dimethylamino)bis(indenyl)diboranes(4)[7].

Synthesis

There are at least four different synthetic pathways by which the synthesis of bis(dimethylamino)bis(indenyl)diboranes(4) can be achieved. These are summarized in Scheme 1.

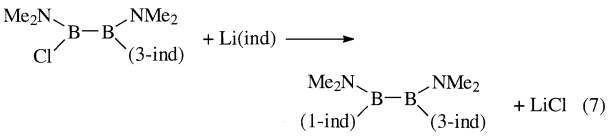
The most straightforward pathway is described by eq. 1 while the route shown in eq. 2 may suffer from deprotonation of the indenyl group; this would lead to B−C bond formation in competition to B−B bond formation.

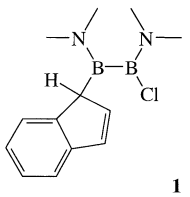
Scheme 1



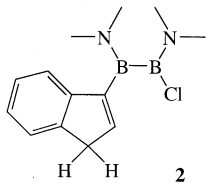
$$B_2(NMe_2)_2Cl_2 + Li(ind) \longrightarrow Me_2N(1\text{-ind})B\text{-}B(Cl)NMe_2 + LiCl \quad (5)$$

$$Me_2N(1\text{-ind})B\text{-}B(Cl)NMe_2 \xrightarrow{\Delta} Me_2N(3\text{-ind})B\text{-}B(Cl)NMe_2 \quad (6)$$





1



2

The results of eq. 3 depend on the acidity of indene and the Lewis acidity of the boron atoms in $B_2(NMe_2)_2(ind)_2$ which may prevent the liberation of Me_2NH and hence the synthesis of $B_2(NMe_2)_2(ind)_2$. The substituent exchange according to eq. 4 is prevented simply by the access to tri(in-

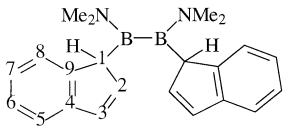
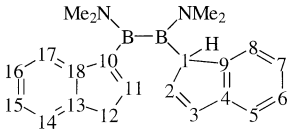
denyl)borane, an as yet unknown triorganylborane. Consequently we studied the reaction described by eq. 1.

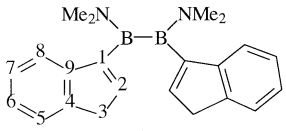
In toluene a surprising result was observed as even after 20 h at ambient temperature only monosubstitution with formation of chlorobis(dimethylamino)(indenyl)diborane(4) (**1**) occurred which was present in solution as the 1-indenyl isomer (eq. 5). On distillation **1** converted into the 3-indenyl isomer **2** (eq. 6).



3



4



5

However, when a small amount of THF was added to the reaction mixture as described by eq. 1 then **1** was only an intermediate on route to bis(dimethylamino)bis(1-indenyl)diborane. Under these conditions **3** was formed and isolated in acceptable yields (55%).

Heating solutions of **3** in toluene under reflux converted this compound into its bis(3-indenyl)derivative **5**. Following this rearrangement using ^{1}H- and ^{13}C-NMR spectroscopy provided evidence that the "mixed" isomer **4** is an intermediate. Actually, **4** can be readily prepared from the chloro(3-indenyl)diborane(4) **2** by allowing it to react with Li(ind) at ambient temperature as shown in eq. 7.

Experiments designed to obtain bis(cyclopentadienyl)bis(dimethylamino)diborane(4) have so far failed. The reaction of TlCp with $(Me_2N)_2B_2Cl_2$ in toluene led to a solution that contained primarily the starting diborane(4) compound in addition to unidentified products (ratio 9:1 according to ^{11}B-NMR spectroscopy). Activation by ultrasound or replacement of TlCp by NaCp and the use of THF as a solvent lead to ether cleavage.

NMR Spectra

NMR-spectroscopic data on compounds **2**−**5** are summarized in the Experimental Section. Assignments were made from the analysis of ^{1}H-^{1}H-COSY and ^{1}H-^{13}C-HETCOR experiments.

The ^{11}B resonances of the indenyldiboranes(4) **3**−**5** all lie in a very narrow range, $\delta = 48 \pm 2$, irrespective of whether the indenyl group is present as the 1- or 3-isomer. However, the linewidth increases as the number of the 3-indenyl groups increases. The observed shielding corresponds to dialkylbis(dimethylamino)diboranes(4)[8]. 3-Indenyl groups should actually lead to a better shielding due to possible B−C π bonding as observed for amino(vinyl)boranes[9]. Therefore, we can assume that the 3-indenyl group is not coplanar with the B_2NC plane. Two ^{1}H- and ^{13}C-NMR signals for the dimethylamino group in **5** indicate hindered rotation about the B−N bonds. In the case of compound **4** there are even four ^{1}H-NMR signals of equal intensity as well as four ^{13}C resonances, which again demonstrate hindered rotation about the B−N bonds. Surprisingly, compound **3** displays eight signals for the Me_2N groups in the ^{1}H-NMR spectrum and shows six ^{13}C resonances. This fact can only be rationalized by assuming the presence of rotamers.

Compound **2** is exceptional in so far as one would expect two separated ^{11}B-NMR signals but only one is actually observed. This can be explained by an inductive effect of the B(Cl)NMe_2 group which brings about stronger B−N bonding on the neighbouring R(Me_2N)B group, as indicated by a deshielding of the protons of the dimethylamino groups. It is a well-known phenomenon that the ^{13}C resonances of carbon atoms bound to a boron atom are often difficult to detect due to the quadrupole-induced broadening of its resonance[8]. Thus only the ^{13}C resonances of the C atom of the 1-indenyl compounds could be determined but not those of the 3-indenyl groups.

The NMR data also suggest free rotation about the B−B bond. However, for the bis(1-indenyl)diborane(4) **3** hindered rotation about the B−C bonds may also be possible. Nevertheless, no firm conclusions as to the structure of the dominant conformation could be derived from NMR experiments. We therefore determined the molecular structures by X-ray crystallography although the results are, of course, restricted to the solid state.

Molecular Structures

Two of the indenyldiboranes(4) gave single crystals from hexane solutions suitable for an X-ray diffraction study. Figures 1 and 2 depict the results whilst Table 1 contains the bonding parameters.

The molecular structures of **3** and **4** confirm the conclusions drawn from the NMR data that **3** contains 1-indenyl groups only, while **4** carries both a 1-indenyl and 3-indenyl substituent.

A significant structural feature of both compounds is the B−B bond, which seems to be slightly longer in **3** than in **4**. However, both B−B bonds are longer than found for the comparable diborane(4) derivatives 1,2-difluorenyl-1,2-dipyrrolidinodiborane(4) [1.697(4) Å][10], 1,2-bis(dimethylamino)-1,2-bis(phenylethynyl)diborane(4) [1.696(8) Å][10], 1,2-bis(dimethylamino)-1,1-diphenyldiborane(4) [1.714(4) Å] and 1,2-bis(dimethylamino)-1,2-dimesityldiborane(4) [1.72(1) Å][11]. It appears from these data that the B−B bond length increases slightly when tetracoordinated C atoms are replaced by trigonal-planar C atoms.

B−N π bonding is indicated by the B−N bond lengths in compounds **3** and **4** which range from 1.386(4)−1.403(2) Å; this fits not only with the hindered rotation about the B−N bonds but also with many other B−N bond lengths of aminoboranes(4)[11]. However, one should note that in compound **4** the longer B−N bond is associated with the boron atom that carries the 1-indenyl substituent. The shorter B−N bond is found at the boron atom with the 3-

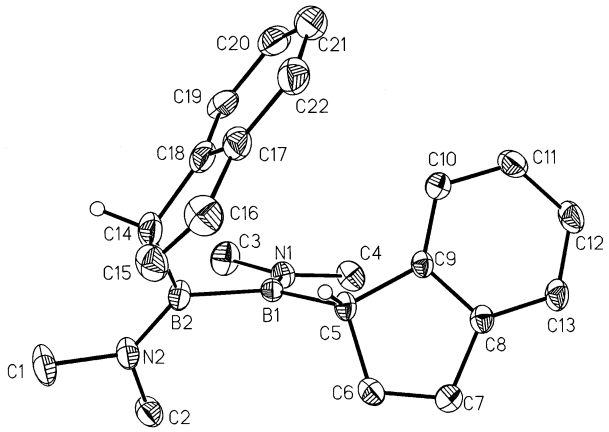
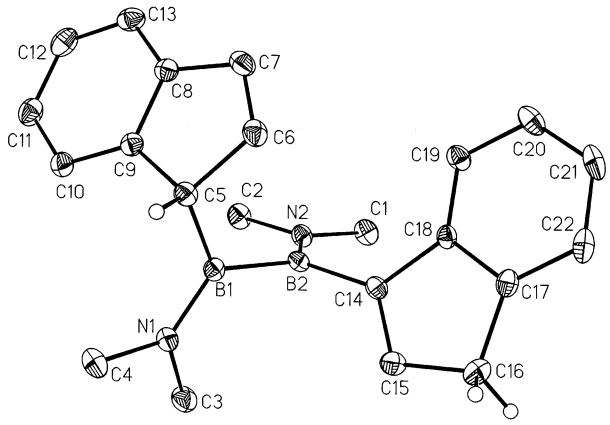
Figure 1. The molecular structure of the bis(1-indenyl)diborane(4) derivative **3** in the crystal; thermal ellipsoids are shown on a 25% probability level; hydrogen atoms (except those of the unique CH_2 groups) are omitted for clarity



indenyl group; this atom is expected to participate in B−C π bonding with a consequent weakening of B−N π bonding.

As expected the lengths of the B−C bonds to the 1-indenyl groups are longer than the B−C bonds of the 3-indenyl substituent reflecting the different hybridization at the carbon atoms. Moreover, the C−C bond lengths clearly show that there is no electron delocalisation in the five-membered rings, and even the benzo rings show significantly different C−C bond lengths due to the disturbance by the *o*-disubstitution.

Figure 2. The molecular structure of the "mixed" bis(1-indenyl)diborane(4) derivative **4** in the crystal; thermal ellipsoids are drawn on a 25% probability level; hydrogen atoms (except for the unique CH and CH_2 group) are omitted for clarity

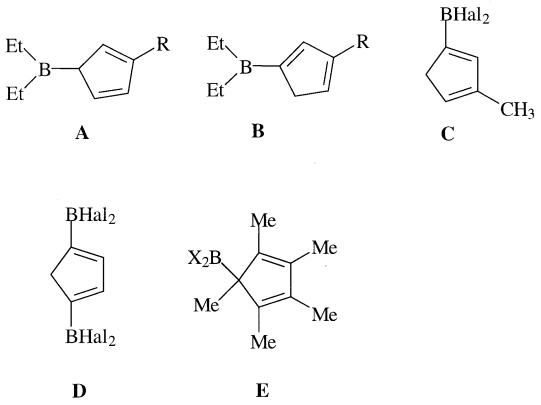


Strong B−N π bonding is indicated not only by short B−N bond lengths but also by planar geometry around the nitrogen and boron atoms. This is the case for these atoms in **3** and **4**. Moreover, the C_2N plane should be coplanar with the B_2C plane, e.g. the torsion angle C−N−B−B should be 0°. This is almost fulfilled for both compounds under consideration, the largest torsion angle being 11.0° (C11−N1−B1−B2 in **4**). While there is little difference between the two molecules there is a large conformational difference in the N−B−B−N torsion angle which is 67.4° for **3** but 89.9° for **4**. Another feature that determines the molecular shape of these molecules in the solid state is the orientation of the respective C^3 parts of the indenyl groups. For **3** the C5C6C9 plane is twisted against the N1B1B2 plane by 75.2°, and the C14C15C18 plane twisted against the N2B2B1 plane by 68.6°. In contrast, the C14C15C18 plane of the 3-indenyl group is rotated out of the N2B2B1 plane by 63.0° while the C5C6C9 plane is twisted against the N1B1B2 plane by 71.6°. As can be seen from Figure 1 the 1-indenyl groups are arranged in such a manner that the unique CH protons (on C5, C14) point in the same direction. This conformation is rather similar to that found in bis(dimethylamino)difluorenyldiborane(4)[10].

Discussion

The study of the indenyldiboranes(4) **2**−**5** show conclusively that the 1-indenyl derivatives represent the kinetic products while the 3-indenyl isomers are the stable thermodynamic products. The former are obtained from indenyllithium and $B_2Cl_2(NMe_2)_2$ at ambient temperature and rearrange to the latter on heating of their toluene solutions or on distillation. Although one might expect that the driving force for the rearrangement is due to B−C π bonding, the molecular structure of **4** provides no support for this assumption because the 3-indenyl group is oriented orthogonally to the NB_2 plane, thus ruling out any B−C π-bonding contribution. This, however, need not be the case in solution.

Similar behaviour has been observed for cyclopentadienylboranes. Grundke and Paetzold[12] have shown that cyclo-



pentadienylboranes RCp−BEt_2 are present as the isomer **A**, and they found no NMR-spectroscopic evidence for isomer **B**.

Moreover, Jutzi and Seufert demonstrated that both the methyl and dihalogenoboryl group of the cyclopentadienyldihalogenoborane are only bonded to a vinylic carbon atom, e.g. like **C**, and the structure **D** follows for bis(dihalogenoborylcyclopentadiene) from NMR data[13]. When protic shifts are excluded, as is the case for (pentamethylcyclopentadienyl)boranes Cp*BX_2 (X = Cl, Br, I, NMe_2) rapid sigmatropic rearrangements are observed, except for X = NMe_2 which possesses a static structure **E** at ambient temperature showing both vinylic- and allylic-bound methyl groups[14]. The indenyldiboranes reported here therefore represent the first examples where both the allylic and the vinylic isomeric species could not only be detected by NMR methods but also isolated. This is due to the fact that the 1,3-sigmatropic rearrangement of the proton occurs slowly and, of course, raises the question of whether indenylboranes $(ind)_{3-x}BX_x$ behave similarly. We will report on these results in due course.

Experimental Section

General: All experiments were performed under anhydrous conditions using Schlenk techniques under N_2 or Ar. All reagents were purified before use either by distillation or crystallization. − Elemental analysis using a Haereus MX instrument were done at the Institute′s microanalytical laboratory. − IR: Perkin FT. − MS: Atlas CH7, 70 eV ionisation energy. − NMR: JEOL GSX 270 and JEOL EX 400, internal TMS (^1H, ^{13}C), external $BF_3 \cdot OEt_2$ (^{11}B). − X-ray: Siemens P4 with CCD area detector, SAINT software for data reduction; SHELX97 program package for structure solution and refinement. Numbering scheme of the NMR data refer to formulae **3**−**5**.

1-Chloro-1,2-bis(dimethylamino)-2-(3-indenyl)diborane(4) (**2**): By analogy to the preparation of **3**, $B_2Cl_2(NMe)_2$ (2.96 g, 16.4 mmol) in toluene (50 ml) was treated with a suspension of Li(ind) (2.0 g, 16.4 mmol) in toluene (30 ml) at −78°C. The insoluble material (found 0.67 g, calcd. for LiCl: 0.69 g) was removed after 2 d. **2** could not be crystallized from hexane, but was distilled at 95−98°C/10^{-3} Torr as a colourless viscous oil. Yield: 2.53 g of **2** (63%).− $C_{13}H_{19}B_2ClN_2$ (260.38): calcd. C 59.97, H 7.35, N 10.76; found C 59.48, H 7.37, N 10.59. − ^{11}B NMR (64 MHz, C_6D_6): δ = 43.6 [$h_{1/2}$ = 480 Hz, $B_2(NMe_2)_2(1\text{-ind})_2$] − ^1H NMR (400 MHz, C_6D_6): δ = 7.53 [d, 1 H, ^3J(H,H) = 7.7 Hz, indenyl: $H^{5/8}$], 7.37 [d, 1 H, ^3J(H,H) = 7.4 Hz, indenyl: $H^{5/8}$], 7.29 [t, 1 H, ^3J(H,H) = 7.7 Hz, indenyl: $H^{6/7}$], 7.15 [t, 1 H, ^3J(H,H) = 7.4 Hz, indenyl: $H^{6/7}$], 6.55 [t, 1 H, ^3J(H,H) = 2.1 Hz, indenyl: H^2], 3.21 [d, 2 H, ^3J(H,H) = 1.8 Hz, indenyl: H^3], 2.74 [s, 3 H, N(CH_3)], 2.61 [s, 3 H, N(CH_3)], 2.54 [s, 3 H, N(CH_3)], 2.52 [s, 3 H, N(CH_3)] − ^{13}C NMR (100 MHz, C_6D_6): δ = 148.5 (indenyl: C^4), 144.9 (indenyl: C^9), 137.1(indenyl: C^2), 126.5 (indenyl: C^8), 124.5 (indenyl: C^5), 124.1 (indenyl: C^7), 122.5 (indenyl: C^6), 44.2 [−N(CH_3)], 41.9 [−N(CH_3)], 41.1 [−N(CH_3)], 40.6 (indenyl: C^3), 37.5 [−N(CH_3)].

1,2-Bis(dimethylamino)-1,2-bis(1-indenyl)diborane(4) (**3**): $B_2(NMe_2)_2Cl_2$ [15] (5.06 g, 28.0 mmol) was dissolved in toluene (20 ml) and the solution cooled to −78°C. A suspension of lithiumindenide (6.84 g, 56.0 mmol), which had been freshly prepared from indene and butyllithium in toluene (90 ml), was added under vigorous stirring. The suspension was allowed to attain ambient temperature within 18 h, and was then heated for 3 h at 68°C, while stirring was continued. At this time the ^{11}B-NMR spectrum showed only a single-resonance signal of the monosubstituted product $Cl(Me_2N)B-B(NMe_2)$ind; 0.3 ml of THF was then added to the yellow suspension and the insoluble material was removed by centrifugation after 1h. After washing with toluene (20 ml) and drying in vacuum, 2.25 g (calcd. 2.38 g for LiCl) of the almost white insoluble material were obtained. Toluene was removed from the combined solutions in vacuum leaving behind a yellowish mass of honey-like appearance. It was then dissolved in hot hexane (75 ml). Some insoluble materials were removed by filtration, and crystals separated within 7 d at −20°C. Yield: 5.2 g of **3** (55%), m.p. 143−145°C. − $C_{22}H_{26}B_2N_2$ (340.08): calcd. X-ray Structure Determinations: Single crystals of compounds **3** and **4** were grown from hexane solutions at −20°C. The selected crystals were covered with perfluoroether oil, and mounted on a glass fibre, placed on the goniometer head and cooled with a gas flow of cold N_2. Preliminary dimensions of the unit cells were calculated from the reflection collected at four different settings of the crystal by recording 15 frames each with a CCD area detector. Data collection was performed with 10 s exposure time per frame by rotating the crystal by 0.3° in φ at two different χ settings. The data on 1350 frames were reduced by using the program SAINT[16] and the structures solved by direct methods using the XS and SHELX97 programs for structure solution and refinement. Non-hydrogen atoms were refined anisotropically, and the hydrogen atoms were included as a riding model in the final cycles of refinement. Relevant data are presented in Table 3.

Crystallographic data (excluding structure factors) have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication no. 101104. Copies of the data can be obtained free of charge on application to CCCD, 12 Union Park, Cambridge, UK, CB2 1EZ [Fax: int. code + 44(0)1223/336033; E-mail: deposit@ccdc.cam.ac.uk].

Keywords: Gold(I) / Silver(I) / S-donor and N-donor ligand

The ligand properties of 2-(phenacylthio)pyridine towards gold(I) and silver(I) have been investigated. From the reactions of the ligand with acetone solutions of $[M(PPh_3)(acetone)]ClO_4$ (M = Ag, Au) under various experimental conditions, complexes $[(AuPPh_3)_n\{py\{SCH_2C(O)Ph\}\text{-}2\}](ClO_4)_n$ and $[(AgPPh_3)_n(OClO_3)_n\{py\{SCH_2C(O)Ph\}\text{-}2\}]$ ($n = 1-3$) have been obtained. The crystal structures of the complexes $[(AuPPh_3)\{py\{SCH_2C(O)Ph\}\text{-}2\}]ClO_4$ and $[(AgPPh_3)(OClO_3)\text{-}\{py\{SCH_2C(O)Ph\}\text{-}2\}]$ have been determined by X-ray diffraction. In the cationic gold complex the metal is linearly coordinated to nitrogen and phosphorus, whereas the corresponding silver complex displays a trigonal planar geometry with pyridine, phosphane and perchlorato ligands.

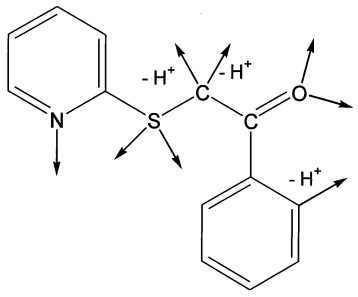
Introduction

The use of functionalized ligands, such as 2-(methylthio)pyridine, pyridine-2(1*H*)-thione, benzoxazole-2(3*H*)-thione,[1] or ylides derived from 2-pyridylmethylene(triaryl)-phosphonium salts,[2][3] has allowed us to synthesize a variety of mono- and polynuclear silver(I) and gold(I) derivatives including a new class of $[Au_3]^{3+}$, $[Au_2Ag]^{3+}$, and $[Au_2Cu]^{3+}$ clusters. Such polynuclear complexes offer the possibility of studying metal−metal interactions in d^{10} systems, which are the subject of considerable interest.[3][4][5][6][7][8][9][10][11][12]

The objective of the present work is to study the ligand properties of 2-(phenacylthio)pyridine [py{$SCH_2C(O)Ph$}-2], of which, as far as we are aware, there is no previously known complex. According to Scheme 1, this ligand could coordinate through the nitrogen, sulfur, or oxygen atoms while the anionic ligands resulting from deprotonation of the methylene group or the *ortho* position of the phenyl ring offer two additional coordination sites, together resulting in the possibility of coordinating up to eight metal centers. In this paper we explore the chemistry of gold(I) and silver(I) complexes with this ligand.

Gold(I) has a limited tendency to coordinate to neutral N or S donor ligands (L_N or L_S). In fact, only a few complexes of the type $[Au(L_N)(PR_3)]^+$ have been described with full experimental and spectroscopic details.[13][14][15][16][17][18][19][20][21] In this family, most complexes contain primary, secondary or tertiary amines while the only reported complexes with pyridinic ligands (L_{py}) are those with L_{py} = py,[22] or 2,2′-bipyridine,[23][24][25] and the dinuclear complex $[Au_2\{\mu_2\text{-}py(PPh_2)\text{-}2\}]^{2+}$.[19]

Scheme 1



Gold(I) complexes with neutral sulfur donor ligands are less frequent and also less stable than those with thiolate and other anionic sulfur ligands.[22][25][24][26][27][28][29][30][31] Such low stability is attributable to the weakness of the Au^I-SR_2 bond. In fact, [AuCl(tht)] (tht = tetrahydrothiophene)[32] is the most widely used starting gold(I) complex because of the facile replacement of the sulfur ligand.[33] From [AuCl(tht)] other synthetic intermediates, such as $[Au(C_6F_5)_n(tht)]$ (n = 1, 3)[32][33][34] have been prepared and used as starting materials for many (pentafluorophenyl)gold(I) and -gold(III) complexes after replacement of tht.[35]

The similarly low tendency of gold(I) to coordinate to both N or S neutral donor ligands prompted us to study

 © WILEY-VCH Verlag GmbH, D-69451 Weinheim, 1998 1434−1948/98/0404−0511 $ 17.50+.50/0

the coordinative preferences of the mixed N-S ligand py{$SCH_2C(O)Ph$}-2 towards the $Au(PPh_3)^+$ moiety. In the absence of X-ray diffraction data, we have previously suggested that in complexes $[Au\{py(SMe)\text{-}2\}(L)]^+$ (L = tht, PPh_3) and $[Au\{py(SMe)\text{-}2\}_2]^+$ the mixed ligand would act as an S- rather than an N-donor ligand according to the preference of the soft gold(I) acid for the softer sulfur base. In fact, gold(I) complexes with pyridine-2-thiol or its conjugate base are always *S*-coordinated.[36][37] Similarly, in the complex $[Au\{py\{CS(=NC_6H_4OMe\text{-}2)\}\text{-}2\}(PPh_3)]$ the $AuPPh_3^+$ group is bonded to sulfur and interacts only weakly with the pyridine N atom.[38] Here we show for the first time the opposite preference of gold(I) for the N- rather than the S-donor atoms in the ligand py{$SCH_2C(O)Ph$}-2.

Synthesis of the Ligand

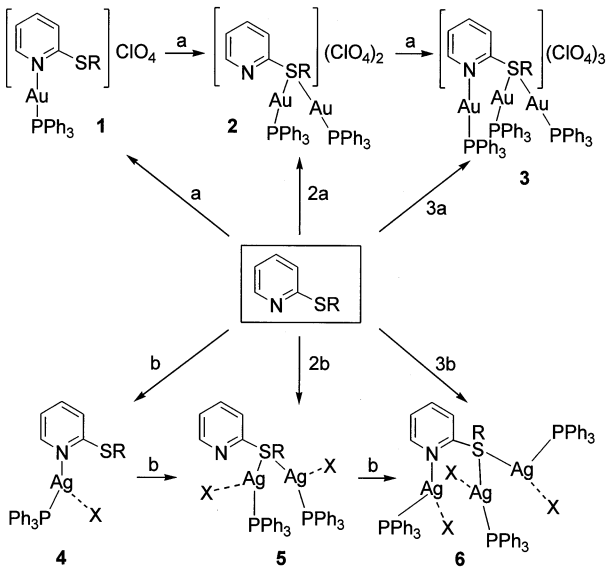
2-(Phenacylthio)pyridinium bromide was first obtained[39] by allowing 2-bromoacetophenone to react with 2-mercaptopyridine in refluxing ethanol for several hours. This and other sulfides resulting from the reaction of α-halo ketones or α-halo acetals with mercaptopyridine can be cyclized in good yield to form thiazolopyridinium salts.[39][40] We have found that equimolar amounts of 2-bromoacetophenone and 2-mercaptopyridine produce, after stirring in diethyl ether at room temperature for only 30 min, a quantitative yield of [Hpy{$SCH_2C(O)Ph$}-2]Br, which in turn reacts with aqueous NaOH to give 2-(phenacylthio)pyridine [py{$SCH_2C(O)Ph$}-2]. As far as we are aware the ligand properties of py{$SCH_2C(O)Ph$}-2 have not previously been explored.

Gold(I) and Silver(I) Complexes

When py{$SCH_2C(O)Ph$}-2 is treated with acetone solutions of $[M(PPh_3)(acetone)]ClO_4$ (M = Au, Ag) in 1:1, 1:2 or 1:3 molar ratios, complexes $[(AuPPh_3)_n\{py\text{-}\{SCH_2C(O)Ph\}\text{-}2\}](ClO_4)_n$ [*n* = 1 (**1**), 2 (**2**), 3 (**3**)] or $[(AgPPh_3)_n(OClO_3)_n\{py\{SCH_2C(O)Ph\}\text{-}2\}]$ [*n* = 1 (**4**), 2 (**5**), 3 (**6**)] are, respectively, obtained (Scheme 2). The reactions leading to polynuclear derivatives can be performed stepwise and thus **2** or **5** can be obtained from **1** or **4** and one equivalent of $[M(PPh_3)(acetone)]ClO_4$ while **3** or **6** can be prepared from **2** or **5** or from **1** or **4** upon addition of one or two equivalents, respectively, of the corresponding $[M(PPh_3)(acetone)]ClO_4$ complex. In the case of the gold complexes the purest products are obtained by the stepwise procedure.

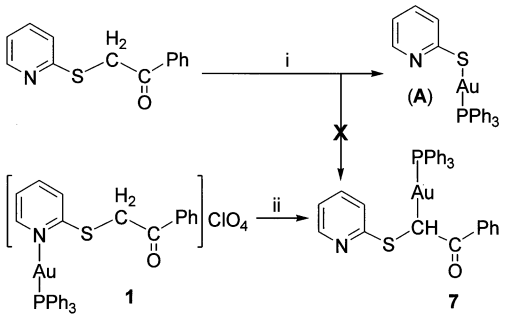
We have shown that (acetylacetonato)gold(I) complexes react with a variety of organic substrates containing moderately acidic protons to give gold(I) complexes, including alkyl, alkynyl, ylide, diphenylphosphide, (diphenylphosphanyl)methanide, hydrosulfide and thiolato derivatives.[1][2][3][17][42][42a] However, the reaction of $[Au(acac)PPh_3]$ with 2-(phenacylthio)pyridine, meant to produce the organometallic complex **7** (Scheme 3), gave instead the known complex **A,** the structure of which we determined by X-ray diffraction methods; it had been previously reported.[36]

Scheme 2[a]



[a] R = $CH_2C(O)Ph$; X = $OClO_3$; a: + $[Au(PPh_3)(acetone)]ClO_4$; b: + $[Ag(PPh_3)(acetone)]ClO_4$.

Scheme 3[a]



[a] i: + $[Au(acac)PPh_3]$ − Hacac; ii: + NaH − H_2 − $NaClO_4$.

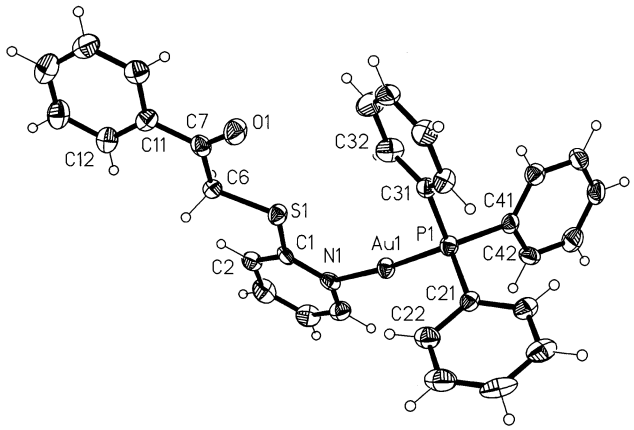
The reaction of **1** with NaH (1:2.3, in dichloromethane, 2.5 h) gave the desired complex **7** resulting from deprotonation of the methylene group and the rearrangement of the $AuPPh_3^+$ group from N to C. The preference of gold for C rather than N donor ligands is well known. Although the elemental analyses of **7** were correct, it is difficult to separate it from traces of the starting material and some decomposition products (see below).

Crystal Structure of Complexes 1 and 4

Complex **1** crystallizes in the triclinic system with 3 molecules of acetone and two independent molecules in the asymetric unit. The crystal structure (Figure 1) shows cations in which the gold atoms are in almost linear environments, with N−Au−P angles of 175.46(12) and 173.91(12)° and tetrahedral ClO_4 anions. The Au−N distances [2.082(4) and 2.092(4) Å] are similar to the 2.086(16) Å found in $[Au_2\{\mu_2\text{-}py(PPh_2)\text{-}2\}]^{2+}$.[19] In $[Au(bipy)(PPh_3)]^+$ a distorted trigonal planar coordination leads as expected to Au−N bond lengths [2.166(2) and 2.406(2) Å] longer than those in **1**.[25]

The Au−P bond lengths [2.2359(13) and 2.2388(13) Å] in **1** are larger than those in $[Au_2\{\mu_2\text{-py}(PPh_2)\text{-}2\}]^{2+}$ [2.215(6) Å][19] or $[Au(bipy)(PPh_3)]^+$ [2.212(1) Å].

Figure 1. Structure of the cation of complex **1**[a]

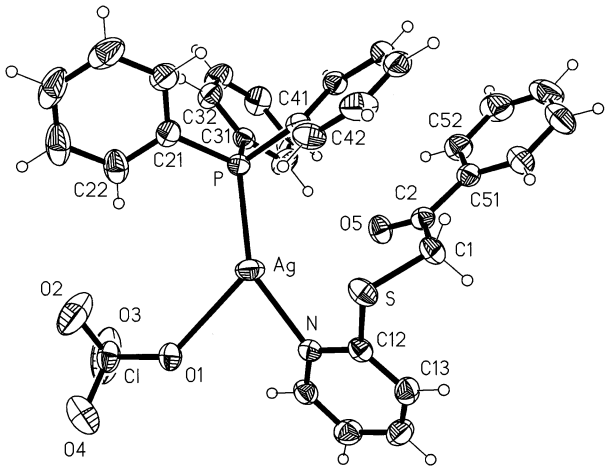


[a] 50% probability ellipsoids; selected bond lengths [Å] and angles [°]: Au(1)−N(1) 0.082(4), Au(2)−N(2) 2.092(4), Au(1)−P(1) 2.2359(13), Au(2)−P(2) 2.2388(13); N(1)−Au(1)−P(1) 175.46(12), N(2)−Au−P(2) 173.91(12).

The coordination of the $AuPPh_3^+$ group to N instead of S [Au···S, 3.071, 3.063(1) Å] is surprising because the soft gold(I) acid should prefer the softer sulfur base; when the ligand is pyridine-2-thiol or its conjugate base, gold(I) is always bonded to sulfur.[36][37] In addition, in the complex $[Au\{py\{C(S)(=NC_6H_4OMe\text{-}2)\}\text{-}2\}(PPh_3)]$ the $AuPPh_3^+$ group is bonded to sulfur (Au−S, 2.317 Å) and only weakly to the pyridine N atom (Au−N, 2.574 Å).[38] Probably the presence of the electron-withdrawing carbonyl group in **1** makes the sulfur atom less soft than usual.

Complex **4** crystallizes in the monoclinic system and its crystal structure (Figure 2) shows the silver atoms in a very distorted trigonal planar environment (the Ag atom lies 0.21 Å out of the plane of the donor atoms. The N−Ag−P [148.5(5)°], P−Ag−O [129.7(6)°], and N−Ag−O [79.0(5)°] bond angles show PPh_3 to be the most sterically demanding ligand. Two of the four Ag−N bond lengths [2.272, 2.268, 2.386, 2.407(4) Å] and the Ag−P [2.380, 2.377(1) Å] bond lengths at the two independent Ag atoms of $[Ag(8\text{-hydroxyquinoline})_2(PPh_3)]^+$ are similar to the Ag−N [2.263(2) Å] and Ag−P [2.3845(7) Å] bond lengths in **4**.[43] In the complex $[Ag(OClO_3)(O_2NO)\{py\{C(AuPPh_3)_2PPh_3\}\text{-}2\}]$[3] the Ag−N [2.178(8) Å] and Ag−$OClO_3$ [2.663(9) Å] bond lengths are shorter and similar, respectively, than the corresponding ones in complex **4** [Ag−O, 2.688(6) Å]. The long Ag−O bond length (compared with Ag−N [2.263(2) Å]) and the wide P−Ag−N [148.5(5)°] bond angle indicate the weak coordination of the anion to Ag^I, as does the wide Cl−O(1)−Ag angle [133.8(1)°]. The sulfur atom forms short intra- [3.097(1) Å] and intermolecular [2.998(1) Å] Ag−S contacts leading to weakly associated, centrosymmetric dimers.

Figure 2. Structure of complex **2**[a]



[a] 50% probability ellipsoids; selected bond lengths [Å] and angles [°]: Ag−N 2.263(2), Ag−P 2.3845(7), Ag−O(1) 2.688(6); N−Ag−P 148.47(6), P−Ag−O 129.7(6), N−Ag−O 79.0(5).

NMR Spectra

Because the resonance from the methylene protons in the ^{1}H-NMR spectrum of complex **1** at −60°C appears as a singlet, we propose that, in solution, the ligand acts as an N donor, as in its solid-state structure. Coordination through the sulfur atom would convert it into a chiral center and the methylene protons would be non-isochronous unless a rapid scrambling of the $AuPPh_3^+$ group between both sp^3 sulfur pairs occurred even at −60°C. In fact, at −60°C the *S*-bonded isomer of the silver complex **4** (**4**-S) is detected because the ^{1}H-NMR spectrum shows an AB system highfield of the CH_2 singlet, and in the ^{31}P-NMR spectrum four doublets corresponding to two different phosphorus nuclei (molar ratio 8:1) resonating at δ = 13.21 [$^1J(P^{109}Ag)$ = 742 Hz, $^1J(P^{107}Ag)$ = 643 Hz; **4**] and 11.69 [$^1J(P^{109}Ag)$ = 555 Hz, $^1J(P^{107}Ag)$ = 481 Hz; **4**-S] are observed. The $^1J(P^{109}Ag)$ and $^1J(P^{107}Ag)$ values are similar to those in complex **6** [$J(P^{109}Ag)$ = 770.6 Hz, $J(P^{107}Ag)$ = 667.6 Hz, *P*AgN; $J(P^{109}Ag)$ = 569 Hz, $J(P^{107}Ag)$ = 493 Hz, 2*P*AgS] where Ag^I is coordinated to both N and S.

The dinuclear complexes **2** and **5** show only one type of phosphorus nucleus at low temperature (−60°C), indicating that both $MPPh_3$ units coordinate to sulfur. This is also a surprising result because, according to the above explanation of the *N*-coordination, the sulfur atom has its donor ability reduced by the vicinity of the electron-withdrawing carbonyl group. However, a reasonable explanation for these facts is based on the marked tendency of gold(I) and silver(I) to establish short M···M contacts, a phenomenon termed aurophilicity,[7][8][9][10][11][12] or numismophilicity (from the Latin numisma = money, coin)[3] when it applies to gold or to the three coinage metals, respectively. Because the numismophilic interactions are weak (of similar energy to hydrogen bonds when the metal is gold)[44] the structure adopted is that in which there is a minimum of repulsion between the phosphane ligands, i.e., the double metalation of the sulfur atom is preferred to the alternative mixed *N*,*S*

metalation. At room temperature, the behavior of these complexes is different. Whereas the silver complex **5** shows a broad resonance, probably because of dissociative processes involving cleavage of S−AgPPh$_3$ and/or Ag−PPh$_3$ bonds, in the gold complex **2** such equilibria do not exist because its spectrum is not significantly different from that at −60°C.

The $^{31}P\{^1H\}$-NMR spectrum of **3** at −60°C consists of two singlets of 2:1 relative intensity, consistent with the structure proposed in Scheme 2, but at room temperature shows only a singlet, indicating that a fluxional process interchanging all three $AuPPh_3^+$ units occurs. Similarly, in the case of **6** the room-temperature $^{31}P\{^1H\}$-NMR spectrum shows a broad resonance, which at −60°C splits into two (2:1 relative intensities) pairs of doublets.

Resonances appearing at δ = 4.75 and 31.02 in the ^{1}H- and ^{31}P-NMR spectra, respectively, of **7** are due to the presence of traces of **1**, while a small amount of $[Au(PPh_3)_2]^+$ could account for the resonance at δ = 44.24. The slight conductivity of **7** (Λ_M = 11 Ω^{-1} cm^2 M^{-1}) is also consistent with the presence of both impurities.

IR Spectra

The bands assignable to the ν̃(CO) mode in the IR spectra of the ligand and the complexes appear in the narrow range of 1672−1680 cm^{-1}. The gold complexes **1**−**3** show the expected two bands for the tetrahedral ClO_4 anion in the ranges 1088−1094 and 621−622 cm^{-1}, respectively. This accords with the marked tendency of gold(I) to give dicoordinate complexes. In complexes **4**, **5** and **6**, a new band around 923 cm^{-1} and two bands in each of the two above-mentioned regions are observed. This is in agreement with the expected splitting when the symmetry of the ClO_4 decreases from T_d to C_{3v}. Therefore, it is reasonable to assume that, in the solid state, each ClO_4 anion is monocoordinated to one metal centre.

These differences among gold(I) and silver(I) complexes in the solid state disappear in acetone solutions, because all complexes show molar conductivities indicating the dissociation of all the perchlorate anions, i.e., complexes **1**−**6** behave as 1:1 electrolytes, **2** and **5** as 2:1 electrolytes, and **3** and **6** as 3:1 electrolytes.[45] Therefore, in acetone solutions of the silver complexes the solvent replaces the anion in the coordination sphere of the metal.

We thank the *DGES* and the *Fonds der Chemischen Industrie* for financial support. M. C. R. A. is grateful for an *Alexander von Humboldt Grant* and to the *Ministerio de Educación y Cultura* for a contract.

Experimental Section

General: The IR spectra, elemental analyses, conductance measurements in acetone and melting-point determinations were carried out as described earlier[42a]. − NMR: Varian Unity-300. Chemical shifts are referred to TMS [^{1}H, $^{13}C\{^1H\}$] or H_3PO_4 [$^{31}P\{^1H\}$]. − If not stated otherwise, the reactions were carried out at room temperature without special precautions against moisture. ***Warning:*** Perchlorate salts with organic cations may be explosive. − 2-Mercaptopyridine (HSpy) was purchased from Fluka and 2-bromoacetophenone [$BrCH_2C(O)Ph$] from Aldrich.

[Hpy{SCH$_2$C(O)Ph}-2]Br: A solution of equimolar amounts of pySH-2 (1.11 g, 10 mmol) and $BrCH_2C(O)Ph$ (1.99, 10 mmol) were stirred in diethyl ether (30 ml) for 0.5 h. The resulting yellow suspension was filtered off, the solid washed with diethyl ether (3 × 15 ml) and air-dried to give 3.07 g (99%) of colorless crystals, m.p. 200°C (ref.[39] 200°C). − IR (Nujol): ν̃ = 1693 cm^{-1} (CO). − $C_{13}H_{12}BrNOS$ (310.2): calcd. C 50.34, H 3.90, N 4.52, S 10.33; found: C 50.18, H 4.07, N 4.62, S 10.44.

py{SCH$_2$C(O)Ph}-2: To a solution of [Hpy{SCH$_2$C(O)Ph}-2]Br (2.48 g, 8 mmol) in water (50 ml) NaOH (0.5 M in water) was added dropwise until pH = 7. The resulting white suspension was extracted with dichloromethane (4 × 20 ml) and the organic layer was dried with anhydrous $MgSO_4$ and then filtered. Removing the volatiles in vacuo gave 514 mg of 2-(phenacylthio)pyridine (28%) as a pale yellow oil. − IR (Nujol): ν̃ = 1668 cm^{-1} (CO). − ^{1}H NMR ([D$_6$]acetone): δ = 4.79 (s, 2 H, C*H*$_2$), 6.93 [m, 1 H, *H4* (py)], 7.22 [m, 1 H, *H3* (py)], 7.3−7.8 [m, 4 H, *H5* (py) + *m-H* (Ph) + *p-H* (Ph)], 8.04 [d, ^3J(HH) = 7 Hz, 2 H, *o-H* (Ph)], 8.34 [m, 1 H, *H6* (py)]. − $C_{13}H_{11}NOS$ (229.3): calcd. C 68.10, H 4.84, N 6.11, S, 13.98; found: C 68.38, H 4.89, N 6.28, S 14.02.

[(AuPPh$_3$)$_n${py{SCH$_2$C(O)Ph}-2}](ClO$_4$)$_n$ [*n* = 1 (**1**), 2 (**2**), 3 (**3**)]. − *Preparation of Solutions of [Au(PPh$_3$)(acetone)]ClO$_4$:* An equimolecular mixture of [AuCl(PPh$_3$)] and $AgClO_4$ (1:1 molar ratio) in degassed acetone (25 ml mmol^{-1}) was stirred for 0.5 h under nitrogen and then the AgCl removed by filtration.

Complex **1**: A solution of [Au(PPh$_3$)(acetone)]ClO_4, from [AuCl(PPh$_3$)] (406 mg, 0.82 mmol) and $AgClO_4$ (107 mg, 0.82 mmol), was added dropwise under nitrogen to a solution containing py{SCH$_2$C(O)Ph}-2 (188 mg, 0.82 mmol) in degassed acetone (15 ml). The resulting suspension was stirred for 0.5 h and then filtered through Celite. The solvent was removed in vacuo and the oily residue was vigorously stirred with diethyl ether (20 ml) for 0.5 h to give 626 mg of **1** (97%), white solid, m.p. 137°C. − IR (Nujol): ν̃ = 1672 cm^{-1} (CO). − Λ_M = 144 Ω^{-1} cm^2 M^{-1}. − ^{1}H NMR (CD_2Cl_2, 20°C): δ = 4.90 (s, 2 H, C*H*$_2$), 7.48−7.67 [m, 20 H, C(O)*Ph* + P*Ph*$_3$], 7.83 [m, 1 H, *H3* (py)], 8.04 [m, 2 H, *H4* (py) + *H5* (py)], 8.50 [m, 1 H, *H6* (py)]. − ^{1}H NMR (CD_2Cl_2, −60°C): δ = 4.95 (s, 2 H, C*H*$_2$), 7.44 − 7.68 [m, 20 H, C(O)*Ph* + P*Ph*$_3$], 7.97 [m, 1 H, *H3* (py)], 8.08 [m, 2 H, *H4* (py) + *H5* (py)], 8.42 [m, 1 H, *H6* (py)]. − $^{31}P\{^1H\}$ NMR (CD_2Cl_2, 20°C and −60°C): δ = 29.44. − $C_{31}H_{26}AuClNO_5PS$ (788.0): calcd. C 47.25, H 3.33, N 1.78, S 4.07; found: C 47.42, H 3.79, N 1.73, S 3.71.

Complex **2**: A solution of [Au(PPh$_3$)(acetone)]ClO_4, from [AuCl(PPh$_3$)] (125 mg, 0.25 mmol) and $AgClO_4$ (53 mg, 0.25 mmol), was added dropwise to a solution containing **1** (200 mg, 0.25 mmol) in degassed acetone (15 ml). The resulting suspension was stirred for 1.5 h and then filtered through Celite. The solution was concentrated (2 ml) and diethyl ether added (20 ml) to give a suspension that was filtered, the solid washed with diethyl ether (5 ml), dried in the air and then in an oven at 60°C for 30 min to give 327 mg of **2** (97%), cream solid, m.p. 103°C. − IR (Nujol): ν̃ = 1672 cm^{-1} (CO). − Λ_M = 183 Ω^{-1} cm^2 M^{-1}. − ^{1}H NMR ([D$_6$]acetone, 20°C): δ = 5.28 (s, 2 H, C*H*$_2$), 7.40−8.36 [m, 38 H, *H3* (py) + *H4* (py) + *H5* (py)+ C(O)*Ph* + P*Ph*$_3$], 9.03 [m, 1 H, *H6* (py)]. − $^{31}P\{^1H\}$ NMR ([D$_6$]acetone, 20°C): δ = 29.66 (s). − $^{31}P\{^1H\}$ NMR ([D$_6$]acetone, −60°C): δ = 28.29 (s). − $C_{49}H_{41}Au_2Cl_2NO_9P_2S$ (1346.7): calcd. C 43.70, H 3.07, N 1.04, S 2.38; found: C 43.68, H 3.33, N 1.19, S 2.28.

Complex **3**: A solution of [Au(PPh$_3$)(acetone)]ClO_4, from [AuCl(PPh$_3$)] (92 mg, 0.19 mmol) and $AgClO_4$ (38 mg, 0.19 mmol), was added dropwise to a solution containing **2** (250 mg, 0.19 mmol) in degassed acetone (10 ml). The resulting suspension was stirred

for 2 h and then filtered through $MgSO_4$. The solvent was evaporated to dryness and the resulting solid stirred with diethyl ether (20 ml) to give a suspension that was filtered and dried under nitrogen to give 355 mg of **3** (98%), cream solid, m.p. 107°C. − IR (Nujol): $\tilde{\nu}$ = 1673 cm^{-1} (CO). − Λ_M = 285 Ω^{-1} cm^2 M^{-1}. − ^1H NMR ([D$_6$]acetone, 20°C): δ = 5.38 (s, 2 H, C*H*$_2$), 7.38−7.64 [m, 51 H, *H3* (py) + C(O)*Ph* + P*Ph*$_3$], 8.07 [m, 2 H, *H4* (py) + *H5* (py)], 8.78 [m, 1 H, *H6* (py)]. − $^{31}P\{^1H\}$ NMR([D$_6$]acetone, 20°C): δ = 29.12 (s). − $^{31}P\{^1H\}$ NMR([D$_6$]acetone, −60°C): δ = 28.21 (s, Ph$_3$*P*AuN), 29.68 (s, Ph$_3$*P*AuS). − $C_{67}H_{56}Au_3Cl_3NO_{13}P_3S$ (1905.4): calcd. C 42.23, H 2.96, N 0.74, S 1.68; found: C 42.14, H 3.27, N 0.62, S 1.70.

[(AgPPh$_3$)$_n$(OClO$_3$)$_n${py{SCH$_2$C(O)Ph}-2}] [*n* = 1 (**4**), (**5**), 3 (**6**)]. − *Preparation of Solutions of [Ag(PPh$_3$)*(acetone)]ClO_4: PPh_3 is added to an equimolecular amount of $AgClO_4$ in degassed acetone (15 ml $mmol^{-1}$).

Complex **4**: A solution of [Ag(PPh$_3$)(acetone)]ClO_4, from $AgClO_4$ (203 mg, 0.98 mmol) and PPh_3 (257 mg, 0.98 mmol), was added dropwise to a solution containing py{SCH$_2$C(O)Ph}-2 (225 mg, 0.98 mmol) in degassed acetone (5 ml) under nitrogen. The resulting suspension was stirred for 75 min and then concentrated to dryness. The residue was washed with diethyl ether (20 ml) and recrystallized from dichloromethane/diethyl ether to give 589 mg of **4** (86%), white solid, m.p. 137°C. − IR (Nujol): $\tilde{\nu}$ = 1677 cm^{-1} (CO). − Λ_M = 101 Ω^{-1} cm^2 M^{-1}. − ^1H NMR (CD_2Cl_2, 20°C): δ = 4.74 (s, 2 H, C*H*$_2$), 7.30−7.67 [m, 20 H, C(O)*Ph* + P*Ph*$_3$], 7.82 [m, 1 H, *H3* (py)], 7.97 [m, 2 H, *H4* (py) + *H5* (py)], 8.57 [m, 1 H, *H6* (py)]. − ^1H NMR (CD_2Cl_2, −60°C): δ = 3.93, 4.22 (AB system, $^2J_{HH}$ = 13 Hz, **4**-S, see Discussion), 4.55 (s, br., 2 H, C*H*$_2$), 7.03−7.77 [m, 21 H, *H3* (py) + C(O)*Ph* + P*Ph*$_3$], 8.05 [m, 2 H, *H4* (py) + *H5* (py)], 8.23 [m, 1 H, *H6* (py)]. − $^{31}P\{^1H\}$ NMR (CD_2Cl_2, 20°C): δ = 15.00 (s, br.). − $^{31}P\{^1H\}$ NMR (CD_2Cl_2, −60°C): δ = 13.21 [2 d, 88% P, $^1J(P^{109}Ag)$ = 742 Hz, $^1J(P^{107}Ag)$ = 643 Hz; **4**, see Discussion], 11.69 [2 d, 12% P, $^1J(P^{109}Ag)$ = 555 Hz, $^1J(P^{107}Ag)$ = 481 Hz; **4**-S, see Discussion]. − $C_{31}H_{26}AgClNO_5PS$ (698.9): calcd. [Au{CH(Spy-2){C(O)Ph}}(PPh$_3$)] (**7**): To a solution of **1** (600.8 mg mg, 0.76 mmol) in dichloromethane (15 ml), NaH (Fluka, 50% in mineral oil, 86 mg, 1.79 mmol) was added. After 2.5 h of stirring, the resulting suspension was filtered through Celite. The solution was concentrated to dryness, the residue stirred with diethyl ether (2 × 15 ml) and the suspension filtered to give 290 mg of **7** (55%), pale cream solid, m.p. 106°C (dec.). − IR (Nujol): $\tilde{\nu}$ = 1638 (CO). − Λ_M = 11 Ω^{-1} cm^2 M^{-1}. − ^1H NMR ($CDCl_3$, 20°C): δ = 4.75 (s, traces, complex **1**, see Discussion), 5.42 [d, 1 H, C*H*, ^3J(PH) = 9.9 Hz], 6.42−7.56 (m, 19 H, PPh_3 + py). − $^{31}P\{^1H\}$ NMR: δ = 31.02 (s, traces, complex **1**, see Discussion), 39.24 (s), 44.24 (s, traces, $[Au(PPh_3)_2]^+$). − $C_{31}H_{25}AuNOPS$ (687.5): calcd. C 54.16, H 3.67, N 2.04, S 4.66; found: C 53.95, H 3.79, N 2.03S 4.55.

X-ray Crystallographic Studies: Crystal data are given in Table 1. Crystals of **1**·1.5 Me_2CO and **2** were mounted in inert oil on a glass fiber and transferred to the diffractometer (Siemens P4 with LT2 low-temperature attachment). Measurements were performed at −100°C using monochromated Mo-K_α radiation (λ = 0.71073 Å).

*wR*2[b]	0.0640	0.0819

[a] $R1 = \sigma||F_o| - |F_c||/\sigma|F_o|$ for reflections with $I > 2\sigma(I)$. − [b] $wR2 = \{\sigma[w(F_o^2 - F_c^2)^2]/\sigma[w(F_o^2)^2]\}^{0.5}$ for all reflections; $w^{-1} = \sigma^2(F^2) + (aP)^2 + bP$, where $P = (2F_c^2 + F_o^2)/3$ and *a* and *b* are constants set by the program.

Unit cell parameters were determined from a least-squares fit of ca. 80 accurately centered reflections (10° < 2θ < 27°). Intensities were registered using ω scans. Absorption corrections were based on ψ scans. The structures were solved by the heavy-atom method and refined anisotropically on F^2 (program SHELXL-93).[46] Hy-

drogen atoms were included using a riding model or as rigid methyl groups.

Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre under the number CCDC-100752. Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK (fax: int. code + (1223)336−033, e-mail: deposit@ccdc.cam.ac.uk).

Keywords: Bis(silyl)phosphanes / Magnesium / NMR spectroscopy / Oligomers / Phosphorus

The metathesis reaction of (dme)$LiPH_2$ and chlorodiisopropylsilane yields $HP(SiHiPr_2)_2$ (**1**) and $P(SiHiPr_2)_3$ (**2**). The metalation of **1** by *n*/*sec*-dibutylmagnesium in heptane leads to the formation of dimeric magnesium bis[bis(diisopropylsilyl)-phosphanide] [(**3**)$_2$]. A toluene solution of magnesium bis[bis-(trimethylsilyl)phosphanide] (**4**) shows a dimer-trimer equilibrium in the $^{31}P\{^1H\}$-NMR spectrum at −40°C with an increasing amount of the dimer with increasing temperature. A molecular mass determination by freezing-point depression in benzene yields a value of 516 g·mol^{-1}, which lies between a monomeric and a dimeric molecule. Cooling of the toluene solution to −30°C leads to the precipitation of single crystals of monoclinic $\{(Me_3Si)_2P-Mg[\mu\text{-}P(SiMe_3)_2]_2\}_2Mg$ [(**4**)$_3$].

Several possibilities for the synthesis of the alkaline earth metal bis[bis(trialkylsilyl)amides] justified the vastly growing interest in the molecular chemistry of the heavier alkaline earth metals.[1][2] The alkaline earth metal bis(phosphanides) are easily accessible by the metalation of bis(trialkylsilyl)phosphane with the above-mentioned bis(trialkylsilyl)amides in toluene, where they precipitate, or in ethers such as tetrahydrofuran (thf) or 1,2-dimethoxyethane (dme), where ether adducts are formed.[3] Eq. (1) shows the preparation of the thf complexes of the alkaline earth metal bis[bis(trimethylsilyl)phosphanides].

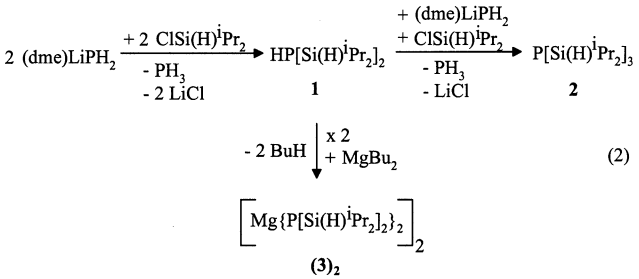
$$M[N(SiMe_3)_2]_2 + 2\ HP(SiMe_3)_2 \xrightarrow{thf} (thf)_nM[P(SiMe_3)_2]_2 \quad (1)$$
$$M/n = Mg/2,\ Ca/4,\ Sr/4,\ Ba/4$$

The bis(trialkylsilyl)phosphanides of the heavier alkaline earth metals precipitate in the absence of neutral coligands such as ethers or amines. Therefore, the soluble ether adducts of the trialkylsilyl-substituted phosphanides[4] and a tmeda complex of $Mg[P(H)Ph]_2$[5] were investigated by solution NMR as well as X-ray crystallography. Further enhancement of the steric demand of the silyl groups reduces the reactivity of the phosphanes. For example, the metalation of bis(triisopropylsilyl)phosphane[6] by calcium bis-[bis(trimethylsilyl)amide] is neither possible in boiling toluene nor in refluxing thf nor a mixture of both.

Solvent-poor alkaline earth metal bis(phosphanides) are gaining interest especially due to the unexpected structures of the dimers in solution as well as the solid state. Ab-initio SCF calculations for $M_2(PH_2)_4$ show for magnesium the "conventional" monocyclic structure $H_2P-Mg(\mu\text{-}PH_2)_2Mg-PH_2$[6] whereas for calcium or strontium the bicyclic structure $H_2P-M(\mu\text{-}PH_2)_3M$ is the lowest in energy.[4d] In the case of dimeric barium bis(phosphanide) even the tricyclic isomer $Ba(\mu\text{-}PH_2)_4Ba$ has to be taken into consideration. Here, the synthesis of the first solvent-free dimeric and trimeric magnesium bis(phosphanides) is presented and the X-ray structure of trimeric magnesium bis-[bis(trimethylsilyl)phosphanide] is discussed in detail.

Preparation

To raise the reactivity of the P−H fragment compared to bis(triisopropylsilyl)phosphane[6][7] the diisopropylsilyl substituents are chosen. The second advantage of this substituent is the basicity of the Si−H moiety which allows an electrostatic attraction to the metal center as well as an agostic interaction between the metal atom and the Si−H bond. The metathesis reaction of (dme)$LiPH_2$ and chlordiisopropylsilane offers an easy approach to bis(diisopropylsilyl)-phosphane (**1**), which is obtained together with tris(diisopropylsilyl)phosphane (**2**) according to eq. (2). The metalation of **1** in toluene with dibutylmagnesium, dissolved in heptane, yields quantitatively dimeric magnesium bis[bis(diisopropylsilyl)phosphanide] [(**3**)$_2$]. However, the efforts of crystallization failed, and an oil remained after the work-up procedures.



(2)

During the metalation of bis(trimethylsilyl)phosphane with commercially available *n*/*sec*-dibutylmagnesium a col-

orless solid precipitates, however, stirring for several hours at room temperature leads to a clear solution. Upon cooling to −30°C crystalline trimeric magnesium bis[bis(trimethylsilyl)phosphanide] [**(4)**$_3$], formed according to eq. (3), precipitates in the shape of colorless cuboids.

$$3\ MgBu_2 + 6\ HP(SiMe_3)_2 \longrightarrow \textbf{(4)}_3 \qquad (3)$$

The addition of tetrahydrofuran yields the already well-known bis(tetrahydrofuran)magnesium bis[bis(trimethylsilyl)phosphanide] (**4**·2 thf).[8] All these magnesium bis(phosphanides) are colorless and very moisture-sensitive.

Spectroscopic Characterization

The NMR data of the phosphanes **1** and **2** clearly show the existence of two chemically different methyl groups. This observation proves that the inversion of the phosphorus atom is very slow on the NMR time scale and the inversion barrier higher than at least 70 kJ·mol^{-1}. No line broadening is observable at room temperature.

The comparison between **1** and **2** shows the influence of the substitution of a hydrogen atom by a diisopropylsilyl group (Table 1). The effects are similar as described for $HP(SiMe_3)_2/P(SiMe_3)_3$.[9] The high-field shift of the ^{31}P signal is accompanied by a low-field shift of the ^{29}Si signal. The ^1J(P,Si) coupling constants of approximately 36 Hz are nearly not affected by this change in the ligand sphere of the phosphorus atom.

For compound **(3)**$_2$ the coupling pattern of two triplets between the bridging and the terminal phosphorus atoms clearly proves its dimeric appearance (Figure 1). Even at elevated temperatures up to 70°C the ligand-exchange processes are very slow on the NMR time scale. The $^2J(P_b,P_t)$ coupling constant of 22.2 Hz lies in the expected range. The ^1J(P,Si) coupling constant within the terminal ligand amounts nearly 39 Hz, whereas for the bridging ligand a value is not deducible, only a line broadening is observed.

For the ^1J(Si,H) coupling constants only a rough estimation can be given due to overlapping of the signals in the ^{29}Si-NMR spectrum and the expected pattern of higher order. For the bridging phosphanide ligand a line separation of approximately 140 Hz can be seen, whereas the ^1J(Si,H) coupling constant of the terminal ligand is clearly larger than 200 Hz. This difference could result from an agostic interaction between the magnesium atom and the Si−H bond[10] or from the different coordination numbers of the phosphorus atoms, in particular under consideration of the strongly differing ^1J(P,Si) coupling constants for the terminal and the bridging substituents. However, only one strong Si−H stretching vibration at 2101 cm^{-1} is observed in the characteristic region for Si−H moieties.

For magnesium bis[bis(trimethylsilyl)phosphanide] (**4**) the determination of the molecular mass by freezing-point depression in benzene yields a value of 516 g·mol^{-1} for a diluted solution, which lies between the mass of a monomer (379 g·mol^{-1}) and a dimer (758 g·mol^{-1}). The ^{1}H- and

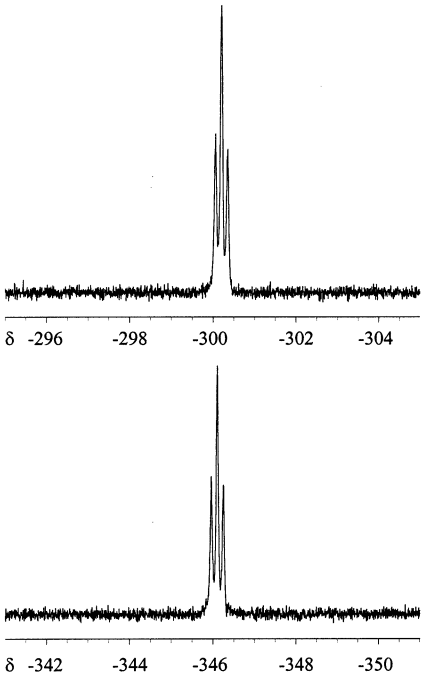
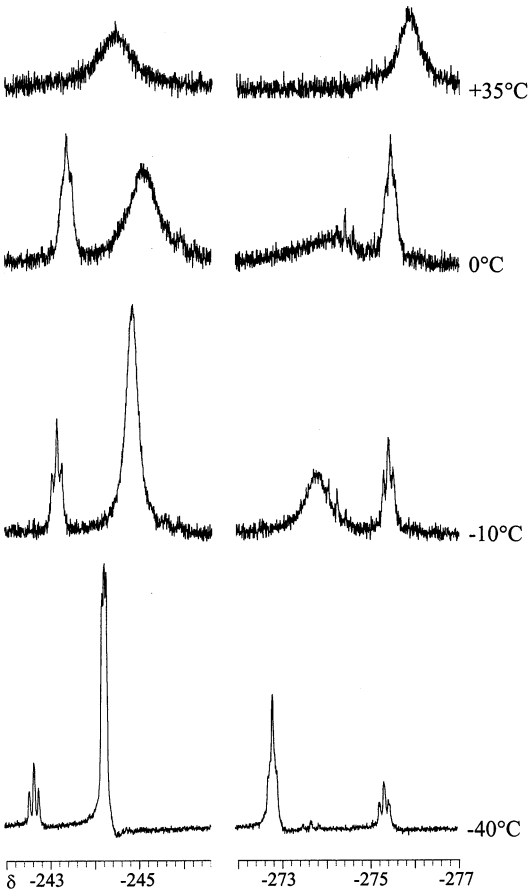
[a] Broad signal. – [b] Four broad signals at δ = 19.7, 19.8, 20.7, and 21.4; assignment to terminal or bridging phosphanide ligands not possible – [c] Very broad signal due to overlapping of the dublets of the CH groups of the terminal and bridging phosphanide ligands; coupling constants not deducible.

Figure 1. ^{31}P{^{1}H}-NMR spectrum of a [D$_8$]toluene solution of magnesium bis[bis(diisopropylsilyl)phosphanide] [**(3)**$_2$] at 25°C; signals of the bridging (top) and terminal (bottom) (*i*Pr$_2$HSi)$_2$P ligands (109.365 MHz)

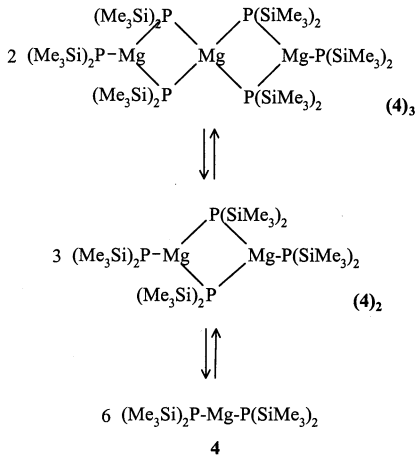


$^{13}C\{^1H\}$-NMR spectra show broad and overlapping signals, an assignment to certain oligomers is not possible. The $^{31}P\{^1H\}$-NMR spectrum recorded at −40°C shows two triplets at δ = −242.55 and −275.44 for the bridging and the terminal $(Me_3Si)_2P$ ligands with a $^2J(P,P)$ coupling constant of 17.9 Hz (Figure 2). In addition to this dimer another isomer with an intensity ratio for the bridging to terminal phosphanide ligands of 2:1 is observed and assigned to the trimer of the type $\{(Me_3Si)_2P-Mg[\mu\text{-}P(SiMe_3)_2]_2\}_2Mg$. This trimer can be crystallized from toluene at −30°C, and its structure is discussed below. Raising of the temperature (Figure 2) leads to an increasing concentration of the dimer at the expense of the trimer. At −40°C the amount of the trimer is 2.5 times higher than the one of the dimer, whereas at 0°C the dimer is 1.1 times more concentrated in solution. The equilibrium is shown in eq. (4), however, at room temperature and higher temperatures coalescence is observed, and the different oligomers are indistinguishable by $^{31}P\{^1H\}$-NMR spectroscopy.

Figure 2. Temperature-dependent $^{31}P\{^1H\}$-NMR spectra of a 0.5 M [D_8]toluene solution of magnesium bis[bis(trimethylsilyl)phosphanide] (**4**); all spectra are internally referenced to a small signal of $P(SiMe_3)_3$ at δ = −251.07 (161.835 MHz); at −40°C the dimeric and trimeric molecules coexist in toluene solution (see text)



Magnesium bis[bis(trimethylsilyl)phosphanide] is monomeric in the gaseous phase as could be shown by mass spectrometry. The found isotopic pattern of the M^+ peak confirms the assignment.

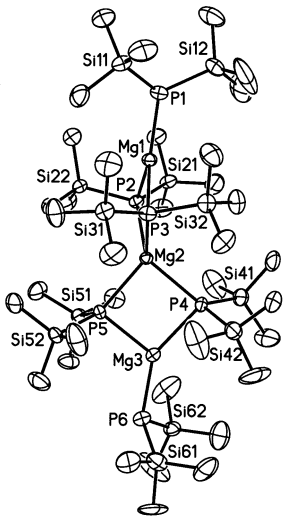


(4)

Molecular Structure of $(4)_3$

The molecular structure and numbering scheme of trimeric magnesium bis[bis(trimethylsilyl)phosphanide] [$(4)_3$] is shown in Figure 3. The coordination sphere around the magnesium atom Mg2 is a distorted tetrahedron, whereas Mg1 and Mg3 are surrounded by a trigonal planar coordination sphere. The four bridging phosphorus atoms are four-coordinate, and the angle sums of the terminal atoms P1 and P6 are 334.3° and 331.6°, respectively. Selected bond lengths and angles of $(4)_3$ are summarized in Table 2.

Figure 3. Molecular structure and the numbering scheme of trimeric magnesium bis[bis(trimethylsilyl)phosphanide] [$(4)_3$]; the ellipsoids represent a probability of 40%; the hydrogen atoms and the labelling of the carbon atoms are omitted for clarity



The influence of the coordination number is clearly seen. The terminal phosphanides show Mg−P bond lengths of approximately 245 pm, whereas the bridging phosphorus atoms show Mg−P distances to the triply coordinated magnesium atoms of 255 pm. A further increase of approximately 10 pm is observed for the bond lengths to the quadruply coordinated magnesium atom Mg2, however, the values lie in a wide range between 260 and 268 pm. The intramolecular strain due to the steric demand of the trimethylsilyl groups leads to a bending of the phosphanide

ligands towards the triply coordinated magnesium atoms Mg1 and Mg3. The bis(tetrahydrofuran)[8] as well as 1,2-dimethoxyethane complexes[11] show Mg−P bond lengths of approximately 250 pm between a triply coordinated phosphorus atom and a fourfold coordinated magnesium center.

The steric strain destabilizes the polymeric structures which presumingly lead to the precipitation of the magnesium bis[bis(trimethylsilyl)phosphanide] right after the metalation reaction. The polymeric structure breaks apart into trimers, which can then be crystallized. Due to longer M−P bonds for the heavier alkaline earth metals and consequently reduced intramolecular steric strain, solvent-free and soluble derivatives of oligomeric bis[bis(trimethylsilyl)phosphanides] are unknown thus far.

Conclusion

Solvent-free magnesium bis[bis(diisopropylsilyl)phosphanide] is soluble in common organic solvents such as toluene or benzene and dimeric in solution. In contrast to this derivative magnesium bis[bis(trimethylsilyl)phosphanide] shows monomeric molecules besides dimers by molecular-mass determination in benzene and a dimer-trimer equilibrium at −40°C in toluene in the $^{31}P\{^1H\}$-NMR spectrum at a 40 times more concentrated solution. Crystallization at −30°C from toluene solution yields single crystals of $\{(Me_3Si)_2P-Mg[\mu\text{-}P(SiMe_3)_2]_2\}_2Mg$. The Mg−P bond lengths vary between 245 and 268 pm depending on the coordination numbers of the metal and phosphorus atoms. In the gaseous phase monomeric magnesium bis[bis(trimethylsilyl)phosphanide] is observed.

This research was supported by the *Deutsche Forschungsgemeinschaft*, Bonn, and the *Fonds der Chemischen Industrie*, Frankfurt/Main. We also thank Prof. Dr. *J. Weidlein* of the University of Stuttgart for the recording of the Raman spectra.

Experimental Section

All experiments and manipulations were carried out under argon purified by passage through BTS catalyst and P_4O_{10}. Reactions were performed by using standard Schlenk techniques and dried, thoroughly deoxygenated solvents. The starting materials (1,2-dimethoxyethane-O,O′)lithium phosphanide[12] and bis(trimethylsilyl)phosphane[13] were prepared by literature procedures. − NMR spectra were recorded with Bruker spectrometers AM200, AC250, and AM400 or Jeol spectrometers GSX270 and EX400. − A Perkin-Elmer Paragon 1000 PC spectrophotometer was used to record the IR spectra; solid substances were measured in Nujol between CsBr windows (vs very strong, s strong, m medium, w weak, vw very weak, sh shoulder). The frequencies in the region of the Nujol vibrations are not listed.

Bis(diisopropylsilyl)phosphane (**1**) *and Tris(diisopropylsilyl)phosphane* (**2**): 5.0 g of $ClSi(H)iPr_2$ (33 mmol) were slowly added at −20°C to a solution of 4.3 g of $(dme)LiPH_2$ (33.2 mmol) in 80 ml of 1,2-dimethoxyethane. After complete addition, the reaction mixture was stirred for additional 2 h at room temperature. All volatile materials were removed in vacuum at room temperature and a subsequent vacuum distillation gave 2.5 g of $HP[Si(H)iPr_2]_2$ (**1**) (9.5 mmol, 57%) at 73°C/0.02 Torr. The residue was dissolved in 10 ml of *n*-pentane. Cooling to −60°C led to the crystallization of 1.3 g of $P[Si(H)iPr_2]_3$ (**2**) (3.5 mmol, 31%). At −60°C the mother liquor was decanted and the crystals which show a melting point of approximately −10°C were dried in vacuum. The NMR data of both compounds are summarized in Table 1.

Physical Data of **1**: IR (CsBr): $\tilde{\nu}$ = 2940 cm^{-1} vs, 2887 s, 2862 vs, 2722 vw, 2287 m (νPH), 2103 vs (νSiH), 1469 s, 1391 m, 1373 m, 1241 w, 1164 w, 1078 m, 1012 s, 922 m, 885 s, 783 vs, 764 vs, 706 w, 648 m, 612 m, 588 w, 563 vw, 482 m, 458 m, 409 w, 351 vw. − Raman: $\tilde{\nu}$ = 2941 cm^{-1} sh, 2919 s, 2889 s, 2863 vs, 2758 vw, 2716 vw, 2327 m, 2106 s, 1465 m, 1446 m, 1386 w, 1366 vw, 1290 w, 1234 s, 1160 w, 1076 m, 971 m, 920 vw, 882 s, 783 m, 761 w, 645 m, 618 s, 590 s, 565 m, 484 vs, 460 s, 408 m, 391 s, 361 w, 270 vs, 153 s. − MS (20 eV, source 490 K, sample 295 K); *m/z* (%): 262 (62.6) [M$^+$], 246 (19.8), 220 (60.0), 203 (100), 178 (16.5), 115 (12.7). − $C_{12}H_{31}PSi_2$ (262.52): calcd. Physical Data of **2**: IR (CsBr): $\tilde{\nu}$ = 2951 cm^{-1} vs, 2887 s, 2862 vs, 2098 vs (νSiH), 1469 s, 1390 m, 1373 m, 1241 w, 1163 vw, 1080 m, 1010 s, 972 vw, 922 m, 880 s, 795 sh, 760 vs, 649 m, 610 m, 592 w, 562 vw, 512 m, 361 vw. − MS (70 eV, source 470 K, sample 320 K); *m/z* (%): 376 (71.0) [M$^+$], 334 (48.3), 292 (55.9), 262 (7.6), 250 (36.3), 249 (37.9), 219 (13.2), 207 (18.8), 203 (17.6), 177 (19.8), 147 (9.6), 135 (21.2), 133 (23.8), 115 (10.2), 105 (15.3), 87 (20.0), 73 (44.3), 59 (100). − $C_{18}H_{45}PSi_3$ (376.78): calcd. C 57.38, H 12.04; found C 55.46, H 11.76.

Magnesium Bis[bis(diisopropylsilyl)phosphanide] (**3**): 1 ml of a 1.0 M solution of *n*/*sec*-dibutylmagnesium in heptane was added

dropwise slowly at 0°C to a solution of 530 mg of bis(diisopropylsilyl)phosphane (2.0 mmol) in 5 ml of toluene. After stirring for 5 additional hours at room temperature, all volatile materials were removed at reduced pressure at room temperature. Residues of toluene were removed at 60°C/10^{-2} mbar. A colorless pyrophoric oil remains, crystallization efforts from various solvents at −20°C and −60°C failed. The elemental analysis showed a low magnesium content and on the other hand high carbon and hydrogen values due to the grease still present in the sample. NMR data are listed in Table 1. − IR (CsBr): $\tilde{\nu}$ = 2940 cm^{-1} vs, 2886 sh, 2865 vs, 2755 vw, 2719 vw, 2101 vs (νSiH), 1462 vs, 1383 m, 1364 m, 1289 w, 1235 m, 1159 vw, 1069 s, 1006 vs, 969 w, 919 m, 879 s, 792 sh, 763 vs, 700 vw, 644 m, 611 s, 590 s, 566 w, 512 s, 483 sh, 410 w.

Magnesium Bis[bis(trimethylsilyl)phosphanide] (**4**): 1.75 ml of bis(trimethylsilyl)phosphane (8.03 mmol) was dissolved in 60 ml of toluene and 4.0 ml of a 1 M heptane solution of *n*/*sec*-dibutylmagnesium was added at room temperature. The precipitation of a colorless solid was observed immediately after complete addition, which dissolved within the next 12 h at room temperature. Reduction of the solution to 20 ml and storage at −30°C yielded 0.43 g of crystalline trimeric **(4)**$_3$ (0.38 mmol, 29%), m.p. 191°C. − NMR ([D_8]toluene, 0.5 mol/l, 25°C); ^{1}H: δ = 0.52 and 0.47 (broad, overlapping signals); ^{13}C{^{1}H}: δ = 5.65, 6.82, and 7.08 (broad overlapping signals); ^{29}Si{^{1}H}: δ = 3.74; ^{31}P{^{1}H}: see text above and Figure 2. − IR (Nujol, CsBr): $\tilde{\nu}$ = 1313 cm^{-1} vw, 1247 vs, 1073 vw, 1028 vw, 855 sh, 829 vs, 749 s, 683 s, 628 vs, 473 s, 460 s, 447 s, 419 s, 370 m, 314 m, 282 w. − MS (70 eV); *m*/*z* (%): 378 (17.0) [M^+], 305 (8.0) [$M^+ - SiMe_3$], 250 (35.1) [$PSi_3Me_9^+$], 178 (53.4) [$HPSi_2Me_6^+$], 163 (40.3) [$HPSi_2Me_5^+$], 147 (100) [$PSi_2Me_4^+$], 73 (89.5) [$SiMe_3^+$]. − $C_{12}H_{36}MgP_2Si_4$ (379.02): calcd. C 38.02, H 9.57; found C 36.93, H 9.22. − Molecular mass: calcd. for monomer: 379; found 516 (by freezing-point depression in benzene, 0.012 mol/l).

X-ray Crystallographic Study of **(4)**$_3$:[14] A suitable single crystal of **(4)**$_3$ was covered with nujol, sealed in a thin-walled capillary and mounted on a four-circle diffractometer Siemens P4 (graphite-monochromated Mo-K_α radiation and SMART area detector). Crystallographic parameters and details of data collection performed at −80°C are summarized in Table 3. No absorption or extinction corrections were applied. The structure was solved by direct methods with the software package SHELXTL Plus[17] and refined with the program SHELXL-93.[16] Neutral atom scattering factors were taken from Cromer and Mann[18] and for the hydrogen atoms from Stewart et al.[19] The non-hydrogen atoms were refined anisotropically whereas the hydrogen atoms were calculated in ideal positions. One of the trimethylsilyl groups shows a two-site disorder (C612, C613/C614, C615) with an occupation ratio of 0.59(3)/0.41(3).

The "Coloring Problem" in Solids: How It Affects Structure, Composition and Properties

Gordon J. Miller

Department of Chemistry, Iowa State University
Ames, IA 50011-3111, USA
E-mail: gmiller@iastate.edu

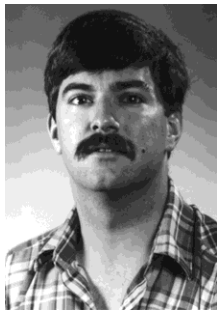
Received October 14, 1997

Keywords: Quantum chemistry / Intermetallic compounds / Transition metal cluster compounds / Crystallography / Electronic structure

The "coloring problem," as applied to the field of solid state chemistry, addresses the issues of structural preference as well as the distribution of different elements within a given structure. Both the connectivity and arrangement of elements in a solid affect physical and chemical properties, so a clear understanding of the forces controlling how elements will arrange themselves in a solid state structure creates the ability to predict structure-composition-property relationships. There are two fundamental energetic contributions that influence how elements in a structure order: the site energy and the bond energy. This review examines how these two parts of the total electronic energy work together to influence the observed structures, compositions, and properties of intermetallics and transition metal cluster compounds.

The study of chemical compounds fundamentally involves elucidation of the relationships among composition, structure, and properties. From a historical perspective, there are two types of compounds: Daltonides and Berthollides. All molecular and many solid state compounds follow the law of definite proportions, which demands integral ratios for their compositions. Berthollides, on the other hand, are nonstoichiometric compounds, and occur only in condensed matter (solids and liquids).[1] Although there are no general rules governing stoichiometry, simple electron counting rules like the octet rule, the 18-electron rule, and Wade's rules provide guidance for stable compositions.[2] Electronic structure theory gives theoretical justification for these simple rules, but application of these quantum mechanical models requires a knowledge of structure, both actual and hypothetical. An additional bonus from the results of electronic structure calculations is the possibility, in principle, of extracting information on physical and chemical properties. Of course, the quantitative accuracy of these predictions depends on the level of approximation used in the quantum mechanical calculations. Such theoretical studies combined with an experimental program involving synthesis, careful structural characterization, and measurements of physical properties allow a thorough examination of the fundamental relationships among composition, structure, and properties. Certain extended solids, in particular intermetallics and transition metal cluster compounds, provide superb examples for systematic investigations of these relationships.

Structure-property relationships can already be witnessed with the main-group elements,[3] and are strongly coupled to valence electron concentration (*vec*), which equals the number of valence *s* and *p* electrons per main-group atom (for the transition elements, valence *s*, *p*, and *d* electrons are



Gordon J. Miller was born in Utica, New York, USA. He received a B.S. degree in chemistry from the University of Rochester in 1982, and a Ph.D. in chemistry, under the supervision of Professor Jeremy K. Burdett, from the University of Chicago in 1986. He then began a postdoctoral research position in the group of Professor Arndt Simon at the Max-Planck-Institut für Festkörperforschung in 1987. In 1990, he joined the chemistry faculty at Iowa State University, where he is currently an Associate Professor. In 1995, he was awarded the Exxon Faculty Fellowship in Solid State Chemistry. His research group is studying structure-property relationships in extended solids, low temperature routes to new inorganic materials, and electronic structure theory of solids.

MICROREVIEWS: This feature introduces the readers to the authors' research through a concise overview of the selected topic. Reference to important work from others in the field is included.

needed; for lanthanides and certainly the actinides, valence *f* electrons must be included as well). For main-group elements with *vec* less than four, closed packed (ccp, hcp or bcc) metallic structures form.[4] If *vec* is greater than or equal to four, open network, nonmetallic structures occur.[4] The inert electron-pair effect in sixth-period elements, e.g., Tl, Pb, Bi, and Po, creates exceptions to these trends.[5] A theoretical technique called second moment scaling of the electronic energy density of states provides a rationale for the observed structural trends of the elements.[6] Complete electronic structure calculations are required, however, to assess observed properties. For example, the observed decrease in electrical conductivity as pressure increases for elemental Ca, Sr, and Ba has been explained by the results of detailed band structure calculations.[7]

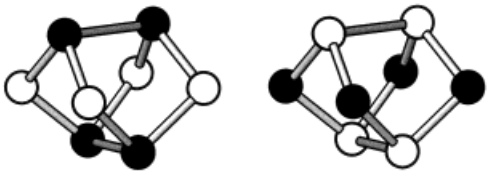
As composition becomes a variable, potential structural complexity increases dramatically with respect to both the network of interatomic connections as well as the exact arrangement of the different atoms throughout the structure. The second aspect is also called the *site preference* problem, which is a specific application of the more general *coloring* problem.[*] How atoms are distributed within a network can influence not only to what extent different atoms occur in a compound, i.e., stoichiometry, but also the nature of the electronic structure, i.e., physical and chemical properties. Moreover, there is a synergism between composition and geometrical structure which are blended via the electronic structure that leads to further chemical diversity. Intermetallic and transition metal cluster compounds are well suited for examining these fundamental problems of extended solids: subtle changes can be made in their compound compositions which allow detailed investigation of site preference. The Hume-Rothery intermetallic phases[9] provide exceptional examples for studying both structural complexities mentioned at the beginning of this paragraph: not only does structure change with *vec*, but the distribution of atoms among the different crystallographic sites in a given Hume-Rothery phase is closely related to its structure. Therefore, for multicomponent systems adopting extended structures the following questions arise: (1) for a given composition, what controls the observed structure; (2) in a given structure, how do the different chemical elements arrange themselves; (3) how does this arrangement of atoms influence the observed physical and chemical properties of a given compound; and (4) what is the fundamental relationship among structure, property, and composition for a particular chemical system?

Background

The coloring problem, better known as the "four-color problem" in mathematics, was one of the best known, unsolved mathematical challenges until it was solved in 1976.[10] It defied solution for over one hundred years (since 1852), while attracting the attention of nearly every mathematician in the late nineteenth and throughout the twentieth century. The original basic problem is "to find the smallest number of colors necessary to color the countries of any map so that each two countries with a common border have different colors."[**] This problem belongs to the discipline of *graph theory.*[12] A *graph* is a collection of points, called *vertices*, with various pairs of points joined by a collection of arcs, called *edges.* A vertex has *valence m* if exactly *m* edges meet at that vertex. A *map* is a graph in which each vertex has valence at least three, and with edges that form simple closed curves, called *faces.* The application of this problem to chemistry is clear: the structures of chemical compounds are often represented by graphs in which atoms occupy *vertices*, and bonds often correspond to *edges* in the graph. The chemist wonders, which coloring has the lowest energy? In these chemical examples, however, "coloring" occurs at the vertices, and not at the faces.[***] the idea of reciprocity is important for justifying the equivalence of these two mathematical problems.[10]

The coloring problem occurs in some classic molecular examples: the simplest case being linear triatomic molecules. Both CO_2 and N_2O are linear molecules, but only CO_2 has inversion symmetry. The explanation for the arrangements OCO or NNO and not OOC or NON is simply that 16-electron triatomic molecules require the more electronegative component to occupy the terminal position, i.e., the site with lower coordination number.[14] This effect also occurs in the cage structures of S_4N_4 and As_4S_4,[15] (see Figure 1) which adopt identical molecular topologies: one site is two-bonded (N in S_4N_4; S in As_4S_4), the other is three-bonded (S in S_4N_4; As in As_4S_4). Since the Pauling electronegativities for these three elements increase from As to S to N, the arrangement of atoms in these molecules has the more electronegative element at the two-bonded position.

Figure 1. Molecular structures of As_4S_4 (left) and S_4N_4 (right); white circles are S atoms, black circles are As or N atoms



As_4S_4 S_4N_4

Molecular orbital theory can substantiate this conclusion through the principle of *topological charge stabilization.*[16] When a Mulliken population analysis[17] is applied to the

[*] A succinct statement of the coloring problem in chemical systems is, "Given a molecular or extended network and several different types of atoms or chemical groups, what is the best way to distribute them in the network for a fixed stoichiometry?"[8]

[**] The German mathematician Möbius is credited with its origination in the form of a puzzle to his students.[11]

[***] In terms of graph theory, another statement of the coloring problem is, "Consider a fixed molecule or solid state framework which is then populated with different sorts of atoms or atom groupings. Such a mapping of vertices to atoms is called a coloring, and the different atoms or units are associated with different colors."[13]

results of a molecular orbital calculation on a *homonuclear* molecular structure, differences in atomic populations, i.e., the number of valence electrons assigned to an atomic site in the molecule, usually occur. For an isostructural *heteronuclear* molecule, the most electronegative element will occupy the site with the largest Mulliken population. The simple Hückel theory can verify this conclusion. Consider a molecule composed of atoms, which are each described by a set of valence atomic orbitals $\{\chi_i\}$ with atomic orbital energies α_i ($\alpha_i < 0$). The strengths of the atomic orbital interactions in the molecule are prescribed by a set of resonance integrals β_{ij} ($\beta_{ij} < 0$). In the LCAO approximation, a molecular orbital is expressed as

$$\psi_n = \Sigma_i \, c_{ni} \, \chi_i \tag{1}$$

where c_{ni} is the numerical coefficient of the i^{th} atomic orbital in the n^{th} molecular orbital and the summation covers all valence atomic orbitals $\{\chi_i\}$ in the molecule. The energy of this molecular orbital can then be written as

$$E_n = \Sigma_i \, c_{ni}^2 \alpha_i + \Sigma_i \, \Sigma_{j \neq i} \, c_{ni} c_{ij} \beta_{ij} \tag{2}$$

The total valence electron energy, E_{mo}, is the sum of the molecular orbital energies E_n times their corresponding occupation numbers ($z_n = 0$, 1, or 2), which gives the result[18]

$$\begin{aligned} E_{\text{mo}} &= \Sigma_n \, z_n \, E_n = \Sigma_n \, z_n \, (\Sigma_i \, c_{ni}^2 \, \alpha_i + \Sigma_i \, \Sigma_{j \neq i} \, c_{ni} \, c_{nj} \, \beta_{ij}) \\ &= \Sigma_i \, (\Sigma_n \, z_n \, c_{ni}^2 \,) \, \alpha_i + \Sigma_i \, \Sigma_{j \neq i} \, (\Sigma_n \, z_n \, c_{ni} \, c_{nj}) \, \beta_{ij} \\ E_{\text{mo}} &= \Sigma_i \, q_i \, \alpha_i + \Sigma_i \, \Sigma_{j \neq i} \, p_{ij} \, \beta_{ij} \end{aligned} \tag{3}$$

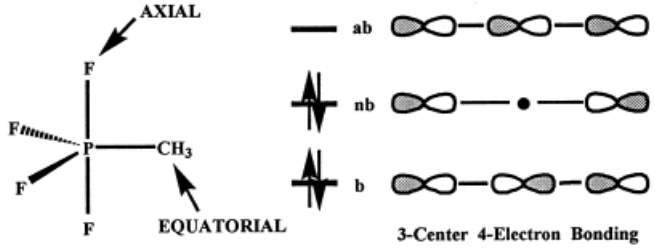
where q_i is the atomic orbital population (Mulliken population in Hückel theory) and p_{ij} is the overlap population[17] (Coulson bond order index[19]) which are defined by the equations

$$q_i = \Sigma_n \, z_n \, c_{ni}^2 \tag{4}$$

$$p_{ij} = \Sigma_n \, z_n \, c_{ni} \, c_{nj} \tag{5}$$

The principle of topological charge stabilization uses just the first term of equation (3), i.e., the most stable coloring of a heteronuclear molecule is the one for which the most electronegative element, i.e., the one with the lowest α_i's, occupies the site with the greatest Mulliken population, q_i, in the *homonuclear* model of the molecule.

Figure 2. Simple representation of three-center four-electron bonding; in the trigonal bipyramidal molecule PF_4CH_3, the methyl group occupies the equatorial position; the linear F−P−F fragment along the axial direction involves three-center four-electron bonding, whose simple molecular orbital picture is shown; the nonbonding orbital has a node at the P atom, which results in the axial sites being generally preferred by the most electronegative ligands



Additional examples of the application of this principle include five-coordinate main group molecules (see Figure 2), which adopt either trigonal bipyramidal or square pyramidal structures.[20] Both arrangements have two inequivalent sets of ligands, labeled axial and equatorial, which immediately lead to a site preference problem. In ten-electron trigonal bipyramidal molecules, e.g., PCl_3F_2 and $PF_4(CH_3)$,[2] the more electronegative F atoms prefer the axial sites, although these molecules undergo rapid pseudorotation. In each case, the more electronegative ligand is involved in three-center four-electron bonding along three collinear atoms.[21] The four electrons in this simple model occupy one bonding and one nonbonding molecular orbital (see Figure 2). The bonding orbital is delocalized throughout the three atomic orbitals, while the nonbonding molecular orbital has only ligand character, which provides the electronic driving force for the observed substitution pattern. Ligands in the equatorial sites of these molecules are involved in two-center two-electron bonding with the central atom. On the other hand, twelve-electron square pyramidal molecules like $XeOF_4$ have the more electronegative ligands (F atoms in $XeOF_4$) in the equatorial sites, which involve two three-center four-electron interactions.

When nonorthogonal atomic orbital basis sets are used in electronic structure calculations, as in the extended Hückel theory,[22] the expression for the total valence electron energy E_{mo} becomes slightly modified from equation (3). The overlap integrals S_{ij} are now explicitly included during calculation of the electronic energy levels, and expressions for the Mulliken population and overlap population become

$$q_i = \Sigma_n \, z_n \, (\, c_{ni}^2 + c_{ni} \, c_{nj} \, S_{ij}) \tag{6}$$

$$p_{ij} = \Sigma_n \, 2 \, z_n \, c_{ni} \, c_{nj} \, S_{ij} \tag{7}$$

Then, after some simple algebraic manipulations of the molecular orbital energy values, the total valence electron energy is

$$E_{\text{mo}} = \Sigma_i \, q_i \, \alpha_i + \Sigma_i \, \Sigma_{j \neq i} \, p_{ij} \, (\beta_{ij} - S_{ij} \, \alpha_i) \tag{8}$$

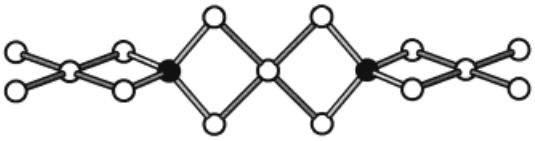
The first term in expressions (3) or (8) can be interpreted as the energy contribution from the valence electron configurations of the different atoms or ions in the structure, which is the *site energy*. The value of this term is sensitive to the degree of charge transfer between atoms as well as the coordination geometry at each site. The second term is a net two-center interaction term, the *bond energy*, and will be minimized when only bonding and nonbonding orbitals are occupied by providing maximum overlap populations p_{ij}.

This type of transformation of the total valence electron energy does not require a knowledge of the eigenstates of the system, i.e., $\{\psi_n\}$, provided another method can calculate the population terms, q_i and p_{ij}.[23] These chemical quantities are the matrix elements of the density matrix,[*]

[*] The density matrix elements are expansion coefficients of the total charge density in the atomic orbital basis set. Diagonal elements are the charge densities to associate with each orbital in the system; off-diagonal elements are bond orders between two different atomic orbitals on different atoms.

which can be determined without knowing the eigenstates by using, for example, the recursion method.[24] Furthermore, expressions (3) and (8) are general for all types of chemical systems: molecules, crystalline solids, amorphous solids, liquids, quasicrystalline solids, and defective crystalline materials. For solids, E_{band} replaces the symbol E_{mo} to describe the total valence electron energy from the occupation of energy bands rather than molecular orbitals. In subsequent discussions, we shall call this energy the total orbital energy, E_{orb}. This transformation of the total energy introduces a much more chemical approach to the analysis of electronic structure of solids. Furthermore, with respect to the "coloring" problem in chemical structures, the tight-binding expressions in equations (3) and (8) point to two contributions: atoms arrange themselves to provide the lowest site energy and to minimize the bond energy.

Figure 3. Structure of the quasi-infinite $^{1}_{\infty}[SnTe_5]^{2-}$ chain in K_2SnTe_5 and Tl_2SnTe_5;[25] white circles are Te atoms, black circles are Sn atoms



Consider one simple example of this problem: the quasi-infinite chain $^{\infty}_{1}[SbTe_5]^{2-}$ found in K_2SnTe_5 and Tl_2SnTe_5 (see Figure 3).[25] As the figure shows, this chain consists of tetrahedrally coordinated Sn atoms alternating with square planar coordinated, albeit slightly distorted, Te atoms, which we can formulate as $^{\infty}_{1}[(SnTe_{4/2})(TeTe_{4/2})]^{2-}$. X-ray diffraction studies are unable to differentiate between Sn ($Z = 50$) and Te ($Z = 52$) for these two sites, but their distribution has been inferred from the known crystal chemistry of these two elements. An extended Hückel calculation performed on a homonuclear chain (using only Te atomic orbital parameters) indicates that the more electropositive element [Sn; lower q_i's in equation (8)] would occupy the tetrahedrally coordinated site, and the more electronegative element [Te; higher q_i's in equation (8)] would occupy the site with square planar coordination. A direct comparison of the two different patterns shows the observed combination to be energetically preferred over the alternative by approximately 10.0 eV per formula unit if only nearest neighbor (four Sn−Te and four Te−Te) interactions are considered. Of this 10.0 eV energy difference, 1.2 eV is attributed to the difference in site energies and 8.8 eV is the difference in bond energies. The dominance of the bond energy difference reflects tetrahedral vs. square planar coordination at the two different sites. When second nearest neighbor interactions are included (Sn···Te along the chain in the tight-binding calculation), this total energy difference increases to 14.4 eV, of which 12.1 eV is due now to a difference in site energies, and 2.3 eV to a difference in bond energies. The dramatic change in how the two components contribute to the total energy arises from a significant difference in the coordination environment: Sn is surrounded by 4 + 2 Te atoms, whereas Te is coordinated by four Te atoms and two Sn atoms. Regardless, the Sn occupies the tetrahedral sites and Te, the square planar sites.

In extended solids the site preference problem has already been well documented for the spinels, $A^{2+}B_2{}^{3+}O_4$.[26] In these oxides, one-half the octahedral holes and one-eighth the tetrahedral holes are occupied by metal ions in the cubic closest packed oxide framework. A *normal* spinel would be $A_{(tet)}{}^{2+}B_{(oct)2}{}^{3+}O_4$, as in $Co_3O_4 \equiv Co_{(tet)}{}^{2+}Co_{(oct)}2^{3+}O_4$, whereas an *inverse* spinel would be $B_{(tet)}{}^{3+}$-$(A_{(oct)}{}^{2+}B_{(oct)}{}^{3+})O_4$, as in $CoFe_2O_4 \equiv Fe_{(tet)}{}^{3+}$-$(Co_{(oct)}{}^{2+}Fe_{(oct)}{}^{3+})O_4$. The crystal field theory achieved success by comparing the energies of octahedral and tetrahedral fields for different d^n electronic configurations. Strong preference for octahedral coordination occurs for d^1-d^4 and d^6-d^9 ions, which has been used to rationalize the different ionic arrangements in spinels. Of course, ligand field theory can also be applied to these examples with identical results.[2]

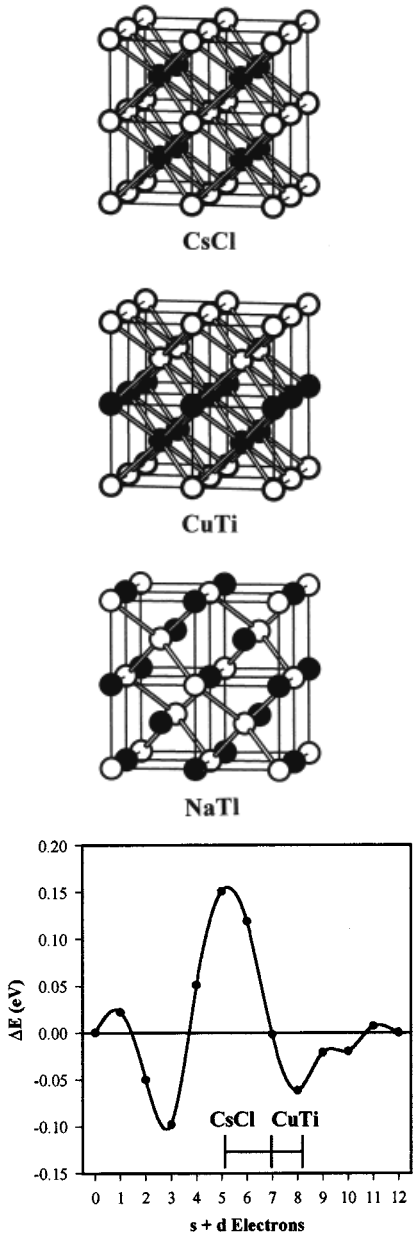
Perhaps a better example of the "coloring" problem is how to color the body-centered cubic (bcc) lattice with two different atoms at equal concentrations, i.e., AB. The cubic CsCl structure (Figure 4) is the alternant variant, with each A atom surrounded by eight nearest neighbor B atoms and six next nearest neighbor A atoms at a 15% larger distance. On the other hand, the CuTi structure (Figure 4) is a tetragonal modification of the bcc arrangement with alternating pairs of (001) planes of atoms. In CuTi, each A atom is coordinated by four A and four B nearest neighbors as well as four A and two B next nearest neighbors; each B atom is surrounded by four A and four B nearest neighbors and four B plus two A next nearest neighbors. In these two examples, the observed coloring depends on the *vec*, as also shown in Figure 4 for binary alloys of the transition metals.[27] Another possible coloring of this lattice is the NaTl structure (Figure 4),[28] which is limited to binary compounds of the pre- and post-transition elements. For the NaTl structure, there are four A and four B nearest neighbors plus six next nearest neighbor B atoms around each A atom. For this problem, semi-empirical calculations nicely reproduce the observed trend in structure.[27]

Therefore, with respect to these examples, the site preference problem is a specific corollary of the more general "coloring" problem. Extended solids offer the additional problem of disorder, which further complicates the problem. A general understanding (i.e., predictive algorithm) remains to be determined to elucidate solutions for the general case, but the following section examines a small number of examples from our research group to help build a body of data for the "coloring" problem in solids.

Applications

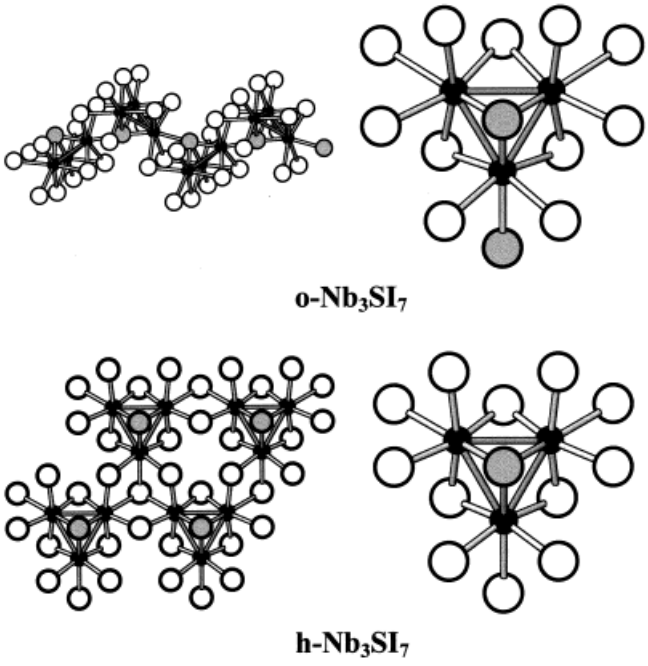
The remainder of this article focuses on specific examples of the "coloring problem" in extended solids from our group's research. The fundamental questions concern how structure, composition, and properties of extended solids are affected by the arrangement of different elements in a compound. Since intermetallic and transition metal cluster compounds are involved, these investigations reveal how

Figure 4. Structures of different AB colorings of the bcc lattice: (very top) CsCl structure; (center top) CuTi structure; (center bottom) NaTl structure; (very bottom) computed energy differences between the CsCl and CuTi arrangements vs. the average number of $s + d$ electrons; CsCl is the reference structure; the more stable structure has the lower value of ΔE for a given number of $s + d$ electrons; experimentally observed values are shown on the diagram



experiment and theory can work symbiotically to pursue some fundamental chemical questions. These applications are organized as follows: (1) kinetically vs. thermodynamically stable structures; (2) structural influences for a single composition but variable electron count; (3) site preferences and composition influenced by nearest neighbor interactions; (4) structure-composition relationships in intermetallics; and (5) composition-property effects.

Figure 5. Structures of the low and high temperature forms of Nb_3SI_7: (top) *o*-Nb_3SI_7; (bottom) *h*-Nb_3SI_7; black circles are Nb atoms, gray circles are S atoms, white circles are I atoms; figures on the left illustrate the two-dimensional layers of clusters, and those on the right show the local environments of the Nb_3 triangles; the point symmetry of the cluster in *o*-Nb_3SI_7 is C_s while in *h*-Nb_3SI_7 it is C_{3v}



1. Kinetic versus Thermodynamic Products: Nb_3SI_7

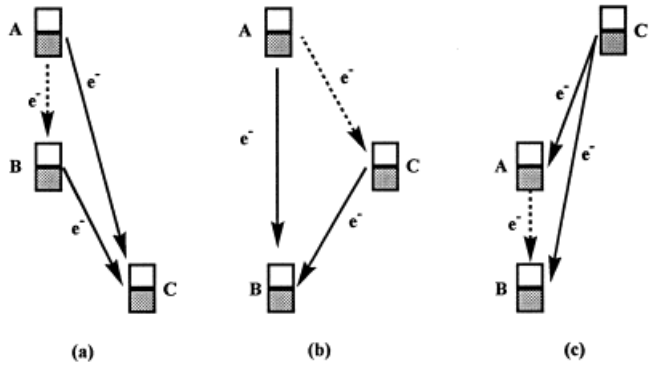
The formation of solid state compounds is certainly controlled by both thermodynamic and kinetic factors. With temperature and pressure as fundamental variables, the complete study of a particular system involves numerous synthetic attempts under different conditions. Recent investigations with ternary transition metal/chalcogen/halogen systems containing metal clusters have uncovered a diverse collection of new layered compounds with various structures and properties.[29] One poignant example is Nb_3SI_7, which has been characterized in three topologically different layered structures (polymorphs, not polytypes!) depending upon the temperatures chosen for synthesis. All three structures, however, contain triangular Nb_3 clusters with capping sulfur atoms. Their differences arise in how these units are linked together. The coloring problem in this system addresses how sulfur and iodine form the anion matrix that contains the Nb_3 clusters.

At temperatures between ca. 300 °C and 650 °C, elemental niobium, sulfur, and iodine react in the molar ratio 3.0:1.0:3.5 to give a crystalline orthorhombic phase, *o*-Nb_3SI_7, whose structural formula is $Nb_3S_{1/2}{}^{i-a}I_3{}^{i}I_{6/2}{}^{a-a}$-$(I_{2/2}{}^{a-a}S_{1/2}{}^{a-i})$.[*] As seen in Figure 5, the Nb_3 triangle is capped by a single sulfur atom (S^i), and each edge is

[*] The notation for transition metal clusters differentiates between ligands bridging edges or faces of a cluster, i.e., X^i (i = *innen* = inner) and those connecting or terminating clusters, X^a (a = *aussen* = outer).[30]

bridged by an iodine atom (I^i). These $[Nb_3(\mu_3\text{-}S)(\mu_2\text{-}I)_3$ units are then connected together by six iodine atoms (I^{a-a}) linking two clusters and three ligands *trans* to the capping sulfur atom (two are I^{a-a} and one is S^{a-i}) linking three clusters. There is just one crystallographic type of sulfur atom in *o*-Nb_3SI_7: it caps an Nb_3 triangle, but it also bonds to an adjacent cluster (thus the S^{i-a} and S^{a-i} designations in the structural formula). In *o*-Nb_3SI_7 sulfur is 3+1 coordinated to Nb in a *cis*-divacant octahedral geometry. This local coordination structure at one of the anions gives rise to the undulating layered structure of *o*-Nb_3SI_7.

Figure 6. Schematic diagrams of the relationships in atomic orbital energies for three different elemental components of ternary compounds; the higher the electronegativity of an element, $\chi(X)$, the lower its valence orbital energies; for these schemes, $\chi(A) < \chi(B)$, so $E(A)'s > E(B)'s$; the interesting chemistry arises by considering how A and B relate to the third component C; (a) $\chi(A) < \chi(B) < \chi(C)$, (b) $\chi(A) < \chi(C) < \chi(B)$, (c) $\chi(C) < \chi(A) < \chi(B)$; electron transfer takes place until a constant electrochemical potential exists throughout the structure



Above ca. 650°C, these elements form a layered hexagonal structure, *h*-Nb_3SI_7,[29] (see Figure 4) whose layers are related to those found in β-Nb_3I_8.[31] The corresponding structural formula for this compound is $Nb_3S_1{}^iI_3{}^iI_{6/2}{}^{a-a}I_{3/3}{}^{a-a}$. Each sulfur atom is just three-coordinated to Nb, and the layers are flat. The structures of *o*-Nb_3SI_7 and *h*-Nb_3SI_7 can be compared by examining the two different packing arrangements of anions: *o*-Nb_3SI_7 involves cubic closest packed anions $(\cdots c\cdots)$[32] with each (111) plane containing 1/8 sulfur and 7/8 iodine, while *h*-Nb_3SI_7 contains an alternating mixture of cubic closest packed and hexagonally closest packed layers $(\cdots hc\cdots)$[32] with sulfur occurring in alternate close packed layers to an extent 1/4 sulfur and 3/4 iodine. In *o*-Nb_3SI_7 the stacking arrangement of one anion "(111)" sheet (i.e., "SI_7") with respect to its two neighboring layers maximizes the S···S internuclear separation, or minimizes the electrostatic repulsion between neighboring sulfide ions. In both close packed anion arrays, Nb atoms occupy 3/8 of the total number of octahedral holes and are located close to the sulfur atoms. A combination of lattice energy[33] and extended Hückel[22] calculations on various models indicates that Nb−Nb bonding is optimized in *h*-Nb_3SI_7, but that the Madelung energy is lower for *o*-Nb_3SI_7. Quenching and annealing experiments conducted at different temperatures show that *o*-Nb_3SI_7 transforms to *h*-Nb_3SI_7 irreversibly at temperatures above ca. 650°C.

Thus, the coloring of the anion network in Nb_3SI_7 strongly influences the resultant total structure of the extended solid involving transition metal clusters. Ionic and covalent forces compete for the formation of a given atomic arrangement. At low temperatures, long range electrostatic interactions guide the formation of the kinetically stable *o*-Nb_3SI_7 by maximizing the separation between sulfide ions. At higher temperatures, however, the atoms rearrange to give a structure with lower internal energy, *h*-Nb_3SI_7, which retains certain structural features, e.g., the Nb_3 triangular cluster.[*]

The ternary niobium/sulfur/iodine system offers a further application of the coloring problem that is only possible in extended solids-nonstoichiometry. $Nb_3S_{1-x}I_{7+x}$ can be prepared from the elements for $x \leq 1$.[29][35] X-ray and neutron diffraction studies on polycrystalline powders and single crystals show that these layered compounds have structures related to β-Nb_3I_8 for $x > 0.6$ and *h*-Nb_3SI_7 for $x < 0.4$. A two-phase mixture of these structures exists for $0.4 < x < 0.6$. Throughout the series, moreover, sulfur and iodine atoms randomly occupy the anion site capping the Nb_3 cluster. Neutron powder diffraction on the compounds β-Nb_3I_8, $Nb_3S_{0.34}I_{7.66}$, and $Nb_3S_{0.64}I_{7.36}$ between 15 K and 300 K did not exhibit any ordering phenomena, i.e., no superstructure reflections nor any symmetry-lowering phase transitions. Magnetic susceptibility measurements give one unpaired electron per μ_3-I capped Nb_3 cluster, except in β-Nb_3I_8. We can understand the lack of superstructure from the electronic structures of μ_3-S capped Nb_3 groups and μ_3-I capped Nb_3 groups in the iodide matrix. Electronic and matrix effects work against each other to produce disorder: the six-electron Nb_3 cluster in Nb_3SI_7 has weaker Nb−Nb bonding but a smaller capping anion (sulfide) than the seven-electron cluster in β-Nb_3I_8. Thus, Nb−Nb distances remain nearly unchanged throughout the series $Nb_3S_{1-x}I_{7+x}$ and the Fermi levels do not vary with the composition variable *x*.

2. Coloring and Structure in Ternary MM′X Intermetallics

Intermetallic compounds adopt structures that are dependent, in part, on the number of valence electrons per formula unit. An understanding of this relationship between structure and electron count requires knowledge of the electronic structures and a good estimation of the structural energy differences for different arrangements of atoms. *Second moment scaling*[6] techniques and the *structural energy difference theorem*[4] have contributed greatly to the recent success of electronic structure calculations for sorting numerous binary intermetallic compounds. The second moment μ_2 for a quasi-continuous distribution of electronic states $\rho(E)$ (as one finds in an extended solid) is defined by the integral

$$\mu_2 = \int_{-\infty}^{\infty} E^2\rho(E)\mathrm{d}E \qquad (9)$$

[*] A new modification, *m*-Nb_3SI_7, has been recently characterized at temperatures exceeding 1000°C, but was first identified in the compound $Nb_7S_2I_{19} = [Nb_3SI_7]_2(NbI_5)$.[34]

Within the tight-binding (LCAO) approximation, this integral expression can be rewritten into a summation

$$\mu_2 = \Sigma_{i=1}^{N} \alpha_i^2 + \Sigma_{i<j} \beta_{ij}^2 \quad (10)$$

N is the number of atomic orbitals in the unit cell, α_i is the atomic orbital energy for the i^{th} atomic orbital, and β_{ij} is the resonance integral between different atomic orbitals i and j. For identical compositions, the first term in equation (10) is the same for all structural models. Second moment scaling, therefore, demands that for all structure types to be compared the unit cell and atomic positional parameters be selected to create equal second terms, $\Sigma_{i<j}\beta_{ij}^2$, and therefore equal μ_2 values. The structural energy difference theorem states that the energy difference between two structures is given to first order by the difference in the bonding contributions to the total energy, i.e., ΔE_{bond}. The total binding energy for a structure is generally the sum of a repulsive term, E_{rep}, and the bonding contribution, E_{bond}. E_{bond} can result from a Madelung (E_{mad}), molecular orbital or band structure (E_{orb}) calculation, while the repulsive term is a combination of short-range electrostatic and Pauli repulsion contributions, which are specifically proportional to coordination numbers. Heine has demonstrated that the second moment μ_2 is proportional to the average coordination number in a given structure.[36] Therefore, performing second moment scaling on various structural models creates equal E_{rep} terms in the total binding energy, and validates the structural energy theorem.[4]

Once the electronic structure calculations are completed, equation (3) or (8) can be used to provide a rationale, in chemical terms, for the predicted sorting diagram: an element will tend to adopt a single type of site that minimizes its site energy and bond energies. For a study of structural changes with valence electron concentration, the site energy changes rapidly with electron count due to the quadratic dependence of atomic orbital energies on charge. The relative electronegativities (χ) of the components in ternary A_x-B_yC systems give rise to three scenarios: (1) $\chi(C) > \chi(B) > \chi(A)$, (2) $\chi(B) > \chi(C) > \chi(A)$, and (3) $\chi(B) > \chi(A) > \chi(C)$. Figure 6 illustrates how electron transfer will take place as these elements form chemical bonds (the greater electronegativity implies lower atomic orbital energies). The sites ultimately selected by elements A and B in the C matrix will follow the ramifications of equation (8): lowest *site* and *bond* energies, which are governed by the extent of electron transfer and orbital overlap. In this first example, we highlight the subtle interplay between site potential and near neighbor interactions at controlling structure in metal-rich phosphides.

The recent synthesis and crystal structure determination of ZrNbP provide two unusual features:[37] (1) ZrNbP crystallizes in the Co_2Si structure type (oP12[*]), whereas Zr_2P (oC108) and Nb_2P (oP54) form other, quite complex structures; and (2) Zr and Nb are completely separated onto different crystallographic sites with no evidence for mixed site occupations nor of any variable composition, $Zr_{1\pm x}Nb_{1\mp x}P$. The miscibility of Zr and Nb is certainly manifested in their binary phase diagram, but does not seem to extend to this ternary compound. Furthermore, ZrNbP differs from ternary (Nb, Ta) sulfides,[38] in which there is only a partial segregation of Nb and Ta atoms onto inequivalent crystallographic sites. But ZrNbP is nonetheless similar to these ternary sulfides because they exist only for specific Ta:Nb ratios. Semi-empirical electronic structure calculations[39] were performed in our group in order to address the following questions: (1) what accounts for the complete segregation of Zr and Nb atoms in ZrNbP?, and (2) what controls the observed structure of ZrNbP with respect to viable alternative structures for the ternary MM′P phosphide system? As it turns out, both questions have the same answer, which relates to the nature of metal−metal bonding in this system. Moreover, the theoretical analysis predicted the structure for the new compound ZrMoP, which was subsequently confirmed by experiment. Therefore, the structure and existence of a new intermetallic compound could be predicted using crystal chemical principles and electronic structure calculations.

Figure 7. (Top) structure of ZrNbP and (bottom) structure of ZrMoP; black circles are Nb or Mo atoms, gray circles are Zr atoms, and white circles are P atoms; figures on the left illustrate metal−phosphorus contacts, figures on the right show metal−metal contacts

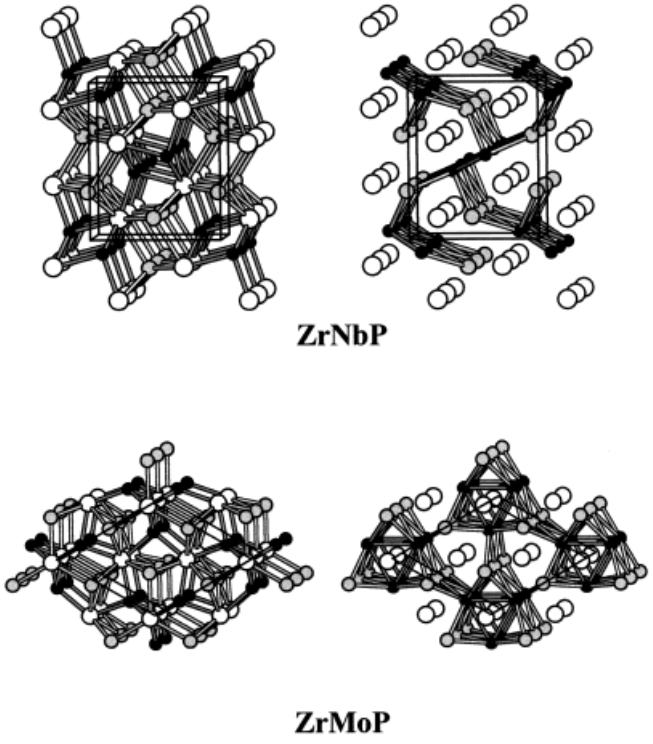


Figure 7 illustrates two projections of ZrNbP along the crystallographic b axis, one of which emphasizes the close metal−phosphorus contacts (d < 3.05 Å) while the other

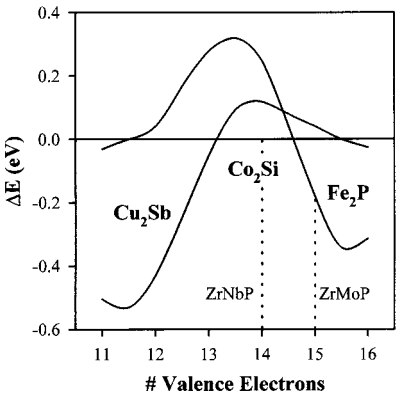
[*] The Pearson symbol[32] describes for a given structure its Laue symmetry, lattice class, and number of atoms in the unit cell. oP12 means primitive orthorhombic with 12 atoms in the unit cell.

shows the metal−metal distances shorter than 3.30 Å. In ZrNbP, Nb is tetrahedrally coordinated and Zr is square pyramidally coordinated by P atoms. With respect to these coordination environments, there are two alternative structures common to many ABC intermetallics: (1) the Fe_2P-type and (2) the Cu_2Sb-type.[32][40] The Fe_2P structure type is also illustrated in Figure 7 to point out both the metal−phosphorus and metal−metal connectivities. In order to compare the total energies of the three structure types at valence electron counts around fourteen per formula unit, second moment scaling and the structural energy theorem were applied. Figure 8 illustrates these results as energy difference curves. Not only do these calculations reflect the stability of the observed structure for ZrNbP, but they also predict the structure of ZrMoP, if it exists, to be the Fe_2P-type. Direct synthesis and single crystal structural characterization of $Hf_{1.06}Mo_{0.94}P$ confirmed this prediction, and revealed the complete segregation of Hf and Mo, respectively, onto the square pyramidal and tetrahedral sites.[39] ZrMoP was also synthesized and characterized by X-ray powder diffraction.[39]

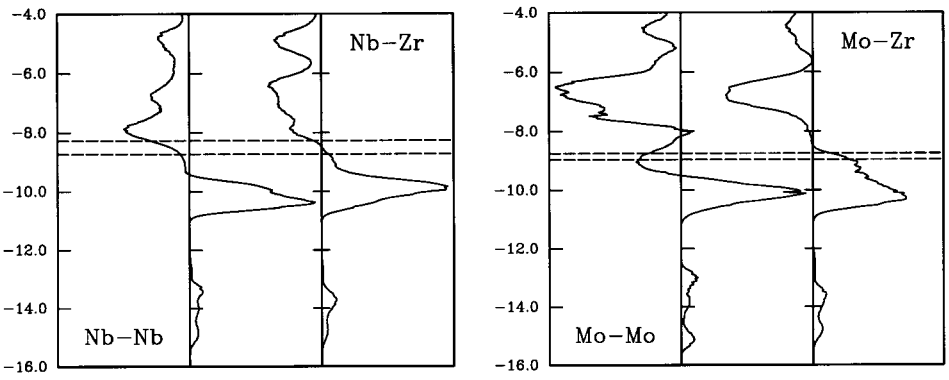
Figure 8. Energy difference curves vs. valence electron count for the Co_2Si-, Fe_2P-, and Cu_2Sb-structure types as possible models for the structure of ZrNbP; the energy of the Co_2Si-structure type is the reference energy ($\Delta E = 0$); the lowest ΔE curve for a given electron count represents the most stable structure among the three models; the electron counts for ZrNbP and ZrMoP are marked



Why does the complete segregation of Zr and Nb in ZrNbP and of Hf and Mo in $Hf_{1.06}Mo_{0.94}P$ occur? The same electronic structure calculations[39] show that the observed, completely segregated sets of metal atoms give the lowest total valence electron energies over all other possible arrangements of metal atoms in ZrNbP and ZrMoP. From equation (8), this segregation provides the lowest site energies for these elements. In addition, analysis of the overlap populations[39][41] for the two shortest metal−metal contacts in each structure reveals that the *heteronuclear* Zr−Nb and Zr−Mo interactions are optimized, i.e., bonding and nonbonding orbitals are filled; antibonding orbitals are empty. At the corresponding Fermi levels, the homonuclear Nb−Nb interactions in ZrNbP are nonbonding whereas the Mo−Mo contacts in ZrMoP show significant antibonding overlap (see Figure 9). These theoretical results are well reflected in the observed bond lengths: the shortest heteronuclear metal−metal distances reflect the differences in atomic radii [d_{min} (Zr−Nb) = 3.014 Å in ZrNbP vs. d_{min} (Hf−Mo) = 2.915 Å in HfMoP], whereas the shortest homonuclear metal−metal distances demonstrate the nature of occupied electronic levels near the Fermi level [d_{min} (Nb−Nb) = 2.816 Å in ZrNbP vs. d_{min} (Mo−Mo) = 3.015 Å in HfMoP]. Thus, total segregation of Zr and Nb in ZrNbP or Hf and Mo in $Hf_{1.06}Mo_{0.94}P$ relies not only on the site energies in each structure, but also on the heteronuclear metal−metal interactions.

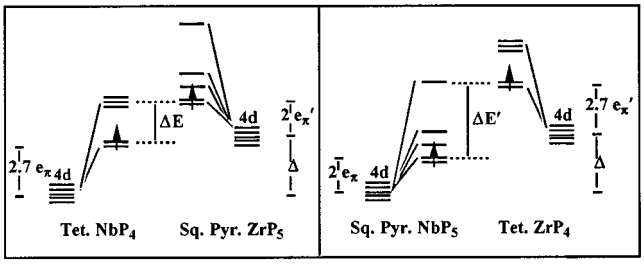
Figure 10 illustrates how the relationship between the site and bond energies arises. Phosphorus atoms create tetrahedral and square pyramidal ligand fields about the metals, which breaks the degeneracy of their valence *d* orbitals. According to electronegativities (see Figure 6) some of the metal valence electrons are transferred to phosphorus to form metal−phosphorus bonds. The electrons remaining in metal valence orbitals are utilized to form heteronuclear and homonuclear metal−metal bonds. Since the strength of orbital interactions is inversely proportional to the energy difference between the two isolated orbitals,[14] the strongest heteronuclear metal−metal interactions occur when the energy difference between occupied valence *d* orbitals of the

Figure 9. Overlap populations[17][41] for the shortest homonuclear and heteronuclear metal−metal bonds in ZrNbP (left) and ZrMoP (right); the dashed lines indicate calculated Fermi levels for 14 and 15 valence electrons per formula unit; positive values (bonding overlap) lie to the right and negative values (antibonding overlap) lie to the left; in ZrNbP, both Nb−Nb and Zr−Nb bonding is optimized; in ZrMoP, Zr−Mo bonding is optimized, but there is significant antibonding character for Mo−Mo bonding at the Fermi level



two different metals is smallest. In ZrNbP and ZrMoP this condition is met when Zr is in square pyramidal coordination and Nb or Mo are tetrahedrally coordinated by P: the difference in valence *d* orbital energies equals the free atomic orbital energy difference, Δ, plus the difference between the *d* orbital energy shifts from the π donor phosphorus ligands (expressed in units of e_π using the angular overlap model[2]). When the more electronegative Nb or Mo atoms are tetrahedrally coordinated, the resulting energy difference is less than when these elements are in the square pyramidal sites. In this manner, optimizing the site energy also minimizes the heteronuclear metal−metal bond energy.

Figure 10. Ligand field effects on the site preference problem in metal-rich ternary phosphides; in each section, the relative energies of the Zr and Nb 4*d* AOs are shown (Δ is energy difference between Nb and Zr 4*d* AOs); under the influence of either tetrahedral or square pyramidal ligand fields of phosphorus, these 4*d* orbitals are split and pushed up in energy by M−P σ* and π* interactions (e_π and e_π' are AOM parameters[2]); (left) $\Delta E = \Delta + 2e_\pi' - 2.7e_\pi$; (right) $\Delta E' = \Delta + 2.7e_\pi' - 2e_\pi$; $\Delta E < \Delta E'$

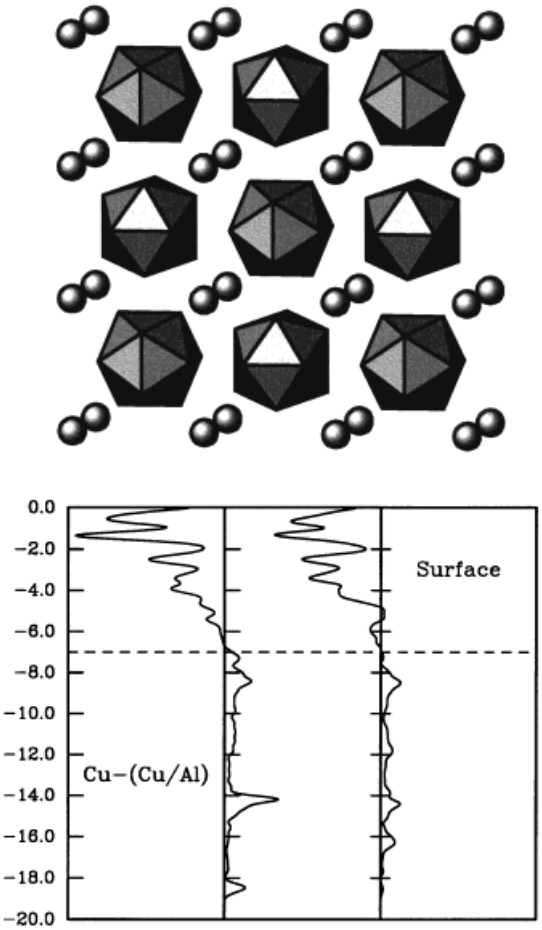


3. Coloring and Composition in Aluminides: Zintl Phases?

The question of chemical composition is closely linked to stable electronic configurations. For ionic and valence compounds (Zintl phases), the octet rule allows the chemist to "understand" chemical stability, since all bonding and nonbonding orbitals should be filled for "stable" chemical species.[42] When the electronegativity differences between elements in a compound are small, as in intermetallics, this rule becomes less well defined, and electronic structure calculations are necessary for a complete analysis. Nevertheless, the principle of bond order optimization by filling bonding and nonbonding orbitals is a compelling driving force for stable chemical compositions in a specific structure, i.e., equations (3) or (8).

Aluminides have been the focus of recent research towards an understanding of the transition from intermetallics to Zintl phases.[43] Post-transition elements form Hume-Rothery compounds[9] with *vec* < 2, while Zintl phases have networks of these elements with *vec* ≥ 4. Ternary aluminides involving an alkali or alkaline earth metal and an element from groups 11, 12, or 13 allow examination of compounds with *vec* values between two and four. A recent example of these efforts is $BaCu_5Al_8$,[44] which adopts the $NaZn_{13}$-type intermetallic structure. Further efforts have demonstrated that this structure occurs for compounds $ACu_{5\pm\varepsilon}Al_{8\mp\varepsilon}$, with A being Ba, Sr, La, or Eu and $\varepsilon \leq 1$.[45] The $NaZn_{13}$ structure type, shown in Figure 11, is a three-dimensional network of interconnected atom-centered (stuffed) icosahedra. Within the $[Cu_{5\pm\varepsilon}Al_{8\mp\varepsilon}]$ icosahedral substructure, there are two crystallographically inequivalent sites: (1) the center of each icosahedron, which is exclusively occupied by Cu; and (2) the surface of each icosahedron which is randomly decorated with $(4 \pm \varepsilon)$ Cu and $(8 \mp \varepsilon)$ Al atoms. Thorough synthetic and crystallographic investigations indicate that no ordering of Cu and Al on the icosahedra occurs even after months of annealing above 1000°C. Electronic structure calculations on various arrangements of Cu and Al in $BaCu_5Al_8$ demonstrate that bonding within the icosahedral framework is optimized (see Figure 11). Combinatorial methods indicate only ten unique ways of arranging four Cu and eight Al atoms in an icosahedron.[46][47] According to molecular orbital calculations, the lowest energy configurations of Cu and Al maximize the separations between Cu atoms. But, since there are six intericosahedral contacts per cluster, there is little energetic driving force for the ordering of Cu and Al. On the other hand, the overlap population curve in Figure 11 suggests that the stable compositions are influenced by the

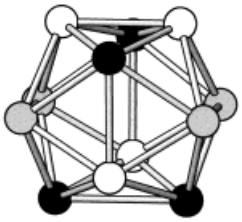
Figure 11. (Top) structure of $BaCu_5Al_8$; shaded circles are Ba atoms, icosahedra correspond to the Cu-centered $[Cu_4Al_8]$ clusters which are tightly interconnected; (bottom) overlap populations for two types of bonds in the icosahedral network: (i) central Cu with surface atoms, and (ii) among difference surface atoms on the icosahedra; note that bonding orbitals are filled and antibonding orbitals are empty at the Fermi level for $BaCu_5Al_8$



valence electron concentration and contribute to the narrow range of composition that has been observed.

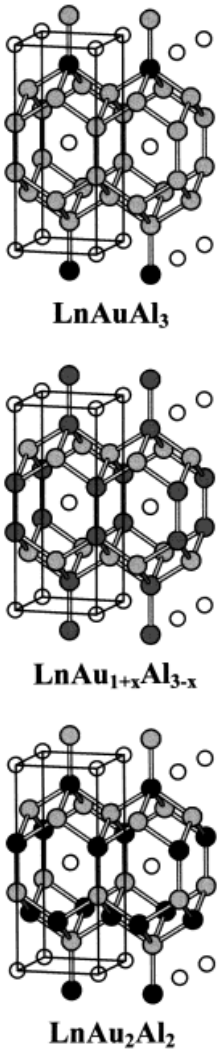
Corresponding reactions with the more electronegative coinage metal, Au, rather than Cu produce a structure which is related to the $NaZn_{13}$-type, but the icosahedron is empty and there is an ordering of Au and Al atoms on the icosahedra (see Figure 12).[45] Both observations result from the repulsive Au−Au interactions that are present in this chemical environment: Au is the most electronegative component which attracts electrons from Al and increases the antibonding interaction between Au atoms. The arrangement of Au and Al corresponds to the lowest energy Au_4Al_8 icosahedron as calculated by molecular orbital methods.

Figure 12. Icosahedron found in $SrAu_{5+x}Al_{7-x}$; black circles are Au atoms, gray circles are a mixture of Au and Al atoms, white circles are Al atoms; the arrangement for the four black Au atoms corresponds to the lowest energy configuration of the icosahedron $[Au_4Al_8]$



Further investigations with Au in this reducing environment produce new compounds[45][48][49] which allow an investigation of the chemistry and coloring problem involving the $BaAl_4$ structure, which is the most prolific intermetallic structure reported, known for more than 600 compounds.[50] This tetragonal structure contains two crystallographically distinct sets of aluminum atoms: one set forms planar square nets (Wyckoff site 4*e*) while the other set form dimers (Wyckoff site 4*f*) which link the square nets together to form a three-dimensional framework. There are numerous ternary variants of $BaAl_4$, in which the Al positions are occupied by two different elements in various ways (see Figure 13): (1) the $ThCr_2Si_2$-type, space group *I*4/*mmm*, with the different elements occupying the two inequivalent crystallographic sites; (2) the $CaBe_2Ge_2$-type, space group *P*4/*nmm*, in which the two elements alternate occupying the layers of square nets and the dimers so that only heteronuclear "Be−Ge" nearest neighbor contacts occur; and (3) the $BaNiSn_3$-type, space group *I*4*mm*, in which the Sn atoms form the square nets and the heteroatomic "Ni−Sn" pairs align in the same direction throughout the structure. The electronic structures of many compounds with these atomic arrangements have been extensively examined[51] and the results are summarized as follows: (1) for main group compounds, the structure is observed with 12−14 valence electrons per formula unit; (2) bonding within each dimer involves two-center two-electron σ bonds at 14 valence electrons, with an increasing π bonding character towards 12 valence electrons; and (3) optimum bonding between atoms on the 4*e* and 4*f* sites occurs at 12 valence electrons, and involves multi-center orbital interactions.

Figure 13. Three different colorings of $BaAl_4$ in ternary $LnAu_{1+x}Al_{3-x}$ intermetallics; black circles are Au atoms, dark gray circles (in center diagram only) are 50% Au/50% Al atoms, light gray circles are Al atoms, white circles are Ln atoms; (top) $LnAuAl_3$; (center) $LnAu_{1+x}Al_{3-x}$ ($0 < x \leq 0.5$); (bottom) $LnAu_2Al_2$



Recent investigations in ternary rare earth/gold/aluminum systems have shown interesting trends with respect to the "coloring" of Au and Al atoms in the covalent network of the $BaAl_4$ structure.[45][48] $LnAu_xAl_{4-x}$, $0.75 \leq x \leq 2$, have been reported for Ln ranging from La to Tb. When $x \geq 1.5$, the $CaBe_2Ge_2$ structure type occurs. For $x < 1.5$, i.e., higher Al concentrations, Au and Al partially disorder to give the $ThCr_2Si_2$-type until the composition $LnAuAl_3$, which shows both the ordered $BaNiSn_3$ and disordered $CeCuAl_3$ structure types. At $x = 0.75$, Au and Al are disordered on the 4*f* site, and show features of the $ThCr_2Si_2$ structure. Therefore, an interesting trend in coloring phenomenon occurs as the composition varies in $LnAu_xAl_{4-x}$ and for which the structural topology remains unchanged. Using equation (8) for these systems, the site energy is minimized when the most electronegative component occupies the 4*e* site, which is the place where Au replaces Al at low Au concentration ($x \leq 1$). As the Au

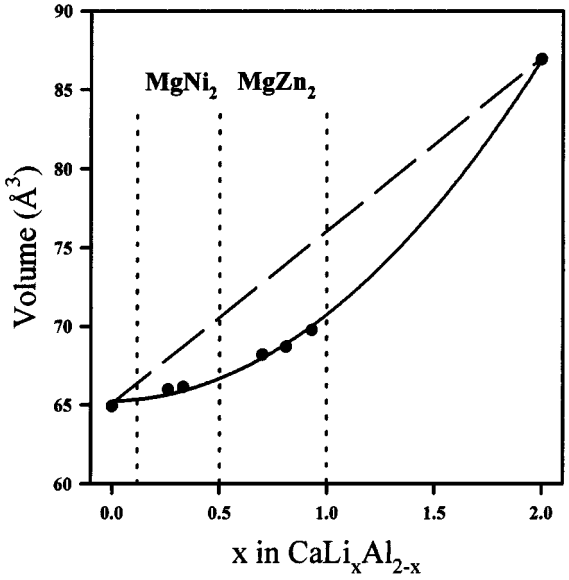
concentration increases, repulsive Au−Au interactions "force" Au atoms to occupy the square net positions 4*d*, until the maximum Au composition $LnAu_2Al_2$ is achieved. If the Au composition were to extend beyond this compound, Au−Au contacts would become necessary. Furthermore, the lowest possible Au concentration is $LnAu_{0.5}Al_{3.5}$ in order to maintain a maximum *vec* of fourteen electrons. When $x < 1$, entropic factors favor the body-centered tetragonal $BaAl_4$-type over the primitive tetragonal $BaNiSn_3$-type with no long range preference for the ordering of Au and Al in the dimers, which is observed for $EuAu_{0.75}Al_{3.25}$[45] Recent experiments have also shown that ordered vacancies enter the Au−Al framework as *vec* approaches fourteen electrons to give $Ln_3Au_2Al_9$ (Ln = Sm, Gd, Tb, Dy, and Yb).[45][49][52]

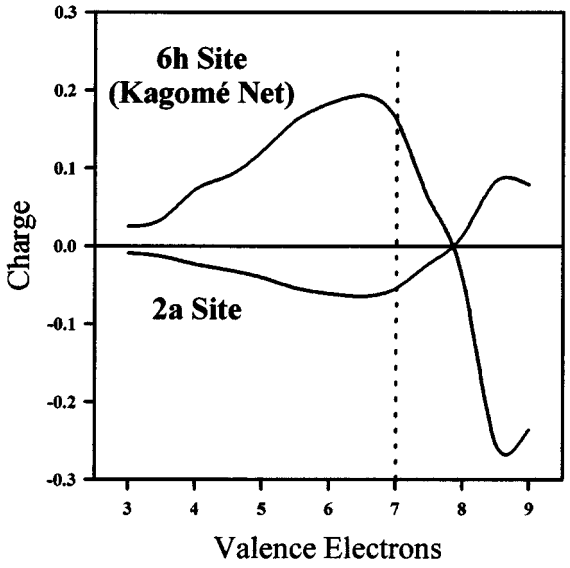
4. Coloring: Structure and Composition in Main Group Laves Phases

In the previous two sections, we have discussed how the coloring problem is tied to either structure or composition in intermetallic compounds. In general, however, these three aspects are closely interrelated, and are often difficult to separate and investigate systematically. An example of this problem occurs in the Ca−Li−Al ternary phase diagram along the line $CaLi_xAl_{2-x}$, which can be reformulated as $(CaLi_2)_y/(CaAl_2)_{1-y}$, $x = 2y$.[53] $CaLi_2$ and $CaAl_2$ form different Laves phase structures:[54] $CaLi_2$ adopts the hexagonal $MgZn_2$-type; and $CaAl_2$ forms the cubic $MgCu_2$-type. There exist many investigations concerning the influence of *vec* on the structures of Laves phases, but this study was the first which pointed out partial site preferences taking place in the framework of the majority component. Figure 14 illustrates how the volumes of the observed phases vary with Li content. When compared to a linear interpolation between the two binary compounds, there is a considerable volume reduction for the ternaries which strongly suggests covalent bonding within the aluminum framework, as found in Zintl phases. As x increases from zero in $CaLi_xAl_{2-x}$, the cubic $MgCu_2$-type structure changes to the hexagonal $MgNi_2$-type structure and then to the $MgZn_2$-type structure. Furthermore, stable compounds occur in $CaLi_xAl_{2-x}$ only for $x < 1$; when synthesis is attempted for phases with $x \geq 1$, disproportionation into $CaLi_2$ and $CaLi_yAl_{2-y}$, $y < 1$, occurs.

With respect to the coloring problem in Laves phases, the cubic $MgCu_2$-type structure has just one kind of majority site, whereas the hexagonal $MgNi_2$ and $MgZn_2$ types have three and two kinds of majority sites, respectively, which lead to potential site preferences. Li and Al show no site preferences in the hexagonal $MgNi_2$-type compounds, e.g., $CaLi_{0.33}Al_{1.67}$, and partial site preferences in the $MgZn_2$-type examples, e.g., $CaLi_{0.88}Al_{1.12}$. In this last compound, one of the majority sites (the kagomé nets; Wyckoff site 6*h*) is 50% Li and 50% Al, while the other crystallographic site (Wyckoff site 2*a*) attracts 75% Al and 25% Li. The reasons for these two coloring patterns stem from both the site energies as well as the driving force for Al in this reducing environment to establish an octet by forming Al−Al bonds.

Figure 14. $CaLi_xAl_{2-x}$ phases; (top) variation in volume per formula unit as the Li content varies from 0% to 100%; the dashed line connecting the two endpoints ($CaAl_2$ and $CaLi_2$) represents Zen's law for a linear variation with composition; the vertical dashed lines separate regions of the types of Laves phase structure observed for the experimental points; (bottom) trend in charges of the majority elements (Li_xAl_{2-x}) for the hexagonal $MgZn_2$-structure type as the number of valence electrons changes; the dashed line shows the maximum number of valence electrons allowed for this structure; the 2*a* site gains electrons, the 6*h* site loses electrons: thus, the more electronegative element would be attracted to the 2*a* site





For the series of observed $CaLi_xAl_{2-x}$ compounds, both semiempirical and density functional theory show that Ca donates just one valence electron to the $[Li_xAl_{2-x}]$ framework. Figure 14 illustrates the deviations from the average Mulliken population for the two majority sites in the hexagonal $MgZn_2$-type structure as a function of valence electron count. Notice that the largest difference in atomic population occurs for six electrons per formula unit

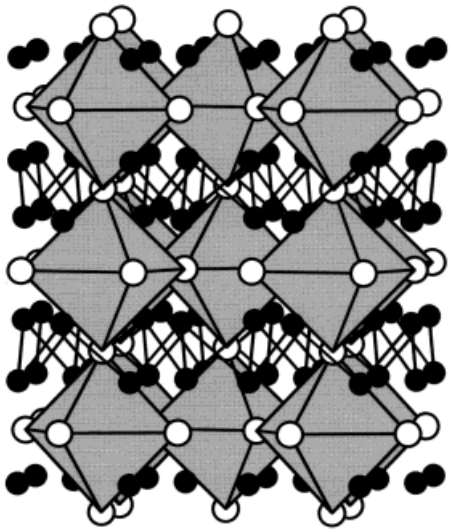
("CaLiAl"), whereas the difference is nearly zero between seven and eight electrons. Thus, $CaAl_2$ (8 electrons) and $CaLi_{0.33}Al_{1.67}$ (7.33 electrons) adopt, respectively, the $MgCu_2$-type and the $MgNi_2$-type structures with no site preferences. On the other hand, $CaLi_{0.88}Al_{1.12}$ (6.25 electrons) do show segregation in agreement with the Mulliken population analysis. However, with respect to minimizing the bond energy component of the total orbital energy from equation (8), a completely random arrangement of Li and Al would be expected. If the Zintl-Klemm formalism is applied to Al in $CaLi_{0.88}Al_{1.12}$ with complete segregation of Li and Al into the two crystallographic sites as far as allowed by the composition, the Ca atoms would donate 1.2 electrons to the $[Li_{0.88}Al_{1.12}]$ framework, which opposes the conclusions from theoretical calculations. Table 1 summarizes three different scenarios for the arrangement of Li and Al atoms in $CaLi_{0.88}Al_{1.12}$: (1) minimum site energy, (2) minimum Al−Al bond energy, and (3) the observed configuration. These results demonstrate that the structure and the partial segregation of Li and Al arise from the synergistic interplay of both the site energy and bond energy terms in the total orbital energy. In addition, the observed structure optimizes the Ca−Ca orbital interactions, as has been shown by calculating pair potentials in $CaAl_2$.[55] In $CaLi_{0.33}Al_{1.67}$, both the site energy and bond energy terms allow for a completely random arrangement of Li and Al throughout the structure.

5. Coloring and Property Effects in Metal-Rich Tellurides

The cases discussed thus far demonstrate minor changes in physical or chemical properties as a function of atomic coloring. This is due primarily to the fact that either the electronic configurations are all closed shell (as in Nb_3SI_7), or the valence electron concentrations are sufficiently low (less than four per atom) as to preclude any significant change in electronic properties. In order to investigate effects of atomic coloring on conductivity properties, focus must be directed towards compounds involving the post-transition elements, whose structures lie close to the border between Zintl phases (valence compounds) and typical intermetallics (Hume−Rothery phases, for example). A particularly interesting set of examples involves the substitution of Sn atoms for Tl atoms in the low temperature superconductor Tl_5Te_3.

Tl_5Te_3 adopts a variation of the tetragonal Cr_5B_3-structure type with a smaller than typical *c*/*a* ratio for these compounds, which leads to a three-dimensional network of vertex-sharing octahedra, $^3_\infty[TlTe_{6/2}]$, stuffed with Tl atoms over each face of the octahedron, i.e., $[TlTe_{6/2}]Tl_{8/2} \triangleq Tl_5Te_3$ (see Figure 15).[56] Tl_5Te_3 has a superconducting transition at 2.2 K,[57] which according to a combination of band structure and lattice energy calculations,[58] can arise from an electronic instability in the electronic band structure that is frustrated by strong short-range repulsive forces which retard any structural distortion. Using simple electron counting, the octahedrally coordinated Tl atoms can be formulated as Tl^{2+}, which is unstable towards disproportionation into Tl^{+1} and Tl^{3+}.[20]

Figure 15. The structure of Tl_5Te_3 and its ternary derivatives; white circles are Te atoms, black circles are Tl atoms; Te octahedra are also illustrated; there is a Tl atom at the center of each octahedron



Böttcher and coworkers have recently synthesized ternary derivatives of Tl_5Te_3.[59] In particular, $SnTl_4Te_3$ was prepared and shown to be metallic. From crystallographic data, the Sn atoms occupy both Tl sites in the parent structure. Replacing a "Tl^{2+}" with a Sn^{2+} is a plausible chemical

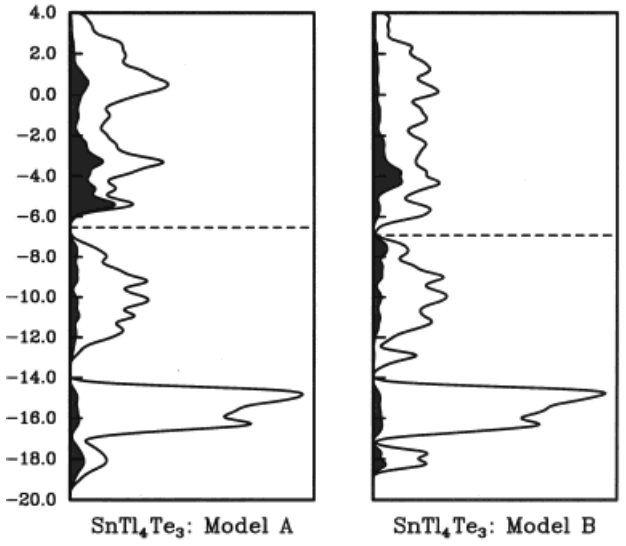
Table 1. Analysis of various coloring models for the $MgZn_2$-type Laves phase $CaLi_{0.88}Al_{1.12}$ with respect to the Zintl-Klemm formalism; the $[Li_{0.88}Al_{1.12}]$ network is described by two crystallographic sites in the space group $P6_3/mmc$: the 2*a* and the 6*h* sites

Coloring Model		− 2*a* Site − Site Occ.	CN by Al[a]	Charge[b]	− 6*h* Site − Site Occ.	CN by Al[a]	Charge[b]	Role of Ca: Electrons, Bond Order
Minimum Site Energy	Al:	100.00%	2.500	−2.500	41.67%	3.667	−1.333	Ca donates 1.21 electrons;
	Li:	0.00%		+1.000	58.33%		+1.000	Ca−Ca Bond Order ca. 0.6
Minimum Bond Energy	Al:	56.25%	3.375	−1.625	56.25%	3.375	−1.625	Ca donates 0.95 electron;
	Li:	43.75%		+1.000	43.75%		+1.000	Ca−Ca Bond Order ca. 0.9
Observed Arrangement	Al:	75.00%	3.000	−2.000	50.00%	3.500	−1.500	Ca donates 1 electron;
	Li:	25.00%		+1.000	50.00%		+1.000	Ca−Ca Bond Order ca. 1.0

[a] CN = coordination number; it represents the average number of Al nearest neighbors. − [b] Charge for Al is based on the 8 − *N*rule; it equals 3 − (8 − CN) = CN − 5. The charge for Li is chosen to be +1 as the most electropositive element in this compound.

substitution, and with an increase the valence electron concentration to a closed subshell configuration, semiconducting behavior would be expected. Indeed, band calculations with Sn completely replacing the octahedrally coordinated Tl atoms produces an energy gap at the Fermi level (Model A: see Figure 16). A combination of electronic band structure and lattice energy calculations reveal that whereas covalent interactions prefer Sn atoms to substitute at the octahedral sites, ionic interactions would rather place Sn atoms at the other Tl sites.[58] When such a substitution mode takes place, $SnTl_4Te_3$ retains its metallic character, but yields a smaller density of states at the Fermi level (Model B: see Figure 16). Therefore, where the substitution for Tl takes place has a dramatic effect on the expected physical properties of the derivative compounds.

Figure 16. Densities of states for two models of Sn atom coloring in $SnTl_4Te_3$; (left) Model A: all Sn atoms occupy the octahedral sites shown as polyhedra in Figure 15; (right) Model B: all Sn atoms occupy the other Tl sites shown as black circles in Figure 15; note that the Fermi level occurs in an energy gap for Model A, but there is no gap in Model B



Summary, Implications, and Future Directions

The coloring problem has powerful ramifications in chemistry. Electronic structure theory provides a theoretical underpinning for its effects, and also allows a simple chemical understanding of the phenomenon. However, can theory really assist the synthetic chemist with this problem? One important goal of synthetic chemists is to prepare new materials, which is often motivated by trying to optimize certain chemical or physical properties, e.g., catalytic activity, thermoelectric behavior, or magnetism to name a few. For the solid state chemist, these efforts are largely Edisonian in nature. Of course, the discovery of some physical property in one example tends to attract attention to the particular structure type in question: for example, superconductivity in cuprates. A working knowledge of the coloring problem, which includes both an imagination for possible new structures as well as an analysis based upon existing structures, will greatly assist the synthetic solid state chemist as the search for new, exciting, and probably more complex materials continues. Complexity can be simply moving from binary to ternary to quaternary systems, where the number of possible new materials increases exponentially.

How atoms arrange themselves in extended solid state structures depends on the number of valence electrons and the differences in electrochemical potentials, which are related to electronegativity, size, and the types of valence electronic structure the atoms bring to the compound. This review attempted to demonstrate that not only is structure a concern, but also the decoration pattern once a network of atoms is in place. Structure-composition-property interrelationships can then be studied by a careful application of experiment and theory − in most cases involving intermetallic compounds, theory is essential in order to develop a description of the electronic structure that harks to the classical chemical ideas for valence compounds. A partitioning of the total electronic energy into a site energy and a bond energy creates two components to the coloring problem. Through the examples presented in this review, i.e., Nb_3SI_7, ZrNbP and ZrMoP, $BaCu_5Al_8$ and $SrAu_6Al_6$, $LnAu_xAl_{4-x}$, $CaLi_xAl_{2-x}$, and $Sn_xTl_{5-x}Te_3$, analysis of both components is necessary to understand the complete structural details of these compounds and to ultimately relate their structures to their physical properties.

Where does the coloring problem take us now? A couple of examples may provide an indication: (1) utilize the Klemm pseudoelement approach[60] to create possible mixed anion matrices for transition metals in order to study electronic transitions, e.g., metal-semiconductor or metal-superconductor transitions, and (2) rely on structural experience in crystalline solids to develop models for systems which lack translational symmetry and yet are beginning to show interesting properties and applications with little fundamental understanding, i.e., quasicrystals and amorphous metals.[61] Our group is beginning to address these questions using the elegant ideas surrounding the coloring problem.

My group's efforts in this field have benefited by the financial support of the *Department of Energy*, the Donors of the *Petroleum Research Fund*, administered by the *American Chemical Society*, and the *National Science Foundation* (DMR-96-27161). Carbonyl and Benzene Complexes of Lithium: Transition-Metal-Like Behaviour of Lithium in Organolithium Compounds☆

Matthias Tacke

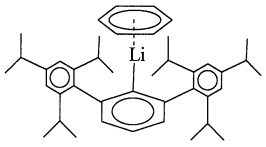
Received November 29, 1997

Keywords: Lithium / (Benzene)lithium complex / (Carbonyl)lithium complex / Ab initio calculations

Complexes of CO and aromatic compounds were believed to be an exclusive domain of transition metals caused by their ability of backbonding to these ligands. But recently, (benzene)lithium and (carbonyl)lithium complexes were characterized by X-ray structure analysis and IR spectoscopy. In order to determine geometries of the complexes and the bonding energies of the benzene and CO molecule to the organolithium starting compound suitable models were chosen in combination with high-level ab initio calculations. For the carbonyl derivative a reaction enthalpy of −8 kcal/mol was found while the interaction with benzene reached unexpectedly −21 kcal/mol. This underlines the ability of lithium to act like a transition metal in subcoordinated organyl compounds without having d orbitals available for bonding.

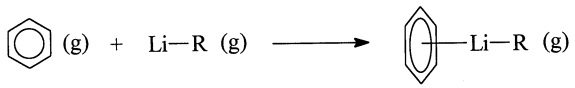
Introduction

Aggregation is a nearly ubiquitous characteristic of organolithium compounds.[1] But if bulky substituents prevent aggregation monomeric organolithium compounds show in benzene solution lithium−benzene π interaction like a transition metal. So $(2,4,6\text{-}i\mathrm{Pr}_3\mathrm{C}_6\mathrm{H}_2)_2\mathrm{C}_6\mathrm{H}_3\mathrm{Li}$ crystallizes from benzene/hexane solution as a monomer with a coordination between the lithium center and the benzene molecule.[2]



If the ligands have sterically less demanding *ortho*-substituted phenyl groups a small number of crystal structures show dimers exhibiting lithium−benzene interactions.[2][3] But X-ray crystallography is unable to measure the strength of this π interaction. This paper presents ab initio calculations on MP2 level for geometries and HF level for IR frequencies and zero-point energies which are able to fill the experimental gap. For these calculations there is no need for selecting highly substituted compounds of course. So three simple types of organolithium compounds are chosen (LiH, LiMe, LiPh)[4] which are allowed to interact with a benzene molecule to determine the reaction enthalpy of the process and to compare calculated and experimental structures.

In a recent spectroscopic study the very early steps of the reaction of organolithium compounds with CO or isonitrile were detected.[5] Liquid xenon (LXe) is used as the reaction medium because it suppresses electron-transfer reactions



(R = H, Me, Ph)

which are known to complicate the reaction.[6] If this reaction is performed at sufficiently low temperature a coordination of CO is found firstly. This unexpected transition-metal-like behaviour of lithium is followed by insertion of carbon monoxide into the lithium−carbon bond which is again expected for transition metal complexes only.

(R = O,NtBu)

Our investigations show that tetrameric methyllithium in combination with high-level MP2 calculations are a suitable model to determine reaction enthalpies and structures of the intermediates which allow comparison with the experimental data.

Results and Discussion

In a first attempt monomeric lithium hydride, which is the simplest model for an organolithium compound, is allowed to interact with benzene on MP2 level. Upon coordination we find a change in reaction enthalpy of −21 kcal/mol which is unexpectedly high. A weak interaction like a hydrogen bonding would give about −3 kcal/mol only. The Li−H stretching frequency decreases from 1420 cm^{-1} in free LiH to 1338 cm^{-1} in the coordinated LiH which means a total change of 6% indicating a major interaction as well. Correspondingly the Li−H bond length varies from 162.4

 © WILEY-VCH Verlag GmbH, D-69451 Weinheim, 1998 1434−1948/98/0505−0537 $ 17.50+.50/0

pm to 163.3 pm upon complexation. There is very little change in bond lengths in the benzene molecule. Even the hydrogen atoms stay nearly in the molecular plane. The resulting lithium−carbon bond length of the adduct in C_{6v} symmetry is 252.0 pm.

To verify this first result the reaction of Li^+ with benzene to form an adduct is calculated. Since this reaction enthalpy is measured to be -37 ± 2 kcal/mol applying ion cyclotron resonance technique[7] it is a unique chance to calibrate the ab initio calculations. The expected C_{6v} species exhibits an Li−C bond of 239.1 pm and a C−C bond of 140.6 pm which is slightly longer than in free benzene (139.6 pm). The enthalpy change is slightly overestimated by this calculation (−41 kcal/mol) showing that method (MP2) and basis set (6-31G**) are suitable to describe the system.

When using monomeric methyllithium as a model the calculation results in −19 kcal/mol for the reaction enthalpy with a new lithium−carbon distance of 251.7 pm. The most precise results are to be expected when monomeric phenyllithium is used since it is nearly the compound found to crystallize with benzene in an η^6-coordination mode. This time the enthalpy change is −21 kcal/mol and a lithium−carbon distance of 247.0 pm is found on average. Figure 1 illustrates the results on the MP2/6-31G** level of theory of the above-mentioned species.

These theoretical results give a consistent picture of the coordination of benzene to organolithium compounds. The calculated geometries of the complexes predict an atom distance of around 250 pm between lithium and carbon in the coordinated benzene. In the X-ray structure a significantly shorter value of 235 pm is determined. The calculations therefore give a reasonable but not excellent prediction of this important parameter. The interaction energy is with about −20 kcal/mol unexpectedly high and shows that the complexes formed are held together with more than weak Li−benzene π interactions as was suggested by the crystal-structure determination.[2] If bis(benzene)chromium is used as a reference compound for the bonding strength of the metal−benzene interaction an interesting comparison becomes available. From thermodynamical values it can be calculated that the reaction of $Cr(C_6H_6)_2$ to a chromium atom and two molecules of benzene needs around 80 kcal/mol.[8] Therefore, the bonding energy of each benzene unit to the chromium center is 40 kcal/mol which is only double the value of the lithium−benzene interaction. The high value is caused by the covalent nature of the lithium−carbon bond in the starting compound making it behave like a transition metal. Because lithium with its only three overall electrons is not able to build up highly ionic organo compounds as its heavier homologues it has to form a polar but covalent bond in a compound like phenyllithium. The subcoordination of lithium is normally moderated by formation of an oligomer with shared bonding electrons. But in the case of $(2,4,6\text{-}i\text{Pr}_3C_6H_2)_2C_6H_3Li$ the bulky substituents force the compound to remain a monomer with only two shared bonding electrons for the lithium center. In benzene solution this bonding type changes dramatically since the six-valence-electron donor benzene can form a stable

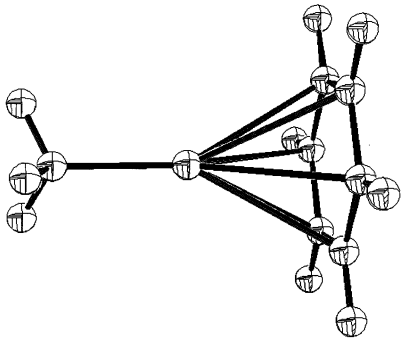
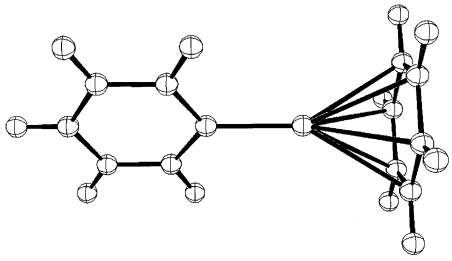
LiH: 163.3, LiC: 252.0, CC: 140.1



LiC(benzene): 251.7 (average)



LiC(benzene): 247.0 (average)

complex and enables the lithium center to end up with an 8-valence-electron environment.

Recently, it was shown, that organolithium compounds are also able to interact with CO[5] in a newly developed LXe cell constructed from one piece of single-crystal silicon.[9] In a first step carbon monoxide is complexed with back bonding to *n*BuLi [ν(CO): 2047 cm^{-1}] and inserts in a second step at higher temperatures into the lithium−carbon bond [ν(CO): 1635 cm^{-1}]. Further warming-up to −20°C results in decomposition of the observed pentanoyllithium intermediate. Probably a lithiated oxycarbene is formed favoured by formation of a strong lithium−oxygen bond.

$$\text{nBuLi} + \text{CO} \xrightarrow[-100°C]{\text{LXe}} [\text{nBuLi-CO}] \xrightarrow[-30°C]{\text{LXe}} [\text{nBu-C(O)Li}]$$

$$\xrightarrow[-20°C]{\text{LXe}} \text{further reaction}$$

With tetrameric lithium hydride as a model substance for ab initio calculations of oligomeric organolithium species it was possible to obtain first structural information[5] about the complexation and insertion of the CO molecule. But the insertion turned out to be a sligthly exothermic partial reaction, which is hard to believe in the light of the successful experiment in liquid xenon. With tetrameric methyllithium as a much better substitute we can now show, that the wrong sign of the reaction enthalpy is caused by the inadequate model. The addition of CO to $(LiMe)_4$ releases −7.8 kcal/mol with the formation of a linear LiCO substructure with a relative long lithium−carbon distance of 234.0 pm. For comparison *d*(Li−C) in tetrameric methyllithium is calculated to 221.0 pm. In contrast to the experiment the calculated compound does not show backbonding to CO as indicated by a higher C−O stretching frequency in comparison to free carbon monoxide. The second possible isomer showing a likewise linear LiOC substructure is higher in energy. The insertion reaction of carbon monoxide into the lithium−carbon is now exothermic (−4.2 kcal/mol) and the resulting acetyl group coordinates with its carbon atom

CO group is detected by IR spectroscopy and is assigned to the (carbonyl)lithium. Warming-up leads to the decomposition of this first species while a second one with a double-bonded CO group appears at the same time. It is plausible that the second intermediate is the organolithium-lithium species coordinating the RC=O group in a μ_3 fashion which shifts the carbonyl stretching frequency to 1635 cm^{-1} which, in turn, is only plausible in this extraordinary complexation mode. This second species finally reacts further resulting an IR spectrum with no C−O stretching frequencies above 1500 cm^{-1}.

Again a comparison of the bonding energy of carbon monoxide to lithium or chromium will help to classify the observed transition-metal-like behaviour of lithium. Chromium atoms react with carbon monoxide to $Cr(CO)_6$ and release nearly 180 kcal/mol which is interpreted as an (averaged) bonding energy between Cr and CO of 30 kcal/mol.[8] The result of the calculation for the lithium−CO bonding energy is less than 8 kcal/mol and indicates a relatively weak interaction. This is not unexpected in the second case since the subcoordination and therefore the transition-metal-like behaviour of lithium is markedly less because now a organolithium cluster is involved instead of a monomeric compound.

This work was supported by the *Deutsche Forschungsgemeinschaft*, the *Fonds der Chemischen Industrie* and the *Irish Research Organisation Forbairt*.

Experimental Section

With a view to determining the structures, IR frequencies and energies of formation the application of theoretical methods are proved advantageous. For this purpose the program package GAUSSIAN 92[10] implemented on an IBM-compatible Pentium computer with 64 MB RAM memory was used. Ab initio calculations were performed at the HF (Hartree-Fock) or MP2 (second

order Møller-Plesset) level of theory using 6-31G** basis set for the species of interest. Harmonic vibrational frequencies, calculated at the HF/6-31G** level only, characterized stationary points and gave the zero-point energy. Therefore, frequencies are scaled by using a factor of 0.89. Geometries were then optimized on MP2/6-31G** level to deliver the electronic energy and geometries for discussion. The sum of the electronic and the zero-point energy was used to calculate differences interpreted as reaction enthalpies at 0 K. For the visualisation of the calculated structures the program ORTEX 5[11] was used.

Received December 18, 1997

Keywords: Lanthanoid(II) complexes / Ytterbium / Thallium / η^2-Pyrazolate complexes / Diphenylmercury / Redox transmetallation / X-ray crystal structure

Ytterbium metal reacts with thallium(I) 3,5-diphenylpyrazolate, or with diphenylmercury and 3,5-diphenylpyrazole (Ph_2pzH) in tetrahydrofuran or 1,2-dimethoxyethane (DME) giving, after appropriate isolation, the first lanthanoid(II) pyrazolate complex, $[Yb(Ph_2pz)_2(DME)_2]$. The molecular structure reveals eight coordinate ytterbium(II) with two *cisoid* η^2-3,5-diphenylpyrazolate and two chelating 1,2-dimethoxyethane ligands.

Redox transmetallation between lanthanoid metals and metal complexes (eq. 1; $n = 2$ or 3; $m = an/b$) and redox transmetallation/ligand exchange involving mercurials (eq. 2; $n = 2$ or 3) provide simple halide free routes to lanthanoid complexes[1][2][3].

$$a\mathrm{Ln} + b\mathrm{M(L)}_m \rightarrow a\mathrm{Ln(L)}_b + b\mathrm{M} \downarrow \quad (1)$$

$$2\mathrm{Ln} + n\mathrm{HgR}_2 + 2n\mathrm{LH} \rightarrow 2\mathrm{Ln(L)}_n + n\mathrm{Hg} \downarrow + 2n\mathrm{RH} \quad (2)$$

Recent examples of eq. 1 involve mercury[4][5] and tin[6] compounds. Use of thallium(I) reagents is currently restricted to cyclopentadienyls[7][8][9][10] and phenolates[11]. We now report the synthesis of the first lanthanoid(II) pyrazolate, $Yb(Ph_2pz)_2$ (Ph_2pzH = 3,5-diphenylpyrazole), by redox transmetallation between thallium(I) 3,5-diphenylpyrazolate, and ytterbium metal and by redox transmetallation/ligand exchange between Yb, Ph_2pzH and $HgPh_2$, together with the X-ray crystal structure of $[Yb(Ph_2pz)_2(DME)_2]$ (DME = 1,2-dimethoxyethane). This opens the use of thallium-based redox transmetallation as a source of lanthanoid organoamides, and increases the versatility of reaction (2).

Thallium(I) 3,5-diphenylpyrazolate was obtained in high yield by reaction of thallium(I) ethoxide with 3,5-diphenylpyrazole in dichloromethane (eq. 3).

$$\mathrm{TlOEt} + \mathrm{Ph_2pzH} \longrightarrow \mathrm{Tl(Ph_2pz)} + \mathrm{EtOH} \quad (3)$$

Reaction of the thallium complex with ytterbium metal in the presence of mercury metal in tetrahydrofuran (THF) and evaporation and crystallisation from DME or reaction of Yb and $Tl(Ph_2pz)$ in DME gave $[Yb(Ph_2pz)_2(DME)_2]$ in good yield (eq. 4). Satisfactory crystallisation was not achieved from THF.

$$\mathrm{Yb} + 2\mathrm{Tl(Ph_2pz)} \xrightarrow{\mathrm{Hg}} \mathrm{Yb(Ph_2pz)_2} + 2\mathrm{Tl}\downarrow \quad (4)$$

The highly air-sensitive product was characterised by elemental analysis and infrared and ^{1}H-NMR spectra, whilst the visible/near infrared spectrum (no bands at 450−1200 nm) indicated the absence of Yb(III). The structure was established by X-ray crystallography below. Although a range of lanthanoid(III) pyrazolates are known[12], particularly $[Ln(R_2pz)_3(L)_n]$ complexes (R = Me, L = THF, n = 1[12c]; R = Ph or *t*Bu, L = THF, DME, or Ph_3PO, n = 1−3[12d-h]), no lanthanoid(II) pyrazolates have previously been reported. It is of particular interest that redox transmetallation/ligand exchange reactions of an excess of ytterbium metal with $Hg(C_6F_5)_2$ and 3,5-di-*tert*-butylpyrazole gave $[Yb((tBu)_2pz)_3(THF)_2]$ rather than a divalent complex[12d][12f], and analogous reactions with 3,5-diphenylpyrazole in this work gave an unidentifiable black insoluble material. However, with $HgPh_2$ as the reagent instead of the commonly used $Hg(C_6F_5)_2$, a smooth high yield synthesis of $[Yb(Ph_2pz)_2(DME)_2]$ was achieved (eq. 5).

$$\mathrm{Yb} + 2\mathrm{Ph_2pzH} + \mathrm{HgPh_2} \rightarrow \mathrm{Yb(Ph_2pz)_2} + 2\mathrm{PhH} + \mathrm{Hg} \downarrow \quad (5)$$

The successful outcome of eq. 5 compared with the failed preparation with $Hg(C_6F_5)_2$, shows that $HgPh_2$ has excellent prospects in redox transmetallation/ligand exchange (eq. 2), despite lower reactivity towards lanthanoid metals than $Hg(C_6F_5)_2$.

 © WILEY-VCH Verlag GmbH, D-69451 Weinheim, 1998 1434−1948/98/0505−0543 $ 17.50+.50/0

By contrast with eq. 4, treatment of thallium(I) 3,5-diphenylpyrazolate with a large excess of samarium metal gave impure (indicated by the Sm analysis) $[Sm(Ph_2pz)_3(DME)_2]$. The DME/Ph_2pz ratio was established by ^{1}H-NMR spectroscopy and corresponds to that in previously prepared $[Ln(Ph_2pz)_3(DME)_2]$ (Ln = La, Nd, or Er)[12h]. A significant high frequency shift of the Ph_2pz resonances from those for $[La(Ph_2pz)_3(DME)_2]$ is consistent with coordination to the paramagnetic ion. The oxidation state was established by the near infrared absorption, which was characteristic of Sm(III)[13], as well as by the typical pale yellow colour of the product solution, whilst the visible region lacked typical Sm(II) absorption near 600cm^{-1}[14]. Thus, even for lanthanoid metals giving accessible divalent compounds, reaction (1) $[M(L)_m = Tl(R_2pz)]$ does not necessarily give a lanthanoid(II) complex.

The molecular structure of $[Yb(Ph_2pz)_2(DME)_2]$ is displayed in Figure 1, together with selected bond distances and angles. Two η^2-Ph_2pz and two chelating DME ligands are bound to ytterbium, giving approximately dodecahedral YbN_4O_4 eight coordination. The common ligands are in a *cisoid* relationship to each other, as indicated by a N-N-centroid−Yb−N′-N′-centroid angle of 101.$_4$° and a O···O-centroid−Yb−O′···O′-centroid angle of 97.$_9$°. The dihedral angle between the two YbN_2 planes is 101.0(2)°. Observation of η^2-pyrazolate coordination for the first lanthanoid(II) pyrazolate is consistent with the predominance of this bonding mode in pyrazolatolanthanoid(III) complexes[12], but where μ-pyrazolate binding, the dominant mode for d-block metals[15], is also known[12a][12b][12c]. The first examples of η^2 coordination for d-block transition metals have recently been reported[15c][16]. With allowance for differences in oxidation state and coordination number[17], the Yb−N distances are comparable with those of lanthanoid(III) pyrazolates[12] and the Yb−O distances are consistent with those of the chelating DME of $[Er(Ph_2pz)_3(\eta^2\text{-DME})(\eta^1\text{-DME})]$[12h]. Thus, subtraction of the ionic radius for eight coordinate Yb^{2+} (1.14 Å)[17] from <Yb-N> gives 1.28 Å comparable (but at the low end) with values, 1.27−1.38 Å[12c-h], for a range of $[Ln(\eta^2\text{-}R_2pz)_3(L)_n]$ (R = Ph or *t*Bu) complexes, whilst a similar subtraction from <Yb-O> gives 1.39 Å, comparable with the 1.42 Å derived from the chelating DME of $[Er(Ph_2pz)_3(\eta^2\text{-DME})(\eta^1\text{-DME})]$[12h] and within the range derived from Ln−O of $[Ln(R_2pz)_3(THF)_n]$ (n = 2 or 3) (R = *t*Bu or Ph) complexes[12e][12f].

A wide ranging study of the syntheses and structures of pyrazolatolanthanoid(II) complexes, especially preparation by redox transmetallation reactions from free metals and thallium(I) pyrazolates, is in progress.

We are grateful to the *Australian Research Council* for financial support and for the award of an Australian Postgraduate Research Award to E. E. D

Experimental Section

The compounds described here are extremely air- and moisture-sensitive and consequently all operations were carried out in an inert atmosphere (purified argon or nitrogen).

(3,5-Diphenylpyrazolato)thallium(I): Thallium(I) ethoxide (3.55 ml, 12.5g, 50.0 mmol) was added to a CH_2Cl_2 (200 ml) solution of 3,5-diphenylpyrazole (11.1g, 50.0 mmol). Addition of thallium(I) ethoxide caused undissolved 3,5-diphenylpyrazole to dissolve. Removal of the CH_2Cl_2 under vacuum yielded 19.4g (92%) of a white crystalline solid, m.p. 195°C (sealed capillary/argon). − IR: $\tilde{\nu}$ = 1600 cm^{-1} m, 1259 m, 1070 m, 1058 s, 1025 m, 972 m, 914 w, 799 m, 758 vs, 693 vs. − ^{1}H NMR (200 MHz, [D$_8$]THF): δ = 7.96 (s, 1 H, 4-H pz),7.12−7.21 (m, 2 H, *p*-H), 7.21−7.27 (m, 4 H, *m*-H), 7.68 (t, 4 H, *o*-H), − MS (70 eV, EI); *m*/*z* (%): 424 (50) [(^{205}Tl)M$^+$], 220 (80) [$C_{15}H_{11}N_2^+$], 205 (100) [^{205}Tl$^+$]. − $C_{15}H_{11}N_2Tl$ (423.6): calcd. C 42.53, H 2.62, N 6.61; found C 42.35, H 2.53, N 6.49.

Bis(1,2-dimethoxyethane)bis(η²-3,5-diphenylpyrazolato)-ytterbium(II) − Method A: A mixture of ytterbium powder (1.73g, 10.0 mmol), mercury metal (ca. 0.10 ml) and (3,5-diphenylpyrazolato)thallium(I) (2.12g, 5.0 mmol) in THF (30 ml) or DME (50 ml) was subjected to ultrasonication for 24 h. The resulting deep red solution with grey suspended solids was allowed to stand for several hours until the suspension settled out. The reaction mixture was then filtered using a filter cannula. In the case where THF was used, the filtrate was evaporated to dryness under vacuum yielding a red solid which was dissolved in DME (40 ml) and allowed to stand for several days at room temp. during which time 1.3 g (66%) of large red crystals formed. In the case where DME was used, evaporation of some DME (ca. 5 ml) and standing for several days

afforded large red crystals of similar appearance in similar yield, m.p. >350°C (sealed capillary/argon). – IR: $\tilde{\nu}$ = 1602 cm^{-1} m, 1156 w, 1121 w, 1099 m, 1071 s, 1025 m, 968 s, 914 w, 863 m, 859 m, 801 w, 757 vs, 722 m, 698 s, 685 s. – Visible/near IR (THF): λ_{max} (ε) = 410 nm (774). – ^{1}H NMR (300 MHz, [D_8]THF): δ = 3.24 (s, 12 H, CH_3O DME), 3.41 (s, 8 H, CH_2 DME), 7.07 (t, 4 H, *p*-H), 7.10 (s, 2 H, 4-H), 7.24 (t, 8 H, *m*-H), 7.92 (d, 8 H, *o*-H). – ^{171}Yb NMR (52.5 MHz, 0.04 M in DME): δ = 480 ($\Delta\nu_{1/2}$ 20 Hz) [relative to $Yb(C_5Me_5)_2(THF)_2$] – $C_{38}H_{42}N_4O_4Yb$ (791.8): calcd.: C 57.64, H 5.35, N 7.08, Yb 21.85; found C 56.88, H 5.24, N 7.59, Yb 22.43.

Method B: A mixture of ytterbium powder (1.73 g, 10.0 mmol), $HgPh_2$ (0.80 g, 2.3 mmol) and 3,5-diphenylpyrazole (1.00 g, 4.5 mmol) in THF (40 ml) was stirred and heated at 60°C for 2 d. The resulting red solution with grey suspended solids was filtered and the filtrate was evaporated to dryness. Recrystallisation of the resulting red solid from DME (20 ml) at −20°C gave 1.37 g (76%) of $[Yb(Ph_2pz)_2(DME)_2]$ as deep red crystals. – IR: Identical with that of the product from A. – $C_{38}H_{42}N_4O_4Yb$ (791.8): calcd. Yb 21.85; found Yb 21.48.

Reaction Between (3,5-Diphenylpyrazolato)thallium(I) and Samarium Metal: A mixture of samarium metal (1.50 g, 10.0 mmol), mercury metal (ca. 0.40 ml) and (3,5-diphenylpyrazolato)thallium(I) (0.85 g, 2.0 mmol) in THF (30 ml) was subjected to ultrasonication for 3 d. The resulting pale yellow solution with grey suspended solids was allowed to stand for several hours. Filtration and evaporation as above yielded a white solid which was recrystallised from a DME/light petroleum mixture giving $[Sm(Ph_2pz)_3(DME)_2]$ 0.42 g, (40%) as a white powder. – IR: $\tilde{\nu}$ = 1604 cm^{-1} m, 1513 w, 1422 w, 1282 w, 970 s, 906 w, 864 s, 800 w, 759 vs, 696 s, 684 s. – Visible/near IR (THF): λ_{max} (ε) = 369 nm (1.5), 402 (2.0), 977 (1.0), 1074 (2.0), 1328 (3.5), 1368 (1.0) . – ^{1}H NMR (300 MHz, [D_8]THF): δ = 3.27 (s, 12 H, CH_3O), 3.39 (s, 8 H, CH_2), 7.30 (t, 6 H, *p*-H), 7.54 (t, 12 H, *m*-H), 7.94 (s, 3 H, 4-H), 9.28 (d, 12 H, *o*-H). – $C_{53}H_{53}N_6O_4Sm$ (988.5): calcd. Sm 15.22; found Sm 16.64.

X-ray Crystallography of [Yb(Ph$_2$pz)$_2$(DME)$_2$]: Single crystals were grown from a saturated DME solution at room temperature over several days. $C_{38}H_{42}N_4O_4Yb$ (791.82), monoclinic, space group $P2_1/a$ (no. 14). a = 7.882(4), b = 18.959(3), c = 24.080(14) Å, β = 91.03(2)°, V = 3598(3) Å^3, Z = 4, D_c = 1.462 g cm^{-3}, μ_{Mo} = 26.4 cm^{-1}, $F(000)$ = 1600, $A^*_{min,max}$ 1.64, 2.17. For X-ray crystallography single crystals 0.20 × 0.38 × 0.33 mm were covered in a heavy oil and sealed into glass capillaries under purified argon. From 6331 diffractometer reflections ($2\theta_{max}$ 50°, $2\theta/\theta$ scan mode; monochromatic Mo K_α radiation; λ = 0.7107$_3$ Å; $T \approx$ 295 K; 18381 total reflections merged (R_{int} = 0.048), 50% crystal decomposition compensated by scaling), 3670 "observed" [$I > 3\sigma(I)$)] used after absorption correction in the final least squares refinement [anisotropic thermal parameters for non-hydrogen atoms, (x, y, z, U_{iso})$_H$ constrained]. R, Rw on $|F|$ were 0.044, 0.044 (statistical weights). Crystallographic data (excluding structure factors) for the structure reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication no. CCDC-101118. Copies of the data can be obtained from The Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [Fax: (int. Keywords: Copper / Trinuclear / Formamidines / Magnetism / Crystal structure

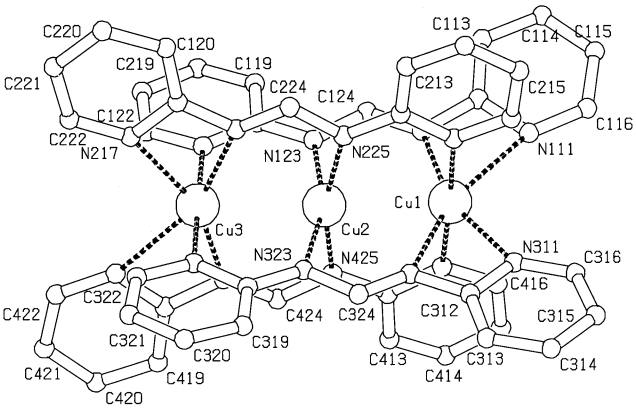
In situ reaction of Cu^{II} triflate with aminopyridine or aminopyrimidine and triethylorthoformate in ethanol results in unique linear trinuclear Cu^{II} complexes with the general formula $[Cu_3(L^-)_4](CF_3SO_3)_2(EtOH)_x$ (L = dehydronated ligand *N,N′*-bis(pyridine-2-yl)formamidine or the new ligand *N,N′*-bis(pyrimidine-2-yl)formamidine). The structure [Cu−Cu−Cu angle 175.19(2)°] consists of four nearly flat molecules of the ligand which contribute to the propeller-type structure around the Cu−Cu−Cu axis. A strong antiferromagnetic interaction between the Cu^{II} ions is observed, resulting in an $S = 1/2$ ground state below 100 K.

Dinuclear and polynuclear exchange-coupled copper(II) complexes are well known, but the number of magnetically as well as structurally investigated trinuclear compounds is quite limited[1]. Also the theory for dinuclear and polynuclear systems is found adequate to describe the exchange parameter of magnetism[1][2], but linear trinuclear compounds are far less discussed. Dinuclear systems are also well documented because their relevance for bioinorganic model systems in copper enzymes[3].

Linear trinuclear Cu^{II} compounds are relatively rare and only few are studied magnetically[4]. A few are known with a CuN_{4-6} chromophore around each Cu^{II} ion[5]. We now wish to report a novel method for in situ synthesis of such trinuclear compounds, which have quite unusual propeller-type structure and a strong magnetic exchange coupling. Compounds $[Cu_3(pdf)_4](CF_3SO_3)_2(EtOH)_{1.5}$ (**1**), in which pdf is the dehydronated ligand *N,N′*-bis(pyridine-2-yl)formamidine, and $[Cu_3(pmf)_4](CF_3SO_3)_2(EtOH)_{0.5}$ (**2**), in which pmf is the dehydronated ligand *N,N′*-bis(pyrimidine-2-yl)-formamidine, were synthesized and characterised.

Structural analysis of **1** shows a linear arrangement of 3 Cu^{II} ions surrounded by 4 ligand molecules in a propeller mode, each of which being tetracoordinating to the 3 copper atoms (Figure 1). The central copper atom is distorted square-planar [angles of 163.46(11), 161.11(11)°] and normal Cu−N distances of ca. 2.0 Å. The outer copper ions are six coordinated with distorted square-based geometry, and a slightly different geometry for each copper. The angles of the basal plane of Cu1 (formed by N211−N311−N411−N125) are 176.84(11) and 158.53(11)° and of Cu3 (formed by N117−N217−N317−N423) are 178.50(11) and 156.83(11)°. The short Cu−N distances for Cu(1) and Cu(3) vary from 1.989(3) to 2.191(3) Å. The axial sites of the geometry are occupied by other nitrogens with Cu−N distances that vary from 2.267(4) to 2.543(3) Å. The axial angles slightly differ from linear [N325−Cu1−N111 = 160.81(11)° and N417−Cu3−N223 = 158.18(11)°], as a result of contraints caused by the ligandshape.

Figure 1. Plot of structure **1** with atom-labelling scheme. H- atoms and non-coordinating triflate anions and the ethanol molecules are omitted for clarity[a]



[a] Selected distances [Å] and angles [°]: Cu(1)−Cu(2) 2.6618(8), Cu(2)−Cu(3) 2.6676(8), Cu(1)−N(411) 1.989(3), Cu(1)−N(211) 1.992(3), Cu(1)−N(125) 2.033(3), Cu(1)−N(311) 2.168(3), Cu(1)−N(325) 2.272(3), Cu(1)−N(111) 2.543(3), Cu(2)−N(425) 1.997(3), Cu(2)−N(225) 2.026(3), Cu(2)−N(123) 2.036(3), Cu(2)−N(323) 2.050(3), Cu(3)−N(317) 2.001(3), Cu(3)−N(117) 2.011(3), Cu(3)−N(423) 2.032(3), Cu(3)−N(223) 2.191(3), Cu(3)−N(217) 2.267(4), Cu(3)−N(417) 2.500(3), N(411)−Cu(1)−N(211) 176.84(11), N(125)−Cu(1)−N(311) 158.53(11), N(111)−Cu(1)−N(325) 160.81(11), N(425)−Cu(2)−N(225) 163.46(11), N(123)−Cu(2)−N(323) 161.11(11), Cu(1)−Cu(2)−Cu(3) 175.19(2), N(317)−Cu(3)−N(117) 178.50(11), N(423)−Cu(3)−N(217) 156.83(11), N(223)−Cu(3)−N(417) 158.18(11).

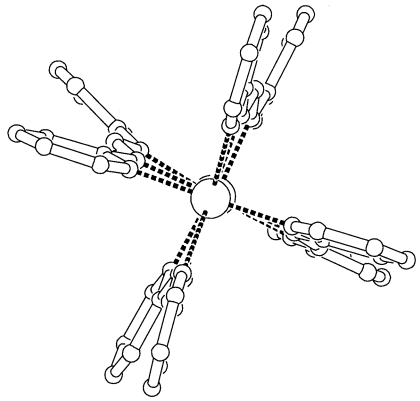
The Cu−Cu distances of 2.6618(8) and 2.6676(8) Å, are only slightly longer than in the two other comparable

 © WILEY-VCH Verlag GmbH, D-69451 Weinheim, 1998 1434−1948/98/0505−0547 $ 17.50+.50/0

CuN_x-bridged linear copper(II) compounds[5a][5c], but shorter than in the azido-bridged trinuclear compounds[4][5b][5d].

The linear angle Cu1−Cu2−Cu3 is 175.19(2)°. Viewing along the Cu−Cu−Cu axis (Figure 2) a propeller type arrangement is visible in which the ligands are almost perpendicular to the axis with angles between the two rings of each ligand which vary from 27.73 to only 8.19°. Hydrogen bonds between the oxygens of the lattice ethanol and the triflate molecules (O···O 2.82 and 3.02 Å) stabilize the lattice.

Figure 2. View along the Cu−Cu−Cu axis of structure (**1**)



The ligand field spectrum of both compounds show a broad band with a double maximum at 16.3 and $20.8 \cdot 10^3$ cm^{-1} for **1** and at 16.9 and $20.9 \cdot 10^3$ cm^{-1} for **2**. These two absorptions are both d-d transitions[6a][6b], and it is tempting to assume that the highest energy is from the central Cu atom, although Cu2 is not perfectly square planar, and the lowest energy from the outer six-coordinated Cu atoms[5c][6c].

The EPR spectra at room temperature shows a broad absorption centered around g = 2.11 and a weaker broad absorption at ca. g = 3.6, which disappear upon cooling to 77 K. The EPR signal sharpens upon cooling and a very weak $g_{//}$ at ca. 2.3 is observed (no $A_{//}$ resolved). No structural conclusions can be drawn from these spectra. Preliminary temperature dependent magnetic susceptibility measurements down to 5 K, shows a magnetic moment of ca. 1.50 B.M. per copper(II) ion at 270 K, which decreases to ca. 1.0 B.M. at 20 K, which indicates an antiferromagnetic coupling between the copper(II) ions within the trinuclear units[6d][5c]. In the area 70−5 K $1/\chi$ vs. T is linear with $\Theta = 0$ and agrees with $\mu = 1.05$ (or 1.8 B.M./Cu_3) which agrees with a ground state only one unpaired electron per 3 Cu^{II}. A preliminary fit on the hamiltonian $H = -2J[(\mathbf{S}_A \cdot \mathbf{S}_B) + (\mathbf{S}_B \cdot \mathbf{S}_C)]$ shows that $J = -100$ cm^{-1} and assumes $J' = 0$.

Further work will deal with related ligands yielding this structure and with a full magnetic study. In summary, we have shown that copper ions can control the template synthesis of tetradentate formamidine ligands, simultanously resulting in linear trinuclear Cu^{II} complexes.

The work described in the present paper has been supported by the *Leiden University Study group WFMO* (Werkgroep Fundamenteel Materialen Onderzoek). Use of the services and facilities of the *Dutch National NWO/SURF Expertise Center CAOS/CAMM*, under grant numbers SON 326-052 and STW NCH99.1751, is gratefully acknowledged.

Experimental Section

General: Ligand field spectra were recorded on a Perkin-Elmer Lambda 900 spectrophotometer using the diffuse reflectance technique, with MgO as a reference. − X-band powder EPR spectra were obtained on a Jeol RE2x electron spin resonance spectrometer, using DPPH (g = 2.0036) as a standard. − Magnetic susceptibilities were measured in the temperature range 5−300 K with a Manics DSM-8 susceptometer. Data were corrected for magnetization of the sample holder and for diamagnetic contributions, which were estimated from the Pascal constants[8].

Synthesis: 2-Aminopyridine and 2-aminopyrimidine are obtained from Acros Organics; metal salts and solvents were commercially available and used without further purification. 1.2 mmol of $Cu(CF_3SO_3)_2$ and 1.2 mmol of 2-aminopyridine or 2-aminopyrimidine were each dissolved in ca. 10 ml of ethanol. To each solution ca. 5 ml of triethylorthoformate was added. The copper solution was added carefully to the amino compound solution and filtered to remove any un-dissolved material. After a few days black crystalline material was obtained, filtered, and air-dried.

Compound **1** $\{[Cu_3(pdf)_4](CF_3SO_3)_2(EtOH)_{1.5}\}$ can also be synthesized directly from the copper(II)triflate salt and the ligand Hpdf (which was synthesized in the literature[7]) in ethanol plus triethylorthoformate to remove the water from the ethanol. Satisfactory elemental analysis were obtained.

X-ray Crystal Structure Analysis: Crystal data for $[Cu_3(pdf)_4](CF_3SO_3)_2(EtOH)_{1.5}$: $C_{49}H_{45}Cu_3F_6N_{16}O_{7.5}S_2$, M = 1346.75, monoclinic, space group $P2_1/c$ (no. 14), a = 12.974(3), b = 17.769(4), c = 24.227(5) Å, β = 92.73(3)°, V = 5579(2) $Å^3$, Z = 4, D_c = 1.603 g cm^{-3}, T = 193 K, μ(Mo-K_α) = 1.295 mm^{-1}, $F(000)$ = 2736, 11365 reflections measured, 10881 independent, R_{int} = 0.0317, (2.52 < θ < 26.54°), a black crystal with dimensions of 0.30 × 0.30 × 0.25 mm was selected, mounted to the glass fiber using the oil drop method[9a]. Rigaku AFC-7S diffractometer, graphite-monochromated Mo-K_α radiation (λ = 0.71073 Å), ω-2θ scans. Data reduction using the TEXSAN[9b] package. The intensity data were corrected for Lorentz and polarization effects and for absorption and extinction. All non H atoms were refined anisotropically. H atoms were situated from difference Fourier map and refined isotropically. The structure was solved using direct methods SHELXS-86[9c]. The weighting scheme $w = 1/[\sigma^2(F_o^2) + (0.0970 P)^2 + 09.6067 P]$, where $P = (F_o^2 + 2 F_c^2)/3$ was adopted. Refinement method full-matrix least-squares on F^2 using SHELXL-93[9d] package converged to $R1$ [$I > 2\sigma(I)$] = 0.0475, $wR2$ = 0.1478 (all data) for 751 parameters, S = 0.892, largest difference peak and hole 1.080 and −0.437 e·$Å^{-3}$.

Crystallographic data (excluding structure factors) for the structure in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication no. CCDC-101041. Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) +44(1223)336-033, E-mail: deposit@ccdc.cam.ac.uk].

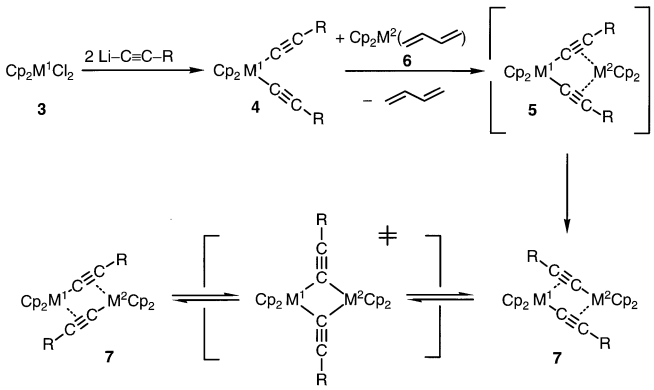
Keywords: Planar-tetracoordinate carbon / Zirconocene / Acetylide complex / Selective protonation

Bis(alkynyl)zirconocene and -hafnocene complexes **4** react with (butadiene)zirconocene or -hafnocene, respectively, to yield the binuclear σ,π-acetylide bridged complexes $[(Cp_2M)_2(\mu\text{-}C{\equiv}C{-}R)_2]$ **7** (M = Zr, Hf; R = CH_3, C_2H_5, or CH_2Ph). The complexes **7** are selectively protonated upon treatment with *N,N*-dimethylanilinium tetraphenylborate or tetrakis(pentafluorophenyl)borate to yield the dinuclear metallocene cation complexes $[(Cp_2M^1)(\mu\text{-}RCC^1{-}H)(\mu\text{-}C{\equiv}C{-}R)M^2Cp_2^+]$ **13** ($M^1 = M^2$ = Zr, **a**–**c**; M^1 = Zr, M^2 = Hf, **h**; $M^1 = M^2$ = Hf, **i**) that contain a planar-tetracoordinate carbon atom (C^1-H) bearing a hydrogen substituent. Complex **13a** was characterized by X-ray diffraction. It reveals an agostic interaction of the C^1-H moiety with the M^2Cp_2 unit. The planar-tetracoordinate carbon unit C^1-H of **13a** exhibits $^{13}C/^1H$ NMR chemical shifts of δ = 161.0 and −0.11 and a coupling constant of $^1J_{CH}$ = 103 Hz. Selective protonation of (μ-alkynyl)bis(group 4 metallocene) complexes containing other additional bridging ligands provides a rather general synthetic entry to planar-tetracoordinate carbon containing complexes of this type: $[Cp_2M^1(\mu\text{-}C{\equiv}C{-}CH_3)(\mu\text{-}Cl)M^2Cp_2]$ (**10a**–**c**, M^1, M^2 = Zr, Hf) and $[Cp_2M^1(\mu\text{-}C{\equiv}C{-}CH_3)(\mu\text{-}CH_3)M^2Cp_2]$ (**11a**,**b**) selectively add a proton from $[(HNMe_2Ph)^+(BAr_4)^-]$ at carbon atom C^1 of the acetylide ligand to yield the corresponding "anti-van't Hoff/LeBel complexes" $[Cp_2M^1(\mu\text{-}CH_3CC^1\text{-}H)(\mu\text{-}X)M^2Cp_2^+]$ (**13d**–**g** and **k**, X = Cl, CH_3), respectively.

Introduction

Planar-tetracoordinate carbon has an electronic structure that is characterized by an electron-deficient σ-system (six electrons making four bonds) and a doubly occupied p-orbital perpendicular to the σ-plane.[1] Principally, σ-electron donor and π-acceptor substituents should stabilize this "unnatural" carbon coordination geometry.[1][2] We have previously prepared a large number of thermodynamically very stable "anti-van't Hoff/Le Bel" compounds of this general type, where the planar-tetracoordinate carbon atom is part of a C=C double bond and has two metal substituents that share a sp^2-orbital in the carbon σ-plane in a three-center-two-electron bond situation.[3] A very favourable situation arises when the two geminal metal substituents have slightly different σ-donor properties. Typical examples are a combination of Cp_2Zr and AlR_2[4] or Cp_2Zr and Cp_2Zr^+.[5] The complexes **1** and **2** are typical examples out of a large variety of such systems. The stabilization energy of planar-tetracoordinate vs. planar-tricoordinate carbon in these complexes is very high (ca. 35 kcal/mol calculated for **1**, ca. 12 kcal/mol experimentally determined for **2**).[6]

The synthetic routes developed and applied so far have allowed for the preparation of a great variety of examples of the complexes of the type **1** and **2** using various combinations of metal complex fragments, bridging ligands X and of the substituents attached at the carbon atoms C^1 (i.e. the planar-tetracoordinate carbon atom) and C^2, but systems bearing a hydrogen at C^1 were not available by these routes.[7] We have now found a rather simple method to solve this synthetic organometallic problem and have prepared a variety of cationic bis(metallocene) complexes of this general type by a regioselective protonation pathway.



Results and Discussion

Synthesis of the Dinuclear Complexes

Dinuclear (μ-alkynyl)zirconocene and -hafnocene complexes were chosen as the starting materials for our new synthesis. We had previously shown that bis(alkynyl)group 4 metallocenes (**4**) react rapidly with in situ generated Cp_2M

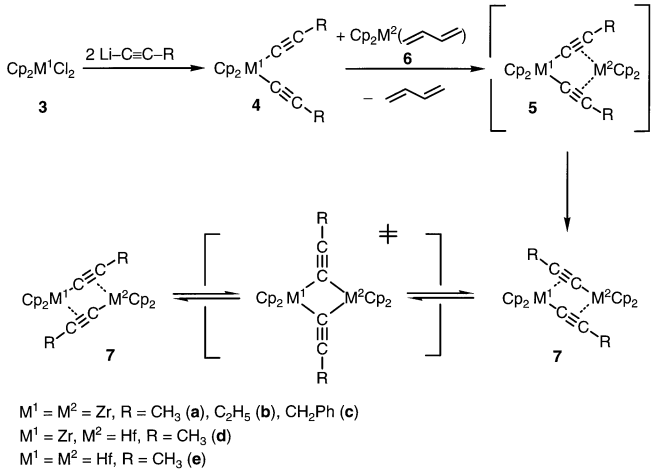
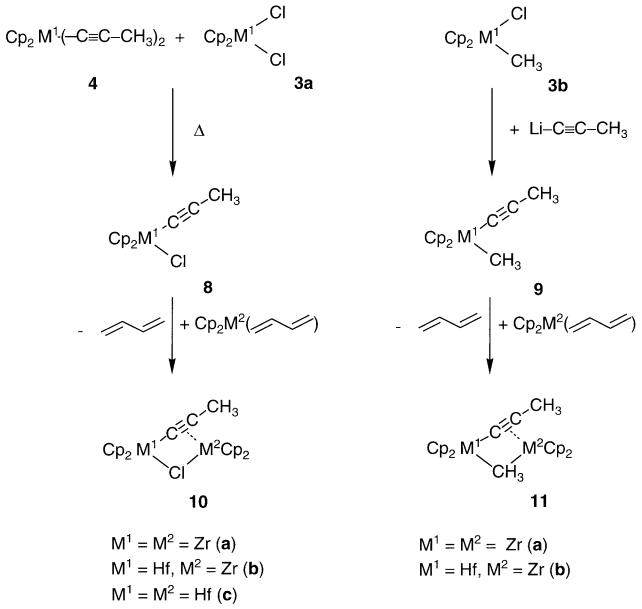


Scheme 2



(M = Zr, Hf) reagents to cleanly form the [(μ-η^1:η^2-alkynyl)$_2$(MCp$_2$)$_2$] type complexes. There is evidence that the C_{2v}-symmetric species **5** are formed first, that subsequently rearrange to the C_{2h}-complexes **6** that are eventually isolated from the reaction.[8]

We have thus treated bis(propynyl)zirconocene **4a** (M^1 = Zr, R = CH$_3$) with (butadiene)zirconocene (**6a**, M^2 = Zr)[9] in benzene at ambient temperature (18 h) and obtained the dinuclear complex **7a** in 70% yield. Complex **7a**, like many examples of this type of complexes, is dynamic and undergoes an intramolecular exchange of the two μ-η^1:η^2-alkynyl ligands within the dinuclear metal complex framework that is rapid on the NMR time scale.[8][10]

Complexes **7b** and **7c** were prepared analogously by treatment of the respective bis(alkynyl)zirconocenes **4b** and **4c** with the (butadiene)zirconocene reagent. Treatment of bis(propynyl)hafnocene (**4a′**) with (butadiene)zirconocene cleanly gave the mixed-metal complex **7d**, and treatment of **4a′** with (butadiene)hafnocene furnished the bis(μ-η^1:η^2-propynyl)bis(hafnocene) complex **7e**. The latter reaction required more drastical reaction conditions (2 d at 60°C) to liberate Cp$_2$Hf in situ.

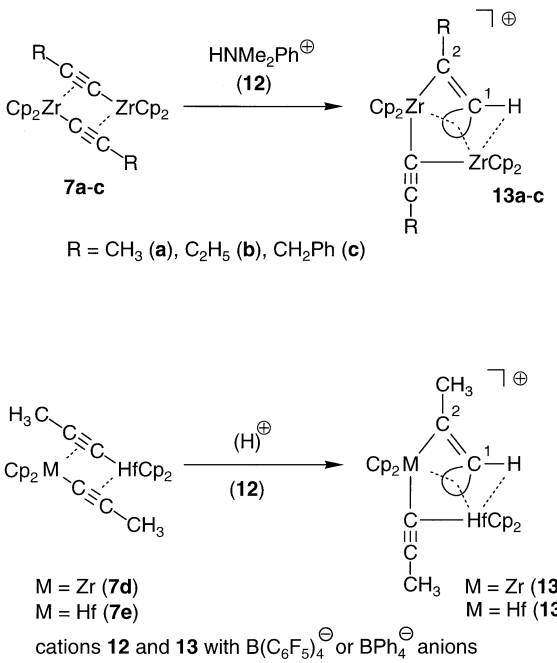
Thermally induced ligand exchange was used to prepare the (propynyl)metallocene chlorides **8**.[8] Subsequent treatment with the (butadiene)metallocenes then gave the (μ-η^1:η^2-propynyl)(μ-chloro)bis(metallocenes) **10a–c** (see Scheme 2). Treatment of **3b** with propynyllithium (to give **9**), followed by treatment with (butadiene)ZrCp$_2$, gave the (μ-η^1:η^2-propynyl)(μ-methyl)bis(metallocenes) **11a**, **b**.

In the synthesis of the μ-methyl bridged systems, only (butadiene)zirconocene was employed as the source for the in situ metallocene generation. Attempts to use the corresponding hafnocene reagent required higher temperatures that led to massive σ-ligand scrambling of the starting materials and precluded a clean product formation.

We then treated the dinuclear (μ-alkynyl)bis(metallocene) complexes **7**, **10**, and **11** with a suitable proton source. As reagents for the proton transfer reaction we choose the *N,N*-dimethylanilinium salts [HNMe$_2$Ph$^+$][B(C$_6$F$_5$)$_4^-$] (**12a**) or [HNMe$_2$Ph$^+$][BPh$_4^-$] (**12b**), respectively. Both reagents had previously been used for the synthesis of donor-ligand stabilized zirconocene derived cations, such as e.g. [Cp$_2$ZrCH$_3^+$] (from Cp$_2$Zr(CH$_3$)$_2$).[11] Thus, the here selected anions had shown to be of a sufficiently low nucleophilicity to not interfere with the formation of very electrophilic group 4 metallocene-based cation systems.

The protonation reactions in all cases led to the formation of the same cationic systems irrespective whether [BPh$_4^-$] or [B(C$_6$F$_5$)$_4^-$] was used as the counteranion. Thus, the bis(μ-η^1:η^2-propynyl)bis(zirconocene) complex **7a** was treated with one molar equivalent of the ammonium salt **12b** at −50°C in dichloromethane. After workup at room temperature a single cationic product was isolated in close to 60% yield that was identified as **13a** spectroscopically and by an X-ray crystal structure analysis (see below). The product exhibits a pair of ^{1}H/^{13}C-NMR Cp signals at δ = 6.03, 5.71 / 109.7, 108.4 (in [D$_2$]dichloromethane) and methyl group resonances at δ = 2.83, 2.44 / 25.1, 10.2. Noteworthy is the [Zr]-σ-alkenyl C^2 ^{13}C-NMR resonance at δ = 217.6 and the ^{1}H/^{13}C-NMR resonances of the planar-tetracoordinate carbon C^1-H group at δ = −0.11 (broad singlet) / 161.0 ($^1J_{CH}$ = 103 Hz). Thus, the planar-tetracoordinate carbon atom exhibits a chemical shift in the olefinic region, as it is expected for sp^2-hybridized carbon, but its $^1J_{CH}$ coupling constant is quite unusual at a very low value of close to 100 Hz. As we shall see, this is a very typical feature of the planar-tetracoordinate carbon compounds that bear a hydrogen substituent at C^1. It is probably the close vicinity of the C^1-H hydrogen to its adjacent zirconium center Zr^2 that results in such a marked decrease of the $^1J_{CH}$ value of this (sp^2)C-H moiety. According to the X-ray crystal structure analysis of **13a** (see below) an α-agostic interaction[12] between C^1-H and Zr^2 must be assumed.

Scheme 3



The protonation reactions of the related complexes **7b** and **7c** proceed analogously to yield the corresponding planar-tetracoordinate carbon complexes **13b** and **13c**, respectively. Some of their typical spectroscopic parameters are listed in Table 1. Protonation of the bis(μ-η^1:η^2-propynyl)bis(hafnocene) complex **7e** also proceeds cleanly to yield **13i**. Noteworthy is here that the C^1-*H* ^{1}H-NMR resonance is shifted markedly to a larger δ-value (+0.42) as compared to the zirconium-containing examples **10a**−**c** (see Table 1), whereas the $^1J_{C^1\text{-}H}$ coupling constant is still very low at 99 Hz. It thus may be that the ^{1}H-NMR C^1-*H* chemical shift is sensitive to the very nature of its closely adjacent metal center. This specific feature turned out to be of some diagnostic value in the protonation reactions of the heterodimetallic precursors.

Protonation of the bis(μ-η^1:η^2-propynyl)($HfCp_2$)($ZrCp_2$) complex **7d** could in principle lead to the formation of two regioisomeric products arising from H^+-addition to either the $CH_3-C\equiv C-HfCp_2$ or the $CH_3-C=C-ZrCp_2$ unit. The reaction of the heterodimetallic complex **7d** with **12b** resulted in the formation of a single organometallic product (**13h**) that was isolated in ca. 50% yield. The product exhibits ^{1}H/^{13}C-NMR pairs of Cp resonances at δ 5.94, 5.72 / 108.6, 108.1, and ^{13}C/^{1}H-NMR signals of the C^1-H unit at δ 162.5 ($^1J_{CH}$ = 100 Hz) and +0.38. The latter value is in the typical range expected of an α-agostic C^1-H moiety at $HfCp_2$. We therefore propose that protonation has occured regioselectively at the $CH_3-C\equiv C-HfCp_2$ part of the starting material **4e**, leading to the heterodinuclear planar-tetracoordinate carbon compound **13h**.

A very similar situation was found when the μ-chloro- and μ-methyl-bridged metallocene complexes were protonated. Treatment of (μ-η^1:η^2-propynyl)(μ-Cl)($ZrCp_2$)$_2$ **10a**

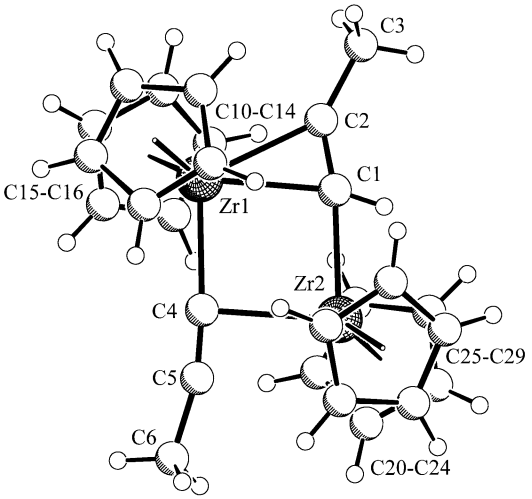
with $[HNMe_2Ph^+][B(C_6F_5)_4^-]$ (**12b**) gave rise to the formation of the planar-tetracoordinate carbon compound **13e** ($^1H/^{13}C$ NMR of the C^1-H unit: δ = 0.51/157.7 ($^1J_{CH}$ = 103 Hz). Protonation of the corresponding mixed metal compound **10b** selectively led to a single product (**13g**) whose C^1-*H* ^{1}H-NMR resonance is found shifted to δ 1.12. A similar value was found in the planar-tetracoordinate carbon complex **13k** containing the $(\mu\text{-Cl})(Cp_2Hf)_2$ framework (see Table 1), and a similar trend was observed upon protonation of **11a** and **11b** giving rise to the selective formation of the planar-tetracoordinate carbon compounds **13d** and **13f**, respectively. In all these cases the $HfCp_2$ unit ended up in the "south-east position" of the planar-tetracoordinate carbon containing dimetallic framework, similarly as it was observed for a related series of mixed metal derivatives of the complex type **2** (see above).

X-ray Crystal Structure Analysis of 13a

Single crystals suited for the X-ray crystal structure analysis were obtained by allowing a solution of **13a** [· $B(C_6F_5)_4^-$] in dichloromethane to equilibrate with toluene by gas-phase diffusion in a closed system. The dimetallic cation **13a** and the $B(C_6F_5)_4^-$ anion are independent in the crystal. In the cation the two zirconocene units are well separated from each other (Zr1···Zr2 separation 3.477 Å). The zirconium centers are connected by means of two hydrocarbyl ligands, namely the $H_3C^3C^2C^1H$ unit and the $C^4C^5C^6H_3$ moiety. The special structural features of the former make complex **13a** so noteworthy. It contains the carbon atom C^1 that is planar-tetracoordinate. Carbon atom C^1 is bonded to C^2 [d C^1-C^2 1.255(9) Å], the metal atoms Zr^1 [d Zr^1-C^1 2.377(6) Å] and Zr^2 [d Zr^2-C^1 2.274(7) Å] and a hydrogen atom (crystallographically located, d C^1-H 0.91 Å). The atoms C^1, C^2, H^1, Zr^1, and Zr^2 are oriented coplanar (their neighboring atoms C^3, C^4, C^5, C^6 are located in the same plane, which is the typical σ-ligand plane of the two group 4 bent metallocene subunits).[13] The bonding angles around the planar-tetracoordinate carbon atom C^1 are 96.7(2)° ($Zr^1-C^1-Zr^2$), 74.1(5)° ($Zr^1-C^1-C^2$), 119° ($C^2-C^1-H^1$), and 70° ($Zr^2-C^1-H^1$) (sum of bonding angles at C^1: 359.8°).

Figure 1. A view of the molecular geometry of **13a**[a]



[a] Selected bond lengths [Å] and angles [°]: Zr1−C1 2.377(6), Zr1−C2 2.365(8), Zr1−C4 2.313(6), Zr2−C1 2.274(7), Zr2−C4 2.406(6), Zr2−C5 2.693(8), Zr2−H1 2.14(7), C1−C2 1.255(9), C1−H1 0.91(7), C2−C3 1.492(10), C4−C5 1.199(9), C5−C6 1.468(10), Zr1−C1−Zr2 96.7(2), Zr1−C4−Zr2 94.9(2), Zr1−C1−C2 74.1(5), Zr1−C1−H1 166(4), Zr1−C2−C1 75.2(5), Zr1−C2−C3 144.0(6), Zr2−C1−C2 170.1(6), Zr2−C1−H1 70(4), C1−C2−C3 140.8(8), Zr1−C4−C5 174.4(6), Zr2−C4−C5 90.3(5), C4−C5−C6 166.6(8).

In a comparison with typical planar-tetracoordinate carbon compounds and related complexes of this general structural type (see Table 2) it becomes apparent that the complexes **13** exhibit a few very special bonding parameters. The Zr^1-C^1 bond, the "extra bond" between the acceptor-metallocene Cp_2Zr^1 and the planar-tetracoordinate carbon center, is the shortest found in the overall series of complexes so far. This bond is by ca. 0.12 Å shorter than its equivalent in the related bis(zirconocene) complex **2a** ($M^1 = M^2 = Zr$, $R^1 = R^2 = CH_3$) (see Scheme 5 and Table 2). Only in the μ-N≡C−Ph complex **14** is this metal-to-bridgehead atom bond shorter. We also note that the C^1-C^2 bond in **13a** is rather short. Also the Zr^1-C^2 separation in **13a** [2.365(8) Å] is much larger than this was found in **2a** [2.182(5) Å]. We conclude that the $Cp_2Zr^1(\mu\text{-}\eta^1\text{:}\eta^2\text{-}H_3C^3-C^2C^1H)(Zr^2Cp_2)$ subunit in **13a** is in its structural details somewhat different from the bonding parameters of the related typical Zr/Zr^+ or Zr/Al containing planar-tetracoordinate carbon complexes (**2**, **1**). In some of its structural characteristics this unit in **13a** still resembles its Zr(μ-acetylide)Zr precursor unit. In some respect this unit behaves more as a "protonated alkynyl complex" than a (μ-alkyne)bis(zirconocene) cation [the $C^1\equiv C^2$ bond length in the $Cp_2Zr-C\equiv C-Ph$ dimer (**7f**) is 1.261(2) Å, the corresponding Zr^1-C^1 and Zr^1-C^2 distances are 2.431(2) and 2.407(2) Å, the Zr^2-C^1 bond length is 2.188(2) Å,[8] see Scheme 5].

The structural similarity between the cationic complex **13a** and its precursor, a neutral (acetylide)metallocene di-

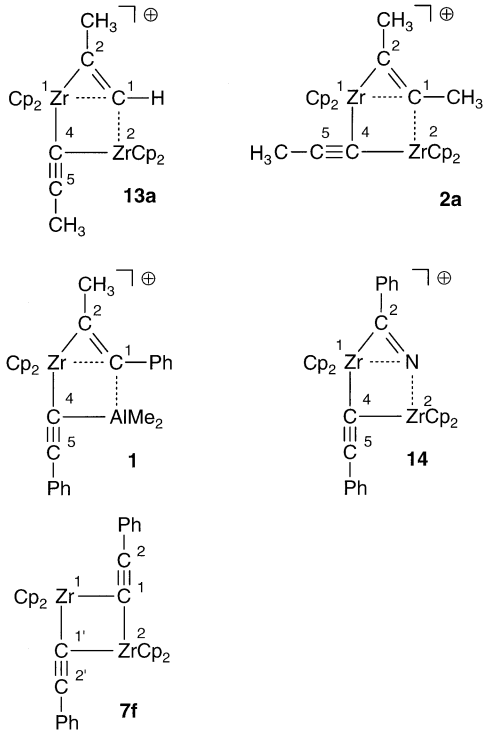
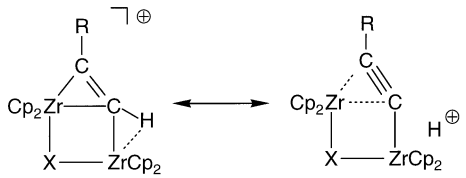
mer (**7**),[8][10] even is extending to the second bridging hydrocarbyl moiety, the μ-propynyl group.[15] In both planar-tetracoordinate carbon complexes **13** and **2** this bridge is rather unsymmetrically located between the two group 4 metallocene moieties. In **2a** it seems to be strongly σ-bonded to the metal atom Zr^2 [d Zr^2-C^4 2.263(4) Å] and leans over to Zr^1 [d Zr^1-C^4 2.472(4) Å, d Zr^1-C^5 2.814(5) Å][5][6] whereas in the complex **13a** we are encountered with the opposite geometric situation: Zr^1 is linked to C^4 by means of a strong σ-type interaction [d Zr^1-C^4 2.313(6) Å] and the C^4-C^5 triple bond [1.199(9) Å] is η^2-coordinated to Zr^2 [d Zr^2-C^4 2.406(6) Å, d Zr^2-C^5 2.693(7) Å]. The latter structural situation is similar as it is typically found in the related complexes **1** and **14** (see Scheme 5).

Scheme 5



Conclusions

Protonation of dimetallic (μ-η^1:η^2-alkynyl)bis(group 4 metallocene) complexes apparently provides a simple and efficient route to stable and easily isolable cationic planar-tetracoordinate carbon compounds. The X-ray crystal structure analysis of a representative example (**13a**) has shown that four substituents (a carbon atom, two metal centers, and a hydrogen) are oriented coplanar with carbon atom C^1 and are all strongly bonded to it. In addition, there is evidence from the NMR spectra and the X-ray structural analysis that there is some electronic interaction of this hydrogen (C^1)-*H* with the adjacent metal center Zr^2. The $^1J_{C^1\text{-}H}$ coupling constant is rather small, and the C^1-H vector seems to be "leaning over" towards Zr^2 ($Zr^2\cdots H$ separation 2.136 Å). These features may indicate the presence of some α-agostic interaction between Zr^2 and the C^1-H bond, but we must also notice that the Zr^1-C^1 and Zr^1-C^2 separations are almost equal in lengths, and that the C^2-C^1 multiple bond is rather short as is the Zr^1-C^4 linkage. All these features seem to indicate some residual structural resemblance of **13a** with its (acetylide)metallocene dimer precursor. The participation of a hyperconjugative formula (**13′**) could possibly be used to illustrate this specific structural situation.



Despite these specific structural details the complexes **13** seem to represent additional examples of a large general class of stable easily prepared planar-tetracoordinate carbon compounds. It appears that the thermochemical stabilization of the planar-tetracoordinate carbon center in these dinuclear complexes is so pronounced that protonation routes typically found in other organometallic systems, such as e.g. protolytic cleavage of metal−carbon σ-bonds, become quite disfavored here. The presence of a (probably rather acidic) hydrogen atom at the "square planar" carbon may open up ways of detecting chemical reactions which are typical for this specific bonding situation of the element carbon and for synthesizing novel, potentially functionalized derivatives. We have begun to carry out such investigations in our laboratory.

Experimental Section

Reactions with organometallic compounds were carried out in an inert atmosphere (argon) using Schlenk type glassware or in a glovebox. Solvents, including deuterated solvents used for NMR spectroscopy, were dried and distilled under argon prior to use. − The following instruments were used for physical characterization of the compounds: Bruker AC 200 P and Varian Unity plus (^{1}H: 600 MHz, ^{13}C: 150 MHz) NMR spectrometers; Nicolet 5 DXC FT-IR spectrometer; elemental analyses were carried out with a Foss-Heraeus CHN-Rapid elemental analyzer, melting points were determined by differential scanning calorimetry (2910 DSC, DuPont/STA Instruments). The spectral assignments were in most cases secured by 2D NMR methods (GHMBC, GHSQC, and GCOSY[16]). The $^1J_{C^1\text{-}H}$ coupling constants were usually determined by means of a selective 1D-GHMBC method. The (alkynyl)metallocene complexes **4** and **7**−**10**, and the (butadiene)metallocenes were prepared according to literature procedures.[8][9]

Preparation of [(μ-Methyl)(μ-propynyl)($ZrCp_2$)$_2$] **11a**: A solution containing 1.0 g (3.6 mmol) of methyl(propynyl)zirconocene and 1.0 g (3.6 mmol) of (butadiene)zirconocene in 25 ml of benzene was stirred for 24 h at room temperature. Pentane (10 ml) was added to precipitate the product, which was collected by filtration, washed three times with pentane and dried in vacuo to yield 790 mg (44%) of **11a**, m.p. 147°C (decomp.). − ^{1}H NMR (200.1 MHz,

300 K, [D$_6$]benzene): δ = 5.24, 5.17 (each s, each 10 H, Cp-H), 2.64 (s, 3 H, 3-H), −2.77 (s, 3 H, CH_3). − ^{13}C NMR (90.6 MHz, 300 K, [D$_6$]benzene): δ = 229.4 (C1), 179.7 (C2), 104.4, 102.5 (Cp), 21.5 (C≡C-CH_3), 6.08 (μ-CH_3). − $C_{24}H_{26}Zr_2$ (496.91): C 58.01, H 5.27; found C 58.13, H 5.72.

Preparation of [(μ-Methyl)(μ-propynyl)(ZrCp$_2$)(HfCp$_2$)] **11b**: Complex **11b** was prepared analogously as described above from 600 mg (1.66 mmol) of methyl(propynyl)hafnocene and 456 mg (1.66 mmol) of (butadiene)zirconocene in 25 ml of benzene (18 h, ambient temperature). Yield of **11b**: 630 mg (65%), m. p. 159°C (decomp.). ^{1}H NMR (200.1 MHz, 300 K, [D$_6$]benzene): δ = 5.22, 5.16 (each s, each 10 H, Cp-H), 2.65 (s, 3 H, 3-H), −3.09 (s, 3 H, CH_3). − ^{13}C NMR (90.6 MHz, 300 K, [D$_6$]benzene): δ = 224.6 (C1), 180.3 (C2), 104.3, 102.4 (Cp), 22.8 (C3), 5.87 (C4). − $C_{24}H_{26}HfZr$ (584.18): C 49.34, H 4.49; found C 47.72, H 4.46.

Protonation of the (μ-Propynyl)zirconocene Dimer **7a**: *Synthesis of* **13a**: A sample of complex **7a** (150 mg, 0.29 mmol) was mixed with solid *N,N*-dimethylanilinium tetrakis(pentafluorophenyl)borate **12a**. Dichloromethane (20 ml) was added at −20°C. The mixture was stirred for 1 h at this temperature and then allowed to warm to ambient temperature. Pentane (5 ml) was added. The precipitated product was collected by filtration, washed with pentane, and dried in vacuo to give 190 mg (59%) of **13a** [with $B(C_6F_5)_4^-$ anion], m.p. 229°C (decomp.). − ^{1}H NMR (599.9 MHz, 300 K, [D$_2$]dichloromethane): δ = 6.02, 5.73 (each s, each 10 H, Cp), 2.83 (d, 3 H, 3-H, $^4J_{HH}$ = 1.8 Hz), 2.44 (s, 3 H, 6-H), −0.11 (br, 1 H, 1-H). − ^{13}C NMR (150.9 MHz, 300 K, [D$_2$]dichloromethane): δ = 217.6 (C2), 161.0 (C1, $^1J_{CH}$ = 103 Hz), 109.7, 108.4 (Cp), 25.1 (C3, $^1J_{CH}$ = 129 Hz), 10.2 (C6, $^1J_{CH}$ = 133 Hz); $B(C_6F_5)_4^-$: 148.5 (*o*-C-F, $^1J_{CF}$ = 242 Hz), 138.5 (*p*-C-F, $^1J_{CF}$ = 245 Hz), 136.7 (*m*-C-F, $^1J_{CF}$ = 244 Hz), 124.2 (br, *i*-C). C4 and C5 not observed. − IR (KBr): ṽ = 3118, 2969, 2919, 2854, 2056 (C≡C), 1645, 1513, 1463, 1262, 1085, 1015, 979, 812 cm^{-1}. − $C_{50}H_{27}BF_{20}Zr_2$ (1200.97): C 50.00, H 2.27; found C 49.26, H 2.58.

X-ray Crystal Structure Analysis of **13a** [· $B(C_6F_5)_4^-$]: Single crystals were obtained by allowing a solution of **13a** in dichloromethane to equilibrate with toluene by diffusion through the gas phase over a period of several days. Formula $C_{50}H_{27}BF_{20}Zr_2$, M = 1200.97, 0.25 × 0.25 × 0.15 mm, a = 15.057(2), b = 16.618(4), c = 18.530(4) Å, β = 99.56(1), V = 4572(2) Å^3, ρ_{calc} = 1.745 g cm^{-3}, μ = 5.75 cm^{-1}, empirical absorption correction via ψ scan data (0.965 ≤ C ≤ 0.999), Z = 4, monoclinic, space group $P2_1/c$ (no. 14), λ = 0.71073 Å, T = 223 K, ω/2θ scans, 9449 reflections collected (±h, +k, −l), [(sinθ)/λ] = 0.62 Å^{-1}, 9156 independent and 5535 observed reflections [$I \geq 2\,\sigma(I)$], 663 refined parameters, R = 0.063, wR^2 = 0.137, max. residual electron density 0.71 (−0.75) e Å^{-3}, hydrogens calculated and riding, hydrogen at C1 found in Difference-Fourier map. Data set was collected with an Enraf Nonius CAD4 diffractometer equipped with a rotating anode FR 591. Programs used: data reduction MolEN, structure solution SHELXS-86, structure refinement SHELXL-93, graphics SCHAKAL-92. Crystallographic data (excluding structure factors) for the structure reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication CCDC-100817. Copies of the data can be obtained free of charge on application to The Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [fax: int. code +44(1223)336-033, e-mail: deposit@ccdc.cam.ac.uk].

Preparation of **13b**. − a) *With $B(C_6F_5)_4^-$ Anion:* 150 mg (0.27 mmol) of bis(1-butynyl)zirconocene **7b** was treated with 220 mg (0.27 mmol) of the anilinium salt **12a** analogously as described above to give 220 mg (66%) of **13b**(· $B(C_6F_5)_4^-$), m.p. 216°C (decomp.). − ^{1}H NMR (200.1 MHz, 300 K, [D$_2$]dichloromethane): δ = 6.03, 5.71 (each s, each 10 H, Cp), 3.04 (dq, 2 H, 3-H, $^4J_{HH}$ = 1.7 Hz, $^3J_{HH}$ = 7.5 Hz), 2.69 (q, 2 H, 7-H, $^3J_{HH}$ = 7.5 Hz), 1.48 (t, 3 H, 8-H, $^3J_{HH}$ = 7.5 Hz), 1.37 (t, 3 H, 4-H, $^3J_{HH}$ = 7.5 Hz), −0.16 (br, 1 H, 1-H). − ^{13}C NMR (150.9 MHz, 300 K, [D$_2$]dichloromethane), cation only: δ = 227.6 (C2), 160.4 (C1, $^1J_{CH}$ = 103 Hz), 129.5 (C6), 108.5, 107.3 (Cp), 36.1 (C4, $^1J_{CH}$ = 129 Hz), 18.4 (C8, $^1J_{CH}$ = 133 Hz), 15.9 (C5, $^1J_{CH}$ = 125 Hz), 14.6 (C3, $^1J_{CH}$ = 124 Hz); C5 not observed. − IR (KBr): ṽ = 3119, 2962, 2918, 2851, 2054 (C≡C), 1642, 1513, 1463, 1262, 1089, 1020, 980, 812 cm^{-1}. − $C_{52}H_{31}BF_{20}Zr_2$ (1229.03): C 50.82, H 2.54; found C 50.09, H 2.68.

b) *With BPh_4^- Anion:* The preparation was carried out analogously as above. Treatment of 200 mg (0.36 mmol) of **7b** with [$HNMe_2Ph^+$][BPh_4^-] (**12b**) (150 mg, 0.37 mmol) gave 185 mg (59%) of **13b**(· BPh_4^-), m.p. 193°C (decomp.).

Preparation of **13c**: Treatment of 150 mg (0.22 mmol) of **7c** with 182 mg (0.22 mmol) of **12b** was carried out analogously as described above to yield 260 mg (87%) of **13c** (m. p. 165°C, decomp.), that was characterized spectroscopically. − ^{1}H NMR (599.9 MHz, 300 K, [D$_2$]dichloromethane): δ = 7.65−7.64 (m, 4 H, Ph-H), 7.38−7.37 (m, 4 H, Ph-H), 7.20−7.18 (m, 2 H, Ph-H), 5.86, 5.74 (s, each 10 H, Cp), 4.23 (d, 2 H, 3-H, $^4J_{HH}$ = 1.4 Hz), 4.04 (s, 2 H, 6-H), −0.47 (br, 1 H, 1-H). − ^{13}C NMR (150.9 MHz, 300 K, [D$_2$]dichloromethane), cation only: δ = 225.2 (C2), 165.3 (C1), 140.8, 126.4 (C4, C5), 132.0, 129.5, 126.6, 119.4 (Ph), 110.2, 107.8 (Cp), 46.6 (C3), 30.9 (C6). − IR (KBr): ṽ = 3123, 2960, 2924, 2853, 2050 (C≡C), 1643, 1514, 1462, 1274, 1085, 978, 813 cm^{-1}.

Preparation of **13d**. − a) *With $B(C_6F_5)_4^-$ Anion:* Analogously as described above, treatment of 150 mg (0.30 mmol) of **11a** with 240 mg (0.30 mmol) of **12a** at −50°C in 20 ml of dichloromethane followed by precipitation at room temperature (5 ml of pentane was added) gave **13d** as a yellow oil. Extensive stirring and washing with pentane eventually yielded **13d** as a sticky solid material, 120 mg (34%), m.p. 162°C (decomp.). − ^{1}H NMR (599.9 MHz, 300 K, [D$_2$]dichloromethane): δ = 6.11, 5.83 (s, each 10 H, Cp), 2.69 (d, 3 H, 3-H, $^4J_{HH}$ = 1.9 Hz), 0.84 (br, 1 H, 1-H), −0.79 (s, 3 H, 4-H). − ^{13}C NMR (150.9 MHz, 300 K, [D$_2$]dichloromethane), cation only: δ = 229.8 (C2), 159.3 (C1, $^1J_{CH}$ = 108 Hz), 110.8, 108.6 (Cp), 28.5 (C3), 13.5 (C4, $^1J_{CH}$ = 111 Hz). − IR (KBr): ṽ = 3123, 2961, 2918, 2850, 1644, 1511, 1470, 1275, 1263, 1095, 1018, 973, 810 cm^{-1}.

b) *With BPh_4^- Anion:* A sample of 150 mg (0.30 mmol) of **11a** was treated with 120 mg (0.30 mmol) of **12b** in 20 ml of dichloromethane at −50°C. The mixture was stirred for 30 min at −50°C, then for 1 h at room temperature. 10 ml of toluene was added dropwise with stirring to precipitate the product that was collected by filtration, washed several times with pentane and dried in vacuo to yield 154 mg (63%) of **13d**(· BPh_4^-), m.p. 210°C (decomp.). − $C_{48}H_{47}Zr_2$ (817.15): C 70.55, H 5.80; found C 69.14, H 5.85.

Preparation of **13e**: Treatment of 150 mg (0.30 mmol) of **10a** with 230 mg (0.30 mmol) of **12a** in 20 ml of dichloromethane analogously as described above gave, after precipitation with 5 ml of pentane, 173 mg (48%) of **13e**, m. p. 193°C (decomp.). − ^{1}H NMR (599.9 MHz, 300 K, [D$_2$]dichloromethane): δ = 6.15, 5.79 (s, each 10 H, Cp), 2.79 (d, 3 H, 3-H, $^4J_{HH}$ = 1.8 Hz), 0.50 (br, 1 H, 1-H). − ^{13}C NMR (150.9 MHz, 300 K, [D$_2$]dichloromethane), cation only: δ = 273.7 (C2), 157.7 (C1, $^1J_{CH}$ = 103 Hz), 112.5, 109.4 (Cp), 25.3 (C3, $^1J_{CH}$ = 129 Hz). − IR (KBr): ṽ = 3126, 2966, 2924, 2853, 1644, 1515, 1463, 1276, 1262, 1086, 979, 816 cm^{-1}. − $C_{47}H_{24}BClF_{20}Zr_2$ (1197.37): C 47.15, H 2.02; found C 47.18, H 2.18.

Preparation of **13f**: 150 mg (0.26 mmol) of **11b** was treated with 114 mg (0.28 mmol) of **12b** in 20 ml of dichloromethane at room temperature (45 min). Precipitation with 10 ml of toluene gave a solid that was washed with pentane and dried in vacuo. Yield of **13f**(· BPh_4^-) 180 mg (77%), m.p. 219°C (decomp.). − ^{1}H NMR (599.9 MHz, 300 K, [D$_2$]dichloromethane): δ = 5.92, 5.83 (s, each 10 H, Cp), 2.75 (d, 3 H, 3-H, $^4J_{HH}$ = 1.8 Hz), 1.48 (br, 1 H, 1-H), −0.72 (s, 3 H, 4-H); BPh_4: 7.41−7.33 (m, 8 H, Ph-H), 7.10−7.07 (m, 8 H, Ph-H), 6.96−6.89 (m, 4 H, Ph-H). − ^{13}C NMR (150.9 MHz, 300 K, [D$_2$]dichloromethane), cation only: δ = 233.7 (C2), 160.1 (C1, $^1J_{CH}$ = 106 Hz), 110.1, 109.2 (Cp), 27.0 (C3), 13.3 (C4, $^1J_{CH}$ = 111 Hz). − IR (KBr): $\tilde{\nu}$ = 3109, 3053, 3029, 2981, 2919, 2893, 1579, 1478, 1426, 1366, 1264, 1015, 816, 741, 705, 607 cm^{-1}. − $C_{48}H_{47}BHfZr$ (904.42): C 63.75, H 5.24; found C 61.28, H 5.20.

Preparation of **13g**: A sample of 150 mg (0.25 mmol) of **10b** was treated with 200 mg (0.25 mmol) of **12a** at −30°C in dichloromethane. After stirring for 30 min at −30°C and 30 min at room temperature the product was precipitated by slowly adding pentane (10 ml) at 0°C. The product was collected by filtration, washed with pentane and dried in vacuo to yield 210 mg (65%) of **13g** [· $B(C_6F_5)_4^-$], m.p. 147°C (decomp.). − ^{1}H NMR (599.9 MHz, 300 K, [D$_2$]dichloromethane): δ = 6.13, 5.85 (s, each 10 H, Cp-H), 2.83 (d, 3 H, 3-H, $^4J_{HH}$ = 1.8 Hz), 1.12 (q, 1 H, 1-H, $^4J_{HH}$ = 1.8 Hz). − ^{13}C NMR (150.9 MHz, 300 K, [D$_2$]dichloromethane), cation only: δ = 227.1 (C2), 156.4 (C1, $^1J_{CH}$ = 99 Hz), 111.3, 109.5 (Cp), 26.2 (C3, $^1J_{CH}$ = 129 Hz). − IR (KBr): $\tilde{\nu}$ = 3251, 3121, 2960, 2921, 2871, 1644, 1514, 1463, 1273, 1087, 979, 819, 661 cm^{-1}. − $C_{47}H_{24}BClF_{20}HfZr$ (1284.64): C 43.94, H 1.88; found C 43.14, H 2.38.

Preparation of **13h**: A sample of 160 mg (0.26 mmol) of **7d** was treated with 190 mg (0.26 mmol) of **12a** at −50°C in 30 ml of dichloromethane. The mixture was stirred at −50°C for 1 h and then warmed up to room temperature. Addition of 5 ml of pentane gave a red oil, that was solidified by means of a prolonged treatment with 20 ml of pentane to give 170 mg (51%) of **13h** [· $B(C_6F_5)_4^-$], m.p. 206°C (decomp.). − ^{1}H NMR (599.9 MHz, 300 K, [D$_2$]dichloromethane): δ = 5.94, 5.72 (s, each 10 H, Cp), 2.84 (d, 3 H, 3-H, $^4J_{HH}$ = 1.8 Hz), 2.53 (s, 3 H, 6-H), 0.37 (br, 1 H, 1-H). − ^{13}C NMR (150.9 MHz, 300 K, [D$_2$]dichloromethane), cation only: δ = 162.5 (C1, $^1J_{CH}$ = 100 Hz), 108.6, 108.1 (Cp), 25.6 (C3), 10.5 (C6). C2, C4, C5 not found. − IR (KBr): $\tilde{\nu}$ = 3126, 2961, 2923, 2853, 1644, 1514, 1467, 1272, 1087, 980, 813 cm^{-1}. − $C_{50}H_{27}BF_{20}HfZr$ (1288.25): C 46.62, H 2.11; found C 47.13, H 2.60.

Preparation of **13i**: Treatment of 150 mg (0.22 mmol) of **7e** with 173 mg (0.22 mmol) of **12a** at −50°C in 20 ml of dichloromethane analogously as described above, followed by addition of 10 ml of toluene gave a brown oil that was solidified by treatment with pentane. Yield of **13i** [· $B(C_6F_5)_4^-$]: 190 mg (63%), m.p. 224°C (decomp.). − ^{1}H NMR (599.9 MHz, 300 K, [D$_2$]dichloromethane): δ = 5.97, 5.65 (s, each 10 H, Cp), 2.90 (d, 3 H, 3-H, $^4J_{HH}$ = 1.8 Hz), 2.46 (s, 3 H, 6-H), 0.41 (br, 1 H, 1-H). − ^{13}C NMR (150.9 MHz, 300 K, [D$_2$]dichloromethane), cation only: δ = 225.1 (C2), 167.4 (C1, $^1J_{CH}$ = 99 Hz), 109.0, 107.4 (Cp), 27.5 (C3, $^1J_{CH}$ = 128 Hz), 12.0 (C6). − IR (KBr): $\tilde{\nu}$ = 3117, 2961, 2920, 2855, 1643, 1514, 1463, 1374, 1263, 1086, 1016, 979, 817 cm^{-1}. − $C_{50}H_{27}BF_{20}Hf_2$ (1375.52): C 43.66, H 1.98; found C 42.99, H 2.44.

Preparation of **13k**: A sample of 150 mg (0.22 mmol) of **10c** was treated with 173 mg (0.22 mmol) of **12a** at −30°C in 20 ml of dichloromethane. After stirring for 1 h at −30°C and 1 h at room temperature the product was precipitated by addition of 5 ml of pentane. The resulting oil was washed with toluene and then solidified by prolonged treatment with 20 ml of pentane to yield 110 mg (37%) of **13k** [· $B(C_6F_5)_4^-$], m.p. 136°C (decomp.). − ^{1}H NMR (599.9 MHz, 300 K, [D$_2$]dichloromethane): δ = 6.12, 5.80 (s, each 10 H, Cp), 3.43 (d, 3 H, 3-H, $^4J_{HH}$ = 4.8 Hz), 1.04 (q, 1 H, 1-H, $^4J_{HH}$ = 4.8 Hz). − ^{13}C NMR (150.9 MHz, 300 K, [D$_2$]dichloromethane), cation only: δ = 228.6 (C2), 160.8 (C1, $^1J_{CH}$ = 97 Hz), 111.1, 108.4 (Cp), 26.3 (C3, $^1J_{CH}$ = 129 Hz). − IR (KBr): $\tilde{\nu}$ = 3129, 2959, 2925, 2854, 1643, 1514, 1463, 1273, 1088, 979, 822 cm^{-1}.

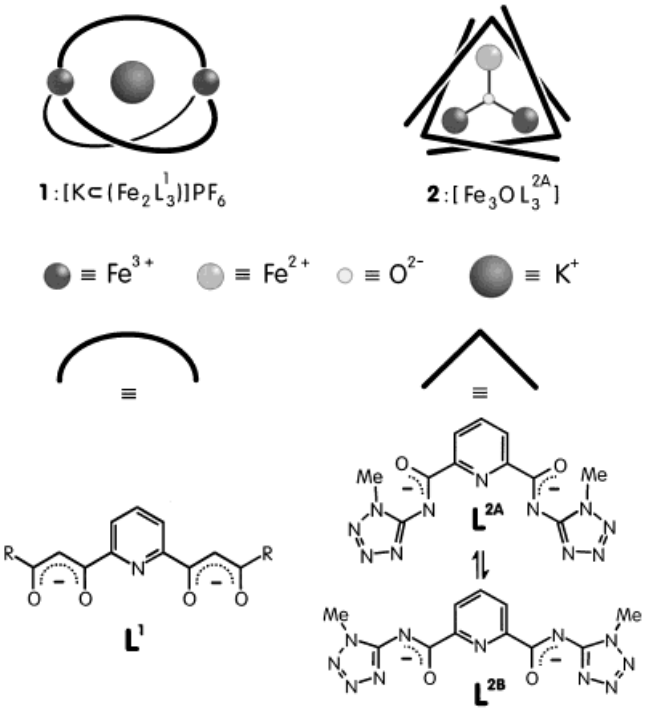
Keywords: Metal(II) complexes / Octanuclear complexes / Supramolecular chemistry / Zinc / Cadmium / Manganese

The reaction of H_2L^1 and H_2L^2 with divalent metal ions leads to octanuclear bis(triple-helical) metal(II) complexes of the general composition $[Zn_8O_2L^2{}_6]$ (**3**) and $[M_8O_2L^1{}_6]$ (**4**: M = Cd^{2+}; **5**: M = Mn^{2+}). NMR studies of the diamagnetic cadmium complex **4c** show six equivalent ligands. Unambiguous characterisation of **5b** was achieved by X-ray crystallographic analysis.

There is considerable interest in the design of metallosupramolecular oligomers containing a defined number of metal ions in a determined spatial arrangement. In principle, it is possible to selectively generate a large variety of structures by choosing the appropriate ligands and metal ions.[1][2] Our interest in polynuclear supramolecular complexes, with two or more Fe^{III} ions bridged by oxygen and nitrogen donor ligands, stems mainly from the importance of oxo-centered polyiron aggregates as model compounds for metalloproteins, oxidation catalysts and corrosion inhibitors.[3]

Complexation of trivalent Fe ions with the doubly negatively charged, pentadentate ligand L^1 leads to the {2}-metallacryptate $[K\subset(Fe_2L^1{}_3)]PF_6$ (**1**).[4] In contrast to L^1, nucleation of iron with the isodentate ligand L^2 yields the triple-helical, oxo-centered, trinuclear mixed-valence iron complex $[Fe_3OL^{2A}{}_3]$ (**2**)[5] but, unexpectedly, no {2}-metallacryptate $[K\subset(Fe_2L^{2B}{}_3)]PF_6$. This result can be explained by the fact that the pentadentate ligand L^2 exists as two different rotamers, L^{2A} and L^{2B} in solution. In the case of L^{2A} the coordination donors are five nitrogen atoms, whereas in the case of L^{2B} the donor atoms are three nitrogen and two oxygen atoms. Due to the topological equivalency of the ligand L^1 and the rotamer L^{2B}, one expects to obtain, using appropriate transition metals, isostructural complexes by nucleation of L^1 and L^2.

Herein we describe the reaction of the pentadentate tritopic ligands L^1 and L^{2B} with divalent metal ions such as zinc, cadmium and manganese. Treatment of 0.75 equiv. of the pyridylene-spacered tetraketone[6] H_2L^1 or the bis(tetrazole)[7] H_2L^2, with one equiv. of zinc acetate, cadmium or manganese dichloride furnishes the coordination compounds **3**−**5** which range from colourless to orange in appearance.



The compositions of these complexes were determined by FAB mass spectrometry (FAB = fast-atom bombardment). The FAB-MS spectrum of complex $[Zn_8O_2L^{2B}{}_6]$ (**3**) exhibits the correct molecular peak and isotopic pattern at *m*/*z* 2519 (Figure 1). According to their FAB-MS data, the corresponding cadmium (**4**) and manganese (**5**) complexes have the same composition.

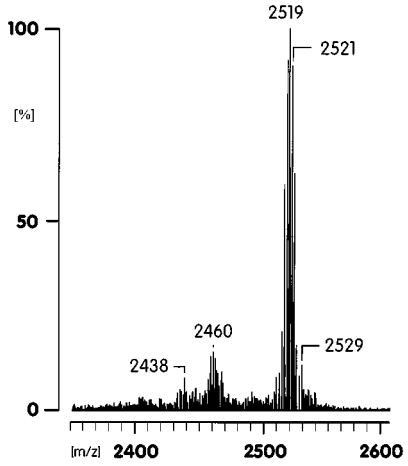
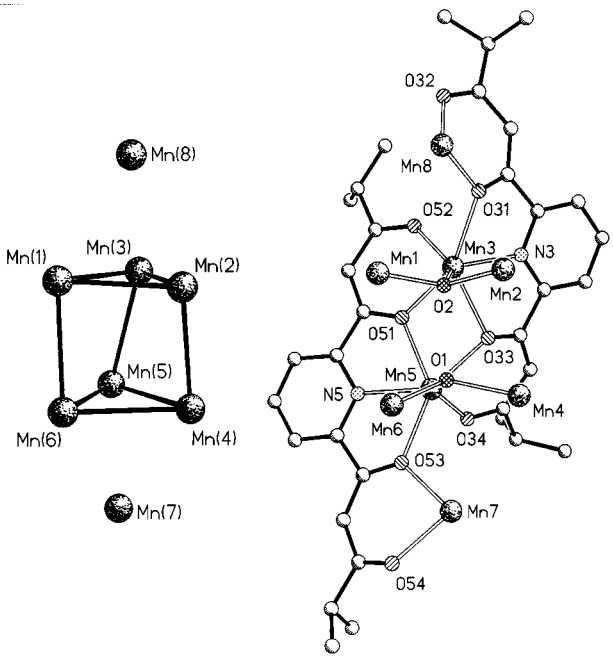
Figure 1. FAB-MS spectrum of zinc complex **3**



^{1}H- and ^{13}C-NMR studies of the diamagnetic cadmium complex [$Cd_8O_2L_6{}^{1c}$] (**4c**) reveals that, in solution, all six ligands are chemically identical, but that the two halves of each ligand are in different magnetic environments. Consequently, the ^{13}C-NMR spectrum of **4c** displays a double set of signals in contrast to the single set of the protonated free ligand H_2L^{1c}.

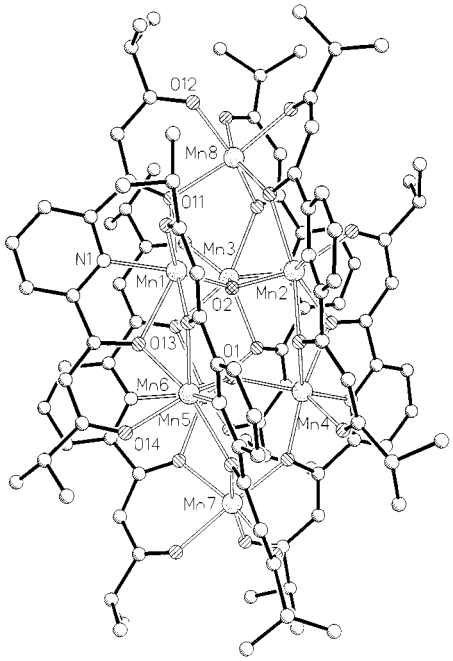
In order to unequivocally establish the structure of the polynuclear systems **3**−**5**, the manganese complex **5b** was taken as a representative example and we carried out an X-ray crystallographic analysis.[8] According to this analysis, **5b** is present in the crystal as a neutral, octanuclear bis(triple-helical) chelate complex. The core of **5b** consists of eight manganese(II) ions, forming a twofold capped, slightly twisted trigonal prism with a μ_3-O^{2-} ion centered in each of the two inner faces (Figure 2.). All the six doubly negatively charged pentadentate ligands L^{1b} link to three manganese atoms. The two antipodal manganese(II) ions are coordinated by three μ_1- and three μ_2-oxygen chelate atoms of three ligands. However, the six metal centers, constituting the trigonal prism, are coordinated by one pyridylene nitrogen and two μ_2-chelate oxygen atoms. Distorted octahedral coordination of these six manganese(II) ions is achieved by two extra μ_3-O^{2-} ions.

Figure 2. Left: Core of the octanuclear complex **5b** to highlight the bicapped distorted trigonal prism; right: Octanuclear core of **5b** showing two ligands and the μ_3-O^{2-} ions; H atoms omitted for clarity, O atoms hatched, C atoms shaded, N atoms empty, Mn atoms dotted



Consequently, in the neutral, octanuclear, bis(triple-helical) complex **5b** all the manganese(II) ions are octahedrally coordinated (Figure 3).

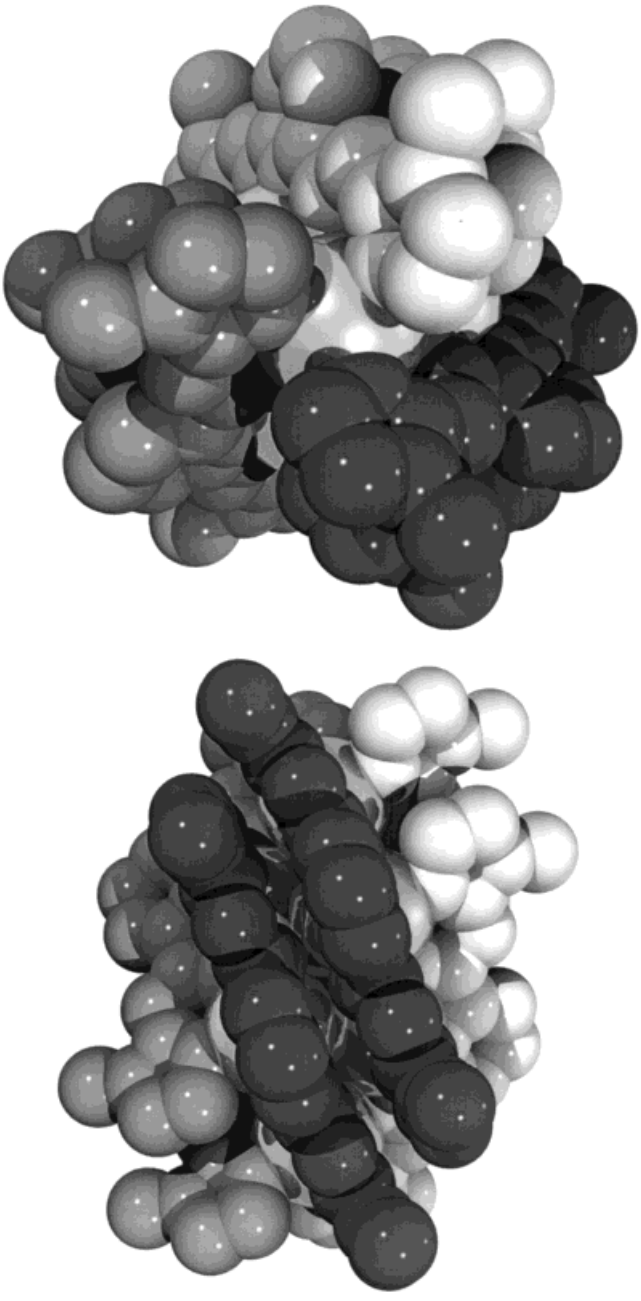
Figure 3. Molecular structure of the octanuclear complex **5b** in the crystal; H atoms omitted for clarity, O atoms hatched, C atoms shaded, N atoms empty, Mn atoms dotted



As shown by X-ray crystallographic analysis[12], the zinc complex **3** is isostructural with **5b**. The space-filling model

of **3** (Figure 4) illustrates the bis(triple-helical) arrangement of the ligands.

Figure 4. Space-filling model of bis(triple-helical) octanuclear $[Zn_8O_2L^{2B}{}_6]$ (**3**); top: view along the C_3 axis; bottom: view along the C_2 axis



The similarity between the core of the octanuclear complex **3** and the metal framework of the iron-molybdenum co-factor of the nitrogenase MoFe protein[13] is noteworthy (Figure 5).

In conclusion these results demonstrate clearly that the formation of metalla-supramolecular structures is highly sensitive with respect to the metal ions, the ligands and their conformation. In contrast to the {2}-iron(III) cryptate **1** and the oxo-centered iron(III) complex **2,** both ligands $(L^1)^{2-}$ and $(L^{2A}/L^{2B})^{2-}$ lead to the isostructural bis(triple-helical) octanuclear complexes, i.e. $[Zn_8O_2L^{2B}{}_6]$ (**3**), $[Cd_8O_2L^1{}_6]$ (**4**) and $[Mn_8O_2L^1{}_6]$ (**5**).

Financial support from the *Deutsche Forschungsgemeinschaft*, the *Volkswagen-Stiftung* and the *Fonds der Chemischen Industrie* is gratefully acknowledged. We would like to thank Prof. Dr. *K.-P. Zeller*, University of Tübingen, for the FAB-MS measurements.

Experimental Section

^{1}H- and ^{13}C-NMR spectra: Jeol JNM-GX-400 (400 MHz; 100 MHz) spectrometer with TMS as internal standard, chemical shifts are given in ppm. − Mass spectra: Varian MAT 3rA (EIMS) or a Finnigan MAT TSQ 70 instrument (ion desorption from *m*-NBA matrix: 10 keV xenon atoms, FAB MS). − Microanalyses: Heraeus CHN-Mikroautomat. − IR: Perkin−Elmer 1420 Ratio-Recording Infrared Spectrophotometer.

General Procedure for the Synthesis of the Bis(tetrazole) Ligand **H_2L^2**: A cooled suspension of 2.0 g (20 mmol) *N*-methylaminotetrazole and 2.0 g (47 mmol) of dry lithium chloride was placed in a three-necked, round-bottom flask, fitted with a condenser. The contents of the flask were stirred, while 2.03 g (10 mmol) of 2,6-pyridinedicarboxylic dichloride was slowly added. The solution was poured into ice-cold water (400 ml), stirred for 2 h and the white precipitate was filtered off, washed with water and dried in vacuo (oil pump).

N,N′-Bis(1-methyl-1H-tetrazol-5-yl)pyridyl-2,6-dicarboxamide (**H_2L^2**): Yield 2.77 g (84%), white powder, m.p. > 250°C (decomp.). − IR (KBr): $\tilde{\nu}$ = 3340 cm^{-1}, 3120 (NH), 3020 (=CH), 2920 (CH_3), 1690 (C=O), 1550 (C=C). − ^{1}H NMR (CD_3CN/CF_3COOD): δ = 4.25 (s, 6 H, 2 CH_3), 8.39 (t, $^3J_{H,H}$ = 7.7 Hz, 1 H, 4-pyridyl-CH), 8.63 (d, $^3J_{H,H}$ = 7.7 Hz, 2 H, 3,5-pyridyl-CH). − ^{13}C NMR

(CD_3CN/CF_3COOD): δ = 37.08 (2 CH_3), 129.84 (3,5-pyridyl-CH), 142.56 (4-pyridyl-CH), 148.13 (2,6-pyridyl-C=), 150.25 (2 CN_2), 164.19 (2 C=O). − MS (EI, 70 eV); *m/z*: 330 [M^+]. − $C_{11}H_{11}N_{11}O_2$ (329.32): calcd. C 40.12, H 3.37, N 46.80; found C 39.55, H 3.74, N 45.93.

General Procedure for the Synthesis of the Octameric Zinc Complex **3**: A solution of 293 mg (1.33 mmol) of $Zn(OAc)_2 \cdot 2\ H_2O$ in methanol (50 ml) was added to a solution of 329 mg (1.0 mmol) bis(tetrazole) H_2L^2 in acetonitrile (400 ml). The reaction mixture was stirred and heated under reflux for 24 h. The resulting precipitate was filtered off washed with diethyl ether and dried in vacuo. The resulting solid was recrystallized from hot acetonitrile.

[$Zn_8O_2L^{2b}{}_6$]$_2$ (**3**): Yield 365 mg (87%) of colourless crystals from acetonitrile, m.p. > 250°C (decomp.). − IR (KBr): $\tilde{\nu}$ = 1640 cm^{-1} (C=O), 1550 (C=C), 1450 (C=N). − MS (FAB, *m*-NBA); *m/z*: 2519 [M^+]. − $C_{66}H_{54}N_{66}O_{14}Zn_8$ (2518.70): calcd. C 31.48, H 2.16, N 36.70; found C 31.53, H 2.98, N 36.16.

General Procedure for the Synthesis of the Pyridyl-Spacered Tetraketones (**H_2L^1**): A suspension of 1.0 g (44 mmol) of freshly cut sodium and diethyl 2,6-pyridinedicarboxylate (4.90 g, 22 mmol) in dry benzene (50 ml) was placed in a three-necked, round-bottom flask, fitted with a condenser. The contents of the flask were stirred, while a solution of the corresponding methyl ketone (44 mmol) in benzene (25 ml) was added dropwise. Stirring at room temp. was continued for 30 min until the yellow sodium salt had precipitated out of the solution. The reaction mixture was heated gently for about 2−4 h. The sodium salt was collected by filtration and washed thoroughly with petroleum ether before drying. The dry solid was added to dilute hydrochloric acid (2 N, 50 ml) and the resulting solid was collected by filtration. The crude products were recrystallized from the mentioned solvents.

1,1′-(2,6-Bispyridyl)bis-1,3-butanedione (**H_2L^{1a}**): [The ^{1}H-NMR spectrum shows the presence of keto-enol tautomers. In the following we describe only the main tautomer (90%), the bis(keto-enol) system.] Yield 2.30 g (42%), yellow microcrystals from methanol, m.p. 60°C. − IR (KBr): $\tilde{\nu}$ = 3450 cm^{-1} (OH), 2920 (CH), 1720 (C=O), 1620 (C=C). − ^{1}H NMR ($CDCl_3$): δ = 2.30 (s, 6 H, 2 CH_3), 6.87 (s, 2 H, 2 =CH), 7.99 (t, $^3J_{H,H}$ = 7.7 Hz, 1 H, 4-pyridyl-CH), 8.24 (d, $^3J_{H,H}$ = 7.7 Hz, 2 H, 3,5-pyridyl-CH), 15.75 (br. s, 2 H, 2 =C−OH). − ^{13}C NMR ($CDCl_3$): δ = 26.13 (2 CH_3), 97.27 (2 =CH), 124.29 (3,5-pyridyl-CH), 138.16 (4-pyridyl-CH), 151.71 (2,6-pyridyl-C=), 180.43 (2 =C−OH), 194.92 (2 C=O). − MS (EI, 70 eV); *m/z*: 247 [M^+]. − $C_{13}H_{13}NO_4$ (247.25): calcd. C 63.15, H 5.31, N 5.67; found C 63.23, H 5.49, N 5.63.

1,1′-(2,6-Bispyridyl)bis-4-methyl-1,3-pentanedione (**H_2L^{1b}**): [The ^{1}H-NMR spectrum shows the presence of keto-enol tautomers. In the following we describe only the main tautomer (75%), the bis-(keto-enol) system.] Yield 2.40 g (36%), yellow microcrystals from methanol, m.p. 44°C. − IR (l, $CHBr_3$): $\tilde{\nu}$ = 3480 cm^{-1} (OH), 2950 (CH), 1600 (C=O), 1550 (C=C). − ^{1}H NMR ($CDCl_3$): δ = 1.27 (d, $^3J_{H,H}$ = 7.0 Hz, 12 H, 4 CH_3), 2.37 [sept, 2 H, 2 $CH(CH_3)_2$], 6.92 (s, 2 H, 2 =CH), 7.98 (t, $^3J_{H,H}$ = 7.7 Hz, 1 H, 4-pyridyl-CH), 8.19 (d, $^3J_{H,H}$ = 7.7 Hz, 2 H, 3,5-pyridyl-CH), 15.81 (br. s, 2 H, 2 =C−OH). − ^{13}C NMR ($CDCl_3$): δ = 19.23 (4 CH_3), 37.55 [2 $CH(CH_3)_2$], 94.67 (2 =CH), 124.63 (3,5-pyridyl-CH), 138.40 (4-pyridyl-CH), 151.80 (2,6-pyridyl-C=), 181.61 (2 =C−OH), 201.79 (2 C=O). − MS (EI, 70 eV); *m/z*: 303 [M^+]. − $C_{17}H_{21}NO_4$ (303.36): calcd. C 67.31, H 6.98, N 4.62; found C 67.02, H 6.88, N 4.69.

1,1′-(2,6-Bispyridyl)bis-4,4′-dimethyl-1,3-pentanedione (**H_2L^{1c}**): Yield 0.93 g (13%), colourless needles from methanol, m.p. 124°C: − IR (l, $CHBr_3$): $\tilde{\nu}$ = 3440 cm^{-1} (OH), 2970 (CH), 1610 (C=O), 1570 (C=C). − ^{1}H NMR ($CDCl_3$): δ = 1.30 (s, 18 H, 6 CH_3), 7.13 (s, 2 H, 2 =CH), 7.99 (t, $^3J_{H,H}$ = 7.8 Hz, 1 H, 4-pyridyl-CH), 8.19 (d, $^3J_{H,H}$ = 7.8 Hz, 2 H, 3,5-pyridyl-CH), 15.90 (br. s, 2 H, 2 = C−OH). − ^{13}C NMR ($CDCl_3$): δ = 27.24 (6 CH_3), 39.87 [2 $C(CH_3)_2$], 92.59 (2 =CH), 123.98 (3,5-pyridyl-CH), 138.21 (4-pyridyl-CH), 151.86 (2,6-pyridyl-C=), 182.39 (2 =C−OH), 202.78 (2 C=O). − MS (EI, 70 eV); *m/z*: 331 [M^+]. − $C_{19}H_{22}NO_4$ (331.41): calcd. C 68.86, H 7.58, N 4.23; found C 68.34, H 7.56, N 4.24.

General Procedure for the Synthesis of the Octameric Cadmium (**4a−c**) *and Manganese* (**5a−c**) *Complexes:* Aqueous ammonia (2 ml, 12%) was added dropwise to a solution of 184 mg (1.0 mmol) cadmium chloride or 126 mg (1.0 mmol) manganese(II) chloride and the appropriate pyridyl-spacered ligand H_2L^1 (0.75 mmol) in ethanol (100 ml), until no more turbidity was seen. To achieve complete precipitation of the products, water (100 ml) was added. The products were filtered off and dried in vacuo (oil pump) and recrystallized from the solvents described above.

[$Cd_8O_2L^{1a}{}_6$] (**4a**): Yield 180 mg (60%), yellow microcrystals from ethanol, m.p. 290°C (decomp.). Because of the total insolubility in all available solvents, detailed NMR investigations could not be carried out. − IR (KBr): $\tilde{\nu}$ = 2970 cm^{-1} (CH), 1610 (C=O), 1585 (C=C). − MS (FAB, *m*-NBA); *m/z*: 2402 [M^+]. − $C_{77}H_{66}Cd_8N_6O_{26}$ (2402.69): calcd. C 38.99, H 2.77, N 3.50; found C 41.60, H 3.99, N 3.61.

[$Cd_8O_2L^{1b}{}_6$] (**4b**): Yield 320 mg (94%), yellow microcrystals from ethanol, m.p. 275°C (decomp.). Because of the total insolubility in all available solvents, detailed NMR investigations could not be carried out. − IR (l, $CHBr_3$): $\tilde{\nu}$ = 2960 cm^{-1} (CH), 1610 (C=O), 1500 (C=C) − MS (FAB, *m*-NBA); *m/z*: 2740 [M^+]. − $C_{102}H_{114}Cd_8N_6O_{26}$ (2739.34): calcd. The R values are: $R1 = \Sigma|F_o - F_c|/\Sigma F_o$ = 0.0552 [I > 2σ(I)]; $wR_2 = [\Sigma w(F_o^2 - F_c^2)^2/\Sigma wF_o^4]^{1/2}$ = 0.1126 (all data); min/max residual electron density −407 e nm^{-3}/596 e nm^{-3}. Four isopropyl groups and one pyridine solvent molecule are disordered over two sites. The electron density at two pyridine nitrogen atoms was modelled as a lithium atom. A hydrogen atom attached to a bridging oxygen atom could not be located in the difference Fourier synthesis. In view of the possibility of disorder, X-ray analysis cannot provide a definite assignment in such a case. Crystallographic data for **5b** were collected with a Stoe-Siemens-Huber four-circle diffractometer with Siemens CCD area detector by using φ-scans on a shock-cooled crystal in an oil drop[9]. Data integration was performed with the program SAINT. A semiempirical absorption correction was applied. The structure was solved by direct methods (SHELXS-97)[10] and refined against F^2 by the least squares[11]. All non-hydrogen atoms were refined anisotropically. For the hydrogen atoms a riding model was employed. All disordered components were refined anisotropically with the assistance of distance and *ADP* restraints. Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication no. CCDC-100830. Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + (1223) 336-033; E-mail: deposit@ccds.cam.ac.uk].

A New Class of Oligonuclear Platinum-Thallium Compounds with a Direct Metal−Metal Bond
3. Unusual Equilibria in Aqueous Solution[◇]

Keywords: Equilibrium / Metal-metal bond / Stability constants / Platinum / Thallium / NMR

A new series of four binuclear platinum-thallium cyano compounds containing a direct and unsupported by ligands metal−metal bond has been prepared in aqueous solution. These compounds are represented by the formula $[(NC)_5Pt-Tl(CN)_{n-1}]^{(n-1)-}$ (n = 1−4 for compounds **I**, **II**, **III** **IV,** respectively) and $[(NC)_5Pt-Tl-Pt(CN)_5]^{3-}$ (for compound **V**). The oligonuclear complexes are synthesised according to the reaction $m Pt(CN)_4^{2-} + Tl^{3+} + nCN^- \rightleftharpoons [Pt_mTl(CN)_{4m+n}]^{3-2m-n}$. Thus, there occurs a change of the coordination number of the Pt center from four (square planar) to six (octahedral). Consequently, the formation of binuclear platinum-thallium cyano compounds involves at least two steps: (i) formation of metal−metal bond and (ii) formation of $(NC)_5Pt-$ unit by a cyanide transfer process. − The complexes exist in an equilibrium, which also includes the parent complexes $Pt(CN)_4^{2-}$ and $Tl(CN)_n^{3-n}$ (n = 0−4), and can be controlled by varying the cyanide concentration and/or pH of the solution. The stability constants of the compounds $\beta_N = [Pt_mTl(CN)_{4m+n}^{3-2m-n}] / \{[Pt(CN)_4^{2-}]^m \cdot [Tl^{3+}] \cdot [CN^-]^n\}$ have been determined by means of multinuclear NMR (^{195}Pt, ^{205}Tl): $\log\beta_N$ = 19.9±0.4, 30.7±0.3, 38.6±0.3, and 44.8±0.2 for **I**, **II**, **III**, and **IV** (m = 1, n = 1−4), and 32.1±0.3 for **V** (m = 2, n = 2), respectively, (in 1 M $NaClO_4$ as ionic medium, at 25 °C). To our knowledge, the present work constitutes the first detailed equilibrium study of metal−metal bonded compounds; it indicates that also other cluster formation reactions described in the literature may represent real equilibria.

Introduction

Starting from the report of Nagle et al. on the six-coordinated platinum in the structure of *trans*-$Tl_2Pt(CN)_4$,[3] a few oligometallic compounds containing platinum and thallium have been synthesised and their properties studied.[4][5][6][7][8][9] Recently, we have published a study of new binuclear platinum-thallium cyano compounds containing a direct metal−metal bond.[1] Their structure has been studied in solution[2] as well as in the solid state.[10] In the present study a new aspect of these small clusters′ chemistry is explored, namely their equilibrium behaviour in aqueous solution. The data on reversible equilibrium processes for metal−metal bonded compounds is practically non-existent.[11][12][13] Also for metal−carbon bonded compounds (excluding cyano complexes) the information is very scarce.[14][15] Equilibrium models, which are routinely used in coordination chemistry, would provide obvious advantages also for cluster chemistry, e.g. to increase the yield of a reaction by shifting the equilibrium in the direction of required species using the law of mass action in a quantitative way, or for catalytic studies providing speciation of the potentially active complexes, thus allowing the chemist to tune their redox potential, selectivity, etc.

Our interest on two-electron transfer reactions in solution prompted us to study the equilibria of the $Tl^{III}-Pt^{II}-CN^-$ system in water. The advantage of these components for a multinuclear NMR study is obvious, all atoms have suitable NMR active nuclei (see in refs.[1] and[2]). ^{205}Tl NMR is superior in sensitivity, and its huge chemical shift scale provides slow exchange regimes for the different species, thus allowing to follow the concentration distribution of the formed clusters. A further advantage of the direct spectroscopic detection of the different species was that the evaluation of the overall stability constant values of this relatively complicated system was possible without any sophisticated data treatment, using only molar ratios calculated from the NMR integrals and the mass balance equations. In this context, the structural change in the geometry of the platinum coordination sphere from four- to six-coordination in a two-step formation reaction of the platinum−thallium cluster is also discussed.

Results and Discussion

Preliminary experiments aimed at finding new complexes[2] indicated that the speciation of the Pt-Tl bimetallic complexes varies at different total concentrations of the

components, Tl^{3+}, $Pt(CN)_4^{2-}$, CN^-, and H^+. Changing the concentration of any of the components shifted the distribution of the reactants and/or products, and demonstrated the existence of several types of chemical equilibria in the solutions.

In solutions with molar ratio Pt/Tl ≤ 1, bimetallic compounds are present only as binuclear species **I**−**IV**, at Pt/Tl > 1 a trimer **V** can be formed. The formation of the complexes in solution can be described by the following equilibrium:

$$m\ Pt(CN)_4^{2-} + Tl^{3+} + n\ CN^- \rightleftharpoons [Pt_mTl(CN)_{4+n}]^{(n-1)-} \quad (1)$$

giving the following overall stability constant:

$$\beta_N = [Pt_mTl(CN)_{4m+n}^{3-2m-n}] / \{[Pt(CN)_4^{2-}]^m \cdot [Tl^{3+}] \cdot [CN^-]^n\} \quad (1a)$$

where $m = 1$, $n = 1$, 2, 3, and 4 for **I**, **II**, **III**, and **IV**; and $m = 2$, $n = 2$ for **V**, respectively. The following simultaneous equilibria taking place in this system must also be considered:

$$Tl^{3+} + n\ CN^- \rightleftharpoons Tl(CN)_n^{3-n} \quad (2)$$

with $\beta_n = [Tl(CN)_n^{3-n}] / \{[Tl^{3+}] \cdot [CN^-]^n\}$,[20] and

$$CN^- + H^+ \rightleftharpoons HCN \quad (3)$$

with $K_H = K_a^{-1} = [HCN] / \{[CN^-][H^+]\}$.[21]

Although the stepwise formation/dissociation of platinum(II) cyano complexes could also be considered, the only species detected in ^{195}Pt-NMR spectra at the current experimental conditions were $Pt(CN)_4^{2-}$ and $[Pt_mTl(CN)_{4m+n}]^{3-2m-n}$ (and in some solutions also $Pt(CN)_6^{2-}$, which formed as a product of a slow photo-induced irreversible redox reaction). This finding is in accordance with the known properties of the complex, $Pt(CN)_4^{2-}$, namely its high stability (different values of $\log\beta_4$ can be found in the literature, ranging from 35 up to 65)[22] and kinetic inertness.[23] Based on these facts the species $Pt(CN)_4^{2-}$ was treated as a stable component.

The "addition reactions" between the complexes $Pt(CN)_4^{2-}$ and $Tl(CN)_n^{3-n}$ resulting in binuclear complexes:

$$Pt(CN)_4^{2-} + Tl(CN)_n^{3-n} \rightleftharpoons [PtTl(CN)_{4+n}]^{(n-1)-} \quad (4)$$

can be represented by the equilibrium constants,

$$K_N^{add} = [PtTl(CN)_{4+n}^{(n-1)-}] / \{[Pt(CN)_4^{2-}] \cdot [Tl(CN)_n^{3-n}]\} \quad (4a)$$

for $n = 1$, 2, 3, and 4, referring to complexes **I**, **II**, **III**, and **IV**, respectively. These constants can be calculated from the signal integrals of the Tl-containing species and the concentration of $Pt(CN)_4^{2-}$. The latter can be calculated from the following mass balance equation:

$$[Pt]_{tot} = [Pt(CN)_4^{2-}] + [\mathbf{I}] + [\mathbf{II}] + [\mathbf{III}] + [\mathbf{IV}] + [Pt(CN)_6^{2-}] \quad (5)$$

where the concentration of $Pt(CN)_6^{2-}$ can be assumed to be practically equal to that of Tl^+, due to the redox reaction: $Tl^{III} + Pt^{II} \rightleftharpoons Tl^+ + Pt^{IV}$. Equilibrium constants were determined and are: $\log K_{II}^{add} = 4.2$ (±0.3), (based on 10 experimental points); $\log K_{III}^{add} = 3.6$ (±0.3), (3 points); $\log K_{IV}^{add} = 2.3$ (±0.1), (21 points). The small number of points for measuring $\log K_{III}^{add}$ is due to the experimental finding that the complex $Tl(CN)_3$ is a minor species existing in an unbuffered region of the titration curve. $Tl(CN)^{2+}$ was not observed at any of the current experimental conditions; hence, a direct determination of K^{add} was not possible. The values of stability constants obtained for the complexes **II**−**IV** demonstrate high thermodynamic stability of the bimetallic Pt-Tl complexes as compared to the reagents.

The formation of the bimetallic species, **II**, **III**, and **IV** can also be described by a stepwise coordination of CN^- ions to **I**:

$$[PtTl(CN)_{4+(n-1)}]^{(n-2)-} + CN^- \rightleftharpoons [PtTl(CN)_{4+n}]^{(n-1)-} \quad (6)$$

giving equilibrium constants, $K_N = [PtTl(CN)_{4+n}^{(n-1)-}] / \{[PtTl(CN)_{4+(n-1)}^{(n-2)-}] \cdot [CN^-]\}$ for $n = 2$, 3 and 4, referring to the complexes $n =$ **II**, **III**, and **IV**, respectively. These constants, K_N, can be calculated from the signal integrals of the Pt-Tl-containing species, measured for suitable titration points and using $[CN^-]$ calculated from the mass balance equation:

$$[CN]_{tot} = [CN^-] + [HCN] + n\,[Tl(CN)_n^{3-n}] + 4\,[Pt(CN)_4^{2-}] + 5\,[\mathbf{I}] + 6\,[\mathbf{II}] + 7\,[\mathbf{III}] + 8\,[\mathbf{IV}] + 6\,[Pt(CN)_6^{2-}] \quad (7)$$

It should be noted, that the protonation equilibrium must also be considered when calculating values of K_N. Free cyanide concentrations were calculated by means of Eq. 3 from the equilibrium hydrogen ion concentration, $[H^+]$, obtained from the pH-potentiometric titrations (see Supplementary Material). The calculated values are: $\log K_{II} = 10.8$ (±0.2), (24 experimental points) and $\log K_{III} = 6.6$ (±0.4), (5 points). The latter one calculated for 5 points is less reliable; for $\log K_{IV}$ no trustworthy value could be calculated, due to the same reasons as discussed above for $\log K_{III}^{add}$. The trend of the constants follows the normal decrease of the stepwise stability constants, although the decrease is somewhat smaller compared to the corresponding values for the parent complexes, $Tl(CN)_2^+$ ($\log K_2 = 13.2$), $Tl(CN)_3$ ($\log K_3 = 8.5$).[20] The pronounced weakening of the bond between thallium and cyanide ligands in **II** and **III** compared to $Tl(CN)_2^+$ and $Tl(CN)_3$, respectively, can be attributed to the strong influence of the $(NC)_5Pt-$ unit coordinated to the thallium atom in these complexes.

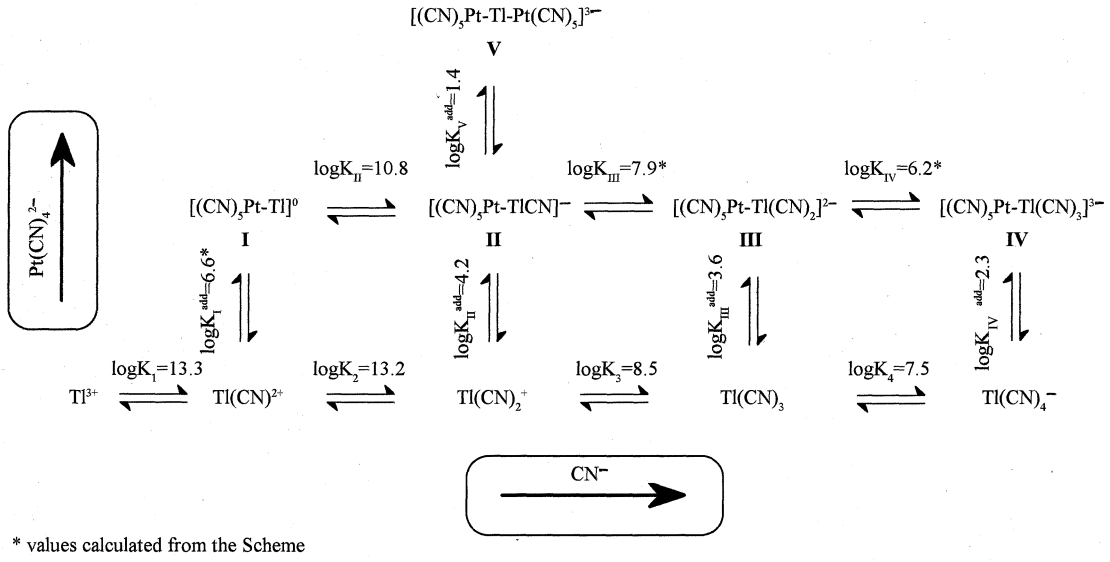
In addition, a trinuclear complex **V** with the formula $[(NC)_5Pt-Tl-Pt(CN)_5]^{3-}$ is formed in solutions where the Pt/Tl ratio is larger than 1. This complex can be considered as an adduct of **II** and $Pt(CN)_4^{2-}$:

$$[PtTl(CN)_6]^- + Pt(CN)_4^{2-} \rightleftharpoons [Pt_2Tl(CN)_{10}]^{3-} \quad (8)$$

with an equilibrium constant,

$$K_V^{add} = [Pt_2Tl(CN)_{10}^{3-}] / \{[Pt(CN)_4^{2-}] \cdot [PtTl(CN)_6^-]\} \quad (8a)$$

K_v ^{add} can easily be calculated from the integral ratios of **II** and **V** (R = [**II**]/[**V**]) measured by ^{205}Tl NMR, and from the equilibrium concentration of $Pt(CN)_4^{2-}$ derived from ^{195}Pt NMR; K_v ^{add} = 1/(R·[$Pt(CN)_4^{2-}$]). It can be noted that no additional data are needed, and the experimental conditions for samples D1−D5 were selected in order to achieve comparable values of integrals for **II** and **V**, and to obtain measurable integrals for [$Pt(CN)_4^{2-}$] in order to minimize the uncertanties related to the integration (see Supplementary Material). Samples, D2−D5 are in fact a serial dilution of D1. The higher the total concentrations the larger the fraction of the trimer. From these data (5 experimental points), K_v ^{add} = 1.44 ±0.03 was calculated (see Scheme).



The equilibria describing the chemical system (components: $Pt(CN)_4^{2-}$, Tl^{3+} , CN^-, and H^+) are shown in the Scheme. It shows how the reactions 4, 6, and 8 result in formation of the different Pt-Tl complexes. These equilibria are related to each other and some of them can be calculated independently. From the known stepwise stability constants ($\log K_n$) for the parent complexes, $Tl(CN)_n^{3-n}$,[20] and the values of $\log K_{II}^{add}$, $\log K_{III}^{add}$, $\log K_{IV}^{add}$, and K_V^{add} determined in this work, we obtain

$\log K_{III} = \log K_3 + \log K_{III}^{add} - \log K_{II}^{add} = 7.9$ and
$\log K_{IV} = \log K_4 + \log K_{IV}^{add} - \log K_{III}^{add} = 6.2$.

In the following, when calculating the overall stability constants β_N, this value of $\log K_{III}$ is used instead of the directly determined and less reliable one (vide supra).

In addition the Scheme gives one more constant which is not directly measurable:

$\log K_I^{add} = \log K_2 + \log K_{II}^{add} - \log K_{II} = 6.6$.

These data can easily be converted to overall stability constants, $\log\beta_N = \log K_N^{add} + \log\beta_n$ (N = **I**−**IV**) and $\log\beta_V = \log\beta_{II} + \log K_V^{add}$ (cf. Eq. 1a); the values of $\log\beta$ are given in Table 1.

A typical distribution diagram of the studied chemical system, calculated using the data of Table 1 and ref.[20], is given in Figure 1. The increase of the free cyanide ion concentration with increasing pH causes further coordination of CN^- to the thallium atom of the binuclear Pt-Tl species and thus the equilibrium shifts towards the formation of Pt-Tl complexes with a higher number of cyanide ligands. In the presence of excess $Pt(CN)_4^{2-}$, compound **II** can also be transferred to **V**, but the formation of the trinuclear complex might be supressed by CN^- competition resulting in formation of compound **III**. At higher pH, the mononuclear complexes of platinum [$Pt(CN)_4^{2-}$] and thallium [$Tl(CN)_4^-$] are also present (i.e. equilibrium 4 is shifted to the left). Decrease of the pH shifts reaction 4 to the right, showing that the metal−metal bond formation in aqueous solution is reversible. Certainly, varying the pH shifts also

Table 1. Overall stability constants[a][b] of the Pt-Tl complexes I−V. $\beta_N = [Pt_mTl(CN)_{4m+n}^{3-2m-n}] / \{[Pt(CN)_4^{2-}]^m \cdot [Tl^{3+}]\cdot[CN^-]^n\}$, where m = 1, n = 1, 2, 3, and 4 for **I**, **II**, **III**, and **IV**; and m = 2, n = 2 for **V**, respectively. III	38.6±0.3
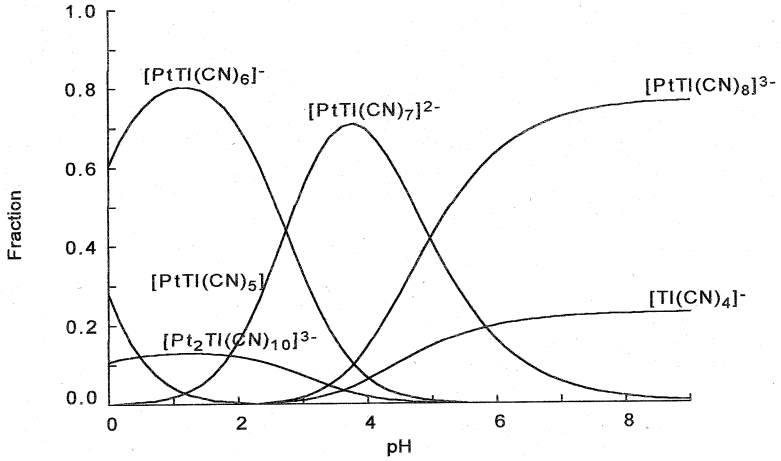
IV	44.8±0.2
V	32.1±0.3

[a] Uncertainties are averaged deviations from the mean value calculated for the individual titration points; and attributed to uncertainties in the $\log K_N^{add}$ values (cf. Eqs. 4a and 8a), except for the error in **I**, which was estimated as the sum of uncertainties in $\log K_{II}^{add}$ and $\log K_{II}$. − [b] The value of $\log K_H$ = 9.3 (cf. eq 3) was estimated from pH-potentiometric titration (titration C) and was used for the calculation of the constants, K_N. Note that the ionic strength, $I \approx$ 1 M, was varying slightly during the titration and could reach up to 1.3 at high pH values.

Figure 1. Typical distribution of thallium-containing species in aqueous solution as a function of pH, as calculated from the determined stability constants (Table 1)[a]



[a] $[Pt]_{tot}$ = 40 mM, $[Tl]_{tot}$ = 30 mM, $[CN]_{tot}$ = 280 mM.

the equilibrium of reaction 6, similarly as for the parent $Tl(CN)_n^{3-n}$ species.

These thermodynamic data (K_N^{add}) could be used as a quantitative measure of the stability or strength of the Pt−Tl bond only if the simple formation of an adduct between platinum and thallium cyanides took place by means of the reaction:

$$Pt(CN)_4^{2-} + Tl(CN)_n^{3-n} \rightleftharpoons (NC)_4Pt-Tl(CN)_n^{(n-1)-} \quad (9)$$

and if the entropy term is negligible. However, the structural data discussed in our recent paper[2] show that in all the bimetallic complexes five cyanides are coordinated directly to the Pt-center, and this $(NC)_5Pt-$ unit is, in turn, coordinated to the Tl atom. The species $[Pt^{II}CN)_5]^{3-}$ has not been reported previously and it is likely that it does not exist; accordingly, no formation constant has been measured.[24] When the free $[CN^-]$ is decreased, the equilibrium is shifted towards species with lower cyanide content, down to complex **I** with no cyanide ligands coordinated to the thallium atom, whereas the $(NC)_5Pt-$ unit remains unchanged. Thus, the stability constant for the coordination of the "fifth" cyanide to the Pt atom must be larger compared to all cyanides bound to thallium in the binuclear compounds.

It seems unreasonable that an extra cyanide ligand would be coordinated to the $Pt^{II}(CN)_4^{2-}$ complex without oxidation of platinum; hence, the formation of the $(NC)_5Pt-$ unit must be preceded or accompanied by an electron transfer from Pt to Tl leading to the formation of a Pt−Tl bond. Therefore, reaction 4 should involve at least two steps: (i) formation of metal−metal bond according to reaction 9 and (ii) formation of $(NC)_5Pt-$ unit by a cyanide transfer reaction. Whether these reactions are simultaneous or not should be subject of further study.

It can be noted that most information on complexes with metal−metal bonds in the literature has been obtained for the solid state; the reported solution studies were aimed mainly at structural characterisation of the species. In this context, the qualitatively studied $[Rh(CO)_2Cl]_2-[Co(CO)_4]^-$ system in toluene can be mentioned;[11] it exhibits some features similar to the bimetallic Pt-Tl cyanide compounds. Heteropolynuclear complexes formed in the Rh-Co solutions are in equilibrium which is governed by the Rh/Co ratio. The presumed bimetallic compound $(R_4N)[Rh(CO)_2ClCo(CO)_4]$ decomposes by addition of either Cl^- or OH^- ions to give mononuclear species. In another carbonyl mixed metal cluster, $[Re_7C(CO)_{21}Tl]^{2-}$, dissociation of μ_3-Tl^I was followed by infrared spectroscopy in acetone and a dissociation constant $K = 2.1 \cdot 10^{-3}$ M was calculated.[13] Also for the related cyano metal clusters equilibrium data are very scarce. A study of a stepwise coordination of cyanide to Mo−Mo and W−W bonded clusters has been published, but a formation of the metal−metal bond is not involved in the qualitative description of the equilibria.[12][25] In another study, an estimated stability constant (10^6) has been reported for the CN-bridged iron-platinum species.[26]

In the case of metal−carbon bonds there are a few papers containing equilibrium data. In our earlier work[14][15] we characterized the formation of monoketonato-thallium(III) ion in aqueous solution. In this equilibrium ketonato and the chloride ligands are in competition for Tl^{III}.

Conclusions

Reaction between $Pt(CN)_4^{2-}$ and $Tl(CN)_n^{3-n}$ (n = 1−4) complexes in aqueous solution results in the formation of a family of heteropolynuclear cyano complexes. Depending on the molar ratio Pt/Tl, cyanide concentration and pH, four binuclear complexes **I−IV** with the general composition $[(CN)_5Pt-Tl(CN)_{n-1}]^{(n-1)-}$ (n = 1− 4) and a trinuclear species **V** with the formula $[(NC)_5Pt-Tl-Pt(CN)_5]^{3-}$ can be obtained.

If kept in dark, the complexes are in chemical equilibrium. The distribution between the bimetallic compounds can be altered by varying the cyanide concentration (e.g. by changing the pH), and/or by changing the Pt/Tl ratio. An

excess of cyanide shifts equilibria 4 and 8 from the Pt-Tl complexes to mononuclear platinum and thallium cyano species. The high values of stability constants calculated for the bimetallic complexes **I−V** imply thermodynamically favourable formation of both the metal−metal bond and the $(CN)_5Pt-$ unit; the latter can be considered to be a ligand coordinated to thallium. Comparison of the stepwise stability constants for $[(CN)_5Pt-Tl(CN)_{n-1}]^{(n-1)-}$ complexes with those for the corresponding parent $Tl(CN)_n^{3-n}$ compounds (cf. Scheme) demonstrates the strong influence of the platinum cyano unit resulting in a substantial weakening of the Tl−C bonds.

It is very unusual that equilibria are reported for metal−metal bonded compounds and, according to our knowledge, the present work constitutes the first detailed equilibrium study of such a system. These results suggest that many of the reactions resulting in cluster formation are real equilibria (although many can be dominantly shifted to one direction) and that they can be studied using the tools of equilibrium coordination chemistry. Further work is certainly required to confirm if this observation applies to other cluster formation reactions which have been reported in the literature.

Supplementary Material

Data of the equilibrium study (tables of titration data from 6 independent potentiometric and NMR titrations and a serial dilution) can be obtained from the authors.

Experimental Section

Materials: A concentrated (1.45 M) aqueous solution of $Tl(ClO_4)_3$ in 3.77 M $HClO_4$ was obtained by anodic oxidation of $TlClO_4$.[16] Solutions of thallium(III) cyanide complexes were synthesised by addition of a calculated volume of a sodium cyanide solution (and NaOH when needed) to the stock solution of thallium(III) perchlorate. Potassium tetracyanoplatinate(II) trihydrate (Aldrich, reagent grade) was used without further purification. The solution of sodium tetracyanoplatinate(II) was prepared by precipitation of potassium perchlorate from the aqueous solution of $K_2Pt(CN)_4$ with an excess of aqueous sodium perchlorate at 275 K and was used as a stock platinum solution.

Equilibrium Studies: All the solutions were kept dark to avoid photochemical decomposition. Samples were prepared by mixing the solutions of $Na_2Pt(CN)_4$ and $Tl(CN)_2^+$ both containing 1 M $NaClO_4$ as ionic medium, and the solutions were kept at room temperature overnight prior to titrations. The complex, $Tl(CN)_2^+$, was prepared from thallium(III) perchlorate (1.45 mol/l Tl^{3+} and 3.77 mol/l H^+) and sodium cyanide solutions (molar ratio CN/Tl = 3) which resulted in exclusive formation of $Tl(CN)_2^+$ species (at the actual pH value). 2.00-ml samples containing $[Tl]_{tot}$ = 54.0 mM, $[Pt]_{tot}$ = 49.8 mM, $[CN]_{tot}$ = 334 mM, were titrated with an aqueous solution of: (titration A) 3.32 M $HClO_4$ (starting pH 4.7) or (titration B) 3.5 M NaCN (starting pH 3.6). In a different experiment, 2.26 ml sample with $[Tl]_{tot}$ = 44.3 mM, $[Pt]_{tot}$ = 57.5 mM, $[CN]_{tot}$ = 341 mM, $[HClO_4]$ = 382 mM was titrated with 3.5 M NaCN (titration C) (see Supplementary Material).

The titrations were performed by using a syringe to add aliquotes of the titrant (5−100 μl) into the NMR tube through a rubber seal, and subsequently recording ^{205}Tl-NMR spectra to measure the signal integrals of the Tl^{III}-containing species and Tl^+. Tl^+ was present as a contaminant in the thallium(III) stock solution and as a product of the slow, but not negligible redox reaction due to the some unavoidable exposure to light. Nevertheless, the Tl^+ content never exceeded 15% of the total thallium concentration.[1][17]

In order to study the formation of the trinuclear complex samples (titration D) were prepared where the Pt/Tl ratio was 2. D1−D5: pH = 1.7±0.2, $[Tl]_{tot}$ = 40.0 mM, 30.0 mM, 20 mM, 15 mM, and 10 mM; $[Pt]_{tot}$ = 2 $[Tl]_{tot}$, $[CN]_{tot}$ = 11 $[Tl]_{tot}$, respectively. ^{205}Tl-NMR spectra were recorded as for the titrations mentioned above, and the $[Pt(CN)_4^{2-}]$ was also measured by integration of the ^{205}Pt-NMR signal. Since the individual species were in the slow exchange regime on the actual ^{205}Tl- and ^{205}Pt-NMR time scales, the signal integrals could be measured and the mole ratios calculated.

In order to measure $[H^+]$, the samples identical to A, B, and C were used to measure the pH by potentiometric titrations. pH values were measured by a combination electrode connected to a pH-meter (Radiometer PHM93). The readings of the electrode were calibrated to pH values using the method of Irving for pH > 1,[18] and by direct determination for pH < 1. These data resulted in *stoichiometric stability constants.*

NMR Measurements: NMR spectra were recorded with Bruker AM400 and Bruker DMX500 spectrometers at a probe temperature of 298 (±0.5) K. The following, typical NMR parameters were used:

^{205}Tl NMR: (AM400) spectrometer frequency (SF) = 230.8 MHz; spectral window (SW) = 50 kHz; pulse width (PW) = 7 μs (flip angle ca. 30°); pulse repetition time 2.16 s; digital resolution 12 Hz/point; and number of scans = 200−1000; (DMX500) SF = 288.49 MHz; SW = 7.2 kHz; pulse width (p1) = 9.6 μs (flip angle 90^0); pulse repetition time 5.33 s; digital resolution 18 Hz/point; number of scans 500. The chemical shifts are referred in ppm toward higher frequency from the ^{205}Tl-NMR signal of an aqueous solution of $TlClO_4$, extrapolated to infinite dilution. The transmitter frequency (O1) was positioned at the resonance of the ^{205}Tl nuclei uncoupled to ^{195}Pt and the intensity of this signal was measured directly from the spectra. In the equilibrium study, the sum of the integrals (in the absolute intensity mode) measured at different points of the NMR titration was not constant because the 90° pulse varied with the acidity of the sample resulting in a non-equal excitation of the signals. This was, however, not a problem since the total concentration of thallium in the titrated solution was known throughout the titration. Aqueous solutions of 25 and 50 mM $TlClO_4$ in 1 M $NaClO_4$ were used to calibrate the signal integrals. The accuracy of the integrals was estimated to 3−5%.

^{195}Pt NMR: (AM400) SF = 85.6 MHz; SW = 50 kHz; PW = 6 μs (flip angle ca. 30°); pulse repetition time 2.16 s; digital resolution 8 Hz/point; number of scans = 1000−10000; (DMX500) SF = 107.03 MHz; SW = 16 kHz ; P(90^0) = 13.0 μs (flip angle 90^0); pulse repetition time 1.3 s; digital resolution 17 Hz/point; number of scans 1500. The chemical shifts were measured relative to an external standard of aqueous 0.1 M Na_2PtCl_6 which is 4533 ppm

to higher frequency from $\Xi(^{195}Pt) = 21.4$ MHz at 25 ^{0}C.[19] A 15.0 mM aqueous solution of $K_2Pt(CN)_4$ was used for calibration of intensities of signals when measuring quantitative integrals. The accuracy of the integrals was estimated to 3−5%.

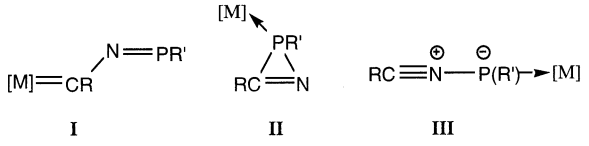
Keywords: Phosphorus heterocycles / 2*H*-Azaphosphirene complexes / Carbene complexes / Chromium / Molybdenum

The synthesis of 3-phenyl-substituted 2*H*-azaphosphirene pentacarbonylchromium and pentacarbonylmolybdenum complexes is reported. New information on the rearrangement cascade, which finally leads to 2*H*-azaphosphirene ring formation, has been obtained through isolation of a reactive intermediate. A comparison of the ^{13}C-, ^{15}N-, ^{31}P-NMR, and UV/vis spectroscopic data and single crystal X-ray structural data of 3-phenyl-substituted 2*H*-azaphosphirene chromium, molybdenum, and tungsten complexes is presented.

Over the last three years we have focussed our attention on the synthesis and chemistry of 2*H*-azaphosphirene tungsten complexes (**II**) (Scheme 1).[2] These complexes show a fascinating reactivity upon ring opening to give, depending on the reaction conditions, nitrilium phosphane ylide tungsten complexes (**III**)[1][3] and/or an electrophilic terminal phosphanediyl tungsten complex.[4] Meanwhile, both reactive intermediates have found several applications in the synthesis of heterocycles.[5]

Scheme 1. 2-Aza-1-phospha-4-metallabutadienes **I**, 2*H*-azaphosphirene metal complexes **II** and their acyclic isomers, the nitrilium phosphane ylide metal complexes **III**; **I**, **II**, **III**: R, R′ = alkyl, aryl; [M] = metal complex fragment



I **II** **III**

Our first synthetic route to 2*H*-azaphosphirene tungsten complexes used a rearrangement cascade in which transiently formed metallaheterobutadienes **I**, which are isomeric to **II** and **III**, were assumed to be key intermediates.[2a] The elucidation of the reaction course was an intriguing problem for us and, therefore, we decided to investigate the reaction of the aminobenzylidene chromium **1a**[6] and molybdenum complex **1b**[7] with [bis(trimethylsilyl)methylene]chlorophosphane (**2**).[8]

When we first carried out the reaction of complex **1a** with methylenechlorophosphane **2** in ether at ambient temperature and in the presence of triethylamine, we obtained a complicated product mixture. According to ^{31}P-NMR spectroscopic measurements the mixture contained approximately ten products, most of them appearing as singuletts in the spectra. Although these products could not be separated by column chromatography, the chromium complex **5** and the 2*H*-azaphosphirene chromium complex **6a**, the latter formed only in small amounts, were easily identified by their typical ^{31}P-nuclear magnetic resonances [**5**: δ = 95.4 (s) and **6a**: δ = −54.3 (s)]. Three other products showed chemical shift values at low field [δ = 518.6 (s)/425.4 (s), and δ = 476.3 (d)/445.1 (d), the latter with a $^{31}P,^{31}P$ coupling constant of 515 Hz]. Because of these typical chemical shift and coupling constant values, their identification was achieved by comparison with the data of compounds known in literature as bis[bis(trimethylsilyl)methyl]diphosphene [δ = 517 (s)][9] and the corresponding mono- and dinuclear diphosphene pentacarbonylchromium complexes, [{$(Me_3Si)_2HCP{=}PCH(SiMe_3)_2$}$Cr(CO)_5$]: δ = 475.8 and 444.3, $^1J(P,P)$ = 516 Hz and [{$(Me_3Si)_2HCP{=}PCH(SiMe_3)_2$}$[Cr(CO)_5]_2$]: δ = 425.9 (s).[10]

In contrast, the molybdenum complex **1b** gave the 2*H*-azaphosphirene molybdenum complex **6b** straight away, but only in low yields (28%). This reaction behavior underlines the close relationship between aminobenzylidene molybdenum and tungsten complexes. Significantly better yields of **6a** (30%) and **6b** (67%) were obtained if the reactions of **1a** and **1b** with **2** were carried out at low temperature (**1a**: −40°C; **1b**: −10°C). Apart from triethylammonium chloride, the 2*H*-azaphosphirene metal complexes **6a**, **b** and the phosphanediyl-bridged dinuclear chromium carbene complex **5a** were obtained in good yields after low-temperature column chromatography. The nature of complex **5a** as a long-lived intermediate was determined by reacting a pure sample of it with triethylamine under similar reaction conditions. Therefore we assume that the overall reaction pro-

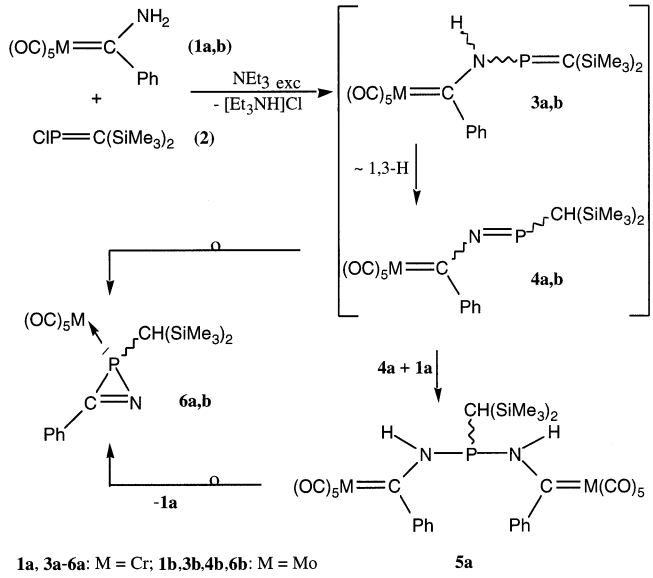
Scheme 2. Synthesis of 2*H*-azaphosphirene metal complexes **6a**, **b**

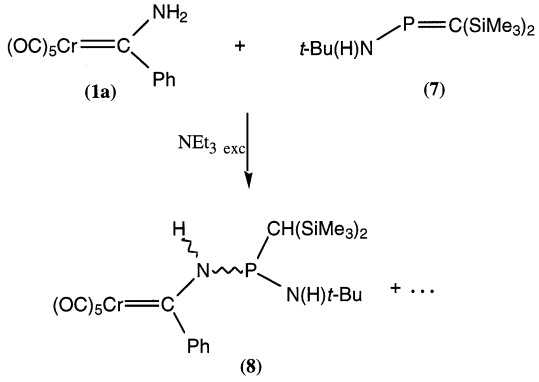


ceeds through the rearrangement cascade depicted in Scheme 2.

An additional experiment was carried out to shed more light on the formation of complex **5a**, which can a priori proceed through 1,2-addition reactions of aminobenzylidene chromium complex **1a** to the P−C and/or P−N double bond of the reactive intermediates **3a** and/or **4a**. In order to distinguish between these two pathways, we mimicked the hypothetical reaction of the first intermediate, **3a**, with the aminobenzylidene chromium complex **1a** by reacting **1a** with [bis(trimethylsilyl)methylene](*tert*-butylamino)phosphane **7**[11] under similar reaction conditions. After approximately one day at ambient temperature, only 18% of **7** was consumed, leading predominantly to one product, **8**, with a chemical shift at δ = 96.8 (Scheme 3). Unfortunately, we could not isolate this product because of subsequent chemical transformations and the lack of stability of **8** precluding chromatography. By comparison of the phosphorus chemical shift of **8** (δ = 96.8) with that of complex **5** (δ = 95.4), and because of the reaction selectivity, we tentatively assign the structure of complex **8** to this product. Nevertheless, the finding that complex **1a** reacted very slowly with compound **7** to give complex **8**, supports the interpretation that complex **5** resulted from a trapping of the 2-aza-1-phospha-4-chromabutadiene **4a**.

Interestingly, the NMR parameters of the carbon and nitrogen atoms of the three-membered ring of the 2*H*-azaphosphirene metal complexes **6a**, **b** and **9**[2b] vary very little with respect to metal exchange (Table 1). This is not the case with the phosphorus resonances, which differ significantly on going from chromium to the tungsten complex; this is a common feature of coordinated tervalent phosphorus compounds.[12] In order to obtain information about the electronic situation of the complexes **6a**, **b**, and **9**, UV/visible spectra were measured and λ_{max} values determined (Table 2). λ_{max} values of 200 and 240 nm should be

Scheme 3



attributable to π-π* electron transitions related to the phenyl groups. Bands appearing as shoulders with λ_{max} values of 330 (**6b**) and 350 nm (**9**), with significantly lower lg ε values, are tentatively assigned to π-π*-electron transitions of the C−N double bonds. It should be noted that some metal carbonyl complexes also show charge-transfer transitions in the range of 300−350 nm.[13] A comparison of the values obtained for **6a**, **b**, and **9** with those of a mixture of related 3-phenyl-1*H*-thiazirene and benzonitrile sulfide (bands with λ_{max} values of 335, 324, 295, and 240 nm) is interesting.[14] This interpretation of these UV/visible spectra remains somewhat unsatisfactory because the bands of benzonitrile sulfide had been assigned unambigously, but those of 3-phenyl-1*H*-thiazirene had not.[14] EI-mass spectrometry experiments have shown that all of these 2*H*-azaphosphirene metal complexes predominantly undergo ring cleavage subsequent to the ionisation process.

Table 2. UV/vis spectroscopic data (hexane, r.t.; λ_{max}/[nm]) of 3-phenyl-2*H*-azaphosphirene metal complexes **6a**, **b**, and **9**

complex	metal	λ_{max} (lg ε)	λ_{max} (lg ε)	λ_{max} (lg ε)	λ_{max} (lg ε)
6a	Cr	−	208 (4.637)	240 (4.599)	−
6b	Mo	198 (4.625)	206 (4.610)	240 (4.697)	330 (3.394)
9	W	198 (4.655)	216 (4.657)	254 (4.590)	350 (3.544)

The molecular structures of the complexes **6a**, **b** were determined by X-ray crystallography (Figure 1 and Table 3).[15] The dimensions of the isostructural complexes **6a**, **b** (therefore, only **6a** is depicted in Figure 1) and the corresponding tungsten complex **9**[2b] differ mainly in their metal-phosphorus bond distances [**6a**: 2.3125(6), **6b**: 2.4772(12), and **9**: 2.470(2) Å] and, as a consequence of this, in the distance between the metal atom and the geometrical center of the C−N double bond (**6a**: 3.542, **6b**: 3.670, and **9**: 3.659 Å). These and previously reported findings[2b] seem to underline that the bonding situation of the heterocyclic ligand of 2*H*-azaphosphirene pentacarbonylmetal complexes should be described as a resonance hybrid of a three-membered ring system with a covalent bonding (**II**) and a π-electron donor-acceptor complex of benzonitrile and the phosphorus atom of the terminal phosphanediyl complex unit (**IV**) (Scheme 4).

Support of the *Deutsche Forschungsgemeinschaft* and the *Fonds der Chemischen Industrie* and ^{15}N-NMR measurements of Priv.-Doz. Dr. *Dietrich Gudat* (Universität Bonn) are gratefully acknowledged.

Experimental Section

General: All operations were carried out under an inert atmosphere of deoxygenated dry nitrogen. Solvents were dried according to standard procedures. − NMR spectra were recorded on a Bruker AC-200 spectrometer (200 MHz for ^1H; 50.3 MHz for ^{13}C; 81 MHz for ^{31}P) using [D_6]chloroform and [D_6]benzene as solvents, the latter as internal standard, or a Bruker AMX-300 (30.4 MHz for ^{15}N) using dichloromethane as solvent and nitromethane as external standard; shifts are given relative to tetramethylsilane (^1H, ^{13}C), to nitromethane (^{15}N) and 85% H_3PO_4 (^{31}P). − MS: Finigan Mat 8430 (70 eV). − Elemental analyses: Carlo Erba analytical gas chromatograph. − IR: Biorad FT-IR-165; UV/vis: Hewlett Packard 8452A.

Procedure for the Preparation of 2H-Azaphosphirene Pentacarbonylmetal(0) Complexes: 0.34 g (1.5 mmol) of **2** and 5 ml of NEt_3 were added at −40°C or −10°C, respectively, to a solution of 1.5 mmol of aminobenzylidene chromium or molybdenum complex **1a**, **b** in 15 ml of diethyl ether. The reaction mixtures were stirred for approximately 40 and 48 hours, respectively, and allowed to warm up slowly to ambient temperature. The yellow/orange reaction mixtures were evaporated to dryness under reduced pressure (0.1 mbar). The residues were extracted with 30 ml of pentane and filtered. The filtration residues were washed twice with 5 ml of pentane, the organic phases combined and the solvent removed under reduced pressure. The residues were purified by column chromatography.

{[2-Bis(trimethylsilyl)methyl-3-phenyl-2H-azaphosphirene-κP]-pentacarbonylchromium(0)} (**6a**): separation by low-temperature chromatography (SiO_2, −40°C; hexane/ether, 9:1) afforded 0.22 g of **6a** (30%) as a yellow powder after removal of the solvent from the first yellow phase. M.p. 104°C (decomp.). − IR (KBr) $\tilde{\nu}$ = 2065 (s) cm^{-1}, 1988 (m), 1968 (vs), 1942 (vs), 1942 (vs) (CO), 1625 (s), 1618 (vw) (CN). − ^1H NMR (C_6D_6): δ = −0.01 (s, 9 H, $SiMe_3$), 0.27 (s, 9 H, $SiMe_3$), 0.57 [d, ^2J(P,H) = 3.97 Hz, 1 H, PC*H*], 7.01 (m_c, 3 H, *m,p*-Ph−*H*), 7.91 (m_c, 2 H, *o*-Ph−*H*). − $^{13}C\{^1H\}$ NMR (C_6D_6): δ = 1.2 [d, ^3J(P,C) = 3.1 Hz, $SiMe_3$], 2.1 [d, ^3J(P,C) = 2.9 Hz, $SiMe_3$], 28.3 [d, ^1J(P,C) = 29.8 Hz, P*C*H], 127.1 [d, ^2J(P,C) = 14.8 Hz, Ph−*C*1], 129.6 (s, Ph−*C*3/3′), 129.7 (s, Ph−*C*2/2′), 134.0 (s, Ph−C4), 193.3 [d, $^{(1+2)}J$(P,C) = 1.7 Hz, P*C*N], 215.9 [d, ^2J(P,C) = 16.8 Hz, *cis*-*C*O], 219.8 [d, ^2J(P,C) = 4.7 Hz, *trans*-*C*O]. − ^{15}N NMR (CH_2Cl_2): δ = −55.3 [d, $^{(1+2)}J$(P,N) = 38.3 Hz]. − $^{31}P\{^1H\}$ NMR (C_6D_6): δ = −54.3 (s). − UV/vis (hexane, c = $2.06 \cdot 10^{-5}$ M): λ_{max} (lg ε) = 208 (4.637), 240 (4.599). − MS (70 eV), [pos.-CI (NH_3)], (^{52}Cr); *m/z* (%): 486 (100) [(M + H)$^+$], 338 (40) [(M + H) − PhCN)$^+$]. − $C_{19}H_{24}CrNO_5PSi_2$ (485.5) calcd. Reaction of [(Aminobenzylidene)pentacarbonylchromium(0)] (**1a**) *with [Bis(trimethylsilyl)methylene](tert-butylamino)phosphane* (**7**) *and Triethylamine*: To 150 mg (0.5 mmol) of **1a** in 6 ml of diethyl ether was added 130 mg (0.5 mmol) of **7** and 0.67 ml of triethylamine at −40°C with continuous stirring. The reaction mixture was allowed to warm up slowly and the reaction course was monitored after 24 h and 36 h by ^{31}P-NMR spectroscopy. The percentage of the compounds were estimated by signal integration, assuming that the relaxation times of the phosphorus nuclei are similar. The ratio of **7**/**8** (signal at δ = 96.8) was determined after 24 h as 82:18 and after 36 h as 64:29:7.

Crystal Structure Determination of **6a**[15]: $C_{19}H_{24}CrNO_5PSi_2$, *M* = 485.54, *P*$\bar{1}$, *a* = 9.1533(10), *b* = 10.7771(10), *c* = 13.5911(10) Å, α = 89.807(6)°, β = 85.161(8)°, γ = 64.298(8)°, *V* = 1202.9(2) Å^3, *Z* = 2, d_{calc} = 1.340 Mg/m^3, μ = 0.669 mm^{-1}, *T* = 173 K. A yellow needle (0.80 × 0.42 × 0.28 mm) was mounted in inert oil. 4502 intensities were measured (2Θ 6−50°, ω-scans, −10 < *h* < 0, −12 < *k* < 11, −16 < *l* < 16) using Mo-*K*α radiation (graphite monochromator) on a Siemens P4 diffractometer. After absorption correction (ψ-scans, min. and max. transmission: 0.847, 0.934), 4213 were unique (R_{int} = 0.0139) and 4208 used for all calculations (program SHELXL-93). The structure was solved by direct methods and refined anisotropically by full-matrix least squares on F^2. All hydrogen atoms (except rigid methyl groups) were refined with a riding model.The final *wR*(F^2) was 0.0724 with conventional *R*(F) 0.0275 for 268 parameters and 100 restraints. Highest peak 0.293, hole −0.235 e/Å.

Crystal Structure Determination of **6b**[15]: $C_{19}H_{24}MoNO_5PSi_2$, *M* = 529.48, *P*$\bar{1}$, *a* = 9.158(2), *b* = 10.782(2), *c* = 13.816(3) Å, α = 89.17(2)°, β = 85.83(2)°, γ = 65.03(2)°, *V* = 1233.2(4) Å^3, *Z* = 2, d_{calc} = 1.426 Mg/m^3, μ = 0.721 mm^{-1}, *T* = 143 K. A pale yellow tablet (0.70 × 0.70 × 0.30 mm) was mounted in inert oil. 4577 intensities were measured (2Θ 6−50°, ω/Θ-scans, −9 < *h* < 10, 0 < *k* < 12, −10 < *l* < 10) using Mo-*K*α radiation (graphite monochromator) on a Stoe STADI-4 diffractometer. After absorption correction (ψ-scans, min. and max. transmission: 0.767, 0.878), 4330 were unique (R_{int} = 0.0214) and used for all calculations (program SHELXL-93). The structure was solved by heavy atom method and refined anisotropically by full-matrix least squares on F^2. All hydrogen atoms (except rigid methyl groups) were refined with a riding model.The final *wR*(F^2) was 0.0926 with conventional *R*(*F*) 0.0382 for 268 parameters and 98 restraints. Highest peak 0.510, hole −0.452 e/Å.

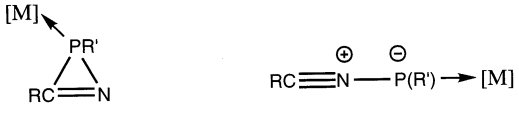
Keywords: Phosphorus heterocycles / 2*H*-Azaphosphirene complexes / Carbene complexes / Tungsten / Cyclizations

The syntheses of 3-heteroaryl-substituted 2*H*-azaphosphirene pentacarbonyltungsten complexes are reported. The products were characterized by multinuclear NMR spectroscopy (^{1}H, ^{13}C, ^{15}N, ^{31}P, ^{183}W); the structure of the 3-*N*-methylpyrryl-substituted 2*H*-azaphosphirene complex was determined by single-crystal X-ray structure analysis.

2*H*-azaphosphirene tungsten complexes (**I**) are of current synthetic interest because of their widespread applicability in heterocycle synthesis. For example, we very recently demonstrated that 2*H*-azaphosphirene tungsten complexes provide a new access to five-membered heterocyclic complexes, through trapping reactions of transiently formed nitrilium phosphane ylide tungsten complexes (**II**) with an acetylene[2] and a nitrile derivative.[3] Therefore, we were interested in the synthesis of 3-heteroaryl-substituted 2*H*-azaphosphirene tungsten complexes. We also wished to test the limits of our initial synthetic approach[4] to 2*H*-azaphosphirene complexes.

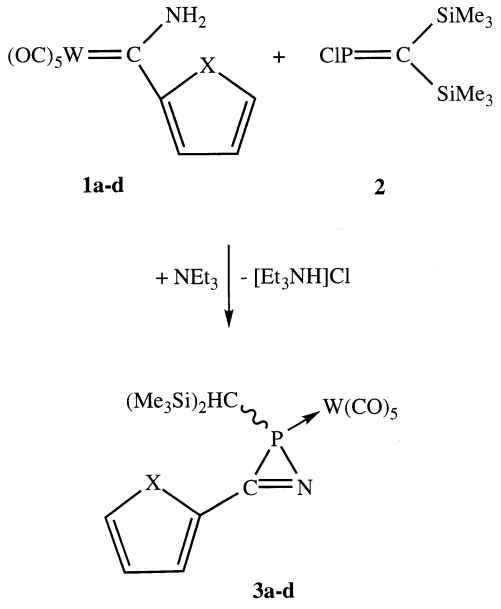
Scheme 1. 2*H*-azaphosphirene tungsten complexes (**I**) and nitrilium phosphane ylide tungsten complexes (**II**) (**I**, **II**: R, R′ = alkyl, aryl; [M] = metal complex fragment)



I **II**

Heteroaryl-substituted aminocarbene tungsten complexes **1a−c** were synthesized according to standard procedures[5] and reacted with [bis(trimethylsilyl)methylene]-chlorophosphane (**2**)[6] in the presence of triethylamine. In a similar way to our previously reported reactions of aryl-substituted aminocarbene complexes,[1][7] these reactions proceeded smoothly to give the 2*H*-azaphosphirene tungsten complexes **3a−c** (Scheme 2). These compounds were isolated in moderate to good yields after low-temperature column chromatography.

Scheme 2. Synthesis of 2*H*-azaphosphirene tungsten complexes **3a−c**



1a,3a: X = NMe; **1b,3b**: X = O; **1c,3c**: X = S; **1d,3d**: HC=CH

The proposed structures of the 2*H*-azaphosphirene tungsten complexes **3a−c** are unambiguously confirmed by their typical NMR data. The assignment of the ^{1}H- and ^{13}C-NMR resonances of the aromatic substituents in **3a−c** is based on a comparison with the corresponding data of 2-formyl-substituted heteroarenes.[8] The chemical shift of the

[◇] Part 9: See ref.[7].

pyrryl nitrogen atom in **3a** compares to reported values of *N*-alkyl pyrroles.[9] The chemical shifts of the atoms in the three membered rings of **3b,c** match those of the phenyl substituted derivative, **3d**, [1] while for the *N*-methylpyrryl-substituted compound, **3a**, both the ^{31}P and ^{15}N resonances display marked shifts to higher field (Table 1). The origin of this phenomenon arises presumably from π-interactions between the five- and three-membered rings and is in accord with the higher π-donor capability of a pyrryl as compared to a thienyl or phenyl substituent. The magnitudes of the carbon-phosphorus coupling constants in **3a−c** [$^{(1+2)}J_{PC}$ = 4.0−8.2 Hz] are larger than in **3d** and related *para*-substituted derivatives (1−3 Hz, ref.[7]) and increase in the same order (**3c** < **3b** < **3a**) as [$^{(1+2)}J_{PN}$]. The values of $\delta^{183}W$ and $^1J_{WP}$ for **3a−c** are essentially constant and lie in the known range for complexes of the type $[W(CO)_5(PR_3)]$.[10] CI EI mass spectrometric experiments revealed that, although only the [(M + H)$^+$] and not the [(M − H)$^-$] ions were detected, these 2*H*-azaphosphirene complexes preferentially show PCN-ring cleavage subsequent to the ionisation processes; this was observed in the positive and negative CI mode. Additionally, the resulting fragment ions indicate subsequent loss of carbon monoxide.

Table 1. Comparison of selected ^{13}C[a], ^{15}N[b], ^{31}P[b], ^{183}W[b] NMR data (δ values, *J*[Hz]) of 3-heteroaryl-2*H*-azaphosphirene tungsten complexes **3a−c**, **d**[7] (exclusively atoms of the three-membered ring and tungsten)

	δ ^{31}P	$^1J_{W,P}$	δ ^{13}C	$^{(1+2)}J_{C,P}$	δ ^{15}N	$^{(1+2)}J_{N,P}$	δ ^{183}W

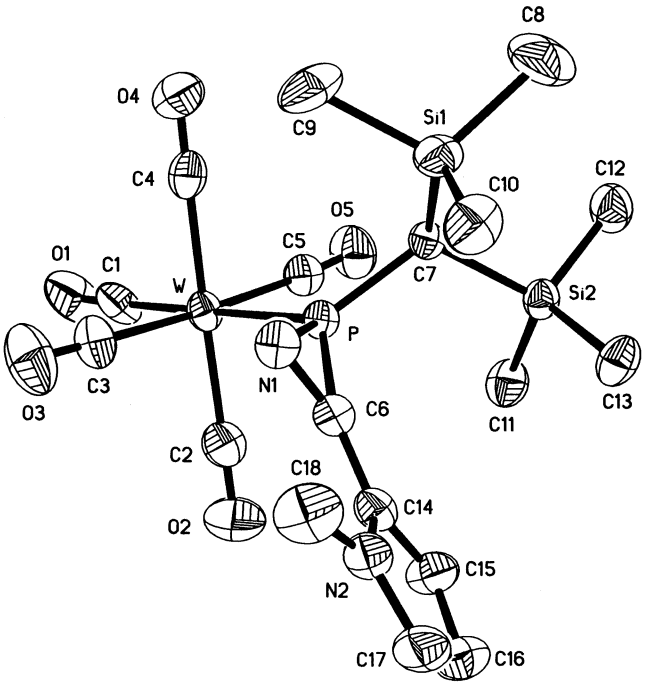
[a] $CDCl_3$, room. temp. − [b] CH_2Cl_2, room. temp.

Figure 1. Molecular structure of **3a** in the crystal (ellipsoids represent 50% probability levels, hydrogen atoms are omitted for clarity). Selected bond lengths [A] and angles [°]: P−C(6) 1.760(4), P−N(1) 1.789(3), N(1)−C(6) 1.296(5), W−P 2.4741(13); C(6)−P−N(1) 42.8(2), C(6)−N(1)−P 67.4(2), N(1)−C(6)−P 69.8(2), N(1)−C(6)−C(14) 138.0(4).



The molecular structure of complex **3a** was confirmed for the solid state by X-ray crystallography (Figure 1).[11] One of the most interesting structural features of **3a** is the almost coplanar arrangement of the two ring systems (interplanar angle 6.4°) which allows an effective π-electron interaction between the *N*-methylpyrryl group (π-donor) and the PCN-ring (π-acceptor). This is strongly supported by the observed bond length equalization of the carbon−carbon bonds in the pyrryl ring [C14−C15 1.389(5), C15−C16 1.385(6), C16−C17 1.396(6) Å] and the inter-ring bond [C6−C14 1.404(5) Å]. The latter is also significantly shorter than the corresponding distance in **3d** [1.457(7) Å][7], while at the same time the C−N double bond [N1−C6 1.296(5) Å] is longer than there [1.272(7) Å[7]].

Support by the *Deutsche Forschungsgemeinschaft* and the *Fonds der Chemischen Industrie* is gratefully acknowledged.

Experimental Section

General: All operations were carried out under deoxygenated dry nitrogen as inert gas, solvents were dried according to standard procedures. − NMR spectra were recorded on a Bruker AC-200 or a Bruker AMX-300 spectrometer (AC-200: 200 MHz for ^1H; 50.3 MHz for ^{13}C; 81 MHz for ^{31}P; AMX-300: 30.4 MHz for ^{15}N; 12.5 MHz for ^{183}W) using [D]chloroform and dichloromethane as solvent and internal standard; shifts are given relative to ext. tetramethylsilane (^1H, ^{13}C), H_3CNO_2 (^{15}N), 85% H_3PO_4 (^{31}P) and WO_4^{2-} (^{183}W). ^{15}N-NMR spectra were recorded using ^{31}P- and ^1H-based polarisation transfer techniques (INEPT); ^{183}W-NMR data were obtained from two dimensional ^{31}P-detected ^{31}P, $^{183}W\{^1H\}$ HMQC spectra. − MS: Finigan Mat 8430 (70 eV). − Elemental analyses: Carlo Erba analytical gas chromatograph. − IR: Biorad FT-IR-165.

General Procedure for the Preparation of Amino(heteroaryl)carbene Tungsten Complexes: The ethoxy(heteroaryl)-carbene tungsten complexes were prepared according to ref.[5] and reacted, without purification, with ammonia. A gentle flow of ammonia was bubbled through a solution of 5 mmol of the ethoxy-(heteroaryl)carbene tungsten complexes in 60 ml of ether until a yellow colour persisted and thin layer chromatography (SiO_2) indicated that all starting material had reacted. All volatile compounds were removed under reduced pressure (0.1 mbar) and the yellow residue was purified by column chromatography. The assignment of the ^1H and ^{13}C resonances of the aromatic heterocyclic substituents of **1a−c** accords with related chromium complexes.[12]

{[Amino(1-methyl-2-pyrryl)carbene]pentacarbonyltungsten(0)} (**1a**): 1.7 g of **1a** (79%) was obtained as a yellow powder after low temperature chromatography (SiO_2, −10°C; hexane/ether 1:1). M.p. 120°C (decomp.). − IR (KBr): $\tilde{\nu}$ = 3451 (m) cm^{-1}, 3351 (m), 3256 (m), (NH), 2061 (m), 1978 (m), 1903 (s), (CO). − ^1H NMR ($CDCl_3$): δ = 3.80 (s, 3 H, N−CH_3), 6.22 (dd, $^3J_{HH}$ = 4.0 Hz, $^3J_{HH}$ = 2.6 Hz, 1 H, pyrryl-C4-*H*), 6.85−6.91 (m, 2 H, pyrryl-C3/5-*H*), 8.07 (br, 2 H, NH_2). − $^{13}C\{^1H\}$ NMR ($CDCl_3$): δ = 37.1 (s, N−*C*H_3), 110.3 (s, pyrryl-*C4*), 123.7 (s, pyrryl-*C5*), 132.0 (s, pyrryl-*C3*), 143.6 (s, pyrryl-*C2*), 198.9 (s, $^1J_{CW}$ = 127.6 Hz, *cis*-*C*O), 202.9

(s, *trans*-*C*O), 240.6 (s, W=*C*R_2). − MS (70 eV), (^{184}W) *m*/*z* (%): 432 (8) [M^+], 404 (11) [M^+ − CO], 352 (53) [M^+ − C_5H_6N], 296 (40) [M^+ − 2 × CO − C_5H_6N], 268 (100) [M^+ − 3 × CO − C_5H_6N], 240 (41) [M^+ − 4 × CO − C_5H_6N], 212 (43) [M^+ − 5 × CO − C_5H_6N], 184 (33) [M^+ − 5 × CO − C_5H_6N − CNH_2]. − $C_{11}H_8N_2O_5W$ (432.0): calcd. C 30.58, H 1.87, N 6.48; found C 30.67, H 1.90, N 6.48.

{[Amino(2-furyl)carbene]pentacarbonyltungsten(0)} (**1b**): 1.5 g of **1b** (71%) was obtained as a yellow-orange powder after low temperature chromatography (SiO_2, −10°C; hexane/ether 1:1). M.p. 95°C (decomp.). − IR (KBr): $\tilde{\nu}$ = 3457 (m) cm^{-1}, 3341 (m), 3256 (m), (NH), 2064 (m), 1976 (m), 1928 (s), 1888 (s), (CO). − ^{1}H NMR ($CDCl_3$): δ = 6.56 (dd, $^3J_{HH}$ = 3.7 Hz, $^3J_{HH}$ = 1.8 Hz, 1 H, furyl-C4-*H*), 7.45−7.47 (m, 1 H, furyl-C3-*H*), 7.54−7.55 (m, 1 H, furyl-C5-*H*), 7.91 (br, 1 H, NH_2), 8.94 (br, 1 H, NH_2). − ^{13}C{^{1}H} NMR ($CDCl_3$): δ = 114.5 (s, furyl-*C4*), 129.4 (s, furyl-*C3*), 145.6 (s, furyl-*C5*), 159.0 (s, furyl-*C2*), 198.4 (s, $^1J_{CW}$ = 129.9 Hz, *cis*-*C*O), 202.6 (s, *trans*-*C*O), 229.8 (s, W=*C*R_2). − MS (70 eV), (^{184}W); *m*/*z* (%): 419 (56) [M^+], 391 (18) [M^+ − CO], 335 (55) [M^+ − 3 × CO], 307 (51) [M^+ − 4 × CO], 279 (100) [M^+ − 5 × CO], 252 (56) [M^+ − 3 × CO − NH_2 − C_4H_3O], 224 (35) [M^+ − 4 × CO − NH_2 − C_4H_3O]. − $C_{10}H_5NO_6W$ (419.0): calcd. C 28.67, H 1.20, N 3.34; found C 28.73, H 1.21, N 3.32.

{[Amino(2-thienyl)carbene]pentacarbonyltungsten(0)} (**1c**): 1.8 g of **1c** (84%) was obtained as a yellow powder after low temperature chromatography (SiO_2, −10°C; hexane/ether 1:1). M.p. 101°C (decomp.). − IR (KBr): $\tilde{\nu}$ = 3426 (m) cm^{-1}, 3343 (m), 3266 (m), (NH), 2064 (m), 1969 (m), 1922 (vs), 1911 (vs), 1888 (s), 1872 (vs), (CO). − ^{1}H NMR ($CDCl_3$): δ = 7.16 (dd, $^3J_{HH}$ = 5.0 Hz, $^3J_{HH}$ = 3.9 Hz, 1 H, thienyl-C4-*H*), 7.60 (dd, $^3J_{HH}$ = 3.9 Hz, $^4J_{HH}$ = 1.1 Hz, 1 H, thienyl-C3-*H*), 7.66 (dd, $^3J_{HH}$ = 5.0 Hz, $^4J_{HH}$ = 1.1 Hz, 1 H, thienyl-C5-*H*), 8.02 (br, 1 H, NH_2), 8.52 (br, 1 H, NH_2). − ^{13}C{^{1}H} NMR ($CDCl_3$): δ = 129.0 (s, thienyl-*C4*), 132.7 (s) and 133.2 (s) (thienyl-*C3*/*C5*), 153.5 (s, thienyl-*C2*), 198.4 (s, $^1J_{CW}$ = 127.2 Hz, *cis*-*C*O), 202.6 (s, *trans*-*C*O), 243.8 (s, W=*C*R_2). − MS (70 eV), (^{184}W); *m*/*z* (%): 435 (49) [M^+], 407 (30) [M^+ − CO], 351 (28) [M^+ − 3 × CO], 295 (100) [M^+ − 5 × CO], 268 (41) [M^+ − 3 × CO − C_4H_3S]. − $C_{10}H_5NO_5SW$ (435.1): calcd. C 27.61, H 1.16, N 3.22, S 7.37; found C 27.68, H 1.16, N 3.15, S 7.40.

General Procedure for the Preparation of 2H-Azaphosphirene-(pentacarbonyl)tungsten Complexes: To a solution of 1.5 mmol of amino(heteroaryl)carbene tungsten complexes **1a−c** in 15 ml of ether was added 0.34 g (1.5 mmol) of **2** and 5 ml of NEt_3 at 0°C. The reaction mixture was stirred at ambient temp. until **2** was consumed (^{31}P-NMR control). The yellow-orange reaction mixture was evaporated to dryness under reduced pressure (0.1 mbar). The residue was extracted with 30 ml of pentane and filtered. The filtration residue was washed twice with 5 ml of pentane, the organic phases combined and the solvent removed under reduced pressure. The residue was purified, if necessary, by low temperature column chromatography (SiO_2, −10°C; hexane/ether 10:1).

{[2-Bis(trimethylsilyl)methyl-3-(1-methyl-2-pyrryl)-2H-azaphosphirene-κP]pentacarbo-nyltungsten(0)} (**3a**): 0.35 g of **3a** (56%) was obtained, after stirring for 20 hours, as a yellow powder. M.p. 112°C (decomp.). − IR (KBr): $\tilde{\nu}$ = 2073 (m) cm^{-1}, 1990 (m), 1952 (s, sh), 1936 (s), 1919 (vs), (CO), 1618 (w) (CN). − ^{1}H NMR ($CDCl_3$): δ = 0.14 (s, 9 H, $SiMe_3$), 0.28 (s, 9 H, $SiMe_3$), 0.58 (d, $^2J_{HP}$ = 2.9 Hz, 1 H, PC*H*), 4.01 (d, $^4J_{HH}$ = 0.5 Hz , 3 H, N−CH_3), 6.37 (dd, $^3J_{HH}$ = 4.1 Hz, $^3J_{HH}$ = 2.5 Hz, 1 H, pyrryl-C4-*H*), 7.04−7.06 (m, 1 H, pyrryl-C3-*H*), 7.10 (m, 1 H, pyrryl-C5-*H*). − ^{13}C{^{1}H} NMR ($CDCl_3$): δ = 1.3 (d, $^3J_{CP}$ = 3.5 Hz, $SiMe_3$), 2.2 (d, $^3J_{CP}$ = 3.1 Hz, $SiMe_3$), 27.2 (d, $^1J_{CP}$ = 24.2 Hz, P*C*H), 36.2 (s, N−*C*H_3), 111.0 (s, pyrryl-*C4*), 120.2 (d, $^2J_{CP}$ = 19.2 Hz, pyrryl-*C2*), 122.3 (s, pyrryl-*C3*), 132.6 (s, pyrryl-*C5*), 179.2 (d, $^{(1+2)}J_{PC}$ = 8.2 Hz, P*C*N), 196.0 (d, $^2J_{CP}$ = 8.9 Hz, *cis*-*C*O), 198.1 (d, $^2J_{CP}$ = 35.6 Hz, *trans*-*C*O). − ^{15}N NMR (CH_2Cl_2): δ = −85.3 (d, $^{(1+2)}J_{NP}$ = 40.1 Hz, PC*N*), −224.3 (d, $^3J_{NP}$ = 1.4 Hz, pyrryl-*N*). − ^{31}P{^{1}H} NMR ($CDCl_3$): δ = −125.8 (s, $^1J_{PW}$ = 293.1 Hz). − ^{31}P{^{1}H} NMR (CH_2Cl_2): δ = −127.9 (s, $^1J_{PW}$ = 294.0 Hz). − ^{183}W NMR (CH_2Cl_2): δ = −3249.8 (d, $^1J_{PW}$ = 294.0 Hz). − MS (pos.-CI, NH_3), (^{184}W) *m*/*z* (%): 621 (100) [(M + H)$^+$], 515 (18) [(M + H)$^+$ − $C_6H_6N_2$], 106 (5) [$C_6H_6N_2^+$]. − MS (neg.-CI, NH_3), (^{184}W) *m*/*z* (%): 513 (100) [(M − H)$^-$ − $C_6H_6N_2$], 485 (18) [(M − H)$^-$ − $C_6H_6N_2$ − CO], 457 (2) [(M − H)$^-$ − $C_6H_6N_2$ − 2 × CO]. − $C_{18}H_{25}N_2O_5PSi_2W$ (620.4): calcd. Keywords: Carbyne complexes / Molybdenum complexes / Oxidations / Tungsten

Oxidation of the phosphaalkenyl-substituted carbyne complexes [Tp′(CO)$_2$M≡C−P=C(NR$_2$)$_2$] (**1a**: M = Mo, R = Me; **1b**: M = W, R = Me; **2a**: M = Mo, R = Et; **2b**: M = W, R = Et) with molecular dioxygen cleanly affords the orange carbyne complexes [Tp′(CO)$_2$M≡C−P(O)$_2$C(NR$_2$)$_2$] [**3a**: M = Mo, R = Me; **3b**: M = W; R = Me; **4a**: M = Mo, R = Et; **4b**: M = W, R = Et; Tp′ = HB(3,5-Me$_2$HC$_3$N$_2$)$_3$], which are functionalized at the methylidyne carbon atom by an α-carbenium phosphinate moiety. The novel compounds have been characterized by IR, ^{1}H-, ^{13}C-, and ^{31}P-NMR spectroscopy. In addition, the molecular structure of **4a** has been determined by a single-crystal X-ray structure analysis.

Introduction

In search for transition-metal complexes with terminal isophosphaalkyne ligands R−P≡C[2][3][4][5][6] we recently obtained phosphaalkenyl-substituted carbyne complexes of the type Tp′(CO)$_2$M≡C−P=C(NR$_2$)$_2$ (**1**, **2**)[1]. These molecules possess electrophilic and nucleophilic centres in close proximity which renders them promissing as precursors for a number of chemical transformations.

Herein we report on the facile oxidation of the phosphaalkenyl carbyne complexes **1**, **2** (M = Mo, W; R = Me, Et) with molecular dioxygen.

Results and Discussion

When crystalline samples of the phosphaalkenyl carbyne complexes **2a** and **2b** were exposed to air for two weeks, a color change from deep-red to orange-red took place. The same oxidation process could be achieved within 2 h using pure oxygen at a pressure of 80 bar. Similarly, compounds **1a** and **1b** were rapidly oxidized under O_2 pressure, whereas in air complete oxidation took about three weeks (eq. 1).

Tp′ = HB(3,5-Me$_2$HC$_3$N$_2$)$_3$
M = Mo **(a)**, W **(b)**
R = Me **(1, 3)**; R = Et **(2, 4)** (1)

Purification of the products was effected by column chromatography on silanized silica, using CH_2Cl_2 and ethanol as eluents, followed by crystallization of the orange-red powdery solids from a CH_2Cl_2/pentane mixture. Compared to the starting materials [**1a**: $\tilde{\nu}$(CO) = 1946, 1864 cm^{-1}; **1b**: 1935, 1848 cm^{-1}; **2a**: 1943, 1859 cm^{-1}; **2b**: 1933, 1845 cm^{-1}], the bands of the carbonyl stretching vibrations in the IR spectra of the products are significantly shifted to higher wavenumbers [**3a**: $\tilde{\nu}$(CO) = 2005, 1918 cm^{-1}; **3b**: 1987, 1893 cm^{-1}; **4a**: 2002, 1923 cm^{-1}; **4b**: 1989, 1894 cm^{-1}]. This observation is consistent with a decreased σ-donor/π-acceptor behavior of the novel organophosphorus carbyne ligands, compared with the phosphaalkenyl carbyne ligands in the precursors **1** and **2**. The PO_2 group of the carbenium phosphinate unit of the products gives rise to medium intensity bands at 1202−1205 and 1066−1068 cm^{-1}, which, by analogy with the IR data of numerous previously described phosphinates[7][8][9], are attributed to the asymmetric and symmetric PO_2 stretching vibrations.

The ^{13}C{^{1}H}-NMR spectra of **3a**, **b** and **4a**, **b** are especially interesting in the low field region, where doublets are observed at δ = 298.7−314.4 for the metal-bound carbon atoms of the carbyne ligands. In the ^{13}C{^{1}H}-NMR spectra of the starting materials, the corresponding resonances are observed at considerably lower field [**1a**: δ = 337 (d, $^1J_{PC}$ = 111.3 Hz); **1b**: 318.3 (d, $^1J_{PC}$ = 101.2 Hz); **2a**: 338.8 (d, $^1J_{PC}$ = 115.6 Hz); **2b**: 319.0 (d, $^1J_{PC}$ = 108.3 Hz)]. More remarkable is the dramatic decrease in the carbon-phosphorus coupling constants from the aforementioned values in **1**, **2a**, **b** to $^1J_{PC}$ = 28.2−54.0 Hz in the products. These observations can be explained in terms of a decreased

[◇] Part 35: Ref.[1].

 © WILEY-VCH Verlag GmbH, D-69451 Weinheim, 1998 1434−1948/98/0505−0579 $ 17.50+.50/0

electron transfer from the organophosphorus ligand to the metal and a decreased 3s orbital contribution in the C−P bond. Doublets at δ = 178.3−181.9 ($^1J_{PC}$ = 91.9−98.1 Hz) are assigned to the tricoordinate carbon atom of the [PC(NMe$_2$)$_2$] moiety of **3a**, **b** and **4a**, **b**. The oxidation of **1**, **2a**, **b** is accompanied by a considerable upfield shift of the resonance of this carbon atom [Δδ = 17.7−24.4], whereas the coupling constants $^1J_{PC}$ remain almost unaffected. The decreased donor capacity of the novel organophosphorus ligands in **3a**, **b** and **4a**, **b** is also reflected in the chemical shifts of the carbonyl carbon atoms, which are shifted from δ = 228.1−230.7 in **1**, **2a**, **b** to δ = 225.9−227.3 in the oxidation products.

The $^{31}P\{^1H\}$-NMR spectra of **3a**, **b** and **4a**, **b** display singlets (δ = −6.85 to +7.0) at higher fields compared to those of the precursors (δ = 49.0−65.9). Interestingly, in the tungsten derivatives **3b** and **4b**, the coupling constants $^2J_{PW}$ = 152.9 and 151.7 Hz clearly exceed the values measured from the spectra of **1b** ($^2J_{PW}$ = 51.4 Hz) and **2b** ($^2J_{PW}$ = 61.6 Hz). The ^{31}P-chemical shifts of our products may be compared to the ^{31}P-NMR data of $(Me_4Sb)^+(O_2PH_2)^-$ (δ = +1.70 in CH_2Cl_2) or $(Me_4Sb)^+(O_2PMe_2)^-$ (δ = −24.50 in CH_2Cl_2)[10].

The mass spectra (LSIMS) show the peaks of the molecular ions of **3a**, **b** and **4a**, **b** as parent ion peaks, underlining the fact that two oxygen atoms are added at the phosphorus centre of the starting materials.

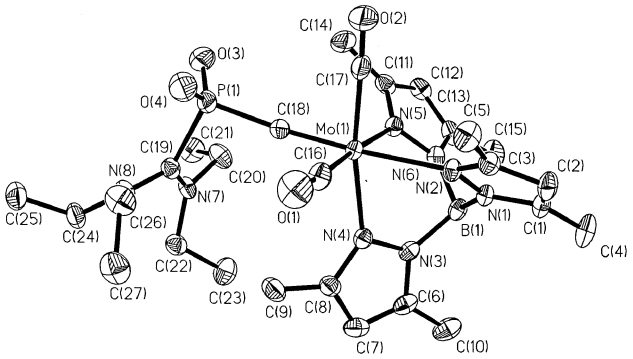
X-ray Structural Analysis of 4a

Single crystals of **4a** were grown from CH_2Cl_2/hexane at 5°C. The results of the structural determination are shown in Figure 1. Selected bond lengths and angles for the complex are given in the caption. Crystalline **4a** consists of monomeric molecules with distorted octahedral geometry. The bond angles between the organophosphorus ligand and the two carbonyl ligands [C(16)−Mo(1)−C(18) = 82.91(14)°; C(17)−Mo(1)−C(18) = 83.53(13)°] are more acute than those in **2b** [85.5(3)°; 88.1(3)°][1]. The angles between the nitrogen donor atoms N(2), N(4) and N(5) of the Tp′ ligand are comparable in **4a** [79.96(9)−83.68(9)°] and **2b** [80.3(2)−82.9(2)°], and are markedly smaller than the ideal 90°. The metal atom lies in the plane defined by the carbon atoms C(5), C(9), and C(14) (deviation 0.083 Å). The most interesting structural feature of the molecule is the geometry of the organophosphorus ligand. The bond length Mo(1)−C(18) of 1.813(3) Å compares well with the corresponding bond length in Tp′(CO)$_2$Mo≡C−S−C$_6$H$_4$NO$_2$-*p* [1.801(4) Å][11], hence this bond has to be regarded as a metal−carbon triple bond.

The valence angle at the *sp*-hybridized methylidene carbon atom Mo(1)−C(18)−P(1) of 166.8(2)° shows only slight deviation from linearity, as was also found for the corresponding valence angle W−C−P in **2b** [167.9(4)°] and for that in the ion [Tp′(CO)$_2$W≡C−PMe$_2$Ph]$^+$ [168.1(5)°][12]. However, unlike in **2b**, the bonds between the phosphorus atom and carbon atoms C(18) [P(1)−C(18) = 1.788(3) Å] and C(19) [P(1)−C(19) = 1.909(3) Å] differ significantly. The standard value for a P−C single bond is 1.85 Å[13]. The tetracoordinate phosphorus atom can be considered as being part of a phosphinate unit $[R^1R^2PO_2]^-$. The phosphorus−oxygen atomic distances differ in length [1.496(3) and 1.467(3) Å] and are shorter than the P−O bond lengths in the hypophosphite ion (1.51 Å)[14].

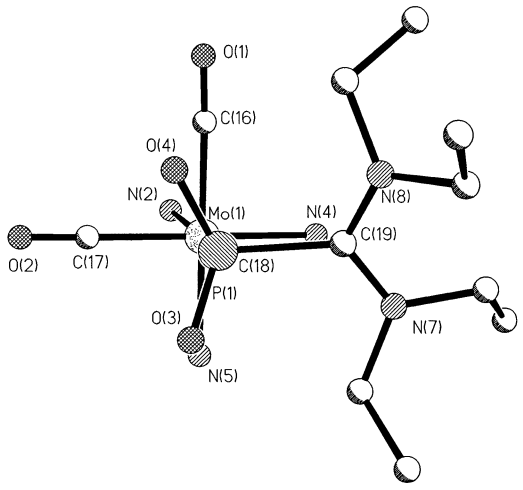
The fourth substituent at the phosphorus atom is a trigonal-planar bis(diethylamino)carbenium unit [sum of bond angles at C(19) = 359.9(2)°]. Accordingly, the carbon−nitrogen bond lengths N(7)−C(19) [1.333(4) Å] and N(8)−C(19) [1.347(4) Å] are shortened compared to the calculated value of a $C_{sp^2}-N_{sp^2}$ single bond [1.450 Å][15].

Figure 1. Molecular structure of **4a**[a]



[a] Selected bond lengths [C] and bond angles [°]: Mo(1)−C(18) 1.813(3), Mo(1)−C(16) 2.004(3), Mo(1)−C(17) 2.000(3), Mo(1)−N(2) 2.326(2), Mo(1)−N(4) 2.227(2), Mo(1)−N(5) 2.219(2), P(1)−O(3) 1.496(3), P(1)−O(4) 1.467(3), P(1)−C(18) 1.788(3), P(1)−C(19) 1.909(3), O(1)−C(16) 1.147(4), O(2)−C(17) 1.139(4), N(7)−C(19) 1.333(4), N(8)−C(19) 1.347(4); C(16)−Mo(1)−C(18) 82.91(14), C(17)−Mo(1)−C(18) 83.53(13), C(16)−Mo(1)−C(17) 87.54(14), C(16)−Mo(1)−N(5) 175.87(11), C(16)−Mo(1)−N(4) 94.70(12), C(17)−Mo(1)−N(4) 170.26(11), N(4)−Mo(1)−N(5) 83.68(9), N(2)−Mo(1)−N(4) 79.96(9), N(2)−Mo(1)−N(5) 82.84(9), N(2)−Mo(1)−C(18) 172.93(12), Mo(1)−C(18)−P(1) 166.8(2), C(18)−P(1)−O(3) 110.81(15), C(18)−P(1)−O(4) 111.03(15), C(18)−P(1)−C(19) 98.57(14), C(19)−P(1)−O(3) 105.24(14), C(19)−P(1)−O(4) 109.94(15), O(3)−P(1)−O(4) 119.10(16), P(1)−C(19)−N(7) 120.4(2), P(1)−C(19)−N(8) 119.4(2), N(7)−C(19)−N(8) 120.1(3).

Figure 2. View along the vector P(1)−C(18)−Mo(1); only the ligating atoms N(2), N(4) and N(5) of the tripod are drawn for clarity



The valence angle C(18)−P(1)−C(19) of 98.57(14)° is significantly compressed, compared with the corresponding C−P−C angle in **2b** [105.7(3)°]. The remarkably long interatomic distance P(1)−C(19) [1.909(3) Å] between the phosphinato and carbenium centres is surprising. It is conceivable that the positively charged carbon atom and the positively polarized phosphorus centre repel each other. The diaminocarbenium unit is oriented towards the tripod ligand in such a way that the bonds P(1)−C(19) and Mo(1)−N(4) are eclipsed (Figure 2).

The *trans*-influence of the methylidyne ligand is reflected in the Mo(1)−N(2) bond length of 2.326(2) Å, which significantly exceeds the lengths of the other two Mo−N bonds [2.219(2) and 2.227(2) Å], which are *trans*-oriented with respect to the carbonyl ligands.

Experimental Section

Unless stated otherwise, standard inert-atmosphere techniques were used for the manipulation of all reagents and reaction products. − Infrared spectra were recorded on a Bruker FT-IR IFS66 spectrometer. − ^{1}H-, ^{13}C-, and ^{31}P-NMR spectra were recorded in CD_2Cl_2 solution on Bruker AC 100 and Bruker AM Avance DRX 500 instruments. Standards: $SiMe_4$ (^{1}H, ^{13}C), external 85% H_3PO_4 (^{31}P). − Elemental analyses were performed in the Microanalytical Laboratory of the University of Bielefeld and in the Microanalytical Laboratory, H. Kolbe, Mülheim, Germany. − Mass spectra (LSIMS) (matrix: *p*-nitrobenzyl alcohol) were obtained with a Varian MAT-CH5-DF spectrometer.

The precursors [Tp′(CO)$_2$M≡C−P=C(NR$_2$)$_2$] (**1a**: M = Mo, R = Me; **1b**: W, Me; **2a**: Mo, Et; **2b**: W, Et) were synthesized according to literature procedures[1]. Dioxygen was taken from a cylinder. Silanized silica gel (Merck) was purchased commercially.

[Tp′(CO)$_2$Mo≡C−P(O)$_2$C(NMe$_2$)$_2$] (**3a**): A solution of [Tp′(CO)$_2$Mo≡C−P=C(NMe$_2$)$_2$] (**1a**) (0.80 g, 1.35 mmol) in 15 ml of dichloromethane was treated with dioxygen in an autoclave at 20°C and 80 bar for 3 h. Thereafter, the ^{31}P{^{1}H}-NMR spectrum of the solution displayed a singlet at δ = −6.8. The solvent and volatile components were then removed in vacuo (ca. 0.1 Torr), and the yellow-brown residue was chromatographed on silanized silica 60 (column: *l* = 15 cm, *d* = 2 cm). Elution with *n*-hexane (300 ml) afforded a yellow fraction, which was discarded. The column was developed with 200 ml of CH_2Cl_2. An orange-red zone was then eluted with ethanol (100 ml) and this fraction was concentrated to dryness. The powdery, ochre residue was dissolved in 25 ml of a CH_2Cl_2/hexane mixture (1:2), and the solution was stored for 7 days at −5°C. Orange-red needles of **3a** separated (0.55 g, 65.3%). − IR (KBr): $\tilde{\nu}$ = 2551 cm^{-1} w [ν(BH)], 2005 vs, 1918 vs [ν(CO)], 1202 m [ν_{as}(PO$_2$)], 1067 m [ν_s(PO$_2$)]. − ^{1}H NMR: δ = 2.36 (s, 3 H, Tp′CH$_3$), 2.41 (s, 3 H, Tp′CH$_3$), 2.64 (s, 6 H, Tp′CH$_3$), 2.78 (s, 6 H, Tp′CH$_3$), 3.42 (s, 12 H, NCH$_3$), 5.80 (s, 1 H, Tp′-H), 5.95 (s, 2 H, Tp′-H). − ^{13}C{^{1}H} NMR: δ = 12.3 (s, Tp′*C*H$_3$), 13.9 (s, Tp′*C*H$_3$), 15.7 (s, Tp′*C*H$_3$), 38.1 (s, NCH$_3$), 106.0 (s, Tp′*C*H), 144.9 (s, Tp′*C*CH$_3$), 145.5 (s, Tp′*C*CH$_3$), 150.8 (s, Tp′*C*CH$_3$), 178.3 (d, $^{1}J_{PC}$ = 93.2 Hz, PCN$_2$), 226.5 (s, CO), 312.6 (d, $^{1}J_{PC}$ = 30.3 Hz, Mo≡C). − ^{31}P{^{1}H} NMR: δ = −6.85 (s). − MS: *m/z* = 626 [M$^+$] (^{98}Mo), 570 [M$^+$ − 2 CO] (^{98}Mo). − $C_{23}H_{34}BMoN_8O_4P$ (624.31): calcd. C 44.25, H 5.49, N 17.95; found C 42.20, H 5.52, N 17.19. Solid samples retained varying amounts of CH_2Cl_2 despite prolonged drying in vacuo.

[Tp′(CO)$_2$W≡C−P(O)$_2$C(NMe$_2$)$_2$] (**3b**): Analogously to the preparation of **3a**, a sample of 0.49 g (58.5%) of orange-red **3b** was obtained by the oxidation of 0.80 g (1.18 mmol) of **1b**. − IR (KBr): $\tilde{\nu}$ = 2551 cm^{-1} w [ν(BH)], 1987 vs [ν(CO)], 1893 vs [ν(CO)], 1202 m [ν_{as}(PO$_2$)], 1067 m [ν_s(PO$_2$)]. − ^{1}H NMR: δ = 2.35 (s, 3 H, Tp′CH$_3$), 2.38 (s, 3 H, Tp′CH$_3$), 2.41 (s, 6 H, Tp′CH$_3$), 2.66 (s, 6 H, Tp′CH$_3$), 3.41 (s, 12 H, NCH$_3$), 5.82 (s, 1 H, Tp′-H), 5.99 (s, 2 H, Tp′-H). − ^{13}C{^{1}H} NMR: δ = 12.6 (s, Tp′*C*H$_3$), 15.0 (s, Tp′*C*H$_3$), 16.9 (s, Tp′*C*H$_3$), 45.1 (s, NCH$_3$), 106.8 (s, Tp′*C*H), 145.4 (s, Tp′*C*CH$_3$), 146.2 (s, Tp′*C*CH$_3$), 152.2 (s, Tp′*C*CH$_3$), 152.4 (s, Tp′*C*CH$_3$), 179.4 (d, $^{1}J_{PC}$ = 91.9 Hz, PCN$_2$), 225.9 (s, CO), 298.7 (d, $^{1}J_{PC}$ = 46.2 Hz, W≡C). − ^{31}P{^{1}H} NMR: δ = 6.6 ($^{2}J_{PW}$ = 152.9 Hz). − MS: *m/z* = 713 [M$^+$], 656 [M$^+$ − 2 CO]. − $C_{23}H_{34}BN_8O_4PW$ (712.22): calcd. C 38.78, H 4.81, N 15.73; found C 38.39, H 4.78, N 15.66.

[Tp′(CO)$_2$Mo≡C−P(O)$_2$C(NEt$_2$)$_2$] (**4a**): As described above, a sample of **2a** (0.90 g, 1.39 mmol) was converted into orange-red **4a** by treatment with molecular dioxygen (yield: 0.67 g, 70.8%). − IR (KBr): $\tilde{\nu}$ = 2551 cm^{-1} w [ν(BH)], 2002 vs [ν(CO)], 1923 vs [ν(CO)], 1203 m [ν_{as}(PO$_2$)], 1066 m [ν_s(PO$_2$)]. − ^{1}H NMR: δ = 1.27 (t, $^{3}J_{HH}$ = 7.1 Hz, 12 H, CH$_2$C*H*$_3$), 2.31 (s, 6 H, Tp′CH$_3$), 2.37 (s, 6 H, Tp′CH$_3$), 2.62 (s, 6 H, Tp′CH$_3$), 3.89 (q, $^{3}J_{HH}$ = 7.1 Hz, 8 H, C*H*$_2$CH$_3$), 5.75 (s, 1 H, Tp′-H), 5.89 (s, 2 H, Tp′-H). − ^{13}C{^{1}H} NMR: δ = 12.9 (s, Tp′*C*H$_3$), 13.9 (s, NCH$_2$*C*H$_3$), 14.5 (s, Tp′*C*H$_3$), 16.4 (s, Tp′*C*H$_3$), 48.1 (s, N*C*H$_2$CH$_3$), 106.6 (s, Tp′*C*H), 145.3 (s, Tp′*C*CH$_3$), 145.9 (s, Tp′*C*CH$_3$), 151.4 (s, Tp′*C*CH$_3$), 181.0 (d, $^{1}J_{PC}$ = 95.3 Hz, PCN$_2$), 227.3 (s, CO), 314.4 (d, $^{1}J_{PC}$ = 28.2 Hz, Mo≡C). − ^{31}P{^{1}H} NMR: δ = −6.51 (s). − MS: *m/z* = 682 [M$^+$] (^{98}Mo), 626 [M$^+$ − 2 CO] (^{98}Mo). − $C_{27}H_{42}BMoN_8O_4P$ (680.42): calcd. C 47.66, H 6.22, N 16.47; found C 46.20, H 6.21, N 15.99. Solid samples retained varying amounts of CH_2Cl_2 despite prolonged drying in vacuo.

[Tp′(CO)$_2$W≡C−P(O)$_2$C(NEt$_2$)$_2$] (**4b**): As described above, 0.65 g (77.9%) of orange-red **4b** was prepared by oxidation of 0.80 g (1.09 mmol) of **2b** with dioxygen at 80 bar. − IR (KBr): $\tilde{\nu}$ = 2552 cm^{-1} w [ν(B−H)], 1989 vs [ν(CO)], 1894 vs [ν(CO)], 1205 m [ν_{as}(PO$_2$)], 1068 m [ν_s(PO$_2$)]. − ^{1}H NMR: δ = 1.30 (t, $^{3}J_{HH}$ = 6.8 Hz, 12 H, CH$_2$C*H*$_3$), 2.34 (s, 3 H, Tp′CH$_3$), 2.37 (s, 3 H, Tp′CH$_3$), 2.40 (s, 6 H, Tp′CH$_3$), 2.69 (s, 6 H, Tp′CH$_3$), 3.92 (q, $^{3}J_{HH}$ = 6.8 Hz, 8 H, C*H*$_2$CH$_3$), 5.81 (s, 1 H, Tp′-H), 5.97 (s, 2 H, Tp′-H). − ^{13}C{^{1}H} NMR: δ = 12.7 (s, Tp′*C*H$_3$), 13.9 (s, NCH$_2$*C*H$_3$), 15.0 (s, Tp′*C*H$_3$), 17.1 (s, Tp′*C*H$_3$), 47.9 (s, N*C*H$_2$CH$_3$), 106.8 (s, Tp′*C*H), 145.4 (s, Tp′*C*CH$_3$), 146.2 (s, Tp′*C*CH$_3$), 152.5 (s, Tp′*C*CH$_3$), 181.9 (d, $^{1}J_{PC}$ = 98.1 Hz, PCN$_2$), 226.5 (s, CO), 299.9 (d, $^{1}J_{PC}$ = 54.0 Hz, W≡C). − ^{31}P{^{1}H} NMR: δ = 7.0 (s, $^{2}J_{WP}$ = 151.7 Hz). − MS: *m/z* = 769 [MH$^+$], 712 [M$^+$ − 2 CO]. − $C_{27}H_{42}BN_8O_4PW$ (768.33): calcd. C 42.21, H 5.51, N 14.58; found C 41.91, H 5.51, N 14.35.

X-ray Crystal Structure Determination of **4a**: Single crystals of **4a** were grown from CH_2Cl_2/hexane at 5°C. A red crystal with the approximate dimensions 0.1 × 0.15 × 0.3 mm^3 was examined with a Siemens SMART CCD area detector system with three axis geometry using Mo-K_α radiation at 173 K. Crystal data and refinement details: Cell dimensions *a* = 16.8674(9), *b* = 15.8355(8), *c* = 13.6762(7) Å, β = 102.9790(10)°, *V* = 3559.6(3) Å^3, *Z* = 4, d_{calcd} = 1.428 g cm^{-3}, μ = 0.608 mm^{-1}, space group $P2_1/c$, data collection of 7737 unique intensities ($2\theta_{max}$ = 54°), semiempirical absorption correction from equivalents, structure solution by direct methods and anisotropic refinement with full-matrix least-squares methods on F^2 for all non-hydrogen atoms, programs used: Siemens SHELXTL-PLUS, SHELXL-97, R_F = 0.0478 for 6115 reflections with $I > 2\ \sigma(I)$, wR_F^2 = 0.0965 for all data, largest diff. peak 0.775 eÅ^{-3}.[16]

Keywords: Cytochrome c / Hyperfine shift / Magnetic susceptibility anisotropy / NMR spectroscopy / Heme proteins

The binding of ammonia to oxidized horse heart cytochrome c has been studied by ^{1}H-NMR, EPR, and CD spectroscopy at pH = 8.0. The affinity constant of the ligand is in the range 1.5−4 M^{-1}. The ^{1}H-NMR spectra of the heme group have been found to be similar to those of the high-pH forms, high-temperature forms, and cyanide adduct of the Met80Ala mutant of *S. cerevisiae* iso-1-cytochrome c. The assignment of a number of signals has led to the determination of the values of the magnetic anisotropy and of the orientation of its axes. The latter are similar to those of the Met80Ala cyanide derivative. The assignment of the high-temperature species has been further pursued during this research. The analysis of the NMR data of the NH_3 adduct leads to the conclusion that substitution of Met80 at high pH or high temperature occurs through a ligand with cylindrical symmetry. This supports the suggestion that Met80 is substituted by a lysine at high pH.

The structure of the native cytochromes c has been extensively characterized by both X-ray crystallography[1][2][3][4][5][6][7] and NMR spectroscopy[8][9][10][11][12]. Several partially unfolded states of the oxidized species have also been detected spectroscopically as a function of temperature, pH, and denaturating agents[13−26] but the structural characterization for these protein forms is not available up to now. One important feature of cytochrome c folding/unfolding processes concerns the involvement of the covalently attached heme group and its axial ligands. The coordination of His and Met stabilizes the native state. Indeed, one of the first steps of ferricytochrome c unfolding upon increasing pH and/or temperature involves the detachment of Met80 from iron coordination[13−26]. In this respect NMR spectroscopy turns out to be a powerful technique for the detection of changes in the iron coordination in ferricytochrome c because the hyperfine shifted resonances are heavily affected by changes in the axial coordination of heme iron[27][28][29][30][31][32][33]. Indeed, through NMR spectroscopy, Hong and Dixon detected two forms of the alkaline isomerized species in slow exchange with the native form on the NMR time scale[34][35]. At neutral pH and temperature above 42°C, Ångstrom et al.[36] observed new species that closely resemble the alkaline isomerized forms. All these species contain low-spin iron(III). Recently, Taler et al. have further characterized the high-temperature species of horse cytochrome c and identified the ^{1}H-NMR resonances of the ε-CH_3 of Met80 in the high-temperature species at typical diamagnetic shift values[14].

It has been proposed that in oxidized cytochrome c at high pH values or at high temperatures the Nζ of a Lys residue substitutes Met80 in binding iron with a pK_a of 8.5−9.5[17][34][35][37][38][39][40][41][42][43][44][45][46][47][48][49]. It is known that pyridine and imidazole bind to iron by replacing Met80[50][51]. We report here an investigation on NH_3 binding to horse heart cytochrome. The results are compared with those related to the high-temperature species, whose characterization has been further extended during this research, with those on the cyanide adduct of the Met80Ala mutant of *S. cerevisiae* cytochrome *c*, and with those on the alkaline forms.

Results

NH_3 Adduct

The formation of the NH_3 adduct of horse heart cytochrome c (hh cyt c, hereafter) upon addition of increasing amounts of a solution of NH_4Br was monitored by ^{1}H-NMR spectroscopy at pH = 8.0 and at 293 K. At this pH this protein is largely in its physiologically relevant conformation, as shown by its ^{1}H-NMR spectrum (Figure 1, A).

Small traces of the alkaline forms are revealed by the peaks marked with asterisks. Upon addition of NH_4Br new resonances appear at δ = 25.2, 23.5, 15.7, 15.5, 11.6, 10.9 whereas the signals of native hh cyt c decrease in intensity (Figure 1, B−D). A broad feature is observed upfield at δ = −11.9. All the above-mentioned resonances are due to non-exchangeable protons because they remain when the spectra are recorded in D_2O.

Analogous titration was performed by circular dichroism spectroscopy (CD) in the Soret region. In the native form, the CD spectrum (Figure 2, A) is characterized by a negative absorption at 417 nm and a positive band at 400 nm, as already reported[40].

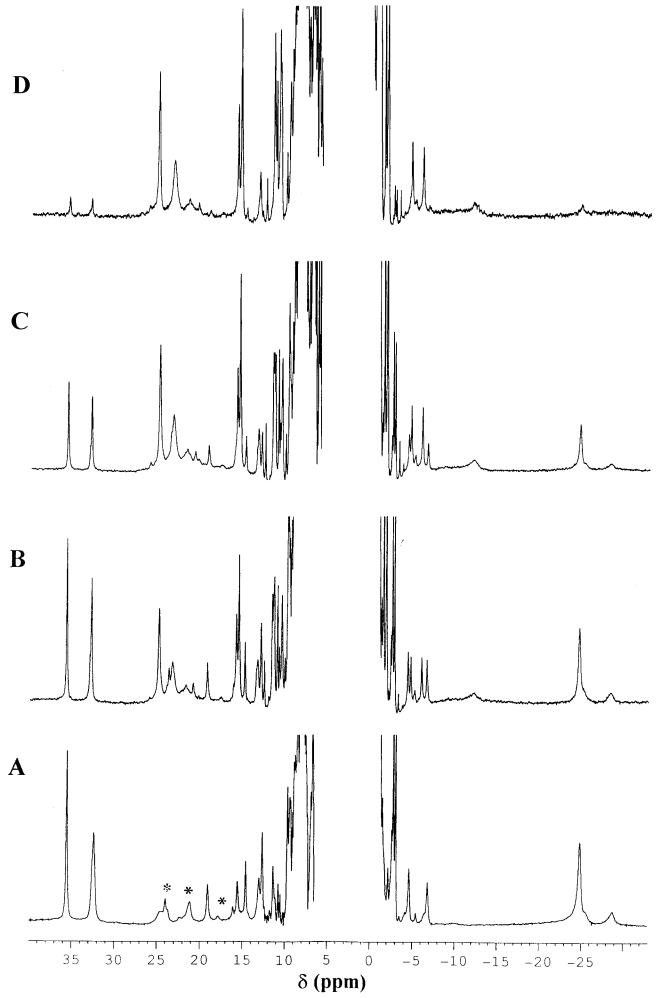

Figure 2. CD spectra on the native hh cyt c (A) and on the NH_3 adduct ([NH_4Br] = 2.7 M) recorded in 100 mM phosphate buffer (pH = 8.0, room temperature)

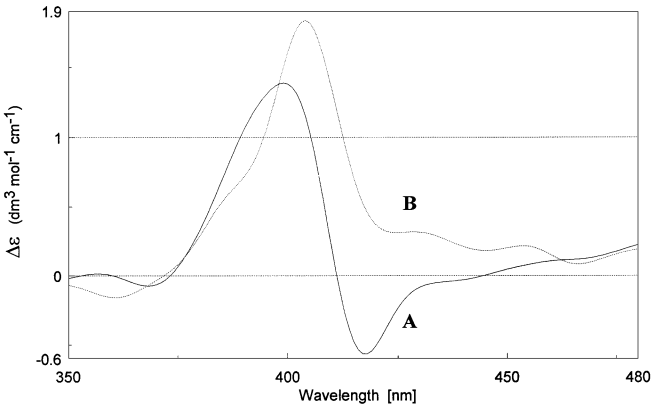

Figure 3. Downfield region of the 600-MHz ^{1}H-NMR EXSY spectrum recorded in H_2O solution (100 mM phosphate buffer, pH = 8.0, T = 293 K) on a sample with a ratio between native and NH_3-bound protein of about 1:1; broken lines indicate EXSY cross peaks between the heme methyl groups in the two protein forms

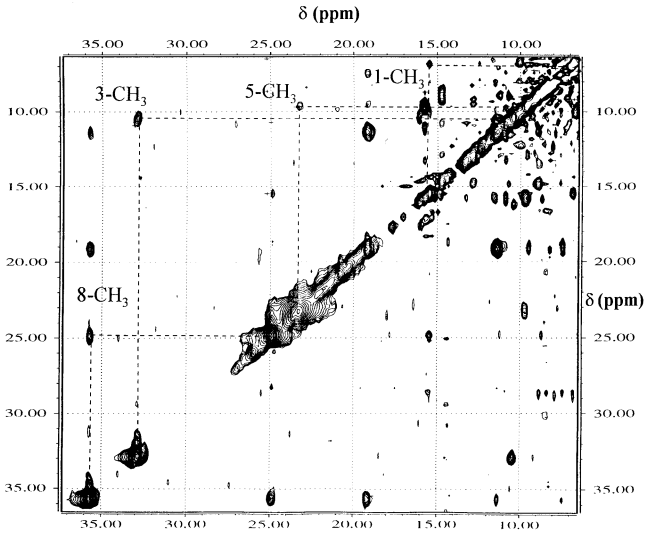

As the ligand concentration increases, the negative band becomes smaller and the positive absorption gains in intensity and moves towards higher wavelenghts. The final spectrum shows an intense positive band with maximum at 407 nm (Figure 2, B). A similar behavior has been reported as a function of an increase in pH and explained with the hypothesis that the negative 417-nm CD band is related to the ligation of the heme iron by Met80[40]. This idea is supported by chemical modification studies on cytochrome c[52].

From the circular dichroism and the ^{1}H-NMR titration, an apparent affinity constant in the range of 1.5−4 M^{-1} can be estimated.

The ^{1}H-NMR spectrum of the NH_3 derivative of hh cyt c was assigned by means of EXSY and NOESY spectroscopy. An EXSY cross peak is clearly detected between 8-CH_3 of the native form and the resonance at δ = 25.2 (Figure 3).

Other EXSY cross peaks have been observed at δ = 11.0 for 3-CH_3, δ = 15.5 for 1-CH_3, and δ = 23.5 for 5-CH_3. The δ-*meso* proton was assigned to the peak at δ = −6.0, thanks to its NOESY connectivities to both 8-CH_3 and 1-CH_3 of the NH_3-bound form. The 7-Hα proton was assigned at δ = 1.8 based on its EXSY connectivity with the 7-Hα of the native protein and on a strong NOESY connectivity with the 8-CH_3 resonance of the NH_3-bound form. The ε-CH_3 of Met80 gives an EXSY cross peak with a signal at δ = −3.3 (data not shown) which is then the corresponding signal in the NH_3 adduct, thus indicating that, in the presence of ammonia, Met80 is detached from iron and moves towards a position characterized by diamagnetic shift values. The β-CH_2 protons of His18 were assigned in the NH_3 adduct at δ = 15.7 and δ = 9.6. Indeed, an exchange cross peak is observed between one β-CH_2 signal at δ = 14.7 in the native form and that at δ = 15.7 in the NH_3 adduct. The resonances of the other β-CH_2 proton in the NH_3-bound and unbound forms are too close to each other to resolve the EXSY connectivity. The resonance was as-

signed by an NOESY experiment. All the above assignments are summarized in Table 1.

The shift pattern for the heme methyl groups is 8-CH_3 > 5-CH_3 > 1-CH_3 > 3-CH_3. The shift spreading is 14.2 ppm and the mean shift value is 18.5 ppm. At the same temperature the mean shift value for the four heme methyl groups of the native species is 21.3 ppm and the shift spreading is 28.9 ppm. At 2.7 M ligand concentrations, the native species is only about 10% of the NH_3-bound form. NOESY and TOCSY experiments were performed to further assign the spectrum of the adduct. The NOESY connectivities observed within the heme moiety are summarized in Scheme 1 (A).

The NOESY experiment allowed us to assign the Hα1 and Hα2 protons of Gly29 from their connectivities with 5-CH_3. The chemical shift of these two protons in the NH_3 adduct is very similar to that of the native form and therefore the EXSY cross peaks are too close to the diagonal to be clearly resolved. Other spin patterns were clearly identified in the TOCSY spectrum recorded in D_2O solution and are reported in Table 2.

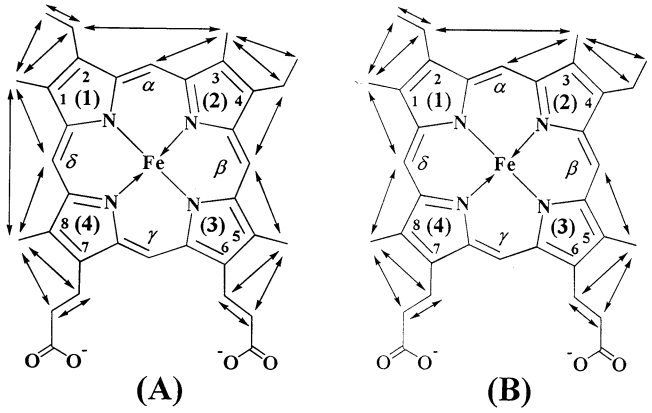
Scheme 1. Schematic representation of a c-type heme; the dipolar connectivities observed between the heme resonances in hh cyt c NH_3 (A) and in the major high-temperature form (B) are also shown



A broad resonance at δ ≈ 280 was also detected in the ^{1}H-NMR spectrum recorded in H_2O, which is probably due to the bound NH_3. No corresponding signal was detected in analogous spectra recorded in D_2O solutions. The broad signal observed at δ = −11.9, which does not exchange in D_2O, remains unassigned. However, its short T_1 value (< 2 ms) supports the idea that it is one of the two not-exchangeable protons of the proximal histidine ring. Non-selective T_1 values were also measured for the heme methyl groups, which are of the order of 70−80 ms.

From the EXSY cross-peak intensity observed between the heme methyl groups and from the above measured T_1 values, an exchange rate of 2−10 s^{-1} can be estimated.

The shift values of the assigned resonances reported in Table 2 allowed us to estimate the magnetic susceptibility tensor parameters for this protein form. The tensor has $\Delta\chi_{ax}$ and $\Delta\chi_{rh}$ values of 4.2 ± 0.2 × 10^{-32} and −2.2 ± 0.1 × 10^{-32} m^3, respectively. The χ_{xx} and χ_{yy} axes are close, although not exactly alligned, to the directions defined by the *meso* protons (the deviation is about 11°), while the χ_{zz} axis deviates by about 16° from the heme normal.

Figure 4. X-band EPR spectra of the NH_3 adduct ([NH_4Br] = 2.7 M, 100 mM phosphate buffer, pH = 8.0) recorded at 4.2 K using 30 dB microwave power and a gain of 800,000 (A), and 20 dB microwave power and a gain of 500,000 (B)

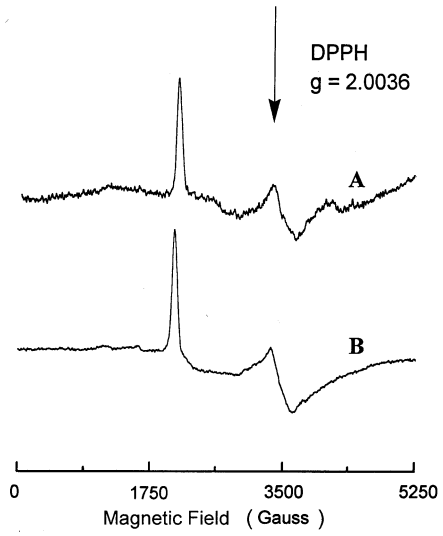


Figure 5. 600-MHz ^{1}H-NMR spectra of native hh cyt c recorded in H_2O solution (100 mM phosphate buffer, pH = 7.0) at various temperatures: (A) T = 293 K; (B) T = 300 K; (C) T = 310 K; (D) T = 320 K; (E) T = 330 K; (F) T = 335 K

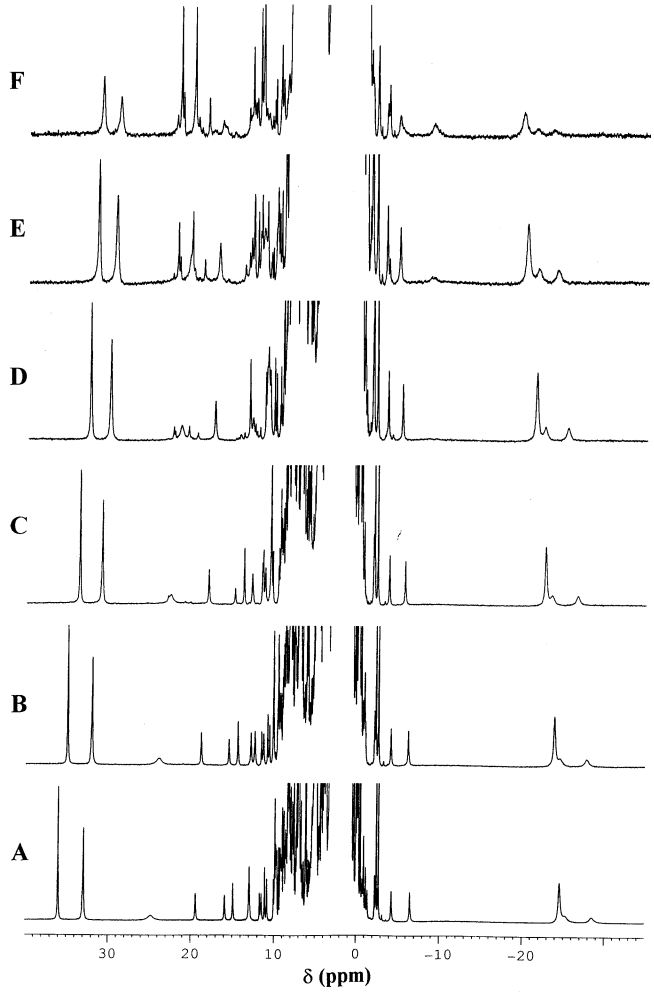


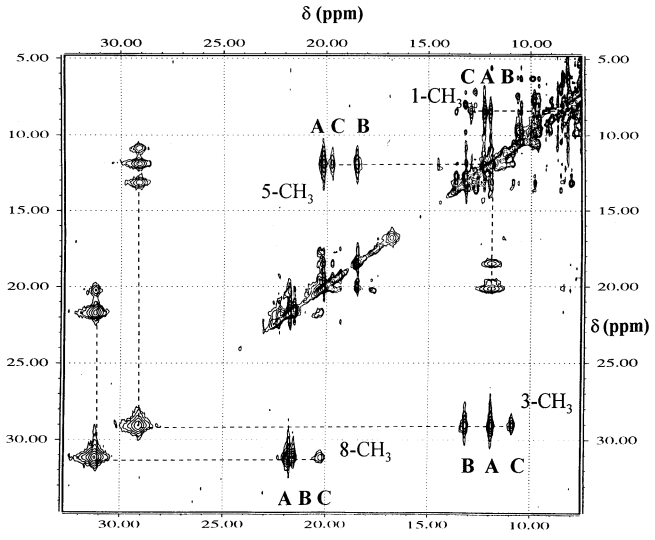
The EPR spectra of the final adduct (2.7 M of NH_4Br) at 4.2 K (Figure 4) show g values of 3.28, 2.01, and 1.66. The g values measured for the NH_3-bound cytochrome c are characteristic for a low-spin iron(III) and are within the range expected for a heme iron coordinated axially by a histidine and an amine group as exemplified by cytochrome f[53].

^{1}H-NMR Spectroscopy on the High-Temperature Species

In Figure 5 the ^{1}H-NMR spectra of oxidized hh cyt c in 100 mM phosphate buffer at pH = 7.0 are shown as a function of temperature in the 293−335 K range. At 293 K only the resonances of the native form are detected[10][54].

Upon increasing the temperature, new hyperfine shifted resonances appear in the 25−20 and 10−13 ppm ranges; a broad signal is also observed at δ = −10. At 335 K the intensity of the signals belonging to the new species is considerably enhanced, being twice as large as the intensity of the native-form resonances. At 335 K, the ^{1}H-NMR resonances due to three out of four heme methyl groups of the native form are well resolved at δ = 31.6, 29.5, and 12.4, while the fourth is at δ = 9.0. Three exchange cross peaks between the native and the high-temperature forms are observed for each methyl group, indicating that three new species are formed (Figure 6).

Figure 6. Downfield region of the 600-MHz ^{1}H-NMR EXSY spectrum of native hh cyt c recorded in H_2O solution (100 mM phosphate buffer, pH = 7.0) at 335 K with a mixing time of 40 ms; broken lines indicate EXSY cross peaks between the heme methyl groups in the native and high-temperature forms; cross peaks due to the three different high-temperature species are labelled accordingly to the concentration of the species: A > B > C



This implies that three different conformations involving the heme and the surrounding residues are present at this temperature. The shifts for these new species are compiled in Table 1. From the peak intensity, the A species is the major one, while the C species has the lowest concentration. The shift range for these resonances corresponds to that reported by Taler et al.[14]. From the EXSY cross-peak intensities, an exchange rate between the native and the

high-temperature forms of the order of 10 s^{-1} can be estimated. EXSY peaks are also observed between the corresponding resonances of the three forms A, B, and C.

EXSY experiments allowed us to identify the 7-propionate Hαs. The 7-propionate Hβs have been assigned on the basis of their NOE connectivities with the 7-Hαs of the same species. Dipolar connectivities were also observed between the 8-CH_3 resonances of the high-temperature forms and the corresponding 7-propionate protons. NOESY cross peaks have been also used to identify the other resonances reported in Table 1. Cross peaks between 5-CH_3 and the α-protons of 6-propionate are detected only for the major of the new species. All the dipolar connectivities between heme resonances observed at 335 K for form A are summarized in Scheme 1 (B).

As already observed by Taler et al.[14] through monodimensional saturation-transfer experiments, two exchange cross peaks were detected in the EXSY experiments between the ε-CH_3 of Met80 of the native form and two resonances at δ = 2.3 and 2.6 of the high-temperature species. Upon saturation of the Hγ proton of Met80 of the native species, located at δ = −22.7, saturation transfer is observed at δ = 3.2 and 2.7. From these assignments, it is clear that all the shift values observed for Met80 in the high-temperature species are typical of a "diamagnetic" methionine and therefore they constitute an additional demonstration that Met80 is detached from the heme iron under these experimental conditions.

By EXSY experiments also some of the His18 resonances were assigned, as reported in Table 1. Only two high-temperature species are detected for this residue.

For the native cytochrome c the heme methyl shift pattern is 8-CH_3 > 3-CH_3 > 5-CH_3 > 1-CH_3. At 335 K the mean shift value for the four heme methyl groups of the native species is 20.6 ppm while the spreading is 22.6 ppm. For the three high-temperature species the observed mean shift values are 17.0, 16.8, and 16.4 ppm for species A, B, and C, respectively. The spreading for the three species is 9.8, 9.6, and 9.4 ppm , in that order. The shift pattern is 8-CH_3 > 5-CH_3 > 1-CH_3 ≈ 3-CH_3.

Discussion

The present data show that NH_3 binds to iron(III) in oxidized hh cyt c by displacing Met80. The system has been characterized by EPR, CD and ^{1}H-NMR spectra. The ^{1}H-NMR spectra of the NH_3 adduct are different from that of the native hh cyt c because Met80 is not bound anymore, but they are, however, very similar to those of the high-temperature forms which experience the detachment of Met80 as well, the binding of another ligand to keep the low-spin nature of the iron. In fact, a heme with only a histidine bound in the fifth position gives rise to a high-spin species as observed in peroxidases[55][56][57][58][59]. Unfortunately, the previous[14] and the present data do not provide evidence for the nature of the sixth ligand. The comparison of the spectra of the NH_3 adduct and of the high-temperature species on one hand, and the spectra of the cyanide derivative of the Met80Ala yeast cytochrome c mutant[60] and of the high-pH species[34] on the other, may be instructive with respect to the conformational and unfolding properties[61][62] of cyt c. It is known[34] that cyt c undergoes a pH-dependent transition with a pK_a of 9.5 at 293 K. Interestingly, the pK_a decreases with increasing temperature, indicating that both pH and temperature cause similar effects. Indeed, Met80 is detached also at high pH[26]. As it results from Table 1, the NMR signals of the high-temperature species are close to those of the alkaline species. The ^{1}H-NMR spectra at high pH and high temperature have been reported also for the cyanide-free Met80Ala yeast cytochrome c[63], where no methionine is bound to the iron. They closely resemble those observed for the native protein under the same experimental conditions, although only one of the two alkaline forms in the mutant has been detected[63].

The ^{1}H-NMR heme shift pattern observed for the high-temperature forms, for the alkaline form, and for the NH_3 adduct closely resembles that of the cyanide adduct of Met80Ala mutant of yeast iso-1-cytochrome c (last column of Table 1)[60]. For the latter protein (at 303 K) the heme methyl resonances order is 8-CH_3 > 5-CH_3 > 1-CH_3 > 3-CH_3, the mean shift value is 17.2 ppm, and the heme methyl signal spreading is 11.2 ppm.

The cyanide adduct of Met80Ala mutant of yeast iso-1-cytochrome c has been extensively characterized by NMR both in terms of structure[60][64] and electronic properties[65][66]. The magnetic susceptibility tensor axes and anisotropies have been evaluated[65] and the contact contribution to the shift for the heme and the axial ligand has been separated from the pseudocontact one (Table 3). The pattern of the contact and pseudocontact contributions to the shift of the porphyrin methyl protons are determined by the orientation of the axial ligands[67−78]. In native cytochrome c both the His and the Met are contributing, whereas in the cyanide adduct of Met80Ala cytochrome c the orientation of the p_π nitrogen orbital of the His ring defines the shift pattern. In the latter system this orbital lies approximately parallel to the β/δ-*meso* direction and the smallest spin density is found for the 3-CH_3 (second column of Table 3)[65]. In native cytochrome c the contact shift pattern is completely different due to the contribution of Met80 which imparts a pairwise pattern to the heme methyl groups on opposite pyrrole rings, the 8-CH_3 and 3-CH_3 having significantly larger shifts than 1-CH_3 and 5-CH_3 (Table 3, third and fourth columns).

Table 3. Contact shift values (ppm) calculated for the NH_3 adduct of hh cyt *c*, the cyanide adduct of Met80Ala *S. cerevisiae* iso-1-cytochrome c (Met80Ala-CN^-)[65], native *S. cerevisiae* cytochrome c (yeast cyt c)[9], hh cyt c[10]

	hh cyt c-NH_3	Met80Ala-CN^-	yeast cyt c	hh cyt c
1-CH_3	24.0	16.9	4.5	3.4
3-CH_3	11.5	10.5	27.1	29.0
5-CH_3	32.0	20.8	7.4	6.1
8-CH_3	27.8	24.6	32.4	33.5

The orientation of the axial ligand determines the in-plane orientation of the magnetic susceptibility tensor axes[72][73][74][75][76][77][78] and then contributes to differentiate the shifts of the methyl signals. The directions of the tensor determined for the NH_3 adduct compare well with those of the cyanide adduct of Met80Ala for which the in-plane axes are essentially aligned with the *meso* proton directions and the *z* direction forms an angle of 6° with the direction of the perpendicular to the heme plane. The contact shift values for the heme methyl groups in the NH_3 adduct are also listed in Table 3 for comparison purposes. Analogously to the cyanide adduct of Met80Ala, the 3-CH_3 experiences the smallest shift.

Unfortunately, the NMR spectrum of the high-temperature species is complicated by the coexistence of four species at the same time. (At higher temperatures the protein denaturates). This prevented us from further extending the assignment of the A, B, and C forms and from calculating the magnetic susceptibility parameters. However, the comparison of the shift patterns of the high-temperature cytochrome c with the NH_3 adduct and with that of the cyanide adduct of the Met80Ala mutant, clearly supports the idea that the sixth axial ligand is axially symmetric. The same indication comes for the high-pH species.

Concluding Remarks

The assignment of the protons of the iron ligands reported in Table 1 for the NH_3 adduct and for the high-temperature species indicates a meaningful similarity between the two species. The similarity extends to the high-pH form of cytochrome c and the cyanide adduct of the Met80Ala mutant. The directions of the magnetic susceptibility anisotropy tensor for the NH_3 adduct are similar to those found in the cyanide adduct of the Met80Ala mutant. All of this has been rationalized in terms of the orientation of the axial histidine being the only factor determining the heme proton shift pattern. This suggests that the other axial ligand in the high-pH and the high-temperature forms has cylindrical symmetry. The results presented here are consistent with the hypothesis of a lysine substituting Met80 at high pH. They also shed further light on the conformational flexibility of the protein under various conditions.

Experimental Section

Sample Preparation: Horse heart cytochrome c (Type VI) was purchased from Sigma Chemical Co. and used without further purification. The ^{1}H-NMR samples were prepared by dissolving the lyophilized protein in 100 mM phosphate buffer to give 2−4 mM solutions. The pH of the NMR samples was adjusted by addition of small volumes of concentrated solutions of NaOH or H_3PO_4. The pH was measured with an Orion Model 720 pH meter and a Microelectrodes, Inc., Model MI-410 microcombination pH probe. The NH_3 adduct was prepared by adding increasing amounts of a concentrated solution of NH_4Br at pH = 8.0. The same sample was used for EPR measurements. Circular dichroism spectra were obtained with a Jasco J500 dicrograph by titrating with NH_4Br a 8.0 μM ferricytochrome c solution (pH = 8.0, 100 mM phosphate buffer).

NMR Spectroscopy: The ^{1}H-NMR spectra were recorded with Bruker DRX 500 and AMX 600 spectrometers. T_1 measurements at 500 MHz were performed with the inversion-recovery method[79]. The 1D saturation-transfer experiments were performed with the superWEFT pulse sequence[80] and were collected using the standard methodology used for nuclear Overhauser effect (NOE) experiments of paramagnetic macromolecules[81]. All other spectra were acquired using presaturation during relaxation delay. EXSY experiments with the native cytochrome c were performed over the full spectral width with mixing times of 25, 40, and 60 ms at different temperatures (300, 310, 320, 330, 335 K). NOESY[82] and TOCSY[83] maps on a smaller spectral width (21 ppm) were collected in H_2O solutions at 335 K with a mixing time of 100 ms and a spin-lock time of 90 ms, respectively. EXSY experiments with a sample containing about 50% of the NH_3 adduct and 50% of the unbound form of cytochrome c were acquired with a mixing time of 40 ms at 293 K. NOESY and TOCSY maps of the completely NH_3-bound species were collected over a smaller spectral width (21 ppm) in H_2O and D_2O solutions at 293 K with a mixing time of 100 ms and a spin-lock time of 90 ms, respectively. − The 2D maps consisted of 4 K or 2 K data points in the F2 dimension. From 512 to 1024 experiments were recorded in the F1 dimension, using 64−512 scans per experiment. Raw data were multiplied in both dimensions by a pure cosine-squared and Fourier transformed to obtain 2048 × 2048 real data points. A polynomial base-line correction was applied in both directions. Data processing was performed using the standard Bruker software package. The 2D maps were analyzed by means of IBM RISC 6000 computers with the aid of the program XEASY (ETH, Zürich)[84].

EPR Spectroscopy: EPR experiments were performed at about 4.2 K with a Bruker ER200 spectrometer, operating at 9.6 GHz, equipped with an Oxford cryostat. The *g* values were calibrated by taking the 2,2-diphenyl-1-pycrylhydrazyl (DPPH) peak as reference (g = 2.0036). Spectra have been recorded using 30 dB microwave power and a gain of 800,000 or 20 dB microwave power and a gain of 500,000.

Magnetic Susceptibility Tensor Parameters: The hyperfine shift, i.e. the difference in shift of a proton in a paramagnetic system from that in an analogous diamagnetic system, includes contact and pseudocontact contributions[85][86][87][88]. The contact coupling is due to the presence of unpaired spin density on the resonating nucleus and vanishes a few chemical bonds away from the metal center. The pseudocontact contribution (δ_{pc}) arises from the magnetic susceptibility anisotropy and depends on the nuclear position with respect to the principal axes of the magnetic susceptibility tensor. Within the metal-centered point-dipole point-dipole approximation, the following equation holds[89]:

$$\delta_{pc} = \frac{1}{12\pi r_i^3}\left[\Delta\chi_{ax}(3n_i^2 - 1) + \frac{3}{2}\Delta\chi_{rh}\left(l_i^2 - m_i^2\right)\right] \quad (1)$$

where $\Delta\chi_{ax}$ and $\Delta\chi_{rh}$ are the axial and the rhombic anisotropies of the magnetic susceptibility induced by the paramagnetic ion, r_i is the distance of the nucleus *i* from the metal ion, and l_i, m_i, and n_i are the direction cosines of the position vector of atom *i* (r_i) with respect to the orthogonal reference system formed by the principal axes of the magnetic susceptibility tensor. − Pseudocontact shifts were determined by subtracting the chemical shifts measured in the reduced species of hh cyt c[90] from those of the NH_3-bound oxidized form of the same protein. The resonances of cysteines 14 and

17, of histidine 18, and of methionine 80 would experience non-negligible contact shifts and therefore were not included in the calculations. The 5 independent parameters (i.e. $\Delta\chi_{ax}$, $\Delta\chi_{rh}$, and three independent direction cosines which define the principal directions of the χ tensor with respect to a metal-centered axis system) were determined by finding the best fit of eq. 1 to a set of pseudocontact shifts[65][66], using the solution structure of horse heart cytochrome c[10].

Received November 25, 1997

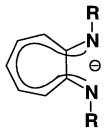
Keywords: Yttrium / Aminotroponiminate / Cyclopentadienyl / Dynamic NMR

Mixed aminotroponiminate ([ATI]$^-$) cyclopentadienyl complexes were prepared using two different synthetic routes. Reaction of $[[(i\text{Pr})_2\text{ATI}]\text{YCl}_2(\text{THF})_2]_2$ (**1**) with KCp* (Cp* = C_5Me_5) or $\text{Li}[C_5H_3(SiMe_3)_2]$ affords $[(i\text{Pr})_2\text{ATI}]\text{YCp}_2$* (**2a**) and $[(i\text{Pr})_2\text{ATI}]\text{Y}[C_5H_3(SiMe_3)_2]_2$ (**2b**), respectively. Moreover, $[(i\text{Pr})_2\text{ATI}]\text{YCp}_2$* has also been obtained from the reaction of Cp_2*$\text{Y}(\mu\text{-Cl})_2\text{Li}(\text{OEt}_2)_2$ (**3**) and $[(i\text{Pr})_2\text{ATI}]$K. The single crystal X-ray structure of $[(i\text{Pr})_2\text{ATI}]\text{YCp}_2$* shows that the steric demand of the $[(i\text{Pr})_2\text{ATI}]^-$ ligand is somewhat similar to that of the well-known cyclopentadienyl group and diazadiene ligand. $[(i\text{Pr})_2\text{ATI}]\text{Y}[C_5H_3(SiMe_3)_2]_2$ shows a dynamic behavior in solution (^{1}H NMR), which is essentially caused by rotation of the cyclopentadienyl group rather than by migration of the $[(i\text{Pr})_2\text{ATI}]^-$ ligand.

Introduction

Recently, there has been significant interest in early transition metal chemistry for the replacement cyclopentadienyl (or related systems) by other ligands in order to generate a similar steric and electronic environment.[1] For example, a number of metal complexes of the lanthanides and group 3 elements have been synthesized in which cyclopentadienyl is replaced by anionic bidentate nitrogen ligands such as amides,[2] benzamidinates,[3] and diazadienes.[4]

The aminotroponiminates ([ATI]$^-$) **A**, have been introduced as cyclopentadienyl alternatives for group 3,[5] group 4,[6] and the lanthanide elements.[5] [ATI]$^-$ is a bidentate mono-anionic ligand that features a 10 π electron backbone.[7] Upon coordination to a metal atom, [ATI]$^-$ forms a five-membered metallacycle adjacent to the seven-membered carbon ring. Recently, it was shown that the heteroleptic yttrium amides $[\text{ATI}]\text{Y}[\text{N}(\text{SiMe}_3)_2]_2$ and $[\text{ATI}]_2\text{Y}[\text{N}(\text{SiMe}_3)_2]$ are active catalysts for the hydroamination/cyclization reaction of aminoalkynes.[8] The new catalysts were obtained by transmetallation of the corresponding chloro precusors $[[\text{ATI}]\text{YCl}_2(\text{THF})_2]_2$ and $[\text{ATI}]_2\text{YCl}$ using $\text{K}[\text{N}(\text{SiMe}_3)_2]$.



A

In order to compare the coordination behavior and the steric demands of both [ATI]$^-$ and cyclopentadienyl groups, our main interest is now focused on mixed cyclopentadienyl-[ATI]$^-$ complexes. In this paper, the synthesis of new cyclopentadienyl-[ATI]$^-$ yttrium complexes starting from the isopropyl derivative $[[(i\text{Pr})_2\text{ATI}]\text{YCl}_2(\text{THF})_2]_2$ (**1**)[5] is reported. These reactions lead to complexes of the general formula $[(i\text{Pr})_2\text{ATI}]\text{YCp}_2$ [Cp = C_5Me_5, $C_5H_3(SiMe_3)_2$]. **1** can be obtained from $[(i\text{Pr})_2\text{ATI}]$K and YCl_3 (Scheme 1).

Results and Discussion

Transmetallation of **1** with a slight excess of potassium pentamethylcyclopentadienyl (KCp*) in THF (Scheme 1), followed by workup in pentane, yields the corresponding dicyclopentadienyl complex $[(i\text{Pr})_2\text{ATI}]\text{YCp}_2$* (**2a**) as a pure yellow solid in fairly good yield. **2a** can also be obtained by the "classical" route using Cp_2*$\text{Y}(\mu\text{-Cl})_2\text{Li}(\text{OEt}_2)_2$ (**3**)[9] as the starting material. Reaction of **3** with 1 equivalent of $[(i\text{Pr})_2\text{ATI}]$K in toluene, followed by extraction with pentane, also affords **2a** (Scheme 1). **2a** is an air and moisture sensitive compound and has been characterized by MS, ^{1}H- and ^{13}C-NMR spectroscopy, and elemental analysis. The ^{1}H-NMR spectrum shows a sharp singlet for the protons of the Cp* unit, and this signal is shifted slightly downfield (δ = 1.94) compared with that of **3** (δ = 1.83).[9] The room temperature ^{1}H- and ^{13}C-NMR spectra point to a symmetrical coordination of the $[(i\text{Pr})_2\text{ATI}]^-$ ligand in solution, which is in agreement with the coordination observed in the solid state (see below). The signal of the isopropyl C*H* of **2a** is well resolved into a septet, but shows a marked upfield shift (δ = 3.82) compared to the starting material **1** (δ = 4.04).[5] In contrast to the anionic dicyclopentadienyl diazadiene complex of lanthanum, $[\text{Cp}_2\text{*La(DAD)}]^-$ {DAD = (Ph)N=C(Ph)C(Ph)=N(Ph)},[10] and the dicyclopentadienyl diazadiene complexes of group 4 metals, Cp_2*M(DAD) (M = Zr, Hf),[11] **2a** does not show a rapid dynamic exchange of the chelating ligand in solution at room temperature. Whereas DAD

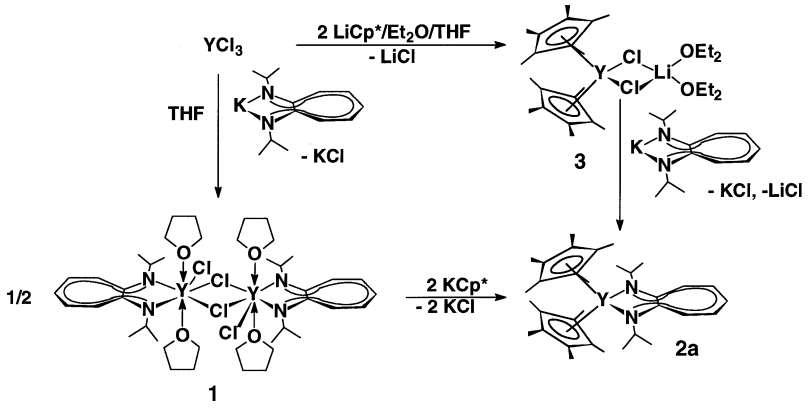
Scheme 1

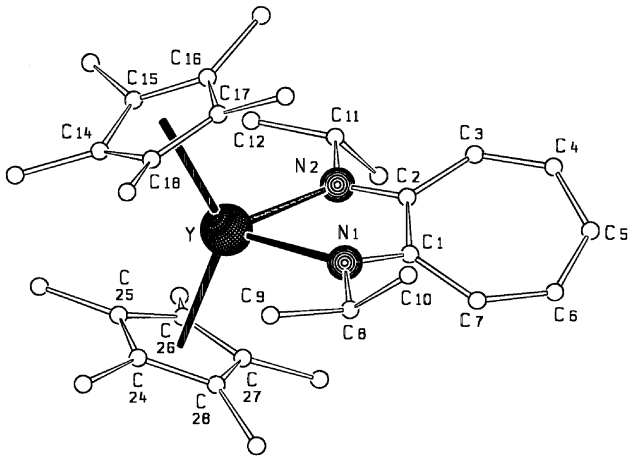


complexes show a rapid migration of the Cp*M unit from one side of the reduced DAD ligand to the other, the rigid geometry of the $[(i\mathrm{Pr})_2\mathrm{ATI}]^-$ ligand (also seen in the single crystal X-ray structure of **2a**) prevents such a strong movement of the Cp_2*Y moiety.

The solid-state structure of **2a** was investigated by single-crystal X-ray diffraction (Figure 1). Suitable crystals were obtained by slow evaporation of a saturated heptane solution of **2a**. The structure reveals a pseudo-tetrahedral arrangement of the ligands around the yttrium atom. The C_g−Y (C_g = Cp*-ring centroids) distances (C_g1−Y 244.6 pm and C_g2−Y 244.2 pm) are in the expected range of other Cp_2*Y^{III} compounds [e.g. 240.8(4) pm in Cp_2*Y(DAD)[10] and 266(2) pm in Cp_2*Y(μ-Cl)$_2$Li(THF)$_2$[12]]. The angle C_g1−Y−C_g2 (133.95°) is approximately five degrees smaller than that in Cp_2*Y(DAD) [138.6(2)°]. Similar bonding modes are observed for Cp_2*Sm[N(*t*Bu)=CHCH=N(*t*Bu)].[13] Both Cp* rings in **2a** are located in a staggered position with respect to each other. A C_2-symmetric coordination of the $[(i\mathrm{Pr})_2\mathrm{ATI}]^-$ ligand along the Y−C5 axis with symmetric N−Y distances [N1−Y 239.8(2) and N2−Y 239.0(3) pm] is observed. The whole $[(i\mathrm{Pr})_2\mathrm{ATI}]^-$ framework is twisted, i.e. the atom C1 (C2) is located about 40 pm above (below) the least-squares mean plane defined by the seven membered ring (C1−C7). This observation is in sharp contrast to the comparable group 4 complexes, $[(i\mathrm{Pr})_2\mathrm{ATI}]_2\mathrm{MCl}_2$ (M = Zr, Hf),[6] which show a planar coordination of the ligand. The N1−Y1−N2 angle [69.38(9)°] is in the range of comparable compounds such as **1** [67.4(2)°][5] and also of Cp_2*Y(DAD) [70.1(1)°], suggesting a similar steric demand for $[(i\mathrm{Pr})_2\mathrm{ATI}]^-$ and DAD.

$[(i\mathrm{Pr})_2\mathrm{ATI}]\mathrm{Y}[\mathrm{C}_5\mathrm{H}_3(\mathrm{SiMe}_3)_2]_2$ (**2b**) is prepared in a similar way to **2a**. Transmetallation of **1** with lithium bis[1,3-(trimethylsilyl)cyclopentadienyl], $\mathrm{Li}[\mathrm{C}_5\mathrm{H}_3(\mathrm{SiMe}_3)_2]$ in toluene in a 2:1 molar ratio (equation 1), followed by workup in pentane, leads to **2b** as a yellow solid in very high yields. **2b** has been characterized by MS, IR, ^{1}H-NMR spectroscopy, and elemental analysis. In contrast to **2a** the ^{1}H-NMR spectrum of **2b** shows a dynamic behavior in solution. At low temperature (213 K) two doublets for the methyl protons of the isopropyl groups of the $[(i\mathrm{Pr})_2\mathrm{ATI}]^-$ ligand are observed along with two singlets for the Me_3Si groups. These

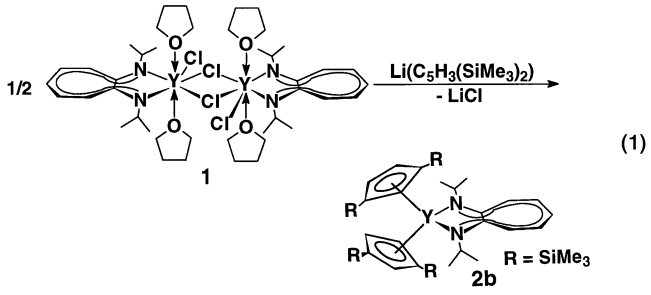
Figure 1. Solid-state structure of **2a** showing the atom labeling scheme, omitting hydrogen atoms (SCHAKAL drawing)[a]



[a] Selected distances [pm] and angles [°]: C1−N1 132.7(4), C2−N2 132.9(4), C14−Y 277.5(3), C15−Y 275.4(3), C16−Y 270.8(3), C17−Y 271.8(3), C18−Y 276.4(3), C24−Y 269.0(4), C25−Y 271.1(3), C26−Y 275.5(3), C27−Y 273.3(3), C28−Y 271.1(4), N1−Y 239.8(2), N2−Y 239.0(3), C_g1−Y 244.6, C_g2−Y 244.2; N2−Y−N1 69.38(9), N1−Y−C14 127.52(10), N2−Y−C14 131.12(10), N1−Y−C15 132.13(10), N2−Y−C15 102.46(10), N1−Y−C16 103.40(9), N2−Y−C16 84.06(10), N1−Y−C17 84.22(9), N2−Y−C17 98.73(10), N1−Y−C18 97.93(10), N2−Y−C18 128.48(10), C_g1−Y−C_g2 133.95 (C_g = ring centroid).

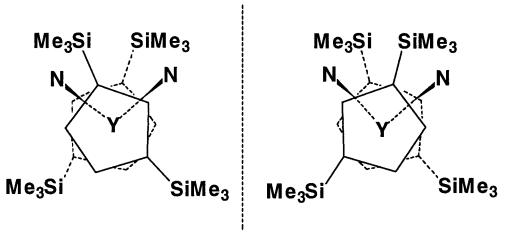
signals start to coalesce with increasing temperature and have a coalescence temperature of about T_c = 273 K. At higher temperatures (313 K and above) the signals due to the methyl protons of the isopropyl groups appear as one doublet and the signal of the Me_3Si groups as a singlet. Since the $[(i\mathrm{Pr})_2\mathrm{ATI}]^-$ ligand does not show a fluctionality in **2a**, these results were interpreted as evidence that the two diastereotopic isopropyl groups exist in different chiral environments and, due to the reciprocal nature of this effect, so do the Me_3Si groups. It was shown earlier that $[\mathrm{C}_5\mathrm{H}_3(\mathrm{SiMe}_3)_2]_2\mathrm{ZrX}_2$ (X = F, Br, I) complexes crystallize in a staggered conformation.[14] These conformations are chiral in the absence of rotation of the cyclopentadienyl groups. In accordance with these results, two enantiomeric conformations are depicted in Figure 2 by considering a stronger repulsion of the Me_3Si groups in the back of the

bent metallocene than in the front. At high temperature both enantiomers interconvert rapidly, thus showing only one set of signals. A similar diastereotopic splitting of the isopropyl signals of the $[(i\mathrm{Pr})_2\mathrm{ATI}]^-$ ligand was observed earlier for the chiral homoleptic compounds $[(i\mathrm{Pr})_2\mathrm{ATI}]_3\mathrm{Ln}$ (Ln = Y, La, Sm).[5]



(1)

Figure 2. Schematic representation of both enantiomers of **2b** observed at low temperature in the ^{1}H NMR (considering the absence of a suitable scrambling mechanism at these temperatures)



From the coalescence temperature (T_c = 273) and the separation ($\Delta\nu$ = 33.21 s^{-1}, 250 MHz NMR) of the two coalescing doublets of the isopropyl groups in the absence of any exchange, the free energy for the rotation about the Y−C_g axis was calculated to be $\Delta G_{Tc}^{\geq}$ = 56.95 kJ/mol, according to equation 2.[15]

$$\Delta G_{Tc}^{\ddagger} = -RT_c\ln(\pi\Delta\nu\, h/\sqrt{2}\, k_b T_c) \quad (2)$$

In summary, new mixed cyclopentadienyl−$[ATI]^-$ complexes of yttrium have been prepared. It has been demonstrated that the steric demand of the $[(i\mathrm{Pr})_2\mathrm{ATI}]^-$ ligand is comparable to that of the well-known cyclopentadienyl groups and diazadiene ligands. The fluctional behavior of $[(i\mathrm{Pr})_2\mathrm{ATI}]\mathrm{Y}[\mathrm{C_5H_3(SiMe_3)_2}]_2$ (**2b**) is essentially caused by rotation of the cyclopentadienyl groups and not by migration of the $[(i\mathrm{Pr})_2\mathrm{ATI}]^-$ ligand.

Experimental Section

General: All manipulations of air-sensitive materials were performed with the rigorous exclusion of oxygen and moisture in flame-dried Schlenk-type glassware either on a dual manifold Schlenk line, or interfaced to a high vacuum (10^{-4} Torr) line, or in an argon-filled Braun Atmospheres glove box. Ether solvents (tetrahydrofuran and diethyl ether) were pre-dried over Na wire and distilled under nitrogen from Na/K alloy benzophenone ketyl. Hydrocarbon solvents (toluene and pentane) were distilled under nitrogen from Na wire. All solvents for vacuum line manipulations were stored in vacuo over Na/K alloy in resealable flasks. Deuterated solvents were obtained from Aldrich Inc. (all 99 atom% D) and were degassed, dried, and stored in vacuo over Na/K alloy in resealable flasks. NMR spectra were recorded on a Bruker AC 250 spectrometer. Chemical shifts are referenced to internal solvent resonances and are reported relative to tetramethylsilane. IR spectra were performed on a Bruker IFS 28, mass spectra were recorded at 70 eV on Varian MAT 711. Elemental analyses were performed in the micro analytical laboratory of the Institut für Anorganische Chemie der Universität Karlsruhe (S. Ariman). KCp*[16], $\mathrm{Li[C_5H_3(SiMe_3)_2]}$,[13] $\mathrm{Cp_2^*Y(\mu\text{-}Cl)_2Li(OEt_2)_2}$,[9] $[(i\mathrm{Pr})_2\mathrm{ATI}]\mathrm{K}$,[5] and $[[(i\mathrm{Pr})_2\mathrm{ATI}]\mathrm{YCl_2(THF)}]_2$,[5] were prepared by literature procedures.

Preparation of [(iPr)$_2$ATI]YCp$_2$* (**2a**) − *Route A:* THF was condensed at −196°C onto a mixture of 189 mg (0.21 mmol) of $\{[(i\mathrm{Pr})_2\mathrm{ATI}]\mathrm{YCl_2(THF)_2}\}_2$ and 174 mg (1.0 mmol) of KCp*, and the mixture was stirred for 18 h at room temperature. The solvent was evaporated in vacuum, and pentane was condensed onto the mixture. The solution was then filtered, and the solvent removed. This procedure was repeated twice. The remaining solid was recrystallized from pentane. − Yield 130 mg (56%).

Route B: THF was condensed at −196°C onto a mixture of 390 mg (0.21 mmol) of $\mathrm{Cp_2^*Y(\mu\text{-}Cl)_2Li(OEt_2)_2}$, and 161 mg (1.0 mmol) of $[(i\mathrm{Pr})_2\mathrm{ATI}]\mathrm{K}$ and the mixture was stirred for 18 h at room temperature. The solvent was evaporated in vacuum, and pentane was condensed onto the mixture. The solution was then filtered, and the solvent removed. The remaining solid was recrystallized from pentane. − Yield 180 mg (49%). − ^{1}H NMR (C_6D_6, 250 MHz, 25°C): δ = 1.17 [d, 12 H, $(CH_3)_2CH$, J(H,H) = 6.3 Hz], 1.94 (s, 30 H, CH_3Cp), 3.82 [sept, 2 H, $(CH_3)_2CH$, J(H,H) = 6.4 Hz], 6.09−6.24 (m, 3 H, $H^{3,5,7}$), 6.84 (dd, 2 H, $H^{4,6}$). − $^{13}C\{^1H\}$ NMR (C_6D_6, 62.9 MHz, 25°C): δ = 13.4 (CH_3Cp), 22.9 [$(CH_3)_2CH$], 49.4 [$(CH_3)_2CH$], 115.1 (C^5), 115.3 (Cp), 119.6 ($C^{3,7}$), 133.4 ($C^{4,6}$), 164.2 ($C^{1,2}$). − EI/MS (70 eV) *m/z* (%): 562 ($[M]^+$, rel. int. 11), 427 ($[M - Cp^*]^+$, 100), 223 ($[Cp^*Y - H]^+$, 64), 204 ($[C_{13}H_{20}N_2]^+$, 87). − $\mathrm{C_{33}H_{49}N_2Y}$ (562.67): calcd. C 70.44, H 8.78, N 4.98; found C 70.03, H 8.57, N 5.31.

Preparation of [(iPr)$_2$ATI]Y(C$_5$H$_3$(SiMe$_3$)$_2$)$_2$ (**2b**): THF was condensed at −196°C onto a mixture of 217 mg (0.25 mmol) of $\{[(i\mathrm{Pr})_2\mathrm{ATI}]\mathrm{YCl_2(THF)_2}\}_2$ and 216 mg (1.0 mmol) of $\mathrm{Li[C_5H_3(SiMe_3)_2]}$, and the mixture was stirred for 18 h at room temperature. The solvent was evaporated in vacuum, and pentane was condensed onto the mixture. The solution was then filtered, and the solvent removed. This procedure was repeated twice. −Yield 335 mg (94%). − IR (KBr) $\tilde{\nu}$ = 1592 cm^{-1} (st), 1506 (vs), 1470 (st), 1249 (st), 833 (vs). − ^{1}H NMR ([D$_8$]toluene, 250 MHz, 70°C): δ = 0.20 (s, 36 H, CH_3Si), 1.38 [d, 12 H, $(CH_3)_2CH$, J(H,H) = 6.6 Hz], 3.56 [sept, 2 H, $(CH_3)_2CH$], 6.09−6. 20 (m, 3 H, $H^{3,5,7}$), 6.16 (d, 2 H, Cp), 6.35 (d, 2 H, Cp), 6.64 (dd, 2 H, $H^{4,6}$), 6.71 (s, 1 H, Cp). − $^{13}C\{^1H\}$ NMR ([D$_8$]toluene, 62.9 MHz, 25°C): δ = 1.4 (CH_3Si), 20.7 [$(CH_3)_2CH$], 46.3 [$(CH_3)_2CH$], 110.6 (Cp), 115.3 (C^5), 117.9 (Cp), 119.5 ($C^{3,7}$), 133.4 ($C^{4,6}$), 164.2 ($C^{1,2}$). − ^{29}Si NMR ([D$_8$]toluene, 49.7 MHz, 25°C): δ = −9.5. − EI/MS (70 eV) *m/z* (%): 710 ($[M]^+$, rel. int. 11), 637 ($[M - C_3H_{15}Si]^+$, 8), 501 $[M - (C_9H_{11}N_2)]^+$, 100), 297 ($[C_{11}H_{21}YSi_2)]^+$ 37). − $\mathrm{C_{35}H_{61}N_2Si_4Y}$ (711.23): calcd. C 59.12, H 8.65, N 3.94; found C 58.75, H 8.71, N 4.50.

Crystal Structure Analysis of **2a**: Stoe-IPDS diffractometer (Mo-K_α radiation); T = 203(3) K; data collection and refinement: SHELXS-86[17], SHELXL-93[18]; monoclinic, space group P-1; lattice constants a = 9.694(2), b = 10.284(2), c = 15.730(3) Å, α = 88.39(2), β = 89.57(2), γ = 75.18(2)°, V = 1515.6(5) Å^3, Z = 2;

μ(Mo-K_α) = 2.666 mm^{-1}; $2\theta_{max.}$ = 26.00; 5511 independent reflections measured, of which 4539 were considered observed with $I > 2\sigma(I)$; max. residual electron density 0.526 and −0.367 e/A^{-3}; 339 parameters (all non hydrogen atoms were calculated anisotropically; the positions of the H atoms were calculated for idealized positions) R_1 = 0.0427. − Further details of the crystal structure investigation are available from the Fachinformationszentrum Karlsruhe, D-76344 Eggenstein-Leopoldshafen (Germany) on quoting the depository number CSD-407970, the name of the author, and the journal citation.

Keywords: Chirality / P ligands / Nickel / Palladium / Platinum

Radical-initiated P−H addition of (1*S*,2*S*)-$C_5H_8(PH_2)_2$ to cycloalkenes gave bis(secondary phosphanes), (1*S*,2*S*)-$C_5H_8[P(H)C_nH_{2n-1}$-*cyclo*$]_2$ (n = 5−8), as mixtures of $R_P,R_{P'}$, $S_P,S_{P'}$, and $R_P,S_{P'}$ diastereomers. The three diastereomers of the peralkylated chiral P_2 ligand (1*S*,2*S*)-$C_5H_8[P(CH_3)C_8H_{15}$-*cyclo*$]_2$ and its complexes with $NiCl_2$, PdI_2, and PtI_2 were prepared. The structures of [(1*S*,2*S*)-$C_5H_8\{P(CH_3)C_8H_{15}$-*cyclo*-(*R*)$\}_2NiCl_2$]·[(1*S*,2*S*)-$C_5H_8\{P(CH_3)C_8H_{15}$-*cyclo*-(*S*)$\}_2NiCl_2$], (1*S*,2*S*)-$C_5H_8\{P(CH_3)C_8H_{15}$-*cyclo*-(*R*)$\}_2PdI_2$, and (1*S*,2*S*)-$C_5H_8\{P(CH_3)C_8H_{15}$-*cyclo*-(*R*)$\}_2PtI_2$ were determined by X-ray diffraction.

The development of novel chiral ligands for applications in catalysis continues to be an important field of synthetic organic and organometallic chemistry[3]. Optically stable bidentate phosphanes exhibiting C_2 chirality in their carbon frameworks are among the most successful ligands employed in a variety of transition metal-catalyzed enantioselective hydrogenations[4]. In many of these widely used chelating bisphosphanes the phosphorus atoms bear two aryl substituents. The correct orientation of these aryl substituents in the coordination sphere has been identified as a stereochemically important feature contributing to the "recognition ability" of the metal complex[5]. The traditional route to this class of compounds involves the nucleophilic substitution with alkali metal diarylphosphides of enantiopure ditosylates derived from optically active natural precursors. This approach suffers the disadvantage that it cannot be applied to the preparation of *P*-alkylated analogs. Attempted replacement reactions using alkali metal dialkylphosphides thus resulted in products originating from P−P coupling and elimination rather than substitution[6]. Our objective has been the development of more variable methods for the synthesis of chiral bidentate phosphorus ligands, starting from the *resolved enantiomers* of chiral bis(primary phosphanes)[1], $H_2P{\cap}PH_2$, and bis(phosphonous dichlorides)[7], $Cl_2P{\cap}PCl_2$, respectively. In this report we describe how the radical-chain addition of the P−H bonds of (1*S*,2*S*)-cyclopentane-1,2-diylbis(phosphane), (1*S*,2*S*)-$C_5H_8(PH_2)_2$ (**1**)[1], across the >C=C< double bonds of several cycloalkenes can conveniently be exploited for the high-yield synthesis of bis(secondary) and bis(tertiary) P_2 ligands (1*S*,2*S*)-$C_5H_8[P(R')R]_2$ (R = cycloalkyl, R′ = H, Me) having chiral phosphorus centers supported on an asymmetric carbon backbone.

Results and Discussion

The AIBN-initiated addition of the $-PH_2$ functions of optically pure **1** across the carbon−carbon double bonds of cycloalkenes C_nH_{2n-2} [AIBN = α,α′-azobis(isobutyronitrile); n = 5−8] in the absence of a diluting solvent (Scheme 1) was employed as a method for the synthesis of (1*S*,2*S*)-cyclopentane-1,2-diyl-linked bis(secondary phosphanes) (1*S*,2*S*)-$C_5H_8[P(H)R]_2$, where R = *cyclo*-C_5H_9 (**2**), *cyclo*-C_6H_{11} (**3**), *cyclo*-C_7H_{13} (**4**), or *cyclo*-C_8H_{15} (**5**). Formation of higher alkylated by-products resulting from consecutive P−H/>C=C< addition steps did not occur in any of the preparations leading to **3**−**5**. We note, however, the observation of threefold and/or completely alkylated derivatives in reactions between **1** and cyclopentene if the latter was employed in a higher than 30-fold excess.

As anticipated for a free-radical-initiated reaction, no diastereoselectivity was observed in any of the examples studied; i. e., a more or less statistical mixture of $R_P,R_{P'}$, $R_P,S_{P'}$ (= $S_P,R_{P'}$), and $S_P,S_{P'}$ diastereomers was obtained in each case. Those compounds with like chirality at phosphorus ($R_P,R_{P'}$ and $S_P,S_{P'}$) are C_2-symmetric and, hence, show ^{31}P-NMR singlet signals; the presence of unlike configurations at the phosphorus atoms of the $R_P,S_{P'}$ isomers renders the two ^{31}P nuclei inequivalent, thus giving rise to AB doublets. For example, the stereoisomeric mixture of bisphosphanes **5** displayed ^{31}P-NMR singlets at δ = −29.30

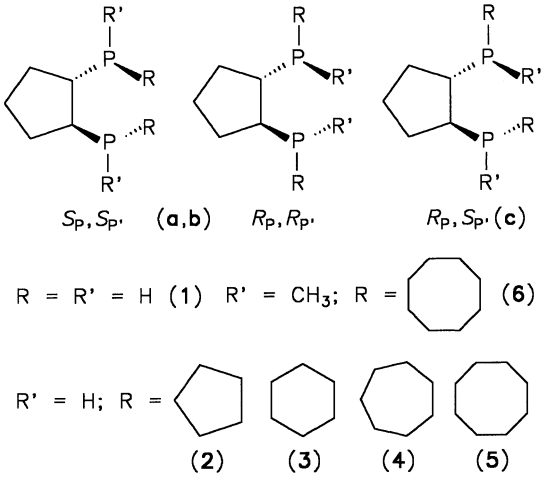
Scheme 1



(C_2-symmetric diastereomer **5a**; 31%) and δ = −22.79 (C_2-symmetric diastereomer **5b**, 19%), together with an AB spectrum characterized by $\delta(P_A)$ = −22.45, $\delta(P_B)$ = −29.52, and $^3J(P_A,P_B)$ = 6.8 Hz ($R_P,S_{P'}$ diastereomer **5c**; 50%).

While the >PH signals of compound **2** suffered from spectral overlap, the >PH groups of one of the two C_2-symmetric diastereomers of bisphosphanes **3**−**5** emerged as (deceptively simple) AA′ subspectra of AMNXX′N′M′A′ spin systems, as expected for $H_AP_X(CH_M<)$-$CH_NCH_{N'}P_{X'}(CH_{M'}<)H_{A'}$ building blocks of symmetry C_2 [$\delta(^1H) \approx 3.3$; $^1J(P,H) \approx 195$, $^3J(H,H) \approx 5$ Hz]. Two-dimensional $\delta(^{31}P\{^1H\})-\delta(^1H\{^{31}P\})$-correlated NMR spectroscopy showed the resonating protons H_A and $H_{A'}$ to be associated with those ^{31}P nuclei that gave rise to the "lower frequency"-singlets, assigned to stereoisomers "**3a**"−"**5a**" [−36 < $\delta(^{31}P)$ < −29]. Furthermore, chemical shift correlation was evident for the "diastereomer **b**"-^{31}P singlet resonances located at higher frequencies [−28 < $\delta(^{31}P)$ < −22] and >P*H* multiplets centered at $\delta(^1H) \approx 3.0$. The contour map demonstrated that the latter proton resonances are also associated with ^{31}P doublets resulting from those phosphorus nuclei P_A of $R_P,S_{P'}$-configurated diastereomers **3c**−**5c**, which were found to resonate at high frequencies, close to the mutually equivalent nuclei of diastereomers **3b**−**5b**. Finally, the correlation spectra enabled the chemical shifts $\delta(P_B)$ of diastereomers **3c**−**5c**, having values similar to those of diastereomers **3a**−**5a**, to be associated with >P*H* multiplets centered around δ = 3.5.

Deprotonation of **5** using 2 equiv. of methyllithium in diethyl ether, followed by hydrolysis of the dilithio derivative so generated, caused the diastereomeric distribution to change in favor of the one diastereomer, **5b**, having its ^{31}P chemical shift at δ = −22.79; diastereomeric distribution after de- and re-protonation: **5a** (16%), **5b** (40%), **5c** (44%). An even more pronounced diastereoselectivity was encountered if the diastereomeric mixture of the dilithiated phosphanes (1*S*,2*S*)-$C_5H_8[P(Li)C_8H_{15}$-*cyclo*$]_2$ was allowed to interact with methyl iodide as an electrophile. The bis(tertiary phosphane) (1*S*,2*S*)-$C_5H_8[P(CH_3)C_8H_{15}$-*cyclo*$]_2$ (**6**) obtained in this way gave ^{31}P-NMR singlets at δ = −11.82 (C_2-symmetric diastereomer **6a**; 72%) and δ = −10.02 (C_2-symmetric diastereomer **6b**; 4%), along with two AB doublets at $\delta(P_A)$ = −6.01 and $\delta(P_B)$ = −14.04 [$^3J(P_A,P_B)$ = 6.2 Hz] originating from the $R_P,S_{P'}$-configurated donor atoms of diastereomer **6c** (24%).

While unequivocal assignment of $R_P,R_{P'}$ or $S_P,S_{P'}$ configuration was not feasible for the C_2-symmetric isomers **a** and **b** in the family of bisphosphanes **2**−**5**, differentiation between the $R_P,R_{P'}$ and $S_P,S_{P'}$ diastereomers was achieved for the bis(tertiary) ligand **6** by structural characterization of three of its nickel, palladium, and platinum complexes [**6**·MX_2] (X = Cl, I). Stirring the diastereomeric mixture **6a**−**c** with $NiCl_2 \cdot 6\,H_2O$ in ethanol or with (1,5-C_8H_{12})PdI_2 or (1,5-C_8H_{12})PtI_2 in dichloromethane cleanly produced the MX_2 adducts (1*S*,2*S*)-$C_5H_8\{P(CH_3)C_8H_{15}$-*cyclo*$\}_2NiCl_2$ (**7**), (1*S*,2*S*)-$C_5H_8\{P(CH_3)C_8H_{15}$-*cyclo*$\}_2PdI_2$ (**8**), and (1*S*,2*S*)-$C_5H_8P(CH_3)C_8H_{15}$-*cyclo*$\}_2PtI_2$ (**9**). The diastereomeric distributions of metal complexes **7**−**9** were found to be largely identical with those of the free ligand **6**. For example, the isomeric mixture of palladium complex **8** contained the C_2-symmetric stereoisomers **8a** [$\delta(^{31}P)$ = 42.83] and **8b** [$\delta(^{31}P)$ = 43.93] accompanied by the $R_P,S_{P'}$-configurated diastereomer **8c** [$\delta(P_A)$ = 47.66, $\delta(P_B)$ = 40.97; $J(P_A,P_B)$ = 20.7 Hz] in proportions of 70%, 3%, and 27%, respectively, suggesting that non-selective coordination rather than preferential binding of one particular stereoisomer **6a**, **6b**, or **6c** had occurred during complex formation.

For the platinum complex, selective precipitation of the prevalent isomer **9a** [$\delta(^{31}P)$ = 24.94] from solution was observed upon crystallzing the mixture of diastereomers **9a**−**c** from chloroform. Column chromatography on silica gel was used to separate the predominant stereoisomers of the nickel and palladium homologues **7a** [$\delta(^{31}P)$ = 42.28] and **8a** [$\delta(^{31}P)$ = 42.83] from their isomeric mixtures. Elution with ethyl acetate/acetone and dichloromethane provided palladium complex **8a** as diastereomerically pure crystals. For the nickel compound, on the other hand, the overall separation remained somewhat unsatisfactory as ^{31}P-NMR spectroscopy showed the predominant diastereomer **7a** to persistently contain ca. 5% of its minor C_2-symmetric diastereomer **7b** [$\delta(^{31}P)$ = 41.17], even after repeated attempts at chromatographic purification.

The configuration at phosphorus in **8a** (= [**6a**·PdI_2]) was established by X-ray diffraction as $R_P,R_{P'}$ (Figure 1), indicating that the uncoordinated bisphosphane diastereomer **6a** has to be assigned $S_P,S_{P'}$ stereochemistry. According to the results of an X-ray structure determination, platinum complex **9a** also has the $R_P,R_{P'}$ configuration (Figure 2). Moreover, crystals of **8a** and **9a** showed isotypism, both belonging to the same tetragonal space group $P4_1$ with virtually identical lattice constants and atomic positions. Samples of (1*S*,2*S*)-C_5H_8 $\{P(CH_3)C_8H_{15}$-*cyclo*$\}_2NiCl_2$ (**7**), largely enriched in diastereomer **7a** (vide supra) by chromatographic work-up, were found to crystallize with difficulty. Eventually, an X-ray diffraction study of a suitable speci-

men grown from acetone revealed that **7a** and its minor C_2-symmetric stereoisomer **7b** tend to co-crystallize, forming $[(1S,2S)\text{-}C_5H_8\{P(CH_3)C_8H_{15}\text{-}cyclo\text{-}(R)\}_2NiCl_2]\cdot[(1S,2S)\text{-}C_5H_8\{P(CH_3)C_8H_{15}\text{-}cyclo\text{-}(S)\}_2NiCl_2]$, **7a·7b** (see Figures 3 and 4), irrespective of their divergent concentrations present in solution.

fined by the MX_2 and MP_2 fragments. These dihedral angles amount to only 3.5° in molecules **7a** and **7b** of the nickel compound, the values for the palladium and platinum complexes **8a** and **9a** being 4.4° and 3.8°, respectively. The P−M−P bite-angle of the chelate ligand is almost the same in **8a** [87.22(7)°] and **9a** [87.7(1)°] and increases only slightly to 88.4(1)° and 89.0(1)° on going to structures **7a** and **7b**. The M−P distances range from 2.157(3) to 2.166(3) Å for *d*(Ni−P) in **7a·7b**, but are 2.256(3) and 2.257(3) Å

for *d*(Pd−P) in molecule **8a**. The M−P bonds of platinum complex **9a**, with lengths of 2.236(3) and 2.237(3) Å, are somewhat shorter than those of its lower homologue **8a**, whereas the lengths of the M−I bonds in the two molecules, 2.649(1) Å (M = Pd) and 2.648(1) Å (M = Pt), are equal within their standard deviations. While the torsion angle between the two planes through P(1), C(10), C(14) and C(10), C(14), P(2) within the chelate back-bones of the three $R_P,R_{P'}$-configurated diastereomers decreases marginally from 50.8° to 50.5° and 48.8° on going from **7a** to **8a** and **9a**, the corresponding value for the P(3)−C(33)−C(37)−P(4) framework of $S_P,S_{P'}$ diastereomer **7b** amounts to only 39.0°. Front views of the complexes, shown schematically for **7b** and **8a** in Figures 5 and 6, identify the puckering of the chelate rings in the λ,δ notation as δ. In the $R_P,R_{P'}$-configurated diastereomers the methyl substituents occupy axial positions with respect to the coordination plane, the torsion angles P−M−P−CH_3 being close to −105° in all three molecules **7a**, **8a**, and **9a**. The orientation of the equatorial pairs of cyclooctyl groups (torsion angles P−M−P−CH<, 130.1−132.5°) can be described as approximately "face-on" (Figure 6), similar to the alignment of the equatorial aryl groups in a variety of structurally characterized transition metal complexes containing perphenylated chelating bisphosphane ligands[5]. The $S_P,S_{P'}$ form of nickel complex **7b**, on the other hand, displays little differentiation between axially and equatorially oriented substituents, the torsion angles being −115.0° and −119.0° for the P−M−P−CH_3 fragments P(4)−Ni(2)−P(3)−C(25) and P(3)−Ni(2)−P(4)−C(39) and 125.8° and 120.7° for the two P−M−P−CH< chains of atoms P(4)−Ni(2)−P(3)−C(24) and P(3)−Ni(2)−P(4)−C(38). The conformation of the cyclooctyl rings can be approximated as "boat-chair"-like in the palladium and platinum complexes, and thus corresponds to the lowest-energy conformation of cycloctane[8][9]. In the two nickel complexes, on the other hand, the C_8H_{15} conformation comes close to "boat-only" if conformational disorder is neglected.

Conclusions

This work has shown that the free-radical-initiated P−H addition of enantiomerically pure bis(primary phosphanes), e.g. (1*S*,2*S*)-$C_5H_8(PH)_2$[1], across the carbon−carbon double bonds of cycloalkenes containing five to eight ring atoms provides an attractive method for the synthesis of the preparation of asymmetric bis(secondary phosphanes). The latter can be derivatized further by metalation and alkylation to give bis(tertiary) P_2 ligands, such as (1*S*,2*S*)-C_5H_8[P(CH_3)C_8H_{15}-*cyclo*]$_2$ (**6**), combining phosphorus-based asymmetry with backbone chirality. Only a few bisphosphanes with asymmetric phosphorus atoms connected to a chiral carbon framework have been reported before[10][11][12][13][14][15]. None of these contains peralkylated phosphanyl substituents −P(R′)R. It was therefore a challenge to isolate the $S_P,S_{P'}$-configurated diastereomer **6a**, observed to predominate in the isomeric mixture of bisphosphanes **6a**−**c**, in optically pure form. Attempts to liberate **6a** from its palladium or platinum complexes **8a** and **9a** were hampered, however, by extensive epimerization at phosphorus, which occurred upon reacting **8a** with excess sodium cyanide in the two-phase system toluene/water. Configurational inversion at phosphorus appears to be facile due to the fact that cyanolysis of **8a** under the conditions outlined before resulted in the liberation of **6** as an isomeric mixture containing 52% of the desired **6a** accompanied by 27% of **6b** and, 21% of **6c**.

Financial support from the *Deutsche Forschungsgemeinschaft* (Bonn) and the *Fonds der Chemischen Industrie* (Frankfurt/Main) is gratefully acknowledged. We are also indebted to *Degussa AG* (Hanau) for generous gifts of palladium and platinum salts.

Experimental Section

All manipulations were performed under nitrogen using standard Schlenk techniques. Solvents were distilled from the appropriate drying agents prior to use. − IR: Mattson Polaris. − NMR: Bruker

DPX 300 (300.1 MHz for ^{1}H, 75.5 MHz for ^{13}C, 121.5 MHz for ^{31}P) and Jeol FT-JNM-EX 270 (109.4 MHz for ^{31}P; for compounds **2**−**4** only) at 20 ± 2°C with TMS as internal or with H_3PO_4 as external standard (downfield positive). − Mass spectra: Jeol MS 700.

(1S,2S)-C_5H_8[P(H)C_5H_9-cyclo]$_2$ (**2**): A suspension of 0.2 g of AIBN in 1.63 g (23.9 mmol) of cyclopentene was added in two portions within 2 h to a gently refluxing solution of 0.64 g (4.77 mmol) of **1**[1] in 1.63 g (23.9 mmol) of cyclopentene. The mixture was stirred at reflux temperature for 4 d. Excess cyclopentene was then removed at room temperature under reduced pressure, and any remaining volatile material was removed from the product by heating at 60°C under a dynamic vacuum. The yield was 1.10 g (85%) of a colorless liquid, which was characterized as the desired bis(secondary phosphane) **2** on the basis of its spectroscopic properties. − MS (FD; toluene, 35 mA, 10 kV): *m*/*z* = 270 [M$^+$]. − IR (film): $\tilde{\nu}$ = 2295 (PH) cm^{-1}. − ^{1}H NMR (C_6D_6): δ = 1.1−2.3 (m, 26 H, C_5H_8 and C_5H_9), 2.86 [dm, ^1J(P,H) = 191 Hz; PH of C_2-symmetric diastereomer **2b** superimposed by P_AH of $R_P,S_{P'}$ diastereomer **2c**], 3.21 [dm, ^1J(P,H) = 193 Hz; PH of C_2-symmetric diastereomer **2a**], 3.45 [dm, ^1J(P,H) = 192 Hz; P_BH of $R_P,S_{P'}$ diastereomer **2c**]. − ^{31}P NMR (C_6D_6): δ = −41.2 (br; C_2-symmetric diastereomer **2a** overlapped by P_B of $R_P,S_{P'}$ diastereomer **2c**), −34.0 (br; C_2-symmetric diastereomer **2b** overlapped by P_A of $R_P,S_{P'}$ diastereomer **2c**); ^3J(P,P) not resolved.

(1S,2S)-C_5H_8[P(H)C_6H_{11}-cyclo]$_2$ (**3**): The preparation of this compound was carried out as described for **2** by reacting 0.68 g (5.07 mmol) of **1** with a total of 3.50 g (42.6 mmol) of cyclohexene, in the presence of a catalytic amount of AIBN (0.2 g), at 60°C for 3 d; yield 1.35 g (89%) of a colorless, viscous liquid. − IR (film): $\tilde{\nu}$ = 2263 (PH) cm^{-1}. − ^{1}H NMR (C_6D_6): δ = 1.1−2.2 (m, 30 H, C_5H_8 and C_6H_{11}), 3.0 [dm (br), ^1J(P,H) = 194 Hz; PH of C_2-symmetric diastereomer **3b** superimposed by P_AH of $R_P,S_{P'}$ diastereomer **3c**], 3.32 ["ddd", ^1J(P,H) = 194, ^3J(H,H) = 3.4, 5.9 Hz; PH of C_2-symmetric diastereomer **3a**], 3.4 [dm (br), ^1J(P,H) = 196 Hz; P_BH of $R_P,S_{P'}$ diastereomer **3c**]. − ^{31}P NMR (C_6D_6): −35.9 [AB-d, ^3J(P,P) = 5 Hz; P_B of $R_P,S_{P'}$ diastereomer **3c**], −35.5 (s; C_2-symmetric diastereomer **3a**), −28.4 (s; C_2-symmetric diastereomer **3b**), −28.2 [AB-d, ^3J(P,P) = 5 Hz; P_A of $R_P,S_{P'}$ diastereomer]; diastereomeric distribution: **3a**, 38%; **3b**, 20%; **3c**, 42%.

(1S,2S)-C_5H_8[P(H)C_7H_{13}-cyclo]$_2$ (**4**): The preparation of this compound was carried out as described for **2** and **3**, by reacting 0.30 g (2.24 mmol) of **1** with 3.00 g (31.2 mmol) of cycloheptene, in the presence of 0.2 g of AIBN, at 60°C for 3 d; yield 0.65 g (89%) of a colorless oil. − MS (FD; toluene, 35 mA, 10 kV): *m*/*z* = 326 [M$^+$]. − IR (film): $\tilde{\nu}$ = 2263 (PH) cm^{-1}. − ^{1}H NMR (C_6D_6): δ = 1.3−2.1 (m, 34 H, C_5H_8 and C_7H_{13}), 3.0 [dm (br), ^1J(P,H) = 194 Hz; PH of C_2-symmetric diastereomer **4b** superimposed by P_AH of $R_P,S_{P'}$ diastereomer **4c**], 3.35 ["ddd", ^1J(P,H) = 194, ^3J(H,H) = 3.4, 6.1 Hz; PH of C_2-symmetric diastereomer **4a**], 3.5 [dt (br), ^1J(P,H) = 196, ^3J(H,H) = 6 Hz; P_BH of $R_P,S_{P'}$ diastereomer **4c**]. − ^{31}P NMR (C_6D_6): −32.7 [AB-d, ^3J(P,P) = 7 Hz; P_B of $R_P,S_{P'}$ diastereomer **4c**], −32.4 (s; C_2-symmetric diastereomer **4a**), −26.4 (s; C_2-symmetric diastereomer **4b**), −26.0 [AB-d, ^3J(P,P) = 7 Hz; P_A of $R_P,S_{P'}$ diastereomer **4c**]; diastereomeric distribution: **4a**, 30%; **4b**, 27%; **4c**, 43%.

(1S,2S)-C_5H_8[P(H)C_8H_{15}-cyclo]$_2$ (**5**): This material was prepared as described above by stirring 0.50 g (3.73 mmol) of **1** in 4.00 g (36. 3 mmol) of cyclooctene, containing AIBN (0.2 g), at 60°C for 3 d; yield 1.12 g (85%) of colorless liquid **5**. MS (FD; toluene, 35 mA, 10 kV): *m*/*z* = 354 [M$^+$]. − IR (film): $\tilde{\nu}$ = 2265 (PH) cm^{-1}. − ^{1}H NMR (C_6D_6): δ = 1.3−2.2 (m, 38 H, C_5H_8 and C_8H_{15}), 3.0 [dm (br), ^1J(P,H) = 192 Hz; PH of C_2-symmetric diastereomer **5b** superimposed by P_AH of $R_P,S_{P'}$ diastereomer **5c**], 3.32 ["ddd", ^1J(P,H) = 194, ^3J(H,H) = 3.4, 5.3 Hz; PH of C_2-symmetric diastereomer **5a**], 3.46 [dt (br), ^1J(P,H) = 196, ^3J(H,H) = 5 Hz; P_BH of $R_P,S_{P'}$ diastereomer **5c**]. − ^{31}P NMR (C_6D_6): −29.52 [AB-d, ^3J(P,P) = 6.8 Hz; P_B of $R_P,S_{P'}$ diastereomer **5c**], −29.30 (s; C_2-symmetric diastereomer **5a**), −22.79 (s; C_2-symmetric diastereomer **5b**), −22.45 (AB-d; P_A of $R_P,S_{P'}$ diastereomer **5c**); diastereomeric distribution: **5a**, 31%; **5b**, 19%; **5c**, 50%.

(1S,2S)-C_5H_8[P(CH_3)C_8H_{15}-cyclo]$_2$ (**6**): A solution of **5** (0.72 g, 2.03 mmol) in 25 ml of THF was treated with 2.60 ml of a 1.6 M hexane solution of *n*-butyllithium (4.16 mmol) at room temperature. The resulting orange solution was stirred for 10 min and then cooled to −25°C. Methyl iodide (7.6 ml of a 0.54 M solution in THF, 4.10 mmol) was then added and the decolorized mixture was evaporated to dryness in vacuo at −25°C. The oily residue was allowed to warm to room temperature, dissolved in toluene, and washed with degassed water. After separation of the organic layer and removal of solvent, the product was extracted from the residue into boiling hexane. Removal of all volatile material from the extracts left ligand **6** as a clear viscous oil; yield 0.73 g (94%). − ^{1}H NMR (C_6D_6): δ = 0.84 ("t", ^2J(P,H) + ^5J(P′,H) = 3.5 Hz; PCH_3 of predominating $S_P,S_{P'}$ diastereomer **6a**), 0.94 ("d", ^2J(P,H) + ^5J(P′,H) = 3.7 Hz; PCH_3 of minor $R_P,R_{P'}$ diastereomer **6b**), 0.81, 1.19 (both "d", ^2J(P,H) + ^5J(P,H) = 3.5 Hz; both PCH_3 of $R_P,S_{P'}$ diastereomer **6c** present in intermediate concentration), 1.3−2.0 (m; 38 H, C_5H_8 and C_8H_{15}). − ^{31}P NMR (C_6D_6): δ = −14.04 [AB-d, ^3J(P_A,P_B) = 6.2 Hz; P_B of $R_P,S_{P'}$ diastereomer **6c**], −11.82 (s; $S_P,S_{P'}$ diastereomer **6a**), −10.02 ($R_P,R_{P'}$ diastereomer **6b**), −6.01 (AB-d; P_A of $R_P,S_{P'}$ diastereomer **6c**); diastereomeric distribution: **6a**, 72%; **6b**, 4%; **6c**, 24%.

(1S,2S)-C_5H_8[P(CH_3)C_8H_{15}-cyclo]$_2$NiCl$_2$ (**7**): To a stirred solution of **6** (0.58 g, 1.52 mmol) in 20 ml of CH_2Cl_2 was added a solution of $NiCl_2 \cdot 6\,H_2O$ (0.37 g, 1.56 mmol) in 30 ml of ethanol. The resulting red-brown mixture was stirred for 8 h and then the solvent was evaporated to give a quantitative yield (0.78 g) of **7** as a brown powder. − $C_{23}H_{44}Cl_2NiP_2$ (512.13): calcd. C 53.9, H 8.7; found C 54.00, H 8.87. − MS (EI, 70 eV, 180°C): *m*/*z* (%) = 512 (21%) [M$^+$], 475 (58) [M$^+$ − Cl], 438 (9%) [M$^+$ − 2Cl], 364 (61%) [M$^+$ − Cl − C_8H_{15}]. − ^{31}P NMR ($CDCl_3$): 38.51 [AB-d, J(P_A,P_B) = 84.6 Hz; P_B of $R_P,S_{P'}$ diastereomer **7c**], 41.17 (s; $S_P,S_{P'}$ diastereomer **7b**), 42.28 (s; $R_P,R_{P'}$ diastereomer **7a**), 45.23 (AB-d; P_A of $R_P,S_{P'}$ diastereomer **7c**); diastereomeric distribution: **7a**, 75%; **7b**, 4%; **7c**, 21%.

The $R_P,S_{P'}$ diastereomer **7c** was removed by chromatography on a column containing silica gel/acetone, which was charged with 0.78 g (1.52 mol) of **7** as a suspension in acetone. Elution with 5% ethyl acetate in acetone, followed by elution with dichloromethane, gave a yellow fraction, which on evaporation of solvent yielded 0.12 g (22%) of microcrystalline **7a**, contaminated by ca. 5% of **7b** (diastereomeric purity estimated by ^{31}P NMR). − ^{13}C{^{31}P,^{1}H} NMR ($CDCl_3$): 3.41 (CH_3), 23.39, 25.44, 25.55, 26.18, 26.89, 27.13, 27.97, 30.53, 31.52 (all CH_2), 34.02 (C_8H_{15}-CH), 44.03 (C_5H_8-CH); the CH_3 and CH resonances showed deceptively simple AA′*X* triplet splitting in the ^{31}P-coupled spectrum: J(P,C) + J(P′,C) = 23.4 Hz (CH_3), 30.2 Hz (C_8H_{15}-CH), and 45.3 Hz (C_5H_8-CH), respectively.

(1S,2S)-C_5H_8[P(CH_3)C_8H_{15}-cyclo]$_2$PdI$_2$ (**8**): To a solution of **6** (1.77 g, 4.65 mmol) in 100 ml of CH_2Cl_2 was added 1.52 g (5.34 mmol) of solid (1,5-C_8H_{12})$PdCl_2$[16]. The orange solution was stirred at room temperature for 10 min and then treated with sodium iodide (2.07 g, 13.81 mmol) to give a brown mixture, which

was stirred for additional 10 h. After filtration and evaporation of the filtrate to dryness, excess (1,5-C_8H_{15})$PdCl_2$ was removed by flash chromatography on a silica gel column with dichloromethane/ethyl acetate (19:1) as the eluent. Evaporation of solvent from the eluate left complex **8** as yellowish red powder; yield 2.95 g (85%). − $C_{23}H_{44}I_2P_2Pd$ (742.72): calcd. C 37.20, H 5.97; found C 37.53, H 6.14. − MS (EI, 70 eV, 180°C): *m/z* (%) = 742 (19%) [M^+], 615 (100%) [M^+ − I]. − ^{31}P NMR ($CDCl_3$): 40.97 [AB-d, $J(P_A,P_B)$ = 20.7 Hz; P_B of $R_P,S_{P'}$ diastereomer **8c**], 42.83 (s; $R_P,R_{P'}$ diastereomer **8a**), 43.93 (s; $S_P,S_{P'}$ diastereomer **8b**), 47.66 (AB-d; P_A of $R_P,S_{P'}$ diastereomer **8c**); diastereomeric distribution: **8a**, 70%; **8b**, 3%; **8c**, 27%.

For isolation of diastereomerically pure **8a**, the isomeric mixture **8a−c** (2.95 g) was chromatographed on a silica gel column, eluting first with with 5% ethyl acetate in acetone and then with dichloromethane as described above for nickel complex **7**. The residue remaining after removal of solvent from the CH_2Cl_2 eluate was thoroughly washed with acetone to give 0.32 g (15%) of **8a** as yellow-red microcrystals. − ^{1}H NMR ($CDCl_3$): 1.3−1.9 (m, 30 H, CH_2), 1.71 ["d", J(P,H) + J(P′,H) = 10.2 Hz; 6 H, CH_3], 2.25−2.55 (m, 6 H, CH and CH_2), 3.15−3.35 (m, 2 H, CH). − ^{13}C{^{31}P,^{1}H} NMR ($CDCl_3$): 6.05 (CH_3), 23.06, 25.31, 25.55, 26.83, 27.48, 28.30, 30.58, 31.86 (all CH_2), 37.32 (C_8H_{15}-CH), 45.47 (C_5H_8-CH); apparently simple AAX' patterns were observed for the CH_3 and CH resonances in the ^{31}P-coupled spectrum: J(P,C) + J(P′,C) = 24.3 Hz (CH_3), 30.6 Hz (C_8H_{15}-CH), and 45.8 Hz (C_5H_8-CH), respectively.

(1S,2S)-C_5H_8[P(CH_3)C_8H_{15}-cyclo]$_2PtI_2$ (**9**): Solid (COD)PtI_2[17] (0.49 g, 0.88 mmol) was added to a stirred solution of 0.33 g (0.86 mmol) of **6** in 40 ml of dichloromethane. After stirring for 10 h the solvent was removed in vacuo to leave a virtually quantitative yield of 0.72 g of the product as a dark yellow solid. − $C_{23}H_{44}I_2P_2Pt$ (831.41): calcd. C 33.23, H 5.33; found C 32.78, H 5.37. − MS (EI, 70 eV, 180°C): *m/z* (%) = 831 (17%) [M^+], 704 (100%) [M^+ − I]. − ^{31}P NMR ($CDCl_3$): 21.90 [AB-d with ^{195}Pt satellites, $J(P_A,P_B)$ = 2.3, ^1J(Pt,P) = 3320 Hz; P_B of $R_P,S_{P'}$ diastereomer **9c**], 24.94 [s with ^{195}Pt satellites, ^1J(Pt,P) = 3333 Hz; $R_P,R_{P'}$ diastereomer **9a**], 26.39 [s with ^{195}Pt-satellites, ^1J(Pt,P) = 3362 Hz; $S_P,S_{P'}$ diastereomer **9b**], 29.04 [AB-d with ^{195}Pt satellites, ^1J(Pt,P) = 3336 Hz; P_A of $R_P,S_{P'}$ diastereomer **9c**]; diastereomeric distribution: **9a**, 76%; **9b**, 6%; **9c**, 18%. − Crystallization of the diastereomeric mixture from chloroform resulted in preferential precipitation of **9a**.

Cyanolysis of Palladium Complex **8a**: A vigorously stirred suspension of 370 mg (0.5 mmol) of **8a** in 10 ml of water and 15 ml of toluene was treated with a ten-fold excess of solid potassium cyanide at room temperature. Stirring was continued for 8 h to produce a colorless two-phase system. The organic layer was separated and the organic phase was extracted twice with 10 ml of water to remove any residual KCN. Evaporation of the combined organic phases left the free ligand **6** as a 52:27:21 mixture of diastereomers **6a**, **6b**, and **6c**.

X-ray Structure Determinations: Single-crystals of (1*S*,2*S*)-C_5H_8{P(CH_3)C_8H_{15}-*cyclo*-(*R*)}$_2NiCl_2$·(1*S*,2*S*)-C_5H_8{P(CH_3)-C_8H_{15}-*cyclo*-(*S*)}$_2NiCl_2$ (**7a·7b**) (size 0.03 × 0.3 × 0.55 mm), (1*S*,2*S*)-C_5H_8{P(CH_3)C_8H_{15}-*cyclo*-(*R*)}$_2PdI_2$ (**8a**) (size = 0.20 × 0.25 × 0.50 mm), and (1*S*,2*S*)-C_5H_8{P(CH_3)C_8H_{15}-*cyclo*-(*R*)}$_2PtI_2$ (**9a**) (size 0.26 × 0.26 × 0.28 mm) were grown from acetone (**7a·7b**), CH_2Cl_2/hexane (**8a**), and $CHCl_3$ (**9a**), respectively. The measurements were made at −95 ± 2°C (**7a·7b**) and at 20 ± 2°C (**8a**, **9a**) on an Enraf-Nonius CAD 4 diffractometer using graphite-monochromated Mo-K_α radiation (λ = 0.7107 Å): orientation matrices and unit cell parameters from the setting anlges of 25 centered medium-angle reflections (**7a·7b**: 12 < 2θ < 16°; **8a**: 15 < 2θ < 34°; **9a**: 17 < 2θ < 26°); collection of the diffraction intensities of Ni complex **7a·7b** by ω scans (data uncorrected for absorption); intensity measurements of Pd and Pt compounds **8a** and **9a** by the ω/2θ scan technique (data corrected for absorption by ψ-scans; **8a**: T_{min} = 0.41, T_{max} = 0.99; **9a**: T_{min} = 0.86, T_{max} = 0.99). The structures were solved by direct methods employing the SIR-92[18] program system and subsequently refined by full-matrix least-squares procedures on F^2 (SHELXL-93[19]) with allowance for anisotropic thermal motion of all non-hydrogen atoms. According to the U_{ij} values of three of the cyclooctyl carbon atoms of **7a·7b**, twofold conformational disorder was suggested for these atoms, which was accounted for by assigning the particular carbon positions split occupancies of 0.45 [C(4a), C(7a)] and 0.55 [C(4b), C(7b)] and of 0.40 [C(31a)] and 0.60 [C(31b)], respectively. H atoms were included in the final structural models assuming ideal geometry and using appropriate riding models. − **7a·7b**: $C_{23}H_{44}Cl_2NiP_2$ (512.13); monoclinic, $P2_1$, a = 12.016(3), b = 16.538(4), c = 12.986(7) Å, β = 103.44(3)°, V = 2510(2) Å^3, Z = 4, $d_{calcd.}$ = 1.355 g cm^{-3}, μ(Mo-K_α) = 1.122 mm^{-1}; 5 ≤ 2θ ≤ 45°, 6843 reflections collected (−12 ≤ h ≤ 12, 0 ≤ k ≤ 17, 0 ≤ l ≤ 13, together with Friedel pairs), 6514 reflections independent ($R_{int.}$ = 0.0359); R_{w2} = 0.1115 for all data and 535 parameters, $w = \{\sigma^2(F_o^2) + [0.0433(F_o^2 + 2F_c^2)/3]^2 + 3.2250(F_o^2 + 2F_c^2)/3\}^{-1}$, R = 0.0463 for 4823 data with $I > 2\sigma(I)$, absolute structure parameter[20]: 0.03(3). − **8a**: $C_{23}H_{44}I_2P_2Pd$ (742.72); tetragonal, $P4_1$, a = 11.205(2), c = 21.650(9) Å, V = 2718(1) Å^3, Z = 4, $d_{calcd.}$ = 1.815 g cm^{-3}, μ(Mo-K_α) = 3.080 mm^{-1}; 5 ≤ 2θ ≤ 54°, 12730 reflections collected (−14 ≤ h ≤ 14, 0 ≤ k ≤ 14, 0 ≤ l ≤ 27, together with Friedel pairs), 5917 reflections independent ($R_{int.}$ = 0.0460); R_{w2} = 0.0906 for all data and 257 parameters, $w = \{\sigma^2(F_o^2) + [0.0386(F_o^2 + 2F_c^2)/3]^2 + 0.5985(F_o^2 + 2F_c^2)/3\}^{-1}$, R = 0.0379 for 4732 data with $I > 2\sigma(I)$, absolute structure parameter[20]: −0.01(3). − **9a**: $C_{23}H_{44}I_2P_2Pt$ (831.41); tetragonal, $P4_1$, a = 11.198(1), c = 21.685(5) Å, V = 2719.2(7) Å^3, Z = 4, $d_{calcd.}$ = 2.031 g cm^{-3}, μ(Mo-K_α) = 7.557 mm^{-1}; 5 ≤ 2θ ≤ 52°, 11460 reflections collected (−13 ≤ h ≤ 13, 0 ≤ k ≤ 13, 0 ≤ l ≤ 26), 5313 reflections independent ($R_{int.}$ = 0.0483); R_w2 = 0.0756 for all data and 254 parameters, $w = \{\sigma^2(F_o^2) + [0.0287(F_o^2 + 2F_c^2)/3]^2 + 0.6041(F_o^2 + 2F_c^2)/3\}^{-1}$, R = 0.0381 for 4102 data with $I > 2\sigma(I)$, absolute structure parameter[20]: −0.005(9). − Further details of the crystal structure determinations may be obtained from the Fachinformationszentrum Karlsruhe, D-76344 Eggenstein-Leopoldshafen (Germany), on quoting the depository numbers CSD-408020 (**7a·7b**), CSD-408024 (**8a**), or CSD-408023 (**9a**).

Keywords: Enolates / Nucleophilic additions / Ruthenium / S ligands / Sulfenes

Sulfene complexes $[CpRu(PR'_3)_2(RHC{=}SO_2)]PF_6$ (**2a**−**d**) are obtained from the corresponding sulfur dioxide complexes **1a**−**c** and diazomethane or -ethane. Reaction of $[CpRu(dppm)(SO_2)]Cl$ (**1d**) and phenyldiazomethane gives the chlorobenzylsulfinato complex $[CpRu(dppm)(SO_2CHPhCl)]$ (**3**). Alternatively, **2a** may be synthesized by sulfur dioxide addition to the carbene complex $[CpRu(dppm)(CH_2)]PF_6$ (**5**) which, in turn, is obtained from the corresponding methyl complex $[CpRu(dppm)(CH_3)]$ and $[Ph_3C]PF_6$. Treatment of **2a**−**d** or **3** with the enolates of cyclic 2-methyl-1,3-diketones, methyl malonates, open-chain cyano or β-oxo esters, and cyclic β-oxo esters gives the C−C coupling products **6a**, **b**, **7a**−**e**, **8a**−**c**, **9a**−**c** in high yields and, in one case, with high diastereoselectivity as well. The functionalized sulfinate ligands thus formed may be alkylated and subsequently removed from the metal center by ligand substitution with acetonitrile. After $MeCN/SO_2$ exchange, the ruthenium complex can be recycled.

Highly reactive and unstable molecules can often be stabilized by coordination to a transition metal − this principle is certainly one of the most fascinating aspects of organic transition-metal chemistry.[1] In an ideal case, the species under consideration is not only "tamed", but is sufficiently modified such that it undergoes novel types of reactions. Sulfenes $R^1R^2C{=}SO_2$ are short-lived intermediates that may be generated for example by 1,2-elimination or [2 + 4]-cycloreversion reactions.[2] Their typical transformations include 1,2-additions across the C=S double bond, nucleophilic addition at sulfur, and cycloadditions.[2][3][4][5][6][7] Recently, we have synthesized $\eta^2(C,S)$-sulfene complexes of the type $[CpRu(PR_3)_2(CH_2{=}SO_2)]^+$ by methylene addition to the corresponding sulfur dioxide complexes.[8][9] In these species, the formal polarity of the sulfene is reversed. Nucleophiles such as halide or pseudohalide ions, amines and phosphanes are added at the carbon atom. With enamines, C−C coupling occurs with high yield and chemoselectivity.[9] We now report on the addition of enolates to sulfene complexes.

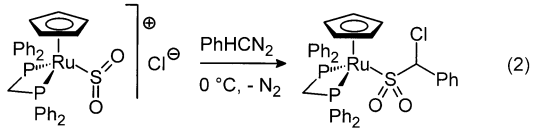
Results

Synthesis of Sulfene Complexes

The reaction of the sulfur dioxide complex **1a** with diazomethane or -ethane to give the sulfene complexes **2a**,**d** has been described previously.[9] Similarly, **1b**, **c** give the sulfene complexes **2b**, **c** (eq. 1).

Attempts to perform analogous reactions of **1a** with phenyldiazomethane, diphenyldiazomethane, or diazoacetic acid esters were unsuccessful. However, when we treated the chloride salt **1d** with phenyldiazomethane, we obtained the chlorobenzylsulfinate complex **3** in high yield (eq. 2). Complex **3** represents a synthetic equivalent for the corresponding phenylsulfene complex (see below).



1d **3** (2)

An alternative synthetic access to sulfene complexes is provided by the addition of SO_2 to carbene complexes.[10][11] Thus, when the methyl complex **4** is treated at low temperature with triphenylmethyl hexafluorophosphate, a red solution of the carbene complex **5** is obtained,[12] which, upon addition of SO_2, undergoes immediate discoloration to yield **2a** (eq. 3). However, in spite of

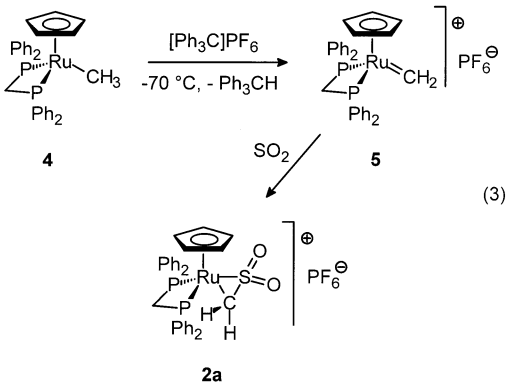
numerous attempts, we have not been able to extend this reaction to complexes of substituted sulfenes.



(3)

2b, **c** are slightly yellow crystalline compounds which, even at −20°C, decompose within a few days. **2c** has spectroscopic properties very similar to those of **2a** and the crystallographically characterized complex $[Cp^*Ru(PMe_3)_2(\eta^2\text{-}CH_2{=}SO_2)]PF_6$.[9] **2b**, on the other hand, is unusual in that it is fluxional on the NMR timescale due to a rapid rotation of the sulfene ligand. Standard treatment[13] of the temperature-dependent ^{31}P-NMR spectra using a two-site exchange model[14] yields an activation barrier of $\Delta G^{\neq} = 60$ kJ mol^{-1}. A similar ligand rotation has been found for the analogous sulfur trioxide complex $[Cp^*Ru(PMe_3)_2(\eta^2\text{-}O{=}SO_2)]PF_6$.[15] In the ^{1}H-NMR spectra, the two non-equivalent protons of the methylene groups give rise to two widely separated signals with the typical geminal coupling of ca. 4 Hz. The high-field signals show additional splitting due to strong coupling with one of the two phosphorus atoms. The ^{13}C resonance of the sulfene carbon atom appears as a doublet at $\delta = -20$. Finally, two fairly strong absorptions in the infrared spectrum at $\tilde{\nu} \approx 1230$ and 1100 cm^{-1} are typical for the $\eta^2(C,S)$-coordinated sulfene ligand.[9]

The chlorobenzylsulfinato complex **3** is a yellow, crystalline, air-stable compound. The two diastereotopic phosphorus atoms give rise to a narrow AB system in the ^{31}P-NMR spectrum, while the resonance of the α-carbon nucleus at the sulfur atom is split into a narrow doublet of doublets due to coupling with the two non-equivalent phosphorus nuclei. Here, the ν(SO) absorptions fall in the typical range of *S*-sulfinato complexes.[16]

Reactions with Enolates

Reactions of **2a** in THF with the sodium enolates of 2-methylcyclopentane-1,3-dione and 2,5,5-trimethylcyclohexane-1,3-dione gave the expected addition compounds **6a**, **b** in good yields (eq. 4).

Similarly, treatment of **2a**, **b** and **d** with the lithium enolates of the diethyl or isopropylidene esters of methylmalonic acid yielded the C−C coupling products **7a**−**d**, while

(5)

Products **6** and **7** were obtained as light-yellow crystalline solids. Due to their symmetrical structure they have fairly simple NMR spectra, which are in full accord with the constitutions shown in eqs. 4 and 5. Of note is the significant downfield shift (> 90 ppm) of the resonance of the former sulfene carbon atom that accompanies its release from the ruthenium atom. In similar experiments, the sulfene complexes **2a**, **b** were treated with the ester enolates of 2-methyl-3-oxobutyric acid and 2-cyanopropionic acid (eq. 6), while **2a**, **d** were allowed to react with the deprotonated esters of 2-oxocyclopentane- and 2-oxocyclohexane-1-carboxylic acids (eq. 7).

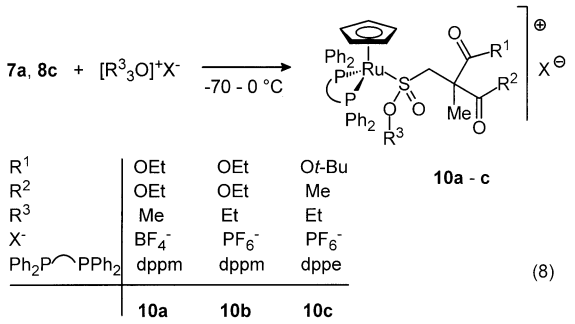
(7)

Again, the expected coupling products were obtained in good yields as light-yellow, air-stable, crystalline materials.

Since a stereocenter adjacent to the sulfene carbon atom is formed in this reaction, the methylene protons as well as the phosphorus nuclei become diastereotopic. **9c** was isolated in 71% yield as a single diastereoisomer. NMR-spectroscopic analysis of the crude reaction mixture revealed an almost quantitative formation of **9c** and none of the opposite diastereomer. Unfortunately, this compound crystallized only as stacks of very thin platelets, which were unsuitable for X-ray structure determination.

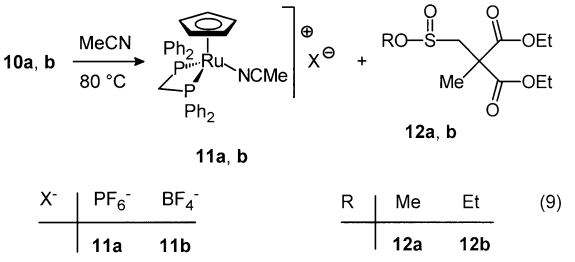
Release of the Sulfinate Ligands

The reactions of **7a** and **8c** with oxonium salts in dichloromethane (eq. 8) gave the expected *O*-alkylation[17] products **10a−c**, which were isolated in almost quantitative yield as yellow, crystalline, highly moisture-sensitive materials. Alkylation of one of the S=O functions introduces a new stereocenter at the sulfur atom and renders the methylene protons as well as the phosphorus nuclei diastereotopic. Only negligible diastereoselectivity (2%) is observed in the formation of **10c**.



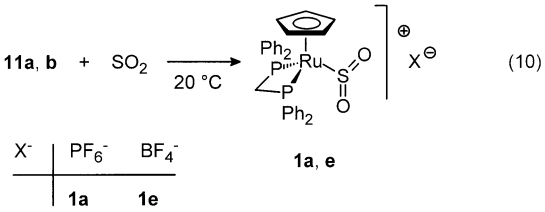
(8)

The role of sulfinic acid esters as ligands in coordination compounds has received very little attention.[17][18] Compared to sulfoxides, they are expected to be quite weak donors. Indeed, when **10a**, **b** are heated in acetonitrile a slow ligand substitution takes place yielding the known acetonitrile complex **11**[19] along with the free esters **12a**, **b** (eq. 9).



(9)

Despite the long reaction time, we observed no rearrangement[20] to the corresponding sulfones. The mixtures could be readily separated by extraction with diethyl ether, leaving **12a**, **b** in quantitative yields as colorless oils. **11** may be converted back into the starting SO_2 complex **1a** or its BF_4^- salt **1e** simply by dissolving it in liquid sulfur dioxide and allowing it to react for a few days at 20°C (eq. 10).



(10)

Discussion

The methylene transfer outlined in eq. 1 is initiated by nucleophilic attack of the diazo compound on the coordinated sulfur dioxide.[9] This explains why less nucleophilic diazo compounds do not react − phenyldiazomethane seems to represent the limiting case. The expected phenylsulfene complex was too unstable to be isolated but, due to its high electrophilicity,[9] could be trapped by the addition of chloride ions. The "inverse synthesis" of the sulfene complex **2a** as outlined in eq. 3 indicates that low-valent cationic carbene complexes such as **5**, which are normally seen as role models of electrophilic carbenes,[21] may also exhibit some nucleophilic character. A further extension of this synthesis to complexes of substituted sulfenes, however, was thwarted by the inaccessibility of the corresponding carbene complexes.

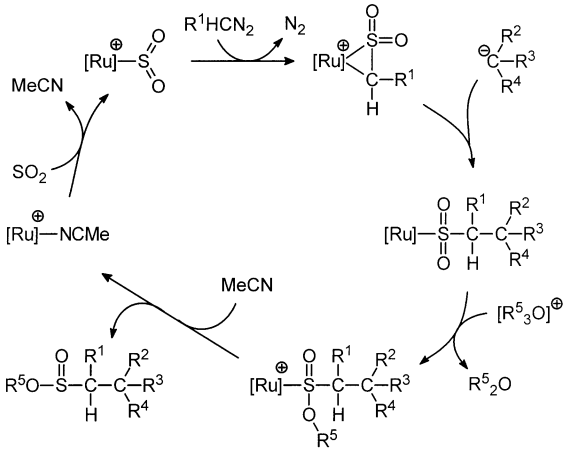
The rapid rotation of the sulfene ligand in **2b** deserves some comment. On the basis of steric considerations alone, it might be tempting to assume that the sulfene ligand can rotate more freely in the less congested dppm complex **2a**. The rotational barrier of a single-faced π-acceptor ligand, however, depends to a large extent on the spatial extension and energy difference of the occupied a′ and a″ frontier orbitals of the [$CpML_2$] fragment.[22] The antisymmetric a″ is the HOMO which is also M−L antibonding. With increasing pyramidalization of the [$CpML_2$] fragment, that is with decreasing L−M−L angle, the energy of this orbital is increased,[23] leading to a stronger fixation of the π-acceptor ligand perpendicular to the symmetry plane of the [$CpML_2$] complex.

Even in the early stages of this project, it soon became apparent that cationic sulfene complexes are highly reactive electrophiles.[8] Compared to uncoordinated sulfene, which adds nucleophiles at the sulfur atom,[2][3] the sulfene complexes studied here exhibit a reversed polarity;[9] only hard nucleophiles such as alkoxides are added at the sulfur atom.[8] Initial attempts to treat **2a** with Na[acac] gave intractable product mixtures, the spectral analyses of which indeed indicated competing C−C and C−O coupling, as well as further reactions initiated by deprotonation of the products. All these problems could readily be overcome by employing salts of tertiary C−H acidic compounds. In these cases, the reactions are clean and give the desired addition products in high yields. Particularly noteworthy is the high diastereoselectivity of the formation of **9c** (eq. 7). This is certainly a result of the rigid fixation of the methylsulfene

ligand in a sterically congested environment, which allows the prochiral enolate to approach in one orientation only.

The alkylation of the sulfinate function to give complexes of sulfinic acid esters provides a means of removing the metal complex from the organic moiety under mild conditions. Furthermore, the ionic acetonitrile complex thus obtained is easily separated from the organic component and can be converted back to the sulfur dioxide complex. A closed cycle is thus created, which allows the assembly of chain-extended sulfinic acid esters from sulfur dioxide, diazomethane or -ethane, and enolates (Scheme 1). Pertinent literature reports sulfinic acid esters to be prone to rearrangement to the corresponding sulfones.[20] Under our conditions, no such rearrangement could be detected, but we have at present no clear explanation as to the unexpected stability of **12a**, **b**.

Scheme 1



Esters of sulfinic acids have a number of important applications in organic synthesis.[24] Most pertinent work has been carried out on arenesulfinic acid esters, which seem to be much more readily accessible than their alkane counterparts. It is thus particularly gratifying that the reaction sequence outlined here not only provides esters of aliphatic sulfinic acids, but also tolerates a number of different functional groups.

This work has been supported by the *Deutsche Forschungsgemeinschaft* (SFB 347 "Selektive Reaktionen Metall-aktivierter Moleküle").

Experimental Section

All experiments were carried out in Schlenk tubes under nitrogen using suitably purified solvents. The crystallization of oily products was often conveniently induced by immersing the Schlenk tube in a small ultrasonic cleaning bath. − IR: Perkin-Elmer 283, Bruker IFS 25. − ^{1}H NMR: Bruker AMX 400, δ values relative to TMS; diastereotopic methylene protons of ethoxy groups invariably gave well-resolved ABX_3 spectra with ^2J(H,H) = 10.5 Hz and ^3J(H,H) = 7.1 Hz; for the sake of simplicity they are denoted in the following as "res. m" (resolved multiplet). − ^{13}C NMR: Bruker AMX 400, δ values relative to TMS; assignments were routinely checked by DEPT; in some cases the ^{13}C-NMR signals of quaternary carbon atoms were too weak to be detected. − ^{31}P NMR: Bruker AMX 400, δ values relative to 85% H_3PO_4. The ^{1}H- and ^{13}C-NMR signals of the phosphane ligands and the ^{31}P-NMR signals of the PF_6^- ion are very similar for all compounds and have therefore been omitted from the lists of spectral data. − Elemental analyses: Analytical Laboratory of the Institut für Anorganische Chemie. − The following starting materials were obtained as described in the literature: $[CpRu(PR_3)_2(SO_2)]X$ (**1a−d**),[25] [CpRu(dppm)Cl],[19] $[CpRu(dppm)(RHC{=}SO_2)]PF_6$ (**2a**, **d**),[9] diazomethane, diazoethane,[26] phenyldiazomethane.[27] Enolates were obtained from the corresponding 1,3-dicarbonyl compounds by deprotonation using lithium diisopropylamide or sodium bis(trimethylsilyl)amide. All other reagents were used as purchased.

[CpRu(dppe)(H$_2$C=SO$_2$)]PF$_6$ (**2b**): To a solution of **1b** (177 mg, 0.23 mmol) in dichloromethane (20 ml) a solution of diazomethane in diethyl ether (1 ml, 0.30 mmol) was added at −70°C. Gas evolution and a rapid color change to light-yellow were observed. The mixture was allowed to warm to 0°C, and all volatiles were removed in vacuo. After recrystallization from dichloromethane/pentane, a tan-colored microcrystalline powder was obtained. Yield 160 mg (89%), m.p. 156°C (dec.). − ^{1}H NMR (400 MHz, CD_2Cl_2, −70°C): δ = 0.02 [dd, ^2J(H,H) = 4.4 Hz, ^3J(P,H) = 16.8 Hz, 1 H, HC=SO_2], 3.30 (br. m, 1 H, HC=SO_2), 5.68 (s, 5 H, C_5H_5). − ^{13}C NMR (100 MHz, CD_2Cl_2, −70°C): δ = −20.2 [d, ^2J(P,C) = 6 Hz, $H_2C{=}SO_2$], 85.6 (s, C_5H_5). − ^{31}P NMR (162 MHz, CD_2Cl_2, −70°C): δ = 73.8 [d, ^2J(P,P) = 20 Hz], 78.7 [d, ^2J(P,P) = 20 Hz]. − IR (Nujol): $\tilde{\nu}$ = 1236, 1093 cm^{-1} (S=O). − $C_{32}H_{31}F_6O_2P_3RuS$ (787.6): calcd. C 48.80, H 3.97, S 4.07; found C 48.88, H 4.14, S 4.01.

[CpRu(PMe$_3$)$_2$(H$_2$C=SO$_2$)]PF$_6$ (**2c**): This compound was prepared analogously from **1c** (120 mg, 0.23 mmol) and diazomethane (0.45 mmol). Yield 109 mg (89%), m.p. 91°C (dec.). − ^{1}H NMR (400 MHz, [D_6]acetone, 20°C): δ = 0.71 [dd, ^2J(H,H) = 3.9 Hz, ^3J(P,H) = 17.6 Hz, 1 H, HC=SO_2], 2.57 (br. m, 1 H, HC=SO_2), 5.92 (s, 5 H, C_5H_5). − ^{13}C NMR (100 MHz, [D_6]acetone, 20°C): δ = −22.3 [d, ^2J(P,C) = 5 Hz, $H_2C{=}SO_2$], 96.0 (s, C_5H_5). − ^{31}P NMR (162 MHz, [D_6]acetone, 20°C): δ = 7.7 [d, ^2J(P,P) = 43 Hz], 9.7 [d, ^2J(P,P) = 43 Hz]. − IR (Nujol): $\tilde{\nu}$ = 1220, 1104 cm^{-1} (S=O). − $C_{12}H_{25}F_6O_2P_3RuS$ (541.4): calcd. C 26.62, H 4.65; found C 26.95, H 4.72.

[CpRu(dppm)(SO$_2$CHClPh)] (**3**): This compound was prepared analogously from **1d** (85 mg, 0.13 mmol) and phenyldiazomethane (0.25 mmol). The crude product was purified by chromatography on a short silica gel column using acetone/dichloromethane (2:1) as eluent. Yield 68 mg (71%), m.p. 171°C (dec.). − ^{1}H NMR (400 MHz, C_6D_6, 20°C): δ = 4.50 (s, 1 H, CHClPh), 4.89 (s, 5 H, C_5H_5). − ^{13}C NMR (100 MHz, C_6D_6, 20°C): δ = 83.2 [t, ^2J(P,C) = 2 Hz, C_5H_5], 83.3 [dd, ^2J(P,C) = 2 Hz, ^2J(P,C) = 1 Hz, CHClPh]. − ^{31}P NMR (162 MHz, C_6D_6, 20°C): δ = 11.0 [d, ^2J(P,P) = 90 Hz], 12.2 [d, ^2J(P,P) = 90 Hz]. − IR (Nujol): $\tilde{\nu}$ = 1184, 1032 cm^{-1} (S=O). − $C_{37}H_{33}ClO_2P_2RuS$ (740.2): calcd. C 60.04, H 4.49; found C 60.65, H 4.57.

[CpRu(dppm)(CH$_3$)] (**4**): A solution of [CpRu(dppm)Cl] (300 mg, 0.51 mmol) in toluene (10 ml) was treated at 20°C with methylmagnesium chloride in THF (1.54 mmol). After 20 h, the excess Grignard reagent was quenched by adding methanol (5 ml). All volatile material was then removed in vacuo and the solid residue was redissolved in toluene (20 ml). The resulting solution was filtered through Celite, and the filtrate was concentrated to a volume of 2 ml. Addition of pentane resulted in the deposition of the product as yellow crystals. Yield 185 mg (64%), m.p. 176°C (dec.). − ^{1}H NMR (400 MHz, C_6D_6, 20°C): δ = 0.20 [t, ^3J(P,H) = 7.1 Hz, 3 H, $RuCH_3$], 4.87 (s, 5 H, C_5H_5). − ^{13}C NMR (100 MHz, C_6D_6,

20°C): δ = −23.1 [t, ^2J(P,C) = 13 Hz, $RuCH_3$], 80.3 [t, ^2J(P,C) = 2 Hz, C_5H_5]. − ^{31}P NMR (162 MHz, C_6D_6, 20°C): δ = 22.8 (s). − $C_{31}H_{30}P_2Ru$ (565.6): calcd. C 65.83, H 5.35; found C 65.52, H 5.42.

[CpRu(dppm)(H$_2$C=SO$_2$)]PF$_6$ (**2a**). − *From* **4**: To a solution of **4** (185 mg, 0.33 mmol) in dichloromethane (20 ml), a solution of $[Ph_3C]PF_6$ (130 mg, 0.34 mmol) in the same solvent (2 ml) was added at −70°C. Sulfur dioxide was then introduced into the deep-red solution, and the mixture allowed to warm to 0°C. After concentration to a volume of 2 ml, the product was precipitated by adding pentane. Yield 218 mg (86%), colorless crystalline powder, identical (NMR, IR) with the known **2a**.[9]

Addition of Enolates: To a solution of Li[N(*i*Pr)$_2$] (25 mg, 0.22 mmol) or Na[N(SiMe$_3$)$_2$] (40 mg, 0.22 mmol) in THF (5 ml), an equimolar amount of the respective C−H acidic compound was added at −70°C. The resulting slurry was then added to a solution of 0.20 mmol of the sulfene complex in THF (10 ml). The mixture was allowed to warm to 20°C and stirred for 2 h. The solvent was then removed in vacuo, the oily residue was taken up in dichloromethane and chromatographed (neutral alumina, activity grade I, acetone/dichloromethane, 2:1). A broad, light-yellow band containing the product was collected. The solvent was evaporated and the product was recrystallized from benzene/pentane.

6a: Yield 76 mg (51%), m.p. 232°C (dec.). − ^{1}H NMR (400 MHz, CD_2Cl_2, 20°C): δ = 0.58 (s, 3 H, CH_3), 2.34−2.48, 2.87−2.92 (m, 4 H, CH_2CH_2), 2.89 (s, 2 H, SO_2CH_2), 4.95 (s, 5 H, C_5H_5). − ^{13}C NMR (100 MHz, CD_2Cl_2, 20°C): δ = 20.2 (s, CH_3), 35.2 (s, CH_2CH_2), 52.9 (s, C_{quat}), 82.3 (s, CH_2SO_2), 84.0 [t, ^2J(P,C) = 2 Hz, C_5H_5], 216.2 (s, CO). − ^{31}P NMR (162 MHz, CD_2Cl_2, 20°C): δ = 12.9 (s). − IR (Nujol): $\tilde{\nu}$ = 1715 (C=O), 1144, 1024 cm^{-1} (S=O). − $C_{37}H_{36}O_4P_2RuS$ (739.8): calcd. C 60.07, H 4.91; found C 60.54, H 5.30.

6b: Yield 124 mg (79%), m.p. 221°C (dec.). − ^{1}H NMR (400 MHz, CD_2Cl_2, 20°C): δ = 0.64 (s, 3 H, CH_3), 0.91 (s, 3 H, CH_3), 1.00 (s, 3 H, CH_3), 2.07 [d, ^2J(H,H) = 14.3 Hz, 2 H, CH_2], 2.82 [d, ^2J(H,H) = 14.3 Hz, 2 H, CH_2], 2.78 (s, 2 H, SO_2CH_2), 4.97 (s, 5 H, C_5H_5). − ^{13}C NMR (100 MHz, CD_2Cl_2, 20°C): δ = 19.1 (s, CH_3), 27.1 (s, CH_3), 30.6 (s, CH_3), 30.9 (s, CMe_2), 52.4(s, CH_2), 62.4 (s, C_{quat}), 78.2 (s, CH_2SO_2), 83.8 (s, C_5H_5), 209.0 (s, CO). − ^{31}P NMR (162 MHz, CD_2Cl_2, 20°C): δ = 13.5 (s). − IR (Nujol): $\tilde{\nu}$ = 1716, 1688 (C=O), 1144, 1032 cm^{-1} (S=O). − $C_{40}H_{42}O_4P_2RuS$ (781.9): calcd. C 61.44, H 5.41; found C 60.96, H 5.26.

7a: Yield 125 mg (78%), m.p. 183°C (dec.). − ^{1}H NMR (400 MHz, $CDCl_3$, 20°C): δ = 1.19 [t, ^3J(H,H) = 7.1 Hz, 6 H, CH_3], 1.36 (s, 3 H, CH_3), 2.86 (s, 2 H, SO_2CH_2), 4.10 (res. m, 4 H, OCH_2), 4.93 (s, 5 H, C_5H_5). − ^{13}C NMR (100 MHz, $CDCl_3$, 20°C): δ = 14.0 (s, CH_3), 19.4 (s, CH_3), 53.2 (s, C_{quat}), 61.0 (s, OCH_2), 73.3 (s, CH_2SO_2), 83.6 (s, C_5H_5), 171.5 (s, CO). − ^{31}P NMR (162 MHz, $CDCl_3$, 20°C): δ = 12.6 (s). − IR (Nujol): $\tilde{\nu}$ = 1740, 1712 (C=O), 1152, 1028 cm^{-1} (S=O). − $C_{39}H_{42}O_6P_2RuS$ (801.8): calcd. C 58.42, H 5.28; found C 57.96, H 5.59.

7b: Yield 129 mg (82%), m.p. 207°C (dec.). − ^{1}H NMR (400 MHz, CD_2Cl_2, 20°C): δ = 1.48 (s, 3 H, CH_3), 1.56 (s, 3 H, CH_3), 1.74 (s, 3 H, CH_3), 2.94 (s, 2 H, SO_2CH_2), 4.95 (s, 5 H, C_5H_5). − ^{13}C NMR (100 MHz, $CDCl_3$, 20°C): δ = 27.0 (s, CH_3), 27.6 (s, CH_3), 30.2 (s, CH_3), 43.4 (s, C_{quat}), 75.3 (s, CH_2SO_2), 83.6 (s, C_5H_5), 106.5 (s, O_2CMe_2), 168.5 (s, CO). − ^{31}P NMR (162 MHz, $CDCl_3$, 20°C): δ = 13.1 (s). − IR (Nujol): $\tilde{\nu}$ = 1744, 1732 (C=O), 1160, 1028 cm^{-1} (S=O). − $C_{38}H_{38}O_6P_2RuS$ (785.8): calcd. C 58.08, H 4.87; found C 58.17, H 4.87.

7c: Yield 124 mg (76%), m.p. 209°C (dec.). − ^{1}H NMR (400 MHz, $CDCl_3$, 20°C): δ = 1.18 [t, ^3J(H,H) = 7.1 Hz, 6 H, CH_3], 1.36 (s, 3 H, CH_3), 2.57 (s, 2 H, SO_2CH_2), 4.07 (res. m, 4 H, OCH_2), 4.85 (s, 5 H, C_5H_5). − ^{13}C NMR (100 MHz, $CDCl_3$, 20°C): δ = 14.0 (s, CH_3), 19.2 (s, CH_3), 53.2 (s, C_{quat}), 61.0 (s, OCH_2), 72.3 (s, CH_2SO_2), 85.6 (s, C_5H_5), 171.4 (s, CO). − ^{31}P NMR (162 MHz, $CDCl_3$, 20°C): δ = 83.0 (s). − IR (Nujol): $\tilde{\nu}$ = 1741, 1725 (C=O), 1142, 1024 cm^{-1} (S=O). − $C_{40}H_{44}O_6P_2RuS$ (815.9): calcd. C 58.89, H 5.44; found C 58.18, H 5.22.

7d: Yield 117 mg (72%), m.p. 207°C (dec.). − ^{1}H NMR (400 MHz, $CDCl_3$, 20°C): δ = 0.41 [t, ^3J(H,H) = 7.3 Hz, 3 H, CH_3], 1.15 [t, ^3J(H,H) = 7.1 Hz, 3 H, CH_3], 1.21 [t, ^3J(H,H) = 7.1 Hz, 3 H, CH_3], 1.43 (s, 3 H, CH_3), 3.66 [q, ^3J(H,H) = 7.3 Hz, 1 H, SO_2CHMe], 4.02 (res. m, 2 H, OCH_2), 4.17 (res. m, 2 H, OCH_2), 5.02 (s, 5 H, C_5H_5). − ^{13}C NMR (100 MHz, $CDCl_3$, 20°C): δ = 11.2 (s, CH_3), 14.2 (s, CH_3), 15.6 (s, CH_3), 57,5 (s, C_{quat}), 61.0 (s, OCH_2), 61.1 (s, OCH_2), 74.5 (s, SO_2CHMe), 82.7 (s, C_5H_5), 171.3 (s, CO), 171.4 (s, CO). − ^{31}P NMR (162 MHz, $CDCl_3$, 20°C): δ = 8.8 [d, ^2J(P,P) = 86 Hz], 11.1 [d, ^2J(P,P) = 86 Hz]. − IR (Nujol): $\tilde{\nu}$ = 1744, 1704 (C=O), 1156, 1024 cm^{-1} (S=O). − $C_{40}H_{44}O_6P_2RuS$ (815.9): calcd. C 58.89, H 5.44; found C 57.99, H 5.07.

7e: This compound was obtained from **3**. To ensure complete reaction the mixture was refluxed for 2 h. Yield 142 mg (81%), m.p. 156°C (dec.). − ^{1}H NMR (400 MHz, C_6D_6, 20°C): δ = 0.75 [t, ^3J(H,H) = 7.1 Hz, 3 H, CH_3], 0.94 [t, ^3J(H,H) = 7.1 Hz, 3 H, CH_3], 2.33 (s, 3 H, CH_3), 3.64 (res. m, 2 H, OCH_2), 3.95 (res. m, 1 H, OCH_2), 4.13 (res. m, 1 H, OCH_2), 4.35 (s, 5 H, C_5H_5), 4.55 (s, 1 H, SO_2CHPh). − ^{13}C NMR (100 MHz, C_6D_6, 20°C): δ = 13.8 (s, CH_3), 14.0 (s, CH_3), 18.2 (s, CH_3), 58,4 (s, C_{quat}), 60.5 (s, OCH_2), 60.8 (s, OCH_2), 78.4 (s, $CHPhSO_2$), 82.6 (s, C_5H_5), 170.3 (s, CO), 170.5 (s, CO). − ^{31}P NMR (162 MHz, C_6D_6, 20°C): δ = 9.9 [d, ^2J(P,P) = 90 Hz], 14.0 [d, ^2J(P,P) = 90 Hz]. − IR (Nujol): $\tilde{\nu}$ = 1725, 1713 (C=O), 1141, 1022 cm^{-1} (S=O). − $C_{45}H_{46}O_6P_2RuS$ (877.9): calcd. C 61.56, H 5.28; found C 61.72, H 5.19.

8a: Yield 114 mg (74%), m.p. 221°C (dec.). − ^{1}H NMR (400 MHz, $CDCl_3$, 20°C): δ = 1.19 [t, ^3J(H,H) = 7.1 Hz, 3 H, CH_3], 1.37 (s, 3 H, CH_3), 1.98 [s, 3 H, $C(O)CH_3$], 2.85 [d, ^2J(H,H) = 13.7 Hz, 1 H, SO_2CH_2], 2.94 [d, ^2J(H,H) = 13.7 Hz, 1 H, SO_2CH_2], 4.10 [q, ^3J(H,H) = 7.1 Hz, 2 H, OCH_2], 4.94 (s, 5 H, C_5H_5). − ^{13}C NMR (100 MHz, $CDCl_3$, 20°C): δ = 14.0 (s, CH_3), 19.3 (s, CH_3), 26.3 (s, CH_3), 58.8 (s, C_{quat}), 61.0 (s, OCH_2), 74.2 (s, CH_2SO_2), 83.7 (s, C_5H_5), 172.2 (s, CO), 205.8 (s, CO). − ^{31}P NMR (162 MHz, $CDCl_3$, 20°C): δ = 12.6 [d, ^2J(P,P) = 90 Hz], 12.9 [d, ^2J(P,P) = 90 Hz]. − IR (Nujol): $\tilde{\nu}$ = 1728, 1708 (C=O), 1148, 1036 cm^{-1} (S=O). − $C_{38}H_{40}O_5P_2RuS$ (771.8): calcd. C 59.14, H 5.22; found C 58.90, H 5.08.

8b: Yield 47 mg (31%), m.p. 211°C (dec.). − ^{1}H NMR (400 MHz, $CDCl_3$, 20°C): δ = 1.28 [t, ^3J(H,H) = 7.1 Hz, 3 H, CH_3], 1.37 (s, 3 H, CH_3), 2.51 [d, ^2J(H,H) = 13.2 Hz, 1 H, SO_2CH_2], 2.75 [d, ^2J(H,H) = 13.2 Hz, 1 H, SO_2CH_2], 4.22 (res. m, 1 H, OCH_2), 4.23 (res. m, 1 H, OCH_2), 4.95 (s, 5 H, C_5H_5). − ^{13}C NMR (100 MHz, $CDCl_3$, 20°C): δ = 13.9 (s, CH_3), 22.2 (s, CH_3), 40.6 (s, C_{quat}), 62.5 (s, OCH_2), 73.0 (s, CH_2SO_2), 83.6 (s, C_5H_5), 119.7 (s, CN), 168.6 (s, CO). − ^{31}P NMR (162 MHz, $CDCl_3$, 20°C): δ = 12.5 [d, ^2J(P,P) = 90 Hz], 13.0 [d, ^2J(P,P) = 90 Hz]. − IR (Nujol): $\tilde{\nu}$ = 1744 (C=O), 1168, 1032 cm^{-1} (S=O). − $C_{37}H_{37}NO_4P_2RuS$ (754.8): calcd. C 58.88, H 4.94, N 1.86; found C 59.09, H 4.45, N 1.23.

O-Alkylation of the Sulfinato Complexes: To a solution of the sulfinato complex (0.1 mmol) in dichloromethane (10 ml), a solution of the oxonium salt in the same solvent was added at −70°C. After being allowed to warm to 20°C, the mixture was concentrated to a volume of 1 ml and the product was precipitated by the addition of pentane. In some instances, **10a** separated as an oil. In this event, it was found that crystallization could be induced by ultrasound treatment under pentane.

10a: Yield 85 mg (94%), m.p. 88°C (dec.). − ^{1}H NMR (400 MHz, CD_2Cl_2, 20°C): δ = 1.10 (s, 3 H, CH_3), 1.20 [t, ^3J(H,H) = 7.2 Hz, 6 H, CH_3], 2.82 (s, 3 H, $SOCH_3$), 3.07 [d, ^2J(H,H) = 15.0 Hz, 1 H, SO_2CH_2], 3.63 [d, ^2J(H,H) = 15.0 Hz, 1 H, SO_2CH_2], 4.15 (res. m, 4 H, OCH_2), 5.31 (s, 5 H, C_5H_5). − ^{13}C NMR (100 MHz, CD_2Cl_2, 20°C): δ = 14.1 (s, CH_3), 14.2 (s, CH_3), 19.3 (s, CH_3), 52.0 (s, $SOCH_3$), 55.7 (s, C_{quat}), 62.2 (s, OCH_2), 62.6 (s, OCH_2), 74.4 (s, CH_2SO_2), 84.6 (s, C_5H_5), 169.7 (s, CO), 169.9 (s, CO). − ^{31}P NMR (162 MHz, CD_2Cl_2, 20°C): δ = 2.6 [d, ^2J(P,P) = 86 Hz], 5.8 [d, ^2J(P,P) = 86 Hz]. − IR (Nujol): $\tilde{\nu}$ = 1726 (C=O) cm^{-1}. − $C_{40}H_{45}BF_4O_6P_2RuS$ (903.7): calcd. C 53.16, H 5.02; found C 52.69, H 5.35.

10b: Yield 91 mg (93%), m.p. 135°C (dec.). − ^{1}H NMR (400 MHz, [D_6]acetone, 20°C): δ = 1.10 [t, ^3J(H,H) = 7.1 Hz, 3 H, CH_3], 1.16 [t, ^3J(H,H) = 7.1 Hz, 3 H, CH_3], 1.21 [t, ^3J(H,H) = 7.1 Hz, 3 H, $SOCH_3$], 1.22 (s, 3 H, CH_3), 2.95 [dq, ^3J(H,H) = 7.1 Hz, ^2J(H,H) = 9.6 Hz, 1 H, OCH_2], 3.07 [d, ^2J(H,H) = 15.1 Hz, 1 H, SO_2CH_2], 3.62 [dq, ^3J(H,H) = 7.1 Hz, ^2J(H,H) = 9.6 Hz, 1 H, OCH_2], 3.88 [d, ^2J(H,H) = 15.1 Hz, 1 H, SO_2CH_2], 4.10 (res. m, 4 H, OCH_2), 5.55 (s, 5 H, C_5H_5). − ^{13}C NMR (100 MHz, [D_6]acetone, 20°C): δ = 13.9 (s, CH_3), 14.0 (s, CH_3), 14.1 (s, CH_3), 19.2 (s, CH_3), 54.1 (s, C_{quat}), 61.9 (s, OCH_2), 62.4 (s, OCH_2), 63.1 (s, OCH_2), 73.6 (s, CH_2SO_2), 85.6 (s, C_5H_5), 169.7 (s, CO), 170.0 (s, CO). − ^{31}P NMR (162 MHz, [D_6]acetone, 20°C): δ = 2.6 [d, ^2J(P,P) = 85 Hz], 5.5 [d, ^2J(P,P) = 85 Hz]. − IR (Nujol): $\tilde{\nu}$ = 1733 (C=O), 1150 (S=O) cm^{-1}. − $C_{41}H_{47}F_6O_6P_3RuS$ (975.9): calcd. 10c: Yield 90 mg (91%), m.p. 118°C (dec.). − ^{1}H NMR (400 MHz, [D_6]acetone, 20°C) (assignment to the two different diastereomers was not possible): δ = 0.75 [t, ^3J(H,H) = 7.0 Hz, 3 H, CH_3], 1.20 (s, 3 H, CH_3), 1.40 (s, 9 H, *t*Bu), 1.93, 2.04 [s, 3 H, C(O)CH_3], 2.71, 2.86, 3.30, 3.32 [d, ^2J(H,H) = 15.2 Hz, 2 H, SO_2CH_2], 2.95 (m, 2 H, $SOCH_2$), 5.41, 5.42 (s, 5 H, C_5H_5). − ^{13}C NMR (100 MHz, [D_6]acetone, 20°C): δ = 13.8, 14.6 (s, CH_3), 18.9, 19.4 (s, CH_3), 25.6, 26.2 (s, CH_3), 27.6, 27.7 (s, *t*Bu), 60.6, 60.7 (s, C_{quat}), 62.4, 62.6 (s, $SOCH_2$), 73.9, 74.2 (s, CH_2SO_2), 83.0, 83.1 (s, CMe_3), 87.4, 87.5 (s, C_5H_5), 169.6, 169.7 (s, CO), 202.3, 202.7 (s, CO). − ^{31}P NMR (162 MHz, [D_6]acetone, 20°C), major (51%) diastereomer: δ = 69.2 [d, ^2J(P,P) = 21 Hz], 73.3 [d, ^2J(P,P) = 21 Hz], minor (49%) diastereomer: δ = 66.2 [d, ^2J(P,P) = 21 Hz], 72.8 [d, ^2J(P,P) = 21 Hz]. − IR (Nujol): $\tilde{\nu}$ = 1716 (C=O), 1150 cm^{-1} (S=O). − $C_{43}H_{51}F_6O_5P_3RuS$ (987.9): calcd. C 52.28, H 5.20, S 3.25; found C 51.99, H 5.33, S 3.15.

Liberation of the Sulfinic Acid Esters: The respective ester complexes **10a**, **b** (0.2 mmol) were dissolved in acetonitrile (10 ml) and heated under reflux (15 h). Thereafter, the mixtures were concentrated to dryness and the resulting residues were suspended in diethyl ether. The acetonitrile complexes **11a**, **b** separated as yellow powders upon ultrasound treatment. In each case, the supernatant was concentrated to dryness, leaving the esters **12a**, **b** as colorless, spectroscopically pure oils in almost quantitative yields.

12a: ^{1}H NMR (400 MHz, $CDCl_3$, 20°C): δ = 1.24 [t, ^3J(H,H) = 7.1 Hz, 6 H, CH_3], 1.58 (s, 3 H, CH_3), 3.16 [d, ^2J(H,H) = 13.6 Hz, 1 H, SO_2CH_2], 3.34 [d, ^2J(H,H) = 13.6 Hz, 1 H, SO_2CH_2], 3.72 (s, 3 H, $SOCH_3$), 4.19 [q, ^3J(H,H) = 7.1 Hz, 4 H, OCH_2]. − ^{13}C NMR (100 MHz, $CDCl_3$, 20°C): δ = 13.9 (s, CH_3), 20.5 (s, CH_3), 51.4 (s, C_{quat}), 62.0 (s, OCH_2), 62.1 (s, OCH_2), 63.0 (s, CH_2SO_2), 170.1 (s, CO).

12b: ^{1}H NMR (400 MHz, $CDCl_3$, 20°C): δ = 1.25 [t, ^3J(H,H) = 7.1 Hz, 6 H, CH_3], 1.32 [t, ^3J(H,H) = 7.1 Hz, 3 H, CH_3], 1.58 (s, 3 H, CH_3), 3.19 [d, ^2J(H,H) = 13.6 Hz, 1 H, SO_2CH_2], 3.36 [d, ^2J(H,H) = 13.6 Hz, 1 H, SO_2CH_2], 4.06 (res. m, 2 H, $SOCH_2$), 4.19 (res. m, 2 H, OCH_2), 4.20 (res. m, 2 H, OCH_2). − ^{13}C NMR (100 MHz, $CDCl_3$, 20°C): δ = 13.9 (s, CH_3), 15.8 (s, CH_3), 20.4 (s, CH_3), 51.5 (s, C_{quat}), 62.0 (s, OCH_2), 62.1 (s, OCH_2), 63.2 (s, $SOCH_2$), 65.0 (s, CH_2SO_2), 170.1 (s, CO), 170.2 (s, CO).

Acetonitrile/SO_2 Exchange: In a small pressure tube, equipped with a Teflon needle valve, liquid sulfur dioxide (5 ml) was condensed onto the acetonitrile complex **11a**, **b** (0.1 mmol). After 7 d at 20°C, the tube was vented and the yellow residue was recrystallized from dichloromethane/pentane.

1a: Yield 72 mg (95%), spectroscopically identical to authentic material.[19]

1e: Yield 67 mg (96%) m.p. 158°C. – ^{31}P NMR (162 MHz, [D$_6$]acetone, 20°C): δ = −3.2 (s). – IR (Nujol): $\tilde{\nu}$ = 1279, 1115 (S=O) cm^{-1}. – $C_{30}H_{27}BF_4O_2P_2RuS$ (701.4): calcd. C 51.37, H 3.88, S 4.57; found C 50.94, H 3.88, S 4.50.

Received December 4, 1997

Keywords: Dihydroxybiphenyl / Iron chelation / Formation constants / Protonation constants

A new water-soluble iron(III) sequestering agent has been designed. The tris-bidentate tripodal ligand consists of three 2,2′-dihydroxybiphenyl subunits connected via amide linkages at their *meta* (4-) positions to a framework of the "tren" type. The key step of the synthesis involves the coupling of suitably substituted monophenyl moieties in order to obtain the biphenyl precursor. The deprotonation constants of the ligand, and the formation and deprotonation constants of the Fe^{III} complex have been determined from potentiometric and spectrophotometric measurements. The results are compared with those of a previously described homologous ligand in which the chelating subunits are attached to the tren framework via the *ortho* (3-) position of the biphenyl rather than the 4-position.

Introduction

Iron overloading is a significant health problem, for which iron chelation therapy is required[1]. A number of limitations to the use of desferrioxamine, the only approved drug for treatment of iron overload (parenteral administration, prohibitive price, short plasma half-life), underline the need for the development of a truly orally effective drug. The search for effective ferric ion chelating agents was originally centered on mimics of natural siderophores [tris(catecholate) or tris(hydroxamate) ligands][2]. Catechol-based ligands are the most powerful in the thermodynamic sense [enterobactin, a tris(catecholate) siderophore produced by *E. Coli* has been shown[3] to have a stability constant for Fe^{III} complexation of 10^{49}], but these ligands are extremely air-sensitive and they have been shown to promote bacterial infections. Hydroxamate-based ligands seem to suffer limitations inherent to all the hydroxamate chelating agents. Recently, potential drugs for iron chelation therapy incorporating "non-natural" chelating subunits have been studied, such as hydroxypyridinone[4], pyridoxal isonicotinoyl hydrazone[5], and 8-hydroxyquinoline[6].

In a previous publication[7], we described tripodal ligands based on three 2,2′-dihydroxybiphenyl subunits connected to a tris(2-aminoethyl)amine (tren) framework via the *ortho* (3-) positions of their phenolic groups (an example, L_o, is depicted in Figure 1). The results obtained with these water-soluble and air-stable ligands were promising[8]. Nevertheless, the complexing ability of these ligands was found to be lower than that of tris(catecholates) or tris(hydroxamates) on the basis of the respective pFe values. The interpretation of molecular modelling studies suggested that connection of the 2,2′-dihydroxybiphenyl chelating pendant arms to the tren framework via the 4-position, i.e. *meta* to the hydroxy group, rather than via the 3-position (*ortho* to the hydroxy group), should be more conducive to an octahedral arrangement of the ligation sites around the metal center. However, this new mode of connection renders impossible the so-called salicylate-like binding of the metal[9] (which generally occurs at low pH). On the other hand, the presence of an amide group at the position *ortho* to the hydroxy group has been shown by Shanzer et al.[10] to result in hydrogen bonding in the complex between the amide and the oxygen coordinated to Fe^{III}. These interactions suggest a preorganization of the ligand around the metal center that improves its binding properties. In order to examine the effect of the position of the amide linkage (*ortho* or *meta* to the phenolic group) on the complexing ability of the ligand, we report herein on the synthesis and iron(III) complexing properties of L_m, a tripodal ligand in which the biphenyl subunits are attached via their 4-positions (Figure 1).

Results and Discussion

Synthesis of Ligands

The synthesis of tripodal ligands based on 2,2′-hydroxy-1,1′-biphenyl subunits, attached either via the 3-position[7a] or the 4-position (this work, Figure 2), is centered on the formation of amide links from carboxylate moieties, which are activated and then conjugated with the tetraamine, tris(2-aminoethyl)amine (tren). Coupling of the protected 2,2′-dimethoxy-1,1′-diphenyl-4-carboxylic acid **9** with tren was most conveniently accomplished using *N*,*N*′-carbonyldiimidazole (CDI).[18] For comparative complexation studies, simple bidentate ligands **14** and **15** were also prepared (Figure 2).

Figure 2. Synthesis of the ligands

(m) BBr_3, CH_2Cl_2, 0 °C ; (n) H_2SO_4, ,SO_3

Sulfonation, using H_2SO_4/oleum, of tripod **11** and of bidentate ligand **14** afforded the water-soluble products **12** and **15**, respectively.

In the previously studied[7a] series of ligands, in which the connection with the spacer tren was at the 3-position of the biphenyl group, the starting material for the synthesis was commercially available 2,2′-hydroxy-1,1′-biphenyl. Functionalization at the position *ortho* to the phenolic hydroxy group was readily and regiospecifically effected by various methods. The synthesis of 2,2′-dimethoxy-1,1′-diphenyl-4-carboxylic acid (**9**) involves heterocoupling[13][19][20] (Figure 3) of the iodo derivative **5** of methyl 2-methoxybenzoate (**4**) and 2-methoxyphenylboronic acid (**7**) (Figure 3B). The iodo derivative was obtained[12] from 5-methyl-2-nitroanisole (**1**) (Figure 3A).

Ligand Deprotonation Constants

The ligand L_m possesses six hydroxy groups and one tertiary amine function and is denoted LH_7^{8-} taking into account the negative charges of the nine sulfonate groups. The deprotonation constants were determined by potentiometric titration of the fully protonated ligand with NaOH in 0.1 M $NaClO_4$ at 25°C (Figure 4a). Analysis of the titration curve yielded only the following five pK_a values: 10.62 ± 0.07; 7.48 ± 0.11; 6.23 ± 0.12; 5.85 ± 0.13, and 4.88 ± 0.13.

Figure 3. Synthesis of 2,2′-dimethoxy-1,1′-diphenyl-4-carboxylic acid **9**

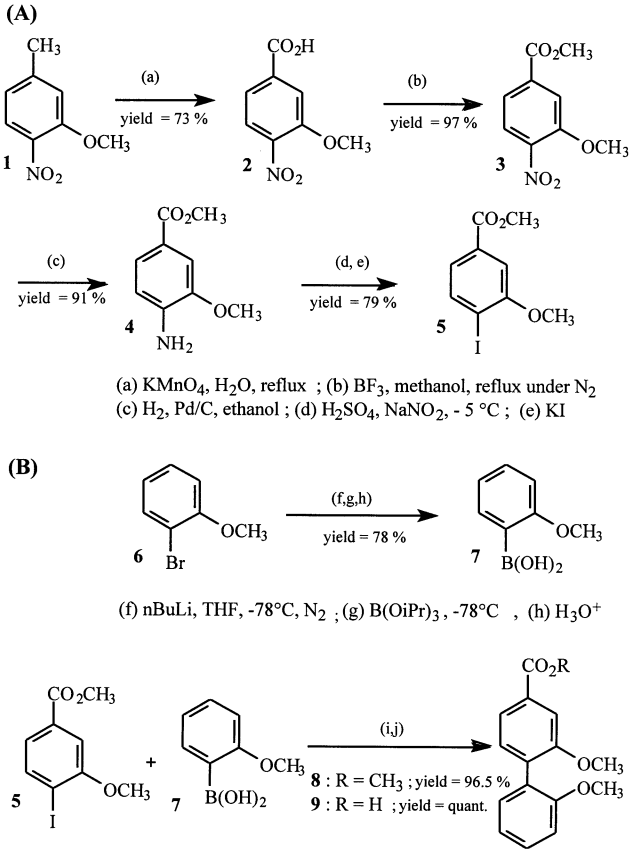

Figure 4. Potentiometric titration curves for (a) 0.5 mmol dm^{-3} ligand L_m; (b) ligand L_m + Fe^{3+} 1:1 0.5 mmol dm^{-3}; m = moles of base added per mol of ligand; all solutions were at 25°C and I = 0.1 mol dm^{-3} ($NaClO_4$); the deprotonation constants of the ligand and the complexation constants were calculated using the SUPERQUAD program[15]

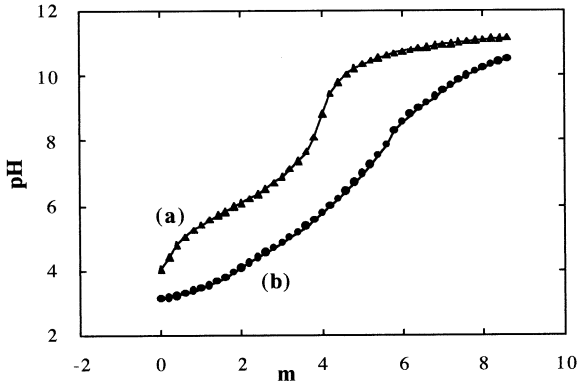
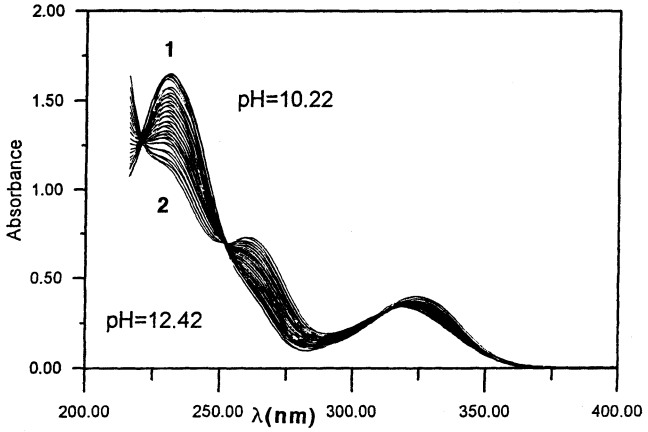


The deprotonation constants of LH_2^{13-} and LH^{14-} species are too high to be accurately determined by direct potentiometry. Spectrophotometric titration was carried out at pH = 10.2−12.7 and revealed one buffer region. The corresponding UV spectra exhibit isosbestic behavior, indicating the presence of only two absorbing species (Figure 5). The data were analyzed using the LETAGROP-

SPEFO[16][17] program (absorbance values at 4 wavelengths). The model delineated involves a single-proton step for the deprotonation equilibrium, yielding a pK_a value of 11.70 ± 0.03. The pK_a values of the monomeric analogue **15** (5,3′,5′-trisulfonate derivative of compound **14**) were also determined: 5.50 ± 0.01 by potentiometry in the acidic range, and 11.68 ± 0.03 by UV/Vis spectrophotometry in the basic range. The value of 5.50 befits a hydroxy group *meta* to the electron-withdrawing amide group.

Figure 5. UV/Vis absorption spectra of the L_m ligand as a function of pH; 1: pH = 10.2; 2: pH = 12.4; $[L_m]$ = 0.05 mmol dm^{-3}; I = 0.1 mol dm^{-3} ($NaClO_4$)

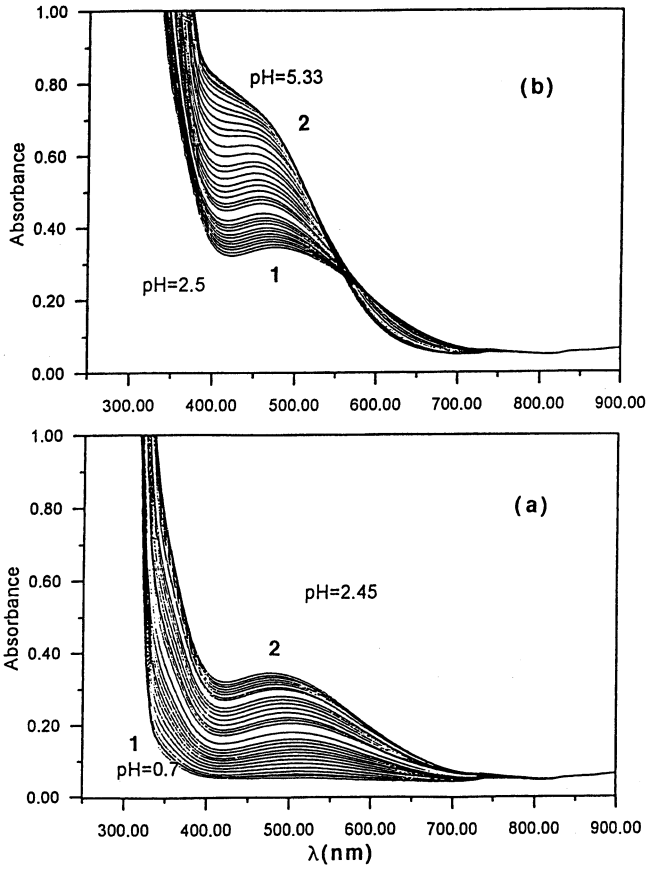


The three lower pK_a values (4.88, 5.85, and 6.23) and the two higher pK_a values (10.62 and 11.70) were assigned to hydroxy groups. The former reflect a roughly statistical separation (log 3 or 0.48), which is consistent with non-interacting arms if one allows for a difference up to one pK unit, as is encountered in several tripodal structures containing 2,2′-dihydroxybiphenyl[7b], catechol[21] or hydroxamate[22] binding units. It should be noted that the average value of these three pK_a′s, 5.65, is very close to the value of 5.50 determined for the monomeric analogue. A similar behavior is expected for the pK_a′s of the three remaining hydroxy groups, the value of 11.70 being very close to that of 11.68, measured for the monomeric analogue. Furthermore, it is assumed that the deprotonation of at least two OH groups, each borne by two different pendant arms of the tripod, induces a change in the UV spectrum. We can thus estimate the third pK_a in this range as having a value of 12.7 on the basis of a statistical separation (see above). The pK_a of 7.48 was attributed to the tertiary amine group by comparison with the value of 7.1 determined for tripodal ligands containing 2,2′-dihydroxybiphenyl subunits[7b].

Stability Constants of Ferric Complexes

Stability constants for the Fe^{III} complexes were determined by means of spectrophotometric and potentiometric titrations. The spectrophotometric behavior of the ferric complexes at a 1:1 metal-to-ligand molar ratio was investigated as a function of pH. The spectrum changed significantly over the pH range 0.7−5.3. The ligand reacts with Fe^{III} in acidic media, as indicated by the absorption spectra (Figure 6a). As the pH was increased from 1 to 2.5, the charge transfer band was found to shift from 520 nm ($\varepsilon \approx$ 600 mol^{-1} dm^3 cm^{-1}) to 470 nm ($\varepsilon \approx$ 1400 mol^{-1} dm^3 cm^{-1}). The absorbance data were processed with the LETAGROP-SPEFO program. The best fit was obtained by considering the formation of the $[FeLH_6]^{6-}$ and $[FeLH_5]^{7-}$ species, generating the values log β_{116}[23] = 61.9 ± 0.1 and log β_{115} = 60.0 ± 0.1, with ε_{max} = 580 mol^{-1} dm^3 cm^{-1} (λ = 520 nm) for $[FeLH_6]^{6-}$ and 1510 mol^{-1} dm^3 cm^{-1} (λ = 480 nm) for $[FeLH_5]^{7-}$. Increasing the pH to 5.3 led to an increase in the band intensity, which was accompanied by a shift to lower wavelength (Figure 6b). The best fitting model for the interpretation of spectrophotometric data was obtained by considering the equilibrium between $[FeLH_5]^{7-}$ and $[FeLH_3]^{9-}$. The calculated value of log β_{113} is 51.8 ± 0.1, with ε = 2600 mol^{-1} dm^3 cm^{-1} at 420 nm (shoulder). Only a marginal spectral change was observed over the pH range 5.3−7.5. At pH > 7.5, absorbances in the range 400−550 nm were found to decrease.

Figure 6. UV/Vis absorption spectra of Fe^{3+}−L_m ligand as a function of pH; (a) 1: pH = 0.7; 2: pH = 2.45; (b) 1: pH = 2.5; 2: pH = 5.3; $[Fe^{3+}]$ = $[L_m]$ = 0.25 mmol dm^{-3}; I = 0.1 mol dm^{-3} ($NaClO_4$)



Potentiometric titration on 1:1 solutions in ferric ion and ligand was also carried out over the pH range 3−10 (Figure 4b). Data were analyzed using the SUPERQUAD program by considering the $[FeLH_5]^{7-}$ species at the beginning of the titration and using the value of β_{115} calculated from the spectrophotometric titration. The model was best fitted (σ_{fit} = 2.9) with six Fe^{III} complex species $[FeLH_4]^{8-}$,

$[FeLH_3]^{9-}$, $[FeLH_2]^{10-}$, $[FeLH]^{11-}$, $[FeL]^{12-}$, and $[FeLOH]^{13-}$ giving the following values of log β_{11h}: log $\beta_{114} = 56.49 \pm 0.02$; log $\beta_{113} = 51.86 \pm 0.03$; log $\beta_{112} = 46.26 \pm 0.04$; log $\beta_{111} = 39.11 \pm 0.06$; log $\beta_{110} = 30.03 \pm 0.08$; log $\beta_{11-1} = 20.26 \pm 0.08$.

From these values, the following deprotonation constants can be deduced for the complexes: $pK_{FeLH5} = 3.51$; $pK_{FeLH4} = 4.63$; $pK_{FeLH3} = 5.60$; $pK_{FeLH2} = 7.15$; $pK_{FeLH} = 9.08$; $pK_{FeL} = 9.77$.

It should be noted that the value of log $\beta_{113} = 51.86$ is in good agreement with that of 51.8 determined from the spectrophotometric study, thus validating the proposed model.

Structural attributes of these complexes can be proposed on the basis of their spectral characteristics. For $[FeLH_5]^{7-}$, the band at 470 nm ($\varepsilon = 1400$ mol^{-1} dm^3 cm^{-1}) is indicative of a dihydroxylate mode of coordination involving one arm of the ligand, as is apparent from comparison with the system Fe^{III} sodium 2,2′-dihydroxybiphenyl-3,5,3′,5′-tetrasulfonate[9]. Over the pH range 2.5−5.3, the observed increase in absorbance and shift to shorter wavelength (shoulder at $\lambda = 430$ nm with $\varepsilon = 2600$ mol^{-1} dm^3 cm^{-1}) suggest a bis(dihydroxylate) coordination involving two arms of the ligand in the $[FeLH_3]^{9-}$ species. A region of constant specific absorbance at pH = 5.3−7.5 indicates no increased degree of coordination to the dihydroxylate groups. At pH > 7.5, a decrease in the absorption in the range 400−550 nm may correspond to the formation of hydroxo complexes. The successive deprotonation constants of the complex $[FeLH_3]^{9-}$ may thus be attributed to deprotonation of the tertiary amine group, of one hydroxy group of the uncoordinated arm, and of the two water molecules that complete the coordination sphere around Fe^{III}. The fact that only two arms of the ligand L_m are involved in coordination of Fe^{III} might be explained in terms of repulsive effects between the negative charges on the sulfonate groups in the 3′-positions. It is assumed that such interactions prevent the formation of a hexadentate coordination cavity involving all three arms.

The pFe ($-\log [Fe^{3+}]$) values have been calculated to provide a comparison of the relative ability of the ligands to complex Fe^{III} (under biologically reasonable conditions, i.e. pH = 7.4, $[L]_{tot} = 10^{-5}$ mol dm^{-3}, $[Fe]_{tot} = 10^{-6}$ mol dm^{-3}). The calculated value for ligand L_m is 19.7. This value shows that the ligand L_m is less effective than the analogous tripodal L_o (pFe = 22.8),[7b] in which the subunits are connected via their 3-positions, i.e. *ortho* to the hydroxy groups. This lower affinity of L_m for Fe^{III} can be partly related to the available coordination modes. The structure of the ligand L_o favours an initial coordination of the salicylate type (with oxygen atoms of the carbonyl and hydroxy groups). A preorganization of the ligand is thus expected for a complexation of the metal ion by the other arms. This cannot occur for L_m.

Conclusion

A multistep synthesis of the tris-bidentate tripodal ligand L_m has been described. This ligand incorporates three 2,2′-dihydroxybiphenyl subunits, which are attached to a central "tren" framework via amide linkages at their 4-positions, i.e. *meta* to the phenolic hydroxy groups. The aim of this work was to compare the complexing ability of L_m with that of L_o, a previously described iron chelator in which the chelating pendant arms are attached via their 3-positions, i.e. *ortho* to the phenolic groups.

The ligand deprotonation constants (six hydroxy groups and one tertiary amine function) and the stability constants β_{11h} of the ferric complexes (in a pH range of 1−10) have been determined. The pFe value of 19.7 calculated for L_m as compared to the value of 22.8 for L_o[7b] reveals an interesting structural effect. Since molecular models suggested that the *meta* connection (L_m) should be more conducive to the formation of an octahedral coordination cavity than the *ortho* connection (L_o), the observed result was unexpected. The structure of the ligand L_o favours an initial coordination of the salicylate type (with oxygen atoms of the carbonyl and hydroxy groups), which is assumed to "preorganize" the ligand for a complexation of the metal ion by the other arms. This is not possible for L_m, thus diminishing its complexing ability towards Fe^{III}. Furthermore, as the coordination changes from a salicylate to a dihydroxylate mode of bonding upon deprotonation of the complex, an amide conformational change is assumed to occur for the complexation of the metal center by L_o. Thus, hydrogen bonding between the amide group and the coordinated oxygen atom (six-membered ring) can occur, which is not possible in the complex of Fe^{III} with L_m. The importance of the preorganization of the ligand was emphasized by Shanzer et al.[10], and seems to play a major role in determining the complexing ability of a given ligand. Thus, for the design of novel ligands, geometry of the octahedral coordination sphere around the metal center is not the sole criterion for the prediction of complexation stability.

We are grateful to Dr. *Hakim Boukhalfa* (L.E.D.S.S., Grenoble) for performing the UV/Vis spectrophotometric measurements.

Experimental Section

Materials and Equipment: Solvents were purified by standard techniques; 5-methyl-2-nitroanisole and 2-bromoanisole are commercially available (Aldrich). The amine "tren" was distilled from sodium. All other compounds were of reagent grade and were used without further purification. Iron(III) stock solutions were prepared by dissolving appropriate amounts of ferric perchlorate hydrate (Aldrich) in standardized $HClO_4/NaClO_4$ solutions. The solutions were standardized for ferric ion spectrophotometrically by using a molar extinction coefficient of 4160 mol^{-1} dm^3 cm^{-1} at 240 nm[11]. − IR spectra were recorded with Perkin-Elmer 397 or Nicolet Impact 400 spectrometers. UV/Vis absorption spectra were recorded using 1.000-cm path length quartz cells with a Perkin-Elmer Lambda 2 spectrometer connected to a COMPAQ Deskpro 386s microcomputer. − Mass spectra were recorded with a NERMAG R 10 1 C mass spectrometer. − ^{1}H- and ^{13}C-NMR spectra were obtained using 5-mm tubes at 25°C with a Bruker AC 200 or a Bruker AM 400 spectrometer. − Microanalyses were performed by the Central Service of CNRS, Solaise (France). − Melting points were determined with a Büchi apparatus and are not corrected.

3-Methoxy-4-nitrobenzoic Acid (**2**): A mixture of 5-methyl-2-nitroanisole (**1**) (25.0 g, 0.15 mol), potassium permanganate (97.5 g, 0.62 mol), and sodium hydrogen carbonate (12.3 g, 0.12 mol) in 1.5 l of water was refluxed for 4 h. Thereafter, the MnO_2 formed was filtered off. The filtrate was cooled to 0°C and acidified with 20% sulfuric acid to pH = 1. The yellow solid thus produced was washed with water, dried, and purified by recrystallization from ethanol (white crystals, 21 g, 73%). – M.p. 226°C (ref.[12] 230–233°C). – ^{1}H NMR (200 MHz, [D$_6$]DMSO): δ = 4.01 (s, 3 H, OCH_3), 7.71 (dd, J_1 = 8.3, J_2 = 1.4 Hz, 1 H), 7.79 (d, J = 1.4 Hz, 1 H), 7.83 (d, J = 8.3 Hz, 1 H). – ^{13}C NMR (50 MHz, [D$_6$]DMSO): δ = 56.8 (OCH_3), 114.6 (CH), 121.3 (CH), 125.0 (CH), 135.8, 141.9, 151.5 (C–O), 165.8 (C=O). – IR (KBr): $\tilde{\nu}$ = 3250–2200 cm^{-1} [ν(OH)], 1680 [ν(C=O)].

Methyl 3-Methoxy-4-nitrobenzoate (**3**): 3-Methoxy-4-nitrobenzoic acid (**2**) (21.0 g, 0.11 mol) was dissolved in methanol (350 ml) under nitrogen. BF_3 (40 ml, 50% w/w in methanol) was added and the mixture was stirred under reflux for 12 h. The solvent was then removed, the residue was treated with water (300 ml), and the resulting suspension was filtered. The collected yellow solid was washed with water (500 ml) and then dried in vacuo (21.9 g, 0.10 mol, 91%). – M.p. 91°C (ref.[12] 90–91°C). – ^{1}H NMR (200 MHz, $CDCl_3$): δ = 3.97 (s, 3 H, CO_2CH_3), 4.02 (s, 3 H, OCH_3), 7.67 (dd, J_1 = 8.3, J_2 = 1.5 Hz, 1 H), 7.71 (d, J = 1.5 Hz, 1 H), 7.84 (d, J = 8.3 Hz, 1 H). – ^{13}C NMR (50 MHz, $CDCl_3$): δ = 52.8 (CO_2CH_3), 56.7 (OCH_3), 114.6 (CH), 121.4 (CH), 125.3 (CH), 134.8, 142.0, 152.4 (C–O), 165.2 (C=O). – IR (KBr): $\tilde{\nu}$ = 1740 cm^{-1} [ν(C=O)].

Methyl 4-Amino-3-methoxybenzoate (**4**): Compound **3** (10.0 g, 47.4 mmol) was dissolved in a mixture of dichloromethane (50 ml) and ethanol (300 ml). The resulting solution was stirred for 12 h under hydrogen in the presence of Pd/charcoal (10% Pd, 923 mg). The catalyst was subsequently removed by filtration and the solvent was evaporated. The yellow solid thus obtained was purified by recrystallization from ethanol (7.84 g, 43.3 mmol, 91%). – M.p. 128°C (ref.[12] 127–128°C). – ^{1}H NMR (200 MHz, $CDCl_3$): δ = 3.86 (s, 3 H, OCH_3), 3.89 (s, 3 H, OCH_3), 4.22 (m, 2 H, NH_2), 6.66 (d, J = 8.0 Hz, 1 H), 7.45 (d, J = 1.7 Hz, 1 H), 7.54 (dd, J_1 = 8.0, J_2 = 1.7 Hz, 1 H). – ^{13}C NMR (50 MHz, $CDCl_3$): δ = 51.6 (CO_2CH_3), 55.5 (OCH_3), 111.1 (CH), 113.1 (CH), 119.5, 124.0 (CH), 141.0, 146.1 (C–O), 167.3 (C=O). – IR (KBr): $\tilde{\nu}$ = 3450–3330 cm^{-1} [ν(NH_2)], 1670 [ν(C=O)].

Methyl 4-Iodo-3-methoxybenzoate (**5**): To a mixture of **4** (8.1 g, 44.7 mmol), water (110 ml) and 20% H_2SO_4 (24 ml), a solution of sodium nitrite (3.47 g, 49.6 mmol) in water (20 ml) was slowly added at 0°C. At the end of the reaction, the excess nitrous acid was destroyed by the addition of urea (800 mg). Then, 20 ml of aqueous KI (7.74 g, 46.6 mmol) was added dropwise and the mixture was stirred for 2 h at 50°C. To the resulting brown mixture was added an aqueous solution of $Na_2S_2O_5$. The product was isolated by extraction with diethyl ether, neutralization with 1 N NaOH (to pH = 5), washing with brine, and drying with Na_2SO_4. The solvent was evaporated and the iodo compound was purified by column chromatography (alumina, pentane containing 3% ethyl acetate), giving a white solid (10.4 g, 33.6 mmol, 72%). – M.p. 50–52°C (ref.[12] 52–53°C). – ^{1}H NMR (200 MHz, $CDCl_3$): δ = 3.92 (s, 3 H, OCH_3), 3.94 (s, 3 H, OCH_3), 7.36 (dd, J_1 = 8.1, J_2 = 1.8 Hz, 1 H), 7.44 (d, J = 1.8 Hz, 1 H), 7.84 (d, J = 8.1 Hz, 1 H). – ^{13}C NMR (50 MHz, $CDCl_3$): δ = 52.3 (CO_2CH_3), 56.5 (OCH_3), 92.6 (CI), 111.2 (CH), 123.3 (CH), 131.6, 139.5 (CH), 158.2 (C–O), 166.5 (C=O). – IR (KBr): $\tilde{\nu}$ = 1720 cm^{-1} [ν(C=O)].

2-Methoxyphenylboronic Acid (**7**): At –78°C, *n*BuLi (80 ml, 1.6 M in hexane, 0.128 mol) was added to a solution of 2-bromoanisole (**6**) (13.3 ml, 0.107 mol) in diethyl ether (100 ml) and the mixture was stirred at this temperature for 30 min. With a protective nitrogen atmosphere, the lithio derivative was then cannulated into a solution of triisopropyl borate (32 ml, 0.214 mol) in diethyl ether. After stirring at –78°C for 30 min, then at room temperature, the mixture was poured into aqueous HCl (10%, 300 ml). The product was extracted with diethyl ether, the combined extracts were washed with water (100 ml), and dried with Na_2SO_4. The oily, crude product was stored in a refrigerator for 24 h, giving white crystals. These somewhat unstable crystals were rapidly washed with cold pentane and then dried in vacuo (11 g, 0.072 mol, 68%). – M.p. 104–105°C (ref.[13] 105–106°C). – ^{1}H NMR (200 MHz, $CDCl_3$): δ = 3.85 (s, 3 H, OCH_3), 6.85 (d, J = 8.3 Hz, 1 H, ArH), 6.93–7.01 (m, 1 H, ArH), 7.34–7.43 (m, 1 H, ArH), 7.77 (dd, J_1 = 7.3, J_2 = 1.8 Hz, 1 H, ArH). – ^{13}C NMR (50 MHz, $CDCl_3$): δ = 55.3 (OCH_3), 109.9 (CH), 121.1 (CH), 132.7 (CH), 136.8 (CH), 164.4 (C–O).

Methyl 2,2′-Dimethoxy-1,1′-diphenyl-4-carboxylate (**8**): To a solution of **5** (1.0 g, 3.42 mmol) in freshly distilled DMF (15 ml) under nitrogen were added **7** (78 mg, 5.13 mmol), Et_3N (1.4 ml, 10.3 mmol), $Pd(OAc)_2$ (23 mg, 0.103 mmol), and P(*o*-Tol)$_3$ (65 mg, 0.212 mmol). The orange solution was heated at 100°C for 3 h, whereupon it became black. The solvent was evaporated and the residue was treated with dichloromethane and 10% ammonia. The organic phase was washed with water and then dried with Na_2SO_4. The orange oil was purified by column chromatography (silica gel; pentane/diethyl ether, 9:1). **8** was obtained as a white solid (0.9 g, 3.3 mmol, 97%). – M.p. 112°C. – R_f = 0.55 (pentane/diethyl ether, 2:1). – ^{1}H NMR (200 MHz, $CDCl_3$): δ = 3.33 (s, 3 H, CO_2CH_3), 3.39 (s, 3 H, OCH_3), 3.50 (s, 3 H, OCH_3), 6.53–6.62 (m, 2 H, ArH), 6.62–6.90 (m, 2 H, ArH), 6.87 (d, J = 7.7 Hz, 1 H), 7.20 (d, J = 1.4 Hz, 1 H), 7.25 (dd, J_1 = 7.7, J_2 = 1.4 Hz, 1 H). – ^{13}C NMR (50 MHz, [D$_6$]DMSO): δ = 52.2 (CO_2CH_3), 55.4 and 55.6 (OCH_3), 111.3 (CH), 111.4 (CH), 120.2 (CH), 121.2 (CH), 126.3, 129.2 (CH), 130.7 (CH), 131.1, 131.4 (CH), 132.2, 156.6 (C–O), 156.7 (C–O), 167.2 (C=O). – IR (KBr): $\tilde{\nu}$ = 1710 cm^{-1} [ν(C=O)]. – MS (EI); *m/z*: 272 [M$^+$], 241, 225, 213, 198. – $C_{16}H_{16}O_4$: calcd. C 70.58, H 5.29; found C 70.40, H 5.47.

2,2′-Dimethoxy-1,1′-diphenyl-4-carboxylic Acid (**9**): Ester **8** (2.0 g, 7.34 mmol) was refluxed with ethanolic KOH (excess) for 3 h. The mixture was then concentrated and 10% HCl was added. The resulting precipitate was filtered off, washed with water, and dried in vacuo to give **9** as a white solid (1.9 g, quant.). – M.p. 170°C. – ^{1}H NMR (200 MHz, $CDCl_3$): δ = 3.78 (s, 3 H, OCH_3), 3.85 (s, 3 H, OCH_3), 6.98–7.07 (m, 2 H, ArH), 7.23–7.28 (m, 1 H, ArH), 7.33–7.41 (m, 1 H, ArH), 7.36 (d, J = 7.8 Hz, 1 H), 7.77 (d, J = 1.5 Hz, 1 H), 7.8 (dd, J = 7.8, 1.5 Hz, 1 H). – ^{13}C NMR (50 MHz, [D$_6$]DMSO): δ = 55.4 and 55.5 (OCH_3), 111.4 (CH), 111.5 (CH), 120.2 (CH), 121.4 (CH), 126.5, 129.1 (CH), 130.8 (CH), 131.1, 131.3 (CH), 132.2, 156.6 (C–O), 156.7 (C–O), 167.2 (C=O). – IR (KBr): $\tilde{\nu}$ = 3600–2300 cm^{-1} [ν(OH)], 1680 [ν(C=O)]. – MS (EI); *m/z*: 258 [M$^+$], 184.

N,N′,N″-(Nitrilotri-2,1-ethanediyl)tris(2,2′-dimethoxy-4-biphenylcarboxamide) (**10**): Under nitrogen, acid **9** (1.0 g, 3.87 mmol) was treated with CDI (690 mg, 4.26 mmol) in freshly distilled THF (50 ml) and the mixture was stirred for 12 h; tren (160 µl, 1.06 mmol) was added and the mixture was stirred overnight at room temperature. The solvent was then evaporated and the brown oil was purified by column chromatography (silica gel, dichloromethane containing 2% isopropylamine) giving **10** as a white solid (1.0 g, 3.50

mmol, 90%). − M.p. 116°C. − R_f = 0.6 (CH_2Cl_2/MeOH, 9:1). − ^{1}H NMR (200 MHz, $CDCl_3$): δ = 2.77 (br. s, 6 H, NCH_2), 3.61 (m, 24 H, NCH_2, OCH_3), 6.84−7.04 (m, 12 H, ArH), 7.24−7.44 (m, 9 H, ArH), 7.50 (br. s, 3 H, NH). − ^{13}C NMR (50 MHz, $CDCl_3$): δ = 38.4 (CH_2), 54.7 (CH_2), 55.3 and 55.4 (OCH_3), 110.2 (CH), 110.9 (CH), 118.6 (CH), 120.1 (CH), 126.7, 128.7 (CH), 131.0 (CH), 131.2 (CH), 134.0, 156.6 (C−O), 156.9 (C−O), 167.8 (C=O). − IR (KBr): $\tilde{\nu}$ = 1635 cm^{-1} [ν(C=O)]. − MSM [FAB(+), NBA matrix]; *m/z*: 867 [M + H^+], 596, 284, 257, 241, 213. − $C_{51}H_{54}N_4O_9 \cdot 3H_2O$: calcd. N,N′,N″-(Nitrilotri-2,1-ethanediyl)tris(2,2′-dihydroxy-5,3′,5′-trisulfo-4-biphenylcarboxamide) (**12**): The hydroxylated tripod **11** (830 mg, 1.06 mmol) was dissolved in 60 ml of oleum (H_2SO_4 + 15% SO_3) at 0°C. The mixture was then stirred at 90°C for 3 h. After cooling to room temperature, the brown solution was cautiously poured onto crushed ice with stirring. With cooling, the solution was brought to pH = 4 by the slow addition of 10% aq. NaOH. Sodium sulfate was eliminated by repeated precipitations by adding methanol. − M.p. > 286°C. − ^{1}H NMR (200 MHz, D_2O): δ = 3.80 (m, 2 H, CH_2), 4.00 (m, 2 H, CH_2), 7.17 (s, 1 H), 7.91 (s, 1 H), 7.94 (d, *J* = 2.3 Hz, 1 H), 8.22 (d, *J* = 2.3 Hz, 1 H). − ^{13}C NMR (50 MHz, CD_3OD): δ = 37.4 (CH_2), 55.3 (CH_2), 118.6 (CH), 128.4 (CH), 129.4, 131.4, 134.1 (CH), 134.5, 134.9 (CH), 137.1, 138.0, 156.4 (C−O), 159.2 (C−O), 174.2 (C=O).

2,2′-Dimethoxy-4-(N,N-dimethylcarbamoyl)-1,1′-biphenyl (**13**): Under nitrogen at room temperature, acid **9** (0.9 g, 3.48 mmol) was treated with CDI (623 mg, 3.84 mmol) in THF (100 ml) for 12 h. The mixture was then cooled to 0°C, dimethylamine (5 ml) was added, and stirring was continued overnight at room temperature. The solvent was then evaporated and the residual brown oil was purified by column chromatography (silica gel, dichloromethane containing 2% isopropylamine) to afford **13** as a white solid (800 mg, 2.80 mmol, 80%). − M.p. 123°C. − ^{1}H NMR (200 MHz, $CDCl_3$): δ = 3.04 (s, 6 H, NCH_3), 3.69 (s, 3 H, OCH_3), 3.71 (s, 3 H, OCH_3), 6.89−6.98 (m, 4 H, ArH), 7.13−7.31 (m, 3 H, ArH). − ^{13}C NMR (50 MHz, $CDCl_3$): δ = 36.0 (NCH_3), 40.0 (NCH_3), 55.6 (OCH_3), 55.7 (OCH_3), 110.0 (CH), 111.1 (CH), 118.7 (CH), 120.3 (CH), 127.0, 128.8 (CH), 129.2, 131.1 (CH), 131.2 (CH), 136.3, 156.9 (C−OMe), 157.0 (C−OMe), 171.5 (C=O). − MS (EI): *m/z*: 285 [M], 257, 213.

2,2′-Dihydroxy-4-(N,N-dimethylcarbamoyl)-1,1′-biphenyl (**14**): To a solution of BBr_3 in dichloromethane (1 M, 20 ml) at 0°C under nitrogen, **13** (900 mg, 3.15 mmol) was added and the mixture was stirred for 12 h at room temperature. The mixture was then treated with methanol and the solvents were evaporated. The residue was redissolved in 20 ml of 10% aq. NaOH and subsequent addition of 10% HCl at 0°C gave **14** as a white precipitate, which was dried in vacuo (800 mg, 3.10 mmol, 98%). − M.p. 186°C. − ^{1}H NMR (200 MHz, [D_6]DMSO): δ = 2.96 (s, 6 H, NCH_3), 6.77−6.90 (m, 4 H, ArH), 7.10−7.88 (m, 3 H, ArH), 9.23 (s, 1 H, OH), 9.43 (s, 1 H, OH). − ^{13}C NMR (50 MHz, [D_6]DMSO): δ = 34.8 (NCH_3), 114.4 (CH), 115.7 (CH), 117.3 (CH), 118.8 (CH), 125.2, 127.0, 128.3 (CH), 131.3 (CH), 131.4 (CH), 136.2, 154.4 (C−OH), 154.6 (C−OH), 154.6 (C=O). − IR (KBr): $\tilde{\nu}$ = 3500−2300 cm^{-1} [ν(OH)], 1600 [ν(C=O)]. − MS (EI); *m/z*: 275 [M], 213.

2,2′-Dihydroxy-4-(N,N-dimethylcarbamoyl)-3,3′,5′-trisulfo-1,1′-biphenyl (**15**): Sulfonation of **14** was performed as for **12**. − M.p. > 286°C. − ^{1}H NMR (200 MHz, CD_3OD): δ = 2.87 (s, 3 H, CH_3), 3.03 (s, 3 H, CH_3), 6.64 (s, 1 H), 7.7 (d, *J* = 2.3 Hz, 1 H), 7.75 (s, 1 H), 8.16 (d, *J* = 2.3 Hz, 1 H). − ^{13}C NMR (50 MHz, CD_3OD): δ = 35.3 (CH_3), 39.8 (CH_3), 114.5 (CH), 126.3, 126.5 (CH), 127.2, 129.9, 132.6 (CH), 132.7 (CH), 133.5, 136.3, 137.0, 154.3 (C−N), 158.0 (C−N), 172.9 (C=O).

Potentiometric Experiments: All measurements were made at 25°C. Solutions were prepared with deionized, doubly distilled water. The ionic strength was fixed at 0.1 M with sodium perchlorate (PROLABO puriss). The pH measurements were performed using a TACUSSEL Ionoprocesseur-II millivoltmeter equipped with glass and calomel electrodes (TACUSSEL). The electrodes were calibrated to read p[H] according to the classical method[14]. Potentiometric titrations employed a TACUSSEL Electroburex burette and a pH meter (Ionoprocesseur-II) connected to a Hewlett Packard microcomputer. The titrations were automated using software developed in our laboratory. The ligands and their iron(III) complexes at concentrations of ca. 0.001 M were titrated with standardized 0.05 M sodium hydroxide. The titration data were refined by the nonlinear least-squares refinement program SUPERQUAD[15] in order to determine the equilibrium constants (protonation and complexation).

Spectrophotometric Experiments: The deprotonation constant of one hydroxy group was determined in the UV region (the ligand concentration in aqueous solution was ca. $5 \cdot 10^{-5}$ M). The ferric complexes were investigated by spectrophotometry: The UV/Vis spectrum of a solution containing equal amounts of ligand and Fe^{III} (10^{-4} M) was monitored as a function of pH over the range 1−10 (adjusted with $HClO_4$ or NaOH); an aliquot was taken from the solution after each adjustment of the pH (which was measured using a pH meter) and its spectrum was recorded. The ionic strength was fixed at 0.1 M with $NaClO_4$/$HClO_4$ for this second set of experiments. The spectrophotometric data were fitted with the LETAGROP-SPEFO program[16][17]. The program uses a nonlinear least-squares method and calculates the thermodynamic constants of the absorbing species and their corresponding electronic spectra. The calculations were performed on the basis of absorbance data at about 6−8 wavelengths (between 400 and 600 nm).

Keywords: Nickel / Oxidation / Phenols / Structure, dynamic NMR spectroscopy

The reaction of substituted phenols and dioxygen with $Ni(PMe_3)_4$ yields the low-spin tetracoordinate diphenolatonickel compounds $Ni(OAr)_2(PMe_3)_2$ [ArOH = 2-*tert*-butylphenol (**1**), 2-*tert*-butyl-4-methylphenol (**2**), 2-*tert*-butyl-6-methylphenol (**3**), 2,4-di(*tert*-butyl)phenol (**4**), 2-*tert*-butyl-4-methoxophenol (**5**), 2-chloro-4-*tert*-butylphenol (**6**), 2-isopropylphenol (**7**), 3-*tert*-butylphenol (**8**)]. As is revealed by variable temperature ^1H- and ^{13}C-NMR spectroscopy the complexes constitute a mixture of two isomers, each of which can be observed separately at lower temperatures when interconversion is slower. An additional 6-carbaldehyde function transforms the phenolate into a chelating ligand, giving rise to a high-spin hexacoordinate compound $Ni(OAr)_2(PMe_3)_2$ (**9**). X-ray crystal-structure determinations of **2** and **3** show a *trans* square-planar structure, and that of **9** shows a *trans* octahedral arrangement of donor atoms P_2O_4. Bulky substituents in the 3- or 4-position, or non-demanding substituents in the 2-position, are less effective in stabilizing molecular diphenolatonickel complexes.

Many low-valent metal compounds, if combined with a proton source and dioxygen, form an oxidizing system. Examples are Fentons reagent, Bartons Gif systems and the Wacker process. Peroxometal complexes are believed to be key intermediates in these reactions.[1] Strongly reducing phosphane complexes of zerovalent nickel are known to form peroxo species according to Eq. 1. In exceptional cases these may be isolated, e.g. with space-filling tricyclohexylphosphane ligands.[2]

$$Ni(PR_3)_4 + O_2 \rightarrow (R_3P)_2NiO_2 \rightarrow Ni + 2\ R_3P{=}O \qquad (1)$$

With the small trimethylphosphane the peroxo intermediate is explosive, and for this reason even small crystals of $Ni(PMe_3)_4$ crackle upon contact with air. Using mol-equivalent amounts of oxygen in solution the system becomes a mild oxidant. On this basis we have developed a new synthesis of molecular diphenolatonickel complexes containing trimethylphosphane ligands.

Conventionally, but not conveniently, unsolvated diphenolatonickel compounds may be prepared in an anhydrous medium as insoluble coordination polymers. Methods using $NiCl_2$ and sodium or lithium phenolates usually afford products which pertinaciously occlude halide impurities.

Some *ortho*-substituted phenols form diphenolatonickel dihydrates that can be converted into anhydrous compounds. These materials cannot be dissolved without reaction.[3] However, with nitrogen donor atoms in a suitable configuration numerous soluble chelate complexes, e. g. with 8-hydroxoquinolines or salicylaldimines, have been shown to exist as molecular compounds with square-planar coordination at the nickel atom. These complexes usually do not accommodate additional phosphane ligands.

In this contribution a novel method of synthesis is described which smoothly affords crystalline diphenolatobis(trimethylphosphane)nickel compounds starting from substituted phenols, $Ni(PMe_3)_4$, and dioxygen.

Results and Discussion

Pale-yellow solutions of $Ni(PMe_3)_4$ and two mol-equivalents of a phenol in hydrocarbon or ether solvents turn dark-red when treated with one mol-equivalent of dioxygen[4] according to Eq. 2. One of the trimethylphosphanes serves as a co-reductant, in this respect resembling the natural methane monooxygenase system.[5]

Using sterically shielding 2-*tert*-butylphenols, mononuclear diphenolatonickel complexes containing trimethylphosphane are obtained in good to excellent yields. Separation from moist trimethylphosphane oxide[6] is conveniently achieved by filtration, and trace impurities can be sublimed from the product in vacuo at 20°C.

Yield [%]	52	78	86[a]	70	54	48	11	8	83

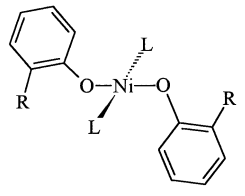
[a] Yield of crude product.

Recrystallization from pentane or ether affords red crystals that can be dried in vacuo without loss of phosphane ligands. While coordination of substoichiometric amounts of triorganophosphanes by diphenolatonickel polymers has been noticed,[7] to the best of our knowledge the molecular trimethylphosphane complexes **1**−**8** constitute a novel type of compound. The 2-*tert*-butyl groups not only prevent formation of coordination polymers by steric shielding but also enhance the reactivity of the phenolic function, when compared with the unsubstituted phenol. In a sluggish reaction with $Ni(PMe_3)_4$ and oxygen this parent phenol gives low yields of insoluble material which, according to the infrared data, appears to be a mixture of nickel oxide and diphenolatonickel containing residual trimethylphosphane ligands.

To investigate the limits of steric demand, the size and positions of phenolic substituents were varied.

Steric Protection of the Phenolate Function

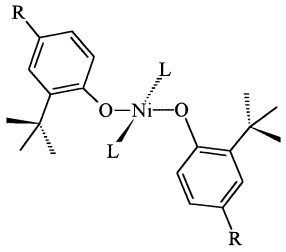
Reducing the size of the substituent in 2-position induces loss of trimethylphosphane while forming insoluble coordination polymers at the expense of molecular diphenolatonickel compounds. This tendency increases from R = CMe_3 to R = H. Moving the protecting *tert*-butyl group to the 3- or 4-position dramatically reduces the yields of molecular complexes.



L = $P(CH_3)_3$

R	CMe_3	$CHMe_2$	2,4,6-Me_3	H
Yield [%]	52	11	0	0
R	2-CMe_3	3-CMe_3	4-CMe_3	
Yield [%]	52	8	0	

Neither steric nor electronic changes in the 4-position can affect the reasonably constant yields of bis(2-*tert*-butylphenolato)bis(trimethylphosphane)nickel compounds.



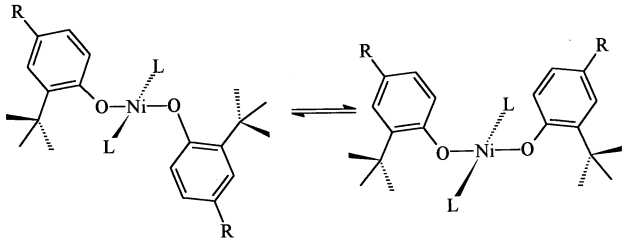
L = $P(CH_3)_3$

R	CMe_3	Me	H	OMe	Cl
Yield [%]	70	78	52	54	48

Thus, the stability of molecular diphenolatonickel complexes containing trimethylphosphane appears to be controlled by the size of the phenolic substituent in 2-position.

NMR Spectroscopy

For steric reasons an optimum configuration of the bis(2-*tert*-butylphenolato)nickel complexes **2** and **3** in solution is likely to be the same as that in the solids, and is characterized by CMe_3 groups pointing away from the plane of coordination (Figures 1 and 2). In the crystal a *transoid* arrangement of CMe_3 substituents (A) is favored, while in solution a second minimum of energy is populated through rotation of phenolato ligands (B), as shown by dynamic ^{1}H-NMR spectroscopy.



L = $P(CH_3)_3$

The room-temperature ^{1}H-NMR spectra (300 MHz) of the complexes **1**, **2**, **4**, **5**, and **7** (Table 1) show a broad one-proton signal at $\delta_H \approx 9 \pm 0.5$, whereas the other protons of the benzene ring show clearly resolved multiplets, e.g. for **2** a doublet of 1.9 Hz for the signal at $\delta_H = 6.65$ and a double doublet of 7.7 and 1.9 Hz for that at $\delta_H = 6.90$. From an analysis and comparison of the NMR data the broad high-frequency signal has to be assigned to 6-H, which is deshielded by the nearby nickel atom. On cooling the solution (e.g. **2** was cooled to 233 K) two clearly resolved doublets are observed for 6-H at $\delta_H = 9.21$ and 8.63 in an intensity ratio of about 2:1 with $J_{6\text{-H},5\text{-H}} = 7.8$ Hz for both signals. Line separations, albeit amounting to only a few Hz (ca. 0.01 ppm), can be seen also for the other protons, an exception being the 4-CH_3 protons. An H,H-COSY spectrum proves that the signals of 5-H of both species overlap at $\delta_H = 6.90$ and those of the 3-H atoms at $\delta_H = 6.65$. On the other hand, when heating a solution of **2** in

Figure 2. Molecular structure of **3** (ORTEP plot without hydrogen atoms)[a]

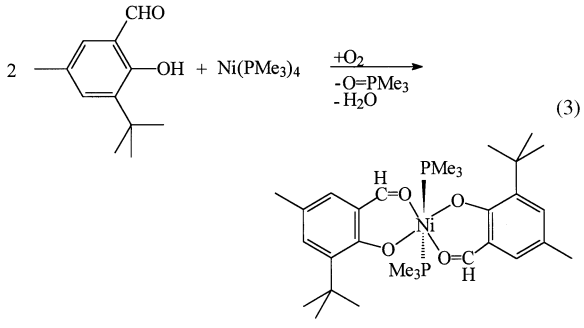
$[D_8]$toluene to 373 K, one doublet at $\delta_H = 9.07$ with $J = 7.8$ Hz appears.

Analogous results are obtained from the ^{13}C-NMR spectra (Table 2), e.g. that of **2**. At 305 K one set of signals is obtained, the one at $\delta_C = 123.0$ exhibiting some line broadening; according to 2D-H,C correlation it has to be attributed to C-6. At 233 K two sets of signals in a ratio of about 2:1 are observed for most C atoms, exceptions being those of C-3 and of both types of CMe_3 under the routine measurement conditions applied.

From these results it has to be concluded that there is a mixture of two rotamers, A and B, which can be observed separately when interconversion is slow on the NMR time scale.

Coordination Number 6

In a suitable conformation an aldehyde or ketone function can serve as additional O-donor ligand. This chelating property has been previously observed in equilibria of ligand dissociation involving pentacoordinate species which are formed in a ligand dismutation reaction from iodo(phenolato)nickel precursors.[8]



Trimethylphosphane is smoothly added to produce hexacoordinate **9** according to Eq. 3. Involvement of both aldehyde groups is evident from a bathochromic coordination shift of the ν(C=O) bands. Both types of diphenolatonickel complexes have been characterized by single-crystal X-ray diffraction.

[a] Selected bond lengths [Å] and angles [°]: Ni−O1 1.868(3), Ni−P1 2.233(1), O1−C1 1.355(6), C1−C7 1.382(8), C6−C7 1.402(8); O1−Ni−P1 94.1(1), O1−Ni−P1′ 85.9(1), C1−O1−Ni 120.6(3).

Molecular Structures of 2, 3, and 9

Single crystals were obtained from pentane solutions at −20°C. Figures 1−3 give the atom numberings and the principal bond lengths and angles.

In all three molecular structures the nickel atom lies on a crystallographic inversion center. Bond lengths show significant deviations only between the hexacoordinate species **9** and the two square-planar complexes. Thus, in **9** the

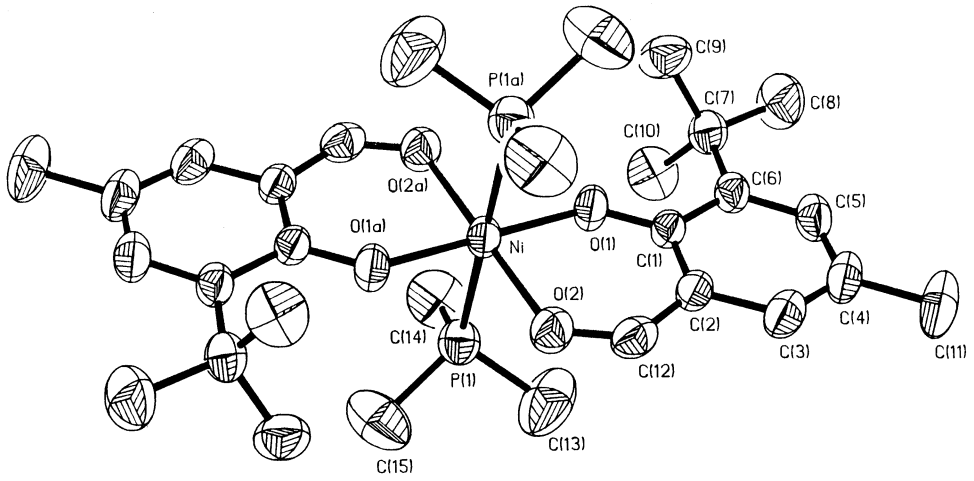
Ni−O distances of 1.995(2) and 2.060(2) Å, which are as expected for octahedral complexes of nickel,[9] exceed those of **2** and **3** by more than 10 pm. Also the large Ni−P distances of 2.482(1) Å are due to octahedral coordination in

Figure 3. Molecular structure of **9** (ORTEP plot without hydrogen atoms)[a]



[a] Selected bond lengths [Å] and angles [°]: Ni−O1 1995(2), Ni−O2 2.060(2), Ni−P1 2.482(1), O1−C1 1.289(2), O2−C12 1.245(3), C4−C11 1.522(3), C6−C7 1.531(4); O1−Ni−P1 87.2(1), O1a−Ni−P1 92.8(1), O2−Ni−P1 89.9(1), O2a−Ni−P1 90.1(1), C1−O1−Ni 130.1(2), C12−O2−Ni 123.9(2).

the 20-electron complex **9** and are similar to those of octahedral nickel(IV) complexes[10] (18 electrons). The diamagnetic square-planar complexes **2** and **3** exhibit shorter Ni−O and Ni−P bond lengths. While Ni−P distances are as expected for 16-electron (trimethylphosphane)nickel complexes[11][12] the Ni−O distances of *trans*-bis(trimethylphosphane)nickel diphenolates are unprecedented as far as we are aware. When compared with a pentacoordinate tripyridinebis(2,4,6-trichlorophenolato)nickel(II)[13] [Ni−O = 2.014(4) Å] Ni−O distances such as 1.868(3) Å for **2** and 1.861(3) Å for **3** are considerably shorter. There is no structural indication for magnetic shielding of the aromatic 6-H nucleus by a close approach to the metal atom (see NMR Spectroscopy) because the calculated distance Ni−H(7) = 2.627 Å seems too large for such interaction. Similarly, in the 6-methyl-substituted compound **3** the distance between the 6-alkyl group and the nickel atom is beyond the radius of interaction.

Table 3. Distortions of square-planar geometries at nickel centres; L = $P(CH_3)_3$

formula	angles
	α=Ni-O-C(1)=120.6(3)° β=P(1)-Ni-O(1)=85.92(12)° γ=P(1a)-Ni-O(1)=94.08(12)°
	α=Ni-O-C(1)=127.3(3)° β=P(1)-Ni-O(1)=81.45(12)° γ=P(1a)-Ni-O(1)=98.55(12)°
	α=Ni-O-C(1)=130.1(2)° β=P(1)-Ni-O(1a)=92.8(1)° γ=P(1)-Ni-O(1)=97.2(1)°

Indeed, the substituent in 6-position points away from the nickel atom. While the angle α = 120.6(3)° in **2** (see Table 3) this angle in **3** is augmented by 6.7°. The sterically demanding 2-*tert*-butyl-6-methylphenolato ligand causes contraction of angles β from 85.92(12)°in **2** to 81.45(12)° in **3**. An even larger angle α in **9** is due to incorporation in the 6-membered chelate ring which also affects angles β and γ.

Conclusion

Molecular diphenolatobis(trimethylphosphane)nickel complexes can be prepared by convenient methods in high yields, if bulky substituents in the 2-position of the phenolato ligand prevent condensation reactions between metal centers. By dynamic NMR spectroscopy 2-*tert*-butyl groups are shown to hinder rotation of phenolato ligands around Ni−O bonds. X-ray crystallography reveals the nickel atoms to be surrounded by a meridian of two phenolato and two trimethylphosphane donors in mutual *trans* positions. These structures have been filed as the first reported for diamagnetic diphenolatonickel compounds. The five-membered chelate rings are all planar and show similar dimensions and the expected increase in bond lengths at the nickel atom as going from square-planar to octahedral coordination. Although in **9** the Ni−P distance represents an extremely long bond [2.482(1) Å], crystals of this compound

do not release trimethylphosphane at 20°C in vacuo. Further investigation of properties of (trimethylphosphane)nickel diphenolates are in progress in order to better understand the role of chelating phenols as active catalysts in olefin oligomerization reactions.[14]

Financial support of this work by the *Fonds der Chemischen Industrie* and the *Deutsche Forschungsgemeinschaft* is gratefully acknowledged.

Experimental Section

General Procedures and Materials: All air-sensitive and volatile materials were handled by standard vacuum techniques and kept under argon. Details have been given elsewhere.[8] $Ni(PMe_3)_4$ was prepared by literature methods,[15] phenols (Merck-Schuchardt) were used as purchased. Measured volumes of oxygen were admitted to the reaction mixture at −70°C and in vacuo.

Bis(2-tert-butylphenolato)bis(trimethylphosphane)nickel (**1**): 510 mg of $Ni(PMe_3)_4$ (1.37 mmol) and 414 mg of 2-*tert*-butylphenol (2.74 mmol) in 60 ml of THF were combined with 25 ml of dioxygen (1.04 mmol). Upon warming the light yellow solution turned dark-red. After 16 h at 20°C, the volatiles were removed in vacuo and the residue extracted with 50 ml of pentane through a glass-sinter disc (G3). Crystallization at −20°C afforded dark-red rhombs. Yield 362 mg (52% based on nickel), m.p. 184−186°C. − IR (Nujol): $\tilde{\nu}$ = 1574 cm^{-1} (C=C), 1044 (C−O), 944 [$\rho(PCH_3)$]. − $C_{26}H_{44}NiO_2P_2$ (509.3): calcd. C 61.32, H 8.71, P 12.16; found C 61.15, H 9.04, P 12.21.

Bis(2-tert-butyl-4-methylphenolato)bis(trimethylphosphane)nickel (**2**): 500 mg of $Ni(PMe_3)_4$ (1.37 mmol) and 452 mg of 2-*tert*-butyl-4-methylphenol (2.74 mmol) in 50 ml of THF at −70°C were combined with 33 ml of dioxygen (1.37 mmol). After warming the mixture to 20°C, the volatile components were removed in vacuo and the residue extracted with 60 ml of pentane. Keeping the dark-red solution at −20°C for 30 h afforded red-brown cubes. Yield 572 mg (78% based on nickel), m.p. 133−135°C. − IR (Nujol): $\tilde{\nu}$ = 1596 cm^{-1} (C=C), 1019 (C−O), 943 [$\rho(PCH_3)$]. − $C_{28}H_{48}NiO_2P_2$ (537.3): calcd. C 62.59, H 9.00, P 11.53: found C 62.96, H 9.48. P 11.78.

Bis(2-tert-butyl-6-methylphenolato)bis(trimethylphosphane)nickel (**3**): 870 mg of $Ni(PMe_3)_4$ (2.40 mmol) and 787 mg of 2-*tert*-butyl-6-methylphenol (4.80 mmol) in 50 ml of THF at −70°C were combined with 50 ml of dioxygen (2.08 mmol). After warming to 20°C, the light-yellow solution turned red-brown and was stirred for a further16 h. The volatiles were removed in vacuo, and the residue extracted with 50 ml of pentane. The crude product was collected as a brown oil (1110 mg, 86%) and used for spectroscopic measurements. Crystallization from 5 ml of pentane at −27°C starting with 900 mg of crude material afforded 260 mg of red-brown crystals (20%), m.p. 169−171°C. − IR (Nujol): $\tilde{\nu}$ = 1581 cm^{-1} (C=C), 950 [$\rho(PCH_3)$]. − ^{1}H NMR ([D$_8$]THF): δ = 0.61 [s (br.), 18 H, $P(CH_3)_3$], 1.30 (s, 6 H, CH_3), 1.50 [s, 18 H, $C(CH_3)_3$], 6.54 (t, J = 7.3 Hz, 1 H, 4-H), 7.00 (m, 2 H, 3-H, 5-H). − ^{13}C NMR ([D$_8$]toluene): δ = 11.88 [s (br.), $P(CH_3)_3$], 20.92 (s, CH_3), 29.94 [$C(CH_3)_3$], 35.21 [s, $C(CH_3)_3$], 114.89 (s, C-3), 124.80 (s, C-5), 128.90 (s, C-4); 141.45 (s, C-2), 143.96 (C-6), 163.07 (s, C-1).

Bis(2,4-di-tert-butylphenolato)bis(trimethylphosphane)nickel (**4**): 1350 mg of $Ni(PMe_3)_4$ (3.72 mmol) and 1530 mg of 2,4-di-*tert*-butylphenol (7.44 mmol) in 70 ml of THF at −70°C were combined with 90 ml of dioxygen (3.74 mmol). Upon warming to 20°C the yellow solution turned dark-red. After 16 h at 20°C, the volatiles were removed in vacuo and trimethylphosphane oxide sublimed from the residue at 30°C/0.1 mbar. Extraction with 60 ml of pentane and crystallization at −20°C afforded dark-red crystals. Yield 1620 mg (70% based on nickel), m.p. 169−171°C. − IR (Nujol): $\tilde{\nu}$ = 1591 cm^{-1} (C=C), 1016 (C−O), 942 [$\rho(PCH_3)$]. − $C_{34}H_{60}NiO_2P_2$ (621.5): calcd. C 65.71, H 9.73, P 9.97; found C 65.78, H 9.65, P 10.03.

Bis(2-tert-butyl-4-methoxyphenolato)bis(trimethylphosphane)nickel (**5**): 420 mg of $Ni(PMe_3)_4$ (1.16 mmol) and 417 mg of 2-*tert*-butyl-4-methoxyphenol (2.74 mmol) in 50 ml of THF at −70°C were combined with 30 ml of dioxygen (1.25 mmol). After warming the solution to 20°C and stirring for 16 h, the volatiles were removed in vacuo. Crystallization from 70 ml of pentane afforded 572 mg of dark-brown crystals (78% based on Ni), m.p. 133−135°C. − IR (Nujol): $\tilde{\nu}$ = 1603 cm^{-1} (C=C), 1018 (C−O), 948 [$\rho(PCH_3)$]. − $C_{28}H_{48}NiO_4P_2$ (569.3): calcd. C 59.07, H 8.50, P 10.88; found C 59.75, H 8.64, P 11.18.

Bis(2-tert-butyl-4-chlorophenolato)bis(trimethylphosphane)nickel (**6**): 770 mg of $Ni(PMe_3)_4$ (2.12 mmol) and 787 mg of 2-*tert*-butyl-4-chlorophenol (4.24 mmol) in 50 ml of THF at −70°C were combined with 50 ml of dioxygen (2.08 mmol). After warming up to 20°C, the volatiles were removed in vacuo and the resulting red-brown solid washed with ether (2 × 10 ml) and recrystallized from THF to afford 590 mg of brown-red crystals, m.p. 154−156°C. − IR (Nujol): $\tilde{\nu}$ = 1603 cm^{-1} (C=C), 1018 (C−O), 948 [$\rho(PCH_3)$]. − ^{1}H NMR ([D$_8$]THF): δ = 0.97 [s (br.), 18 H, $P(CH_3)_3$], 1.19 [s, 18 H, $C(CH_3)_3$], 6.79 [s (br.), 2 H, 3-H], 7.09 (s, 2 H, 5-H). − $C_{26}H_{42}Cl_2NiO_2P_2$ (580.2): calcd. C 53.83, H 7.30, P 10.68; found C 52.97, H 7.40, P 10.88.

Bis(2-isopropylphenolato)bis(trimethylphosphane)nickel(**7**): 620 mg of $Ni(PMe_3)_4$ (1.71 mmol) and 465 mg of 2-isopropylphenol (3.42 mmol) in 50 ml of THF at −70°C were combined with 50 ml of dioxygen (2.08 mmol). Stirring at −30°C for 1 h gave a dark red solution. Upon careful removal of volatiles in vacuo at −20°C (within 16 h) and extraction of the residue with 50 ml of pentane a large amount of red oil was obtained from which, after three months, dark-red crystals were deposited. These were isolated by washing with acetone in the cold, yielding 120 mg of red platelets (11% based on Ni), m.p. 109−112°C. − IR (Nujol): $\tilde{\nu}$ = 1591 cm^{-1} (C=C), 1036 (C−O), 948 [$\rho(PCH_3)$]. − ^{1}H NMR ([D$_8$]THF): δ = 0.97 [s, 18 H, $P(CH_3)_3$], 1.01 [d, J = 7 Hz, 12 H, $CH(CH_3)_2$], 3.08 [quint, J = 7 Hz, 2 H, $CH(CH_3)_2$], 6.34 (t, J = 7 Hz, 2 H, 3-H), 7.05 (m, 4 H, 2-H, 4-H), 8.71 [s (br.), 2 H, 6-H]. − ^{13}C NMR ([D$_8$]THF): δ = 9.79 [t′, N = 2 Hz, $P(CH_3)_3$], 21.49 [s, $CH(CH_3)_2$], 25.93 [$CH(CH_3)_2$], 113.57 (s, C-4), 122.99 (s, C-6), 124.82, 125.09 (s, C-3, C-5); 141.45 (s, C-2), 137.68 (s, C-2), 162.38 (s, C-1). − $C_{33}H_{52}NiO_2P_2$ (617.5): calcd. C 64.19, H 8.49; found C 64.70, H 8.60.

Bis(3-tert-butylphenolato)bis(trimethylphosphane)nickel (**8**): 880 mg of $Ni(PMe_3)_4$ (2.42 mmol) and 728 mg of 3-*tert*-butylphenol (4.85 mmol) in 70 ml of THF at −70°C were combined with 50 ml of dioxygen (2.08 mmol). Stirring at −30°C for 1 h gave a dark-red solution. Upon removal of volatiles in vacuo, and extraction of the residue with 50 ml of pentane at −30°C, 520 mg of $Ni(PMe_3)_4$ was recovered. A second extraction with 50 ml of pentane at 25°C gave 158 mg of red platelets (15% based on Ni), m.p. 112−117°C. − IR (Nujol): $\tilde{\nu}$ = 3430 cm^{-1} (OH), 1643 [δ(OH)], 1591 (C=C), 1036 (C−O), 948 [$\rho(PCH_3)$]. − $C_{46}H_{72}NiO_4P_2$ (809.7): calcd. C 68.23, H 8.89, P 7.65; found C 67.50, H 9.08, P 7.73.

Bis(2-tert-butyl-4-methyl-6-formylphenolato)bis(trimethylphosphane)nickel (**9**): 560 mg of $Ni(PMe_3)_4$ (1.54 mmol) and 580 mg of 3-*tert*-butyl-5-methylsalicylaldehyde (3.02 mmol) in 50 ml of THF

at −70°C were combined with 38 ml of dioxygen (1.58 mmol). Upon warming the solution slowly turned brown. After 24 h at 20°C, the volatiles were removed in vacuo and the residue extracted with 50 ml of pentane. Keeping the solution at 8°C for 70 h afforded yellow-brown crystals. Yield 656 mg (83% based on nickel), m.p. 153−156°C. IR (Nujol): $\tilde{\nu}$ = 1596 cm^{-1} (C=O), 1024 (C−O), 943 [ρ(PCH_3)]. – ^{1}H NMR ([D_8]toluene): extremely broad signals at δ = 1.1−84.7. – $C_{30}H_{48}NiO_4P_2$ (593.4): calcd. C 60.73, H 8.15, P 10.44; found C 60.76, H 7.97, P 10.41.

Crystal-Structure Analyses: Crystal data are presented in Table 4.

Data Collection. – *Complex* **2**: A dark-red specimen was sealed under argon in a glass capillary and mounted on a Philips PW 1100 diffractometer. Using graphite-monochromated Mo-K_α radiation lattice parameters were obtained from 25 centered reflections. Intensities were collected (ω scan) and Lp corrections were applied. The structure was solved (SHELX 86) using a full-matrix least-squares refinement (SHELX 93). All non-hydrogen atoms were treated anisotropically, hydrogen atoms were held in idealized fixed positions. – *Complex* **3**: A dark-red specimen was sealed under argon in a glass capillary and mounted on a Siemens R3m/V diffractometer. Using graphite-monochromated Mo-K_α-radiation lattice parameters were obtained from 25 centered reflections. Intensities were collected (ω scan) and Lp and empirical absorption corrections were applied (4 scans). The structure was solved (SHELXS 86) and refined (SHELXL 93). Non-hydrogen atoms were refined anisotropically, hydrogen atoms were fixed in idealized positions. – *Complex* **9**: An orange-brown crystal was sealed and mounted as given for **3**. Lattice parameters were obtained from 25 centered reflections. Intensities were collected and four standard reflections were recorded every 400 measured reflections showing only random intensity fluctuations. Lp corrections and empirical absorption correction were applied (ψ scans, min./max. transmission 0.824/0.868). The structure was solved by Patterson and Fourier methods. Full-matrix least-squares refinement was based on F. All non-hydrogen atoms were refined anisotropically, hydrogen atoms were held in calculated positions. Scattering factors and structure refinement: SHELXTL-Plus (G. M. Sheldrick, **1990**).

Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre. Copies of the data [CCDC-100867 (**2**), -100866(**3**), -100880 (**9**)] can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [Fax: (internat.) + 44(1223)336-033, E-mail: deposit@chemcrys.cam.ac.uk).

Received December 8, 1997

Keywords: Alkyne complexes / Carbonyl complexes / Cobalt / CO-Replacement

The reaction of dicarbonyl(η^5-cyclopentadienyl)cobalt (**1**) and some of the Cp-ring substituted congeners with bis(*tert*-butylsulfonyl)acetylene (BTSA) results in the replacement of one CO group by the BTSA moiety. The variation of the yields and reaction times indicates a dependence of the reactivity of **1**−**6** with BTSA as a function of substituents. X-ray investigations of the products show that the alkyne unit is strongly bound to the metal.

So far, substitution reactions at dicarbonyl(η^5-cyclopentadienyl)cobalt [$CpCo(CO)_2$] (**1**)[1][2][3] with alkynes could not be stopped at the monosubstitution stages, although such complexes have been postulated as intermediates.[4] In the reported cases follow-up reactions led to cyclobutadiene complexes, cyclopentadienone complexes or benzene derivatives.[5][6][7][8][9][10][11] In order to contribute to the clarification of the mechanism of dimerization or trimerization of alkynes we investigated the reaction of $CpCo(CO)_2$ with alkynes having electron-acceptor groups. Acceptor groups were chosen because we thought that replacement of only one CO group could best be accomplished by a triple bond with stronger acceptor properties than diphenyl acetylene. Therefore bis(*tert*-butylsulfonyl)acetylene (BTSA) was our first choice because this compound has been found to be a powerful dienophile.[12][13] This led us to investigate the ligand properties of BTSA. In this paper we report experiments with **1**[3] and the substituted congeners dicarbonyl(η^5-methylcyclopentadienyl)- (**2**)[14], dicarbonyl(η^5-trimethylsilylcyclopentadienyl)- (**3**)[15][16], dicarbonyl(η^5-methoxycarbonylcyclopentadienyl)- (**4**)[17], dicarbonyl-(η^5−1-ethyl-2,3,4,5-tetramethylcyclopentadienyl)- (**5**)[18][19], and dicarbonyl(η^5-pentaallylcyclopentadienyl)cobalt (**6**)[20].

Results and Discussion

The reaction of BTSA with **1**−**6** was accomplished by stirring solutions of **1**−**6** and BTSA in methylene chloride at room temperature. After 2−11 days the reaction was complete and the corresponding products could be isolated (Scheme 1). The monoalkyne complexes **7**−**12**, respectively, were obtained in yields between 36% and 85%. In addition to yields we list in Table 1 the reaction time which was required for complete conversion of starting materials. The data show that **4** having an electron withdrawing substituent on the Cp ring results in reduced yield (**10**, 39%) and increased reaction time (11 d) as compared to **1**. The lower yield encountered in the case of **12** we ascribe to steric effects. However, we can not exclude that the mechanism of the substitution might be different as compared to the other examples, because the five vinyl groups might act as ligands with formation of intermediate chelate complexes, which finally react to the observed, less strained product **12**.

Scheme 1

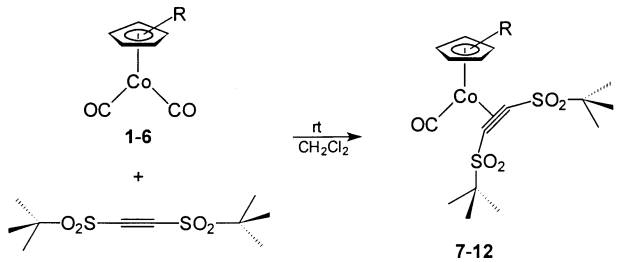

Table 1. reaction times, yields, and selected spectroscopical features of **7**−**12**

Compound	**7**	**8**	**9**	**10**	**11**	**12**

All resulting compounds (**7**−**12**) were characterized by their spectroscopic and analytical data. With the exception of **10** we were also able to grow single crystals allowing a more detailed study of the molecular parameters by using the X-ray technique. The molecular structures of **7** and **12** are shown in Figure 1.

Figure 1. Top: Molecular structure of one of both independent molecules of **7** in the unit cell. Bottom: Molecular structure of **12**. Ellipsoids are at the 50% probability level.

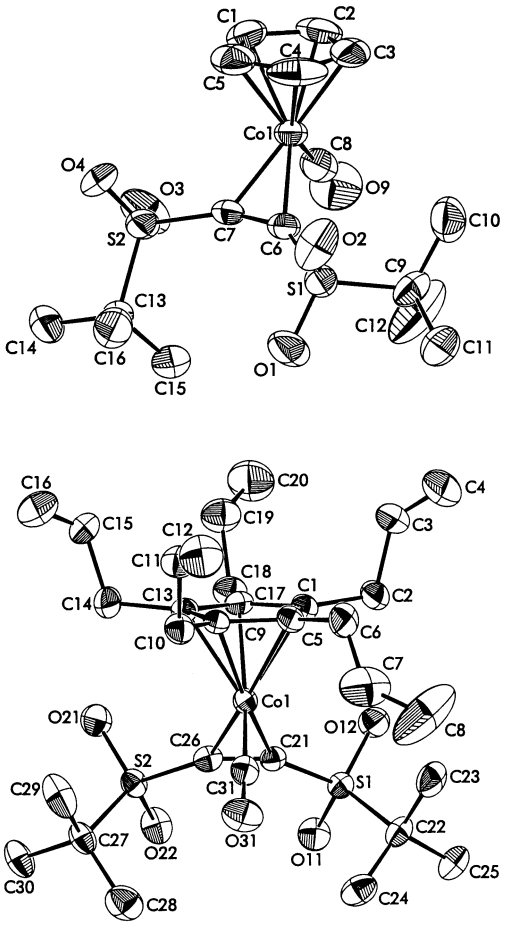

Table 2. Selected structural parameters of **7**−**9**, **11**, and **12**. The distances (*d*) are given in pm, the angles in degrees

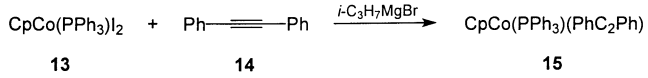
Compound	**7**		**8**	**9**	**11**	**12**
d(C≡C)	126.4(5)	126.8(5)	127.0(3)	126.7(3)	126.9(3)	126.1(5)
d(≡C−Co)	194.2(3)	196.9(3)	194.7(3)	194.5(2)	195.2(2)	196.3(4)
	194.6(4)	196.8(3)	194.9(3)	195.9(2)	196.8(2)	196.4(4)
angle at C≡C−S	142.8(3)	142.2(3)	146.4(2)	145.0(2)	143.3(2)	140.9(3)
	158.5(3)	158.1(3)	158.9(2)	159.1(2)	155.9(2)	140.7(3)
torsion angle at S−C≡C−S	16(1)	13(1)	18(1)	15.6(1)	12.3(6)	3.0(1)
d(Co−CO)	176.1(4)	175.8(4)	177.0(3)	176.2(3)	175.3(2)	177.8(5)
d(C≡O)	113.5(5)	113.7(5)	113.1(4)	112.9(4)	113.9(2)	113.0(5)
d(Co−center of Cp)	170.2(2)	170.0(2)	169.6(2)	169.8(2)	170.2(1)	170.8(2)

The most relevant distances and angles of **7**−**9**, **11**, and **12** are listed in Table 2. A pronounced lengthening of the C−C bond of the alkyne unit was observed, from 119.1 pm in the uncomplexed state to 126.1−127.0 pm in the complexes. The deviation from linearity of up to 40° is considerable. These results are supported by vibrational spectra which show that the wave number for the uncomplexed BTSA unit (2160 cm^{-1} from Raman spectrum) is shifted to lower values (1734−1779 cm^{-1}).

Analogous results were reported by Yamazaki et al. for a related complex obtained by treating the diiodide of bis(triphenylphosphane)(η^5-cyclopentadienyl)cobalt (**13**) with tolane and isopropylmagnesium bromide.[21] The monosubstituted product **15** shows a C-C triple-bond stretching frequency of 1818 cm^{-1} which is considerably higher than that found in our examples.

Scheme 2



The complexes **7**−**12** are interesting intermediates on our endeavors to isolate a CpCo complex with two alkyne units and CpCo-capped push-pull cyclobutadiene complexes.

Experimental Section

General Methods. Moisture- and oxygen-sensitive reactions were conducted in oven-dried glassware under argon. Solvents were dried and distilled under argon before use; THF, diethylether, *n*-pentane, and *n*-hexane from sodium, dichloromethane from CaH_2. − Melting points are uncorrected. − Materials used for column chromatography: Silica gel 60 (Macherey-Nagel), alumina (Merck). − ^{1}H-NMR and ^{13}C-NMR: Bruker AS 200 (^{1}H at 200 MHz and ^{13}C at 50.33 MHz), Bruker WH 300 (^{1}H at 300 MHz, ^{13}C at 75.47 MHz) using the solvent as internal standard. − IR: Bruker Vector 22 FT-IR. − UV: Hewlett Packard HP8452A. − MS: Low resolution: ZAB-2F; high resolution: JEOL JMS-700. − Elemental analyses were carried out by the Mikroanalytisches Laboratorium der Universität Heidelberg. − The dicarbonyl(η^5-cyclopentadienyl)cobalt complexes **1**[3], **2**[14], **3**[15][16], **4**[17], and **5**[18][19] were prepared according to literature methods.

Dicarbonyl(η^5-pentaallylcyclopentadienyl)cobalt (**6**). Iodine (2.60 g, 10.2 mmol) was added at r.t. in portions to a stirred solution of 3.50 g (10.2 mmol) of dicobaltoctacarbonyl in 250 ml of anhydrous THF. The solution turned to a dark green color with vigorous foaming. After stirring for 1 h at room temperature, the solution was cooled to −40 °C and 6.17 g (20.3 mmol) of potassium pentaallylcyclopentadienide[20] was added. The reaction mixture was allowed to warm to room temperature overnight. After additional stirring for 1 d at room temperature the solvent was removed in vacuo, the residue dissolved in dichloromethane and chromatographed (alumina, 6% water, 30 × 3 cm). Elution with *n*-hexane yielded 2.51 g (33%) of **6** as a dark red, air-sensitive oil. − ^{1}H NMR (200 MHz, $CDCl_3$): δ = 2.92−2.96 (m, 10 H, CH_2), 4.81−5.00 (m, 10 H, =CH_2), 5.61−5.81 (m, 5 H, =CH). − ^{13}C NMR (50.32 MHz, $CDCl_3$): δ = 29.10 (CH_2), 99.62 (Cp-C), 115.40 (=CH), 137.21 (=CH_2), 183.85 (C≡O). − IR (film): $\tilde{\nu}$ = 3078 cm^{-1}, 3007, 2978, 2915, 2843, 2010, 1944, 1637, 1440, 1414, 1286, 993, 911,

617, 556. − UV/Vis (CH_2Cl_2): λ_{max} (lg ε) = 222 nm (5.00). − MS (EI, 70 eV): *m/z* = 352 [M^+ − CO], 324 [M^+ − 2CO].

General Procedure for the Preparation of the Carbonyl(η⁵-cyclopentadienyl)(η²-bis[tert-butylsulfonyl]acetylene)cobalt(I) Complexes. The dicarbonyl(η⁵-cyclopentadienyl)cobalt complex was added at ambient temperature to a solution of bis(*tert*-butylsulfonyl)acetylene (BTSA) in 50 ml of dichloromethane. After stirring for 2−11 d at r.t. the solvent was removed in vacuo and the product was isolated by silica gel chromatography (silica gel, *n*-pentane/diethyl ether).

Carbonyl(η⁵-cyclopentadienyl)(η²-bis[tert-butylsulfonyl]acetylene)cobalt(I) (**7**); Starting material: 300 mg (1.67 mmol) of dicarbonyl(η⁵-cyclopentadienyl)cobalt (**1**), 890 mg (3.34 mmol) of BTSA. Reaction time: 3 d. Silica gel chromatography (*n*-pentane/diethyl ether, 1:2). Yield: 508 mg (73%) of **7** as an orange solid, m.p. 110°C (decomposition). − ^{1}H NMR (300 MHz, $CDCl_3$): δ = 1.52 (s, 18 H, CH_3), 5.29 (s, 5 H, Cp-H). − ^{13}C NMR (75.47 MHz, $CDCl_3$): δ = 23.38 [C(*C*H_3)$_3$], 61.52 [*C*(CH_3)$_3$], 86.93 (Cp-C), 93.72 (≡C). − IR (KBr): $\tilde{\nu}$ = 3119 cm^{-1}, 2979, 2936, 2866, 2017, 1772, 1476, 1395, 1295, 1116. − UV/Vis (CH_2Cl_2): λ_{max} (lg ε) = 256 nm (4.14). − MS (EI, 70 eV): *m/z* = 390 [M^+ − CO], 270, 245, 214, 141, 124. − HRMS (FAB+): [M + H^+] $C_{16}H_{24}CoO_5S_2$: calcd. 419.0319; found 419.0332. − $C_{16}H_{23}CoO_5S_2$ (418.425): calcd. C 45.93, H 5.54; found C 45.79, H 5.61.

Carbonyl(η⁵-methylcyclopentadienyl)(η²-bis[tert-butylsulfonyl]acetylene)cobalt(I) (**8**); Starting material: 330 mg (1.70 mmol) of dicarbonyl(η⁵-methylcyclopentadienyl)cobalt (**2**), 906 mg (3.40 mmol) of BTSA. Reaction time: 2 d. Silica gel chromatography (*n*-pentane/diethyl ether, 3:1). Yield: 624 mg (85%) of **8** as an orange solid, m.p. 91°C (decomposition). − ^{1}H NMR (300 MHz, $CDCl_3$): δ = 1.44 (s, 3 H, Cp-CH_3), 1.53 (s, 18 H, C(CH_3)$_3$), 5.13/5.52 (pt, 4 H, Cp-H). − ^{13}C NMR (75.47 MHz, $CDCl_3$): δ = 11.55 (Cp-CH_3), 23.55 [C(*C*H_3)$_3$], 61.54 [*C*(CH_3)$_3$], 83.24/90.22 (Cp-C), 97.70 [Cp(*C*)-CH_3], 104.55 (≡C). − IR (KBr): $\tilde{\nu}$ = 3119 cm^{-1}, 2978, 2932, 2867, 2023, 1778, 1475, 1365, 1297, 1117. − UV/Vis (CH_2Cl_2): λ_{max} (lg ε) = 258 nm (4.32). − MS (FAB+): *m/z* = 433 [M + H^+], 405. − HRMS (FAB+): [M + H^+] $C_{17}H_{26}CoO_5S_2$: calcd. 433.0554; found 433.0554. − $C_{17}H_{25}CoO_5S_2$ (432.452): calcd. C 47.22, H 5.83; found C 47.03, H 5.86.

Carbonyl(η⁵-trimethylsilylcyclopentadienyl)(η²-bis[tert-butylsulfonyl]acetylene)cobalt(I) (**9**): Starting material: 420 mg (1.67 mmol) of dicarbonyl(η⁵-trimethylsilylcyclopentadienyl)cobalt (**3**), 890 mg (3.34 mmol) of BTSA. Reaction time: 6 d. Silica gel chromatography (*n*-pentane/diethyl ether, 1:1). Yield: 639 mg (78%) of **9** as a yellow solid, m.p. 116°C (decomposition). − ^{1}H NMR (300 MHz, $CDCl_3$): δ = 0.34 [s, 9 H, Si(CH_3)$_3$], 1.49 [s, 18 H, C(CH_3)$_3$], 5.20/5.35 (b, 4 H, Cp-H). − ^{13}C NMR (75.47 MHz, $CDCl_3$): δ = −0.62 [Si(CH_3)$_3$], 23.43 [C(*C*H_3)$_3$], 61.58 [*C*(CH_3)$_3$], 91.60 (≡C), 91.94/92.05 (Cp-C), 94.35 [Cp(*C*)-Si]. − IR (KBr): $\tilde{\nu}$ = 3092 cm^{-1}, 2980, 2956, 2867, 2022, 1779, 1459, 1393, 1295, 1115. − UV/Vis (CH_2Cl_2): λ_{max} (lg ε) = 258 nm (4.14). − MS (FAB+): *m/z* = 491 [M + H^+], 463, 389. − HRMS (FAB+): [M^+] $C_{19}H_{31}CoO_5S_2Si$: calcd. 490.0714; found 490.0779. − $C_{19}H_{31}CoO_5S_2Si$ (490.608): calcd. C 46.52, H 6.37; found C 46.55, H 6.46.

Carbonyl(η⁵-methoxycarbonylcyclopentadienyl)(η²-bis[tert-butylsulfonyl]acetylene)cobalt(I) (**10**): Starting material: 357 mg (1.50 mmol) of dicarbonyl(η⁵-methoxycarbonylcyclopentadienyl)-cobalt (**4**), 800 mg (3.00 mmol) of BTSA. Reaction time: 11 d. Silica gel chromatography (*n*-pentane/diethyl ether, 1:1). Yield: 280 mg (39%) of **10** as an orange solid, m.p. 114°C (decomposition).

Carbonyl(η^5-pentaallylcyclopentadienyl)(η^2-bis[tert-butylsulfonyl]acetylene)cobalt(I) (**12**): Starting material: 304 mg (0.80 mmol) of dicarbonyl(η^5-pentaallylcyclopentadienyl)cobalt (**6**), 426 mg (1.60 mmol) of BTSA. Reaction time: 3 d. Silica gel chromatography (*n*-pentane/diethyl ether, 5:1). Yield: 180 mg (36%) of **12** as a yellow solid, m.p. 106°C (decomposition). – ^{1}H-NMR (300 MHz, $CDCl_3$): δ = 1.50 (s, 18 H, CH_3), 3.11–3.16 (td, 10 H, CH_2, ^3J = 6.2 Hz, ^4J = 1.6 Hz), 4.92–5.02 (dd, 5 H, CH=CH_{cis}H, $^3J_{trans}$ = 17.0 Hz, $^2J_{gem}$ = 1.4 Hz), 4.98–5.04 (dd, 5 H, CH=CH_{trans}H, $^3J_{cis}$ = 10.2 Hz, $^2J_{gem}$ = 1.4 Hz), 5.71–5.86 (tdd, 5 H, C*H*=CH_2, $^3J_{trans}$ = 17.0 Hz, $^3J_{cis}$ = 10.2 Hz, ^3J = 6.2 Hz). – ^{13}C NMR (75.47 MHz, $CDCl_3$): δ = 23.52 [$C(CH_3)_3$], 28.94 (CH_2), 61.91 [$C(CH_3)_3$], 101.50 (Cp-C), 103.21 (≡C), 116.81 (=CH_2), 135.14 (-CH=). – IR (KBr): $\tilde{\nu}$ = 3079 cm^{-1}, 2979, 2937, 2870, 2002, 1734, 1637, 1453, 1415, 1365, 1301, 1118, 993, 914, 636. – UV/Vis (CH_2Cl_2): λ_{max} (lg ε) = 294 nm (4.47). – MS (FAB+): *m*/*z* = 619 [M + H^+], 591. – HRMS (FAB+): [M + H^+] $C_{31}H_{44}CoO_5S_2$: calcd. 619.1962; found 619.2037. – $C_{31}H_{43}CoO_5S_2$ (618.748): calcd. C 60.18, H 7.00; found C 60.22, H 7.07.

X-ray Diffraction Analyses: The reflections were collected with a Nonius-CAD4 diffractometer (**11**), a Siemens Nicolet-Syntex-R3 diffractometer (**7**, **8**, **9**) and a Siemens CCD diffractometer (**12**). Intensities were corrected for Lorentz and polarisation effects. The structures were solved by direct methods (**7**, **8**, **9**, **12**: SHELXS-86[22]; **11**: SIR-92[23]). The structural parameters of the nonhydrogen atoms were refined anisotropically according to a full-matrix-least-squares technique (F^2). The hydrogen atoms were refined with fixed thermal parameters or calculated parameters. Refinement was carried out with SHELXL-93[24]. Table 3 contains the crystallographic data and details of the refinement procedure. Crystallographic data (excluding structure factors) have been deposited with the Cambridge Crystallograhic Data center as supplementary publication no CCDC–100891. Copies of data can be obtained free of charge on application to CCDC, 12, Union Road, Cambridge CB12 IEZ, UK [fax: int. code +44 (0)1223/336/033, email: deposit@ccdc.ac.uk].

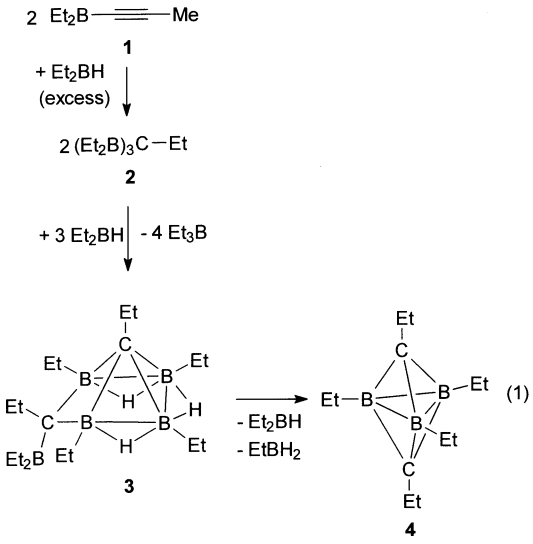
Keywords: Ab initio calculations / Boron / Carboranes / NMR spectroscopy

Hydroboration of diethyl(1-propynyl)borane **1** with tetraethyldiborane(6) in the presence of a catalytic amount of trimethyl- or tributyltin chloride gave two new organo-substituted carboranes **6** and **7** with 2,3,5-tricarba-*nido*-hexaborane(7) and 2,3,4-tricarba-*nido*-hexaborane(7) skeletons, respectively, along with polymeric material and the known organo-substituted 1-carba-*arachno*-pentaborane(10) (**3**) and pentaethyl-1,5-dicarba-*closo*-pentaborane(5) (**4**). Selective $^{11}B(5,6)$ decoupled ^{13}C-NMR spectra indicate an unprecedented B(5)−ethyl−B(6) bridge in **7**. This structure is supported by the agreement between experimental and calculated ^{11}B- and ^{13}C-chemical shifts on a model compound **7d** with methyl groups in the 1,2,3,5,6-positions and an ethyl group bridging B(5) and B(6).

Introduction

Treatment of tetraborane(10) with alkynes gave the first 2,3,4-tricarba-*nido*-hexaboranes(7) with a B(5)−H−B(6) bridge;[1] these early observations have, at least in part, been confirmed recently,[2] and the formation of the parent compound has been reported for the first time.[2b] Köster et al. have tentatively assigned (on the basis of mass spectra) the structure of 1,5,6-triethyl-2,3,4-trimethyl-2,3,4-tricarba-*nido*-hexaborane(7) to one of the minor products in the complex mixture which is obtained by dehalogenation of diethylboron chloride with lithium in THF.[3] An alternative route to small carboranes involves hydroboration of 1-alkynyl(diethyl)boranes in the presence of a large excess of Et_2BH,[5] which gives rise to hydroboration followed by Et_2BH-catalyzed condensations.[5][6][7] This method has afforded [Eq. (1)] the *arachno*-carborane **3**,[7] which is a precursor of the *closo*-carborane **4**. The formation of **3** in high yield requires that the hydroboration of **1** takes place stereoselectively to give **2** as a reactive intermediate prior to the condensation reactions. If this is not the case, products other than **3** will be formed, as reported in this work.

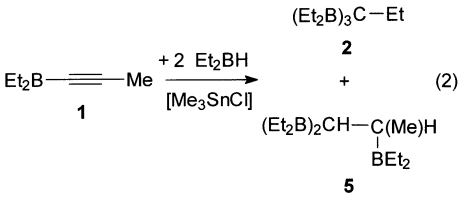


Results and Discussion

Synthesis. Conditions that reduce the stereoselectivity of the hydroboration of **1** will lead to mixtures containing compounds **2** and **5** [Eq. (2)]; hence, condensation reactions may give carboranes other than **3**. Therefore, we have studied the reaction of **1** with Et_2BH under various conditions. As long as a large excess of Et_2BH is used, **3** is the major product, although more side-products are formed if **1** is added to Et_2BH at room temperature or above, rather than at −78°C. The use of only a slight excess of Et_2BH (2.1 equivalents) results in mainly polymeric material containing just traces (< 1%, according to ^{11}B-NMR spectra) of carboranes, but the presence of a small amount of trimethyl- or tributyltin chloride leads to the formation of interesting products. Examination of the ^{11}B-NMR spectra of such reaction mixtures, after removing readily volatile material, shows not only the presence of polymers (ca. 60%), but also new types of carboranes **6** (ca. 15%) and **7** (ca. 10%) along with the known carboranes **3** (ca. 10%) and **4** (ca. 5%). Unlike **7**, pure carborane **6** could not be isolated. However, **6** was readily identified by its characteristic[8] ^{11}B-NMR data

 © WILEY-VCH Verlag GmbH, D-69451 Weinheim, 1998 1434−1948/98/0505−0633 $ 17.50+.50/0

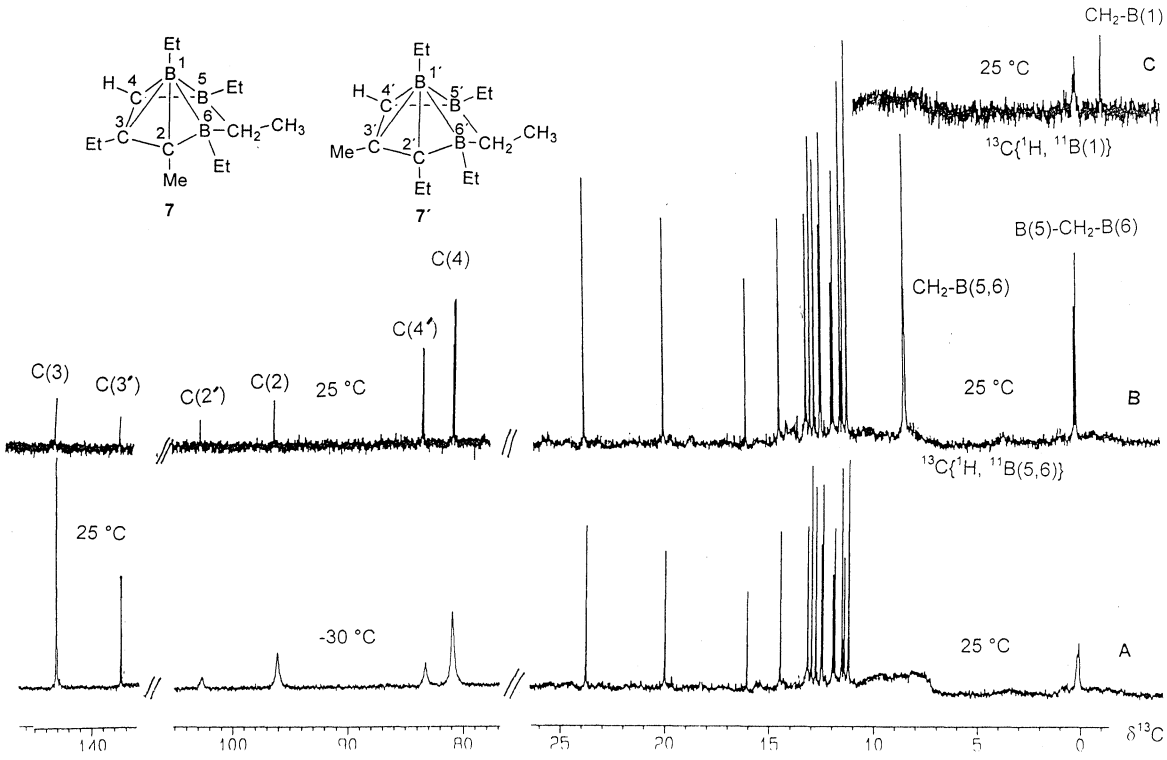
[$\delta^{11}B(1) = -36.4$ and $\delta^{11}B(4,6) = 21.9$] as a 2,3,5-tricarba-*nido*-hexaborane(7) derivative. **6** is not stable to oxidation or hydrolysis but **7** is, meaning the latter can be separated and isolated. The compounds **7** do not react with Na[Et_3BH] after prolonged heating at 60°C in hexane, with Et_3Al in hexane at room temperature, or with bases such as pyridine.



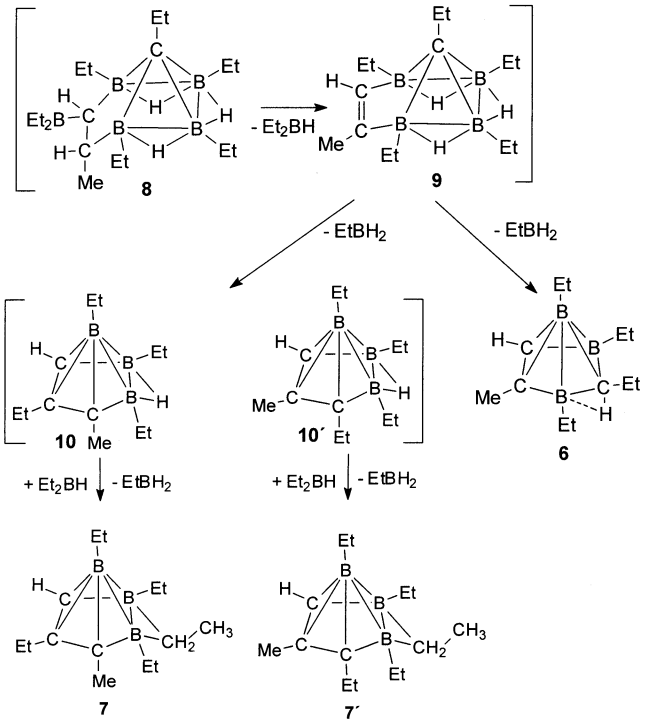
Potential intermediates prior to the formation of the carboranes **6** and **7** are shown in Scheme 1. It is suggested that the C_2-bridged compound **8** is formed in a similar way to **3**.[7] The C_2-bridged *arachno*-carborane **9** is comparable with a benzo derivative that has already been characterized.[9] The intermediacy of **9** (prior to elimination of $EtBH_2$[10][11] and rearrangement) has been proposed in order to explain the formation of 2,3,5-tricarba-*nido*-hexaborane(7) derivatives analogous to **6**.[8b] Although other rearrangements of **9** have not been observed before,[8b] it is conceivable that insertion of the formerly apical CEt group takes place not only into B−H−B bonds but also into B−C or C−C bonds, accompanied or followed by elimination of $EtBH_2$. This explains the formation of **10** and **10′** which, under the reaction conditions, can undergo irreversible H/Et exchange to give the isomers **7** and **7′** (in repeated experiments the ratio of **7**/**7′** varied from 3:1 to 2:3). The B(5)−Et−B(6) bridge in **7** is an unprecedented structural feature in borane and carborane chemistry. Bridging triorganosilyl, -germyl, and -stannyl groups have been observed previously, e.g. in the case of *nido*-pentaborane(9) derivatives.[12]

NMR Spectroscopic Results: The ^1H-, ^{11}B- and ^{13}C-NMR data of **7** (Table 1 and Experimental Section) are fully consistent with a 2,3,4-tricarba-*nido*-hexaborane(7) cage bearing terminal ethyl groups at all boron atoms, a hydrogen at C(4) and a methyl or a ethyl group at C(2) or C(3). There was no indication of the initially expected B−H−B group, either in the ^1H-NMR spectra (with or without ^{11}B decoupling) or in the ^{11}B-NMR spectra (with and without ^1H decoupling); this evidence definitely precludes the structures **10** and **10′**. However, there were additional signals due to an ethyl group for each isomer in the ^1H- and ^{13}C-NMR spectra. ^{13}C-NMR spectra of a mixture of **7** and **7′**, recorded under various conditions, are shown in Figure 1. The aliphatic region displays fourteen sharp ^{13}C resonances (two CH_2 and twelve CH_3 groups with carbon atoms not linked to boron), and in the region for the cage carbon atoms two sharp signals [$^{13}C(3,3')$] and four

Figure 1. 125.8-MHz ^{13}C-NMR spectra of a mixture of **7** and **7′** (ca. 10 mg in 0.5 ml of $CDCl_3$). **A**: Normal $^{13}C\{^1H\}$-NMR spectrum; the region of the boron bonded cage carbon atoms has been taken from a spectrum recorded at −30°C in order to show the broadened ^{13}C-NMR signals which are exceedingly broad in the spectrum at 25°C. **B**: The selective heteronuclear $^{13}C\{^{1\,H,\ 11}B(5,6)\}$ triple-resonance experiment shows sharpening of the B(5)−$^{13}CH_2$−B(6), $^{13}CH_2$−B(5,6), and $^{13}C(2, 2', 4, 4')$ signals. **C**: The selective heteronuclear $^{13}C\{^1H,^{11}B(1)\}$ triple-resonance experiment only gives rise to sharpening of the $^{13}CH_2$−B(1) signal.



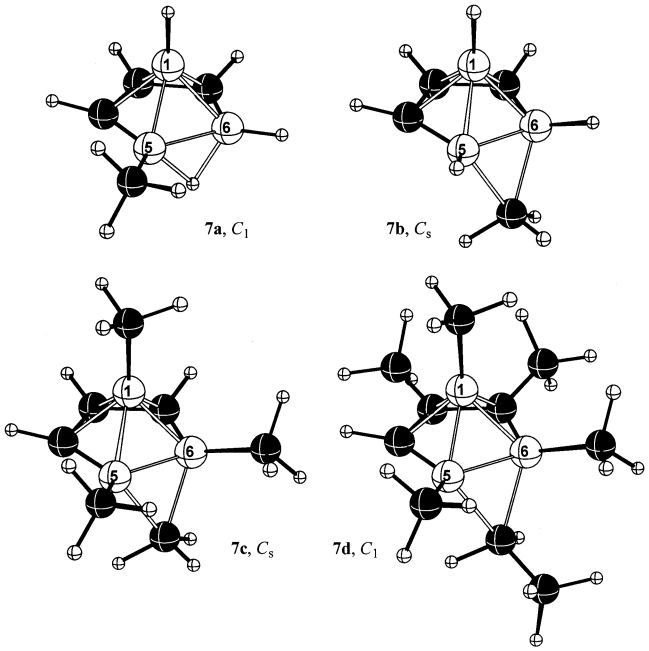
Scheme 1



broad signals [^{13}C(2,2′) and 13C(4,4′)] are observed, as required for the two isomers **7** and **7′**. The unique μ-^{13}C(CH_2) signals (Figure 1, A and C) are significantly broadened [although less than the ^{13}C(CH_2) resonance of terminal BEt groups] as a result of scalar relaxation of the second kind[13][14] (partially relaxed scalar ^{13}C-^{11}B spin-spin coupling). This was proved by selective ^{11}B(5,6) decoupling (Figure 1, B) which, as expected, causes sharpening of the ^{13}C(2, 2′, 4, 4′) and ^{13}C(CH_2) signals of the terminal B(5,6)Et groups, and also the μ-^{13}C(CH_2) signal of the ethyl group in the B(5)−Et−B(6) bridge. Decoupling of B(1) (Figure 1, C) has no appreciable effect on the appearance of the ^{13}C-NMR spectrum except for sharpening of the ^{13}C(CH_2) resonance of the apical BEt group. The greater broadening of the terminal ^{13}C(CH_2) signal of the BEt groups with respect to that of the bridging B−Et−B [i.e. $^1J(^{13}C_{terminal},^{11}B) > {}^1J(^{13}C_{bridging},^{11}B)$] is reminiscent of the $^1J(^{11}B,^1H)$ in diborane(6) where the magnitude of the coupling constant of the terminal ^{1}H nucleus is approximately three times greater than that of the bridging ^{1}H nucleus.

MO Calculations: We applied the ab initio/GIAO/NMR method,[15][16] a powerful computational tool for the determination of polyhedral borane and carborane structures, to establish, in the absence of X-ray determinations the structural assignment for **7**.[17] The chemical shifts, computed for various optimized models, are compared with experimental NMR data. The methyl-bridged μ-Me-2,3,4-$C_3B_3H_6$ model compound **7b** not only allows the investigation of the chemical shifts of a bridging alkyl group (the new feature in **7** and **7′**, which is represented in **7b**) but also a thermodynamic stability assessment in comparison with the hydrogen bridge isomer (5-Me-2,3,4-$C_3B_3H_6$, **7a**, Figure 2). The 18.3 kcal mol^{-1} lower energy of **7a** than **7b** quantifies the extend to which methyl bridging is normally unfavourable. However, the methyl bridge has no large effect on the chemical shifts (compare **7b** to **7a**): The differences are ca. −10 ppm for C(2,4), +8 ppm for C(3), and ca. −5 ppm for B(6) (Table 1).[18] In particular, the apical B(1) has almost the same d^{11}B value of δ = −52 in **7a** and **7b**.

Figure 2 Geometries (bond lengths in pm) of model compounds **7a**−**d**, optimized at MP2(fc)/6-31G*[a]



[a] **7a**: B1−C2 172.0, B1−C3 173.0, B1−C4 172.1, B1−B5 176.8, B1−B6 175.4, C2−C3 142.7, C3−C4 142.9, C2−B6 153.6, C4−B5 153.8, B5−B6 177.6, B5−μH 133.3, B6−μH 130.9. − **7b**: B1−C2 170.6, B1−C3 173.1, B1−B5 176.4, C2−C3 142.9, C2−B6 154.5, B5−B6 176.3, B5−μCH_3 179.5. − **7c**: B1−C2 171.2, B1−C3 173.7, B1−B5 176.9, C2−C3 142.9, C2−B6 154.9, B5−B6 177.4, B5−μCH_3 1.802. − **7d**: B1−C2 170.5, B1−C3 174.9, B1−C4 169.7, B1−B5 177.0, B1−B6 176.1, C2−C3 143.2, C3−C4 143.7, C2−B6 156.2, C4−B5 154.6, B5−B6 176.2, B5−μCH_2 185.1, B6−μCH_2 180.4.

Because of the large size of **7** and **7′** and the many possible orientations of the ethyl groups, model compounds were computed instead. The addition of methyl substituents to **7b** at B(1) and B(5,6) to give **7c** results in the expected d^{11}B increase of ca. 10 ppm but has no significant influece on the geometry (compare **7b** and **7c**, Figure 2). While the chemical shifts computed for **7c** correspond reasonably well with the measured values for **7** and **7′**, our best model, a 1,2,3,5,6-pentamethyl tricarbahexaborane(7) with a bridging ethyl group, gives better agreement with almost all the data in Table 1. The differences between **7c** and **7d** can be ascribed to electronic effects of the additional alkyl substituents to the cage in **7d**.[19] The constitution of **7** and **7′** with their unique B−alkyl−B bridge is supported by the above computations.

The B−μ-C and B(5)−B(6) distances computed for **7b**−**d** (Figure 2) show that the bridging alkyls are involved in deltahedral (three-centre) bonding. Corner protonated

cyclopropane (a CH_3^+ π complex of ethylene) provides an anology in carbon chemistry.[20]

Support of this work by the *Deutsche Forschungsgemeinschaft* and the *Fonds der Chemischen Industrie* is gratefully acknowledged.

Experimental Section

All synthetic work (except for the purification of **7** and **7′**) and handling of samples was carried out in an atmosphere of N_2 or Ar, observing all necessary precautions to exclude traces of oxygen or moisture. The starting materials were commercial samples (Me_3SnCl or nBu_3SnCl) or were prepared as described [Et_2BH[4], $Et_2B-C{\equiv}CMe$[6b]]. – NMR spectra: Bruker ARX 250 and DRX 500 spectrometers; the latter was equipped with a triple resonance probe head for the $^{13}C\{^{1\,H,\,11}B\}$ experiments; chemical shifts are reported with respect to Me_4Si [δ^1H ($CHCl_3/CDCl_3$) = 7.24; δ^1H ($C_6C_5CD_2H$) = 2.03; $\delta^{13}C$ ($CDCl_3$) = 77.0; $\delta^{13}C$ ($C_6D_5CD_3$) = 20.4] and Et_2O-BF_3 [$\delta^{11}B$ = 0 for $\Xi(^{11}B)$ = 32.083971 MHz]. – Electron impact (EI) mass spectra (70 eV): VARIAN MAT CH 7 with direct inlet.

5,6-μ-Ethyl-1,3,5,6-tetraethyl-2-methyl-2,3,4-tricarba-nido-hexaborane(7) (**7**) *and 5,6-μ-Ethyl-1,2,5,6-tetraethyl-3-methyl-2,3,4-tricarba-nido-hexaborane(7)* (**7′**): Et_2BH (1.326 g, 16.7 mmol hydride) was added at −78°C to diethyl(1-propynyl)borane **1** (1.799 g, 16.7 mmol) containing trimethyltin chloride (0.2 g) within 10 min. The reaction mixture was allowed to warm to room temperature and heated to 50°C. A further quantity of Et_2BH (1.344 g, 16.8 mmol hydride) diluted with BEt_3 (20 ml) was added over a period of 90 min, and the mixture was stirred at 50°C for a further 4 h. All volatile material was removed in vacuo, and fractional distillation of the residue gave a mixture (0.326 g; b.p. 70−80°C/10^{-3} Torr) of the carboranes **6** (55%), **7** and **7′** (35%) together with small amounts of unidentified products. The distillate was diluted with hexane (10 ml) and stirred in the presence of air for 10 h. The resulting solution was filtered, the solvent was removed in vacuo, and the residue was redistilled. The distillate [0.134 g (7%) of a colorless liquid; b.p. 74−77°C / 10^{-3} Torr] contained the carboranes **7** and **7′** in a ratio varying from 3:1 to 2:3 in repeated experiments, always in approximately the same yield.

7: ^1H NMR (500.1 MHz, 25°C, $CDCl_3$): δ = 4.03 [s, 1 H, C(4)H], 2.21 (m, 1 H), 2.01 (m, 1 H), 1.02 [t, 3 H, C(3)Et], 1.66 [s, 3 H, C(2)Me], 1.48 (m, 2 H), 0.18 (t, 3 H, μ-Et), 0.23 (m, 2 H), 0.68 [t, 3 H, B(1)Et], 0.88 (m, 2 H), 0.85 (m, 2 H), 1.18 (t, 3 H), 1.13 [t, 3 H, B(5,6)Et]. – ^{11}B NMR (160.6 MHz, 25°C, $CDCl_3$): δ = −34.4 [B(1)], 3.0, 5.4 [B(5,6)]. – ^{13}C NMR (125.8 MHz, 25°C, [D_8]toluene): δ = 143.3 [C(3)], 96.0 [broad, C(2)], 80.9 [broad, $^1J(^{13}C^1H)$ = 163.0 Hz, C(4)], 11.4 [C(3)*Me*], 24.0, 12.2 [C(2)*Et*], −0.3 (broad), 13.0 (μ-Et), −1.0 (broad), 11.8 [B(1)Et], 8.8 (broad), 8.7 (broad), 13.4, 11.7 [B(5,6)Et]. – EI-MS (70 eV): *m/z* (%) = 230 (5) [M^+], 201 (50) [M^+ − Et].

Keywords: Manuscripts / Scriptoria / TXRF / Micro-Ramanspectroscopy / Pigments / Middle Ages / Azurite / Gold initials / Workshops / Renaissance / Mercatellis / Codicology

Assigning related medieval manuscripts to different workshops on the basis of codicological characteristics, is not straightforward. We present the first attempt to distinguish between scriptoria by means of a large-scale total reflection X-ray fluorescence (TXRF) analysis of pigment elements and an identification of pigment molecules with micro-Raman spectroscopy. We analyzed 324 colored items in 10 medieval manuscripts, of which 7 are folio-sized illuminated manuscripts, all ordered by Raphael de Mercatellis in the late 15th and early 16th century. Palettes in miniatures were not yet examined. Blue palettes are exclusively azurite-based and are easily differentiated by means of the respective amounts of Ti, Ba, and As. Differences for green palettes are also pronounced. The green Cu-based pigment was not yet identified, but it certainly is not malachite or verdigris. Red pigments used are HgS, vermilion, and Pb_3O_4, red lead. The Flemish gold-leaf technique is used. The 7 Mercatellis manuscripts show two different palettes, both different from the non-Mercatellis manuscripts. The grouping of the Mercatellis manuscripts according to date and to palettes is, in general, consistent with a grouping on the basis of a classical codicological analysis, although some conflicting results are obtained. A quantitative and qualitative reconstruction of palettes by means of TXRF- and Raman-spectra, provides with a complimentary and objective tool for distinguishing between scriptoria.

Introduction

Confronting conclusions of (art-)historians about important artifacts from the past with those obtained by scientific experimental techniques, remains an intellectual challenge[1]. Well-known examples are the proton milliprobe analysis of Gutenberg's bible[2] and the debate that arose about the Shroud of Turin[3][4][5].

The late Middle Ages and the early Renaissance are crucial periods for the transfer of knowledge, since exactly then a large manuscript-production was confronted with the in-(ter)vention of printing. Many medieval manuscripts are illuminated and decorated. The quality of their miniatures not seldom compares well with that of paintings by illustrious contemporary artists[6]. But, whereas today almost everything is known about the contents of these manuscripts, in some intriguing cases little is known, until today, about the workshops (scriptoria) involved. Using a codicological approach, *distinguishing* between workshops producing *similar* manuscripts is very difficult, when no alternative historical sources are available, e.g. archives in abbeys or monasteries regarding their scriptoria or other identification means, sometimes left in the manuscript by scribes or illuminators[6].

Only recently, progress has been made in *identifying* pigment *elements* used in paintings and in medieval manuscripts[7][8] by TXRF (total reflection X-ray fluorescence) spectrometry, a technique conceived already in 1971[9][10]. The use of micro-Raman spectroscopy in manuscripts for identifying *molecules* started in 1984[11]. This technique was also recently applied by Clark et al.[12][13][14].

Sampling in manuscripts for these analyses is non-destructive and a large number of samples can be taken without damaging the manuscript. One sample provides enough material for both TXRF and Raman analyses. Despite all these possibilities, no large scale study has yet been reported on a *quantitative* reconstruction of palettes in a series of *related* medieval manuscripts. The 80 manuscripts, ordered by *Raphael de Mercatellis*[15], an illegitimate son of Philip the Good, Duke of Burgundy, represent such a series. A codicological analysis of the 60 remaining Mercatellis manuscripts, now held by libraries all over the world, has been carried out[16][17][18] and led to a classification of all

Mercatellis manuscripts in function of their codicological characteristics.

Given the technical and artistic skills required and the financial implications for producing manuscripts[6], the actual number of Mercatellis workshops must have been rather small, since these manuscripts were all made in the region Ghent-Bruges, where there was a tradition of manuscript-manufacturing in the late Middle Ages and early Renaissance. Scriptoria, working in this very typical and famous *Ghent-Bruges style*, however, did not make Mercatellis manuscripts[17]. Who exactly produced these 80 Mercatellis manuscripts remains an open and still intriguing question, although several suggestions have been made[16][17][18].

Therefore, we decided to use two analytical techniques to reconstruct both qualitatively (with Raman) and quantitatively (with TXRF) some Mercatellis palettes. The initials, the paragraph marks, the rubrication, and especially the very typical colored decorations *in margine* provide with an excellent basis for pigment analysis and palette reconstruction. This study is a first step in a larger project, aiming at an inventory of palettes of scriptoria, to be used for the identification of other historically important manuscripts of unknown or uncertain origin.

Manuscripts

Table 1 gives a short description (with date), the codicological group, determined by a number of visible characteristics, and the number of parts of the 7 Mercatellis manuscripts (M1–M7) studied. Three non-Mercatellis manuscripts (nM1–nM3) were also analyzed.

Results and Discussion

Elements Detected by TXRF: Table 1 also shows the distribution of the 324 samples, taken by rubbing a dry and clean cotton-wool swab (Q-tip) over the not-varnished colored surfaces (initial, paragraph-mark, rubrication, ...). With a Mo-tube, 12 elements were detected: Ca, Fe, Zn, Cu, Hg, Au, Pb, Ti, As, Mn, Ni, and Sr. With a W-tube Ba, Ag, Sn, and Sb could be retraced. Since nanogram samples can not be weighted, concentrations must be estimated by normalizing the sum of the elements detected to 100. This is by no means exact, since elements with atom number < 11 can not be detected.

Element Classification and Pigment Identification by Micro-Raman Spectra: Ca, Fe, and Zn are considered as *non-pigment elements*. Their presence in the majority of samples is due to the preparation of the parchment and to the presence of (traces of) ink. Although ink is not considered here as a pigment, samples taken from the inks predominantly contain Ca, Fe, and Zn and the latter two elements are highly correlated. Raman spectra of white grains show that Ca is mainly present as $CaSO_4$ (gypsum) and $CaCO_3$ (chalk).

The only *pigment key-element for blue and green* is Cu. The blue pigment used is azurite, easily identified by Raman. The green pigment, usually believed to be malachite or verdigris, must be another still unidentified but certainly Cu-based pigment (malachite and verdigris were not yet detected by Raman).

Two *pigment key-elements were found for red*: Hg in the pigment vermilion (HgS) and Pb in the pigment red lead (Pb_3O_4), both identified by Raman.

Two *precious elements* were detected Ag and Au (mainly in 38 gold initials).

Finally, 8 (to 11) *minor elements* were found: Ti, Ba, As, Sn, Ni, Mn, Sr, and Sb (to be combined with Cu, Hg, and Pb when *not* present as a main pigment element). The white pigment $BaSO_4$ was identified by Raman. All Raman spectra will be presented elsewhere[19].

Blue, Green, and Red Palettes: Figure 1 shows the experimental TXRF-results (percentages of elements found) for each of the 9 blue samples in nM2, without the main pigment element Cu and the non-pigment elements Ca, Fe, and Zn. For 7 samples, the overall constitution is very similar and amounts to an average of about 6% of the sample total. In the samples on pages 1 and 2, Ba is *not* detected.

This is not surprising, since Ba in this manuscript is the key-element in the whitener $BaSO_4$.

Figure 1. All 9 blue samples for nM2, without Cu and non-pigment elements (8% level)

The consistent reproduction of nearly the same percentages for each of the minor elements in the samples must result from the fact that a large number of basic manuscript elements (parchment, parchment preparation, pigment, pigment composition, granular structure, adhesion, resistance to rubbing, ...) remains invariant throughout the complete manuscript.

These observations lead to the conclusion that this 800-page *pecia* manuscript, made in Paris in the 14th century, was made in a single workshop, whereby the same technique and material (azurite) was used for blue initials and paragraph-marks. A specific whitener, $BaSO_4$, was used in the larger part of the manuscript (except in the first pages).

Conversely, these results demonstrate the consistency of the sampling and of the TXRF-analysis.

In Figure 2 on the other hand, the *average* composition for blue and green samples is given for all manuscripts.

Two very different *blue palettes* appear: one for the group M1-M4-M5 and another one for M2-M3-M6-M7, although the same pigment azurite is used in both cases. But, although within each group the palettes are very similar, the *averaged totals* of the element percentages differ significantly, in contrast with the results in Figure 1. For blue, the palette of nM2 resembles that found for M1, but the "absolute" amounts of material vary from 2.5% for M1 to over 5% for nM2 (a difference of a factor of 2).

In the hypothesis that the same, yet unidentified, Cu-based green pigment is used in all Mercatellis manuscripts M1−7, the *green palettes* confirm the group M1-M4-M5 but the pair M6-M7 emerges. Green for M2-M3 is intermediate. For green, the nM1 palette compares with those found for M2 and M3.

This grouping is further confirmed by the *red palettes* (not shown)[19]: two red pigments are identified by Raman (HgS, vermilion and Pb_3O_4, red lead).

The 7 Mercatellis manuscripts can therefore be divided in 2 distinct palette-groups:

Palette-group I: **M1**, *1505?*; **M4**, *1505?*, and **M5**, *date?.*

Palette-group II: (**M2**, *1492/94*))*?*; **M3**, *1492*; **M6**, *date?*, and **M7**, *1479*.

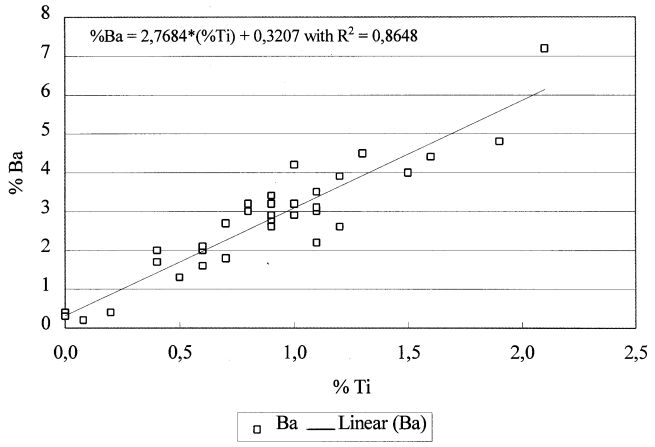
The detailed confrontation of this result with a codicological analysis is given below. A first conclusion is that the yet undated manuscript M5 can be situated around *1505* and the other one M6 in the period 1479−94 (with a preference for *1479*).

Group II is the oldest, as it goes back to pigments used from 1479 onwards, and remained active at least for some 15 years, using the same style and the same coloring technique.

Ba/Ti-Ratio in Blue Samples: Another detail on palettes revealed by TXRF spectrometry is shown in Figure 3, where %Ba is plotted against %Ti for 34 *blue* samples, in which Ba is detected. The average Ba/Ti ratio equals 2.8, with a correlation R^2 better than 0.86. The observed fluctuations in this ratio (not shown) remain between ± 40%, a result to be expected in the case of element ratio's on account of the accuracy of TXRF analyses. The origin of this ratio is not yet clear.

Figure 2. Average palettes for blue and green (without Cu and Ca) for all manuscripts

Figure 3. %Ba versus %Ti for 34 blue data points



Raman spectra show that Ba is present as $BaSO_4$, a whitener (see also Figure 1). The molecule containing Ti remains a problem. Normally it would be $FeTiO_3$, but an Fe-Ti correlation was not (yet) found. TiO_2, a modern whitener, must be excluded, since it is generally accepted that this pigment was not known in the Middle Ages (although the mineral rutile, found in the Alps, is known as a gem from Antiquity). Raman did not reveal any traces of TiO_2. No correlation was found for Ti or Ba with any of the 14 other elements. Their presence as a pair is mainly restricted to blue samples in *group I* manuscripts *and in nM2*.

Almost no As is found in the blue samples of *Group I* manuscripts, where large amounts of Ti and Ba are found. The opposite situation applies for *Group II* (see Figure 2).

Gold: The two classical types of illuminations are present in Mercatellis manuscripts: *shell* (or liquid) *gold* is used mainly in *decorations in margine*, whereas *gold leaf* is reserved for *initials*. Shell gold was detected in 25 leaves and ranks out of 60 rubbed, although just rubbing of a colored surface was intended.

Gold initials continue to be real eye-catchers of medieval manuscripts, as intended 500 years ago. Gold is not always used for the initial itself but also for its *background*. Gold-leaf techniques can vary locally[6]: in Flanders and Germany, the parchment is first covered with a *brownish gesso* where an illumination is wanted, on which the gold leaf is fixed when the gesso was dry. In many Mercatellis manuscripts, this brownish gesso shows through the parchment at the back of the initial.

In most of the 38 gold initials, silver is detected and the Ag/Au ratio varies from 0.01 to 0.15. In one M2-initial 37% Ag was found, exactly as much as Au. Another initial (first page in M2) contains 4,4% Sn, which *could* indicate that mosaic or synthetic gold (SnS_2) was used, but this is highly improbable*. In *group II*, three initials are found with Pb/Au ratios between 6 and 1, whereas usually only a few percent Pb is found. In all three, gold leaf is used in the background. Here, lead is probably originating from white decorations in the initial (internal contamination, see also below).

In Figure 4, a logarithmic scale is used to plot the Cu/Au ratios for 37 gold initials (for one initial Cu/Au = 0). The majority of initials shows a low Cu "palette" (Ag, Cu, Hg, Pb, and Ni contribute 10 to 15% to the sample-total). However, for 10 initials in the two *palette-groups* (i.e. the 10 data points in Figure 4 with black background), the slope of the line connecting the data points almost vanishes and a plateau emerges at an average Cu/Au ratio of about 1:75. This *might* indicate that, irrespective of the palette-group, orders for gold (or gold leaves) were invariantly placed with the same merchant or that the same kind of coin was used for making gold leaves[6]. However, further work remains to be done on this point.

The first 12 gold initials in Figure 4 have a relatively high Cu/Au ratio (>0.1). High Cu/Au- and Pb/Au-ratios for gold initials must be explained by internal and/or external contamination. Sampling small decorated gold initials can easily lead to contamination by pigment elements in the initial's decorations (internal contamination). But, samples were also taken from large initials, where internal contamination can be avoided. Even then, as much as 30% Ca can be found, indicating that "external" contamination is substantial. This contamination is due to the intense contact between *facing pages* in a manuscript, kept closed almost constantly for about 500 years by means of straps. This kind of contamination is even clearly visible in M1: the white lower margin on f. 263r almost shows a "color-copy" of a decoration *in margine* on folio 262v.

TXRF and Raman Results versus Classical Codicological Results

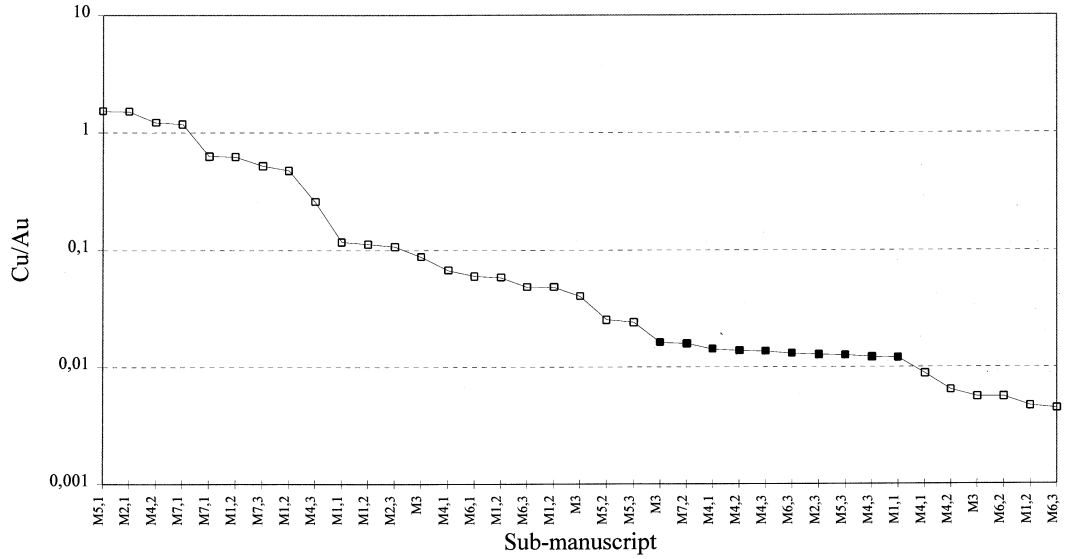
Only the identification of pigments used in manuscripts by means of Raman spectroscopy allows one to reconstruct palettes on the basis of TXRF results. In this work, Raman spectra provided with conclusive evidence concerning the presence of some important (pigment-)molecules, such as $BaSO_4$, HgS, Pb_3O_4, $CaSO_4$, $CaCO_3$, $2CuCO_3 \cdot Cu(OH)_2$. Attempts to identify Ti molecules and lapis lazuli were not yet successful (miniatures were not yet analyzed in this work). Given the importance attached to blue pigments in the making of medieval manuscripts[1][6](see also below), it is a pity that *lapis lazuli* can not be detected by TXRF. So far, we did not yet find Raman evidence for lapis lazuli in any of the 93 blue samples but the Raman analysis shows that the blue pigment used in all manuscripts, studied here, is azurite. This observation allows us to confront the results of the palette reconstruction for blue illustrations, obtained in this work, with the results of codicological analyses on the same Mercatellis manuscripts. This confrontation is done on two levels: the complete manuscript and the sub-manuscripts (see Table 1).

The Complete Manuscripts

A classical codicological analysis is based upon a comparison of the visible characteristics of 60 Mercatellis

* Sn is found in only 7 of 324 samples (1 gold initial and *6 blue ranks*), and is highly correlated with Pb (%Pb = 5.456 × %Sn − 5.88 with R^2 = 0.9647). Here Pb, with Sn, is probably used as white lead (to be confirmed by Raman spectra).

Figure 4. Ratios Cu/Au for gold initials, descending order



manuscripts still in existence[16][17][18]. Applying TXRF and Raman makes some invisible characteristics also visible.

The different codicological groups for the 7 Mercatellis manuscripts are given in Table 1. The result of the confrontation of the codicological with the analytical studies is given in Table 2.

Table 2. Confrontation of a codicological classification (CC) with palette-groups for 7 Mercatellis manuscripts

CC[a]/*Palette-group*[b]	**2(1)**	**3(2)**	**3(3)**	**3(6)**	**3(8)**
Palette-group I			M1	M4	M5
Palette-group II	M3, M7	M2			***M6***

[a] Taken from Table 1. – [b] This work.

For 6 out of 7 Mercatellis manuscripts, an acceptable result is obtained. However, the palette reconstruction suggests that the dividing line for the codicological classification should not be drawn between the major codicological groups **2** and **3** but between the codicological subgroups **3(2)** and **3(3)**, if the palette classification for M2 is valid (see above). In addition, M6 and M7 have similar palettes, whereas the codicological analysis reveals differences. This result for M6 is intriguing, so we further quantified and refined the palette reconstruction for blue decorations, which have always been important in manuscripts and since azurite is the only blue pigment found.

Correlation Between Sub-Manuscripts on the Basis of Blue Palettes

In Table 1, the 4th column gives the number of *parts* distinguished codicologically in the 7 Mercatellis manuscripts, giving a total of 18 sub-manuscripts (see bottom line in Table 1). Correspondingly, sub-manuscripts are distinguished as follows: the 2 different parts in M1 will be designated as $M_{1,1}$ and $M_{1,2}$ and so on for all 7 Mercatellis manuscripts.

Table 3 gives a correlation matrix for these 18 Mercatellis sub-manuscripts, calculated on the basis of the average percentages found for 10 *minor* elements in blue samples: Hg, Au, Ti, Ba, Ag, As, Sn, Ni, S and Sb. The correlation matrix consists of the Pearson product-moment correlation coefficients for the variables. A positive correlation between 0.6 and 1, rounded off, is given in bold; the identity in the diagonal is given by *1*.

The first 8 sub-manuscripts of *palette-group I* are similar (except in part for $M_{5,3}$) and the 10 sub-manuscripts of *palette-group II* form an even more homogenous set (in each case a *positive* correlation is found). There is no or a slightly negative correlation between sub-manuscripts of the two different *groups I and II* (except in part for $M_{6,3}$).

Parts $M_{5,3}$ and $M_{6,3}$ are slightly different from the other parts in M5 and M6. But, Table 3 also shows that most parts distinguished codicologically are not only consistent with the complete manuscript but also with the Mercatellis palette-groups *I and II*, the manuscript belongs to. Removing one (sub-)manuscript from one palette-group to the other, as suggested codicologically (see Table 2), would distort the symmetry of Table 3.

The blue palette of nM2 is correlated with *group I* and less with *group II* (see also Figure 1 and Figure 2). This is remarkable, since the *pecia* nM2 originates from Paris. The fact that a similar technique was used by geographically separated scriptoria in the 14th century for a completely different kind of manuscript, is an extra argument for distinguishing between two local Mercatellis workshops, which used different blues.

The refined analysis in Table 3 confirms that both M2 and M6 are members of *palette-group II*, which is in support of their position in Table 2. An extra codicological argument for the position of M6 is that the size and the ruling of this manuscript are the same as for Mercatellis manuscripts in group **2(3)**[16].

Conclusion

The 7 Mercatellis manuscripts analyzed were certainly made in Flanders using two different coloring techniques but also in two different periods, suggesting that also two different workshops were involved in their production. A large scale TXRF- and Raman-analysis can indeed lead to a quantitative reconstruction of palettes in medieval manuscripts and, even for related manuscripts, palette-differences can be detected. These differences must be attributed either to different hands or techniques, simultaneously available in the *same scriptorium*, to an evolution in manufacturing techniques in the *same scriptorium* or to *different scriptoria*.

The authors are greatly in debt to Prof. Dr. *R. Klockenkämper* and Dr. *A. von Bohlen* of the Institute for Spectroscopy and Applied Spectroscopy (ISAS), Dortmund. We also thank Dr. *W. De Vos*, Dr. *A. Arnould*, o.p., and Prof. Dr. *K. G. Van Acker* for their critical advise. A generous grant of the *Fund for Scientific Research-Flanders* (FWO-Vlaanderen) in support of this work is gratefully acknowledged.

Keywords: Aziridines / Coordination / Ring opening / Metallacyle / N-Chirality

The photolytically induced CO substitution reactions of $CpMn(CO)_3$ with *N*-phenylaziridine and of $W(CO)_6$ with 2,2-dimethylaziridine lead to the *N*-coordinated aziridine complexes $Cp(CO)_2Mn\{N(Ph)CH_2CH_2\}$ and $(CO)_5W\{N(H)CH_2CMe_2\}$. Both are stable with respect to thermal alkene elimination. The thermal reaction of $Cp(CO)_3MoCl$ with *N*-hydroxyethylaziridine leads to the metallaheterocyclic compound $Cp(CO)_2MoNH(CH_2CH_2OH)CH_2CH_2C(O)$. It might be formed by several reaction steps including a Cl migration with nucleophilic ring opening, a CO insertion reaction forming the β-aminoacyl ligand and finally a hydrolytic process. The X-ray structure analysis of $Cp(CO)_2Mn\{N(Ph)CH_2CH_2\}$ and $(CO)_5W\{N(H)CH_2CMe_2\}$ shows three-membered-ring ligands *N*-bonded to the metal atoms with a trigonal pyramidal configuration at the nitrogen atoms. The X-ray structure analysis of $Cp(CO)_2MoNH(CH_2CH_2OH)CH_2CH_2C(O)$ reveals a five-membered heterocyclic ring system, including the molybdenum atom, a carbonyl function and an ammonium center.

Introduction

The photolytic reactions of $CpMn(CO)_3$ with thiirane, C_2H_4S, or thiirane *S*-oxide, C_2H_4SO, lead to CO substitution and elimination of ethene with formation of the intensively colored S and SO complexes, $\{CpMn(CO)_2\}_2S$ (green) and $\{CpMn(CO)_2\}_2SO$ (violet)[1][2]. Both dinuclear compounds show a central, symmetrically-bridging 3c4e-π-system. With their planar Mn_2SO_n skeleton (n = 0, 1), they demonstrate isolobal bis-metalorganic analogues of SO_2 and SO_3. The coordination of C_2H_4S- and C_2H_4SO ligands to transition metals via sulfur was first reported to exist in $(Ph_3P)_2Pt\{S(O)_nC_2H_4\}$ (n = 0, 1)[3] and $[CpRu(PPh_3)_2(S\text{-}C_2H_4)]O_3SCF_3$[4]. Ring-opening and oxidative-addition reactions of C_2H_4S and C_2H_4SO onto transition metal complexes have not yet been observed.

The isoelectronic aziridine-derivatives $N(R)CH_2CR'R''$ are expected to react in a similar fashion. Firstly, the coordination of aziridines onto transition metal centers via its nitrogen atom should also be possible. Subsequent ethene elimination might result in the formation of mono- and dinuclear nitrene complexes. This would be a new synthetic approach to nitrene complexes. A third type of reaction could be ring-opening leading to four-membered ring systems by an oxidative-addition process. However, five-membered ring systems could also form, especially with hydrido complexes of transition metals e. g., by a nucleophilic attack of the alkylidene part on the electrophilic carbon atom of a carbonyl ligand.

Beck et al. have described the reactivity of aziridines with metalcarbonyl and metalcarbonylhydrido complexes[5]. They observed two types of reactions of aziridines: simple coordination as *N*-coordinate ligands, as well as ring-opening to give metallacycles. Both types of complexes were characterized mainly by their IR spectra[5][6][7][8]. Two examples of the five-membered metallacycles have been characterized by X-ray structure analysis[9][10][11][12]. Angelici et al. reported the reaction of aziridine with platinum(II)-nitrile complexes to give aziridino-amidines, 2-imidazolines and to *trans*-$[PtCl_2\{N(H)=C(Ph)NC_2H_4\}_2]$ complexes[13]. Coordination of the aziridine to the Pt-atom was not observed. In a recent paper, Beck et al.[14] described the reaction of a *N*-functionalized L-aziridine-2-carboxylate (ac) with some chloro-bridged transition-metal complexes to give e.g. $(OC)_2Rh(ac)$, $(\eta^5\text{-}C_5Me_5)(Cl)Ir(ac)$, $(\eta^3\text{-}C_3H_5)$-$Pd(ac)$, $Me_2NCH_2C_6H_4Pd(ac)$, $(R_3P)(Cl)Pd(ac)$ (R = Et, Bu, Ph), $(Ph_3P)(Cl)Pt(ac)$ and $[(Ph_3P)_2Pt(ac)]BF_4$. All these complexes are formed by HCl-elimination and by ring formation. They are the first structurally characterized N-aziridine complexes which possess an additional carboxylato-*O* bond to the transition metal (bidentate-*N*,*O*). Recently, the monodentate and *N*-coordinate benzylaziridine complex $Cp(CO)_2Mn\{N(Bz)CH_2CH_2\}$ was sucessfully synthesized and characterized[15].

In this paper the photolytic reactions of $CpMn(CO)_3$ and $W(CO)_6$ with different N- and C-substituted aziridines are reported. These lead to new *N*-coordinate mono-aziridine complexes. In addition, the thermal reaction of $Cp(CO)_3MoCl$ with *N*-hydroxyethylaziridine, which results in the formation of an interesting five-membered transition-metallacycle, is described.

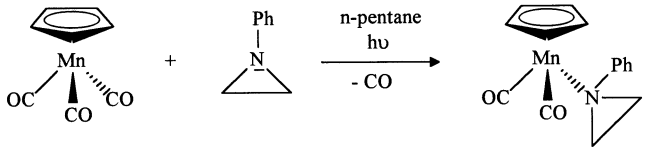
Results and Discussion

$CpMn(CO)_3$ and *N*-phenylaziridine $N(C_6H_5)C_2H_4$ (**1a**) are photolysed for 3.5 h in *n*-pentane at −35°C. The clear

 © WILEY-VCH Verlag GmbH, D-69451 Weinheim, 1998 1434−1948/98/0505−0645 $ 17.50+.50/0

yellow solution turns orange after warming to r. t. Crystallisation provided monoclinic orange colored crystals of **2** (Scheme 1). **2** is neither light- nor air-sensitive. The formation of **2** results from a simple substitution reaction of one CO ligand for the nucleophilic nitrogen atom of the aziridine ligand (2e donor). **2** is also obtained by photolysing first $CpMn(CO)_3$ in thf to give the labile complex $CpMn(CO)_2$thf, which then is allowed to react with the aziridine ligand within 4 h to give **2**. The yield of **2** is higher for the "direct" synthesis in *n*-pentane (76%) than for the "indirect" in thf (56%).

Scheme 1

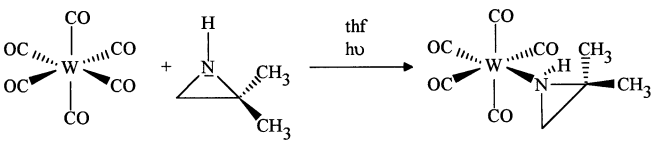


1a **2**

In accordance with the utilisation of *N*-substituted aziridines described later, the analagous reaction products of *C*-substituted N(H)-aziridines and further metal complexes are also of interest. By using such *C*-substituted aziridines the question as to whether the alkene elimination takes place by activation, therefore obtaining nitrene complexes by a new method, can be answered. In the case where alkene elimination is not observed, the N−H bond cleavage should be attempted by the nucleophilic attack of strong bases to obtain a new nucleophilic center at the N of the aziridine ligand. This would then be attempted to react with other electrophilic compounds. With 16e-fragments like $[CpMn(CO)_2]$, or 17e-fragments like $CpFe(CO)_2$ anionic or neutral μ_2-N bridged dimetallo complexes should be built up.

Thus, $W(CO)_6$ is first photolysed in thf for 2 h at r. t., followed by addition of one equivalent of 2,2-dimethylaziridine $N(H)CH_2CMe_2$ (**1b**). After evaporating the solution to dryness and removal of some $W(CO)_6$ by sublimation, the residue is dissolved in thf. Careful layering of n-pentane at −22°C yields yellow crystals of **3** (Scheme 2.). These are neither air, nor light sensitive and they are soluble in acetone, CH_2Cl_2 and thf. No $H_2C{=}CMe_2$ elimination was observed on heating.

Scheme 2



1b **3**

In contrast to both 16e complex fragments, where neutral addition products were obtained with aziridines, aziridines were reacted with 17e complex fragments in the hope of obtaining cationic addition products. Therefore, $CpMo(CO)_3Cl$ was reacted with *N*-hydroxyethylaziridine, $N(CH_2CH_2OH)C_2H_4$ (**1c**), in acetone at 60°C. After cooling to r. t., a dark red solution was obtained from which yellow-orange crystals of **4** separated on evaporation.

However, instead of the expected cationic complex $[Cp(CO)_2MoN(CH_2CH_2OH)CH_2CH_2)]Cl$, the new neutral metallacycle $Cp(CO)_2MoNH(CH_2CH_2OH)CH_2CH_2C(O)$ (**4**) was surprisingly obtained. Its formation requires several steps and the presence of traces of water. Firstly, a migration of the Cl onto the N atom giving the corresponding metallate and aziridinium ion. They undergo a nucleophilic ring opening process to give the β-aminoethyl ligand which as nucleophile attacks the electrophilic C atom of one of the CO ligands to give the β-aminoacyl ligand. The reaction is finished by the coordination of the amine to the metal to form the five-membered metallacycle. We believe that the replacement of the Cl substituent for H takes place during the long crystallization process. The presence of water could be derived from the hydroxyethyl substituent by condensation. Beck et al. have described a similar complex[5][10][11][14], the hydrido complex $CpMo(CO)_3H$ was used as a starting material. Therefore there was no hydrolytic process necessary.

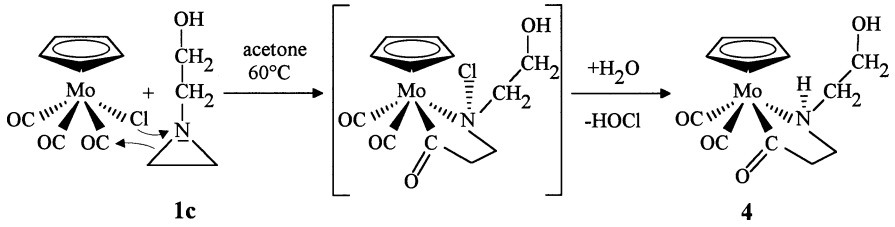
The composition and structure of **2**, **3** and **4** were confirmed by elemental analyses, MS, ^{1}H-, $^{13}C\{^1H\}$-NMR and IR spectra, as well as by X-ray structure analyses.

The IR spectrum of **2** shows two ν(CO) vibrations at 1917.7 and 1839.1 cm^{-1} (in CH_2Cl_2), or 1915.8 and 1844.8 cm^{-1} (in KBr), respectively. The IR spectrum in KBr also shows the ν(CH) at 3106.4 and 3011.2 cm^{-1}, as well as the $\nu(C-N_{tert.})$ vibration at 1358.6 cm^{-1}. The IR spectrum of **3** exhibits three bands at 1974.7, 1924.8 and 1888.6 cm^{-1} for terminal CO groups ($2A_1 + E$, C_{4V} local symmetry). In the IR spectrum of **4**, ν(CO) bands at 2020.7 and 1936.3 cm^{-1} are observed for the two terminal ligands. A third ν(CO)-band at 1844.9 cm^{-1} is due to the carbonyl group within the ring.

In the EI-MS spectrum of **2**, the $[M^+]$ signal appears at 295.0 u, together with signals at 239.0 u and 120.0 u for $[M^+ - 2\ CO]$ and $[M^+ - 2\ CO - N(Ph)CH_2CH_2]$. In the EI-MS spectrum of **3**, the parent ion $[M^+]$ appears at 395.0 u, together with peaks at 367.0 for $[M^+ - CO]$, 339.0 for $[M^+ - 2\ CO]$, 309.0 for $[M^+ - 3\ CO - 2\ H]$, 281.0 for $[M^+ - 4\ CO]$, 253.0 for $[M^+ - 5\ CO]$ and 71.0 for $[HNCH_2CMe_2]$. **4** does not give the $[M^+]$ signal, the mass spectrum shows only fragments.

In the ^{1}H-NMR spectrum of **2**, the phenyl protons are found as singlets at 7.27 (*ortho*), 7.20 (*meta*) and 7.06 (*para*) ppm. In comparison with the free *N*-phenylaziridine ligand, these are deshielded by 0.11 to 0.40 ppm. The Cp protons give rise to a singlet at δ 4.25, which in comparison with $CpMn(CO)_3$ lies 0.51 ppm upfield. The aziridine ring protons are observed at 2.38 ppm as a broad singlet in **2**, whereas in **1a** two triplets are found at δ 3.58 and 3.38. The ^{1}H-NMR spectrum of **3** is characterized by 2 triplets at 2.50 and 2.35 ppm for the CH_2 ring protons, a triplett at δ 4.35 for the NH proton (ABX system), and two singlets at δ 1.40 and 1.35 for the methyl groups. In the ^{1}H-NMR spectrum of **4**, the Cp protons are observed at δ 5.32 as a singlet, shifted 0.56 ppm upfield from the $CpMo(CO)_3Cl$ starting

Scheme 3



material. At 5.29 ppm, the OH proton of **4** is better shielded by 0.19 ppm relative to the free *N*-hydroxyethyl aziridine ligand. The signals for the *N*-2-hydroxyethyl and for the ethene group within the ring in **4** appear as 4 triplets at 3.80 (CH_2O), 3.63 (CH_2CO), 2.99 (CH_2N) and at δ 2.82 (CH_2N).

In the $^{13}C\{^1H\}$-NMR spectrum of **2**, the signals for the CO groups and the Cp ligand lie at δ 288.36 and 83.70, respectively. The different carbon atoms of the phenyl ring are detected between δ 129.28 and 122.70 (4 signals). Coordination of **1a** to the manganese atom in **2** leads to two signals which are very close together and shifted upfield for

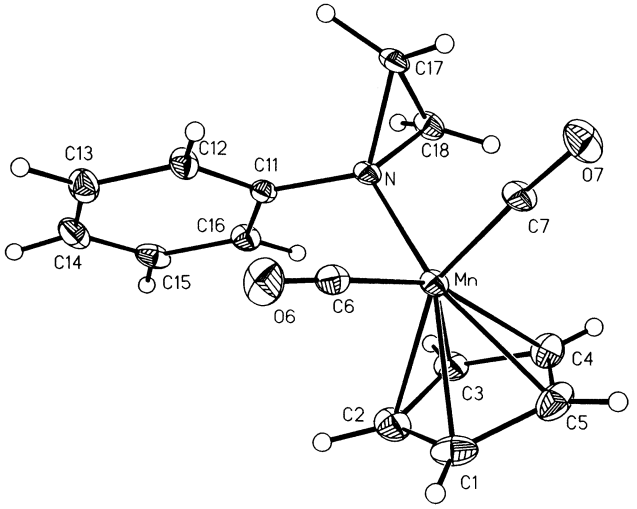
the two ring carbon atoms. They lie at 41.92 and 41.85 ppm, compared with δ 45.43 and 43.18 for free **1a**. In the $^{13}C\{^1H\}$-NMR spectrum of **3**, a signal at δ 191.21 for the tertiary carbon atom, at 68.05 ppm for the CH_2N ring group and only a singlet at 25.67 ppm for the two CH_3 substituents is observed. In the $^{13}C\{^1H\}$-NMR spectrum of **4**, signals are observed at 213.43 and 205.86 ppm (CO ligand and carbonyl function), 94.45 (Cp), 64.05 (s, C(12)H_2O) and at 52.09 ppm (s, C(11)H_2N). The C atoms of the five-membered ring are found at 50.66 ppm (s, C(10)H_2N) and 44.14 ppm (s, C(9)H_2CO).

Single crystals suitable for X-ray diffraction analysis of **2**, **3** and **4** were obtained. The crystal structure analysis data are summarized in Table 1 and the molecular structures and the most important bond lengths and angles are given in Figures 1, 2 and 3.

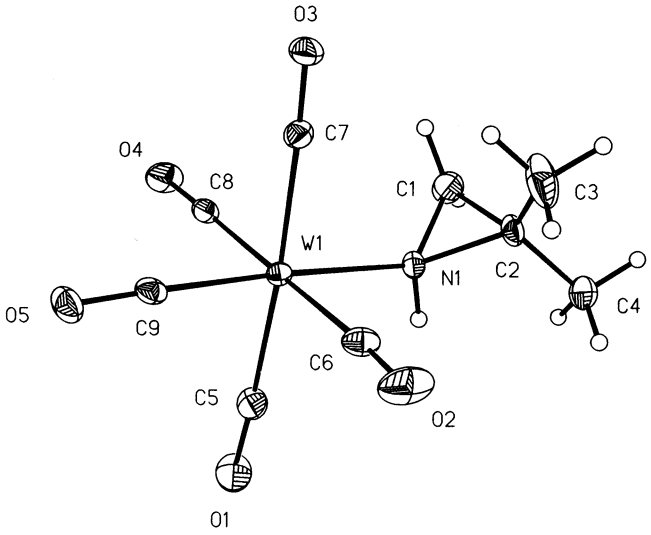
Figure 1. Molecular structure of **2**[a] in the crystal. Thermal ellipsoids are represented at a 25% probability scale



[a] Selected bond lenghts [Å] and bond angles [°]: Mn−N 2.096(5), Cp−$Mn_{average}$ 2.141(7), N−C11 1.446(7), N−C17 1.506(7), N−C18 1.491(8), C17−C18 1.480(9), C11−N−Mn 115.2(3), C17−N−Mn 121.7(4), C18−N−Mn 119.5(4), C7−Mn−C6 88.1(3), Mn−C6−O6 175.3(6), Mn−C7−O7 174.0(6), C18−N−C17 59.2(4), C17−C18−N 60.9(4), C18−C17−N 59.9(4), C11−N−C18 116.3(5), C11−N−C17 113.6(5).

The configuration at the Mn- and the N-atom of **2** is distorted tetrahedral. The Mn−N bond length of 2.096(5) Å indicates a single bond; the two bonds N−C17 (1.506(7) Å) and N−C18 (1.491(8) Å) are practically of equal length, while N−C11 (1.446(7) Å) is somewhat shorter. The bond length C17−C18 with 1.480(9) Å is a little bit shorter in comparison with typical C−C-single bonds and as found in aziridines[9]. While the C18−N−C17 angle within the ring is 59.2(4)°, the two angles C11−N−C17 and C11−N−C18 outside the ring lie between 116.3(5)° and 113.6(5)°. The angles C17−N−Mn (121.7(4)°) and C18−N−Mn (119.5(4)°), containing a manganese atom, are close to 120°. The angle C11−N−Mn (115.2(3)°), C11 being the *ipso*-carbon of the phenyl ligand, is also very large. The plane of the aziridine ligand nearly approaches orthogonality to the plane of the cyclopentadienyl ligand (71.3°).

Figure 2. Molecular structure of **3**[a] in the crystal. Thermal ellipsoids are represented at a 25% probability scale

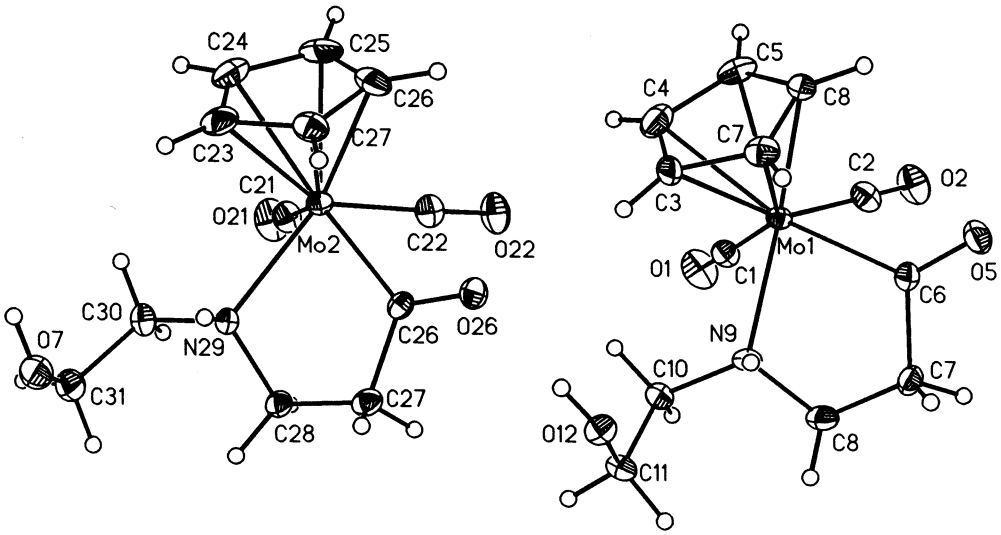


[a] Selected bond lenghts [Å] and bond angles [°]: W1−N1 2.307(8), N1−C1 1.488(14), N1−C2 1.500(13), C1−C2 1.48(2), C2−C3 1.49(2), C2−C4 1.504(14), C9−W1−C6 89.3(4), C6−W1−C8 177.9(3), C6−W1−C7 90.4(4), C7−W1−C5 176.2(4), C2−C1−N1 60.7(7), C1−C2−N1 59.9(7), C1−N1−C2 59.4(7), C1−N1−W1 128.8(6), C2−N1−W1 132.9(6), C8−W1−N1 91.0(4), C5−W1−N1 88.6(4), C3−C2−N1 116.8(9), C1−C2−C3 120.6(11), C3−C2−C4 115.0(10), N1−C2−C4 114.5(8).

The coordination sphere around the tungsten atom in **3** can be described as a distorted octahedron with maximum deviations of 4.8° for C7−W1−N1 and 3.5° for C9−W1−N1 from 90° and 180°, respectively. The W1−N1 bond length of 2.307(8) Å lies in the expected region for a single bond. The distance C1−C2 of 1.48(2) Å is again slightly shorter than that found for C−C single bonds and comparable to C17−C18 of **2**[9]. However, both bonds C2−C3 and C2−C4 are found to be somewhat longer (1.49(2) Å and 1.504(14) Å). The bond lengths N1−C1 and N1−C2 are to be considered to be of equal length (1.49(1) Å and 1.50(1) Å). Because of the C2 substituents both angles C1−N1−W1 and C2−N1−W1 are different (128.8(6)° and 132.9(6)°). The ring-angle C1−N1−C2 is again the smallest (59.4(7)°).

In **4**, the molybdenum atom possesses a distorted tetragonal pyramidal configuration with the Cp ligand in apical position. It is also part of the five-membered heterocyclic ring system, which is formed by the β-aminoacyl ligand[6][8][10][11]. Whereas the Mo1−N10 bond of 2.267(4) Å is very long, that of Mo1−C8 is remarkably shorter at 2.180(5) Å. The bonds N10−C10 and N10−C11 are almost equal (1.473(6) Å and 1.484(6) Å) and their length is typical for N−C single bonds. Of both C−C bonds within the ring, that of C8−C9 (1.536(7) Å) is significantly larger than that of C9−C10 (1.497(7) Å). While the atom distance O9−C8 of the carbonyl group is 1.233(6) Å, the bond length O12−C12, where O12 belongs to an OH group, corresponds with a single bond (1.432(6) Å). Within the five-membered ring with envelope conformation, the angle C8−Mo1−N10 of 73.4(2)° is the most acute and the angle

Figure 3. Molecular structure of **4**[a] in the crystal. Thermal ellipsoids are represented at a 25% probability scale



[a] Selected bond lenghts [Å] and bond angles[°]: Cp−$Mo1_{average}$ 2.348(5), Mo1−N10 2.267(4), Mo2−N31 2.280(4), Mo1−C8 2.180(5), Mo2−C28 2.162(4), Mo1−C6 1.929(6), O9−C8 1.233(6), O28−C28 1.239(5), C8−C9 1.536(7); C9−C10 1.497(7), N10−C10 1.473(6), N10−C11 1.484(6), C11−C12 1.523(6), C12−O12 1.432(6), C6−Mo1−C7 75.4(2), C7−Mo1−C8 121.3(2), C7−Mo1−N10 82.6(2), C8−Mo1−N10 73.4(2), Mo1−C6−O6 178.5(5), Mo1−C7−O7 175.5(4), N10−Mo1−C8 73.4(2), Mo1−C8−C9 127.5(4), C8−C9−C10 111.8(4), C9−C10−N10 108.7(4), C10−N10−Mo1 109.8(3).

C9−C8−Mo1 of 115.7(3)° the most open, because of the sp^2-hybridized C8 atom. The other three angles C8−C9−C10 (111.8(4)°), C9−C10−N10 (108.7(4)°) and C10−N10−Mo1 (109.8(3)°) are approximately equal. The ring shows envelope conformation, where N10 is placed −0.75 Å out of the plane Mo1−C8−C9−C10, with an interplanar angle to the Mo1−N10−C10 plane of 47.2° (respective data for N31 is −0.75 Å and for Mo2−C28−C29−C30 the interplanar angle to the Mo2−N31−C30 plane is 46.3°). The isolated crystals contain only one of the possible isomers with the relative configuration *RS*/*SR*.

Conclusion and Scopes

The results demonstrate that aziridine ligands coordinate much more effectively to transition metals than thiiranes. The latter prefer an ethene elimination and formation of sulfur complexes. The first aziridine complex has only recently been published[15]. **2** and **3** are two further examples. **3** is the first aziridine complex with a chiral N atom. We are continuing investigations in this field with more electrophilic, metalorganic-complex fragments to induce ethene elimination as a new synthetic approach to nitrene complexes. Moreover, aziridines can react, after coordination, with carbonyl ligands via ring-opening and by a redox reaction to produce the new metallaheterocycle **4**. We hope to elucidate the mechanism of its formation.

These complexes may find use in the therapeutic use of aziridines, which has been known since the fifties. Currently, there are detailed investigations on the cytostatic, cytotoxic and mutagenic activity of aziridine components[16][17][18][19][20][21][22]. In recent years organometallic transition complexes have gained a wide interest in cancer diagnostics[23]. It is planned to test such aziridine and aziridine-based complexes for such applications.

Experimental Section

To remove oxygen, all operations were carried out under an argon atmosphere in dry and argon-saturated solvents[24] . $CpMn(CO)_3$[25], $W(CO)_6$[25], $CpMo(CO)_3Cl$[25], *N*-phenylaziridine[26] and 2,2-dimethylaziridine[27] were prepared in accordance with literature procedures. *N*-hydroxyethylaziridine was used as purchased from Aldrich. The photolytic reactions were carried out by using a mercury-high-pressure lamp TQ 150 Hanau (as an inside dipping lamp) in a modified glass apparatus with an overflow tube, which allows a sufficient vertical mixing of the reaction solution. − IR: Perkin-Elmer 598 and Nicolet FT-IR. − NMR: Jeol EX-400 (^{1}H: 399.784 MHz and ^{13}C: 100.540 MHz) and Jeol GSX-270 (^{1}H: 240.0 MHz and ^{13}C: 61.0 MHz), both with [D_6]acetone and $CDCl_3$ as solvents and TMS as internal standard. − MS: Finnigan MAT 900 (20 kV), Varian MAT CH7 (70 eV).

N-Phenylaziridine-dicarbonyl-η^5-cyclopentadienyl-manganese(I) (**2**): 0.81 g (6.8 mmol) $CpMn(CO)_3$ and 2.73 g (13.4 mmol) of **1a** were photolysed at −35°C in 400 ml *n*-pentane for 3.5 h with strong stirring. The elimination of 1 mol of CO was controlled by IR spectroscopy. Thereafter, the clear orange solution was allowed to attain r. t. during 4 h and then the solvent was partially evaporated. After 24 h, orange crystals of **2** had formed; yield 1.54 g (76.6%); m.p. 149°C. − IR (CH_2Cl_2): $\tilde{\nu}$ [cm^{-1}] = 1917.7vs, 1839.1 vs (CO); IR (KBr): $\tilde{\nu}$ [cm^{-1}] = 3106.4 s, 3011.2 s (CH); 1915.8 vs, 1844.8 vs (CO); 1358.6 s (C-$N_{tert.}$). − ^{1}H-NMR ([D_6]acetone): δ = 7.27 (s, o-Ph, 2 H), 7.20 (s, m-Ph, 2 H), 7.06 (s, *p*-Ph, 1 H), 4.25 (s, Cp, 5 H), 2.38 (s, $(CH_2)_2$, 4 H). − ^{13}C{^{1}H}-NMR ([D_6]acetone): δ = 288.36 (s, CO), 129.28 (s, Ph, C_{ipso}), 129.25 (s, Ph, C_{ortho}), 123.06 (s, Ph, C_{meta}), 122.70 (s, Ph, C_{para}), 83.70 (s, Cp), 41.92 (s, CH_2), 41.85 (s, CH_2). − MS-EI (70 eV): 296.0 [M^+ + H], 295.0 [M^+], 239.0 [M^+ − 2 CO], 211.0 [M^+ − 2 CO − C_2H_4], 176.0 [M^+

− $N(Ph)C_2H_4$], 148.0 [M^+ − CO − $N(Ph)C_2H_4$], 120.0 [M^+ − 2 CO − $N(Ph)C_2H_4$]. − $C_{15}H_{14}MnNO_2$ (295.22): calcd. C 61.05, H 4.74, N 4.74; found. C 60.55, H 5.02, N 4.84.

2,2-Dimethylaziridine-pentacarbonyl-tungsten(0) (**3**): A solution of 1.0 g (2.8 mmol) of $W(CO)_6$ was photolysed while stirring in 400 ml thf at r. t. for 2 h. The elimination of 1 mole CO was observed by IR-spectroscopy. Then 0.20 g (2.8 mmol) of **1b** were added. The yellow solution turned orange within 1 h. After evaporating the solvent and sublimation of unreacted $W(CO)_6$ from the residue in vacuum at 60°C, the remaining material was dissolved in 50 ml of thf and covered with a layer of *n*-pentane (10 ml). After 48 h at −22°C yellow crystals of **3** had formed; yield 0.53 g (47%); m.p. 98°C. − IR (CH_2Cl_2): $\tilde{\nu}$ [cm^{-1}] = 1974.7 m, 1924.8 vs, 1888.6 m (CO). − ^{1}H-NMR ($CDCl_3$): δ = 1.85 (m, CH_2, 2 H), 1.40 (s, CH_3, 3 H), 1.35 (s, CH_3, 3 H). − $^{13}C\{^1H\}$-NMR ($CDCl_3$): δ = 191.21 (CMe_2), 68.05 (CH_2N), 25.67 (CH_3). − EI-MS (70 eV); *m/z* (%): 395.0 [M^+], 367.0 [M^+ − CO], 339.0 [M^+ − 2 CO], 309.0 [M^+ − 3 CO − 2 H], 281.0 [M^+ − 4 CO], 253.0 [M^+ − 5 CO], 71.0 [$HNCH_2CMe_2$]. − $C_9H_9NO_5W$ (395.02): calcd. C 27.36, H 2.30, N 3.54; found. C 27.00, H 2.03, N 2.68.

1,1-Dicarbonyl(η^5-cyclopentadienyl)-2-hydroxyethylmolybda(1)-aza(2)-cyclopentan(5)-one (**4**): To the red solution of 0.38 g (1.4 mmol) of $CpMo(CO)_3Cl$ in 125 ml acetone, were added two mol-equivalents of **1c** (0.22 ml, 2.7 mmol) while stirring. The solution was then heated to 60°C for 1 h, during which the color of the solution became darker. After cooling to r. t. and partially evaporating the solvent in a vacuum, yellow-orange crystals of **4** formed; yield 0.23 g (60%); m.p. 113°C. − IR (CH_2Cl_2): $\tilde{\nu}$ [cm^{-1}] = 2020.7 m, 1936.3 vs $(CO)_{terminal}$, 1844.9 s $(CO)_{carbonyl}$. − ^{1}H-NMR ([D_6]acetone): δ = 5.32 (s, Cp, 5 H), 5.29 (s, OH, 1 H), 3.80 (t, CH_2O, 2 H), 3.63 (t, C(11)H_2, 2 H), 2.99 (t, C(10)H_2, 2 H), 2.82 (t, C(9)H_2, 2 H). − $^{13}C\{^1H\}$-NMR ([D_6]acetone): δ = 213.43 $(CO)_{terminal}$, 205.86 $(CO)_{carbonyl}$, 94.45 (Cp), 64.05 (CH_2OH), 52.09 (C(11)H_2), 50.66 (C(10)H_2), 44.14 (C(9)H_2). − $C_{12}H_{15}MoNO_4$ (333.20): calcd. C 43.26, H 4.54, N 4.20; found. C 43.12, H 4.67, N 4.77.

X-Ray Structure Determinations of **2**, 3 and **4**[28]: The crystal structure, experimental specifications and refinement data are given in Table 1. Selected single crystals were mounted on in a glass fiber or a capillary with perfluoroether oil, and aligned on a Siemens P4 diffractometer in a N_2 cold stream equipped with a scintillation counter (**2**) or a CCD area detector (**3**, **4**). Data collection for the determination of the unit cell as well as for the structure determination was performed at −80°C (**2**), using MoK_α radiation (λ = 0.71073 Å) and a graphite monochromator. Data reduction was performed with programs XSCANX Ver. 2.2 or SAINT Ver. 4 (Siemens Analytical Instruments), and structure solution with direct (**2**, **4**) or heavy atom methods (**3**). The SHELXL and SHELX93 programs were used for structure refinement (on F^2) and documentation. Non hydrogen atoms are presented in anisotropic description. Hydrogen atoms were placed in calculated positions and refined with fixed isotropic U using the riding model (**3**) or freely unfined (**2**, **4**). In case of compound **3** the atom H1 was found in the difference Fourier synthesis and was freely refined isotropically.

Keywords: Secondary carbaboranyldiphosphane / Transition-metal complexes / Crystal structure

When a mixture of stereoisomers of *rac*- and *meso*-1,2-bis(phenylphosphanyl)-1,2-dicarba-*closo*-dodecaborane(12) (**1a**, **b**; **1a/1b** = 3:1) is treated with $[Cp_2ZrMe_2]$ in boiling toluene for 2 h, the formation of three phosphorus-containing products, namely *meso*-$[Cp_2Zr(PPh)_3]$ (**3**), $(PPh)_4$ (**4**) and $(PPh)_5$ (**5**), ratio 2.8:1.1:1.0, was observed by ^{31}P-NMR spectroscopy. In the ^{11}B-NMR spectrum of the reaction mixture, only signals for 1,2-dicarba-*closo*-dodecaborane(12) were observed. When zirconocene, prepared in situ from $[Cp_2ZrCl_2]$ and BuLi, was treated with **1a**, **b** at low temperature and then heated to reflux in toluene for 2 h, only formation of **3** and 1,2-dicarba-*closo*-dodecaborane(12) was observed. The mixture of stereoisomers of **1a**, **b** reacts with CuCl in THF to give *rac*- and *meso*-[CuCl(THF){1,2-$(PHPh)_2C_2B_{10}H_{10}$}] (**7a**, **b**), which is only stable in THF solution and loses THF in vacuo over several hours to yield the insoluble colorless complex $[CuCl\{1,2\text{-}(PHPh)_2C_2B_{10}H_{10}\}]_n$ (**8**). In THF solution, **7** reacts with PPh_3 to give the stable isolable complex $[CuCl(PPh_3)\{1,2\text{-}(PHPh)_2C_2B_{10}H_{10}\}]$ (**9**). No reaction of **1a**, **b** is observed with $[Cp'Mo(CO)_3]_2$ ($Cp' = C_5H_4Me$) in boiling THF, while only decomposition occurs in boiling toluene. However, [(NBD)Mo(CO)$_4$] (NBD = norbornadiene) reacts smoothly with **1a** in toluene at room temperature to give *cis*-*rac*-$[Mo(CO)_4\{1,2\text{-}(PHPh)_2C_2B_{10}H_{10}\}]$ (**10**). Compounds **7**, **9**, and **10** were characterized spectroscopically (^{1}H, ^{31}P, ^{11}B, ^{13}C NMR, IR), and an X-ray structure determination was carried out on **10**.

Organo-element and organic derivatives of dicarba-*closo*-dodecaboranes(12) have received increasing attention during the last decade due to their interesting chemical and physical properties. Thus, these compounds have been employed as catalysts[1][2], as doping reagents in semiconductor materials[3], as precursors for ceramic materials[4], and in medical areas[5][6][7]. Hence applications in medicine can be envisioned for related carbaboranylphosphanes and their transition-metal complexes[8].

While tertiary phosphanyl derivatives of dicarba-*closo*-dodecaboranes(12), which were first reported in 1963[9], have been employed as ligands in transition-metal chemistry and as starting materials for the preparation of other *closo*-carbaborane(12)-containing organophosphorus compounds[10], their secondary analogues have remained largely unexplored[11]. We have recently reported the synthesis and spectroscopic properties of the first secondary bis(phosphanyl)carbaboranes, *rac*- and *meso*-1,2-bis(phenylphosphanyl)-1,2-dicarba-*closo*-dodecaborane(12) (**1a**, **1b**), as well as the molecular structure of the *rac* isomer **1a**[12].

We now report reactions and coordination properties of **1a**, **b** towards transition-metal complexes.

Results and Discussion

Reactions of 1,2-Bis(phenylphosphanyl)-1,2-dicarba-*closo*-dodecaborane(12) (1)

We have studied the reaction of a mixture of stereoisomers of *rac*- and *meso*-1,2-bis(phenylphosphanyl)-1,2-dicarba-*closo*-dodecaborane(12) [**1** (mixture of stereoisomers), **1a** (*rac*), **1b** (*meso*)][12] with various transition-metal complexes, i.e., $[Cp_2ZrMe_2]$ ($Cp = C_5H_5$), $[Cp_2ZrCl_2]$/BuLi, CuCl, $[Cp'Mo(CO)_3]_2$ ($Cp' = C_5H_4Me$) and [(NBD)Mo(CO)$_4$] (NBD = norbornadiene) (Scheme 1). As already observed in the reaction of **1** with sulfur[12], the chemical reactivity of **1** differs markedly from that of comparable carbaboranyldiphosphanes with tertiary phosphanyl groups or alkyl- or aryl-substituted secondary diphosphanes. In the case of dimethylzirconocene, the course of reaction is similar to that observed with the primary phosphane $PhPH_2$[13].

Reaction of 1a, b with Dimethylzirconocene or Zirconocene

When a mixture of stereoisomers of **1** (**1a/1b** = 3:1) was treated with dimethylzirconocene in boiling toluene for 2 h (Scheme 1), the formation of three phosphorus-containing products − *meso*-$[Cp_2Zr(PPh)_3]$ (**3**)[13][14], $(PPh)_4$ (**4**)[15], and $(PPh)_5$ (**5**)[16] (ratio 2.8:1.1:1.0) − was observed by ^{31}P-NMR spectroscopy. The ^{1}H-NMR spectrum of the reaction mixture showed the presence of unreacted dimethylzirconocene (ca. 75%). **3** was isolated in 23% yield (based on reacted dimethylzirconocene) and characterized by comparison of its NMR data with those reported in the literature[13][14]. In the ^{11}B-NMR spectrum of the reaction mixture, only signals for 1,2-dicarba-*closo*-dodecaborane(12) were observed. As **1** exhibits remarkable thermal stability (up to 195°C in undecane solution), the formation of the

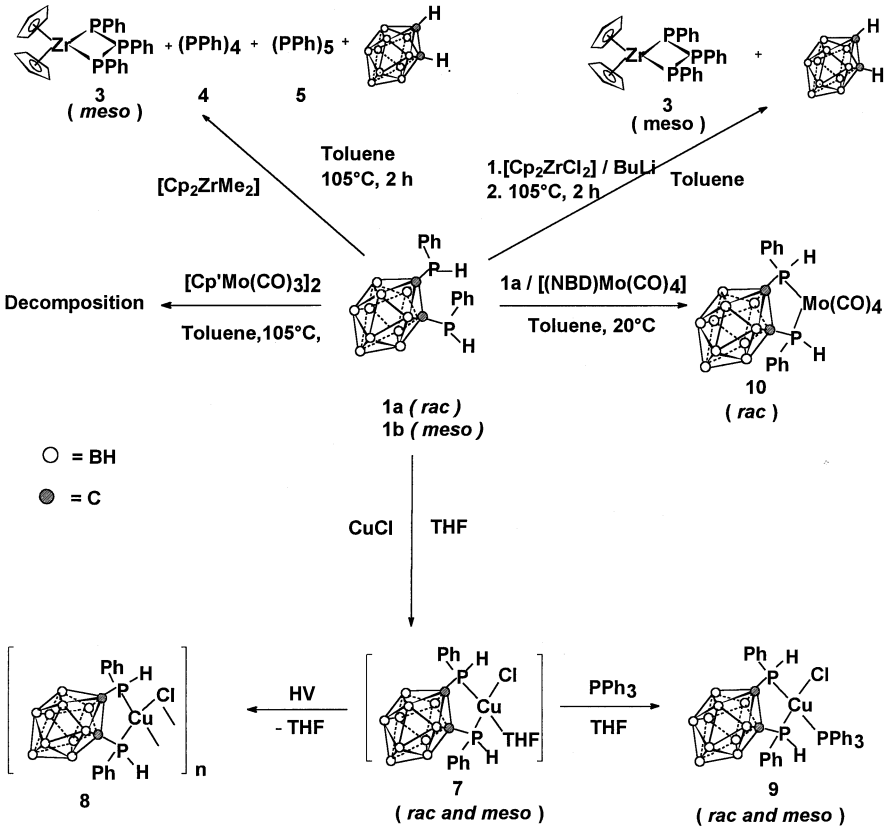
Scheme 1



observed products **3**−**5** and 1,2-dicarba-*closo*-dodecaborane(12) must be due to reaction with dimethylzirconocene rather than decomposition of **1**.

When a mixture of stereoisomers of **1** (**1a/1b** = 3:1) is treated with "zirconocene", prepared in situ from $[Cp_2ZrCl_2]$ and BuLi by the Negishi method[17], followed by 2 h reflux in toluene, formation of **3** and 1,2-dicarba-*closo*-dodecaborane(12) is observed (Scheme 1); the cyclo-oligophosphanes **4** and **5** are not formed. The course of the reaction was monitored by ^{31}P-NMR spectroscopy. At room temperature, the spectrum of the burgundy red solution exhibits two major resonances at $\delta = -2.0$ ($^1J_{PH}$ = 233 Hz) and $\delta = -2.6$ ($^1J_{PH}$ = 230 Hz), which may be due to the *rac* and *meso* isomers of the intermediate $[Cp_2Zr\{1,2\text{-}(PHPh)_2C_2B_{10}H_{10}\}]$ (**6**). On heating the solution to reflux for 2 h, the signals corresponding to **6** are replaced by those of **3** and two low-intensity signals at $\delta = -24$ and $\delta = -31$ from an as yet unknown compound. Apparently, **6** decomposes with elimination of 1,2-dicarba-*closo*-dodecaborane(12) and formation of **3** as the final product.

The fact that **4** and **5** are not formed suggests the involvement of a different intermediate in the reaction between dimethylzirconocene and **1** in refluxing toluene. A phosphanylidenezirconocene complex, which is the most likely intermediate, was not observed.

Reaction of 1a, b with Copper(I) Chloride

A mixture of stereoisomers of **1** (**1a/1b** = 3:1) reacts with copper(I) chloride in THF over 1 h to give a yellow solution, which we believe contains the THF adduct *rac*- and *meso*-$[CuCl(THF)\{1,2\text{-}(PHPh)_2C_2B_{10}H_{10}\}]$ (**7**) (Scheme 1, Table 1), based on NMR studies. **7** is only stable in THF solution and as a solid loses THF in vacuo over several hours to yield the insoluble colorless complex $[CuCl\{1,2\text{-}(PHPh)_2C_2B_{10}H_{10}\}]_n$ (**8**). The latter is comparable to $[CuCl\{1,2\text{-}(PPh_2)_2C_2B_{10}H_{10}\}]$[18], which was obtained from $CuCl_2$ and 1,2-bis(diphenylphosphanyl)-1,2-dicarba-*closo*-dodecaborane(12). In THF solution, **7** reacts with PPh_3 to give the stable isolable complex $[CuCl(PPh_3)\{1,2\text{-}(PHPh)_2C_2B_{10}H_{10}\}]$ (**9**) in 92% yield (Scheme 1). **9** is soluble in THF and toluene. In the ^{31}P-NMR spectrum, only two broad signals are observed for coordinated PPh_3 and **1**, and this is due to the quadrupole moment of Cu. In the ^{1}H-NMR spectrum, signals for the P−H protons and the phenyl (PH*Ph* and P*Ph*$_3$) ligands are observed in the ratio 2:10:15. In contrast to complex **7** and the free ligand **1**, signals corresponding to *rac*- and *meso*-**9** were not observed. In the ^{13}C-NMR spectrum, the C atoms of the carbaborane cluster appear as a multiplet at $\delta = 81.3$. Signals corresponding to coordinated PPh_3 are observed in the us-

[a] PPh_3. − [b] Observed splitting in virtual triplet.

ual range for PPh_3−CuCl complexes[18][19] (Table 1). Molecular-mass determination with a vapor-pressure osmometer showed **9** to be monomeric in solution (calcd. 722, found 724). In conclusion, the data given are in agreement with a tetrahedral structure for **9**, in which the bis(phosphanyl)carbaborane is coordinated in a chelating fashion (Scheme 1). According to the NMR data (Table 1), the THF adduct **7** has a similar structure. Due to the low solubility of **8**, attempts to determine the molecular structure in solution were unsuccessful. A comparison with the CuCl complexes [CuCl{1,2-$(PPh_2)_2C_2B_{10}H_{10}$}][18] and [CuCl{1-$(PPh_2)C_2B_{10}H_{11}$}$_2$]$_n$[20] suggests an oligomeric structure.

Reaction of 1a, b with Carbonylmolybdenum Complexes

The reaction of **1a**, **b** with carbonylmolybdenum complexes depends on the nature of the Mo complex employed (Scheme 1). Thus, in contrast to primary and secondary alkyl- and arylphosphanes[21], no reaction is observed with [Cp′Mo(CO)$_3$]$_2$ (Cp′ = C_5H_4Me) in boiling THF. In boiling toluene reaction did occur, but a complex mixture of products was formed that could not be separated, isolated, or characterized.

However, [(NBD)Mo(CO)$_4$] reacts smoothly with **1a** in toluene at room temperature to give *cis-rac*-[Mo(CO)$_4${1,2-$(PHPh)_2C_2B_{10}H_{10}$}] (**10**; Scheme 1) in 73% yield. In the solid state, **10** is air- and moisture-stable. In solution, however, **10** slowly decomposes on exposure to air.

Molecular Structure of *cis-rac*-[Mo(CO)$_4${1,2-$(PHPh)_2C_2B_{10}H_{10}$}] (10)

Single crystals of **10** were obtained from toluene/hexane solution at −5°C. **10** crystallizes in the centrosymmetric space group $P2_1/c$. The X-ray structure determination (Figure 1) shows that both enantiomers of the racemic isomer are present in the unit cell. The bis(phosphanyl)carbaborane is coordinated in a chelating fashion. The structural parameters of **1a**[12] remain almost unchanged on coordination to the Mo atom [$C_{cluster}$−$C_{cluster}$ 1.683(2) (**1a**), 1.681(3) Å (**10**); P−$C_{cluster}$ 1.8727(13) (**1a**), 1.873(2), 1.872(2) Å (**10**); P−C_{Ph} 1.8244(14) (**1a**), 1.815(2), 1.813(2) Å (**10**)]. A comparison of **10** with *cis*-tetracarbonyl{1,4-η^2-[1,2-dimethyl-1,2-bis(phenylphosphanyl)disilane]}molybdenum(0) (*cis-rac*-**11**)[22], the only other structurally characterized complex of an $Mo(CO)_4$ fragment with a coordinated secondary diphosphane ligand (Figure 2), shows that the Mo−P bond lengths [2.4445(6), 2.4559(6) Å (**10**); 2.550(1) Å (**11**)] and P−Mo−P bond angle [84.31(2) (**10**); 89.4(1)° (**11**)] of **10** are smaller.

For the Mo−CO groups *trans* to the coordinated P atoms, the Mo−C distances are larger [2.015(3), 2.017(3)Å (**10**); 1.994(4) Å (**11**)] and the C−O bond lengths shorter [1.139(3), 1.140(3)Å (**10**); 1.152(5) Å (**11**)] in **10**. Similar trends, that is, lengthening of the Mo−P and C−O bonds and shortening of the Mo−C bonds, are observed for the complexes [$Mo(CO)_4(PMePhR)_2$] (R = Me, Ph)[23], [$Mo(CO)_4${1,2-$(PPh_2)_2C_2H_4$}][24] and [$Mo(CO)_4${1,2-$(PPh_2)_2C_2H_2$}][25] (Table 2), which are similar to **11**. This suggests increased π-acceptor properties of the P atoms in **1a**, in comparison with other phenyl-substituted phosphanes or diphosphanes[29], due to the presence of the electron-deficient carbaboranyl ligand in **1a**[30]. Accordingly, in the IR spectrum the CO vibrations of **10** are shifted to higher wavenumbers by 10−20 cm^{-1} compared with other tetracarbonyl(diphosphane)- or -bis(phosphane)molybdenum complexes[26][27][28] (Table 2).

Discussion of ^{31}P- and ^{1}H-NMR Data of 1, 7, 9, and 10

The mixture of stereoisomers of **1a**, **b** exhibits ^{31}P- and ^{1}H-NMR spectra in which the signals of the *HP*−CC−*PH* group appear as multiplets corresponding to an AA′XX′ spin system[12]. Simulation of the ^{1}H-NMR spectra allowed the corresponding coupling constants to be calculated [**1a**: $^{1}J_{PH}$ = 244 Hz, $^{3}J_{PP}$ = 84 Hz; **1b**: $^{1}J_{PH}$ = 239 Hz, $^{3}J_{PP}$ = 87 Hz][31]. Similar coupling patterns were observed in the ^{1}H-NMR spectra of **7**, **9** and **10**. The P-P coupling of the P−C−C−P fragment was observed only in the ^{1}H-NMR

Figure 1. Molecular structure of *cis-rac*-[Mo(CO)$_4${1,2-(PHPh)$_2$C$_2$B$_{10}$H$_{10}$}] (**10**); only one of the present enantiomers (*R*,*R*) with its atom-numbering scheme is shown (SHELXTL PLUS; XP)[37][a]

***rac*-11**

spectra of **7** and **9**. For **10**, the coupling constant of the P−Mo−P fragment ($^2J_{PP}$ = 19 Hz) was observed in the ^{1}H-NMR spectrum[27]. However, due to line broadening in the proton-coupled ^{31}P-NMR spectra, only P-H coupling was observed for **9** and **10**, and for **7** only one broad signal ($\nu_{1/2} \approx 600$ Hz) was present. As expected, for all complexes the coupling constant $^1J_{PH}$ increases on coordination (Table 1).

Conclusions

The reaction of the recently reported 1,2-bis(phenylphosphanyl)-1,2-dicarba-*closo*-dodecaborane(12) (**1a, b**)[12] with several transition-metal complexes is dependent on the metal and the complex employed (Scheme 1). With electron-poor zirconocene derivatives, reactions similar to those of primary phosphanes are observed[13]. In contrast, the electron-rich compounds CuCl and [(NBD)Mo(CO)$_4$] react with formation of the chelate complexes **7** and **10**, respectively. In vacuum **7** loses THF in the solid state and oligomerizes. With PPh_3, the stable monomeric complex **9** is obtained. In **10**, the carbaboranylbis(phosphane) ligand exhibits a higher π-acceptor ability compared to other diphosphanes in complexes of Mo(CO)$_4$, due to the presence of the electron-deficient carbaboranyl fragment.

We gratefully acknowledge support from the *Fonds der Chemischen Industrie. Chemetall GmbH* has provided a generous donation of alkyllithium compounds. F. S. thanks the *Alexander-von-Humboldt-Stiftung* for a fellowship.

Experimental Section

All experiments were carried out under purified dry argon. Solvents were dried and freshly distilled under argon. − The NMR spectra were recorded with an AVANCE DRX 400 spectrometer (Bruker); ^{1}H NMR: internal standard solvent (benzene), external standard TMS; ^{13}C NMR: external standard TMS, internal standard solvent; ^{31}P NMR: external standard 85% H_3PO_4; ^{11}B NMR: external standard $BF_3 \cdot Et_2O$. − The IR spectra were recorded with an FT-IR spectrometer Perkin-Elmer System 2000 in the range of 350−4000 cm^{-1}. − Molecular-mass determination: Vapour Pressure Osmometer (Knauer), in $CHCl_3$ at 35°C. − X-ray structural analysis: Siemens SMART CCD diffractometer. − The melting points were determined in sealed capillaries under argon and are uncorrected. − [Cp_2ZrMe_2][32], [Cp_2ZrCl_2][33], [Cp′Mo(CO)$_3$]$_2$[34]

[a] *rac* isomer. − [b] *meso* isomer.

and [(NBD)Mo(CO)$_4$][35] were prepared by literature procedures. 1,2-Bis(phenylphosphanyl)-1,2-dicarba-*closo*-dodecaborane(12) (**1**) was prepared as described earlier[12]. CuCl and PPh_3 are commercially available.

Reaction of **1** *with Dimethylzirconocene:* A mixture of stereoisomers of **1** (1.2 g, 3.33 mmol, **1a/1b** = 3:1) and dimethylzirconocene (0.84 g, 3.35 mmol) were heated in toluene (20 ml) at 105°C for 2 h. After allowing the mixture to cool to room temperature, the solvent was distilled off. The resulting residue was characterized by ^{1}H-,^{11}B- and ^{31}P-NMR spectroscopy. *meso*-[$Cp_2Zr(PPh)_3$] (**3**) was isolated by washing the residue with hexane and ether, and then dissolving it in toluene. Filtration and cooling the solution to −30°C gave 0.4 g of **3** (23% based on [Cp_2ZrMe_2]). The spectroscopic data of **3** are in agreement with those reported previously[13][14].

Reaction of **1** *with Zirconocene Dichloride/BuLi:* At −80°C, BuLi in hexane (2 equiv.) was added slowly to a suspension of [Cp_2ZrCl_2] (0.29 g, 1.15 mmol) in toluene (10 ml) to generate "zirconocene" in situ. The mixture was stirred at −80°C for 1 h, then at −50°C for 15 min. The mixture was quickly brought to 20°C and a solution of **1** (0.35 g, 0.97 mmol, **1a/1b** = 3:1) in toluene (15 ml) was added. Samples for ^{11}B- and ^{31}P-NMR studies were taken after stirring the reaction mixture for 4 h at room temperature and for 2 h at 105°C.

Reaction of **1** *with CuCl. − [1,2-Bis(phenylphosphanyl)-1,2-dicarba-closo-dodecaborane(12)](tetrahydrofuran)copper(I) Chloride* (**7**) *and [1,2-Bis(phenylphosphanyl)-1,2-dicarba-closo-dodecaborane(12)]copper(I) Chloride* (**8**): A mixture of **1** (0.93 g, 2.58 mmol, **1a/1b** = 3:1) and CuCl (0.2 g, 2.22 mmol) in THF (25 ml) was stirred at room temperature for 1 h. The solvent was then removed from the clear yellow solution in vacuo to give a yellow solid (presumably the THF adduct **7**) which turned colorless after 2 h in vacuo, giving the final product **8**. The solid was washed with THF, toluene, and ether to give 0.78 g (76%) of **8**; dec. 267°C. − IR (KBr): $\tilde{\nu}$ = 3055 cm^{-1} (ν C−H), 2579 (ν B−H), 2350 (ν P−H). − $C_{14}H_{22}B_{10}ClCuP_2$ (459.39): calcd. C 36.60, H 4.83, Cl 7.72; found C 37.25, H 4.71, Cl 7.59. − **7** was characterized in [D_8]THF solution by ^{31}P-, ^{1}H- and ^{11}B-NMR spectroscopy (Table 1).

Reaction of **1** *with CuCl and PPh$_3$. − [1,2-Bis(phenylphosphanyl)-1,2-dicarba-closo-dodecaborane(12)](triphenylphosphane)copper(I) Chloride* (**9**): A mixture of **1** (0.7 g, 1.94 mmol, **1a/1b** = 3:1) and CuCl (0.19 g, 1.92 mmol) in THF (25 ml) was stirred at room temperature for 1 h. PPh_3 (0.5 g, 1.91 mmol) was added and the mixture stirred for 16 h. After filtration, the solvent was removed by distillation to give 1.28 g (92%) of **9** which can be recrystallized from THF/toluene; m.p. 218−219°C. − $C_{32}H_{37}B_{10}ClCuP_3$ (721.68): calcd. C 53.26, H 5.17, Cl 4.91; found C 53.55, H 5.17, Cl 5.59.

[1,2-Bis(phenylphosphanyl)-1,2-dicarba-closo-dodecaborane(12)]tetracarbonylmolybdenum(0) (**10**): A mixture of **1a** (0.7 g, 1.94 mmol) and [(NBD)Mo(CO)$_4$] (0.6 g, 1.93 mmol) in toluene (30 ml) was stirred at room temperature for 20 h. The solvent was removed in vacuo and the resulting solid was recrystallized from toluene/hexane (20 ml/10 ml). At −5°C crystals of **10** were obtained. Yield 0.8 g (73%); dec. 252−254°C. − $C_{18}H_{22}B_{10}MoO_4P_2$ (568.34): calcd. C 38.04, H 3.90; found 38.70, H 4.18.

Data Collection and Structural Refinement of **10**[36]: Data (Mo-K_α, λ = 0.71073 Å) were collected with a Siemens CCD (SMART). All observed reflections (2Θ range: 2−52°) were used for determination of the unit-cell parameters. The structures were solved by direct methods (SHELXTL PLUS[37]) and subsequent difference Fourier syntheses, and refined by full-matrix least squares on F^2 (SHELXTL PLUS[37]). Mo, O, P, B, and C atoms refined anisotropically, H atoms located and refined isotropically. Empirical absorption correction with SADABS[38]. − Crystal data: $C_{18}H_{22}B_{10}MoO_4P_2$, M = 568.34, white crystals, 0.4 × 0.3 × 0.2 mm, monoclinic, space group $P2_1/c$ (no. 14), T = 293(2) K, a = 22.012(1), b = 6.8393(4), c = 18.657(1) Å, β = 111.978(1)°, V = 2604.7(3) Å^3, Z = 4, $D_{calcd.}$ = 1.449 Mg m^{-3}, F(000) = 1136, μ(Mo-K_α) = 0.651 mm^{-1}, 11162 reflections collected with 1° < Θ < 26°; 4622 of these were independent; 404 parameters, *GOOF* = 1.100, residual electron density 0.321/−0.474 Å^{-3}, refinements converge to $R1$ = 0.0284, $wR2$ = 0.0734 [for reflections with $I > 2\sigma(I)$], $R1$ = 0.0335, $wR2$ = 0.0766 (all data).

Keywords: Cadmium / Crown compounds / Pentafluorophenyl / Potassium / S ligands

Bis(pentafluorophenyl)cadmium, $[Cd(C_6F_5)_2]$, reacts with equimolar amounts of triphenylmethanethiol, TrtSH, in toluene to give $[\{Cd(C_6F_5)(STrt)\}_4] \cdot 1.5$ tol (**1**). The cuboidal complex of **1** has been transformed into the heterometallic cuboidal complex $[\{Cd(C_6F_5)(STrt)\}_3(OH)K(THF)_3]$ (**2**) by reaction with KOH in tetrahydrofuran. In the presence of 18-crown-6, the compound $[K(18\text{-crown-6})(THF)_2][\{Cd(C_6F_5)(STrt)\}_3(OH)] \cdot THF$ (**3**) has been obtained instead of **2**. X-ray structure analysis shows the anion of **3** to be an incomplete cuboidal complex, which alternatively can be described as a cyclic trimer of the $\{Cd(C_6F_5)(STrt)\}$ unit stabilized by a μ_3-hydroxo ligand. The compound $[K(18\text{-crown-6})(THF)_2][Cd(C_6F_5)(STrt)_2]$ (**4**) has been isolated from reaction mixtures containing **1**, KSTrt and 18-crown-6. The cadmium atom in **4** is three-coordinated, in contrast to the cadmium atoms in **1**−**3**, which are situated in strongly distorted coordination tetrahedra. Intramolecular $C_6H_5\cdots C_6F_5\cdots C_6H_5$ stacks in **4** are interpreted as resulting from attractive ligand−ligand interactions. Spectroscopic data, particularly from ^{13}C-NMR and IR spectra, are consistent with the order of ligand deficiency: **1** > **2** > **3** > **4**. The macrocyclic, eight-coordinate complex $[K(18\text{-crown-6})(THF)_2]^+$ in **3** and **4** contains *trans* arranged THF ligands.

Metal complexes having an overall donor-to-metal ratio which is smaller than the typical coordination number adopted with the respective donors can be termed "ligand-deficient"[1]. Ligand deficiency is accompanied by low coordination numbers and/or the formation of oligomeric species with bridging ligands, and − most important − by the tendency to bind additional ligands[2]. Of course, the simple arithmetic of this concept is only useful, if the reactivity is not determined by other factors such as metal−metal bonding or the character of the metal−ligand bonds.

We found that bis(pentafluorophenyl)cadmium, $[Cd(C_6F_5)_2]$, is a suitable starting material for the synthesis of ligand-deficient chalcogenolato complexes of the general formula $[Cd_n(C_6F_5)_{2n-p}(ER)_p]$ (E = O or S; R = alkyl, aryl)[1][3]. A convenient method for the preparation of $[Cd(C_6F_5)_2]$ by thermal decarboxylation of $Cd(O_2CC_6F_5)_2$ has been described by Schmeißer and Weidenbruch[4]. Crystals of $[Cd(C_6F_5)_2]$ consist of two-coordinate monomers, as shown by X-ray structure determination[5]. Protolysis reactions with alcohols and thiols according to Eq. 1 allowed the syntheses of several new multinuclear complexes, most of which were also characterized by X-ray crystal structure analysis[1][3][6].

$$n\,[Cd(C_6F_5)_2] + p\,REH \rightarrow [Cd_n(C_6F_5)_{2n-p}(ER)_p] + p\,C_6F_5H \quad (1)$$

One of these complexes is $[\{Cd(C_6F_5)(STrt)\}_4]$ [Trt = triphenylmethyl ("trityl")], whose preparation and typical ligand-deficient behaviour towards the nucleophiles HO^- and $TrtS^-$ are described in this paper. The crystal structures of the resulting degradation products, a tri- and a mononuclear complex, respectively, are presented.

Syntheses

Starting from $[Cd(C_6F_5)_2]$, we have studied various reactions, which are shown in Schemes 1 and 2. The partial protolysis of $[Cd(C_6F_5)_2]$ with triphenylmethanethiol (TrtSH) in toluene (Eq. 2) yields $[\{Cd(C_6F_5)(STrt)\}_4] \cdot 1.5$ tol (**1**). X-ray structure analysis has revealed that **1** contains a cuboidal $\{Cd_4(\mu_3\text{-}SR)_4\}^{4+}$ core, which is structurally very similar to that of the already described *t*BuS$^-$ analogue[1]. The X-ray structure of **1** is therefore not included here, but will be detailed in a forthcoming paper together with the structure of the *di*nuclear alkoxo complex $[\{Cd(C_6F_5)(OTrt)\}_2]$[6].

1 exhibits the characteristic reactivity of a ligand-deficient complex towards potential ligands. It is degraded to the trinuclear complex $[\{Cd(C_6F_5)(STrt)\}_3(OH)]^-$ by reaction with the appropriate amount of hydroxide (Eqs. 3 and 4). The potassium hydroxide used in this reaction must be prepared in situ from potassium metal and water to be sufficiently reactive. Depending on whether or not 18-crown-6 has been added, $[K(18\text{-crown-6})(THF)_2][\{Cd(C_6F_5)(STrt)\}_3(OH)] \cdot THF$ (**3**) or $[\{Cd(C_6F_5)(STrt)\}_3(OH)K(THF)_3]$ (**2**), respectively, can be isolated. The anion of **3** is an incomplete cuboidal complex (see Scheme 2), whose structure will be discussed below. The structure of **2** has been unambiguously established from single-crystal X-ray diffraction data.

Scheme 1

$$4\,[Cd(C_6F_5)_2] + 4\,TrtSH \xrightarrow[-4\,C_6HF_5]{\text{toluene}} [\{Cd(C_6F_5)(STrt)\}_4]\cdot 1.5\,tol \quad (2)$$

1

$$3\,[\{Cd(C_6F_5)(STrt)\}_4] + 4\,KOH \xrightarrow{THF} 4\,[\{Cd(C_6F_5)(STrt)\}_3(OH)K(THF)_3] \quad (3)$$

2

$$3\,[\{Cd(C_6F_5)(STrt)\}_4] + 4\,KOH + 4\,18\text{-crown-6} \xrightarrow{THF} 4\,[K(18\text{-crown-6})(THF)_2][\{Cd(C_6F_5)(STrt)\}_3(OH)]\cdot THF \quad (4)$$

3

$$[\{Cd(C_6F_5)(STrt)\}_3(OH)K(THF)_3] + 18\text{-crown-6} \xrightarrow{THF} [K(18\text{-crown-6})(THF)_2][\{Cd(C_6F_5)(STrt)\}_3(OH)]\cdot THF \quad (5)$$

3

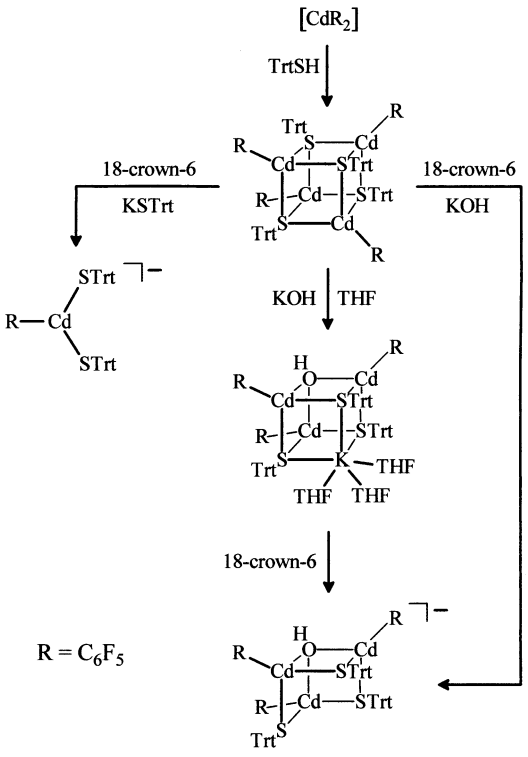
$$0.5\,[\{Cd(C_6F_5)(STrt)\}_4] + KSH + 18\text{-crown-6} \xrightarrow[-C_6HF_5]{THF} [K(18\text{-crown-6})(THF)_2][Cd(C_6F_5)(STrt)_2] + CdS\downarrow \quad (6)$$

4

$$[\{Cd(C_6F_5)(STrt)\}_4] + 4\,KSTrt + 4\,18\text{-crown-6} \xrightarrow[\text{toluene}]{THF/} 4\,[K(18\text{-crown-6})(THF)_2][Cd(C_6F_5)(STrt)_2] \quad (7)$$

4

Scheme 2



Unfortunately, the crystal quality was low, and thus the structure determination does not meet the usual standards. Therefore, only some basic crystal data are given here (see Experimental Section). **2** can be transformed into **3**: the $\{K(THF)_3\}^+$ group is removed by addition of 18-crown-6 (Eq. 5).

Interestingly, the reaction of **1** with monohydrogensulphide differs strongly from that with hydroxide. The SH^- ends up completely as cadmium sulphide (Eq. 6). We have already noticed the same type of different behaviour between H_2S and H_2O when reacted with $[Cd(C_6F_5)_2]$. With H_2S the only isolable product is CdS[1], while the partial hydrolysis of $[Cd(C_6F_5)_2]$ yields $[\{Cd(C_6F_5)(OH)\}_4]$, which could be isolated and structurally characterized by Weidenbruch et al.[7]. The second product in Eq. 6, namely the new compound $[K(18\text{-crown-6})(THF)_2][Cd(C_6F_5)(STrt)_2]$ (**4**), is more conveniently prepared from **1**, KSTrt and 18-crown-6 according to Eq. 7. The compounds **1**−**4** decompose on exposure to air, **4** apparently being most sensitive.

It is worth noting, that triphenylmethanethiolate has rarely been used as a sterically hindered ligand[8], especially when the wealth of data on bulky *aromatic* thiolate ligands is considered[9]. The main reason for this seems to be the fear, that C−S bond cleavage may occur. The C−S bonds of aliphatic thiols are in fact weaker than those of aromatic thiols. In some cases, C−S scission reactions have even led to isolable sulfido complexes[10]. However, in the syntheses of the compounds **1**−**4** the use of triphenylmethanethiol-(ate) has been found unproblematic[11].

Spectroscopic Properties

The ^{13}C-NMR spectra reflect the decrease of ligand deficiency, i. e. the decreasing electronic stress of the thiolate ligands, in the sequence **1**→**2**→**3**→**4**. The signal of the α-C atoms of the $TrtS^-$ groups is found at δ = 74.20 (**1**), 65.78 (**2**), 63.81 (**3**), and 63.30 (**4**), respectively. The chemical-shift difference between **2** and **3** may indicate, that for **2** the coordination of $\{K(THF)_3\}^+$ by the $[\{Cd(C_6F_5)(STrt)\}_3(OH)]^-$ anion, as found in the solid state, is retained in solution. However, the influence of the different solvents is difficult to estimate (**2**: C_6D_6, **3**: $CDCl_3$). A clear, but reverse trend is also observed for the *ipso*-C atoms of the $TrtS^-$ ligands: δ = 147.0 (**1**), 149.8 (**2**), 150.1 (**3**), and 153.6 (**4**), respectively. The remaining ^{13}C-NMR signals of the phenyl groups were found to be relatively insensitive to the coordi-

nation mode of the $TrtS^-$ ligand (μ_3, μ_2 or terminal). They span ranges of less than 2.0 ppm each.

The C_6F_5 ligands are terminally coordinated in all four compounds. Here, some less pronounced trends of the spectroscopic properties are observed: (i) for the ^{19}F-NMR signal of the *para*-F atom: $\delta = -156.7$ (**1**), -158.0 (**2**), and -160.4 (**3** and **4**), respectively, and (ii) for the C−F stretching frequency in the IR spectra: 954 (**1**), 949 (**2**), 948 (**3**), and 945 cm^{-1} (**4**), respectively. For the educt $[Cd(C_6F_5)_2]$ the C−F stretching vibration has been observed at 956 cm^{-1} [4]. A dependence of ν(C−F) on the metal oxidation state has been reported for pentafluorophenyl complexes of palladium and platinum: M^{IV} 968 ± 3, M^{II} 955 ± 6, and M^{I} 946 ± 6 cm^{-1} [12]. Thus, an increase in ligand deficiency shifts ν(C−F) into the same direction as an increasing oxidation state of the coordination centre does − in accordance with chemical intuition.

In the $TrtS^-$ ligands of **4** two types of *ortho*-H atoms can be distinguished by ^1H-NMR spectroscopy. Their intensity ratio of 2:1 is consistent with a structure that possesses an intramolecular $C_6H_5\cdots C_6F_5\cdots C_6H_5$ stack as observed in the solid state and discussed below.

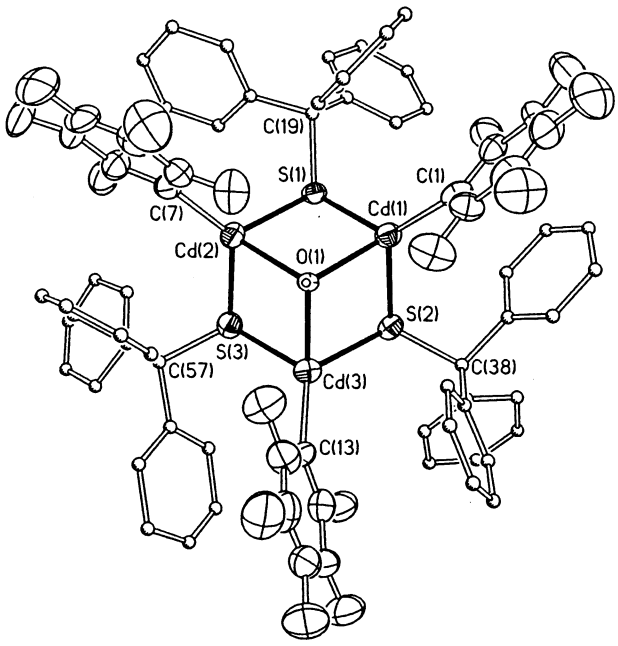
X-ray Crystal Structures of 3 and 4

Crystals of **3** consist of $[\{Cd(C_6F_5)(STrt)\}_3(OH)]^-$ complexes, $[K(18\text{-crown-}6)(THF)_2]^+$ counterions and non-coordinating THF molecules. The trinuclear cadmium complex is shown in Figure 1. It can be regarded as a cyclic trimer of the $\{Cd(C_6F_5)(STrt)\}$ unit stabilized by a μ_3-hydroxo ligand. An alternative description is that of an incomplete cuboidal complex. As shown in Scheme 2, this complex can actually be prepared by removal of the $\{K(THF)_3\}^+$ corner from the heterometallic cuboidal complex $[\{Cd(C_6F_5)(STrt)\}_3(OH)K(THF)_3]$ (**2**). A structurally related, but homoleptic trinuclear complex has been described, namely $[Cd_3\{SC_6H_2(iPr)_3\text{-}2,4,6\}_7]^-$ [13].

The $[\{Cd(C_6F_5)(STrt)\}_3(OH)]^-$ complex in **3** closely approaches C_3 symmetry. Its central, chair-like Cd_3S_3 ring is strongly puckered, the metal part being contracted by the small μ_3-OH^- ligand. This contraction becomes obvious by comparison with the situation in $[\{Cd(C_6F_5)(STrt)\}_4]$ [6]: for **3** a shortening of the mean Cd···Cd distance (**3**: 3.57 Å) by 0.36 Å, an increase of the mean S−Cd−S angle by 9°, and a decrease of the mean Cd−S−Cd angle by 7° are observed. The coordination tetrahedra around the cadmium atoms are severely distorted with bond angles ranging from 87.6° for S−Cd−O to 130.4° for S−Cd−C (mean values). As may be expected from the different coordination modes of the thiolate, in **3** the mean Cd−S bond length (2.56 Å) is smaller than in **1** (2.65 Å), but larger than in **4** (2.467(1) Å) and in $[Cd(STrt)_2(tmeda)]$ (2.44 Å) [8b], where the ligands are terminally bonded.

Crystals of **4** are composed of $[Cd(C_6F_5)(STrt)_2]^-$ anions and $[K(18\text{-crown-}6)(THF)_2]^+$ cations. The cadmium complex (see Figure 2) is situated on a crystallographic twofold axis of rotation, which passes through the atoms Cd, C(1), C(4), and F(3). To our knowledge, $[Cd(C_6F_5)(STrt)_2]^-$ is the first cadmium complex reported to have an S_2C donor

Figure 1. View of the complex $[\{Cd(C_6F_5)(STrt)\}_3(OH)]^-$ in crystals of **3**; the hydrogen atoms of the thiolate ligands have been omitted for clarity; thermal ellipsoids are drawn with 30% probability[a]

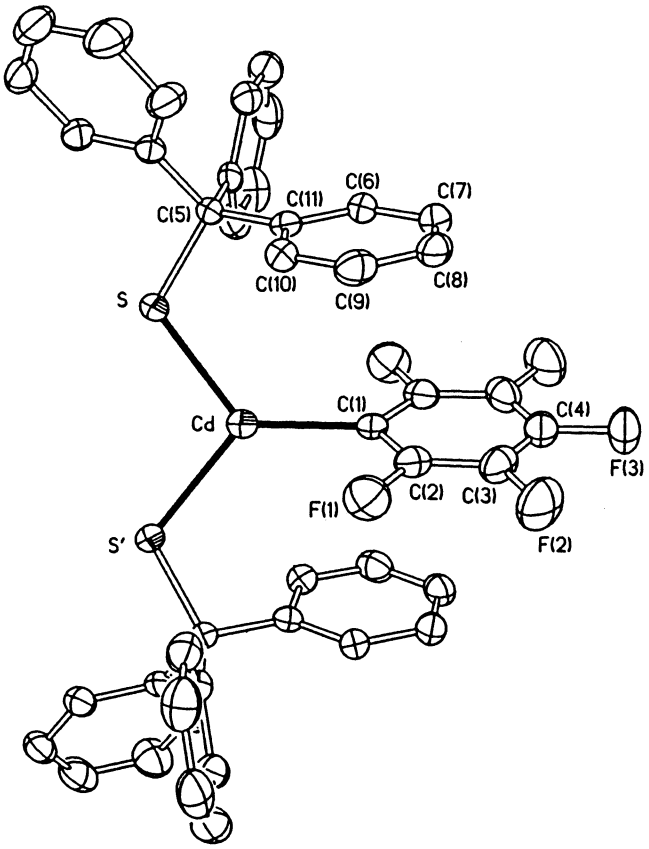


[a] Selected bond lengths [Å] and angles [°], mean values in brackets: Cd(1)−S(1) 2.542(3), Cd(1)−S(2) 2.586(3), Cd(2)−S(1) 2.568(3), Cd(2)−S(3) 2.545(3), Cd(3)−S(2) 2.563(3), Cd(3)−S(3) 2.583(3), Cd(1)−O(1) 2.395(6), Cd(2)−O(1) 2.408(7), Cd(3)−O(1) 2.368(7), Cd(1)−C(1) 2.16(1), Cd(2)−C(7) 2.18(1), Cd(3)−C(13) 2.20(1), S(1)−C(19) 1.87(1), S(2)−C(38) 1.89(1), S(3)−C(57) 1.87(1), S−Cd−S 90.91(9)−95.16(9) [93.0], S−Cd−O 86.0(2)−88.5(2) [87.6], S−Cd−C 126.1(3)−135.4(3) [130.4], O−Cd−C 111.4(4)−114.3(4) [113.1], Cd−S−Cd 87.4(1)−88.76(9) [88.2], Cd−O−Cd 95.7(3)−98.2(3) [96.6].

set [14][15]. The observed bond lengths and angles at the Cd atom are unexceptional. There is, however, a striking structural features of this complex, namely the mutual orientation of the trityl groups and the pentafluorophenyl ligand. The C_6H_5 ring containing the C atoms C(6) to C(11) and the symmetry related one in the same complex are arranged above and below the C_6F_5 group. A $C_6H_5\cdots C_6F_5\cdots C_6H_5$ intramolecular stack results, in which the plane of the C_6F_5 group forms an angle of 4.6° with each of the C_6H_5 planes. The atom C(1) lies nearly perpendicular over the centroid of the C_6 ring of the phenyl group (deviation: ca. 1.0°). The C(1)···centroid distance is 3.37 Å.

The alternating stacking in complexes between polyfluorinated and non-fluorinated aromatic molecules is a well-known structural phenomenon in organic chemistry. Dahl has studied a number of such molecular complexes containing hexafluorobenzene as the fluorinated component [16]. He has reported mean interplanar distances in the stacks ranging from 3.39 to 3.56 Å. These values correspond approximately to the van der Waals thickness of typical aromatic molecules of 3.4 Å [17]. When viewed perpendicular to the ring planes, a slipped orientation of adjacent rings is usually observed. This is also true for the $C_6H_5\cdots C_6F_5$ pairs in **4**. The close structural similarity to the molecular complex *p*-xylene−hexafluorobenzene [18] is shown in Figure 3. Recent

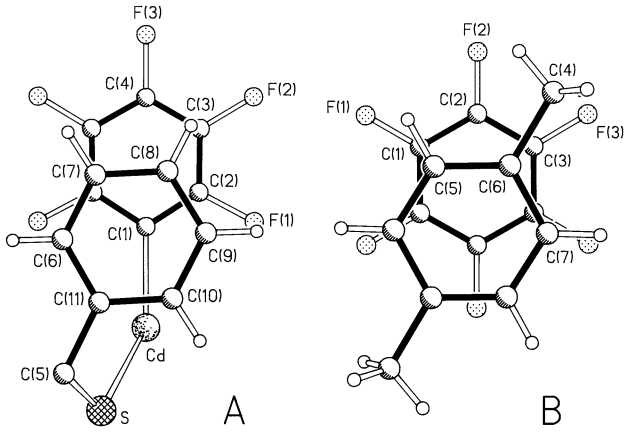
Figure 2. View of the complex $[Cd(C_6F_5)(STrt)_2]^-$ in crystals of **4**; hydrogen atoms have been omitted for clarity; thermal ellipsoids are drawn with 30% probability[a]



[a] Selected bond lengths [Å] and angles [°]: Cd−S 2.467(1), Cd−C(1) 2.180(6), S−C(5) 1.876(4), S−Cd−S′ 103.39(5), S−Cd−C(1) 128.31(3), Cd−S−C(5) 111.7(1).

results indicate, that the attractive forces between polyfluorinated and non-fluorinated aromatic molecules are largely electrostatic in nature[19].

Figure 3. The slipped parallel arrangement of aromatic rings in $[Cd(C_6F_5)(STrt)_2]^-$ (A) and in the *p*-xylene−hexafluorobenzene molecular complex[18] (B); the mean C_6 planes of the fluorine-containing groups are exactly parallel to the projection plane; small circles represent hydrogen atoms.



We believe, that attractive interligand interactions are the most probable cause of the $C_6H_5\cdots C_6F_5\cdots C_6H_5$ stacking in **4**. No other *intra*molecular causes can be recognized. In fact, the sterical demand of the thiolate ligands should favour other arrangements, especially those with one trityl group above and the other below the $CdS_2C(1)$ plane. The possibility cannot be ruled out, however, that packing forces contribute to determine the observed structure. Regarding the expected weakness of $C_6H_5\cdots C_6F_5$ interactions[19b][20], the ^{1}H-NMR results on **4** (see above) should not be interpreted as a proof, but merely as a possible indication of aromatic-ring stacking in solution. Intramolecular stacks of phenyl and pentafluorophenyl groups are also observed in crystals of the compounds **1**−**3** (cf. Figure 1). In these cases, it cannot be decided whether or not these arrangements are enforced by sterical crowding. The face-to-face orientation of C_6H_5 and C_6F_5 groups in metal complexes is not particularly rare, though it has mostly been neglected in structure discussions. The Cambridge Structural Database (CSD)[14] contains ca. 30 examples where in metal coordination spheres attractive interactions of the type described above seem possible. A detailed analysis is, however, beyond the scope of this paper.

In both **3** and **4**, the cationic part is formed by the macrocyclic complex $[K(18\text{-crown-}6)(THF)_2]^+$. The CSD[14] lists four other structures containing this complex[21]. The metal ion in $[K(18\text{-crown-}6)(THF)_2]^+$ is in an O_8 environment, the THF ligands being in *trans* position. The mean K−O(macrocycle) bond lengths are 2.79 (**3**) and 2.80 Å (**4**), respectively. Due to disorder of the THF ligands in both compounds, the K−O(THF) bond lengths are less accurate. Their mean values are 2.78 (**3**) and 2.76 Å (**4**), respectively.

This work was supported by the *Deutsche Forschungsgemeinschaft* and the *Fonds der Chemischen Industrie*. We are indebted to Prof. *H. Vahrenkamp* for the ^{19}F-NMR spectra and to Mr. *W. Saak* for collecting the diffraction data

Experimental Section

General: Bis(pentafluorophenyl)cadmium was prepared from $Cd(O_2CC_6F_5)_2$ according to a literature method[4]. Triphenylmethanethiol (Merck) was treated with activated charcoal in boiling ethanol and recrystallized twice from diethyl ether prior to use. Tetrahydrofuran was pretreated with KOH and subsequently destilled from $LiAlH_4$ under nitrogen. Toluene and *n*-hexane were refluxed over Na/K alloy and destilled under nitrogen. All other commercially available chemicals were used as received. The cadmium complexes described below were prepared and handled under an atmosphere of dry nitrogen in a glove box; storage was also under dry nitrogen. − IR: Bio-Rad FTS 7PC and Beckman IR-4220. − ^{1}H and $^{13}C\{^1H\}$ NMR: Bruker AM-300, chemical shifts relative to TMS, solvent signal as internal reference in the ^{13}C-NMR spectra ($CDCl_3$: δ_c = 77.00, C_6D_6: δ_c = 128.00). ^{19}F NMR: chemical shifts relative to $CFCl_3$. Prior to use, all NMR solvents were treated with molecular sieves to remove water. − Elemental analyses: Mikroanalytisches Laboratorium Beller, D-37004 Göttingen, Germany. − *Caution!* Cadmium compounds are highly toxic and probably carcinogenic. Therefore they should be handled with care to avoid exposure.

[{Cd(C$_6$F$_5$)(STrt)}$_4$]·1.5 tol (**1**): 2.76 g (10.0 mmol) of triphenylmethanethiol, dissolved in 10 ml of toluene, was added to a solution of 4.47 g (10.0 mmol) of $[Cd(C_6F_5)_2]$ in 25 ml of toluene.

After some minutes, a white, microcrystalline precipitate of **1** started separating from the yellow solution. The product was isolated within the next hour (on prolonged standing, a brown colouring occurred), thoroughly washed with toluene and dried in vacuo. Yield: 5.42 g (92%), m.p. 145°C (dec.). – IR (KBr): $\tilde{\nu}$ = 954 cm^{-1} (s, CF). – ^{13}C NMR (75.5 MHz, $CDCl_3$): δ = 21.44 (tol), 74.20 (Ph_3C), 125.3 (tol), 127.2 (Ph-*para* in Ph_3C), 127.9 (Ph-*meta* in Ph_3C), 128.2 (tol), 129.0 (tol), 129.7 (Ph-*ortho* in Ph_3C), 137.9 (tol), 147.0 (Ph-*ipso* in Ph_3C)[22]. – ^{19}F NMR (188.3 MHz, $CDCl_3$): δ = −109.3 (m, 8 F, C_6F_5-*ortho*), −156.7 (m, 4 F, C_6F_5-*para*), −162.0 (m, 8 F, C_6F_5-*meta*). – $C_{110.5}H_{72}Cd_4F_{20}S_4$ (2357.7): calcd. C 56.29, H 3.08, Cd 19.07, F 16.12, S 5.44; found C 55.81, H 3.02, Cd 19.14, F 16.2, S 5.63.

[{Cd(C_6F_5)(STrt)}$_3$(OH)K(THF)$_3$] (**2**): 39 mg (1.0 mmol) of freshly cut potassium metal was added to a solution of 18 µl (1.0 mmol) of water in 8 ml of tetrahydrofuran. After stirring overnight, a suspension of potassium hydroxide had formed. Traces of unreacted potassium were removed. 1.77 g (0.75 mmol) of **1**, dissolved in 12 ml of tetrahydrofuran, was added. The reaction mixture was stirred until the potassium hydroxide had completely reacted. Then the clear, colourless solution was carefully layered with *n*-hexane in the reaction flask. After 2 d, colourless crystals of **2** had separated, which were isolated on a large-pored glass filter, washed with *n*-hexane and dried in vacuo. Yield 1.20 g (62%), m.p. 146−147°C. – IR (KBr): $\tilde{\nu}$ = 949 cm^{-1} (s, CF). – ^1H NMR (300 MHz, CD_3CN): δ = 1.80 (m, 12 H, CCH_2C), 2.11 (br., 1 H, OH), 3.65 (m, 12 H, CH_2O), 6.91−7.03 (m, 27 H, Ph-*meta* and -*para*), 7.14 ("d", 18 H, Ph-*ortho*). – ^{13}C NMR (75.5 MHz, C_6D_6): δ = 25.68 (CCH_2C), 65.78 (Ph_3C), 67.77 (CH_2O), 126.8 (Ph-*para*), 127.7 (Ph-*meta*), 129.9 (Ph-*ortho*), 149.8 (Ph-*ipso*)[22]. – ^{19}F NMR (188.3 MHz, C_6D_6): δ = −110.8 (m, 6 F, C_6F_5-*ortho*), −158.0 (m, 3 F, C_6F_5-*para*), −161.9 (m, 6 F, C_6F_5-*meta*). – Crystallographic data (23°C): monoclinic, space group $P2_1/n$, a = 15.07(1), b = 21.75(1), c = 25.49(1) Å, β = 90.89(5)°, V = 8354 Å^3, Z = 4, $\rho_{calcd.}$ = 1.540 gcm^{-3}. – $C_{87}H_{70}Cd_3F_{15}KO_4S_3$ (1937.0): calcd. C 53.95, H 3.64, Cd 17.41, F 14.71, K 2.02, S 4.97; found C 53.07, H 3.70, Cd 17.57, F 14.1, K 2.10, S 4.62.

[K(18-crown-6)(THF)$_2$][{Cd(C_6F_5)(STrt)}$_3$(OH)]·THF (**3**): *Method A*: In tetrahydrofuran, potassium hydroxide was prepared as described above for **2**, but with the addition of 264 mg (1.00 mmol) of 18-crown-6. To the suspension 1.77 g (0.75 mmol) of **1**, dissolved in 12 ml of tetrahydrofuran, was added. After the reaction mixture had become clear, it was diluted with 15 ml of toluene and then layered with *n*-hexane. **3** separated as a colourless, crystalline solid, which was isolated, washed with *n*-hexane and dried in vacuo. Yield 1.49 g (68%), m.p. 165−166°C. – IR (KBr): $\tilde{\nu}$ = 948 cm^{-1} (s, CF). – ^1H NMR (300 MHz, CD_3CN): δ = 1.80 (m, 12 H, CCH_2C), 2.12 (br., 1 H, OH), 3.56 (s, 24 H, 18-crown-6), 3.64 (m, 12 H, CH_2O in THF), 7.02−7.13 (m, 27 H, Ph-*meta* and -*para*), 7.32 ("d", 18 H, Ph-*ortho*). – ^{13}C NMR (75.5 MHz, $CDCl_3$): δ = 25.58 (CCH_2C), 63.81 (Ph_3C), 67.93 (CH_2O in THF), 70.18 (18-crown-6), 125.6 (Ph-*para*), 126.8 (Ph-*meta*), 129.7 (Ph-*ortho*), 150.1 (Ph-*ipso*)[22]. – ^{19}F NMR (188.3 MHz, $CDCl_3$): δ = −110.9 (m, 6 F, C_6F_5-*ortho*), −160.4 (m, 3 F, C_6F_5-*para*), −163.7 (m, 6 F, C_6F_5-*meta*). – $C_{99}H_{94}Cd_3F_{15}KO_{10}S_3$ (2201.3): calcd. C 54.02, H 4.30, Cd 15.32, F 12.95, K 1.78, S 4.37; found C 53.98, H 4.35, Cd 15.14, F 13.0, K 1.92, S 4.50.

Method B: 0.97 g (0.50 mmol) of **2** was dissolved in 20 ml of tetrahydrofuran. To the stirred solution 132 mg (0.50 mmol) of 18-crown-6 was added. After the crown ether had dissolved, first toluene and then *n*-hexane were carefully layered over the reaction mixture. Nearly colourless crystals of **3** separated during the next 4 d. The product was isolated, washed with *n*-hexane and dried in vacuo. Yield 0.94 g (85%).

[K(18-crown-6)(THF)$_2$][Cd(C_6F_5)(STrt)$_2$] (**4**): 39 mg (1.0 mmol) of freshly cut potassium metal was added to a stirred solution of 276 mg (1.00 mmol) of triphenylmethanethiol in 2 ml of tetrahydrofuran. After ca. 4 h, the metal had completely reacted, and a clear, light yellow solution had formed. This solution was slowly dropped into a solution of 589 mg (0.250 mmol) of **1** in 2 ml of toluene. 264 mg (1.00 mmol) of 18-crown-6 was added. Then *n*-hexane was carefully layered over the light brown solution in the reaction flask. After 2 d, nearly colourless crystals of **4** had formed, which were isolated on a large-pored glass filter, washed with *n*-hexane, dried in vacuo, and finally stored in a refrigerator. Yield 1.01 g (79%). – IR (KBr): $\tilde{\nu}$ = 945 cm^{-1} (s, CF). – ^1H NMR (300 MHz, CD_3CN): δ = 1.80 (m, 8 H, CCH_2C), 3.56 (s, 24 H, 18-crown-6), 3.64 (m, 8 H, CH_2O in THF), 7.00−7.14 (m, 18 H, Ph-*meta* and -*para*), 7.33 ("d", 8 H, Ph-*ortho*), 7.47 ("d", 4 H, Ph-*ortho*). – ^{13}C NMR (75.5 MHz, C_6D_6): δ = 25.78 (CCH_2C), 63.30 (Ph_3C), 67.77 (CH_2O in THF), 70.16 (18-crown-6), 125.3 (Ph-*para*), 127.3 (Ph-*meta*), 130.7 (Ph-*ortho*), 153.6 (Ph-*ipso*)[22]. – ^{19}F NMR (188.3 MHz, C_6D_6): δ = −110.2 (m, 2 F, C_6F_5-*ortho*), −160.4 (m, 1 F, C_6F_5-*para*), −163.2 (m, 2 F, C_6F_5-*meta*). – $C_{64}H_{70}CdF_5KO_8S_2$ (1277.9): calcd. C 60.15, H 5.52, Cd 8.80, F 7.43, K 3.06, S 5.02; found C 59.87, H 5.65, Cd 8.37, F 7.3, K 4.03, S 5.10.

X-ray Crystal Structure Analysis of **3** *and* **4**: Intensity data were measured at 23°C on a Siemens/STOE AED2 diffractometer. Graphite-monochromated MoK_α radiation, ω scans, structure solutions by direct methods[23], refinements on F^2 values (full-matrix least-squares)[24].

A suitable single crystal of **3** was obtained by layering first a small amount of toluene and then *n*-hexane over a solution of the compound in tetrahydrofuran. $C_{99}H_{94}Cd_3F_{15}KO_{10}S_3$, M = 2201.3, pale brown crystal, crystal size 0.65 × 0.53 × 0.27 mm, monoclinic, space group $P2_1/c$, a = 25.464(3), b = 14.248(2), c = 28.421(4) Å, β = 104.40(3)°, V = 9988(2) Å^3, Z = 4, $\rho_{calcd.}$ = 1.464 gcm^{-3}, $F(000)$ = 4456, $\mu(MoK_\alpha)$ = 0.82 mm^{-1}. 11954 reflections collected, intensity variation during data collection: −24%, 3° ≤ 2Θ ≤ 43°, 0 ≤ h ≤ 26, 0 ≤ k ≤ 14, −29 ≤ l ≤ 28, empirical absorption correction, T_{min} = 0.3081, T_{max} = 0.4240. 11472 independent reflections (R_{int} = 0.0407) of which 11470 were used in the final refinement, 802 parameters, S (on F^2) = 1.022, $R1$ (all data) = 0.1415, $wR2$ (all data) = 0.1699, $R1$ [$I > 2\sigma(I)$] = 0.0678, max. and min. electron density in final difference map: +0.52 and −0.42 eÅ^{-3}. Each of the THF molecules was assumed to be disordered on two positions, occupied in the ratio of 3:2. A common isotropic U value was refined for the non-hydrogen atoms of each individual position. Anisotropic displacement parameters were refined for all other non-hydrogen atoms, except the C atoms of the trityl groups. All H atoms were included on idealized positions.

A single crystal of **4**, suitable for X-ray structure determination, was grown by layering *n*-hexane over a dilute solution of the compound in tetrahydrofuran. $C_{64}H_{70}CdF_5KO_8S_2$, M = 1277.9, pale yellow crystal, crystal size 0.76 × 0.53 × 0.46 mm, monoclinic, space group $C2/c$, a = 20.230(2), b = 13.897(1), c = 22.512(2) Å, β = 101.65(1)°, V = 6198.6(9) Å^3, Z = 4, $\rho_{calcd.}$ = 1.369 gcm^{-3}, $F(000)$ = 2648, $\mu(MoK_\alpha)$ = 0.55 mm^{-1}. 5721 reflections collected, intensity variation during data collection: −15%, 3.6° ≤ 2Θ ≤ 48°, 0 ≤ h ≤ 23, 0 ≤ k ≤ 15, −25 ≤ l ≤ 25, no absorption correction. 4868 independent reflections (R_{int} = 0.0312) of which all were used in the final refinement, 372 parameters, S (on F^2) = 1.107, $R1$ (all data) = 0.0977, $wR2$ (all data) = 0.1098, $R1$ [$I > 2\sigma(I)$] = 0.0510, max. and min. electron density in final difference map: +0.50 and

-0.32 eÅ^{-3}. Anisotropic displacement parameters were refined for the non-hydrogen atoms, except in the THF ligand, which was assumed to be disordered on three equally occupied positions. A common isotropic U value was refined for the non-hydrogen atoms of each individual position. A total of 30 restraints (DFIX instructions) were used to generate idealized geometries for the THF molecules. For practical reasons, an envelope conformation was chosen with metrical data (C−O 1.43, C−C 1.54 Å; C−O−C 106, O−C−C and C−C−C 104°) close to the values found for free THF[25]. All H atoms were included on idealized positions.

Crystallographic data (excluding structure factors) for the structures reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication no. CCDC-100805. Copies of the data can be obtained free of charge on application to CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [Fax: int. code +44(1223)336-033; E-mail: deposit@ccdc.cam.ac.uk].

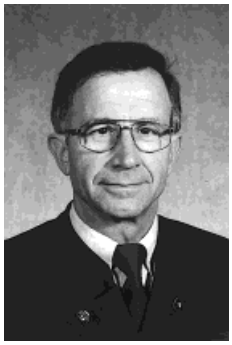
Keywords: Aminoethyl-functionalized cyclopentadienyl complexes / d-Block elements / Hemilabile N-ligands / Intramolecular coordination / Tethered aminoethyl groups / Water-soluble organometallics

The introduction of an aminoethyl side chain into cyclopentadienyl compounds of many d-block elements leads to interesting changes in structure and reactivity compared to the parent species: (i) A hemilabile bonding situation is observed in complexes with low-valent transition-metal centers; (ii) amino-group coordination to an adjacent metal or nonmetal center creates novel types of bimetallic compounds; (iii) complexes with a tethered ammoniumethyl group often show good solubility in protic solvents, relevant with regard to organometallic chemistry in water. These features together with others are described in this review, which informs about the synthesis and properties of this new type of transition-metal complexes.

Introduction

Undoubtedly, the cyclopentadienyl group, C_5H_5 (Cp), is one of the most important ligands in organometallic chemistry.[1] In the last decade, an increasing number of new ring-substituted cyclopentadienyl fragments has appeared in the literature. Variations in the Cp-ligand periphery often result in dramatic changes in physical and chemical properties of the corresponding compounds. These changes can be attributed to electronic and steric effects caused by the partial or full replacement of the hydrogen atoms by other groups.[2]

The chemistry of Cp complexes containing a donor-functionalized side chain is a rapidly growing area that is currently being explored by several research groups.[3][4][5][6][7][8][9] This review concentrates on complexes of d-block elements containing aminoethyl-substituted Cp ligands. The first complexes of this type were introduced by Green et al. in 1983; the dimethylamino func-



Prof. Dr. P. Jutzi studied chemistry at the Technical University of Munich and received his Ph.D. degree under the supervision of Prof. Dr. M. Schmidt at the University of Marburg .After his habilitation at the University of Würzburg in 1971 he was appointed associate professor in 1974. In 1978 he moved as full professor of Inorganic Chemistry to the University of Bielefeld. His scientific interest is in the field of experimental organometallic chemistry. Topics of research are: I) Cyclopentadienyl chemistry of p- and d-block elements, II) nanometer-sized materials.

Dr. Thomas Redeker studied chemistry at the University of Bielefeld and received his Ph.D degree in early 1997. The thesis entitled "Metallocenes of the elements titanium and zirconium with the diisopropylaminoethylcyclopentadienyl ligand" was performed in Prof. Jutzi's laboratories, supported by a fellowship of the "Fonds der Chemischen Industrie" and awarded with the "Abschlußzertifikat" of the "Fonds der Chemischen Industrie". Currently, he is working in the group of Prof. Dr. H. D. Kaesz (UCLA, USA) as a postdoctoral fellow. His project, the MOCVD of titanium films, is supported by a grant from the "Deutsche Forschungsgemeinschaft".

MICROREVIEWS: This feature introduces the readers to the authors' research through a concise overview of the selected topic. Reference to important work from others in the field is included.

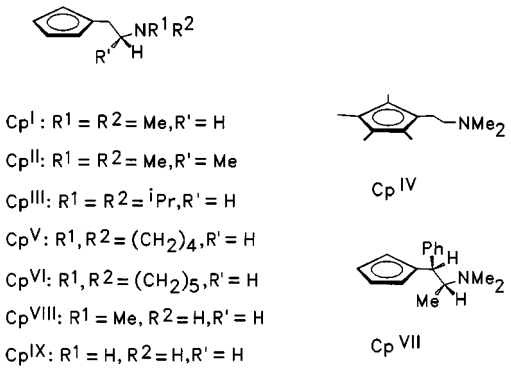
tion was attached to a functionalized Cp ring only in the last step of the synthesis.[7a] The first synthesis of an aminoethyl-functionalized cyclopentadiene was described by Wang and co-workers in 1991. They prepared complexes with the (dimethylaminoethyl)cyclopentadienyl ligands Cp^{I} and Cp^{II} (Figure 1).[7f] Our laboratory contributed to this new field with compounds bearing the ligands Cp^{III} and Cp^{IV} (Figure 1).[9] Cyclopentadienyl ligands Cp^{V} and Cp^{VI} with pyrrolidyl and piperidyl functions as pendant groups were introduced by Herrmann and co-workers (Figure 1).[8c] The chiral dimethylaminoethyl-functionalized cyclopentadienyl ligand Cp^{VII} was described by van der Zeijden only recently (Figure 1).[8b][8l] The cyclopentadienyl ligand Cp^{VIII} with only one methyl substituent at the nitrogen atom was also introduced by Wang and co-workers.[8u] Tyler and Avey synthesized complexes with the Cp^{IX} ligand which contains the parent amino function.[7h]

Figure 1

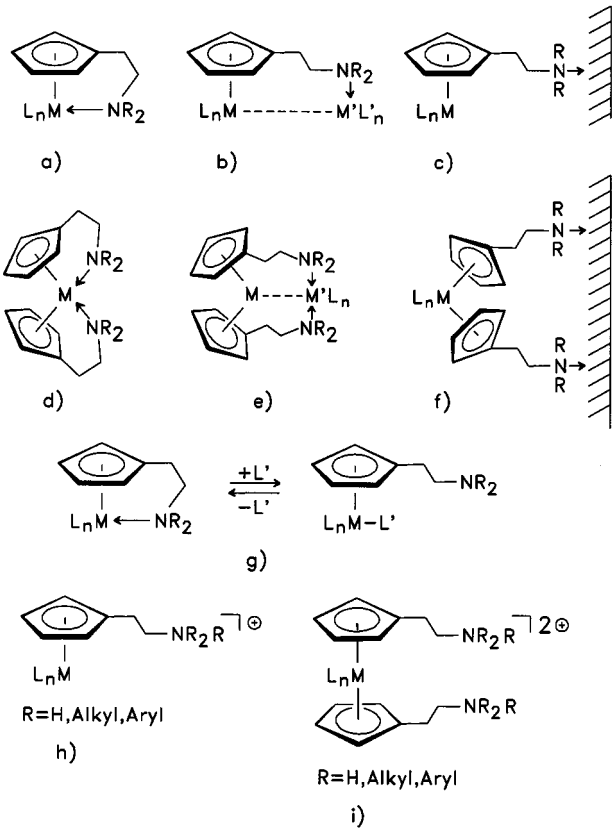


Apart from the general interest in novel ligand systems, we are investigating aminoethyl-functionalized Cp ligands for the following reasons (see Figure 2):

– The nitrogen atom of the aminoethyl group can coordinate to a metal center and block a vacant coordination site (see Figure 2a, d). Otherwise highly reactive intermediates or reaction products will be stabilized by this interaction, thus allowing unprecedented structures and chemical properties. Interesting bonding situations are expected as a function of the formal oxidation state of the respective metal. As documented by many examples, a cyclopentadienyl ligand stabilizes transition metals in high as well as in low oxidation states. On the other hand, the amino group favours coordination to metals in a high oxidation state (hard–hard interactions according to Pearson's concept). To metals in a low oxidation state, only weak interactions are anticipated, which might be strenghtened by the chelate effect; in this case, the aminoethyl-functionalized Cp ligand should behave as a hemilabile ligand. To metals in a high oxidation state, rather strong interactions are expected, which might allow the isolation of compounds even with cationic (aminoethyl)cyclopentadienyl units. In general, a ligated amino group will render the central atom much more electron-rich.

– The hemilabile bonding situation will allow an easy ligand exchange, as described in Figure 2g. The reversible

Figure 2



coordination to a reactive metal center is of special interest in connection with catalytic processes; it seems possible to stabilize a highly reactive, electronically and sterically unsaturated intermediate by weakly occupying the vacant coordination site, until the actual substrate coordinates and replaces the amino group. Such processes might increase the lifetime and also the selectivity of the catalyst. A versatile catalyst design is conceivable by modifying the aminoethyl group.

– The amino function can coordinate to an adjacent electron-deficient metal (or nonmetal) center (Figure 2b, e). The resulting homo- or hetero-bimetallic complexes might be stabilized by different kinds of additional interaction; synergetic effects are expected.

– The amino group allows an interaction with Lewis or Broensted acidic surfaces (see Figure 2c, f); this effect is of special interest with regard to the heterogenisation of homogenous catalysts.

– Pendant amino or ammonium groups might have drastical consequences concerning the solubility of respective complexes. The development of an organometallic chemistry in water[10] can be promoted by the application of protonated or alkylated (arylated) aminoethyl-functionalized Cp compounds (see Figure 2h, i).

– Amino or ammonium groups in the side chain might exert electronic and steric effects and thus might induce changes in the chemistry compared to that of the parent compounds. Electronic and steric effects can be altered by

variation of the substitution pattern at the cyclopentadienyl as well as at the amino fragment.

– The presence of N–H bonds in the side chain (Figure 1, compounds Cp^{VIII}, Cp^{IX}) allows further functionalization of the amino group by substitution reactions.

– The presence of protonated amino groups (Figure 2h, i; R′ = H) in principal permits proton-transfer reactions and thus opens new synthetic pathways.

This listing of effects unequivocally explains the current interest in aminoethyl-functionalized Cp complexes. In the following, we present a complete survey of d-block element complexes containing aminoethyl-functionalized cyclopentadienyl systems. Synthetic and structural aspects as well as important properties of these compounds are described with special emphasis to the effects of the tethered aminoethyl function.

Titanium and Zirconium Complexes

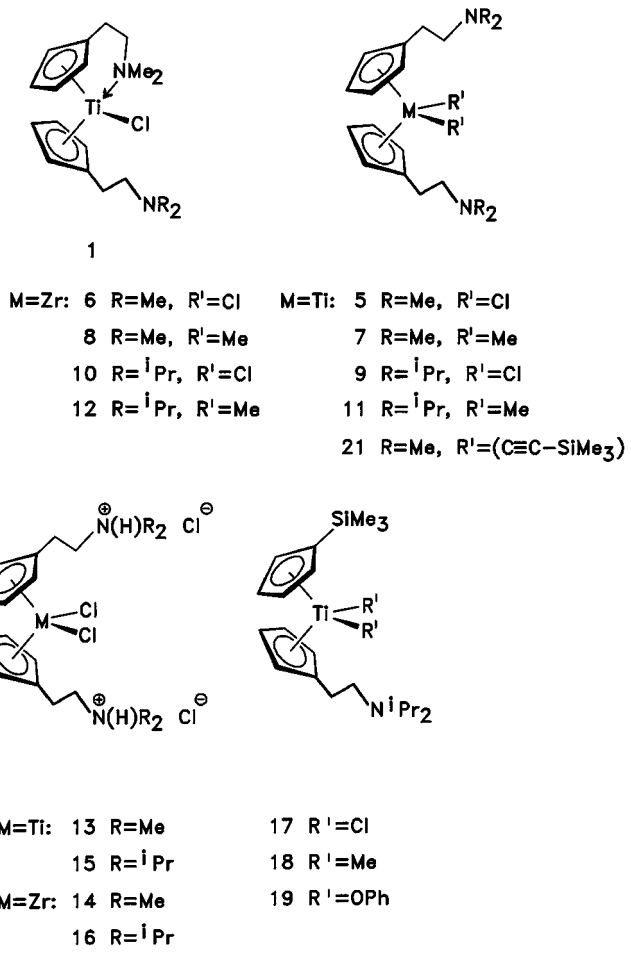
We started our efforts in this field synthesizing titanium compounds with the Cp^{I} and the Cp^{III} ligand. The titanium(III) complexes Cp^{I}_2TiCl (**1**) (Figure 3) and Cp^{III}_2TiCl (**2**) were prepared by the reaction of $Cp^{I}Li$ and $Cp^{III}Li$, respectively, with $TiCl_3$.[9m] A single-crystal X-ray structure analysis of **1** revealed a pseudo-tetrahedral coordination sphere and thus the interaction of only one of the two amino groups with the titanium center.[9m] The structure of **2** containing the bulkier diisopropylaminoethyl-functionalized cyclopentadienyl ligand Cp^{III} is still unknown.[9w] The extreme air sensitivity of **2** compared to **1** indicates the non-coordinating nature of the amino function. The organo derivatives Cp^{I}_2TiR (**3**: R = Me; **4**: R = Bz) could be synthesized by simple substitution reactions.[9m] Only very recently, the titanium(III) compound $[(Me_2NCH_2CH_2)Me_4C_5][C_5H_5]TiCl$ with an intramolecular amino-group coordination was synthesized and structurally characterized.[8aa]

In metallocene dichlorides of the type $Cp^{I}_2MCl_2$ (**5**: M = Ti; **6**: M = Zr) (Figure 3), the intramolecular interaction of the amino group turns out to be rather weak. Intermolecular interaction finally dominates due to the formation of insoluble coordination polymers; the structures of these species are still unknown.[8z][9m] The corresponding dimethyl-substituted compounds $Cp^{I}_2MMe_2$ (**7**: M = Ti; **8**: M = Zr) are highly reactive and were therefore only characterized by ^{1}H-NMR spectroscopy.

The metallocene dichlorides $Cp^{III}_2MCl_2$ (**9**: M = Ti; **10**: M = Zr) (Figure 3) could be characterized completely.[9q] A single-crystal X-ray structure analysis of the titanium species **9** reveals a monomeric structure with no intramolecular coordination of the diisopropylamino functions to the metal center. The non-coordinating nature in **9** and **10** can be attributed to steric effects of the isopropyl substituents.

The dialkylaminoethyl functions in this type of metallocene complexes dramatically change the physical as well as the chemical properties. In contrast to the parent complexes Cp_2MCl_2, both types $Cp^{I}_2MCl_2$ and $Cp^{III}_2MCl_2$ are extremely air- and moisture-sensitive. This is due to the effect

Figure 3



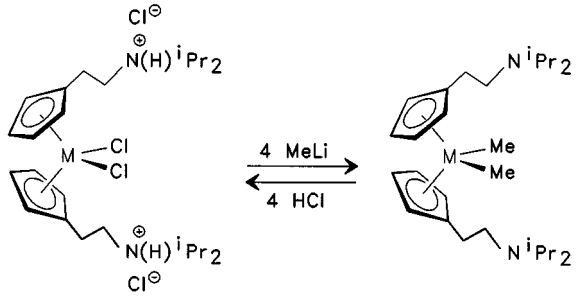
of the amino groups which facilitate the hydrolysis by enhancing the concentration of the attacking OH^- nucleophiles and by trapping the arising hydrogen chloride.

The methyl-substituted metallocenes $Cp^{III}_2MMe_2$ (**11**: M = Ti; **12**: M = Zr) (Figure 3) could be formed straightforwardly by the reaction of the corresponding metallocene dichlorides with methyllithium.[9q] The titanium derivative **11** exhibits a remarkable thermal stability. In contrast to the temperature- and light-sensitive complex Cp_2TiMe_2, for which an autocatalytic, "catastrophic" decomposition is reported[11], **11** is stable for several days under inert gas at room temperature. To explain this phenomenon, we propose a protecting effect of the N*i*Pr_2 group, which prohibits an α-elimination decomposition. Until now, an intramolecular coordination could not be proved unequivocally.

The metallocene dichlorides **5**, **6**, **9** and **10** could be converted quantitatively into the corresponding hydrochlorides $Cp^{I}_2MCl_2 \times 2$ HCl (**13**, **14**) and $Cp^{III}_2MCl_2 \times 2$ HCl (**15**, **16**) (Figure 3).[9q] In these compounds the protonated amino groups lead to drastic changes in the physical and chemical properties as compared to those of the non-protonated species. The hydrochlorides show an excellent solubility and stability in polar solvents such as chloroform or acetonitrile. Furthermore, solvolysis of the M–Cl bonds in protic solvents such as methanol or even water is prevented.

This is due to the effect of the ammonium groups which function as Broensted acids and reduce the concentration of the attacking OH^- nucleophiles, which are responsible for the hydrolytic process. Because of their exceptional stability, the hydrochlorides possess a long shelf life. Furthermore, they are useful starting materials for the synthesis of catalytically relevant species. For example, the metallocene dichloride dihydrochlorides **15** and **16** could be transformed with four equivalents of methyllithium into the dimethyl compounds **11** and **12** (Scheme 1).[9q] It is remarkable that a quantitative retransformation of the dimethyl compounds **11** and **12** back to the hydrochlorides **15** and **16** could be achieved by reaction with four equivalents of HCl in methanolic solution. No decomposition products were observed.

Scheme 1

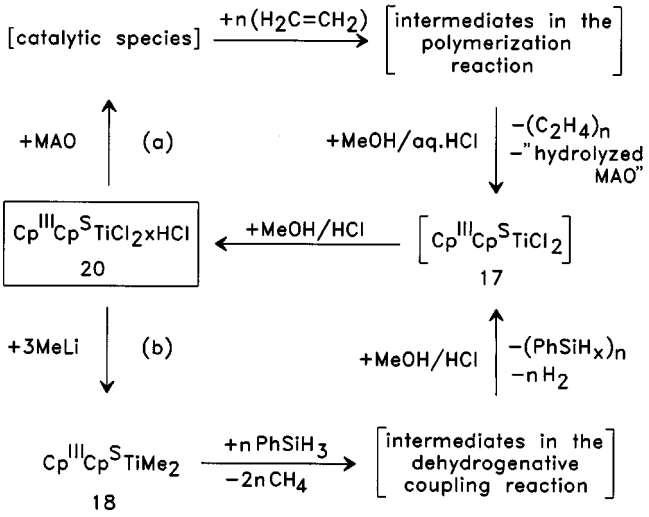


The mixed bent-sandwich complex $Cp^{III}Cp^{S}TiCl_2$ (**17**) (Cp^S = $CpSiMe_3$) containing only one (diisopropylaminoethyl)cyclopentadienyl ligand could be obtained by treating a solution of the halfsandwich complex $Cp^{S}TiCl_3$ with one equivalent of $Cp^{III}Li$ (Figure 3).[9r] The corresponding substituted derivatives $Cp^{III}Cp^{S}TiR_2$ [R = Me (**18**); PhO (**19**)] (Figure 3) as well as the hydrochloride $Cp^{III}Cp^{S}TiCl_2 \times HCl$ (**20**) can be synthesized in analogy to the symmetric titanocene complexes as described above.[9q] Only very recently, other titanocene derivatives with the Cp^{IV} ligand were synthesized and structurally characterized. They all show a non-coordinating amino group, but intermediate ligation was postulated to explain the observed reaction products.[8aa]

The metallocene dichlorides as well as the hydrochlorides containing the Cp^{III} ligand are catalyst precursors for the polymerization of ethylene; the productivities of the catalyst systems are comparable to those of the parent metallocene derivatives.[9q][9r] Furthermore, high catalytic activity in the dehydrocoupling of phenylsilane is observed for the methyl- and phenoxy-substituted derivatives.[9q][9r] The poly(phenylsilanes) obtained exhibit analytical data similar to those prepared with the parent catalyst system.

After the reaction, the catalytic species or its decomposition products generally remain in the polymer (leave-in catalysts) or are destroyed during the separation process and thus cannot be employed again. In our case, the influence of the diisopropylaminoethyl side chain provides sufficient stability to allow for efficient recycling of the pre-catalysts by a simple extraction procedure with methanol and aqueous HCl, as shown in Scheme 2 for complex **20**.[9v]

Scheme 2



Enders et al. described the reaction of the polymeric titanocene $Cp^{I}_2TiCl_2$ (**5**) with two equivalents of $LiC{\equiv}CSiMe_3$ to afford the temperature-sensitive, monomeric bis(alkynyl)titanocene derivative $Cp^{I}_2Ti(C{\equiv}CSiMe_3)_2$ (**21**) (Figure 3).[8z] The reaction of **21** with AgCl and $Cu(SC_6H_4CH_2NMe_2)_2$, respectively, yielded the heterobimetallic titanium-silver and titanium-copper complexes $[Cp^{I}_2Ti(C{\equiv}CSiMe_3)_2][AgCl]$ (**22**) and $[Cp^{I}_2Ti(C{\equiv}CSiMe_3)_2][Cu(SC_6H_4CH_2NMe_2)_2]$ (**23**); a coordination of the N functions to the metal centers could not be observed.[8z]

Further mixed aminoethyl-functionalized zirconocene complexes have been prepared by Tanaka et al.[8t] $Cp(IndCH_2CH_2NMe_2)ZrCl_2$ (**24**) and $Cp^*(IndCH_2CH_2NMe_2)ZrCl_2$ (**25**) (Ind = C_9H_6, Cp* = C_5Me_5) (Figure 4) could be obtained by the reaction of the appropriately substituted indenyllithium with Cp^*ZrCl_3 and $CpZrCl_3$.[8t] NMR spectroscopy did not reveal any indication of an amino-group coordination. These complexes, activated with 2 equiv. of *n*BuLi, catalyze the dehydrocoupling polymerization of phenylsilane to afford high-molecular-weight poly(phenylsilanes). ^{29}Si-NMR spectroscopy indicates that the microstructure of the resulting polymers is predominantly syndiotactic.[8t]

29 R=iPr,R'=Me

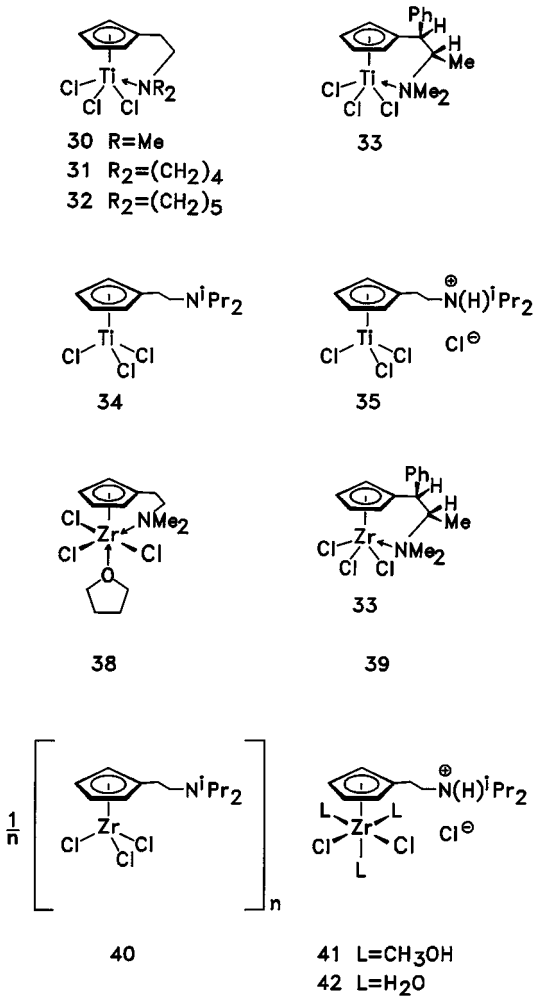
In the context of our studies of metallocene complexes with early transition metals we focussed our efforts also on the synthesis of ansa-zirconocenes. There is considerable interest in the preparation of ansa-zirconocenes as precursors for olefin polymerization catalysts;[12] the bridging unit as well as the substituents of both Cp rings greatly influence the activity and the stereoselectivity of the polymerization reaction.

Very recently, we synthesized the compounds $[(C_{13}H_8)CMe_2(C_5H_3CH_2CH_2NMe_2)]ZrCl_2$ (**26**) and $[(C_{13}H_8)CMe_2(C_5H_3CH_2CH_2N\mathit{i}Pr_2)]ZrCl_2$ (**27**), which are the first examples of dialkylaminoethyl-functionalized ansa-zirconocenes (Figure 4).[9x] Single-crystal X-ray analyses reveal the monomeric structure of these complexes. The amino groups are not coordinating to the zirconium center. The dialkyaminoethyl-functionalized side chains in β-position to the C_1 bridge might be essential for affecting the stereoselectivity in the polymerization of propylene. The dimethyl derivatives **28** and **29** (Figure 4) were obtained in high yields by the reaction of **26** and **27**, respectively, with two equivalents of methyllithium.[9x] Complexes **28** and **29** are highly moisture-sensitive, orange-yellow oils with a good solubility in nonpolar aprotic solvents such as toluene. Examinations of these complexes with respect to their potential use in catalytic reactions are in progress.

Although group-4 metallocenes dominate the homogeneous Ziegler-Natta polymerizations of ethylene and propylene, also halfsandwich complexes are employed as precursors in many catalytic reactions. In this context, several titanium and zirconium halfsandwich complexes containing dialkylaminoethyl functionalized cyclopentadienyl ligands were synthesized.

The compound Cp^ITiCl_3 (**30**) is the first titanium halfsandwich complex with an intramolecularly coordinating amino function, as reported by Rausch and co-workers (Figure 5).[7n] The amino group affects significantly the catalytic reactivity of **30** as compared to that of the parent complex $CpTiCl_3$. The system **30**/MAO (MAO: methylaluminoxane) shows a considerably lower activity towards styrene and an impressively increased activity towards ethylene and propylene. This is most likely due to the coordination behaviour of the amino group which influence the coordination of the incoming monomer.[7n] Cyclopentadienyl complexes of titanium with tethered pyrrolidinyl and piperidinyl functions were introduced by Herrmann and co-workers.[8c] The titanium halfsandwich complexes Cp^VTiCl_3 (**31**) and $Cp^{VI}TiCl_3$ (**32**) were prepared by the reaction of the silylated cyclopentadiene precursor with $TiCl_4$. X-ray crystal-structure results confirm the intramolecular nitrogen coordination to the titanium(IV) center (Figure 5). Van der Zeijden designed the chiral dimethylaminoethyl-functionalized cyclopentadienyl titanium halfsandwich complex $Cp^{VI}TiCl_3$ (**33**) by the reaction of the trimethylsilyl derivative $Cp^{VII}SiMe_3$ with $TiCl_4$ (Figure 5).[8l] In the titanium compound **33** the nitrogen side chain is only weakly coordinated, NMR spectroscopy indicates a fluxional coordination of the amino side arm. This is in contrast to Cp^ITiCl_3 (**30**), where a rigid intramolecular coordination is observed.

Figure 5



In the halfsandwich complex $Cp^{III}TiCl_3$ (**34**), synthesized by our group,[9u] the amino group is obviously not strongly coordinating intramolecularly to the titanium center (Figure 5); however, a weak intermolecular coordination was observed. The different coordination behaviour of **34** as compared to **30**−**33** can be attributed to steric effects of the bulkier isopropyl substituents at the amino function. Complex **34** reacted with one equivalent of HCl under protonation of the amino group to give the monomeric hydrochloride $Cp^{III}TiCl_3 \times HCl$ (**35**), which shows excellent solubility in polar solvents (Figure 5).[9u] Similar O-brigded dimers $[Cp^ITiCl]_2O \times 2HCl$ (**36**)[7n] and $[Cp^{VII}TiCl]_2O \times 2HCl$ (**37**)[8l] were obtained by the reaction of the halfsandwich complexes **30** and **33,** respectively, with traces of water.

In the trichlorozirconium complex $Cp^IZrCl_3 \times THF$ (**38**) an intramolecular coordination of the amino group takes place. (Figure 5). The monomeric structure of the THF adduct was proved by a single-crystal X-ray structure investigation.[9m] Van der Zeijden also synthesized the chiral zirconium species $Cp^{VII}ZrCl_3$ (**39**) (Figure 5).[8l] In contrast

to the corresponding titanium species $Cp^{VII}TiCl_3$ (**33**), the amino group is firmly coordinated to the metal center. Moreover, **39** still behaves as a moderate Lewis acid and catalyzes the Diels-Alder reaction of methacroleine with cyclopentadiene, but without measurable enantiomeric excess.[8l]

The zirconium compound $[Cp^{III}ZrCl_3]_x$ (**40**) (Figure 5) containing the bulkier diisopropylaminoethyl group forms a coordination polymer, comparable to the situation found for the analogous titanium species **34**.[9u] Compound **40** reacted with one equivalent of HCl under protonation of the amino group to give the monomeric air- and moisture-stable hydrochloride **41**, which crystallized with two additional methanol molecules in the coordination sphere of the zirconium atom (Figure 5).[9u] The reaction of **41** with water, which involves exchange of the donor ligands, led to the formation of the air- and water-stable hydrochloride **42** (Figure 5).[9u]

The extremely high air and moisture sensitivity of all described neutral halfsandwich complexes is worth mentioning. In contrast, the halfsandwich complexes with a protonated amino function are stable against air and moisture and soluble in protic solvents such as methanol. These properties of the protonated sandwich and halfsandwich compounds may be of special interest with regard to organometallic chemistry in water.

Vanadium, Chromium and Molybdenum Complexes

Only recently Enders and co-workers[8z] described the synthesis of the first dimethylaminoethyl-functionalized vanadocene and chromocene derivatives. The reaction of two equivalents of the metallated Cp^I ligand with in-situ prepared VCl_2 and $CrCl_2$, repectively, afforded the paramagnetic vanadocene and chromocene compounds $Cp^I{}_2M$ [M = V (**43**); M = Cr (**44**)]. The paramagnetic behaviour (spin-only value) is comparable to that of the parent complexes Cp_2Cr and Cp_2V. NMR data did not reveal any coordination of the N functions.

The first dimethylaminoethyl-functionalized bis(cyclopentadienyl)molybdenum complex was already synthesized by Green et al. in 1983.[7a] The functionalized molybdenum complex $[Mo(C_5H_4CH_2CH_2I)_2I_2]$ (**45**) (Scheme 3) reacted with dimethylamine and subsequently with ammonium hexafluorophosphate to give the ionic compound $[Mo(Cp^I)(C_5H_4CH_2CH_2NMe_2H)H]^{2+}[PF_6]^-{}_2$ (**46**) with the dimethylamino group intramolecularly coordinating to the molybdenum center. The structure of **46** as proposed on the basis of ^{1}H-NMR data is shown in Scheme 3.

Only very recently, the synthesis of halfsandwich complexes of chromium (type **46a**–**d**, Figure 5a) with an intramoleculary coordinating amino group was reported. These compounds were obtained as deep blue species by the reaction of $Cr(THF)_3Cl_3$ with the corresponding cyclopentadienyl alkali metal salts. In the mixture with MAO (MAO: methylaluminoxane), highly effective catalysts for olefin polymerisation are formed. Surprisingly, full catalytic activity is already reached in a molar Al/Cr ratio of 45–300:1.[*]

46d

Wang and co-workers[7f] synthesized various molybdenum halfsandwich complexes in which the pendant dimethylaminoethyl group is coordinating intramolecularly to the metal center. Reaction of $Mo(CO)_6$ with Cp^ILi and subsequently with iodine led to the tricarbonyl complex $Cp^IMo(CO)_3I$ (**47**), which was transformed into the dicarbonyl compound $Cp^IMo(CO)_2I$ (**48**) (Scheme 4) by irradiation. Treatment of **48** with silver tetrafluoroborate led to the ionic molybdenum complex **49** (Scheme 4).[7f] An intramolecular coordination of the amino group takes place in **48** as well as in **49**.[7f]

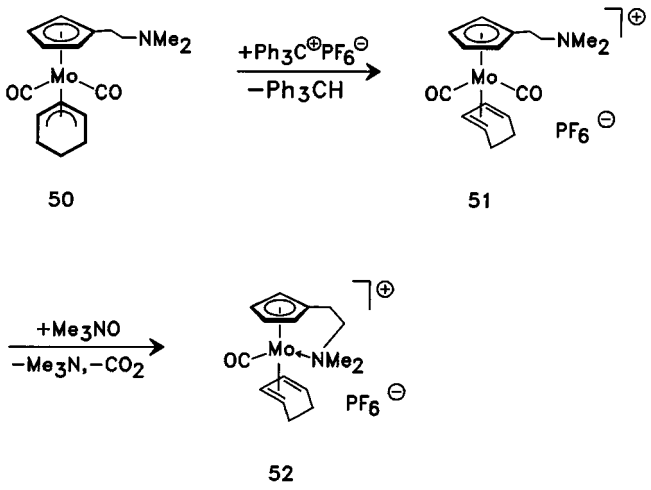
49

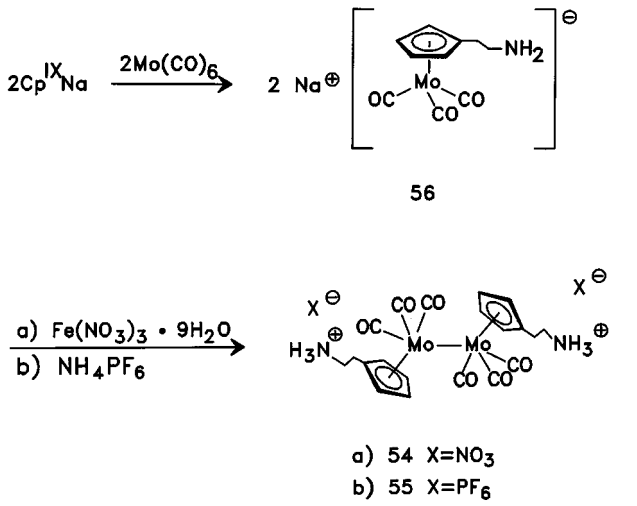
The dimethylaminoethyl-functionalized cyclopentadienylmolybdenum complex $(C_6H_9)Cp^IMo(CO)_2$ (**50**) (Scheme 5) was prepared by adding Cp^ILi to $(C_6H_8)Mo(CO)_2(CH_3CN)_2Br$.[7g] Reaction of **50** with trityl hexafluorophosphate provided the ionic compound $[(C_6H_8)Cp^IMo(CO)_2]^+[PF_6]^-$ (**51**) by hydride abstraction (Scheme 5). Treatment of **51** with trimethylamine *N*-oxide

[*] Note added in proof: P. Jolly, K. Ionas, G. P. I. Verkovnic, German Patent 19630580 A1, **1998**.

Scheme 5



Scheme 6



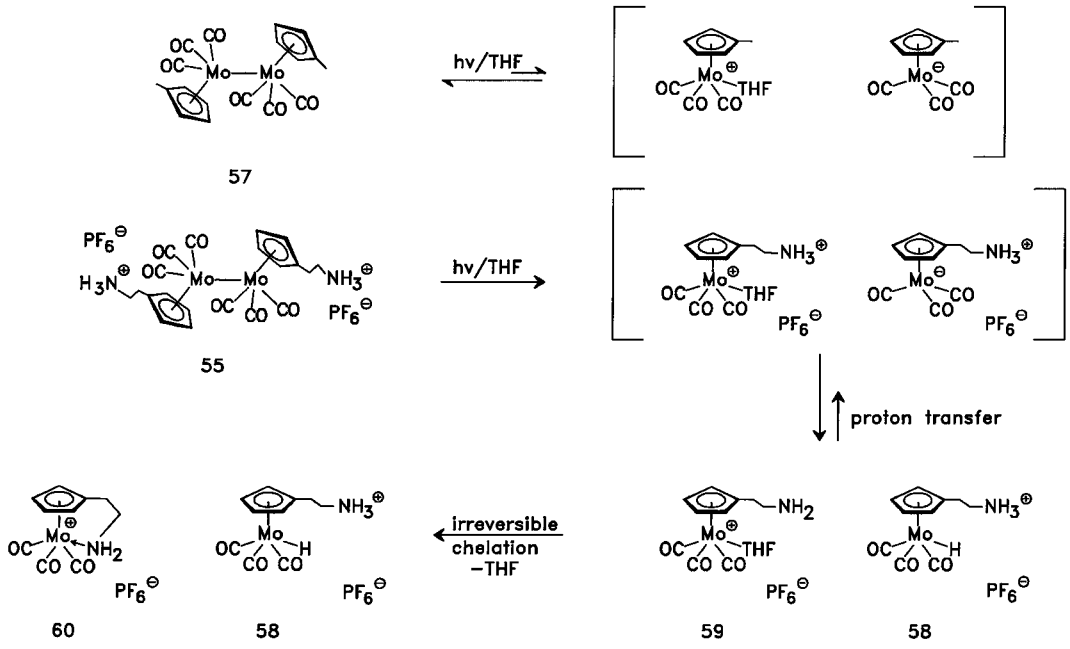
removed carbon monoxide to give $[(C_6H_8)(C_5H_4CH_2CH_2NMe_2)Mo(CO)]^+[PF_6]^-$ (**52**). (Scheme 5). A single-crystal X-ray structure analysis of **52** confirmes the intramolecularly coordinating dimethylamino group and the *exo* conformation of the cyclohexadiene ligand.[7g] Cationic dienylmolybdenum complexes are pertinent substrates for organic syntheses. Complexes of type **52** are particularly interesting because the electrophilicity is weakened as a result of amine coordination. Furthermore, the metal center is now chiral.

The dinuclear molydenum complex $[Cp^{IV}Mo(CO)_2]_2$ (**53**) was synthesized by our group.[9k] The structure analysis revealed that the side chains do not coordinate to the central metal atoms and lie on opposite sides of the Mo−Mo axis.[9k]

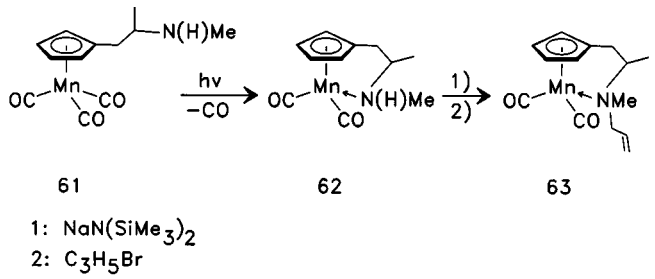
Avey and Tyler described the synthesis of the ammonioethyl-functionalized dimeric molybdenum complexes $Cp^{IX}{}_2Mo_2(CO)_6 \times 2$ HX (**54**: X = NO_3; **55**: X = PF_6) by reaction of $Cp^{IX}Na$ with $Mo(CO)_6$ and by subsequent oxidation of the anion $[Cp^{IX}Mo(CO)_3]^-$ (**56**) with $Fe(NO_3)_3 \cdot 9\ H_2O$ in water. The exchange of the anion in **54** with NH_4PF_6 afforded **55** (Scheme 6).[7h] It is noteworthy that in contrast to **55,** which is soluble in common organic solvents like THF, complex **54** is soluble and stable in aqueous solution.

Interestingly, the photochemistry of **55** differs from that of the parent complex $Cp^x{}_2Mo_2(CO)_6$ (**57**) (Cp^x = C_5H_4Me). Mechanistic work established that the different reactivities can be ascribed to a supramolecular effect of the tentacle ligand.[7l] Irradition of either dimer complex led to photolytic cleavage of the metal−metal bond. The photogenerated 17-electron radical complexes then reacted with THF (the solvent) to form 19-electron adducts; disproportionation then followed. The initial products were $[Cp^xMo(CO)_3(THF)]^+$, $[Cp^xMo(CO)_3]^-$ and

Scheme 7



Scheme 8



$[Cp^{IX}Mo(CO)_3(THF)]^+$, $[Cp^{IX}Mo(CO)_3]^-$, respectively (Scheme 7). In the case of the dimer **57**, a facile back reaction of these products ensued, and the net result was no reaction, even in the presence of an excess of $[C_6H_5CH_2CH_2NH_3]^+[PF_6]^-$.[7l] In the case of the tentacle dimer $Cp^{IX}{}_2Mo(CO)_6 \times 2\ HPF_6$ (**55**), proton transfer from the ammonium group to the anion yielded $Cp^{IX}Mo(CO)_3H \times HPF_6$ (**58**) and $[Cp^{IX}Mo(CO)_3THF]^+[PF_6]^-$ (**59**), and then facile coordination of the free amine by displacing the THF ligand effectively blocked the back reaction by forming $[Cp^{IX}Mo(CO)_3]^+[PF_6]^-$ (**60**) irreversibly.

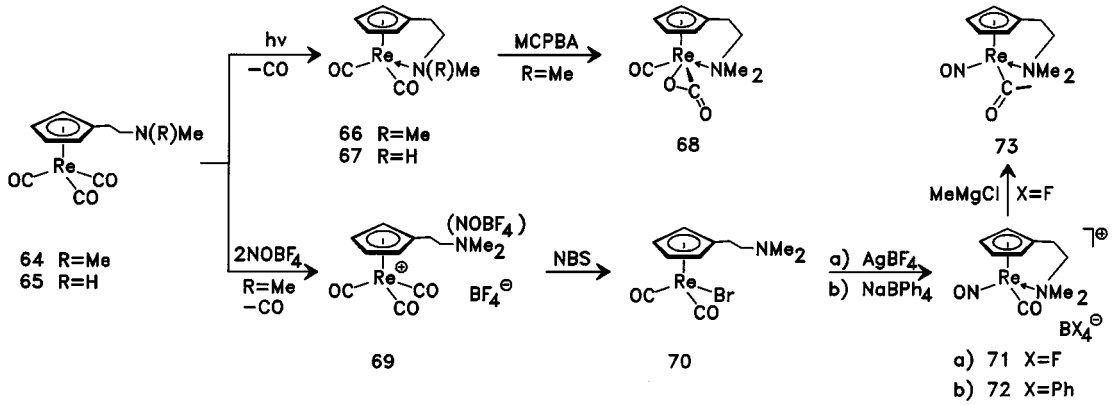
The described cooperative interaction between the tentacle ligands and the unstable initial products of disproportionation to yield stable products is regarded as an example of supramolecular reactivity.[7l]

Manganese and Rhenium Complexes

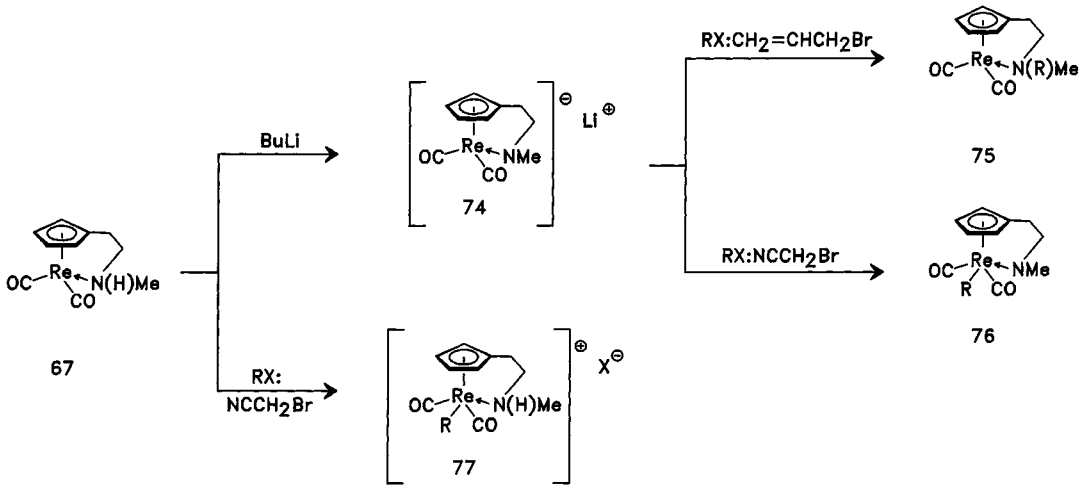
Wang et al.[7e] synthesized the manganese complex $Cp^{VIII}Mn(CO)_3$ (**61**) by treating $Mn(CO)_5Br$ with $Cp^{VIII}Li$ (Scheme 8). Irradiation of **61** removed carbon monoxide and gave rise to an intramolecular amine-group ligation to provide complex **62** (Scheme 8).[7e] Deprotonation of **62** with $NaN(SiMe_3)_2$ and subsequent addition of allyl bromide led to the alkylation product **63** (Scheme 8). The X-ray analysis clearly shows that allylation occurred at the nitrogen atom and not at the manganese center.[7e] The sequence **62** → **63** is an example of further amino-group functionalization in complexes with aminoethyl-substituted Cp ligands still containing N−H functions.

The first rhenium complexes containing an *N*-functionalized cyclopentadienyl ligand and further interesting reaction sequences were reported by Wang et al.[8d] The lithium salts $Cp^{I}Li$ and $Cp^{VIII}Li$ were shown to react with $Re(CO)_5Br$ to provide the halfsandwich complexes $Cp^{I}Re(CO)_3$ (**64**) and $Cp^{VIII}Re(CO)_3$ (**65**) (Scheme 9). Irradiation of **64** and **65** afforded the complexes $Cp^{I}Re(CO)_2$ (**66**) and $Cp^{VIII}Re(CO)_2$ (**67**), respectively, in which the

Scheme 9



Scheme 10



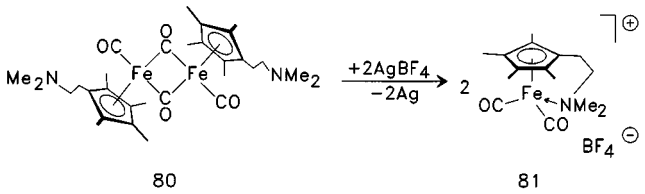
amino group is bound intramolecularly to the rhenium center (Scheme 9).[8d][8u] Oxidation of **66** with 3-chloroperoxybenzoic acid (MCPBA) provided the complex $Cp^IRe(CO)(CO_2)$ (**68**) (Scheme 9), the first example of a mononuclear CO_2 complex in rhenium chemistry. The structure of **68** is confirmed by X-ray crystallography.[8u] Reaction of **65** with two equivalents of $NOBF_4$ gave the nitrosylrhenium complex $[Cp^IRe(NO)(CO)_2]^+[BF_4]^- \times NOBF_4$ (**69**),[8k] which was treated with NBS to afford the bromo complex $Cp^IReBr(NO)(CO)$ (**70**) (Scheme 9). Removal of the bromide ion with $AgBF_4$ resulted in amino-group coordination to give the ionic complex $[Cp^IRe(CO)(NO)]^+[BF_4]^-$ (**71**) (Scheme 9). The X-ray diffraction study of the corresponding tetraphenylborate $[Cp^IRe(CO)(NO)]^+[BPh_4]^-$ (**72**) confirms the amino-group coordination.[8k] Reaction of the rhenium complex **71** with alkylating reagents occurred at the carbonyl carbon atom to provide acyl complexes. For instance, the reaction with methylmagnesium chloride led to the acyl derivative $Cp^IRe(NO)(COMe)$ (**73**) in which the amino group is still coordinating (Scheme 9).[8k] It is worth mentioning that the corresponding triphenylphoshane complex did not react with alkylmetal reagents to provide acyl complexes. Obviously, the influence of the amino function is necessary for this synthetic pathway.

Deprotonation of the N−H function in **67** with *n*BuLi led to the ionic compound **74** (Scheme 10), which reacted with electrophiles such as $CH_2{=}CHCH_2Br$ at the nitrogen center to provide the complex $[C_5H_4CH_2CH_2N(Me)(CH_2{=}CHCH_2)]Re(CO)_2$ (**75**) with to different substituents at the nitrogen atom (Scheme 10).[8u] This is another example of a further functionalization of an aminoethyl-substituted Cp ligand. However, **74** reacted with electrophiles such as $BrCH_2CN$ to give the alkylrhenium compound $Cp^IRe(CO)_2CH_2CN$ (**76**) (Scheme 10). Thus, the regioselectivity is dependent on the nature of the electrophile and can be explained on the basis of the hard-soft acid-base principle.[8u] Reaction of the neutral complex **66** with $BrCH_2CN$ gave exclusively the alkylrhenium compound $[Cp^IRe(CO)_2CH_2CN]^+[Br]^-$ (**77**).[8u] It is remarkable that the parent rhenium complex $CpRe(CO)_3$ does not react with $BrCH_2CN$. Thus, the electron donation of the amino ligand is important to promote the reactivity towards carbon electrophiles.

Iron Complexes

Treatment of $FeCl_2$ in THF with two equivalents of the lithiated ligand $Cp^{IV}Li$ yielded the dimethylaminoethyl-functionalized ferrocene $Cp^{IV}{}_2Fe$ (**78**).[9a] The analogous ferrocene $Cp^I{}_2Fe$ (**79**) could be synthesized in a similar manner.[7s] Not unexpectedly, no amino-group coordination is observed; the 18-electron rule is obeyed in both complexes by η^5-Cp bonding. Reaction of $Cp^{IV}H$ with $Fe(CO)_5$ led to the formation of the dimeric dicarbonyl(cyclopentadienyl)iron complex $[Cp^{IV}Fe(CO)_2]_2$ (**80**). In this compound, no intramolecular displacement of a CO ligand by the amino groups could be initiated.[9c] However, the cationic cyclopentadienyl iron halfsandwich complex $[Cp^{IV}Fe(CO)_2]^+[BF_4]^-$ (**81**), which was obtained by the reaction of **80** with $AgBF_4$, is stabilized by an intramolecular coordination of the amino group (Scheme 11).[9c]

Scheme 11

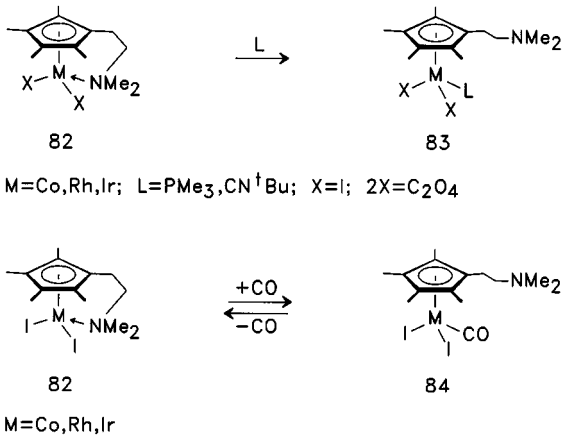


80 81

Cobalt, Rhodium and Iridium Complexes

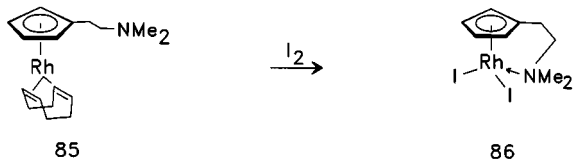
Several halfsandwich complexes with the Cp^{IV} ligand and with the central atoms cobalt, rhodium and iridium were obtained by classical synthetic routes.[9b][9h] In compounds of the type $Cp^{IV}ML_2$ (M = Co, Rh, Ir; L = CO, C_2H_4) with the metals in the oxidation state +1, amino-group coordination is generally not observed. In compounds with the metals in the oxidation state +3, coordination depends on the further ligands present. The interplay between the donor ligands and the metal center can be tuned to a certain extent. An irreversible displacement was observed in the reaction of complexes of the type $Cp^{IV}MX_2$ (**82**) (M = Co, Rh, Ir; X = I; $X_2 = C_2O_4$) with stoichiometric amounts of trimethylphosphane or *tert*-butyl isonitrile to afford $Cp^{IV}M(L)X_2$ (**83**). With carbon monoxide, the displacement reaction leading to $Cp^{IV}M(CO)I_2$ (**84**) is reversible (Scheme 12).[9b][9h]

Scheme 12



Poilblanc et al. described the synthesis of the rhodium(I) complex $Cp^IRh(cod)$ (**85**) (Scheme 13) by reaction of Cp^INa with $[Rh(cod)Cl]_2$.[8w] Oxidation with iodine resulted in the formation of the rhodium(III) complex Cp^IRhI_2 (**86**) (Scheme 13) with a coordinating amino group.

Scheme 13



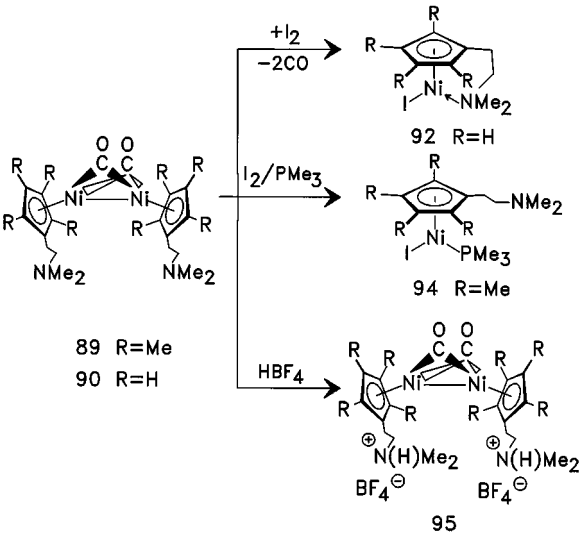
85 86

The reaction of **85** with HCl afforded the corresponding water-soluble hydrochloride $Cp^{I}Rh(cod) \times HCl$ (**87**). It is noteworthy that a reversible transformation to **85** could be achieved by treating **87** with a slight excess of *n*-butyllithium. The water-soluble rhodicinium complex $Cp^{I}_2RhCl \times 2\ HCl$ (**88**) was obtained by the reaction of the cyclopentadiene $Cp^{I}H$ with $Na_3RhCl_6 \times 12\ H_2O$.[8w]. Generally, the synthesis of this kind of compounds requires previous deprotonation of the cyclopentadiene by an auxiliary base. In case of the preparation of **88**, the role of the auxiliary basic reagent is probably adopted by the free amino group attached to the cyclopentadiene. The solubility of **87** and **88** in water is interesting in the context of a screening for antitumor activity.[8w]

Nickel, Palladium and Platinum Complexes

We were successful in the preparation of the dimeric carbonylnickel(I) complex $[Cp^{IV}Ni(CO)]_2$ (**89**) (Scheme 14) by the reaction of $Ni(CO)_4$ with $Cp^{IV}Li$ and subsequent oxidation with CuCl.[9n] The analogous complex $[Cp^{I}Ni(CO)]_2$ (**90**) (Scheme 14) containing the Cp^{I} ligand could be synthesized by Fischer and co-workers by a synproportionation of the nickelocene Cp^{I}_2Ni (**91**) with $Ni(CO)_4$.[8n][8o][8p] As expected, in both complexes no coordination of the pendant dimethylamino groups is observed.

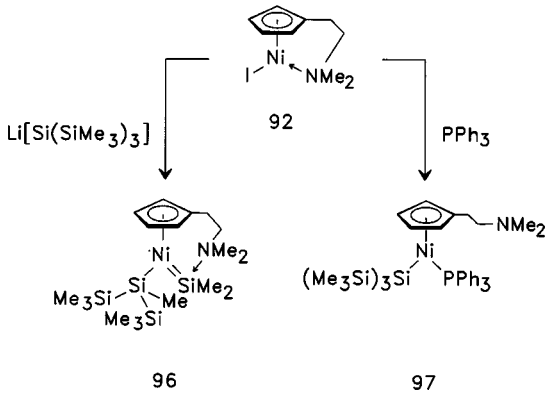
Scheme 14



Cleavage of **90** with iodine gave the monomeric nickel complex $Cp^{I}NiI$ (**92**) with a coordinating amino group (Scheme 14).[8n][8o][8p] The CO-free complex **92** might be an interesting starting material for MOCVD studies. Attemps to prepare the corresponding permethylated complex $Cp^{IV}NiI$ (**93**) failed.[9g] Cleavage of **89** with iodine in the presence of PMe_3 afforded the monomeric nickel(II) halfsandwich complex $Cp^{IV}Ni(PMe_3)I$ (**94**) (Scheme 14).[9n] Complex **89** reacted with two equivalents HBF_4 under protonation of the amino groups to give the ionic, air stable compound $[Cp^{IV}Ni(CO)]_2 \times 2HBF_4$ (**95**) (Scheme 14), which shows excellent solubility and stability in polar solvents such as nitromethane and acetonitrile.[9n]

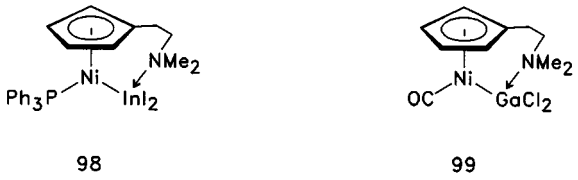
The reaction of **92** with $[(thf)_3Li\{Si[Si(CH_3)_3]_3\}]$ finally afforded the nickel halfsandwich complex **96** (Scheme 15). This is the first example in which the amino function coordinates to an element (silicon) directly attached to the central metal. The structure of **96** is proven by a single-crystal X-ray structure analysis. When **92** was treated with $[(thf)_3Li\{Si[Si(CH_3)_3]_3\}]$ in the presence of PPh_3, the "normal" substitution product $Cp^{IV}Ni(PPh_3)I$ (**97**) was obtained (Scheme 15).[8n][8o][8p]

Scheme 15



The reaction of **92** with PPh_3 and with low-valent indium bromide in the presence of NaI afforded the complex μ-$Cp^{I}Ni(PPh_3)InI_2$ (**98**) (Figure 16) with intramolecular coordination of the dimethylamino group.[8n][8o][8p] Another complex in which the amino group is coordinating to the adjacent electron-deficient metal center is the heterobimetallic compound μ-$Cp^{I}Ni(CO)GaCl_2$ (**99**) (Figure 6) which was obtained by the reaction of $[Cp^{I}Ni(CO)]_2$ (**90**) with Ga_2Cl_4.[8n][8o][8p] Both complexes **98** and **99** might be interesting as MOCVD precursors for nickel-indium and nickel-gallium alloy thin films.

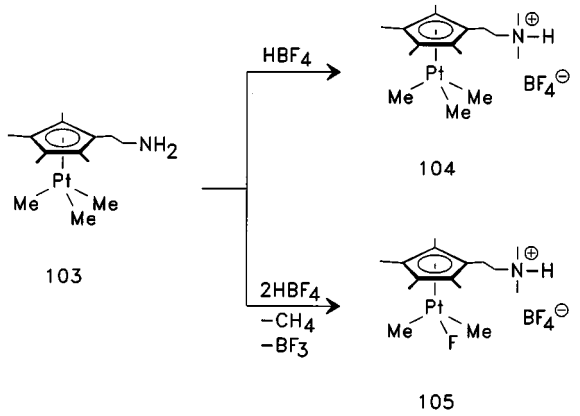
Figure 6



In the chemistry of palladium only dimethylaminoethyl-functionalized cyclopentadienyl complexes with the permethylated Cp^{IV} ligand are known. Reaction of $[Pd(CO)Cl]_n$ with $[Cp^{IV}MgCl]_2$ gave the thermally labile dimeric palladium complex $(Cp^{IV}PdCO)_2$ (**100**) in a mixture with $Cp^{IV}H$.[9n] The synthesis of the palladium halfsandwich complex $Cp^{IV}PdC_3H_5$ (**101**) demonstrated that even in complexes with the palladium metal in the +2 oxidation state, the amino group could not compete with a π-allyl ligand.[9n] The preparation of the dimeric platinum(I) complex $[Cp^{IV}Pt(CO)]_2$ (**102**) failed.[9g] However, the halfsandwich complex $Cp^{IV}PtMe_3$ (**103**) with a Pt^{IV} metal center was obtained in the reaction of $[IPtMe_3]_4$ with $Cp^{III}Li$ (Scheme 16).[9n] In this complex the 18-electron rule is obeyed, and thus no coordination of the amino group is ex-

pected. The reaction of **103** with one equivalent of HBF_4 did not result in an elimination of methane and subsequent amino coordination, but led to the formation of $Cp^{IV}PtMe_3 \times HBF_4$ (**104**) with a protonated amino group, which shows an excellent solubility in polar solvents (Scheme 16).[9n] With two equivalents of HBF_4, however, elimination of methane did occur, and **103** was transformed into the fluoro-substituted compound $Cp^{IV}Pt(F)Me_2 \times HBF_4$ (**105**) (Scheme 16).[9n]

Scheme 16



Conclusion

Similarly to the parent cyclopentadienyl ligand, aminoethyl-functionalized systems can be used as complexing agents for almost any transition metal. There are several good reasons to tether an amino group, as already pointed out in more detail in the introduction; many of the potential effects discussed have already been realized in very recent investigations. The possibility to modify at the cyclopentadienyl core as well as at the amino side group offers an enormous synthetic flexibility. In complexes containing (aminoethyl)cyclopentadienyl ligands, the following effects are of special interest:

− A hemilabile bonding situation is typical of compounds of low-valent transition metals. Amino-group coordination stabilizes otherwise highly reactive intermediates by a weak interaction (soft metal−hard ligand). The reversibility of this process should allow to control the reactivity and also the catalytic properties of the relevant metal complex in more detail.

− The amino group can bind to another metal (non-metal) center and thus create or stabilize novel types of bimetallic complexes.

− Compounds with a tethered ammonium group often show an exceptional stability against air and moisture and a high solubility in protic solvents; this phenomenon is important with regard to organometallic chemistry in water.

These features, together with the others described in this article, augur well for the development of a rich and interesting future chemistry of aminoethyl-functionalized cyclopentadienyl complexes of the transition metals.

The experimental work reported from our group was accomplished by *Jürgen Dahlhaus*, *Jürgen Kleimeier*, *Marc Oliver Kristen*, *Christian Müller*, and *Thomas Redeker*; X-ray crystal-structure analyses were performed by *Beate Neumann* and *Hans-Georg Stammler*. The dedication and expertise of these co-workers is very gratefully acknowledged. We thank *Marion Welschof* for preparing the drawings. Funding was kindly provided by the *Deutsche Forschungsgemeinschaft*, by the *Fonds der Chemischen Industrie*, and by the University of Bielefeld. We are grateful to the *BASF AG*, to the *Degussa AG*, and to the *Wittko AG* for gifts of chemicals.

☆ Dedicated to Professor *Heinrich Nöth* on the occasion of his 70th birthday.

Keywords: Tripodal ligands / Pyrazolyl donors / Molybdenum / Hydrogen bonds / 2D-NMR

The chlorine functions of $CH_3C(CH_2Cl)_3$, **1**, may be replaced by pyrazolyl (pz) as well as imidazolyl (im) residues under the conditions of nucleophilic substitution leading to tripodal ligands $CH_3C(CH_2X)_3$, X = pz, **2**; X = im, **3**. As a means of introducing two nitrogen donors and one phosphorus donor into a tripod ligand, substitution of the Br and OMs functions in $O(CH_2)_2C(CH_2Br)(CH_2OMs)$, **8**, by nitrogen nucleophiles and subsequent cleavage of the oxetane ring by a phosphide nucleophile to give $HOCH_2C(CH_2PPh_2)(CH_2X)_2$ has been developed, furnishing **10a** (X = pz) and **10d** (X = NEt_2), respectively. For the synthesis of **10a**, K-pz was used as the nucleophile, while **10d** was prepared using azide in the initial step, which then had to be transformed into NEt_2 in two subsequent steps. The nucleophugic functions of the oxetane **8** undergo selective substitution by K-pz and $KPPh_2$ in THF to produce $O(CH_2)_2C(CH_2PPh_2)(CH_2pz)$, **9b**. Phosphide cleavage of the oxetane function leads to $HOCH_2C(CH_2PPh_2)(CH_2PR_2)(CH_2pz)$, R = Ph, **10b**; R = 3,5-$Me_2(C_6H_3)$, **10c**. – The tris(pyrazolyl) tripod ligand **2** reacts with $(MeCN)_3Mo(CO)_3$ to give **2** · $Mo(CO)_3(MeCN)$, **12a**, in which only two of the three donor functions are coordinated. Upon reaction with **10a**, the same reagent gives **10a** · $Mo(CO)_4$, **12b**, with one pyrazolyl coordinated and the other involved in intramolecular hydrogen bonding to the CH_2OH function (N···H–O distance 280 pm). Blocking of the OH function of **10a** by etherification, i.e. to form $EtOCH_2C(CH_2PPh_2)(CH_2pz)_2$, **11**, does not dramatically affect the coordination capabilities with **11** · $Mo(CO)_3(MeCN)$, **12d**, being formed upon treatment with $(MeCN)_3Mo(CO)_3$. Again only one pz function is coordinated to the metal. Bidentate coordination by two phosphorus donors of **10c** is observed in **10c** · $Mo(CO)_3(MeCN)$, **12d**. The dangling arm pz donor function and the CH_2OH group are intermolecularly hydrogen-bonded in this case. When the bulky $P[3,5\text{-}Me_2(C_6H_3)]_2$ substituent of **10c** is replaced by the less sterically demanding PPh_2 donor in **10b**, η^3-coordination is finally observed with the formation of **10b** · $Mo(CO)_3$, **13**. The coordination capabilities of the new ligands are rationalized in terms of the size (six-, seven-, and eight-membered rings) and interference of the chelate cycles. All compounds have been characterized by the usual analytical and spectroscopic methods, with a complete assignment of the NMR data achieved by a combination of 2D-NMR techniques in some cases. The structures of the coordination compounds have additionally been deduced by X-ray methods.

Introduction

The coordination chemistry of tripod ligands has considerable potential in many fields of chemistry: Tripod ligands are essential constituents of many bioinorganic model compounds[1], the stabilization of unconventional ligands by tripod metal templates has found widespread application[2] and catalytic applications of tripod metal templates are a rapidly developing field[3]. As a special type of tripod ligands, molecules containing three different donor groups bonded to a neopentane backbone $CH_3C(CH_2X)(CH_2Y)(CH_2Z)$ have been shown to be productive in coordination chemistry, as well as in catalysis. Sacconi and his group, as well as the group of Bianchini, have made extensive contributions to the application of $CH_3C(CH_2PPh_2)_3$ in preparative and in catalytic chemistry[3][4]. Nevertheless, the potential offered by neopentane-based tripod ligands is still far from being fully exploited. Tripod ligands of this type with up to three different donor groups have only recently become available. While the synthetic strategies for introducing phosphorus donors are well developed[5a][5b][5c][5d][5e], including the EPC synthesis of chiral tripod ligands with three different phosphorus donor groups[5f][5g][5h], general strategies for the synthesis of tripod ligands containing, amongst others, nitrogen donor functions are still lacking. A special route into the chemistry of such ligands based upon the aminolytic cleavage of neopentane-based oxetanes has recently been reported[6] and some particular cases based on the nucleophilic substitution of functionalized neopentane derivatives by azide are known[7].

We report herein on our efforts to devise new methods by which tripod ligands **A** $RCH_2C(CH_2X)(CH_2Y)(CH_2Z)$ with the donor set X, Y, Z containing at least one nitrogen donor can be synthesized.

Special emphasis is put on the introduction of the pyrazolyl donor function, the reason being that this type of functionality has been shown to be highly efficient in tris(pyrazolyl)borate tripod ligands[8]. On the other hand, each

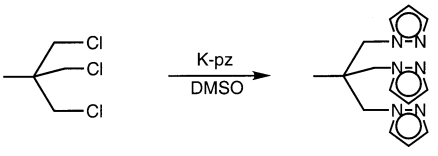
A

pyrazolyl donor function linked to the neopentane backbone in $RCH_2C(CH_2X)(CH_2Y)(CH_2Z)$ increases the ring size in the chelate cage $RCH_2C(CH_2X)(CH_2Y)(CH_2Z)M$ by one over the sterically ideal arrangement of three six-membered rings forming a bicyclooctane-type chelate cage that results when all three donor atoms of X, Y, Z are directly linked to the neopentane carbon skeleton. This increase in ring size (seven-membered chelate rings with one pyrazolyl entity and even eight-membered chelate rings with more than one of these entities) to some extent disfavours the tripodal coordination of such ligands. Given the excellent ligand properties of pyrazolyl ligands on one side and the expected destabilization of η^3-coordination by the introduction of pyrazolyl donor functions into neopentane-based tripod ligands, facile equilibration between η^3- and η^2-coordination modes in such ligand-metal templates may be envisaged. This means that introducing pyrazolyl donor functions into neopentane-based tripod ligands has the potential of allowing the synthesis of coordination compounds in which the pyrazolyl-containing arm of a tripod ligand is easily coordinated and decoordinated, thus reversibly protecting a coordination site at the metal center in the sense of an auxiliary ligand.

This paper deals with the synthesis of tripod ligands $RCH_2C(CH_2X)(CH_2Y)(CH_2Z)$ containing one to three nitrogen donor functions with the other donors being PR_2 groups. The coordination behaviour of these tripod ligands containing up to three pyrazolyl nitrogen donors is probed by characterization of their tricarbonylmolybdenum derivatives.

Synthesis of Tripod Ligands Starting from Tris(chloromethyl)ethane

Tris(chloromethyl)ethane **1**[9] reacts with an excess of potassium pyrazolate (K-pz) in DMSO with substitution of all three chlorine functions by pyrazolyl groups.



1 2

The tripod ligand **2** was obtained by bulb-to-bulb distillation in a kugelrohr apparatus in around 46% yield as a colourless oil, which solidified to give colourless needles after few days. Spectroscopic data and elemental analyses unequivocally confirmed its constitution (Tables 1 and 2, Exp. Section).

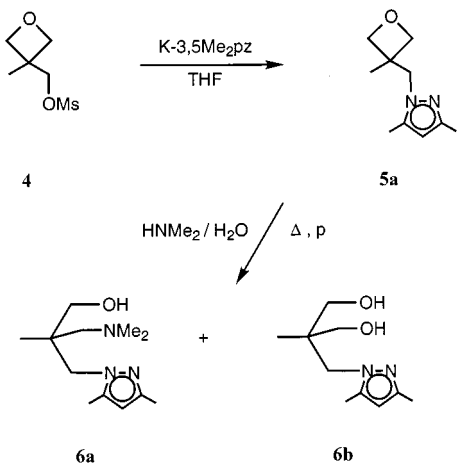
Since the reaction yielding **2** proceeded unexpectedly well – bearing in mind the sluggish reactivity of neopentane derivatives in nucleophilic substitution[7a][10] – it appeared worthwhile to attempt to introduce imidazolyl donors by the same type of straightforward approach. Imidazolyl residues at the neopentane backbone are appealing in so far as it has been shown that multidentate imidazolyl-functionalized ligands may be transformed into multidentate carbene ligands, with the additional merit of making use of the known stability of transition metal-imidazolinylidene carbene bonds[11]. Reaction of the trichloride **1** with potassium imidazolate in DMSO indeed resulted in the tripodal system **3**, albeit in modest yield only.

1 3

Compound **3** was isolated by bulb-to-bulb distillation from the ethereal extract after hydrolysis of the reaction mixture. As a consequence of the high boiling point of free imidazole and of the tripod ligand **3**, appreciable thermal decomposition occurred under the conditions of the distillation. Moreover, increasing the temperature and the reaction time in the synthesis of **3** did not increase the yield because of decomposition of the reaction system into a brown, viscous oil of unknown composition. Compound **3**, as obtained after distillation, consists of colourless needles. Spectroscopic data and elemental analyses confirm the given constitution (Tables 1 and 2, Exp. Section).

Synthesis of Tripod Ligands Starting from Monofunctionalized Oxetanes

Functionalized oxetanes $O(CH_2)_2C(CH_3)(CH_2X)$ have been shown to undergo aminolytic cleavage of the oxetane ring[6][12]. This method works when CH_2OR and CH_2SR substituents are present in the oxetane ring[6]. While this strategy failed in the presence of CH_2PR_2 substituents, we have now found that amino substituents are well tolerated. The pyrazolyl-substituted oxetane **5a** was obtained in good yields from the functionalized oxetane **4** by nucleophilic substitution with potassium 3,5-dimethylpyrazolate (K-3,5-Me_2pz).

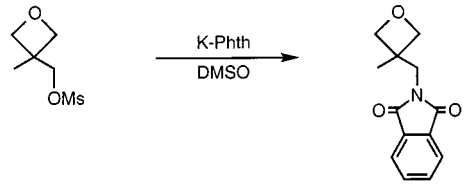


4 5a

6a 6b

Compound **5a** underwent aminolytic cleavage of the oxetane moiety upon treatment with $HNMe_2/H_2O$ at 40 bar/170°C. The product **6a** was accompanied by the bis(hydroxy) compound **6b**. Of course, under the drastic reaction conditions necessary to observe any reaction at all, hydrolytic cleavage effectively competes with aminolytic cleavage. Products **6a/6b** were not completely separable by Vigreux distillation; fractions containing **6a/6b** in ratios up to 4:1 were obtained at best. Compounds **6a/6b** could nevertheless be unequivocally characterized by derivatization (**7a/7b**).

Alternative and potentially more general methods for the exchange of the OMs group by an amine function have been examined. The standard procedure[13] of using potassium phthalimide (K-Phth) as the nitrogen nucleophile works well. While K-Phth is known to react with oxiranes with ring opening[13], the oxetane moiety in **4** stays intact and so this compound can be transformed to the phthalimide derivative **B** in high yields. **B** was fully characterized by its analytical and spectroscopic data (Exp. Section).

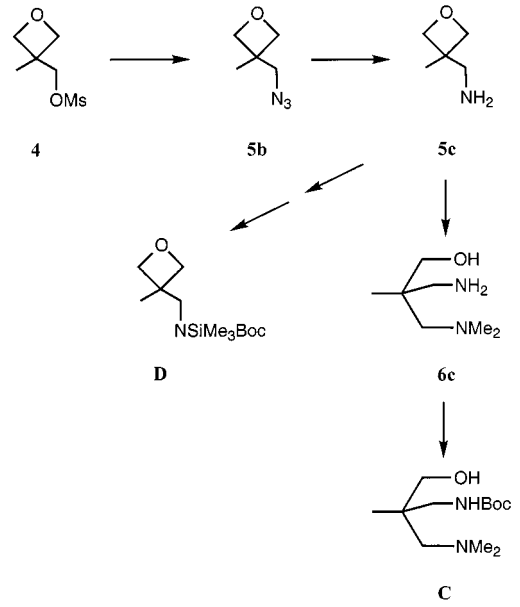


4 **B**

However, any attempt to transform the phthalimide group into an amine function proved problematic. While the cleavage of neopentane-bound phthalimide groups in $CH_3C(CH_2Phth)_3$ has been shown to proceed in the presence of 25% KOH over a period of a few days at room temperature[14], **B** showed no reaction under the same conditions. Hydrazinolysis of **B** was not very effective either; NMR control of the reaction mixture showed that the oxetane functionality was also affected under the drastic conditions necessary (boiling for 10 h). From the reaction mixture obtained after this time, the amine (**5c**) could not be separated.

An alternative strategy starting from **B** might have been possible through its reaction with $LiPPh_2$. If this nucleophile would selectively attack the oxetane ring[5d][5e] of **B**, a subsequent hydrazinolytic cleavage of the phthalimide moiety would no longer be impeded by the reactivity of the oxetane functionality (see above). However, when red $LiPPh_2$ was treated with a solution of colourless **B**, an immediate colour change to deep-green ensued, indicating a reaction at the phthalimide moiety[15]. Reaction control by ^{31}P-NMR spectroscopy showed that a multitude of PPh_2 derivatives of different kinds (^{31}P NMR: δ from −40 to +40) was formed under these conditions. In summary, potassium phthalimide does not appear to be the correct choice of nitrogen nucleophile for the problem at hand.

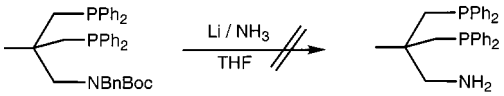
The use of azides as nitrogen nucleophiles is a well-established method, even for polyfunctional and sensitive compounds[16]. This method has previously proved successful in the synthesis of tripod ligands of type **A**[7], and it works as well with **4** as the starting compound. The transformation of **4** into the azide derivative **5b** has been reported in the patent literature, where no details of the procedure were given[17a]. We found that solutions of **4** in DMSO react with a threefold excess of NaN_3 to produce **5b**.



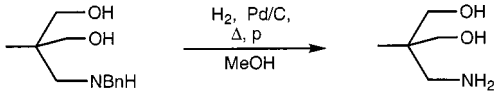
Optimum yields of around 90% were obtained after 30 h at 130°C. Shorter reaction times gave reduced yields (10 h: 50%), while prolonged heating or higher temperatures also reduced the yield (48 h: 55%) (caution: **5b** "AMMO" and several of its polymers are used as explosives[17b] and appropriate care has to be taken in its preparation and work-up). After dilution of the reaction mixture with two equiv. of water, **5b** was extracted into diethyl ether. The presence of **5b** in the ethereal solution was evidenced by an azide band at 2103 cm^{-1} in the IR spectrum. A small amount of the ethereal solution was concentrated to an extent that allowed the characterization of **5b** by ^1H NMR (Exp. Section). The reactivity of **5b** towards PPh_3 gave further proof of its identity: the corresponding iminophosphorane was formed immediately (^{31}P NMR: $\delta = +10.6$), which upon hydrolysis yielded **5c**. Compound **5c** was purified by distillation under reduced pressure, with appropriate care being taken in view of its volatility. The identity of **5c** was obvious from its analytical data (Exp. Section) as well as from its reaction with $HNMe_2/H_2O$ at 30 bar/130°C, which furnished **6c** (Exp. Section). This potential tripod ligand, containing two different nitrogen donors and one oxygen donor, was also fully characterized. Several attempts have been made to further derivatize **6c** with the aim of replacing its OH group by a PPh_2 group. This intended type of transformation requires protection of the NH_2 group. Boc-protection has been found to be adequate, allowing the formation of **C** as a colourless, microcrystalline solid (for analytical and spectroscopic data, see Exp. Section). However, deprotonation of **C** by a minimum of two equivalents of *n*BuLi, subsequent treatment of the product with an excess of MsCl, followed by addition of $LiPPh_2$, resulted in unseparable

product mixtures. These mixtures are not a result of cleavage of the Boc group by *n*BuLi, since **C** can be recovered after treatment with two equivalents of *n*BuLi under the same conditions after hydrolytic work-up. Selective deprotonation of the OH group in the presence of an NHBoc functionality has been reported to occur for HBocNCH(Me)CH_2OH[17c]. In this case, mesylation of the alcohol function was achieved using $MsCl/NEt_3$, whereas in the present case the use of NEt_3 as a base is not feasible since the product obtained after mesylation cannot be purified, presumably due to decomposition by internal cyclization[7a]. If the product mixture is treated with $LiPPh_2$ without any intermediate purification step, a complex mixture of compounds results, with the desired PR_2 substitution occurring only to a minor extent (< 10% according to ^{31}P-NMR data).

A solution to these problems might possibly have been found in replacing the NH function by an $NSiR_3$ function. When **C** was treated with one equivalent of *n*BuLi, and then the reaction mixture was quenched with TMSCl, the *N*-silylated product was obtained. However, mesylation and subsequent reaction with $LiPPh_2$ was again unselective and an unseparable mixture of products was obtained once more. Benzyl-protection of the NHBoc group might appear to be an alternative. However, we found that $CH_3C(CH_2PPh_2)_2(CH_2NBnBoc)$[6], which has been used as a model compound, does not allow for a straightforward debenzylation with the Li/NH_3/THF reagent[18a].



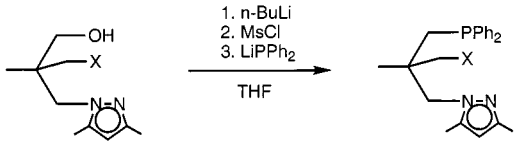
In the present case, only a small yield of $CH_3C(CH_2PPh_2)_2(CH_2NH_2)$ was obtained, which after chromatography was sufficiently pure for identification by NMR spectroscopy with reference to an authentic sample[7b]. Even though the transformation of carbamate-type NBn groups into NH_2 groups by alkali metal in liquid ammonia solutions under carefully controlled conditions is known to work in other cases[18b], the reluctance of the system to undergo a debenzylation reaction does not appear to be due to the presence of the PPh_2 group alone. While hydrogenolytic cleavage of the NBn function is not possible with the model compound due to phosphorus poisoning of the catalyst, it should work well with $CH_3C(CH_2OH)_2(CH_2NBnH)$[6]. With this compound, however, no reaction was observed under conditions using 10% Pd/C catalyst at 1 bar H_2 and 25°C. Only at 60°C under 60 bar H_2 and with reaction times of 12 h was the amine-functionalized product $CH_3C(CH_2OH)_2(CH_2NH_2)$ **E** obtained (Exp. Section).



E

This result suggests that the difficulties observed in the debenzylation reactions are mainly due to the notoriously low reactivity of neopentane derivatives[10]. Even though $CH_3C(CH_2OH)_2(CH_2NH_2)$ is accessible by a debenzylation procedure, its further functionalization is impeded by the same sort of problems as already described for **6c**. The problem of functionalizing **6c** might also potentially be overcome by tracing back the synthesis of **6c** a few steps: Starting from **5c**, Boc-protection and subsequent silylation results in a product **D**, in which the CH_2NH_2 substituent is transformed into a $CH_2NBocSiMe_3$ functionality (see above). When this protected intermediate **D** is treated with $LiPPh_2$, an unseparable reaction mixture nevertheless results (^{31}P NMR: δ from −40 to +40). Tracing one step further back, **5b** produces the iminophosphorano-substituted oxetane $O(CH_2)_2C(CH_3)(CH_2N{=}PPh_3)$ in a clean reaction. If the oxetane moiety of this intermediate would undergo nucleophilic cleavage with $LiPPh_2$, a phosphorus donor might be introduced at such an early stage. However, in practice, this reaction also results in an unseparable mixture (^{31}P NMR) of different phosphorus-containing products.

In contrast to the reluctance of **6c** to undergo further functionalization, **6a** as well as **6b** can be transformed into the phosphorus-containing tripod ligands **7a** and **7b** by the standard procedure[6].



6a : X = NMe_2
6b : X = OH

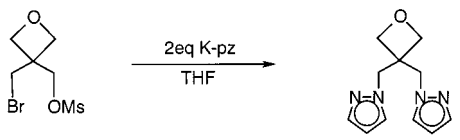
7a : X = NMe_2
7b : X = PPh_2

While **6a** and **6b** are invariably obtained as mixtures (see above), their derivatives **7a** and **7b** can be easily separated by column chromatography owing to the fact that **7a** bearing an NMe_2 group migrates much more slowly than **7b**. Compounds **7** are obtained as colourless, analytically and spectroscopically pure oils (Tables 1 and 2, Exp. Section).

Synthesis of Tripod Ligands Starting from Difunctionalized Oxetanes

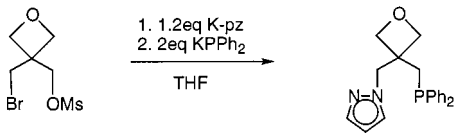
In the synthesis of neopentane-based tripod ligands, the use of difunctionalized oxetanes such as **8**[19] has the additional merit of producing a CH_2OH group at the backbone of the tripod ligand $HOCH_2C(CH_2X)(CH_2Y)(CH_2Z)$, which lends itself to further functionalization of the ligand. Compound **8** has successfully been used as a starting material in the synthesis of phosphorus-containing CH_2OH-functionalized tripod ligands[5d]. Its reaction with nitrogen nucleophiles allows access to mixed donor set tripod ligands containing a CH_2OH group at the quaternary carbon. Thus, **8** reacted with 2 equivalents of K-pz in THF to form the bis(pyrazolyl) derivative **9a**, which was purified by distil-

lation and obtained as a pale-yellow, viscous oil (Exp. Section).



8 **9a**

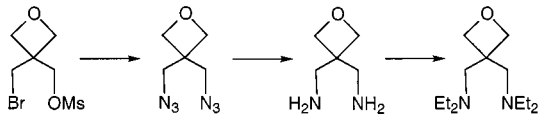
When **8** was treated first with 1.2 equiv. of K-pz and then with 2 equiv. of $KPPh_2$, the substitution product **9b** was obtained in moderate yields. **9b** could be separated from some less polar co-products (including excess $HPPh_2$) by flash chromatography and was obtained as a colourless, microcrystalline solid.



8 **9b**

The identity of the products **9** was established beyond doubt by elemental analyses and mass spectrometry, as well as by NMR spectroscopy (Exp. Section). As usual with 3,3-bis-substituted oxetanes, the symmetric (**9a**) and unsymmetric (**9b**) substitution patterns, respectively, are immediately evident from the multiplicity of the ^{1}H-NMR signals of the oxetane CH_2 groups (Exp. Section)[5d].

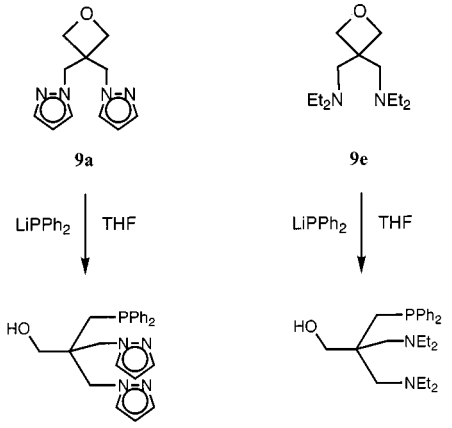
The use of azide as a nucleophile for the substitution of difunctional oxetanes has been reported previously[20a]. Use of **8** as the electrophilically-substituted oxetane instead of $O(CH_2)_2C(CH_2Cl)_2$[20a] was found to increase the yield of **9c** from 25% to around 90%, as inferred from the transformation of **9c** to the corresponding amine **9d** by PPh_3/H_2O.



8 **9c** **9d** **9e**

The NH_2 functions of **9d** could be transformed into NEt_2 functions by treatment with ethyl iodide/K_2CO_3 in ethanol, resulting in a high yield of **9e**[20c]. The oxetane derivatives **9d** and **9e** were fully characterized by their analytical and spectroscopic data (Exp. Section). The potentially explosive **9c** was characterized by its ^{1}H-NMR spectrum, an azide band at 2105 cm^{-1} in the IR spectrum, and its derivatization to **9d**.

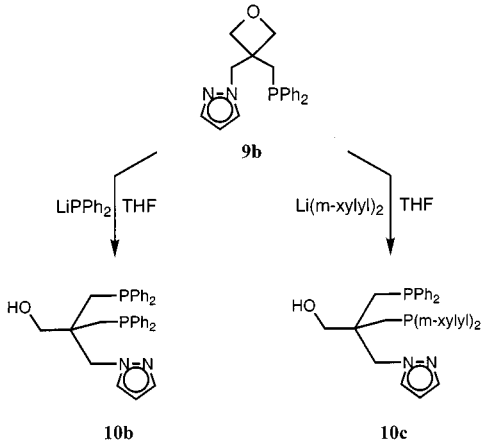
The difunctionalized oxetanes **9a**, **9b**, and **9e** underwent nucleophilic cleavage of the oxetane ring upon treatment with $LiPPh_2$ in boiling THF, resulting in the CH_2OH-functionalized tripod ligands **10**.



9a **9e**

10a **10d**

Compounds **10** were obtained as colourless oils upon chromatographic work-up. Elemental analyses, mass spectra, and NMR data were consistent with the given constitution in each case (Tables 1 and 2, Exp. Section).



9b

10b **10c**

The diastereotopicity of the protons of some of the CH_2 groups in the neopentane framework is of considerable help in assigning the relevant signals to the individual CH_2 entities. For instance, the protons at the pyrazolyl-substituted CH_2 groups of **10a** are diastereotopic, while those of the CH_2PPh_2 and CH_2OH moieties, respectively, are not.

The appearance of the corresponding ^{1}H-NMR signals clearly reflects this difference (Table 1). Analogous arguments help in assigning the ^{1}H-NMR data of the other compounds **10**; the resolution obtainable at 200 MHz does, however, preclude a complete assignment of the ^{1}H-NMR spectra of **10c** and **10d** (Table 1).

Functionalization of the CH_2OH group at the backbone of tripod ligands is generally hampered by difficulties[21]. Problems arise because of the reduced reactivity of neopentane derivatives as well as due to the fact that tripod ligands, by definition, contain other nucleophilic groups (the ligand entities!) besides the CH_2OH entity. Thus, treatment of **10d** for example with KO*t*Bu/EtI in THF not unexpectedly results in a mixture of products, probably because of partial quaternization of the amine donor functions.

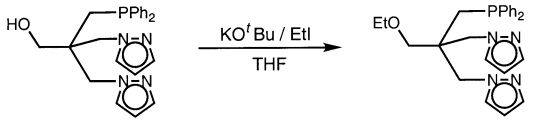
[a] $J = {}^2J_{HH}$ unless otherwise stated, coupling constants in Hz. – [b] All pyrazolyl-H′s (except for **7a** and **7b**) give broad signals due to $^3J_{HH}$ coupling (unresolved at 200 Mhz) and integrate as 1 H.

The pyrazolyl residues, being more resistant to electrophilic attack compared to the NEt_2 nucleophiles, should not be prone to problems resulting from quaternization and, indeed, **10a** is transformed to its ethyl ether derivative without complications. The complete set of analytical and spectroscopic data obtained for **11** is in accord with its proposed constitution (Tables 1 and 2, Exp. Section).

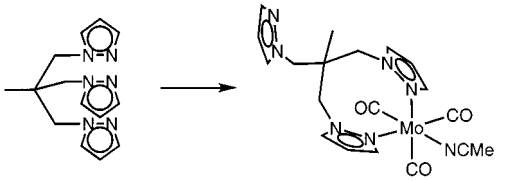


10a **11**

Coordination Chemistry

The coordination behaviour of the novel ligands was tested with $(MeCN)_3Mo(CO)_3$ as the substitution-labile precursor[22]. With the tris(pyrazolyl)-substituted ligand **2**, displacement of only two MeCN groups was observed, resulting in the $Mo(MeCN)(CO)_3$ derivative **12a**, in which **2** acts as a bidentate ligand.

On the basis of its mass spectrum and its ν(CO) IR data, **12a** might appear to be a compound of the composition **2**·$Mo(CO)_3$, containing η^3-coordinated **2** (Table 5, Exp. Section). The ^{1}H-NMR data obtained for **12a**, however, clearly demonstrate that only two pyrazolyl functions are coordinated, while the third one plays the role of a dangling arm (Table 3). The signals attributable to the CH_2pz groups show a clear 2:1 intensity pattern, with the signals of the coordinated residues significantly shifted compared to those of the dangling arm CH_2pz entity (Table 3). This 2:1 pattern is also evident in the ^{13}C-NMR data of **12a** on inspection of the signals of the CH_2pz and pyrazolyl carbons



2 **12a**

(Table 4). The presence of a coordinated acetonitrile can also be deduced by NMR (Tables 3 and 4). Even if the shift imposed on the MeCN ligand by coordination is not always large enough to allow unequivocal differentiation between a coordinated and a non-coordinated acetonitrile, the relative intensity of the MeCN signal in the ^{1}H-NMR spectrum of **12a** shows that just one MeCN is present in each molecule (Table 3), which, in accord with the 18-electron rule and the findings described below (for **12c**, **12d**), leads to the given constitution for **12a**.

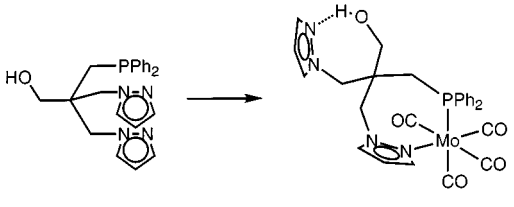
[a] Solvent: CD_2Cl_2; the CD_2Cl_2 was condensed into the NMR tubes prior to flame sealing. − [b] Solvent: $CDCl_3$.

While η^3-coordination did not occur with **2**, having three pyrazolyl donor functions, it appeared probable that the exchange of one pz donor by a PPh_2 group might favour the facial coordination of ligands such as **10a**. While **2** would form a chelate cage with three condensed eight-membered chelate cycles, only one eight-membered cycle and two seven-membered cycles would result from the η^3-coordination of **10a**. However, reaction of **10a** with



10a **12b**

$(MeCN)_3Mo(CO)_3$ affords **12b** as the only isolable product.

The presence of an $Mo(CO)_4$ group in **12b** is evident from the ν(CO) bands, as well as from its mass spectrum (Table 5, Exp. Section). The formation of $Mo(CO)_4$ derivatives from $(MeCN)_3Mo(CO)_3$ is well-documented in tripod coordination chemistry[6][21b]. The ^1H-NMR spectrum of **12b** cannot be completely resolved at 200 MHz; nevertheless, the groups of signals show the expected integral ratios (Table 3). For the bridging hydrogen evident in the solid-state structure (see below), no signal could be assigned, nor could an appropriate band be found in the IR spectrum of **12b**.

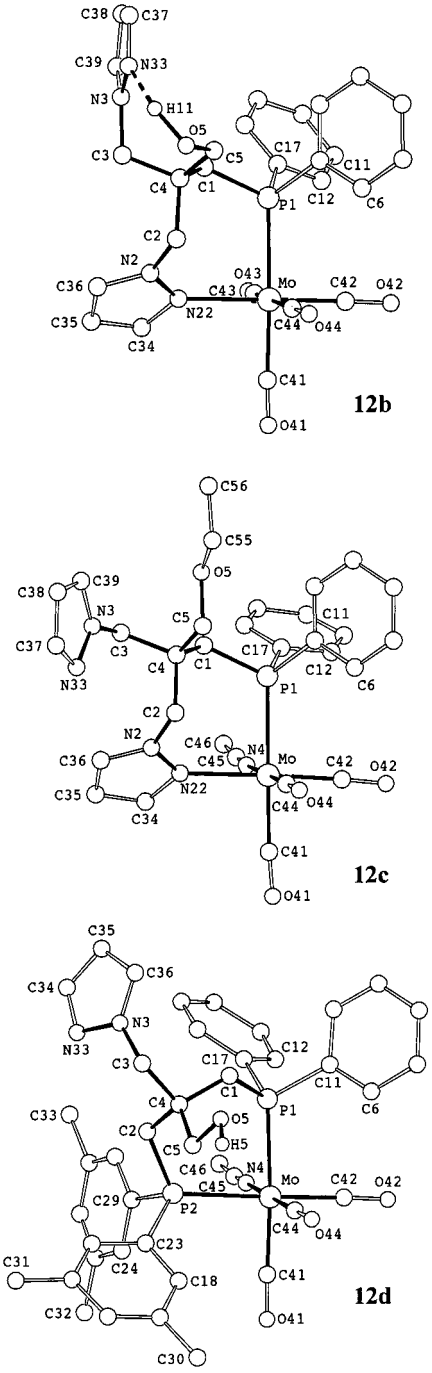
Crystals of **12b** suitable for X-ray analysis were obtained from dichloromethane by vapour-phase diffusion with petroleum ether (40/60). The structure of **12b**, as determined by single-crystal X-ray analysis (Table 8)[23a], is shown in Figure 1: η^2-coordination of the ligand by one pyrazolyl and one phosphorus donor results in the formation of a seven-membered chelate cycle. The tendency of the pyrazolyl ligand to enforce coplanarity between the bonds radiating from the two nitrogen centers in the ring (torsion angle Mo−N−N−C 1.9°, Table 6) results in a characteristic puckering at the other positions of the seven-membered ring, which is also observed for the corresponding entity in **12c** (Figure 1, Table 6).

A peculiar feature of the structure of **12b** is the formation of a strong OH−N hydrogen bond between the dangling arm pyrazolyl entity and the CH_2OH group. The corresponding N−O distance amounts to only 280 pm; the position of the bridging hydrogen has been successfully refined (Table 6).

A seven-membered ring is formed, with the OH group and the pyrazolyl entity linked by the hydrogen bond (Figure 1). With the coplanarity of the H−N−N−C fragment of this ring, its conformation is similar to that observed for the chelate ring (for torsion angles, see Table 6). Since it appears that in **12b** (see also **12d**) the OH proton competes successfully with the metal in coordinating the second pyrazolyl function of **10a**, η^3-coordination of a ligand of the type **10a** might possibly have resulted when the OH function of **10a** was transformed into the OEt function of **11**. However, it was found that **11** produces **12c** when reacted with $(MeCN)_3Mo(CO)_3$, in which again only two donor functions coordinate to the metal center (Figure 1). One pyrazolyl donor and the ethoxy group remain uncoordinated.

The conformation of the seven-membered chelate cycle closely resembles that observed for **12b** (for torsion angles, see Table 6). On the other hand, the rotational orientation

Figure 1. Conformations as observed for **12b**, **12c**, and **12d** in the solid state[a]



[a] The numbering scheme selected for compounds **12** allows direct comparison with the data given in ref.[6].

of the dangling arm functions is distinctly different from the situation in **12b**, where these donor functions are connected by a strong hydrogen bond (Table 6, Figure 1). Since the conformations of the chelate rings in **12b** and **12c** are nevertheless almost identical, this means that there is little interference between the conformation of the chelate ring at the metal center and the orientation of the substituents at C4 (Figure 1, Table 6). The spectroscopic data obtained

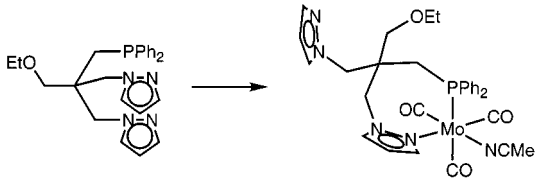
[a] The numbering scheme is such that chemically equivalent atoms have the same numbers in molecules **12b**, **12c** and **12d**.



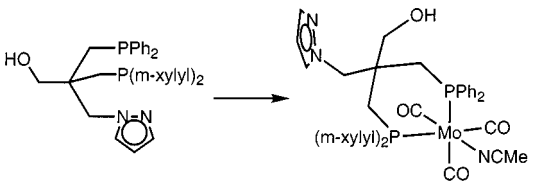
11 **12c**

for **12c** are roughly similar to those obtained for **12a** (Tables 3, 4, and 5). With the structure of **12c** known, this is an indirect proof of the validity of the constitution assigned to **12a**. The ^{1}H-NMR data of **12c** have been analysed in some detail (Table 3). Since at 200 MHz the signals of the five different types of CH_2 groups of **12c** are largely overlapped, a series of 2D-NMR experiments (see Exp. Section) was essential to allow complete assignment of all the individual signals (Tables 3 and 4). A rather astonishing result of these experiments was that the diastereotopic protons of the CH_2P group were found to have their resonances separated by about 1.5 ppm (Table 3). An equally large shift difference was observed for the two diastereotopic protons at the coordinated CH_2pz group (δ = 4.28, 5.37, Table 3). The dangling arm CH_2pz entity has a more normal shift difference (δ = 4.10, 4.28, Table 3) between its diastereotopic protons[6]. The observed strong differentiation between the two

hydrogens at the CH_2 groups in the chelate ring calls for an explanation, since correspondingly large shift differences have, to our knowledge, not hitherto been observed in compounds of neopentane-based ligands, nor in coordination compounds containing the CH_2pz group as part of a ligand[6][24]. It is assumed that the magnetic anisotropy of the dangling arm pyrazolyl entity is responsible for the observed difference in the magnetic shielding of the CH_2 groups within the chelate ring.

The two different types of pyrazolyl entities in **12c** give rise to several ^{1}H resonances in the aromatic region [Table 3; for the numbering scheme, see Figure 4 (Exp. Section)]. The resonance of the central CH group at C4 is well-separated on the highfield side of this range. The resonance of this group is significantly shifted downfield upon coordination (Table 3). An unequivocal assignment of the resonances of the CH groups at C3 and C5 was possible with the combined application of 2D-NMR experiments (Tables 3 and 4, Exp. Section). The ^{1}H signals of the phenyl substituents at the phosphorus could also be fully assigned (Table 3). The ^{13}C-NMR spectrum of **12c** shows an upfield shift for the methylene carbons bound to the coordinated PPh_2 and pyrazolyl entities and a downfield shift for the carbons of the coordinated pyrazolyl entity, while the ^{13}C signals of the non-coordinated CH_2pz group exhibit no shift at all (compared to the free ligand, see Tables 2 and 4). The information gleaned from these NMR experiments is important in so far as no data have hitherto been reported pertaining to the complete and absolute assignment of non-coordinated and coordinated pyrazolyl functions in the same coordination compound[24].

The fact that **11**, containing two pyrazolyl donor functions, acts only as a bidentate ligand, even though the OH group, which competes with the metal coordination of one pyrazolyl donor in the reactions of **10a**, is blocked as an OEt function, indicates that η^3-coordination of neopentane-based tripod ligands will tolerate at most one pyrazolyl donor. An attempt was therefore made to coordinate **10c**, which contains one pyrazolyl and two phosphorus donors, in an η^3-fashion to an $Mo(CO)_3$ fragment. Again, under standard conditions, only bidentate coordination of **10c** was observed, with the $Mo(MeCN)(CO)_3$ fragment coordinated to the two phosphorus donors of the ligand.



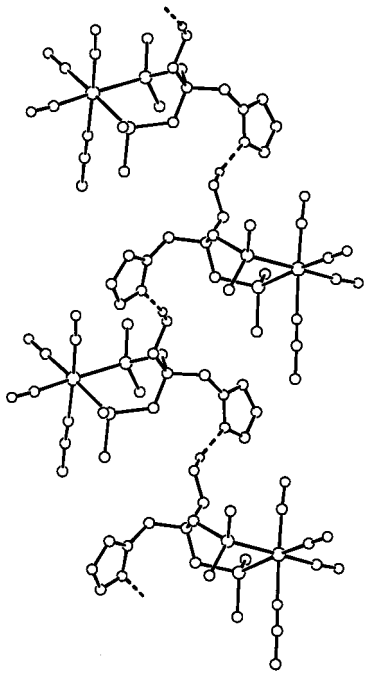
10c **12d**

The presence of a dangling arm pyrazolyl function is indicated by the ^{1}H-NMR data, where the CH_2pz group as well as the CH group at C4 of the pyrazolyl ring show their resonances in the ranges expected for non-coordinated CH_2pz groups (cf. **12c**, Table 5). The coordination of the two phosphorus donors is evident from the ^{31}P-NMR data (Table 3). From the mass spectrum of **12d**, the η^2-coordination of the ligand is not apparent since, as with **12a** and **12c**, the MeCN group is no longer present in the ions detected; [**10c**·$Mo(CO)_3^+$] is the ion with the highest *m*/*z* ratio observed.

The given constitution of **12d** was unequivocally proven by X-ray analysis. Small single crystals of **12d** were obtained by vapour-phase diffusion of petroleum ether (40/60) into the reaction mixture after it had been reduced to half of its original volume. The crystals were found to be very sensitive to air and moisture, but could be subjected to X-ray analysis when immersed in perfluorinated polyether oil and immediately cooled to −70°C (Exp. Section). The coordination of the two phosphorus donors leads to the formation of a six-membered chelate cycle (Figure 1). The conformation of the chelate ring does not correspond to a distinct chair-type arrangement (almost C_s symmetric), which has been observed in quite a number of related structures derived from neopentane-based tripod ligands in an η^2-coordination mode[6][25]. It does not conform to a twistboat arrangement either, which is again found in the structures of some closely related molecules[6][25]. In this context, the structure of $CH_3C(CH_2PPh_2)_2(CH_2Cl)Mo(CO)_4$[23b] is of interest, in which the chelate cycle adopts a distorted chair conformation (P1−C1−C2−P2 = 62.5°, see below). This compound was prepared in order to study the reactivity of the CH_2Cl group with the phosphorus donors protected by an $Mo(CO)_4$ entity − a strategy which has proved useful in certain ligand syntheses[26]. Its structure was analysed in order to get some appraisal of the accessibility of the CH_2Cl group to nucleophiles. The chlorine function has been found to point outwards, away from the molybdenum center[23b]. In contrast, the presence of two sterically demanding functionalities (CH_2pz, CH_2OH) at the central carbon atom in compound **12d** leads to some irregular distortion, which is best described as a chair conformation with some twist, as indicated by the torsion angle P1−C1−C2−P2 of 35.8°. This angle is close to 0° for a chair or boat conformation and around 70° for a pure twist-boat (see above)[6]. This type of distortion of the chelate ring in **12d** has not previously been observed in the coordination chemistry of neopentane-based tripod ligands acting in an η^2-coordination mode. One reason for the distortion observed in **12d** may be the fact that the pyrazolyl substituent and the OH group are both involved in intermolecular hydrogen bonding. The individual molecules are linked by this hydrogen bonding to form chains spiralling around the 2_1 axis, characterizing the symmetry of the crystal in the space group $P2_1/c$. Figure 2 shows a projection illustrating the arrangement in this infinite spiral.

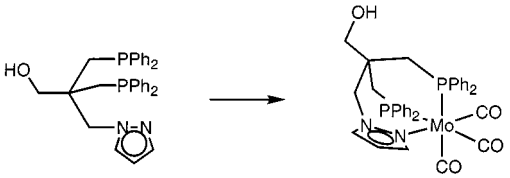
In spite of the unconventional folding of the chelate ring of **12d**, the rotational position of the PPh_2 moieties relative to the idealized octahedral axis of the coordination polyhedron and the rotational position of the phenyl groups relative to the Mo−P axis are not dissimilar from those observed in quite a number of other essentially similar compounds (Table 6)[6].

Figure 2. Hydrogen bonding pattern as observed for **12d** in the crystal[a]



[a] For the sake of clarity, the aryl groups are represented by their *ipso*-carbon atom only; for structural features of **12d** see also Figure 1 and Table 6.

The idea that a tripod ligand of type **A** with only one pyrazolyl donor group and two phosphorus donors should be capable of η^3-coordination appears to be ruled out at first glance by the η^2-coordination observed for **12d**. However, it may be argued that the steric bulk introduced by the 3,5-dimethylphenyl substituents at P2 may be a factor in favouring η^2-coordination, which, as shown for the solid-state structure of **12d**, is then additionally stabilized by intermolecular hydrogen bonding. To verify this argument, the reactivity of **10b** towards $(MeCN)_3Mo(CO)_3$ was tested. While with this ligand intermolecular hydrogen bonding might also favour η^2-coordination, the reduced steric demand of **10b** − two PPh_2 groups instead of one PPh_2 and one $P(3,5\text{-}Me_2Ph)_2$ group − might successfully compete, such that η^3-coordination could result. Such a facial coordination of **10b** is in fact observed, with the $Mo(CO)_3$ derivative **13** being formed.

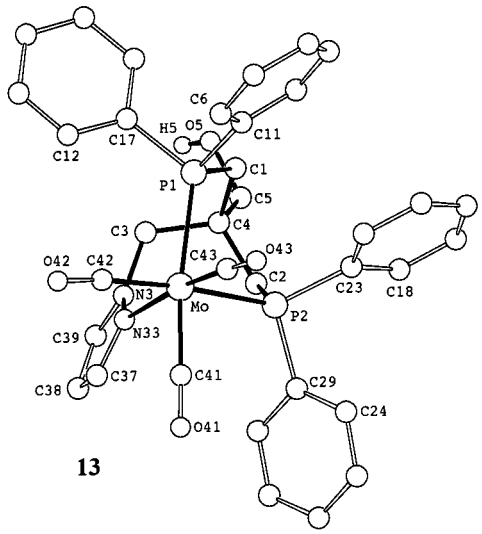


10b **13**

The fact that the ligand **10b** is coordinated in an η^3-binding mode cannot, of course, convincingly be deduced from the appearance of the molecular ion in the mass spectrum (see above), nor is it proved by the observation of the ν_{CO} IR pattern, even though this corresponds to the $A_1 + E$ envelope [Table 5, expected idealized local C_3 symmetry for this type of coordination of the $Mo(CO)_3$ chromophore]. The coordination of the two phosphorus donors on the other hand is clearly evident from the ^{31}P-NMR data (Table 5). The fact that the pyrazolyl donor is coordinated as well is at least not contradicted by the corresponding ^{1}H-NMR data (Table 3). The NMR data give convincing evidence for the fact that the OH group is not coordinated to the metal (Table 3).

Again, the constitution was unambiguously proved by an X-ray analysis performed on well-formed needles obtained from dichloromethane solutions of **13** by vapour-phase diffusion with petroleum ether (40/60). Two crystallographically independent molecules **13** are observed in the crystal (Figure 3). The overall conformations of the two molecules are rather similar, as shown by the torsion angles given in Table 7 (even the torsional positions of the aryl substituents are almost equivalent in the two symmetrically independent species within the crystal).

Figure 3. Conformation as observed for **13/1** in the solid state[a]



13

[a] **13/1** and **13/2** designate the two crystallographically independent molecules in the crystal of **13**. The structure of **13/2** corresponds in its overall arrangement to the structure shown for **13/1**. The numbering scheme chosen for **13** allows for the direct comparison with the data given in ref.[6].

The relative arrangement of the aryl substituents is in accord with a pattern previously described for η^3-coordinated tripod ligands containing two PPh_2 groups and one nitrogen donor[6], even though the chelate cage of **13** contains two seven-membered and only one six-membered cycle, while the cages of comparable molecules[6] contain the standard set of three condensed six-membered cycles. The main difference between the two individual molecules **12** within the crystal is a different orientation of the CH_2OH group relative to the chelate cage (Table 7). This difference in orientation results from the fact that, of the two independent molecules, one is engaged as a proton donor in a hydrogen bond, with one carbonyl group of the other molecule acting as the proton acceptor. The interaction is very weak (d_{O-O} = 299 pm, d_{O-H} = 229 pm, O−H−O =

[a] The numbering scheme adopted for **13/2** relates chemically equivalent atoms by adding 100 to the numbers used in **13/1** (not including molybdenum). The torsion angles given refer to a selection of enantiomers such that the skew of the chelate scaffolding has the same sense for both individual molecules.

144.2°), but is clearly present, as found in the solid-state structure. The OH group of the second molecule shows no close contacts to other hydrogen-accepting positions within the crystal.

The interatomic distances within the five individual molecules (**12b−d** and two molecules **13/1** and **13/2** in the crystal of **13**) are in rather close agreement. The Mo−P bond lengths span a range approximately between 250 and 255 pm (Tables 6 and 7). The Mo−N distances to the pyrazolyl donors are similarly found in a narrow range (228−233 pm), while the coordinated acetonitriles in **12c** and **12d** show significantly shorter Mo−N distances (220−222 pm). The Mo−C(CO) distances are in the usual range. A significant shortening of the Mo−C(CO) bond *trans* to to the pyrazolyl donor is observed in all molecules (Mo−C42 for **12b−d**, Mo−C43 for **13/1**, **13/2**). The Mo−C(CO) bonds *trans* to the acetonitrile ligands are also significantly shorter (Mo−C44 in **12c/d**) than the Mo−C(CO) bonds that are *trans* to an Mo−P bond. This observation reflects the higher donor/acceptor ratio of the nitrogen donors relative to a phosphane ligand. The bite angles P−Mo−N and P−Mo−P, respectively, span a range between 82° and 95° (Tables 6 and 7); angles smaller than 90° are generally observed. An angle of over 90° occurs only in **13**, where in both of the two independent molecules one of the P−Mo−N angles has a value around 95°. This large angle appears to be the result of the steric strain within the seven-membered chelate cycles. This strain leads to a folding of these cycles (Figure 3), which increases the steric burden on one of the phosphorus donors (P1), while relieving the burden on the other (P2). The angle P1−Mo−N33 responds to this strain by increasing accordingly. The presence of strain in the chelate cage of **13** is also indicated by the conformation of the six-membered chelate cycle, which, although in a situation where the chelate cage consists of three condensed six-membered rings, i.e. the normal tripod metal templates $RCH_2C(CH_2X)(CH_2Y)(CH_2Z)M$, is invariably found in an approximate boat arrangement[27]. In **13**, there is an appreciable twist in the boat conformation of this ring (P1−C1−C2−P2 = −39.7°, P101−C101−C102−P102 = −33.7°), which is similar to the twist observed in **12d**, where steric strain was also invoked as an explanation (see above).

Conclusions

1. It is found that pyrazolyl as well as imidazolyl donors may be incorporated into neopentane-based tripod ligands by means of nucleophilic substitution reactions with potassium pyrazolate and potassium imidazolate, respectively.

2. It is shown that the oxetane ring of substituted oxetanes $O(CH_2)_2C(CH_3)(CH_2X)$ undergoes aminolytic cleavage to furnish $CH_3C(CH_2X)(CH_2Y)(CH_2OH)$ systems, with X being an amine or a pyrazolyl substituent and Y being an amine function.

3. It is demonstrated that starting from $O(CH_2)_2$-$C(CH_2Br)(CH_2OMs)$, by selective substitution of the nucleophugic groups and subsequent nucleophilic cleavage of the oxetane moiety, chiral tripod ligands $HOCH_2C(CH_2PR_2)(CH_2Y)(CH_2Z)$ with mixed nitrogen/phosphorus donor sets may be obtained.

4. It is observed that potential tripod ligands $HOCH_2$-$C(CH_2pz)_{3-n}(CH_2PR_2)_n$ tend to act as bidentate chelate ligands when less than two phosphorus donors are present. The size of the chelate ring is invoked as an explanation, with this argument being corroborated by X-ray analysis.

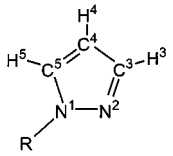
We are grateful to the *German Science Foundation (DFG)*, *SFB 247*, the *VW Foundation (Stiftung Volkswagenwerk)*, and the *Fonds der Chemischen Industrie* for financial support. The author would especially like to thank *F. Rominger* for help with the data collection for the X-ray structure analysis of **12b** and **12c**. The technical support by *Th. Jannack* (mass spectrometry) and the *Microanalytical Laboratory of the Institute of Organic Chemistry* is gratefully acknowledged.

Experimental Section

All manipulations involving phosphanes were carried out under an argon atmosphere by means of standard Schlenk techniques and were monitored by TLC (Macherey-Nagel & Co., Polygram SIL G/UV_{254}). − The aminolytic cleavage of oxetanes was carried out in an HR 100 stainless steel high-pressure laboratory reactor (Berghof/Maasen GmbH) equipped with inlet and outlet valves and a manometer. − The bulb-to-bulb distillations were performed in a kugelrohr apparatus (Büchi). − All solvents were dried by standard methods[28] and distilled under argon. The solvents $CDCl_3$ and CD_2Cl_2 used for the NMR spectroscopic measurements were degassed by three successive "freeze-pump-thaw" cycles and dried over 4 A molecular sieves. − NMR: Bruker Avance DPX 200 at 200.13 MHz (^1H), 50.323 MHz ($^{13}C\{^1H\}$), 81.015 MHz ($^{31}P\{^1H\}$), T = 298 K, chemical shifts (δ) in ppm with respect to $CHCl_3$ (^1H: δ = 7.27, ^{13}C: δ = 77.0) and CH_2Cl_2 (^1H: δ = 5.32, ^{13}C: δ = 53.5)

as internal standards. ^{31}P chemical shifts (δ) in ppm with respect to 85% H_3PO_4 (^{31}P: δ = 0) as external standard. − 2D-NMR experiments: DQF-COSY[29a], TOCSY[29b], NOESY[29c], HMQC[29d], and HMBC[29e] experiments were performed in order to allow the complete assignment of protons and carbons in **12c**. − IR: Bruker FT-IR IFS-66, CaF_2 cells. − MS (EI): Finnigan MAT 8320; fast-atom bombardment (FAB) xenon, matrix: 4-nitrobenzyl alcohol. − Melting points: Gallenkamp MFB-595 010; uncorrected values. − Elemental analyses: Microanalytical Laboratory of the Organisch-Chemisches Institut, Universität Heidelberg. The procedures used for determining the carbon content often give falsely low values when Mo is present in a compound owing to the formation of incombustible Mo carbide; nitrogen values generally tend to be to low as well. − The silica gel (Kieselgel z.A. 0.06−0.2 mm, J. T. Baker Chemicals B.V.) used for chromatography was degassed at 1 mbar for 24 h and saturated with argon. A solution of 2.5 M *n*BuLi in hexanes was used for deprotonations. $Mo(CO)_6$ was sublimed before use. **1**[9], $(MeCN)_3Mo(CO)_3$[22], **4**[19] and **8**[5d] were prepared according to literature procedures. All other chemicals were obtained from commercial suppliers and used without further purification.

Figure 4. NMR numbering scheme for the pyrazolyl ring[24]



X-ray Structure Determinations: Suitable crystals were taken directly out of the mother liquor, immersed in perfluorinated polyether oil and fixed to a glass capillary at 200 K. The measurements for **12d** and **13** were carried out on a Siemens P4 four-circle diffractometer (equipped with a low temperature device) with graphite-monochromated Mo-K_α radiation. The measurements for **12b** and **12c** were carried out on a Siemens CCD/SMART System (equipped with a low temperature device) also with graphite-monochromated Mo-K_α radiation. All calculations were performed using the SHELXT-PLUS[30] software package. Structures were solved by direct methods with the SHELXS-86 program[30a] and refined with the SHELX-93 program[30b]. Graphical handling of the structural data during solution and refinement was performed with XPMA[31]. An absorption correction (ψ-scan, Δψ = 10°) was applied to the data for **12d** and **13**. An empirical absorption correction was applied in the cases of **12b** and **12c**. Atomic coordinates and anisotropic parameters of the non-hydrogen atoms were refined by full-matrix least-squares calculations. Data for the structure determination are compiled in Table 8.

Ligand Synthesis

1,1,1-Tris(pyrazol-1-yl-methyl)ethane (**2**): 3.40 g (50 mmol) of pyrazole was dissolved in 100 ml of DMSO and deprotonated at 0°C with 5.61 g (50 mmol) of KO*t*Bu. After warming to room temperature, 1.58 g (9 mmol) of tris(chloromethyl)ethane **1** in 10 ml of DMSO was added. The resulting mixture was stirred for 12 h at 120°C. The solution was then cooled and the DMSO was evaporated in vacuo (10^{-1} mbar). 60 ml of water was added to the oily brown residue and after stirring for 20 min., the brown solution was extracted with 50 ml portions of diethyl ether (5×). The combined organic phases were concentrated in vacuo (10^{-1} mbar). The brown residue was divided into three portions, which were separately purified by bulb-to-bulb distillation. After removing the pyrazole at 120°C (0.5 mbar), the temperature was raised further and 1.11 g (4.1 mmol, 46%) of **2** was obtained as colourless needles (200−250°C/0.5 mbar). − MS (EI); *m/z* (%): 270 (10) [M^+], 189 (100) [$M^+ - CH_2pz$], 121 (59) [$M^+ - CH_2pz - pz$], 81 (45) [CH_2pz^+]. − $C_{14}H_{18}N_6$ (270.34): calcd. C 62.19, H 6.71, N 31.10; found C 61.86, H 6.88, N 29.90.

1,1,1-Tris(imidazol-1-yl-methyl)ethane (**3**): 4.08 g (60 mmol) of imidazole was dissolved in 120 ml of DMSO and deprotonated at 0°C with 6.73 g (60 mmol) of KO*t*Bu. After warming to room temperature, 1.76 g (10 mmol) of tris(chloromethyl)ethane **1** in 10 ml of DMSO was added. The resulting mixture was stirred for 14 h at 120°C. The solution was then cooled and the DMSO was evaporated in vacuo (10^{-1} mbar). 70 ml of water was added to the reddish-brown residue. After stirring for 20 min, the brown solution was extracted with 30 ml portions of THF (5×) and subsequently with 20 ml portions of dichloromethane (3×). The combined organic phases were dried over $MgSO_4$, filtered, and concentrated in vacuo (10^{-1} mbar). The resulting orange-coloured oil was divided into three portions, which were separately purified by bulb-to-bulb distillation. 0.35 g (1.3 mmol, 13%) of **3** as colourless crystals (230°C/0.02 mbar) was obtained. − MS (EI); *m/z* (%): 271 (67) [M^+], 189 (28) [$M^+ - CH_2$imidazole], 121 (100) [$M^+ - CH_2$imidazole − imidazole], 81 (81) [CH_2imidazole$^+$]. − $C_{14}H_{18}N_6$ (270.34): calcd. C 62.19, H 6.71, N 31.10; found C 61.75, H 6.57, N 30.67.

3-Methyl-3-(3,5-dimethylpyrazol-1-yl-methyl)oxetane (**5a**); 4.80 g (60 mmol) of 3,5-dimethylpyrazole was dissolved in 150 ml of THF and deprotonated at 0°C with 6.74 g (60 mmol) of KO*t*Bu. The solution was then allowed to warm to room temperature. In a second flask, 9.00 g (50 mmol) of 3-methyl-3-(methylsulfonyloxymethyl)oxetane **4** in 100 ml of THF was cooled to 0°C. The potassium pyrazolate solution was then added and the reaction mixture was refluxed for 4 h. The jelly-like mixture was then quenched by the addition of 50 ml of water and the aqueous phase was extracted with 30 ml portions of diethyl ether (2×). The combined organic phases were washed with brine, dried over $MgSO_4$, filtered, and distilled through a 20 cm Vigreux column at 1 mbar. 6.85 g (38 mmol, 76%) of **9a** was obtained as a colourless oil (b.p. 128−133°C, 1 mbar). − ^1H NMR ($CDCl_3$): δ = 1.18 (s, 3 H, CqCH_3), 2.13, 2.15 (2s, 6 H, pzCH_3), 4.05 (s, 2 H, CH_2pz), 4.29, 4.70 (2d, 4 H, oxetane-CH_2, $^2J_{HH}$ = 5.8 Hz), 5.72 [s, 1 H, C*H(4)*pz]. − ^{13}C NMR ($CDCl_3$): δ = 11.8, 13.9 (2s, pzCH_3), 22.3 (s, CqCH_3), 41.5 (s, Cq), 54.5 (s, CH_2pz), 81.0 (s, oxetane-CH_2), 105.2 [s, *C(4)*pz], 139.5 [s, *C(5)*pz], 148.0 [s, *C(3)*pz]. − MS (EI); *m/z* (%): 180 (30) [M^+], 149 (55) [M^+ − CHO], 109 (100) [CH_2pz^+], 96 (22) [pz^+]. − $C_{10}H_{16}N_2O \cdot 1/3\ H_2O$* (180.25): calcd. C 64.49, H 9.02, N 15.04; found C 64.47, H 9.05, N 15.05. *The water content was inferred from the analytical results, which were well reproducible.

3-Azidomethyl-3-methyloxetane (**5b**): 18.0 g (0.1 mol) of 3-methyl-3-(methylsulfonyloxymethyl)oxetane **4** and 19.0 g (0.3 mol) of NaN_3 were dissolved in 300 ml of DMSO. This mixture was stirred vigorously for 30 h at 120°C. After cooling to room temperature, 600 ml water was added and the solution was carefully extracted with 100 ml portions of diethyl ether (4×). The combined organic phases were concentrated in vacuo (10^{-1} mbar) to half of the initial volume (CAUTION: explosive). A sample of 1 ml was concentrated to dryness at 10^{-2} mbar (0°C) in order to obtain spectroscopic data of **5b**. − IR (Et_2O): ν = 2103 (s, $-N_3$). − ^1H NMR ($CDCl_3$): δ = 1.28 (s, 3 H, CH_3), 3.48 (s, 2 H, CH_2N), 4.31, 4.39 (2d, 4 H, $^2J_{HH}$ = 6.0 Hz, oxetane-CH_2). − ^{13}C NMR ($CDCl_3$): δ = 23.1 (s, *C*H_3), 40.5 (s, *Cq*), 58.1 (s, *C*H_2N), 79.6 (s, oxetane-*C*H_2).

3-Aminomethyl-3-methyloxetane (**5c**): 23.7 g (90 mmol) of PPh_3 was added slowly to a well-stirred ethereal solution of **5b**. Evolution

[a] Due to badly resolved, disordered solvent molecules.

of nitrogen was observed over a period of two hours. The reaction mixture was then stirred at room temperature for 10 h [reaction control: ^{31}P NMR: PPh_3, δ = −7.2, imidophosphorane (R−N=PPh_3), δ = +10.6; IR: ν = 2103 (s, R−N_3)]. Subsequently, addition of 1.8 ml of water and refluxing for two hours led to cleavage of the imidophosphorane (reaction control: ^{31}P NMR: O=PPh_3, δ = +28.2). The solvent was removed under reduced pressure (100 mbar) using a trap (−70°C). The residue was distilled through a 10 cm Vigreux column at 20 mbar while the head was cooled to −10°C (using a cryostat) and the collecting flask was ice-cooled. 9.1 g (82 mmol, 82%) **5c** was obtained as a colourless oil; b.p. of 40°C (20 mbar). − ^{1}H NMR ($CDCl_3$): δ = 1.21 (s, 3 H, CH_3), 2.86 (s, 2 H, CH_2N), 4.35, 4.41 (2d, 4 H, $^2J_{HH}$ = 5.8 Hz, oxetane-CH_2). − ^{13}C NMR ($CDCl_3$): δ = 21.1 (s, *C*H_3), 40.4 (s, *Cq*), 49.1 (s, *C*H_2S), 80.2 (s, oxetane-*C*H_2). − MS (EI), *m/z* (%): 129 (9) [$M^+ \cdot H_2O$], 101 (10) [M^+]. − $C_5H_{11}NO \cdot 1/10$ DMSO/H_2O* (110.76): calcd. C 56.39, H 10.74, N 12.65; found C 56.29, H 10.97, N 12.91. *The DMSO content was estimated by NMR; the water content was inferred from elemental analysis.

3-(tert-Butyloxycarbonyl)aminomethyl-3-methyloxetane (*Boc-***5c**): Boc-protection of **5c** was carried out on a 25 mmol sample according to a previously published procedure[6]. After work-up, Boc-**5c** was obtained as a colourless oil, which could be crystallized by overlayering a dichloromethane solution with petroleum ether (40/60). After two days, 4.07 g (20 mmol, 81%) of Boc-**5c** was isolated in the form of colourless needles. − ^{1}H NMR ($CDCl_3$): δ = 1.26 (s, 3 H, CqCH_3), 1.42 (s, 9 H, *Boc*), 3.26 (d, 2 H, $^3J_{HH}$ = 6.4 Hz, CH_2N), 4.31, 4.43 (2d, 4 H, $^2J_{HH}$ = 5.8 Hz, oxetane-CH_2), 5.25 (bs, 1 H, N*H*). − ^{13}C NMR ($CDCl_3$): δ = 22.3 (s, CqCH_3), 28.7, 79.7, 158.1 (3s, *Boc*), 40.5 (s, *Cq*), 47.4 (s, *C*H_2N), 80.5 (s, oxetane-*C*H_2). − MS (EI), *m/z* (%): 201 (2) [M^+], 145 (69) [$M^+ - C_4H_9$], 115 (100) [N*Boc*$^+$]. − $C_{10}H_{19}NO_3$ (201.27): calcd. C 59.68, H 9.52, N 6.96; found C 59.63, H 9.57, N 6.89.

3-(tert-Butyloxycarbonyl)(trimethylsilyl)aminomethyl-3-methyloxetane (**D**): Deprotonation of Boc-**5c** with 1 equiv. of *n*BuLi in THF at −70°C followed by addition of 1.2 equiv. TMSCl yielded **D** after removal of the solvent in vacuo (10^{-1} mbar). − ^{1}H NMR ($CDCl_3$): δ = 0.28 (s, 9 H, Si*Me*$_3$), 1.37 (s, 3 H, CqCH_3), 1.51 (s, 9 H, *Boc*), 3.18 (s, 2 H, CH_2N), 4.18, 4.68 (2d, 4 H, $^2J_{HH}$ = 5.8 Hz, oxetane-CH_2).

3-Phthalimidomethyl-3-methyloxetane (**B**): 9.0 g (50 mmol) of 3-methyl-3-(methylsulfonyloxymethyl)oxetane **4** and 10.2 g (55 mmol) of potassium phthalimide were dissolved in 400 ml of DMSO. This mixture was stirred vigorously for 4 h at 120°C. After cooling to 50°C, the DMSO was removed in vacuo (10^{-1} mbar) and 50 ml of water was added to the residue. The product was extracted with 40 ml portions of dichloromethane (4×). The combined organic phases were washed with brine, dried over $MgSO_4$, filtered, and concentrated at 10^{-1} mbar. The resulting light-yellow oil crystallized after 2 h at 0°C. 10.3 g (44.6 mmol, 89%) of **B** was obtained as colourless needles after washing the crystalline material with portions of petroleum ether (40/60) (3 × 20 ml). − ^{1}H NMR ($CDCl_3$): δ = 1.29 (s, 3 H, CqCH_3), 3.80 (s, 2 H, CH_2N), 4.27, 4.64 (2d, 4 H, $^2J_{HH}$ = 6.2 Hz, oxetane-CH_2), 7.66−7.81 (m, 4 H, *aromat. H*). − ^{13}C NMR ($CDCl_3$): δ = 22.6 (s, Cq*C*H$_3$), 41.1 (s, *Cq*), 44.7 (s, *C*H$_2$N), 80.9 (s, oxetane-*C*H$_2$), 123.6−134.5 (*aromat. C*). − MS (EI), *m/z* (%): 231 (67) [M^+], 201 (100) [$M^+ - CH_2O$]. − $C_{13}H_{13}NO_3$ (231.25): calcd. C 67.52, H 5.67, N 6.06; found C 67.25, H 5.66, N 6.05.

The aminolytic cleavage of the oxetanes **5a** and **5c** was performed in an autoclave (see above) according to a previously published procedure[6].

(±)-2-Dimethylaminomethyl-2-(3,5-dimethylpyrazol-1-yl-methyl)-2-methylpropan-1-ol (**6a**) *and 2-Methyl-2-(3,5-dimethylpyrazol-1-yl-methyl)propane-1,3-diol* (**6b**): 9.0 g (50 mmol) of **5a** was heated in an aqueous dimethylamine solution. After one week at 40 bar and 170°C, a product mixture of **6a/6b** in an overall yield of around 40% was obtained. The products **6a/6b** could not be completely separated by distillation through a 20 cm Vigreux column (10^{-1} mbar). Two fractions were collected above 100°C (**I**: 3.05 g, 130−150°C, **6a/6b** ratio = 4:1 and **II**: 1.81 g, 150−165°C, **6a**7**6b** ratio = 1:5; ratios estimated from ^{1}H-NMR data).

(±)-2-Aminomethyl-2-dimethylaminomethyl-2-methylpropan-1-ol (**6c**): 2.22 g (20 mmol) of **5c** was heated in an aqueous dimethylamine solution. The reaction was complete after 48 h at 30 bar and 140°C. After work-up, distillation through a micro Vigreux column in vacuo yielded 1.31 g (9 mmol, 45%) of **6c** as a colourless oil, b.p. 56°C (1.4 mbar). − ^{1}H NMR ($CDCl_3$): δ = 0.77 (s, 3 H, CqCH_3), 2.27 (s, 6 H, NMe_2), 2.37 (m, 2 H, CH_2N), 2.57, 2.80 (2bd, 2 H, $^2J_{HH}$ = 12.6 Hz, CH_2N), 2.95 (bs, 2 H, NH_2), 3.53 (bs, 2 H, CH_2O). − ^{13}C NMR ($CDCl_3$): δ = 20.0 (s, CqCH_3), 40.0 (s, *Cq*), 48.3, 67.2 (s, *C*H$_2$N), 48.8 (s, NMe_2), 71.1 (s, *C*H$_2$O). − $C_7H_{18}N_2O\cdot 1/4\ H_2O$ (146.23): calcd. C 55.78, H 12.37, N 18.58; found C 55.67, H 11.68, N 18.25.

(±)-2-(tert-Butyloxycarbonyl)aminomethyl-2-dimethylaminomethyl-2-methylpropan-1-ol (*Boc*-**6c**): Boc-protection of **6c** was carried out on a 6.4 mmol sample according to a previously published procedure[6]. After work-up, Boc-**6c** was obtained as a colourless oil, which solidified after a few days at 0°C yielding 1.56 g (6.3 mmol, 99%) of Boc-**6c** as colourless crystals. − ^{1}H NMR ($CDCl_3$): δ = 0.83 (s, 3 H, CqCH_3), 1.48 (s, 9 H, *Boc*), 2.29 (m, 2 H, CH_2N), 2.34 (s, 6 H, NMe_2), 2.93 (bs, 1 H, N*H*), 3.16, 3.45 (2m, 4 H, CH_2N, CH_2OH), 5.01 (bs, 1 H, O*H*). − ^{13}C NMR ($CDCl_3$): δ = 20.0 (s, Cq*C*H$_3$), 28.8, 79.8, 158.5 (3s, *Boc*), 40.7 (s, *Cq*), 45.6, 67.6, 68.9 (3s, *C*H$_2$N, *C*H$_2$O), 49.0 (s, NMe_2). − MS (EI), *m/z* (%): 246 [M$^+$], 173 [M$^+$ − C_4H_9O]. − $C_{12}H_{26}N_2O_3$ (246.35): calcd. C 58.51, H 10.64, N 11.37; found C 58.25, H 10.51, N 11.07.

2-Aminomethyl-2-methylpropane-1,3-diol (**E**): 3.95 g (19 mmol) of 2-benzylaminomethyl-2-methylpropane-1,3-diol[6] was dissolved in 50 ml of methanol. 0.6 g of 10% Pd/C was added and the mixture was stirred under 60 bar H_2 pressure at 60°C for 12 h (the reaction was monitored by ^{1}H NMR). The catalyst was then removed by filtration and the residue was distilled through a micro Vigreux column. 1.65 g (13.9 mmol, 73%) of **E** was obtained as a colourless oil (b.p. 63−65°C, 23 mbar). − ^{1}H NMR ($CDCl_3$): δ = 0.76 (s, 3 H, CqCH_3), 2.80 (s, 2 H, CH_2N), 3.58 (bs, 4 H, CH_2OH). − ^{13}C NMR ($CDCl_3$): δ = 18.3 (s, Cq*C*H$_3$), 40.1 (s, *Cq*), 48.2 (s, *C*H$_2$N), 68.8 (s, *C*H$_2$OH). − MS (EI), *m/z* (%): 120 [M$^+$]. − $C_5H_{13}NO_2$ (119.16): calcd. C 50.40, H 11.60, N 11.75; found C 49.59, H 10.41, N 10.75.

2-(tert-Butyloxycarbonyl)aminomethyl-2-methylpropane-1,3-diol (*Boc*-**E**): Boc-protection of **E** was carried out on a 10 mmol sample according to a previously published procedure[6]. After work-up, 2.1 g (9.6 mmol, 96%) of Boc-**E** was obtained as a colourless, microcrystalline solid. − ^{1}H NMR ($CDCl_3$): δ = 0.76 (s, 3 H, CqCH_3), 1.48 (s, 9 H, *Boc*), 3.24 (d, 2 H, $^3J_{HH}$ = 7.0 Hz, CH_2N), 3.42, 3.55 (2d, 4 H, $^2J_{HH}$ = 11.4 Hz, CH_2OH), 3.83 (bs, 1 H, N*H*). − ^{13}C NMR ($CDCl_3$): δ = 17.9 (s, Cq*C*H$_3$), 28.7, 80.7, 158.5 (3s, *Boc*), 41.4 (s, *Cq*), 43.8 (s, *C*H$_2$N), 68.5 (s, *C*H$_2$OH). − MS (EI), *m/z* (%): 220 (13) [M$^+$], 56 (100) [$C_4H_8^+$]. − $C_{10}H_{21}NO_4$ (219.28): calcd. C 54.77, H 9.65, N 6.39; found C 54.73, H 9.69, N 6.22.

Preparation of **7a** and **7b**: The transformation of alcohol functions into PPh_2 groups was performed according to a previously published procedure[6].

2-(Dimethylaminomethyl)-2-(diphenylphosphanylmethyl)-2-(3,5-dimethylpyrazol-1-ylmethyl)ethane (**7a**): Activation of **6a**[6] (fraction **I**, see above) and subsequent substitution with $LiPPh_2$ gave, after flash chromatography, 1.58 g (4 mmol, 33%) of a very viscous oil. − R_f = 0.2 (PE/Et_2O, 2:1). − ^{31}P NMR ($CDCl_3$): δ = −27.0 (s). − MS (EI); *m/z* (%): 393 (14) [M$^+$], 335 (34) [M$^+$ − CH_2NMe_2], 239 (14) [M$^+$ − CH_2NMe_2 − 3,5-Me_2pz], 183 (30) [PPh_2^+], 98 (39) [3,5-Me_2pz$^+$], 58 (100) [$CH_2NMe_2^+$]. − $C_{24}H_{32}N_3P$ (393.51): calcd. C 73.25, H 8.20, N 10.68, P 7.87; found C 72.05, H 8.30, N 10.14, P 7.55.

2,2-Bis(diphenylphosphanylmethyl)-2-(3,5-dimethylpyrazol-1-ylmethyl)ethane (**7b**): Activation of **6b**[6] (fraction **II**, see above) and subsequent substitution with $LiPPh_2$ gave, after flash chromatography, 1.71g (3.2 mmol, 40%) of **7b** as a viscous oil. − R_f = 0.6 (PE/Et_2O, 2:1). − ^{31}P NMR ($CDCl_3$): δ = −27.3 (s). − MS (EI); *m/z* (%): 534 (20) [M$^+$], 457 (100) [M$^+$ − Ph], 349 (5) [M$^+$ − CH_2PPh_2], 199 (8) [$CH_2PPh_2^+$], 185 (13) [PPh_2^+], 78 (4) [Ph$^+$]. − $C_{34}H_{36}N_2P_2$ (534.62): calcd. C 76.39, H 6.79, N 5.24, P 11.59; found C 75.79, H 7.00, N 5.01, P 11.42.

3,3-Bis(pyrazol-1-ylmethyl)oxetane (**9a**): 7.49 g (110 mmol) of pyrazole was dissolved in 300 ml of THF and deprotonated at 0°C with 12.35 g (110 mmol) of KO*t*Bu. After warming to room temperature and stirring for 20 min., a white precipitate of potassium pyrazolate was formed. This suspension was added at 0°C to a solution of 12.96 g (50 mmol) of **8** in 200 ml of THF and the reaction was completed by refluxing for 4 h. The jelly-like mixture was then quenched by the addition of 100 ml of water and the aqueous phase was extracted with 50 ml portions of diethyl ether (2×). The combined organic phases were washed with brine, dried over $MgSO_4$, filtered, and distilled through a 20 cm Vigreux column. 8.90 g (41 mmol, 82%) of **9a** was obtained as a pale-yellow oil (b.p. 138−145°C, 10^{-1} mbar). − ^{1}H NMR ($CDCl_3$): δ = 4.31 (s, 4 H, oxetane-CH_2), 4.68 (s, 4 H, CH_2pz), 6.23 [t, 2 H, $^3J_{HH}$ = 2 Hz, CH(4)pz], 7.37 [d, 2 H, $^3J_{HH}$ = 2 Hz, CH(3)pz], 7.52 [d, 2 H, $^3J_{HH}$ = 2 Hz, CH(5)pz]. − ^{13}C NMR ($CDCl_3$): δ = 45.4 (s, Cq), 54.3 (s, CH_2pz), 78.0 (s, oxetane-CH_2), 105.6 [s, C(4)pz], 131.4 [s, C(5)pz], 140.5 [s, C(3)pz]. − MS (EI); *m/z* (%): 218 (18) [M$^+$], 188 (99) [M$^+$ − OCH_2], 137 (57) [M$^+$ − CH_2pz], 120 (100) [M$^+$ − OCH_2 − pz], 81 (96) [CH_2pz^+], 69 (42) [pzH$^+$]. − $C_{11}H_{14}N_4O$ (218.26): calcd. C 60.53, H 6.47, N 25.67; found C 58.98, H 6.46, N 24.98.

3-(Diphenylphosphanylmethyl)-3-(pyrazol-1-ylmethyl)oxetane (**9b**): 1.63 g (24 mmol) of pyrazole was dissolved in 100 ml of THF and deprotonated at 0°C with 2.69 g (24 mmol) of KO*t*Bu. After warming to room temperature, a white precipitate of potassium pyrazolate was formed. This suspension was added at 0°C to a solution of 12.96 g (50 mmol) of **8** in 200 ml of THF and the reaction was completed by refluxing for 5 h. In another flask, 7.44 g (40 mmol) of $HPPh_2$ was dissolved in 50 ml of THF and deprotonated with 4.49 g (40 mmol) of KO*t*Bu at 0°C. After warming to room temperature and stirring for 20 min., the red potassium phosphide solution was added dropwise to the first reaction mixture, which was maintained at 0°C. After warming to room temperature and stirring for 10 h (the phosphide substitution was monitored by TLC), the then yellow solution was quenched by the addition of 100 ml of deoxygenated water. The aqueous phase was extracted with 50-ml portions of diethyl ether (2×). The combined organic phases were washed with deoxygenated brine, dried over $MgSO_4$, filtered, and concentrated in vacuo. The resulting viscous

oil was purified by column chromatography on silica gel using petroleum ether (40/60)/diethyl ether (1:1) as eluent to obtain 3.32 g (10 mmol, 49%) of **9b** as a colourless, microcrystalline powder. – R_f = 0.1 – ^{1}H NMR ($CDCl_3$): δ = 2.43 (bs, 2 H, CH_2P), 4.50 (2d, 4 H, CH_2O, $^2J_{HH}$ = 6.4 Hz), 4.65 (s, 2 H, CH_2N), 6.23 [t, 1 H, $^3J_{HH}$ = 2 Hz, C*H(4)*pz], 7.31 [d, 1 H, $^3J_{HH}$ = 2 Hz, C*H(3)*pz], 7.35–7.49 (10 H, *aromat. H*), 7.55 [d, 1 H, $^3J_{HH}$ = 2 Hz, C*H(5)*pz]. – ^{13}C NMR ($CDCl_3$): δ = 34.7 (d, *C*H_2P), 44.1 (d, *Cq*), 56.9 (s, CH_2N), 80.3 (d, CH_2O), 105.6 [s, *C(4)*pz], 129.0–140.3 (*aromat. C*), 131.1 [s, *C(5)*pz], 140.3 [s, *C(3)*pz]. – ^{31}P NMR ($CDCl_3$): δ = –26.8 (s). – MS (EI); *m/z* (%): 336 (29) [M^+], 305 (48) [M^+ – OCH_2], 199 (40) [$CH_2PPh_2^+$], 183 (100) [M^+ – PPh_2], 121 (73) [M^+ –OCH_2 –CH_2PPh_2], 81 (26) [CH_2pz^+]. – $C_{20}H_{21}N_2OP$ (336.37): calcd. C 71.41, H 6.29, N 8.33, P 9.21; found C 71.34, H 6.48, N 8.32, P 9.16.

3,3-Bis(azidomethyl)oxetane (**9c**)[20a]: Compound **9c** was prepared as described for compound **5b** (see above). Starting with 12.9 g (50 mmol) of **8**, two equiv. of NaN_3 were employed. After careful work-up (CAUTION: explosive), a sample of 1 ml was concentrated to dryness at 10^{-2} mbar (0°C) in order to obtain spectroscopic data of **9c**. – IR (Et_2O): ν = 2105 (s, –N_3). – ^{1}H NMR ($CDCl_3$): δ = 3.48 (s, 4 H, CH_2N), 4.35 (s, 4 H, oxetane-CH_2).

3,3-Bis(aminomethyl)oxetane (**9d**)[20b]: Compound **9d** was prepared as described for compound **5c** (see above). Two equiv. of PPh_3 and of water were employed. 3.9 g (31 mmol, 62%) of **9d** was obtained upon distillation as a colourless oil (b.p. 86°C, 3 mbar), which was found to contain 1/2 equivalent of water (as inferred from the elemental analysis, see also[20b]). – ^{1}H NMR ($CDCl_3$): δ = 1.10 (bs, 4 H, NH_2), 2.97 (s, 4 H, CH_2N), 4.37 (s, 4 H, oxetane-CH_2). – ^{13}C NMR ($CDCl_3$): δ = 43.9 (s, *C*H_2N), 44.6 (s, *Cq*), 78.3 (s, oxetane-*C*). – MS (EI); *m/z* (%): 117 (100) [M^+]. – $C_5H_{12}N_2O \cdot 1/2\ H_2O$ (125.17): calcd. C 47.98, H 10.47, N 22.38; found C 47.49, H 9.92, N 21.39.

3,3-Bis(diethylaminomethyl)oxetane (**9e**)[20c]: 2.32 g (20 mmol) of **9d** and 6.09 g (44 mmol) of K_2CO_3 were dissolved in 40 ml of EtOH. 11.5 ml (144 mmol) of EtI was slowly added, the reaction mixture was refluxed for 12 h, and then concentrated in vacuo to half of its initial volume. To the concentrate, 10 ml of aqueous NaOH (10%) was added and the mixture was extracted with 20 ml portions of dichloromethane (3×). The combined organic phases were washed with deoxygenated brine (2×), dried over $MgSO_4$, filtered, and concentrated in vacuo. Distillation through a 20 cm Vigreux column at 3 mbar furnished 3.01 g (13.2 mmol, 73%) of **9e** as a colourless oil (b.p. 91°C, 3 mbar). – ^{1}H NMR ($CDCl_3$): δ = 1.02 (t, 12 H, $^3J_{HH}$ = 7.2 Hz, NCH_2CH_3), 2.53 (q, 8 H, $^3J_{HH}$ = 7.2 Hz, NCH_2CH_3), 2.74 (s, 4 H, CH_2N), 4.45 (s, 4 H, oxetane-CH_2). – ^{13}C NMR ($CDCl_3$): δ = 11.8 (s, NCH_2CH_3), 44.8 (s, *Cq*), 47.8 (s, NCH_2CH_3), 57.7 (s, *C*H_2N), 80.0 (s, oxetane-*C*). – MS (EI); *m/z* (%): 228 (4) [M^+], 155 (39) [M^+ – NEt_2], 126 (63) [M^+ – NEt_2 – Et], 86 (100) [$CH_2NEt_2^+$]. – $C_{13}H_{28}N_2O$ (228.38): C 68.37, H 12.36, N 12.27; found C 67.70, H 11.71, N 12.14.

Preparation of **10a**–**10d**: 1 equiv. of the appropriately substituted oxetane was dissolved in THF (3 ml per mmol oxetane). In a second flask, 1.2 equiv. of $HPPh_2$ was dissolved in THF (2 ml per mmol $HPPh_2$) and deprotonated at 0°C with 1.2 equiv. of *n*BuLi. After warming to room temperature and stirring for 20 min., the red lithium phosphide solution was added dropwise to the oxetane solution at 0°C. The mixture was allowed to warm to room temperature, while the reaction progress was monitored by TLC. Upon completion (4–10 h), the reaction was quenched by the addition of deoxygenated water. The aqueous phase was extracted with small portions of diethyl ether (3×). The combined organic phases were washed with deoxygenated brine, dried over $MgSO_4$, filtered, and concentrated in vacuo yielding the crude products as colourless oils.

3-(Diphenylphosphanyl)-2,2-bis(pyrazol-1-ylmethyl)propan-1-ol (**10a**): The crude product was purified by column chromatography on silica gel using petroleum ether (40/60)/diethyl ether (1:1) and pure diethyl ether (after elution of $HPPh_2$) to obtain 5.57 g (13.8 mmol, 81%) of **10a** as a colourless, microcrystalline powder. – R_f = 0.15 (Et_2O) – ^{31}P NMR ($CDCl_3$): δ = –29.0 (s). – MS (EI); *m/z* (%): 403 (96) [M^+], 323 (68) [M^+ – CH_2pz], 255 (91) [M^+ – CH_2pz – pz], 199 (82) [$CH_2PPh_2^+$], 121 (100) [$CHPPh^+$], 81 (38) [CH_2pz^+]. – $C_{23}H_{25}N_4OP$ (404.45): calcd. C 68.30, H 6.23, N 13.85, P 7.66; found C 68.31, H 6.40, N 13.17, P 7.53.

2,2-Bis(diphenylphosphanylmethyl)-3-(pyrazol-1-yl)propan-1-ol (**10b**): The crude product was purified by column chromatography on silica gel using petroleum ether (40/60)/diethyl ether (3:2) and pure diethyl ether (after elution of $HPPh_2$) to obtain 2.78 g (5.3 mmol, 78%) of **10b** as a colourless, microcrystalline powder. – R_f = 0.3 (Et_2O) – ^{31}P NMR ($CDCl_3$): δ = –29.5 (s). – MS (EI); *m/z* (%): 522 (12) [M^+], 445 (100) [M^+ – Ph], 367 (55) [M^+ – 2 Ph], 183 (39) [PPh_2^+]. – $C_{32}H_{34}N_2OP_2$ (524.58): C 73.25, H 6.54, N 5.34, P 11.82; found C 73.37, H 6.24, N 5.31, P 11.78.

2-(Diphenylphosphanylmethyl)-2-(3,5-dimethylphenyl)-phosphanylmethyl]-3-(pyrazol-1-yl)propan-1-ol (**10c**): The crude product was purified by column chromatography on silica gel using petroleum ether (40/60)/diethyl ether (3:2) and pure diethyl ether (after elution of the diarylphosphanes) to obtain 1.75 g (3.0 mmol, 82%) of **10c** as a colourless, microcrystalline powder. – R_f = 0.25 (Et_2O) – m.p. 54.9°C. – ^{31}P NMR ($CDCl_3$): δ = –29.5 (d, $^4J_{PP}$ = 8.7 Hz), –29.8 (bs). – MS (EI); *m/z* (%): 577 (20) [M^+], 500 (55) [M^+ – Ph], 472 (35) [M^+ – (3,5-Me_2Ph)], 423 (43) [M^+ – 2 Ph], 241 (19) [P(3,5-Me_2Ph)$_2^+$], 101 (100) [(3,5-Me_2Ph)$^+$]. – $C_{36}H_{40}N_2OP_2$ (578.67): calcd. C 74.71, H 6.97, N 4.84, P 10.71; found C 74.57, H 7.19, N 4.67, P 10.47.

2,2-Bis(diethylaminomethyl)-3-(diphenylphosphanyl)propan-1-ol (**10d**): The crude product was purified by column chromatography on silica gel using petroleum ether (40/60)/diethyl ether (1:1) to obtain 2.23 g (5.4 mmol, 82%) of **10d** as a colourless, viscous oil. – R_f = 0.25. – ^{31}P NMR ($CDCl_3$): δ = –28.4 (s). – MS (EI); *m/z* (%): 413 (3) [M^+], 328 (10) [M^+ – CH_2NEt_2], 183 (12) [$CH_2PPh_2^+$], 86 (100) [$CH_2NEt_2^+$]. – $C_{25}H_{39}N_2OP$ (414.57): calcd. C 72.43, H 9.48, N 6.76, P 7.47; found C 72.34, H 9.56, N 6.65, P 7.48.

3-(Diphenylphosphanyl)-2,2-bis(pyrazol-1-yl-methyl)propyl Ethyl Ether (**11**): 855 mg (2.1 mmol) of **10a** was dissolved in 40 ml of THF and the solution was cooled to 0°C. Addition of 1.18 g (10.6 mmol) of KO*t*Bu yielded a clear, yellow solution. After 20 min., 0.84 ml (10.6 mmol) of EtI in 10 ml of THF was added dropwise. The reaction mixture was stirred overnight at room temperature [TLC control (PE/Et_2O, 3:2): **10a**: R_f = 0.1; **11**: R_f = 0.3]. The reaction was then quenched by the addition of 10 ml of deoxygenated water and the aqueous phase was extracted with 10 ml portions of diethyl ether (2×). The combined organic phases were washed with deoxygenated brine, dried over $MgSO_4$, filtered, and concentrated in vacuo. The resulting viscous oil was purified by column chromatography on silica gel using petroleum ether (40/60)/diethyl ether (3:2) to obtain 832 mg (1.9 mmol, 91%) of **11** as a colourless, viscous oil, which solidified after two days. – R_f = 0.3. – ^{31}P NMR ($CDCl_3$): δ = –29.0 (s). – MS (EI); *m/z* (%): 403 (96) [M^+], 323 (68) [M^+ – CH_2pz], 255 (91) [M^+ – CH_2pz – pz], 199 (82) [$CH_2PPh_2^+$], 121 (100) [$CHPPh^+$], 81 (38) [CH_2pz^+]. –

$C_{25}H_{29}N_4OP$ (432.51): calcd. C 69.43, H 6.76, N 12.95, P 7.16; found C 69.39, H 6.81, N 12.99, P 7.16.

Coordination Chemistry

Preparation of **12a**−**12d**, **13**: A stirred solution of 1 mmol ligand in 100 ml of dichloromethane was cooled to −70°C and 0.95 mmol (288 mg) of freshly prepared $(MeCN)_3Mo(CO)_3$ was added. After 2−4 h, all of the $(MeCN)_3Mo(CO)_3$ had dissolved, resulting in a clear, yellow solution. The solvent was then removed at 10^{-1} mbar without heating of the solution. The complexes were recrystallized at 0°C by vapour diffusion of petroleum ether (40−60) into a solution of the crude product in dichloromethane.

η^2-[1,1,1-Tris(pyrazol-1-yl-methyl)ethane]monoacetonitriletricarbonylmolybdenum(0) (**12a**): Yield 398 mg (0.81 mmol, 81%) of **12a** as a brown solid, m.p. 135−138°C (dec). − MS (FAB), *m/z* (%) [Frag.] : 452 (92) [$M^+ - CH_3CN$], 428 (43) [$M^+ - CH_3CN -$ CO], 396 (41) [$M^+ - CH_3CN - 2$ CO], 368 (100) [$M^+ - CH_3CN - 3$ CO]. − $C_{19}H_{21}MoN_7O_3$ (491.36): calcd. C 46.41, H 4.31, N 19.95; found C 44.20, H 4.18, N 18.30.

η^2-P,N-[3-(Diphenylphosphanyl)-2,2-bis(pyrazol-1-ylmethyl)propan-1-ol]tetracarbonylmolybdenum(0) (**12b**): Yield 514 mg (0.8 mmol, 84%) of **12b** as a light-brown solid. Recrystallization afforded 220 mg (0.36 mmol, 36%) of **12b** in the form of yellow crystals suitable for X-ray structural analysis, m.p. 200−205°C (dec). − MS (FAB), *m/z* (%): 614 (4) [M^+], 586 (13) [$M^+ -$ CO], 558 (7) [$M^+ - 2$ CO], 530 (16) [$M^+ - 3$ CO], 502 (21) [$M^+ - 4$ CO], 421 (100) [(**10a**-O)$^+$], 403 (41) [(**10a**)$^+$]. − $C_{27}H_{25}MoN_4O_5P$ (612.43): calcd. C 52.95, H 4.11, N 9.15, P 5.06; found C 51.55, H 3.88, N 8.91, P 5.00.

η^2-P,N-[3-(Diphenylphosphanyl)-2,2-bis-(pyrazol-1-yl-methyl)propyl Ethyl Ether]-monoacetonitriletricarbonylmolybdenum(0) (**12c**): Yield 516 mg (0.79 mmol, 79%) of **12c** as a light-yellow solid. Recrystallization afforded 131 mg (0.20 mmol, 20%) of **12c** in the form of colourless crystals suitable for X-ray structural analysis, m.p. 85°C (dec). − MS (FAB), *m/z* (%): 614 (41) [$M^+ - CH_3CN$], 586 (24) [$M^+ - CH_3CN -$ CO], 558 (39) [$M^+ - CH_3CN - 2$ CO], 530 (77) [$M^+ - CH_3CN - 3$ CO], 449 (100) [(**11**-O)$^+$], 433 (84) [(**11**)$^+$]. − $C_{30}H_{32}MoN_5O_4P$ (653.53): calcd. C 55.14, H 4.94, N 10.72, P 4.74; found C 54.84, H 4.67, N 10.40, P 4.60.

η^2-P,P-{2-(Diphenylphosphanylmethyl)-2-(3,5-dimethylphenyl)phosphanylmethyl]-3-(pyrazol-1-yl)propan-1-ol}monoacetonitriletricarbonylmolybdenum(0) (**12d**): The preparation of **12d** was carried out similarly to that of **12c** above. After 4 h, all of the $(MeCN)_3Mo(CO)_3$ had dissolved, resulting in a clear brown solution, which was concentrated to half of the initial volume and layered with petroleum ether (40−60). After one day at 0°C, small colourless needles suitable for X-ray structural analysis were obtained. The crystals were found to be very sensitive and turned black within seconds on exposure to air. − Yield 152 mg (0.19 mmol, 19%) of **12d**. − MS (FAB), *m/z* (%): 760 (16) [$M^+ - CH_3CN$], 732 (21) [$M^+ - CH_3CN -$ CO], 704 (16) [$M^+ - CH_3CN - 2$ CO], 676 (100) [$M^+ - CH_3CN - 3$ CO], 578 (26) [(**10c**)$^+$]. − $C_{41}H_{43}MoN_3O_4P_2$ (799.71): calcd. C 61.58, H 5.42, N 5.25, P 7.75; found C 61.79, H 6.15, N 4.63, P 7.83.

η^3-[2,2-Bis(diphenylphosphanylmethyl)-2-(pyrazol-1-ylmethyl)propan-1-ol]tricarbonylmolybdenum(0) (**13**): Yield 632 mg (0.9 mmol, 90%) of **13** as a light-yellow solid. Recrystallization afforded 197 mg (0.35 mmol, 35%) of **13** in the form of pale-yellow crystals suitable for X-ray structural analysis, m.p. 190−195°C (dec). − MS (FAB), *m/z* (%): 703 (48) [M^+], 674 (100) [$M^+ -$ CO], 648 (8) [$M^+ - 2$ CO], 619 (32) [$M^+ - 3$ CO]. − $C_{35}H_{32}MoN_2O_4P_2$ (702.54): calcd. C 59.84, H 4.59, N 3.99, P 8.82; found C 59.63, H 5.13, N 3.81, P 8.75.

Keywords: Genetic Algorithms / Force field calculations / Refinement of force field parameters / Tripod metal compounds / Conformational analysis

Force field parameters used to describe the conformation of coordination compounds involving transition metals are generally derived by a trial-and-error procedure, until a somehow satisfying agreement between the calculated and observed conformations of a few members of a class of related compounds is reached. It is shown in this paper that a more general and less biased alternative is available, applicable to many structures at a time. Genetic Algorithms will effectively optimize force field parameters in an automatic way, on the basis of a potentially exhaustive set of all the structural data available for a given class of compounds. The feasibility of this procedure has been demonstrated by the derivation of force field parameters describing the conformational behaviour of *tripod*-$Mo(CO)_3$ compounds [*tripod* = $RCH_2C(CH_2X)(CH_2Y)(CH_2Z)$, X,Y,Z = PR′R′′)] by simultaneous optimization based on the structure of ten individual molecules. With the force field parameters relevant to the organic part of these compounds taken from MM2*, the parameters involving contributions from the Mo center were refined. The agreement between observed and calculated structures is characterized by an rms deviation of around 0.3 Å for the ten structures contained in the data base. To assess the validity of this approach, the conformational space of $CH_3C(CH_2PPh_2)_3Mo(CO)_3$ was explored exhaustively. A contour diagram representing the relative energy of the molecule with respect to the rotational positions of its phenyl groups was found to effectively reproduce the scatter of these conformational parameters as earlier derived from an analysis of 82 relevant compounds. − As a further assessment, the conformational space of $CH_3C[CH_2P(o\text{-Tol})_2]_3Mo(CO)_3$, which was not included in the data base, has been analyzed. It is found that the structure corresponding to the global energy minimum corresponds to that observed in the crystal with an rms deviation of only 0.3 Å. The novel approach to problems of this type − Genetic Algorithms had not previously been applied in this context − thus appears promising.

Introduction

The reactivity of ligand-metal templates is largely determined by their conformations. Homogeneous catalysis by such templates has been shown to be strongly dependent on even minor changes in the conformation as well as in the conformational flexibility of the templates themselves.[1] Methods of predicting these conformational properties would hence be of considerable practical importance. "Understanding" conformations in the sense of being able to model them would be a crucial step in any attempt to understand homogeneous catalysis. In spite of the success quantum chemical methods nowadays have to rationalize and predict the properties of even relatively large ligand−metal templates[2][3], these methods are not yet in a state to allow for an extensive conformational search in a practicable amount of time. As an alternative, force field methods have become popular since N. L. Allinger and his group demonstrated how successful these methods can be.[4][5] Attractive as these methods are, they are hampered by difficulties when applied to inorganic compounds, especially those containing transition metals. Not only is it the broad span of coordination numbers and coordination geometries accessible to one and the same type of metal which is at the basis of these problems, but it is as well the lack of reliable spectroscopic and thermodynamic data which would allow for an appropriate assessment of force field parameters. Nevertheless, inorganic chemists have successfully addressed conformational problems by force field methods[6][7][8] and have devised different strategies to overcome the intrinsic difficulties. These methods rely by and large on an educated guess of the relevant parameters and the subsequent improvement of these initially chosen parameters by trial and error. The quality of the parameters is generally judged by the accuracy with which the chosen set of parameters will reproduce the structures of a few selected examples of the class of compounds to be modelled. There are two basic problems associated with this type of methodology:

(a) The structures which are used to assess the validity of a specific force field approach are taken from solid-state structure determinations. The approach of fitting force field

 © WILEY-VCH Verlag GmbH, D-69451 Weinheim, 1998 1434−1948/98/0606−0693 $ 17.50+.50/0

parameters to these structures is acceptable as a tool of parameter evaluation only if it is shown that these structures and the conformations represented by them reflect the "inner" molecular potential of the compounds and are not significantly influenced by the outer potential acting on the molecular entities within a crystal.

(b) The method of just selecting a few structures and then fitting the force field parameters on this reduced set of information by trial and error procedures does not appear to be the state of the art with respect to the computing capabilities now available.

In an attempt to understand the conformational flexibility of *tripod*−metal templates, an alternative strategy has been developed, which tries to make the maximum use of the information contained in molecular structures as determined by solid-state crystallography.

With regard to the problem outlined under (a) above, a statistical analysis of 82 structures containing the *tripod*−metal template $CH_3C(CH_2PPh_2)_3Co$ in compounds of the type *tripod*−CoL_2 and *tripod*−CoL_3 was performed in order to find out whether these structures might be taken as an unbiased sample representing the inner molecular forces, not largely disturbed by the crystal environment.[9][10] Irrespective of the statistical tools used (factor analysis, cluster analysis, partial least-squares, scattergraphs, neural networks), the analysis showed that the observed conformations are determined by the inner forces, and thus that they correspond to local minima on the molecular energy hypersurface. This result means that the conformations of *tripod*−metal compounds as determined by X-ray crystallography contain the information necessary for developing an appropriate force field: it is a necessary condition for a set of force field parameters to reproduce these conformations as at least local minima on the energy hypersurface described by it.

With regard to point (b) above, the task of deriving parameter sets from the observed conformations that give the optimal reproduction of the observed structures is a problem of global optimization. This class of mathematical problem has not yet found a unique solution in applied mathematics, nor is there a solution guaranteeing that the global minimum will be found in a finite number of steps in general. Nevertheless, several types of approaches exist, the practicability of which has been demonstrated in quite a number of optimization problems.[11][12] In the present work, Genetic Algorithms (GA) have been used as the optimizing tool. In this paper, we report how, by use of this approach, sets of force field parameters may be automatically derived from a structural database. Compounds of the type *tripod*−$Mo(CO)_3$ [*tripod* = $RCH_2C(CH_2X)(CH_2Y)(CH_2Z)$, X,Y,Z = PR′R″] serve as the specific example. The quality of the parameter sets thus derived is assessed by their ability to reproduce conformations as well as general conformational patterns. It is further validated by the correct prediction of the conformation of a specific *tripod*−$Mo(CO)_3$ compound that had not been part of the data basis.

Data Basis

Compounds of the type *tripod*−$Mo(CO)_3$ containing *tripod* ligands $RCH_2C(CH_2X)(CH_2Y)(CH_2Z)$ with up to three different donor groups X,Y,Z = PR′R″ are generally accessible by reacting $(CH_3CN)_3Mo(CO)_3$ with the appropriate *tripod* ligand.[13][14][15][16] The structures of a number of such compounds have been determined by X-ray crystallography.[13][14][15][16] When this work was commenced, nine relevant structure determinations had been reported[17] referring to ten crystallographically independent molecules of this type. To illustrate the overall structural characteristics of this type of compound, Figure 1 shows two mutually orthogonal projections of the structure of $CH_3C(CH_2PPh_2)_3Mo(CO)_3$.

Figure 1. Two orthogonal projections of the solid-state structure of $CH_3C(CH_2PPh_2)_3Mo(CO)_3$; the numbering scheme given is used throughout the text

The constitutions of all the structural examples included in the data base are given in Table 1.

In order to elaborate a force field description for this class of molecules, the parameters involving bonds to the molybdenum atom had to be evaluated from first principles.The force constants describing the organic part of the compounds on the other hand were taken from the well-established MM2* force field.[4][18] The force field parameters describing the force field interactions involving the metal were incorporated as defined by the expressions given in Figure 2. These parameters were in part refined by the methods described below.

Refinement of the Force Field: Any refinement of the force field will correspond to a search for the set (or sets) of parameter values that best reproduce the conformations present in the data base as local or even global minima on the corresponding energy hypersurface (surfaces). To perform this search in an automatic way, the strategy of Genetic Algorithms has been used throughout in this work. In the realm of molecular modelling, Genetic Algorithms have already been used to scan an energy hypersurface for minimum energy conformations. In the analysis and prediction of the conformation of biological macromolecules, the introduction of these algorithmic methods has in some cases dramatically improved the validity of the predictions.[19][20] To the problem of conformational search on an energy hypersurface, an inverse problem exists: given the confor-

mations which correspond to − at least local − minima on the energy hypersurface, a search on the hypersurface defined by the force field parameters themselves should lead to an optimized parameter set.[21] With the efficiency of Genetic Algorithms in mind, and with the given formal logical analogy of these two problems, it appears natural to apply Genetic Algorithms to adapt a force field to a set of conformations. The formal logical complementarity of the two problems, (a) to find an optimized conformation on the basis of a given force field, and (b) to find an optimized force field on the basis of given conformations, is illustrated in Figure 3.

Figure 3. Complementary problems − analogous solutions

[a] Adaptation of a conformation to a given force field. − [b] Adaptation of force field parameters to a given conformation

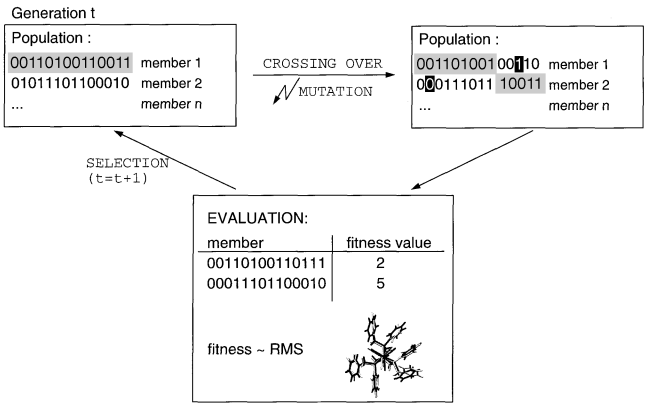
In case (a), the conformation − symbolized by a circle, a square and a triangle, connected in a gear-like arrangement − has to be changed such that it optimally fits into a given pre-designed matrix, the structure of which is strictly defined by the force field used. In case (b), on the other hand, the conformation of the object is fixed and it is the matrix which has to adapt its shape to the conformation presented by the object, i.e. the force field parameters defining the shape of the matrix have to be changed to this end. To solve

these problems in both cases, even if they are logically complementary an optimization procedure must be invoked.

To devise such a procedure, whatever form it takes, the relative quality of a given approximation has to be defined by some numerical qualifiyer that numerically represents the overall performance of this particular approximation. In terms of the language of Genetic Algorithms, this qualifier is called the "fitness value" of a given approximation. In the case considered, the root-mean-square deviation between observed and calculated atom positions is a simple and efficient qualifier and is therefore used throughout in this work. An optimization procedure, whatever its form, has then to find approximations which minimize the discrepancy between observation and model, i.e., in the language of Genetic Algorithms, to find approximations with the optimal fitness values. Because of the a priori unpredictable shape of the hypersurface on which the minimization procedure is performed, analytical methods based on different types of gradients will not generally lead to the desired solution. Purely stochastic methods, on the other hand, will in principle solve the problem, albeit possibly only in an infinite amount of time. With these Monte Carlo type procedures, the hypersurface is probed at random and finding a solution basically relies on Cicero's old statement: "Quis est enim, qui totum diem iaculans, non aliquando conlineet ?"[22] Imagine how long it might take to find the highest elevation in the Alps by this purely stochastic procedure.[23] While completely deterministic analytical methods cannot generally solve the problem and while, as described, stochastic methods may be practically inapplicable, a combination of deterministic and stochastic strategies may well be successful.

Genetic Algorithms may be seen as an algorithmic implementation of both these principles.[24][25][26] The terminology associated with Genetic Algorithms is by and large the same as that used in biology to describe the evolutionary process. As far as we know, the Darwinian principle of "survival of the fittest" is based on two underlying basic molecular processes: crossing over and mutation. The higher the fitness of an individual within a given population, the higher its chance of reproducing; the offspring resulting from sexual reproduction will then have DNA blueprints from the mother as well as from the father, which will generally have fitness values well above the average. In this way and by occasional mutations, sufficient diversity is retained in each generation of a population such as to guarantee dynamic evolution. On the other hand transmithose DNA blueprints which have already led to a high fitness of the parent individuals is at the basis of the evolutionary optimization process and represents the deterministic part of it. Pieces of information which have already been evaluated as being efficient are at least in part inherited and used in the next evolutionary optimization step. To apply this evolutionary strategy to numerical problems, a set of parameters for which the optimized values are to be found is encoded as a binary string (Figure 4).

Figure 4. Force field parameter refinement with Genetic Algorithms

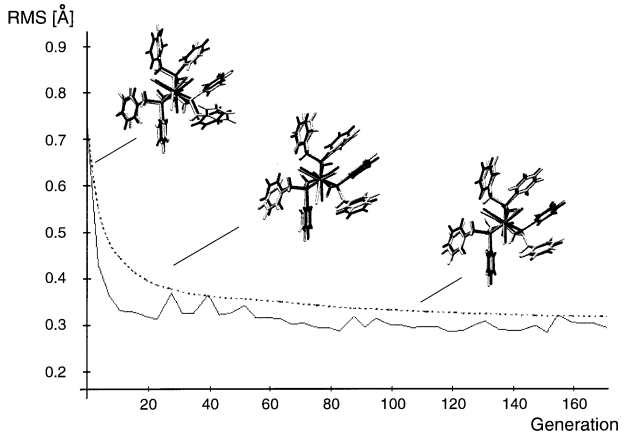


A "population" of such strings, each one representing a set of parameters, is generated at random. The fitness of all these parameter sets is then evaluated. For the problem at hand, this means that the set of parameters is applied to optimize the structures starting with the conformations as represented in the database. The rms deviations (see Experimental Section) between the structures as derived from the force field approach and those in the database are calculated, and taken to assess the fitness value for this specific set of parameters. This procedure is performed for all the members of a population (Figure 4). To produce the next generation with an intentionally increased fitness, those members of the parent population that are already ranked highly on the fitness scale are preferentially selected to reproduce. Mating is simulated by switching the information encoded in the binary strings, with the switching point being selected at random (Figure 4). By this crossover procedure, the population of the next generation is built up. To increase diversity, point mutations − changing a 0 to a 1 and vice versa − are occasionally performed at random. The procedure is then repeated to produce generation after generation and it is generally observed that the fitness increases from population to population. A typical result of the application of this procedure to the problem at hand is shown in Figure 5.

The dotted line represents the mean of the fitness values of all precedent populations at a given generation. It is seen that the discrepancy decreases exponentially. The lower curve represents the overall fitness of each individual population. It is seen that even after 160 generations, the fitness is still able to change. The population is not stuck in a niche, but is still capable of adapting. There is no guarantee that the optimal set of parameters has already been found, nor is there of course, by the very nature of the problem, any guarantee that a unique solution exists at all. The increase of the quality with which the best parameter set in a generation reproduces the conformation in the database is shown in Figure 5 as an overlay of the computed (grey) and the observed (red) conformations of **2** as an example.

A great advantage of applying Genetic Algorithms as minimizers stems from the fact that their algorithmic struc-

Figure 5. Genetic Algorithms at work[a]



[a] The force field model is optimized such that the calculated conformations (i.e. grey) will reproduce the observed ones (i.e. red) increasingly well. The dotted line represents the cumulated fitness, which steadily increases as indicated. The average fitness of each individual population is represented by the continous line.

ture is inherently parallel, and hence the time-consuming steps (in the present case force field minimization of 10 structures) may naturally be distributed over the equivalent number of processors in a parallel computing environment (see Experimental Section). Yet another advantage may be seen in the fact that Genetic Algorithms have no problems in evaluating a whole subspace of solutions that will reproduce the observations equally well. Why should there exist a subspace of solutions and not just one optimal solution to a given problem? In the problem at hand, it is in fact to be expected that there will be several combinations of force field parameters, which − although individually numerically quite different − will reproduce the observations in conformational space equally well. This is to be expected owing to the fact that there are strong and sometimes even linear dependencies between the parameters. Consider a triangle with sides *a*, *b*, *c*. Given the length of the sides *a* and *b*, the length of *c* is as well determined by the angle subtended between *a* and *b* as it is by the value for the distance itself. In a force field approximation as applied the angle as well as the distance would be determined by individual potential functions for the angle and its deformation on the one hand and the distance and its change on the other. Trying to extract force constants for these two functions from a set of observations of triangles would inevitably lead to a multitude of solutions − in principal an infinite number of solutions − corresponding to the linear dependence between the angle and the distance. All these solutions will, of course, reproduce the observations equally well. While in spectroscopy this problem has been well delineated and is appropriately handled[27], molecular modelling as generally applied does not bother about it. As far as the refinement of force field parameters on the basis of a given set of conformations is concerned, the dependencies in parameter space would be cumbersome to handle by analytical refinement methods, while Genetic Algorithms would just produce a collection of solutions that would all reproduce the observations equally well.

With regard to the physical meaning of the parameters derived by such a refinement, it is evident from the above that individual parameters as such do not necessarily have to have a definite physical meaning. It is only the whole ensemble of parameters, which altogether have the physical meaning that, fed into the appropriate force field program, they will reproduce and hopefully predict conformations in agreement with empirical observations. Nevertheless, it is pleasing to apply, wherever possible, force constants that have been assessed by independent physical methods, and which then have a definite meaning even as individuals. With this in mind, the $Mo-C_{CO}$ stretching constant was set throughout at a value taken from the literature (Table 2), as was the Mo−C−O bending force constant.[28][29] Two parameter sets were finally refined (Table 2), with different degrees of freedom. The set designated as *mm2f* has the two aforementioned force constants at fixed values. The equilibrium distances and angles were set at the mean values observed for the sample in all cases, except for the $Mo-C_{CO}$ distance and the Mo−C−O angle, which were allowed to refine while the corresponding force constants were held at the fixed values (Table 2). Refinement thus mainly applied to the different types of force constants (Table 2). In the set of parameters designated as *mm2t*, the above set was augmented by allowing the torsion potentials involving contributions from molybdenum to refine (Table 2). This set was created for several reasons. Firstly, it seemed of interest to ascertain whether an augmented set of parameters would lead to a better refinement, as would in principle be expected, and whether the refinement procedure as applied would be able to converge on a set of values, even though these parameters are not so well-defined by the variance apparent in the data set. (The variance of values referring to these parameters in the data set would not lead one to expect that a stringent refinement would be possible at all). The second reason for deriving an augmented set of parameters was the curiosity to see how the introduction of these additional potentials would influence the values of the force field parameters common to both parameter sets. It is seen that the individual values for bond stretching and angle bending parameters are indeed quite different in both sets.

If these two sets of parameters are now applied to the ten compounds in the data base, to find the local minimum that best corresponds to the observed conformation, the results obtained (Table 1) are very similar for both parameter sets, even though individual parameters are grossly different in the two cases (Table 2). The rms deviation between observed and calculated structures as defined above is consistently somewhat smaller with the augmented force field *mm2t* than that derived using the *mm2f* approach (Table 1). This applies to the individual structures as well as to the sample as a whole (Table 1). With only a small difference between the quality of fit obtained from force field calculations based on the *mm2f* parameter set and that based on the *mm2t* set, the latter having 15 additional parameters, it

appears that on statistical reasoning the set *mm2f* is built on firmer grounds and should thus be preferred. Anyhow, the rms deviation between the two conformations for each compound obtained by applying one or the other set in the force field geometry optimization is considerably smaller than the rms of the difference between the observed and calculated structures in each case (Table 1). To illustrate the quality of fit obtained from the parameter set *mm2f*, Figure 6 shows an overlay of experimental and calculated conformations of four examples taken from the data set.

Figure 6. Overlay of calculated (grey) and observed (red) structures of compounds **1**, **3**, **5** and **6** (see Table 1)

The agreement is clearly quite satisfying. It may well be that the predominance of (mainly repulsive) interactions between the organic moieties of the ligands, which is characteristic of *tripod*-metal templates, is largely responsible for this degree of agreement. The conformations are thus dominated by forces that have been thoroughly modelled for organic compounds.[4][5]

If the parameters as evaluated here have the physical meaning of reproducing the conformational behaviour of *tripod*-metal compounds as a whole, the general trends and regularities observed for these compounds must be reliably reproduced by the force field approach. By analysis of 82 *tripod*-metal compounds[9], it has been found that the torsional positions occupied by the phenyl groups of the PPh_2 donors of *tripod* ligands form a regular pattern when plotted against each other in a type of scattergraph.[9] This analysis is shown in Figure 7 (black dots).[30]

Figure 7. Contour plot representing lines of equal energy as calculated for compound **1** based on the *mm2f* parameter set, with relative energies colour-coded as shown. The coordinates (φ) refer to the rotational positions of the two phenyl groups of a PPh_2 group in **1**. The black dots represent experimental points based on the analysis of 82 structures.[9] Pictograms of torsion angles φ refer to a projection of the molecule as presented in Figure 1 (left). For each PPh_2 group, φ_{2n+1} and φ_{2n} follow each other when counting in a clockwise sense referring to this projection. Grey lines represent energetically feasible pathways for rotational reorientation

This scattergraph is projected onto a contour-line diagram representing lines of equal energy as computed on the basis of the *mm2f* parameter set. It is evident from Figure 7 that regions of low energy (1, 2) correspond to regions which are densely occupied by experimental points. Regions of high energy (6) are not occupied at all. Region 3 corresponding to a two-ring flip transition[9] is in contrast quite densely populated. The contour plot shows that the energy differences between the regions 1 and 2 on the one hand and 3 are only small. Regions 4 and 5 correspond to one-ring flip transitions.[9] It has already been argued[9] that the extension of experimental points towards these regions indicates the feasibility of one-ring flip transitions. The potential pathways for a rotational rearrangement of the phenyl

rings at a PPh_2 grouphad already been delineated by lines as shown in Figure 7[9]. It is satisfying to see that the energy separation between the regions 3 and 2 and the transition point 4 is modest (roughly 10 kJ/mol), so that the free rotation of such phenyl groups as observed by NMR even at a temperature of −80°C finds is counterpart in the diagram.

Satisfying as the result shown by Figure 7 is, a more specific validation of the force field approach as developed would be the prediction of the conformation of a specific compound that had not already been included in the data set used to derive the force field. For this purpose, the conformational space available to $CH_3C[CH_2P(o\text{-Tol})_2]_3$-$Mo(CO)_3$ (**11**) was systematically analyzed by the above force field approach. It was not clear at that time that the compound could be prepared and even structurally characterized by X-ray analysis, and so it was especially satisfying to find that the subsequently determined crystal structure[31] agreed exceedingly well with the structure obtained as the global minimum from the force field calculations.

Figure 8. Overlay of the conformation of $CH_3C[CH_2P(o\text{-Tol})_2]_3$-$Mo(CO)_3$ as observed by X-ray analysis and calculated on the basis of the *mm2f* set (global minimum)

Figure 8 shows an overlay of the conformation as obtained from the conformational search (grey) and that observed in the crystal (red). Irrespective of the parameter set used (*mm2f*, *mm2t*), the global minimum was found at the same place in conformational space. The rms deviation between the two model conformations amounted to only 0.11 Å. The rms difference between the model conformations and the conformation observed in the crystal is very small as well (*mm2f*: 0.37 Å, *mm2t*: 0.42 Å)

The results obtained to date using this novel type of approach are sufficiently promising to warrant further investigations along such lines. While, from the results presented, it appears probable that the conformations of related molecules will be reliably predicted, it will be interesting to see whether the calculated energy hypersurfaces are approximately on scale with experimental data. The application of this method to problems pertaining to the conformational flexibility of *tripod*−$Mo(CO)_3$ compounds in solution (forthcoming paper) should give an answer to this question.

In summary, a novel approach to the derivation of force field parameters for metal-containing compounds is presented. It is shown that refinement of force field parameters on the basis of solid-state structures can be efficiently performed by the application of Genetic Algorithms. These algorithms are robust and allow for the simultaneous refinement of many force field parameters on an extended data basis containing many structures. When applied to *tripod*−$Mo(CO)_3$ compounds, the approach leads to models with a high predictive power with respect to specific conformations of these molecules, as well as to their overall conformational behaviour.

Financial support by the *German Science Foundation* (DFG HU 151/24-1), the *Fonds der Chemischen Industrie* and the Graduiertenkolleg "*Selektivität in der organischen und metallorganischen Synthese und Katalyse*" is gratefully acknowledged. The computations were made possible by grants of computing time at *Parsytec (IWR Heidelberg*) and CRAY (*KFA Jülich*) parallel computing environments. One of us (J. H.) wishes to thank the Graduiertenkolleg "*Modellierung und wissenschaftliches Rechnen in Mathematik und Wissenschaft*" (*IWR Heidelberg*).

Experimental Section

(a) *Force Field Calculations:* In order to apply the methodology of Genetic Algorithms to the problem of refining sets of force constants, it is necessary to have the force field program available as a source text. Since almost all modern force field programs are nowadays only commercially available and are delivered to the customer as executable files that will run only on a specific type of machine, these commercial programs are of no help. Instead of writing a whole new package for force field calculations, YAMMP[32], a program set written by R. K. Z. Tan et al. in ″C″, which is available as a public domain source code, was used as the core. The force field expressions implemented in this program were changed to correspond to the potentials applied in MacroModels MM2*.[18] Test runs on a vast sample of different compounds were performed with both programs to ensure that the results produced by MacroModel and those produced by the modified YAMMP program were numerically identical. Two converters which transform the MacroModel data format into the YAMMP data format were implemented and YAMMP was embedded in a number of shells so as to allow its use on different types of single processor machines (e.g. Pentium, SGI) as well as on different types of parallel computing systems (Parsytec GC, CRAY T3E).

To evaluate the rms deviation between two structural models, the mutual translational and rotational positions of the two models were optimized by a least-squares procedure using in part the *quatfit* program of D. Heisterberg[33] and in part a program based on the same algorithmic approach written by K. Allinger. The root-mean-square deviation was defined as the square root of the sum of the squares of the deviations between all n corresponding pairs of atoms divided by the square root of n (hydrogen atoms were included in these calculations throughout).

(b) *Optimization by Genetic Algorithms:* The force field parameter refinement was performed with the program *GAPAO*, written in ″C″, which uses functions from the *PGA-Genetic Algorithm Package.*[34] These functions are fully parallelized and are based on the *Message Passing Interface Library.*[35] This standard parallelization platform is available for all types of Unix systems, even for a net-

work of Linux PC's, and thus *GAPAO* has been installed on a Parsytec GC/Power Plus as well as on a CRAY T3E. Parallelization in this case means that all the evaluations of the parameter sets − implying the time-consuming energy minimizations of all the basis conformations − are performed on different processors. This leads to a tremendous economization of time and is thus another important advantage of the optimization procedure as applied.

Different crossing-over types and different selection routines are available.[34] In the cases reported, the approach of uniform crossing-over has been used.[36] To this end a mask of 0s and 1s with the length of the corresponding bitstring is generated at random. Applied according to the crossing over probability this mask then indicates which bits from the parents have to be taken to produce offspring. This type of crossing-over turned out to be especially useful in the treatment of large-scale parameterization problems.

The traditional "fortune wheel" selection type has been used as the selection routine.[25] This type of selection means that the probability of a given bitstring to be chosen to produce an offspring is proportional to its fitness value. Furthermore, an elitistic optimization strategy[25] has been adopted throughout, i.e. the best parameter set found in a given population is always left unchanged and taken into the next generation.

Evaluation was performed by energy minimization of all the structures contained in the data basis. To this end, the function *KA MMOPTfct*, written in C by K. Allinger, was used. The Polak-Ribière conjugate gradient minimization method[11][12] was employed and minimization was always driven to convergence (convergence criterion: 0.01 Å/iteration).

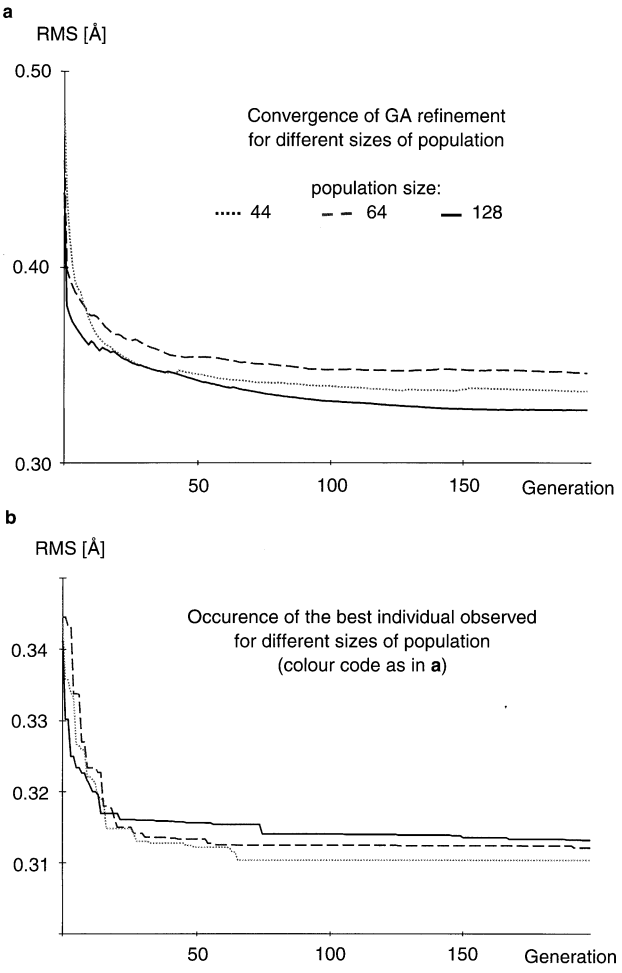
Parameters referring to force constants for bond stretching were encoded in the range 0.0−2.0 mdyn/Å. Parameters referring to force constants for angle bending were encoded in the range 0.0−1.5 mdyn/(rad^2). Torsional force constants k_{t1}, k_{t2}, and k_{t3} (see Figure 2) were encoded in a range between −1.5 and +1.5 kcal/mol. The refined Mo−C−O angle (see Table 2) was optimized in an interval between 170° and 180°; the Mo−C bond length was allowed to refine in an interval from 1.7 Å to 2.2 Å. Different subsequent runs were performed, each taking as its starting point the best results of the foregoing process, gradually augmenting the number of bits encoding the corresponding parameters in a stepwise manner from 5 to 8, and thus improving the resolution of the refined parameters.

Another way of overcoming the problem of discreteness in the optimization process was to apply a "hill climbing heuristic" to the best parameter set found and thus to locally optimize the corresponding parameters. This feature is implemented in the *GAPAO* program (*GAPAO-h)* by the strategy of altering or diminishing in a stepwise manner one parameter after another in the best parameter set, such that the resulting rms deviations become smaller. This is done until no further amelioration is achieved by such adjustments.

The method as described lends itself to a principally unlimited number of variations and it is a matter of experience to select appropriate values for the size of a population, and for the rates of crossing-over and mutation. This is exemplified in Figures 9a and b, which refer to different refinement runs for the parameters characterized by *mm2f*.

The rates of crossing-over and mutation were left unchanged for the three runs shown in Figure 9, with values that were found to be especially appropriate for the parameterization problem at hand (values given in Figure 9). The size of the population was different for the three runs. Not unexpectedly, the cumulated overall fitness,

Figure 9. How to find the appropriate GA protocol. Parameters used in the GA runs presented in a and b: crossing-over rate = 0.8, mutation rate = 0.02



which is the mean of all the previously assessed fitness values, improves with the size of the population (see Figure 9a). However, the real aim of the optimization is not to find the population with the maximum overall fitness, but rather to find one member of a population − from which ever generation − which is the fittest individual of all, i.e. the search is aimed at the best set of force field parameters. Figure 9b illustrates that of the three runs described, the one based on a population of 60 randomly selected parameter sets produces the optimal solution after about 60 generations, with no better solution being found after more than 100 subsequent generations. The run based on a population size of 128 obviously takes far longer to converge. The run based on 44 individuals shows rapid convergence, but appears to be stuck at a lower quality solution.

In summary, it may be said that quite some experience and in some respects "green fingers" are needed to successfully apply Genetic Algorithms. However, this statement applies to other methods of global optimization as well and is not specific to the physical model analyzed here.

Calculations were performed on a CRAY T3E-512 with 512 compute nodes (600 MFLOPS/processor, 128 MB/processor, 333 MHz) and a Parsytec GC/Power Plus-192 (192 Power PC 601, 80 MHz, 32 MB/processor).

(c) *Conformational Analyses:* The φ_1/φ_2 contour plot of the PPh_2 conformations in **1**, as shown in Figure 7, is based on a grid search with a resolution of 5° for each P−Ph rotation φ (a φ value of 0° corresponds to an orientation of the phenyl ring perpendicular to the plane defined by the three P atoms, see Figure 7). Due to the C_2 symmetry of the phenyl groups, their rotation is periodic with a period of 180°, thus leading to 36 × 36 = 1296 grid points to describe one PPh_2 group. To account for the molecule as a whole, the multitude of orientations accessible to the remaining PPh_2 groups and to the chelate scaffolding have to be appropriately represented in the corresponding calculations. To this end, the torsion of the scaffolding τ[9] was uniformly set to starting values of 11° or 34°, respectively, leading to 2 × 1296 = 2592 starting geometries. In these conformations, the rotational arrangement at the remaining PPh_2 groups was set such that it corresponded to the regularites derived from an extensive analysis of such compounds ($\tau_{1/2/3}$ = 11°: $\varphi_{3/5}$ = 36°; $\varphi_{4/6}$ = 49°; $\tau_{1/2/3}$ = 34°: $\varphi_{3/5}$ = −50°, $\varphi_{4/6}$ = −29°; for the meaning of the numbers, see Figures 1 and 7).[9] (The conformations of a molecule such as **1** are chiral in general; only one of the enantiomers needs to be considered in the grid search due to this mirror symmetry in conformational space.)

A total of 2592 starting geometries were generated by the program *confgenrub* (written in "C" for that purpose) and then minimized by the program *bmin* as included in Version 5.0 of the molecular modelling software package MacroModel[18], using the force field MM2* and the parameter set *mm2f* described above. In order to evaluate the energy at each of the 1296 grid points, the rotational positions at the selected PPh_2 group at P1 (the orientation of the phenyl group as defined by the coordinate values of the grid point) had to be fixed during minimization. This was achieved by the technique of using a dummy atom, Du: A dummy atom was placed at a distance of 1 Å from the atom P_1, perpendicular to the plane defined by the 3 phosphorous positions, in the direction pointing towards the metal atom. Technically, this was achieved by imposing 3 restraints on its position: the distance P_1−Du as well as the angles P_2−P_1−Du and P_3−P_1−Du were fixed by giving them suitably steep potentials. The torsion angles φ_1 and φ2 were kept at the preordained values by imposing a corresponding restraint on the relevant torsion angles Du−P_1−C_{ipso}−C_{ortho}. Force constants as applied for this purpose were: distances: 500 kJ/Å^2, angles: 9999 kJ/rad^2, torsion angles: 9999 kJ/mol for k_{t1} (see Figure 2).

The refinement was performed using the Polak-Ribière minimizer with a gradient of 0.01Å/iteration and a maximum of 500 iteration steps as the limiting criteria. No cut-off was set for nonbonded interactions.

After minimization of each pair of conformations (two different τ values, see above) calculated for every grid point, the one with the lower energy was chosen to represent the energy (diagram in Figure 7).

The final contour plot as shown in Figure 7 was obtained by taking into account the isoenergetic enantiomeric conformation in each case. The mirror symmetry of the problem is apparent by a diagonal mirror plane characterizing the symmetry of the plot. The *plot2D* option of MacroModel was used to prepare the contour plot shown in Figure 7. The result of this procedure as depicted was obtained using the *mm2f* parameter set. Repeating the same procedure with the *mm2t* set produced a contour plot with the same overall characteristics.

A complete conformational search was performed for **11**. To generate the starting conformations for the search, the rotations of the tolyl groups about their P−C_{ipso} bonds were set at the initial values of φ = −135°, −45°, 135°. These torsional positions were defined with respect to a dummy atom, the position of which was generated as described above. The φ values refer to the torsion angle Du−P−C_{ipso}−$C_{ortho(Me\text{-}substituted)}$. The torsional arrangement of the cage was set by assigning a value of 20° to each of the 3 torsion angles τ.

Combining the four predefined orientations of each tolyl group in all possible combinations for the six tolyl groups present in the molecule gives a total of 4^6 = 4096 starting conformations. In this set, there are 16 (2^4) conformations that occur only once because of the C_3-symmetry of the molecule. The remaining 4096 − 16 = 4080 conformations occur in isoenergetic triplets. While physically indeterminable, they differ in assigning the same values of the six tolyl rotations φ to the P(*o*-Tol)$_2$ groups at P1P2P3, P2P3P1 or P3P1P2 in this sequence of cyclic permutations. Thus only (4096 − 16)/3 + 16 = 1376 starting geometries had finally to be taken into account. Minimization was performed as described above, with the criteria of a limiting gradient of 0.001Å/iteration and the maximum number of 2000 iterations allowed.

The calculations were carried out on two Silicon Graphics Indigo^2 MIPS R4400 workstations, 200 MHz, 128 MB RAM, operating under IRIX 5.3.

Table 2. Parameter sets *mm2t* and *mm2f*. Refined parameters are labelled with an asterisk

(a) Bond stretching

	parameter set *mm2f*		parameter set *mm2t*	
	r_0 [Å]	k_b [mdyn/ Å]	r_0 [Å]	k_b [mdyn/ Å]
Mo−C1	1.99*	2.00	1.94*	2.00
Mo−P	2.53	1.98*	2.53	0.75*

(b) Angle bending

	parameter set *mm2f*		parameter set *mm2t*	
	α_0 [°]	k_a [mdyn/rad^2]	α_0 [°]	k_a [mdyn/rad^2]
P−Mo−P	83.70	1.18*	83.70	0.53*
C1−Mo−C1	87.10	0.33*	87.10	0.39*
C1−Mo−P	94.90/175.90	0.1*	94.90/175.90	0.25*
Mo−C1−O	173.0*	0.47	170.00*	0.47
Mo−P−C2	119.0	0.29*	119.00	0.43*
Mo−P−C3	114.50	0.02*	114.50	0.29*

(c) Torsion

	parameter set *mm2f*			parameter set *mm2t*		
	k_{t1}[a]	k_{t2}[a]	k_{t3}[a]	k_{t1}[a]	k_{t2}[a]	k_{t3}[a]

[29] Since bending force constants derived from spectroscopy may not be too accurate (see for instance ref.[5]), refinement was also performed including the Mo−C−O force constant in the subset of variable parameters. The force field parameters derived for this augmented set did not show an improvement over those with the bending force constants at the value given. It was observed, however, that the refined values of this force constant tended to be smaller than the value taken from the literature.
[30] In the scattergraph published previously for the same data (ref.[9]), a distortion by a partially incorrect treatment of symmetry had been introduced; this is now corrected in the diagram presented in Figure 7. We thank H. B. Bürgi for helpful discussions.

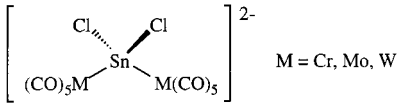
Keywords: Germanium / Tin / Lead / ^{119}Sn NMR / Dynamic NMR / Salt metathesis

The sodium salts $Na_2[\{(CO)_5M\}_2EX_2]$ (M = Cr, Mo, W; E = Ge, Sn, Pb; X = Cl, I, $OOCCH_3$) react with 2,2′-bipyridine (bipy) to form neutral compounds $[\{(CO)_5M\}_2E(bipy)]$ (E = Sn: **1a–1c**; E = Ge: **3a**; E = Pb: **4**). 1,10-Phenanthroline (phen) analogues of compounds **1a–1c** and **3a** $[\{(CO)_5M\}_2E(phen)]$ (E = Sn: **1d–1f**, E = Ge: **3b**) are as well accessible. The 2,2′-bipyridine ligand in **1** may be formally replaced by two pyridine (py) ligands resulting in $[\{(CO)_5M\}_2Sn(py)_2]$ (**1g**: M = Cr, **1h**: M = W). The bis-bidentate ligand 2,2′-bipyrimidine (bpmd) is found to coordinate just one $[\{(CO)_5M\}_2Sn]$ entity in $[\{(CO)_5M\}_2Sn(bpmd)]$ (**2b**: M = Cr, **2c**: M = W). The biimidazolato (biim) ligand binds two $[\{(CO)_5Cr\}_2Sn]$ moieties in $[\{(CO)_5Cr\}_2Sn(biim)Sn\{Cr(CO)_5\}_2]^{2-}$, **2a**. It is shown by ^{1}H-NMR that the pyrimidine entities in these compounds (**2b**, **2c**) are able to rotate by a full 180° turnaround with respect to one another. This process must involve complete de-coordination of at least one of the two nitrogen donors in again at least one of the chelate cycles, the activation energy for this process being around 60 kJ/mol. By ^{119}Sn-NMR spectroscopy of almost all of the tin compounds described it is shown that equilibria between $[\{(CO)_5M\}_2Sn(L_2)]$ and $[\{(CO)_5M\}_2Sn(L)]$ + L exist in all cases. From the temperature dependence of the δ values it is concluded that the activation barriers for this association/dissociation process is below 10 kJ/mol. The structures of all new compounds are documented by X-ray analyses and all compounds are characterized by the usual analytical and spectroscopical techniques.

Introduction

The chemistry of low-valent main-group compounds may considerably be expanded by using organometallic protective groups to electronically and sterically inhibit the decomposition of such species. Thus while neither Bi_2 nor Sn_6^{2-} are known as such at ambient temperature their organometallic derivatives $[\{(CO)_5W\}_3Bi_2]$[1] and $[\{(CO)_5Cr\}_6Sn_6]^{2-}$[2] are well characterized species. In order to exploit the unconventional chemistry of compounds containing low-valent tin aggregates embedded in an organometallic matrix, starting materials which contain reactive tin−halide bonds and have the tin centers already coordinated to organometallic building blocks should be useful. With this idea in mind syntheses of various salts containing anions of type **A** (Figure 1) had been developed[3][4].

Figure 1. Anions of type **A**



A

It had been found that the salts formed with $[Ph_4P]^+$ counter ions are quite unreactive and correspondingly indefinitely stable at room temperature under an inert atmosphere[4]. When, however, these salts are metathesized with $Na[BPh_4]$ the highly reactive sodium salts $[Na(solv)_x]_2[\{(CO)_5M\}_2SnCl_2]$ are formed[4]. The difference in reactivity of these two types of salts is illustrated by the observation that the phosphonium salts do not react with sodium 8-oxoquinolate, $Na[C_9H_6NO]$, while the sodium salt $[Na(solv)_x]_2[\{CO)_5Cr\}_2SnCl_2]$ instantaneously does[4]. The resulting anion $[\{(CO)_5Cr\}_2Sn(oxinato)]^-$ contains a tetrahedrally coordinated tin center (formal oxidation state: Sn^0) with two coordination positions occupied by the anionic chelate ligand[4].

We report here that an analogous procedure allows for the replacement of the two halide substituents in **A** by neutral nitrogen-based chelate ligands leading to neutral adducts of types **1** and **2** which as well contain tin in the formal oxidation state of zero. Analogous reactivity is observed for the homologues of type **A** anions containing germanium or lead instead of tin. 2,2′-Bipyridine or 1,10-phenanthroline adducts of Ge^0, **3**, and Pb^0, **4**, stabilized by coordination to two $[(CO)_5Cr]$ groups are thus obtained.

Results and Discussion

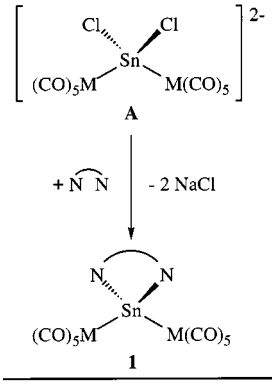
a) Compounds 1 Containing 2,2′-Bipyridine or 1,10-Phenanthroline as Chelating Ligands

THF solutions of the sodium salts of the anions of type **A**, $[\{(CO)_5M\}_2SnCl_2]^{2-}$, are prepared from $[Ph_4P]_2[\{(CO)_5M\}_2SnCl_2]$ by salt metathesis with $Na[BPh_4]$

 © WILEY-VCH Verlag GmbH, D-69451 Weinheim, 1998 1434−1948/98/0606−0703 $ 17.50+.50/0

as described[4]. Upon addition of 2,2′-bipyridine (bipy) or 1,10-phenanthroline (phen) the initially yellow solutions turn deep red immediately and take on a turbid appearance caused by the precipitation of NaCl.

Table 1. Complexes of type **1**



no.	M	N N
1a	Cr	bipy
1b	Mo	bipy

1g	Cr	2 · py
1h	W	2 · py

Chromatographic workup, separating compounds **1** from the decomposition products $[M(CO)_6]$, $[M(CO)_4(bipy)]$, and $[M(CO)_4(phen)]$, respectively, leads to **1a**−**1f** in yields of around 50%. The compounds are obtained as microcrystalline deep red materials of analytical purity. Crystals suitable for X-ray analyses are obtained by vapour diffusion from THF/diethyl ether/petroleum ether (boiling range 40−60°C). **1a**−**1f** are analogues of the known species $[\{Cp'(CO)_2Mn\}_2Sn(bipy)]$[5] and $[\{Cp'(CO)_2Mn\}_2Sn(phen)]$[6].

The IR-ν_{CO} spectra of **1a**−**1f** show the three-band pattern (Table 4, Figure 2) characteristic of $[LM(CO)_5]$ species[7]; in a few cases an additional shoulder around 1960 cm^{-1} is observed (Table 4) indicating either a local symmetry lower than C_{4v} or coupling between the two $[(CO)_5M]$ chromophores. The IR-ν_{CO} absorptions of the neutral compounds **1** are shifted to somewhat higher energies relative to the absorptions of the dianionic starting materials (e.g. $[Na(THF)_x]_2[\{(CO)_5Cr\}_2SnCl_2]$: ν_{CO} (THF) = 2040 w, 2007 s, 1920 vs, 1895 sh cm^{-1}, Figure 2) as would be expected when reducing the charge in an $[LM(CO)_5]$ compound[8].

The ^{1}H-NMR spectra show the expected shifts of the proton resonances of the ligands (Table 2). The observed low-field shifts are somewhat higher than those found for the $[Cp'(CO)_2Mn]$ analogues of compounds **1**[5][6]. This indicates that the coordination of the chelate ligands is somewhat stronger for **1a**−**1f** as compared to their $[Cp'(CO)_2Mn]$ analogues[5][6].

This is in fact what would be expected taking into account the relative π-donor capabilities of $[Cp'(CO)_2Mn]$ and $[(CO)_5M]$ (M = Cr, Mo, W): with $[Cp'(CO)_2Mn]$ being the stronger π-donor[9] the cumulene-type compounds $[Cp^R(CO)_2Mn{=}Sn{=}Mn(CO)_2Cp^R]$ (Cp^R = Cp, Cp′, Cp*)[10] are available as such. Their 2,2′-bipyridine and 1,10-phenanthroline derivatives corresponding to **1a**−**1f** are directly obtained from the cumulenes by adding the chelate bases[5][6] and the compounds may thus be considered as Lewis base stabilized organometallic cumulenes. The interaction with the Lewis base chelate ligands remains weak in

this case reflecting the extensive Mn-d_π−Sn-p_π back-donation which effectively stabilizes even the base-free cumulenes. The weaker back-donation from the $[(CO)_5M]$ fragments makes the cumulene compounds $[(CO)_5M{=}Sn{=}M(CO)_5]$ so unstable that they have not yet been isolated as such[11]. Compounds **1a**−**1f** may be considered as base-stabilized forms of such species. Due to the inherent lack of sufficient back-donation from the metals the tin center in the hypothetical cumulenes $[(CO)_5M{=}Sn{=}M(CO)_5]$ is highly electron-deficient and will act as an effective Lewis acidic center towards the chelate bases. The shifts of the ^{1}H-NMR resonances of the ligands upon coordination are indicative of this interaction.

This interaction is mirrored by the ^{13}C-NMR resonances (Table 3). With reference to the ^{13}C-NMR data of the free ligands the ^{13}C signals of the coordinated ligands consistently show the high-field (C_a, C_e) and low-field (C_b, C_c, C_d, and C_f) shifts which are known to be characteristic of the coordination of these chelate bases[12]. A theoretical explanation of this characteristic pattern of high- and low-field shifts has been put forward[13]. The individual resonances for the carbonyl carbon atoms C_{ax} and C_{eq} of the $[(CO)_5M]$ entities are generally well resolved (Table 3); only in the case of **1b** the quality of the spectroscopic data did not reveal the resonance of the axial carbonyl group.

[a] In THF. − [b] In [D$_6$]acetone, 25°C. − [c] $^1J(^{183}W,^{119}Sn)$ = 578 Hz; intensity ratio of peaks 15:100:15. − [d] $^1J(^{183}W,^{119}Sn)$ = 520 Hz; intensity ratio of peaks 14:100:15. − [e] $^1J(^{183}W,^{119}Sn)$ = 575 Hz; intensity ratio of peaks 16:100:14. − [f] $^1J(^{183}W,^{119}Sn)$ = 540 Hz; intensity ratio of peaks 19:100:20. − [c]−[f] The intensity of the satellites is close to the value of 29% as expected from coupling of a tin nucleus with two equivalent tungsten nuclei.

The NMR data which are most characteristic for the particular bonding situation in compounds **1** are the ^{119}Sn-NMR resonances (Table 4). The absorptions occur at relatively low field in the broad range of shifts[14] hitherto observed for tin compounds of δ = − 2171 (Cp_2Sn[15]) to δ = + 3301 ([{Cp*(CO)$_2$Mn}$_3$Sn][16]).

The resonances observed for the tungsten compounds **1c** and **1f** consistently occur at higher fields similar to those of their chromium and molybdenum analogues[4].

The ^{119}Sn-NMR shifts of all compounds **1** are strongly temperature-dependent throughout. In the observable range of temperatures the shifts increase with a slope of around 1.5 ppm/K with increasing temperature. This increase is monotonic though not strictly linear (cf. Figure 3).

This behavior may be rationalized by the assumption of two different species which are close in energy to each other, but which have widely different ^{119}Sn-NMR shifts. One of these species should contain four-coordinate tin (type **B**, Figure 4) in accord with the solid-state structure (vide infra). The other one is assumed to be a species where one of the two nitrogen atoms of the chelate ligand is de-coordinated (type **C**, Figure 4). This type of arrangement would lead to a bonding situation close to the one characteristic of inidene-type compounds $L_n{=}X(R){=}ML_n$[17].

The 3-center-4-π system characterizing the bonding situation in inidene compounds has a dramatic effect on the NMR shift of the central atom X. It has been found that with phosphorus in this position ^{31}P-NMR shifts range from δ = 900 to δ = 1400, well out of the range of shifts documented for all other phosphorus compounds[18]. This strong low-field shift is in addition well correlated with the inverse of the energy ΔE ($^1/_{\Delta E}$) of the π-π* transition in these compounds[18]. Taken together these observations lend strong weight to an interpretation which relates the

Figure 3. Temperature-dependent ^{119}Sn-NMR spectrum of **1a** (left) and **1e** (right) and graphs obtained from Equation 1

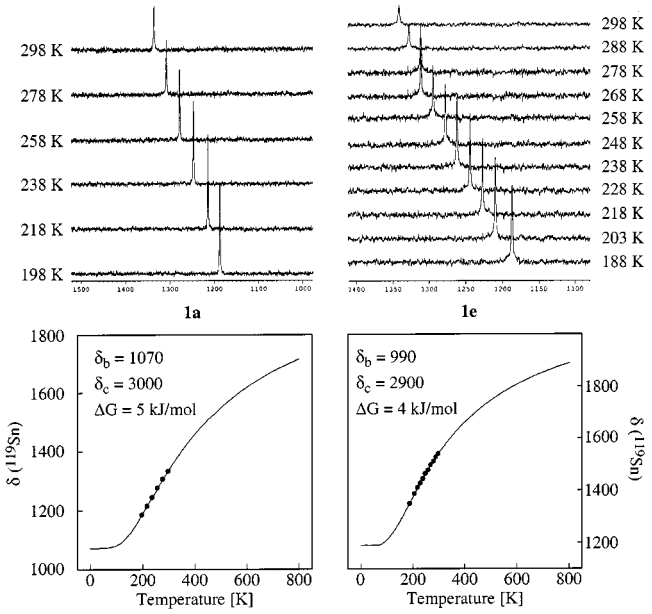

Figure 4. Equilibrium between four- and three-coordinated tin species **1d**−**1f**

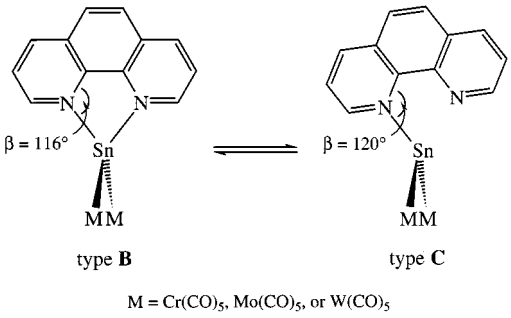

observed low-field shifts to the low HOMO-LUMO gap characterizing the 3-center-M⋯X⋯M-4π systems. The same type of arguments has been used to rationalize the extreme ^{119}Sn-NMR low-field shift of around δ = 3300 for a compound containing a M⋯X⋯M-π system as well[16]. A species of the type **C** as shown in Figure 4 would thus be expected to have its resonance around δ = 3000.

A guess for the shift which should be expected for a compound with four-coordinate tin (type **B**) may be based on the observation that $[Ph_4P]_2[\{(CO)_5Cr\}_2SnCl_2]$ shows one single temperature-independent signal at δ = 924 with its tungsten analogue $[Ph_4P]_2[\{(CO)_5W\}_2SnCl_2]$ resonating at δ = 605 again independent of temperature. The resonances of the chelate compounds of type **B** (Figure 4) would hence be expected somewhere around δ = 500 to δ = 1000.

An equilibrium as depicted in Figure 4 does not appear to be ruled out by MO considerations: EHT calculations[19] give an energy difference of only around 10 kJ/mol between the two isomeres (type **B** and **C**, Figure 4) with the chelate compound (type **B**) being the more stable.

The experimental observations are well in accord with the above assumptions. If a dynamic equilibrium as given in Figure 4 is assumed the ^{119}Sn-NMR shift of the equilibrium mixture of the two isomeres is given by $\delta_{obs.} = x_B\delta_B + x_C\delta_C$ with the molar fractions x_B and x_C and the shifts of the pure isomeres δ_B and δ_C, respectively. The observed temperature dependence of $\delta_{obs.}$ is then a consequence of the temperature dependence of the equilibrium constant pertaining to this isomerisation process and is given by Equation 1.

$$\delta_{obs.} = \frac{\delta_B + \delta_C \cdot e^{-\frac{\Delta G}{RT}}}{1 + e^{-\frac{\Delta G}{RT}}} \quad (1)$$

Fitting the parameters of δ_B, δ_C, and ΔG of the corresponding Equation 1 to the observed values results in a favorable agreement with the assumptions made above: the values for δ_B are estimated by this procedure in a range of δ = 990 to δ = 1070 for all four-coordinate compounds of type **B** (Figure 4). The values estimated for δ_C are in a range of δ = 2900 to δ = 3000. The values of ΔG range between 4 and 5 kJ/mol. All these values and ranges of values are completely independent of any guess made for the quantitative items δ_B, δ_C, and ΔG above. They are extracted from the observed material alone by the single assumption of a dynamic equilibrium as given in Figure 4 with no quantitative restrictions put on this equilibrium other than the experimental data. Graphs typical for the quality of fit obtained are shown for **1a** and **1e** in Figure 3. It is evident that quite some extrapolation is involved when the values δ_B and especially δ_C are to be determined by the fitting procedure. Nevertheless the ranges of δ_B and δ_C compare favorably with the expectations and the observed temperature dependence of $\delta_{obs.}$ is neatly reproduced.

The interpretation of the temperature dependence of the ^{119}Sn-NMR shifts in terms of an intramolecular equilibrium is further corroborated by the observation that addition of the free ligands (bipy, phen) to the solutions does not change the appearence of the ^{119}Sn-NMR spectra.

The equilibrium between species with η^2-coordinated ligands (type **B**) and η^1-coordinated ones (type **C**) as delineated should mirror itself into an appropriate behavior of the proton resonances of the ligands.

Figure 5. Temperature-dependent ^{1}H-NMR spectrum of **1e**

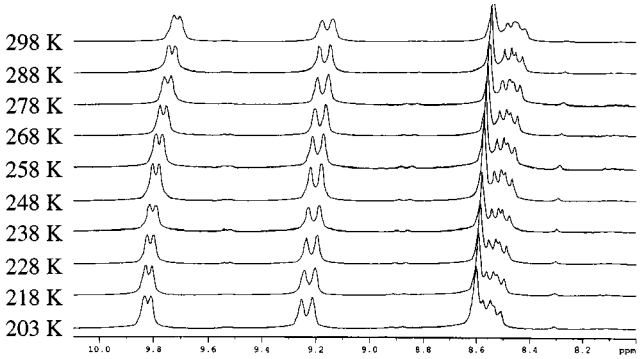

Figure 5 showing the temperature dependence of the ^{1}H-NMR spectrum of **1e** as an example demonstrates that with raising temperature all of the signals are continuously shifted to higher fields. Qualitatively this is well in accord with what would be expected on the basis of the partial de-coordination of the ligand characterizing the equilibrium depicted in Figure 4: with the ligands being less tightly bound in the mean with increasing temperature their signals should move towards the ones of the free ligands (Table 2).

Applying Equation 1 to the ^{1}H-NMR data of **1e** (Figure 5) with one set of limiting resonances fixed on the values of the free ligand [δ_C = 9.13 (H_a), 8.42 (H_c), 7.91 (H_f), 7.72 (H_b)] the other set of limiting resonances is derived as [δ_B = 9.96 (H_a), 9.57 (H_c), 8.87 (H_f), 8.70 (H_b)]. The value of ΔG characterizing the equilibrium is obtained as 2 kJ/mol and is − with respect to experimental accuracy (Figure 5) and the narrow range of temperatures studied − in satisfying agreement with the value of ΔG = 4 kJ/mol as extracted from ^{119}Sn-NMR measurements (vide supra). It is worth noting that the worst quality of fit is obtained for the data pertaining to the protons H_a of the α-CH groups. The sensitiveness of the resonances of these protons to minor changes in the coordination environment is amply been demonstrated in the literature[20]. Overall the successful modeling of the temperature dependence of the NMR spectra of compounds **1** and the qualitative agreement of the estimates made by these models for the reaction enthalpy, independent of whether ^{119}Sn- or ^{1}H-NMR data are analyzed, are in favor of the belief that the underlying basic assumption of an equilibrium (Figure 4) is correct.

The equilibrium (Figure 4) suggests that species with just one donor ligand should be stable as such without the necessity of a second donor ligand. Under these premises it appeared worthwhile to probe whether, excluding the chelate effect, one pyridine (py) molecule as a Lewis base would suffice to stabilize the underlying cumulene-type compounds to such an extent that inidene like adducts [$(CO)_5M{=}Sn(py){=}M(CO)_5$] could be isolated or whether a second pyridine molecule whould coordinate, leading to [$(CO)_5M{=}Sn(py)_2{=}M(CO)_5$], compounds, formally isoelectronic to the dianions [$\{(CO)_5M\}_2SnHal_2]^{2-}$[3][4].

b) Compounds 1 Containing Two Pyridine Donors

When THF solutions of the sodium salts [$Na(THF)_x$][$\{(CO)_5M\}_2SnCl_2$] (type **A**) are treated with a fourfold equimolar excess of pyridine, adduct formation is indicated by a change in the IR-ν_{CO} pattern. Isolation of the pyridine adducts **1g** and **1h**, albeit in yields below 20%, is possible by column chromatography. Compounds **1g** and **1h** are obtained as yellow microcrystalline solids. **1g** and **1h** are definitely less stable than the chelate adducts **1a**−**1f**: under conditions where **1a**−**1f** are indefinitely stable in THF solutions **1g** and **1h** gradually disintegrate to produce unsoluble greenish materials.

The IR-ν_{CO} absorptions (Table 4) of **1g** and **1h** are within a few wavenumbers found at the same positions as those of the corresponding 2,2′-bipyridine adducts **1a** and **1c**.

The ^{1}H-NMR spectra of **1g** and **1h** in [D_6]acetone (Table 2) with the corresponding low-field shifts relative to free pyridine clearly reveal the coordination of the pyridine ligands. The proton signals shift to lower fields as the temperature is lowered with the same type of observation having already been described for **1a**−**1f**.

The ^{13}C-NMR data (Table 3) equally well demonstrate the coordination of the heterocycles in **1g** and **1h**. Again the individual resonances of the carbonyl carbon atoms are observable and distinguishable (Table 3).

The ^{119}Sn-NMR data are indicative of dynamic equilibria in these cases as well. When CD_2Cl_2 is used as the solvent for **1h** sharp tungsten-modulated signals are observed over the whole range of temperatures (298−168 K). With decreasing temperature a monotonically increasing high-field shift of the signal is observed: at 298 K the resonance occurs at δ = 1271 at 168 K is is found at δ = 1164. If it is assumed that the underlying chemical process is again a coordination/de-coordination equilibrium similar to the one shown in Figure 4 and if it is further assumed that the pyridine, when de-coordinated remains close to the tin in the solvent cage an analysis as performed for the chelate compounds (vide supra) results in δ_B = 1100, δ_C = 2200, and ΔG = 5 kJ/mol, respectively, with the species of type **B** being the more stable. The quality of fit is similar to the one shown in Figure 3 for the chelate compounds **1a** and **1e**. This refers to the data from solutions of **1h** in CD_2Cl_2.

Solutions of **1h** in [D_6]acetone show the same type of temperature dependence of the ^{119}Sn-NMR signal with the additional complication that the signal starts to broaden at 240 K and is completely vanishing in the background at 230 K reappearing as a sharp signal at 210 K. It is assumed that some exchange with the [D_6]acetone solvent is responsible for this phenomenon. With the chelate compounds **1a** and **1e** this type of observation is not made; steric reasons are a rationale for this difference in behavior. Anyhow, the dynamic situation with **1h** is more complicated than the one described for **1a** and **1e** since addition of the free ligand pyridine is found to cause a high-field shift in the ^{119}Sn-NMR spectrum while starting with pure **1h** increasing dilution will shift the signal to the low-field side. These experiments indicate that coordination/de-coordination equilibria of the same type as depicted in Figure 4 must be at the basis of the observed phenomena.

c) Molecular Structures of Compounds 1a−1h

The molecular structures of all the compounds of **1a**−**1h** have been determined by X-ray analyses (Tables 5, 10, and 11). The similar allover geometry of the individual molecules within each class (**1a**−**1c**, **1d**−**1f**, **1g** and **1h**) warrants the discussion of the structures with reference to Figure 6, showing only the [$(CO)_5Cr$] derivatives[21].

This similarity is also illustrated by the fact that the crystal structures of **1a**−**1c** are isotypic (Table 10) as are those of **1d**−**1f** which include one THF solvate per molecule **1** (Tables 10 and 11) and those of **1g** and **1h** (Table 11). The environment of the tin centers in **1a**−**1h** is distorted tetrahedral (Table 5).

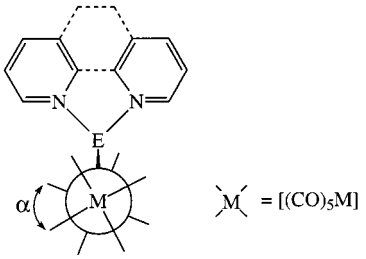
torsion angle α [c]	25	24	24	40	40	40	44	44

[a] Estimated standard deviations in units of the least significant figures given in each case are quoted in parentheses. − [b] Average values; the standard deviations refer to the largest individual esd in each set. − [c] α refers to the torsion angle $C_{CO(eq)}-M-M-C_{CO(eq)}$ as defined in Figure 7.

The tin−metal distances in compounds **1a**−**1h** are very similar (Table 5) within each class (Sn−Cr, Sn−Mo, Sn−W) for the three types of compounds (**1a**−**1c**, **1d**−**1f**, **1g**, and **1h**). Within each individual compound the two tin−

metal distances are close of being even numerically equal. The geometric data characterizing the Sn−{M(CO)$_5$} entities in each compound are again very similar (Table 5). While the distances are appropriately modulated by the kind of metal (Cr, Mo, or W) the same general trends are found in all compounds. The axial metal−carbonyl bonds are without exception some 2−4 pm shorter than the equatorial ones (Table 5). The equatorial M−CO entities tend to bend towards the tin center with the Sn−M−C_{eq} angles somewhat smaller than 90° throughout, and consequently the C_{ax}−M−C_{eq} angles somewhat larger than 90° (Table 5). The torsion angles α [$C_{CO(eq)}$−M−M−$C_{CO(eq)}$, Figure 7] are as well similar within each class of compounds (**1a**−**1c**, **1d**−**1f**, **1g**, and **1h**). While for **1a**−**1c** a more eclipsed orientation with α ≈ 24° is found to be preferred, a more staggered conformation is observed for **1d**−**1f** (α ca. 40°) and for **1g** and **1h** (α ≈ 44°) (Table 5).

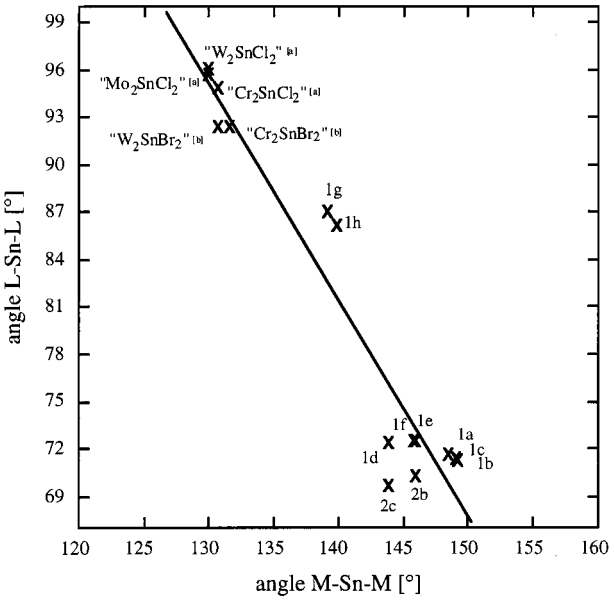
Figure 7. Newman projection of a compound of type **1**; view along the M−M axis



The Sn−N distances observed for **1a**−**1f** are close to their mean value of 229 pm within a few pm in all these compounds (Table 5). The quality of the data obtained for the tungsten compound **1c** is too low (Tables 10 and 11) to warrant a detailed discussion of individual differences; the same applies to the tungsten compound **1h**. A comparison of the 2,2′-bipyridine adduct **1a** and the bis-pyridine adduct **1g** suggests a somewhat weaker Sn−N interaction in **1g** (Sn−N: 232.0 pm) than in **1a** (Sn−N: 228.5 pm) (Table 5). The most apparent difference between the three classes of compounds (**1a**−**1c**, **1d**−**1f**, **1g**, and **1h**) is found in the angular distribution around the tin center: the M−Sn−M angles are close to 149° for the 2,2′-bipyridine adducts (Table 5) while they average at around 145° for the 1,10-phenanthroline adducts (Table 5). For the bis-pyridine adducts they are definitely smaller with values around 139° (Table 5).

The trend observed for the M−Sn−M angles is counterbalanced by an opposite trend in the N−Sn−N angles (Table 5, Figure 8): with 2,2′-bipyridine as the ligand this angle is constant at 71.3° (Table 5) within the limits of error for all three compounds **1a** −**1c**; with 1,10-phenanthroline (**1d**−**1f**) the angle stays at 72.4° (Table 5). For the bis-pyridine derivatives **1g** and **1h** angles of 86.5° (Table 5) are observed being again practically identical for the two compounds in this class. The rather small N−Sn−N angles observed for **1a**−**1c** and **1d**−**1f** are thus obviously a consequence of the chelate binding mode. While in the compounds **1g** and **1h** the two separate pyridine donors are

Figure 8. Correlation between the angles around the tin center



[a] Values for the chloride compounds [{(CO)$_5$M}$_2$SnCl$_2$]$^{2-}$ (M = Cr, Mo, W) are taken from ref.[3] − [b] Values for the bromide compounds [{(CO)$_5$M}$_2$SnBr$_2$]$^{2-}$ (M = Cr, W) are taken from ref.[4].

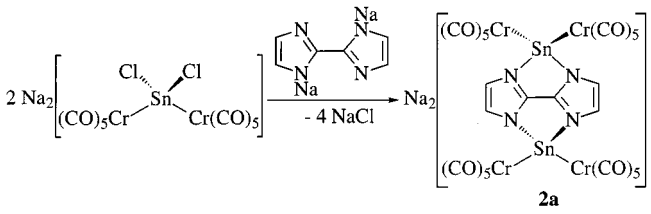
free to occupy the individually optimal positions, for the chemically related dianions [{(CO)$_5$M}$_2$SnHal$_2$]$^{2-}$ (M = Cr, Mo, W: Hal = Cl[3]; M = Cr, W: Hal = Br[4]), were two halide donors bind to the tin center, the angles Hal−Sn−Hal are around 94° so that it is propable to assume that an angle of around 90° is characteristic for an unstrained L−Sn−L arrangement in this type of compound. The trend apparent from the structures of **1a**−**1h** that a small N−Sn−N angle is accompanied by a large M−Sn−M angle is also apparent from the fact that the M−Sn−M angles observed for [{(CO)$_5$M}$_2$SnHal$_2$]$^{2-}$ are close to 131°[3][4]. The corresponding data for quite a number of compounds of the general formula [{(CO)$_5$M}$_2$SnL$_2$]^n (n = 0, L$_2$ = 2,2′-bipyridine, 1,10-phenanthroline, 2 pyridine, 2,2′-bipyrimidine; n = −2, L = Cl, Br) are collected in the diagram of Figure 8 which illustrates the correlation between M−Sn−M and L−Sn−L angles in this type of compounds.

d) Compounds 2 Containing Biimidazolato or 2,2′-Bipyrimidine Chelating Ligands

Since the bidentate chelate ligands 2,2′-bipyridine and 1,10-phenanthroline form the stable mononuclear adducts **1** bis-bidentate chelate bases should give dinuclear compounds. When disodium biimidazolate, $C_6H_4N_4Na_2$, is treated with [Na(THF)$_x$]$_2$[{(CO)$_5$Cr}$_2$SnCl$_2$][3][4] the dinuclear tin(0) compound **2a** is obtained (Scheme 1).

2a is separated from the reaction mixture by chromatographic workup. Crystals suitable for X-ray analysis are obtained by addition of 12-Crown-4 to a THF solution of **2a** followed by vapor diffusion from THF/diethyl ether/petroleum ether (boiling range 40−60°C).

Scheme 1. Reaction of $Na_2[\{(CO)_5Cr\}_2SnCl_2]$ with disodium biimidazolate

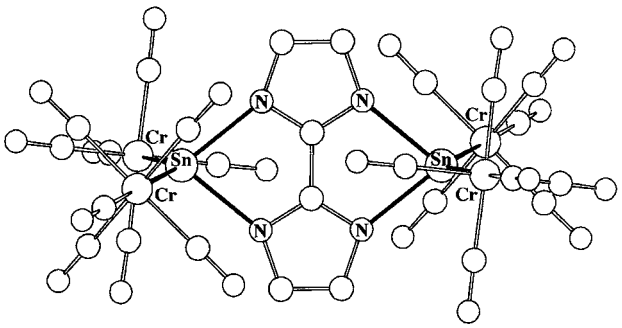


The IR-$\tilde{\nu}_{CO}$ spectrum in THF is consistent with the presence of $[(CO)_5Cr]$ groups (Table 4)[7]; in comparison with the IR-ν_{CO} spectra of **1a** and **1d** the absorption pattern observed for **2a** shows two additional resonances apparent as shoulders. The somewhat reduced local symmetry or some coupling between the individual $[(CO)_5Cr]$ chromophores may be the reason for this[7]. Relative to the absorptions observed for the neutral species **1a** and **1d** the center of gravity of the ν_{CO}-band pattern is shifted to slightly lower energies as expected.

The ^{1}H- and ^{13}C-NMR data of **2a** (see Experimental Section) are consistent with the ligand acting as a bis-bidentate chelate bridge.

A value of $\delta = 1149$ is observed for the ^{119}Sn-NMR resonance (Table 4) of **2a**. The ^{119}Sn-NMR shift is thus about 200 ppm upfield from the shifts observed for **1a** and **1d** and is close to the value observed for $[Ph_4P]_2[\{(CO)_5Cr\}_2SnCl_2]$ ($\delta = 924$)[4]. Even though no temperature-dependent ^{119}Sn-NMR data of **2a** could be obtained, the relatively strong high-field shift of the ^{119}Sn-NMR signal of **2a** suggests that there is no dynamic coordination/de-coordination equilibrium active for this compound.

Figure 9. Molecular structure of the dianion of **2a**



The X-ray analysis of **2a** (Tables 6 and 12, Figure 9) which is a centrosymmetric molecule in the solid state reveals the general type of bonding as inferred from the spectral data. The individual trends already discussed for compounds **1** are equally well seen in the structure of **2a** (Table 6). With respect to the diagram (Figure 8) correlating the bond angles M−Sn−M and N−Sn−N **2a** is an outlyer with values of 135° and 77°, respectively (Table 6) being found for **2a**. It is not clear whether it is the steric encumbrance in the dinuclear tin species **2a** or some peculiarity connected with the biimidazolato bridging ligand which causes this deviation.

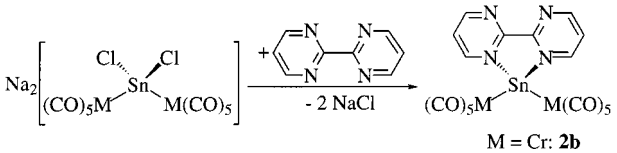
Procedures analogous to the one which leads to the dinuclear compound **2a** with biimidazolate as the ligand gave, under the workup procedures applied to obtain compounds **1**, only the mononuclear species **2b** and **2c** with 2,2′-bipyrimidine (bpmd) as the potential bis-bidentate chelate ligand (Scheme 2).

Scheme 2. Reaction of $Na_2[\{(CO)_5M\}_2SnCl_2]$ (M = Cr, W) with 2,2′-bipyrimidine



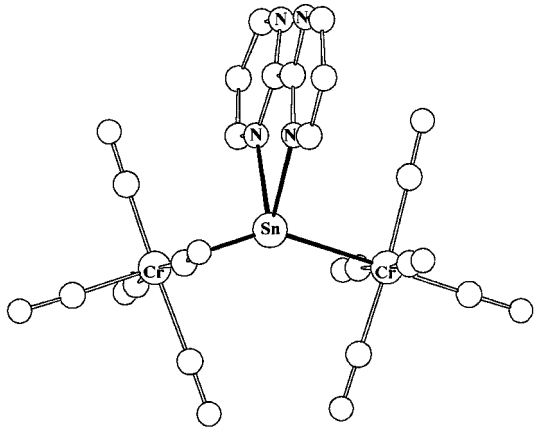
M = Cr: **2b**
M = W: **2c**

The IR-$\tilde{\nu}_{CO}$ data of **2b** and **2c** are in excellent qualitative accord with the corresponding data of compounds **1** (Table 4).

The mononuclearity of **2b** and **2c** is unequivocally proofed by X-ray analyses for both compounds (Tables 6 and 12, Figure 10). While the quality of the diffraction data obtained for the tungsten compound **2c** does not warrant a detailed discussion of individual geometric parameters the structure analysis of **2b** is of standard accuracy.

Since 2,2′-bipyridine is a direct analogue of 2,2′-bipyrimidine a comparison of structures **1a** and **2b** should be informative. Many of the general trends discussed for com-

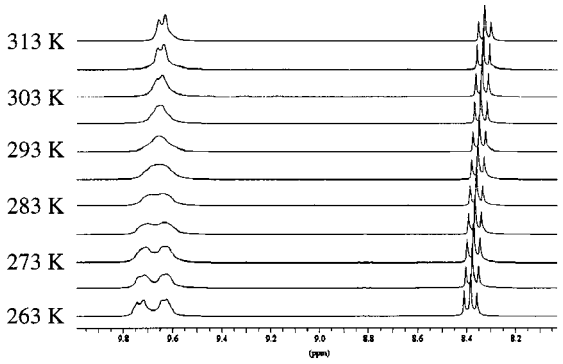
Figure 10. Molecular structure of **2b**



pounds **1** are as well observed for compounds **2** (Tables 5 and 6). The fact that the Cr−Sn bond is more than 3 pm longer than the one observed in **1a** (Table 5) has no explanation at the moment because at the same time the Sn−N distances in **2b** [236.5 (7) pm, Table 6] are definitely longer than the Sn−N bonds in the 2,2′-bipyridine derivative **1a** [228.5 (3) pm, Table 5]. Nevertheless, the angles characterizing the coordination at the tin center are very similar for both compounds as are the angles relevant to describe the coordination of the chromium centers in both compounds (Tables 5 and 6, Figure 9).

In contrast to the mononuclear structure of **2b** and **2c** the proton-NMR signals observed for these compounds at ambient temperature show a pattern (Figure 11) which indicates at least C_{2v} symmetry for the ligand surroundings while only C_s symmetry is possible with the static structure found in the solid state (Figure 10).

Figure 11. Temperature-dependent ^{1}H-NMR spectrum of **2c**



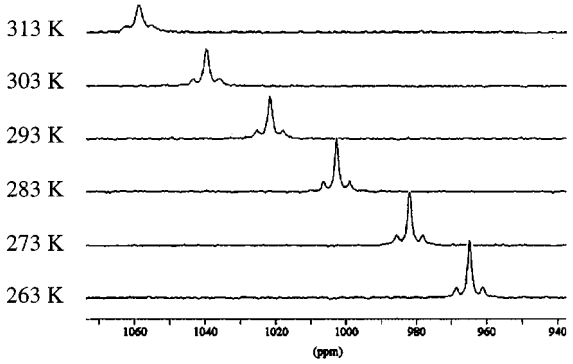
In the static structure the protons H_a and H_c (see insert, Table 2) have definitely different environments, while they give rise to only one broad signal at 298 K (Figure 11, $\delta \approx 9.6$). By variable-temperature NMR measurements (Figure 11) it is shown that upon cooling two doublets evolve from this envelope which are clearly resolved at 263 K (Figure 11). The appearance of the spectra at low temperatures thus corresponds to the static C_s-symmetric structure as is observed in the solid state (Figure 10). At higher temperatures the broad envelope observed at 298 K sharpens and a clear doublet is apparent at 313 K (Figure 11) indicating C_{2v} symmetry in the time average. The process which gives rise to this temperature dependence is then one which equilibrates all the four donor positions of the 2,2′-bipyrimidine ligand in **2c**.

According to the discussions made in the previous parts of this paper the most propable equilibration pathway is the one where one Sn−N bond is opened thus allowing the now uncoordinated pyrimidyl residue to rotate. Recoordination of this pyrimidyl entity necessarily leads to the equilibration of its donor functions. With the same type of process operating for the other pyrimidyl part of the chelate ligand all four donor positions are equilibrated on the time average. The coalescence temperature for this process as observed for **2c** (Figure 11) is around 288 K corresponding to an activation barrier of around 61±1 kJ/mol[22]. The same type of ^{1}H-NMR observation is made for **2b** with a coalescence temperature of 293 K. The activation energy (64±1 kJ/mol) is the same within the limits of error as the one found for **2c**. These energies refer to a process different from the one discussed in connection with the dynamic behavior of **1**: the process discussed there for 2,2′-bipyridine or 1,10-phenanthroline derivatives, respectively, involved nothing but a wagging motion of the chelate ligands with one of the nitrogen donors remaining tightly bound and the other one just shifting away from the tin by some 50 pm (Sn···N ca. 284 pm) without completely loosing the contact to its tin neighbor (type **C**, Figure 4). In the case of **2b** and **2c** this contact is completely lost by a full 180° rotation of the ring. Such a rotation is not possible for 1,10-phenanthroline and the observation that the 1,10-phenanthroline derivative **1e** behaves quite like the 2,2′-bipyridine derivative **1a** (vide supra) lends quite some credit to the interpretation of the dynamic processes in these cases. For **2b** and **2c** one Sn−N bond is completely broken and EHT calculations performed on [{(CO)$_5$Cr}$_2$Sn(bipy)] (**1a**) as a model compound suggest that quite some additional energy is needed for this process of completely breaking the bond.

The ^{13}C-NMR data of **2b** and **2c** are formally in accord with the static structure as observed in the solid state (Figure 10) and individual signals are observed for every type of chemically different carbon atoms (Table 3). This is due to the different time window of ^{1}H- and ^{13}C-NMR spectroscopy and especially to the large difference in resonance frequency of C_a and C_c (Table 3)[23]. At 313 K the resonances of C_a and C_c have just started to fade away yet without a time averaged signal being apparent. Further heating is precluded by the low boiling point of the [D$_6$]acetone solvent used.

The type of dynamic process as discussed for the 2,2′-bipyridine and 1,10-phenanthroline adducts **1** should likewise be apparent for **2b** and **2c** (Figure 12). In these cases the weakening of one of the two Sn−N bonds at each tin center should be a low lying pre-equilibrium step with reference to the complete bond breaking and rotation process which is evident by the coalscence experiments discussed above. If no further deep energy minima are met along the reaction coordinate of bond breaking and ring rotation −

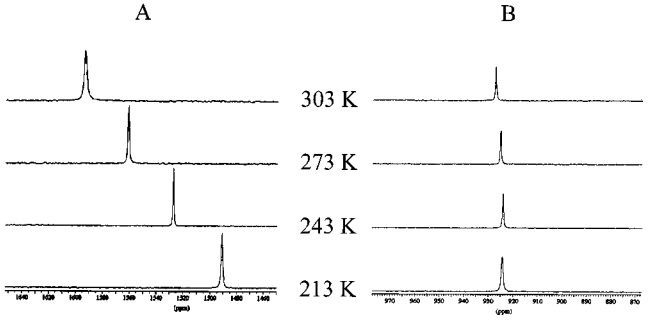
Figure 12. Temperature-dependent ^{119}Sn-NMR spectrum of **2c**



as is evident by the ^{1}H-NMR data – this additional dynamic process will not mirror itself into the temperature dependence of the ^{119}Sn-NMR spectrum and this is what is indeed observed. Fitting equation 1 as discussed for **1a** and **1e** to the shift values observed at different temperatures (Figure 12) for **2c** leeds to the values $\delta_B = 800$, $\delta_C = 3600$ and $\Delta G = 6$ kJ/mol with B and C refering to the use of the symbols in Figure 4. These values are in good agreement to the ones obtained for **1a** and **1e**.

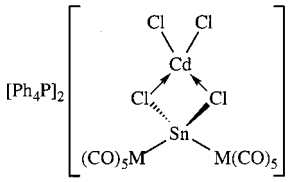
Observations made for $[\{(CO)_5M\}_2SnCl_2]^{2-}$ (M = Cr, Mo, W) lend some additional credit to the above reasoning: the ^{119}Sn-NMR resonances of the salt $[Ph_4P]_2[\{(CO)_5Cr\}_2SnCl_2]$[4] occurs at $\delta = 924$ with a only slight temperature dependence as generally induced by solvation processes (Figure 13, B).

Figure 13. Comparison of the temperature dependence of the ^{119}Sn-NMR resonances of $[Na(solv)_x]_2[\{(CO)_5Cr\}_2SnCl_2]$ (A) and $[Ph_4P]_2[\{(CO)_5Cr\}_2SnCl_2]$ (B)



The disodium salt of the same dianion on the other hand shows a ^{119}Sn-NMR resonance which is strongly temperature dependent (Figure 13, A). The shift values observed between 213 K and 303 K span a range between $\delta = 1593$ and $\delta = 1490$. The IR-ν_{CO} absorptions of these two salts are different as well[4] with the absorption pattern observed for the disodium salt occuring at higher energies as compared to the one of the $[Ph_4P]$ salt[4]. A clue as to what the reason for these differences might be comes from the following observation: when THF solutions of the $[Ph_4P]_2[\{(CO)_5M\}_2SnCl_2]$ are treated with an equimolar amount of $CdCl_2$ the infrared band pattern changes to the one characteristic for the disodium salts $([Na(THF)_x]_2[\{(CO)_5M\}_2SnCl_2]$: $\tilde{\nu}_{CO}$ (THF): M = Cr: 2040 w, 2007 s, 2000 sh, 1920 vs, 1895 sh cm^{-1}, Figure 2; M = Mo: 2051 vw, 2025 s, 1949 sh, 1929 vs, 1901 s; M = W: 2052 w, 2027 m 1926 vs, 1894 s). The ^{119}Sn-NMR spectrum of solution of $[Ph_4P]_2[\{(CO)_5W\}_2SnCl_2 \cdot CdCl_2]$ for example taken at 300 K shows a signal at $\delta = 1250$, very similar to the one observed for the disodium salt ($\delta = 1268$). It is plausible to assume that $CdCl_2$ will interact with the $SnCl_2$ part of the dianion by association with the chlorine functions to produce an adduct of type **D** (Figure 14)

Figure 14. Possible form of an association between $[Ph_4P]_2[\{(CO)_5M\}_2SnCl_2]$ (M = Cr, Mo, W) and $CdCl_2$



D

Several forms of association are of course conceivable with the extreme of a complete separation of the adduct into the two anions "$[CdCl_3]^-$" and $[\{(CO)_5Cr\}_2SnCl]^-$. The observed shift in the IR-ν_{CO} absorptions (vide supra) fits into this idea as does the observation that the ^{119}Sn-NMR spectra of $[Ph_4P]_2[\{(CO)_5M\}_2SnCl_2 \cdot CdCl_2]$ are strongly temperature-dependent while the ones of $[Ph_4P]_2[\{(CO)_5M\}_2SnCl_2]$ are not. Fitting the NMR data of $[Ph_4P]_2[\{(CO)_5W\}_2SnCl_2 \cdot CdCl_2]$ to an equilibrium of this type leads to a ΔG value of 5 kJ/mol for the relevant process and values of $\delta_B = 1000$ and $\delta_C = 3200$ with respect to Equation 1. These values are not to different from the ones estimated for a comparable equilibrium in the case of compounds **1** and **2**.

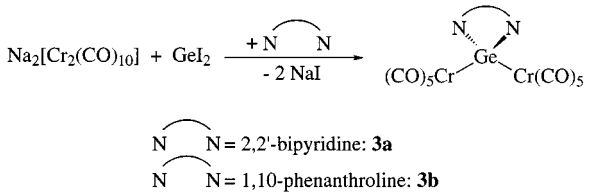
If THF solutions of $[Ph_4P]_2[\{(CO)_5M\}_2SnCl_2]$ are treated with equimolar amounts of $CoCl_2$, $FeCl_2$, or $MnCl_2$ the IR-ν_{CO} absorption pattern shifts accordingly with the resulting spectrum being equal to the one observed when $CdCl_2$ is used as the halide abstractor and altogether equal to the one observed for THF-solutions of $[Na(THF)_x]_2[\{(CO)_5M\}_2SnCl_2]$. When, on the other hand, solutions of $Na_2[\{(CO)_5M\}_2SnCl_2]$ in THF are treated with a large excess of [2.2.2]-Cryptand the IR-ν_{CO} absorption pattern as well as the ^{119}Sn-NMR resonances shift to the value characteristic for $[Ph_4P]_2[\{(CO)_5M\}_2SnCl_2]$[4]: the encrypted sodium ion can no longer act as a halide abstractor. Any attempts to isolate the product $[\{(CO)_5M\}_2SnCl]^-$ formed by halide abstraction from $[\{(CO)_5M\}_2SnCl_2]^{2-}$ have failed so far. The isolation of $[Ph_4P]_2[Zn_2Cl_6]$[24] from the reaction of $[Ph_4P]_2[\{(CO)_5Cr\}_2SnCl_2]$ and $ZnCl_2$ does however show that chloride abstraction is in fact occuring with the $ZnCl_2$ reagent.

e) Analogous Compounds with Germanium and Lead

The germanium analogue **3a** of **1a** is prepared from the reaction of $Na_2[Cr_2(CO)_{10}]$ with GeI_2 in the presence of

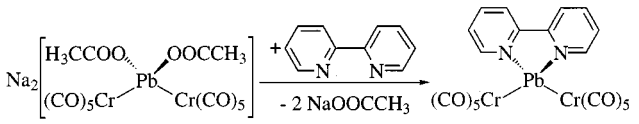
2,2′-bipyridine. The same procedure when performed with 1,10-phenanthroline instead of 2,2′-bipyridine as the chelating ligand leads to **3b** the germanium analogue of **1d** (Scheme 3).

Scheme 3. Reaction of $Na_2[Cr_2(CO)_{10}]$ with GeI_2 in the presence of a chelate ligand



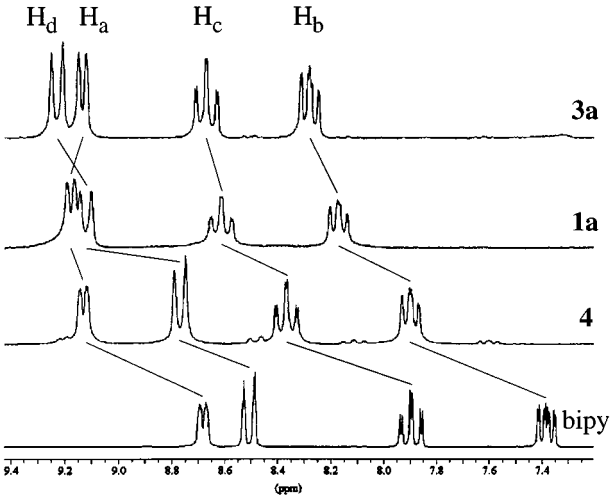
The lead analogue **4** of **1a** is accessible by the reaction of $[\{(CO)_5Cr\}_2Pb(OOCCH_3)_2]^{2-}$ [4] with 2,2′-bipyridine (Scheme 4).

Scheme 4. Reaction of the disodium salt $[\{(CO)_5Cr\}_2Pb(OOCCH_3)_2]^{2-}$ with 2,2′-bipyridine



All three compounds are characterized by IR-$\tilde{\nu}_{CO}$, ^{1}H-NMR, and ^{13}C-NMR spectroscopy (Tables 2−4). The NMR shifts observed relative to the resonances of the free ligands clearly indicate a chelate type coordination in each case (Tables 2 and 3). The ^{1}H-NMR pattern observed for the resonances of the 2,2′-bipyridine ligands in the series of the germanium, tin, and lead compounds (**3a**, **1a**, and **4**) are compared to the ^{1}H-NMR pattern observed for the free ligand in Figure 15.

Figure 15. Comparison of the ^{1}H-NMR spectra of $[\{(CO)_5Cr\}_2E(bipy)]$ (E = Ge: **3a**; E = Sn: **1a**; E = Pb: **4**) with the ^{1}H-NMR spectrum of free 2,2′-bipyridine



It is seen that the low-field shift upon coordination is smallest for the lead compound **4** and largest for the germanium compound **3a** (Table 2, Figure 15). This may be taken as an indication of the continuously stronger interaction between the main group center and the 2,2′-bipyridine ligand going from lead to germanium. An interesting special feature apparent from Figure 15 is that the signals originating from H_a and H_d change their relative position with respect to one another when going from the tin (**1a**) to the germanium compound **3a**. This type of observation had already been made with other coordination compounds of 2,2′-bipyridine and 1,10-phenanthroline and has prompted to some tentative explanations[20].

torsion angle α[c]	19	40	42	25

[a] Estimated standard deviations in units of the least significant figures given in each case are quoted in parentheses. − [b] Average values; the standard deviations refer to the largest individual esd in each set. − [c] α refers to the torsion angle $C_{CO(eq)}-M-M-C_{CO(eq)}$ as defined in Figure 7.

The structures of **3** and **4** have been determined by X-ray crystallography (Tables 7 and 13). The overall geometry closely corresponds to the one observed for the other 2,2′-bipyridine and 1,10-phenanthroline compounds described in this paper. The structures will therefore be discussed with implicit reference to Figure 2 which shows the general structural pattern with respect to the $[\{(CO)_5Cr\}_2Sn(L_2)]$ analogues **1a** and **1d**. The crystal of **3a** contains two crystallographically independent molecules designated as **3a**/1 and **3a**/2 in Table 7. The only very minor deviations in the scalar properties of the two crystallographically independent species **3a** (Table 7) demonstrate that the structures are to a very large extent determined by the inner molecular potential and not strongly influenced by the outer forces caused by the potential imposed onto the molecules by the crystal lattice. On the other hand the torsion angles characterizing the skew of the arrangement of the equatorial carbonyl groups of the $[(CO)_5Cr]$ entities relative to each other is different in the two individual molecules of **3a** (Table 7). This means that the corresponding torsional mode is a very soft one as expected. The Ge−N distances observed in **3a** (205 pm) are significantly shorter than the ones found in its

analogue [{Cp′(CO)$_2$Mn}$_2$Ge(bipy)] (Ge−N: 211.5 pm)[5]. The same trend is observed for the 1,10-phenanthroline compound **3b** (**3b** has crystallographic C_2 symmetry) with an Ge−N distance of 206.9 pm versus the equivalent distance in [{Cp′(CO)$_2$Mn}$_2$Ge(phen)] of 216.8 pm[6]. The Pb−N distances in the lead compound **4** fit to this trend as well. Due to absorption effects the structure analysis is not very accurate but it is still beyond doubt that the Pb−N distances in **4** (243 pm, Table 7) are significantly shorter than the ones found in [{Cp′(CO)$_2$Mn}$_2$Pb(bipy)] (Pb−N: 255.7 pm)[5]. An explanation for this trend based on the different π-donor capabilities of [Cp′(CO)$_2$Mn] versus [(CO)$_5$Cr] has already been given above. Yet another trend is seen when comparing the data collected in Tables 5 and 7: the M−E−M angle systematically increases along the series of germanium, tin, and lead compounds. This trend is as well apparent from the data known for the [Cp′(CO)$_2$Mn] analogues of **1a**, **3a**, and **4**[5][6] and their isoelectronic cationic analogues [{Cp′(CO)$_2$Mn}$_2$E(bipy)]$^+$ (E = As[25], Sb[25], Bi[26]).

f) Cyclovoltammetry of Compounds 1a−3b

Cyclovoltammetric data have been obtained (see Experimental Section) for all compounds but **4** and are listed in Table 8.

Table 8. Cyclovoltammetric data[a]

[a] Pt/SCE electrode/nBu$_4$NPF$_6$/CH$_3$CN; see Experimental Section.

A first reductive electron transfer occurs in the region between −0.8 and −1.4 V. Although the redox processes are only in part fully reversible a comparison of the observed potentials is revealing. For a given set of ligands reductions are found at closely similar values independent of the [(CO)$_5$M] groups to which the main-group center is bonded (compare: **1a**−**1c**, L$_2$ = bipy, −1.2 V; **1d**−**1f**, L$_2$ = phen, −1.2 V; **1g**−**1h**, L$_2$ = 2 py, −1.4 V; **1a**−**1c**, L$_2$ = bpmd, −0.9 V). Furthermore, the potential at which reduction occurs does appear to be independent of the kind of main-group center (compare: **1a**, Sn, L$_2$ = bipy, −1.2 V; **3a**, Ge, L$_2$ = bipy, −1.1 V). These observations indicate that the LUMO in all the compounds is ligand centered. Even the second reduction waves (Table 8) conform to this statement. Although some of the comparisons made are not completely sound on a thermodynamic basis due to partially irreversible electron transfer processes (Table 8) the trends are altogether clear. A reliable comparison can be made for **1a** (L$_2$ = bipy) and **2b** (L$_2$ = bpmd) because in each case the first reduction is fully reversible with the second one being quasireversible. It is observed that the first reduction of **1a** is by 30 kJ/mol more difficult than the first reduction of **2b**. The difference in electron affinity of the 2,2′-bipyridine versus the 2,2′-bipyrimidine ligand is mirrored by these data which again is in favour of the conclusion that the LUMO is ligand centered in each case.

While the reduction is thus ligand-centered the oxidation of the compounds **1a**−**3b** appears to be metal-centered: independent of the ligand but slightly dependent on the metal the oxidation waves are observed in the range of 0.7−1.0 V. In most cases the first oxidation wave occurs in this range (Table 8). In the case of **1g** and **1h**, where two pyridine molecules act as the L$_2$ donor set, the first irreversible oxidation is found at a lower potential of around 0.6 V already while the second one is again in the range discussed above. It is assumed that the first irreversible oxidation wave refers to the species which result from **1g** and **1h** by loss of one pyridine ligand. The corresponding dissociation equilibrium is evident from NMR and has been explained above. With the biimidazolato bridging ligand, species **2a**, which undergoes no reduction in the potential range studied, three oxidation waves are observed, all of them irreversible. But the last one with 0.9 V (Table 8) again being in the range characteristic of all the other compounds where this complication by several oxidation steps does not occur. Comparison of the oxidation potentials observed for **1a** (Sn) and **3a** (Ge) shows that the observed potentials are also practically independent of the main-group center. Taken together these findings indicate that the HOMO of the compounds is metal-centered with the exception of the dianionic compound **2a**.

Concluding Remarks

It is shown that even though the cumulene-type compounds [(CO)$_5$M=E=M(CO)$_5$] (E = Ge, Sn, Pb; M = Cr, Mo, W) are not yet known in the free state, their base adducts [{(CO)$_5$M}$_2$E(L$_2$)] are stable and well-characterized compounds. Their structures as determined by X-ray crystallography reveal a common bonding pattern for all the compounds of this type. By comparison of a series of compounds of the type [{(CO)$_5$M}$_2$Sn(L$_2$)] it is demonstrated that in an unstrained compound the angle sustained at the tin center by the donors of L$_2$ should be close to 90°. The M−E−M angles (E = Ge, Sn, Pb) are in the range between 133° and 155° systematically increasing from E = Ge over E = Sn to E = Pb. From NMR-spectroscopic data of the corresponding 2,2′-bipyridine adducts [{(CO)$_5$Cr}$_2$E(bipy)] it is inferred that the bonding interaction between the chelate ligand and the main-group element decreases in the series E = Ge to E = Pb. The temperature dependence of the ^{119}Sn-NMR shifts observed for compounds **1** and **2** is consistently interpreted in terms of an equilibrium [{(CO)$_5$M}$_2$E(L$_2$)] ⇌ [{(CO)$_5$M}$_2$E(L)] + L. With 2,2′-bi-

pyrimidine as a spectroscopic probe in $[\{(CO)_5M\}_2Sn(bpmd)]$ (M = Cr, W) this process of partial de-coordination is more directly evident from dynamic ^{1}H-NMR spectroscopy.

The financial support by the *Deutsche Forschungsgemeinschaft* (SFB 247) and the *Fonds der Chemischen Industrie* is gratefully acknowledged.

Experimental Section

General: All manipulations were carried out under argon by means of standard Schlenk techniques at 20°C unless mentioned otherwise. All solvents were dried by standard methods and destilled under argon. [D$_6$]acetone used for the NMR spectroscopic measurements was degassed by three successive "freeze-pump-thaw" cycles and dried over 4-A molecular sieves. Silica gel (Kieselgel z. A. 0.06−0.2 mm, J. T. Baker Chemicals B.V.) used for chromatography and Kieselgur (Kieselgur, gereinigt, geglüht, Erg. B.6, Riedel de Haen AG) used for filtration were degassed at 1 mbar at 180°C for 12 h and saturated with argon. − NMR: Bruker Avance DPX 200 at 200.13 MHz (^{1}H), 50.323 MHz (^{13}C{^{1}H}), 74.631 MHz (^{119}Sn{^{1}H}); chemical shifts (δ) in ppm with respect to [D$_6$]-acetone (^{1}H: δ = 2.04; ^{13}C: δ = 29.8) as internal standards and to $SnMe_4$ (^{119}Sn: δ = 0 at 25°C), respectively, as external standard. − IR: Bruker FT-IR IFS-66; CaF_2 cells. − UV/Vis/NIR: Perkin Elmer Lambda 19; cells (0.2 cm; Hellma 110 suprasil). − MS (FAB or EI): Finnigan MAT 8400; Nibeol (4-nitrobenzyl alcohol) or TEA (triethanol amine) matrices, respectively. − Elemental analyses: microanalytical laboratory of the Organisch-Chemisches Institut, Universität Heidelberg. − Melting points: Gallenkamp MFB-595 010; the values are not corrected. − Cyclic voltammetry: Methrohm "Universal Meß- und Titriergefäß", Methrohm GC electrode RDE 628, platinum electrode, SCE electrode, Princeton Applied Research potentiostat Model 273, 10^{-3} M in 0.1 M nBu$_4$NPF$_6$/CH_3CN. − The dinuclear sodium salts of the composition $Na_2[\{(CO)_5M\}_2EX_2]$ (E = Sn: M = Cr, Mo, W; X = Cl; E = Pb: M = Cr; X = $OOCCH_3$) were prepared by salt metathesis reaction from the corresponding stable phosphonium salts $[Ph_4P]_2[\{(CO)_5M\}_2EX_2]$ as described[4]. The biimidazole[27] and the metallates $Na_2[M_2(CO)_{10}]$ (M = Cr, Mo, W) were prepared as reported[28]. All other chemicals were commercially obtained and used without further purification.

Bis(pentacarbonylchromium)(2,2′-bipyridine)tin, [{(CO)$_5$Cr}$_2$-Sn(bipy)] (**1a**), *and Bis(pentacarbonylchromium)(1,10-phenanthroline)tin, [{(CO)$_5$Cr}$_2$Sn(phen)]* (**1d**): $Na_2[\{(CO)_5Cr\}_2SnCl_2]$ (310 mg; 0.5 mmol) was dissolved in THF (30 ml) and solid 2,2′-bipyridine (78 mg; 0.5 mmol) or solid 1,10-phenanthroline (90 mg; 0.5 mmol), respectively, was added in one portion. The clear orange solution turned deep red immediately. After stirring for 30 min, the solvent was removed in vacuo. The resulting red oil was dissolved in THF (3 ml) and chromatographed on silica gel (20 cm; Ø = 3 cm; diethyl ether). Elution with diethyl ether gave two bands. The first yellow band was identified by IR spectroscopy to be $[Cr(CO)_6]$[29]. The second pink band was also characterized by spectroscopic comparison (IR[30], ^{1}H-, and ^{13}C-NMR spectra) and found to be $[(CO)_4Cr(bipy)]$ or $[(CO)_4Cr(phen)]$, respectively. A third red-brown band which contained the compound **1a** or **1d** was eluted with THF. The resulting solution was taken to dryness leaving **1a** (230 mg; 71%) or **1d** (230 mg; 68%), respectively, as red solids. Single crystals of **1a** and **1d** were obtained within 3 d by applying the method described below.

Bis(pentacarbonylmolybdenum)(2,2′-bipyridine)tin, [{(CO)$_5$Mo}$_2$-Sn(bipy)] (**1b**), *and Bis(pentacarbonylmolybdenum)(1,10-phenanthroline)tin, [{(CO)$_5$Mo}$_2$Sn(phen)]* (**1e**): A yellow solution of $Na_2[\{(CO)_5Mo\}_2SnCl_2]$, obtained by salt metathesis reaction of $[Ph_4P]_2[\{(CO)_5Mo\}_2SnCl_2]$ (1340 mg; 1 mmol) with $Na[BPh_4]$ (684 mg; 2 mmol)[4], was filtered through Kieselgur (3 cm) into a Schlenk tube which already contained solid 2,2′-bipyridine (156 mg; 1 mmol) or solid 1,10-phenanthroline (180 mg; 1 mmol), respectively. The resulting deep red solution was filtered through Kieselgur (3 cm) and taken to dryness. The resulting red oil was redissolved in THF (3 ml) and slowly chromatographed (max. 50 drops/min) on silica gel (20 cm; Ø = 3 cm; diethyl ether). Two bands were obtained by elution with diethyl ether. The first yellow band was identified by IR spectroscopy to be $[Mo(CO)_6]$[29]. The second pink band was also characterized by spectroscopic comparison (IR[30], ^{1}H-, and ^{13}C-NMR spectra) and found to be $[(CO)_4Mo(bipy)]$ or $[(CO)_4Mo(phen)]$, respectively. A third red-brown band, containing the compound **1b** or **1d**, was eluted with THF. From the red-brown solution 310 mg (41%) of **1b** or 290 mg (38%) of **1d**, respectively, were obtained by removing the solvent in vacuo. Applying the method described below gave single crystals of **1b** and **1d** within 3 d.

Bis(pentacarbonyltungsten)(2,2′-bipyridine)tin, [{(CO)$_5$W}$_2$-Sn(bipy)] (**1c**), *and Bis(pentacarbonyltungsten)(1,10-phenanthroline)tin, [{(CO)$_5$W}$_2$Sn(phen)]* (**1f**). − *Method A:* The disodium salt $Na_2[\{(CO)_5W\}_2SnCl_2]$ (442 mg; 0.5 mmol) was dissolved in THF (30 ml). Solid 2,2′-bipyridine (78 mg; 0.5 mmol) or solid 1,10-phenanthroline (90 mg; 0.5 mmol), respectively, was added in one portion. The orange solution turned deep red immediately. After stirring for 30 min, the solvent was evaporated in vacuo. The oily red residue was redissolved in THF (3 ml) and chromatographed on silica gel (20 cm; Ø = 3 cm; diethyl ether). Elution with diethyl ether gave two bands. The first yellow band was found to contain $[W(CO)_6]$, the second pink band contained $[(CO)_4W(bipy)]$ or $[(CO)_4W(phen)]$, respectively. These compounds were characterized by comparison of spectroscopic data[29][30] (IR, ^{1}H-, and ^{13}C-NMR spectra). **1c** or **1f** were eluted with THF as a third red-brown band. The resulting solution was taken to dryness leaving 310 mg (67%) of **1c** or 350 mg (71%) of **1f**, respectively, as red microcrystalline powders.

Method B: To a stirred orange solution of the disodium metallate $Na_2[W_2(CO)_{10}]$ (347 mg; 0.5 mmol) in ethanol (30 ml) was added solid $SnCl_2$ (95 mg; 0.5 mmol) in one portion. The solution turned deep red immediately. After stirring for 30 min, the solution was filtered through Kieselgur (3 cm). By addition of solid 2,2′-bipyridine (78 mg; 0.5 mmol) or solid 1,10-phenanthroline (90 mg; 0.5 mmol), respectively, the corresponding chelate complex precipitated. After additional stirring for 30 min, the red solid was separated from the mother liquor by filtration, washed with ethanol (2 × 5 ml) and diethyl ether (2 × 5 ml), and taken to dryness. Yields: **1c**: 260 mg (57%); **1f**: 270 mg (56%).

Single crystals of **1c** or **1f** were obtained within 3 d by applying the method described below.

Bis(pentacarbonylchromium)bis(pyridine)tin, [{(CO)$_5$Cr}$_2$-Sn(py)$_2$] (**1g**), *and Bis(pentacarbonyltungsten)bis(pyridine)tin, [{(CO)$_5$W}$_2$Sn(py)$_2$]* (**1h**): To a stirred orange solution of $Na_2[\{(CO)_5Cr\}_2SnCl_2]$ (620 mg; 1 mmol) or $Na_2[\{(CO)_5W\}_2SnCl_2]$ (884 mg; 1 mmol), respectively, was added pyridine (316 mg; 4 mmol) in one portion. No colour change of the solution was observed upon the addition. After 30 min of stirring, the solution was

$[Cr(CO)_6]$ or $[W(CO)_6]$, respectively (identified by comparison of IR spectroscopic data[29]). A second yellow band, eluted with diethyl ether, consisted of a mixture of $[Cr(CO)_6]$ and $[(CO)_5Cr(py)]$ or $[W(CO)_6]$ and $[(CO)_5W(py)]$, respectively, as identified by IR spectroscopy[29][30]. With THF a third yellow band was obtained consisting of pure **1g** or **1h**, respectively. Evaporation of the solvent left **1g** and **1h** as yellow oils. Yield: **1g**: 100 mg (15%); **1h**: 140 mg (15%). Single crystals of **1g** and **1h** were obtained within 8 d by applying the method given below.

Bis[bis(12-crown-4)sodium] Tetrakis(pentacarbonylchromium)-(biimidazolato)distannate(0), [Na-(12-crown-4)$_2$]$_2$[{(CO)$_5$Cr}$_2$-Sn(biim)Sn{Cr(CO)$_5$}$_2$] (**2a**): $Na_2[\{(CO)_5Cr\}_2SnCl_2]$ (310 mg; 0.5 mmol) was dissolved in THF (30 ml). Upon addition of solid disodium biimidazolate [45 mg; 0.25 mmol; obtained by heterogenous reaction of biimidazole (34 mg; 0.25 mmol) and NaH (14 mg; 0.6 mmol) in THF without further purification] no colour change was observed. After 30 min, the yellow solution was filtered through Kieselgur (3 cm). 12-Crown-4 (90 mg; 0.5 mmol) was added to the reaction mixture. Evaporation of the solvent in vacuo left 760 mg (80%) of **2a** as a yellow-brown solid. Applying the method described below gave single crystals of **2a** within 14 d.

2a·(12-crown-4)$_2$: ^{1}H NMR ([D$_6$]acetone, 25°C): δ = 7.22 (s, 4 H, imidazolato-H), 3.65 [s, 64 H, CH_2-(12-crown-4)]. − ^{13}C NMR ([D$_6$]acetone, 25°C): δ = 230.0 (CO_{ax}), 222.5 (CO_{eq}), 144.0 (*C*-2, biimidazolate), 127.1 (*C*-4 and *C*-5, biimidazolate), 62.5 (CH_2, 12-crown-4).

Bis(pentacarbonylchromium)(2,2′-bipyrimidine)tin, [{(CO)$_5$-Cr}$_2$Sn(bpmd)] (**2b**), *and Bis(pentacarbonyltungsten)(2,2′-bipyrimidine)tin, [{(CO)$_5$W}$_2$Sn(bpmd)]* (**2c**): $Na_2[\{(CO)_5Cr\}_2SnCl_2]$ (620 mg; 1 mmol) or $Na_2[\{(CO)_5W\}_2SnCl_2]$ (884 mg; 1 mmol), respectively, was dissolved in THF (50 ml). Upon the addition of solid 2,2′-bipyrimidine (79 mg; 0.5 mmol) the orange solution turned deep red immediately. The solvent was evaporated in vacuo after stirring the solution for 30 min. The red oily residue was dissolved in THF (3 ml) and chromatographed on silica gel (20 cm; Ø = 3 cm; diethyl ether). Two bands were obtained by elution with diethyl ether. The first yellow band was identified by comparison of IR spectra[29] and found to be $[Cr(CO)_6]$ or $[W(CO)_6]$, respectively. The second pink band was identified to be $[(CO)_4Cr(bpmd)]$ or $[(CO)_4W(bpmd)]$, respectively, by comparison of their IR spectra with the IR spectra of the corresponding 2,2′-bipyridine complexes (vide supra)[30]. With THF a third red-brown band was eluted which contained **2b** or **2c**, respectively. Evaporation of the solvent left **2b** and **2c** as red solids. Yield: **2b**: 150 mg (45%); **2c**: 170 mg (36%). Single crystals of **2b** and **2c** were obtained within 12 d by applying the method described below.

Bis(pentacarbonylchromium)(2,2′-bipyridine)germanium, [{(CO)$_5$-Cr}$_2$Ge(bipy)] (**3a**), *and Bis(pentacarbonylchromium)(1,10-phenanthroline)germanium, [{(CO)$_5$Cr}$_2$Ge(phen)]* (**3b**): To a stirred, orange solution of $Na_2[Cr_2(CO)_{10}]$ (430 mg; 1 mmol) in THF (50 ml) was added solid GeI_2 (326 mg; 1 mmol) in one portion. After 5 min of stirring, solid 2,2′-bipyridine (156 mg; 1 mmol) or solid 1,10-phenanthroline (180 mg; 1 mmol), respectively, was added and the deep red solution was filtered through Kieselgur (3 cm). After 30 min of stirring, the solvent was evaporated. The solid residue was redissolved in THF (3 ml) and chromatographed on silica gel (20 cm; Ø = 3 cm; diethyl ether). Elution with diethyl ether gave two bands. The first yellow band was identified by IR spectroscopy to be $[Cr(CO)_6]$[29]. The second pink band was found to consist of $[(CO)_4Cr(bipy)]$ or $[(CO)_4Cr(phen)]$, respectively, by comparison of IR[30], ^{1}H-, and ^{13}C-NMR spectra. The compounds **3a** and **3b** were eluted with THF as the third red-brown band. Evaporation of the solvent left the compounds as red microcrystalline powders. Yields:

3a: 150 mg (25%); **3b**: 160 mg (25%). Single crystals of **3a** and **3b** suitable for X-ray structural analyses were obtained within 7 d by the method described below.

Bis(pentacarbonylchromium)(2,2′-bipyridine)lead, [{(CO)$_5$Cr}$_2$Pb(bipy)] (**4**): The disodium salt $Na_2[\{(CO)_5Cr\}_2Pb(OOCCH_3)_2]$ (694 mg; 0.5 mmol) was dissolved in dichloromethane (30 ml) and solid 2,2′-bipyridine (78 mg; 0.5 mmol) was added in one portion. The orange solution turned deep red immediately. After 30 min of stirring, the solution was taken to dryness. The oily red residue was dissolved in THF (3 ml) and chromatographed slowly (max. 50 drops/min) on silica gel (20 cm; Ø = 3 cm) with diethyl ether. The first yellow band was identified by spectroscopic comparison (IR spectra) to be $[Cr(CO)_6]$[29]. A second red band consisted of a mixture of **4** and $[(CO)_4Cr(bipy)]$ (identified by comparison of spectroscopic data[30]). A third red band contained pure **4**. The ethereal solution was taken to dryness leaving **4** as a red microcrystalline powder. Yield: **4**: 170 mg (45%). To grow single crystals of **4** the method described below was applied.

Procedure of Growing Single Crystals of **1**−**4**: A concentrated THF solution (5 ml) of the chelate complex **1**−**4** was shared out between three test tubes (Ø = 1 cm) which were brought into a Schlenk tube (250 ml). Diethyl ether (30 ml), which was in the tube, was allowed to diffuse through the gas-phase into the THF solutions (3 h). After this period of time, the diethyl ether was replaced by petroleum ether (boiling range 40−60°C; 50 ml). Vapor diffusion of the petroleum ether (boiling range 40−60°C) gave single crystals of **1**−**4** suitable for X-ray structure analyses.

X-ray Structure Determinations: The measurements for **1**−**4** were carried out with a Siemens P4 four-circle diffractometer with graphite-monochromated Mo-K_α radiation. The intensities of three check reflections (measured every 100 reflections) remained constant throughout the data collection, thus indicating crystal and electronic stability. All calculations were performed using the SHELXT PLUS software package. The structures were solved by direct methods with the SHELXS-86 program and refined with the SHELX93 program[31]. The program XPMA[32] was used for the graphical handling of the data. Absorption corrections (ψ scan, Δψ = 10°) were applied to the data. The structures were refined in fully or partially anisotropic models by full-matrix least-squares calculations. Hydrogen atoms were introduced at calculated positions. Tables 10−13 compile the data for the structure determinations. Peculiarities about the structures are as follows: **1c**: In this tungsten-containing compound one carbon atom of an equatorial carbonyl group could only be refined isotropically. **1d**: The crystal analyzed contained one THF per molecule **1d** with one of the THF carbon atoms refined isotropically in a disordered position (occupation: 0.6:0.4). **1e**: The crystal used contained one THF per molecule as well; again one of the THF carbon atoms was found in a split position (occupation: 0.7:0.3; anisotropic refinement). **1f**: All atoms of the solvent molecule THF included in the unit cell of **1f** showed some disorder (occupation: 0.6:0.4) and thus were refined only isotropically. **2a**: One of the crown ether molecules showed disorder. **2b**: The equatorial carbonyl groups at one chromium atom had to be refined in split positions (Δα ≈ 25°, with α defined as shown in Figure 7; occupation: 0.52:0.48). **2c**: The crystal analyzed contained 0.4 THF per unit cell with the oxygen atom showing some disorder (occupation: 0.5:0.5). Further details of the crystal-structure investigations may be obtained from the Fachinformationszentrum Karlsruhe, D-76344 Eggenstein-Leopoldshafen (Germany), on quoting the depository numbers CSD-408203 (**1a**), -408201 (**1b**), -408206 (**1c**), -408197 (**1d**), -408204 (**1e**), -408196 (**1f**), -408205 (**1g**), -408207 (**1h**), -408198 (**2a**), -408209 (**2b**), -408199 (**2c**), -408231 (**3a**), -408202 (**3b**), -408200 (**4**).

[21] Despite of the close similarity of the structures of compounds **1** within each series (**1a**–**1c**, **1d**–**1f**, **1g**, and **1h**) the molydenum derivatives **1b** and **1e** differ from their chromium and tungsten analogues in their solubility. In contrast to the latter the molybdenum compounds are soluble in toluene and their solubility in diethyl ether is definitely higher than the one observed for the corresponding chromium and tungsten species which are only sparingly soluble in this solvent. In accord to the known relative substitution lability of $[(CO)_5Mo]$ derivatives relative to their $[(CO)_5Cr]$ and $[(CO)_5W]$ analogues which is assumed to be due to an additional associative pathway operative in the molybdenum case, it may be inferred that the above solvents solubilize the molybdenum compounds **1b** and **1e** by some kind of association (J. P. Collman, L. S. Hegedus, J. R. Norton, R. G. Finke, *Principles and Applications of Organotransition Metal Chemistry*, University Science Books, Mill Valley, California, **1987**, pp. 235–278.).

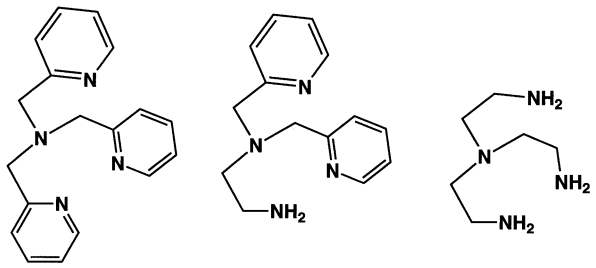
Keywords: Manganese / EPR spectroscopy / Spectroelectrochemistry / Mixed-valent compounds / Tripodal ligands

The synthesis and structural characterization of the novel $[Mn^{III,IV}{}_2O_2(N,N\text{bispicen})_2](ClO_4)_3{\cdot}CH_3CN$ complex employing the tetradentate ligand *N*,*N*bispicen = *N*,*N*-bis(2-pyridylmethyl)-1,2-diaminoethane are reported. Magnetic properties were determined and show that the ground state is a spin doublet. This can be quantitatively interpreted by antiferromagnetic coupling between a Mn(III) high spin and a Mn(IV) ($J = -316\ cm^{-1}$). The 16 line solution EPR spectrum exhibits an unusual splitting in the low field resonances.The following rhombic tensors were needed to simulate the EPR spectrum: $|A_{1x}| = 160\ 10^{-4}\ cm^{-1}$, $|A_{1y}| = 144\ 10^{-4}\ cm^{-1}$, $|A_{1z}| = 109\ 10^{-4}\ cm^{-1}$, $|A_{2x}| = 69\ 10^{-4}\ cm^{-1}$, $|A_{2y}| = 72\ 10^{-4}\ cm^{-1}$, $|A_{2z}| = 75\ 10^{-4}\ cm^{-1}$, $g_x = 2.001$, $g_y = 1.996$, $g_z = 1.984$. The classical ligand field theory of local $[g^{III}]$ and $[g^{IV}]$ tensors implemented with the first order perturbation theory to describe the properties of the pair does not result in a satisfying description of the $[g^{1/2}]$ tensor unless a large reduction in the spin-orbit constant is invoked. A simplified version of second-order perturbation theory leads to effects in qualitative agreement with experiment but weak as expected from the large $|J|$ value. The magnitude of these effects depends, however, on the anisotropy effects on each Mn ion. It is suggested that determination of the anisotropy of the magnetic properties of the monomeric Mn(III) and Mn(IV) moieties would be a valuable goal for a future study of these mixed valent di-manganese-di-μ-oxo complexes. The complex exhibits two quasi-reversible waves in the cyclic voltammogram, one at $E_{1/2} = 0.18$ V vs SCE for the III/IV ↔ III/III couple and the other at $E_{1/2} = 0.98$ V vs SCE for the III/IV ↔ IV/IV couple. The UV-Vis spectra of the three redox states have been recorded spectroelectrochemically.

During the last twenty years, several di-μ-oxo dimanganese complexes have been structurally characterized. There is still a continuing interest in these compounds due to their relevance to the water-oxidizing enzyme in photosystem II[1][2] and their redox catalytic properties, as shown with the mixed-valent complex $[Mn_2O_2(bpy)_4]^{3+}$[3][4][5] and its 1,10-phenantroline analogue.[4] Similar complexes using linear tetradentate ligands like *N*,*N*′-bis(2-pyridylmethyl)-1,2-diaminoethane (bispicen)[6] have been prepared in order to study their redox properties in relation to their structures.[7] We report herein the synthesis and characterization of a new dinuclear mixed-valence di-μ-oxo manganese complex with the tetradentate ligand *N*,*N*-bis(2-pyridylmethyl)-1,2-diaminoethane (*N*,*N*bispicen), an isomer of bispicen which presents a tertiary amino group as well as a primary amino group instead of the two secondary amino groups in bispicen. *N*,*N*bispicen is thus a tripodal ligand similar to tris(2-pyridylmethyl)amine (TPA)[8] and tris(2-aminoethyl)-amine (tren)[9] as shown in Scheme 1.

Scheme 1



The *N*,*N*bispicen ligand has recently been used in the preparation of Fe(II) spin transition systems.[10] Unexpectedly the two primary amino groups of the two *N*,*N*bispicen ligands in the $[Mn_2O_2(N,N\text{bispicen})_2]^{3+}$ cation studied here

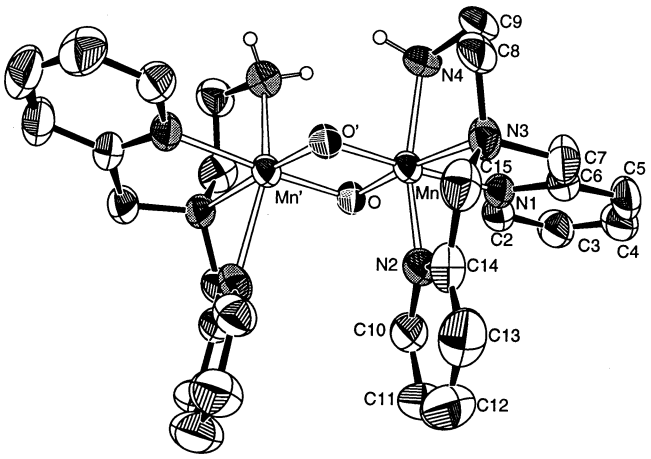
 © WILEY-VCH Verlag GmbH, D-69451 Weinheim, 1998 1434−1948/98/0721−0727 $ 17.50+.50/0

were found in a "*cis*" configuration relatively to the Mn_2O_2 diamond core. This unusual feature gives the potential to assemble two such dimanganese complexes in a dimer of dimers.

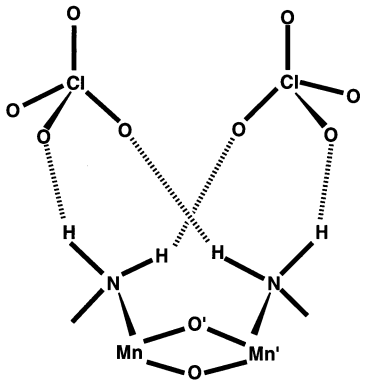
Results and Discussion

Structure: The structure of the $[Mn_2O_2(N,N\text{bispicen})_2]^{3+}$ cation is represented in Figure 1. This cation contains a dimanganese-di-μ-oxo unit which presents no axis of symmetry. The geometry about each manganese center is approximately octahedral, with ligating atoms from the two oxo bridges and the four nitrogen atoms from the *N,N*bispicen ligand. The Mn−Mn distance is 2.646(2) Å, which is comparable to the value found in dimanganese(III,IV)-di-μ-oxo complexes previously reported.[6][8][9][11][12] The two primary amino groups from the two *N,N*bispicen ligands are situated in the same half-space delimited by the Mn_2O_2 plane. This arrangement is probably due to a combination of two different effects. Firstly, a network of hydrogen bonds can be identified involving both NH_2 groups and the two ClO_4^- anions as represented in Scheme 2.

Figure 1. ORTEP diagram of the $[Mn_2O_2(N,N\text{bispicen})_2]^{3+}$ cation with thermal ellipsoids at 50% probability; the atom labels are shown for only one chemically symmetrical part of molecule; the labeling of the Part A and Part B of molecule are similar



Scheme 2



This network can be described as a cycle made of 2 Cl, 2 N, 4 O and 4 H atoms. The four distances O−N are 3.153 Å, 2.964 Å, 2.951 Å and 3.193 Å, all consistent with the presence of H bonds. Secondly a π-π interaction between the two pyridine groups appears to participate in the stabilisation of this structure. The shortest distance is that between the carbon atoms C10 and C10′ which is equal to 3.291 Å. The N2−N2′ distance is 3.412 Å.

The inequivalence between the Mn(IV) (Mn) and Mn(III) (Mn′) ions is easily recognizable from the bond distances (Table 1). The Mn equatorial pyridine distances Mn−N1 and Mn′−N′1 are, respectively 2.036(5) Å and 2.057(5) Å and the Mn-equatorial tertiary amine distances Mn−N3 and Mn′−N′3 are respectively 2.069(5) Å and 2.121(5) Å. These distances are less sensitive to the oxidation state of manganese than the axial ones. The Mn axial pyridine distances Mn−N2 and Mn′−N′2 are respectively equal to 2.015(6) Å and 2.238(6) Å and the axial Mn primary amine distances Mn−N4 and Mn′−N4′ are respectively 2.047(5) and 2.283(6) Å. This is in agreement with a $d_p^3d_{z^2}$ configuration for the Mn(III) ion (with the *z* axis perpendicular to the Mn_2O_2 plane).[12] An antibonding molecular orbital which is half occupied for the Mn(III) ion and empty for the Mn(IV) ion results fom the interaction of the d_{z^2} orbital with the σ orbitals of the axial pyridine N2 atom and the axial primary amino-group N4 atom. In previous studies it has been found that the average axial Mn(III) primary amine distance is 2.276 Å[9] in $[Mn_2O_2(tren)_2]^{3+}$ and the average axial Mn(III) pyridine distance in $[Mn_2O_2(TPA)_2]^{3+}$ is 2.233 Å.[8] These distances are similar to those found here.

Table 1. Selected bond lengths (Å) and angles (deg) for $[Mn^{III,IV}{}_2O_2(N,N\text{bispicen})_2](ClO_4)_3{\cdot}CH_3CN$

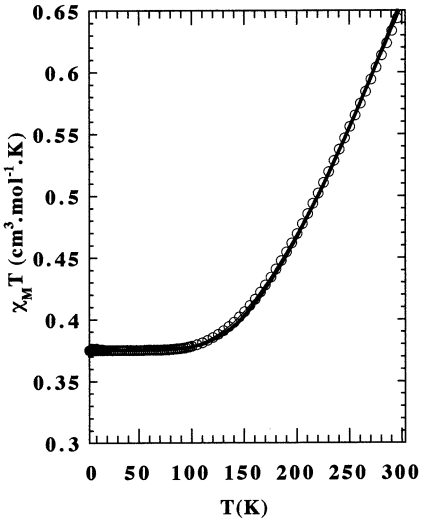
O−Mn′−O′	84.6(2)	Mn−O′−Mn′	93.7(2)

This structure can be compared in more general terms to the numerous examples already reported containing the $[Mn_2O_2]^{3+}$ core.[6][7][8][9][12][13][14] The difference between the average Mn−N(axial ligand) distances around both Mn ions reflects the asymmetry in electron distribution between the two Mn ions.[6] Here the value is 0.230 Å, which is comparable to that found for $[Mn_2O_2(bisimMe_2en)_2]^{3+}$ (0.204

Å).[12] In summary the $[Mn_2O_2(N,N\text{bispicen})_2]^{3+}$ cation is a new example of a complex of this family where the valences are profoundly differentiated.

Magnetic Susceptibility: The molar magnetic susceptibility χ_M of ground crystals of $[Mn_2O_2(N,N\text{bispicen})_2](ClO_4)_3.CH_3CN$ was measured as a function of the temperature *T*. The results are shown in Figure 2 in the form of the $\chi_M T$ versus *T* plot.

Figure 2. Product of the magnetic susceptibility per mole by temperature for $[Mn_2O_2(N,N\text{bispicen})_2](ClO_4)_3.CH_3CN$; the solid line was generated by the best fit parameters given in the text



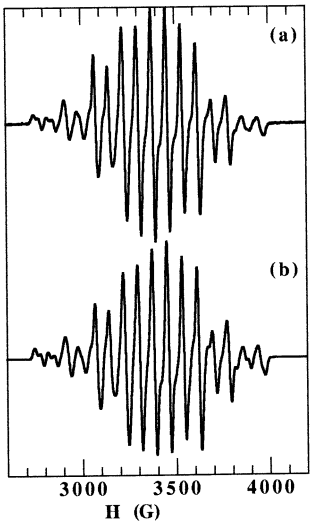
$\chi_M T$ decreases from 0.64 $cm^3mol^{-1}K$ at 292 K to a plateau at 0.38 $cm^3mol^{-1}K$ around 60 K. This is characteristic of an antiferromagnetic coupling between the electronic spins of the Mn(III) and Mn(IV) ions which produces a spin S = 1/2 ground state. This coupling is expressed by the Heisenberg hamiltonian $= -J\,\mathbf{S}_1\cdot\mathbf{S}_2$.The susceptibility was calculated according to:

$$\chi_M T = (N\beta^2 g^2/3k)(\Sigma S(S+1)(2S+1) \exp[J(S(S+1)/2kT)])/\Sigma(2S+1)\exp[J(S(S+1)/2kT)]$$

The best fit was obtained with $g = 2$ (kept constant) and $J = -316$ cm^{-1}. This value is close to that found for $[Mn_2O_2(\text{bispicMe}_2\text{en})_2](ClO_4)_3.H_2O$ ($J = -320$ cm^{-1})[11] and $[Mn_2O_2(bpy)_4](ClO_4)_3.2H_2O$ ($J = -300 \pm 14$ cm^{-1})[15] but clearly smaller than that of the strongest antiferromagnetic couplings, *J* down to -544 cm^{-1}, found in some $[Mn_2O_2L_2]^{3+}$ complexes (L representing a tetradentate ligand of the bispicen family) of ref[7], for which unfortunately no structural data is available.

EPR Spectrum: The EPR spectrum of $[Mn_2O_2(N,N\text{bispicen})_2]^{3+}$ was recorded at 10 K in acetonitrile (Figure 3a). As a first approximation this spectrum can be described as containing 16 lines, as previously observed for related complexes. Actually one may observe on closer inspection that the two lowest field lines are split. To our knowledge this feature is not generally observed in dimanganese (III,IV)-di-μ-oxo units. Another example can be found in the published spectrum of $[Mn_2O_2(TPA)_2]^{3+}$ although this was not commented upon by the authors.[16] It should be noted that the topologies of both complexes are similar. A simulation (not shown) with an axial constraint was first achieved with the following parameters: $|A_{1xy}| = 148\cdot10^{-4}$ cm^{-1}, $|A_{1z}| = 106\cdot10^{-4}$ cm^{-1}, $|A_{2xy}| = 72\cdot10^{-4}$ cm^{-1}, $|A_{2z}| = 72\cdot10^{-4}$ cm^{-1}, $g_{xy} = 1.999$, $g_z = 1.984$. The tensors were taken parallel to each other. The agreement factor *R* was found equal to 0.06. An improved simulation with $R = 0.02$, (Figure 3b) was obtained by letting the tensors become rhombic (but parallel): $|A_{1x}| = 160\cdot10^{-4}$ cm^{-1}, $|A_{1y}| = 144\cdot10^{-4}$ cm^{-1}, $|A_{1z}| = 109\cdot10^{-4}$ cm^{-1}, $|A_{2x}| = 69\cdot10^{-4}$ cm^{-1}, $|A_{2y}| = 72\cdot10^{-4}$ cm^{-1}, $|A_{2z}| = 75\cdot10^{-4}$ cm^{-1}, $g_x = 2.001$, $g_y = 1.996$, $g_z = 1.984$, $g_{iso} = 1.994$ with a line width equal to 11 G. This new set of values reproduced the splitting in the two lowest field lines mentioned above. It can be observed that the $[Mn_2O_2(tren)_2]^{3+}$ does not present this low-field feature although the ligand is also of the tripodal type. However the structure of this dimer is quite different, with the ligand bridging the two metal ions.[9]

Figure 3. X-band cw-EPR spectrum of $[Mn_2O_2(N,N\text{bispicen})_2]^{3+}$ in an 0.1 M NBu_4ClO_4 acetonitrile solution. Spectrometer setting: modulation amplitude, 1.91 G; $T = 10$ K; $\nu = 9.4384$ GHz; (a) experimental spectrum; (b) simulated spectrum



In general the spectra of the Mn(III)Mn(IV) pairs have been simulated using axial *g* and *A* tensors.[9][12][17] A rhombic simulation has been proposed for $[Mn_2O_2(bpy)_4]^{3+}$[18] (1.998, 1.992, 1.982, iso: 1.991). A ^{55}Mn ENDOR study of the same compound has used axial hyperfine tensors.[17] An X and Q band EPR and ^{55}Mn ENDOR study of $[(TACN)MnO_2(CH_3CO_2)Mn(TACN)]^{2+}$[19] has lead to rhombic tensors, in particular $g = 2.000$, 1.998, 1.984, iso: 1.994. The expression for a rhombic *g* tensor for Mn(III) has been given in ref[20]

$$\begin{aligned} g_x &= 2 - 2(\lambda/\Delta)(\cos\delta - \sqrt{3}\sin\delta)^2 \\ g_y &= 2 - 2(\lambda/\Delta)(\cos\delta + \sqrt{3}\sin\delta)^2 \\ g_z &= 2 - 8(\lambda/\Delta)(\cos\delta)^2 \end{aligned} \quad (1)$$

where λ is the spin orbit constant, Δ the energy gap between the "t_{2g}" and the "e_g"-like orbitals and δ a parameter reflecting the composition of the ground state as $|\phi> =$

$\cos\delta\ |d_{xz}d_{yz}d_{xy}d_{z^2}> + \sin\delta\ |d_{xz}d_{yz}d_{xy}d_{x^2-y^2}>$. It is also known that for the ground state of an antiferromagnetically coupled Mn(III)Mn(IV) pair one has

$$[g^{1/2}] = 2[g^{III}] - [g^{IV}] \quad (2)$$

The anisotropy of $[g^{III}]$ ($g_{perpendicular}{}^{III} = 1.990$, $g_{//}{}^{III} = 1.960$ for an elongated Mn(III) complex)[21] is larger than that of $[g^{IV}]$ ($g_{perpendicular}{}^{IV} = 1.991$, $g_{//}{}^{IV} = 1.995$ for Mn(IV) in TiO_2).[22] Initially assuming $[g^{IV}] = g^{IV}$ is isotropic, the three parameters δ, λ/Δ and g^{IV} can then be adjusted to reproduce the g values obtained. One finds $\delta = 8.14°$ ($\cos\delta = 0.9899$, $\sin\delta = 0.1416$), $\lambda/\Delta = 0.0012875$, and $g^{IV} = 1.996$. Consequently the system would be largely described by the $|d_{xz}d_{yz}d_{xy}d_{z^2}>$ wave function on Mn(III). From the type of distorsion observed in the structure it is tempting to consider the EPR z axis parallel to the axis of elongation observed in the structure. Although the g^{IV} and δ values seem reasonable, the λ/Δ ratio is smaller than expected. Indeed using $\lambda = 88\ cm^{-1}$ for the free Mn(III) ion,[20] one gets $\Delta = 68000\ cm^{-1}$ which is too large a value. This straightforward approach is thus not satisfying.

If isotropy for $[g^{IV}]$ is not assumed, the following general expression, deduced from equations 1 and 2, can be used to estimate λ/Δ.

$$g_{iso}{}^{1/2} = 4 - 8(\lambda/\Delta) - g^{IV}{}_{iso} \quad (3)$$

For instance with the value $g^{IV}{}_{iso} = 1.992$ for Mn(IV) in TiO_2[22] and $\lambda = 88\ cm^{-1}$, one finds $\Delta = 50300\ cm^{-1}$ which is still unlikely. The Δ value can be decreased by taking into account a reduction of λ reflecting covalency effects and decreasing $g^{IV}{}_{iso}$.

One may wonder if eq 2 is fully appropriate and if the extra terms due to anisotropy effects discussed by Zheng et al.[18] play a role. These terms are due to the perturbation of the spin doublet ground state by the excited spin levels. These effects have been studied for Fe(II)Fe(III) dimers in ref[23] and[24]. For the spin doublet ground state of an Mn(III)Mn(IV) pair one obtains the following modification of eq 2.

$$[g^{1/2}] = 2[g^{III}] - [g^{IV}] + (2/5)([g^{III}] - [g^{IV}])(7[D^{III}] + 2[D^{IV}])(2/-J) \quad (4)$$

Due to the large value of J, the correction introduced is expected to be small. Preliminary calculations for an elongated Mn(III) system ($\Delta g^{III} = g_{perpendicular}{}^{III} - g_{//}{}^{III} = 6\lambda/\Delta > 0$, $D^{III} < 0$) and assuming an isotropic Mn(IV) ion ($D^{IV} = 0$), show that

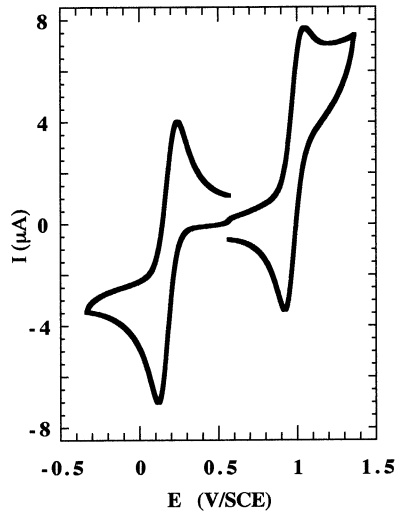
$$g_{iso}{}^{1/2} = 4 - 8(\lambda/\Delta) - g^{IV}{}_{iso} + (2/5)(14D^{III}/3(-J))(-2/3)(6\lambda/\Delta) \quad (5)$$

For $D^{III} < 0$, this indeed decreases the computed value for Δ by an amount proportional to D^{III} (1.6% for $D^{III} = -5\ cm^{-1}$, 3.1% for $D^{III} = -10\ cm^{-1}$). Due to the large J value as said above, this effect is weak unless the anisotropy energies be large. Nevertheless we feel that this problem has to be studied in more details for the following reasons. Little is known about the zero-field splitting energy value for Mn(III) and Mn(IV) ions in these dimers. It could well be that the zero-field splitting energy value for Mn(III) is substantial in these dimers due to a mixing of the $^3T_1$ state into the ^5E ground state of the Mn(III) ion, an effect shown recently by Caneschi et al. in a Mn(III) monomer.[21] Examination of the Tanabe-Sugano diagram for a d^4 ion shows that for a strong ligand field the $^3T_1$ state comes close to the ^5E ground state as one could sensibly predict in the case of dimers with nitrogeneous ligands. The properties of the Mn(IV) moiety also certainly deserve to be studied. In summary we propose that in order to understand in depth the electronic structure of these dimers, a better knowledge of the monomeric moieties has first to be achieved.

As for the A values, the $[A^{III}]$ presents the usual anisotropy with the lowest absolute value along the axis corresponding to the lowest g value (z) and the highest absolute principal value of the $[A^{IV}]$ tensor along the same axis.[19]

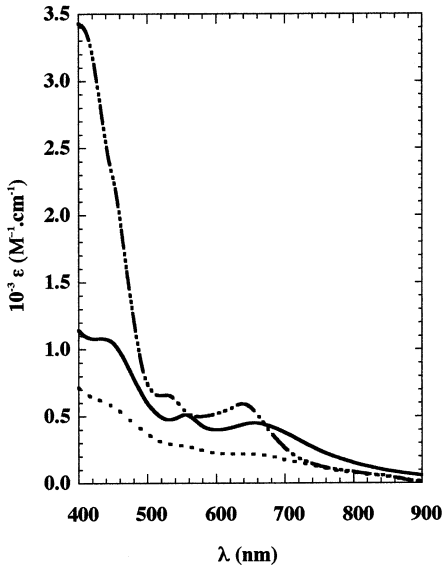
Redox Properties: The cyclic voltamogram of $[Mn_2O_2(N,N\text{bispicen})_2]^{3+}$ obtained in acetonitrile is shown in Figure 4. It shows two quasi-reversible waves, one at 0.18 V and the other at 0.98 V vs SCE. The $E_{1/2}$ value of 0.18 V corresponds to the one-electron couple III/IV $\leftrightarrow$ III/III, while that at 0.98 V represents the couple III/IV $\leftrightarrow$ IV/IV. Those two potentials are very similar to those previously reported for similar complexes with tetradentate ligands.[25]

Figure 4. Cyclic voltammetry of $[Mn_2O_2(N,N\text{bispicen})_2](ClO_4)_3.CH_3CN$ in acetonitrile, with 0.1 M $(TBA)ClO_4$ as supporting electrolyte; potentials are referenced vs SCE



UV-Vis Spectroelectrochemistry: The spectrum of the $[Mn_2O_2(N,N\text{bispicen})_2]^{3+}$ complex as recorded in acetonitrile, is shown in Figure 5. It is comparable to those previously described for analogous dimanganese (III,IV)-di-μ-oxo units, the characteristic parameters of which have been summarized in ref[25]. It consists of a shoulder in the UV region and two bands of medium intensity in the visible region, which can be attributed as follows[26]: the 433 nm ($1080\ M^{-1}cm^{-1}$) band corresponds to a mixed contribution of Mn(IV) oxo LMCT and Mn(IV) d-d transitions, that at

Figure 5. Visible spectroelectrochemistry of the mixed-valent complex $[Mn_2O_2(N,N\text{bispicen})_2](ClO_4)_3\cdot CH_3CN$ in acetonitrile: (___) no potential applied; (–···–) oxidation at +1.14 V/SCE; (···) reduction at −0.13 V/SCE



555 nm (511 $M^{-1}cm^{-1}$) to a Mn(IV) d-d transition and that at 654 nm (450 $M^{-1}cm^{-1}$) to Mn(IV) oxo LMCT.

After oxidation at +1.14 V/SCE, the spectrum of the Mn(IV)Mn(IV) form was obtained. The intensity of the absorption at 433 nm increases dramatically. This can be understood on the basis of the oxidation of the Mn(III) ion to Mn(IV). Apparently the Mn(IV) d-d band has shifted from 555 to 528 nm and its intensity has increased to 657 $M^{-1}cm^{-1}$. The band at 654 nm shifts to higher energy (637 nm) and also increases in intensity (592 $M^{-1}cm^{-1}$). This is in agreement with the attribution of such a band to an oxo Mn(IV) LMCT. After electrolysis at −0.13 V/SCE, a large decrease in the intensity of the spectrum is observed. Features at 661 (213 $M^{-1}cm^{-1}$), 556 (274 $M^{-1}cm^{-1}$) and 443 nm (595 $M^{-1}cm^{-1}$) are detected. At this potential, the Mn(III)Mn(III) form is obtained. The modifications described above are reversible by varying the potential applied appropriately. The observations reported above are very similar to those made by Brewer et al.[27] on $[Mn_2O_2(14\text{-}aneN_4)_2]^{3+}$ where 14-aneN$_4$ stands for 1,4,8,11-tetraazacyclotetradecane.

Conclusion

We have characterized a new di-μ-oxo bridged mixed valence manganese complex employing the tetradentate ligand *N,N*bispicen. The structure of the Mn(III)Mn(IV) complex has been resolved. Unexpectedly, the two primary amino groups from the two *N,N*bispicen ligands of the complex are situated on the same side of the space delimited by the Mn_2O_2 plane. Electronic, magnetic and redox properties have been reported. The EPR spectrum presents splitting of the resonances at low field which are most probably due to the rhombicity in the $[A^{III}]$ tensor. We remarked that the usual theory of the [*g*] tensor is not satisfactory unless λ is much reduced. We propose that second-order perturbation by excited spin levels on the spin doublet ground state, of the type described by Sage et al. for Fe(II)Fe(III) complexes and by Zheng et al. for Mn(III)Mn(IV), could lead to a better description if the zero-field splitting energy in those systems is important. Measurement of this energy by magnetization study and high-field EPR will be undertaken in a near future on the monomeric moieties corresponding to these dimers. The opportunity to use the two amino groups from the two *N,N*bispicen ligands in order to link two dinuclear complexes to form a tetranuclear complex will be explored.

This work has been supported in part by the *European Training and Mobility of Researchers* "Ru-Mn Artificial Photosynthesis" program (contract EU HMC network ERBXCT 94 0524).

Experimental Section

Compound Preparation: All chemical reagents were supplied by Aldrich and used without further purification. The ligand *N,N*-bis(2-pyridylmethyl)-1,2-diaminoethane (abbreviation: *N,N*bispicen) was prepared by following the procedure in ref[28]. This ligand has also recently been described in ref[10].

Caution: *Perchlorate salts of compounds containing organic ligands are potentially explosive. Only small quantities of those compounds should be prepared and handled behind suitable protective shields.*

$[Mn^{III,IV}{}_2O_2(N,N\text{bispicen})_2](ClO_4)_3\cdot CH_3CN$: 190 mg of *N,N*bispicen (0.785 mmol) were dissolved in 4 ml of absolute ethanol. To this solution 210.5 mg of $Mn(O_2CCH_3)_3.2H_2O$ (0.785 mmol) were added. After stirring for 1/2 hour, the resulting brown solution was filtered, and to the filtrate was added an absolute ethanol solution (4 ml) of $NaClO_4\cdot H_2O$ (220.5 mg, 1.57 mmol). A brown microcrystalline solid started to precipitate immediately. The solid was collected by filtration, washed thoroughly with absolute ethanol and dried under vacuum. The elemental analysis corresponds to a Mn(III)Mn(III) dimer $[Mn_2O_2(N,N\text{bispicen})_2](ClO_4)_2\cdot 1.3H_2O\cdot 1.3C_2H_5OH$. This powder was EPR silent. − $C_{30.6}H_{46.4}Cl_2Mn_2N_8O_{12.6}$: calcd C 40.43, H 5.11, Cl 7.82, Mn 12.11, N 12.33; found C 40.48, H 5.00, Cl 7.84, Mn 12.11, N 12.01. Dark single crystals characterized as $[Mn^{III,IV}{}_2O_2(N,N\text{bispicen})_2](ClO_4)_3\cdot CH_3CN$ were grown by slow diffusion of a mixture of CH_2Cl_2-$CHCl_3$ (1:1) into a concentrated solution of the powder in CH_3CN under air. − $C_{30}H_{39}Cl_3Mn_2N_9O_{14}$: calcd C 37.30, H 4.07, Cl 11.01, Mn 11.39, N 13.05; found C 37.47, H 3.94, Cl 10.95, Mn 11.38, N 13.0. − IR: $\tilde{\nu}$ = 3429 (br) cm^{-1}, 1607 (s), 1571 (w), 1480 (m), 1466(m), 1444(m), 1292 (m), 1144 (w), 1091 (vs), 766 (m), 697 (m), 660 (m), 625 (s). Symbols: br broad; vs very strong; s strong; m medium; w weak; sh shoulder. The single crystals of $[Mn^{III,IV}{}_2O_2(N,N\text{bispicen})_2](ClO_4)_3\cdot CH_3CN$ were used for all subsequent physical measurements.

Electrochemical Measurements: Cyclic voltammetry was measured using a EGG PAR potentiostat (M 273 model). The working electrode was a Pt disk of 3 mm diameter, carefully polished with diamond pastes and ultrasonically rinsed in ethanol before use. A Pt wire was used as counter electrode and as reference, a Ag/$AgClO_4$ electrode, prepared in acetonitrile and separated by a fritted disk from the main solution (270 mV above the potential of the saturated calomel electrode). The experiment was carried out on a carefully degassed solution by argon flushing.

Magnetic Susceptibility Measurements: Magnetic susceptibility measurements in the 4.2−300 K temperature range were carried

out with a MPMS5 SQUID magnetometer (Qantum Design Inc.). The calibration was made at 298K using palladium reference sample furnished by Quantum Design Inc. Ground crystals of $[Mn^{III,IV}_2O_2(N,N\text{bispicen})_2](ClO_4)_3.CH_3CN$ were used.

Crystallographic Data Collection and Refinement of the Structure of $[Mn^{III,IV}_2O_2(N,N\text{bispicen})_2](ClO_4)_3\cdot CH_3CN$: The crystal data of $[Mn^{III,IV}_2O_2(N,N\text{bispicen})_2](ClO_4)_3\cdot CH_3CN$ and the parameters of data collection are summarized in Table 2. A prismatic black crystal with the dimensions 0.9 × 0.25 × 0.15 mm was mounted in a glass capillary with 0.5 mm diameter. The unit-cell and intensity data were measured with an Enraf-Nonius CAD-4 diffractometer with graphite monochromated Mo-K_α radiation (λ = 0.71073 Å). The cell constants were obtained by least-squares procedures based upon the 2Θ values of 25 reflections measured in the ranges $20.8° < 2\Theta < 21.6°$ at ambient temperature. All reflection intensities were collected in the range $4° < 2\Theta < 50°$ within [$-19 \le h \le 19$, $-13 \le k \le 13$, $0 \le l \le 29$]. The total number of the collected and independent reflections are 16114 and 7870. Due to the peculiar form of the single crystal an empirical absorption correction was carried out. The structure was solved by direct methods with the program SHELXS86[29] and refined by using the SHELXL93[30] programs. The figure was prepared with ORTEP II.[31] The molecular cation was located in a general crystallographic position as well as three perchlorate anions and the molecule of acetonitrile. Observed disorder in the stucture involved the anions; all were disordered over two sites with non-identical occupations (0.60 and 0.40). The stucture was refined by full-matrix least-squares approximation based on F^2. Refinement was anisotropic for non-H atoms. Hydrogen positions were calculated by assuming geometrical positions and were included in the structural model (In addition, a cluster of electron density with seven different peak positions was found and these were not identified). Final refinement of this model was continued until convergence when $R1$ = 0.066 for $F^2 > 2\sigma(F^2)$ and R_w = 0.242. The final difference map showed two largest residual peaks of 0.68 and −0.66 eÅ^{-3}. Crystallographic data (excluding structure factors) for the structure reported in this paper have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication no. CCDC-100897. Copies of the data can be obtained free of charge on application to The Director, CCDC, 12 Union Road, Cambridge CB2 1EZ, UK [Fax: (int. Code) +44(1223)336-033, E-mail: deposit@chemcrys.cam.ac.uk, World Wide Web: http://www.ccdc.cam.ac.uk].

EPR Spectroscopy: EPR spectrum was recorded on Bruker ER 200 D spectrometer at X-band. For low temperature studies, an Oxford Instruments continuous flow liquid helium cryostat and a temperature control system were used. In order to get a good quality glass a 0.1 M solution of NBu_4ClO_4 in acetonitrile was used as solvent.

EPR Simulation: Simulation of the EPR spectrum was performed using a FORTRAN program originally developed by Drs L. K. White and R. L. Belford at University of Illinois. The program simulates powder spectra for S = 1/2 systems and can include four different hyperfine interactions using perturbation theory. It was modified to allow for calculation of the hyperfine contributions to the spectra to the second order.[32] Briefly, for each transition, the resonant field was calculated using perturbation theory up to the second order for the hyperfine coupling terms and the resulting stick spectrum was then convolved with Gaussian functions. This simulation program is coupled to a minimization program in order to find the set of parameters giving the lowest possible value of the agreement factor defined as $R = \Sigma_i(Y_i^{calc} - Y_i^{exp})^2/\Sigma_i Y_i^{exp\ 2}$.

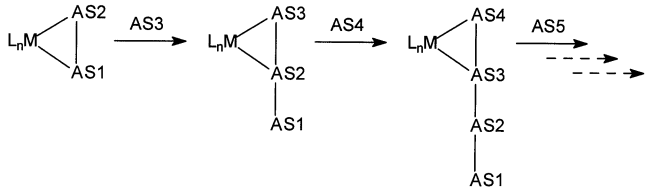
Keywords: Catalysis / Oligomerization / Organometallics / Oligopeptides / Ruthenium complexes

Consecutive addition of one-equivalent portions of glycine ethyl ester to [(*p*-cymene)Ru(GGGOMe−H^+)Cl] leads to considerable amounts of (tetra- to nonapeptide)ruthenium complexes in a one-pot reaction, in which the (*p*-cymene)RuCl fragment acts as a catalyst. The analogous reaction with alanine methyl ester affords AGGG and AAGGG complexes as the main products. The course of these metal-catalyzed peptide oligomerizations has been followed by mass spectrometry. The synthesis and characterization of the pentapeptide complex [(C_6Me_6)Ru(GGGGGOMe−H^+)] is reported.

Introduction

There have been several reports on the formation of peptides from α-amino acid esters[2] or α-amino acids[3] in the presence of metal ions or metal complexes. Recently, our group reported a metal-promoted peptide synthesis in which non-activated α-amino acid esters are assembled in the coordination spheres of half-sandwich complexes of ruthenium, rhodium, and iridium.[4] This method permits the elongation of a coordinated peptide ester at its *N*-terminus with a defined amino acid sequence. In previous studies[4] we focused on stoichiometric reactions between peptide complexes and amino acid esters. However, according to the proposed mechanism, it should be possible to produce polypeptides using only catalytic amounts of these organometallic complexes (Scheme 1).

Scheme 1



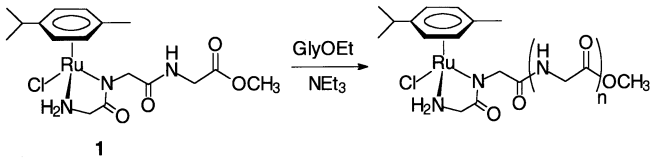
Therefore, we became interested in ascertaining whether longer peptide chains could be obtained by repetitive additions of α-amino acid esters to half-sandwich (peptide)metal complexes. In this paper, we report on the formation of tetra- to nonapeptides by means of a one-pot reaction of [(*p*-cymene)Ru(GGGOMe−H^+)Cl] (**1**) with glycine or alanine esters according to Scheme 1.

[◇] Part 104: Ref.[1].

Results and Discussion

Repetitive additions (every 24 h) of one equivalent of glycine ethyl ester (GlyOEt) to [(*p*-cymene)Ru(GGGOMe−H^+)Cl] (**1**) in the presence of triethylamine gave ruthenium complexes with increased chain length of the peptide (Scheme 2). The reaction resembles living polymerization processes.[5] A large excess of α-amino acid ester was avoided in order to reduce autocondensation reactions.

Scheme 2



1

The course of the metal-catalyzed peptide oligomerization was followed by FAB mass spectrometry. This analytical tool allows the simultaneous determination of the various intact (peptide)Ru^{II} complexes that are present in the reaction mixture.[6] The relative amount of each peptide complex was estimated by comparing the appropriate peak heights. Table 1 and Figure 1A show how the distribution of the higher peptides changes as the complex is "fed" with successive one-equivalent portions of glycine ester. Significant amounts of hepta- to nonapeptides are obtained after the addition of 8 equivalents of GlyOEt. The time course of product formation reflects the statistical growth of the peptide chain. The limiting factor of this reaction was the increased viscosity of the solution after the addition of several portions of the amino acid. It should be emphasized, however, that the presence of the lipophilic (*p*-cymene)Ru^{II} fragment strongly increases the solubility of the otherwise

notoriously insoluble polyglycine peptides in organic solvents.

Figure 1. Catalytic formation of polypeptide complexes by consecutive addition (every 24 h) of glycine ethyl ester (A) or alanine methyl ester (B)

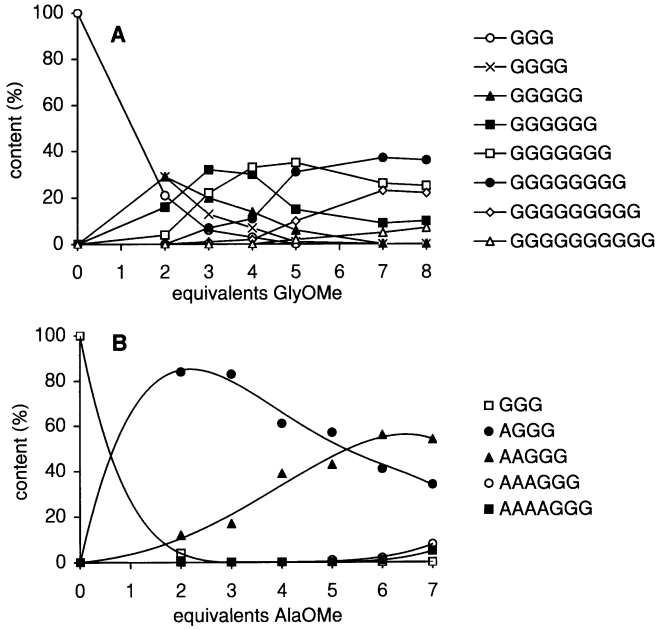

Table 1. Formation of (oligoglycine)ruthenium complexes following successive additions of one-equivalent portions of glycine ethyl ester

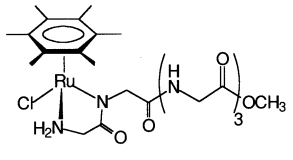
Peptide	Start	Portion no. 2	3	4	5	7	8
triglycine	100	21	6	3	0	0	0
tetraglycine	0	29	13	7	1	0	0
pentaglycine	0	29	20	14	6	0	0
hexaglycine	0	17	32	30	15	9	10
heptaglycine	0	4	22	33	35	26	25
octaglycine	0	0	7	11	31	37	26
nonaglycine	0	0	1	2	10	23	22
decaglycine	0	0	0	0	2	5	7

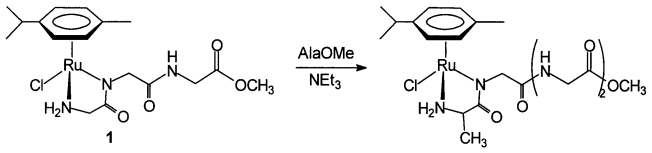
For comparison, a (pentaglycine methyl ester)ruthenium complex **2** was prepared directly from $[(C_6Me_6)RuCl_2]_2$ and GGGGGOMe. *N*,*N*-coordination in **2** is proven by the IR absorptions at 1660 and 1579 cm^{-1}.[4]



2

While with glycine ethyl ester and **1** the relative amount of any single product does not exceed 40% because of similar reactivities of all the products, with alanine methyl ester (AlaOMe) and **1** a different situation is encountered. Scheme 3 illustrates the reaction of **1** with one equivalent of AlaOMe. The larger steric bulk of this amino acid seems to prevent it from undergoing successive condensation reactions. Therefore, a substantial build-up of the AGGG complex (up to 84%) and the AAGGG complex (up to 56%) is observed (Figure 1B). Only minor amounts of peptide complexes with more than two alanine residues are produced, even after the addition of 7 equivalents of AlaOMe.

Scheme 3



The experiments described herein demonstrate that (*p*-cymene)Ru^{II} complexes are able to catalyze the formation of oligopeptides from simple amino acid esters. We are currently investigating whether this strategy can be applied to generate oligopeptides with a different amino acid content and/or a longer chain length. In certain cases, this new synthetic approach might be an interesting alternative to conventional methods of peptide synthesis.

Experimental Section

Reactions were carried out in Schlenk tubes under N_2 or Ar. Methanol (puriss., < 0.05% H_2O) was saturated with N_2 and stored over molecular sieves (3 Å). $[(p\text{-cymene})RuCl_2]_2$ and $[(C_6Me_6)RuCl_2]_2$ were prepared according to literature procedures.[7] The free amino acid esters were prepared from the hydrochlorides by treatment with NEt_3 in dichloromethane. NEt_3·HCl precipitated upon addition of pentane. − IR: Perkin-Elmer 841, Nicolet 520; PE = polyethylene. − NMR: JEOL EX 400. − MS: Finnigan MAT 90 mass spectrometer.

[(p-Cymene)Ru(GGGOMe−H⁺)Cl] (**1**): A solution of 288 mg (1.2 mmol) of GGGOMe·HCl and 1.2 mmol of NaOMe in 10 ml of methanol was added to a suspension of 367 mg (0.6 mmol) of $[(p\text{-cymene})RuCl_2]_2$ in 20 ml of methanol. After stirring for 2 h, the mixture was concentrated in vacuo to a volume of 2 ml. NaCl precipitated upon the addition of 10 ml of dichloromethane and 3 ml of pentane and was separated by centrifugation. The solvent was then removed in vacuo. After the addition of pentane, an oily red compound was obtained. The product was purified by recrystallization from methanol/diethyl ether. Yellow powder. Yield 543 mg (94%). − M.p. 203−206°C (decomposition). − IR (KBr): $\tilde{\nu}$ = 3333 cm^{-1} (m), 3275 (m, sh), 3128 (m, NH), 1748 (s, C=O, ester), 1665 (s, amide I, uncoord.), 1583 (vs, amide I, coord.), 1535 (m, amide II). − IR (PE): $\tilde{\nu}$ = 286 cm^{-1} (w), 253 (m, RuCl). − ^{1}H NMR (400 MHz, $CDCl_3/CD_3OD$): δ = 1.27 [d, ^3J = 7 Hz, 6 H, $CH(CH_3)_2$], 2.21 (s, 3 H, $ArCH_3$), 2.83 [sept, ^3J = 7 Hz, 1 H, $CH(CH_3)_2$], 3.15 (m, 2 H, NH_2CH_2), 3.76 (s, 3 H, OCH_3), 3.94 (m, 2 H, CH_2CO_2), 4.11 (d, ^2J = 17 Hz, 1 H, NCH_2CO), 4.78 (d, ^2J = 16 Hz, 1 H, NCH_2CO), 5.36−5.58 (m, 4 H, C_6H_4). − ^{13}C NMR (68 MHz, $CDCl_3/CD_3OD$): δ = 18.63 ($ArCH_3$), 22.00, 23.10 [$CH(CH_3)_2$], 31.13 [$CH(CH_3)_2$], 40.94 (CH_2CO_2), 46.76 (NH_2CH_2), 52.54 (OCH_3), 54.74 (NCH_2CONH), 80.83, 81.95, 82.10, 82.47, 96.46, 101.76 (C_6H_4), 170.71 (CO_2Me), 174.45, 180.36 (CON). − $C_{17}H_{26}ClN_3O_4Ru \cdot 1/2\ H_2O$ (481.9): calcd. C 42.37, H 5.65, N 8.72; found C 42.56, H 5.87, N 8.55.

[(C$_6$Me$_6$)Ru(GGGGGOMe−H$^+$)Cl] (**2**): 311 µl (0.19 mmol) of NaOMe/MeOH (1.19 M) was added dropwise to a suspension of 65 mg (0.19 mmol) of GGGGGOMe·HCl and 62 mg (0.09 mmol) of $[(C_6Me_6)RuCl_2]_2$ in 15 ml of methanol. After 1 h, a small amount of a precipitate was separated by centrifugation and the solvent was removed in vacuo. The residue was treated with 5 ml of dichloromethane, 1 ml of methanol, and 2.5 ml of pentane and NaCl was removed by centrifugation. The product precipitated upon addition of 30 ml of pentane and was purified by recrystallization from methanol/dichloromethane (2:1)/diethyl ether. Orange crystals. Yield 40 mg (35%). − M.p. 198°C (decomposition). − IR (KBr): $\tilde{\nu}$ = 3289 cm^{-1} (s, NH), 3243 (sh, NH), 1758 (m, C=O, ester), 1743 (m, C=O, ester), 1691 (sh, amide I, uncoord.), 1660 (vs, amide I, uncoord.), 1579 (vs, amide I, coord.). − ^{1}H NMR (400 MHz, CD_3OD): δ = 2.13 (s, 18 H, $ArCH_3$), 3.14 (s, 2 H, NH_2CH_2), 3.31 (CH_2 together with CD_2HOD), 3.37 (s, 2 H, CH_2), 3.73 (s, 3 H, OCH_3), 3.89 (br. s, 2 H, CH_2), 3.95 (s, 2 H, CH_2). − $C_{23}H_{36}ClN_5O_6Ru\cdot H_2O$ (633.1): calcd. C 43.63, H 6.05, N 11.06; found C 44.01, H 6.24, N 11.02.

Peptide Synthesis: 213 mg (0.45 mmol) of $[(p\text{-cymene})RuCl_2]_2$ was dissolved in 20 ml of methanol and 347 µl (2.5 mmol) of NEt_3 was added as co-catalyst. Once per day one portion of 57 µl (0.55 mmol) of GlyOEt was added to the solution. Just before adding the third portion, a sample of 1.9 ml (first data point) was removed from the reaction vessel. Peptide complexes were isolated after precipitation with 30 ml of diethyl ether and were analyzed by mass spectrometry. The reaction volume was kept constant by adding 2 ml of methanol. Subsequent data points were obtained similarly. As the amount of complex in the solution decreased, the amount of GlyOEt added was decreased accordingly. After addition of the seventh portion, the viscosity increased and magnetic stirring became problematic. The solution showed thixotropic properties. − Peptide synthesis with AlaOMe was performed analogously using 152 mg (0.32 mmol) of $[(p\text{-cymene})RuCl_2]_2$ and 250 µl of NEt_3 dissolved in 20 ml of methanol.

MS Analysis: FAB-MS measurements were performed using *m*-NBA as the matrix. For each peptide complex present, three to four well-separated peak groups can be identified, corresponding to [M − Cl$^-$], [M − Cl$^-$ + H$^+$ + Na$^+$], [M + H$^+$], and [M + Na$^+$]. Ionization occurs without decomposition of the complex. Semi-quantitative analyses were performed by comparing the sums of the relevant peak heights.

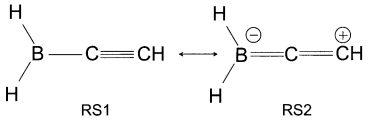
A theoretical analysis was performed to quantify the π-electron-accepting ability of the boron atom in ethynylboranes. An expansion technique was employed which permits to obtain a set of localized bonding schemes and their weights from a delocalized molecular orbital determinantal wavefunction. The derived manifold of bonding schemes is close to the classical resonance hybrid used in organic chemistry (valence-bond description). We quantified the π-electron transfer into the empty π-orbital of the boron atom by investigating nine model compounds where substituents with π-electron-donating ability are adjacent to a boron atom. This led to an ordering of the substituents according to their electron-donating ability towards boron. The boron atom hesitates to accept π-electrons from the ethynyl group in ethynylboranes in particular when good π-donors like amino groups are present. The π-electron donation from the vinyl group to the adjacent boron centre is slightly stronger than from the ethynyl group. Nitrogen lone-pair electrons are easily transferred to a neighbouring boron centre. Bonding schemes and their weights are in line with computed bond lengths and rotational barriers. Moreover, our theoretical results rationalize previous NMR and X-ray experiments and are in line with the reactivity of related compounds. It is demonstrated that bond lengths alone do not necessarily correlate with the degree of π-bonding and should be discussed with caution. The analysis is substantiated by showing that weights for covalent bonding schemes, as obtained from the simple restricted closed-shell MO determinant, correlate with bond strengths. Furthermore, a correlation of bonding-scheme weights with quantities based on the fragment orbital approach is presented. This novel correlation elucidates molecular properties which determine the extent of the π-electron transfer to the boron atom and permits a quantitative interpretation and prediction of intramolecular π-bonding.

Introduction

Ethynylboranes are characterized by a carbon−carbon triple bond directly attached to a Lewis acid boron atom[1]. Its electron-accepting ability may lead to an electron transfer from the adjacent alkynyl π-electron system into the empty π-orbital of the boron atom. This is illustrated in Scheme 1 for the parent compound ethynylborane **1a**.

Scheme 1. Two resonance structures symbolizing the electron-accepting ability of the boron atom



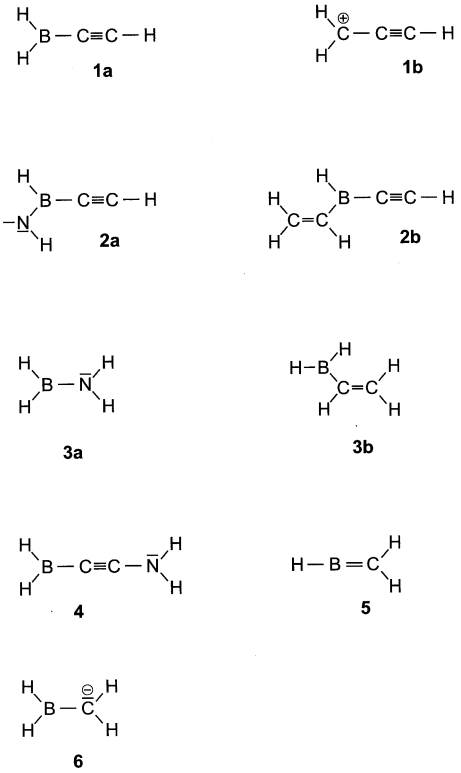
The π-electron structure of ethynylborane is described by the two resonance structures RS1 and RS2 which symbolize an alkynylborane and a heteroallene, respectively. In the heteroallene resonance structure RS2 one of the two π-electrons delocalized above and below the molecular plane is transferred to the boron atom. This transfer leads to a partial double bond between the boron atom and the alkynyl group accompanied by a formal negative and a positive charge at the boron and the terminal carbon atom, respectively (see Scheme 1). The relative weights of RS1 and RS2 in the resonance hybrid for those compounds have been debated for some time. X-ray crystallographic results[2] do not show a significant lengthening of the carbon−carbon triple bond or a shortening of the boron−carbon bond. In analogy to phenyl- and vinylboranes, NMR data for ethynylboranes have been interpreted in the light of a substantial B=C double bond character[3]. Calculated bond lengths and rotational barriers[2h][2i] of several alkynylboranes support a rather weak B=C double bond. Thus, the various findings appear partially contradictory. Moreover, they permit only indirect conclusions about the electronic structure of ethynylboranes and have not been quantified in a concise manner up to now.

Ab initio quantum chemistry provides a more direct access to the electronic structure of ethynylboranes. The predominantly applied computational methods are based on the molecular orbital method[4]. There, spin-coupled electron pairs are located in molecular orbitals delocalized over the whole molecule. Scheme 1, however, represents a set of valence-bond resonance structures which describe spin-coupled electron pairs strictly localized in bonds. Thus, a valence-bond calculation for ethynylboranes would be the ap-

 © WILEY-VCH Verlag GmbH, D-69451 Weinheim, 1998 1434−1948/98/0606−0733 $ 17.50+.50/0

propriate method for computing the weights of RS1 and RS2 contained in the valence-bond wave function. They would indicate the importance of RS1 and RS2 for the electronic structure of ethynylboranes. An alternative way is to compute a molecular orbital wave function and to analyze this wave function a posteriori in terms of resonance structures and their weights[5]. Recently, a concise method was proposed for expanding a determinantal wave function composed of delocalized molecular orbitals into a set of determinantal wave functions consisting of localized atomic orbitals[6]. The procedure permits to obtain from a delocalized molecular orbital wave function weights for localized bonding schemes which are close to the resonance structures of organic chemistry. Thus, the method is suited to discuss the frequent problem about the weight of a particular resonance structure in a resonance hybrid. In the following sections we use this technique to investigate the π-electron-accepting ability of the boron atom in ethynylboranes. We do this by obtaining weights for localized bonding schemes for a characteristic set of molecules. Our set of model compounds is represented in Scheme 2.

Scheme 2. The set of model compounds selected for quantifying the π-electron donation into the empty π-AO of boron



Ethynylborane (**1a**) is the parent compound of alkynylboranes and the main objective of our investigation. The BH_2 group is isoelectronic with the methylene cation CH_2^+. The differences in their π-electron-accepting properties are illustrated by compairing **1a** and the ethynylmethylene cation (**1b**). In **1a** and **1b**, only the ethynyl groups donate π-electrons to the BH_2 and the CH_2^+ group, respectively. However, the π-electron-donating properties of amino and vinyl groups are also well established[3b][7]. In **2a** and **2b** competitive π-electron donation may occur and we investigate the competitive electron-donating abilities of the amino, vinyl and ethynyl groups, for which aminoborane (**3a**) and vinylborane (**3b**) serve as reference compounds. Our set of model compounds comprised also 2-aminoethynylborane (**4**) where the electron attraction of the BH_2 group and the electron donation of the NH_2 group are mediated by the ethynyl group. This should lead to a push-pull π-electron transfer in **4**. In methyleneborane (**5**) the sp-hybridized boron atom itself provides a π-electron and a full carbon−boron double bond exists. In the methylborane carbanion (**6**) only a partial B=C double bond is formed which stabilizes the carbanion by delocalizing the negative charge. Compounds **5** and **6** were included in this study to put the amount of B=C double bonding (as expected from resonance structure RS2) in perspective.

Computational Methods

Applied Programs and the Expansion Technique

Quantum chemical calculations were performed by using the Gaussian 92/DFT suite of ab initio programs operating under OpenVMS[8]. The restricted Hartree-Fock (RHF) method[9] and the 6−311G** basis sets[10] were applied to optimize the geometries of the molecules.

We used the recently proposed technique[6] to expand a molecular orbital (MO) determinantal wave funtion Ψ^{mo} into N_D determinantal wave functions Ψ_i^{ao} composed of atomic orbitals (AOs).

$$\Psi^{mo} = \sum_{i=1}^{N_D} c_i \Psi_i^{ao} \qquad (1)$$

The expansion coefficients c_i in (1) are determinants of matrices which contain definite selections of the canonical MO coefficients. The weight w_i of a definite Ψ_i^{ao} in the expansion (1) was computed by means of

$$w_i = \frac{c_i^2}{\sum_{j=1}^{N_D} c_j^2} \qquad (2)$$

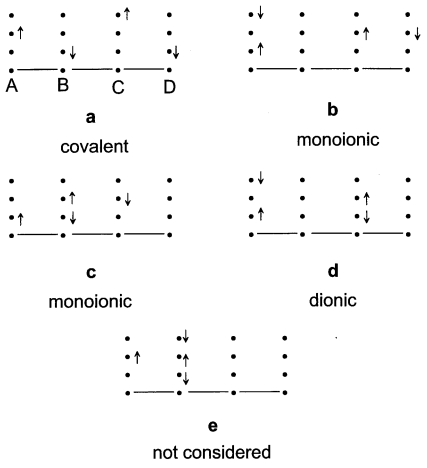
Equation 1 leads to an expansion of the delocalized wave function Ψ^{mo} into wave functions Ψ_i^{ao} which are strictly localized. Any Ψ_i^{ao} represents a definite occupation pattern of the localized atomic spin orbitals. Hence, we analyze the delocalized MO wave function in terms of local spin occupations and their weights[6]. Furthermore, local bonding schemes are obtained by drawing lines between electrons of opposite spin-localized at adjacent atoms of the molecule. These bonding schemes are close to the resonance structures drawn by organic chemists[6]. We are mainly interested in the π-electron distribution. Therefore, MO determinants Ψ^{mo} composed of π-MOs were expanded.

The Expansion Technique and Extended AO Basis Sets

We employed the extended basis set 6−311G[11] to expand Ψ^{mo} into the Ψ_i^{ao}s. We note, that eq. 1 holds also when extended basis sets are employed[6]. Thus, the Ψ_i^{ao}s contain the various groups of contracted gaussian functions which represent the π-AOs. Use of the 6−311G basis set requires a recipe for computing the total weights of the various local spin occupations.

Consider a planar molecule with four π-electrons distributed over four adjacent π-AOs. Each of them is represented by three groups of primitive gaussians. Consequently, various types of spin occupations can occur in the Ψ_i^{ao}s[12] (Scheme 3).

Scheme 3. Several types of local spin occupations occuring when the 6−311G basis is applied in the expansion technique; the occupation schemes are used to obtain local atomic spin occupations



The covalent spin occupation of type (a) describes a complete spin alternation. We obtain the total weight of the local covalent spin occupation by adding up all weights of those 81 Ψ_i^{ao}s which describe the general spin-occupation pattern given by (a). The total weight for a local monoionic spin occupation is obtained by sampling the weights for Ψ_i^{ao}s with occupation patterns of type (b). A similar sampling is performed to compute the total weight for further monoionic and diionic spin occupations resulting from cases (c) and (d), respectively. However, eq. 1 produces also Ψ_i^{ao}s for energetically unfavourable spin occupations of type (e) which allocate three electrons at one atom. Those spin occupations have very small weights and are neglected in our weight sampling.

Relating Weights and Bond Strengths

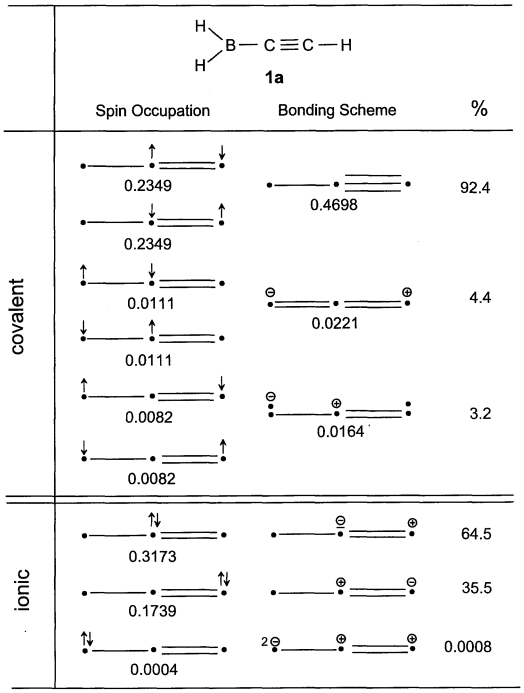
We also relate weights for bonding schemes to the strengths of the bonds designated by the bonding schemes. For this purpose the second derivatives of the molecular energy with respect to definite internal coordinates are needed. These coordinates are the bond lengths in the *z*-matrix[13] defining the molecular geometries. We computed the second derivatives by repeating the last step in the geometry optimization but we used an analytic hessian (FOPT=CALCALL)[8]. The second derivatives of the energy with respect to the internal coordinates of the *z*-matrix were printed out by means of the option IOP(1/33 = 1)[8].

Results

π-Electron Donation from the Alkynyl Group to the Isoelectronic BH_2 and CH_2^+Groups

In ethynylborane (**1a**) the Lewis acidic BH_2 group is directly attached to the ethynyl group (see Scheme 1). Two π-electrons of this group can be transferred to the BH_2 group by partially occupying the empty π-orbital of the boron atom. Thus, two π-electrons of the ethynyl group can delocalize over three π-AOs and a partial boron−carbon π-bond can be formed (see Scheme 1). In order to investigate the extent of this π-bonding we expanded a restricted closed-shell MO determinant for the two π-electrons into the set of all 81 AO determinants. We derived local spin occupations by sampling the corresponding AO determinants as outlined above. Local spin occupations and their weights are given in the first column of Table 1.

Table 1. Bonding schemes and their weights for ethynylborane (**1a**); the covalent weights show that the boron atom hesitates to accept π-electrons from the ethynyl group



Generally, a line in a bonding scheme represents a spin-coupled electron pair localized in bonds or at an atom by forming a lone pair[14]. In the second column of Table 1 spin occupations of the first column are converted into bonding schemes. Equal weights of spin-inverted spin occupations are added up to derive weights for bonding schemes. All covalent AO determinants give rise to three covalent bonding schemes. All ionic AO determinants make up three ionic bonding schemes (see Table 1). It is well known that expanding an uncorrelated restricted MO determinant produces weights for the covalent and ionic bonding schemes which are too small and too large, respectively[15].

This problem could be alleviated by using a correlated wavefunction to obtain localized bonding schemes, the procedure for which is, however, computationally more involved. Former work has demonstrated that geometries for boron compounds are reproduced reasonably well by RHF calculations. Moreover, it was shown previously that *within the subspaces* of the covalent and ionic bonding schemes the weights can be expected to appear in correct relative order[16]. Therefore, the weights of covalent bonding schemes in Table 1 should indicate their relative importance. Because this work concentrates solely on the relative importance of covalent bonding schemes, all ionic bonding schemes have been omitted for clarity for the other compounds in this study. In the following we estimate the importance of a covalent bonding scheme by its weight precentage value, where 100% is the weight sum of all covalent bonding schemes. Table 1 shows that the two π-electrons reside mainly on the alkynyl group (92.4%). A heteroallene structure with a B=C double bond is only of minor importance (4.4%). The weight for the singlet diradicaloid bonding scheme is small (3.2%) but of comparable magnitude. These results suggest that the boron atom hesitates to accept a single π-electron from the alkynyl group. It also avoids to accept a spin-coupled electron pair as indicated by the very small weight of the respective charge-separated bonding scheme. These conclusions seem to be supported by the optimized geometries. The carbon−carbon triple bond length of the alkynyl group is 1.1927 Å, a value close to the carbon−carbon triple bond length of acetylene (1.204 Å)[17]. Thus, the C≡C bond in **1a** is in essence an acetylene triple bond. A value of 1.5250 Å is computed for the B−C bond length in **1a**. This value is close to the computed B−C bond length in BH_2-CH_3 (1.578 Å)[18]. The small bond shortening is in line with the different carbon hybridizations present in **1a** and BH_2-CH_3 (sp vs. sp^3). All results support the notion that the double-bond character of the B−C bond in **1a** is small.

In **1b** the ethynyl group is adjacent to the positively charged CH_2^+ group which is isoelectronic to the BH_2 group of **1a**, but expected to be a much stronger π-acceptor due to its positive charge. As for **1a**, the covalent AO determinants for **1b** lead to three local covalent spin occupations and bonding schemes as recorded in Table 2.

Table 2. Bonding schemes and their weights for model compound **1b**; the covalent weights indicate the two π-electrons are delocalized

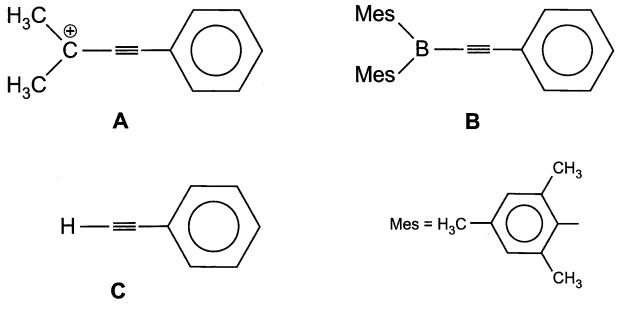
 0.0633		12.1

They show that the two π-electrons are almost equally localized in the CH_2-CCH bond region (42.2%) and in the $CH_2C{\equiv}CH$ bond region (45.7%). Hence, the carbon−carbon triple bond experiences a removal of π-electrons but also positive charge is accumulated in this bond region as indicated by the first bonding scheme of Table 2. These two effects have an opposite influence on the carbon−carbon triple bond length which therefore remains unaffected. In contrast, the carbon−carbon single bond CH_2-CCH should have a significant double-bond character. Both conclusions are supported by the optimized bond lengths: The CH_2-CCH bond length of 1.3414 Å is close to the carbon−carbon bond length in ethylene (1.337 Å)[19], but the $CH_2C{\equiv}CH$ bond length is 1.2096 Å, a value near 1.204 Å which is the carbon−carbon bond length in acetylene[17]. Thus, in spite of the *massive* π-electron withdrawal from the triple bond its bond length remains virtually unchanged. This fact emphasizes that geometrical parameters are at best an indirect measure of electronic properties. The leading covalent bonding schemes of Table 2 describe the well-known delocalization of the positive charge[20] among the two terminal carbon atoms. A feature of cation **1b** seems to be its notable singlet biradical character. This is indicated by the appreciable weight of the third covalent bonding scheme (12.1%). This conclusion illustrates an advantage of the applied procedure: The singlet biradical character of a closed-shell molecule is contained in a restricted closed-shell MO determinant. However, it remains hidden but is revealed by the expansion technique[6].

The effective charge delocalization in alkynyl-substituted carbocations has been demonstrated by Olah et al.[21] using NMR spectroscopy.

Scheme 4. A set of alkynyl-substituted compounds where π-electron delocalization operates; compound **C** serves as a comparison



In **A** (see Scheme 4), the ^{13}C chemical shift of the *para*-carbon atom of the phenyl ring is $\delta_p = 145.5$ or $\Delta\delta_p = 16.8$ downfield from that of the respective carbon atom in **C**[21]. In **B**, $\Delta\delta_p$ is only 1 ppm[3d] supporting our notion that despite of their isoelectronic nature, the X−C≡C π-interaction is much weaker in ethynylboranes (X = R_2B) than in the carbocation (X = R_2C^+). By comparing the results for model compounds **1b** and **1a** we have presented two extreme cases of a strong and weak electron delocalization, respectively, which are most likely inaccessible preparatively. In those ethynylboranes known, competitive π-electron donation from other substituents to boron might diminish the

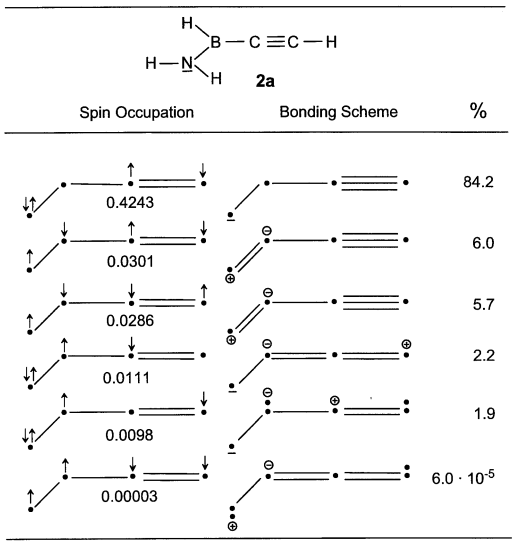
B−C≡C π-interaction even further. A quantitative estimate of these substituent effects is presented in the next section.

Competitive π-Electron Donations from the Amino, Vinyl, and Ethynyl Groups to the BH_2 Group

There is ample experimental evidence for the formation of a partial boron−nitrogen double bond in aminoboranes. For example, NMR spectroscopy shows a hindered rotation about the B−N bond and a rotational barrier of ca. 20 kcal/mol is measured[7f][7i] and confirmed by computational methods[22]. In aminoboranes with three-coordinate boron atoms the B−N bond length is ca. 1.40 Å and the nitrogen atom is planar[7a][7f][7i]. In related compounds with tetra-coordinated boron atoms, however, the B−N bond is ca. 0.05 Å longer and the nitrogen atom is pyramidal[7a][7f][7i]. π-Electron donation from a vinyl group to a neighbouring boron centre is considered to be much weaker, but firmly established[1d]. We have calculated the relative weights for all covalent bonding schemes in amino(ethynyl)borane (**2a**) and ethynyl(vinyl)borane (**2b**) in order to determine the relative π-donating abilites of the three substituents.

The four π-electrons in **2a** occupy two π-MOs delocalized over four π-AOs. By expanding a restricted closed-shell MO determinant we obtained a set of 4356 AO determinants for the four π-electrons. The results for the local covalent spin occupations and their weights as obtained by sampling the corresponding AO determinants are displayed in Table 3.

Table 3. Covalent bonding schemes and their weights for the amino(ethynyl)borane (**2a**)

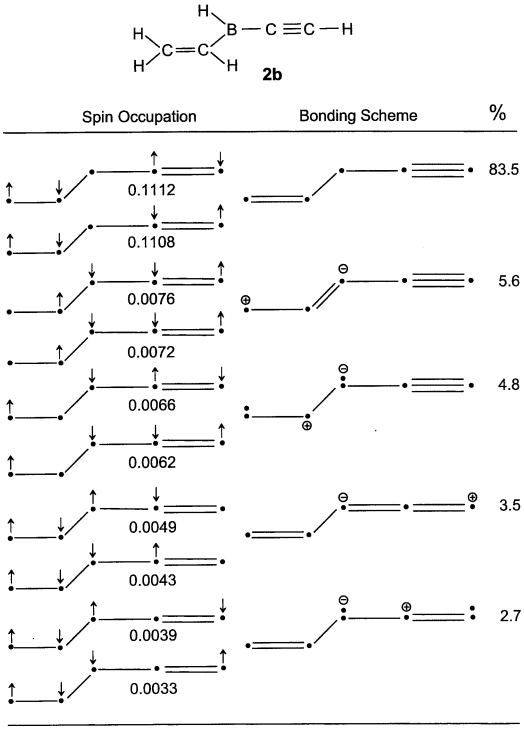


As before, any line in a bonding scheme symbolizes a spin-coupled electron pair present in the corresponding local spin occupation. A single local spin occupation, however, may be compatible with various ways of drawing lines and its weight contributes to the weights of several bonding schemes[6]. Such a case is the second spin occupation in Table 3 contributing at least to a biradical scheme with a central double bond and to a scheme with a triple bond in the alkynyl group and an N=B double bond. The alkynyl carbon−carbon bond is much shorter (1.1904 Å) than the boron−carbon bond (1.5495 Å) and the bonding scheme comprising an alkynyl triple bond should be energetically much more favourable. Therefore, we attributed the weight of the second spin occupation solely to the bonding scheme with the alkyne triple and the N=B double bond (see Table 3). Similar arguments have been applied previously to derive bonding schemes from local spin occupations where the conversion is non-unique[6].

Weights in Table 3 indicate that the four π-electrons in **2a** prefer the ethynyl group and the nitrogen lone pair (84.2%). However, the boron atom accepts an electron from the nitrogen lone pair by forming a partial nitrogen−boron double bond $H_2N{=}BHCCH$ (11.7%). The formation of a π-bond between the boron atom and the ethynyl group is rather unfavourable (2.2%). The singlet biradical character of **2a** is also negligible (1.9%). In aminoborane (**3a**) (36 AO determinants for two π-electrons delocalized over two centres) the weight for the resonance hybrid with a B=N double bond is 11.2%. These results imply that the boron atom readily accepts an electron from the nitrogen lone pair, but much less from the ethynyl group. In addition, the ethynyl group is a fairly electronegative substituent at the boron centre. Its electron withdrawal through the σ bond is balanced by a slightly stronger π-electron donation from the nitrogen atom (11.7% vs. 11.2%). This idea had been advanced previously but remained unsubstantiated until now. Former computations[23] have shown that a barrier of 32.4 kcal/mol exists for a rotation about the nitrogen−boron bond. This barrier height points to a partial double-bond character and is in line with the exceptional stability of aminoboranes. Lone-pair electron donation has been exploited frequently for stabilizing otherwise inaccessible boron compounds e.g. diborane compounds[2g][24], boranes with B=C[25], B=N[26] and B=P[27] bonds. ^{13}C chemical shifts for compounds similar to **2a** have been analyzed in some detail. They are in line with an ethynyl group without electron deficit[2d][2e][2f][2h][28]. These experimental findings corroborate our theoretical result that the boron atom avoids to accept π-electrons from the C≡C triple bond provided a good π-donor like the amino group in **2a** is present. A direct comparison between two weak π-donors is possible in compound **2b** (Table 4). In **2b**, four π-electrons are distributed over five π-AOs and we obtained 11025 AO determinants.

The results in Table 4 highlight the preference of the four π-electrons for the vinyl and the ethynyl groups (83.5%). The boron atom accepts only weakly a π-electron from the vinyl group by forming the boron−carbon double bond $H_2CCH{=}BHCCH$ [5.6%, compared to 5.2% in vinylborane (**3b**)]. Electron donation from the ethynyl group by forming an $H_2CCHBH{=}CCH$ boron−carbon double bond is even less favourable (3.5%). The various singlet biradical bonding schemes appear only with small weights. However, *the vinyl group is a slightly better π-electron donator than the alkynyl group.* Our conclusions are substantiated by the optimized carbon−carbon bond lengths for the vinyl and the ethynyl group which are 1.3300 Å and 1.1921 Å, respectively. They are close to the bond lengths of ethylene (1.337

Table 4. Covalent bonding schemes and their weights for the ethynyl(vinyl)borane (**2b**); the boron atom accepts only weakly π-electrons; the π-donation is slightly stronger from the vinyl than from the ethynyl group



Å)[19] and of acetylene (1.204 Å)[17], respectively. The boron−carbon bonds $H_2CCH-BHCCH$ and $H_2CCHBH-CCH$ in **2b** have lengths of 1.5491 Å and 1.5358 Å, respectively. Again, these values reflect the trend imposed by the different hybridization states of the carbon atoms.

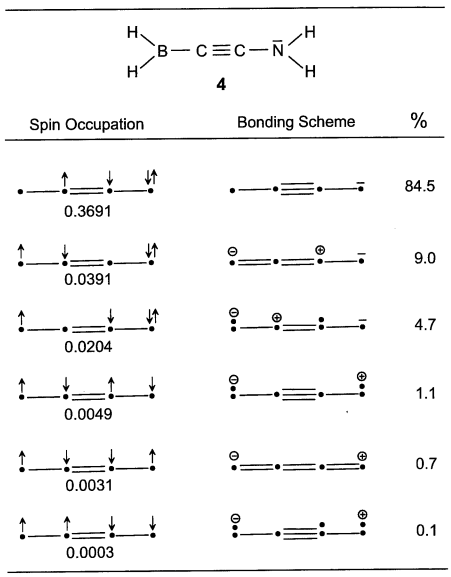
Conclusions from the Expansion Results

The following picture emerges consistantly from the above expansion results. The lone-pair electrons of an amino group are donated efficiently into the empty π-orbital of boron. Adjacent carbon−carbon double or triple bonds are an order of magnitude weaker π-electron donors. In the absence of a good π-electron donor, however, the boron centre excerts its full Lewis acidity and the extent of B=C bonding is doubled but still remains small (2.2% in **2a**, Table 3, vs. 4.4% in **1a**, Table 1). In the presence of a comparably potent π-donor, e.g. the vinyl group, an ethynyl group will only excert half of its maximal electron-donating ability (3.5%, Table 4). Moreover, the weights show that the vinyl group is more electron-donating than the ethynyl group (5.6% vs. 3.5%, Table 4). This is corroborated by ^{13}C-NMR data on dimesitylboranes[29].

Electron Donation from an NH_2 to the BH_2 Group Mediated by an Alkynyl Group

2-Aminoethynylborane (**4**) is of push-pull type and the electron transfer is mediated by the π-electrons of the alkynyl group perpendicular to the molecular plane. Due to this intramolecular electron transfer a partial $H_2B=CCNH_2$ double bond is expected. In order to verify this assumption we expanded a restricted MO determinant[6] for the four π-electrons and we obtained 4356 AO determinants. Subsequently, we derived covalent local spin occupations and their weights by sampling weights of the corresonding AO determinants. The results are compiled in Table 5.

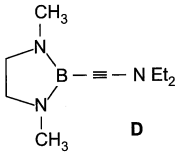
Table 5. Covalent bonding schemes and their weights for the "push-pull" 2-aminoethynylborane (**4**)



Spin occupation four is characterized by complete spin alternation and its weight can contribute to the weights of several bonding schemes. Again, we attributed the total weight solely to the bonding scheme conceived to have the lowest energy. Table 5 shows that the four π-electrons prefer the alkynyl group and the nitrogen atom by forming a lone pair (84.5%). The weight for the second bonding scheme illustrates that the boron atom accepts also a π-electron from the ethynyl group by forming a partial boron−carbon double bond (9.0%) but two π-electrons remain at nitrogen as a lone pair. This result accords with the notion that the coulomb repulsion between the nitrogen lone pair and the π-electrons of the alkynyl group is important. It is reduced when two alkynyl π-electrons leave the alkynyl group by forming the partial $H_2B=CCNH_2$ double bond. A push-pull character of a molecule is frequently described by resonance structures with a maximal number of covalent bonds[30] similar to the fifth bonding scheme of Table 5. Its small weight, however, shows that the formation of a completely delocalized push-pull system is highly unfavourable. The boron−carbon double-bond character in **4** (9.0%) is larger than in **1a** (4.4%). This accords with the computed boron−carbon bond lengths which are 1.4932 Å in **4** and 1.5250 Å in **1a**. Nöth et al. synthesized compound **D**[31] (see Scheme 5) which contains the "push-pull" part of model compound **4**. B=C π-bonding in **D**, however, is diminished by the two amino groups at the boron atom.

None of the spectroscopic data [δ ^{13}C, $\delta^{11}B$, ν_{CC} (IR)] of **D** are significantly different from other ethynylboranes.

Scheme 5: An alkynylborane which contains a push-pull entity; the push-pull character is dwarfed by two amino substituents at the boron centre



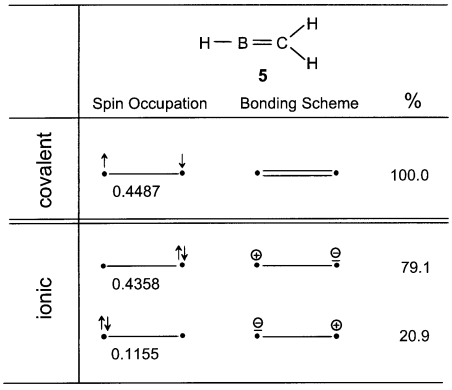
D

These findings are in line with the analysis for the model compounds **2a** and **3a**. The boron atom in **D** accepts lone-pair electrons from the adjacent nitrogen atoms but not from the ethynyl group. Accordingly, **D** could not be photodimerized to form a push-pull-stabilized cyclobutadiene[30].

Strong Carbon−Boron Double Bonds

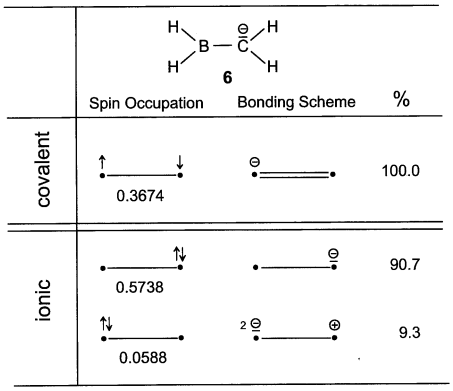
So far we have concentrated on the formation of a partial B=C double bond through π-donation from an adjacent ethynyl or vinyl group. We will now use our expansion technique to investigate two compounds with strong B=C double bonds. In methyleneborane (**5**), the sp-hybridized boron atom provides itself one π-electron and a full boron−carbon double bond is present[32]. In contrast, the methylborane carbanion (**6**) will develop a partial (but probably strong) B=C double bond because a π-electron of the negatively charged carbon centre may be transferred to the empty π-orbital of the sp^2-hybridized boron atom. We expanded the restricted MO determinants for the two π-electrons and sets of 36 AO determinants were obtained. Weights for covalent and ionic local spin occupations were obtained by sampling the weights of the corresponding AO determinants (Tables 6 and 7).

Table 6. Bonding schemes and their weights for methyleneborane (**5**)



The only covalent bonding scheme for **5** evolves with a weight of 44.9% when referred to the weights of all bonding schemes. This value is close to 50% which is the weight for the covalent bonding scheme of ethylene when a restricted MO determinant is expanded[33]. The proximity of both values shows that a pronounced boron−carbon π-bond is present in methyleneborane (**5**). The π-bond in $H_2C{=}BH$ is further substantiated by its computed short bond length of 1.3741 Å. The weights for the two ionic bonding schemes show that the π-bond is polar and the electrons prefer the carbon atom. As mentioned before, when an uncorrelated wavefunction is expanded the absolute weights for all ionic bonding schemes will be overestimated at the expense of the covalent bonding schemes. Table 6 exemplifies for compound **5** that the covalent weight is only 10% smaller than the covalent weight in ethylene.

Table 7. Bonding schemes and their weights for the methylborane carbanion (**6**)



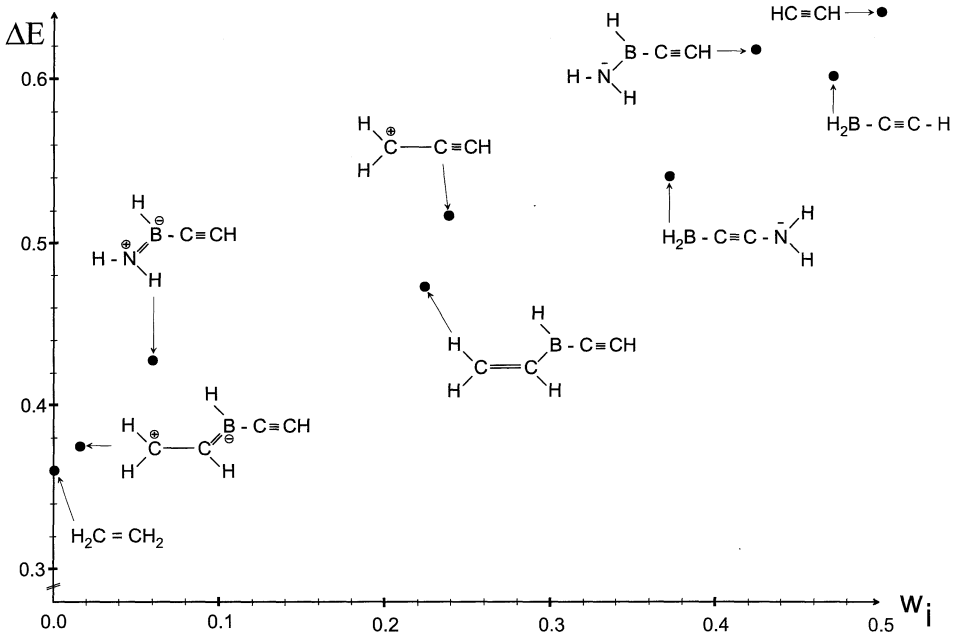
Evidently, the boron−carbon bond in **6** possesses significant double-bond character (36.7%). This supports the notion that the sp^2-hybridized boron atom efficiently stabilizes the carbanion centre by forming a partial double bond accompanied by a delocalization of the negative charge. A decrease of the negative charge at the sp^2-hybridized carbon atom is supported by ^{13}C-NMR data: For the methylene carbon atom in a dialkylmethyleneborane anion, a ^{13}C chemical shift of $\delta = 54.5$ was observed[34]. This value suggests a significant deshielding of the methylene carbon atom as a consequence of π-electron delocalization. The B=C double-bond character in **6** is also corroborated by the calculated B−C bond length of 1.4446 Å. This value is much smaller than 1.5250 Å which is the boron−carbon bond length in the alkynylborane **1a**. Moreover, a rotation about the B−C bond leads to a local minimum located 26.7 kcal/mol higher in energy than the planar ground state[35].

Computed Weights and Bond Strength

We have applied weights for localized bonding schemes to evaluate the electron-accepting ability of a boron atom bonded to a π-electron-donating group. A large electron attraction is indicated by a large weight for those covalent bonding schemes which describe a π-bond between the boron atom and the electron-donating group. Thus, we assume that the weights for covalent bonding schemes are obtained in the correct relative order. The weights were obtained by expanding a restricted closed-shell MO determinant for the π-electrons into the set of AO determinants. It is well known that expanding such an uncorrelated MO determinant leads to covalent and ionic weights which are too small and too large, respectively[15]. Expansions of correlated MO wave functions, however, produce correct weights[36]. In this section we show that even the uncorrelated restricted MO determinant leads to meaningful covalent weights whose relative magnitudes correlate with bond strengths.

Consider the leading bonding scheme RS1 for **1a**. It locates two π-electrons into the C=C bond region and an alkynyl group is indicated. A large or a small weight for this bonding scheme designates the triple bond as strong or weak, respectively. A measure for the C≡C triple-bond strength at the equilibrium geometry is the energy increase ΔE which occurs when the bond is elongated by an amount ΔR (see Appendix for details). Figure 1 correlates this energy increase ΔE with the computed weights for all covalent bonding schemes of Tables 1−7 with at least one C≡C triple bond.

Figure 1. A correlation between weights for bonding schemes and computed ΔE values; bonding schemes are considered where at least one C≡C triple bond occurs

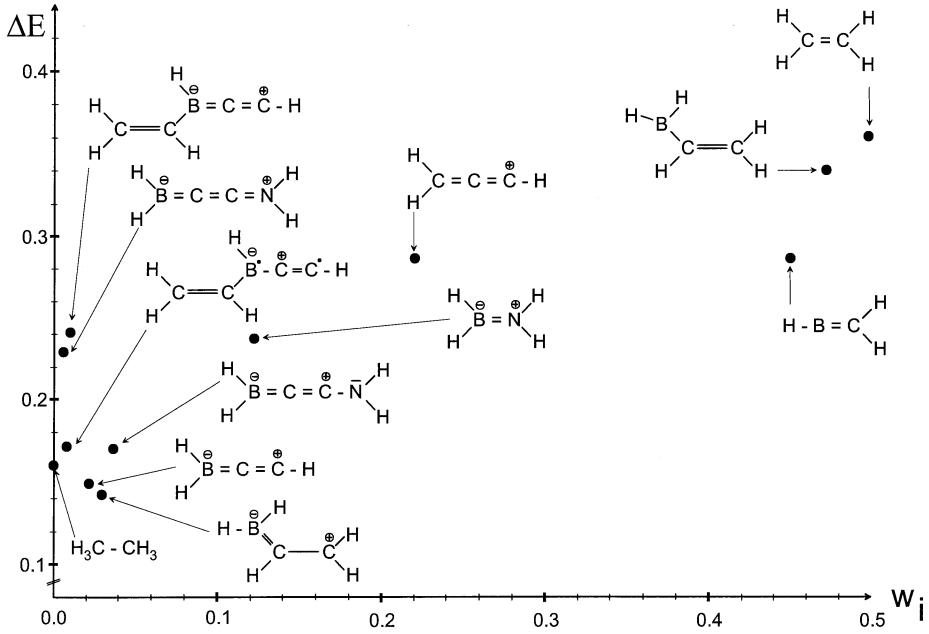


On the abscissa their weights are given and on the ordinate the corresponding energy increases ΔE are recorded (computed by means of eq. 5 or eq. 9). The needed second derivatives were obtained at the RHF/6−311G** level of theory as described in "Computational Methods". Figure 1 shows that a correlation exists between ΔE values and the weights for covalent bonding schemes. The entry for acetylene (0.5) confines the rightmost upper end of the correlation line. In our context, ethylene can be considered as an acetylene molecule devoid of one π-bond and we attribute weight zero to ethylene. Its entry marks the leftmost lower end of the correlation line. The fact that acetylene and ethylene are members of the correlation line supports a qualitative weight rationalization. All leading covalent bonding schemes for **1a**, **2a**, and **4** locate two π-electrons into the alkynyl groups. Their entries appear near acetylene, which shows that the π-systems in **1a**, **2a** and **4** are acetylene-like. The leading covalent bonding scheme for **2b** locates two π-electrons into the alkynyl but also two π-electrons into the vinyl group (see Figure 1). Its intermediate weight shows that both groups are relevant. At the leftmost lower part of the correlation line, different covalent bonding schemes of **2a** and **2b** appear. They attribute two π-electrons to the ethynyl group and two π-electrons to the N=B and C=B double bonds, respectively. Their small weights, however, indicate that an occurrence of N=B, and C=B double bonds in combination with an ethynyl C≡C triple bond is unfavourable in **2a** and **2b**. The small weights suggest the notion that the ΔE values for these bonding schemes are determined by the bonds which remain when the π-bonds of the bonding schemes are not drawn. Thus, the small ΔE values should be determined by the strongest remaining bond which is the double bond of the alkynyl groups and hence appear near the value for ethylene (see Figure 1).

A similar treatment was carried out for bonding schemes with double bonds. On the abscissa of Figure 2, weights are recorded for covalent bonding schemes of Tables 1−7 which comprise at least one double bond.

The corresponding ΔE values are given on the ordinate. Figure 2 shows that a fair correlation between weights and ΔE values exists. The ethylene entry confines the righmost upper part of the correlation line with a weight of 0.5 and ethane (attributed weight zero) delimits the leftmost lower part of the correlation line. The dominating covalent bonding schemes for **3b** and **5** appear near the ethylene entry (see Figure 2). This proximity shows that the π-bonds in **3b** and **5** are similar to the strong π-bond in ethylene. The bonding schemes for the $H_2C{=}CCH$ double bond in **1b** and the $H_2N{=}BH_2$ double bond in **3a** appear at the middle of the correlation line. This intermediate location, between ethylene and ethane, shows that these π-bonds have a significant single-bond character. The covalent bonding schemes for C=B double bonds in **1a**, **3b** and **4** are located at the lower left part of the correlation line. Their small weights show that drawing of double bonds is unjustified. These boron−carbon bonds are in essence single bonds and the entries appear near ethane. The location of two π-electrons

Figure 2. A correlation between weights for bonding schemes and computed ΔE values; the bonding schemes comprise at least one C=C double bond



into the vinyl group combined with a singlet biradical arrangement of the remaining two π-electrons is unfavourable for **2b**. The corresponding bonding scheme appears with a small weight (see Figure 2). At the lower leftmost part of the correlation line, deviations are found for two covalent bonding schemes of **2b** and **4**. They both locate four π-electrons into two π-bonds. However, their small weights show that they should be regarded as *two* single bonds. This may explain the deviation from the correlation line where small Δ*E* values are determined by only *one* single bond.

Discussion and Conclusion

In the previous sections we have evaluated the π-electron-accepting ability of an sp^2-hybridized boron atom bonded to a π-electron-donating entity. The π-electron-attraction can be viewed as an intramolecular π-electron transfer. It leads to a partial B=X double bond where X is an atom of the electron-donating substituent. This double-bond character increases in the sequence of model compounds **1a** < **3b** < **3a** < **6**. Our analysis is rooted in the framework of valence-bond theory. An alternative way, however, is to analyse the π-bond character of the B=X bonds by means of the qualitative perturbational approach in terms of fragment molecular orbitals[38]. In the following we show that a correlation between computed weights and quantities based on the fragment-orbital approach exists. This correlation leads to an elucidation of factors which are responsible for the extent of the B=X double-bond character.

Consider the parent ethynylborane (**1a**) where an intramolecular π-electron transfer may occur from the alkynyl group to the BH_2 group. The acceptor (A) fragment orbital is the lowest unoccupied molecular orbital (LUMO) of the borane BH_3. The donor (D) orbital is one of the degenerate π-orbitals of acetylene. Electron transfer occurs within the model compound **1a** which can be viewed as donor acceptor complex (DA). The π-electron transfer transforms the π-orbital of D into the π-orbital of (DA). This occurs by mixing the LUMO of A into the π-orbital of D[38]. An efficient π-electron transfer is manifested by an π-orbital energy in (DA) which is significantly lower than in D[38]. For model compounds **1a**, **3b**, **3a**, **1b** and **6** the operation of this concept is illustrated in Table 8.

In the first column the computed orbital energies of the acceptor fragment orbitals are recorded. These are the LUMOs of BH_3 and of CH_3^+. In the third column the energies of the donor fragment orbitals of the reference donor molecules D are given. Electron transfer in the model compounds (DA) leads to new π-orbitals and their computed MO energies are given in column two. The energy differences Δ*E* between the π-orbital energies in (DA) and (D) are recorded in column four. The Δ*E* values show the intramolecular electron transfer increases in the sequence **1a** < **3b** < **3a** < **6**. This ordering accords with the weights for the corresponding covalent bonding schemes. However, the Δ*E* value for compound **1b** is far too large and incompatible with the intermediate weight for the covalent bonding scheme. The donor orbitals for the substituted boranes are energy lowered only by mixing in the acceptor orbitals of BH_3 and the overall net charges of (D) and (DA) are identical. In **1b**, however, a positive charge is present which is absent in the donor fragment (D). This leads to an additional energy lowering of the donor π-orbital and the Δ*E* value is exaggerated. A better interpretation is given in the following by interrelating computed weights to quantities derived from the fragment molecular orbital approach. Any bonding scheme for the B=X double bonds is charcterized by a definite expansion coefficient c_i (see eq. 1). For the

Table 8. The fragment orbital approach as applied to a selection of model compounds; they are considered as donor acceptor molecules (DA) where a π-electron donation occurs from the donor fragments D to the acceptors fragments A; the relevant MO energies ε and the energie decreases ΔE are given

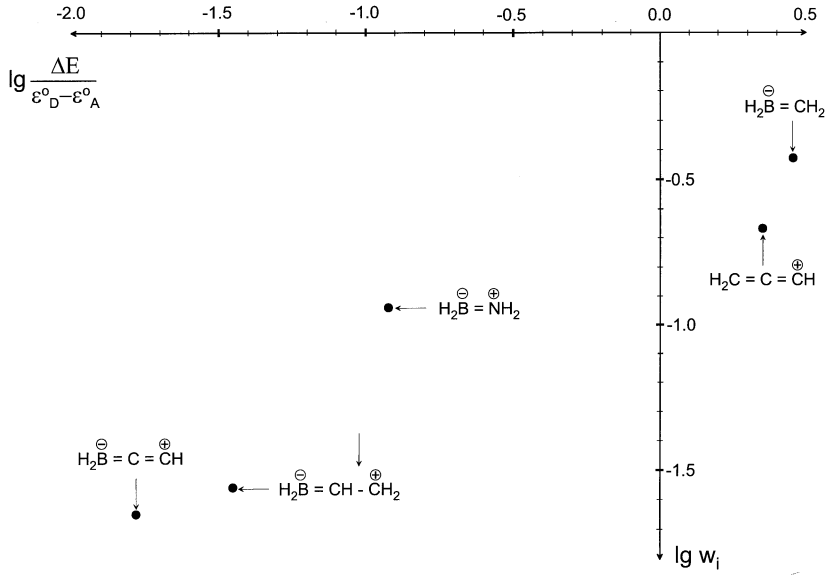
molecules in Table 8, c_i is simply the product between the π-MO coefficients $c_{\mu\pi}$ and $c_{\nu\pi}$.

$$c_i = c_{\mu\pi}c_{\nu\pi} \qquad (3)$$

Here, μ and ν refer to an AO of boron and of the adjacent atom X, respectively. The boron coefficients $c_{\mu\pi}$ are much smaller than the coefficients $c_{\nu\pi}$ for atom X. Moreover, $c_{\nu\pi}$ can be reasonably approximated by the unperturbed MO coefficient of the donor orbital. The small boron coefficients $c_{\mu\pi}$, however, are determined in the perturbational fragment approach by a first-order improvement of the donor MO[38]. This improvement is proportional to a first-order coupling integral divided by the energy difference between the donor and the acceptor orbital, namely $(\varepsilon_D - \varepsilon_A)$[39]. Weights w_i are proportional to the squares of the expansion coefficients c_i (see eq. 2). Therefore, the w_i should correlate linearly with a quantity which is the square of the first-order coupling integral divided by the square of $(\varepsilon_D - \varepsilon_A)$. The computed ΔE values of Table 8 can be considered as second-order perturbation energies[40]. The analytic form of the second-order perturbation energies[40] and the above reasoning leads us to conclude that the w_i values should correlate linearly with ΔE divided by $(\varepsilon_D - \varepsilon_A)$. The logarithm of the $\Delta E/(\varepsilon_D - \varepsilon_A)$ values are recorded in the last column of Table 8. Figure 3 shows that they correlate reasonably with the logarithms of the w_i values.

This correlation leads immediately to an explanation of the relative ordering of weights in terms of properties of the fragment orbitals. A small weight for the B=X double bond is expected provided the ΔE values are small and the energy difference $(\varepsilon_D - \varepsilon_A)$ is large. This situation holds for ethynylborane (**1a**) and vinylborane (**3b**). Large ΔE values supplemented by a small energy difference $(\varepsilon_D - \varepsilon_A)$ determine large B=X weights. This is valid for the ethynyl carbocation

Figure 3. A correlation between bonding-scheme weights and a quantity based on the fragment molecular orbital approach



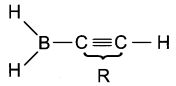
1b and the borane carbanion **6**. Aminoborane (**3a**) represents an intermediate case. Thus, a large B=X double-bond character is expected provided the donating fragment has a low π-electron ionization potential. This is certainly true for the carbanion fragment in **6**. The π-electron ionization potential of acetylene (11.4 eV)[41] and ethylene (10.5 eV)[41] are larger and the B=C double-bond character in **1a** and **3b** is rather small. Due to the ionization potentials, however, the B=C double-bond character in **3b** should be slightly larger than in **1a**. This accords with the corresponding weights which are 4.4% in **1a** and 5.2% in **3b**. Moreover, the extent of the double-bond character is also determined by the energy of the acceptor orbital. The high energy of the BH_3 acceptor orbital implies a small weight for the B=C double bond in ethynylborane (**1a**). On the contrary, the low energy of the acceptor orbital of CH_3^+ leads to a rather large weight for the C=C double bond in **1b**. The derived qualitative explanation holds also for the π-bond present in a planar borylphosphane H_2B-PH_2. The optimized geometry of H_2B-PH_2 is characterized by a pyramidal phosphanyl group and the lone pair at the PH_2 group is oriented away from the BH_2 group. Therefore, only a weak B=P π-bond is present in H_2B-PH_2 at the equilibrium geometry[42]. However, computational results at a *planar* C_{2v} geometry of H_2B-PH_2 indicate a B=P bond slightly *stronger* than the B=N bond in **3a**[43]. This finding is in line with the concepts determining the correlation line of Figure 3. The 3p electrons at the planar PH_2 fragment have a lower ionization potential than the 2p electrons at the NH_2 fragment. Consequently, the weight for the B=P bond should be larger than the weight for the B=N bond.

The authors are greatful to Prof. *K. Wieghardt* for his support of this work and to Prof. *R. Köster*, Dr. *G. Olbrich* and Dr. *F. Mark* for helpful discussions. The technical assistance of *K. Sand* is also gratefully acknowledged.

Appendix

Consider a bonding scheme with one bond of length R (exemplified for **1a** in Scheme 6).

Scheme 6. A bonding scheme where only one π-bond is indicated; the only bond parameter is the bond length R



The energy E at a bond length R, elongated by ΔR, is given up to second order in ΔR by

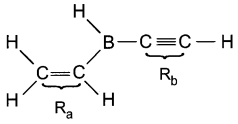
$$E(0+\Delta R)=E(0)+\left(\frac{dE}{dR}\right)^{0}\Delta R+\frac{1}{2}\left(\frac{d^2E}{dR^2}\right)\Delta R^2+.. \qquad (4)$$

If we assume an optimized geometry for **1a**, the first derivative in eq. 4 vanishes. Furthermore, we apply a reference elongation with a squared norm of unity. Thus, ΔR^2 is unity and the energy increase ΔE is given by

$$\Delta E = E(0+1)-E(0)=\frac{1}{2}\left(\frac{d^2E}{dR^2}\right)^{0} \qquad (5)$$

We see, ΔE is given by half of the curvature when the reference elongation is applied. A representative covalent bonding scheme for two π-bonds is the leading scheme for the ethynyl(vinyl)borane (**2b**) represented in Scheme 7.

Scheme 7. A bonding scheme where two π-bonds are indicated; the two bonds have the bond lengths R_a and R_b



It locates four π-electrons into two π-bonds such that a C≡C triple and a C=C double bond is formed. A measure for their combined bond strength is the energy increase resulting when the two bonds are stretched by ΔR_a and ΔR_b (see Scheme 7). The energy up to second order in ΔR_a and ΔR_b at the distorted geometry is given by eq. 6.

$$E(0+\Delta R_a,0+\Delta R_b)=E(0,0)+\frac{1}{2}\left(\frac{\delta^2E}{\delta R_a^2}\right)^{00}\Delta R_a^2+\frac{1}{2}\left(\frac{\delta^2E}{\delta R_b^2}\right)^{00}\Delta R_b^2+... \qquad (6)$$

Here, we have applied the Taylor expansion for a function depending on two parameters[37]. The expansion is simplified by the vanishing of the first derivatives implied by the use of optimized geometries. Moreover, we neglected the mixed second derivatives. This is suggested by the fact that the double and the triple bonds are well separated. A coupling between the two bonds should be negligible. Again, a reference elongation is chosen such that the squared norm of the elongation vector is unity. Thus, we have

$$\Delta R_a^2+\Delta R_b^2=1 \qquad (7)$$

Moreover, we partition the elongations such that eq. 8 holds.

$$\Delta R_a^2=\Delta R_b^2=\frac{1}{2} \qquad (8)$$

Based on these assumptions, we obtain an energy increase ΔE given by eq. 9.

$$\Delta E = E\left(0+\sqrt{\frac{1}{2}},0+\sqrt{\frac{1}{2}}\right)-E(0,0)=\frac{1}{4}\left[\left(\frac{\delta^2E}{\delta R_a^2}\right)^{00}+\left(\frac{\delta^2E}{\delta R_b^2}\right)^{00}\right] \qquad (9)$$

The ΔE given by eq. 5 and eq. 9 are based on a different number of bond elongations, namely one and two, respectively. The squared norm of both elongations, however, is equal and unity. This property permits us to compare bonding schemes with a different number of bonds by computing ΔE values. Our notion is that covalent bonding schemes with large (small) weights indicate strong (weak) bonds and they should be characterized by large (small) ΔE values. In Figure 1, weights for bonding schemes and ΔE values are correlated.

Keywords: Gallium / Silicon / Heterocycles / Main group elements

The reaction of $Ga_2X_4 \cdot 2$ dioxane with four equivalents of $(Me_3Si)_3SiLi(thf)_3$ (= hypersilyllithium) affords for X = Br a 1,3,2,4-disiladigalletane together with tetrahedral hypersilylgallium(I). For X = Cl an anionic 1,2,3,4-silatrigalletanate, a four-membered heterocycle with a Ga_3 unit, is isolated. These primary examples of gallium/group-14 heterocycles have been investigated by NMR spectroscopy as well as by X-ray single-crystal structure analysis. In addition, the synthesis and structure of bis(hypersilyl)gallium chloride is described. This monomeric molecule has a nearly T-shaped Si_2GaCl framework.

The tris(trimethylsilyl)silyl (= hypersilyl) group has proved to be a very useful substituent in gallium chemistry. Not only trivalent gallanes like $tmp_2GaSi(SiMe_3)_3$,[1] $Y_2GaSi(SiMe_3)_3 \cdot thf$ (Y = Me, Cl),[2] $Cl_2Ga[Si(SiMe_3)_3]_2 \cdot Li(thf)_2$[3], and $[(EtO)_2GaSi(SiMe_3)_3]_2$[2] are accessible but the hypersilyl group is also excellently capable of stabilizing a number of low-valent gallium compounds with gallium−gallium bonds. This includes hypersilyl-substituted digallanes $[(Me_3Si)_3Si]_2Ga-Ga[Si(SiMe_3)_3]_2$ and $[(Me_3Si)_3SiGa(Cl)-Ga(Cl)Si(SiMe_3)_3]_2$[4] as well as an anionic tetragallane $[(Me_3Si)_3SiGa\{Ga(I)Si(SiMe_3)_3\}_3]^-$ and the polyhedral nonagallane $[\{(Me_3Si)_3Si\}_6Ga_9]^-$.[5] The hypersilyl-substituted tetrahedral gallium(I) cluster $[(Me_3Si)_3SiGa]_4$ proved to be very stable towards dissociation into monomeric units.[6] In all these cases the hypersilyl group remained unaffected. Consequently, the central silicon atom is bonded to only one gallium atom and no cyclic compounds are known with gallium and silicon atoms as ring-building elements. In the following we describe results, where the inherent capability of the hypersilyl ligand for Si−Si bond cleavage is used for the synthesis of gallium−silicon heterocycles, which feature a tetracoordinate silicon atom bonded to two gallium atoms.

Reactions

By treating $[(Me_3Si)_3SiGa(Cl)-Ga(Cl)Si(SiMe_3)_3]_2$ (**1**) with two equivalents of $Li(thf)_3Si(SiMe_3)_3$ (Eq. 1) disproportionation of the gallium(II) species is achieved. Accompanying $[(Me_3Si)_3SiGa]_4$ (**2**), bis(hypersilyl)gallium chloride (**3**) is isolated in this reaction. Recently, we have described the synthesis of **2**[6] together with $Cl_2Ga[Si(SiMe_3)_3]_2 \cdot Li(thf)_2$ (**4**) and several not further characterized byproducts by reaction of $Ga_2Cl_4 \cdot 2$ dioxane with three equivalents $Li(thf)_3Si(SiMe_3)_3$ (Eq. 2). Another reaction course is observed, if $Ga_2Cl_4 \cdot 2$ dioxane, dissolved in tetrahydrofuran, is treated with four equivalents of $Li(thf)_3Si(SiMe_3)_3$ (Eq. 3). In this reaction the disproportionation of the gallium(II) species leads again to several hypersilylgallium compounds in oxidation state III, but no **2** is observed. Instead, black crystals of the unprecedented gallium/silicon heterocycle **5** are isolated. On the other hand, the analogous reaction of $Ga_2Br_4 \cdot 2$ dioxane with four equivalents of $Li(thf)_3Si(SiMe_3)_3$ affords **6** together with **2** (Eq. 4). The latter cocrystallizes with $Si(SiMe_3)_4$, which is formed during the reaction course. It is plausible, that **2** and bis(hypersilyl) gallium bromide are formed by disproportionation at first. **6** forms formally by elimination of bromotrimethylsilane from the sterically crowded $[(Me_3Si)_3Si]_2GaBr$. This takes place in the presence of excess $Li(thf)_3Si(SiMe_3)_3$, consequently the halosilane reacts further to produce $Si(SiMe_3)_4$ (Scheme 1). The pathway leading to **5** obviously also includes a step of disproportionation, but now an oligomeric hypersilylgallium(I) reacts with $Li(thf)_3Si(SiMe_3)_3$. Thus, a possible intermediate might be the three-membered gallacycle $[Ga_3\{Si(SiMe_3)_3\}_4]^-$. Migration of a trimethylsilyl group from an $Si(SiMe_3)_3$ group at the four-coordinate gallium center to a three-coordinate one and insertion of the remaining $Si(SiMe_3)_2$ unit into a Ga−Ga bond affords **5**.

Spectroscopic Characterization

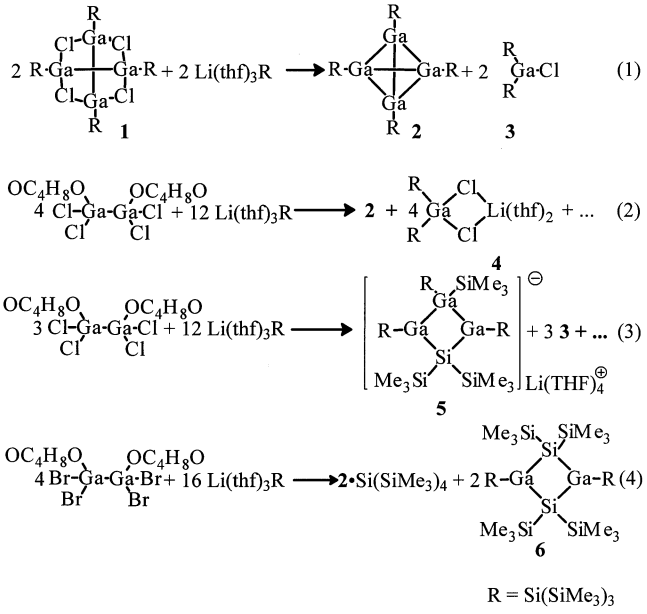
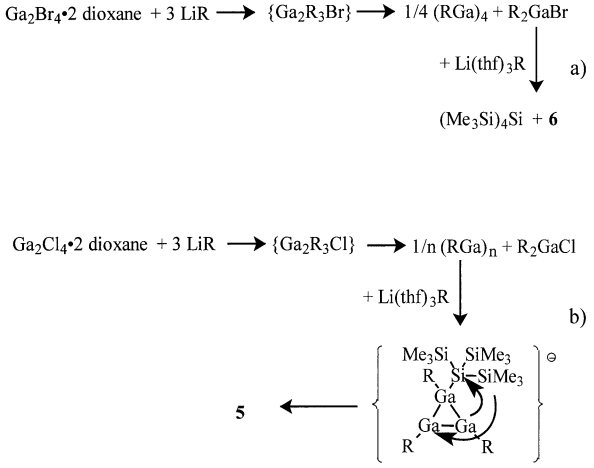


Scheme 1. Proposed reaction pathways to **6** (a) and **5** (b)



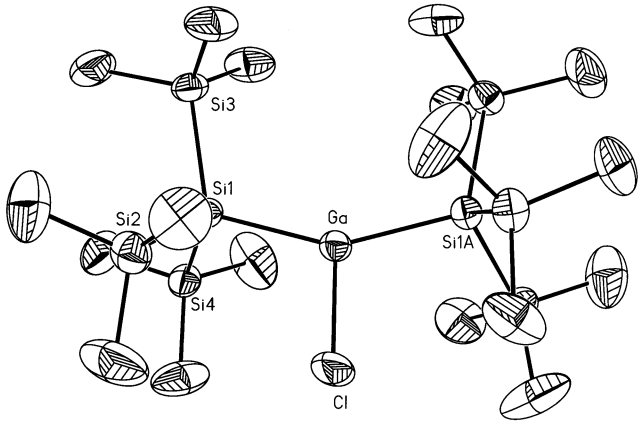
The ^{1}H- and ^{13}C-NMR spectra for **5** show two signals for the hypersilyl groups, one for the Ga−$SiMe_3$ group and two for the $Si(SiMe_3)_2$ unit, as is expected. In the ^{29}Si-NMR spectrum for the eight chemical different silicon atoms eight signals are observed. All trimethylsilyl groups, including the gallium-bonded one, resonate in the typical range between δ = −8.8 and −14.2. The central silicon atoms of the hypersilyl groups give rise to two signals at δ = −120.2 and −131.4. The signal for the ring silicon atom is identified at δ = −4.3. In **6** the signal for the ring silicon atoms is observed at δ = −3.3, that for the central atom of the hypersilyl group at δ = −103.8. Whereas there are no comparable data available for silicon atoms bonded to two gallium atoms, the chemical shifts for the hypersilyl silicon atoms are in the typical range known for other hypersilylgallium derivatives.[2] For example, the central silicon atom in $tmp_2GaSi(SiMe_3)_3$[1] resonates at δ = −115.3, in $Cl_2GaSi(SiMe_3)_3 \cdot thf$[2] at δ = −127.8, and in $[(PhO)_3GaSi(SiMe_3)_3]^-$[2] at δ = −141.7. Electron-precise compounds with Ga−Ga bonds like $[(Me_3Si)_3SiGa(Cl)-Ga(Cl)Si(SiMe_3)_3]_2$[4] have signals in this range (δ = −112.2), too. This is only a small variation compared to other hypersilyl derivatives; here chemical shifts from δ = −33.4 for $(Me_3Si)_3SiF$[7] to −189.4 for $Li(thf)_3Si(SiMe_3)_3$[15c] are known. The chemical shifts of the gallium compounds seem to be affected by the electron-withdrawing properties of the ligands at and the coordination number of the gallium center. But the bonding situation at the gallium center obviously has the largest impact. In the electron-deficient tetrahedral cluster **1**, the signal for the hypersilyl silicon atom is observed at δ = −68.7. This shift to higher frequencies compared to other gallium compounds must be due to the multicenter-bonding situation the gallium atoms are involved in.

In the mass spectrum (70 eV) of **6** not only the molecular peak at *m/z* = 980 and the typical fragmentation pathway, i.e. loss of CH_3, $SiMe_3$, and $Si(SiMe_3)_3$ are observed, but in addition at *m/z* = 490 the radical cation $[(Me_3Si)_3SiGaSi(SiMe_3)_2]^{+\cdot}$ and consequent fragmentation occurs.

X-ray Structure Analysis

3 crystallizes in the hexagonal space group $P6_122$ with $Z = 6$. The crystal consists of well-separated monomeric molecules of **3** with a severely distorted trigonal-planar coordinated gallium center (Figure 1). The Ga−Si distance is 240.3(2) pm, which is comparable to the one in $Me_2Ga(thf)-Si(SiMe_3)_3$ [d_{GaSi} = 241.1(3) pm],[2] but shorter than in $tmp_2Ga-Si(SiMe_3)_3$ [d_{GaSi} = 246.8(1) pm].[1] Here, due to the three versus only two space-filling substituents the hypersilyl groups must minimize their steric interactions by bond elongation. In **3** this is achieved by a wide SiGaSi bond angle [150.3(1)°]. This is very wide, compared to other monomeric R_2GaCl compounds like $[(Me_3Si)_2N]_2GaCl$[8] [N−Ga−N = 128.5(2)°], $(2,4,6\text{-}iPr_3C_6H_2)_2GaCl$[9] [C−Ga−C = 133.8(7)°], and $(2,4,6\text{-}tBu_3C_6H_2)_2GaCl$[10] [C−Ga−C = 135.6(2)°]. Only $(Mes_2C_6H_3)_2GaCl$ [C−Ga−C = 153.5(5)°] is even more T-shaped.[11]

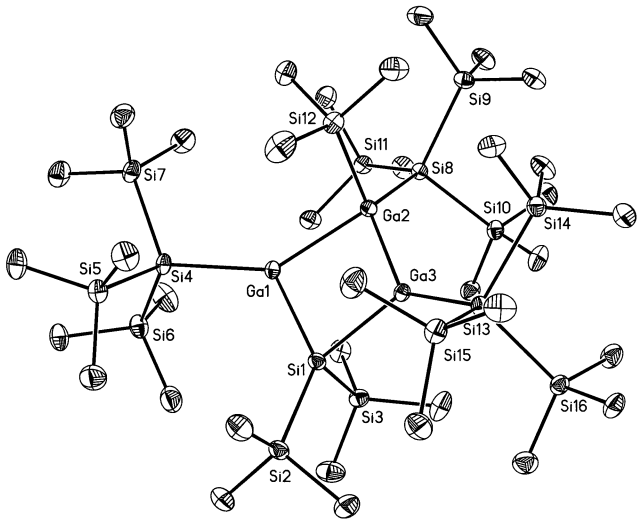
Figure 1. View of a molecule of **3**[a]



[a] Selected bond lengths [pm] and angles [°]: Ga−Cl 222.4(3), Ga−Si1 240.3(2), Si1−Si4 235.8(3), Si1−Si3 235.(3), Si1−Si2 236.1(3); Cl−Ga−Si1 104.83(5), Si1−Ga−Si1 150.33(10), Si4−Si1−Si3 110.1(1), Si4−Si1−Si2 113.96(10), Si3−Si1−Si2 110.9(1), Si4−Si1−Ga 102.42(8), Si3−Si1−Ga 113.79(9), Si2−Si1−Ga 105.36(9).

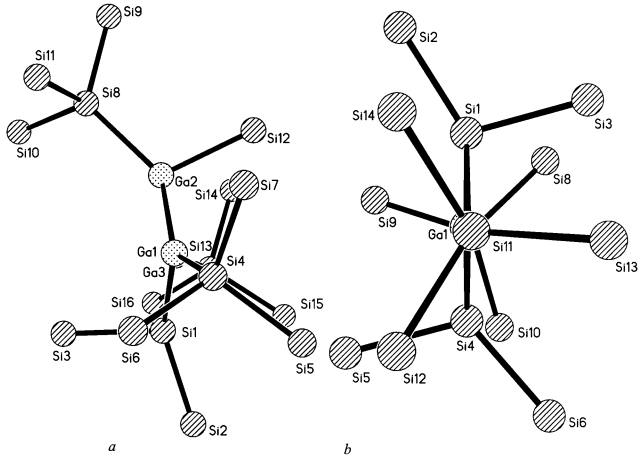
5 crystallizes monoclinic, space group $P2_1/n$, and consists of anionic Ga_3Si heterocycles (Figure 2) and isolated $Li(thf)_4$ cations. The heterocycle **5** is diamond-shaped with acute angles of 84.52(5)° at the ring silicon atom and of 81.39(3)° at the tetracoordinated gallium center. The wide angles [97.78(4), 95.96(4)°] are as expected at the three-coordinate gallium atoms. As is indicated by the sum of angles the ring adopts a flat butterfly structure; the Si1Ga1Ga2 and Si1Ga3Ga2 plane orthogonals intersect at 20.6°. Consequently, the two hypersilyl groups at Ga1 and Ga3 are on the same side of the ring, the hypersilyl group at Ga2 is in *trans* position to them. Nevertheless, the attachment of so many bulky substituents to that four-membered ring results in a considerable distortion of the bond angles and the coordination spheres around Ga2 and Ga3 (Figure 3a). Inspecting the ring silicon atom, at first, the Si2−Si1−Si3 angle, namely the angle between the trimethylsilyl groups is near the tetrahedral angle, but the trimethylsilyl group (Si2) on the inner side of the butterfly has very wide Si2−Si1−Ga2,3 angles. This means the Si1−Si2 bond has only an angle of 26.5° with the Si1Ga2Ga3 plane. In contrast, the Si1−Si3 bond is nearly perpendicular to this plane (Si3Si1//Si1Ga2Ga3: 100.5°). At the tetracoordinated gallium atom Ga2 the situation is similar. The Si8−Ga2−Si12 angle [110.37(6)°] is near the tetrahedral angle, too. The bond Ga2−Si8, involving the central atom of the attached hypersilyl group, has wide angles with the Ga2−Ga1,3 bonds [Si8−Ga2−Ga1 126.64(4)°; Si8−Ga2−Ga3 128.57(4)°], but, in contrast, the corresponding angles involving the trimethylsilyl silicon atom Si12 have values of only 105.67(5)° and 98.09(5)°. This means angles between the Ga2Ga1Ga3 plane and the Si8−Ga2 and Si12−Ga2 bonds of 36.4° and 106.8°, respectively. Furthermore, the steric crowding in **5** causes a no longer exactly planar arrangement around Ga1 and Ga3. Both atoms are 16 pm above the plane through their neighboring atoms. The Ga−Ga bond lengths in the trigallane unit of **5** [255.27(9), 252.88(9) pm] are in the typical range for other hypersilyl-substituted oligogallanes like $[(Me_3Si)_3SiGa(Cl)-Ga(Cl)Si(SiMe_3)_3]_2$ (d_{GaGa} = 250.5 pm),[4] $[(Me_3Si)_3SiGa\{Ga(I)Si(SiMe_3)_3\}_3]^-$ (d_{GaGa} = 253.3 pm)[5] and $[(Me_3Si)_3Si]_2Ga-Ga[Si(SiMe_3)_3]_2$ (d_{GaGa} = 259.9 pm).[4] Only one structurally investigated compound with a trigallane unit is known so far, $Ga_3I_5 \cdot 3\ PEt_3$.[12] In this gallium subhalide shorter Ga−Ga bond lengths [d_{GaGa} = 245.1(1), 246.0(1) pm] are observed. The Ga−Si($SiMe_3$) distances in **5** [d_{GaSi} = 248.4 pm] are very long compared to other hypersilylgallium compounds, as is discussed above. There is no difference between the Ga−Si bond lengths involving three- or four-coordinate gallium atoms in **5**. In contrast, the Ga−$SiMe_3$ bond length is 5 pm shorter. As we have noted earlier,[2] the Ga−Si bond lengths are very sensitive to steric requirements. In this sense, the shorter bond length to the trimethylsilyl group is expected, but further structural data on molecules with Ga−$SiMe_3$ bonds are not available, yet. The ring silicon atom is also in a novel environment. For this atom bonded to two gallium atoms Ga−Si bond lengths of 247.5(2) and 245.2(2) pm are observed, thus in the range of long Ga−Si bonds. The Si−Si and Si−C bond lengths are in the normal range for these bond types.

Figure 2. View of the heterocyclic anion in **5**; the methyl groups have been omitted for clarity[a]



[a] Selected bond lengths [pm] and angles [°]: Ga1−Ga2 255.27(9), Ga2−Ga3 252.88(9), Ga1−Si1 247.5(2), Ga3−Si1 245.2(2), Ga1−Si4 248.4(2), Ga2−Si8 248.4(2), Ga2−Si12 243.6(2), Ga3−Si13 248.3(2), Si1−Si2 235.4(2), Si1−Si3 236.5(2), Si−$SiMe_3$ 235.5; Si1−Ga1−Ga2 94.78(4), Ga3−Ga2−Ga1 81.39(3), Si1−Ga3−Ga2 95.96(4), Ga3−Si1−Ga1 84.52(5), Si1−Ga1−Si4 119.60(6), Si4−Ga1−Ga2 144.07(5), Si12−Ga2−Si8 110.37(6), Si12−Ga2−Ga3 105.67(5), Si8−Ga2−Ga3 128.57(4), Si12−Ga2−Ga1 98.09(5), Si8−Ga2−Ga1 126.64(4), Si1−Ga3−Si13 125.63(5), Si13−Ga3−Ga2 136.59(5), Si2−Si1−Si3 106.12(8), Si2−Si1−Ga3 127.03(7), Si3−Si1−Ga3 98.00(7), Si2−Si1−Ga1 135.74(7), Si3−Si1−Ga1 97.47(7).

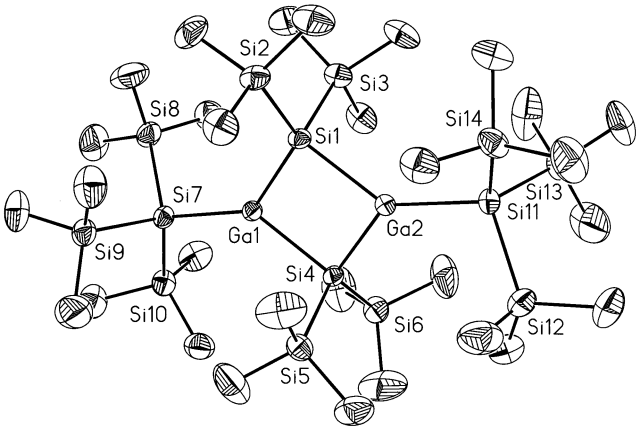
Figure 3. Side-on view of a) anionic **5**, b) one of the two independent molecules of **6**; the methyl groups have been omitted for clarity



Compound **6** (Figure 4) crystallizes triclinic, space group $P\bar{1}$, with two independent molecules in the asymmetric unit. The nearly planar four-membered gallium/silicon heterocycles have an approximately quadratic alternating Ga_2Si_2 framework of distorted trigonal-planar coordinated gallium and tetrahedrally coordinated silicon centers. Thus, the inner ring angles at the gallium atoms are 91.6°, those at the silicon atoms 88.4°, on an average. The Ga−Si bond lengths in the ring (d_{GaSi} = 242.1 pm on an average) vary only by

2 pm. The exocyclic gallium−silicon bond lengths are similar to the innercyclic, too. But, if **5** and **6** are compared, it has to be noted, that all Ga−Si bonds are shortened by more than 5 pm. This is, at least in part, a consequence of the replacement of a $[Ga(SiMe_3)Si(SiMe_3)_3]^-$ unit by the less bulky $Si(SiMe_3)_2$ group. In spite of the reduction of steric crowding, the *anti*-standing trimethylsilyl groups are bonded either in a flat or nearly perpendicular manner to the heterocycle (Figure 3b). The corresponding angle pairs between Si−Si bonds and the Ga_2Si planes are 31 and 104.3° or 42.3 and 115.9°, respectively. It has to be noted, that the two independent molecules differ only a little in the orientation of the approximately staggered hypersilyl groups to one another.

Figure 4. View of a molecule of **6**[a]



[a] Selected bond lengths [pm] and angles [°]: Ga1−Si1 242.89(9), Ga1−Si4 241.2(1), Ga1−Si7 241.5(1), Ga2−Si1 242.5(1), Ga2−Si4 241.68(9), Ga2−Si11 242.5(1), Si1−Si2 232.8(1), Si1−Si3 233.9(1), Si4−Si5 233.7(2), Si4−Si6 232.4(1), Si−$SiMe_3$ 234.0; Si4−Ga1−Si1 91.59(4), Si4−Ga2−Si1 91.57(4), Ga2−Si1−Ga1 88.11(3), Ga1−Si4−Ga2 88.68(3), Si4−Ga1−Si7 132.66(3), Si7−Ga1−Si1 135.74(3), Si4−Ga2−Si11 132.77(4), Si11−Ga2−Si1 135.64(3), Si2−Si1−Si3 107.27(5), Si2−Si1−Ga2 128.62(5), Si3−Si1−Ga2 96.78(5), Si2−Si1−Ga1 127.47(5), Si3−Si1−Ga1 102.77(5), Si6−Si4−Si5 116.52(5), Si6−Si4−Ga1 123.73(5), Si5−Si4−Ga1 100.53(5), Si6−Si4−Ga2 120.08(5), Si5−Si4−Ga2 101.97(5).

Conclusions

With **5** and **6** we have described two novel gallium- and silicon-containing heterocycles, which have both been prepared starting from gallium(II) halides, showing that the hypersilyl ligand is not only useful as a bulky substituent, but is also a valuable source for $Si(SiMe_3)_2$ units. **6** is formally a dimer of a hypothetical silagallene $RGa{=}SiR'_2$, **5** is a novel substituted trigallane derivative. Obviously, in all reactions described in this work disproportionation takes place. The different product distributions reflect the sensitivity of low-valent gallium halide reaction chemistry. Only small variations in the reaction conditions may either proceed in retention or cleavage of the initial Ga−Ga bond. In the latter case gallium(III) compounds and new oligogallanes are formed; in the worst case elemental gallium precipitates.

We thank Prof. Dr. *H. Schnöckel* for his support of this work. We are also indepted to Mr. *H. Piotrowski* and Prof. Dr. *P. Klüfers* for collecting the crystallographic data set for **5**. Financial support by the *Deutsche Forschungsgemeinschaft*, the *Fonds der Chemischen Industrie*, and *Chemetall GmbH* is gratefully acknowledged.

Experimental Section

General: All handling was performed under purified nitrogen or in vacuo using Schlenk techniques. − NMR: Bruker ACP 200 and 250. − MS: Varian MAT 711 with direct inlet. − Gallium halides were prepared from the elements,[14] $(Me_3Si)_3SiLi(thf)_3$[15] as described in the literature. Other chemicals were used as purchased. − X-ray Crystallographic Study:[13] Suitable crystals were mounted with a perfluorated polyether oil on the tip of a glass fiber and cooled immediately on the goniometer head. Data collections were performed in ω-scan with Mo-K_α radiation (graphite monochromator) on a Stoe STADI4 (**3**, **5**) or Stoe IPDS (**6**) diffractometer using the commercial software. Structures were solved using the program XS from Siemens SHELXTL (PC) and refined against F^2 (full matrix) with SHELXL93. All non-hydrogen atoms were refined anisotropically. All hydrogen atoms bonded to carbon atoms were included as riding model with fixed isotropic U's in the final refinement. For further details see Table 1.

Bis[tris(trimethylsilyl)silyl]gallium Chloride (**3**): Into a solution of $[(Me_3Si)_3Si]_4Ga_4Cl_4$ (**1**) (0.51 g, 0.36 mmol) in 20 ml of tetrahydrofuran a solution of $LiSi(SiMe_3)_3 \cdot 3$ thf (0.34 g, 0.73 mmol) in 15 ml of tetrahydrofuran was added dropwise at 60°C (at room temperature no reaction was observed). After stirring the resulting red solution for additional 12 h at room temperature all volatiles were removed in vacuo. The residue was suspended in 10 ml of pentane. Upon filtration the solution was reduced to a volume of 2 ml and cooled to −25°C. Yellow prisms of **3** crystallized followed by black violet plates of **2**.

Lithium 2,4,4-Tris(trimethylsilyl)-1,2,3-tris[tris(trimethylsilyl)silyl]-1,3-digalla-2-gallata-4-silacyclobutane · 4 THF (**5**): A solution of $Ga_2Cl_4 \cdot 2$ dioxane (0.49 g, 1.07 mmol) in 15 ml of tetrahydrofuran was added dropwise at −78°C to a solution of $LiSi(SiMe_3)_3 \cdot 3$ thf (2.00 g, 4.25 mmol) in 20 ml of tetrahydrofuran. After slowly warming to ambient temperature, the mixture was stirred for another 12 h, then all volatiles were removed in vacuo and the residue was extracted three times with 20 ml of pentane, each. The insoluble residue was treated with 15 ml of toluene and sonicated for 5 min. The red solution was filtered. Upon standing a dark red oil separated, which was redissolved in methylcyclohexane/tetrahydrofuran (25:1). At 0°C 0.15 g of **5** (14%) crystallized as black-red prisms. From the pentane fraction bis(hypersilyl)gallium chloride could be identified as one of the gallium(III) products. − ^{1}H NMR ([D$_8$]THF): δ = 0.30 [54 H, 1,3-Si($SiMe_3$)$_3$], 0.25 (9 H, 2-$SiMe_3$), 0.20 [27 H, 2-Si($SiMe_3$)$_3$], 0.17, 0.13 (9 H each, 4-$SiMe_3$). − ^{13}C NMR ([D$_8$]THF): δ = 11.8, 8.2 (4-$SiMe_3$), 5.8 [1,3-Si($SiMe_3$)$_3$], 5.6 [2-Si($SiMe_3$)$_3$], 3.6 (2-$SiMe_3$). − ^{29}Si NMR ([D$_8$]THF): δ = −4.3 (Si-4), −8.8 [2-Si(*Si*Me_3)$_3$], −9.4 [1,3-Si(*Si*Me_3)$_3$], −11.8 (4-$SiMe_3$), −12.7 ($GaSiMe_3$), −14.2 (4-$SiMe_3$), −120.2 [1,3-*Si*($SiMe_3$)$_3$], −131.4 [2-*Si*($SiMe_3$)$_3$]. − MS (70 eV, EI, ^{69}Ga): *m/z* (%) = 536 (5) $[Ga\{Si(SiMe_3)_3\}_2]^+$, 389 (16) $[Me_3SiGaSi(SiMe_3)_3]^+$, 316 (10) $[GaSi(SiMe_3)_3]^+$, 248 (94) $[HSi(SiMe_3)_3]^+$, 174 (83) $[Si(SiMe_3)_2]^+$, 160 (100) $[HSi(SiMe_3)(SiMe_2)]^+$, 73 (76) $[SiMe_3]^+$. − $C_{52}H_{140}Ga_3LiO_4Si_{16}$ (1495.2): calcd. Keywords: Phosphorus chemistry / Phosphonium salts / Diazadiphosphetidines / Phosphazoles / 1-Azaallyl compounds

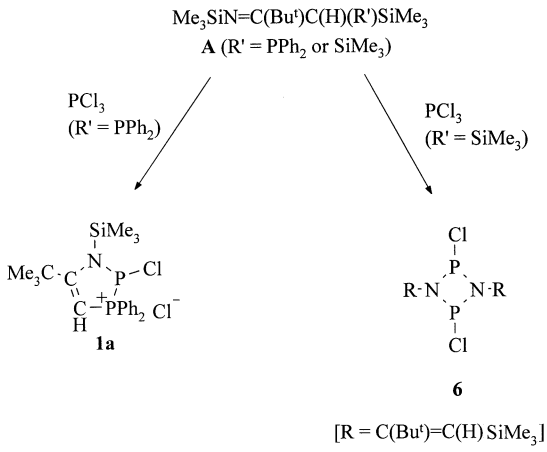
We report the preparation of the novel phosphonium salts $[Ph_2P^aP(NR'_2)N(R)C(tBu)=C^bH]A(P^a–C^b)$ (**2a**; R′ = Et, R = SiMe$_3$, A = Cl; **2b**: R′ = Me, R = SiMe$_3$, A = Cl; **2c**: R = Et, R′ = SiMe$_3$, A = [OSO_2CF_3]; **2d**: R′ = Et, R = SiMe$_3$, A = [BPh_4]; **4**: R′ = Et, R = H, A = Cl) and *trans*-1,3,2,4-diazadiphosphetidines $R'_2NP^aN(R)P(NR'_2)N^c(R)(P^a–N^c)$ [**3a**: R′ = Et, R = C(*t*Bu)=C(H)PPh_2; **3b**: R′ = Me, R = C(*t*Bu)=C(H)PPh_2; **7**: R′ = Me, R = C(*t*Bu)=C(H)SiMe$_3$]. Reaction of **3a** with Cu_2I_2 led to the *P*- and *P,P′*-centred complexes [Cu(I)(**3a**)] (**5a**) and [{Cu(I)}$_2$(**3b**)] (**5b**) [R = C(*t*Bu)=C(H)PPh_2]. The phosphazole $N^aC(tBu)C(H)C^cP^aN(Me)(CH_2)_2N^cMe(N^a–P^a)(C^c–N^c)$ (**8**) was obtained by a remarkable heterocycloaddition reaction from the diazadiphosphetidine $ClP^aN(R)P(Cl)N^bR(P^a–N^b)$ [**6**: R = C(*t*Bu)=C(H)SiMe$_3$] and the electron-rich olefin $[=C^aN(Me)(CH_2)_2N^aMe(C^a–N^a)]_2$ and was oxidised with S_8 yielding $N^aC(tBu)C(H)C^cP^a(S)N(Me)(CH_2)_2N^cMe(N^a–P^a)(C^c–N^c)$ (**9**). Compounds **2–9** were characterised by multinuclear NMR spectroscopy, mass spectrometry for **5–9**, while single-crystal X-ray diffraction data are provided for **3a** and **5a**.

Introduction

Recently we reported that treatment of the ketimine $Me_3SiN=C(Bu^t)CH(R')SiMe_3$ (**A**: R′ = PPh_2; **B**: R′ = SiMe$_3$) with PCl_3 gave the novel phosphonium salt $[Ph_2P^aP(Cl)N(SiMe_3)C(tBu)=C^bH]Cl(P^a–C^b)$ (**1a**) or the *trans*-1,3,2,4-diazadiphosphetidine **6** (Scheme 1)[1].

Scheme 1



The chloride **1a** was thermolabile and decomposed during attempted recrystallisation, whereas the corresponding triflate or tetraphenylborate was stable. We now present further reactions of the two phosphorus-containing heterocycles **1a** and **6**.

[◇] Part 1: Ref.[1].

Results and Discussion

The reaction of **1a** with $Me_3SiNR'_2$ led (step i in Scheme 2), by Me_3SiCl elimination, to the P^{III}-dialkylamino derivatives **2a** and **2b**. Both compounds were thermally labile and were isolated as crude materials from the reaction mixture by removing the solvent and washing the residue with pentane. They were characterised solely by multinuclear NMR spectroscopy.

After resolvation in hot toluene, **2a** or **2b** eliminated a second equivalent of Me_3SiCl and cooling gave (step ii in Scheme 2) colourless crystals of the *trans*-diazadiphosphetidine **3a** or **3b** in nearly quantitative yield. Each gave satisfactory (parent ion) mass spectra and microanalyses. NMR-spectroscopic studies showed that the *P,P′*-bis(diethylamino) compound **3a** existed in solution as mixture of two *trans* isomers, which only differed in the orientation of their substituents at the endocyclic nitrogen atom. In the minor isomer (henceforth identified as *syn*), both diphenylphosphane end groups were close to the same endocyclic phosphorus atom (this conformation is also adopted in the CuI complex **5a**, see Figure 3), while in the major (*anti*) isomer they were close to endocyclic phosphorus atoms of adjacent molecules (as in the crystal, Figure 2). The bis(dimethylamino) analogue **3b**, by contrast, was found to exist solely as the *anti* isomer.

Replacing Cl^- of **2a** by a bulkier anion by treatment with $Ag[OSO_2CF_3]$ or $Na[BPh_4]$ gave (step iii in Scheme 2) the thermally stable five-membered heterocycle **2c** or **2d**. Each was recrystallised from a mixture of CH_2Cl_2 and pentane

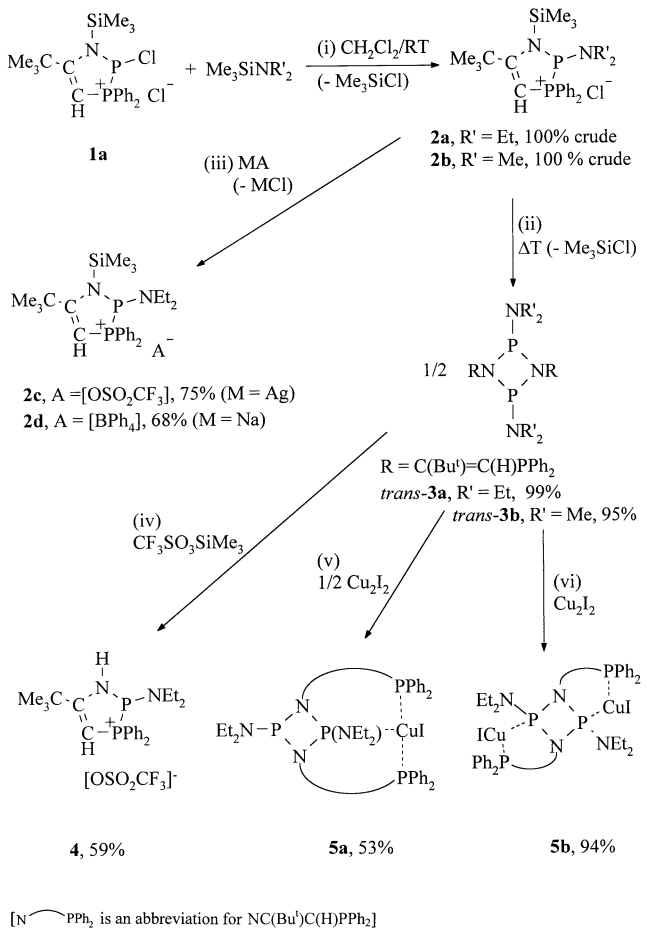
Scheme 2. Some reactions of the phosphonium salt **1a**

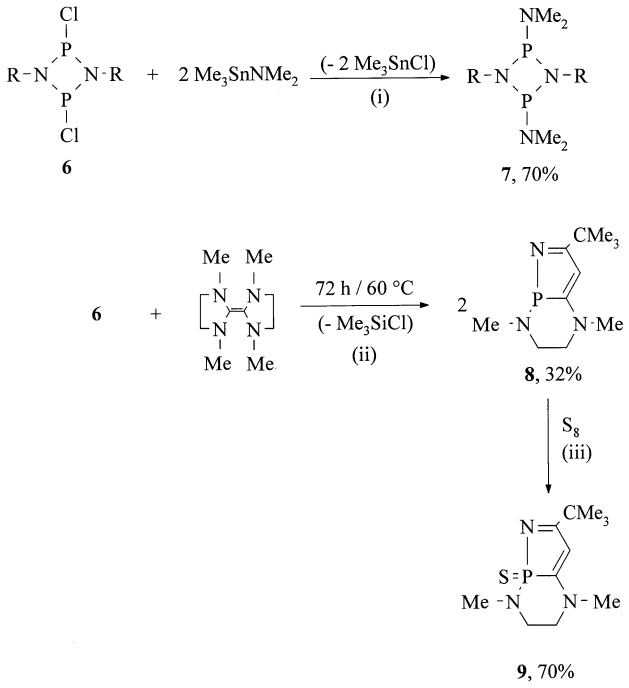


and was fully characterised. Remarkably, the conversion of the phosphonium chloride **2a** into the diazadiphosphetidine **3a** proved to be quasi-reversible as was shown by treatment of **3a** with $CF_3SO_3SiMe_3$ in hot toluene (80°C, 96 h) which yielded (step iv in Scheme 2) the phosphonium triflate **4**; the cation is the desilylated analogue of that in **2a**. The fate of the Me_3Si group at N was not established. A similar observation had, however, been made for the reaction of $Me_3SiN{=}C(t\text{Bu})CH(PPh_2)SiMe_3$ (**A**: R′ = PPh_2) with $PhPCl_2$ or $EtPCl_2$ (cf. Scheme 1) giving $Ph_2P^aP(R'')N(H)C(t\text{Bu}){=}C^bH(P^a{-}C^b)Cl$ (R'' = Ph or Et), with no trace of the $SiMe_3$-substituted product being detected[1].

The ability of a diazaphosphetidine to act as ligand is well documented[2] and is now demonstrated for **3a** by the synthesis (steps v or vi of Scheme 2) of the iodocopper(I) complexes **5a** or **5b** from a mixture of **3a** and Cu_2I_2 in hot toluene. Thus, compound **3a** behaved as a novel terminal tridentate (**5a**) or bridging bis(bidentate) (**5b**) ligand. The related reaction of **3b** with AgI led, under similar reaction conditions, to the disappearance of AgI, and the formation of a white precipitate, presumably an Ag analogue of **5b**, but its extreme insolubility in standard solvents including hot $CHCl_3$ or CH_3CN prevented its characterisation. This was not surprising, as even **5b** was only very sparingly soluble in hot toluene or $CHCl_3$, which may be due to its being a polymer of infinite chain length, with **5b** moieties bridging CuI units (*anti* isomer). The *syn* isomer of **5a** was, by contrast, a monomer both in the gas phase (parent ion in the mass spectrum) and in the crystal (see Figure 3). As a consequence, **5a** was much more soluble than **5b** in, for example, hot toluene.

Further reactions of the diazadiphosphetidine **6** are illustrated in Scheme 3. Treatment of **6** with Me_3SnNMe_2 led (i in Scheme 3) in a clean reaction to the *trans*-diazadiphosphetidine **7**, which with $LiNEt_2$ gave an inseparable mixture of products, whereas Me_3SiNEt_2 proved to be unreactive. The treatment of **6** with the electron-rich olefin [$=C^aN(Me)(CH_2)_2N^aMe(C^a{-}N^a)]_2$[3] led not, as we had anticipated, by chlorine abstraction to a stable phosphorus-centred radical, as had been reported for formation of PR'_2 from $ClPR'_2$ [R′ = $CH(SiMe_3)_2$][4], but (step ii in Scheme 3) to the fused bicyclic compound $N^aC(t\text{Bu})C(H)C^cP^aN(Me)(CH_2)_2N^cMe(N^a{-}P^a)(C^c{-}N^c)$ (**8**). The latter was distillable in a vacuum at 130°C and crystallised at room temperature after several days. Compound **8** was converted (step iii in Scheme 3) into its P^V derivative **9** by treatment with S_8 and crystallisation from Et_2O.

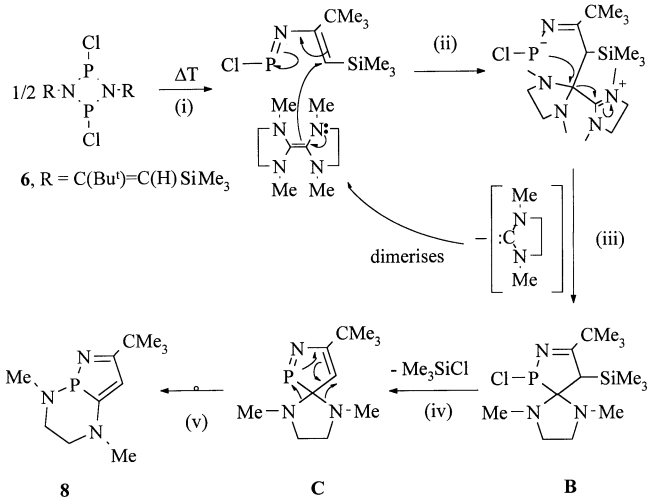
Scheme 3. Some reactions of the *trans*-diazadiphosphetidine **6** [R = C(*t*Bu)C(H)$SiMe_3$]



A plausible reaction pathway for the formation of **8** is outlined in Scheme 4. The first step (i in Scheme 4) is the dissociation of **6** into the transient monomer, the iminophosphane, which is subjected to nucleophilic attack (step ii in Scheme 4) by the electron-rich olefin known[5] to be a powerful C-centred nucleophile. A reversible dimerisation of an iminophosphane has been reported for *t*BuP=N*t*Bu[6]. In step (iii) (which may be synchronous with ii), a *spiro* bycyclic compound **B** is formed with electron-rich

carbene elimination (this can dimerise to reform the electron-rich olefin). Loss of Me_3SiCl from **B** thus leads (step iv in Scheme 4) to **C**, which isomerises (step v in Scheme 4) into the more stable bicyclic compound **8**.

Scheme 4. Proposed reaction pathway from **6** + [=$C^aN(Me)(CH_2)_2$-$N^aMe(C^a-N^a)]_2$ to **8**



NMR-Spectra and Solution Behaviour

In the following discussion of the NMR spectra of the new cyclic phosphonium salts **2** and **4** we also include data on five related compounds $[Ph_2P^aP(R'')N(R')C(t\text{Bu})=C^bH(P^a-C^b)]$A {R′ = $SiMe_3$, R″ = Cl and A = Cl (**1a**), $[OSO_2CF_3]$ (**1b**), $[BPh_4]$ (**1c**); A = Cl, R′ = H, R″ = Ph (**10a**), Et (**10b**)} which had been reported earlier[1]. The data are summarised in Table 1. Each was insoluble in hydrocarbons or Et_2O, but readily soluble in CH_2Cl_2. As a general rule, the NH compounds (i.e., R′ = H) **4**, **10a** and **10b** were thermally stable and were easily crystallised from aromatic solvents, while solutions of the $NSiMe_3$ derivatives **1a**−**2d** were much less so and, in particular for A = Cl, decomposed at room temperature. Compounds with the bulkier anions (A = $[OSO_2CF_3]$ or $[BPh_4]$) were sufficiently stable to be purified by recrystallisation from mixtures of CH_2Cl_2 and Et_2O or pentane.

The ^{31}P-NMR spectral shift values for the λ^4P^+ (Table 1) were in the region reported for typical phosphonium salts[7]. The assignments of individual ^{31}P-NMR spectroscopic shift values and $J_{H\text{-}P}$ coupling constants were made on the basis of 2D-^{31}P-^{1}H correlation experiments for **2d**, **4**, **10a**, and **10b** (as an example, see Figure 1). These showed cross-peaks for NH, CH, and for each set of *o*-hydrogen atoms at the benzene rings of the λ^4P^+ and hence established the identity of the λ^4P^+. The remaining doublet is consequently attributed to λ^3P, an assignment further supported by its broadening attributable to the quadrupolar moment of the adjacent nitrogen atom.

The $^1J_{PP}$ coupling constants were on the low side of previously reported values (240−424 Hz)[8][9][10] in related systems, but showed the general trend[8] of increasing with increasing electron-donating strength of the substituent at the λ^3P (**2c** being an exception).

The comparatively small effect of changing the anion A^- (compounds **1a**−**1c**, **2a**, **2c**, **2d**) on the ^{31}P-NMR shift value for λ^3P, and in particular on the size of the $^1J_{PP}$ coupling constants makes it plausible to assume that in solution the phosphonium salts exist as separated ion pairs even for the comparatively small chloride anion. Larger differences in ^{31}P-NMR spectroscopic shifts {$\Delta\delta[^{31}P(\lambda^3P)]$ = 6−18 ppm} and coupling constants (Δ^1J_{PP} = 35−58 Hz) in the related urea-bridged derivatives [*t*Bu(Ph)P^aP(R)N(Me)-C(O)N^b(Me)(P^a-N^b)]A (R = Me, Et, *i*Pr, *t*Bu, Ph, Xyl, 9-Anth, $CHCl_2$, or CH_2SiMe_3) have been attributed to a change in structure from a zwitterionic form for the chloride to a separated ion pair for the tetraphenylborate[8].

Other interesting features were: (i) the ^{1}H-NMR spectroscopic shift of the ring C*H* adjacent to λ^4P^+ seemed to depend mainly on the nature of the counterion. Independent of other substituents they varied from $\delta \approx 10$ for A = Cl, through $\delta \approx 8$ for A = $[OSO_2CF_3]$ to $\delta \approx 6$ for A = $[BPh_4]$; (ii) the large $^4J_{H\text{-}\lambda^4P}$ coupling constants of 10−16 Hz for the NH compounds **4** and **10**; and (iii) $\delta[^{13}C\{^1H\}]$ = 78 for the ring *C*H and δ = 190 for the ring *C*N, a value usually associated with a carbon atom doubly bonded to an oxygen or nitrogen atom. Items (ii) and (iii) indicate a considerable delocalisation of π-electron density in the heterocycle between N and λ^4P^+.

The ^{31}P-NMR spectroscopic shift of $\delta \approx 186$ for the endocyclic phosphorus atom of the diazadiphosphetidine **3a**, **3b**, or **7** in $CDCl_3$ solution is appropriate for each having *trans*-orientated substituents at the phosphorus atom[11][12][13][14][15][16][17][18][19][20][21]. While **7** showed only a singlet for the magnetically equivalent phosphorus atoms of the PN heterocycle, the spectrum of **3a** indicated the presence of two isomers in a ratio of approximately 3:1. The set of signals of the major isomer assigned to be of the *anti* isomer (as in the crystal) showed an AA′XX′ spectral pattern with two pseudo triplets, one for the PPh_2 (X) groups at δ = −29.4 and the other for the ring phosphorus (A) at δ = 186.6. The spectrum was readily simulated on the basis of J_{AX} = 202.6 and $J_{AA'}$ = 20.4 Hz. The CP-MAS ^{31}P-NMR spectrum of **3a** showed the signals only of the major (δ = −29.4 and δ = 186.6, J_{PP} = 190 Hz), but not of the minor, isomer. It is, however, not inevitable that the minor isomer exists only in solution and not in the solid, because the larger line width and the less favourable signal-to-noise ratio of the solid-state NMR spectrum compared to that in solution may have obscured the CP-MAS signals of the minor isomer. The solution ^{31}P-NMR spectrum of the latter showed features consistent with its being the *syn* isomer, having a conformation similar to **5a**. Only a doublet was observed for the PPh_2 groups, while the ring phosphorus atom close to the PPh_2 groups gave rise to a triplet of doublets due to a coupling with *P*Ph_2 and the other endocyclic phosphorus atom, respectively. Variable-temperature solution ^{31}P-NMR spectroscopic studies on the isomeric mixture of **3a** showed no temperature dependence for the ratio

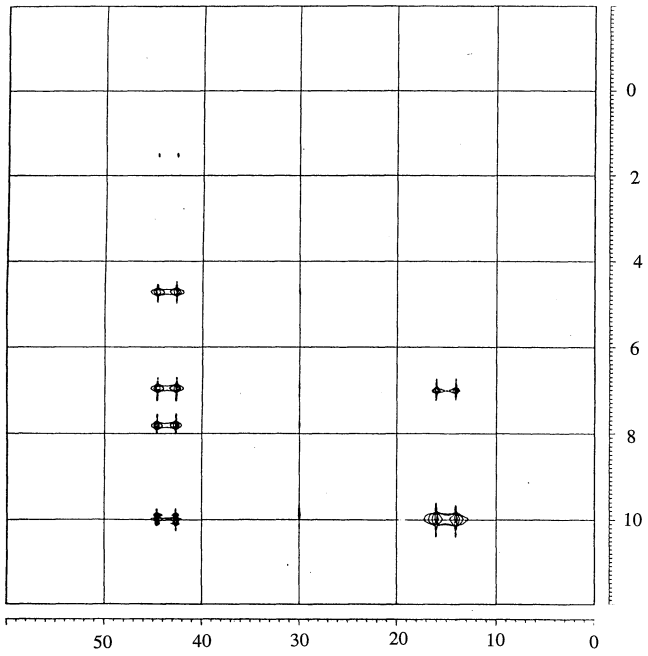
Figure 1. 2D-^{31}P{^{1}H} ^{1}H-NMR correlation spectrum of $Ph_2P^aP(Ph)N(H)C(t\text{Bu})=C^bH(P^a-C^b)Cl$ (**10a**)



of the two isomers between −45 and +60°C, while prolonged heating (12 h at 60°C) led to complete decomposition of the sample. No signals attributable to the formation of a *cis* isomer were observed.

In solutions of the metal complexes **5a** or **5b**, the ^{31}P-NMR spectral signal for the metal-coordinated ring phosphorus atoms was shifted by ca. 50 ppm to lower frequency, whereas the influence on the chemical shifts of the PPh_2 groups was only small. Probably due to the quadrupolar moment of the coordinated copper centre, the lines were, particularly for **5a**, so broad that any coupling information was obscured. Slightly sharper lines were observed for **5b**, so that $J_{P(A)P(X)}$ = 297 Hz was determined, being ca. 100 Hz larger than in the free ligand **3a**. The unusual magnitude of these coupling constants in **3** and **5**, being in the lower range of reported directly bonded P-P coupling constants[11], is attributed to a through-space coupling rather than a $^4J(^{31}P\text{-}^{31}P)$. This is supported by the close P···P contacts between phosphane and ring phosphorus atoms in the crystal structures of **3a** [3.262(1) Å] and **5a** [3.252(3) and 3.319(3) Å]. A similar effect had been observed for **6**, where the closeness of the ring phosphorus atom and the trimethylsilyl group gave rise to a coupling ($J_{P\text{-}H}$ = 1.3 Hz[1]) between these two groups.

There has been much interest in the *cis*/*trans* isomerism in 1,3,2,4-diazadiphosphetidines, with the *cis* generally the thermodynamically and the *trans* the kinetically favoured isomer (refs.[14][15][16][17][18][19][20][21][22][23], and literature cited therein). For bulky ligands at N and P, the *trans* isomer is usually thermodynamically favoured. Studies into the relationship between isomer and the chemical shift δ(^{31}P) showed the signals of the *cis* isomer to be ca. 50−90 ppm at higher frequency than in the *trans* isomer[14][18][19][20][21][22][23]. Each of the diazadiphosphetidines having the bulky C(*t*Bu)=C(H)R′ (R′ = $SiMe_3$ and PPh_2) substituent at N, which we have so far characterised, has invariably adopted the *trans* conformation.

The ^{31}P-NMR spectroscopic shifts previously reported for *trans*-diazadiphosphetidines coordinated to metals were for most part in the same region (δ ≈ 130−170[2]) as observed for **5a** and **5b**. Only for Pd or Pt complexes, values of 40 or 80 ppm to lower frequency have been observed. The direction of the shift change, as between the free ligand and the complex upon coordination, seems largely to depend on the metal[2]. Since **5a** and **5b** are, to our knowledge, the first compexes of diazadiphosphetidines with copper, no comparative data are available.

The structures of **8** and **9** were determined with the help of multinuclear NMR spectra and MS. The assignments of the ^{13}C-NMR spectroscopic shifts were made on the basis of (i) their chemical shift values and (ii) the information derived from $J_{P\text{-}C}$ coupling constants (when compared with literature data[24]). The interpretation of the ^{1}H-NMR spectroscopic shift data required NOE-difference NMR-spectroscopic studies. Irradiation of an individual *t*Bu group gave a 6.4% enhancement for the olefinic CH signal, while irradiation of the CNMe group gave enhancements of 3.9 and 2.0% for the CH and the *exo*-H at the neighbouring CH_2 group, respectively. The hydrogen atoms of the remaining CH_2 groups were not unambiguously identified, as any NOE enhancement was obscured due to the closeness of these signals to the centre of irradiation.

The spectra of **9** were very similar to those of **8**, the major difference being a higher frequency shift of the CH proton in the ^{1}H-NMR spectrum and a similar effect in the ^{13}C-NMR spectrum for the carbon atom directly bonded to the phosphorus atom (**8**: C*H*: δ = 5.83; *C*P: δ = 183.2; **9**: C*H*: δ = 5.26; *C*P: δ = 166). A further difference was the magnitude of the coupling constants of the nuclei close to the phosphorus atom, being much larger for **9** [$^{3}J(^{1}H\text{-}^{31}P)$ = 30.0; $^{1}J(^{13}C\text{-}^{31}P)$ = 94.4; $^{2}J(^{13}C\text{-}^{31}P)$ = 46.4 Hz] than for **8** [$^{3}J(^{1}H\text{-}^{31}P)$ = 17.1; $^{1}J(^{13}C\text{-}^{31}P)$ = 4.1; $^{2}J(^{13}C\text{-}^{31}P)$ = 36.0 Hz].

X-ray Structural Analysis of 3a and 5a

The X-ray molecular structures of **3a** and **5a** are illustrated in Figures 2 and 3, with the atom-numbering scheme and selected bond lengths and angles being shown in Tables 2 and 3.

The crystalline compound **3a** is centrosymmetric and adopts a *trans* configuration with the substituents at N(1) being *anti* to one another. The $P^{a}NPN^{a}(P^{a}-N^{b})$ ring is planar, with the *N*-ligating sp^2-carbon atoms also coplanar, the sum of angles at nitrogen (Σ N) being 360°. The endocyclic ring angle at nitrogen, 100.8(1)°, is much larger than that at phosphorus, 79.2(1)°. The N(2)−P(2)−N(1) and N(2)−P(2)−N(1′) bond angles are significantly narrower than tetrahedral, indicating the presence of a stereochemically active lone pair at P(2). The alkenyl groups have the (*E*) configuration, so as to minimise steric effects, the *tert*-butyl group being *trans* to PPh_2. As a consequence, there are close contacts between the phosphorus atom of one diphenylphosphane group [P(1)] and one ring phosphorus atom [P(1)−P(2): 3.262(1) Å] which may account for the large coupling constant between P(1) and P(2) (J_{PP} = 190 Hz) observed in the solid-state ^{31}P-NMR spectrum. The *exo* P−N distances [P(2)−N(2): 1.671(3) Å] are much shorter than the *endo* ones [P(2)−N(1): 1.751(1); P(2)−N(1′): 1.730(2) Å].

In general, the skeletal geometry of **3b** closely resembles that of other known *trans*-1,3,2,4-diazadiphosphetidines, such as $[(MeO)PN(Ph)]_2$[25], $\{[F_3C(F_2C)_2H_2C]PN(tBu)\}_2$[21], $[(F_3CH_2CO)PN(Ph)]_2$[14], $[(Ph_2N)PN(Ph)]_2$[17], $[(C_6H_4Me\text{-}4)OPN(Ph)]_2$[20], $[Me_2C^{a}(CH_2)_3(Me)_2C^{b}NPN(SiMe_3)(C^{a}-C^{b})]_2$[26] and $\{[Me_3Si)_2N]PN(SiMe_3)\}_2$[27].

In the CuI complex **5a**, the copper centre is surrounded in a distorted tetrahedral fashion by the iodine, the ring phosphorus P(1) and the two phosphorus atoms P(3) and P(4) of the *exo*-diphenylphosphane groups, Figure 4. The coordination to the metal atom leads to a *syn* conformation in the diazadiphosphetidine and a slight puckering

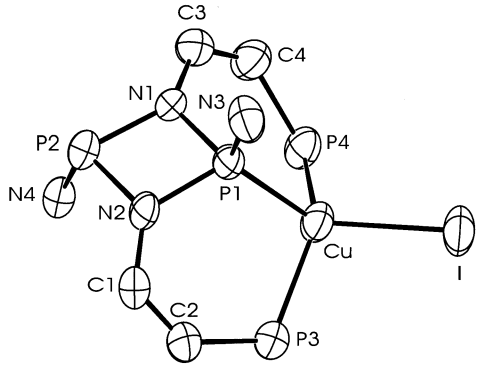
of the PN heterocycle [angle between the planes P(1)N(2)P(2) and P(1)N(1)P(1): 5.7(7)°]. The *exo* P−N bond lengths [P(1)−N(3): 1.643(7); P(2)−N(4): 1.649(8) Å] are considerably shorter than the *endo* ones [P(1)−N(2):

1.736(6); P(2)−N(1): 1.754(6); P(1)−N(1): 1.723(7); P(2)−N(2): 1.755(7) Å], but the influence of metal coordination on the endocyclic P−N bonds is only small (Table 2). The Cu−I [2.574(1) Å] and Cu−P distances [Cu−P(1): 2.223(2); Cu−P(3): 2.306(3); Cu−P(4): 2.292(3) Å] are within the range of values reported for four- and three-coordinated phosphanecopper(I) complexes: $[CuI(PPh_3)_3]$ triclinic: $Cu-P_{av.}$ 2.34(1), Cu−I 2.686(1) Å[28]; $[CuI(PPh_3)_3]$ trigonal: $Cu-P_{av.}$ 2.355(8), Cu−I 2.67(1) Å[28]; $[(Cu\{\mu\text{-}I\}\{P(c\text{-}C_6H_{11})_3\})_2]$: Cu−P 2.23(1), $Cu-I_{av.}$ 2.58(1) Å[29]; $[(Cu\{\mu\text{-}I\}\{P(Ph)(CH_2CH_2PPh_2)_2\})_2]$: Cu−P 2.263(4)−2.325(5), Cu−I 2.614(2) Å[30]; $[Cu(PMe_3)(\mu\text{-}I)_2Cu(PMe_3)_2]$[31], $[\{Cu(\mu\text{-}I)(PPh_2Me)\}_2] \cdot SO_2$: $Cu-P_{av}$ 2.250(2), $Cu-I_{av}$ 2.719(1) Å[32]; $[(Cu\{\mu\text{-}I\}\{P(C_6H_4Me\text{-}4)_3\})_2](C_6H_5Me)_2$: Cu−P 2.238(4), $Cu-I_{av}$ 2.583(2) Å[33]. For two-coordinate phosphanecopper complexes, the observed Cu−P distances are usually slightly smaller: $[CuBr\{P(C_6H_2Me_3\text{-}2,4,6)_3\}]$ 2.193(2) Å[34]; $[CuX\{P(C_6H_2(OMe)_3\text{-}2,4,6\}_3]$ with X = Cl 2.177(1), X = Br 2.197(3), X = I, Cu−P 2.188(4) Å[35]; $[Cu\{N(SiMe_3)C(tBu)=C(H)SiMe_3\}(PPh_3)]$ 2.145(3) Å[36]. Apart from the already mentioned puckering of the ring, the nature of the backbone of the heterocycle in **5a** is similar to that of the free ligand **3a**.

Figure 4. Molecular structure of **5a** (core atoms only)



We are grateful to the *E.U.* for the award of a fellowship to M. L., within the framework of the HCM Programme (Contract No. ERBCHBGCT930264) and *ESPRC* for a follow-up grant for M. L. We also thank Dr. *A. C. Avent*, Mr. *C. Dadswell*, Dr. *G. Lawless*, and Professor *P. J. Parsons* for helpful discussions.

Experimental Section

All manipulations were carried out under argon, using standard Schlenk techniques. Solvents were distilled from drying agents and degassed. − The NMR spectra were recorded in C_6D_6 or $CDCl_3$ at 298 K using the following Bruker instruments: AC-P 250 (^{1}H 250.1 MHz; ^{11}B 80.3 MHz; ^{13}C 62.9 MHz; ^{31}P 101.2 MHz), DPX 300 (^{1}H 300.1 MHz; ^{13}C 75.5 MHz; ^{31}P 121.5 MHz), and AMX 500 (^{1}H 500.1MHz; ^{13}C 125.7 MHz) and referenced internally to residual solvent resonances in the case of ^{1}H and ^{13}C spectra. The ^{31}P and ^{11}B spectra were referenced externally to H_3PO_4 and $BF_3(OEt_2)$, respectively. Unless otherwise stated, all NMR spectra, other then ^{1}H, were proton-decoupled. − Electron-impact mass spectra were taken from solid samples using a Kratos MS 80 RF instrument. − Melting points were taken in sealed capillaries and are uncorrected. Elemental analyses were determined by Medac Ltd., Brunel University. Due to incorporation of solvent, some of the phoshonium salts and the copper complexes **5** gave unsatisfactory elemental analyses.

Preparation of the Phosphonium Chlorides $[Ph_2P^aP(NR'_2)N(SiMe_3)C(tBu)=C^bH(P^a-C^b)]A$ (**2a**: R′ = Et, A = Cl; **2b**: R′ = Me, A = Cl; **2c**: R′ = Et, A = OSO_2CF_3; **2d**: R′ = Et, A = BPh_4): Me_3SiNEt_2[2] (0.34 ml, 1.82 mmol) was added to a solution of $[Ph_2P^aP(Cl)N(SiMe_3)C(tBu)=C^bH(P^a-C^b)]Cl$ (**1**)[1] (0.83 g, 1.82 mmol) in CH_2Cl_2 (15 ml) at −50°C. The yellow solution was slowly warmed to room temperature and stirred for 1 h. Removal of volatiles in vacuo gave crude **2a** (0.90 g, 100%). − ^{1}H NMR ($CDCl_3$): δ = 0.15 [s, $SiMe_3$], 0.84 [s, broad, Me], 1.61 [s, *t*Bu], 2.2−3.1 [m, very broad, CH_2], 7.52−7.69 [Ph, 10 H], 10.08 [dd, CH, $J(^1H\text{-}^{31}P)$ 27.5 and 27.6 Hz]. − ^{31}P NMR ($CDCl_3$): δ = 74.4 [d, λ^3P, $^1J(^{31}P\text{-}^{31}P)$ = 269.1 Hz], 29.0 [d, λ^4P, $^1J(^{31}P\text{-}^{31}P)$ = 269.1 Hz].

Crude compound **2b** (1.45 g, 100%) was prepared in an identical fashion, from **1** (1.40 g, 3.07 mmol) and Me_3SiNMe_2 (0.49 ml, 3.07 mmol). − ^{1}H NMR ($CDCl_3$): δ = 0.13 [s, $SiMe_3$], 1.59 [s, *t*Bu], 2.60 [s, very broad, CH_3], 5.26 [s, CH_2Cl_2], 7.46−7.73 [Ph, 10 H], 9.90 [s, broad, CH]. − ^{31}P NMR ($CDCl_3$): δ = 74.9 [d, λ^3P, $^1J(^{31}P\text{-}^{31}P)$ = 263.5 Hz], 30.1 [s, broad, λ^4P^+]. − ^{13}C NMR ($CDCl_3$): δ = 5.2 [s, $SiMe_3$], 30.9 [s, $C(CH_3)_3$], 41.3 [d, $C(CH_3)_3$, $^3J(^{13}C\text{-}^{31}P)$ = 13.8 Hz], NMe_2 signal not observed, 53.4 [s, CH_2Cl_2], 69.0 [d, CH, $^1J(^{13}C\text{-}^{31}P)$ = 20.2 Hz], 120.1 [d, *ipso* C, $^1J(^{13}C\text{-}^{31}P)$ = 66.3 Hz], 127.3−133.7 [Ph], 190.6 [s, broad, CN].

Compound **2c** or **2d** was obtained by adding $Ag(OSO_2CF_3)$ (0.21 g, 0.81 mmol) or $Na[BPh_4]$ (0.46 g , 1.36 mmol) at −40°C to a solution of **2a** (0.4 g, 0.81 mmol; or 0.67 g, 1.36 mmol, respectively) in CH_2Cl_2 (15 ml). The mixture was allowed to warm to room temperature and was stirred for another 4 h or 2.5 h, then filtered and all volatiles were removed from the filtrate in vacuo. The crude product was recrystallised from a mixture of CH_2Cl_2 and pentane to give colourless crystals of **2c** (0.36 g, 75%) or **2d** (0.59 g, 68%).

2c: ^{1}H NMR ($CDCl_3$): δ = 0.13 [s, $SiMe_3$], 0.74 [m, broad, Me], 1.56 [s, *t*Bu], 2.50 [m, very broad, CH_2], 3.09 [m, very broad CH_2], 7.60−7.84 [Ph, 10 H], 7.97−8.04 [d, 2 H], 8.23 [dd, CH, $^3J(^1H\text{-}^{31}P)$ 27.7 Hz, $^2J(^1H\text{-}^{31}P)$ 19.7 Hz]. − ^{31}P NMR ($CDCl_3$): δ = 84.5 [d, λ^3P, $^1J(^{31}P\text{-}^{31}P)$ = 190.4 Hz], 31.2 [s, very broad, λ^4P^+]. − ^{13}C NMR ($CDCl_3$): δ = 5.0 [s, $SiMe_3$], 13.1 [s, Me], 30.3 [s, $C(CH_3)_3$], 41.4 [d, $C(CH_3)_3$, $^3J(^{13}C\text{-}^{31}P)$ = 13.0 Hz], 45 [s, very broad CH_2], CH and OSO_2CF_3 signals not identified, 116.9 [d, *ipso* C, $^1J(^{13}C\text{-}^{31}P)$ = 71.2 Hz], 118.7 [d, *ipso* C, $^1J(^{13}C\text{-}^{31}P)$ = 50.6 Hz], 130.1 [d, Ph, $J(^{13}C\text{-}^{31}P)$ = 12.4 Hz], 130.5 [d, Ph, $J(^{13}C\text{-}^{31}P)$ = 13.1 Hz], 132.7 [d, Ph, $J(^{13}C\text{-}^{31}P)$ = 9.9 Hz], 133.8 [s, Ph], 134.3 [s, Ph], 135.1 [d, Ph, $J(^{13}C\text{-}^{31}P)$ = 9.4 Hz], 188.8 [d, CN, $^2J(^{13}C\text{-}^{31}P)$ = 11.8 Hz].

2d · $(CH_2Cl_2)_{0.5}$: Mp 105°C (dec.). − $C_{49.5}H_{60}BClN_2P_2Si_2$ (819.41): calcd. C 72.6, H 7.38, N 3.42; found C 70.7, H 7.30, N 3.39. − ^{1}H NMR ($CDCl_3$): δ = 0.22 [s, $SiMe_3$], 0.69 and 0.80 [s, broad, Me], 1.40 [s, *t*Bu], 2.24−2.93 [m, very broad, CH_2], 5.28 [s, CH_2Cl_2], 6.11 overlapping dd, CH, $J(^1H\text{-}^{31}P)$ = 29.5 Hz], 6.94 [t, 4 H, $J(^1H\text{-}^{31}P)$ = 7.1 Hz], 7.07 [t, 8 H, $J(^1H\text{-}^{31}P)$ = 7.3 Hz], 7.48−7.69 [m, 16 H]. − ^{31}P NMR ($CDCl_3$): δ = 86.5 [d, λ^3P, $^1J(^{31}P\text{-}^{31}P)$ = 279.5 Hz], 33.2 [d, λ^4P^+, $^1J(^{31}P\text{-}^{31}P)$ = 279.5 Hz]. − ^{11}B NMR ($CDCl_3$): δ = −9.1. − ^{13}C NMR ($CDCl_3$): δ = 5.0 [s, $SiMe_3$], 14.8 [s, Me], 30.3 [s, $C(CH_3)_3$], 40.6 [d, $C(CH_3)_3$, $^3J(^{13}C\text{-}^{31}P)$ = 14.1 Hz], 41.5 [s, CH_2], δ 43.7 [d, CH_2 $^1J(^{13}C\text{-}^{31}P)$ = 37.0 Hz], δ 53.4 [s, CH_2Cl_2], δ 72.5 [d, CH, $^1J(^{13}C\text{-}^{31}P)$ = 16.9 Hz], 118.3 [d, *ipso* C, $^1J(^{13}C\text{-}^{31}P)$ = 68.0 Hz], 121.5 [s, BPh], 122.5 [d, *ipso*-C, $^1J(^{13}C\text{-}^{31}P)$ = 24.7 Hz], 125.4 [s, BPh], 130.1 [t, Ph], 132.0 [d, Ph, $J(^{13}C\text{-}^{31}P)$ = 6.4 Hz], 133.5 [d, Ph, $J(^{13}C\text{-}^{31}P)$ = 9.7 Hz],

$SiMe_3$], 1.19 [s, *t*Bu], 2.75 [d/t, NMe_2], 4.36 [s, CH]. − ^{31}P NMR (C_6D_6): δ = 187. − ^{13}C NMR (C_6D_6): δ = 2.0 [s, $SiMe_3$], 30.6 [s, $C(CH_3)_3$], 37.7 [t, NMe_2, $^2J(^{13}C\text{-}^1H)$ = 9.1 Hz], 39.8 [s, $C(CH_3)_3$], 100.4 [s, CH], 160.8 [s, CN].

Preparation of $N^aC(tBu)C(H)C^eP^aN(Me)(CH_2)_2N^cMe(N^a{-}P^a)(C^c{-}N^c)$ (**8**): A mixture of [$ClP^aN(R)P(Cl)N^bR(P^a{-}N^b)$] (**6**)[1] (0.71 g, 1.5 mmol) and [$=C^aN(Me)(CH_2)_2N^aMe(C^a{-}N^a)]_2$[3] (0.30 g, 1.5 mmol) in toluene (15 ml) was stirred for 60 h at 50°C. Removal of the solvent and distillation (130°C, 10^{-2} Torr) of the residue in vacuo gave the yellow oil **8** (0.22 g, 32%), which slowly crystallised; mp 58−60°C. − MS; *m*/*z* (%): 225 (80) $[M]^+$, 210 (67) $[M - Me]^+$, 197 (10) $[M - CH_2CH_2]^+$, 182 (90) $[M - MeNCH_2]^+$. −^{1}H NMR ($CDCl_3$): δ = 1.36 [s, *t*Bu], 2.08 [m, CH_2], δ 2.30 [m, CH_2], 2.37 [m, CH_2], 2.41 [d, NMe $^4J(^1H\text{-}^{31}P)$ = 2.7 Hz], 2.58 [d, NCH_3 $^3J(^1H\text{-}^{31}P)$ = 12.9 Hz], 3.06 [ddd, CH_2], 5.83 [d, CH, $^3J(^1H\text{-}^{31}P)$ = 17.1 Hz]. − ^{31}P NMR ($CDCl_3$): δ = 98.9 [s]. − ^{13}C NMR ($CDCl_3$): δ = 29.2 [d, $C(CH_3)_3$, $^4J(^{13}C\text{-}^{31}P)$ = 2.3 Hz], 38.4 [d, $C(CH_3)_3$, $^3J(^{13}C\text{-}^{31}P)$ = 7.5 Hz], 40.6 [s, NCH_3], 42.9 [d, NCH_3 $^2J(^{13}C\text{-}^{31}P)$ = 38.5 Hz], 51.5 [d, NCH_2, $^2J(^{13}C\text{-}^{31}P)$ = 3.1 Hz], 53.7 [s, NCH_2], 98.5 [d, CH, $^2J(^{13}C\text{-}^{31}P)$ = 36.0 Hz], 183.2 [d, CP, $^1J(^{13}C\text{-}^{31}P)$ = 4.1 Hz], 185.8 [s, CN].

Preparation of $N^aC(tBu)C(H)C^eP^a(S)N(Me)(CH_2)_2N^cMe(N^a{-}P^a)(C^c{-}N^c)$ (**9**): Sulfur (0.02 g, 0.63 mmol) was added to a solution of **8** (0.1 g, 0.44 mmol) in toluene (5 ml) and the mixture was stirred for 15 h, then filtered and the solvent removed from the filtrate in vacuo. Recrystallisation of the residue from Et_2O gave yellow crystals of **9** (0.07 g, 70%); mp 126°C (dec.). − HR-MS: calcd. for $C_{11}H_{20}N_3PS$ 257.1116; found 257.1118. − MS; *m*/*z* (%): 257 (100) $[M]^+$, 242 (15) $[M - Me]^+$, 224 (27) $[M - HS]^+$, 214 (65) $[M - MeNCH_2]^+$, 201 (15) $[M - Me_2C{=}CH_2]^+$. − ^{1}H NMR ($CDCl_3$): δ = 1.21 [s, *t*Bu], 2.05 [m, CH_2], 2.15 [s, NMe], 2.27 and 2.35 [m, CH_2], 2.56 [d, NMe, $^3J(^1H\text{-}^{31}P)$ = 12.0 Hz], 4.33 [ddd, CH_2], 5.26 [d, CH, $^3J(^1H\text{-}^{31}P)$ = 30.0 Hz]. − ^{31}P NMR ($CDCl_3$): δ = 83.6 [s]. − ^{13}C NMR ($CDCl_3$): δ = 28.2 [d, $C(CH_3)_3$], 35.3 [s, NCH_3], 35.3 [d, $C(CH_3)_3$, $^4J(^{13}C\text{-}^{31}P)$ = 25.0 Hz], 39.1 [d, NCH_3, $^2J(^{13}C\text{-}^{31}P)$ = 5.7 Hz], 46.8 [s, NCH_2], 50.9 [d, NCH_2, $^2J(^{13}C\text{-}^{31}P)$ = 12.4 Hz], 94.1 [d, CH, $^2J(^{13}C\text{-}^{31}P)$ = 46.4 Hz], 166.9 [d, CP, $^1J(^{13}C\text{-}^{31}P)$ = 94.4 Hz], 193.8 [d, CN, $^2J(^{13}C\text{-}^{31}P)$ = 7.5 Hz].

X-ray Structure Determination of the Diazadiphosphetidines **3a** *and* **5a**[37]: Data were collected with an Enraf-Nonius CAD4 diffractometer using monochromatic Mo-K_α radiation and single crystals sealed under argon in Lindemann capillaries. Cell dimensions were calculated from the setting angles for 25 reflections with 9° < θ < 13°. Intensities were measured by an ω-2θ scan. Corrections were made for Lorentz and polarisation effects and in the case of **5a** for absorption. There was no crystal decay as measured by two standard reflections. Positions of non-hydrogen atoms were derived by direct methods using SHELXS-86[38] and refined on F^2 with anisotropic thermal parameters by full-matrix least squares using SHELXL-93[39]. Further details are in Table 4.

Organometallic Compounds of Group 13, 54[◇]

Novel Organoborane Lewis Acids via Selective Boron-Tin Exchange Processes − Steric Constraints to Electrophilic Initiation by the Boron Halide☆

John J. Eisch*, and Boguslaw W. Kotowicz

Department of Chemistry, The State University of New York at Binghamton,

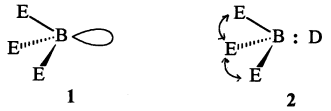
Received March 12, 1998

Keywords: Organometallics / Boron / Lithium / Tin / Metal-metal exchange / Electrophilic reagents

With the purpose of preparing novel mono- and bidentate organoboron Lewis acids, the scope and limitations of synthesizing the requisite organoboranes by the boron-tin exchange between a boron halide and the appropriate organostannane have been examined in detail. The following organotin derivatives have been obtained either from the corresponding RMgBr or RLi reagent and Me_nSnCl_{4-n} or from a Barbier procedure using the organic halide, Me_3SnCl and magnesium metal: 1,2-bis(trimethylstannyl)ethyne, *o*-, *m*-, and *p*-bis(trimethylstannyl)benzenes, α,*o*-bis(trimethylstannyl)toluene, α,α-bis(trimethylstannyl)-*o*-xylene, and 2,2-dimethyl-2-stannaindane. The individual interaction of the 1,2-bis(trimethylstannyl)ethyne and the isomeric bis(trimethylstannyl)benzenes with Et_2BBr produced the corresponding bis(diethylboryl)-derivatives. By contrast, with Et_2BCl the α,*o*-bis(trimethylstannyl)toluene gave only *o*-diethylboryl-α-trimethylstannyltoluene and with BCl_3 the α,α′-bis(trimethylstannyl)-*o*-xylene formed only α,α′-bis(chlorodimethylstannyl)-*o*-xylene. Furthermore, in the attempted double boron-tin exchange between *o*-bis(trimethylstannyl)benzene and BCl_3, an unprecedented rearrangement of the 1-(dichloroboryl)-2-(trimethylstannyl)benzene intermediate into its 1-[chloro(methyl)boryl]-2-(chlorodimethylstannyl) isomer was observed. Likewise, *o*-bis(trimethylstannyl)benzene with $PhBCl_2$ produced by a similar rearrangement 1-[methyl(phenyl)boryl]-2-(chlorodimethylstannyl)benzene. The thermolysis of such boranes led variously to definite dimers or ill-defined oligomers. Preliminary studies of the properties of these organoboranes have identified the heightened Lewis acidity of 1,2-bis(diethylboryl)ethyne and the π-electron delocalization involving the $2p_z$-boron orbitals in the 9,10-dihydro-9,10-diboraanthracene system. Finally, an electronic mechanism for the boron-tin exchange has been developed to account for the selectivity of the boron halide's attack at unsaturated carbon–tin bonds.

As part of an ongoing investigation of Ziegler-Natta olefin-polymerization catalysis the present study has explored the synthesis of novel Group-13 Lewis acids for their potential suitability as cocatalysts with cyclopentadienyl transition metal derivatives in such homogeneous polymerizations.[1][2][3][4] In this contribution the preparation of organoborane Lewis acids bearing substituents of enhanced electron-withdrawing power (**1**) and diminished steric demand (**2**) and possibility multidentate boron centers (**3**) has been the principal focus of research. The electron-withdrawing group E in **1** could favorably be a halide (F > Cl > Br > I) and an organyl group other than alkyl (sp^3) having greater *p*-character, such as aryl (sp^2) or 1-alkynyl (sp). As to steric demands (**2**), smaller groups E (Me versus *t*Bu; 1-alkenyl versus alkyl; and 1-alkynyl versus 1-alkenyl) should engender less B-strain upon the boron center accepting the donor group D and rehybridizing to sp^3. Finally, the coordination of suitably sized donor D (**3**) should be stabilized by chelation, as has been abundantly established by the pioneering researches of Köster and coworkers with *cis*-1,2-diborylalkenes.[5]



In order to synthesize the required organoborane Lewis acids, most of which are mixed or unsymmetrical boranes, such as $PhBCl_2$ or $Et_2B-C\equiv C-BEt_2$, a preparative route occurring under mild conditions is required, so as to minimize any tendency of the desired product E_2BE' to redistribute rapidly into E_3B and E'_3B.[6] For this desideratum it was found that the transmetallation reaction between the appropriate organostannane and a boron halide was generally a feasible route (Eq. 1).[7]

$$R{-}SnMe_3 + \underset{E = R, X}{Et_2B{-}X} \longrightarrow \underset{\mathbf{1}}{R{-}BE_2} + Me_3Sn{-}X \qquad (1)$$

In some situations where such a tin-boron exchange failed to produce the desired borane, it was instead found

that the analogous tin-lithium exchange is more suitable and that the desired transformation is then attainable by treating the lithium derivative RLi with E_2B-X (Eqs. 2, 3).

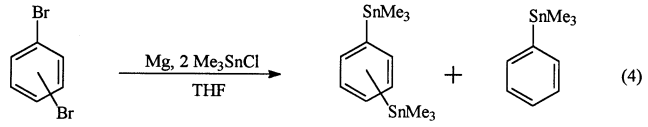
$$R-SnMe_3 \xrightarrow[\text{eq. 2}]{Bu^nLi} R-Li \xrightarrow[\text{eq. 3}]{E_2B-X} R-BE_2 \quad \mathbf{1}$$
$$\text{- } Bu^nSnMe_3 \qquad \text{- LiX}$$

Finally, each of the successes or failures of the tin-boron exchanges in achieving its intended transformation has provided us with valuable insight into the reaction mechanisms of such processes.

Results

Preparation of Organotin Precursors

Where successfully applicable, the organotin precursors, such as 1,2-bis(trimethylstannyl)ethyne (**3**), phenyl(trimethyl)tin (**4**), benzyl(trimethyl)tin (**5**), and 2,2-dimethyl-2-stannaindane (**6**) were prepared from the appropriate lithium or magnesium reagent and either Me_3SnCl or Me_2SnCl_2, as required, and were generally attainable according to published procedures[8] or procedures given in this article (cf. infra). The other precursors, containing two trimethylstannyl groups, were individually prepared from the corresponding organyl dibromide or dichloride by preparing the organomagnesium intermediate from magnesium metal in THF in the presence of the organotin chloride reactant (Barbier procedure[9]). Small to moderate amounts of the trimethylstannyl derivative (**9**) were formed as a side product (Eq. 4).



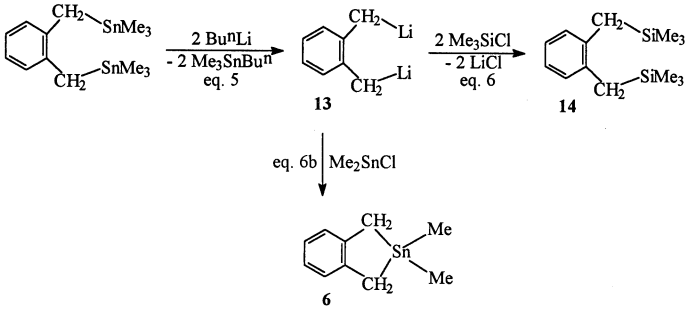
(4)

7a = o **8a** = 44% **9a** = 41%
7b = m **8b** = 49% **9b** = 23%
7c = p **8c** = 66% **9c** = 20%

In a similar manner, α,*o*-bis(trimethylstannyl)toluene (**10**) and α,α′-bis(trimethylstannyl)-*o*-xylene (**11**) were prepared from *o*-bromobenzyl bromide in 45% yield and from α,α′-dichloro-*o*-xylene in 85% yield, respectively.

Preparation of Organolithium Precursors

Unusual lithium reagents employed in this study were prepared by the following procedures: a) dilithioethyne (**12**) by either the action of 3 equivalents of *n*-butyllithium on trichloroethylene[10] or the action of 2 equivalents of the lithium reagent on acetylene; b) α,α′-dilithio-*o*-xylene (**13**) from stirring 2.2 equivalents of *n*-butyllithium and 1 equivalent of **11** vigorously for 96 h, whereupon a yellow precipitate of **13** formed; quenching such a reaction mixture with excess Me_3SiCl, hydrolytic work-up and distillation yielded 87% of α,α′-bis(trimethylsilyl)-*o*-xylene (**14**) and 90% of *n*-butyl(trimethyl)tin, indicating that **13** had been formed in at least 90% yield (Eqs. 5–6).



Similarly, the dissolution of **13** in anhydrous diethyl ether and the slow introduction of 1 equivalent of Me_2SnCl_2 led to the isolation of 75% of 2,2-dimethyl-2-stannaindane[11] (**6**) (Eq. 6b).

Preparation of Organoboranes by Boron-Tin Exchange Reactions

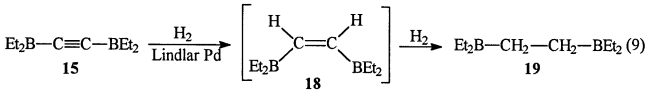
1,2-Bis(diethylboryl)ethyne (**15**): This organoborane could be prepared by the interaction of bromo(diethyl)borane (**16**) with dilithioethyne (**12**), but since the most convenient source of **12** involved the action of *n*-butyllithium on trichloroethylene in THF, **12** was generated as a solid complex with LiCl and 0.5 equiv. of THF. The complexed THF in 12 was then easily cleaved in the reaction of **12** with Et_2BBr, producing also **17** and lowering the yield of **15** (Eq. 7).

$$\underset{\mathbf{12}}{LiC\equiv CLi \cdot 0.5\ THF} \xrightarrow[(2.5\ \text{equiv.})]{Et_2BBr_2} \underset{\mathbf{15}\ 39\%}{Et_2B-C\equiv C-BEt_2} + \underset{\mathbf{17}\ 93\%}{Et_2B-O-(CH_2)_4Br} \quad (7)$$

The boron-tin exchange between **16** and 1,2-bis(trimethylstannyl)ethyne (**3**) in pentane precludes this side reaction and permits **15** to be isolated cleanly and in good yield (65%) by distillation. As with all such unsymmetrical boranes, their distillation had to be conducted at as low a temperature (and hence pressure) as possible to minimize redistribution and the formation of triethylborane (cf. infra) (Eq. 8).

$$\underset{\mathbf{3}}{Me_3Sn-C\equiv C-SnMe_3} \xrightarrow[\text{- } Me_3SnBr]{\mathbf{16}} \underset{\mathbf{15}}{Et_2B-C\equiv C-BEt_2} \xrightarrow{\Delta} Et_3B\uparrow \quad (8)$$

Attempts were made to reduce **15** selectively to (*Z*)-1,2-bis(diethylboryl)ethene (**18**) with dihydrogen and a Lindlar catalyst, but the hydrogenation could not be halted but proceeded to form 1,2-bis(diethylboryl)ethane (**19**) (Eq. 9). In recording the NMR spectra of **15** and **19** in various solvents, it was discovered that **15**, but not **19**, forms a complex with two equivalents of THF. For example, the ^{11}B signal of **15** in C_6D_6 occurs at $\delta = 72.0$ but in THF is found at $\delta = 36.9$.

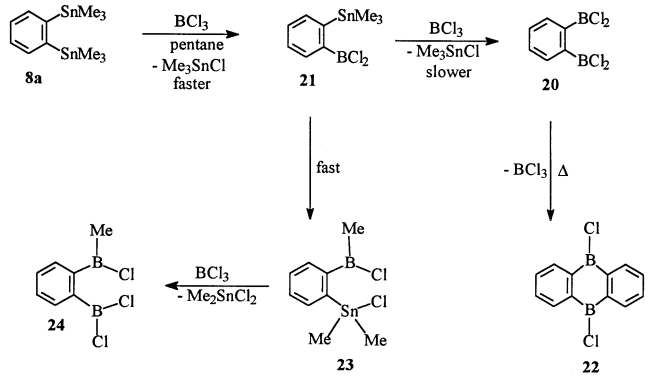


(9)

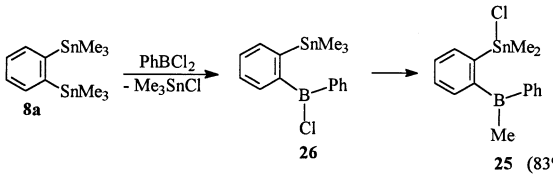
1,2-Bis(dichloroboryl)benzene (**20**): Despite the reported preparation of **20** in 88% yield from the interaction of **8a** with BCl_3 in a 1:3 ratio in CH_2Cl_2 at −78 °C,[12] attempts to

reproduce this result in our laboratory under the specified conditions or under a variety of modified procedures did not lead to high yields of isolable **20** but rather to the monomethylated derivative **24** when a large excess of BCl_3 was employed. Other reactions conducted with different ratios of reactants and in different solvents (alkanes, arenes, CH_2Cl_2) gave mixtures of **20**−**24**. An unmistakable sign that the reaction between **20** and BCl_3 (1:2 ratio) was taking an unexpected course was the isolation of a precipitate composed of 44% of the expected 2 equivalents of Me_3SnCl and 40% of 1 equivalent of the unexpected Me_2SnCl_2. The source of the Me_2SnCl_2 can best be explained by a relatively fast boron-tin exchange leading from **8a** to **21**, which rearranges relatively rapidly to **23** and this undergoes a second boron-tin exchange to produce **24** more rapidly than the diminished concentration of **21** can generate **20**. The small proportion of **22** produced could have arisen from either **20** or **24**.

Scheme 1

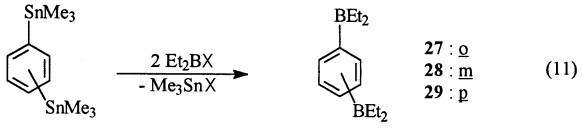


1-[Methyl(phenyl)bory]l-2-(chlorodimethylstannyl)benzene (**25**): Confirmation of the foregoing unusual rearrangement (**21**−**23**) came from the reaction of **8a** with phenylboron dichloride at −78°C. The by-product Me_3SnCl was isolated in 78% yield and **25** was isolated by distillation (Eq. 10), a clear indication that **26** is an intermediate in this novel transformation.



(10)

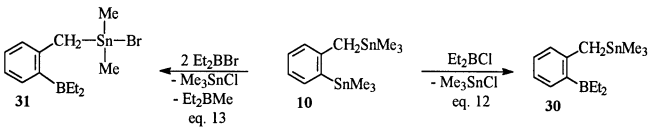
1,2-, 1,3-, and 1,4-Bis(diethylboryl)benzenes (**27**−**29**): These isomeric diborylbenzenes were readily prepared in high yield (> 80%) by treating the individual bis(trimethylstannyl)benzenes (**8a**−**8c**) with 2 equivs. of Et_2BBr or Et_2BCl and removing the Me_3SnX under reduced pressure at 50°C (Eq. 11).



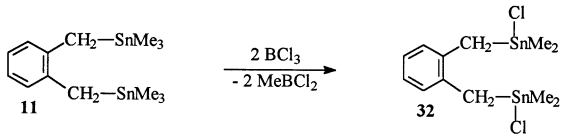
(11)

Diethyl(phenyl)borane could also be prepared similarly from trimethyl(phenyl)tin in 89% yield.

o-(Diethylboryl)-α-(trimethylstannyl)toluene (**30**): The interaction of α,*o*-bis(trimethylstannyl)toluene (**10**) with Et_2BCl (1:2 ratio) at 25°C led cleanly to 90% of **30** after all volatiles were removed (Eq. 12). When the reaction was conducted with Et_2BBr and with a 4-h heating period, boron-tin exchange had also occurred at tin−methyl bond of **30** as well, forming **31** also in 90% yield (Eq. 13).



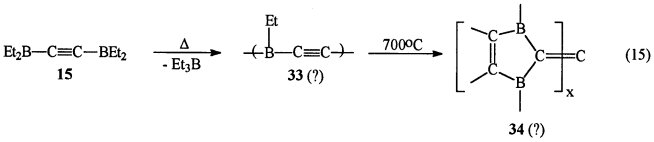
α,α′-Bis(dichloroboryl)-o-xylene (**32**) *(attempted):* The interaction of α,α′-bis(trimethylstannyl)-*o*-xylene (**11**) with BCl_3 (1:2 ratio) from −50 to 25°C led to the formation instead of 85% of α,α′-bis(chlorodimethylstannyl)-*o*-xylene (**32**), the product of the boron-tin exchange at the tin−methyl bond (eq. 14).



(14)

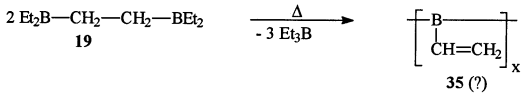
Thermolysis of Organoboranes

1,2-Bis(diethylboryl)ethyne (**15**): A neat sample of **15** was heated to 120°C and the evolved liquid permitted to reflux for 2 h. Evaporation of the evolved liquid under reduced pressure allowed the condensation of 1.0 equivalent of Et_3B and a red-brown viscous oil remained (**33**). Subsequent heating up to 700°C in a TGA apparatus left a shiny black residue of empirical formula (by elemental analyses) of $C_3B_2H_{0.14}$ (**34**) (Eq. 15).



(15)

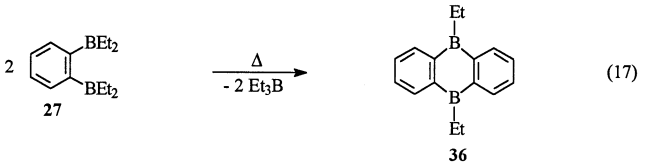
1,2-Bis(diethylboryl)ethane (**19**): Heating **19** to 180°C for 2 h and subsequent cooling similarly led to the evolution of 1.5 equiv. of Et_3B and a yellow residue (**35**) that lost no further weight up to 350°C in a TGA apparatus (Eq. 16).



(16)

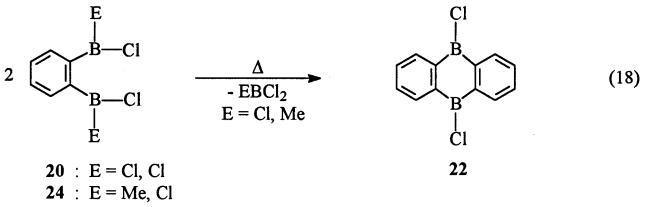
1,2-Bis(diethylboryl)benzene (**27**): Heating **27** in refluxing heptane for 18 h formed 9,10-diethyl-9,10-dihydro-9,10-diboraanthracene (**36**) almost quantitatively. The triethylborane eliminated was removed with the heptane by evaporation under reduced pressure. Yellow **36** was crystallized from pentane at −78°C (Eq. 17).

1,2-Bis(dichloroboryl)benzene (**20**) *or 1-(Dichloroboryl)-2-loro(methyl)boryl]benzene* (**24**): Individual samples or



(17)

mixtures of **20** and **24** gradually formed 9,10-dichloro-9,10-dihydro-9,10-diboraanthracene (**22**) when heated at reflux in heptane (Eq. 18). Samples of **22** were purified by sublimation as yellow needles.



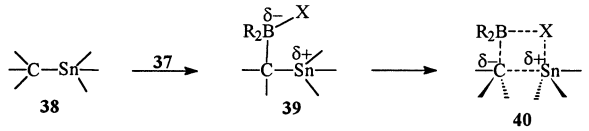
(18)

Discussion

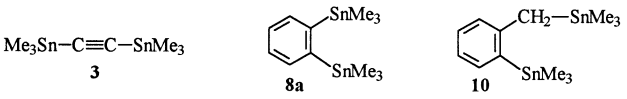
Selectivity of Boron-Tin Exchange

The attack by a boron halide R_2B-X (**37**) on an organotin substrate (**38**) can be viewed as passing through a transition state (**39**) involving electrophilic attack of R_2B-X on the C−Sn bond or one involving concerted electrophilic attack by boron and nucleophilic attack by halide (**40**) (Scheme 2).

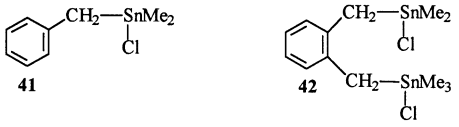
Scheme 2



If the carbon in **38** is involved in π-bonding (sp- or sp^2-hybridized carbon), this situation would explain why transition state **39**, involving principally electrophilic attack by R_2B-X, should be relatively lower in energy and hence rate-determining for the boron-tin exchange. Furthermore, transition state **39** would account readily for the following: 1) the selective borylation of **3** at the acetylenic carbon−tin bonds rather than the methyl carbon−tin bonds; 2) the exclusive borylation of mono- and bis(trimethylstannyl)benzenes, such as **8a**, at the aryl carbon−tin bonds; and 3) the sole monoborylation of **10** at the aryl carbon−tin bond, even when 2 equiv. of the boron halide, Et_2BCl, were employed. Thus, generally when an sp- or sp^2-hybridized carbon−tin bond is pitted against an sp^3-hybridized carbon−tin bond in boron-tin exchange processes, the former carbon centers always react faster (cf. infra for an intramolecular exception to this conclusion.)

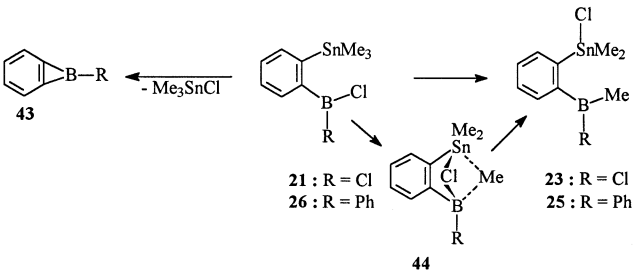


A further interesting structural example of such boron-tin exchanges are the benzylic trimethyltin derivatives, such as benzyltrimethyltin (**5**) and α,α-bis(trimethylstannyl)-*o*-xylene (**11**), which present competing carbon−tin bonds, namely benzylic C−Sn and methyl C−Sn bonds, both formally involving identical sp^3-hybridized carbon centers. When **5** and **11** were individually treated with an excess of BCl_3, they were converted into **41** and **42**, respectively. Thus, exchange took place selectively at the methyl carbon-tin bond. With the absence of any π-electron density at the carbon center, a transition state like **39** would no longer be a low-energy configuration and a bridging transition state resembling **40** may be more accessible. The carbon group bridging between tin and carbon would be more appropriate the smaller its steric requirements would be. Therefore, the greater reactivity of the methyl carbon−tin bond would stem from the methyl group's smaller steric size and better bridging property, compared with the bulkier benzyl group. It should be noted that trimethylaluminum exists as a stable dimer with bridging methyl groups, while tribenzylaluminum is monomeric.



The exceptional instance where an sp^3-hybridized carbon−tin bond enters into a boron-tin exchange more readily than an available sp^2-hybridized carbon−tin bond is the facile intramolecular boron-tin exchange first observed in this study (Scheme 1 and Eq. 10) and depicted generally in Scheme 3. Undoubtedly, the failure of **21** or **26** to undergo the boron-tin exchange with the elimination of Me_3SnCl and the formation of benzoborirene **43** stems from the extremely strained transition state of type **39** that would have been required. A four-center transition state involving the methyl groups (**44**), on the other hand, is easily attainable.

Scheme 3



Thermal Redistribution of Unsymmetrical Organoboranes

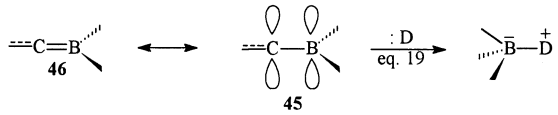
The unsymmetrical organoboranes synthesized in this study uniformly underwent a redistribution of groups upon heating over 100°C. With diethylboryl derivatives the amount of evolved triethylborane corresponded rather well with the selective formation of defined oligomers or polymers. The formation of the dihydro-9,10-diboraanthracene (**36**, Eq. 17) from the 1,2-diborylbenzene **27** and the production of some polymeric structure of the Et−B−C≡C− unit (**33**, Eq. 15) are illustrative. If such thermolyses are continued up to 700°C, there are indications that boron carbides of unusual stoichiometry may result. Such thermoly-

sis of diborylacetylene **15** yields a glistening black solid of approximate composition C_3B_2. Further work is required to learn whether this solid **34** (Eq. 15) is a novel boron carbide or a mixture of B_4C and carbon.[13]

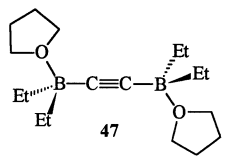
Unusual Properties of Unsymmetrical Organoboranes

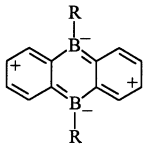
An exploration of the boron-tin exchange route to organoboranes has been undertaken, in order to prepare such boranes that might exhibit novel properties, such as enhanced Lewis acidity and unusual spectral properties.[14] Both kinds of properties would involve the ability of the $2p_z$-orbital on tricoordinate boron to accept electron density, either intermolecularily from a Lewis base (Eq. 19) or from an adjacent π-electron cloud (resonance structure **45** and **46**, Scheme 4).

Scheme 4



Although the study of the properties of such boranes has just begun, two observations are already noteworthy: 1) 1,2-bis(diethylboryl)ethyne (**15**) readily forms a stable bis-complex with THF (**47**), whereas the structurally similar 1,2-bis(diethylboryl)ethane (**19**) does not complex with THF at all nor do Et_3B, $PhBEt_2$, or the dihydro-9,10-diboraanthracene **36**; and 2) both the known 9,10-dichloro- (**22**) and the novel 9,10-diethyl- (**36**) -9,10-dihydro-9,10-diboraanthracenes absorb in the visible spectrum (yellow) and exhibit their ^{11}B-NMR signals shifted considerably upfield ($\delta <$ 70), that is, attributable to a more shielded boron nucleus, than those of $PhBEt_2$ or *o*-$(Et_2B)_2C_6H_4$ (**27**), whose ^{11}B signals occurs at $\delta = 78-80$. Both the electronic and the ^{11}B-NMR spectral data are consistent with the interaction of the $2p_z$-orbitals of boron in **22** and **36** with the adjacent π clouds (**48**).





As to the enhanced Lewis acidity of **15** over **19**, it is to be expected that the steric F-strain generated in complex **47** by the neighboring C≡C group would be somewhat smaller than that of an adjacent CH_2-CH_2 group in such a complex formed by **19** and two THF units. But such steric factors alone seem inadequate in explaining the enhanced acidity of **15**. Therefore, we propose that the enhanced electronegativity of the sp-hybridized carbon centers in **15** withdraws electron density more effectively along the σ C−B bond, thereby enhancing the Lewis acidity of boron.

Our continuing studies will investigate the significance and consequences of π-electron interactions between boron and unsaturated carbon.[15]

This research was initiated as part of a materials science project sponsored by *Akzo Corporate Research America Inc.* and was completed under support of the *National Science Foundation* and a Senior Scientist Award to the principal investigator by the *Alexander von Humboldt Foundation*

Experimental Section

General Techniques: All preparations and purification procedures involving manipulations with oxygen- and moisture-sensitive reagents were carried out under an anhydrous, oxygen-free argon or nitrogen atmosphere employing Schlenk techniques.[16] Those procedures which did not require a protective atmosphere but involved working with toxic chemicals (such as boron and tin compounds) were carried out in an exhaust hood evacuating air at 100 ft/min. For the operations under reduced pressure the required vacuum was provided either by a rotary vacuum oil pump (down to 0.1 Torr) or by a water pump (down to 10 Torr) and toxic volatiles were condensed in cold baths.

In instances when acetylene and hydrogen were used, tanks were connected through purification columns directly to the one of the manifold′s outlets. Acetylene was purified by passing through a bubbler with concentrated sulfuric acid and a 25-cm column filled with activated charcoal and 4-Å molecular sieves. Hydrogen was delivered to the system after passing through a similar column filled only with 4-Å molecular sieves. When a volume of hydrogen needed to be measured, a calibrated gas buret was used.

Commercially available solvents of reagent grade were purified according to the recommended methods.[16] Solvents used in reactions were always freshly distilled under argon or nitrogen from the appropriate drying agents: aliphatic hydrocarbons from $LiAlH_4$; toluene from sodium; dichloromethane from CaH_2; and ethers from sodium/benzophenone combination. Deuteriated solvents (Cambridge Scientific) for NMR measurements of oxygen- and moisture-sensitive substance were vacuum-transferred to the Schlenk glass vessels and stored over 4-Å molecular sieves under argon. − Nuclear magnetic resonance (NMR) spectra were recorded with Bruker AM 360 (^{1}H: 360.0 MHz, ^{11}B: 115.5 MHz, ^{13}C: 90.5 MHz, ^{27}Al: 93.8 MHz, ^{119}Sn: 134.2 MHz) or Bruker-IBM AM 300 (^{1}H: 299.9 MHz, ^{11}B: 96.2 MHz, ^{13}C NMR: 75.4 MHz, ^{27}Al: 78.2 MHz, ^{119}Sn: 111.8 MHz) instruments. [D_6]Benzene, [D]chloroform, or 95% tetrachloromethane and 5% [D_6]benzene mixture were used as solvents. The chemical shifts are reported on a δ scale in parts per million (ppm) from the reference signals set as $\delta = 0$. The following substances served as references: ^{1}H and ^{13}C NMR: tetramethylsilane (TMS), internal; ^{11}B NMR: boron trifluoride−diethyl ether ($BF_3 \cdot Et_2O$), external; ^{119}Sn NMR: tetramethyltin (Me_4Sn), external. − Gas chromatographic analysis (GC) was performed with a Hewlett-Packard Chromatograph, model 5880A, with helium as the carrier gas.

Lithium Compounds

Dilithioethyne (**12**). − *Method 1:*[10] A flask was charged with a solution of *n*-butyllithium (231 ml of 2.0 M pentane solution, 0.462 mol) and then the pentane was removed under vacuum. With cooling a mixture of freshly distilled THF (50 ml) and Et_2O (50 ml) was slowly added to the residue. The resulted solution was cooled to −78°C and stirred for 0.5 h. Then a solution of trichloroethylene (20.2 g, 0.154 mol) in 50 ml of Et_2O was added dropwise. After completion of the addition the resulting clear yellow solution was stirred for 2 h at −78°C and then allowed to warm up to ambient temperature. A white precipitate gradually began to fill the flask and at approximately 0°C the flask was full of solid. The solvents

were removed partly by filtration and partly in vacuum. The yellow solid was washed with pentane (2 × 100 ml), filtered, and dried under vacuum (0.5 Torr, 40°C). Analysis of the resulting powder (20.4 g) allowed an estimation of its composition as $Li_2C_2 \cdot LiCl \cdot 0.5$ THF with 29.8% content of dilithioethyne (6.07 g, 96%).[17]

Method 2: A solution of *n*-butyllithium (70 ml of 2.5 M in hexane, 0.175 mol) was diluted with freshly distilled hexane (100 ml) and cooled to −15°C. With vigorous stirring acetylene was then passed through the solution at a rate maintaining the reaction temperature below −10°C. After approximately 15 min, a white precipitate started to form. When gas evolution was evident (bubbling through the check valve) a slow delivery of acetylene was continued for 0.5 h and then stopped. The reaction mixture was allowed to warm up to room temperature and then was heated at reflux for 2 h to expel all dissolved gas. The solvent was removed partly by filtration and partly by evaporation in vacuum. The remaining white solid residue was washed with hexane (2 × 100 ml), filtered and dried in vacuum (0.5 Torr, 60°C). The resulting fine, white powder (3.40 g) was analyzed and found to have 92% of dilithioethyne (**12**) (3.13 g, 82%).

1,4-Dilithiobenzene: The reaction of 1,4-bis(trimethylstannyl)-benzene (0.86 g, 2.1 mmol) with *n*-butyllithium (2.8 ml of 1.6 M hexanes solution, 4.3 mmol) in pentane/diethyl ether (1:1 v/v, 10 ml) after stirring for 2 d gave 0.75 g of colorless precipitate. The precipitate was derivatized with methyl iodide to give 92% of *p*-xylene. *n*-Butyl(trimethyl)tin was formed in 95% yield.[11]

1,4-Bis(trimethylsilyl)benzene: To a similarly prepared suspension of 1,4-dilithiobenzene was added 2.1 equiv. of chlorotrimethylsilane. Usual work-up provided crude solid 1,4-bis(trimethylsilyl)-benzene, which was washed with cold pentane (90%; recrystallized from hexane, mp 92−93°C).

α,α′-Dilithio-o-xylene (**13**): The reaction of α,α′-bis(trimethylstannyl)-*o*-xylene (0.80 g, 1.85 mmol with *n*-butyllithium (2.4 ml of 1.6 M hexanes solution, 3.8 mmol) in pentane/diethyl ether (1:1 v/v, 10 ml) after stirring for 2 d gave 0.62 g of a bright yellow precipitate. The precipitate was derivatized with methyl iodide to give 90% of 1,2-diethylbenzene. *n*-Butyl(trimethyl)tin was formed in 89% yield.

Tin Compounds

1,2-Bis(trimethylstannyl)ethyne (**3**): To a stirred suspension of dilithioethyne (1.22 g, 32.2 mmol) in 100 ml of dry pentane at −25°C was added dropwise over 40 min a solution of trimethyltin chloride (12.94 g, 65.0 mmol) in 100 ml of pentane. The reaction was then warmed to room temperature and heated at reflux for 1 h. The lithium chloride was filtered off and the filtrate upon concentration deposited pale yellow crystals. The crude product was recrystalized from pentane at −78°C and dried under vacuum (40°C, 5 Torr) to give off-white crystals of 1,2-bis(trimethylstannylethyne) (8.56 g, 76%); mp 57−59°C (mp 58−60°C). − ^{1}H NMR (C_6D_6): δ = 0.15 (s, 18 H, J_{Sn-H} = 58 Hz). − ^{13}C NMR (C_6D_6): δ = 8.0 (Sn-*C*H$_3$, J_{Sn-C} = 400 Hz), 115.8 (Sn−*C*≡*C*−Sn). − ^{119}Sn NMR (C_6D_6) δ = 80.9. − A corresponding reaction with trimethyltin bromide yielded 64% of the product.

1,2-Bis(trimethylstannyl)benzene (**8a**): Magnesium turnings (3.16 g, 130 mmol) in 20 ml of THF were activated with 0.3 ml of ethylene bromide. A fresh 50-ml portion of THF was then added and 0.2 ml more of ethylene bromide was injected. The mixture was heated at reflux until gas evolution stopped. At reflux a solution of 1,2-dibromobenzene (5.89 g, 25 mmol) in 30 ml of THF and trimethyltin chloride (50 ml of 1.0 M THF solution, 50 mmol) was added dropwise. As the reaction progressed, a green-brown solution developed. After the addition the reaction mixture was heated at reflux for 6 h, poured into 150 ml of a cold, saturated aqueous solution of ammonium chloride and then extracted with two 75-ml portions of ethyl ether. The extracts were washed with water, dried with anhydrous Na_2SO_4, and then concentrated under reduced pressure. Vacuum distillation of the remaining residue gave 1,2-bis(trimethylstannyl)benzene (**8a**) as a colorless, viscous liquid (4.46 g, 44%); bp 90−94°C/0.1 Torr (bp 92−94°C/0.145 Torr). − ^{1}H NMR (C_6D_6): δ = 0.28 (s, 18 H, J_{Sn-H} = 52 Hz), 7.15 (dd, *J* = 5.3, 3.5 Hz, 2 H), 7.52 (dd, *J* = 5.3, 3.5 Hz, 2 H). − ^{13}C NMR (C_6D_6) δ = −7.2 (Sn-*C*H$_3$), 127.4, 137.3, 151.6 (C_{ar}-Sn). − ^{119}Sn NMR (C_6D_6): δ = 34.1. − *Trimethyl(phenyl)tin* (**9**) (2.46 g, 41%) was isolated as a major by-product; bp 65−68°C/0.1 Torr). − ^{1}H NMR (C_6D_6): δ = 0.20 (s, 9 H, J_{Sn-H} = 54 Hz), 7.20 (m, 3 H), 7.43 (dd, 2 H). − ^{13}C NMR (C_6D_6) δ = −9.9 (Sn-*C*H$_3$), 128.5, 136.1, 142.0 (C_{ar}-Sn). − ^{119}Sn NMR (C_6D_6): δ = 29.9. − The following bis(trimethylstannyl) derivatives were also prepared analogously.

1,3-Bis(trimethylstannyl)benzene (**8b**): This compound was prepared from 1,3-dibromobenzene (5.89 g, 25 mmol) and trimethyltin chloride (50 ml of 1.0 M THF solution, 50 mmol). Vacuum distillation yielded trimethyl(phenyl)tin (**9**) (1.37 g, 23%) and the desired compound as a colorless liquid (4.93 g, 49%); bp 92−95°C/0.1 Torr. − ^{1}H NMR (C_6D_6): δ = 0.24 (s, 18 H, J_{Sn-H} = 54 Hz), 7.27 (t, *J* = 7 Hz, 1 H, J_{Sn-H} = 10 Hz), 7.44 (d, *J* = 7 Hz, 2 H, J_{Sn-H} = 46 Hz), 7.79 (s, 1 H, J_{Sn-H} = 42 Hz). − ^{13}C NMR (C_6D_6): δ = −9.7 (Sn-*C*H$_3$), 128.5, 136.2, 142.0, 143.3. − ^{119}Sn NMR (C_6D_6): δ = 30.4.

1,4-Bis(trimethylstannyl)benzene (**8c**): This compound was prepared from 1,4-dibromobenzene (6.63 g, 28 mmol) and trimethyltin chloride (56 ml of 1.0 M THF solution, 56 mmol). The crude product was recrystallized from pentane at −78°C to give 1,4-bis(trimethylstannyl)benzene as short, white needles (7.44 g, 66%); mp 125−127°C (mp 124°C).[18] − ^{1}H NMR (C_6D_6): δ = 0.24 (s, 18 H, J_{Sn-H} = 54 Hz), 7.49 (s, 4 H). − ^{13}C NMR (C_6D_6) δ = −9.9 (Sn-*C*H$_3$), 136.0, 142.1 (C_{ar}-Sn). − ^{119}Sn NMR (C_6D_6): δ = 30.8.

α,o-Bis(trimethylstannyl)toluene (**10**): This compound was prepared from 2-bromobenzyl bromide (5.61 g, 22.5 mmol) and trimethyltin chloride (50 ml of 1.0 M THF solution, 50 mmol). Vacuum distillation of the crude product yielded the compound as a colorless, viscous liquid (4.21 g, 45%); bp 89−92°C/0.1 Torr. − ^{1}H NMR (C_6D_6): δ = 0.03 (s, 9 H, J_{Sn-H} = 52 Hz), 0.28 (s, 9 H, J_{Sn-H} = 52 Hz), 2.38 (s, 2 H, J_{Sn-H} = 62 Hz), 6.97−7.00 (m, 2 H), 7.12 (d, *J* = 7 Hz, 1 H), 7.38 (d, *J* = 7 Hz, 1 H). − ^{13}C NMR (C_6D_6): δ = −9.6 (CH_2-Sn-*C*H$_3$), −8.2 (C_{ar}-Sn-*C*H$_3$), 24.2 (Sn-*C*H$_2$), 123.6, 126.8, 129.1, 136.7, 138.7, 149.9. − ^{119}Sn NMR (C_6D_6): δ = 36.6 [Ph-*Sn*-(CH$_3$)$_3$], −0.8 [Ph-CH$_2$-*Sn*-(Me)$_3$].

α,α′-Bis(trimethylstannyl)-o-xylene (**11**): This compound was prepared from α,α′-dichloro-*o*-xylene (4.34 g, 24.6 mmol) and trimethyltin chloride (50 ml of 1.0 M THF solution, 50 mmol). The crude product was distilled under vacuum to yield the pure derivative as a colorless, viscous liquid (9.14 g, 85%); bp 92−95°C/0.05 Torr. − ^{1}H NMR (C_6D_6): δ = 0.04 (s, 18 H, J_{Sn-H} = 54 Hz), 2.16 (s, 4 H, J_{Sn-H} = 62 Hz), 6.93 (s, 4 H). − ^{13}C NMR (C_6D_6): δ = −9.5 (Sn-*C*H$_2$), 124.3, 128.3, 138.4 (C_{ar}-Sn). − ^{119}Sn NMR (C_6D_6): δ = 2.7.

α-(Trimethylstannyl)-o-xylene was formed as a reaction by-product (0.51 g, 7%). − ^{1}H NMR (C_6D_6) δ = −0.02 (s, J_{Sn-H} = 50 Hz, 9 H), 2.05 (s, 2 H), 6.90 (m, 2 H), 6.92 (m, 2 H), 7.04 (d, 1 H). − ^{13}C NMR (C_6D_6): δ = −9.7 (Sn-*C*H$_3$), 18.2 (Sn-*C*H$_2$), 124.0, 126.4, 127.6, 130.3, 133.3, 141.5 (C_{ar}-Sn). − ^{119}Sn NMR (C_6D_6): δ = 2.4.

α,α′−Bis(chlorodimethylstannyl)-o-xylene (**32**): To a stirred solution of α,α′-bis(trimethylstannyl)-*o*-xylene (4.78 g, 11 mmol) in dry pentane (50 ml) at −50°C was added 22 ml of a 1.0 M hexane solution of boron trichloride in portions of 0.5 ml over 1.5 h. During the addition a white precipitate formed. After the addition the reaction was stirred at −50°C for 2 h and then allowed to reach ambient temperature. Upon warming the initially formed precipitate redissolved. When the reaction mixture reached room temperature, a new precipitate formed. The reaction mixture was stirred for 12 h at room temperature and the precipitate was then filtered off, washed twice with two 20-ml portions of dry pentane and dried under vacuum (1 Torr, room temp.) to give the desired derivative as a white, moisture-sensitive powder (4.04 g, 85%). − ^{1}H NMR (C_6D_6): δ = 0.27 (s, 12 H, J_{Sn-H} = 56 Hz), 2.48 (s, 4 H, J_{Sn-H} = 70 Hz), 6.90 (m, 4 H). − ^{13}C NMR (C_6D_6): δ = −2.0 (Sn-*C*H$_3$), 25.3 (Sn-*C*H$_2$), 125.7, 129.1, 135.8. − ^{119}Sn NMR (C_6D_6): δ = 2.44.

2,2-Dimethyl-2-stannaindane (**6**): A suspension of 10 mmol of α,α′-dilithio-*o*-xylene was prepared from 11 mmol of α,α′-bis(trimethylstannyl)-*o*-xylene and 22 mmol of *n*-butyllithium according to the aforementioned procedure. After dilution with dry diethyl ether, the lithium reagent was treated at 0°C with an ether solution of 10 mmol of dimethyltin dichloride. The reaction was stirred at reflux for 2 h and then poured into a solution of aqueous NH_4Cl. Usual work-up gave an orange-yellow oil with the desired stannaindane as the major component by NMR criteria. Distillation under reduced pressure gave an 85% yield of colorless product. − ^{1}H NMR (C_6D_6): δ = 0.09 (s, J_{Sn-H} = 55 Hz, 6 H), 2.20 (s, J_{Sn-H} = 41 Hz, 4 H), 7.03 (dd, *J* = 5.3, 3.5 Hz, 2 H), 7.03 (dd, *J* = 4.5, 3.5 Hz, 2 H). − ^{13}C NMR (C_6D_6): δ = −10.1 (Sn-*C*H$_3$), 17.95 (Sn-*C*H$_2$), 125.4, 131.2, 143.6 (C_{ar}-Sn).

Boron Compounds

1,2-Bis(diethylboryl)ethyne (**15**). − *Method A:* In this method the active dilithioethyne was prepared from trichloroethylene and *n*-butyllithium (cf. supra). The composition of solids from this reaction varied and the actual proportions of Li_2C_2, LiCl, and THF had to be analyzed after each preparation. The quantity of the dilithioethane used in the preparation described here refers to 14.7 g of a solid of the composition 33% Li_2C_2, 37% LiCl, and 30% THF by weight. An excess of Et_2BBr was used to allow for the formation of diethyl[(4-bromo)butoxy]borane ($Et_2B-O-[CH_2]_4Br$), a side-product formed from a THF ring cleavage reaction by Et_2BBr even at low temperatures.

A solution of diethylboron bromide (47.2 g, 0.317 mol) in 100 ml of dry pentane was added to a stirred suspension of the dilithioethyne (4.85 g, 0.128 mol) in 100 ml of pentane at such a rate as to maintain the temperature below 40°C. After the addition, the reaction mixture had turned red-brown. Lithium bromide was filtered off and the pentane was removed from the filtrate under reduced pressure. The residue was then distilled at 0.3 Torr to yield 1,2-bis(diethylboryl)ethyne as a colorless liquid (8.1 g, 39%); bp 40−50°C/0.3 Torr. − ^{1}H NMR (C_6D_6): δ = 1.08 (t, *J* = 7 Hz, 12 H), 1.19 (q, *J* = 7 Hz, 8 H). − ^{13}C NMR (C_6D_6): δ = 9.4 (CH$_2$-*C*H$_3$), 20.6 (br., CH$_2$-*C*H$_3$), 137.2 (br., B-*C*≡*C*-B). − ^{11}B NMR (C_6D_6): δ = 72.

Diethyl(4-bromobutoxy)borane was formed as a reaction by-product (12.52 g, 93%); recovered as a distillation residue. − ^{1}H NMR (C_6D_6): δ = 0.76 (q, *J* = 7 Hz, 4 H), 0.93 (t, *J* = 7 Hz, 6 H), 1.04 (m, 2 H), 1.62 (m, 2 H), 3.01 (t, *J* = 7 Hz, 2 H), 3.50 (t, *J* = 6 Hz, 2 H). − ^{13}C NMR ($CDCl_3$): δ = 8.0 (CH$_2$-*C*H$_3$), 12.1 (br., B-*C*H$_2$), 29.7, 30.3, 33.4, 64.2 (O-*C*H$_2$). − ^{11}B NMR (C_6D_6) δ = 53.2.

Method B: To a stirred solution of diethylboron bromide (0.68 g, 4.6 mmol) in 10 ml of dry pentane at −30°C was added a solution of bis(trimethylstannyl)ethyne (0.80 g, 2.3 mmol) in 20 ml of dry pentane. After the addition, the reaction mixture was stirred for 1 h at 25°C and then cooled to −78°C, upon which white trimethyltin bromide precipitated. After this solid was filtered off at −78°C, pentane was partly removed from the cold filtrate under reduced pressure and the residue was allowed to warm up to ambient temperature. A fresh 10-ml portion of dry pentane was added to the residue and the solution again cooled to −78°C whereupon further precipitate was filtered off. The pentane was partly removed from the filtrate in vacuo and the remaining residue distilled under vacuum to give 1,2-bis(diethylboryl)ethyne (0.24 g, 65%) containing less than 2 mol-% of trimethyltin bromide.

1,2-Bis(diethylboryl)ethane (**19**): The modified Lindlar catalyst used here refers to the commercial product $Pd/CaCO_3$. In the original Lindlar procedure the catalyst, $Pd/CaCO_3$, was partly deactivated by addition of quinoline. Since quinoline forms a pale yellow complex with bis(diethylboryl)ethyne and the hydrogenation then does not proceed at all, the palladium catalyst used in these experiments was not poisoned with quinoline. A suspension of the modified Lindlar catalyst (0.16 g) in 5 ml of cyclohexane was stirred at room temperature under a slow flow of hydrogen gas for 1 h. Thereafter a solution of bis(diethylboryl)ethyne (1.31 g, 8.1 mmol) in 10 ml of cyclohexane was introduced and the hydrogen flow was stopped. From there the reaction was carried out by admission of hydrogen gas from a calibrated gas burette. The reaction was stopped when the hydrogen consumption had ceased. Hydrogen was purged by a stream of argon passing through the flask. The cyclohexane was removed under reduced pressure and the residue distilled under vacuum to yield pure 1,2-bis(diethylboryl)ethane (1.2 g, 85%). bp 30−34°C/2 Torr. − ^{1}H NMR (C_6D_6): δ = 1.0−1.3 (m), no signals at δ = 2.0−10.0. − ^{13}C NMR (C_6D_6): signals at δ = 10−30, no signals at δ = 40−150. − ^{11}B NMR (C_6D_6): δ = 75.

Pyrolysis of 1,2-Bis(diethylboryl)ethyne (**15**): This compound (1.45 g, 9 mmol) was slowly heated under argon at about 100°C, whereupon a colorless liquid began to distill. The heating was continued until the internal temperature reached 120°C. Further gentle reflux was maintained for 2 more hours after which the reaction mixture was cooled to room temperature and the volatiles removed under vacuum. The distillate consisted of triethylborane (0.99 g, 10 mmol). The red-brown residue (0.45 g) was then heated to 350°C under vacuum to give a viscous dark oil and then up to 700°C in a TGA apparatus to yield a glistening black solid which contained 55.13% C, 38.12% B, and 2.68% H, approximating an empirical formula of $C_3H_2H_{0.14}$.

Pyrolysis of 1,2-bis(diethylboryl)ethane (**19**): 1,2-Bis(diethylboryl)ethane (**19**) (0.64 g, 3.9 mmol) was slowly heated under argon to 120°C where triethylborane started to distill. Further heating in a TGA apparatus was continued until the internal temperature reached approximately 350°C and the evolution of volatiles had stopped. The reaction was cooled to room temperature and volatile substances removed under vacuum, which proved to be triethylborane (0.59 g, 6.0 mmol). The composition of the yellow residue (0.03 g) was not determined.

1,2-Bis(dichloroboryl)benzene (**20**) *and 1-Dichloro-2-[chloro(methyl)boryl]benzene* (**24**): To a stirred solution of 1,2-bis(trimethylstannyl)benzene (**8a**) (2.31 g, 5.7 mmol) in 20 ml of dry pentane was added a solution of boron trichloride (11.4 ml of 1.0 M hexanes solution, 11.4 mmol) at −40°C. During the addition a white precipitate formed gradually. The precipitate was separated from the solution at −40°C and dried under vacuum to give 1.51 g of white

solid identified as a mixture of trimethyltin chloride (5.0 mmol, 44%) and dimethyltin dichloride (2.3 mmol, 40%). From the solution the solvents were removed in vacuo to give 1.23 g of a yellow oil. Since the separation of the substances present in the residue was unsuccessful, the components were identified spectroscopically.

1-Dichloroboryl-2-[chloro(methyl)boryl]benzene (40 mol-%) (**24**): ^{1}H NMR (C_6D_6): δ = 1.21 (s, 3 H), 7.19 (dd, *J* = 5.5, 3.3 Hz, 2 H), 8.18 (dd, *J* = 5.5, 3.3 Hz, 2 H). − ^{13}C NMR (C_6D_6): δ = 9.5, 133.9, 136.4. − ^{11}B (C_6H_6): δ = 33. − *1-[Chloro(methyl)boryl]-2-(chlorodimethylstannyl)benzene* (65 mol-%) (**23**): ^{1}H NMR (C_6D_6): δ = 0.24 (s, 6 H), 1.21 (s, 3 H), 7.42 (d, 1 H) 7.86 (td, 1 H), 7.92 (d, 1 H) 8.36 (td, 1 H). − ^{13}C NMR (C_6D_6): δ = −0.3 (Sn-*C*H$_3$), 10.0 (B-CH$_3$), 132.8, 133.8, 135.8, 136.4. − ^{11}B (C_6H_6): δ = 38.7. − ^{119}Sn (C_6H_6): δ = 172.1. − *9,10-Dichloro-9,10-Dihydro-9,10-diboraanthracene* (**22**)[19] (ca. 10 mol-%). − ^{1}H NMR (C_6D_6): δ = 7.27 (dd, *J* = 5.55, 3.5 Hz, 4 H), 7.68 (dd, J = 5.5, 3.5 Hz, 4 H). − ^{13}C NMR (C_6D_6): δ = 132.9, 137.1.

When the reaction was repeated by employing 6.0 mmol of 1,2-bis(trimethylstannyl)benzene and 24.0 mmol of boron trichloride, Me_3SnCl and Me_2SnCl_2 were filtered off from the chilled reaction solution (−40°C), the filtrate freed of volatiles and the residue distilled under vacuum to yield 80% of **24**.

Diethyl(phenyl)borane: A solution of trimethyl(phenyl)tin (2.65 g, 11 mmol) in 10 ml of dry pentane was added dropwise to a stirred solution of diethylboron bromide (1.80 g, 12 mmol) in 10 ml of pentane at room temperature. The reaction mixture was heated under atmospheric pressure until pentane started to distill. When distillation stopped, the reaction was heated and stirred at 70°C for 3 h. The volatiles were removed under vacuum to give a clear, brownish liquid which was identified as nearly pure diethyl(phenyl)borane (1.43 g, 89%). − ^{1}H NMR (C_6D_6): δ = 1.01 (t, *J* = 7.8 Hz, 6 H), 1.54 (q, *J* = 7.8 Hz, 4 H), 7.25 (m, 3 H), 7.75 (d, *J* = 6.5 Hz, 2 H). − ^{13}C NMR (C_6D_6): δ = 8.8 (-*C*H$_3$), 16.0 (br., B-*C*H$_2$), 128.2, 132.1, 134.5, 139.3 (C_{ar}-B). − ^{11}B NMR (C_6D_6): δ = 78.1.

1,2-Bis(diethylboryl)benzene (**27**): A solution of 1,2-bis(trimethylstannyl)benzene (1.81 g, 4.5 mmol) in 5 ml of dry pentane was added dropwise to a refluxing solution of diethylboron bromide (1.78 g, 12 mmol) in 10 ml of pentane. After the addition, the reaction mixture was heated at reflux for 1 h. The pentane and unreacted Et_2BBr were removed under reduced pressure and a fresh 10-ml portion of dry pentane was added to the yellow residue and the solution was cooled to −78°C. Upon cooling a precipitate was formed and was filtered off at −78°C. The pentane was removed from the filtrate under vacuum to give a crude product as a lemon-colored oil (1.16 g). Distillation of the crude product yielded **27** as a yellowish, viscous liquid (0.81 g, 84%). During distillation partial decomposition with the evolution of some triethylborane was observed. − ^{1}H NMR (C_6D_6): δ = 1.00 (t, *J* = 8 Hz, 12 H), 1.35 (q, *J* = 8 Hz, 8 H), 7.24 (dd, *J* = 5.0, 3.0 Hz, 2 H), 7.35 (dd, *J* = 5.0, 3.0 Hz, 2 H). − ^{13}C NMR (C_6D_6): δ = 8.2 (CH$_2$-*C*H$_3$), 21.6 (br., B-*C*H$_2$-CH$_3$), 128.6, 130.3, 139.7 (C_{ar}-B). − ^{11}B NMR (C_6D_6): δ = 80.8.

9,10-Diethyl-9,10-dihydro-9,10-diboraanthracene (**36**): A solution of 1,2-bis(diethylboryl)benzene (**27**) (0.98 g, 4.6 mmol) in dry heptane (10 ml) was heated under reflux for 12 h. The solvent was then gradually distilled off as the reaction temperature rose to 140°C. The residue was stirred at 140−150°C for 6 h and the volatiles then were removed under vacuum. The oily, yellow residue (0.63 g) contained (**36**) and unreacted (**27**) in an approximate molar ratio of 1.0:0.3. Freshly distilled pentane (10 ml) was added to the residue and the resulting solution was cooled to −78°C, whereupon a fine, pale yellow precipitate settled out. The colorless supernatant solution was decanted and the precipitate dried under vacuum. The precipitate was identified by spectral data as pure **36** (0.12 g, 23%). − ^{1}H NMR (C_6H_6): δ = 1.09 (t, *J* = 8.2 Hz, 6 H), 1.89 (q, *J* = 8.2 Hz, 4 H), 7.33 (dd, *J* = 5.4, 3.2 Hz, 4 H), 8.01 (dd, *J* = 5.3, 3.4 Hz, 4 H). − ^{13}C NMR (C_6H_6): δ = 10.3 (*C*H$_3$), 12.4 (br., B-*C*H$_2$), 132.7, 136.0, 145.6 (br., C_{ar}-B). − ^{11}B NMR (C_6H_6): δ = 67.5.

1,3-Bis(diethylboryl)benzene (**28**): A solution of 1,3-bis(trimethylstannyl)benzene (1.46 g, 3.6 mmol) in 3 ml of dry pentane and diethylboron chloride (0.85 g, 8.1 mmol) were stirred at room temperature for 1 h. Thereupon the reaction mixture was heated under atmospheric pressure until the pentane started to distill. Then, the reaction mixture was stirred and heated to 70°C for 3 h. Volatiles were removed under vacuum to leave a yellowish, oily residue that was identified as essentially pure 1,3-bis(diethylboryl)benzene (0.67 g, 87%). − ^{1}H NMR (C_6D_6): δ = 1.07 (t, *J* = 7.9 Hz, 12 H), 1.62 (q, *J* = 7.8 Hz, 8 H), 7.35 (t, *J* = 7.5 Hz, 1 H), 7.87 (d, *J* = 7.3 Hz, 2 H), 8.45 (s, 1 H). − ^{13}C NMR (C_6D_6): δ = 8.8 (*C*H$_3$), 17.3 (br., B-*C*H$_2$), 127.7, 137.8, 139.4, 140.3. − ^{11}B NMR (C_6D_6): δ = 78.5. − Attempts to further purify the crude product by distillation failed and resulted in its significant decomposition with the liberation of triethylborane.

A parallel procedure was conducted with 1,4-bis(trimethylstannyl)benzene (**8**) and diethylboron chloride to provide a 90% yield of 1,4-bis(diethylboryl)benzene (**29**) at the stage where volatiles had been removed from the reaction mixture. Attempted distillation again led to the evolution of triethylborane.

2-(Diethylboryl)-α-(trimethylstannyl)toluene (**30**): At room temperature a solution of α,2-bis(trimethylstannyl)toluene (1.71 g, 4 mmol) in 3 ml of dry pentane was added dropwise to a neat sample of diethylboron chloride (0.85 g, 8 mmol). The reaction mixture was stirred at room temperature for 1 h and then heated gradually until pentane started to distill. The reaction mixture then was stirred and heated at 70°C for 3 h. After that, volatiles were removed under reduced pressure to leave a pale yellow, oily mixture of **30** and unreacted tin derivative in approximately a 1:1 molar ratio. The residue was then allowed to react further with an excess of Et_2BCl (1.0 g, 10 mmol). After stirring the mixture at 60°C for 12 h, the volatiles were removed in vacuo. The clear yellow oil was identified by spectral data as 2-(diethylboryl)-α-(trimethylstannyl)-toluene. Further purification of the crude product by distillation resulted in its partial decomposition. − ^{1}H NMR (C_6D_6): δ = 0.03 (s, J_{Sn-H} = 52 Hz, 9 H), 1.03 (t, *J* = 7.6 Hz, 6 H), 1.49 (q, *J* = 7.6 Hz, 4 H), 2.20 (s, 2 H, J_{Sn-H} = 72 Hz), 6.93 (t, *J* = 7.5 Hz, 1 H), 6.94 (d, *J* = 6.2 Hz, 1 H), 7.00 (t, *J* = 7.4 Hz, 1 H), 7.12 (td, *J* = 7.4, 1.2 Hz, 1 H). − ^{13}C NMR (C_6D_6): δ = −9.5 (Sn-*C*H$_3$, *J* = 324, 308 Hz), 8.95 (B-CH$_2$-*C*H$_3$), 21.6 (Sn-*C*H$_2$, *J* = 300, 244 Hz), 22.0 (br., *C*H$_2$), 123.1, 127.6, 128.36, 128.42, 143.1 (*C*H$_{ar}$-B). − ^{11}B NMR (C_6D_6): δ = 85.3. − ^{119}Sn NMR (C_6D_6): δ = 3.7.

2-(Diethylboryl)-α-(bromodimethylstannyl)toluene (**31**): A solution of α,2-bis(trimethylstannyl)toluene (2.11 g, 5 mmol) in 5 ml of dry pentane was added to a solution of diethylboron bromide (1.78 g, 12 mmol) in 5 ml of pentane at room temperature. The reaction mixture was heated at reflux for 3 h and then the pentane was partly distilled off under atmospheric pressure. The residue was further heated at 70°C for 4 h. The volatiles were removed under vacuum to leave a colorless oil of almost pure **31** (1.75 g, 90%). − ^{1}H NMR (C_6D_6): δ = 0.31 (s, J_{Sn-H} = 55 Hz, 6 H), 0.97 (t, *J* = 7.5 Hz, 6 H), 1.44 (q, *J* = 7.5 Hz, 4 H), 2.58 (s, 2 H, J_{Sn-H} = 68 Hz); 6.85−7.05 (m, 4 H). − ^{13}C NMR (C_6D_6): δ = −2.6 (Sn-*C*H$_3$), 8.9 (B-CH$_2$-*C*H$_3$), 22.1 (br., B-*C*H$_2$), 27.9 (Sn-*C*H$_2$), 124.3, 127.9,

128.6, 128.7, 139.1 (C_{ar}-Sn). – ^{11}B NMR (C_6D_6): δ = 84.9. – ^{119}Sn NMR (C_6D_6): δ = 3.6.

1-[Methyl(phenyl)boryl]-2-(chlorodimethylstannyl)benzene (**25**): A solution of 1,2-bis(trimethylstannyl)benzene (1.85 g, 4.6 mmol) in 10 ml of pentane was added dropwise to a refluxing solution of dichloro(phenyl)borane (0.73 g, 4.6 mmol) in 10 ml of pentane. The reaction mixture was then heated at reflux for 1 h and thereafter cooled to −78°C. The precipitate of trimethyltin chloride (0.71 g, 78%) was filtered off at −78°C and the volatiles were removed from the filtrate under reduced pressure. The light yellow oil (1.69 g) was further distilled under vacuum (0.1 Torr, 60°C) to give partly decomposed **25** (1.03 g, 61%). – ^{1}H NMR (C_6D_6): δ = 0.16 (s, 6 H, J_{Sn-H} = 56 Hz), 1.26 (s, 3 H), 7.01 (t, J = 7.2 Hz, 2 H), 7.09 (d, J = 7.2 Hz, 1 H), 7.20−7.29 (m, 2 H), 7.42 (m, 2 H), 8.07 (d, 1 H). – ^{13}C NMR (C_6D_6): δ = 0.5 (Sn-CH_3), 12.5 (br., B-CH_3), 128.5, 128.7, 129.6, 132.4 (B-C_{ar}), 132.8, 133.1, 136.2, 137.2 (B-C_{ar}), 137.7, 147.0 (Sn-C_{ar}).

Keywords: Oxazolines / Charge-transfer / 4,4'-Bipyridine / Enantioselective hydrosilylation / Rh(I)-complexes

Novel 2-(4,4′-bipyridin-2-yl)oxazolines, bearing a chiral oxazoline moiety, were synthesised starting from 4,4′-bipyridine and selectively monomethylated in the *N′*-position. After coordination to rhodium these electron-poor ligands are supposed to exhibit charge-transfer effects with electron-donating substrates in the Rh(I)-catalysed enantioselective hydrosilylation (see next publication). Similar effects were expected from 4,4′-bipyridine- and pyrazine-bisoxazolines after complexation with rhodium. For comparison 2-(4-phenylpyridin-2-yl)oxazoline ligands were synthesised. Rh(I)-complexes of selected ligands were prepared and characterised, including an X-ray structure analysis.

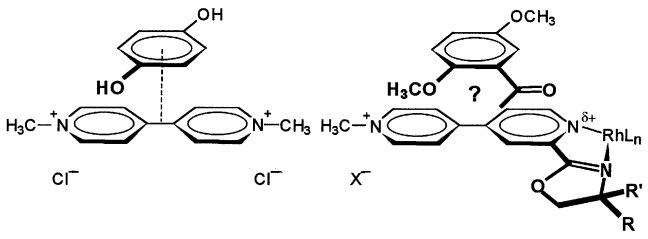
Introduction

A well-known example in asymmetric catalysis is the Rh(I)-catalysed enantioselective hydrosilylation of prochiral ketones, which after hydrolysis gives chiral secondary alcohols[2][3][4]. Asymmetric induction is brought about by *in situ* Rh(I)-catalysts consisting of $[Rh(cod)Cl]_2$ and preferably nitrogen ligands[5][6][7]. In particular, ligands containing chiral oxazolines proved to be effective[8][9][10][11].

Our point of interest was a possible pre-orientation of the substrate to be hydrosilylated with respect to the catalytic centre. Such a pre-orientation of the metal bound prochiral ketone might result in a higher enantiodiscrimination. We propose charge-transfer interactions for this pre-orientation. Charge-transfer interactions usually appear in systems consisting of electron-donating and electron-accepting compounds[12][13][14][15]. In addition to the isolation of stable charge-transfer complexes, e.g. the paraquat-hydroquinone adduct[16][17] (Scheme 1), charge-transfer interactions were used as a template effect for ring closure reactions[18].

We tried to introduce charge-transfer interactions in the Rh(I)-catalysed hydrosilylation using the electron-rich 2,5-dimethoxyacetophenone as the substrate. The acceptor had to be a chiral ligand whose electron-accepting properties should be amplified by coordination to Rh(I). *N′*-Methylated 2-(4,4′-bipyridin-2-yl)oxazolines **1**, which resemble paraquat after coordination to Rh, promised to be a suitable

Scheme 1



system (Scheme 1). The ligands of type **1** contain the same chelating unit as the ligands of type **2**, which were among the first successful chiral nitrogen ligands in enantioselective catalysis[11][19]. Since the formation of oxazoline rings is straightforward and the necessary enantiopure amino alcohols are accessible by reduction of amino acids, chirality should be easily introduced into 4,4′-bipyridine-oxazolines, provided a synthesis of the 2-cyano precursor is found. Another task is the selective methylation of the *N′*-position, which is necessary to increase the electron accepting properties of the 4,4′-bipyridine system.

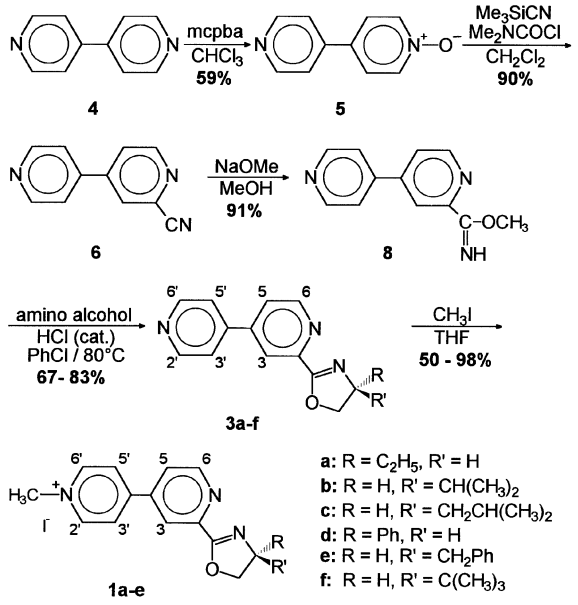
In this paper we describe the synthesis and characterisation of 2-(4,4′-bipyridin-2-yl)oxazolines and their *N*′-methylated derivatives, 2-(4-phenylpyridin-2-yl)oxazolines, 4,4′-bipyridine- and pyrazine-bisoxazolines as well as some Rh(I)-complexes[20]. The next paper reports on the catalytic results.

The 2-(4,4′-Bipyridin-2-yl)oxazolines 3a-f

Six novel 2-(4,4′-bipyridin-2-yl)oxazolines **3a-f** were prepared from 4,4′-bipyridine via the four-step synthesis shown in Scheme 3.

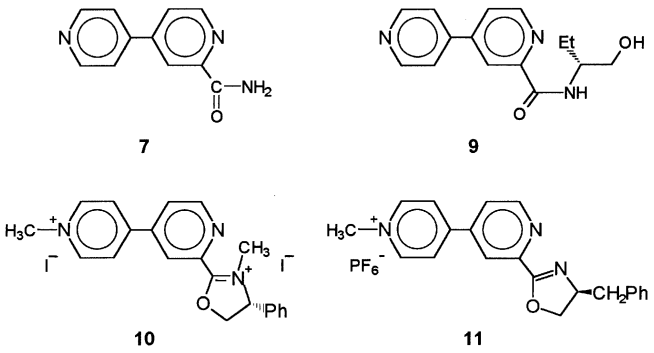
Scheme 3



In a variation of known procedures[21][22][23], 4,4′-bipyridine (**4**) was oxidised to the *N*-oxide **5** with *m*-chloroperbenzoic acid (mcpba) in $CHCl_3$. Chromatography on SiO_2 using an acetone/methanol gradient was necessary to separate the desired **5** from unreacted 4,4′-bipyridine and 4,4′-bipyridine *N*,*N*′-dioxide. α-Cyanation of the *N*-oxide **5** with trimethylsilyl cyanide and dimethylcarbamoyl chloride in CH_2Cl_2[24] yielded the nitrile **6** in 90% (Scheme 3) which had been only prepared as *N*,*N*′-bisquarternised salts[25]. A small amount of a side-product was obtained, characterised as the previously unknown 4,4′-bipyridine-2-carboxamide **7** (Scheme 4), probably resulting from partially hydrolysed **6**. Conversion of **6** into the carboximidate **8** (91% yield) was accomplished by stirring **6** for 2 d in dry methanol containing catalytic amounts of methanolate[26], according to Scheme 3. The resulting iminoether **8** was air-stable and could be stored for months if kept dry. The acid-catalysed condensation of **8** and enantiopure amino alcohols gave the corresponding oxazolines **3a-f** (Scheme 3). After flash chromatography and recrystallisation all six new ligands were obtained analytically pure in good yields (67−83%). By $^{13}C/^{1}H$ correlation experiments for **3c** all its protons and carbon atoms could be assigned. Comparison of their chemical shifts with those of the other ligands allowed almost complete assignment of their signals, too.

The oxazolines were unstable towards acids. Crude **3a** in chlorobenzene was almost completely transferred into the aqueous layer while shaking with 2 N HCl, thereby hydrolysing to the hydroxyalkylamide **9** (Scheme 4). After treatment of **9** with *p*-tosyl chloride and triethylamine in $CHCl_3$ according to ref.[27] the original oxazoline **3a** was restored.

Scheme 4



The *N*′-Methylated 2-(4,4′-Bipyridin-2-yl)oxazolines 1a−e and 11

The 2-(4,4′-bipyridin-2-yl)oxazolines **3a-e** were treated with excess methyl iodide in absolute THF at room temperature according to Scheme 3. A comparable selective *N*′′-methylation of 2,2′;4,4′′-terpyridine was reported by Persaud and Barbiero[28]. For **3e** nearly quantitative quarternisation of the *N*′-position occurred selectively and the product **1e** was isolated as an orange solid. The location of the methyl group was determined unequivocally by NMR spectroscopy. The AA′BB′ system of the Py′ ring in the ^{1}H NMR spectrum was shifted downfield compared to the non-methylated ligand **3e** and the CH_3 group showed a cross-peak with H-2′ and H-6′ in the NOESY spectrum. In the ^{13}C NMR spectrum the signals of C-2′ and C-6′ are broader than the other peaks due to the quadrupol momentum of the quarternised nitrogen.

For **3a-d** the analogous reactions gave the corresponding *N*′-methylated ligands **1a-d** (Scheme 3) in satisfying yields (50−63%). Here, the formation of a red side-product was observed. It could be removed by fractional crystallisation from methanol/ether solutions at −20°C. For **3d** the side-product was recrystallised from aqueous acetone/methanol yielding dark red tetrahedra, which were characterised as the dimethylated compound **10** (Scheme 4). 2D NMR experiments (NOESY and $^{13}C/^{1}H$ correlations) showed that the second methyl group is attached to the oxazoline-nitrogen. The methylated ligands **1a-e** are orange solids, which are hygroscopic and have to be stored under dry nitrogen. Spectroscopic characterisation including a $^{13}C/^{1}H$ NMR correlation spectrum for **1c** allowed almost complete assignment of all carbon and hydrogen atoms.

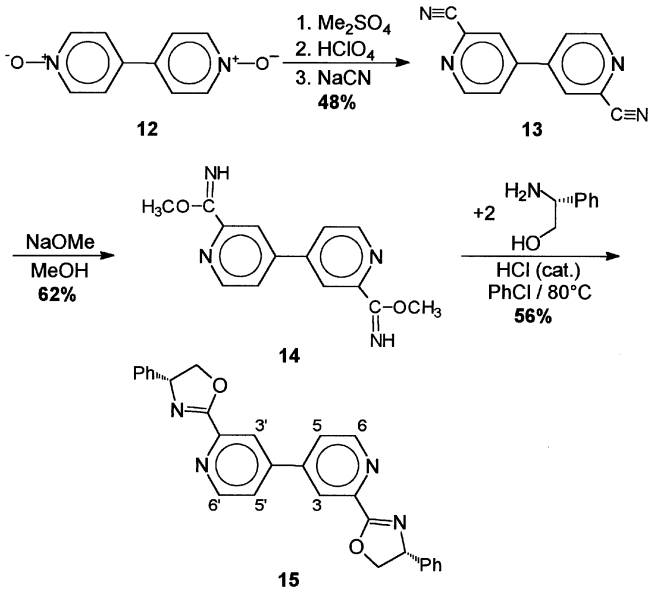
By treating **1e** (dissolved in water) with saturated aqueous NH_4PF_6 the iodide was substituted by hexafluorophosphate to yield **11** in 88% (Scheme 4), which was sparingly

soluble in methanol and could be recrystallised from boiling water.

The 2,2′-Bis(oxazolin-2-yl)-4,4′-bipyridine 15, the 2,5-Bis(oxazolin-2-yl)-3,6-dimethylpyrazine 19 and the 2-(4-Phenylpyridin-2-yl)oxazolines 23a,b

Since the *N*-oxidation of 4,4′-bipyridine **4** always yielded ca. 30% *N*,*N*′-dioxide **12**, the novel bisoxazoline **15** could be prepared via the dinitrile **13**[29] and the biscarboximidate **14**[30] (Scheme 5).

Scheme 5

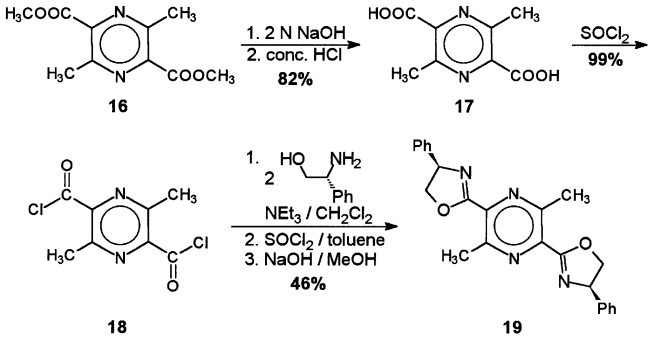


4,4′-Bipyridine *N*,*N*′-dioxide **12** as a single product was obtained in excellent yield (95%) by oxidation of 4,4′-bipyridine **4** with excess H_2O_2/urea adduct and phthalic anhydride in CH_2Cl_2 (80% yield were reported by using smaller amounts of oxidising agent[31]). Condensation of **14** with 2 equivalents of *(R)*-α-phenylglycinol yielded **15** as the first example of a chiral C_2-symmetrical 4,4′-bipyridine derivative, which is able to coordinate to two metal centres. The corresponding 2,2′-bipyridine-bisoxazoline was synthesised by Nishiyama et al.[32]. In the ^{1}H NMR spectra **15** and its mono-oxazoline counterpart **3d** display nearly identical chemical shifts for the oxazoline protons and the ABX system of the pyridine ring.

Since pyrazine is a ″shortened″ 4,4′-bipyridine, a Rh(I)-coordinated pyrazoline-bisoxazoline could also exhibit charge-transfer properties. Such a bisoxazoline was synthesised starting from dimethyl 3,6-dimethylpyrazine-2,5-dicarboxylate **16**[33]. After hydrolysis of **16** to **17**, the diacid chloride **18** was prepared using $SOCl_2$. Without isolation of intermediates the two oxazoline rings were condensed via a three-step reaction (Scheme 6). The pyrazine-bisoxazoline **19** was obtained in 46% yield.

For comparison two 2-(4-phenylpyridin-2-yl)oxazolines **23a,b** were synthesised from commercially available 4-phenylpyridine *N*-oxide **20** using the same reactions as for **3a-f** via the intermediates **21** and **22** (Scheme 7). **23a,b** differ from **3c** and **3e**, respectively, only in the nature of the 4-

Scheme 6



substituent (phenyl vs. 4′-pyridine). Thus, the spectroscopic data of **23a,b** are very similar to their 4,4′-bipyridine counterparts.

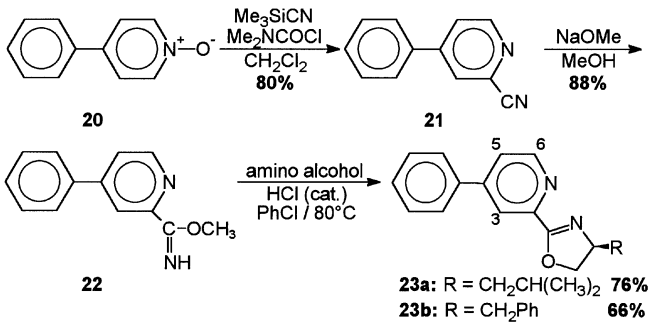
The Rh(I) Complexes 24−28

To ascertain that the 4,4′-bipyridine-oxazolines **3** prefer chelate coordination via pyridine- and oxazoline-*N* with regard to a monodentate coordination via *N*′, a series of Rh(I)-complexes was synthesised. All complexes were prepared by adding a solution of $[Rh(cod)Cl]_2$ in CH_2Cl_2 to the dissolved ligand. Exchange of chloride by PF_6^- (**24**, **25**) or BF_4^- (**26**) gave the corresponding red complexes in 82−92% yields (Scheme 8).

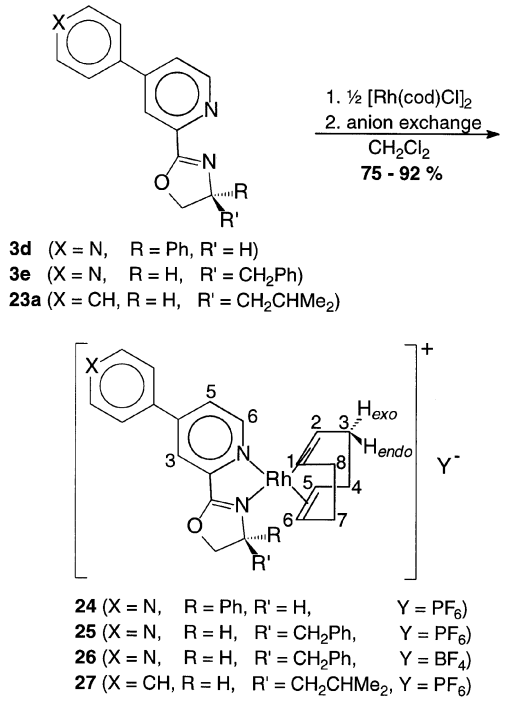
The ^{1}H NMR data (including COSY) proved the chelate coordination, because for **24** H-6 exhibited a strong downfield shift (0.87 ppm) compared to the free ligand **3d** due to the proximity of the rhodium. On the other hand H-2′/H-6′ did not shift at all. The $[Rh(cod)\mathbf{3e}]^+$-complexes were synthesised with two different anions (**25** = PF_6^-, **26** = BF_4^-). Interestingly, both the ^{1}H and ^{13}C NMR spectra showed significant differences especially for the pyridine signals. All three pyridine protons H-3, H-5 and H-6 and the carbon atoms C-5 and C-6 of **26** were shifted downfield compared to **25**. The olefinic ^{13}C atoms of 1,5-cyclooctadiene coupled with ^{103}Rh giving rise to doublets ($^1J_{C,Rh}$ = 12.6−12.9 Hz) in both ^{13}C NMR spectra.

The Rh(I)-complex **27** (Scheme 8) derived from the oxazoline **23a** (75% yield) showed broad signals for all 1,5-cyclooctadiene carbons in the ^{13}C NMR spectrum, but long-range couplings between ^{103}Rh and ^{13}C atoms of the ligand were identified. The carboxylic and the methine carbons of the oxazoline ring gave rise to doublets ($^2J_{C,Rh}$ =

Scheme 7



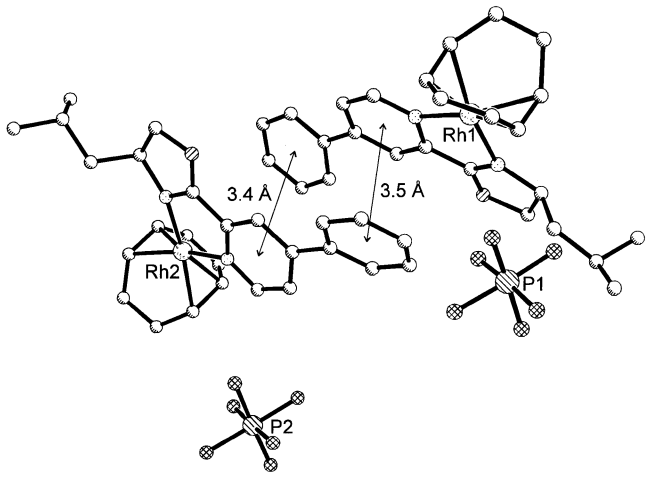
Scheme 8



1.4 Hz and 2.1 Hz, respectively). Similarly, the pyridine carbons C-6, C-5 and C-3 appeared as doublets ($^2J_{C,Rh}$ = 0.6 Hz and $^3J_{C,Rh}$ = 0.9 Hz). Analogous couplings were not found for **25** and **26**.

By slow diffusion of ether into a $CHCl_3$ solution of **27** red needles suitable for an X-ray structure analysis were obtained. There are two independent species in the unit cell (Figure 1).

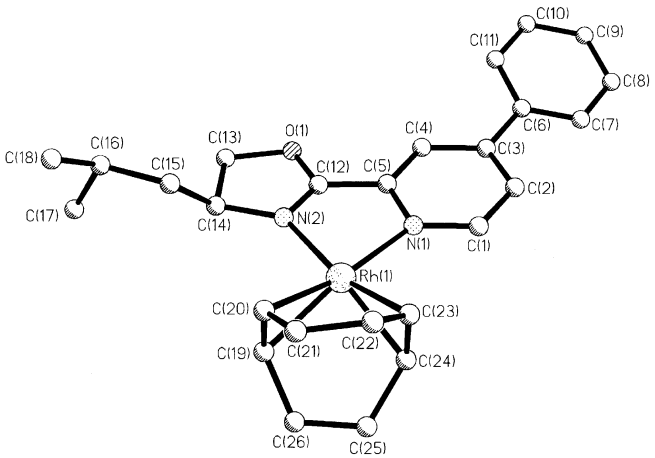
Figure 1. Molecular structure of the two different species in the unit cell of **27**



Both cations differ to some extent in the arrangement of the cod-ligands. The most interesting feature is the orientation of the two aromatic rings of both complexes. Each phenyl ring is oriented in a plane above the pyridine ring of the other cation and vice versa (arrows in Figure 1). The angles phenyl plane versus pyridine plane of the other cation are very small (2.7° and 6.7°, respectively). With 3.4−3.5 Å the distances of the aromatic rings are similar to that between graphite layers (3.35 Å). This π-stacking is probably amplified by charge-transfer interactions between the electron-rich phenyl and the electron-accepting pyridine ring.

Figure 2 shows the molecular structure of one of the cations of **27**, establishing the expected square planar coordination of rhodium by the two nitrogen atoms of ligand **23a** and the two double bonds of 1,5-cyclooctadiene. The (*S*)-configuration of the chiral carbon atom in the oxazoline ring was unequivocally proven. Selected bond lengths and angles are summarised in Table 1. For further details and the CSD number see Experimental Section.

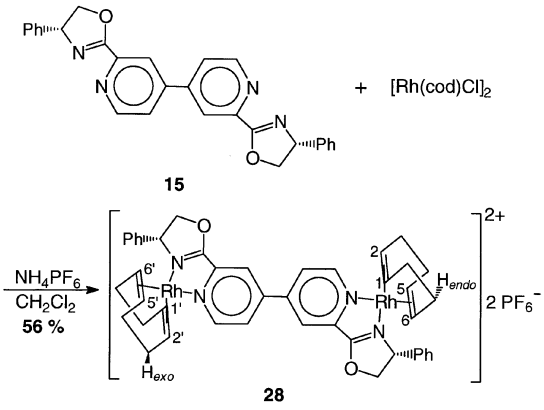
Figure 2. Molecular structure of one of the cations of **27**[a]



[a] Selected bond lengths [Å] and angles [°]: Rh1−N1 2.119, Rh1−N2 2.102, Rh1−(C23=C24)[b] 1.995, Rh1−(C19=C20)[b] 2.025, C23−C24 1.366, C19−C20 1.353, N2−C14 1.498, C14−C13 1.526, C13−O1 1.458, O1−C12 1.328 C12−C5 1.461, C12−N2 1.269; (C23=C24)-Rh1−(C19=C20)[b] 87.3, N1−Rh1−N2 79.4, Rh1−N1−C5 112.5, N1−C5−C12 113.8, C5−C12−N2 122.3, Rh1−N2−C12 111.8, N2−C12−O1 120.0, C12−O1−C13 104.7, O1−C13−C14 106.0, C13−C14−N2 102.2, C14−N2−C12 106.8, phenyl/pyridine (same cation) 20.7 and 27.1. − [b] C19=C20/C23=C24: statistical middle of the olefinic double bond.

Reaction of bisoxazoline **15** with $[Rh(cod)Cl]_2$ (2 equivalents of Rh) yielded the dinuclear complex **28** in 56% yield

Scheme 9



(Scheme 9). The symmetry introduced by the bridging of **15** between two Rh(cod) units showed up in the ^{1}H NMR spectrum of **28**, the signals of which were somewhat broadened (no sharpening even at −80°C, 250 MHz, CD_2Cl_2).

We thank the *Fonds der Chemischen Industrie* for providing a *Kekulé* scholarship for R.S. and for financial support.

Experimental Section

General: Chromatography: Merck silica gel 60 (63−200 mesh). − Melting points (not corrected): Büchi SMP 20 (open capillaries). − Elemental analyses: Microanalytical Laboratory, University of Regensburg. − ^{1}H/^{13}C NMR: Bruker AW-80 (80 MHz, T = 31°C), AC-250 (250/62.9 MHz, T = 24°C) and ARX-400 (400/100.6 MHz, T = 21°C), TMS or the solvent itself as internal standard. For optimal resolution some spectra were altered after acquisition using Bruker WIN NMR 5.0/5.1 software. The protons H-2′/H-6′ and H-3′/H-5′ in all 4,4′-bipyridine derivatives form AA′BB′ spin systems and were assigned as centred multiplets (AA′BB′). The two diastereotopic protons of the oxazoline CH_2 group are differentiated as H_Z and H_E (*cis* and *trans*, respectively, with regard to the methine proton). The abbreviations *qC* in the ^{13}C NMR data represent quarternary carbon atoms. − MS: Finnigan MAT 95 (FAB and FD), Finnigan MAT 311 A (EI, 70 eV). High-resolution mass spectra were recorded at the Max-Planck-Institut für medizinische Forschung in Heidelberg: VG Analytic ZAB 2E/70SE (FAB) and Joel JMS-SX102A (EI, 70 eV); the abbreviation K^+ represents the cationic species of salt like compounds. − IR: Beckman IR 4240 (solids as KBr pellets, liquids as films between NaCl plates); only characteristic bands are listed. − Optical rotation: Perkin-Elmer Polarimeter 241 (0.1 or 0.2 dm cuvettes).

Materials: Commercially available reagents were used without further purification. All anhydrous solvents were stored under nitrogen.

Abbreviations: cod = η^4-1,5-cyclooctadiene, *m*-NBA = *m*-nitrobenzyl alcohol, Ox = oxazoline, PE = petroleum ether (b.p. 40−60°C), TFA = trifluoroacetic acid.

4,4′-Bipyridine N-Oxide Hemihydrate (**5**): To a stirred solution of 10.0 g (64.0 mmol) of 4,4′-bipyridine (**4**) in $CHCl_3$ (200 ml) was added during 6 h a solution of 57−86% mcpba (12.9 g, max. 64.0 mmol) in $CHCl_3$ (500 ml). After 3 d four portions of mcpba (2.0 g each) in $CHCl_3$ (150 ml each) were added every 24 h. Stirring at r. t. was continued for a total of 17 d. The solution was reduced to ca. 30 ml and the mixture was separated by column chromatography (SiO_2, 20 × 5 cm). Elution with acetone yielded unreacted **4** (R_f = 0.5 [methanol]) and *m*-chlorobenzoic acid. After removing the acid by extracting a $CHCl_3$ solution with 2 N NaOH, 1.05 g (6.7 mmol, 10.5%) of 4,4′-bipyridine were reisolated. With an acetone/methanol gradient (4:1 → 3:1) the desired product **5** (R_f = 0.31 [methanol]) was obtained. Recrystallisation from acetone afforded 6.07 g (33.5 mmol, 55%) of **5**. Cream-coloured crystals, mp. 170°C (ref.[21]: 180°C, ref.[22]: 174−176°C). − ^{1}H NMR (250 MHz, D_2O): δ = 7.50 (AA′BB′, 2 H, H-3′, H-5′), 7.70 (AA′BB′, 2 H, H-3, H-5), 8.20 (AA′BB′, 2 H, H-2, H-6), 8.42 (AA′BB′, 2 H, H-2′, H-6′). − MS (EI): *m/z* (%) = 172 (100) [M^+], 156 (38) [M^+ − O], 155 (18), 116 (16), 90 (14), 89 (15), 63 (14), 51(14). − IR (KBr): $\tilde{\nu}$ (cm^{-1}) = 1250/1225 s (NO). − $C_{10}H_8N_2O$ Γ 1/2 H_2O (181.20): calcd. C 66.29, H 5.01, N 15.46; found C 66.11, H 5.22, N 15.15. With pure methanol as liquid phase 4.41 g (19.7 mmol, 31%) of 4,4′-bipyridine *N,N′*-dioxide **12** as the dihydrate were eluted (R_f = 0.1 [methanol]).

4,4′-Bipyridine-2-carbonitrile (**6**): 6.0 g (33.1 mmol) of **5** were dissolved under nitrogen in dry CH_2Cl_2 (70 ml). After adding 4.8 ml (38.4 mmol) of trimethylsilyl cyanide the solution was stirred for 5 min and then treated with 3.1 ml (33.7 mmol) of dimethylcarbamoyl chloride. Stirring at r. t. was continued for 2 d. The solvent was evaporated and the yellow residue treated with 10% aqueous K_2CO_3 (70 ml). The solid was sucked off and dried. Recrystallisation from acetone yielded 5.4 g (29.8 mmol, 90%) of **6**. White solid, m.p. 238−240°C. − ^{1}H NMR (250 MHz, [D_6]DMSO): δ = 7.93 (AA′BB′, 2 H, H-3′, H-5′), 8.21 (dd, ^3J = 5.2 Hz, ^4J = 1.9 Hz, 1 H, H-5), 8.57 (dd, ^4J = 1.9 Hz, ^5J = 0.9 Hz, 1 H, H-3), 8.78 (AA′BB′, 2 H, H-2′, H-6′), 8.90 (dd, ^3J = 5.2 Hz, ^5J = 0.9 Hz, 1 H, H-6). − ^{13}C NMR (100.6 MHz, [D_6]DMSO): δ = 117.6 (*C*N), 121.6 (C-3′, C-5′), 125.4/126.8 (C-3 and C-5), 133.8 (C-2), 142.6 (C-4), 146.2 (C-4′), 150.9 (C-2′, C-6′), 152.3 (C-6). − MS (EI): *m/z* (%) = 181 (100) [M^+], 180 (21), 57 (21). − IR (KBr): $\tilde{\nu}$ (cm^{-1}) = 2240 w (C≡N). − $C_{11}H_7N_3$ (181.20): calcd. C 72.92, H 3.89, N 23.19; found C 72.84, H 4.15, N 22.87.

If the crude product was purified by flash chromatography (SiO_2, 15 × 4.5 cm) with PE/acetone (1:1) 300 mg (1.5 mmol, 4.5%) of a side-product (R_f = 0.31 [acetone]) were obtained. It crystallised from ether and was characterised as *4,4′-bipyridine-2-carboxamide* (**7**). Colourless needles, m.p. 176−178°C. − ^{1}H NMR (250 MHz, $CDCl_3$): δ = 6.00 (br s, 1 H, N*H*H′), 7.61 (AA′BB′, 2 H, H-3′, H-5′), 7.71 (dd, ^3J = 5.1 Hz, ^4J = 1.9 Hz, 1 H, H-5), 7.92 (br s, 1 H, NH*H′*), 8.50 (dd, ^4J = 1.9 Hz, ^5J = 0.8 Hz, 1 H, H-3), 8.71 (dd, ^3J = 5.1 Hz, ^5J = 0.8 Hz, 1 H, H-6), 8.78 (AA′BB′, 2 H, H-2′, H-6′). − ^{13}C NMR (62.9 MHz, $CDCl_3$): δ = 120.3 (C-3 or C-5), 121.4 (C-3′, C-5′), 123.9 (C-5 or C-3), 144.7/147.2 (qC), 149.2 (C-6), 150.7 (qC), 150.8 (C-2′, C-6′), 166.3 (*C*=O). − MS (EI): *m/z* (%) = 199 (53) [M^+], calcd. for $C_{11}H_9N_3O$ 199.07456, found 199.07442, diff. −0.14 mmu/0.7 ppm, 157 (12), 156 (100) [M^+ − HNCO], 155 (41) [M^+ − $CONH_2$], 129 (16), 128 (14), 102 (11), 101 (11). − IR (KBr): $\tilde{\nu}$ (cm^{-1}) = 3415/3380/3290/3200 m (NH), 1795/1775/1690 s (C=O).

Methyl 4,4′-Bipyridine-2-carboximidate (**8**): 50 mg (2.2 mmol) of sodium were dissolved in dry methanol (35 ml) under nitrogen. Then 1.63 g (9.0 mmol) of **6** were added and allowed to react for 2 d at r. t. The suspension became finally a clear solution. After adding 0.1 ml (1.6 mmol) of acetic acid the solvent was evaporated. The residue was treated with warm ether (ca. 400 ml). Insoluble inorganic salts were removed by hot filtration. Cooling of the filtrate to −20°C afforded 1.74 g (8.2 mmol, 91%) of white crystals, m.p. 134−136°C. **8** is easily hydrolysed but can be stored for months if kept dry. − ^{1}H NMR (250 MHz, C_6D_6): δ = 3.94 (s, 3 H, C*H*$_3$), 6.76 (dd, ^3J = 5.1 Hz, ^4J = 1.9 Hz, 1 H, H-5), 6.78 (AA′BB′, 2 H, H-3′, H-5′), 7.86 (dd, ^4J = 1.9 Hz, ^5J = 0.9 Hz, 1 H, H-3), 8.33 (dd, ^3J = 5.1 Hz, ^5J = 0.9 Hz, 1 H, H-6), 8.53 (AA′BB′, 2 H, H-2′, H-6′), 9.98 (br s, 1 H, N*H*). − ^{13}C NMR (62.9 MHz, C_6D_6): δ = 53.7 (*C*H$_3$), 118.8 (C-3), 121.2 (C-3′, C-5′), 122.6 (C-5), 144.6/147.1/149.1 (qC), 150.1 (C-6), 151.1 (C-2′, C-6′), 166.2 (*C*=N). − MS (EI): *m/z* (%) = 213 (87) [M^+], 183 (15), 182 (83) [M^+ − OCH_3], 170 (17) [M^+ − CH_3 − CO], 157 (10), 156 (100) [M^+ − OCH_3 − CN], 155 (39) [M^+ − OCH_3 − HCN], 101 (13), 51 (11). − IR (KBr): $\tilde{\nu}$ (cm^{-1}) = 3310 w (NH), 1655 s (C=N), 1370 vs (CO). − $C_{12}H_{11}N_3O$ (213.24): calcd. C 67.59, H 5.67, N 19.71; found C 67.44, H 5.48, N 19.32.

General Procedure I (Preparation of Oxazolines): To a solution of **8** (2.3 g, 10.8 mmol) and 10.8 mmol of the amino alcohol in dry chlorobenzene (20 ml) one drop of conc. HCl was added and the solution was stirred at 80°C with a gentle stream of nitrogen bubbling through. After 47−68 h the cooled solution was directly purified by flash chromatography.

(+)-2-[4-(R)-Ethyloxazolin-2-yl]-4,4′-bipyridine (**3a**): Amino alcohol: 2-*(R)*-aminobutan-1-ol. 14 × 3.5 cm SiO_2 with PE/acetone (1:1) as eluent (R_f = 0.32 [acetone]). Recrystallisation from ether/PE yielded 1.83 g (7.2 mmol, 67%) of colourless crystals, m.p. 73−76°C. − ^{1}H NMR (250 MHz, $CDCl_3$): δ = 1.05 (t, ^3J = 7.4 Hz, 3 H, CH_3), 1.69 (″oct″, $^3J \approx$ 7.0 Hz, 1 H, CH_AH$_B$CH$_3$), 1.84 (m, 1 H, CH$_A$$H_BCH_3$), 4.18 (″t″, ^2J = ^3J = 8.1 Hz, 1 H, Ox-CH_ZH$_E$), 4.35 (m, 1 H, Ox-C*H*), 4.62 (dd, ^2J = 8.1 Hz, ^3J = 9.3 Hz, 1 H, Ox-CH$_Z$$H_E$), 7.60 (AA′BB′, 2 H, *H-3′, H-5′*), 7.64 (dd, ^3J = 5.1 Hz, ^4J = 1.8 Hz, 1 H, H-5), 8.32 (d, ^4J = 1.8 Hz, 1 H, H-3), 8.76 (AA′BB′, 2 H, H-2′, H-6′), 8.82 (d, ^3J = 5.1 Hz, 1 H, *H-6*). − ^{13}C NMR (62.9 MHz, $CDCl_3$): δ = 10.0 (*C*H$_3$), 28.5 (*C*H$_2$CH$_3$), 68.4 (Ox-*C*H), 72.9 (Ox-*C*H$_2$), 121.4 (C-3′, C-5′), 121.6 (C-3), 122.9 (C-5), 144.8/146.4/148.0 (qC), 150.5 (*C*-6), 150.8 (C-2′, C-6′), 162.4 (*C*=N). − MS (EI): *m/z* (%) = 253 (11) [M$^+$], 225 (28), 224 (100) [M$^+$ − C$_2$H$_5$], 208 (13), 196 (20), 182 (13), 169 (25), 155 (26). − IR (KBr): $\tilde{\nu}$ (cm^{-1}) = 3030 w, 2965/2930 m, 2870/2860 w (CH), 1640 s (C=N). − $C_{15}H_{15}N_3O$ (253.30): calcd. General Procedure II (N′-Methylation): 2.6 mmol of 2-(4,4′-bipyridin-2-yl)oxazoline (**3**) were dissolved in dry THF (30 ml) under nitrogen. After adding 3.0 ml (48.0 mmol) of methyl iodide the light-protected solution was stirred for 63−90 h at r. t. The resulting reddish precipitate was collected and washed with dry ether (3 × 5 ml). The red side-product was removed by dissolving the precipitate in dry methanol and adding dry ether till an appearing cloudiness just faded. After cooling (−20°C) only the side-product crystallised and was filtered off. Dry ether (5−15 ml) was added to the resulting filtrate and after cooling to −20°C the pure, hygroscopic product **1** was obtained.

(+)-N′-Methyl-2-[4-(S)-benzyloxazolin-2-yl]-4,4′-bipyridinium Hexafluorophosphate (**11**): 460 mg (1.0 mmol) of **1e** were dissolved in water (15 ml) and treated with 1 ml of saturated aqueous NH_4PF_6. The precipitated yellow solid was collected after 30 min and washed with little water. After recrystallisation from boiling water 420 mg (0.9 mmol, 88%) of **11** were isolated. Light yellow, hygroscopic solid, m.p. > 120°C (dec.). − ^{1}H NMR (250 MHz, [D$_6$]acetone): δ = 2.90 (dd, ^2J = 13.9 Hz, ^3J = 7.5 Hz, 1 H, CH_AH$_B$Ph), 3.11 (dd, ^2J = 13.9 Hz, ^3J = 6.3 Hz, 1 H, CH$_A$$H_B$Ph), 4.24 (dd, ^2J = 8.3 Hz, ^3J = 7.5 Hz, 1 H, Ox-CH_ZH$_E$), 4.55 (dd, ^2J = 8.3 Hz, ^3J = 9.5 Hz, 1 H, Ox-CH$_Z$$H_E$), 4.69 (s, 3 H, N-C$H_3$), 4.67−4.86 (m, 1 H, Ox-C*H*), 7.13−7.38 (m, 5 H, Ph-*H*), 8.12 (dd, ^3J = 5.2 Hz, ^4J = 2.0 Hz, 1 H, H-5), 8.53 (dd, ^4J = 2.0 Hz, ^5J = 0.8 Hz, 1 H, H-3), 8.71 (AA′BB′, 2 H, H-3′, H-5′), 8.92 (dd, ^3J = 5.2 Hz, ^5J = 0.8 Hz, 1 H, H-6), 9.25 (AA′BB′, 2 H, H-2′, H-6′). − MS (FAB, MeOH/glycerol): *m/z* = 476 (weak) [MH$^+$], 330 [K$^+$]. − IR (KBr): $\tilde{\nu}$ (cm^{-1}) = 3150/3060/3030/2970/2910 w (CH), 1650 s (C=N), 840 vs, 555 s (PF). $C_{21}H_{20}F_6N_3OP$ • H_2O (493.39): calcd. C 51.12, H 4.49, N 8.52; found C 51.12, H 4.44, N 8.36. − Optical rotation (*c* = 2.2, acetone): $[\alpha]^{22}_D$ = +7.7, $[\alpha]^{22}_{578}$ = +8.6, $[\alpha]^{22}_{546}$ = +10, $[\alpha]^{22}_{436}$ = +20.

4,4′-Bipyridine N,N′-Dioxide Dihydrate (**12**): 5.4 g (57.4 mmol) of commercially available H_2O_2/urea adduct and 8.5 g (57.4 mmol) of phthalic anhydride were suspended in CH_2Cl_2 (60 ml). After 15 min 2.0 g (12.8 mmol) of 4,4′-bipyridine (**4**) were added and stirred for 3 d. Then the resulting suspension was poured into a saturated solution of aqueous $NaHCO_3$ (200 ml) and continuously extracted with $CHCl_3$ for 3 d. Removing the solvent and recrystallisation from water afforded 2.72 g (12.1 mmol, 95% [ref.[31]: 80%]) of 4,4′-bipyridine *N,N′*-dioxide as the yellow dihydrate, m.p. > 250°C (ref.: 305°C[31], 305−306°C[36], 335°C[21]). − ^{1}H NMR (250 MHz, D_2O): δ = 7.84 (AA′BB′, 4 H, H-3,3′, H-5,5′), 8.30 (AA′BB′, 4 H, H-2,2′, H-6,6′). − MS (FD, MeOH): *m/z* = 188 [M$^+$]. − IR (KBr): $\tilde{\nu}$ (cm^{-1}) = 1255 s, 1245 vs (NO). $C_{10}H_8N_2O_2$ • 2 H_2O (224.22): calcd. C 53.57, H 5.39, N 12.49; found C 53.98, H 5.42, N 12.26.

4,4′-Bipyridine-2,2′-dicarbonitrile (**13**): **12** (1.7 g, 7.6 mmol) and dimethyl sulfate (15 ml, 157.7 mmol) were heated at 140°C for 30 min. The cooled solution was treated with ethanol (30 ml) and 70% $HClO_4$ (10 ml). The precipitated solid was collected, dried, dissolved in water (90 ml), weakly alkalised with Na_2CO_3 and cooled on ice. A solution of 2.6 g (59 mmol) of NaCN in water (25 ml) was added and the precipitation completed by stirring for 1 h. After washing the filtered precipitate with ice water it was dried in vacuo over P_4O_{10}. Recrystallisation from ethanol yielded 760 mg (3.7 mmol, 48%) of the white dinitrile **13**. − ^{1}H NMR (250 MHz, [D$_6$]DMSO): δ = 8.29 (dd, ^3J = 5.2 Hz, ^4J = 1.9 Hz, 2 H, H-5, H-5′), 8.66 (dd, ^4J = 1.9 Hz, ^5J = 0.9 Hz, 2 H, H-3, H-3′), 8.95 (dd, ^3J = 5.2 Hz, ^5J = 0.9 Hz, 2 H, H-6, H-6′). − MS (EI): *m/z* (%) = 206 (100) [M$^+$]. − IR (KBr): $\tilde{\nu}$ (cm^{-1}) = 2230 m (C≡N).

Dimethyl 4,4′-Bipyridine-2,2′-dicarboximidate (**14**): 50 mg (2.2 mmol) of sodium were dissolved in dry methanol (40 ml) under nitrogen. 750 mg (3.6 mmol) of **13** were added and stirring at r. t. was continued for 4 d. After addition of acetic acid (0.1 ml, 1.6 mmol) the solvent was evaporated and the residue treated with warm ether (300 ml). Inorganic salts were removed by hot filtration. Cooling the filtrate to −20°C lead to 600 mg (2.2 mmol, 62%) of **14**. Colourless crystals, m.p. 211−214°C. − ^{1}H NMR (250 MHz, $CDCl_3$): δ = 4.07 (s, 6 H, CH_3), 7.66 (dd, ^3J = 5.1 Hz, ^4J = 1.8 Hz, 2 H, H-5, H-5′), 7.86 (dd, ^4J = 1.8 Hz, ^5J = 0.8 Hz, 2 H, H-3, H-3′), 8.79 (dd, ^3J = 5.1 Hz, ^5J = 0.8 Hz, 2 H, H-6, H-6′), 9.31 (br s, 2 H, N*H*). − ^{13}C NMR (62.9 MHz, $CDCl_3$): δ = 54.0 (*C*H$_3$), 118.8 (C-3, C-3′), 123.0 (C-5, C-5′), 146.7/148.8 (qC), 150.1 (C-6, C-6′), 166.2 (*C*=N). − MS (EI): *m/z* (%) = 270 (100) [M$^+$], 240 (15), 239 (63) [M$^+$ − OCH$_3$], 227 (20), 214 (14), 213 (83) [M$^+$ − OCH$_3$ − CH$_3$OH], 182 (13), 181 (15), 180 (23), 156 (12), 155 (18), 153 (13), 58 (17). − IR (KBr): $\tilde{\nu}$ (cm^{-1}) = 3300/3265 m (NH), 1645 s (C=N), 1365 vs (CO). − $C_{14}H_{14}N_4O_2$ (270.29): calcd. C 62.21, H 5.22, N 20.73; found C 62.21, H 5.18, N 20.32.

(−)-2,2′-Bis[4-(R)-phenyloxazolin-2-yl]-4,4′-bipyridine (**15**): Following general procedure I 580 mg (2.1 mmol) of **14** and 590 mg (4.3 mmol) of *(R)*-α-phenylglycinol were heated at 80°C in dry chlorobenzene (20 ml) for 6 d. Flash chromatography (SiO_2, 9.5 × 2.5 cm) with PE/acetone (1:1) as eluent (R_f = 0.37 [acetone]) followed by recrystallisation from PE/ether afforded 520 mg (1.2 mmol, 56%) of **15**. Light yellow foam, m.p. 102−105°C. − ^{1}H NMR (250 MHz, $CDCl_3$): δ = 4.44 (″t″, ^2J = ^3J = 8.6 Hz, 2 H, Ox-CH_ZH$_E$), 4.94 (dd, ^2J = 8.6 Hz, ^3J = 10.2 Hz, 2 H, Ox-CH$_Z$$H_E$), 5.50 (dd, ^3J = 8.6 Hz, ^3J = 10.2 Hz, 2 H, Ox-C*H*), 7.30−7.41 (m, 10 H, Ph-*H*), 7.74 (dd, ^3J = 5.0 Hz, ^4J = 1.9 Hz, 2 H, H-5, H5′), 8.50 (dd, ^4J = 1.9 Hz, ^5J = 0.9 Hz, 2 H, H-3, H-3′), 8.86 (dd, ^3J = 5.0 Hz, ^5J = 0.9 Hz, 2 H, H-6, H-6′). − ^{13}C NMR (62.9 MHz, $CDCl_3$): δ = 70.5 (Ox-*C*H), 75.5 (Ox-*C*H$_2$),

122.1/123.4 (C-3, C-3′ and C-5, C-5′), 126.9 (*o*- or *m*-Ph-*C*), 127.9 (*p*-Ph-*C*), 128.9 (*m*- or *o*-Ph-*C*), 141.6 (qC of Ph), 145.8/148.0 (qC), 150.7 (C-6, C-6′), 163.6 (*C*=N). − MS (EI): *m/z* (%) = 446 (100) [M^+], calcd. for $C_{28}H_{22}N_4O_2$ 446.1743, found 446.1737, diff. −0.5 mmu/1.2 ppm, 416 (28) [$M^+ - CH_2O$], 315 (20), 301 (20), 296 (21), 269 (31), 91 (44), 90 (42), 89 (24). − IR (KBr): $\tilde{\nu}$ (cm^{-1}) = 3055/3025/2890 w (CH), 1640 s (C=N). − Optical rotation (*c* = 1.27, $CHCl_3$): $[\alpha]^{22}_D = -78$, $[\alpha]^{22}_{578} = -82$, $[\alpha]^{22}_{546} = -95$, $[\alpha]^{22}_{436} = -168$, $[\alpha]^{22}_{365} = -271$.

3,6-Dimethylpyrazine-2,5-dicarboxylic Acid (**17**): 1.4 g (6.2 mmol) of dimethyl 3,6-dimethylpyrazine-2,5-dicarboxylate (**16**)[133] were refluxed in 2 N NaOH (50 ml) for 30 min. The cooled solution was acidified with conc. HCl and the precipitate filtered off. After recrystallisation from ethyl acetate 1.0 g (5.1 mmol, 82%) of **17** were obtained. Colourless crystals, m.p 195°C (ref. 194−195°C[37], 200−201°C[38]). − ^{1}H NMR (80 MHz, [D_6]acetone): δ = 2.78 (s, CH_3). − IR (KBr): $\tilde{\nu}$ (cm^{-1}) = 3465 s (OH), 1705 s (C=O).

3,6-Dimethylpyrazine-2,5-dicarboxylic Acid Chloride (**18**): 970 mg (5.1 mmol) of **17** and 1.1 ml of $SOCl_2$ were refluxed for 2 h. Excess $SOCl_2$ was removed in vacuo and the residue (1.18 g, 5.1 mmol, 99%), m.p. 98°C, was directly used in the next reaction. − ^{1}H NMR (80 MHz, $CDCl_3$): δ = 2.85 (s, CH_3). − MS (EI): *m/z* (%) = 234 (14)/232 (21) [M^+], 199 (33)/197 (100) [M^+ − Cl], 171 (24)/169 (74) [M^+ − Cl − CO], 143 (13)/141 (41) [M^+ − Cl − 2 CO], 106 (17) [M^+ − 2 Cl − 2 CO]. − IR (KBr): $\tilde{\nu}$ (cm^{-1}) = 1755 vs (C=O), 880/865 s (CCl).

(+)-2,5-Bis[4-(R)-phenyloxazolin-2-yl]-3,6-dimethylpyrazine (**19**): To a solution of (*R*)-α-phenylglycinol (1.36 g, 9.9 mmol) and dry triethylamine (1.4 ml) in CH_2Cl_2 (15 ml) was added during 15 min a solution of **18** (1.15 g, 4.9 mmol) in CH_2Cl_2 (12 ml) at 0°C under nitrogen. The mixture was stirred for 16 h at r. t. The solvent was removed and the residue treated with toluene (30 ml) and $SOCl_2$ (2.2 ml). After refluxing for 1 h the cooled solution was evaporated. A solution of NaOH (800 mg, 20.0 mmol) in methanol (40 ml) was added and refluxing continued for 3.5 h. To the cooled solution ether (100 ml) and brine (30 ml) were added. The organic layer was collected and the aqueous layer extracted with acetone (3× 30 ml). After washing with brine (20 ml) the combined organic layers were dried over $MgSO_4$ and evaporated. The oily residue was purified by flash chromatography (SiO_2, 10 × 3 cm) with PE/ethyl acetate (1:1) as eluent (R_f = 0.65 [ethyl acetate]). Recrystallisation from ether/acetone yielded 900 mg (2.3 mmol, 46%) of **19**. Light yellow solid, m.p. 143°C. − ^{1}H NMR (250 MHz, $CDCl_3$): δ = 2.99 (s, 6 H, CH_3), 4.35 (″t″, $^2J = {}^3J \approx 8.6$ Hz, 2 H, Ox-CH_ZH$_E$), 4.90 (dd, ^2J = 8.7 Hz, ^3J = 10.2 Hz, 2 H, Ox-CH$_Z$$H_E$), 5.56 (dd, ^3J = 8.5 Hz, ^3J = 10.2 Hz, 2 H, Ox-C*H*), 7.31 (m, 2 H, *p*-Ph-*H*), 7.34 (m, 4 H, *o*- or *m*-Ph-*H*), 7.38 (m, 4 H, *m*- or *o*-Ph-*H*). − ^{13}C NMR (62.9 MHz, $CDCl_3$): δ = 23.4 (*C*H_3), 71.1 (Ox-*C*H), 74.6 (Ox-*C*H_2), 126.7 (*o*- or *m*-Ph-*C*), 127.8 (*p*-Ph-*C*), 128.9 (*m*- or *o*-Ph-*C*), 141.0/141.7/151.6 (qC), 162.4 (*C*=N). − MS (EI): *m/z* (%) = 398 (100) [M^+], 307 (32), 121 (24), 118 (39), 104 (73), 103 (27), 91 (57), 89 (24). − IR (KBr): $\tilde{\nu}$ (cm^{-1}) = 3050/3020/2950/2920/2890 w (CH), 1645 s (C=N). − $C_{24}H_{22}N_4O_2$ (398.46): calcd. C 72.34, H 5.56, N 14.06; found C 72.21, H 5.57, N 13.90. − Optical rotation (*c* = 1.29, $CHCl_3$): $[\alpha]^{22}_D = +53$, $[\alpha]^{22}_{578} = +57$, $[\alpha]^{22}_{546} = +68$, $[\alpha]^{22}_{436} = +171$.

4-Phenylpyridine-2-carbonitrile (**21**): 5.0 g (29.2 mmol) of commercially available 4-phenylpyridine *N*-oxide (**20**) and 4.0 ml (32.0 mmol) of trimethylsilyl cyanide were dissolved in CH_2Cl_2 (50 ml) and stirred for 5 min under nitrogen. After adding 2.7 ml (29.3 mmol) of dimethylcarbamoyl chloride the resulting solution was stirred at r. t. for 2 d. A solution of 10% aqueous K_2CO_3 (50 ml) was added and stirring continued for 10 min. The organic layer was separated and the aqueous layer extracted with CH_2Cl_2 (2× 25 ml). The combined organic layers were washed with 25 ml of brine and dried over $MgSO_4$. Recrystallisation from PE (750 ml) yielded 4.2 g (23.3 mmol, 80%) of **21**. Colourless needles, m.p. 99°C (ref.: 99−100°C[39], 99°C[40][41], 98−99°C[42]). − ^{1}H NMR (250 MHz, $CDCl_3$): δ = 7.49−7.66 (m, 5 H, Ph-*H*), 7.72 (dd, ^3J = 5.2 Hz, ^4J = 1.6 Hz, 1 H, H-5), 7.90 (dd, ^4J = 1.6 Hz, ^5J = 0.8 Hz, 1 H, H-3), 8.75 (dd, ^3J = 5.2 Hz, ^5J = 0.8 Hz, 1 H, H-6). − ^{13}C NMR (62.9 MHz, $CDCl_3$): δ = 117.4 (*C*N), 124.6/126.4 (C-3 and C-5), 127.0/129.5 (*o*- and *m*-Ph-*C*), 130.2 (*p*-Ph-*C*), 134.6/136.0/149.9 (qC), 151.5 (C-6). − MS (EI): *m/z* (%) = 180 (100) [M^+], 179 (18), 153 (11). − IR (KBr): $\tilde{\nu}$ (cm^{-1}) = 2220 w (C≡N). − $C_{12}H_8N_2$ (180.21): calcd. C 79.98, H 4.47, N 15.54; found C 79.77, H 4.65, N 15.40.

Methyl 4-Phenylpyridine-2-carboximidate (**22**): 20 mg (0.9 mmol) of sodium were dissolved in dry methanol (8 ml) under nitrogen. 1.26 g (7.0 mmol) of **21** were added and stirring at r. t. was continued for 90 h. After addition of a few drops of acetic acid the solvent was evaporated and the residue treated with warm ether (70 ml). Inorganic salts were removed by hot filtration. After evaporation of the solvent and recrystallisation from PE 1.31 g (6.2 mmol, 88%) of the imino ether **22** were obtained as a light yellow solid, m.p. 81−83°C. − ^{1}H NMR (250 MHz, C_6D_6): δ = 3.93 (s, 3 H, CH_3), 6.95 (dd, ^3J = 5.1 Hz, ^4J = 1.8 Hz, 1 H, H-5), 6.99−7.28 (m, 5 H, Ph-*H*), 8.05 (dd, ^4J = 1.8 Hz, ^5J = 0.8 Hz, 1 H, H-3), 8.36 (dd, ^3J = 5.0 Hz, ^5J = 0.8 Hz, 1 H, H-6), 10.02 (br s, 1 H, N*H*). − ^{13}C NMR (62.9 MHz, C_6D_6): δ = 53.7 (*C*H_3), 119.0/122.9 (C-3 and C-5), 127.3/129.26 (*o*- and *m*-Ph-*C*), 129.27 (*p*-Ph-*C*), 138.2 (qC of Ph), 148.8/149.8 (qC), 149.9 (C-6), 166.7 (*C*=N). − MS (EI): *m/z* (%) = 212 (79) [M^+], 182 (17), 181 (83) [$M^+ - OCH_3$], 156 (13), 155 (100) [$M^+ - CH_3 - CN$], 154 (29) [$M^+ - CH_3 - HCN$], 153 (11), 128 (17), 127 (27), 77 (17), 43 (17). − IR (KBr): $\tilde{\nu}$ (cm^{-1}) = 3290 m (NH), 1655 s (C=N), 1365 vs (CO). − $C_{13}H_{12}N_2O$ (212.25): calcd. [34] This compound has to accept an electron in the mass spectrometer, because otherwise no peak at *m/z* = 331 should occur. The expected peak for the dication at 165.5 (= 331/2) is extremely weak. The signal at *m/z* = 332 is not only due to the ^{13}C isotope pattern but must additionally represent a protonated species.
